When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_newzealand_driver_license_number` finds content that matches the pattern.
- A keyword from `Keywords_newzealand_driver_license_number` is found.

A DLP policy has low confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_newzealand_driver_license_number` finds content that matches the pattern.

Poland physical addresses

Article • 08/19/2024

This unbundled named entity detects patterns related to physical address from Poland. It's also included in the All Physical Addresses bundled named entity SIT.

Confidence level

Medium

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Cloud Support

Cloud support is available for the following:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

Poland REGON number

Article • 08/19/2024

Format

9-digit or 14-digit number

Pattern

nine digit or 14-digit number:

- nine digits or
- nine digits
- hyphen
- five digits

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_polish_regon_number` finds content that matches the pattern.
- A keyword from `Keywords_polish_regon_number` is found.

A DLP policy has low confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_polish_regon_number` finds content that matches the pattern.

XML

```
      <!-- Polish REGON Number  -->

Romania physical addresses

Article • 08/19/2024

This unbundled named entity detects patterns related to physical address from Romania. It's also included in the All Physical Addresses bundled named entity SIT.

Confidence level

Medium

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Cloud Support

Cloud support is available for the following:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

Russia passport number domestic

Article • 08/19/2024

Format

10-digit number

Pattern

10-digit number:

- two digits
- an optional space or hyphen
- two digits
- an optional space
- six digits

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regex `Regex_Russian_Passport_Number_Domestic` finds content that matches the pattern.
- A keyword from `Keyword_Russian_Passport_Number` is found.

```
XML
```

```
      <!-- Russian Passport Number Domestic -->
      <Entity id="76ec2f5d-cedb-48e1-8070-1998794af445"
patternsProximity="300" recommendedConfidence="75">

- Microsoft 365 Department of Defense

Last updated on 06/19/2026

Russia taxpayer identification number

Format

10 or 12 digits, validated by a checksum function.

Pattern

10 digits (organizations) or 12 digits (individuals):

- Four digits (tax authority code)
- Five or six digits (serial number)
- One or two check digits

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Checksum

Yes

Definition

A data loss prevention (DLP) policy has high confidence that it detects this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_Russian_Taxpayer_Identification_Number` finds content that matches the pattern.
- A keyword from `Keyword_Russian_Taxpayer_Identification_Number` is found.

A DLP policy has medium confidence that it detects this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_Russian_Taxpayer_Identification_Number` finds content that matches the pattern.

XML

```
    <!-- Russian Taxpayer Identification Number -->
    <Entity id="81145f47-868a-464c-956a-eed7696fdcdf" patternsProximity="300"

Singapore physical addresses

This unbundled named entity detects patterns related to physical address from Singapore. It is also included in the All Physical Addresses bundled named entity SIT.

Confidence level

Medium

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Cloud Support

Cloud support is available for the following services:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

Last updated on 06/19/2026

Slack access token

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

A combination of up to 34 characters consisting of letters, digits, and special characters.

Pattern

A token prefix (case-sensitive) `xoxp-`, `xoxb-`, `xoxa-`, `xoxr-`, `xoxo-`, `xoxs-`, or `xoxe-`

A combination of up to 29 characters:

- 29 a-z (not case-sensitive)
- 0-9 or hyphens (-)

for example:

`xoxp-abcdef-abcdef-abcdef-abcdef`

Credential example

`slack_token= xoxp-abcdef-abcdef-abcdef-abcdef;`

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No**, additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used to access Slack platform functionalities (for example Bot tokens, User tokens and App-level tokens).

It uses several primary resources:

- Patterns of Slack user/bot/workspace token.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName.
- Patterns of mockup values, redactions, and placeholders.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders such as credential type or usage descriptions that are in the position where an actual secret value should be present won't be matched.

Keywords

Keyword_SlackTokens:

- `xox`

Slovakia personal number

Article • 08/19/2024

Format

Nine or 10 digits containing optional backslash

Pattern

- six digits representing date of birth
- optional slash (/)
- three digits
- one optional check digit

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_slovakia_eu_national_id_card` finds content that matches the pattern.
- A keyword from `Keywords_slovakia_eu_national_id_card` is found.

A DLP policy has low confidence that it detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_slovakia_eu_national_id_card` finds content that matches the pattern.

Spain passport number

Article • 08/19/2024

Format

an eight- or nine-character combination of letters and numbers with no spaces or delimiters

Pattern

an eight- or nine-character combination of letters and numbers:

- two digits or letters
- one digit or letter (optional)
- six digits

Checksum

Not applicable

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_spain_eu_passport_number` finds content that matches the pattern.
- A keyword from `Keywords_eu_passport_number` or `Keywords_spain_eu_passport_number` is found.

- The regular expression `Regex_spain_eu_passport_date` finds date in the format DD-MM-YYYY or a keyword from `Keywords_eu_passport_date` is found

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_spain_eu_passport_number` finds content that matches the pattern.
- A keyword from `Keywords_eu_passport_number` or `Keywords_spain_eu_passport_number` is found.

Spain physical addresses

Article • 08/19/2024

This unbundled named entity detects patterns related to physical address from Spain. It's also included in the All Physical Addresses bundled named entity SIT.

Confidence level

Medium

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Cloud Support

Cloud support is available for the following:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

Spain social security number (SSN)

Article • 08/19/2024

Format

11-12 digits

Pattern

11-12 digits:

- two digits
- a forward slash (optional)
- seven to eight digits
- a forward slash (optional)
- two digits

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_spanish_social_security_number` finds content that matches the pattern.
- The checksum passes.
  - A keyword from `Keywords_spain_eu_ssn_or_equivalent` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_spanish_social_security_number` finds content that matches the pattern.
- The checksum passes.

Spain tax identification number

Article • 08/19/2024

Format

seven or eight digits and one or two letters in the specified pattern

Pattern

Spanish Natural Persons with a Spain National Identity Card:

- eight digits
- one uppercase letter (case-sensitive)

Non-resident Spaniards without a Spain National Identity Card

- one uppercase letter "L" (case-sensitive)
- seven digits
- one uppercase letter (case-sensitive)

Resident Spaniards under the age of 14 years without a Spain National Identity Card:

- one uppercase letter "K" (case-sensitive)
- seven digits
- one uppercase letter (case-sensitive)

Foreigners with a Foreigner's Identification Number

- one uppercase letter that is "X", "Y", or "Z" (case-sensitive)
- seven digits
- one uppercase letter (case-sensitive)

Foreigners without a Foreigner's Identification Number

- one uppercase letter that is "M" (case-sensitive)
- seven digits
- one uppercase letter (case-sensitive)

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_spain_eu_tax_file_number` or `Func_spain_eu_DL_and_NI_number_citizen` finds content that matches the pattern.
- A keyword from `Keywords_spain_eu_tax_file_number` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_spain_eu_tax_file_number` or `Func_spain_eu_DL_and_NI_number_citizen` finds content that matches the pattern.

SQL Server connection string

Article • 08/19/2024

Format

The string `User Id`, `User ID`, `uid`, or `UserId` followed by the characters and strings outlined in the pattern below.

Pattern

- the string `User Id`, `User ID`, `uid`, or `UserId`
- any combination of between 1-200 lower- or uppercase letters, digits, symbols, special characters, or spaces
- the string `Password` or `pwd` where `pwd` isn't preceded by a lowercase letter
- an equal sign (=)
- any character that isn't a dollar sign ($), percent symbol (%), greater than symbol (>), at symbol (@), quotation mark ("), semicolon (;), left brace([), or left bracket ({)
- any combination of 7-128 characters that aren't a semicolon (;), forward slash (/), or quotation mark (")
- a semicolon (;) or quotation mark (")

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `CEP_Regex_SQLServerConnectionString` finds content that matches the pattern.
- A keyword from `CEP_GlobalFilter` isn't found.
- The regular expression `CEP_PasswordPlaceHolder` doesn't find content that matches the pattern.
- The regular expression `CEP_CommonExampleKeywords` doesn't find content that matches the pattern.

SQL

```
<!---SQL Server Connection String>
<Entity id="e76b6205-d3cb-46f2-bd63-c90153f2f97d" patternsProximity="300"
recommendedConfidence="85">
  <Pattern confidenceLevel="85">
        <IdMatch idRef="CEP_Regex_SQLServerConnectionString" />
        <Any minMatches="0" maxMatches="0">
            <Match idRef="CEP_GlobalFilter" />
            <Match idRef="CEP_PasswordPlaceHolder" />
            <Match idRef="CEP_CommonExampleKeywords" />
        </Any>
    </Pattern>
</Entity>
```

Keywords

CEP_GlobalFilter

- some-password
- somepassword
- secretPassword
- sample

CEP_PasswordPlaceHolder

This sensitive information type identifies these keywords by using a regular expression, not a keyword list.

- `Password` or `pwd` followed by 0-2 spaces, an equal sign (=), 0-2 spaces, and an asterisk (*) -OR-
- `Password` or `pwd` followed by:
  - Equal sign (=)
  - Less than symbol (<)

    - Any combination of 1-200 characters that are upper- or lowercase letters, digits, an asterisk (*), hyphen (-), underline (_), or whitespace character
    - Greater than symbol (>)

CEP_CommonExampleKeywords

This sensitive information type identifies these keywords by using a regular expression, not a keyword list.

Sweden national ID

Article • 08/19/2024

Format

10 or 12 digits and an optional delimiter

Pattern

10 or 12 digits and an optional delimiter:

- two digits (optional)
- Six digits in date format YYMMDD
- delimiter of "-" or "+" (optional)
- four digits

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_swedish_national_identifier` finds content that matches the pattern.
- A keyword from `Keywords_swedish_national_identifier` is found
- The checksum passes.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_swedish_national_identifier` finds content that matches the pattern.
- The checksum passes.

XML

```

Sweden passport number

Article • 08/19/2024

Format

eight digits

Pattern

eight consecutive digits

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- the regular expression Regex_sweden_passport_number finds content that matches the pattern.
- a keyword from `Keywords_eu_passport_number` or `Keyword_sweden_passport` is found.
- the regular expression `Regex_sweden_eu_passport_date` finds a date in the format DD MMM/MMM YY (01 JAN/JAN 12) or a keyword from `Keywords_eu_passport_date` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- the regular expression Regex_sweden_passport_number finds content that matches the pattern.
- a keyword from `Keywords_eu_passport_number` or `Keyword_sweden_passport` is found.

- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

Sweden tax identification number

Article • 08/19/2024

Format

10 digits and a symbol in the specified pattern

Pattern

10 digits and a symbol:

- six digits that correspond to the birth date (YYMMDD)
- a plus sign or minus sign
- three digits that make the identification number unique where:
  - for numbers issued before 1990, the seventh and eighth digit identify the county of birth or foreign-born people
  - the digit in the ninth position indicates gender by either odd for male or even for female
- one check digit

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_sweden_eu_tax_file_number` finds content that matches the pattern.

- A keyword from `Keywords_sweden_eu_tax_file_number` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_sweden_eu_tax_file_number` finds content that matches the pattern.

Swiss Social Security Number AHV

The Swiss Social Security Number AHV (Alters- und Hinterlassenenversicherung) is a unique personal identification number used in Switzerland.

Format

13-digit number

Pattern

13-digit number:

- three digits - 756
- an optional dot
- four digits
- an optional dot
- four digits
- an optional dot
- two digits

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A data loss prevention (DLP) policy has high confidence that it detects this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_swiss_social_security_number_ahv` finds content that matches the pattern.
- A keyword from `Keywords_swiss_social_security_number_ahv` is found.

A DLP policy has medium confidence that it detects this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_swiss_social_security_number_ahv` finds content that matches the pattern.

XML

```
      <!-- Swiss SSN AHV Number -->

- Five letters (not case-sensitive) or the digit "9" in place of a letter.
- One digit.
- Five digits in the date format MMDDY for date of birth. The seventh character is incremented by 50 if driver is female; for example, 51 to 62 instead of 01 to 12.
- Two letters (not case-sensitive) or the digit "9" in place of a letter.
- Five digits.

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_uk_drivers_license` finds content that matches the pattern.
- A keyword from `Keywords_eu_driver's_license_number` is found.
- The checksum passes.

A DLP policy has low confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_uk_drivers_license` finds content that matches the pattern.
- The checksum passes.

U.K. national insurance number (NINO)

Article • 08/19/2024

This sensitive information type entity is included in the EU National Identification Number sensitive information type. It's also available as a stand-alone sensitive information type entity.

Format

seven characters or nine characters separated by spaces or dashes

Pattern

two possible patterns:

- two letters (valid NINOs use only certain characters in this prefix, which this pattern validates; not case-sensitive)
- six digits
- either 'A', 'B', 'C', or 'D' (like the prefix, only certain characters are allowed in the suffix; not case-sensitive)

OR

- two letters
- a space or dash
- two digits
- a space or dash
- two digits
- a space or dash
- two digits
- a space or dash
- either 'A', 'B', 'C', or 'D'

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_uk_nino` finds content that matches the pattern.
- A keyword from `Keyword_uk_nino` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_uk_nino` finds content that matches the pattern.

XML

U.S. drivers license number

Article • 08/19/2024

Format

Depends on the state

Pattern

depends on the state - for example, New York:

- nine digits formatted like ddd ddd ddd will match.
- nine digits like ddddddddd won't match.

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_new_york_drivers_license_number` finds content that matches the pattern.
- A keyword from `Keyword_[state_name]_drivers_license_name` is found.
- A keyword from `Keyword_us_drivers_license` is found.

A DLP policy has low confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_new_york_drivers_license_number` finds content that matches the pattern.
- A keyword from `Keyword_[state_name]_drivers_license_name` is found.
- A keyword from `Keyword_us_drivers_license_abbreviations` is found.
- No keyword from `Keyword_us_drivers_license` is found.

U.S. social security number (SSN)

Article • 08/19/2024

Format

nine digits, which may be in a formatted or unformatted pattern

> **Note**
>
> If issued before mid-2011, an SSN has strong formatting where certain parts of the number must fall within certain ranges to be valid (but there's no checksum).

Pattern

four functions look for SSNs in four different patterns:

- `Func_ssn` finds SSNs with pre-2011 strong formatting that are formatted with dashes or spaces (ddd-dd-dddd OR ddd dd dddd)
- `Func_unformatted_ssn` finds SSNs with pre-2011 strong formatting that are unformatted as nine consecutive digits (ddddddddd)
- `Func_randomized_formatted_ssn` finds post-2011 SSNs that are formatted with dashes or spaces (ddd-dd-dddd OR ddd dd dddd)
- `Func_randomized_unformatted_ssn` finds post-2011 SSNs that are unformatted as nine consecutive digits (ddddddddd)

Checksum

No

Keyword Highlighting

Ukraine passport domestic

Article • 08/19/2024

Format

nine digits

Pattern

nine digits

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regex `Regex_Ukraine_Passport_Domestic` finds content that matches the pattern.
- A keyword from `Keyword_Ukraine_Passport_Domestic` is found.

XML

```
      <!-- Ukraine Passport Domestic -->
      <Entity id="1817a540-221f-4459-9202-3bd78b81d803"
patternsProximity="300" recommendedConfidence="75">
        <Pattern confidenceLevel="75">
        <IdMatch idRef="Regex_Ukraine_Passport_Domestic"/>
          <Match idRef="Keyword_Ukraine_Passport_Domestic"/>
```

```
          </Pattern>
        </Entity>
```

Ukraine physical addresses

This unbundled named entity detects patterns related to physical address from Ukraine. It is also included in the All Physical Addresses bundled named entity SIT.

Confidence level

Medium

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Cloud Support

Cloud support is available for the following services:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

Last updated on 06/19/2026

User login credentials

This SIT is also included in the All credentials bundled SIT.

> **ⓘ Important**
>
> Because credential scanning SITs are a type of advanced classifier, you must enable advanced classification before implementing them. For information about enabling advanced classification, and about configuring endpoints and the supported file types, see Advanced classification scanning and protection.

Format

A paired username and password used in general authentication process.

or

A paired username and password used in PuTTY connection manager.

or

Plain text password used in code snippets.

or

A combination of 88 characters consisting of letters, digits, and special characters.

Pattern

Various username and password formats, for example:

`username=...;password=********;`
`user id=...;password=********;`
`uid=...;pwd=********;`
`DB_USER=...;DB_PASS=********;`
`Service Account=...;Password=********;`

or

XML

```
An XML element <login>
An embeded XML element <login>
Inner XML content
An embeded XML element </login>
An embeded XML element <password>
Inner XML content
An embeded XML element </password>
An XML element </login>
```

for example

`<login> <login>ZYXWVU_1</login> <password>ZY…`

or

Various password formats in code snippets, for example:

`new X509Certificates2(`

`ConvertTo-SecureString -String ********`

`password = "********"`

`"password" : "********"`

`UserPasswordCredential(`

or

A combination of 86 characters:

- a-z (not case-sensitive)
- 0-9
- forward slashes (/)
- or plus signs (+)
- ends with two equal signs (=)

format example:

`aB1cD2eF/3gH4iJ5kL6+mN7oP8qR==`

Credential example

|Confidence Band|Example| |----|----| |High| `initial catalog=host_name;database=db_name;uid=user_name;password=********** | |Medium|` user=user_name;password=********** | |Low| N/A |

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used in general user login process.

It uses several primary resources:

- Patterns of Plain-text username and password.
- Patterns of Plain-text username and password in PuTTYcm database file.
- Patterns of Password context in code.
- Patterns of Base64 encoded 512 bits symmetric key.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName, Id, AccountName.
- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Keywords

Keyword_LoginCredentials:

Last updated on 04/09/2026

X.509 certificate private key (preview)

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

A combination of up to 20,000 characters consisting of letters, digits, and special characters.

or

A combination of up to 40 characters consisting of upper-case letters, space, and dashes.

Pattern

A combination of up to 20,000 characters:

- a-z (not case-sensitive)
- 0-9
- forward slashes (/)
- or plus signs (+)
- Up to two equal signs (==)

format example:

```
cD2eF3gH4iJ5kL6mN7/oP+qR9sT=
```

or

five dashes (-)

And a combination of up to 30 characters:

- A-Z (case-sensitive)
- spaces
- 5 dashes (-)

for example:

`-----BEGIN PRIVATE KEY-----`

Credential format example

`-----BEGIN PRIVATE KEY----- cD2eF3gH4iJ5kL6mN7/oP+qR9sT=...`

> **Important**
>
> This example has been truncated. It's not a detectable example of this SIT.

Checksum

Yes

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used as a private component in SSL certificates.

It uses several primary resources:

- Patterns of Base64 encoded string literal.
- Patterns of Certificate private key header.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName.
- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Sensitive information type functions

Article • 07/21/2023

Sensitive information types (SIT) can use functions as primary elements for identifying sensitive items. For example, the Credit Card Number SIT uses the Func_credit_card function to detect credit card number.

This article explains what these functions look for, so you can better understand how the predefined sensitive information types work. For more information, see Sensitive information type entity definitions

Func_us_date

Func_us_date looks for dates in common U.S. formats. The common formats are "month/day/year", "month-day-year", and "month day year ". The names or abbreviations of months aren't case-sensitive.

Examples:

- December 2, 2016
- Dec 2, 2016
- dec 02 2016
- 12/2/2016
- 12/02/16
- Dec-2-2016
- 12-2-16

Accepted month names:

- English
  - January, February, march, April, may, June, July, August, September, October, November, December
  - Jan. Feb. Mar. Apr. May June July Aug. Sept. Oct. Nov. Dec.

Func_eu_date

Fund_eu_dates looks for dates in common E.U. formats (and most places outside the U.S.), such as "day/month/year", "day-month-year", and "day month year". The names or abbreviations of months aren't case-sensitive.

Examples:

- 2 Dec 2016
- 02 dec 2016
- 2 Dec 16
- 2/12/2016
- 02/12/16
- 2-Dec-2016
- 2-12-16

Accepted month names:

- English
  - January, February, march, April, may, June, July, August, September, October, November, December
  - Jan. Feb. Mar. Apr. May June July Aug. Sept. Oct. Nov. Dec.

- Dutch
  - januari, februari, maart, April, mei, juni, juli, augustus, September, ocktober, October, November, December
  - jan feb maart apr mei jun jul aug sep sept oct okt nov dec
- French
  - janvier, février, mars, avril, mai, juin juillet, août, septembre, octobre, novembre, décembre
  - janv. févr. mars avril mai juin juil. août sept. oct. nov. déc.
- German
  - jänuar, februar, märz, April, mai, juni juli, August, September, oktober, November, dezember
  - Jan./Jän. Feb. März Apr. Mai Juni Juli Aug. Sept. Okt. Nov. Dez.
- Italian
  - gennaio, febbraio, marzo, aprile, maggio, giugno, luglio, agosto, settembre, ottobre, novembre, dicembre
  - genn. febbr. mar. apr. magg. giugno luglio ag. sett. ott. nov. dic.
- Portuguese
  - janeiro, fevereiro, março, marco, abril, maio, junho, julho, agosto, setembro, outubro, novembro, dezembro
  - jan fev mar abr mai jun jul ago set out nov dez
- Spanish
  - enero, febrero, marzo, abril, mayo, junio, julio, agosto, septiembre, octubre, noviembre, diciembre
  - enero feb. marzo abr. mayo jun. jul. agosto sept./set. oct. nov. dic.

Func_eu_date1 (deprecated)

> ⓘ **Note**
>
> This function is deprecated because it supports only Portuguese month names, which are now included in the `Func_eu_date` function above.

This function looks for a date in the format commonly used in Portuguese. The format for this function is the same as `Func_eu_date`, differing only in the language used.

Examples:

- 2 Dez 2016
- 02 dez 2016
- 2 Dez 16

- 2/12/2016
- 02/12/16
- 2-Dez-2016
- 2-12-16

Accepted month names:

- Portuguese
  - janeiro, fevereiro, março, marco, abril, maio, junho, julho, agosto, setembro, outubro, novembro, dezembro
  - jan fev mar abr mai jun jul ago set out nov dez

Func_eu_date2 (deprecated)

> ⓘ **Note**
>
> This function is deprecated because it supports only Dutch month names, which are now included in the `Func_eu_date` function above.

This function looks for a date in the format commonly used in Dutch. The format for this function is the same as `Func_eu_date`, differing only in the language used.

Examples:

- 2 Mei 2016
- 02 mei 2016
- 2 Mei 16
- 2/12/2016
- 02/12/16
- 2-Mei-2016
- 2-12-16

Accepted month names:

- Dutch
  - januari, februari, maart, April, mei, juni, juli, augustus, September, ocktober, October, November, December
  - jan feb maart apr mei jun jul aug sep sept out okt nov dec

Func_expiration_date

Func_expiration_date looks for dates that are in formats commonly used by credit and debit cards. This function will match dates in format of "month/year", "month-year", "[month name] year", and "[month abbreviation] year". The names or abbreviations of months aren't case-sensitive.

Examples:

- MM/YY -- for example, 01/11 or 1/11
- MM/YYYY -- for example, 01/2011 or 1/2011
- MM-YY -- for example, 01-22 or 1-11
- MM-YYYY -- for example, 01-2000 or 1-2000

The following formats support YY or YYYY:

- Month-YYYY -- for example Jan-2010 or january-2010 or Jan-10 or january-10
- Month YYYY -- for example, 'january 2010' or 'Jan 2010' or 'january 10' or 'Jan 10'
- MonthYYYY -- for example, 'january2010' or 'Jan2010' or 'january10' or 'Jan10'
- Month/YYYY -- for example, 'january/2010' or 'Jan/2010' or 'january/10' or 'Jan/10'

Accepted month names:

- English
  - January, February, march, April, may, June, July, August, September, October, November, December
  - Jan Feb Mar Apr May June July Aug Sept Oct Nov Dec

Func_us_address

Func_us_address looks for a U.S. state name or postal abbreviation followed by a valid zip code. The zip code must be one of the correct zip codes associated with the U.S. state name or abbreviation. The U.S. state name and zip code can't be separated by punctuation or letters.

Examples:

- Washington 98052
- Washington 98052-9998
- WA 98052
- WA 98052-9998

Custom sensitive information type filters reference

09/26/2025

In Microsoft Purview, you can define filters or other checks while creating a custom sensitive information type (SIT).

List of supported filters and use cases

AllDigitsSame Exclude

Description: Allows you to exclude matches that have all digits as duplicate digits, such as 111111111 or 111-111-111

Defining filters:

XML

```xml
<Filters id="ssn_filters">
    <Filter type="AllDigitsSameFilter"></Filter>
</Filters>
```

Using it in rule package at the entity level:

XML

```xml
<Entity id="50842eb7-edc8-4019-85dd-5a5c1f2bb085" patternsProximity="300"
recommendedConfidence="85"  filters="ssn_filters">
      <Pattern confidenceLevel="85">
        <IdMatch idRef="Func_ssn" />
      </Pattern>
</Entity>
```

Using it in rule package at the pattern level:

XML

```xml
<Entity id="50842eb7-edc8-4019-85dd-5a5c1f2bb085" patternsProximity="300"
recommendedConfidence="85">
      <Pattern confidenceLevel="85"  filters="ssn_filters">
        <IdMatch idRef="Func_ssn" />
      </Pattern>
</Entity>
```

TextMatchFilter StartsWith

Description: Allows you to define the starting characters for the entity. It has two variants, *exclude* and *include*.

For example, to *exclude* the numbers starting with 0500, 91, 091, 010 in a list like this:

- 0500-4500-027
- 91564721450
- 91-8523697410
- 700-8956-7844
- 1000-3265-9874
- 0100-7892-3012

you can use the following XML:

XML

```
<Filters id="phone_number_filters_exc">
    <Filter type="TextMatchFilter" direction="StartsWith" logic="Exclude"
textProcessorId="Keyword_false_positives_sw">
</Filter>
</Filters>

  <Keyword id="Keyword_false_positives_sw">
    <Group matchStyle="string">
      <Term>0500</Term>
      <Term>91</Term>
      <Term>091</Term>
      <Term>0100</Term>
    </Group>
  </Keyword>
```

Similarly, to *include* the numbers starting with 0500, 91, 091, 0100 in a list like this:

- 0500-4500-027
- 91564721450
- 91-8523697410
- 700-8956-7844
- 1000-3265-9874
- 0100-7892-3012

you can use the following XML:

XML

```
<Filters id="phone_filters_inc">
    <Filter type="TextMatchFilter" direction="StartsWith" logic="Include"
textProcessorId="Keyword_false_positives_sw">
</Filter>
```

TextMatchFilter EndsWith

Description: Allows you to define the ending characters for the entity.

For example, to *exclude* the numbers ending with 0500,91,091, 0100 in a list like this:

- 1234567891
- 1234-5678-0091
- 1234.4567.7091
- 1234-8091-4564

you can use the following XML:

XML

```
<Filters id="phone_number_filters_exc">
    <Filter type="TextMatchFilter" direction="EndsWith" logic="Exclude"
textProcessorId="Keyword_false_positives_sw">
</Filter>

  <Keyword id="Keyword_false_positives_sw">
    <Group matchStyle="string">
      <Term>0500</Term>
      <Term>91</Term>
      <Term>091</Term>
      <Term>0100</Term>
    </Group>
  </Keyword>
```

For example, to *include* the numbers ending with 0500, 91, 091, 0100, in a list like this:

- 1234567891
- 1234-5678-0091
- 1234.4567.7091
- 1234-8091-4564

You can use the following XML:

XML

```
<Filters id="phone_filters_inc">
    <Filter type="TextMatchFilter" direction=" EndsWith" logic="Include"
textProcessorId="Keyword_false_positives_sw">
</Filter>
```

TextMatchFilter Full

Description: Allows you to prohibit certain matches to prevent them from triggering the rule, such as excluding 4111111111111111 from the list of valid credit card matches.

For example, to *exclude* credit card numbers like 4111111111111111 and 3241891031113111 in a list like this:

- 4485 3647 3952 7352
- 4111111111111111
- 3241891031113111

you can use the following XML:

XML

```
<Filters id="cc_number_filters_exc">
    <Filter type="TextMatchFilter" direction="Full" logic="Exclude"
textProcessorId="Keyword_false_positives_full">
</Filter>

  <Keyword id="Keyword_false_positives_full">
    <Group matchStyle="string">
      <Term>4111111111111111</Term>
      <Term>3241891031113111</Term>
    </Group>
  </Keyword>
```

Likewise, to *include* credit card numbers like 4111111111111111 and 3241891031113111 in a list like this:

- 4485 3647 3952 7352
- 4111111111111111
- 3241891031113111

you can use the following XML:

XML

```
<Filters id="cc_filters_inc">
    <Filter type="TextMatchFilter" direction="Full" logic="Include"
```

```
textProcessorId="Keyword_false_positives_full">
</Filter>
```

TextMatchFilter Prefix

Description: Allows you to define the preceding characters that should be always excluded or included. For example, if **Credit card number** is preceded by 'Order ID:', then remove the match from the valid matches.

For example, to exclude occurrences of phone numbers that have **Phone number** and **call me at** strings before the phone number, in a list like this:

- Phone number 091-8974-653278
- Phone 45-124576532-123
- 45-124576532-123

you can use the following XML:

XML

```
<Filters id="cc_number_filters_exc">
    <Filter type="TextMatchFilter" direction="Prefix" logic="Exclude"
textProcessorId="Keyword_false_positives_prefix">
</Filter>
  <Keyword id="Keyword_false_positives_prefix">
    <Group matchStyle="string">
      <Term>phone number</Term>
      <Term>call me at</Term>
    </Group>
  </Keyword>
```

Similarly, to include occurrences that have **credit card** and **card #** strings before the credit card number, in a list like this:

- Credit card 45-124576532-123
- 45-124576532-123 (which could be phone number)

you can use the following XML:

XML

```
<Filters id="cc_filters_inc">
    <Filter type="TextMatchFilter" direction="Full" logic="Include"
textProcessorId="Keyword_true_positives_prefix">
</Filter>

  <Keyword id="Keyword_true_positives_prefix">
```

```
    <Group matchStyle="string">
      <Term>credit card</Term>
      <Term>card #</Term>
    </Group>
  </Keyword
```

TextMatchFilter Suffix

Description: Allows you to define the following characters that should be always excluded or included. For example, if Credit card number is followed by '/xuid' then remove the match from the valid matches.

For example, top exclude occurrences if there are five more instances of four digits as suffix in a list like this:

- 1234-5678-9321 4500 9870 6321 48925566
- 1234-5678-9321

you can use the following XML:

XML

```
<Filters id="cc_number_filters_exc">
    <Filter type="TextMatchFilter" direction="Prefix" logic="Exclude"
textProcessorId="Regex_false_positives_suffix">
</Filter>

  <Regexid="Regex_false_positives_suffix">(\d{4}){5,}</Regex>
```

You can also exclude occurrences if they are followed by **/xuidsuffix**, like the one in this list:

- 1234-5678-9321 /xuid
- 1234-5678-9321

you can use this XML:

XML

```
<Filters id="cc_number_filters_exc">
    <Filter type="TextMatchFilter" direction="Prefix" logic="Exclude"
textProcessorId="Keyword_false_positives_suffix">
</Filter>

  <Keyword id="Keyword_false_positives_suffix">
    <Group matchStyle="string">
      <Term>/xuid</Term>
```

```
    </Group>
  </Keyword>
```

Similarly, to include an occurrence only if it is followed by **cvv** or **expires**, such as the two in this list:

- 45-124576532-123
- 45-124576532-123 cvv 966
- 45-124576532-123 expires 03/23

you can use this XML:

XML

```
<Filters id="cc_filters_inc">
    <Filter type="TextMatchFilter" direction="Full" logic="Include"
textProcessorId="Keyword_true_positives_suffix">
</Filter>

  <Keyword id="Keyword_true_positives_suffix">
    <Group matchStyle="string">
      <Term>cvv</Term>
      <Term>expires</Term>
    </Group>
  </Keyword>
```

Using filters in rule packages

Filters can be defined on the entire SIT or on a pattern. Here are some examples.

At the sensitive information type level

Filters at Entity - will cover all child patterns

The filters will be applied to **all** the instances classified by any of the patterns in that entity / sensitive information type.

XML

```
<Entity id="6443b88f-2808-482a-8e1a-3ae5026645e1" patternsProximity="300"
recommendedConfidence="85" filters="CompositeFiltersAtEntityLevel">
      <Pattern confidenceLevel="85">
        <IdMatch idRef="Regex_denmark_id" />
      </Pattern>
</Entity>
```

At the individual pattern of the sensitive information type level

Filters only at the pattern level.

The filter will be applied to only the instances matched by the pattern.

XML

```
<Entity id="50842eb7-edc8-4019-85dd-5a5c1f2bb085" patternsProximity="300"
recommendedConfidence="85">
      <Pattern confidenceLevel="85"  filters="CompositeFiltersAtPattern">
        <IdMatch idRef="Keyword_cc_verification" />
      </Pattern>
</Entity>
```

At the sensitive information type level with an additional filter on some of the patterns of that entity

Filters at Entity + pattern

The filters will be applied to **all** the instances classified by any of the patterns in that entity / sensitive information type. The pattern level filter will filter the instances matched by that pattern.

XML

```
<Entity id="6443b88f-2808-482a-8e1a-3ae5026645e1" patternsProximity="300"
recommendedConfidence="85" filters="CompositeFiltersAtEntityLevel">
      <Pattern confidenceLevel="85" filters="CompositeFiltersAtPattern">
        <IdMatch idRef="Regex_denmark_id" />
      </Pattern>
</Entity>
```

Sensitive information type limits

These limits apply to all Microsoft Purview policies that use SITs.

To ensure high performance and lower latency, there are limitations in custom SIT configurations, as described in the following table.

Expand table

Limit	Value
Maximum number of custom SITs created through the Microsoft Purview portal	500
Maximum length of regular expression	1024 characters
Maximum length for a given term in a keyword list	50 characters
Maximum number of terms in keyword list	2048
Maximum number of distinct regexes per SIT	20
Maximum combined size for all keyword dictionaries (post compression)	1MB (~1,000,000 characters)
Maximum number of rule packages	10
Maximum number of SITs per rule package	50
Maximum size of a rule package	150KB
Capturing group in a regular expression	1

> **Note**
>
> The regex pattern must use exactly one primary capturing group. Use noncapturing groups for any prefix/suffix (for example: `(?:prefix)(primary capturing group)(?:suffix)`). Multiple top-level capturing groups separated by `|` outside the primary group aren't supported; put alternation variants inside the single capturing group. For more information, see Create a custom sensitive information type.

> **Note**

If you have a business need to create more than 500 custom SITs, please raise a support ticket.

Instance count supported values for SIT

The SIT instance count limit applies when using SITs in these solutions:

- Microsoft Purview Data Loss Prevention policies
- Microsoft Purview Information Protection policies
- Microsoft Purview Data Lifecycle Management
- Communication Compliance
- Microsoft Purview Records Management
- Microsoft Defender for Cloud Apps
- Microsoft Priva

For a scanned item to satisfy the rule criteria, the number of unique instances of a SIT in any single item must fall between the min and max values. This is called the **Instance count**.

- **Min** field: the lower limit (minimum number) of unique instances of a SIT that must be found in an item to trigger a match. The min field supports values of 1 to 500.
- **Max** field: the upper limit on the number of unique instances of a SIT that can be found in an item and still trigger a match. The max field supports the following values:
  - 1 to 500 - Use a value between `1` and `500` when you want to set a specific upper limit of 500 or less on the number of instances of a SIT in an item.
  - Any - Use `Any` when you want to ensure that the unique instance count criterion is satisfied when an undefined number of unique instances of a SIT are found in a scanned item and that the specified number of unique instances meets or exceeds the minimum number of unique instances value. In other words, the unique instance count criteria are met as long as the min value is met.

For example, if you want the rule to trigger a match when at least 500 unique instances of a SIT are found in a single item, set the **min** value to `500` and the **max** value to `Any`.

Learn about named entities

09/26/2025

Named entities are sensitive information types (SIT). They're complex dictionary and pattern-based classifiers that you can use to detect person names, physical addresses, and medical terms and conditions. You can see them in the **Microsoft Purview portal** > **Data classification** > **Sensitive info types**. Here's a partial list of where you can use SITs:

- Microsoft Purview Data Loss Prevention policies (DLP)
- Sensitivity labels
- Insider risk management
- Microsoft Defender for Cloud Apps
- Microsoft Purview Information Protection
- Data Lifecycle Management
- Records management
- Microsoft Purview eDiscovery
- Microsoft Priva
- Exact data match sensitive information types

DLP makes special use of named entities in *enhanced policy templates*, which are preconfigured DLP policies that you can customize for your organizations needs. You can also create your own DLP policies from a blank template and use a named entity SIT as a condition. Entity Match and other advanced classifiers are offered only to users with E5 licenses.

Examples of named entity SITs

Named entity SITs come in two flavors, *bundled* and *unbundled*

Bundled named entity SITs detect all possible matches. Use them as broad criteria in your DLP policies for detecting sensitive items.

Unbundled named entity SITs have a narrower focus, like a single country. Use them when you need a DLP policy with a narrower detection scope.

> **Note**
>
> To use named entity SITs, you must activate Advanced classification scanning and protection for the relevant data loss prevention settings before they will be discoverable.

Here are some examples of named entity SITs. You can find all of them in Sensitive information type entity definitions.

Expand table

Named Entity	Description	Bundled/Unbundled
All full names	Detects all possible matches of full names	bundled
All physical addresses	Detects all possible matches of physical addresses	bundled
All medical terms and conditions	Detects all possible matches of medical terms and conditions	bundled
Australia Physical Addresses	Detects patterns related to physical addresses from Australia. Included in All physical addresses SIT.	unbundled
Blood Test Terms	Detects terms related to blood tests, such as 'hCG'. English terms only. Included in All medical terms and conditions SIT	unbundled
Brand Medication Names	Detects names of brand medication, such as 'Tylenol'. English terms only. Included in All medical terms and conditions.	unbundled

Examples of enhanced DLP policies

Here are some examples of enhanced DLP policies that use named entity SITs. You can find all 10 of them in the **Microsoft Purview portal** Navigate to **Data loss prevention** > **Create policy**. Enhanced templates can be used in DLP and auto-labeling.

Expand table

Policy category	Template	Description
Financial	U.S. Gramm-Leach-Bliley Act (GLBA) Enhanced	Helps detect the presence of information subject to Gramm-Leach-Bliley Act (GLBA), including information like social security numbers or credit card numbers. This enhanced template extends the original by also detecting people's full names, U.S./U.K. passport number, U.S. driver's license number and U.S. physical addresses.
Medical and health	Australia Health Records Act (HRIP Act) Enhanced	Helps detect the presence of information commonly considered to be subject to the Health Records and Information Privacy (HRIP) act in Australia, like medical account number and tax file number. This enhanced template extends the original by also detecting people's full names, medical terms and conditions, and Australia physical addresses.
Privacy	General Data Protection	Helps detect the presence of personal information for individuals inside the European Union (EU) to help meet GDPR privacy obligations.

Policy category	Template	Description
	Regulation (GDPR) Enhanced	This enhanced template detects people's full names and physical addresses for countries in the EU.

Use named entities in your data loss prevention policies

Read through Named entities in sensitive information types before you start to use named entity SITs.

Before you begin

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions

The account you use to create and edit data loss prevention (DLP) policies, must have the **DLP Compliance Management** role permissions. For more information, see Add users or groups to a Microsoft Purview built-in role group.

Supported locations

You can use named entity SITs and enhanced policies to detect and protect sensitive items in these locations:

- SharePoint sites
- OneDrive accounts
- Teams chat and channel messages
- Devices (Windows 10/11 endpoint devices)
- Exchange mailboxes
- Microsoft Defender for Cloud Apps

Named entity SITs and enhanced policies aren't supported for:

- On-premises repositories
- Power BI

Create and edit enhanced policies

To create or edit a DLP policy, use the procedures in Create and Deploy data loss prevention policies.

Workloads and services that support named entities

The following workloads and services support named entities:

- **Microsoft 365 eDiscovery** supports the use of named entities in Substrate services.
- **Microsoft Defender for Cloud Apps** supports the use of named entities in Defender for Cloud Apps policies in the Defender for Cloud Apps portal.
- **Insider Risk Management** supports the use of named entities in Substrate services.
- **Records Management** supports the use of named entities.
- **Exact Data Match Sensitive Information Types** supports the use of named entities.

Unified DLP support for named entities

The following table shows named entity support in Unified DLP workloads and services.

Expand table

Workload/Services	Support for Named Entities
Office Win32 clients policy tip	Not supported
Office WAC clients policy tip	Supported
OWA policy tip	Not supported
Outlook for Microsoft 365 policy tip	Supported
Endpoints (Windows 10, and 11 devices)	Supported
Exchange Transport rules	Supported
OneDrive for Business data-at-rest	Supported
SharePoint Online data-at-rest	Supported
Teams data-at-rest	Supported
Email messages data-at-rest	Supported for tenants with Privacy Service Plan
Microsoft Defender for Cloud Apps	Supported

Autolabeling support for named entities

The following table lists named entity support for autolabeling workloads and services.

Expand table

Workload/Services	Support for Named Entities
Office Win32 clients offline	Supported, user must select label and manually apply
Online Office Win32 clients online	Supported with old confidence scheme
Outlook online	Supported with old confidence scheme
Office WAC client	Supported
OWA	Supported
Exchange transport	Supported
OneDrive for Business data-at-rest	Supported
SharePoint Online data-at-rest	Supported
Microsoft Purview Information Protection scanner	Not supported

Known issues

The following table summarizes current known issues when using named entities and their impact.

Expand table

Issue	Impact
DLP Policy tips (OWA, Outlook, Office Win32 clients)	Policy tips with entity condition results in "no match"
Asian language support for person name (Chinese, Japanese, Korean)	Named entities supported for Latin-based character set only (that is, kanji isn't supported) for person name
On-premises repositories	Not supported as a workload
Power BI (preview)	Not supported

Best practices for using named entity SITs

Here are some practices you can use when you create or edit a policy that uses a named entity SIT.

- Use low instance counts (three to five) when you're looking for data that's in a spreadsheet and the keyword that's required by the SIT for that data is only in the column header. For example, let's say you're looking for US Social Security numbers, and the keyword `Social Security Number` only occurs in the column header. Since the values (the corroborative evidence) are in the cells below, it's likely that only the first few instances would be in close enough proximity to the keyword to be detected.

- If you're using a named entity SIT, like All Full Names, to help find US Social Security numbers, use larger instance counts such as 10 or 50. Then, when both the person names and the SSNs are detected together, you're more likely to get true positives.

- You can use Autolabeling simulations to test the accuracy of named entity SITs. Run a simulation using a named entity SIT to see what items match the policy. With this information, you can fine tune accuracy by adjusting the instance counts and confidence levels in your custom policies or the enhanced template conditions. You can iterate simulations until the accuracy is where you want it before deploying a DLP or autolabeling policy containing named entities in production. Here's an overview of the autolabeling simulation workflow:

1. Identify the SIT or combination of SITs you want to test in simulation mode, either custom or cloned and edited
2. Identify or create a sensitivity label to be applied when the autolabeling policy finds a match in Exchange, SharePoint sites, or OneDrive accounts
3. Create a sensitivity autolabeling policy that uses the SIT from step 1 and with same Conditions and Exceptions that are used in your DLP policy
4. Run the policy simulation
5. View the results
6. Tune the SIT or policy and the instance count and confidence levels to reduce false positives.
7. Repeat until you get the accuracy results you want

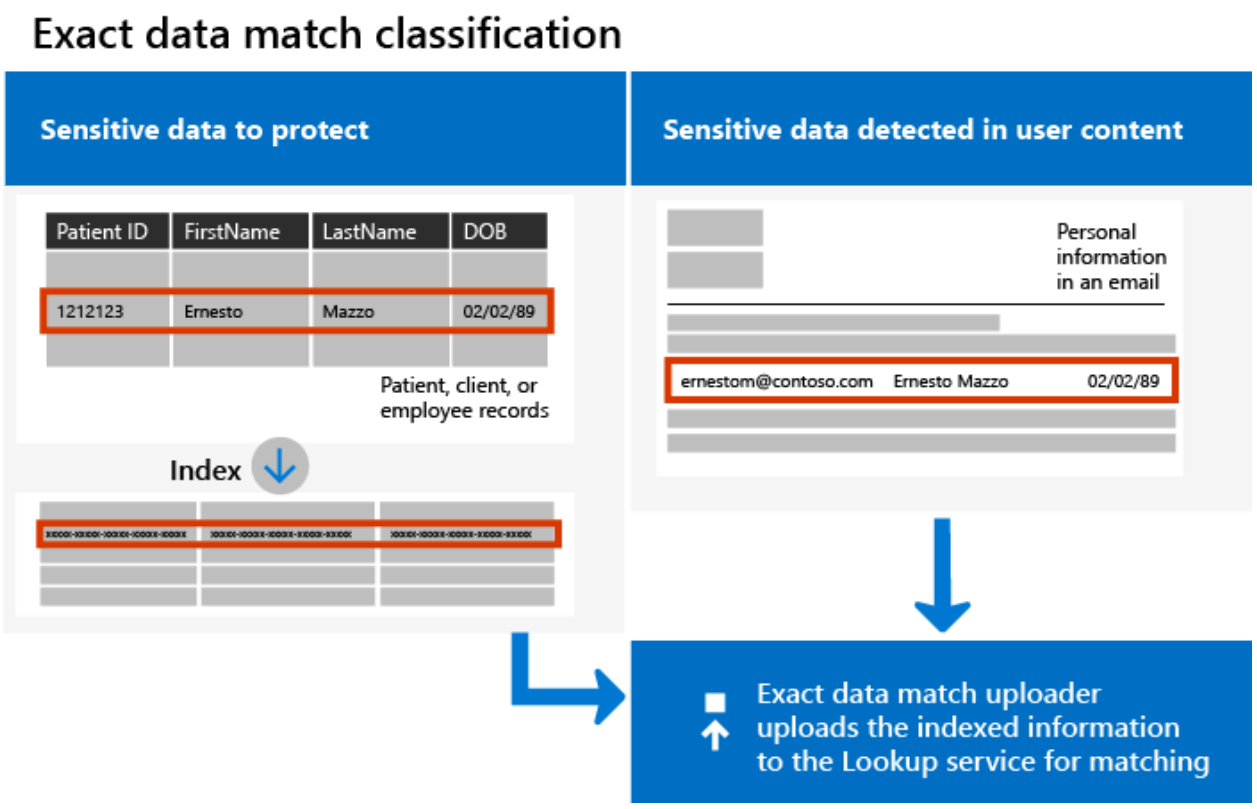
Learn about exact data match based sensitive information types

Article • 01/21/2025

Sensitive information types (SITs) are used to help identify sensitive data so that you can prevent it from being inadvertently or inappropriately shared. They're also used to help in locating relevant data in eDiscovery, and to apply governance actions to certain types of information. You define a custom SIT based on:

- patterns
- keyword evidence such as *employee*, *social security number*, or *ID*
- character proximity to evidence in a particular pattern
- confidence levels



But what if you want a custom SIT that uses exact or nearly exact data values, instead of one that finds matches based on generic patterns? With Exact Data Match (EDM) based classification, you can create a custom sensitive information type that is designed to:

- be dynamic and easily refreshed
- result in fewer false positives
- work with structured sensitive data
- handle sensitive information more securely, not sharing it with anyone, including Microsoft
- be used with several Microsoft cloud services

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the **Microsoft Purview trials hub**. Learn details about **signing up and trial terms**.

EDM-based classification enables you to create custom SITs that refer to exact values in a database of sensitive information. The database can be refreshed daily and can contain up to 100 million rows of data. So, as employees, patients, and clients come and go, and as records change, your custom sensitive information types remain current and applicable. And, you can use EDM-based classification with policies, such as Microsoft Purview Data Loss Prevention policies or Microsoft Cloud App Security file policies.

The following diagram shows the fundamental workings of EDM classification:

> ⓘ Note
>
> Microsoft Purview Information Protection supports the following languages that use double-byte character sets:
>
> - Chinese (simplified)
> - Chinese (traditional)
> - Korean
> - Japanese
>
> This support is available for sensitive information types. For more information, see Information protection support for double byte character sets: Release Notes (preview).

What's different in an EDM SIT

When you work with EDM SITs, it's helpful to understand a few concepts that are unique to them.

Schema

A *schema* is an XML file. Microsoft Purview uses the schema to determine whether or not your data contains strings that match those that your sensitive information types are

designed to detect.

The schema XML file defines:

- The name of the schema, later referred to as the *DataStore*.
- The field names that your sensitive information source table contains. There's a 1:1 mapping of schema field names to the column names in the sensitive information source table.
- Which corroborative evidence fields require multi-token match mode.
- Which data fields are searchable.
- Whether or not configurable matches are supported for each field. A *configurable match* is one with parameters that modify a search, such as ignoring delimiters and case in searched values.

Sensitive information source table

The sensitive information source table contains the values that the EDM SIT looks for. The table is made up of columns and rows. The column headers are the field names, the rows are instances of items and each cell in a row contains the values for that item instance for that field.

Here's a simple example of a sensitive information source table.

Expand table

First Name	Last Name	Date of Birth
Isaiah	Langer	05-05-1960
Ana	Bowman	11-24-1971
Oscar	Ward	02-12-1998

Rule package

Every sensitive information type has a rule package. You use the rule package in an EDM SIT to define the various components of your EDM SIT. The following table provides a description of each component.

Expand table

Component	Description
Match	Specifies the primary element (data field) to be used in exact lookup. It can be a regular expression with or without a checksum validation, a keyword list, a keyword dictionary, or a function.
Classification	Specifies the sensitive information type match that triggers an EDM lookup.
Supporting elements	Elements that, when found, provide evidence that helps increase the confidence of the match. For example, the occurrence of a last name in close proximity to an actual social security number. A supporting element can be a regular expression with or without a checksum validation, a keyword list, a keyword dictionary, or a single- or multi-token string match.
Confidence level (High, Medium, Low)	Indication of how much supporting evidence is detected in addition to the primary element. The more supporting evidence an item contains, the higher the confidence that a matched item contains the sensitive info you're looking for. For more information about confidence levels, see Fundamental parts of a sensitive information type.
Proximity	The number of characters between primary and supporting element.

You supply your own schema and data

Microsoft Purview comes with many built-in SITs that are predefined. These SITs come with schemas, REGEX patterns, keywords, and confidence levels. However, with EDM SITs, you're responsible for defining the schema, as well as the primary and secondary fields that identify sensitive items. Because the schema and primary and secondary data values are all highly sensitive, you encrypt them via a hash function that includes a randomly generated or self-supplied salt value. Only the hashed values are uploaded to the service, so your sensitive data is never in the open.

Primary and secondary support elements

When you create an EDM SIT, you define a *primary element* field in the rule package. EDM then searches all of your content for the primary element. So that EDM can detect them, primary elements must be discoverable through an existing SIT.

> **Note**
>
> For a complete list of the available SITs., see Sensitive information type entity definitions

You need to find a built-in SIT that detects the sensitive information that you want your EDM SIT to detect. For example, if your EDM SIT schema has *U.S. social security number* as the primary element, when you create your EDM schema, you'd associated it with the U.S. Social Security Number (SSN) SIT. Primary elements must follow a defined pattern in order to be detected.

When the primary element is found in a scanned item, EDM then looks for *secondary* elements (also called *supporting* elements). Unlike primary elements, secondary elements have the option of following a pattern. If secondary elements contain multiple tokens, those elements need to either be associated with a SIT that can detect that content or that can be configured for multi-token matching. In all cases, secondary elements must be within a certain proximity to the primary element in order for a match to be detected.

How matching works

EDM works by comparing strings in your documents and emails against values in the sensitive information source table. It uses this comparison to determine whether the values in the scanned content are present in the table. The determination is done by comparing one-way cryptographic hashes.

> **Tip**
>
> You can use both EDM SITs and the predefined SITs that they are based on, together in DLP rules to improve the detection of sensitive data. Use the EDM SIT with higher confidence levels, and the predefined SIT with lower confidence levels. For example, use an EDM SIT that looks for social security number and other supporting data with strict requirements with high confidence. If configured for high-confidence matches, EDM generates a DLP match when only a few instances are detected. To trigger a DLP match when greater numbers of occurrences are detected, use a built-in SIT, such as the *U.S. Social Security Number*.

How supporting elements work with EDM

As discussed in What's different in an EDM SIT, supporting elements are *elements that, when found, provide evidence that helps increase the confidence of the match*.

With support for EDM SITs, you can look for and detect supporting elements that are composed of multiple fields. Supporting element matches can consist of keyword lists, keyword dictionaries, single alphanumeric strings, or multi-token strings.

Let's look at an example. Presume that you want to detect U.S. Social Security numbers. To increase the match confidence, your supporting elements include `first name`, `last name`, and `date of birth` (DoB). So, your source table looks something like this:

Expand table

SSN	FirstName	LastName	DoB
987-65-4320	Isaiah	Langer	05-05-1960
078-05-1120	Ana	Bowman	11-24-1971
219-09-9999	Oscar	Ward	02-12-1998

When looking for matching supporting elements in a protected file, your EDM SIT checks for each supporting element (both individually and in combination) once the primary element is detected.

For instance, say that the first social security number is detected. The exact data match functionality next looks for combinations of supporting elements across all the columns in your source table:

- Isaiah
- Langer
- 05-05-1960
- Isaiah Langer
- Isaiah 05-05-1960
- Langer 05-05-1960
- Isaiah Langer 05-05-1960

Multi-token matching

Multi-token matching is designed to be used when your corroborative evidence field contains multi-token values but matching such values to a SIT isn't easily accomplished. For instance, when you have an `Address` field containing values like `1 Microsoft Way, Redmond, WA` or `123 Main Street, New York, NY`.

This feature allows EDM to compare the hashes of consecutive words in the content with the hashes of the multi-token fields in your data source. If they're identical, EDM produces a match. This way, EDM can detect multi-token fields such as names, addresses, medical conditions, or any other corroborative evidence fields that might contain more than one word, as long as they're marked as multi-token in your EDM schema.

For example, if you select multi-token matching as the match option, you get two additional benefits:

1. Your policies will detect content that matches multiple fields across the columns in your source table.
2. Your source table can include fields with string values that consist of a preconfigured number of words. The following table shows a sample source table:

Expand table

SSN	Name	Street Address
987-65-4320	*Isaiah Langer*	*1432 Lincoln Road*
078-05-1120	*Ana Bowman*	*8250 First Street*
219-09-9999	*Oscar Ward*	*424 205th Avenue*

With multi-token matching, the **Name** and **Street Address** fields are matched both as independent supporting element strings and in combination as individual fields. So, when matched as multi-token strings as supporting elements for Social Security number 987-65-4320, the matches are:

- Isaiah Langer
- 1432 Lincoln Road

When matched in combination, the match is like this:

- Isaiah Langer + 1432 Lincoln Road

Multi-token matching is also supported for double-byte character sets, which generally don't use spaces to separate words.

Services that EDM supports

Get started with exact data match sensitive information types in Microsoft Purview

Creating an exact data match (EDM) sensitive information type (SIT) and making it available is a multiphase process. You can use the *new experience*, *classic experience*, or PowerShell. This article helps Microsoft Purview administrators compare the new and classic experiences and choose the right one for their needs. Before you begin, review the supported regions and required licenses and permissions.

Applies to:

- Create EDM SIT using the new experience
- Create EDM SIT using the classic experience

EDM SITs can be used in:

- Microsoft Purview Data Loss Prevention
- Auto-labeling (service and client side)
- Microsoft Purview Insider Risk Management
- Microsoft Purview eDiscovery
- Microsoft Defender for Cloud Apps

Before you begin

Familiarize yourself with the concepts and terminology in these articles:

- Learn about sensitive information types
- Learn about exact data match based sensitive information types

Supported regions

The exact data match feature is available in these regions:

- Asia Pacific
- Australia
- Brazil
- Canada

- Europe
- France
- Germany
- India
- Japan
- Korea
- Norway
- Qatar
- South Africa
- Switzerland
- United Arab Emirates
- United Kingdom
- United States
- US Department of Defense (DoD)
- US Government Community Cloud (GCC)
- US Government Community Cloud High (GCC High)

To find out where your tenant is hosting data at rest, see Where your Microsoft 365 customer data is stored and refer to the data center city locations listed there.

Required licenses and permissions

You must be a Global Admin, Compliance Admin, or Exchange Admin to perform the tasks described in this article. To learn more about Purview permissions, see Permissions in the Microsoft Purview portal.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. This helps improve security for your organization. Global Administrator is a highly privileged role that should only be used in scenarios where a lesser privileged role can't be used.

See the Microsoft 365 security and compliance licensing guidance for complete licensing information.

Portal links for your subscription

The following table lists the correct portal URLs for each subscription environment.

Expand table

Portal	Worldwide / GCC	GCC High	DoD
Office SCC	purview.microsoft.com	scc.office365.us	scc.protection.apps.mil
Microsoft Defender portal	security.microsoft.com	security.microsoft.us	security.apps.mil
Microsoft Purview portal	purview.microsoft.com	purview.microsoft.us	purview.apps.mil

New EDM experience

The new EDM experience combines the functionality of the EDM schema and EDM sensitive information type tools into a single user experience. The new experience offers the following benefits:

- A simplified workflow
- Automated schema and SIT creation
- Additional guardrails to ensure better performance

Simplified workflow

With the new experience, the schema and SIT are created in a single workflow. Creating the schema and SIT together means there are fewer steps, better guidance on mapping primary elements to default SITs, and clearer descriptions of default confidence levels for the rules.

When you need to see the status of an EDM SIT in the creation process, the new experience reports the current creation status in the UI.

- *Data not yet uploaded*
- *Data upload percent*
- *Data upload complete*
- *Indexing complete*
- *Data upload failed*
- *Data indexing failed*

Automated schema and SIT creation

In the new experience you can provide a sample data file that has the same header values and enough rows (10-20) of representative data to the system. The system validates the format and creates the schema based on the headers. You then identify the primary fields in the schema and

the system recommends the SITs that best match the primary fields to associate them with. If you don't want to upload the file, you can enter the same values manually in the UI.

> **Important**
>
> Be sure to use sample data values that aren't sensitive; however, also make sure that the sample values are in the same format as your actual sensitive data. Using nonsensitive data is essential because the sample data file doesn't get encrypted and hashed when you upload it in the same way that your actual sensitive information table does. The data from the sample data file isn't retained nor accessible once the EDM SIT is created.

The system generates the EDM SIT detection rules, one for each primary field. Based on detection of the primary fields, the system creates high and medium confidence rules using all the other fields as corroborative evidence. You can manually add low confidence rules if needed.

Additional guardrails to ensure better performance

The system warns you if it finds a primary field mapped to a SIT that detects a broad range of values, called a *loosely defined SIT*. Mapping a primary field to a loosely defined SIT can cause the system to perform lookups on large numbers of strings that aren't related to the kind of content that you're looking for. Mapping between these types of SITs and primary fields can result in false negatives and decrease performance.

> **Note**
>
> A *loosely defined SIT*, such as a custom SIT that looks for all personal identification numbers, has detection rules that allow for greater variability in the items detected. A *strongly defined SIT*, such as a U.S. Social Security Number, has detection rules that only allow a narrow, well-defined set of items to be detected.

The system will also warn you if the values in the primary field you select occur multiple times in a large number of rows. Repeated primary-field values across many rows can cause large numbers of result sets to be returned and processed, which could cause a time-out. Timeouts can result in missed detections and poor performance.

Choosing the right EDM SIT creation experience for you

You can toggle back and forth between the new and classic experiences, but we recommend using the new experience unless your needs fall into one or more of these four use cases, as described below.

Mapping multiple EDM SITs to the same schema

In EDM, you can create a maximum of 10 schemas. Each time you create an EDM SIT using the new experience, a new schema is created. This results in a 1:1 mapping between EDM schema and EDM SIT. The new experience doesn't support mapping multiple SITs to the same schema.

Creating or managing more than 10 EDM SITs

Because the new experience doesn't support mapping multiple SITs to the same schema, you're limited to creating and managing 10 EDM SITs. In the classic experience, you can map multiple EDM SITs to the same schema and so have more than 10 EDM SITs. Using the new flow, you receive an error if you try to create an eleventh EDM schema and you won't be able to view more than 10 EDM SITs.

Specifying the name of your EDM schema

If you need to specify a name for your EDM SIT schemas, you have to use the classic experience to create and manage them. Because the new experience automatically creates the schema, you don't get the opportunity to give your schema a custom name. The autogenerated name is a concatenation of the EDM SIT name and the word *schema*. For example, if the EDM SIT name is *PatientNumber*, the schema name would be *PatientNumberschema*.

Editing EDM schemas created in the classic experience

All schemas that are created using the classic experience or uploaded as an XML file using PowerShell aren't viewable or manageable in the new experience.

Once you choose your method of creating EDM SITs, select the link for your chosen experience in the Next steps section: new experience or classic experience.

Next steps

Create exact data match sensitive information type in the New Experience workflow

Creating and making an exact data match (EDM) based sensitive information type (SIT) available is a multi-phase process. EDM-based sensitive information types can be used in Microsoft Purview data loss prevention policies, eDiscovery, and certain content governance tasks. This article outlines the workflow and links to the procedures for each of the phases

Applies to these EDM scenarios

This article covers the new experience. If you want to create an EDM SIT using the classic experience, see Create EDM SIT classic experience.

Before you begin

Make sure you review:

- Learn about EDM based SITs
- Get started with exact data match based sensitive information types (Overview)

Overview of the EDM workflow (New experience)

The following table summarizes the phases of the EDM workflow and the requirements for each phase.

Expand table

Phase	Requirements
Phase 1: Export source data for exact data match based sensitive information type	*Read* access to the sensitive data
Phase 2:Create the sample file	Knowledge of the data fields (the column headers in your source table) and the format of the data you will be looking for in each column.
Phase 3: Create the EDM SIT	Access to the **Microsoft Purview portal** and permissions to create and edit EDM SITs

Phase	Requirements
Phase 4: Hash and upload the sensitive information source table for exact data match sensitive information types	- Custom security group and user account - To **Hash and upload from one computer**: Local admin access to a computer with direct internet access and to host the EDM Upload Agent - To **Hash and upload from separate computers**: Local admin access to a computer with direct internet access to host the EDM Upload Agent for uploading your data and *Local Admin* access to a secure computer for hosting the EDM Upload Agent and for hashing the sensitive information source table. - *Read* access to the sensitive information source table file.
Phase 5: Test an exact data match sensitive information type	Access to the Microsoft Purview portal.

Export source data for exact data match based sensitive information types

This article explains how to prepare and export your sensitive data table for use with exact data match (EDM) based sensitive information types in Microsoft Purview. You learn how to choose primary and secondary fields, structure your data, and save it in a supported format so you can create an EDM schema.

Products and services this export procedure applies to

- New experience
- Classic experience

The sensitive data table is a text file containing rows of values against which you compare the content in your documents to identify sensitive data. These values might be personally identifiable information, product records, or other sensitive data in text form that you want to detect in your content and protect.

Once you export the data in your table (in one of the supported formats), you can create an EDM schema.

Define your EDM sensitive information type

When you define your EDM sensitive type, one of the most critical decisions is to define which fields are your primary fields. Primary fields need to follow a detectable pattern and be defined as searchable fields (columns) in your EDM schema. Secondary fields don't need to follow any pattern since they'll be compared against all the text surrounding matches to the primary fields.

Use these rules to help you decide which columns you should use as primary fields:

- If you must detect sensitive data based on the presence of a single value matching a field in your sensitive data table, regardless of the presence of any other sensitive data surrounding it, that column must be defined as a primary element for an EDM SIT.
- If multiple combinations of different fields in your sensitive data table must be detected in content, identify the columns that are common to most such combinations and designate them as primary elements. Designate combinations of the other fields as secondary elements.

- If a column you want to use as a primary element doesn't follow a detectable pattern, like `any text string` or follows detectable patterns that would be present somewhere in a large percentage of documents or emails, choose other, better structured, columns as primary elements.

For example, if you have the columns `full name`, `date of birth`, `account number`, and `Social Security Number`, even if the first and last names are the columns that are common to the different combinations of data you want to detect, such strings don't follow patterns that are easily identifiable and might be difficult to define as a sensitive information type. There are a number of reasons for this:

- some names might not start with an uppercase character
- some might be formed by two, three,or more words/strings
- some might contain numbers or other non-alphabetical characters. Dates of birth can be identified more easily but, since every email and most documents will contain at least one date, a `DateOfBirth` field is also not a good candidate. Instead, use fields such as Social Security numbers and account numbers, which are good candidates for primary fields.

Sample file templates

To make selecting your primary fields easier, we've put together some sample file templates for:

- U.S. Healthcare data
- U.S. Financial data
- U.S. Insurance data

These are comma separated value (.csv) files that have the most commonly used values across those industry verticals as column headers, along with Microsoft-generated synthetic values in the rows. Use the column headers to help you decide on your primary fields. Best practice is to export only the source data that is required. The column headers suggest the most relevant fields.

To learn how to use the sample file templates, see How to use the sample file templates.

Save sensitive data in *.csv*, *.tsv*, or *pipe-separated* format

Save your sensitive data as a supported text format by following these steps:

1. Identify the sensitive information you want to use. Export the data to an app such as Microsoft Excel and save the file as a text file. The file can be saved in any of the following formats: *.csv* (comma-separated values), *.tsv* (tab-separated values), or (|)(pipe-separated) format. The .tsv format is recommended in cases where your data values might include commas, such as street addresses. The data file can include a maximum of:

    - Up to 100 million rows of sensitive data
    - Up to 32 columns (fields) per data source
    - Up to 10 columns (fields) marked as searchable

2. Structure the sensitive data in the .csv or .tsv file such that the first row includes the names of the fields used for EDM-based classification. In your file you might have field names such as "ssn", "birthdate", "firstname", "lastname". The column header names can't include spaces or underscores. For example, a sample .csv file named *PatientRecords.csv*, and its columns include *PatientID*, *MRN*, *LastName*, *FirstName*, *SSN*, and more.

3. Pay attention to the format of the sensitive data fields; in particular, fields that might contain commas in their content. For example, a street address that contains the value "Seattle, WA" would be parsed as two separate fields if the .csv format is selected. To avoid this, use the .tsv format or surrounded the comma containing values by double quotes in the sensitive data table. If comma containing values also contain spaces, you need to create a custom SIT that matches the corresponding format. For example, a SIT that detects multi-word string with commas and spaces in it.

Next steps

Choose the next article based on the experience you're using:

Create an EDM SIT sample file (New experience)

Creating and making an exact data match (EDM) based sensitive information type (SIT) available is a multi-phase process. EDM-based SITs can be used in Microsoft Purview data loss prevention policies, eDiscovery, and certain content governance tasks.

Applies to: EDM SIT new experience

- New experience

If you want to create an EDM SIT using the classic experience see, Create EDM SIT classic experience.

Before you begin

Before you create the sample file, complete the following prerequisite:

- Make sure you've complete the steps in Export source data for exact data match based sensitive information type.

Formatting the sample file

The system will extract the column names from the sample file to create the schema, and will recommend base SITs to map the sample field data to. The sample file must be formatted identically to your source sensitive information table file and should contain synthetic values that are representative of your actual data. The file can be saved in **.csv** (comma-separated values), **.tsv** (tab-separated values), or pipe-separated (|) format, but should be the same as your actual source sensitive information table file. The **.tsv** format is recommended in cases where your data values include commas, such as street addresses.

- Use about 10-20 rows of data to ensure that the system has enough samples to work with.
- Field values that contain commas must be enclosed in quotes ".
- The first row must be the header row and contain column names.
- The file must contain at least one row of data.
- Each row of data must contain the correct number of fields, corresponding to the headers.
- The sample file can contain up to 32 columns.

- The sample file can't exceed 2.5 MB in size.
- Column (field) names must start with a letter, be at least three characters long, and consist of only alphanumeric characters (A-Z, a-z, 0-9) and can't include spaces, underscores, or other special characters.

For example, if your actual data uses tab delimited (**.tsv**) format and looks like this:

```
FirstName       LastName        PatientNumber   CreditCardNumber
Nathan  Rigby   111-22-3333     4111111111111111
Remy    Morris  444-55-6666     5111111111111111
Markus  Long    77-88-9999      6111111111111111
...
```

Then your sample file must have the same column headers, but use synthetic values for the rows, like this

Expand table

FirstName	LastName	PatientNumber	CreditCardNumber
Eric	Solomon	987-65-4321	9000000000000000
Lisa	Taylor	123-45-6789	500000000000000
Andre	Lawson	234-56-7890	200000000000000

How to use the sample file templates

If you're in the U.S. Healthcare, U.S. Financial Services, or U.S. Insurance industry verticals, you can start with the following sample file templates to speed up the sample file creation process. These files contain the most commonly used column headers across the respective industries as a well as synthetic values in the fields.

- U.S. Healthcare data
- U.S. Financial data
- U.S. Insurance data

To use these templates:

1. Download the sample file template for your industry.
2. Compare the column headers in the template to your actual source data and pick the ones you want to use as primary fields in your customized sample file.
3. Compare the formatting of your actual source data with the formatting of the synthetic values. Change the formatting of the synthetic values to match the formatting of your

source data values.

4. Save your customized sample file to use when you create EDM SIT schema and rule package.

> **Tip**
>
> When working in the new experience, you have the option to upload a sample file or enter the sample file values manually. We recommend creating the sample file.

Next steps

- **For new experience**: Create EDM SIT schema and rule package

ⓘ**Note:** The author created this article with assistance from AI. Learn more

---

Last updated on 06/26/2026

Create an EDM SIT schema and rule package (New experience)

You can create both the exact data match (EDM) schema and EDM sensitive information type (SIT) in the new experience by using a single workflow in the Microsoft Purview Portal.

Supported experiences

- New experience

If you want to create an EDM SIT using the classic experience, see Create an EDM SIT (Classic experience). If you need help deciding whether to use the new experience or the classic experience, see Choosing the right EDM SIT creation experience for you.

Before you begin

Make sure to complete the steps in the following articles before beginning the procedures described in this article.

1. Export source data for exact data match based sensitive information types
2. Create the EDM SIT sample file (New experience)

If you aren't familiar with EDM-based SITs or their implementation, ***it's essential*** to familiarize yourself with the concepts in the following articles:

- Learn about sensitive information types
- Learn about exact data match based sensitive information types
- Learn about multi-token matching
- Get started with exact data match based sensitive information types
- Create an exact data match SIT (New experience)
- Sensitive information type entity definitions

Permissions

To create, test, and deploy a custom sensitive information type (which an EDM SIT is) in the Microsoft Purview portal, use an account that is in *one* of these roles:

- Compliance administrator

- Global administrator

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

For more information about roles and permissions, see About admin roles in Office 365.

Important considerations

Following are several important considerations you should take into account when creating your EDM schema and EDM-based SITs.

- **Before selecting your primary elements,** review the built-in SITs to get an idea of which ones best meet your needs.
- **For each EDM SIT, you must select at least one primary element** and no more than 10 primary elements. If you have a multi-token corroborative data field, choose one of the following options:
    1. Select **Multi-token matching**.
    2. Map the elements in your multi-token fields to a SIT that can detect that content. (The more fields with unique values that you map, the more accurate your EDM SIT will be. Mapping multiple fields also helps improve performance, reduce the processing load, and avoid system timeouts.)
- When selecting the primary elements for your SIT, **select fields that ensure each row in your data table is unique**. For example, **don't** use fields like `FirstName` or `DateOfBirth`. Why? Because first names and dates of birth are likely to be duplicated throughout your sensitive data table. Instead, use fields with unique values, such as `SocialSecurityNumber` or `BankAccountNumber`.
- **Recommendation:** Build your EDM schema from a sample data file. If you build your EDM schema from a sample data file, make sure that the file adheres to the following requirements:
    - Data must be organized as a table, with columns and rows. Use your field names for the column headers. (The rows in your table correspond with your individual data items.)
    - Field names can include only alphanumeric characters.

    - Field names must start with a letter and must consist of at least three alphanumeric characters.
    - If these naming requirements are not met, errors may occur when uploading your sample data file.

- If you use a sample file of sensitive information to configure your EDM SIT, the system suggests the existing SIT for each field that best detects the uploaded data, if such a SIT is available. Microsoft Purview defaults to single-token matching for detecting sensitive content. So, if no existing SITs are able to detect the data for a field in your EDM schema, it applies the single-token matching mode. ***It is critical*** that you make sure that the SIT suggested for each element will detect the exact string you want to monitor:

    1. Make sure that the suggested SIT **doesn't contain any surrounding characters that differ from the content you want to detect**.
    2. Make sure that the suggested SIT **doesn't exclude any valid portion of the string as stored in your sensitive information table**.
    3. Make sure that the SIT you use **closely matches the *format*** of the data you want to detect. For example, look for something like `Nine digits with optional hyphens or spaces` rather than simply `digits`, or check for `A combination of 32 characters consisting of letters and digits` rather than simply `text strings`.

       Using SITs that closely match the format of the data you're trying to detect is another way to improve the accuracy of your results and shorten the time it takes for the matching to complete.

> ⓘ **Note**
>
> All of your data is saved as you navigate forward (**Next**) and backward (**Back**) through the tool while making your selections. Backward navigation only supports moving from top-level page to top-level page and from sub-page to sub-page. You can't navigate backward from a top-level page to the preceding sub-page or from a sub-page to a preceding top-level page.

Create your EDM schema and SIT

The following procedure provides step-by step guidance for creating your EDM schema and SITs using the new experience. For a conceptual overview and diagram of the EDM schema and SIT creation workflow, see Overview of the EDM workflow (New experience).

Create the EDM schema and sensitive information type

Follow these steps to create an EDM classifier in the Microsoft Purview portal:

1. Open **Data classification** > **EDM classifiers**.
2. Make sure the **New EDM experience** toggle is set to **On**.
3. Choose + **Create EDM classifier**.
4. Name the SIT and add a description. The system uses this name, appended with the word *schema*, for the associated schema it generates.
5. Choose **Next**.
6. Select the method you want to use for your schema: either **Upload a file containing sample data**, or **Manually define your data structure**. (Best practice is to upload a sample data file. The rest of this procedure assumes that you upload a sample data file.)

   In either case, you need the information discussed in Create an EDM SIT sample file (New experience) for your sample file.
7. Choose **Next**.
8. Select your sample file and then select **Upload file**. Choose **Next**.
   (If errors display during the upload, address them and then try again.)
9. On the **Select primary elements** page:
   a. In the **Primary element** column, select your primary element. Each primary element must be mapped to a SIT. Best practice is to select fields that show **Full match** under the **Match Validation** column.
   b. In the **Match mode** column for each field, designate which of the following matching options to apply:

      - **Option 1:** Do nothing to accept the system-suggested SIT.
      - **Option 2:** Expand the dropdown menu. Under **Sensitive Info type (SIT)**, choose the pencil (**Edit**) icon and then select another existing SIT.
      - **Option 3:** Under **Match mode** select **Single token**.
      - **Option 4:** Under **Match mode** select **Multi-token**.
10. Choose **Next**.

11. **Configure settings for data in selected columns**.

    - The toggle **Use the same settings for all columns** is set to **On** by default. If you want to use separate settings for each data field, set the toggle to **Off**.
    - The **Data in columns are case-insensitive** option is selected by default. To enforce **case-sensitive** detection, uncheck this box.
    - If needed, select the option to **Ignore delimiters and punctuation for data in all columns** You can then either select the delimiters and punctuation marks you want to ignore from a list or you can enter custom delimiters and punctuation marks to ignore.

    > ⓘ **Important**
    >
    > If you select the **Ignore Delimiters** option for the primary element column in your schema, make sure that the SIT you map it to is designed to match data both with and without the selected delimiters.

12. **Configure detection rules for primary elements**.

    - Specify the **proximity limit** in terms of the number of characters within which the supporting element should be found in proximity of the primary element. By default, it's set at 300.
    - Select the **proximity detection mode**.
        - **Wide Mode:** Matches the primary element against supporting elements from all primary matches within the defined proximity range. This mode provides a broader context, which can increase the likelihood of detecting relevant associations.
        - **Narrow Mode:** Matches the primary element only against its own supporting element within the proximity range. This mode focuses on tighter, more specific matches, reducing the chance of false positives.
    - Select the **unique counting mode**.
        - **Primary Match-level Counting:** Counts each matching combination of primary and supporting elements separately—even within the same row. Choose this if you want a detailed view of all sensitive matches.
        - **Row-level Counting:** Counts each row only once, even if multiple elements match in it. Use this when you care about how many unique records (rows) are sensitive, not how many elements matched.
    - Define the **detection rules for high, medium, and low confidence levels**. The high confidence rule should include more supporting elements within close proximity of the

primary element, whereas a low confidence rule would contain little to no supporting elements in close proximity

13. Choose **Submit**.

Once you're finished, EDM automatically generates one detection rule for each of the primary elements you identified. EDM also creates a *high-confidence* rule and a *medium-confidence* rule. High-confidence rules have more matching requirements than medium-confidence rules, which, in turn, have more requirements than low-confidence rules. (Low-confidence rules must be created manually.) You can review and edit these rules on the **Configure detection rules for primary elements** page.

> **Tip**
>
> Those elements that are not selected as primary can still be used as corroborative (supporting) evidence. The more supporting elements found that are in a defined proximity to primary elements, the higher the confidence that the match is a true positive.

Recommendations

Keep the following recommendations in mind when creating, downloading, and testing your EDM schema and SIT.

- Wait at least one hour after creating or editing a schema before downloading and using it for the EDM data upload. This helps ensure that the schema has synced with the system. If a schema is downloaded too soon, an error message might display when attempting to download the schema via the command line.

- Do not use the EDM Upload Agent to download, manually edit, and then re-upload a schema. Doing so results in an error because using the EDM Upload Agent to download a schema adds tags to the schema that don't pass schema creation checks.

- To help ensure that all corroborative evidence is detected, take one of the following actions:
  - Trim multi-token corroborative evidence fields to the maximum number of tokens supported by the multi-token feature (currently five tokens).
  - Map the multi-token field to a SIT that can fully detect the multi-token data. - After

creating or editing your EDM SIT, test it using the following PowerShell cmdlet and then wait 24 hours before testing it in a data loss prevention (DLP) policy solution.

PowerShell

```
Test-DataClassification  -ClassificationNames “[Your EDM sensitive info type]” -
TexttoClassify “[your own text to scan for matches]”
```

Next steps

After you create your EDM schema and rule package, hash and upload your sensitive data:

- Hash and upload the sensitive information source table for EDM SITs

Use multi-token matching for corroborative evidence in EDM SITs

Article • 12/11/2023

To use multi-token matching to identify corroborative evidence for your EDM sensitive information types, you must explicitly opt in for multi-token support for each multi-token corroborative evidence field. You can do this either through the new EDM UI experience or through the schema XML update process. Following are the steps for each method.

Opt-in through the new EDM UI experience

The new EDM UI experience guides you through the process of creating or editing an EDM schema and uploading your data. You can access it from the Microsoft Purview Portal, under **Data classification** > **Sensitive info types** > **Exact data match**.

When you upload a sample file, EDM automatically maps the SIT that can best detect the sample data in each field. If none of the SITs in your environment can detect the sample data in a field, EDM defaults to single-token matching. Single-token matching means that EDM only compares the hashes of individual strings identified in DLP policy fields with each individual string in the content. The field selected as the primary element for your schema must be mapped to a SIT. In contrast, corroborative evidence fields can either be mapped to a SIT or can be configured for either single-token or multi-token matching.

However, if the sample data in a policy field contains multi-token values and if EDM is operating in single-token mode, a warning displays stating that using single-token matching might result in missed detections. In this case, you can switch to multi-token matching. When you use multi-token matching, EDM compares the hashes of consecutive tokens (strings) in the policy fields against consecutive tokens in the content, up to a maximum number of tokens supported by this feature. The current maximum is five (5) tokens. For example, if your field contains the value "Jane Doe", EDM compares the hashes of "Jane", "Doe", and "Jane Doe" with the content. It then produces a match if the hashes of any of these combinations are identical to the hashed value in your data source.

> **Tip**

To ensure multi-token match detection, trim multi-token corroborative evidence fields to the maximum number of tokens supported. Alternatively, map the multi-token fields to a SIT that can fully detect the multi-token data.

In contrast, if you select multi-token matching for a field that only contains single-token data, a warning displays stating that using multi-token matching might result in higher latency. Higher latency in matching occurs because multi-token matching is inefficient. Additionally, multi-token matching isn't required if the actual EDM data that is later hashed and uploaded is expected to be a single-token field. In general, if any of the fields you use for corroborative evidence can be mapped to a SIT, do that instead of relying on single-token or multi-token matching.

Make sure that your sample data is fully representative of your production data. If your sample file doesn't include multi-token values, but your production data does, you might not get a warning for multi-token matches. For instance, this can occur in cases where your sample data includes only single-token values for a `FirstName` field, but your production data includes multi-token values for the same field.

Opt-in through the EDM schema XML update process

You can also create or update an XML schema to implement multi-token matching for corroborative evidence using PowerShell.

Here's a sample XML schema with multi-token settings for protecting patient records:

XML

```
<EdmSchema xmlns="http://schemas.microsoft.com/office/2018/edm">
 <DataStore name="DemoMTCorroborativeEvidenceSchema"
            description="Test" version="1">
  <Field name="Name"
         searchable="false"
      caseInsensitive="true"
      ignoredDelimiters=""
      isMultiToken="false"/>
  <Field name="SSN"
         searchable="true"
      caseInsensitive="true"
      ignoredDelimiters=""
      isMultiToken="false"/>
  <Field name="PatientID"
      searchable="false"
      caseInsensitive="true"
      ignoredDelimiters=""
```

```
        isMultiToken="false"/>
    <Field name="MedicalCondition"
        searchable="false"
        caseInsensitive="true"
        ignoredDelimiters=""
        isMultiToken="true"/>
    <Field name="Address"
           searchable="false"
        caseInsensitive="true"
        ignoredDelimiters=""
        isMultiToken="true"/>[Learn about exact data match based sensitive
information types](sit-learn-about-exact-data-match-based-sits.md#learn-
about-exact-data-match-based-sensitive-information-types)
  </DataStore>
</EdmSchema>
```

Each corroborative evidence field can be configured for multi-token support through the new XML parameter `isMultiToken`. This parameter can be set to `true` or `false`. Any field with `isMultiToken` set to `true` is treated as a multi-token field and is compared with consecutive strings in the content, up to the maximum number of tokens supported by this feature. EDM treats fields with `isMultiToken` set to `false`, or that don't have this parameter, as single-token fields. These fields are only compared with individual strings in the content.

For more information about what an EDM schema is, see the Schema section of the Learn about exact data match based sensitive information types article.

For details about creating an EDM schema, see Create your EDM schema and SIT.

Test an exact data match sensitive information type

This article explains how to test an exact data match (EDM) sensitive information type (SIT) to verify that it correctly detects the sensitive data you want to protect. It covers testing methods available in the Microsoft Purview portal and PowerShell, as well as troubleshooting tips for common detection issues.

Products and services this EDM testing article applies to

This article covers testing for both EDM experience versions:

For instructions on creating an EDM SIT before testing, see the workflow for your experience:

- Create an EDM SIT using the new experience
- Create an EDM SIT using the classic experience

Overview of EDM SIT testing

This section explains how to verify that your exact data match (EDM) sensitive information type (SIT) correctly detects the information you want to protect. After your EDM SIT has been created, and an hour after verifying that your sensitive information table has finished uploading and indexing, you can test detection by using the **Test** function in the **Sensitive information types** section in the Microsoft Purview Portal.

> **Note**
>
> Changes in an existing EDM SIT can take some time to propagate across the system. If you're making changes to an EDM SIT in order to troubleshoot detection issues, make sure to wait at least one hour after making those changes before using the **Test** function to validate their impact.

Regardless of the method you use for testing, the test results include matches for both the specific EDM SIT and for the primary elements that are configured for that EDM SIT.

Methods for testing your EDM SIT

There are two methods that you can use to test your EDM SIT.

Expand table

Method	Available in New EDM experience	Available in New and Classic EDM experience
Sensitive information type (SIT) method	Yes	Yes
EDM classifiers method	Yes	No

> **Note**
>
> If you're using the Classic EDM experience, you must use the SIT method.

Testing an EDM SIT with the Sensitive Information Types method

To test an EDM SIT with the **Sensitive Information Types** method, take the following steps.

1. Sign in to the Microsoft Purview portal > **Information Protection** > **Classifiers** > **Sensitive info types**.
2. Select your EDM SIT from the list and then select the **Test** icon.
3. In the flyout pane, upload a file that contains data you want to detect. For example, create a file that contains a subset of the rows in your sensitive information table. If you used the *configurable match* feature in your schema to define ignored delimiters, make sure the sample file includes examples with and without those delimiters.
4. Choose **Test**.
5. After the file has been uploaded and scanned, check for matches to your EDM SIT.
6. If the **Test** function in the SIT detects a match, verify that the SIT isn't trimming it or extracting the matched item incorrectly. Common issues include SITs that:
    - Extract only a substring of the full string that should be detected
    - Pick up only the first word in a multi-word string

- Include extra symbols or characters in the extraction

For details about the regular expressions used in SIT pattern definitions and extraction logic, see the Regular Expression Language - Quick Reference.

Test your EDM SIT with the EDM Classifier method

To test an EDM SIT with the **EDM Classifier** method, follow these steps.

1. Sign in to the Microsoft Purview portal > **Information Protection** > **Classifiers** > **EDM classifiers**.
2. Make sure that the **New EDM experience** toggle is set to **On**.
3. Select your EDM SIT from the list and then select the **Test** icon.
4. Upload a file that contains data you want to detect. For example, create a file that contains a subset of the rows in your sensitive information table. If you used the *configurable* match feature in your schema to define ignored delimiters, make sure your sample file includes examples with and without those delimiters.
5. After the file has been uploaded and scanned, check for matches to your EDM SIT.
6. If the **Test** function in the SIT detects a match, verify that the SIT isn't trimming it or extracting the matched item incorrectly. Common issues include SITs that:
    - Extract only a substring of the full string that should be detected
    - Pick up only the first word in a multi-word string
    - Include extra symbols or characters in the extraction

Test your EDM SIT using PowerShell

Use the `Test-DataClassification` cmdlet to test your EDM sensitive information type against sample text and verify whether the classifier detects expected matches. For the `-ClassificationNames` parameter, supply the display name of the EDM sensitive information type you want to test. For `-TexttoClassify`, provide the sample text you want to scan for matches.

PowerShell

```
Test-DataClassification  -ClassificationNames “[Your EDM sensitive info type]” -TexttoClassify “[your own text to scan for matches]”
```

Regardless of the method you use for testing, the test results will include matches for both the specific EDM SIT and for the primary elements that are configured for that EDM SIT.

> **Note**
>
> An uploaded-file or text test doesn't refresh classification for existing SharePoint and OneDrive files. Changing an EDM SIT or its primary SIT doesn't by itself refresh classification for unchanged historical files. To update classification for those files, use **on-demand classification**. Review the scan scope, EDM scan-cost considerations, and active-policy effects before starting a scan.

Test your EDM SIT with information protection policies

You can see where your EDM SIT is being used, and how accurate it is in production, by using it in policies:

1. Create an auto-labeling policy and run it in **Simulation overview**.
2. Add some content that triggers the EDM SIT, along with content that won't trigger the EDM SIT, to a location that your policy is monitoring.
3. Open the **Items to review** tab to check the matches.
4. Based on the simulation results, tune your policy conditions and EDM SIT settings as appropriate to improve detection accuracy.

Once you're satisfied with the results of your testing and tuning, your EDM-based custom SIT is ready for use in information protection policies, for instance:

- DLP policies
- Auto-labeling policies
- Microsoft Defender for Cloud Apps

Troubleshooting tips

If your EDM SIT doesn't detect any matches in your data, the following tips might help you diagnose the problem.

Expand table

Issue	Troubleshooting tip
No matches found	Confirm that your sensitive data was uploaded correctly using the commands explained in Hash and upload the sensitive information source table for exact data match sensitive information types.
No matches found	Test the SIT you used when you configured the primary element in each of your patterns. This test verifies whether the SIT can match the examples in the item. Using an incorrectly defined SIT as the classification element of an EDM SIT is the most common cause for detection failures in EDM.
The SIT you selected for a primary element in the EDM type doesn't find a match in the item or finds fewer matches than you expected	Confirm that the SIT supports the separators and delimiters that occur in the content. Be sure to include the ignored delimiters defined in your schema.
The SIT associated with your primary element finds matches in your content, but the EDM SIT doesn't.	• Check whether your REGEX statements are catching whitespace delimiters at the start or end of an item you want to detect. For instance, look for statements that include the `\s` delimiter. If whitespace delimiters are included, the whitespace won't match the hashed value in the data table. Instead, use a word delimiter, such as `\b`. • Check your REGEX statements to ensure that they capture the entire string you want to detect, not just a substring. For example, consider this pattern for email addresses: `\b[a-zA-Z]{2,30}@[a-zA-Z]{2,20}.[a-zA-Z]{2,3}\b`. This pattern will correctly match *user@contoso.com*, but will only capture *user@contoso.co.jp* in an incomplete form.
An EDM SIT with primary elements, but no defined secondary elements, detects items but doesn't detect matches (or detects fewer matches than expected) when both primary and secondary elements are required.	If values in a column used for secondary evidence aren't composed of a single word or of strings that don't contain spaces, commas, or other word separators, there are two ways to test: 1. Select the multi-token matching option. 2. Associate the values with a SIT that uses either a REGEX designed to detect multi-word strings that follow the desired pattern (for example, a fixed number of consecutive words that start with an uppercase character), or a keyword dictionary that lists all of the unique values in that column. For example, if there's an additional evidence column for a person's city or residence, you can create a list with all the unique city names from the table and then use it to create a dictionary-based sensitive information type. Use this SIT as the classification element for the corresponding column in your EDM SIT by exporting and editing the EDM SIT definition in XML. For more information, see Create a rule package manually.

Issue	Troubleshooting tip
SIT test function doesn't detect any matches at all.	Verify that the SIT you selected includes requirements for additional keywords or other validations. For built-in SITs, see Sensitive information type entity definitions to determine what the minimum requirements are for matching each type.
The **Test** functionality works but your SharePoint or OneDrive items aren't being detected in DLP or auto-labeling rules	Check the policy scope and conditions, and whether classification for the existing files reflects the SIT definitions you intend to use. A direct test doesn't establish classification coverage for stored files. For auto-labeling, see Auto-labeling classification and simulation concepts; restarting simulation doesn't itself refresh classification. Use on-demand classification when classification needs updating, after reviewing scope, costs, and active-policy effects.
DLP or auto-labeling rules that require multiple matches don't trigger	Make sure that the proximity requirements for both your EDM SIT and the base SITs are met. For example, if the maximum distance between the primary element and supporting keywords is 300 characters, but the keywords are only present in the first row of a long table, only the first few rows of matching values are likely to meet the proximity requirements. Modify your SIT definitions to support more relaxed proximity rules or use the **Anywhere in the document** option for the additional evidence conditions.
Detection of an EDM SIT is inconsistent or erratic	Make sure that the SIT you used as the base for the primary element in your EDM SIT isn't detecting unnecessary content. Using a SIT that matches too much unrelated content, such as *any* word, *any* number, or *all* email addresses, can cause the service to ignore relevant matches. Check the number of content pieces that match the sensitive type you used for your primary elements in content explorer. To estimate whether the SIT is matching too much content: 1. Divide the number of content items in the Microsoft Purview Content Explorer by the number of days since the sensitive type was created. 2. If the number of matches per day is in the range of hundreds of thousands or more, it's possible that the primary SIT is too broad.

For recommendations and best practices on selecting the right sensitive information type for an EDM SIT, see Learn about exact data match based sensitive information types.

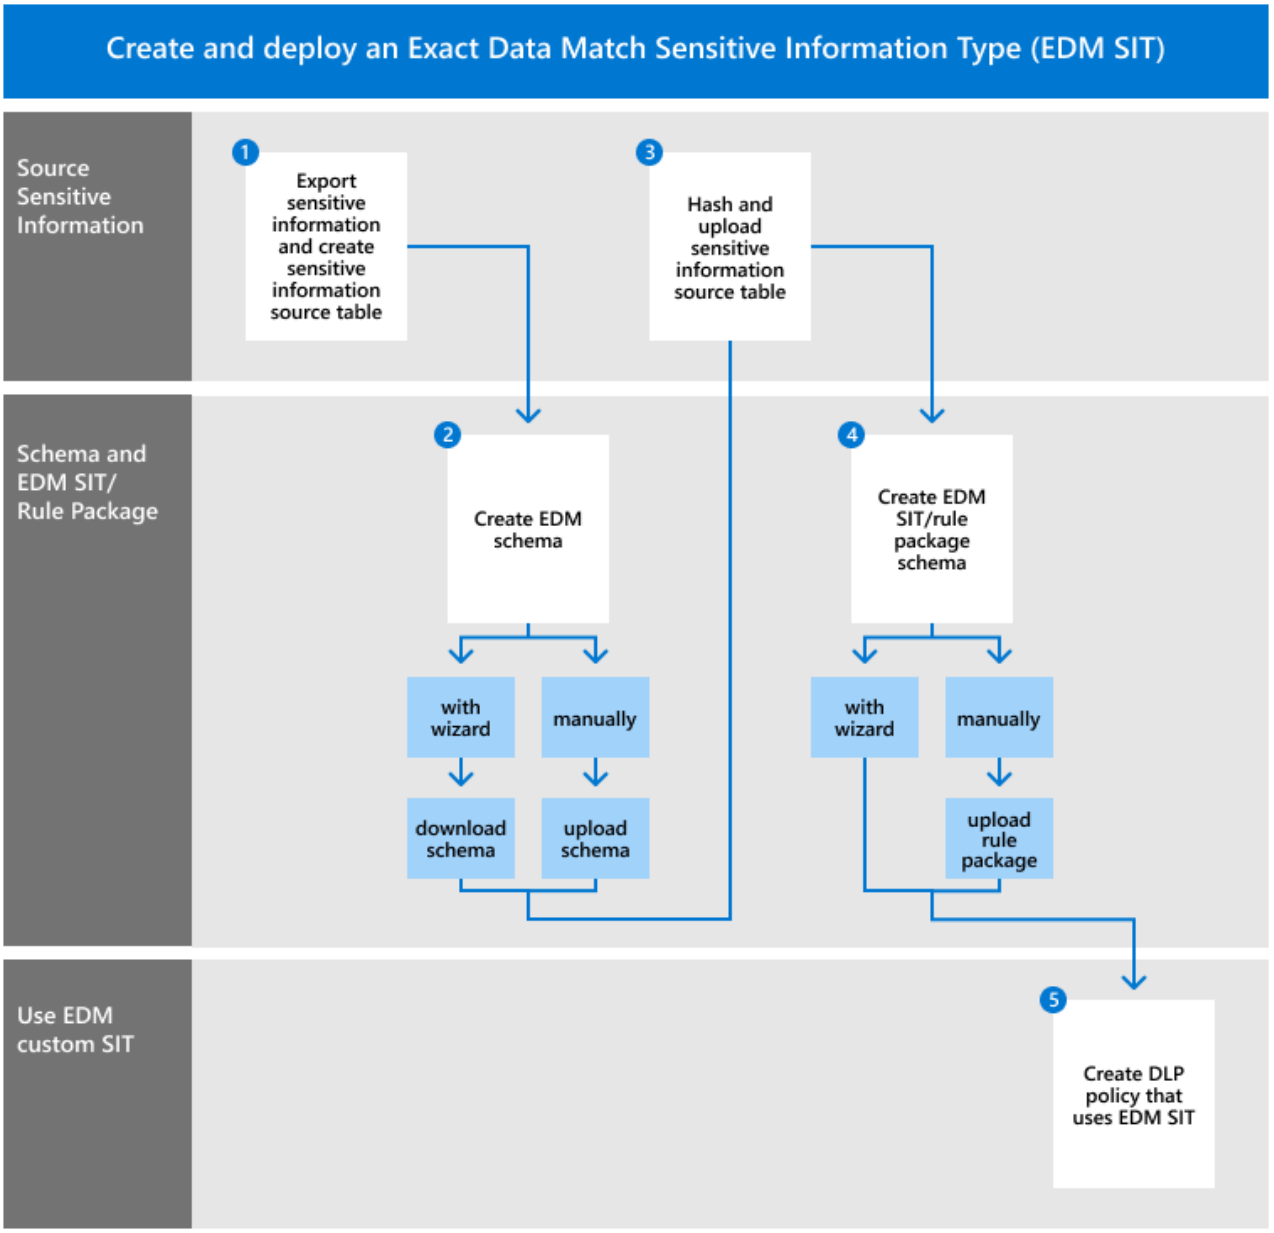
Create an exact data match sensitive information type (Classic experience workflow)

09/26/2025

Creating and making a sensitive information type (SIT) based on exact data matching criteria (an EDM SIT) is a multi-phase process. These SITs can be used in Microsoft Purview data loss prevention policies, auto-labeling, eDiscovery, and certain content governance tasks. This article outlines the workflow and links to the procedures for each phase using the classic experience.

Applies to

- Classic experience



If you want to create an EDM SIT using the new experience see, Create an EDM SIT (New experience).

Before you begin

Make sure you review:

- Learn about EDM based SITs
- Get started with exact data match based sensitive information types overview

Overview of the EDM workflow (Classic experience)

Expand table

Phase	What's needed
Phase 1: Export source data for exact data match based sensitive information types	- Read access to the sensitive data
Phase 2: Create the schema for exact data match based sensitive information types	- Access to the sensitive information type wizard in the Microsoft Purviews portal - access to the Microsoft 365 admin center via Security & Compliance PowerShell
Phase 3: Hash and upload the sensitive information source table for exact data match sensitive information types	- Custom security group and user account - **Hash and upload from one computer**: local admin access to a computer with direct internet access and to host the EDM Upload Agent

Phase	What's needed
	- **Hash and upload from separate computers**: local admin access to a computer with direct internet access and host the EDM Upload Agent for the upload and local admin access to a secure computer to host the EDM Upload Agent to hash the sensitive information source table - Read access to the sensitive information source table file the schema file
Phase 4: Create exact data match sensitive information type/rule package	- Access to the Microsoft Purview portal
Test an exact data match sensitive information type	- Access to the Microsoft Purview portal

Export source data for exact data match based sensitive information types

This article explains how to prepare and export your sensitive data table for use with exact data match (EDM) based sensitive information types in Microsoft Purview. You learn how to choose primary and secondary fields, structure your data, and save it in a supported format so you can create an EDM schema.

Products and services this export procedure applies to

- New experience
- Classic experience

The sensitive data table is a text file containing rows of values against which you compare the content in your documents to identify sensitive data. These values might be personally identifiable information, product records, or other sensitive data in text form that you want to detect in your content and protect.

Once you export the data in your table (in one of the supported formats), you can create an EDM schema.

Define your EDM sensitive information type

When you define your EDM sensitive type, one of the most critical decisions is to define which fields are your primary fields. Primary fields need to follow a detectable pattern and be defined as searchable fields (columns) in your EDM schema. Secondary fields don't need to follow any pattern since they'll be compared against all the text surrounding matches to the primary fields.

Use these rules to help you decide which columns you should use as primary fields:

- If you must detect sensitive data based on the presence of a single value matching a field in your sensitive data table, regardless of the presence of any other sensitive data surrounding it, that column must be defined as a primary element for an EDM SIT.
- If multiple combinations of different fields in your sensitive data table must be detected in content, identify the columns that are common to most such combinations and designate them as primary elements. Designate combinations of the other fields as secondary elements.

- If a column you want to use as a primary element doesn't follow a detectable pattern, like `any text string` or follows detectable patterns that would be present somewhere in a large percentage of documents or emails, choose other, better structured, columns as primary elements.

For example, if you have the columns `full name`, `date of birth`, `account number`, and `Social Security Number`, even if the first and last names are the columns that are common to the different combinations of data you want to detect, such strings don't follow patterns that are easily identifiable and might be difficult to define as a sensitive information type. There are a number of reasons for this:

- some names might not start with an uppercase character
- some might be formed by two, three,or more words/strings
- some might contain numbers or other non-alphabetical characters. Dates of birth can be identified more easily but, since every email and most documents will contain at least one date, a `DateOfBirth` field is also not a good candidate. Instead, use fields such as Social Security numbers and account numbers, which are good candidates for primary fields.

Sample file templates

To make selecting your primary fields easier, we've put together some sample file templates for:

- U.S. Healthcare data
- U.S. Financial data
- U.S. Insurance data

These are comma separated value (.csv) files that have the most commonly used values across those industry verticals as column headers, along with Microsoft-generated synthetic values in the rows. Use the column headers to help you decide on your primary fields. Best practice is to export only the source data that is required. The column headers suggest the most relevant fields.

To learn how to use the sample file templates, see How to use the sample file templates.

Save sensitive data in *.csv*, *.tsv*, or *pipe-separated* format

Save your sensitive data as a supported text format by following these steps:

1. Identify the sensitive information you want to use. Export the data to an app such as Microsoft Excel and save the file as a text file. The file can be saved in any of the following formats: *.csv* (comma-separated values), *.tsv* (tab-separated values), or (|)(pipe-separated) format. The .tsv format is recommended in cases where your data values might include commas, such as street addresses. The data file can include a maximum of:

    - Up to 100 million rows of sensitive data
    - Up to 32 columns (fields) per data source
    - Up to 10 columns (fields) marked as searchable

2. Structure the sensitive data in the .csv or .tsv file such that the first row includes the names of the fields used for EDM-based classification. In your file you might have field names such as "ssn", "birthdate", "firstname", "lastname". The column header names can't include spaces or underscores. For example, a sample .csv file named *PatientRecords.csv*, and its columns include *PatientID*, *MRN*, *LastName*, *FirstName*, *SSN*, and more.

3. Pay attention to the format of the sensitive data fields; in particular, fields that might contain commas in their content. For example, a street address that contains the value "Seattle, WA" would be parsed as two separate fields if the .csv format is selected. To avoid this, use the .tsv format or surrounded the comma containing values by double quotes in the sensitive data table. If comma containing values also contain spaces, you need to create a custom SIT that matches the corresponding format. For example, a SIT that detects multi-word string with commas and spaces in it.

Next steps

Choose the next article based on the experience you're using:

Create the schema for exact data match based sensitive information types

Applicability for classic EDM schema creation

This procedure applies to the classic exact data match (EDM) sensitive information type (SIT) creation experience.

To simplify schema file creation, you can use the exact data match schema and sensitive information type pattern tool.

If you aren't familiar with EDM-based SITS or their implementation, you should familiarize yourself with:

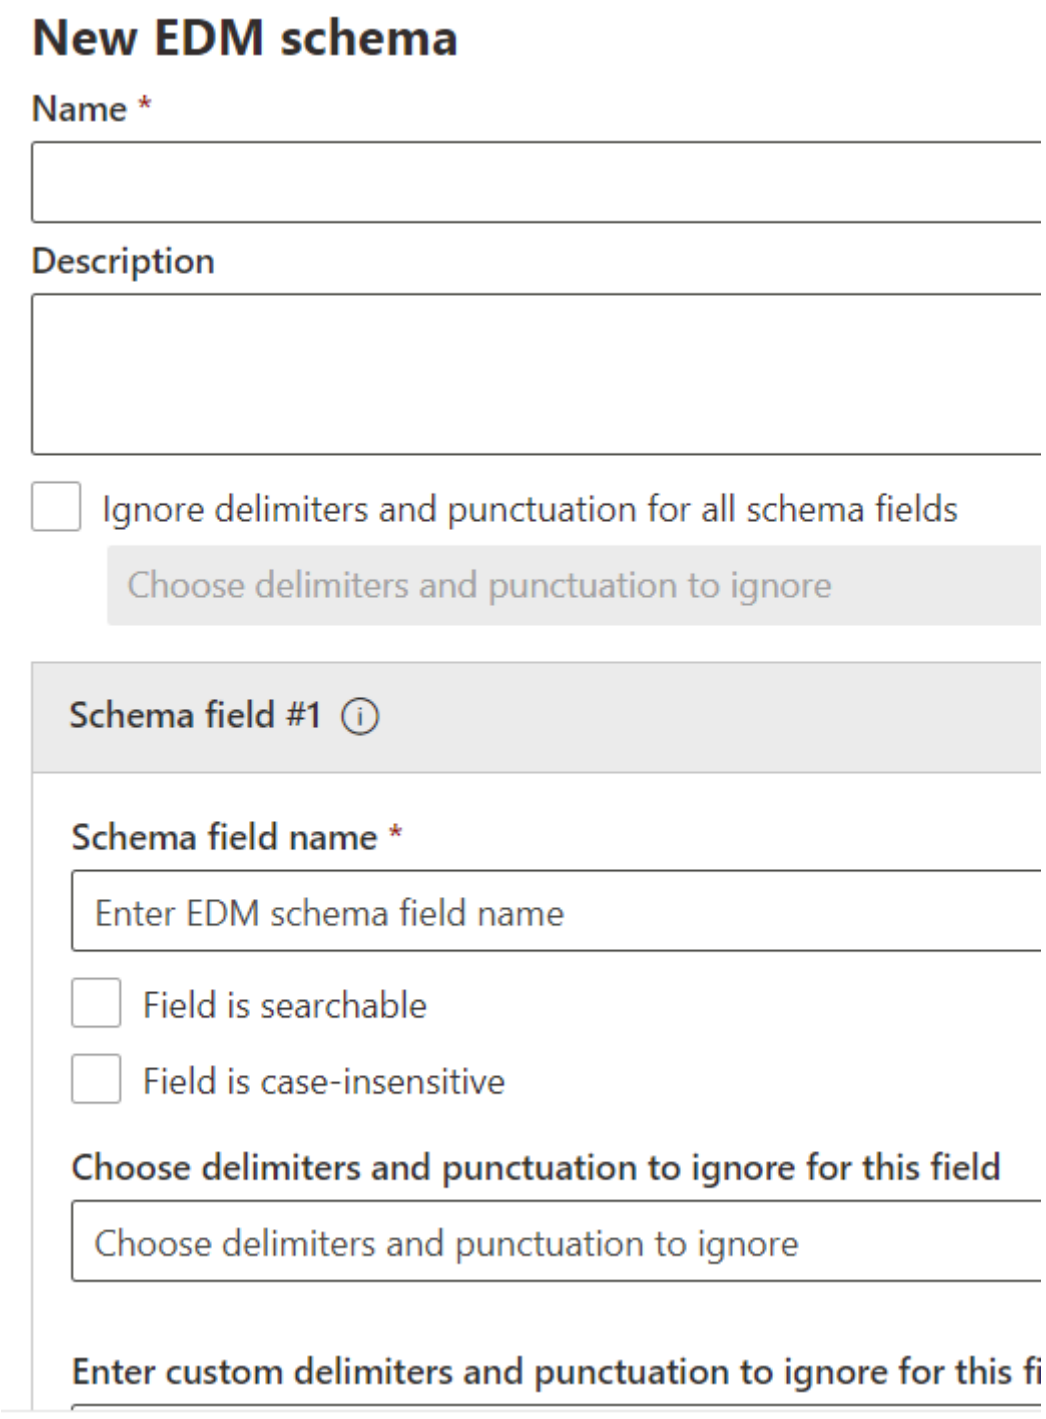
- Learn about sensitive information types
- Learn about exact data match based sensitive information types
- Get started with exact data match based sensitive information types

A single EDM schema can be used in multiple sensitive information types that use the same sensitive data table. You can create up to 10 different EDM schemas in a Microsoft 365 tenant.

Use the Exact Data Match Schema and Sensitive Information Type Tool

You can use the exact data match schema and sensitive information type tool to help simplify the schema file creation process.

Prerequisites



- Perform the steps in Export source data for exact data match based sensitive information type.

Use the exact data match schema and sensitive information type pattern tool

Perform the following steps to create an EDM schema by using the pattern tool:

1. Sign in to the Microsoft Purview portal > **Information Protection** > **Classifiers** > **EDM classifiers** > **EDM schemas** (available when the **New EMD experience** is toggled to **Off**).

2. Choose **Create EDM schema** to open the schema tool configuration flyout.

3. Fill in an appropriate **Name** and **Description**.

4. Choose **Ignore delimiters and punctuation for all schema fields** if you want to apply the **Ignore...** behavior for the entire schema. For more information about configuring EDM to ignore case or delimiters, see Using the caseInsensitive and ignoredDelimiters fields for more details on this feature.

5. Fill in your desired values for your **Schema field #1** and add more fields as needed. Each schema field must be identical to the column headers in your sensitive information source file.

6. If you want, set the per-field values for the following:

   - **Field is searchable**
   - **Field is case-insensitive**
   - **Choose delimiters and punctuation to ignore for this field**
   - **Enter custom delimiters and punctuation for this field**

   > ⓘ **Important**
   >
   > At least one, but no more than ten, of your schema fields must be designated as searchable.

7. Choose **Save**. Your schema is now listed and available for use.

   > ⓘ **Important**
   >
   > If you want to remove a schema that is already associated with an EDM SIT, you must first delete the EDM SIT. Deleting a schema that has a data store associated with it also deletes the data store within 24 hours.

Exporting the EDM schema file in XML format

If you created the EDM schema in the EDM schema tool, you must export the schema file in XML format. You'll need the XML file to complete the Hash and upload the sensitive information source table for exact data match sensitive information types phase.

1. Connect to Security & Compliance PowerShell.

2. To export the EDM schema to a local XML file so you can review or modify its field definitions, use this syntax:

   PowerShell

   ```
   $Schema = Get-DlpEdmSchema -Identity "[your EDM Schema name]"
   Set-Content -Path ".\Schemafile.xml" -Value $Schema.EdmSchemaXML
   ```

3. Save this file for later use.

Create and upload the exact data match schema file manually

As you create your schema file, your column headers (data fields) must adhere to the following naming requirements:

- Must start with a letter and must consist of at least three alphanumeric characters.
- Must include only alphanumeric characters.

Use the following syntax for each column/data field:

XML

```xml
<Field name="FieldName" searchable="true/false" caseInsensitive="true/false"
ignoredDelimiters="delimiter characters" />
```

Using the caseInsensitive and ignoredDelimiters fields

The following XML schema example uses the `caseInsensitive` and `ignoredDelimiters` fields to show how EDM handles case differences and delimiter characters.

When you include the `caseInsensitive` field set to the value of `true` in your schema definition, EDM won't exclude an item based on case differences. For example, EDM sees the values **FOO-1234** and **fOo-1234** as being identical for the `PatientID` field.

When you include the `ignoredDelimiters` field with supported characters, EDM ignores those characters. So EDM sees the values **FOO-1234** and **FOO#1234** as being identical for the `PatientID` field.

When both `caseInsensitive` and `ignoredDelimiters` are used together, EDM sees **FOO-1234** and **fOo#1234** as identical and classifies the item as a patient record sensitive information type.

Both `caseInsensitive` and `ignoredDelimiters` are used on a per-field basis.

> ⓘ **Important**
>
> If you configure *spaces* to be ignored, that configuration will only be effective for primary field columns for which a sensitive information type that can detect multi-word strings is

defined. Otherwise, the comparison will be made against each individual word in the content being analyzed.

The `ignoredDelimiters` flag supports any nonalphanumeric character, here are some examples:

- -
- /
- _
- *
- ^
- #
- [
-]
- {
- }
- \
- ~

The `ignoredDelimiters` flag doesn't support:

- characters 0-9
- A-Z
- a-z
- "
- ,
- Delimiters used as *Token Separators*

ⓘ Important

When defining your EDM sensitive information type, `ignoredDelimiters` will not affect how the Classification sensitive information type associated with the primary element in an EDM pattern identifies content in an item. So, if you configure `ignoredDelimiters` for a searchable field, you have to make sure the sensitive information type used for a primary element based on that field will pick strings both with and without those characters present.

The number of columns in your sensitive information source table and the number of fields in your schema must match, order doesn't matter.

The characters that are used as *token separators* behave differently than the other delimiters. Here are some examples:

- \ (space)
- \t
- ,
- .
- ;
- ?
- !
- \r
- \n

When you include a *token separator*, EDM breaks the token where the separator is. For example, EDM sees the value **Middle-Last Name** into **Middle-Last** and **Name** for the `LastName` field. If the `ignoredDelimiters` is included for the `LastName` field with the character '-', that action only happens after the value is broken. In the end, EDM would see the following values **MiddleLast** and **Name**.

To use the following characters as `ignoredDelimiters` and not *token separators*, a SIT that matches the corresponding format needs to be associated with the field. For example, a SIT that detects a multi-word string with dashes in it needs to be associated with the `LastName` field.

- .
- ;
- !
- ?
- \

It's possible to associate sensitive information types (SITs) with secondary elements using PowerShell.

1. Define the schema in XML format (similar to the following example). Name this schema file **edm.xml** and then configure it such that, for each column in the sensitive information source table, there's a line that uses the syntax:

   `\<Field name="" searchable=""/\>`.

   - Use column names for *Field name* values.

- Use `searchable="true"` for the fields that you want to be searchable and primary fields up to a maximum of five fields. At least one field must be searchable.

As an example, the following XML file defines the schema for a patient records database, with five fields specified as searchable: `PatientID`, `MRN`, `SSN`, `Phone`, and `DOB`.

(You can copy, modify, and use our example.)

XML

```
<EdmSchema xmlns="http://schemas.microsoft.com/office/2018/edm">
      <DataStore name="PatientRecords" description="Schema for patient records"
version="1">
            <Field name="PatientID" searchable="true" caseInsensitive="true"
ignoredDelimiters="-,/,*,#,^" />
            <Field name="MRN" searchable="true" />
            <Field name="FirstName" />
            <Field name="LastName" />
            <Field name="SSN" searchable="true" />
            <Field name="Phone" searchable="true" />
            <Field name="DOB" searchable="true" />
            <Field name="Gender" />
            <Field name="Address" />
      </DataStore>
</EdmSchema>
```

Once you have created the EDM schema file in XML format, you have to upload it to the cloud service.

2. Connect to Security & Compliance PowerShell.

3. To upload the database schema, run the following command:

PowerShell

```
New-DlpEdmSchema -FileData ([System.IO.File]::ReadAllBytes('.\\edm.xml')) -
Confirm:$true
```

You'll be prompted to confirm, as follows:

> **Confirm**
>
> **Are you sure you want to perform this action?**
>
> **New EDM Schema for the data store 'patientrecords' will be imported.**
>
> **[Y] Yes [A] Yes to All [N] No [L] No to All [?] Help (default is "Y"):**

> **Tip**
>
> If you want your changes to occur without confirmation, don't use `-Confirm:$true` in Step 3.

> **Note**
>
> It can take between 10-60 minutes to update the EDMSchema with additions. The update must complete before you execute steps that use the additions.

Next steps

After you create your EDM schema, proceed to hash and upload your sensitive data. See Hash and upload the sensitive information source table for exact data match sensitive information types.

Hash and upload the sensitive information source table for exact data match sensitive information types

Overview

This article shows you how to hash and upload your sensitive information source table as part of the exact data match (EDM) sensitive information type workflow. After you create an EDM schema and configure your sensitive information type, you use the EDM Upload Agent to hash your source data and securely upload it to Microsoft 365. The article covers prerequisites, data formatting requirements, and step-by-step instructions for both single-computer and two-computer upload methods. The procedures in this article apply to the following workflows:

Products and services this hashing and upload procedure applies to

- Create exact data match sensitive information type new experience
- Create exact data match sensitive information type classic experience

Hash and upload the sensitive information source table

In this phase, you:

1. Set up a custom security group and user account.
2. Set up the Exact Data Match (EDM) Upload Agent tool.
3. Use the EDM Upload Agent tool to hash, with a salt value, the sensitive information source table, and upload it.

To hash and upload your sensitive data, use either the **Two-computer method** or the **Single computer method** as described in Hash and upload your data. You can't use custom hashing for uploading data. You can only use these two methods as described in the documentation for hashing and uploading.

Best practice is to use two computers to separate the processes of hashing and uploading your sensitive data. Separating the steps across two computers helps ensure that your actual data is never available in clear text form on a computer that might be compromised due to its

connection to the internet. Separating hashing and uploading across two computers also makes any issues you encounter easier to isolate.

Prerequisites

Before you hash and upload your sensitive information source table, make sure you meet the following technology, account, schema, and data formatting requirements.

Technology requirements

To use the EDM Upload Agent to hash and upload your sensitive data, ensure that the following requirements are in place.

- A work or school account for Microsoft 365. This account must be added to the **EDM_DataUploaders** security group.
- A computer with one of the following operating systems. This computer runs the **EDM Upload Agent**.
  - Windows 10 and later versions
  - Windows server 2019 and later versions
  - Windows Server 2016 with .NET version 4.6.2
- A directory on the computer you use for uploading your data. This directory contains:
  - The EDM Upload Agent.
  - Your sensitive information data file in *.csv*, *.tsv*, or pipe (|) format. By default, the EDM Upload Agent expects your data file to be in .csv format. > [!TIP]

    > You can use a file with data that is separated by tabs or pipes (instead of commas), by indicating either the "(Tab)" or "(|)" options with the `/ColumnSeparated` parameter. For example: `EdmUploadAgent.exe /UploadData /DataStoreName PatientRecords /DataFile C:\Edm\Hash\PatientRecords.csv /HashLocation C:\Edm\Hash /Schema edm.xml /AllowedBadLinesPercentage 5`

  - The output hash and salt files that are created when completing the hash procedure.
  - The datastore name from the **edm.xml** file. Our example uses `PatientRecords`.

Security group and user account requirements

The account you use to upload your sensitive information source table must be a member of one of these roles to create and manage the exact data match sensitive information types.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Expand table

Role	Can create security groups and add members	Notes
Groups Administrator	Yes	Best least privilege option
User Administrator	Yes	Most commonly used role
Global Administrator	Yes	Grants full control, don't use

You can use an existing security group or create a new one for managing EDM data uploads.

1. Go to the admin center using the appropriate portal link for your subscription and create a security group called **EDM_DataUploaders**.
2. Add one or more users to the **EDM_DataUploaders** security group. These users manage the database of sensitive information.

Exact Data Match Schema

If you used the EDM schema and sensitive information type tool for the **new** experience or the EDM sensitive information type/rule package for the **classic** experience, you **must** download that schema to hash your sensitive information source table. For more information, see Exporting the EDM schema file in XML format.

To download the EDM schema file for your sensitive information type, open a Command Prompt window and run the following command:

```
EdmUploadAgent.exe /SaveSchema /DataStoreName <schema name> /OutputDir <path to output folder>
```

Data formatting requirements

Before you hash and upload your sensitive data, run a search for any special characters in the table that might cause problems in parsing the content.

To catch formatting or column-mapping issues before you upload, validate the data file against the EDM schema by using the EDM Upload Agent with the following syntax:

```
PowerShell
EdmUploadAgent.exe /ValidateData /DataFile [data file] /Schema [schema file]
```

Common formatting issues

The following formatting problems commonly cause validation or parsing errors when you prepare your sensitive information source table.

1. **Mismatched number of columns:** This issue can be due to the presence of commas or quote characters within values in the table that EDM interprets as column delimiters. Unless they're surrounding a whole value, single and double quotes can cause the tool to misidentify the start and end of individual columns.
2. **Single quote characters or commas inside a value:** For example, if a person's name includes a single quote such as *Tom O'Neil* or a city's name starts with an apostrophe such as *'s-Gravenhage*, you need to modify the data export process used to generate the sensitive information table and surround such columns with double quotes.
3. **Double quote characters inside values:** Best practice is to use the tab-delimited format for the table. Tab-delimited tables are less susceptible to such issues.

Hash and upload your data

Select the appropriate EDM Upload Agent for your organization.

Expand table

EDM Upload Agent version	Description
Commercial + GCC	Most commercial customers should use this option.
GCC-High	This option is specifically for high-security government cloud subscribers.
DoD	This option is specifically for United States Department of Defense cloud customers.

Each version of the EDM Upload Agent automatically adds a salt value to your hashed data. If you choose, you can provide your own salt value by using the `/Salt` parameter when running the EDM Upload Agent.

> **⚠ Warning**
>
> If you choose to use your own salt value, you can't go back to use the standard version of the EDM Upload Agent for your use case. If you want to hash and upload from one computer, the computer you use must be able to connect directly to your Microsoft 365 tenant. Additionally, your clear-text sensitive information source table file must reside on this computer so that it can be hashed.

Two-computer method

Your sensitive information source table is formatted as clear-text. By using one computer for the hash step and a different computer for the upload step, you protect your data from being exposed in clear text on a computer with a direct connection to your Microsoft 365 tenant.

> **ⓘ Important**
>
> The two-computer method requires that **the same version of the EDM Upload Agent must be installed on both computers**. You can then copy the hash file and the salt file from the secure machine to a computer that can connect directly to your Microsoft 365 tenant.

1. On the computer in the secure environment, run the following command in a Command Prompt window: `EdmUploadAgent.exe /CreateHash /DataFile [data file] /HashLocation [hash file location] /Schema [Schema file] /AllowedBadLinesPercentage [value]` For example: `EdmUploadAgent.exe /CreateHash /DataFile C:\Edm\Data\PatientRecords.csv /HashLocation C:\Edm\Hash /Schema edm.xml /AllowedBadLinesPercentage 5`

   This command outputs a hashed file and a salt file with these extensions if you didn't specify the `/Salt <saltvalue>` option:

   - EdmHash
   - EdmSalt

2. Securely copy these files to the computer you use to upload your sensitive information source table (for example, **PatientRecords.csv**) to your tenant.

3. Authorize the EDM Upload Agent:
   a. As an admin, open a Command Prompt window.
   b. Switch to the directory where the EDM Upload Agent is installed. (The recommended directory is **C:\EDM\Data**.)
   c. Run the following command:

```
EDM Upload Agent.exe /Authorize
```

> **Important**
>
> You must run the EDM Upload Agent from the folder where it's installed and you must sindicate the full path to your data files.

4. Sign in with your work or school Microsoft 365 account. (The account that was added to the **EDM_DataUploaders** security group). Your tenant information is extracted from the user account to make the connection.

5. To upload the hashed data, run the following command in a Command Prompt window:

```
EdmUploadAgent.exe /UploadHash /DataStoreName \<DataStoreName\> /HashFile \
<HashedSourceFilePath\ /ColumnSeparator ["{Tab}"|"|"]
```

   For example: `EdmUploadAgent.exe /UploadHash /DataStoreName PatientRecords /HashFile C:\\Edm\\Hash\\**PatientRecords.EdmHash**`

6. To verify that the upload of your sensitive data was successful, run the following command in a Command Prompt window:

```
EdmUploadAgent.exe /GetDataStore
```

   If the upload was successful, a list of data stores and when they were last updated displays.

7. To display all of the data uploads to a particular store, and when they were updated, run the following command in a Command Prompt window:

```
EdmUploadAgent.exe /GetSession /DataStoreName <DataStoreName>
```

> **Tip**

To automate the hash and upload process after you have created it the first time, see Refresh your exact data match sensitive information source table file.

Advanced multi-token configuration options

The following settings control how the EDM Upload Agent handles multi-token values during data upload. Configure these options in the **app.config** file.

Admins can upload upload values that exceed the multi-token limit by truncating the exceeding token to columns.

- **Configuration**: Controlled via **app.config**
- **Default Behavior**: Support is disabled by default

Admins can disable the minimum multi-token optimization feature.

- **Configuration**: Controlled via **app.config**
- **Default Behavior**: Optimization is enabled by default.

EDM and double-byte character set languages

Exact data match supports double-byte characters, such as those used in Chinese, Japanese, and Korean. However, it doesn't support string matches for corroborative evidence encoded as double byte characters. Neither does it match multi-token CJK text detected in the classified content, unless globalization for EDM is enabled as described later in this document. In all cases, a SIT must be mapped to any multi-token text, both for the primary field and for corroborative evidence fields.

To invoke exact data matching for double-byte characters, take the following steps:

1. Create an EDM Sensitive Information Type (SIT) configured to match on the double-byte character set language, such as Japanese kanji.
2. Ensure that you download and install version 17.01.0495.0 (or later) of the EDM Upload Agent
3. Update the **EdmUploadAgent.exe.config** file's globalization parameter to true: `<add key="IsGlobalizationEnabled" value="true">`
4. Hash and upload a source table with the data to be matched.

EDM Parse Quotes Scenarios

`ParseQuotesExhaustiveScenariosByDefault` is an optional configuration attribute that's available while uploading the data. It is designed to resolve data ingestion errors caused by complex formatting in source files, such as CSVs containing fields with embedded commas, inconsistent single/double quoting, or escaped characters. By default, the value of `ParseQuotesExhaustiveScenariosByDefault is false`. To enable this setting add the ParseQuotesExhaustiveScenariosByDefault="true" in the upload **EdmUploadAgent.exe.config** file.

- Double Quotes ("): If a field starts with a double quote, the parser looks for the matching closing double quote. Commas inside the quotes are treated as text, not separators. For example: Input row (Raw CSV) values are "ID",First Name,"Title, Role" then Parsed values (result) will be: `ID`, `First Name`, `Title, Role`. Double quotes have a higher hierarchy than single quotes. A single quote found inside a double-quoted string is treated as a literal character.

- Single Quotes ('): If a field starts with a single quote, the parser treats it as a delimited string similar to double quotes.

- No Quotes: If the field does not start with a quote, the data is ingested as-is until the next separator is found.

Next steps

After you upload the source table, continue with the appropriate next step for your experience.

- **For the new experience**: Test an exact data match sensitive information type
- **For the classic experience**: Create exact data match sensitive information type/rule package

ⓘ**Note:** The author created this article with assistance from AI. Learn more

Last updated on 06/26/2026

Create exact data match sensitive information type/rule package

Products and services this rule package procedure applies to

- Create an EDM SIT using the classic experience workflow

You can create an exact data match (EDM) SIT (SIT) by using the Use the Exact Data Match schema and SIT pattern tool in the Microsoft Purview Portal, or you can create the rule package manually as an XML file. You can also combine the two methods by using one method to create the schema and later using the other method to edit it.

If you are not familiar with EDM-based SITS or their implementation, you should familiarize yourself with:

- Learn about sensitive information types
- Learn about exact data match based sensitive information types
- Get started with exact data match based sensitive information types

Prerequisites

Perform the steps in these articles:

1. Export source data for exact data match based sensitive information types
2. Create the schema for exact data match based sensitive information types
3. Hash and upload the sensitive information source table for exact data match sensitive information types

- Whether you will be creating an EDM SIT using the tool or the rule package XML file via PowerShell, you must have Compliance administrator or Global administrator role to create, test, and deploy a custom SIT through the UI. See About admin roles in Office 365.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. This helps improve security for your organization. Global Administrator is a highly privileged role that should

only be used in scenarios where a lesser privileged role can't be used.

- Identify one of the built-in SITs to use as the Primary elements SIT.
  - If none of the built-in SITs will match the data in the column you selected you will have to create a custom SIT that does.
  - If you selected the Ignored Delimiters option for the primary element column in your schema, make sure the custom SIT you create will match data with and without the selected delimiters.
  - If you use a built-in SIT, make sure it will detect exactly the strings you want to select, and not include any surrounding characters or exclude any valid part of the string as stored in your sensitive information table.

See Sensitive information type entity definitions and Create custom sensitive information types.

Use the Exact Data Match schema and SIT pattern tool

You can use the Exact Data Match schema and SIT pattern tool to create your SIT files to help simplify the process.

An EDM SIT is composed of one or more patterns. Each pattern describes a combination of fields from the schema that will be used to identify sensitive content in a document or email (evidence).

1. Sign in to the Microsoft Purview portal > **Information Protection** > **Classifiers** > **EDM classifiers**.
2. a. Set the **New EDM experience** toggle to **Off**
3. Choose **EDM sensitive info types** and **Create EDM sensitive info type** to open the Sensitive Information Type configuration tool.
4. Select **Choose an existing EDM schema** and pick the schema you created in Create the schema for exact data match based sensitive information types. Select **Add**.
5. Choose **Next** and choose **Create pattern**.
6. Pick the **Confidence level** and **Primary element**. To learn more about confidence levels, see Learn about sensitive information types.
7. Choose the **Primary element's sensitive info type** to associate it with to define what text in the document will be compared with all the values in the primary element field. See SIT Entity Definitions to learn more about the available sensitive information types.

> **Important**
>
> Select a SIT that closely matches the format of the content you want to find. Selecting a SIT that matches unnecessary content, such as one that matches *all* text strings, or *all* numbers can cause excessive load in the system, which can result in sensitive information remaining undetected.

8. Select your **Supporting elements** and match options.
9. Choose **Done**.
10. Choose **Create pattern** if you want to create additional patterns for your EDM SIT.
11. Select **Next**.
12. Choose your desired **Recommended confidence level** and **Character proximity**. This will be the default value for the whole EDM SIT. (For information on character proximity, see Understanding proximity). Select **Next**.
13. Choose **Next** and fill in a **Name** and **Description for admins**.

    As you create your schema file, your column headers (data fields) must adhere to the following naming requirements:
    - Must start with a letter and must consist of at least three alphanumeric characters.
    - Must include only alphanumeric characters.
14. Review and choose **Submit**.

Edit or delete a SIT pattern

To edit or delete an existing EDM SIT pattern, perform the following steps:

1. Sign in to the Microsoft Purview portal > **Information Protection**> **Classifiers** > **EDM classifiers**.
2. a. Set the **New EDM experience** toggle to **Off**
3. Choose **EDM sensitive info types**.
4. Pick the EDM SIT you want to edit.
5. Choose **Edit EDM sensitive info type** or **Delete EDM sensitive info type** from the flyout.

6. For the steps to edit an EDM sensitive info type, see Use the Exact Data Match schema and SIT pattern tool.

Working with specific types of data

For performance reasons, it is critical that you use patterns that will minimize the number of unnecessary matches. For example, you might use a SIT based on the regular expression.

`\b\w*\b`

This regular expression would match every individual word or number in any document or email. Matching every word or number would cause the service to be overloaded with matches and miss detecting true matches. Using more precise patterns can avoid this situation. Here are some recommendations for identifying the right configuration for some common types of data.

Email addresses: Email addresses can be easy to identify, but because they are so common in sensitive content, they might cause a significant load in the system if used as a primary field. Use email adderss only as secondary evidence. If they must be used as primary evidence, when you define your custom SIT use logic to exclude items where email addresses are used as `From` or `To` fields in emails. Also use logic to exclude email addresses from your company's domain to reduce the number of unnecessary strings that need to be matched.

Phone numbers: Phone numbers can come in many different formats, including or excluding country/region prefixes, area codes, and separators. To reduce the false negatives while keeping load to a minimum, use them only as secondary elements, exclude all likely separators, like parenthesis and dashes and only include in your sensitive data table the part that will always be present in the phone number.

People's names: Don't use people's names as primary elements if using a SIT based on a regular expression as the classification element for this EDM type, because they are difficult to distinguish from common words.

If you must use a primary element that is hard to identify with a specific pattern (such as a project code name), that could generate a high volume of matches to be processed, make sure you include keywords in the SIT you use as the classification element for your EDM type. For example, if using project code names that are also regular words, you can use the word `project` as required additional evidence in close proximity to the project name regular expression-based pattern in the SIT you use as the classification element for your EDM type. Or, you might consider using a SIT based on a regular dictionary as the classification element for your EDM SIT.

When trying to match numeric strings, specify the allowed ranges of numbers such as the number of digits or the starting digits, if known. If you need to match a relatively flexible range of numbers, you can use keywords in the base SIT to reduce the number of matches. For example, if trying to match account numbers consisting of 7-11 digits, add the words `account`, `customer`, `acct.` to the SIT as required additional evidence. This reduces the likelihood of unnecessary matches that could result in exceeding the limits of EDM matches that can be processed.

If a field you need to use as a primary element follows a simple pattern that might result in large numbers of matches, and you can't add the presence of keywords as additional evidence in the SIT, you can instead require a minimum number of occurrences of that pattern. For example, you could use a custom SIT defined in the following way to detect at least 29 other five-digit numbers surrounding a potential five-digit number to match against in your sensitive content:

XML

```
<Entity id="00aa00aa-bb11-cc22-dd33-44ee44ee44ee"
                patternsProximity="300"
                recommendedConfidence="85"
                relaxProximity="false">
                <Pattern confidenceLevel="85"
                           proximity="300">
                           <IdMatch idRef="MRN"/>
                           <Match idRef="30 AccountNrs"
                                 minCount="30"
                                 proximity="3000"
                                 uniqueResults="true"/>
                </Pattern>
     </Entity>
     <Regex id="30 AccountNrs">\d{5}</Regex>
```

In some cases, you might have to identify certain account or record identification numbers that for historical reasons don't follow a standardized pattern. For example, `Medical Record Numbers` can be composed of many different permutations of letters and numbers within the same organization. Even though it might be hard at first to identify a pattern, closer inspection often lets you narrow down a pattern that describes all valid values without causing an excessive number of invalid matches. For example, it might be detected that "all MRNs are at least seven characters in length, have at least two numerical digits in them, and if they have any letters in them, they start with one". Creating a regular expression based on such criteria should allow you to minimize unnecessary matches while capturing all the desired values, and further analysis might allow increased precision by defining separate patterns that describe different formats.

Create a rule package manually

This procedure shows you how to create a file in XML format called a rule package (with Unicode encoding), and then upload it into Microsoft Purview using Security & Compliance PowerShell cmdlets.

> **Note**
>
> If the SIT that you map to can detect multi-word corroborative evidence, the secondary elements you define in a manually created rule package can be mapped to the SIT. For example, the name `John Smith` would not match as a secondary element because we'd compare `John` and `Smith` found in the content separately to the term `John Smith` uploaded in one of the fields, if that corroborative evidence field wasn't mapped to a SIT that can detect that pattern.
>
> There's a limit of 10 rule packages in a Microsoft 365 tenant. Since a rule package can contain an arbitrary number of sensitive information types, you can avoid creating a new rule package each time you want to define a new SIT using this method, instead export an existing rule package and add your sensitive information types to the XML before re-uploading it.

1. Create a rule package in XML format (with Unicode encoding), similar to the following example. (You can copy, modify, and use our example.)

   When you set up your rule package, make sure to correctly reference your .csv, .tsv, or pipe (|) delimited sensitive information source table file and **edm.xml** schema file. You can copy, modify, and use our example. In this sample xml the following fields need to be customized to create your EDM sensitive type:

   - **RulePack id & ExactMatch id**: Use New-GUID to generate a GUID.
   - **Datastore**: This field specifies EDM lookup data store to be used. You provide the data source name of the configured EDM Schema.
   - **idMatch**: This field points to the primary element for EDM.
   - **Matches**: Specifies the field to be used in exact lookup. You provide a searchable field name in EDM Schema for the DataStore.
   - **Classification**: This field specifies the SIT match that triggers EDM lookup. You can use the name or GUID of an existing built-in or custom SIT.

> **Note**
>
> Be aware that any string that matches the SIT provided will be hashed and compared to every entry in the sensitive information source table. To avoid performance issues if you choose a custom SIT for the classification element, don't use one that will match a large percentage of content. For example one that matches "any number" or "any five-letter word". You can differentiate it by adding supporting keywords or including formatting in the definition of the custom classification SIT.

- **Match**: This field points to additional evidence found in proximity of idMatch.
- **Matches**: You provide any field name in EDM Schema for DataStore.
- **Resource idRef:** This section specifies the name and description for sensitive type in multiple locales
  - You provide GUID for ExactMatch ID.
  - **Name** & **description**: customize as required.

           <match matches="MRN"/>
```

```
            <match matches="FirstName"/>
            <match matches="LastName"/>
            <match matches="Phone"/>
            <match matches="DOB"/>
          </Any>
        </Pattern>
      </ExactMatch>
      <LocalizedStrings>
        <Resource idRef="E1CC861E-3FE9-4A58-82DF-4BD259EAB371">
          <Name default="true" langcode="en-us">Patient SSN Exact Match.
</Name>
          <Description default="true" langcode="en-us">EDM Sensitive type for
detecting Patient SSN.</Description>
        </Resource>
      </LocalizedStrings>
    </Rules>
</RulePackage>
```

2. Upload the rule package by running the following PowerShell command:

PowerShell

```
New-DlpSensitiveInformationTypeRulePackage -FileData
([System.IO.File]::ReadAllBytes('.\\rulepack.xml'))
```

> **Note**
>
> The syntax of the rule package file is the same as for other sensitive information types. For complete details on the syntax of the rule package file and for additional configuration options, and for instructions on modifying and deleting sensitive information types using PowerShell, Create a custom SIT using PowerShell.

Next step

After you create your rule package, continue with the following article:

- **For the Classic experience**: Test an exact data match SIT

Note: The author created this article with assistance from AI. Learn more

Last updated on 06/26/2026

Test an exact data match sensitive information type

This article explains how to test an exact data match (EDM) sensitive information type (SIT) to verify that it correctly detects the sensitive data you want to protect. It covers testing methods available in the Microsoft Purview portal and PowerShell, as well as troubleshooting tips for common detection issues.

Products and services this EDM testing article applies to

This article covers testing for both EDM experience versions:

For instructions on creating an EDM SIT before testing, see the workflow for your experience:

- Create an EDM SIT using the new experience
- Create an EDM SIT using the classic experience

Overview of EDM SIT testing

This section explains how to verify that your exact data match (EDM) sensitive information type (SIT) correctly detects the information you want to protect. After your EDM SIT has been created, and an hour after verifying that your sensitive information table has finished uploading and indexing, you can test detection by using the **Test** function in the **Sensitive information types** section in the Microsoft Purview Portal.

> **Note**
>
> Changes in an existing EDM SIT can take some time to propagate across the system. If you're making changes to an EDM SIT in order to troubleshoot detection issues, make sure to wait at least one hour after making those changes before using the **Test** function to validate their impact.

Regardless of the method you use for testing, the test results include matches for both the specific EDM SIT and for the primary elements that are configured for that EDM SIT.

Methods for testing your EDM SIT

There are two methods that you can use to test your EDM SIT.

Expand table

Method	Available in New EDM experience	Available in New and Classic EDM experience
Sensitive information type (SIT) method	Yes	Yes
EDM classifiers method	Yes	No

> **Note**
>
> If you're using the Classic EDM experience, you must use the SIT method.

Testing an EDM SIT with the Sensitive Information Types method

To test an EDM SIT with the **Sensitive Information Types** method, take the following steps.

1. Sign in to the Microsoft Purview portal > **Information Protection** > **Classifiers** > **Sensitive info types**.
2. Select your EDM SIT from the list and then select the **Test** icon.
3. In the flyout pane, upload a file that contains data you want to detect. For example, create a file that contains a subset of the rows in your sensitive information table. If you used the *configurable match* feature in your schema to define ignored delimiters, make sure the sample file includes examples with and without those delimiters.
4. Choose **Test**.
5. After the file has been uploaded and scanned, check for matches to your EDM SIT.
6. If the **Test** function in the SIT detects a match, verify that the SIT isn't trimming it or extracting the matched item incorrectly. Common issues include SITs that:
    - Extract only a substring of the full string that should be detected
    - Pick up only the first word in a multi-word string

- Include extra symbols or characters in the extraction

For details about the regular expressions used in SIT pattern definitions and extraction logic, see the Regular Expression Language - Quick Reference.

Test your EDM SIT with the EDM Classifier method

To test an EDM SIT with the **EDM Classifier** method, follow these steps.

1. Sign in to the Microsoft Purview portal > **Information Protection** > **Classifiers** > **EDM classifiers**.
2. Make sure that the **New EDM experience** toggle is set to **On**.
3. Select your EDM SIT from the list and then select the **Test** icon.
4. Upload a file that contains data you want to detect. For example, create a file that contains a subset of the rows in your sensitive information table. If you used the *configurable* match feature in your schema to define ignored delimiters, make sure your sample file includes examples with and without those delimiters.
5. After the file has been uploaded and scanned, check for matches to your EDM SIT.
6. If the **Test** function in the SIT detects a match, verify that the SIT isn't trimming it or extracting the matched item incorrectly. Common issues include SITs that:
    - Extract only a substring of the full string that should be detected
    - Pick up only the first word in a multi-word string
    - Include extra symbols or characters in the extraction

Test your EDM SIT using PowerShell

Use the `Test-DataClassification` cmdlet to test your EDM sensitive information type against sample text and verify whether the classifier detects expected matches. For the `-ClassificationNames` parameter, supply the display name of the EDM sensitive information type you want to test. For `-TexttoClassify`, provide the sample text you want to scan for matches.

PowerShell

```
Test-DataClassification  -ClassificationNames “[Your EDM sensitive info type]” -TexttoClassify “[your own text to scan for matches]”
```

Regardless of the method you use for testing, the test results will include matches for both the specific EDM SIT and for the primary elements that are configured for that EDM SIT.

> **Note**
>
> An uploaded-file or text test doesn't refresh classification for existing SharePoint and OneDrive files. Changing an EDM SIT or its primary SIT doesn't by itself refresh classification for unchanged historical files. To update classification for those files, use **on-demand classification**. Review the scan scope, EDM scan-cost considerations, and active-policy effects before starting a scan.

Test your EDM SIT with information protection policies

You can see where your EDM SIT is being used, and how accurate it is in production, by using it in policies:

1. Create an auto-labeling policy and run it in **Simulation overview**.
2. Add some content that triggers the EDM SIT, along with content that won't trigger the EDM SIT, to a location that your policy is monitoring.
3. Open the **Items to review** tab to check the matches.
4. Based on the simulation results, tune your policy conditions and EDM SIT settings as appropriate to improve detection accuracy.

Once you're satisfied with the results of your testing and tuning, your EDM-based custom SIT is ready for use in information protection policies, for instance:

- DLP policies
- Auto-labeling policies
- Microsoft Defender for Cloud Apps

Troubleshooting tips

If your EDM SIT doesn't detect any matches in your data, the following tips might help you diagnose the problem.

Expand table

Issue	Troubleshooting tip
No matches found	Confirm that your sensitive data was uploaded correctly using the commands explained in Hash and upload the sensitive information source table for exact data match sensitive information types.
No matches found	Test the SIT you used when you configured the primary element in each of your patterns. This test verifies whether the SIT can match the examples in the item. Using an incorrectly defined SIT as the classification element of an EDM SIT is the most common cause for detection failures in EDM.
The SIT you selected for a primary element in the EDM type doesn't find a match in the item or finds fewer matches than you expected	Confirm that the SIT supports the separators and delimiters that occur in the content. Be sure to include the ignored delimiters defined in your schema.
The SIT associated with your primary element finds matches in your content, but the EDM SIT doesn't.	• Check whether your REGEX statements are catching whitespace delimiters at the start or end of an item you want to detect. For instance, look for statements that include the `\s` delimiter. If whitespace delimiters are included, the whitespace won't match the hashed value in the data table. Instead, use a word delimiter, such as `\b`. • Check your REGEX statements to ensure that they capture the entire string you want to detect, not just a substring. For example, consider this pattern for email addresses: `\b[a-zA-Z]{2,30}@[a-zA-Z]{2,20}.[a-zA-Z]{2,3}\b`. This pattern will correctly match *user@contoso.com*, but will only capture *user@contoso.co.jp* in an incomplete form.
An EDM SIT with primary elements, but no defined secondary elements, detects items but doesn't detect matches (or detects fewer matches than expected) when both primary and secondary elements are required.	If values in a column used for secondary evidence aren't composed of a single word or of strings that don't contain spaces, commas, or other word separators, there are two ways to test: 1. Select the multi-token matching option. 2. Associate the values with a SIT that uses either a REGEX designed to detect multi-word strings that follow the desired pattern (for example, a fixed number of consecutive words that start with an uppercase character), or a keyword dictionary that lists all of the unique values in that column. For example, if there's an additional evidence column for a person's city or residence, you can create a list with all the unique city names from the table and then use it to create a dictionary-based sensitive information type. Use this SIT as the classification element for the corresponding column in your EDM SIT by exporting and editing the EDM SIT definition in XML. For more information, see Create a rule package manually.

Issue	Troubleshooting tip
SIT test function doesn't detect any matches at all.	Verify that the SIT you selected includes requirements for additional keywords or other validations. For built-in SITs, see Sensitive information type entity definitions to determine what the minimum requirements are for matching each type.
The **Test** functionality works but your SharePoint or OneDrive items aren't being detected in DLP or auto-labeling rules	Check the policy scope and conditions, and whether classification for the existing files reflects the SIT definitions you intend to use. A direct test doesn't establish classification coverage for stored files. For auto-labeling, see Auto-labeling classification and simulation concepts; restarting simulation doesn't itself refresh classification. Use on-demand classification when classification needs updating, after reviewing scope, costs, and active-policy effects.
DLP or auto-labeling rules that require multiple matches don't trigger	Make sure that the proximity requirements for both your EDM SIT and the base SITs are met. For example, if the maximum distance between the primary element and supporting keywords is 300 characters, but the keywords are only present in the first row of a long table, only the first few rows of matching values are likely to meet the proximity requirements. Modify your SIT definitions to support more relaxed proximity rules or use the **Anywhere in the document** option for the additional evidence conditions.
Detection of an EDM SIT is inconsistent or erratic	Make sure that the SIT you used as the base for the primary element in your EDM SIT isn't detecting unnecessary content. Using a SIT that matches too much unrelated content, such as *any* word, *any* number, or *all* email addresses, can cause the service to ignore relevant matches. Check the number of content pieces that match the sensitive type you used for your primary elements in content explorer. To estimate whether the SIT is matching too much content: 1. Divide the number of content items in the Microsoft Purview Content Explorer by the number of days since the sensitive type was created. 2. If the number of matches per day is in the range of hundreds of thousands or more, it's possible that the primary SIT is too broad.

For recommendations and best practices on selecting the right sensitive information type for an EDM SIT, see Learn about exact data match based sensitive information types.

Modify Exact Data Match schema to use configurable matching

This article walks administrators through modifying an existing Exact Data Match (EDM) schema to enable configurable matching using PowerShell. By adding the `caseInsensitive` and `ignoredDelimiters` flags to your schema, you can allow Microsoft Purview to match sensitive data while ignoring case differences and specified delimiter characters.

Applies to: EDM SIT creation with PowerShell

- Exact data match (EDM) sensitive information type (SIT) creation using PowerShell.

Exact Data Match (EDM) based classification enables you to create custom sensitive information types that refer to exact values in a database of sensitive information. When you need to allow for variants of an exact string, you can use *configurable matching* to tell Microsoft Purview to ignore case and some delimiters.

> **Important**
>
> Use this procedure to modify an existing EDM schema and data file to enable configurable matching using PowerShell. You must already have an EDM schema and uploaded data file before you begin.

1. Uninstall the **EdmUploadAgent.exe** from the computer that you use to connect to Microsoft 365 for EDM schema and data file upload purposes

2. Download the appropriate **EdmUploadAgent.exe** file for your subscription using the following links:

    - Download EDM Upload Agent for Commercial + GCC - Most commercial customers should use this option
    - Download EDM Upload Agent for GCC-High - This option is specifically for high-security government cloud subscribers
    - Download EDM Upload Agent for DoD - This option is specifically for United States Department of Defense cloud customers

3. Authorize the EDM Upload Agent so it can perform schema export and data upload operations in your environment. Open a Command Prompt window (as an administrator) and run the following command:

```dos
EdmUploadAgent.exe /Authorize
```

4. If you don't have a current copy of the existing schema, you need to download a copy of the existing schema. To do so, run this command:

```dos
EdmUploadAgent.exe /SaveSchema /DataStoreName <dataStoreName> [/OutputDir [Output dir location]]
```

5. Customize the schema so each column utilizes `caseInsensitive` and / or `ignoredDelimiters`. The default value for `caseInsensitive` is "false" and for `ignoredDelimiters`, the default is an empty string.

> **Note**
>
> The underlying custom sensitive information type or built-in sensitive information type used to detect the general regex pattern must support detection of the input variations listed with ignoredDelimiters. For example, the built-in U.S. Social Security Number (SSN) sensitive information type can detect variations in the data that include dashes, spaces, or lack of spaces between the grouped numbers that make up the SSN. As a result, the only delimiters that are relevant to include in EDM's `ignoredDelimiters` for SSN data are: dash and space.

Here's a sample schema that simulates case-insensitive matching by creating the extra columns needed to recognize case variations in the sensitive data.

```XML
<EdmSchema xmlns="http://schemas.microsoft.com/office/2018/edm">
  <DataStore name="PatientRecords" description="Schema for patient records policy" version="1">
            <Field name="PolicyNumber" searchable="true" />
            <Field name="PolicyNumberLowerCase" searchable="true" />
            <Field name="PolicyNumberUpperCase" searchable="true" />
            <Field name="PolicyNumberCapitalLetters" searchable="true" />
```

```
  </DataStore>
</EdmSchema>
```

In the sample schema with `PolicyNumberLowerCase`, `PolicyNumberUpperCase`, and `PolicyNumberCapitalLetters` columns, the variations of the original `PolicyNumber` column aren't necessary if both `caseInsensitive` and `ignoredDelimiters` are added.

To update this schema so that EDM uses configurable matching, use the `caseInsensitive` and `ignoredDelimiters` flags. Here's how that looks:

XML

```
<EdmSchema xmlns="http://schemas.microsoft.com/office/2018/edm">
  <DataStore name="PatientRecords" description="Schema for patient records
policy" version="1">
         <Field name="PolicyNumber" searchable="true" caseInsensitive="true"
ignoredDelimiters="-,/,*,#,^" />
  </DataStore>
</EdmSchema>
```

For information on the characters supported by the `ignoredDelimiters` flag, see Using the caseInsensitive and ignoredDelimiters fields.

6. Connect to Security & Compliance PowerShell

> **Note**
>
> If your organization has set up Customer Key for Microsoft 365 at the tenant level, Exact Data Match will make use of its encryption functionality automatically. This is available only to E5 licensed tenants in the Commercial cloud. For more information, see Overview of Customer Key.

7. Import the updated schema XML back into Microsoft Purview to apply the configurable matching changes to the EDM datastore. Run the following command:

PowerShell

```
Set-DlpEdmSchema -FileData ([System.IO.File]::ReadAllBytes('.\\edm.xml')) -
Confirm:$true
```

8. If necessary, update the data file to match the new schema version.

> **Tip**
>
> Optionally, you can run a validation against your CSV file before uploading it by running:
>
> `EdmUploadAgent.exe /ValidateData /DataFile [data file] /Schema [schema file]`
>
> For example: `EdmUploadAgent.exe /ValidateData /DataFile C:\data\testdelimiters.csv /Schema C:\EDM\patientrecords.xml`
>
> For more information on all of the parameters supported by EdmUploadAgent.exe, run
>
> `EdmUploadAgent.exe /?`

9. Open a Command Prompt window (as an administrator) and run the following command to hash and upload your sensitive data:

```dos
EdmUploadAgent.exe /UploadData /DataStoreName [DS Name] /DataFile [data file]
/HashLocation [hash file location] /Salt [custom salt] /Schema [Schema file]
```

Create notifications for exact data match activities

When you create custom sensitive information types with exact data match (EDM), there are a number of activities that are created in the audit log. You can use the New-ProtectionAlert PowerShell cmdlet to create notifications that let you know when these activities occur:

- `CreateSchema`
- `EditSchema`
- `RemoveSchema`
- `UploadDataFailed`
- `UploadDataCompleted`

> **Note**
>
> The ability to create notifications for EDM activities is available for the World Wide and GCC clouds only.

Prerequisites

Your account must have one of the following roles:

- Global administrator
- Compliance administrator
- Exchange Online administrator

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. This helps improve security for your organization. Global Administrator is a highly privileged role that should only be used in scenarios where a lesser privileged role can't be used.

To learn more about DLP permissions, see Permissions in the Microsoft Purview portal.

EDM-based classification is included in these subscriptions:

- Office 365 E5

- Microsoft 365 E5
- Microsoft Purview Suite (formerly known as Microsoft 365 E5 Compliance)
- Microsoft E5/A5 Information Protection and Governance

To learn more about DLP licensing, see Microsoft 365 licensing guidance for security & compliance.

Before you begin, ensure you can connect to Security & Compliance PowerShell.

Configure notifications for EDM activities

1. Connect to Security & Compliance PowerShell.
2. Run the `New-ProtectionAlert` cmdlet using the activity that you want to create the notification for. For example, if you want to be notified when the `UploadDataCompleted` action occurred, run:

   PowerShell

   ```
   New-ProtectionAlert -Name "EdmUploadCompleteAlertPolicy" -Category Others -
   NotifyUser <address to send notification to> -ThreatType Activity -Operation
   UploadDataCompleted -Description "Custom alert policy to track when EDM upload
   Completed" -AggregationType None
   ```

   For the `UploadDataFailed` activity, you can run:

   PowerShell

   ```
   New-ProtectionAlert -Name "EdmUploadFailAlertPolicy" -Category Others -NotifyUser
   <SMTP address to send notification to> -ThreatType Activity -Operation
   UploadDataFailed -Description "Custom alert policy to track when EDM upload
   Failed" -AggregationType None -Severity High
   ```

Manage your exact data match schema

Editing the schema for EDM-based classification manually

If you want to make changes to your EDM schema, for example the **edm.xml** file, such as changing which fields are used for EDM-based classification, follow these steps:

> **Tip**
>
> You can change your EDM schema and sensitive information table source file to take advantage of **configurable match**. When configured, EDM will ignore case differences and some delimiters when it evaluates an item. This makes defining your xml schema and your sensitive data files easier. To learn more see, Using the caseInsensitive and ignoredDelimiters fields.

1. Edit your **edm.xml** file (this file is discussed in the Create the schema for exact data match based sensitive information types.
2. Connect to Security & Compliance PowerShell.
3. To update your database schema, run the following command:

   PowerShell

   ```
   Set-DlpEdmSchema -FileData ([System.IO.File]::ReadAllBytes('.\\edm.xml')) -
   Confirm:$true
   ```

   You're prompted to confirm as follows:

   > Confirm
   >
   > Are you sure you want to perform this action?
   >
   > EDM Schema for the data store 'patientrecords' will be updated.
   >
   > [Y] Yes [A] Yes to All [N] No [L] No to All [?] Help (default is "Y"):

> **Tip**
>
> If you want your changes to occur without confirmation, don't use `-Confirm:$true` in Step 3.

> **Note**
>
> It can take between 10-60 minutes to update the EDMSchema with additions. The update must complete before you execute steps that use the additions.

Removing the schema for EDM-based classification manually

If you want to remove the schema you're using for EDM-based classification, follow these steps:

1. Connect to Security & Compliance PowerShell.
2. Run the following command, substituting the data store name of "patient records" with the one you want to remove (using the patientrecords store as an example):

```
PowerShell
Remove-DlpEdmSchema -Identity 'patientrecords'
```

You're prompted to confirm the following message:

> Confirm
>
> Are you sure you want to perform this action?
>
> EDM Schema for the data store 'patientrecords' will be removed.
>
> [Y] Yes [A] Yes to All [N] No [L] No to All [?] Help (default is "Y"):

> **Tip**
>
> If you want the schema removal to occur without confirmation, omit the `-Confirm:$true` parameter from the `Remove-DlpEdmSchema` command.

Edit or delete the EDM schema with the wizard

To edit or delete an EDM schema by using the wizard, follow these steps:

1. Open **Compliance center** > **Data classification** > **Classifiers**.
2. Choose **EDM classifiers**.
3. Double-click on the EDM SIT you want to edit.
4. Choose **Edit EDM sensitive info type** or **Delete EDM sensitive info type** from the flyout.
5. Follow the steps in the wizard to complete your edits or to delete the classifier.

> **Important**
>
> If you want to remove a schema, and it is already associated with an EDM sensitive info type, you must first delete the EDM sensitive info type, then you can delete the schema.

Note: The author created this article with assistance from AI. Learn more

Refresh your exact data match sensitive information source table file

Refresh an exact data match sensitive information database

This article explains how to refresh the sensitive information source table used by exact data match (EDM) sensitive information types in Microsoft Purview. Use this procedure when your source data changes and you need to update the uploaded data. Compliance administrators can refresh the database up to 5 times in every 24-hour period by rehashing and reuploading the sensitive information source table. Each refresh overwrites the existing sensitive information source table with the new one.

1. Re-export the sensitive data to an app, such as Microsoft Excel, and save the file in .csv, .tsv format or pipe-delimited (|) format. Keep the same file name and location you used when you previously hashed and uploaded the file. See, Export source data for exact data match based sensitive information types for details on exporting your sensitive data and getting it into the correct format.

   > ⓘ **Note**
   >
   > If there are no changes to the structure (field names) of the sensitive information source table file, you won't need to make any changes to your database schema file when you refresh the data. But if you must make changes, make sure to edit the database schema and your rule package accordingly. See, Manage your exact data match schema for the steps to edit or remove a schema. To learn how to dit or remove your EDM SIT/rule package, see Create exact data match sensitive information type/rule package.

2. Use the procedures in Hash and upload the sensitive information source table for exact data match sensitive information types to upload your sensitive information table source file.

3. You can use Task Scheduler to automate the Hash and upload the sensitive information source table for exact data match sensitive information types procedure. You can schedule tasks using several methods:

Expand table

Method	What to do
PowerShell	See the ScheduledTasks documentation and the Example PowerShell script for Task Scheduler
Task Scheduler API	See the Task Scheduler documentation
Windows user interface	In Windows, click **Start**, and type Task Scheduler. Then, in the list of results, right-click **Task Scheduler**, and choose **Run as administrator**.

Example PowerShell script for Task Scheduler

The following examples include PowerShell scripts you can use to schedule tasks for hashing data and uploading hashed data:

Schedule hashing and upload in a combined step

Use the following PowerShell script to schedule hashing and upload as a single combined task:

PowerShell

```
param(\[string\]$dataStoreName,\[string\]$fileLocation)
\# Assuming current user is also the user context to run the task
$user = "$env:USERDOMAIN\\$env:USERNAME"
$edminstallpath = 'C:\\Program Files\\Microsoft\\EdmUploadAgent\\'
$edmuploader = $edminstallpath + 'EdmUploadAgent.exe'
$csvext = '.csv'
$schemaext = '.xml'
\# Assuming file name is same as data store name and file is in .csv format
$dataFile = "$fileLocation\\$dataStoreName$csvext"
\# Assuming location to store hash file is same as the location of csv file
$hashLocation = $fileLocation
\# Assuming Schema file name is same as data store name
$schemaFile = "$fileLocation\\$dataStoreName$schemaext"
$uploadDataArgs = '/UploadData /DataStoreName ' + $dataStoreName + ' /DataFile ' +
$dataFile + ' /HashLocation' + $hashLocation + ' /Schema ' + $schemaFile
\# Set up actions associated with the task
$actions = @()
$actions += New-ScheduledTaskAction -Execute $edmuploader -Argument $uploadDataArgs -
WorkingDirectory $edminstallpath
\# Set up trigger for the task
$trigger = New-ScheduledTaskTrigger -Weekly -DaysOfWeek Sunday -At 2am
\# Set up task settings
$principal = New-ScheduledTaskPrincipal -UserId $user -LogonType S4U -RunLevel
Highest
$settings = New-ScheduledTaskSettingsSet -RunOnlyIfNetworkAvailable -
StartWhenAvailable -WakeToRun
```

```
\# Create the scheduled task
$scheduledTask = New-ScheduledTask -Action $actions -Principal $principal -Trigger
$trigger -Settings $settings
\# Get credentials to run the task
$creds = Get-Credential -UserName $user -Message "Enter credentials to run the task"
$password=\[Runtime.InteropServices.Marshal\]::PtrToStringAuto(\
[Runtime.InteropServices.Marshal\]::SecureStringToBSTR($creds.Password))
\# Register the scheduled task
$taskName = 'EDMUpload\_' + $dataStoreName
Register-ScheduledTask -TaskName $taskName -InputObject $scheduledTask -User $user -
Password $password
```

Schedule hashing and upload as separate steps

Use the following PowerShell script to schedule hashing and upload as separate tasks:

PowerShell

```
param(\[string\]$dataStoreName,\[string\]$fileLocation)
\# Assuming current user is also the user context to run the task
$user = "$env:USERDOMAIN\\$env:USERNAME"
$edminstallpath = 'C:\\Program Files\\Microsoft\\EdmUploadAgent\\'
$edmuploader = $edminstallpath + 'EdmUploadAgent.exe'
$csvext = '.csv'
$edmext = '.EdmHash'
$schemaext = '.xml'
\# Assuming file name is same as data store name and file is in .csv format
$dataFile = "$fileLocation\\$dataStoreName$csvext"
$hashFile = "$fileLocation\\$dataStoreName$edmext"
\# Assuming Schema file name is same as data store name
$schemaFile = "$fileLocation\\$dataStoreName$schemaext "

\# Assuming location to store hash file is same as the location of csv file
$hashLocation = $fileLocation
$createHashArgs = '/CreateHash' + ' /DataFile ' + $dataFile + ' /HashLocation ' +
$hashLocation + ' /Schema ' + $schemaFile
$uploadHashArgs = '/UploadHash /DataStoreName ' + $dataStoreName + ' /HashFile ' +
$hashFile
\# Set up actions associated with the task
$actions = @()
$actions += New-ScheduledTaskAction -Execute $edmuploader -Argument $createHashArgs -
WorkingDirectory $edminstallpath
$actions += New-ScheduledTaskAction -Execute $edmuploader -Argument $uploadHashArgs -
WorkingDirectory $edminstallpath
\# Set up trigger for the task
$trigger = New-ScheduledTaskTrigger -Weekly -DaysOfWeek Sunday -At 2am
\# Set up task settings
$principal = New-ScheduledTaskPrincipal -UserId $user -LogonType S4U -RunLevel
Highest
$settings = New-ScheduledTaskSettingsSet -RunOnlyIfNetworkAvailable -
StartWhenAvailable -WakeToRun
\# Create the scheduled task
```

```
$scheduledTask = New-ScheduledTask -Action $actions -Principal $principal -Trigger
$trigger -Settings $settings
\# Get credentials to run the task
$creds = Get-Credential -UserName $user -Message "Enter credentials to run the task"
$password=\[Runtime.InteropServices.Marshal\]::PtrToStringAuto(\
[Runtime.InteropServices.Marshal\]::SecureStringToBSTR($creds.Password))
\# Register the scheduled task
$taskName = 'EDMUpload\_' + $dataStoreName
Register-ScheduledTask -TaskName $taskName -InputObject $scheduledTask -User $user -
Password $password
```

Learn about trainable classifiers

Trainable Classifiers

This categorization method is well suited to content that can't be easily identified using either the manual or automated pattern-matching methods. A classifier learns how to identify a type of content by looking at hundreds of examples of the content you want to detect.

> ⓘ **Note**
>
> **In Preview:** You can view the trainable classifiers in content explorer by expanding **Trainable Classifiers** in the filters panel. The trainable classifiers automatically display the number of incidents found in SharePoint and Teams, without requiring any labeling. If you don't want to use this feature, you must file a request with Microsoft Support. This request disables the display of your sensitive data that isn't used in any labeling policies within Content Explorer. You can disable scanning of your data as well. If scanning is turned off, sensitivity labeling and DLP policies with those classifiers don't work.

Where you can use classifiers

Use classifiers as a condition for:

- Auto-labeling Office files with sensitivity labels
- Automatically applying a retention label policy based on a condition
- Communication compliance supports Microsoft provided trainable classifiers only.
- Sensitivity label conditions. (See Automatically apply a sensitivity label to Microsoft 365 data)
- Data loss prevention

> ⓘ **Important**
>
> Classifiers only work with items that aren't encrypted.

Types of classifiers

- **Microsoft provided Pretrained classifiers** - Microsoft created and pretrained multiple classifiers that you can start using without training them. These classifiers appear with the status of `Ready to use`. These classifiers evaluate items in all languages listed in the suppported languages columns.
- **Custom trainable classifiers** - If you need to identify and categorize your content beyond what the pretrained classifiers cover, you can create and train your own classifiers.

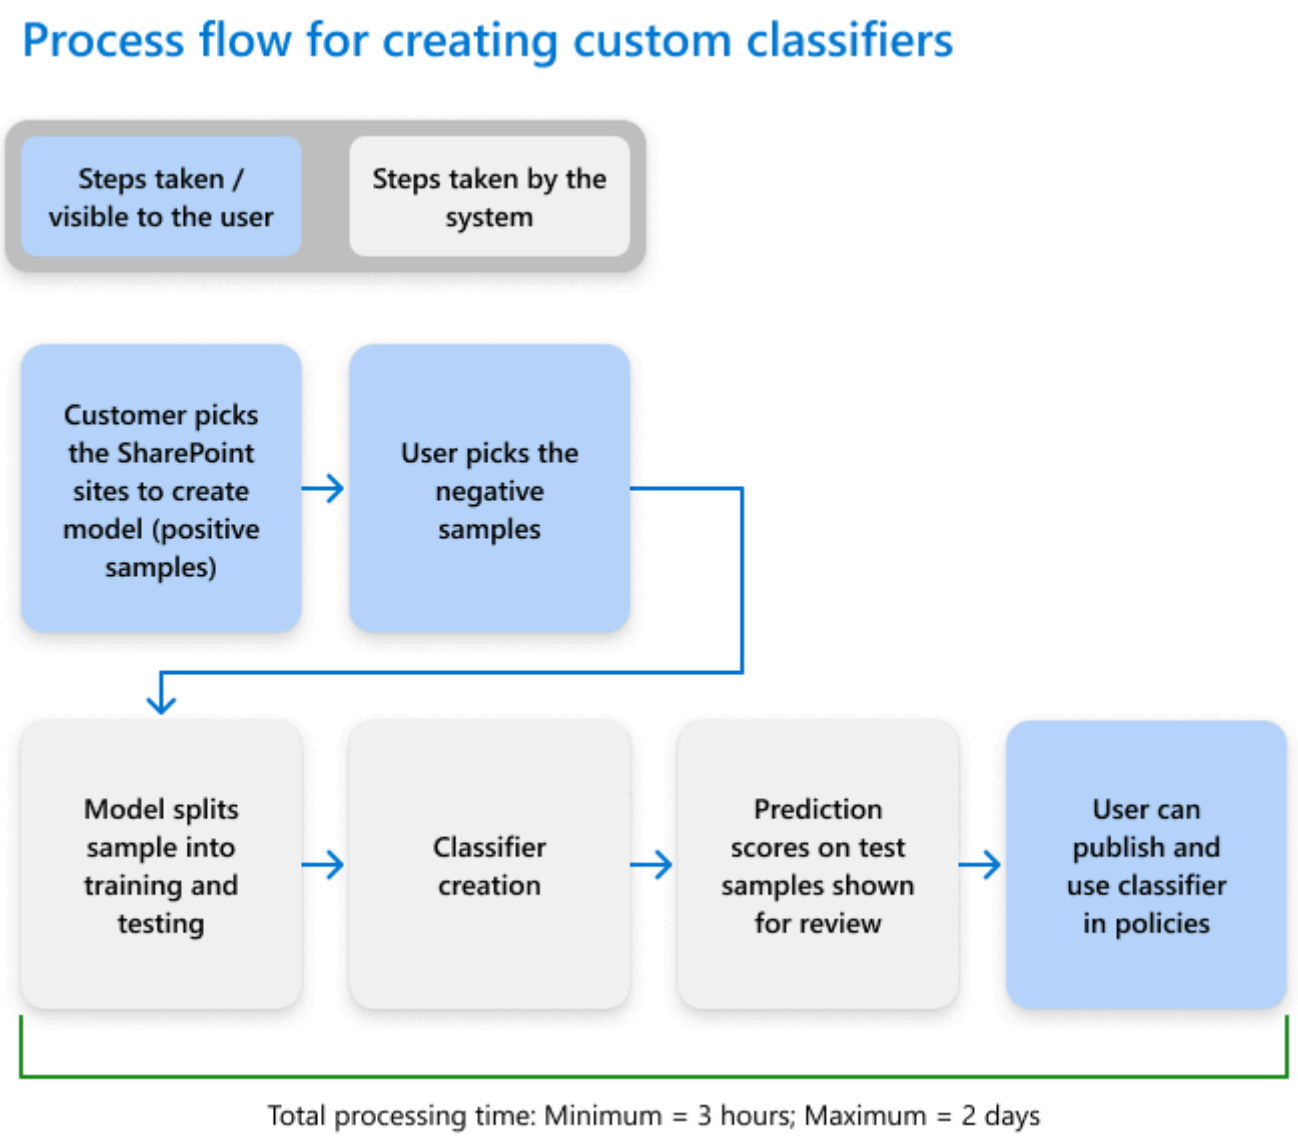
For a complete list of all pretrained classifiers, see Trainable classifiers definitions.

Custom classifiers

> **Important**
>
> **Language limitation:** Support for custom classifiers is limited to English.

When the Microsoft provided pretrained classifiers don't meet your needs, you can create and train your own classifiers. There's more work involved with creating your own, but they're better tailored to your organization's needs.

To create a custom trainable classifier, you start by feeding it one set of examples that are definitely in the category, and another set of examples that are definitely not in the category. Microsoft Purview processes those examples and the classifier then makes predictions as to whether any given item falls into the category you're building. You then confirm the results, sorting out the true positives, true negatives, false positives, and false negatives to help increase the accuracy of its predictions.



When you publish the classifier, it sorts through items in locations like SharePoint and Exchange, and classifies the content.

For example, you can create trainable classifiers for:

- Legal documents - such as attorney client privilege, closing sets, statement of work
- Strategic business documents - like press releases, merger and acquisition, deals, business or marketing plans, intellectual property, patents, design docs
- Pricing information - like invoices, price quotes, work orders, bidding documents
- Financial information - such as organizational investments, quarterly or annual results

Process flow for creating custom classifiers

The following flow diagram illustrates the process for creating and publishing a classifier for use in compliance solutions, such as retention policies and communication supervision. For more detail on creating a custom trainable classifier, see Get started with trainable classifiers.

> **Tip**
>
> If you create a new SharePoint site and folder for your seed data, allow at least an hour for that location to be indexed before creating the trainable classifier that uses that seed data.

Retraining classifiers

Retraining published custom classifiers isn't supported. If you need to improve the accuracy of a trainable classifier you published, remove the classifier and start over with larger sample sets.

To improve the accuracy of an unpublished classifier, review the test results, update the data set with additional data, and restart the training.

Get started with trainable classifiers

09/26/2025

A Microsoft Purview trainable classifier is a tool you can train to recognize various types of content by giving it samples to evaluate. Once trained, you can use it to identify items for application of Office sensitivity labels, Communications compliance policies, and retention label policies.

Implementing a custom trainable classifier requires two steps:

1. Provide two sets of sample data (selected by humans).
   a. A set that contains only items that belong in the category.
   b. A set that contains only items that **do not** belong in the category.
2. Test the classifier's ability to detect matches.

This article explains how to create and test a custom classifier.

For more information about the different types of classifiers, see Learn about trainable classifiers.

> **Important**
>
> Microsoft Purview Communication Compliance supports the use of the Microsoft provided trainable classifiers only. Custom trainable classifiers aren't supported.

Prerequisites

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions

To use classifiers in the following scenarios, you need the following permissions:

Expand table

Scenario	Required Role Permissions
Retention label policy	Record Management Retention Management
Sensitivity label policy	Security Administrator Compliance Administrator Compliance Data Administrator
Communication compliance policy	Insider Risk Management Administrator Supervisory Review Administrator

> **Important**
>
> By default, only the user who creates a custom classifier can train it and review predictions made by that classifier.

Prepare for a custom trainable classifier

Before you create a custom trainable classifier, it's helpful to understand what's involved.

Overall workflow

For more information about the overall workflow of creating custom trainable classifiers, see the process flow for creating custom trainable classifiers.

Seed content

To ensure that your trainable classifier can independently and accurately identify that an item belongs to a particular category of content, you must present it with many samples of the type of content that is in the category. This feeding of samples to the trainable classifier is known as *seeding*. A human must select the seed content, and that content must include two sets of data: one set contains only items that strongly represent the content the classifier is designed to detect (positive samples) and a second set contains items that clearly don't belong (negative samples).

You need at least 50 positive samples (up to 500) and at least 150 negative samples (up to 1,500) to train a classifier. The more samples you provide, the more accurate the predictions the classifier makes will be. The trainable classifier processes up to the 2,000 most recently created samples (by file created date/time stamp).

> **Tip**
>
> For best results, have at least 200 items in your test sample set that includes at least 50 positive examples and at least 150 negative examples.

How to create a trainable classifier

In preview: The following process automates the testing of trainable classifiers and shortens the creation workflow from 12 days to two days. In some cases, the process can take only a few hours.

1. Collect between 50 and 500 seed content items that strongly represent the data you want the classifier to positively identify as being in the category. For a list of supported file types, see Default crawled file name extensions and parsed file types in SharePoint Server.

2. Collect a *second* set of seed content (from 150 to 1,500 items) that represents data that **don't** belong in the category.

3. Place the positive and negative seed content in separate SharePoint folders. Each folder must be dedicated to holding *only the seed content*. Make note of the site, library, and folder URL for each set.

   > **Tip**
   >
   > If you create a new SharePoint site and folder for your seed data, allow at least an hour for that location to be indexed before creating the trainable classifier that uses that seed data.

4. Sign in to the Microsoft Purview portal with either Compliance admin or Security admin role access and navigate to **Data loss prevention** > **Data classification** > **Classifiers**.

> **Important**
>
> The account you use must have access to the seed content folders in SharePoint.

1. Select the **Trainable classifiers** tab.

2. Select **Create trainable classifier**.

3. Add the source of your **positive** examples: select the SharePoint site, library, and folder URL for the seed content that the classifier should detect and then choose **Next**.

4. Add the source of your **negative** examples: select the SharePoint site, library, and folder URL for the seed content that the classifier should ignore and then choose **Next**.

5. Review the settings and select **Create trainable classifier**.

6. Within 24 hours or less, the trainable classifier processes the seed data and builds a prediction model. The classifier status is **In progress** while it processes the seed data. When the classifier finishes processing the seed data, the status changes to **Training is complete and items have been tested**.

7. When training completes and items are (automatically) tested, publish the classifier by choosing **Publish for use**.

After you publish your classifier, it's available as a condition in Office auto-labeling with sensitivity labels, autoapply retention label policy based on a condition, and in Communication compliance.

Test your classifier

After the trainable classifier processes enough positive and negative samples to build a prediction model, test the predictions it makes. When you test the classifier, you verify whether its predictions are correct. After the classifier processes all the data, you can go through the results to verify whether each prediction is correct, incorrect, or uncertain. Microsoft uses this feedback in aggregate to improve the prediction model.

Increase classifier accuracy

Classifiers, such as sensitive information types (SIT) and trainable classifiers, are used in various types of policies to identify sensitive information. Like most such models, sometimes they identify an item as being sensitive that isn't. Or, they may not identify an item as being sensitive when it actually is. These are called false positives and false negatives.

This article shows you how to confirm whether items matched by a classifier are true positives (a **Match**) or false positives (**Not a match**) and provide **Match**/**Not a match** feedback. You can use that feedback to tune your classifiers to increase accuracy. You can also send redacted versions of the document as well as the **Match**, **Not a Match** feedback to Microsoft if you want to help increase the accuracy of the classifiers that Microsoft provides.

The **Match**, **Not a match** and **Contextual Summary** experiences are available in:

- Data Explorer - for SharePoint sites, OneDrive sites
- Content Explorer - for SharePoint sites, OneDrive sites
- Sensitive Information Type Matched Items page - for SharePoint sites, OneDrive sites
- Trainable Classifier Matched Items page - for SharePoint sites, OneDrive sites
- Microsoft Purview Data Loss Prevention (DLP) Alerts page - for SharePoint sites, OneDrive, and emails in Exchange
- Microsoft Threat Protection (MTP) Alerts page - for SharePoint sites, OneDrive sites, and emails in Exchange

The standalone **Contextual Summary** capability is also available in the following location:

- Microsoft Purview Information Protection (MIP) Auto-labeling simulation matched items - for SharePoint sites, OneDrive sites

Supported classifiers and feedback capabilities

Expand table

Classifier	Contextual summary	Redacted preview panel	Match and Not a Match
SIT	Yes	Yes	Yes
Custom SIT	Yes	No	Yes
Fingerprint SIT	No	No	Yes

Classifier	Contextual summary	Redacted preview panel	Match and Not a Match
Exact data match SIT	No*	No	No
Named entities	No*	No	No
Credential scan	No	No	No
Built-in Trainable classifiers	Yes **	Yes	Yes
Custom trainable classifier	No	No	Yes

* These classifiers are supported in MIP Auto-labeling simulation matched items - for SharePoint sites and OneDrive sites.

** List of Built-in Trainable classifiers and which support contextual summary.

> **Important**
>
> The match/not a match feedback and contextual summary experience support items in: SharePoint sites & OneDrive sites - for Content Explorer, Sensitive Information Type and Trainable Classifier Matched Items, DLP Alerts and MTP Alerts. Emails in Exchange - for DLP Alerts and MTP Alerts. The contextual summary experience supports items in: SharePoint sites and OneDrive sites - for MIP simulation matched items

Licensing requirements for classifier accuracy tuning

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Known limitations

The following limitations apply to the contextual summary and feedback experience:

- The contextual summary only shows a limited number of matches in any given item, not all matches.
- The contextual summary and feedback experience is only available for items created or updated after the feedback experience was enabled for the tenant. Items that were classified before the feature was enabled may not have the contextual summary and feedback experience available.

How to evaluate match accuracy and provide feedback

The contextual summary experience, where you indicate whether a matched item is a true positive (**Match**) or a false positive (**Not a match**), is similar in Content Explorer, Sensitive Information Type Matched Items, Trainable Classifier Matched Items, DLP Alerts, and MTP Alerts.

> **Important**
>
> You must have already deployed DLP policies that use either SITs or trainable classifiers to OneDrive sites, SharePoint sites, or Exchange mailboxes. You must also have had items match before any items appear in the **Contextual summary** page.

Using Content Explorer

This example shows you how to use the **Contextual Summary** tab to give feedback.

1. Sign in to the Microsoft Purview portal > **Solutions** > **Data Lifecycle Management** > **Explorers** > **Content explorer**.
2. Type the name of the SIT or trainable classifier that you want to check matches for in **Filter on labels, info types, or categories**.
3. Select the SIT.
4. Select the location and make sure that there's a non-zero value in the **Files** column. (The only supported locations are SharePoint and OneDrive.)
5. Open the folder and then select a document.
6. Select the link in the **Sensitive info type** column for the document to see which SITs the item matched and the confidence level.
7. Choose **Close**
8. Open a document and select the **Contextual Summary** tab.
9. Review the item and confirm whether or not it's a match.
10. If it's a match, choose **Close**. You're finished.
11. If it's not a match, choose **Not a match**.
12. If you make a mistake and chose the wrong option, select **Withdraw feedback** next to **Close**. This puts the item back into the **Not a match**/**Match** state.
13. Review the item and redact or un-redact any text.
14. Choose **Close**.

Using the Sensitive Information Type Matched Items page

You can access the same **Match**, **Not a match**, and **Contextual Summary** feedback options on the **Sensitive Info types** page.

1.Sign in to the Microsoft Purview portal > **Solutions** > **Data Lifecycle Management** > **Classifiers** > **Sensitive info types**.

1. In the **Search** field, enter the name of the SIT whose accuracy you want to check.
2. Open the SIT. This brings up **Overview** tab. Here you can see the count of the number of items that match, a count of the number of items that aren't a match, and the number of items with feedback.
3. Select the **Matched items** tab.
4. Open the folder and select a document. Only SharePoint, OneDrive are supported locations here. Make sure that there's a non-zero value in the **Files** column.
5. Select the link in the **Sensitive info type** column for an item to see which SITs the item matched and the confidence level.
6. Choose **Close**.
7. Open a document and then select the **Contextual Summary** tab.
8. Review the item and confirm whether it's a match.
9. If it's a match, choose **Match** and then **Close**.
10. If it isn't a match, choose **Not a Match**.
11. If you make a mistake and select the wrong option, select **Withdraw feedback** next to **Close**. This puts the item back into the **Not a match/Match** state.
12. Choose **Close**.

Using the Trainable Classifier Matched Items page

Use the Trainable Classifier Matched Items page to review matches and provide feedback:

1.Sign in to the Microsoft Purview portal > **Solutions** > **Data Lifecycle Management** > **Classifiers** > **Trainable classifiers**.

1. Select the trainable classifier whose accuracy you want to check.
2. Open the trainable classifier. This brings up **Overview** tab. Here you can see the count of the number of items that match, a count of the number of items that aren't a match, and the number of items with feedback.
3. Select the **Matched items** tab.
4. Open the folder and open a document. Only SharePoint, OneDrive are supported locations here. Make sure that there's a non-zero value in the **Files** column.
5. Open a document and then select the **Contextual Summary** tab.

6. Review the item and confirm whether it's a match.
7. If it's a match, choose **Match** and then choose **Close**.
8. If it isn't a match, choose **Not a Match**.
9. If you make a mistake and select the wrong option, choose **Withdraw feedback** next to **Close**. This puts the item back into the **Not a match/Match** state.
10. Choose **Close**.

Using the Data Loss Prevention Alerts page

Use a DLP alert to review the matched item and submit feedback:

1. Sign in to the Microsoft Purview portal > **Solutions** > **Data loss prevention** > **Alerts**.
2. Choose an alert.
3. Choose **View details**.
4. Choose the **Events** tab.
5. Maximize the **Details** tab.
6. Review the item and confirm whether it's a match.
7. Choose **Actions**.
8. If it's a match, close the window. You're finished.
9. If it's not a match, choose **Actions** and then **Not a match**.
10. Review the item and redact or un-redact any text.
11. Close the window.

Using the feedback to tune your classifiers

If your SITs or trainable classifiers are returning too many false positives based on the feedback, try some of these options to refine them and increase their accuracy.

Tune trainable classifiers with feedback

Retraining custom classifiers is no longer supported. If you need to improve the accuracy of the trainable classifiers you created, remove the classifier and begin fresh with larger sample sets. For more information, see Get started with trainable classifiers.

Tune sensitive information types with feedback

To improve sensitive information type accuracy, consider the following tuning options:

- Increase the thresholds of sensitive information types found to determine severity. It's okay to use different thresholds for individual classifiers.

- Understand confidence levels and how they're defined. Try using a low confidence with high instance count, or a higher confidence level with a low instance count.
- Clone and modify the built-in SITs to include other conditions, such as the presences of keywords, more stringent value matching, or stronger formatting requirements.
- Modify a custom SIT to exclude known prefixes, suffixes, or patterns. For example, a custom SIT to detect phone numbers might trigger for every email if your email signatures or document headers include phone numbers. Excluding your organization's phone number sequences from your custom SIT can prevent the rule from triggering for every email or document.
- Include more dictionary-based SITs as conditions to narrow down the matches to those items that talk about the relevant articles. For example, a rule for matching patient diagnostics may be enhanced by requiring the presence of words like diagnostic, diagnosis, condition, symptom, and patient.
- For named-entity SITs, like **All Full Names**, it's best to set a higher instance count threshold, like 10 or 50. If both the person names and the Social Security Numbers (SSNs) are detected together, it's more likely that the SSNs are truly SSNs, and we reduce the risk that the policy doesn't trigger because too few SSNs are detected.

Trainable classifiers definitions

Microsoft Purview comes with multiple pretrained classifiers. They appear in the **Microsoft Purview portal** > **Data classification** > **Trainable classifiers** view with the status of `Ready to use`.

All Microsoft provided classifiers evaluate items in all the languages listed in the Supported languages columns of the tables below. For more information on how to use trainable classifiers, see Learn about trainable classifiers.

> **Important**
>
> Built-in trainable and global classifiers don't provide an exhaustive or complete list of terms or language across these areas. Further, language and cultural standards continually change, and in light of these realities, Microsoft reserves the right to update these classifiers in its discretion. While classifiers can assist your organization in detecting these areas, classifiers are not intended to provide your organization's sole means of detecting or addressing the use of such language. Your organization, not Microsoft or its subsidiaries, remains responsible for all decisions related to monitoring, scanning, blocking, removal, and retention of any content identified by a pre-trained classifier, including compliance with local privacy and other applicable laws. Microsoft encourages consulting with legal counsel before deployment and use.

Actuary reports

Expand table

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
This classifier is used to identify reports prepared by an organization's actuary on the current and future conditions of funds, such as pension or insurance pools. These documents analyze the organization's loss experience using probability theory and statistical analysis to determine if the fund is on track to meet the needs of its dependents.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one	English	Yes

Adult, racy, and gory images

Expand table

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects images that are potentially inappropriate. Scanning and detection are supported for Exchange Online email messages, and Microsoft Teams channels and chats.	Detects content in .jpeg, .png, .gif, and .bmp files.	N/A	N/A

> **Note**
>
> Images must be between 100 kilobytes (KB) and 4 megabytes (MB) in size and be greater than 50 x 50 pixels in height x width dimensions.

Agreements

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects components of a business plan including business opportunity, plan of achieving the outcomes, market study, and competitor analysis.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .eml, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa files.	English	No

Completion certificates

Expand table

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects official documents that are issued at the end of a project or work by a project manager or a contractor. This document is used to testify that work on a particular project has been completed as per a contract or an agreement.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt files.	English	Yes

Compliance policies

Expand table

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Identifies confidential documentation across various major compliance policies, including GDPR, HIPAA, ISO, PCI, SOC, and SSAE 18 compliance.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .txt	English	Yes

Construction specifications

Expand table

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects construction specifications for commercial and industrial projects like factories, plants, commercial offices, airports, roads.	Captures guidelines on the quality, quantity, types of building material, processes, etc. Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa files.	English	Yes

Control system and SCADA files

Expand table

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Identifies documents that set the framework for approval, updates, amendments, change tracking, publication (internal or external), and version control. It also identifies Supervisory Control and Data Acquisition (SCADA) files.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .txt	English	Yes

Corporate sabotage

Expand table

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects messages that mention acts to damage or destroy corporate assets or property. This classifier can help customers manage regulatory compliance obligations such as NERC Critical Infrastructure Protection standards or state by state regulations like Chapter 9.05 RCW in Washington state.	Detects content in .msg, .docx, .pdf, .txt, .rtf, .jpeg, .jpg, .png, .gif, .bmp, .svg files.	English	Yes

> **Important**
>
> This classifier can capture a large volume of bulk sender/newsletter content. In Communication Compliance, you can mitigate the detection of large volumes of bulk sender/newsletter content by selecting the **Filter email blasts** check box when you create the policy. You can also edit an existing Communication Compliance policy to turn on this feature.

Credit report

Expand table

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Identifies statements that inform about an individual's or organization's credit activity and current credit situation. This includes loan payment history and the status of credit accounts. It must include a credit report or credit score.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml	English	Yes

Customer complaints

Expand table

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
The customer complaints classifier detects feedback and complaints made about your organization's products or services. This classifier can help you meet regulatory requirements on the detection and triage of complaints, like the Consumer Financial Protection Bureau and Food and Drug Administration requirements.	For Communications Compliance, it detects content in .msg, and .eml files. For the rest of Microsoft Purview Information Protection services, it detects content in .docx, .pdf, .txt, .rtf, .jpg, .jpeg, .png, .gif, .bmp, .svg files.	English	No

Customer files

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Identifies files related to customers, such as personal account files, account information files, grievance records, and feedback files.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa, .txt, .one, .msg, .eml	English	Yes

Discrimination

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects explicit discriminatory language and is sensitive to discriminatory language against the African American/Black communities when compared to other communities.	This applies to communications compliance, it's a text based classifier.	English	Yes

Employee disciplinary action

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects files relating to disciplinary action including a reprimand or corrective action in response to employee misconduct, rule violation, or poor performance.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml files.	English	Yes

Employee insurance

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects documents pertaining to employee medical insurance and workplace disability insurance.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa files.	English	Yes

Employment agreement

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects employment agreement containing details like the starting date, salary, compensation, duties of employment.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt files.	English	Yes

Employee pension records

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects documents that are related to employee's pension records such as claim forms, declaration forms, schemes, and benefit statement.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa, .txt, .one, .msg, .eml files.	English	Yes

Employee stocks and financial bond records

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects documents that are related stock and financial bonds award by organization to employees. Identifies employee stocks and financial bonds details that fall under employee's payroll. Contains details like bond clause, allocations, equity.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa, .txt, .one, .msg, .eml files.	English	Yes

Enterprise risk management

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Enterprise risk management includes financial risks, strategic risks, operational risks, and risks associated with accidental losses. This category consists of methods used by organizations to manage risks and seize opportunities related to the achievement of their objectives.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt files.	English	Yes

Environmental permits and clearances

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
This classifier is used to identify documents related to the procedure of obtaining clearance from the government for the installation and modification (amendment) of certain projects.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa, .eml	English	Yes

Facility permits

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Identifies permits that include permission to construct or operate a facility. These include authorizations, licenses, or equivalent control documents issued by the relevant authority.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .txt	English	Yes

Factory incident investigation reports

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
This classifier is used to identify formal recordings of facts related to workplace accidents, injuries, or near misses. These reports aim to uncover the circumstances and conditions that led to the event to prevent future incidents.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa, .txt, .one	English	Yes

Finance

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects content in corporate finance, accounting, economy, banking, and investment categories.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa, .xlsx, .xlsm, .xlsb, .xls, .csv, .xltx, .xltm, .xlt, .xlam, .xla files.	English	Yes

Financial audit

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects files, documents, and reports pertaining to financial audit, both external or internal audit undertaken in an organization.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml files.	English	Yes

Financial statement

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects financial statements like income statement, balance sheet, cash flow statement, statement of changes in equity.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .xlsx, .xlsm, .xlsb, .xls, .csv, .xltx, .xltm, .xlt, .xlam, .xla files.	English	Yes

Freight documents

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects documents that authorize the export or import of a good in a specific quantity from source to destination. This model categorizes different documents including Bill of Ladings, Certificate of Origin, Commercial Invoice, Export import customs declaration, Importer Security Filing (ISF).	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa, .txt, .one files.	English	Yes

Garnishment

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Identifies documents related to garnishment notices, records, and earnings attachments. It covers the legal process of withholding money from paychecks to be sent to another party.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one	English	Yes

Gifts & entertainment

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects messages that suggest exchanging gifts or entertainment in return for service, which violates regulations related to bribery. This classifier can help customers manage regulatory compliance obligations such as Foreign Corrupt Practices Act (FCPA), UK Bribery Act, and FINRA Rule 2320.	Detects content in .msg, .docx, .pdf, .txt, .rtf, .jpeg, .jpg, .png, .gif, .bmp, .svg files.	English	Yes

> **Important**
>
> This classifier can capture a large volume of bulk sender/newsletter content. In Communication Compliance, you can mitigate the detection of large volumes of bulk sender/newsletter content by selecting the **Filter email blasts** check box when you create the policy. You can also edit an existing Communication Compliance policy to turn on this feature.

Harassment

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects a specific category of offensive language text items related to offensive conduct targeting one or multiple individuals based on the following traits: race, ethnicity, religion, national origin, gender, sexual orientation, age, disability.	Detects content in .msg, .docx, .pdf, .txt, .rtf, .jpeg, .jpg, .png, .gif, .bmp, .svg files.	- Arabic - Chinese (Simplified) - Chinese (Traditional) - Dutch - English - French - German - Italian - Korean - Japanese - Portuguese - Spanish	Yes (English)

Health/Medical forms

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects various forms and files that are used for systematic documentation of a patient's admission details, medical history, patient information, and prior authorization request and are typically used in medical/health services.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa files.	English	Yes

Healthcare

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects content in medical and healthcare administration aspects such as medical services, diagnoses, treatment, claims, etc.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa, .xlsx, .xlsm, .xlsb, .xls, .csv, .xltx, .xltm, .xlt, .xlam, .xla files.	English	Yes

Human resources

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects content in human resources related categories of recruitment, interviewing, hiring, training, evaluating, warning, and termination.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa, .xlsx, .xlsm, .xlsb, .xls, .csv, .xltx, .xltm, .xlt, .xlam, .xla files.	English	Yes

Invoice

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects invoices containing an itemized summary of the purchase, the total balance owed, current payment due, and various payment methods.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .eml, .xlsx, .xlsm, .xlsb, .xls, .csv, .xltx, .xltm, .xlt, .xlam, .xla files.	English	Yes

Intellectual property

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects content in intellectual property related categories such as trade secrets and similar confidential information.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa, .xlsx, .xlsm, .xlsb, .xls, .csv, .xltx, .xltm, .xlt, .xlam, .xla files.	English	Yes

Information technology

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects content in information technology and cybersecurity categories such as network settings, information security, hardware, and software.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa, .xlsx, .xlsm, .xlsb, .xls, .csv, .xltx, .xltm, .xlt, .xlam, .xla files.	English	Yes

IT infra and network security documents

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Identifies documents that outline rules for computer network access, policy enforcement, and basic architecture of a company's security or network security environment. It also covers documents related to access control, data security, storage policy, and maintenance plans.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa		
English	Yes		

Lease deeds

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
This classifier is used to identify documents detailing lease information such as period, amount, and agreements. It includes facility, factory, and real estate lease deeds, as well as responsibilities of the lessor and lessee, deposits, due dates, and consequences of lease violations.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa	English	Yes

Legal affairs

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects content in legal affairs-related categories such as litigation, legal process, legal obligation, legal terminology, law, and legislation.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml files.	English	Yes

Legal agreements

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects various legally binding documents/ contracts/ agreements like Arbitration agreements, Power of Attorney, Purchase Agreements between two parties.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .txt files.	English	Yes

Letters of credit

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Identifies documents sent from banks or financial institutions that guarantee a seller will receive a buyer's payment on time and for the full amount.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa, .txt, .one	English	Yes

License agreement

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects license agreements, contains terms and conditions for use and compensation for the licensor.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt files.	English	Yes

Loan agreements and offer letters

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects loan agreements, offer letters, and terms and conditions contained within the document.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml files.	English	Yes

Manufacturing batch records

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects manufacturing batch documents that include details around the entire manufacturing process and the history of a product batch.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml files.	English	Yes

Marketing collaterals

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
This classifier is used to identify various marketing materials utilized by organizations for outreach. This includes battle cards, fact sheets, product brochures, product launch materials, press releases, and product catalogs.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .txt	English	Yes

Merger and acquisition files

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects documents including letter of intent, term sheets, and related files.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml files.	English	Yes

Meeting notes

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects documents and notes containing information specific to meetings.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa files.	English	Yes

Money laundering

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects signs that suggest money laundering or engagement in acts to conceal or disguise the origin or destination of proceeds. This classifier helps customers manage regulatory compliance obligations such as the Bank Secrecy Act, the USA Patriot Act, FINRA Rule 3310, and Anti-Money Laundering Act of 2020.	Detects content in .msg, .docx, .pdf, .txt, .rtf, .jpeg, .jpg, .png, .gif, .bmp, .svg files.	English	Yes

> **Important**
>
> This classifier can capture a large volume of bulk sender/newsletter content. In Communication Compliance, you can mitigate the detection of large volumes of bulk sender/newsletter content by selecting the **Filter email blasts** check box when you create the policy. You can also edit an existing Communication Compliance policy to turn on this feature.

MoU files (Memorandum of understanding)

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Identifies documents related to memoranda of understanding, annexures, corrigenda, and addenda. These documents are typically not legally binding.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa	English	Yes

Network design files

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects technical documentation about networks of computers. This includes various components of network, how they're connected, their architecture, how they perform, and where they troubleshoot.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa files.	English	Yes

Non-disclosure agreement

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects nondisclosure agreements (NDAs).	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt files.	English	Yes

OSHA records

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Identifies Occupational Safety and Health Administration (OSHA) recordkeeping forms. This includes the Log of Work-Related Injuries and Illnesses (OSHA Form 300), Summary of Work-Related Injuries and Illnesses (OSHA Form 300A), and the Injury and Illness Incident Report (OSHA Form 301).	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa, .txt, .one	English	Yes

Paystub

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects paystub/salary statement files.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .xlsx, .xlsm, .xlsb, .xls, .csv, .xltx, .xltm, .xlt, .xlam, .xla files.	English	Yes

Personal financial information

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects documents related to different personal financial records consisting of financial statements, real estate planning, and retirement plans. Consists of details of all assets and liabilities held by an individual.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .txt, .one files.	English	Yes

Procurement

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects content in categories of bidding, quoting, purchasing, and paying for supply of goods and services.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml, .xlsx, .xlsm, .xlsb, .xls, .csv, .xltx, .xltm, .xlt, .xlam, .xla files.	English	No

Project documents

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects project reports and documents, which include project planning documents, project charter documents and schedules.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa files.	English	Yes

Profanity

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects a specific category of offensive language text items that contain expressions that embarrass most people.	Detects content in .msg, .docx, .pdf, .txt, .rtf, .jpeg, .jpg, .png, .gif, .bmp, .svg files.	- Arabic - Chinese (Simplified) - Chinese (Traditional) - Dutch - English - French - German - Italian - Korean - Japanese - Portuguese - Spanish	Yes (English)

Prompt Shields

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects adversarial user input attacks such as user prompt injection attacks (jailbreak). User prompt injection attacks will deliberately exploit system vulnerabilities to elicit unauthorized behavior from the LLM.	Generative AI prompts	English	No

> **Note**
>
> This classifier can be configured in Communication Compliance and evaluates generative AI prompts ONLY

Protected material

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects known text content that may be protected under copyright or branding laws. Detecting the display of protected material in generative AI responses ensures compliance with intellectual property laws and maintains content originality	Generative AI responses	English	No

> **Note**
>
> This classifier can be configured in Communication Compliance and evaluates generative AI responses ONLY

Quotation

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects documents that offer to sell goods or services for a set price, based on certain conditions. It contains a description of the goods or services, the price of the goods or rate of the service, the quantity, and a total cost.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .eml, .xlsx, .xlsm, .xlsb, .xls, .csv, .xltx, .xltm, .xlt, .xlam, .xla files.	English	Yes

Regulatory collusion

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects messages that can violate regulatory anti-collusion requirements such as an attempted concealment of sensitive information. This classifier can help customers manage regulatory compliance obligations such as the Sherman Antitrust Act, Securities Exchange Act 1933, Securities Exchange Act of 1934, Investment Advisers Act of 1940, Federal Commission Act, and Robinson-Patman Act.	Detects content in .msg, .docx, .pdf, .txt, .rtf, .jpeg, .jpg, .png, .gif, .bmp, .svg files.	English	No

> **Important**
>
> This classifier can capture a large volume of bulk sender/newsletter content. In Communication Compliance, you can mitigate the detection of large volumes of bulk sender/newsletter content by selecting the **Filter email blasts** check box when you create the policy. You can also edit an existing Communication Compliance policy to turn on this feature.

Resume

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects a resume document that a job applicant provides an employer, which has a detailed statement of the candidate's prior work experience, education, and accomplishments.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .txt files.	English	Yes

Safety records

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects documents that are related to facility/factory safety. These documents can be facility safety plan, safety assessments and audit reports, emergency response and evacuation plan, and equipment's inspection reports concerning safety measurements.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa, .txt, .one, .eml files.	English	Yes

Sales and revenue

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects sales reports, revenue/income statement and sales/demand forecasting reports for organizations.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa files.	English	Yes

Software product development files

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects files used in software development; including product requirements document, product testing and planning, files including test cases, and test reports.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml files.	English	Yes

Source code

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects items that contain a set of instructions and statements written computer programming languages on GitHub: ActionScript, C, C#, C++, Clojure, CoffeeScript, Go, Haskell, Java, JavaScript, Lua, MATLAB, Objective-C, Perl, PHP, Python, R, Ruby, Scala, Shell, Swift, TeX, Vim Script.	Detects content in .c, .h, .w, .cs, .cake, .csx, .cpp, .c++, .cc, .cp, .cxx, .hh, .hpp, .hxx, .java, .js, .m, .matlab, .pl, .perl, .pm, .prl, .ipb, .php, .php3, .php4, .php5, .py, .pyc, .pyo, .r, .rl, .rb, .irb, .swift, .as, .clj, .cljs, .cljc, .coffee, .Go, .hs, .hsc, .lua, .lub, .m, .mm, .scala, .sca, .Tex,T, .xs, . sh, .vim, .edn, .javac, .lhs, .mjs, .pod, .r, .rda, .RData, .rds, .rb, .bash, .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .eml, .msg, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa, .xlsx, .xlsm, .xlsb, .xls, .csv, .xltx, .xltm, .xlt, .xlam, .xla, .sc, .litcoffee files.	N/A	No

> **Note**
>
> Source code is trained to detect when the bulk of the text is source code. It doesn't detect source code text that is interspersed with plain text.

Standard operating procedures and manuals

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects sets of documented instructions created to help workers perform routine operations or manufacturing tasks.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt files.	English	Yes

Statement of accounts

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
A statement of account is a detailed report of the contents of an account. Identifies documents related to statement of accounts, accounts payable, and accounts receivable.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .xlsx, .xlsm, .xlsb, .xls, .csv, .xltx, .xltm, .xlt, .xlam, .xla files.	English	Yes

Statement of work

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects statement of work (SOW) containing details like requirements, responsibilities, terms and conditions for both parties.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt files.	English	Yes

Stock manipulation

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects signs of possible stock manipulation, such as recommendations to buy, sell, or hold stocks that can suggest an attempt to manipulate the stock price. This classifier can help customers manage regulatory	Detects content in .msg, .docx, .pdf, .txt, .rtf, .jpeg, .jpg, .png,	English	Yes

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
compliance obligations such as the Securities Exchange Act of 1934, FINRA Rule 2372, and FINRA Rule 5270.	.gif, .bmp, .svg files.		

> **Important**
>
> This classifier can capture a large volume of bulk sender/newsletter content. In Communication Compliance, you can mitigate the detection of large volumes of bulk sender/newsletter content by selecting the **Filter email blasts** check box when you create the policy. You can also edit an existing Communication Compliance policy to turn on this feature.

Tax documents

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects tax related content such as tax planning, tax forms, tax filing, tax regulations.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt, .one, .msg, .eml, .pptx, .pptm, .ppt, .potx, .potm, .pot, .ppsx, .ppsm, .pps, .ppam, .ppa, .xlsx, .xlsm, .xlsb, .xls, .csv, .xltx, .xltm, .xlt, .xlam, xla files.	English	Yes

Threat

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects a specific category of offensive language text items related to threats to commit violence or do physical harm or damage to a person or property.	Detects content in .msg, .docx, .pdf, .txt, .rtf, .jpeg, .jpg, .png, .gif, .bmp, .svg files.	- Arabic - Chinese (Simplified) - Chinese	Yes (English)

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
		(Traditional) - Dutch - English - French - German - Italian - Korean - Japanese - Portuguese - Spanish	

Unauthorized disclosure

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Detects sharing of information containing content that is explicitly designated as confidential or internal to unauthorized individuals. This classifier can help customers manage regulatory compliance obligations such as FINRA Rule 2010 and SEC Rule 10b-5.	Detects content in .msg, .docx, .pdf, .txt, .rtf, .jpeg, .jpg, .png, .gif, .bmp, .svg files.	English	Yes

> **Important**
>
> This classifier can capture a large volume of bulk sender/newsletter content. In Communication Compliance, you can mitigate the detection of large volumes of bulk sender/newsletter content by selecting the **Filter email blasts** check box when you create the policy. You can also edit an existing Communication Compliance policy to turn on this feature.

Wire transfer

Description	File types	Supported Languages	Contextual summary and keyword highlighting summary
Wire transfer is a method of electronic funds transfer from one person or entity to another. The model captures all the wire transfer receipts and acknowledgments.	Detects content in .docx, .docm, .doc, .dotx, .dotm, .dot, .pdf, .rtf, .txt files.	English	Yes

Word count requirements

Pretrained classifiers require documents to contain at least 200 words for classification. Documents with fewer than 200 words aren't classified by these classifiers. This minimum doesn't apply to custom trainable classifiers during training or classification.

Communication compliance classifiers have separate minimum word count requirements for messages, as listed in the following table. To identify and take action on messages below the listed minimums, create a custom keyword dictionary for communication compliance policies that detect inappropriate language.

Classifier	Minimum word count	Language
Threat, Harassment, and Profanity	Six words	- Dutch - French - German - Italian - Japanese - Portuguese - Spanish
Threat, Harassment, and Profanity	12 words	- Arabic - Chinese Simplified - Chinese Traditional - Korean
Threat and Harassment	Three words	English
Profanity	Five words	English
Corporate sabotage - Customer complaints - Gifts & entertainment - Money laundering - Regulatory collusion	Six words	English

Classifier	Minimum word count	Language
- Stock manipulation - Unauthorized disclosure

All credentials sensitive information types

"All credentials" is a bundled-entity sensitive information type (SIT). It detects credentials from all supported services and environments, which include Amazon, Azure, GitHub, Google, Microsoft general, Slack and more.

> **Important**
>
> Because the **All Credetials** SIT is a bundled SIT, it ***does not*** contain any keywords. The keywords that it detects are based on the individual SITs it contains. Refer to the individual SITs for keyword information.

For information about implementing bundled SITs, see Learn about named entities.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a bundled SIT in an endpoint DLP policy. This requirement is specific to the combination of bundled SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

Various

Pattern

Various

Checksum

No

Keyword Highlighting

Not supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Description

The All credentials SIT is a bundled SIT that scans for individual credential types. This includes checksum evaluated values and keyword/pattern combinations. The All credential entity scans for any of the underlying credential information type checksums and/or patterns are detected in a document.

Contains

This bundled entity SIT contains these individual SITs:

- Amazon S3 Client Secret Access Key
- ASP.NET Machine Key
- Microsoft Entra Client Access Token
- Microsoft Entra Client Secret
- Microsoft Entra user Credentials
- Azure App Service Deployment Password
- Azure Batch Shared Access Key
- Azure Bot Framework Secret Key
- Azure Bot Service App Secret
- Azure Cognitive Search API Key
- Azure Cognitive Service Key
- Azure Container Registry Access Key

Document fingerprinting

Article • 03/31/2025

Document fingerprinting is a Microsoft Purview feature that takes a standard form that you provide and creates a sensitive information type (SIT) based on that form. Document fingerprinting makes it easier for you to protect sensitive information by identifying standard forms that are used throughout your organization. This article describes the concepts behind document fingerprinting and how to create a document fingerprint using the user interface or using PowerShell.

Document fingerprinting includes the following benefits:

- SITs created from document fingerprinting can be used as a detection method in DLP policies scoped to Exchange, SharePoint, OneDrive, Teams, and Devices.
- MIP auto-labeling can use document fingerprinting as a detection method in Exchange, SharePoint, and OneDrive.
- Document fingerprint features can be managed through the Microsoft Purview user interface.
- Partial matching is supported.
- Exact matching is supported.
- Improved detection accuracy
- Support for detection in multiple languages, including dual-byte languages such as Chinese, Japanese, and Korean.

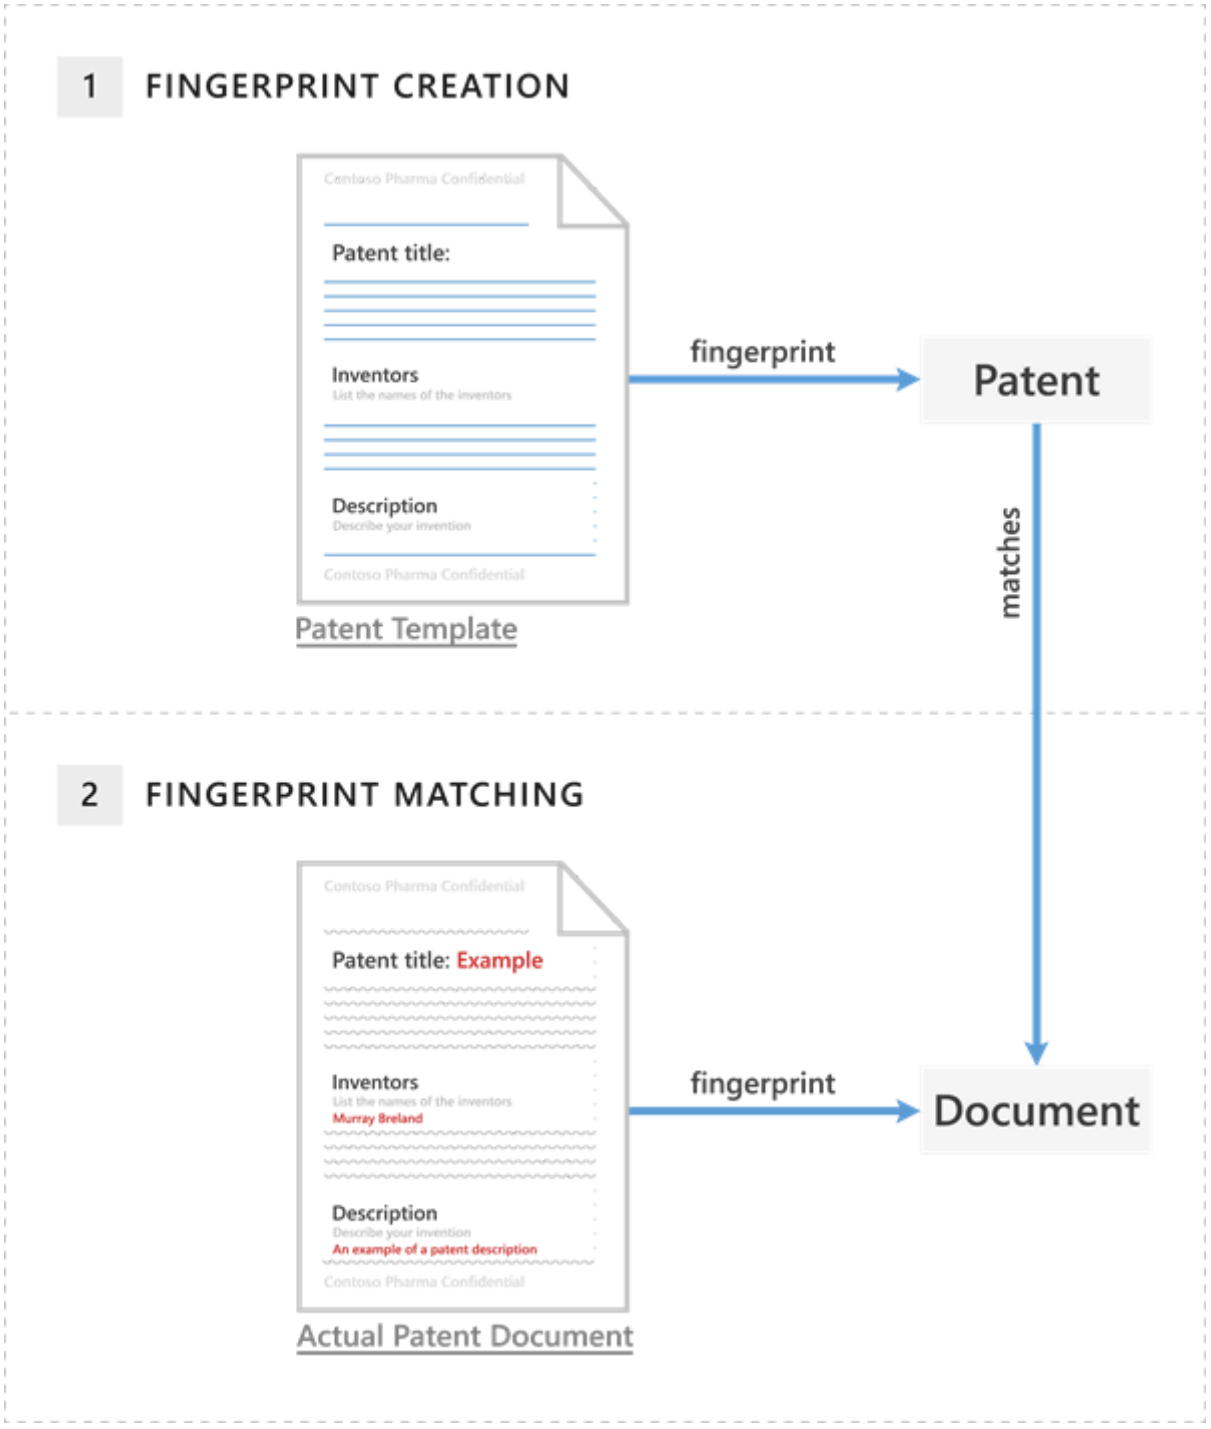
> **Important**
>
> If you are an E5 customer, we recommend updating your existing fingerprints to take advantage of the full document fingerprint feature set. If you are an E3 customer, we recommend upgrading to an E5 license. If you choose not to, you won't be able to modify existing fingerprints or create new ones after April, 2023.

Basic scenario for document fingerprinting

As mentioned, the document fingerprinting feature converts a standard form of information into a sensitive information type (SIT), which you can use in the rules of your DLP policies. For example, you can create a document fingerprint based on a blank patent template and then create a DLP policy that detects and blocks all outgoing patent templates with sensitive content filled in. Optionally, you can set up policy tips to notify senders that they might be sending sensitive information, and that the sender

should verify that the recipients are qualified to receive the patents. This process works with any text-based forms used in your organization. Other examples of forms that you can upload include:

- Government forms
- Health Insurance Portability and Accountability Act (HIPAA) compliance forms
- Employee information forms for Human Resources departments
- Custom forms created specifically for your organization



Ideally, your organization already has an established business practice of using certain forms to transmit sensitive information. To enable detection, upload an empty form to be converted to a document fingerprint. Next, set up a corresponding policy. Once you complete these steps, DLP detects any documents in outbound mail that match that fingerprint.

For more information on designing a DLP policy, see Design a data loss prevention policy.

For more informaiton on creating and deploying a DLP policy, see Create and Deploy data loss prevention policies.

How document fingerprinting works

You know documents don't have actual fingerprints, but the name helps explain the feature. In the same way a person's fingerprints have unique patterns, frequently used forms (templates) can have patterns of words that are unique to them. You can use the SIT that's based on this pattern to detect files that were created using the same template. This is why uploading a form or template creates the most effective type of document fingerprint. Everyone who fills out a form uses the same original set of words and then adds their own words to the document. Documents to be scanned can't be password protected and must contain all the text from the original form.

The patent template contains the blank fields **Patent title**, **Inventors**, and **Description**, along with descriptions for each of those fields — that's the word pattern. When you upload the original patent template, it's in one of the supported file types and in plain text. MIcrosoft Purview converts this word pattern into a document fingerprint, which is a small Unicode XML file containing a unique hash value that represents the original text. As a security measure, the original document itself isn't stored; only the hash value is stored. The original document can't be reconstructed from the hash value. The patent fingerprint is represented in a SIT that you can use as a condition in a DLP policy.

For example, if you set up a DLP policy that prevents regular employees from sending outgoing messages containing patents, DLP uses the patent fingerprint SIT to detect patents and block those emails. Alternatively, you might want to let your legal

department be able to send patents to other organizations because it has a business need for doing so. To allow specific departments to send sensitive information, create exceptions for those departments in your DLP policy. Alternatively, you can allow them to override a policy tip with a business justification.

> **Important**
>
> Text in embedded documents is not considered for fingerprint creation. You need to provide sample template files that don't contain embedded documents.

Limitations of document fingerprinting

Document fingerprinting doesn't detect sensitive information in the following cases:

- Password protected files
- Files that contain images only
- Documents that don't contain all the text from the original form used to create the document fingerprint
- Files larger than 4 MB

> **Note**
>
> To use document fingerprinting with devices, Advanced classification scanning and protection must be turned on.

Fingerprints are stored in a separate rule pack. This rule pack has a maximum size limit of 300 KB. Given this limit, you can create approximately 100 fingerprints per tenant.

> **Note**
>
> The template used to create a fingerprint should have at least 256 characters. The supported extracted text length for the fingerprint template must be between 256 and 204,800 characters.

The following examples show what happens if you create a document fingerprint based on a patent template. However, you can use any form as a basis for creating a document fingerprint.

Example: Create a patent document that matches the document fingerprint of a patent template

1. In the Microsoft Purview portal, navigate to **Data Loss Prevention** or **Information Protection** > **Classifiers** > **Sensitive info types**.
2. On the **Sensitive info types** page, choose **+ Create Fingerprint based SIT**.
3. Enter a name and description for your new SIT.
4. Upload the file you wish to use as the fingerprint template.
5. OPTIONAL: Adjust the requirements for each confidence level. (For more information, see Partial matching and Exact matching.)
6. Choose **Next**.
7. Review your settings and then choose **Create**.
8. When the confirmation page displays, choose **Done**.

PowerShell example of a patent document matching a document fingerprint of a patent template

PowerShell

```
>> $Patent_Form = ([System.IO.File]::ReadAllBytes('C:\My
Documents\patent.docx'))

>> New-DlpSensitiveInformationType -Name "Patent SIT" -FileData $Patent_Form
-ThresholdConfig @{low=40;medium=60;high=80} -IsExact $false -Description
"Contoso Patent Template"
```

Partial matching

To configure partial matching of a document fingerprint, when you are setting the configuration options during template upload, set the confidence level, choose **Low**, **Medium**, or **High**, and designate how much of the text in the file must match the fingerprint in terms of a percentage between 30% - 90%.

A high confidence level returns the fewest false positives but might result in more false negatives. Low or medium confidence levels return more false positives but few to zero false negatives.

- **low confidence**: Matched items contain the fewest false negatives but the most false positives. Low confidence returns all low, medium, and high confidence matches.
- **medium confidence**: Matched items contain an average number of false positives and false negatives. Medium confidence returns all medium, and high confidence

matches.

- **high confidence**: Matched items contain the fewest false positives but the most false negatives.

Exact matching

To configure exact matching of a document fingerprint, select **Exact** as the value for the high confidence level. When you set the high confidence level to **Exact**, only files that have exactly the same text as the fingerprint are detected. If the file has even a small deviation from the fingerprint, it won't be detected.

Already using fingerprint SITs?

Your existing fingerprints and policies/rules for those fingerprints should continue to work. If you don't want to use the latest fingerprint features, you don't have to do anything.

If you have an E5 license and want to use the latest fingerprint features, you have 2 choices:

- Create a new fingerprint.
- migrate a policy to the newer version.

> ⓘ **Note**
>
> Creating new fingerprints using the templates on which a fingerprint already exists is not supported.

Create a custom sensitive information type based on document fingerprinting using PowerShell

Currently, you can create a document fingerprint only in Security & Compliance PowerShell.

To create a custom SIT based on a document fingerprint, use the **New-DlpSensitiveInformationType** cmdlet. The following example creates a new document fingerprint named “Contoso Customer Confidential” based on the file C:\My Documents\Contoso Customer Form.docx.

PowerShell

```
$Employee_Form = ([System.IO.File]::ReadAllBytes('C:\My Documents\Contoso
Customer Form.docx'))

New-DlpSensitiveInformationType -Name "Contoso Customer Confidential" -
FileData $Employee_Form -ThresholdConfig @{low=40;medium=60;high=80} -
IsExact $false -Description "Message contains Contoso customer information."
```

Finally, add the "Contoso Customer Confidential" sensitive information type to a DLP policy in the Microsoft Purview portal. This example adds a rule to an existing DLP policy, named "ConfidentialPolicy".

PowerShell

```
New-DlpComplianceRule -Name "ContosoConfidentialRule" -Policy
"ConfidentialPolicy" -ContentContainsSensitiveInformation @{Name="Contoso
Customer Confidential"} -BlockAccess $True
```

You can also use the Fingerprint SIT in mail flow rules in Exchange, as shown in the following example. To run this command, you first need to connect to Exchange PowerShell. Also, note that it takes time for the SITs to sync with the Exchange admin center.

PowerShell

```
New-TransportRule -Name "Notify :External Recipient Contoso confidential" -
NotifySender NotifyOnly -Mode Enforce -SentToScope NotInOrganization -
MessageContainsDataClassification @{Name=" Contoso Customer Confidential"}
```

DLP can now detect documents that match the Contoso Customer Form.docx document fingerprint.

For syntax and parameter information, see:

- New-DlpFingerprint
- New-DlpSensitiveInformationType
- Remove-DlpSensitiveInformationType
- Set-DlpSensitiveInformationType
- Get-DlpSensitiveInformationType

Edit, test, or delete a document fingerprint

To do this in the Microsoft Purview portal, open the fingerprint SIT you want to edit, test, or delete and choose the appropriate icon.

To do this via PowerShell, run the following commands:

Edit a document fingerprint

```
PowerShell

>> Set-DlpSensitiveInformationType -Name "Fingerprint SIT" -FileData
([System.IO.File]::ReadAllBytes('C:\My Documents\file1.docx')) -
ThresholdConfig @{low=30;medium=50;high=80} -IsExact $false-Description "A
friendly Description"
```

Test a document fingerprint

```
PowerShell

>> $r = Test-DataClassification -TextToClassify "Credit card information
Visa: 4485 3647 3952 7352. Patient Identifier or SSN: 452-12-1232"
>> $r.ClassificationResults
```

Delete a document fingerprint

```
PowerShell

>> Remove-DlpSensitiveInformationType "Fingerprint SIT"
```

Migrate an existing fingerprint SIT to a via the Microsoft Purview Portal

1. Open the Microsoft Purview portal > **Information Protection** > **Classifiers** > **Sensitive info types**.
2. Open the SIT containing the fingerprint that you want to migrate.
3. Choose **Edit**.
4. Upload the same fingerprint file again.
5. Review the fingerprint settings > **Done**.

Migrate a fingerprint using PowerShell

Enter the following command:

```PowerShell
Set-DlpSensitiveInformationType -Name "Old Fingerprint" -FileData
([System.IO.File]::ReadAllBytes('C:\My Documents\file1.docx')) -
ThresholdConfig @{low=30;medium=50;high=80} -IsExact $false-Description "A
friendly Description"
```

Learn about optical character recognition in Microsoft Purview

By using optical character recognition (OCR) scanning, Microsoft Purview can scan images for sensitive information. OCR scanning is an optional feature that you must enable at the tenant level. After you enable it, select the locations where you want to scan images. You can scan images in Exchange, SharePoint, OneDrive, Teams, Windows, and macOS devices. When you configure the OCR settings, Microsoft Purview applies your existing policies for data loss prevention (DLP), records management, and insider risk management (IRM) to images and text-based content. For example, if you configure the DLP condition *content contains sensitive information* and include a data classifier such as the **Credit Card** sensitive information type (SIT), Microsoft Purview scans for credit card numbers in both text and images at all of the chosen locations.

Workflow at a glance

Expand table

Phase	What's needed
Create Azure subscription if needed	If your organization doesn't already have an Azure pay-as-you-go subscription for your tenant, your Global admin needs to start by creating an Azure account.
Estimate your OCR scanning charges	Use the OCR cost estimator to estimate the expected charges for your specific use cases.
Set up pay-as-you-go billing to enable OCR.	Your Global or SharePoint admin must follow the instructions in Set up Microsoft Syntex billing in Azure to add a subscription for OCR.
Configure OCR scanning settings	The Compliance admin for your organization configures the OCR settings for your tenant.

Prerequisites

To use OCR scanning, your organization's Global admin needs to verify that an Azure pay-as-you-go subscription is in place. If not, they need to set up the subscription by following the instructions in Create your initial Azure subscriptions.

Configure billing

When you enable OCR, all sensitive information types and trainable classifiers can detect characters that are in images.

Because it's an optional feature, your Global admin must set up pay-as-you-go billing to enable OCR. Refer to the instructions in Set up Microsoft Syntex billing in Azure to add a subscription for OCR.

> **Note**
>
> After you enter billing information in Microsoft Syntex, your Compliance admin can configure OCR in Microsoft Purview without any extra setup or licensing requirements.
>
> You can find OCR pay-as-you-go pricing information on the Set up Microsoft Syntex billing in Azure page.

Estimate your OCR scanning charges

Each image scanned counts as one transaction. This pricing means that stand-alone images (JPEG, JPG, PNG, BMP, or TIFF) each count as a single transaction. It also means that *each page* in a PDF file is charged separately. For example, if there are 10 pages in a PDF file, an OCR scan of the PDF file counts as 10 separate scans. For information on using the OCR cost estimator, see Estimate your OCR costs.

> **Note**
>
> To reduce your OCR costs, the service uses the following caching mechanisms: Small images, such as logos and signatures that are sent in email via Microsoft Exchange, are scanned and billed only once per unique image across all users of the tenant for a moving window of five days. For Endpoint, the cache is maintained for 30 days. Caching is local to each endpoint device and only classifiers identified on the image and image hash are stored. Customer data isn't stored. There's no caching mechanism for standalone images in SharePoint and OneDrive. However, in embedded file types, if only text is updated, images aren't scanned again.
>
> The service checks multiple parameters, including image stream hash and image size, to see if it can use the cache. If any parameter doesn't match, the service OCRs the image again.

Additionally, you can use each scanned image in any number of policies across data loss prevention, insider risk management, auto-labeling, and records management at no extra charge.

> **Important**
>
> For information about the Adobe requirements for using Microsoft Purview Data Loss Prevention (DLP) features with PDF files, see this article from Adobe: Microsoft Purview Information Protection Support in Acrobat.

Configure your OCR settings

To configure OCR scanning for your tenant, follow these steps:

1. Sign in to the Microsoft Purview portal.
2. Select **Settings**.
3. Select **Optical character recognition (OCR)** to enter your OCR configuration settings.
4. Select the locations where you want to scan images.
5. Select the groups that you want included or excluded from OCR scans.
6. Select **Done**.

For the full list of locations where OCR scans images and the solutions that act on the results, see Supported locations and solutions.

Permissions

To create and deploy policies, your account must be a member of one of these role groups:

- Compliance administrator
- Compliance data administrator
- Global administrator
- Information Protection
- Information Protection Admin

> **Note**
>
> In general, OCR settings take effect about an hour after you turn them on.

> **Note**
>
> For information on OCR functionality in Microsoft Purview Communication Compliance, see Create and manage communication compliance policies.

Supported locations and solutions

Expand table

Location	Supported Solutions
Exchange	Data loss prevention Information protection: Auto-labeling policies Records management: Autoapply retention label policies[1]
SharePoint sites	Data loss prevention Insider risk management[2] Records management: Autoapply retention label policies[1]
OneDrive accounts	Data loss prevention Records management: Autoapply retention label policies[1]
Teams chat and channel messages	Data loss prevention Insider risk management[2]
Devices	Data loss prevention Insider risk management[2]

[1] Supports keywords and sensitive information types.

[2] Considers sensitive information types and trainable classifiers present in images for risk scoring.

Supported file types

This functionality supports scanning images in the following file types, with the noted requirements:

Expand table

Locations	Supported file types
Exchange	JPEG, JPG, PNG, BMP, TIFF, and PDFs (scanned). Embedded images in DOCX, PPTX, XLSX, RAR, TAR, ZIP, 7z, and hybrid PDFs (containing searchable text and images) with a limit of 20 embedded images scanned per file.
SharePoint and OneDrive	BMP, PNG, JPEG, JPG, JFIF, ARW, CR2, CRW, ERF, GIF, MEF, MRW, NEF, NRW, ORF, PEF, RAW, RW2, RW1, SR2, TIF, TIFF, HEIC, HEIF, ARI, BAY, CAP, CR3, DCS, DCR, DRF, EIP, FFF, IIQ, K25, KDC, MOS, PTX, PXN, RAF, RWL, SRF, SRW, X3F, DNG, PDFs (scanned and hybrid containing searchable text and images) Embedded images in DOCX, PPTX, XLSX
Teams, Windows, and macOS endpoint	JPEG, JPG, PNG, BMP, TIFF, and PDF (image only)

Image requirements

Expand table

Requirement	Limit
File size (Exchange, Teams)	20 MB max
File size (SharePoint, OneDrive, Windows, and macOS endpoints)	50 MB max
Image resolution	50 × 50 px minimum, 16,000 × 16,000 px maximum

Important

- Only images uploaded after OCR is enabled are scanned.
- OCR extracts only the first 2 million characters of text.
- By default, incoming email (email from users outside the organization), internal mails (email shared within the users of the organization), and outgoing email (email sent to users outside the organization) are subject to OCR scanning. To exclude incoming mails from OCR scan, change the OCR settings from the default scope of **All sender groups** to the **Specific sender groups** and specify the internal groups that you want OCR to scan. To restrict OCR scans to mails sent outside the organization only, select the option under **Advanced Setting (Only Exchange)**. After selecting this checkbox, neither incoming mails nor any internal communications are OCRed. For information on changing the configurations, see Configure your OCR settings.
- Data loss prevention policy tips aren't supported for images in Exchange.

- If you **exclude a path** in the endpoint data loss prevention settings, OCR doesn't scan images in those folders.
- When OCR is turned on for Windows and macOS devices, the devices start sending messages to the cloud for scanning. The default bandwidth limit is **1,024 MB of data per device per day**. OCR stops scanning images once this daily limit is reached. If you want to continue scanning images, you can increase the bandwidth limit.
- For Endpoint Device, ensure that any network settings aren't obstructing the OCR, and a wildcard should be present allowing blob.core.windows.net endpoints.
- For Exchange, the feature supports embedded images in DOCX, PPTX, XLSX, RAR, TAR, ZIP, 7z, and hybrid PDFs (containing searchable text and images) with a limit of 20 embedded images scanned per file.

Supported languages

OCR scanning supports more than 150 languages.

Summary

- To use OCR, set up Microsoft Syntex pay-as-you-go billing. (You don't need to set up Microsoft Syntex itself.)
- Configure OCR at the tenant level, so once OCR is configured, it's available to the entire Microsoft Purview stack.
- You don't need to create separate data classifiers for OCR. Once OCR is configured, existing sensitive information types, exact data match based sensitive information types, trainable classifiers, and fingerprint SITs scan images as well as documents and emails.
- Microsoft Purview eDiscovery supports OCR at the case level. For more information, see Search and analytics settings in eDiscovery.

Last updated on 04/30/2026

Estimate your OCR costs

You can use the OCR cost estimator tool (preview) to estimate your optical character recognition (OCR) scanning costs. The tool scans your selected locations—such as Exchange, SharePoint, OneDrive, Teams, and Endpoint—and projects how much OCR processing will cost before you enable it. Use this article to run an estimation, review the results, and download cost reports.

Prerequisites

To enable the OCR cost estimator tool on Endpoint, you must first install the latest Windows Update released on February 29, 2024 or later.

Estimate your bill

To estimate your bill, follow these instructions:

1. Sign in to the Microsoft Purview portal.
2. Select **Settings**.
3. Select **Optical character recognition (OCR)**
4. Under **Estimate the cost of an OCR scan for free**, select **Try for free**.
5. In the flyout pane, select the locations where the files you want to scan are found and then choose **Run estimation**.
6. After **Estimation started successfully** displays in the flyout pane, select **View estimation** next to **Predict OCR cost estimate for free** to view the **Estimation** page.
7. To enable OCR scans from the **Estimation** page, select **Turn on OCR** in the flyout pane and then follow the steps to configure your OCR settings.

> **Note**
>
> Running an OCR estimation can take around 24 hours to complete the first time. After the first estimation completes, the dashboard is refreshed daily and can be viewed anytime.

Edit the scope of your estimate

To change which locations are included in the estimate, follow these steps:

1. On the **Estimation** page, select **Edit scope** from the dropdown menu next to **Enable OCR**.

2. In the flyout pane, edit the locations with files that you wish to scan and then select **Restart estimation**.

Download your estimate

To download your estimate reports, follow these steps:

1. On the **Estimation** page, select **Download Report** from the dropdown menu next to **Enable OCR**.
2. In the flyout pane, select **Download all**, or select the individual reports you want to download.

Cancel an in-progress estimate

To cancel an estimate that is currently running, follow these steps:

1. On the **Estimation** page, Select **Stop estimation** from the dropdown menu next to **Enable OCR**.
2. On the next page, confirm your choice.

Restart a stopped estimate

To restart a stopped estimate, follow these steps:

1. On the **Estimation** page, select **Start estimation** from the dropdown menu next to **Enable OCR**.
2. In the flyout pane, edit the locations with files that you wish to scan and then select **Start estimation**.

Limitations

Be aware of the following limitations when using the OCR cost estimator:

- OCR and OCR cost estimator can't run at the same time.
- OCR cost estimator can be used only once by a customer and can't be re-enabled. Once turned on, you will have 90 days to complete 30-day estimation. You may pause the estimation any number of times
- Reports must be downloaded after using estimator. The data from dashboards is deleted after 90 days from the date estimator is first turned on.
- Estimation for embedded and standalone image is only supported for the Exchange workload. Estimation for embedded images in SharePoint and OneDrive is not supported

yet.

- Estimation of images in pdf files is supported in Exchange and Teams. Estimation of images in pdf files isn't supported in SharePoint and OneDrive. As a result, your actual OCR bill for SharePoint and OneDrive may be higher than estimated, since OCR will run in SharePoint and OneDrive on all supported file types listed in Supported file types
- For Endpoint, each pdf file is estimated to have an image count of 4. This is the current average with OCR customers.
- In Exchange and Teams, there is the ability to cache small images, such as logos or email signatures, without being charged.
- Downloaded reports show the **To Date** in the **Estimation Timeframe** column as the date of latest scan (current date in case of ongoing scan) for all the rows in the report.
- All incoming emails and Teams messages from outside the organization are estimated if the scope is set to "ALL" when configuring OCR Cost Estimator for Exchange and Teams.
- All dashboards are reset when you restart estimation. Use the download report of the scan history before restarting an estimation. Even with the same location and scope, estimation can be restarted from scratch.

Create and analyze an on-demand classification scan

Microsoft Purview on-demand classification identifies and classifies sensitive content in historical data stored in SharePoint, OneDrive, and endpoints. On-demand classification extends the classification capabilities to files that aren't classified or modified for a long time, files that are never classified, or files that need updated classification on previously classified files.

On-demand classification updates classification results; matching policies determine any resulting actions. For SharePoint and OneDrive, updated results can trigger active policies, including policies that apply or remove sensitivity labels. On-demand classification isn't an auto-labeling simulation.

To decide whether existing files need updated classification or only policy reevaluation, see Auto-labeling classification and simulation concepts. Existing, correct classifications don't need to be refreshed for every auto-labeling policy change.

On-demand classification taken with Information Protection's continuous classification brings a two-pronged approach to keeping sensitive items aligned with your organization's latest security policies.

By using on-demand classification, organizations can:

- Extend protection to previously unclassified or inactive files, increasing overall coverage.
- Strengthen data protection across your environment without relying on end-user actions.
- Reduce the risk of AI tools surfacing unlabeled or unprotected information. Do it all natively, without exporting your data or relying on fragmented tools.

SKU and subscriptions licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Billing

This feature uses pay-as-you-go billing or per-user licensing for Microsoft Purview capabilities or both. To help you understand and manage your usage, Microsoft Purview provides a **Usage center** in the Microsoft Purview portal. For more information, see Manage pay-as-you-go and per-user licensing usage. To learn more about Purview billing, see Purview billing models..

> **Note**
>
> The actual billed amount may be lower than the estimated cost if some items or locations are skipped during the scan. Items can be skipped if they are empty files (excluded to avoid unnecessary billing), if the scan is canceled, or if the subscription expires before completion. Locations may be skipped if another scan is already running on the same location at the same time.

Permissions

To run a scan, you must be a member of the following role group:

- Compliance Administrator

To view classification results, you must be a member of one of these role groups:

- Content Explorer Content Viewer
- Content Explorer List Viewer

Create an on-demand classification scan

Before starting classification for SharePoint or OneDrive, review the scan scope, estimated charges, and active policies that might act on the updated results. Check that the file date range and selected classifiers cover the historical files you intend to classify. A policy you're testing can remain in simulation while other active policies act on those files.

1. Sign in to the Microsoft Purview portal.
2. Go to **Data loss prevention** > **Classifiers** > **On-demand classification** or **Information Protection** > **Classifiers** > **On-demand classification**.
3. Select **New scan**.
4. Follow the instructions in the wizard. During this process, you define the following settings:
    - Name and description

- Scope and location - You can choose to scan all SharePoint sites and OneDrive accounts, only specific ones, or skip certain sites and accounts from the scan. For endpoint devices, you can scope the scan by users.
- Classifiers to scan for
- File last modified date range you want to scan
- File extensions you want to scan

After you complete the wizard, the estimation process begins. The estimation duration depends on the scope of the scan.

> ⓘ **Note**
>
> By default, the scan includes all items created or modified within the past year, across all supported file extensions. It also includes every available classifier configured in your tenant. If you choose to scan for specific classifiers, you can select up to 50 at a time.

5. From the **On-demand classification** list view, select the scan you created.
6. Select **View estimation**.

> ⓘ **Note**
>
> After reviewing the estimates, you can edit the scan to narrow or expand the scope. Select **Edit scan** and rerun the estimation scan.

7. Select **Start classification.**

Analyze on-demand classification results

1. From **On-demand classification**, select a scan from the list.
2. Select **View estimation**.
3. On the **Estimation overview** tab, review scan results, including progress, items found, and estimated cost. To cancel in-progress scans, select **Cancel Scan**.
4. On the **Items for review** tab, review specific items found during the scan. You can filter and export the result.

Devices that don't respond are ones that don't send endpoint telemetry signals for over 72 hours. Devices with expired scan validity don't have a valid scan in the last 72 hours.

Additional considerations

- Classification can start up to 30 days after estimation, but minimizing the gap ensures greater accuracy in final counts and costs.
- Tenants using EDM classifiers should be aware that On-Demand Classification scans (including estimation and classification) rescan previously classified files, which can increase overall scan costs. To mitigate this impact, tenants can exclude the EDM classifier from the scan scope.
- Impact of classifier selection on scan cost: The classifiers selected for an on-demand scan influence how many files are identified for processing. Scan cost is determined by the total number of files scanned—not the number of classifiers. Selecting a broader set of classifiers may increase the number of files in scope and raise overall cost. However, this approach ensures files are assessed against all relevant classifiers in a single scan, reducing the risk of missed sensitive data and limiting the need for additional scans later.

Applies to SharePoint and OneDrive

- Each scan can process up to 150,000 locations and 100 million files. The system enforces these limits based on scan estimation results.

  > ⓘ **Note**
  >
  > In On-Demand Classification estimation scans (simulation), you see a difference between the number of matched locations and the number of users or accounts included in the scan scope. Simulation results are based on mailbox locations rather than unique users. A single user can have multiple mailboxes (for example, a primary mailbox along with archive or system mailboxes), and each mailbox is treated as a separate location during scanning. As a result, the total number of matched locations can exceed the number of users in scope, even when the scan is correctly applied at the user level.

- If you select specific classifiers during a scan, only those classifiers have their classification results updated for the scanned files. Other classifiers present in the files might remain unevaluated and might not trigger their associated policies.

- If a location is in scope of multiple active scans, only one scan processes it successfully and marks it skipped for others.

- Each file, once scanned, is evaluated against Data Loss Prevention (DLP), Information Protection (MIP), Data Lifecycle Management (DLM), and Insider Risk Management (IRM) policies, triggering appropriate actions as per matching policies.
- Content Explorer updates within seven days of scanning to reflect newly classified content.
- Adaptive scopes for SharePoint on-demand classification let administrators define scan scope dynamically based on site attributes (such as URL, name, or metadata) instead of selecting sites manually. The scan automatically includes all sites that match the criteria and updates as sites change, enabling scalable, accurate coverage with minimal manual maintenance. To learn more, see Adaptive scopes.
- Administrative units (AUs) for SharePoint on-demand classification let organizations scope and manage scans within defined administrative boundaries, enabling delegated administration across large or distributed environments. Administrators can create and manage scans only for sites within their assigned AUs, and access to scan configuration and results is limited to AU-scoped admins. This supports least-privilege access, simplifies ownership across regions or departments, and ensures alignment with existing governance in Microsoft Purview. For more information, see Administrative units in Microsoft Purview.

Applies to Windows 10/11 endpoints

- Ensure that the machine has a minimum four virtual processors and a minimum of 4,096 MB memory.
- Each device is limited to 2 GB of data discovery bandwidth per rolling 24-hour period (independent of DLP). Scanning pauses once the limit is reached and resumes after 24 hours.
- Only devices that successfully complete estimation are included in classification.
- In addition to DLP-excluded paths, certain system folders are automatically excluded from data discovery.

Get started with on-demand classification for endpoints

On-demand classification identifies and classifies sensitive content in files at rest on Windows endpoints. It's the endpoint workload of on-demand classification, which also covers SharePoint and OneDrive.

> **Note**
>
> This article covers on-demand classification for endpoints. For real-time endpoint protection, see Learn about Endpoint data loss prevention.

What on-demand classification covers on endpoints

Endpoint DLP classifies files in real time when they're accessed, modified, or shared. On-demand classification extends that coverage to inactive and historical files at rest that Endpoint DLP hasn't processed.

Expand table

Capability	Scope	Trigger
Endpoint DLP (real-time)	Active files (modified, accessed, shared)	Real-time, automatic
On-demand classification	Inactive/historical files at rest	Admin-initiated scan

Together, these capabilities help ensure that both active and inactive files on endpoints are classified according to your organization's current policies.

What on-demand classification doesn't do

Expand table

On-demand classification...	Details
Doesn't apply sensitivity labels	It classifies files but doesn't label them. Combine with auto-labeling policies to apply labels based on classification results.

On-demand classification...	Details
Doesn't enforce DLP policies directly	Classification results feed into policies, but enforcement happens through Endpoint DLP when files are accessed or shared.
Doesn't replace Endpoint DLP	Endpoint DLP handles real-time protection. On-demand classification covers historical files that Endpoint DLP hasn't processed.

How on-demand classification works

On-demand classification uses a two-phase approach: estimation followed by classification.

Phase 1: Estimation

After you create a scan, the estimation process begins on scoped devices. The endpoint agent performs a metadata-only pass without reading file contents or running classifiers:

- Enumerates files that match your scope criteria (selected users, file types, last modified date range).
- Evaluates file eligibility gates, including file size limits, supported file types, and time window filters.
- Checks eligibility for previously classified files by comparing classifier history and file modification state against previous scan results.
- Reports aggregated metadata to the Microsoft Purview service, including eligible file counts and estimated reusable files.

No file contents are read and no classifiers are executed during estimation.

> ⓘ **Note**
>
> Estimation numbers may differ from the final classification results. Estimation reflects a point-in-time metadata snapshot. Files may change, devices may go offline, or previously classified file eligibility may shift between estimation and classification. This is expected behavior.

Phase 2: Classification

After reviewing the estimation:

- Select **Start classification** to begin classification.

- Each file is evaluated against your sensitive information types (SITs) and trainable classifiers.
- Files are evaluated against DLP, Microsoft Information Protection (MIP), data lifecycle management (DLM), and insider risk management (IRM) policies simultaneously.
- Previously classified files with unchanged content and classifiers are retained without rescanning.

Phase 3: Review results

After classification completes:

- View results on the **Items for review** tab.
- Filter and export classified items.
- Monitor device status and scan progress.

Prerequisites

Devices must be onboarded to Microsoft Purview endpoint data loss prevention. For onboarding and device requirements, see Get started with Endpoint data loss prevention.

Expand table

Action	Required role
Create and run a scan	Compliance Administrator
View classification results	Content Explorer Content Viewer or Content Explorer List Viewer

For licensing requirements, see Microsoft 365 guidance for security & compliance.

Create your first endpoint scan

Step 1: Navigate to on-demand classification

1. Go to the Microsoft Purview portal.
2. In the left navigation, select **Data Loss Prevention** > **Classifiers**.
3. Select the **On-demand classification** tab.
4. Select **New scan**.

Step 2: Configure your scan

Expand table

Setting	Description	Guidance
Name & description	A name to identify this scan	Use a descriptive name, such as "Finance team endpoint scan, quarterly"
Scope & location	Select **Endpoints** and choose which users' devices to scan	Start with a small user group for your first scan
Classifiers	Select which SITs and trainable classifiers to scan for (up to 50)	Include only the classifiers you need. More classifiers means longer scan time.
File last modified range	Filter files by when they were last modified	Use this to focus on files from a specific time period
File extensions	Which file types to include	Leave as default (all supported types) unless you need to narrow scope

Endpoint scans are scoped by user. All onboarded devices for selected users are included. System folders (Windows, Program Files) are automatically excluded.

Step 3: Start estimation

1. Review your scan configuration.
2. Select **Create scan**.
3. The estimation phase begins automatically.

Step 4: Review estimation and start classification

Once estimation completes, review the estimated file count and projected scope. Select **Start classification** to begin.

You can start classification before estimation reaches 100%. Starting at 80–90% progress is recommended: the final 10–20% typically reflects slow-responding devices, and devices that have completed estimation begin classification immediately while remaining devices join as they finish.

Step 5: Review results

After classification completes:

1. Open your scan and select the **Items for review** tab.
2. Filter results by classifier, file type, or sensitivity.

Bandwidth throttling

Each device has a data discovery bandwidth limit per rolling 24-hour period. This limit is independent of other DLP bandwidth and prevents the scan from affecting device performance. When a device reaches the limit, scanning pauses automatically and resumes after the period resets.

Last updated on 08/21/2026

Best practices for on-demand classification on endpoints and billing

Understand how to plan large-scale scans and how to optimize usage.

Billing model

On-demand classification uses a pay-as-you-go billing model. You're billed only for files that are actively classified. Previously classified files, skipped files, and failed files aren't billed. Usage is reported in the **Microsoft Purview Usage Center**, and charges appear on your Azure subscription bill.

For current pricing and licensing, see Microsoft Purview pricing.

Previously classified files

When a file has already been classified and neither the file content nor the classifiers have changed, the existing classification result is retained on subsequent scans without rescanning. This applies to files classified by prior on-demand scans, as well as files classified by real-time Endpoint DLP when advanced classification is enabled.

Conditions for previously classified files

> **Note**
>
> Reuse of previously classified verdicts requires that the earlier scan used advanced classification. For Endpoint DLP, advanced classification must be enabled on the DLP policy for its verdicts to be reusable by later on-demand scans.

A file qualifies as previously classified when all the following are true:

- File content unchanged since last verdict.
- The classifiers in the current scan are the same as, or a subset of, the classifiers used in the original scan, and those classifiers are unchanged.
- Classifier definitions unchanged.
- The device has the latest Windows cumulative updates installed.

Previously classified results apply across: on-demand → on-demand, on-demand → Endpoint DLP, and Endpoint DLP → on-demand.

Previously classified files are visible in results

Previously classified files appear in scan results and audit logs under classification status. The file was evaluated and the existing verdict was confirmed. It doesn't mean the file was skipped or removed from results; it only wasn't rescanned.

> **Important**
>
> Previously classified file recognition isn't retroactive. It only applies to scans run after the required Windows update version 10.8821 is installed. Scans completed before this update aren't eligible. Your first post-update scan establishes the baseline for all future scans.

What affects scan volume

Expand table

Reduces rescanning	Increases rescanning
Previously classified files on repeat scans	Changing classifiers between scans
Files already classified by Endpoint DLP (cross-path)	Large number of new or modified files
Narrowing file scope with date range and file type filters	Broad file scope (more file types, longer date ranges)

Estimation accuracy over time

An estimate stays representative for a limited window from the day estimation started. Within this window, the estimated file count closely reflects what classification will process. You can still start classification later, but expect higher variance in file counts as files on devices are added, modified, or deleted over time.

A common scenario: an administrator runs estimation, submits the projected scope for budget approval, and the approval cycle takes weeks. If estimation itself also drags out (for example, waiting for slow-responding devices to reach 100%), the combined delay can push classification past the window where the estimate stays representative.

How to keep the estimate accurate

- **Start with a pilot.** Run a small pilot scan (10–20 users) first to get per-user data for the approval process.
- **Start classification early.** Don't wait for estimation to reach 100%. Starting at 80–90% progress is recommended. Devices that have completed estimation begin classification immediately.
- **Run estimation and classification back-to-back** if your organization is comfortable with the projected scope.

Best practices for large-scale scans

Finalize classifiers first

Finalize your sensitive information types and trainable classifiers before starting a scan. Changing classifiers during or between scans invalidates previously classified files and increases rescanning.

> **Tip**
>
> Establish a change-freeze period for classifiers before large scans. Coordinate with your team to ensure that SIT and trainable classifier changes are paused until the scan completes.

Start with a phased rollout

Expand table

Phase	Scope	Goal
Phase 1	10–20 users	Validate the scan works and understand per-device timing. Complete the full cycle from start estimation to complete classification.
Phase 2	50–100 users	Identify device issues and gather per-user data. Complete the full cycle from start estimation to complete classification.
Phase 3	Full rollout	Scale to all target users with known expectations. Complete the full cycle from start estimation to complete classification.

The more devices in your scan, the more files are processed in parallel.

Batch large tenants

For organizations with thousands of users, consider batching scans into groups of users per scan. This approach keeps each scan within the estimation accuracy window, allows batches to run in

parallel, and makes it easier to track progress per batch.

> **Note**
>
> A device can only be part of one active scan at a time. Before adding a device to a new estimation or classification scan, ensure its previous scan has reached Classification Complete, Classification Cancelled, or Estimation Cancelled state.

Handle offline devices

In any large scan, some devices will be offline. Don't wait for 100% device coverage. Run a follow-up scan later to catch devices that missed the first round. Previously classified files aren't rescanned, so the follow-up scan only processes newly scanned files.

After the scan

- Download scan reports promptly; they're retained for a limited period of 30 days.
- Plan regular scans (monthly or quarterly) to keep classification current if the classifiers are changed or policy has been modified, since previously classified files aren't rescanned.

Key considerations

- The estimation phase reads only metadata. You can assess scope before committing to classification.
- Subsequent scans typically process fewer files than the initial scan because previously classified files with unchanged content and classifiers aren't rescanned.
- Classification runs on the device. Only classification results and metadata are sent to the Microsoft Purview service.
- On-demand classification uses the same classifiers and Microsoft Purview portal as your existing compliance solutions.

FAQ and reference for endpoint scans

Answers to common questions and key terms for on-demand classification for Windows endpoints in Microsoft Purview.

General

Does on-demand classification apply sensitivity labels to files?

No. On-demand classification identifies and classifies sensitive content but doesn't apply sensitivity labels. To apply labels based on classification results, configure auto-labeling policies.

Is on-demand classification required for Endpoint DLP to work?

No. Endpoint DLP works independently and classifies files in real time when they're created, modified, or used. On-demand classification is a separate, complementary capability that covers historical files at rest.

Does on-demand classification affect the user experience on endpoints?

On-demand classification runs in the background with minimal resource usage. A per-device bandwidth limit ensures scanning doesn't degrade device performance.

Does turning on a DLP policy automatically classify historical data?

No. DLP policies classify files when they're accessed, modified, or shared (real-time classification). Historical files that remain untouched aren't retroactively classified by DLP, however you can utilize JIT feature to prevent data loss. On-demand classification is required to cover those files.

Classification and labeling

Why was my file classified but not labeled?

Classification and labeling are separate steps. Classification identifies whether a file contains sensitive content. Labeling applies a sensitivity label based on classification results. For labels to be applied, configure auto-labeling policies.

Does opening or editing a file trigger reclassification?

Yes, but through Endpoint DLP (real-time classification), not on-demand classification. When a file is modified, the Endpoint DLP engine reclassifies it automatically. On-demand classification runs only when an admin starts a scan.

Do I need to rerun on-demand classification when I create a new SIT?

Yes, if you want historical files evaluated against the new SIT. Existing verdicts were created using the classifiers available at scan time. A new SIT isn't automatically applied to previously classified files. A new scan that includes the new SIT classifies the files against it.

Cost and billing

Is estimation billed?

No. Estimation is a metadata-only pass. The endpoint agent enumerates files and evaluates eligibility gates (file size, type, time window) and previously classified file potential, but doesn't read file contents or run classifiers. No charges are incurred during estimation.

What is the billing model?

On-demand classification uses a pay-as-you-go billing model. You're billed only for files that are actively classified. Previously classified files and failed files aren't billed. For current pricing and licensing, see Microsoft Purview pricing.

Will I be charged twice if I scan the same files again?

No. Files that haven't changed and use the same classifiers are recognized as previously classified files and aren't rescanned or billed.

Why do I have to pay if DLP has already scanned the file?

If the file qualifies as previously classified, you don't. Files classified by real-time Endpoint DLP are recognized as previously classified during on-demand scans at no charge, if the file content and classifiers haven't changed. This is cross-path recognition.

Why is my actual scan volume lower than the estimate?

The estimate shows an upper bound and assumes all files will be classified. Actual volume is lower because previously classified files aren't rescanned, some devices may be offline, and some files might be deleted before classification.

How do I see my usage and charges?

Usage is reported in the Microsoft Purview Usage Center. Charges appear on your Azure subscription bill.

Scans

Can I cancel a running scan?

Yes. Already-classified files remain classified. Canceling doesn't undo completed work.

Can I run multiple scans at the same time?

Yes. If a device is scoped by multiple active scans, the first scan is processed while the other scans are queued.

Can I start classification before estimation reaches 100%?

Yes. Starting at 80–90% progress is recommended. The final 10–20% typically reflects slow-responding devices, and waiting for them can push the overall estimation phase past the window where the estimate stays representative. Devices that have completed estimation begin classification immediately, and remaining devices join as they finish.

What happens if I change classifiers during a scan?

Changing sensitive information types or trainable classifiers during a scan invalidates the estimation. You should re-estimate before continuing to classification if you want the estimated and classified numbers to match.

What files are excluded from scanning?

System folders are automatically excluded: the Windows directory, Program Files, legacy application data folders, and Windows Error Reporting data. On-demand classification scans user data directories such as Documents, Desktop, and Downloads.

Devices

Why does my device show "Not responding"?

The device hasn't sent signals for an extended period, currently cutoff limit is 48 hours. This typically means the device is powered off, hibernating, or not connected to the network.

What are the device requirements?

Devices must be onboarded to Microsoft Purview endpoint DLP and have the latest Windows cumulative updates installed. For full device requirements, see Get started with Endpoint data loss prevention.

Does on-demand classification work on macOS?

Not currently. macOS support is planned but no release date is available.

Results

Where can I see which files failed?

Individual failed files aren't listed in the portal or audit logs. The portal shows the total count of failed files. Review the error categories in Monitor and troubleshoot endpoint scans for common causes.

Why don't audit log counts match Items for review counts?

Audit logs and the Items for review tab use different data sources and counting logic. Timing differences, deduplication, and filter differences can cause minor discrepancies. A small gap is normal.

What is the difference between "skipped" and "failed" files?

Expand table

Status	Meaning	Billed
Classified	File was scanned and classified	Yes
Previously classified	File was scanned previously and had a valid prior verdict	No
Skipped	Excluded by filters	No
Failed	Could not be scanned (encrypted, locked, access denied)	No

Previously classified files

When are files not recognized as previously classified?

Files aren't recognized as previously classified when the file was earlier not classified using advanced classification, has been modified, classifier definitions have changed, or new classifiers were added that weren't in the original classification.

Does this work between on-demand and Endpoint DLP?

Yes. Previously classified file recognition works across on-demand → on-demand, on-demand → Endpoint DLP, and Endpoint DLP → on-demand.

Is previously classified file recognition retroactive?

No. Previously classified file recognition only applies to scans run after the required Windows update is installed. Your first post-update scan establishes the baseline for all future scans.

Feature gaps

Can I mark false positives in the scan results?

There's no built-in workflow to mark items as false positives directly within on-demand classification results. Export results and manage them externally, or report false positive SIT matches through your normal classifier tuning process.

Does the portal show an estimated time remaining for scans?

No. The portal shows scan progress but doesn't provide an estimated time of completion.

The on-demand classification option isn't visible in my portal. What should I do?

In some environments, backend provisioning may be required. Verify licensing and endpoint DLP onboarding. If all prerequisites are met, contact Microsoft Support for backend enablement.

Key terms

Expand table

Term	Definition
On-demand classification	Admin-initiated scan that classifies sensitive content in files at rest on endpoints.
Estimation	First phase that enumerates files, evaluates eligibility gates, and checks previously classified file potential using metadata only. No file content is read. The estimate stays representative for a limited window from the day estimation started.
Classification	Second phase that scans files against classifiers and is billed under the pay-as-you-go model.
Verdict	Classification result stored on a file, recording which classifiers matched.
Previously classified files	Files with existing classification results from prior scans or classified by Endpoint DLP in real time. These files aren't rescanned or billed when content and classifiers are unchanged. Requires latest Windows updates.
Active data	Files frequently modified, accessed, or shared. Classified by Endpoint DLP in real time.
Inactive/historical data	Files at rest that haven't been recently modified. The target of on-demand classification.

Next steps

- Get started with on-demand classification for endpoints
- Best practices for on-demand classification on endpoints and billing
- Monitor and troubleshoot endpoint scans

Last updated on 08/21/2026

Monitor and troubleshoot endpoint scans

Track scan progress, understand device and scan statuses, and resolve common issues with on-demand classification for Windows endpoints.

Viewing scan progress

1. Go to the Microsoft Purview portal.
2. Navigate to **Data Loss Prevention** > **Classifiers** > **On-demand classification**.
3. Select your scan to view detailed progress.

The scan details page shows:

Expand table

Metric	Description
Scan status	Overall scan phase (estimation or classification) and progress
Files scanned	Number of files processed so far
Files in scope	Total estimated files from the estimation phase
Devices active	Devices currently scanning
Devices not responding	Devices that haven't reported recently
Devices where scan validity expired	Devices that exceeded the signal validity threshold and were removed from scan scope

> **Note**
>
> Scan progress in the portal isn't real-time. Updates arrive periodically as devices report their status.

Understanding scan statuses

Estimation phase

Expand table

Status	Meaning	Action
Estimation in progress	Devices are counting files and reporting scope	Wait for periodic progress updates
Estimation complete	Ready to start classification	Review results and start classification
Estimation cancelled	Admin cancelled the estimation	Create a new scan if needed
Estimation failed	An error occurred	Check device health and requirements

Classification phase

Expand table

Status	Meaning	Action
Classification in progress	Files are being scanned and classified	Monitor progress
Classification complete	All devices finished	Review results in the **Items for review** tab
Classification cancelled	Admin cancelled classification	Already-classified files are preserved
Classification failed	An error occurred	See troubleshooting sections below

Understanding device statuses

Expand table

Status	Meaning	Action needed
Active	Device responded recently, scanning normally	No
Not responding	No recent signals. The device is likely offline or powered down. A device that's once marked not responding won't participate any further in the scan.	No
Completed	Device finished its portion of the scan	No
Paused	Device reached the data discovery bandwidth limit	Resumes automatically after the period resets

Each device has a signal validity threshold. If a device doesn't send any event within this window, it's marked as "Not responding" and is out of scope for the scan.

> **Note**
>
> "Not responding" doesn't indicate a device failure. It typically means the device is offline.
> Common reasons: device powered off, user on leave, device on a different network.

Interpreting results

After classification completes:

Expand table

Metric	What it means
Files classified	Files actively scanned and classified (billable)
Previously classified files	Files with existing verdicts retained without rescanning, or already covered by another active scan
Files failed	Files that couldn't be classified (encrypted, locked). Not billed.
Files skipped	Files not found on the system (deleted before the scan moved to the classification phase), empty extracted text in small files, label- or password-protected files, and text extraction or format detection errors

Understanding result number differences

Expand table

Metric	What it counts	When it updates
Items found (estimation)	Total files matching your scope and filters	During estimation
New matches (classification)	Files actively scanned, a subset of items found	During classification
Items for review (portal tab)	Classified items that matched at least one classifier	During and after classification
Audit log entries	Events logged per classification action	After classification, with possible delay

> **Note**

Items found ≠ items classified. Items found is the estimation-phase count (all files in scope). Items classified is the classification-phase count (files actually scanned, minus previously classified and failed files). The difference is primarily due to previously classified files.

> **Note**
>
> Items for review ≠ audit log count. These use different data sources and may show slightly different numbers. A small discrepancy is normal.

Skipped file counts are only finalized during the classification phase, not during estimation.

> **Note**
>
> Endpoint on-demand classification scan results don't flow into Content Explorer. Review results from the **Items for review** tab on the scan.

Troubleshooting

Quick reference

Expand table

Symptom	Likely cause	Solution
Item count appears to drop or reset mid-scan	Previously classified files are deducted from the live classified count	Expected behavior. The final count reflects net new classifications, not a scan restart.
Device shows "Not responding"	No recent signals	Device is offline. This device won't be part of the current scan.
Estimation stuck at x%	Outdated Sense/Defender client on devices	Upgrade to the latest Sense/Defender client through Windows Update
Very low file count	Bandwidth limit reached	Expected. Wait for the bandwidth period to reset.
High failure count	File access errors	See error categories below
Unexpected rescanning	Classifiers changed	Finalize classifiers before starting scans

Classification errors

Failed files aren't billed. Common error categories:

Expand table

Category	Examples	Solution
Access errors	Access denied, cloud file placeholder not available locally	Check file permissions; sync cloud files locally
Encryption errors	File encrypted, password-protected, BitLocker locked volume	Expected. Encrypted files can't be classified.
Format errors	File type not supported, corrupt file	Check file extension filters; no action needed for corrupt files
Lock errors	File locked by another application	Transient. File is retried on the next scan.
I/O errors	File or path not found (deleted or moved during scan)	No action needed
System errors	Local scan database full, unexpected error	Check disk space; restart device and retry

> **Note**
>
> A small percentage of file failures is normal. Investigate only if failure counts indicate a systemic issue such as permissions problems across many files.

Estimation shows different numbers than classification

This is expected. Estimation counts all files in scope. Classification skips previously classified files that already have valid verdicts, and some devices may be offline during classification. Estimation provides an upper bound; the actual classification volume is typically lower.

Agent downgrades

If the endpoint agent (Defender/Sense client) is downgraded or rolled back while a scan is active, scan progress may be affected. Coordinate agent updates with your scan schedule.

Scan not appearing in the portal

In some environments, backend provisioning may be required before the feature appears. Verify your tenant's licensing and that endpoint DLP is enabled with devices onboarded. If all prerequisites are met, contact Microsoft Support for backend enablement.

Where to find diagnostic information

Expand table

Information	Location
Scan progress and status	Purview portal → On-demand classification → your scan
Classified items with matches	Items for review tab
Audit trail of scan events	Unified audit log
Failed file count	Scan summary

When to contact support

Contact Microsoft Support if:

- Scans fail repeatedly with system errors across multiple devices.
- Estimation doesn't progress despite devices being online and meeting requirements.
- Billing charges don't match expected classification volume.

> **Note**
>
> If you're looking for information about sensitivity labels that you see and can select in your Office apps, check their documentation. For example, Apply sensitivity labels to your files.
>
> The information on this page is for IT administrators who can create and configure those labels by using the Microsoft Purview management solution.

To get their work done, people in your organization collaborate with others both inside and outside the organization. This collaboration means that content no longer stays behind a firewall—it can roam everywhere, across devices, apps, and services. When content roams, you want it to do so in a secure, protected way that meets your organization's business and compliance policies.

Sensitivity labels from Microsoft Purview Information Protection let you classify and protect your organization's data, while making sure that user productivity and their ability to collaborate isn't hindered.

The following example from Excel shows how users might see an applied sensitivity label from the window bar, and how they can easily change the label by using the sensitivity bar that's available with the latest versions of Office. The labels are also available from the **Sensitivity** button on the **Home** tab from the ribbon.

To apply sensitivity labels, users must be signed in with their Microsoft 365 work or school account.

> ⓘ Note
>
> For US Government tenants, sensitivity labels are supported for all platforms.
>
> If you use the Microsoft Purview Information Protection client and scanner, see the Azure Information Protection Premium Government Service Description.

You can use sensitivity labels to:

- **Provide protection settings that include encryption and content markings.** For example, apply a "Confidential" label to a document or email, and that label encrypts the content and applies a "Confidential" watermark. Content markings include headers and footers as well as watermarks, and encryption can also restrict what actions specified people can take on the content.

- **Extend SharePoint protection when files are downloaded** when you configure a default sensitivity label for SharePoint document libraries and select the option to extend protection for unencrypted files. Then, when these files are downloaded, the current SharePoint permissions travel with the labeled file.

- **Protect content in Office apps across different platforms and devices.** Supported by Word, Excel, PowerPoint, and Outlook on the Office desktop apps and Office for the web. Supported on Windows, macOS, iOS, and Android. For other apps, check their documentation.

- **Protect content in third-party apps and services** by using Microsoft Defender for Cloud Apps. With Defender for Cloud Apps, you can detect, classify, label, and protect content in third-party apps and services, such as SalesForce, Box, or DropBox, even if the third-party app or service doesn't read or support sensitivity labels.

- **Identify content for eDiscovery cases**. The condition builder to create search queries in eDiscovery supports sensitivity labels that are applied to content. For example, as part of your eDiscovery case, restrict content to files and emails that have a "Highly Confidential" sensitivity label. Or conversely, exclude content to files and emails that have a "Public" sensitivity label.

- **Protect containers** that include Teams, Microsoft 365 Groups, SharePoint sites, Viva Engage communities, and Loop workspaces. For example, set privacy settings, external user access and external sharing, access from unmanaged devices, and control how channels can be shared with other teams.

- **Protect meetings and chat** by labeling (and optionally, encrypting) meeting invites and any responses, and enforce Teams-specific options for the meeting and chat.

- **Extend sensitivity labels to Power BI**: When you turn on this capability, you can apply and view labels in Power BI, and protect data when it's saved outside the service.

- **Extend sensitivity labels to assets in Microsoft Purview Data Map**: When you turn on this capability, currently in preview, you can apply your sensitivity labels to files and schematized data assets in Microsoft Purview Data Map. The schematized data assets include SQL, Azure SQL, Azure Synapse, Azure Cosmos DB, and AWS RDS.

- **Extend sensitivity labels to third-party apps and services.** Using the Microsoft Information Protection SDK, third-party apps can read sensitivity labels and apply protection settings.

- **Label content without using any protection settings.** You can also just apply a label as a result of identifying the sensitivity of the data. This action provides users with a visual mapping of your organization's data sensitivity, and the labels can generate usage reports

and activity data for data that has different levels of sensitivity. Based on this information, you can always choose to apply protection settings later.

- **Protect data when Microsoft 365 Copilot is used.** Copilot and agents recognize and integrate sensitivity labels into the user interactions to help keep labeled data protected. For more information, see the following section Sensitivity labels for Microsoft 365 Copilot and Microsoft 365 Copilot Chat.

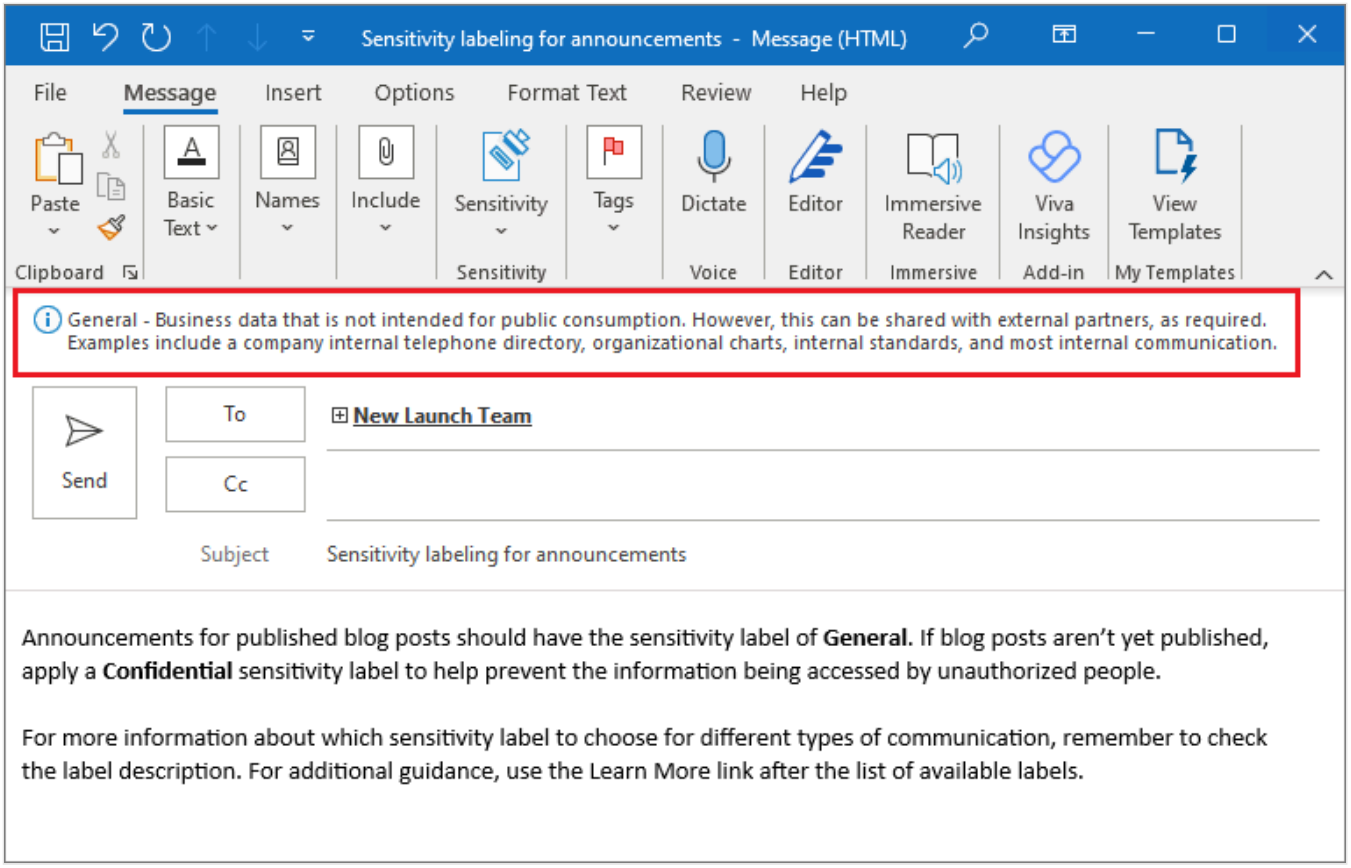
In all these cases, sensitivity labels from Microsoft Purview can help you take the right actions on the right content. With sensitivity labels, you can identify the sensitivity of data across your organization, and the label can enforce protection settings that are appropriate for the sensitivity of that data. That protection then stays with the content.

For more information about these and other scenarios that are supported by sensitivity labels, see Common scenarios for sensitivity labels. To see how your sensitivity labels are being used, view the reports from the Microsoft Purview portal.

New features are being developed all the time that support sensitivity labels, so you might also find it useful to check the Microsoft 365 roadmap.

What a sensitivity label is

When you assign a sensitivity label to content, it's like a stamp that you apply. The label is:



- **Customizable.** You can create categories that fit your organization's specific business needs for different levels of sensitive content. For example, you might use categories like Personal, Public, General, Confidential, and Highly Confidential.

- **Clear text.** Because the label is stored in clear text in the metadata for files and emails, third-party apps and services can read it and then apply their own protective actions, if required.

- **Persistent.** Because the label is stored in metadata for files and emails, the label stays with the content, no matter where you save or store it. The label identification that's unique to your organization becomes the basis for applying and enforcing policies that you configure.

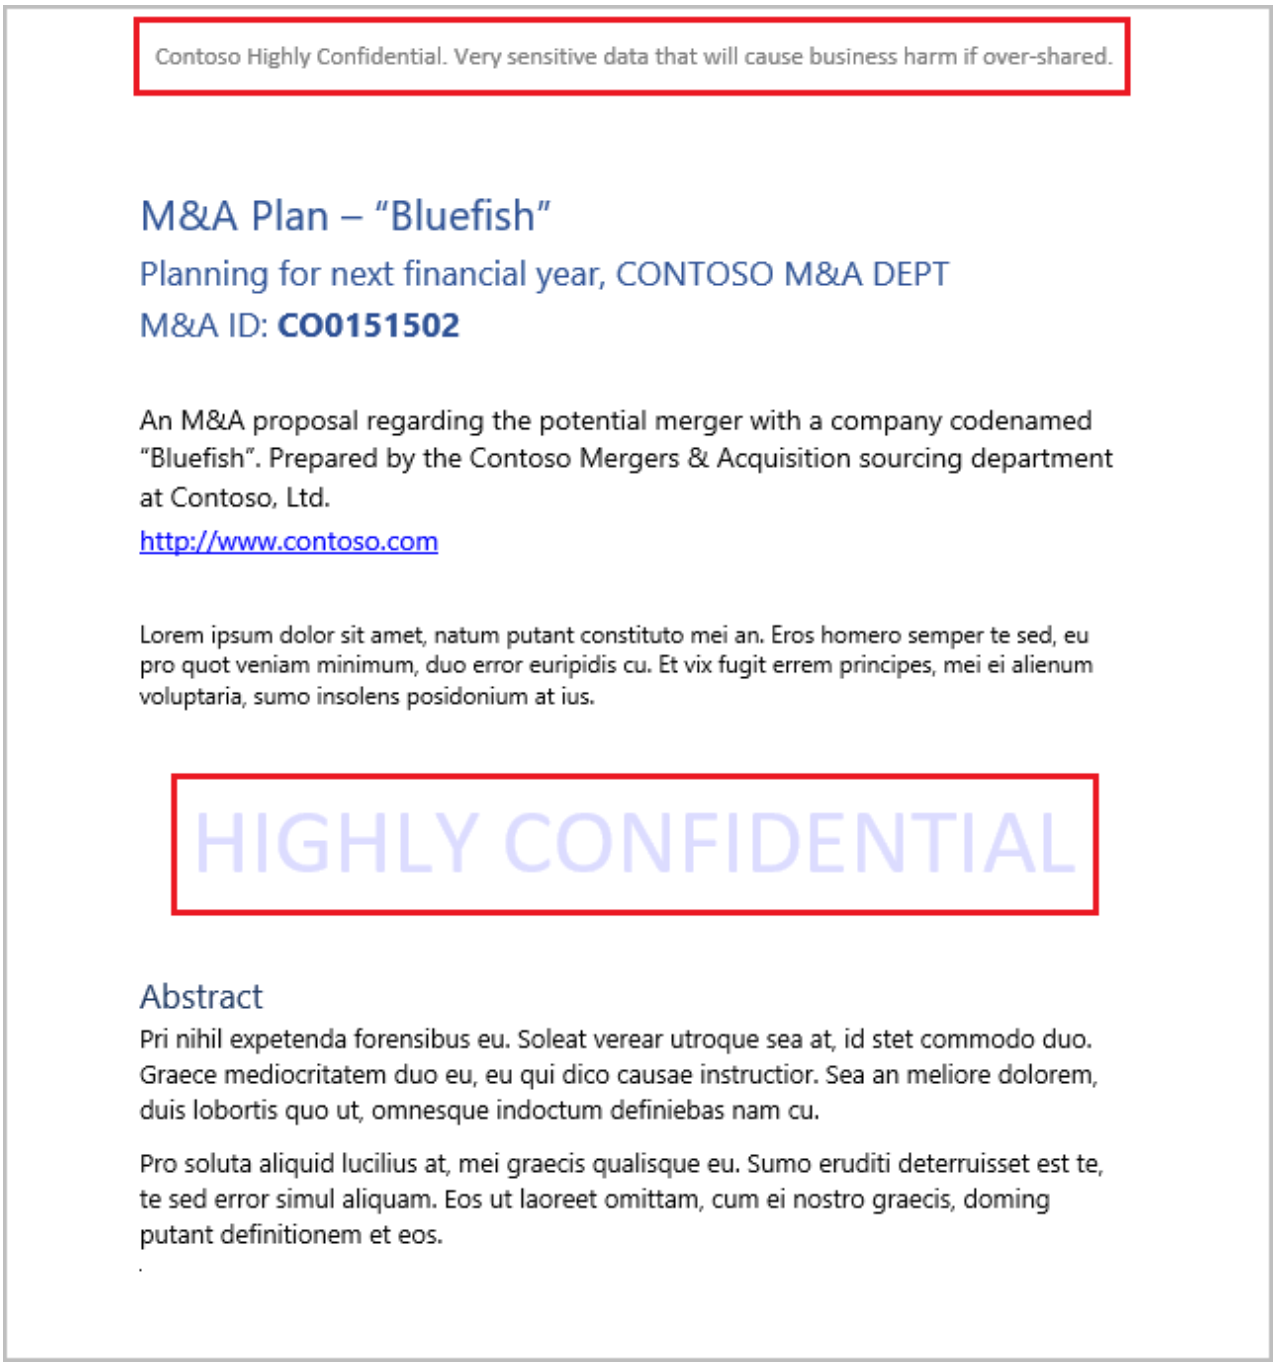
When users in your organization view an applied sensitivity label, it appears like a tag on apps and can be easily integrated into their existing workflows. Users from other organizations or guests can't see your sensitivity labels in apps.

The following example shows an opened email where another user has applied the sensitivity label named **General**, which doesn't apply encryption. The label description supplied by the admin displays more detail to users about the category of data identified by this sensitivity label.

> **Note**
>
> Don't confuse sensitivity labels with Outlook's built-in sensitivity levels that indicate the sender's intention but can't provide data security.

Each item that supports sensitivity labels can have a single sensitivity label applied to it from your organization. Documents and emails can have both a sensitivity label and a retention label applied to them.

What sensitivity labels can do



After you apply a sensitivity label to content, such as an email, meeting invite, document, or Loop page, the label enforces any configured protection settings on the content. You can configure a sensitivity label to:

- **Control access to content by using encryption** for emails, meeting invites, and documents to prevent unauthorized people from accessing this data. You can also choose

which users or groups have permissions to perform which actions and for how long. For example, you can choose to allow all users in your organization to modify a document while a specific group in another organization can only view it. Alternatively, instead of administrator-defined permissions, you can allow your users to assign permissions to the content when they apply the label.

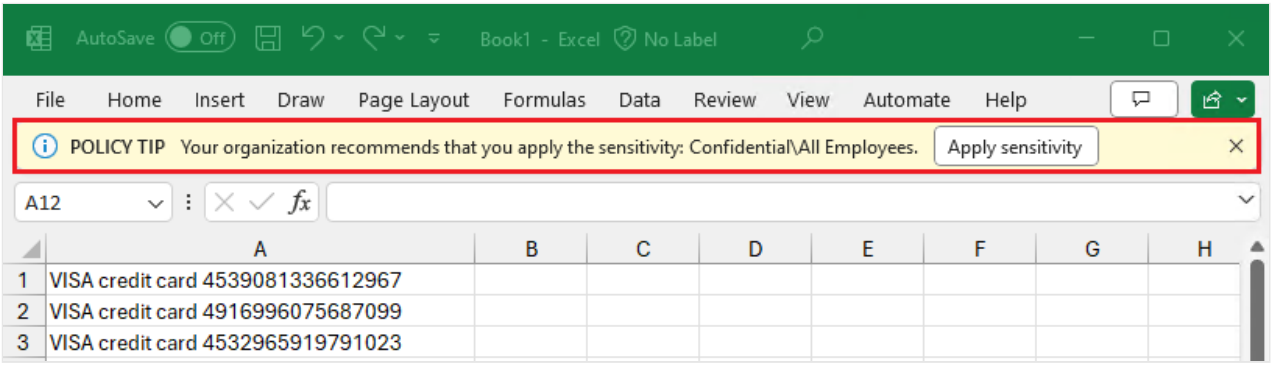
For more information about the encryption-based access control settings when you create or edit a sensitivity label, see Restrict access to content by using encryption in sensitivity labels.

- **Mark the content** when you use Office apps, by adding watermarks, headers, or footers to email, meeting invites, or documents that have the label applied. You can apply watermarks to documents and Loop components and pages, but not to email or meeting invites. For other apps, check their documentation. Example header and watermark:

Content markings also support variables. For example, insert the label name or document name into the header, footer, or watermark. For more information, see Content markings with variables.

Need to check when content markings are applied? See When Office apps apply content marking and encryption.

If you have templates or workflows that are based on specific documents, test those documents with your chosen content markings before you make the label available for users. Some string length restrictions to be aware of:



Watermarks are limited to 255 characters. Headers and footers are limited to 1,024 characters, except in Excel. Excel has a total limit of 255 characters for headers and footers

but this limit includes characters that aren't visible, such as formatting codes. If that limit is reached, the string you enter isn't displayed in Excel.

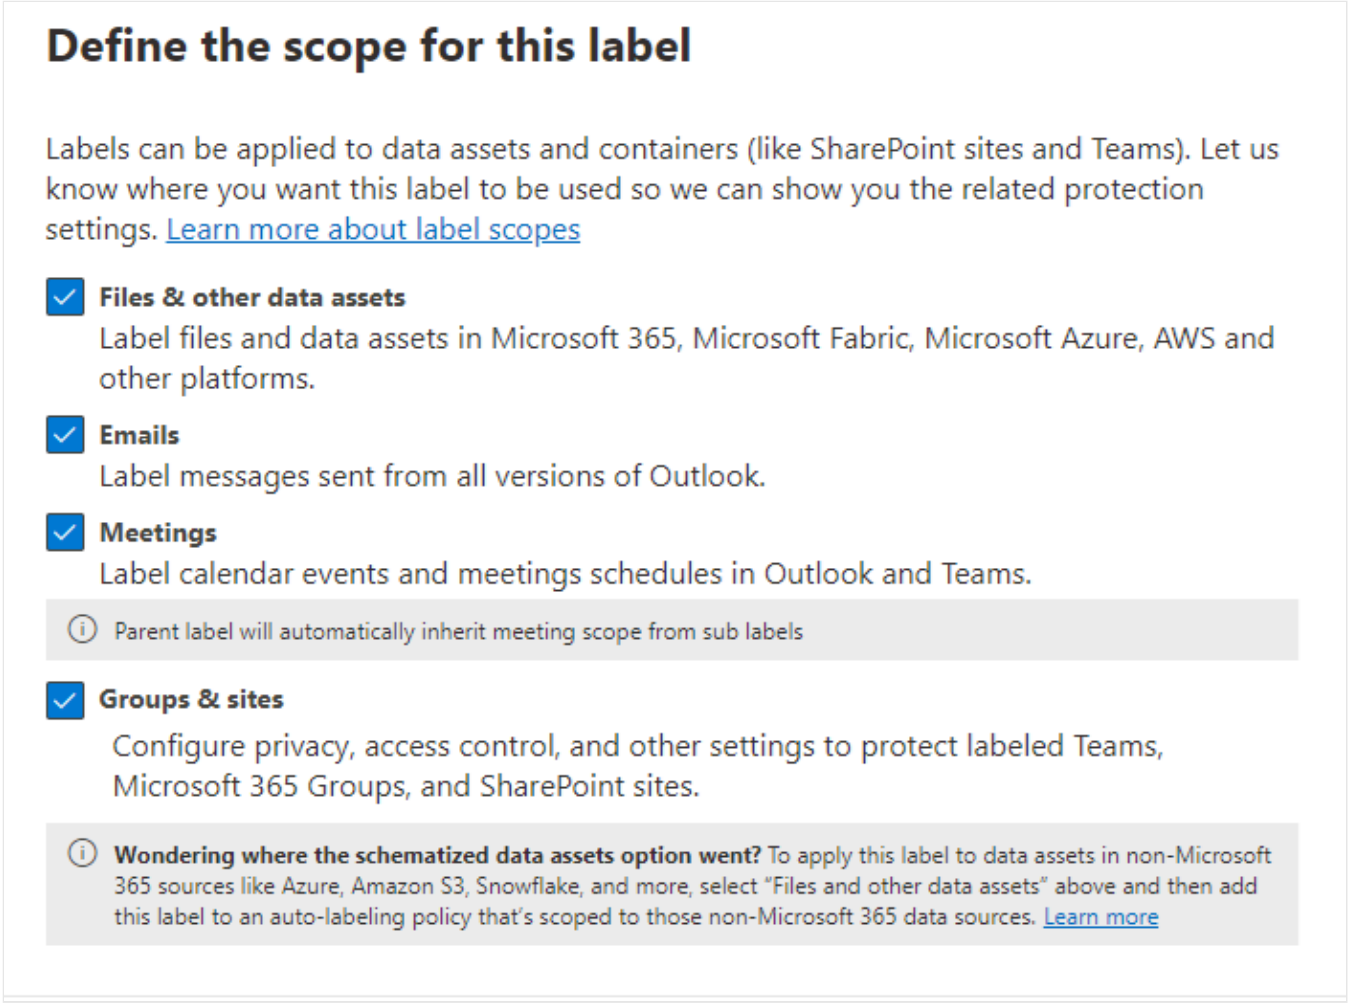
- **Protect content in containers such as sites and groups** when you enable the capability to use sensitivity labels with containers.

  You can't configure protection settings for groups and sites until you enable this capability. This label configuration doesn't result in individual items being automatically labeled but instead, the label settings protect content by controlling access to the container where content can be stored. These settings include privacy settings, external user access and external sharing, access from unmanaged devices, private teams discoverability, and sharing controls for channels.

- **Apply the label automatically to files and emails, or recommend a label.** Choose how to identify sensitive information that you want labeled, and the label can be applied automatically, or you can prompt users to apply the label that you recommend by using a policy tip. If you recommend a label, you can customize the prompt but the following example shows the automatically generated text:

  For more information about the **Auto-labeling for files and emails** settings when you create or edit a sensitivity label, see Automatically apply a sensitivity label to Microsoft 365 data for Office apps, and Labeling in Microsoft Purview Data Map.

- **Set the default sharing link type** for SharePoint sites and individual documents. To help prevent users from oversharing, set the default scope and permissions for when users share documents from SharePoint and OneDrive.



For more label configurations, see Manage sensitivity labels for Office apps.

Label scopes

When you create a sensitivity label, you choose the label's scope. The scope determines two things:

- Which label settings you can configure for that label
- The availability of the label to apps and services, which includes whether users can see and select the label

This scope configuration means you can have sensitivity labels that are just for items such as files, emails, and meetings, and can't be selected for groups and sites. Similarly, you can have sensitivity labels that are just for groups and sites and can't be selected for items.

By default, the **Files & other data assets** scope is always selected for a new label. As well as files for Office, Loop, and Power BI, it includes items from Microsoft Fabric, and data assets for Microsoft Purview Data Map when you extend your sensitivity labels beyond Microsoft 365. For more information about which items support sensitivity labels:

- For Office files: Office file types supported
- For Microsoft Loop: Sensitivity labels to protect Loop components and pages
- For Power BI: Supported export paths
- For Microsoft Fabric: Information protection in Microsoft Fabric
- For Data Map: Data sources that connect to Data Map

For other apps, check their documentation. Support for sensitivity labels is continually expanding.

Typically, you select the **Emails** scope together with **Files & other data assets**, because emails often include files as attachments and share the same sensitivity. Many labeling features require both options to be selected, but there might be times when you want a new label to be available for emails only. For more information, see Scope labels to just files or emails.

The scope for **Meetings** includes calendar events, Teams meetings options, and Team chat. You must also select the **Files & other data assets** scope and **Emails** scope for this option. For more information about this labeling scenario, see Use sensitivity labels to protect calendar items, Teams meetings, and chat.

The **Groups & sites** scope becomes available and selected by default when you enable sensitivity labels for containers and synchronize labels. This option lets you protect content in SharePoint sites, Teams sites, Viva Engage communities, and Loop workspaces by labeling those containers but doesn't label the items in them.

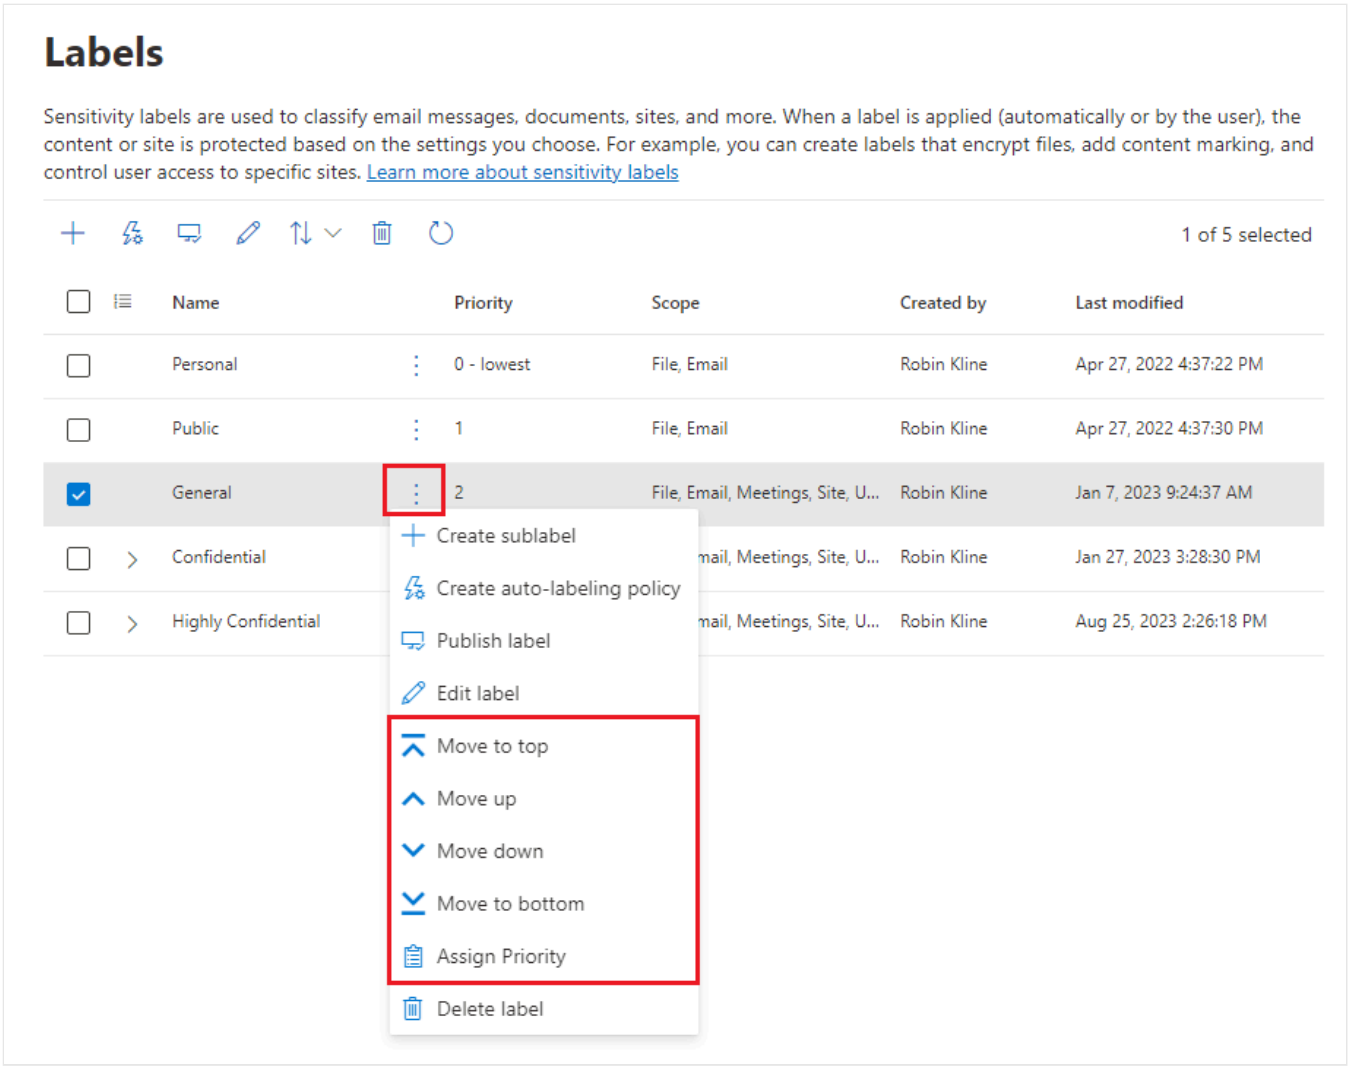
> ⓘ **Note**
>
> Items that were previously in the **Schematized data assets** scope are now included in **Files & other data assets**.

If you don't select one or more scopes, you see the first page of the configuration settings for these scopes, but you can't configure the settings. For these pages that have unavailable options, select **Next** to continue to configure settings for the next scope. Or, select **Back** to change the label's scope.

Label priority (order matters)

When you create your sensitivity labels in the Microsoft Purview portal, they appear in a list on the **Labels** page from **Information Protection**. In this list, the order of the labels is important because it sets their priority. You want your most restrictive sensitivity label, such as Highly Confidential, to appear at the **bottom** of the list, and your least restrictive sensitivity label, such as Personal or Public, to appear at the **top**.

You can apply just one sensitivity label to an item such as a document, email, or container. If you use the option that requires your users to provide a justification for changing a label to a lower sensitivity for files, emails, and meetings, the order of this list identifies the lower



sensitivity. However, this option doesn't apply to sublabels that share the priority of their parent label, and it doesn't apply to data assets or labels that protect containers.

> **Note**
>
> If you're using the **modern label scheme** that replaces parent labels with label groups, sublabels in the same label group also don't support the justification setting.

The priority of sublabels is used with automatic labeling, though. When you configure auto-labeling policies, multiple matches can result for more than one label. Then, the last sensitive label is selected, and then if applicable, the last sublabel. When you configure the auto-labeling label setting (rather than auto-labeling policies) for sublabels themselves, the behavior is a little different when these labels share the same parent label or label group. For example, a sublabel configured for automatic labeling is preferred over a sublabel configured for recommended labeling. For more information, see How multiple conditions are evaluated when they apply to more than one label.

The priority of sublabels is also used with label inheritance from email attachments.

When you select a sensitivity label, you can change its priority by using the options to move it to the top or bottom of the list if it's not a sublabel, move it up or down by one label, or directly assign a priority number. For example:

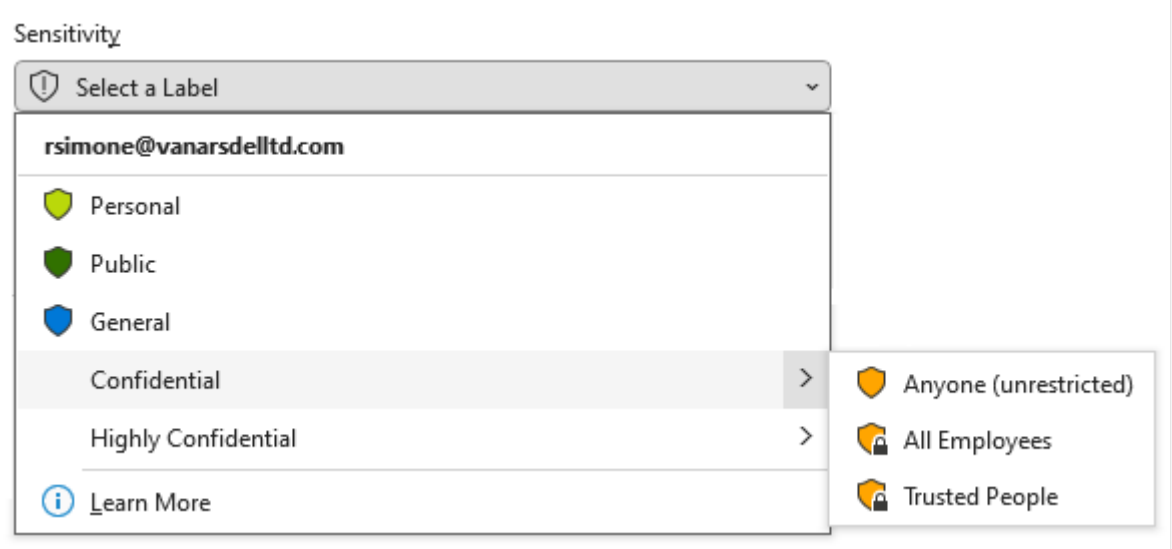
Sublabels that use parent labels or label groups

You might often want to logically group sensitivity labels in a two-tier hierarchy, to denote the overall sensitivity level but provide labels with different settings. As an example from the default sensitivity labels:

Confidential

- Anyone (unrestricted)
- All Employees
- Trusted People

In apps, users first see **Confidential** and then must select one of the other sensitivity labels, such as **All Employees**. The applied sensitivity label is then **Confidential \ All Employees**.



Sensitivity labels from the second tier don't inherit any settings from the first tier label, except the label color. In our example, the **Confidential** label is simply a text label with no protection settings, and can't be applied by itself to content.

The initial implementation to group labels in this two-tier hierarchy used parent labels and sublabels. The configuration of parent labels looked the same as the configuration of sublabels, but behaved differently when sublabels were published to users.

To reduce this complexity, label groups are now replacing parent labels. Label groups look and behave the same to users, but have configuration options only for the settings that they support: the label name, descriptions, color, and priority. You can't publish label groups themselves, only the labels within the groupings.

If you're still using parent labels with sublabels: Don't choose a parent label as the default label, or configure a parent label to be automatically applied (or recommended). If you do, the parent label can't be applied.

Example of how sublabels display for users:

If required, you can manually convert parent labels to label groups. For more information, see Migrate parent sensitivity labels to label groups.

Editing or deleting a sensitivity label

If you delete a sensitivity label from the Microsoft Purview portal, the label isn't automatically removed from content, and any protection settings continue to be enforced on content that had that label applied.

If you edit a sensitivity label, the version of the label that you applied to content is what's enforced on that content.

For detailed information about what happens when you delete a sensitivity label and how this action differs from removing it from a sensitivity label policy, see Removing and deleting labels.

Sensitivity label limitations per tenant

A single tenant can have a high number of sensitivity labels (1,000+), with one exception: If the label applies encryption that specifies the users and permissions, there's a maximum of 500 labels per tenant supported with this configuration. However, as a best practice to lower admin overhead and reduce complexity for your users, try to keep the number of labels to a minimum.

> **Tip**
>
> Real-world deployments show that effectiveness is noticeably reduced when users have more than five main labels or more than five sublabels per main label. You might also find that some applications can't display all your labels when too many are published to the same user.

What label policies can do

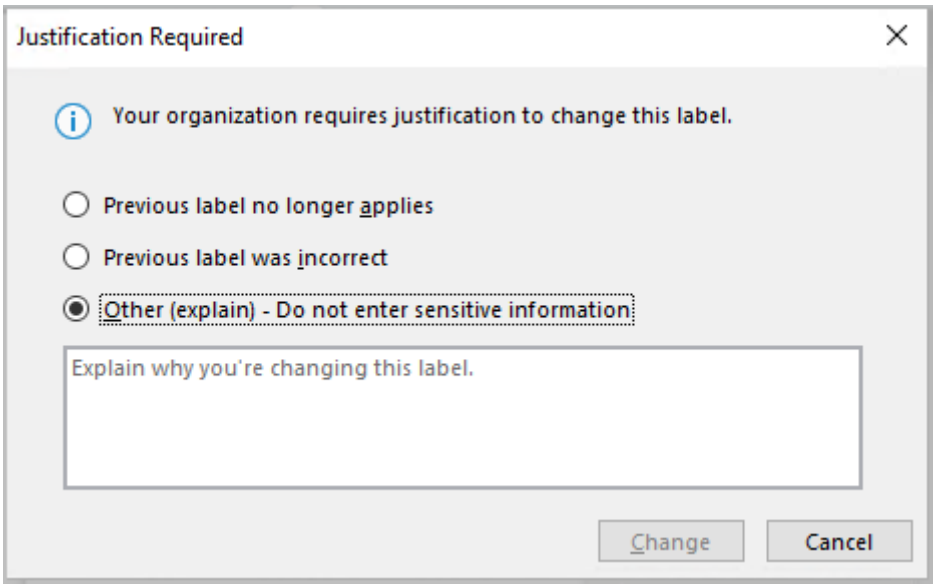
After you create your sensitivity labels, you need to publish them to make them available to people and services in your organization. The sensitivity labels can then be applied to Office documents and emails, and other items that support sensitivity labels.

Unlike retention labels, which are published to locations such as all Exchange mailboxes, sensitivity labels are published to users or groups. Apps that support sensitivity labels can then display them to those users and groups as labels that they can apply.

Although the default is to publish labels to all users in your organization, multiple label policies let you publish different sensitivity labels to different users if needed. For example, all users see labels that they can apply for Public, General, and Confidential, but only users in your legal department also see a Highly Confidential label that they can apply.

All users in the same organization can see the name of a sensitivity label applied to content, even if that label isn't published to them. They don't see sensitivity labels from other organizations.

When you configure a publishing label policy, you can:



- **Choose which users and groups see the labels.** Labels can be published to any specific user or email-enabled security group, distribution group, or Microsoft 365 group (which can have dynamic membership) in Microsoft Entra ID.

- **Specify a default label** for unlabeled documents and Loop components and pages, emails and meeting invites, new containers (when you've enabled sensitivity labels for containers), and also a default label for Power BI content. You can specify the same label for all five types of items, or different labels. Users can change the applied default sensitivity label to better match the sensitivity of their content or container.

  Consider using a default label to set a base level of protection settings that you want applied to all your content. However, without user training and other controls, this setting can also result in inaccurate labeling. It's usually not a good idea to select a label that applies encryption as a default label to documents. For example, many organizations need to send and share documents with external users who might not have apps that support the encryption or they might not use an account that can be authorized. For more information about this scenario, see Sharing encrypted documents with external users.

  > **ⓘ Important**
  >
  > When you have **sublabels**, be careful not to configure the parent label as a default label.

- **Require a justification for changing a label.** For files, emails, and meetings, but not for groups and sites (used by Teams and SharePoint), if a user tries to remove a label or replace it with a label that has a lower priority, by default the user must provide a justification to perform this action. For example, a user opens a document labeled Confidential (order number 3) and replaces that label with one named Public (order number 1). For Office apps, this justification prompt is triggered once per app session. When you use the Microsoft Purview Information Protection client, the prompt is triggered for each file. Administrators can read the justification reason along with the label change in activity explorer.

- **Require users to apply a label** for the different types of items and the containers that support sensitivity labels. Also known as mandatory labeling, these options ensure a label must be applied before users can save files and send emails or meeting invites, create new groups or sites, and when they use unlabeled content for Power BI.

  For documents and emails, a label can be assigned manually by the user, automatically as a result of a condition that you configure, or be assigned by default (the default label option previously described). An example prompt when a user is required to assign a label:

  For more information about mandatory labeling for documents and emails, see Require users to apply a label to their email and documents.

  For containers, a label must be assigned at the time the group or site is created.

  For more information about mandatory labeling for Power BI, see Mandatory label policy for Power BI.

  Consider using this option to help increase your labeling coverage. However, without user training, these settings can result in inaccurate labeling. In addition, unless you also set a corresponding default label, mandatory labeling can frustrate your users with the frequent prompts.

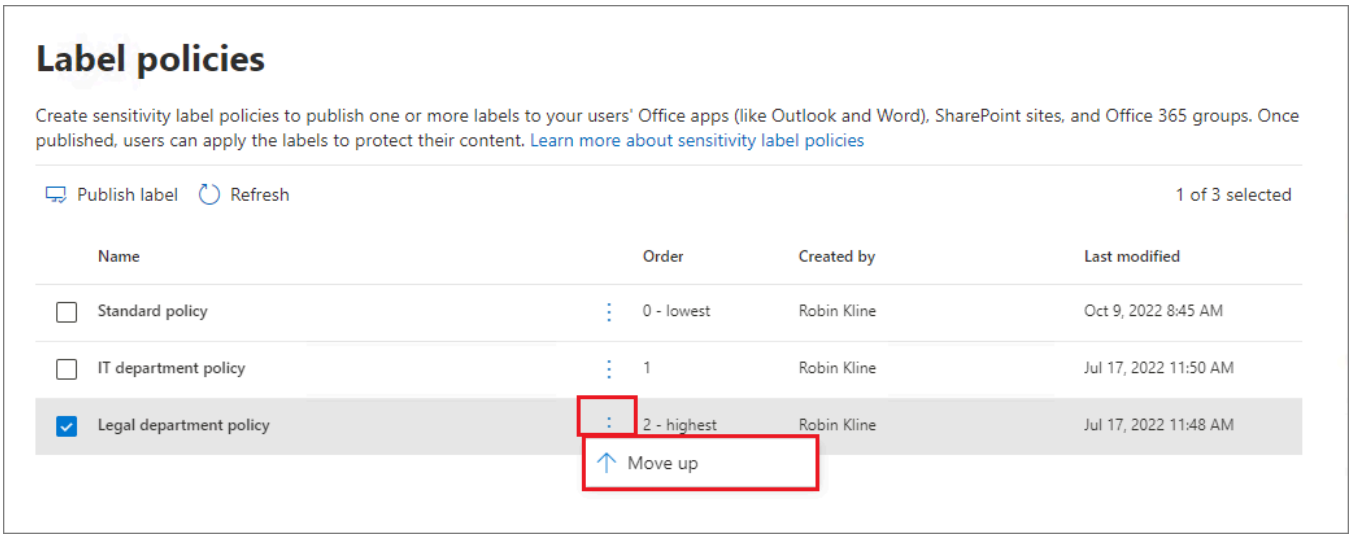
- **Provide help link to a custom help page.** If your users aren't sure what your sensitivity labels mean or how they should be used, you can provide a Learn More URL that appears after the list of available sensitivity labels in the Office apps. For example:

For more label policy configurations, see Manage sensitivity labels for Office apps.

After you create a publishing label policy that assigns new sensitivity labels to users and groups, users start to see those labels in their Office apps. Allow up to 24 hours for the latest changes to replicate throughout your organization.

Label policy priority (order matters)

You make your sensitivity labels available to users by publishing them in a sensitivity label policy that appears in a list on the **Label policies** page. Just like sensitivity labels (see Label priority (order matters)), the order of the sensitivity label policies is important because it reflects their priority: The label policy with lowest priority is shown at the top of the list with the **lowest** order number, and the label policy with the highest priority is shown at the bottom of the list with the **highest** order number.



A label policy consists of:

- A set of labels.
- The users and groups that will be assigned the policy with labels.
- The scope of the policy and policy settings for that scope (such as default label for files and emails).

You can include a user in multiple label policies, and the user gets all the sensitivity labels and settings from those policies. If there's a conflict in settings from multiple policies, the settings

from the policy with the highest priority (highest order number) is applied. In other words, the highest priority wins for each setting.

If you don't see the label policy setting behavior that you expect for a user or group, check the order of the sensitivity label policies. You might need to move the policy down. To reorder the label policies, select a sensitivity label policy, choose the Actions ellipsis for that entry, and then select **Move down** or **Move up**. For example:

From the preceding screenshot example that shows three label policies, all users are assigned the standard label policy, so it's appropriate it has the lowest priority (lowest order number of 0). Only users in the IT department are assigned the second policy that has the order number 1. For these users, if there are any conflicts in settings between their policy and the standard policy, the settings from their policy wins because it has a higher order number.

Similarly for users in the legal department, who are assigned the third policy with distinct settings. It's likely these users have more stringent settings, so it's appropriate that their policy has the highest order number. It's unlikely a user from the legal department is in a group that's also assigned to the policy for the IT department. But if they are, the order number 2 (highest order number) ensures the settings from the legal department always take priority if there's a conflict.

> **Note**
>
> Remember: If there's a conflict of settings for a user who has multiple policies assigned to them, the setting from the assigned policy with the highest order number is applied.

Sensitivity labels for Microsoft 365 Copilot and Microsoft 365 Copilot Chat

Microsoft 365 Copilot, Microsoft 365 Copilot Chat, and Copilot agents recognize and use the sensitivity labels that you apply to protect your organization's data. These labels provide an extra layer of protection. For example, in Microsoft 365 Copilot Chat conversations that can reference data from different types of items, users see the sensitivity label with the highest priority (typically, the most restrictive label). Similarly, when Copilot and agents support sensitivity label inheritance, they select the sensitivity label with the highest priority.

If the labels apply encryption from Microsoft Purview Information Protection, Copilot and agents check the usage rights for the user. Then, Copilot and agents return data from an item only if the user is granted permissions to copy (the EXTRACT usage right) from that item.

For more detailed information about how sensitivity labels help protect your data when you use Copilot and other AI apps, see the following articles:

- Microsoft Purview data security and compliance protections for generative AI apps
- Use Microsoft Purview to manage data security & compliance for Microsoft 365 Copilot & Microsoft 365 Copilot Chat
- Considerations to manage Microsoft 365 Copilot for security and compliance

Sensitivity labels and Azure Information Protection

The older labeling client, the Azure Information Protection unified labeling client, is now replaced with the Microsoft Purview Information Protection client to extend labeling on Windows to File Explorer, PowerShell, the on-premises scanner, and provide a viewer for encrypted files.

Office apps support sensitivity labels with a subscription version of Office, such as Microsoft 365 Apps for enterprise.

Sensitivity labels and the Microsoft Information Protection SDK

Because a sensitivity label is stored in the metadata of a document, third-party apps and services can read from and write to this labeling metadata to supplement your labeling deployment. Additionally, software developers can use the Microsoft Information Protection

SDK to fully support labeling and encryption capabilities across multiple platforms. To learn more, see the General Availability announcement on the Tech Community blog.

You can also learn about partner solutions that are integrated with Microsoft Purview Information Protection.

Deployment guidance

For deployment planning and guidance that includes licensing information, permissions, deployment strategy, a list of supported scenarios, and end-user documentation, see Get started with sensitivity labels.

To learn how to use sensitivity labels to comply with data privacy regulations, see Deploy information protection for data privacy regulations with Microsoft 365.

Last updated on 04/15/2026

Get started with sensitivity labels

> *Microsoft Purview service description*

For information about what sensitivity labels are and how they can help you protect your organization's data, see Learn about sensitivity labels.

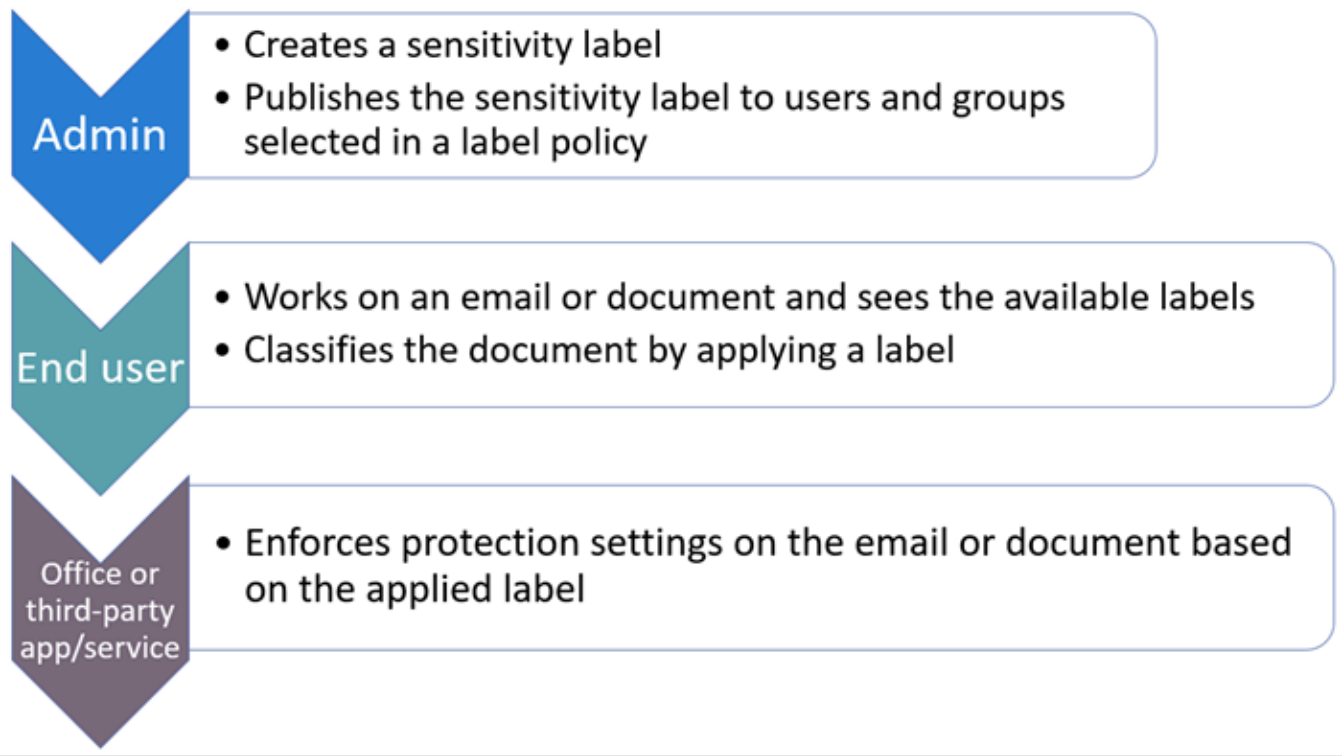
When you're ready to start protecting your organization's data by using sensitivity labels:

1. **Create the labels.** Create and name your sensitivity labels according to your organization's classification taxonomy for different sensitivity levels of content. Use common names or terms that make sense to your users. If you don't already have an established taxonomy, consider starting with label names such as Personal, Public, General, Confidential, and Highly Confidential. You can then use sublabels to group similar labels by category.

   For each label, specify a tooltip to help users select the appropriate label and consider including specific examples. However, don't make the tooltip so long that users won't read it, and be aware that some apps might truncate long tooltips.

   > ⓘ **Note**
   >
   > For some recommended examples, see the label names and descriptions for the default sensitivity labels. For more guidance about defining a classification taxonomy, see Data classification & sensitivity label taxonomy.

   Always test and tailor your sensitivity label names and tooltips with the people who need to apply them.



2. **Define what each label can do.** Configure the protection settings you want associated with each label. For example, you might want lower sensitivity content (such as a "General" label) to have just a header or footer applied, while higher sensitivity content (such as a "Confidential" label) should have a watermark and encryption.

3. **Publish the labels.** After your sensitivity labels are configured, publish them by using a label policy. Decide which users and groups should have the labels and what policy settings to use. A single label is reusable—you define it once, and then you can include it

in several label policies assigned to different users. So for example, you could pilot your sensitivity labels by assigning a label policy to just a few users. Then when you're ready to roll out the labels across your organization, you can create a new label policy for your labels and this time, specify all users.

> **Tip**
>
> You might be eligible for the automatic creation of default labels and a default label policy that takes care of steps 1-3 for you. For more information, see Default labels and policies for Microsoft Purview Information Protection.

The basic flow for deploying and applying sensitivity labels is summarized in the following diagram. It identifies the roles and actions of admins, end users, and then Office or third-party apps or services that respectively create labels, apply them, and enforce the label settings.

Licensing and billing requirements for sensitivity labels

A number of different per-user subscriptions support sensitivity labels for Microsoft 365 apps and services, and the licensing requirements for users depend on the features you use. Admins also need a license to manage sensitivity labels.

To see the options for licensing your users to benefit from Microsoft Purview features, see the Microsoft Purview service description. For sensitivity labels, see the Microsoft Purview Information Protection sensitivity labeling section and related PDF download for feature-level licensing requirements.

Specific to non-Microsoft 365 data sources, applying sensitivity labels in the Data Map and using protection policies requires you to set up pay-as-you-go billing in your organization.

> **Tip**
>
> Because features for this solutions use pay-as-you-go billing or per-user licensing for Microsoft Purview, you might find it helpful to use the **Usage center** to help you understand and manage your usage. For more information, see **Manage pay-as-you-go and per-user licensing usage**.

Permissions required to create and manage sensitivity labels

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview **roles and permissions**.

Members of your compliance team who will create and sensitivity labels need permissions to the Microsoft Purview portal. You can use the following role groups:

- **Information Protection**
- **Information Protection Admins**
- **Information Protection Analysts**
- **Information Protection Investigators**
- **Information Protection Readers**

For an explanation of each one, and the roles that they contain, select a role group in the Microsoft Purview portal, and then review the description in the flyout pane. Or, see Role groups in Microsoft Defender for Office 365 and Microsoft Purview compliance.

Alternatively to using the default role groups, you can create a new role group and add the **Sensitivity Label Administrator** role to this group. For a read-only role, use **Sensitivity Label Reader**.

Another option is to add users to the **Compliance Data Administrator**, **Compliance Administrator**, or **Security Administrator** role group.

For configuration instructions, see Permissions in the Microsoft Purview portal.

These permissions are required only to create and configure sensitivity labels and their label policies. They are not required to apply the labels in apps or services. If additional permissions are needed for specific configurations that relate to sensitivity labels, those permissions will be listed in their respective documentation instructions.

Support for administrative units

Sensitivity labels support administrative units that have been configured in Microsoft Entra ID:

- You can assign administrative units to members of role groups that are used with Microsoft Purview Information Protection. Edit these role groups and select individual members, and then the **Assign admin units** option to select administrative units from Microsoft Entra ID. These administrators are now restricted to managing just the users in those administrative units.

- You can define the initial scope of sensitivity label policies and auto-labeling policies when you create or edit these policies. When you select administrative units for Exchange and OneDrive, only the users in those administrative units will be eligible for the policy. When you select administrative units for SharePoint, only the sites in those administrative units will be eligible for the policy.

- Protection policies don't support administrative units.

The configuration of administrative units and the accuracy of their membership is a Microsoft Entra ID dependency. Although the main purpose of administrative units is to ensure the security best practice of least privileges, using administrative units for your labeling policies can simplify their configuration and maintenance.

For example, your organization has configured administrative units for specific countries, and you need to publish a new sensitivity label just to users in France and assign specific policy settings to these users:

1. You sign in to the Microsoft Purview portal. Your account is a member of the **Information Protection Admins** role group, and your account in that role group has been assigned administrative units for France, Germany, and Spain.

2. When you create the sensitivity label policy, you see just three administrative units and select the one for France, keeping the default of all users and groups.

   This configuration automatically scopes the policy to all users in France. You don't need to worry about which groups to select or manually select users. You also don't need to worry about changing the policy when there are new users in France, because this change is handled by the administrative unit in Microsoft Entra.

For more information about how Microsoft Purview supports administrative units, see Administrative units.

Deployment strategy for sensitivity labels

A successful strategy to deploy sensitivity labels for an organization is to create a working virtual team that identifies and manages the business and technical requirements, proof of concept testing, internal checkpoints and approvals, and final deployment for the production environment.

Using the table in the next section, we recommend identifying your top one or two scenarios that map to your most impactful business requirements. After these scenarios are deployed, return to the list to identify the next one or two priorities for deployment.

> **Tip**
>
> To help accelerate your deployment, use the **Overview** page from **Information Protection** in the **Microsoft Purview portal** to see labeling recommendations and reports specific to your organization, and more.

Common scenarios for sensitivity labels

All scenarios require you to Create and configure sensitivity labels and their policies.

Expand table

I want to ...	Documentation
Manage sensitivity labels for Office apps so that content is labeled as it's created—includes support for manual labeling on all platforms	Manage sensitivity labels in Office apps
Extend labeling to Windows File Explorer and PowerShell	Extend sensitivity labeling on Windows
Encrypt documents and emails with sensitivity labels and restrict who can access that content and how it can be used	Restrict access to content by using sensitivity labels to apply encryption
Ensure that documents from SharePoint sites retain their current permissions when files are downloaded, and protect them against move and copy	Configure SharePoint with a sensitivity label to extend permissions to downloaded documents
Protect Teams meetings, from meeting invites and responses, to protecting the meeting itself and related chat	Use sensitivity labels to protect calendar items, Teams meetings and chat
Protect Teams voicemail messages	Enable protected voicemail in your organization
Enable sensitivity labels for Office for the web, with support for coauthoring, eDiscovery, data loss prevention, search—even when documents are encrypted	Enable sensitivity labels for files in SharePoint and OneDrive
Use sensitivity labels with Microsoft Loop to protect Loop content	Use sensitivity labels with Microsoft Loop
Files in SharePoint to be automatically labeled with a default sensitivity label	Configure a default sensitivity label for a SharePoint document library
Use co-authoring and AutoSave in Office desktop apps when documents are encrypted	Enable co-authoring for files encrypted with sensitivity labels
Automatically apply sensitivity labels to documents and emails	Automatically apply a sensitivity label to Microsoft 365 data
Use sensitivity labels to protect content in Teams, SharePoint, Viva Engage, and Loop	Use sensitivity labels with containers (groups and sites)
Use sensitivity labels to configure the default sharing link type for sites and individual documents in SharePoint and OneDrive	Use sensitivity labels to set the default sharing link for sites and documents in SharePoint and OneDrive
Apply a sensitivity label to a document understanding model, so that identified documents in a SharePoint library are automatically classified and protected	Apply a sensitivity label to a model in Microsoft Syntex
Prevent or warn users about sharing files or emails with a specific sensitivity label	Use sensitivity labels as conditions in DLP policies

I want to ...	Documentation
Apply a sensitivity label to a file when I receive an alert that content containing personal data is being shared and needs protection	Investigate and remediate alerts in Privacy Risk Management
Apply a retention label to retain or delete files or emails that have a specific sensitivity label	Automatically apply a retention label to retain or delete content
Discover, label, and protect files stored in data stores that are on premises	Deploying the information protection scanner to automatically classify and protect files
Discover, label, and protect files stored in data stores that are in the cloud	Discover, classify, label, and protect regulated and sensitive data stored in the cloud
Label SQL database columns by using the same sensitivity labels as those used for files and emails so that the organization has a unified labeling solution that can continue to protect this structured data when it's exported	Data Discovery & Classification for Azure SQL Database, Azure SQL Managed Instance, and Azure Synapse Analytics SQL Data Discovery and Classification for SQL Server on-premises
Apply and view labels in Power BI, and protect data when it's saved outside the service	Sensitivity labels in Power BI
Label items in Microsoft Fabric, to restrict access and grant read-only or full control permissions to users	Create and manage protection policies for Fabric
Monitor and understand how sensitivity labels are being used in my organization	Reports overview Additionally, view the information protection reports from the Microsoft Purview portal
Audit sensitivity labeling in my organization	Audit log activities - Sensitivity label activities
Identify content for eDiscovery cases based on applied sensitivity labels, such as Confidential and Highly Confidential	Use the condition builder to create search queries in eDiscovery
Extend sensitivity labels to third-party apps and services	Microsoft Information Protection SDK
Extend sensitivity labels across content in my Microsoft Purview Data Map assets, such as Azure Blob Storage, Azure Files, Azure Data Lake Storage, and multi-cloud data sources	Labeling in Microsoft Purview Data Map

End-user documentation for sensitivity labels

The most effective end-user documentation will be customized guidance and instructions you provide for the label names and configurations you choose. You can use the label policy setting **Provide users with a link to a custom help page** to specify an internal link for this documentation.

In Office apps, users can then easily access your customized help from the **Sensitivity** button, **Learn More** menu option. If you don't specify a link in the policy setting, users don't see this menu option in their apps.

From the Microsoft Purview Information Protection file labler in Windows File Explorer, users can access the same customized help from **Help and Feedback** > **Tell Me More** in the file labeler dialog box.

You can use the following resources for basic instructions:

- Apply sensitivity labels to your files
  - Custom permissions for files
- Apply sensitivity labels to email messages in Outlook
- Known issues with sensitivity labels in Office
- Automatically apply or recommend sensitivity labels to your files and emails in Office
  - Known issues with automatically applying or recommending sensitivity labels
- Create protected PDFs from Office files
- Sensitivity labels for Teams meetings
- Apply sensitivity labels to your Outlook meetings.
- Sensitivity labels in Viva Engage
- Label and protect files in File Explorer in Windows

If your sensitivity labels apply encryption for PDF documents, these documents can be opened with Microsoft Edge on Windows or Mac. For more information, see View protected PDFs using Microsoft Edge on Windows or Mac.

Create and configure sensitivity labels and their policies

> *Microsoft Purview service description*

All Microsoft Purview Information Protection solutions are implemented by using sensitivity labels. To create and publish these labels, use the Microsoft Purview portal.

First, create and configure the sensitivity labels that you want to make available for apps and other services. For example, the labels you want users to see and apply from Office apps.

Then, create one or more label policies that contain the labels and policy settings that you configure. When you publish the label policy to your chosen users:

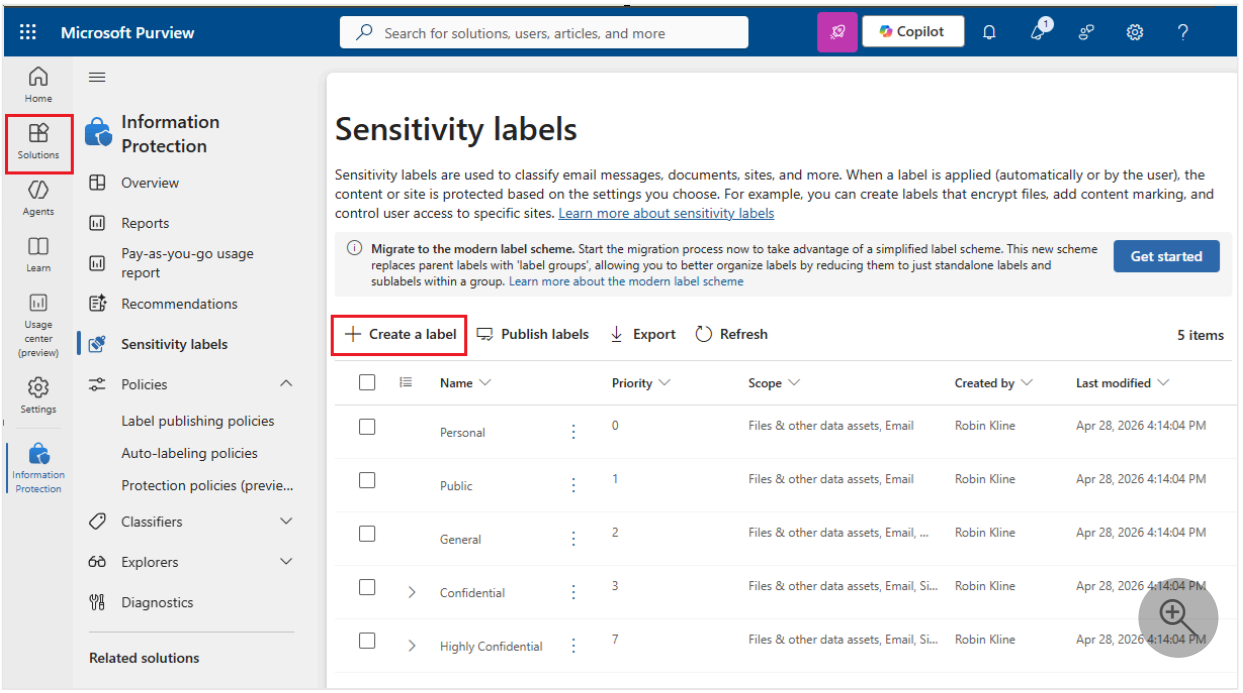
- The labels become visible to these users in their apps that support sensitivity labels
- The policy settings are applied to these users

> **Note**
>
> You might be eligible for the automatic creation of default labels and a default label policy. Even if you have some labels, you might find it useful to see the configuration of these default labels that we're creating for new customers. For example, you can make the same manual configurations to help accelerate your own label deployment.
>
> For more information, see Default labels and policies for Microsoft Purview Information Protection.

Before you begin

To make sure you have permissions to create and manage sensitivity labels, see Permissions required to create and manage sensitivity labels.

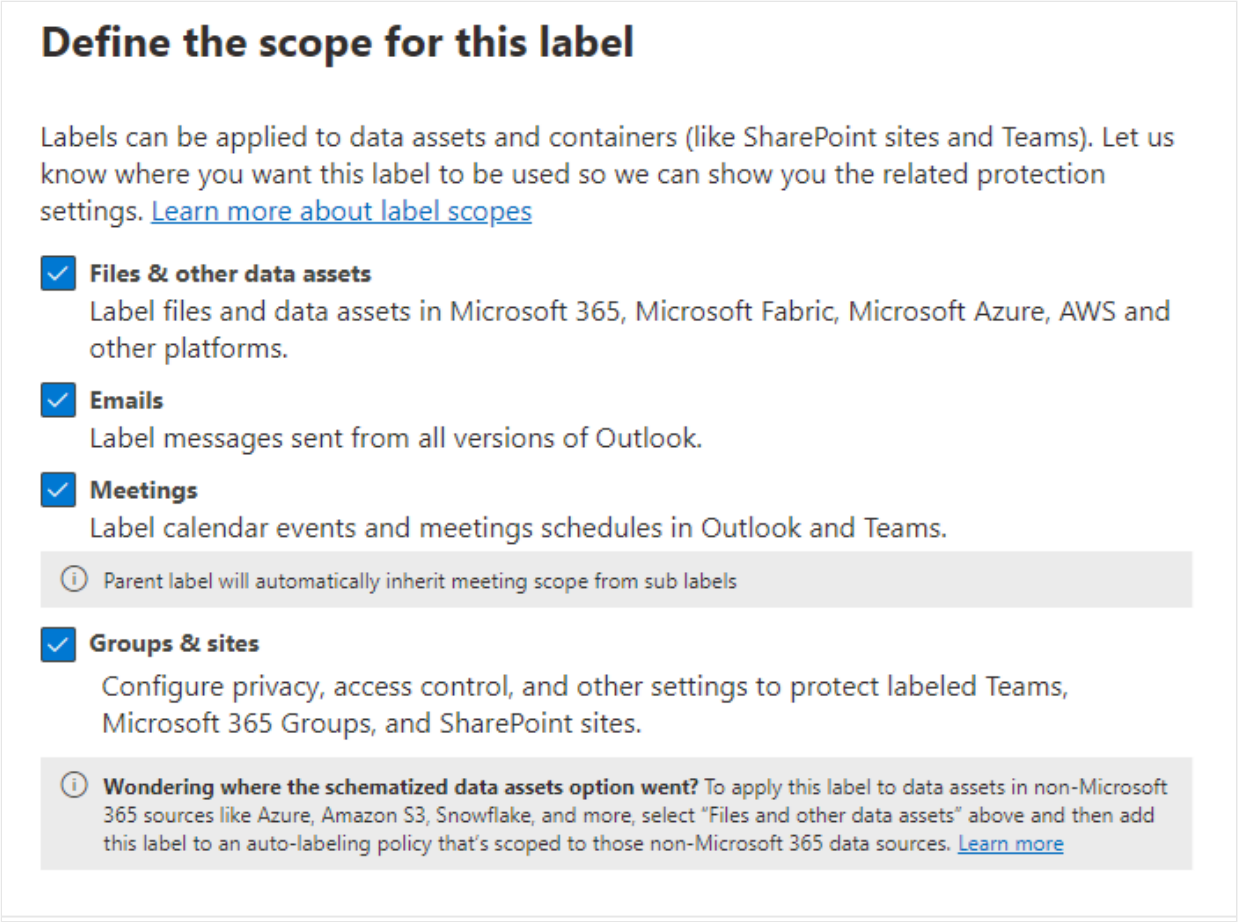
Create and configure sensitivity labels



Choose the **Modern label scheme** tab if you don't already have any sensitivity labels or your tenant was created beginning October 1, 2025. Or, you manually migrated to the modern label

scheme. In both cases, you see a green message bar on the **Sensitivity labels** page that confirms your tenant is successfully migrated to the modern label scheme.

Classic label scheme



1. Sign in to the Microsoft Purview portal > **Solutions** > **Information Protection** > **Sensitivity labels**

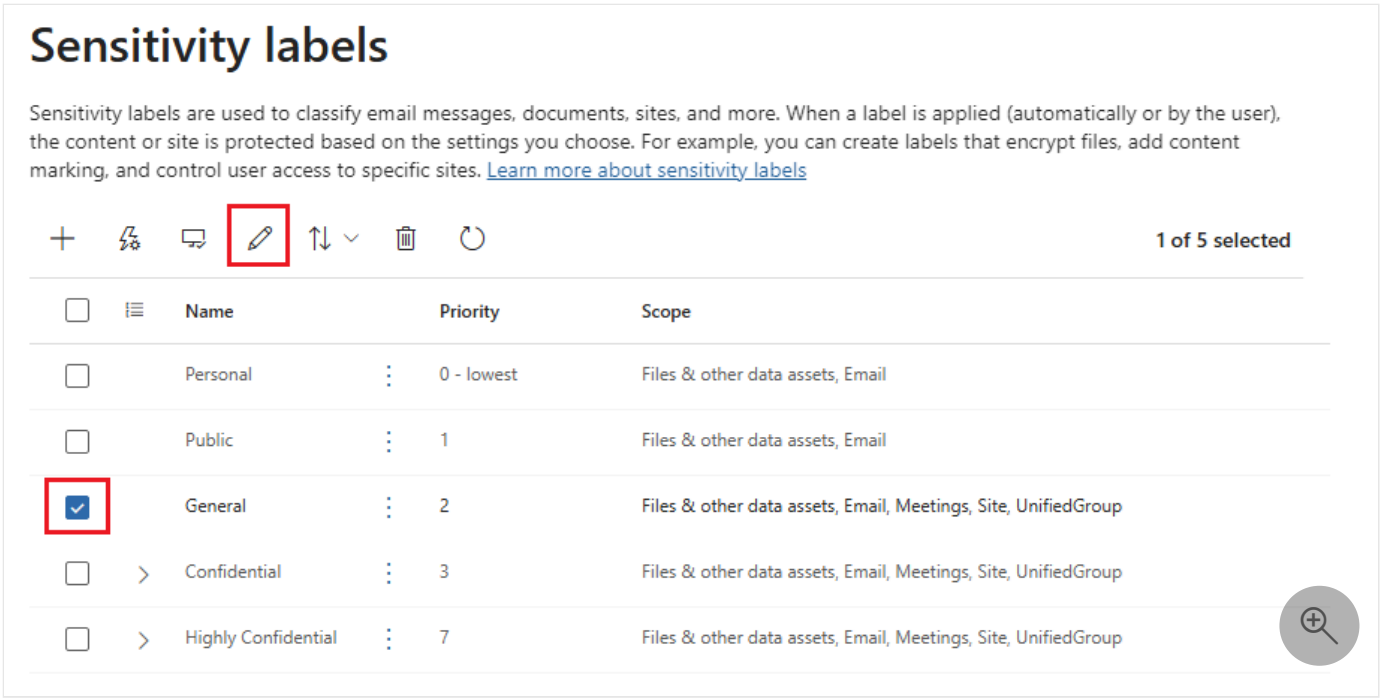
2. On the **Sensitivity labels** page, select + **Create a label** to start the new sensitivity label configuration. For example, from the Microsoft Purview portal:

> **Note**
>
> If you need guidance to create new labels, see Get started with sensitivity labels.

3. On the **Define the scope for this label** page, the options selected determine the label's scope for the settings that you can configure and where they'll be visible when they're published:

You can't select **Meetings** unless **Files & other data assets** and **Emails** are also selected. For more information about this dependency and extending labels to include meetings, see Use sensitivity labels to protect calendar items, Teams meetings, and chat.

If scope options aren't selected, you see the first page to configure the settings for the scope, but you can't configure them and the labels won't be available for users to select in these apps.



4. Follow the configuration prompts for the label settings.

   For more information about the label settings, see What sensitivity labels can do from the overview information and use the help in the UI for individual settings.

5. Repeat these steps to create more labels. However, if you want to create a sublabel, first select the parent label and select **...** for **Actions**, and then select **Create sublabel**.

6. When you've created all the labels you need, review their order and if necessary, move them up or down. To change the order of a label, select **...** for **Actions**, and then select one of the reordering options, such as **Move up** or **Move down**. For more information, see Label priority (order matters) from the overview information.

To edit an existing label, select it, and then select the **Edit label** icon. For example:

This action starts the **Edit sensitivity label** configuration, which lets you change all the label settings.

Don't delete a label unless you understand the impact for users. For more information, see the Removing and deleting labels section.

> **Note**
>
> If you edit a label that's already published by using a label policy, no extra steps are needed when you finish the configuration. For example, you don't need to add it to a new label policy for the changes to become available to the same users. However, allow up to 24 hours for the changes to replicate to all apps and services.

Until you publish your labels, they won't be available to select in apps or for services. To publish the labels, they must be added to a label policy.

> **Important**
>
> On this **Labels** tab, do not select the **Publish labels** tab (or the **Publish label** button when you edit a label) unless you need to create a new label policy. You need multiple label policies only if users need different labels or different policy settings. Aim to have as few

label policies as possible—it's not uncommon to have just one label policy for the organization.

Additional label settings with Security & Compliance PowerShell

Additional label settings are available with the Set-Label cmdlet from Security & Compliance PowerShell.

For example:

- Use the *LocaleSettings* parameter for multinational deployments so that users see the label name and tooltip in their local language. The following section has an example configuration that specifies the label name and tooltip text for French, Italian, and German.
- Advanced settings supported by built-in labeling are included in the PowerShell documentation. For more help in specifying these PowerShell advanced settings, see the PowerShell tips for specifying the advanced settings section. For additional advanced settings supported by the Microsoft Purview Information Protection client, see the separate documentation for these settings.

Example configuration to configure a sensitivity label for different languages

The following example shows the PowerShell configuration for a label named "Public" with placeholder text for the tooltip. In this example, the label name and tooltip text are configured for French, Italian, and German.

As a result of this configuration, users who have Office apps that use those display languages see their label names and tooltips in the same language. Similarly, if you have the Microsoft Purview Information Protection client installed to label files from File Explorer, users who have those language versions of Windows see their label names and tooltips in their local language when they use the right-click actions for labeling.

For the languages that you need to support, use the Office language identifiers (also known as language tags), and specify your own translation for the label name and tooltip.

Before you run the commands in PowerShell, you must first connect to Security & Compliance PowerShell.

PowerShell

```
$Languages = @("fr-fr","it-it","de-de")
$DisplayNames=@("Publique","Publico","Oeffentlich")
$Tooltips = @("Texte Français","Testo italiano","Deutscher text")
$label = "Public"
$DisplayNameLocaleSettings = [PSCustomObject]@{LocaleKey='DisplayName';
Settings=@(
@{key=$Languages[0];Value=$DisplayNames[0];}
@{key=$Languages[1];Value=$DisplayNames[1];}
@{key=$Languages[2];Value=$DisplayNames[2];})}
$TooltipLocaleSettings = [PSCustomObject]@{LocaleKey='Tooltip';
Settings=@(
@{key=$Languages[0];Value=$Tooltips[0];}
@{key=$Languages[1];Value=$Tooltips[1];}
@{key=$Languages[2];Value=$Tooltips[2];})}
Set-Label -Identity $Label -LocaleSettings (ConvertTo-Json $DisplayNameLocaleSettings
-Depth 3 -Compress),(ConvertTo-Json $TooltipLocaleSettings -Depth 3 -Compress)
```

PowerShell tips for specifying the advanced settings

Although you can specify a sensitivity label by its name, we recommend using the label GUID to avoid potential confusion over specifying the label name or display name. The label name is unique in your tenant, so you can be sure you're configuring the correct label. The display name isn't unique and could result in configuring the wrong label. To find the GUID and confirm the label's scope:

PowerShell

```
Get-Label | Format-Table -Property DisplayName, Name, Guid, ContentType
```

To remove an advanced setting from a sensitivity label, use the same AdvancedSettings parameter syntax, but specify a null string value. For example:

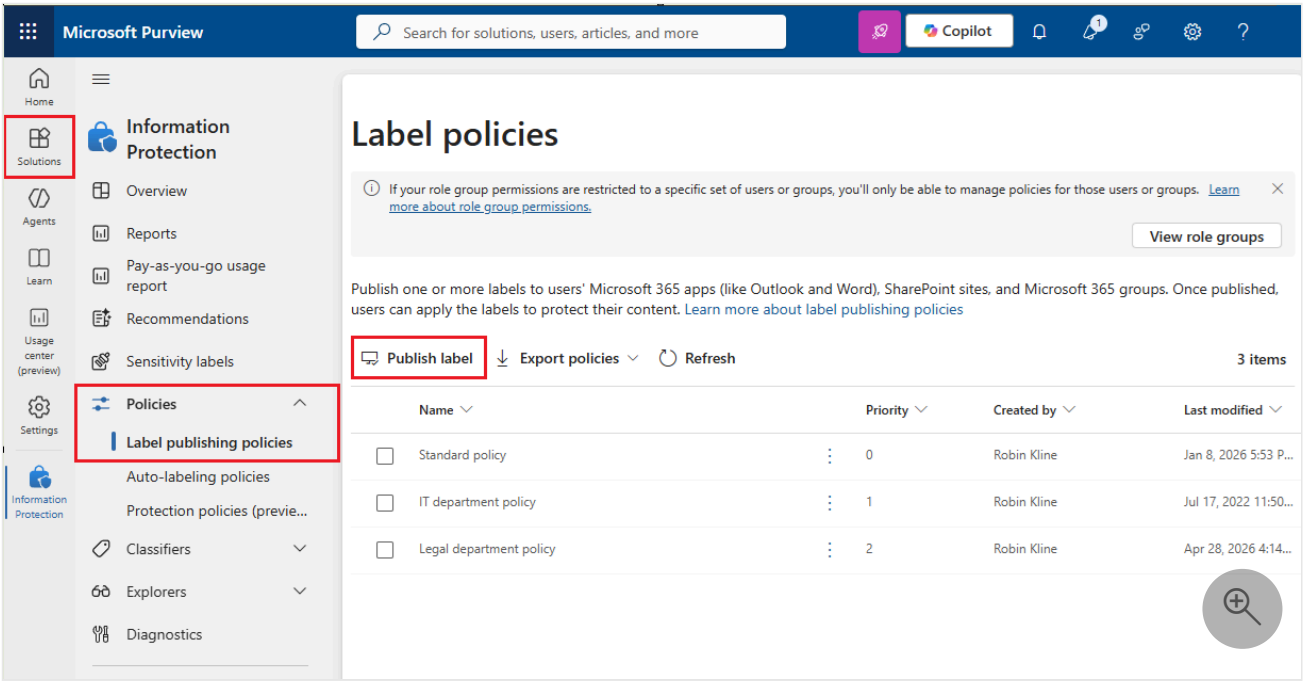
PowerShell

```
Set-Label -Identity 8faca7b8-8d20-48a3-8ea2-0f96310a848e -AdvancedSettings
@{DefaultSharingScope=""}
```

To check your label's configuration, including advanced settings, use the following syntax with your own label GUID:

PowerShell

```
(Get-Label -Identity 8faca7b8-8d20-48a3-8ea2-0f96310a848e).settings
```



Publish sensitivity labels by creating a label policy

As part of the label policy, you select users and groups to have sensitivity labels and label policy settings. For lower administrative maintenance, groups are recommended rather than individual users. However, if a user is removed from a group you specify, the label policy is automatically removed for that user.

Groups supported: Email-enabled security groups, non-mail enabled security groups, distribution groups, Microsoft 365 groups (that can have dynamic membership) in Microsoft Entra ID.

1. Sign in to the Microsoft Purview portal > **Solutions** > **Information Protection** > **Publishing policies**.

2. On the **Label policies** page, select **Publish label** to start the **Create policy** configuration. For example, from the Microsoft Purview portal:

> **Note**
>
> For more information about the **Export policies** option that can capture detailed information about these policies and all sensitivity labels in your tenant, see Export policy configuration in Microsoft Purview.

If you had default sensitivity labels created for you, you also have a default label publishing policy, which you can modify or supplement with additional policies.

3. On the **Choose sensitivity labels to publish** page, select the **Choose sensitivity labels to publish** link. Select the labels that you want to make available in apps and to services, and then select **Add**.

   > **Important**
   >
   > If you're using the classic label scheme: When you select a sublabel, make sure you also select its parent label.

4. For the **Assign admin units**: If your organization is using administrative units in Microsoft Entra ID, the label policy can be automatically restricted to specific users by selecting administrative units. If your account has been assigned administrative units, you must select one or more administrative units.

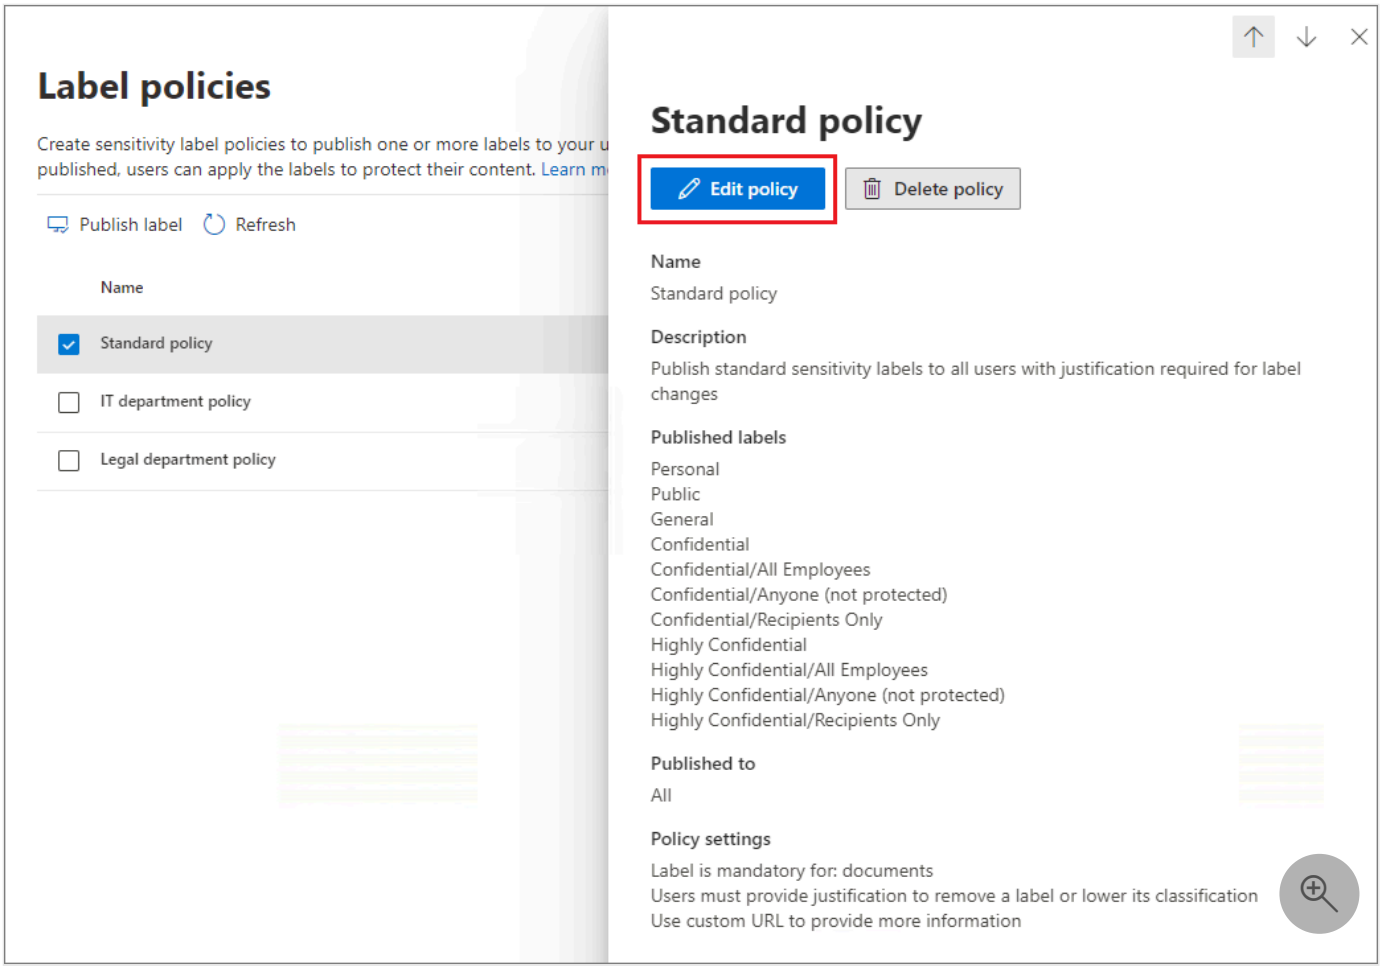
   If you don't want to restrict the policy by using administrative units, or your organization hasn't configured administrative units, keep the default of **Full directory**.

5. Follow the prompts to complete the configuration.

   The policy settings that you see match the scope of the labels that you selected. For example, if you selected labels that have just the **Files & other data assets** scope, you don't see the policy settings **Apply this label by default to groups and sites** and **Require users to apply a label to their groups and sites**.

   For more information about these settings, see What label policies can do from the overview information and use the help in the UI for individual settings.

   For labels configured for **Microsoft Purview Data Map assets (preview)**: These labels don't have any associated publishing policy settings.



6. Repeat these steps if you need different publishing policy settings for different users or scopes. For example, you want additional labels for a group of users, or a different default label for a subset of users. Or, if you have configured labels to have different scopes.

7. If you have more than one label policy that might result in a conflict for a user, review the policy order and if necessary, move them up or down. To change the order of a label policy, select **...** for **Actions**, and then select one of the reordering options. For more information, see Label policy priority (order matters) from the overview information.

Completing the **Create policy** configuration automatically publishes the label policy. To make changes to a published policy, simply edit it. There's no specific publish or republish action for

you to select.

To edit an existing label policy, select it, and then select the **Edit Policy** button from the flyout pane:

This action starts the **Create policy** configuration, which lets you edit which labels are included and the label settings. When you complete the configuration, any changes are automatically replicated to the selected users and services.

Additional label policy settings with Security & Compliance PowerShell

Additional label policy settings are available with the Set-LabelPolicy cmdlet from Security & Compliance PowerShell.

The cmdlet documentation includes the advanced settings that are supported by built-in labeling. For additional advanced settings supported by the Microsoft Purview Information Protection client, see the separate documentation for these settings.

Create and configure protection policies

Protection policies are currently in preview and apply to items stored outside Microsoft 365. For example, in Microsoft Fabric, Microsoft Azure Storage, and Microsoft Data Lake Storage Gen 2.

For more information, see Authoring and publishing protection policies.

When to expect new labels and changes to take effect

For labels and label policy settings, allow 24 hours for the changes to propagate through the services. There are many external dependencies that each have their own timing cycles, so it's a good idea to wait this 24-hour time period before you spend time troubleshooting labels and label policies for recent changes.

However, there are some scenarios where label and label policy changes can take effect much faster or be longer than 24 hours. For example, for new and deleted sensitivity labels for Word, Excel, and PowerPoint on the web, you might see updates replicate within the hour. But for configurations that depend on populating a new group and group membership changes, or network replication latency and bandwidth restrictions, these changes might take 24-48 hours.

Use PowerShell for sensitivity labels and their policies

You can now use Security & Compliance PowerShell to create and configure all the settings you see in your labeling admin center. This means that in addition to using PowerShell for settings that aren't available in the labeling admin centers, you can now fully script the creation and maintenance of sensitivity labels and sensitivity label policies.

See the following documentation for supported parameters and values:

- New-Label
- New-LabelPolicy
- Set-Label
- Set-LabelPolicy

> **Tip**
>
> When you're configuring advanced settings for a sensitivity label, you might find it helpful to reference the **PowerShell tips for specifying the advanced settings** section on this page.

You can also use Remove-Label and Remove-LabelPolicy if you need to script the deletion of sensitivity labels or sensitivity label policies. However, before you delete sensitivity labels, make

sure you read the next section.

Removing and deleting labels

In a production environment, it's unlikely that you'll need to remove sensitivity labels from a label policy, or delete sensitivity labels. It's more likely that you might need to do one or either of these actions during an initial testing phase. Make sure you understand what happens when you do either of these actions.

Removing a label from a label policy is less risky than deleting it, and can always be added back later if needed. You can't delete a label if it's still in a label policy.

When you remove a label from a label policy so that the label is no longer published to the originally specified users, the next time the label policy is refreshed, users no longer see that label to select in their Office apps. If that label is already applied, the label isn't removed from the content or container. For example, users who are using built-in labeling in desktop apps for Word, Excel, and PowerPoint, still see the applied label name on the status bar. An applied container label continues to protect the Teams or SharePoint site.

In comparison, when you delete a label:

- If the label applied encryption, the underlying protection template is archived so that previously protected content can still be opened. Because of this archived protection template, you can't create a new label with the same name. Although it's possible to delete a protection template by using PowerShell, don't do this unless you're sure you don't need to open content that was encrypted with the archived template.

- For documents stored in SharePoint or OneDrive and you've enabled sensitivity labels for Office files: When you open the document in Office for the web, you won't see the label applied in the app, and the label name no longer displays in the **Sensitivity** column in SharePoint. If the deleted label applied encryption and the services can process the encrypted contents, the encryption is removed. Egress actions from these services result in the same outcome. For example, download, copy to, move to, and open with an Office desktop or mobile app. Although the label information remains in the file's metadata, apps can no longer map the label ID to a display name, so users will assume a file isn't labeled.

- For documents stored outside SharePoint and OneDrive or you haven't enabled sensitivity labels for Office files, and for emails: When you open the content, the label information in the metadata remains, but without the label ID to name mapping, users don't see the applied label name displayed (for example, on the status bar for desktop apps). If the

deleted label applied encryption, the encryption remains and users still see the name and description of the now archived protection template.

- For containers, such as sites in SharePoint and Teams: The label is removed and any settings that were configured with that label are no longer enforced. This action typically takes between 48-72 hours for SharePoint sites, and can be quicker for Teams and Microsoft 365 Groups. Until the label deletion process is complete, users might not be able to open the content that was previously protected by the sensitivity label.

- Be aware that without a GUID-to-name mapping available after you delete a label, deleted labels can display as GUIDs rather than label names in applications such as content explorer and activity explorer.

As with all label changes, removing a sensitivity label from a label policy or deleting a sensitivity label takes time to replicate to all users and services.

Next steps

To configure and use your sensitivity labels for specific scenarios, you might find the following articles helpful:

- Restrict access to content by using encryption in sensitivity labels
- Automatically apply a sensitivity label to Microsoft 365 data
- Use sensitivity labels with containers (groups and sites)
- Enable sensitivity labels for files in SharePoint and OneDrive

To monitor how your labels are being used, view the reports from the Microsoft Purview portal: **Solutions** > **Information Protection** > **Reports**

Last updated on 10/07/2026

Migrate parent sensitivity labels to label groups

> *Microsoft Purview service description*

> **Note**
>
> Migration is automatic if you have a new tenant beginning October 1, 2025 or the migration of parent labels won't create a new sublabel with the same name because you have applicable parent labels. In both these cases, your sensitivity labels will automatically use the modern label scheme to benefit from better organization and reduced deployment complexity.

Previously, parent labels were used to organize sensitivity labels in a two-tier hierarchy. To reduce complexity, their replacement, label groups, don't support settings other than name, description, color, and priority.

For more information about parent labels and label groups, see Sublabels that use parent labels or label groups.

To migrate your parent sensitivity labels to sensitivity label groups, use the Microsoft Purview portal if you see the information banner displayed in the following instructions.

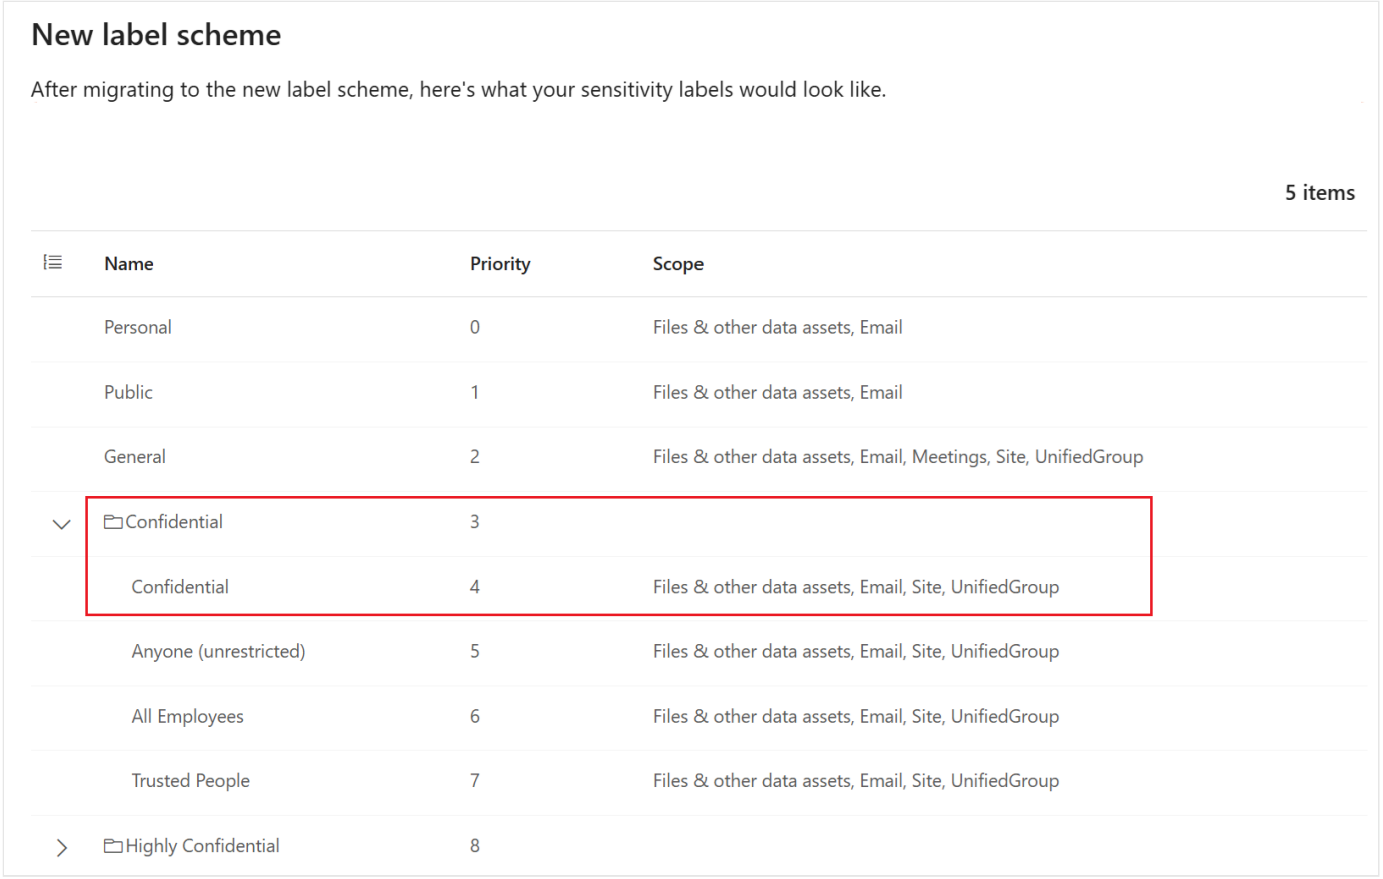
> **Caution**
>
> Label migration is irreversible. We highly recommend that you first test the migration by using a test tenant that has the same sensitivity label configurations as your production tenant.

Before you begin

First, make sure you have permissions to create and manage sensitivity labels. For more information, see Permissions required to create and manage sensitivity labels.

Then, understand the impact of parent labels that if applicable, will be migrated to a sublabel with the same name, in addition to a label group. If this scenario applies to you, you must decide whether you want to leave these new sublabels published after the migration, or you want to unpublish them:

- If you decide to unpublish these new sublabels, you can do this manually, or use PowerShell scripts to automatically unpublish them.
- If you leave these new sublabels published, decide whether you will need to edit them post migration and before users can select them.



This new sublabel creation ensures that all users and services that might have accessed the parent label as a standalone label will continue to be able to access it after the migration.

- It's configured for label actions that include encryption, content marking, auto-labeling, and PowerShell advanced settings.
- It's included in a different publishing policy from its sublabels.
- It has a different label scope from its sublabels in one or more of the following ways:
  - A sublabel is configured for a label scope that the parent label isn't configured for.
  - Within the same label policy, the parent label has one or more scopes that aren't configured for any of its sublabels.

The resulting sublabel that's created has the same name, label GUID, and settings as the original parent label. Without reconfiguration, this new sublabel will be available to select in a policy where previously it couldn't be selected as a parent label.

> ⓘ **Note**
>
> Because label GUIDs are unique in your tenant, they are used by backend services and configurations to reliably identify a sensitivity label. For example, we recommend you **use the GUID rather than the label name to configure advanced settings**.
>
> To ensure business continuity post migration, the new sublabel inherits the GUID from the applicable parent label, and the new label group is given a new GUID.

You can confirm whether you have applicable parent labels before the labels are migrated when you review the proposed new label scheme as part of the migration process. In the following example, the parent label **Confidential** is identified as an applicable parent label, with the result that a new sublabel of the same name will be created:

PowerShell scripts for unpublishing sublabels from applicable parent labels

These PowerShell commands use Security & Compliance PowerShell.

Script One: Before the migration, run the following command to fetch all policies that publish parent labels.

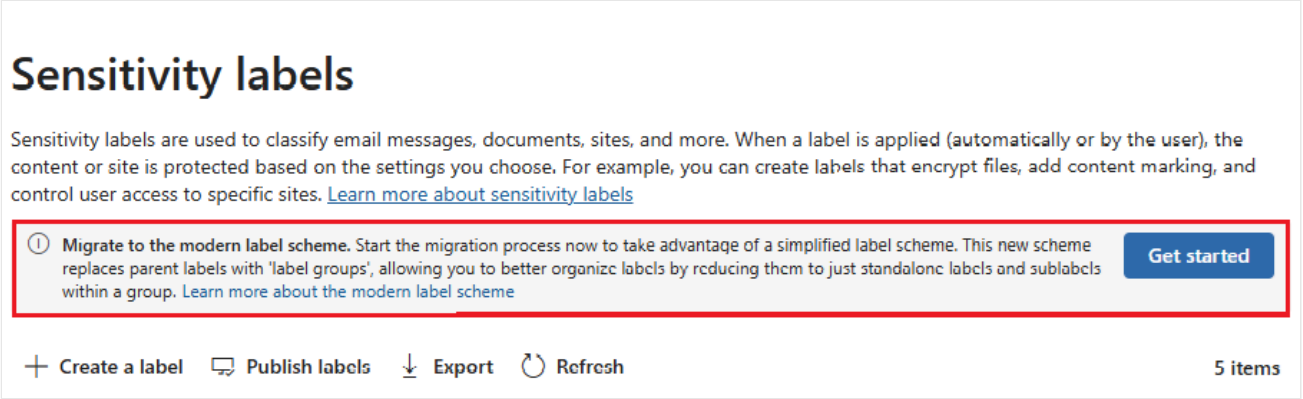
PowerShell

```
$parents = (Get-Label | ? { $_.ParentId -ne $null } | %{ echo $_.ParentId } | Sort-Object -Unique)
$parentLabels = ($parents | % { Get-Label -Identity $_.Guid })
$policyPublishingParent = @{}
$policies = Get-LabelPolicy; $parentLabels | % { $parent = $_.Name; $policies | ? { $_.Labels -contains $parent } |
% { echo "$($_.Name) policy has published $parent"; $(If ($policyPublishingParent.Keys -notcontains $_.Name) {
$policyPublishingParent[$_.Name] = @() }); $policyPublishingParent[$_.Name] += $parent } }
```

Don't close your PowerShell session but keep it open during the label migration.

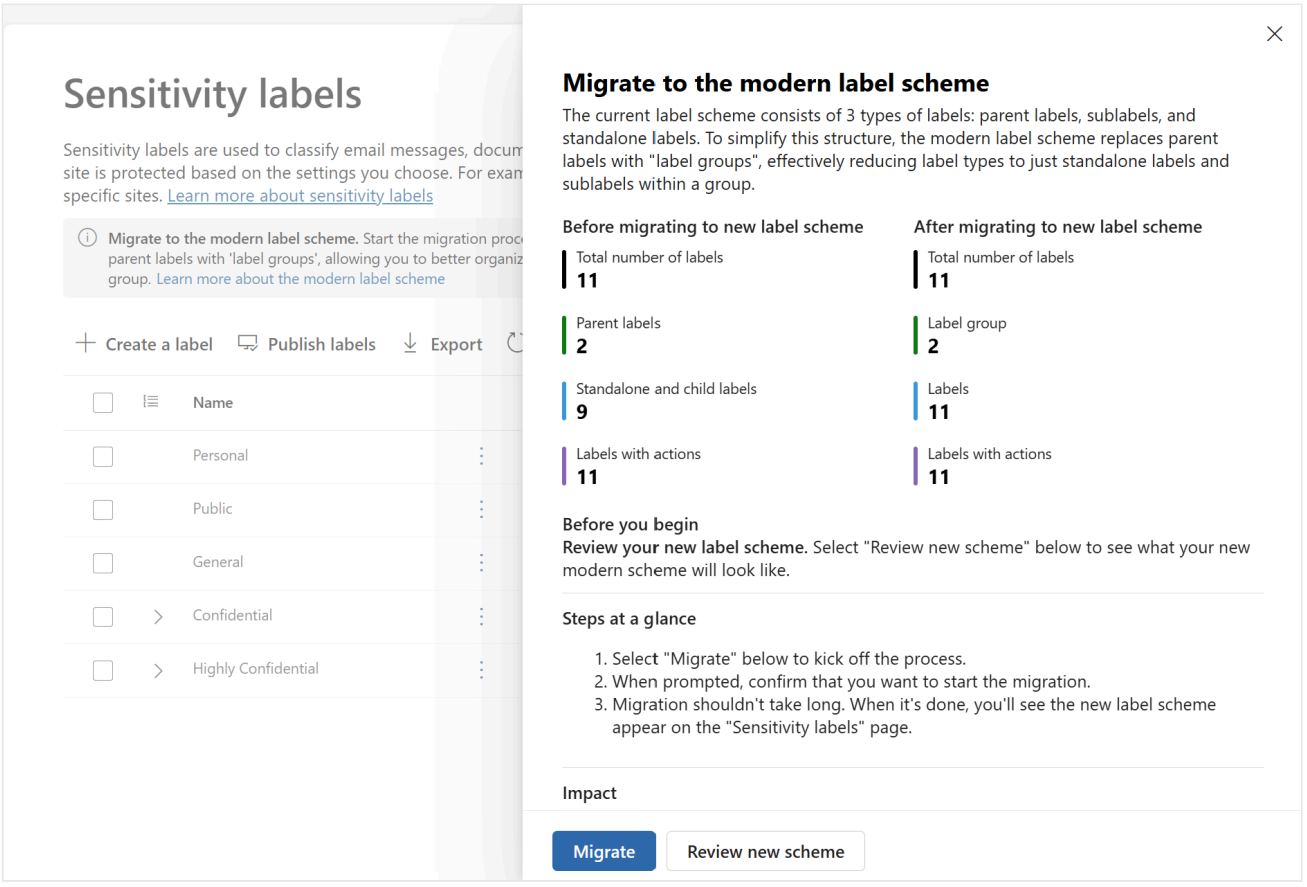
Script Two: As soon as migration is complete, run the following script to unpublish the newly created sublabels from applicable parent labels:

PowerShell



```
$policyPublishingParent.Keys | % { $policyToRemove = $_;
$policyPublishingParent.Item($policyToRemove) | % {
Set-LabelPolicy -Identity $policyToRemove -RemoveLabels $_ }
```

Migrate to the modern label scheme



Migration is gradually rolling out, so migrating your parent labels to label groups might not yet be available for your tenant.

1. Sign in to the Microsoft Purview portal > **Solutions** > **Information Protection** > **Sensitivity labels**

2. On the **Sensitivity labels** page, if you see an information banner **Migrate to the modern label scheme**, label migration is available to your tenant. From this banner, select **Get started** to start the migration:

3. On the **Migrate to the modern label scheme** flyout pane, you see a summary of your sensitivity labels before and after the migration. For more details, select the **Review new scheme** button at the bottom of the pane. For example:

4. The **New label scheme** page shows you how your migrated labels will look in the Microsoft Purview portal, with a folder icon next to what used to be parent labels. This page will also alert you to any naming conflicts that need to be resolved before the migration. For example, the **General** parent label has a sublabel that's also named **General**. All sublabels must have a unique name from their parent label.

   You can use the **Download** button to save a copy to a CSV file. The default name is NewLabelSchemecsv.csv.

> **ⓘ Important**
>
> Even if you don't have alerts to resolve, use this opportunity to carefully review the labels and consider making changes to them before you migrate so you can remove or minimize the applicable parent labels that will create a new sublabel if they're not needed. After making changes, restart the migration and check the post-migration information again from this page.
>
> For example, you might have parent labels that you've never used as standalone labels, but are configured for encryption or content markings. Label actions are one of the reasons why migration creates a new sublabel that you might not need.

5. When you're ready to migrate your labels, select the **Migrate** button.

> **Note**
>
> If you have applicable parent labels that will create new sublabels and you decided to use a script to automatically unpublish them, run Script One before you select **Migrate**.

The migration process doesn't take long, typically just a few minutes to an hour. However, as a precaution, allow up to 24 hours. While the migration is in progress, we don't recommend making any changes to the label configuration because those changes will likely be lost.

When the migration is complete, the browser refreshes, and the new label scheme is displayed with a message to confirm that the migration is complete.

> **Note**
>
> If you have applicable parent labels that will create new sublabels and you decided to use a script to automatically unpublish them, now run Script Two.

Next steps

For instructions to manage your migrated labels, see Create and configure sensitivity labels. Review your new label groups and migrated labels, and make any changes that you need. For example, reconfigure or unpublish any new labels that were created from parent labels.

For parent labels that were migrated to label groups, and for existing sublabels, users won't see or experience any changes in their apps. For example, priority ordering behaves the same and a default sublabel continues to be honored.

Last updated on 04/17/2026

Restrict access to content by using sensitivity labels to apply encryption

> *Microsoft Purview service description*

When you create a sensitivity label, you can restrict access to content that the label will be applied to. For example, with the encryption settings for a sensitivity label, you can protect content so that:

- Only users within your organization can open a confidential document or email.
- Only users in the marketing department can edit and print the promotion announcement document or email, while all other users in your organization can only read it.
- Users can't forward an email or copy information from it that contains news about an internal reorganization.
- The current price list that is sent to business partners can't be opened after a specified date.
- Only the people sent a meeting invite to kick off a confidential project can open the meeting invite and they can't forward it to others.

When a document, email, or meeting invite is encrypted, access to the content is restricted, so that it:

- Can be decrypted only by users authorized by the label's encryption settings.
- Remains encrypted no matter where it resides, inside or outside your organization, even if the file's renamed.
- Is encrypted both at rest (for example, in a OneDrive account) and in transit (for example, email as it traverses the internet).

Finally, as an admin, when you configure a sensitivity label to apply encryption, you can choose either to:

- **Assign permissions now**, so that you determine exactly which users get which permissions to content with that label.
- **Let users assign permissions** when they apply the label to content. This way, you can allow people in your organization some flexibility that they might need to collaborate and get their work done.

The encryption settings are available when you create or edit a sensitivity label in the Microsoft Purview portal.

> **Note**
>
> A sensitivity label in Outlook can apply S/MIME protection rather than encryption and permissions from the Azure Rights Management service. For more information, see Configure a label to apply S/MIME protection in Outlook.

Understand how the encryption works

Unless you're using S/MIME for Outlook, encryption that's applied by sensitivity labels to documents, emails, and meeting invites all use the Azure Rights Management service (Azure RMS) from Microsoft Purview Information Protection. This protection solution uses encryption, identity, and authorization policies. To learn more, see What is Azure Rights Management?.

When you use this encryption solution, the **super user** feature ensures that authorized people and services can always read and inspect the data that has been encrypted for your organization. If necessary, the encryption can then be removed or changed. For more information, see Configure Azure Rights Management super users for discovery services or data recovery.

> **Important**
>
> You can also use sensitivity labels to apply encryption to audio and video streams for Teams meetings, but this uses a different method of encryption and not the Azure Rights Management service that's used for emails, meeting invites, and documents. For more information about the encryption used for Teams meetings, see the Media encryption from the Teams security guide.

Important prerequisites

Before you can use encryption, you might need to do some configuration tasks. When you configure encryption settings, there's no check to validate that these prerequisites are met.

- Activate Azure Rights Management

For sensitivity labels to apply encryption with rights management, the Azure Rights Management service from Microsoft Purview Information Protection must be activated for your tenant. In newer tenants, this is the default setting, but you might need to manually activate the service. For more information, see Activate the Azure Rights Management service.

- Check for network requirements

  You might need to make some changes on your network devices such as firewalls. For details, see Firewalls and network infrastructure.

- Check your Microsoft Entra configuration

  There are some Microsoft Entra configurations that can prevent authorized access to encrypted content. For example, cross-tenant access settings and Conditional Access policies. For more information, see Microsoft Entra configuration for encrypted content.

- Configure Exchange for Azure Rights Management

  Exchange doesn't have to be configured for Azure Rights Management before users can apply labels in Outlook to encrypt their emails. However, until Exchange is configured for Azure Rights Management, you don't get the full functionality of encryption with rights management.

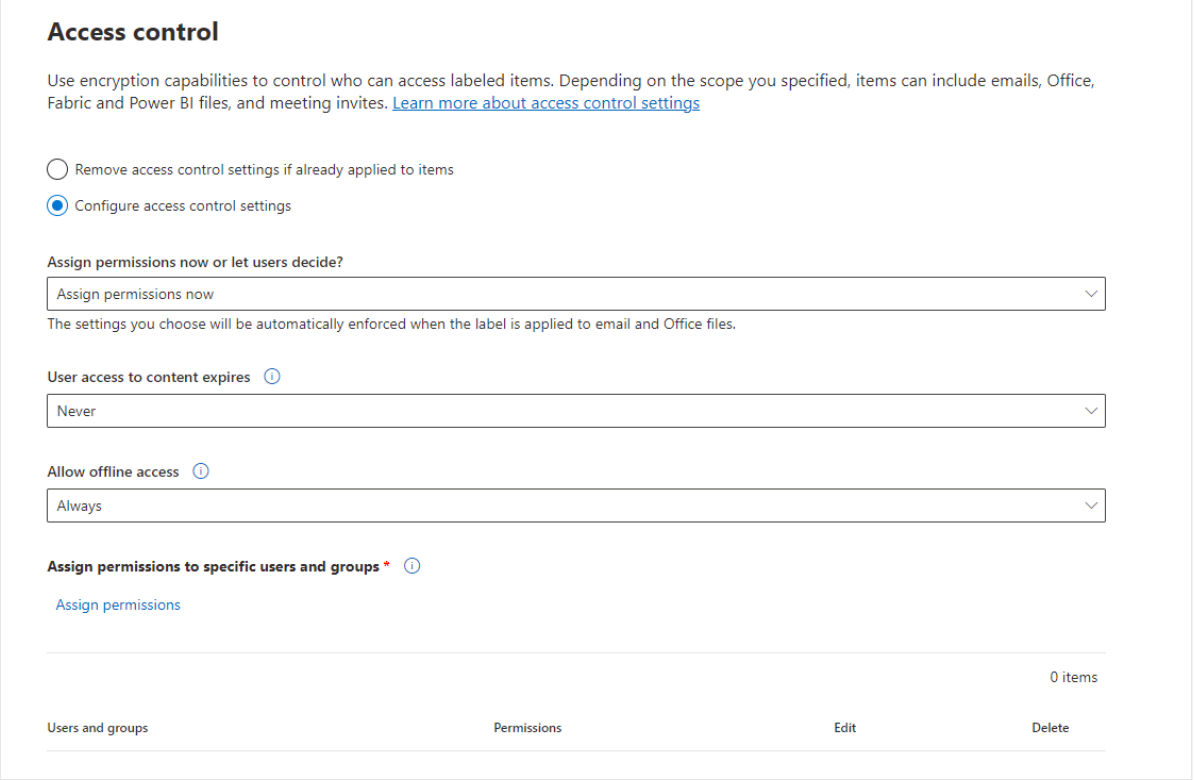
  For example, users can't view encrypted emails or encrypted meeting invites on mobile phones or with Outlook on the web, encrypted emails can't be indexed for search, and you can't configure Exchange Online DLP for Rights Management protection.

  To ensure that Exchange can support these additional scenarios:
  - For Exchange Online, see the instructions for Exchange Online: IRM Configuration.
  - For Exchange on-premises, you must deploy the RMS connector and configure your Exchange servers.

How to configure a label for encryption

1. Follow the general instructions to create or edit a sensitivity label and make sure the **Files & other data assets** option is selected for the label's scope:

2. Then, on the **Choose protection settings for the types of items you selected** page, make sure you select **Control access**.



3. On the **Access control** page, select one of the following options:

   - **Remove access control settings if already applied to items**: When you select this option, applying the label removes existing encryption, even if it was applied independently from a sensitivity label.

     It's important to understand that this setting can result in a sensitivity label that users might not be able to apply when they don't have sufficient permissions to

remove the existing encryption. For more information about this scenario, see the What happens to existing encryption when a label's applied section.

- **Configure access control settings**: Turns on encryption with rights management and makes the following settings visible:

Instructions for these settings are in the following Configure encryption settings section.

Editing labels to newly apply encryption or change existing encryption settings

It's a common deployment strategy to initially configure sensitivity labels that don't apply encryption, and later edit some of the existing labels to apply encryption. When the label changes reach your apps, the labels that you edited will apply that encryption for newly labeled items.

For files accessed in SharePoint and OneDrive when you've enabled SharePoint and OneDrive for sensitivity labels the new encryption status of files automatically change when these files are next accessed. For example, they're opened in Office for the web, or downloaded. There's no need to remove the label and reapply it. For example, files that were previously unencrypted become encrypted.

For other items that are already labeled, they retain their previous encryption status unless you remove the label and reapply it. For example, after changing the sensitivity label to now apply encryption, when you open previously labeled and unencrypted documents or emails in Office Desktop or Office Mobile, those items remain unencrypted unless you remove the label and reapply it. Similarly, if you change the sensitivity label settings to not apply encryption (remove the option for access control), those items remain encrypted unless you remove the label and reapply it.

For items that are already labeled with encryption and the assign permissions now option, when you change the encryption settings for users or permissions, the new settings will be applied for existing items when users authenticate with the encryption service. In most cases, there's no need to remove and reapply the label. However, if users have already opened an encrypted document or email, they won't get the new settings until their use license has expired and they must reauthenticate. For more information about this scenario, see the related frequently asked question for how the encryption works.

Whenever you change the encryption options for letting users assign permissions, that change only applies to newly labeled or relabeled items. For example:

- You change the label from assigning permissions now to let users assign permissions, or the other way around
- You change the label from Do Not Forward to Encrypt-Only, or the other way around

What happens to existing encryption when a label's applied

If a sensitivity label is applied to unencrypted content, the outcome for the encryption options you can select is self-explanatory. For example, if you didn't select **Control access**, the content remains unencrypted.

However, the content might be already encrypted. For example, another user might have applied:

- Their own permissions, which include user-defined permissions when prompted by a label, custom permissions by the Microsoft Purview Information Protection client, and the **Restricted Access** document protection from within an Office app.
- A rights management template that encrypts the content independently from a label. This category includes mail flow rules that apply encryption by using rights protection.
- A label that applies encryption with permissions assigned by the administrator.

The following table identifies what happens to existing encryption when a sensitivity label is applied to that content:

Expand table

	Encryption: Not selected	Encryption: Configured	Encryption: Remove
Permissions specified by a user	Original encryption is removed	New label encryption is applied	Original encryption is removed
Rights management template	Original encryption is preserved	New label encryption is applied	Original encryption is removed
Label with administator-defined permissions	Original encryption is removed	New label encryption is applied	Original encryption is removed

In the cases where the new label encryption is applied or the original encryption is removed, this happens only if the user who applies the label has a usage right or role that supports this action:

- The usage right Export or Full Control.
- The role of Rights Management issuer or Rights Management owner, or super user.

If the user doesn't have one of these rights or roles, the label can't be applied and so the original encryption is preserved. The user sees the following message: **You don't have permission to make this change to the sensitivity label. Please contact the content owner.**

For example, the person who applies Do Not Forward to an email message can relabel the thread to replace the encryption or remove it, because they're the Rights Management owner for the email. But except for super users, recipients of this email can't relabel it because they don't have the required usage rights.

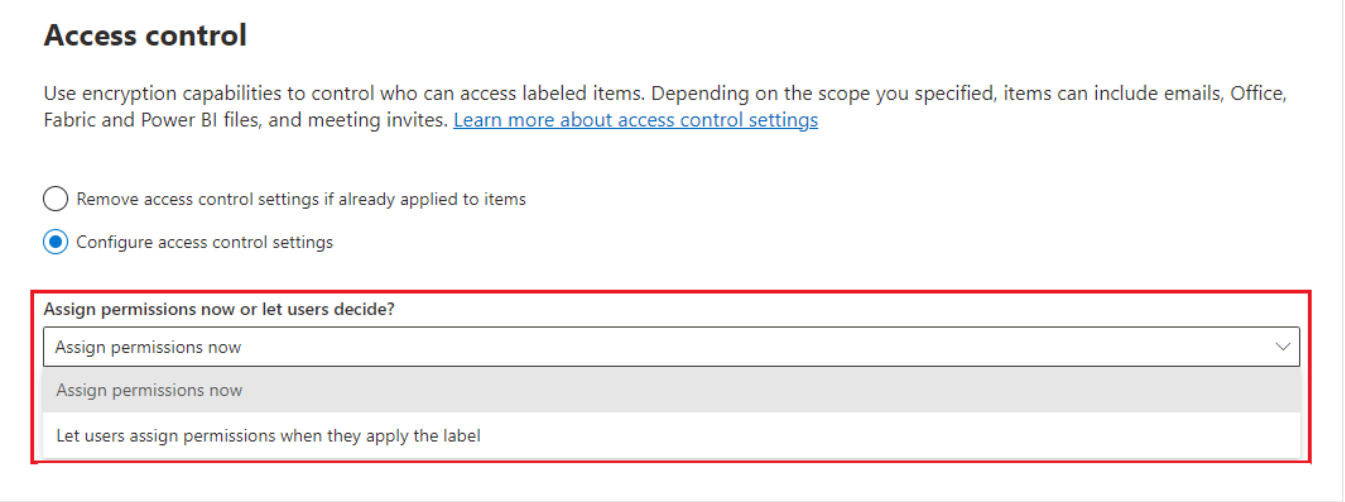
Email attachments for encrypted email messages and meeting invites

When an email message or meeting invite is encrypted by any method, any unencrypted Office documents that are attached to the email or invite automatically inherit the same encryption settings. You can't turn off this encryption inheritance, for example, with a setting or label scoping.

Any sensitivity label from the email message or meeting invite is not inherited by the attachment but could be automatically applied when a user in the same tenant opens the document. For more information, see Encryption-based label matching for documents.

Documents that are already encrypted and then added as attachments always preserve their original encryption.

Configure encryption settings



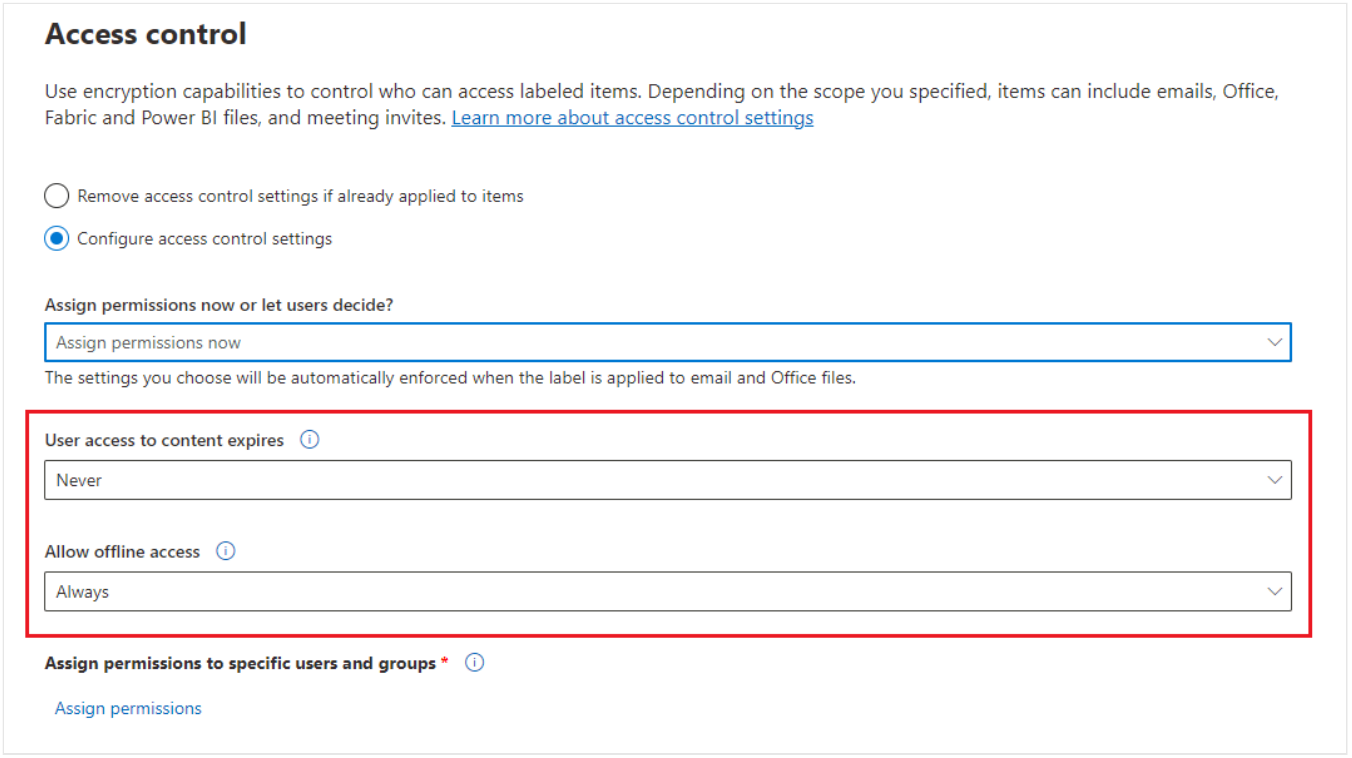
When you select **Configure access control settings** on the **Access control** page to create or edit a sensitivity label, choose one of the following options:

- **Assign permissions now**, so that you can determine exactly which users get which permissions to content that has the label applied. For more information, see the next section Assign permissions now.
- **Let users assign permissions** when your users apply the label to content. With this option, you can allow people in your organization some flexibility that they might need to collaborate and get their work done. For more information, see the Let users assign permissions section on this page.

For example, if you have a sensitivity label named **Highly Confidential** that will be applied to your most sensitive content, you might want to decide now who gets what type of permissions to that content.

Alternatively, if you have a sensitivity label named **Business Contracts**, and your organization's workflow requires that your people collaborate on this content with different people on an unplanned basis, you might want to allow your users to decide who gets permissions when they assign the label. This flexibility both helps your users' productivity and reduces the requests for your admins to update or create new sensitivity labels to address specific scenarios.

Choosing whether to assign permissions now or let users assign permissions:



Assign permissions now

Use the following options to control who can access email, meeting invites (if enabled), or documents to which this label is applied. You can:

- **Allow access to labeled content to expire**, either on a specific date or after a specific number of days after the label is applied. After this time, users won't be able to open the labeled item. If you specify a date, it's effective midnight on that date in your current time zone. Some email clients might not enforce expiration and show emails past their expiration date, due to their caching mechanisms.

- **Allow offline access** never, always, or for a specific number of days after the label is applied. Use this setting to balance any security requirements you have with the ability for users to open encrypted content when they don't have an internet connection. If you restrict offline access to never or a number of days, when that threshold is reached, users must be reauthenticated and their access is logged. For more information about how this process works, see the following section about the Rights Management use license.

Access control settings for encrypted content:

Recommendations for the expiry and offline access settings:

Expand table

Setting	Recommended setting
User access to content expires	**Never** unless the content has a specific time-bound requirement.
Allow offline access	Depends on the sensitivity of the content: - **Only for a number of days** = **7** for sensitive business data that could cause damage to the business if shared with unauthorized people. This recommendation offers a balanced compromise between flexibility and security. Examples include contracts, security reports, forecast summaries, and sales account data. - **Never** for when the label is configured for dynamic watermarks and any very sensitive business data that would cause damage to the business if it was shared with unauthorized people. This recommendation prioritizes security over flexibility, and ensures that if you remove one or more users' access to the document, they won't be able to open it. Examples include employee and customer information, passwords, source code, and pre-announced financial reports. - **Always** for less sensitive content where it doesn't matter if users can continue to open encrypted content for up to 30 days (or the configured use license validity period for the tenant) after their access is removed and they have previously opened the encrypted content.

Only labels that are configured to assign permissions now support different values for offline access. Labels that let users assign the permissions automatically use the tenant's Rights Management use license validity period. For example, labels that are configured for Do Not Forward, Encrypt-Only, and prompt users to specify their own permissions. The default value for this setting is 30 days.

Rights Management use license for offline access

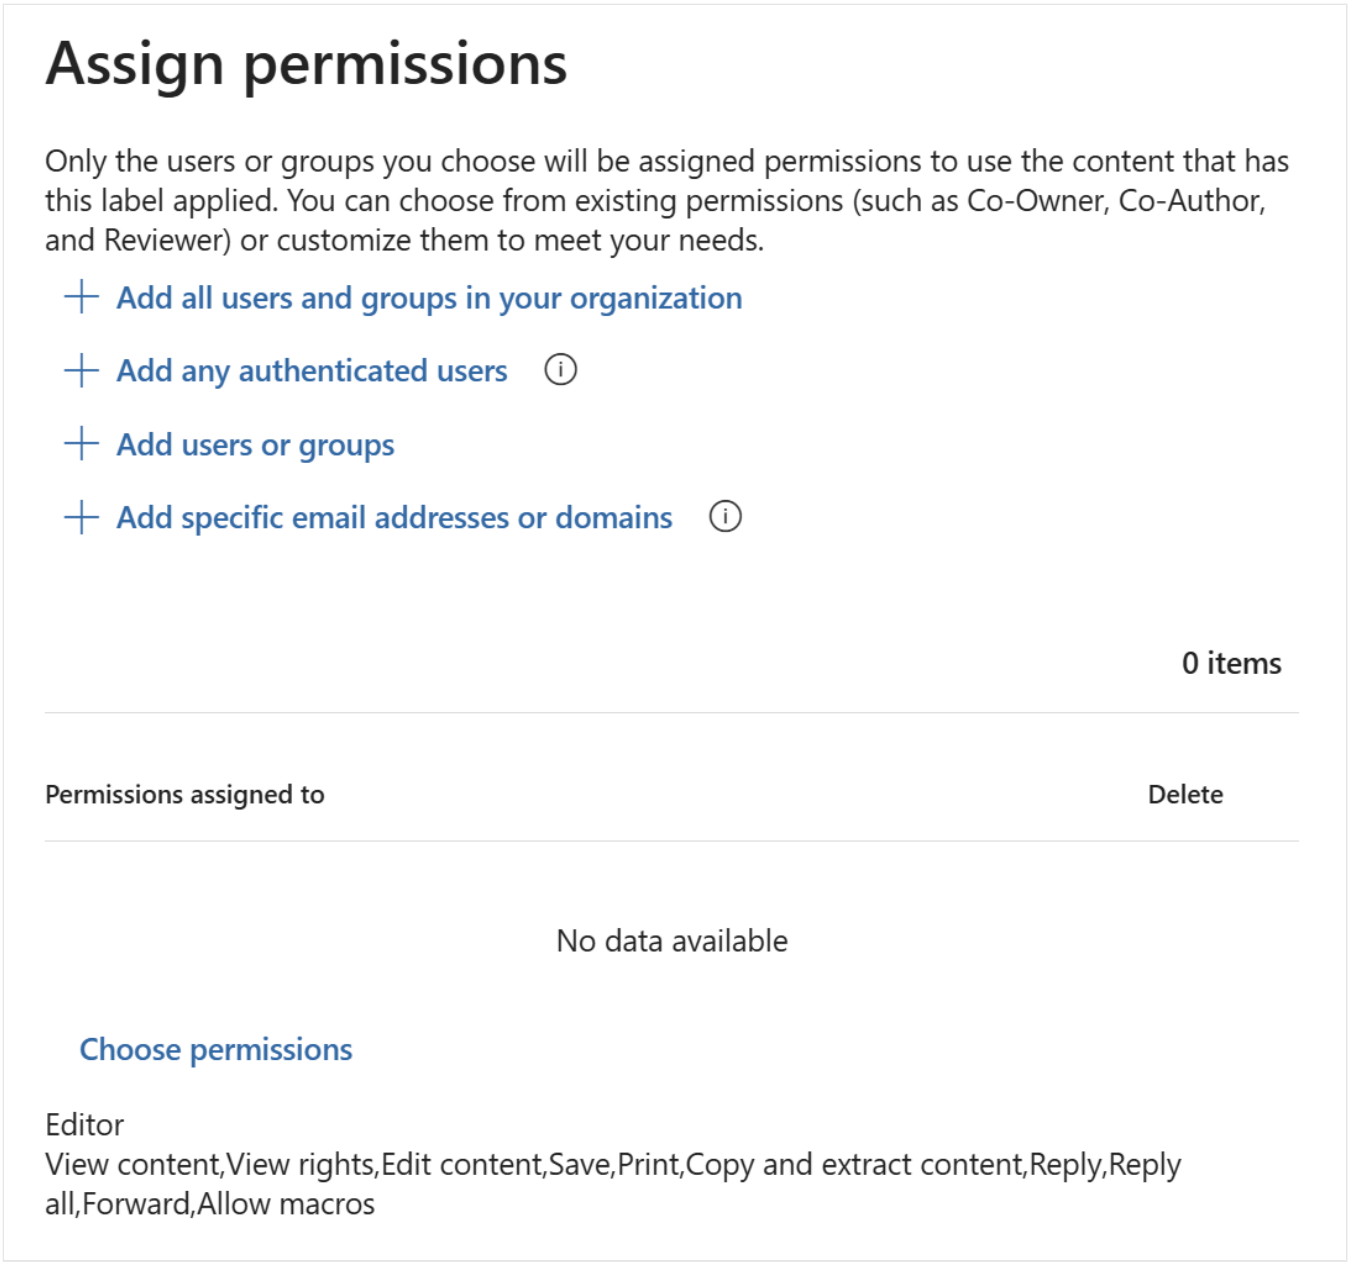
> **Note**
>
> Although you can configure the encryption setting to allow offline access, some apps might not support offline access for encrypted content. For example, labeled and encrypted files in Power BI Desktop won't open if you're offline.

When a user opens an item that's been protected by encryption from the Azure Rights Management service, an Azure Rights Management use license for that content is granted to the user. This use license is a certificate that contains the user's usage rights for the document

or email, and the encryption key that was used to encrypt the content. The use license also contains an expiration date if this has been set, and how long the use license is valid.

If no expiration date has been set, the default use license validity period for a tenant is 30 days. For the duration of the use license, the user isn't reauthenticated or reauthorized for the content. This process lets the user continue to open the protected document or email without an internet connection. When the use license validity period expires, the next time the user accesses the protected document or email, the user must be reauthenticated and reauthorized.

In addition to reauthentication, the encryption settings and user group membership is reevaluated. This means that users could experience different access results for the same item if there are changes in the encryption settings or group membership from when they last accessed the content.



To learn how to change the default 30-day setting, see Rights Management use license.

Assign permissions to specific users or groups

You can grant permissions to specific people so that only they can interact with the labeled content:

1. First, add users or groups that will be assigned permissions to the labeled content.
2. Then, choose which permissions those users should have for the labeled content.

Assigning permissions:

Add users or groups

When you assign permissions, you can choose:

- Everyone in your organization (all tenant members). This setting excludes guest accounts.
- Any authenticated users. Make sure you understand the requirements and limitations of this setting before selecting it.
- Any specific user or email-enabled security group, distribution group, or Microsoft 365 group in Microsoft Entra ID. The Microsoft 365 group can have static or dynamic membership. You can't use a dynamic distribution group from Exchange because this group type isn't synchronized to Microsoft Entra ID. You also can't use a security group that isn't email-enabled.

Although you can specify groups that contain mail contacts as a convenient method to grant access to multiple people outside your organization, there's currently a known issue with this configuration. For more information, see Mail contacts in groups have intermittent access to encrypted content.

- Any email address or domain. Use this option to specify all users in another organization who uses Microsoft Entra ID, by entering any domain name from that organization. You can also use this option for social providers, by entering their domain name such as **gmail.com**, **hotmail.com**, or **outlook.com**.

  > **Note**
  >
  > If you specify a domain from an organization that uses Microsoft Entra ID, you can't restrict access to that specific domain. Instead, all verified domains in Microsoft Entra ID are automatically included for the tenant that owns the domain name you specify.

When you choose all users and groups in your organization or browse the directory, the users or groups must have an email address.

As a best practice, use groups rather than users. This strategy keeps your configuration simpler.

Requirements and limitations for "Add any authenticated users"

This setting doesn't restrict who can access the content that the label encrypts, while still encrypting the content and providing you with options to restrict how the content can be used (permissions), and accessed (expiry and offline access). However, the application opening the encrypted content must be able to support the authentication being used. For this reason, federated social providers such as Google, and onetime passcode authentication work only for email and meeting invites, and only when you use Exchange Online. Microsoft accounts can be used with Office 365 apps and the Microsoft Purview Information Protection viewer.

> **Note**
>
> Consider using this setting with SharePoint and OneDrive integration with Microsoft Entra B2B when sensitivity labels are enabled for Office files in SharePoint and OneDrive.

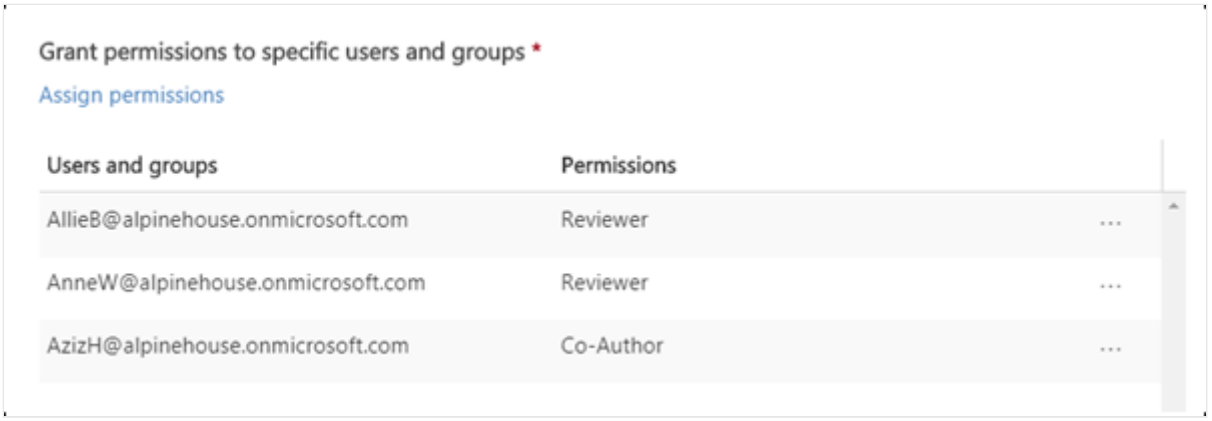
Some typical scenarios for any authenticated users setting:

- You don't mind who views the content, but you want to restrict how it's used. For example, you don't want the content to be edited, copied, or printed.
- You don't need to restrict who accesses the content, but you want to be able to confirm who opens it.
- You have a requirement that the content must be encrypted at rest and in transit, but it doesn't require access controls.

Choose permissions

When you choose which permissions to allow for those users or groups, you can select either:

- A predefined permissions level with a preset group of rights, such as Editor or Restricted Editor.
- Custom permissions, where you choose one or more usage rights.



For more information to help you select the appropriate permissions, see Usage rights and descriptions.

Note that the same label can grant different permissions to different users. For example, a single label can assign some users as Restricted Editor and a different user as Owner, as shown in the following screenshot.

To do this, add users or groups, assign them permissions, and save those settings. Then repeat these steps, adding users and assigning them permissions, saving the settings each time. You

can repeat this configuration as often as necessary, to define different permissions for different users.

Rights Management issuer (user applying the sensitivity label) always has Full Control

By default, encryption for a sensitivity label uses the Azure Rights Management service from Microsoft Purview Information Protection. When a user applies a sensitivity label to protect a document or email by using encryption, that user becomes the Rights Management issuer for that content.

The Rights Management issuer is always granted Full Control permissions for the document or email, and in addition:

- If the encryption settings include an expiration date, the Rights Management issuer can still open and edit the document or email after that date.
- The Rights Management issuer can always access the document or email offline.
- The Rights Management issuer can still open a document after it's revoked.

For more information, see Rights Management issuer and Rights Management owner.

Dynamic watermarks

Identify the minimum versions of Office apps required by using the capabilities tables and the rows for **Dynamic watermarks**.

When a user accesses a file with this sensitivity label applied, by default, their Universal Principal Name (UPN) is dynamically inserted as a watermark on each page of the file. Typically, a user's UPN is the same as their email address. If you select **Customize text (optional)**, you can specify a custom string that also supports including the date and time.

This watermark is highly visible when viewing the file on a device, and persists when printed, although not when exported. This watermarking is more secure than the standard content markings for a label, because the user can't easily manually remove or change it.

The watermark is removed when a user relabels the document, choosing a sensitivity label that applies a different dynamic watermark, or no dynamic watermark. However, as with all encrypted content, a user must have the usage right of Export or Full Control to remove the existing encryption.

This protective watermarking is supported only for sensitivity labels that apply encryption and we also recommend that the encryption option of **Allow offline access** is set to **Never**. As with other encryption settings, dynamic watermarks are supported across tenants. Use it for your most sensitive documents as a visual deterrent against screen captures by the person who opened the document. However, be aware of the following considerations.

Limitations in Office where dynamic watermarks are not yet supported, so the document opens without apply the watermark:

- File preview for attachments in Outlook
- PowerPoint Live in Microsoft Teams

Unless opening the document falls into one of the exceptions previously listed, one of the following must be true to open a labeled document that applies dynamic watermarks:

- The user is the Rights Management owner, which most of the time, means they applied the label themselves. For more information, see Rights Management issuer and Rights Management owner.
- The user opens the document with an app that understands dynamic watermarks. Use the capabilities tables and the row **Dynamic watermarks** to confirm supported versions.
- The user opens the document in Office on the web.

If none of these conditions are met when a user opens the document in an Office app, and they're not one of the listed exceptions, the document won't open. Make sure you understand this restriction before you use this label configuration.

> **⊗ Caution**
>
> Except for the listed limitations, Microsoft Office apps will either deny access if they don't support dynamic watermarks, or enforce dynamic watermarks if they do.

Considerations for previously labeled documents:

- Like all changed encryption settings, a newly configured dynamic watermark doesn't immediately get applied when you already have a valid Rights Management use license for a document. After the use license expires, you must reauthenticate to the Azure Rights Management service to open the document and then the dynamic watermark setting gets applied.
- There's no automatic detection and resolution if the sensitivity label previously applied a standard watermark as a content marking.

Double Key Encryption

> ⓘ **Note**
>
> For built-in labeling, identify the minimum versions required by using the capabilities tables and the row **Double Key Encryption (DKE)**.

Select the **Double Key Encryption** label option only after you've configured the Double Key Encryption service and you need to use this double key encryption for files and emails that will have this label applied. After the label is configured and saved, you won't be able to edit it.

For more information, prerequisites, and configuration instructions, see Double Key Encryption (DKE).

Let users assign permissions

> ⓘ **Important**
>
> Not all labeling clients support all the options that let users assign their own permissions. Use this section to learn more.

Often referred to as "user-defined permissions", you can use the following options to let users assign permissions when they manually apply a sensitivity label to content:

- In Outlook, a user can select restrictions equivalent to the Do Not Forward option or Encrypt-only for their chosen recipients.

The Do Not Forward option is supported by all email clients that support sensitivity labels. However, applying the **Encrypt-Only** option with a sensitivity label is a more recent release. For email clients that don't support this capability, the label won't be visible.

To check the minimum versions of Outlook apps that use built-in labeling to support applying the Encrypt-Only option with a sensitivity label, use the capabilities table for Outlook and the row **Let users assign permissions: - Encrypt-Only**.

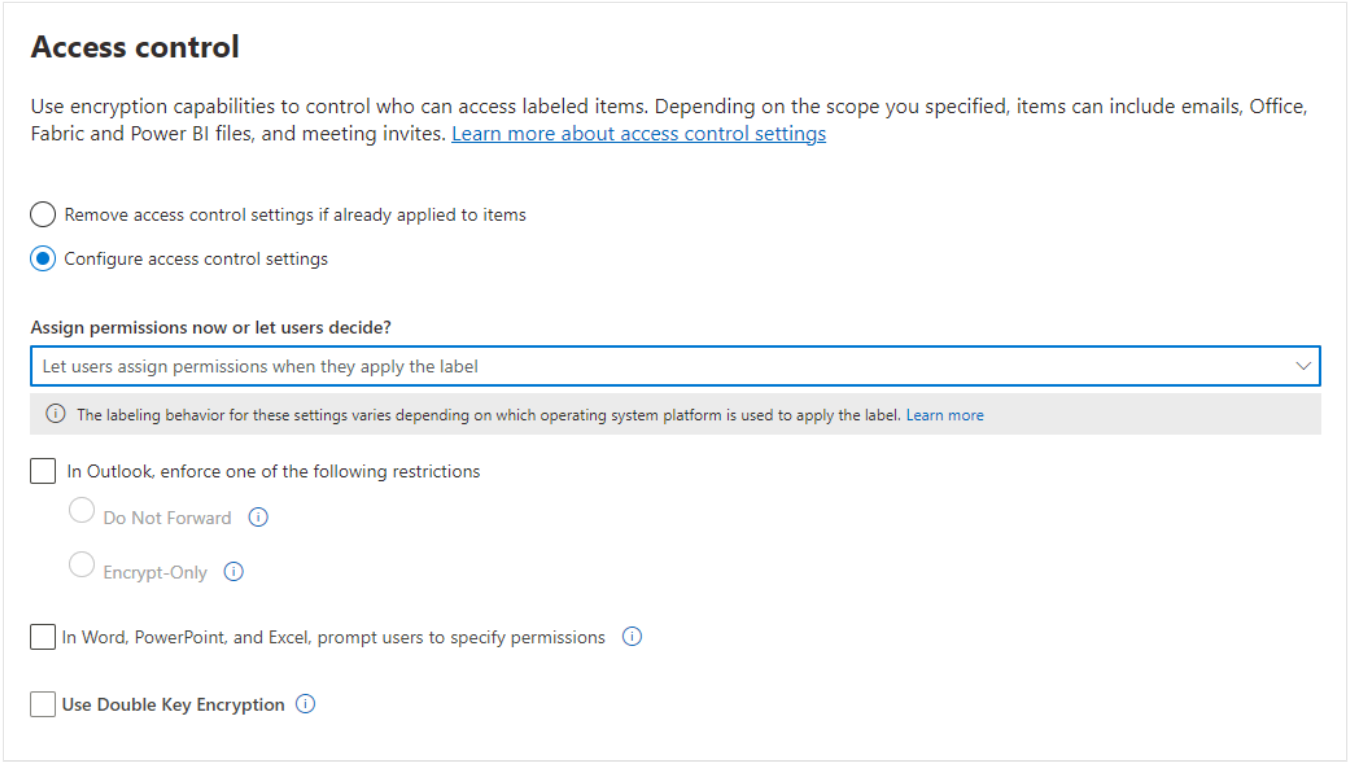
- In Word, PowerPoint, and Excel, unless the label is configured to extend permissions for a SharePoint document library, a user is prompted to select their own permissions for specific users, groups, or organizations.

  For Office apps that don't support this capability, the label either won't be visible for users, or the label is visible for consistency but it can't be applied with an explanation message to users.

  To check which Office apps support this option, use the capabilities table for Word, Excel, and PowerPoint and the rows for **Let users assign permissions**.

> **Note**
>
> You won't be able to use these configurations if the label scope excludes email (for Do Not Forward and Encrypt-Only) or excludes files (for prompting users in Word, PowerPoint, and Excel). For more information, see Scope labels to just files or emails.

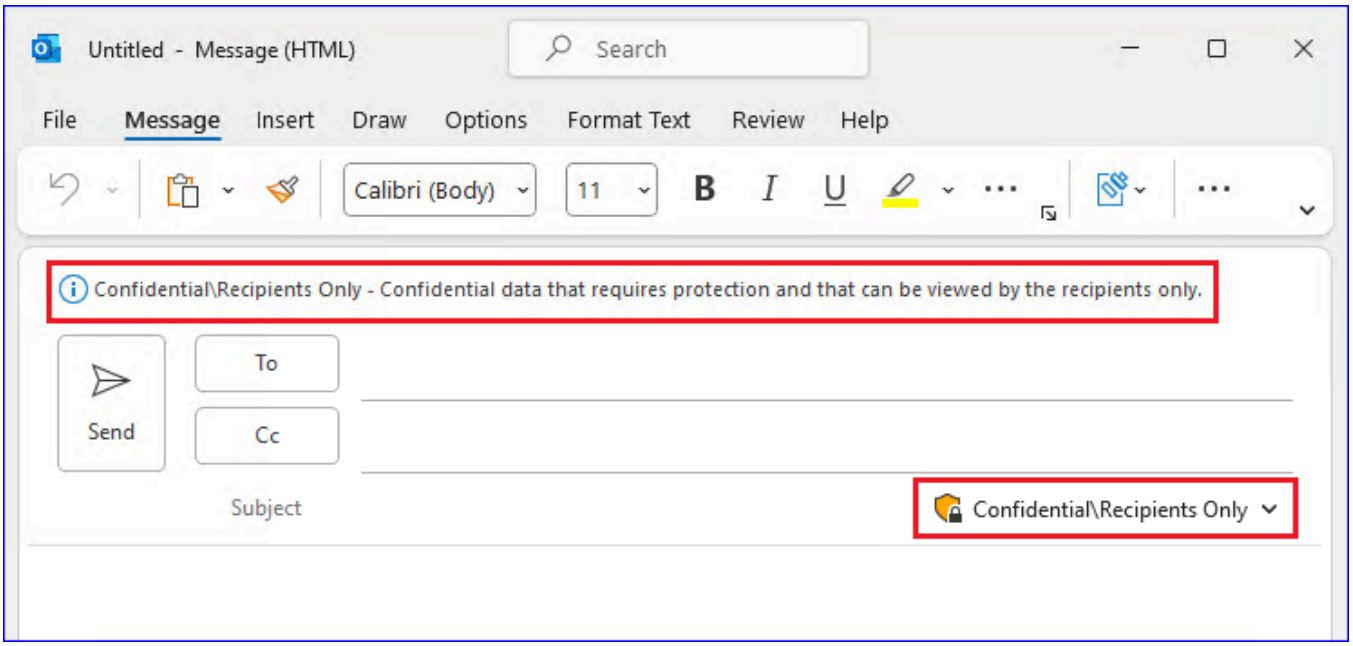
When the options are supported, use the following table to identify when users see the sensitivity label:



Expand table

Setting	Label visible in Outlook	Label visible in Word, Excel, PowerPoint
In Outlook, enforce restrictions with the Do Not Forward or Encrypt-Only option	Yes	No
In Word, PowerPoint, and Excel, prompt users to specify permissions	No	Yes

When both settings are selected, the label is therefore visible in both Outlook and in Word, Excel, and PowerPoint.



A sensitivity label that lets users assign permissions can be recommended to users, but can only be automatically applied for the Do Not Forward and Encrypt-Only options.

Configuring the user-assigned permissions:

Outlook restrictions

In Outlook, when a user applies a sensitivity label that lets them assign permissions to a message, you can choose the **Do Not Forward option** or **Encrypt-Only**. The user will see the label name and description at the top of the message, which indicates the content's being protected. Unlike Word, PowerPoint, and Excel (see the next section), users aren't prompted to select specific permissions. For this configuration, the administrator controls the permissions, but not who has access.

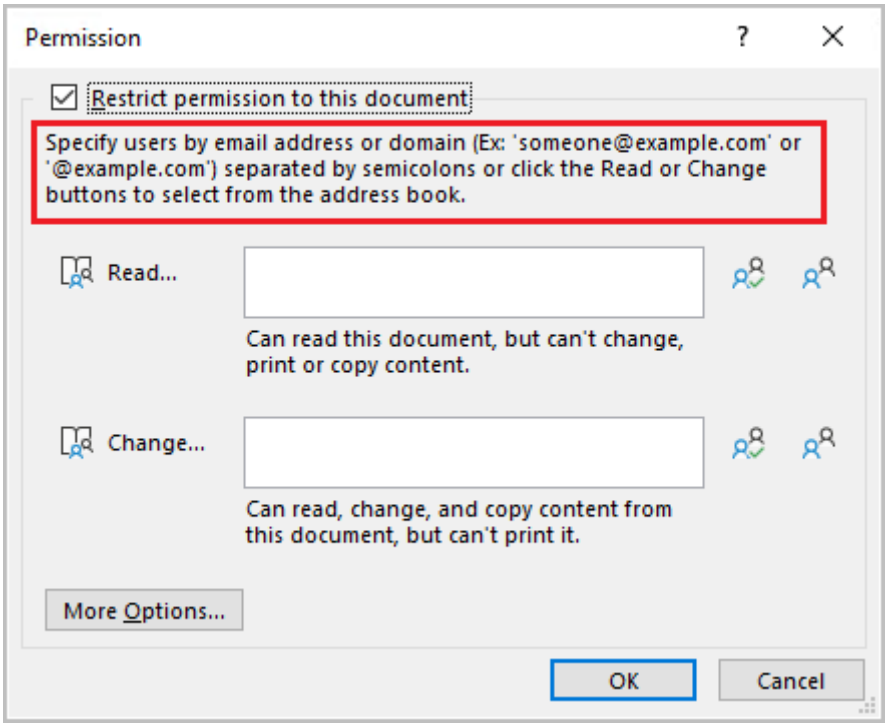
When either of these options are applied to an email, the email is encrypted and recipients must be authenticated. Then, the recipients automatically have restricted usage rights:

- **Do Not Forward**: Recipients can't forward the email, print it, or copy from it. For example, in the Outlook client, the Forward button isn't available, the Save As and Print menu options aren't available, and you can't add or change recipients in the To, Cc, or Bcc boxes.

  For more information about how this option works, see Do Not Forward option for emails.

- **Encrypt-Only**: Recipients have all usage rights except Save As, Export and Full Control. This combination of usage rights means that the recipients have no restrictions except that they can't remove the protection. For example, a recipient can copy from the email, print it, and forward it.

  For more information about how this option works, see Encrypt-only option for emails.



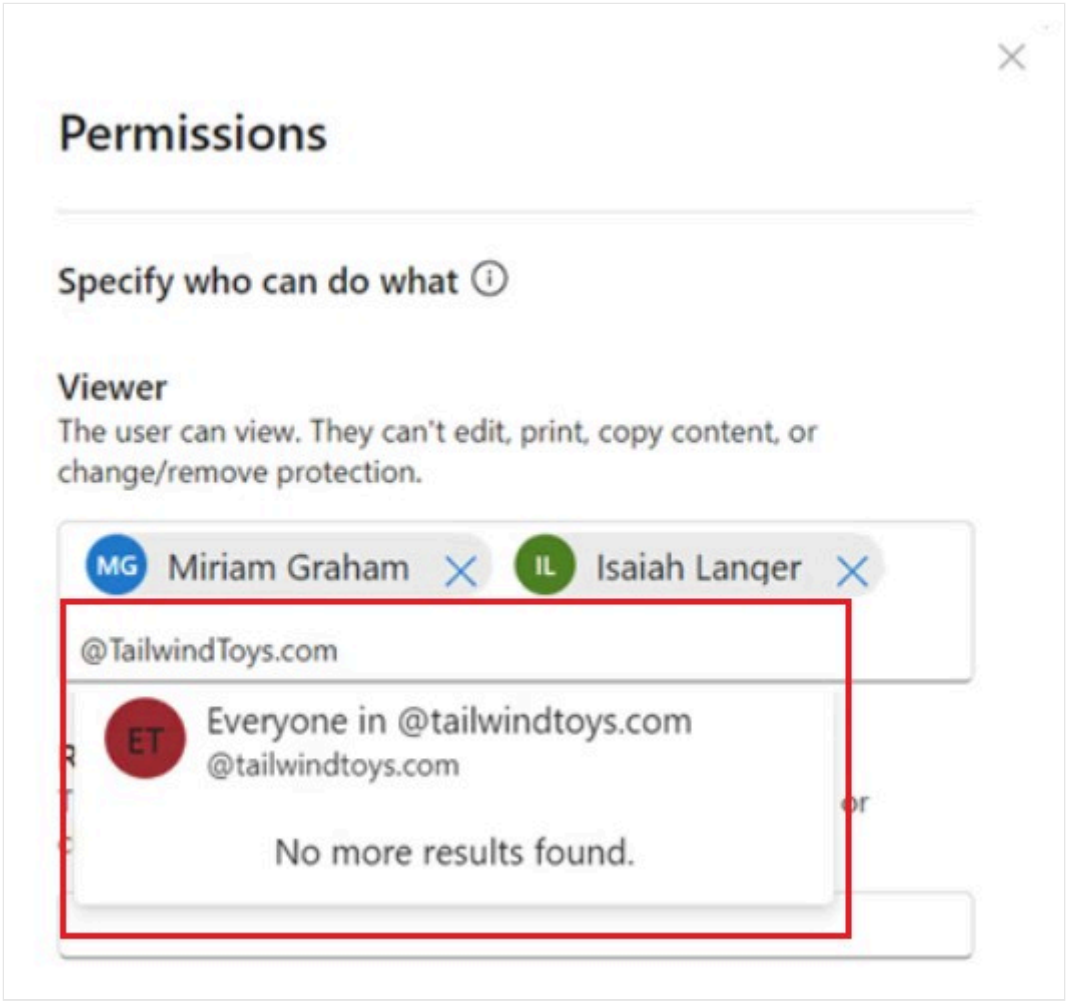
Unencrypted Office documents that are attached to the email or meeting invite automatically inherit the same restrictions. For Do Not Forward, the usage rights applied to these documents are Edit Content, Edit; Save; View, Open, Read; and Allow Macros. If the user wants different usage rights for an attachment, or the attachment isn't an Office document that supports this inherited protection, the user needs to encrypt the file before attaching it to the email or meeting invite.

Word, PowerPoint, and Excel permissions

In Word, PowerPoint, and Excel, when a user applies a sensitivity label that lets them assign permissions to a document, the user is prompted to specify their choice of users and permissions for the encryption. For this configuration, the user and not the administrator controls both who can access the document, and what permissions they have.

Support for organization-wide custom permissions

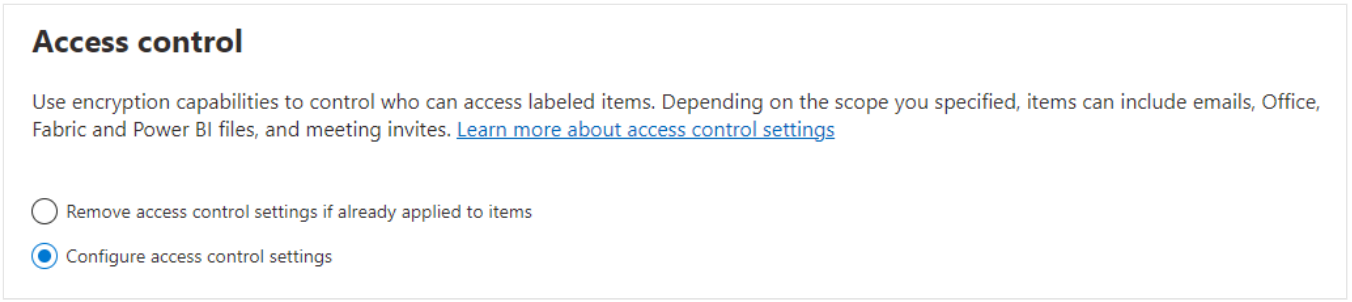
For labeling in Windows and using Office for the web, users can additionally specify a domain name when they're prompted to specify their choice of users and permissions. When a domain name is entered, the permissions will apply to all users in an organization that owns the domain and it is in Microsoft Entra ID. To identify the minimum versions that support this setting, use the capabilities table and the row **Let users assign permissions:- Prompt users for custom permissions (users, groups, and organizations)**.



> **Note**
>
> The displayed dialog box is updated in the latest versions of Microsoft 365 for Windows apps, but the support for organization-wide custom permissions remains when a domain name is entered. Information about this support is included in the popup information box.

For example, a user types **@contoso.com** (or **contoso.com**) and grants read access. Because Contoso Corporation owns the contoso.com domain, all users in that domain and all other domains that the organization owns in Microsoft Entra ID will be granted read access.

> **Note**
>
> When you specify these values, don't surround them with quotation marks.



When you use Office for the web, typing the @ character automatically displays a selectable entry for everybody in the organization. For example:

It's important to let users know that access isn't restricted to just the users in the domain specified. For example, **@sales.contoso.com** wouldn't restrict access to users in just the sales subdomain, but also grant access to users in the marketing.contoso.com domain, and even users with a disjoint namespace in the same Microsoft Entra tenant. For user documentation, see Custom permissions for files.

Example configurations for the encryption settings

For each example that follows, do the configuration from the **Access control** page when the **Configure access control settings** option is selected:

Example 1: Label that applies Do Not Forward to send an encrypted email to a Gmail account

This label displays only in Outlook and Outlook on the web, and you must use Exchange Online. Instruct users to select this label when they need to send an encrypted email to people using a Gmail account (or any other email account outside your organization).

Your users type the Gmail email address in the **To** box. Then, they select the label and the Do Not Forward option is automatically added to the email. The result is that recipients can't forward the email, or print it, copy from it, or save the email outside their mailbox by using the **Save As** option.

1. On the **Access control** page: For **Assign permissions now or let users decide?** select **Let users assign permissions when they apply the label**.
2. Select the checkbox: **In Outlook, enforce restrictions equivalent to the Do Not Forward option**.
3. If selected, clear the checkbox: **In Word, PowerPoint, and Excel, prompt users to specify permissions**.
4. Select **Next** and complete the configuration.

Example 2: Label that restricts read-only permission to all users in another organization

This label is suitable for sharing very sensitive documents as read-only, and the documents always require an internet connection to view them.

This label isn't suitable for emails.

1. On the **Access control* page: For **Assign permissions now or let users decide?** select **Assign permissions now**.
2. For **Allow offline access**, select **Never**.

3. Select **Assign permissions**.
4. On the **Assign permissions** pane, select **Add specific email addresses or domains**.
5. In the text box, enter the name of a domain from the other organization, for example, **fabrikam.com**. Then select **Add**.
6. Select **Choose permissions**.
7. On the **Choose permissions** pane, select the dropdown box, select **Viewer**, and then select **Save**.
8. Back on the **Assign Permissions** pane, select **Save**.
9. On the **Access control** page, select **Next** and complete the configuration.

Example 3: Add external users to an existing label that encrypts content

The new users that you add will be able open documents and emails that have already been protected with this label. The permissions that you grant these users can be different from the permissions that the existing users have.

1. On the **Access control** page: For **Assign permissions now or let users decide?** make sure **Assign permissions now** is selected.
2. Select **Assign permissions**.
3. On the **Assign permissions** pane, select **Add specific email addresses or domains**.
4. In the text box, enter the email address of the first user (or group) to add, and then select **Add**.
5. Select **Choose permissions**.
6. On the **Choose permissions** pane, select the permissions for this user (or group), and then select **Save**.
7. Back on the **Assign Permissions** pane, repeat steps 3 through 6 for each user (or group) that you want to add to this label. Then click **Save**.
8. On the **Access control** page, select **Next** and complete the configuration.

Example 4: Label that encrypts content but doesn't restrict who can access it

This configuration has the advantage that you don't need to specify users, groups, or domains to encrypt an email or document. The content will still be encrypted and you can still specify usage rights, an expiry date, and offline access.

Use this configuration only when you don't need to restrict who can open the protected document or email. See more information about this setting.

1. On the **Access control** page: For **Assign permissions now or let users decide?** make sure **Assign permissions now** is selected.
2. Configure settings for **User access to content expires** and **Allow offline access** as required.
3. Select **Assign permissions**.
4. On the **Assign permissions** pane, select **Add any authenticated users**.

   For **Users and groups**, you see **Authenticated users** automatically added. You can't change this value, only delete it, which cancels the **Add any authenticated users** selection.
5. Select **Choose permissions**.
6. On the **Choose permissions** pane, select the dropdown box, select the permissions you want, and then select **Save**.
7. Back on the **Assign Permissions** pane, select **Save**.
8. On the **Access control** page, select **Next** and complete the configuration.

Considerations for encrypted content

Encrypting your most sensitive documents and emails helps to ensure that only authorized people can access this data. However, there are some considerations to take into account:

- If your organization hasn't enabled sensitivity labels for Office files in SharePoint and OneDrive:
  - Search, eDiscovery, and Delve won't work for encrypted files.

    - DLP policies work for the metadata of these encrypted files (including retention label information) but not the content of these files (such as credit card numbers within files).
    - Users can't open encrypted files using Office for the web. When sensitivity labels for Office files in SharePoint and OneDrive are enabled, users can use Office for the web to open encrypted files, with some limitations that include encryption that has been applied with an on-premises key (known as "hold your own key", or HYOK), double key encryption, and encryption that has been applied independently from a sensitivity label.

- If you share encrypted documents with people outside your organization, you might need to create guest accounts and modify Conditional Access policies. For more information, see Sharing encrypted documents with external users.

- When authorized users open encrypted documents in their Office apps, they see the label name and description in a yellow message bar at the top of their app. When the encryption permissions extend to people outside your organization, carefully review the label names and descriptions that will be visible in this message bar when the document is opened.

- For multiple users to edit an encrypted file at the same time, they must all be using Office for the web or you've enabled co-authoring for files encrypted with sensitivity labels and all users have Office apps that support this feature. If this isn't the case, and the file is already open:
    - In Office apps (Windows, Mac, Android, and iOS), users see a **File In Use** message with the name of the person who has checked out the file. They can then view a read-only copy or save and edit a copy of the file, and receive notification when the file is available.
    - In Office for the web, users see an error message that they can't edit the document with other people. They can then select **Open in Reading View**.

- The AutoSave functionality in Office apps is disabled for encrypted files if you haven't enabled co-authoring for files encrypted with sensitivity labels. Users see a message that the file has restricted permissions that must be removed before AutoSave can be turned on.

- Office for Windows supports labels that apply encryption when users aren't connected to the internet. But for the other platforms (macOS, iOS, Android), users must be online to apply these labels in Office apps. The Microsoft Purview Information Protection client

must also be online to apply these labels in File Explorer and PowerShell. Users don't have to be online to open encrypted content. For more information about offline access, see the Rights Management use license for offline access section.

- Encrypted files might take longer to open in Office apps (Windows, Mac, Android, and iOS).
- If a label that applies encryption is added by using an Office app when the document is checked out in SharePoint, and the user then discards the checkout, the document remains labeled and encrypted.
- Unless you've enabled co-authoring for files encrypted with sensitivity labels, the following actions for encrypted files aren't supported from Office apps (Windows, Mac, Android, and iOS), and users see an error message that something went wrong. However, SharePoint functionality can be used as an alternative:
  - View, restore, and save copies of previous versions. As an alternative, users can do these actions using Office for the web when you enable and configure versioning for a list or library.
  - Change the name or location of files. As an alternative, users can rename a file, folder, or link in a document library in SharePoint.

For the best collaboration experience for files that are encrypted by a sensitivity label, we recommend you use sensitivity labels for Office files in SharePoint and OneDrive and Office for the web.

Next steps

Need to share your labeled and encrypted documents with people outside your organization? See Sharing encrypted documents with external users.

To use sensitivity labels to encrypt video and audio streams for Teams meetings, see Use sensitivity labels to protect calendar items, Teams meetings and chat.

Automatically apply a sensitivity label to Microsoft 365 data

> *Microsoft Purview service description*

> **Note**
>
> For information about automatically applying a sensitivity label to data stored outside Microsoft 365 and in the data map, see Labeling in Microsoft Purview Data Map.

> **Tip**
>
> **Start here — pick your task**
>
> - **I'm setting up my first auto-labeling policy.** Review the Prerequisites for auto-labeling policies first, then follow Creating an auto-labeling policy.
> - **I want to label Exchange email based on the subject, sender, or recipient.** See Example: Apply a label to Exchange email based on the subject.
> - **I'm deciding between labeling in Office apps and an auto-labeling policy.** See Compare auto-labeling for Office apps with auto-labeling policies.
> - **My simulation results look wrong or incomplete.** See Auto-labeling classification and simulation concepts to distinguish available classification, policy matches, and actual labeling. For simulation requirements and workflow, see Learn about simulation mode.
> - **I turned on a policy after simulation and want to review coverage.** See Review coverage by simulation context.
> - **I want SharePoint default library labels to apply to existing files.** See Apply default sensitivity labels from SharePoint document libraries to existing files.
> - **A file wasn't labeled, or has an unexpected label.** Start with Why was — or wasn't — a specific file labeled? to choose the checks for your file. For a reported failure, see Resolve auto-labeling failures in SharePoint and OneDrive files.
> - **My active policy has stopped matching Exchange email.** See Policy rule fails to load.
> - **I'm hitting a limit** (500,000 files/day, 100 policies, 1,000 explicitly selected SharePoint sites, or 20,000,000 files in simulation). See How to configure auto-labeling policies

for SharePoint, OneDrive, and Exchange, and Use PowerShell for auto-labeling policies to target up to 50,000 SharePoint sites by using an adaptive scope.

- **Auto-labeling isn't available in my region.** The **Auto-labeling** page isn't visible in unsupported regions. See the regional availability prerequisite.
- **I want to set a default label for Teams meetings, sites, groups, or Microsoft 365 Copilot.** This article covers files and emails. For container-level default labels (including Teams instant meetings and Meet Now), see Use sensitivity labels with Microsoft Teams, Microsoft 365 groups, and SharePoint sites. For Copilot default labels, see Considerations for Microsoft 365 Copilot.

When you create a sensitivity label, you can automatically assign that label to Microsoft 365 items such as files and emails when the data matches conditions that you specify.

This ability to apply sensitivity labels to content automatically is important because:

- You don't need to train your users when to use each of your classifications.
- You don't need to rely on users to classify all content correctly.
- Users no longer need to know about your policies—they can instead focus on their work.

There are two different methods for automatically applying a sensitivity label to content in Microsoft 365:

- **Client-side labeling when users edit documents or compose (also reply or forward) emails**: Use a label that's configured for auto-labeling for files and emails (includes Word, Excel, PowerPoint, and Outlook).

  This method supports recommending a label to users, as well as automatically applying a label. But in both cases, the user decides whether to accept or reject the label, to help ensure the correct labeling of content. This client-side labeling has minimal delay for documents because the label can be applied even before the document is saved. However, not all client apps support auto-labeling.

  For configuration instructions, see How to configure auto-labeling for Office apps on this page.

- **Service-side labeling when content is already saved (in SharePoint or OneDrive) or emailed (processed by Exchange Online)**: Use an auto-labeling policy.

You might also hear this method referred to as auto-labeling for data at rest (documents in SharePoint and OneDrive) and data in transit (email that is sent or received by Exchange). For Exchange, it doesn't include emails at rest (mailboxes).

Auto-labeling policies run in the service, so they don't depend on which app version a user has installed. They're available across your organization from the moment you turn a policy on, which makes them suitable for labeling at scale. Because the user doesn't interact with the labeling process, auto-labeling policies don't support *recommended* labeling — instead, run the policy in simulation before you turn it on to help ensure correct labeling.

For configuration instructions, see How to configure auto-labeling policies for SharePoint, OneDrive, and Exchange on this page.

Auto-labeling for SharePoint and OneDrive

- PDF documents and Office files for Word (.docx), PowerPoint (.pptx), and Excel (.xlsx) are supported.
  - These files can be auto-labeled at rest before or after the auto-labeling policies are created. Files can't be auto-labeled if they're part of an open session (the file is open).
  - Currently, attachments to list items aren't supported and won't be auto-labeled.

  > **Important**
  >
  > PDF labeling must be enabled for your tenant before an auto-labeling policy can process PDFs in SharePoint and OneDrive. Enable it by selecting the **Protect PDFs with Auto-labeling** banner in the Microsoft Purview portal, or by using PowerShell. If PDF labeling isn't enabled, PDFs are skipped entirely: PDFs aren't evaluated or sent for labeling, and no label is applied. For instructions, see Adding support for PDF.
- Maximum of 500,000 automatically labeled files in your tenant per day.
- Maximum of 100 auto-labeling policies per tenant. In the portal, each policy can target up to 1,000 explicitly included or excluded SharePoint sites, or up to 100 explicitly included or excluded OneDrive individual users or groups. If you keep the default configuration of **All**, this configuration is exempt from these maximums.
- For SharePoint, an auto-labeling policy can use an adaptive scope to target up to 50,000 sites. For configuration instructions, see Use PowerShell for auto-labeling policies.
- Existing values for modified, modified by, and the date aren't changed as a result of auto-labeling policies—for both simulation mode and when labels are applied.

- When the label applies encryption, the Rights Management issuer and Rights Management owner is the account that last modified the file.
- To apply default sensitivity labels from SharePoint document libraries to existing files, see Apply default sensitivity labels from SharePoint document libraries to existing files.

Auto-labeling for Exchange

- PDF attachments and Office attachments are scanned for the conditions you specify in your auto-labeling policy. When there's a match, the email is labeled but not the attachment.
  - For PDF files, if the label applies encryption, these files are encrypted by using Message encryption when your tenant is enabled for PDF attachments.
  - For these Office files, Word, PowerPoint, and Excel are supported. If the label applies encryption and these files are unencrypted, they're now encrypted by using Message encryption. The encryption settings are inherited from the email.
- To label and protect emails that contain Teams voicemail messages, see the configuration instructions in Enable protected voicemail in your organization.
- If you have Exchange mail flow rules or Microsoft Purview Data Loss Prevention (DLP) policies that apply IRM encryption: When content is identified by these rules or policies and an auto-labeling policy, the label is applied. If that label applies encryption, the IRM settings from the Exchange mail flow rules or DLP policies are ignored. However, if that label doesn't apply encryption, the IRM settings from the mail flow rules or DLP policies are applied in addition to the label.
- Email that has IRM encryption with no label will be replaced by a label with any encryption settings when there's a match by using auto-labeling.
- Incoming email is labeled when there's a match with your auto-labeling conditions. For this outcome to apply to senders outside your organization, the Exchange location must be set to **All** included and **None** excluded. If the label is configured for encryption:
  - That encryption is always applied when the sender is from your organization.
  - By default, that encryption isn't applied when the sender is outside your organization but can be applied by configuring **Additional settings for email** and specifying a Rights Management owner.
- When the label applies encryption, the Rights Management issuer and Rights Management owner is the person who sends the email when the sender is from your own organization. When the sender is outside your organization, you can specify a Rights Management owner for incoming email that's labeled and encrypted by your policy.
- If the label is configured to apply content markings with variables, be aware that for incoming email, this configuration can result in displaying the names of people outside

your organization.

> **Note**
>
> For some new customers, we're offering the automatic configuration of default auto-labeling settings for both client-side labeling and service-side labeling. Even if you're not eligible for this automatic configuration, you might find it useful to reference their configuration. For example, you can manually configure existing labels and create your own auto-labeling policies with the same settings to help accelerate your labeling deployment.
>
> For more information, see Default labels and policies for Microsoft Purview Information Protection.

Compare auto-labeling for Office apps with auto-labeling policies

Use the following table to help you identify the differences in behavior for the two complementary automatic labeling methods:

Expand table

Feature or behavior	Label setting: Auto-labeling for files and emails	Policy: Auto-labeling
App dependency	Yes (minimum versions)	No *
Restrict by location	No	Yes
Conditions: Sharing options and additional options for email	No	Yes
Conditions: Exceptions	No	Yes
Conditions: Nested rule logic (AND/OR/NOT)	No	Yes
Support for PDF files	No	Yes
Support for images	No	Yes
Recommendations, policy tooltip, and user overrides	Yes	No
Simulation mode	No	Yes
Exchange attachments checked for conditions	No	Yes

Feature or behavior	Label setting: Auto-labeling for files and emails	Policy: Auto-labeling
Apply visual markings	Yes	Yes (email only)
Override IRM encryption applied without a label	Yes if the user has the minimum usage right of Export	Yes (email only)
Label incoming email	No	Yes
Assign a Rights Management owner for emails sent from another organization	No	Yes
Replace manually applied label that has lower priority	No	Yes (configurable)
Remove existing label in SharePoint or OneDrive	No	Yes

* Auto-labeling isn't currently available in all regions because of a backend Azure dependency. If your tenant can't support this functionality, the **Auto-labeling** page isn't visible in the Microsoft Purview portal. For more information, see Azure dependency availability by country.

Licensing and where to find each surface

Auto-labeling is gated by license, and the two surfaces (client-side and service-side) appear in different places in the portal. If you expect to see auto-labeling and it isn't there, verify the license first.

Expand table

Surface	Configured in	Included with
Client-side auto-labeling (Office apps)	Sensitivity label configuration → **Auto-labeling for files and emails** page	Microsoft 365 E5, Microsoft 365 E5 Compliance, Microsoft 365 E5 Information Protection & Governance, Azure Information Protection Premium P2 (standalone)
Service-side auto-labeling (SharePoint, OneDrive, Exchange)	Microsoft Purview portal → **Information Protection** → **Policies** → **Auto-labeling policies**	Same E5 / P2-tier SKUs as above
Container-level default labels (Teams, groups, sites)	Documented in Use sensitivity labels with Microsoft Teams, Microsoft 365 groups, and SharePoint sites	Not covered on this page

For the authoritative, per-SKU feature matrix (including current entitlements for Microsoft 365 Business Premium, Frontline, Education, and Government clouds), see Microsoft 365 licensing guidance for security and compliance.

Common licensing symptoms:

- **You have E3 or Business Premium.** Auto-labeling of files and emails isn't included at this SKU. Sensitivity labels and manual labeling are — auto-labeling requires an E5 / P2-tier add-on.
- **You have E5 but don't see auto-labeling policies in the portal.** Confirm you're in the Microsoft Purview portal (not the legacy Compliance Center), that your role includes **Compliance Administrator** or **Compliance Data Administrator**, and that your region supports auto-labeling (Azure dependency availability by country).
- **You have E5 and see the page, but saving a new policy fails with "No matching database is available."** This is a known transient backend condition. Retry the save; if it fails repeatedly over 24 hours, open a support case with the policy configuration.

How multiple conditions are evaluated when they apply to more than one label

The labels are ordered for evaluation according to their position that you specify in the Microsoft Purview portal: The label positioned first has the lowest position (least sensitive, so lowest priority) and the label positioned last has the highest position (most sensitive, so highest priority). The label with the highest order number is selected.

This behavior is also true for service-side auto-labeling (auto-labeling policies) when sublabels share the same parent label: If after evaluation and ordering, more than one sublabel from the same parent label meets the auto-labeling conditions, the sublabel with the highest order number is selected and applied.

However, the behavior is a little different for client-side auto-labeling (auto-labeling settings in the label). If multiple sublabels from the same parent label match the conditions:

- If a file is not already labeled, the highest order sublabel that's configured for automatic labeling is always selected, rather than the highest order sublabel that's configured for recommended labeling. If none of these sublabels are configured for automatic labeling but only recommended labeling, the highest order sublabel is selected and recommended.

- If a file is already labeled with a sublabel from the same parent, no action is taken and the existing sublabel remains. This behavior applies even if the existing sublabel was a default

label or automatically applied.

For more information about label priority, see Label priority (order matters).

Considerations for label configurations

The following considerations apply to both client-side labeling and service-side labeling.

Don't configure a parent label to be applied automatically or recommended

If you're using parent labels with sublabels, rather than label groups: You can't apply a parent label (a label with sublabels) to content. Make sure that you don't configure a parent label to be auto-applied or recommended in Office apps, and don't select a parent label for an auto-labeling policy. If you do, the parent label won't be applied to content.

To use automatic labeling with sublabels that have parent labels, make sure you publish both the parent label and the sublabel.

For more information about parent labels, label groups, and sublabels, see Sublabels that use parent labels or label groups.

Label scoping that excludes files or emails

To automatically apply a sensitivity label to content, the label's scope must include **Files & other data assets** to automatically apply a label to documents, and **Emails** to automatically apply a label to emails.

For more information when you select just one of these label scopes, see Scope labels to just files or emails.

Will an existing label be overridden?

An auto-labeling policy that applies a sensitivity label won't remove an existing sensitivity label to leave content unlabeled. However, for SharePoint and OneDrive, an auto-labeling policy configured to automatically remove a label can remove the selected label, including when the label was manually applied, and leave the content unlabeled.

Default behavior whether automatic labeling will override an existing label:

- When content has been manually labeled, that label won't be replaced by automatic labeling.
- Automatic labeling will replace a lower priority sensitivity label that was automatically applied, but not a higher priority label.

  > **Tip**
  >
  > For example, the sensitivity label at the top of the list in the Microsoft Purview portal is named **Public** with an order number (priority) of 0, and the sensitivity label at the bottom of the list is named **Highly Confidential** with an order number (priority of 4). The **Highly Confidential** label can override the **Public** label but not the other way around.

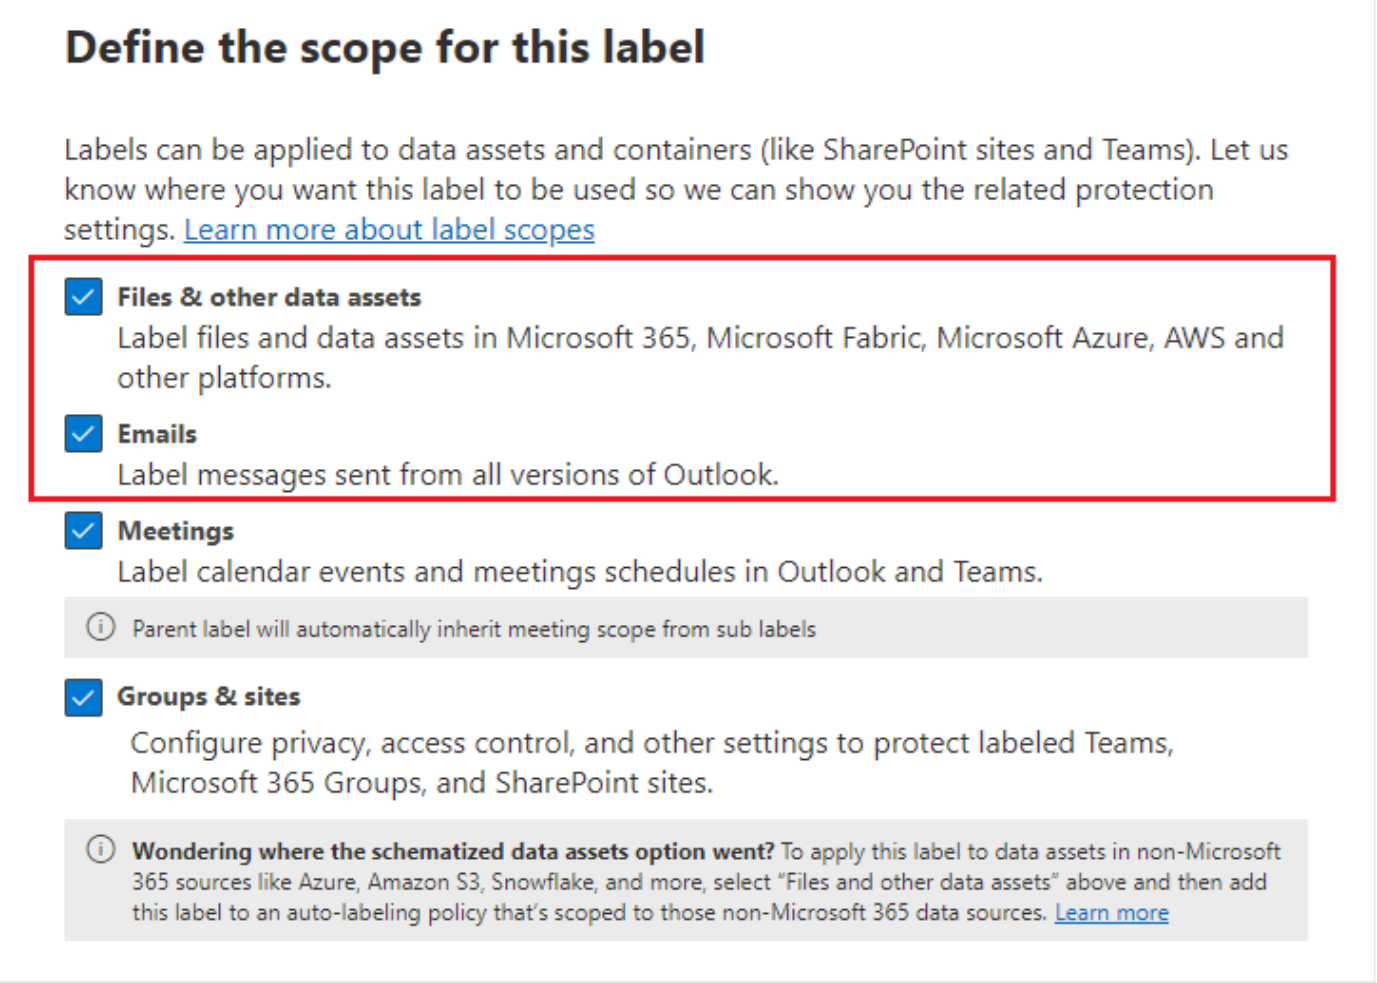
For auto-labeling policies that apply a sensitivity label, you can select a setting to override a manually applied label that has lower priority. This setting isn't required for an auto-labeling policy configured to automatically remove a label.

Expand table

Existing label	Override with label setting: Auto-labeling for files and emails	Override with policy: Auto-labeling
Manually applied, lower priority	No	No by default, but configurable
Manually applied, higher priority	No	No
Automatically applied or default label, lower priority	Yes *	Yes
Automatically applied or default label, higher priority	No	No

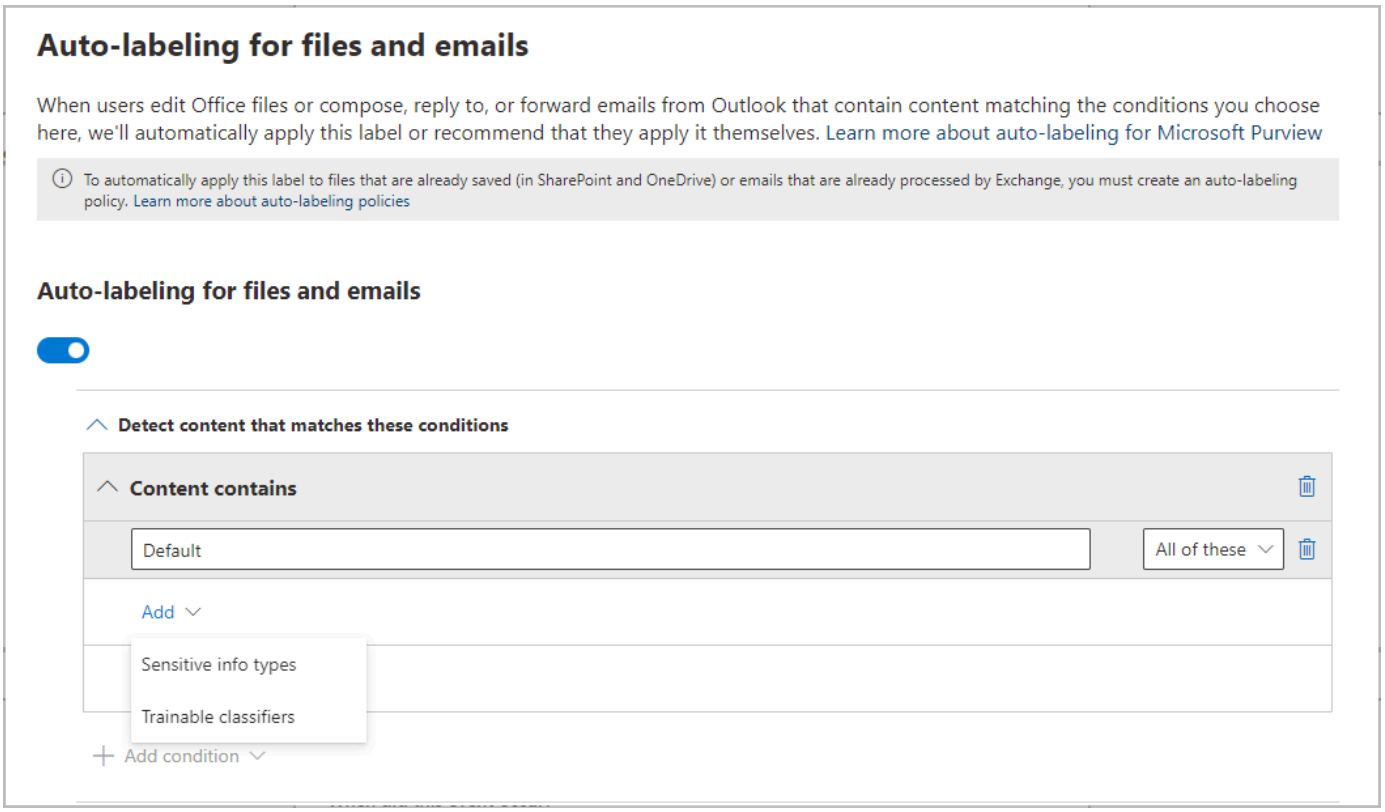
* There's an exception for sublabels that share the same parent label

The configurable setting for auto-labeling policies is on the **Additional label settings** page.



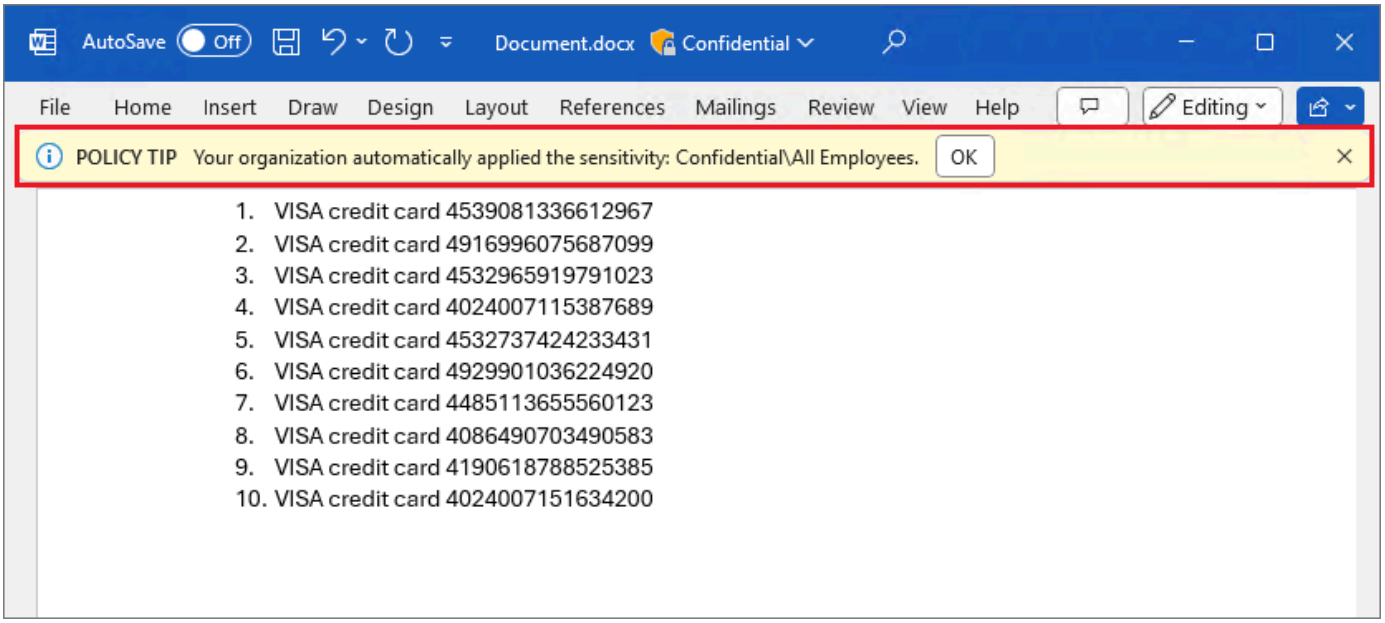
How to configure auto-labeling for Office apps

> **Tip**



Looking for **auto-labeling policies for SharePoint, OneDrive, or Exchange** (service-side auto-labeling for files at rest and emails in transit)? Skip ahead to **How to configure auto-labeling policies for SharePoint, OneDrive, and Exchange**. The section on this page is for client-side auto-labeling in Word, Excel, PowerPoint, and Outlook.

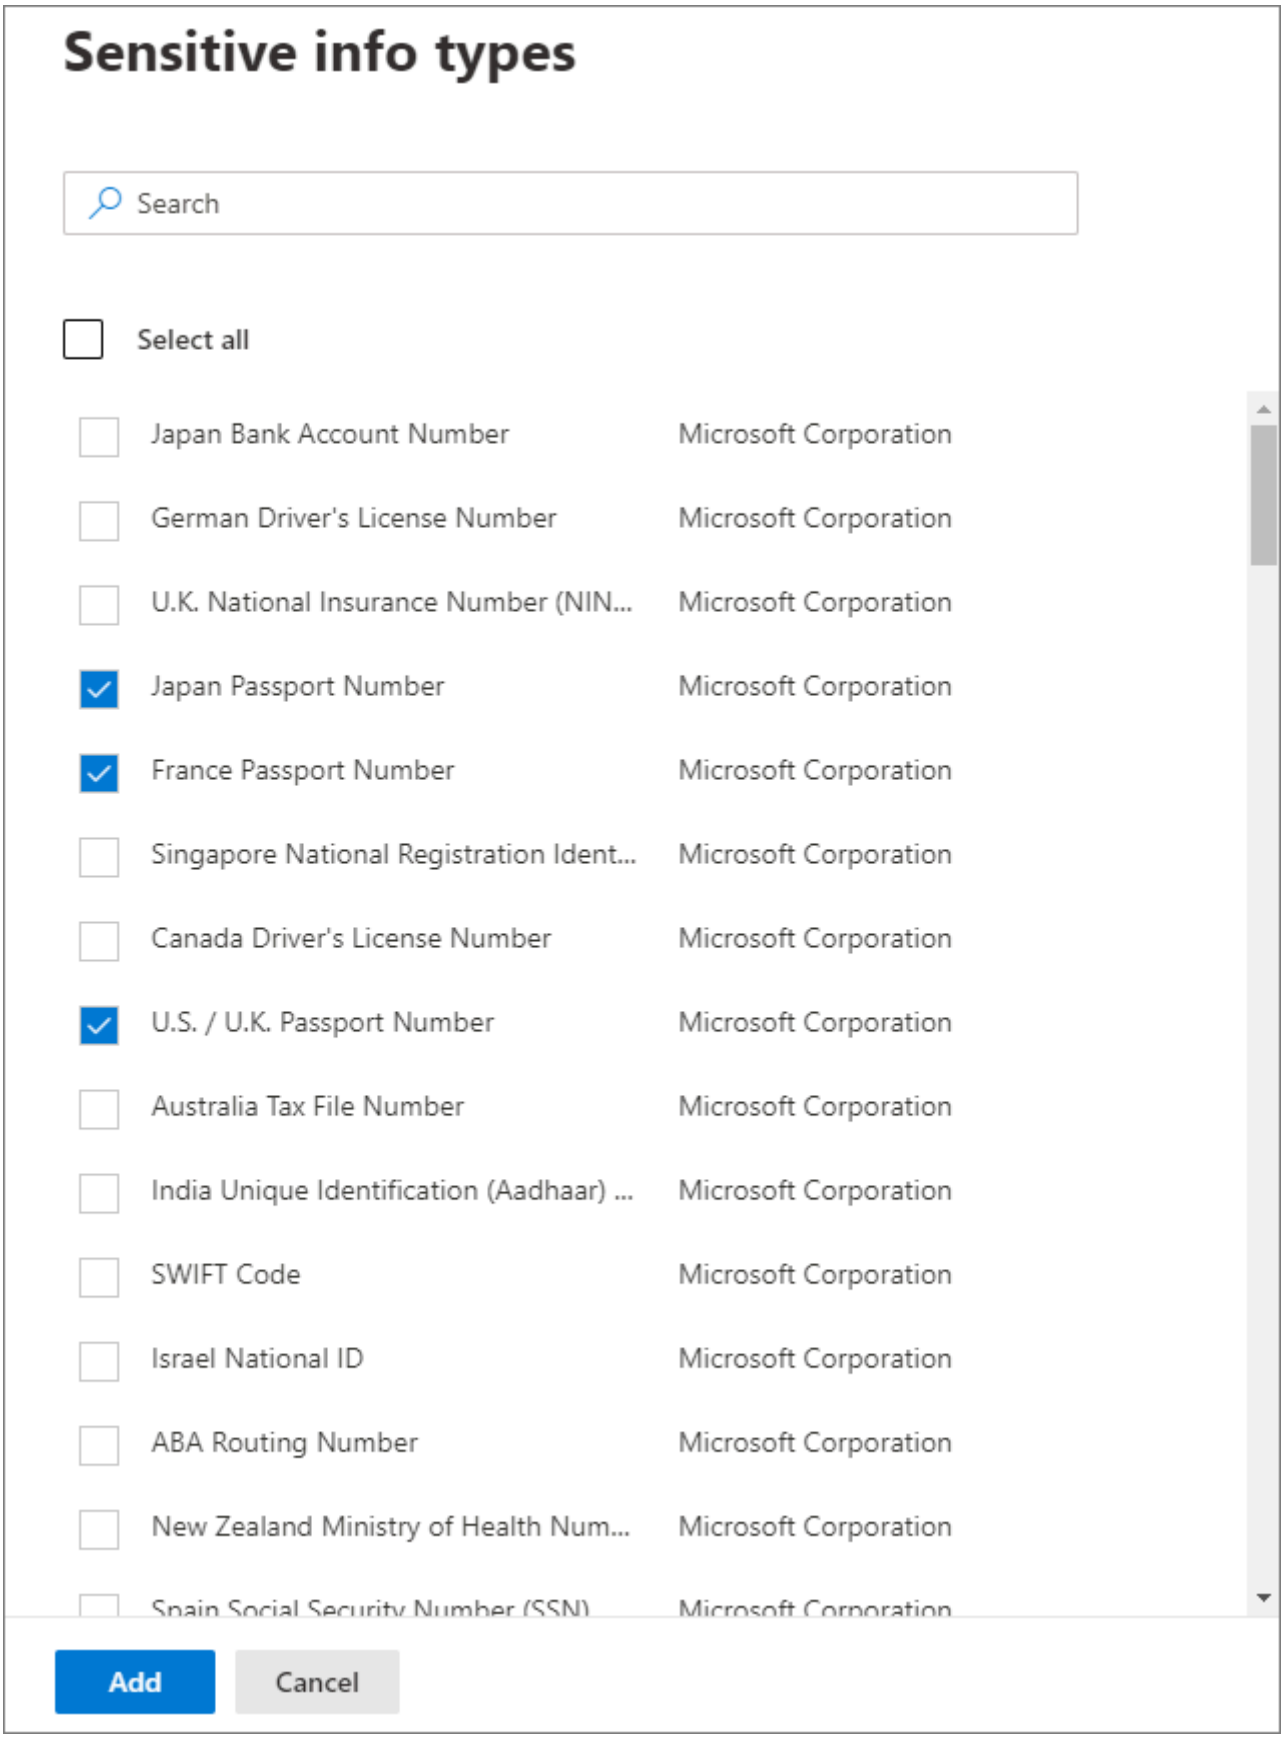
Check the minimum versions required for automatic labeling in Office apps.



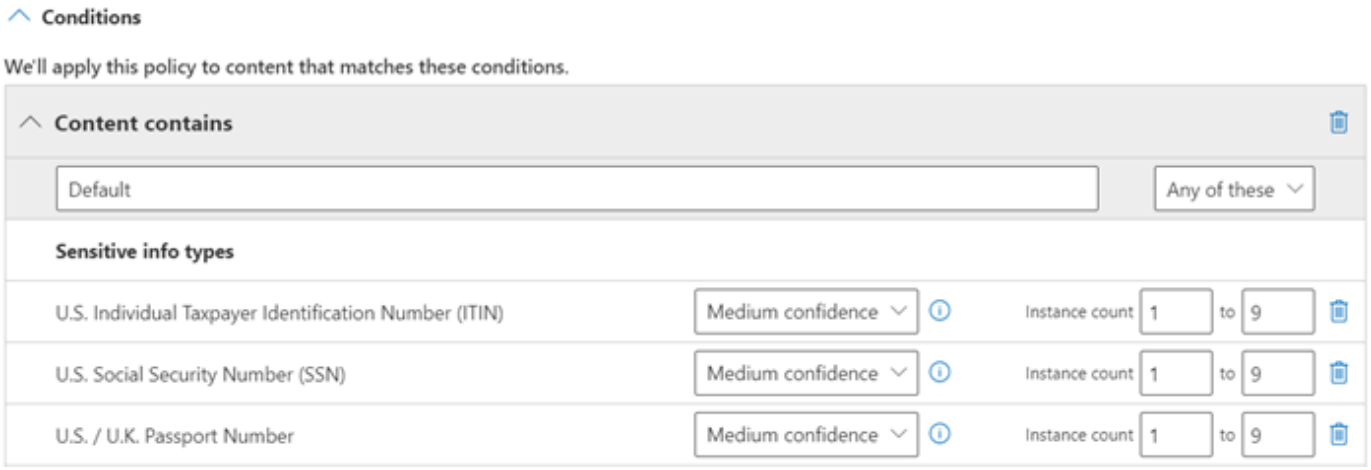
The auto-labeling settings for Office apps are available when you create or edit a sensitivity label. Make sure the label scope **Files & other data assets** is selected to auto-label documents, and **Emails** is selected to auto-label emails. For example:

As you move through the configuration, you see the **Auto-labeling for files and emails** page where you can choose from a list of sensitive info types or trainable classifiers:

When this sensitivity label is automatically applied, the user sees a notification in their Office app. For example:



Because of a timing issue, auto-labeling for Office apps might not trigger if you also use mandatory labeling. For details, see the additional information for configuring the policy setting Require users to apply a label to their email and documents.



Configuring sensitive info types for a label

When you select the **Sensitive info types** option, you see the same list of sensitive information types as when you create a data loss prevention (DLP) policy. So you can, for example,

automatically apply a Highly Confidential label to any content that contains customers' personal information, such as credit card numbers, social security numbers, or passport numbers:

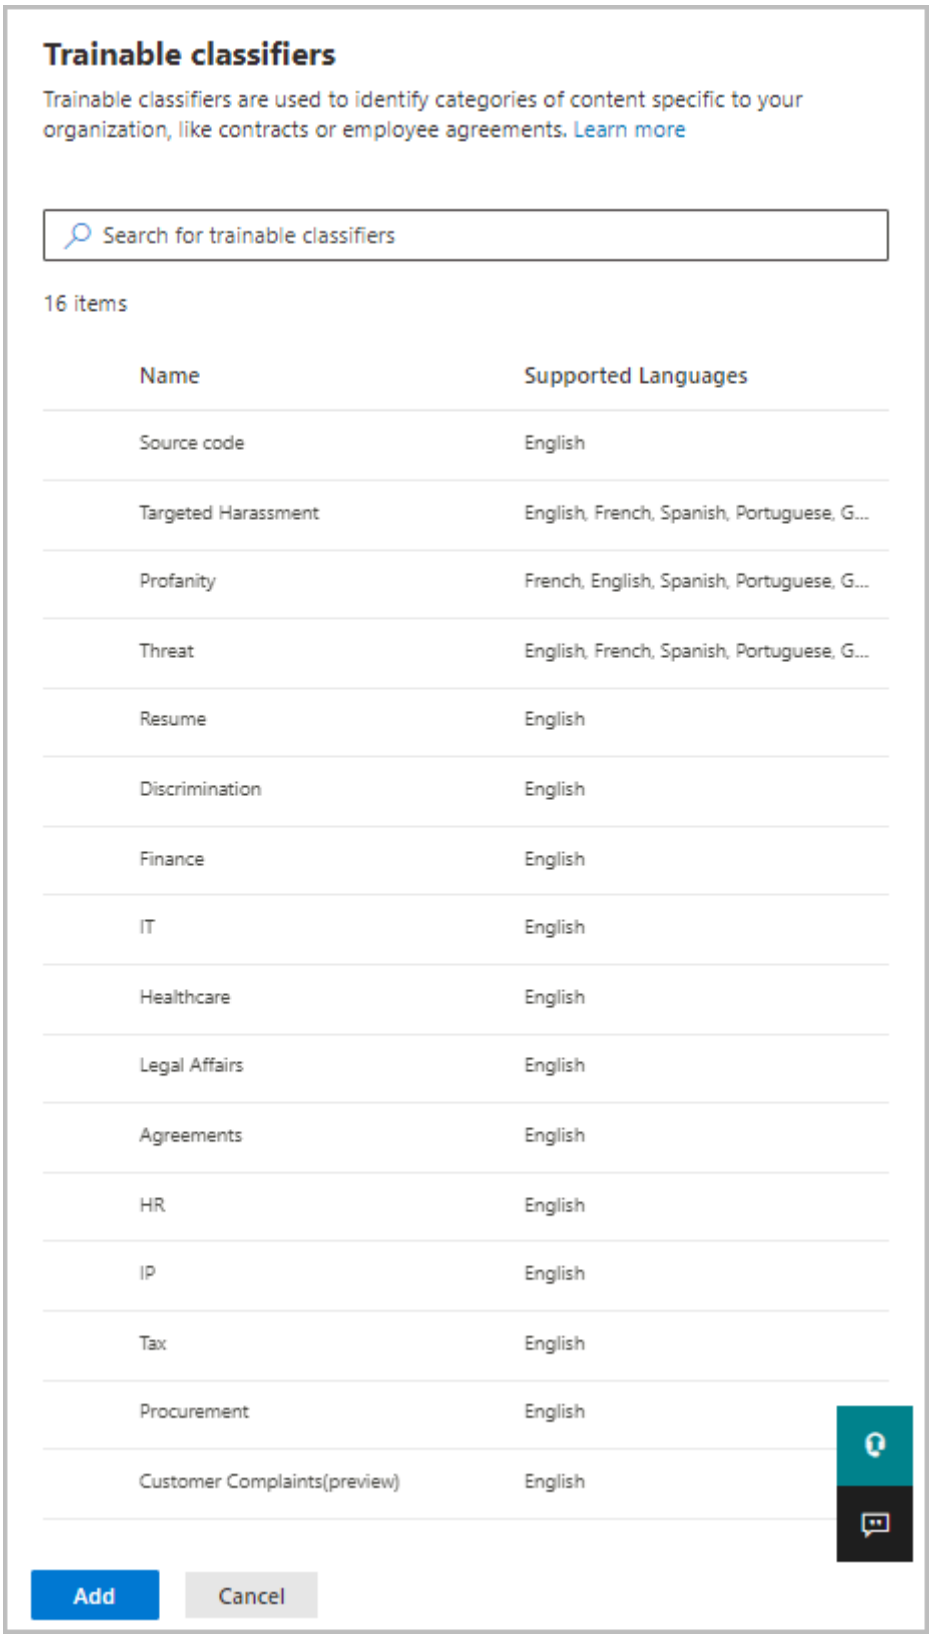
Similarly to when you configure DLP policies, you can then refine your condition by changing the instance count and match accuracy. For example:

You can learn more about confidence levels from the DLP documentation: More on confidence levels

> **Important**
>
> Sensitive information types have two different ways of defining the max unique instance count parameters. To learn more, see **Instance count supported values for SIT**.

Also similarly to DLP policy configuration, you can choose whether a condition must detect all sensitive information types, or just one of them. And to make your conditions more flexible or complex, you can add groups and use logical operators between the groups.

Custom sensitive information types with Exact Data Match



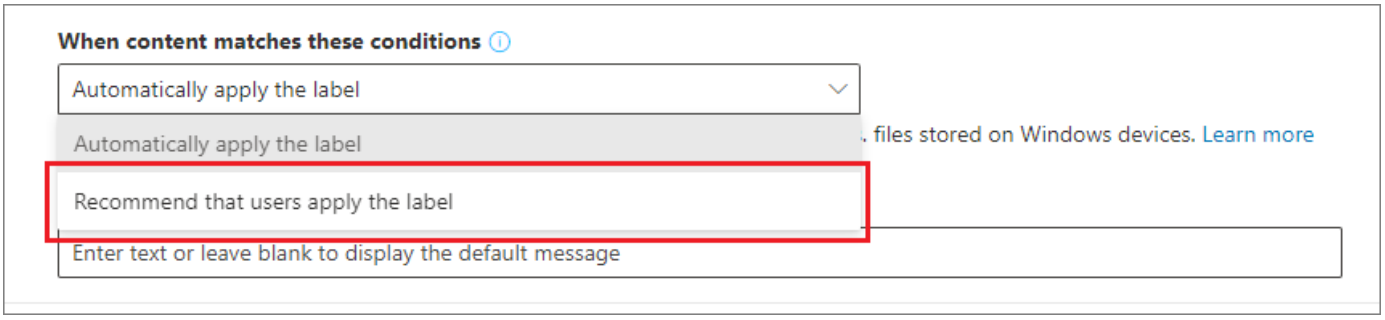
You can configure a sensitivity label to use exact data match based sensitive information types for custom sensitive information types. However, currently, you must also specify at least one sensitive information type that doesn't use EDM. For example, one of the built-in sensitive information types, such as **Credit card number**.

If you configure a sensitivity label with only EDM for your sensitive information type conditions, the auto-labeling setting is automatically turned off for the label.

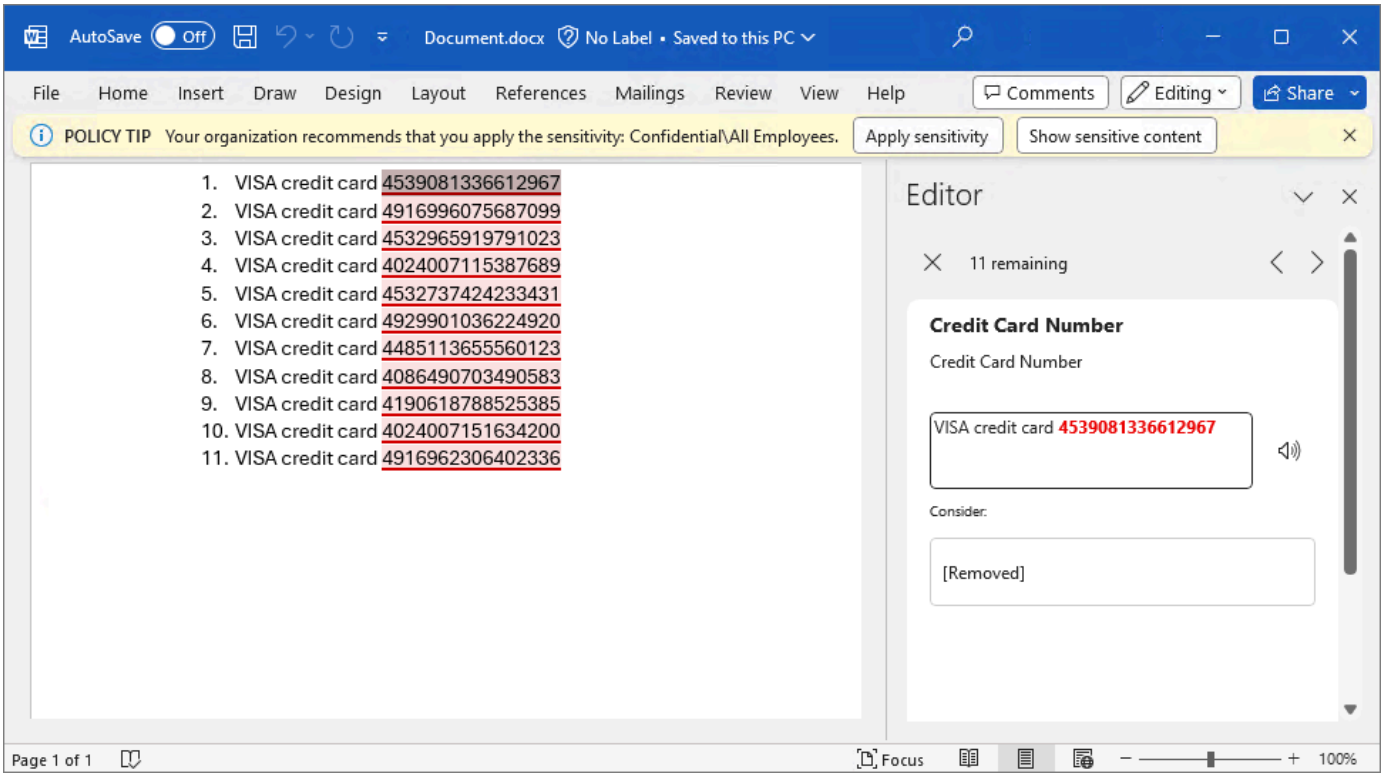
Configuring trainable classifiers for a label

If you use this option with Microsoft 365 Apps for Windows version 2106 or lower, or Microsoft 365 Apps for Mac version 16.50 or lower, make sure you've published in your tenant at least one other sensitivity label that's configured for auto-labeling and the sensitive info types option. This requirement isn't necessary when you use later versions on these platforms.

When you select the **Trainable classifiers** option, select one or more of the pretrained or custom trainable classifiers:



The available pretrained classifiers are often updated, so there might be more entries to select than the ones displayed in this screenshot.



For more information about these classifiers, see Learn about trainable classifiers.

Recommend that the user applies a sensitivity label

If you prefer, you can recommend to your users that they apply the label. With this option, your users can accept the classification and any associated protection, or dismiss the recommendation if the label isn't suitable for their content.

When you use built-in labeling with the desktop versions of Word, users have an additional option to **Show sensitive content** with the recommended label prompt. When they select this button, the Editor pane steps the user through each detection. The user can then remove the sensitive data or leave it with a better understanding of why the sensitivity label was recommended. When they have this extra information, users have more confidence to select the **Apply sensitivity** button. For example:

This example shows the default recommended label prompt, but as with automatic labeling, you can customize this text to be more meaningful or specific for your users. For example, include your organization's name or reference your IT department to increase visibility and give users more confidence that this isn't a generic message that might not be applicable to them.

> **Tip**
>
> Although recommending a sensitivity label interrupts a user's workflow, it's a very efficient way to educate users in the moment about sensitive data that they work with. To see this in action, watch the video: **Automatically Classify & Protect Documents & Data**
>
> Recommended labeling is particularly powerful when it's coupled with this option to step the users through each instance of sensitive content that's detected. It can lead to more accurate labeling, not just for the immediate item, but also for future items that require manual labeling, or for modified items that might now need relabeling.

When automatic or recommended labels are applied

Not all Office apps support automatic and recommended labeling. For more information, see Support for sensitivity label capabilities in apps.

Other considerations:

- You can't use automatic labeling for documents and emails that were previously manually labeled, or previously automatically labeled with a higher sensitivity. Remember, you can only apply a single sensitivity label to a document or email (in addition to a single retention label).
- You can't use recommended labeling for documents or emails that were previously labeled with a higher sensitivity. When the content's already labeled with a higher sensitivity, the user won't see the prompt with the recommendation and policy tip.
- For recommended labels in the desktop versions of Word, the sensitive content that triggered the recommendation is flagged so that users can review and remove the sensitive content instead of applying the recommended sensitivity label.

For details about how these labels are applied in Office apps, example screenshots, and how sensitive information is detected, see Automatically apply or recommend sensitivity labels to your files and emails in Office.

Convert your label settings into an auto-labeling policy

If the label includes sensitive info types for the configured conditions, you'll see an option at the end of the label creation or editing process to automatically create an auto-labeling policy that's based on the same auto-labeling settings.

However, if the label contains trainable classifiers as a label condition:

- When the label conditions contain just trainable classifiers, you won't see the option to automatically create an auto-labeling policy.
- When the label conditions contain trainable classifiers and sensitivity info types, an auto-labeling policy will be created for just the sensitive info types.

Although an auto-labeling policy is automatically created for you by auto-populating the values that you would have to select manually if you created the policy from scratch, you can still view and edit the values before they are saved.

By default, all locations for SharePoint, OneDrive, and Exchange are included in the auto-label policy, and when the policy is saved, it runs in simulation mode. There's no check that you've enabled sensitivity labels for Office files in SharePoint and OneDrive, which is one of the prerequisites for auto-labeling to apply to content in SharePoint and OneDrive.

How to configure auto-labeling policies for SharePoint, OneDrive, and Exchange

> **Note**
>
> Don't use Exchange auto-labeling policies to send encrypted emails for mass mailing distributions. These policies aren't designed for this purpose and can result in sending failures and non-delivery receipts. For this scenario, the label setting to automatically send emails is more suitable.

Make sure you're aware of the prerequisites before you configure auto-labeling policies. Use the Pre-flight checklist to confirm each one in a single scan, then review the full Prerequisites for auto-labeling policies below for details.

Pre-flight checklist

Before you create an auto-labeling policy, confirm each item below. Missing any one of them typically causes the policy to run without labeling any files, with no error surfaced in the portal. Each item links to the full guidance further down this article.

- [ ] **Auditing is turned on for Microsoft 365.** Required for simulation. See Turn audit log search on or off.

- [ ] **Sensitivity labels are enabled for Office files in SharePoint and OneDrive.** Required before any label can be applied to files in those locations. See Enable sensitivity labels for Office files in SharePoint and OneDrive.
- [ ] **Auto-labeling is available in your region.** If the **Auto-labeling** page isn't visible in the Microsoft Purview portal, your tenant is in an unsupported region. See Azure dependency availability by country.
- [ ] **The label you plan to apply is not a parent label.** Parent labels (labels that have sublabels) can't be applied to content. If you select one, the policy will run but nothing will be labeled. See Don't configure a parent label to be applied automatically or recommended.
- [ ] **The label's scope matches your target content.** To label files, the label scope must include **Files & other data assets**. To label emails, it must include **Emails**. See Label scoping that excludes files or emails.
- [ ] **If the label applies encryption to SharePoint or OneDrive content:** the label is configured with **Assign permissions now**, and **User access to content expires** is set to **Never**. See the encryption details in Prerequisites for auto-labeling policies.
- [ ] **Classification covers the sensitive information types you intend to use.** Policies can evaluate existing files using available classification results, but changing a custom SIT doesn't by itself refresh those results for unchanged files. Review when historical files need updated classification, including the effects of on-demand classification on active policies.
- [ ] **You have the roles required to review simulation results.** Viewing file contents in the source view requires the **Data Classification Content Viewer** role (included in the Content Explorer Content Viewer, Information Protection, and Information Protection Investigators role groups). Global admins don't have this role by default.
- [ ] **You have the roles required to turn the policy on after simulation.** Turning a policy from **Ready to turn on** to **On** requires **Compliance Administrator** or **Compliance Data Administrator**. Without one of these roles, the **Turn on policy** button appears greyed out even after a successful simulation.

When every item is confirmed, continue to Prerequisites for auto-labeling policies for the full details, then to Creating an auto-labeling policy.

Prerequisites — detailed reference

Every prerequisite for an auto-labeling policy is listed below. Confirm each item before you configure a policy — missing any one typically causes the policy to run without labeling any files, with no in-portal error surfaced.

- Simulation mode:

    - Auditing for Microsoft 365 must be turned on. If you need to turn on auditing or you're not sure whether auditing is already on, see Turn audit log search on or off.
    - To view file or email contents in the source view, you must have the **Data Classification Content Viewer** role, which is included in the **Content Explorer Content Viewer** role group, or **Information Protection** and **Information Protection Investigators** role groups. Without the required role, you don't see the preview pane when you select an item from the **Items to review** tab. Global admins don't have this role by default.

- To auto-label files in SharePoint and OneDrive:

    - You have enabled sensitivity labels for Office files in SharePoint and OneDrive.

    - If you want the policy to process PDFs, you have enabled PDF support by using the portal banner or PowerShell. Otherwise, PDFs are skipped without being evaluated or sent for labeling.

    - For OneDrive, the OneDrive account must be associated with the corresponding user account. A OneDrive account that isn't associated with its user account (sometimes called a detached OneDrive account) isn't supported for auto-labeling or simulation. Use a properly associated OneDrive account, or move the content to a supported SharePoint or OneDrive location, and then rerun simulation.

    - At the time the auto-labeling policy runs, the file mustn't be open by another process or user. A file that's checked out for editing falls into this category, and similarly, all files in a library that's configured to require documents to be checked out.

    - If historical files haven't been classified or need updated classification, use on-demand classification. This isn't required for every policy change. Review scan scope, estimates, and active-policy effects before starting classification.

    - If you plan to use sensitive information types:
        - Policy evaluation uses available classification results for existing SharePoint and OneDrive files. Changing a custom SIT definition doesn't by itself reclassify unchanged historical files, and a file's last-modified date alone doesn't establish its classification time. See Policy changes aren't classifier changes.
        - Validate custom SITs with representative matching and nonmatching files by using Test sensitive information types. Then review policy simulation separately; a direct SIT test doesn't establish classification coverage for existing files.

- If you plan to use document properties as a condition (**Document property is**), this option uses SharePoint managed properties in the same way as they are used for DLP policies. Use exact string matches; regex patterns aren't supported. For more information about managed properties as a search method, see Manage the search schema in SharePoint.

  > **Important**
  >
  > When a document property is mapped to a SharePoint managed property, such as `RefinableString11`, values containing an ampersand (`&`) might not match an auto-labeling rule that uses **Document property is**. For example, documents with the mapped value `Billing & payment document` might remain unlabeled. Plan around this known limitation rather than relying on a future fix. Consider using a classification value without ampersands, keeping the document metadata and rule value consistent. Before deploying broadly, review simulation results and confirm actual label application in a limited scope.

- If you have an auto-labeling policy configured to replace a manually applied label but another active auto-labeling policy is configured to apply a label without this option, the label won't be replaced. Because simulation shows the result of one policy, simulation results for the replace label policy show the label as replaced but the conflict is resolved when all policies run.

- If you have an auto-labeling policy configured to remove a label but another active auto-labeling policy is configured to apply a label and the conditions are matched, the label will be applied rather than removed. This behavior applies even when the apply-label policy applies a different label than the label selected for removal. Because simulation shows the result of one policy, simulation results for the label removal policy show the label as removed but the conflict is resolved when all policies run.

- If you choose to remove a label that applies encryption, encryption is automatically removed with the label.

- One or more sensitivity labels created and published (to at least one user) that you can select for your auto-labeling policies. For these labels:
  - It doesn't matter if the auto-labeling in Office apps label setting is turned on or off, because that label setting supplements auto-labeling policies, as explained in the introduction.

- If the labels you select are configured to use visual markings (headers, footers, watermarks), these markings aren't applied to documents when you use auto-labeling.
- If the labels apply encryption:
  - When the auto-labeling policy includes locations for SharePoint or OneDrive, the label must be configured for the **Assign permissions now** setting, and **User access to content expires** must be set to **Never**.
  - When the auto-labeling policy is just for Exchange, the label can be configured for either **Assign permissions now** or **Let users assign permissions** (for the Do Not Forward or Encrypt-Only options). You can't auto-apply a label that's configured to apply S/MIME protection.

Scoping a policy with users and groups

Scope options differ by workload. For supported selections and Exchange sender-scope behavior, see **Choose locations** in Creating an auto-labeling policy.

Learn about simulation mode

Simulation mode is supported for auto-labeling policies and woven into the workflow. You can't automatically label documents and emails, or remove labels, until your policy has run at least one simulation.

For existing SharePoint and OneDrive files, simulation evaluates policy matches using available classification results. Restarting simulation doesn't itself reclassify the content. See Auto-labeling classification and simulation concepts for when to change a policy and when to refresh classification.

> ⓘ **Important**
>
> **What "simulation mode" does — and doesn't — do**
>
> Simulation is designed to evaluate and log matches without applying (or removing) labels. It is not a fully silent dry run. Before you run a simulation, know these behaviors that customers frequently misdiagnose as bugs:
>
> - **Simulation still generates activity alerts.** If a Microsoft Purview alert policy is configured on auto-labeling or sensitive-information-type activity, matches surfaced during simulation trigger those alerts. To avoid mass alert email while validating a policy, temporarily scope or disable the alert policy for the simulation window.

- **Policy actions depend on status and permissions.** If **Turn on policy**, **Edit**, or **Delete** is unavailable, check the current policy status and your permissions. For **Turn on policy**, also check the simulation status. Review any displayed error before retrying.
- **A duplicated policy lands in simulation by default and doesn't notify you.** Duplicating an existing policy creates a new policy in simulation regardless of the source policy's state. If you expect the duplicate to inherit the source's active state, it won't.
- **Simulation and DLP share the same test-mode surface.** Some **Items to review** views can mix auto-labeling and DLP results and can fail to load if either signal is under load. If a view returns an error, retry a few hours later before you open a support case.
- **Simulation limits are documented separately.** The following guidance covers item caps (100 per site displayed, 50,000-record CSV export ceiling, and 20,000,000-item scan limit), the 12-hour target completion time, and stall detection.

Simulation mode supports up to 20,000,000 matched files. If more than this number of files are matched from an auto-labeling policy, you can't turn on the policy to apply the labels. In this case, you must reconfigure the auto-labeling policy so that fewer files are matched, and rerun simulation. This maximum of 20,000,000 matched files applies to simulation mode only and not to an auto-labeling policy that's already turned on to apply sensitivity labels.

> ⓘ **Note**
>
> Simulation results can differ from what happens when the policy is turned on:
>
> - Simulation shows the result of a *single* policy. When more than one auto-labeling policy applies to the same content (for example, one policy replaces an existing label and another applies a label without that option), the conflict is resolved only when *all* policies run—so the enforced result can differ from any single policy's simulation.
> - Classification results or file contents can change after simulation. A simulation match doesn't prove that classification used the latest SIT definition or that enforcement will successfully label the file. See Classification, policy evaluation, and enforcement.
> - For Exchange, simulation evaluates email that's sent and received during the run, so email results aren't consistent unless the same messages are sent and received again.

Workflow for an auto-labeling policy:

> ⓘ **Important**

Before you edit an auto-labeling policy or run simulation again, export any available results that you need for later comparison. See **Preserve results before editing or rerunning**.

1. Create and configure an auto-labeling policy.
2. Run the policy in simulation mode, which can take 12 hours to complete. The completed simulation triggers an email notification that's sent to the user configured to receive activity alerts.
3. Review the results, and if necessary, refine your policy. For example, you might need to edit the policy rules to reduce false positives, or remove some sites so that the number of matched files doesn't exceed 20,000,000. Rerun simulation mode and wait for it to complete again.
4. Repeat step 3 as needed.
5. Deploy in production.

The simulated deployment runs like the WhatIf parameter for PowerShell, for a specific point in time. You see results reported as if the auto-labeling policy had applied your selected label, using the rules that you defined. You can then refine your rules for accuracy if needed, and rerun the simulation. However, because auto-labeling for Exchange applies to emails that are sent and received, rather than emails stored in mailboxes, don't expect results for email in a simulation to be consistent unless you can send and receive the exact same email messages.

Simulation mode also lets you gradually increase the scope of your auto-labeling policy before deployment. For example, you might start with a single location, such as a SharePoint site, with a single document library. Then, with iterative changes, increase the scope to multiple sites, and then to another location, such as OneDrive.

For details about the newer simulation overview, see Review simulation results for auto-labeling policies. **Sample items**, when displayed, shows the sampled item count. **Contextual summary** is available in supported portal experiences; viewing matched content requires the **Data Classification Content Viewer** role.

Finally, you can use simulation mode to provide an approximation of the time needed to run your auto-labeling policy, to help you plan and schedule when to run it without simulation mode.

Note

If simulation doesn't include expected files, check the policy's scope and conditions, whether files changed after the run, and whether classification reflects the SIT definitions you intend to use. Rerun simulation to review updated policy matches. Rerunning doesn't refresh classification or confirm successful labeling; see **When historical files need updated classification**.

Apply default sensitivity labels from SharePoint document libraries to existing files

SharePoint document libraries can be configured with a default sensitivity label. SharePoint applies this label to new files and to files that users edit in the library. Files that already existed in the library before the default label was configured might remain unlabeled.

To extend your default library label deployment to existing files, create an auto-labeling policy that applies the default sensitivity label from each selected SharePoint document library to eligible existing files at rest. This policy type doesn't inspect file content to choose a label. The label comes from the SharePoint document library's default sensitivity label setting.

Use this configuration when:

- You already use default sensitivity labels for SharePoint document libraries.
- You want the default library label to apply to files that already exist in those libraries.
- You want service-side labeling for files at rest, instead of relying on users to open or edit each file.
- You want to apply the label selected by the SharePoint library configuration, rather than build separate sensitive information type or classifier conditions.

Before you create this type of policy, confirm these requirements:

- Sensitivity labels are enabled for Office files in SharePoint and OneDrive. For more information, see Enable sensitivity labels for Office files in SharePoint and OneDrive.
- The sensitivity labels that can be used as default library labels are created and published to the appropriate users or groups.
- One or more SharePoint document libraries in your target sites have a default sensitivity label configured.
- You have permissions to create and manage auto-labeling policies.
- You have permission to read the SharePoint site and document library metadata required to identify libraries with default sensitivity labels. For the currently supported configuration

path, use Compliance Administrator or an existing SharePoint or Microsoft Entra role with this access, such as SharePoint Administrator.

When you create the policy, select the option to apply default sensitivity labels from SharePoint document libraries to existing files. Select specific SharePoint sites rather than **All**. This policy type doesn't support administrative-unit scoping, so the simplified wizard doesn't include the **Assign admin units** step.

In portal experiences that validate default library labels, each selected SharePoint site needs at least one library with a default sensitivity label. If a site can't be added, use the displayed error to choose your next step:

- **No default library label is configured:** Choose another site, or configure a default sensitivity label for a document library in that site, then try again.
- **Default labels couldn't be verified:** Check your access to the site and its library metadata, then try again. This message doesn't mean that the site has no default library label.

For example:

1. A SharePoint document library has the default sensitivity label **Confidential**.
2. The library contains files that were uploaded before **Confidential** was configured as the library default.
3. You create an auto-labeling policy that uses the default SharePoint document library label configuration.
4. The policy evaluates existing files in that library.
5. Eligible files are labeled **Confidential** by the policy.

For this policy type, simulation identifies files in document libraries that have a default sensitivity label configured. Review the simulation results before you turn on the policy to confirm that the expected SharePoint sites, document libraries, default library labels, and files are included.

If the simulation results don't include files you expected, confirm that the document library has a default sensitivity label configured, the SharePoint site is included in the policy scope, and sensitivity labels are enabled for Office files in SharePoint and OneDrive.

Currently, you can create one auto-labeling policy of this type per tenant, and include up to 10 SharePoint sites in the policy. The policy evaluates only SharePoint document libraries that have a default sensitivity label configured, and applies labels only to eligible supported files. Files might not be labeled if they're open, checked out, locked, unsupported, encrypted in an unsupported way, or otherwise unavailable when the policy evaluates them.

If you need to label existing files across more than 10 SharePoint sites, create the policy for up to 10 sites first. After labeling for those sites is complete and you've reviewed the results, edit the policy to replace the site selection with the next batch of up to 10 sites.

Creating an auto-labeling policy

To create a policy, follow these steps. Page order and available settings can vary by portal experience; follow the settings shown in your wizard.

1. Sign in to the Microsoft Purview portal > **Solutions** > **Information Protection** > **Policies** > **Auto-labeling policies**.

   > **Note**
   >
   > If you don't see the option for auto-labeling, this functionality isn't currently available in your region because of a backend Azure dependency. For more information, see Azure dependency availability by country.

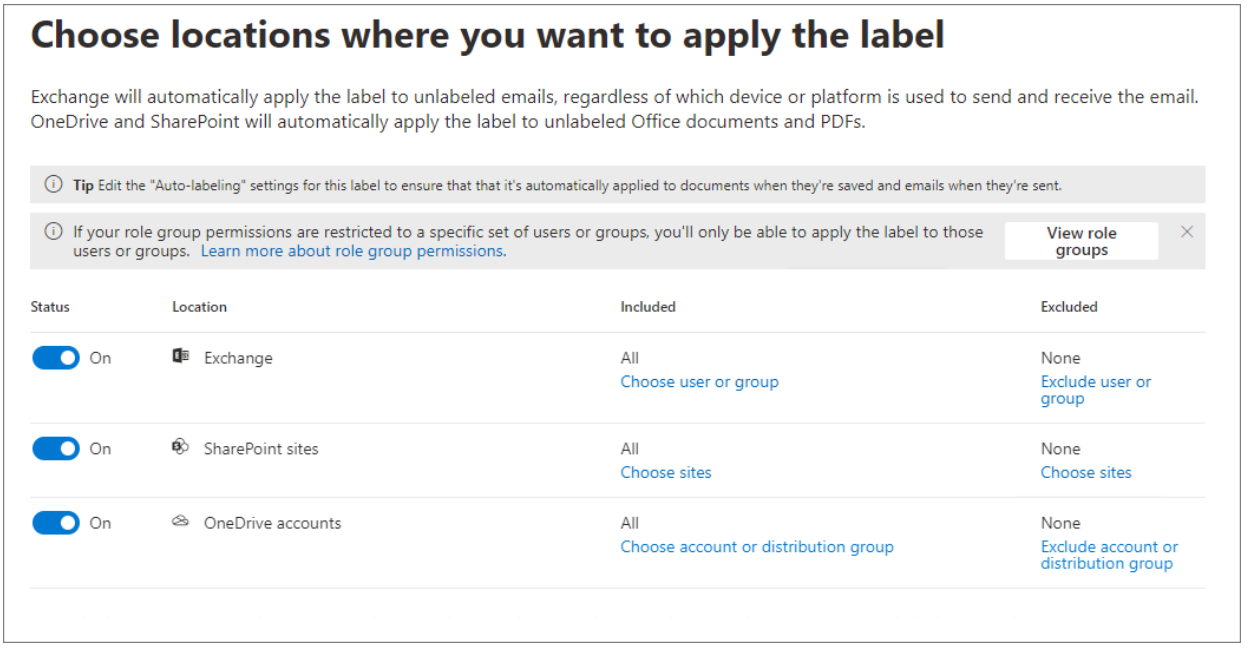
2. Select + **Create auto-labeling policy**. Choose whether you want to apply a sensitivity label, or remove a label. Then follow the instructions according to the option you chose.

Automatically apply label only

3. For the page **Choose info you want this label applied to**: Select one of the categories, such as **Financial**, and then select a corresponding regulation, such as **Canadian Financial Data**. You can refine your search by using the template search or dropdown box for countries or regions. Or, select **Custom** > **Custom policy** if the templates don't meet your requirements. Select **Next**.

4. For the page **Name your auto-labeling policy**: Provide a unique name, and optionally a description to help identify the automatically applied label, locations, and conditions that identify the content to label.

5. For the **Choose a label to auto-apply** page: Select + **Choose a label**, select and add a label from the **Choose a sensitivity label** pane, and then select **Next**.



6. For the page **Assign admin units**: If your organization is using administrative units in Microsoft Entra ID, auto-labeling policies for Exchange and OneDrive can be automatically restricted to specific users and auto-labeling policies for SharePoint can

be automatically restricted to the specific sites configured for the selected administrative units. If your account has been assigned administrative units, you must select one or more administrative units.

If you don't want to restrict the policy by using administrative units, or your organization hasn't configured administrative units, keep the default of **Full directory**.

> **Note**
>
> If you are editing an existing policy and change the administrative units, you must now reconfigure the locations in the next step.

7. For the page **Choose locations where you want to apply the label**: Select and specify locations for Exchange, SharePoint, and OneDrive. If you don't want to keep the default of **All** included for your chosen locations, select the link to choose specific instances to include, or select the link to choose specific instances to exclude. Then select **Next**.

> **Note**
>
> For organizations that are using administrative units and selected in the policy:
>
> - For SharePoint, you can't use the **Included** or **Excluded** options and must use the **All** default selection.

- For Exchange and OneDrive, you can use the **Included** or **Excluded** options, but see and can select only users from the administrative units selected in the previous step.

If you use the **Included** or **Excluded** options:

- For the **Exchange** location, the policy is applied according to the sender address of the recipients specified. Most of the time, you'll want to keep the default of **All** included with **None** excluded. This configuration is suitable even if you're testing for a subset of users. Instead of specifying your subset of users here, use the advanced rules in the next step to configure conditions to include or exclude recipients in your organization. Otherwise, when you change the default settings here:
  - If you change the default of **All** included and instead, choose specific users or groups, email sent from outside your organization will be exempt from the policy.
  - If you keep the default of **All** included but specify users or groups to exclude, email that these excluded users send will be exempt from the policy, but not email that they receive.

- For the OneDrive location, you must specify users or groups. Previously, you had to specify sites by URLs. Any existing OneDrive URL sites in auto-labeling policies will continue to work but before you can specify new OneDrive locations, or for restricted admins, you must first delete any existing site URLs. Groups supported: distribution groups, Microsoft 365 groups, mail-enabled security groups, and security groups.

- For the SharePoint location, you can explicitly select up to 1,000 individual sites. To dynamically target up to 50,000 sites, use a SharePoint adaptive scope. For example, an adaptive scope can use the `SiteTemplate` property to include or exclude communication sites, group-connected sites, Teams private channel sites, classic team sites, or OneDrive sites. For instructions to associate an adaptive scope with an auto-labeling policy, see Use PowerShell for auto-labeling policies.

8. For the **Set up common or advanced rules** page: Keep the default of **Common rules** to define rules that identify content to label across all your selected locations. If you need different rules per location, including some rules that are only available for Exchange, or SharePoint sites and OneDrive accounts, select **Advanced rules**. Then select **Next**.

The rules use conditions that include sensitive information types, trainable classifiers, sharing options, and other conditions:

- To select a sensitive information type or trainable classifier as a condition, under **Content contains**, select **Add**, and then choose **Sensitive info types** or **Trainable classifiers**.
- To select sharing options as a condition, under **Content is shared**, choose either **only with people inside my organization** or **with people outside my organization**.
- Other conditions that you can select:
  - Attachment or file extension is
  - Attachment or document name matches words or phrases
  - Attachment or document property is
  - Attachment or document size equals or is greater than

In **Advanced rules**, the name condition is **Attachment name matches words or phrases** for Exchange, or **Document name contains words or phrases** for SharePoint and OneDrive.

If your location is **Exchange** and you selected **Advanced rules**, there are additional conditions that you can select:

- Sender IP address is
- Recipient domain is
- Recipient is
- Attachment is password protected
- Any email attachment's content could not be scanned
- Any email attachment's content didn't complete scanning
- Header matches patterns
- Subject matches patterns
- Recipient address contains words
- Recipient address matches patterns
- Sender address matches patterns
- Sender domain is
- Recipient is a member of
- Sender is

If your location is **SharePoint sites** or **OneDrive accounts** and you selected **Advanced rules**, there is one other condition that you can select:

- Document created by

9. Depending on your previous choices, you'll now have an opportunity to create new rules by using conditions and exceptions.

   The configuration options for sensitive information types are the same as those you select for auto-labeling for Office apps. If you need more information, see Configuring sensitive info types for a label.

   When you've defined the rules and confirmed their status is on, select **Next** and complete the remaining settings shown by the wizard.

10. Specify optional configurations on the **Additional label settings** page:

    - **Emails only**: Applicable for both incoming and outgoing emails. When you select this setting, an existing sensitivity label will always be overriden for emails if the sensitivity label you chose for the policy has a higher priority. Use this setting to override manually labeled emails with a higher priority label when sensitive content is detected.

    - **All locations**: Applicable for emails and for files in SharePoint and OneDrive. When you select this setting, an existing sensitivity label will always be overriden if the sensitivity label you chose for the policy has a higher priority. Use this setting to override manually labeled emails and files with a higher priority label when sensitive content is detected.

    - **Apply encryption to email received from outside your organization**: This option is visible only when the selected sensitivity label applies encryption. If you then select this option to apply encryption to email received from outside your organization, you must assign a Rights Management owner. This configuration ensures that an authorized person in your organization has Full Control usage rights for these emails sent from your outside your organization and now encrypted. This role might be needed to later remove the encryption, or assign different usage rights for users in your organization.

      For **Assign a Rights Management owner**, specify a single user by an email address that's owned by your organization. Don't specify a mail contact, a shared mailbox, or any group type, because these aren't supported for this role.

11. For the **Decide if you want to test out the policy now or later** page: Select **Run policy in simulation mode** if you're ready to run the auto-labeling policy now, in simulation

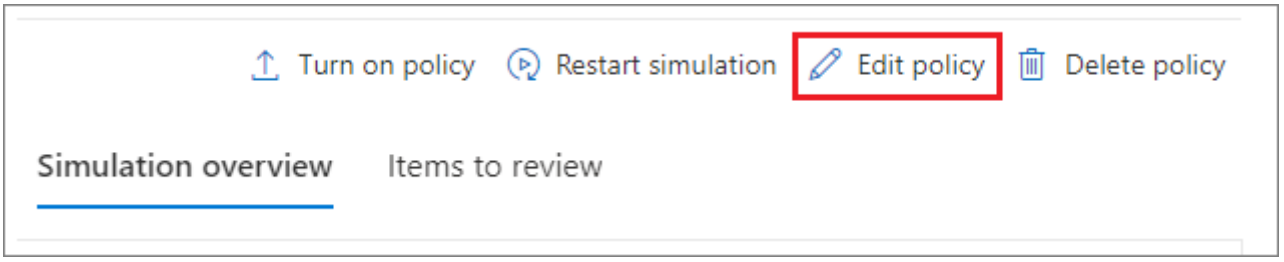
mode. Then decide whether to automatically turn on the policy if it's not edited for 7 days:

If you're not ready to run simulation, select **Leave policy turned off**.

12. For the **Summary** page: Review the configuration of your auto-labeling policy and make any changes that you need, and complete the configuration.

Example: Apply a label to Exchange email based on the subject

In this example, an auto-labeling policy applies the **High Confidence** sensitivity label when an email subject matches the fictional project codename `Project Atlas`.



1. Make sure the **High Confidence** sensitivity label is published to at least one user and its scope includes **Emails**.
2. Follow the preceding steps to create a policy that automatically applies a label. Select **Custom** > **Custom policy**, and then select the **High Confidence** label.
3. On the **Choose locations where you want to apply the label** page, select **Exchange**. Keep the default of **All** included and **None** excluded if the policy must evaluate incoming email from outside your organization.
4. On the **Set up common or advanced rules** page, select **Advanced rules**. Create a rule for Exchange, add the **Subject matches patterns** condition, and enter a regular expression that matches `Project Atlas` in the subject. For information about regular expressions for this condition, see SubjectMatchesPatterns.
5. Run the policy in simulation mode and send representative test messages while simulation is running. Review the matching messages on the **Items to review** tab, and then turn on the policy.

> **Note**
>
> You don't need an Exchange mail flow rule or a data loss prevention (DLP) policy for this configuration. Exchange auto-labeling policies evaluate messages in transit as they're sent or received; they don't evaluate existing messages stored in mailboxes. Similarly, simulation evaluates messages sent or received while the simulation is running.

Now on the **Information protection** > **Auto-labeling** page, you see your auto-labeling policy in the **Simulation** or **Off** section, depending on whether you chose to run it in simulation mode or not. Select your policy to see the details of the configuration and status (for example, **Policy simulation is still running**). For policies in simulation mode, select the **Items to review** tab to see which emails or documents matched the rules that you specified.

Before selecting **Edit policy**, preserve simulation results you need for comparison. You can modify your policy directly from this interface:

- For a policy in the **Off** section, select the **Edit policy** button.
- For policy in the **Simulation** section, select the **Edit policy** option at the top of the page, from either tab.

When you're ready to run the policy without simulation, select the **Turn on policy** option.

> **Note**
>
> Files with no content (i.e. zero bytes in size) may not be labeled.

Auto-labeling policies run continuously until they're deleted. For example, new and modified files will be included with the current policy settings.

Removing or downgrading sensitivity labels with an auto-labeling policy

An auto-labeling policy can also be used to **remove** a sensitivity label from files that match its conditions — for example, to strip an encryption-enforcing label before content is migrated, shared externally, or reclassified. This mode is powerful, and it also has documented behaviors that customers frequently misdiagnose as a bug when a large removal run appears to do nothing after activation.

Before you turn on a removal or downgrade policy, know these behaviors:

- **A simulation match doesn't guarantee successful label removal.** Review actual removal results and failures after the policy is turned on. See Learn about simulation mode for reasons simulation and enforcement results can differ.
- **A removal policy can remove a label that applies Microsoft Purview encryption.** The associated encryption is also removed. Password-protected files and files protected with external or non-Microsoft encryption aren't supported and might report `EncryptedFileNotSupported`. Simulation confirms that files match the policy conditions, but doesn't guarantee that enforcement can successfully modify them.
- **After cross-tenant migration, the source-tenant label often isn't recognized in the target tenant.** The label's tenant-scoped identity moves with the file's metadata but the target tenant's label set doesn't include it, so a target-tenant removal policy can't find the label to strip. Republish the label in the target tenant (or use PowerShell to strip metadata directly) before you run a removal policy.
- **A conflicting active policy that applies a label wins.** If another auto-labeling policy has conditions that match the same files and applies a label, the label-apply wins over the label-remove even when the policy applies a different label than the label selected for removal. The label removal policy might show these files as removed in simulation because simulation evaluates one policy at a time, but after all active policies run, matching files stay labeled instead of becoming unlabeled. See the Prerequisites — detailed reference note beginning "If you have an auto-labeling policy configured to remove a label" for the full conflict-resolution behavior.
- **Removing a label that applies encryption also removes the encryption.** This is intentional but frequently surprising to admins who expected the file to become "unlabeled but still protected." If you need to retain the existing label-applied encryption, don't remove that label with an auto-labeling policy.

To create a removal policy, use the **Automatically remove label only** tab in Creating an auto-labeling policy above.

Monitoring your auto-labeling policy

After your auto-labeling policy is turned on, you can view the labeling progress for files in your chosen SharePoint and OneDrive locations. Emails aren't included in the labeling progress because they're automatically labeled as they're sent.

> **Note**
>
> Exchange email isn't included in policy-level labeling progress, **Insights** enforcement metrics, or the **Labeled items** view. These views report on files in SharePoint and OneDrive.
>
> To verify labeling for an Exchange email, use Activity explorer and filter for the **Sensitivity label applied** activity. Narrow the results by date, sensitivity label, location, and item details, and review **How applied** to verify that the label was applied automatically. Allow 60 to 90 minutes for the activity to appear. Activity explorer identifies the resulting label and how it was applied, but doesn't identify the specific auto-labeling policy or rule that applied the label to an Exchange message.

The labeling progress includes the files to be labeled or unlabeled by the policy, the affected files for the last seven days, and the total files affected. Because of the maximum of labeling 100,000 files a day, this information provides you with visibility into the current labeling progress for your policy and how many files are still to be labeled.

When you first turn on your policy, you initially see a value of 0 for files to be labeled until the latest data is retrieved. This progress information updates every 48 hours, so you can expect to see the most current data about every other day. In the earlier policy flyout experience, selecting a policy shows labeling progress by the top 10 sites. The newer full **Overview** page shows **Top 15 sites** instead. The information on the flyout pane might be more current than the aggregated policy information displayed on the **Auto-labeling** main page. To have visibility on all auto-labeling policy progress, use activity explorer for the most up to date information for files and emails that were auto-labeled.

You can also see the results of your auto-labeling policy by using content explorer when you have the appropriate permissions:

- **Content Explorer List Viewer** role group lets you see a file's label but not the file's contents.
- **Content Explorer Content Viewer** role group, and **Information Protection** and **Information Protection Investigators** role groups let you see the file's contents.

Content explorer provides a current snapshot of labeled items and doesn't identify the auto-labeling policy that applied a label. Counts can take up to seven days to update, so use Activity

explorer instead for recent labeling activity.

However currently, restricted admins won't be able to see labeling activities for OneDrive in activity explorer.

> **Tip**
>
> You can also use content explorer to identify locations that have documents with sensitive information, but are unlabeled. Using this information, consider adding these locations to your auto-labeling policy, and include the identified sensitive information types as rules.

Policy-level labeling activity for SharePoint and OneDrive

For auto-labeling policies that are turned on and target SharePoint and OneDrive, you can monitor them right from the main **Auto-labeling** page and use the per-policy review pages. Use these pages to monitor day-to-day labeling activity, spot-check labeled files, and investigate labeling failures.

To view the review pages, you need one of the following roles:

- Compliance Administrator
- Compliance Data Administrator
- Information Protection Admin
- Information Protection Analyst

Contextual summary is available in supported portal experiences. To view matched text inside a file, you also need the **Data Classification Content Viewer** role.

To open the newer review pages, go to **Solutions** > **Information Protection** > **Policies** > **Auto-labeling policies**. Select a policy, then select **View details** in the policy details panel. Earlier portal experiences might open Activity explorer instead. Most data on the review pages reflects activity from the last 30 days.

The newer review page has separate **Overview**, **Labeled items**, and **Labeling failures** tabs. For policies that remove labels, the item tabs are **Label removed items** and **Label removal failures**.

The **Overview** tab shows labeled and failed file counts and **Top 15 sites**. Its **Labeling activity overview** chart has separate successful and failed series for the last 30 days. For removal policies, the chart is **Label removal activity overview**. The **Configuration details** section shows the policy's locations, exclusions, and rule summary.

The policy details panel's **Insights** tab summarizes the sensitive information types detected in labeled files. A **Labeling failures** card shows the total failure count and the top three failure reasons. For details, see Use the Insights tab to analyze auto-labeling policies.

Use **Labeled items** to review successfully labeled files. Use **Labeling failures**, or **Review items** on the **Labeling failures** card, to investigate failures. Select a file and review its failure reason. In experiences with a **Details** tab, open that tab to find **Failure reason**. File previews and contextual summaries depend on the portal experience and your permissions.

Review the failure reason even when few files fail. Transient infrastructure failures are retried automatically, but file format, protection, or label configuration failures might require action regardless of volume. Some unsupported files require no action. Follow the reason-specific guidance in Resolve auto-labeling failures in SharePoint and OneDrive files.

Review coverage by simulation context

In supported portal experiences, **Coverage by simulation context** (preview) reports on SharePoint and OneDrive files. Run the policy in simulation mode, then turn it on before reviewing coverage. The coverage report helps you see which files were labeled, pending, or not labeled, and whether those files were found in the latest simulation run.

View coverage can be hidden if the policy isn't turned on or simulation completion information is missing. If the entry is greyed out, point to it or move keyboard focus to it to read the tooltip. The tooltip distinguishes an expired simulation from an unsupported Exchange-only policy. Rerunning an Exchange-only policy in simulation doesn't enable file coverage.

Use this report to:

- Review how labeling activity is distributed after the latest simulation run.
- Identify files that were found in simulation and then labeled during enforcement.
- Review files that are pending, not yet attempted, or failed to apply a label.
- Investigate files that don't have a match in the latest simulation run.

Coverage is based on labeling activity after the latest simulation run and is available for 30 days. After 30 days, **View coverage** is unavailable for that simulation run. To view coverage again, run the policy in simulation mode again and then review the updated coverage report.

The coverage report isn't an all-time policy total and isn't intended to be an exact reconciliation between simulation and enforcement. All-time labeled totals can include activity from before or after the coverage window, so they might not match the counts shown in the coverage report.

To open the coverage report:

1. In the Microsoft Purview portal, go to **Information Protection** > **Policies** > **Auto-labeling policies**.
2. Select an auto-labeling policy that includes SharePoint or OneDrive, has completed simulation, and is turned on.
3. In the **Coverage** column, select **View coverage**.

The report groups files by labeling outcome and simulation context.

Expand table

Area	What it means
Observed files	Files included in this report because they were found during simulation, enforcement, or both.
Labeled during enforcement	Files that had a label applied during enforcement.
Not labeled during enforcement	Files that don't have a successful label application in this report.
Found in simulation	Files that were found in the latest simulation run.
No simulation match found	Files that weren't matched to the latest simulation run.
Pending	Files that don't have a final enforcement outcome yet.
Not yet attempted	Files that enforcement hasn't attempted to label yet.
Failed to apply label	Files that enforcement attempted to label, but the attempt failed.

Select a bucket in the chart to open an item list for that bucket. Depending on the bucket, item details can include the file name, location, workload, label, last activity time, status, and failure reason when available.

Files under **No simulation match found** can be files that were created, changed, or classified after the latest simulation run completed. They can also appear when the report doesn't have enough information to identify a more specific reason. Files under **Failed to apply label** were attempted during enforcement, but the label wasn't applied. Open the item list and review the failure reason when available.

Why was — or wasn't — a specific file labeled?

For files in SharePoint and OneDrive, first check what the policy reports. Select the policy, then **View details** in the policy details panel. In the newer experience, use **Labeled items** to review successful labeling or **Labeling failures** to investigate a failure. Earlier portal experiences might open Activity explorer instead.

A simulation match doesn't confirm that a label was applied. A file missing from **Labeling failures** isn't proof of success either. Choose the guidance that matches what you see:

- **The policy is on, but the file isn't labeled.** Check the policy's locations and conditions, then the file's eligibility. Follow Policy is on but files aren't labeled.
- **The file has an unexpected label or protection.** Review the policy's conditions and exceptions, label replacement rules, and other matching policies before changing anything. Follow Existing label or protection isn't what you expect.
- **The reports show different numbers.** Check which time period and locations each report covers. SharePoint and OneDrive file views don't include Exchange email. Follow Numbers don't agree or Exchange activity is missing.

If the file reports a failure, review **Failure reason** (on the **Details** tab, if present). For reason-specific actions, see Resolve auto-labeling failures in SharePoint and OneDrive files.

A new or changed policy can evaluate existing files using available classification. Changing a custom sensitive information type doesn't by itself reclassify unchanged files. A file's last-modified date doesn't establish its classification time. For classification refresh and policy evaluation checks, see Auto-labeling classification and simulation concepts.

If your rule uses **Document property is** with a mapped SharePoint managed property, check whether the value contains an ampersand (`&`). See the mapped-property limitation in Prerequisites — detailed reference.

Monitoring your daily labeling volume

Use the main **Auto-labeling** page to review labeling activity across your policies. Depending on your portal experience, you might see **Files Labeled Today** or the newer **Files labeled in the last 30 days** chart. The chart shows daily counts and an average calculated over all 30 days.

These views count label-applied and label-changed activity for SharePoint and OneDrive files associated with your auto-labeling policies. They don't include Exchange email. Use them to spot activity trends, not to measure remaining daily capacity or the number of unique files currently labeled or protected.

Policy rule fails to load

In rare cases, a malformed rule in an auto-labeling policy can prevent the policy from loading correctly. The most common symptom is that Exchange messages stop matching an otherwise enabled auto-labeling policy, and there might not be any item-level labeling failure to review because the rule never loaded in the first place.

This is different from the SharePoint and OneDrive item-level labeling failures described earlier in this section. Those failures mean a specific file was evaluated against the policy but couldn't be labeled (for example, because of file format or existing protection). A rule-load failure means the policy's rule couldn't be compiled or loaded at all, so *no* content is evaluated against that rule until the problem is fixed.

If you suspect a policy has stopped matching content and there's no corresponding item-level failure, contact Microsoft Support. Support can check whether a rule failed to load and, if so, identify which specific rule is affected.

> **Important**
>
> Only delete and recreate a rule after Microsoft Support has identified the specific rule that failed to load. Don't delete rules from a policy as a general troubleshooting step, because this removes their enforcement.

If Support confirms that a specific rule needs to be recreated, use the following sequence:

1. Record the current configuration of the affected rule before you delete it, including the policy name, rule name, target label, workload/scope, conditions, exceptions, priority, and enabled state. You can use Get-AutoSensitivityLabelRule to retrieve and save these details.
2. Delete only the rule that Microsoft Support identified, using Remove-AutoSensitivityLabelRule. Don't delete other rules in the policy.
3. Recreate the rule with the same configuration you recorded, using New-AutoSensitivityLabelRule.
4. Run the policy in simulation mode to confirm the recreated rule matches content as expected.
5. For Exchange, validate the rule by using newly sent or received messages, because auto-labeling for Exchange doesn't apply to messages already at rest in a mailbox.
6. Turn on the policy and confirm that matching activity resumes as expected.

> ⚠ **Warning**
>
> After you delete the affected rule, enforcement from that rule is paused until it's recreated and the change propagates. Plan for a change window and expect a delay before the recreated rule is fully in effect.

Exchange auto-labeling rule limits

When you configure an Exchange auto-labeling rule in the Microsoft Purview portal, the **Sender domain is** condition accepts up to **600 domain entries**. If you exceed this limit, saving the policy fails with an error that identifies the maximum of 600.

This limit describes the domain entries in the condition. It doesn't establish a combined domain limit across all rules in a policy.

For Exchange auto-labeling policies, check the parameter-specific limits in New-AutoSensitivityLabelRule and Set-AutoSensitivityLabelRule. These limits are separate from the number of policies or locations that you can configure.

For example, the FromAddressMatchesPatterns parameter documentation specifies a maximum of 10 regular expressions, with up to 128 characters per expression. These figures describe the values for that parameter, not a combined limit for all conditions in a policy.

Support for multiple values doesn't mean an unlimited number of values. If the parameter reference doesn't specify a maximum for your configuration, contact Microsoft Support for guidance.

Use PowerShell for auto-labeling policies

You can use Security & Compliance PowerShell to create and configure auto-labeling policies. This means you can fully script the creation and maintenance of your auto-labeling policies, which also provides a more efficient method of specifying multiple locations for SharePoint and OneDrive.

To target more than 1,000 SharePoint sites, associate an existing SharePoint adaptive scope with the policy by using the `-SharePointAdaptiveScopes` parameter (or `-SharePointAdaptiveScopesException` for exclusions) with New-AutoSensitivityLabelPolicy. An adaptive scope supports up to 50,000 SharePoint sites per policy. This doesn't increase the portal limit; instead, it replaces static site enumeration with dynamic adaptive-scope membership.

Before rerunning simulation, preserve simulation results you need for comparison.

Before you run the commands in PowerShell, you must first connect to Security & Compliance PowerShell. To use PowerShell to start or rerun an auto-labeling policy simulation, connect by using Connect-IPPSSession with the *EnableSearchOnlySession* switch:

PowerShell

```
Connect-IPPSSession -EnableSearchOnlySession -UserPrincipalName <admin-UPN>
```

The *EnableSearchOnlySession* switch is required so that the simulation job can be submitted correctly. If a simulation started from PowerShell remains in progress, reconnect in a new PowerShell session with this switch and rerun the simulation, or use the Microsoft Purview portal.

To create a new auto-labeling policy:

PowerShell

```
New-AutoSensitivityLabelPolicy -Name <AutoLabelingPolicyName> -SharePointLocation "
<SharePointSiteLocation>" -ApplySensitivityLabel <Label> -Mode
TestWithoutNotifications
```

This command creates an auto-labeling policy for a SharePoint site that you specify. For a OneDrive location, use the *OneDriveLocation* parameter, instead.

To add more sites to an existing auto-labeling policy:

PowerShell

```
$spoLocations = @("<SharePointSiteLocation1>","<SharePointSiteLocation2>")
Set-AutoSensitivityLabelPolicy -Identity <AutoLabelingPolicyName> -
AddSharePointLocation $spoLocations -ApplySensitivityLabel <Label> -Mode
TestWithoutNotifications
```

This command specifies the new SharePoint URLs in a variable that is then added to an existing auto-labeling policy. To add OneDrive locations instead, use the *AddOneDriveLocation* parameter with a different variable, such as *$OneDriveLocations*.

To create a new auto-labeling policy rule:

PowerShell

```
New-AutoSensitivityLabelRule -Policy <AutoLabelingPolicyName> -Name
<AutoLabelingRuleName> -ContentContainsSensitiveInformation @{"name"= "00aa00aa-bb11-
```

```
cc22-dd33-44ee44ee44ee"; "mincount" = "2"} -Workload SharePoint
```

For an existing auto-labeling policy, this command creates a new policy rule to detect the sensitive information type of **U.S. social security number (SSN)**, which has an entity ID of 00aa00aa-bb11-cc22-dd33-44ee44ee44ee. To find the entity IDs for other sensitive information types, refer to Sensitive information type entity definitions.

For more information about the PowerShell cmdlets that support auto-labeling policies, their available parameters and some examples, see the following cmdlet help:

- Get-AutoSensitivityLabelPolicy
- New-AutoSensitivityLabelPolicy
- New-AutoSensitivityLabelRule
- Remove-AutoSensitivityLabelPolicy
- Remove-AutoSensitivityLabelRule
- Set-AutoSensitivityLabelPolicy
- Set-AutoSensitivityLabelRule

Tips to increase labeling reach

Although auto-labeling is one of the most efficient ways to classify, label, and protect Office and PDF files that your organization owns, check whether you can supplement it with any of the following methods to increase your labeling reach:

- For SharePoint document libraries, you can apply a default sensitivity label for new and edited files. To extend the same default label to existing files, use an auto-labeling policy that applies default sensitivity labels from SharePoint document libraries to existing files. For more information, see Configure a default sensitivity label for a SharePoint document library.

- With Microsoft Syntex, you can apply a sensitivity label to a document understanding model, so that identified documents in a SharePoint document library are automatically labeled.

- For Outlook messages, you can apply a sensitivity label based on attachments that are labeled.

- When you use the Microsoft Purview Information Protection client:
  - For files in on-premises data stores, such as network shares and SharePoint Server libraries: Use the scanner to discover sensitive information in these files and label them

appropriately. If you're planning to migrate or upload these files to SharePoint in Microsoft 365, use the scanner to label the files before you move them to the cloud.

- Encourage manual labeling after providing users with training which sensitivity labels to apply. When you're confident that users understand which label to apply, consider configuring a default label and mandatory labeling as policy settings.

Additionally, consider marking new files as sensitive by default in SharePoint to prevent guests from accessing newly added files until at least one DLP policy scans the content of the file.

Microsoft Purview auto-labeling classification and simulation concepts

In Microsoft Purview, service-side auto-labeling is a policy-based capability that applies or removes sensitivity labels. For existing files in SharePoint and OneDrive, classification, policy evaluation, and label enforcement are distinct stages. These distinctions help you interpret unexpected matches and decide whether to change a policy, update classification, or investigate a labeling failure.

This article focuses on policies that use sensitive information types (SITs). A new or changed policy can evaluate existing files using available classification results. Changing a custom SIT or restarting simulation doesn't, by itself, refresh classification for unchanged historical files.

Classification, policy evaluation, and enforcement

Each stage answers a different question. A policy match isn't evidence that the content was freshly classified or that a label was successfully applied.

Expand table

Stage	What it does	What the result means
Classification	Identifies sensitive content and records classification results, such as the SIT, match count, and confidence.	The results describe what classification detected when it processed the file.
Policy evaluation and simulation	Evaluates the policy's scope and conditions using available classification results for SIT conditions. Simulation reports matches without applying or removing labels.	The file matched the evaluated policy. The match doesn't prove that classification used the latest SIT definition.
Enforcement	Applies or removes a label according to the active policies, file eligibility, and applicable label rules.	The actual labeling outcome must be checked separately from the simulation match.

Policy changes aren't classifier changes

Changing the conditions that a policy evaluates isn't the same as changing how a SIT detects sensitive content.

Expand table

Change or action	Effect on existing SharePoint and OneDrive files
Create or change an auto-labeling policy or rule	Can evaluate existing in-scope files using available classification results. Existing, correct classifications don't need to be refreshed for every policy change.
Change a custom SIT definition	Doesn't by itself reclassify unchanged historical files. Available results can still reflect the earlier definition.
Restart auto-labeling simulation	Reevaluates policy matches. It doesn't itself reclassify the underlying content.
Run on-demand classification	Classifies files within the scan scope. If you select specific classifiers, only those classifiers have their results updated for the scanned files.

Creating a policy that references a new SIT isn't proof that all historical files have been classified with that SIT. Review classification coverage rather than assuming that either the policy creation date or the SIT creation date establishes coverage.

Why an older file can appear in simulation

Supported files can be eligible for auto-labeling whether they existed before or after the policy was created. An older file can match a new policy because classification results are already available for it. The file's last-modified date alone doesn't establish when it was last classified.

For example, a file already has classification results for a SIT. You create a policy that uses that SIT, or change the policy's required match count. The file can match the policy without being edited or freshly classified.

In a different example, you narrow a custom SIT definition after a file was classified. If the file's classification hasn't been refreshed, simulation can still match using the earlier results. This is one possible explanation for a discrepancy, not a diagnosis for every unexpected match.

Uploaded-file tests and policy simulation answer different questions

The SIT **Test** function evaluates an uploaded file against the SIT. Auto-labeling simulation evaluates the policy's scope and conditions using available classification results for existing SharePoint and OneDrive files. A successful uploaded-file test doesn't establish that historical files have the same classification results.

Use Test sensitive information types with representative positive and negative examples to validate your custom detector. Your organization is responsible for deciding whether a custom SIT meets its detection requirements and obligations. A successful test or simulation doesn't certify regulatory coverage.

When a direct test and simulation disagree, consider the SIT definition used for classification as well as the policy's conditions and scope. Don't assume that restarting simulation refreshes classification.

When historical files need updated classification

Use on-demand classification when relevant historical files haven't been classified or need updated classification, such as after a custom SIT change. Scope the scan to the relevant locations, file date range, file types, and classifiers. Check that the date range includes the historical files you intend to evaluate. Review estimates and charges before starting classification.

> **Important**
>
> On-demand classification isn't an auto-labeling simulation. Updated classification can trigger actions from other active matching policies, including labeling, label removal, and other protection or lifecycle actions. Review active policies before starting the scan, even if the auto-labeling policy you're testing is still in simulation.

After classification completes, review auto-labeling simulation results before deciding whether to turn on the policy you're testing. Refreshing classification doesn't itself undo existing labels; label changes depend on the applicable policies or an authorized labeling action.

Simulation doesn't guarantee enforcement

Simulation evaluates one policy. When policies are active, competing policies and label replacement rules can affect the outcome. File eligibility, protection, and labeling failures can also prevent a matching file from being labeled.

Use policy-level labeling activity to review actual outcomes and failures. Coverage by simulation context helps compare those outcomes with the latest simulation; it isn't an exact reconciliation or an all-time policy total.

These distinctions don't explain a stalled simulation, a source view that fails to open, or results that remain inconsistent after the relevant checks. Use the auto-labeling troubleshooting

guidance and contact Microsoft Support if the issue persists.

Review simulation results for auto-labeling policies in Microsoft Purview

Before you enforce an auto-labeling policy, run it in simulation mode. Simulation reports policy matches without applying or removing labels. Review the match results and source distribution to decide whether the policy is ready for enforcement.

This article describes the newer simulation overview page. Available fields and review options can vary by portal experience. To review policy results after you turn on a policy, see Monitor your auto-labeling policy.

For existing SharePoint and OneDrive files, simulation uses available classification results. Restarting simulation reevaluates policy matches; it doesn't itself reclassify the content after a SIT change. See Auto-labeling classification and simulation concepts to distinguish direct SIT tests, classification refresh, and enforcement.

> **Important**
>
> Before you begin, make sure that you have the required roles and permissions. For more information, see Policy-level labeling activity for SharePoint and OneDrive.
>
> To view matched text in a file on **Items to review**, you also need the **Data Classification Content Viewer** role.

Review the simulation overview

Make sure the policy is running in simulation mode and has started evaluating the configured locations. Then follow these steps:

1. Sign in to the Microsoft Purview portal.
2. Select **Solutions** > **Information Protection** > **Policies** > **Auto-labeling policies**.
3. Select the name of a policy that is running in simulation mode.
4. In the policy details panel, select **Summary** > **View details** to open the **Simulation overview** page.

On the **Simulation overview** page, the following key metrics about the policy are available:

Expand table

Field	Description
Label	The sensitivity label that the policy applies to matched items.
Status	Simulation status: **Simulation in progress**, **Simulation almost complete**, **Simulation complete**, **Simulation expiring soon**, **Expired**, or **Policy can't be published**.
Duration	The length of time the simulation has been running in days and hours.
Matched items	The total number of items that matched the policy conditions across all workloads.
Sample items	When displayed, the number of sampled items available for review. Samples are retained for 30 days. See Preserve results before editing or rerunning.
Policy matches per rule	Shows details about the policy rules and their matches: - **Total Rules:** the number of rules in the policy, not the number of rules with matches. - **Total Matches:** the number of items that matched rules. - **Rule name:** the name of the rule in the policy. - **Matches:** the number of items that matched this rule. - **Location:** The workload where matches occurred (Exchange, SharePoint, or OneDrive). Use the per-rule match counts to identify which rules matched and whether each rule produces the expected results.
Matches by source	A donut chart showing matches distributed across workloads, with an item count and percentage for each of the following workloads: - **Exchange**: Email messages that matched the policy. Matched Exchange items are based on sampled data and might not represent all mailboxes in the policy scope. - **SharePoint**: Files in SharePoint sites that matched. - **OneDrive**: Files in OneDrive accounts that matched.
Sensitive info types	This table lists the sensitive information types (SITs) detected across the matched items and the number of matches for each type. Use it to identify which SITs produce the most matches.
Configuration details	Shows the policy's locations, exclusions, and rule configuration. Review these details alongside the match results to check the policy scope.
Review sample items	Select **Review sample items**, when displayed, to open **Items to review**. For each item, you can: - Preview the file or email content, where supported and with the required permissions. - View properties such as the file location, modified date, and detected SITs. - Read a **Contextual summary**, in supported portal experiences, that explains why the item matched. Viewing matched content requires the **Data Classification Content Viewer** role.

> **Note**
>
> The **Matched items** count is an **estimate**, not a count of successfully labeled files. Enforcement results can differ because files or classification results change, other active policies affect the outcome, or labeling fails. For details, see Simulation doesn't guarantee enforcement.

Preserve results before editing or rerunning

Before you edit an auto-labeling policy or restart simulation, export any available results that you need for later comparison. Check the exported file before you make changes.

Don't assume that sample retention guarantees access to results from earlier runs in the policy view or export. Export-size limits are separate from prior-run availability. Don't rely on filters or a larger export limit to recover results that are no longer available.

Next steps

Based on the simulation results, choose the appropriate next step:

- **Turn on policy** when the policy is eligible and you've reviewed the results and warnings. **Simulation complete**, **Simulation almost complete**, and **Simulation expiring soon** can be eligible states, but eligibility doesn't replace checking that the matches meet your requirements.
- **Edit the policy** when its scope or conditions don't meet your requirements. First, preserve results you need for comparison. Review sample items to distinguish false positives from valid matches, edit the conditions as needed, and restart simulation to reevaluate policy matches.
- **Refresh classification when needed** if historical files haven't been classified or their classification needs to reflect a changed SIT. Review on-demand classification scope, costs, and active-policy effects before starting a scan. A simulation restart alone doesn't refresh classification.

> **Important**

If you configure a scheduled turn-on date, the policy is scheduled to turn on automatically without waiting for your review. The displayed date isn't confirmation that activation succeeded. Cancel the scheduled turn-on date if you need more time.

Use the Insights tab to analyze auto-labeling policies in Microsoft Purview

The **Insights** tab provides an at-a-glance view of an auto-labeling policy's performance directly in the policy details panel. Its contents vary depending on whether the policy is running in simulation or enforcement mode, helping you understand how the policy identifies or labels content.

This article describes the newer Insights layout. Available fields and review options can vary by portal experience.

Availability also depends on the policy's mode and locations:

- **Simulation:** The tab is available for policies that include Exchange, SharePoint, or OneDrive.
- **Enforcement:** The tab is available only when the policy includes SharePoint or OneDrive.

The tab isn't available for disabled policies or Exchange-only policies that are turned on. For an Exchange-only policy that's turned on, use Activity explorer to review email labeling activity.

For more information on simulation, see Review simulation results for auto-labeling policies. For more information on enforcement, see Monitor your auto-labeling policy.

> **Important**
>
> Before you begin, make sure that you have the required roles and permissions. For more information, see **Policy-level labeling activity for SharePoint and OneDrive**.

To open the Insights tab:

1. Sign in to the Microsoft Purview portal.
2. Select **Solutions** > **Information Protection** > **Policies** > **Auto-labeling policies**.
3. Select a policy that is running in simulation mode or is turned on and includes SharePoint or OneDrive.
4. In the policy details panel, select **Insights**.
5. (Optional) Select **View details** to open the full policy overview. For policies in enforcement mode, earlier portal experiences might open Activity explorer instead.

Simulation mode: When the policy runs in simulation mode, the Insights tab shows a lightweight summary of the simulation findings. These findings include:

- General information about the policy, including **Label**, **Status**, **Duration**, **Results** (or total matches), and **Sample items**, when displayed.
- **Turn on date**, which shows scheduled automatic activation when configured; otherwise, no date is shown. This date isn't confirmation that activation succeeded. The separate **Start date/time** field shows the displayed simulation start date and time.
- **Rules and matches**, which shows the total number of rules in the policy and the total matches found. The rule total doesn't count only rules with matches. To identify which rules matched, select **View details** and review the per-rule match counts on the full simulation overview.
- **Matches by source**, which is a donut chart of matches across Exchange (purple), SharePoint (green), and OneDrive (blue).
- **Matches by sensitive info type**, which is a table listing each detected sensitive information type (SIT) and its match count.

> ⓘ Note
>
> Exchange matched-item counts are estimates based on sampled data.

Enforcement mode: When the policy is actively labeling files, the Insights tab shows 30-day operational metrics. **Insights** shows the following metrics about the policy:

> ⓘ Note
>
> Policy-level enforcement metrics and the **Labeled items** view report only files in SharePoint and OneDrive. They don't include Exchange email, including voicemail messages stored in Exchange. To verify labeling for an Exchange email, use Activity explorer and allow 60 to 90 minutes for the activity to appear.

Expand table

Field	Description
Sensitivity label	The sensitivity label applied by the policy.
Status	The current status of the policy.

Field	Description
Turn on date	The activation date and time displayed by the portal. Don't use this field as an immutable record of the policy's first activation.
Total labeled to date	The total number of SharePoint and OneDrive files labeled by the policy.
Duration	The number of days calculated from the displayed enforcement turn-on date.
Last simulated results	The results of the most recent simulation before enforcement was turned on.
Completed on	The date when the most recent simulation completed.
Count of auto-labeled and failed files	A donut chart showing files processed in the last 30 days: - **Labeled (green):** Files that were successfully labeled. - **Failed (red):** Files that matched but couldn't be labeled.
Labeling failures	The card shows the total number of failed items and the **Top 3 failure reasons**, sorted by volume. For more information, see Resolve auto-labeling failures in SharePoint and OneDrive files.
Top 10 sensitive info types	The table lists the sensitive information types (SITs) most frequently detected when this policy applied labels during the last 30 days. It includes the **Files labeled** count for each SIT.
Labels per source	To identify whether failures are concentrated to a specific workload, **Labels per source** shows a breakdown of labeled and failed item counts for SharePoint and OneDrive.

For the daily trend, select **View details** and open **Overview** in the newer full review experience. **Labeling activity overview** shows separate successful and failed series for the last 30 days. For removal policies, the chart is **Label removal activity overview**. This chart isn't part of the newer Insights layout.

Review failure reasons even when few files fail. Transient infrastructure failures are retried automatically, but configuration, protection, or file format failures might require action regardless of volume. Some unsupported files require no action. Follow the reason-specific guidance in Resolve auto-labeling failures in SharePoint and OneDrive files.

> ⓘ **Note**
>
> The Insights tab provides less data for non-Microsoft locations.

Use sensitivity labels to protect collaborative workspaces (groups and sites)

> *Microsoft Purview service description*

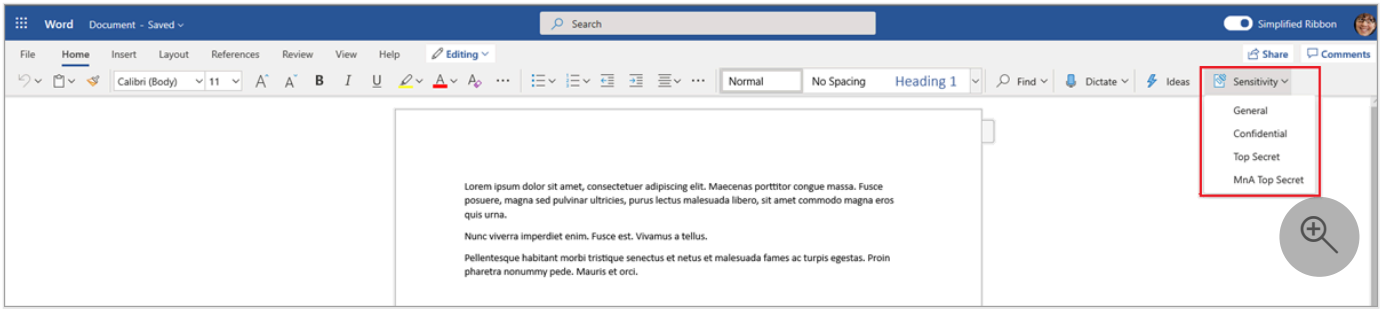
In addition to using sensitivity labels to protect items such as documents and emails, you can also use sensitivity labels to protect content in the following containers: Microsoft Teams sites, Microsoft 365 groups, SharePoint sites, Viva Engage communities, and Loop workspaces. To protect these collaborative workspaces, use the following label settings:

- Privacy (public or private)
- External user access
- External sharing from SharePoint sites
- Access from unmanaged devices
- Authentication contexts
- Prevent discovery of private teams for users who have this capability
- Shared channels control for team invitations
- Default sharing link for a SharePoint site (PowerShell-only configuration)
- Site sharing settings (PowerShell-only configuration)
- Default label for channel meetings

> **Important**
>
> The settings for unmanaged devices and authentication contexts work in conjunction with Microsoft Entra Conditional Access. You must configure this dependent feature if you want to use a sensitivity label for these settings. Additional information is included in the instructions that follow.

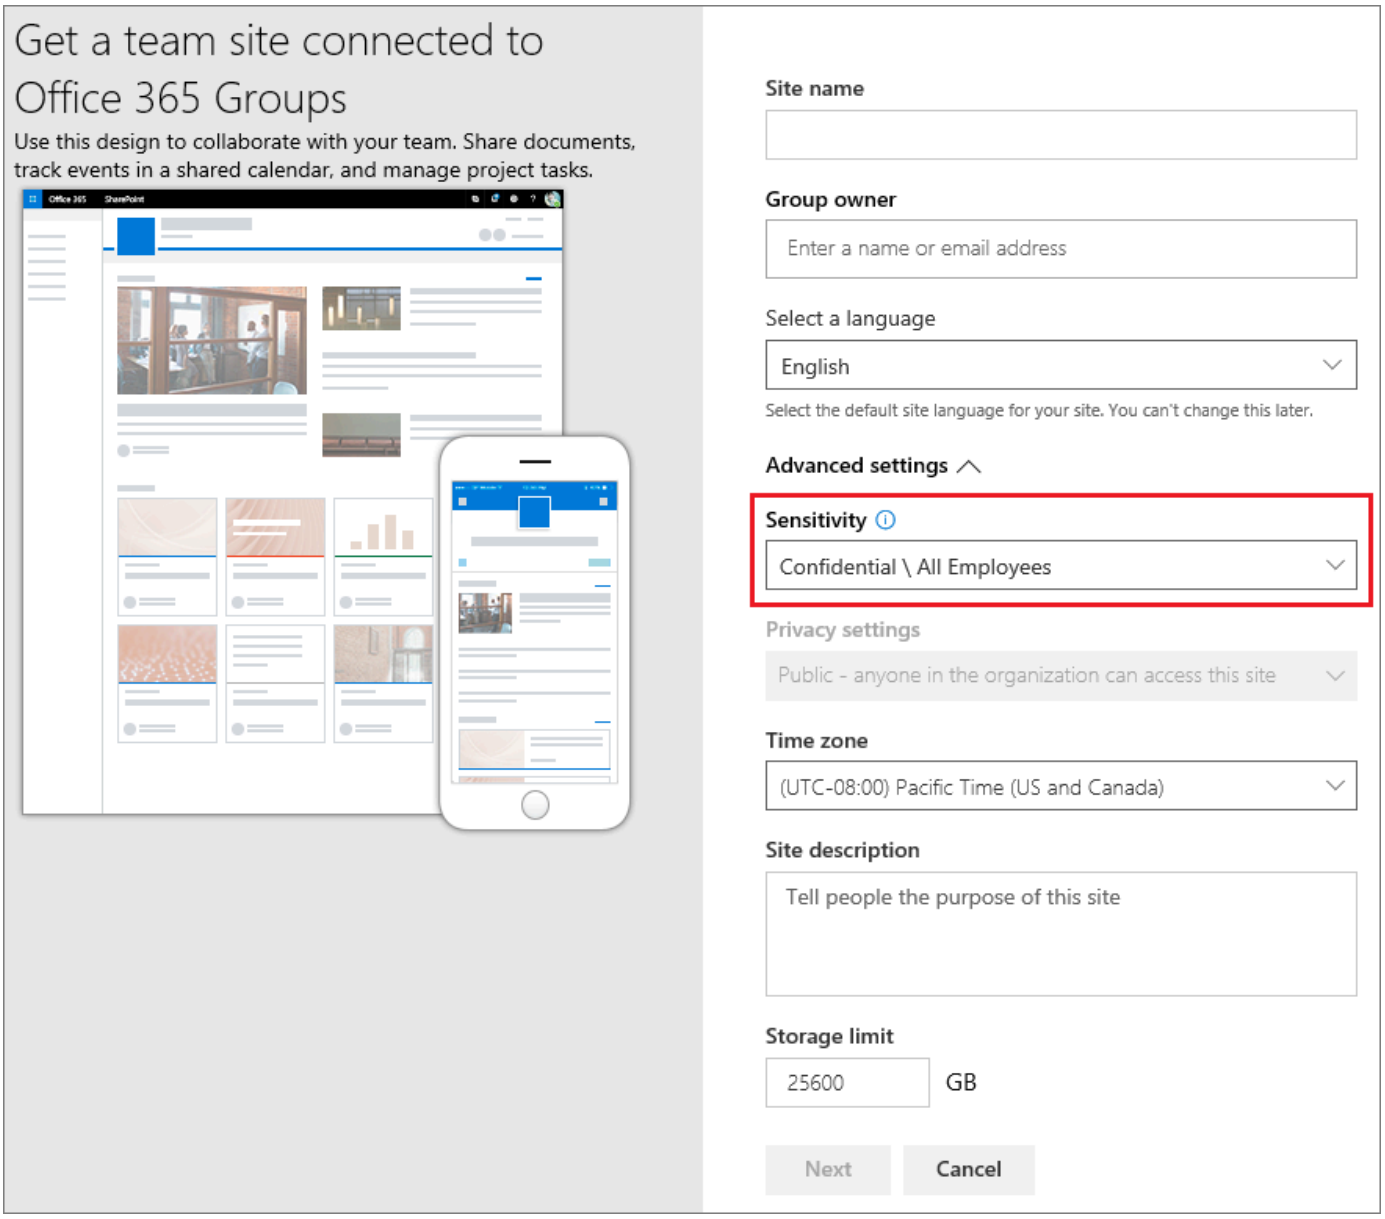
Support for container-level protection by using sensitivity labels is growing all the time. Refer to the documentation for each collaborative workspace and the Microsoft public roadmap to learn about new capabilities.

When you apply a sensitivity label to a supported container, the label automatically applies the sensitivity category and configured protection settings to the workspace.



Be aware that some label options can extend configuration settings to site owners that are otherwise restricted to administrators. When you configure and publish the label settings for external sharing options and the authentication context, a site owner can now set and change these options for a site by applying or changing the sensitivity label for a team or site. Don't configure these specific label settings if you don't want site owners to be able to make these changes.

Items in these containers however, do not inherit the labels and therefore don't apply any item-level label settings, such as content markings and encryption. So that users can label their documents in SharePoint sites or team sites, make sure you've enabled sensitivity labels for Office files in SharePoint and OneDrive.



Container labels don't support displaying other languages and display the original language only for the label name and description.

Using sensitivity labels for containers

Before you enable and configure sensitivity labels for containers, users can see and apply sensitivity labels to items in their apps. For example, from Word:

After you enable and configure sensitivity labels for containers, users can additionally see and apply sensitivity labels to containers that support them. These include Microsoft team sites, Microsoft 365 groups, SharePoint sites, Viva Engage communities, and Loop workspaces. For example, when you create a new team site from SharePoint:

After a sensitivity label has been applied to a site, you must have the following role to change that label in SharePoint or Teams:

- For a group-connect site: Microsoft 365 group Owners
- For a site that isn't group-connected: SharePoint site admin

> **Note**
>
> Sensitivity labels for containers support Teams shared channels. If a team has any shared channels, they automatically inherit sensitivity label settings from their parent team, and that label can't be removed or replaced with a different label.

How to enable sensitivity labels for containers and synchronize labels

If you haven't yet enabled sensitivity labels for containers, do the following set of steps as a one-time procedure:

1. Because this feature uses Microsoft Entra functionality, follow the instructions from the Microsoft Entra documentation to enable sensitivity label support: Assign sensitivity labels to Microsoft 365 groups in Microsoft Entra ID.

2. You now need to synchronize your sensitivity labels to Microsoft Entra ID. First, connect to Security & Compliance PowerShell.

   For example, in a PowerShell session that you run as administrator, sign in with a global administrator account.

3. Then run the following command to ensure your sensitivity labels can be used with Microsoft 365 groups:

   PowerShell

   ```
   Execute-AzureAdLabelSync
   ```

How to configure groups and site settings for containers

After sensitivity labels are enabled for containers as described in the previous section, you can then configure protection settings for groups and sites in the sensitivity labeling configuration. Until sensitivity labels are enabled for containers, the settings are visible but you can't configure them.

1. Follow the general instructions to create or edit a sensitivity label and make sure you select **Groups & sites** for the label's scope:

When only this scope is selected for the label, the label isn't displayed in Office apps that support sensitivity labels and can't be applied to files and emails. Having this separation of labels can be helpful for both users and administrators, but can also add to the complexity of your label deployment.

For example, you need to carefully review your label ordering because SharePoint detects when a labeled document is uploaded to a labeled site. In this scenario, an audit event and email are automatically generated when the document has a higher priority sensitivity label than the site's label. For more information, see the Auditing sensitivity label activities section on this page.

2. Then, on the **Define protection settings for groups and sites** page, select the options you want to configure:

   - **Privacy and external user access settings** to configure the **Privacy** and **External users access** settings.
   - **External sharing and Conditional Access settings** to configure the **Control external sharing from labeled SharePoint sites** and **Use Microsoft Entra Conditional Access to protect labeled SharePoint sites** setting.
   - **Private teams discoverability and shared channel controls** to configure the settings to prevent users who can discover private teams from finding a private team with this

sensitivity label applied, and channel sharing controls for invitations to other teams.

Apply a label to channel meetings: This additional option is applicable only if you are editing an existing label where the scope includes meetings, and you've configured labels to protect meetings. Select a sensitivity label to automatically apply to channel meetings and all channel chats. For non-channel meetings, you can select a default label as a policy setting.

3. If you selected **Privacy and external user access settings**, now configure the following settings:

   - **Privacy**: Keep the default of **Public** if you want anyone in your organization to access the container where this label is applied.

     Select **Private** if you want access to be restricted to only approved members in your organization.

     Select **None** when you want to protect content in the container by using the sensitivity label, but still let users configure the privacy setting themselves.

     The settings of **Public** or **Private** set and lock the privacy setting when you apply this label to the container. Your chosen setting replaces any previous privacy setting that might be configured for the container, and locks the privacy value so it can be changed only by first removing the sensitivity label from the container. After you remove the sensitivity label, the privacy setting from the label remains and users can now change it again.

   - **External user access**: Control whether the owner can add guests to the container, similar to Manage guest access in Microsoft 365 groups.

4. If you selected **External sharing and Conditional Access settings**, now configure the following settings:

   - **Control external sharing from labeled SharePoint sites**: Select this option to then select either external sharing for anyone, new and existing guests, existing guests, or only people in your organization. For more information about this configuration and settings, see the SharePoint documentation, Turn external sharing on or off for a site.

   - **Use Microsoft Entra Conditional Access to protect labeled SharePoint sites**: Select this option only if your organization has configured and is using Microsoft Entra Conditional Access. Then, select one of the following settings:

- **Determine whether users can access SharePoint sites from unmanaged devices**: This option uses the SharePoint feature that uses Microsoft Entra Conditional Access to block or limit access to SharePoint and OneDrive content from unmanaged devices. For more information, see Control access from unmanaged devices from the SharePoint documentation. The option you specify for this label setting is the equivalent of running a PowerShell command for a site, as described in steps 3-5 from the Block or limit access to a specific SharePoint site or OneDrive section from the SharePoint instructions.

  For additional configuration information, see More information about the dependencies for the unmanaged devices option at the end of this section.

- **Choose an existing authentication context**: This option lets you enforce more stringent access conditions when users access SharePoint sites that have this label applied. These conditions are enforced when you select an existing authentication context that has been created and published for your organization's Conditional Access deployment. If users don't meet the configured conditions or if they use apps that don't support authentication contexts, they are denied access.

  For additional configuration information, see More information about the dependencies for the authentication context option at the end of this section.

  Examples for this label configuration:

  - You choose an authentication context that is configured to require multifactor authentication (MFA). This label is then applied to a SharePoint site that contains highly confidential items. As a result, when users from an untrusted network attempt to access a document in this site, they see the MFA prompt that they must complete before they can access the document.

  - You choose an authentication context that is configured for terms-of-use (ToU) policies. This label is then applied to a SharePoint site that contains items that require a terms-of-use acceptance for legal or compliance reasons. As a result, when users attempt to access a document in this site, they see a terms-of-use document that they must accept before they can access the original document.

5. If you selected **Private teams discoverability and shared channel controls**:

- For **Private teams discoverability**, use the **Allow users to discover private teams that have this label applied** checkbox when you've configured a Teams policy that allows

private teams discovery:

- When the checkbox is selected (the default setting), a private team with the sensitivity label applied will be discoverable for a user who is allowed to discover private teams.
- When the checkbox is cleared, a private team with the sensitivity label applied will remain hidden and won't be discoverable for all users.

- For **Teams shared channels**, when a team has a sensitivity label applied, you can allow or prevent other teams from being invited to the original team's shared channels. For more information about shared channels, see Shared channels in Microsoft Teams.

  > **Important**
  >
  > These options for Teams shared channels have a dependency on the settings on the previous **Privacy and external user access** page. If you select an option that's not compatible with these previous settings, you see a validation message to change your selection. Alternatively, you can go back in the configuration to change the dependent setting.

  Options include **Internal only**, **Same label only**, and **Private team only**. Only the last option can potentially remove previously invited teams, and none of the options affect invitations to individual users.

The site and group settings take effect when you apply the label to a container that supports sensitivity labels. If the label's scope includes files and emails, other label settings such as encryption and content marking aren't applied to the items within the container.

If your sensitivity label isn't already published, now publish it by adding it to a sensitivity label policy. The users who are assigned a sensitivity label policy that includes this label will be able to select it for sites and groups.

More information about the dependencies for the unmanaged devices option

If you don't configure the dependent conditional access policy for SharePoint as documented in Use app-enforced restrictions, the option you specify here will have no effect. Additionally, it will have no effect if it's less restrictive than a configured setting at the tenant level. If you have configured an organization-wide setting for unmanaged devices, choose a label setting that's either the same or more restrictive

For example, if your tenant is configured for **Allow limited, web-only access**, the label setting that allows full access will have no effect because it's less restrictive. For this tenant-level setting, choose the label setting to block access (more restrictive) or the label setting for limited access (the same as the tenant setting).

Because you can configure the SharePoint settings separately from the label configuration, there's no check in the sensitivity label configuration that the dependencies are in place. These dependencies can be configured after the label is created and published, and even after the label is applied. However, if the label is already applied, the label setting won't take effect until after the user next authenticates.

More information about the dependencies for the authentication context option

To display in the drop-down list for selection, authentication contexts must be created, configured, and published as part of your Microsoft Entra Conditional Access configuration. For more information and instructions, see the Configure authentication contexts section from the Microsoft Entra Conditional Access documentation.

Not all apps support authentication contexts. If a user with an unsupported app connects to the site that's configured for an authentication context, they see either an access denied message or they are prompted to authenticate but rejected. The apps that currently support authentication contexts:

- Office for the web, which includes Outlook for the web
- Microsoft Teams for Windows and macOS (excludes Teams web app)
- Microsoft Planner
- Microsoft 365 Apps for Word, Excel, and PowerPoint; minimum versions:
  - Windows: 2103
  - macOS: 16.45.1202
  - iOS: 2.48.303
  - Android: 16.0.13924.10000
- Microsoft 365 Apps for Outlook; minimum versions:
  - Windows: 2103
  - macOS: 16.45.1202
  - iOS: 4.2109.0
  - Android: 4.2025.1

- OneDrive sync app, minimum versions:
  - Windows: 21.002
  - macOS: 21.002
  - iOS: 12.30
  - Android: Not yet supported

Known limitations:

- For the OneDrive sync app, supported for OneDrive only and not for other sites.
- The following features and apps might be incompatible with authentication contexts, so we encourage you to check that these continue to work after a user successfully accesses a site by using an authentication context:
  - Workflows that use Power Apps or Power Automate
  - Third-party apps

Configure settings for the default sharing link type for a site by using PowerShell advanced settings

In addition to the label settings for sites and groups that you can configure from the Microsoft Purview portal, you can also configure the default sharing link type for a site. Sensitivity labels for documents can also be configured for a default sharing link type. These settings that help to prevent over-sharing are automatically selected when users select the **Share** button in their Office apps.

For more information and instructions, see Use sensitivity labels to configure the default sharing link type for sites and documents in SharePoint and OneDrive.

Configure site sharing permissions by using PowerShell advanced settings

Another PowerShell advanced setting that you can configure for the sensitivity label to be applied to a SharePoint site is **MembersCanShare**. This setting is the equivalent configuration that you can set from the SharePoint admin center > **Site permissions** > **Site Sharing** > **Change how members can share** > **Sharing permissions**.

The three options are listed with the equivalent values for the PowerShell advanced setting **MembersCanShare**:

Expand table

Option from the SharePoint admin center	Equivalent PowerShell value for MembersCanShare
Site owners and members can share files, folders, and the site. People with Edit permissions can share files and folders.	MemberShareAll
Site owners and members, and people with Edit permissions can share files and folders, but only site owners can share the site.	MemberShareFileAndFolder
Only site owners can share files, folders, and the site.	MemberShareNone

For more information about these configuration options, see Change how members can share from the SharePoint community documentation.

Example, where the sensitivity label GUID is **8faca7b8-8d20-48a3-8ea2-0f96310a848e**:

PowerShell

```
Set-Label -Identity 8faca7b8-8d20-48a3-8ea2-0f96310a848e -AdvancedSettings
@{MembersCanShare="MemberShareNone"}
```

For more help in specifying PowerShell advanced settings, see PowerShell tips for specifying the advanced settings.

Sensitivity label management

Use the following guidance for when you create, modify, or delete sensitivity labels that are configured for sites and groups.

Creating and publishing labels that are configured for sites and groups

Use the following guidance to publish a label for your users when that label is configured for site and group settings:

1. After you create and configure the sensitivity label, add this label to a label policy that applies to just a few test users.

2. Wait for the change to replicate:

    - New label: Wait at least one hour, unless your configured settings include Teams shared channel controls. If that's the case, wait at least 24 hours.
    - Existing label: Wait at least 24 hours.

For more information about the timing of labels, see When to expect new labels and changes to take effect.

3. After this wait period, use one of the test user accounts to create a team, Microsoft 365 group, or SharePoint site with the label that you created in step 1.

4. If there are no errors during this creation operation, you know it's safe to publish the label to all users in your tenant.

Modifying published labels that are configured for sites and groups

As a best practice, don't change the site and group settings for a sensitivity label after the label has been applied to teams, groups, or sites. If you do, remember to wait at least 24 hours for the changes to replicate to all containers that have the label applied.

In addition, if your changes include the **External users access** setting:

- The new setting applies to new users but not to existing users. For example, if this setting was previously selected and as a result, guest users accessed the site, these guest users can still access the site after this setting is cleared in the label configuration.

- The privacy settings for the group properties hiddenMembership and roleEnabled aren't updated.

Deleting published labels that are configured for sites and groups

If you delete a sensitivity label that has the site and group settings enabled, and that label is included in one or more label policies, this action can result in creation failures for new teams, groups, and sites. To avoid this situation, use the following guidance:

1. Remove the sensitivity label from all label policies that include the label.

2. Wait at least one hour.

3. After this wait period, try creating a team, group, or site and confirm that the label is no longer visible.

4. If the sensitivity label isn't visible, you can now safely delete the label.

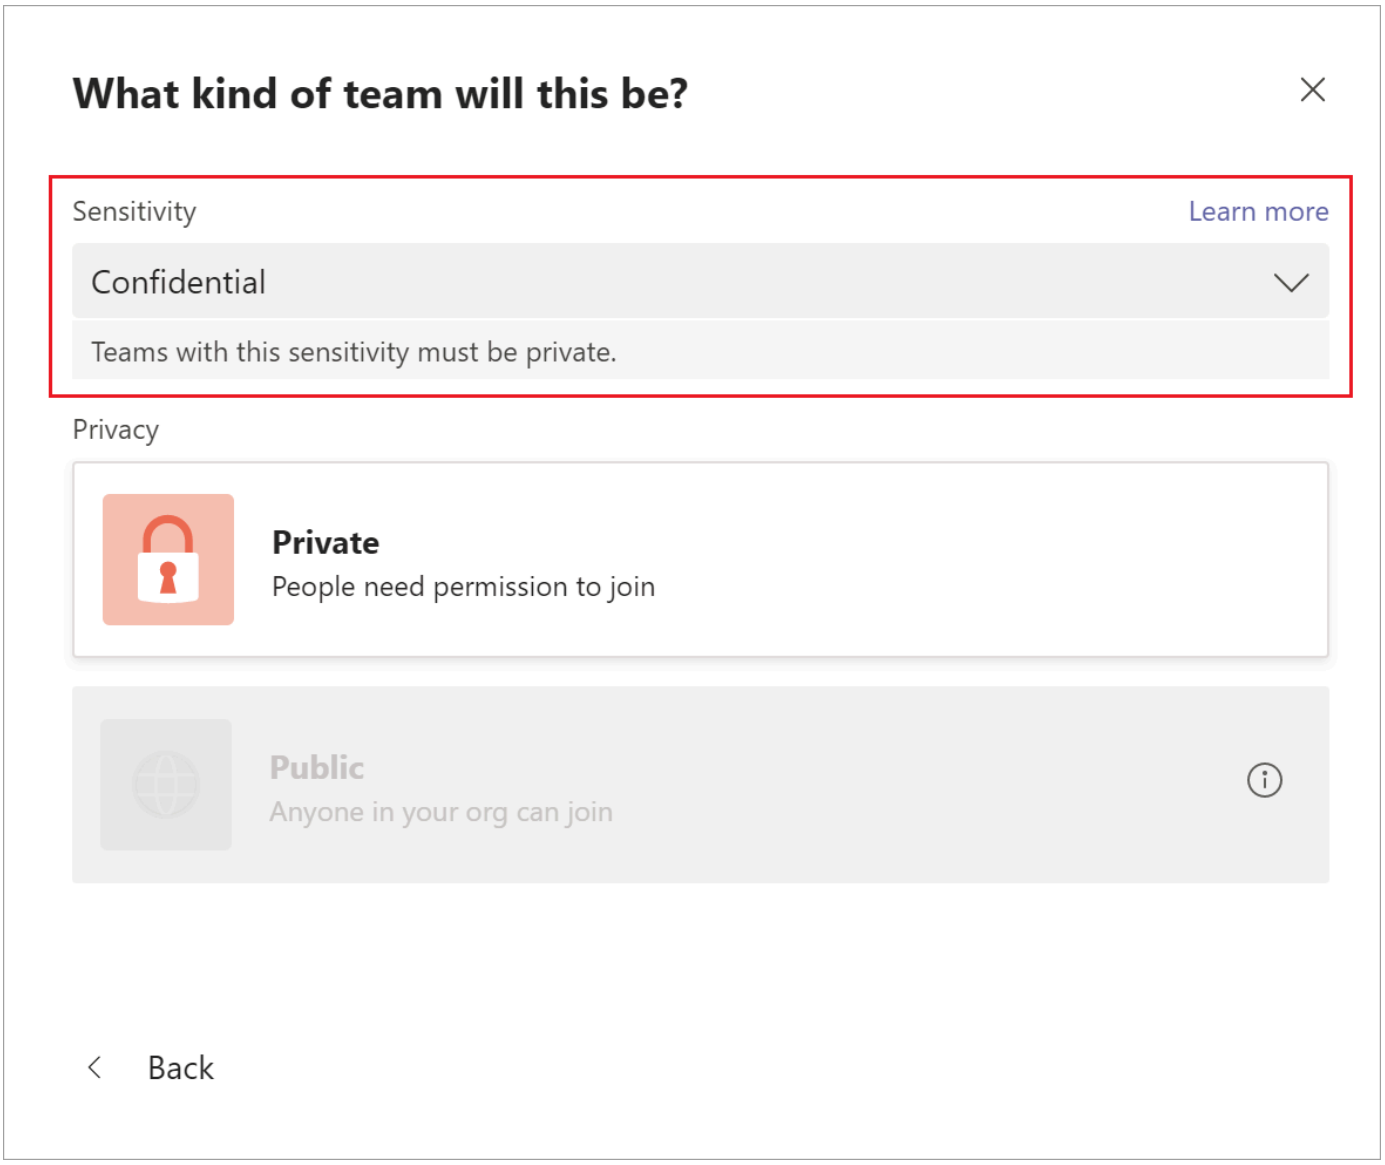
How to apply sensitivity labels to containers

You're now ready to apply the sensitivity label or labels to the following containers:

- Microsoft 365 group in Microsoft Entra ID
- Microsoft Teams team site
- Microsoft 365 group in Outlook on the web
- SharePoint site
- Loop workspaces
- Viva Engage communities

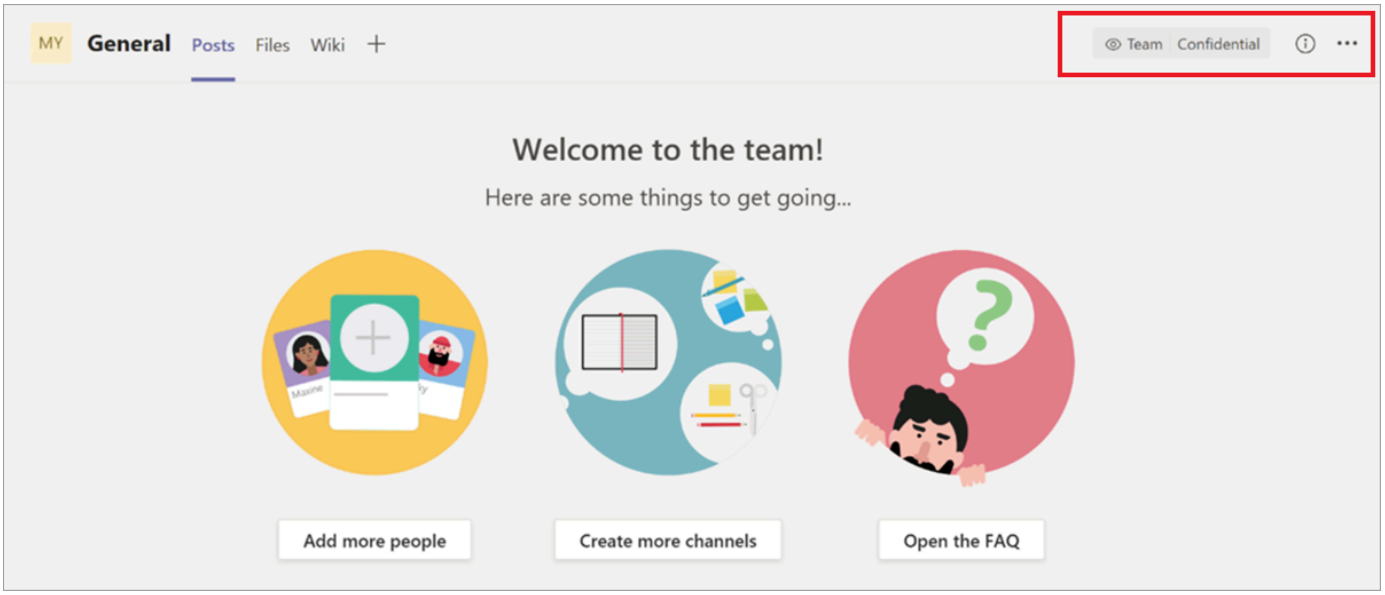
You can use PowerShell if you need to apply a sensitivity label to multiple sites.

Apply sensitivity labels to Microsoft 365 groups



You're now ready to apply the sensitivity label or labels to Microsoft 365 groups. Return to the Microsoft Entra documentation for instructions:

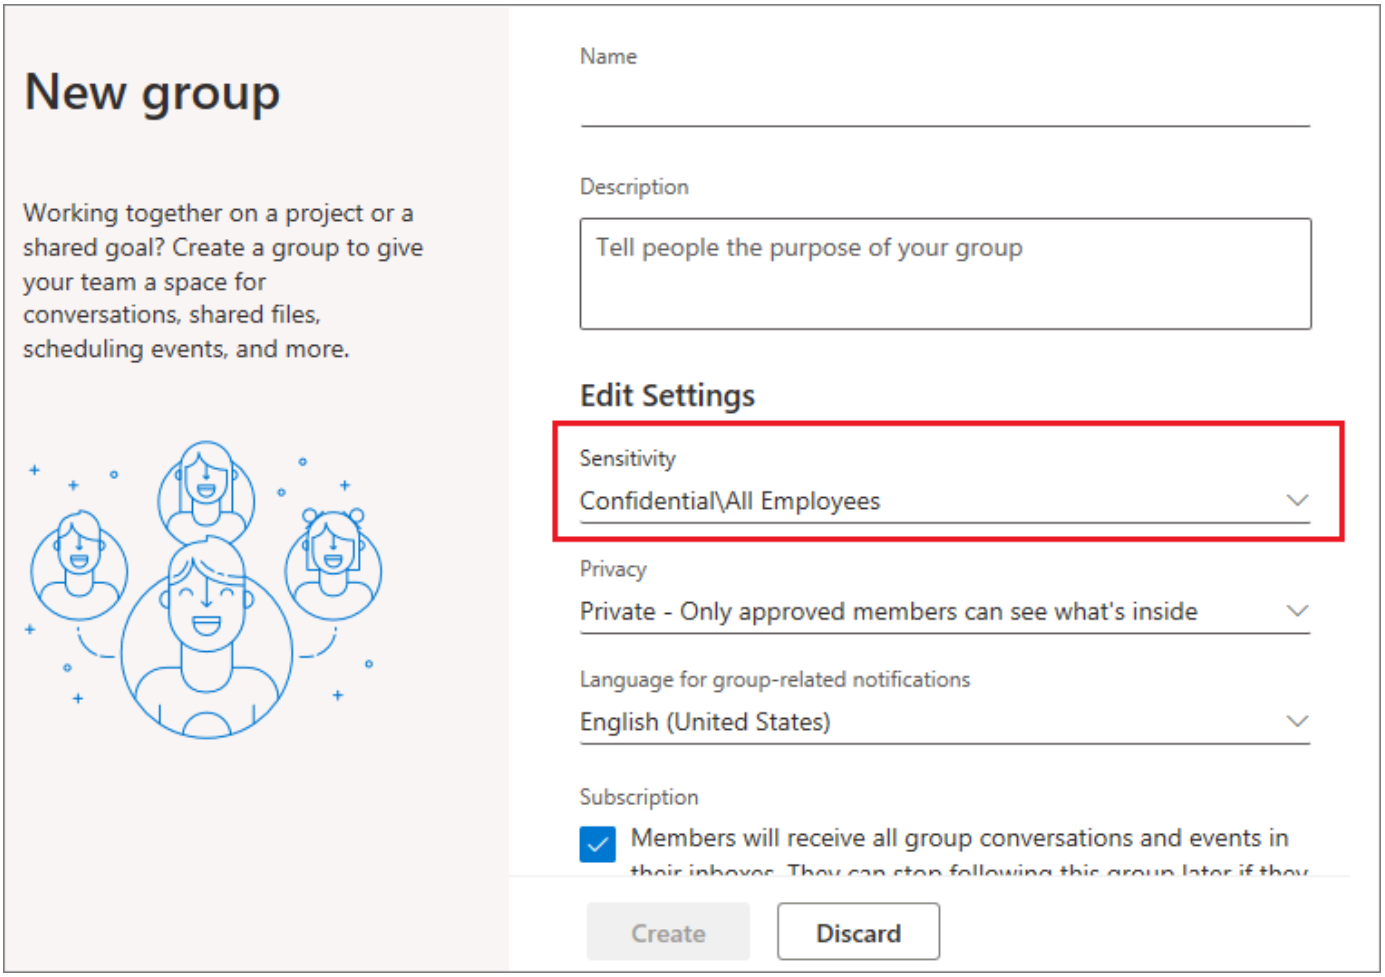
- Assign a label to a new group in Azure portal
- Assign a label to an existing group in Azure portal
- Remove a label from an existing group in Azure portal.



Apply a sensitivity label to a new team

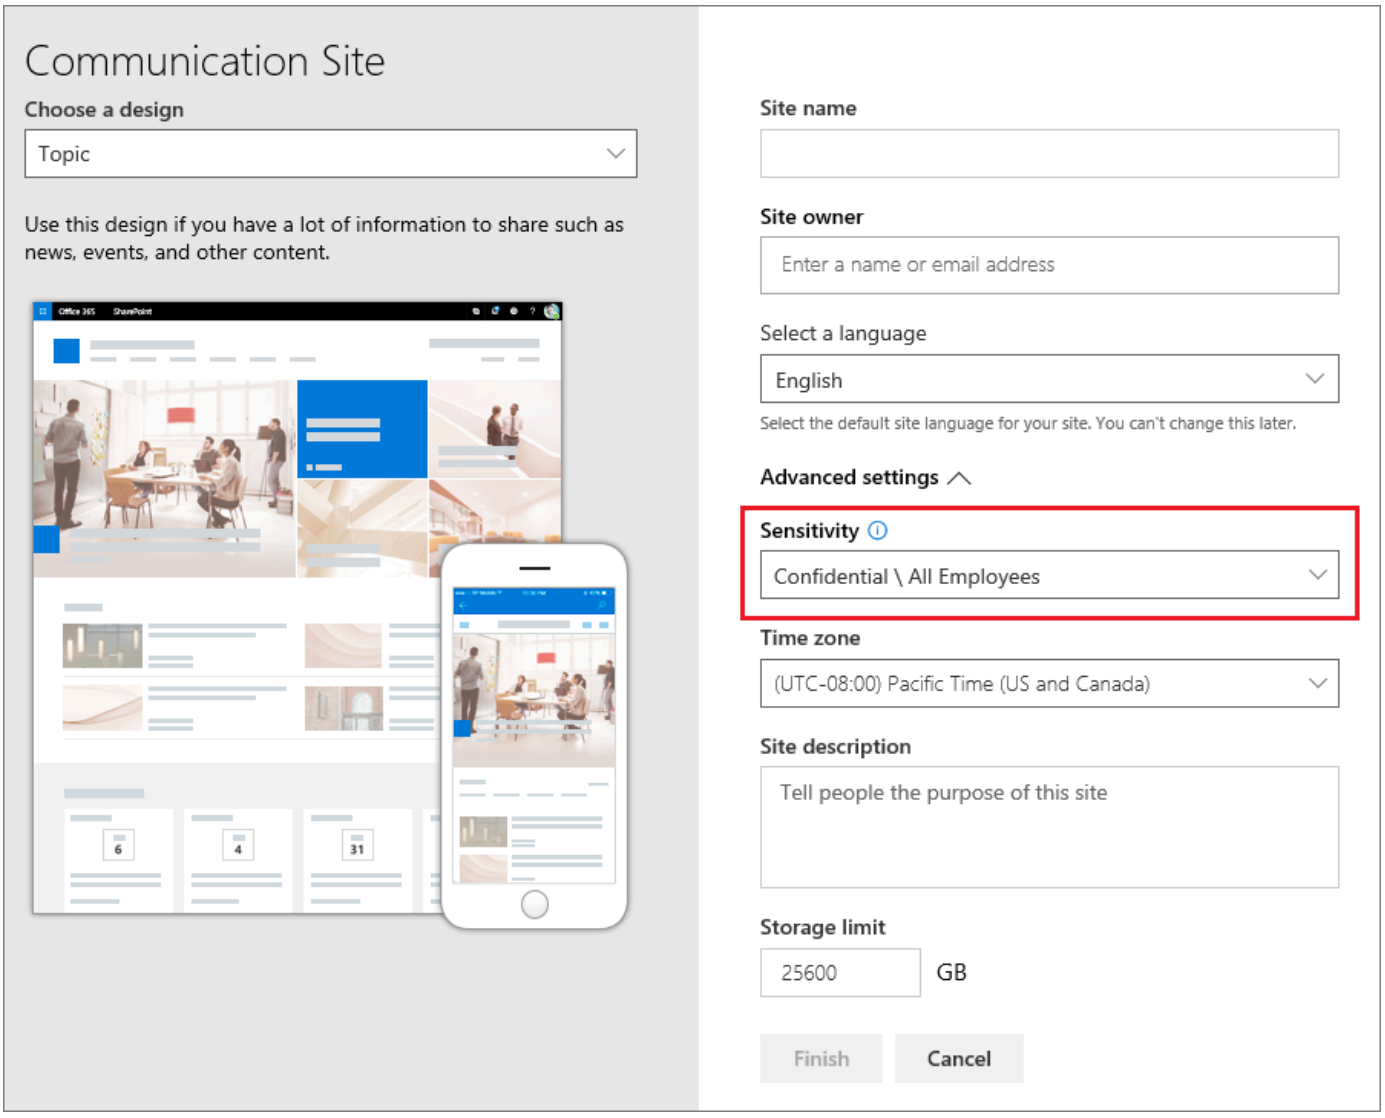
Users can select sensitivity labels when they create new teams in Microsoft Teams. When they select the label from the **Sensitivity** dropdown, the privacy setting might change to reflect the label configuration. Depending on the external users access setting you selected for the label, users can or can't add people outside the organization to the team.

Learn more about sensitivity labels for Teams



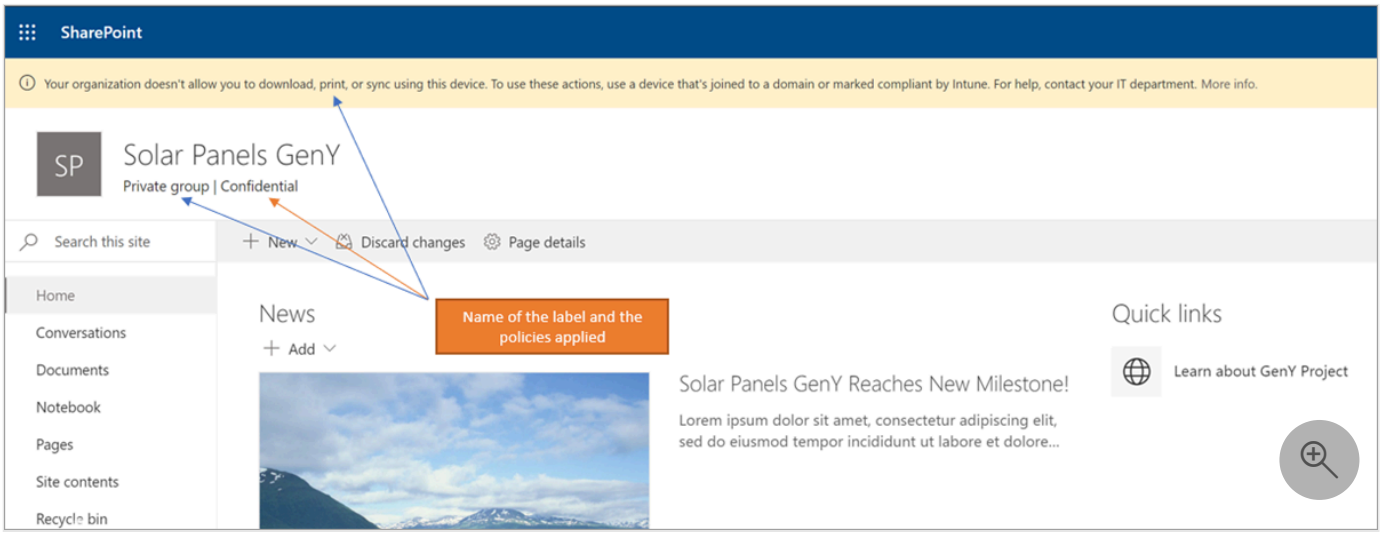
After you create the team, the sensitivity label appears in the upper-right corner of all channels.

The service automatically applies the same sensitivity label to the Microsoft 365 group and the connected SharePoint team site.



Apply a sensitivity label to a new group in Outlook on the web

In Outlook on the web, when you create a new group, you can select or change the **Sensitivity** option for published labels:



Apply a sensitivity label to a new site

Admins and end users can select sensitivity labels when they create modern team sites and communication sites, and expand **Advanced settings**:

The dropdown box displays the label names for the selection, and the help icon displays all the label names with their tooltip, which can help users determine the correct label to apply.

When the label is applied, and users browse to the site, they see the name of the label and applied policies. For example, this site has been labeled as **Confidential**, and the privacy setting is set to **Private**:

Use PowerShell to apply a sensitivity label to multiple sites

You can use the Set-SPOSite and Set-SPOTenant cmdlet with the *SensitivityLabel* parameter from the current SharePoint Online Management Shell to apply a sensitivity label to many sites. You can use the same procedure to replace an existing label. The sites can be any SharePoint site collection, or a OneDrive site.

Make sure you have version 16.0.19418.12000 or later of the SharePoint Online Management Shell.

1. Open a PowerShell session with the **Run as Administrator** option.
2. If you don't know your label GUID: Connect to Security & Compliance PowerShell and get the list of sensitivity labels and their GUIDs.

   PowerShell

   ```
   Get-Label |ft Name, Guid
   ```

3. Now connect to SharePoint Online PowerShell and store your label GUID as a variable. For example:

   PowerShell

   ```
   $Id = [GUID]("e48058ea-98e8-4940-8db0-ba1310fd955e")
   ```

4. Create a new variable that identifies multiple sites that have an identifying string in common in their URL. For example:

   PowerShell

   ```
   $sites = Get-SPOSite -IncludePersonalSite $true -Limit all -Filter "Url -like 'documents"
   ```

5. Run the following command to apply the label to these sites. Using our examples:

   PowerShell

   ```
   $sites | ForEach-Object {Set-SPOTenant $_.url -SensitivityLabel $Id}
   ```

This series of commands lets you label multiple sites across your tenant with the same sensitivity label, which is why you use the Set-SPOTenant cmdlet, rather than the Set-SPOSite cmdlet that's

for per-site configuration. However, use the Set-SPOSite cmdlet when you need to apply a different label to specific sites by repeating the following command for each of these sites: `Set-SPOSite -Identity <URL> -SensitivityLabel "<labelguid>"`

View and manage sensitivity labels in the SharePoint admin center

To view, sort, and search the applied sensitivity labels, use **Active sites** in the SharePoint admin center. You might need to first add the **Sensitivity** column:

For more information about managing sites from the Active sites page, including how to add a column, see Manage sites in the SharePoint admin center.

You can also change and apply a label from this page:

1. Select the site name to open the details pane.
2. Select the **Policies** tab, and then select **Edit** for the **Sensitivity** setting.
3. From the **Edit sensitivity setting** pane, select the sensitivity label you want to apply to the site. Unlike user apps, where sensitivity labels can be assigned to specific users, the admin center displays all container labels for your tenant. After you've chosen a sensitivity label, select **Save**.

For information about managing sensitivity labels for containers in SharePoint Embedded, which are the equivalent of sites, see Manage SharePoint Embedded containers in SharePoint Admin Center.

Support for sensitivity labels

When you use admin centers that support sensitivity labels, with the exception of the Microsoft Entra admin center, you see all sensitivity labels for your tenant. In comparison, user apps and services that filter sensitivity labels according to publishing policies can result in you seeing a subset of those labels. The Microsoft Entra admin center also filters the labels according to publishing policies.

The following apps and services support sensitivity labels configured for sites and group settings:

- Admin centers:
  - SharePoint admin center
  - Teams admin center
  - Microsoft 365 admin center
  - Microsoft Purview portal
- User apps and services:
  - SharePoint
  - Teams
  - Outlook on the web and for Windows, macOS, iOS, and Android
  - Forms
  - Stream
  - Planner
  - Loop
  - Viva Engage

The following apps and services don't currently support sensitivity labels configured for sites and group settings:

- Admin centers:
  - Exchange admin center
- User apps and services:
  - Dynamics 365
  - Project
  - Power BI

- My Apps portal

Auditing sensitivity label activities

> **Important**
>
> If you use label separation by selecting just the **Groups & sites** scope for labels that protect containers: Because of the **Detected document sensitivity mismatch** audit event and email described in this section, consider ordering labels before labels that have a scope for **Files & other data assets**.

If somebody uploads a document to a site that's protected with a sensitivity label and their document has a higher priority sensitivity label than the sensitivity label applied to the site, this action isn't blocked. For example, you've applied the **General** label to a SharePoint site, and somebody uploads to this site a document labeled **Confidential**. Because a sensitivity label with a higher priority identifies content that's more sensitive than content that has a lower priority order, this situation could be a security concern.

Although the action isn't blocked, it automatically generates an email that's sent to the person who uploaded the document, and also sent to site owners and site admins (maximum of 100 in total). As a result, both the user and these administrators can identify documents that have this misalignment of label priority and take action if needed. For example, delete or move the uploaded document from the site.

> **Important**
>
> If the file is in the Preservation Hold library, it's not supported to interact with files in this location. Files can automatically move into the Preservation Hold library as a result of compliance requirements to automatically retain files that users delete or are cloud attachments. For more information, see Learn about retention for SharePoint and OneDrive.

It wouldn't be a security concern if the document has a lower priority sensitivity label than the sensitivity label applied to the site. For example, a document labeled **General** is uploaded to a site labeled **Confidential**. In this scenario, an auditing event and email aren't generated.

> **Note**

Just as for the policy option that requires users to provide a justification for changing a label to a lower classification, sublabels for the same parent label are all considered to have the same priority.

To search the audit log for this event, look for **Detected document sensitivity mismatch** from the **File and page activities** category.

The automatically generated email has the subject **Incompatible sensitivity label detected** and the email message explains the labeling mismatch with a link to the uploaded document and site. It also contains a line for your own internal documentation: **HelpLink : Troubleshooting Guide**. You must configure the hyperlink for the troubleshooting guide by using the Set-SPOTenant cmdlet with the *LabelMismatchEmailHelpLink* parameter. For example:

PowerShell

```
Set-SPOTenant -LabelMismatchEmailHelpLink "https://support.contoso.com"
```

The email message also has a Microsoft documentation link that provides basic information for users to change the sensitivity label: Apply sensitivity labels to your files and email in Office

Except for the internal URL that you must specify, these automated emails can't be customized. However, you can prevent them from being sent when you use the following PowerShell command from Set-SPOTenant:

PowerShell

```
Set-SPOTenant -BlockSendLabelMismatchEmail $True
```

When somebody adds or removes a sensitivity label to or from a site or group, these activities are also audited but without automatically generating an email.

All these auditing events can be found in the Sensitivity label activities section from the audit log activities documentation.

How to disable sensitivity labels for containers

You can turn off sensitivity labels for Microsoft Teams, Microsoft 365 groups, and SharePoint sites by using the same instructions from Enable sensitivity label support in PowerShell. However, to disable the feature, in step 5, specify `$setting["EnableMIPLabels"] = "False"`.

In addition to making all the settings unavailable for groups and sites when you create or edit sensitivity labels, this action reverts which property the containers use for their configuration. Enabling sensitivity labels for Microsoft Teams, Microsoft 365 groups, and SharePoint sites switches the property used from **Classification** to **Sensitivity**. When you disable sensitivity labels for containers, the containers ignore the Sensitivity property and use the Classification property again.

This means that any label settings from sites and groups previously applied to containers won't be enforced, and containers no longer display the labels.

If these containers have Microsoft Entra classification values applied to them, the containers revert to using the classifications again. Be aware that any new sites or groups that were created after enabling the feature won't display a label or have a classification. For these containers, and any new containers, you can now apply classification values. For more information, see SharePoint "modern" sites classification and Create classifications for Office groups in your organization.

Use sensitivity labels to protect calendar items, Teams meetings, and chat

> *Microsoft Purview service description*

> **Note**
>
> You won't be able to configure all the options referenced on this page if a Teams Premium license isn't found for your tenant. For those settings, you'll see an information bar in the Microsoft Purview portal that your organization doesn't have this license.

In addition to using sensitivity labels to protect documents and emails, you can extend sensitivity labels to protect meeting invites and responses that use Outlook and Teams, and to protect Teams meetings and chat:

- Meeting organizers apply a sensitivity label to meeting invites from Outlook or Teams. Recipients in your organization see the sensitivity label and all recipients see any headers or footers as configured content markings. Optionally, the meeting invite can be encrypted so only authorized people can see it and access the meeting link. Usage rights can further restrict access, for example, preventing the invite from being forwarded.

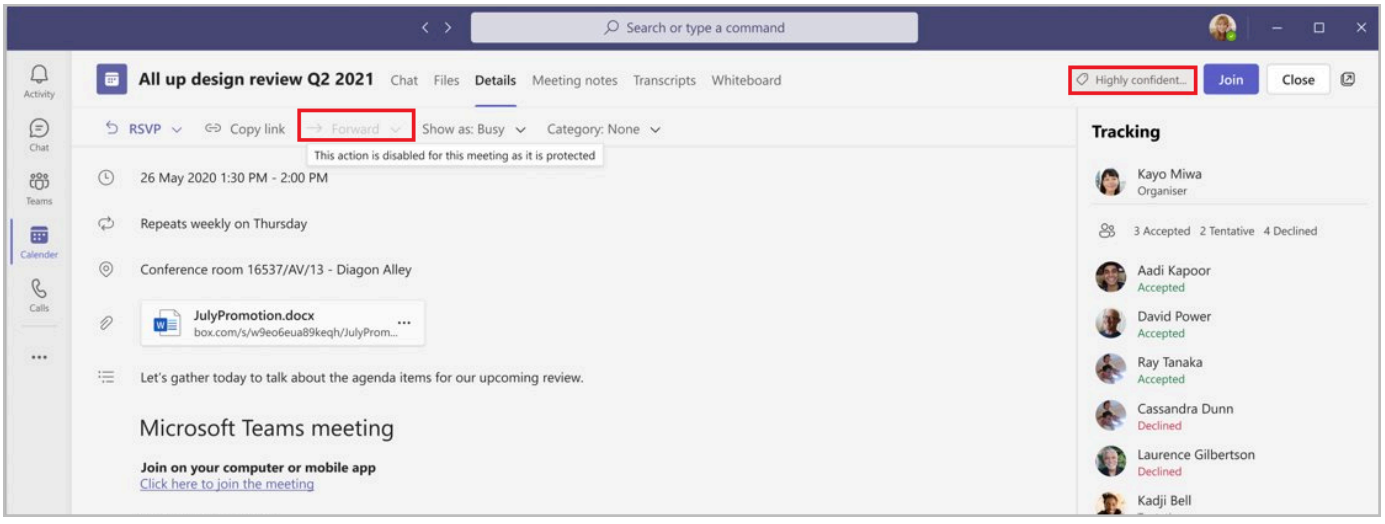
  The encryption works similarly to how you can apply a label with encryption to an email. As with email encryption, if recipients aren't using an email client that can decrypt this meeting invite, they're directed to Outlook on the web or the encryption portal where they can read the invite and access the meeting link.

- The sensitivity label from the meeting invite is automatically inherited by the meeting and protects it even before the meeting starts. For example, prevent copying from the chat if this has been configured for the label. When the meeting starts, it will enforce any meeting options, such as who can bypass the lobby and present.

- Participants from your organization see the label during the Teams meetings. Any meeting settings applied by the label can't be changed directly in Teams. When a label enforces these settings, users see a lock and message that explains the settings are applied by a sensitivity label.

Meeting settings that you can apply with a sensitivity label:

- Who can bypass the lobby
- Who can present
- Who can record and transcribe
- Encryption for meeting video and audio
- Automatically record
- Video watermark for screen sharing and camera streams
- Prevent copying and forwarding of meeting chat, live caption, and transcripts
- Detect sensitive content during screen sharing



Users can apply sensitivity labels to meeting invites when they use Outlook or Teams:

- For Outlook, applying, changing, and viewing sensitivity labels for meeting invites and appointments are supported with Outlook on the web, and with minimum versions of Windows, macOS, iOS and Android. For other versions, platforms, and email clients, encrypted meeting invites can be opened in the same way as encrypted email.

- For Teams, applying, changing, and viewing sensitivity labels for meeting invites are supported with Teams on the web, and with minimum versions of Windows, macOS, iOS and Android.

For more information about those minimum versions, see the Requirements section.

Example showing a Teams meeting invite that has the label **Highly confidential**, and the label applies encryption settings that prevent the invite from being forwarded:

Requirements

To apply a sensitivity label to meeting invites and appointments using Outlook, users must use Outlook on the web or use built-in labeling from Microsoft 365 Apps for enterprise. For supported versions across Windows, macOS, iOS, and Android, see the capabilities table for Outlook and the row that specifies labeling for **Calendar items**.

To apply a sensitivity label to meeting invites using Teams, enforce meeting options and chat, and display and change sensitivity labels in Teams non-channel meetings, users must use Teams on the web with Edge or Chrome, or one of the following Teams clients:

- **Teams client for Windows**: 1.5.00.32158+
- **Teams client for macOS**: 1.5.00.32154+
- **Teams mobile app for iOS**: 5.23.0+
- **Teams mobile app for Android**: 1416/1.0.0.2023235001+

> ⓘ **Important**
>
> If meeting participants or organizers don't use a Teams client that meets these requirements, the configured label meeting options can't be enforced for these users.

Sensitivity labels that apply S/MIME protection or Double Key Encryption (DKE) can't be used to protect calendar items, Teams meetings, and chat.

Limitations

- Preventing copying chat and meeting-related content has some limitations that are listed in the Prevent copying and forwarding for chats and meeting content section on this page.
- Calendar items don't support label encryption that uses S/MIME or Double Key Encryption. You must use the default encryption that uses the Azure Rights Management service, with either admin-defined permissions (the option **Assign permissions now**) or user-defined permissions (the option **Let users assign permissions**).
- Automatic and recommended labeling isn't supported.
- No support for mailboxes on-premises; user mailboxes must be in Exchange Online.

Specific to Outlook:

- No support for group calendar meeting invites; participants must be specific users.

- As with labeled and encrypted email, if somebody forwards a meeting invite from an email client other than Outlook, any applied encryption persists but information about the sensitivity label is removed from the email headers.

- The Share to Teams option doesn't support sensitivity labels. If the selected sensitivity label applies encryption, the action is prevented with a message that the content is restricted. If the selected sensitivity label doesn't apply encryption, the action isn't prevented but the sensitivity label isn't displayed in Teams.

- For Outlook for Windows, when a labeled and encrypted meeting invite or response is sent, the following configuration setting must be enabled: **Outlook Options** > **Advanced** > **International options** > **Automatically select encoding for outgoing messages**

- Shared calendars:
  - When a user shares their calendar with others, only the calendar owner can create and change sensitivity labels for meetings in that calendar.
  - A shared mailbox calendar doesn't support applying and changing sensitivity labels for meetings.

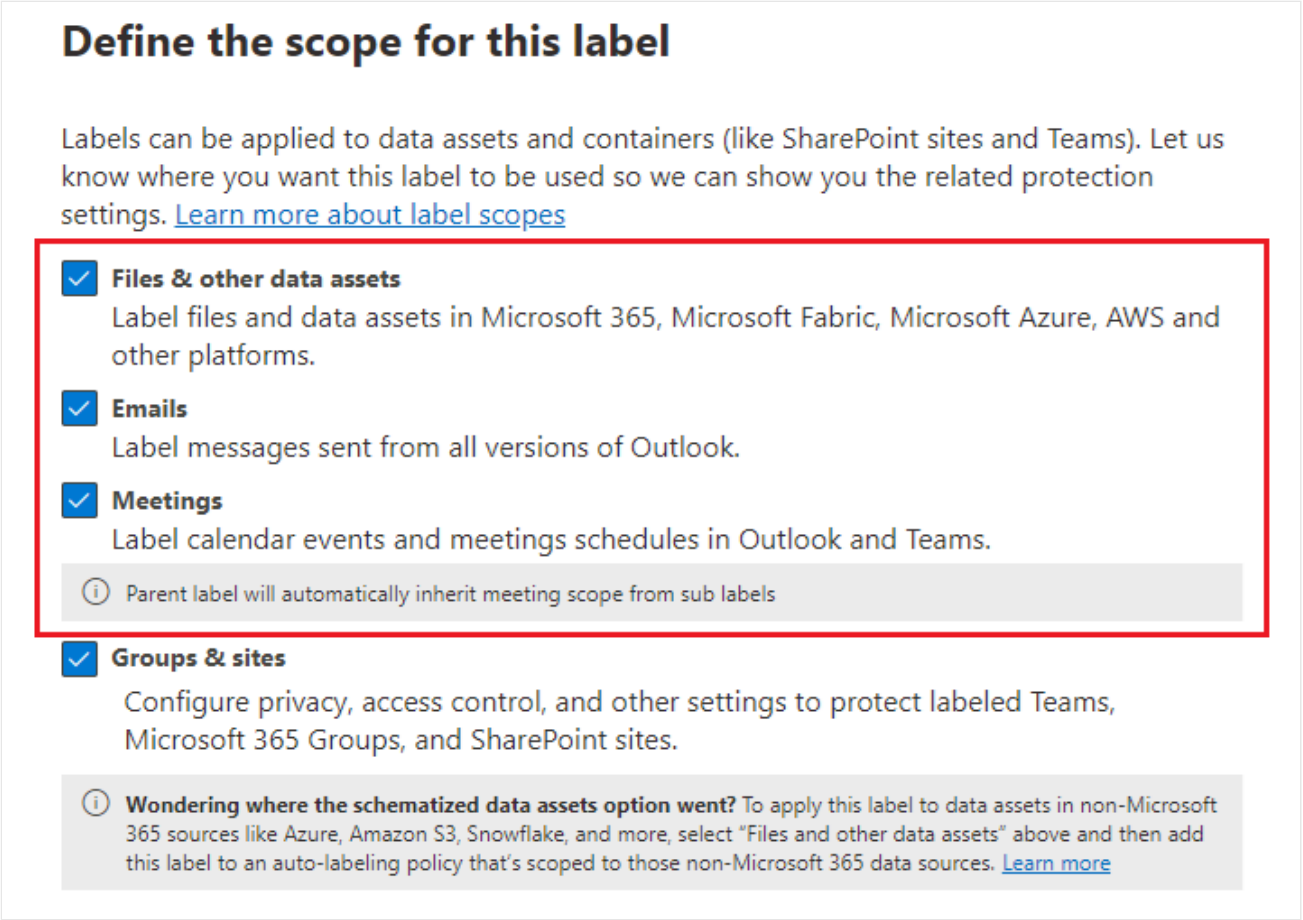
- For a meeting series:
  - The organizer can apply a sensitivity label for the meeting series but not to individual occurrences.
  - Exceptions for a meeting series will be labeled (and encrypted if applicable) only if they're created after the label is applied to the meeting series. Existing exceptions, including those in the future, won't be labeled.
  - If the organizer changes the meeting body or attachments for a meeting series after it's encrypted by a sensitivity label, existing exceptions won't be updated with those changes.
  - If the organizer changes any meeting attributes (such as start date, end date, location, the meeting body, or attachments) for a specific occurrence in a series after it's encrypted by a sensitivity label, this action automatically creates an exception for the series with the same label for the meeting series.

Specific to Teams:

- While a meeting is in session, a sensitivity label can't prevent participants from inviting people to join by copying the meeting link, or by sharing via default email or the Outlook calendar. These choices are from the Teams meeting **Share invite** option.

- If there's a label change made in Teams while the meeting is progress, any changes to the following meeting options won't take effect for the current meeting unless the organizer ends and restarts the meeting:
  - Who can record and transcribe
  - Encryption for meeting video and audio
  - Automatically record and transcribe
  - Video watermark for screen sharing and camera streams

- The following meeting options won't take effect for a Meet Now meeting:
  - Who can record and transcribe
  - Encryption for meeting video and audio
  - Automatically record and transcribe
  - Video watermark for screen sharing and camera streams



- Sensitivity labels can't be applied to live events.

- Labeling meeting invites with Graph APIs isn't supported.

How to configure a sensitivity label to protect calendar items, Teams meetings, and chat

1. Follow the general instructions to create or edit a sensitivity label and make sure the following label scopes are selected:

   - **Files & other data assets**
   - **Emails**
   - **Meetings**

All three options are needed because of their interdependency. A meeting consists of a calendar event, the invitation and responses, related attachments, related emails, and the actual Teams meeting. As a result, all these items need the same sensitivity label applied to protect the meeting.

2. On the **Choose protection settings for labeled items** page:

   - Select **Apply or remove encryption** if you want to encrypt meeting invites and responses, and any Office attachment in that calendar item
   - Select **Apply content marking** if you want to add headers or footers to meeting invites and responses
   - Select **Protect Teams meetings and chat** to display the label in Teams meetings and enforce Teams-specific settings for the Teams meeting itself and chat messages

3. On the subsequent pages, configure settings for the options you've selected.

   For more information about configuring encryption for meeting invites, see Restrict access to content by using sensitivity labels to apply encryption.

   For more information about the headers and footers that you can apply to meeting invites, see the **Mark the content** information from What sensitivity labels can do.

For more information about the settings that you can configure for Teams meetings and chat:

- Use the Teams documentation for an explanation of each setting. For information about how the settings interact with other configuration methods for Teams, see Use Teams meeting templates, sensitivity labels, and admin policies together for sensitive meetings.
- Specific to the option to prevent copy in chat, see the next section on this page, Prevent copying chat to the clipboard label setting.

4. Complete the label configuration and then create or configure other sensitivity labels if you need different settings for other labels.

Prevent copying and forwarding for chats and meeting content

The label setting **Prevent copying and forwarding of meeting chat, live caption, and transcripts** also extends to AI-generated meeting recap content.

The setting is enforced for all channel chats, even outside channel meetings. For non-channel meetings, it's enforced only for meetings.

The methods supported to prevent these actions:

- Select the text and then right-click > **Copy** or Ctrl+C
- Forward messages
- Share to Outlook
- Copy link

This setting can't prevent screen captures and doesn't apply to developer tools or third-party apps.

Configure a corresponding sensitivity label publishing policy

1. Make sure the label is published to meeting organizers and participants.
2. Configure label policy settings that are specific just to calendar items, Teams meetings, and chat:
   - **Apply a default label to meetings and calendar events**

- For Outlook: The default label is applied to new calendar events and to existing unlabeled calendar events when they are updated.
- For Teams: The default label is applied to new calendar events but won't be automatically applied when an existing unlabeled meeting is updated.

> ⓘ **Note**
>
> These settings are independent from, rather than override, the similar policy settings for emails. For example, if you don't select the setting to apply a default label to meetings and calendar events, but do select the setting to apply a default label for emails, no default label is applied to calendar events.

- **Require users to apply a label to their meetings and calendar events**
- **Inherit label from files shared to meetings**

  For Teams meetings, automatically apply or recommend that the meeting is labeled with the highest priority sensitivity label from files shared for the meeting when that label is published to the meeting organizer.

  These files can be shared in the chat or uploaded in the **Shared** tab of the meeting, or presented via Live share. Files shared via screen share or Window share, or shared any other way won't be inherited to meetings.

  A meeting that already has a sensitivity label with a higher priority label won't be overriden. However, a manually applied sensitivity label with a lower priority can be overriden.

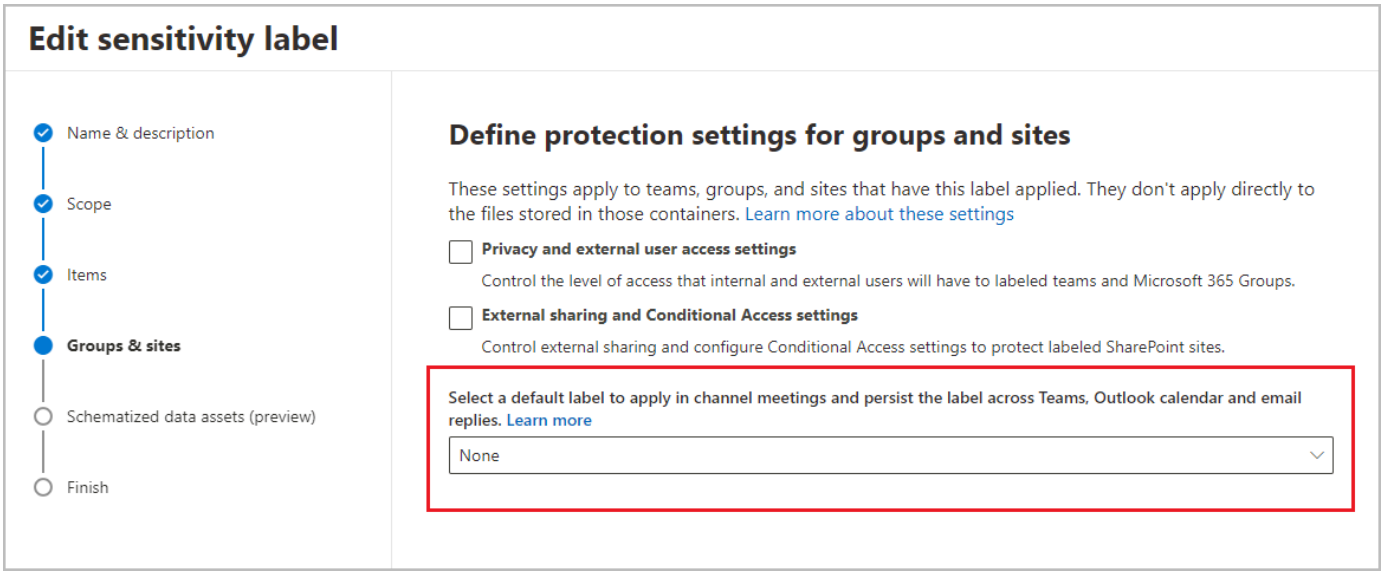
  For Teams desktop and web clients, a notification event is sent to the meeting organizer if label inheritance happens before the meeting starts.

- **Apply meeting label to artifacts**

  This setting is in preview and for MP4 files, requires you to enable sensitivity labeling support for MP4.

  > ⓘ **Important**
  >
  > If MP4 support isn't enabled, these files aren't labeled when you select this option.

For Teams meetings, automatically apply the meeting's sensitivity label to recordings and their transcripts (.mp4 files), and to meeting notes (.loop files) at the time the artifact is saved to SharePoint or OneDrive. If the meeting label changes later, the inherited label doesn't automatically change.



Recordings respect any access permissions and usage rights from label encryption settings and can be played directly in a web browser and supported experiences such as SharePoint, Teams, or Clipchamp. However, if a recording and transcript has a label that applies encryption, you can't download them. You can download them if the label doesn't apply encryption, but a downloaded file in this case doesn't retain the labeling information.

You can, if required, manually relabel these files in SharePoint or OneDrive, by using the file's **Details** pane. For example, change the label to one that doesn't apply encryption so that you can then download and share with others. As with all sensitivity labels, you must have the appropriate permissions to change a sensitivity label that applies encryption, which is always the case for the meeting owner.

How to configure and apply a label for channel meetings

To apply your label meeting options to channel meetings, the sensitivity label must be associated with a container label for the channel. Then, all channel meetings and chats inherit the associated label, which can't be changed by users.

This association is a setting that's available only when you edit an existing label for groups and sites. Then, you can select a sensitivity label that you've configured in the previous procedure:

> **Note**
>
> The option to select this default sensitivity label to protect channel meetings and chat is available only when both of the following conditions apply:
>
> - You're editing an existing sensitivity label, rather than creating a new label.
> - The label's scope includes files, emails, and meetings.

If you select a label that applies encryption, it can be a label with admin-defined permissions (**Assign permissions now**) or user-defined permissions (**Do Not Forward** and **Encrypt-Only**).

End-user documentation

To help end users understand how to apply and change sensitivity labels in Teams and Outlook, see the following articles:

- Sensitivity labels for Teams meetings.
- Apply sensitivity labels to your Outlook meetings.

Remember to provide your own guidance which named label to apply for different types of meetings. Then, users can focus on the label name instead of the individual settings applied by the label.

Enable sensitivity labels for files in SharePoint and OneDrive

> *Microsoft Purview service description*

Enable built-in labeling for supported Office files and PDF files in SharePoint and OneDrive so that users can apply your sensitivity labels in Office for the web. When this feature is enabled, users see the **Sensitivity** button on the ribbon so they can apply labels, and see any applied label name on the status bar.

Users can also see and apply sensitivity labels without having to first open the files, by using the details pane in SharePoint and OneDrive. This labeling method is also available from the **Files** tab in Microsoft Teams.

Enabling this feature also results in SharePoint and OneDrive being able to process the contents of Office files and optionally, PDF documents that have been encrypted by using a sensitivity label. The label can be applied in Office for the web, or in Office desktop apps and uploaded or saved in SharePoint and OneDrive. Until you enable this feature, these services can't process encrypted files, which means that coauthoring, eDiscovery, data loss prevention, search, and other collaborative features won't work for these files.

After you enable sensitivity labels for these files in SharePoint and OneDrive, for new and changed files that have a sensitivity label that applies encryption with a cloud-based key (and doesn't use Double Key Encryption):

- For Word, Excel, and PowerPoint files, and uploaded PDF files, SharePoint and OneDrive recognize the label and can now process the contents of the encrypted file.
- When users download or access these files from SharePoint or OneDrive, the sensitivity label and any encryption settings from the label are enforced and remain with the file, wherever it's stored. Ensure you provide user guidance to use only labels to protect documents. For more information, see Information Rights Management (IRM) options and sensitivity labels.
- When users upload labeled and encrypted files to SharePoint or OneDrive, they must have at least View usage rights to those files. For example, they can open the files outside

SharePoint. If they don't have this minimum usage right, the upload is successful but the service doesn't recognize the label and can't process the file contents.

- Use Office for the web (Word, Excel, PowerPoint) to open and edit Office files that have sensitivity labels that apply encryption. The permissions that were assigned with the encryption are enforced. You can also use auto-labeling for these documents.
- External users can access documents that are labeled with encryption by using guest accounts. For more information, see Support for external users and labeled content.
- eDiscovery supports full-text search for these files and data loss prevention (DLP) policies support content in these files.

> **Note**
>
> If encryption has been applied with an on-premises key (a key management topology often referred to as "hold your own key" or HYOK), or by using **Double Key Encryption**, the service behavior for processing the file contents doesn't change. So for these files, coauthoring, eDiscovery, data loss prevention, search, and other collaborative features won't work.
>
> The SharePoint and OneDrive behavior also doesn't change for existing files in these locations that are labeled with encryption using a single Azure-based key. For these files to benefit from the new capabilities after you enable sensitivity labels for Office files in SharePoint and OneDrive, the files must be either downloaded and uploaded again, or edited.

After you enable sensitivity labels for Office files in SharePoint and OneDrive, three new audit events are available for monitoring sensitivity labels that are applied to documents in SharePoint and OneDrive:

- **Applied sensitivity label to file**
- **Changed sensitivity label applied to file**
- **Removed sensitivity label from file**

You can disable sensitivity labels for Office files in SharePoint and OneDrive (opt-out) at any time.

If you're currently protecting documents in SharePoint by using SharePoint Information Rights Management (IRM), be sure to check the SharePoint Information Rights Management (IRM) and sensitivity labels section on this page.

Requirements

These new capabilities work with sensitivity labels only.

Use the OneDrive sync app version 19.002.0121.0008 or later on Windows, and version 19.002.0107.0008 or later on macOS. Both these versions were released January 28, 2019. For more information, see the OneDrive release notes. After you enable sensitivity labels for SharePoint and OneDrive, users who run an older version of the sync app see a prompt to update it.

Supported file types

After you enable sensitivity labels for SharePoint and OneDrive, the following Office file types support sensitivity labeling scenarios.

Applying a sensitivity label in Office for the web or in SharePoint:

- **Word**: .docx, .docm
- **Excel**: .xlsx, .xlsm, .xlsb
- **PowerPoint**: .pptx, .ppsx

Uploading a labeled Office document, and then extracting and displaying that sensitivity label:

- **Word**: .doc, .docx, .docm, .dot, .dotx, .dotm
- **Excel**: .xls, .xlt, .xla, .xlc, .xlm, .xlw, .xlsx, .xltx, .xlsm, .xltm, .xlam, .xlsb
- **PowerPoint**: .ppt, .pot, .pps, .ppa, .pptx, .ppsx, .ppsxm, .potx, .ppam, .pptm, .potm, .ppsm

Video support (MP4 files)

This support requires you to first enable it by using PowerShell.

MP4 files support manually applying sensitivity labels, but can't be labeled automatically or by default. Additionally, MP4 files can automatically inherit a sensitivity label from a Teams meeting.

To turn on support for MP4 video files, use the Set-SPOTenant cmdlet with the *EnableSensitivityLabelForVideoFiles* parameter:

PowerShell

```
Set-SPOTenant -EnableSensitivityLabelForVideoFiles $true
```

For Microsoft 365 Multi-Geo, you must connect to each of your geo-locations and run the command separately.

When MP4 files have a sensitivity label that applies encryption, they can't be downloaded. All labeled MP4 files support playback in SharePoint, Teams, and Clipchamp.

Sensitivity labels that apply encryption must be configured with the Assign permissions now option, rather than user-defined permissions.

Adding support for PDF

You can enable support for PDFs for the following scenarios:

- Applying a sensitivity label in Office for the web
- Uploading a labeled document, and then extracting and displaying that sensitivity label
- Search, eDiscovery, and data loss prevention
- Auto-labeling policies and default sensitivity labels for SharePoint document libraries

Sensitivity labels don't support signed PDFs.

> **Important**
>
> Enabling PDF support can increase the number of files that get automatically labeled by existing auto-labeling policies, which support a maximum of 100,000 files a day.

To turn on support from the Microsoft Purview portal:

- Sign in to the Microsoft Purview portal > **Solutions** > **Information Protection** > **Sensitivity labels** > **Policies** > **Auto-labeling policies**

  Then, if you see a message **Protect PDFs with Auto-labeling**, select this banner to confirm you want to turn on PDF protection for files in SharePoint and OneDrive.

Alternatively, you can turn on PDF support by using PowerShell. Use the Set-SPOTenant cmdlet with the *EnableSensitivityLabelforPDF* parameter:

PowerShell

```
Set-SPOTenant -EnableSensitivityLabelforPDF $true
```

This PDF parameter requires a minimum version of 16.0.24211.12000 for the SharePoint Online Management Shell. For more information about how to install this PowerShell module or run the cmdlets, see the section on this page to enable support for sensitivity labels.

For Microsoft 365 Multi-Geo: Similarly to the instructions to run the PowerShell command to enable support for sensitivity labels, you must connect to each of your geo-locations, and then run the command to enable support for PDFs.

Support for labels configured for user-defined permissions

User-defined permissions refers to an encryption configuration and the setting **Let users assign permissions when they apply the label** and the checkbox **In Word, PowerPoint, and Excel, prompt users to specify permissions** is selected.

After you've enabled sensitivity labels for SharePoint and OneDrive, content labeled with user-defined permissions can be inspected for search, data loss prevention, and eDiscovery. This functionality applies to only newly uploaded and edited files.

The following actions support labels configured for user-defined permissions:

- When a document is labeled with user-defined permissions and uploaded to SharePoint or OneDrive, these services can now process the document so that it can be opened and edited in Office for the web, and the label name is displayed in the **Sensitivity** column.
- Labels with this configuration are displayed in Office for the web. Before users select these labels to specify users and permissions, or change the label applied, make sure you've enabled co-authoring for files encrypted with sensitivity labels.

To support AutoSave and co-authoring for these encrypted files by using a desktop app, co-authoring for files encrypted with sensitivity labels must first be enabled.

This functionality comes with the following change in behavior for encryption:

- If an existing file that's labeled with user-defined permissions is relabeled with a sensitivity label that doesn't apply encryption, the original encryption is removed rather than preserved. For more information, see What happens to existing encryption when a label's applied.

Limitations

- SharePoint and OneDrive can't process some files that are labeled and encrypted from Office desktop apps when these files contain Power Query data, data stored by custom add-ins, or custom XML parts such as Cover Page Properties, content type schemas, custom Document Information Panel, and Custom XSN. This limitation also applies to files that include a bibliography, and to files that have a Document ID added when they're uploaded.

  For these files, either apply a label without encryption so that users can later open them in Office for the web, or instruct users to open the files in their desktop apps. Files that are labeled and encrypted only in Office for the web aren't affected.

- SharePoint and OneDrive don't support sensitivity labels if you applied the labels before enabling these services for sensitivity labels. The labels aren't recognized and if the labels applied encryption, the contents aren't processed. For the labels and encryption to be supported by SharePoint and OneDrive, download these files and then upload them to their original location.

- SharePoint and OneDrive can't process encrypted files when the label that applied the encryption has either of the following configurations for encryption:

  - **User access to content expires** is set to a value other than **Never**.

  - **Double Key Encryption** is selected.

    For labels with either of these encryption configurations, the labels aren't displayed to users in Office for the web. If they're parent labels, this means that users don't see that label's sublabels, even if the sublabels aren't configured to apply encryption.

    Additionally, the new capabilities can't be used with labeled documents that already have these encryption settings. For example, these documents aren't returned in search results, even if they're updated.

- SharePoint and OneDrive can't read or apply sensitivity labels when the document is password-protected.

- SharePoint and OneDrive prevents downloading MP4 files with sensitivity labels that apply encryption. If these files have labels that don't apply encryption, they can be downloaded but the labeling information is lost.

- For performance reasons, when you upload or save a document to SharePoint and the file's label doesn't apply encryption, the **Sensitivity** column in the document library can take a

while to display the label name. Factor in this delay if you use scripts or automation that depend on the label name in this column.

- If a document is labeled while it's checked out in SharePoint, the **Sensitivity** column in the document library doesn't display the label name until the document is checked in and next opened in SharePoint.

- If a labeled and encrypted document is downloaded from SharePoint or OneDrive by an app or service that uses a service principal name, and then uploaded again with a label that applies different encryption settings, the upload fails. An example scenario is Microsoft Defender for Cloud Apps changes a sensitivity label on a file from **Confidential** to **Highly Confidential**, or from **Confidential** to **General**.

  The upload doesn't fail if the app or service first runs the Unlock-SPOSensitivityLabelEncryptedFile cmdlet, as explained in the Remove encryption for a labeled document section. Or, before the upload, the original file is deleted, or the file name is changed.

- Users might experience delays in being able to open encrypted documents in the following Save As scenario: With a desktop version of Office, a user chooses Save As for a document that has a sensitivity label that applies encryption. The user selects SharePoint or OneDrive for the location, and then immediately tries to open that document in Office for the web. If the service is still processing the encryption, the user sees a message that the document must be opened in their desktop app. If they try again in a couple of minutes, the document successfully opens in Office for the web.

- For encrypted documents, printing, downloading, exporting, and creating a copy aren't supported in Office for the web.

- For encrypted documents in Office for the web, screen captures aren't prevented. However, when documents are labeled and encrypted, and the **Copy** usage right isn't granted, Office for the web prevents copying to clipboard in the same way as desktop apps prevent this action.

- By default, Office desktop apps and mobile apps don't support co-authoring for files that are labeled with encryption. These apps continue to open labeled and encrypted files in exclusive editing mode. To change the default behavior, see Enable co-authoring for files encrypted with sensitivity labels.

- If an admin changes settings for a published label that's already applied to files downloaded to users' sync client, users might be unable to save changes they make to the file in their OneDrive Sync folder. This scenario applies to files that are labeled with encryption, and also when the label change is from a label that didn't apply encryption to a label that does apply encryption. Users see a red circle with a white cross icon error, and they're asked to save new changes as a separate copy. Instead, they can close and reopen the file, or use Office for the web.

- Sensitivity labels that are configured for automatic labeling are supported for Office for the web when the label settings for conditions are for sensitive information types only. Automatic labeling isn't supported for Office for the web when the conditions include trainable classifiers.

- Users can experience save problems after going offline or into a sleep mode when instead of using Office for the web, they use the desktop and mobile apps for Word, Excel, or PowerPoint. For these users, when they resume their Office app session and try to save changes, they see an upload failure message with an option to save a copy instead of saving the original file.

- Documents that are encrypted in the following ways can't be opened in Office for the web:
  - Encryption that uses an on-premises key ("hold your own key" or HYOK)
  - Encryption that was applied by using Double Key Encryption
  - Encryption that was applied independently from a label, for example, by directly applying a Rights Management protection template.

- Labels configured for other languages aren't supported and display the original language only.

- If you delete a label that's been applied to a document in SharePoint or OneDrive, rather than remove the label from the applicable label policy, the document when downloaded isn't labeled or encrypted. In comparison, if the labeled document is stored outside SharePoint or OneDrive, the document remains encrypted if the label is deleted. Although you might delete labels during a testing phase, it's very rare to delete a label in a production environment.

- When a labeled and encrypted Office file larger than 12 MB is copied or moved to a different site, SharePoint can no longer process this file. As a result, the **Sensitivity** column doesn't display the label name and users can't open the file using Office for the web. Users can successfully open the file when they use an Office client app.

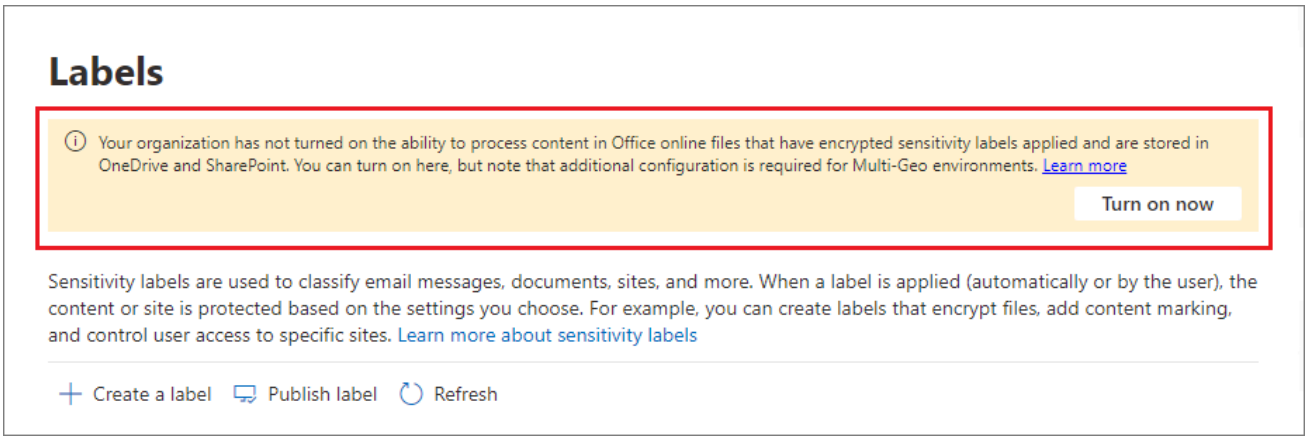
- In the following scenario, users from an external tenant can't open files protected with a user-defined permissions sensitivity label in Office for the web. The same limitation also applies when users open the file from SharePoint or OneDrive with Microsoft Office desktop applications.
  - A user (UserA) from an external tenant (fabrikam) is invited as a guest user to the contoso tenant.
  - The sensitivity label applied to the file grants permissions to a group in the external fabrikam tenant, and UserA is a member of that group.
  - The file is uploaded to SharePoint in the contoso tenant, and UserA attempts to open the file in Office for the web.

  To allow an external tenant user to open a file protected with a user-defined permissions sensitivity label, use one of the following methods:
  - Grant permissions directly to the external user in the sensitivity label.
  - Add the external user to a group in the contoso tenant, and grant permissions to that contoso tenant group in the sensitivity label.

How to enable sensitivity labels for SharePoint and OneDrive (opt-in)

> ⓘ **Note**
>
> Enabling sensitivity labels for SharePoint and OneDrive automatically enables **sensitivity labels for Loop components and pages**. However, enabling sensitivity labels for OneNote requires an additional step that uses PowerShell.

You can enable the new capabilities by using the Microsoft Purview portal, or by using PowerShell. See the following sections for instructions.



As with all tenant-level configuration changes for SharePoint and OneDrive, it takes about 15 minutes for the change to take effect.

Use the portal to enable support for sensitivity labels

This option is the easiest way to enable sensitivity labels for SharePoint and OneDrive. You must sign in as a global administrator for your tenant.

1. Sign in to the Microsoft Purview portal > **Solutions** > **Information Protection** > **Sensitivity labels**.

2. If you see a message to turn on the ability to process content in Office online files, select **Turn on now**:

   The command runs immediately and when the page is next refreshed, you no longer see the message or button.

> **Note**
>
> If you have Microsoft 365 Multi-Geo, you must use PowerShell to enable these capabilities for all your geo-locations. See the next section for details.

Use PowerShell to enable support for sensitivity labels

As an alternative to using the Microsoft Purview portal, you can enable support for sensitivity labels by using the Set-SPOTenant cmdlet from SharePoint Online PowerShell. The same Set-SPOTenant cmdlet can then be run again to enable sensitivity labels for OneDrive.

If you have Microsoft 365 Multi-Geo, you must use PowerShell to enable this support for all your geo-locations.

Prepare the SharePoint Online Management Shell

Before you run the PowerShell command to enable sensitivity labels for Office files in SharePoint and OneDrive, ensure that you're running SharePoint Online Management Shell version 16.0.19418.12000 or later. To additionally support sensitivity labels for OneNote, you need SharePoint Online Management Shell version 16.0.26914.12004 or later. If you already have the latest version, you can skip to next procedure to run the PowerShell command.

1. If you installed a previous version of the SharePoint Online Management Shell from the PowerShell gallery, update the module by running the following cmdlet.

   ```
   PowerShell
   Update-Module -Name Microsoft.Online.SharePoint.PowerShell
   ```

2. Alternatively, if you have installed a previous version of the SharePoint Online Management Shell from the Microsoft Download Center, you can also go to **Add or remove programs** and uninstall the SharePoint Online Management Shell.

3. In a web browser, go to the Download Center page and Download the latest SharePoint Online Management Shell.

4. Select your language and then select **Download**.

5. Choose between the x64 and x86 .msi file. Download the x64 file if you run the 64-bit version of Windows or the x86 file if you run the 32-bit version. If you don't know, see Which version of Windows operating system am I running?

6. After you download the file, run the file and follow the steps in the Setup configuration.

Run the PowerShell command to enable support for sensitivity labels

To enable the new capabilities, use the Set-SPOTenant cmdlet with the *EnableAIPIntegration* parameter:

1. Using a work or school account that has SharePoint admin privileges in Microsoft 365, connect to SharePoint. To learn how, see Getting started with SharePoint Online Management Shell.

   > **Note**
   >
   > If you have Microsoft 365 Multi-Geo, use the -Url parameter with Connect-SPOService, and specify the SharePoint Online Administration Center site URL for one of your geo-locations.

2. Run the following command and press **Y** to confirm:

   ```
   PowerShell
   ```

```
Set-SPOTenant -EnableAIPIntegration $true
```

3. For Microsoft 365 Multi-Geo: Repeat steps 1 and 2 for each of your remaining geo-locations.

4. If you want to additionally enable sensitivity labels for OneNote (supported at the section level), run *Set-SPOTenant* again, but use the following command:

   PowerShell

   ```
   Set-SPOTenant -EnableSensitivityLabelforOneNote $true
   ```

   This command currently doesn't support Microsoft 365 Multi-Geo.

Publishing and changing sensitivity labels

When you use sensitivity labels with SharePoint and OneDrive, keep in mind that you need to allow for replication time when you publish new sensitivity labels or update existing sensitivity labels. This replication time is especially important for new labels that apply encryption.

For example, you create and publish a new sensitivity label that applies encryption and it very quickly appears in a user's desktop app. The user applies this label to a document and then uploads it to SharePoint or OneDrive. If the label replication hasn't completed for the service, the new capabilities aren't applied to that document on upload. As a result, the document isn't returned in search or for eDiscovery, and the document can't be opened in Office for the web.

For more information about the timing of labels, see When to expect new labels and changes to take effect.

As a safeguard, publish new labels to just a few test users first, wait for at least one hour, and then verify the label behavior on SharePoint and OneDrive. Wait at least a day before you make the label available to more users by either adding more users to the existing label policy, or adding the label to an existing label policy for your standard users. By the time your standard users see the label, it has already synchronized to SharePoint and OneDrive.

SharePoint Information Rights Management (IRM) and sensitivity labels

SharePoint Information Rights Management (IRM) is an older technology to protect files at the list and library level by applying encryption and restrictions when users download files. This older

protection technology is designed to prevent unauthorized users from opening the file while it's outside SharePoint.

In comparison, sensitivity labels provide the protection settings of visual markings (headers, footers, watermarks) in addition to encryption. The encryption settings support the full range of usage rights to restrict what users can do with the content, and the same sensitivity labels are supported for many scenarios. Using the same protection method with consistent settings across workloads and apps results in a consistent protection strategy.

However, you can use both protection solutions together and the behavior is as follows:

- If you upload a file with a sensitivity label that applies encryption, SharePoint can't process the content of these files so coauthoring, eDiscovery, DLP, and search aren't supported for these files.
- If you label a file using Office for the web, any encryption settings from the label are enforced. For these files, coauthoring, eDiscovery, DLP, and search are supported.
- If you download a file that's labeled by using Office for the web, the label is retained and any encryption settings from the label are enforced rather than the IRM restriction settings.
- If you download an Office or PDF file that isn't encrypted with a sensitivity label, IRM settings are applied.
- If you enabled any of the additional IRM library settings, which include preventing users from uploading documents that don't support IRM, these settings are enforced.

With this behavior, you can be assured that all Office and PDF files are protected from unauthorized access if they're downloaded, even if they aren't labeled. However, labeled files that are uploaded don't benefit from the new capabilities.

Search for documents by sensitivity label

Use the managed property **InformationProtectionLabelId** to find all documents in SharePoint or OneDrive that have a specific sensitivity label. Use the following syntax:
`InformationProtectionLabelId:<GUID>`

For example, to search for all documents that are labeled as "Confidential" and that label has a GUID of `8faca7b8-8d20-48a3-8ea2-0f96310a848e`, type the following text in the search box:

```
```

```
InformationProtectionLabelId:8faca7b8-8d20-48a3-8ea2-0f96310a848e
```

Search can't find labeled documents in a compressed file, such as a .zip file.

To get the GUIDs for your sensitivity labels, use the Get-Label cmdlet:

1. First, connect to Office 365 Security & Compliance PowerShell.

   For example, in a PowerShell session that you run as administrator, sign in by using a compliance administrator account.

2. Then run the following command:

   PowerShell

   ```
   Get-Label |ft Name, Guid
   ```

For more information about using managed properties, see Manage the search schema in SharePoint.

Remove encryption for a labeled document

There might be rare occasions when a SharePoint administrator needs to remove encryption from a document stored in SharePoint. Any user who has the Rights Management usage right of Export or Full Control assigned to them for that document can remove encryption that was applied by the Azure Rights Management service from Microsoft Purview Information Protection. For example, users with either of these usage rights can replace a label that applies encryption with a label without encryption. A super user could also download the file and save a local copy without the encryption.

As an alternative, a SharePoint admin can run the Unlock-SPOSensitivityLabelEncryptedFile cmdlet, which removes both the sensitivity label and the encryption. This cmdlet runs even if the admin doesn't have access permissions to the site or file, or if the Azure Rights Management service is unavailable.

For example:

PowerShell

```
Unlock-SPOSensitivityLabelEncryptedFile -FileUrl
"https://contoso.com/sites/Marketing/Shared Documents/Doc1.docx" -JustificationText
"Need to decrypt this file"
```

Requirements:

- SharePoint Online Management Shell version 16.0.20616.12000 or later.
- The encryption is applied by a sensitivity label with admin-defined encryption settings (the Assign permissions now label settings). Double Key Encryption isn't supported for this cmdlet.

The justification text is added to the audit event of **Removed sensitivity label from file**, and the decryption action is also recorded in the usage logging for the Azure Rights Management service.

How to disable sensitivity labels for SharePoint and OneDrive (opt-out)

After you disable these new capabilities, SharePoint and OneDrive can't process newly labeled and encrypted files. As a result, coauthoring, eDiscovery, data loss prevention, search, and other collaborative features won't work for these files. However, these capabilities continue to be supported for files that were labeled and encrypted before you disabled sensitivity labels.

This mixed protection state can result in higher administrative overheads with help desk incidents to investigate the inconsistent behavior. It might also be a problem for compliance requirements.

To better understand the behavior of labeled files before and after disabling sensitivity labels for SharePoint and OneDrive, use the **Label behavior** tab.

Disable instructions

To disable these new capabilities, you must use PowerShell. By using the SharePoint Online Management Shell and the Set-SPOTenant cmdlet, specify the same *EnableAIPIntegration* parameter as described in the Use PowerShell to enable support for sensitivity labels section. But this time, set the parameter value to false and press **Y** to confirm:

PowerShell

```
Set-SPOTenant -EnableAIPIntegration $false
```

If you have Microsoft 365 Multi-Geo, you must run this command for each of your geo-locations.

Next steps

After you enable sensitivity labels for files in SharePoint and OneDrive, consider automatically labeling files by using either, or both, of the following labeling methods:

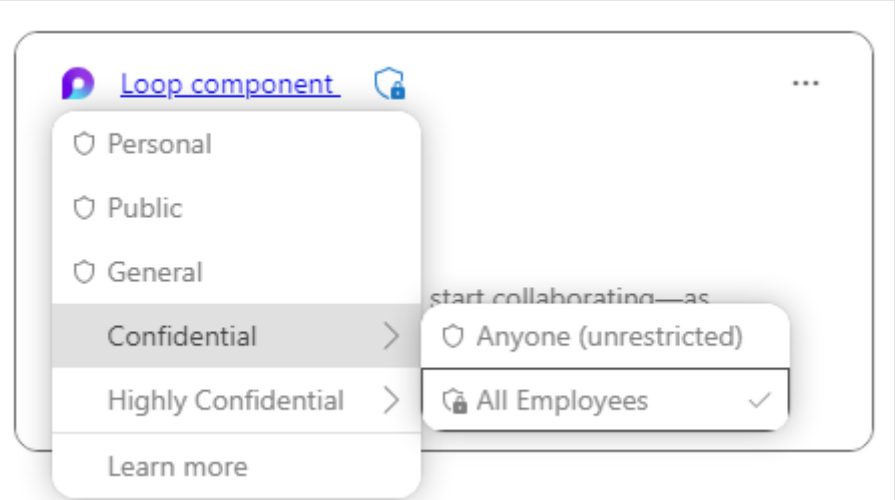
- Applying a default sensitivity label for document libraries, for new and edited files in SharePoint. For more information, see Configure a default sensitivity label for a SharePoint document library.
- Auto-labeling policies that use content inspection for files in SharePoint and OneDrive. For more information, see Automatically apply a sensitivity label to Microsoft 365 data.

Do you need to share your labeled and encrypted documents with people outside your organization? See Sharing encrypted documents with external users.

- Learn about Double Key Encryption

Last updated on 08/07/2026

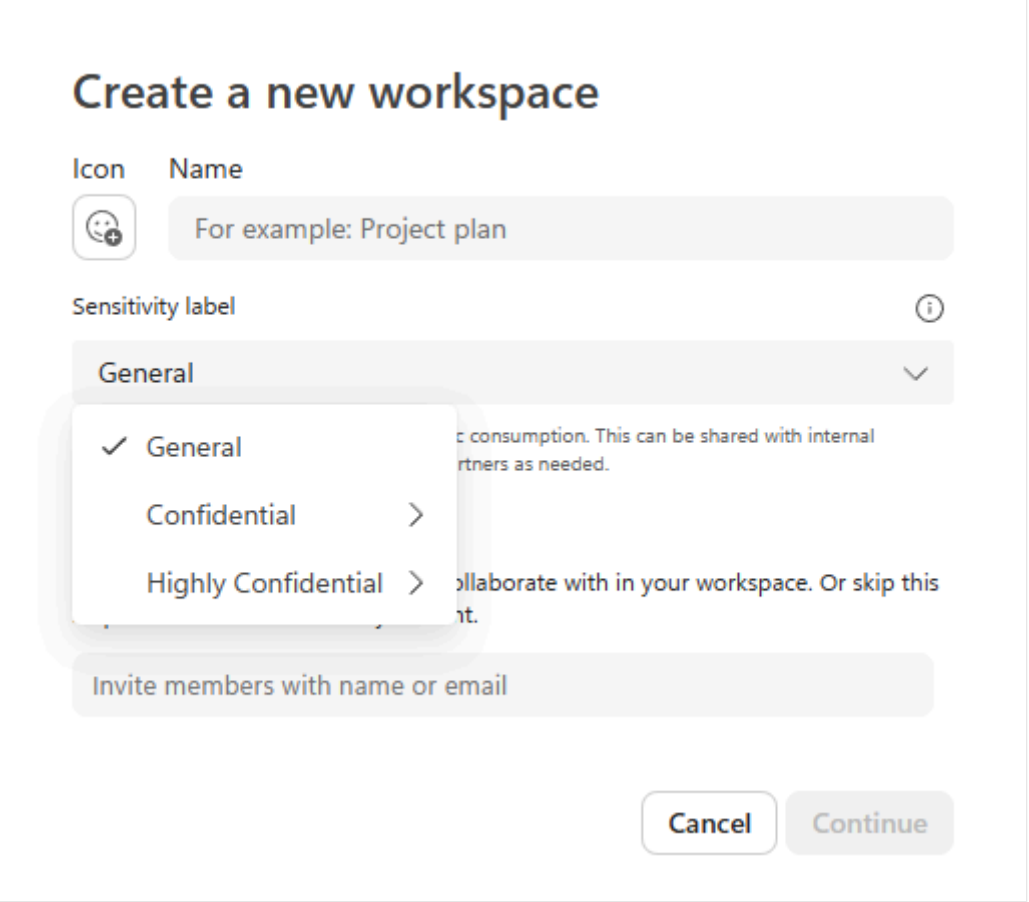
Use sensitivity labels with Microsoft Loop



> *Microsoft Purview service description*

Use your sensitivity labels with Microsoft Loop to add an extra layer of protection to the Loop-related data that users create with this app. This protection extends to Microsoft 365 Copilot.

Loop supports sensitivity labels at the file level, to help protect components and pages:



- Users can manually apply sensitivity labels that are published to them with the **Files & other data assets** label scope, including sensitivity labels that apply encryption configured to apply permissions now.
- Watermarks as a label setting are supported but not variables in the text string.
- Mandatory labeling and a default document label are supported as settings from a label publishing policy.
- Other policy settings supported:
  - Justification to remove a label or lower its priority
  - The "Learn more" link

Example Loop component that's currently labeled with the **Confidential \ All Employees** sensitivity label that applies encryption, displaying other available labels:

Loop supports sensitivity labels at the container level, to help protect access to workspaces:

- This functionality is supported for tenant-owned workspaces on the web version of the Loop app.
- You can apply a sensitivity label when you create a new workspace, or apply or change a sensitivity label as a More (...) workspace configuration.
- Using the SharePoint admin center with the SharePoint Embedded administrator role, you can see and change applied sensitivity labels from **Containers** > **Active containers**.

See the following sections for more details about requirements, supported scenarios, and limitations when you use sensitivity labels with Loop.

For information where Loop-related content is stored, see Overview of Loop storage.

Sensitivity labels to protect Loop components and pages

The ability to apply sensitivity labels to Loop components and pages requires that SharePoint and OneDrive is enabled for sensitivity labels. Then, you can apply sensitivity labels to loop components and pages in the following apps:

- The Loop app (web and mobile)
- Loop in Outlook (desktop, mobile, web)
- Microsoft 365 Copilot Chat in Microsoft Copilot Pages

When Loop components and pages are encrypted by sensitivity labels, Microsoft 365 Copilot honors the EXTRACT usage right. Microsoft 365 Copilot won't summarize this Loop data unless the user is granted this usage right.

As with sensitivity labels that are applied to documents in SharePoint and OneDrive, the following auditing events are supported:

- **Applied sensitivity label to file**
- **Changed sensitivity label applied to file**
- **Removed sensitivity label from file**

Sensitivity label inheritance for components and pages

Any unlabeled Loop components on the page inherit the sensitivity label applied to the page. That label is retained if you move it to another Loop page.

A Loop page can inherit a higher priority sensitivity label from Copilot in the Loop app when referenced files are labeled. If more than one file is referenced and labeled, the page inherits the label with the highest priority.

Limitations for Loop components and pages

The following labeling capabilities aren't supported:

- Label names and descriptions for other languages
- Headers and footers
- Variables in watermarks and dynamic watermarks
- Automatic and recommended labeling
- Sensitivity labels that are configured for any of the following encryption settings:
  - **Let users assign permissions**, sometimes known as "user-defined permissions"
  - **User access to content expires** is set to a value other than **Never**
  - **Double Key Encryption** is selected

Because the task management tools in Microsoft Planner and Microsoft To Do don't support encryption, they stop synchronizing a Loop component or page that's encrypted by a sensitivity label.

Sensitivity labels to protect Loop workspaces

The ability to apply sensitivity labels to Loop workspaces at the tenant-level requires that sensitivity labels are enabled for containers and that the label scope includes **Groups & sites**. Then, you can apply sensitivity labels to Loop workspaces in the Loop web app so that content in those workspaces is protected by the following label settings documented in Use sensitivity labels to protect collaborative workspaces (groups and sites):

- External user access
- External sharing from SharePoint sites
- Access from unmanaged devices
- Authentication contexts

- Default sharing link for a SharePoint site (PowerShell-only configuration)
- Site sharing settings (PowerShell-only configuration)

Although Loop workspaces are stored in SharePoint Embedded containers rather than SharePoint sites, the listed sensitivity label settings for sites are functionally the same.

Limitations for Loop workspaces

As with sensitivity labels that you apply to Loop components and pages, sensitivity labels for Loop workspaces don't support label colors or label names and descriptions for other languages.

The following Loop content isn't protected by the container label settings:

- Linked files
- Files uploaded to a workspace because these files are stored in the user's OneDrive
- Videos that are created in a workspace because these files are stored in the user's OneDrive

Configure a default sensitivity label for a SharePoint document library

06/10/2025

> *Microsoft 365 licensing guidance for security & compliance*

When SharePoint is enabled for sensitivity labels, you can configure a default label for document libraries. Then, any new files uploaded to that library, or existing files edited in the library will have that label applied if they don't already have a sensitivity label, or they have a sensitivity label but with lower priority.

For example, you configure the **Confidential** label as the default sensitivity label for a document library. A user who has **General** as their policy default label saves a new file in that library. SharePoint will label this file as **Confidential** because of that label's higher priority. For a quick summary of the possible outcomes, see Will an existing label be overridden on this page.

A default label offers a baseline level of protection and a form of automatic labeling without content inspection. To help you distinguish between this feature's default label with the default label in label policies:

- **Default sensitivity label for a document library**: Location-based labeling, applicable only for SharePoint. Overrides a lower-priority label unless manually applied.
- **Default sensitivity label from a policy**: Always applicable for all locations. Never overrides an existing label.

When you use Office for the web to create or edit a file, the default sensitivity label for a document library can be applied without delays. However, labeling is not immediate if you upload a file or create it using Microsoft 365 Apps on Windows, macOS, iOS or Android, and then save to SharePoint:

- File upload: it can take a few minutes for the label to be applied.
- Microsoft 365 Apps: the label is applied after the app is closed.

To read the preview announcement for this feature, see the blog post.

Tip

If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and

compliance needs. Start now at the Microsoft Purview trials hub. Learn details about signing up and trial terms.

Will an existing label be overridden?

Summary of outcomes:

Expand table

Existing label	Override with library default label
Manually applied, any priority	No
Automatically applied, lower priority	Yes
Automatically applied, higher priority	No
Default label from policy, lower priority	Yes
Default label from policy, higher priority	No

Requirements

- You've created and published sensitivity labels that include the label scope of **Files & other data assets** and these labels are published to the users who will select a default sensitivity label for a SharePoint document library.
- You've enabled sensitivity labels for Office files in SharePoint and OneDrive. To check this status, you can run `(Get-SPOTenant).EnableAIPIntegration` from the SharePoint Online Management Shell to confirm the value is set to **True**.
- To support sensitivity labels for PDFs, you've added support for PDFs in SharePoint. To check this status, you can run `(Get-SPOTenant).EnableSensitivityLabelforPDF` from the SharePoint Online Management Shell to confirm the value is set to **True**.
- SharePoint Information Rights Management (IRM) is not enabled for the library. This older technology isn't compatible with using a default sensitivity label for a SharePoint document library. If a library is enabled for IRM, you won't be able to select a default sensitivity label.
- Site admin permissions are needed to apply and change the sensitivity label in SharePoint.

- Files must contain content to be labeled. Empty files are labeled when they are updated with content.

If you need to review a list of file types that are supported by sensitivity labels in SharePoint, see Supported file types.

Limitations

- Doesn't apply to existing files at rest in SharePoint.
- Unless you've enabled co-authoring for files encrypted with sensitivity labels, you'll see a delay in applying the default sensitivity label for a document library when users select the **File** > **Save as** option.
- As with sensitivity labels for Office for the web, some label configurations that apply encryption aren't suitable for SharePoint, and so don't support a default sensitivity label for a SharePoint document library:
  - **Let users assign permissions when they apply the label** and the checkbox **In Word, PowerPoint, and Excel, prompt users to specify permissions** is selected. This setting is sometimes referred to as "user-defined permissions".
  - **User access to content expires** is set to a value other than **Never**.
  - **Double Key Encryption** is selected.

How to configure a default sensitivity label for a SharePoint document library

This configuration is done by a SharePoint site admin: Add a sensitivity label to SharePoint document library.

> **Important**
>
> From the **Library settings** pane, select a sensitivity label and don't select the checkbox **Extend protection on download, copy, or move**. This setting is currently in preview and supports a different labeling scenario. For more information, see Configure SharePoint with a sensitivity label to extend permissions to downloaded documents.

Monitoring application of library default sensitivity labels

Use the SharePoint **Sensitivity** column to see the names of sensitivity labels applied to files. When the label has been applied by this features, the tooltip for the label name displays **This file has been automatically labeled**. However, this tooltip isn't exclusive to the default sensitivity label for a document library. It also displays when sensitivity labels are applied by using auto-labeling policies or as a result of a user's default label from sensitivity label policies.

To specifically identify when the label was applied because of the library's default sensitivity label, use the audit log search tool and the **Applied sensitivity label file** auditing event from the **Sensitivity label activities** group. Then:

1. Select an entry to view the details in a flyout pane.
2. From the details pane, scroll to the **SensitivityLabelEventData section**, and identify the value for **ActionScourceDetails**.
3. A value of **6** is used for when the label was applied because of the default sensitivity label for the document library.

To audit the configuration setting for this feature, use the **Updated list** auditing event from the **SharePoint list activities** group. In the details flyout pane for the document library, scroll to the **SensitivityLabelEventData** section where **OldSensitivityLabelId** and **SensitivityLabelId** can reflect three changes of states:

- Sensitivity label applied
- Sensitivity label changed from one label to another
- Sensitivity label removed

To map sensitivity label GUIDs to label names, use the Get-Label cmdlet:

1. First, connect to Security & Compliance PowerShell.
2. Then run the following command, where you specify the GUID:

```
PowerShell

Get-Label -Identity "<GUID>" | Name
```

How to turn off this feature

If you need to, you can turn off this feature that supports a default sensitivity label for SharePoint document libraries. This is a tenant-level setting that requires you to use the Set-SPOTenant cmdlet with the *DisableDocumentLibraryDefaultLabeling* parameter set to **True** by using the current SharePoint Online Management Shell:

PowerShell

```
Set-SpoTenant -DisableDocumentLibraryDefaultLabeling $true
```

After you run this command, you won't see the option to configure **Default sensitivity labels** for a document library. You won't be able to select a default sensitivity label for new or existing libraries.

For document libraries that were previously configured for a default sensitivity label:

- The label selection for the document library remains but is deactivated so new files won't have the selected sensitivity label applied.
- Sensitivity labels that were applied as a default label aren't removed.

As with all tenant-level configuration changes for SharePoint, it takes about 15 minutes for the change to take effect.

Next steps

Default labeling ensures a minimum level of protection but doesn't take into account the file contents that might require a higher level of protection. Consider supplementing this labeling method with automatic labeling that uses content inspection, and encourage manual labeling for users to replace the default label when needed.

Configure SharePoint with a sensitivity label to extend permissions to downloaded documents

Summarize this article for me

> *Microsoft Purview service description*

When SharePoint is enabled for sensitivity labels, you can configure document libraries to extend the existing SharePoint site permissions to documents when they're downloaded from the library. Then, any previously unlabeled files from that library continue to be protected with the current SharePoint permissions for the user, even though the files have left the original SharePoint boundary.

For example, you select the **Confidential \ Trusted People** label as the sensitivity label to extend permissions for a document library. In that library, a site is configured to allow only read permissions to a specfiic group of users. A user from that group downloads a file from the site, and that file is now labeled as **Confidential \ Trusted People**. Even though the file is no longer in SharePoint, that user can still only view and not edit the content or remove the label. Only users with access to the file in SharePoint have access to the downloaded file. Users without access to the file in SharePoint won't be able to open that downloaded file, no matter where it's stored.

Additionally, the file has a just-in-time layer of protection because the user who downloaded the file also won't be able to open it under the following circumstances:

- Permissions for that user are removed from the file
- The file is deleted from the site
- The site is no longer active
- The file is moved to a different site

If the SharePoint permissions for the user are changed, those changes are reflected for the downloaded file.

When these labeled files are in the document library, they're also protected from copy and move actions:

- The files can't be copied to or moved to a different site.
- The files can be copied to or moved to a different document library within the same site only if the user has SharePoint permissions to create or delete lists.

The specified sensitivity label is applied to all files that are unlabeled, and to files that are labeled but the label configuration doesn't apply encryption. Files that are synchronized with OneDrive also get labeled.

For existing files that are labeled but not encrypted, a manually applied label is also replaced with the specified label. For a quick summary of the possible outcomes, see Will an existing label be overridden on this page.

Because unencrypted files can be relabeled, this labeling configuration is well-suited to organizations that are early in their labeling deployment and haven't yet labeled files in SharePoint sites by using other methods.

Will an existing label be overridden?

Summary of outcomes:

Expand table

Existing label	Override with library label to extend permissions
Label applied using any methods (manual, automatic, default label from policy) and label configuration doesn't apply encryption, any priority	Yes
Label applied using any methods (manual, automatic, default label from policy) and label configuration does apply encryption, any priority	No

Requirements

- You've created and published sensitivity labels, published to the users who will select the sensitivity label for a SharePoint document library. Labels require the following configuration:
  - The label scope of **Files and other data assets**
  - Access control is selected with the encryption setting of **Let users assign permissions when they apply the label** and the checkbox **In Word, PowerPoint, and Excel, prompt users to specify permissions** is selected. This setting is sometimes referred to as "user-defined permissions."

    > **Note**

> In this application of the label, users won't be prompted for permissions but their SharePoint permissions will be automatically applied when a file is downloaded, copied, or moved from the site.

- You've enabled sensitivity labels for Office files in SharePoint and OneDrive. To check this status, you can run `(Get-SPOTenant).EnableAIPIntegration` from the SharePoint Online Management Shell to confirm the value is set to **True**.
- Your tenant has been enabled for co-authoring for files encrypted with sensitivity labels.
- To support sensitivity labels for PDFs, you've added support for PDFs in SharePoint. To check this status, you can run `(Get-SPOTenant).EnableSensitivityLabelforPDF` from the SharePoint Online Management Shell to confirm the value is set to **True**.
- Windows apps from Microsoft 365 Apps for enterprise that download files require a minimum version of 2402 from Current Channel, Monthly Enterprise Channel, or Semi-Annual Enterprise Channel.
- SharePoint Information Rights Management (IRM) isn't enabled for the library. This older technology isn't compatible with using a sensitivity label for a SharePoint document library. If a library is enabled for IRM, you won't be able to select a sensitivity label.
- Site admin permissions are needed to apply and change the sensitivity label in SharePoint.
- Files must contain content to be labeled.

If you need to review a list of file types that are supported by sensitivity labels in SharePoint, see Supported file types.

Mapping of SharePoint permissions to usage rights

Use the following table to understand how the SharePoint permissions for a user are extended to rights management usage rights and permission levels when a file is downloaded, or copied and moved outside the site.

Expand table

SharePoint permission	Usage rights applied	Permission levels
Owner	Full control over the content, all permissions, and the sensitivity label applied:	Owner

SharePoint permission	Usage rights applied	Permission levels
	VIEW, EXTRACT, DOCEDIT, EDIT, EXPORT, COMMENT, PRINT, FORWARD, REPLY, REPLYALL, VIEWRIGHTSDATA, EDITRIGHTSDATA, OBJMODEL *, OWNER *	
Edit	Full control over the content but can't change the sensitivity label applied: VIEW, EXTRACT, DOCEDIT, EDIT, EXPORT, COMMENT, PRINT, FORWARD, REPLY, REPLYALL, VIEWRIGHTSDATA	Editor
Read	Can view and copy the content but can't change the content or the sensitivity label applied: VIEW, VIEWRIGHTSDATA, EXTRACT	No equivalent permission level, Viewer is the closest

* Currently, these usage rights aren't applied and as a result, the user can change the sensitivity label, but can't remove it.

Limitations

The following limitations apply when you use this configuration:

- Users can't manually apply sensitivity labels that aren't configured to apply encryption.
- Users won't be able to open downloaded files offline; they must be able to connect to the original site.
- Users won't be able to open downloaded files if the original SharePoint site, folder, or file is deleted.
- Files labeled with this configuration can't be moved or copied to another site.
- Files labeled with this configuration don't support the **Save As** option, and won't save with this option unless they are the minimum versions that include client-side improvements:
  - Windows: Version 2601+ in Current Channel and Monthly Enterprise Channel
  - macOS: Version 16.103+
  - iOS: Version 2.103+
  - Android: Version 16.0.19426+
- Files labeled with this configuration can only be moved or copied to another document library within the same site if users have SharePoint permissions to create or delete lists. The label isn't retained for the copied or moved file.

- This configuration can override a previously manually applied label if the label isn't configured to apply encryption.
- Files labeled with this configuration currently aren't displayed as labeled in content explorer.
- Microsoft 365 Copilot can reference the labeled files if users have SharePoint read permissions to them, but won't summarize these files. Because files can't be summarized, they also can't be used by Copilot to generate new content.

> **Note**
>
> As with all files that are encrypted with Azure Rights Management, a **super user** can open encrypted documents if that becomes necessary because the original location is no longer accessible.

How to configure a SharePoint document library for a sensitivity label that extends permissions to downloaded documents

This configuration first requires that you enable the capability for the tenant by using PowerShell with the SharePoint Online Management Shell. Then, a new checkbox becomes available for document library settings.

Run the PowerShell command to enable support to extend SharePoint permissions

Ensure that you're running SharePoint Online Management Shell version 16.0.25430.12000 or later.

To enable the new capabilities, use the Set-SPOTenant cmdlet with the *ExtendPermissionsToUnprotectedFiles* parameter:

1. Using a work or school account that has SharePoint admin privileges in Microsoft 365, connect to SharePoint. To learn how, see Getting started with SharePoint Online Management Shell.

   > **Note**

If you have Microsoft 365 Multi-Geo, use the -Url parameter with **Connect-SPOService**, and specify the SharePoint Online Administration Center site URL for one of your geo-locations.

2. Run the following command and press **Y** to confirm:

```
PowerShell
Set-SPOTenant -ExtendPermissionsToUnprotectedFiles $true
```

   If you see an error informing you that the feature isn't enabled, it's most likely because the rollout hasn't reached your tenant yet.

3. For Microsoft 365 Multi-Geo: Repeat steps 1 and 2 for each of your remaining geo-locations.

As with all tenant-level configuration changes for SharePoint, it takes about 15 minutes for the change to take effect.

Configure SharePoint document libraries with a default label to extend permissions

For each SharePoint document library that you want to have this configuration, follow the instructions for Add a sensitivity label to SharePoint document library, and select the checkbox **Extend protection on download, copy or move**:

You won't see this checkbox until the previous PowerShell command has completed.

After you've selected a sensitivity label that applies encryption with user-defined permissions, save the configuration.

> **Note**
>
> This feature is mutually exclusive with the option to select a default sensitivity label for a SharePoint document library that supports sensitivity labels without encryption, and sensitivity labels that are configured with the option **Assign permissions now** (sometimes referred to as "admin-defined permissions").

The selected sensitivity label will be applied to all files that are unlabeled, and files that are labeled but the label configuration doesn't apply encryption. The **Sensitivity** column for the document library displays your selected label for existing, new, and edited files. Users see the selected label displayed when they open the file for editing but won't experience any changes in permissions as a result of the label.

After the library is configured with the sensitivity label, all existing files will be resynchronized if the library is synced via the OneDrive sync client. The resynchronization process can take a while and until it's complete, the extended protection won't be applied.

> **Important**
>
> In the SharePoint document library that you've configured for the sensitivity label, users can't remove the applied sensitivity label in their Office apps and can change it only if the replacement label applies encryption.

Monitoring application of the sensitivity label that extends SharePoint permissions

Because this configuration extends the functionality of a default sensitivity label for a document library, you monitor its configuration in the same way. The sensitivity label GUID will identify the encryption configuration for user-defined permissions. There's no separate labeling auditing event for when a file is downloaded, copied, or moved.

How to turn off this feature

If you want a specific SharePoint document library to no longer extend permissions with a sensitivity label, clear the **Extend protection on download, copy or move** checkbox as a SharePoint document library setting. Then:

- Files in the document library that were previously labeled with this configuration will revert to either their original label that didn't apply encryption, or unlabeled if that was their original status before the checkbox was selected.
- Files synchronized with OneDrive will be resynchronized and similarly revert to their previous label status. The resynchronization process can take a while and until it's complete, the extended protection will remain.
- Labeled files that are now downloaded retain their label.

If you want to turn off this feature at the tenant-level when it has been previously enabled and configured, first clear the **Extend protection on download, copy or move** checkbox from all document libraries where it's been selected. Then, use the same Set-SPOTenant cmdlet with the *ExtendPermissionsToUnprotectedFiles* parameter, but set the value to **false**. Then:

- The **Extend protection on download, copy or move** checkbox is no longer visible as a SharePoint document library setting.

If you turn off the feature at the tenant level without first clearing the checkbox for a document library, the configuration remains but without the checkbox to turn it off.

In this scenario, to turn off the configuration, run the PowerShell command to enable support to extend SharePoint permissions to display the checkbox again, so you can clear it. If you don't want to reenable support at the tenant level, contact Microsoft Support to talk you through PowerShell commands to remove the configuration for a specific document library.

Next steps

Although this configuration provides immediate protection at scale for files stored in SharePoint, it doesn't take into account the file contents that might require a higher level of protection. Consider supplementing this labeling method with automatic labeling that uses content inspection to apply sensitivity labels with encryption.

Enable co-authoring for files encrypted with sensitivity labels

> *Microsoft 365 licensing guidance for security & compliance*.

Enable the setting to support co-authoring for Office desktop apps so that when documents are labeled and encrypted by sensitivity labels, multiple users can edit these documents at the same time.

Without this setting enabled for your tenant, users must check out an encrypted document stored in SharePoint or OneDrive when they use Office desktop apps. As a result, they can't collaborate in real time. Or, they must use Office for the web when sensitivity labels are enabled for Office files in SharePoint and OneDrive.

In addition, enabling this functionality results in the AutoSave functionality being supported for these labeled and encrypted files.

For the release announcement, see the blog post Co-authoring on Microsoft Information Protection encrypted documents is now generally available.

Metadata changes for sensitivity labels

> **Important**
>
> After you enable the setting for co-authoring, labeling information for unencrypted files is no longer saved in custom properties.
>
> Don't enable this setting if you use any apps, services, scripts, or tools that read or write labeling metadata to the old location.

Before you enable the setting to support co-authoring for Office desktop apps, understand that this action changes the labeling metadata that Office files save and read.

The labeling metadata includes information that identifies your tenant and applied sensitivity label. The change that this setting makes is the metadata format and location for Word, Excel, and PowerPoint files. You don't need to take any action for encrypted files or emails because the metadata change for encrypted files is backward-compatible, and there are no changes for emails. However, you do need to be aware of the metadata changes for encrypted files that can be automatically upgraded but aren't backward-compatible.

This change affects both newly labeled files and already labeled files. When you use apps and services that support the co-authoring setting:

- For files that are newly labeled, only the new format and location is used for the labeling metadata.
- For files that are already labeled, the next time the file is opened and saved, if the file has metadata in the old format and location, that information is copied to the new format and location.

For more information about this metadata change, see the following resources:

- Blog post: Upcoming Changes to Microsoft Information Protection Metadata Storage
- Open Specifications: 2.6.3 LabelInfo versus Custom Document Properties

Because of these changes, don't enable this setting if your organization has any apps, services, scripts, or tools that read or write labeling metadata to the old location. If you enable this setting, some example consequences include:

- A document that is labeled appears to users as unlabeled.
- A document displays an out-of-date label to users.
- Co-authoring and AutoSave don't work for a labeled and encrypted document if another user has it open in a Office desktop app that doesn't support the new labeling metadata. Be aware that this scenario can also occur for users outside your organization if external users and invited guests have the file open.
- An Exchange Online mail flow rule that identifies labels as custom properties in Office attachments fails to encrypt the email and attachment, or incorrectly encrypts them.

For a list of apps and services that support this setting and the changes to the labeling metadata, see the following section.

Prerequisites

Make sure you understand the following prerequisites before you turn on this feature.

- To turn this capability on or off, you need at least the DLP Compliance Management or Information Protection Admin role. Alternative roles include the Security Administrator and Compliance Administrator roles.
- Sensitivity labels must be enabled for Office files in SharePoint and OneDrive for the tenant. If this feature isn't already enabled, it is automatically enabled when you select the setting to turn on co-authoring for files with sensitivity labels.

- Microsoft 365 Apps for enterprise:
  - **Windows**: Minimum version 2107 from Current Channel or Monthly Enterprise Channel, or minimum version 2202 from Semi-Annual Enterprise Channel
  - **macOS**: Minimum version 16.51
  - **iOS**: Minimum version 2.58
  - **Android**: Minimum version 16.0.14931

- All apps, services, and operational tools in your tenant must support the new labeling metadata. If you use any of the following apps or services, check the minimum versions required:

  - **Microsoft Purview Information Protection client and scanner:**
    - Minimum version of 3.0 that you can install from the Microsoft Download Center, or minimum version of 2.12.62.0 for the older Azure Information Protection unified labeling client and scanner

  - **OneDrive sync app for Windows or macOS:**
    - Minimum version of 19.002.0121.0008

  - **Endpoint data loss prevention (Endpoint DLP):**
    - Windows 10 1809 with KB 4601383
    - Windows 10 1903 and 1909 with KB 4601380
    - Windows 10 2004 with KB 4601382
    - Windows versions later than Windows 10 2004 are supported without KB updates

  - **Apps and services that use the Microsoft Information Protection SDK:**
    - Minimum version of 1.7

Microsoft 365 services automatically support the new labeling metadata when you turn on this feature. For example:

- Auto-labeling policies
- DLP policies that use sensitivity labels as conditions
- Microsoft Defender for Cloud Apps configured to apply sensitivity labels

Limitations

Before you enable the tenant setting for co-authoring for files encrypted with sensitivity labels, make sure you understand the following limitations of this feature.

- Because of the labeling metadata changes, all apps, services, and operational tools in your tenant must support the new labeling metadata for a consistent and reliable labeling experience.

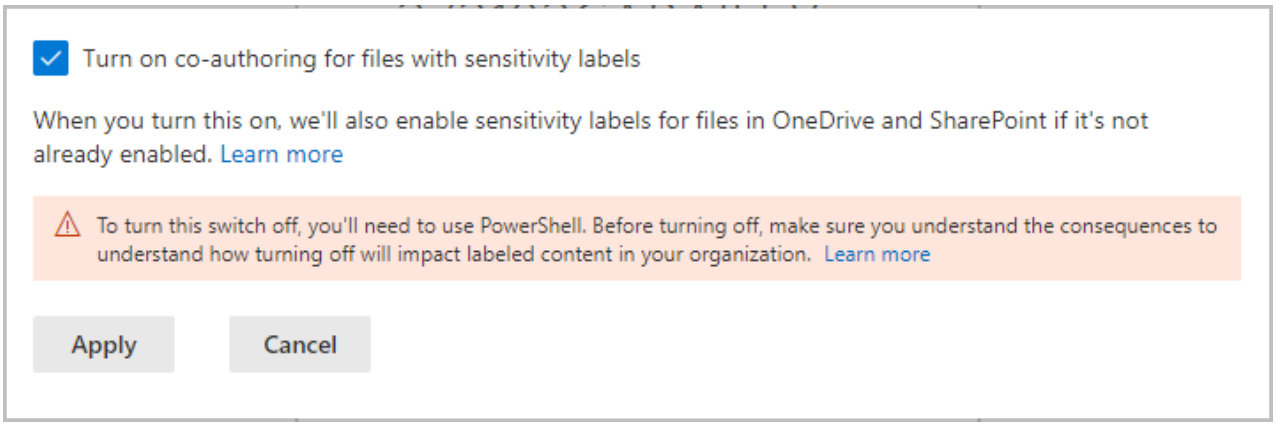
Specific to Excel: Metadata for a sensitivity label that doesn't apply encryption can be deleted from a file if somebody edits and saves that file by using a version of Excel that doesn't support the metadata changes for sensitivity labels.

- Co-authoring and AutoSave aren't supported for Office documents that use the label encryption configuration **User access to content expires** when it's set to a value other than **Never**, or **Double Key Encryption** is configured.

  Labels with these configurations do still display in Office apps. However, when users select these labels and nobody else is editing the document, they're warned that co-authoring and AutoSave won't be available. If somebody else is editing the document, users see a message that the labels can't be applied.

- Co-authoring and AutoSave are supported with specific versions and limitations for sensitivity labels that are configured for user-defined permissions. This encryption configuration refers to the setting **Let users assign permissions when they apply the label** and the checkbox **In Word, PowerPoint, and Excel, prompt users to specify permissions** is selected.

How to enable co-authoring for files with sensitivity labels



> ⊗ **Caution**
>
> Enable this option only after you read and understand the metadata changes, prerequisites, limitations, and any known issues documented on this page.

For this configuration, use an account that has at least the DLP Compliance Management or Information Protection Admin role.

1. Sign in to the Microsoft Purview portal > **Settings** > **Solution settings** > **Information Protection** > **Co-authoring for files with sensitivity labels**.

2. On the **Co-authoring for files with sensitivity labels** page, read the summary description, prerequisites, and what to expect.

   Then select **Turn on co-authoring for files with sensitivity labels**, and **Apply**:

3. Wait 24 hours for this setting to replicate across your environment before you use this new feature for co-authoring.

If you need to disable this feature

> **Important**
>
> If you do need to disable this feature, for example, you've discovered some apps don't support the metadata changes and you can't immediately update these apps, be aware that labeling information can be lost.

After you enable co-authoring for files with sensitivity labels for your tenant, you can't disable this setting in the Microsoft Purview portal. This action is supported only by using PowerShell. This setting isn't one that you casually disable. Check and understand the prerequisites, consequences, and limitations before you enable the setting.

If you do disable this setting for your tenant:

- For apps and services that support the new labeling metadata, they now revert to the original metadata format and location when labels are read or saved.
- The new metadata format and location for Office documents that were used while the setting was enabled won't be copied to the original format and location. As a result, this labeling information for unencrypted Word, Excel, and PowerPoint files will be lost.
- Co-authoring and AutoSave no longer work in your tenant for labeled and encrypted documents.
- Sensitivity labels remain enabled for Office files in OneDrive and SharePoint.

To disable co-authoring for your tenant

Use the Set-PolicyConfig cmdlet with the *EnableLabelCoauth* parameter.

1. In a PowerShell session, connect to Security & Compliance PowerShell.
2. Run the following command:

```
PowerShell
Set-PolicyConfig -EnableLabelCoauth:$false
```

The command completes without a prompt or confirmation.

Use sensitivity labels to configure the default sharing link type for sites and documents in SharePoint and OneDrive

09/26/2025

> *Microsoft 365 licensing guidance for security & compliance*.

As an additional configuration to the settings you see in the Microsoft Purview portal for sensitivity labels, you can use these labels to configure settings for the default sharing link type for a SharePoint site or OneDrive account, and for individual documents. These settings are automatically selected, but not highly visible to users when they select the **Share** button in their Office apps. As an example:

The default sharing link type sets the scope (who) and permissions (view or edit) that are automatically selected when users share files and folders. Although users can always override these default settings before sending the sharing link, the settings you choose provide a safe baseline. Typically, users don't change the settings before sharing.

At the site level (SharePoint site or OneDrive account), sensitivity labels provide a convenient alternative for setting the default sharing link type that can be configured for a site in the SharePoint admin center. For more information, see Change the default link type for a site from the SharePoint documentation.

This site-level configuration works well for SharePoint sites that have documents all with the same level of sensitivity. But if sites contain some documents that have a higher level of sensitivity that require more restrictive settings, you can configure a sensitivity label with different settings for the default sharing link type, and then apply this label to documents.

In this scenario where the site has default sharing link type settings, and a document in that site has different default link type settings, the more restrictive scope settings will be applied at the time the user selects the sharing option for the document. For example:

- The default sharing link type for the site is scoped to anybody in your organization. A document in that site is labeled with the default sharing link type set to specific people. When a user shares that document, the default sharing link type selected will be scoped to specific people.

- The default sharing link type for the site is scoped to specific people, with edit permissions. A document in that site is labeled with the default sharing link type set to anybody in the organization, with view permissions. When a user shares that document, the default sharing link type selected will be scoped to specific people with edit permissions.

Configuring the default link type for documents might also be appropriate without the site-level setting. For example, although SharePoint sites are typically organized to host the same type of documents, that isn't the case for OneDrive accounts. Users typically save a wide range of files to OneDrive, often including a mix of personal and business documents. Setting a default link type for all documents for a user's OneDrive account is probably not practical, but individual documents can still benefit from these settings. For example:

- Documents labeled **Highly Confidential** have a default sharing link type that restricts sharing to specific people rather than anybody in the organization.
- Documents labeled **General** have a default sharing link type that restricts sharing to people in your organization.
- Documents labeled **Personal** have a default sharing link type that allows sharing to anyone with the link.

Prerequisites

To apply the default sharing link type for sites, sensitivity labels must be enabled for containers. If this capability isn't yet enabled for your tenant, see How to enable sensitivity labels for containers and synchronize labels.

To apply the default sharing link type for documents in SharePoint and OneDrive, sensitivity labels must be enabled for these services. If this capability isn't yet enabled for your tenant, see How to enable sensitivity labels for SharePoint and OneDrive (opt-in).

In a PowerShell session, you must connect to Security & Compliance PowerShell to configure the settings for the default sharing link type.

> **Note**
>
> Although not required, it's easiest to first create and configure sensitivity labels in the Microsoft Purview portal, and then modify these labels with the settings that configure the default sharing link type.

How to configure settings for the default sharing link type

The configuration settings for the default sharing link type use the PowerShell *AdvancedSettings* parameter with the Set-Label and New-Label cmdlets from Security & Compliance PowerShell:

- **DefaultSharingScope**: The available values are:
  - **SpecificPeople**: Sets the default sharing link to specific people (only the people the user specifies)
  - **Organization**: Sets the default sharing link for only people in your organization
  - **Anyone**: Sets the default sharing link to anyone with the link, which is equivalent to anonymous access

- **DefaultShareLinkPermission**: The available values are:
  - **View**: Sets the default link permission to view permissions
  - **Edit**: Sets the default link permission to edit permissions

These two settings and values are the equivalent of the parameters *DefaultSharingScope* and *DefaultShareLinkPermission* from the Set-SPOSite cmdlet.

Another configuration for the default sharing link type is to use the **DefaultShareLinkToExistingAccess** advanced setting, which is the equivalent of the parameter

DefaultLinkToExistingAccess from the Set-SPOSite cmdlet. When you set this value to **True**, it overrides the other two advanced settings and their values.

PowerShell examples, where the sensitivity label GUID is **8faca7b8-8d20-48a3-8ea2-0f96310a848e**:

- To set the default sharing link type to SpecificPeople:

  PowerShell

  ```
  Set-Label -Identity 8faca7b8-8d20-48a3-8ea2-0f96310a848e -AdvancedSettings
  @{DefaultSharingScope="SpecificPeople"}
  ```

- To set the default sharing link type permissions to Edit:

  PowerShell

  ```
  Set-Label -Identity 8faca7b8-8d20-48a3-8ea2-0f96310a848e -AdvancedSettings
  @{DefaultShareLinkPermission="Edit"}
  ```

- To set the default sharing link type to people with existing access:

  PowerShell

  ```
  Set-Label -Identity 8faca7b8-8d20-48a3-8ea2-0f96310a848e -AdvancedSettings
  @{DefaultShareLinkToExistingAccess="True"}
  ```

For more help to specify PowerShell advanced settings, see PowerShell tips for specifying the advanced settings.

To configure the settings for the default sharing link type for a site, the scope of the sensitivity label must include **Groups & sites** when you create the sensitivity label in the Microsoft Purview portal. After it's created, you see this displayed as **Site, UnifiedGroup** in the **Scope** column on the **Labels** page, and the PowerShell *ContentType* setting also displays this same value. For documents, the scope must include **Files & other data assets**, which displays as **File, Email**. Then:

- When the scope includes **Groups & sites**, you can apply the label to a site, which sets the default sharing link type for that site. For information how to apply a sensitivity label to a site, see How to apply sensitivity labels to containers.

- When the scope of the sensitivity label includes **Files & other data assets**, you can apply the label to documents, which sets the default sharing link type for that document. The label can be applied manually or automatically.

Tip

You can also specify that the label is the default sensitivity label to be applied for new sites or new documents, as a **label policy setting**.

Manage sensitivity labels in Office apps

> *Microsoft Purview service description*

When you have published sensitivity labels from the Microsoft Purview portal, they start to appear in Office apps for users to classify and protect data as it's created or edited.

This article helps you successfully manage sensitivity labels in Office apps. For example, you can find additional configuration information for specific labeling features.

Sensitivity labeling support in apps

To use sensitivity labels in Office apps, you must use a subscription edition of Office. Use the licensing link at the top of this page to identify eligible plans. Sensitivity labels aren't supported for standalone editions of Office, sometimes called "Office Perpetual".

For Outlook (Windows, macOS, iOS, Android, and on the web), the mailbox must be hosted in Exchange Online. Sensitivity labels aren't supported for mailboxes that are hosted on-premises. This on-premises limitation also applies to shared mailboxes, even if the users accessing them have mailboxes in Exchange Online.

Support for sensitivity label capabilities in apps

Use the tables in Minimum versions for sensitivity labels in Office apps to identify the minimum Office version that introduced specific capabilities for sensitivity labels in Office apps, or whether the label capability is in public preview.

In addition to listing the minimum versions for Windows, macOS, iOS, and Android, the tables also include whether the capability is supported for Office for the web:

- Capabilities table for Word, Excel, and PowerPoint
- Capabilities table for Outlook

Office for iOS and Office for Android: Sensitivity labels are built into the Office app.

For information about Loop, see Use sensitivity labels with Microsoft Loop.

> **Tip**

Label and policy settings that refer to Office documents also apply to Loop components and pages.

Office built-in labeling and the Azure Information Protection client

The Windows Office add-in from the Azure Information Protection unified labeling client is now retired and no longer supported. It's replaced by sensitivity labels that are built into Office apps that support labeling.

Because the add-in is no longer supported, the Office policy setting **Use the Azure Information Protection add-in for sensitivity labeling** must be set to **Not configured** (the default), or **Disabled**. If this setting is configured for **Enabled**, you won't be able to use sensitivity labeling in Office apps.

To check for this setting:

- If you're using Group Policy, use the latest Microsoft 365 Apps for enterprise administrative templates and navigate to this setting from **User Configuration/Administrative Templates/Microsoft Office 2016/Security Settings**.
- If you're using the Cloud Policy service for Microsoft 365, search for the setting by name.

The other labeling capabilities from this older labeling client are supported with the Microsoft Purview Information Protection client. For more information, see Extend sensitivity labeling on Windows.

If you need to turn off built-in labeling in Office apps on Windows

To use sensitivity labeling in Office apps, you must have one or more label policies published to users from the Microsoft Purview portal, and a supported version of Office.

If both of these conditions are met but you need to turn off sensitivity labels in Windows Office apps, use the Office policy setting **Use the Sensitivity feature in Office to apply and view sensitivity labels**. Set the value to 0 by selecting **Disabled**.

For Group Policy and Microsoft 365 Apps for enterprise administrative templates, navigate to this setting from **User Configuration/Administrative Templates/Microsoft Office 2016/Security**

Settings. If you're using the Cloud Policy service for Microsoft 365, search for this setting by name. The setting takes effect when these Office apps restart.

If you later need to revert this configuration, change the value to 1 by selecting **Enabled**. You might also need to enable this setting if the **Sensitivity** button isn't displayed on the ribbon as expected. For example, a previous administrator turned this labeling setting off.

Because this setting is specific to Windows Office apps, it has no impact on other apps on Windows that support sensitivity labels (such as Power BI) or other platforms (such as macOS, mobile devices, and Office for the web). If you don't want some or all users to see and use sensitivity labels across all apps and all platforms, don't assign a sensitivity label policy to those users.

> **Tip**
>
> If you want to display built-in labels for only Outlook or for only Word, Excel, and PowerPoint, you can achieve this outcome with a per-label setting. For more information, see Scope labels to just files or emails.

Office file types supported

Generally, Office apps that have built-in labeling for Word, Excel, and PowerPoint files support the Open XML format (such as .docx and .xlsx) but not the Microsoft Office 97-2003 format (such as .doc and .xls), Open Document Format (such as .odt and .ods), or other formats.

> **Note**
>
> You can prevent users from opening or saving the older file types for Word, Excel, and PowerPoint in Windows. For instructions, see Block specific file format types in Office 2016.

When a file type isn't supported for sensitivity labels, the **Sensitivity** button isn't available in the Office app.

Supported file types for Office apps on Windows, macOS, iOS, and Android:

- **Word**: .docx, .docm, .dotx, .dotm
- **Excel**: .xlsx, .xlsb; .xlsm, .xltm, .xltx
- **PowerPoint**: .pptx, .pptm, .potx, .potm, .ppsx, .ppsm

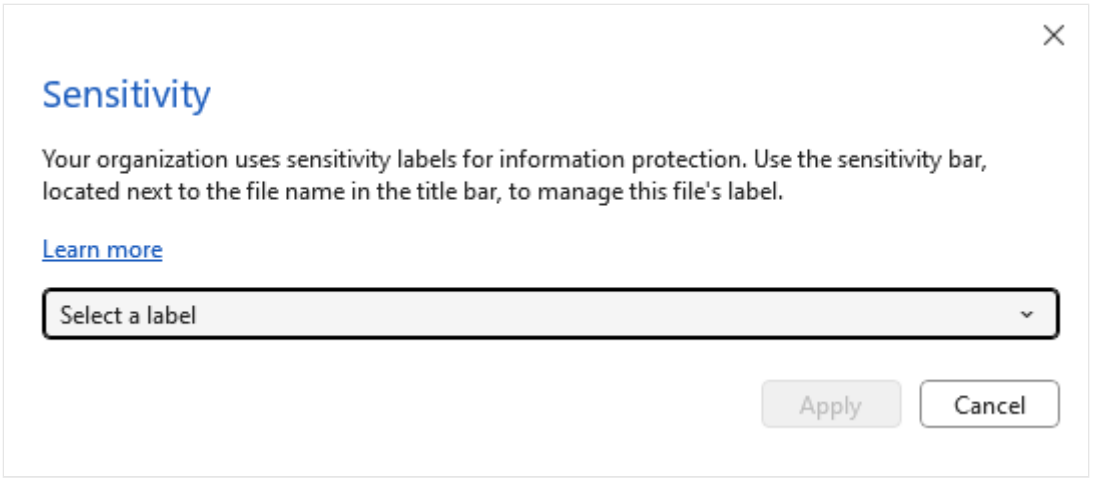
For file types supported for SharePoint and OneDrive when these services are enabled for sensitivity labels, see Enable sensitivity labels for files in SharePoint and OneDrive.

Labeling for embedded files isn't supported, even with the listed file types.

For labeling scenarios outside Office apps, check their documentation for file types supported. For example, the additional file types supported by the Microsoft Purview information protection client and scanner.

Protection templates and sensitivity labels

Administrator-defined protection templates, such as those you define for Microsoft Purview Message Encryption, aren't visible in Office apps when you're using built-in labeling. This simplified experience reflects that there's no need to select a protection template, because the same settings are included with sensitivity labels that have encryption enabled.



You can convert an existing template into a sensitivity label when you use the New-Label cmdlet with the *EncryptionTemplateId* parameter.

Information Rights Management (IRM) options and sensitivity labels

Sensitivity labels that you configure to apply encryption remove the complexity from users to specify their own encryption settings. In Office apps, these individual encryption settings might still be manually configured by users by using Information Rights Management (IRM) options. For example, for Windows apps:

- For a document: **File** > **Info** > **Protect Document** > **Restrict Access**
- For an email: From the **Options** tab > **Encrypt**

The latest Word, Excel, and PowerPoint apps for Windows and Mac no longer let users select Information Rights Management (IRM) options when they have sensitivity labels. Instead, users see a dialog box that prompts them to use a sensitivity label to apply information protection. The message also explains how to later access the sensitivity bar to select and change labels:

For Outlook and older Office apps that let users select Information Rights Management options, users can override settings from an applied sensitivity label with their own encryption settings. For example:

- A user applies the **Confidential \ All Employees** label to a document and this label is configured to apply encryption settings for all users in the organization. This user then manually configures the IRM settings to restrict access to a user outside your organization. The end result is a document that's labeled **Confidential \ All Employees** and encrypted, but users in your organization can't open it as expected.

- A user applies the **Confidential \ Recipients Only** label to an email and this email is configured to apply the encryption setting of **Do Not Forward**. In the Outlook app, this user then manually selects the IRM setting for Encrypt-Only. The end result is that while the email does remain encrypted, it can be forwarded by recipients, despite having the **Confidential \ Recipients Only** label.

  As an exception, for Outlook on the web, the options from the **Encrypt** menu aren't available for a user to select when the currently selected label applies encryption.

- A user applies the **General** label to a document, and this label isn't configured to apply encryption. This user then manually configures the IRM settings to restrict access to the document. The end result is a document that's labeled **General** but that also applies encryption so that some users can't open it as expected.

If the document or email is already labeled, a user can do any of these actions if the content isn't already encrypted, or they have the usage right Export or Full Control.

Guidance for a consistent label experience

For a more consistent label experience with meaningful reporting, provide appropriate labels and guidance for users to apply only labels to protect documents and emails. For example:

- For exception cases where users must assign their own permissions, provide labels that let users assign their own permissions.
- Instead of users manually removing encryption after selecting a label that applies encryption, provide a sublabel alternative when users need a label with the same classification, but no encryption. Such as:
  - **Confidential \ All Employees**
  - **Confidential \ Anyone (no encryption)**
- Upgrade to the latest versions that don't let users select IRM settings for Word, Excel, and PowerPoint. For Outlook, consider disabling IRM settings to prevent users from selecting them:
  - Outlook for Windows:
    - Registry keys `DWORD:00000001` *DisableDNF* and *DisableEO* from `HKEY_CURRENT_USER\Software\Microsoft\Office\16.0\Common\DRM`
    - Make sure that the Group Policy setting **Configure default encryption option for the Encrypt button** isn't configured
  - Outlook for Mac:
    - Keys *DisableEncryptOnly* and *DisableDoNotForward* security settings documented in Set preferences for Outlook for Mac
  - Outlook on the web:
    - Parameters *SimplifiedClientAccessDoNotForwardDisabled* and *SimplifiedClientAccessEncryptOnlyDisabled* documented for Set-IRMConfiguration
  - Outlook for iOS and Android: These apps don't support users applying encryption without labels, so nothing to disable.

> ⓘ **Note**
>
> If users manually remove encryption from a labeled document that's stored in SharePoint or OneDrive and you've **enabled sensitivity labels for Office files in SharePoint and OneDrive**, the label encryption will be automatically restored the next time the document is accessed or downloaded.

Encryption-based label matching for documents

When a document has been encrypted with administrator-defined permissions, the encryption policy is embedded in the document. This happens independently from labeling. For example, when an Office attachment inherits encryption from an email message, or a user has applied a rights management template by using Information Rights Management (IRM) in their Office app. If a sensitivity label in the tenant matches that same encryption policy, Office apps will automatically assign that matching label to the document.

In this scenario, the matching sensitivity label can label an unlabeled document, and replace an existing label that doesn't apply encryption. For example, the **General** label is replaced with **Confidential / All Employees**. Content markings from the matching label aren't automatically applied.

This scenario helps to move older encryption solutions from rights management templates to sensitivity labels that apply encryption with rights management.

However, you'll also see this behavior with a labeling scenario for email and meetings attachments when they are opened by the recipient. For example:

1. A user creates an email and attaches an unencrypted Office document, and then applies a label to the email.

   The label applies encryption with permissions that are set by the administrator, rather than the Do Not Forward or Encrypt-Only options. For example, for the label configuration, the admin selects **Assign permissions now**, and specifies all employees have read access.

2. When the email is sent, the attachment automatically inherits the encryption with rights management, but not the label.

3. When a recipient in the same tenant opens the encrypted document, a matching label for the admin-defined permissions is automatically displayed for the document, and persists if the document is saved.

   As an auditing event that's displayed in activity explorer, this user applied the label, not the email sender.

Encryption-based label matching works only within the tenant, and all the following conditions apply:

- The document is unlabeled or the existing label doesn't apply encryption
- The document is encrypted with admin-defined permissions
- The matching sensitivity label is published to the user who opens the document

- The label scope of the matching sensitivity label includes **Files & other data assets**

The matching label persists if the document is saved.

Sensitivity label compatibility

With RMS-enlightened apps: If you open a labeled and encrypted document or email in an application that supports the Microsoft rights management (RMS) technology but doesn't support sensitivity labels, the app still enforces encryption and rights management.

With the Microsoft Purview Information Protection client: You can view and change sensitivity labels that you apply to documents with Office apps by using the Microsoft Purview Information Protection client, and you can view and change labels applied by the Microsoft Purview Information Protection client in Office apps.

With other versions of Office: Any authorized user can open labeled documents and emails in other versions of Office. However, you can only view or change the label in supported Office versions or by using the Microsoft Purview Information Protection client. Supported Office app versions are listed in the previous section.

Support for SharePoint and OneDrive files protected by sensitivity labels

To use the Office built-in labeling client with Office for the web for documents in SharePoint or OneDrive, make sure you've enabled sensitivity labels for Office files in SharePoint and OneDrive.

Support for external users and labeled content

When you label a document or email, the label is stored as metadata that includes your tenant and a label GUID. When a labeled document or email is opened by an Office app that supports sensitivity labels, this metadata is read and only if the user belongs to the same tenant, the label displays in their app. For example, for built-in labeling for Word, PowerPoint, and Excel, the label name displays on the status bar. This behavior excludes guest accounts.

This implementation means that if you share documents with another organization that uses different label names, each organization can apply and see their own label applied to the document. Guest users won't see your labels in their apps.

> ⓘ **Note**

Two exceptions where another organization can't apply their own sensitivity labels:

- Using Office for the web, external users connect to your SharePoint sites or OneDrive locations and don't see their sensitivity labels because the site is owned by another organization.
- Using co-authoring from desktop or mobile apps, external users won't be able to apply their own sensitivity labels that are configured to apply encryption.

The same is true for email (and labeled calendar events) sent by Outlook. However, email clients other than Outlook might not retain the label metadata in the email headers. For example, users replying or forwarding from another organization that doesn't use Outlook will likely result in the original email label no longer visible to the original organization because the label metadata hasn't been retained. If that label applied encryption, the encryption persists to protect the contents.

The following elements from an applied label are visible to users outside your organization:

- Content markings. When a label applies content markings that include a header, footer, or watermark, these are added directly to the content and remain visible until somebody modifies or deletes them.
- The name and description of the underlying protection template from a label that applied encryption. This information can be displayed in a message bar at the top of the content, to provide information about who is authorized to view the content, and their usage rights for that content.

Sharing encrypted documents with external users

Although you can restrict access to users in your own organization, you can also extend access to any other user who has an account in Microsoft Entra ID. By default, these external users will be authenticated without any additional configuration. However, there might be additional configuration required for Microsoft Entra External Identities cross-tenant access settings and Conditional Access.

If external users don't have an account in Microsoft Entra ID, they can authenticate by using guest accounts in your tenant. These guest accounts can also be used to access shared documents in SharePoint or OneDrive when you have enabled sensitivity labels for Office files in SharePoint and OneDrive.

For more information about the optional Microsoft Entra features and using guest accounts for authentication requirements, see Microsoft Entra configuration for encryption content.

All Office apps and other applications that understand rights management technology from Microsoft can open encrypted documents after the user has successfully authenticated.

Because dynamic watermarks are an encryption setting, they're supported across organizations and will display the name of the person who opens the document as a result of a sensitivity label that's published in another tenant.

When Office apps apply content marking and encryption

Office apps apply content marking and encryption with a sensitivity label differently, depending on the app you use.

Expand table

App	Content marking	Encryption
Word, Excel, PowerPoint on all platforms	Immediately	Immediately
Outlook (classic) for PC	After Exchange Online sends the email or meeting invite	Immediately
Outlook for Mac *, new Outlook for Windows, Outlook on the web, iOS, and Android	After Exchange Online sends the email or meeting invite	After Exchange Online sends the email or meeting invite

* Version 16.79+ with the new Outlook for Mac. Earlier versions encrypt immediately.

For emails, content marking can be applied more than once if the message is processed by the Exchange transport service more than once. For example, you're using a third-party signature service for emails that are sent outside the organization.

Because Outlook for Mac, new Outlook for Windows, Outlook on the web, iOS, and Android don't encrypt items locally, copies stored in the Sent folder also aren't encrypted. If users send items from their Sent folders (for example, to forward or Reply All), instruct them to first remove and then reapply the sensitivity label that applies encryption

Solutions that apply sensitivity labels to files outside Office apps do so by applying labeling metadata to the file. In this scenario, content marking from the label's configuration isn't inserted into the file but encryption is applied. The content markings aren't automatically applied when you open those documents in Office apps. Similarly, the content markings aren't removed when a label is removed outside Office apps, even if those documents are then later opened in an Office app.

Scenarios that include applying a sensitivity label outside Office apps include:

- The scanner, File Explorer, and PowerShell from the Microsoft Purview Information Protection client
- Auto-labeling policies for SharePoint and OneDrive
- Exported labeled and encrypted data from Power BI
- Automatically applied labels from Microsoft Defender for Cloud Apps

For these scenarios, using their Office apps, a user can apply the label's content markings by temporarily removing or replacing the current label and then reapplying the original label.

Content markings with variables

> **Important**
>
> If your Office apps don't support this capability, they apply the markings as the original text specified in the label configuration, rather than resolving the variables. See the tables in Minimum versions for sensitivity labels in Office apps.

When you configure a sensitivity label for content markings, you can use the following variables in the text string for your header, footer, or watermark:

Expand table

Variable	Description	Example when label applied
`${Item.Label}`	Label display name of the label applied	**General**
`${Item.Name}`	File name or email subject of the content being labeled	**Sales.docx**
`${Item.Location}`	Path and file name of the document being labeled, or the email subject for an email being	**\\Sales\2020\Q3\Report.docx**

Variable	Description	Example when label applied
	labeled	
`${User.Name}`	Display name of the user applying the label	**Richard Simone**
`${User.PrincipalName}`	Microsoft Entra user principal name (UPN) of the user applying the label	**rsimone@contoso.com**
`${Event.DateTime}`	Date and time when the content is labeled, in the local time zone of the user applying the label in Microsoft 365 apps, or UTC (Coordinated Universal Time) for Office Online and auto-labeling policies	**8/10/2020 1:30 PM**

> **Note**
>
> The syntax for these variables is case-sensitive.

Dynamic watermarks also support inserting the email address of a user. However, content marking with a variable uses the email address of the user applying the label, which is suitable for accountability. Dynamic watermarks display the email address of the user who is currently opening the document, which acts as a visual deterrent against data leakage.

Additional considerations:

- All content markings with or without variables can be applied with labels that don't apply encryption. Dynamic watermarks can only be applied with labels that apply encryption.
- All content markings with or without dynamic variables can be changed or removed by the user after it's applied to the labeled content. Dynamic watermarks, once applied, can't be changed or removed without removing the label or exporting (if allowed) the content.
- All content markings with or without dynamic variables can be customized with different fonts, colors, orientation. Dynamic watermarks don't support this customization.

The restrictions that come with dynamic watermarks provide more security, but could also prevent the document from opening in a desktop version of Office that doesn't support this capability. Use dynamic watermarks only when you need this level of protection, and standard content marking when you don't. For detailed information, see the Dynamic watermarks documentation.

Setting different content markings for Word, Excel, PowerPoint, and Outlook

As an additional variable, you can configure content markings per Office application type by using an "If.App" variable statement in the text string, and identify the application type by using the values **Word**, **Excel**, **PowerPoint**, or **Outlook**. You can also abbreviate these values, which is necessary if you want to specify more than one in the same If.App statement.

Use the following syntax:

```
${If.App.<application type>}<your visual markings text> ${If.End}
```

As with the other content markings, the syntax is case-sensitive, which includes the abbreviations for each application type (WXPO).

Examples:

- **Set header text for Word documents only:**

  `${If.App.Word}This Word document is sensitive ${If.End}`

  In Word document headers only, the label applies the header text "This Word document is sensitive". No header text is applied to other Office applications.

- **Set footer text for Word, Excel, and Outlook, and different footer text for PowerPoint:**

  `${If.App.WXO}This content is confidential. ${If.End}${If.App.PowerPoint}This presentation is confidential. ${If.End}`

  In Word, Excel, and Outlook, the label applies the footer text "This content is confidential." In PowerPoint, the label applies the footer text "This presentation is confidential."

- **Set specific watermark text for Word and PowerPoint, and then watermark text for Word, Excel, and PowerPoint:**

  `${If.App.WP}This content is ${If.End}Confidential`

  In Word and PowerPoint, the label applies the watermark text "This content is Confidential". In Excel, the label applies the watermark text "Confidential". In Outlook, the label doesn't apply any watermark text because watermarks as content markings aren't supported for Outlook.

Require users to apply a label to their email and documents

> **Important**
>
> This configuration is sometimes referred to as mandatory labeling. To check for supported Office versions, see the tables in Minimum versions for sensitivity labels in Office apps.
>
> To use mandatory labeling for documents but not emails, see the instructions in the next section that explains how to configure Outlook-specific options.
>
> To use mandatory labeling for Power BI, see Mandatory label policy for Power BI.

When the policy setting **Require users to apply a label to their email and documents** is selected, users assigned the policy must select and apply a sensitivity label in their Office apps:

- For documents (Word, Excel, PowerPoint): When an unlabeled document is opened or saved.
- For emails (Outlook): At the time users send an unlabeled email message. For Outlook Mobile, this can be changed to when the email message is first composed.

Additional information:

- Unlabeled means a sensitivity label published from the user's tenant isn't applied to the content. Sensitivity labels applied by other tenants are ignored by this policy setting.
- When users are prompted to add a sensitivity label because they open an unlabeled document, they can add a label or choose to open the document in read-only mode.
- When mandatory labeling is in effect, users can't remove sensitivity labels from documents, but can change an existing label.
- When mandatory labeling is in effect, the print to PDF option will be unavailable when a document is labeled or encrypted. For more information, see the PDF support section on this page.
- When mandatory labeling is configured together with auto-labeling for Office apps for the same user, the user can be prompted to apply a label before auto-labeling is triggered. Because auto-labeling doesn't override a manually applied sensitivity label but can override

a default label, a potential workaround for this timing issue is to configure a default label for the user who is configured for both mandatory labeling and auto-labeling for Office apps.

For guidance about when to use this setting for mandatory labeling, see the information about policy settings.

> **Note**
>
> If you use the default label policy setting for documents and emails in addition to mandatory labeling:
>
> The default label always takes priority over mandatory labeling. However, if you use a version of Office that doesn't yet support a default label for existing documents, users will be prompted to apply a sensitivity label for each new document.
>
> Identify the minimum versions of Word, Excel, and PowerPoint that support a default label for existing documents by using the capabilities table and the row **Apply a default label to existing documents**.

For Outlook Mobile, change when users are prompted for a label

This setting requires a minimum version of 4.2316.0 for Outlook for Android and Outlook for iOS.

You can use a Microsoft Intune Managed apps app configuration policy to configure a setting from the Intune App Software Development Kit (SDK) that changes when users are prompted to select a sensitivity label for Outlook Mobile.

Instead of prompting for a label on send when mandatory labeling is configuring for emails, this configuration results in prompting for a label when a user first composes a message.

This configuration requires you to specify the following key/value pair as a general configuration setting in the policy:

Expand table

Key	Value
com.microsoft.outlook.Mail.LouderMandatoryLabelEnabled	true

Outlook-specific options for default label and mandatory labeling

Identify the minimum versions of Outlook that support these features by using the capabilities table for Outlook and the row **Different settings for default label and mandatory labeling**.

When the Outlook app supports a default label setting that's different from the default label setting for documents:

- In the label policy configuration from the Microsoft Purview portal, on the **Apply a default label to emails** page: You can specify your choice of sensitivity label that will be applied to all unlabeled emails, or no default label. This setting is independent from the **Apply this label by default to documents** setting on the previous **Policy settings for documents** page of the configuration.

When the Outlook app doesn't support a default label setting that's different from the default label setting for documents: Outlook will always use the value you specify for **Apply this label by default to documents** on the **Policy settings for documents** page of the label policy configuration.

When the Outlook app supports turning off mandatory labeling:

- In the label policy configuration from the Microsoft Purview portal, on the **Policy settings** page: Select **Require users to apply a label to their email or documents**. Then select **Next** > **Next** and clear the checkbox **Require users to apply a label to their emails**. Keep the checkbox selected if you want mandatory labeling to apply to emails as well as to documents.

When the Outlook app doesn't support turning off mandatory labeling: If you select **Require users to apply a label to their email or documents** as a policy setting, Outlook will always prompt users to select a label for unlabeled emails.

Scope labels to just files or emails

> **Note**
>
> Identify the minimum versions that support this feature by using the capabilities tables, and the row **Scope labels to files or emails**.

Unless this capability is supported on all the platforms used by your users, they will have an inconsistent labeling experience. For example, Word on one platform doesn't display a label that they see on a different platform.

This configuration is available when you create or edit a sensitivity label in the Microsoft Purview portal:

- To scope labels to just Word, Excel, and PowerPoint: Make sure the option for **Files & other data assets** is selected, and not the option for **Emails**.
- To scope labels to just Outlook, make sure the option for **Emails** is selected, and not the option for **Files & other data assets**.

> ⚠ **Warning**
>
> Although you can edit an existing label and remove the **Files & other data assets** scope, we don't recommend you do this because existing configurations might no longer work as expected. For example, a SharePoint site admin wouldn't understand why a sensitivity label that they selected as a default label for a document library no longer applies the label.
>
> If you want a sensitivity label just for emails, create a new label with just the **Emails** scope rather than edit an existing label.

Make sure both options are selected if you don't need to scope the labels to just Word, Excel, and PowerPoint, or to just Outlook.

Remember that other label configurations can also influence whether sensitivity labels are visible in apps. Check the documentation for the label configurations that you use.

> ⓘ **Note**
>
> The **Files & other data assets** option can include items other than Office files, for example, Power BI files. Check the application's documentation to verify, and remember to test all labeling apps and services used by your organization.

Be aware that this configuration affects both client apps and services, manual labeling and automatic labeling. For example:

- Default labels:
  - If the scope doesn't include email, a configured default label for email won't be applied.

    - If the scope doesn't include files, a configured default label for files won't be applied and can't be selected as a default sensitivity label for a SharePoint document library.

- Auto-labeling policies:
    - If the scope doesn't include email, you can't select the label for an auto-labeling policy that includes the Exchange location.
    - If the scope doesn't include files, you can't select the label for an auto-labeling policy that includes the SharePoint and OneDrive locations.

- Encryption that lets users assign permissions:
    - If the scope doesn't include email, you won't be able to select the encryption options of **Do Not Forward** or **Encrypt-Only**.
    - If the scope doesn't include files, you won't be able to select the encryption option **In Word, PowerPoint, and Excel, prompt users to specify permissions**.

- Label inheritance from email attachments:
    - For this configuration, the label must be scoped to both files and emails.

In addition, if a label has been previously applied but then removed from one of the scopes, users will no longer see that label applied for the scope in the apps that support this feature.

Because of the impact of scoping labels to just files or emails, some existing labeling configurations will prevent you from removing the scope options for **Files & other data assets** and **Emails**:

- Default label in label policies
- Default label to apply in channel meetings
- Label selected for auto-labeling policies

Before you can scope a label to just files or emails, you must first remove it if it's configured as one of these default labels, and remove it from any auto-labeling policies.

Limitations:

- If you use any label policy settings with a sensitivity label that's scoped to just **Files & other data assets** or scoped to just **Emails**, the same policy must also include at least one label with both scope options.

- If the label is configured as the default label in one or more label policies, and Outlook isn't configured with its own default label in the same policy, you can't remove the scope for **Email**. As a workaround, first remove this label as the default label. You'll then be able to

remove the email scope. Finally, reselect the now modified label as the default label for documents.

Configure a label to apply S/MIME protection in Outlook

> **Note**
>
> Identify the minimum versions of Outlook that support this feature by using the capabilities table for Outlook and the row **Apply S/MIME protection**.
>
> If you configure a label to apply S/MIME protection but your version of Outlook for Windows doesn't yet support it, the label is still displayed and can be applied, but the S/MIME settings are ignored. You won't be able to select this label for Exchange auto-labeling policies or configure it to protect calendar items, Teams meetings, and chat.

This configuration is not available in the Microsoft Purview portal. You must use PowerShell advanced settings with the Set-Label or New-Label cmdlet after you've connected to Security & Compliance PowerShell.

Use these settings only when you have a working S/MIME deployment and want a label to automatically apply this protection method for emails rather than the default protection that uses Rights Management encryption from Azure Information Protection. The resulting protection will be the same as when a user manually selects S/MIME options from Outlook.

Expand table

Configuration	Advanced setting key/value
S/MIME digital signature	SMimeSign="True"
S/MIME encryption	SMimeEncrypt="True"

The label you configure for these settings doesn't have to be configured for encryption in the Microsoft Purview portal. But if it is, S/MIME protection replaces the Rights Management encryption only in Outlook. For other apps, the label applies the encryption settings specified in the Microsoft Purview portal.

Example PowerShell commands, where the sensitivity label GUID is **8faca7b8-8d20-48a3-8ea2-0f96310a848e**:

PowerShell

```
Set-Label -Identity "8faca7b8-8d20-48a3-8ea2-0f96310a848e" -AdvancedSettings
@{SMimeSign="True"}

Set-Label -Identity "8faca7b8-8d20-48a3-8ea2-0f96310a848e" -AdvancedSettings
@{SMimeEncrypt="True"}
```

For more help in specifying PowerShell advanced settings, see PowerShell tips for specifying the advanced settings.

Configure label inheritance from email attachments

> **Note**
>
> Identify the minimum versions of Outlook that support this feature by using the capabilities table for Outlook, and the row **Label inheritance from email attachments**.

Turn on email inheritance for when users attach labeled documents to an email message that isn't manually labeled. With this configuration, a sensitivity label is dynamically selected for the email message, based on the sensitivity labels that are applied to the attachments and published to the user. The highest priority label is dynamically selected when it's supported by Outlook.

Whether this label inheritance will override an existing label on the email message:

- When an email message has been manually labeled, that label won't be replaced by label inheritance from email attachments.
- Label inheritance from email attachments will replace a lower priority sensitivity label that is automatically applied or applied as a default label, but won't override a higher priority label.

You configure this setting in the sensitivity label policy, on the **Default settings for emails** page. For the section **Inherit label from attachments**, select the checkbox **Email inherits highest priority label from attachments**. The attachment must be a physical file, and can't be a link to a file (for example, a link to a file on Microsoft SharePoint or OneDrive).

When you select this checkbox, you can then further select the following option: **Recommend users apply the attachments label instead of automatically applying it.** Without this selection, the label is automatically applied but users can still remove the label or select a different label before sending the email.

By default, if the automatically selected label applies encryption, the same encryption is applied to the email. For example, if the highest priority label applies encryption with Full Control to the Marketing group, the email will be protected with Full Control to the Marketing group. If the highest priority label applies the encryption option of Do Not Forward, the email message is also labeled and encrypted with Do Not Forward.

However, consider the outcome when an email client doesn't support a specific protection action that's been applied to an attachment:

- **Double Key Encryption**: Behavior depends on whether Outlook supports this encryption method. Use the capabilities tables and the row **Double Key Encryption (DKE)** to confirm support for your version.
    - When Outlook supports DKE: If the highest priority label applies the encryption setting for Double Key Encryption and **Assign permissions now**, Outlook for Windows applies that label and protection to the email message. The label and protection isn't applied if the label is configured for **Let users assign permissions when they apply the label**.
    - When Outlook doesn't support DKE: If the highest priority label applies Double Key Encryption, no label or encryption is selected for the email message in Outlook for Windows.
- **Custom permissions for Word, PowerPoint, and Excel**: If the highest priority label applies just user-defined permissions for Word, PowerPoint, and Excel (the option **Let users assign permissions when they apply the label** and **In Word, PowerPoint, and Excel, prompt users to specify permissions**), no label or protection is selected for the email message because Outlook doesn't support this label configuration.

PDF support

Use the tables in Minimum versions for sensitivity labels in Office apps to identify supported versions.

Office for Windows: Word, Excel, and PowerPoint support the following methods to convert an Office document into a PDF document:

- File > Save As > PDF
- File > Export > PDF
- Share > Send a Copy > PDF

This action is logged with the **Renamed file** audit event from the File and page activities auditing group. In the auditing search results in the Microsoft Purview portal, you'll see the details of this auditing event display **SensitivityLabeledFileRenamed** for the **Activity** field.

Office for iOS: Word, Excel, and PowerPoint support the following methods to convert an Office document into a PDF document:

- Export > PDF
- Send a copy > Send as a PDF

Office for Android: Word, Excel, and PowerPoint support the following methods to convert an Office document into a PDF document:

- Share > Send a Copy -> PDF

Office for the web: You must download the file from the browser. The following methods are supported to convert an Office online document into a PDF document:

- Word and PowerPoint on the web:
  - Save as > Download as PDF > Download
- Excel on the web:
  - Export > Download as PDF > Download
  - Print > Print > Download as PDF > Download

When the PDF is created, it inherits the label with any content markings. For Windows, if the label applied encryption, that encryption is also inherited. Encrypted PDFs can be opened with Microsoft Edge on Windows or Mac. For more information, see View protected PDFs using Microsoft Edge on Windows or Mac.

SharePoint and OneDrive support the following PDF scenarios:

- When you've enabled SharePoint and OneDrive for sensitivity labels and added PDF support. Then, PDFs are supported when you upload a labeled PDF document with or without encryption applied, these services can process the file such that search, eDiscovery, and data loss prevention can inspect the contents, and the sensitivity label name is displayed for users.

- Auto-labeling policies can apply a sensitivity label and encryption (if configured) to PDF documents when PDF support is added.

Outlook doesn't currently support PDF attachments inheriting encryption from a labeled message. However, Outlook now does support warning or blocking users from printing to PDF, as

described next.

PDF scenarios not supported:

- Print to PDF

  If users select this option, they are warned that the document or email will lose the protection of the label, and encryption (if applied), and must confirm to continue. If your sensitivity label policy requires justification to remove a label or lower its classification, they see this prompt.

  Because this option removes the sensitivity label, this option won't be available to users if you're using mandatory labeling. This configuration refers to the sensitivity label policy setting that requires users to apply a label to their emails and documents.

- PDF/A format and encryption

  This PDF format designed for long-term archiving isn't supported when the label applies encryption and will prevent users from converting Office documents to PDF. For configuration information, see the Group Policy documentation for Enforce PDF compliance with ISO 19005-1 (PDF/A).

- Password protection and encryption

  The option **File** > **Info** > **Protect Document** > **Encrypt with Password** isn't supported when the document's label applies encryption. In this scenario, the encrypt with password option becomes unavailable for users.

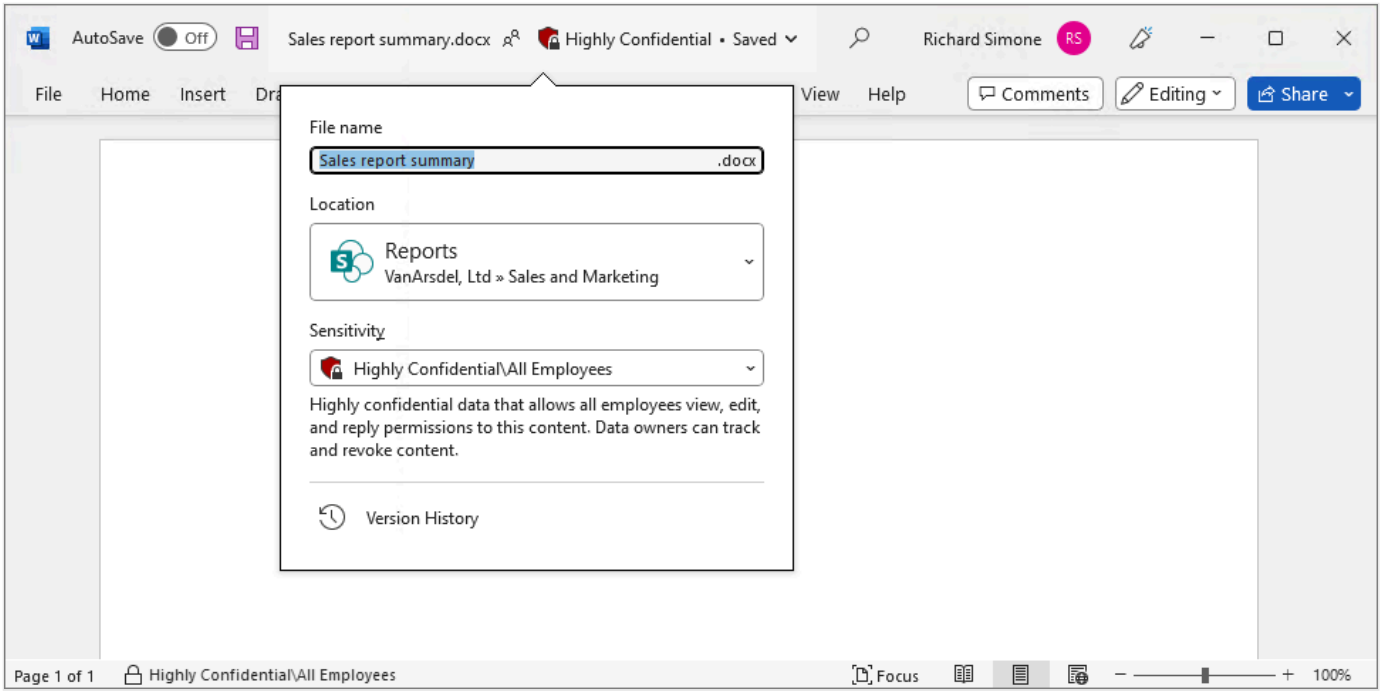
For more information about exporting to PDF, see the announcement Apply sensitivity labels to PDFs created with Office apps.

For end user documentation, see Create protected PDFs from Office files and View protected PDFs using Microsoft Edge on Windows or Mac.

Disabling PDF support

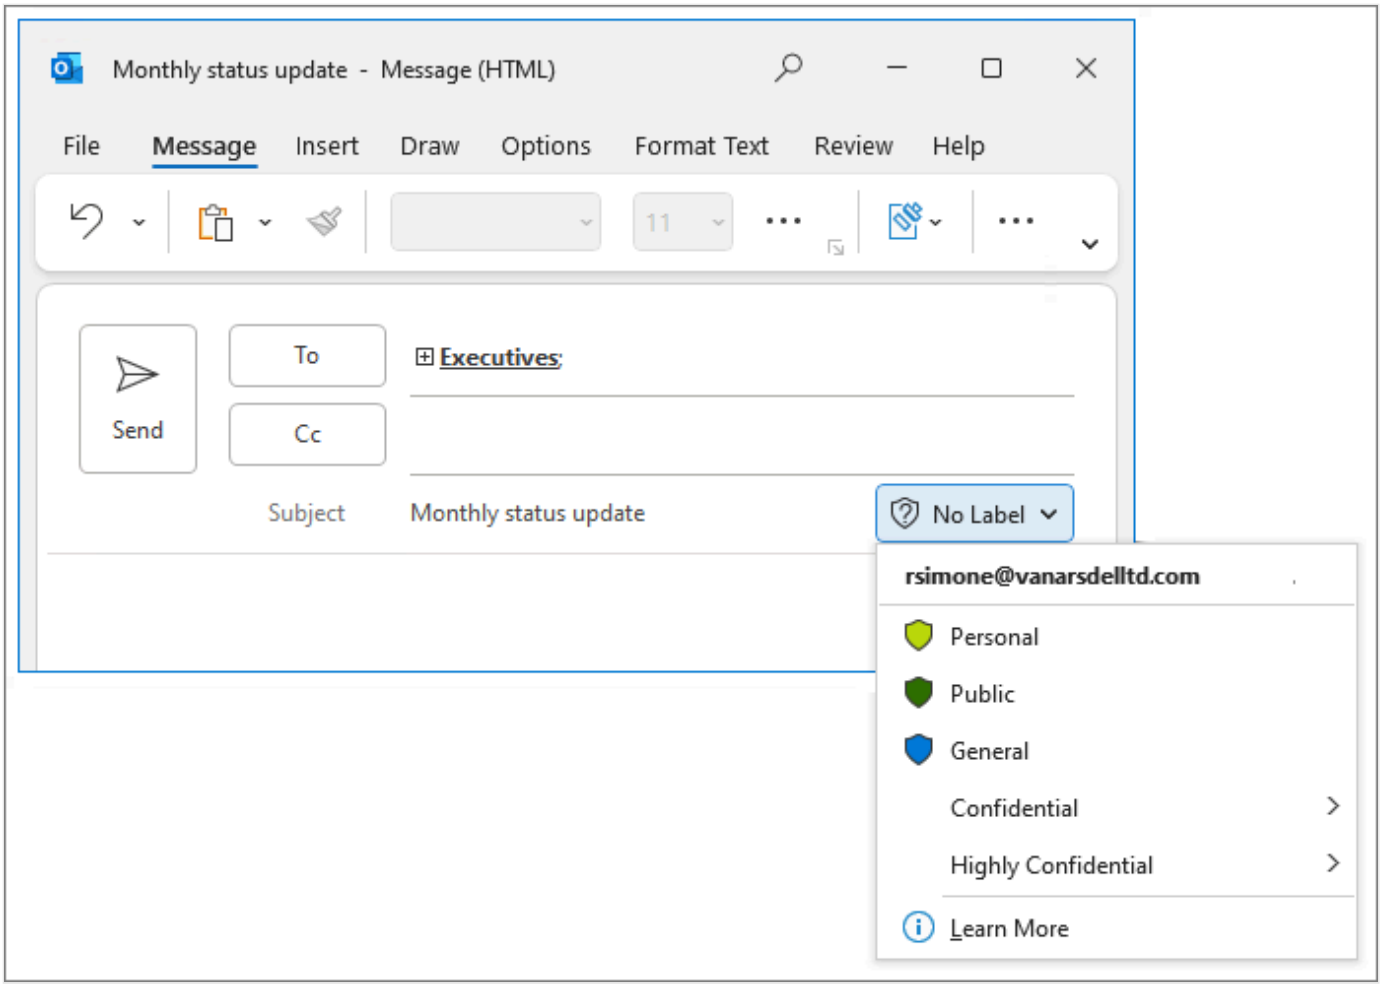
If you need to disable the PDF support in Office apps for Word, Excel, and PowerPoint, you can do so by using a Group Policy Office setting under **User Configuration/Administrative Templates/Microsoft Office 2016/Microsoft Save As PDF and Save As XPS add-ins**:

- **Use the Sensitivity feature in Office to apply sensitivity labels to PDFs**



Configure this setting to be **Disabled**.

Deploy this setting by using Group Policy, or by using the Cloud Policy service for Microsoft 365.



Sensitivity bar

Use the tables in Minimum versions for sensitivity labels in Office apps to identify which Office versions support the sensitivity bar.

When Word, Excel, and PowerPoint support this feature, sensitivity labels are displayed in a sensitivity bar next to the file name on the top window bar. For example:

When Outlook supports this feature, the sensitivity bar is displayed on the **Subject** line of the email. For example:

Information about the labels and the ability to select or change a label are also integrated into user workflows that includes save and rename, export, share, print, and convert to PDF. For more information and example screenshots, see the blog post announcement, New sensitivity bar in Office for Windows.

As part of this high visibility, these labels also support colors. For more information, see the next section.

Label colors

If your labeling apps don't support this capability, they don't display the configured label colors. To identify supported versions for Office apps, see the tables in Minimum versions for sensitivity labels in Office apps.

Newly created labels don't have a color by default. Use the Microsoft Purview portal to select one of 10 standard colors for sensitivity labels. The **Label color** configuration is on the first page of the label configuration after the label name and description.

You can't select colors for sublabels because they automatically inherit the label color from their [parent label or group label](sensitivity-labels.md#sublabels-that-use-parent-labels-or label-

groups).

If a label is configured for a different color from one of the 10 default colors, you see a **Use previously assigned custom color** check box selected, and the standard color options aren't available. You can change the custom color to one of the standard colors by first clearing the checkbox, and then you can select one of the standard colors.

You can't use the Microsoft Purview portal to configure a different custom color. Instead, use PowerShell, as described in the next section.

Configuring custom colors by using PowerShell

You can use the Security & Compliance PowerShell advanced setting **color** to set a color for a sensitivity label. This configuration supports colors that you can't configure in the Microsoft Purview portal.

To specify your choice of color, use a hex triplet code for the red, green, and blue (RGB) components of the color. For example, #40e0d0 is the RGB hex value for turquoise.

For more information about these codes, see the <color> page from the MSDN web docs, and you might also find RapidTables helpful. You can identify these codes in many applications that let you edit pictures. For example, Microsoft Paint lets you choose a custom color from a palette and the RGB values are automatically displayed, which you can then copy.

Example PowerShell command, where the sensitivity label GUID is **8faca7b8-8d20-48a3-8ea2-0f96310a848e**

PowerShell

```
Set-Label -Identity 8faca7b8-8d20-48a3-8ea2-0f96310a848e -AdvancedSettings
@{color="#40e0d0"}
```

For more information to help you specify PowerShell advanced settings for sensitivity labels, see PowerShell tips for specifying the advanced settings.

Specify a default sublabel for a parent label or label group

Note

Identify the minimum versions of Office that support this setting by using the capabilities tables and the row **Default sublabel for parent or group label**.

This configuration is not available in the Microsoft Purview portal. You must use the PowerShell advanced setting *DefaultSubLabelId* with the Set-Label or New-Label cmdlet after you've connected to Security & Compliance PowerShell.

By default, users select a [parent label or group label](sensitivity-labels.md#sublabels-that-use-parent-labels-or label-groups) to see the sublabels that they can apply, and then select one of those sublabels. If you specify a default sublabel for a parent label or label group, when users select the parent label or label group, a sublabel is automatically selected and applied for them.

As an example, the parent label **Confidential** is configured with a default sublabel, **All Employees**. The next parent label, **Highly Confidential**, doesn't have a default sublabel configured. You can tell the difference with the end of label bar for **Confidential** that isn't visible for **Highly Confidential**:

When users select to the left of that vertical bar, they are selecting **Confidential\All Employees** automatically with a single selection. If they need a different sublabel, they must select to the right of the vertical bar to select the label expansion that then displays all the sublabels for selection. In comparison, if they select **Highly Confidential**, the sublabels for that label are always displayed for selection.

After you configure this label setting, remember to update your end-user documentation accordingly.

Example PowerShell command, where the parent sensitivity label or label group GUID is **8faca7b8-8d20-48a3-8ea2-0f96310a848e** and its sublabel that you want to specify as the default is **1ace2cc3-14bc-4142-9125-bf946a70542c**:

PowerShell

```
Set-Label -Identity "8faca7b8-8d20-48a3-8ea2-0f96310a848e" -AdvancedSettings
```

```
@{DefaultSubLabelId="1ace2cc3-14bc-4142-9125-bf946a70542c"}
```

For more help in specifying PowerShell advanced settings, see PowerShell tips for specifying the advanced settings.

Prevent connected experiences that analyze content

> **Note**
>
> Support for this setting differs for clients and apps. Identify the minimum versions of Office that support this setting by using the capabilities tables and the rows **Prevent some connected experiences that analyze content** and **Prevent all connected experiences that analyze content**.

This configuration isn't available in the Microsoft Purview portal. You must use the PowerShell advanced setting *BlockContentAnalysisServices* with the Set-Label or New-Label cmdlet after you've connected to Security & Compliance PowerShell.

The setting lets you prevent content in Word, Excel, PowerPoint, and Outlook (for **Prevent all connected experiences that analyze content**) from being sent to Microsoft for content analysis as a privacy control. However, when it's set, it means that some services won't work as designed, such as data loss prevention policy tips for Outlook, automatic and recommended labeling, and Microsoft 365 Copilot.

> **Important**
>
> Although content with the configured sensitivity label will be excluded from Microsoft 365 Copilot in the named Office apps, the content remains available to Microsoft 365 Copilot for other scenarios. For example, in Teams, and in Microsoft 365 Copilot Chat.

Example PowerShell command, where the sensitivity label **Confidential\Project Onyx** has a GUID of **8faca7b8-8d20-48a3-8ea2-0f96310a848e** and you want to prevent all documents and emails with this label in Office apps from being sent to Microsoft connected experiences for analysis:

PowerShell

```
Set-Label -Identity "8faca7b8-8d20-48a3-8ea2-0f96310a848e" -AdvancedSettings
@{BlockContentAnalysisServices="True"}
```

To return the setting back to the default of sending the labeled content to Microsoft connected experiences for analysis, remove the setting or set the value to False.

For more help in specifying PowerShell advanced settings, see PowerShell tips for specifying the advanced settings.

On newer Windows clients and on all supported MacOS and mobile client versions, the setting affects all connected experiences that analyze content in Word, Excel, and PowerPoint. Supported versions are listed in the **Prevent all connected experiences that analyze content** row.

On older Windows versions of Word, Excel, PowerPoint, and Outlook that are listed in the **Prevent some connected experiences that analyze content** row, the following subset of connected experiences are impacted by this setting:

Expand table

Connected experiences	Apps
Automatic alt txt	Word, PowerPoint, Excel, Outlook
Automatically apply or recommend sensitivity labels	Word, PowerPoint, Excel, Outlook
Microsoft 365 Copilot	Word, PowerPoint, Excel, Outlook
Microsoft Purview Data Loss Prevention policy tips	Outlook
PowerPoint Designer	PowerPoint
Similarity checker	Word
Translator	Word, PowerPoint, Excel, Outlook

Auditing labeling activities

For information about the auditing events that are generated by sensitivity label activities, see the Sensitivity label activities section from the audit log activities documentation.

This auditing information is visually represented in content explorer and activity explorer to help you understand how your sensitivity labels are being used and where this labeled content is located.

You can also create custom reports with your choice of security information and event management (SIEM) software when you export and configure the audit log records. For larger-scale reporting solutions, see the Office 365 Management Activity API reference.

> **Tip**
>
> To help create custom reports, see the following blog posts:
>
> - Microsoft Purview audit log activities via O365 Management API - Part 1
> - Microsoft Purview audit log activities via O365 Management API - Part 2

End-user documentation

- Apply sensitivity labels to your files and email in Office
  - Known issues with sensitivity labels in Office
- Automatically apply or recommend sensitivity labels to your files and emails in Office
  - Known issues with automatically applying or recommending sensitivity labels
- Create protected PDFs from Office files

Minimum versions for sensitivity labels in Office apps

> *Microsoft Purview service description*

The capabilities tables on this page supplement Manage sensitivity labels in Office apps by listing the minimum Office version that introduced specific capabilities for sensitivity labels built in to Word, Excel, PowerPoint, and Outlook. Alternatively, the tabels indicate if the label capability is in public preview or not available.

For other apps that support sensitivity labels, check their documentation.

New versions of Office apps are made available at different times for different update channels. For Windows, you'll get the new capabilities earlier when you're on the Current Channel or Monthly Enterprise Channel, rather than Semi-Annual Enterprise Channel. The minimum version numbers can also be different from one update channel to the next. For more information, see Overview of update channels for Microsoft 365 Apps and Update history for Microsoft 365 Apps.

New capabilities that are in private preview aren't included in the tables but you might be able to join these previews by nominating your organization for the Microsoft Information Protection private preview program.

Tip

When you compare the minimum versions in the tables with the versions you have, remember the common practice of release versions to omit leading zeros.

For example, you have version 4.2128.0 and read that 4.7.1+ is the minimum version. For easier comparison, read 4.7.1 (no leading zeros) as 4.**0007**.1 (and not 4.** 7000**.1). Your version of 4.2128.0 is higher than 4.0007.1; so, your version is supported.

Sensitivity label capabilities in Word, Excel, and PowerPoint

The numbers listed are the minimum Office application versions required for each capability.

> **Note**
>
> For Windows and the Semi-Annual Enterprise Channel, the minimum supported version numbers might not yet be released. Learn more.

Future releases

For information about new labeling capabilities that are planned for future releases, use the Microsoft 365 roadmap.

Last updated on 08/14/2026

Extend sensitivity labeling on Windows

The Microsoft Purview Information Protection client extends sensitivity labels beyond labels that are built into Microsoft 365 apps and services, and supports a wider range of file types.

This client runs on Windows only and replaces the Azure Information Protection (AIP) unified labeling client. It has the following components:

Expand table

Component	Description
Information protection scanner	Used to discover, label, and encrypt files on data stores such as network shares and SharePoint Server libraries.
Information protection file labeler	Used to apply sensitivity labels and encryption using File Explorer.
Information protection viewer	Used to view files that are encrypted.
Microsoft Purview Information Protection PowerShell module	Used to adjust sensitivity labels on files, and install and configure Microsoft Purview Information Protection scanner.

There's no Office Add-in with the Microsoft Purview Information Protection client because this functionality is replaced with sensitivity labels that are built into Office.

For the latest release information and support timelines for each client version, see Microsoft Purview Information Protection client - Release management and supportability.

Requirements for deploying the information protection client

To use the Microsoft Purview Information Protection client, install this client on Windows computers where you want to use the client components.

You also must meet the following requirements:

Operating Systems

The following operating systems support the Microsoft Purview Information Protection client:

- **Windows 11**, including Windows 11 Enterprise multi-session
- **Windows 10 (x64)** (Handwriting isn't supported in the Windows 10 RS4 build and later)
- **Windows Server 2019**
- **Windows Server 2016**

ARM64 is supported for the viewer and file labeler, but isn't supported for the scanner or PowerShell.

Install or upgrade the information protection client

If you install the Microsoft Purview Information client interactively and the Azure Information Protection (AIP) unified labeling client is detected, you can upgrade the older client after you acknowledge the AIP Add-in for Office will be removed.

> ⓘ **Note**
>
> Upgrades by using Microsoft Update Catalog or any other non-interactive installation require a registry key configuration if any Azure Information Protection client versions are present on the local computer.

There are two options for installing the information protection client:

- Installing the information protection client using the **.exe** installer
- Installing the information protection client using the **.msi** installer

If you're upgrading the information protection scanner, either from the Azure Information Protection (AIP) unified labeling client or a previous version of the information protection client, see Upgrade the Microsoft Purview Information Protection scanner before using these client installation instructions.

Install using the .exe installer

To install the information protection client with the .exe file:

1. Download the executable version of the Microsoft Purview Information Protection client from the Microsoft Download Center. For example, **PurviewInfoProtection.exe**.

   > ⓘ **Important**

If there is a preview version available, use that version only for testing. It is not intended for end users in a production environment.

2. For a default installation, simply run the executable. To view all installation options, first run the executable with **/help**. For example:

   `PurviewInfoProtection.exe **/help**`

   a. To silently install the client, run:

      `PurviewInfoProtection.exe /quiet`

   b. To silently install only the PowerShell cmdlets, run:

      `PurviewInfoProtection.exe PowerShellOnly=true /quiet`

   > **Note**
   >
   > By default, the option to send usage statistics to Microsoft is enabled. To disable this option, make sure to take one of the following steps:
   >
   > - During installation, specify **AllowTelemetry=0**
   > - After installation, update the registry key as follows: **EnableTelemetry=0**.

3. To complete the installation, restart any instances of File Explorer.

4. Confirm that the installation was successful by checking the install log file, which is created in the **%temp%** folder by default.

   The install log file has the following naming format:

   `Microsoft_Azure_Information_Protection_<number>_<number>_MSIP.Setup.Main.msi.log`

   For example:

   Microsoft_Azure_Information_Protection_20161201093652_000_MSIP.Setup.Main.msi.log

   In the log file, search for the following string: **Product: Microsoft Purview Information Protection--Installation completed successfully**. If the installation failed, this log file contains details to help you identify and resolve any problems.

   > **Tip**
   >
   > You can change the location of the installation log file with the **/log** installation parameter.

Log file locations

Client and scanner log files are located in the following locations on the Windows computer:

- **\ProgramFiles (x86)\Microsoft Purview Information Protection** (64-bit operating systems only)
- **\Program Files\Microsoft Purview Information Protection** (32-bit operating systems only)
- **%localappdata%\Microsoft\MSIP**

Supported languages

The information protection client supports the same languages that Office 365 supports. For a list of these languages, see the International availability page from Office.

For these languages, menu options, dialog boxes, and messages from the Microsoft Purview Information Protection client display in the user's language. There's a single installer that detects the language, so no additional configuration is required to install the information protection client for different languages.

However, label names and descriptions that you specify aren't automatically translated when you configure labels in the admin portal. For users to see labels in their preferred language, provide your own translations and configure them for the labels by using PowerShell and the *LocaleSettings* parameter for Set-Label. For more information, see Example configuration to configure a sensitivity label for different languages.

Supported file types

This section lists the file types supported by the Microsoft Purview Information Protection client. For the listed file types, WebDav locations aren't supported.

> **Tip**
>
> When you encrypt file types that don't have built-in support for encryption and so use generic encryption, we recommend that you assign the permission of co-owner to these files.

Sensitivity labels without encryption

The following file types can be labeled without encryption.

- **Adobe Portable Document Format:** .pdf
- **Microsoft Project:** .mpp, .mpt
- **Microsoft Publisher:** .pub
- **Microsoft XPS:** .xps .oxps
- **Images:** .jpg, .jpe, .jpeg, .jif, .jfif, .jfi. png, .tif, .tiff
- **Autodesk Design Review 2013:** .dwfx
- **Adobe Photoshop:** .psd
- **Digital Negative:** .dng
- **Microsoft Office:** The following file types, including 97-2003 file formats and Office Open XML formats for Word, Excel, and PowerPoint.

Expand table

Word	Excel	PowerPoint	Visio
.doc	.xls	.potm	.vdw
.docm	.xlsb	.potx	.vsd
.docx	.xlsm	.pps	.vsdm
.dot	.xlsx	.ppsm	.vsdx
.dotx	.xltm	.ppsx	.vss
	.xltx	.ppt	.vssm
		.pptx	.vst
			.vstm
			.vssx
			.vstx

Excluded folders and file types

To help prevent users from changing files that are critical for computer operations, some file types and folders are automatically excluded from classifying and labeling. If users try to label these files by using the information protection client, they see a message that those files are excluded.

Excluded folders

The following folders are excluded from classifying and labeling by the information protection client:

- Windows
- Program Files (\Program Files and \Program Files (x86))
- \ProgramData
- \AppData (for all users)

File types that can't be encrypted by default

Any file that is password-protected can't be natively encrypted by the client unless the file is currently open in the application that applies the encryption. You most often see PDF files that are password-protected but other applications, such as Office apps, also offer this functionality.

File types supported for inspection

The information protection client uses Windows IFilter to inspect the contents of documents. Windows IFilter is used by Windows Search for indexing. As a result, the following file types can be inspected when you use the Set-FileLabel -Autolabel PowerShell command.

Expand table

Application type	File type
Word	.doc, .docx, .docm, .dot, .dotx
Excel	.xls, .xlt, .xlsx, .xlsm, .xlsb
PowerPoint	.ppt, .pps, .pot, .pptx
PDF	.pdf
Text	.txt, .xml, .csv

Scanning .ZIP files

You can use the information protection scanner or the Set-FileLabel PowerShell command to inspect .zip files.

> **Note**
>
> When your information protection scanner is installed on a Windows server computer, you must also install the Microsoft Office iFilter in order to scan .zip files for sensitive information types. For more information, see the Microsoft download site.

After finding sensitive information, if the .zip file should be labeled and encrypted with a label, from the scanner deployment instructions, specify the .zip file name extension with the PowerShell **PFileSupportedExtensions** advanced setting.

Example scenario:

A file named *accounts.zip* contains Excel spreadsheets with credit card numbers. You have a sensitivity label named *Confidential \ Finance*, which is configured to discover credit card numbers and automatically apply the label with encryption that restricts access to the Finance group.

After inspecting the file, the client from your PowerShell session labels this file as *Confidential \ Finance*. Next, the client applies generic encryption to the file so that only members of the Finance groups can unzip it, and renames the file *accounts.zip.pfile*.

Integration with Endpoint data loss prevention

The Endpoint data loss prevention (DLP) setting **Advanced label-based protection for all files on devices** enhances productivity for users who label and encrypt file types other than those for Office and PDF.

For these files, although access and any usage restrictions from the encryption settings are enforced by DLP when the label is applied, the encryption is applied when the files leave the computer. As a result, the file name extension for the local files don't change and users can continue to view and edit the files in their standard application.

For more information, see Learn about Advanced Label Based Protection.

Support for disconnected computers

By default, the information protection client automatically tries to connect to the internet to download sensitivity labels and sensitivity label policy settings from Microsoft Purview.

If you have computers that can't connect to the internet for a period of time, you can export and copy files that manually manages the policy for the information protection client.

To support disconnected computers from the information protection client:

1. Choose or create a user account in Microsoft Entra ID that you will use to download labels and policy settings that you want to use on your disconnected computer.

2. As an additional label policy setting for this account, turn off sending audit data to Microsoft Purview by using the *EnableAudit* PowerShell advanced setting with Set-LabelPolicy from Security & Compliance PowerShell.

   We recommend this step because if the disconnected computer does have periodic internet connectivity, it will send logging information to Microsoft Purview that includes the user name from step 1. That user account might be different from the local account you're using on the disconnected computer.

3. From a computer with internet connectivity that has the information protection client installed and signed in with the user account from step 1, download the labels and policy settings.

4. From this computer, export the log files.

   For example, run the Export-DebugLogs cmdlet, or use the **Export Logs** option from the client's **Help and Feedback** dialog box from file labeler.

   The log files are exported as a single compressed file.

5. Open the compressed file, and from the MSIP folder, copy any files that have an .xml file name extension.

6. Paste these files into the **%localappdata%\Microsoft\MSIP** folder on the disconnected computer.

7. If your chosen user account is one that usually connects to the internet, enable sending audit data again, by setting the **EnableAudit** value to **True**.

Be aware that if a user on this computer selects the **Reset Settings** option from **Help and feedback** in the file labeler, this action deletes the policy files and leaves the client inoperable

until you manually replace the files or the client connects to the internet so it can download the files it needs.

The Information Protection client requires an active internet connection to apply encryption; therefore, the disconnected computers solution is supported only for labels that do not apply encryption.

If your disconnected computer is running the information protection scanner, there are additional configuration steps you must take. For more information, see Restriction: The scanner server cannot have internet connectivity from the scanner deployment instructions.

Supported customizations

The information protection client supports PowerShell advanced settings and some registry settings that might be needed for specific scenarios or users.

For the PowerShell advanced settings that are supported with New-Label or Set-Label, and New-LabelPolicy or Set-LabelPolicy from Security & Compliance PowerShell, see Advanced settings for Microsoft Purview Information Protection client.

Use the following sections to help you configure the registry for supported customizations.

Enable non-interactive upgrade from the Azure Information Protection client

If you install the Microsoft Purview Information Protection client and the Azure Information Protection unified labeling client is detected, an interactive installation of the client requires you to acknowledge that the AIP Add-in for Office from the older client will be removed.

To use a non-interactive installation for the client, such as Microsoft Update Catalog, Group Policy, or scripting, you must either first uninstall the Azure Information Protection client, or create and configure the following registry key for the local computer:

HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Microsoft\MSIP\AllowMajorVersionUpgrade (DWORD)

Set the value to **1** to silently allow the upgrade and uninstall the AIP Office add-in; **0** blocks the upgrade if the Azure Information Protection client is installed.

Change the local logging level

By default, the Purview Information Protection client writes client log files to the **%localappdata%\Microsoft\MSIP** folder. These files are intended for troubleshooting by Microsoft Support.

To change the logging level for these files, locate the following value name in the registry and set the value data to the required logging level:

HKEY_CURRENT_USER\SOFTWARE\Microsoft\MSIP\LogLevel

Set the logging level to one of the following values:

- **Off**: No local logging.
- **Error**: Errors only.
- **Warn**: Errors and warnings.
- **Info**: Minimum logging, which includes no event IDs (the default setting for the scanner).
- **Debug**: Full information.
- **Trace**: Detailed logging (the default setting for clients).

This registry setting doesn't change the information that's sent to Microsoft Purview auditing.

Enable data boundary settings

Following Microsoft's commitment to EU data boundary, EU customers who use the Microsoft Purview Information Protection client can send their data to the EU to be stored and processed.

Turn on this feature in the information protection client by changing the following registry key that specifies the location to send events:

- Registry key: **HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Microsoft\MSIP\DataBoundary (DWORD)**
- Values:
  - `Default = 0`
  - `North_America = 1`
  - `European_Union = 2`

Enable system default browser for authentication

Use the system default browser for authentication in Microsoft Purview Information Protection client. By default, the information protection client opens Microsoft Edge for authentication.

Turn on this feature in the information protection client by enabling the following registry key:

- Registry key: **HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Microsoft\MSIP\MSALUseSytemDefaultBrowserAuth (DWORD)**
- Values:
  - `Disabled = 0`
  - `Enabled = 1`

Hide the "Apply sensitivity label with Microsoft Purview" menu option in File Explorer

To hide the **Apply sensitivity label with Microsoft Purview** right-click menu option in File Explorer, create the following DWORD registry key that has the value name of **LegacyDisable** and any value data:

HKEY_CLASSES_ROOT\AllFilesystemObjects\shell\Microsoft.Azip.RightClick

How to apply sensitivity labels using the information protection client

After the Microsoft Purview Information Protection client is installed, you can apply sensitivity labels that you've created and published, by using:

- File Explorer
- PowerShell
- The information protection scanner, after installing and configuring it

> **Important**
>
> If you are upgrading from the Azure Information Protection (AIP) unified labeling client, see **Upgrade the scanner from the Azure Information Protection client (version 2.x)**.

To view encrypted documents, see View protected files with the Microsoft Purview Information Protection viewer.

Use Microsoft Purview sensitivity label policies for non-Microsoft connected apps (preview)

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Auto-labeling isn't limited to Microsoft 365 locations. Through the integration between Microsoft Purview Information Protection and Microsoft Defender for Cloud Apps, you can automatically apply your Microsoft Purview sensitivity labels to files stored in non-Microsoft connected apps, such as Box and Google Workspace. Because these labels use the same sensitive information types and classifiers similar to Microsoft 365, your sensitive content is classified and protected consistently, wherever it's stored.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Supported non-Microsoft apps

Microsoft Purview supports auto-labeling policies for the following non-Microsoft apps:

- Box
- Google Workspace

> **Note**
>
> These apps are rolling out in phases. Not all apps may be available in your tenant at the same time. Check the Microsoft 365 roadmap for the latest availability information.

Before you begin

Licensing requirements

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions

The account you use to create and deploy policies must be a member of one of these role groups:

- Compliance administrator
- Compliance data administrator
- Information Protection
- Information Protection Admin
- Security administrator

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. This helps improve security for your organization. Global Administrator is a highly privileged role that should only be used in scenarios where a lesser privileged role can't be used.

Publish labels

To select sensitivity labels when setting up auto-labeling policies, the labels must first be published. For more information on creating and publishing labels, see Create and configure sensitivity labels and their policies.

Set up a Microsoft Defender for Cloud Apps connector

Before you can apply auto-labeling policies to a non-Microsoft app, you must connect that app to Microsoft Defender for Cloud Apps using an app connector. Purview uses the existing Microsoft Defender for Cloud Apps connectors to access capabilities in the non-Microsoft app.

For instructions on setting up app connectors, see Connect apps to get visibility and control with Microsoft Defender for Cloud Apps.

After you connect your cloud apps to Defender for Cloud Apps, you can create auto-labeling policies for them in Microsoft Purview.

Create an auto-labeling policy for non-Microsoft connected apps

You can use auto-labeling policies to automatically apply or remove sensitivity labels on data stored in non-Microsoft connected apps. For the general procedure to create an auto-labeling policy, see Automatically apply a sensitivity label to Microsoft 365 data.

To create an auto-labeling policy scoped to non-Microsoft connected apps:

1. Sign in to the Microsoft Purview portal.
2. Go to **Solutions** > **Information protection** > **Policies** > **Auto-labeling policies** > **+ Create auto-labeling policy**.
3. On **What type of auto-labeling policy do you want to create?**, choose **Automatically apply labels only**.
4. Select **Custom** > **Custom policy** > **Next**.

   > **Important**
   >
   > Non-Microsoft connected app policies are only supported with the **Custom** policy template. The predefined Financial, Medical and health, and Privacy templates don't support non-Microsoft app locations.

5. Enter a name and description for the auto-labeling policy, then select **Next**.
6. On **Choose a label to auto-apply**, choose **Choose a label**. On **Choose a sensitivity label**, select all labels to include in the policy, and then select **Add** > **Next**.
7. On **Assign admin units**, the scope is set to **Full directory**. Administrative units aren't supported for non-Microsoft app locations.
8. On **Choose locations where you want to apply the label**, select one or more of the supported non-Microsoft apps (such as **Box** or **Google Workspace**).

   > **Important**

Non-Microsoft app locations can be selected together, but they can't be combined with other locations like SharePoint, Exchange, SQL Server, Azure Storage or OneDrive in the same policy.

9. By default, the policy applies to all instances of the selected app. To scope the policy to specific tenants, select **Edit**.
   a. To exclude instances, in **All instances**, select **Exclude instances** > **+ Exclude instance**. From the list of instances, select instances to exclude from the policy, and then select **Done** > **Done**.
   b. To apply the policy to specific instances, select **Specific instances** > **+ Include instance**. From the list of instances, select instances to include, then select **Done** > **Done**.
10. Select **Next** to proceed.
11. On **Set up common or advanced rules**, begin creating rules by selecting **Advanced Rules**. Select **Next**.
12. Select **+ New rule**, and provide a **Name** and **Description**.
13. Configure **Conditions** for the rule. The conditions you can use vary by app.
14. Select **Save** to save the rule, then select **Next**.
15. On **Additional label settings**, optionally select **All locations** to replace existing labels with lower priority in the selected applications. Select **Next**.
16. On **Decide if you want to test out the policy now or later**, choose either **Turn on policy** or **Leave policy turned off**. Select **Next**.

    > ⓘ **Important**
    >
    > **Simulation mode** isn't supported for non-Microsoft connected app policies.

17. Review your settings and select **Create policy** to create the policy.

Attribute availability by app

The conditions and actions you can use in a policy depend on the item attributes that each app makes available. Most attributes are available for all supported apps, but some aren't available for

certain apps. Use the following table to understand which attributes you can rely on when you build rules for a specific app.

Expand table

Attribute	Description	Availability
Name	The display name of the item.	Available in all apps
File access level	The item's access level, which indicates its sharing scope.	Available in all apps
Created date	The date the item was created.	Not available
Modified date	The date the item was last modified.	Available in all apps
Collaborators	The users the item is shared with, including their roles.	Not available
Parent folders	The parent folders that contain the item.	Available in all apps

Monitoring and reporting

Activity explorer

Activity explorer supports non-Microsoft connected app policies. You can monitor labeling policy activity for your non-Microsoft apps in the same way you monitor Microsoft 365 locations.

Content explorer

Content explorer isn't supported for non-Microsoft connected apps. You can't browse or inspect content stored in these apps through Content explorer.

Known issues

The following is a list of known issues when using non-Microsoft connected apps for sensitivity label policies:

- **Encrypted files** – Encrypted files stored in non-Microsoft apps aren't currently supported for classification.
- **PDF files** – PDF files stored in non-Microsoft apps aren't currently supported for classification.
- In Microsoft Purview for Microsoft 365, when a sensitivity label is applied automatically through an auto-labeling policy, a higher-priority label replaces any existing lower-priority label. However, for Box and Google Workspace, if a label has already been applied to a file

by an auto-labeling policy, it cannot be replaced by a higher-priority label from **another** auto-labeling policy. For more information, see Automatically apply a sensitivity label to Microsoft 365 data.

Related content

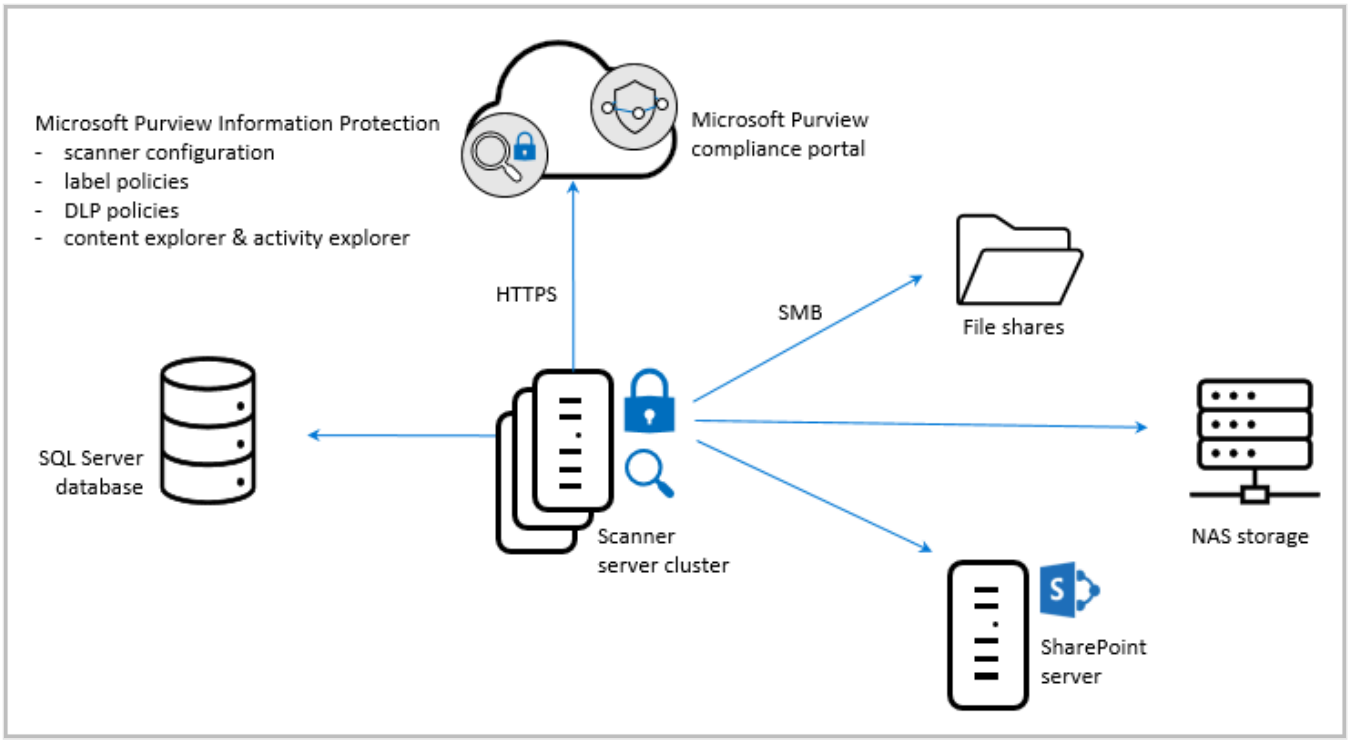
Learn about the information protection scanner

> **Note**
>
> There's a new version of the information protection scanner. For more information, see Upgrade the Microsoft Purview Information Protection scanner.

Use the information in this section to learn about the Microsoft Purview Information Protection scanner, and then how to successfully install, configure, run and if necessary, troubleshoot it.

This scanner runs as a service on Windows Server and lets you discover, classify, and protect files on the following data stores:



- **UNC paths** for network shares that use the SMB or NFS (Preview) protocols.
- **SharePoint document libraries and folder** for SharePoint Server (versions currently in mainstream support). For more information see the SharePoint Server Support Policy updated product servicing policy for SharePoint Server SE.

To classify and protect your files, the scanner uses sensitivity labels configured in the Microsoft Purview portal.

Overview of the scanner

The information protection scanner can inspect any files that Windows can index. If you configure sensitivity labels to apply automatic classification, the scanner can label discovered files to apply that classification, and optionally apply or remove protection. For information about the sensitive information types (SITs) supported by the information protection scanner, see Sensitive Information Types supported by Microsoft Purview Information Protection scanner.

The following image shows the scanner architecture, where the scanner discovers files across your on-premises and SharePoint servers.

To inspect your files, the scanner uses IFilters installed on the computer. To determine whether the files need labeling, the scanner uses sensitive information types and pattern detection, or regex patterns.

The scanner uses the Microsoft Purview Information Protection client, and can classify and protect the same types of files as the client. For more information, see Supported file types.

Do any of the following to configure your scans as needed:

- **Run the scanner in discovery mode only** to create reports that check to see what happens when your files are labeled.
- **Run the scanner to discover files with sensitive information**, without configuring labels that apply automatic classification.
- **Run the scanner automatically** to apply labels as configured.
- **Define a file types list** to specify specific files to scan or to exclude.

> **Note**
>
> The scanner does not discover and label in real time. It systematically crawls through files on data stores that you specify. Configure this cycle to run once, or repeatedly.

> **Tip**
>
> The scanner supports scanner clusters with multiple nodes, enabling your organization to scale out, achieving faster scan times and broader scope.

Deploy multiple nodes right from the start, or start with a single-node cluster and add additional nodes later on as you grow. Deploy multiple nodes by using the same cluster name and database for the **Install-Scanner** cmdlet.

The scanning process

When scanning files, the information protection scanner runs through the following steps:

1. Determine whether files are included or excluded for scanning.

2. Inspect and label files.

3. Label files that can't be inspected.

For more information, see Files not labeled by the scanner.

1. Determine whether files are included or excluded for scanning

The scanner automatically skips files that are excluded from classification and protection, such as executable files and system files. For more information, see Excluded file types.

The scanner also considers any file lists explicitly defined to scan, or exclude from scanning. File lists apply for all data repositories by default, and can also be defined for specific repositories only.

To define file lists for scanning or exclusion, use the **File types to scan** setting in the content scan job. For example:

For more information, see Deploying the scanner to automatically classify and protect files.

2. Inspect and label files

After identifying excluded files, the information protection scanner filters again to identify files supported for inspection.

These filters are the same ones used by the operating system for Windows Search and indexing, and require no extra configuration. Windows IFilter is also used to scan file types that are used by Word, Excel, and PowerPoint, and for PDF documents and text files.

For a full list of file types supported for inspection, and other instructions for configuring filters to include .zip and .tiff files, see File types supported for inspection.

After inspection, supported file types are labeled using the conditions specified for your labels. If you're using discovery mode, these files can either be reported to contain the conditions specified for your labels, or reported to contain any known sensitive information types.

Stopped scanner processes

If the scanner stops before completing a scan for a large number of files in your repository, you may need to increase the number of dynamic ports for the operating system that hosts the files.

For example, server hardening for SharePoint is one reason why the scanner would exceed the number of allowed network connections, and therefore stop.

To check whether server hardening for SharePoint is the cause of the scanner stopping, check for the following error message in the scanner logs at **%localappdata%\Microsoft\MSIP\Logs\MSIPScanner.iplog** (multiple logs are compressed into a zip file):

```
Unable to connect to the remote server ---> System.Net.Sockets.SocketException: Only one usage of each socket address (protocol/network address/port) is normally permitted IP:port
```

For more information about how to view the current port range and increase it if needed, see Settings that can be modified to improve network performance.

> **Tip**
>
> For large SharePoint farms, you may need to increase the list view threshold, which has a default of **5,000**.
>
> For more information, see the **Manage large lists and libraries in SharePoint**.

3. Label files that can't be inspected

For any file types that can't be inspected, the scanner applies the default label from its sensitivity label policy, or the default label configured for the scanner.

Files not labeled by the scanner

The scanner can't label files under the following circumstances:

- When the file type doesn't support labeling without encryption. For a list of file types that are supported for this label configuration, see Sensitivity labels without encryption.
- When the label applies encryption, but the scanner doesn't support the file type.

  By default, the scanner encrypts just Office file types, and PDF files when they are protected by using the ISO standard for PDF encryption.

  Other types of files can be added for encryption when you change the types of files to protect.

Example: After inspecting .txt files, the scanner can't apply a label that doesn't apply encryption, because the .txt file type doesn't support sensitivity labels without encryption.

However, if the label is configured to apply encryption, and the .txt file type is included for the scanner to protect, the scanner can label the file.

Next steps

For more information about deploying the scanner, see the following articles:

- Scanner deployment prerequisites
- Configuring and installing the scanner
- Running scans using the scanner

You can also use PowerShell to interactively classify and protect files from your desktop computer. For more information about this and other scenarios that use PowerShell, see Set up the information protection client using PowerShell.

Last updated on 03/26/2026

Get started with the information protection scanner

Article • 04/17/2025

> **Note**
>
> There's a new version of the information protection scanner. For more information, see Upgrade the Microsoft Purview Information Protection scanner.

Before installing the scanner from Microsoft Purview Information Protection, make sure that your system complies with basic Azure Information Protection requirements.

Additionally, the following requirements are specific for the scanner:

- Windows Server requirements
- Service account requirements
- SQL server requirements
- Information protection client requirements
- Label configuration requirements
- SharePoint requirements
- Microsoft Office requirements
- File path requirements

If you can't meet all the requirements listed for the scanner because they are prohibited by your organization's policies, see the alternative configurations section.

When deploying the scanner in production or testing the performance for multiple scanners, see Storage requirements and capacity planning for SQL Server.

When you're ready to start installing and deploying your scanner, continue with Configuring and installing the information protection scanner.

Windows Server requirements

You must have a Windows Server computer to run the scanner, which has the following system specifications:

Expand table

Specification	Details
Processor	4 core processors
RAM	8 GB
Disk space	10-GB free space (average) for temporary files. The scanner requires sufficient disk space to create temporary files for each file that it scans, four files per core. The recommended disk space of 10 GB allows for 4 core processors scanning 16 files that each have a file size of 625 MB.
Operating system	64-bit versions of: - Windows Server 2025 - Windows Server 2022 - Windows Server 2019 - Windows Server 2016 **Note**: For testing or evaluation purposes in a non-production environment, you can also use any Windows operating system that is supported by the information protection client. Server Core and Nano Server aren't supported.
- Network connectivity	Your scanner computer can be a physical or virtual computer with a fast and reliable network connection to the data stores to be scanned. If internet connectivity is not possible because of your organization policies, see Deploying the scanner with alternative configurations. Otherwise, make sure that this computer has internet connectivity that allows the following URLs over HTTPS (port 443): - *.aadrm.com - *.azurerms.com - *.informationprotection.azure.com - informationprotection.hosting.portal.azure.net - *.aria.microsoft.com - *.protection.outlook.com
NFS shares	To support scans on NFS shares, services for NFS must be deployed on the scanner machine. On your machine, navigate to the **Windows Features (Turn Windows features on or off)** settings dialog, and select the following items: **Services for NFS** > **Administrative Tools** and **Client for NFS**.

Specification	Details
Microsoft Office iFilter	When your scanner is installed on a Windows server machine, you must also install the Microsoft Office iFilter in order to scan .zip files for sensitive information types. For more information, see the Microsoft download site .

Service account requirements

You must have a service account to run the scanner service on the Windows Server computer, as well as authenticate to Microsoft Entra ID and download the scanner's policy.

Your service account must be an Active Directory account and synchronized to Microsoft Entra ID.

If you cannot synchronize this account because of your organization policies, see Deploying the scanner with alternative configurations.

This service account has the following requirements:

Expand table

Requirement	Details
Log on locally user right assignment	Required to install and configure the scanner, but not required to run scans. Once you've confirmed that the scanner can discover, classify, and protect files, you can remove this right from the service account. If granting this right even for a short period of time is not possible because of your organization policies, see Deploying the scanner with alternative configurations.
Log on as a service user right assignment.	This right is automatically granted to the service account during the scanner installation and this right is required for the installation, configuration, and operation of the scanner.
Permissions to the data repositories	- **File shares or local files**: Grant **Read**, **Write**, and **Modify** permissions for scanning the files and then applying classification and protection as configured. - **SharePoint**: You must grant **Full Control** permissions for scanning the files and then applying classification and protection to the files that meet the conditions in the Azure Information Protection policy. - **Discovery mode**: To run the scanner in discovery mode only, **Read** permission is sufficient.

Requirement	Details
For labels that reprotect or remove protection	To ensure that the scanner always has access to encrypted files, make this account a super user for Azure Information Protection, and ensure that the super user feature is enabled. Additionally, if you've implemented onboarding controls for a phased deployment, make sure that the service account is included in the onboarding controls you've configured.
Specific URL level scanning	To scan and discover sites and subsites under a specific URL, grant **Site Collector Auditor** rights to the scanner account on the farm level.
License for information protection	Required to provide file classification, labeling, or protection capabilities to the scanner service account. For more information, see the Microsoft 365 guidance for security & compliance.

SQL server requirements

To store the scanner configuration data, use an SQL server with the following requirements:

- **A local or remote instance.**

  We recommend hosting the SQL server and the scanner service on different machines, unless you're working with a small deployment. Additionally, we recommend having a dedicated SQL instance that serves the scanner database only, and that is not shared with other applications.

  If you're working on a shared server, make sure that the recommended number of cores are free for the scanner database to work.

  SQL Server 2016 is the minimum version for the following editions:

  - SQL Server Enterprise
  - SQL Server Standard
  - SQL Server Express (recommended for test environments only)

- **An account with Sysadmin role to install the scanner.**

  The Sysadmin role enables the installation process to automatically create the scanner configuration database and grant the required **db_owner** role to the service account that runs the scanner.

If you cannot be granted the Sysadmin role or your organization policies require databases to be created and configured manually, see Deploying the scanner with alternative configurations.

- **Capacity.** For capacity guidance, see Storage requirements and capacity planning for SQL Server.
- **Case insensitive collation**.

> **Note**
>
> Multiple configuration databases on the same SQL server are supported when you specify a custom cluster name for the scanner, or when you use the preview version of the scanner.

Storage requirements and capacity planning for SQL Server

The amount of disk space required for the scanner's configuration database and the specification of the computer running SQL Server can vary for each environment, so we encourage you to do your own testing. Use the following guidance as a starting point.

For more information, see Optimizing the performance of the scanner.

The disk size for the scanner configuration database will vary for each deployment. Use the following equation as guidance:

```cli
100 KB + <file count> *(1000 + 4* <average file name length>)
```

For example, to scan 1 million files that have an average file name length of 250 bytes, allocate 2-GB disk space.

For multiple scanners:

- **Up to 10 scanners**, use:
  - 4 core processors
  - 8-GB RAM recommended
- **More than 10 scanners** (maximum 40), use:
  - 8 core processes
  - 16-GB RAM recommended

Information protection client requirements

For a production network, you must have the current general availability version of the Microsoft Purview Information Protection client installed on the Windows Server computer.

For more information, see the Install or upgrade the information protection client.

> **Important**
>
> You must install the full client for the scanner. Do not install the client with just the PowerShell module.

Label configuration requirements

You must have at least one sensitivity label configured in the Microsoft Purview portal for the scanner account, to apply classification and, optionally, encryption.

The *scanner account* is the account that you'll specify in the **DelegatedUser** parameter of the Set-Authentication cmdlet, run when configuring your scanner.

If your labels don't have auto-labeling conditions, see the instructions for alternative configurations below.

For more information, see:

- Learn about sensitivity labels
- Automatically apply a sensitivity label to Microsoft 365 data
- Restrict access to content by using encryption in sensitivity labels
- Configuring and installing the information protection scanner

SharePoint requirements

To scan SharePoint document libraries and folders, ensure that your SharePoint server complies with the following requirements:

Expand table

Requirement	Description
Supported versions	Supported versions include: SharePoint 2019, SharePoint 2016, and SharePoint 2013. Other versions of SharePoint are not supported for the scanner.

Requirement	Description
Versioning	When you use versioning, the scanner inspects and labels the last published version. If the scanner labels a file and content approval is required, that labeled file must be approved to be available for users.
Large SharePoint farms	For large SharePoint farms, check whether you need to increase the list view threshold (by default, 5,000) for the scanner to access all files. For more information, see Manage large lists and libraries in SharePoint.
Long file paths	If you have long file paths in SharePoint, ensure that your SharePoint server's httpRuntime.maxUrlLength value is larger than the default 260 characters. For more information, see the next section, Avoid scanner timeouts in SharePoint.

Avoid scanner timeouts in SharePoint

If you have long file paths in SharePoint version 2013 or higher, ensure that your SharePoint server's httpRuntime.maxUrlLength value is larger than the default 260 characters.

This value is defined in the **HttpRuntimeSection** class of the `ASP.NET` configuration.

To update the HttpRuntimeSection class:

1. Back up your **web.config** configuration.
2. Update the **maxUrlLength** value as needed. For example:

   ```
   c#
   ```

   ```
   <httpRuntime maxRequestLength="51200" requestValidationMode="2.0"
   maxUrlLength="5000"  />
   ```

3. Restart your SharePoint web server and verify that it loads correctly.

   For example, in Windows Internet Information Servers (IIS) Manager, select your site, and then under **Manage Website**, select **Restart**.

Microsoft Office requirements

To scan Office documents, your documents must be in one of the following formats:

- Microsoft Office 97-2003
- Office Open XML formats for Word, Excel, and PowerPoint

For more information, see Supported file types.

File path requirements

By default, to scan files, your file paths must have a maximum of 260 characters.

To scan files with file paths of more than 260 characters, install the scanner on a computer with one of the following Windows versions, and configure the computer as needed:

Expand table

Windows version	Description
Windows 2016 or later	Configure the computer to support long paths
Windows 10 or Windows Server 2016	Define the following group policy setting: **Local Computer Policy** > **Computer Configuration** > **Administrative Templates** > **All Settings** > **Enable Win32 long paths**. For more information long file path support in these versions, see the Maximum Path Length Limitation section from the Windows 10 developer documentation.
Windows 10, version 1607 or later	Opt in for the updated **MAX_PATH** functionality. For more information, see Enable Long Paths in Windows 10 versions 1607 and later.

Deploying the scanner with alternative configurations

The prerequisites listed above are the default requirements for the scanner deployment, and recommended because they support the simplest scanner configuration.

The default requirements should be suitable for initial testing, so that you can check the capabilities of the scanner.

However, in a production environment, your organization's policies may be different than the default requirements. The scanner can accommodate the following changes with additional configuration:

- Discover and scan all sites and subsites under a specific URL
- Restriction: The scanner server cannot have internet connectivity

- Restriction: The scanner service account cannot be synchronized to Microsoft Entra ID but the server has internet connectivity
- Restriction: The service account for the scanner cannot be granted the **Log on locally** right
- Restriction: You cannot be granted Sysadmin or databases must be created and configured manually
- Restriction: Your labels do not have auto-labeling conditions

Discover and scan all SharePoint sites and subsites under a specific URL

The scanner can discover and scan all SharePoint sites and subsites under a specific URL with the following configuration:

1. Start **SharePoint Central Administration**.
2. On the **SharePoint Central Administration** website, in the **Application Management** section, click **Manage web applications**.
3. Click to highlight the web application whose permission policy level you want to manage.
4. Choose the relevant farm and then select **Manage Permissions Policy Levels**.
5. Select **Site Collection Auditor** in the **Site Collection Permissions** options, then grant **View Application Pages** in the Permissions list, and finally, name the new policy level **Scanner site collection auditor and viewer**.
6. Add your scanner user to the new policy and grant **Site collection** in the Permissions list.
7. Add a URL of the SharePoint that hosts sites or subsites that need to be scanned. For more information, see Configure the scanner settings.

To learn more about how to manage your SharePoint policy levels see, manage permission policies for a web application.

Restriction: The scanner server cannot have internet connectivity

While the information protection client can't apply encryption without an internet connection, the scanner can still apply labels based on imported policies.

To support a disconnected computer, use one of the following methods:

- Use the Microsoft Purview portal (recommended when possible)
- Use PowerShell

Use the Microsoft Purview portal with a disconnected computer

To support a computer that can't connect to the Microsoft Purview portal, perform the following steps:

1. Configure labels in your policy, and then use the procedure to support disconnected computers to enable offline classification and labeling.
2. Enable offline management for content jobs as follows:

   Enable offline management for content scan jobs:

   a. Set the scanner to function in **offline** mode, using the Set-ScannerConfiguration cmdlet.

   b. Configure the scanner in the Microsoft Purview portal by creating a scanner cluster. For more information, see Configure the scanner settings.

   c. Export your content job from the **Information protection - Content scan jobs** pane using the **Export** option.

   d. Import the policy using the Import-ScannerConfiguration cmdlet.

   Results for offline content scan jobs are located at:
   %localappdata%\Microsoft\MSIP\Scanner\Reports

Use PowerShell with a disconnected computer

Perform the following procedure to support a disconnected computer using PowerShell only.

> **Important**
>
> Admins of Azure China 21Vianet scanner servers *must* use this procedure in order to manage their content scan jobs.

Manage your content scan jobs using PowerShell only:

1. Set the scanner to function in **offline** mode, using the Set-ScannerConfiguration cmdlet.

2. Create a new content scan job using the Set-ScannerContentScan cmdlet, making sure to use the mandatory `-Enforce On` parameter.

3. Add your repositories using the Add-ScannerRepository cmdlet, with the path to the repository you want to add.

   > **Tip**
   >
   > To prevent the repository from inheriting settings from your content scan job, add the `OverrideContentScanJob On` parameter, as well as values for additional settings.
   >
   > To edit details for an existing repository, use the **Set-ScannerRepository** command.

4. Use the Get-ScannerContentScan and Get-ScannerRepository cmdlets to return information about your content scan job's current settings.

5. Use the Set-ScannerRepository command to update details for an existing repository.

6. Run your content scan job immediately if needed, using the Start-Scan cmdlet.

   Results for offline content scan jobs are located at:
   %localappdata%\Microsoft\MSIP\Scanner\Reports

7. If you need to remove a repository or an entire content scan job, use the following cmdlets:

   - Remove-ScannerContentScan
   - Remove-ScannerRepository

Restriction: You cannot be granted Sysadmin or databases must be created and configured manually

Use the following procedures to manually create databases and grant the **db_owner** role, as needed.

- Procedure for the scanner database

If you can be granted the Sysadmin role *temporarily* to install the scanner, you can remove this role when the scanner installation is complete.

Do one of the following, depending on your organization's requirements:

Expand table

Restriction	Description
You can have the Sysadmin role temporarily	If you temporarily have the Sysadmin role, the database is automatically created for you and the service account for the scanner is automatically granted the required permissions. However, the user account that configures the scanner still requires the **db_owner** role for the scanner configuration database. If you only have the Sysadmin role until the scanner installation is complete, grant the **db_owner** role to the user account manually.
You cannot have the Sysadmin role at all	If you cannot be granted the Sysadmin role even temporarily, you must ask a user with Sysadmin rights to manually create a database before you install the scanner. For this configuration, the **db_owner** role must be assigned to the following accounts: - Service account for the scanner - User account for the scanner installation - User account for scanner configuration Typically, you will use the same user account to install and configure the scanner. If you use different accounts, they both require the **db_owner** role for the scanner configuration database. Create this user and rights as needed. If you specify your own cluster name, the configuration database is named **AIPScannerUL_<cluster_name>**.

Additionally:

- You must be a local administrator on the server that will run the scanner
- The service account that will run the scanner must be granted Full Control permissions to the following registry keys:
  - `HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Microsoft\MSIPC\Server`
  - `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSIPC\Server`

If, after configuring these permissions, you see an error when you install the scanner, the error can be ignored and you can manually start the scanner service.

Manually create a database and user for the scanner, and grant db_owner rights

If you need to manually create your scanner database and/or create a user and grant **db_owner** rights on the database, ask your Sysadmin to perform the following steps:

1. Create a database for scanner:

```
SQL
```

```
**CREATE DATABASE AIPScannerUL_[clustername]**

**ALTER DATABASE AIPScannerUL_[clustername] SET TRUSTWORTHY ON**
```

2. Grant rights to the user that runs the installation command and is used to run scanner management commands. Use the following script:

```
SQL

if not exists(select * from master.sys.server_principals where sid =
SUSER_SID('domain\user')) BEGIN declare @T nvarchar(500) Set @T = 'CREATE
LOGIN ' + quotename('domain\user') + ' FROM WINDOWS ' exec(@T) END
USE DBName IF NOT EXISTS (select * from sys.database_principals where sid =
SUSER_SID('domain\user')) BEGIN declare @X nvarchar(500) Set @X = 'CREATE
USER ' + quotename('domain\user') + ' FROM LOGIN ' +
quotename('domain\user'); exec sp_addrolemember 'db_owner', 'domain\user'
exec(@X) END
```

3. Grant rights to scanner service account. Use the following script:

```
SQL

if not exists(select * from master.sys.server_principals where sid =
SUSER_SID('domain\user')) BEGIN declare @T nvarchar(500) Set @T = 'CREATE
LOGIN ' + quotename('domain\user') + ' FROM WINDOWS ' exec(@T) END
```

Restriction: The service account for the scanner cannot be granted the Log on locally right

If your organization policies prohibit the **Log on locally** right for service accounts, use the *OnBehalfOf* parameter with Set-Authentication.

For more information, see Run information protection labeling cmdlets unattended.

Restriction: The scanner service account cannot be synchronized to Microsoft Entra ID but the server has internet connectivity

You can have one account to run the scanner service and use another account to authenticate to Microsoft Entra ID:

- **For the scanner service account**, use a local Windows account or an Active Directory account.

- **For the Microsoft Entra account**, specify the Microsoft Entra user in the Set-Authentication cmdlet, in the *DelegatedUser* parameter.

  If you are running the scan under any user other than the scanner account, make sure to specify the scanner account in *OnBehalfOf* parameter as well.

  For more information, see Run information protection labeling cmdlets unattended.

Restriction: Your labels do not have auto-labeling conditions

If your labels do not have any auto-labeling conditions, plan to use one of the following options when configuring your scanner:

Expand table

Option	Description
Discover all info types	In your content scan job, set the **Info types to be discovered** option to **All**. This option sets the content scan job to scan your content for all sensitive information types.
Use recommended labeling	In your content scan job, set the **Treat recommended labeling as automatic** option to **On**. This setting configures the scanner to automatically apply all recommended labels on your content.
Define a default label	Define a default label in your policy, content scan job, or repository. In this case the scanner applies the default label on all files found.

Next steps

Once you've confirmed that your system complies with the scanner prerequisites, continue with Configuring and installing the information protection scanner.

For an overview about the scanner, see Learn about the information protection scanner.

Configure and install the information protection scanner

Summarize this article for me

> **Note**
>
> There's a new version of the information protection scanner. For more information, see Upgrade the Microsoft Purview Information Protection scanner.

This article describes how to configure and install the Microsoft Purview Information Protection scanner, formerly named *Azure Information Protection unified labeling scanner*, or the on-premises scanner.

> **Tip**
>
> While most customers will perform these procedures in the admin portal, you may need to work in PowerShell only.
>
> For example, if you are working in an environment without access to the admin portal, such as Azure China 21Vianet, follow the instructions in Use PowerShell to configure the scanner.

Overview

Before you start, verify that your system complies with the required prerequisites.

Then, use the following steps to configure and install the scanner:

1. Configure the scanner settings
2. Install the scanner
3. Get a Microsoft Entra token for the scanner
4. Configure the scanner to apply classification and protection

Next, perform the following configuration procedures as needed for your system:

Expand table

Procedure	Description
Change which file types to protect	You may want to scan, classify, or protect different file types than the default. For more information, see The scanning process.
Upgrading your scanner	Upgrade your scanner to use the latest features and improvements.
Editing data repository settings in bulk	Use import and export options to make changes in bulk for multiple data repositories.
Use the scanner with alternative configurations	Use the scanner without configuring labels with any conditions
Optimize performance	Guidance to optimize your scanner performance

If you don't have access to the scanner pages in the Microsoft Purview portal, configure any scanner settings in PowerShell only. For more information, see Use PowerShell to configure the scanner and Supported PowerShell cmdlets.

Configure the scanner settings

Before you install the scanner, or upgrade it from an older general availability version, configure or verify your scanner settings. For this configuration, you can use either the Microsoft Purview portal.

To configure your scanner in the Microsoft Purview portal:

1. Sign in using one of the following roles:

- **Compliance Administrator**
- **Compliance Data Administrator**
- **Security Administrator**
- **Organization Management**

2. Sign in to the Microsoft Purview portal > **Settings** card > **Information Protection** > **Information protection scanner**.

3. Create a scanner cluster. This cluster defines your scanner and is used to identify the scanner instance, such as during installation, upgrades, and other processes.

4. Create a content scan job to define the repositories you want to scan.

Create a scanner cluster

To create a scanner cluster in the Microsoft Purview portal:

1. From the tabs on the **Information protection scanner** page, select **Clusters**.
2. On the **Clusters** tab, select **Add** +.
3. On the **New cluster** pane, enter a meaningful name for the scanner, and an optional description.

   The cluster name is used to identify the scanner's configurations and repositories. For example, you might enter **Europe** to identify the geographical locations of the data repositories you want to scan.

   You'll use this name later on to identify where you want to install or upgrade your scanner.
4. Select **Save** to save your changes.

Create a content scan job

Deep dive into your content to scan specific repositories for sensitive content.

To create your content scan job on the Microsoft Purview portal:

1. From the tabs on the **Information protection scanner** page, select **Content scan jobs**.
2. On the **Content scan jobs** pane, select **Add** +.
3. For this initial configuration, configure the following settings, and then select **Save**.

Expand table

Setting	Description
Content scan job settings	- **Schedule**: Keep the default of **Manual** - **Info types to be discovered**: Change to **Policy only**
DLP policy	If you're using a data loss prevention policy, set **Enable DLP rules** to **On**. For more information, see Use a DLP policy.
Sensitivity policy	- **Enforce sensitivity labeling policy**: Select **Off** - **Label files based on content**: Keep the default of **On** - **Default label**: Keep the default of **Policy default** - **Relabel files**: Keep the default of **Off**
Configure file settings	- **Preserve "Date modified", "Last modified" and "Modified by"**: Keep the default of **On** - **File types to scan**: Keep the default file types for **Exclude** - **Default owner**: Keep the default of **Scanner Account** - **Set repository owner**: Use this option only when using a DLP policy.

Setting	Description

4. Open the content scan job that was saved, and select the **Repositories** tab to specify the data stores to be scanned.

   Specify UNC paths and SharePoint Server URLs for SharePoint on-premises document libraries and folders.

   > ⓘ Note
   >
   > SharePoint Server 2019, SharePoint Server 2016, and SharePoint Server 2013 are supported for SharePoint. SharePoint Server 2010 is also supported when you have extended support for this version of SharePoint.

   To add your first data store, while on the **Repositories** tab:

   a. On the **Repositories** pane, select **Add**:

   b. On the **Repository** pane, specify the path for the data repository, and then select **Save**.

   - For a network share, use `\\Server\Folder`.
   - For a SharePoint library, use `http://sharepoint.contoso.com/Shared%20Documents/Folder`.
   - For a local path: `C:\Folder`
   - For a UNC path: `\\Server\Folder`

   > ⓘ Note
   >
   > Wildcards are not supported and WebDav locations are not supported. Scanning of OneDrive locations as repositories is not supported.

   If you add a SharePoint path for **Shared Documents**:

   - Specify **Shared Documents** in the path when you want to scan all documents and all folders from Shared Documents. For example: `http://sp2013/SharedDocuments`
   - Specify **Documents** in the path when you want to scan all documents and all folders from a subfolder under Shared Documents. For example: `http://sp2013/Documents/SalesReports`
   - Or, specify only the **FQDN** of your SharePoint, for example `http://sp2013` to discover and scan all SharePoint sites and subsites under a specific URL and subtitles under this URL. Grant scanner **Site Collector Auditor** rights to enable this.

For the remaining settings on this pane, don't change them for this initial configuration, but keep them as **Content scan job default**. The default setting means that the data repository inherits the settings from the content scan job.

Use the following syntax when adding SharePoint paths:

Expand table

Path	Syntax
Root path	`http://<SharePoint server name>` Scans all sites, including any site collections allowed for the scanner user. Requires additional permissions to automatically discover root content
Specific SharePoint subsite or collection	One of the following: - `http://<SharePoint server name>/<subsite name>` - `http://SharePoint server name>/<site collection name>/<site name>` Requires additional permissions to automatically discover site collection content
Specific SharePoint library	One of the following: - `http://<SharePoint server name>/<library name>` - `http://SharePoint server name>/.../<library name>`
Specific SharePoint folder	`http://<SharePoint server name>/.../<folder name>`

5. Repeat the previous steps to add as many repositories as needed.

You're now ready to install the scanner with the content scanner job that you've created. Continue with Install the scanner.

Install the scanner

After you've configured the scanner, perform the following steps to install the scanner. This procedure is performed fully in PowerShell.

1. Sign in to the Windows Server computer that will run the scanner. Use an account that has local administrator rights and that has permissions to write to the SQL Server master database.

> **ⓘ Important**
>
> You must have the information protection client installed on your machine before installing the scanner.
>
> For more information, see Prerequisites for installing and deploying the information protection scanner.

2. Open a Windows PowerShell session with the **Run as an administrator** option.

3. Run the Install-Scanner cmdlet, specifying your SQL Server instance on which to create a database for the information protection scanner, and the scanner cluster name that you specified in the preceding section:

   ```PowerShell
   Install-Scanner -SqlServerInstance <name> -Cluster <cluster name>
   ```

   Examples, using the scanner cluster name of **Europe**:

   - For a default instance: `Install-Scanner -SqlServerInstance SQLSERVER1 -Cluster Europe`
   - For a named instance: `Install-Scanner -SqlServerInstance SQLSERVER1\SCANNER -Cluster Europe`
   - For SQL Server Express: `Install-Scanner -SqlServerInstance SQLSERVER1\SQLEXPRESS -Cluster Europe`

   When you're prompted, provide the Active Directory credentials for the scanner service account.

   Use the following syntax: `\<domain\user name>`. For example: `contoso\scanneraccount`

4. Verify that the service is now installed by using **Administrative Tools** > **Services**.

   The installed service is named **Microsoft Purview Information Protection Scanner** and is configured to run by using the scanner service account that you created.

Now that you've installed the scanner, you need to get a Microsoft Entra token for the scanner service account to authenticate, so that the scanner can run unattended.

Get a Microsoft Entra token for the scanner

A Microsoft Entra token allows the scanner to authenticate to the Microsoft Purview Information Protection Scanner service, enabling the scanner to run unattended.

For more information, see Run information protection labeling cmdlets unattended.

> **Note**
>
> Support for certificate-based authentication is in public preview. For more information, see Certificate-based authentication

To get a Microsoft Entra token:

1. Navigate to the Azure Portal and proceed to the **Microsoft Entra ID** Blade.
2. In the Microsoft Entra ID side pane, click **App Registrations**.
3. At the top, go ahead and click **+ New registration**.
4. In the Name section type in **InformationProtectionScanner**.
5. Leave **Supported account types** as default.
6. For the Redirect URI, leave the type as Web but type in **http://localhost** for the entry portion and click **Register**.
7. On the Overview page of this application, note down in your text editor of choice the following IDs: **Application (client) ID** and **Directory (tenant) ID**. You will need this later when setting up the Set-AIPAuthentication command.
8. On the side pane, navigate to **Certificates and Secrets**.
9. Click on **+ New client secret**.
10. In the dialog box that shows up, enter a description for your secret and set it to Expire **In 1 year** and then Add the secret.
11. You should see now under the client secrets section that there is an entry with the **Secret Value**. Go ahead and copy this value and store it in the file where you saved the Client ID and Tenant ID. This is the only time you will be able to see the secret value, it will not be recoverable if you don't copy it at this time.
12. On the side pane, navigate to **API Permissions**.
13. Go ahead and select **Add a permission**.

14. When the screen shows, select **Azure Rights Management Service**. Then select **Application Permissions**.

15. Click the drop down for **Content** and put checkmarks down for **Content.DelegatedReader** and **Content.DelegatedWriter**. Then at the bottom of the screen, click **Add Permissions**.

16. Navigate back the **API Permissions** section and add another permission.

17. This time, for the Select an API section, click on **APIs my organization uses**. In the search bar, type in **Microsoft Information Protection Sync Service** and select it.

18. Select **Application Permissions** and then in the **Unified Policy** drop down, checkmark the permission **UnifiedPolicy.Tenant.Read**. Then at the bottom of the screen, click **Add Permissions**.

19. Back on the **API Permissions** screen, click **Grant Admin Consent** and look for the operation being successful (signified by a green checkmark).

20. From the Windows Server computer, if your scanner service account has been granted the **Log on locally** right for the installation, sign in with this account and start a PowerShell session.

    Run Set-Authentication, specifying the values that you copied from the previous step:

    PowerShell

    ```
    Set-Authentication -AppId <ID of the registered app> -AppSecret <client secret
    sting> -TenantId <your tenant ID> -DelegatedUser <Azure AD account>
    ```

    For example:

    PowerShell

    ```
    $pscreds = Get-Credential CONTOSO\scanner
    Set-Authentication -AppId "77c3c1c3-abf9-404e-8b2b-4652836c8c66" -AppSecret
    "OAkk+rnuYc/u+]ah2kNxVbtrDGbS47L4" -DelegatedUser scanner@contoso.com -
    TenantId "9c11c87a-ac8b-46a3-8d5c-f4d0b72ee29a" -OnBehalfOf $pscreds
    Acquired application access token on behalf of CONTOSO\scanner.
    ```

Tip

If your scanner service account cannot be granted the **Log on locally** right for the installation, use the *OnBehalfOf* parameter with **Set-Authentication**, as described in as described in **Run information protection labeling cmdlets unattended**.

The scanner now has a token to authenticate to Microsoft Entra ID. This token is valid for one year, two years, or never, according to your configuration of the **Web app /API** client secret in Microsoft Entra ID. When the token expires, you must repeat this procedure.

Continue using one of the following steps, depending on whether you're using the Microsoft Purview portal to configure your scanner, or PowerShell only:

Admin portal only

You're now ready to run your first scan in discovery mode. For more information, see Run a discovery cycle and view reports for the scanner.

Once you've run your initial discovery scan, continue with Configure the scanner to apply classification and protection.

For more information, see Run information protection labeling cmdlets unattended.

Configure the scanner to apply classification and protection

The default settings configure the scanner to run once, and in reporting-only mode. To change these settings, edit the content scan job.

Tip

If you're working in PowerShell only, see **Configure the scanner to apply classification and protection - PowerShell only**.

To configure the scanner to apply classification and protection in the Microsoft Purview portal::

1. In the Microsoft Purview portal, on the **Content scan jobs** tab, select a specific content scan job to edit it.

2. Select the content scan job, change the following, and then select **Save**:

    - From the **Content scan job** section: Change the **Schedule** to **Always**

- From the **Enforce sensitivity labeling policy** section: Change the radio button to **On**

3. Make sure a node for the content scan job is online, then start the content scan job again by selecting **Scan now**. The **Scan now** button only appears when a node for the selected content scan job is online.

The scanner is now scheduled to run continuously. When the scanner works its way through all configured files, it automatically starts a new cycle so that any new and changed files are discovered.

Use a DLP policy

Using a data loss prevention policy enables the scanner to detect potential data leaks by matching DLP rules to files stored in file shares and SharePoint Server.

- **Enable DLP rules in your content scan job** to reduce the exposure of any files that match your DLP policies. When your DLP rules are enabled, the scanner may reduce file access to data owners only, or reduce exposure to network-wide groups, such as **Everyone**, **Authenticated Users**, or **Domain Users**.
- **In the Microsoft Purview portal**, determine whether you are just testing your DLP policy or whether you want your rules enforced and your file permissions changed according to those rules. For more information, see Create and Deploy data loss prevention policies

DLP policies are configured in the Microsoft Purview portal. For more information about DLP licensing, see Get started with the data loss prevention on-premises scanner.

> **Tip**
>
> Scanning your files, even when just testing the DLP policy, also creates file permission reports. Query these reports to investigate specific file exposures or explore the exposure of a specific user to scanned files.
>
> To use PowerShell only, see **Use a DLP policy with the scanner - PowerShell only**.

To use a DLP policy with the scanner in the Microsoft Purview portal:

1. In the Microsoft Purview portal, navigate to the **Content scan jobs** tab and select a specific content scan job. For more information, see Create a content scan job.

2. Under **Enable DLP policy rules**, set the radio button to **On**.

   > **Important**

> Do not set **Enable DLP rules** to **On** unless you actually have a DLP policy configured in Microsoft 365.
>
> Turning this feature on without a DLP policy will cause the scanner to generate errors.

3. (Optional) Set the **Set repository owner** to **On**, and define a specific user as the repository owner.

   This option enables the scanner to reduce the exposure of any files found in this repository, which match the DLP policy, to the repository owner defined.

DLP policies and *make private* actions

If you are using a DLP policy with a *make private* action, and are also planning to use the scanner to automatically label your files, we recommend that you also define the unified labeling client's **UseCopyAndPreserveNTFSOwner** advanced setting.

This setting ensures that the original owners retain access to their files.

For more information, see Create a content scan job and Automatically apply a sensitivity label to Microsoft 365 data.

Change which file types to protect

By default the scanner protects Office file types and PDF files only.

Use PowerShell commands to change this behavior as needed, such as to configure the scanner to protect all file types, just as the client does, or to protect additional, specific file types.

For a label policy that applies to the user account downloading labels for the scanner, specify a PowerShell advanced setting named **PFileSupportedExtensions**.

For a scanner that has access to the internet, this user account is the account that you specify for the *DelegatedUser* parameter with the Set-Authentication command.

Example 1: PowerShell command for the scanner to protect all file types, where your label policy is named "Scanner":

PowerShell

```
Set-LabelPolicy -Identity Scanner -AdvancedSettings @{PFileSupportedExtensions="*"}
```

Example 2: PowerShell command for the scanner to protect .xml files and .tiff files in addition to Office files and PDF files, where your label policy is named "Scanner":

PowerShell

```
Set-LabelPolicy -Identity Scanner -AdvancedSettings
@{PFileSupportedExtensions=ConvertTo-Json(".xml", ".tiff")}
```

For more information, see Change which file types to protect.

Upgrade your scanner

If you've previously installed the scanner and want to upgrade, use the instructions described in Upgrade the Microsoft Purview Information Protection scanner.

Then, configure and use your scanner as usual, skipping the steps to install your scanner.

Edit data repository settings in bulk

Use the **Export** and **Import** buttons to make changes for your scanner across several repositories.

This way, you don't need to make the same changes several times, manually, in the Microsoft Purview portal.

For example, if you've a new file type on several SharePoint data repositories, you may want to update the settings for those repositories in bulk.

To make changes in bulk across repositories in the Microsoft Purview portal:

1. In the Microsoft Purview portal, select a specific content scan job and navigate to the **Repositories** tab within the pane. Select the **Export** option.

2. Manually edit the exported file to make your change.

3. Use the **Import** option on the same page to import the updates back across your repositories.

Use the scanner with alternative configurations

The scanner usually looks for conditions specified for your labels in order to classify and protect your content as needed.

In the following scenarios, the scanner is also able to scan your content and manage labels, without any conditions configured:

- Apply a default label to all files in a data repository
- Remove existing labels from all files in a data repository
- Identify all custom conditions and known sensitive information types

Apply a default label to all files in a data repository

In this configuration, all unlabeled files in the repository are labeled with the default label specified for the repository or the content scan job. Files are labeled without inspection.

Configure the following settings:

Expand table

Setting	Description
Label files based on content	Set to **Off**
Default label	Set to **Custom**, and then select the label to use
Enforce default label	Select to have the default label applied to all files, even if they're already labeled by turning **Relabel files** and **Enforce default label** on

Remove existing labels from all files in a data repository

In this configuration, all existing labels are removed, including protection, if protection was applied with the label. Protection applied independently of a label is retained.

Configure the following settings:

Expand table

Setting	Description
Label files based on content	Set to **Off**
Default label	Set to **None**
Relabel files	Set to **On**, with the **Enforce default label** set to **On**

Identify all custom conditions and known sensitive information types

This configuration enables you to find sensitive information that you might not realize you had, at the expense of scanning rates for the scanner.

Set the **Info types to be discovered** to **All**.

To identify conditions and information types for labeling, the scanner uses any custom sensitive information types specified, and the list of built-in sensitive information types that are available to select, as defined in your labeling management center.

Optimize scanner performance

> **Note**
>
> If you're looking to improve the responsiveness of the scanner computer rather than the scanner performance, use an advanced client setting to limit the number of threads used by the scanner.

Use the following options and guidance to help you optimize scanner performance:

Expand table

Option	Description
Have a high speed and reliable network connection between the scanner computer and the scanned data store	For example, place the scanner computer in the same LAN, or preferably, in the same network segment as the scanned data store. The quality of the network connection affects the scanner performance because, to inspect the files, the scanner transfers the contents of the files to the computer running the scanner Microsoft Purview Information Protection Scanner service. Reducing or eliminating the network hops required for the data to travel also reduces the load on your network.
Make sure the scanner computer has available processor resources	Inspecting the file contents and encrypting and decrypting files are processor-intensive actions. Monitor the typical scanning cycles for your specified data stores to identify whether a lack of processor resources is negatively affecting the scanner performance.

Option	Description
Install multiple instances of the scanner	The scanner supports multiple configuration databases on the same SQL server instance when you specify a custom cluster name for the scanner. **Tip**: Multiple scanners can also share the same cluster, resulting in quicker scanning times. If you plan to install the scanner on multiple machines with the same database instance, and want your scanners to run in parallel, you must install all your scanners using the same cluster name.
Check your alternative configuration usage	The scanner runs more quickly when you use the alternative configuration to apply a default label to all files because the scanner doesn't inspect the file contents. The scanner runs more slowly when you use the alternative configuration to identify all custom conditions and known sensitive information types.

Additional factors that affect performance

Additional factors that affect the scanner performance include:

Expand table

Factor	Description
Load/response times	The current load and response times of the data stores that contain the files to scan will also affect scanner performance.
Scanner mode (Discovery / Enforce)	Discovery mode typically has a higher scanning rate than enforce mode. Discovery requires a single file read action, whereas enforce mode requires read and write actions.
Policy changes	Your scanner performance may be affected if you've made changes to the autolabeling in the label policy. Your first scan cycle, when the scanner must inspect every file, will take longer than subsequent scan cycles that by default, inspect only new and changed files. If you change the conditions or autolabeling settings, all files are scanned again. For more information, see Rescanning files.
Regex constructions	Scanner performance is affected by how your regex expressions for custom conditions are constructed.

Factor	Description
	To avoid heavy memory consumption and the risk of timeouts (15 minutes per file), review your regex expressions for efficient pattern matching. For example: - Avoid greedy quantifiers - Use non-capturing groups such as `(?:expression)` instead of `(expression)`
Log level	Log level options include **Debug**, **Info**, **Error** and **Off** for the scanner reports. - **Off** results in the best performance - **Debug** considerably slows down the scanner and should be used only for troubleshooting. For more information, see the *ReportLevel* parameter for the Set-ScannerConfiguration cmdlet.
Files being scanned	- With the exception of Excel files, Office files are more quickly scanned than PDF files. - Unprotected files are quicker to scan than protected files. - Large files obviously take longer to scan than small files.

Use PowerShell to configure the scanner

This section describes the steps required to configure and install the scanner when you don't have access to the scanner pages in the Microsoft Purview portal, and must use PowerShell only.

> ⓘ **Important**
>
> - Some steps require Powershell whether or not you are able to access the scanner pages in the Microsoft Purview portal, and are identical. For these steps, see the earlier instructions in this article as indicated.
> - If you're working with the scanner for Azure China 21Vianet, additional steps are required in addition to the instructions detailed here. For more information, see Microsoft Purview Information Protection for Office 365 operated by 21Vianet.

For more information, see Supported PowerShell cmdlets.

To configure and install your scanner:

1. Start with PowerShell closed. If you've previously installed the information protection client and scanner, make sure that the **Microsoft Purview Information Protection Scanner** service is stopped.

2. Open a Windows PowerShell session with the **Run as an administrator** option.

3. Run the Install-Scanner command to install your scanner on your SQL server instance, with the **Cluster** parameter to define your cluster name.

   This step is identical whether or not you're able to access the scanner pages in the Microsoft Purview portal. For more information, see the earlier instructions in this article: Install the scanner

4. Get an Azure token to use with your scanner, and then reauthenticate.

   This step is identical whether or not you're able to access the scanner pages in the Microsoft Purview portal. For more information, see the earlier instructions in this article: Get a Microsoft Entra token for the scanner.

5. Run the Set-ScannerConfiguration cmdlet to set the scanner to function in offline mode. Run:

   PowerShell

   ```
   Set-ScannerConfiguration -OnlineConfiguration Off
   ```

6. Run the Set-ScannerContentScan cmdlet to create a default content scan job.

   The only required parameter in the **Set-ScannerContentScan** cmdlet is **Enforce**. However, you might want to define other settings for your content scan job at this time. For example:

   PowerShell

   ```
   Set-ScannerContentScan -Schedule Manual -DiscoverInformationTypes PolicyOnly -
   Enforce Off -DefaultLabelType PolicyDefault -RelabelFiles Off -
   PreserveFileDetails On -IncludeFileTypes '' -ExcludeFileTypes '.msg,.tmp' -
   DefaultOwner <account running the scanner>
   ```

   The syntax above configures the following settings while you continue the configuration:

   - Keeps the scanner run scheduling to *manual*
   - Sets the information types to be discovered based on the sensitivity label policy
   - Does *not* enforce a sensitivity label policy

- Automatically labels files based on content, using the default label defined for the sensitivity label policy
- Does *not* allow for relabeling files
- Preserves file details while scanning and auto-labeling, including *date modified*, *last modified*, and *modified by* values
- Sets the scanner to exclude .msg and .tmp files when running
- Sets the default owner to the account you want to use when running the scanner

7. Use the Add-ScannerRepository cmdlet to define the repositories you want to scan in your content scan job. For example, run:

```
PowerShell
Add-ScannerRepository -OverrideContentScanJob Off -Path 'c:\repoToScan'
```

Use one of the following syntaxes, depending on the type of repository you're adding:

- For a network share, use `\\Server\Folder`.
- For a SharePoint library, use `http://sharepoint.contoso.com/Shared%20Documents/Folder`.
- For a local path: `C:\Folder`
- For a UNC path: `\\Server\Folder`

> ⓘ **Note**
>
> Wildcards are not supported and WebDav locations are not supported.
>
> To modify the repository later on, use the Set-ScannerRepository cmdlet instead.

If you add a SharePoint path for **Shared Documents**:

- Specify **Shared Documents** in the path when you want to scan all documents and all folders from Shared Documents. For example: `http://sp2013/SharedDocuments`
- Specify **Documents** in the path when you want to scan all documents and all folders from a subfolder under Shared Documents. For example: `http://sp2013/Documents/SalesReports`
- Or, specify only the **FQDN** of your SharePoint, for example `http://sp2013` to discover and scan all SharePoint sites and subsites under a specific URL and subtitles under this URL. Grant scanner **Site Collector Auditor** rights to enable this.

Use the following syntax when adding SharePoint paths:

Expand table

Path	Syntax
Root path	`http://<SharePoint server name>` Scans all sites, including any site collections allowed for the scanner user.
Specific SharePoint subsite or collection	One of the following: - `http://<SharePoint server name>/<subsite name>` - `http://SharePoint server name>/<site collection name>/<site name>`
Specific SharePoint library	One of the following: - `http://<SharePoint server name>/<library name>` - `http://SharePoint server name>/.../<library name>`
Specific SharePoint folder	`http://<SharePoint server name>/.../<folder name>`

Continue with the following steps as needed:

- Configuration for customers in China
- Run a discovery cycle and view reports for the scanner
- Use PowerShell to configure the scanner to apply classification and protection
- Use PowerShell to configure a DLP policy with the scanner

Use PowerShell to configure the scanner to apply classification and protection

1. Run the Set-ScannerContentScan cmdlet to update your content scan job to set your scheduling to always and enforce your sensitivity policy.

   PowerShell

   ```
   Set-ScannerContentScan -Schedule Always -Enforce On
   ```

   > **Tip**
   >
   > You may want to change other settings on this pane, such as whether file attributes are changed and whether the scanner can relabel files. For more information about the settings available, see the full Set-ScannerContentScan documentation.

2. Run the Start-Scan cmdlet to run your content scan job:

PowerShell

```
Start-Scan
```

The scanner is now scheduled to run continuously. When the scanner works its way through all configured files, it automatically starts a new cycle so that any new and changed files are discovered.

Use PowerShell to configure a DLP policy with the scanner

Run the Set-ScannerContentScan cmdlet again with the **-EnableDLP** parameter set to **On**, and with a specific repository owner defined.

For example:

PowerShell

```
Set-ScannerContentScan -EnableDLP On -RepositoryOwner 'domain\user'
```

Certificate-based authentication (Public Preview)

Using certificate-based authentication with the information protection scanner

This section describes how to configure the Microsoft Purview Information Protection scanner to authenticate using a certificate instead of a client secret.

Prerequisites

Before configuring certificate-based authentication, ensure you have:

- The Microsoft Purview Information Protection scanner installed
- Administrative access to the Windows Server running the scanner
- Access to the Microsoft Entra app registration used by the scanner
- Windows PowerShell 5.1

Step 1: Obtain or create a certificate

You have two options for obtaining a certificate:

1. **CA-issued certificate**: Request a certificate from your organization's Certificate Authority.

2. **Self-signed certificate**: Create a self-signed certificate.

Option A: Using a CA-issued certificate (production)

Using a CA-issued certificate provides:

- Automatic trust via the existing PKI infrastructure
- Centralized certificate lifecycle management
- Compliance with organizational security policies
- No need to skip certificate chain validation

Certificate requirements

When requesting a certificate from your CA, ensure it meets these requirements:

Expand table

Requirement	Value
Key Algorithm	RSA
Key Length	2048 bits minimum (4096 recommended)
Key Usage	Digital Signature
Private Key	Exportable (for backup) or marked for the machine
Validity	Per your organization's policy (typically 1-2 years)

Review documentation from your CA for specific instructions on requesting a certificate with these parameters.

After obtaining the key from your enterprise CA, install the certificate in the Local Machine store on each Windows Server running the scanner. Make sure to install the certificate in the **Personal** store of the Local Machine.

Exporting the public key for Microsoft Entra

After the certificate is issued and installed, export the public key:

PowerShell

```
# Find the certificate (adjust the subject filter as needed)
$cert = Get-ChildItem Cert:\LocalMachine\My | Where-Object { $_.Subject -like
```

```
"*PurviewScanner*" }
Export-Certificate -Cert $cert -FilePath "C:\temp\PurviewScanner.cer"
```

Option B: Using a self-signed certificate

A self-signed certificate can be created on a single server, then imported to servers across the scanner cluster.

PowerShell

```powershell
# Create certificate in Local Machine store with RSA provider
$cert = New-SelfSignedCertificate `
    -Subject "CN=PurviewScanner" `
    -CertStoreLocation Cert:\LocalMachine\My `
    -KeyExportPolicy Exportable `
    -KeySpec Signature `
    -KeyLength 2048 `
    -KeyAlgorithm RSA `
    -HashAlgorithm SHA256 `
    -NotAfter (Get-Date).AddYears(2) `
    -Provider "Microsoft Enhanced RSA and AES Cryptographic Provider"

# Display the certificate details
Write-Host "Certificate created successfully"
Write-Host "Thumbprint: $($cert.Thumbprint)"
Write-Host "Subject: $($cert.Subject)"
```

> **ⓘ Important**
>
> The `-Provider "Microsoft Enhanced RSA and AES Cryptographic Provider"` parameter is required. Using CNG (Cryptography Next Generation) providers will result in "Keyset does not exist" errors when the scanner attempts to authenticate.

Export the public key

Export the certificate's public key to upload to Microsoft Entra:

PowerShell

```powershell
# Export public key certificate (.cer file)
Export-Certificate -Cert $cert -FilePath "C:\temp\PurviewScanner.cer"
```

Step 2: Grant private key permissions to the scanner service account

The scanner service account must have permission to read the certificate's private key. Without this permission, authentication will fail with "Keyset does not exist" errors.

Using the Certificate Manager UI

1. Open the Local Machine certificate store:
    - Press `Win + R`, type `certlm.msc`, and press Enter
2. Navigate to **Certificates - Local Computer**
3. Right-click on the certificate you created (e.g., "PurviewScanner") and select **All Tasks** > **Manage Private Keys**
4. Click **Add** and enter the scanner service account name (e.g., `CONTOSO\ScannerService`)
5. Select the account and ensure **Read** permission is checked
6. Click **OK** to save

Using PowerShell

Alternatively, grant permissions using PowerShell. Make sure to replace the service account name with your actual scanner service account.

PowerShell

```
# Get the certificate
$cert = Get-ChildItem Cert:\LocalMachine\My | Where-Object { $_.Subject -eq
"CN=PurviewScanner" }

# Get the private key file path
$privateKey =
[System.Security.Cryptography.X509Certificates.RSACertificateExtensions]::GetRSAPri
vateKey($cert)
$keyPath = $privateKey.Key.UniqueName
$fullKeyPath = "$env:ALLUSERSPROFILE\Microsoft\Crypto\RSA\MachineKeys\$keyPath"

# Get current ACL
$acl = Get-Acl $fullKeyPath

# Add read permission for the scanner service account
$serviceAccount = "CONTOSO\ScannerService"  # Replace with your scanner service
account
$accessRule = New-Object
System.Security.AccessControl.FileSystemAccessRule($serviceAccount, "Read",
"Allow")
$acl.AddAccessRule($accessRule)
```

```
# Apply the updated ACL
Set-Acl $fullKeyPath $acl
```

Step 3: Upload the certificate to Microsoft Entra

Register the certificate's public key with the app registration used by the scanner.

For detailed instructions on uploading a certificate to a Microsoft Entra app registration, see Register a certificate with Microsoft Entra.

After uploading, note the certificate thumbprint displayed in the portal - it should match the thumbprint from Step 1.

Step 4: Configure the scanner to use certificate authentication

Use the `Set-Authentication` cmdlet with certificate parameters instead of the `-AppSecret` parameter.

PowerShell

```
# Get credentials for the scanner service account
$pscreds = Get-Credential CONTOSO\ScannerService

# Set authentication using certificate thumbprint
Set-Authentication `
    -AppId "your-app-id-guid" `
    -TenantId "your-tenant-id-guid" `
    -DelegatedUser "scanner@contoso.com" `
    -CertificateThumbprint "your-certificate-thumbprint" `
    -CertificateStoreLocation LocalMachine `
    -CertificateStoreName My `
    -OnBehalfOf $pscreds
```

The certificate chain is validated automatically for certificates issued by a trusted CA. If validation fails, ensure:

- The CA's root certificate is in the Trusted Root Certification Authorities store
- Any intermediate CA certificates are in the Intermediate Certification Authorities store

> ⓘ **Note**
>
> If you're using a self-signed certificate, add the `-SkipCertificateChainValidation` parameter to bypass chain validation, which will fail for self-signed certificates.

Authenticate using certificate subject name

Alternatively, you can specify the certificate by its subject name:

PowerShell

```powershell
# Get credentials for the scanner service account
$pscreds = Get-Credential CONTOSO\ScannerService

# Set authentication using certificate subject name
Set-Authentication `
    -AppId "your-app-id-guid" `
    -TenantId "your-tenant-id-guid" `
    -DelegatedUser "scanner@contoso.com" `
    -CertificateSubjectName "PurviewScanner" `
    -CertificateStoreLocation LocalMachine `
    -CertificateStoreName My `
    -OnBehalfOf $pscreds
```

> **Note**
>
> If you're using a self-signed certificate, add the `-SkipCertificateChainValidation` parameter to bypass chain validation, which will fail for self-signed certificates.

Parameter reference

Expand table

Parameter	Description
`-CertificateThumbprint`	The SHA-1 thumbprint of the certificate to use for authentication. Cannot be used with `-CertificateSubjectName`.
`-CertificateSubjectName`	The subject name (CN) of the certificate to use for authentication. Cannot be used with `-CertificateThumbprint`.
`-CertificateStoreLocation`	The certificate store location. Use `LocalMachine` for the scanner service. Valid values: `CurrentUser`, `LocalMachine`. Default: `CurrentUser`.
`-CertificateStoreName`	The certificate store name. Default: `My` (Personal store).
`-SkipCertificateChainValidation`	Skips certificate chain validation. Required for self-signed certificates.

Troubleshooting

"Keyset does not exist" error

This error typically indicates one of the following issues:

1. **Private key permissions**: The scanner service account doesn't have read access to the certificate's private key. See Step 2 to grant permissions.
2. **CNG provider**: The certificate was created with a CNG provider instead of an RSA provider. Recreate the certificate using the `-Provider "Microsoft Enhanced RSA and AES Cryptographic Provider"` parameter.

"Certificate not found" error

Verify that:

- The thumbprint or subject name is correct
- The certificate is in the specified store (`LocalMachine\My` by default)
- The certificate has not expired

"A certificate chain could not be built" error

For self-signed certificates, use the `-SkipCertificateChainValidation` parameter. For CA-issued certificates, ensure the full certificate chain (including intermediate CAs) is installed on the server.

401 Unauthorized or "invalid_client" error

Verify that:

- The certificate's public key is uploaded to the correct Microsoft Entra app registration
- The app registration ID matches the `-AppId` parameter
- The certificate has not expired
- The tenant ID is correct

Migrating from secret to certificate authentication

To migrate an existing scanner from secret-based to certificate-based authentication:

1. Create and configure the certificate as described above
2. Run `Set-Authentication` with the certificate parameters
3. The new authentication configuration will overwrite the previous secret-based configuration

4. Restart the scanner service

```powershell
# Restart the scanner service after changing authentication
Restart-Service -Name "Microsoft Purview Information Protection Scanner"
```

See also

- Run information protection labeling cmdlets unattended
- Register a certificate with Microsoft Entra

Supported PowerShell cmdlets

This section lists PowerShell cmdlets supported for the information protection scanner and instructions for configuring and installing the scanner with PowerShell only.

Supported cmdlets for the scanner include:

- Add-ScannerRepository
- Clear-Authentication
- Export-DebugLogs
- Get-FileStatus
- Get-ScannerConfiguration
- Get-ScannerContentScan
- Get-ScannerRepository
- Get-ScanStatus
- Import-ScannerConfiguration
- Install-Scanner
- New-CustomPermissions
- Remove-FileLabel
- Remove-ScannerContentScan
- Remove-ScannerRepository

- Set-Authentication
- Set-FileLabel
- Set-ScannerConfiguration
- Set-ScannerContentScan
- Set-ScannerDatabase
- Set-ScannerRepository
- Start-Scan
- Start-ScannerDiagnostics
- Stop-Scan
- Uninstall-Scanner
- Update-ScannerDatabase

Next steps

Once you've installed and configured your scanner, start scanning your files.

Last updated on 02/20/2026

Running the information protection scanner

Article • 03/31/2025

> **Note**
>
> There's a new version of the information protection scanner. For more information, see Upgrade the Microsoft Purview Information Protection scanner.

Once you've confirmed your system requirements and configured and installed your scanner, run a discovery scan to get started.

Use other steps detailed below to manage your scans moving forward.

- Stop a scan
- Rescanning files

For more information, see Learn about the Microsoft Purview Information Protection scanner.

> **Tip**
>
> While most customers will perform these procedures in the admin portal, you may need to work in PowerShell only.
>
> For example, if you are working in an environment without access to the Azure portal, such as Azure China 21Vianet scanner servers, authenticate to the PurviewInformationProtection PowerShell module, and then continue with instructions in this article for PowerShell only.

Run a discovery cycle and view reports for the scanner

Use the following procedure after you've configured and installed your scanner to get an initial understanding of your content.

Perform these steps again as needed when your content changes.

1. Start a scan on your content scan job.

Do either of the following to start a content scan job:

- **Use the Microsoft Purview portal.** On the **Information protection scanner - Content scan jobs** pane, select your content scan jobs, and then select the **Scan now** option. The **Scan now** option only appears once a content scan job is selected.
- **Use a PowerShell command.** Run `Start-Scan` to start the scan.

2. Wait for the scanner to complete its cycle. The scan completes when the scanner has crawled through all the files in the specified data stores.

   Do either of the following to monitor scanner progress:

   - **Use the Microsoft Purview portal.** On the **Information protection scanner - Content scan jobs** pane, select **Refresh**.

     Wait until you see values for the **LAST SCAN RESULTS** column and the **LAST SCAN (END TIME)** column.

   - **Use a PowerShell command.** Run `Get-ScanStatus` to monitor the status change.

3. When the scan is complete, review the reports stored in the **%*localappdata*%\Microsoft\MSIP\Scanner\Reports** directory.

   - The .txt summary files include the time taken to scan, the number of scanned files, and how many files had a match for the information types.
   - The .csv files have more details for each file. This folder stores up to 60 reports for each scanning cycle and all but the latest report is compressed to help minimize the required disk space.

     When a scan is completed, a `Summary_<x>.txt` file is created with the scan summary.

> **Note**
>
> Scanners send collected data information to Microsoft Purview Information Protection every five minutes, so that you can view the results in near real time from the admin portal. For more information, see Analytics and central reporting for Azure Information Protection.
>
> The admin portal displays information about the last scan only. If you need to see the results of previous scans, return to the reports that are stored on the scanner

computer, in the %*localappdata*%\Microsoft\MSIP\Scanner\Reports folder.

Initial configurations instruct you to set the **Info types to be discovered** to **Policy only**. This configuration means that only files that meet the conditions you've configured for automatic classification are included in the detailed reports.

If you don't see any labels applied, check that your label configuration includes automatic rather than recommended classification, or enable **Treat recommended labeling as automatic** (available in scanner version 2.7.x.x and above).

If the results are still not as you expect, you might need to reconfigure the conditions that you specified for your labels. If that's the case, reconfigure the conditions as needed, and repeat this procedure until you're satisfied with the results. Then, update your configuration automatically, and optionally protection.

Changing log levels or locations

Change the level of logging by using the *ReportLevel* parameter with Set-ScannerConfiguration.

The report folder location or name can't be changed. If you want to store reports in a different location, consider using a directory junction for the folder.

For example, use the Mklink command: `mklink /j D:\Scanner_reports C:\Users\aipscannersvc\AppData\Local\Microsoft\MSIP\Scanner\Reports`

If you've performed these steps after an initial configuration and installation, continue with Configure the scanner to apply classification and protection.

Stopping a scan

To stop a currently running scan before it's complete, use either of the following methods:

- **Microsoft Purview portal.** Select **Stop scan**:
- **Run a PowerShell command.** Run the following command:

```
PowerShell

Stop-Scan
```

Rescanning files

For the first scan cycle, the scanner inspects all files in the configured data stores. For subsequent scans, only new or modified files are inspected.

It's useful to inspect all files again when you want the reports to include all files, when you have changes that you want to apply across all files, and when the scanner runs in discovery mode.

To manually run a full rescan in the Microsoft Purview portal:

1. Navigate to the **Information protection scanner - Content scan jobs** pane in the Microsoft Purview portal.
2. Select your content scan job from the list, and then select the **Rescan all files** option:

When a full scan is complete, the scan type automatically changes to incremental so that for subsequent scans, only new or modified files are scanned again.

> **Tip**
>
> If you've made changes to your content scan job, the portal will prompt you to skip a full rescan. To ensure that your rescan occurs, make sure to select **No** in the prompt that appears.

Trigger a full rescan by modifying your settings

Earlier versions of the scanner scanned all files whenever the scanner detected new or changed settings for automatic and recommended labeling. The scanner automatically refreshed the policy every four hours.

In scanner versions 2.8.85.0 or later, the information protection scanner skips the full rescan for updated settings to ensure consistent performance. Make sure that you run a full rescan manually as needed.

For example, if you've changed **Sensitivity policy** settings from **Enforce** = **Off** to **Enforce** = **On**, make sure to run a full rescan to apply your labels across your content.

> **Note**

In scanner version 2.7.101.0 and lower, you may want to refresh the policy sooner than every four hours, such as while testing. In such cases, manually delete the contents of the **%LocalAppData%\Microsoft\MSIP\mip<processname>\mip** directory and restart the Microsoft Purview Information Protection Scanner service.

If you've also changed encryption settings for your sensitivity labels, wait an extra 15 minutes from when you saved the updated encryption settings before restarting the Microsoft Purview Information Protection Scanner service.

Next steps

You can also use PowerShell to interactively classify and protect files from your desktop computer. For more information about this and other scenarios that use PowerShell, see Set up the information protection client using PowerShell.

Microsoft Purview Information Protection scanner feature control (preview)

Scanner administrators can enable, disable, and configure Microsoft Purview Information Protection scanner features at the cluster level. Use PowerShell to manage feature settings across all nodes in a cluster.

Admin-controlled feature configuration is available with Microsoft Purview Information Protection client and scanner version 3.2.89.0 (preview) or later.

How feature control works

Scanner features are configured once per scanner cluster. The settings are stored centrally in the shared scanner cluster database, which means:

- An administrator runs a configuration cmdlet once from any node in the cluster, and all nodes pick up the change on the next scan cycle.
- No service restart is required.
- Nodes can't get into mismatched feature states.
- Disabling a feature stops the action that the feature performs (for example, writing to a new database table or producing a new file). Existing data isn't deleted, so a disabled feature can be re-enabled later without data loss.
- Features that aren't explicitly configured use their default state (typically **off**). Defaults for each feature are listed under Currently supported features.

Custom Reporting is the first feature delivered through admin-controlled feature configuration. For details about that feature, see Custom Reporting (preview).

Evolution of control: PowerShell and the Microsoft Purview portal

Admin-controlled feature configuration is designed to evolve over time. Supported features are initially configured by using PowerShell. As features become available in the Microsoft Purview portal, the portal becomes the source of truth for those features.

The following rules apply when both surfaces are available for a feature:

- **PowerShell first.** Until a feature is exposed in the Microsoft Purview portal, administrators configure it from PowerShell on any node in the cluster. Settings configured this way are tracked as managed by PowerShell.
- **Portal takes precedence.** When a feature has been configured from the Microsoft Purview portal, the portal becomes the source of truth for that feature. PowerShell attempts to change a portal-managed feature are ignored with a warning, and the cluster state remains unchanged. Other features in the same `-FeatureSettings` call that aren't portal-managed are still applied.
- **No synchronization.** Settings aren't synchronized between PowerShell and the portal. Not every scanner feature will end up being configurable from the portal. When a feature *is* available in the portal and has been configured there, that portal-configured setting takes precedence and prevents updates from PowerShell. There's a single source of truth for each feature at any time.
- **Get always reflects state.** Regardless of where a feature was configured, Get-ScannerConfiguration returns the current state and source for every configured feature. Administrators can audit the cluster from PowerShell at any time.

This PowerShell-to-portal management model means scanner administrators can adopt new features through PowerShell as soon as they reach public preview, and switch to portal-based management at their own pace as features become available there.

Supported cmdlets and the `-FeatureSettings` parameter

The following cmdlets accept the `-FeatureSettings` parameter:

Expand table

Cmdlet	Purpose
Install-Scanner	Configure features as part of a new scanner node installation.
Set-ScannerConfiguration	Configure features on an existing scanner cluster. The change applies to every node in the cluster.
Get-ScannerConfiguration	Return the current state and source for every configured feature, including features that were configured from the Microsoft Purview portal.

`-FeatureSettings` accepts a PowerShell **hashtable** of feature name and setting pairs, using the same pattern as `-AdvancedSettings`:

- The hashtable key is the feature name (for example, `CustomReporting`).
- The hashtable value is the setting for that feature. Supported values for each feature are listed in the Currently supported features table.

Both the feature name and its value are validated before any change is written. If any entry is invalid, the cmdlet terminates with an error and no entries from the hashtable are applied.

For background on the `-AdvancedSettings` pattern, including PowerShell quoting and hashtable tips, see PowerShell tips for specifying the advanced settings and the -AdvancedSettings parameter on **Set-Label**.

Example: Enable Custom Reporting on an existing cluster

Run the following from any node in the scanner cluster:

PowerShell

```
Set-ScannerConfiguration -FeatureSettings @{CustomReporting=$true}
```

All nodes in the cluster pick up the change on their next scan cycle.

Example: Enable Custom Reporting at install time

Use the following command to enable Custom Reporting when you install a new scanner node:

PowerShell

```
Install-Scanner -SqlServerInstance SQLSERVER1 -Cluster Europe -FeatureSettings
@{CustomReporting=$true}
```

Example: Review the current feature state

Run the following command to review the current feature configuration for the cluster:

PowerShell

```
Get-ScannerConfiguration
```

For each configured feature, the `Features` line in the output shows the current state and which surface configured it (PowerShell or the Microsoft Purview portal). For example, with Custom Reporting enabled from PowerShell:

```
Features             : {CustomReporting: True (Source: PowerShell)}
```

Features that have never been configured don't appear and use their default state.

Disable a feature

To turn Custom Reporting off, set its value to `$false`. Existing data that the feature wrote isn't deleted; the scanner stops performing the feature's action on the next scan cycle.

PowerShell

```powershell
Set-ScannerConfiguration -FeatureSettings @{CustomReporting=$false}
```

Currently supported features

The following table lists the currently supported scanner features and their configuration values:

Expand table

Feature name	Default	Supported values	Description
`CustomReporting`	Off	`$true`, `$false`	Populates the Custom Reporting tables and columns in the scanner cluster database. See Custom Reporting (preview).

Additional features will be added over time and listed in the Microsoft Purview Information Protection client release notes.

Microsoft Purview Information Protection scanner Custom Reporting (preview)

This article describes the Microsoft Purview Information Protection scanner **Custom Reporting** feature (preview). Custom Reporting gives scanner administrators the data they need in the scanner cluster database to build their own reports against scan results—including labeling, protection state, and matched sensitive information types (SITs).

Custom Reporting is available with Microsoft Purview Information Protection client and scanner version 3.2.89.0 or later. Custom Reporting is enabled by an administrator through Scanner feature control.

What Custom Reporting enables

Without Custom Reporting, the scanner produces per-scan CSV and TXT reports and stores a limited set of operational data in the cluster database. To build a complete picture of file state—what changed, what's labeled, what's protected, and what kinds of sensitive data exist where—administrators have to combine multiple CSV exports across scan cycles and load them into a separate reporting tool.

Custom Reporting moves file-state and SIT-match data into the scanner cluster database so that administrators can:

- Query the present and previous label, protection state, and SIT counts for every scanned file in a repository.
- Compute deltas between scans (for example, the change in number of matched SITs per file).
- See which sensitive information types were matched on which files, and how many matches per type.
- Connect the scanner cluster database to a reporting tool of their choice (for example, Power BI, an enterprise reporting warehouse, or a SQL-based dashboarding tool) without first having to stitch CSV exports together.

The scanner remains the source of truth. Custom Reporting writes the additional reporting data to the scanner cluster database on the next scan cycle after the feature is enabled.

Database schema

The reporting tables and columns required by Custom Reporting were first added to the scanner cluster database schema in client version 3.2.57.0. Until Custom Reporting is enabled, the new columns and tables exist but aren't populated. Existing scanner functionality is unchanged.

> **Note**
>
> You don't need to install client version 3.2.57.0 first. Whether you're installing the scanner fresh or upgrading from any earlier version, the scanner deploys the full database schema (including the Custom Reporting tables and columns) on install or upgrade.

When Custom Reporting is enabled by using Scanner feature control, the scanner starts populating the following data on the next scan cycle.

Additions to `dbo.ScannerFiles`

`dbo.ScannerFiles` continues to hold one row per scanned file. Custom Reporting populates the following additional columns to capture file state and the delta between the current and previous scan:

Expand table

Column	Type	Description
`LabelName`	`NVARCHAR(MAX)`, nullable	Current label name applied to the file. `NULL` if unlabeled.
`PrevLabelId`	`NVARCHAR(MAX)`, nullable	Label ID applied at the previous scan, stored as a string. `NULL` if previously unlabeled.
`PrevLabelName`	`NVARCHAR(MAX)`, nullable	Label name applied at the previous scan. `NULL` if previously unlabeled.
`ProtectionState`	`NVARCHAR(MAX)`, nullable	Current protection state for the file at the end of the scan.
`PrevProtectionState`	`NVARCHAR(MAX)`, nullable	Protection state recorded at the previous scan.
`ClassificationCount`	`INT`, default `0`	Count of sensitive information type matches on the file at the current scan.
`LatestScanSessionId`	`UNIQUEIDENTIFIER`, nullable	Identifies the most recent scan session that touched the file. Used to compute deltas across scan cycles.

Column	Type	Description
`FileStatus`	`NVARCHAR(MAX)`, nullable	Final disposition of the file in the scan cycle (for example, the requires-justification status set by `ProcessJob`, or `Failed` for files that couldn't be processed).

New table: `dbo.MatchedClassificationAction`

`dbo.MatchedClassificationAction` is a new table that stores the matched sensitive information types per file per scan. Each row represents one matched SIT for a single file in a single scan session.

Expand table

Column	Type	Description
`Id`	`BIGINT IDENTITY` (primary key)	Surrogate key for the row.
`FilePath`	`NVARCHAR(MAX)`, nullable	Full path of the file that the SIT was matched on.
`FileHashPath`	`BINARY(64)`, nullable	Hash of the file path. Joins to `dbo.ScannerFiles.HashPath` and is indexed for join performance.
`ScanSessionId`	`UNIQUEIDENTIFIER`, nullable	Identifies the scan session in which the SIT was matched. Joins to `dbo.ScannerFiles.ScanSessionId` and is indexed.
`MatchedInformationTypeName`	`NVARCHAR(MAX)`, nullable	Display name of the matched sensitive information type (for example, `U.S. social security number (SSN)`).
`MatchedInformationTypeId`	`UNIQUEIDENTIFIER`, nullable	GUID of the matched SIT. The same GUID is used in the local Microsoft Purview Information Protection logs for `Workload=OnPremisesFileShareScanner`.
`MatchedInformationTypeCount`	`INT`, default `0`	Number of matches for this SIT in the file.
`ConfidenceScore`	`INT`, default `0`	Confidence score of the match.

New table: `dbo.ScannedFilesArchive`

`dbo.ScannedFilesArchive` is a new table that stores a historical archive of files the scanner processed, with rows tied to the scan session that created them. Unlike the live `dbo.ScannerFiles`

table, which only keeps the latest state of each file, this table preserves prior archived states for change tracking, reporting, and auditing.

Files that the scanner skips because nothing has changed since the previous scan session aren't re-inserted, so later scan sessions don't contain a complete snapshot of all files. Instead, only the existing archive entry from the session that last processed the file remains, which keeps the archive lean while preserving a history of meaningful changes.

Expand table

Column	Type	Description
`Id`	`BIGINT IDENTITY` (primary key)	Surrogate key for the row.
`HashPath`	`BINARY(64)`	Hash of the file path. Joins to `dbo.ScannerFiles.HashPath`.
`FullPath`	`NVARCHAR(MAX)`	Full path of the file at the time of the scan session.
`ScanSessionId`	`UNIQUEIDENTIFIER`	The scan session that produced this archive row.
`LastModifiedTime`	`DATETIME2`, nullable	Last-modified timestamp of the file as observed during the scan session.
`LabelId`	`UNIQUEIDENTIFIER`, nullable	Label ID applied to the file at the time of the scan session.
`IssueCount`	`INT`, default `0`	Number of issues recorded against the file in this scan session.
`EndScan`	`DATETIME2`, nullable	Time the file completed processing in this scan session.
`JobStartTime`	`DATETIME2`, nullable	Time the processing job for this file started.
`LabelName`	`NVARCHAR(MAX)`, nullable	Label name applied at the time of this scan session.
`PrevLabelId`	`NVARCHAR(MAX)`, nullable	Label ID at the previous scan session, stored as a string.
`PrevLabelName`	`NVARCHAR(MAX)`, nullable	Label name at the previous scan session.
`ProtectionState`	`NVARCHAR(MAX)`, nullable	Protection state at the time of this scan session.
`PrevProtectionState`	`NVARCHAR(MAX)`, nullable	Protection state at the previous scan session.
`ClassificationCount`	`INT`, default `0`, nullable	Count of sensitive information type matches in this scan session.
`LatestScanSessionId`	`UNIQUEIDENTIFIER`, nullable	The latest scan session known to have touched the file at the time this archive row was recorded.

Column	Type	Description
`FileStatus`	`NVARCHAR(MAX)`, nullable	Disposition of the file in the scan session (for example, `Modified` or `Deleted`).

`dbo.ScanSummary` (per-scan totals) is unchanged.

Example questions Custom Reporting can answer

Once Custom Reporting is populating the database, administrators can run queries such as:

- Which repositories have the highest concentration of matched SITs, and how has that concentration changed since the last scan?
- Which files were labeled or relabeled during the most recent scan cycle, and what was the previous label?
- Which files are still unlabeled but contain matches for one or more sensitive information types?
- Which sensitive information types are most prevalent in a given repository, and at what confidence?
- Which files transitioned from unprotected to protected (or the reverse) since the last scan?

Enable Custom Reporting

Custom Reporting is turned on through admin-controlled feature configuration. From any node in the scanner cluster, run:

PowerShell

```powershell
Set-ScannerConfiguration -FeatureSettings @{CustomReporting=$true}
```

To enable Custom Reporting at install time on a new scanner node, use the `-FeatureSettings` parameter with Install-Scanner:

PowerShell

```powershell
Install-Scanner -SqlServerInstance SQLSERVER1 -Cluster Europe -FeatureSettings
@{CustomReporting=$true}
```

To confirm the current state, run:

PowerShell

```
Get-ScannerConfiguration
```

The change takes effect on every node in the cluster on the next scan cycle. No service restart is required.

To stop populating the Custom Reporting columns and table, run:

PowerShell

```
Set-ScannerConfiguration -FeatureSettings @{CustomReporting=$false}
```

Disabling Custom Reporting stops new writes. Data already written to the reporting columns and tables isn't deleted, so the feature can be re-enabled later without data loss.

Plan your scanner cluster database for reporting

When you turn on Custom Reporting, the scanner cluster database stores significantly more data:

- Additional columns per file in `dbo.ScannerFiles`
- One row per matched SIT per file per scan in `dbo.MatchedClassificationAction`
- Archive rows in `dbo.ScannedFilesArchive` for files the scanner processes and archives during a scan session (not for every unchanged file in every cycle)

Building reports against the scanner cluster database also adds a read workload that runs alongside the scanner's operational reads and writes.

Before you enable Custom Reporting in production, consider:

- **Cluster size and scan volume.** Estimate the number of files scanned per cycle, the typical number of SIT matches per file, and how often you scan. Use those numbers to size the database.
- **Operational impact.** Reporting queries against the same database that the scanner is writing to can compete with the scanner for resources during a scan cycle.
- **The reporting workload you actually want.** Interactive dashboards, scheduled extracts, and ad-hoc queries each have very different impacts.

For most production deployments, we recommend hosting the scanner cluster database on SQL Server Enterprise so that you can dedicate a read-only replica to reporting. With a SQL Server Always On availability group, you can route reporting traffic to a readable secondary replica. Reporting queries then run on the secondary replica instead of competing with the scanner's operational workload on the primary.

This separation lets reporting tools (for example, Power BI) connect to the read-only replica and refresh on their own cadence without affecting scan throughput on the primary.

> **Note**
>
> The scanner itself always reads from and writes to the primary database. Only your custom reporting workload should be pointed at a read-only replica.

Limitations during preview

- Custom Reporting doesn't include a built-in dashboard in this preview. Customers build their own reports against the scanner cluster database.
- Settings configured by admin-controlled feature configuration aren't synchronized with the Microsoft Purview portal. Not every scanner feature will end up being configurable from the portal. For features that are also configurable from the Microsoft Purview portal, a setting configured in the portal takes precedence and prevents updates from PowerShell.

Sensitive Information Types supported by Microsoft Purview Information Protection scanner

Article • 07/01/2024

The Microsoft Purview Information Protection scanner supports the following sensitive information types (SITs).

- ABA Routing Number
- Argentina National Identity (DNI) Number
- Argentina Unique Tax identification Key (CUIT/CUIL)
- Australia Bank Account Number
- Australia Driver's License Number
- Australia Medical Account Number
- Australia Passport Number
- Australia Tax File Number
- Australia Business Number
- Australia Company Number
- Austria Driver's License Number
- Austria Identity Card
- Austria Passport Number
- Austria Social Security Number
- Austria Tax identification Number
- Austria Value Added Tax (VAT) Number
- Azure DocumentDB Auth Key
- Azure IAAS Database Connection String and Azure SQL Connection String
- Azure IoT Connection String
- Azure Publish Setting Password
- Azure Redis Cache Connection String
- Azure SAS
- Azure Service Bus Connection String
- Azure Storage Account Key
- Azure Storage Account Key (Generic)
- Belgium Driver's License Number
- Belgium National Number
- Belgium Passport Number
- Belgium Value Added Tax Number
- Brazil CPF Number

- Brazil Legal Entity Number (CNPJ)
- Brazil National ID Card (RG)
- Bulgaria Driver's License Number
- Bulgaria Passport Number
- Bulgaria Uniform Civil Number
- Canada Bank Account Number
- Canada Driver's License Number
- Canada Health Service Number
- Canada Passport Number
- Canada Personal Health identification Number (PHIN)
- Canada Social Insurance Number
- Chile Identity Card Number
- China Resident Identity Card (PRC) Number
- Credit Card Number
- Croatia Driver's License Number
- Croatia Identity Card Number
- Croatia Passport Number
- Croatia Personal identification (OIB) Number
- Cyprus Driver's License Number
- Cyprus Identity Card
- Cyprus Passport Number
- Cyprus Tax identification Number
- Czech Driver's License Number
- Czech Personal Identity Number
- Czech Passport Number
- Denmark Driver's License Number
- Denmark Passport Number
- Denmark Personal identification Number
- Drug Enforcement Agency (DEA) Number
- EU Debit Card Number
- EU Driver's License Number
- EU National identification Number
- EU Passport Number
- EU Social Security Number (SSN) or Equivalent identification
- EU Tax identification Number (TIN)
- Estonia Driver's License Number
- Estonia Passport Number
- Estonia Personal identification Code
- Finland Driver's License Number
- Finland European Health Insurance Number
- Finland National ID

- Finland Passport Number
- France Driver's License Number
- France Health Insurance Number
- France National ID Card (CNI)
- France Passport Number
- France Social Security Number (INSEE)
- France Tax identification Number
- France Value Added Tax Number
- Germany Driver's License Number
- Germany Passport Number
- Germany Identity Card Number
- Germany Tax identification Number
- Germany Value Added Tax Number
- Greece Driver's License Number
- Greece National ID Card
- Greece Passport Number
- Greece Social Security Number (AMKA)
- Greece Tax identification Number
- Hong Kong Identity Card (HKID) Number
- Hungary Driver's License Number
- Hungary Passport Number
- Hungary Personal identification Number
- Hungary Social Security Number (TAJ)
- Hungary Tax identification Number
- Hungary Value Added Tax Number
- IP Address
- IP Address v4
- IP Address v6
- India Driver's License Number
- India GST Number
- India Permanent Account Number (PAN)
- India Unique identification (Aadhaar) Number
- India Voter Id Card
- Indonesia Identity Card (KTP) Number
- International Banking Account Number (IBAN)
- International Classification of Diseases (ICD-9-CM)
- International Classification of Diseases (ICD-10-CM)
- Ireland Driver's License Number
- Ireland Passport Number
- Ireland Personal Public Service (PPS) Number
- Israel Bank Account Number

- Israel National identification number
- Italy Driver's License Number
- Italy Fiscal Code
- Italy Passport Number
- Italy Value Added Tax Number
- Japan Bank Account Number
- Japan Driver's License Number
- Japan My Number Corporate
- Japan My Number Personal
- Japan Passport Number
- Japan Residence Card Number
- Japan Resident Registration Number
- Japan Social Insurance Number (SIN)
- Latvia Driver's License Number
- Latvia Passport Number
- Latvia Personal Code
- Lithuania Driver's License Number
- Lithuania Passport Number
- Lithuania Personal Code
- Luxembourg Driver's License Number
- Luxembourg National identification Number (Natural persons)
- Luxembourg National identification Number (Non-natural persons)
- Luxembourg Passport Number
- Malaysia Identity Card Number
- Malaysia Passport Number
- Malta Driver's License Number
- Malta Identity Card Number
- Malta Passport Number
- Malta Tax ID Number
- Medicare Beneficiary Identifier (MBI) card
- Mexico Unique Population Registry Code (CURP)
- Netherlands Citizen's Service (BSN) Number
- Netherlands Driver's License Number
- Netherlands Passport Number
- Netherlands Tax identification Number
- Netherlands Value Added Tax Number
- New Zealand Driver License Number
- New Zealand Inland Revenue number
- New Zealand Ministry of Health Number
- New Zealand Social Welfare Number
- New Zealand bank account number

- Norway Identity Number
- Philippines Passport Number
- Philippines Unified Multi-Purpose ID Number
- Poland Driver's License Number
- Poland Identity Card
- Poland National ID (PESEL)
- Poland Passport Number
- Poland REGON Number
- Poland Tax identification Number
- Portugal Citizen Card Number
- Portugal Driver's License Number
- Portugal Passport Number
- Portugal Tax identification Number
- Qatari ID Card Number
- Romania Driver's License Number
- Romania Passport Number
- Romania Personal Numerical Code (CNP)
- Russia Passport Number (Domestic)
- Russia Passport Number (International)
- SQL Server Connection String
- SWIFT Code
- Saudi Arabia National ID
- Singapore Driver's License Number
- Singapore National Registration Identity Card (NRIC) Number
- Singapore Passport Number
- Slovakia Driver's License Number
- Slovakia Passport Number
- Slovakia Personal Number
- Slovenia Driver's License Number
- Slovenia Passport Number
- Slovenia Tax identification Number
- Slovenia Unique Master Citizen Number
- South Africa identification Number
- South Korea Driver's License Number
- South Korea Passport Number
- South Korea Resident Registration Number
- Spain DNI
- Spain Driver's License Number
- Spain Passport Number
- Spain Social Security Number (SSN)
- Spain Tax identification Number

- Sweden Driver's License Number
- Sweden National ID
- Sweden Passport Number
- Sweden Tax identification Number
- Switzerland Social Security Number AHV
- Taiwan National ID
- Taiwan Passport Number
- Taiwan Resident Certificate (ARC/TARC)
- Thai Population identification Code
- Turkey National identification number
- U.K. Driver's License Number
- U.K. Electoral Roll Number
- U.K. National Health Service Number
- U.K. National Insurance Number (NINO)
- U.K. Unique Taxpayer Reference Number
- U.S. / U.K. Passport Number
- U.S. Bank Account Number
- U.S. Driver's License Number
- U.S. Individual Taxpayer identification Number (ITIN)
- U.S. Social Security Number (SSN)
- UAE Identity Card Number
- UAE Passport Number
- Ukraine Passport Number (Domestic)

Upgrade the Microsoft Purview Information Protection scanner

Article • 06/28/2024

Use the following instructions to upgrade the information protection scanner to the latest version from the Microsoft Purview Information Protection client:

- From the Azure Information Protection unified labeling client (2.x)
- From a previous version of the scanner from the Microsoft Purview Information Protection client (3.x)

For the latest release information and support timelines for each version, see Microsoft Purview Information Protection client - Release management and supportability.

Upgrade the scanner from the Azure Information Protection client (version 2.x)

> **ⓘ Important**
>
> Upgrading the Microsoft Purview Information Protection scanner from client version 2.x to version 3.x requires additional and specific steps because service names and other components are renamed.
>
> To avoid misconfigurations that can result in the scanner no longer working, make sure you follow each step that follows.

1. On any scanner node in the cluster, run the following command and make a note of the SQL database name and cluster:

   PowerShell

   ```
   Get-AIPScannerConfiguration
   ```

2. Get ready to install the new version of the scanner on each node in the cluster by stopping the scanner service:

   PowerShell

```
Net Stop AIPScanner
```

3. Uninstall the existing scanner service:

```PowerShell
Uninstall-AIPScanner
```

4. Restart the Windows server computer to completely remove the service.

5. Uninstall version 2.x of the Azure Information Protection unified labeling client.

6. Install version 3.x of the Microsoft Purview Information Protection client

7. Install the scanner from the information protection client:

```PowerShell
Install-Scanner -SqlServerInstance <SQL\InstanceName> -Cluster
<cluster-name>
```

   For example, to upgrade the scanner that uses the SQL Server instance named SCANNER that runs on the server named SQLSERVER1 and uses the cluster name of EU as the database for the scanner configuration:

```PowerShell
Install-Scanner -SqlServerInstance SQLSERVER1\SCANNER -Cluster EU
```

   For more details and other examples that include using the SQL Server default instance and SQL Server Express, see the examples from Install-Scanner.

8. Stop the scanner service:

```PowerShell
Net Stop MIPScanner
```

9. Update the scanner database: On one scanner node, run the following command:

```PowerShell
Update-ScannerDatabase
```

10. Start the scanner service on the Windows server computer.

11. For each node in the cluster, start the scanner service:

```
PowerShell

Net Start MIPScanner
```

The scanner is now upgraded for the Microsoft Purview Information Protection client and ready to resume any scanning jobs that are configured.

Upgrade a previous version of the scanner from the information protection client (version 3.x)

Use the following instructions to upgrade the scanner from an earlier version from the Microsoft Purview Information Protection client (version 3.x).

For example, you're upgrading from a preview version of the Microsoft Purview Information Protection client to a general availability (GA) version. Or, you're upgrading from a GA version of the Microsoft Purview Information Protection client to the latest version of this client.

1. Get ready to install the new version of the scanner on each node in the cluster by stopping the scanner service:

```
PowerShell

Net Stop MIPScanner
```

2. Install the latest version of the Microsoft Purview Information Protection client.

3. Update the scanner database: On one scanner node, run the following command:

```
PowerShell

Update-ScannerDatabase
```

4. Start the scanner service on the Windows server computer.

5. For each node in the cluster, start the scanner service:

```
PowerShell
```

```
Net Start MIPScanner
```

The scanner is now upgraded to the latest version from the Microsoft Purview Information Protection client and ready to resume any scanning jobs that are configured.

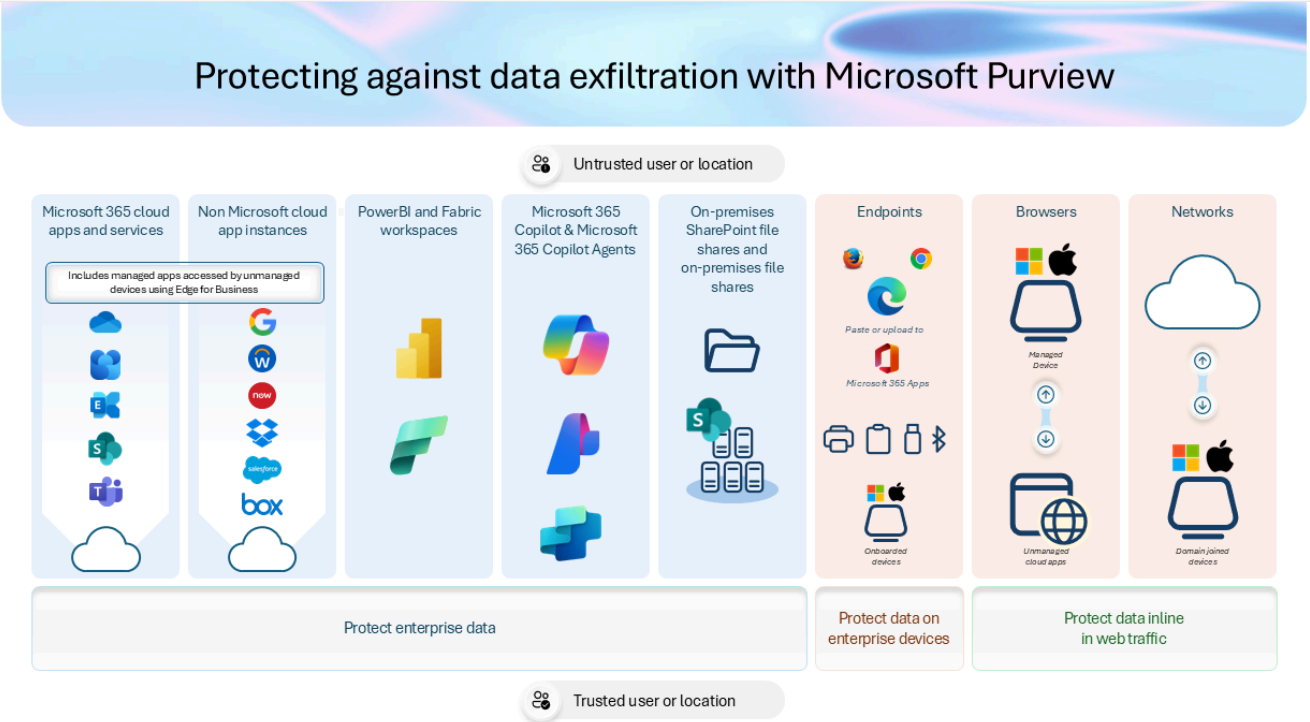
Learn about data loss prevention

Organizations control sensitive information like:



- financial data
- proprietary data
- credit card numbers
- health records
- Social Security numbers

To help protect this sensitive data, and to reduce the risk from oversharing, they need a way to help prevent their users from inappropriately sharing sensitive data with people who shouldn't have it. This practice is called data loss prevention (DLP).

In Microsoft Purview, you implement data loss prevention by defining and applying DLP policies. A DLP policy can help you identify, monitor, and automatically protect sensitive in **Enterprise applications & devices** and **Inline web traffic** data. DLP policies act on a variety of locations, methods of data transmission, and types of user activities.

DLP uses deep content analysis—not a simple text scan. It analyzes content:

- For primary data matches to keywords
- By the evaluation of regular expressions
- By internal function validation
- By secondary data matches that are in proximity to the primary data match
- DLP also uses machine learning algorithms and other methods to detect content that matches your DLP policies
- Inline by Microsoft Edge for business for Windows devices that haven't been onboarded into Microsoft Purview (preview) and Use Network Data Security to help prevent sharing sensitive information with unmanaged AI (preview)

Enterprise applications and devices

DLP monitors and protects against oversharing in enterprise apps and on devices. It targets Microsoft 365 locations, like Exchange and SharePoint, and locations you add, like on-premises file shares, endpoint devices, and non-Microsoft cloud apps. These locations and sources include:

- Microsoft 365 services, like Exchange, SharePoint, OneDrive accounts, and Teams chat and channel messages
- Office applications, such as Word, Excel, and PowerPoint
- Devices running Windows 10, Windows 11, and the three most recent versions of macOS
- Non-Microsoft cloud apps
- On-premises file shares and on-premises SharePoint
- Microsoft Fabric and Power BI workspaces
- Microsoft 365 Copilot and Copilot chat (preview)
- Managed cloud apps

Create DLP policies for **Enterprise applications & devices** to cover these locations.

Inline web traffic

DLP, with collection policies, monitors and protects against oversharing to **Unmanaged cloud apps** by targeting data transmitted on your network and in Microsoft Edge for Business. Create

policies that target Inline web traffic (preview) and Network activity (preview) to cover locations like:

- OpenAI ChatGPT—for **Edge for Business** and **Network** options
- Google Gemini—for **Edge for Business** and **Network** options
- DeepSeek—for **Edge for Business** and **Network** options
- Microsoft Copilot—for **Edge for Business** and **Network** options
- Over 34,000 cloud apps in the Microsoft Defender for Cloud Apps cloud app catalog—**Network** option only

Before you start

1. Administrative units
2. Learn about Microsoft Purview Data Loss Prevention
3. Plan for data loss prevention (DLP) - by working through this article you will:
   a. Identify stakeholders
   b. Describe the categories of sensitive information to protect
   c. Set goals and strategy
4. Collection Policies solution overview
5. Collection policy reference
6. Data Loss Prevention policy reference - this article introduces all the components of a DLP policy and how each one influences the behavior of a policy
7. Design a DLP policy - this article walks you through creating a policy intent statement and mapping it to a specific policy configuration.
8. Create and Deploy data loss prevention policies - This article presents some common policy intent scenarios that you map to configuration options, then it walks you through configuring those options.
9. Learn about investigating data loss prevention alerts - This article introduces you to the lifecycle of alerts from creation, through final remediation and policy tuning. It also introduces you to the tools you use to investigate alerts.

- Microsoft 365 Service Descriptions

DLP in Microsoft Purview

DLP is just one of the Microsoft Purview tools that you use to help protect your sensitive items wherever they live or travel. You should understand the other tools in the Microsoft Purview tool set, how they interrelate, and work better together. See, Microsoft Purview tools to learn more about the information protection process.

Protective actions of DLP policies

DLP policies monitor the activities that users take on sensitive items and, if the policy conditions are met, take protective actions. For example, when a user attempts a prohibited action, like copying a sensitive item to an unapproved location or sharing medical information in an email, DLP can:

- show a pop-up policy tip to the user that warns them that they might be trying to share a sensitive item inappropriately
- block the sharing and, via a policy tip, allow the user to override the block and capture the users' justification
- block the sharing without the override option
- for data at rest, sensitive items can be locked and moved to a secure quarantine location
- for Teams chat, the sensitive information won't be displayed

All DLP monitored activities are recorded to the Microsoft 365 Audit log by default and routed to Activity explorer.

DLP lifecycle

A DLP implementation typically follows these major phases.

- Plan for DLP
- Prepare for DLP
- Deploy your policies in production

Plan for DLP

DLP monitoring and protection are native to the applications that users use every day. This helps to protect your organization's sensitive items from risky activities, even if your users are unaccustomed to data loss prevention thinking and practices. If your organization and your users are new to data loss prevention practices, the adoption of DLP might require a change to your business processes, and there will be a culture shift for your users. But, with proper planning,

testing and tuning, your DLP policies protect your sensitive items while minimizing any potential business process disruptions.

Technology planning for DLP

Keep in mind that DLP as a technology can monitor and protect your data at rest, data in use and data in motion across Microsoft 365 services, Windows 10, Windows 11, and macOS (three latest released versions) devices, on-premises file shares, and on-premises SharePoint. There are planning implications for the different locations, the type of data you want to monitor and protect, and the actions to be taken when a policy match occurs.

Business processes planning for DLP

DLP policies can block users from performing prohibited activities, like inappropriate sharing of sensitive information via email. As you plan your DLP policies, you must identify the business processes that touch your sensitive items. The business process owners can help you identify appropriate user behaviors that should be allowed and inappropriate user behaviors that should be protected against. You should plan your policies and deploy them in simulation mode, and evaluate their impact, before running them in more restrictive modes.

Organizational culture planning for DLP

A successful DLP implementation is as much dependent on getting your users trained and acclimated to data loss prevention practices as it is on well planned and tuned policies. Since your users are heavily involved, be sure to plan for training for them too. You can strategically use policy tips to raise awareness with your users before changing the policy status from simulation mode to more restrictive modes.

Prepare for DLP

You can apply DLP policies to data at rest, data in use, and data in motion in locations such as:

- Exchange Online email
- SharePoint sites
- OneDrive accounts
- Teams chat and channel messages
- Instances: Microsoft Defender for Cloud Apps
- Devices: Windows 10, Windows 11, and macOS (three latest released versions)
- On-premises repositories
- Fabric and Power BI workspaces

- Microsoft 365 Copilot (preview)

Each one has different prerequisites. Sensitive items in some locations, like Exchange online, can be brought under the DLP umbrella by just configuring a policy that applies to them. Others, such as on-premises file repositories, require a deployment of Microsoft Purview Information Protection scanner. You'll need to prepare your environment, code draft policies, and test them thoroughly before activating any blocking actions.

Deploy your policies in production

Design your policies

Start by defining your control objectives, and how they apply across each respective workload. Draft a policy that embodies your objectives. Feel free to start with one workload at a time, or across all workloads - there's no impact yet. For more information, see Create and deploy data loss prevention policies.

Implement policy in simulation mode

Evaluate the impact of the controls by implementing them with a DLP policy in simulation mode. Actions defined in a policy aren't applied while the policy is in simulation mode. It's ok to apply the policy to all workloads in simulation mode, so that you can get the full breadth of results, but you can start with one workload if you need to. For more information, see Policy Deployment.

Monitor outcomes and fine-tune the policy

While in simulation mode, monitor the outcomes of the policy and fine-tune it so that it meets your control objectives while ensuring you aren't adversely or inadvertently impacting valid user workflows and productivity. Here are some examples of things to fine-tune:

- Adjust the locations and people/places that are in or out of scope
- Tune the conditions that are used to determine if an item and what is being done with it matches the policy
- Refine the sensitive information definitions
- Add new controls
- Add new people
- Add new restricted apps
- Add new restricted sites

> ⓘ **Note**

Stop processing more rules doesn't work in simulation mode, even when it's turned on.

Enable the control and tune your policies

Once the policy meets all your objectives, turn it on. Continue to monitor the outcomes of the policy application and tune as needed.

> **Note**
>
> In general, policies take effect about an hour after being turned on.

DLP policy configuration overview

You have flexibility in how you create and configure your DLP policies. You can start from a predefined template and create a policy in just a few clicks or you can design your own from the ground up. No matter which you choose, all DLP policies require the same information from you.

1. **Choose what you want to monitor** - DLP comes with many predefined policy templates to help you get started or you can create a custom policy.

    - A predefined policy template, such as Financial data, Medical and health data, Privacy data all for various countries and regions.
    - A custom policy that uses the available sensitive information types (SIT), retention labels, and sensitivity labels.

2. **Choose administrative scoping** - DLP supports assigning Administrative Units to some **Enterprise applications & devices** policies. Administrators who are assigned to an administrative unit can only create and manage policies for the users, groups, distribution groups, accounts, and sites that they're assigned to. So, policies can be applied to all users, groups, and sites by an unrestricted administrator, or they can be scoped to administrative units. See, Policy Scoping for more DLP specific details. See, Administrative units for the details on administrative units across Microsoft Purview Information Protection.

3. **Choose where you want to monitor** - You pick one or more locations that you want DLP to monitor for sensitive information. You can monitor:

Expand table

location	include/exclude by
Exchange email	distribution groups
SharePoint sites	sites
OneDrive accounts	accounts or distribution groups
Teams chat and channel messages	account or distribution group
Windows 10, Windows 11, and macOS (three latest released versions) devices	users and groups + devices and device groups
Microsoft Cloud App Security	instance
On-premises repositories	repository file path
Fabric and Power BI	workspaces
Microsoft 365 Copilot (preview)	account or distribution group

> ⓘ **Note**
>
> The users and groups mentioned above should be Online users and M365, Exchange online, and Microsoft Entra groups

4. **Choose the conditions that must be matched for a policy to be applied to an item** - You can accept preconfigured conditions or you can define custom conditions. Some examples are:

    - item contains a specified type of sensitive information that is being used in a certain context. For example, 95 social security numbers being emailed to recipient outside your org.
    - item has a specified sensitivity label
    - item with sensitive information is shared either internally or externally

5. **Choose the action to take when the policy conditions are met** - The actions depend on the location where the activity is happening. Some examples are:

    - SharePoint/Exchange/OneDrive: Block people who are outside your organization from accessing the content. Show the user a tip and send them an email notification that they're taking an action that is prohibited by the DLP policy.
    - Teams Chat and Channel: Block sensitive information from being shared in the chat or channel.

- Windows 10, Windows 11, and macOS (three latest released versions) Devices: Audit or restrict copying a sensitive item to a removable USB device.
- Office Apps: Show a popup notifying the user that they're engaging in a risky behavior and block or block but allow override.
- On-premises file shares: move the file from where it's stored to a quarantine folder.

> **Note**
>
> The conditions and the actions to take are defined in an object called a *rule*.

Create and deploy a DLP policy

All DLP policies are created and maintained in the Microsoft Purview portal. See, Create and Deploy data loss prevention policies for more information.

After you create a DLP policy, it's stored in a central policy store, and then synced to the various content sources, including:

- Exchange, and from there to Outlook on the web and Outlook
- OneDrive
- SharePoint sites
- Office desktop programs (Excel, PowerPoint, and Word)
- Microsoft Teams channels and chat messages

After the policy is synced to the right locations, it starts to evaluate content and enforce actions.

Viewing policy application results

DLP reports a vast amount of information to Microsoft Purview from monitoring policy matches and actions, to user activities. You need to consume and act on that information to tune your policies and triage actions taken on sensitive items. The telemetry goes into the Microsoft 365 audit Logs first, is processed, and makes its way to different reporting tools. Each reporting tool has a different purpose.

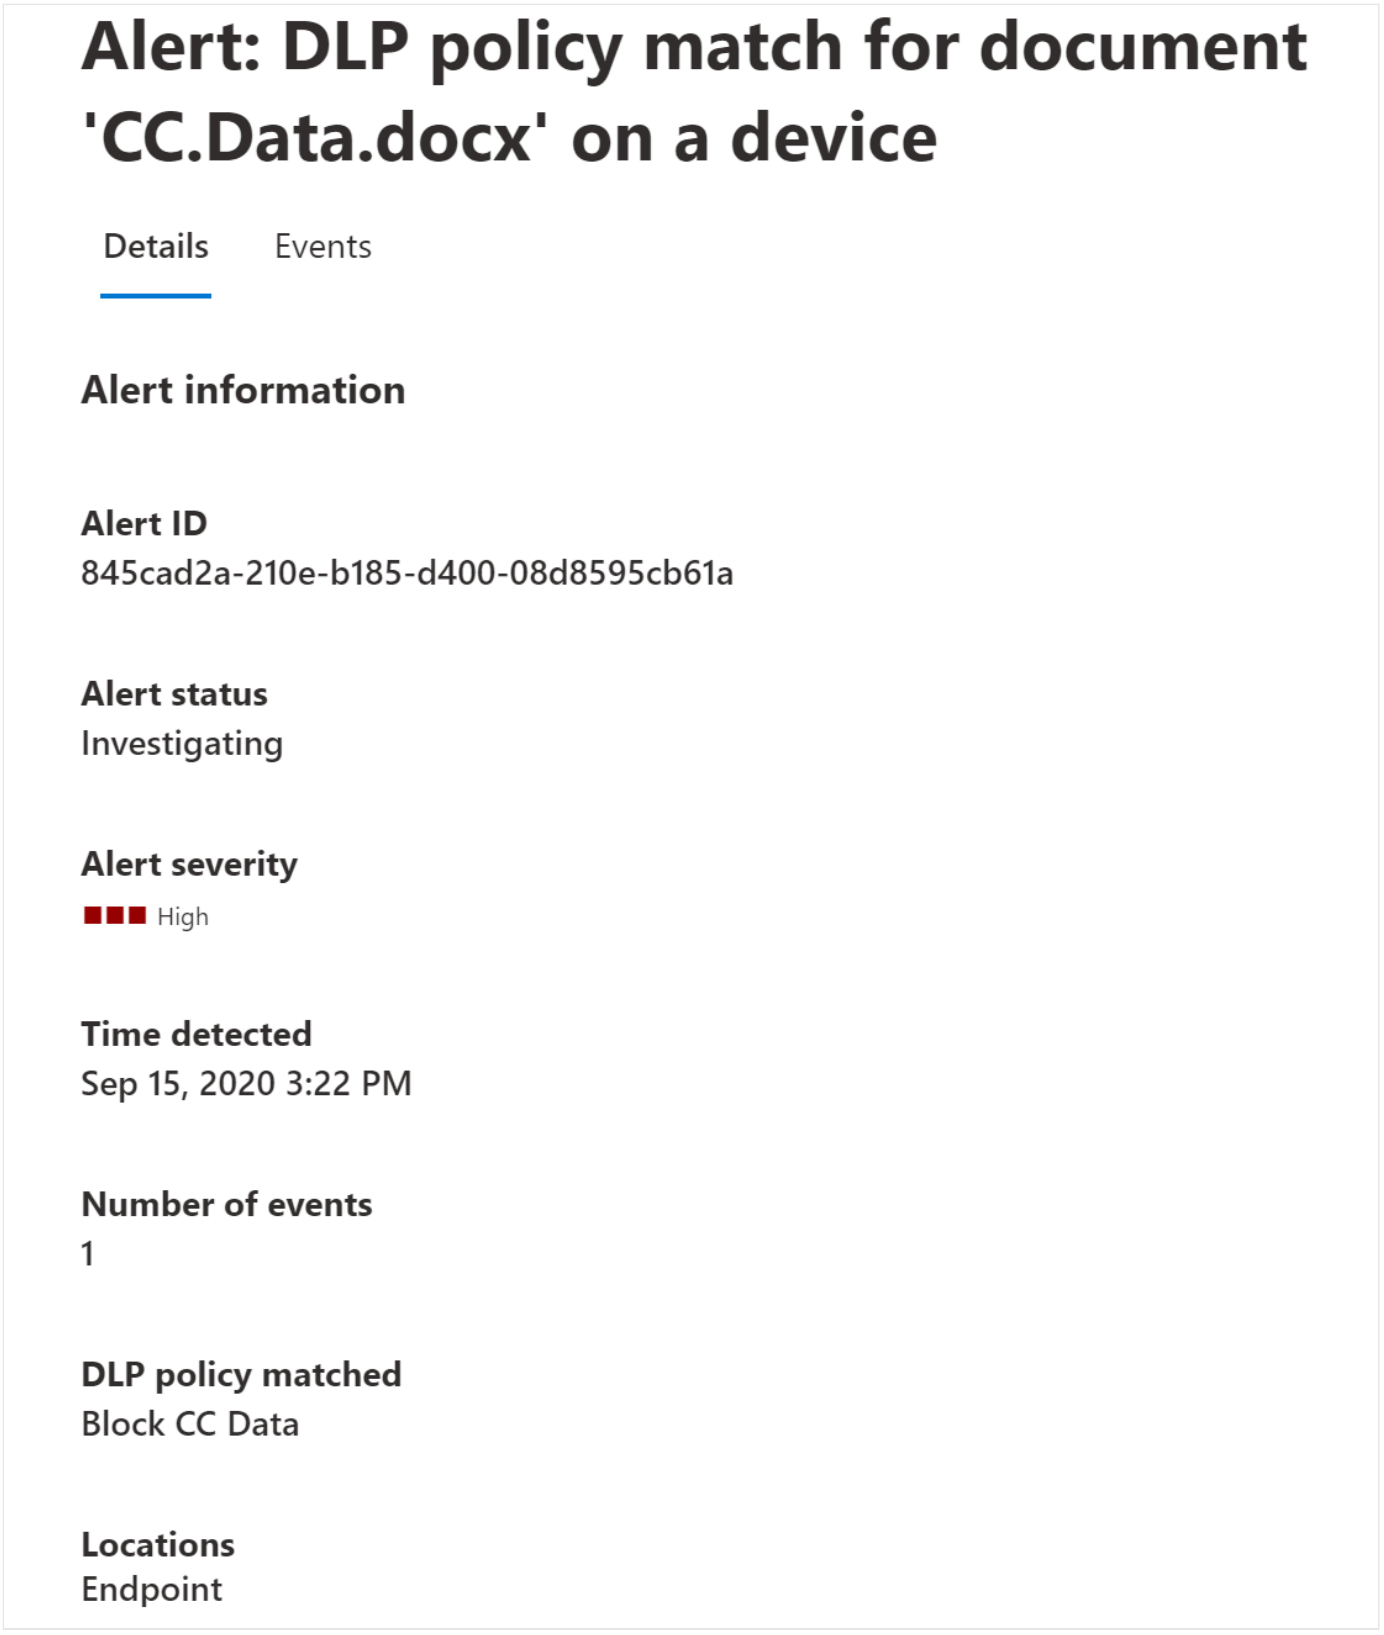
Overview page

The DLP **Overview** page gives you quick access to important information about your DLP policies, including:

- **Policy sync status**
- **Device status**
- **Top activites detected**
- **Device overall health**

You can investigate incidents for Microsoft Purview Data Loss Prevention (DLP) from the Microsoft Defender portal **Incidents & alerts** > **Incidents**. See Investigate data loss incidents with Microsoft Defender XDR and Investigate alerts in Microsoft Defender XDR.

DLP Alerts



DLP can generate alerts when a user(s) performs an activity that meets the criteria of a rule in a DLP policy, and you have incident reports configured to generate alerts. Depending on your subscription level, alerts can be aggregated on a time window/rule basis or on a time windows/user basis(preview).

DLP posts the alert for investigation in the DLP Alerts dashboard. Use the DLP Alerts dashboard to view alerts, triage them, set investigation status, and track resolution. Alerts are also routed to Microsoft Defender portal where you can do all the alert dashboard tasks plus more.

DLP alerts are available in the Microsoft Defender portal for six months. They're only available in the Microsoft Purview DLP alerts dashboard for 30 days.

If you're an administrative unit restricted admin, you'll only see the DLP alerts for your administrative unit.

Here's an example of alerts generated by policy matches and activities from Windows 10 devices.

You can also view details of the associated event with rich metadata in the same dashboard.

Event: Sensitive info in 'CC.Data.docx' - File copied to clipboard

Note

Alerts are generated differently for emails than they are for SharePoint or OneDrive items. In SharePoint and OneDrive, DLP scans existing items as well as new ones and generates an alert whenever a match is found. In Exchange, new email messages are scanned and an alert is generated if there's a policy match. DLP ***does not*** scan or match previously existing email items that are stored in a mailbox or archive.

For more information on Alerts, see:

- Alerts in DLP policies: Describes alerts in the context of a DLP policy.
- Get started with data loss prevention alerts: Covers the necessary liscensing, permissions, and prerequisites for DLP alerts and alert reference details.
- Create and deploy data loss prevention policies: Includes guidance on alert configuration in the context of creating a DLP policy.
- Learn about investigating data loss prevention alerts: Covers the various methods for investigating of DLP alerts.
- Investigate data loss incidents with Microsoft Defender XDR: How to investigate DLP alerts in Microsoft Defender portal.

DLP Activity Explorer and reports

The Activity explorer tab on the DLP page has multiple filters you can use to view DLP events. Use this tool to review activity related to content that contains sensitive info or has labels applied, such as what labels were changed, files were modified, and matched a rule.

You can view the last 30 days of DLP information in Activity Explorer using these preconfigured filters:

- Endpoint DLP activities
- Files containing sensitive info types
- Egress activities
- DLP policies that detected activities
- DLP policy rules that detected activities

Expand table

To see this information	Select this activity
User overrides	**DLP rule undo**
Items that match a DLP rule	**DLP rule matched**

You can also access DLP report using via these cmdlets in the Security & Compliance PowerShell.

1. Connect to Security & Compliance PowerShell

Use these cmdlets:

- Get-DlpDetailReport

- Get-DlpDetectionsReport
- Get-DlpSiDetectionsReport

However, DLP reports need to pull data from across Microsoft 365, including Exchange. For this reason, the following cmdlets for DLP reports are available in Exchange PowerShell. To use the cmdlets for these DLP reports, take the following steps:

1. Connect to Exchange PowerShell

Use these cmdlets:

- Get-DlpDetailReport
- Get-MailDetailDlpPolicyReport

DLP Rule Undo event

A DLP Rule Undo event occurs when a previously matched DLP rule no longer applies to a document, causing the rule to be effectively reversed. This can happen in two main scenarios: when a user modifies content so it no longer meets the rule conditions, or when a policy or rule is changed and triggers re-evaluation of already-classified content. During this re-evaluation, if a document no longer satisfies the rule criteria, a DLP Rule Undo event is generated. For example, if a policy is configured to detect documents containing at least five Social Security numbers and a user uploads a document with ten, the rule will initially match. If the user later removes the sensitive data so the document no longer meets the threshold, the rule is undone. Similarly, if an administrator updates the policy to require fifteen Social Security numbers, the same document will no longer meet the criteria upon re-evaluation, resulting in a DLP Rule Undo event.

Contextual summary

You can see the text that surrounds the matched content, like a credit card number in a **DLPRuleMatch** event in Activity explorer.

DLPRuleMatch events are paired with user egress activities such as "CopyToClipboard" or "CloudEgress". They should be right next to (or at least very close to) each other in Activity explorer. You want to look at both because the **user activity** contains details about the matched policy and the **DLPRuleMatch** event contains the details about the text that surrounds the matched content.

For endpoint, be sure that you have applied KB5016688 for Windows 10 devices and KB5016691 for Windows 11 devices or above.

For more information, see Get started with activity explorer.

To learn how to use data loss prevention to comply with data privacy regulations, see Deploy information protection for data privacy regulations with Microsoft Purview (aka.ms/m365dataprivacy).

Last updated on 06/26/2026

Plan for data loss prevention (DLP)

Every organization plans for and implements data loss prevention (DLP) differently. Why? Because every organization's business needs, goals, resources, and situation are unique. However, there are elements that are common to all successful DLP implementations. This article presents the best practices for planning a DLP deployment.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

5. Collection policy reference
6. Data Loss Prevention policy reference - this article introduces all the components of a DLP policy and how each one influences the behavior of a policy
7. Design a DLP policy - this article walks you through creating a policy intent statement and mapping it to a specific policy configuration.
8. Create and Deploy data loss prevention policies - This article presents some common policy intent scenarios that you map to configuration options, then it walks you through configuring those options.
9. Learn about investigating data loss prevention alerts - This article introduces you to the lifecycle of alerts from creation, through final remediation and policy tuning. It also introduces you to the tools you use to investigate alerts.

Multiple starting points

Many organizations choose to implement DLP to comply with various governmental or industry regulations. For example, the European Union's General Data Protection Regulation (GDPR), or the Health Insurance Portability and Accountability Act (HIPAA), or the California Consumer Privacy Act (CCPA). They also implement data loss prevention to protect their intellectual property. However, the starting place and ultimate destination in the DLP journey vary.

Organizations can start their DLP journey from several different points:

- With a platform focus, like wanting to protect information in Teams Chat and Channel messages or on Windows 10 or 11 devices
- Knowing the sensitive information they want to prioritize protecting, such as health care records, and going straight to defining policies to protect it
- Without knowing what their sensitive information is, where it is, or who is doing what with it; so, they start with discovery and categorization and take a more methodical approach
- Without knowing what their sensitive information is, where it is, or who is doing what with it, they go straight to defining policies and then using those outcomes to refine them
- Knowing that they need to implement the full Microsoft Purview Information Protection stack, and a plan to take a longer term, methodical approach

These are just some examples of how customers can approach DLP. It doesn't matter where you start from; DLP is flexible enough to accommodate various types of information protection journeys from start to a fully realized data loss prevention strategy.

Overview of planning process

The Learn about Microsoft Purview Data Loss Prevention introduces the three different aspects of the DLP planning process. We go into more detail here on the elements that are common to all DLP plans.

Identify stakeholders

When implemented, DLP policies can be applied across large portions of your organization. Your IT department can't develop a broad ranging plan on their own without negative consequences. You need to identify the stakeholders who can:

- identify the regulations, laws, and industry standards your organization is subject to
- identify the categories of sensitive items to be protected
- identify the business processes they're used in
- identify the risky behavior that should be limited

- prioritize which data should be protected first, based on the sensitivity of the items and risk involved
- outline the DLP policy match event review and remediation process

In general, these needs tend to be 85% regulatory and compliance protection, and 15% intellectual property protection. Here are some suggestions on roles to include in your planning process:

- Regulatory and compliance officers
- Chief risk officer
- Legal officers
- Security and compliance officers
- Business owners for the data items
- Business users
- IT

Describe the categories of sensitive information to protect

Once identified, the stakeholders then describe the categories of sensitive information to be protected and the business processes that they're used in. For example, DLP defines these categories:

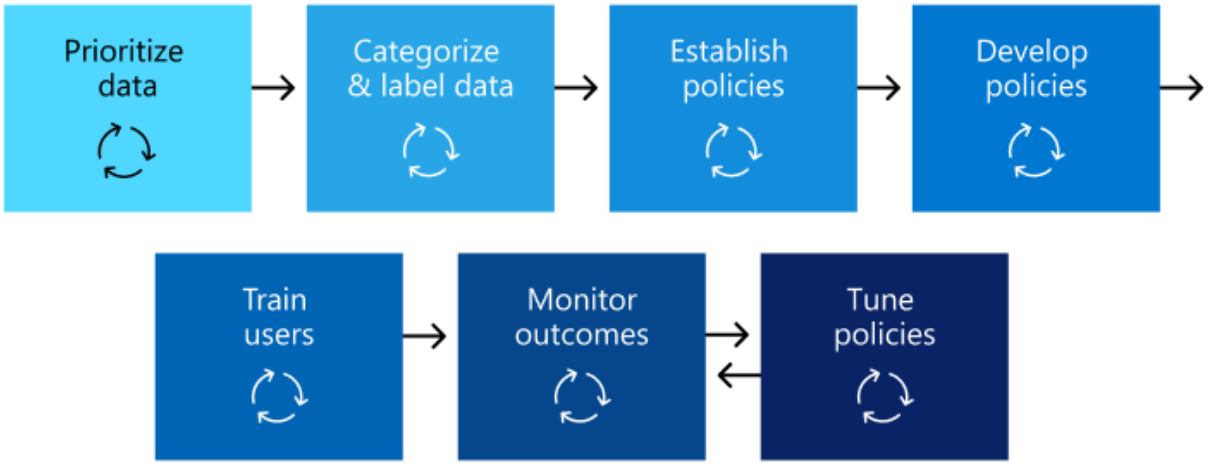
- Financial
- Medical and health information
- Privacy
- Custom

Stakeholders might identify the sensitive information as "We are a data processor, so we have to implement privacy protections on data subject information and financial information".

Set goals and strategy

Once you have identified your stakeholders, know which sensitive information needs protection, and where it's used, the stakeholders can set their protection goals and IT can develop an implementation plan.

Set implementation plan



Your implementation plan should include:

- a map of your starting state, desired end state, and the steps to get from one to the other

- a plan for how you'll address discovery of sensitive items
- a plan for developing policies and the order in which policies you'll implement them
- a plan for how you'll address any prerequisites
- a plan for how you'll simulate policies before implementing them for enforcement
- a plan for how you'll train your end users
- a plan for how you'll tune your policies
- a plan for how you'll review and update your data loss prevention strategy based on changing regulatory, legal, industry standard, or intellectual property protection and business needs

Map out path from start to desired end state

Documenting how your organization is going to get from its starting state to the desired end state is essential to communicating with your stakeholders and setting the project scope. Here's a set of steps that are commonly used to deploy DLP. You'll want more detail than the graphic shows, but you can use it to frame your DLP adoption path.

Sensitive item discovery

There are multiple ways to discover what individual sensitive items are and where they're located. You may have sensitivity labels already deployed or you may have decided to deploy a broad DLP policy to all locations that only discovers and audits items. To learn more, see Know your data.

Policy planning

As you begin your DLP adoption, you can use these questions to focus your policy design and implementation efforts.

What laws, regulations, and industry standards must your organization comply with?

Because many organizations come to DLP with the goal of regulatory compliance, answering this question is a natural starting place for planning your DLP implementation. But, as the IT implementer, you're probably not positioned to answer it. Instead, you should consult your legal team and business executives for an answer.

Example Your organization is subject to U.K. financial regulations.

What sensitive items must your organization protect from leakage?

Once you know where your organization stands in terms of regulatory compliance needs, you'll have some idea of what sensitive items need to be protected from leakage. You'll also have an idea about how you want to prioritize policy implementation to protect those items. This knowledge helps you choose the most appropriate DLP policy templates. Microsoft Purview comes with preconfigured DLP templates for Financial, Medical and health, and Privacy policy templates. Additionally, you can build your own using the Custom template. As you design and create your actual DLP policies, having a working knowledge of the sensitive items you need to protect helps you choose the right sensitive information type.

Example To get started quickly, you might pick the preconfigured `U.K. Financial Data` policy template, which includes the `Credit Card Number`, `EU Debit Card Number`, and `SWIFT Code` sensitive information types.

How you want your policies scoped

If your organization has implemented administrative units, you can scope your DLP policies by administrative unit or leave the scope default, which applies policies to the full directory. For more information, see Policy Scoping.

Where are the sensitive items and what business processes are they involved in?

The items that contain your organization's sensitive information are used every day in the course of doing business. You need to know where instances of that sensitive information may occur and what business processes they're used in. Knowing this helps you choose the right locations to apply your DLP policies. DLP policies can be applied to the following locations:

- Exchange online email
- SharePoint sites

- OneDrive accounts
- Teams chat and channel messages
- Windows 10, 11 and macOS Devices
- Microsoft Defender for Cloud Apps
- On-premises repositories

Example Your organization's internal auditors are tracking a set of credit card numbers. They keep a spreadsheet of them in a secure SharePoint site. Several of the employees make copies and save them to their work OneDrive site, which is synced to their Windows 10 device. One of these employees pastes a list of 14 credit card numbers into an email and tries to send it to the outside auditors for review. In this case, you'd want to apply the policy to the secure SharePoint site, all the internal auditors OneDrive accounts, their Windows 10 devices, and Exchange email.

What is your organization's tolerance for leakage?

Different groups in your organization may have different views on what counts as an acceptable level of sensitive item leakage. Achieving the perfection of zero leakage may come at too high a cost to the business.

Example Your organization's security group and legal team both feel that there should be no sharing of credit card numbers with anyone outside the org. They insist on zero leakage. However, as part of their regular review of credit card number activity, the internal auditors must share some credit card numbers with third-party auditors. If your DLP policy prohibits all sharing of credit card numbers outside the org, there will be a significant business process disruption and added cost to mitigate the disruption in order for the internal auditors to complete their tracking. This extra cost is unacceptable to the executive leadership. To resolve this issue, there needs to be an internal conversation to decide an acceptable level of leakage. Once that is decided, the policy can provide exceptions for certain individuals to share the information, or, it can be applied in audit-only mode.

> **Important**
>
> To learn how to create a policy intent statement and map it to policy configurations see, Design a data loss prevention policy

Planning for prerequisites

Before you can monitor some DLP locations, there are prerequisites that must be met. See the **Before you begin** sections of the following articles:

- Get started with the data loss prevention on-premises scanner
- Get started with Endpoint data loss prevention
- Get started with the Microsoft compliance extension
- Use data loss prevention policies for non-Microsoft cloud apps

Policy deployment

When you create your DLP policies, you should consider rolling them out gradually, so you can assess their impact and test their effectiveness before fully enforcing them. For example, you don't want a new DLP policy to unintentionally block access to thousands of documents or to break an existing business process.

If you're creating DLP policies with a large potential impact, we recommend following this sequence:

1. **Run the policy in simulation mode, without Policy Tips** and then use the DLP reports, and any incident reports, to assess the impact of the policies. You can use DLP reports to view the number, location, type, and severity of policy matches. Based on the results, you can fine-tune your policies as needed. In simulation mode, DLP policies won't impact the productivity of people working in your organization. It's also good to use this stage for testing out your workflow for DLP event review and issue remediation.

2. **Run the policy in simulation mode with notifications and Policy Tips** so that you can begin to teach users about your compliance policies and prepare them for when the policies are applied. It's useful to have a link to an organization policy page that provides more details about the policy in the Policy Tip. At this stage, you can also ask users to report false positives, so that you can further refine the conditions and reduce the number of false positives. Move to this stage once you have confidence that the results of applying the policies match what they stakeholders had in mind.

3. **Start full policy enforcement** so that the actions in the rules are applied and the content is protected. Continue to monitor the DLP reports and any incident reports or notifications to make sure that the results are what you intend.

End-user training

You can configure your policies so that, when a DLP policy is triggered, email notifications are sent automatically, and policy tips are shown to admins and end users. Policy tips are useful ways to raise awareness of risky behaviors on sensitive items and train users to avoid those behaviors in the future.

Review DLP requirements and update strategy

The regulations, laws, and industry standards that your organization is subject to will change over time, as will your business goals for DLP. Be sure to include regular reviews of all these areas so that your organization stays in compliance and so your DLP implementation continues to meet your business needs.

Approaches to deployment

Expand table

Customer business needs description	Approach
Contoso Bank is in a highly regulated industry and has many different types of sensitive items in many different locations. Contoso: - knows which types of sensitive information are top priority - must minimize business disruption as policies are rolled out - has involved business process owners - has IT resources and can hire experts to help plan, design, and deploy - has a premier support contract with Microsoft	- Take time to understand what regulations they must comply with and how they're going to comply. - Take time to understand the "better together" value of the Microsoft Purview Information Protection stack - Develop a sensitivity labeling scheme for prioritized items and apply it - Design and code policies, deploy them in simulation mode, and train users - Repeat and refine policies
TailSpin Toys doesn't know what sensitive data they have or where it is, and they have little to no resource depth. They use Teams, OneDrive, and Exchange extensively.	- Start with simple policies on the prioritized locations. - Monitor what gets identified - Apply sensitivity labels accordingly - Refine policies and train users
Fabrikam is a small startup. They want to protect their intellectual property and must move quickly. They're willing to dedicate some resources, but can't afford to hire outside experts. Other considerations: - Sensitive items are all in Microsoft 365 OneDrive / SharePoint - Adoption of OneDrive and SharePoint is slow. Many employees still use DropBox and Google drive to store and share items - Employees value speed of work over data protection discipline - All 18 employees have new Windows devices	- Take advantage of the default DLP policy in Teams - Use the "restricted by default" setting for SharePoint items - Deploy policies that prevent external sharing - Deploy policies to prioritized locations - Deploy policies to Windows devices - Block uploads to cloud storage solutions other than OneDrive

Design a data loss prevention policy

Taking the time to design a policy before you implement it gets you to the desired results faster, with fewer unintended issues, than creating it and then tuning by trial and error alone. Having your policy designs documented will help you in communications, policy reviews, troubleshooting, and further tuning.

If you're new to Microsoft Purview DLP, it's helpful to work through these articles before you start designing a policy:

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Before you begin

1. Administrative units
2. Learn about Microsoft Purview Data Loss Prevention
3. Plan for data loss prevention (DLP) - by working through this article you will:
   a. Identify stakeholders
   b. Describe the categories of sensitive information to protect
   c. Set goals and strategy
4. Collection Policies solution overview
5. Collection policy reference
6. Data Loss Prevention policy reference - this article introduces all the components of a DLP policy and how each one influences the behavior of a policy
7. Design a DLP policy - this article walks you through creating a policy intent statement and mapping it to a specific policy configuration.
8. Create and Deploy data loss prevention policies - This article presents some common policy intent scenarios that you map to configuration options, then it walks you through configuring those options.
9. Learn about investigating data loss prevention alerts - This article introduces you to the lifecycle of alerts from creation, through final remediation and policy tuning. It also introduces you to the tools you use to investigate alerts.

Policy design overview

Designing a policy is mostly about clearly defining your business needs, documenting them in a policy intent statement, and then mapping those needs to policy configuration. You use the decisions you made in your planning phase to inform some of your policy design decisions.

Define intent for the policy

You should be able to summarize, in a single statement, the business intent for every policy you have. Developing this statement drives conversations in your organization and, when fully fleshed out, this statement directly links the policy to a business purpose and provides a roadmap for policy design. The steps in the Plan for data loss prevention (DLP) article helps you get started on your policy intent statement.

Remember that, as described in the DLP policy configuration overview, all DLP policies require you to:

- Choose what you want to monitor
- Choose the Policy Scoping.
- Choose where you want to monitor .
- Choose the conditions that must be matched for a policy to be applied to an item.
- Choose the action to take when the policy conditions are met.

For example, here's a fictitious first draft of an intent statement that provides answers to all five questions:

"We're a U.S. based organization, and we need to detect Office documents that contain sensitive health care information covered by HIPAA that are stored in OneDrive/SharePoint and to protect against that information being shared in Teams chat and channel messages and restrict everyone from sharing them with unauthorized third parties".

As you develop a policy design, you'll likely modify and extend the statement.

Map business needs to policy configuration

Let's break down the example draft statement and map it to DLP policy configuration points. This example assumes that you're using an unrestricted DLP admin account and that administrative units aren't configured.

> **Important**

Be sure you understand the difference between an *unrestricted administrator* and an *administrative unit restricted administrator* by reading Administrative units before you start.

Expand table

Statement	Configuration question answered and configuration mapping
"We're a U.S. based organization, and we need to detect Office documents that contain sensitive health care information covered by HIPAA...	- **What to monitor**: Office docs, use the U.S. Health Insurance Act (HIPAA) template - **Conditions for a match**: (preconfigured but editable) - item contains U.S. SSN and Drug Enforcement Agency (DEA) number, International Classification of Diseases (ICD-9-CM), International Classification of Diseases (ICD-10-CM), content is shared with people outside my organization - drives conversations to clarify the triggering threshold for detection like confidence levels, and instance count (called leakage tolerance).
...that are stored in OneDrive/SharePoint and protect against that information being shared in Teams chat and channel messages...	- **Where to monitor**: Location scoping by including or excluding OneDrive and SharePoint sites and Teams chat/channel accounts or distribution groups. **Policy scoping** (preview): Full directory
...and restrict everyone from sharing those items with unauthorized third parties."	- **Actions to take**: You add *Restrict access or encrypt the content in Microsoft 365 locations* - drives conversation on what actions to take when a policy is triggered including protective actions like sharing restrictions, awareness actions like notifications and alerts, and user empowerment actions like allow user overrides of a blocking action

This example doesn't cover all the configuration points of a DLP policy; it would need to be expanded. However, it should get you thinking in the right direction as you develop your own DLP policy intent statements.

Important

Keep in mind that the location(s) you pick impact whether you can use sensitive information types, sensitivity labels, and retention labels. The location(s) you pick also impact the actions that are available. See Data Loss Prevention policy reference for more information.

Complex rule design

The above HIPAA content in SharePoint and OneDrive is a simple example of a DLP policy. The DLP rule builder supports boolean logic (AND, OR, NOT) and nested groups.

> **Important**
>
> - All existing **Exceptions** are replaced with a NOT condition in a nested group inside of the **Conditions**.
> - You need to create groups in order to use multiple operators.

> **Important**
>
> When an action in Office desktop client apps, (Word, Outlook, Excel, and PowerPoint) matches a policy that uses complex conditions, the user will only see policy tips for rules that use the **Content contains sensitive information** condition.

- *Example 1 We need to block emails to all recipients that contain credit card numbers, OR that have the 'highly confidential' sensitivity label applied, but do NOT block the email if it is sent from someone on the finance team to adele.vance@contoso.com*
- *Example 2 Contoso needs to block all emails that contain a password protected file OR a zip document file extension ('zip' or '7z'), but do NOT block the email if the recipient is in the contoso.com domain OR the fabrikam.com domain, OR the sender is a member of the Contoso HR group.*

https://learn-video.azurefd.net/vod/player?id=0edf38a9-89fb-4bc5-95f4-48c70053e031&locale=en-us&embedUrl=%2Fpurview%2Fdlp-policy-design

> **Important**
>
> - Using the NOT condition in a nested group replaces the **Exceptions** functionality.
> - You need to create groups in order to use multiple operators.

> **Important**
>
> When an action in Office desktop client apps (Word, Outlook, Excel, and PowerPoint) matches a policy that uses complex conditions, the user will only see policy tips for rules that use the **Content contains sensitive information** condition.

Policy Design Process

1. Complete the steps in Plan for data loss prevention (DLP) - by working through this article you will:
   a. Identify your stakeholders
   b. Describe the categories of sensitive information to protect
   c. Set goals and strategy
   d. Define your policy deployment plan

2. Familiarize yourself with Data Loss Prevention policy reference so that you understand all the components of a DLP policy and how each one influences the behavior of a policy.

3. Familiarize yourself with what the DLP policy templates include.

4. Develop your policy intent statement with your key stakeholders. Refer to the example earlier in this article.

5. Determine how this policy fits into your overall DLP policy strategy.

6. Map the items in your policy intent statement to configuration options.

7. Decide which policy template you start from: predefined or custom.

8. Go through the template and assemble all information required before you create the policy. It's likely that you will find that there are some configuration points that aren't covered in your policy intent statement. That's ok. Go back to your stakeholders to iron out the requirements for any missing configuration points.

9. Document the configuration of all the policy settings and review them with your stakeholders. You can reuse your policy intent statement mapping to configuration points, which is now fully fleshed out.

10. Create a draft policy and refer back to your policy deployment plan.

Create and deploy data loss prevention policies

Microsoft Purview Data Loss Prevention (DLP) policies include many configuration options. Each option changes the policy's behavior. The articles in this series cover some of the most common DLP policy scenarios. They walk you through configuring those options to give you hands-on experience with the DLP policy creation process. When you familiarize yourself with these scenarios, you gain the foundational skills that you need to use the DLP policy creation UX to create your own policies.

How you deploy a policy is as important policy design. You have multiple options to control policy deployment, including policy state, actions, and scope, as described in the Deploy and manage DLP policies section of this article. This article shows you how to use these options so that the policy achieves your intent while avoiding costly business disruptions.

In preview You can change the display name of DLP policies and rules. Once you rename a policy or a rule, any existing records retain their previous name in activity explorer evetns, in alerts and in audit records. New records will reflect the new name in activity explorer events, in alerts and in audit records. These names will remain until the items age out of the system.

Orient yourself to DLP

1. Administrative units
2. Learn about Microsoft Purview Data Loss Prevention
3. Plan for data loss prevention (DLP) - by working through this article you will:
    a. Identify stakeholders
    b. Describe the categories of sensitive information to protect
    c. Set goals and strategy
4. Collection Policies solution overview
5. Collection policy reference
6. Data Loss Prevention policy reference - this article introduces all the components of a DLP policy and how each one influences the behavior of a policy
7. Design a DLP policy - this article walks you through creating a policy intent statement and mapping it to a specific policy configuration.
8. Create and Deploy data loss prevention policies - This article presents some common policy intent scenarios that you map to configuration options, then it walks you through

configuring those options.

9. Learn about investigating data loss prevention alerts - This article introduces you to the lifecycle of alerts from creation, through final remediation and policy tuning. It also introduces you to the tools you use to investigate alerts.

SKU/subscriptions licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions

The account you use to create and deploy policies must be a member of one of these role groups:

- Compliance administrator
- Compliance data administrator
- Information Protection
- Information Protection Admin
- Security administrator

> **Important**
>
> Before you start, make sure you understand the difference between an *unrestricted administrator* and an *administrative unit restricted administrator* by reading Administrative units.

Granular Roles and Role Groups

You can use these roles and role groups to fine tune your access controls.

Here's a list of applicable roles. To learn more, see Permissions in the Microsoft Purview portal.

- DLP Compliance Management
- Information Protection Admin
- Information Protection Analyst
- Information Protection Investigator
- Information Protection Reader

Here's a list of applicable role groups. To learn more, see Permissions in the Microsoft Purview portal.

- Information Protection
- Information Protection Admins
- Information Protection Analysts
- Information Protection Investigators
- Information Protection Readers

Policy creation scenarios for Enterprise applications & devices

The previous article, Design a DLP policy, introduces you to the methodology of creating a policy intent statement and then mapping that intent statement to policy configuration options.

- Help prevent sharing credit card numbers through email
- Help prevent sharing sensitive items via SharePoint and OneDrive with external users
- Help protect files that Endpoint Data Loss Prevention fails to scan
- Help protect files that Endpoint Data Loss Prevention doesn't scan
- Help protect against sharing of a defined set of unsupported files
- Disable Microsoft Purview data loss prevention scanning for some supported files and apply controls
- Help prevent sharing Power BI reports with credit card numbers

Policy creation scenarios for Inline web traffic

The following scenarios show how to create DLP policies for inline web traffic.

- Help prevent sharing via Microsoft Edge for Business to unmanaged AI apps from managed devices
- Help Prevent Users from Sharing Sensitive Info with Cloud Apps in Edge for Business
- Help prevent sharing sensitive information with unmanaged AI apps via network data security

Deploy and manage DLP policies

A successful policy deployment isn't just about getting the policy into your environment to enforce controls on user actions. A haphazard, rushed deployment can negatively impact business processes and annoy your users. Those consequences slow acceptance of DLP

technology in your organization and the safer behaviors it promotes. Ultimately, those consequences make your sensitive items less safe in the long run.

Before you start your deployment, make sure you read through Policy deployment. It gives you a broad overview of the policy deployment process and general guidance.

The following guidance covers the three types of deployment controls—state, actions, and scope—that you use in concert to manage your policies in production. You can change any of these controls at any time, not just during policy creation.

Three axes of deployment management

Use three axes to control the policy deployment process: scope, state, and actions. Always take an incremental approach to deploying a policy, starting from the least impactful DLP simulation mode through full enforcement.

Recommended deployment control configurations

The following table summarizes recommended combinations of policy state, scope, and action impact during deployment.

Expand table

When your policy state is	Your policy scope can be	Impact of policy actions
Run the policy in simulation mode	Policy scope of locations can be narrow or broad	- You can configure any action - No user impact from configured actions - Admin sees alerts and can track activities
Run the policy in simulation mode with policy tips	Policy should be scoped to target a pilot group and then expand the scope as you tune the policy	- You can configure any action - No user impact from configured actions - Users can receive policy tips and alerts - Admin sees alerts and can track activities
Turn it on	All targeted location instances	- All configured actions are enforced on user activities - Admin sees alerts and can track activities

When your policy state is	Your policy scope can be	Impact of policy actions
Keep it off	n/a	n/a

Policy state

State is the primary control you use to roll out a policy. When you finish creating your policy, set the state of the policy to **Keep it off**. Leave it in this state while you work on the policy configuration and until you get a final review and sign off. Set the state to:

- **Run the policy in simulation mode**: No policy actions are enforced, events are audited. While in this state, you can monitor the impact of the policy in the DLP simulation mode overview and the DLP **Activity explorer** console.
- **Run the policy in simulation mode and show policy tips while in simulation mode**: No actions are enforced, but users receive policy tips and notification emails to raise their awareness and educate them.
- **Turn it on right away**: This is full enforcement mode.
- **Keep it off**: The policy is inactive. Use this state while developing and reviewing your policy before deployment.

You can change the state of a policy at any time.

Policy actions

Actions are what a policy does in response to user activities on sensitive items. Because you can change these actions at any time, you can start with the least impactful, *Allow* (for devices) and **Audit only** (for all other locations), gather and review the audit data, and use it to tune the policy before moving to more restrictive actions.

- **Allow**: The user activity is allowed to occur, so no business processes are impacted. You get audit data and there aren't any user notifications or alerts.

  > ⓘ **Note**
  >
  > The **Allow** action is only available for policies that are scoped to the **Devices** location.

- **Audit only**: The user activity is allowed to occur, so no business processes are impacted. You get audit data and you can add notifications and alerts to raise awareness and train your users to know that what they're doing is a risky behavior. If your organization intends to enforce more restrictive actions later on, you can tell your users that too.

- **Block with override**: The user activity is blocked by default. You can audit the event, raise alerts and notifications. This action impacts the business process, but your users are given the option to override the block and provide a reason for the override. Because you get direct feedback from your users, this action can help you identify false positive matches, which you can use to further tune the policy.

  > ⓘ **Note**
  >
  > For Exchange online and SharePoint in Microsoft 365, you configure overrides in the user notification section.

- **Block**: The user activity is blocked no matter what. You can audit the event, raise alerts and notifications.

Define policy scope

Every policy is scoped to one or more locations, such as Exchange, SharePoint in Microsoft 365, Teams, and Devices. By default, when you select a location, all instances of that location fall under the scope and none are excluded. You can further refine which instances of the location (such as sites, groups, accounts, distribution groups, mailboxes, and devices) that the policy is applied to by configuring the include/exclude options for the location. To learn more about your include/exclude scoping options, see DLP policy locations.

In general, you have more flexibility with scoping while the policy is in **Run the policy in simulation mode** state because no actions are taken. You can start with just the scope you designed the policy for or go broad to see how the policy would impact sensitive items in other locations.

When you change the state to **Run the policy in simulation mode and show policy tips**, narrow your scope to a pilot group that can give you feedback and be early adopters who can be a resource for others when they come onboard.

When you move the policy to **Turn it on right away**, you broaden the scope to include all the instances of locations that you intended when the policy was designed.

Policy deployment steps

Use the following steps to roll out a DLP policy safely from initial review through full enforcement.

1. After you've created the policy and set its state to **Keep it off**, do a final review with your stakeholders.
2. Change the state to **Run the policy in simulation mode**. The location scope can be broad at this point so you can gather data on the behavior of the policy across multiple locations or just start with a single location.
3. Tune the policy based on the behavior data so that it better meets the business intent.
4. Change the state to **Run the policy in simulation mode and show policy tips**. Refine the scope of locations to support a pilot group if needed and make use of includes/excludes so that the policy is first rolled out to that pilot group.
5. Gather user feedback and alert and event data. If needed, tune the policy and your plans. Make sure you address all the issues that your users bring up. Your users will most likely encounter issues and raise questions about things that you didn't think of during the design phase. Develop a group of super users at this point. They can be a resource to help train other users as the scope of the policy is increased and more users come onboard. Before you go to the next stage of deployment, make sure that the policy is achieved your control objectives.
6. Change the state to **Turn it on right away**. The policy is fully deployed. Monitor DLP alerts and DLP activity explorer. Address alerts.

ⓘ**Note:** The author created this article with assistance from AI. Learn more

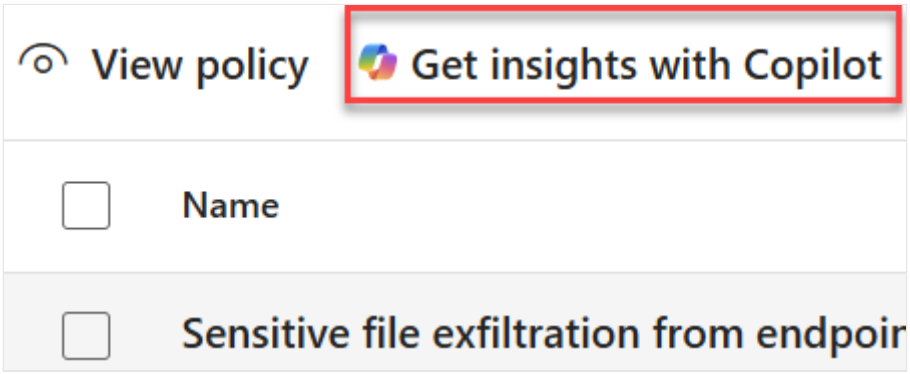
Test your Data Loss Prevention policies

You should test and tune the behavior of your Microsoft Purview Data Loss Prevention (DLP) policies as part of your DLP policy deployment. This article introduces you to two of the basic methods you can use to test policies in your DLP environment.



Simulation mode

When you deploy a new policy or need to modify an existing one, you should run it in simulation mode, and then review the alerts to assess its accuracy. Simulation mode allows you to see how an individual policy affects all the items that are in the policy's scope without actual enforcement. You use it to find out what items match a policy.

Get insights with Microsoft Security Copilot

> **Note**
>
> The **Get insights with Copilot** feature is in preview.

Get insights with Copilot is a Security Copilot skill that is embedded in the Microsoft Purview Data Loss Prevention policy page. It can help you understand what you policies are doing in your organization, and where they're active.

Select one or multiple policies, then select the **Get insights with Copilot** button. Copilot then generates a response that gives you information about the selected policies like:

- Where your policies are looking for sensitive information.
- What kind of sensitive information your policies are looking for.
- What scenarios trigger the policies.

- How end users are impacted by the policies.
- How the admins are notified.

You can further pivot your investigation by administrative units, locations DLP protects and, types of data that's been classified

Prerequisites

- Your organization must be licensed for Microsoft Security Copilot.
- The account you use to access the **Get insights with Copilot** feature must be in the Information protection admin role.

Use the Test-DlpPolicies cmdlet

Test-DlpPolicies is a cmdlet that allows you to see which DLP policies scoped to SharePoint and OneDrive match (or don't match) an individual item in SharePoint or OneDrive.

Before you begin

- You must be able to connect to Exchange Online PowerShell.
- You must have a valid SMTP address to send the report to. For example: `dlp_admin@contoso.com`
- You must have the site ID where the item is located.
- You must have the direct link path to the item.

> **Important**
>
> - Test-DlpPolicies only works for items that are in SharePoint or OneDrive.
> - Test-DlpPolices only reports results for policies that include SharePoint alone, OneDrive alone, or both SharePoint and OneDrive in their scope.
> - Test-DlpPolices works only with simple conditions. It doesn't work with complex, grouped, or nested conditions.

Use Test-DlpPolicies

To see which DLP policies an item matches, follow these steps:

Get the direct link path to the item

To get the direct link path for the item, follow these steps:

1. Open the SharePoint or OneDrive folder in a browser.
2. Select the file's ellipsis and select **details**.
3. In the details pane, scroll down and select **Path**. Copy the direct link and save it.

   For example:

`https://contoso.sharepoint.com/personal/user_contoso_com/Documents/test.docx`

Get the site ID

To get the site ID, follow these steps:

1. Connect to Exchange Online PowerShell.
2. For SharePoint, use the following syntax to get the site ID and save it:

PowerShell

```
$reportAddress = "email@contoso.com"

$siteName = "SITENAME@TENANT.onmicrosoft.com"

$filePath =
"https://Contoso.sharepoint.com/sites/SOMESITENAME/Shared%20Documents/TESTFILE.ppt
x"

$r = Get-Mailbox -Identity $siteName -GroupMailbox

$e = $r.EmailAddresses | Where-Object {$_ -like '*SPO*'}

Test-DlpPolicies -SiteId $e.Substring(8,36) -FileUrl $filePath -Workload SPO -
SendReportTo $reportAddress
```

3. For OneDrive, use the following syntax to get the site ID and save it.

PowerShell

```
$reportAddress = "email@contoso.com"

$odbUser = "USER@TENANT.onmicrosoft.com"

$filePath = "https://contoso-
```

```
my.sharepoint.com/personal/userid_contoso_onmicrosoft_com/Documents/TESTFILE.docx
"

$r = Get-Mailbox -Identity $odbUser

$e = $r.EmailAddresses | Where-Object {$_ -like '*SPO*'}

Test-DlpPolicies -SiteId $e.Substring(8,36) -FileUrl $filePath -Workload ODB -
SendReportTo $reportAddress
```

Here's an example of a returned value:

`36ca70ab-6f38-7f3c-515f-a71e59ca6276`

Run Test-DlpPolicies

After you have the site ID and the direct link path, run the cmdlet to test your policies.

- Run the following syntax in the PowerShell window:

PowerShell

```
Test-DlpPolicies -workload <workload> -Fileurl <path/direct link> -SendReportTo
<smtpaddress>
```

For example:

`Test-DlpPolicies -workload <ODB> -Fileurl <https://contoso.sharepoint.com/personal/user_contoso_com/Documents/test.docx> -SendReportTo <dlp_admin@contoso.com>`

Interpret the report

The report is sent to the SMTP address specified in the `-SendReportTo` parameter of the `Test-DlpPolicies` command. There are multiple fields. Here are explanations of the most important ones.

Expand table

Field name	Means
Classification ID	The sensitive information type (SIT) the item is categorized as
Confidence	The confidence level of the SIT

Field name	Means
Count	The total number of times the SIT value was found in the item, this includes duplicates
Unique Count	The number SIT values found in the item with duplicates eliminated
Policy Details	The name and GUID of the policy that was evaluated
Rules - Rule Details	The DLP rule name and GUID
Rules - Predicates - Name	The condition defined in the DLP rule
Rules - Predicates - IsMatch	Whether the item matched the conditions
Predicates - Past Actions	Any actions, like notify user, block, block with override that 's been taken on the item
Predicates - Rule's Actions	The action defined in the DLP rule
Predicates - IsMatched	Whether the item matched the rule
IsMatched	Whether the item matched the overall policy

Learn about using regular expressions (regex) in data loss prevention policies

A *regular expression*, commonly referred to as a *regex*, is a sequence of characters that defines a search pattern. Regular expressions are primarily used for pattern matching with strings and in string matching; for example, in "find and replace" operations. You can use a regex in Microsoft Purview Data Loss Prevention (DLP) to define patterns that help you identify and classify sensitive data, or to help detect patterns in content. The most common regex uses in Microsoft Purview DLP are:

- Defining a custom sensitive information types.
- Leveraging the `SubjectOrBodyMatchesPatterns` condition in a DLP rule (Read more here.)

This article describes common issues that occur when working with regular expressions and how you can resolve them.

Potential validation issue when using a regex with DLP

- Basic units of the pattern, such as literal characters, digits, whitespace, and punctuation marks can be represented by themselves or by special symbols called metacharacters, such as `\d` for any digit, `\s` for any whitespace, or `\.` for a literal dot.
- The basic units, when combined with quantifiers, specify how many times they can or must occur in a match. For example, `*` means zero or more, `+` means one or more, `?` means zero or one, and `{n,m}` means between `n` and `m` times. For example, `\d+` means one or more digits, `\s?` means optional whitespace, and `a{3,5}` means between three and five instances of the literal character **a**.
- A regex either uses a positive lookbehind or a negative lookbehind. A *lookbehind* is used to check whether there's a match before a certain position in the input string, without including the actual characters in the match. A positive lookbehind is used to match when the lookbehind pattern **is** present, while a negative lookbehind is used to match when the lookbehind pattern **is not** present.
- Consider this example: `(?<=^|\s|_)`. This example shows a lookbehind that includes three possibilities:

    1. `^` asserts the position. In this case, it requires the pattern matching to begin at the start of the line.

2. `\s` detects any whitespace characters as a match.
3. `_` matches the literal underscore character (_).

- In the previous example, possibilities #2 and #3 will each match a single character. However, possibility #1 only indicates where the matching should start. It will not produce results with respect to any character matches.
- Take a second example, `^\d+$`. This regex will only detect a string composed entirely of digits, from start to end.
- Regex pattern validations in conditions are case insensitive by default. To honor the case sensitivity please add (?-i) to the pattern

How to get extracted text

A regex is matched on the extracted text of the content, rather than on the content itself. So, even when the pattern appears to be on the content, it might not match when evaluating a DLP policy.

To ensure that you capture the appropriate matches, take the following steps:

1. Use the Test-TextExtraction cmdlet to get the extracted text, which will consist of a stream of strings.
2. Next, use the extracted text for matching the regular expression.

For instance:

PowerShell

```
$data = ([System.IO.File]::ReadAllBytes('<FilePath>'))
$tr = Test-TextExtraction -FileData $data
$tr.ExtractedResults.ExtractedStreamText | Format-List
```

How to verify sensitive information type detection

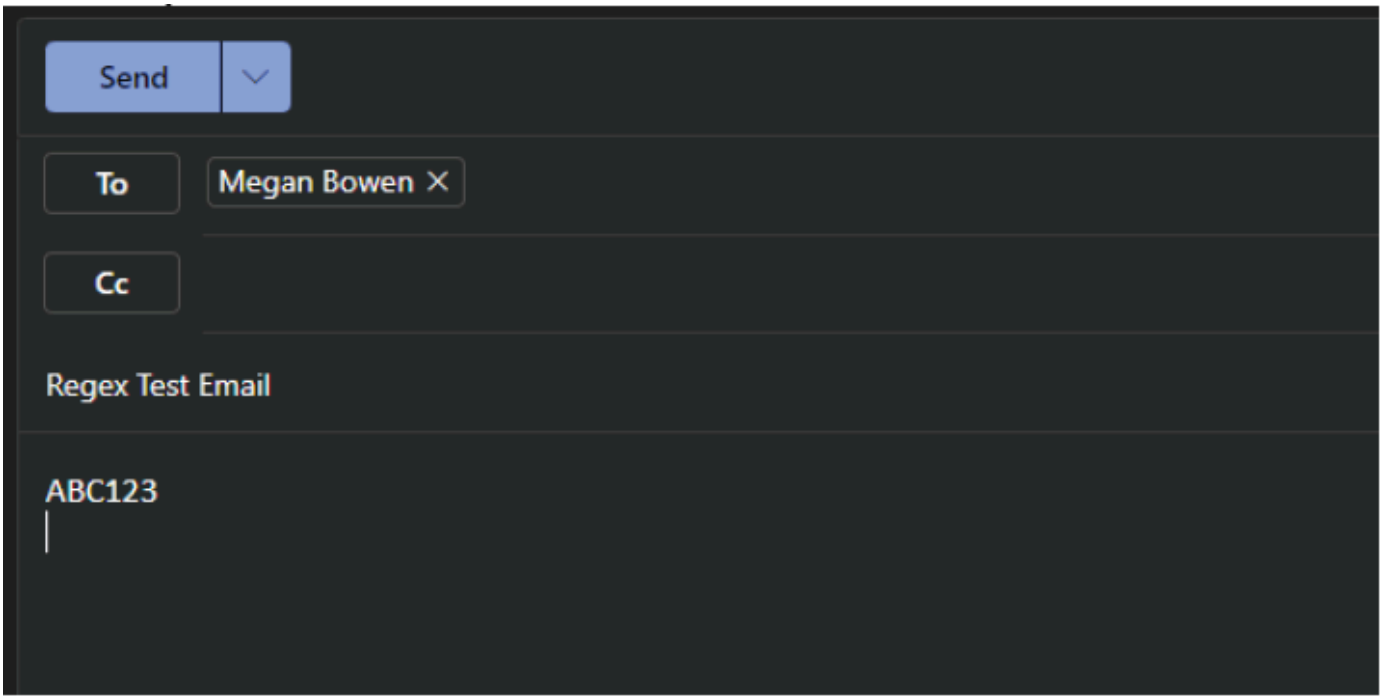
To verify sensitive information type (SIT) detection, we need to take the text we just extracted and then run the Test-DataClassification cmdlet on it to verify detection. The results of running the cmdlet will indicate whether there are any SIT matches for the regex.

For example:

PowerShell

```
$textStream = $tr.ExtractedResults.ExtractedStreamText | Out-String
$result = Test-DataClassification -TextToClassify $textStream
```

```
$result.ClassificationResults | Format-List
```



Example of using a regex in a DLP policy rule

In this example, we will block email that contains strings starting with *ABC* followed by a number.

Regex used: `^ABC\d`

DLP rule sample: `New-DlpComplianceRule -Name "Rule_00" -Policy "Policy_00" -SubjectOrBodyMatchesPatterns "^ABC\d" - BlockAccess $True`

Sample email

While it seems that the regex will detect a match with this mail item, the extracted text looks like this:

```
Regex Test Email ABC123
```

As you can see, the extracted text begins with the content in the subject line of the email, rather than with the content in the body of the email. However, the inclusion of the assertion character, `^`, at the start of the regex requires that the *ABC*... string must be at the start of the extracted text for a match to be detected.

To resolve this issue, you can change the regex to `ABC\d`.

Regex requirements for custom sensitive information types

When you define a regex for a custom sensitive information type, the pattern must follow a specific structure to work correctly with Microsoft Purview classification. This requirement applies whether you create the SIT through the Microsoft Purview portal or PowerShell.

The required structure is:

`(?:prefix)(primary capturing group)(?:suffix)`

Where:

- Use **exactly one** capturing group for the primary match. Use noncapturing groups `(?: ... )` for any prefix/suffix or other grouping.
- All match variants must be handled **inside** that single capturing group using `|` (alternation).
- Multiple capturing groups separated by `|` at the top level are **not supported** and are blocked during validation.

If your regex contains multiple top-level capturing groups, the SIT fails to classify content on Endpoint DLP and other workloads.

Example of an invalid pattern:

`(?:[\s,;])([A-Z]{2}[0-9]{3})(?:[\s,;])|(?:[\s,;])([A-Z]{2}[A-Z]{4}[0-9])(?:[\s,;])|(?:[\s,;])([A-Z]{2}[0-9]{5})(?:[\s,;])`

This pattern has three separate capturing groups at the top level. Instead, consolidate all variants into one capturing group:

Example of a valid pattern:

`(?:[\s,;])([A-Z]{2}[0-9]{3}|[A-Z]{2}[A-Z]{4}[0-9]|[A-Z]{2}[0-9]{5})(?:[\s,;])`

For more information on limits, see Sensitive information type limits.

Learn about Adaptive Protection in Data Loss Prevention

Article • 03/31/2025

Adaptive Protection in Microsoft Purview integrates Microsoft Purview Insider Risk Management with Microsoft Purview Data Loss Prevention (DLP). When insider risk identifies a user who is engaging in risky behavior, they are dynamically assigned to a inside risk level. Then Adaptive Protection can automatically create a DLP policy to help protect the organization against the risky behavior that's associated with that inside risk level. As users insider risk levels change in insider risk management, the DLP policies applied to users can adjust.

You can manually create DLP policies that help protect against risky behaviors that insider risk identifies too.

Refer to Help dynamically mitigate risks with Adaptive Protection to learn about Adaptive Protection and how to configure it.

How Adaptive Protection shows up in DLP policies

If you're unfamiliar with DLP policies, you should review these articles before working with Adaptive Protection:

- Learn about data loss prevention
- Plan for data loss prevention (DLP)
- Data Loss Prevention policy reference
- Design a data loss prevention policy

Once Adaptive Protection is configured in insider risk, a condition called **User's risk level for Adaptive Protection is** will be available to use in rules that are configured for policies scoped to Exchange Online, Devices, and Teams locations.

The condition **Insider risk level for Adaptive Protection is** has three values:

- **Elevated risk level**
- **Moderate risk level**
- **Minor risk level**

These insider risk level profiles are defined in insider risk. You can select one, two or all three in a policy rule. Learn more about insider risk levels.

You can manually configure DLP policies that are part of Adaptive Protection and also use the quick setup configuration in insider risk to create DLP policies automatically from a template.

Manual configuration

You manually configure an Adaptive Protection DLP policy just like you would configure any other policy. Just select the **Insider risk level for Adaptive Protection is** condition and the insider risk level profiles that you want, configure all the other policy options and deploy the policy according to your normal procedures.

Quick setup configuration

If quick setup is used to configure Adaptive Protection in insider risk, DLP policies are created automatically, so you should be on the lookout for them. Quick setup will create one policy for Teams and Exchange Online with two rules, one for the elevated risk profile and one for the moderate and minor insider risk levels. It will also create one policy for Devices with two rules, one for the elevated risk profile and one for the moderate and minor insider risk levels.

> **Tip**
>
> Insider risk presents a view of just the DLP policies that use the **Insider risk level for Adaptive Protection is** condition. Open **Microsoft Purview portal** > **Insider risk management** > **Adaptive protection** to see the list. You'll need DLP to be in one of these roles to access the insider risk node:

- Compliance administrator
- Compliance Data administrator
- Organization management (Users who are not global administrators must be Exchange administrators to see and take action on devices that are managed by Basic Mobility and Security for Microsoft 365)
- Global administrator
- DLP compliance management
- View-only DLP compliance management

> **Important**

Microsoft recommends that you use roles with the fewest permissions. This helps improve security for your organization. Global Administrator is a highly privileged role that should only be used in scenarios where a lesser privileged role can't be used.

Policy values for Teams and Exchange online DLP policy

This is the configuration for the Teams and Exchange DLP policy created during Quick Setup. The policy name is **Adaptive Protection policy for Teams and Exchange DLP**.

Rule: Adaptive Protection block rule for Teams and Exchange DLP

Expand table

DLP policy element	Configured value
Conditions	**Insider risk level for Adaptive Protection is** **- Elevated Risk Level** AND **- Content is Shared from Microsoft 365 With people outside my organization**
Actions	**Restrict access or encrypt the content in Microsoft 365 locations** **- Block only people outside your organization**
User Notification	**On** **- Notify user with a policy tip** **– Notify the user who sent, shared, or last modified the content**
User Override	**Off**
Incident reports	**On** **- Severity Level – Low** **- Send alert every time an activity matches the rule**
Additional Options	**Off**
Status	**Run the policy in simulation mode** **- Policy Tips** not selected

Rule: Adaptive Protection audit rule for Teams and Exchange DLP

Expand table

DLP policy element	Configured value
Conditions	**Insider risk level for Adaptive Protection is** **- Moderate Risk Level, Minor Risk Level** AND **- Content is Shared from Microsoft 365 With people outside my organization**
Actions	None
User Notification	**On** **- Notify user with a policy tip** **- Notify the user who sent, shared, or last modified the content**
User Override	**Off**
Incident reports	**On** **- Severity Level – Low** **- Send alert every time an activity matches the rule**
Additional Options	**Off**
Status	**Run the policy in simulation mode** - **Policy tips** not selected

Policy values for Devices DLP policy

This is the configuration for the Devices DLP policy created during Quick Setup. The policy name is **Adaptive Protection policy for Endpoint DLP**.

> **ⓘ Important**
>
> For Adaptive Protection to work on Devices, you must either enable Advanced classification scanning and protection or if you are manually creating the Adaptive Protection policy, select the **File Type is** condition.

> **ⓘ Important**
>
> If a user is targeted by a default Adaptive Protection Device DLP policy and is targeted by an independent Device DLP policy, only the actions of the *most restrictive* policy will be applied.

Rule: Adaptive Protection block rule for Endpoint DLP

Expand table

DLP policy element	Configured value
Conditions	**Insider risk level for Adaptive Protection is** **- Elevated Risk Level** AND **- File Type is** **- Word processing** **- Spreadsheet** **- Presentation** **- Archive** **- Mail**
Actions	**Audit or Restrict activities on Devices** **- Upload to a restricted cloud service domain or access from unallowed browsers - Block** **File activities for all apps** **- Apply restrictions to specific activity** **- Copy to clipboard – Block** **- Copy to removable USB device – Block** **- Copy to network share – Block** **- Print – Block** **Restricted App activities - Access by restricted apps - Block**
User Notification	**Off**
User Override	**Off**
Incident reports	**On** **- Severity Level – Low** **- Send alert every time an activity matches the rule**
Additional Options	**Off**
Status	**Run the policy in simulation mode** **- Policy Tips** option not selected

Rule: Adaptive Protection rule for Endpoint DLP

Expand table

DLP policy element	Configured value
Conditions	**Insider risk level for Adaptive Protection is** **- Moderate Risk Level, Minor Risk Level**

DLP policy element	Configured value
	AND - **File Type is** - **Word processing** - **Spreadsheet** - **Presentation** - **Archive** - **Mail**
Actions	**Audit or Restrict activities on Devices** **- Upload to a restricted cloud service domain or access from unallowed browsers – Audit** **File activities for all apps** **- Apply restrictions to specific activity** **- Copy to clipboard – Audit** **- Copy to removable USB device – Audit** **- Copy to network share – Audit** **-Print – Audit** **Restricted App activities** **- Access by restricted apps - Audit**
User Notification	**Off**
User Override	**Off**
Incident reports	**On** **- Severity Level – Low** **- Send alert every time an activity matches the rule**
Additional Options	**Off**
Status	**Run the policy in simulation mode** - **Policy tips** option not selected

Learn about data loss prevention simulation mode

Article • 03/14/2025

Run the policy in simulation mode, otherwise known as simulation mode, for Microsoft Purview Data Loss Prevention (DLP) policies replaces the **Test** and **Test with policy tips** policy states. When a policy is in simulation mode, it's run as if it were being enforced, without any actual enforcement. Unlike the **Test** modes, all matched items and alerts are reported in a separate dashboard. This makes it easy to see the impact of the policy before you enforce it by keeping all the simulation results separate from the results of policies that are being enforced.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Simulation mode provides:

- An isolated experience to run and assess policies.
- A summary dashboard that gives you visibility into the impact of the policies across different locations and shows which items were matched.
- A flat list of matched items at a policy level.

Simulation mode for DLP policies is a tool you can use for tuning your data loss prevention policies at any time. You should incorporate it into your policy creation and deployment process. Using simulation mode to tune a policy reduces false positives without impact to your users or business processes. Use it as part of your deployment process for new policies, use it to test changes to existing policies before enforcing those changes in production.

For example:

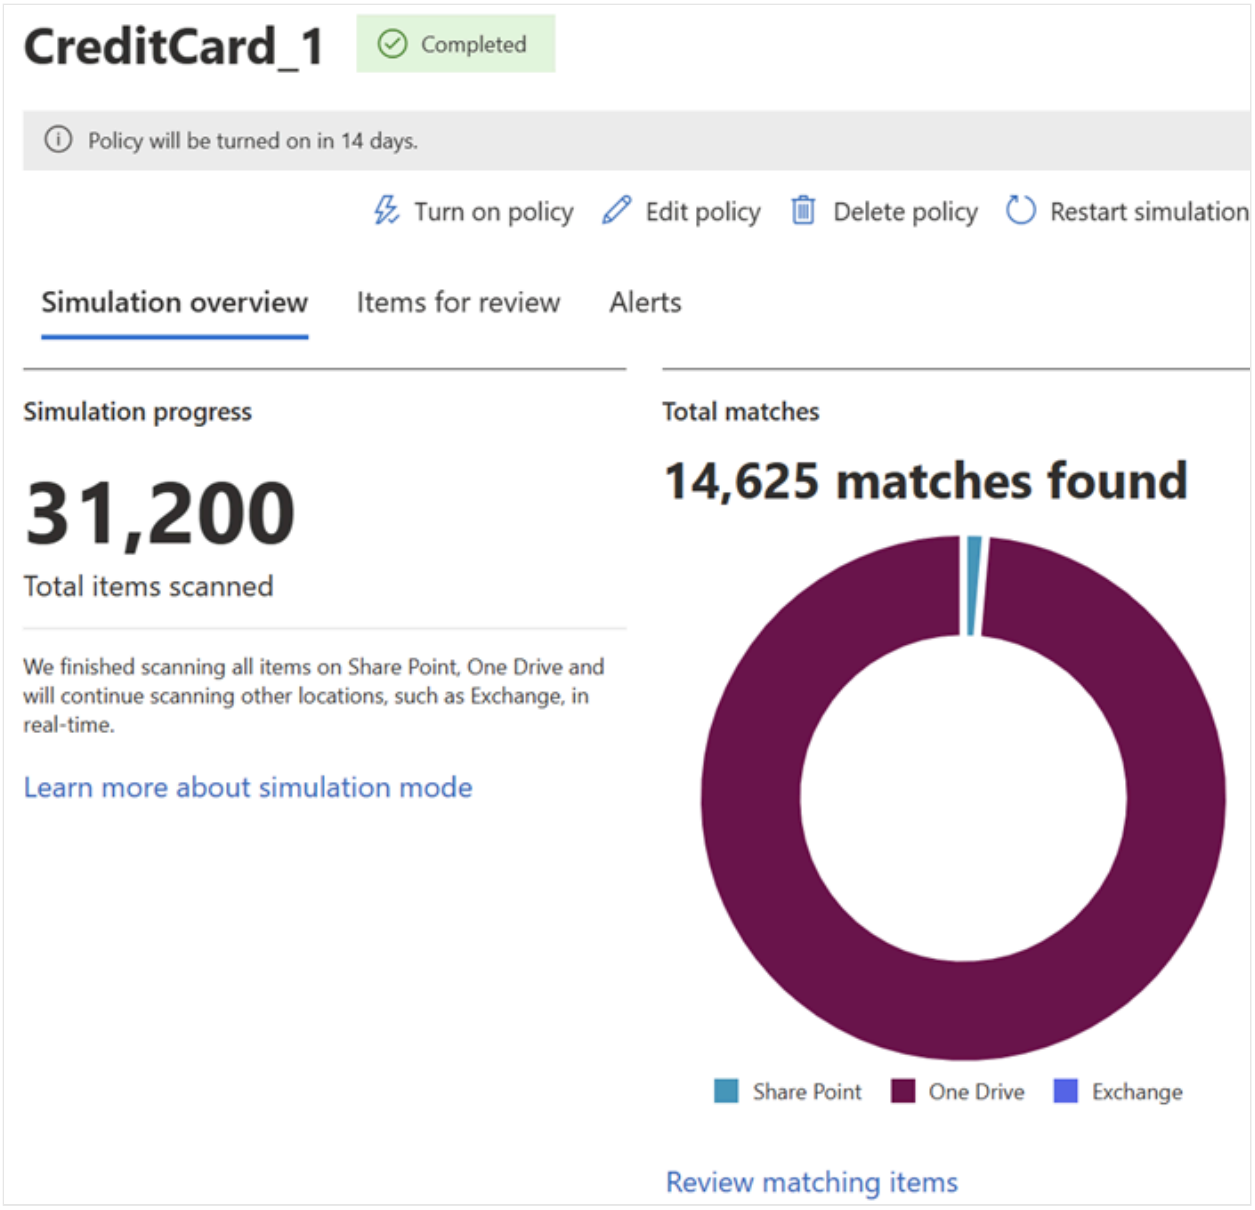
DLP policy *Protect Credit Cards v1* is in production, but is throwing too many false positives. You think you know what is wrong, but you don't want to experiment with changes to it in production to find out. You can make a copy of policy *Protect Credit Cards v1*, call it *Protect Credit Cards v2*, make tuning changes, and then run *v2* in simulation mode. If it the changes have the desired result, then you can turn off *v1* and set *v2* to enforce mode.

> **Important**
>
> Simulations can run for up to 15 days so the results are not a point in time snapshot. For SharePoint Online and OneDrive for Business locations, all existing and new/changed items are evaluated. For Exchange, Teams, Devices locations only items that are new during simulation are evaluated. Data from a simulation run is kept for 30 days.

Placing a policy in simulation mode

See Get started with the data loss prevention simulation mode for the procedures to manage simulation mode for a policy.

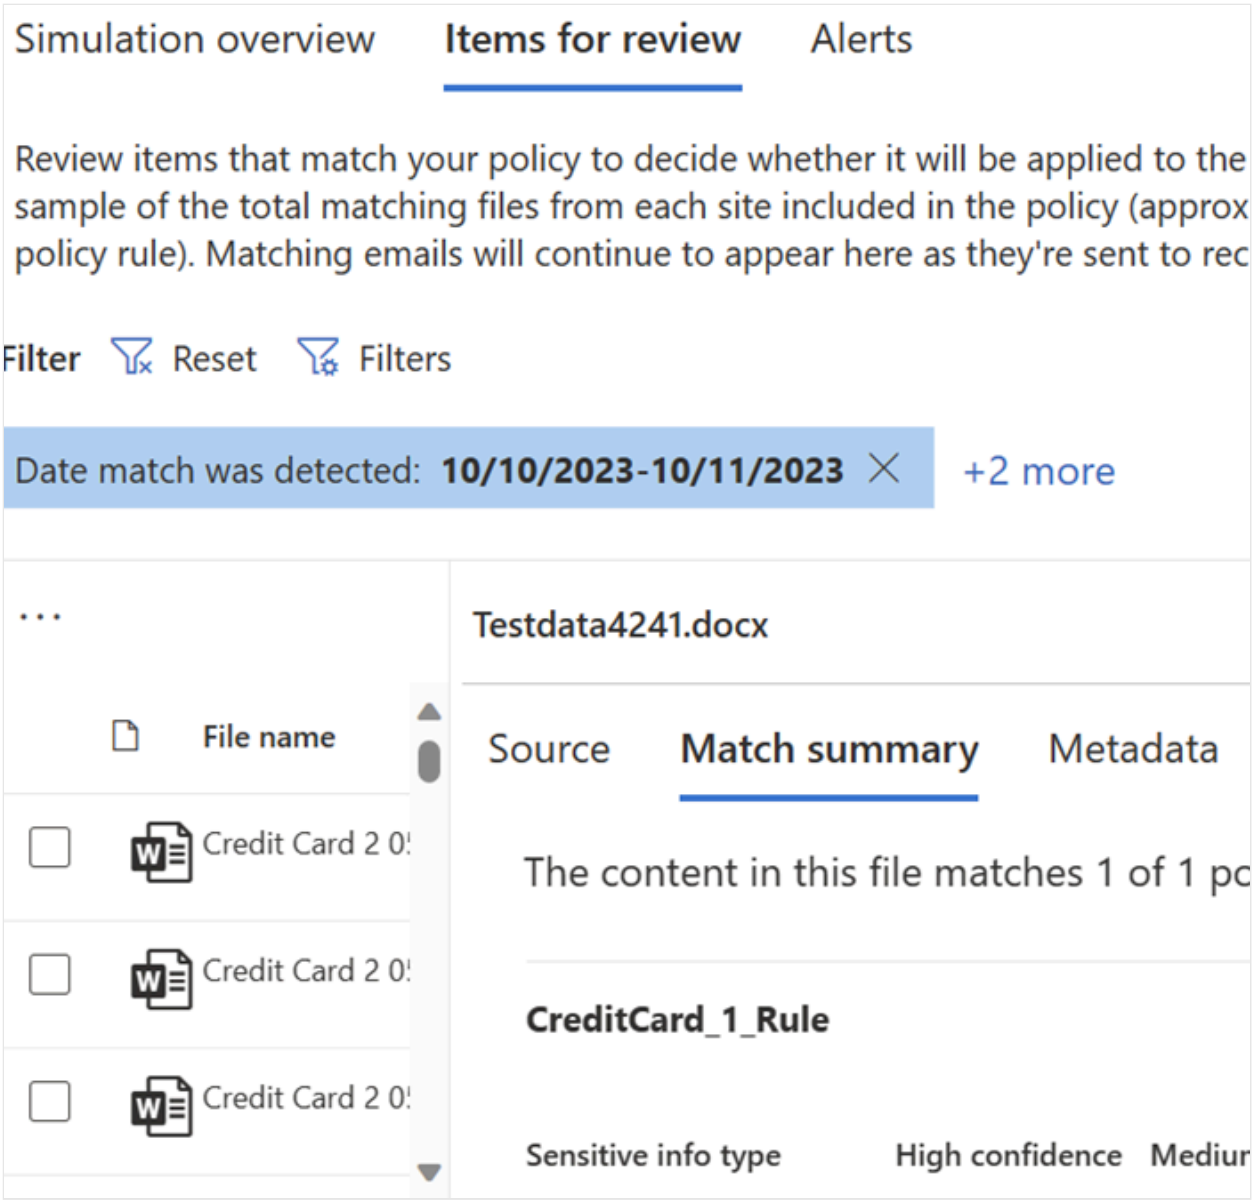
Simulation results



See Get started with the data loss prevention simulation mode for the steps to access simulation results. Simulation results are presented across three pages.

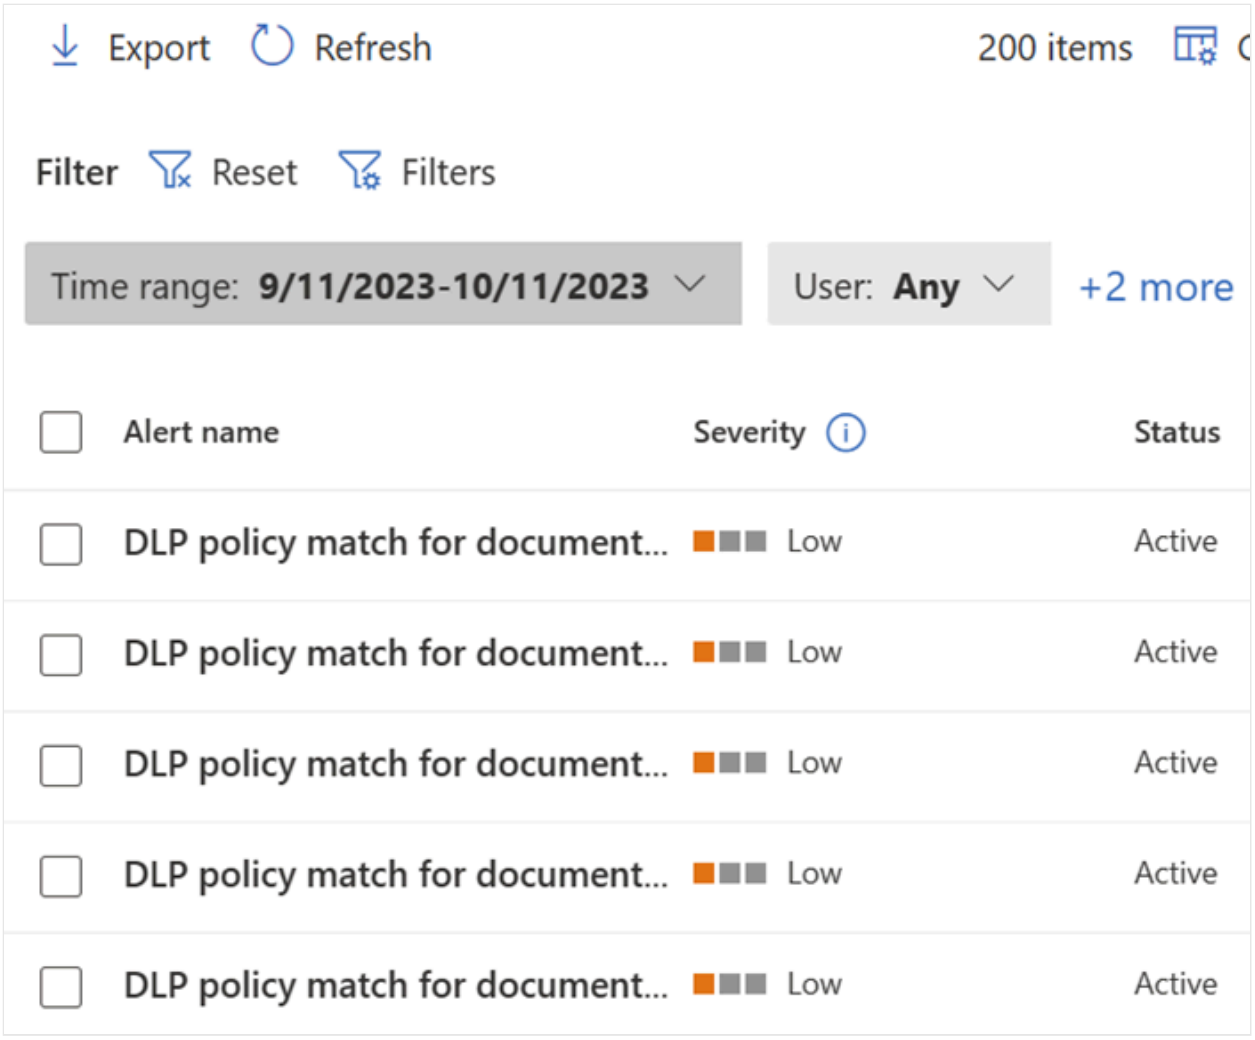
Simulation overview

The **Simulation overview** tab gives you basic information on:



- the status of the policy simulation (complete, in progress or expired)
- status of scanning per location
- total items scanned
- total matches found
- matched items for each location
- links to the matched items

and other information.



Items for review

The **Items for review** tab shows a flat list of the items that matched the policy in simulation and lets you read the source item along with item metadata much like Content explorer.

Alerts

The simulation mode alerts tab shows a flat list of all the alerts that were generated when an item matched the policy in simulation. It has the same format as the DLP alerts console.

Important

While a policy is in simulation mode, all simulation alerts are only surfaced in the simulation alerts tab. They don't show up in the DLP alerts console and they don't flow into the Microsoft Defender portal.

Feedback

Was this page helpful? Yes No

Get started with the data loss prevention simulation mode

You can use Microsoft Purview Data Loss Prevention (DLP) simulation mode to see:

- The impact of a policy on your production environment without enforcement.
- All the items that would be matched by a policy if it were enforced.

This article walks you through simulation mode prerequisites, configuration options and how to view simulation results.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Before you begin

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions

The account you use to interact with simulation mode must be in the Information Protection admin role. For more information on the roles and role groups necessary to use simulation mode, see Permissions. For more information on roles and role groups in Microsoft Purview compliance, see Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview compliance

Configure system settings for DLP simulation mode

To see matched items from endpoint devices in their native application on the **Items for review**, you must configure evidence collection for file activities on devices.

Manage DLP simulation mode

You can set a policy to be in simulation mode when you create it or after it's been created. You can also turn off simulation mode for a policy that's already in simulation mode.

1. Use the steps in Create and Deploy data loss prevention policies to create a new policy or edit an existing policy.
2. The last step in the policy configuration workflow is **Simulate or turn on the policy**. Select **Run the policy in simulation mode** to enable simulation mode. Select either **Turn it on right away** or **Keep it off** to disable simulation mode. You can further select:
   a. **Show policy tips with in simulation mode** to help educate your users when they take actions that might trigger policy actions.
   b. **Turn the policy on if it's not edited within fifteen days of the simulation** to turn the policy on without further interaction.
3. Select **Next** and **Submit**.

After disabling simulation mode, it can take up to 24 hours for the insights to stop appearing on the Overview page.

Viewing DLP policies in simulation mode

Perform the following steps to view a policy that is running in simulation mode.

1. Sign in to the Microsoft Purview portal > **Data Loss Prevention** > **Policies**.
2. Select a policy with a status of **In simulation** or **In simulation with notifications** to open the fly-out pane.
3. Select **View simulation** to see the **Simulation overview**, **Items for review**, and **Alerts** tabs.

Simulation mode status messages

> **Note**
>
> Scan results from running a policy in simulation mode are saved for 30 days. You can continue to run the policy in simulation mode longer than that, but only the results for the most recent 30-day period are displayed.

When a policy runs in simulation mode, content scanning in most locations occurs in real time, that is, it occurs when an email or Teams message is sent. Content scanning for the SharePoint and OneDrive locations works a little differently. In addition to scanning content when documents are uploaded to these locations, policies running in simulation mode can display three additional progress messages: *Completed*, *In progress*, and *Expired*. The following table identifies and describes the status messages available for each location:

Simulation mode scan status by location

The following table lists the scan status messages by location.

Expand table

Location	Status message descriptions
Exchange	**Real-time** - Content is scanned when message is sent
SharePoint	**Completed** - Signifies that scanning the existing content in Sharepoint and/or OneDrive is complete. This status message only displays when SharePoint and/or OneDrive are the only locations in scope. **In progress** - Signifies that the simulation is running. Results are updated as more matches are found.
OneDrive	**Completed** - Signifies that scanning the existing content in Sharepoint and/or OneDrive is complete. This status message only displays when SharePoint and/or OneDrive are the only locations in scope. **In progress** - Signifies that the simulation is running. Results are updated as more matches are found.
Teams chat and channel messages	**Real-time** - Content is scanned when message is sent
Devices	**Real-time** - Content is scanned when transferred off the device
Fabric and Power BI	**Real-time** - Content is scanned when uploaded

The following table explains the status messages related to the progress of the overall policy simulation.

Overall simulation mode status

The following table explains the overall simulation status values.

Expand table

Simulation status	Description
Completed	Only available when a DLP policy scope is limited to SharePoint, OneDrive, or both. Indicates that all data at rest has been scanned.
In progress	Simulation scanning is underway. Results are updated as additional policy matches are detected.
Expired	The policy being simulated is more than 30 days old. Microsoft Purview retains simulation data for only 30 days. To get scan results for data at rest scanned prior to the most recent 30-day window, re-run the scan.

Only the first 100 items matched in the SharePoint and OneDrive locations are displayed for review. This might differ from the total number of matched items.

Simulation events are displayed up in activity explorer. You can filter on *Policy mode*, which has *TestWithNotifyUser*, *TestWithoutNotifyUser* and *enforce* values.

Learn about Advanced label-based protection for all files on devices

07/22/2025

This setting enhances productivity for users that label and encrypt file types other than those for Office and PDF by using the Microsoft Purview Information Protection client. Typical examples of file types other than Office and PDF include .txt, .jpg, .csv, and files from third-party applications.

When users label and encrypt these files with the information protection client and without this setting for advanced label-based protection:

- The encrypted file changes its file name extension and becomes read-only, and can no longer be opened by apps that support the original file name extension. Instead, the file opens in the Microsoft Purview Information Protection viewer. To make any changes to the file, users must manually remove the label with encryption.
- Although the encryption can include restrictive permissions, such as not allowing copy and save for specific users, not all files can support these restrictions. As a result, when these files are opened in the information protection viewer, users are informed of the configured permissions, but the permissions can't be enforced. This type of encryption is referred to as generic, rather than native.

For a better understanding of the file name extension changes for encrypted files, see Supported file types from the information protection client documentation. Also be aware of the standard client exceptions for files that are critical for computer operations.

When you configure users for the endpoint data loss prevention setting **Advanced label-based protection for all files on devices** and use the information protection client, the following changes occur for file types that aren't supported by Office or that are PDF files:

- When a user selects a sensitivity label that applies encryption, the file name extension now doesn't change. As a result, there's no change to the user workflow because they can continue to view and edit the file in their standard application. Endpoint DLP tracks and monitors the file, enforcing configured permissions without requiring the information protection viewer.

> **Note**
>
> Because the file name extension hasn't changed, users can confirm that the label is applied by using the Microsoft Purview Information Protection File Labeler.

- Only if the user copies or moves the file from the computer, does the file name change:
  - If the file is copied or moved to a network drive or USB device, the file there has the changed file name extension that requires the information protection viewer to open it.
  - If the file is copied or moved to any other location (Bluetooth device, over remote desktop, or uploaded to the cloud), a local copy of the file is created with the changed file name extension that requires the information protection viewer to open it. Endpoint DLP informs the user that they must use this version of the file to manually copy or move it to the new location.
  - If the operation to encrypt the file fails, the copy or move activity is blocked to ensure that the unencrypted file remains on the device and isn't exfiltrated.

Here's a summary of the differences when you label files other than Office and PDF and you use just the information protection client rather than the client with endpoint DLP advanced label-based protection:

Expand table

Labeling behavior	Just the client	The client with endpoint DLP setting enabled
Files labeled with encryption retain their original file name extension	No The file name extension always changes	Yes The file extension is changed when egress happens.
Files labeled with encryption can be opened and edited with the original application or others that support the original file type	No Always requires the information protection viewer	Yes The file extension is changed when egress happens.
Configured permissions for labeled and encrypted files are enforced	Native encryption: Yes Generic encryption: No	Yes The following permissions are enforced until egress: view, extract, print

Prepare your Windows devices

Make sure that the Windows devices that you need to onboard meet these requirements:

- Anti-malware Client Version 4.18.25050 or newer is required.

- Window build:
  - Windows 10: See update details
  - Windows 11 22H2: See update details
  - Windows 11 23H2: See update details
  - Windows 11 24H2: See update details
- Information protection client version: 3.1.309 or newer is required.

User experience

Expand table

Labeling scenario	Activity	User experience	Activity explorer
File being labeled	Information protection File Labeler	A user right-clicks to open Information Protection Viewer to label specific file. The user can assign a label through the Viewer, Endpoint DLP will assign the label to the file but keep the file in original extension.	Label applied, no DLP Rule Matched, no Alert
Labeled file being moved off of the device	File copied to removable media, File copied to network share	A user moves a labeled file to a removable media or network share, the file will be encrypted, e.g. .ptxt file extension, when land on the network share or removable media with a Windows toast. This version of the file must be opened with the information protection viewer and can't be monitored by DLP.	File copied to USB removable device or File copied to a network share, no DLP Rule Matched, no Alert
Labeled file being moved off of the device	File transferred through Bluetooth, File transferred over remote desktop, or File uploaded to the cloud	A user uploads a labeled file out of the machine through listed channels, the activity will be blocked, a copy of the file will be created, and the copied file will be encrypted, e.g. .ptxt file extension, a toast will pop up asking the user to retry the operation with the labeled new copy. This version of the file must be opened with the information protection viewer and can't be monitored by DLP. The original file on the computer retains the .txt file extension and can still be opened and edited with any text editor. DLP continues to monitor this file.	File copied or moved using unallowed Bluetooth app or File copied or moved using RDP or File copied to cloud app

Labeling scenario	Activity	User experience	Activity explorer
Encrypted file being moved on the device that is using this feature, for example .ptxt	Information protection Viewer	A user moves an encrypted labeled file into a machine that has this feature onboarded, the file will be kept in encrypted extension, the user can double-click to open the Information Protection Viewer. The Information Protection Viewer will pop up a notification, user can click Continue button to decrypt the file to original file extension with label assigned.	
Encrypted file being moved on the device that is using this feature onboarded, for example .ptxt	Information protection File Labeler	A user moves an encrypted labeled file into a machine that has this feature onboarded, the file will be kept in encrypted extension, the user can right-click to open the Information Protection Viewer. The user can change the label through the Viewer, the file will be kept in encrypted format.	Label changed, Label removed, Protection applied, Protection removed.
Labeled file being opened through a native application	N/A	A user opens a labeled file through a native application, and perform Print or Copy activity which violate the permission associated with the label, the activity will be blocked with a toast.	File copied to clipboard or File printed, no DLP Rule Matched, no Alert

Considerations

- Supported only for sensitivity labels that apply encryption. For sensitivity labels without encryption, the behavior and supported file types are the same as for the information protection client.
- Not supported for labeling files on network locations or USB drives.
- The applied sensitivity labels won't be detected as conditions in DLP policies before egress.
- When multiple files are selected for labeling, and they include Office files or PDF files, the Office files, and PDF files won't be labeled or encrypted. User will see failure message on the Information Protection File Labeler application.
- Endpoint DLP doesn't enforce all rights management usage rights before egress: VIEW, EXTRACT, and PRINT are supported.
- The Save As option doesn't automatically inherit the current label and encryption settings. The user must label the new file.

- The Microsoft Purview Information Protection PowerShell module doesn't recognize the DLP setting. Labeling files using PowerShell will encrypt and change the file extension. Only use the Microsoft Purview Information Protection File Labeler when you enable the DLP setting.

Configure device proxy and internet connection settings for Microsoft Purview Endpoint DLP

Microsoft Endpoint technologies use Microsoft Windows HTTP (WinHTTP) to report data and communicate with the Microsoft endpoint cloud service. The embedded service runs in system context using the LocalSystem account.

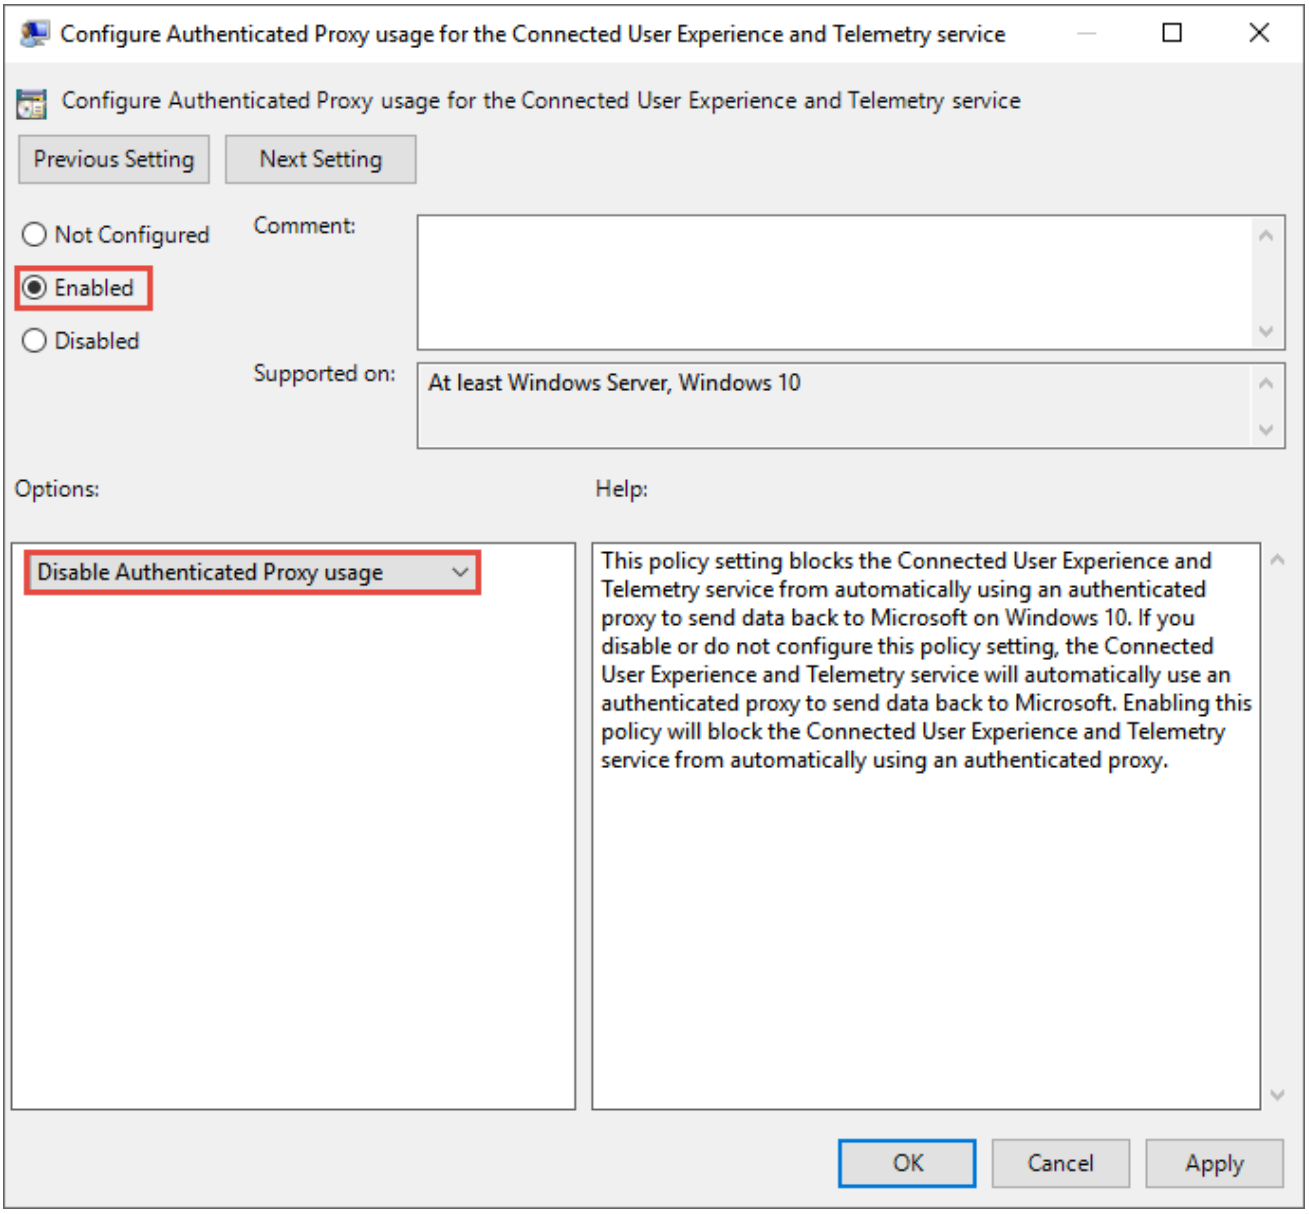
> **Tip**
>
> For organizations that use forward proxies as a gateway to the Internet, you can use network protection to investigate behind a proxy. For more information, see **Investigate connection events that occur behind forward proxies**.

The WinHTTP configuration setting is independent of the Windows Internet (WinINet) Internet browsing proxy settings and can only discover a proxy server by using the following auto discovery methods:

- Transparent proxy
- Web Proxy Auto-discovery Protocol (WPAD)

  > **Note**
  >
  > If you're using Transparent proxy or WPAD in your network topology, you don't need special configuration settings. For more information on Defender for Endpoint URL exclusions in the proxy, see **Enable access to Endpoint DLP cloud service URLs in the proxy server**.

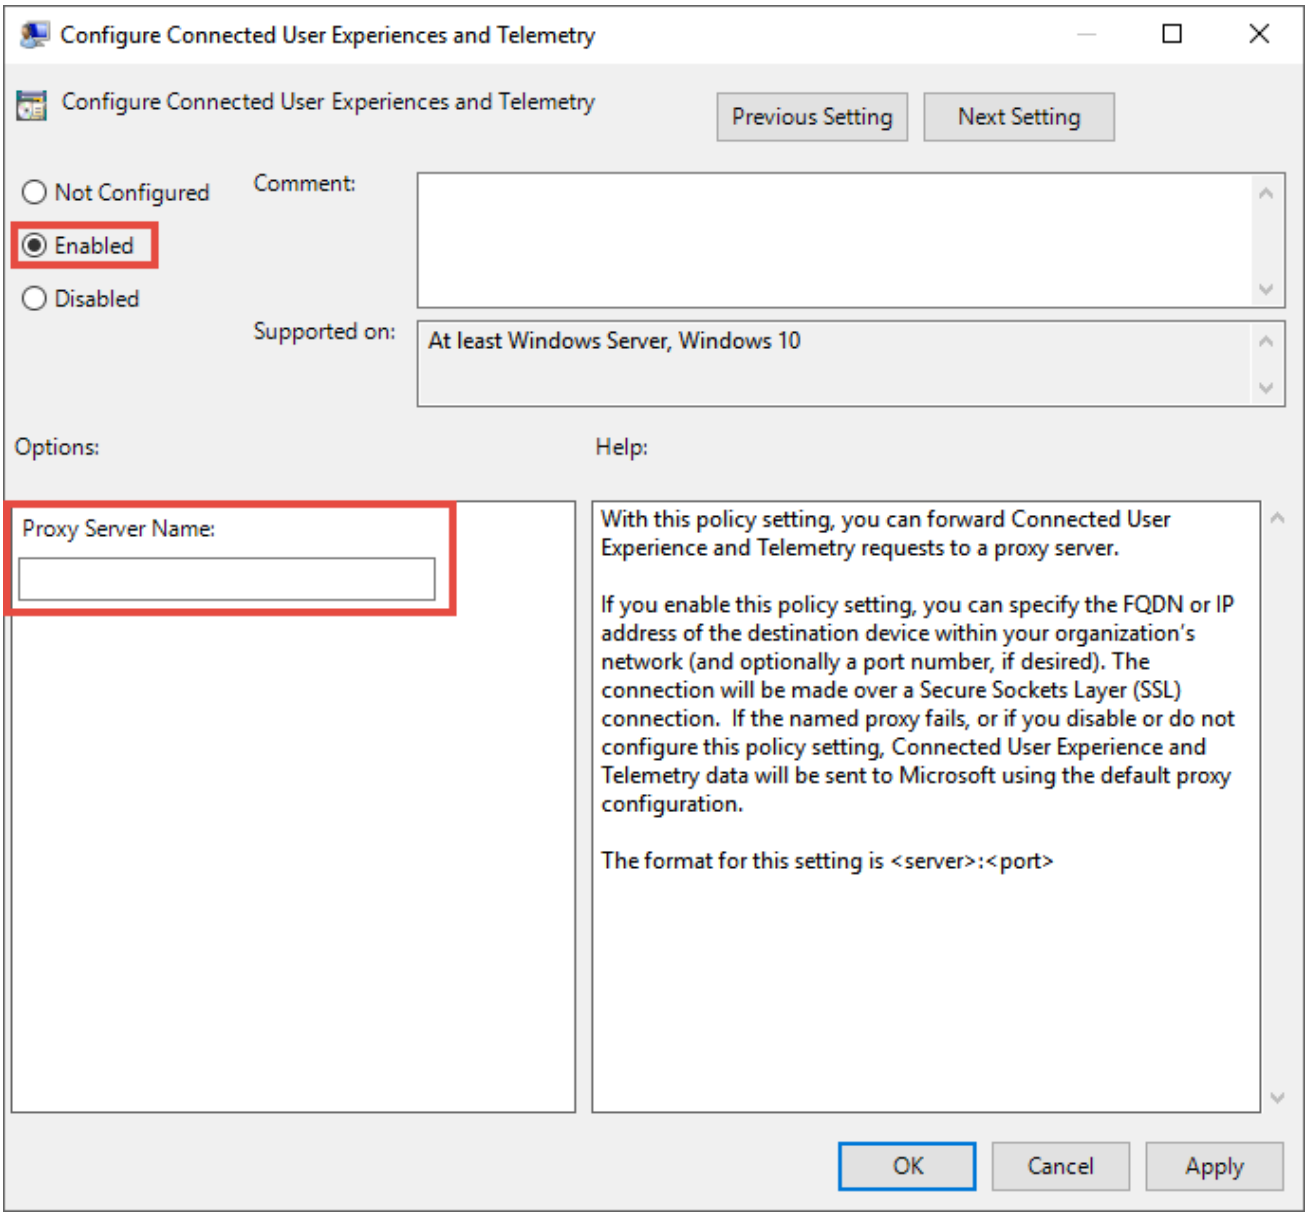
- Manual static proxy configuration:
  - Registry-based configuration
  - WinHTTP configured using netsh command – Suitable only for desktops in a stable topology (for example: a desktop in a corporate network behind the same proxy)



Configure the proxy server manually using a registry-based static proxy

For endpoint devices that aren't permitted to connect to the Internet, you need to configure a registry-based static proxy. You need to configure the registry-based static proxy to allow only Microsoft Endpoint DLP to report diagnostic data and communicate with Microsoft endpoint cloud service.

The static proxy is configurable through Group Policy (GP). The Group Policy settings can be found under:



1. Open **Administrative Templates** > **Windows Components** > **Data Collection and Preview Builds** > **Configure Authenticated Proxy usage for the Connected User Experience and Telemetry Service**

2. Set it to **Enabled** and select **Disable Authenticated Proxy usage**:

3. Open **Administrative Templates** > **Windows Components** > **Data Collection and Preview Builds** > **Configure connected user experiences and telemetry**:

   Configure the proxy

   The policy sets two registry values `TelemetryProxyServer` as REG_SZ and `DisableEnterpriseAuthProxy` as REG_DWORD under the registry key `HKLM\Software\Policies\Microsoft\Windows\DataCollection`.

   The registry value TelemetryProxyServer is in this format <server name or ip>:<port>. For example: **10.0.0.6:8080**

   The registry value `DisableEnterpriseAuthProxy` should be set to 1.

Configure the proxy server manually using "netsh" command

Use netsh to configure a system-wide static proxy.

> **Note**
>
> This will affect all applications including Windows services which use WinHTTP with default proxy. - Laptops that are changing topology (for example: from office to home) will malfunction with netsh. Use the registry-based static proxy configuration.

1. Open an elevated command line:
   a. Go to **Start** and type **cmd**
   b. Right-click **Command prompt** and select **Run as administrator**.

2. Enter the following command and press **Enter**:

   ```
   netsh winhttp set proxy <proxy>:<port>
   ```

   For example: **netsh winhttp set proxy 10.0.0.6:8080**

3. To reset the winhttp proxy, enter the following command and press **Enter**:

   ```
   netsh winhttp reset proxy
   ```

See Netsh Command Syntax, Contexts, and Formatting to learn more.

Enable access to Endpoint DLP cloud service URLs in the proxy server

If a proxy or firewall is blocking all traffic by default and allowing only specific domains through, add the domains listed in the Microsoft Defender for Endpoint service URLs spreadsheet to the allowed domains list.

This Microsoft Defender for Endpoint service URLs spreadsheet lists the services and their associated URLs that your network must be able to connect to. You should ensure that there are no firewall or network filtering rules that would deny access to these URLs, or you may need to create an allow rule specifically for them.

If a proxy or firewall has HTTPS scanning (SSL inspection) enabled, exclude the domains listed in the Microsoft Defender for Endpoint service URLs spreadsheet from HTTPS scanning. If a proxy or firewall is blocking anonymous traffic, as Endpoint DLP is connecting from system context, make sure anonymous traffic is permitted in the previously listed URLs.

Verify client connectivity to Microsoft cloud service URLs

Verify the proxy configuration completed successfully, that WinHTTP can discover and communicate through the proxy server in your environment, and that the proxy server allows traffic to the Defender for Endpoint service URLs.

1. Download the MDATP Client Analyzer tool to the PC where Endpoint DLP is running on.

2. Extract the contents of MDATPClientAnalyzer.zip on the device.

3. Open an elevated command line:
   a. Go to **Start** and type **cmd**.
   b. Right-click **Command prompt** and select **Run as administrator**.

4. Enter the following command and press **Enter**:

   ```
   HardDrivePath\MDATPClientAnalyzer.cmd
   ```

   Replace *HardDrivePath* with the path where the MDATPClientAnalyzer tool was downloaded to, for example

   C:\Work\tools\MDATPClientAnalyzer\MDATPClientAnalyzer.cmd

5. Extract the **MDATPClientAnalyzerResult.zip*** file created by tool in the folder used in the *HardDrivePath*.

6. Open **MDATPClientAnalyzerResult.txt** and verify that you have performed the proxy configuration steps to enable server discovery and access to the service URLs. The tool checks the connectivity of Defender for Endpoint service URLs that Defender for Endpoint client is configured to interact with. It then prints the results into the **MDATPClientAnalyzerResult.txt** file for each URL that can potentially be used to communicate with the Defender for Endpoint services. For example:

   Windows Command Prompt

   ```
   Testing URL: https://xxx.microsoft.com/xxx
   1 - Default proxy: Succeeded (200)
   2 - Proxy auto discovery (WPAD): Succeeded (200)
   3 - Proxy disabled: Succeeded (200)
   4 - Named proxy: Doesn't exist
   5 - Command-line proxy: Doesn't exist
   ```

If at least one of the connectivity options returns a (200) status, then the Defender for Endpoint client can communicate with the tested URL properly using this connectivity method.

However, if the connectivity check results indicate a failure, an HTTP error is displayed (see HTTP Status Codes). You can then use the URLs listed in Enable access to Endpoint DLP cloud service URLs in the proxy server. The URLs you'll use will depend on the region selected during the onboarding procedure.

> **Note**
>
> The Connectivity Analyzer tool is not compatible with attack surface reduction rule **Block process creations originating from PSExec and WMI commands**. You will need to temporarily disable this rule to run the connectivity tool.
>
> When the TelemetryProxyServer is set, in Registry or via Group Policy, Defender for Endpoint will fall back to direct if it can't access the defined proxy. Related topics:

Get started with Power Automate integration in Microsoft Purview DLP

Microsoft Power Automate is a workflow service that automates actions across applications and services. By using flows from templates or created manually, you can automate common tasks associated with these applications and services. Microsoft Purview Data Loss Prevention (DLP) can take various actions across locations on sensitive content identified as per DLP policies. With Power Automate integration, you can now trigger custom Power Automate workflows as a DLP rule action.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Before you begin

Before you start using Power Automate integration in Microsoft Purview DLP, read the following information on subscription, licensing, permissions, and supported locations.

Subscriptions & licensing

Review the following subscription and licensing requirements for Microsoft Purview DLP and Power Automate.

Purview DLP

Power Automate integration in Microsoft Purview DLP is available for all existing DLP customers with no other Purview license requirements.

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Power Automate

The access premium connectors when configuring custom flows you need a Power Automate plan. A Power Automate licenses is not needed to access the templates.

Permissions

The following permissions apply when using Power Automate integration in Microsoft Purview DLP:

- There is no change to required role for DLP policy authoring in Microsoft Purview portal to use Power Automate integration as a DLP rule action.
- See Get started with Power Automate for information about Power Automate roles.

Supported locations in policy

Power Automate integration for DLP supports the following policy locations:

- Exchange emails
- Files in SharePoint Online & OneDrive
- Windows devices (24H2 and above)

Create a workflow

Create a custom workflow using the DLP trigger provided as part of Microsoft Purview connector. You can create a workflow from any of the following experiences:

- Power Automate portal
- DLP rule authoring page: Add **Start a Power Automate workflow** as an action, and then create the workflow using a template or a custom workflow using DLP trigger.

You can select or update the Power Automate workflow linked to a DLP rule just like any other rule action.

Use a template

The following Power Automate template is available to support process automation for DLP rule violations:

Notify manager when a DLP policy is violated: Some organizations might need to have immediate management notification when a user violates a policy. When the **Notify manager when a DLP policy is violated** flow is configured and selected, the manager of the violating user is sent an email message with the following information about the event:

- User name
- Policy name

You can customize the sender and add additional information by editing the workflow in Power Automate.

Create a custom Power Automate flow

Some processes and workflows for your organization might not fit an available template. If no available template fits your organization's processes, you can create custom Power Automate flows to meet your specific needs. Power Automate flows are flexible and support extensive customization, but can require configuration to integrate with data loss prevention policies:

1. Create a flow that performs one or more tasks after a data loss prevention event. For details on how to create an automated flow, see Create a flow in Power Automate.
2. Select the Microsoft Purview connector: Search for and select the Microsoft Purview connector. For more information on connectors, see: Connector reference overview.
3. Choose data loss prevention triggers for your flow.
4. Choose from available Power Automate connectors for your flow.

Share a Power Automate flow

By default, a Power Automate flow is only available to the user who created it. For other administrators to access and use a flow, the flow creator must share it. For information on how to share a flow, see: Share a cloud flow

Known issues and limitations

For files in SharePoint and OneDrive, Power Automate workflows are executed only for new or modified content. Preexisting files matching the rules don't trigger a flow.

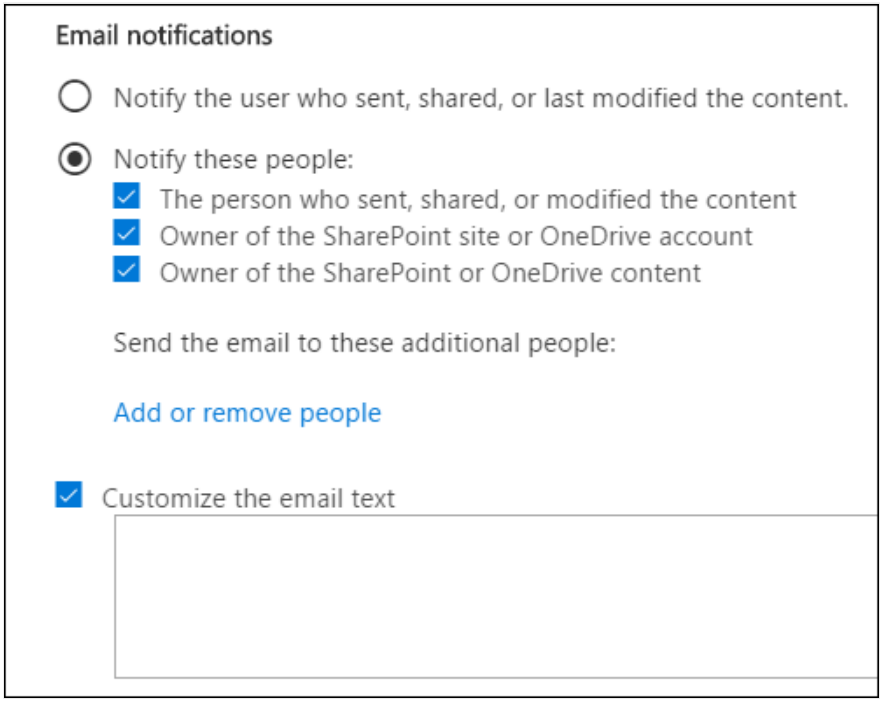
Send email notifications and show policy tips for DLP policies

You can use a Microsoft Purview Data Loss Prevention (DLP) policy to identify, monitor, and protect sensitive information across Microsoft 365. You want people who work with sensitive information to stay compliant with your DLP policies without being blocked from getting their work done. This is where email notifications and policy tips can help.

When you create a DLP policy, you can configure the user notifications to:

- Send an email notification to the people you choose that describes the issue.
- Display a policy tip for content that conflicts with the DLP policy:
  - For Outlook on the web and Outlook 2013 and later, the policy tip appears at the top of a message above the recipients while the message is being composed.
  - For documents in a OneDrive account or SharePoint site, the policy tip shows as a warning icon that appears on the item. To view more information, you can select an item and then choose **Information** in the upper-right corner of the page to open the details pane.
  - For Excel, PowerPoint, and Word documents that are stored on a OneDrive site or SharePoint site that's in scope of a DLP policy, the policy tip appears on the Message Bar and the Backstage view (**File** menu > **Info**).

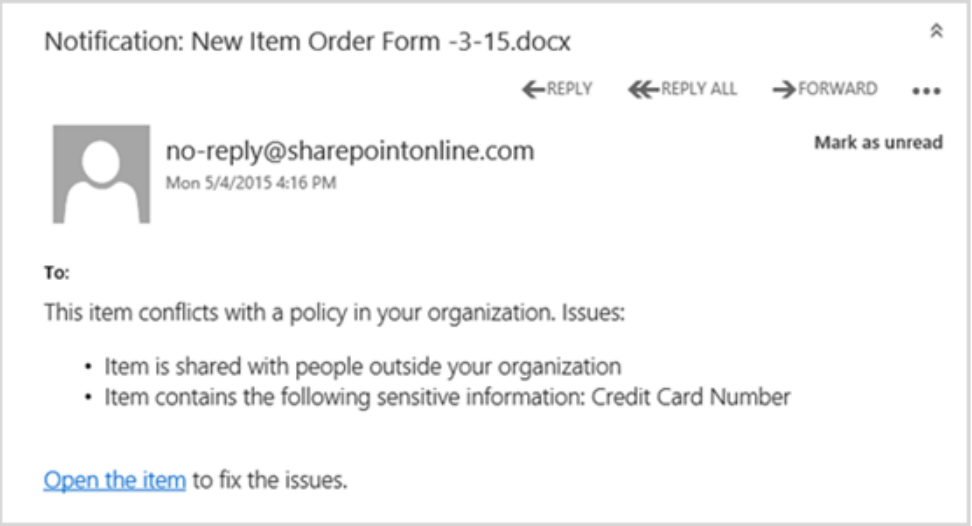
> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.



> **Note**
>
> Notification emails are sent unprotected.

Options for configuring email notifications

For each rule in a DLP policy, you can:

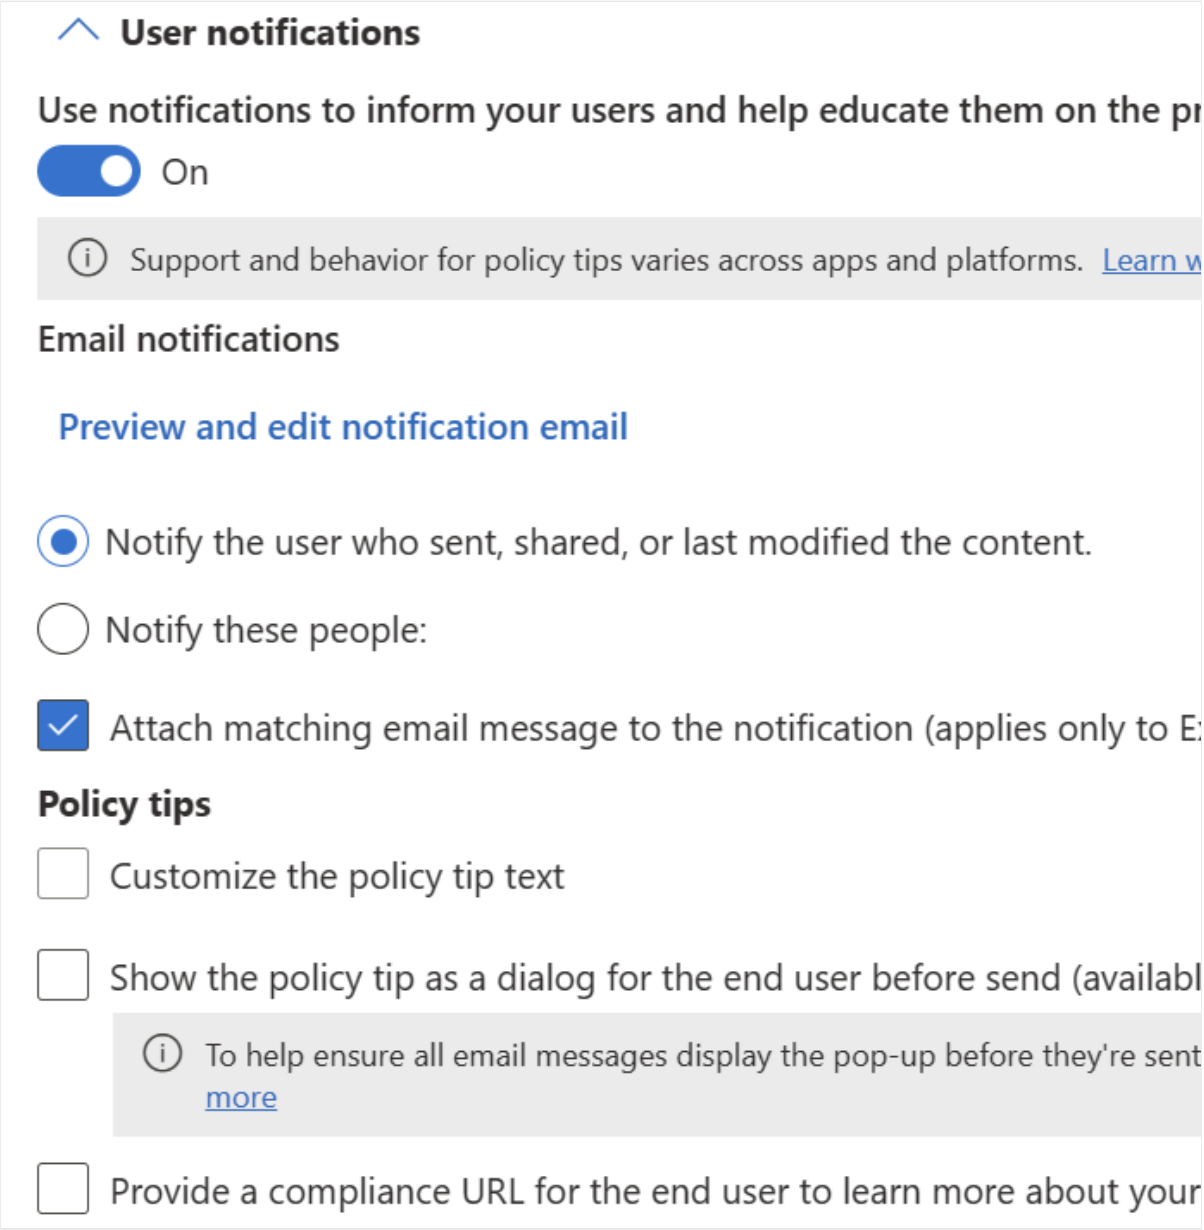


- Send the notification to the people you choose. These people can include the owner of the content, the person who last modified the content, the owner of the site where the content is stored, or a specific user.
- Customize the text that's included in the notification by using HTML or tokens. For more information, see Custom email notifications.

> **Note**
>
> - You can send email notifications only to individual recipients, not to groups or distribution lists.
> - Only new content triggers an email notification. Editing existing content triggers policy tips, but not email notifications.
> - External senders receive only a templatized notification without full details to prevent any unintended loss of information about the policy configuration.

Default email notification

Notifications have a **Subject** line that begins with the action taken, such as `Notification`, `Message Blocked` for email, or `Access Blocked` for documents. If the notification is about a document, the notification message body includes a link. That link takes you to the site where the document's stored and opens the policy tip for the document, where you can resolve any issues. If the notification is about a message, the notification includes as an attachment the message that matches a DLP policy.



By default, notifications display text similar to the following for an item on a site. You configure the notification text separately for each rule, so the text that's displayed differs depending on which rule is matched.

Expand table

If the DLP policy rule does this...	Then the default notification for SharePoint or OneDrive documents says this...	Then the default notification for Outlook messages says this...
Sends a notification but doesn't allow override	This item conflicts with a policy in your organization.	Your email message conflicts with a policy in your organization.
Blocks access, sends a notification, and allows override	This item conflicts with a policy in your organization. If you don't resolve this conflict, access to this file might be blocked.	Your email message conflicts with a policy in your organization. The message wasn't delivered to all recipients.
Blocks access and sends a notification	This item conflicts with a policy in your organization. Access to this item is blocked for everyone except its owner, last modifier, and the primary site admin.	Your email message conflicts with a policy in your organization. The message wasn't delivered to all recipients.

Custom email notifications

You can create a custom email notification template for end user email notifications for each rule. Then send it instead of sending the default email notification. This option is available for policies scoped to the Exchange, SharePoint, and OneDrive locations.

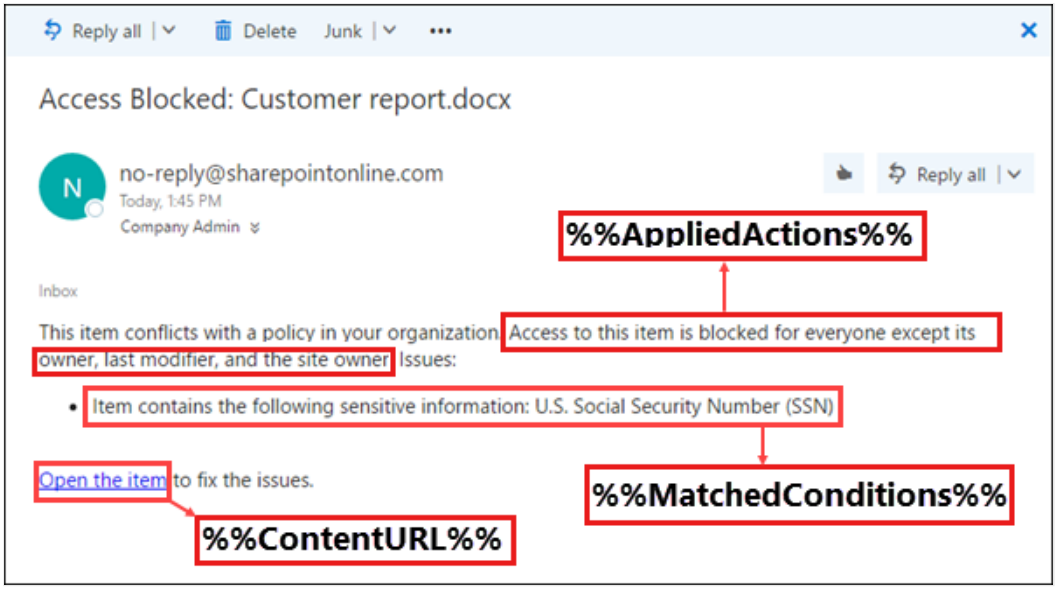
Select **Preview and edit notification email** to create a customized template when you edit or create a rule in a policy.

The custom email notification supports HTML and customization of these fields:

- Sender display name: Define a custom value that suits your organization's needs. There's a 70 character limit. Setting this value doesn't change the sender's email address.
- Email subject: Define a custom value to make the email subject more meaningful to your end users. There's a 256 character limit.
- Email body: Define a custom value that has greater meaning to your users. There's a 5120 character limit. You can use HTML or markdown to include images, formatting, and other branding in the notification. Custom definition for the email body supports the use of inline styling. If you add actions that users can take to email, only markdown can be used to format the email body.

> ⓘ Note

If you configure a sender email alias in Exchange Admin Center mailboxes, it overwrites the **sender display name** that you configure here.



You can also use the following tokens to help customize the body of the email. Tokens are variables that get replaced by specific information when the notification is sent. For example, the %%ContentURL%% token is replaced by the URL of the document on the SharePoint site or OneDrive site.

Expand table

Token	Description	Available for Exchange	Available for SharePoint	Av for On
%%MatchedConditions%%	The conditions that the content matched. Use this token to inform people of possible issues with the content.	Yes	Yes	Yes
%%ContentURL%%	The URL of the document on the SharePoint site or OneDrive site.	No	Yes	Yes
%%AppliedActions%%	The actions applied to the content. This token is populated only when the action - **Restrict access or encrypt the content in Microsoft 365 locations** is selected in the DLP rule configuration	Yes	Yes	Yes
%%BlockedMessageInfo%%	The details of the message that was blocked. Use this token to inform people of the details of the message that was blocked. This token is populated only when the action - **Restrict access or encrypt the content in Microsoft 365 locations** is selected in the DLP rule configuration	Yes	No	No
%%ContentId%%	The unique identifier of the message.	Yes	No	No
%%TimestampForIncidentOccurrence%%	Timestamp in UTC of when the DLP policy conditions were matched.	Yes	Yes	Yes
%%MatchedConditionsAndValues%%	The matched DLP condition and values. This token doesn't cover the *content contains sensitive info* condition. For matched SITs and redacted values, see %%MatchedSITAndSurroundingcontext%%	Yes	Yes	Yes
%%Filename%%	For SharePoint and OneDrive matches, this token shows the document name. For Exchange, it shows the email attachment name.	Yes	Yes	Yes
%%PolicyName%%	The matched DLP policy name.	Yes	Yes	Yes
%%PolicyRule%%	The matched DLP rule name.	Yes	Yes	Yes

Token	Description	Available for Exchange	Available for SharePoint	Av for On
%%Workload%%	The workload name where the match occurred.	Yes	Yes	Yes
%%MatchedSITAndSurroundingcontext%%	The matched SITs and the redacted values.	Yes	Yes	Yes
%%UserEmail%%	The email address of the end user associated with the matched content.	Yes	Yes	Yes
%%SiteAdmin%%	For SharePoint sites, this token shows the email address of the site administrator.	No	Yes	No
%%EmailSubject%%	For Exchange, this token shows the email subject.	Yes	No	No
%%EmailRecipients%%	For Exchange, this token shows the list of email recipients.	Yes	No	No
%%FileOwner%%	For SharePoint and OneDrive matches, this token shows the name of file owner.	No	Yes	Yes

> ⓘ Note
>
> Use the HTML tag to style the tokens. For example, <div\ "style="color:blue; font-size: 12px;"> %%MatchedConditions%% renders the token in font size 12 px and font color blue.

Actionable email notifications for OneDrive and SharePoint workloads

> ⓘ Note

Actionable email notifications for OneDrive and SharePoint workloads are in preview.

Admins can add controls to customized email notifications. These controls enable users to fix the issue that caused the DLP policy match or otherwise remediate issues on OneDrive folders or SharePoint sites directly from the email. This streamlines the remediation process. The controls are:

- **Stop sharing file**: Removes any sharing access and links on the file.
- **Delete file**: Deletes the file.
- **Apply sensitivity or retention label on the file**: Opens the OneDrive or SharePoint folder or site where the file is located so the user can apply the sensitivity or the retention label.
- **Override the policy**: Requires the end user to add business justification and overrides the policy.
- **Report false positive**: Requires the end user to enter the justification and notifies the admin via audit log.
- **Report unable to take action**: Requires the end user to enter the justification and notifies the admin via audit log.

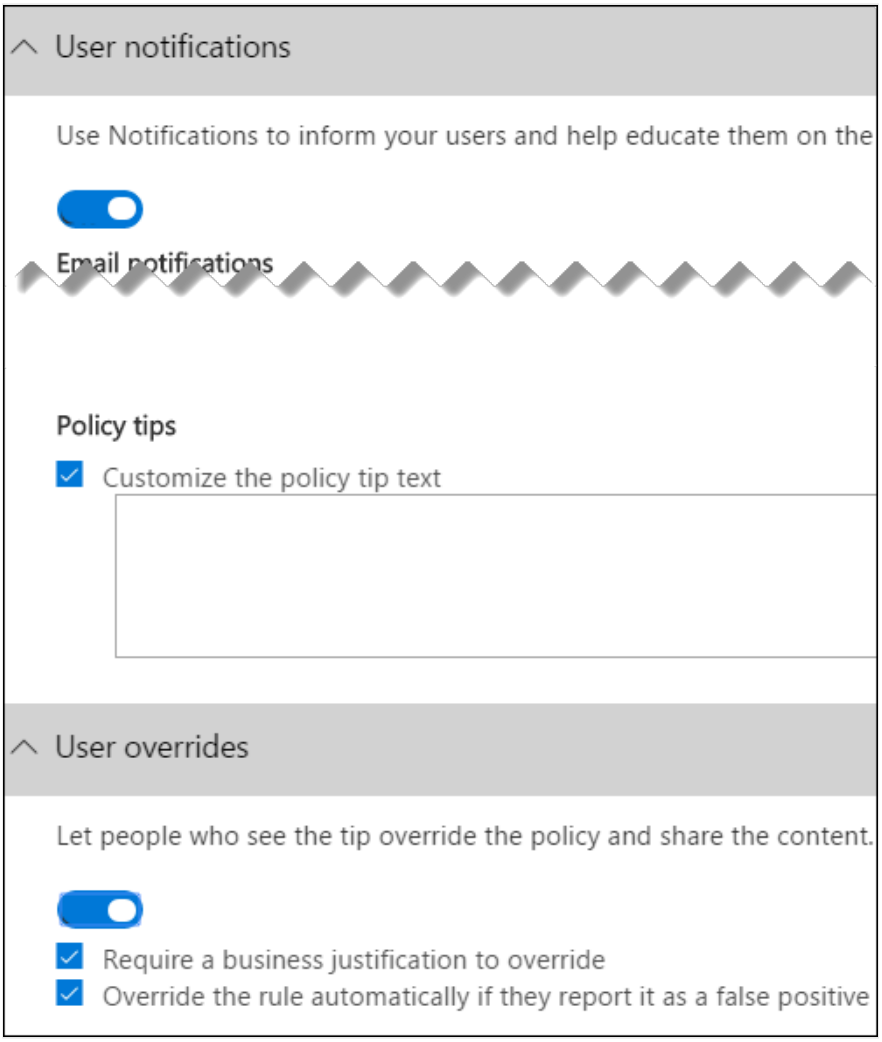
To make these options available to your users in notification emails, select them when you configure the email notification.

> ⓘ **Note**
>
> Only markdown mode can be used to format the email body if you add actions to the email.

Actions details in unified audit logs:

- Delete, Stop share, Apply label: Record types = **SharepointFileOperation**
- Override, Report false positive, Report unable to take action: Activities - operation names = **DLPInfo**, Record types = **ComplianceDLPSharePoint**

Options for configuring policy tips



For each rule in a DLP policy, you can configure policy tips to:

- Notify the person that the content conflicts with a DLP policy, so they can take action to resolve the conflict. You can use the default text (see the tables below) or enter custom text about your organization's specific policies.

- Allow the person to override the DLP policy. Optionally, you can:

    - Require the person to enter a business justification for overriding the policy. This information is logged and you can view it in the DLP reports in the **Reports** section of the portal.

- Allow the person to report a false positive and override the DLP policy. This information is also logged for reporting, so that you can use false positives to fine tune your rules.

For example, say you have a DLP policy applied to OneDrive sites that detects personal data, and this policy has three rules:

1. First rule: If fewer than five instances of this sensitive information are detected in a document, and the document is shared with people inside the organization, the **Send a notification** action displays a policy tip. For policy tips, no override options are necessary because this rule is simply notifying people and not blocking access.

2. Second rule: If more than five instances of this sensitive information are detected in a document, and the document is shared with people inside the organization, the **Block access to content** action restricts the permissions for the file, and the **Send a notification** action allows people to override the actions in this rule by providing a business justification. Your organization's business sometimes requires internal people to share personal data, and you don't want your DLP policy to block this work.

3. Third rule: If more than five instances of this sensitive information are detected in a document, and the document is shared with people outside the organization, the **Block access to content** action restricts the permissions for the file, and the **Send a notification** action doesn't allow people to override the actions in this rule because the information is

shared externally. Under no circumstances should people in your organization be allowed to share personal data outside the organization.

User override support

The override option is per rule, and it overrides all of the actions in the rule.

Content can match several rules in a DLP policy or several different DLP policies, but only the policy tip from the most restrictive rule that has the highest priority is shown. This includes policies that are in simulation mode. This setup prevents people from seeing a cascade of policy tips.

For example, if a document matches three rules in a DLP policy, and the rules have these configurations, rule LMN is applied and the policy tip from rule LMN is shown to the user.

Expand table

Rule name	Rule priority	Rule action	Rule action applied
ABC	1	Send notification	No
LMN	2	Block access and send notification	Yes
XYZ	3	Block	No

If the policy tips in the most restrictive rule allow people to override the rule, then overriding this rule also overrides any other rules that the content matched.

If you set the NotifyAllowOverride action to WithoutJustification or WithJustification or FalsePositives, make sure BlockAccess is set to true and BlockAccessScope has appropriate value. Otherwise, the policy tip comes up but the user doesn't find an option to override the email with justification.

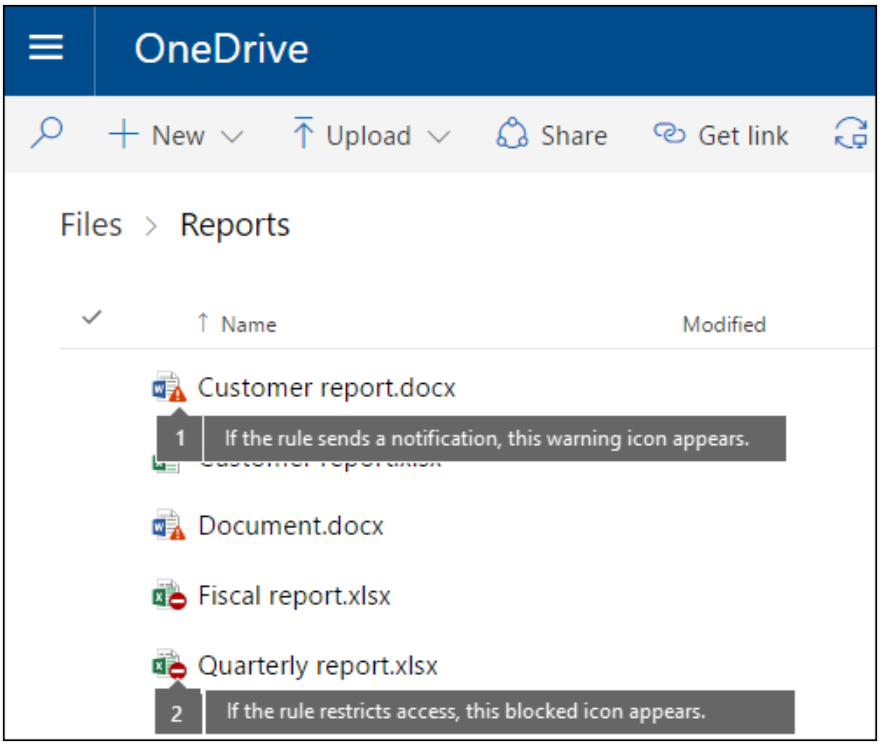
To see overrides in policy tips in Outlook on the web, the policy must be set to the *Turn it on* state. The policy action must also be configured to block with override.

Availability of override

The following table shows when override is available for each notification and block-action combination.

Expand table

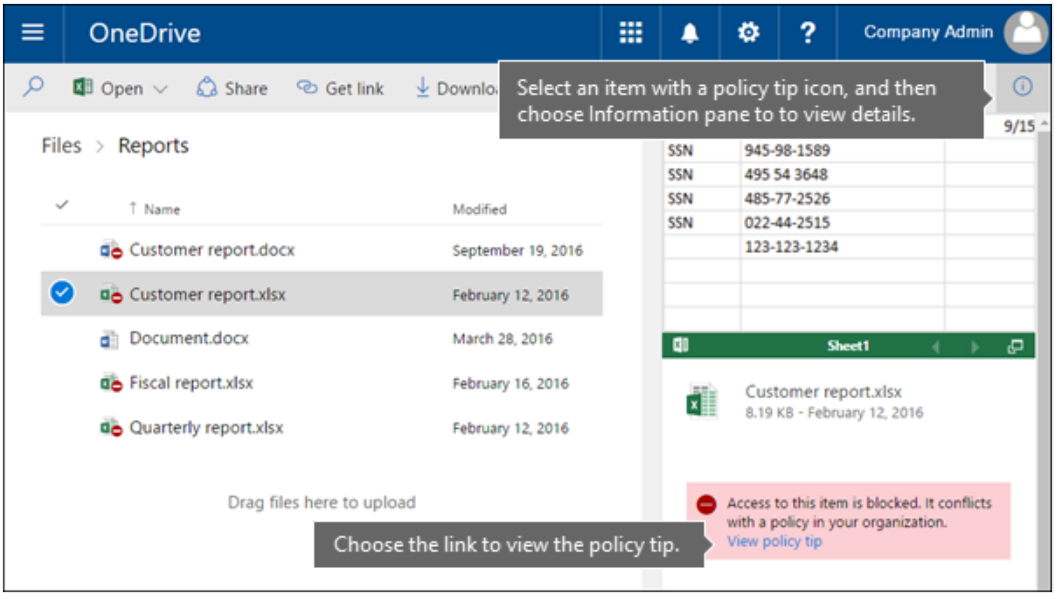
Notification Rule	Notify/Block action	Override available	Require Justification
Notify only	Notify	No	No
Notify + AllowOverride	Notify	No	No



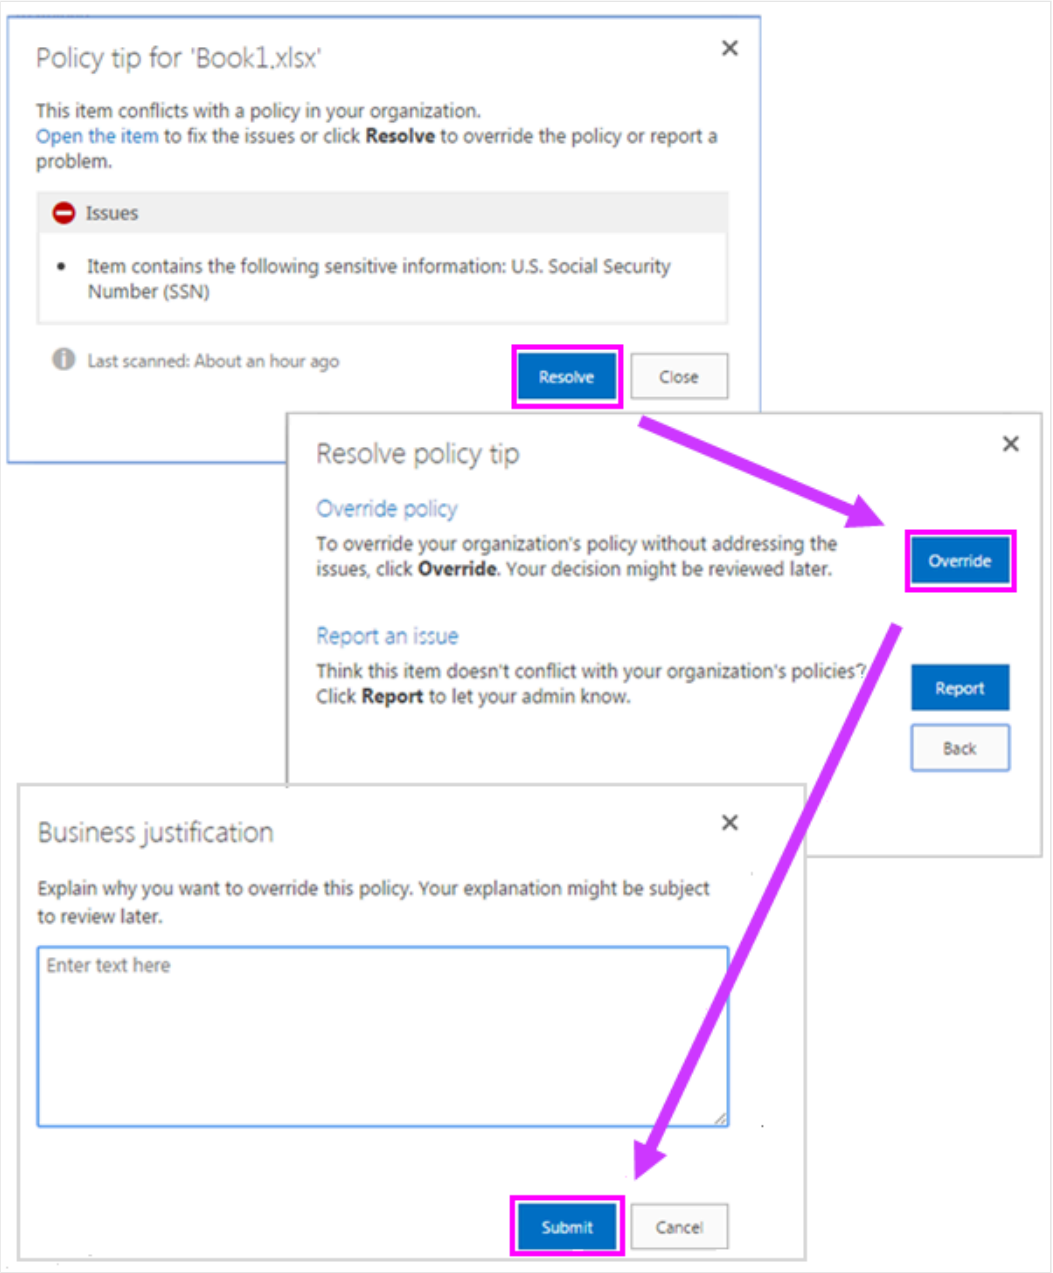
Notification Rule	Notify/Block action	Override available	Require Justification
Notify + AllowOverride + False positive	Notify	No	No
Notify + AllowOverride + With justification	Notify	No	No
Notify + AllowOverride + False positive + Without justification	Notify	No	No
Notify + AllowOverride + False positive + With justification	Notify	No	No
Notify + Block	Block	No	No
Notify + Block + AllowOverride	Block	Yes	No
Notify + Block + AllowOverride + False positive	Block	Yes	No
Notify + Block + AllowOverride + With justification	Block	Yes	Yes
Notify + Block + AllowOverride + False positive + Without justification	Block	Yes	No
Notify + Block + AllowOverride + False positive + With justification	Block	Yes	Yes

Policy tips on OneDrive sites and SharePoint sites

When a document on a OneDrive site or SharePoint site matches a rule in a DLP policy that uses policy tips, special icons appear on the document:



1. If the rule sends a notification about the file, the warning icon appears.



2. If the rule blocks access to the document, the blocked icon appears.

To take action on a document, select an item, choose **Information** in the upper-right corner of the page to open the details pane, then select **View policy tip**.

The policy tip lists the issues with the content. If the policy tips are configured with these options, you can choose **Resolve**, then **Override** the policy tip or **Report** a false positive.

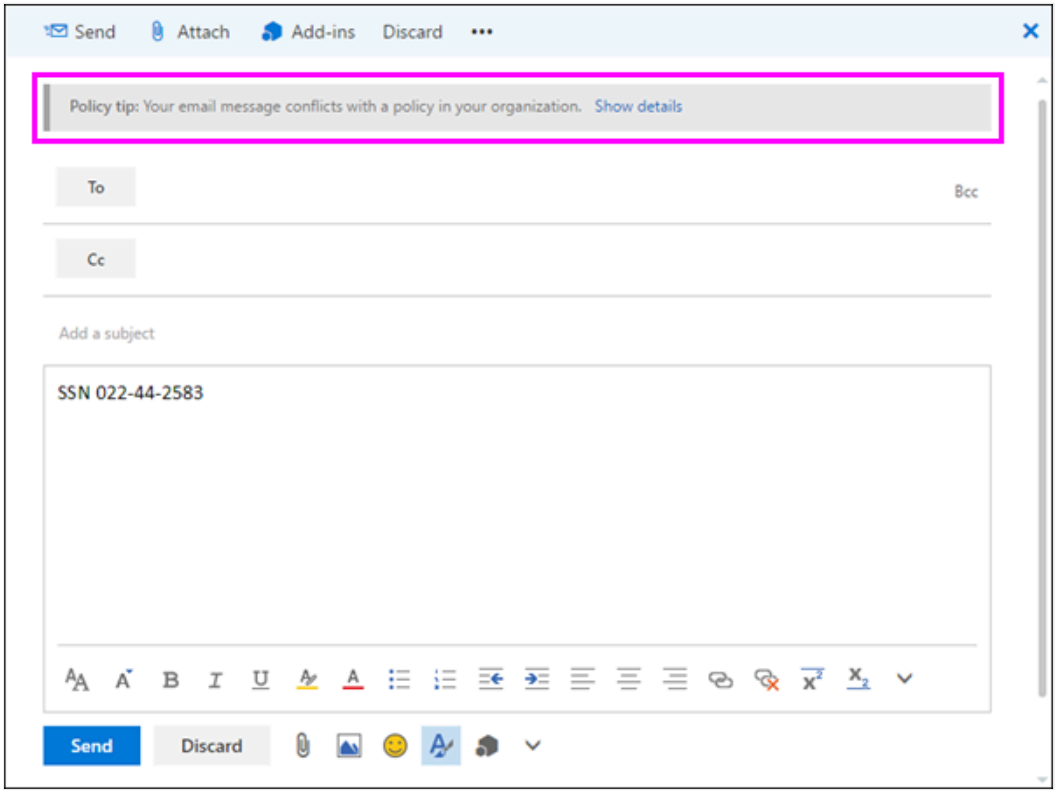
DLP policies sync to sites and content is evaluated against them periodically and asynchronously, so there might be a short delay between the time you create the DLP policy and the time you begin to see policy tips. There might be a similar delay from when you resolve or override a policy tip to when the icon on the document on the site goes away.

Default text for policy tips on sites

By default, policy tips display text similar to the following for an item on a site. The notification text is configured separately for each rule, so the text that displays differs depending on which rule is matched.

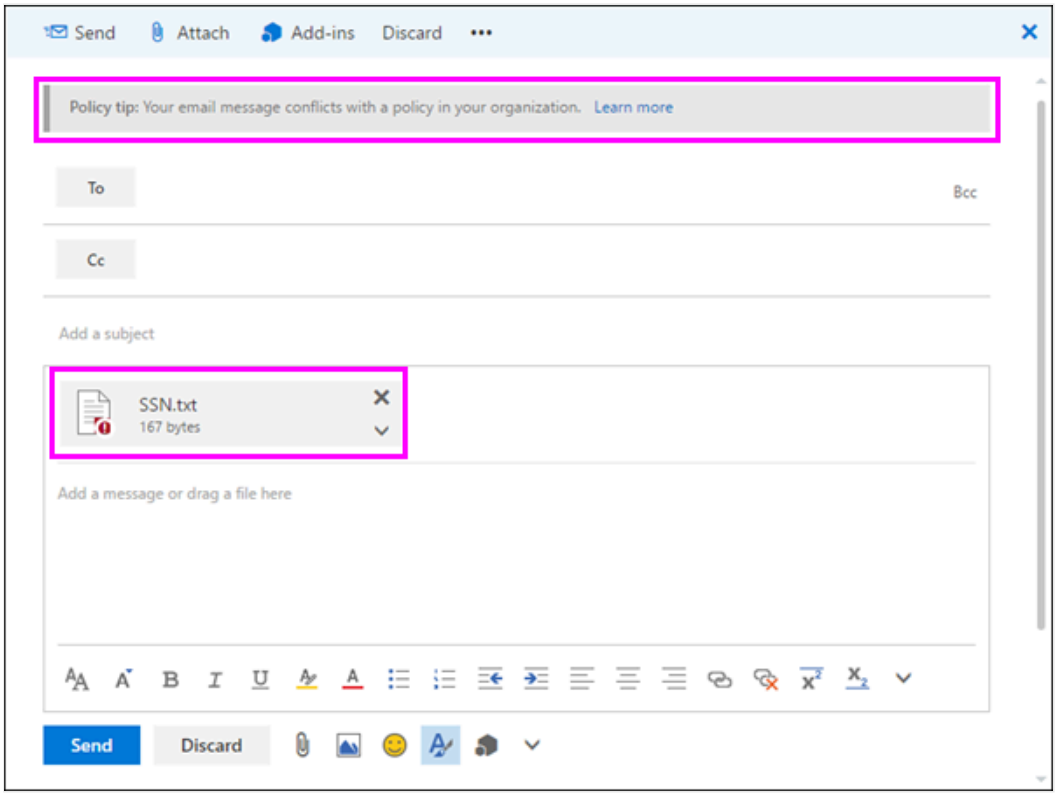
Expand table

If the DLP policy rule does this...	Then the default policy tip says this...
Sends a notification but	This item conflicts with a policy in your organization.



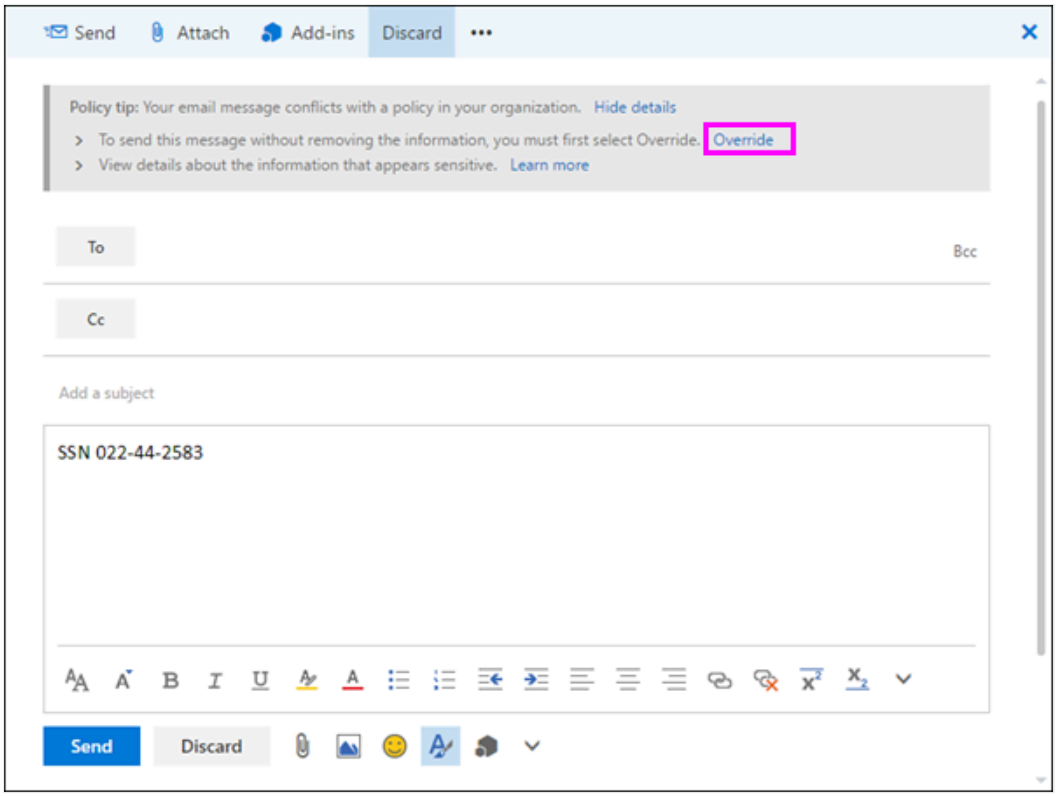
If the DLP policy rule does this...	Then the default policy tip says this...
doesn't allow override	
Blocks access, sends a notification, and allows override	This item conflicts with a policy in your organization. If you don't resolve this conflict, access to this file might be blocked.
Blocks access and sends a notification	This item conflicts with a policy in your organization. Access to this item is blocked for everyone except its owner, last modifier, and the primary site admin.

Custom text for policy tips on sites

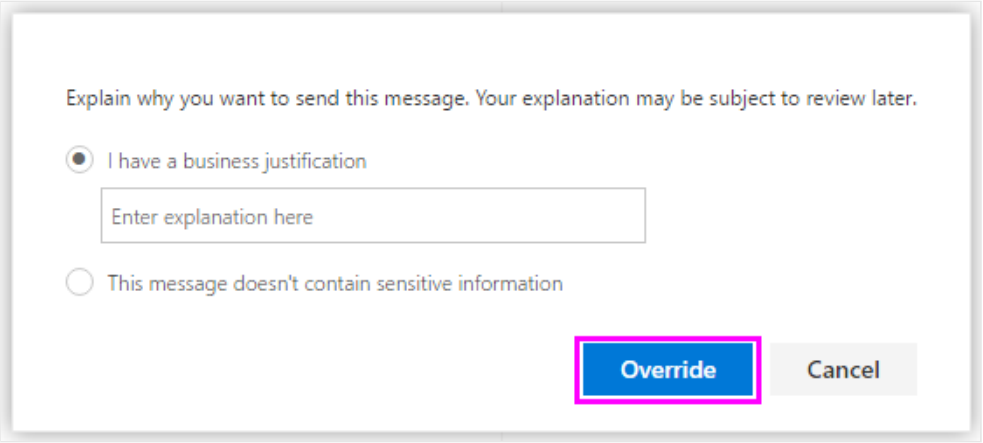


You can customize the text for policy tips separately from the email notification. Unlike custom text for email notifications (described in Custom email notifications), custom text for policy tips doesn't accept HTML or tokens. Instead, custom text for policy tips is plain text only with a 256-character limit.

Policy tips in Outlook on the web and Outlook 2013 and later



When you compose a new email in Outlook on the web and Outlook 2013 and later, you see a policy tip if you add content that matches a rule in a DLP policy, and that rule uses policy tips. The policy tip appears at the top of the message, above the recipients, while the message is being composed.



Policy tips work whether the sensitive information appears in the message body, subject line, or even a message attachment as shown here.

If the policy tips are configured to allow override, you can choose **Show Details** > **Override** > enter a business justification or report a false positive > **Override**.

When you add sensitive information to an email, there might be latency between when you add the sensitive information and when the policy tip appears. When emails are encrypted with Microsoft Purview Message Encryption and the policy used to detect them uses the detected encryption condition, policy tips don't appear.

Policy tips in the Exchange admin center vs. the Microsoft Purview portal

Policy tips can work either with DLP policies and mail flow rules created in the Exchange admin center, or with DLP policies, but not both. This limitation exists because these policies are stored in different locations, but policy tips can draw only from a single location.

If you configure policy tips in the Exchange admin center, any policy tips that you configure in the Purview portal don't appear to users in Outlook on the web and Outlook 2013 and later until you turn off the tips in the Exchange admin center. This behavior ensures that your current Exchange mail flow rules (also known as transport rules) continue to work until you choose to switch over to the Purview portal.

While policy tips can draw only from a single location, email notifications are always sent, even if you're using DLP policies in both the Purview portal and the Exchange admin center.

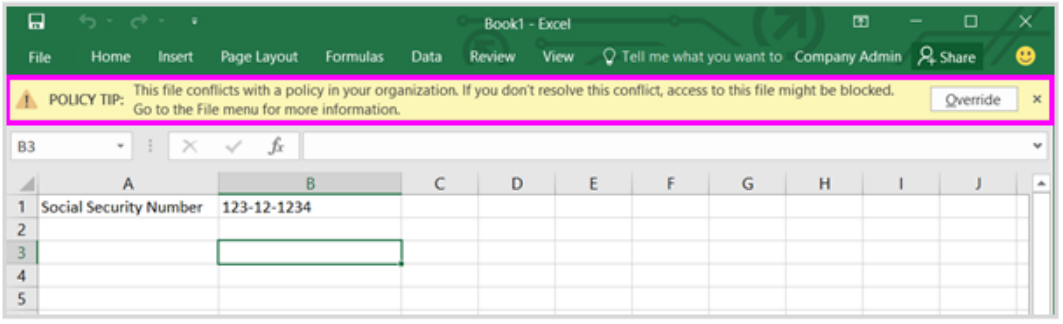
Default text for policy tips in email

By default, policy tips display text similar to the following text for email.

Expand table

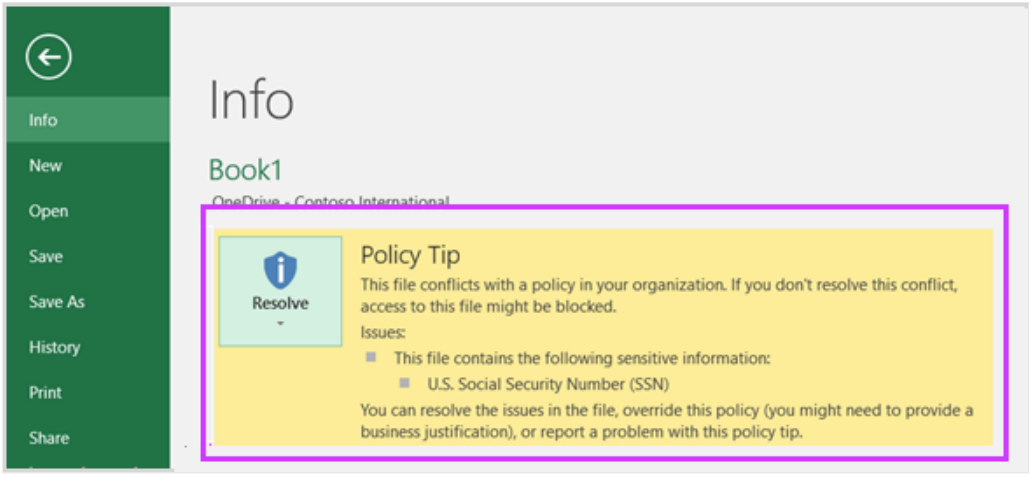
If the DLP policy rule does this...	Then the default policy tip says this...
Sends a notification but doesn't allow override	Your email conflicts with a policy in your organization.
Blocks access, sends a notification, and allows override	Your email conflicts with a policy in your organization.
Blocks access and sends a notification	Your email conflicts with a policy in your organization.

Policy tips in Excel, PowerPoint, and Word



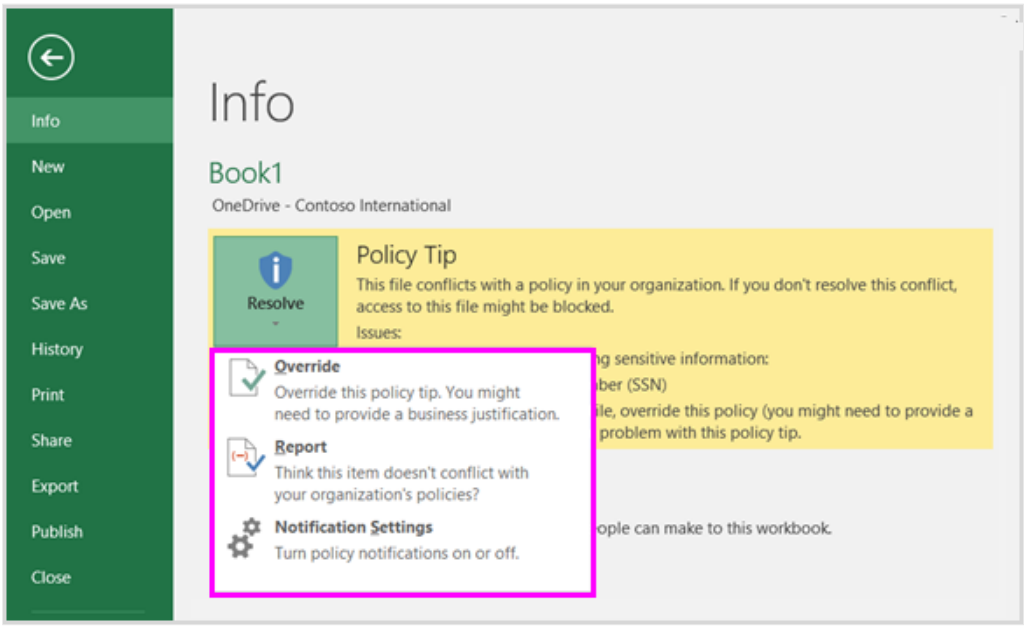
When people work with sensitive content in the desktop versions of Excel, PowerPoint, and Word, policy tips notify them that the content conflicts with a DLP policy. This feature requires that:

- The Office document is stored on a OneDrive site or SharePoint site.
- The site is included in a DLP policy that's configured to use policy tips.



Office desktop programs automatically sync DLP policies directly from Microsoft 365, and then scan your documents to ensure that they don't conflict with your DLP policies.

Depending on how you configure the policy tips in the DLP policy, people can choose to ignore the policy tip, override the policy with or without a business justification, or report a false positive.



Policy tips appear on the Message Bar.

Policy tips also appear in the Backstage view (on the **File** tab).

If you configure policy tips in the DLP policy with these options, you can choose **Resolve** to **Override** a policy tip or **Report** a false positive.

In each of these Office desktop programs, people can choose to turn off policy tips. If turned off, policy tips that are simple notifications don't appear on the Message Bar or Backstage view (on the **File** tab). However, policy tips about blocking and overriding still appear, and the user still receives the email notification. In addition, turning off policy tips doesn't exempt the document from any DLP policies that you applied to it.

Default text for policy tips in Excel 2016, PowerPoint 2016, and Word 2016

By default, policy tips display text similar to the following text on the Message Bar and Backstage view of an open document. You configure the notification text separately for each rule, so the text that displays differs depending on which rule is matched.

Expand table

If the DLP policy rule does this...	Then the default policy tip says this...
Sends a notification but doesn't allow override	This file conflicts with a policy in your organization. Go to the **File** menu for more information.
Blocks access, sends a notification, and allows override	This file conflicts with a policy in your organization. If you don't resolve this conflict, access to this file might be blocked. Go to the **File** menu for more information.
Blocks access and sends a notification	This file conflicts with a policy in your organization. If you don't resolve this conflict, access to this file might be blocked. Go to the **File** menu for more information.

Custom text for policy tips in Excel, PowerPoint, and Word

You can customize the text for policy tips separately from the email notification. Unlike custom text for email notifications (described in Custom email notifications), custom text for policy tips

doesn't accept HTML or tokens. Instead, custom text for policy tips is plain text only with a 256-character limit.

Use sensitivity labels as conditions in DLP policies

You can use sensitivity labels as a condition in DLP policies for these locations:

- Exchange email messages
- SharePoint
- OneDrive
- Devices
- Instances
- On-premises repositories
- Microsoft 365 Copilot
- Fabric and Power BI workspaces
- Inline web traffic (Unmanaged cloud apps and adaptive app scopes)

Sensitivity labels appear as an option in the **Content contains** condition list.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Supported items, file types, scenarios, and policy tips

You can use sensitivity labels as conditions on these items and in the following scenarios.

Supported items

Expand table

Service	Item type	Available to policy tip	Enforceable	Notes
Exchange	email message	Yes	Yes	
Exchange	email attachment	Yes	Yes	
SharePoint	items in SharePoint	Yes	Yes	
OneDrive	items	Yes	Yes	
Teams	Teams and channel messages	Not applicable	Not applicable	
Teams	attachments	Yes	Yes	If SharePoint or OneDrive are included as locations in your DLP policy, you don't need to set Teams as a location. This is because attachments sent in Teams over 1:1 chat or channels are automatically uploaded to OneDrive and SharePoint and will be evaluated by DLP then.
Devices	items	Yes	Yes	
MCAS (preview)	items	Yes	Yes	
Inline web traffic	Uploaded and downloaded files	No	Yes	DLP policies don't support custom policy tips for inline web traffic.

> **Note**
>
> DLP's ability to detect sensitivity labels in SharePoint and OneDrive is limited. For more information, see Enable sensitivity labels for files in SharePoint and OneDrive.

Supported file types

Expand table

Workload	File types supported
Exchange emails	.docx, .xlsx, .pptx, .pdf, .pfile
SharePoint	.docx, .xlsx, .pptx, .pdf
OneDrive	.docx, .xlsx, .pptx, .pdf
endpoint devices	.docx, .xlsx, .pptx, .pdf, .pfile
Inline web traffic	.docx, .xlsx, .pptx, .pdf, .pfile, .eml - legacy Office file types, .doc, .xls, and .ppt, aren't supported.

Supported scenarios

- DLP Admin can see a list of all sensitivity labels in the tenant when they choose to include one or more sensitivity labels as a condition.
- All workloads support using sensitivity labels as a condition, as shown in the support matrix.
- DLP policy tips continue to show across workloads for DLP policies that contain one or more sensitivity labels as a condition.
- Sensitivity labels appear as part of the incident report email if a DLP policy with one or more sensitivity labels as a condition is matched.
- Sensitivity label details show in the DLP rule match audit log for DLP policy matches that contain a sensitivity label as a condition.
- For policies that apply to the Inline web traffic location, content that's encrypted can't be extracted for evaluation by DLP. The only conditions that work are metadata based ones, for example:
- **Content contains** > **Sensitivity label** returns the label name
- **File size** returns the size of the encrypted file
- **File extension is** returns the extension of the encrypted file Conditions that rely on the content being evaluated don't work, for example:
- **Content contains** > **Sensitive information type**
- **Content contains** > **Trainable classifiers**
- **File type is**

Support policy tips

Expand table

Workload	Policy tips supported/not supported
OWA	supported
Outlook for Windows	supported
SharePoint	supported
OneDrive	supported
endpoint devices	not supported
Inline web traffic	not supported

> **Note**
>
> If you use sensitivity labels as a condition and policy tips in a DLP policy for Exchange, and, at the same time, you have mandatory labeling for sensitivity labels configured, when a user selects a label through the Mandatory Labeling prompt, the client does not re-invoke the DLP Policy Tips evaluation gate with the newly applied label. In result, the policy tip is **not ** going to show, but the action configured in the DLP policy will be enforced.

Last updated on 08/17/2026

Learn about DLP file quarantine for SharePoint and OneDrive

> **Note**
>
> The features described in this article are in preview. Organizations sometimes need to go beyond blocking access to sensitive files. When a file contains highly sensitive content that shouldn't exist in a particular SharePoint or OneDrive location, blocking access alone might not be enough — the file itself needs to be removed from the location entirely. Data loss prevention (DLP) file quarantine for SharePoint and OneDrive gives administrators the ability to automatically move files that match a DLP policy rule to an admin-controlled quarantine location.

What is file quarantine?

File quarantine is a DLP policy action for SharePoint and OneDrive locations. When you configure a DLP policy with the quarantine action, files that match the policy rule are:

- Removed from the original SharePoint or OneDrive location.
- Moved to an admin-defined quarantine site in SharePoint.
- Replaced at the original location with a tombstone text file that contains an admin-configured message.

File quarantine is the most restrictive DLP action available for SharePoint and OneDrive. It removes access from everyone, including the file owner.

When to use file quarantine

Use file quarantine when your organization needs to:

- **Isolate highly sensitive content** — For example, a file containing confidential business data, such as revenue numbers for an unannounced project, is stored in a SharePoint location where it shouldn't be. The file needs to be removed from that location and placed somewhere that only authorized administrators can access.
- **Remove access from the file owner** — In some cases, the file owner shouldn't retain access to the content. For example, the file was placed in an insecure location and the owner needs

to work with an administrator to find a more secure way to store and share it.
- **Provide stronger protection than blocking alone** — Blocking prevents sharing but leaves the file in place. Quarantine removes the file entirely from the original location.

How file quarantine works

When a file in a SharePoint or OneDrive location matches a DLP policy rule that has the quarantine action configured, the following sequence occurs:

1. **Permission removal** — All existing permissions and sharing links on the file are removed.
2. **File move** — A system account moves the file from the original location to the configured admin quarantine site. The folder structure of the original location is preserved in the quarantine site.
3. **Tombstone file creation** — A text (.txt) file with the same name as the original file replaces it at the source location. The tombstone file displays an admin-configured message and includes the relative path of the quarantined file. The full quarantine folder path isn't disclosed to the file owner.
4. **Audit and alerting** — An audit record is created that includes the quarantine file location. A DLP rule match event appears in Activity Explorer, and DLP alerts include the quarantine file location, the file owner, and the original file path.

File identity

Each file in SharePoint and OneDrive is uniquely identified by its doc ID, not by its file name. DLP uses the doc ID to track files through the quarantine and restore process.

Quarantine site exclusion

Once you designate a SharePoint site as the quarantine location, the contents of that site are automatically excluded from DLP rule evaluation. You don't need to manually add the quarantine site to an exclusion list. This automatic exclusion prevents conflicts where a quarantined file could match another DLP rule and create circular enforcement behavior.

Files eligible for quarantine

The quarantine action only applies to files that are created or modified after the policy with the quarantine action is turned on. Files that existed before the policy was activated aren't evaluated for the quarantine action. This design prevents a situation where a broadly scoped policy

accidentally quarantines a large number of existing files, which would be difficult to reverse because file restore is a manual process.

> **Important**
>
> This behavior is specific to the quarantine action. Other DLP actions, such as block, apply to all files in scope, regardless of when they were created. If your organization uses on-demand classification, files that are scanned and classified by an on-demand scan can trigger the quarantine action if the classification result matches a DLP policy rule for the first time.

> **Note**
>
> The quarantine action is not available as an on-demand classification action. On-demand classification only scans and classifies files — it doesn't take enforcement actions.

Supported file types

File quarantine supports all file types that DLP supports for SharePoint and OneDrive locations.

Tombstone files

When a file is quarantined, a tombstone text file replaces it at the original location. The tombstone file:

- Uses the original file's name with a `.txt` extension.
- Displays an admin-configured message. Administrators configure this message in DLP settings. For example, the message might instruct the file owner to contact a specific email address for assistance.
- Includes the relative path of the quarantined file within the quarantine site. The full quarantine folder path isn't provided, because the quarantine location is a confidential admin-controlled site.

The file owner can view the tombstone file to understand why their file was removed and who to contact.

Manual file restore

There's no automated file restore for quarantined files. All file restore is a manual process. Administrators decide when and whether to restore a quarantined file.

Admins might restore files when:

- The sensitive content is determined to be harmless in context.
- The file usage is approved for valid business reasons.
- The policy match is a false positive.

To restore a quarantined file:

1. Locate the quarantined file in the quarantine site.
2. Identify the original file path by using audit logs.
3. Move the file from the quarantine site back to the original location. The quarantine site admin must have access to the original location.
4. Delete the tombstone file from the original location.

Post-restore behavior

After a file is restored:

- **Original sharing permissions aren't restored.** The file owner or admin must reconfigure sharing permissions.
- **Only the latest file version is restored.** Previous versions aren't preserved through the quarantine and restore process.
- **The same DLP rule won't re-quarantine the restored file**, even if the file is modified or the policy rule is updated. This behavior is intentional to prevent quarantine loops. Other DLP rules continue to apply normally to the restored file.

Known limitations

- **No automated restore** — All file restore is manual. There's no restore action available in the Microsoft Purview portal.
- **Sharing permissions not preserved** — Original sharing permissions and links aren't retained through the quarantine and restore cycle.
- A maximum of **200,000 items per tenant within a 24-hour period** may be processed for quarantine. Items exceeding this limit may be processed at a later time.

Relationship to other quarantine features

DLP file quarantine for SharePoint and OneDrive is separate from these related features:

- **Endpoint DLP auto-quarantine** — Applies only to files on Windows and macOS devices. It moves files to a local quarantine folder on the device. SharePoint and OneDrive file quarantine operates on cloud-hosted files.
- **Microsoft Defender for Cloud Apps file quarantine** — A similar quarantine capability that exists in Microsoft Defender for Cloud Apps (MDA). DLP file quarantine for SharePoint and OneDrive is designed for organizations that want to manage quarantine directly from Microsoft Purview.

Help prevent sharing credit card numbers through email

This section shows how to create a Microsoft Purview Data Loss Prevention (DLP) policy that blocks emails containing credit card numbers. It follows the process described in Design a data loss prevention policy. Work through this scenario in your test environment to familiarize yourself with the policy creation UI.

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important as policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

Prerequisites and assumptions

This scenario uses the *Highly confidential* sensitivity label, so it requires that you create and publish sensitivity labels. To learn more, see:

- Learn about sensitivity labels
- Get started with sensitivity labels
- Create and configure sensitivity labels and their policies

This procedure uses a hypothetical distribution group *Finance team* at Contoso.com and a hypothetical SMTP recipient *adele.vance@fabrikam.com*.

This procedure uses alerts, see: Get started with the data loss prevention alerts

Policy intent statement and mapping

We need to block emails to all recipients that contain credit card numbers or that have the 'highly confidential' sensitivity label applied except if the email is sent from someone on the finance team to adele.vance@fabrikam.com. We want to notify the compliance admin every time an email is

blocked and notify the user who sent the item and no one can be allowed to override the block. Track all occurrences of this high risk event in the log and we want the details of any events captured and made available for investigation

Expand table

Statement	Configuration question answered and configuration mapping
"We need to block emails to all recipients..."	- Where to monitor: **Enterprise applications & devices** and **Exchange** - Administrative scope: **Full directory** - Action: **Restrict access or encrypt the content in Microsoft 365 locations** > **Block users from receiving email or accessing shared SharePoint, OneDrive, and Teams files** > **Block everyone**
"...that contain credit card numbers or have the 'highly confidential' sensitivity label applied..."	- What to monitor: use the **Custom template** - Conditions for match: edit it to add the *highly confidential* sensitivity label
"...except if..."	- Condition group configuration: Create a nested boolean NOT condition group joined to the first conditions using a boolean AND
"...the email is sent from someone on the finance team..."	- Condition for match: **Sender is a member of**
"...and..."	- Condition for match: add a second condition to the NOT group
"...to adele.vance@fabrikam.com..."	- Condition for match: **Recipient is**
"...Notify..."	- User notifications: **enabled** - Policy tips: **enabled**
"...the compliance admin every time an email is blocked and notify the user who sent the item..."	- Policy tips: **enabled** - Notify these people: **selected** - The person who sent, shared, or modified the content: **selected** - Send the email to these additional people: add the email address of the compliance administrator
"...and no one can be allowed to override the block...	- **Allow overrides from M365 Services**: not selected
"...Track all occurrences of this high risk event in the log and we want the details of any events captured and made available for investigation."	- Use this severity level in admin alerts and reports: **high** - Send an alert to admins when a rule match occurs: **selected**

Statement	Configuration question answered and configuration mapping
	- Send alert every time an activity matches the rule: **selected**

Steps to create the policy

> **Important**
>
> For this policy creation procedure, accept the default include and exclude values and leave the policy turned off. Change these values when you deploy the policy.

1. Sign in to the Microsoft Purview portal.
2. Open the **Data loss prevention** solution and go to **Policies** > **+ Create policy**.
3. Select **Enterprise applications & devices**.
4. Select **Custom** from the **Categories** list.
5. Select **Custom** from the **Regulations** list.
6. Select **Next**.
7. Enter a **Name** and a **Description** for the policy. You can use the policy intent statement here.

   > **Important**
   >
   > You can't rename policies.

8. Select **Next**.
9. **Assign admin units**. To apply the policy to all users, accept the default setting.
10. Select **Next**.
11. Choose where to apply the policy. Select only the **Exchange email** location. Deselect all the other locations.
12. Select **Next**.

13. On the **Define policy settings** page, the **Create or customize advanced DLP rules** option should already be selected.
14. Select **Next**.
15. Select **Create rule**. Name the rule and provide a description.
16. Under **Conditions**, select **Add condition** > **Content contains**.
17. (Optional) Enter a **Group name**.
18. (Optional) Select a **Group operator**.
19. Select **Add** > **Sensitive info types** > **Credit Card Number**.
20. Select **Add**.
21. Still within the **Content contains** section, select **Add** > **Sensitivity labels** > **Highly confidential** and then select **Add**.
22. Next, beneath the **Content contains** section, select **Add group**.
23. Leave the Boolean operator set to **AND**, then set the toggle to **NOT**.
24. Select **Add condition**.
25. Select **Sender is a member of**.
26. Select **Add or remove distribution groups**.
27. Select **Finance Team** and then select **Add**.
28. Select **Add condition** > **Recipient is**.
29. In the email field, enter *adele.vance@fabrikam.com* and select **Add** .
30. Under **Actions**, select **Add an action** > **Restrict access or encrypt the content in Microsoft 365 locations**.
31. Select **Block users from receiving email or accessing shared SharePoint, OneDrive, and Teams files**, then select **Block everyone**.
32. Set the **User notifications** toggle to **On**.
33. Select **Email notifications** > **Notify the person who sent, shared, or last modified the content**.

34. Choose whether or not to **Attach matching email message to the notification**.
35. Choose whether or not to add **Policy tips**.
36. Under **User ovverides**, make sure that **Allow overrides from Microsoft 365 apps and services ...** is *NOT* selected.
37. Under **Incident reports**, set **Use this severity level in admin alerts and reports** to **High**.
38. Set **Send alert every time an activity matches the rule** toggle to **On**.
39. Select **Save**.
40. Select **Next**, then select **Run the policy in simulation mode**.
41. Select **Next** and then select **Submit**.
42. Select **Done**.

Configure default protection for classification failures in Data loss prevention for Exchange (preview)

Microsoft Purview data loss prevention (DLP) policies for Exchange Online can detect and act on classification failures—cases where the classification service can't fully scan a document. This article shows you how to enable classification failure detection and use the improved conditions to apply protection actions for specific failure types, such as timeouts and throttling.

Enable classification failure detection

To enable classification failure detection, you can update the setting in the Purview portal or use PowerShell. Allow up to one hour for the setting change to synchronize across the service before validating policy behavior.

> **Important**
>
> This setting applies to Exchange Online only. It doesn't affect SharePoint, OneDrive, Teams, or Endpoint DLP policies.

- **Purview Portal**: To access the setting, from the Microsoft Purview portal, go to **Settings** on the left navigation menu > **Data loss prevention** > **Scan failure settings for Exchange**. In **Scan failure settings for Exchange** turn on the toggle.
- **PowerShell**: Connect to Security & Compliance PowerShell and run the following commands.

```powershell
Connect-IPPSSession
$json = '{"Classification":{"State":1}}'  # To disable, set State to 0
Set-PolicyConfig -DlpErrorHandlingConfig $json
```

Improved conditions for file attachments

By default, these conditions detect only text extraction failures. After you enable classification failure detection, they also detect classification failures such as timeouts, throttling, and other errors.

The following table compares each condition's capabilities before and after you enable classification failure detection.

Expand table

Condition	Default capabilities	Capabilities after you enable detection
Document couldn't be scanned	Text extraction failures (for example, the file couldn't be opened, the format is unsupported, or the file is password protected).	All text extraction failures, plus Classification failures (for example, when the classification service can't complete scanning of a document because of a timeout, throttling, or another error).
Document didn't complete scanning	Partial text extraction (for example, content exceeded extraction limits).	Partial text extraction, plus partial classification failures—for example, when at least one classifier (sensitive information type, exact data match, or trainable classifier) succeeded, but one or more of the others failed because of a timeout, throttling, or another error.

> **Note**
>
> If your tenant already has rules that use these conditions, you might see an increase in DLP rule matches after you enable detection.

To take different actions for specific classification failure types—**Timeout**, **Throttled**, or **Other**—use the **DocumentScanFailures** condition. Combine it with either **Document couldn't be scanned** or **Document didn't complete scanning** using AND; **DocumentScanFailures** can't be used on its own.

For the complete list of attachment conditions, see Attachments.

Rule ordering

Scan-failure rules detect failures only from classifiers that DLP has already evaluated. If a content-detection rule is placed after a scan-failure rule and its classifier fails, the failure won't be detected.

To avoid missed detections, order your rules so that content-detection rules (sensitive information types, exact data matches, and trainable classifiers) have higher priority than scan-failure rules (Timeout, Throttled, Other):

- Content rules at priorities 1–3.
- Scan-failure rules at priorities 4–6.

The following table shows an example that follows this pattern.

Expand table

Priority	Rule	Condition	Action
1	Detect credit cards	Content contains Credit Card Number	Block
2	Detect account numbers	Content contains Account Number	Block
3	Detect EDM match	Content contains EDM SIT	Block
4	Full scan timeout	DocumentIsUnsupported AND DocumentScanFailures = Timeout	Audit
5	Partial scan throttling	ProcessingLimitExceeded AND DocumentScanFailures = Throttled	Audit
6	Other scan errors	DocumentIsUnsupported AND DocumentScanFailures = Other	Audit

Help prevent sharing sensitive items via SharePoint and OneDrive with external users

This article uses the process you learned in Design a data loss prevention policy to show you how to create a Microsoft Purview Data Loss Prevention (DLP) policy that helps prevent users from sharing sensitive items via SharePoint and OneDrive with external users. Work through these scenarios in your test environment to familiarize yourself with the policy creation UI.

For SharePoint and OneDrive, you create a policy to help prevent sharing of sensitive items with external users via SharePoint and OneDrive.

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

Prerequisites and assumptions

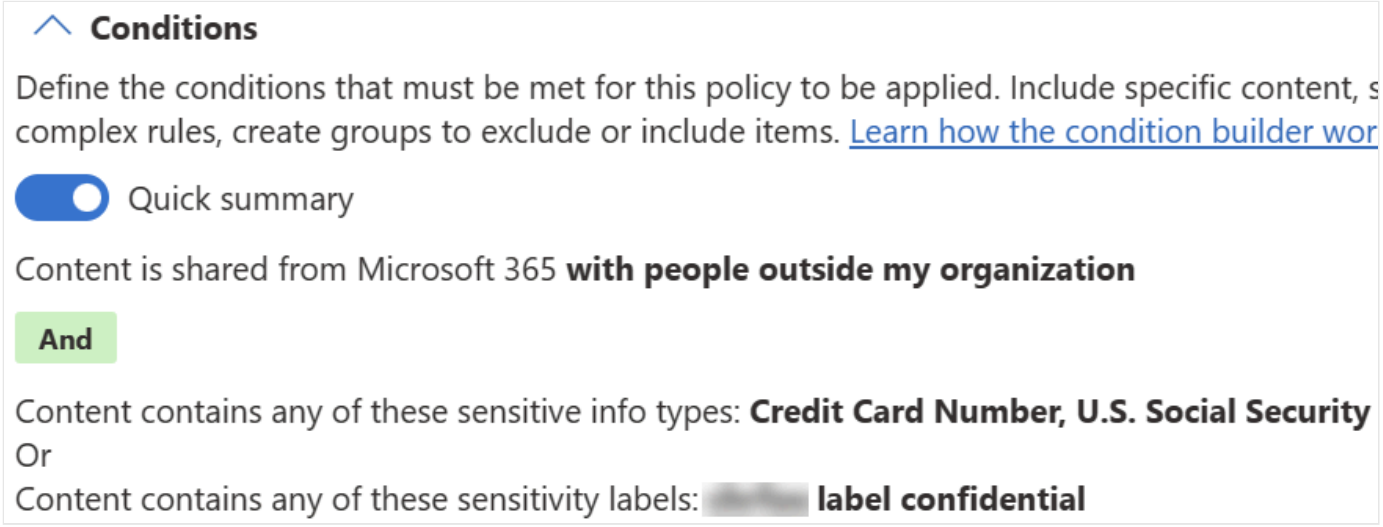
This scenario uses the *Confidential* sensitivity label, so it requires you to create and publish sensitivity labels. To learn more, see:

- Learn about sensitivity labels
- Get started with sensitivity labels
- Create and configure sensitivity labels and their policies

This procedure uses a hypothetical distribution group *Human Resources* and a distribution group for the security team at Contoso.com.

The policy creation procedure in this article uses alerts. To learn more, see Get started with the data loss prevention alerts

Policy intent statement and mapping



We need to block all sharing of SharePoint and OneDrive items to all external recipients that contain social security numbers, credit card data or have the "Confidential" sensitivity label. We don't want this to apply to anyone on the Human Resources team. We also have to meet alerting requirements. We want to notify our security team with an email every time a file is shared and then blocked. In addition, we want the user to be alerted via email and within the interface if possible. Lastly, we don't want any exceptions to the policy and need to be able to see this activity within the system.

Expand table

Statement	Configuration question answered and configuration mapping
"We need to block all sharing of SharePoint and OneDrive items to all external recipients..."	- Administrative scope: **Full directory** - Where to monitor: **Enterprise applications & devices**, **SharePoint sites**, **OneDrive accounts** - Conditions for a match: First **Condition** > **Shared outside my org** - Action: **Restrict access or encrypt the content in Microsoft 365 locations** > **Block users from receiving email or accessing shared SharePoint, OneDrive** > **Block only people outside your organization**
"...that contain social security numbers, credit card data or have the "Confidential" sensitivity label..."	- What to monitor: use the **Custom** template - Condition for a match: Create a second condition that is joined to the first condition with a boolean AND - Conditions for a match: Second condition, first condition group > **Content contains Sensitive info types** > **U.S. Social Security Number (SSN)**, **Credit Card Number** - **Condition group configuration** Create a second Condition group connected to the first by boolean OR - Condition for a match: Second condition group, second condition > **Content contains any of these sensitivity labels** > **Confidential**.
"...We don't want this to apply to anyone on the Human Resources team..."	- Where to apply: exclude the Human Resources Team OneDrive accounts
"...We want to notify our Security team with an email every time a file is shared and then blocked..."	- Incident reports: **Send an alert to admins when a rule match occurs** - Send email alerts to these people (optional): add the Security team - Send an alert every time an activity matches the rule: **selected** - Use email incident reports to notify you when a policy match occurs: **On** - Send notifications to these people: add individual admins as desired

Statement	Configuration question answered and configuration mapping
	- You can also include the following information in the report: select **all options**
"...In addition, we want the user to be alerted via email and within the interface if possible..."	- User notifications: **On** - Notify users in Office 365 with a policy tip: **selected**
"...Lastly, we don't want any exceptions to the policy and need to be able to see this activity within the system..."	-User overrides: **not selected**

When you configure the conditions, the summary looks like this:

Steps to create policy

> **Important**
>
> For this policy creation procedure, leave the policy turned off. Change these settings when you deploy the policy.

1. Sign in to the Microsoft Purview portal.
2. Select **Data loss prevention** > **Policies** > **+ Create policy**.
3. Select **Enterprise applications & devices**.
4. Select **Custom** from both the **Categories** list and the **Regulations** list.
5. Select **Next**.
6. Enter a **Name** and a **Description** for the policy. You can use the policy intent statement here.

> **Important**

You can't rename policies.

1. Select **Next**.
2. Accept the default **Full directory** on the **Assign admin units** page.
3. Select **Next**.
4. Choose where to apply the policy.
   a. Ensure that the **SharePoint sites** and **OneDrive accounts** locations are selected.
   b. Deselect all other locations.
   c. Select **Edit** in the **Actions** column next to **OneDrive accounts**.
   d. Select **All users and groups** and then select **Exclude users and groups**.
   e. Select **+Exclude** and then **Exclude groups**.
   f. Select **Human Resources**.
5. Select **Done** and then select **Next**.
6. On the **Define policy settings** page, the **Create or customize advanced DLP rules** option should already be selected. Select **Next**.
7. On the **Customize advanced DLP rules** page, select **+ Create rule**.
8. Give the rule a **Name** and a **description**.
9. Select **Add condition** and use these values:
   a. Select **Content is shared from Microsoft 365**.
   b. Select **with people outside my organization**.
10. Select **Add condition** to create a second condition and use these values.
    a. Select **Content contains**.
11. Select **Add** > **Sensitivity labels** > and then **Confidential**.
12. Select **Add**.
13. Under **Actions**, add an action with these values:
    a. **Restrict access or encrypt the content in Microsoft 365 locations**.
    b. **Block only people outside your organization**.
14. Set the **User Notifications** toggle to **On**.
15. Select **Notify users in Office 365 services with a policy tip** and then select **Notify the user who sent, shared, or last modified the content**.
16. Under **User overrides**, make sure that **Allow override from M365 services** is *NOT* selected.
17. Under **Incident reports**:
    a. Set **Use this severity level in admin alerts and reports** to **Low**.
    b. Set the toggle for **Send an alert to admins when a rule match occurs** to **On**.
18. Under **Send email alerts to these people (optional)**, choose **+ Add or remove users** and then add the email address of the security team.
19. Select **Save** and then select **Next**.

20. On the **Policy mode** page, choose **Run the policy in simulation mode** and **Show policy tips while in simulation mode**.
21. Select **Next** and then select **Submit**.
22. Select **Done**.

Variant: Block specific external domains or users (public preview)

This variant uses the same scenario as the main SharePoint and OneDrive external sharing policy but swaps the action to demonstrate the **Block access for specific external domains or users** suboption, available in public preview for SharePoint and OneDrive only. Use this variant when you need to block access for a specific list of external domains or user SMTPs rather than blocking all external recipients.

Policy intent statement (variant)

We need to block sharing of SharePoint and OneDrive items containing social security numbers, credit card data, or the "Confidential" sensitivity label to people on our list of restricted external domains (for example, `adatum.com`) and to specific guest SMTPs (for example, `j.doe@firstupconsultants.com`). All other external recipients are allowed. We don't want this to apply to anyone on the Human Resources team. Alerting is supported for this action. User notification and override capability are not supported for this action.

Configuration mapping (variant)

The following table maps the variant policy intent to the corresponding configuration choices.

Expand table

Statement	Configuration question answered and configuration mapping
"...block sharing... to people on our list of restricted external domains... and to specific guest SMTPs..."	- Action: **Restrict access or encrypt the content in Microsoft 365 locations** > **Block users from receiving email or accessing shared SharePoint, OneDrive** > **Block access for specific external domains or users** - Specify each restricted domain with **Domain IS** (for example, `adatum.com`). - Specify each restricted user with **User IS** (for example, `j.doe@firstupconsultants.com`). - (Optional) Use **Domain IS NOT** or **User IS NOT** to explicitly allow specific domains or users that would otherwise match a block list.

All other mapping rows from the main SharePoint and OneDrive external sharing scenario — administrative scope, conditions, exclusions, incident reports, user notifications, and user overrides — are unchanged.

Steps to create the variant policy

Follow the same procedure in Steps to create policy, with one change at the **Actions** step:

- Under **Actions**, add an action with these values:

    1. **Restrict access or encrypt the content in Microsoft 365 locations**.
    2. **Block access for specific external domains or users**.
    3. Add each restricted domain by using **Domain IS** (for example, `adatum.com`).
    4. Add each restricted user by using **User IS** (for example, `j.doe@firstupconsultants.com`).
    5. (Optional) Use **Domain IS NOT** or **User IS NOT** to add allow entries that override a block entry.

> ⓘ **Note**
>
> When you use **Block access for specific external domains or users**: if a user or domain appears in both allow and block lists, the block takes effect (most restrictive wins). If a file matches both an allow rule and a block rule, evaluation is per rule — allowed users and domains are permitted, blocked users and domains are denied, and users in neither list are blocked by default. Internal users and domains can't be blocked with this suboption; use **Block everyone** for internal users.

> ⓘ **Important**
>
> Public preview limitations: image files aren't protected by this suboption, and multiple audit records can be generated for certain actions on a blocked file by a blocked user.

Help prevent sharing Power BI reports with credit card numbers

Overview

> **Note**
>
> The features used in this scenario are in preview.

This article uses the process you learned in Design a data loss prevention policy to show you how to create a Microsoft Purview data loss prevention (DLP) policy that helps protect against unintentional sharing of Power BI reports that contain credit card numbers. Work through this scenario in your test environment to familiarize yourself with the policy creation UI.

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important as policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

Prerequisites and assumptions

This scenario uses the *Highly Confidential - Internal* sensitivity label, so it requires that you create and publish sensitivity labels. To learn more, see:

- Learn about sensitivity labels
- Get started with sensitivity labels
- Create and configure sensitivity labels and their policies

The following policy creation procedure uses alerts. For setup information, see Get started with the data loss prevention alerts.

Policy intent statement and mapping

We need to block external users from reports containing credit card numbers, unless the data is labeled with the 'Highly Confidential - Internal' sensitivity lable, in which case a protection policy restricts access to select security groups. We want to notify the compliance admin to know whenever a semantic model is blocked and the data owner to be aware the restriction took place. We also want internal users to be aware that the data is highly confidential and that they shouldn't share it outside the organization.

Expand table

Statement	**Configuration question answered and configuration mapping**
"We need to block external users..."	- Where to monitor: **Fabric and Power BI** - Administrative scope: **Full directory** - Action: **Restrict access or encrypt the content in Microsoft 365 locations** > **Block users from receiving email or accessing shared SharePoint, OneDrive, and Teams files, and Power BI items** > **Block only people outside your organization**
"...from reports containing credit card numbers..."	- What to monitor: use the **Custom template** - Conditions for match: edit it to add the *Credit Card Number* sensitive info type.
"...except if the data is labeled with the *Highly Confidential - Internal* sensitivity label..."	- Condition group configuration: Create a nested boolean NOT condition group joined to the first condition using a boolean AND - Condition for match: edit it to add the *Highly Confidential - Internal* sensitivity label.
"We want to notify the compliance admin to know whenever a semantic model is blocked..."	-Incident reports: **Send an alert to admins when a rule match occurs**: **On** - Send an alert every time an activity matches the rule: **selected**
"...the data owner to be aware the restriction took place. We also want internal users to be aware that the data is highly confidential and that they shouldn't share it outside the organization."	- User notifications: **On** - Microsoft 365 files and Microsoft Fabric items: Notify users in Office 365 service with a policy tip or email notifications: **selected** - Policy tips: Customize the policy tip text: **selected**. Add text in the text box explaining the rules governing sharing highly confidential data.

Steps to create the policy

> **Important**
>
> For this policy creation procedure, accept the default include and exclude values and leave the policy turned off. Change these values when you deploy the policy.

1. Sign in to the Microsoft Purview portal.
2. Open the **Data loss prevention** solution and go to **Policies**.
3. Select **Create policy**.
4. Select **Enterprise applications & devices**.
5. Select **Custom** from the **Categories** list.
6. Select **Custom policy** from the **Regulations** list.
7. Select **Next**.
8. Enter a name and description for the policy. You can use the policy intent statement here.

   > **Important**
   >
   > Policies can't be renamed

9. Select **Next**.
10. Accept the **Full directory** default under **Admin units**.
11. Select **Next**.
12. Choose where to apply the policy. Select only the **Fabric and Power BI workspaces** location.
13. Select **Next**.
14. On the **Define policy settings** page, make sure the **Create or customize advanced DLP rules** option is selected.
15. Select **Next**.
16. Select **+ Create rule**. Name the rule and provide a description.
17. Under **Conditions**, select **Add condition** > **Content contains** > **Add** > **Sensitive info types**.
18. Select the info types that apply to credit card numbers.
19. Select **Add**.
20. Next, under the **Content contains** section, select **Add group**.
21. Leave the Boolean operator set to **AND**, then set the toggle to **NOT**.
22. In the line below the toggle, select **Add condition** > **Content contains** > **Add** > **Sensitivity labels**.
23. Select the sensitivity label **Highly Confidential - Internal**.
24. Select **Add**.

25. Under **Actions**, select **Add an action** > **Restrict access or encrypt the content in Microsoft 365 locations** > **Block users from receiving email or accessing shared SharePoint, OneDrive, and Teams files, and Power BI items** > **Block only people outside your organization**.
26. Under **User notifications**, set the toggle to **On**.
27. Select **Notify users in Office 365 service with a policy tip or email notifications**, and then select **Customize the policy tip text**.
28. Provide a policy tip that explains that the data in the report is highly confidential is not to be shared outside the organization.
29. Under **Incident reports**, set **Use this severity level in admin alerts and reports** to **High**.
30. Make sure the **Send an alert to admins when a rule match occurs** toggle is set to **On**.
31. Make sure the **Send alert every time an activity matches the rule** radio button is selected.
32. Select **Save**.
33. Review the rule, then select **Next**.
34. Make sure the **Run the policy in simulation mode** radio button and the **Show policy tips while in simulation mode** checkbox are selected.
35. Select **Next**.
36. Review the policy, then select **Submit**.
37. Select **Done**.

Create a DLP policy to protect documents with FCI or other properties

Microsoft Purview Data Loss Prevention (DLP) policies can use classification properties or item properties to identify sensitive items. For example you can use:

- Windows Server File Classification infrastructure (FCI) properties
- SharePoint document properties
- third-party system document properties

For example, your organization might use Windows Server FCI to identify items with personal data, such as social security numbers, and then classify those documents by setting the **Personally Identifiable Information** property to **High**, **Moderate**, **Low**, **Public**, or **Not PII** based on the type and number of occurrences of personal data found in each document.

In Microsoft 365, you can create a DLP policy that identifies documents that have that property set to specific values, such as **High** and **Medium**, and then takes an action such as blocking access to those files. The same policy can have another rule that takes a different action if the property is set to **Low**, such as sending an email notification. This way, DLP integrates with Windows Server FCI and can help protect Office documents uploaded or shared to Microsoft 365 from Windows Server-based file servers.

A DLP policy simply looks for a specific property name/value pair. Any document property can be used, as long as the property has a corresponding managed property for SharePoint search. For example, a SharePoint site collection might use a content type named **Trip Report** with a required field named **Customer**. Whenever a person creates a trip report, they must enter the customer name. This property name/value pair can also be used in a DLP policy—for example, if you want a rule that blocks access to the document for guests when the **Customer** field contains **Contoso**.

If you want to apply your DLP policy to content with specific Microsoft 365 labels, don't follow the steps here. Instead, refer to lCreate and Deploy data loss prevention policies.

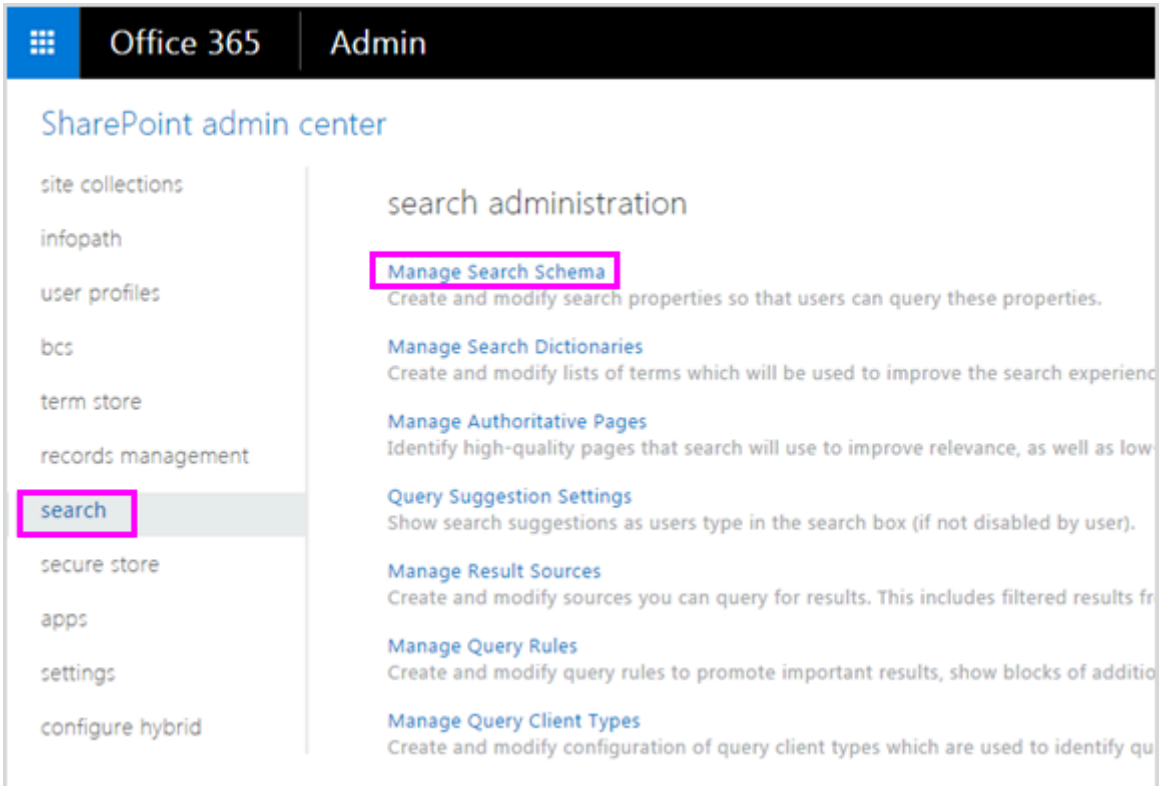
> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Before you create the DLP policy

Before you can use a Windows Server FCI property or other property in a DLP policy, you need to create a managed property in the SharePoint admin center. Here's why.

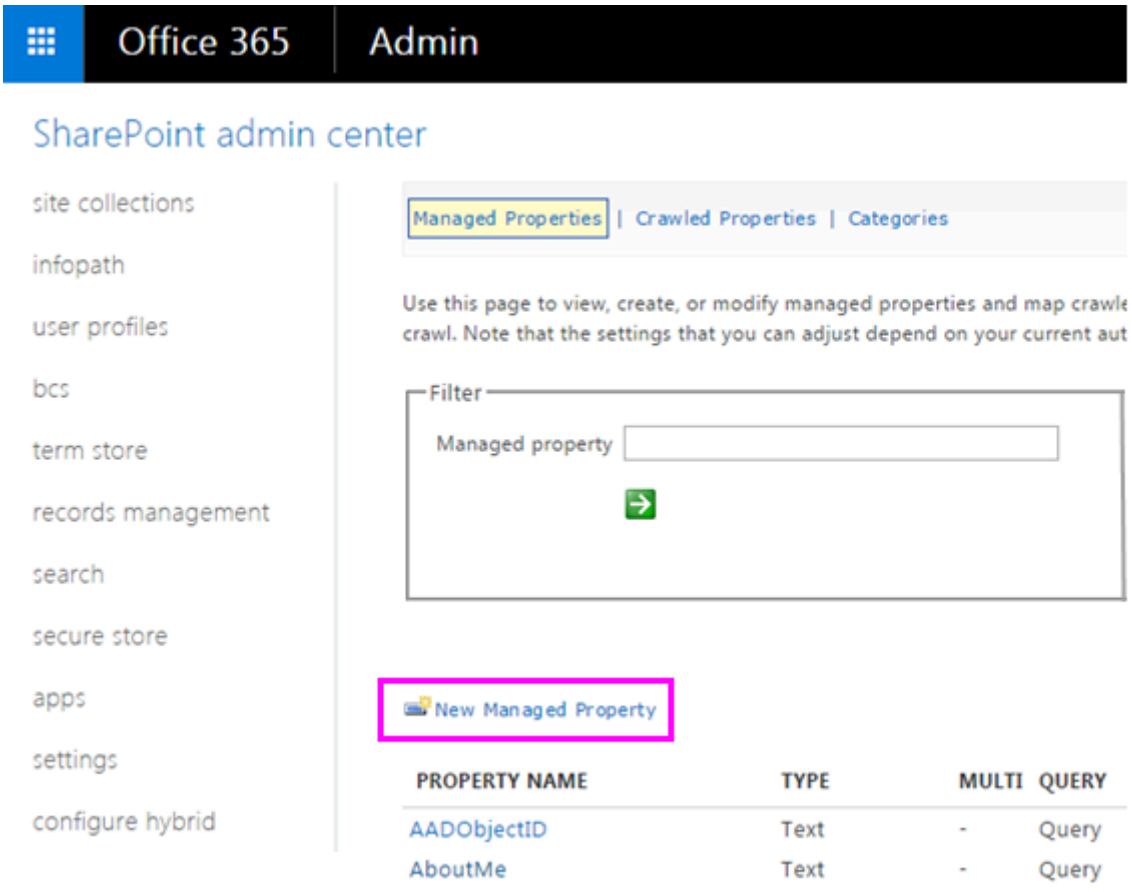
In SharePoint and OneDrive, the search index is built up by crawling the content on your sites. The crawler picks up content and metadata from the documents in the form of crawled properties. The search schema helps the crawler decide what content and metadata to pick up. (Examples of metadata are the author and the title of a document.) However, to get the content and metadata from the documents into the search index, the crawled properties must be mapped to managed properties. Only managed properties are kept in the index. For example, a crawled property related to author is mapped to a managed property related to author.

> **Note**
>
> Be sure to use a managed property name, not a crawled property name, when creating DLP rules using the `ContentPropertyContainsWords` condition. This is important because DLP uses the search crawler to identify and classify sensitive information on your sites, and then stores that sensitive information in a secure portion of the search index. When you upload a document to Office 365, SharePoint automatically creates crawled properties based on the document properties. However, to use an FCI or other property in a DLP policy, that crawled property needs to be mapped to a managed property so that the content with that property is kept in the index.



For more information on search and managed properties, see Manage the search schema in SharePoint Online.

Step 1: Upload a document with the needed property to Office 365

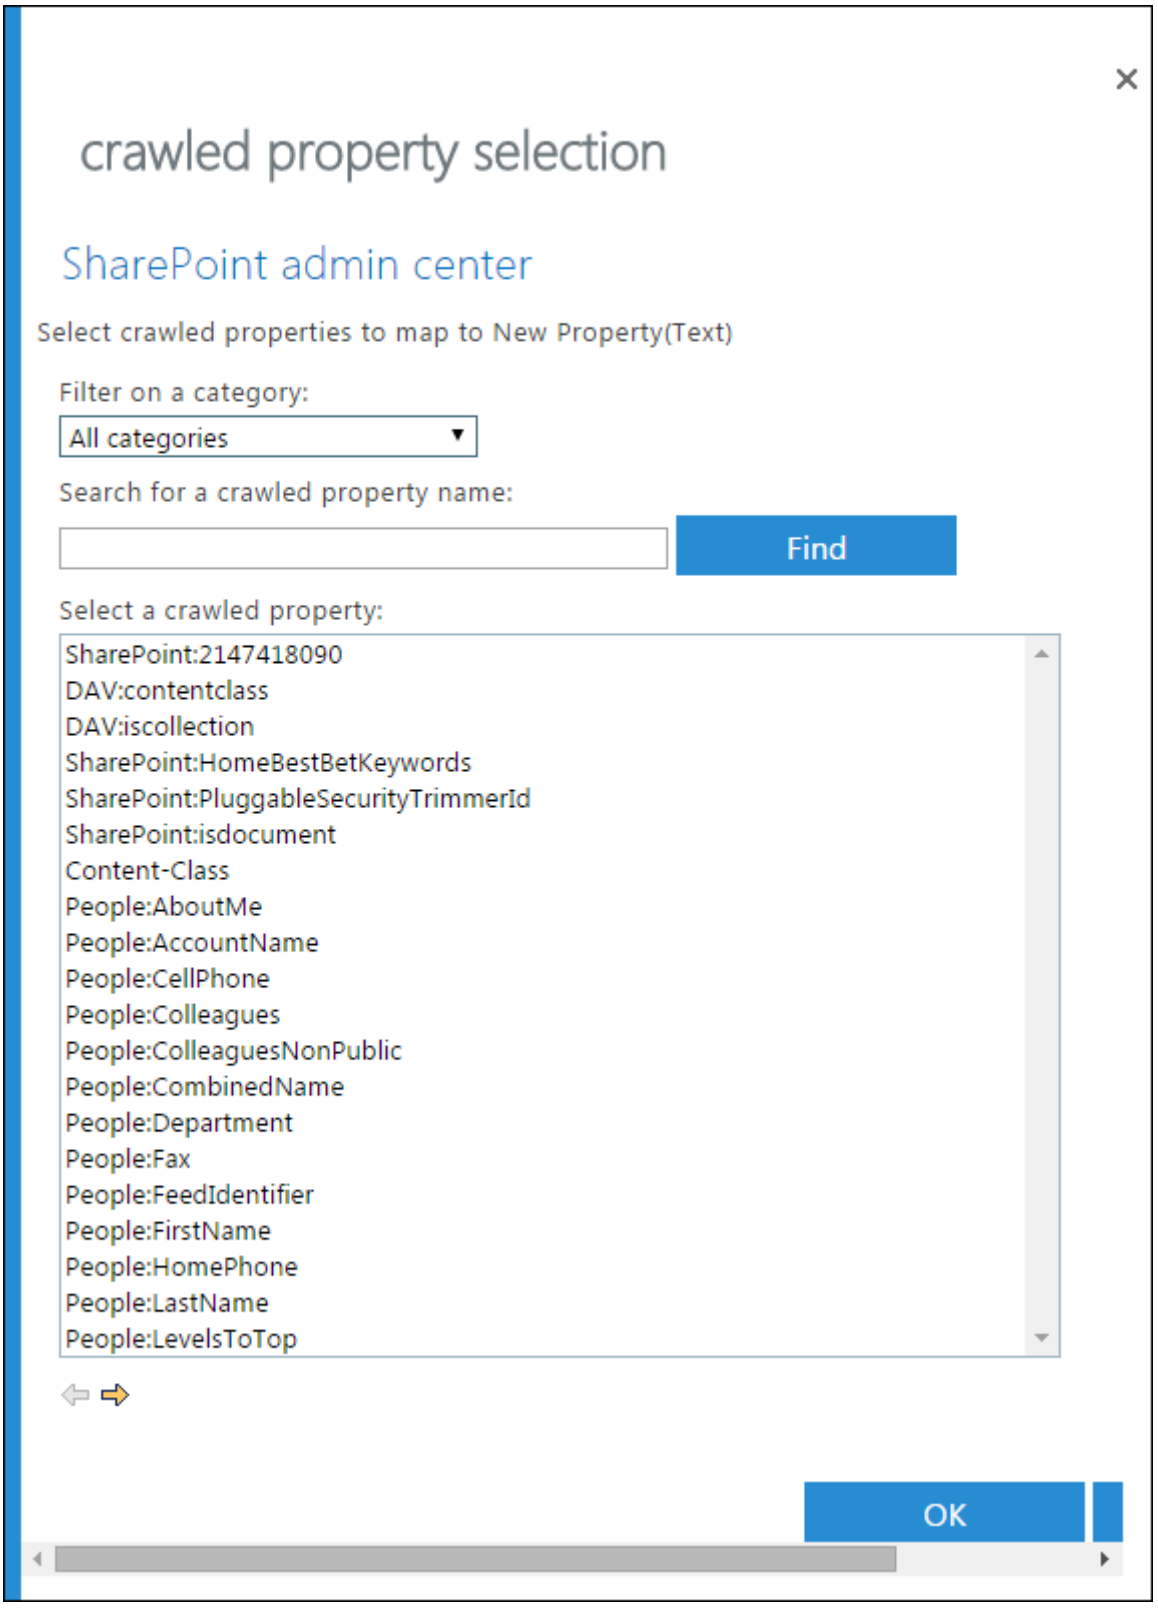


First, you need to upload a document with the property that you want to reference in your DLP policy. Microsoft 365 detects the property and automatically create a crawled property from it. In the next step, you'll create a managed property, and then map the managed property to this crawled property.

Step 2: Create a managed property

1. Sign in to the Microsoft 365 admin center.
2. In the left navigation pane, choose **Admin centers** > **SharePoint**. You're now in the SharePoint admin center.
3. In the left navigation pane, choose **search**. On the **search administration** page, choose **Manage Search Schema**.

4. On the **Managed Properties** page > **New Managed Property**.



5. Enter a name and description for the property. This name is what will appear in your DLP policies.

6. For **Type**, choose **Text**.

7. Under **Main characteristics**, select **Queryable** and **Retrievable**.

8. Under **Mappings to crawled properties** choose **Add a mapping**.

9. In the **crawled property selection** dialog box, find and select the crawled property that corresponds to the Windows Server FCI property or other property that you'll use in your DLP policy, then choose **OK**.

10. At the bottom of the page choose **OK**.

Create a DLP policy that uses an FCI property or other property

In this example, an organization is using FCI on its Windows Server-based file servers; specifically, they're using the FCI classification property named **Personally Identifiable Information** with

possible values of **High**, **Moderate**, **Low**, **Public**, and **Not PII**. Now they want to use their existing FCI classification in their DLP policies in Office 365.

To begin, they follow the steps above to create a managed property in SharePoint Online, which maps to the crawled property created automatically from the FCI property.

Next, they create a DLP policy with two rules that both use the condition **Document properties contain any of these values**:

- **FCI PII content - High, Moderate** The first rule restricts access to the document if the FCI classification property **Personally Identifiable Information** equals **High** or **Moderate** and the document is shared with people outside the organization.
- **FCI PII content - Low** The second rule sends a notification to the document owner if the FCI classification property **Personally Identifiable Information** equals **Low** and the document is shared with people outside the organization.

After you create the DLP policy

Completing the steps in the previous sections creates a DLP policy that will quickly detect content with that property, but only if that content is newly uploaded (so that the content's indexed), or if that content is old but edited (so that the content's reindexed).

To detect content with that property everywhere, you need to have your library, site, or site collection reindexed, so that the DLP policy is aware of all the content with that property. In SharePoint, content is automatically crawled when content is edited. Specific SharePoint sites can't be manually reindexed.

> ⊗ **Caution**
>
> Reindexing a site for DLP scenarios isn't possible.

For more information, see Manually request crawling and reindexing of a site, a library, or a list.

Reindex a site (optional)

1. On the site, choose **Settings** (gear icon in upper right) > **Site Settings**.
2. Under **Search**, choose **Search and offline availability** > **Reindex site**.

Learn about the data loss prevention on-premises repositories

Article • 03/31/2025

When you select the **On-premises repositories** location, Microsoft Purview Data Loss Prevention (DLP) can enforce protective actions on on-premises data-at-rest in file shares and SharePoint document libraries and folders. This gives you the visibility and control you need to ensure that sensitive items are used and protected properly, and to help prevent risky behavior that might compromise them. The DLP detects sensitive information by using built-in or custom sensitive information types, sensitivity labels or file properties. The information about what users are doing with sensitive items is made visible in activity explorer and you can enforce protective actions on those items via DLP policies.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

DLP relies on Microsoft Purview Information Protection scanner

DLP relies on a full implementation of the Microsoft Purview Information Protection scanner to monitor, label, and protect sensitive items. If you haven't implemented Information Protection scanner, you must do so before you can use DLP. For more information, read these articles:

- What is Azure Information Protection
- Learn about the information protection scanner
- Get started with the information protection scanner
- Configuring and installing the information protection scanner
- Microsoft Purview Information Protection client - Release management and supportability

DLP On-premises repository actions

DLP detects files in on-premises repositories by looking for the following:

- sensitive information types
- sensitivity labels
- file extension
- custom document properties on Office files only

When a detected file matches a DLP policy, DLP can take one of the following four actions.

Expand table

Action	Description
Block people from accessing file stored in on-premises scanner - Block everyone	When enforced, this action blocks access to all accounts except the content owner, the account that last modified the item, and the administrator. It does this by removing all accounts from NTFS/SharePoint permissions at the file level except for the file owner, repository owner (set in the Use a DLP policy setting in content scan job), last modifier (can be identified in SharePoint only), and admin. The scanner account is also granted FC rights on the file.
Block only people who have access to your on-premises network and users in your organization who weren't granted explicit access to the files from accessing file	When enforced, this action removes the ***Everyone***, ***NT AUTHORITY\authenticated users***, and ***Domain Users*** SIDs from the file access control list (ACL). Only users and groups that have been explicitly granted rights to the file or parent folder will be able to access the file.
Set permissions on the file (permissions will be inherited from the parent folder)	When enforced, this action forces the file to inherit the permissions of its parent folder. By default, this action will only be enforced if the permissions on the parent folder are more restrictive than the permissions that are already on the file. For example, if the ACL on the file is set to allow only ***specific users*** and the parent folder is configured to allow the ***Domain Users*** group, the parent folder permissions wouldn't be inherited by the file. You can override this behavior by selecting the **Inherit even if parent permissions are less restrictive** option.
Remove the file from improper location	When enforced, this action replaces the original file with a stub file with .txt extension and places a copy of the original file in a quarantine folder.

What's different in the on-premises scanner

There are a few extra concepts that you need to be aware of before you dig into the on-premises scanner.

Scanner repositories and content scan jobs

You must create a content scan job for the information protection scanner and identify the repositories that host the files that you want to DLP to evaluate. Make sure you enable DLP rules in the created content scan job.

Policy tips

Policy tips aren't available in on-premises scanner.

Viewing DLP on-premises scanner events

You view DLP data in the Microsoft Purview portal activity explorer.

Next steps

Now that you've learned about the Information Protection on-premises scanner, your next steps are:

1. Get started with the On-premises repositories location
2. Use the DLP on-premises scanner

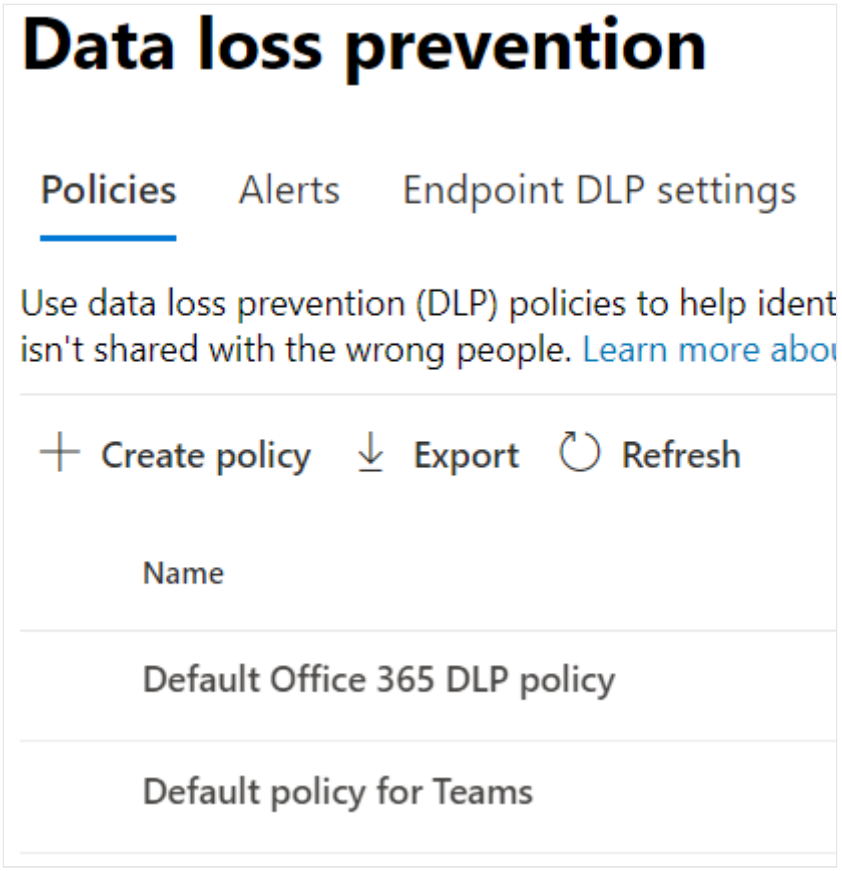
Learn about the default data loss prevention policy in Microsoft Teams

Article • 03/28/2025

Microsoft Purview Data Loss Prevention capabilities have been extended to include Microsoft Teams chat and channel messages, including private channel messages. As a part of this release, we created a default DLP policy for Microsoft Teams for first-time customers to the Microsoft Purview portal.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Licensing



For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

What does the default policy do?

The default DLP policy for Teams tracks all the credit card numbers shared internally and externally to the organization. This policy is on by default for all users of the tenant. It does not generate any policy tips for end users but does generate an Alert event and also triggers a low severity email to the admin (added in the policy). Administrator can view the activities and edit the policies details by logging into the Microsoft Purview portal.

Admins can view this policy in the Microsoft Purview portal. Navigate to **Data Loss prevention** > **Policies**.

Edit or delete the default policy

To edit the default policy for better performance or to delete it, just use an account with **DLP Compliance Management** permissions. For more information, see, Permissions.

Feedback

Data loss prevention and Microsoft Teams

If your organization has Microsoft Purview Data Loss Prevention (DLP), you can define policies that help prevent people from sharing sensitive information in a Microsoft Teams channel or chat session. Here are some example scenarios:

- **Protecting sensitive information in messages**. Suppose that someone attempts to share sensitive information in a Teams chat or channel with guests (external users). If you have a DLP policy defined in your tenant to prevent this, messages with sensitive information that are sent to external users are deleted. However, your tenant must be the initiator of the chat or the thread. This happens automatically, and within seconds, according to how your DLP policy is configured.

- **Protecting sensitive information in documents**. Suppose that someone attempts to share a document with guests in a Microsoft Teams channel or chat, and the document contains sensitive information. If you have a DLP policy defined to prevent this, the document won't open for those users. Your DLP policy must include SharePoint and OneDrive in order for protection to be enforced. This is an example of DLP for SharePoint that shows up in Microsoft Teams, and therefore requires that users are licensed for Office 365 DLP (included in Office 365 E3), but doesn't require that users be licensed for Office 365 Advanced Compliance.

- **Protecting communications in Teams Shared Channels**. Shared channels are built on Microsoft Entra B2B direct connect, so each participant remains signed in to their own (home) tenant and doesn't get an identity object in the host tenant. Because DLP evaluation is driven by the sender's identity, each user's messages are evaluated against the DLP policies of their own tenant, regardless of which tenant owns the shared channel. For example, let's say there's a shared channel owned by Team A of Contoso, where Contoso has a DLP policy P1 and Fabrikam has a DLP policy P2. There are three ways to share the channel:
  - **Share with member**: You invite User1 from Contoso to join the shared channel without making them a member of Team A. User1's messages are evaluated against Contoso's DLP policies (P1), the same policies that apply to User1 elsewhere in Contoso.
  - **Share with team (internally)**: You share the channel with another team within Contoso, Team B. Messages from Team A and Team B users are evaluated against Contoso's DLP policies. If Team A and Team B are scoped to different policies, each user is still evaluated against the policies that target them.

    - **Share with team (cross tenant)**: You share the channel with a team, Team F, in Fabrikam. Contoso's DLP policies (P1) apply to messages sent by Team A (Contoso) users. Fabrikam's DLP policies (P2) apply to messages sent by Team F (Fabrikam) users. Contoso can't enforce its DLP policies on Fabrikam users' messages, and vice versa.

- **Protecting communications when chatting with external users in Microsoft Teams**.

People from different Microsoft 365 organizations who use the *external* access feature can participate in the same chat session. DLP policy enforcement in these cross-tenant conversations is based on the hosting tenant, which is the tenant that initiated the chat or thread.

For example, suppose UserA, UserB, and UserC are from Contoso, while UserX, UserY, and UserZ are from Fabrikam, and they participate in the same Teams group chat. Contoso's DLP policies apply to messages sent by Contoso users only when Contoso is the hosting tenant, such as when UserA, UserB, or UserC created the chat. In this case, Fabrikam's DLP policies aren't evaluated or enforced on messages sent by UserX, UserY, or UserZ, and Contoso's DLP policies aren't applied to those Fabrikam users.

Therefore, in a cross-tenant conversation, a user's home-tenant DLP policies don't automatically follow the user into a conversation hosted by another tenant.

For more information on using Microsoft Teams to chat with people external to your organization, see Manage external meetings and chat with people and organizations using Microsoft identities

> **Tip**

> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

DLP Licensing for Microsoft Teams

Data loss prevention capabilities include Microsoft Teams chat and channel messages, **including private channel messages** for:

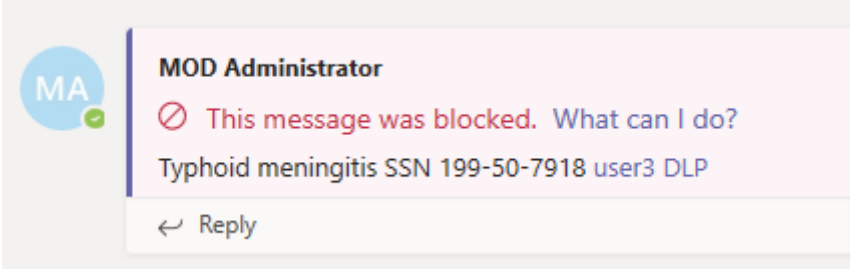
- Office 365 E5/A5/G5
- Microsoft 365 E5/A5/G5
- Microsoft 365 E5/A5/G5 Information Protection and Governance
- Microsoft 365 E5/A5/G5/F5 Compliance and F5 Security & Compliance

Office 365 and Microsoft 365 E3 include DLP protection for SharePoint, OneDrive, and Exchange. This also includes files that are shared through Teams because Teams uses SharePoint and OneDrive to share files.

Support for DLP protection in Teams Chat requires an E5 license.

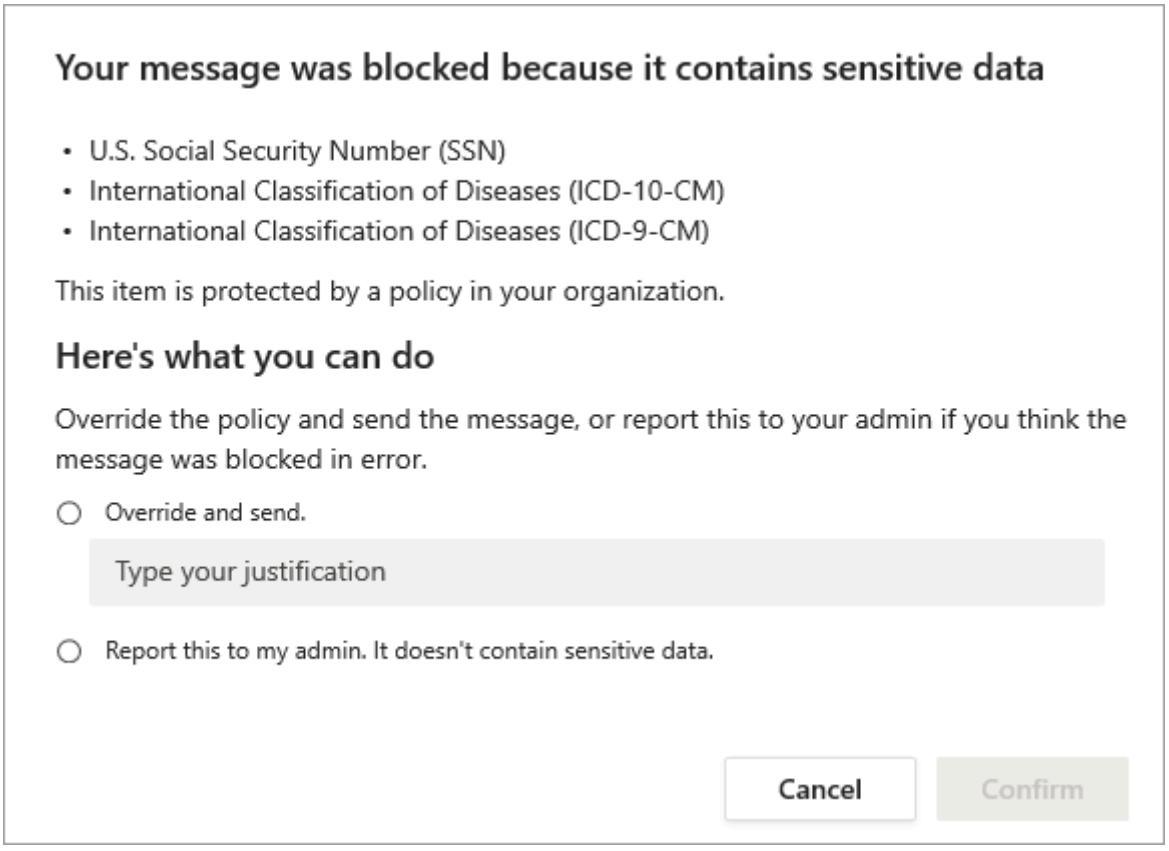
> **Important**
>
> For information on licensing, see Microsoft 365, Office 365, Enterprise Mobility + Security, and Windows 11 Subscriptions for Enterprises.

Scope of DLP protection



DLP protection is applied differently to Teams entities and is described in the table that follows.

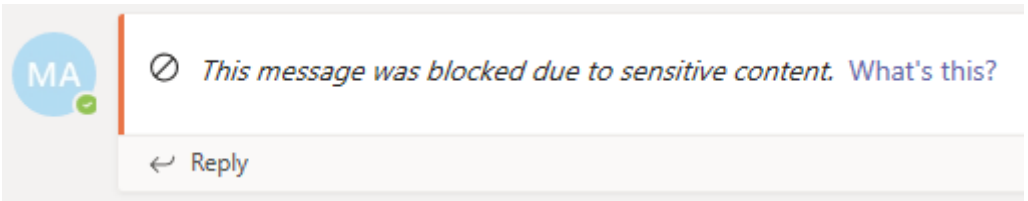
Expand table



Policy scope	Teams Entities	DLP Protection
Individual user accounts	1:1/n chats	Yes
Individual user accounts	Standard, private and shared channel messages	No
Security groups/distribution group/non-mail-enabled security group	1:1/n chats	Yes
Security groups/distribution group/non-mail enabled security group	Standard, private and shared channel messages	Yes
Microsoft 365 groups	1:1/n chats	Yes
Microsoft 365 groups	Standard, private and shared channel messages	Yes

Policy tips help educate users

Similar to how DLP policy tips work in Exchange, Outlook, SharePoint, OneDrive, and on Windows Devices, policy tips in Teams appear when an action triggers with a DLP policy. Here's an example of a policy tip:



Here, the sender attempted to share a social security number in a Microsoft Teams channel. The **What can I do?** Link opens a dialog box that provides options for the sender to resolve the issue. Notice that the sender can opt to override the policy or notify an admin to review and resolve the issue.

You can choose to allow users in your organization to override a DLP policy. When you configure your DLP policies, you can use the default policy tips, or customize policy tips for your organization.

Returning to our example, when a sender has shares a social security number in a Teams channel, here's what the recipient sees:

DLP protections are applied to the actual messages in the chat or channel thread. Message information is also shown in the short preview in Activity notifications that are created from chat or channel message. When there's a match to a DLP policy, the corresponding preview is hidden, and a "Preview Unavailable" message is shown instead of the blocked preview. An Activity entry is also generated for the sender if the message sent matched a DLP policy. Flagged and blocked messages, activities are created stating "Your message has been blocked".

DLP for Microsoft Teams does not send user notification emails like DLP for Exchange, SharePoint, and OneDrive. Instead, users only receive message flags as notifications.

To customize policy tips

To perform this task, you must be assigned a role that has permissions to edit DLP policies. To learn more, see Permissions in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal >**Data loss prevention** > **Policies**.
2. Select a policy, and then choose **Edit policy** (the pencil icon).
3. Navigate through the tool until you come to the **Customize advanced DLP rules** screen.
4. Either create a new rule, or edit an existing rule for the policy.
5. Scroll down to **User notifications** and set the **Use notifications to inform your users and help educate them on the proper use of sensitive info** toggle to **On**.
6. Under **Microsoft 365 services**, select **Notify users in Office 365 service with a policy tip**.
7. Under **Policy tips**, select **Customize the policy tip text**.
8. Specify the text you want to use for the policy tip.
9. If the policy tip applies to user activities in Microsoft Exchange and you want a dialog box to display the tip before an email is sent, select **Show the policy tip as a dialog for the end user before send**.
10. Choose **Save** and then **Next**.
11. On the **Policy mode** page, check the box next to **Show policy tips while in simulation mode** if desired.
12. Choose **Next**, choose **Submit**, and then choose **Done**.

Add Microsoft Teams as a location to existing DLP policies

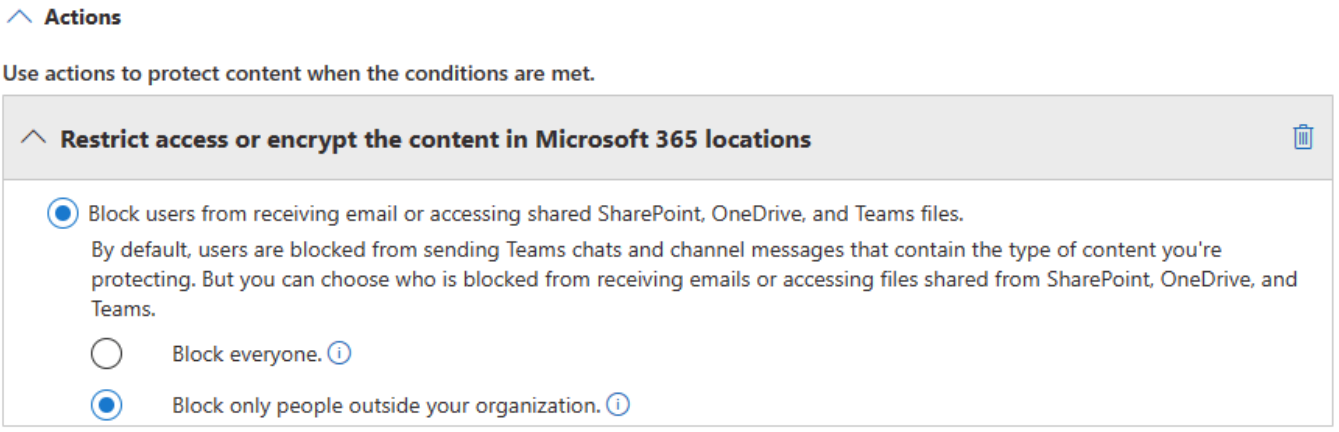
To perform this task, you must be assigned a role that has permissions to edit DLP policies. To learn more, see Permissions in the Microsoft Purview portal

1. Sign in to the Microsoft Purview portal > **Data loss prevention** > **Policies**.
2. Select a policy, and then choose **Edit policy** (the pencil icon).
3. Navigate through the tool until you arrive at the **Choose locations to apply the policy** page.
4. Select **Teams chat and channel messages**.
5. Choose **Next** and work your way through to the end of the process.
6. Choose **Submit**.

Allow approximately one hour for your changes to work their way through your data center and sync to user accounts.

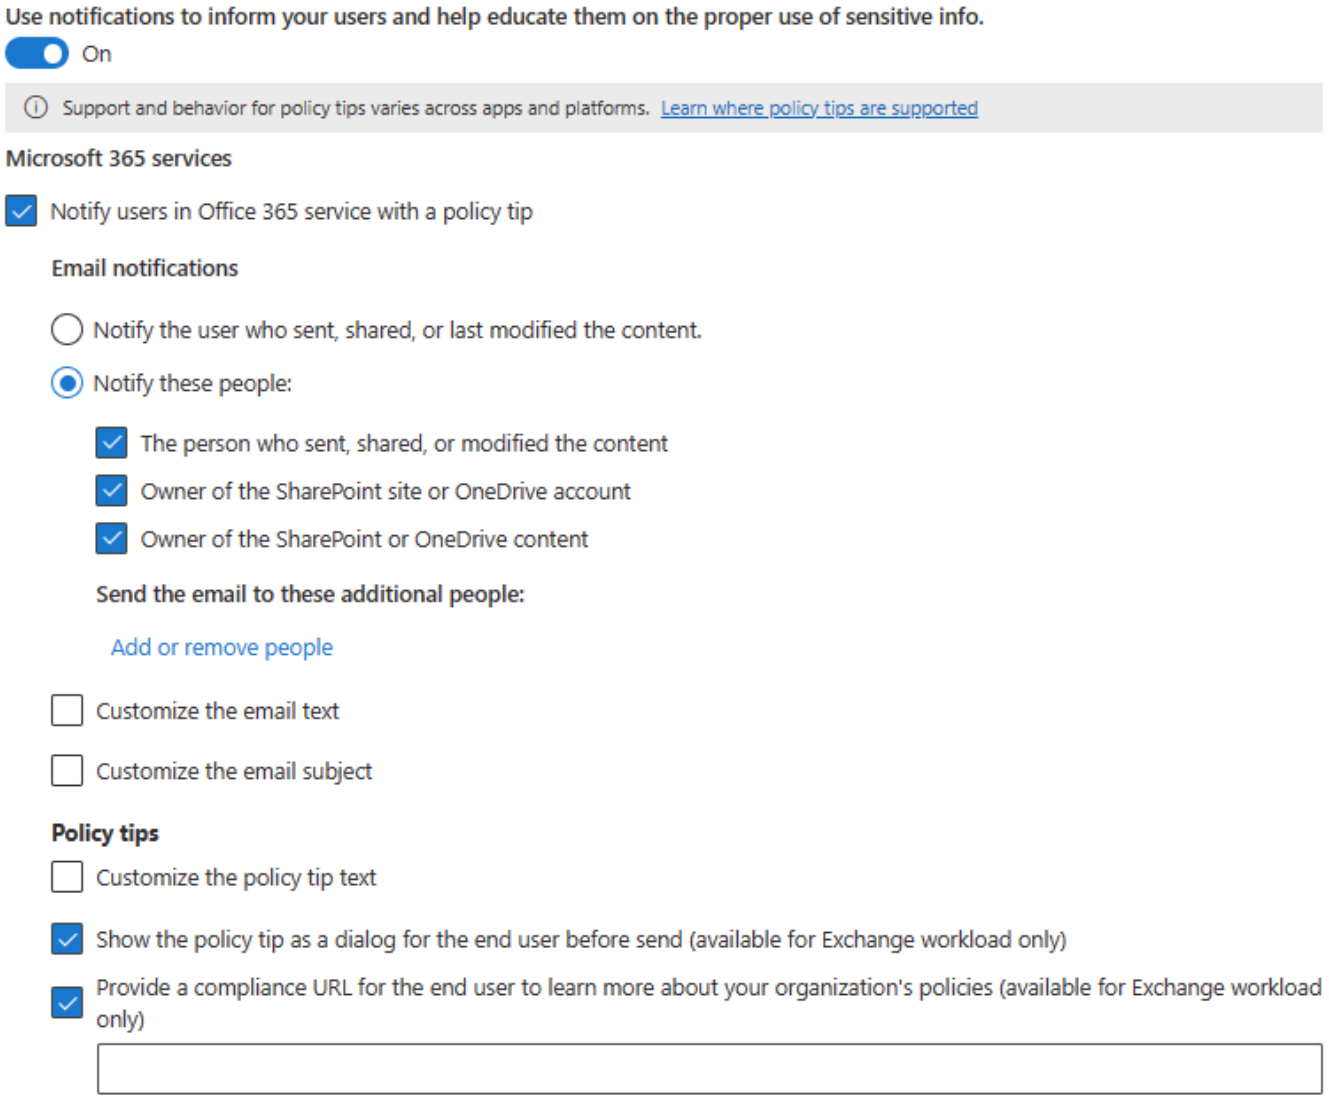
Define a new DLP policy for Microsoft Teams

For information about how to create and implement a new DLP policy, see Create and Deploy data loss prevention policies.



Prevent external access to sensitive documents

You can ensure that documents are protected until DLP scans and marks them as safe to share by marking new files as sensitive by default.



Recommended DLP policy structure

- **Conditions**
- **Content contains any of these sensitive information types**: [Select all that apply]
- **Content is shared from Microsoft 365** > **with people outside my organization**
- **Actions**
  - **Add an action**

- Restrict access or encrypt the content in Microsoft 365 locations > Block only people outside your organization

- Use notifications to inform your users and help educate them on the proper use of sensitive info > Notify users in Office 365 with a policy tip
- **Notify these people** [Select all that apply]
- **Policy tips** [Select all that apply]

> **Note**
>
> The sender address for incident reports is *no-reply@teams.mail.microsoft.com*.

Last updated on 08/28/2026

Learn about using Microsoft Purview Data Loss Prevention to protect interactions with Microsoft 365 Copilot, Copilot Chat, and Cowork

Microsoft Purview Data Loss Prevention (DLP) can help you protect interactions with Microsoft 365 Copilot, Copilot Chat, and Cowork in the following ways:

- **Restrict Microsoft 365 Copilot, Copilot Chat, and Cowork from using external web search when prompts contain sensitive data.** You can use DLP policies to prevent these Copilot experiences from sending sensitive information to external web services. When a prompt contains sensitive information types (SITs)—such as credit card numbers, passport numbers, Social Security numbers, or custom SITs defined by your organization—these experiences automatically block the use of external web search as a grounding source for that prompt. Instead, they continue to generate responses using permitted internal Microsoft 365 data sources. This prevents prompt text that matches the configured SITs from being sent to external search providers for that request.

- **Restrict Microsoft 365 Copilot, Copilot Chat, and Cowork from processing sensitive prompts.** You can create a DLP policy to help protect against the use of sensitive information types (SITs), such as credit card numbers, passport numbers, or Social Security numbers in prompts submitted in these Copilot experiences. This includes Microsoft-provided SITs and custom SITs that you create. This real-time control helps organizations reduce data leakage and oversharing risks. It prevents these experiences from returning a response when prompts contain sensitive data and from using that sensitive data for both internal and external web searches.

- **Restrict Microsoft 365 Copilot, Copilot Chat, and Cowork from processing sensitive files and emails.** You can create a DLP policy to prevent these Copilot experiences from using files and emails that have sensitivity labels when generating responses.

- **Restrict Microsoft 365 Copilot and Copilot Chat from processing external email (preview).** You can prevent Microsoft 365 Copilot and Copilot Chat from using emails sent from external domains as grounding data for responses. When this control is enabled, Copilot excludes external emails received by users from being referenced or summarized during

prompt processing, while continuing to use internal Microsoft 365 data sources where permitted. This protection helps organizations reduce the risk of prompt injection and untrusted data influence. Copilot responses are grounded only in content from trusted internal sources.

> **Important**
>
> You can't use both content contains sensitive info types and content contains sensitivity labels conditions in the same rule. You can create a rule for each condition in the same policy, but not in the same rule.

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions

Accounts with one of the following roles or role groups can create or edit a DLP policy for the Microsoft 365 Copilot and Copilot Chat location:

- **Microsoft Entra AI Admin** - Role for managing all aspects of Microsoft 365 Copilot and AI-related enterprise services in Microsoft 365.
- **Purview Data Security AI Admin** - Role for editing Data Loss Prevention policies related to Copilot and viewing AI content in Data Security Posture Management. This role doesn't have access to read prompts and responses of AI interactions.
- **Purview Data Security AI Admins** - Use this group to assign editing capabilities for Data Loss Prevention policies related to Copilot and viewing AI content in Data Security Posture Management. Review the role description for access details. It contains the Data Security AI Admin role.
- **Purview Compliance Administrator**
- **Purview Compliance Data Administrator**
- **Purview Information Protection**
- **Purview Information Protection Admin**
- **Purview Security Administrator**

- **Microsoft Entra Global Admin** - Role for managing all aspects of Microsoft Entra ID and Microsoft services that use Microsoft Entra identities.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Block sensitive information types in web search

To prevent Microsoft 365 Copilot, Copilot Chat, and Cowork from sending sensitive data to external web search providers when grounding responses:

1. Sign in to the Microsoft Purview portal.
2. Go to **Data Loss Prevention** > **Policies** and select **+ Create policy**.
3. Select the **Custom** template, then **Custom policy**.
4. On the **Locations** page, set the **Microsoft 365 Copilot and Copilot Chat** location to on.
5. Add a rule with the **Content contains** > **Sensitive information types** condition and choose the SITs you want to detect.
6. In the same rule, set the action to **Prevent Copilot from processing content** > **Performing Web Searches**.
7. Save and turn on the policy.

When a user prompt contains the configured SITs, Copilot and Cowork block external web search as a grounding source and continue to generate the response using allowed internal Microsoft 365 data sources.

Block SITs in web search use case example

Contoso wants employees to use Microsoft 365 Copilot for productivity, but doesn't want sensitive customer data sent to external web search providers when Copilot grounds responses on the web.

To meet this business need, Contoso configures a DLP policy as follows:

1. Targets the **Microsoft 365 Copilot and Copilot Chat** policy location.

2. Adds a rule with the **Content contains** > **Sensitive information types** condition that detects the SITs representing sensitive customer data.

3. Sets the rule action to **Prevent Copilot from processing content** > **Performing Web Searches**.

When a user submits a prompt containing those SITs, Copilot doesn't send the prompt to external web search providers. Copilot still returns a response grounded in internal Microsoft 365 data sources where the user has access.

Block sensitive information types in prompts

This feature is in preview and is rolling out to all tenants with access to Microsoft 365 Copilot and Copilot Chat. Check whether rollout has reached your tenant. It's available in Microsoft 365 Copilot, Copilot Chat, Cowork, and Copilot in Word, Excel, and PowerPoint.

To set this up, create DLP policies that use the **Microsoft 365 Copilot and Copilot Chat** policy location with the **Content contains** > **Sensitive information types** condition. This policy prevents Copilot and Cowork from returning a response when prompts contain sensitive data. Only out-of-the-box and custom SITs are currently supported.

> **Tip**
>
> During preview, the user messaging in Word, Excel, PowerPoint might not clearly state that the interaction with Copilot in those products is blocked due to an organizational policy. The sensitive prompt is still restricted, and Copilot won't provide a response.

Block SITs in prompts use case example

Contoso encourages their employees to use Microsoft 365 Copilot to enhance productivity, but they don't want their users placing Canada physical addresses or EU debit card numbers into prompts.

To meet this business need, Contoso creates a DLP policy that targets the Microsoft 365 Copilot and Copilot Chat location and has a rule that uses the **Content contains** > **Sensitive information types** > **Canada physical addresses** or **EU debit card numbers** condition to identify prompts that contain those SITs. The actions in the rule are configured to **Restrict Copilot from processing content** > **Processing prompts**.

When a user attempts to submit a prompt that contains either of these sensitive information types, they receive a message indicating that the request can't be completed because it contains

sensitive information that the organization has blocked Microsoft 365 Copilot from using.

Block files and emails with sensitivity labels from being processed

This feature is available in Microsoft 365 Copilot, Copilot Chat, Cowork, and Copilot in Word, Excel, and PowerPoint.

To set this up, create DLP policies that use the **Microsoft 365 Copilot and Copilot Chat** policy location with the **Content contains** > **Sensitivity labels** condition to exclude items from being processed. Identified items still appear in the citations of the response, but Copilot and Cowork don't access or use the content of the item in the response.

Block items with sensitivity labels example use case

Contoso establishes and applies a sensitivity label taxonomy to their data. The taxonomy includes these labels:

- **Highly Confidential**
- **Confidential**
- **Internal**
- **Public**
- **Personal**

They deploy Microsoft 365 Copilot and Copilot Chat to help users find and use Contoso enterprise information in their organization. They want to minimize the risk of General Data Protection Regulation (GDPR) data being included in Microsoft 365 Copilot and Copilot Chat summaries and also exclude private information from summaries. They create a DLP policy that uses the **Microsoft 365 Copilot and Copilot Chat** policy location with the **Content contains** > **Sensitivity labels** condition to exclude items that have the **Personal** sensitivity label from being processed in the response summary and also to exclude items that have the **Highly Confidential** sensitivity label from being processed in the response summary.

Coverage of email and file content

The DLP for **Microsoft 365 Copilot and Copilot Chat** policy location supports specific content that Copilot processes across various experiences.

Microsoft 365 Copilot and Copilot Chat rule configured to protect items with sensitivity labels supports:

- File items, which are stored and items that are actively open. For more information on supported file types, see: file types supported by sensitivity labels.
- Emails sent on or after January 1, 2025.
- Calendar invites aren't supported.

> **Note**
>
> When a file is open in Word, Excel, or PowerPoint and has a sensitivity label for which DLP policy is configured to prevent processing by Microsoft 365 Copilot and Copilot Chat, the skills in these apps are disabled. Certain experiences that don't reference file content or that aren't using any large language models aren't currently blocked on the user experience.

Block external email from being processed (preview)

This feature is in preview. It applies to Microsoft 365 Copilot and Copilot Chat, including email summarization and reasoning experiences that use email data.

To set this up, create DLP policies that use the **Microsoft 365 Copilot and Copilot Chat** policy location with the **Email is received from** > **External users** condition. When the policy detects that an email was received from a sender outside your organization's accepted domains, Copilot excludes that email from grounding, summarization, and citation. Copilot continues to use internal Microsoft 365 data sources where permitted, and the user's access to the email itself isn't affected.

The policy evaluates email metadata only - specifically, the sender domain compared against your tenant's accepted domains. The body of the email isn't inspected.

Block external email use case example

Contoso wants employees to keep using Microsoft 365 Copilot for productivity, but is concerned that external email could carry untrusted instructions or prompt-injection content. They want Copilot to ground responses only in trusted internal data.

To meet this need, Contoso creates a DLP policy that targets the Microsoft 365 Copilot and Copilot Chat location with a rule that uses the **Email is received from** > **External users** condition. The action is configured to **Prevent Copilot from processing content**.

When a user prompts Copilot to summarize their inbox or reason over recent email, external emails are excluded from grounding. Copilot returns a response based on internal email and other permitted Microsoft 365 sources, and the user sees a message that some content was excluded by an organizational policy.

Files uploaded in prompts

You can upload files when you craft a prompt for Microsoft 365 Copilot to analyze. DLP can't scan the contents of files that you upload directly into prompts, so evaluation of the uploaded file for sensitive data doesn't occur. DLP only checks the text you type into the prompt itself.

Supported conditions and actions

The **Microsoft 365 Copilot and Copilot Chat** policy location supports the following conditions and actions:

Expand table

Conditions	Supported policy actions	Description
Content contains > Sensitivity labels	**Prevent Copilot from processing content**	Detects when a file or an email in Exchange has a chosen sensitivity label. Copilot and Cowork don't process the content of the item or use it in the response summary, but the item could be available in the citations of the response.
Content contains > Sensitive information types	**Prevent Copilot from processing content > Processing prompts**	Detects when the text entered directly into a Copilot or Cowork prompt contains chosen sensitive information types. The experience doesn't respond to the prompt. The prompt isn't used for internal or web searches.
Content contains > Sensitive information types	**Prevent Copilot from processing content > Performing Web Searches**	Detects when the text entered directly into a Copilot or Cowork prompt contains chosen sensitive information types. The experience blocks the use of external web search as a grounding source for that prompt.
Email is received from > External users	**Prevent Copilot from processing content**	Detects when an email was received from a sender outside your organization's accepted domains. The external email is excluded from being used by Copilot for grounding, summarization, or citation. Email body content isn't inspected; only sender metadata is evaluated.

> **Note**

All Microsoft 365 Copilot prompts run in the security context of the user who initiates the prompt. This means for a user to see an item in a prompt response, they must first have the necessary permissions to access the content of the item. You can then use the **Microsoft 365 Copilot and Copilot Chat** policy location feature to exclude items from being processed in the response summary.

In Word, Excel, and PowerPoint the **Microsoft 365 Copilot and Copilot Chat** policy to prevent Copilot from processing content is evaluated at file open. If a sensitivity label is applied mid-session, the policy will be enforced starting the next time the file is opened.

Customize the link in Copilot policy tips

When a DLP rule blocks a Copilot interaction, the standard Copilot message includes a **Learn about access restrictions** link. By default, the link opens Microsoft Learn. You can configure the rule so that the link opens an existing page that explains your organization's policies or tells users where to get help.

> **Tip**
>
> Using a URL that clearly explains why the policy is in place can help users understand the reason for a block.

You don't need to create a new website for this setting. You can use an existing SharePoint page, help desk page, compliance site, or other webpage that the affected users have permission to access. Microsoft Purview doesn't create or host the destination page.

To customize the link:

1. Create or edit a DLP policy for the **Microsoft Copilot and Chat** location.
2. In the rule's user notification settings, turn on **Policy Tips**.
3. Select **Provide a compliance URL for the end user to learn more about your organization's policies**.
4. Enter the full URL of the existing page, including `https://` and the domain name. For example, enter `https://contoso.sharepoint.com/sites/compliance/data-handling`, not `/sites/compliance/data-handling`.
5. Save the rule.

When the rule blocks an interaction, the **Learn about access restrictions** link opens the page that you specified. Only the link destination changes. The standard Copilot block message, the link text, and the DLP enforcement action remain unchanged. If you don't configure a compliance URL, the link continues to open Microsoft Learn.

Availability

- The **Microsoft 365 Copilot and Copilot Chat** policy location is only available in the **Custom** policy template.
- When you select the **Microsoft 365 Copilot and Copilot Chat** policy location, all other locations for that policy are disabled.
- DLP alerts, DLP notifications, and policy simulation mode are supported.
- Updates to a DLP policy can take up to four hours to reflect in Microsoft 365 Copilot and Copilot Chat experience.

Admin units

The **Microsoft 365 Copilot and Copilot Chat** policy location doesn't support **Admin units**.

Learn about the default data loss prevention policy for Microsoft 365 Copilot location

To help you get started with Microsoft Purview data loss prevention (DLP) for the Microsoft 365 Copilot location, Microsoft created a default DLP policy called **Default DLP policy - Protect sensitive M365 Copilot interactions**. The policy is referenced in the **Safeguard sensitive data in Copilot interactions** banner.

> ⓘ **Note**
>
> See these message center announcements MC1182689 and MC1181998.

> ⓘ **Important**
>
> The default policy detects sensitive information types (SIT) in user prompts. The **Default DLP policy - Protect sensitive M365 Copilot interactions** is initially configured to **Run the policy in simulation mode** > **Show policy tips while in simulation mode**. This means that the event will only be logged. If you want to block processing of the prompt, you must change the state of the policy to enforce mode.

You can edit this policy to better suit your organization's needs. To edit the default policy for better performance or to delete it, use an account with **DLP Compliance Management** permissions. For more information, see Permissions. For example, you can:

- Change the **Policy mode** to **Turn the policy on immediately** which enforces the block prompt processing action or you can **Leave the policy turned off**.
- Delete it if you don't need it.
- Add or remove sensitive information types to the policy.
- Add or remove users and groups.
- Remove sensitive information types that aren't relevant to your organization to reduce false positives and improve performance.

You can perform these actions through both the simplified experience by selecting **Get started** in the banner and through the full policy editor flow by selecting the policy in the list of policies and selecting the edit button.

Microsoft recommends that you at least edit the policy to turn on **Incident reports** and add your security team as recipients of the email notifications, so they're aware of potential

sensitive information being shared in the prompts.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

What does the policy do?

The policy is in simulation mode by default, which means it doesn't block the prompt but generates an alert and sends an email to the admin (if configured). This approach helps you understand the impact of the policy and make necessary adjustments before enforcing it. It initially includes all tenant users and groups in scope and detects these SITs:

- ABA Routing Number
- Argentina National Identity (DNI) Number
- Argentina Unique Tax Identification Key (CUIT/CUIL)
- Australia Bank Account Number
- Australia Driver's License Number
- Australia Medical Account Number
- Australia Passport Number
- Australia Tax File Number
- Australian Business Number
- Australian Company Number
- Austria Tax Identification Number
- Azure SAS
- Azure Storage Account Key (Generic)
- Belgium National Number
- Brazil CPF Number
- Brazil Legal Entity Number (CNPJ)
- Brazil National ID Card (RG)
- Canada Bank Account Number

- Canada Driver's License Number
- Canada Health Service Number
- Canada Personal Health Identification Number (PHIN)
- Canada Social Insurance Number
- Chile Identity Card Number
- Colombia National ID
- Credit Card Number
- Croatia Personal Identification (OIB) Number
- Czech Personal Identity Number
- Denmark Personal Identification Number
- Drug Enforcement Agency (DEA) Number
- Estonia Personal Identification Code
- Finland National ID
- France National ID Card (CNI)
- France Social Security Number (INSEE)
- Germany Identity Card Number
- Germany Tax Identification Number
- Germany Value Added Tax Number
- Greek Tax identification Number
- Hungarian Social Security Number (TAJ)
- India GST Number
- India Permanent Account Number (PAN)
- India Unique Identification (Aadhaar) Number
- International Banking Account Number (IBAN)
- IP Address
- IP Address v4
- IP Address v6
- Ireland Passport Number
- Israel Bank Account Number
- Italy Fiscal Code
- Italy Passport Number
- Japan Bank Account Number
- Japan Passport Number
- Japanese My Number Personal
- Latvia Personal Code
- Lithuania Personal Code
- Luxembourg National Identification Number (Non-natural persons)
- Malaysia Identity Card Number
- Medicare Beneficiary Identifier (MBI) card
- Mexico Unique Population Registry Code (CURP)
- Netherlands Citizen's Service (BSN) Number

- Netherlands Tax Identification Number
- Netherlands Value Added Tax Number
- New Zealand bank account number
- New Zealand Inland Revenue number
- New Zealand Ministry of Health Number
- New Zealand Social Welfare Number
- Norway Identity Number
- Poland National ID (PESEL)
- Poland Tax Identification Number
- Polish REGON Number
- Portugal Tax Identification Number
- Saudi Arabia National ID
- Singapore National Registration Identity Card (NRIC) Number
- Slovakia Personal Number
- Slovenia Tax Identification Number
- South Africa Identification Number
- Spain DNI
- Spain Driver's License Number
- Spain Tax Identification Number
- Sweden National ID
- SWIFT Code
- Taiwan Passport Number
- Thai Population Identification Code
- Turkish National Identification number
- U.K. National Health Service Number
- U.K. National Insurance Number (NINO)
- U.K. Unique Taxpayer Reference Number
- U.S. / U.K. Passport Number
- U.S. Bank Account Number
- U.S. Driver's License Number
- U.S. Individual Taxpayer Identification Number (ITIN)
- U.S. Social Security Number (SSN)

The policy doesn't generate any policy tips for end users, but it does generate an Alert event. It also triggers a low severity email to the admin (added in the policy). Administrators can view the activities and edit the policy details by signing in to the Microsoft Purview portal.

Admins can view this policy in the Microsoft Purview portal. Go to **Data Loss prevention** > **Policies**.

Get started with data loss prevention for on-premises repositories

> **Note**
>
> There's a new version of the information protection scanner. For more information, see Upgrade the Microsoft Purview Information Protection scanner.

This article walks you through the prerequisites and configuration for using the Microsoft Purview Data Loss Prevention on-premises repositories location in a DLP policy.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Before you begin

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

> **Important**
>
> All users who contribute to the scanned location, either by adding files or consuming files, need to have a license, not just the scanner user.

Permissions

Data from DLP can be viewed in activity explorer. There are four roles that grant permission to activity explorer, the account you use for accessing the data must be a member of any one of them.

- Compliance administrator
- Security administrator
- Compliance data administrator
- Global administrator

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Roles and Role Groups

There are roles and role groups in the Microsoft Purview portal that you can test to fine-tune your access controls.

Here's a list of applicable roles. To learn more about them, see Permissions in the Microsoft Purview portal.

- Information Protection Admin
- Information Protection Analyst
- Information Protection Investigator
- Information Protection Reader

Here's a list of applicable role groups. To learn more, see Permissions in the Microsoft Purview portal.

- Information Protection
- Information Protection Admins
- Information Protection Analysts
- Information Protection Investigators
- Information Protection Readers

DLP on-premises repositories prerequisites

Before you deploy DLP on-premises repositories, ensure that the following prerequisites are met:

- The Microsoft Purview Information Protection scanner implements DLP policy matching and policy enforcement. The scanner is installed as part of the information protection client, so

your installation must meet all the prerequisites for the rights management encryption service, the information protection client, and the information protection scanner.

- Deploy the client and scanner. For more information, see, Install or upgrade the information protection client and, Configuring and installing the information protection scanner.
- There must be at least one label and policy published in the tenant, even if all your detection rules are based on sensitive information types only.

Deploy the DLP on-premises scanner

Perform the following steps to deploy the DLP on-premises scanner:

1. Sign in to the Microsoft Purview portal.

2. Follow the procedures in Install or upgrade the information protection client.

3. Follow the procedures in Configuring and installing the information protection scanner to complete the scanner installation.
   a. You must create a content scan job and specify the repositories that host the files to be evaluated by the DLP engine.
   b. Enable DLP rules in the created content scan job, and set the **Enforce** option to **Off** (unless you want to proceed directly to the DLP enforcement stage).

4. Verify that your content scan job is assigned to the right cluster. If you haven't created a content scan job, create a new one and assign it to the cluster that contains the scanner nodes.

5. Connect to the Microsoft Purview portal and add your repositories to the content scan job that will perform the scan.

6. Do one of the following to run your scan:
   a. Set the scanner schedule
   b. Use the manual **Scan Now** option in the portal
   c. Run **Start-Scan** PowerShell cmdlet

   > **Important**
   >
   > Remember that the scanner runs a delta scan of the repository by default and files that were scanned in the previous scan cycle will be skipped, unless the file was changed or you initiated a full rescan. A full rescan can be initiated by using the **Rescan all files** option in the UI or by running **Start-Scan -Reset**.

7. Open the Microsoft Purview portal > Data Loss Prevention > Policies.

8. Choose + **Create policy** and create a test DLP policy. See Create and Deploy data loss prevention policies if you need help with creating a policy. Be sure to **Run the policy in simulation mode** until you're comfortable with this feature. Use these parameters for your policy:
   a. Scope the DLP on-premises repositories rule to specific locations if needed. If you scope **locations** to **All**, all files scanned will be subject to the DLP rule matching and enforcement.
   b. When specifying the locations, you can use either exclusion or inclusion list. You can either define that the rule is relevant only to paths matching one of the patterns listed in inclusion list or, all files, except the files matching the pattern listed in inclusion list. No local paths are supported. Here are some examples of valid paths:

      - \\server\share
      - \\server\share\folder1\subfolderabc
      - *\folder1
      - *secret*.docx
      - *secret*.*
      - https:// sp2010.local/sites/HR
      - https://*/HR

   a. Here are some examples of unacceptable values use:

      - *
      - *\a
      - Aaa
      - c:\
      - C:\test

> **Important**
>
> The *exclusion* list takes precedence over the *inclusions* list.

Viewing DLP alerts

Use the following steps to view alerts for your on-premises DLP policies:

1. Open Data loss prevention in the Microsoft Purview portal and select **Alerts**.

2. Refer to the procedures in Get started with the data loss prevention Alerts dashboard and Investigate data loss incidents with Microsoft Defender XDR to view alerts for your on-premises DLP policies.

Viewing DLP data in activity explorer and audit log

> **Note**
>
> The Information Protection scanner requires that auditing be enabled. Auditing is enabled by default in Microsoft 365.

1. Open the Data classification page for your domain in the Microsoft Purview portal and select **Activity explorer**.
2. Refer to the procedures in Get started with Activity explorer to access and filter all the data for your on-premises scanner locations.
3. Open the Audit log. The DLP rule matches are available in the Audit log UI or accessible by Search-UnifiedAuditLog in PowerShell.

Next steps

Now that you've deployed a test policy for DLP on-premises locations and can view the activity data in Activity explorer, create production DLP policies to protect your sensitive items.

- Using DLP on-premises

Use the data loss prevention on-premises repositories location

To help familiarize you with Microsoft Purview Data Loss Prevention on-premises features and how they surface in DLP policies, we've put together a couple of scenarios for you to follow. These scenarios show you how to discover files that match DLP rules across Activity Explorer, the audit log, and the information protection scanner, and how to enforce protective actions on on-premises file shares and SharePoint document libraries. Specifically, the first scenario covers where DLP rule-match data appears when scanning on-premises repositories, and the second scenario walks through enabling policy enforcement so that protective actions are applied to scanned files.

> **Important**
>
> These DLP on-premises scenarios are not the official procedures for creating and tuning DLP policies. Refer to the following topics when you need to work with DLP policies in general situations:
>
> - Learn about data loss prevention
> - Create and Deploy data loss prevention policies

Scenario: Discover files matching DLP rules

Data from DLP surfaces in several areas:

View on-premises repository events in Activity Explorer

DLP reports rule matches are available in Activity Explorer.

View on-premises repository events in the Microsoft 365 audit log

The DLP rule matches are also available in the Audit log UI (see Search the audit log) and are accessible via PowerShell through theSearch-UnifiedAuditLog.

Use the information protection scanner to inspect matching files

Discovery data is available in a local report in .csv format and is stored under:

%localappdata%\Microsoft\MSIP\Scanner\Reports\DetailedReport_%timestamp%.csv report.

Look for the following columns:

- DLP Mode
- DLP Status
- DLP Comment
- DLP Rule Name
- DLP Actions
- Owner
- Current NTFS Permissions (SDDL)
- Applied NTFS Permissions (SDDL)
- NTFS permissions type

Scenario: Enforce DLP rule

If you want to enforce DLP rules on scanned files, enforcement must be enabled both on the content scan job and at the policy level in DLP.

Configure DLP to enforce policy actions

To turn on enforcement for your DLP policy targeting on-premises repositories, complete the following steps:

1. Sign in to the Microsoft Purview portal
2. Navigate to **Data loss prevention** > **Policies**.
3. Select the DLP policy that is targeted to the on-premises location repositories you have configured for the scanner.
4. Edit the policy.
5. On the **Policy Mode** page, select **Turn the policy on immediately**.
6. Choose **Next** and then choose **Submit**.
7. Choose **Done**.

Get started with data loss prevention policies for Fabric and Power BI

This article provides a general overview of Microsoft Purview Data Loss Prevention (DLP) policies for Fabric and Power BI. The target audience is Fabric administrators, security and compliance teams, and Fabric data owners. If you're a data owner and want to know how to respond when a policy tip tells you your item has a DLP policy match, see Respond to a DLP policy match in Fabric. If you're a Fabric admin or a security and compliance admin and need to audit alerts on DLP policy matches, see Monitor DLP policy matches in Fabric.

Overview

To help organizations detect and protect their sensitive data, Fabric supports Microsoft Purview Data Loss Prevention (DLP) policies. When a DLP policy for Fabric detects a supported item type containing sensitive information, the policy triggers the configured actions. These actions can include:

- Attaching a policy tip to the item that explains the nature of the sensitive content.
- Registering an alert for administrators on the data loss prevention **Alerts** page in the Microsoft Purview portal.
- Sending email alerts to administrators and specified users.
- Restricting access to the item.

For more detail, see How do DLP policies for Fabric and Power BI work.

For DLP policies, a *member of the organization* means a user with UserType = Member. This includes users who sign in with an external account. Because their UserType is Member, they're treated as internal users. In contrast, users with UserType = Guest are considered external. The **Block only people outside your organization** setting applies to these Guest users.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Licensing and permissions

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions

You can view data from DLP for Fabric and Power BI in Activity explorer. Four roles grant permission to Activity explorer; the account you use for accessing the data must be a member of any one of them.

To view the Activity explorer, your account must be a member of any of the following roles:

- Compliance administrator
- Security administrator
- Compliance data administrator

Billing

DLP evaluation workloads impact capacity consumption. For information about how this consumption is metered and billed, see Learn about Microsoft Purview billing models.

How DLP policies for Fabric and Power BI work

You define a DLP policy in the data loss prevention section of the Microsoft Purview portal. In the policy, you specify the conditions, such as which sensitivity labels and sensitive info types you want to detect. You also specify the actions that the system takes when it detects a policy match.

When DLP policies evaluate a supported item type, they check if it matches the conditions in a DLP policy. If it does, the policy's specified actions take place. DLP policies start with the following actions:

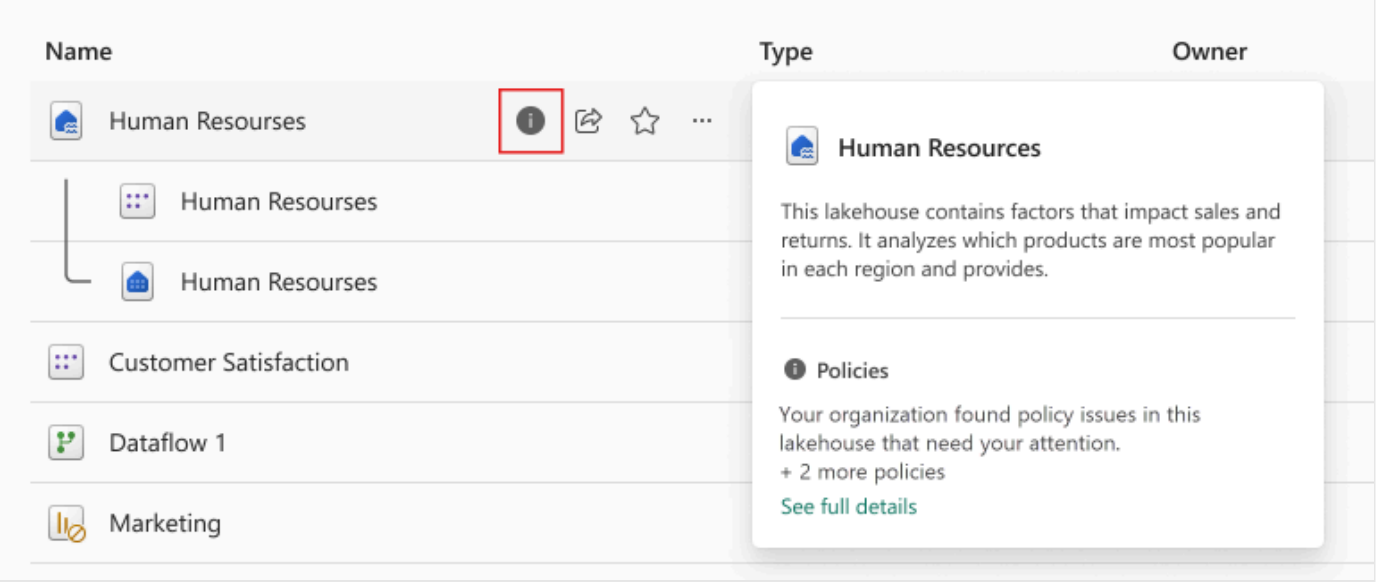
Semantic models

DLP policies evaluate a semantic model whenever one of the following events occurs:

- Publish
- Republish
- On-demand refresh

- Scheduled refresh

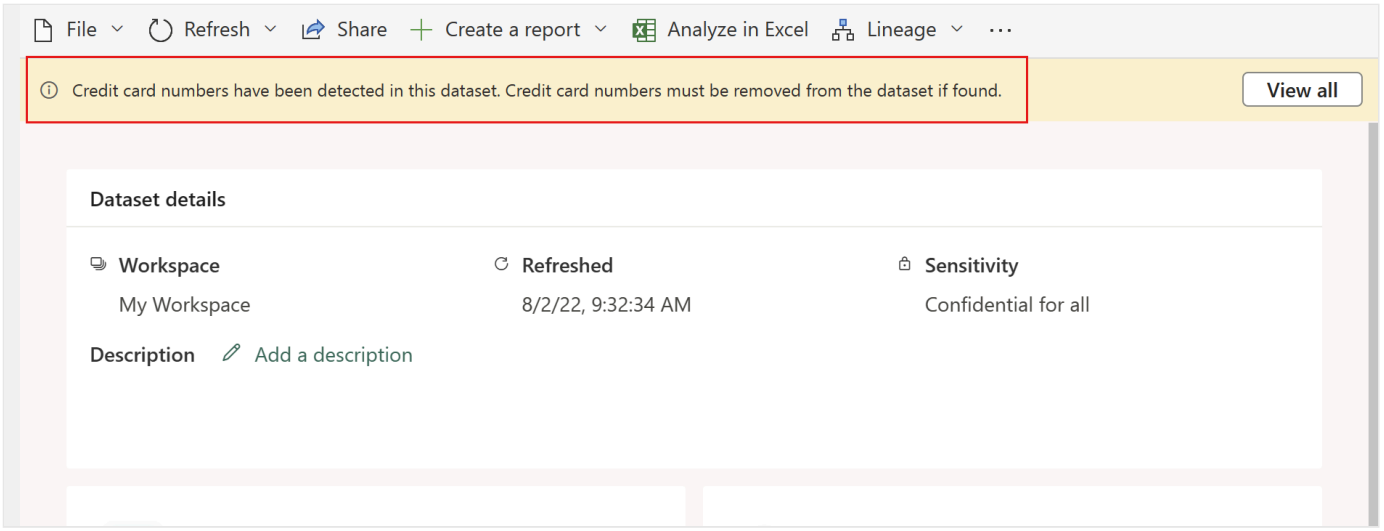
> **Note**
>
> DLP evaluation of the semantic model doesn't occur if either of the following is true:
>
> - An account using service principal authentication initiates the event (publish, republish, on-demand refresh, scheduled refresh).
> - The semantic model owner is a service principal.



Fabric Items

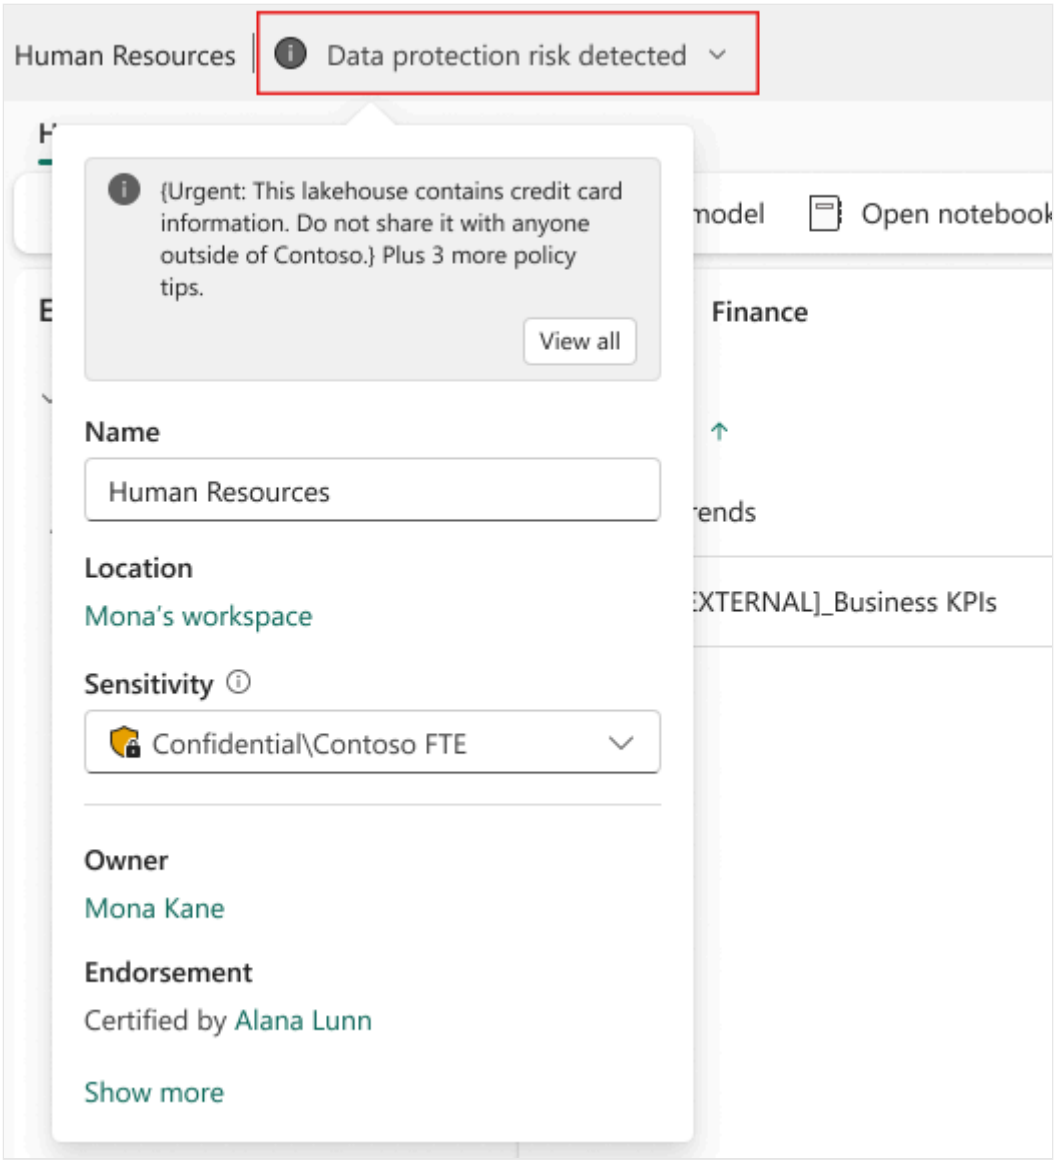
DLP policies evaluate a Fabric item, such as a lakehouse, SQL database, or Mirrored database, when the data within it changes. Changes include getting new data, connecting a new source, adding tables, updating existing tables, and more.

What happens when a Fabric DLP policy flags an item



When a DLP policy detects an issue with an item, it takes the following actions:

If you enable **user notification** in the policy, Fabric marks the item with an icon that indicates a DLP policy detected an issue with the item. When you hover over the icon, a hover card appears that provides an option to see the full details in a side panel. For more information about what you see in the side panel, see Respond to a DLP violation in Fabric.



For semantic models, opening the details page shows a policy tip that explains the policy violation and how to handle the type of sensitive information detected. Selecting **View all** opens

a side panel with all the policy details.

> **Note**
>
> If you hide the policy tip, it doesn't get deleted. It appears the next time you visit the page.

For Fabric items, such as lakehouses, the indication appears in the header in edit mode. Opening the flyout makes it possible to see more details about the policy tips affecting the item. Selecting **View all** opens a side panel with all the policy details.

If you enable alerts in the policy, an alert records on the data loss prevention **Alerts** page in the Microsoft Purview portal. If configured, an email is sent to administrators and/or specified users. For more information, see Monitor and manage DLP policy violations.

Supported actions

When Fabric items or semantic models meet the conditions in a DLP policy, the actions defined in the policy are applied. DLP policies for Fabric and Power BI support three actions:

- Notify the user through a policy tip.
- Generate an alert. Administrators and users can receive alert emails. Additionally, administrators can monitor and manage alerts on the **Alerts** tab in the Purview portal.
- Restrict access (preview). When you configure a policy with the restrict access action and a policy match occurs, the policy restricts access to the data owners or to members of the organization, depending on the policy configuration. All other users lose access to the item.

For information about what triggers DLP evaluation, see How DLP policies for Fabric and Power BI work.

Supported item types

DLP policies for Fabric and Power BI currently support the following item types.

- Semantic models
- Lakehouses
- Warehouses
- KQL databases
- Mirrored databases
- SQL databases
- Cosmos databases

See Considerations and limitations for exceptions.

Supported condition types

DLP policy rules for Fabric and Power BI support sensitivity labels and a subset of sensitive info types (see considerations and limitations) as conditions. Learn more about Purview Sensitive Info Types and confidence levels.

Configure a DLP policy for Fabric and Power BI

For information about creating a DLP policy for Fabric or Power BI, see Help prevent sharing Power BI reports with credit card numbers and adapt it to your own scenario.

Gain visibility into DLP activity and adoption

After deploying DLP policies, administrators can use Fabric governance experiences in the OneLake catalog to understand how data loss prevention policies are being used across their organization. These insights can help organizations:

- Identify workspaces and items evaluated by DLP policies.
- Understand where sensitive information is being detected.
- Track policy adoption across business units and workspaces.
- Prioritize remediation of high-risk data assets.
- Measure the effectiveness of DLP investments and governance programs.

Together, DLP insights help security and compliance teams move beyond individual policy violations and understand their overall data protection posture.

Considerations and limitations

- DLP policies apply to workspaces. Only workspaces hosted in Fabric or Premium capacities are supported. For more information, see Microsoft Fabric concepts and licenses.
- DLP policy templates aren't supported for Fabric DLP policies. When creating a DLP policy for Fabric, choose the custom policy option.
- DLP policies for Fabric aren't supported for sample semantic models, streaming datasets, or semantic models that connect to their data source via DirectQuery or live connection. This limitation includes semantic models with mixed storage, where some of the data comes via import-mode and some comes via DirectQuery.
- DLP policies for Fabric apply only on data in tables stored in Delta format.
- Delta tables are treated as text files for the purpose of scanning considerations.
- DLP policies for Fabric support all the primitive Delta types except *timestamp_ntz*.
- DLP policies for Fabric aren't supported for the following Delta Parquet data types:
  - Binary, timestamp_ntz, Struct, Array, List, Map, Json, Enum, Interval, Void.
  - Data with LZ4, Zstd, and Gzip compression codecs.
- Advanced classifiers, such as exact data match (EDM), trainable classifiers, credential classifiers, and named entities aren't supported by DLP for Fabric. If you select an advanced classifier in the condition of a policy, the policy returns no results even if the item contains data that satisfies the advanced classifier. Other classifiers specified in the policy return results if any.
- DLP policies for Fabric aren't supported in the China North region. See How to find the default region for your organization to learn how to find your organization's default data region.
- Onboarding a new tenant to DLP can take a few hours, depending on the number of supported workspaces that are being onboarded.

Last updated on 07/22/2026

Get started with oversharing pop-ups in Outlook

When you configure appropriate Microsoft Purview Data Loss Prevention (DLP) policy, DLP checks email messages before they're sent for any labeled or sensitive information and apply the actions defined in the DLP policy. Oversharing pop-ups require a Microsoft 365 **E5 subscription**, along with a version of Outlook that supports oversharing pop-ups. For more information in required version, see Oversharing dialog for Outlook for Microsoft 365.

> **Important**
>
> The following is a hypothetical scenario with hypothetical values. It's only for illustrative purposes. You should substitute your own sensitive information types, sensitivity labels, distribution groups, and users when implementing this feature.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Before you begin

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions

The account you use to create and deploy policies must be a member of one of the following role groups

- Compliance administrator
- Compliance data administrator

- Information Protection
- Information Protection Admin
- Security administrator

> **Important**
>
> Read **Administrative units** before you start to make sure you understand the difference between an *unrestricted administrator* and an *administrative unit restricted administrator*.

Granular roles and role groups

There are several roles and role groups that you can use to fine tune access controls for Microsoft Purview DLP policy management.

Here's a list of applicable roles. To learn more, see Permissions in the Microsoft Purview portal.

- DLP Compliance Management
- Information Protection Admin
- Information Protection Analyst
- Information Protection Investigator
- Information Protection Reader

Here's a list of applicable role groups. To learn more about them, see Permissions in the Microsoft Purview portal.

- Information Protection
- Information Protection Admins
- Information Protection Analysts
- Information Protection Investigators
- Information Protection Readers

Prerequisites and assumptions

In Outlook for Microsoft 365, an oversharing pop-up displays a pop-up before a message is sent. To enable these pop-ups, first scope your policy to the Exchange location and then select the **Show policy tip as a dialog for the user before send** option in the policy tip when you create a data loss prevention (DLP) rule for that policy.

Our example scenario uses the *Highly confidential* sensitivity label, so it requires that you have created and published sensitivity labels. To learn more, see:

- Learn about sensitivity labels
- Get started with sensitivity labels
- Create and configure sensitivity labels and their policies

This procedure uses *contoso.com*. a hypothetical company domain.

Policy intent statement and mapping

For this example, our policy intent statement is:

We need to block emails to all recipients that have the 'highly confidential' sensitivity label applied, unless the recipient domain is contoso.com. We want to notify the user with a pop-up dialogue when they send the email. No users can be allowed to override the block.

Expand table

Statement	Configuration question answered and configuration mapping
"We need to block emails to all recipients..."	- **Where to monitor**: Exchange - **Administrative scope**: Full directory - **Action**: Restrict access or encrypt the content in Microsoft 365 locations > Block users from receiving email or accessing shared SharePoint, OneDrive, and Teams files > Block everyone
"...that have the 'highly confidential' sensitivity label applied..."	- **What to monitor**: use the Custom template - **Conditions for a match**: edit it to add the *highly confidential* sensitivity label
"...unless..."	**Condition group configuration** - Create a nested boolean NOT condition group joined to the first conditions using a boolean AND
"...the recipient domain is contoso.com."	**Condition for match**: Recipient domain is
"...Notify..."	**User notifications**: enabled
"...the user with a pop-up dialogue when they send..."	**Policy tips**: selected - **Show policy tip as a dialog for the end user before send**: selected
"...No users can be allowed to override the block...	**Allow overrides from M365 Services**: not selected

To configure oversharing pop-ups with default text, the DLP rule must include these conditions:

- **Content contains** > **Sensitivity labels** > **choose your sensitivity label(s)**

and one or more of the following recipient-based conditions

- Recipient is
- Recipient is a member of
- Recipient domain is

When these conditions are met, the policy tip displays untrusted recipients while the user is writing the mail in Outlook, before they send it.

If the block rules defined in the DLP policy are met, the message will be blocked regardless of how **Policy tips** is configured.

Steps to configure "wait on send"

Optionally, you can set the *dlpwaitonsendtimeout Regkey (Value in dword)* on all the devices where you want to implement "wait on send" for oversharing pop-ups. This registry key (*RegKey*) defines the maximum amount of time to hold the email when a user selects **Send**. This allows the system to complete the DLP policy evaluation for labeled or sensitive content. You can find this RegKey under:

Software\Policies\Microsoft\office\16.0\Outlook\options\Mail

You can set this *RegKey* via group policy, **Specify wait time to evaluate sensitive content**, script, or other mechanism for configuring registry keys.

If you're using Group Policy, make sure you download the most recent version of the Group Policy Administrative Template files for Microsoft 365 Apps for enterprise and then navigate to **User Configuration** > **Administrative Templates** > **Microsoft Office 2016** > **Security Settings** > **Specify wait time to evaluate sensitive content**. If you're using the Cloud Policy service for Microsoft 365, search for the setting by name to configure it.

When this value is set and the DLP policy is configured, email messages are checked for sensitive information before they're sent. If a message contains a match to the conditions defined in the policy, a policy tip notification appears before the user select **Send**..

The *dlpwaitonsendtimeout* registry key allows you to specify the **wait on send** behavior for your Outlook clients.

Here's what each *dlpwaitonsendtimeout* setting means:

Not configured or **Disabled**: This is the default. When *dlpwaitonsendtimeout* isn't configured, the message isn't checked before the user sends it. The email message is sent immediately once

Send is clicked. The DLP data classification service evaluates the message and apply the actions defined in the DLP policy.

Enabled: The email message is checked when the **Send** is clicked but before the message is sent. You can set a time limit on how long to wait for DLP policy evaluation to complete (**T** value, in seconds). If the policy evaluation doesn't complete in the specified time a **Send anyway** button appears allowing the user to bypass the presend check. The **T** value range is 0 to 9999 seconds.

> **Important**
>
> If the **T** value is greater than 9999, it's replaced with 10000 and the **Send Anyway** button doesn't appear. This holds the message until the policy evaluation completes and doesn't provide the user with an *override* option. The duration for completing the evaluation can vary depending on factors such as internet speed, content length, and the number of policies defined. Some users may encounter policy evaluation messages more frequently than others, depending on the policies that are deployed on their mailbox.

To learn more about configuring and using GPO see, Administer Group Policy in a Microsoft Entra Domain Services managed domain.

Steps to create a DLP policy for an oversharing pop-up

Perform the following steps to create a DLP policy that triggers an oversharing pop-up in Outlook.

1. Sign in to the Microsoft Purview portal > **Data loss prevention** > **Policies**
2. Choose + **Create policy**.
3. Select **Custom** from the **Categories** list.
4. Select **Custom** from the **Regulations** list.
5. Give the policy a name.
6. Fill in a description. You can use the policy intent statement here.
7. Select **Next**.
8. Select **Full directory** under **Admin units**.
9. Select only the **Exchange email** location.

10. Select **Next**.
11. On the **Define policy settings** page, select **Create or customize advanced DLP rules**.
12. The **Create or customize advanced DLP rules** option should already be selected.
13. Select **Next**.
14. Select **Create rule**. Name the rule and provide a description.
15. Select **Add condition** > **Content contains** > **Add** > **Sensitivity labels** > **Highly confidential**. Choose **Add**.
16. Select **Add group** > **AND** > **NOT** > **Add condition**.
17. Select **Recipient domain is** > **contoso.com**. Choose **Add**.

    > **Tip**
    >
    > You can also use **Recipient is** or **Recipient is a member of** instead of **Recipient domain is** to trigger an oversharing pop-up.

18. Select **Add an action** > **Restrict access or encrypt the content in Microsoft 365 locations**.
19. Select **Block users from receiving email or accessing shared SharePoint, OneDrive, and Teams files, and Power BI items**.
20. Select **Block everyone**.
21. Set the **User notifications** toggle to **On**.
22. Select **Policy tips** > **Show the policy tip as a dialog for the end user before send (available for Exchange workload only)**.
23. *If already selected*, uncheck the **Allow override from M365 services** option.
24. Choose **Save**.
25. Change the **Status** toggle to **On** and then choose **Next**.
26. On the **Policy mode** page, select **Run the policy in test mode** and check the box for the **Show policy tips while in simulation mode** option.
27. Choose **Next** and then choose **Submit**.

28. Choose **Done**.

PowerShell steps to create policy

DLP policies and rules can also be configured in PowerShell. To configure oversharing pop-ups using PowerShell, first you create a DLP policy (using PowerShell) and add DLP rules for each warn, justify or block pop-up type.

You'll configure and scope your DLP Policy using New-DlpCompliancePolicy. Then, you configure each oversharing rule using New-DlpComplianceRule

To configure a new DLP policy for the oversharing pop-up scenario use this code snippet:

PowerShell

```
PS C:\> New-DlpCompliancePolicy -Name <DLP Policy Name> -ExchangeLocation All
```

This sample DLP policy is scoped to all users in your organization. Scope your DLP Policies using `-ExchangeSenderMemberOf` and `-ExchangeSenderMemberOfException`.

Expand table

Parameter	Configuration
-ContentContainsSensitiveInformation	Configures one or more sensitivity label conditions. This sample includes one. At least one label is mandatory.
-ExceptIfRecipientDomainIs	List of trusted domains.
-NotifyAllowOverride	"WithJustification" enables justification radio buttons, "WithoutJustification" disables them.
-NotifyOverrideRequirements	"WithAcknowledgement" enables the new acknowledgment option. This is optional.

To configure a new DLP rule to generate a *warn* pop-up using trusted domains, run the following PowerShell code:

PowerShell

```
PS C:\> New-DlpComplianceRule -Name <DLP Rule Name> -Policy <DLP Policy Name> -
NotifyUser Owner -NotifyPolicyTipDisplayOption "Dialog" -
ContentContainsSensitiveInformation @(@{operator = "And"; groups =
@(@{operator="Or";name="Default";labels=@(@{name=<Label GUID>;type="Sensitivity"})})})
-ExceptIfRecipientDomainIs @("contoso.com","microsoft.com")
```

To configure a new DLP rule to generate a *justify* pop-up using trusted domains, run this PowerShell code:

PowerShell

```
PS C:\> New-DlpComplianceRule -Name <DLP Rule Name> -Policy <DLP Policy Name> -
NotifyUser Owner -NotifyPolicyTipDisplayOption "Dialog" -BlockAccess $true -
ContentContainsSensitiveInformation @(@{operator = "And"; groups = @(@{operator =
"Or"; name = "Default"; labels = @(@{name=<Label GUID 1>;type="Sensitivity"},@{name=
<Label GUID 2>;type="Sensitivity"})})}) -ExceptIfRecipientDomainIs
@("contoso.com","microsoft.com") -NotifyAllowOverride "WithJustification"
```

To configure a new DLP rule to generate a *block* pop-up using trusted domains, run this PowerShell code:

PowerShell

```
PS C:\> New-DlpComplianceRule -Name <DLP Rule Name> -Policy <DLP Policy Name> -
NotifyUser Owner -NotifyPolicyTipDisplayOption "Dialog" -BlockAccess $true -
ContentContainsSensitiveInformation @(@{operator = "And"; groups = @(@{operator =
"Or"; name = "Default"; labels = @(@{name=<Label GUID 1>;type="Sensitivity"},@{name=
<Label GUID 2>;type="Sensitivity"})})}) -ExceptIfRecipientDomainIs
@("contoso.com","microsoft.com")
```

For more information, see Business justification X-Header.

Use data loss prevention policies for non-Microsoft cloud apps

> **Important**
>
> The Instances policy location in Microsoft Purview Data Loss Prevention (DLP) and policy creation experiences are being retired on January 6th, 2027, as part of the retirement of Microsoft Defender for Cloud Apps file policies. Recreate your policies in Purview using dedicated policy locations for supported non-Microsoft connected apps before this date. For more information, see Migrate file policies to Microsoft Purview.

You can scope DLP policies to **Instances** to monitor, detect, and take actions when sensitive items are used and shared via non-Microsoft cloud apps.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Before you begin

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions

The account you use to create and deploy policies must be a member of one of these role groups

- Compliance administrator
- Compliance data administrator
- Information Protection
- Information Protection Admin
- Security administrator

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. This helps improve security for your organization. Global Administrator is a highly privileged role that should only be used in scenarios where a lesser privileged role can't be used.

Prepare your Defender for Cloud Apps environment

Before you configure DLP policies scoped to **Instances**, you must prepare your Defender for Cloud Apps environment. For instructions, see Quickstart: Get started with Microsoft Defender for Cloud Apps.

Connect a non-Microsoft cloud app

To use a DLP policy that's scoped to a specific non-Microsoft cloud app, the app must be connected to Defender for Cloud Apps. For information, see:

- Connect Box
- Connect Dropbox
- Connect Google Workspace
- Connect Salesforce
- Connect Cisco Webex

After you connect your cloud apps to Defender for Cloud Apps, you can create DLP policies for those apps.

Create a DLP policy scoped to a non-Microsoft cloud app

Refer to Create and Deploy data loss prevention policies for the procedures to create a DLP policy. Keep these points in mind as you configure your policy:

1. Sign in to the Microsoft Purview portal.
2. Open **Data loss prevention** > **Policies** > **+ Create policy**.
3. Select **Custom** > **Custom policy**.
4. Name the policy and add a description.

5. Set the **Admin units** scope as desired.

6. On the **Locations** page, toggle the **Instances** location to on.

7. To select a specific app or instance, select **Edit** > **Specific instances** > **+ Include instances** and then the instances (cloud apps) you want to include. If you don't select a instance, the policy will be scoped to all connected apps in your Microsoft Defender for Cloud Apps tenant.

8. **Create rule** with the desired settings. For more information on policy creation, see Create and Deploy data loss prevention policies.
   a. Under **Actions** select **Restrict Third Party Apps** and select any of the apps listed.

> **Note**
>
> When you create a DLP policy that is scoped to **Instances**, the same policy will be automatically created in Microsoft Defender for Cloud Apps.

Last updated on 08/28/2026

Use Microsoft Purview data loss prevention policies for non-Microsoft connected apps (preview)

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Microsoft Purview Data Loss Prevention (DLP) extend to non-Microsoft connected apps, allowing you to detect, monitor, and protect sensitive data at rest in non-Microsoft SaaS applications. You can create DLP policies that apply to data stored in these non-Microsoft apps, using the same classification engine and policy framework available for Microsoft 365 locations.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Supported non-Microsoft apps

Microsoft Purview supports DLP policies for the following non-Microsoft apps:

- Box
- Dropbox
- Google Workspace
- Salesforce

> **Note**
>
> These apps are rolling out in phases. Not all apps may be available in your tenant at the same time. Check the Microsoft 365 roadmap for the latest availability information.

Before you begin

Licensing requirements

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions

The account you use to create and deploy policies must be a member of one of these role groups:

- Compliance administrator
- Compliance data administrator
- Information Protection
- Information Protection Admin
- Security administrator

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. This helps improve security for your organization. Global Administrator is a highly privileged role that should only be used in scenarios where a lesser privileged role can't be used.

Set up a Microsoft Defender for Cloud Apps connector

Before you can apply DLP policies to a non-Microsoft app, you must connect that app to Microsoft Defender for Cloud Apps using an app connector. Purview uses the existing Microsoft Defender for Cloud Apps connectors to access capabilities in the non-Microsoft app.

For instructions on setting up app connectors, see Connect apps to get visibility and control with Microsoft Defender for Cloud Apps.

After you connect your cloud apps to Defender for Cloud Apps, you can create DLP policies for them in Microsoft Purview.

Create a DLP policy for non-Microsoft connected apps

To create a DLP policy scoped to non-Microsoft connected apps:

1. Sign in to the Microsoft Purview portal.
2. Go to **Solutions** > **Data Loss Prevention** > **Policies** > **+ Create policy**.
3. On **What info do you want to protect?**, choose the **Enterprise applications & devices** option.
4. Select **Custom** > **Custom policy**, and then select **Next**.

   > **Important**
   >
   > Non-Microsoft connected app policies are only supported with the **Custom** policy template. The predefined Financial, Medical and health, and Privacy templates don't support non-Microsoft app locations.

5. Enter a name and description for the DLP policy, then select **Next**.
6. On **Assign admin units**, the scope is set to **Full directory**. Administrative units aren't supported for non-Microsoft app locations.
7. On **Choose where to apply the policy**, select one or more of the supported non-Microsoft apps (such as **Box**, **Dropbox**, **Google Workspace**, and **Salesforce**.

   > **Important**
   >
   > Non-Microsoft app locations can be selected together, but they can't be combined with other locations like SharePoint, OneDrive, Exchange, Fabric, or Devices in the same policy.

8. By default, the policy applies to all instances of the selected app. To scope the policy to specific tenants, select **Edit**.
   a. To exclude instances, in **All instances**, select **Exclude instances** > **+ Exclude instance**. From the list of instances, select instances to exclude from the policy, and then select **Done** > **Done**.
   b. To apply the policy to specific instances, select **Specific instances** > **+ Include instance**. From the list of instances, select instances to include, then select **Done** > **Done**.
9. Select **Next** to proceed.

10. On **Define policy settings**, select **Create or customize advanced DLP rules** to define an advanced DLP rule. Only advanced DLP rules are supported for non-Microsoft connected apps. Select **Next**.
11. Select + **Create rule**, and provide a **Name** and **Description**.
12. Configure **Conditions** for the rule. The conditions you can use vary by app.
13. Configure **Actions** for the rule. The available actions vary by app.
14. Configure **Notifications**. Note the following limitations for non-Microsoft apps:
    - **Policy tips** aren't supported.
    - **User overrides** aren't supported.
15. Select **Save** to save the rule, then select **Next**.
16. On **Policy mode**, choose either **Turn the policy on immediately** or **Leave the policy turned off**. Select **Next**.

    > ⓘ **Important**
    >
    > **Simulation mode** isn't supported for non-Microsoft connected app policies.

17. Review your settings and select **Submit** to create the policy.

Attribute availability by app

The conditions and actions you can use in a policy depend on the item attributes that each app makes available. Most attributes are available for all supported apps, but some aren't available for certain apps. Use the following table to understand which attributes you can rely on when you build rules for a specific app.

Expand table

Attribute	Description	Availability
Name	The display name of the item.	Available in all apps
File access level	The item's access level, which indicates its sharing scope.	Available in all apps
Created date	The date the item was created.	Not available in Dropbox

Attribute	Description	Availability
Modified date	The date the item was last modified.	Available in all apps
Collaborators	The users the item is shared with, including their roles.	Available in all apps
Parent folders	The parent folders that contain the item.	Available in all apps

Monitoring and reporting

Activity explorer

Activity explorer supports non-Microsoft connected app policies. You can monitor DLP policy activity for your non-Microsoft apps in the same way you monitor Microsoft 365 locations.

Content explorer

Content explorer isn't supported for non-Microsoft connected apps. You can't browse or inspect content stored in these apps through Content explorer.

Alerts

DLP alerts are supported for non-Microsoft connected app policies. Alerts appear in the DLP alerts dashboard alongside alerts from other locations.

Known issues

The following is a list of known issues when using non-Microsoft connected apps for DLP policies:

- **Encrypted files** – Encrypted files stored in non-Microsoft apps aren't currently supported for classification.
- **PDF files** – PDF files stored in non-Microsoft apps aren't currently supported for classification.

Learn about the default Office 365 DLP policy

To help you protect sensitive data in Microsoft Office 365 apps, Microsoft created a default Microsoft Purview data loss prevention (DLP) policy called **Default Office 365 DLP policy**.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

What does the default policy do?

This default policy looks for items with the sensitive information type Credit card number It's configured like this.

- Admin units: **Full directory**
- Choose where to apply the policy:
  - **Exchange email** > **All groups**
  - **SharePoint sites** > **All sites**
  - **OneDrive accounts** > **All users and groups**
- Conditions:
  - **Content is shared from Microsoft 365** > **with people outside my organization** AND
  - **Content contains** > **Credit card number**
- User Notifications:
  - **On**
  - **Notify these people** > **The person who sent, shared, or modified the content** and **Owner of the SharePoint site or OneDrive account** and **Owner of the SharePoint or OneDrive content**.
  - **Attach matching email message to the notification (applies only to Exchange)**
  - With customized policy tip text.

- Policy mode: **Turn the policy on immediately**

Administrator can view the activities and edit the policies details by logging into the Microsoft Purview portal.

Admins can view this policy in the Microsoft Purview portal. Navigate to **Data Loss prevention** > **Policies**.

Edit or delete the default policy

To edit the default policy for better performance or to delete it, just use an account with **DLP Compliance Management** permissions. For more information, see, Permissions.

Last updated on 03/24/2026

Get started with DLP file quarantine for SharePoint and OneDrive

> **Note**
>
> The features described in this article are in preview. This article walks you through the prerequisites and configuration for using the DLP file quarantine action for SharePoint and OneDrive locations.

Before you begin

Licensing

For information on licensing, see:

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

DLP file quarantine for SharePoint and OneDrive is only available for E5 licenses.

Permissions

To configure and manage DLP file quarantine, you need one of the following Microsoft Entra ID roles:

- Compliance administrator
- Security administrator
- Compliance data administrator

Recommended permissions for quarantine site management

Because the quarantine site contains highly sensitive files, the administrator who manages it should also have the following data classification permissions:

- **Data Classification List Viewer** — Allows viewing items listed in Data Explorer.
- **Data Classification Content Viewer** — Allows viewing the actual contents of items in Data Explorer.

> ![CAUTION] These permissions aren't technically required to configure or use file quarantine. However, you should use the same criteria when selecting accounts for administering this feature as you do for selecting accounts to be members of the **Data Classification List Viewer** and **Data Classification Content Viewer** roles. You should apply the same account-selection criteria because the quarantine site can contain files with sensitive content that the admin might need to inspect before deciding whether to restore or delete them. To learn more, see Get started with Data Explorer.

Roles and role groups

Here's a list of applicable roles. To learn more about them, see Permissions in the Microsoft Purview portal.

- Information Protection Admin
- Information Protection Analyst
- Information Protection Investigator
- Information Protection Reader

Here's a list of applicable role groups. To learn more, see Permissions in the Microsoft Purview portal.

- Information Protection
- Information Protection Admins
- Information Protection Analysts
- Information Protection Investigators
- Information Protection Readers

Deploy a DLP policy with the quarantine action

For step-by-step instructions on how to configure quarantine settings and create and deploy a policy see, Create a DLP policy to quarantine files in SharePoint and OneDrive.

View quarantine alerts

Use the following steps to view alerts for quarantined files:

1. Open the Microsoft Purview portal and go to **Data loss prevention** > **Alerts**.
2. Review alerts for policies that use the quarantine action. DLP alerts and DLP rule match events include:

- The quarantine file location.
- The file owner.
- The original file path.

3. For more information, see Get started with the data loss prevention alerts dashboard and Investigate data loss incidents with Microsoft Defender XDR.

View quarantine activity in Data Explorer

Use Activity explorer to review quarantine-related DLP events:

1. Open the Microsoft Purview portal and go to **Data classification** > **Activity explorer**.
2. Filter for DLP policy rule match events related to your quarantine policy.
3. For more information, see Get started with Activity explorer.

Restore a quarantined file

File restore is a manual process.

> **Important**
>
> After restore, original sharing permissions aren't restored. Only the latest file version is preserved. The same DLP rule won't re-quarantine the restored file, even if the file or policy is modified. Other DLP rules continue to apply.

To restore a quarantined file:

1. Locate the quarantined file in the quarantine site.
2. Identify the original file path by using audit logs or the DLP alert details.
3. Move the file from the quarantine site back to the original location.
4. Delete the tombstone text file from the original location.

Next steps

Now that you've configured DLP file quarantine settings, you're ready to create a policy:

- Create a DLP policy to quarantine files in SharePoint and OneDrive

Create a DLP policy to quarantine files in SharePoint and OneDrive

> **Note**
>
> The features described in this article are in preview. This article uses the process you learned in Design a data loss prevention policy to show you how to create a Microsoft Purview data loss prevention (DLP) policy that automatically quarantines files containing sensitive information in SharePoint and OneDrive. Work through this scenario in your test environment to familiarize yourself with the quarantine action and policy creation UI.

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users. How you deploy a policy is as important as policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

Prerequisites and assumptions

Before you start, make sure you've completed the following:

Create a quarantine site in SharePoint

The quarantine destination must be a SharePoint site within your tenant. You can use any SharePoint site template. The quarantine site can't be a OneDrive location.

When you set up your quarantine site:

- **Restrict access.** Make sure the site is accessible only by the administrators who manage quarantine operations. Don't share it with information workers or general users.
- **Don't use a site that contains active business content.** Create a dedicated site for quarantine purposes.

- **Manage the lifecycle.** Administrators are responsible for access control and lifecycle management of the quarantine site.

> **Tip**
>
> If your organization uses on-demand classification, it's recommended that you exclude the quarantine site from on-demand classification scans. While scanning the quarantine site doesn't compromise security, excluding it avoids unnecessary processing.

Configure quarantine settings in Microsoft Purview

Before you can select the quarantine action in a DLP policy, you must configure the quarantine folder path and tombstone file message in DLP settings.

> **Important**
>
> You can't select the quarantine action in a DLP policy until you complete this configuration. The policy creation wizard prompts you to configure these settings first if they aren't already set.

1. Sign in to the Microsoft Purview portal.
2. Go to **Data loss prevention** > **Settings**.
3. Select **File quarantine**.
4. Under **Quarantine folder path**, select a SharePoint site from the list of available sites.

   > **Note**
   >
   > The site list is automatically populated from your tenant's SharePoint sites. You can't manually enter a path. If you recently created a new SharePoint site, it might take time for the site to appear in the list. If the site you need isn't listed, wait and check back later.

5. Under **Replacement file message**, provide the text content for the tombstone file that replaces each quarantined file. For example:

"This file has been moved to a secure quarantine location because it matched a data loss prevention policy. Contact your compliance administrator at compliance@contoso.com for assistance."

6. Save your settings.

> **Important**
>
> You can't select the quarantine action in a DLP policy until you complete this configuration. The policy creation wizard prompts you to configure these settings first if they aren't already set.

Sensitivity label requirements

This scenario uses the *Highly Confidential* sensitivity label. To learn more, see:

- Learn about sensitivity labels
- Get started with sensitivity labels
- Create and configure sensitivity labels and their policies

Alert configuration

This procedure uses alerts. See Get started with the data loss prevention alerts.

Policy intent statement and mapping

We need to quarantine files in SharePoint and OneDrive that contain financial data classified as "Highly Confidential," so that the files are removed from their original location and placed in a secure admin-controlled quarantine site. We want a tombstone file left in the original location to notify the file owner. We want the compliance admin alerted whenever a file is quarantined.

Expand table

Statement	Configuration question answered and configuration mapping
"We need to quarantine files in SharePoint and OneDrive..."	- **Where to monitor:** SharePoint sites, OneDrive accounts - **Administrative scope:** Full directory - **Action:** Restrict access or encrypt the content in Microsoft 365 locations > **Block everyone and move file to quarantine location**

Statement	Configuration question answered and configuration mapping
"...that contain financial data classified as 'Highly Confidential'..."	- **What to monitor:** Use the **Custom template** - **Conditions for match:** Add the sensitive info types that apply to the financial data your organization needs to protect (for example, *Credit Card Number*, *U.S. Bank Account Number*). - **Additional condition:** Content contains > Sensitivity labels > *Highly Confidential*
"We want the compliance admin alerted whenever a file is quarantined."	- **Incident reports:** Send an alert to admins when a rule match occurs: **On** - Send alert every time an activity matches the rule: **selected** - Severity level: **High**
"We want a tombstone file left in the original location to notify the file owner."	- Tombstone file content is configured in **DLP Settings** > **File quarantine** (not in the policy itself). Verify that the tombstone message is configured before you create this policy.

Steps to create the policy

> **Important**
>
> For this policy creation procedure, accept the default include and exclude values and leave the policy turned off. Change these values when you deploy the policy.

Create the policy

Perform the following steps to create the DLP policy in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Open the **Data loss prevention** solution and go to **Policies**.
3. Select **Create policy**.
4. Select **Enterprise applications & devices**.
5. Select **Custom** from the **Categories** list.
6. Select **Custom policy** from the **Regulations** list.
7. Select **Next**.
8. Enter a name and description for the policy. You can use the policy intent statement here.

> **ⓘ Important**
>
> Policies can't be renamed.

9. Select **Next**.
10. Accept the **Full directory** default under **Admin units**.
11. Select **Next**.
12. Choose where to apply the policy. Select only the following locations:
    - **SharePoint sites**
    - **OneDrive accounts**
13. Select **Next**.
14. On the **Define policy settings** page, make sure the **Create or customize advanced DLP rules** option is selected.
15. Select **Next**.
16. Select **+ Create rule**. Name the rule and provide a description.
17. Under **Conditions**, select **Add condition** > **Content contains** > **Add** > **Sensitive info types**.
18. Select the sensitive info types that apply to the financial data you want to protect (for example, *Credit Card Number*, *U.S. Bank Account Number*).
19. Select **Add**.
20. Optionally, add a sensitivity label condition:
    a. Under the **Content contains** section, select **Add group**.
    b. Leave the Boolean operator set to **AND**.
    c. Select **Add condition** > **Content contains** > **Add** > **Sensitivity labels**.
    d. Select the **Highly Confidential** sensitivity label.
    e. Select **Add**.
21. Under **Actions**, select **Add an action** > **Restrict access or encrypt the content in Microsoft 365 locations**.
22. Select **Block everyone and move file to quarantine location**.

> **Note**
>
> If quarantine settings aren't configured, you're prompted to configure them. Select the link to open the **File quarantine** settings page in a new tab, complete the configuration, and then return to the policy creation wizard.

23. Under **User notifications**, set the toggle to **On** if you want to notify users through policy tips.
24. Under **Incident reports**, set **Use this severity level in admin alerts and reports** to **High**.
25. Make sure the **Send an alert to admins when a rule match occurs** toggle is set to **On**.
26. Select **Send alert every time an activity matches the rule**.
27. Select **Save**.
28. Review the rule, then select **Next**.
29. Select the **Run the policy in simulation mode** radio button.

> **Tip**
>
> Simulation mode is supported for the quarantine action. Use simulation mode to evaluate the impact of the policy before you turn it on. Review the policy matches in Activity Explorer and the DLP alerts dashboard to verify that the policy targets the files you expect.

30. Select **Next**.
31. Review the policy, then select **Submit**.
32. Select **Done**.

Validate the policy

After the policy is deployed, validate the following:

Expand table

Scenario	Expected result
A file matching the policy is uploaded to a SharePoint site in scope.	The file is moved to the quarantine site. A tombstone file appears at the original location. A DLP alert is generated.
Check the tombstone file at the original location.	The tombstone file displays the admin-configured message and the relative path of the quarantined file.
Review the DLP alert.	The alert shows the file owner, original file path, and quarantine file location.
Review Activity Explorer.	A DLP rule match event appears with quarantine file location details.

Learn about Endpoint data loss prevention

You can use Microsoft Purview Data Loss Prevention (DLP) to monitor the actions that are being taken on items you've determined to be sensitive and to help prevent the unintentional sharing of those items.

Endpoint data loss prevention (Endpoint DLP) extends the activity monitoring and protection capabilities of DLP to Windows 10/11, macOS (the three latest released major versions) devices, and Windows certain server versions. Once devices are onboarded into the Microsoft Purview solutions, the information about what users are doing with sensitive items is made visible in activity explorer. You can then enforce protective actions on those items via DLP policies.

When are files classified by Endpoint DLP?

Endpoint DLP classifies files under the following conditions:

- **Creation or Modification:** Every time a file is created or modified, it is fully scanned for sensitive information types (SITs) and labels. The file is then evaluated for matches against DLP policies and rules.
- **Reading an Already Classified File:** When an already classified file is read, Endpoint DLP checks for any changes to the policies, rules, or SITs. If there is a change in the DLP configuration, it re-evaluates the policies and rules, but it will not re-extract the text.

> **Tip**
>
> If you're looking for device control for removable storage, see **Microsoft Defender for Endpoint Device Control Removable Storage Access Control**.

> **Note**
>
> Endpoint DLP cannot detect the sensitivity label from another tenant on a document.

Endpoint DLP Windows 10/11 and macOS support

Endpoint DLP allows you to onboard devices running Windows Server 2019 and later versions.

> **Note**
>
> Installing the supported Windows Server KBs disables the *Classification* feature on the server. This means that Endpoint DLP won't classify files on the server. However, Endpoint DLP will still protect those files on the server that were classified before those KBs were installed on server. To ensure this protection, install Microsoft Defender version 4.18.23100 (October 2023) or later.

By default, Endpoint DLP isn't enabled for Windows servers when they're initially onboarded. Before you can see Endpoint DLP events for your servers in Activity Explorer, you must first Enable Endpoint DLP for Windows Servers.

Once properly configured, the same data loss protection policies can be automatically applied to both Windows PCs and Windows servers.

Scoping DLP policies for endpoints

Microsoft Purview Data Loss Prevention (DLP) policies can be applied to multiple locations, including endpoint devices. When a DLP policy includes the **Devices** location, the policy can be scoped by both users and devices. For a DLP policy to be enforced on an endpoint, both the user and the device must be included in the policy scope.

Expand table

Device in scope	User in scope	Policy applied
Yes	Yes	Yes
No	Yes	No
No	Yes	No

This enables more precise data protection controls based on who is accesing data and from which device. For more information, see Device scoping.

For implementation details see Create policy using device scoping.

Endpoint activities you can monitor and take action on

Endpoint DLP enables you to audit and manage the following types of activities users take on sensitive items that are physically stored Windows 10, Windows 11, or macOS devices.

Expand table

Activity	Description	Windows 10 (21H2, 22H2), Windows 11 (21H2, 22H2), Windows Server 2019 and later versions for Endpoints (X64)	Windows 11 (21H2, 22H2) for Endpoints (ARM64)	macOS three latest released versions	Auditable/ Restrictable
Upload to a restricted	Detects when a user attempts to upload an item to a restricted	Supported	Supported	Supported	Auditable and

cloud service domain or access from an unallowed browser	service domain or access an item through a browser. If they're using an unallowed browser, the upload activity is blocked and the user is redirected to use Microsoft Edge. Microsoft Edge then either allows or blocks the upload or access based on the DLP policy configuration. You can block, warn, or audit when protected files can be uploaded or prevented from being uploaded to cloud services based on the allow/unallowed domains list in **Data loss prevention settings**. When the configured action is set to warn or block, other browsers (defined on the unallowed browsers list under **Data loss prevention settings**) are blocked from accessing the file.				restrictable
Paste to supported browsers	Detects when a user attempts to paste content to a restricted service domain. Evaluation is performed on the content that is being pasted. This evaluation is independent of how the source item that the content came from is classified.	Supported	Supported	Preview	Auditable and restrictable
Copy to clipboard	When a user attempts to copy content from a protected file, you can block, block with override, or audit the copying of protected files to a clipboard on an endpoint device. If the rule is configured to **Block** or **Block with override** copying is blocked when the source content is sensitive except when the destination is within the same Microsoft 365 Office app. This activity also applies to redirected clipboards when using Azure Virtual Desktop with Windows 365.	Supported	Supported	Supported	Auditable and restrictable
Copy to USB	When this activity is detected, you can block, warn, or audit the	Supported	Supported	Supported	Auditable and

removable device	copying or moving of protected files from an endpoint device to USB removable media.				restrictable
Copy to a network share	When this activity is detected, you can block, warn, or audit the copying or moving of protected files from an endpoint device to any network share, including redirected USB devices that are displayed as network shares on an Azure Virtual Desktop with Windows 365.	Supported	Supported	Supported	Auditable and restrictable
Print	When this activity is detected, you can block, warn, or audit the printing of protected files from an endpoint device. This activity also applies to redirected printers when using Azure Virtual Desktop together with Windows 365.	Supported	Supported	Supported	Auditable and restrictable
Copy or move using unallowed Bluetooth app	Detects when a user attempts to copy an item to an unallowed Bluetooth app (as defined in the list of unallowed Bluetooth apps in **Data loss prevention settings** > **Endpoint settings**).	Supported	Supported	Supported	Auditable and restrictable
Copy or move using RDP	Detects when a user attempts to copy an item to a remote desktop session.	Supported	Supported	Not supported	Auditable and restrictable
Create an item	Detects the creation of an item.	Supported	Supported	Supported	Auditable
Rename an item	Detects the renaming of an item.	Supported	Supported	Supported	Auditable
Access by restricted apps	Detects when an application that is on the restricted apps list (as defined in restricted apps and app groups) attempts to access protected files on an endpoint device.	Supported	Supported	Supported	
Create Windows Recall snapshots (in preview)	Detects when there is an item or Teams message that contains a sensitive information type or has a senstivity label applied that	Supported	Not supported	Not supported	Auditable and restrictable

would be included in a Windows Recall snapshot.

Copy to clipboard behavior

When you configure a rule to **Block** or **Block with override** when a user attempts the Copy to clipboard activity on content from a file that matches the policy, end users see this behavior with these configurations:

- Word file 123 contains sensitive information that matches the copy to clipboard Block rule.
- Excel file 123 contains sensitive information that matches the copy to clipboard Block rule.
- PowerPoint file 123 contains sensitive information that matches the copy to clipboard Block rule.
- Word file 789 doesn't contain sensitive information.
- Excel file 789 doesn't contain sensitive information.
- PowerPoint file 789 doesn't contain sensitive information.
- Notepad (or any non Microsoft Office based app or process) file XYZ contains sensitive information that matches the copy to clipboard Block rule.
- Notepad (or any non Microsoft Office based app or process) file ABC doesn't contain sensitive information.

Expand table

Source	Destination	Behavior
Word file 123/Excel file 123/PowerPoint file 123	Word file 123/Excel file 123/PowerPoint file 123	copy and paste are allowed, in other words intra file copy and paste is allowed.
Word file 123/Excel File 123/PowerPoint file 123	Word file 789/Excel file 789/PowerPoint file 789	copy and paste are blocked, in other words inter file copy and paste is blocked.
Word file 789/Excel file 789/PowerPoint file 789	Word file 123/Excel File 123/PowerPoint file 123	copy and paste are allowed
Word file 123/Excel file 123/PowerPoint file 123	Notepad file ABC	copy and paste are blocked
Notepad file XYZ	any	copy is blocked

Source	Destination	Behavior
Notepad file ABC	any	copy and paste are allowed

> **Note**
>
> When a DLP rule that blocks copying is applied to an open file, copying from any other file within the same application (even files with no DLP rules applied) is restricted while the DLP blocked file is open.

Endpoint DLP and Unsaved Files

If data is never saved to a file on the local device, Endpoint DLP cannot scan or classify it. For example, if a user opens a document in Word and saves it directly to a USB device without first storing it locally, Endpoint DLP cannot inspect or block that action.

Best practice for endpoint DLP policies

Say you want to block all items that contain credit card numbers from leaving endpoints of Finance department users. We recommend:

- Create a policy and scope it to endpoints and to that group of users.
- Create a rule in the policy that detects the type of information that you want to protect. In this case, set **content contains** to *Sensitive information type**, and select **Credit Card**.
- Set the actions for each activity to **Block**.

For more information on designing your DLP policies, see Design a data loss prevention policy .

> **Note**
>
> In Microsoft Purview, DLP policy evaluation of sensitive items occurs centrally, so there's no time lag for policies and policy updates to be distributed to individual devices. When a policy is updated in Microsoft Purview portal, it generally takes about an hour for those updates to be synchronized across the service. Once policy updates are synchronized, items on targeted devices are automatically reevaluated the next time they're accessed or modified. In preview, you can also use **on-demand classification** to identify and classifies sensitive content in historical data stored in SharePoint and OneDrive. For Authorized Groups changes, the policy needs 24 hours to sync.

Monitored files

Files monitored via policy

Endpoint DLP monitors these file types policy in Windows 10, 11:

Expand table

File Type	Format	Monitored file extensions
Word processing	Word	`.doc, .docx, .docm, .dot, .dotx, .dotm, .docb, .obd, obt`
Spreadsheet	Excel, CSV, TSV	`.xls, .xlsx, .xlt, .xlm, .xlsm, .xlsb, .xlb, .xlc, .csv, .tsv`
Presentation	PowerPoint	`.ppt, .pptx, .pptm, .pps, .ppsx, .ppsm, .pot, .potx, .potm, .ppam, .pos`
Archive	Zip, RAR, 7z, TAR	`.zip, .rar, .7z, .tar, .gz, .arj, .bz2, .cab, .chm, .lzh, .lzma, .mhtml, .xar, .xz`
Adobe PDF	PDF	`.pdf`
Text	Text	`.asm, .bat, .c, .cmd, .cpp, .cs, .csv, .cxx, .def, .dic, .h, .hpp, .hxx, .idl, .inc, .inx, .java, .m3u, .mpx, .php, .pl, .pos, .txt, .vcf, .vcs`
HTML	HTML	`.ascx, .asp, .aspx, .hta, .htm, .htw, .htx, .jhtml, .html`
JSON	JSON	`.json, .adaptivecard, .messagecard`
Mail	Mail	`.eml, .msg, .nws`
XML	XML	`.infopathml, .jsp, .mspx`
Microsoft Office xml	Microsoft Office xml	`.excelml, .powerpointml, .wordml`
Protected Files	PFile	`.pbmp, .pgif, .pjfif, .pjpe, .pjpeg, .pjpg, .ppng, .ptif, .ptiff, .ptxt, .pxla, .pxlam, .pxml`
Other	Other	`.dfx, .dxf, .fluid, .mime, .pointpub, .rtf, .vtt`

Endpoint DLP monitors these file types policy in the latest three major releases of macOS:

Expand table

File Type	Format	Monitored file extensions
Word processing	Word	`.doc, .docx, .docm, .dot, .dotx, .dotm, .docb`
Spreadsheet	Excel, CSV, TSV	`.xls, .xlsx, .xlt, .xltx, .xltm, .xlw, .xlm, .xlsm, .xlsb, .xlb, .xlc, .csv, .tsv`
Presentation	PowerPoint	`.ppt, .pptx, .pptm, .pps, .ppsx, .ppsm, .pot, .potx, .potm, .ppam, .pos`
Archive	Zip, RAR, 7z, TAR	`.zip, .zipx, .rar, .7z, .tar`
Adobe PDF	PDF	`.pdf`
Text	Text	`.asm, .bat, .c, .cmd, .cpp, .cs, .csv, .cxx, .dic, .h, .hpp, .hxx, .idl, .inc, .inx, .inf, .inx, .java, .m3u, .mpx, .php, .pl, .pos, .txt, .vcf, .vcs`
HTML	HTML	`.ascx, .asp, .aspx, .css, .hta, .htm, .htw, .htx, .jhtml, .html, .mht`
JSON	JSON	`.json, .adaptivecard, .messagecard`
Mail	Mail	`.eml, .msg, .nws`
XML	XML	`.infopathml, .jsp, .mspx`
Microsoft Office xml	Microsoft Office xml	`.excelml, .powerpointml, .wordml`
Other	Other	`.pointpub, .rtf, .vtt`

These file types can be monitored through policy settings in Windows 10, 11 and macOS devices, if OCR is enabled:

`.jpg, .png, .tif, .tiff, .bmp, .jpeg`

Endpoint DLP scans files with the specified extensions listed above. If you need to protect or monitor files not listed, use the 'Apply restrictions to only unsupported file extensions' feature. The key differences between this feature and the **File extension is** condition are:

- Endpoint DLP scans content for the **File extension is** condition, allowing you to see Sensitive info type values in events or alerts. In contrast, the **Apply restrictions to only unsupported file extensions** feature does not scan file content.
- The **File extension is** condition triggers content scanning, which may consume higher machine resources like CPU and memory, potentially causing performance issues for some

file types. For more details on the **Apply restrictions to only unsupported file extensions** feature, refer to the following resources:

- Help protect files that Endpoint Data Loss Prevention doesn't scan
- Help protect against sharing of a defined set of unsupported files

Files audited regardless of policy match

Activities can be audited on these file types in Windows 10, 11, and in the latest three major releases of macOS, even if no policy match exists:

Expand table

Windows 10, 11	macOS
`.doc, .docx, .docm, .dot, .dotx, .dotm, .docb, .xls, .xlsx, .xlt, .xlm, .xlsm, .xltx, .xltm, .xlsb, .xlw, .ppt, .pptx, .pos, .pps, .pptm, .potx, .potm, .ppam, .ppsx, .pbix, .pdf, .csv, .tsv, .zip, .rar, .7z, .tar, .war, .gz, .dlp`	`.doc, .docx, .docm, .dot, .dotx, .dotm, .docb, .xls, .xlsx, .xlt, .xlm, .xlsm, .xltx, .xltm, .xlsb, .xlw, .ppt, .pptx, .pos, .pps, .pptm, .potx, .potm, .ppam, .ppsx, .pbix, .pdf, .csv, .tsv`

> **Note**
>
> These file types can be audited, regardless of a policy match, in Windows 10, 11 and macOS devices, so long as OCR is enabled:
>
> `.jpg, .png, .tif, .tiff, .bmp, .jpeg`

> **Important**
>
> For information about the Adobe requirements for using Microsoft Purview Data Loss Prevention (DLP) features with PDF files, see this article from Adobe: Microsoft Purview Information Protection Support in Acrobat.

If you only want to monitor data from policy matches, you can turn off the **Always audit file activity for devices** in the **Data loss prevention settings** > **Endpoint settings**.

If the **Always audit file activity for devices** setting is on, activities on any Word, PowerPoint, Excel, PDF, and .csv files are always audited, even if the device isn't targeted by any policy.

To ensure activities are audited for all supported file types, create a custom DLP policy.

Endpoint DLP monitors activity-based on MIME type, so activities are captured, even if the file extension is changed, for these files types:

After the extension is changed to any other file extension:

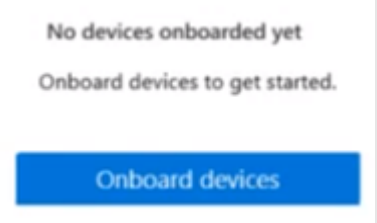
- `.doc`
- `.docx`
- `.xls`
- `.xlsx`
- `.ppt`
- `.pptx`
- `.pdf`

If the extension is changed only to supported file extensions:

- `.txt`
- `.msg`
- `.rtf`
- `.c`
- `.cpp`
- `.h`
- `.cs`
- `.java`
- `.tsv`

Unsupported File types

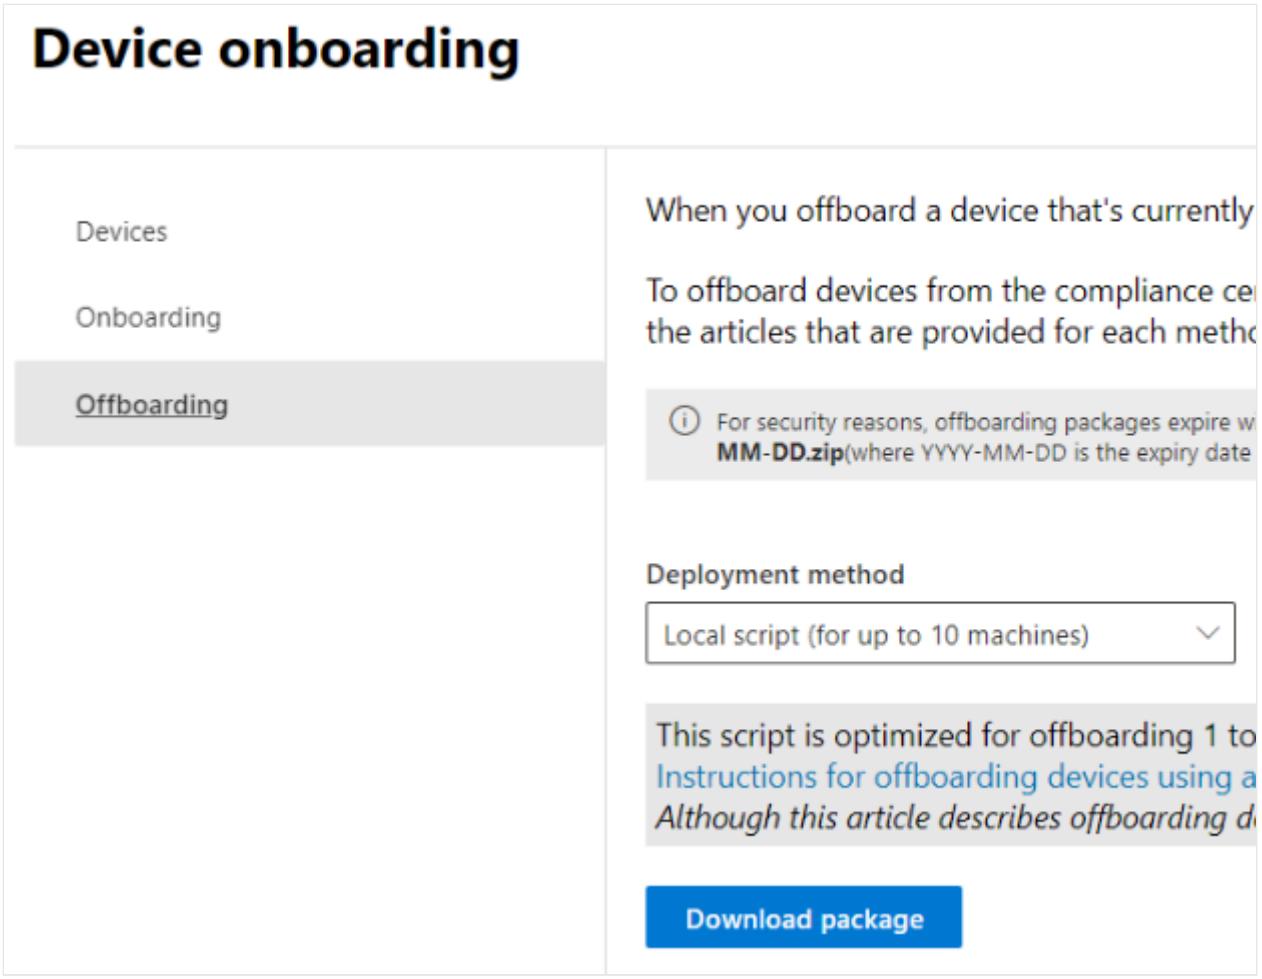
Endpoint DLP does not support monitoring for the following file types:



- `.exe`
- `.dll`
- `.sys`
- `.lib`
- `.obj`
- `.mui`
- `.spl`
- `.drv`
- `.pf`
- `.crdownload`
- `.ini`

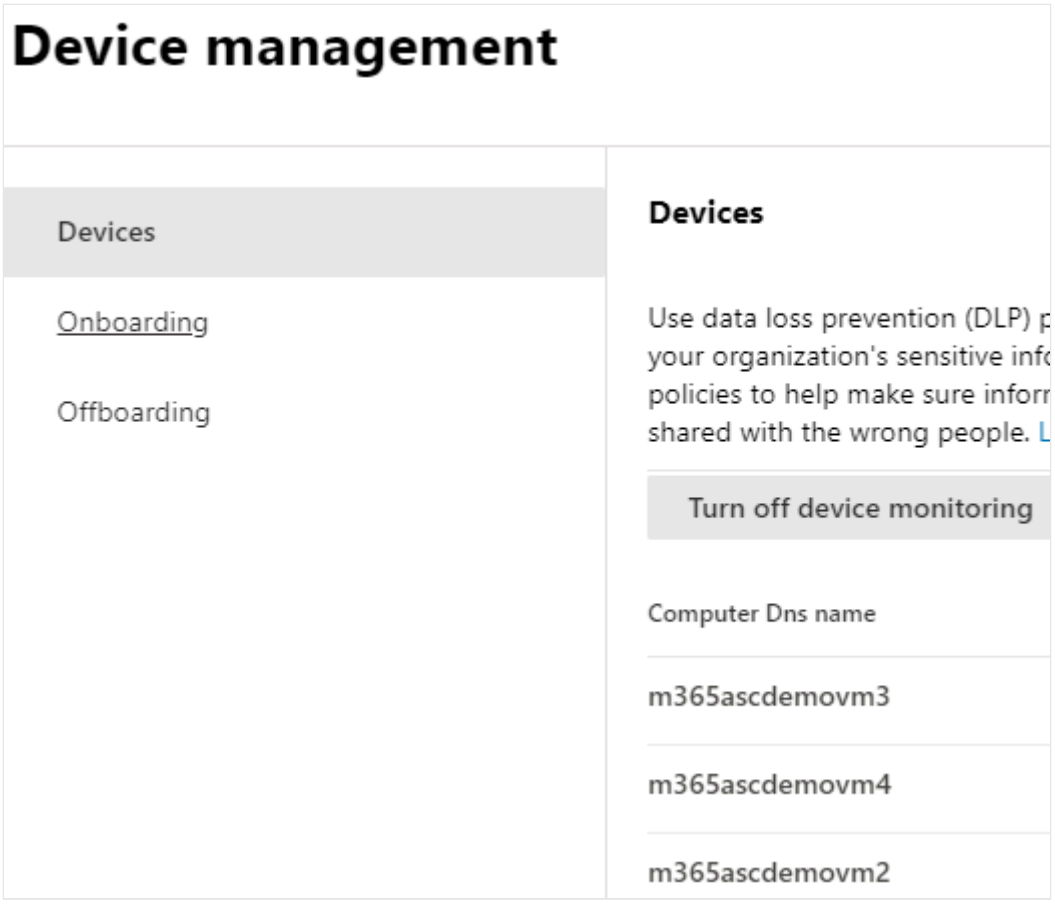
What's different in Endpoint DLP

There are a few extra concepts that you need to be aware of before you dig into Endpoint DLP.



Enabling Device management

Device management is the functionality that enables the collection of telemetry from devices and brings it into Microsoft Purview solutions like Endpoint DLP and insider risk management. You need to onboard all the devices you want to use as locations in your DLP policies.

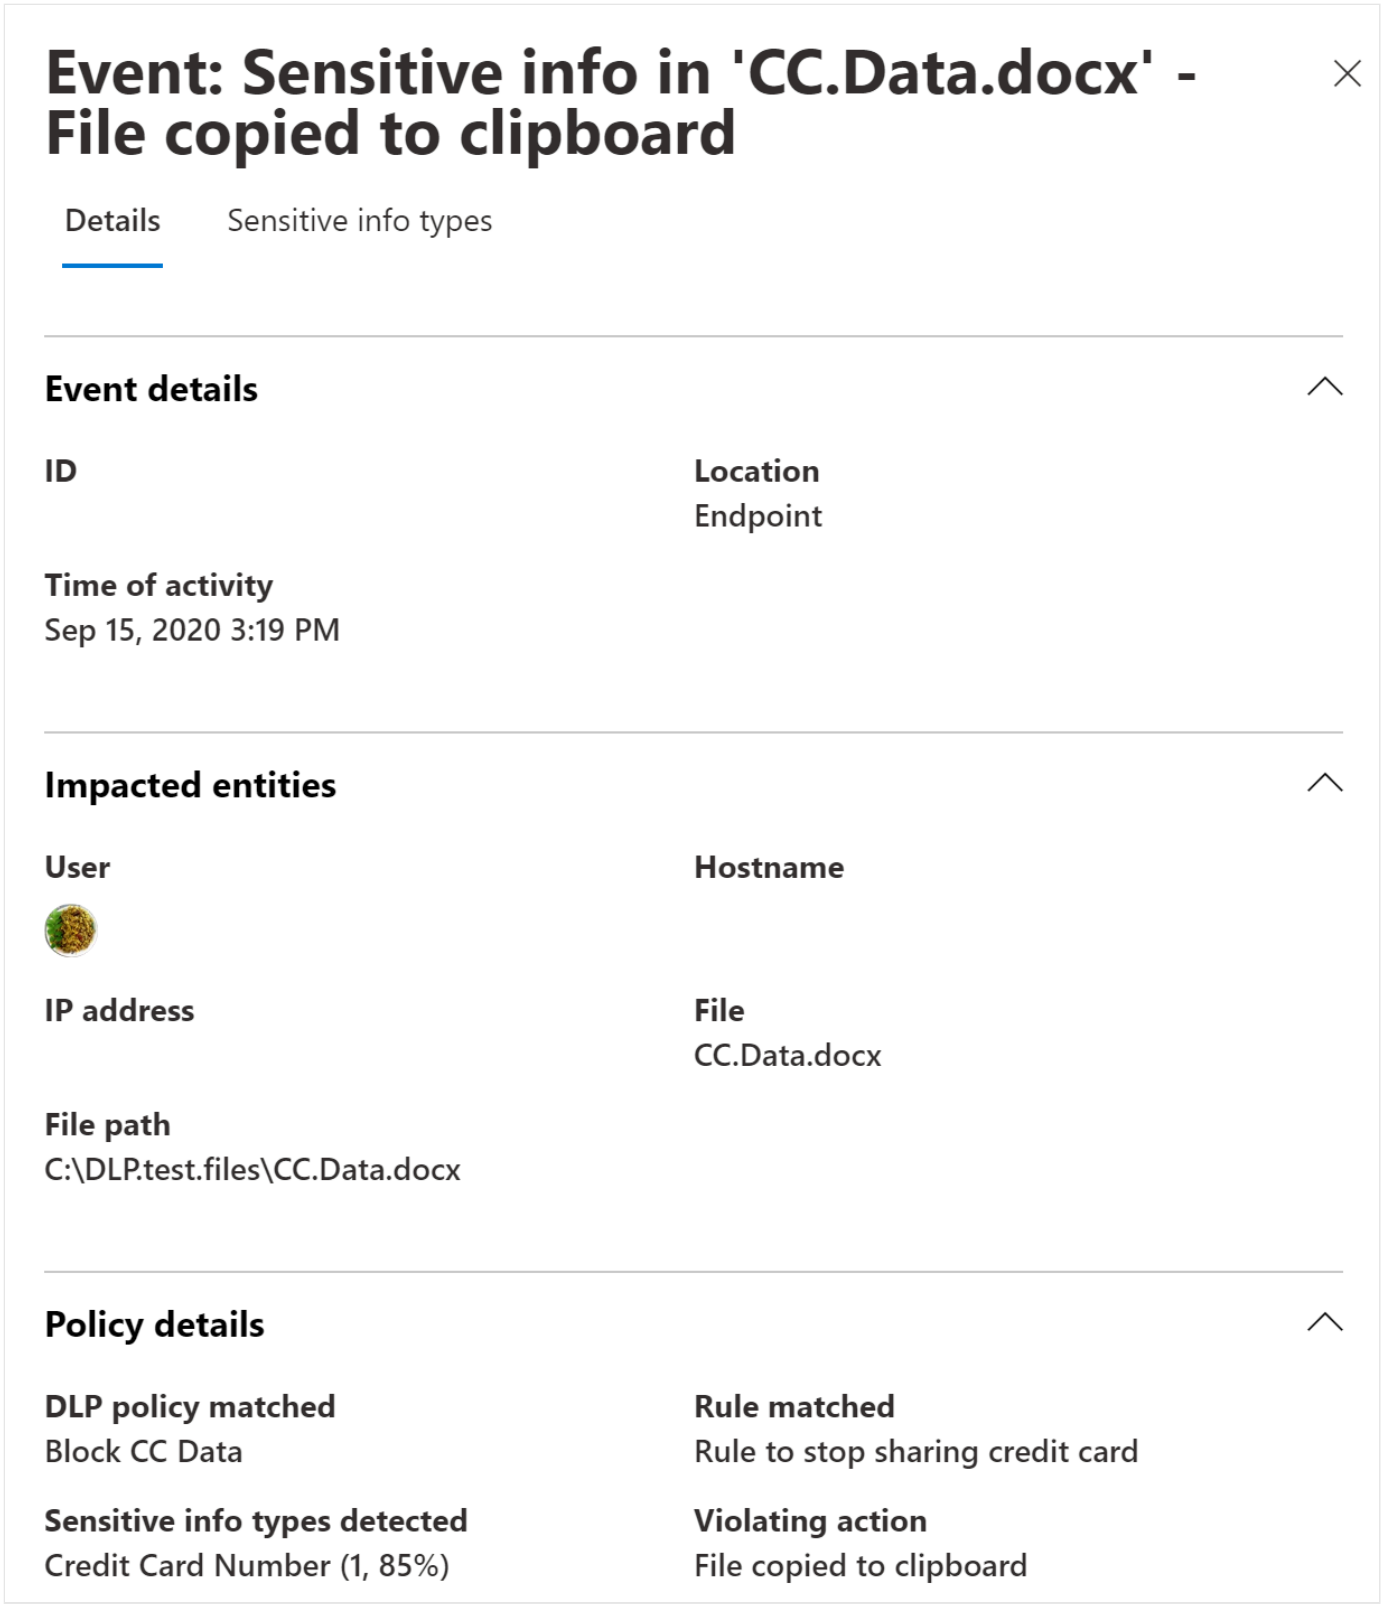


Onboarding and offboarding are handled via scripts that you download from the device management center. The device management center has custom scripts for each of the following deployment methods:

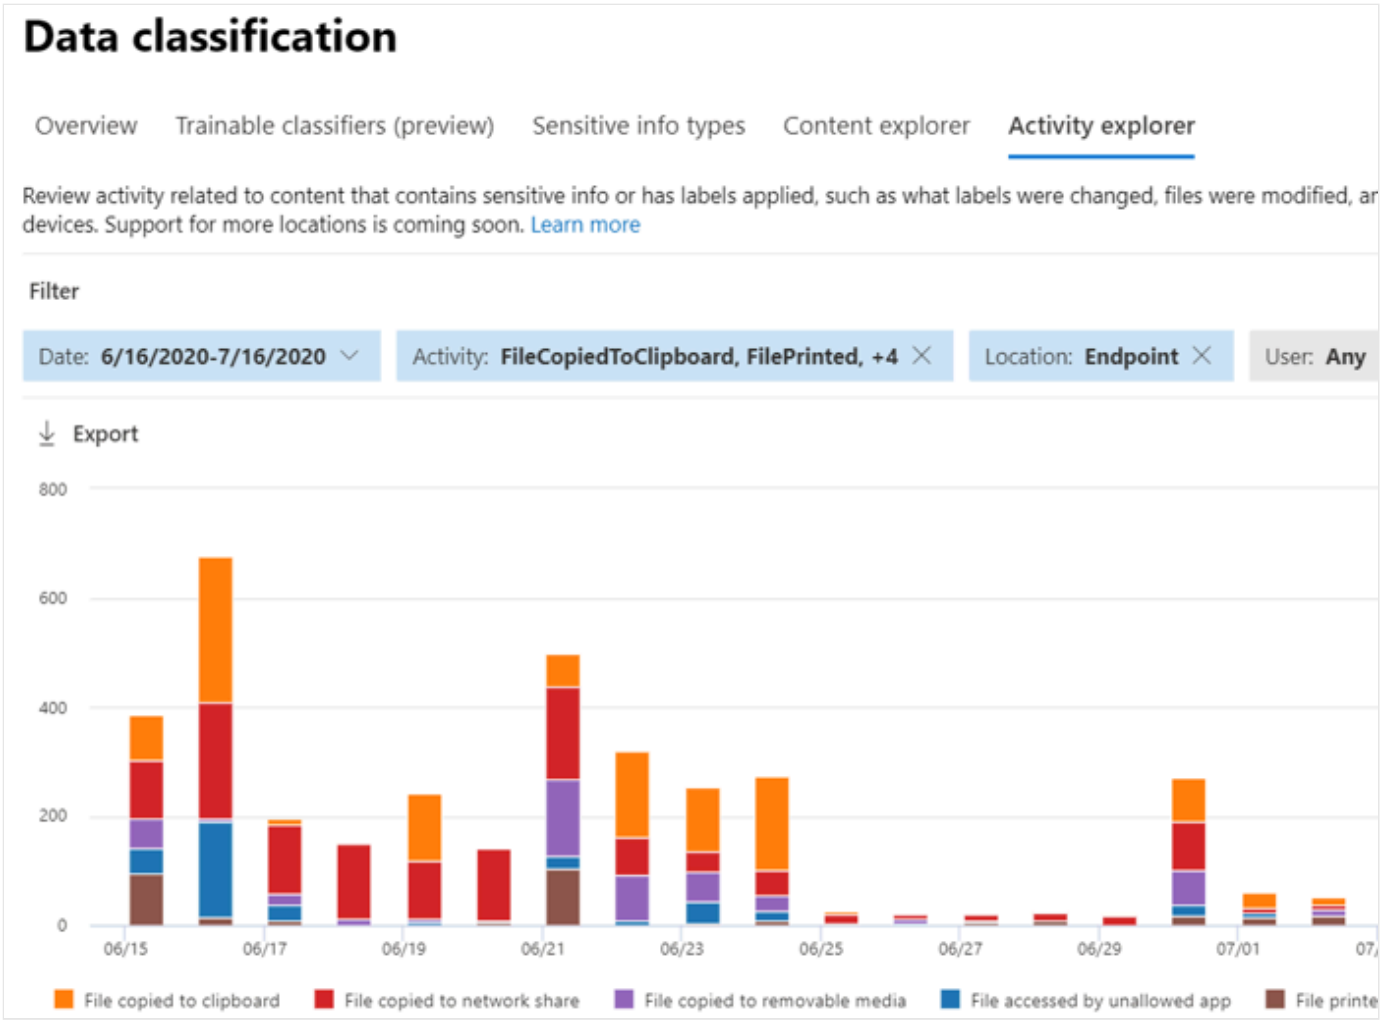
- Local script (up to 10 machines)
- Group policy
- System Center Configuration Manager (version 1610 or later)
- Mobile Device Management/Microsoft Intune
- VDI onboarding scripts for non-persistent machines

Use the procedures in Getting started with Microsoft 365 Endpoint DLP to onboard devices.

Onboarding devices to Defender also onboards them to DLP. So, if you have onboarded devices through Microsoft Defender for Endpoint, those devices show up automatically in the list of devices. You need only **Turn on device monitoring** to use endpoint DLP.



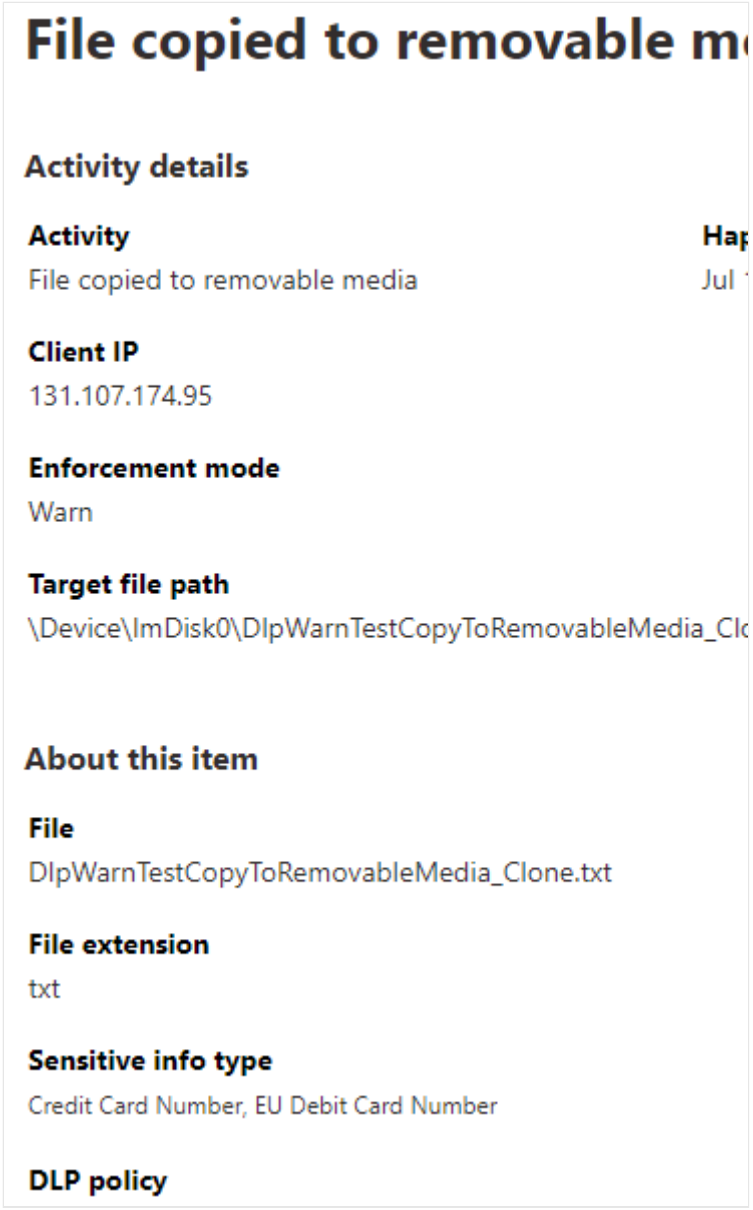
Viewing Endpoint DLP data



You can view alerts related to DLP policies enforced on endpoint devices by going to the DLP Alerts Management Dashboard and Investigate data loss incidents with Microsoft Defender XDR.

You can also view details of the associated event, with rich metadata, in the same dashboard

Once a device is onboarded, information about audited activities flows into Activity explorer even before you configure and deploy any DLP policies that have devices as a location.



Endpoint DLP collects extensive information on audited activity.

For example, if a file is copied to removable USB media, you'd see these attributes in the activity details:

- activity type
- client IP
- target file path
- happened timestamp
- file name
- user
- file extension
- file size
- sensitive information type (if applicable)
- sha1 value
- sha256 value
- previous file name
- location
- parent

- filepath
- source location type
- platform
- device name
- destination location type
- application that performed the copy
- Microsoft Defender for Endpoint device ID (if applicable)
- removable media device manufacturer
- removable media device model
- removable media device serial number

Why are all endpoint policies on all onboarded devices?

A device can support multiple user accounts. Because endpoint policies are scoped to users, different users of the device may have different policies scoped to them. Therefore, the device

must have access to all endpoint DLP policies in order to evaluate items. All devices that are onboarded into Purview are scanned regardless if the user is in scope.

Endpoint DLP and offline devices

When a Windows endpoint device is offline, existing policies continue to be enforced on existing files. Additionally, with just-in-time protection enabled and in "block" mode, when a new *file* is created on an offline device, the file is still prevented from being shared until the device connects to the data classification service and evaluation completes. If a new *policy* is created on the server, or an existing policy is modified, those changes are updated on the device once it reconnects to the internet.

> **Important**
>
> This functionality isn't supported on macOS endpoint devices.

Consider the following use cases.

1. Policies that have been pushed to a device will continue to be applied to files already classified as sensitive even after the device goes offline.
2. Policies that are updated while a device is offline won't be pushed to that device. Similarly, such policies won't be enforced on that device, until the device is back online. However, the outdated policy that exists on the offline device will still be enforced. Just-in-time protection

If notifications are configured to display, they'll always display when DLP policies are triggered, regardless of whether or not the device is online.

> **Note**
>
> While policies that have already been pushed to an offline device are enforced, the enforcement events don't appear in activity explorer until the device is back online.

DLP policies regularly sync to endpoint devices. If a device is offline, the policies can't be synchronized. In this case, the **Devices list** reflects that the device is out of sync with the policies in on the server.

Just-in-time protection

Just-in-time protection blocks egress activities on these monitored files until policy evaluation completes successfully:

- Items that have never been evaluated.
- Items on which the evaluation has gone stale. These are previously evaluated items that haven't been reevaluated by the current, updated cloud versions of the policies.

For more information on how just-in-time protection works,see Learn about just-in-time protection, and Get started with Microsoft Purview Data Loss Prevention just-in-time protection.

Next steps

Now that you've learned about Endpoint DLP, your next steps are:

1. Onboard Windows 10 or Windows 11 devices into Microsoft Purview overview
2. Onboard macOS devices into Microsoft Purview overview
3. Configure endpoint data loss prevention settings
4. Using Endpoint data loss prevention

Get started with endpoint data loss prevention

Endpoint data loss prevention (Endpoint DLP) is part of the Microsoft Purview Data Loss Prevention (DLP) suite of features you can use to discover and protect sensitive items across Microsoft 365 services. For more information about all of Microsoft's DLP offerings, see Learn about data loss prevention. To learn more about Endpoint DLP, see Learn about Endpoint data loss prevention

Microsoft Endpoint DLP allows you to monitor onboarded Windows 10, and Windows 11 and onboarded macOS devices running any of the three latest released versions. Once a device is onboarded, DLP detects when sensitive items are used and shared. This gives you the visibility and control you need to ensure that they're used and protected properly, and to help prevent risky behavior that might compromise them.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Before you begin

SKU/subscriptions licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

> **Important**
>
> Endpoint DLP policy targeting can be configured using a combination of users and devices. If a policy is scoped to devices where the signed-in users do not meet the **required criteria**, ensure those users or devices or both are explicitly excluded from the policy. Failure to do so may lead to unintended policy enforcement behavior.

Configure proxy on the Windows 10 or Windows 11 device

If you're onboarding Windows 10 or Windows 11 devices, check to make sure that the device can communicate with the cloud DLP service. For more information, see, Configure device proxy and internet connection settings for Microsoft Purview Endpoint DLP.

Windows 10 and Windows 11 Onboarding procedures

For a general introduction to onboarding Windows devices, see:

- Onboard Windows devices into Microsoft 365 overview

For specific guidance to onboarding Windows devices, see:

Expand table

Article	Description
Onboard Windows 10 or 11 devices using Group Policy	Use Group Policy to deploy the configuration package on devices.
Onboard Windows 10 or 11 devices using Microsoft Endpoint Configuration Manager	You can use either use Microsoft Endpoint Configuration Manager (current branch) version 1606 or Microsoft Endpoint Configuration Manager (current branch) version 1602 or earlier to deploy the configuration package on devices.
Onboard Windows 10 or 11 devices using Microsoft Intune	Use Microsoft Intune to deploy the configuration package on device.
Onboard Windows 10 or 11 devices using a local script	Learn how to use the local script to deploy the configuration package on endpoints.
Onboard non-persistent virtual desktop infrastructure (VDI) devices	Learn how to use the configuration package to configure VDI devices.

Endpoint DLP support for virtualized environments

You can onboard virtual machines as monitored devices in Microsoft Purview portal. There's no change to the onboarding procedures listed above.

The table that follows lists the virtual operating systems that are supported by virtualization environments.

Expand table

Virtualization platform	Windows 10	Windows 11	Windows Server 2019	Windows Server 2022 21H2, 22H2, Data Center
Azure virtual desktop (AVD)	• Single session supported for 21H2, 22H2 • Multi session supported for 21H2, 22H2	• Single session supported for 21H2, 22H2 • Multi session supported for 21H2, 22H2	Single session and Multi session supported.	Supported
Windows 365	• Supported for 21H2, 22H2	• Supported for 21H2, 22H2	Not applicable	Not applicable
Citrix Virtual Apps and Desktops 7 (2209 and higher)	• Single session supported for 21H2, 22H2 • Multi session supported for 21H2, 22H2	• Single session supported for 21H2, 22H2 • Multi session supported for 21H2, 22H2	Supported	Supported
Amazon workspaces	• Single session supported for 21H2, 22H2	Not applicable	• Windows 10 powered by Windows Server 2019	Not applicable
Hyper-V	• Single session supported for 21H2, 22H2 • Multi session with Hybrid AD join supported for 21H2, 22H2	• Single session supported for 21H2, 22H2 • Multi session with Hybrid AD join supported for 21H2, 22H2	Supported with Hybrid AD join	Supported with Hybrid AD join

Known issues

1. You can't monitor **Copy to Clipboard** and **Enforcing Endpoint DLP** on Azure Virtual Desktop environments via browsers. However, the same egress operation will be monitored by **Endpoint DLP for actions via Remote Desktop Session (RDP)**.
2. Citrix XenApp doesn't support access by restricted app monitoring.

Limitations

1. Handling of USBs in virtualized environments: USB storage devices are treated as network shares. You need to include the **Copy to network share** activity to monitor **Copy to a USB device**. All activity explorer events for virtual devices and incident alerts show the **Copy to a network share** activity for all copy to USB events.

macOS onboarding procedures

For a general introduction to onboarding macOS devices, see:

- Onboard macOS devices into Microsoft Purview

For specific guidance to onboarding macOS devices, see:

> **Important**
>
> There are important permission changes for Microsoft Purview Endpoint DLP in macOS 27. If you're onboarding or upgrading devices that run macOS 27, review the updated guidance before deployment. For more information, see Microsoft Purview Endpoint DLP on macOS 27 (Preview).

Microsoft Purview Endpoint DLP changes in macOS 27 overview (preview)

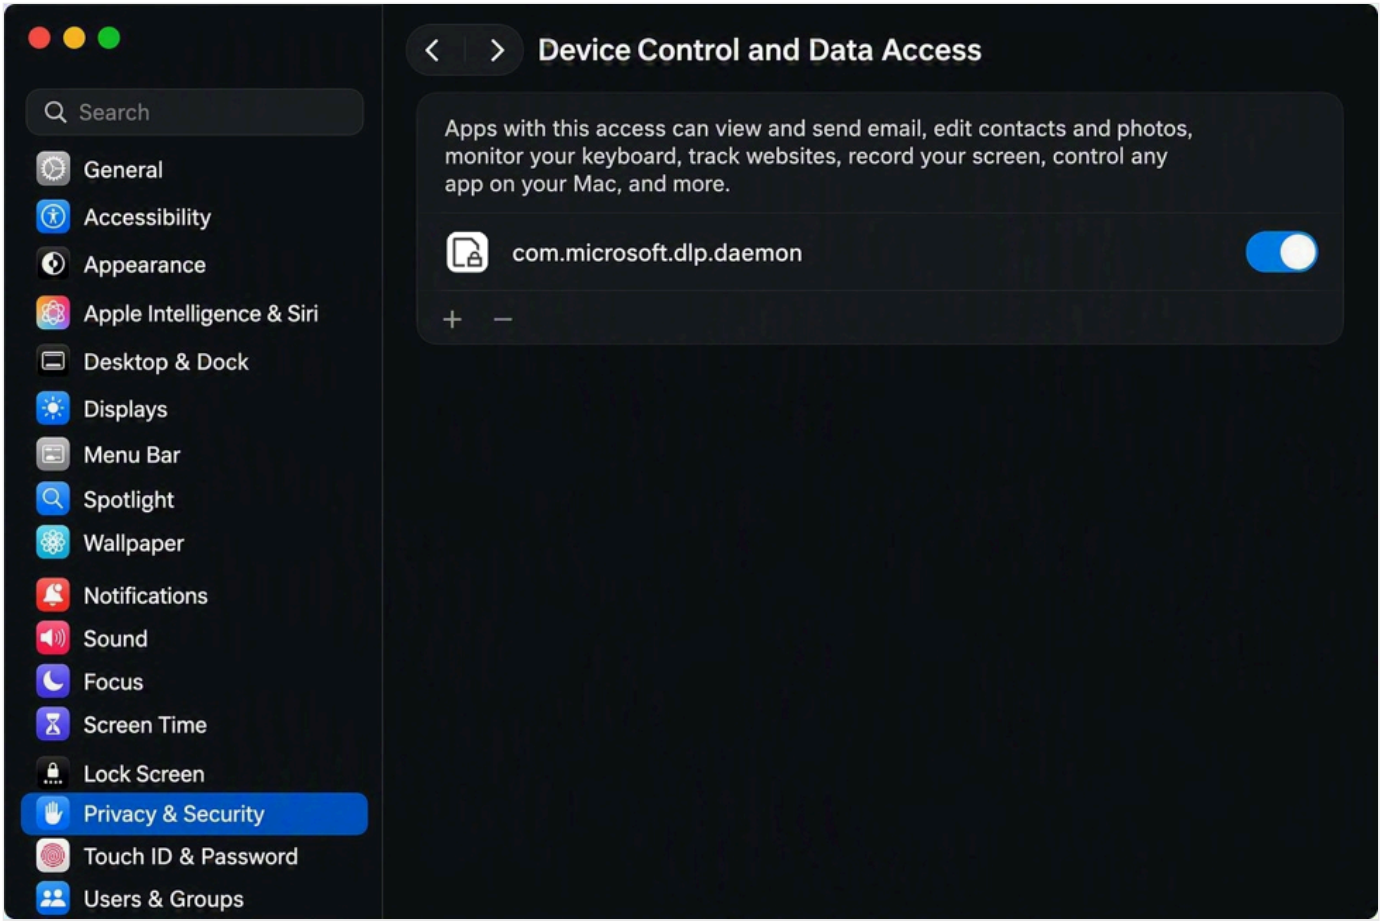
Microsoft Purview Endpoint Data Loss Prevention (Endpoint DLP) uses macOS permissions to identify websites, applications, files, and active content involved in user activities. This information helps Endpoint DLP evaluate policies and apply protection actions for activities such as uploading sensitive data to websites and cloud services or copying sensitive content to a browser.

Before macOS 27 (Golden Gate), Endpoint DLP relied on the **Accessibility** permission for browser and website visibility. In macOS 27, **Device Control and Data Access** manages this capability. Users can disable this permission after it's deployed through mobile device management (MDM), which can affect Endpoint DLP's ability to get browser and website context. To help maintain data protection coverage, administrators can configure protection modes, monitor permission status, and guide users to restore the required permission when needed.

This article describes the changes introduced in macOS 27, their impact on Endpoint DLP, and how administrators can prepare their organization. Administrators can configure protection modes, monitor affected devices, and validate deployment readiness.

> **Important**
>
> Use Endpoint DLP client version 101.26072 or later with this macOS 27 guidance.

Prerequisites

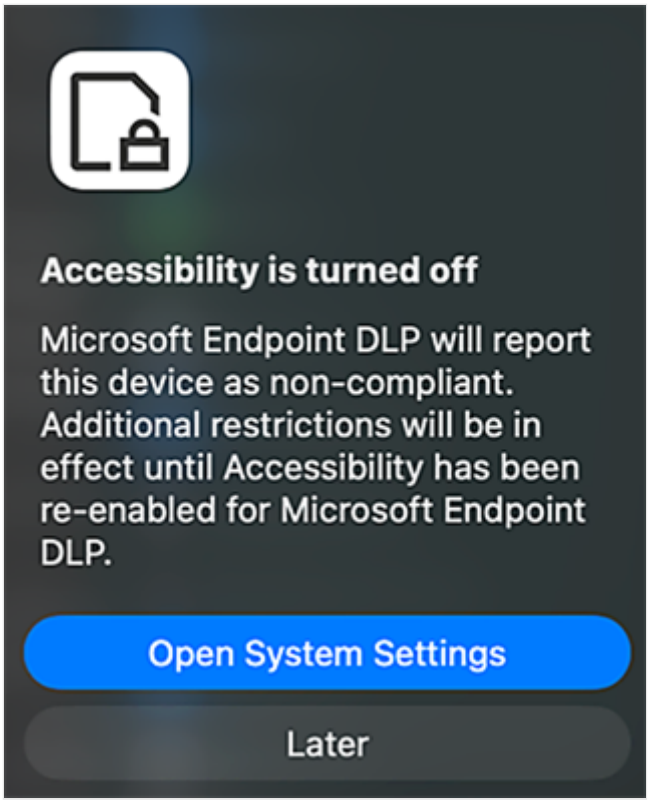


- Endpoint DLP client version 101.26072 or later.
- Familiarity with onboarding macOS devices into Microsoft Purview.

Permission changes in macOS 27

On macOS 27, Endpoint DLP uses **Device Control and Data Access** permission to support browser visibility, activity monitoring, and policy enforcement. The permission lets Endpoint DLP identify the active browser, website, application, and file associated with user activity. This context supports policies for activities such as uploading sensitive files and pasting sensitive content into browsers.

In macOS 27, the permission is under **Settings** > **Privacy & Security** > **Device Control and Data Access**. In earlier macOS versions, the permission is under **Settings** > **Privacy & Security** > **Accessibility**.



In some macOS interfaces, management profiles, and diagnostic logs, Microsoft Endpoint DLP might appear as `com.microsoft.dlp.daemon.app` or `com.microsoft.dlp.daemon`. These identifiers refer to the Endpoint DLP application.

Behavior when permission is turned off

When Endpoint DLP detects that a user turned off the Microsoft Purview Endpoint DLP permission under **Device Control and Data Access**, Endpoint DLP can no longer get URL and browser context for Safari, Chrome, and Firefox. Endpoint DLP responds by:

1. Displaying a notification that prompts the user to restore the permission (see the following screenshot).

2. Applying administrator-configured protection settings when browser URL context is unavailable.

Administrators can configure separate protection modes for:

- Uploading sensitive files to websites and cloud services
- Copying sensitive data to a browser

Protection modes

Endpoint DLP provides **Enforce**, **Audit**, and **Off** modes for cloud egress and paste-to-browser activities when the permission is unavailable. The default for both settings is **Enforce**.

Uploading sensitive files to websites and cloud services

Setting name: Restricted protection mode for cloud egress

This setting controls how Endpoint DLP handles uploads of sensitive files when browser and website context are unavailable.

- **Enforce**: Applies upload protection. Endpoint DLP treats supported non-Edge browsers, such as Safari, Chrome, and Firefox, as restricted destinations and enforces the most restrictive applicable policy action.
- **Audit**: Records and monitors the condition without enforcing upload restrictions.

- **Off**: Doesn't apply permission-related upload protection.

Copying sensitive data to a browser

Setting name: Restricted protection mode for paste to browse

This setting controls how Endpoint DLP handles copy-and-paste activities into browsers when browser and website context are unavailable.

- **Enforce**: Applies policy actions, such as block or warn.
- **Audit**: Records events without enforcing restrictions.
- **Off**: Doesn't apply permission-related browser copy-and-paste protection.

Permission notification

Setting name: Permission notification (`notification`)

Endpoint DLP can notify users when the permission is turned off. The notification explains why permission is required and prompts the user to restore access. Administrators can customize the notification message.

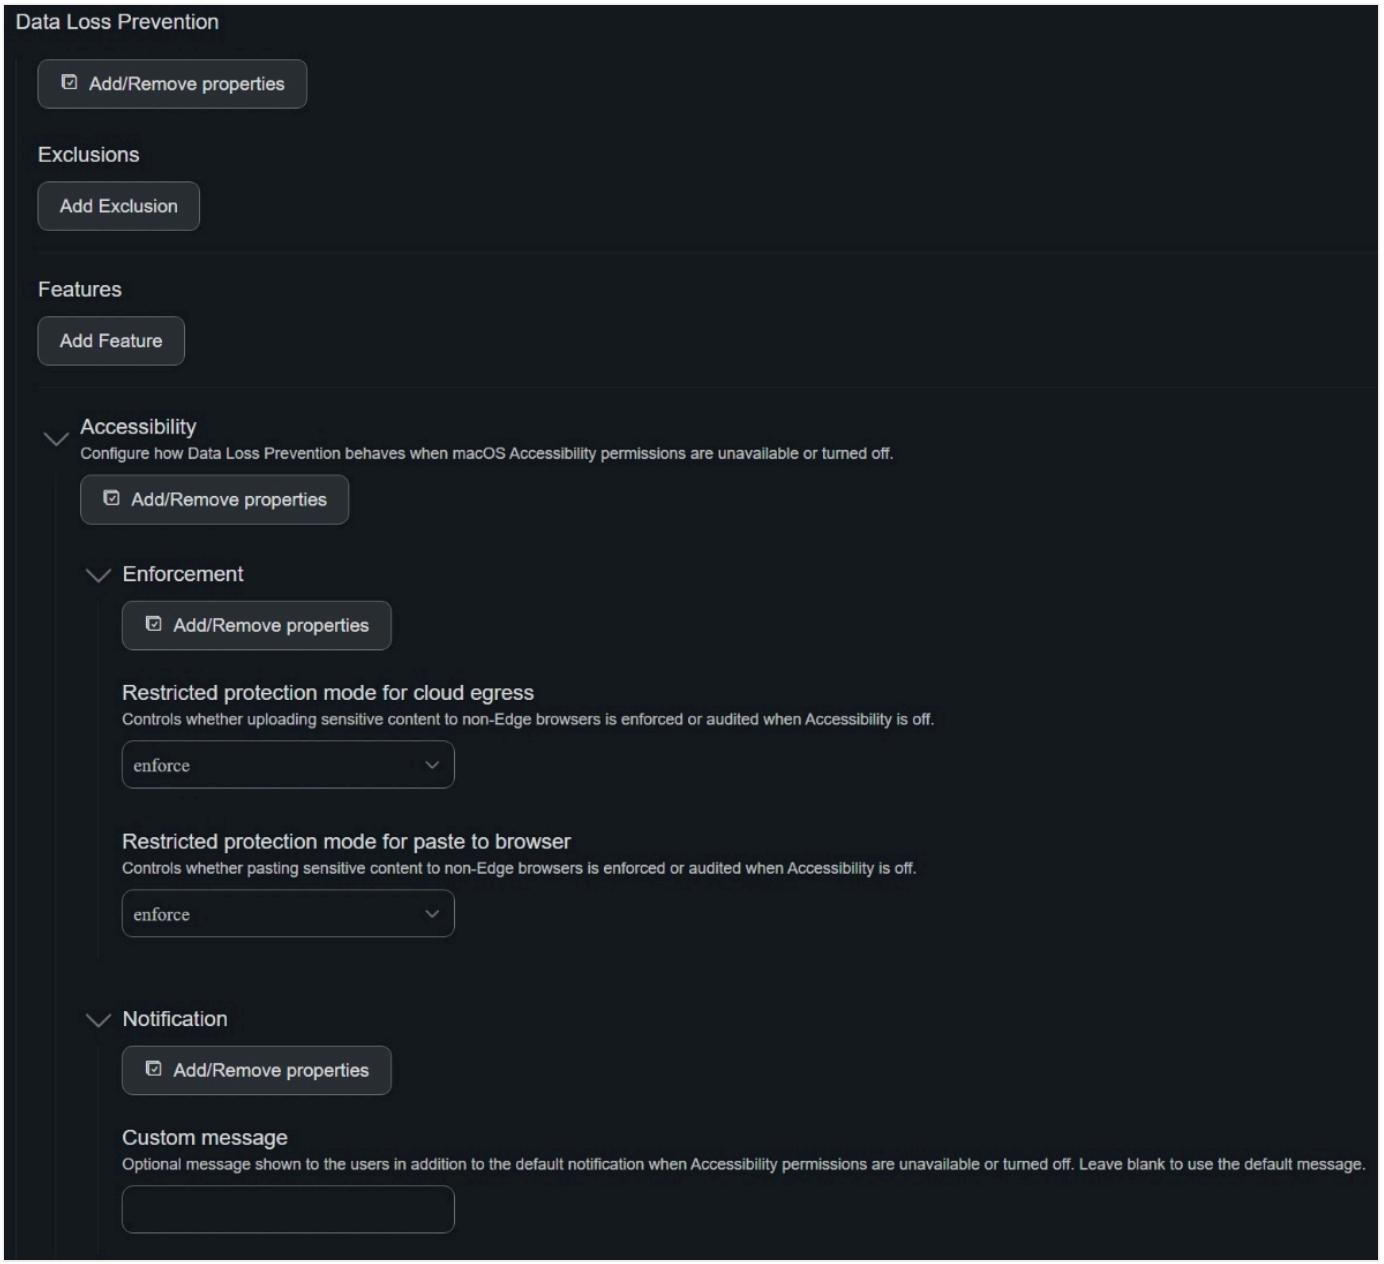
The profile settings map to the following configuration keys:

Expand table

Customer scenario	Setting name	Configuration key
Uploading sensitive files to websites and cloud services	Restricted protection mode for cloud egress	`unallowedBrowserMode`
Copying sensitive data to a browser	Restricted protection mode for paste to browser	`pasteToBrowserMode`
Permission notification	Permission notification	`notification`

The following source fragment sets both protection modes to Enforce:

XML



```
<key>accessibility</key>
                    <dict>
                        <key>enforcement</key>
                        <dict>
                            <key>unallowedBrowserMode</key>
                            <string>enforce</string>
                            <key>pasteToBrowserMode</key>
```

```
                            <string>enforce</string>
                        </dict>
                        <key>notification</key>
                        <dict>
                            <key>Microsoft Endpoint DLP will report this device as
non-compliant. Additional restrictions will be in effect until Accessibility has been
re-enabled for Microsoft Endpoint DLP</key>
                            <string/>
                        </dict>
                    </dict>
```

MDM configuration options

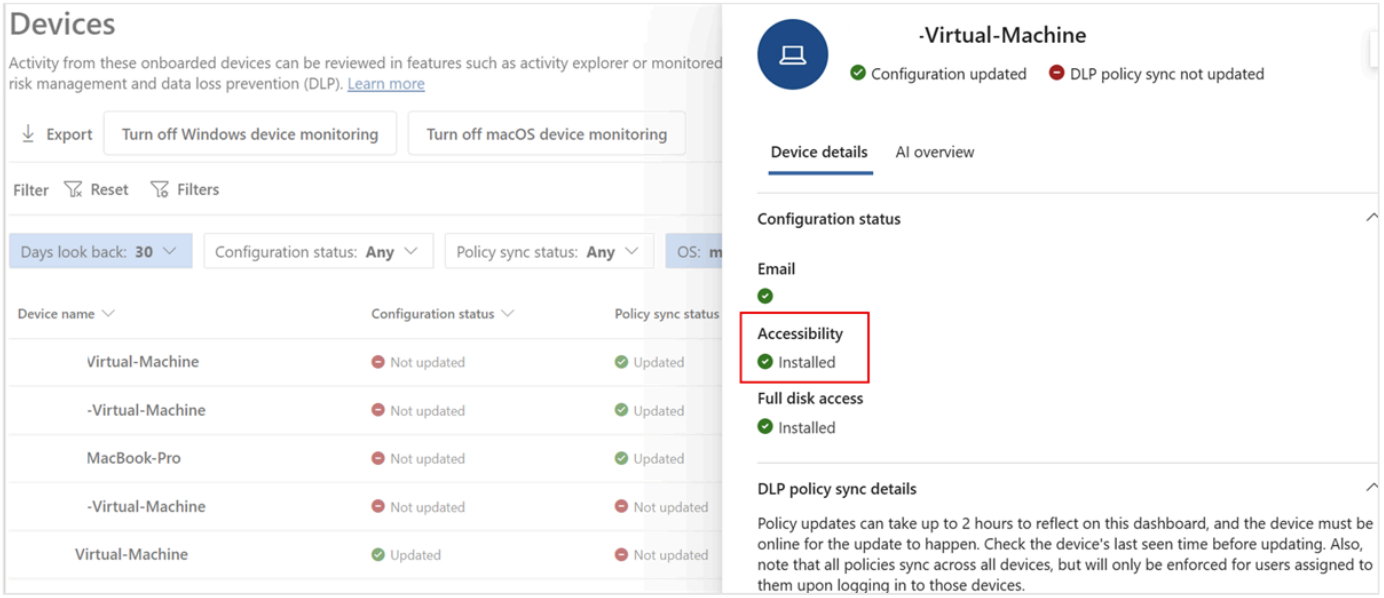
Microsoft provides configuration samples for Microsoft Intune and Jamf Pro. These options configure the protection modes and the message that prompts users to turn on the permission.

- **Microsoft Intune**: Use the sample com.microsoft.wdav.mobileconfig configuration profile as the starting point for deployment.
- **Jamf Pro with `schema.json`**: Update the existing Microsoft Defender for Endpoint preferences configuration profile to use the latest schema.json. The configuration is under **Data Loss Prevention** > **Accessibility**.
- **Jamf Pro with a property list**: Use the sample com.microsoft.wdav.plist.

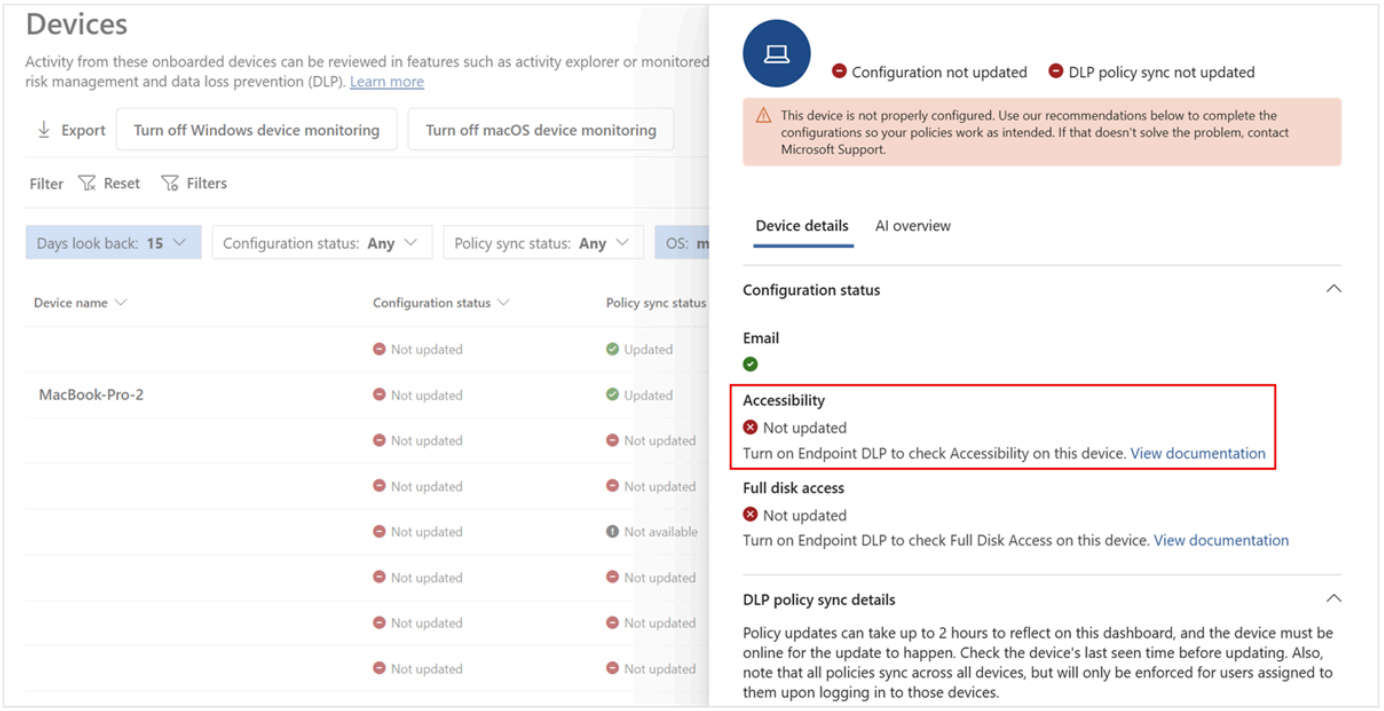
Audit mode

Audit mode lets administrators assess the effect of unavailable permissions before they enable enforcement. Endpoint DLP continues to detect when the permission is turned off and can notify users to restore access, but it doesn't apply the additional restricted protection behavior for cloud egress or paste-to-browser activities.

Audit mode can reduce user disruption while administrators identify affected devices. During this assessment, controls that would normally apply when browser context is unavailable aren't enforced. This condition can leave a temporary protection gap until the permission is restored or enforcement is enabled.



The following source fragment sets both protection modes to Audit:



XML

```
<key>accessibility</key>
                    <dict>
                        <key>enforcement</key>
                        <dict>
                            <key>unallowedBrowserMode</key>
                            <string>audit</string>
                            <key>pasteToBrowserMode</key>
                            <string>audit</string>
                        </dict>
                        <key>notification</key>
                        <dict>
                            <key>Microsoft Endpoint DLP will report this device as
non-compliant. Additional restrictions will be in effect until Accessibility has been
re-enabled for Microsoft Endpoint DLP</key>
                            <string/>
                        </dict>
                    </dict>
```

Permission monitoring

Monitor Endpoint DLP permission status in Microsoft Purview. The device details pane shows the **Accessibility** configuration status for an onboarded macOS device. A status of **Installed** indicates the required permission is configured, while **Not updated** indicates the permission isn't available to Endpoint DLP and requires administrator attention. See the following screenshot examples.

Administrator readiness

Preparing Endpoint DLP for macOS 27 includes the following activities:

1. Review the updated macOS deployment guidance for Endpoint DLP.
2. Deploy or validate the required Endpoint DLP permission configuration on managed macOS devices.
3. Upgrade to Endpoint DLP client version 101.26072 or later.
4. Monitor the **Device Onboarding** page for devices that report the permission as off.
5. Configure user notifications and educate users to restore the permission if it's turned off.

Configure endpoint data loss prevention settings

Centrally configured settings control many aspects of endpoint data loss prevention (DLP) behavior. These settings apply to all DLP policies for devices. Use these settings to control the following behaviors:

- Cloud egress restrictions
- Various types of restrictive actions on user activities per application
- File path exclusions for Windows and macOS devices
- Browser and domain restrictions
- Appearance of business justifications for overriding policies in policy tips
- Whether actions performed on Office, PDF, and CSV files are automatically audited

To access these settings, from the Microsoft Purview portal, go to **Data loss prevention** > **Overview** > **Data loss prevention settings** > **Endpoint settings**.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

> **Important**

Advanced classification scanning and protection

When you turn on advanced classification scanning and protection, the Microsoft Purview cloud-based data classification service scans items, classifies them, and returns the results to the local machine. Because advanced classification runs in the cloud, you can take advantage of classification techniques such as exact data match classification, trainable classifiers, credential classifiers, and named entities in your DLP policies.

> **Note**
>
> The **Paste to browser** action doesn't support advanced classification.

When you turn on advanced classification, the local device sends content to the cloud services for scanning and classification. If you're concerned about bandwidth usage, set a limit on how much bandwidth can be used in a rolling 24-hour period. You configure the limit in **Endpoint DLP settings** and it applies per device. If you set a bandwidth usage limit and that usage limit is exceeded, DLP stops sending the user content to the cloud. At that point, data classification continues locally on the device but classification by using exact data match, named entities, trainable classifiers, and credential classifiers isn't available. When the cumulative bandwidth usage drops below the rolling 24-hour limit, communication with the cloud services resumes.

If bandwidth usage isn't a concern, select **Do not limit bandwidth. Unlimited** to allow unlimited bandwidth use.

Advanced classification file scanning size limits

Even if you enable **Do not limit bandwidth. Unlimited** for advanced classification, limits still exist on the size of individual files that the system can scan.

- There's a 64-MB limit on text files.
- There's a 50-MB limit on image files when Optical Character Recognition (OCR) is enabled.

Advanced classification doesn't work for text files larger than 64 MB, even if you set the bandwidth limit to **Do not limit bandwidth. Unlimited**.

The following Windows versions (and later versions) support advanced classification scanning and protection.

- All Windows 11 versions
- Windows 10 versions 20H1/21H1 or higher (KB 5006738)
- Windows 10 RS5 (KB 5006744)

> **Note**
>
> - Support for advanced classification is available for Office (Word, Excel, PowerPoint) and PDF file types.
> - DLP policy evaluation always occurs in the cloud, even if user content isn't being sent.

> **Tip**
>
> To use advanced classification for Windows 10 devices, you must install KB5016688. To use advanced classification for Windows 11 devices, you must install KB5016691 on those Windows 11 devices. Additionally, you must enable advanced classification before **Activity explorer** displays contextual text for DLP rule-matched events. To learn more about contextual text, see the "Contextual summary" section in Learn about data loss prevention.

Advanced label-based protection for all files on devices

When you turn on advanced label-based protection, users can work on files - including files other than Office and PDF files - that have sensitivity labels applying access control settings in an unencrypted state, on their devices. Endpoint DLP continues to monitor and enforce access control and label-based protections on these files even in an unencrypted state. It automatically encrypts them before they're transferred outside from a user's device. For more information about advanced label-based protection, see Learn about Advanced Label Based Protection.

> **Note**
>
> Advanced label-based protection is supported only on onboarded Windows devices.

File path exclusions

To exclude certain paths from DLP monitoring, DLP alerts, and DLP policy enforcement on your devices, set up file path exclusions to turn off those configuration settings. Files in excluded locations aren't audited. Any files that you create or modify in those locations aren't subject to DLP policy enforcement. To configure path exclusions in DLP settings, go to Microsoft Purview portal > **Data loss prevention** > **Overview** > **Data loss prevention settings** > **Endpoint settings** > **File path exclusions for Windows**.

File path exclusions for Windows

Use the following logic to construct your exclusion paths for Windows 10 and Windows 11 devices:

- A valid file path that ends with `\` means only files directly under the specified folder are excluded.
  Example: `C:\Temp\`
- A valid file path that ends with `\*` means only files within subfolders of the specified folder are excluded. Files directly under the specified folder itself aren't excluded.
  Example: `C:\Temp\*`
- A valid file path that ends without `\` or `\*` means all files directly under the specified folder and all of its subfolders are excluded.
  Example: `C:\Temp`
- A path with a wildcard between `\` from each side.
  Example: `C:\Users\*\Desktop\`
- A path with a wildcard between `\` from each side and with `(number)` to specify the exact number of subfolders to exclude.
  Example: `C:\Users\*(1)\Downloads\`
- A path with SYSTEM environment variables.
  Example: `%SystemDrive%\Test\*`
- A mix of all the patterns described here.
  Example: `%SystemDrive%\Users\*\Documents\*(2)\Sub\`

Windows file paths excluded by default

- `%SystemDrive%\\Users\\*(1)\\AppData\\Roaming`
- `%SystemDrive%\\Users\\*(1)\\AppData\\Local`

File path exclusions for Mac

You can also add your own exclusions for macOS devices.

- File path definitions are case insensitive, so `User` is the same as `user`.
- Wildcard values are supported. So a path definition can contain an asterisk (`*`) in the middle of the path or at the end of the path.
  Example: `/Users/*/Library/Application Support/Microsoft/Teams/*`

macOS file paths excluded by default

`/System`

Recommended file path exclusions for macOS

For performance reasons, Endpoint DLP includes a list of recommended file path exclusions for macOS devices. If you set the **Include recommended file path exclusions for Mac** toggle to **On**, the following paths are also excluded:

- `/Applications`
- `/usr`
- `/Library`
- `/private`
- `/opt`
- `/Users/*/Library/Logs`
- `/Users/*/Library/Containers`

- `/Users/*/Library/Application Support`
- `/Users/*/Library/Group Containers`
- `/Users/*/Library/Caches`
- `/Users/*/Library/Developer`

Keep the **Include recommended file path exclusions for Mac** toggle set to **On**. However, you can stop excluding these paths by setting the **Include recommended file path exclusions for Mac** toggle to **Off**.

Set up evidence collection for file activities on devices

When DLP identifies items that match policies on devices, it can copy them to an Azure storage account. Copying matched items to an Azure storage account is useful for auditing policy activity and troubleshooting specific matches. Use the **Set up evidence collection for file activities on devices** settings to add the name and URL of the storage account.

> **Note**
>
> Before you enable evidence collection, create an Azure storage account and a container in that storage account. You must also configure permissions for the account. As you set up your Azure storage account, keep in mind that you probably want to use a storage account that's in the same Azure region or geopolitical boundary as your tenant. Consider configuring Azure storage account access tiers and Azure storage account pricing.

- For more information on copying matched items to Azure storage, see Learn about collecting files that match data loss prevention policies from devices.
- For more information on how to configure this feature, see Get started with collecting files that match data loss prevention policies from devices.

Network share coverage and exclusions

Network share coverage and exclusions extends endpoint DLP policies and actions to new and edited files on network shares and mapped network drives. If just in time protection is also enabled, just in time protection coverage and exclusions are extended to network shares and mapped drives. To exclude a specific network path for all monitored devices, add the path value in **Exclude these network share paths**.

> **Important**
>
> To use **Network share coverage and exclusions**, devices must have the following updates applied:
>
> - Windows 10 - March 21, 2023—KB5023773 (OS Builds 19042.2788, 19044.2788, and 19045.2788) Preview, March 28, 2023—KB5023774 (OS Build 22000.1761) Preview
> - Windows 11 - March 28, 2023—KB5023778 (OS Build 22621.1485) Preview
> - Microsoft Defender April-2023 (Platform: 4.18.2304.8 | Engine: 1.1.20300.3)
> - macOS Last 3 OS versions supported; Minimum Defender app version supported - 101.24122.0005

The following table shows the default settings for network share coverage and exclusions.

Expand table

Network share coverage and exclusions	Just in time protection	Resultant behavior
Enabled	Disabled	- DLP policies scoped to Devices are applied to all network shares and mapped drives that the device connects to. Supported actions: Devices
Disabled	Enabled	- Just-in-time protection is applied only to the files on storage devices that are local to the endpoint.
Enabled	Enabled	- DLP policies scoped to Devices are applied to all network shares and mapped drives that the device connects to. Supported actions: Devices - Just-in-time protection is applied to all network shares and mapped drives that the device connects to.

Network share coverage and exclusions complements DLP On-premises repository actions. The following table shows the exclusion settings and the resulting behavior depending on whether DLP is enabled or disabled for on-premises repositories.

Expand table

Network share coverage and exclusions	DLP on-premises repositories	Resultant behavior
Enabled	Disabled	- DLP policies scoped to Devices are applied to all network shares and mapped drives that the device connects to. Supported actions: Devices
Disabled	Enabled	- Policies that are scoped to On-premises repositories can enforce protective actions on on-premises data-at-rest in file shares and SharePoint document libraries and folders. DLP On-premises repository actions
Enabled	Enabled	- DLP policies scoped to Devices are applied to all network shares and mapped drives that the device connects to. Supported actions: Devices - Policies that are scoped to On-premises repositories can enforce protective actions on on-premises data-at-rest in file shares and SharePoint document libraries and folders. DLP On-premises repository actions

Restricted apps and app groups

Restricted apps

The **Restricted apps** list is a custom list of applications that you create. You configure what actions DLP takes when someone uses an app on the list to ***access*** a DLP-protected file on a device. The **Restricted apps** list is available for Windows 10/11 and macOS devices running any of the three latest macOS releases.

Some apps have a web-based interface in addition to a locally installed version of the application. In preview, when you add an app that users can access both locally and through a web-based interface to a **Restricted app group** or as a **Restricted app**, DLP enforces any applicable policies for accessing a protected file through Edge for the browser app interface and on the device for the application-based interface.

> **Important**
>
> - Don't include the path to the executable for Windows devices. Include only the executable name, such as `browser.exe`.

- The action (`audit`, `block with override`, or `block`) that you define for apps on the restricted apps list only applies when a user attempts to ***access*** a protected item.

When you select **Access by restricted apps** in a policy and a user uses an app on the restricted apps list to access a protected file, the activity is `audited`, `blocked`, or `blocked with override`, depending on how you configured the **Restricted apps** list. If an app on the **Restricted apps** list is also a member of a **Restricted app group**, the actions you configure for activities in the **Restricted app group** override the actions you configure for the **Restricted apps** list. All activity is audited and available for review in activity explorer.

> **Important**
>
> Endpoint DLP protections trigger when a restricted app tries to access a file, either by a user or by the application itself. To exclude a path from enforcement, add it to the exclusion list. This path is where the files identified in Activity Explorer are located.

Restricted app groups

Restricted app groups are collections of apps that you create in DLP settings and then add to a rule in a policy. When you add a restricted app group to a policy, you can take the actions defined in the following table.

Expand table

Restricted App group option	What it allows you to do
Don't restrict file activity	Tells DLP to allow users to access DLP protected items using apps in the app group without taking any action when the user attempts to **Copy to clipboard**, **Copy to a USB removable drive**, **Copy to a network drive**, or **Print** from the app.
Apply a restriction to all activity	Tells DLP to `Audit only`, `Block with override`, or `Block` when a user attempts to access a DLP-protected item using an app that's in the relevant app group
Apply restrictions to a specific activity	This setting allows a user to access a DLP-protected item using an app that is in the app group. It also allows you to select a default action (`Audit only`, `Block`, or `Block with override`) for DLP to take when a user attempts to **Copy to clipboard**, **Copy to a USB removable drive**, **Copy to a network drive**, and **Print**.

You can add a maximum of 50 apps into a single group and you can create a maximum of 10 groups. This gives a maximum of 500 apps that the policy actions can be assigned to.

> **Important**
>
> Settings in a restricted app *group* override any restrictions set in the restricted apps *list* when they are in the same rule. So, if an app is on the restricted apps list and is also a member of a restricted apps group, the settings of the restricted apps group is applied.

Block all apps except for a list of allowed apps

You can create a list of allowed applications and block all others. By creating a list of allowed applications and blocking all others, you don't need to create and manage a comprehensive list of untrusted applications. This feature helps simplify policy management and enhances your control over app-based file activities.

> **Note**
>
> Common background applications such as **teamsupdate.exe** or **svchost.exe** are preconfigured to bypass enforcement to prevent unintentional interference with essential

operations.

In this procedure, you apply the restriction level of **Allow** to explicitly allow activity for a defined app group, and then block any apps that aren't on this list. Because the policy blocks apps that aren't in the allowed group, apps that have no restriction level defined are effectively blocked, and apps that have a restriction level defined as **Allow** are explicitly allowed. You define a restricted app group to allow that app group, but you also define the restricted app group to block any apps that have no defined restrictions.

1. Go to endpoint DLP settings.
2. Define allowed or sanctioned apps in the **Restricted Apps and app groups** list.
3. In your existing or new endpoint DLP policy, locate the **File activities for apps in restricted app groups** setting.
4. Add the desired restricted app group.
5. Select **Apply restriction to all activity**, and select **Allow**. Audit and Off will not work.
6. For all other apps, set the **Access by apps that aren't on the 'unallowed apps' list** setting to **Block**.

How DLP applies restrictions to activities

Interactions between **File activities for apps in restricted app groups**, **File activities for all apps**, and the **Restricted app activities** list are scoped to the same rule.

Restricted app groups overrides

Configurations defined in **File activities for apps in restricted app groups** override the configurations in the **Restricted app activities** list and **File activities for all apps** in the same rule.

Restricted app activities and File activities for all apps

The configurations of **Restricted app activities** and **File activities for all apps** work in concert if the action defined for **Restricted app activities** is either `Audit only`, or `Block with override` in the same rule. Why? Actions defined for **Restricted app activities** only apply when a user accesses a file using an app that's on the list. Once the user has access, the actions defined for activities in **File activities for all apps** apply.

For example, you add Notepad.exe to **Restricted apps** and configure **File activities for all apps** to **Apply restrictions to specific activity**. You configure both as shown in the following table:

Expand table

Setting in policy	App name	User activity	DLP action to take
Restricted app activities	Notepad	Access a DLP protected item	Audit only
File activities for all apps	All apps	Copy to clipboard	Audit only
File activities for all apps	All apps	Copy to a USB removeable device	Block
File activities for all apps	All apps	Copy to a network share	Audit only
File activities for all apps	All apps	Print	Block
File activities for all apps	All apps	Copy or move using unallowed Bluetooth app	Blocked
File activities for all apps	All apps	Remote desktop services	Block with override

When User A opens a DLP-protected file using Notepad, DLP allows the access and audits the activity. While still in Notepad, User A then tries to copy content from the protected item to the

clipboard. This action is successful, and DLP audits the activity. User A then tries to print the protected item from Notepad and the activity is blocked.

> **Note**
>
> When the DLP action to take in **Restricted app activities** is set to `block`, all access is blocked and the user can't perform any activities on the file.

File activities for all apps only

If an app *isn't* in the **File activities for apps in restricted app groups** or the **Restricted app activities** list, or *is* in the **Restricted app activities** list, with an action of either `Audit only`, or `Block with override`, any restrictions defined in the **File activities for all apps** are applied in the same rule.

macOS devices

You can also prevent macOS apps from accessing sensitive data by adding them to the **Restricted app activities** list.

> **Note**
>
> Enter cross-platform apps with their unique paths for the OS they're running on.

To find the full path of Mac apps:

1. On the macOS device, open **Activity Monitor**. Find and double-click the process you want to restrict.
2. Select the **Open Files and Ports** tab.
3. Make a note of the full path name, including the name of the app. For example,

- `/System/Applications/TextEdit.app/Contents/MacOS/TextEdit`

Auto-quarantine

To prevent sensitive items from syncing to the cloud by cloud sync apps such as *onedrive.exe*, add the cloud sync app to the **Restricted apps** list with **Auto-quarantine**.

When enabled, autoquarantine triggers when a restricted app attempts to access a DLP-protected sensitive item. Auto-quarantine moves the sensitive item to an admin-configured folder. If configured to do so, autoquarantine can leave a placeholder (`.txt`) file in place of the original. You can configure the text in the placeholder file to tell users the new location of the item, and other pertinent information.

Use the autoquarantine feature when an unallowed cloud-sync app tries to access an item that is protected by a blocking DLP policy. DLP might generate repeated notifications. You can avoid these repeated notifications by enabling **Auto-quarantine**.

You can also use autoquarantine to prevent an endless chain of DLP notifications for the user and admins. For more information, see Help prevent exposure of sensitive files by configuring auto-quarantine for OneDrive sync

Unsupported file extension exclusions

Use the **Document could not be scanned** condition together with **Apply restrictions to only unsupported file extensions** in your DLP policies to restrict activities involving files with extensions that aren't supported by endpoint DLP. Because this condition can potentially include many unsupported file extensions, refine detection by adding unsupported extensions to exclude.

For more information, see Help protect files that Endpoint Data Loss Prevention doesn't scan and Help protect against sharing of a defined set of unsupported files.

> **Note**
>
> Don't add a `.` when you add an extension. Use the latest anti-malware client version.

> **Important**
>
> When you select **Actions** > **Audit or restrict activities on devices** rule configuration, the **Apply restrictions to only unsupported file extensions** option appears. The **Apply restrictions to only unsupported file extensions** configuration option doesn't support scoping by **Device and device groups** in the policy location setting.

Blocking specific file extensions in DLP policies can lead to unexpected behavior if an application that is marked as unallowed needs to access files with those extensions as part of its normal operation. For example, certain apps might read or temporarily open files, like `.dll`, `.json`, `.tmp` during routine processes such as rendering, caching, or validating content. If you block these extensions, the app might fail to function properly, causing errors, incomplete workflows, or enforcement pop-ups unrelated to user intent. Before implementing extension-based restrictions, make sure you know which apps interact with these file types during standard operations, and whether alternative controls, such as app restrictions or contextual rules, can achieve the security goal without disrupting functionality.

Unallowed Bluetooth apps

To prevent people from transferring files protected by your policies via specific Bluetooth apps, add those apps to the **Unallowed Bluetooth apps** list in Endpoint DLP settings.

Browser and domain restrictions to sensitive data

Restrict sensitive files that match your policies from being shared with unrestricted cloud service domains.

Unallowed browsers

For Windows devices, you can restrict the use of specified web browsers by their executable names. The specified browsers can't access files that match the conditions of an enforced DLP policy where the upload-to-cloud services restriction is set to `block` or `block override`. When these browsers are blocked from accessing a file, end users see a toast notification asking them to open the file through Microsoft Edge.

For macOS devices, you must add the full file path. To find the full path of Mac apps:

1. On the macOS device, open **Activity Monitor**. Find and double-click the process you want to restrict.
2. Choose the **Open Files and Ports** tab.
3. Make sure to make a note of the full path name, including the name of the app.

Service domains

The **Service domains** setting works with the **Audit or restrict activities on devices** setting in the workflow for creating a rule within a DLP policy.

When you create a rule, use actions to protect your content when certain conditions are met. When creating rules for endpoint devices, choose the **Audit or restrict activities on devices** option, and select one of these options:

- Audit only
- Block with override
- Block

To control whether sensitive files that your policies protect can be uploaded to specific service domains, go to **Endpoint DLP Settings** > **Browser and domain restrictions to sensitive data** and choose whether to *block* or *allow* **Service domains** by default.

> ⓘ **Note**
>
> The **Service domains** setting only applies to files uploaded by using Microsoft Edge, or by using instances of Google Chrome or Mozilla Firefox that have the Microsoft Purview Chrome Extension installed.

Block service domains

When you set the **Service domains** list to **Block**, use the **Add cloud service domain** to specify domains that you want to block. All other service domains are allowed. When the Service domains list is set to Block, DLP policy restrictions only apply when a user attempts to upload a sensitive file to any of the domains on the list.

For example, consider the following configurations:

- A DLP policy is configured to detect sensitive items that contain physical addresses and the **Audit or restrict activities on devices** option is set to **Audit only**.
- The **Service domains** setting is set to **Block**.
- contoso.com IS NOT on the list.
- wingtiptoys.com IS on the list.

In this case, if a user attempts to upload a sensitive file with physical addresses to contoso.com, the upload is allowed to complete and an audit event is generated but no alert is triggered.

In contrast, if a user attempts to upload a sensitive file with credit card numbers to wingtiptoys.com, the user activity - the upload - is also allowed to complete and both an audit event and an alert are generated.

Another example, consider the following configuration:

- A DLP policy is configured to detect sensitive items that contain physical addresses and the **Audit or restrict activities on devices** option is set to **Block**.
- The **Service domains** setting is set to **Block**.
- contoso.com IS NOT on the list.
- wingtiptoys.com IS on the list.

In this case, if a user attempts to upload a sensitive file with physical addresses to contoso.com, the upload is allowed to complete and an audit event is generated but no alert is triggered.

In contrast, if a user attempts to upload a sensitive file with credit card numbers to wingtiptoys.com, the user activity - the upload - is blocked and both an audit event and an alert are generated.

Allow service domains

When you set the **Service domains** list to **Allow**, use the **Add cloud service domain** to specify domains that are allowed. All other service domains have DLP policy restrictions enforced. When the Service domains list is set to Allow, DLP policies only apply when a user attempts to upload a sensitive file to any of the listed domains.

For example, here are two starting configurations:

- A DLP policy is configured to detect sensitive items that contain credit card numbers and the **Audit or restrict activities on devices** option is set to **Block with override**.
- The **Service domains** setting is set to **Allow**.
- contoso.com IS NOT on the **Allow** list.
- wingtiptoys.com IS on the **Allow** list.

In this case, if a user attempts to upload a sensitive file with credit card numbers to contoso.com, the upload is blocked, a warning displays, giving the user the option to override the block. If the user chooses to override the block, an audit event is generated and an alert is triggered.

However, if a user attempts to upload a sensitive file with credit card numbers to wingtiptoys.com, the policy restriction *isn't* applied. The upload is allowed to complete, and an audit event is generated but no alert is triggered.

- A DLP policy is configured to detect sensitive items that contain physical addresses and the **Audit or restrict activities on devices** option is set to **Audit only**.
- The **Service domains** setting is set to **Allow**.
- contoso.com IS NOT on the list.
- wingtiptoys.com IS on the list.

In this case, if a user attempts to upload a sensitive file with physical addresses to contoso.com, the upload is allowed to complete and both an audit event and an alert are generated.

In contrast, if a user attempts to upload a sensitive file with credit card numbers to wingtiptoys.com, the user activity - the upload - is also allowed to complete, an audit event is generated but no alert is triggered.

> **Important**
>
> When you set the service restriction mode to **Allow**, you must configure at least one service domain before the system enforces restrictions.

Summary table: Allow or block behavior

The following table shows how the system behaves depending on the settings listed.

Expand table

Endpoint DLP Service domain setting	DLP policy rule Audit or restrict activities on devices setting	User goes to a listed site	User goes to a site NOT listed
Allow	Audit only	- User activity is audited - No alert is generated - No DLP policies are applied	- User activity is audited - An alert is generated - DLP policies are applied in Audit mode
Allow	Block with override	- User activity is audited - No alert is generated - No DLP policies are applied	- User activity is audited - An alert is generated - DLP policies are applied in Block with override mode
Allow	Block	- User activity is audited - No alert is generated - No DLP policies are applied	- User activity is audited - An alert is generated - DLP policies are applied in Block mode
Block	Audit only	- User activity is audited - An alert is generated - DLP policies are applied in Audit mode	- User activity is audited - No alert is generated - No DLP policies are applied

Endpoint DLP Service domain setting	DLP policy rule Audit or restrict activities on devices setting	User goes to a listed site	User goes to a site NOT listed
Block	Block with override	- User activity is audited - An alert is generated - DLP policies are applied in Block with override mode	- User activity is audited - No alert is generated - No DLP policies are applied
Block	Block	- User activity is audited - An alert is generated - DLP policies are applied in Block mode	- User activity is audited - No alert is generated - No DLP policies are applied

When you add a domain to the list, use the FQDN format of the service domain without the ending period (`.`). Use `*.` as a wildcard to specify all domains or subdomains. Exclude the protocol (anything before `//`) from the domain. Only include the host name, without any subsites.

For example:

Expand table

Input	URL matching behavior
contoso.com	**Matches the specified domain name, and any subsite**: ://contoso.com ://contoso.com/ ://contoso.com/anysubsite1 ://contoso.com/anysubsite1/anysubsite2 (etc.) **Does not match sub-domains or unspecified domains**: ://anysubdomain.contoso.com ://anysubdomain.contoso.com.AU
*.contoso.com	**Matches the specified domain name, any subdomain, and any site**: ://contoso.com ://contoso.com/anysubsite ://contoso.com/anysubsite1/anysubsite2 ://anysubdomain.contoso.com/ ://anysubdomain.contoso.com/anysubsite/ ://anysubdomain1.anysubdomain2.contoso.com/anysubsite/ ://anysubdomain1.anysubdomain2.contoso.com/anysubsite1/anysubsite2 (etc.) **Does not match unspecified domains** ://anysubdomain.contoso.com.AU/
`www.contoso.com`	**Matches the specified domain name**: `www.contoso.com` **Does not match unspecified domains or subdomains** ://anysubdomain.contoso.com/, in this case, you have to put the FQDN domain name itself `www.contoso.com`

You can configure up to 50 domains under **Sensitive Service domains**.

> **Note**

The Service domains list setting only applies to file uploads to websites. Actions like pasting into a browser don't follow the Service Domain list.

Sensitive service domain groups

When you add a website to **Sensitive service domains**, you can set the policy to `audit`, `block with override`, or fully `block` user activity when users attempt to take any of the following actions:

- print from a website
- copy data from a website
- save a website as local files
- upload or drag/drop a sensitive file to an excluded website
- paste sensitive data to an excluded website

The following table shows which browsers support these features:

Expand table

Browser	Supported Feature
Microsoft Edge	- Print the site - Copy data from the site - Save the site as local files (save-as) - Paste to supported browsers - Upload to a restricted cloud service domain
Google Chrome (with the Microsoft Purview extension)	- Paste to supported browsers - Upload to a restricted cloud service domain
Mozilla Firefox (with the Microsoft Purview extension)	- Upload to a restricted cloud service - Paste to supported browsers

For the **Paste to supported browsers** action, there might be a brief time lag between when the user attempts to paste text into a web page and when the system finishes classifying it and responds. If this classification latency happens, you might see both policy-evaluation and check-complete notifications in Microsoft Edge or policy-evaluation toast on Chrome and Firefox. Here are some tips for minimizing the number of notifications:

1. Notifications trigger when a policy for the target website is configured to **Block** or **Block with override** the **Paste to supported browsers** for that user. You can configure the overall action to **Audit** and then use the exceptions to **Block** the target websites. Alternately, you can set the overall action to **Block** and then use the exceptions to **Audit** the secure websites.
2. Use the latest Antimalware client version.
3. Ensure your version of Microsoft Edge is 120 or higher.
4. Install these Windows KBs:
   a. Windows 10: KB5032278, KB5023773
   b. Windows 11 21H2: KB5023774
   c. Win 11 22H2: KB5032288, KB5023778
5. On macOS, ensure your antimalware Client version is 101.25022.0003 or later.

The **Paste to supported browsers** action doesn't follow the behavior defined in the Service Domain list. However, if Sensitive Service Domain Groups are configured on the rule for Paste To Browser, the system honors the configured Sensitive Service Domain Groups.

> **Note**
>
> The **Service domains** setting only applies to files uploaded by using Microsoft Edge or an instance of Google Chrome or Mozilla Firefox that has the Microsoft Purview Chrome Extension installed. The Generative AI Websites group contains these supported sites. The

group is used for default policies within Data Security Posture Management for AI and can't be edited or deleted.

For devices, you must configure the **Sensitive service domains** list to use the **Upload to a restricted cloud service domain** action in a DLP policy. You can also define website groups that you want to assign policy actions to that are different from the global website group actions. You can add a maximum of 100 websites into a single group and you can create a maximum of 150 groups. This configuration gives a maximum of 15,000 websites that the policy actions can be assigned to. For more information, see Help prevent risky user activity by monitoring or restricting access to sensitive service domains.

> **Important**
>
> Regarding the **Paste to supported browser** action. If 'Collect original file as evidence for all selected file activities on Endpoint' is enabled on the rule for this feature, garbage characters might appear in the source text if the user's Windows device doesn't have Antimalware Client Version 4.18.23110 or newer installed. Select **Actions** > **Download** to view the actual content.

For more information, see Help prevent leakage of sensitive content by restricting paste actions into browsers.

Supported syntax for designating websites in a website group

If you use URLs to identify websites, don't include the networking protocol as part of the URL (for instance, *https://* or *file://*). Instead, use a flexible syntax to include and exclude domains, subdomains, websites, and subsites in your website groups. For example,

- Use `*.` as a wildcard to specify all domains or all subdomains.
- Use `/` as a terminator at the end of a URL to scope to that specific site only.

When you add a URL without a terminating slash mark (`/`), that URL is scoped to that site and all subsites. You can only add `*.` to the beginning of a domain. The `/` terminator is only supported at the end of a domain.

This syntax applies to all http/https websites. Here are some examples:

Expand table

URL added to the website group	URL matches	URL doesn't match
contoso.com	http://contoso.com https://contoso.com https://contoso.com/ https://contoso.com/allsubsites1 https://contoso.com/allsubsites1/allsubsites2	https://allsubdomains.contoso.com https://allsubdomains.contoso.com.a https://www.contoso.com
contoso.com/	http://contoso.com https://contoso.com https://contoso.com/	https://contoso.com/allsubsites1 https://contoso.com/allsubsites1/alls https://allsubdomains.contoso.com https://allsubdomains.contoso.com/ https://www.contoso.com
*.contoso.com	http://contoso.com https://contoso.com https://www.contoso.com https://www.contoso.com/allsubsites https://contoso.com/allsubsites1/allsubsites2 https://allsubdomains.contoso.com https://allsubdomains.contoso.com/allsubsites https://allsubdomains1.allsubdomains2.contoso.com/allsubsites1/allsubsites2	https://allsubdomains.contoso.com.a
*.contoso.com/xyz	http://contoso.com/xyz/ https://contoso.com/xyz/	https://contoso.com/xyz https://allsubdomains.contoso.com/

URL added to the website group	URL matches	URL doesn't match
	https://contoso.com/xyz/allsubsites/ https://allsubdomains.contoso.com/xyz/ https://allsubdomains.contoso.com/xyz/allsubsites https://allsubdomains1.allsubdomains2.contoso.com/xyz/allsubsites https://allsubdomains1.allsubdomains2.contoso.com/xyz/allsubsites1/allsubsites2	
*.contoso.com/xyz/	http://contoso.com/xyz https://contoso.com/xyz https://contoso.com/xyz/ https://allsubdomains.contoso.com/xyz https://allsubdomains.contoso.com/xyz/	https://contoso.com https://contoso.com/xyz/allsubsites/ https://allsubdomains.contoso.com/ https://allsubdomains1.allsubdomair https://allsubdomains1.allsubdomair

Supported syntax for designating IP ranges or IP addresses (preview)

In preview, DLP supports using IP address and address ranges to identify websites. Set the Match type to *IP address* or *IP address range* and then enter a specific IP address or an IP range in the **Sensitive service domain** field. Select **Add site** to add the selection to the Sensitive service domain group.

Examples of supported syntax:

- 1.1.1.1
- 1.1.1.1-2.2.2.2
- 2001:0db8:85a3:0000:0000:8a2e:0370:7334
- 2001:0db8:85a3:0000:0000:8a2e:0370:7320-2001:0db8:85a3:0000:0000:8a2e:0370:7334

> **Important**
>
> URLs support these actions:

- **Print the site**
- **Copy data from the site**
- **Save the site as local files (save-as)**
- **Paste to supported browsers**
- **Upload to a restricted cloud service domain**

> IP address and IP address range support these actions:

- **Print the site**
- **Copy data from the site**
- **Save the site as local files (save-as)**
- **Upload to a restricted cloud service domain** (Windows only)

Sensitive service domain groups contain a preconfigured group for **Generative AI websites**. For a list of all the websites in this group, see List of AI sites supported by Microsoft Purview Data Security Posture Management for AI.

Additional settings for Endpoint DLP

Business justification in policy tips

You can control how users interact with the business justification option in Options for configuring policy tips. This option appears when users perform an activity that's protected by the **Block with override** setting in a DLP policy. The business justification setting is global. Choose from one of the following options:

- **Show default options and custom text box**: By default, users can select either a built-in justification or enter their own text.

- **Only show default options**: Users can only select from a list of built-in justifications.
- **Only show custom text box**: Users can only enter a custom justification. The text box appears in the end-user policy tip notification, without a list of options.

Customizing the options in the drop-down menu

You can create up to five customized options that appear when users interact with the policy notification tip by selecting **Customize the options drop-down menu**.

Expand table

Option	Default text
option 1	**This is part of an established business workflow** or enter customized text
option 2	**My manager has approved this action** or enter customized text
option 3	**Urgent access required; I'll notify my manager separately** or enter customized text
Show false positive option	**The information in these files is not sensitive** or enter customized text
option 5	**Other** or enter customized text

Turn on automatic diagnostic logging for endpoint DLP

Microsoft Purview Always-on diagnostics feature automatically records comprehensive trace logs, saving you time and enabling faster troubleshooting. For more information, see Always-on diagnostics for endpoint DLP.

Enable Endpoint DLP for Windows Servers

Endpoint DLP supports Windows Server 2019 and later versions.

After you onboard a Windows Server, turn on Endpoint DLP support to apply endpoint protection.

To work with the DLP alert management dashboard:

1. In the Microsoft Purview portal, go to **Data loss prevention** > **Overview**.
2. Choose **Settings** in the upper right corner.
3. On **Settings**, select **Endpoint settings** and expand **Endpoint DLP support for onboarded servers**.
4. Set the toggle to **On**.

Always audit file activity for devices

By default, when you onboard devices, the system automatically audits activity for Office, PDF, and CSV files. You can review this activity in activity explorer. Turn off this feature if you want to audit this activity only when onboarded devices are included in an active policy. The **Always audit file activity for devices** setting enables the auditing of file activities for documents where a DLP Rule didn't match: File Created, File Modified, File Renamed, File created on removable media, and File created on network share.

The system always audits file activity for onboarded devices, regardless of whether they're included in an active policy.

Printer groups

Use this setting to define groups of printers that you want to assign policy actions to that are different from the global printing actions.

The most common use case for creating printer groups is to use them for limiting the printing of contracts to only those printers in an organization's Legal department. After you define a printer group here, you can use it in all of your policies that are scoped to **Devices**. For more information on configuring policy actions to use authorization groups, see Create policy to manage printer access using authorization groups.

You can create a maximum of 20 printer groups. Each group can contain a maximum of 50 printers.

> ⓘ **Note**
>
> Printer groups are available for devices running any of the following Windows versions:
>
> - Windows 10 and later (21H1, 21H2, and later) - KB5020030
> - Win 11 21H2 - KB5019157
> - Win 11 22H2 - KB5020044
> - Windows Server 2022 - KB5020032

Let's look at an example. Say you want your DLP policy to block printing of contracts to all printers except for those that are in the legal department.

1. Use the following parameters to assign printers in each group.

    - **Friendly printer** name - the Friendly printer name is the value showing on the UX when you select the Printer.
    - **USB printer** - A printer connected through a computer's USB port. Select this option if you want to enforce any USB printer while leaving the USB product ID and USB vendor ID unselected. You can also assign a specific USB printer by specifying its USB product ID and USB vendor ID.
    - **USB product ID** - Get the **Device Instance** path value from the printer device property details in device manager. Convert that value the to Product ID and Vendor ID format. For more information, see Standard USB identifiers.
    - **USB vendor ID** - Get the **Device Instance** path value from the printer device property details in device manager. Convert that value to the Product ID and Vendor ID format. For more information, see Standard USB identifiers.
    - **IP range**
    - **Print to file** - Microsoft Print to PDF or Microsoft XPS Document Writer. If you only want to enforce Microsoft Print to PDF, you should use Friendly printer name with 'Microsoft Print to PDF'.
    - **Universal print deployed on a printer** - For more information on universal printers, see Set up Universal Print.
    - **Corporate printer** - is a print queue shared through on-premises Windows print server in your domain. Its path might look like this: \print-server\contoso.com\legal_printer_001.
    - **Print to local** - Any printer connecting through Microsoft print port but not any of above types. For example: print through remote desktop or redirect printer.

> ⓘ **Note**

You shouldn't use multiple parameters of **USB printer**, **IP range**, **Print to file**, **Universal print deployed on a printer**, **Corporate printer**, and **Print to local**.

2. Assign each printer in the group a **Display name**. These names appear only in the Microsoft Purview console.
3. Create a printer group named **Legal printers** and add individual printers (with an alias) by their friendly name; for instance: `legal_printer_001`, `legal_printer_002`, and `legal_color_printer`. (You can select multiple parameters at once to help you unambiguously identify a specific printer.)
4. Assign the policy actions to the group in a DLP policy:
   - `Allow` (audit with no user notifications or alerts)
   - `Audit only` (you can add notifications and alerts)
   - `Block with override` (blocks the action, but the user can override)
   - Preview, a fix to address the unnecessary resubmission to queue the print job after initial override, has been implemented.
   - `Block` (blocks no matter what)

Create a printer group

1. Open the Microsoft Purview portal and go to **Data Loss Prevention** > **Overview** > settings gear icon in the upper right corner > **Data Loss Prevention** > **Endpoint DLP settings** > **Printer groups**.
2. Select + **Create printer group**.
3. Enter a name for the group.
4. Select **Add printer**.
5. Enter a **Friendly name** for the printer. Make sure the name matches the value from the printer's device property details in Device Manager.
6. Select the parameters and provide the values to unambiguously identify the specific printer.
7. Select **Add**.
8. Add other printers as needed.
9. Select **Save** and then **Close**.

File extension groups

Use this setting to define groups of file extensions that you want to assign policy actions to. For example, you can apply a **File could not be scanned** policy only to file extensions in the created groups.

> ⓘ **Note**
>
> Don't add a `.` when you add an extension.

Disable classification

Use this setting to exclude specific file extensions from Endpoint DLP classification.

For files that are on the Monitored files list, you can disable classification through this setting. When you add a file extension to this setting, Endpoint DLP doesn't scan content in files with this extension. As a result, Endpoint DLP doesn't perform policy evaluation based on the content of those files. You can't see content information for the purposes of conducting investigations.

> ⓘ **Note**

Don't add a `.` when you add an extension.

Removable USB device groups

Use this setting to define groups of removable storage devices, such as USB thumb drives, that you want to assign policy actions to that are different from the global removable storage actions. For example, say you want your DLP policy to block items with engineering specifications from being copied to removable storage devices, except for designated USB-connected hard drives that are used to back up data for offsite storage.

You can create up to 20 groups, with up to 50 removable storage devices in each group.

> **Note**
>
> Removable USB device groups are available for devices running any of the following Windows versions:
>
> - Windows 10 and later (21H1, 21H2) with KB 5018482
> - Windows 11 21H2, 22H2 with KB 5018483
> - Windows 10 RS5 (KB 5006744) and Windows Server 2022

Use the following parameters to define your removable storage devices.

- **Storage device friendly name** - Get the Friendly name value from the storage device property details in device manager. Wildcard values (*) are supported.
- **USB product ID** - Get the Device Instance path value from the USB device property details in device manager. Convert it to Product ID and Vendor ID format. For more information, see Standard USB identifiers.
- **USB vendor ID** - Get the Device Instance path value from the USB device property details in device manager. Convert it to Product ID and Vendor ID format. For more information, see Standard USB identifiers.
- **Serial number ID** - Get the serial number ID value from the storage device property details in device manager. Wildcard values (*) are supported.
- **Device ID** - Get the device ID value from the storage device property details in device manager. Wildcard values (*) are supported.
- **Instance path ID** - Get the device ID value from the storage device property details in device manager. Wildcard values (*) are supported.
- **Hardware ID** - Get the hardware ID value from the storage device property details in device manager. Wildcard values (*) are supported.

You assign each removable storage device in the group an **Alias**. The alias is a friendly name that only appears in the Microsoft Purview console. So, continuing with the example, you create a removable storage device group named **Backup** and add individual devices (with an alias) by their friendly name, like `backup_drive_001`, and `backup_drive_002`.

You can multiselect the parameters and then the printer group includes all devices that satisfy those parameters.

You can assign these policy actions to the group in a DLP policy:

- `Allow` (audit with no user notifications or alerts)
- `Audit only` (you can add notifications and alerts)
- `Block with` override (blocks the action, but the user can override)
- `Block` (blocks no matter what)

Create a removable USB device group

1. Open the Microsoft Purview portal and go to **Data Loss Prevention** > **Overview** > settings gear icon in the upper right corner > **Data Loss Prevention** > **Endpoint DLP settings** > **Removable USB device groups**.
2. Select + **Create removable storage device group**.
3. Enter a **Group name**.
4. Select **Add removable storage device**.
5. Enter an **Alias**.
6. Select the parameters and enter the values to clearly identify the specific device.
7. Select **Add**.
8. Add other devices to the group as needed.
9. Select **Save** and then **Close**.

The most common use case for creating removable storage groups is to specify which removable storage devices users can copy files to. Generally, copying is only allowed for devices in a designated **Backup** group.

After you define a removable storage device group, you can use it in all of your policies that are scoped to **Devices**. For more information about configuring policy actions to use authorization groups, see Create policy to manage printer access using authorization groups.

Network share groups

Use this setting to define groups of network share paths that you want to assign policy actions to that are different from the global network share path actions. For example, say you want your DLP policy to prevent users from saving or copying protected files to network shares except the network shares in a particular group.

> **Note**
>
> Network share groups are available for devices running any of the following Windows versions:
>
> - Windows 10 and later (21H1, 21H2) with KB 5018482
> - Windows 11 21H2, 22H2 with KB 5018483
> - Windows 10 RS5 (KB 5006744) and Windows Server 2022

To include network share paths in a group, define the prefix that they all the shares start with. For example:

- '\Library' matches:
  - \Library folder and all its subfolders.
- You can use wildcards, for example '\Users*\Desktop' matches:
  - '\Users\user1\Desktop'
  - '\Users\user1\user2\Desktop'
  - '\Users*\Desktop'
- You can also use environmental variables, for example:
  - %AppData%\app123
- Wildcard values are supported. So a path definition can contain an asterisk (`*`) in the middle of the path or at the end of the path.
  Example: `\\Lib*` covers `\\Libray`

You can assign the following policy actions to the group in a DLP policy:

- `Allow` (audit with no user notifications or alerts)
- `Audit only` (you can add notifications and alerts)

- `Block with override` (blocks the action, but the user can override)
- `Block` (blocks no matter what)

After you define a network share group, you can use it in all of your DLP policies that are scoped to **Devices**. For more information about configuring policy actions to use authorization groups, see Create policy to manage printer access using authorization groups.

Create a Network Share group

1. Open Microsoft Purview portal and go to **Data Loss Prevention** > **Overview** > settings gear icon in the upper right corner > **Data Loss Prevention** > **Endpoint DLP settings** > **Network share groups**.
2. Select + **Create network share group**.
3. Enter a **Group name**.
4. Add the file path to the share.
5. Select **Add**.
6. Add other share paths to the group as needed.
7. Select **Save** and then **Close**.

VPN settings

Use the VPN list to control only those actions that are carried out over that VPN.

> **Note**
>
> VPN settings are available for devices running any of these versions of Windows:
>
> - Windows 10 and later (21H1, 21H2) with KB 5018482
> - Windows 11 21H2, 22H2 with KB 5018483
> - Windows 10 RS5 (KB 5006744)

When you list a VPN in **VPN Settings**, you can assign the following policy actions to it:

- `Allow` (audit with no user notifications or alerts)
- `Audit only` (you can add notifications and alerts)
- `Block with override` (blocks the action, but the user can override)
- `Block` (blocks no matter what)

You can apply these actions individually or collectively to the following user activities:

- Copy to clipboard
- Copy to a USB removable device
- Copy to a network share
- Print
- Copy or move using unallowed (restricted) Bluetooth app
- Copy or move using RDP

When you configure a DLP policy to restrict activity on devices, you can control what happens to each activity performed when users are connected to your organization within any of the VPNs listed.

Use the **Server address** or **Network address** parameters to define the VPN allowed.

Get the server address or network address

1. On a DLP monitored Windows device, open a **Windows PowerShell** window as an administrator.
2. Run the following cmdlet. It returns multiple fields and values.

```
```

PowerShell

```
Get-VpnConnection
```

1. Among the results of the cmdlet, find the **ServerAddress** field and record that value. Use the **ServerAddress** when you create a VPN entry in the VPN list.
2. Find the **Name** field and record that value. The **Name** field maps to the **Network address** field when you create a VPN entry in the VPN list.

Add a VPN

1. Open Microsoft Purview portal and go to **Data Loss Prevention** > **Overview** > settings gear icon in the upper right corner > **Data Loss Prevention** > **Endpoint DLP settings** > **VPN settings**.
2. Select **Add or edit VPN addresses**.
3. Enter either the **Server address** or **Network address** that you recorded after running `Get-VpnConnection`.
4. Select **Save**.
5. Close the item.

> **Important**
>
> Under the **Network restrictions** setting, you also see **Corporate network** as an option. **Corporate network** connections are all connections to your organization's resources. You can see if a device is using a **Corporate network** by running the `Get-NetConnectionProfile` cmdlet as an administrator. If the `NetworkCategoryId` in the output is `DomainAuthenticated`, it means the machine is connected to the **Corporate network**. If the output is anything else, the machine isn't. In some cases, a machine can be both VPN connected and **Corporate network** connected. If both are selected under the **Network restrictions**, Endpoint DLP applies the action based on the order. If you want the action for VPN to be the one that's applied, move the VPN entry above **Corporate network** to have higher priority than the action for **Corporate network**.

> See Create policy to manage file activities by implementing network exceptions for more information on configuring policy actions to use network exceptions.

Protect FTP and SFTP transfers with Microsoft Purview Endpoint DLP

Endpoint data loss prevention (DLP) in Microsoft Purview can monitor and protect sensitive data transferred over FTP and SFTP from managed Windows devices. Endpoint DLP evaluates these transfers against your policy rules, just as it does other device activities such as copying to USB devices or network shares. You can review the resulting events in Activity explorer.

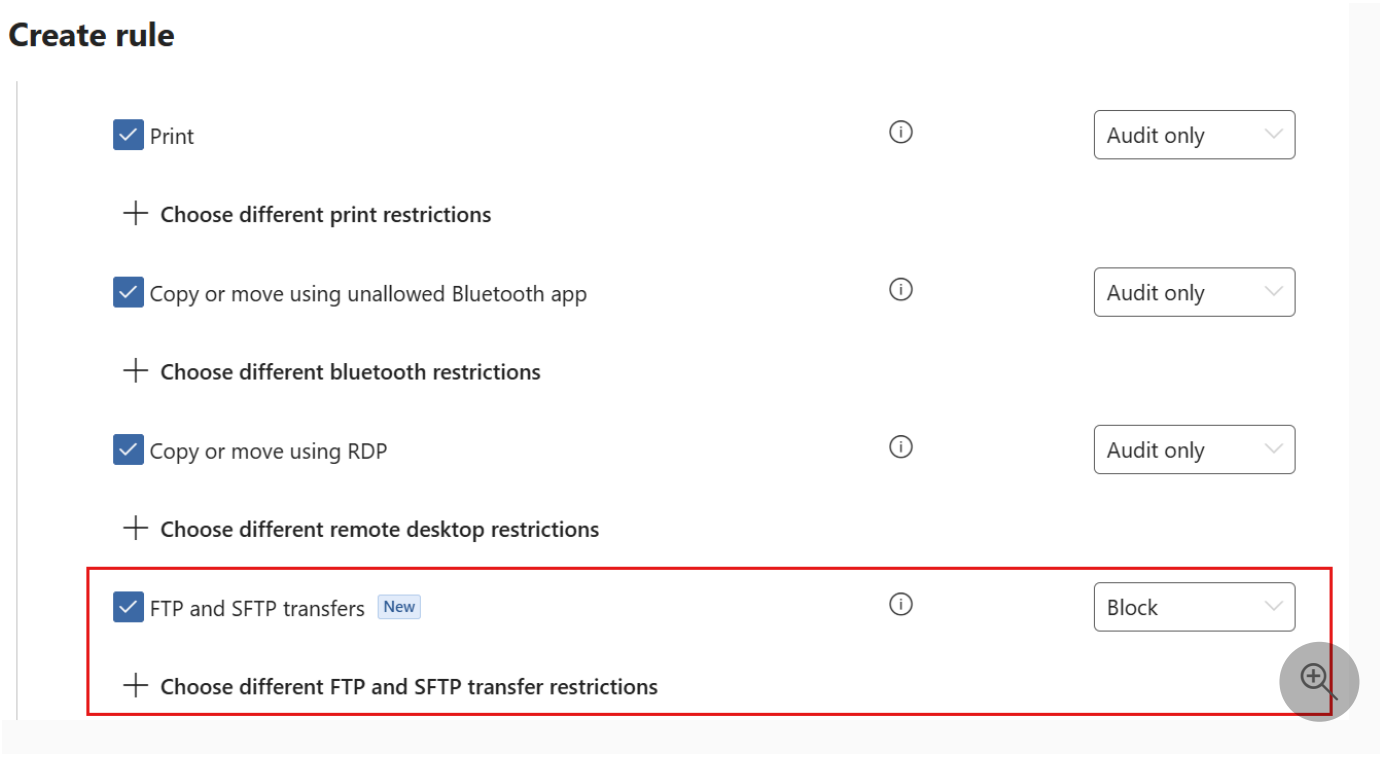
This protection isn't turned on by default. This article explains how to add FTP and SFTP transfers to an Endpoint DLP policy rule and review the resulting events.

Before you begin, review the device onboarding and permissions requirements in Prerequisites.

Prerequisites

- Devices onboarded to Microsoft Purview.
- Permissions to create and deploy DLP policies and view Activity explorer. Use the least-privileged roles needed for these tasks.

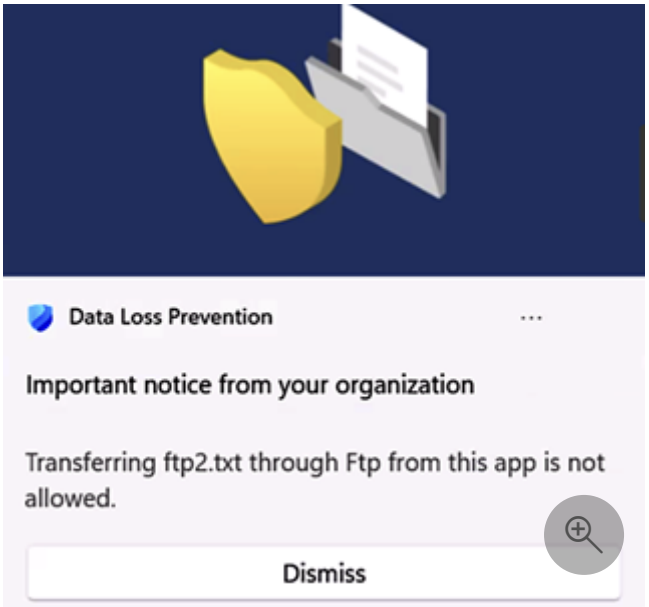
Create the policy



We recommend starting with a small pilot group and setting the action to Audit only. Review Activity explorer to understand how users transfer files over FTP/SFTP before you deploy the policy broadly.

To create the policy:

1. In the Microsoft Purview portal, go to Data loss prevention > Policies > Create policy.
2. On the Locations page, select Devices, and then scope the policy to the users or device groups you want.
3. Create a rule, and add the conditions you want to detect, such as sensitive information types or sensitivity labels.
4. Under Actions, select Audit or restrict activities on devices.
5. In File activities for all apps, select Apply restrictions to specific activity.
6. Select the FTP and SFTP transfers checkbox, and then choose an action. Supported actions are Audit only, Block, Block with override, and Allow.
7. (Optional) Turn on policy tips under User notifications.



8. Review and publish the policy.

The Create rule page shows FTP and SFTP transfers selected with its action set to Block.

End-user notification

Example of an end-user notification for a blocked FTP transfer:

Review activity

Use Activity explorer to review the details of each transfer.

1. Open Activity explorer.

2. Filter Activity to File transfer by FTP/SFTP. Review the user, device, file, matched policy, and action for each transfer.

Collect full file evidence

FTP and SFTP transfers support full file evidence (FFE) collection. Enable evidence collection in Endpoint DLP settings and configure it in your DLP policy. When a user attempts to transfer a matched file, a complete copy can be saved.

For requirements and setup, see Get started with evidence collection for file activities on devices.

Endpoint DLP policy scenarios in Microsoft Purview

This article provides guidance on using Endpoint Data Loss Prevention (DLP) capabilities within Microsoft Purview to help safeguard sensitive information across organizational devices. It focuses on practical, scenario-based approaches for creating and modifying DLP policies, including auditing, alerting, blocking actions, and enforcing controls on how sensitive data is accessed, shared, or transferred. By addressing common administrative use cases, this guidance helps define how policies can be applied across endpoints and integrated services to monitor and regulate user activity effectively.

By applying these scenarios, administrators can reduce data loss risks, support compliance, and gain better visibility into user activity. This scenario-based approach helps strengthen data governance and improves the organization's overall security posture.

> **Important**
>
> These Endpoint DLP scenarios aren't the official procedures for creating and tuning DLP policies. For general situations, see the following topics:

Before you begin

SKU and subscription licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

These scenarios require that you already onboard devices and that they report to Activity explorer. If you didn't onboard devices yet, see Get started with Endpoint data loss prevention.

> **Important**
>
> Before you start, make sure you understand the difference between an unrestricted administrator and an administrative unit restricted administrator. For more information, see Administrative units.

Endpoint DLP policy scenarios

The following scenarios show common Endpoint DLP policy configurations you can implement:

- Create policy to audit activities using a template (audit only mode)
- Create policy to manage printer access using authorization groups
- Create policy to detect and alert on U.S. PII data exposure
- Help prevent unauthorized sensitive data sharing with block actions and allow overrides
- Help prevent risky user activity by monitoring or restricting access to sensitive service domains
- Help prevent leakage of sensitive content by restricting paste actions into browsers
- Help prevent exposure of sensitive files by configuring auto-quarantine for OneDrive sync
- Help prevent sharing of sensitive items with unauthorized cloud apps and services
- Create policy to manage file activities by implementing network exceptions

Create policy to audit activities using a template (audit only mode)

This scenario shows how to create a Microsoft Purview DLP policy using the U.S. PII Data Enhanced template to monitor sensitive data on endpoint devices. The policy runs in audit-only (simulation) mode, enabling visibility into user activity and data risk without impacting users, while using policy tips and Activity explorer for validation and analysis.

This scenario assumes an unrestricted administrator creating a policy with full directory scope.

Prerequisites and assumptions

This article uses the process you learned in Design a data loss prevention policy to show you how to create a Microsoft Purview Data Loss Prevention (DLP) policy. Work through these scenarios in your test environment to familiarize yourself with the policy creation UI.

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

This scenario uses the *Confidential* sensitivity label, so you must create and publish sensitivity labels before proceeding. To learn more, see:

- Learn about sensitivity labels
- Get started with sensitivity labels
- Create and configure sensitivity labels and their policies

This procedure uses a hypothetical distribution group *Human Resources* and a distribution group for the security team at Contoso.com.

This policy-creation scenario uses alerts. To learn more, see Get started with the data loss prevention alerts.

Policy intent statement and mapping

We, Contoso, want to begin evaluating how sensitive information—specifically U.S. Personally Identifiable Information (PII)—is being handled on endpoint devices across our organization. Before enforcing restrictions, we want visibility into user activity and potential data risk without impacting productivity.

To achieve this, we will create a policy that monitors activity on devices, detects when U.S. PII is involved, and records those events for analysis. When users perform actions that match the policy conditions, we want to show policy tips to raise awareness and educate them, but we do not want to block or restrict their actions at this stage.

Expand table

Statement	Configuration question answered and configuration mapping
"We want to evaluate how sensitive (U.S. PII) data is being used on endpoint devices…"	- Administrative scope: Full directory - Where to monitor: Devices - Scope: All users, devices
"We want to detect content that matches U.S. Personally Identifiable Information (PII) definitions…"	- Template selection: U.S. Personally Identifiable Information (PII) Data Enhanced - Conditions for a match: Built-in sensitive information types included in the template
"We want to observe activity without impacting users or blocking business processes…"	- Protection actions: No restrictive actions configured - Mode: Audit-only behavior via simulation mode
"We want to capture and review events when policy conditions are met…"	- Monitoring and reporting: Activity explorer used to review matched events - Alerts/events generated for matching activities
"We want to educate users at the time of activity without enforcing restrictions…"	- User experience: Policy tips enabled (Show policy tips while in simulation mode) - No blocking or override prompts configured
"We want to safely test the policy before enforcing it in production…"	- Policy mode: Run in simulation mode - Deployment approach: Validate behavior before switching to enforcement

Steps to create policy

1. Sign in to the Microsoft Purview portal. > **Data loss prevention** > **Policies**.
2. Choose + **Create policy**.
3. Select **Data stored in connected sources**.
4. For this scenario, under **Categories**, choose **Privacy**.
5. Under **Regulations** choose **U.S. Personally Identifiable Information (PII) Data Enhanced**, and then choose **Next**.
6. Give your new policy a **Name** and **Description**, and then choose **Next**.
7. Accept the default **Full directory** under **Admin units**. Select **Next**.
8. Select the **Devices** location and deselect all other locations and then choose **Next**.
9. On the **Define policy settings** page, choose **Next**.
10. On the **Info to protect page**, choose **Next**.
11. On the **Protection actions** page, choose **Next** again.
12. On the **Customize access and override settings** page, choose **Audit or restrict activities on Devices** and then choose **Next**.
13. On the **Policy mode** page, accept the default **Run the policy in simulation mode** and select **Show policy tips while in simulation mode**.
14. Choose **Next**.
15. Choose **Submit**.
16. Once the new policy is created, choose **Done**.

Now it's time to test your policy:

1. On the **Data Loss Prevention** home page, open **Activity explorer**.
2. Try to share a test item from your Endpoint DLP device that contains content matching the sensitive information types in the **U.S. Personally Identifiable Information (PII) Data Enhanced** template. Sharing the test item should trigger the policy.

3. Back in **Activity explorer**, check the list of activities for the policy-match event generated by the test share action.

Create policy to manage printer access using authorization groups

This scenario demonstrates how to use **authorization groups** in Microsoft Purview DLP to enforce a default block on sensitive data actions while allowing controlled exceptions. In this example, printing of documents classified as legal content is restricted across all devices, except for a defined set of approved **legal department printers**.

Combining **device-level print restrictions** with a printer allowlist enables organizations to protect sensitive information while still supporting legitimate business workflows. This scenario also illustrates how authorization groups can be reused for other scenarios, such as removable storage devices or network shares.

This scenario is for an unrestricted admin creating a full directory policy.

The procedures in this article require that you already have devices onboarded and reporting into Activity explorer. If you haven't onboarded devices yet, see Get started with Endpoint data loss prevention.

Authorization groups are mostly used as allowlists. You assigned policy actions to the group that are different than the global policy actions. In this scenario, we go through defining a printer group and then configuring a policy with block actions for all print activities except for the printers in the group. The procedures for defining a printer group and configuring policy exceptions are essentially the same for **Removeable storage device groups**, and **Network share groups**.

In this scenario, we define a group of printers that the legal department uses for printing contracts. Printing contracts to any other printers is blocked.

Prerequisites and assumptions

This article uses the DLP policy design process described in Design a data loss prevention policy to show you how to create a Microsoft Purview Data Loss Prevention (DLP) policy. Work through these scenarios in your test environment to familiarize yourself with the policy creation UI.

> **Important**

This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

This scenario uses the *Confidential* sensitivity label, so it requires you to create and publish sensitivity labels. To learn more, see:

- Learn about sensitivity labels
- Get started with sensitivity labels
- Create and configure sensitivity labels and their policies

This procedure uses a hypothetical distribution group *Human Resources* and a distribution group for the security team at Contoso.com.

The policy-creation procedure in this article uses alerts, see: Get started with the data loss prevention alerts

Policy intent statement and mapping

*We, Contoso, want to prevent users from printing sensitive legal content to unauthorized printers while still allowing approved business workflows for the legal department. In this scenario, documents that match the **Legal Affairs** trainable classifier should be protected from being printed broadly across the organization, but users in Legal must be able to print those documents to a defined set of approved printers.*

*To achieve this, we will create a policy that applies print restrictions on devices for content classified as legal in nature. Printing will be blocked by default, but an **authorization group** of approved printers will be configured as an exception and allowed. This enables a strong default-protect posture while supporting legitimate business needs through a controlled allowlist model.*

Expand table

Statement	Configuration question answered and configuration mapping
"We want to protect sensitive legal documents from being printed to	- Administrative scope: Full directory - Where to monitor: Devices only

Statement	Configuration question answered and configuration mapping
unauthorized printers…"	- Policy scope: All users/devices covered by the policy
"We want to identify documents that contain legal-sensitive content…"	- Condition: **Content contains** = Trainable classifiers, **Legal Affairs**
"We want to restrict printing of that sensitive content across endpoint devices…"	- Action: **Audit or restrict activities on devices** - Activity type: **File activities on all apps** - Restriction model: **Apply restrictions to specific activity**
"We want printing to be blocked by default unless explicitly allowed…"	- Activity restriction: **Print** = **Block**
"We want approved legal department printers to be exempt from the default block…"	- Endpoint settings: Create a **Printer group** named **Legal printers** - Group members can be defined by friendly printer name, USB product/vendor ID, IP range, print-to-file, Universal Print, corporate printer, or print to local
"We want different policy behavior for approved printers than the global policy action…"	- Authorization group behavior: **Choose different print restrictions** - Printer group restriction: Add **Legal printers** - Group-specific action: **Allow**
"We want approved printing activity to remain visible for audit purposes without creating unnecessary alerts…"	- Allow action behavior: Allowed print activity is recorded in the audit log - No alert or user notification is generated for the allowlisted printer action
"We want to test the policy safely before enforcement…"	- Policy mode: **Run the policy in simulation mode** - User experience: **Show policy tips while in simulation mode**
"We want to use this same design pattern for other authorized destinations in the future…"	- Reusable authorization group model: Same approach applies to **Removable storage device groups** and **Network share groups**

Steps to create policy

Create and use printer groups

Perform the following steps to create a printer group for approved legal printers:

1. Sign in to the Microsoft Purview portal > **Data loss prevention** > **Settings** (gear in the upper left hand corner) > **Data Loss Prevention** > **Endpoint settings** > **Printer groups**.

2. Select **Create printer group** and enter a **Group a name**. In this scenario, we use `Legal printers`.

3. Select **Add printer** and provide a name. You can define printers by:
   a. Friendly printer name
   b. USB product ID
   c. USB vendor ID
   d. IP range
   e. Print to file
   f. Universal print deployed on a printer
   g. Corporate printer
   h. Print to local

4. Select **Close**.

Configure policy printing actions

Perform the following steps to configure the DLP policy's printing actions and assign the printer group exception:

1. Sign in to the Microsoft Purview portal.

2. Navigate to **Data loss prevention** > **Policies**.

3. Select **Create policy**.

4. **Data stored in connected sources**.

5. Select the **Custom** from the **Categories** then **Custom policy** template from **Regulations**.

6. Give your new policy a **Name** and **Description**.

7. Accept the default **Full directory** under **Admin units**.

8. Scope the location to only the **Devices** location.

9. Create a rule with the following values:
   a. Add a **Condition**: **Content contains** = **Trainable classifiers**, **Legal Affairs**
   b. **Actions** = **Audit or restrict activities on devices**
   c. Then pick **File activities on all apps**
   d. The select **Apply restrictions to specific activity**
   e. Select **Print** = **Block**

10. Select **Choose different print restrictions**
11. Under **Printer group restrictions**, select **Add group** and select **Legal printers**.
12. Set **Action** = **Allow**.

    > **Tip**
    >
    > The **Allow** action wil record and audit event to the audit log, but not generate an alert or notification.

13. Select **Save** and then **Next**.
14. Accept the default **Run the policy in simulation mode** value and choose **Show policy tips while in simulaiton mode**. Choose **Next**.
15. Review your settings and choose **Submit**.
16. The new DLP policy appears in the **Data loss prevention** > **Policies** list.

Create policy to detect and alert on U.S. PII data exposure

This scenario shows how to enhance an existing Microsoft Purview DLP policy by enabling **real-time alerting** for policy matches involving U.S. PII data. Alerts are configured to notify administrators each time a match occurs, improving visibility and response readiness while the policy continues to run without restricting user activity.

This scenario is for an unrestricted admin modifying a full directory scoped policy.

Prerequisites and assumptions

This article applies the policy design process from Design a data loss prevention policy to show you how to modify an existing Microsoft Purview Data Loss Prevention (DLP) policy. Work through these scenarios in your test environment to familiarize yourself with the policy creation UI.

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

This scenario uses the *Confidential* sensitivity label, so it requires you to create and publish sensitivity labels. To learn more, see:

- Learn about sensitivity labels
- Get started with sensitivity labels
- Create and configure sensitivity labels and their policies

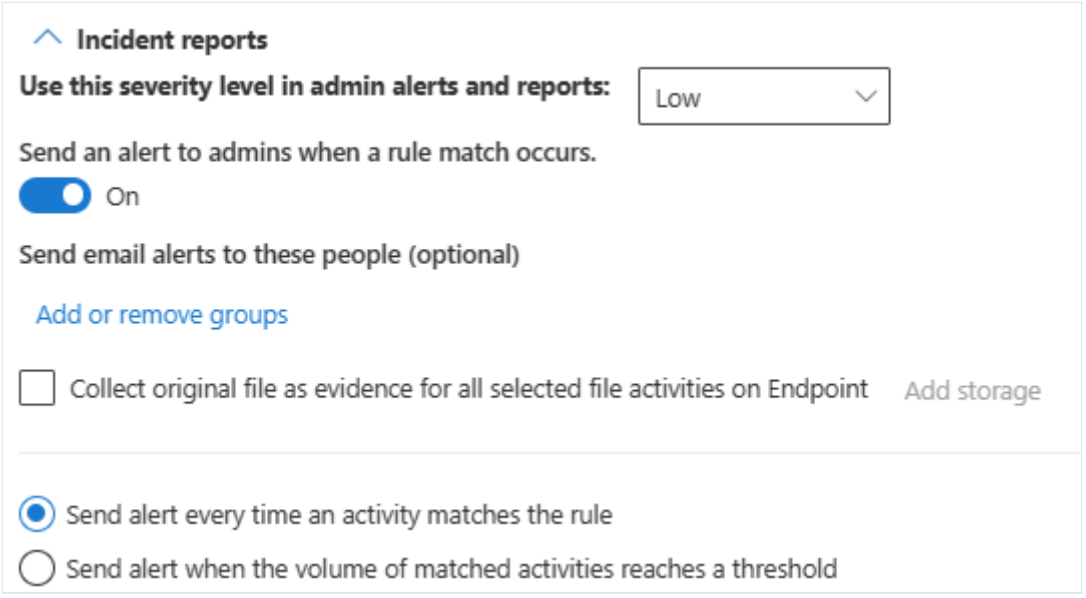
This procedure uses a hypothetical distribution group *Human Resources* and a distribution group for the security team at Contoso.com.

This procedure uses alerts, see: Get started with the data loss prevention alerts

Policy intent statement and mapping

We, Contoso, have already deployed a policy to monitor U.S. Personally Identifiable Information (PII) activity on endpoint devices in audit mode. After reviewing initial results, we now want to enhance our visibility by ensuring that administrators are proactively notified when policy matches occur.

To achieve this, we will modify the existing policy to generate alerts whenever low-volume PII-related activity is detected. These alerts will be sent in real time to administrators so they can quickly review and respond to potential risks. The policy will continue to operate without restricting user activity, maintaining the audit-first approach while improving incident awareness and response readiness.



Expand table

Statement	Configuration question answered and configuration mapping
"We want to enhance our existing monitoring policy without changing its scope…"	- Administrative scope: Full directory (unchanged) - Where to monitor: Devices (unchanged) - Existing policy reused and edited
"We want to generate alerts when U.S. PII policy conditions are matched…"	- Rule edited: Low volume of content detected scenarios U.S. PII Data Enhanced - Condition: Existing PII detection logic from template retained
"We want administrators to be notified automatically when matches occur…"	- Incident reports: Enable 'Send an alert to admins when a rule match occurs' - Recipients: Default admin and additional configured recipients
"We want immediate visibility into every matching event…"	- Alert frequency: Send alert every time an activity matches the rule
"We want to improve response readiness without disrupting users…"	- Protection actions: No blocking or restriction changes - Policy continues in audit/simulation behavior
"We want to validate alerting behavior alongside activity tracking…"	- Monitoring: Activity explorer used to correlate events and alerts - Testing: Trigger policy using test file with matching PII content

Steps to create policy

Perform the following steps to edit the existing policy and enable alerting:

1. Sign in to the Microsoft Purview portal > **Data loss prevention** > **Policies**.
2. Choose the **U.S. Personally Identifiable Information (PII) Data Enhanced** policy that you created in Create an endpoint DLP policy to audit activity on devices. This policy must already exist in your environment before you proceed.
3. Choose **Edit policy**.
4. Go to the **Customize advanced DLP rules** page and edit the **Low volume of content detected scenarios U.S. PII Data Enhanced**.
5. Scroll down to the **Incident reports** section and toggle **Send an alert to admins when a rule match occurs** to **On**. Email alerts are automatically sent to the administrator and anyone else you add to the list of recipients.

6. For the purposes of this scenario, choose **Send alert every time an activity matches the rule**.
7. Choose **Save**.
8. Leave all other policy and rule settings unchanged. Choose **Next** through the remaining wizard pages, and then select **Submit** to save the policy changes.
9. Try to share a test item containing content that will trigger the U.S. Personally Identifiable Information (PII) Data Enhanced condition. Sharing the test item should trigger a policy

match and generate an alert.

10. Check the activity explorer for the event.

ⓘ**Note:** The author created this article with assistance from AI. Learn more

Help prevent unauthorized sensitive data sharing with block actions and allow overrides

This scenario demonstrates how to transition an existing Microsoft Purview DLP policy from monitoring to enforcement by blocking the sharing of sensitive U.S. PII data. The policy is updated to use **block with override**, preventing high-risk actions while still allowing users to proceed when justified.

This approach strengthens data protection by reducing the risk of data exfiltration, while maintaining business continuity through controlled user overrides and continued visibility into user activity via Activity explorer.

This scenario is for an unrestricted admin modifying a full directory policy.

Prerequisites and assumptions

This article uses the process you learned in Design a data loss prevention policy to show you how to create a Microsoft Purview Data Loss Prevention (DLP) policy. Work through these scenarios in your test environment to familiarize yourself with the policy creation UI.

> ⓘ **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

This scenario uses the *Confidential* sensitivity label, so it requires you to create and publish sensitivity labels. To learn more, see:

- Learn about sensitivity labels
- Get started with sensitivity labels

- Create and configure sensitivity labels and their policies

This procedure uses a hypothetical distribution group *Human Resources* and a distribution group for the security team at Contoso.com.

This procedure generates data loss prevention alerts when policy rules are triggered. To learn how to configure and review these alerts, see Get started with the data loss prevention alerts.

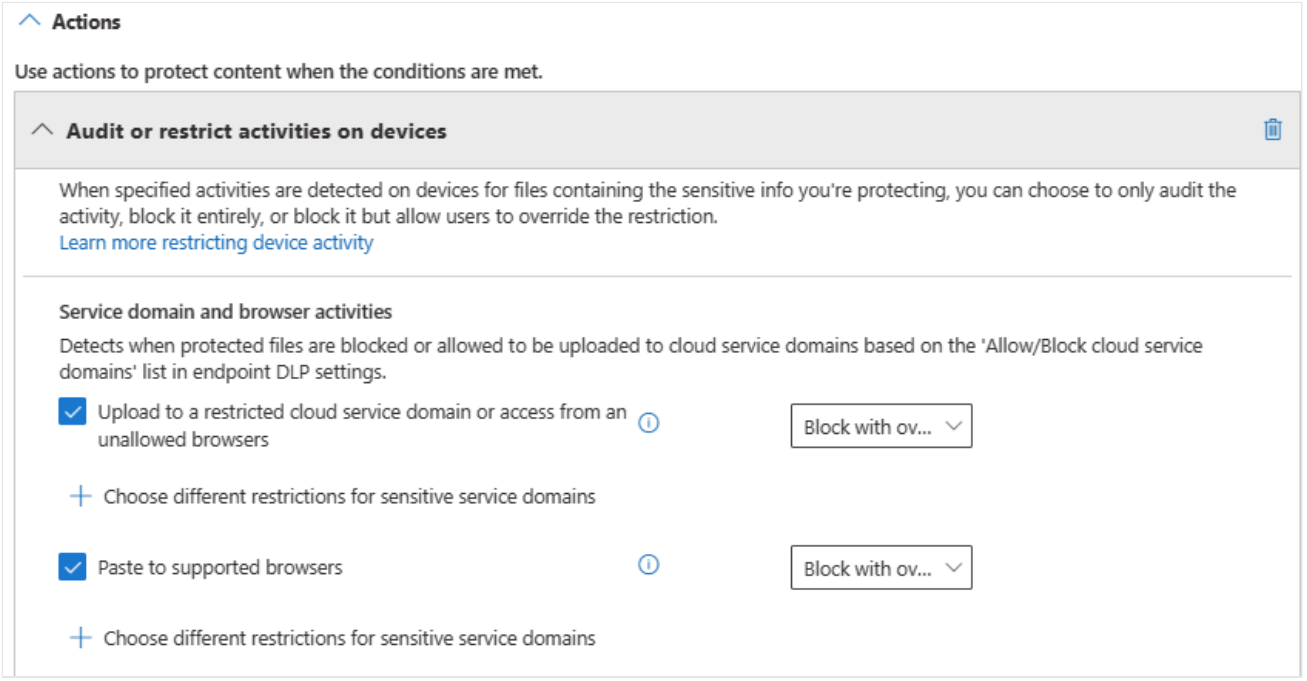
Policy intent statement and mapping

We, Contoso, have already deployed and tuned a policy that detects U.S. Personally Identifiable Information (PII) on endpoint devices and provides visibility and alerting. After validating the policy behavior, we now want to move to enforcement by preventing users from sharing sensitive information outside the organization.

To achieve this, we will modify the existing policy so that when PII is detected in user actions involving service domains or browsers, the action is blocked. However, to maintain business flexibility, users will be allowed to override the block with justification.

This ensures strong data protection while still enabling users to proceed in legitimate business scenarios when necessary.

Expand table



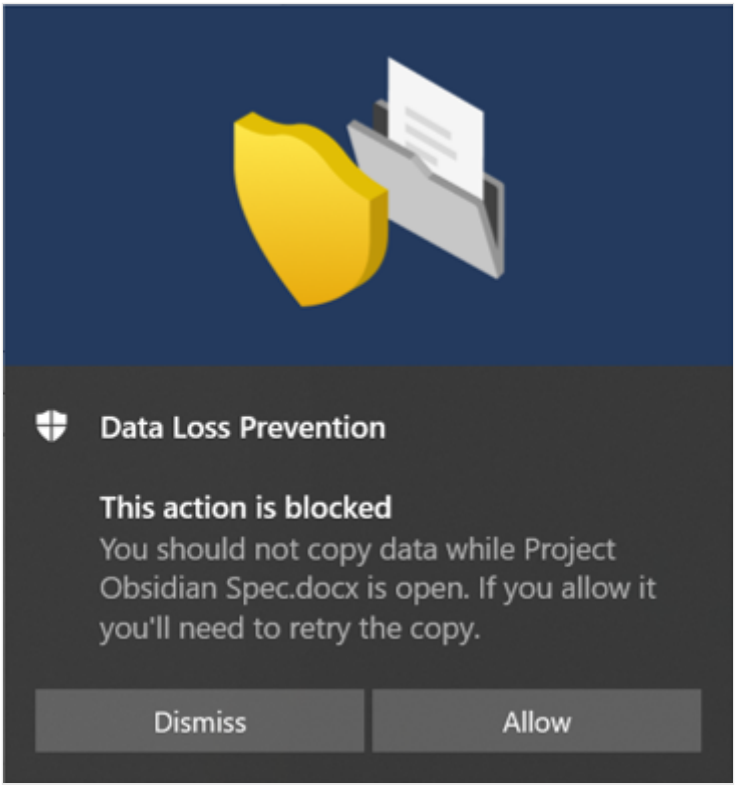
Statement	Configuration question answered and configuration mapping
"We want to transition from monitoring to enforcing protection of U.S. PII on endpoint devices..."	- Administrative scope: Full directory (unchanged) - Where to monitor: Devices (unchanged) - Existing policy reused and updated for enforcement
"We want to prevent users from sharing sensitive data outside the organization..."	- Actions: Audit or restrict activities on Windows devices - Activity types: Service domain and browser activities
"We want to block high-risk actions involving sensitive data..."	- Action configuration: Block with override enabled for service domain and browser activities
"We want to allow users to proceed in legitimate cases with accountability..."	- Override behavior: Allow override with user justification captured - User interaction: Prompt displayed on endpoint when action is blocked
"We want consistent enforcement across different sensitivity levels..."	- Rule coverage: Apply same block with override settings to both low-volume and high-volume

Statement	Configuration question answered and configuration mapping
	detection rules
"We want to maintain visibility into enforcement events and user behavior..."	- Monitoring: Activity explorer logs blocked and overridden events - Alerts/events: Captured for investigation and auditing
"We want to validate enforcement behavior through testing..."	- Testing: Trigger policy using test file containing PII data and attempt external sharing - Expected result: User receives block prompt with override option

Steps to create policy

Perform the following steps to edit the existing policy and enable block with override behavior.

1. Sign in to the Microsoft Purview portal > **Data loss prevention** > **Policies**.
2. Choose your existing **U.S. Personally Identifiable Information (PII) Data** policy that you previously created for monitoring on endpoint devices.
3. Choose **Edit policy**.
4. Go to the **Customize advanced DLP rules** page and edit the **Low volume of content detected scenarios U.S. PII Data Enhanced**.
5. Scroll down to the **Actions** > **Audit or restrict activities on Windows device** section and set both options under the **Service domain and browser activities** to **Block with override**.



6. Choose **Save**.

7. Edit the **High volume of content detected scenarios U.S. PII Data Enhanced** rule. Scroll down to **Actions** > **Audit or restrict activities on Windows device**, set both options under **Service domain and browser activities** to **Block with override**, and then choose **Save**.

8. Leave all other existing policy settings unchanged by choosing **Next** through the rest of the wizard, and then select **Submit** to apply the policy changes.

9. Attempt to share a test item that contains content that will trigger the U.S. Personally Identifiable Information (PII) Data condition with someone outside your organization. This sharing attempt should trigger the policy.

   You see a popup like this on the client device:

10. Check Activity explorer for the blocked or overridden sharing event generated by the test action.

Help prevent risky user activity by monitoring or restricting access to sensitive service domains

Overview

This scenario demonstrates how to monitor and control user interactions with sensitive websites using Microsoft Purview DLP. By defining **sensitive service domains**, organizations can audit or restrict actions such as copying, printing, or saving web content when users access these sites.

Policy enforcement occurs in a supported, DLP-aware browser environment, ensuring consistent control and user guidance. This enables organizations to protect sensitive data accessed through web applications while maintaining flexibility to tailor controls based on business needs.

> ⓘ **Note**
>
> The following web browsers are supported:
>
> - Microsoft Edge (Win/macOS)
> - Chrome (Win/macOS)- Microsoft Purview extension for Chrome Windows only
> - Firefox (Win/macOS)- Microsoft Purview extension for Firefox Windows only
> - Safari (macOS only)

Prerequisites and assumptions

This article uses the process you learned in Design a data loss prevention policy to show you how to create a Microsoft Purview Data Loss Prevention (DLP) policy. Work through these scenarios in your test environment to familiarize yourself with the policy creation UI.

> ⓘ **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

This scenario uses the *Confidential* sensitivity label, so it requires you to create and publish sensitivity labels. To learn more, see:

- Learn about sensitivity labels
- Get started with sensitivity labels
- Create and configure sensitivity labels and their policies

This procedure uses a hypothetical distribution group *Human Resources* and a distribution group for the security team at Contoso.com.

The policy configuration in this article uses alerts. To learn more, see Get started with the data loss prevention alerts

Policy intent statement and mapping

We, Contoso, want to monitor and control how users interact with sensitive websites to reduce the risk of data exposure through browser-based activities. Specifically, we want to audit or restrict actions such as copying data, printing content, or saving web pages locally when users access designated sensitive service domains.

*To achieve this, we will define a set of **sensitive service domains** and configure a policy that detects when users access these sites through supported browsers. When a match occurs, we will apply activity-specific controls—such as auditing or blocking printing, copying, or file-saving actions—while ensuring users are redirected to supported browsers (such as Microsoft Edge) where these controls can be enforced consistently.*

This approach enables granular control of in-browser data handling for sensitive sites, helping protect organizational data while maintaining flexibility in how policies are applied and tuned over time.

Expand table

Statement	Configuration question answered and configuration mapping
"We want to monitor and control user interactions with designated sensitive websites..."	- Administrative scope: Full directory - Where to monitor: Devices only - Policy scope: All users/devices (or scoped test users)

Statement	Configuration question answered and configuration mapping
"We want to define which websites are considered sensitive for monitoring or restriction..."	- Endpoint settings: Configure **Service domains** and **Sensitive service domain groups** - Domains defined using URL/IP/IP range with wildcard support
"We want to detect when users access these sensitive sites in supported browsers..."	- Condition: **User accessed a sensitive site from Edge** - Browser coverage: Supported browsers with Microsoft Purview extensions where applicable
"We want to ensure policy enforcement occurs in a DLP-aware browser..."	- Browser handling: Redirect unsupported browsers (e.g., Chrome/Firefox) to **Microsoft Edge** when accessing sensitive domains
"We want to audit or restrict specific user activities performed on sensitive websites..."	- Actions: **Audit or restrict activities when users access sensitive sites** - Activity controls include: copy, print, save as local files
"We want fine-grained control over which activities are monitored or blocked..."	- Action configuration: Select individual user activities (copy, print, save) - Choose audit, block, or block with override depending on requirement
"We want to flexibly apply controls across different sets of sensitive domains..."	- Rule configuration: Assign one or more **Sensitive service domain groups** - Reusable group design for scalability
"We want to finalize and deploy the policy for immediate use..."	- Policy mode: Submit and enable policy - Deployment: Active policy with configured monitoring/restriction behavior

Steps to create the sensitive service domains policy

Perform the following steps to configure sensitive service domains and create the DLP policy.

Configure Sensitive service domains

Use the following steps to define sensitive service domains and create a DLP policy that monitors or restricts user activity on those domains.

1. Sign in to the Microsoft Purview portal > **Data loss prevention** > **Settings** (gear icon in the upper left hand corner) > **Data Loss Prevention** > **Endpoint settings** > **Browser and domain restrictions to sensitive data** > **Service domains**.

2. Set **Service domains** to **Block**.

3. To control whether sensitive files can be uploaded to specific domains, select **Add cloud service domain**.
4. Enter the domain that you want to audit or block and choose the + button. Repeat for any additional domains. Choose **Save**.
5. Under **Sensitive service domain groups**, choose **Create sensitive service domain group**.
6. Give the group a name, select the **Match type** you want (you can select from **URL**, **IP address**, **IP address range**), and enter the URL, IP address, or IP address range to be audited or blocked. When matching a URL, you can add multiple websites to a group and use wildcards to cover subdomains. For example, `www.contoso.com` for just the top level website or *.contoso.com for corp.contoso.com, hr.contoso.com, fin.contoso.com.
7. Select **Save**.
8. In the left navigation pane, select **Data loss prevention** > **Policies**.
9. On the policy template page, select **Data stored in connected sources**.
10. Create and scope a policy that is applied only to the **Devices** location. For detailed steps on scoping a policy to the Devices location, see Create and Deploy data loss prevention policies. Be sure to scope the **Admin units** to **Full directory**.
11. Create a rule that uses the condition **the user accessed a sensitive site from Edge**, and the action **Audit or restrict activities when users access sensitive sites in Microsoft Edge browser on Windows devices**.
12. In the action, under **Sensitive Site Restrictions**, select **Add or remove Sensitive site groups**.
13. Create and/or select the **Sensitive site groups** you want. Any website under the group(s) you select here will be redirected to Microsoft Edge when opened in Chrome or Firefox (so long as the Microsoft Purview extension is installed).
14. Select **Add**.
15. Select the user activities you want to monitor or restrict and the actions you want Microsoft Purview to take in response to those activities.
16. Finish configuring the rule and policy and choose **Submit** and then **Done**.

Help prevent leakage of sensitive content by restricting paste actions into browsers

This scenario demonstrates how to restrict users from pasting sensitive content into browser-based applications using Microsoft Purview DLP. By evaluating content at the moment it is pasted, organizations can detect and control sensitive information in real time, regardless of where the content originated.

Using **Paste to browser** controls with **Sensitive service domain groups**, this approach enables flexible enforcement—such as auditing, warning, or blocking paste actions—based on the destination website. This approach helps reduce the risk of accidental data exposure while allowing policies to be tailored for different levels of risk.

The **Paste to browser** activity operates independently of the source file's classification and requires rules configured with **Sensitive service domain groups**. It is not supported with the **Service domains** endpoint DLP setting. For more information, see Endpoint activities you can monitor and take action on

> ⓘ **Note**
>
> The following web browsers are supported:
>
> - Microsoft Edge (Win/macOS)
> - Chrome (Win/macOS)- Microsoft Purview extension for Chrome Windows only
> - Firefox (Win/macOS)- Microsoft Purview extension for Firefox Windows only
> - Safari (macOS only)

> ⓘ **Important**
>
> - If you have configured evidence collection for file activities on devices and your Antimalware Client Version on the device is older than 4.18.23110, when you implement this scenario, *Restrict pasting sensitive content into a browser*, you will see random characters when you attempt to view the source file in Alert details. To see the actual source file text, you should download the file.

- If **Document could not be scanned** is selected as the action for the matched rule, the evidence file will not be captured.

Prerequisites and assumptions

This article uses the process you learned in Design a data loss prevention policy to show you how to create a Microsoft Purview Data Loss Prevention (DLP) policy. Work through these scenarios in your test environment to familiarize yourself with the policy creation UI.

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

This scenario uses the *Confidential* sensitivity label, so it requires you to create and publish sensitivity labels. To learn more, see:

- Learn about sensitivity labels
- Get started with sensitivity labels
- Create and configure sensitivity labels and their policies

This procedure uses a hypothetical distribution group *Human Resources* and a distribution group for the security team at Contoso.com.

The policy configuration procedure uses alerts, see: Get started with the data loss prevention alerts

Policy intent statement and mapping

We, Contoso, want to prevent users from unintentionally exposing sensitive information by pasting it into web forms or browser-based applications. Sensitive data—such as personally identifiable information or other regulated content—can be copied from local files or applications and pasted into websites, creating a potential data exfiltration risk.

*To address this, we will create a policy that evaluates content dynamically at the moment it is pasted into a supported browser. Based on the sensitivity of the pasted content and the destination website, we will audit, warn, or block the action. We will also use **Sensitive service domain groups** to apply different levels of enforcement depending on the target websites. This allows us to balance security and usability by applying stricter controls to higher-risk domains while allowing flexibility for trusted sites.*

Expand table

Statement	Configuration question answered and configuration mapping
"We want to prevent sensitive data from being pasted into web forms or browser fields..."	- Administrative scope: Full directory - Where to monitor: Devices only - Policy scope: All users/devices or targeted users
"We want to evaluate content at the time it is pasted, regardless of its source..."	- Condition: Content contains selected **Sensitive info types** - Evaluation: Real-time classification at paste event (independent of source file classification)
"We want to control paste actions based on the sensitivity of the content..."	- Action: **Audit or restrict activities on devices** - Activity type: **Paste to supported browsers**
"We want different levels of enforcement depending on the destination website..."	- Endpoint settings: Create **Sensitive service domain groups** - Rule design: Associate paste restrictions with specific domain groups
"We want to audit, warn, or block paste actions based on risk level..."	- Action configuration: Set to **Audit**, **Block with override**, or **Block** depending on enforcement needs
"We want flexibility to tailor restrictions across different categories of websites..."	- Policy design: Multiple URL/domain groups (e.g., trusted vs untrusted sites) - Use exceptions or multiple rules for granular control
"We want to ensure enforcement occurs consistently across supported browsers..."	- Browser support: Microsoft Edge, Chrome, Firefox (with extensions), Safari - Endpoint DLP integration ensures policy enforcement in supported browsers
"We want users to be informed when paste actions are evaluated or restricted..."	- User experience: Policy tips or notifications triggered during paste evaluation - Behavior note: Possible brief delay while classification completes
"We want to deploy and test the policy with appropriate enforcement level..."	- Policy mode: Configurable (test, audit, or enforce) - Deployment: Submit policy and validate behavior with

Statement	Configuration question answered and configuration mapping
	test scenarios

Steps to create policy

You can set up different levels of enforcement when it comes to blocking data from being pasted into a browser. To do this, create different URL groups. For instance, you can create a policy that warns users against posting U.S. Social Security Numbers (SSN) to any website, and that triggers an audit action for websites in Group A. You can create another policy that completely blocks the paste action--without giving a warning--for all of the websites in Group B.

Create a URL group

Perform the following steps to create a sensitive service domain group for browser paste restrictions.

1. Sign in to the Microsoft Purview portal > **Data loss prevention** > **Settings** (gear icon in the upper left hand corner) > **Data Loss Prevention** > **Endpoint settings**, and scroll down to **Browser and domain restrictions to sensitive data**. Expand the section.

2. Scroll down to **Sensitive service domain groups**.

3. Choose **Create sensitive service domain group**.
   a. Enter a **Group name**.
   b. In the **Sensitive service domain** field, enter the URL for the first website you want to monitor and then choose **Add site**.
   c. Continue adding URLs for the rest of the websites you want to monitor in this group.
   d. When you are finished adding all URLs to your group, choose **Save**.

4. Create as many separate groups of URLs as you need.

Restrict pasting content into a browser

Use the following steps to create a DLP policy that restricts pasting sensitive content into a browser.

1. Sign in to the Microsoft Purview portal > **Data loss prevention** > **Policies**.

2. Under **Data stored in connected sources**, select **Devices**.

3. Create a DLP policy scoped to **Devices**. For information on how to create a DLP policy, see Create and Deploy data loss prevention policies.
4. On the Define policy settings page in the DLP policy creation flow, select **Create or customize advanced DLP rules** and then choose **Next**.
5. On the **Customize advanced DLP rules** page, choose **Create rule**.
6. Enter a name and description for the rule.
7. Expand **Conditions**, choose **Add condition**, and then select the **Sensitive info types**.
8. Under **Content Contains**, scroll down and select the new sensitive information type that you previously chose or created.
9. Scroll down to the **Actions** section, and choose **Add an action**.
10. Choose **Audit or restrict activities on devices**
11. In the **Actions** section, under **Service domain and browser activities**, select **Paste to supported browsers**.
12. Set the restriction to **Audit**, **Block with override**, or **Block**, and then choose **Add**.
13. Choose **Save**.
14. Choose **Next**
15. Choose whether you want to test your policy, turn it on right away, or keep it off, and then choose **Next**.
16. Choose **Submit**.

> **Important**
>
> There may be a brief time lag between when the user attempts to paste text into a web page and when the system finishes classifying it and responds. If this classification latency happens, you may see both policy-evaluation and check-complete notifications in Edge or policy-evaluation toast on Chrome and Firefox. Here are some tips for minimizing the number of notifications:
>
> 1. Notifications are triggered when policy for the target website is configured to **Block** or **Block with override** paste to browser for that user. You can configure setting the

overall action to **Audit** and then list the target websites using the exceptions as **Block**. Alternately, you can set the overall action to **Block** and then list secure websites using the exceptions as **Audit**.

2. Use latest Antimalware client version.
3. Use latest Edge browser version, especially Edge 120.
4. Install these Windows KBs

- Windows 10: KB5032278
- Windows 11: KB5032288

Help prevent exposure of sensitive files by configuring auto-quarantine for OneDrive sync

This scenario shows how to configure Endpoint DLP to prevent synchronization of **Highly Confidential** files to cloud sync apps like OneDrive while avoiding repeated notifications. By using **auto-quarantine** and restricted app controls, sensitive files are automatically moved to a secure location and replaced with a placeholder, enabling effective protection without creating a poor user experience from repeated sync attempts.

This scenario is for an unrestricted admin creating a full directory policy.

Prerequisites and assumptions

This article uses the process you learned in Design a data loss prevention policy to show you how to create a Microsoft Purview Data Loss Prevention (DLP) policy. Work through these scenarios in your test environment to familiarize yourself with the policy creation UI.

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

This scenario uses the *Confidential* sensitivity label, so it requires you to create and publish sensitivity labels. To learn more, see:

- Learn about sensitivity labels
- Get started with sensitivity labels
- Create and configure sensitivity labels and their policies

This procedure uses a hypothetical distribution group *Human Resources* and a distribution group for the security team at Contoso.com.

This scenario uses alerts. For more information, see Get started with the data loss prevention alerts

Policy intent statement and mapping

We, Contoso, want to prevent users from synchronizing highly sensitive files to cloud synchronization applications such as OneDrive from endpoint devices. In this scenario, files labeled ***Highly Confidential*** *must not be synchronized to cloud storage through restricted sync apps.*

At the same time, we want to avoid repeated DLP notifications and poor user experience caused by failed sync retries. To do that, we will use ***Endpoint DLP auto-quarantine*** *so that when a restricted sync app attempts to process a protected file, the original file is automatically moved to a quarantine location and replaced with a placeholder text file. This both prevents exfiltration and stops the sync client from repeatedly retrying the same blocked file.*

We also want users to be informed when the action is blocked, and we want administrators to be able to validate and investigate the resulting events through ***Activity explorer****.*

Expand table

Statement	Configuration question answered and configuration mapping
"We want to prevent users from synchronizing files labeled Highly Confidential to cloud sync apps such as OneDrive..."	- Administrative scope: Full directory - Where to monitor: Devices - Policy scope: Devices only, with optional targeting to specific test users - Condition: Content contains the sensitivity label **Highly Confidential**
"We want to treat cloud synchronization apps as restricted applications for these sensitive files..."	- Endpoint settings: Create a restricted app group named **Cloud Sync apps** - Restricted apps include OneDrive executables for Windows and macOS - Restricted app group is referenced by the DLP rule
"We want to block restricted apps from performing file activities on these sensitive items..."	- Rule action: **Audit or restrict activities on devices** - Activity type: **File activities for apps in restricted app groups** - Restriction: **Apply a restriction to all activity** > **Block**

Statement	Configuration question answered and configuration mapping
“We want to avoid looping DLP notifications and repeated cloud sync retries for blocked sensitive files…”	- Endpoint DLP setting: Enable **Auto-quarantine for unallowed apps** - Quarantine behavior: Move the original file to a configured quarantine folder - File handling: Append date/time stamp to quarantined file name
“We want the user to understand what happened to the blocked file…”	- Auto-quarantine response: Replace the original file with a **.txt placeholder file** containing a custom message - Placeholder message includes tokens such as **%%FileName%%**, **%%PolicyName%%**, and **%%QuarantinePath%%**
“We want users to be notified in real time when the sync action is blocked…”	- User notifications: Turn **User notifications** On - Endpoint behavior: Show users a **policy tip notification** when the blocked activity occurs
“We want this protection to apply immediately once the rule is active…”	- Policy creation: Custom policy with advanced DLP rules - Deployment mode: **Turn it on right away**
“We want to validate that blocking, quarantine, and user messaging all work together correctly…”	- Test procedure: Create a Word document, apply the **Highly Confidential** label, and copy it into the local OneDrive sync folder - Expected outcome: User sees a notification toast, the source file is replaced by a placeholder text file, and the original file appears in the quarantine folder
“We want administrators to be able to review the enforcement event after testing…”	- Monitoring and investigation: Use **Activity explorer** - Filters: Set location to **Devices** and filter by the policy name to review the policy match and action outcome

Steps to create policy

Complete the following procedures to configure Endpoint DLP settings, create the policy, and test auto-quarantine.

Before you begin

In this Endpoint DLP auto-quarantine scenario, synchronizing files with the **Highly Confidential** sensitivity label to OneDrive is blocked. This is a complex scenario with multiple components and procedures. You need:

- A Microsoft Entra user account to target and an onboarded Windows 10/11 or macOS computer that is already synchronizing a local OneDrive folder with OneDrive cloud storage.

- Sensitivity labels configured and published—see Get started with sensitivity labels and Create and configure sensitivity labels and their policies.

There are three procedures.

1. Configure the Endpoint DLP Autoquarantine settings.
2. Create a policy that blocks sensitive items that have the **Highly Confidential** sensitivity label.
3. Create a Word document on the Windows 10/11 or macOS device that the policy targets, apply the label, and copy the document to the user account's local OneDrive folder that is being synchronized.

Configure Endpoint DLP unallowed app and Autoquarantine settings

Perform the following steps to create a restricted app group and configure auto-quarantine settings for cloud sync apps.

1. Sign in to the Microsoft Purview portal > **Data loss prevention** > **Settings** (gear in the upper left hand corner) > **Data loss prevention** > **Endpoint settings**.

2. Expand **Restricted apps and app groups**.

3. Under **Restricted app groups**, choose **Add restricted app group**. Enter *Cloud Sync apps* as the group name.

4. Select the **Auto-quarantine** box.

5. For the **App name**, enter *OneDrive*. For the Windows **Executable name**, enter *onedrive.exe*, then choose the + button. For the macOS **Executable name**, enter */Applications/OneDrive.app/Contents/MacOS/OneDrive*, then choose the + button. This disallows onedrive application on devices from accessing items with the **Highly Confidential** label.

   > **Note**
   >
   > To restrict other common cloud sync app on macOS devices, add the below path
   >
   > - Box: `/Applications/Box Sync.app/Contents/MacOS/Box Sync`
   > - Dropbox: `/Applications/Dropbox.app/Contents/MacOS/Dropbox`
   > - Google Drive: `/Applications/Google Drive.app/Contents/MacOS/Google Drive`

- iCloud: `System/Library/PrivateFrameworks/CloudDocsDaemon.framework/Versions/A/Support/bird`

6. Choose **Save**.
7. Under **Auto-quarantine settings** choose **Edit auto-quarantine settings**.
8. Enable **Auto-quarantine for unallowed apps**.
9. Enter the path to the folder on local machines where you want the original sensitive files to be moved to. For example:

> `%homedrive%%homepath%\Microsoft DLP\Quarantine` for the username *Isaiah Langer* will place the moved items in a folder named:
>
> *C:\Users\IsaiahLanger\Microsoft DLP\Quarantine\OneDrive*
>
> A separate path for the macOS device is required, such as `/System/Applications/Microsoft DLP/Quarantine`

1. Append a date and time stamp to the original file name.

> **ⓘ Note**
>
> DLP auto-quarantine will create sub-folders for the files for each unallowed app. So if you have both *Notepad* and *OneDrive* in your unallowed apps list, a sub-folder will be created for **\OneDrive** and another sub-folder for **\Notepad**.

2. Choose **Replace the files with a .txt file that contains the following text** and enter the text you want in the placeholder file. For example for a file named *auto quar 1.docx*, you could enter:

> %%FileName%% contains sensitive info that your organization is protecting with the data loss prevention (DLP) policy %%PolicyName%%. The file was moved to the quarantine folder: %%QuarantinePath%%

will leave a text file that contains this message:

> auto quar 1.docx contains sensitive info that your organization is protecting with the data loss prevention (DLP) policy. It was moved to the quarantine folder: C:\Users\IsaiahLanger\Microsoft DLP\Quarantine\OneDrive\auto quar 1.docx.

3. Choose **Save**.

Configure a policy to block OneDrive synchronization of files with the sensitivity label "Highly Confidential"

Use the following steps to create a DLP policy that blocks OneDrive synchronization for files labeled **Highly Confidential**.

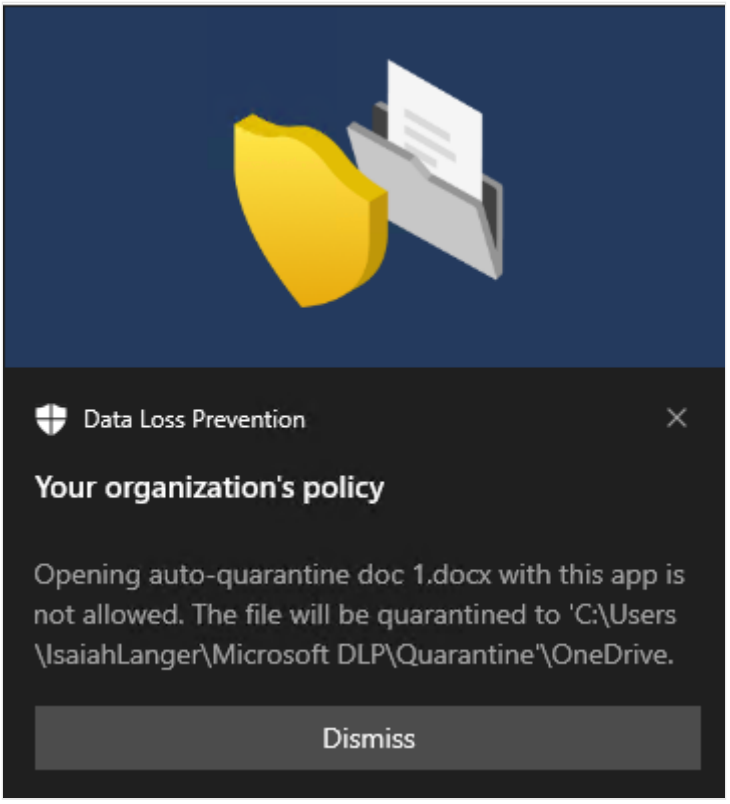
1. Sign in to the Microsoft Purview portal > **Data loss prevention** > **Policies**.
2. Select **Create policy**.
3. **Data stored in connected sources**.
4. For this scenario, choose **Custom**, then **Custom policy**. Choose **Next**.
5. Fill in the **Name** and **Description** fields, choose **Next**.
6. Select **Full directory** under **Admin units**.
7. Toggle the **Status** field to off for all locations except **Devices**. If you have a specific end user account that you want to test this from, be sure to select it in the scope. Choose **Next**.
8. Accept the default **Create or customize advanced DLP rules** selection and choose **Next**.
9. Create a rule with these values:
   a. **Name** > *Scenario 4 Autoquarantine*.
   b. Under **Conditions** choose **Add condition** and then **Content Contains**.
   c. Enter a group name, for example *Highly Confidential Sensitivity Labels* and then choose **Add**.
   d. Select **Sensitivity labels** then **Highly Confidential** and choose **Add**.
   e. Under **Actions** choose **Add an action**.
   f. Select **Audit or restrict activities on devices** > **File activities for apps in restricted app groups**.
   g. Choose **Add restricted app group** then choose the *Cloud Sync Apps* group you created previously.
   h. Choose **Apply a restriction to all activity** > **Block**. For the purposes of this scenario, clear all the other activities.

i. Under **User notifications**, toggle **User notifications** to **On** and under **Endpoint devices** choose **Show users a policy tip notification when an activity** if not already enabled.

10. Choose **Save** and **Next**.
11. Choose **Turn it on right away**. Choose **Next**.
12. Review your settings and choose **Submit**.

> **Note**
>
> Allow at least an hour for the new policy to be replicated and applied to the target Windows 10 computer.

13. The new DLP policy appears in the policy list.



Test Autoquarantine on the Windows 10/11 device

Perform the following steps to verify that auto-quarantine blocks the sync attempt and replaces the file with a placeholder. Before testing, wait at least an hour for the new policy to replicate and apply to the target device.

1. Sign in to the Windows 10/11 computer with the user account you included in the **Devices** scope for the policy.
2. Create a folder whose contents won't be synchronized to OneDrive. For example:

   > *C:\auto-quarantine source folder*

3. Open Microsoft Word and create a file in the autoquarantine source folder. Apply the **Highly confidential** sensitivity label; see Apply sensitivity labels to your files and email in Office.
4. Copy the file you created to your OneDrive synchronization folder. A user notification toast should appear telling you that the action isn't allowed and that the file will be quarantined. For example, for user name *Isaiah Langer*, and a document titled *autoquarantine doc 1.docx* you would see this message:

The message reads:

> Opening auto-quarantine doc 1.docx with this app is not allowed. The file will be quarantined to *C:\Users\IsaiahLanger\Microsoft DLP\OneDrive*

5. Choose **Dismiss**.
6. Open the place holder text file. It is named **auto-quarantine doc 1.docx_*date_time*.txt**.
7. Open the quarantine folder and confirm that the original file is there.
8. Check Activity explorer for data from the monitored endpoints. Set the location filter for devices and add the policy, then filter by policy name to see the effect of the *Scenario 4 Autoquarantine* policy. For information on using activity explorer, see Get started with activity explorer.
9. Check Activity explorer for the event.

Help prevent sharing of sensitive items with unauthorized cloud apps and services

This scenario demonstrates how to restrict unintentional sharing of sensitive information to unapproved cloud applications and services using Microsoft Purview DLP. By defining **sensitive service domains** and enforcing controls through supported browsers, organizations can monitor and guide how sensitive data is uploaded or accessed.

> **Note**
>
> The following web browsers are supported:
>
> - Microsoft Edge (Win/macOS)
> - Chrome (Win/macOS)- Microsoft Purview extension for Chrome Windows only
> - Firefox (Win/macOS)- Microsoft Purview extension for Firefox Windows only
> - Safari (macOS only)

When a policy is configured for the **Devices** location, unsupported browsers are prevented from accessing sensitive content, and users are redirected to Microsoft Edge, where DLP controls can block or restrict actions based on policy conditions. This browser-aware enforcement helps reduce the risk of data exfiltration while maintaining a consistent and guided user experience.

To implement this approach, you define restricted destinations (domains, services, or IPs), specify unsupported browsers, and configure DLP rules that detect sensitive content and apply controls such as **Upload to cloud services** and **Access from unallowed browser**.

The sensitive service domain and browser-restriction configuration enables organizations to audit user behavior, refine policies, and progressively enforce stricter controls as needed, while minimizing disruption to legitimate business activities.

Prerequisites and assumptions

This article uses the process you learned in Design a data loss prevention policy to show you how to create a Microsoft Purview Data Loss Prevention (DLP) policy. Work through these scenarios in your test environment to familiarize yourself with the policy creation UI.

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

This scenario uses the *Confidential* sensitivity label, so it requires you to create and publish sensitivity labels. To learn more, see:

- Learn about sensitivity labels
- Get started with sensitivity labels
- Create and configure sensitivity labels and their policies

This procedure uses a hypothetical distribution group *Human Resources* and a distribution group for the security team at Contoso.com.

The policy-creation procedure in this article uses alerts. For more information, see Get started with the data loss prevention alerts

Policy intent statement and mapping

We, Contoso, want to prevent users from unintentionally sharing sensitive information to unapproved cloud applications and services from endpoint devices. At the same time, we want to ensure users can continue to access and work with non-sensitive data without unnecessary restrictions.

*To achieve this, we will define a set of **restricted cloud service domains** and enforce controls when sensitive information is detected in user activity. When users attempt to upload sensitive content to these unapproved services—or access such content through unsupported browsers—we will audit the activity and guide users toward supported, compliant workflows (such as using Microsoft Edge).*

Using restricted cloud service domains with audit-first enforcement allows us to gradually enforce controls by first auditing user behavior, understanding risk patterns, and refining the policy before moving to stricter enforcement if needed.

Expand table

Statement	Configuration question answered and configuration mapping
"We want to prevent users from sharing sensitive information to unapproved cloud apps and services..."	- Administrative scope: Full directory - Where to monitor: Devices only - Policy scope: All users/devices (or targeted users for testing)
"We want to define which cloud services are considered unallowed for sensitive data sharing..."	- Endpoint settings: Create **Sensitive service domain group** - Domains defined using URL/IP/IP range (with wildcard support) - Group reused in policy rules
"We want to detect sensitive content being shared to these services..."	- Conditions: Content contains selected **Sensitive info types** - Detection logic: Built-in or custom sensitive information types
"We want to monitor attempts to upload sensitive content or access it through unsupported browsers..."	- Actions: **Upload to a restricted cloud service domain or access from an unallowed browser** - Browser control integrated with Endpoint DLP
"We want to initially observe user behavior without blocking business processes..."	- Action mode: **Audit only** for service domain and browser activities - No blocking or override enforced at this stage
"We want to redirect users toward supported, policy-aware browsers..."	- Endpoint behavior: Unallowed browsers are prevented from accessing sensitive content - User experience: Redirection to Microsoft Edge where DLP controls are enforced
"We want to maintain flexibility to extend protections over time..."	- Design capability: Add more domain groups, apps, and policies as needed - Policy extensibility: Supports future transition to block or block with override
"We want to monitor and optionally control other file activities across apps..."	- Additional actions: Configure **File activities for all apps** as needed - Fine-grained monitoring or restriction of endpoint behaviors
"We want this policy to be active immediately for evaluation..."	- Policy mode: **Turn it on right away** - Deployment: Immediate enforcement in audit mode

Steps to create policy

Perform the following steps to create the sensitive service domain group and configure the DLP policy.

1. Sign in to the Microsoft Purview portal > **Data loss prevention** > **Settings** (gear icon in the upper left hand corner) > **Data Loss Prevention** > **Endpoint DLP settings** > **Browser and domain restrictions to sensitive data** > **Sensitive service domain groups**.
2. Select **Create sensitive service domain group**.
3. Name the group.
4. Enter the **Sensitive service domain** for the group. You can add multiple websites to a group and use wildcards to cover subdomains. For example, `www.contoso.com` for just the top level website, or: *.contoso.com for corp.contoso.com, hr.contoso.com, fin.contoso.com.
5. Select the **Match type** you want. You can select from **URL**, **IP address**, **IP address range**.
6. Select **Save**.
7. In the left navigation pane, select **Data loss prevention** > **Policies**.
8. On the **Choose locations to apply the policy** page, select **Data stored in connected sources** and then choose **Next**.
9. Create and scope a policy that is applied only to the **Devices** location. For more information on how to create a policy, see Create and Deploy data loss prevention policies. Be sure to scope the **Admin units** to **Full directory**.
10. On the **Define policy settings** page, select **Create or customize advanced DLP rules** and choose **Next**.
11. Create a rule, as follows:
    a. Under **Conditions**, select + **Add condition** and select **Content contains** from the drop-down menu.
    b. Give the group a name.
    c. Choose **Add** and then select **Sensitive info types**.
    d. Select a **Sensitive info type** from the flyout pane, then choose **Add**.
    e. Add the action **Audit or restrict activities on devices**.
    f. Under **Service domain and browser activities**, choose **Upload to a restricted cloud service domain or access from an unallowed browser** and set the action to **Audit only**.
    g. Select + **Choose different restrictions for sensitive service domains** and then choose **Add group**.

h. On **the Choose sensitive service domain groups** flyout, select the sensitive service domain group(s) you want, choose **Add** and then choose **Save**.
i. Under **File activities for all apps**, select the user activities you want to monitor or restrict and the actions for DLP to take in response to those activities.
j. Finish creating the rule and choose **Save** and then **Next**.
k. On the confirmation page, choose **Done**.
l. On the **Policy mode** page, choose **Turn it on right away**. Choose **Next** and then **Submit**.

Create policy to manage file activities by implementing network exceptions

This scenario shows how to use **network-based conditions** in Microsoft Purview DLP to apply different protections based on where users access sensitive data. By defining VPN connections and configuring **network exceptions**, the policy adjusts actions—such as auditing or blocking clipboard activity—based on network context, enabling more precise control for hybrid work environments without uniformly restricting user activity.

This scenario is for an unrestricted admin creating a full directory policy.

Prerequisites and assumptions

This scenario requires that you already have devices onboarded and reporting into Activity explorer. If you haven't onboarded devices yet, see Get started with Endpoint data loss prevention.

In this scenario, we define a list of VPNs that hybrid workers use for accessing organization resources.

This article uses the process you learned in Design a data loss prevention policy to show you how to create a Microsoft Purview Data Loss Prevention (DLP) policy. Work through these scenarios in your test environment to familiarize yourself with the policy creation UI.

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

This scenario uses the *Confidential* sensitivity label, so it requires you to create and publish sensitivity labels. To learn more, see:

- Learn about sensitivity labels
- Get started with sensitivity labels
- Create and configure sensitivity labels and their policies

This procedure uses a hypothetical distribution group *Human Resources* and a distribution group for the security team at Contoso.com.

This procedure uses alerts, see: Get started with the data loss prevention alerts

Policy intent statement and mapping

We, Contoso, want to control how sensitive legal content is handled based on the network context in which users are operating. In particular, we want to apply different levels of restriction depending on whether users are connected through trusted corporate networks or VPN connections used by hybrid workers.

*To achieve this, we will define known VPN connections and use them in **network exception rules** within a DLP policy. This allows us to enforce stricter controls—such as blocking clipboard activity with override—when users are connected through specific VPNs, while maintaining less restrictive (audit-only) behavior in other contexts. This approach enables contextual data protection that adapts to how and where users access sensitive data.*

Expand table

Statement	Configuration question answered and configuration mapping
"We want to apply different data protection controls depending on the network users are connected from…"	- Administrative scope: Full directory - Where to monitor: Devices only - Policy scope: All users/devices or targeted users
"We want to identify VPN connections used by hybrid workers…"	- Endpoint settings: Configure **VPN settings** using Server address or Network address - Data gathered via PowerShell commands (Get-VpnConnection, Get-NetConnectionProfile)
"We want to detect sensitive legal content handled on endpoints…"	- Condition: **Content contains** = Trainable classifiers, **Legal Affairs**
"We want to control specific user activities involving sensitive content…"	- Action: **Audit or restrict activities on devices** - Activity type: **File activities on all apps** - Specific activity: **Copy to clipboard** (extendable to others like print or USB copy)

Statement	Configuration question answered and configuration mapping
"We want less restrictive monitoring under normal conditions..."	- Default activity action: **Audit only** for copy to clipboard
"We want stricter controls when users are connected through defined VPN networks..."	- Network exception: Select **VPN** and set action to **Block with override** - Priority: VPN must be set as top priority in network exception configuration
"We want to support user productivity while maintaining accountability..."	- Override capability: Users can proceed with justification when blocked under VPN conditions
"We want to ensure correct precedence of network-based rules..."	- Configuration behavior: VPN rules take precedence over Corporate network settings when ordered correctly - Caution: 'Apply to all activities' can overwrite other activity-specific configurations
"We want to safely test the policy behavior before full enforcement..."	- Policy mode: **Run in simulation mode** - User experience: **Show policy tips while in simulation mode**
"We want to validate policy behavior through monitoring and testing..."	- Monitoring: Use **Activity explorer** to review policy matches - Testing: Perform clipboard copy action under different network conditions (VPN vs non-VPN)

Steps to create policy

The following procedures walk you through defining VPN settings, verifying corporate network connectivity, and creating the DLP policy with network-based controls.

Create and use a Network exception

Network exceptions enable you to configure Allow, Audit only, Block with override, and Block actions to file activities based on the network from which users access sensitive files. You can select from the VPN settings list you've defined and use the **Corporate network** option. The actions can be applied individually or collectively to these user activities:

- Copy to clipboard
- Copy to a USB removable device
- Copy to a network share
- Print

- Copy or move using unallowed Bluetooth app
- Copy or move using RDP

Get the Server address or Network address

Use the following steps to retrieve the Server address or Network address values needed to define a VPN entry in the endpoint DLP settings.

1. On a DLP monitored Windows device, open a **Windows PowerShell** window as an administrator.
2. Run this cmdlet:

```
PowerShell
Get-VpnConnection
```

3. Running this cmdlet returns multiple fields and values.
4. Find the **ServerAddress** field and record that value. You use this when you create a VPN entry in the VPN list.
5. Find the **Name** field and record that value. The **Name** field maps to the **Network address** field when you create a VPN entry in the VPN list.

Determin if the device is connected through a Corporate network

Use the following steps to verify whether the device is currently connected through a corporate network.

1. On a DLP monitored Windows device, open a **Windows PowerShell** window as an administrator.
2. Run this cmdlet:

```
PowerShell
Get-NetConnectionProfile
```

3. If the **NetworkCategory** field is **DomainAuthenticated**, then the device is connected to a corporate network. If its anything else, the device's connection is not through a corporate network.

Add a VPN

After you collect the server or network address, use the following steps to add the VPN to the Endpoint DLP settings.

1. Sign in to the Microsoft Purview portal.
2. Open **Settings** > **Data Loss Prevention** > **Endpoint settings** > **VPN settings**.
3. Select **Add or edit VPN addresses**.
4. Provide either the **Server address** or **Network address** value that you recorded in the Get the Server address or Network address procedure.
5. Select **Save**.
6. Close the item.

Configure policy actions

Use the following steps to create the DLP policy and configure its network-based controls for file activities.

1. Sign in to the Microsoft Purview portal.
2. Open **Data Loss Prevention** > **Policies**.
3. Select **Create policy**
4. On the **Choose what to protect** page, select **Data stored in connected sources**.
5. Select **Custom** from the **Categories** list, then select the **Custom policy** template from **Regulations**.
6. Name your new policy and provide a description.
7. Select **Full directory** under **Admin units**.
8. Scope the location to **Devices** only.
9. Create a rule where:
   a. **Content contains** = **Trainable classifiers**, **Legal Affairs**
   b. **Actions** = **Audit or restrict activities on devices**
   c. Then pick **File activities on all apps**

d. The select **Apply restrictions to specific activity**

e. Select the actions that you want to configure **Network exceptions** for.

10. Select **Copy to clipboard** and the **Audit only** action

11. Select **Choose different copy to clipboard restrictions**.

12. Select **VPN** and set the action to **Block with override**.

> ⓘ **Important**
>
> When you want to control the activities of a user when they're connected through a VPN *you must* select the VPN and make the VPN the top priority in the **Network exceptions** configuration. Otherwise, if the **Corporate network** option is selected, then that action defined for the **Corporate network** entry will be enforced.

> ⊗ **Caution**
>
> The **Apply to all activities** option will copy the network exceptions that are defined here and apply them to all the other configured specific activities, like **Print**, and **Copy to a network share**. ***This will overwrite the network exceptions on the other activities The last saved configuration wins.***

13. **Save**.

14. Accept the default **Run the policy in simulation mode** value and choose **Show policy tips while in simulation mode**. Choose **Next**.

15. Review your settings and choose **Submit** and then **Done**.

16. The new DLP policy appears in the policy list.

Create a DLP policy that uses device scoping

This scenario shows how to scope a Microsoft Purview Endpoint DLP policy to specific device groups. For example, you can enforce a policy only when Finance users access data from Windows devices while excluding macOS devices. Device groups are commonly defined using dynamic device groups in Microsoft Entra ID.

This scenario is for an unrestricted admin creating a full directory policy.

This scenario requires that you already have devices onboarded and reporting into activity explorer. If you haven't onboarded devices yet, see Get started with Endpoint data loss prevention.

Prerequisites and assumptions

This article uses the process you learned in Design a data loss prevention policy to show you how to create a Microsoft Purview Data Loss Prevention (DLP) policy. Work through these scenarios in your test environment to familiarize yourself with the policy creation UI.

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important as policy design. Deploy a DLP policy shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

You've created a dynamic device group.

Policy intent statement and mapping

An organization wants to enforce a DLP policy that blocks copying sensitive items with credit card data to USB devices when Finance users access data from Windows devices, and does not apply when the same users work from macOS devices.

Expand table

Statement	Configuration question answered and configuration mapping
"An organization wants to enforce a DLP policy that blocks copying sensitive items with credit card data to USB devices..."	- Administrative scope: Full directory - Where to monitor: Devices only - Policy scope: All users/Finance Windows Devices group
"when Finance users access data from Windows devices..."	- Condition: **Content contains** = **Credit Card Number**
"...and does not apply when the same users work from macOS devices..."	- Action: **Audit or restrict activities on devices** - Activity type: **File activities on all apps** - Restriction model: **Apply restrictions to specific activity** - **Copy to a removable USB device** = **Block**

Create a device group

If you're unfamiliar with dynamic device groups, see:

- Create or update a dynamic membership group in Microsoft Entra ID
- Manage rules for dynamic membership groups in Microsoft Entra ID.

To create the device group for this scenario:

1. Create a new dynamic device group named **Finance Windows Device** for the Windows devices that the finance team uses.

Create a policy scoped to the dynamic device group

1. Sign in to the Microsoft Purview portal > **Data loss prevention** > **policies**.
2. Select **Create policy**.
3. Select **Enterprise applications & devices**.
4. Select the **Custom** from the **Categories** then **Custom policy** template from **Regulations**. Select **Next**.
5. Give your new policy a **Name** and **Description**.

6. Accept the default **Full directory** under **Admin units**.
7. Scope the location to only the **Devices** location.
8. Select **Edit** on the **Devices** location.
9. Accept the default **All users, groups, and adaptive scopes**
10. Select **Specific devices and device groups** and add the **Finance Windows Device** that you created.
11. Create a rule with the following values:
    - **Condition**: **Content contains** = **Sensitive Info types** = **Credit Card Number**
    - **Action**: **Audit or restrict activities on devices** > **File activities for all apps** > **Apply restrictions to specific activity** > **Copy to a removable USB device** = **Block**.
12. Select **Save** and then **Next**.
13. Accept the default **Run the policy in simulation mode** value and choose **Show policy tips while in simulation mode**. Choose **Next**.
14. Review your settings and choose **Submit**.

The new DLP policy appears in the policy list.

Troubleshooting endpoint data loss prevention configuration and policy sync

This article provides detailed instructions for:

1. Determining the device configuration and policy sync status values for Windows devices and macOS devices that are successfully onboarded into Microsoft Purview Data Loss Prevention (DLP).
2. Identifying and resolving any issues with the configuration status and the policy sync status.
3. Reviewing and understanding the device attribute that are available for each device and their meaning.

Device configuration and policy sync status values

Configuration status and the **Policy sync status** of all your onboarded devices have three possible values.

The **Configuration status** value shows you if the device is configured correctly, is sending a heartbeat signal to Purview, and the last time the configuration was validated. For Windows devices, configuration includes checking the status of Microsoft Defender Antivirus always-on protection and behavior monitoring.

The **Policy sync status** shows you if the device received the latest policy version, or if the corresponding policies synced successfully to the device.

Expand table

Field value	Configuration status	Policy sync status
Updated	Device health parameters are enabled and correctly set. This status indicates that the device's configuration is up to date with the recommended settings.	Device is up to date with the current versions of policies.
Not updated	Certain settings need attention. Follow the steps in the workflow diagram to address issues. You might need to enable the configuration settings for this device. Follow	This device isn't synced the latest policy updates. It might take up to 2 hours for the status in the devices list to update. Follow the steps in the workflow diagram to address issues.

Field value	Configuration status	Policy sync status
	the procedures in Microsoft Defender Antivirus always-on protection	
Not available	Device properties aren't available in the device list. This condition might be because the device doesn't meet the minimum OS version to provide visibility into its properties, or configuration, or if the device was just onboarded. Follow the steps in the workflow to address issues.	Device properties aren't available in the device list. This condition might be because the device doesn't meet the minimum OS version to provide visibility into its properties, or configuration, or if the device was just onboarded. Follow the steps in the workflow to address issues. System shows **Not available** if there is no Endpoint DLP policy.

> **Important**
>
> Devices must be online for the policy update to happen. If the status isn't updating, check the last time the device was seen.

Device attribute details

To maintain overall device health from a DLP perspective, go beyond determining the configuration and policy sync status and troubleshooting any issues found. You need to understand the attributes of an onboarded device. The values for these attributes can provide useful information to help you track the device health.

Expand table

Device attribute	Note
Last seen	The most recent time that the device was determined to be online.
Last policy sync time	The timestamp of the previous instance when the device downloaded the latest policy versions.
OS	The current operating system.
Defender engine version	The version of the antivirus engine on the device.
Defender Mocamp version	The version of the Defender client.
MDATP device ID	The unique identifier assigned to this device.

Device attribute	Note
Valid user	This indicates if the currently logged on user has a corresponding Entra ID account and is in scope of a DLP policy that's targeted at Devices.
Sensitive Data Activity	This provides a view all sensitive data activity for this device for the last 30 days.
Advanced classification bandwidth usage exceeded	This attribute shows if the bandwidth usage limit for Advanced Classification has been exceeded in the past 24 hours.
Endpoint DLP status	Shows if Endpoint DLP is enabled or disabled for the device.

Access device attribute data using Advanced Hunting

In addition to viewing device attributes in the Microsoft Purview portal, you can access the same Endpoint DLP device data through the DeviceInfo table in Advanced hunting.

Previously, you could get device attribute data manually through the **Export** functionality on the Device onboarding page in the Microsoft Purview portal.

With the `DeviceInfo` table, you can:

- Query device attribute data using KQL
- Retrieve up-to-date information without manual exports
- Analyze device status across your environment
- Integrate device data into custom dashboards and third-party reporting platforms

Access device data

To retrieve device attribute data:

1. Go to the **Microsoft Defender portal**
2. Navigate to **Investigation & response** > **Hunting** > **Advanced hunting**
3. Query the **`DeviceInfo`** table
4. Expand the **`DlpInfo`** column to view Endpoint DLP device details

Sample query:

Kusto

```
DeviceInfo
| where DlpInfo != ""
| project DlpInfo
```

DlpInfo

The **DlpInfo** column contains Endpoint Data Loss Prevention device information in JSON format. The JSON object can be used to query and report on device configuration status, policy synchronization status, Endpoint DLP enablement, and other configuration details for onboarded devices. These values correspond to the device information available in the DLP device onboarding page.

Example value:

JSON

```
{
 "IsDlpConfigurationValid": true,
 "DlpPolicyLastModifiedTimeUTC": "2026-01-14T20:00:47Z",
 "IsDlpEnabled": true,
 "IsDefenderRealTimeProtectionEnabled": true,
 "IsDefenderBehaviorMonitoringEnabled": true,
 "HasDlpACBandwidthExceeded": false,
 "HasDlpValidUpn": true,
 "DlpUpn": "user@contoso.com"
}
```

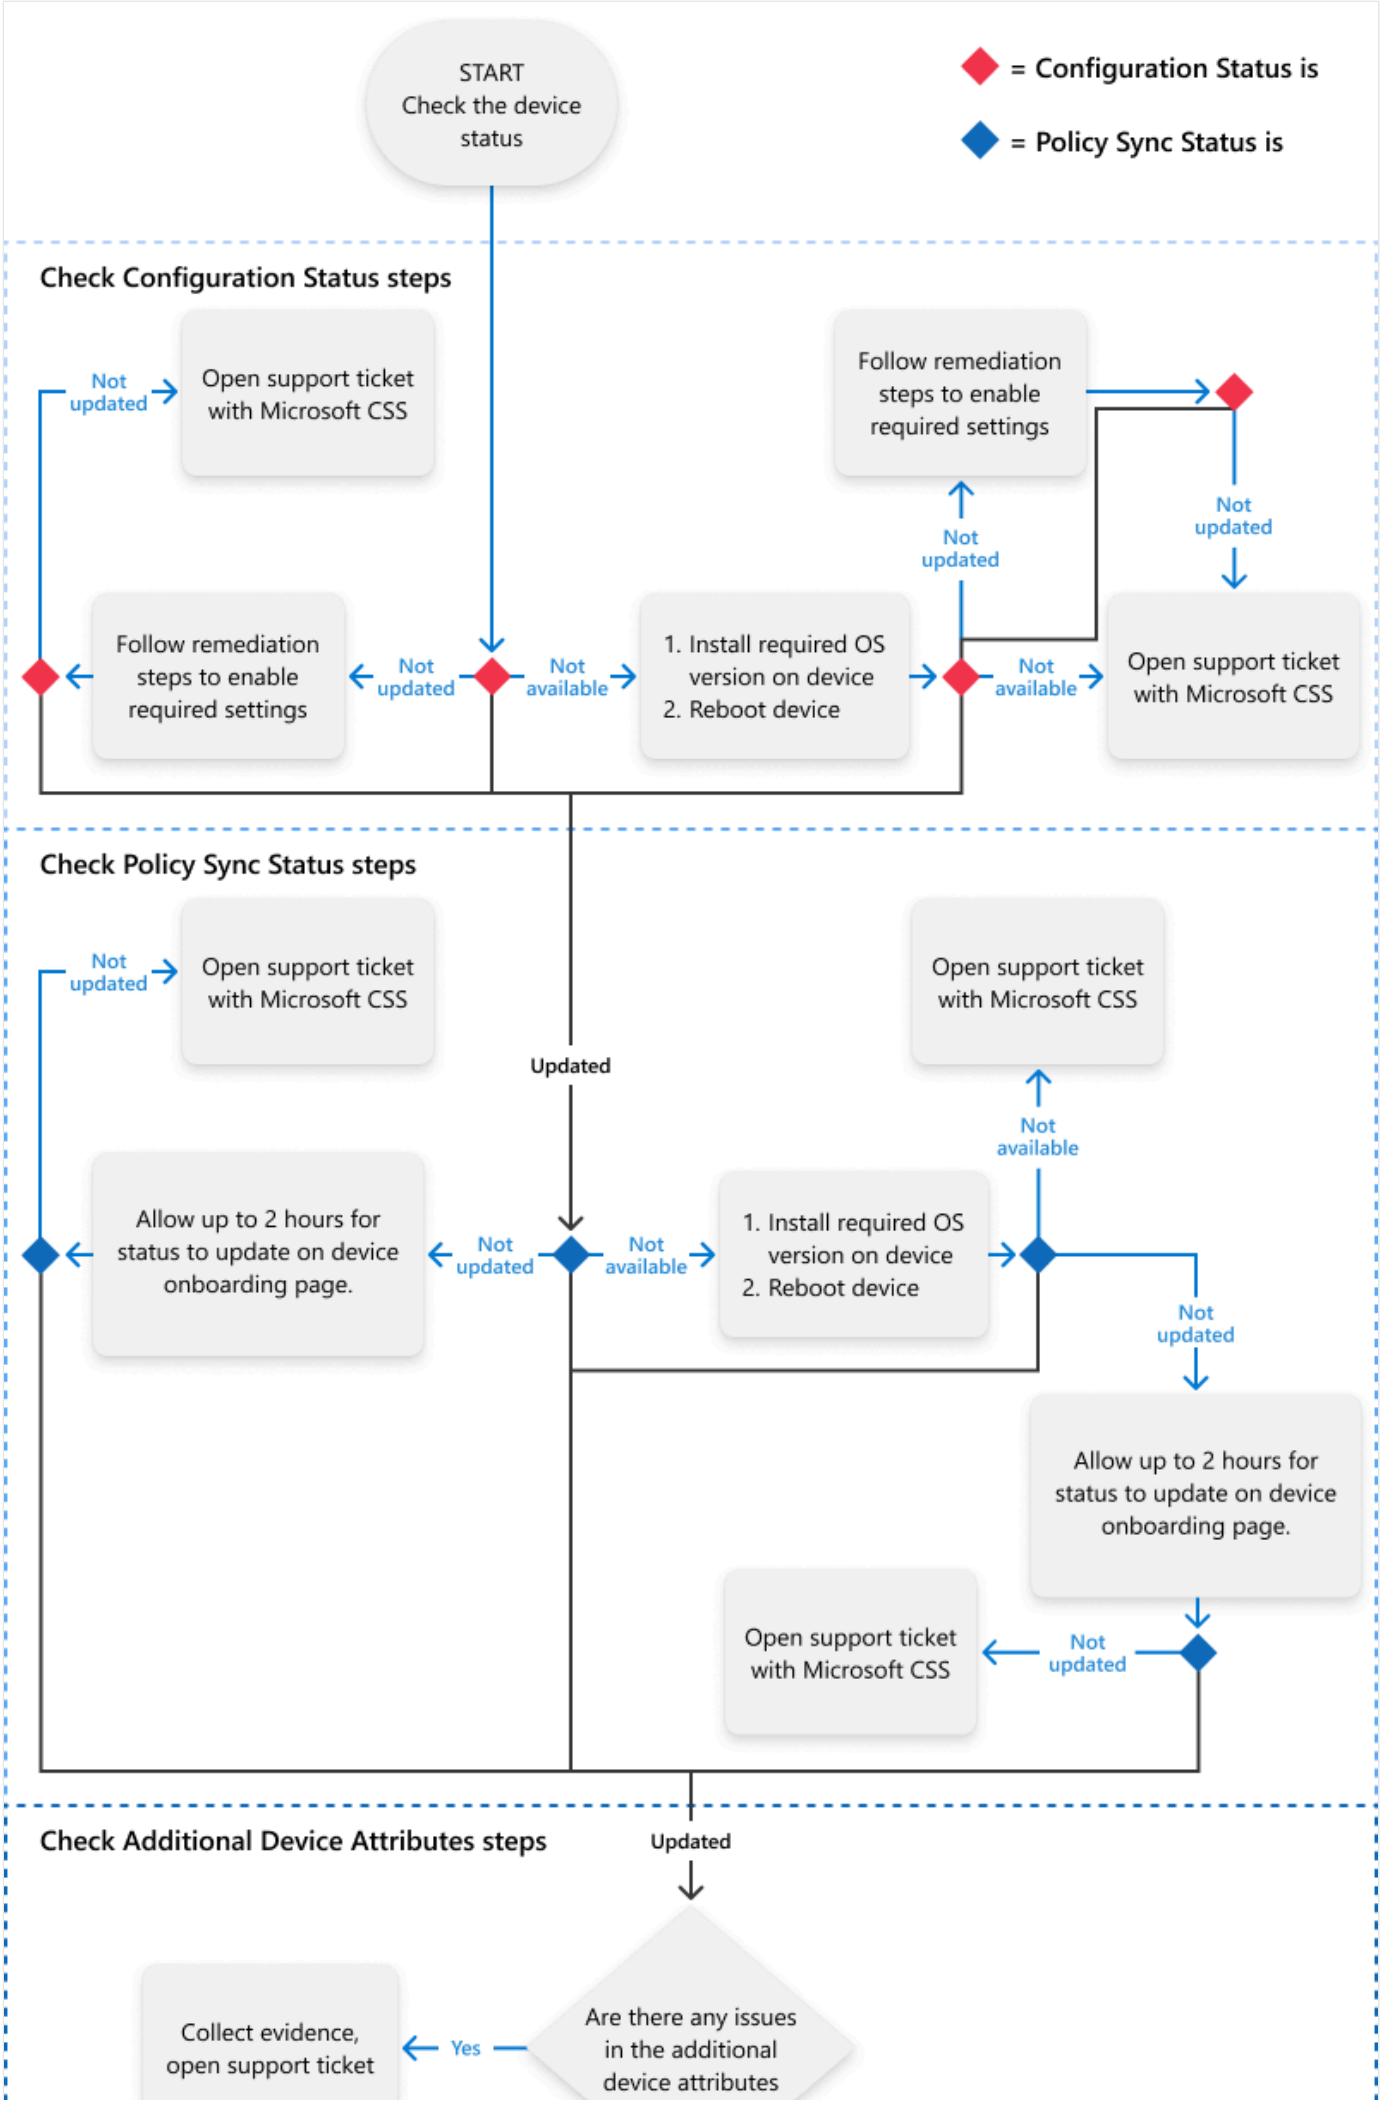
The following properties can be returned in the `DlpInfo` object:

Expand table

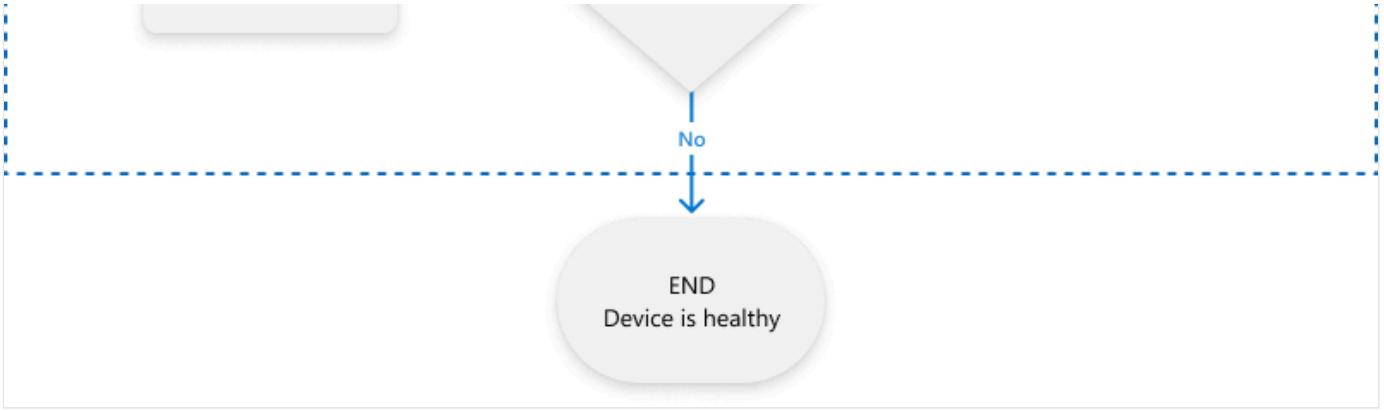
Property	Data type	Description
IsDlpConfigurationValid	`boolean`	Indicates whether the device configuration health is valid.
DlpPolicyLastModifiedTimeUTC	`datetime`	Timestamp of the most recent DLP policy modification associated with the device, in Coordinated Universal Time (UTC).
IsDlpEnabled	`boolean`	Indicates whether Endpoint DLP is enabled on the device.
IsDefenderRealTimeProtectionEnabled	`boolean`	Indicates whether Microsoft Defender Real-time Protection is enabled on the device.

Property	Data type	Description
IsDefenderBehaviorMonitoringEnabled	`boolean`	Indicates whether Microsoft Defender Behavior Monitoring is enabled on the device.
HasDlpACBandwidthExceeded	`boolean`	Indicates whether the device has exceeded the DLP Advanced Classification bandwidth threshold.
HasDlpValidUpn	`boolean`	Indicates whether the device is associated with a valid user principal name (UPN).
DlpUpn	`string`	User principal name (UPN) associated with the device.

Relationship to device attribute details



The fields in the `DlpInfo` column correspond directly to the device attributes described earlier. This correspondence enables you to investigate configuration and policy sync issues across multiple devices without relying on point-in-time exports.



Use this data to:

- Identify devices with invalid configurations
- Detect devices that aren't ready for Endpoint DLP enforcement
- Perform large-scale analysis beyond what the portal UI offers

Configuration and policy sync troubleshooting workflow

This diagram provides a workflow that walks you through the steps for diagnosing and resolving configuration and policy synchronization status for onboarded devices.

Check configuration status and resolve issues

1. Sign in to the Microsoft Purview portal > **Settings** (gear icon in the upper right corner) > **Device onboarding** > **Devices**.
2. Apply filters to narrow down the list of devices and simplify your investigation.
3. Select a device to open the details pane for more information on the configuration status.
4. If the status is **Updated**, the device is configured correctly. No further action is required. You can move on to Check policy sync status and resolve issues.
5. If the status is **Not available** or **Not updated**, follow the remediation steps in the details pane and the steps in the workflow diagram.

Check policy sync status and resolve issues

1. Sign in to the Microsoft Purview portal > **Settings** (gear icon in the upper right corner) > **Device onboarding** > **Devices**.
2. Apply filters to narrow down the list of devices and simplify your investigation.
3. Select a device to open the details pane for more information on the policy sync status.
4. If the status is **Updated**, the device successfully received the latest policy version. No further action is required. You can move on to Check device details.
5. If the status is **Not updated** or **Not available**, follow the remediation steps in the details pane and the steps in the workflow diagram.

> **Tip**
>
> You can see the overall status of how policy sync to devices is working on the **Policy status** report. The **Policy status** report is available in the Microsoft Purview compliance portal on the > **Data loss prevention** > **Overview** page.

Check device details

1. Sign in to the Microsoft Purview portal > **Settings** (gear icon in the upper right corner) > **Device onboarding** > **Devices**.
2. Apply filters to narrow down the list of devices and simplify your investigation.
3. Select a device to open the details pane for more information on the specific device attributes under **Device details**.

Collect evidence for a support ticket

If self-remediation isn't successful, gather evidence and open a support ticket for comprehensive support analysis.

From the **Device details** section, record the values for these fields:

- **OS**
- **Defender engine version**
- **Defender client version**
- **MDATP device ID**
- **Valid user**

For more guidance, see:

- Run the client analyzer on Windows
- Run the client analyzer on macOS and Linux

Last updated on 06/29/2026

Learn about Microsoft Purview Data Loss Prevention just-in-time protection

Use endpoint data loss prevention (DLP) just-in-time (JIT) protection to detect and block egress activities on monitored files while policy evaluation completes.

JIT audits and blocks these user egress activities on protected items:

- Copy to a removable media
- Copy to a network share
- Print
- Copy or move using Remote Desktop Protocol (RDP)
- Copy or move using a blocked Bluetooth app
- Copy to clipboard: JIT Audit by default
- Upload to a restricted cloud service domain

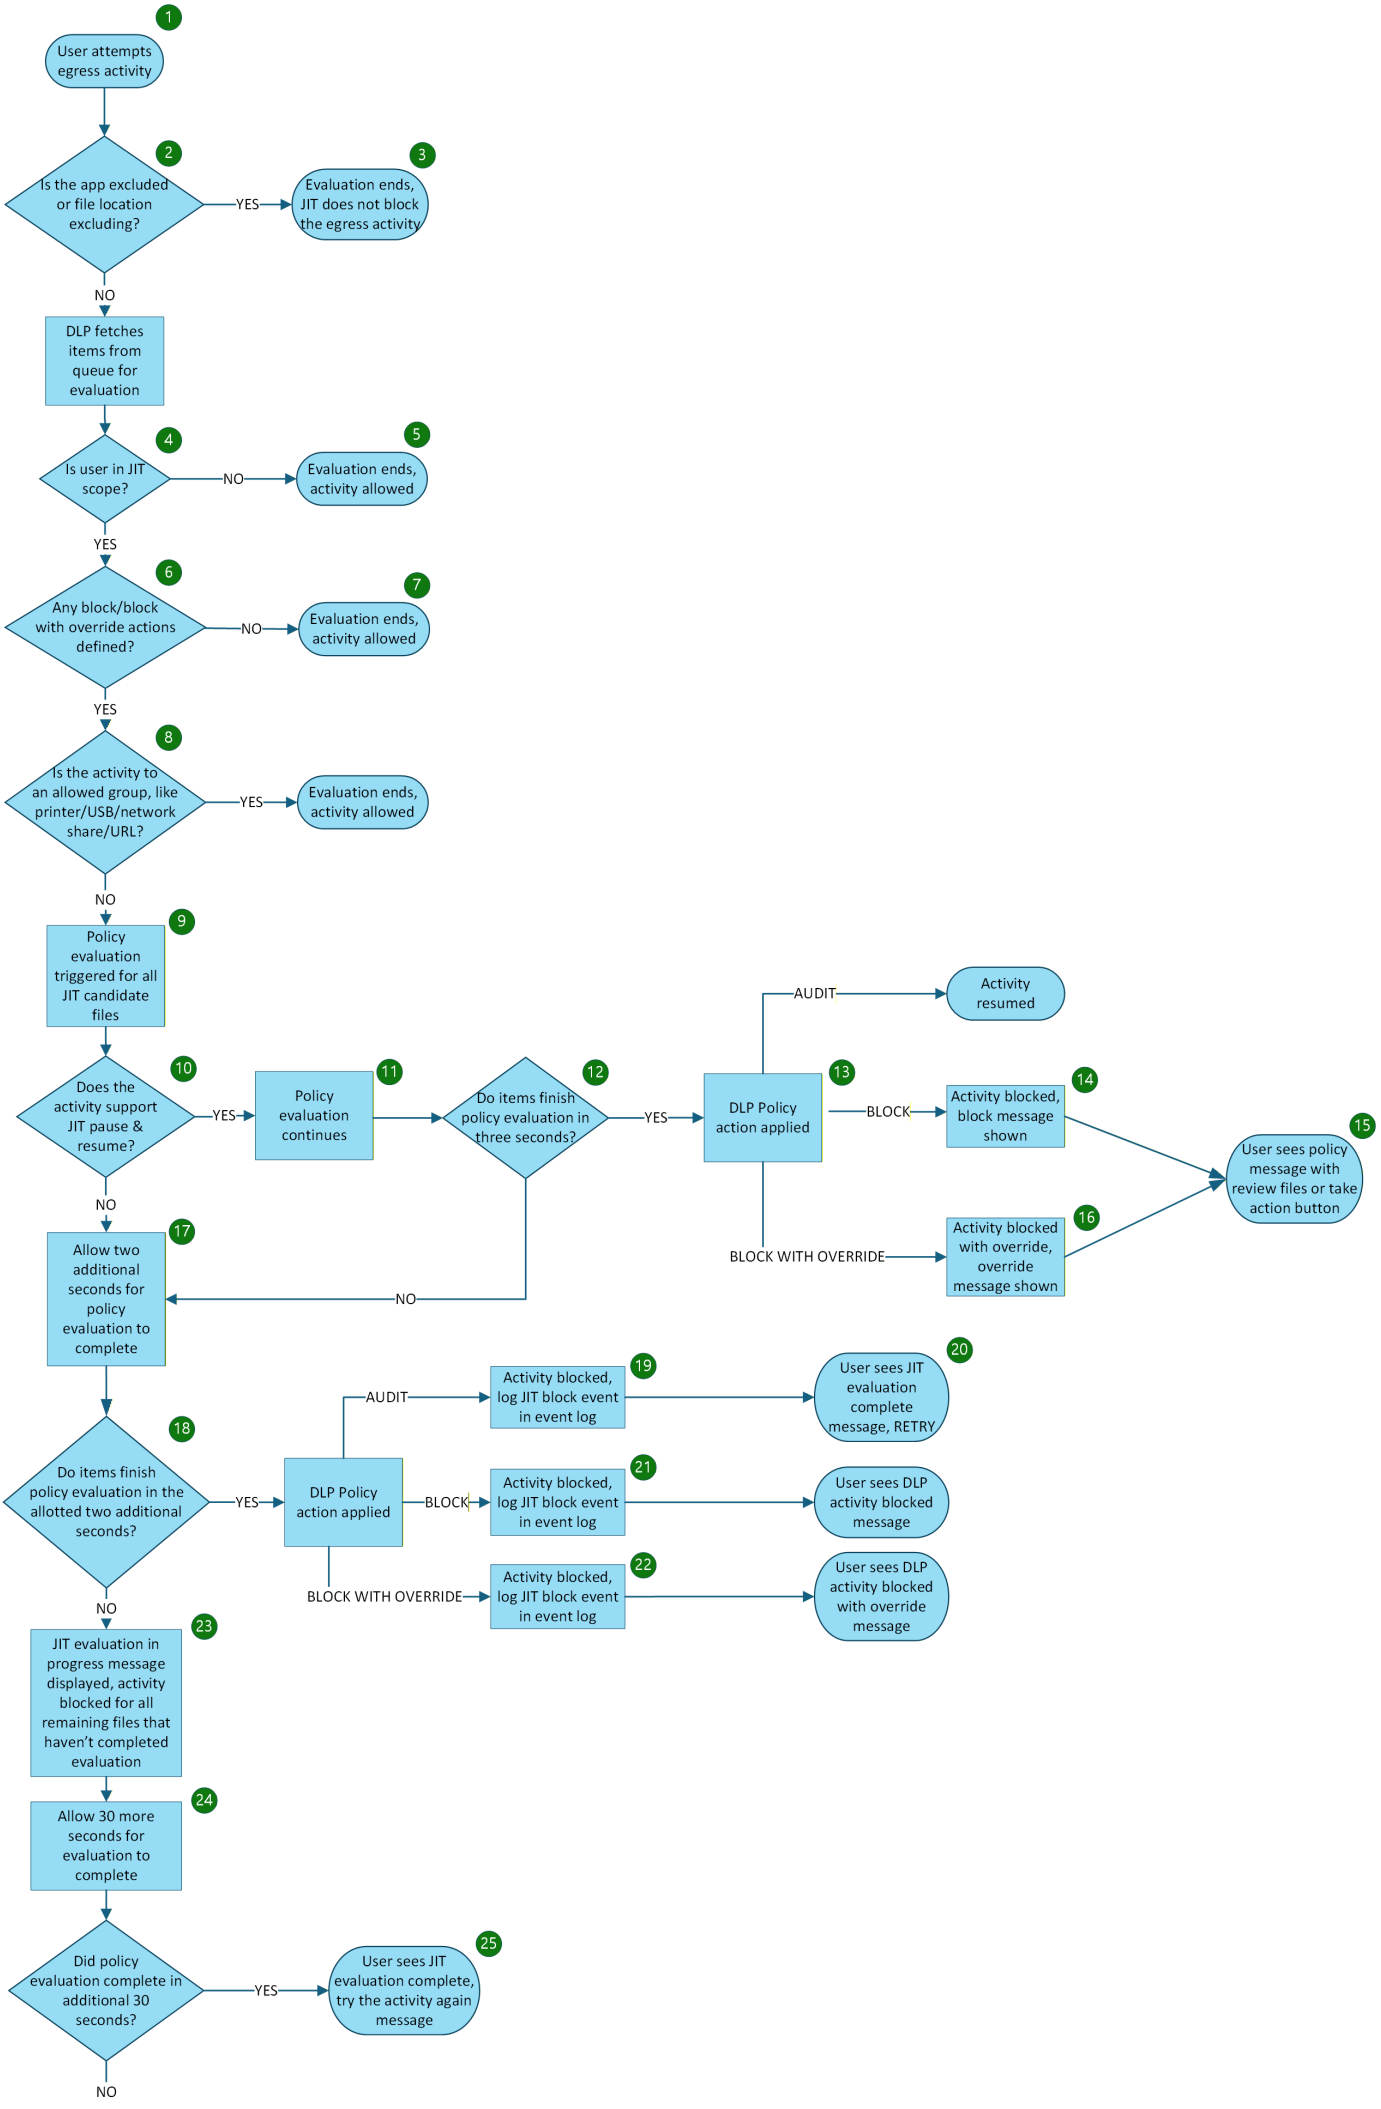
Terms

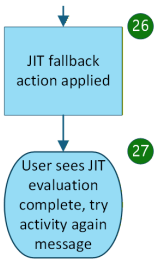
This article uses the following terms:

- **stale classification**: A classification that isn't produced by the most current version of a DLP policy. If you update a policy after an item is evaluated and classified, the item has a stale classification until the policy re-evaluates it.
- **JIT candidate file**: Files that DLP hasn't evaluated or that have a stale classification.
- **JIT audit**: After you enable JIT, Endpoint DLP generates an event in activity explorer for every JIT candidate file. In the JIT activity explorer event, the **JIT triggered** field has the value `true`, and the **Enforcement mode** value is `Audit`.
- **JIT block**: After you enable JIT, Endpoint DLP blocks the activity and generates an event in activity explorer for every JIT candidate file. In the JIT activity explorer event, the **JIT triggered** field has the value `true`, and the **Enforcement mode** field has the value `Block`.

> **Note**
>
> Endpoint DLP doesn't generate a `DLPRuleMatch` event or an alert.

- **JIT in progress notification**: When users who are in scope for JIT attempt an egress activity on a JIT candidate file, Endpoint DLP might block the egress activity and display a toast notification. This toast is called the JIT in progress toast.
- **JIT evaluation complete notification**: When Endpoint DLP finishes policy evaluation for a JIT candidate file, Endpoint DLP shows a toast notification to let the user know. This notification is called the JIT evaluation complete toast.
- **JIT event**: Endpoint DLP records and shows a JIT event in activity explorer when JIT audit or JIT block actions trigger. The event has the `JIT triggered` value set to `true`.
- **Fallback action in case of failure**: This configuration specifies the enforcement mode that DLP should apply when the policy evaluation doesn't complete. No matter which value you select, the relevant telemetry shows in activity explorer.





How JIT protection works

JIT protection blocks the egress activity when all the following conditions are true:

- A user attempts an egress activity on an item that has never been classified or that is classified with a stale policy. A stale policy means the file was classified with a policy that has since been updated, and the file hasn't been reclassified with the updated policy.
- The user is in the scope of JIT.
- Microsoft Purview Data Loss Prevention (DLP) policies exist that block or block with override for the *egress activity*.
- The egress activity isn't to an allowed location. For example, an allowed printer, USB device, URL, or network share.
- The egress activity doesn't support JIT pause and resume.
- The DLP policy evaluation *doesn't* complete in five seconds.

JIT workflow

1
User attempts egress activity
2
Is the app excluded or file location excluding?
YES
3
Evaluation ends, JIT does not block the egress activity
NO
DLP fetches items from queue for evaluation
4
Is user in JIT scope?
NO
5
Evaluation ends, activity allowed
YES
6
Any block/block with override actions defined?
NO
7
Evaluation ends, activity allowed
YES
8
Is the activity to an allowed group, like printer/USB/network share/URL?
YES
Evaluation ends, activity allowed
NO
9
Policy evaluation triggered for all JIT candidate files
10
Does the activity support JIT pause & resume?
YES
11
Policy evaluation continues
12
Do items finish policy evaluation in three seconds?
YES
13
DLP Policy action applied
AUDIT
Activity resumed
BLOCK
14
Activity blocked, block message shown
BLOCK WITH OVERRIDE
16
Activity blocked with override, override message shown
15
User sees policy message with review files or take action button
NO
17
Allow two additional seconds for policy evaluation to complete
18
Do items finish policy evaluation in the allotted two additional seconds?
YES
DLP Policy action applied
AUDIT
19
Activity blocked, log JIT block event in event log
20
User sees JIT evaluation complete message, RETRY
BLOCK
21
Activity blocked, log JIT block event in event log
User sees DLP activity blocked message
BLOCK WITH OVERRIDE
22
Activity blocked, log JIT block event in event log
User sees DLP activity blocked with override message
NO
23
JIT evaluation in progress message displayed, activity blocked for all remaining files that haven't completed evaluation
24
Allow 30 more seconds for evaluation to complete
Did policy evaluation complete in additional 30 seconds?
YES
25
User sees JIT evaluation complete, try the activity again message
NO

1. A user attempts an egress activity on an onboarded device for one or more JIT candidate items.
2. If the activity involves an app on the excluded app list, an excluded file path location, or an excluded file extension, the process ends.
3. The evaluation ends and the activity isn't blocked by JIT. No notification message is shown to the user and no JIT audit event is logged.
4. DLP confirms that the user is in scope for JIT. If yes, evaluation continues. If not, the process ends at step 5.
5. JIT doesn't block the activity. No notification is shown, and a JIT audit event is logged.
6. DLP checks if any DLP rule defines **Block** or **Block with override** actions for the attempted activity. If yes, evaluation continues. If not, the process ends with the behavior noted in step 5.
7. JIT doesn't block the activity. No notification is shown, and a JIT audit event is logged.
8. DLP checks if the activity is to an allowed printer group, USB group, network share, or URL. If yes, JIT doesn't block the activity and policy evaluation ends.
9. JIT evaluation is triggered.
10. JIT checks to see if the activity supports JIT pause and resume.
11. If yes, evaluation continues.
12. For all the activities that complete policy evaluation within three seconds, the policy action is applied.
13. For **audit** action, the activity resumes, there's no message shown to the user and a JIT audit event is logged in the audit log.
14. For **block** action, the activity is blocked. A blocked activity message is shown to the user and a JIT audit event is logged in the audit log.

15. User sees policy message with **Review files** button or **Take action** button. Policy evaluation ends.

16. For **block with override** action, the activity is blocked, the block with override message is shown to the user so they can override the block as needed, and both JIT audit event and the block with override event are logged in the audit log.

17. For all the items that didn't complete DLP policy evaluation within three seconds OR don't support resume, JIT evaluation allows two more seconds.

18. For all activities that complete DLP policy evaluation within the allotted two seconds, the policy action is applied.

19. For **audit** policy action, the activity is blocked because the activity doesn't support resume and a JIT block event is logged in the audit log.

20. User sees the policy evaluation complete message and is told to retry. Policy evaluation ends.

21. For **block** policy action, the activity is blocked, a blocked activity message is shown, and a JIT block event is logged in the audit log and evaluation ends.

22. For **block with override** policy action, the activity is blocked, the block with override message is shown so the user can override the block as needed, and both JIT block event and block with override event are logged in the audit log and evaluation ends.

23. For all the items that didn't complete DLP policy evaluation within the total five seconds, the activity is blocked, the **Just-in-time in progress** message is shown to the user. A JIT block event is logged in the audit log.

24. The JIT in progress allows 30 more seconds for the policy evaluation to complete while the activity is blocked.

25. If the DLP policy evaluation completes within these 30 seconds, the user is shown the **Just-in-time evaluation complete** message and the user is asked to retry the activity again.

26. If DLP policy evaluation doesn't complete within the 30 seconds, the JIT fallback action is applied.

27. The **JIT policy evaluation complete** message is shown to the user and evaluation ends. The user is prompted to try the activity again.

User experience of just-in-time protection

This section describes the user experience with antimalware client version **4.18.25080 or later**.

Resume support for each activity

If the policy evaluation finishes within 3 seconds, Endpoint DLP automatically resumes these activities:

- Copy to a removable media
- Copy to a network share

If the policy evaluation takes longer than 3 seconds, you need to repeat the activity after the JIT policy evaluation complete notification appears.

Repeat these activities after Endpoint DLP completes the policy evaluation:

- Print
- Copy or move using Remote Desktop Protocol (RDP)
- Copy or move using unallowed Bluetooth app
- Copy to clipboard: JIT Audit by default

Perform an activity on a single file

When a user performs an activity on a single file, Endpoint DLP takes the JIT audit action when:

- the user isn't in the JIT Scope setting
- there's no **Block** or **Block with override** for the activity
- the activity is to an allowed printer, removable media, network share, or website
- the policy evaluation for the file completes within 5 seconds for activities that support JIT resume, or completes within seconds for activities that don't support JIT resume.

Endpoint DLP blocks the activity with a notification (no alert) and applies JIT block only when the policy evaluation takes more than 5 seconds.

Perform an activity on multiple files

When a user performs an activity on multiple files simultaneously, Endpoint DLP takes the JIT audit action when:

- the user isn't in the JIT Scope setting

- there's no **Block** or **Block with override** for the performed activity
- the activity is to an allowed printer, or to an allowed removable media, or to an allowed network share

For JIT candidate files, Endpoint DLP triggers policy evaluation, consolidates notifications for files that finish within 5 seconds for activities that support resume, and automatically resumes the activity. If the activity doesn't support resume, Endpoint DLP triggers policy evaluation and consolidates notifications for files that finish within 2 seconds. In both cases, Endpoint DLP doesn't raise a JIT in progress toast. It only shows the final policy verdict in the consolidated toast.

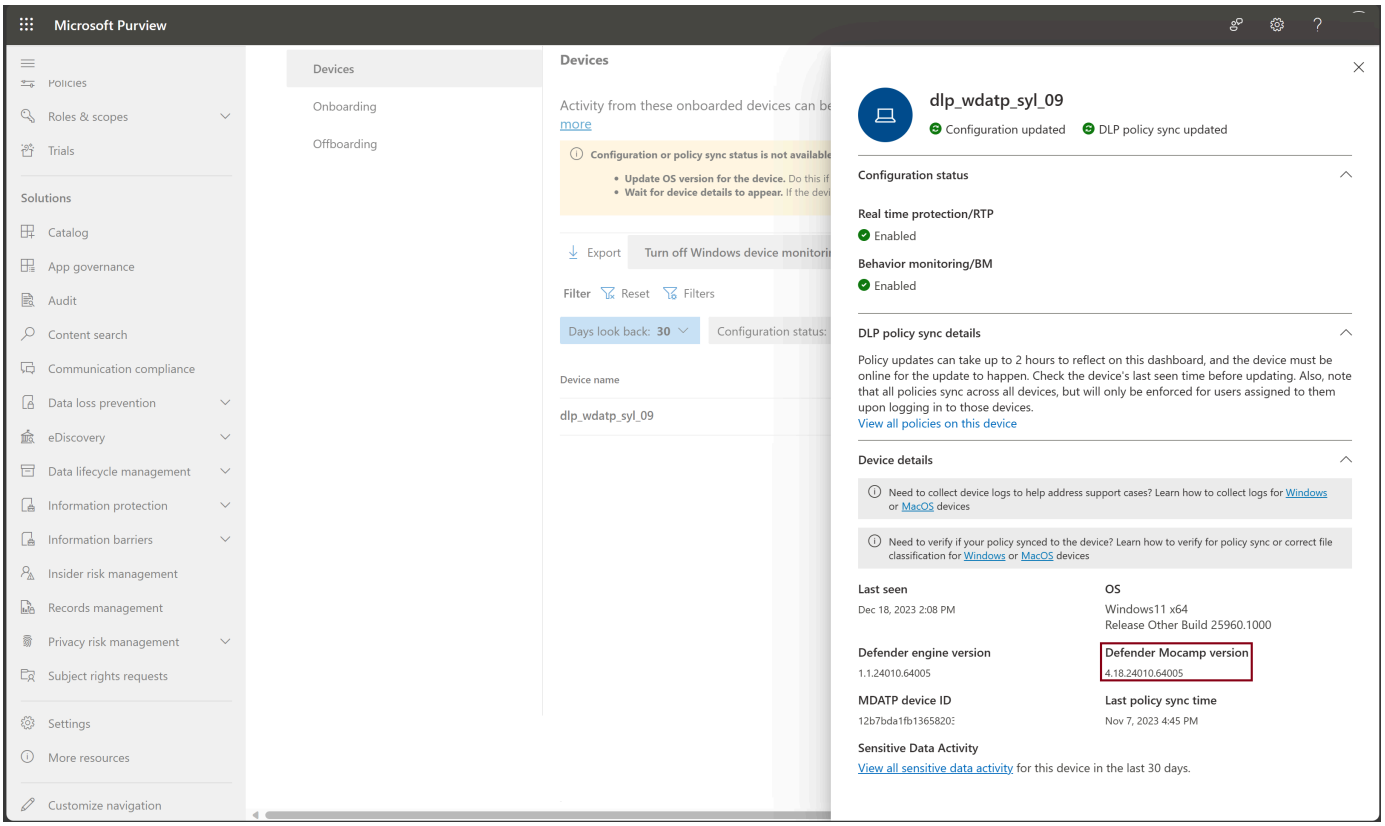
Get started with Microsoft Purview Data Loss Prevention just-in-time protection

Use endpoint data loss prevention (DLP) just-in-time (JIT) protection to detect and block egress activities on monitored files while policy evaluation completes.

Applies to

JIT protection for Endpoint DLP supports these devices:

- Windows 10
- Windows 11
- macOS (the three most recent versions)



Best practice for deploying Just-in-time protection

> **Note**
>
> Allow at least an hour for JIT setting updates, including disabling JIT, to be pushed to client devices.

Step 1: Prepare your environment

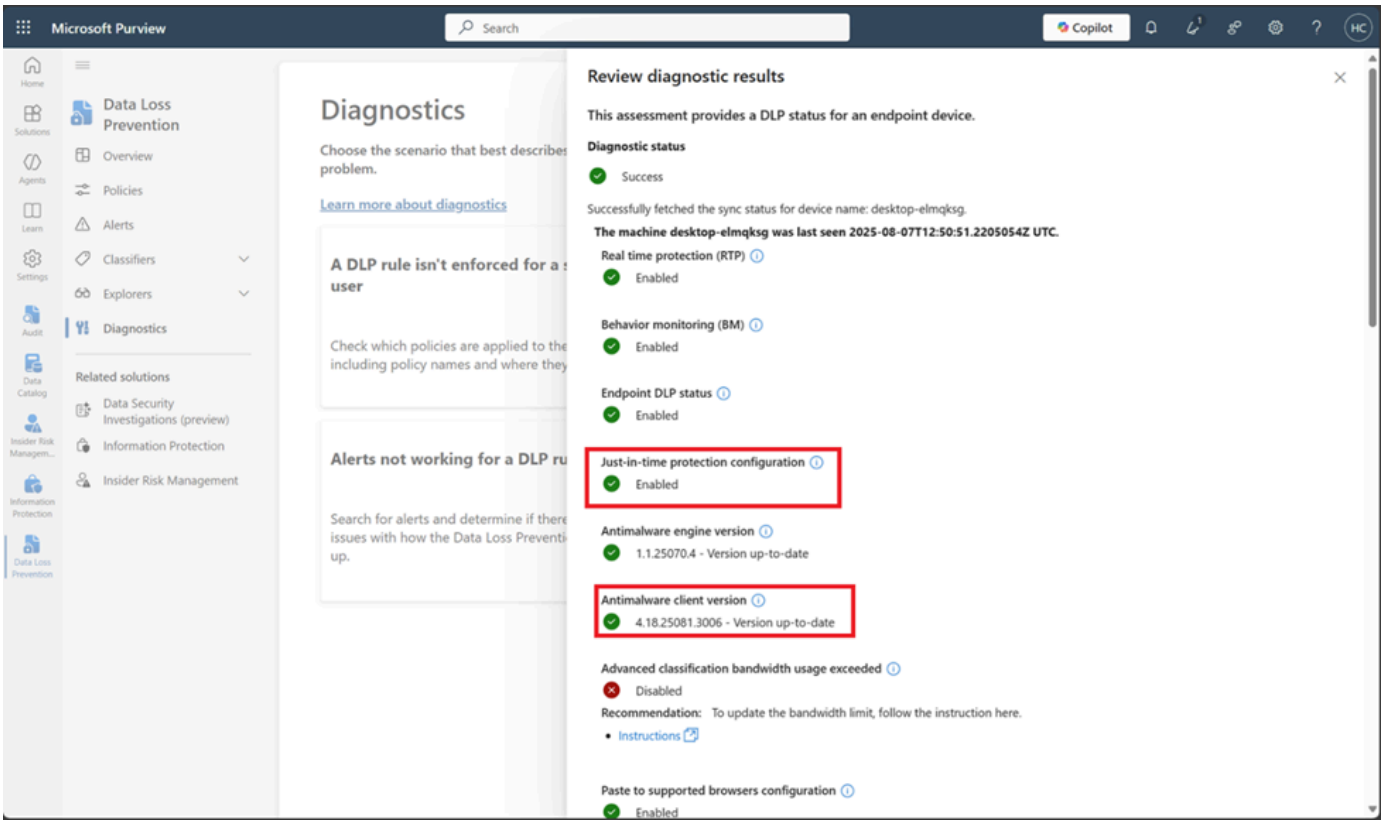
Before you can deploy just-in-time protection, you must first deploy antimalware Client version 4.18.23080 or later. The just-in-time protection end user experience is improved in version 4.18.25080 or later.

> **Tip**
>
> To maximize user productivity, configure and deploy your Endpoint DLP policies to your devices before enabling just-in-time protection. This approach prevents unnecessary blocking of user activity during policy evaluation.

> **Note**
>
> For machines with an outdated version of the antimalware client, disable just-in-time protection by installing one of the following KBs:
>
> - Windows 10 - KB5032278
> - Windows 11 - KB5032288

1. To find out which devices have the necessary antimalware client, go to **Security portal** > **Investigation & response** > **Advanced hunting**, and run this query.

Kusto



```
`DeviceRegistryEvents`
| where InitiatingProcessVersionInfoInternalFileName == "MsMpEng.exe" and Timestamp >= ago(60d)
| summarize arg_max(Timestamp, *) by DeviceId
| distinct DeviceName, DeviceId, vTimeStamp = Timestamp, AntiMalwareClientVersion = InitiatingProcessVersionInfoProductVersion
| extend Meet_Minimum_JIT_Version = strcmp(AntiMalwareClientVersion, "4.18.23080") // whether the device has required minimum JIT version
| extend Meet_Latest_JIT_Version = strcmp(AntiMalwareClientVersion, "4.18.25080") // whether the device has latest JIT improvement
| project DeviceId, Meet_Latest_JIT_Version, Meet_Minimum_JIT_Version, AntiMalwareClientVersion
| summarize dcount(DeviceId) by AntiMalwareClientVersion // distribution of AntiMalwareClientVersion
```

```
// | summarize dcount(DeviceId) by Meet_Minimum_JIT_Version //how many devices meet
minimum JIT version
// | summarize dcount(DeviceId) by Meet_Latest_JIT_Version //how many devices meet
latst JIT improvements
| order by dcount_DeviceId desc
```

Here's an example of the output of the query.

AntiMalwareClientVersion	dcount_DeviceId
4.18.25090.3009	6
4.18.25080.5	3
4.18.25101.3017	2
4.18.25100.9002	2
4.18.25111.3003	1
4.18.25090.3008	1
4.18.25111.3001	1
4.18.25101.3024	1
4.18.25101.3006	1
4.18.25101.3028	1

You can also go to **Data Loss Prevention** > **Diagnostics page**, and select **Endpoint DLP not working** card to check whether a specific device meets JIT prerequisite.

Step 2: Deploy JIT protection

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data Loss Prevention** > **Just-in-time protection**.
3. Under **Choose which locations to monitor**, select the checkbox next to **Devices**.
4. Under **Fallback action in case of failure**, select **Allow users to complete actions**. This option lets the user action complete if the classification fails.

> **⊗ Caution**
>
> Don't choose the **Block users from completing actions** option until you fully understand the impact of this feature.

Selecting **Allow users to complete actions** or **Block users from completing actions** doesn't change whether *JIT Block* is triggered. Blocking by JIT is applied if the user is in scope. The **Allow users to complete actions** or **Block users from completing actions** setting controls Endpoint DLP enforcement when classification fails.

If you select **Allow users to complete actions**, Endpoint DLP allows the egress activity when classification fails. If you select **Block users to complete actions**, Endpoint DLP blocks the egress

activity when classification fails.

Step 3: Estimate the number of JIT protection events for your deployment

Validate the JIT protection scope and fallback action settings after each rollout stage until the number of events is stable. Make sure you understand the possible size of the user group you want to enforce the policy on, based on the following telemetry calculations.

Estimate the impact of deploying JIT protection by performing the following calculation based on the events in activity explorer:

- N = The number of unique machines firing JIT events.
- S = The total number of machines within the scope of your deployment.

`N/S` yields the percentage of machines that might experience a JIT protection block event.

With this information, you should know how many machines will be affected by implementing the JIT Block mode when you expand the scope, and how many possible support tickets you may see. Then, you can decide whether or not to expand the scope.

Step 4: Fine-tune JIT protection through other Additional settings

In addition to the **Fallback action in case of failure** setting, you can also use the following settings to fine-tune JIT protection:

- **Control copying to clipboard**: Turn on this setting to prevent users from copying content to the clipboard while JIT protection is evaluating the file.

> ⓘ **Note**
>
> Turning on **Control copying to clipboard** might impact user's productivity. Be sure to test the impact on productivity before turning on this setting.

- **App exclusions for Windows**: You can exclude maximum 50 apps here from JIT protection on Windows devices.
- **App exclusions for Mac**: You can exclude maximum 50 apps here from JIT protection on Mac devices.

- **File extensions exclusions**: Files with extensions you add here aren't evaluated by JIT protection.
- **File path exclusions for Windows**: Files in these locations aren't evaluated by JIT protection.
- **File path exclusions for Mac**: Files in these locations aren't evaluated by JIT protection.

If you want to change the scope of JIT protection after tuning all these settings, return to **Settings** > **Data Loss Prevention** > **Just-in-time protection** in the Microsoft Purview portal and update the monitored locations.

Exclusions for Just-in-time protection

File path exclusion settings in JIT are different from **File path exclusions for Windows** setting found via **Data loss prevention** > **Settings** > **Endpoint settings** > **File path exclusions for Windows**.

- **File path exclusions** in JIT only excludes specific file paths from JIT protection. In all other cases, Microsoft Purview still applies Endpoint DLP classification and protection for files in those folders.
- **File path exclusions for Windows** setting prevents Purview from applying Endpoint DLP classification and protection for files under the specified folders.
- **File extension exclusions**: Files with these extensions aren't evaluated by JIT protection.

Step 5: Deploy JIT protection in 'Block users from completing actions' for the 'Fallback action in case of failure' setting

The **Block users from completing actions** option for **Fallback action in case of failure** controls the enforcement mode that DLP applies when classification fails. This setting doesn't control JIT Block or JIT Audit for JIT candidate files. JIT Block or JIT Audit is controlled by how the policy is scoped. No matter which value you select here, the relevant telemetry displays in activity explorer.

Help protect files that Endpoint Data Loss Prevention fails to scan

This article uses the process you learned in Design a data loss prevention policy to show you how to create a Microsoft Purview Data Loss Prevention (DLP) policy that helps protect files on supported Windows and macOS devices where the scanning process fails. Work through this scenario in your test environment to familiarize yourself with the policy creation UI.

> **Note**
>
> Applying controls to supported files that fail scanning is currently in preview.

Use this scenario when you want to apply Audit, Block, or Block with override controls on user activities for files that are on the Monitored files list but fail to be scanned by Endpoint DLP.

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

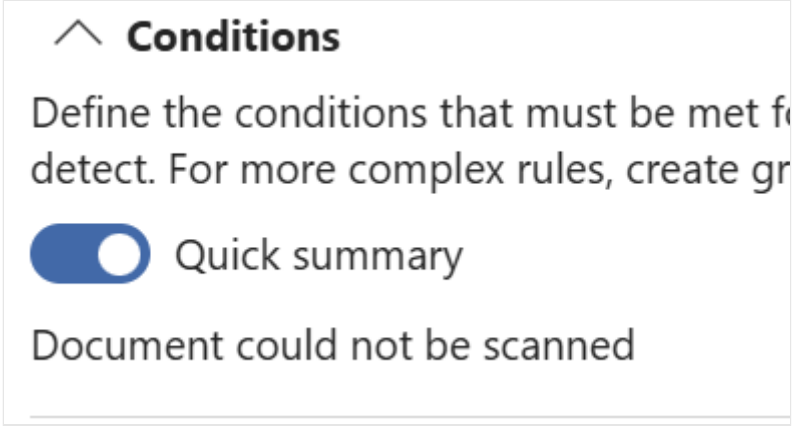
How you deploy a policy is as important policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

Prerequisites and assumptions

This scenario requires that you already have devices onboarded and reporting into activity explorer. If you haven't onboarded devices yet, see Get started with Endpoint data loss prevention.

> **Important**
>
> This feature only supports following action types:
>
> - Upload to a restricted cloud service domain

- Copy to a removable USB device
- Copy to a network share
- Print



Policy intent statement and mapping

Sometimes scanning fails for files that endpoint DLP supports. There might be sensitive information in those files, but we don't know. When scanning fails for a file on any of our onboarded devices, we want to prevent users from copying that file to a USB device or to a network share.

Expand table

Statement	Configuration question answered and configuration mapping
"When scanning fails for a file on any of our onboarded devices ..."	- Administrative scope: **Full directory** - Where to monitor: **Enteprise applications & devices**, **Devices** -Scope: **Allusers, groups, devices, device groups** - Conditions: **Document could not be scanned**
"...we want to prevent users from copying that file to a USB device or to a network share."	- Action : select **audit or restrict activities on devices** - clear **Upload to a restriced cloud service domain or access from an unallowed browser** - select **Apply restrictions to specific activity** - select **Copy to a removable USB device**, and **Block with override** - select **Copy to a network share** and **Block with override** clear **Copy to clipboard**, **Print**, **Copy or move using unallowed Bluetooth app**, and **Copy or move using RDP**

When you configure the conditions, the summary looks like this:

Steps to configure policy actions

Perform the following steps to configure the policy actions for this scenario.

> **Important**
>
> For the purposes of this policy creation procedure, leave the policy turned off. Change the policy activation settings when you deploy the policy.

1. Sign in to the Microsoft Purview portal.
2. Open **Data Loss Prevention** > **Policies**.
3. Select **Create policy**.
4. Select **Enterprise applications & devices**.
5. Select the **Custom** from the **Categories** then **Custom policy** template from **Regulations**.
6. Name your new policy and provide a description.
7. Select **Full directory** under **Admin units**.
8. Scope the location to **Devices** only.
9. Create a rule where:
    a. In **Conditions**:
        i. Select **Document could not be scanned**
    b. In **Actions**:
        i. Select **Audit or restrict activities on devices**.
        ii. Clear **Upload to a restriced cloud service domain or access from an unallowed browser**
        iii. Select **Apply restrictions to specific activity**
        iv. Select **Copy to a removable USB device**, and **Block with override**
        v. Select **Copy to a network share**, and **Block with override**
        vi. Clear **Copy to clipboard**, **Print**, **Copy or move using unallowed Bluetooth app**, and **Copy or move using RDP**
10. **Save**.
11. Choose **Turn on the policy immediately**. Choose **Next**.
12. Review your settings and choose **Submit**.

Help protect files that Endpoint Data Loss Prevention doesn't scan

This article uses the process you learned in Design a data loss prevention policy to show you how to create a Microsoft Purview Data Loss Prevention (DLP) policy that helps protect files that Endpoint DLP doesn't support. Work through these scenarios in your test environment to familiarize yourself with the policy creation UI.

Apply controls to all unsupported files, is in *preview*.

Use the "Apply controls to all unsupported files" scenario to apply Audit, Block, or Block with override controls on user activities for files that aren't on the Monitored files list without enumerating all the file extensions through the **File extension is** condition. Use the **Apply restrictions to only unsupported file extensions** configuration to create a blanket policy to place controls on files like .mp3, .wav, and .dat.

> ⊗ **Caution**
>
> The ability to apply controls to all files is a powerful capability. If you implement this capability without proper caution, the policy might have unintended consequences. Test this policy in a nonproduction environment before deploying it to your production environment. The unsupported-files policy example also shows how you can (optionally) exclude specific file extensions from the scope of the policy.

> ⓘ **Important**
>
> When you select the **Audit or restrict activities on devices** action in the policy configuration **Actions**, the **Apply restrictions to only unsupported file extensions** shows up. **Apply restrictions to only unsupported file extensions** configuration option ***DOES NOT*** support scoping by **Device and device groups** in the policy location setting.

These actions are supported:

- Upload to a restricted cloud service domain
- Copy to a removable USB device
- Copy to a network share

- Print

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

Policy intent statement and mapping

*There are many types of files that endpoint DLP doesn't scan, more than we can track. We don't know if there is sensitive information in those files, and so we want to have a checkpoint in place before our user try to copy those files to a USB device or to a network share. We don't want to disrupt users workflow for the **abc** file type which is well known to us and poses no threat of data leakage.*

Expand table

Statement	Configuration question answered and configuration mapping
“There are many types of files that endpoint DLP doesn't scan,...”	- Administrative scope: **Full directory** - Where to monitor: **Enterprise applications & devices**, **Devices** - Scope: **Allusers, groups, devices, device groups**
"...We don't want to disrupt users workflow for the **abc** file type which is well known to us and poses no threat of data leakage."	- Endpoint settings: create a Unsupported file extension exclusions list and add the file extension **abc** to the list.
"...more than we can track. We don't know if there is sensitive information in those files, and so we want to have a checkpoint in place before they try to copy those files to a USB device or to a network share..."	- Conditions for a match: **Document could not be scanned** action : select **audit or restrict activities on devices** - clear **Upload to a restriced cloud service domain or access from an unallowed browser**

Statement	Configuration question answered and configuration mapping
	- select **Apply restrictions to specific activity** - select **Copy to a removable USB device**, and **Block with override** - select **Copy to a network share and Block with override** - clear **Copy to clipboard**, **Print**, **Copy or move using unallowed Bluetooth app**, and **Copy or move using RDP** - select **file could not be scanned**. - select **apply restrictions to only unsupported file extensions**.

> **Important**
>
> The difference between the **Apply restrictions to only unsupported file extensions** option and the **File extension is** condition is:
>
> - Endpoint DLP scans content for **File extension is** condition. For example, you see **Sensitive info type** value on the event or alert; on the other hand, the **Apply restrictions to only unsupported file extensions** option doesn't scan file content.
> - **File extension is** condition triggering content scanning might consume higher machine resource, like CPU and memory, and might cause application performance issue for some file types.

Steps to add a file type to unsupported file extension exclusions

Use the **Unsupported file extension exclusions** setting to exclude file extensions from the policy.

1. Sign in to the Microsoft Purview portal
2. Open **Settings** > **Data Loss Prevention** > **Endpoint DLP settings** > **Unsupported file extension exclusions**.
3. Select **Add file extensions**.
4. Provide extensions.
5. Select **Save**.
6. Close the item.

Steps to configure policy actions

1. Sign in to the Microsoft Purview portal.
2. Open **Data Loss Prevention** > **Policies**.
3. Select **Enterprise applications & devices**.
4. Select **Create policy** and select the **Custom** from the **Categories** then **Custom policy** template from **Regulations**.
5. Name your new policy and provide a description.
6. Select **Full directory** under **Admin units**.
7. Scope the location to **Devices** only.
8. Create a rule where:
    a. In **Conditions**:
        i. Select **Document could not be scanned**.
    b. In **Actions**:
        i. Select **Audit or restrict activities on devices**.
        ii. Clear **Upload to a restriced cloud service domain or access from an unallowed browser**.
        iii. Select **Apply restrictions to specific activity**.
        iv. Select **Copy to a removable USB device**, and **Block with override**.
        v. Select **Copy to a network share**, and **Block with override**.
        vi. Clear **Copy to clipboard**, **Print**, **Copy or move using unallowed Bluetooth app**, and **Copy or move using RDP**.
        vii. Select **Apply restrictions to only unsupported file extensions**.
9. **Save**.
10. Choose **Turn on the policy immediately**. Choose **Next**.
11. Review your settings and choose **Submit**.

> **Important**
>
> You can't use **Document could not be scanned** together with other conditions in the "Apply controls to all unsupported files" scenario.

Note: The author created this article with assistance from AI. Learn more

Help protect against sharing of a defined set of unsupported files

Create a Microsoft Purview Data Loss Prevention (DLP) policy that helps protect against sharing of a defined set of unsupported files. This article walks you through the configuration steps using the process described in Design a data loss prevention policy. Work through these scenarios in your test environment to familiarize yourself with the policy creation UI.

How you deploy a policy is as important policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

Apply controls to some file types is in *preview*.

Use the unsupported file extensions configuration to apply Audit, Block with override, or Block controls to a list of file types only. For example, you can apply controls to video files like .mp3 files (which aren't monitored by endpoint Data Loss Prevention) only.

> **ⓘ Important**
>
> When you select the **Audit or restrict activities on devices** action in the policy configuration **Actions**, the **Apply restrictions to only unsupported file extensions** shows up. **Apply restrictions to only unsupported file extensions** configuration option ***DOES NOT*** support scoping by **Device and device groups** in the policy location setting.

The following device actions are supported for unsupported file extension restrictions:

- Upload to a restricted cloud service domain
- Copy to a removable USB device
- Copy to a network share
- Print

The unsupported file extensions policy configuration uses a combination of a **File extension group** and the **Document could not be scanned** condition. The unsupported file extensions configuration doesn't use the **File extension is** condition. This policy configuration means that Microsoft Purview endpoint Data Loss Prevention (DLP) doesn't scan the content of the files that

you include in the **File extension group** and you don't see values for **Sensitive info type** in events or alerts that are generated by policy matches.

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

Policy intent statement and mapping

We, Wingtip Toys, have a list of file types on devices which are NOT on the monitored files list and that we want to apply controls to. We know that they're not on the monitored files list for Endpoint DLP. We want to prevent users from copying those files to a USB device or to a network share. When they do try, we want to let them know, to educate them, that they are attempting a prohibited action.

Expand table

Statement	Configuration question answered and configuration mapping
“We have a list of file types on devices that are *NOT* on the Monitored files list and that we want to apply controls to....”	- Administrative scope: **Full directory** - Where to monitor: **Devices** -Scope: **Allusers, groups, devices, device groups**
"we want to apply controls to a list of file types on devices that are on the Monitored files list but that is not covered by Endpoint DLP scanning..."	- Conditions for a match: **Document could not be scanned** - Action: select **audit or restrict activities on devices** - clear **Upload to a restriced cloud service domain or access from an unallowed browser** - select **Apply restrictions to specific activity** - select **Copy to a removable USB device**, > **Block** - **Copy to a network share** > **Block** - clear **Copy to clipboard**, **Print**, **Copy or move using unallowed Bluetooth app**, and **Copy or move using RDP** - select **file could not be scanned** - select **apply restrictions to only unsupported file extensions**.
"We know that they're not on the monitored files list for Endpoint DLP."	- Endpoint settings: create a **File extension group**
"...We need to prevent users from copying those files to a USB device or to a network share."	- Conditions for a match: **Document could not be scanned** - Action: select **audit or restrict activities on devices** - clear **Upload to a restricted cloud service domain or access from**

Statement	Configuration question answered and configuration mapping
	an unallowed browser - select **Apply restrictions to specific activity** - select **Copy to a removable USB device**, > **Block** - **Copy to a network share** > **Block** - clear **Copy to clipboard**, **Print**, **Copy or move using unallowed Bluetooth app**, and **Copy or move using RDP** - select **file could not be scanned** - select **apply restrictions to only unsupported file extensions**.
"When they do try, we want to let them know, to educate them, that they are attempting a prohibited action."	- Use notifications to inform your users and help educate them on the proper use of sensitive info: **On** - Endpoint devices > Show users a policy tip notification when an activity is restricted...: **selected** - Customize the notification: **selected** > Notification Title: **Wingtip toys don't copy files** > **Notification Content**: FYI, Wingtip Toy policy doesn't let you copy that type of file to USB device or a network share. *(preview) Ability to add hyperlinks in Endpoint policy tip notifications*

Steps to create a file extension group

The following steps use the Microsoft Purview portal. To learn more, see Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Open **Settings** > **Data Loss Prevention** > **Endpoint DLP settings** > **File extension groups**.
3. Select **Create file extension group** and enter a **Group name**. In this scenario, use `Non-classified file extensions`.
4. Provide extensions.
5. Select **Save**.
6. Close the item.

Steps to configure policy actions

Perform the following steps to configure the policy actions for this scenario.

1. Sign in to the Microsoft Purview portal.
2. Open **Data Loss Prevention** > **Policies**.
3. Select **Create policy**.
4. Select **Enterprise applications & devices**.
5. Select **Custom** from the **Categories** then select **Custom policy** template from **Regulations**.
6. Name your new policy and provide a description.

7. Select **Full directory** under **Admin units**.
8. Scope the location to **Devices** only.
9. Create a rule where:
    a. In **Conditions**.
        i. **Document could not be scanned**.
    b. In **Actions**:
        i. Select: **Audit or restrict activities on devices**.
        ii. Clear: **Upload to a restricted cloud service domain or access from an unallowed browser**.
        iii. Select: **Apply restrictions to specific activity**.
        iv. Clear: **Copy to clipboard**.
        v. Select: **Copy to a removable USB device** > **Block**.
        vi. Select: **Copy to a network share** > **Block**.
        vii. Clear: **Print**.
        viii. Clear: **Copy or move using unallowed Bluetooth app**.
        ix. Clear: **Copy or move using RDP**.
        x. Clear: **Access by restricted apps**.
        xi. Select: **Apply restrictions to only unsupported file extensions**.
        xii. Select: **Add file extension group** and select `Non-classified file extensions`.
10. Set **User notifications** to **On**.
    a. Under **Endpoint devices** select **Show users a policy tip notification when an activity is restricted...**.
    b. Select **Customize the notification**.
        i. Enter `Wingtip toys don't copy files` in the **Notification Title**.
        ii. Enter `FYI, Wingtip Toy policy doesn't let you copy that type of file to USB device or a network share` in the **Notification Content**.
11. **Save**.
12. Choose **Turn the policy on immediately**. Choose **Next**.
13. Review your settings and choose **Submit**.

> **Important**
>
> You can't use the **Document could not be scanned** condition with other conditions in this scenario.

Note: The author created this article with assistance from AI. Learn more

Disable Microsoft Purview data loss prevention scanning for some supported files and apply controls

This article shows you how to create a Microsoft Purview data loss prevention (DLP) policy that disables scanning for selected supported file types and applies audit or restriction controls to those files, using the process described in Design a data loss prevention policy. Work through this scenario in your test environment to familiarize yourself with the policy creation UI.

Disable scanning for some supported files and apply controls is in *preview*.

Use the disable-classification configuration to save local resource consumption by disabling scanning of some file types on the Monitored files list. You can apply Audit, Block, or Block with override controls to those file types.

> **Important**
>
> This feature only supports the following action types:
>
> - Upload to a restricted cloud service domain
> - Copy to a removable USB device
> - Copy to a network share
> - Print

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important as policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

Policy intent statement and mapping

Bellows College needs to conserve resources on all our users Windows devices and cutting down on the scanning of files by DLP would be a big help. We have a list of file types that we know the contents of because they are auto generated. These file types are on the supported file types list. There's no need to scan these auto generated files, but we do want to prevent users from copying them to a USB device or to a network share. When they do try, we want to let them know, to educate them, that they are attempting a prohibited action.

Expand table

Statement	**Configuration question answered and configuration mapping**
"Bellows College needs to conserve resources on all our users Windows devices and cutting down on the scanning of files by DLP would be a big help..."	- Administrative scope: **Full directory** - Where to monitor: **Enterprise applications & devices**, **Devices** -Scope: **Allusers, groups, devices, device groups**
"...We have a list of file types that we know the contents of because they are auto generated. These file types are on the supported file types list. There's no need to scan these auto generated files..."	- Endpoint settings: create a **File extension group** - Disable classification
...but we do want to prevent users from copying them to a USB device or to a network share...	- Conditions for a match: **Document could not be scanned** Action : select **audit or restrict activities on devices** - clear **Upload to a restriced cloud service domain or access from an unallowed browser** - select **Apply restrictions to specific activity** - select **Copy to a removable USB device**, > **Block** - **Copy to a network share** > **Block** - clear **Copy to clipboard**, **Print**, **Copy or move using unallowed Bluetooth app**, and **Copy or move using RDP** - select **file could not be scanned**.
"...When they do try, we want to let them know, to educate them, that they are attempting a prohibited action..."	- Use notifications to inform your users and help educate them on the proper use of sensitive info: **On** - Endpoint devices > Show users a policy tip notification when an activity is restricted...: **selected** - Customize the notification: **selected** > **Notication Title**: Bellows College IT don't copy files > **Notification Content**: FYI, Bellows College data loss prevention policies don't let you copy that type of file to USB device or a network share

Create a File extension group

Select the appropriate tab for the portal you're using. To learn more about the Microsoft Purview portal, see Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Open **Settings** > **Data Loss Prevention** > **Endpoint DLP settings** > **File extension groups**.
3. Select **Create file extension group** and enter a **Group name**. In this scenario, we use `Student Class Registration file extensions`.
4. Enter the extensions.
5. Select **Save**.
6. Close the item.

Disable classification

Use the **Disable classification** setting to exclude specific file extensions from Endpoint DLP classification.

1. Sign in to the Microsoft Purview portal.
2. Open **Settings** > **Data Loss Prevention** > **Endpoint DLP settings** > **Disable classification**.
3. Select **Add or edit file extensions**.
4. Enter the extensions.
5. Select **Save**.
6. Close the item.

Configure policy actions

Perform the following steps to configure the policy actions for this scenario.

1. Sign in to the Microsoft Purview portal.
2. Open **Data Loss Prevention** > **Policies**.
3. Select **Create policy**.
4. Select **Enterprise applications & devices**.
5. Select **Custom** from the **Categories** then select **Custom policy** template from **Regulations**.
6. Name your new policy and provide a description.
7. Select **Full directory** under **Admin units**.
8. Scope the location to **Devices** only.
9. Create a rule where:
    a. In **Conditions**:
        i. **Document could not be scanned**.
    b. In **Actions**:

i. Select: **Audit or restrict activities on devices**.
ii. Select: **Apply restrictions to specific activity**.
iii. Clear: **Copy to clipboard**.
iv. Select: **Copy to a removable USB device** > **Block**.
v. Select: **Copy to a network share** > **Block**.
vi. Clear: **Print**.
vii. Clear: **Copy or move using unallowed Bluetooth app**.
viii. Clear: **Copy or move using RDP**.
ix. Clear: **Access by restricted apps**.
x. Select: **Apply restrictions to only unsupported file extensions**.
xi. Select: **Add file extension group** and select `Student Class Registration file extensions`.

c. **Save**.

10. Choose **Turn it on right away**. Choose **Next**.
11. Review your settings and choose **Submit**.

> **Important**
>
> You can't use the **Document could not be scanned** condition with other conditions in this policy scenario.

Always-on diagnostics for endpoint DLP

The Always-on diagnostics feature in Microsoft Purview enables continuous, automated trace logging for endpoint data loss prevention (DLP). This functionality significantly reduces administrative overhead by eliminating the need for manual log configuration and issue reproduction.

When a support case is opened with Microsoft, diagnostic logs are often required to assist with root cause analysis. With Always-on diagnostics enabled, comprehensive telemetry is already available, allowing administrators to bypass traditional data collection steps. This not only accelerates the support workflow but also improves accuracy in identifying and resolving issues.

Diagnostic logs can be securely uploaded directly to Microsoft Support, streamlining case submission and accelerating time-to-resolution. This proactive logging approach enhances operational efficiency and improves support responsiveness.

Trace logs

When an admin turns on Always-on diagnostics, the feature is enabled on all onboarded Windows devices, including servers, and all onboarded macOS devices. When an Endpoint DLP policy does not behave as expected for an in-scope user or device, the customer opens a Microsoft support case. To expedite troubleshooting, Microsoft Support requests diagnostic trace logs, which the customer administrator collects from the affected device using documented procedures. The collected data is protected by Microsoft through restricted access controls and a proprietary log format.

Understanding upload behavior and operational constraints

Trace uploads typically occur within a 24-hour polling window and require the device to remain online for the upload to complete. Only one active collection request is supported per device at any given time, and additional requests can be initiated only after the prior request completes, fails, or is deleted. Restart-based upload acceleration is supported, but restarting the device isn't required to complete an upload. It's intended only to speed up the process. Collection requests may remain pending if the device is offline, wiped, reimaged, reassigned, or otherwise unable to respond.

Admins are responsible for monitoring the status of collection requests and for taking action when failures occur. If a request fails, admins must retry or re-initiate the request as needed to ensure successful data collection.

Understanding log access, security, and data storage compliance

Logs aren't available for direct download by admins and are stored in a proprietary Microsoft-internal format that can only be decoded using Microsoft tools. Access to logs is restricted to Microsoft personnel who are members of designated access groups, and all such access is fully audited to ensure accountability and security.

Logs are stored in Microsoft-managed Azure Blob Storage and comply with Microsoft security and privacy standards, including GDPR. Data remains within the tenant's data residency region and is retained for 180 days unless manually deleted earlier. After the retention period, logs are automatically purged and can't be recovered, and no backup or extended retention is supported.

> **Important**
>
> This feature is only for authorized eDLP troubleshooting scenarios (whether functioning or not). It must not be used for investigative or non-support purposes, including any activity outside approved troubleshooting workflows.
>
> This feature is supported on Windows and macOS.

Permissions required for always-on diagnostics

Roles required to view and create log collection requests

There are multiple roles that allow you to view and create log collection requests. The account you use must be a member of any one of them.

Microsoft Entra roles

- Compliance Administrator
- Security Administrator
- Global Administrator

> **Important**

Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Purview roles for viewing and creating log collection requests

Must be assigned at the tenant level; scoped admins are not supported:

- OrganizationConfiguration
- ManageAlerts
- ViewOnlyManageAlerts
- InformationProtectionAdmin
- InformationProtectionAnalyst
- InformationProtectionInvestigator

Roles required to enable the feature

The account that you use must be a member of any one of the following roles to turn on Always-on diagnostics.

Microsoft Entra roles for enabling always-on diagnostics

- Compliance Administrator
- Security Administrator
- Global Administrator

Important

Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Purview roles (tenant-level only)

The following tenant-level Purview roles can enable Always-on diagnostics:

- OrganizationConfiguration
- ComplianceAdmin
- SecurityAdmin

- DLPComplianceManagement
- InformationProtectionAdmin

Prerequisites

The device must be onboarded to Microsoft Purview and actively reporting with Always-on Diagnostics enabled. It must maintain continuous network connectivity and be able to reach Microsoft upload endpoints, including *.blob.core.windows.net. Outbound HTTPS traffic to Microsoft services must not be blocked by firewalls, proxies, or security policies, and any proxy configuration must allow outbound HTTPS traffic without interception or modification that would prevent uploads.

If you are using Windows Server, you must enable endpoint DLP for Windows Servers before turning on Always-on diagnostics, because endpoint DLP is disabled by default on Windows Server.

If you are using macOS, the device must be onboarded to Microsoft Purview through Intune, JAMF Pro, or another MDM solution. For more information, see Onboard macOS devices into Microsoft Purview.

Supported Windows operating systems

The following table lists the supported Windows client and server versions for Always-on diagnostics.

Expand table

OS	Version	Minimum Build
Windows 11	24H2	Build 26100.4202
Windows 11	23H2	Build 22621.5039 and 22631.5039
Windows 11	22H2	Build 22621.5039 and 22631.5039
Windows 10	22H2	Build 19045.5917
Windows 10	21H2	Build 19045.5917
Windows Server 2019	-	Build 17763.7434
Windows Server 2022	-	Build 20348.3807
Windows Server 2025	-	Build 26100.4349

> **Important**
>
> Endpoint DLP is disabled by default on Windows Server. You must enable endpoint DLP for Windows Servers to support always-on diagnostics.

Supported macOS versions

Always-on diagnostics is supported on onboarded macOS devices running any of the three latest released versions. Always-on diagnostics requires build 101.26042.xxxx or later.

Supported processors

macOS devices with x64 and M1, M2, and M3 (ARM64) processors are supported.

Turn on Always-on diagnostics and enable upload

Perform the following steps to turn on Always-on diagnostics and enable log upload. These settings apply to both Windows and macOS devices.

1. Sign in to the Microsoft Purview portal.
2. Navigate to **Settings** > **Data Loss Prevention** > **Always-on diagnostics (preview)**.
3. Select **On**.
4. Set the cache storage period. A 90-day cache storage period is recommended.
5. Set the maximum storage for the device. The value must be between 500 and 1,500 MB.
6. Select **Save**.
7. To enable upload, under **Automatically upload device logs** select **Share diagnostics with Microsoft**.

Request device logs

When you identify an issue and open a support case with Microsoft, you can request that the log files be sent to Microsoft Support. The procedure is the same for Windows and macOS devices.

1. In Purview, select one of the locations to initiate a request for log files.
   a. From **Settings** > **Device onboarding** > **Devices**, select a device from the list.
   b. From **Data Loss Prevention** > **Alerts** > **Events**, select an event from the list.
   c. From **Data Loss Prevention** > **Explorers** > **Activity explorer**, select an alert from the list.
2. Based on the location you chose, under **Always-on Diagnostics** select **Request device log**.

3. Select the date range and provide a short description.
4. Select **Submit collection request**.
5. After you submit the request, you must wait until the request is complete. Navigate to **Settings** > **Data Loss Prevention** > **Always-on diagnostics (preview)**.
6. From the list, identify the device under investigation. When the status is complete, provide the associated request number to Microsoft Support.

Learn about the Microsoft Purview extension for Chrome

10/07/2025

Endpoint data loss prevention (endpoint DLP) extends the activity monitoring and protection capabilities of Microsoft Purview Data Loss Prevention (DLP) to sensitive items on Windows 10/11 devices. Once you onboard devices into the Microsoft Purview solutions, information about what users are doing with sensitive items is made visible in activity explorer. Then you can enforce protective actions on those items using data loss prevention policies.

After you install the Microsoft Purview extension for Chrome on a Windows 10/11 device, your organization can monitor attempts to access or upload a sensitive item to a cloud service in Google Chrome, and enforce protective actions via DLP.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Activities you can monitor and take action on

The extension enables you to audit and manage the following types of activities users take on sensitive items on devices running Windows 10/11.

Expand table

activity	description	supported policy actions
file copied to cloud	Detects when a user attempts to upload a sensitive item to a restricted service domain through the Chrome browser	audit, block with override, block
file printed	Detects when a user attempts to print a sensitive item from the Chrome browser to a local or network printer	audit, block with override, block
file copied to clipboard	Detects when a user attempts to copy & paste information from a sensitive item in the Chrome browser into another app, process, or item.	audit, block with override, block
file copied to removable storage	Detects when a user attempts to copy a sensitive item or information from the Chrome browser to removable media or	audit, block with override, block

activity	description	supported policy actions
	USB device	
file copied to network share	Detects when a user attempts to copy a sensitive item or information from the Chrome browser to a network share or mapped network drive.	audit, block with override, block

> **Note**
>
> Microsoft Purview Insider Risk Management requires that this extension be installed to monitor and take action on activities in the Chrome browser. For more information, see Learn about and configure Insider Risk Management browser signal detection.

Purview Chrome extension behavior

The DLPEngine caches all files for about 15 minutes by default to prevent repeated upload attempts. During the cache period, the file is blocked from being uploaded to any domain, so if you upload to an unallowed domain and then immediately to an allowed domain, the cached response may block the upload.

> **Tip**
>
> Microsoft recommends that you use Microsoft Edge if you need to upload files in quick succession.

Deployment process

1. Get started with endpoint data loss prevention
2. Onboarding tools and methods for Windows 10/11 devices
3. Install the extension for Chrome on your Windows 10/11 devices

   > **Note**
   >
   > Command access for the user is a prerequisite for the Microsoft Purview Extension extension for Chrome to work.

4. Create and Deploy data loss prevention policies that restrict upload to cloud service, or access by unallowed browsers actions and apply them to your Windows 10/11 devices

Next steps

See Get started with the Microsoft Purview extension for Chrome for complete deployment procedures and scenarios.

Get started with the Microsoft Purview extension for Chrome

Use these procedures to roll out the Microsoft Purview extension for Chrome.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

> **Note**
>
> The Microsoft Purview extension for Chrome only works on Windows devices. You don't need the extension to enforce data loss prevention on macOS devices.

Before you begin

To use the Microsoft Purview extension for Chrome, you must onboard the device into Endpoint data loss prevention (DLP). Review these articles if you're new to DLP or Endpoint DLP:

- Learn about the Microsoft Purview extension for Chrome
- Learn about Microsoft Purview Data Loss Prevention
- Create and Deploy data loss prevention policies
- Learn about Endpoint data loss prevention
- Get started with Endpoint data loss prevention
- Onboarding tools and methods for Windows 10/11 devices
- Configure device proxy and internet connection settings for Microsoft Purview Endpoint DLP
- Using Endpoint data loss prevention

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

- Your organization must be licensed for Endpoint DLP.
- Your devices must run Windows 10 x64 (build 1809 or later).
- The device must have Antimalware Client version 4.18.2202.x or later. Check your current version by opening the **Windows Security** app, select the **Settings** icon, and then select **About**.

Permissions

You can view data from Endpoint DLP in Activity explorer. Seven roles grant permission to view and interact with the activity explorer. The account you use to access the data must be a member of at least one of these roles.

- Global administrator
- Compliance admin
- Security admin
- Compliance data admin
- Global reader
- Security reader
- Reports reader

> ⓘ **Important**
>
> Use roles with the fewest permissions to improve security for your organization. Global Administrator is a highly privileged role that you should only use in scenarios where a lesser privileged role can't be used.

Roles and role groups

You can use roles and role groups to fine tune your access controls.

Here's a list of applicable roles. To learn more about them, see Permissions in the Microsoft Purview portal.

- Information Protection Admin
- Information Protection Analyst
- Information Protection Investigator
- Information Protection Reader

Here's a list of applicable role groups. To learn more about them, see Permissions in the Microsoft Purview portal.

- Information Protection
- Information Protection Admins
- Information Protection Analysts
- Information Protection Investigators
- Information Protection Readers

Overall installation workflow

Deploying the extension is a multistage process. You can install it on one machine at a time, or you can use Microsoft Intune or Group Policy for organization-wide deployments.

1. Prepare your devices.
2. Basic Setup Single Machine Selfhost
3. Deploy using Microsoft Intune
4. Deploy using Group Policy
5. Test the extension
6. Use the Alerts Management Dashboard to view Chrome DLP alerts
7. Viewing Chrome DLP data in activity explorer

Prepare infrastructure

If you're rolling out the extension to all your monitored Windows 10/11 devices, you should remove Google Chrome from the unallowed app and unallowed browser lists. For more information, see Unallowed browsers. If you're only rolling it out to a few devices, you can leave Chrome on the unallowed browser or unallowed app lists. The extension bypasses the restrictions of both lists for those computers where it's installed.

> **Important**
>
> If you configure a Chrome NativeMessageBlocklist, you must configure a NativeMessageAllowlist that includes the Chrome extension.

Prepare your devices

1. Use the procedures in these articles to onboard your devices:

a. Get started with Endpoint data loss prevention

b. Onboarding Windows 10 and Windows 11 devices

c. Configure device proxy and internet connection settings for Microsoft Purview Endpoint DLP

> **Important**
>
> Microsoft Purview upgraded Purview Chrome extension to Manifest V3. If you already have Purview Chrome extension installed, you should see automatic upgrade on your machine to 3.0.0.239 or higher.

Set up the extension on a single self-hosted machine

Installing the extension from the Chrome Web Store is the recommended method for a single machine.

1. Go to Microsoft Purview Extension - Chrome Web Store (google.com).
2. Install the extension by following the instructions on the Chrome Web Store page.

Deploy using Microsoft Intune

Use the Microsoft Intune deployment method for organization-wide deployments.

Force-install the Chrome extension with Microsoft Intune

Using the settings catalog, follow these steps to manage Chrome extensions:

1. Sign in to the Microsoft Intune admin center.
2. Go to **Configuration Profiles**.
3. Select **Create Profile**.
4. Select **Windows 10 and later** as the platform.
5. Select **Settings catalog** as the profile type.
6. Select **Custom** as the template name.
7. Select **Create**.

8. Enter a name and optional description on the **Basics** tab and select **Next**.
9. Select **Add settings** on the **Configuration settings** tab.
10. Select **Google** > **Google Chrome** > **Extensions**.
11. Select **Configure the list of force-installed apps and extensions**.
12. Change the toggle to **Enabled**.
13. Enter the following value for the extensions and app IDs and update URL: `echcggldkblhodogklpincgchnpgcdco;https://clients2.google.com/service/update2/crx`.
14. Select **Next**.
15. Add or edit scope tags on the **Scope tags** tab as needed and select **Next**.
16. Add the required deployment users, devices, and groups on the **Assignments** tab and select **Next**.
17. Add applicability rules on the **Applicability Rules** tab as required and select **Next**.
18. Select **Create**.

Deploy by using Group Policy

If you don't want to use Microsoft Intune, you can use group policies to deploy the extension across your organization.

Add the Chrome extension to the ForceInstall list

Perform the following steps to add the extension to Chrome's force-install list through Group Policy:

1. In the Group Policy Management Editor, go to your OU.
2. Expand the following path: **Computer/User configuration** > **Policies** > **Administrative templates** > **Classic administrative templates** > **Google** > **Google Chrome** > **Extensions**. This path might vary depending on your configuration.
3. Select **Configure the list of force-installed extensions**.
4. Right-click and select **Edit**.
5. Select **Enabled**.

6. Select **Show**.
7. Under **Value**, add the following entry:
   `echcggldkblhodogklpincgchnpgcdco;https://clients2.google.com/service/update2/crx`
8. Select **OK** and then **Apply**.

Test the extension

Test uploads to cloud services and access from unallowed browsers

Use the following test to verify that Chrome DLP blocks uploads to restricted cloud destinations:

1. Create or get a sensitive item and try to upload a file to one of your organization's restricted service domains. The sensitive data must match one of our built-in Sensitive Info Types, or one of your organization's sensitive information types. You should get a DLP toast notification on the device you're testing from that shows that uploading the file isn't allowed when the file is open.

Simulate other DLP scenarios in Chrome

Now that you removed Chrome from the disallowed browsers/apps list, you can run simulation scenarios to confirm that the behavior meets your organization's requirements:

- Copy data from a sensitive item to another document using the Clipboard
  - To test, open a file that is protected against copy to clipboard actions in the Chrome browser and attempt to copy data from the file.
  - Expected result: A DLP toast notification showing that copying data to the clipboard isn't allowed when the file is open.
- Print a document
  - To test, open a file that is protected against print actions in the Chrome browser and attempt to print the file.
  - Expected result: A DLP toast notification showing that printing the file isn't allowed when the file is open.
- Copy to USB Removable Media
  - To test, try to save the file to a removable media storage.
  - Expected result: A DLP toast notification showing that saving the file to removable media isn't allowed when the file is open.
- Copy to Network Share
  - To test, try to save the file to a network share.

- Expected result: A DLP toast notification showing that saving the file to a network share isn't allowed when the file is open.

Use the Alerts Management Dashboard to view Chrome DLP alerts

Use the following steps to view Chrome DLP alerts in the Alerts dashboard:

1. Open the **Data loss prevention** page in the Microsoft Purview portal and select **Alerts**.
2. Refer to the procedures in Get started with the data loss prevention Alerts dashboard and Investigate data loss incidents with Microsoft Defender XDR to view alerts for your Endpoint DLP policies.

View Chrome DLP data in Activity Explorer

Use the following steps to view Chrome DLP activity in Activity explorer:

1. Open the Microsoft Purview portal > **Information protection** > **Explorers** > **Activity explorer**.
2. Follow the procedures in Get started with Activity explorer to access and filter all the data for your Endpoint devices.

Next steps

After you onboard devices and view the activity data in Activity explorer, create DLP policies that protect your sensitive items.

- Using Endpoint data loss prevention

Learn about the Microsoft Purview extension for Firefox

Article • 08/21/2024

Endpoint data loss prevention (endpoint DLP) extends the activity monitoring and protection capabilities of Microsoft Purview data loss prevention (DLP) to sensitive items that are on Windows 10/11 devices. Once you onboard devices to the Microsoft Purview solutions, the information about what users are doing with sensitive items is made visible in activity explorer. Then you can enforce protective actions on those items via DLP policies.

After you install the Firefox extension on a Windows 10/11 device, your organization can monitor when a user attempts to access or upload a sensitive item to a cloud service using Mozilla Firefox, and enforce protective actions via DLP.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Activities you can monitor and take action on

The extension enables you to audit and manage the following types of activities users take on sensitive items on devices running Mozilla Firefox in Windows 10.

Expand table

activity	description	supported policy actions
file copied to cloud	Detects when a user attempts to upload a sensitive item to a restricted service domain through the Firefox browser	audit, block with override, block
file printed	Detects when a user attempts to print a sensitive item that is open in the Firefox browser to a local or network printer	audit, block with override, block
file copied to clipboard	Detects when a user attempts to copy information from a sensitive item in the Firefox browser into another app,	audit, block with override, block

activity	description	supported policy actions
	process, or item.	
file copied to removable storage	Detects when a user attempts to copy a sensitive item or information from a sensitive item in the Firefox browser to removable media or USB device	audit, block with override, block
file copied to network share	Detects when a user attempts to copy a sensitive item or information from the Firefox browser to a network share or mapped network drive.	audit, block with override, block

Deployment process

1. Get started with endpoint data loss prevention
2. Onboarding tools and methods for Windows 10 devices
3. Install the extension for Firefox extension on your Windows 10 devices
4. Create and Deploy data loss prevention policies that restrict upload to cloud service, or access by unallowed browsers actions and apply them to your Windows 10 devices

Next steps

See Get started with the Microsoft Purview extension for Firefox for complete deployment procedures and scenarios.

Get started with the Microsoft Purview extension for Firefox

Use these procedures to roll out the Microsoft Purview extension for Firefox.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Recommended reading

To use the Microsoft Purview extension for Firefox, the device must be onboarded into endpoint DLP. Review these articles if you're new to DLP or endpoint DLP

If you're new to Microsoft Purview DLP, here's a list of the core articles you'll need as you implement DLP:

1. Administrative units
2. Learn about Microsoft Purview Data Loss Prevention - the article you're reading now introduces you to the data loss prevention discipline and Microsoft's implementation of DLP
3. Plan for data loss prevention (DLP) - by working through this article you will:
   a. Identify stakeholders
   b. Describe the categories of sensitive information to protect
   c. Set goals and strategy
4. Data Loss Prevention policy reference - this article introduces all the components of a DLP policy and how each one influences the behavior of a policy
5. Design a DLP policy - this article walks you through creating a policy intent statement and mapping it to a specific policy configuration.
6. Create and Deploy data loss prevention policies - This article presents some common policy intent scenarios that you'll map to configuration options, then it walks you through configuring those options.
7. Learn about investigating data loss prevention alerts - This article introduces you to the lifecycle of alerts from creation, through final remediation and policy tuning. It also introduces you to the tools you use to investigate alerts.

Additionally, you should be familiar with the information in these articles:

- Learn about Microsoft Purview extension for Firefox
- Learn about endpoint data loss prevention
- Get started with Endpoint data loss prevention
- Onboarding tools and methods for Windows 10 devices
- Configure device proxy and internet connection settings for Microsoft Purview Endpoint DLP
- Using Endpoint data loss prevention

Licensing and subscription requirements

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

- Your organization must be licensed for Endpoint DLP
- Your devices must be running Windows 10 x64 build 1809 or later.
- The device must have Antimalware Client Version is 4.18.2202.x or later. Check your current version by opening **Windows Security** app, select the **Settings** icon, and then select **About**.

Permissions

Data from Endpoint DLP can be viewed in Activity explorer. There are seven roles that grant permission to activity explorer, the account you use for accessing the data must be a member of any one of them.

- Compliance admin
- Security admin
- Compliance data admin
- Global reader
- Security reader
- Reports reader
- Global administrator

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. This helps improve security for your organization. Global Administrator is a highly privileged role that should

only be used in scenarios where a lesser privileged role can't be used.

Roles and Role Groups

There are roles and role groups that you can use to fine tune your access controls.

Here's a list of applicable roles. To learn more about them, see Permissions in the Microsoft Purview portal.

- Information Protection Admin
- Information Protection Analyst
- Information Protection Investigator
- Information Protection Reader

Here's a list of applicable role groups. To learn more about these role groups, see Permissions in the Microsoft Purview portal.

- Information Protection
- Information Protection Admins
- Information Protection Analysts
- Information Protection Investigators
- Information Protection Readers

Overall installation workflow

Deploying the extension is a multi-phase process. You can choose to install on one machine at a time, or use Microsoft Intune or Group Policy for organization-wide deployments.

1. Prepare your devices.
2. Basic Setup Single Machine Selfhost
3. Deploy using Microsoft Intune
4. Deploy using Group Policy
5. Test the extension
6. Use the Alerts Management Dashboard to view Firefox DLP alerts
7. Viewing Firefox DLP data in activity explorer

Prepare infrastructure

If you're rolling out the extension to all your monitored Windows 10 devices, you should remove Mozilla Firefox from the unallowed app and unallowed browser lists. For more information, see

Unallowed browsers. If you're only rolling it out to a few devices, you can leave Firefox on the unallowed browser or unallowed app lists. The extension bypasses the restrictions of both lists for those computers where it's installed.

Prepare your devices

1. Use the procedures in these articles to onboard your devices:
   a. Get started with Endpoint data loss prevention
   b. Onboarding Windows 10 and Windows 11 devices
   c. Configure device proxy and internet connection settings for Microsoft Purview Endpoint DLP

Set up a basic single-machine self-hosted deployment

The single-machine self-host installation is the recommended method.

1. Download the initial XPI file.
2. Locate the extension in your file explorer and drag the file into an open Mozilla Firefox window.
3. Confirm the installation.

Deploy using Microsoft Intune

Use the Microsoft Intune setup method for organization-wide deployments.

Configure force install with Microsoft Intune

Before adding the extension to the list of force-installed extensions, it's important to ingest the Firefox ADMX. The following steps explain how to ingest the Firefox ADMX into Microsoft Intune. Before beginning these steps, please ensure you have downloaded the latest Firefox ADMX from the Firefox GitHub.

The following steps can be followed to ingest Firefox ADMX.

1. Sign in to the Microsoft Intune Admin Center.
2. Navigate to **Devices** then to **Configuration**.
3. Select **Create New Policy**.

4. Select **Windows 10 and later** as the platform.
5. Select **Templates** and **Custom** as profile type then click **Create**.
6. Enter a descriptive name like *Firefox ADMX* and an optional description.
7. Click **Add** *OMA-URI Settings* and enter the following policy information.

   Name: Descriptive name.

   Description: Optional description

   OMA-URI:
   `./Device/Vendor/MSFT/Policy/ConfigOperations/ADMXInstall/Firefox/Policy/FirefoxAdmx`

   Data type: `String`

   Value: Copy all of the text from the downloaded *firefox.admx* file into the *Value* field
8. Select create.

After ingesting the Firefox ADMX, follow the Microsoft Intune procedure in this section to create a configuration profile for the Microsoft Purview extension for Firefox.

1. Sign in to the Microsoft Intune admin center.
2. Navigate to Configuration Profiles.
3. Select **Create Profile**.
4. Select **Windows 10** as the platform.
5. Select **Custom** as profile type.
6. Select the **Settings** tab.
7. Select **Add**.
8. Enter the following policy information.

   OMA-URI:
   `./Device/Vendor/MSFT/Policy/Config/Firefox~Policy~firefox~Extensions/ExtensionSettings`
   Data type: `String`
   Value: `<enabled/><data id="ExtensionSettings"`
   `value='{"microsoft.defender.browser_extension.native_message_host@microsoft.com":`

`{"installation_mode": "force_installed", "install_url": "https://github.com/microsoft/purview/raw/main/endpointDLP/browser_extension/prod-1.1.0.212.xpi","updates_disabled":false}}'/>`

9. Note: It's critical that `updates_disabled` is set to `false` so that the extension can automatically update over time.

10. Select create.

Deploy using Group Policy

If you don't want to use Microsoft Intune, you can use group policies to deploy the extension across your organization.

Add the Firefox extension to the force-install list

Use the following steps to add the Firefox extension to the force-install list in Group Policy.

1. In the Group Policy Management Editor, navigate to your organizational unit (OU).

2. Expand the following path **Computer/User configuration** > **Policies** > **Administrative templates** > **Classic administrative templates** > **Firefox** > **Extensions**. This path may vary depending on your configuration.

3. Select **Extensions to install**.

4. Right click and select **Edit**.

5. Select **Enabled**.

6. Select **Show**.

7. Under **Value**, add the following entry:
   `https://github.com/microsoft/purview/raw/main/endpointDLP/browser_extension/prod-1.1.0.212.xpi`

8. Select **OK** and then **Apply**.

Test the extension

Use the following procedures to validate that the Microsoft Purview extension for Firefox is working correctly in common DLP scenarios.

Test uploads to cloud services and access from blocked browsers

Use the following test to verify cloud egress blocking behavior in Firefox.

1. Create or get a sensitive item and, try to upload a file to one of your organization's restricted service domains. The sensitive data must match one of our built-in Sensitive Info Types, or one of your organization's sensitive information types. You should get a DLP toast notification on the device you're testing from that shows that this action isn't allowed when the file is open.

Testing other DLP scenarios in Firefox

Now that you've removed Firefox from the disallowed browsers/apps list, you can run simulations on the policy for these scenarios below to confirm the behavior meets your organization's requirements:

- Copy data from a sensitive item to another document using the Clipboard
  - To test, open a file that is protected against copy to clipboard actions in the Firefox browser and attempt to copy data from the file.
  - Expected Result: A DLP toast notification showing that this action isn't allowed when the file is open.
- Print a document
  - To test, open a file that is protected against print actions in the Firefox browser and attempt to print the file.
  - Expected Result: A DLP toast notification showing that this action isn't allowed when the file is open.
- Copy to USB Removable Media
  - To test, try to save the file to a removable media storage.
  - Expected Result: A DLP toast notification showing that this action isn't allowed when the file is open.
- Copy to Network Share
  - To test, try to save the file to a network share.
  - Expected Result: A DLP toast notification showing that this action isn't allowed when the file is open.

Use the Alerts Management Dashboard to view Firefox DLP alerts

Use the following steps to review Firefox DLP alerts in the Alerts dashboard.

1. Open the **Data loss prevention** page in the Microsoft Purview portal and select **Alerts**.
2. Refer to the procedures in Get started with the data loss prevention Alerts dashboard and Investigate data loss incidents with Microsoft Defender XDR to view alerts for your Endpoint DLP policies.

Use Activity Explorer to view Firefox DLP data

Use Activity explorer to review and filter Firefox DLP activity data for onboarded devices.

1. Open **Activity explorer**.
2. Refer to the procedures in Get started with Activity explorer to access and filter all the data for your Endpoint devices.

Known issues and limitations

Be aware of the following limitations when deploying the Microsoft Purview extension for Firefox.

1. Incognito mode isn't supported and must be disabled.

Next steps

After onboarding devices and verifying activity data in Activity explorer, create DLP policies that protect your sensitive items.

Learn about evidence collection for file activities on devices

When you're investigating a Microsoft Purview Data Loss Prevention (DLP) incident or troubleshooting a DLP policy, it can be helpful to have a complete copy of the item that matched the policy to refer to. DLP can copy the item that matches a DLP policy from onboarded Windows devices or macOS devices (preview) to an Azure storage account. DLP incident investigators and administrators that have been granted the appropriate permissions on the Azure storage blob can then access the files.

To get started configuring and using the feature, see Get started with collecting files that match data loss prevention policies from devices.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

If you're new to Microsoft Purview DLP, here's a list of the core articles you need as you implement DLP:

1. Administrative units
2. Learn about Microsoft Purview Data Loss Prevention - This article introduces you to the data loss prevention discipline and Microsoft's implementation of DLP.
3. Plan for data loss prevention (DLP) - by working through this article you will:
   a. Identify stakeholders
   b. Describe the categories of sensitive information to protect
   c. Set goals and strategy
4. Data Loss Prevention policy reference - This article introduces all the components of a DLP policy and how each one influences the behavior of a policy.
5. Design a DLP policy - This article walks you through creating a policy intent statement and mapping it to a specific policy configuration.
6. Create and Deploy data loss prevention policies - This article presents some common policy intent scenarios that you'll map to configuration options, then it walks you through configuring those options.

Where evidence collection for file activities on devices fits in Purview

Endpoint DLP is part of the larger DLP offering and part of the larger range of services offered in Microsoft Purview. You should understand how evidence collection for file activities on devices fits into the larger set of service offerings.

Evidence collection for file activities on devices and eDiscovery

This feature makes copies of items that match DLP policies on onboarded Windows devices or macOS devices (preview) and places those copies in an Azure storage account. These copies aren't held in a changeless state and aren't evidence in the legal sense of the term. If you need to find and hold items for legal purposes, you should use the Microsoft Purview eDiscovery solutions. Electronic discovery, or eDiscovery, is the process of identifying and delivering electronic information that can be used as evidence in legal cases.

Evidence collection for file activities on devices and contextual summary

When an item and the activity that a user takes on that item match the conditions defined in a DLP policy, a **DLPRuleMatch** event shows up in Activity explorer. This is true for every location that DLP supports. The **DLPRuleMatch** event contains a limited amount of the text that surrounds the matched content. This limited amount of text is called contextual summary.

It's important to understand the difference between evidence collection for file activities on devices and a contextual summary. Evidence collection for file activities on devices are available for onboarded Windows devices or macOS devices (preview). It saves a copy of the entire item that matched a policy to the Azure storage account. A contextual summary is captured for every DLP policy rule match and only contains a limited amount of the text that surrounds the target text that triggered the match.

Evidence collection for file activities on devices and Data Security Investigations

Microsoft Purview Data Security Investigations can query endpoint DLP evidence collection data as an additional data source for security investigations. Investigators can use the endpoint DLP evidence collection (preview) search option in Data Security Investigations to aggregate endpoint events and analyze them collectively using AI-powered tools, rather than triaging individual alerts

one by one. Data Security Investigations queries whatever data is already collected by your endpoint DLP policies — no additional configuration is required beyond enabling evidence collection.

Covered user activities

You can configure evidence collection for file activities on devices to save a copy of a matched item to the Azure storage account when a user attempts to do one of these activities on a matched item:

- Copy to a removable USB
- Copy to network share
- Print
- Copy or move using unallowed Bluetooth app
- Copy or move through RDP
- Upload to cloud service domains or access from an unallowed browser
- Paste to supported browsers
- Access by restricted apps

The detection of these activities is configured in the DLP policy. For more information on how to create a DLP policy, see, Create and Deploy data loss prevention policies and Using Endpoint data loss prevention.

Covered actions

When you enable evidence collection for file activities on devices in Endpoint DLP settings and configure a DLP policy to use this feature, it saves a copy of a matched item for these actions:

- Audit only
- Block with override
- Block

These actions are configured in the DLP policy. For more information on how to create a DLP policy, see Create and Deploy data loss prevention policies and Using Endpoint data loss prevention.

Design considerations

Regions for your Azure Storage accounts

To comply with regulatory requirements, make sure that the Azure storage accounts that you use are in the same geopolitical or regulatory boundaries as the devices that they're being copied from. Also, be aware of the geopolitical location of the DLP investigators who will access the sensitive items once they're saved. Consider using Administrative units to scope the administration of the users and devices appropriately for each DLP policy. To learn how to use data loss prevention to comply with data privacy regulations, see Deploy information protection for data privacy regulations with Microsoft Purview. Evidence collection for file activities on devices supports up to 10 Azure storage accounts.

To learn how to use data loss prevention to comply with data privacy regulations, see Deploy information protection for data privacy regulations with Microsoft Purview.

Local storage and bandwidth

By default, copies of matched items are saved asynchronously to the configured Azure storage account over the existing network connection. If the device doesn't have connectivity, matched items are save locally, up to the 500-MB limit. You can save items locally up to 60 days.

While the device has connectivity to the Azure storage account URL, there's no limit on bandwidth usage. The bandwidth that evidence collection for file activities on devices uses doesn't affect the default or configured bandwidth limits for Advanced classification scanning and protection.

Azure storage accounts

Customers are responsible for creating and managing their own Azure storage accounts. If you're new to Azure storage, see:

- What is Azure Blob storage
- Introduction to Azure Storage
- Create a storage account

Items that match a policy are copied from the users' device to the Azure storage account blob in the security context of the logged in user. So, all users who are in-scope for the policy must have read and write permission to the blob storage. For more information, see Get started with collecting files that match data loss prevention policies from devices

Similarly, all administrators who are reviewing the saved items must have `read` permission to the Azure storage account blob. For more information, see Get started with collecting files that match data loss prevention policies from devices.

Storing evidence when sensitive information is detected

Supported file types

For more information on supported file types, see Supported file types for storing and previewing evidence.

Supported storage types

You have two options for storing the evidence Purview collects when it detects sensitive information in your content. You can use a **Customer-managed** data store, or a **Microsoft Managed** data store. The option you should use depends on your requirements and your use cases. To help you decide, review the comparison table that follows.

Storage type comparison

Matched files continue to be included in alert results even after changing your storage type as long as the role-based access control (RBAC) permissions remain intact. Since customer managed storage is owned by customers, DLP admins can continue to download files directly from the storage on a per-file basis.

The following table identifies the differences between customer-managed storage and Microsoft-managed storage for collecting evidence of the sensitive information detected in your content.

Expand table

Feature Element	Customer Managed	Microsoft Managed
File retention	You can keep files as long as you need/want to.	Files are retained for a maximum of 180 days.
Upload limit	You can upload files based on your blob storage size settings.	You can upload upto 5 GB per day at the overall tenant level.
Endpoint settings	You must add blob storage (container URLs) in the endpoint settings and then use the Microsoft Entra admin center to configure explicit user permissions on the blob for in-scope users.	All configuration and permissions are handled with a single click when configuring your endpoint settings.
Policy and location	You must add and configure storage blobs on a per-policy	No storage selection is needed for specific policy locations.

Feature Element	Customer Managed	Microsoft Managed
configuration	basis for each location where a policy is applied.	
Access to storage	Users with relevant permissions to storage blob can access the evidence	No human access to storage. Evidence is uploaded and rendered by the system.
Data store location/region	Chosen by the customer	The same region as your Microsoft Purview tenant.
Charges	Storage costs are charged in addition to the cost of your Entra subscription.	Storage cost today is included in E5. However, Microsoft will monitor storage usage and may charge additionally based on excessive usage. This will be communicated to customers separately should there be a change in the business model.
Network configuration	You must allow the container URLs for your storage blobs to pass through your network firewall.	You must include **compliancedrive.microsoft.com** on an "allow" list, so that it can pass through the network firewall.
Retention	Customers can selectively archive and purge to free up storage)	30 days on Purview and 180 days on Defender XDR
Preview and Download Permissions	Read access on storage blobs, RBAC roles **Data Classification Content Viewer** to preview the evidence and **Data Classification Content Download** to download the evidence	RBAC roles **Data Classification Content Viewer** to preview the evidence and **Data Classification Content Download** to download the evidence

Changing storage types

Customers can switch between storage types at any time. However, best practice is to carefully plan for the type of storage you'll need over the long term and select the appropriate option for your use case. For more information on the differences between the two types of storage, see the Storage type comparison table.

> ⓘ **Note**
>
> When switching storage types, you'll need to refresh your policies to ensure that they are applied to the files in the new data store.

Impact of changing storage types on evidence files

Matched files continue to be included in alert results, even after you change the storage management type, provided that the role-based access control (RBAC) permissions do not change.

Because you own your customer-managed storage solution, your DLP admins can continue to download files directly on a per-file basis after they have been moved to the Microsoft-managed storage solution.

Next step

Your next step is to configure evidence collection for file activities on devices.

For more information, see Get started with collecting files that match data loss prevention policies from devices.

Last updated on 06/22/2026

Get started with collecting files that match data loss prevention policies from devices

This article walks you through the prerequisites and configuration steps for evidence collection for file activities on devices and introduces how to view the items that are copied and saved.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Here are the high level steps for configuring and using evidence collection for file activities on devices.

1. Onboard devices
2. Understand your requirements
3. Create your managed Azure storage account
4. Add an Azure storage blob to your account
5. Enable and configure evidence collection on a storage account managed by Microsoft
6. Configure your DLP policy
7. View usage of Microsoft managed storage

Before you begin

Before you start these procedures, you should review Learn about evidence collection for file activities on devices.

Licensing requirements for evidence collection

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

See the prerequisites licensing requirements for Microsoft Entra ID P1 or P2 needed to create custom role-based access control (RBAC).

Permissions

Standard Microsoft Purview Data Loss Prevention (DLP) permissions are required. For more information, see Permissions.

Permissions for preview or download of evidence

When you want to preview or download the evidence, the account used needs to be in these roles:

- Preview the evidence: Data Classification Content Viewer
- Download the evidence: Data Classification Content Download

The Data Classification Content Download role is preassigned to these built-in role groups:

- Data Security Management
- Information Protection
- Information Protection Investigators

If you need to manage users, roles and role groups, see Permissions in the Microsoft Purview portal.

Onboard devices

Before you can use copy matched items you have to onboard Windows 10/11 devices or macOS devices (Preview) into Purview, see Onboard Windows devices into Microsoft 365 overview.

Understand your requirements

> **Important**
>
> Each container inherits the permissions of the storage account that it is in. You can't set different permissions per container. If you need to configure different permissions for different regions, you must create multiple storage accounts, not multiple containers.

You should have answers to the following question before setting up your Azure storage and scoping the feature to users.

Do you need to compartmentalize items and access along role or departmental lines?

For example, if your organization wants to have one set of administrators or DLP event investigators who can view saved files from your senior leadership and another set of administrators or DLP event investigators for saved items from human resources, you should create one Azure storage account for your organization's senior leadership and another for the Human Resources department. This ensures that the Azure storage admins or DLP event investigators can only see the items that matched DLP policies from their respective groups.

Do you want to use containers to organize saved items?

You can create multiple evidence containers within the same storage account for sorting saved files. For example, one for files saved from the HR department and another for those from the IT department.

What is your strategy for protecting against saved item deletion or modification?

In Azure Storage, data protection refers to both the strategies for protecting the storage account and data within it from being deleted or modified and to restoring data after it's deleted or modified. Azure storage also offers options for disaster recovery, including multiple levels of redundancy, to protect your data from service outages due to hardware problems or natural disasters. It can also protect your data using customer-managed failover if the data center in the primary region becomes unavailable. For more information, see Data protection overview.

You can also configure immutability policies for your blob data that protects against the saved items being overwritten or deleted. For more information, see Store business-critical blob data with immutable storage

Supported file types for storing and previewing evidence

The following table shows which file types can be stored and previewed as evidence.

Expand table

Can be Stored	Can be Previewed
All file types provided they match the policy	All file types supported for previewing files in OneDrive, SharePoint, and Teams

> ⓘ Note
>
> To understand how to create policies for different file types see Create and deploy DLP policies

Save matched items to your preferred storage

To save the evidence that Microsoft Purview detects when your data loss prevention policies are applied, you need to set up storage. There are two ways to set up storage for evidence collection:

1. Create customer-managed storage
2. Create Microsoft-managed storage

For more information and a comparison of these two types of storage, see Storing evidence when sensitive information is detected.

Create customer-managed storage

The procedures for setting up your Azure storage account, container, and blobs are documented in the Azure Blob Storage documentation. Here are links to relevant articles you can refer to help you get started:

1. Introduction to Azure Blob Storage
2. Create a storage account
3. Default to and authorize access to blobs using Microsoft Entra ID
4. Manage blob containers using the Azure portal
5. Manage block blobs with PowerShell

> ⓘ Note
>
> Make sure to select **Enable public access from all networks while creating the storage account**. Support for Virtual networks and IP addresses and use of private access isn't available

Be sure to save the name and URL of the Azure blob container. To view the URL, open the Azure storage portal > **Home** > **Storage Accounts** > **Container** > **Properties**

The format for the Azure blob container URL is: `https://storageAccountName.blob.core.windows.net/containerName`.

Add an Azure storage blob to your account

There are several ways you can add an Azure storage blob to your account. Chose *one* of the methods below.

1. Sign in to the Microsoft Purview portal and choose the **Settings** gear in the menu bar.
2. Choose **Data Loss Prevention**.
3. Select **Endpoint DLP settings**.
4. Expand **Setup evidence collection for file activities on devices**.
5. Change the toggle from **Off** to **On**.
6. In the **Set evidence cache on device** field, select the amount of time evidence should be saved locally when the device is offline. You can choose **7**, **30**, or **60** days.
7. Select a **storage type** (*Customer managed store* or *Microsoft managed store*) and then select **+ Add storage**.
    a. For **Customer-managed storage**:
        i. Choose **Customer managed store**: and then choose **+ Add storage**.
        ii. Enter give the account a name and enter the **URL** for the storage blob.
        iii. Choose **Save**.
    b. For **Microsoft-managed storage**:
        i. Choose **Microsoft managed store**

To add Azure blob storage using the DLP policy creation workflow in the Microsoft Purview portal:

1. Sign in to the Microsoft Purview portal and choose **Data Loss Prevention**.
2. Follow the steps to create a new policy.
3. At the **Locations** step, make sure that only the **Devices** location is selected, and then choose **Next**.
4. At the Policy settings step, select Create or customize advanced DLP rules.
5. Select **+Create rule** and add **Conditions**, **Actions**, **User notifications** and **User overrides** with values of your choosing.
6. In the **Incident reports** section, the **Send an alert to admins when a rule match occurs** toggle should be **On** by default. (If it isn't, turn it on.)
7. Select the checkbox next to **Collect original file as evidence for all selected file activities on Endpoint**.
8. Select the activities you want to collect evidence for.
9. Select **Add storage** next to the checkbox item.

10. On the **Endpoint DLP settings** page, expand **Setup evidence collection for file activities on devices** and make sure that the option is toggled to **On**.

Set permissions on the Azure blob storage

Using Microsoft Entra authorization, you must configure two sets of permissions (role groups) on the blobs:

1. One for the administrators and investigators so they can view and manage evidence
2. One for users who need to upload items to Azure from their devices

Best practice is to enforce *least privilege* for all users, regardless of role. By enforcing least privilege, you ensure that user permissions are limited to only those permissions necessary for their role. To configure user permissions, create roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

Permissions on Azure blob for administrators and investigators

Once you create the role group for DLP incident investigators, you must configure the permissions described in the Investigator actions and Investigator data actions sections that follow.

For more information on configuring blob access, see these articles:

- How to authorize access to blob data in the Azure portal
- Assign share-level permissions.

Investigator actions

Configure these object and action permissions for the investigator role:

Expand table

Object	Permissions
Microsoft.Storage/storageAccounts/blobServices	Read: List Blob Services
Microsoft.Storage/storageAccounts/blobServices	Read: Get blob service properties or statistics
Microsoft.Storage/storageAccounts/blobServices/containers	Read: Get blob container

Object	Permissions
Microsoft.Storage/storageAccounts/blobServices/containers	Read: List of blob containers
Microsoft.Storage/storageAccounts/blobServices/containers/blobs	Read: Read blob
Microsoft.Storage/storageAccounts/blobServices/generateUserDelegationKey/action	Other: Generate a user delegation key

Investigator data actions

Assign the following data actions to the investigator role.

Expand table

Object	Permissions
Microsoft.Storage/storageAccounts/blobServices/containers/blobs	Read: Read Blob

Your JSON for the investigator role group should look like this:

JSON

```
"permissions": [
            {
                "actions": [
                 "Microsoft.Storage/storageAccounts/blobServices/read",
                 "Microsoft.Storage/storageAccounts/blobServices/containers/read",

"Microsoft.Storage/storageAccounts/blobServices/generateUserDelegationKey/action"
                ],
                "notActions": [],
                "dataActions": [

"Microsoft.Storage/storageAccounts/blobServices/containers/blobs/read"
                ],
                "notDataActions": []
            }
        ]
```

Permissions on Azure blob for users

Assign these object and action permissions to the Azure blob for the user role:

User actions

Assign the following object and action permissions to the user role.

Expand table

Object	Permissions
Microsoft.Storage/storageAccounts/blobServices	Read: List Blob Services
Microsoft.Storage/storageAccounts/blobServices/containers	Read: Get blob container
Microsoft.Storage/storageAccounts/blobServices/containers	Write: Put blob container

User data actions

Assign the following data actions to the user role.

Expand table

Object	Permissions
Microsoft.Storage/storageAccounts/blobServices/containers/blobs	Write: Write Blob
Microsoft.Storage/storageAccounts/blobServices/containers/blobs	Other: Add blob content

The JSON for user role group should look like this:

JSON

```
"permissions": [
  {
     "actions": [
       "Microsoft.Storage/storageAccounts/blobServices/containers/read",
       "Microsoft.Storage/storageAccounts/blobServices/containers/write",
       "Microsoft.Storage/storageAccounts/blobServices/read"
     ],
     "notActions": [],
     "dataActions": [
         "Microsoft.Storage/storageAccounts/blobServices/containers/blobs/add/action",
         "Microsoft.Storage/storageAccounts/blobServices/containers/blobs/write"
     ],
     "notDataActions": []
    }
 ]
```

Enable and configure evidence collection on a storage account managed by Microsoft

To enable and configure evidence collection on a storage account managed by Microsoft from within the Microsoft Purview portal:

1. Sign in to the Microsoft Purview portal > **Settings** gear in the menu bar.
2. Choose **Data Loss Prevention**.
3. Select **Endpoint DLP settings**.
4. Expand **Setup evidence collection for file activities on devices** and set the toggle to **On**.
5. Under **Select storage type**, choose **Microsoft managed storage**.

> **Tip**
>
> After you configure Microsoft-managed storage, you can use **Data Security Investigations** to query and analyze evidence collected from endpoint DLP policies across multiple users and time periods.

Configure your DLP Policy

Create a DLP policy as you normally would. For policy configuration examples, see Create and Deploy data loss prevention policies.

Configure your policy using these settings:

- Make sure that **Devices** is the only location selected.
- In **Incident reports**, toggle **Send an alert to admins when a rule match occurs** to **On**.
- In **Incident reports**, select **Collect original file as evidence for all selected file activities on Endpoint**.
- Select the storage account you want.
- Select the activities for which you want to copy matched items to Azure storage, such as:
  - **Access by restricted apps (preview)**
  - **Paste to supported browsers**
  - **Upload to cloud service domains or access unallowed browsers**
  - **Copy to a removable USB device**
  - **Copy to a network share**
  - **Print**
  - **Copy or move using an unallowed Bluetooth app**
  - **Copy or move using RDP**

View usage of Microsoft Managed Storage

You can view and export the daily usage for past 6 months for Microsoft Managed storage.

1. Sign in to the Microsoft Purview portal > **Settings** gear in the menu bar.

2. Choose **Data Loss Prevention**.
3. Select **Endpoint DLP settings**.
4. Expand **Setup evidence collection for file activities on devices**.
5. Click on **View Usage** button, a panel will open. Here you can see month wise graph of daily usage and also export the usage data.

Preview and Download the evidence

There are different ways to preview your evidence, depending on which type of storage you select.

Expand table

Storage Type	Preview options
Customer-managed	- Use activity explorer - Use the Microsoft Purview portal
Microsoft Managed	- Use activity explorer - Use the Purview portal

> **Note**
>
> Reminder, the account you use to preview and download needs to be in these roles:
>
> - Preview the evidence: Data Classification Content Viewer
> - Download the evidence: Data Classification Content Download

Preview evidence via Activity explorer

Use the following steps to preview evidence in Activity explorer.

1. Sign in to the Microsoft Purview portal > **Data loss prevention** > **Activity explorer**.
2. Using the **Date** dropdown, select the **Start** and **End** dates for the period you're interested in.
3. In the list of results, double-click the line item of the activity you want to investigate.
4. In the flyout pane, the link to the Azure blob where the evidence is stored appears under **Evidence file**.
5. Select the Azure blob storage link to display the file that was matched.

Preview evidence via the Purview portal Alerts page

Use the following steps to preview evidence from the Alerts page in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal > **Data loss prevention** > **Alerts**.
2. Using the **Date** dropdown, select the **Start** and **End** dates for the period you're interested in.
3. In the list of results, double-click the line item of the activity you want to investigate.
4. In the flyout pane, select **View details**.
5. Select the **Events** tab.
6. In the **Detail** pane, select the **Source tab**. The file that was matched displays.

> **Note**
>
> If the file that was matched already exists in the Azure storage blob, it won't be uploaded again until changes are made to the file and a user takes an action on it.

Known issues

- The maximum size for files that can be uploaded from a device is 500 MB.
- If Just-in-Time Protection is triggered on a scanned file, OR if the file is stored on a network share, the evidence file is not collected.
- When multiple files are opened in the same process (non-office apps) and one of the files matching a policy is egressed, DLP events are triggered for all files. No evidence is captured.
- If multiple policy rules are detected in a single file, the evidence file is only stored if the most restrictive policy rule is configured to collect evidence.

Get started with data loss prevention protections for Recall

> **Note**
>
> Microsoft Purview Data Loss Prevention (DLP) protection for Recall snapshots feature is *in preview*

Recall is a Copilot+ PC feature that allows users to search locally saved and locally analyzed snapshots of their screen using natural language. To help protect against the inclusion of sensitive content in these snapshots, you can use DLP policies. The following sections walk you through the prerequisites and configuration steps you perform to start using DLP protections for Recall.

DLP protections for Recall are supported for sensitive information types and sensitivity labeled items in:

- Sensitivity labeled Teams channels
- Sensitivity labeled Teams meeting chats
- SIT or sensitivity labeled files that are opened with Microsoft 365 Copilot App (Word, Excel PowerPoint web apps) using Microsoft Edge for Business
- Labeled emails Outlook
- Locally stored files with sensitivity labels or SITs
- Files stored in the cloud that with sensitivity labels or SITS that get opened in Office apps (Word, Excel, PowerPoint) on the device

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Before you begin

IT admins can set policies that give Copilot+ PC users the option to enable saving snapshots. The user must then opt in to taking snapshots. For more information, see Manage Recall.

Prerequisites

Before you configure DLP protections for Recall, ensure the following prerequisites are met:

- meet all device prerequisites for Recall as described in Manage Recall.
- Microsoft Purview endpoint DLP is enabled for the tenant the Copilot+ PC is onboarded to endpoint data loss prevention.
- Microsoft Intune is running on the tenant to create Windows tenant policies.
- Copilot+ PC must be running
  - Windows build greater than 262100.67225
  - Anti-malware Client version greater than 4.18.2508.5 or higher
  - Teams version 25290.205.4069.4 or higher
  - Office desktop apps (Word, Excel, PowerPoint) version 19127 or higher
  - Microsoft Edge for Business. For more information, see Automatic activation of your Microsoft Purview DLP policy in Microsoft Edge

Set the following Group Policy settings on the Copilot+ PC to enable DLP protections for Recall using either Microsoft Intune or Local Group Policy Editor.

Expand table

Local Group Policy	Set to	Required	Notes
WindowsAI > Turn off saving snapshots for use with Recall	Disable	Yes	This policy makes the Recall feature available to users to opt in. This doesn't automatically start Recall for users. Users must launch recall and opt-in to taking snapshots on their machines.
WindowsAI > Set maximum duration for storing snapshots used by Recall	30-180	Optional	This is the retention period for snapshots in days

Local Group Policy	Set to	Required	Notes
WindowsAI/Set maximum storage for snapshots used by Recall	10-150	Optional	This is the storage limit. For more information, see, Manage Recall.
WindowsAI > SetDataLossPreventionProvider policy	HKEY_LOCAL_MACHINE\software\microsoft\windows defender; value:InstallLocation; binary:endpointdlp.dll; minversion:4.18.25080.5	Yes	This registry value sets the DLP provider (Microsoft Purview) to be used with Recall. This capability is implemented as a public API.

For more information, see: SetDataLossPreventionProvide

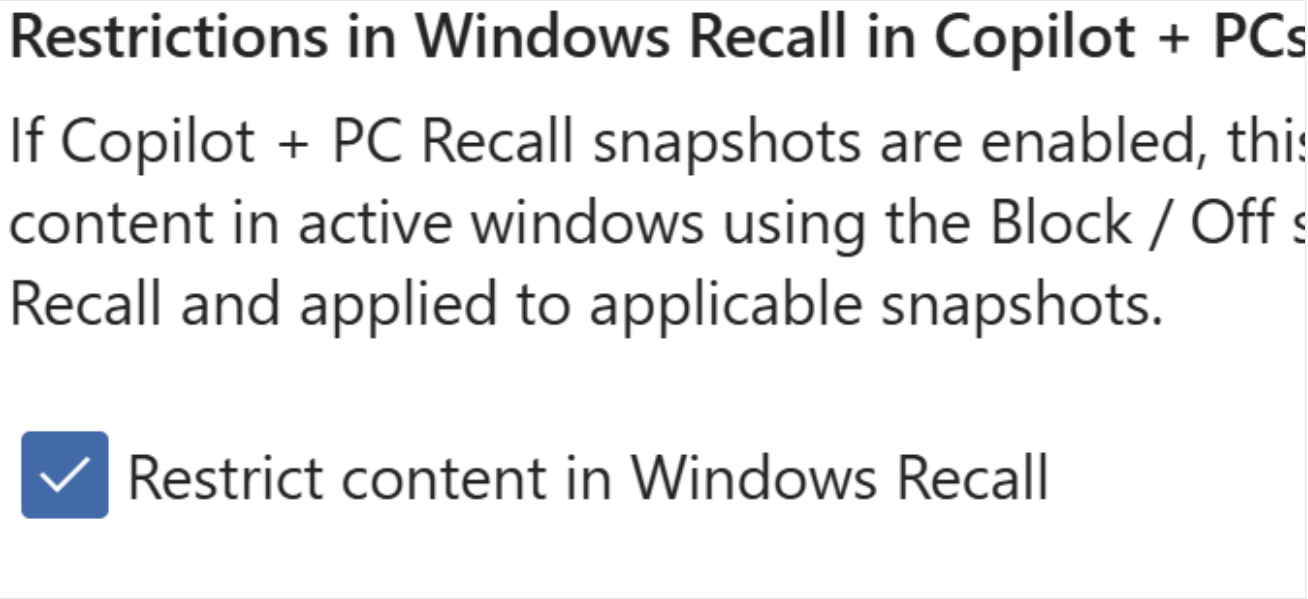
Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions

For information on the permissions required to create and manage DLP policies, see Permissions for creating and deploying DLP policies.



Configuring DLP policy protections for Recall

When you configure a Copilot+ PC so that the user can opt in to Recall, and the user does opt in, you can create new DLP policies or edit existing policies to include protections for Recall.

For general information on creating DLP policies, see Create and deploy a data loss prevention policy.

The setting to enable DLP protections for Recall is available when you create or edit a DLP policy in **Enterprise Applications & devices** policies. In the policy editing workflow under **Actions** >

Audit or restrict activities on devices > **Restrictions in Windows Recall in Copilot+ PCs** > **Restrict content in Windows Recall**. You can select **Audit only** or **Block**.

If you select **Audit only**, then the user doesn't see any notification when a snapshot is taken that contains sensitive information. However, the event is logged in the DLP reports.

If you select **Block**, then when a snapshot is taken that contains sensitive information, then the sensitive content isn't included in the snapshot.

View Recall related events in Microsoft Purview Activity Explorer.

Learn about the default DLP policy for devices

To help you protect sensitive data on endpoint devices, Microsoft provides a default Microsoft Purview data loss prevention (DLP) policy called **Default policy for devices**.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

What does the default policy do?

This default policy looks for items with the sensitive information type Credit card number It's configured like this.

- Admin units: **Full directory**
- Choose where to apply the policy: **Devices** > **All users, groups, devices, device groups**
  - **SharePoint sites** > **All sites**
  - **OneDrive accounts** > **All users and groups**
- Conditions:
  - **Content contains** > **Credit card number**
- Action:
  - **Audit or restrict activities on devices**
    - **Upload to a restricted cloud service domain or access from an unallowed browser** > **Audit only**
    - **Copy to clipboard** > **Audit only**
    - **Copy to a removable USB device** > **Audit only**
    - **Copy to a network share** > **Audit only**
    - **Print** > **Audit only**
    - **Copy or move using unallowed Bluetooth app** > **Audit only**

    - **Copy or move using RDP** > **Audit only**
  - **App access restrictions** > **Access by restricted apps** > **Audit only**
- Policy mode: **Turn the policy on immediately**

Administrator can view the activities and edit the policies details by logging into the Microsoft Purview portal.

Admins can view this policy in the Microsoft Purview portal. Navigate to **Data Loss prevention** > **Policies**.

Edit or delete the default policy

To edit the default policy for better performance or to delete it, just use an account with **DLP Compliance Management** permissions. For more information, see, Permissions.

Last updated on 03/24/2026

Learn about Data Loss Prevention for Cloud Apps in Edge for Business

Microsoft Purview Data Loss Prevention (DLP) monitoring and protection are built right into the Microsoft Edge for Business browser. You don't need to onboard the device into Microsoft Purview. This integration helps you stop users from sharing sensitive information to and from cloud apps by using Edge for Business.

Before you begin

If you're new to Microsoft Purview collection policies, Microsoft Purview pay-as-you-go billing models, or Microsoft Purview DLP, familiarize yourself with the information in these articles:

- Collection policies
- Learn about data loss prevention
- Learn about Microsoft Purview billing models
- Get started with activity explorer

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Protecting data shared from a managed device to an unmanaged app in Edge for Business is a pay-as-you-go feature. For more information, see Learn more about pay-as-you-go-capabilities and request definitions. For information on setting up the pay-as-you-go billing model, see Enable Microsoft Purview pay-as-you-go features for new customers.

Scenarios where data in Microsoft Entra-registered (managed) apps is protected while using Edge for Business are included in a Microsoft 365 E5 or equivalent license.

Permissions

Permissions to create and deploy Microsoft Purview DLP policies are found here.

You also need permissions for prerequisites and configurations outside of Microsoft Purview. For more information on required permissions, see Supported cloud apps.

Managed devices

You can protect Windows 10 and Windows 11 devices that are managed by Microsoft Intune. Users must sign in to the device using their work or school account.

On these devices, Edge for Business connects directly with Microsoft Purview and Microsoft Edge services to get policy updates and apply protections. Microsoft Edge configuration policies block users from using protected unmanaged cloud apps in unprotected browsers. If users try to access an unmanaged app in an unprotected browser, they're blocked and must use Edge for Business.

Microsoft Purview DLP policies can help prevent sharing via Edge for Business from managed devices to unmanaged AI apps, and Microsoft Purview collection policies can be applied to interactions with unmanaged AI apps from managed devices. Policies targeting unmanaged apps on managed devices apply across all Edge browser profiles (work profile, personal profile and InPrivate).

Unmanaged devices

Unmanaged devices aren't connected to Intune or joined to your organization using Microsoft Entra. Users don't sign into the device with their work or school account. Instead, they sign into their Edge for Business work profile to access organization managed apps from their unmanaged device.

Edge for Business applies DLP policies for unmanaged devices to the work profile identity. These policies don't apply when users choose a personal or InPrivate profile, except when the work profile used to open the InPrivate window has a policy applied. When you target policies to managed apps on unmanaged devices, you must enforce the work profile in Edge for Business. Protections for unmanaged devices help prevent users from sharing sensitive information with cloud apps in Edge for Business.

Supported cloud apps

Microsoft Entra connected (managed) apps

Microsoft Entra connected (managed) apps are business apps set up for Microsoft Entra single sign-on (SSO). Policies apply when users access them in Edge for Business by using work or

school account credentials. Policies for managed apps in Edge for Business are supported on unmanaged devices and managed devices and policies apply only in Edge work profile.

To activate policies that apply to managed apps, you need additional permissions for Conditional Access administration and Microsoft Defender for Edge In-Browser protection.

Unmanaged cloud apps

Your organization doesn't manage these apps. Users access them without signing in by using their Microsoft work or school account. You can use policies for unmanaged cloud apps in Edge for Business on Intune-managed devices and the policies apply across all Edge browser profiles (work profile, personal profile and InPrivate).

> **Important**
>
> Microsoft Purview browser and network data security policies don't apply to B2B guest users.

To fully activate DLP policies for unmanaged apps, additional groups and policies are required outside of Purview. This behavior is automated and triggered by the admin action in Purview. After you save your first Purview collection or DLP policy targeting unmanaged apps in Edge for Business, the Microsoft Edge management service automatically creates and manages the required configurations and policies outside of Purview. To learn more, see Automatic activation of your Microsoft Purview DLP policy in Microsoft Edge.

To fully activate your Purview policies in Edge for Business, the admin needs these permissions:

- Directory Reader
- Microsoft Edge administration
- Microsoft Intune administration

Browser policies in Edge for Business support these unmanaged apps:

- Adobe Firefly
- CapCut
- ChatGPT (consumer)
- Cohere
- DeepAI
- DeepSeek

- Google Gemini
- Grok (xAI)
- Meta AI
- Microsoft Copilot 365 Chat
- Notion AI
- Otter.ai
- Perplexity AI
- QwenAI
- Qwen Chat
- Runway
- Textcortex
- Textcortex Zenochat
- You (You.com)

> **Note**
>
> The unmanaged cloud app features apply to the consumer versions of Microsoft 365 Copilot and ChatGPT. For more information on the enterprise versions of these apps and available Purview features see, Learn more about Microsoft 365 Copilot Enterprise protections and Use Microsoft Purview to manage data security & compliance for ChatGPT Enterprise.

Supported browsers

DLP policies for cloud apps in the browser work directly in Edge for Business.

Edge for Business

These features are available in the two latest stable versions of Edge for Business, starting with version 144. For more information on Edge for Business versions, see Microsoft Edge Releases.

> **Important**
>
> Microsoft Purview browser data security policies don't apply to B2B guest users.

> **Tip**

Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Activities you can monitor and take action on

You can audit and manage these activities on sensitive items in the browser:

Expand table

Activity	Device Type	App Type	Supported Policy Actions
Upload text	Managed	Unmanaged	allow, block, both actions audited
Upload file	Managed, Unmanaged	Managed, Unmanaged	allow, block, both actions audited
Download file	Managed, Unmanaged	Managed	allow, block, both actions audited
Cut/copy data	Managed, Unmanaged	Managed	allow, block, both actions audited
Paste data	Managed, Unmanaged	Managed	allow, block, both actions audited
Print data	Managed, Unmanaged	Managed	allow, block, both actions audited
Protected clipboard (Preview)	Managed, Unmanaged	Managed	See Microsoft Edge Protected Clipboard (preview)
Screen capture (Preview)	Managed, Unmanaged	Managed	See Microsoft Edge Protected Clipboard (preview)

Some activities have limitations:

- Cut/copy data, paste data, and print data activities can only be used with the managed or unmanaged devices condition.
- Download file activity isn't supported for apps that don't follow Microsoft Edge for Business's download pipeline.

> **Note**
>
> Policy sync status displays N/A for DLP policies that use the built-in protections in Edge for Business. These policies use a different activation and delivery path than other DLP locations

and don't report through the same policy sync status field. Activation or configuration failures are surfaced in the Microsoft Purview portal.

Policies for managed app interactions

DLP policies that target managed apps in the browser apply to Edge for Business in Windows 10/11 and macOS desktop devices when the user signs in to their Edge for Business work profile.

Edge for Business automatically disables developer tools and blocks the apps from opening in native clients when policies apply to managed apps (in both audit and block modes).

To activate protections in the Edge for Business work profile for managed apps:

- Onboard apps to Conditional Access app control.
- Import user groups from connected apps. This step allows you to target Groups in your Entra Conditional Access policy and your Purview policies for managed apps in Edge for Business.
- Set up a Microsoft Entra Conditional Access policy with custom session controls.
- Configure Edge for Business in-browser protection.
- Create a Microsoft Purview DLP policy that targets managed app interactions.
- (Optional) Activate protected clipboard and screen capture prevention capabilities in the Microsoft Admin Portal settings for Microsoft Edge.

For full implementation details, see Help Prevent Users from Sharing Sensitive Info with Cloud Apps in Edge for Business.

> **Important**
>
> Protections might not apply in Edge for Business to managed apps included in a Microsoft Purview browser policy if the user is in scope for both a Microsoft Purview managed cloud app DLP policy *and* a Microsoft Defender session policy *or* Microsoft Purview endpoint DLP policy. You must remove or exclude the users from the Microsoft Defender and the endpoint DLP policies for the managed cloud apps in Edge for Business policy to apply.

When you add users to policies for the first time, the policy might not be applied right away if they're already signed in to the app. The policy applies after their token expires and they sign in

again. You can change the sign-in frequency by using conditional access session controls to shorten the wait time.

Some known limitations in Conditional Access app control can impact Microsoft Purview policies that target managed apps in the browser. For more information, see known limitations in Conditional Access app control.

Accessing data from managed app interactions

You can view policy data and alerts in Defender XDR investigations.

Policies for unmanaged app interactions

DLP policies that target unmanaged apps in the browser apply to Microsoft Edge for Business on Windows 10 and Windows 11 desktop devices managed by Microsoft Intune. For setup details, see Help prevent sharing via Edge for Business to unmanaged AI apps from managed devices.

> **Important**
>
> Microsoft Purview inline protection in Microsoft Edge for Business for unmanaged apps doesn't support tenants that use multi-admin approval in Microsoft Intune. For more information, see **Multi-admin approval**.

When you activate a Microsoft Purview DLP policy for unmanaged cloud apps, Purview automatically creates the required Microsoft Edge configuration policies and Microsoft Intune policies (outside of Purview) and assigns the included users.

If you configure the DLP policy to block, users in scope can't use unprotected browsers where the policy doesn't apply. This restriction doesn't affect their experience in Microsoft Edge for Business.

For more information, see Activate your Microsoft Purview policy in Microsoft Edge.

Activating protections in Microsoft Edge for Business follows these phases:

- Create a Microsoft Purview DLP policy targeting unmanaged app interactions.
- Microsoft Edge management service automatically creates the configuration policies that activate DLP policies in Microsoft Edge for Business. The configuration policies use Microsoft Intune policies to activate your Microsoft Purview policies in Microsoft Edge for Business.

- Create a collection policy targeting unmanaged apps in the browser to identify additional sensitive data sharing that might be happening across your organization.

> **Important**
>
> If the **automatic behaviors** fail to sync, Microsoft Purview shows an error message. Purview doesn't enforce DLP and collection policies for unmanaged apps in Edge for Business until you resolve the error. An admin with the **required permissions** must resync to resolve the error. For more information, see **activate your Microsoft Purview policy in Microsoft Edge**.

Accessing data from unmanaged app interactions

You can view activities and audit log entries in activity explorer, audit logs, and Defender XDR investigations. In activity explorer, filter by enforcement plane set to browser. Data specific to AI apps is also visible in DSPM for AI.

Considerations for unmanaged cloud apps policies

Review this information when you configure policies that include unmanaged cloud apps, or when you troubleshoot unexpected policy behavior:

- When multiple catalog entries exist for the same app with differences in the entry name (for example, QwenAI and Qwen Chat), include all entries for the app to avoid unintended coverage gaps.
- Some unmanaged AI apps like Runway and Meta AI might intermittently send content in encoded form to dynamically generated endpoints, which can impact policy enforcement.
- Policies that target unmanaged apps can capture interactions from both the consumer and enterprise versions of an app when the app's URL is shared across instances (for example, ChatGPT consumer and ChatGPT enterprise).
- When you target an unmanaged cloud app in an Edge for Business browser policy, detection is based on the destination app's traffic, which isn't always exactly the same as the originating app.
- Inline evaluation size limits: Microsoft Purview evaluates up to 4 MB of content for uploadText, and files up to 3 MB for uploadFile.

Default policies for unmanaged AI apps from Microsoft Data Security Posture Management for AI

Microsoft Purview Data Security Posture Management for AI (DSPM for AI) offers recommended policies to monitor and block supported unmanaged generative AI apps. Use one-click policies in DSPM for AI to apply them.

Working with Microsoft Purview Endpoint data loss prevention

Endpoint DLP policies are prioritized over inline DLP policies for cloud apps in Edge for Business if the same user, context, and action are configured in both policies. For example, if you have an Endpoint DLP policy that blocks a file uploads, and you also have an inline policy for cloud apps in Edge for Business that monitors file uploads. the Endpoint DLP policy is prioritized and applied. For more information, see Learn about Endpoint data loss prevention.

Learn about Microsoft Purview Network Data Security

Microsoft Purview network data security helps organizations monitor, classify, and apply protections to unmanaged and untrusted cloud app traffic, including generative AI apps. Purview provides these capabilities through integrations with one or more secure access service edge (SASE) or secure browser solutions:

- **Microsoft Entra Global Secure Access**: To learn how to configure content policies that integrate with Purview, see Create a content policy to filter network content.
- **Non-Microsoft SASE and secure browser solutions** (general availability or preview, depending on the integration): Find these solutions in the Security Store in Microsoft Purview Data Loss Prevention.

Network data security utilizes the same classifiers already configured in other Microsoft Purview policies, extending discovery and protection to the network layer through collection policies for data discovery, data loss prevention policies for protection, or both, depending on your organization's needs.

With network data security, you can identify, block, and alert on sensitive content that's shared through these interactions:

- Interactions with generative AI through browsers, apps, and add-ins, such as ChatGPT, Gemini, and Claude.
- Files uploaded to unsanctioned cloud storage providers, including Dropbox, Box, and Google Drive.
- Emails and file attachments shared with cloud email providers, such as Gmail.
- Form submissions through online form services, including Google Forms.
- Social media posts on common services like Facebook and X.

Before you begin

If you're new to Microsoft Purview collection policies, Microsoft Purview pay-as-you-go billing models, or Microsoft Purview DLP, you should familiarize yourself with the information in these articles:

- Collection Policies solution overview

- Learn about data loss prevention
- Learn about Microsoft Purview billing models
- Get started with activity explorer

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

- **Network data security with Microsoft Entra Global Secure Access** requires **one** of the following license combinations:
  - Microsoft 365 E7 per-seat licenses
  - Purview E5 (or equivalent) per-seat licenses *and* Entra Internet Access (or equivalent) licenses

- **Network data security with non-Microsoft SASE and secure browser solutions** requires:
  - Purview E5 (or equivalent) per-seat licenses *and* the Microsoft Purview pay-as-you-go billing model. Learn about Microsoft Purview billing models

> **Note**
>
> You must configure pay-as-you-go for your Microsoft 365 tenant to use Purview network data security with non-Microsoft SASE and secure browser solutions. For information on setting up the pay-as-you-go billing model, see **Enable Microsoft Purview pay-as-you-go features for new customers**.
>
> Pay-as-you-go is not required to be set up for integration with Microsoft Entra Global Secure Access.

How network data security works

From a broad perspective, the Microsoft Purview network data security solution combines two components:

Network security solution

The network data security solution integrates secure access service edge (SASE) and non-Microsoft secure browser solutions directly into Microsoft Purview. The integrated solutions

monitor network traffic and send the data to Microsoft Purview for classification and policy evaluation. When you apply protections via the use of DLP policies, the communication between the integrated solution and Microsoft Purview is in real time. If you are using network data security for monitoring only via collection policies, the communication is asynchronous.

For more information on which integrations are supported, see the Security Store in Microsoft Purview Data Loss Prevention.

> **Important**
>
> If you choose to integrate with non-Microsoft partners, they will be able to access and possibly store some policy configuration, including user identifiers. Their terms, conditions, and privacy policy will govern the usage and storage of this data.

Microsoft Purview

You configure the integration between Microsoft Purview and the network security solution using the Security Store. This integration establishes the bidirectional communication channel between the network security solution and Microsoft Purview.

Next, configure a collection policy or data loss prevention policy that defines the conditions, activities, and cloud apps that you want the network security solution to collect and send to Microsoft Purview.

- For more information on how to create a collection policy for network data security, see Scenario 1 Detect sensitive data shared with unmanaged cloud apps via network.
- For more information on how to create a data loss prevention policy for network data security, see Use Network Data Security to help prevent sharing sensitive information with unmanaged AI

Microsoft Purview shares the appropriate DLP and collection policy configuration with your integrated network security solution, and the solution sends any matching network data to Microsoft Purview for classification and policy evaluation. If you configure content capture in the collection policy, the full conversation that happens between the user and the AI app is captured and sent to Microsoft Purview as well.

After the data is classified, it's available in activity explorer and activity explorer in Data Security Posture Management (DSPM). If a data loss prevention policy is matched, and you have configured alerts, they will be available in DLP alerts.

After you configure the integration between Microsoft Purview and your network security solution, allow up to 24 hours for your policies to be distributed to the network security solution and for the first data to show up. Once the two services fully communicate with each other, it can take up to 30 minutes for data about a request from a client to a website or cloud app to appear in the audit log and activity explorer.

> **Important**
>
> Purview network data security policies don't apply to B2B guest users.

Supported network data security collection policy configuration

The Microsoft Purview side of the configuration is done via a collection policy. Here are the configuration options that are supported:

- **Conditions** - The conditions you can use in a network data security collection policy are the same as the conditions you can use in other Microsoft Purview policies. For example, you can use the **Content contains** > **Sensitive information types** condition to classify sensitive items that are being shared with generative AI and other unmanaged cloud apps.

- **Activities** - Network data security supports four activities:
  - **Text sent to or shared with cloud or AI app**.
  - **File uploaded to or shared with cloud or AI app**.
  - **Text received from cloud or AI app**.
  - **File downloaded from cloud or AI app**.

> **Note**
>
> The activities supported may differ depending on integrated SASE solution. Check with your SASE solution provider for details on supported activities. Microsoft Entra Global Secure Access supports all supported activities.

- **Data sources** - These are the locations that the endpoint device is communicating with.
  - **Unmanaged cloud apps** - Network data security collection policies support all the sources that are in the Microsoft Defender for Cloud Apps Cloud app catalog which includes over 35,000 discoverable cloud apps.
  - **Adaptive app scopes** - all apps in multiple categories including generative AI, cloud storage, collaboration, social network, and webmail.

Supported network data security data loss prevention policy configuration

The Microsoft Purview side of the configuration is done via a data loss prevention policy. Here are the configuration options that are supported:

- **Data sources** - These are the locations that the endpoint device is communicating with.
  - **Unmanaged cloud apps** - Network data security collection policies support all the sources that are in the Microsoft Defender for Cloud Apps Cloud app catalog which includes over 35,000 discoverable cloud apps.
  - **Adaptive app scopes** - all apps in multiple categories including generative AI, cloud storage, collaboration, social network, and webmail.

- **Conditions** - The conditions you can use in a network data security collection policy are the same as the conditions you can use in other Microsoft Purview policies. For example, you can use the **Content contains** > **Sensitive information types** condition to classify sensitive items that are being shared with generative AI and other unmanaged cloud apps.

- **Activities** - Network data security supports four activities:
  - **Text sent to or shared with cloud or AI app**.
  - **File uploaded to or shared with cloud or AI app**.
  - **Text received from cloud or AI app**.
  - **File downloaded from cloud or AI app**.

- **Actions** - Network data security supports **Audit only** and **Block** actions.

> ⓘ **Note**
>
> The activities and actions supported may differ depending on integrated solution. Check with your solution provider for details on supported activities. Microsoft Entra Global Secure Access supports all supported activities and actions.

Default policy from Microsoft Purview Data Security Posture Management

Microsoft Purview Data Security Posture Management (DSPM) offers recommendations to help monitor communications with generative AI apps. Select the recommendation **Extend insights into sensitive data in AI app interactions** to create a one-click policy named **DSPM for AI - Detect sensitive info shared with AI via network**. After it's created, you can edit this default policy for network data security as you would any collection policy.

Considerations for unmanaged cloud apps policies

Review this information when you configure policies that include unmanaged cloud apps, or when you troubleshoot unexpected policy behavior:

- When multiple catalog entries exist for the same app with differences in the entry name (for example, QwenAI and Qwen Chat), include all entries for the app to avoid unintended coverage gaps.
- Some unmanaged AI apps like Runway and Meta AI might intermittently send content in encoded form to dynamically generated endpoints, which can impact policy enforcement.
- Policies that target unmanaged apps can capture interactions from both the consumer and enterprise versions of an app when the app's URL is shared across instances (for example, ChatGPT consumer and ChatGPT enterprise).
- Inline evaluation size limits: Microsoft Purview evaluates up to 4 MB of content for uploadText and downloadText, and files up to 3 MB for uploadFile and downloadFile.

> **Note**
>
> The unmanaged cloud app features only apply to the consumer version of Microsoft Copilot. For more information on the enterprise version and available Purview features, see Learn more about Microsoft Copilot Enterprise protections.

Supported network protocols

All network data security integrations support classifying traffic sent and received from an endpoint device over HTTP and HTTPS protocols to websites, cloud apps, and generative AI services. Support for WebSocket protocol may differ depending on the integrated SASE or non-Microsoft secure browser solution. Check with your solution provider for details on supported protocols.

Accessing network data security data

Data from network data security appear in activity explorer, Data Security Posture Management activity explorer events, and if alerts are enabled, DLP alerts.

Activity explorer

In activity explorer, you can filter events with **enforcement plane** set to *network*. This filter shows you activities that network data security policies generate.

Billing model

Network data security uses the *request* as unit of measure for pay-as-you-go billing purposes when using non-Microsoft SASE and secure browser integrations. A request is each network call made from a device or browser to a website or API. This definition doesn't include the responses to the requests. For more information on pay-as-you-go billing for network data security, see Other Microsoft Purview solutions that use pay-as-you-go pricing and Requests.

Here are some examples:

Expand table

Activity	Data type	Example
Text sent to or shared with cloud or AI app	Human readable strings transmitted inline	- submitting a form with textual information - sending raw text or a prompt to a generative AI - the body of an email - sending JSON data to an API
File uploaded to or shared with cloud or AI app	Byte streams, including text based file, binary files, txt files, source code, documents, images, videos, .exe's, .pdf's, archive files	- Uploading a profile picture to social media - sending a document or .pdf file as an email attachment - sharing a document with generative AI - transferring a document or .zip files to a cloud storage solution

Next steps

- Scenario 1 Detect sensitive data shared with unmanaged cloud apps via network
- Use Network Data Security to help prevent sharing sensitive information with unmanaged AI
- If using Microsoft Entra Global Secure Access, see Create a content policy to filter network content

Last updated on 09/16/2026

Use Network Data Security to help prevent sharing sensitive information with unmanaged AI

> **Note**
>
> Some features used in this scenario are in preview.

This article uses the process you learned in Design a data loss prevention policy to show you how to create a Microsoft Purview data loss prevention (DLP) policy that helps prevent sharing sensitive information with unmanaged AI apps through network data security using an integrated SASE solution, such as Microsoft Entra Global Secure Access, or non-Microsoft secure browser solution. Work through this scenario in your test environment to familiarize yourself with the policy creation UI.

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy this DLP policy scenario is as important as policy design. Create and deploy a data loss prevention policy shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

Prerequisites and assumptions

> **Important**
>
> Before you start this procedure, read Learn about Microsoft Purview Network Data Security. It provides important information about the prerequisites and assumptions for this scenario, including considerations for unmanaged apps policies.

Before you begin, make sure the following prerequisites and assumptions are met:

- You have an supported SASE or secure enterprise browser integration. For more information on which integrations are supported, see the Security Store in Microsoft Purview Data Loss Prevention.
- If you're using Microsoft Entra Global Secure Access
  - The device must be Entra ID joined.
  - You must configure a Transport Layer Security inspection policy
  - You must configure a content policy in Microsoft Entra GSA Internet Access.
- If you are using a non-Microsoft SASE or secure enterprise browser provider
  - Ensure you've configured Purview pay-as-you-go billing. For more information, see Enable Microsoft Purview pay-as-you-go features for new customers.
  - Ensure you've completed the integration steps outlined in your provider's documentation.
- This procedure uses hypothetical distribution groups, one named *Finance Team*, and another group for the *Security Team*. You have to create these groups in your environment or substitute your own groups.

Policy intent statement and mapping

We want to embrace responsible AI use within our organization while protecting customer and organizational sensitive data from intentional or accidental exposure. Because the Finance department regularly handles highly sensitive information, we need to create a policy that blocks Finance users from sharing sensitive content with any unsanctioned generative AI application. Since many of our users have flexibility in which browser they choose to use, as well as the ability to use locally installed AI apps and Office add-ins, we need to ensure broad endpoint coverage through network data security protection. Given the sensitivity of the Finance department's access to data, we need to prevent financial data, personally identifiable information (PII), or confidential documents from being shared through text prompts or uploaded files. Then, to ensure efficient and quick incident management, we must generate alerts and ensure our security team is notified via email any time a block occurs. Lastly, we want this policy to take effect immediately to begin protecting company data as soon as possible.

Expand table

Statement	Configuration question answered and configuration mapping
Because the Finance department regularly handles highly sensitive information, we need to create a policy that blocks Finance users from sharing sensitive content with any unsanctioned generative AI application.	Choose cloud apps to apply the policy: - Select + **Add cloud apps** - Select the **Adaptive app scopes** tab - Choose **All unmanaged AI apps** and select **Add** - Select **Edit scope** - Select **Include only specific** - Choose the **Finance department** group
Since many of our users have flexibility in which browser they choose to use, as well as the ability to use locally installed AI apps and Office add-ins, we need to ensure broad endpoint coverage through network data security protection.	Choose where to enforce the policy: - Enable **Network and non-Microsoft secure browsers**
Given the sensitivity of the Finance department's access to data, we need to prevent financial data, personally identifiable information (PII), or confidential documents...	Customize advanced DLP rules: - Select + **Create rule** - Select + **Add condition** and choose **Content contains** - Select **Add** and chooose **Sensitive info types** - Select **ABA Routing Number**, **U.S. Bank Account Number**, **Credit Card Number**, **U.S. Social Security Number (SSN)** and select **Add** - Select **Add** and choose **Sensitivity labels** - Choose **Confidential** and select **Add** - Ensure the **Group operator** is set to **Any of these**
...from being shared through text prompts or uploaded files.	Actions: - Select + **Add an action** and choose **Restrict browser and network activities** - Select **Text sent to or shared with cloud or AI apps** and **File uploaded to or shared with cloud or AI apps** - Select **Block** for both
Then, to ensure efficient and quick incident management, we must generate alerts and ensure our security team is notified via email any time a block occurs.	Incident reports: - Set the severity level to **High** -Ensure **Send an alert to admins when a rule match occurs** is **On** - Select + **Add or remove users** and choose the **SecurityOps distribution group** - Ensure **Send alert every time an**

Statement	Configuration question answered and configuration mapping
	activity matches the rule is selected, and then **Save** the rule
Lastly, we want this policy to take effect immediately to begin protecting company data as soon as possible.	Policy mode: - Select **Turn the policy on immediately**

Configure SASE provider integration

> **Important**
>
> You must have a Secure Access Service Edge (SASE) or non-Microsoft secure browser provider integrated with Purview to begin discovering and protecting content shared over the network.

To integrate your provider with Purview, complete the following steps:

1. Sign in to the Microsoft Purview portal.
2. Open the **Data Loss Prevention** solution and select **Security Store** from the left navigation bar.
3. Select **Get solution** for the provider you're using.
4. Complete the setup steps provided by your integrated SASE or secure browser provider.

Steps to create policy

To create the DLP policy, complete the following steps:

1. Sign in to the Microsoft Purview portal.
2. Select **Data loss prevention** > **Policies** > **+ Create policy**.
3. Select **Inline web traffic**.
4. Select **Custom** from the **Categories** list and then select **Custom policy** from the **Regulations** list.
5. Choose **Next**.
6. Enter a policy name and provide an optional description. You can use the policy intent statement here.
7. Choose **Next**.
8. Select **+ Add cloud apps**.

9. Select the **Adaptive app scopes** tab, then choose **All unmanaged AI apps** and select **Add (1)**.
10. Select **Edit scope** on **All unmanaged AI apps**.
11. Select the **Include only specific** option on the **Add or edit the scope for All Unmanaged AI Apps**.
12. Select **+ Add inclusions**.
13. Select **Specific users and groups**.
14. Search for and select the **Finance department** group, then select **Add**.
15. Select **Save and close**.
16. Choose **Next**.
17. On the **Choose where to enforce the policy** page, ensure **Network and non-Microsoft secure browsers** is **On**, then select **Next**.

> ⓘ **Note**
>
> If using a non-Microsoft SASE or secure enterprise browser integration, you must have pay-as-you-go configured. Learn more about pay-as-you-go billing.

18. On the **Define policy settings** page, ensure **Create or customize advanced DLP rules** is selected and select **Next**.
19. On the **Customize advanced DLP rules** page, select **+ Create rule**.
20. Give the rule a unique **name** and optional description.
21. Under **Conditions**
    a. Select **+ Add condition** then choose **Content contains**.
    b. Select **Add** and choose **Sensitive info types**.
    c. Choose **ABA Routing Number**, **U.S. Bank Account Number**, **Credit Card Number**, **U.S. Social Security Number (SSN)** and select **Add**.
    d. Select **Add** and choose **Sensitivity labels**
    e. Choose **Confidential** and select **Add**.
    f. Ensure the **Group operator** is set to **Any of these** for the **Content contains group**.
22. Under **Actions**
    a. Select **+ Add an action** and choose **Restrict browser and network activities**.
    b. Select **Text sent to or shared with cloud or AI apps** and **File uploaded to or shared with cloud or AI apps**.
    c. Select **Block** for both.
23. Under **Incident reports**
    a. Set the **Severity level in admin alerts and reports** to **High**

    b. Ensure **Send an alert to admins when a rule match occurs** is **On**
    c. Select **+ Add or remove users** and choose the **SecurityOps distribution group**
    d. Ensure **Send alert every time an activity matches the rule** is selected
24. Select **Save**.
25. Review the rule configuration, ensure it's status is **On**, and select **Next**.
26. On the **Policy mode** page choose **Turn the policy on immediately** and then select **Next**.
27. Review the policy information then select **Submit** to create the policy.

Help prevent sharing via Microsoft Edge for Business to unmanaged AI apps from managed devices

This article uses the process you learned in Design a data loss prevention policy to show you how to create a Microsoft Purview data loss prevention (DLP) policy that helps prevent sharing sensitive information from organization managed devices to unmanaged AI apps in Microsoft Edge for Business. Work through this scenario in your test environment to familiarize yourself with the policy creation UI.

Use this scenario to use the Edge for Business browser as the control point to block the sharing of sensitive information to unmanaged AI apps. The policy that's created here applies across all Edge browser profiles (work profile, personal profile and InPrivate) on Windows devices that are managed by Microsoft Intune.

> **Important**
>
> Microsoft Purview inline protection in Microsoft Edge for Business for unmanaged apps doesn't support tenants that use multi-admin approval in Microsoft Intune. For more information, see Multi-admin approval.

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important as policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business disruptions.

Prerequisites and assumptions

This procedure uses hypothetical distribution groups, one named *Finance Team*, and another group for the *Security Team*.

> **Important**
>
> Before you start this procedure, read Learn about Data Loss Prevention for Cloud Apps in Edge for Business. It provides important information about the prerequisites and assumptions for this scenario.

Implementing DLP policies for unmanaged apps in the browser follows these phases:

1. Create a DLP policy targeting unmanaged apps in the browser (the procedure in this article) in the Microsoft Purview Data Loss Prevention portal.
2. The creation of the DLP policy triggers the Microsoft Edge management service to automatically create the Microsoft Edge configuration policies required to activate DLP policies in Edge for Business. The configuration policies use Microsoft Intune policies to fully activate your Microsoft Purview policies in Microsoft Edge.
3. (optional) Create a collection policy that targets unmanaged apps in the browser to identify other sensitive data sharing across your organization.

> **Important**
>
> Activating a Purview DLP policy for unmanaged cloud apps automatically adds included users to the required Microsoft Edge configuration policies. When the Purview DLP policy is set to block, included users are blocked from using unprotected browsers where the policy doesn't apply. The experience in Edge for Business isn't impacted. For more information see: activate your Microsoft Purview policy in Microsoft Edge.

Billing and licensing requirements

This feature uses pay-as-you-go billing or per-user licensing for Microsoft Purview capabilities or both. To help you understand and manage your usage, Microsoft Purview provides a **Usage center** in the Microsoft Purview portal. For more information, see Manage pay-as-you-go and per-user licensing usage. To learn more about Purview billing, see Purview billing models..

Policy intent statement and mapping

We need to block members of the finance team from sharing sensitive information to unmanaged AI apps in Edge for Business. Other teams don't have access to this highly sensitive information, so

the block only needs to apply to this team. When their prompts contain information like bank account, routing, or the SWIFT (Society for Worldwide Interbank Financial Telecommunication) numbers of our international customers, the sharing is blocked. We also have to meet alerting requirements. We want to notify our security team with an email every time there's a match to the policy. Lastly, we want the policy to take effect as soon as possible after testing, and we need to be able to see related activity within the system.

Expand table

Statement	Configuration question answered and configuration mapping
We need to block members of the finance team from sharing sensitive information to unmanaged AI apps via Edge...	- Choose where to apply the policy: **Edge for Business** -Administrative scope: **Full directory** - Where to apply the policy: **Adaptive app scopes** > **All unmanaged AI apps**
Other teams don't have access to this information, so the block only needs to apply to this team...	- scope for each app" **specific users and groups, Include users and groups** > **Finance Team**
When their text prompts contain information like bank account, routing or the SWIFT numbers of our international customers, the sharing should be blocked.	What to monitor: - use the **custom policy template** - Conditions for a match: **Content contains Sensitive info types** > **ABA Routing Number**, **Australia Bank Account Number**, **Canada Bank Account Number**, **International Bank Account Number (IBAN)**, **Israel Bank Account Number**, **Japan Bank Account Number**, **New Zealand bank account number**, **SWIFT Code**, **U.S Bank Account Number** - Action: **Restrict browser and network activities** > **Text upload** > **Block** and **File upload** > **Block**
We also have to meet alerting requirements. We want to notify our security team with an email every time there's a match to the policy.	- Incident reports: **Send an alert to admins when a rule match occurs** - Send email alerts to these people (optional): add the **Security team** - Send an alert every time an activity matches the rule: **selected** - Use email incident reports to notify you when a policy match occurs: **On** - Send notifications to these people: add individual admins as desired - You can also include the following information in the report: **select all options**
...Lastly, we want the policy to take effect as soon as possible after testing and need to be able to see related activity within the system....	Policy mode: **on in simulation**

Create the policy for unmanaged AI apps

1. Sign in to the Microsoft Purview portal.
2. Select **Data loss prevention** > **Policies** > **+ Create policy**.
3. Select **Inline web traffic**.
4. Select **Custom** from the **Categories** list and then select **Custom policy** from the **Regulations** list.
5. Choose **Next**.
6. Enter a policy name and provide a description. You can use the policy intent statement here.

> **Important**
>
> You can't rename policies.

1. Choose **Next**.
2. Select **+ Add cloud apps** > **Adaptive app scopes**
   a. Select **All unmanaged AI apps** > **Add.** Unmanaged apps in the Generative AI category are included in this scope.

> **Important**
>
> Not all unmanaged AI apps are supported in Edge for Business. Adaptive app scopes apply only to the supported unmanaged AI apps in Edge for Business. For more information, see Supported apps for browser DLP.

1. Select **Edit scope**
2. Select **Include only specific**
3. Choose **+ Add inclusions**
4. Select **Finance Team**
5. Select **Add** and then select **Save and Close** and then select **Next**.
6. On the **Choose where to enforce the policy** step, select **Edge for Business.**
7. On the **Define policy settings** page, the **Create or customize advanced DLP rules** option should already be selected.
8. Choose **Next**.
9. On the **Customize advanced DLP rules** page, select **+ Create rule**.

10. Enter a name and description for the rule.

11. Select **Add condition** and use these values:
    a. Select **Content contains**.
    b. Select **Add** > **Sensitive information types** > **Sensitive info types** > **ABA Routing Number**, **Australia Bank Account Number**, **Canada Bank Account Number**, **International Bank Account Number (IBAN)**, **Israel Bank Account Number**, **Japan Bank Account Number**, **New Zealand bank account number**, **SWIFT Code**, **U.S Bank Account Number**.

12. Select **Add**.

13. Under **Actions**, add an action with these values:

    a. **Restrict browser and network activities**

    b. **Text sent to or shared with cloud or AI apps** > **Block**

    c. **File uploaded to or shared with cloud or AI app** > **Block**

14. Under **Incident reports** select:
    a. Set **Use this severity level in admin alerts and reports** to **Low**.
    b. Set the toggle for **Send an alert to admins when a rule match occurs** to **On**.
    c. Under **Send email alerts to these people (optional)**, select **+ Add or remove users** and then add the email address of the security team.

15. Select **Save** and then select **Next**.

16. On the **Policy mode** page, select **Run the policy in simulation mode**.

17. Select **Next** and then select **Submit**.

18. Select **Done**.

19. The Microsoft Edge management service automatically creates the required configuration policies and required Microsoft Intune policies to activate your Microsoft Purview policies in Microsoft Edge. Additional permissions are required for Microsoft Intune administration and Microsoft Edge administration for this step.

> ⓘ **Important**

If the automatic Purview DLP configuration sync in Microsoft Edge fails, Microsoft Purview shows an error message. Purview doesn't enforce DLP and collection policies for unmanaged apps in Edge for Business until you resolve the error. An admin with the required permissions for unmanaged cloud apps must resync to resolve the error. For more information, see activate your Microsoft Purview policy in Microsoft Edge.

> **Note**
>
> When the action of the policy is configured to **Block**, users are blocked at the device level from opening Firefox and other browsers. They are also blocked from opening Chrome if Microsoft Purview extension for Chrome isn't installed or is out of date. In Chrome with Microsoft Purview extension, access to a dynamic set of generative AI apps is blocked. For more information, see: Activate your Microsoft Purview policies in Microsoft Edge

Steps to review outcomes of the policy in Microsoft Purview activity explorer

See Activity explorer overview for instructions on how to monitor and view activities in the Activity explorer tool.

Steps to review outcomes of Microsoft Purview policy in Microsoft Defender

See Investigate and respond in Microsoft Defender XDR for instructions on how to investigate and respond using Microsoft Defender.

Help prevent users from sharing sensitive information with cloud apps in Microsoft Edge for Business

Use this procedure to create a Microsoft Purview data loss prevention (DLP) policy that blocks users from exfiltrating sensitive information from business-managed apps (such as ServiceNow and Workday) in Microsoft Edge for Business. This procedure follows the policy design process described in Design a data loss prevention policy. Work through this scenario in your test environment to familiarize yourself with the policy creation UI.

Use the managed-app browser DLP policy scenario to block users from exfiltrating sensitive information from business-managed apps such as ServiceNow and Workday through Microsoft Edge.

Prerequisites:

- Onboard the apps to Microsoft Entra Conditional Access with session controls applied.
- Block access to the protected apps outside the Edge work profile.

When the policy applies:

This policy takes effect when users access the protected apps in Edge for Business and sign in with their work or school account for both the Edge work profile and the app. Edge for Business applies DLP policies for unmanaged devices only to the work profile. These policies don't apply to personal or InPrivate profiles unless the work profile that opens the InPrivate window has a policy applied. To target managed apps on unmanaged devices, enforce the work profile in Edge for Business.

> **Important**
>
> This article presents a hypothetical scenario with hypothetical values. It's only for illustrative purposes. Substitute your own sensitive information types, sensitivity labels, distribution groups, and users.

How you deploy a policy is as important as policy design. This article shows you how to use the deployment options so that the policy achieves your intent while avoiding costly business

disruptions.

Prerequisites and assumptions

The following policy-creation procedure uses a hypothetical distribution group named *External*. For more information on DLP protections applying in the browser, see browser data security resources.

> **Important**
>
> Read **Learn about Data Loss Prevention for Cloud Apps in Edge for Business** before you start this procedure. It provides important information about the prerequisites and assumptions for this scenario.

Setting up a policy to protect data sharing with Microsoft Entra-managed apps in the browser follows these phases:

1. Onboard apps to Conditional Access app control.
2. Import user groups from connected apps. Importing user groups is necessary for you to target groups in your Entra Conditional Access policy and your Purview policies for managed apps in Edge for Business.
3. Create a Microsoft Entra Conditional Access policy that's configured with custom session controls enabled and using the client apps condition for browser.
4. Enable Edge for Business in-browser protection, configured to enforce Edge work profile sign in for business apps on all devices.
5. Create a Microsoft Purview DLP policy targeting user interactions with managed apps.
6. (optional) Activate Protected Clipboard and Screen Capture prevention capabilities in the Microsoft Admin Portal settings for Microsoft Edge. See the Get started with Protected Clipboard for Microsoft Edge for Business instructions.
7. Review outcomes of Microsoft Purview policy in Microsoft Defender.

> **Important**

The user and the app must both be in scope for all the prerequisite protections for the policy to apply to the user in Edge.

Policy intent statement and mapping

We need to allow users to access resources in business apps from their BYOD and personal devices, but block them from downloading the data to those devices. Contractors and vendor employees use these types of devices to collaborate for their work activities. When they attempt to download files containing sensitive information, like customer banking information, the action should be blocked. We also have to meet alerting requirements. Lastly, we want this to take effect as soon as possible.

Expand table

Statement	Configuration question answered and configuration mapping
We need to allow users to access resources in business apps like Workday from their BYOD and personal devices, but block them from downloading the data to their devices ...	- Choose where to apply the policy: **Enterprise apps and Devices** -Administrative scope: **Full directory** - Where to apply the policy: **Managed apps** > **Workday**
Contractors and vendor employees use these types of devices to collaborate for their work activities....	- scope alongside apps" **specific users and groups, Include users and groups** > **External**
When they attempt to download files containing sensitive information, like customer banking information, the action should be blocked.	What to monitor: - use the **custom policy template** - Conditions for a match: **Content contains Sensitive info types** > **ABA Routing Number**, **Australia Bank Account Number**, **Canada Bank Account Number**, **International Bank Account Number (IBAN)**, **Israel Bank Account Number**, **Japan Bank Account Number**, **New Zealand bank account number**, **SWIFT Code**, **U.S Bank Account Number** - Action: **Restrict browser and network activities** > **File download ** > **Block**.
We also have to meet alerting requirements. Our security team must have a way to investigate and take actions against the policy match outcomes.	- Incident reports: **Send an alert to admins when a rule match occurs** is on by default
...Lastly, we want this to take effect as soon as possible....	Policy mode: **on **

Steps to set up prerequisites

Complete the following steps to set up the prerequisites before you create the DLP policy:

1. Onboard apps to Conditional Access app control. For more information, please see Onboard non-Microsoft IdP catalog apps for Conditional Access app control and Onboard non-Microsoft IdP custom apps for Conditional Access app control.

2. Import user groups. Sign into the Microsoft Defender XDR, select **Settings** > **Cloud Apps** > **System** > **User groups** > **+ Import.** For more information, please see Import user groups from connected apps.

3. Sign into the Microsoft Entra admin center.

4. Create a new Conditional Access policy that targets cloud apps with session controls and using the and using the client apps condition for browser..
   a. **Custom policy** must be selected in the session controls dropdown.
   b. **Browser** must be selected in **Conditions** > **Client Apps**

5. In the Microsoft Defender portal at https://security.microsoft.com), go to System > Settings > Cloud apps > Conditional Access App Control section > Edge for Business protection. Or, to go directly to the Edge for Business protection page, use https://security.microsoft.com/cloudapps/settings?tabid=edgeIntegration .

6. Configure in-browser protection for Edge on, selecting **Allow access only from Edge** and **All devices**

> **Important**
>
> To include groups in policies targeting managed cloud apps, you must first **import user groups from connected apps**.

Steps to create the policy

1. Sign in to the Microsoft Purview portal.
2. Select **Data loss prevention** > **Policies** > **+ Create policy**.
3. Select **Enterprise apps and Devices**.
4. Select **Custom** from the **Categories** list and then **Custom policy** from the **Regulations** list.
5. Choose **Next**.
6. Provide a policy name and give a description. You can use the policy intent statement here.

7. Select **Next**.
8. Accept the default **Full directory** on the **Assign admin units** page.
9. Choose **Next**.
10. Select **Managed cloud apps**
11. Select **Specific users and groups**.
12. Choose + **Include** and then **Include groups**.
13. Select **External**.
14. Choose **Done** and then choose **Next**.
15. Select + **Include managed apps**.
16. Select **Workday**
17. Choose **Done**
18. On the **Define policy settings** page, the **Create or customize advanced DLP rules** option should already be selected.
19. Choose **Next**.
20. On the **Customize advanced DLP rules** page, select + **Create rule**.
21. Name the rule and give a description.
22. Select **Add condition** and use these values:
    a. Select **Content contains**.
    b. Select **Add** > **Sensitive information types** > **Sensitive info types** > **ABA Routing Number**, **Australia Bank Account Number**, **Canada Bank Account Number**, **International Bank Account Number (IBAN)**, **Israel Bank Account Number**, **Japan Bank Account Number**, **New Zealand bank account number**, **SWIFT Code**, **U.S Bank Account Number**.
23. Choose **Add**.
24. Under **Actions**, add an action with these values:
    a. **Restrict browser and network activities**
    b. **File download** > **Block**
25. Under **Incident reports** select: 2. The toggle for **Send an alert to admins when a rule match occurs** defaults to **On**.
26. Choose **Save** and then choose **Next**.
27. On the **Policy mode** page, choose **On**.
28. Choose **Next** and then choose **Submit**.
29. Choose **Done**.

> **Important**
>
> The DLP policy won't be applied in Edge until all requirements are met.

Steps to activate Microsoft Edge for Business Protected Clipboard and Screen Capture protections (optional)

See the Get started with Protected Clipboard for Microsoft Edge for Business instructions.

Steps to review outcomes of a Microsoft Purview policy in Microsoft Defender

See Investigate and respond in Microsoft Defender XDR for instructions on how to review and act on policy match outcomes.

Learn about investigating data loss prevention alerts

This article introduces you to the alert investigation flow and the tools you can use to investigate DLP alerts.

Before you begin

1. Administrative units
2. Learn about Microsoft Purview Data Loss Prevention
3. Plan for data loss prevention (DLP) - by working through this article you will:
   a. Identify stakeholders
   b. Describe the categories of sensitive information to protect
   c. Set goals and strategy
4. Collection Policies solution overview
5. Collection policy reference
6. Data Loss Prevention policy reference - this article introduces all the components of a DLP policy and how each one influences the behavior of a policy
7. Design a DLP policy - this article walks you through creating a policy intent statement and mapping it to a specific policy configuration.
8. Create and Deploy data loss prevention policies - This article presents some common policy intent scenarios that you map to configuration options, then it walks you through configuring those options.
9. Learn about investigating data loss prevention alerts - This article introduces you to the lifecycle of alerts from creation, through final remediation and policy tuning. It also introduces you to the tools you use to investigate alerts.

The lifecycle of a DLP alert

All alerts and your interaction with them go through these six steps:

- Trigger
- Notify
- Triage
- Investigate
- Remediate
- Tune

Trigger

The life of a Microsoft Purview Data Loss Prevention (DLP) alert starts when the conditions defined in the policy are matched. When a policy match occurs, the actions defined in the policy are triggered, which can include generating an alert if the policy is configured to do so.

DLP policies are typically configured to monitor for and generate alerts when:

- Sensitive information, such as personally identifying data or intellectual property, is exfiltrated from your organization.
- Sensitive information is shared inappropriately with people outside or inside your organization.
- Users engage in risky activities, such as downloading sensitive information to removable media.

Notify

When an alert is generated, it's sent to the Microsoft Defender portal as an incident and the DLP alert management dashboard. DLP policies can be configured to send notifications to users, administrators, and other stakeholders via email.

In the notify phase Microsoft Purview:

- Reports on DLP policy matches and user overrides.
- You can use Activity explorer to view DLP related activities and filter for report generation purposes.

To export activity data for reporting use Export-ActivityExplorerData (ExchangePowerShell) | Microsoft Doc by using O365 Management Activity API or Incident API.

> **Note**
>
> The Microsoft Defender portal retains incidents for six months. The DLP alert management dashboard retains alerts for 30 days.

Triage

In this step, you analyze an alert and any associated logs and decide if the alert is a true positive or a false positive. If it's a true positive, you set the priority of the alert based on the severity of the issue and its impact on your organization and assign an owner. If it's a false positive, you can unblock the user and move on to the next alert.

Defender portal groups DLP events into incidents. Incidents are a collection of related alerts that are grouped together based on all the other signals that Defender is receiving. For

example, when you have a DLP policy configured to monitor and alert on sensitive files on SharePoint sites, and a user downloads a file from a SharePoint site and then uploads it to a personal OneDrive, and then shares it with an external user, Defender groups all of those alerts into a single incident. This is a powerful feature that allows you to focus on the most important alerts first.

In the Defender portal you can immediately start triaging incidents and use tags, comments, and other features to structure your incident management. You should be utilizing the Incidents page in the Microsoft Defender portal to manage your DLP alerts. You can filter the Incidents queue to view all incidents with Microsoft Purview DLP alerts by selecting **Filters** and choose **Service Source: Data Loss Prevention**.

If you have enabled sharing of insider risk management data with Microsoft Defender XDR (preview) - you'll see the severity level of the Insider Risk Management policy that is associated with a user in the DLP alerts page. Insider Risk Management severity levels are: **Low**, **Medium**, **High**, and **None**. You can use this information to prioritize your investigation and remediation efforts. This information will also be available in the Microsoft 365 Defender portal in the details of the incident.

Triage with Microsoft Security Copilot

Another tool you can use to help triage alerts it Microsoft Security Copilot. Security Copilot is a cloud-based AI platform that can assist security and compliance professionals in protecting their organization's data. It is available in the DLP Alerts dashboard and in Data Security Posture Management.

Triage with Microsoft Security Copilot DLP Alert Triage Agent (preview)

In preview, Microsoft Security Copilot for Purview supports the DLP Alert Triage Agent. Microsoft Security Copilot agents are AI powered processes that are designed to help you with specific role based tasks.

Investigate

The main goal of the investigation stage is for the assigned owner to correlate evidence, determine the cause and full impact of the alert and decide on a remediation plan. The assigned owner is responsible for deeper investigation and remediation of the alert. The primary alert investigation tools are the Microsoft Defender portal and the DLP alert management dashboard. You might also use Activity explorer to investigate alerts. You can also share alert events with other users in your organization.

You can take advantage of DLP features like:

- Evidence collection for file activities on devices makes files like email and documents that matched a policy easily accessible.
- Use Content explorer to deeply investigate the content in the incident.

You can use both Microsoft Defender portal and Purview tools to triage and investigate alerts, but the Microsoft Defender portal provides more capabilities for managing alerts and incidents, such as:

- View all your DLP alerts grouped under incidents in the Microsoft Defender XDR incident queue.
- View intelligent inter-solution (DLP-MDE, DLP-MDO) and intra-solution (DLP-DLP) correlated alerts under a single incident.
- Hunt for compliance logs along with security under Advanced Hunting.
- In-place admin remediation actions on user, file, and device.
- Associate custom tags to DLP incidents and filter by them.
- Filter by DLP policy name, tag, Date, service source, incident status, and user on the unified incident queue.

If you're sharing insider risk management data with Defender (preview), you can see the **User activity summary** of all the exfiltration activities the user has engaged in up to the past 120 days.

Remediate

Your remediation plan is unique to your organization's policies, the industry, the geopolitical regulations it must comply with, and business practices. How your organization chooses to respond to an alert revolves around the accuracy of the alert (true positive, false positive, false negative), the severity of the issue, and the impact on your organization.

Remediation actions can include:

- Monitor only, no further action required.
- No further action required because the actions take by the policy sufficiently mitigated the risk.
- Risk mitigated by automated policy actions but user education is necessary.
- The issue wasn't fully mitigated by the policy, so further clean up and risk mitigation is required along with more user training.
- Via Adaptive Protection in Data Loss Prevention (preview) where DLP integrates with Insider Risk Management, you can assign a risk level to the user for further monitoring and actions.

With the Defender portal, you can immediately take remediation actions on alerts and incidents. For example:

- Reset password
- Disable account
- View user activity
- Actions on DLP detections
- Remove document
- Apply sensitivity label
- Unshare
- Download email
- Advanced Hunting
- Isolate Device
- Collect investigation pack from Device
- Run AV Scan
- Quarantine file
- Disable user
- Reset pwd
- Delete email
- Move mail to other mailbox folder
- Download file

Tune

Based on the accuracy and effectiveness of your policy, you might need to update it so it remains effective. You've already tuned your policy during the policy creation and deployment process, but as your data estate and business needs change, policies have to be updated to continue to be effective. These changes are best tracked in the policy intent statement and the policy configuration.

Items you tune:

- The scope of the policy.
- The conditions required for a policy match.
- The actions taken when a policy match occurs.
- Notifications sent to users and administrators.

For more information about mapping business needs to policy design and testing policies, see:

- Design a data loss prevention policy
- Test your Data Loss Prevention policies

Toolsets

There are multiple tools that you can use to investigate and manage Microsoft Purview Data Loss Prevention (DLP) alerts. There are:

- Microsoft Defender portal
- Microsoft Purview portal Alerts dashboard
- Activity explorer
- Content explorer
- Key features in the embedded experience
- Key features in the standalone experience
- Data Security Posture Management

Microsoft recommends using the unified incident queue in Microsoft Defender portal to manage your DLP alerts. However, your organization may have needs that can be met by using the DLP alert management dashboard in addition to the Microsoft Defender portal.

Microsoft Defender portal

- DLP alerts are integrated with other events and alerts into a single incident queue, which provides a more complete picture of the incident.
- Six months of incident history is available.
- Advanced hunting is available.
- Investigate data loss incidents with Microsoft Defender XDR - You can manage DLP incidents along with security incidents from **Incidents & alerts** > **Incidents** on the quick launch of the Microsoft Defender portal.
- Responding to your first incident in Microsoft Defender XDR
- Incident response with Microsoft Defender XDR
- Prioritize incidents in Microsoft Defender XDR
- Manage incidents in Microsoft Defender XDR
- Investigate incidents in Microsoft Defender XDR
- Investigate alerts in Microsoft Defender XDR
- Proactively hunt for threats with advanced hunting in Microsoft Defender XDR

Microsoft Purview portal

- Alerts dashboard, Activity explorer, and Content explorer are all available in the Microsoft Purview portal. You can summarize alerts using Microsoft Security Copilot Investigate a DLP alert
- You can set an alert status to **Investigating**.
- You can share alert events with other users in your organization.

- Download files from OneDrive and SharePoint (data classification content viewer role is required for this action)

If you're new to using the DLP Alerts dashboard, you should read through these articles to help you get started.

- Get started with the data loss prevention Alerts dashboard
- Share data loss prevention alert events (preview)
- Get started with data loss prevention alerts
- Get started with activity explorer
- Get started with content explorer

Next steps

- Investigate data loss prevention alerts with Microsoft Defender XDR
- Get started with the data loss prevention Alerts dashboard

Last updated on 11/18/2025

Get started with the Data Loss Prevention Alerts dashboard

Microsoft Purview Data Loss Prevention (DLP) policies can take protective actions to prevent unintentional sharing of sensitive items. You can be notified when an action is taken on a sensitive item by configuring alerts for DLP.

You use the DLP alert management dashboard in the Microsoft Purview portal to view alerts, events, and associated metadata for DLP policy violations.

If you're new to DLP alerts, you should review Get started with the data loss prevention alerts.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Microsoft Purview portal shows alerts for DLP policies that are enforced on the following workloads:

- Exchange email
- SharePoint sites
- OneDrive accounts
- Teams chat and channel messages
- Devices
- Instances
- On-premises repositories
- Fabric and Power BI

Prerequisites and permissions

Make sure you have the necessary prerequisites:

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Roles and Role Groups

If you want to view the DLP alert management dashboard or to edit the alert configuration options in a DLP policy, you must be a member of one of these role groups:

- Compliance Administrator
- Compliance Data Administrator
- Security Administrator
- Security Operator
- Security Reader
- Information Protection Admin
- Information Protection Analyst
- Information Protection Investigator

To learn more about these role groups, see Permissions in the Microsoft Purview portal.

Here's a list of applicable role groups:

- Information Protection
- Information Protection Admins
- Information Protection Analysts
- Information Protection Investigators

To access the DLP alert management dashboard, you need the *Manage alerts* role and either of these two roles:

- DLP Compliance Management
- View-Only DLP Compliance Management

To access the Content preview feature and the Matched sensitive content and context features, you must be a member of the *Content Explorer Content Viewer* role group, which has the *Data classification content viewer* role preassigned.

Configure DLP alerts

To learn how to configure an alert in your DLP policy, see Create and Deploy data loss prevention policies.

> **Important**

Your organization's audit log retention policy configuration controls how long an alert remains visible in the console. See Manage audit log retention policies for more information.

Investigate a DLP alert

There are three tools you can use to investigate DLP alerts in the DLP Alerts dashboard:

- The **DLP Alerts** dashboard in standard view
- The **DLP Alerts** dashboard in Alert Triage Agent (Preview)
- Microsoft Security Copilot

Standard view

To investigate an alert using the standard DLP Alerts dashboard view, follow these steps:

1. Sign in to the Microsoft Purview portal > **Data loss prevention**.
2. Select **Alerts** to view the **DLP Alerts** dashboard.
3. Use the **Filter** fields to refine the list of alerts.
4. Choose **Customize columns** to list the properties you want to see.
5. To sort the results in ascending or descending order, double-click the column header.
6. Double-click an alert for more information about it.
7. The **Details** tab opens by default and provides high-level information about the alert.
8. Select **Summarize with Copilot**. This causes the Microsoft Security Copilot to generate a summary of the alert. The alert summary will contain the:

    - alert severity
    - alert title
    - the name of the policy that was matched
    - the name of the file involved and a link to the file
    - alert status
    - the email address of the user who performed the action that matched the policy

9. Select the ellipsis in the **Security Copilot** summary to:

    - copy the summary to the clipboard
    - regenerate the summary
    - open the alert in the Security Copilot standalone experience.

10. Select **View details** to open the **Overview** tab. The **Overview** tab provides a summary of the following information:

    - What happened
    - Who performed the actions that caused the policy match
    - Additional information about the policy match

11. The **Events** tab lists all of the events associated with the alert. Select any event in the list to get detailed information about the event. For each event, choose the **Actions** drop down for a list of actions you can take on the alert, such as verifying whether or not the alert has identified a true match or a false positive.
12. The **User activity summary** tab requires that sharing be turned *On* in the **insider risk management** settings Once enabled, the **User activity summary** tab provides all the exfiltration activities the user has engaged in (up to the past 120 days). Users must be in scope of an insider risk management policy to see the **User activity summary** tab.
13. After you investigate the alert, return to the **Overview** tab where you can **View details** to triage and manage the disposition of the alert, add comments and assign ownership of the alert. (To see the history of workflow management.)
14. After you take the required action for the alert, set the **Status** of the alert to **Resolved**.

Alert Triage Agent

In preview, Microsoft Security Copilot in Purview supports Security Copilot Agents (preview). The Alert Triage Agent helps reduce the time it takes to triage alerts by reasoning over the alerts and identifying the ones that pose the greatest risk to your organization.

1. Sign in to the Microsoft Purview portal > **Data loss prevention** with appropriate permissions, see DLP agent permissions and roles for Data Loss Prevention workloads or IRM agent permissions and roles for Insider Risk Management workloads.

2. Select **Alerts** to view the **DLP Alerts** dashboard.

3. Set the Alerts page view toggle to **Alert Triage Agent**.

4. Choose the category (**All**, **Needs attention**, **Less urgent**, or **Not categorized**) to see the alerts that are relevant to your task.

5. Select the triaged alert to view the **Agent summary**, an **Overview**, and **Events** associated with the alert.

> **Note**
>
> If an alert contains multiple assets, the agent will summarize the top 10 assets that contributed to the summary of findings and the decision on which category to assign the alert to.

6. After you review the summary, you can select **Manage alert** to assign it to an analyst, change the status of the alert or add more comments.

Security Copilot

Security Copilot is a cloud-based AI platform that can assist security and compliance professionals in protecting their organization's data. You can use it to summarize Microsoft Purview alerts, triage alerts and to drill down into your Microsoft Purview data. It is available in the DLP Alerts dashboard and in Data Security Posture Management.

Create a shareable link to an alert event

Users with the appropriate permissions can view Microsoft Purview Data Loss Prevention (DLP) alerts in the DLP Alerts console. However, as alerts are triaged and investigated, you may want to share alert events with users who don't have access to DLP and the alerts console. You can create a shareable link to an alert event:

1. In the Purview Portal, navigate to **Data Loss Prevention**, and then select **Alerts**.
2. Select an alert, and then select **View details**.
3. On the Alert details screen, select the **Events** tab just below the alert title to view the events contained in this alert.
4. Select the event you want to share, and then click the **Actions** button at the bottom of the screen to see the **Actions** menu.
5. Select Copy event link, and then select Copy to copy the shareable link to the event.
6. Now you can paste the link from your clipboard to share the link via chat, email, or other means.

View other matched conditions in DLP events

Microsoft Purview supports showing matched conditions in a DLP event to reveal the exact cause for a flagged DLP policy. This information shows up in:

- DLP Alerts console

- Activity explorer
- Microsoft Defender for Business portal

In the **Events** tab, open **Details** to see **Other matched conditions**.

Enhanced matched conditions for Exchange Online (preview)

For Exchange Online DLP events, matched conditions include enhanced detail for non-sensitive information type (SIT) conditions in addition to SIT matches. For the full list of supported condition categories and detail levels, see Enhanced matched conditions for Exchange DLP events.

Prerequisites

Make sure the following requirements are met before you use matched conditions on endpoints:

- Must be running Windows 10 x64 (build 1809 or later) or Windows 11.
  - See March 21, 2023—KB5023773 (OS Builds 19042.2788, 19044.2788, and 19045.2788) Preview for required minimum Windows Operating System builds.
- Matched conditions data is available for valid E3 and E5 license holders.
- Enable Auditing.
- Enable Advanced classification scanning and protection.

Matched events information is supported for these conditions

Get started with the data loss prevention alerts

Your Microsoft Purview Data Loss Prevention (DLP) policies can be configured to generate alerts when the conditions in a rule are matched. Alerts are configured in DLP policy rules.

For a brief overview of alerts see:

- DLP Alerts
- Incident reports

This article includes the licensing and permission details and other crucial information you need as you work with alerts.

DLP alerts can be investigated and managed in the Microsoft Defender XDR dashboard and in the Microsoft Purview portal. The Microsoft Defender XDR dashboard is the recommended location for investigating and managing DLP alerts. The Microsoft Purview portal is the recommended location for creating and editing DLP policies.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Types of DLP alerts

Alerts can be sent every time an activity matches a rule or they can be aggregated to cut down on the noise. There are two types of alerts that can be configured in DLP policies.

Single-event alerts Single-event alerts are typically used in policies that monitor for highly sensitive events that occur in a low volume, like a single email with 10 or more customer credit card numbers being sent outside your organization. By default when events from a single rule occur in a one minute window of each other they are aggregated for E5 license and 15 mins for E3 license. In preview, single-event alerts can be aggregated on per rule per user basis. This is called user and rule-based alert aggregation.

Aggregate-event alerts are typically used in policies that monitor for events that occur in a higher volume over a period of time. For example, an aggregate alert can be triggered when 10 individual emails each with one customer credit card number is sent outside your org over 48 hours.

Before you begin

Before you begin, make sure you have these prerequisites:

Licensing for alert configuration options

The following licensing requirements apply to each alert configuration option:

- **Single-event alert configuration**: All organizations with a DLP subscription (E1, E3, E5, F1, G1, E3, G3, E5, G5) can configure policies to generate an alert for every time a triggering activity occurs.
- **Aggregated alert configuration**: To configure aggregate alert policies based on a threshold, you must have either of the following configurations:
  - An A5 subscription
  - An E5 or G5 subscription
  - An E1, F1, or G1 subscription or an E3 or G3 subscription that includes one of the following features:
    - Office 365 Advanced Threat Protection Plan 2
    - Microsoft Purview Suite (formerly known as Microsoft 365 E5 Compliance)
    - Microsoft 365 eDiscovery and Audit add-on license

Customers who use endpoint DLP and who are eligible for Teams DLP will see their endpoint DLP policy alerts and Teams DLP policy alerts in the DLP alert management dashboard.

Roles and Role Groups

If you want to view the DLP alert management dashboard or to edit the alert configuration options in a DLP policy, you must be a member of one of these role groups:

- Compliance Administrator
- Compliance Data Administrator
- Security Administrator
- Security Operator
- Security Reader
- Information Protection Admin

- Information Protection Analyst
- Information Protection Investigator

To learn more about these role groups, see Permissions in the Microsoft Purview portal

Here's a list of applicable role groups. To learn more about these role groups, see Permissions in the Microsoft Purview portal.

- Information Protection
- Information Protection Admins
- Information Protection Analysts
- Information Protection Investigators

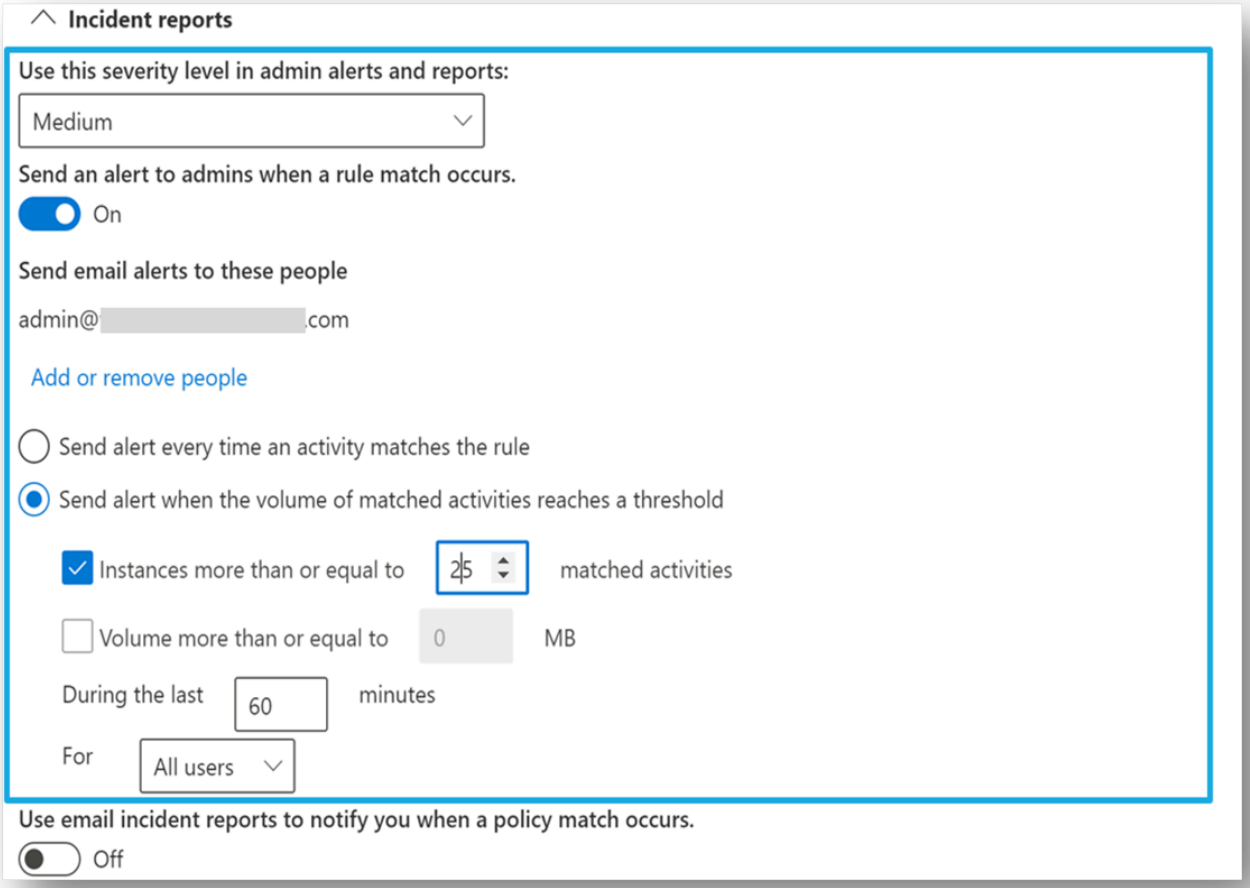
To access the DLP alert management dashboard, you need the *Manage alerts* role and either of these two roles:

- DLP Compliance Management
- View-Only DLP Compliance Management

To access the Content preview feature and the Matched sensitive content and context features, you must be a member of the *Content Explorer Content Viewer* role group, which has the *Data classification content viewer* role preassigned.

> **Tip**
>
> If the admin requires access to alerts but not contextual/sensitive information, you can create and assign a custom role that does not include Data Classification Content Viewer permission.

Configure DLP alerts



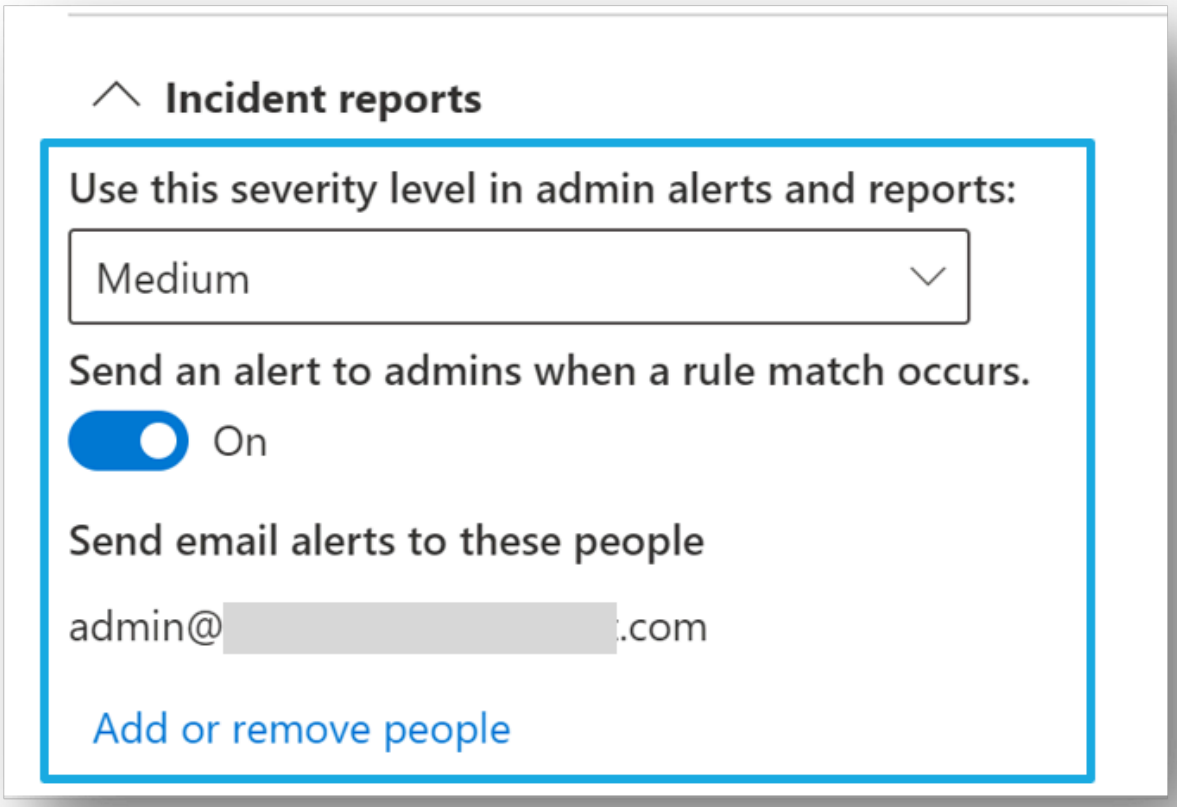
To learn how to configure an alert in your DLP policy, see Create and Deploy data loss prevention policies. There are different alert configuration experiences depending on your licensing.

> **Note**
>
> It may take up to 3 hours to generate alerts after you configure or modify existing alerts in a DLP policy.

An Alert email, Incident Report email, and User Notification will only be sent once per document. If a document with a **Content is Shared** condition is shared twice, there will still be only one notification.

Aggregate event alert configuration

If you're licensed for aggregated alert configuration options, then you'll see options to generate alerts for each rule match, when thresholds are met, and within a defined time window when you create or edit a DLP policy.



This configuration allows you to set up a policy to generate an alert:

- every time an activity matches the conditions in a rule for default aggregation based on a rule or of user and rule based aggregation.
- when the defined threshold is met or exceeded based on the number of matches or the volume of or on the volume of exfiltrated data
- for activities that meet the criteria that you define within a speficied time window

Single event alert configuration

If you're licensed for single-event alert configuration options, then you'll see the single-event alert settings when you create or edit a DLP policy. Use this option to create an alert that's raised every time a DLP rule match happens.

User and rule based alert aggregation (preview)

When you enable user based alert aggration in DLP setting at the tenant level, single event alerts are aggregated based on users. The rule match events must occur within the configurable time window (15, 30, 45 and 60 minutes). Alerts are generated per rule match event per user.

Compare alert aggregation options

Expand table

I want DLP to...	Time window	Aggregation type	Notes
...generate single alert when an email containing credit card information is sent by any number of users.	These windows *are not* configurable by the admin -E5: 60 seconds -E3: 15 minutes	- User based alert aggregation is set to **Off** at the tenant level. - Single event alert aggregation configured	- Applies to multiple users for one rule.

I want DLP to...	Time window	Aggregation type	Notes
		at the rule level and is available if match occurs within time window. -Aggregate DLP rule matches of multiple users into one alert.	
...generate one alert for each email sender when an email containing credit card information is sent out.	This time window *is configurable* by the admin at the tenant level. - 15 - 60 minutes	- User based alert aggregation is set to **On** at the tenant level. - Single event alert aggregation configured at the rule level. -Aggregate DLP rule matches by single user into one alert.	- For single user per rule. - Expect an increase in alert volume. - If the alert is closed within the aggregation time window and a new match occurs for the same user and rule, then the new rule match will be aggregated into the same alert.
...to generate an alert when more than 100 sensitive files are accessed by multiple users within 60 minutes.	- Configured at the rule level, 60-999 minutes.	- Threshold based aggregation - Aggregate DLP rule matches based on count of matches. - User based alert aggregation not applicable.	- pivots on rules - Use this for multiple users for one rule. - Only works for the **All users** option.
...to generate an alert when more than 25 MB data is exfiltrated by multiple users within 60 minutes.	Configured at the rule level, 60-999 minutes.	-Threshold based aggregateon based on the volume of data. - user based alert aggregation not applicable.	- pivots on rules - Use this for multiple users for one rule. - Only works for the **All users** option.

Types of DLP alert events

Here are some of the events associated with an alert. In the Alert dashboard, you can choose a particular event to view its details.

Review event details

The following table describes the event details shown for alert events.

Expand table

Property name	Description	Event types
ID	unique ID associated with the event	all events
Location	workload where the event was detected	all events
time of activity	time of the user activity that matched the criteria of the DLP policy	

Review affected entities in an alert

The following table lists the entities that can be associated with a DLP alert event.

Expand table

Property name	Description	Event types
user	user who took the action that caused the policy match	all events
hostname	host name of the computer where the DLP policy match occurred	device events
IP address	IP address of the computer where the DLP policy match occurred	device events
sha1	SHA-1 hash of the file	device events
sha256	SHA-256 hash of the file	device events
MDATP device ID	endpoint device MDATP ID	
file size	size of the file	SharePoint, OneDrive, and device events
file path	the absolute path of the item involved with the DLP policy match	SharePoint, OneDrive, and devices events
email recipients	if an email was the sensitive item that matched the DLP policy, this field includes the recipients of that email	Exchange events
email subject	subject of the email that matched the DLP policy	Exchange events
email attachments	names of the attachments in the email that matched the DLP policy	Exchange events
site owner	name of the site owner	SharePoint and OneDrive events
site URL	full of the URL of the SharePoint or OneDrive site where the	SharePoint and OneDrive

Property name	Description	Event types
	DLP policy match occurred	events
file created	time of creation of the file that matched the DLP policy	SharePoint and OneDrive events
file last modified	the last time that the file that matched the DLP policy was changed	SharePoint and OneDrive events
file size	size of the file that matched the DLP policy	SharePoint and OneDrive events
file owner	owner of the file that matched the DLP policy	SharePoint and OneDrive events

Review policy details for an alert

The following table describes the policy-related details available for alert events.

Expand table

Property name	Description	Event types
DLP policy matched	name of the matched DLP policy	all events
rule matched	name of the matched DLP policy rule	all events
sensitive information types (SIT) detected	SITs that were detected as part of the DLP policy match	all events
actions taken	actions that were taken that caused the DLP policy match	all events
violating action	action on the endpoint device that raised the DLP alert	device events
user overrode policy	did the user override the policy via a policy tip	all events
use override justification	the text of the reason provided by the user for the override	all events

Important

Your organization's audit log retention policy configuration controls for how long an alert remains visible in the console. For more information, see **Manage audit log retention policies**.

Get started with the data loss prevention analytics

Microsoft Purview data loss prevention (DLP) analytics helps customers understand top data protection risks, blind spots, and policy and posture improvement opportunities in their organization. It can help you investigate these risks using intelligent Purview features, and mitigate them in a few simple steps.

This section introduces DLP analytics concepts, prerequisites, and configuration steps to start using it.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

DLP analytics shows customers their top data loss risks and vulnerabilities and how to mitigate them through new or improved policies. DLP analytics helps mitigate risks in three ways:

- It communicates the top item oversharing risks through the **Risk Spotlighting** card on the DLP overview page in the Microsoft Purview portal. Analytics reports on top risks, blind spots, and policy improvement opportunities based on past 30 days data.
- Help prevent users from sharing additional sensitive information externally by creating new DLP policies with one click. Policy creation recommendations are based on industry best practices and risks found in the tenant.
- Improve the accuracy of existing policies via the **Policy Improvement** card with one click.

Risks and recommendations are refreshed every week.

When DLP analytics is enabled, it scans signals on user activity, sensitive data sharing patterns, and policy information to generate insights that help you set up and refine DLP policies. It takes seven days to generate recommendations after you turn on DLP analytics.

Before you begin

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions

To see DLP analytics your account must be one of these two roles:

- Global admin
- Compliance Administrator

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. This helps improve security for your organization. Global Administrator is a highly privileged role that should only be used in scenarios where a lesser privileged role can't be used.

Enable DLP risk-detection analytics

DLP analytics is turned **Off** by default. You need to explicitly opt in. Scans run every hour on your data present in audit logs and policy data.

> **Note**
>
> It takes seven days to start seeing analytics and recommendations in your tenant once analytics are re-enabled.

1. Sign in to the Microsoft Purview portal > **Data loss prevention** > **Overview**
2. Check the **Turn on analytics for risk detection and policy refinement opportunities (preview)** option.
3. Select **Turn on analytics**

Disable DLP analytics

After disabling DLP analytics, it can take up to 24 hours for the insights to stop appearing on the Data loss prevention **Overview** page.

1. Sign in to the Microsoft Purview portal > **Settings** (gear in the menu bar) > **Data Loss Prevention** > **Analytics (preview)**.
2. Set the **Activate analytics** toggle to **Off**.

View policies created by DLP analytics

To identify policies created by DLP analytics, perform the following steps:

1. Sign in to the Microsoft Purview portal > **Data Loss Prevention** > **Policies**.
2. Look for policy names in this format: *RiskSpotlighting-YYYY-MM-DD*.

Review policies updated by DLP analytics

When you tell DLP analytics to update an existing policy, it makes all updates in a new version of the policy. The name of the original policy is appended with *_copy* and the original policy is turned off. The new version is then deployed. For example:

1. There's a policy named *All credit cards* that is generating too many false positives.
2. DLP analytics suggests changes to the policy to reduce false positives.
3. You tell DLP analytics to update the policy.
4. DLP analytics creates a new version of the policy named *All credit cards*
5. DLP analytics renames the original version of the policy to *All credit cards_copy* and sets its status to **Keep it off**.
6. DLP analytics deploys the new version of the policy named *All credit cards* and sets it status to **Turn it on**.

Design a data loss prevention policy

Taking the time to design a policy before you implement it gets you to the desired results faster, with fewer unintended issues, than creating it and then tuning by trial and error alone. Having your policy designs documented will help you in communications, policy reviews, troubleshooting, and further tuning.

If you're new to Microsoft Purview DLP, it's helpful to work through these articles before you start designing a policy:

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about **Microsoft Security Copilot in Microsoft Purview**.

Before you begin

1. Administrative units
2. Learn about Microsoft Purview Data Loss Prevention
3. Plan for data loss prevention (DLP) - by working through this article you will:
   a. Identify stakeholders
   b. Describe the categories of sensitive information to protect
   c. Set goals and strategy
4. Collection Policies solution overview
5. Collection policy reference
6. Data Loss Prevention policy reference - this article introduces all the components of a DLP policy and how each one influences the behavior of a policy
7. Design a DLP policy - this article walks you through creating a policy intent statement and mapping it to a specific policy configuration.
8. Create and Deploy data loss prevention policies - This article presents some common policy intent scenarios that you map to configuration options, then it walks you through configuring those options.
9. Learn about investigating data loss prevention alerts - This article introduces you to the lifecycle of alerts from creation, through final remediation and policy tuning. It also introduces you to the tools you use to investigate alerts.

Policy design overview

Designing a policy is mostly about clearly defining your business needs, documenting them in a policy intent statement, and then mapping those needs to policy configuration. You use the decisions you made in your planning phase to inform some of your policy design decisions.

Define intent for the policy

You should be able to summarize, in a single statement, the business intent for every policy you have. Developing this statement drives conversations in your organization and, when fully fleshed out, this statement directly links the policy to a business purpose and provides a roadmap for policy design. The steps in the Plan for data loss prevention (DLP) article helps you get started on your policy intent statement.

Remember that, as described in the DLP policy configuration overview, all DLP policies require you to:

- Choose what you want to monitor
- Choose the Policy Scoping.
- Choose where you want to monitor .
- Choose the conditions that must be matched for a policy to be applied to an item.
- Choose the action to take when the policy conditions are met.

For example, here's a fictitious first draft of an intent statement that provides answers to all five questions:

"We're a U.S. based organization, and we need to detect Office documents that contain sensitive health care information covered by HIPAA that are stored in OneDrive/SharePoint and to protect against that information being shared in Teams chat and channel messages and restrict everyone from sharing them with unauthorized third parties".

As you develop a policy design, you'll likely modify and extend the statement.

Map business needs to policy configuration

Let's break down the example draft statement and map it to DLP policy configuration points. This example assumes that you're using an unrestricted DLP admin account and that administrative units aren't configured.

> **Important**

Be sure you understand the difference between an *unrestricted administrator* and an *administrative unit restricted administrator* by reading Administrative units before you start.

Expand table

Statement	Configuration question answered and configuration mapping
"We're a U.S. based organization, and we need to detect Office documents that contain sensitive health care information covered by HIPAA...	- **What to monitor**: Office docs, use the U.S. Health Insurance Act (HIPAA) template - **Conditions for a match**: (preconfigured but editable) - item contains U.S. SSN and Drug Enforcement Agency (DEA) number, International Classification of Diseases (ICD-9-CM), International Classification of Diseases (ICD-10-CM), content is shared with people outside my organization - drives conversations to clarify the triggering threshold for detection like confidence levels, and instance count (called leakage tolerance).
...that are stored in OneDrive/SharePoint and protect against that information being shared in Teams chat and channel messages...	- **Where to monitor**: Location scoping by including or excluding OneDrive and SharePoint sites and Teams chat/channel accounts or distribution groups. **Policy scoping** (preview): Full directory
...and restrict everyone from sharing those items with unauthorized third parties."	- **Actions to take**: You add *Restrict access or encrypt the content in Microsoft 365 locations* - drives conversation on what actions to take when a policy is triggered including protective actions like sharing restrictions, awareness actions like notifications and alerts, and user empowerment actions like allow user overrides of a blocking action

This example doesn't cover all the configuration points of a DLP policy; it would need to be expanded. However, it should get you thinking in the right direction as you develop your own DLP policy intent statements.

Important

Keep in mind that the location(s) you pick impact whether you can use sensitive information types, sensitivity labels, and retention labels. The location(s) you pick also impact the actions that are available. See Data Loss Prevention policy reference for more information.

Complex rule design

The above HIPAA content in SharePoint and OneDrive is a simple example of a DLP policy. The DLP rule builder supports boolean logic (AND, OR, NOT) and nested groups.

> **Important**
>
> - All existing **Exceptions** are replaced with a NOT condition in a nested group inside of the **Conditions**.
> - You need to create groups in order to use multiple operators.

> **Important**
>
> When an action in Office desktop client apps, (Word, Outlook, Excel, and PowerPoint) matches a policy that uses complex conditions, the user will only see policy tips for rules that use the **Content contains sensitive information** condition.

- *Example 1 We need to block emails to all recipients that contain credit card numbers, OR that have the 'highly confidential' sensitivity label applied, but do NOT block the email if it is sent from someone on the finance team to adele.vance@contoso.com*
- *Example 2 Contoso needs to block all emails that contain a password protected file OR a zip document file extension ('zip' or '7z'), but do NOT block the email if the recipient is in the contoso.com domain OR the fabrikam.com domain, OR the sender is a member of the Contoso HR group.*

https://learn-video.azurefd.net/vod/player?id=0edf38a9-89fb-4bc5-95f4-48c70053e031&locale=en-us&embedUrl=%2Fpurview%2Fdlp-policy-design

> **Important**
>
> - Using the NOT condition in a nested group replaces the **Exceptions** functionality.
> - You need to create groups in order to use multiple operators.

> **Important**
>
> When an action in Office desktop client apps (Word, Outlook, Excel, and PowerPoint) matches a policy that uses complex conditions, the user will only see policy tips for rules that use the **Content contains sensitive information** condition.

Policy Design Process

1. Complete the steps in Plan for data loss prevention (DLP) - by working through this article you will:
   a. Identify your stakeholders
   b. Describe the categories of sensitive information to protect
   c. Set goals and strategy
   d. Define your policy deployment plan

2. Familiarize yourself with Data Loss Prevention policy reference so that you understand all the components of a DLP policy and how each one influences the behavior of a policy.

3. Familiarize yourself with what the DLP policy templates include.

4. Develop your policy intent statement with your key stakeholders. Refer to the example earlier in this article.

5. Determine how this policy fits into your overall DLP policy strategy.

6. Map the items in your policy intent statement to configuration options.

7. Decide which policy template you start from: predefined or custom.

8. Go through the template and assemble all information required before you create the policy. It's likely that you will find that there are some configuration points that aren't covered in your policy intent statement. That's ok. Go back to your stakeholders to iron out the requirements for any missing configuration points.

9. Document the configuration of all the policy settings and review them with your stakeholders. You can reuse your policy intent statement mapping to configuration points, which is now fully fleshed out.

10. Create a draft policy and refer back to your policy deployment plan.

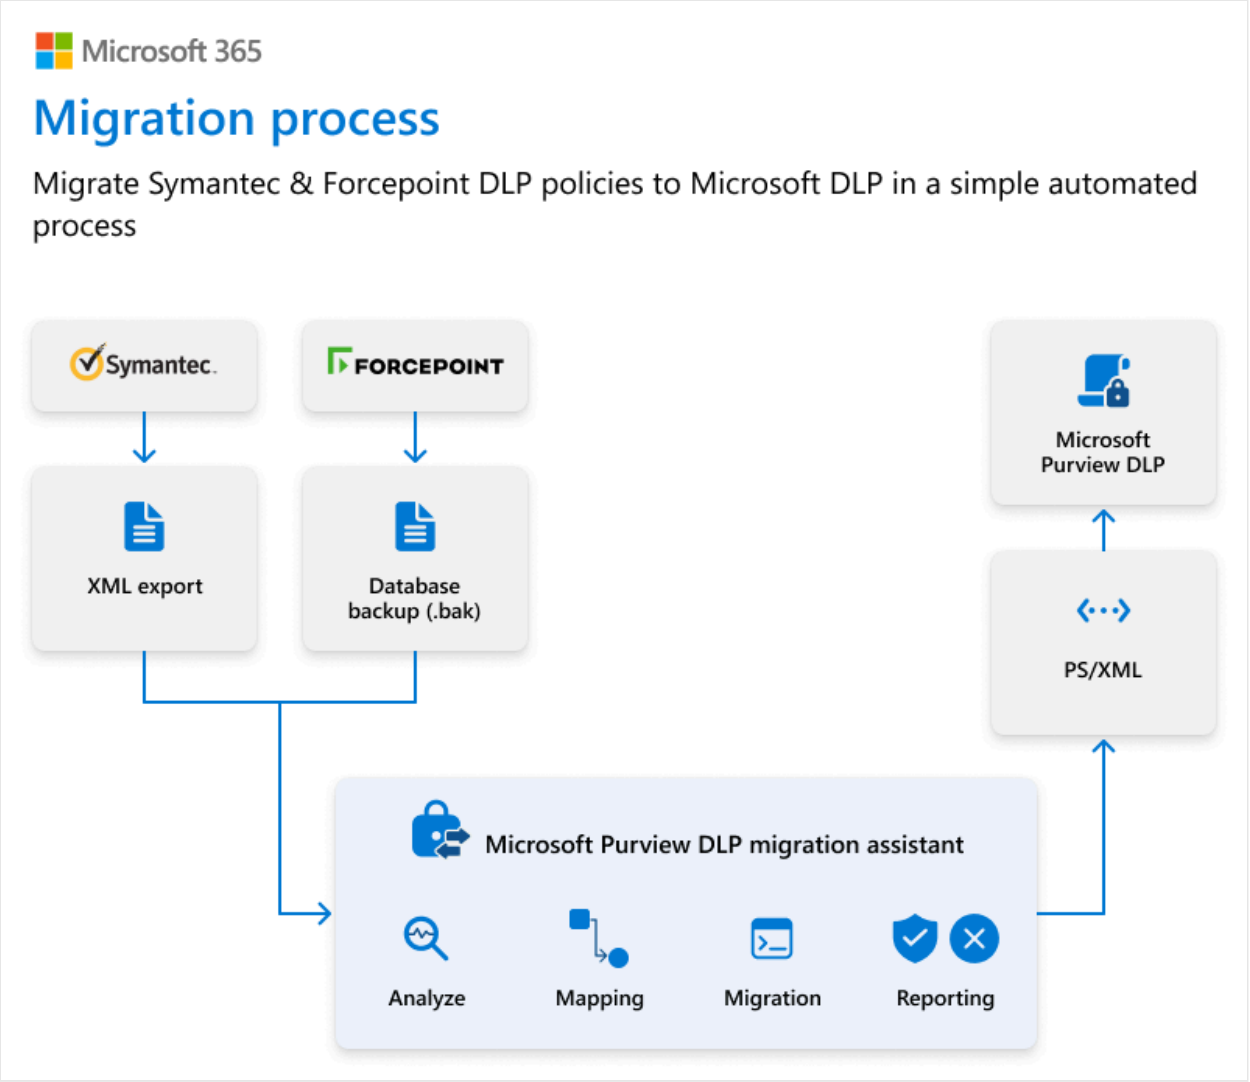
Learn about the Microsoft Purview Data Loss Prevention migration assistant for Symantec and Forcepoint

Article • 01/28/2025

This article helps you to learn about the Microsoft Purview Data Loss Prevention migration assistant for Symantec and Forcepoint.

The migration assistant is a Windows-based desktop application for migrating your Symantec and Forcepoint data loss prevention (DLP) policies to Microsoft Purview Data Loss Prevention. This article takes you through the five-step migration process. The migration assistant accepts Symantec DLP policy XML exports and Forcepoint DLP policy backup, performs mapping, and creates equivalent DLP policies through PowerShell scripts. You can use the migration assistant to create DLP policies in **Run the policy in simulation mode**. Policies in simulation mode won't affect your live data or impact your existing business processes.



What can the migration assistant help with?

The migration assistant helps with some of the tasks involved in a DLP migration project:

- In a manual migration scenario, you need to perform a feasibility analysis between the source and target DLP platforms, map the features, migrate policies manually, and test and tweak DLP policies. With the migration assistant, your migrated DLP policies can be up and running within minutes of starting the migration assistant process.
- With migration assistant, you can quickly scale up your migration project. You can start by moving a single policy manually to multiple policies at the same time.
- The migration assistant automatically identifies sensitive information types (SITs) or Data Identifiers in source policies and creates custom SITs in your Microsoft tenant. It also moves all of your custom regular expressions and keywords in a few clicks.
- The migration assistant detects which conditions, exclusions, and actions are currently used in source policies and automatically creates new rules with the same conditions and actions.
- The migration assistant provides you with a detailed migration report that includes the migration status and recommendations at the policy level.
- The migration assistant ensures that your DLP policy migration project is private and takes place within the boundaries of your organization.

How does the migration assistant for Symantec and Forcepoint work?

Here's how the migration process works:

Each time the migration assistant runs, it performs the following steps:

- **Input:** The migration assistant ingests one or more Symantec DLP policy XML files or Forcepoint DLP policy backup (.bak) file.
- **Analyze:** The migration assistant interprets the files and identifies Symantec and Forcepoint DLP policy constructs.
- **Rationalize:** The migration assistant maps the identified Symantec and Forcepoint DLP policy constructs to Microsoft DLP capabilities. It performs validations for Microsoft DLP platform limitations.
- **Migrate:** The migration assistant runs PowerShell scripts for the DLP scenarios identified and supported by the Microsoft Purview DLP platform.
- **Report:** The migration assistant reports which policies were migrated successfully, which were partially migration, and which ones couldn't be migrated. It also provides recommendations to improve future migrations.

Understand mapping of Symantec and Forcepoint DLP elements to Microsoft Purview DLP elements

The migration assistant translates different policy elements from Symantec DLP to Microsoft Purview DLP.

Symantec DLP supported versions

The migration assistant supports migrating DLP policies from Symantec versions 15.0 through 16.0, maintenance packs included.

Forcepoint DLP supported versions

The migration assistant supports migrating DLP policies from Forcepoint versions 8.0 through 10.0.

Supported Workloads

The migration assistant migrates policies into these workloads:

Expand table

Workload	Migration assistant support
Exchange	Yes
SharePoint	Yes
OneDrive	Yes
Teams chat and channel messages	Yes
Endpoint devices	Yes

> **Tip**
>
> You can use the migration assistant to extend your policy to more workloads than the ones detected in the input Symantec or Forcepoint DLP policy.

Classification Elements

Here's how the migration assistant maps Symantec and Forcepoint elements to Purview DLP elements.

Expand table

Symantec Classification Element	Microsoft Purview DLP Classification Element
Regular Expression	Create a new custom sensitive information type (SIT) with the regular expression.
Keyword	Create a new custom SIT with a keyword list or keyword dictionary.
Keyword Pair	Create a new custom SIT with first keyword list as primary element & second keyword list as a supporting element with 300 char proximity.
Data Identifier	Map to a preconfigured SIT if an equivalent is available, else create a new custom SIT.

Here are the mapping details of optional validators for sensitive information types (also known as Data Identifiers in Symantec DLP) that the migration assistant uses while translating Symantec DLP policies:

Expand table

Symantec Optional Validators	Microsoft Purview DLP Optional Validators
Exclude exact match	Exclude specific matches
Exact Match Data Identifier Check	N/A
Exclude beginning characters	Starts or doesn't start with characters
Exclude ending characters	Ends or doesn't end with characters
Exclude prefix	Include or Exclude prefixes
Exclude suffix	Include or Exclude prefixes
Number Delimiter	N/A
Require beginning characters	Starts or doesn't start with characters
Exact Match	N/A
Duplicate digits	Exclude duplicate characters
Require ending characters	Ends or doesn't end with characters
Find keywords	Available as both primary & supporting elements

Regular Expressions – Potential validation issues to be aware of

When you upload your rule package XML file, the system validates the XML and checks for known bad patterns and obvious performance issues. Here are known issues that the validation process checks a regular expression for.

- Can't begin or end with alternator "|", which matches everything because it's considered an empty match.
  - For example, "|a" or "b|" won't pass validation.
- Can't begin or end with a ".{0,m}" pattern, which has no functional purpose and only impairs performance.
  - For example, ".{0,50}ASDF" or "ASDF.{0,50}" won't pass validation.
- Can't have ".{0,m}" or ".{1,m}" in groups, and can't have ".*" or ".+" in groups.
  - For example, "(.{0,50000})" won't pass validation.
- Can't have any character with "{0,m}" or "{1,m}" repeaters in groups.
  - For example, "(a*)" won't pass validation.
- Can't begin or end with ".{1,m}"; instead, use just "."
  - For example, ".{1,m}asdf" won't pass validation; instead, use just ".asdf".
- Can't have an unbounded repeater (such as "*" or "+") on a group.
  - For example, "(xx)*" and "(xx)+" won't pass validation.

Condition and Exception Mapping

Here's how the migration assistant maps Symantec and Forcepoint, condition and exception elements for various workloads to Microsoft Purview DLP conditions.

Exchange Workload

Expand table

Condition/Exception in Symantec	Condition in Microsoft Purview DLP
Content Matches Regular Expression	Content contains SIT
Content Matches Keyword	Content contains SIT
Content Matches Data Identifier	Content contains SIT
Content Matches Classification	Not supported
File Properties • File name	One or more of the following: • Document name is

Condition/Exception in Symantec	Condition in Microsoft Purview DLP
• File type	• File extension is
Message Attachment or File Type Match	One or more of the following: • Attachment is password protected • Attachment's file extension is
Message Attachment or File Size Match	Document size equals or is greater than
Message Attachment or File Name Match	One or more of the following: • Document name contains words or phrases • Document name matches patterns
Message/Email Properties and Attributes	One or more of the following: • Email subject contains
Sender/User Matches Pattern	One or more of the following: • Sender is • Sender is a member of • Sender domain is • Sender address contains words • Sender address matches patterns • Sender IP address is
Recipient Matches Pattern	One or more of the following: • Recipient is a member of • Recipient domain is • Recipient is • Recipient address contains words • Recipient address matches patterns
Sender/User based on a Directory Server Group	Not supported
Recipient based on a Directory Server Group	Not supported
Content Matches Exact Data from an Exact Data Profile (EDM)	Not supported
Content Matches Document Signature from an Indexed Document Profile (IDM)	Not supported
Detect using Vector Machine Learning profile (VML)	Not supported

Condition/Exception in Symantec	Condition in Microsoft Purview DLP
Protocol Monitoring • SMTP protocol	Exchange (EXO) DLP policy

Endpoint Devices, SharePoint Online, OneDrive, and other workloads

Expand table

Condition/Exception in Symantec	Condition in Microsoft Purview DLP
Content Matches Regular Expression	Content contains SIT
Content Matches Keyword	Content contains SIT
Content Matches Data Identifier	Content contains SIT
Message Attachment or File Type Match	Document's file extension is
Protocol Monitoring • HTTP • HTTPS • FTP	Cross-workload DLP policy(s)
Protocol Monitoring: Endpoint Device Type • CD/DVD • Removable storage • Copy to network share • Printer/Fax • Clipboard • Cloud storage • Application File Access • SEP Intensive Protection	One or more of the following (Devices): • Copy to USB removable media • Copy to network share • Copy to clipboard • Print • Upload to cloud service domains or access by browsers that aren't allowed

Response Rules

Here's how the migration assistant maps Symantec and Forcepoint response rules to Microsoft Purview DLP actions.

Expand table

Symantec Response Rule	Microsoft Purview DLP Action
Generate DLP Incident	Generate Alert
Logging (Syslog)	Audit logs
Network Prevent: Modify SMTP Message • Modify email subject • Modify header	One or more of the following: • Prepend subject • Set headers
Network Prevent: Block SMTP Message • Bounce message to sender • Redirect message to this address	One or more of the following: • Block / Restrict access • Send user notification • Redirect message to
Send Email Notification	Send User Notification
Endpoint Prevent • Notify • Notify with Cancel • Block	One or more of the following (Endpoint Devices) • Notify • Block • Audit
User Cancel	One or more of the following: • Block / Restrict access • User Overrides

Next steps

Now that you've learned about the Microsoft Purview Data Loss Prevention migration assistant for Symantec, your next steps are to:

1. Get started with the Microsoft Purview Data Loss Prevention migration assistant for Symantec and Forcepoint
2. Use the Microsoft Purview Data Loss Prevention migration assistant for Symantec and Forcepoint

Get started with the Microsoft Purview Data Loss Prevention migration assistant for Symantec and Forcepoint

This article walks you through the prerequisites and installation of the Microsoft Purview Data Loss Prevention migration assistant.

Before you begin

If you're using the Microsoft Purview Data Loss Prevention migration assistant for the first time, ensure the following prerequisites are met:

> **Tip**
>
> If the application won't launch after completing all the steps in this article, refer to Troubleshoot the DLP migration assistant.

1. Have an appropriate Microsoft 365 subscription

You'll need the appropriate DLP licensing for the locations that the migrated policies are scoped to. Check the DLP licensing requirements.

2. Have appropriate user role and privileges

You need to have either the *Global Administrator or Compliance Administrator* role to be able to use the migration assistant.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. This helps improve security for your organization. Global Administrator is a highly privileged role that should only be used in scenarios where a lesser privileged role can't be used.

3. Check your Operating System

You can only install and run the migration assistant on these operating systems:

- Windows 11,10,8.1,7
- Windows Vista
- Windows Server 2008+
- Windows Server 2003 (excluding IA-64)

4. Install PowerShell

You must have PowerShell v7.2.6 or higher installed on the host machine. Download Powershell-7.2.6-win-x64.msi core on your machine.

5. Install .NET

You must have .NET desktop runtime v6.0.13 or higher installed on the host machine. Download .NET 6.0 Desktop Runtime (v6.0.13) - Windows x64 Installer (microsoft.com).

Export DLP policies

Before you begin the migration process, you need to export your DLP policies from your current DLP solution.

Symantec DLP

You need to export your Symantec DLP policies as XML files from Symantec DLP. Export the policies using the Symantec DLP policy export procedures.

Forcepoint DLP

You need to export your Forcepoint DLP policies using the backup capability from Forcepoint DLP. Export the policy backup using the Forcepoint DLP policy backup procedures.

Installation steps

Follow these steps to install the Microsoft Purview Data Loss Prevention migration assistant for Symantec:

1. Download and launch the **Microsoft Purview Data Loss Prevention migration assistant** file.
2. The following dialog box will open. Select **Next**.
3. Review the End-User License Agreement.

4. After reviewing, accept the License Agreement and select **Next**.
5. Select the location where you want to install the migration assistant and select **Next**.
6. Once installer is ready, select **Install** to begin installation.
7. Wait while the migration assistant is being installed.
8. Once migration assistant is installed, select **Finish** and close the dialog box.

Next steps

Now that you have installed Microsoft Purview Data Loss Prevention migration assistant for Symantec and Forcepoint, you're ready to move on to your next step where you use the migration assistant.

- Using the Microsoft Purview Data Loss Prevention migration assistant for Symantec and Forcepoint

Use the Microsoft Purview Data Loss Prevention migration assistant for Symantec and Forcepoint

The Microsoft Purview Data Loss Prevention migration assistant for Symantec and Forcepoint helps you migrate your existing Symantec or Forcepoint DLP policies to Microsoft Purview DLP. The assistant maps data identifiers, keywords, and regular expressions to Microsoft sensitive information types (SITs), and migrates rules, conditions, and actions. By the end of this procedure, your policies are active in Microsoft Purview DLP and ready for testing.

Before you start, make sure you've met these prerequisites:

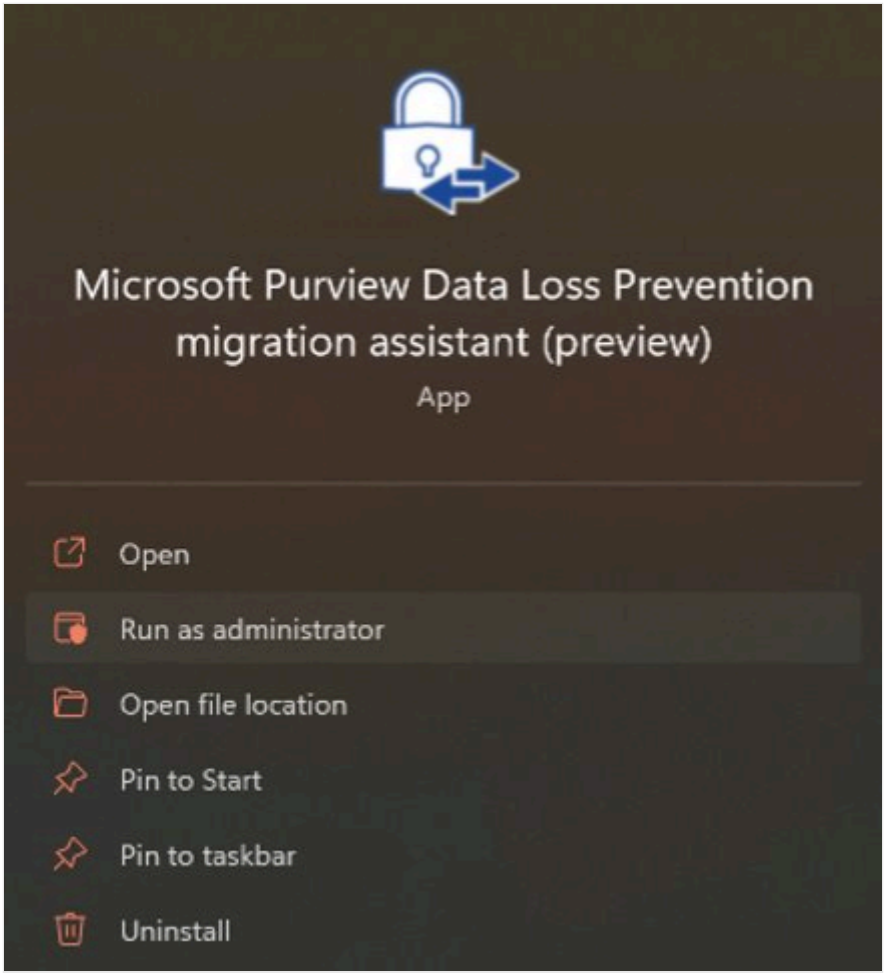
- Complete the steps in the Before you begin section.
- Export the required DLP policy files from your current DLP solution.

After a policy is migrated, you can test and fine-tune it in Microsoft Purview DLP.

Steps for migration

Use these steps to perform a DLP policy migration:

- Step 1: Sign in to your account
- Step 2: Upload the policies that are being migrated
- Step 3: Edit policy settings
- Step 4: Review premigration feasibility report
- Step 5: Merge policies and select policy mode
- Step 6: Migration in progress
- Step 7: View the migration report
- Next steps: After policy import



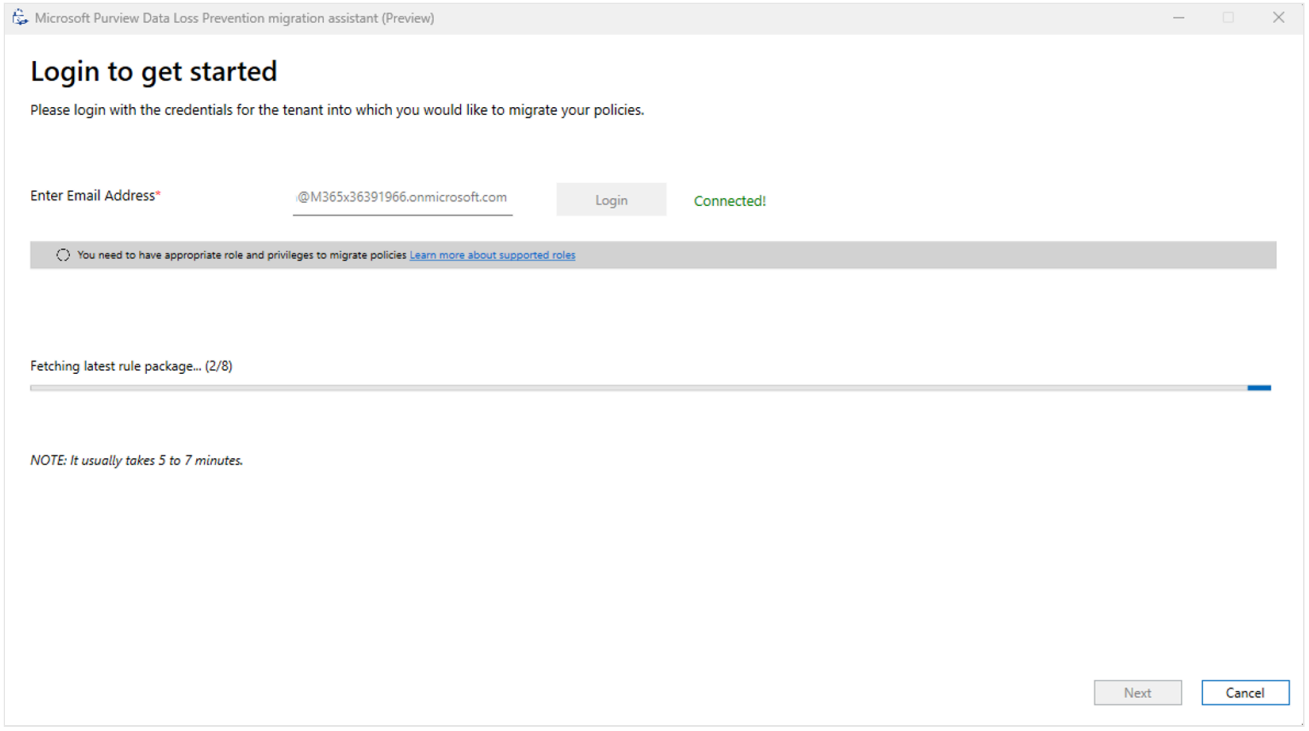
Interactive guide

Check out the Use the Microsoft Purview DLP migration assistant interactive guide for a visual walkthrough of the migration process.

Step 1: Sign in to your account

After you install and launch the migration assistant, sign in to your account.

> **Important**
>
> The first time you launch the migration assistant, choose the **Run as administrator** option. Running as administrator is required because the migration assistant might need to install additional components if they aren't already available on your machine.
>
> For all subsequent launches, you can launch the migration assistant normally and don't need to run as administrator.



To sign in to the migration assistant:

1. You're greeted with a welcome screen.
   a. Select **Get Started** and the migration assistant checks if your environment is set up correctly.
   b. Select **Next**.
2. Enter your username and select **Login**.

   - Enter your password in the browser window that opens and select **Sign in**.

> **Note**
>
> This application uses the Exchange Online PowerShell module. Basic authentication must be enabled in WinRM on the local computer. For more information, see Prerequisites for the Exchange Online PowerShell module.

3. Wait for sign-in validation. The migration assistant fetches the information required for later stages of the migration process.

4. After you're signed in, choose **Next**.

Step 2: Upload the policies that are being migrated

You need to upload your current DLP policy exports, which act as input for the migration assistant. The policies you upload will be migrated to the Microsoft Purview DLP platform.

1. Select which DLP solution you want to migrate policies from.

2. To upload the files, select **Browse**.

3. Select the required policy files in the File Explorer pop-up window and choose **Open**.

    a. Symantec DLP

        i. For migrating policies from Symantec DLP, you need to upload the XML files that you have exported from Symantec DLP.

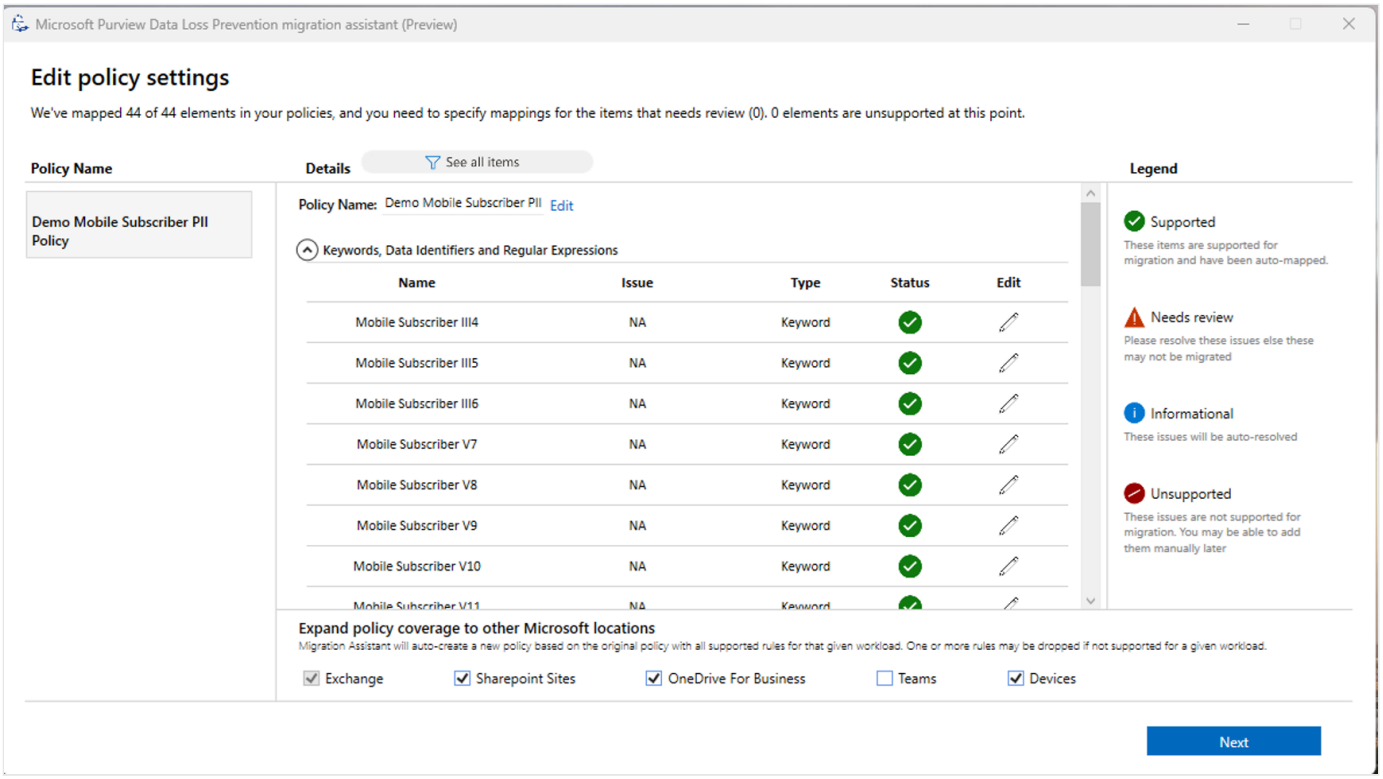
        ii. You can select more than one XML file to migrate multiple policies at a time. Migrate one to three policies at a time to avoid confusion during later stages of the migration

process.

> **Note**
>
> Ensure that the XML files you upload are Symantec DLP policy exports only and no other kind of XML.

b. Forcepoint DLP

i. For migrating policies from Forcepoint DLP, you need to upload the policy backup (.bak) file from Forcepoint DLP.



4. The tool shows you a list of your selected input policy files. You can modify your selection from the policy list.

5. After you complete the selection of policy files you want to migrate, select **Next** to move to the next step.

Step 3: Edit policy settings

After you input the policies you want to migrate, the migration assistant processes those files and maps Symantec and Forcepoint DLP policy elements to Microsoft DLP elements.

> **Important**
>
> There may be some items that may need your review and will be marked with 'Needs review' warning symbol.

Keywords, data identifiers, and regular expressions

Symantec DLP and Forcepoint DLP differ from Microsoft Purview Information Protection in how they allow users to define sensitive information that needs to be protected.

Microsoft Purview Information Protection allows users to define sensitive items that need protection as sensitive information types (SITs), or through trainable classifiers. Microsoft provides many commonly used SITs like Credit Card Number that are preconfigured. If the preconfigured SITs don't meet your needs, you can create your own custom SITs.

The most common ways Symantec and Forcepoint users specify the types of sensitive information that need protection are:

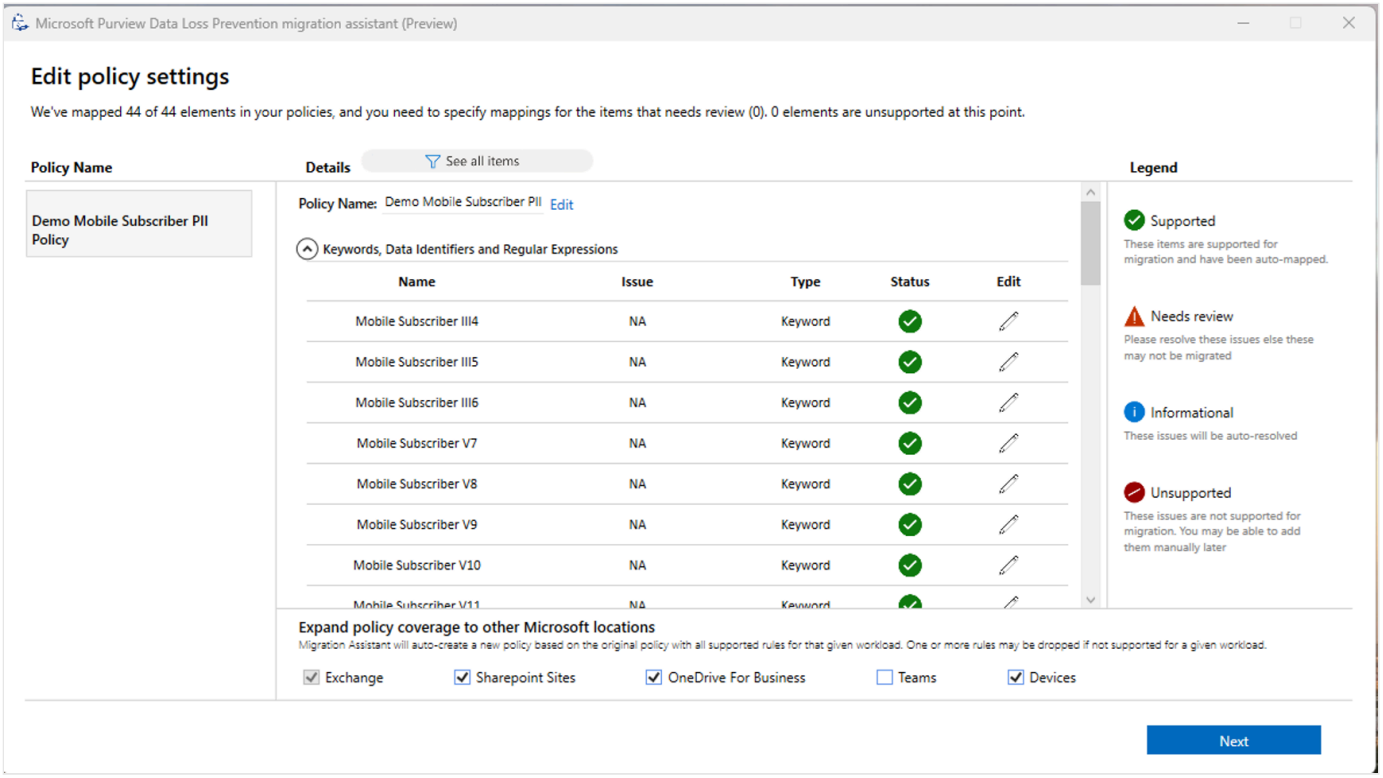
- Using out-of-box (OOB) data identifiers
- Customizing OOB data identifiers
- Defining regular expressions or keywords in DLP rules

The migration assistant handles OOB data identifiers, customized OOB data identifiers, and regular expressions or keywords in one of two ways:

- **Map to an existing OOB SIT:** For each sensitive data type that has an equivalent SIT in Microsoft DLP, the migration assistant attempts to create a 1:1 mapping. It automatically maps OOB Symantec or Forcepoint data identifiers to preconfigured Microsoft SITs, if an equivalent exists. If you want to bring the Symantec or Forcepoint data identifier over as-is, you can create a new SIT as described in the next step.

- **Migrate as a new custom SIT:** For each sensitive data type that doesn't have an equivalent SIT in Microsoft DLP, the migration assistant automatically creates a new SIT. Similarly, any regular expressions or keywords defined directly in rules are brought over as a new custom SIT.

> **Note**
>
> Regular expressions or keywords defined directly at the rule-level of Symantec or Forcepoint policies take on the name of the rule itself and appear in the **Source** column. If there are multiple regular expressions or keywords, they take the rule name followed by roman numerals.
>
> Each of these items is migrated separately as a custom SIT. Migrating each regular expression or keyword as a separate custom SIT can lead to confusion. Review and rename these SITs as soon as possible.
>
> You can't edit the name of these SITs within the migration assistant. You can edit the names of these custom SITs from the Microsoft Purview portal or via PowerShell after the policy migration is complete.



Inclusions, exclusions, and response rules

The current version of the migration assistant brings over policies with '*Generate Incident Report*' as a default action. Also, DLP policies in Microsoft DLP automatically log events in Unified Audit Log and won't need a separate action equivalent to 'Syslog' in Symantec DLP.

In addition to the automatically migrated response rules (or DLP actions), you can manually add (or remove) actions to the policies after the migration assistant has successfully migrated the policies.

You can see a list of all your policies and rules along with their status. Select different policies from the left column to see details for each policy. By default, the tool displays all items that need review. You can toggle to see all items in a given policy by choosing the **Show All Items** button at

the top of the Details section.

Policy details

Policy Name - You can edit the name of the policy before migration.

Each policy is divided into two sections:

- Keywords, data identifiers, and regular expressions — These are migrated as sensitive information types (SITs) in Microsoft DLP.

- Rules — These are automatically mapped to different Microsoft DLP conditions. Each row in the table shows:
  - The name that the SIT will have when migrated
  - Potential issues that may affect migration
  - Type of rule as detected from the input policy
  - Status:
    - Blank/empty status — This row element is migrated without issues.
    - Needs Review — This row element might have one or more issues and might require input from you.
    - Informational — This row element might have one or more changes needed for migration but will be autoresolved.
    - Unsupported — This row element isn't supported for migration by the tool and might need to be migrated manually after the tool exits.
  - Edit button

Extend policy coverage to other Microsoft locations: - You can extend your current Symantec policies to other Microsoft locations in addition to the original scope of the policy.

For example, a Purview DLP policy that's scoped to email can be extended to SharePoint, OneDrive, Teams, and Endpoint Devices.

The migration assistant auto-creates a new policy based on the original policy with all supported rules for that given workload. One or more rules may be dropped if not supported for a given workload.

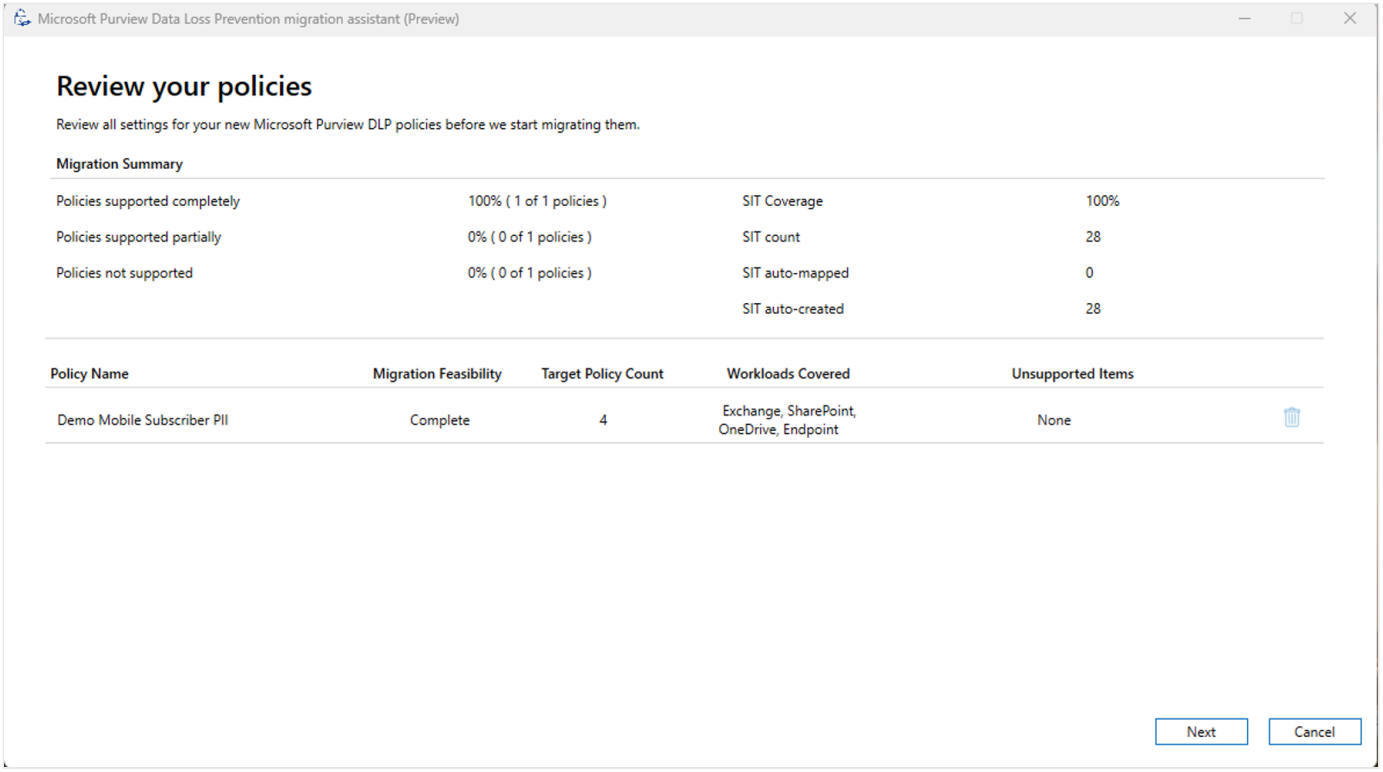
For example, the **Email subject is** condition may be dropped while extending an email (Exchange) DLP policy to OneDrive.

Some checkboxes may be disabled by default if there are no supported conditions available in extended locations.

Editing a row element — When you select a row element to edit, you're taken to an **Edit** screen with more details. If there are issues, they're reported through a yellow banner at the top of the screen. Make changes to the content in the editable sections. Those changes are incorporated at the time of migration. After you resolve the issues, the yellow banner disappears.

Use existing SITs from the tenant to automatically replace the current SIT. You can replace the current SIT (which is being edited) with another SIT from your tenant.

You can manually change any of the mappings by selecting the corresponding row in the 'Target' column. This opens a drop-down list with all the OOB SITs and any custom SITs you previously created. Select the SIT you want to map to the source item. Alternatively, you can choose **New SIT** from the drop-down. The migration assistant then brings over the source SIT as a new custom SIT.



We strongly recommend using existing SITs to replace current SITs wherever possible. Reusing existing SITs helps reduce creation of duplicate SITs and reduces the effort of optimizing multiple custom SITs of the same kind. Learn more about sensitive information type entity definitions.

> **⚠ Warning**
>
> Microsoft DLP platform has a threshold for up to 10 rule packages per tenant. This limit is enough for most customers, but the creation of many duplicate custom SITs may quickly lead you to hitting this threshold without the ability to create any new custom SITs.

After you've reviewed all the policies and the rules within them, select **Next**. If one or more of the policies contain at least one element with *Needs Review* status, then you'll see a **Continue with errors** button instead of **Next**.

Step 4: Review premigration feasibility report

The premigration feasibility report shows you how policies will be migrated. Review this report and make any necessary adjustments before starting a migration run.

Review the details and choose **Next**.

Step 5: Merge policies and select policy mode

Each DLP policy is split into multiple rules depending on the workloads selected and support for underlying conditions and exceptions for those workloads.

The tool allows you to merge each of these rules with compatible target policies for the same workload. These target policies can be existing Microsoft Purview DLP policies you created earlier, or new policies that you're importing along with the policy you want to merge.

Merging policies together creates a single Microsoft Purview DLP policy with multiple rules. Consolidating multiple rules into a single policy allows for better management of policies.

For each DLP policy that is created, you can set it to one of three states:

- On (**Yes, turn it on right away**)
- Simulate (**Run the policy in simulation mode** and **Show policy tips**)
- Off (**No, keep it off. I'll turn it on later**)

Set the state in the migration assistant before migrating a policy:

1. Choose whether to turn on or off from the following three options:

   - Turn on policy immediately.
   - Turn on policy in simulation mode first. Remove from simulation mode later manually.
   - Keep it off. Turn it on later manually.

   We recommend bringing over the policies first in simulation mode. You can monitor the alerts that the policy generates and fine-tune the policy as required by your organization. After your policy is fine-tuned, you can turn it on.

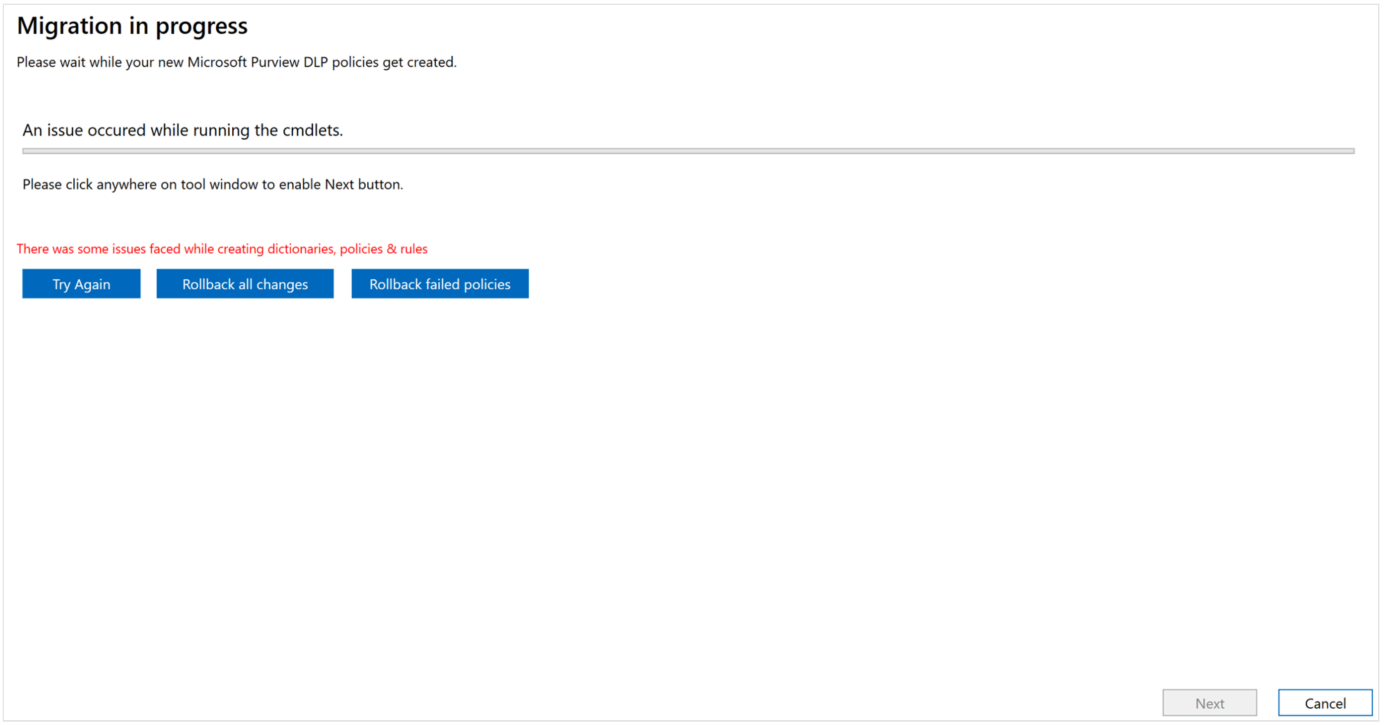
2. Select **Start Migration** to import your policy. A new PowerShell window opens asking you to sign in again.

   After you sign in, PowerShell scripts run to create new policies in Microsoft DLP with all the data from the input policy files, and any settings you configured during the previous migration assistant steps.

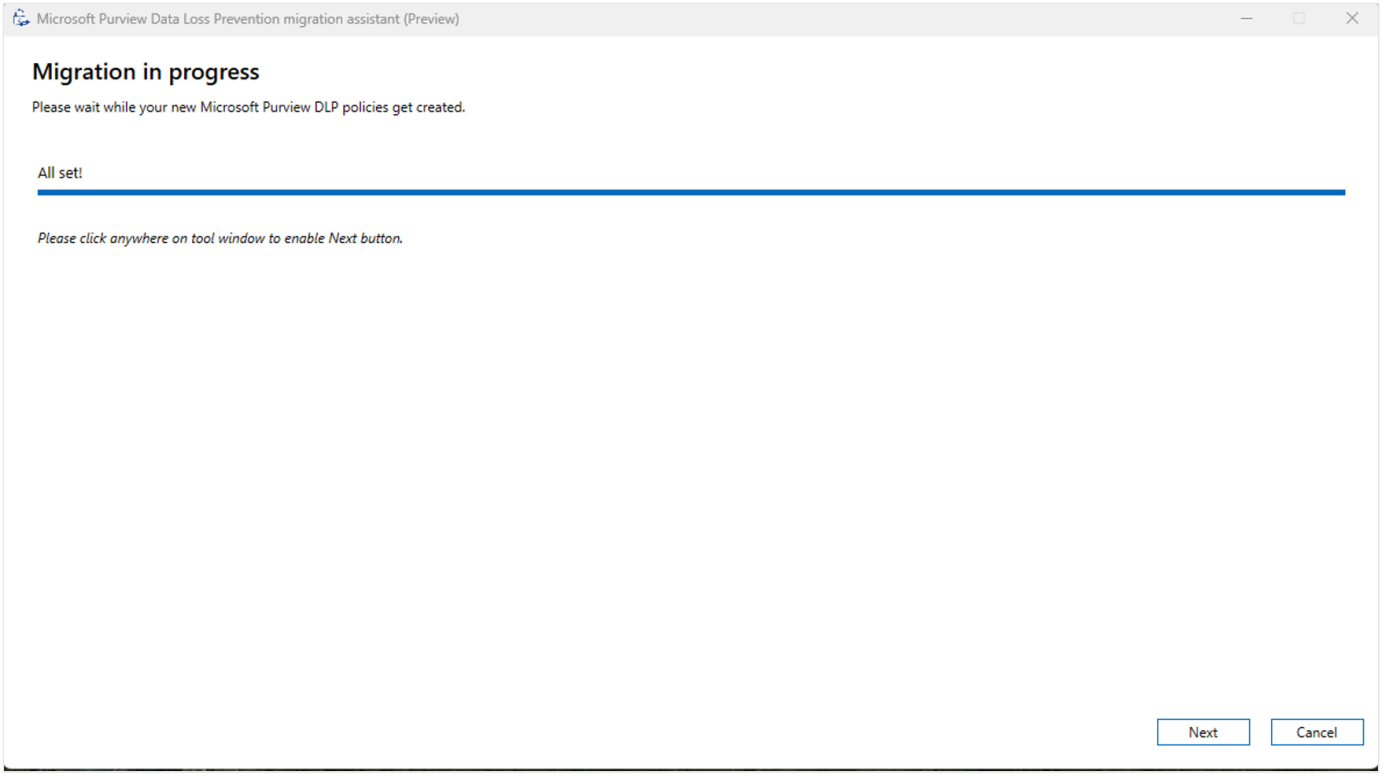
   Wait until the script finishes with a Success/Failure message. Then, new SITs and policies start appearing in the Purview portal.

Step 6: Migration in progress

In this step, the migration tool creates DLP policies in the Microsoft Purview portal.



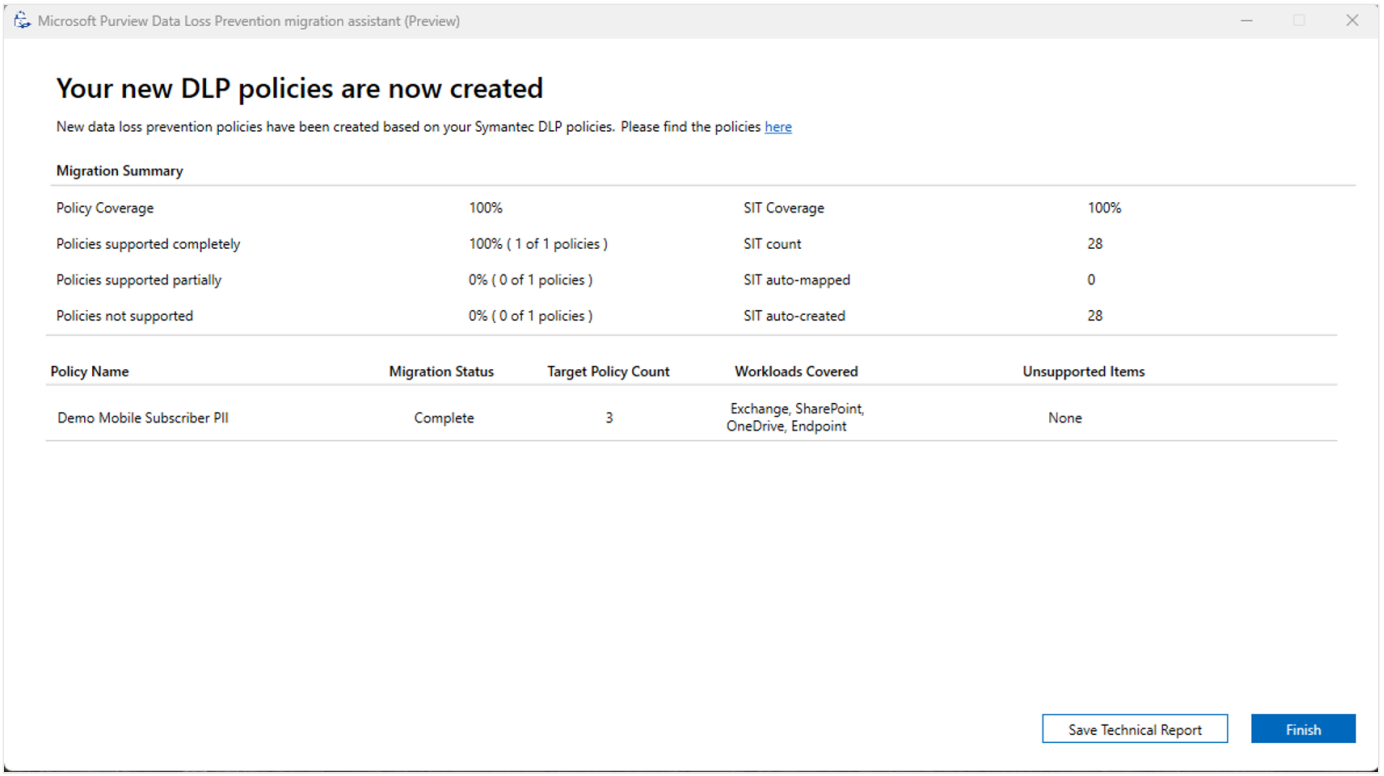
> ⓘ **Note**
>
> Don't close the tool window while policies are being created. Closing the tool might cause incomplete SITs and policies, which could require manual cleanup.



If an error occurs during migration, you can choose one of these actions:

- **Try Again** — Policy creation is attempted again.
- **Rollback all changes** — All SITs and policies for that session are deleted.
- **Rollback failed policies** — Only the failed SITs and policies for that session are deleted.

> **Important**
>
> When you choose to rollback any changes, the rollback can take two to four hours to complete. Keep the migration assistant tool window open for the entire duration for a successful rollback.

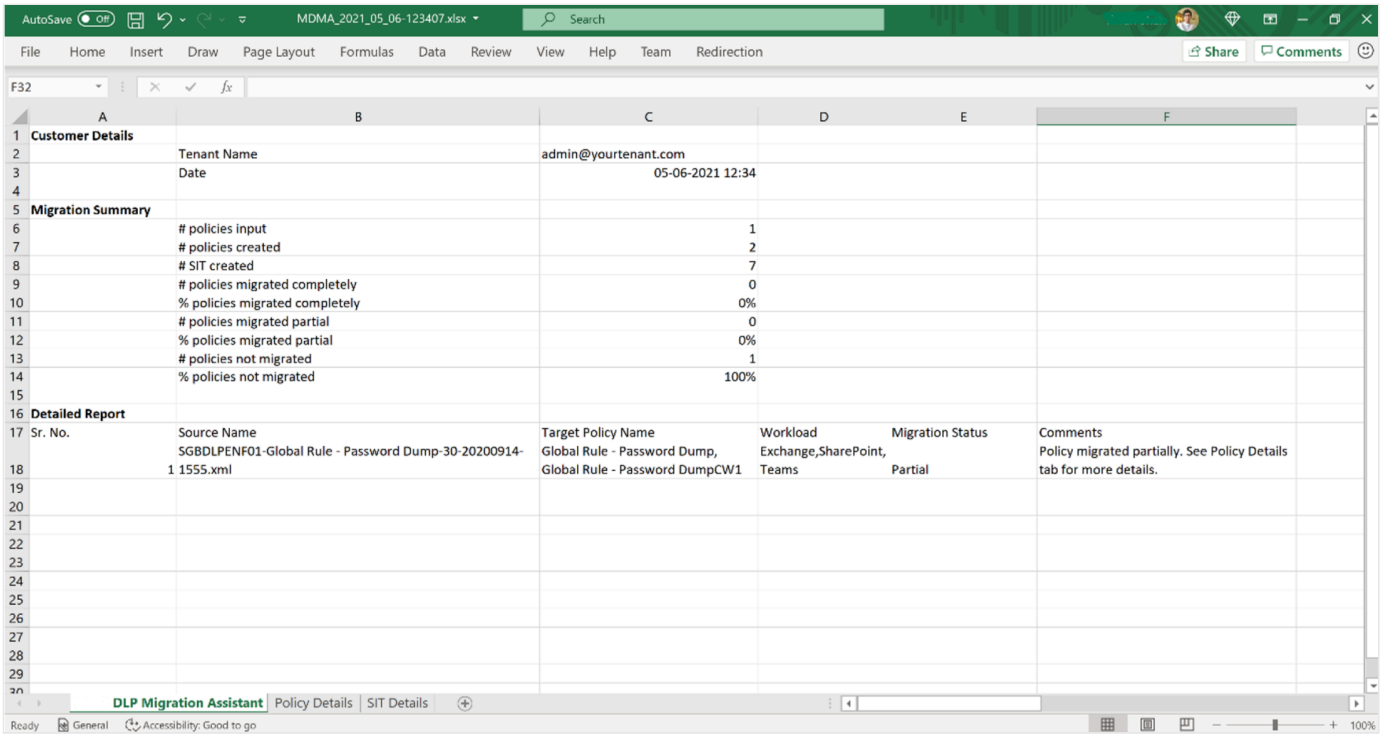


After the policies are migrated, select **Next** to view the migration report.

Step 7: View the migration report

You can view the migration report after your policies are imported and the migration process is complete.

Each session gets its own report. A session begins at the time you launch the app and ends when you exit the app or when migration process is completed.

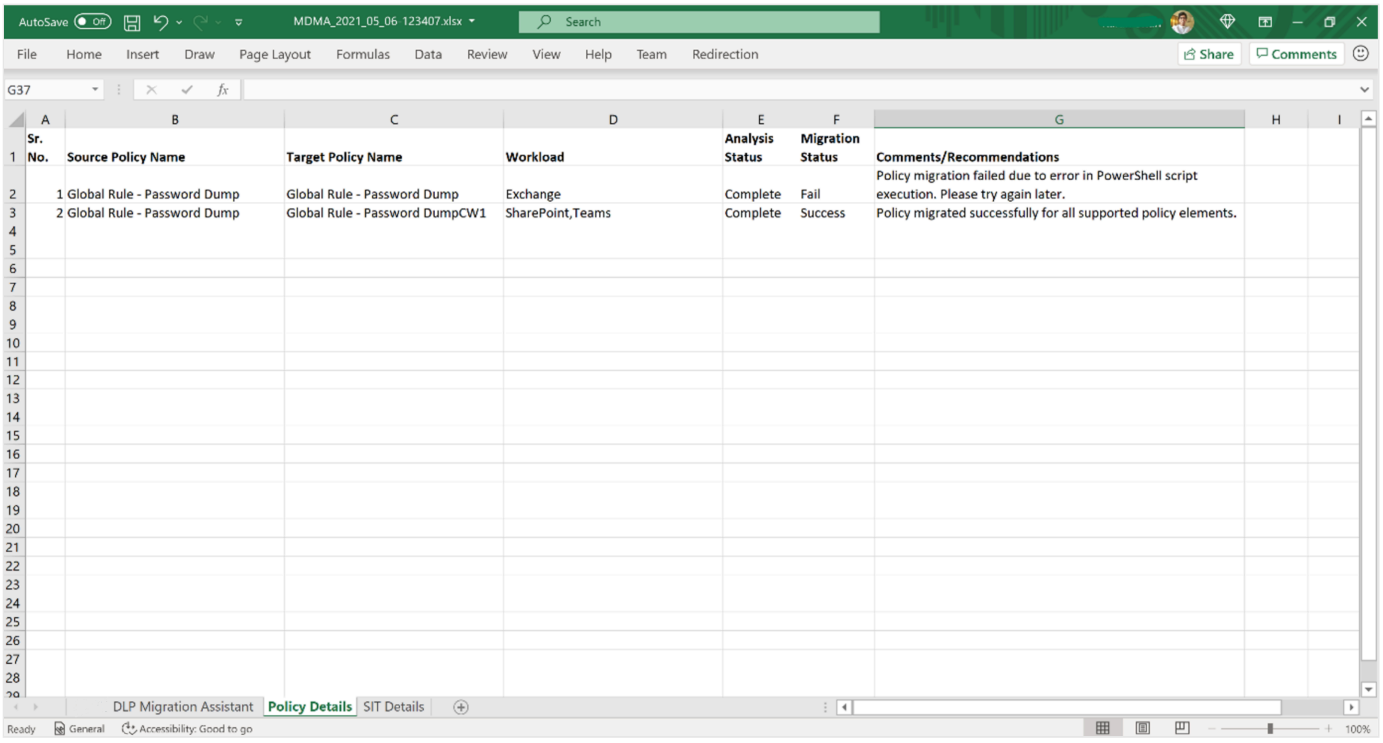


Technical report

You can select the **Save Technical Report** button to save a more detailed Excel-based report that is divided into three sheets:

- Overview
- Policy Details
- SIT Details

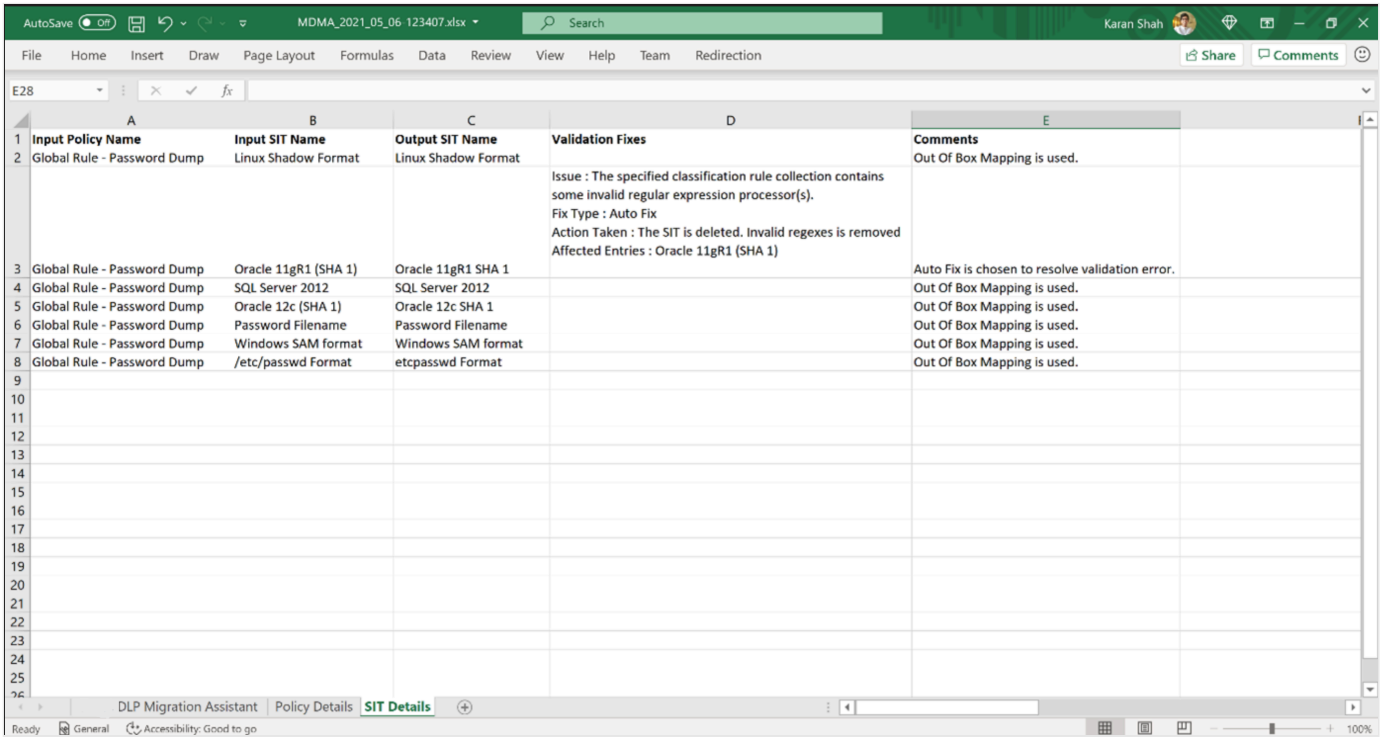
Overview Sheet — This sheet provides an overview of the migration session with the following details:



- Tenant's name.
- Timestamp of session.
- Overall summary stats for that session.
- Input policy level details, migration status and comments/recommendations.

	A	B	C	D	E	F
1	**Customer Details**					
2		Tenant Name	admin@yourtenant.com			
3		Date	05-06-2021 12:34			
4						
5	**Migration Summary**					
6		# policies input	1			
7		# policies created	2			
8		# SIT created	7			
9		# policies migrated completely	0			
10		% policies migrated completely	0%			
11		# policies migrated partial	0			
12		% policies migrated partial	0%			
13		# policies not migrated	1			
14		% policies not migrated	100%			
15						
16	**Detailed Report**					
17	Sr. No.	Source Name	Target Policy Name	Workload	Migration Status	Comments
18	1	SGBDLPENF01-Global Rule - Password Dump-30-20200914-1555.xml	Global Rule - Password Dump, Global Rule - Password DumpCW1	Exchange,SharePoint, Teams	Partial	Policy migrated partially. See Policy Details tab for more details.

Policy Details — This sheet provides a detailed view of each migrated policy created or not created with the following information:



- Mapping of source policy and target policy(s) created.
- List of workloads each policy is applied to.
- Analysis status stating if the policy is migrated completely, partially or can't migrate.
    - For workloads other than Exchange, this would typically show as *Complete* since we create a policy with the *Content contains* condition, which is supported across all workloads.
- Migration status describing if the policy migration was a success or failure.
- Comments/recommendations with more details of that policy.

Sr. No.	Source Policy Name	Target Policy Name	Workload	Analysis Status	Migration Status	Comments/Recommendations
1	Global Rule - Password Dump	Global Rule - Password Dump	Exchange	Complete	Fail	Policy migration failed due to error in PowerShell script execution. Please try again later.
2	Global Rule - Password Dump	Global Rule - Password DumpCW1	SharePoint,Teams	Complete	Success	Policy migrated successfully for all supported policy elements.

SIT Details — This sheet provides information about all the sensitive information types (SITs) that were migrated with the following information:

- Policy-wise mapping of Input and Output SITs created.
- Validation fixes with information about validation errors that occurred during the migration process.
- Comments about SIT automapping, and remediation steps.

Input Policy Name	Input SIT Name	Output SIT Name	Validation Fixes	Comments
Global Rule - Password Dump	Linux Shadow Format	Linux Shadow Format		Out Of Box Mapping is used.
Global Rule - Password Dump	Oracle 11gR1 (SHA 1)	Oracle 11gR1 SHA 1	Issue : The specified classification rule collection contains some invalid regular expression processor(s). Fix Type : Auto Fix Action Taken : The SIT is deleted. Invalid regexes is removed Affected Entries : Oracle 11gR1 (SHA 1)	Auto Fix is chosen to resolve validation error.
Global Rule - Password Dump	SQL Server 2012	SQL Server 2012		Out Of Box Mapping is used.
Global Rule - Password Dump	Oracle 12c (SHA 1)	Oracle 12c SHA 1		Out Of Box Mapping is used.
Global Rule - Password Dump	Password Filename	Password Filename		Out Of Box Mapping is used.
Global Rule - Password Dump	Windows SAM format	Windows SAM format		Out Of Box Mapping is used.
Global Rule - Password Dump	/etc/passwd Format	etcpasswd Format		Out Of Box Mapping is used.

Next steps: After policy import

Visit the Purview portal and validate the policies you migrated.

Check sensitive information types

Use the following steps to verify and tune the migrated SITs:

1. To validate that the SITs were created, navigate to **Data Classification** > **Classifiers** > **Sensitive Info Types** and look for the SITs. You can also sort the list on **Publisher** and check for SITs with a publisher name of “DLP Migration Tool”.

2. Rename SITs as needed. For many SITs, you may notice there are similar names, often followed by roman numerals. To avoid confusion and duplication post-migration, you should rename these SITs. This is true for cases where your regular expressions and keywords are defined directly in rules within your input Symantec or Forcepoint DLP policies.

3. Test and fine-tune SITs as needed. You should test and fine-tune the migrated SITs. The migration assistant creates new SITs with a few standard settings, which might not be right for your tenant so look out for the following:
   a. Regular expressions: Unsupported or deleted regexes (during migration)
   b. Keywords
      i. Case sensitive versus insensitive keywords
      ii. String versus word match
      iii. Proximity
      iv. Optional validators

Check DLP policies

Use the following checks to validate and finalize the migrated DLP policies:

1. **Validate the DLP policies created**

   Select **Data Loss Prevention** from the left panel and check if new policies are created.

2. **Add any missing policy elements**

   While most Symantec and Forcepoint DLP policy elements (like conditions, exclusions, or actions) are migrated, some elements from your input policy might be dropped during the migration process. Dropping some policy elements during migration is a known limitation of the migration assistant. In this scenario, manually add these elements to the policy, as they're supported by the Microsoft Purview DLP platform.

3. **Test and fine-tune the policy**

   You can test the policy and fine-tune it for the needs of your organization.

4. **Turn the policy on**

   After fine-tuning, you can turn on the policy or put it in production mode.

5. **Bring over any remaining policies**

   You can go back to bring over the next policy or next batch of policies using the migration assistant.

Troubleshooting

If you see an error on welcome screen after selecting **Get Started**, follow these steps:

1. Confirm that you've installed all the prerequisites using the links/versions mentioned in Before you start.
2. Ensure that you've restarted the machine after installing the prerequisites.
3. Ensure that you're running the tool in *admin mode* using the **Run as administrator** option when starting the application.
4. Ensure that your PowerShell module path is set correctly using these steps:
   a. Go to **Edit system environment variables**.
   b. Add this path in the **PsModulePath** user variable: `C:\Program Files\PowerShell\7\Modules`.
   c. Move this up and keep at the top.
   d. Restart the tool in administrator mode.

If you're unable to install/uninstall due to another app/process installation, follow these steps:

1. Right click on the task bar to open Task Manager. If necessary, choose **More Details**.
2. On the **Details** tab, look for *msiexec.exe* and select **End Task**.
3. Try to install or uninstall again, or, wait until the installation is finished.

To report issues to Microsoft:

1. **Collect logs** - Find the logs generated by the migration assistant on your local machine at the following path: `C:\Users\<username>\AppData\Local\Temp\MigrationAssistantforMicrosoftPurviewDLP\Logs`.
2. **Send email** - Send us the details about your issue along with the latest logs at dlpmigrations@microsoft.com or contact your CXE / FastTrack / Microsoft partner to share

your feedback and suggestions.

Report errors and provide feedback

To report errors, raise feature requests, or share more feedback, reach out to us at dlpmigrations@microsoft.com or contact your CXE / FastTrack / Microsoft partner.

Telemetry notice

Data Collection: This software might collect information about you and your use of the software, and send it to Microsoft. Microsoft might use this information to improve our products and services. If you want to turn off telemetry, you can reach out to us, and we provide you with a separate version of the tool with telemetry turned off.

There are also some features in the software that might enable you and Microsoft to collect data from users of your applications. If you use these features, you must comply with applicable law, including providing appropriate notices to users of your applications with a copy of Microsoft's privacy statement. Our privacy statement is located at Microsoft Privacy Statement. You can learn more about data collection and use in the help documentation and our privacy statement. Your use of the software operates as your consent to these practices.

Data Loss Prevention policy reference

Microsoft Purview Data Loss Prevention (DLP) policies have many components to configure. To create an effective policy, you need to understand what the purpose of each component is and how its configuration alters the behavior of the policy. This article provides a detailed anatomy of a DLP policy.

DLP platform considerations

Also, you need to be aware of these constraints of the platform:

- Maximum number of MIP + MIG policies in a tenant: 10,000
- Maximum size of a DLP policy (100 KB)
- Maximum number of DLP rules:
  - In a policy: Limited by the size of the policy
  - In a tenant: 600
- Maximum size of an individual DLP rule: 100 KB (102,400 characters)
- Generate Incident Report evidence limit: 100, with each SIT evidence, in proportion of occurrence
- Maximum size of text scanned from a file: The first 2 million characters (~2 MB) of extractable text. If a file exceeds this limit, first two million characters are scanned, and a "Document didn't complete scanning" signal is emitted.
- Maximum number of nested levels of data scanned from a file: The first three levels. If a file exceeds this limit, data in the first three levels are scanned, and a *Document didn't complete scanning* event is emitted.
- Regex size limit for all matches predicted: 20 KB
- Policy name length limit: 64 characters
- Policy rule length limit: 64 characters
- Comment length limit: 1,024 characters
- Description length limit: 1,024 characters
- Maximum size of Endpoint DLP Settings: 16,384 characters

Default DLP policies

There are four default DLP policies that are created in every tenant. These policies are designed to help you get started with DLP and provide a baseline level of protection for your organization. You can edit or delete these policies as needed.

Default Office 365 DLP policy

This policy detects the presence of credit card numbers in externally shared documents and emails. For more information, see Learn about the default data loss prevention policy for Microsoft 365 Copilot location

Default policy for Teams

The default DLP policy for Teams tracks all the credit card numbers shared internally and externally to the organization. For more information see, Learn about the default data loss prevention policy in Microsoft Teams

Defaul policy for devices

This policy detects the presence of credit card numbers in files on devices when users perform specific activities (such as printing a file). When detected, the activity is only audited (not blocked). Admins will receive an alert, but policy tips won't be displayed to users. You can edit these actions at any time. For more information, see Learn about the default DLP policy for device.

Default DLP policy for Microsoft 365 Copilot location

Prevent data leakage and oversharing by restricting Microsoft 365 Copilot and agents from using sensitive info in Copilot interactions. For more information, see Learn about the default DLP policy for Microsoft 365 Copilot location.

Policy templates

There are five types of DLP policy templates across two categories.

Enterprise applications & devices

- enhanced policies
- policies that can detect and protect types of **Financial** information.
- policies that can detect and protect types of **Medical and health** information.
- policies that can detect and protect types of **Privacy** information.
- A **Custom** policy template that you can use to build your own policy if none of the others meet your organization's needs.

The following table lists all policy templates and the sensitive information types (SIT) that they cover.

Inline web traffic policies

- A **Custom** policy template that you can use to build your own policy.

Policy scoping

See, Administrative units to make sure you understand the difference between an unrestricted admin and an administrative unit restricted admin.

DLP policies are scoped at two different levels. The first level applies unrestricted admin scope policies to all of the following in your organization (depending on the locations that are selected) or to subgroups of your organization, called Administrative Unit restricted policies:

- users

- groups
- distribution groups
- accounts
- sites
- cloud app instances
- on-premises repositories
- Fabric and Power BI workspaces

At this level, an administrative unit restricted admin will only be able to pick from the administrative units that they're assigned to. DLP support admin unit scoping for some of the locations protected under Enterprise applications & devices.

The second level of DLP policy scoping is by the locations that DLP supports. At this level, both unrestricted and administrative unit restricted administrators see only the users, distribution groups, groups, and accounts that were included in the first level of policy scoping and that are available for that location.

Support for adding SharePoint sites to Administrative Units

Microsoft Purview supports adding SharePoint sites to existing administrative units. When you assign a DLP policy for the SharePoint location to an administrative unit, the policy will only apply to the sites that are part of that administrative unit. The option to further edit the scope to include or exclude specific sites isn't available. The policy applies to all sites that are part of the administrative unit.

Here's an example use case:

Contoso has created an Entra ID administrative unit for the engineering department and has assigned certain administrators to manage the users and groups for that department. The engineering department has a SharePoint site that is used to store sensitive information. Contoso wants to ensure that the DLP policy for the engineering department SharePoint sites only applies to the SharePoint site that is part of the administrative unit. By assigning the DLP policy to the administrative unit, the policy will only apply to the SharePoint site that is part of that administrative unit. Also, the administrative unit restricted administrator will only be able to manage the DLP policy for that site and only see policy match result data for the administrative unit in activity explorer and the alert dashboard.

Unrestricted policies

Unrestricted policies are created and managed by users in these role groups:

- Compliance administrator
- Compliance data administrator
- Information Protection
- Information Protection Admin
- Security administrator

See, the Permissions article for more details.

Unrestricted administrators can manage all policies and see all the alerts and events that flow from policy matches into the Alerts dashboard and DLP Activity Explorer.

Administrative unit restricted policies

Administrative units are subsets of your Microsoft Entra ID directory and are created for the purposes of managing collections of users, groups, distribution groups, and accounts. These collections are typically created along business group lines or geopolitical areas. Administrative units have a delegated administrator who is associated with an administrative unit in the role group. These are called administrative unit restricted admins.

DLP supports associating policies with administrative units. See Administrative units for implementation details in the Microsoft Purview portal. Administrative unit admins need to be assigned to one of the same roles or role groups as administrators of unrestricted DLP policies in order to create and manage DLP policies for their administrative unit.

Expand table

DLP Administrative Role Group	Can
Unrestricted administrator	- create and scope DLP policies to entire organization - edit all DLP policies - create and scope DLP policies to administrative units - view all alerts and events from all DLP policies
Administrative Unit Restricted administrator - must be a member of/assigned to a role group/role that can administer DLP	- create and scope DLP policies only to the administrative unit that they're assigned to - edit DLP policies that are associated to their administrative unit - view alerts and events only from the DLP policies that are scoped to their administrative unit

Locations

A DLP policy can find and protect items that contain sensitive information across multiple locations.

Expand table

Location	Supports Administrative Units	Include/Exclude scope	Data state	Other prerequisites
Exchange Online	Yes	- distribution groups assigned or dynamic - security groups - non email enabled security groups assigned or dynamic) - Microsoft 365 groups assigned or dynamic	data-in-motion	No
SharePoint	Yes	site locations and, in preview, adaptive scopes at the policy level. If the policy is scoped to an administrative unit that includes SharePoint sites, the policy will only apply to all sites in the administrative unit, no further scoping is possible	data-at-rest data-in-use	No
OneDrive	Yes	- Distribution groups - Security groups - Non email enabled security groups - Microsoft 365 groups (Group members only, not the group as an entity)	data-at-rest data-in-use	No
Teams chat and channel messages	Yes	- Distribution groups - Security groups - Mail-enabled security groups - Microsoft 365 groups (Group members only, not the group as an entity)	data-in-motion data-in-use	See Scope of DLP protection
Instances	No	Cloud app instance	data-at-rest	- Use data loss prevention policies for non-Microsoft cloud apps
Devices	Yes	- Distribution groups - Security groups - Non-email enabled security groups	data-in-use data-	- Learn about Endpoint data loss prevention - Get started with

Location	Supports Administrative Units	Include/Exclude scope	Data state	Other prerequisites
		- Microsoft 365 groups (Group members only, not the group as an entity) - Dynamic groups	in-motion	Endpoint data loss prevention - Configure device proxy and internet connection settings for Microsoft Purview Endpoint DLP
On-premises repositories (file shares and SharePoint)	No	Repository	data-at-rest	- Learn about the data loss prevention on-premises repositories - Get started with data loss prevention for on-premises repositories
Fabric and Power BI	No	Workspaces	data-in-use	No
Non-Microsoft connected apps (preview)	No	Cloud app instance	data-at-rest	- Use DLP and sensitivity label policies for non-Microsoft connected apps - Only available in the **Custom** policy template - Set up a Microsoft Defender for Cloud Apps connector
Microsoft 365 Copilot (preview)	No	Account or Distribution group	data-at-rest data-in-use	- Only available in the **Custom** policy template
Managed cloud apps	No	Account or Distribution group	data-in-motion	- Only available in the **Custom** policy template
Unmanaged cloud apps	No	Account or Distribution group	data-in-motion	- Only available in the **Custom** policy template

> **Note**
>
> In the **Devices** location, the **Devices and device groups** setting supports only **Audit or restrict activities on devices**. You can't use it with **Audit or restrict activities when users access sensitive sites in the Microsoft Edge browser on Windows devices** under **Rule Actions**.

Exchange location scoping

If you choose to include specific distribution groups in Exchange, the DLP policy is scoped to the emails sent by members of that group or sent to members of that group. Similarly, excluding a distribution group excludes all the emails sent by the members of that distribution group or from policy evaluation.

Expand table

Group Type	Membership Type	Supported during Policy Creation	Supported during Rule Evaluation	Notes
Non-Mail Enabled Security Groups	Assigned	Yes	No	Enabled for specific customers only
Non-Mail Enabled Security Groups	Dynamic	Yes	No	
Mail-Enabled Security Groups	Assigned	Yes	Yes	
Distribution Groups	Assigned	Yes	Yes	
Distribution Groups	Dynamic	Yes	Yes	
Microsoft 365 Groups	Assigned	Yes	Yes

Adaptive Scopes	Dynamic	No	No	

Expand table

Sender is	Recipient is	Resultant behavior
In scope	N/A	Policy is applied

Sender is	Recipient is	Resultant behavior
Out of scope	In scope	Policy isn't applied

Exchange location scope calculation

Here's an example of how Exchange location scope is calculated:

Say you have four users in your org and two distribution groups that you use for defining Exchange location inclusion and exclusion scopes. Group membership is set up like this:

Expand table

Distribution Group	Membership
Group1	User1, User2
Group2	User2, User3
No group	User4

Expand table

Include setting	Exclude setting	Policy applies to	Policy doesn't apply to	Explanation of behavior
All	None	All senders in the Exchange org (User1, User2, User3, User4)	N/A	When neither are defined, all senders are included
Group1	None	Member senders of Group1 (User1, User2)	All senders who aren't members of Group1 (User3, User4)	When one setting is defined and the other isn't, the defined setting is used
All	Group2	All senders in the Exchange org who aren't members of Group2 (User1, User4)	All senders who are members of Group2 (User2, User3)	When one setting is defined and the other isn't, the defined setting is used
Group1	Group2	User1	User2, User3, User4	Exclude overrides include

You can choose to scope a policy to the members of distribution lists, dynamic distribution groups, and security groups. A DLP policy can contain no more than 50 such inclusions and exclusions.

OneDrive location scoping

When scoping a policy for OneDrive locations, in addition to applying your DLP policies to all users and groups in your organization, you can limit the scope of a policy to specific users and groups. DLP supports scoping policies to up to 100 individual users.

For instance, if you want to include more than 100 users, you must first put those users in distribution groups or security groups, as appropriate. You can then scope your policy to up to 50 groups.

In some cases, you might want to apply a policy to one or two groups, plus two or three individual users who don't belong to either of those groups. Here, the best practice is to **put those two or three individuals into a group of their own**. This is the only way to make sure that the policy is scoped to all intended users.

The reason for this is that, when you list only users, DLP adds all of the users specified to the policy scope. Similarly, when you add only groups, DLP adds all the members of all the groups to the policy scope.

Say you have the following groups and users:

Expand table

Distribution Group	Membership
Group1	User1, User2
Group2	User2, User3

If you limit the scope of a policy to *only* users or *only* groups, the DLP applies the policy to users as illustrated in the following table:

Expand table

Specified scope	DLP Scope evaluation behavior	Users in scope
(Users only) User1 User2	DLP takes the union of the specified users	User1, User2
(Groups only) Group1 Group2	DLP takes the union of the specified groups	User1, User2, User3

However, when users and groups are mixed in the scoping configuration, things get complicated. Here's why: DLP only scopes policies to users to **the intersection** of the listed groups and users.

DLP uses the following order of operations when determining which users and groups to include in the scope:

1. Evaluate the union of group membership
2. Evaluate the union of users
3. Evaluate the intersection of group members and users, that is, where the results overlap

It then applies the scope of the policy to the intersection of group members and users.

Let's extend our example, working with the same set of groups, and let's add User4, who isn't in a group:

Expand table

Distribution Group	Membership
Group1	User1, User2
Group2	User2, User3
No group	User 4

The following table explains how policy scoping works in cases where users and groups are both included in the scoping instructions.

Expand table

Specified scope	DLP Scope evaluation behavior	Users in scope

Group1
Group2
User3
User4
	First evaluation: Union of groups:
	`(Group1 + Group2) = User1, User2, User3`
	
	Second evaluation: Union of users:
	`(User3 + User4) = User3, User4`
	
	Third evaluation: Intersection of groups and Users (the overlap):
	
	`(Group1 + Group2) = User1, User2, User3`
	
	`(User3 + User4) = User3, User4`
		User3
		(User3 is the only user that appears in the results of both the first and second evaluations.)

Specified scope	DLP Scope evaluation behavior	Users in scope

Group1
Group2
User1
User3
User4
	First evaluation: Union of groups: `(Group1 + Group2) = User1, User2, User3`
	
	Second evaluation: Union of users: `(User1 + User3 + User4) = User1, User3, User4`
	
	Third evaluation: Intersection of groups and Users (the overlap):
	
	`(Group1 + Group2) = User1, User3`
	
	`(User1 + User3, User4) = User1, User3, User4`
		User1, **User3**
		(These are the only users that appear in the results of both the first and second evaluations.)

SharePoint location scoping

When scoping a policy for SharePoint locations, you can limit the scope of a policy to specific SharePoint sites and adaptive scopes. DLP supports scoping policies to up to 100 sites.

Device scoping

Microsoft Purview Data Loss Prevention (DLP) policies that include the **Devices** location can be scoped by **users** and by **devices**. A policy is enforced on an endpoint only when *both* the user and the device are included in the policy scope. If a user is in scope but the device is not, the policy isn't applied. Similarly, if a device is in scope but the user is not, the policy isn't applied.

Use 101.25072 or higher build for this feature support on macOS.

Device scoping does not support Microsoft Entra registered.

Here's how to configure the scope of a DLP policy for different outcomes.

Expand table

If you want to target the policy to...	Set user scope to...	Set device scope to...	Example use case
All users on all	**All users and groups**	**All devices and device groups**	Use this for general enforcement of DLP policies on all devices in your

If you want to target the policy to...	Set user scope to...	Set device scope to...	Example use case
onboarded devices			organization. This is the default setting for DLP policies.
All users on specific devices	**All users and groups**	either **All devices and device groups** with **Exclude devices and device groups** and add the devices to be excluded or **Specific devices and device groups** and add the devices to be included	Use this to apply a restrictive policy to kiosk devices that will be used by multiple users.
Specific users on all onboarded devices	either **All users and groups** with **Exclude users and groups** and add the users to be excluded or **Specific users and groups** and add the users to be included	**All devices and device groups**	Use this to help control data leakage by specific users on all devices in your organization.
Specific users on specific devices	**Specific users and groups**	**Specific devices and device groups**	Say you have special use devices in payroll that are used for printing checks and there are only a few accounts that are allowed to use those devices for printing checks. You can scope a restrictive endpoint DLP policy to those user accounts on those specific devices

Location support for how content can be defined

DLP policies detect sensitive items by matching them to a sensitive information type (SIT), or to a sensitivity label or a retention label. Each location supports different methods of defining sensitive content. How content can be defined when you combine locations in a policy, can change from how it can be defined when limited to a single location.

> **Important**
>
> When you select multiple locations for a policy, a "no" value for a content definition category takes precedence over "yes" value. For example, when you select SharePoint sites

only, the policy supports detecting sensitive items by one or more of SIT, by sensitivity label or by retention label. But, when you select SharePoint sites ***and*** Teams chat and channel messages locations, the policy will only support detecting sensitive items by SIT.

Expand table

Location	Content can be defined by SIT	Content can be defined sensitivity label	Content can be defined by retention label
Exchange email online	Yes	Yes	No

Managed cloud apps	Yes	No	No
Unmanaged cloud apps	Yes	Yes	No

DLP supports using trainable classifiers as a condition to detect sensitive information. Content can be defined by trainable classifiers in Exchange, SharePoint sites, OneDrive accounts, Teams Chat and Channels, Devices, and unmanaged cloud apps. For more information, see Trainable Classifiers.

Note

DLP supports detecting sensitivity labels on emails and attachments. For more information, see Use sensitivity labels as conditions in DLP policies.

Rules

Rules are the business logic of DLP policies. They consist of:

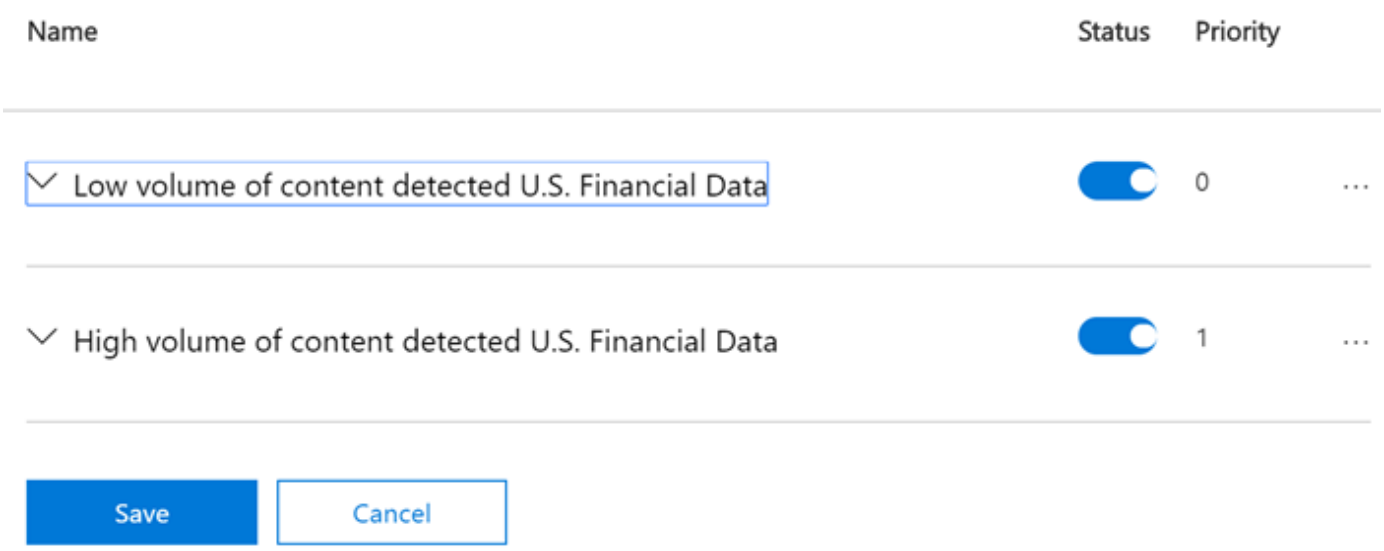
- **Conditions** that when matched, trigger the policy
- **Actions** that determine the activities included and outcomes of a match.
- **User notifications** to inform your users when they're doing something that triggers a policy and help educate them on how your organization wants sensitive information treated
- **User Overrides** when configured by an admin, allow users to selectively override a blocking action
- **Incident reports** that notify admins and other key stakeholders when a rule match occurs
- **Additional options** which define the priority for rule evaluation and can stop further rule and policy processing.

A policy contains one or more rules. Rules are executed sequentially, starting with the highest-priority rule in each policy.

How DLP classification works

DLP evaluates an item for sensitive information when the item is created, read, or modified. Evaluation is also initiated by on demand classification. However, events such as **DLP Rule Matched** only appear in Audit log or activity explorer when a user attempts an activity that matches a DLP policy.

Here's a list of some of the user activities that DLP can monitor and take actions on:



- Text upload via Microsoft Edge browser using integrated capabilities
- File upload via Microsoft Edge browser using integrated capabilities
- File download via Microsoft Edge browser using integrated capabilities
- Cut/copy data via Microsoft Edge browser using integrated capabilities
- Paste data via Microsoft Edge browser using integrated capabilities
- Print data via Microsoft Edge browser using integrated capabilities
- Print data from other locations

- Copy to removable media
- Copy to network share
- Copy to clipboard
- Transfer using Bluetooth
- File accessed by unallowed app
- Paste to browsers other than Microsoft Edge
- Print data
- Transfer using remote desktop
- An item that is created, read, or modified will match a DLP rule and policy on the client if the conditions and user activity are met. This is audited as file activity, such as FileRead, or FileRenamed.
- If an activity is met, then a DLP rule match event appears in activity explorer as a 'DLP Rule Matched' event. An event describing the mode of egress will also be generated.
- Policies take actions and actions are different from conditions. A rule can match on a file even if no actions are performed.

The priority by which rules are evaluated and applied

Hosted service locations

For the hosted service locations, like Exchange, SharePoint, and OneDrive, each rule is assigned a priority in the order in which it's created. This means that the rule created first has first priority, the rule created second has second priority, and so on.

When content is evaluated against rules, the rules are processed in priority order. If content matches multiple rules, the first rule evaluated that has the *most* restrictive action is enforced. For example, if content matches all of the following rules, *Rule 3* is enforced because it's the highest priority, most restrictive rule:

- Rule 1: only notifies users
- Rule 2: notifies users, restricts access, and allows user overrides
- *Rule 3: notifies users, restricts access, and doesn't allow user overrides*
- Rule 4: restricts access

Rules 1, 2, and 4 would be evaluated, but not applied. In this example, matches for all of the rules are recorded in the audit logs and shown in the DLP reports, even though only the most restrictive rule is applied.

You can use a rule to meet a specific protection requirement, and then use a DLP policy to group together common protection requirements, such as all of the rules needed to comply with a specific regulation.

For example, you might have a DLP policy that helps you detect the presence of information subject to the Health Insurance Portability and Accountability Act (HIPAA). This DLP policy could help protect HIPAA data (the "what") across all SharePoint sites and all OneDrive sites (the "where") by finding any document containing this sensitive information that's shared with people outside your organization (the conditions) and then blocking access to the document and sending a notification (the actions). These requirements are stored as individual rules and grouped together as a DLP policy to simplify management and reporting.

For endpoints

When an item matches multiple DLP rules, DLP goes uses through a complex algorithm to decide which actions to apply. Endpoint DLP applies the aggregate or sum of most restrictive actions. DLP uses these factors when making the calculation.

Policy priority order When an item matches multiple policies and those policies have identical actions, the actions from the highest priority policy are applied.

Rule priority order When an item matches multiple rules in a policy and those rules have identical actions, the actions from the highest priority rule are applied.

Mode of the policy When an item matches multiple policies and those policies have identical actions, the actions from all policies that are in **Turn it on** state (enforce mode) are applied preferentially over the policies in **Run the policy in simulation mode with policy tips** and **Run the policy in simulation mode** state.

Run the policy in simulaiton mode changes the action that's applied at runtime

When policies are matched and in the **Run the policy in simulation** state, they apply different actions than they would if they are in the **Turn it on right away** state.

Expand table

Action configured in the policy is	**When policy state is** Run the policy in simulation mode **and** Show policy tips in simulation mode **is off, the applied action is**	**When policy state is** Run the policy in simulation mode **and** Show policy tips while in simulation mode **is on, the applied action is**
Block	Audit	Block with override
Block with override	Audit	Block with override
Audit only	Audit	Audit
Allow	Allow	Allow

Action When an item matches multiple policies and those policies differ in actions, the aggregate or sum of the most restrictive actions are applied.

Authorization groups configuration When an item matches multiple policies and those policies differ in action, the aggregate, or sum, of the most restrictive actions are applied.

override options When an item matches multiple policies and those policies differ in the override option, actions are applied in this order:

No override > *Allow override*

Here are scenarios that illustrate the runtime behavior. For the first three scenarios, you have three DLP policies configured like this:

Expand table

Policy name	**Condition to match**	**Action**	**Policy priority**
ABC	Content contains credit card number	Block print, audit all other user egress activities	0
MNO	Content contains credit card number	Block copy to USB, audit all other user egress activities	1
XYZ	Content contains U.S. social security number	Block copy to clipboard, audit all other user egress activities	2

Item contains credit card numbers

An item on a monitored device contains credit card numbers, so it matches policy ABC and policy MNO. Both ABC and MNO are in *Turn it on* mode.

Policy	Cloud egress action	Copy to clipboard action	Copy to USB action	Copy to network share action	Unallowed apps action	Print action	Copy via Bluetooth action	Copy to remote desktop action
ABC	Audit	Audit	Audit	Audit	Audit	**Block**	Audit	Audit
MNO	Audit	Audit	**Block**	Audit	Audit	Audit	Audit	Audit
Actions applied at runtime	Audit	Audit	**Block**	Audit	Audit	**Block**	Audit	Audit

Item contains credit card numbers and U.S. social security numbers

An item on a monitored device contains credit card numbers and U.S. social security numbers, so this item matches policy ABC, policy MNO, and policy XYZ. All three policies are in *Turn it on* mode.

Policy	Cloud egress action	Copy to clipboard action	Copy to USB action	Copy to network share action	Unallowed apps action	Print action	Copy via Bluetooth action	Copy to remote desktop action
ABC	Audit	Audit	Audit	Audit	Audit	**Block**	Audit	Audit
MNO	Audit	Audit	**Block**	Audit	Audit	Audit	Audit	Audit
XYZ	Audit	**Block**	Audit	Audit	Audit	**Block**	Audit	Audit
Actions applied at runtime	Audit	**Block**	**Block**	Audit	Audit	**Block**	Audit	Audit

Item contains credit card numbers, different policy state

An item on a monitored device contains credit card number, so it matches policy ABC and policy MNO. Policy ABC is in *Turn it on* mode and policy *MNO* is in **Run the policy in simulation mode** state.

Policy	Cloud egress action	Copy to clipboard action	Copy to USB action	Copy to network share action	Unallowed apps action	Print action	Copy via Bluetooth action	Copy to remote desktop action
ABC	Audit	Audit	Audit	Audit	Audit	**Block**	Audit	Audit

Policy	Cloud egress action	Copy to clipboard action	Copy to USB action	Copy to network share action	Unallowed apps action	Print action	Copy via Bluetooth action	Copy to remote desktop action
MNO	Audit	Audit	**Block**	Audit	Audit	Audit	Audit	Audit
Actions applied at runtime	Audit	Audit	Audit	Audit	Audit	**Block**	Audit	Audit

Item contains credit card numbers, different override configuration

An item on a monitored device contains credit card number, so it matches policy ABC and policy MNO. Policy ABC is in *Turn it on* state and policy *MNO* is in *Turn it on* state. They have different *Override* actions configured.

Policy	Cloud egress action	Copy to clipboard action	Copy to USB action	Copy to network share action	Unallowed apps action	Print action	Copy via Bluetooth action	Copy to remote desktop action
ABC	Audit	Audit	**Block with override**	Audit	Audit	**Block**	Audit	Audit
MNO	Audit	Audit	**Block without override**	Audit	Audit	Audit	Audit	Audit
Actions applied at runtime	Audit	Audit	**Block without override**	Audit	Audit	**Block**	Audit	Audit

Item contains credit card numbers, different authorization groups configuration

An item on a monitored device contains credit card number, so it matches policy ABC and policy MNO. Policy ABC is in *Turn it on* state and policy *MNO* is in *Turn it on* state. They have different *authorization group* actions configured.

Policy	Cloud egress action	Copy to clipboard action	Copy to USB action	Copy to network share action	Unallowed apps action	Print action	Copy via Bluetooth action	Copy to remote desktop action
ABC	Audit	Audit	**Auth group A - Block**	Audit	Audit	**Auth group A - Block**	Audit	Audit
MNO	Audit	Audit	**Auth group A - Block with override**	Audit	Audit	**Auth group B - block**	Audit	Audit
Actions applied at runtime	Audit	Audit	**Auth group A - Block**	Audit	Audit	**Auth group A - Block, Auth group B - Block**	Audit	Audit

Conditions

Conditions are where you define what you want the rule to look for and the context in which those items are being used. They tell the rule: when you find an item that looks like *this* and is being used like *that*—it's a match and the rest of the actions in the policy should be taken on it. You can use conditions to assign different actions to different risk levels. For example, sensitive content shared internally might be lower risk and require fewer actions than sensitive content shared with people outside the organization.

> ⓘ **Note**
>
> Users who have non guest accounts in a host organization's Active Directory or Microsoft Entra tenant are considered as people inside the organization.

Content contains

All locations support the **Content contains** condition. You can select multiple instances of each content type and further refine the conditions by using the **Any of these** (logical OR) or **All of these** (logical AND) operators:

- sensitive information types
- sensitivity labels
- retention labels
- Trainable Classifiers

The rule will only look for the presence of any **sensitivity labels** and **retention labels** you pick.

SITs have a predefined **confidence level** which you can alter if needed. For more information, see More on confidence levels.

> **Important**
>
> SITs have two different ways of defining the maximum unique instance count parameters. To learn more, see **Instance count supported values for SIT**.

> Duplicate SIT words across different attachments in a single email are only counted once toward the unique count.

Adaptive Protection in Microsoft Purview

Adaptive protection integrates Microsoft Purview Insider Risk Management risk profiles into DLP policies so that DLP can help protect against dynamically identified risky behaviors. When configured in insider risk management, the **Insider risk level for Adaptive Protection is** will show up as condition for Exchange Online, Devices, Teams, and unmanaged cloud apps locations. Refer to Learn about Adaptive Protection in Data Loss Prevention for more details.

Conditions that Adaptive Protection supports

- Insider risk level for Adaptive Protection is supported with these values:
- Elevated risk level
- Moderate risk level
- Minor risk level

Condition context

The available context options change depending on which location you choose. If you select multiple locations, only the conditions that the locations have in common are available.

Conditions Exchange supports

> **Note**
>
> DLP policies for Exchange scan non system generated emails and journaling emails.

- Content contains
- Insider risk level for Adaptive Protection is
- Content isn't labeled
- Content is shared from Microsoft 365
- Content is received from
- Sender IP address is
- Header contains words or phrases
- Sender AD Attribute contains words or phrases
- Content character set contains words
- Header matches patterns
- Sender AD Attribute matches patterns
- Recipient AD Attribute contains words or phrases
- Recipient AD Attribute matches patterns
- Recipient is member of
- Document property is
- Any email attachment's content could not be scanned
- Document or attachment is password protected
- Has sender overridden the policy tip
- Sender is a member of
- Any email attachment's content didn't complete scanning
- Recipient address contains words
- File extension is
- Recipient domain is
- Recipient is
- Sender is
- Sender domain is
- Recipient address matches patterns
- Document name contains words or phrases
- Document name matches patterns
- Subject contains words or phrases
- Subject matches patterns

- Subject or body contains words or phrases
- Subject or body matches patterns
- Sender address contains words
- Sender address matches patterns
- Document size equals or is greater than
- Document content contains words or phrases
- Document content matches patterns
- Message size equals or is greater than
- Message type is
- Message importance is

> **Tip**
>
> For more information on the conditions that Exchange supports, including PowerShell values, see: **Data loss prevention Exchange conditions and actions reference**.

Conditions SharePoint supports

- Content contains
- Content is shared from Microsoft 365
- Document property is
- Document could not be scanned
- Document or attachment is password protected
- Document didn't complete scanning
- File extension is
- Document name contains words or phrases
- Document size equals or is greater than
- Document created by
- Document creation date is on or after
- Document creation date is on or before

- Document modification date is on or after
- Document modification date is on or before

Conditions OneDrive accounts support

- Content contains
- Content is shared from Microsoft 365
- Document property is
- Document could not be scanned
- Document or attachment is password protected
- Document didn't complete scanning
- File extension is
- Document name contains words or phrases
- Document size equals or is greater than
- Document created by
- Document is shared
- Document creation date is on or after
- Document creation date is on or before
- Document modification date is on or after
- Document modification date is on or before

Conditions Teams chat and channel messages support

- Content contains
- Insider risk level for Adaptive Protection is
- Content is shared from Microsoft 365
- Recipient domain is
- Recipient is
- Sender is
- Sender domain is

Conditions managed cloud apps support

- Content contains
- File extension is
- Document size equals or is greater than
- Managed or unmanaged devices (the cut/copy data, paste data, and print data activities only support the managed or unmanaged devices condition).

Conditions unmanaged cloud apps support

- Content contains
- Content not fully scanned
- File cannot be scanned
- File extension is
- File is not labeled
- File is password protected
- File size is greater than
- File type is
- Insider risk level for Adaptive Protection is
- URL contains text (preview)

(Preview) The **URL contains text** condition detects when the URL of the unmanaged cloud app contains specified text strings. You can use it as a condition to scope DLP rules to specific URLs, or as an exception to exclude specific URLs from policy enforcement. For example, you can create a rule that blocks uploading sensitive data to any GitHub URL that doesn't contain your organization's name while allowing uploads to your organization's GitHub repositories. This condition is supported for browser and network detection and doesn't require devices to be onboarded to endpoint DLP.

> **Important**
>
> Encrypted files can't be inspected for sensitive info types or trainable classifiers.

Conditions supported for Endpoints

- **Content contains:** Specifies content to be detected. For details on supported file types, see Files scanned for content.

- **Content is not labeled:** Detects content that doesn't have a sensitivity label applied. To help ensure only supported file types are detected, you should use this condition with the **File extension is** or **File type is** conditions. PDF and Office files are supported:

File Type	Format	Monitored file extensions
Word processing	Word, PDF	.doc, .docx, .docm, .dot, dotx, .dotm, .docb, .pdf
Spreadsheet	Excel, CSV, TSV	.xls, .xlsx, .xlt, .xlm, .xlsm, xltx, xltm, xlsb, .xlw, .csv, .tsv
Presentation	PowerPoint	.ppt, .pptx, .pos, .pps, .pptm, .potx, .potm, .ppam, .ppsx

- **Document could not be scanned:** Applies to files that can't be scanned for one of the following reasons:
  - File contains one or more transient text-extraction errors
  - File is password-protected
  - File size exceeds the supported limit (Maximum file sizes: 64 MB for uncompressed files; 256 MB for compressed files)
  - Microsoft classification engine (MCE) timeout or failure

- **Document name contains words or phrases:** Detects documents with file names that contain any of the words or phrases you specify, for example: `file`, `credit card`, `patent`, etc.

- **Document name matches patterns:** Detects documents where the file name matches specific patterns. The evaluation considers the entire path of the document, not just the document's name. The pattern is checked as a string match, meaning it can match any part of the document path. To define the patterns, use wild cards.

> ⓘ **Note**
>
> Due to potential performance issues, this condition will gradually be phased out from Purview Endpoint DLP. We recommend using the 'Document name contains words or phrases' condition instead.

- **Document or attachment is password protected:** Detects only protected files that are open. The following files are supported:
- Archive files (ZIP, .7z, RAR)
  - Office files
  - PDFs
  - Symantec PGP encrypted files

- **Document size equals or is greater than:** Detects documents with file sizes that are equal to or greater than the specified value. DLP only supports content inspection for files less than 64 MB.

  > ⓘ **Important**
  >
  > We recommend setting this condition to detect items that are larger than 10KB

- **File type is:** Detects the following file types:

File type	Apps	Monitored file extensions
Word processing	Word, PDF	doc, .docx, .docm, .dot, dotx, .dotm, .docb, .pdf
Spreadsheet	Excel, CSV, TSV	.xls, .xlsx, .xlt, .xlm, .xlsm, xltx, xltm, xlsb, .xlw, .csv, .tsv
Presentation	PowerPoint	.ppt, .pptx, .pos, .pps, .pptm, .potx, .potm, .ppam, .ppsx
Email	Outlook	.msg

  > ⓘ **Important**
  >
  > The **file extensions** and **file types** options *can't* be used as conditions in the same rule. If you want to use them as conditions in the same policy, they must be in separate rules.

To use the **File type is** condition, you must have one of the following versions of Windows:

- Windows Endpoints (X64):
  - Windows 10 (21H2, 22H2)
    - Windows 10 21H2 update details
    - Windows 10 22H2 update details

- Windows Endpoints (ARM64):
  - Windows 11 (21H2, 22H2)
    - Windows 11 21H2 update details
    - Windows 11 22H2 update details

- **File extension is:** In addition to detecting sensitive information in files with the same extensions as those covered by the **File type is** condition, you can use the **File extension is** condition to detect sensitive information in files with any file extension you need to monitor. To do so, add the necessary file extensions, separated by commas to a rule in your

policy. The **File extension is** condition is supported only for those versions of Windows that support the **File type is** condition. **File extension is** doesn't support archive file types.

> ⚠ **Warning**
>
> Including any of the following file extensions in your policy rules might significantly increase the CPU load: .dll, .exe, .mui, .ost, .pf, .pst.

- **Scanning did not complete:** Applies when the scanning of a file started, but stopped before the entire file was scanned. The primary reason for an incomplete scan is that extracted text within the file exceeds the maximum size allowed. (Maximum sizes for extracted text: Uncompressed files: The first 4 MB of extractable text; Compressed files: N=1000 / Extraction Time = 5 minutes.)

- **Document property is:** Detects documents with custom properties matching specified values. For example: `Department = 'Marketing'`, `Project = 'Secret'`. To specify multiple values for a custom property, use double quotes. For example, "Department: Marketing, Sales". Supported file types are Office and PDF:

File Type	Format	Monitored file extensions
Word processing	Word, PDF	.doc, .docx, .docm, .dot, dotx, .dotm, .docb, .pdf
Spreadsheet	Excel, CSV, TSV	.xls, .xlsx, .xlt, .xlm, .xlsm, xltx, xltm, xlsb, .xlw, .csv, .tsv
Presentation	PowerPoint	.ppt, .pptx, .pos, .pps, .pptm, .potx, .potm, .ppam, .ppsx

- **The user accessed a sensitive website from Microsoft Edge:** For more information, see Help prevent risky user activity by monitoring or restricting access to sensitive service domains.

- **Insider risk level for Adaptive Protection is:** Detects the insider risk level.

See also: Endpoint activities you can monitor and take action on.

Operating system requirements for five conditions

- Document could not be scanned
- Document name contains words or phrases
- Document name matches patterns
- Document size equals or is greater than
- Scanning did not complete

To use any of these conditions, your endpoint devices must be running one of the following operating systems:

- **Windows 11 23H2:** December 4, 2023—KB5032288 (OS Builds 22621.2792 and 22631.2792) Preview
- **Windows 11 22H2:** December 4, 2023—KB5032288 (OS Builds 22621.2792 and 22631.2792) Preview - Microsoft Support
- **Windows 11 21H2:** December 12, 2023—KB5033369 (OS Build 22000.2652) - Microsoft Support
- **Windows 10 22H2:** November 30, 2023—KB5032278 (OS Build 19045.3758) Preview - Microsoft Support
- **Windows 10 21H2:** November 30, 2023—KB5032278 (OS Build 19045.3758) Preview - Microsoft Support
- **Windows Server 2022/2019:** November 14, 2023—KB5032198 (OS Build 20348.2113) - Microsoft Support (or later)

Operating system requirements for Condition 'Document Property is'

- **Windows 11:** February 29, 2024—KB5034848 (OS Builds 22621.3235 and 22631.3235) Preview - Microsoft Support (or later)
- **Windows 10:** February 29, 2024—KB5034843 (OS Build 19045.4123) Preview - Microsoft Support (or later)

> **Important**
>
> For information about the Adobe requirements for using Microsoft Purview Data Loss Prevention (DLP) features with PDF files, see this article from Adobe: **Microsoft Purview Information Protection Support in Acrobat**.

Conditions Instances supports

- Content contains
- Content is shared from Microsoft 365

Conditions On-premises repositories support

- Content contains
- File extension is
- Document property is

Conditions Fabric and Power BI support

- Content contains

Conditions Microsoft 365 Copilot supports

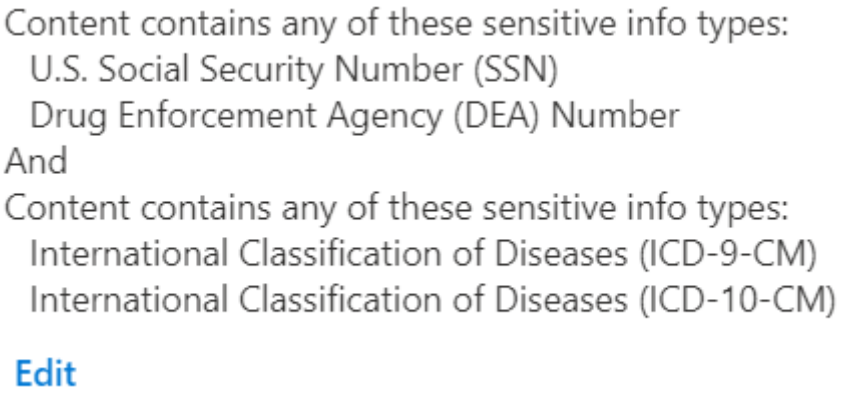
This feature is in preview.

- Content contains (sensitivity labels)
- Content contains (sensitive information types)
- Email is received from (External users) (preview)

Condition groups

Sometimes you need a rule to identify only one thing, such as all content that contains a U.S. Social Security Number, which is defined by a single SIT. However, in many scenarios where the types of items you're trying to identify are more complex and therefore harder to define, more flexibility in defining conditions is required.

For example, to identify content subject to the U.S. Health Insurance Act (HIPAA), you need to look for:



- Content that contains specific types of sensitive information, such as a U.S. Social Security Number or Drug Enforcement Agency (DEA) Number.

  AND

- Content that's more difficult to identify, such as communications about a patient's care or descriptions of medical services provided. Identifying this content requires matching keywords from large keyword lists, such as the International Classification of Diseases (ICD-9-CM or ICD-10-CM).

You can identify this type of data by grouping conditions and using logical operators (AND, OR) between the groups.

For the **U.S. Health Insurance Act (HIPAA)**, conditions are grouped like this:

The first group contains the SITs that identify an individual and the second group contains the SITs that identify medical diagnosis.

Conditions can be grouped and joined by boolean operators (AND, OR, NOT) so that you define a rule by stating what should be included and then defining exclusions in a different group joined to the first by a NOT. To learn more about how Purview DLP implements booleans and nested groups see, Complex rule design.

DLP platform limitations for conditions

Condition	Workload	Limit	Cost of Evaluation
Content Contains	EXO/SPO/ODB	125 SITs per rule	High
Content is shared from Microsoft 365	EXO/SPO/ODB	-	High
Sender IP address is	EXO	Individual range length <= 128; Count <= 600	Low
Has sender overridden the policy tip	EXO	-	Low
Sender is	EXO	Individual email length <= 256; Count <= 600	Medium
Sender is a member of	EXO	Count <= 600	High
Sender domain is	EXO	Domain name length <= 67; Count <= 600	Low
Sender address contains words	EXO	Individual word length <= 128; Count <= 600	Low
Sender address matches patterns	EXO	Regex length <= 128 char; Count <= 600	Low

Condition	Workload	Limit	Cost of Evaluation
Sender AD attribute contains words	EXO	Individual word length <= 128; Count <= 600	Medium
Sender AD attribute matches patterns	EXO	Regex length <= 128 char; Count <= 600	Medium
Content of email attachment(s) can't be scanned	EXO	Supported file types	Low
Incomplete scan of email attachment content	EXO	Extracted content size > 2 MB (2 million characters)	Low
Attachment is password-protected	EXO	File types: Office files, .PDF, .ZIP, and 7z	Low
Attachment's file extension is	EXO/SPO/ODB	Count <= 600 per rule	High
Recipient is a member of	EXO	Count <= 600	High
Recipient domain is	EXO	Domain name length <= 67; Count <= 5000	Low
Recipient is	EXO	Individual email length <= 256; Count <= 600	Low
Recipient address contains words	EXO	Individual word length <= 128; Count <= 600	Low
Recipient address matches patterns	EXO	Count <= 300	Low
Document name contains words or phrases	EXO	Individual word length <= 128; Count <=600	Low
Document Name matches patterns	EXO	Regex length <= 128 char; Count <= 300	Low
Document property is	EXO/SPO/ODB	-	Low
Document size equals or is greater than	EXO	-	Low
Subject contains words or phrases	EXO	Individual word length <= 128; Count <= 600	Low
Header contains words or phrases	EXO	Individual word length <= 128; Count <= 600	Low

Condition	Workload	Limit	Cost of Evaluation
Subject or body contains words or phrases	EXO	Individual word length <= 128; Count <= 600	Low
Content character set contains words	EXO	Count <= 600	Low
Header matches patterns	EXO	Regex length <= 128 char; Count <= 300	Low
Subject matches patterns	EXO	Regex length <= 128 char; Count <= 300	Low
Subject or body matches patterns	EXO	Regex length <= 128 char; Count <= 300	Low
Message type is	EXO	-	Low
Message size over	EXO	-	Low
With importance	EXO	-	Low
Sender AD attribute contains words	EXO	Each attribute key value pair: has Regex length <= 128 char; Count <= 600	Medium
Sender AD attribute matches patterns	EXO	Each attribute key value pair: has Regex length <= 128 char; Count <= 300	Medium
Document contains words	EXO	Individual word length <= 128; Count <= 600	Medium
Document matches patterns	EXO	Regex length <= 128 char; Count <= 300	Medium

Actions

Any item that makes it through the ***conditions*** filter has any ***actions*** that are defined in the rule applied to it. You have to configure the required options to support the action. For example, if you select Exchange with the **Restrict access or encrypt the content in Microsoft 365 locations** action, you need to choose from these options:

- Block users from accessing shared SharePoint, OneDrive, and Teams content
  - Block everyone. Only the content owner, last modifier, and site admin will continue to have access
  - Block only people from outside your organization. Users inside your organization continue to have access.

- Encrypt email messages (applies only to content in Exchange)

The actions that are available in a rule depend on the locations that have been selected. The available actions for each individual location are listed below.

> **Important**
>
> For SharePoint and OneDrive locations, documents will be proactively blocked right after detection of sensitive information (regardless of whether the document is shared or not) for all guests; internal users continue to have access to the document.

Supported actions: Exchange

When DLP policy rules are applied in Exchange, they may be **halting**, **non-halting**, or **neither**. Most of the rules that Exchange supports are non halting. Non halting actions are applied after processing the subsequent rules and policies.

DLP actions are taken on inbound encrypted emails that are in scope of a policy, such as block, *but* to maintain the confidentiality of the encryption, the event won't appear in Activity Explorer or in the Alert and the content of the message won't be accessible to anyone other than the recipient.

However, when a *halting* action is triggered by a DLP policy rule, Purview stops processing any subsequent rules. For instance, when the *Restrict access or encrypt the content in Microsoft 365 locations* action is triggered, no further rules or policies are processed.

If an action is *neither* halting nor non halting, Purview waits for the result of the action to occur before continuing. So, when an outgoing email triggers the *Forward the message for approval to sender's manager* action, Purview waits to get the manager's decision on whether or not the email may be sent. If the manager approves, the action behaves as a non halting action and the subsequent rules are processed. In contrast, if the manager rejects sending the email, *Forward the message for approval to sender's manager* behaves as a halting action and blocks sending the email; no subsequent rules or policies are processed.

The following table lists the actions that Exchange supports, and indicates whether they're halting or non halting.

Action	Halting / Non halting
Restrict access or encrypt the content in Microsoft 365 locations (Block Everyone, Block only people outside your organization)	Halting
Restrict access or encrypt the content in Microsoft 365 locations (Encrypt Email Messages)	Non - Halting
Set headers	Non halting
Remove header	Non halting
Redirect the message to specific users	Non halting
Forward the message for approval to sender's manager	Neither
Forward the message for approval to specific approvers	Neither

Remove message encryption and rights protection	Non halting
Prepend Email Subject	Non halting
Add HTML Disclaimer	Non halting
Modify Email Subject	Non halting
Deliver the message to the hosted quarantine	Halting
Apply branding to encrypted messages	Non halting

Tip

For the **Apply branding to encrypted messages** action, if you already have Microsoft Purview Message Encryption implemented, the templates automatically show up in the drop-down list. If you want to implement Microsoft Purview Message Encryption, see **Add your organization's brand to your Microsoft Purview Message Encryption encrypted messages** for background on message encryption and how to create and configure your branding templates.

For more information on the actions that Exchange supports, including PowerShell values, see: Data loss prevention Exchange conditions and actions reference.

Supported actions: SharePoint

- Restrict access or encrypt the content in Microsoft 365 locations
  - Block everyone
  - Block only people from outside your organization
  - Block access for specific external domains or users (in public preview)

The **Block access for specific external domains or users** sub-option lets you block external access by domain (for example, `partner.com`) or by user SMTP (for example, `user@example.com`). You can also specify allow lists by using **Domain IS NOT** or **User IS NOT**. Internal users and domains can't be blocked with this sub-option; continue to use **Block everyone** for internal users.

> **Note**
>
> When you use **Block access for specific external domains or users**: if a user or domain appears in both allow and block lists, the block takes effect (most restrictive wins). If a file matches both an allow rule and a block rule, evaluation is across all matching rules — allowed users and domains are permitted, blocked users and domains are denied, and users in neither list are blocked by default.

Supported actions: OneDrive

- Restrict access or encrypt the content in Microsoft 365 locations
  - Block everyone
  - Block only people from outside your organization
  - Block access for specific external domains or users (in public preview)

The **Block access for specific external domains or users** sub-option lets you block external access by domain (for example, `partner.com`) or by user SMTP (for example, `user@example.com`). You can also specify allow lists by using **Domain IS NOT** or **User IS NOT**. Internal users and domains can't be blocked with this sub-option; continue to use **Block everyone** for internal users.

> **Note**
>
> When you use **Block access for specific external domains or users**: if a user or domain appears in both allow and block lists, the block takes effect (most restrictive wins). If a file

matches both an allow rule and a block rule, evaluation is per rule — allowed users and domains are permitted, blocked users and domains are denied, and users in neither list are blocked by default.

Supported actions: Teams Chat and Channel Messages

- Restrict access or encrypt the content in Microsoft 365 locations

Supported actions: Devices

The **Devices** location supports these actions:

- Restrict access or encrypt the content in Microsoft 365 locations
  - Block users from receiving email, or accessing shared SharePoint, OneDrive, Teams files, and Power BI items
- Audit or restrict activities when users access sensitive sites in Microsoft Edge browsers on Windows devices
  - Sensitive site restrictions
- Audit or restrict activities on devices
  - Upload to a restricted cloud service domain or access from an unallowed browser
  - Paste to supported browsers
- File activities for all apps
  - Copy to clipboard
  - Copy to removable USB device
  - Copy to a network share
  - Print
  - Copy or move using unallowed Bluetooth app
  - Copy or move using RDP
  - File activities for apps in restricted app groups
  - App access restrictions
    - Access by restricted apps
    - Access by apps not included in restricted apps list or any restricted app groups added to rule
    - *in preview* Restrictions in Windows Recall in Copilot+ PCs
    - Apply restrictions to only unsupported file extensions Start a Power Automate flow

Important

When you select the **Audit or restrict activities on devices** action, the **Apply restrictions to only unsupported file extensions** shows up. **Apply restrictions to only unsupported file extensions** configuration option ***DOES NOT*** support scoping by **Device and device groups** in the policy location setting.

You can tell DLP to **Allow**, **Audit only**, **Block with override**, or **Block** (the actions) these user activities for onboarded Windows devices.

You can tell DLP to **Audit only**, **Block with override**, or **Block** (the actions) these user activities for onboarded macOS devices.

- **Block**: User related activity is blocked, and auditing is enabled. Admins may optionally see alerts.
- **Block with override**: This option acts as a standard block but permits users to bypass it. By clicking the 'Allow' button on the toast notification or the 'Ok' button on the Microsoft Edge notification, users can proceed. Once allowed, Endpoint DLP will automatically resume for actions including 'Copy to a network share', 'Copy to a removable USB device', and 'Print'. For other actions, users will need to repeat the process after clicking 'Allow' to bypass the policy.
- **Audit**: No blocking of activities, but auditing is enabled, and admins may optionally see alerts.
- **Allow**: Activities are allowed without triggering alerts, but auditing is still enabled.
- **Off**: No blocking or auditing of activities.

Enforcement mode	Block user	Alert generation	Auditing record generation
Block	Yes	Yes if alert is turned on for the DLP rule	Yes
Block with override	Yes	Yes if alert is turned on for the DLP rule	Yes
Audit	No	Yes if alert is turned on for the DLP rule	Yes
Allow	No	Never triggered	Yes
Off	No	No	No

Supported actions: Managed cloud apps

You can tell DLP to **Audit only** or **Block** (the actions) for user activities in managed cloud apps on Windows and macOS devices.

Supported actions: Unmanaged cloud apps

You can tell DLP to **Audit only** or **Block** (the actions) for user activities in unmanaged cloud apps on Windows.

More information on supported actions

You can find more details here about actions:

- Restrict access or encrypt content in Microsoft 365 locations
- Audit or restrict activities when users access sensitive sites in Microsoft Edge browsers on Windows devices
- Audit or restrict activities on devices
- Service domain and browser activities
- File activities for all apps
- Restricted app activities
- File activities for apps in restricted app groups

Restrict access or encrypt content in Microsoft 365 locations

Use this to block users from receiving email, or accessing shared SharePoint, OneDrive, Teams files, and Power BI items. This action can block everyone or block only people who are outside your organization. For SharePoint and OneDrive locations only, you can also block access for specific external domains or user SMTPs (in public preview).

Audit or restrict activities when users access sensitive sites in Microsoft Edge browsers on Windows devices

Use this action to control when users attempt to:

Activity	Description/options
Print the site	Detects when users try to print a protected site from an onboarded device.
Copy data from the site	Detects when users try to copy data from a protected site from an onboarded device.
Save the site as local files (Save-As)	Detects when users try to save a protected site as local files from an onboarded device.

Audit or restrict activities on devices

Use this to restrict user activities by Service domain and browser activities, File activities for all apps, Restricted app activities. To use **Audit or restrict activities on devices**, you have to configure options in **DLP settings** and in the policy in which you want to use them. See, Restricted apps and app groups for more information.

DLP rules with the action **Audit or restrict activities on devices** can have **Block with override** configured. When this rule is applied to a file, any attempt to perform a restricted action on the file is blocked. A notification is displayed with the option to override the restriction. If the user chooses to override, the action is permitted for a period of 1 minute, during which the user can retry the action without restriction. The exception to this behavior is when a sensitive file is dragged and dropped into Microsoft Edge, which will immediately attach the file if the rule is overridden.

Service domain and browser activities

When you configure the **Allow/Block cloud service domains** and the **Unallowed browsers** list (see Browser and domain restrictions to sensitive data) and a user attempts to upload a protected file to a cloud service domain or access it from an unallowed browser, you can configure the policy action to `Audit only`, `Block with override`, or `Block` the activity.

Activity	Description/options
Upload to a restricted cloud services domain or access from an unallowed app	Detects when protected files are blocked or allowed to be uploaded to cloud service domains. See, Browser and domain restrictions to sensitive data and Help prevent risky user activity by monitoring or restricting access to sensitive service domains.
Paste to supported browsers	Detects when users paste sensitive information into a text field or web form using Microsoft Edge, Google Chrome (with Microsoft Purview extension), or Mozilla Firefox (with Microsoft Purview extension). Evaluation is independent of the classification of the source file. For more information, see: Endpoint activities you can monitor and take action on.

Paste to Browser limitations

Only certain rule conditions work with Paste to Browser events due to the fact that the rules are being evaluated only on the clipboard data. Paste to Browser won't evaluate based on where the text is being copied from.

Rule conditions that work with Paste to Browser:

- Content contains
- Content is not labeled

Additional notes:

- Paste to Browser supports SITs, not Sensitivity Labels.
- Paste to Browser doesn't evaluate on text smaller than 30 characters.
- Advanced Classification isn't supported.
- Contextual Summary doesn't show for Paste to Browser events.
- Paste to Browser takes 2 seconds to evaluate before allowing the paste action.
- IF JIT is configured to block on fallback, it blocks pasting.
- Paste to Browser only classifies the first 4 MB of text from the clipboard

File activities for all apps

With the **File activities for all apps** option, you select either **Don't restrict file activities** or **Apply restrictions to specific activities**. When you select **Apply restrictions to specific activities**, the actions that you select here are applied when a user has accessed a DLP protected item.

Activity	Description/options
Copy to clipboard	Detects when protected files are copied to the clipboard on an onboarded device. For more information, see Endpoint activities you can monitor and take action on and Copy to clipboard behavior
Copy to a removable device	Detects when protected files are copied or moved from an onboarded device to a removable USB device. For more information, see Removable USB device groups.
Copy to a network share	Detects when protected files are copied or moved from an onboarded device to any network share. For more information, see Endpoint activities you can monitor and take action on and Network share coverage and exclusions.
Print	Detects when a protected file is printed from an onboarded device. For more information, see Printer groups.
Copy or move using unallowed Bluetooth app	Detects when a protected file is copied or moved from an onboarded Windows device using an unallowed Bluetooth app. For more information, see Unallowed Bluetooth apps. This isn't supported for macOS.
Copy or move using RDP	Detects when users copy or move protected files from an onboarded Windows device to another location using RDP. This isn't supported for macOS.

Restricted app activities

Previously called Unallowed apps, *restricted app activities* are apps that you want to place restrictions on. You define these apps in a list in Endpoint DLP settings. When a user attempts to access a DLP protected file using an app that is on the list, you can either `Audit only`, `Block with override`, or `Block` the activity. DLP actions defined in **Restricted app activities** are overridden if

the app is a member of restricted app group. Then the actions defined in the restricted app group are applied.

Activity	Description/options
Access by restricted apps	Detects when unallowed apps try to access protected files on an onboarded Windows device. For more information, see Restricted apps and app groups.

File activities for apps in restricted app groups

You define your restricted app groups in Endpoint DLP settings and add restricted app groups to your policies. When you add a restricted app group to a policy, you must select one of these options:

- Don't restrict file activity
- Apply restrictions to all activity
- Apply restrictions to specific activity

When you select either of the *Apply restrictions* options, and a user attempts to access a DLP protected file using an app that is in the restricted app group, you can either `Audit only`, `Block with override`, or `Block` by activity. DLP actions that you define here override actions defined in **Restricted app activities** and **File activities for all apps** for the app.

For more information, see Restricted apps and app groups.

> **Note**
>
> The devices location provides many subactivities (conditions) and actions. To learn more, see Endpoint activities you can monitor and take action on.

> **Important**
>
> The **Copy to clipboard** condition detects when a user copies information from a *protected file* to the clipboard. Use **Copy to clipboard** to block, block with override, or audit when users copy information from a protected file.
>
> The **Paste to supported browsers** condition detects when a user attempts to paste sensitive text into a text field or web form using Microsoft Edge, Google Chrome with Microsoft Purview extension, or Mozilla Firefox with Microsoft Purview extension *regardless of where*

that information came from. Use **Paste to supported browsers** to block, block with override, or audit when users paste sensitive information into a text field or web form.

Instances actions

- Restrict access or encrypt the content in Microsoft 365 locations
- Restrict Third Party Apps

On-premises repositories actions

- Restrict access or remove on-premises files.
  - Block people from accessing files stored in on-premises repositories
  - Set permissions on the file (permissions inherited from the parent folder)
  - Move file from where it's stored to a quarantine folder

See, DLP On-premises repository actions for full details.

Fabric and Power BI actions

- Notify users with email and policy tips
- Send alerts to Administrator
- Restrict access

> **Note**
>
> Applicable to supported item types only.

Microsoft 365 Copilot actions

This feature is in preview.

- Exclude content in the location

Managed cloud apps actions

- Restrict browser and network activities

Unmanaged cloud apps actions

- Restrict browser and network activities

Actions available when you combine locations

If you select Exchange and any other single location for the policy to be applied to, the

- Restrict access or encrypt the content in Microsoft 365 locations and all actions for the non-Exchange location actions are available.

If you select two or more non-Exchange locations for the policy to be applied to, the

- Restrict access or encrypt the content in Microsoft 365 locations and all actions for non-Exchange locations actions are available.

For example, if you select the Exchange and Devices locations, these actions are available:

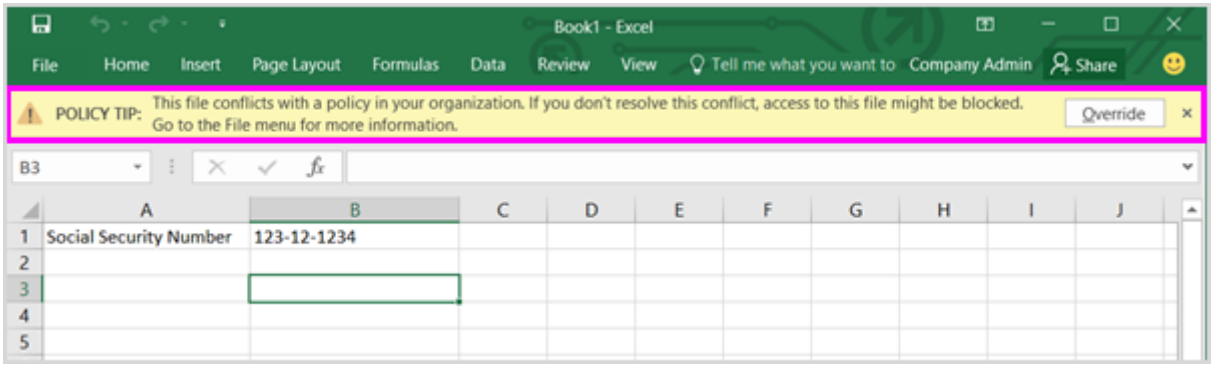
- Restrict access or encrypt the content in Microsoft 365 locations
- Audit or restrict activities on Windows devices

If you select Devices and Instances, these actions are available:

- Restrict access or encrypt the content in Microsoft 365 locations
- Audit or restrict activities on Windows devices
- Restrict Third Party Apps

Whether an action takes effect or not depends on how you configure the mode of the policy. You can choose to run the policy in simulation mode with or without showing policy tip by selecting the **Run the policy in simulation mode** option. You choose to run the policy as soon as an hour after it's created by selecting the **Turn it on right away** option, or you can choose to just save it and come back to it later by selecting the **Keep it off** option.

DLP platform limitations for actions



Action Name	Workload	Limits
Restrict access or encrypt content in Microsoft 365	EXO/SPO/ODB	**Block access for specific external domains or users** sub-option: image files aren't protected; multiple audit records can be generated for certain actions on a blocked file by a blocked user (public preview, SPO/ODB only).
Set headers	EXO	
Remove header	EXO	
Redirect the message to specific users	EXO	Total of 100 across all DLP rules. Can't be DL/SG

Action Name	Workload	Limits
Forward the message for approval to sender's manager	EXO	Manager should be defined in AD
Forward the message for approval to specific approvers	EXO	Groups aren't supported
Add recipient to the **To** box	EXO	Recipient count <= 10; Can't be DL/SG
Add recipient to the **Cc** box	EXO	Recipient count <= 10; Can't be DL/SG
Add recipient to the **Bcc** box	EXO	Recipient count <= 10; Can't be DL/SG
Add the sender's manager as recipient	EXO	Manager attribute should be defined in AD
Apply HTML disclaimer	EXO	
Prepend subject	EXO	
Apply message encryption	EXO	
Remove message encryption	EXO	
(preview) Exclude content in Copilot location	Microsoft 365 Copilot (preview)	Only content in SharePoint and OneDrive for Business can be excluded from being processed by Microsoft 365 Copilot

User notifications and policy tips

When a user attempts an activity on a sensitive item in a context that meets the conditions of a rule (for example, content such as an Excel workbook on a OneDrive site that contains personal data (PII) and is shared with a guest), you can let them know about it through user notification emails and in-context policy tip popups. These notifications are useful because they increase awareness and help educate people about your organization's DLP policies.

An Alert email, Incident Report email, and User Notification will only be sent once per document. If a document with a 'Content is Shared' condition is shared twice, there will still be only one notification.

> **Important**
>
> - Notification emails are sent unprotected.
> - Email notifications are only supported for the Microsoft 365 services.

Email notifications support by selected location

Selected location	Email notifications supported
Devices	- Not supported
Exchange + Devices	- Supported for Exchange - Not supported for Devices
Exchange	- Supported
SharePoint + Devices	- Supported for SharePoint - Not supported for Devices
SharePoint	- Supported
Exchange + SharePoint	- Supported for Exchange - Supported for SharePoint
Devices + SharePoint + Exchange	- Not supported for Devices - Supported for SharePoint Supported for Exchange
Teams	- Not supported
OneDrive	- Supported for OneDrive for work or school - Not supported for Devices
Fabric and Power-BI	- Not supported
Instances	- Not supported
On-premises repositories	- Not supported

Selected location	Email notifications supported
Exchange + SharePoint + OneDrive	- Supported for Exchange - Supported for SharePoint - Supported for OneDrive
Microsoft 365 Copilot (preview)	- Not supported
Managed cloud apps	- Not supported
Unmanaged cloud apps	- (Preview) Supported for email notifications. See Email notifications for browser and network (preview).

Email notifications for browser and network (preview)

When a DLP rule is configured for unmanaged cloud apps (browser and network), you can enable email notifications to notify end users via email when their activity is blocked. This is different from the inline pop-up notifications that appear directly in the browser, such as in Microsoft Edge for Business. Email notifications are particularly useful for integrations that don't support pop-up notifications, such as the Android Global Secure Access integration.

You can configure email notifications for:

- The person who performed the blocked activity.
- Additional recipients, such as admins or compliance officers.

Email notification batching

Email notifications are batched to prevent a flood of communications:

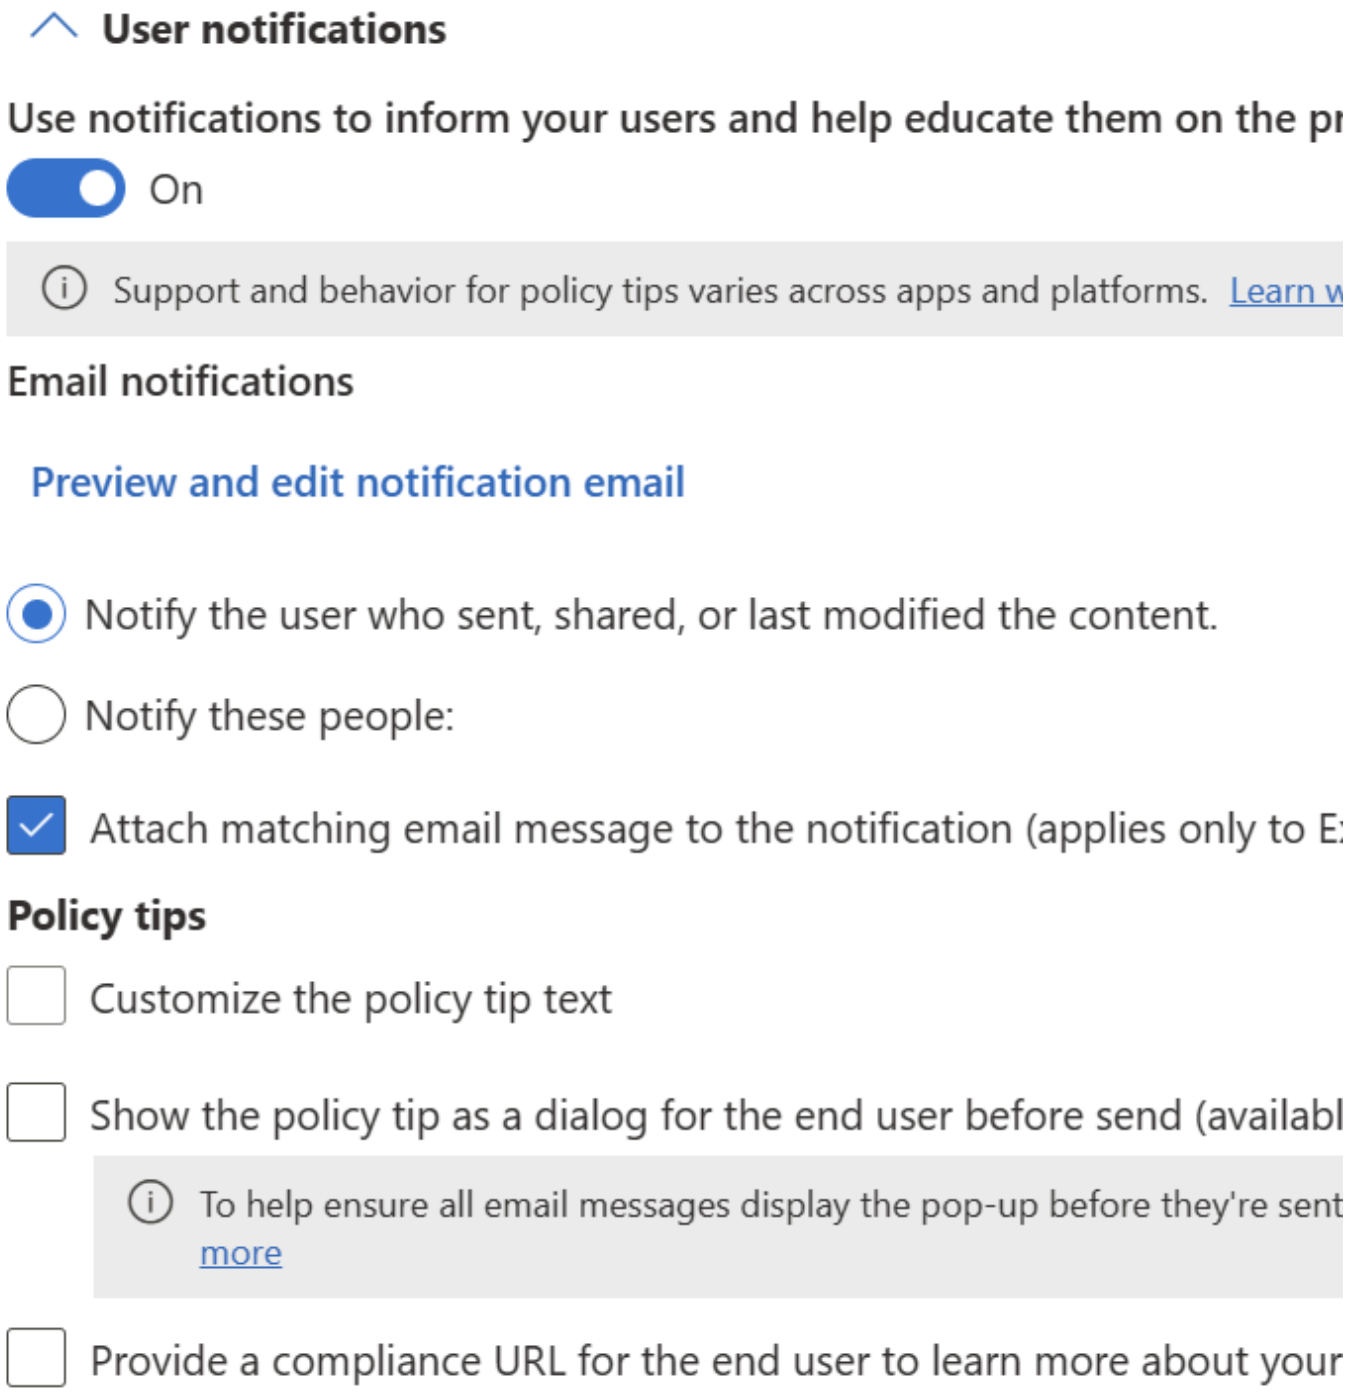
- The **first** policy match sends an email notification immediately (within seconds of the activity).
- Any additional policy matches within a rolling **10-minute window** are batched into a single email notification that lists all blocked activities.
- After 10 minutes with no further policy matches, the window resets. The next policy match sends an immediate notification and starts a new 10-minute window.

The batched email lists all blocked activities as individual entries, regardless of whether they were triggered by the same or different DLP rules for the same user.

You can also give people the option to override the policy, so that they're not blocked if they have a valid business need or if the policy is detecting a false positive.

Policy tips and user notifications configuration options

The user notifications and policy tips configuration options vary depending on the monitoring locations you've selected. If you selected:



- Exchange
- SharePoint
- OneDrive
- Teams Chat and Channel
- Instances

You can enable/disable user notifications for various Microsoft apps, see Data Loss Prevention policy tips reference.

You can also enable/disable notifications with a policy tip.

- email notifications to the user who sent, shared, or last modified the content OR
- notify specific people

Furthermore, you can customize the email text, subject, and the policy tip text.

For detailed information on customizing end user notification emails, see Custom email notifications.

If you selected Devices only, you get all the same options that are available for Exchange, SharePoint, OneDrive, Teams Chat and Channel, and Instances, plus the option to customize the notification title, content, and add a hyperlink in the form of a *Get Support* button that appears on the Windows 10/11 device.

Custom policy tip notifications character limits

Policy tip notifications are subject to the following character limits:

Variable	Character Limit
`TITLE`	120
`CONTENT`	250
`JUSTIFICATION`	250

Hyperlink has no character limit but is limited to the remaining space available in the entire DLP package. The hyperlink must be a resolvable URL, and it's abstracted behind a selectable control. The more information hyperlink is available in Microsoft 365 Office apps.

You can customize the title and body of text using the following parameters.

Common name	Parameter	Example
file name	%%FileName%%	Contoso doc 1
process name	%%ProcessName%%	Word
policy name	%%PolicyName%%	Contoso highly confidential
action	%%AppliedActions%%	pasting document content from the clipboard to another app

%%AppliedActions%% substitutes these values into the message body:

action common name	value substituted in for %%AppliedActions%% parameter
copy to removeable storage	*writing to removable storage*
copy to network share	*writing to a network share*
print	*printing*
paste from clipboard	*pasting from the clipboard*
copy via bluetooth	*transferring via Bluetooth*
open with an unallowed app	*opening with this app*
copy to a remote desktop (RDP)	*transferring to remote desktop*
uploading to an unallowed website	*uploading to this site*
accessing the item via an unallowed browser	*opening with this browser*

Using this customized text

%%AppliedActions%% File name %%FileName%% via %%ProcessName%% isn't allowed by your organization. Select 'Allow' if you want to bypass the policy %%PolicyName%%

produces this text in the customized notification:

pasting from the clipboard File Name: Contoso doc 1 via WINWORD.EXE isn't allowed by your organization. Select the 'Allow' button if you want to bypass the policy Contoso highly confidential

You can localize your custom policy tips by using the Set-DlpComplianceRule -NotifyPolicyTipCustomTextTranslations cmdlet.

Custom Policy Tips show for the most restrictive rule, not necessarily the rule that's performing the restriction.

> ⓘ **Note**
>
> User notifications and policy tips aren't available for the On-premises location
>
> Only the policy tip from the highest priority, most restrictive rule is shown. For example, a policy tip from a rule that blocks access to content will be shown over a policy tip from a rule that simply sends a notification. This prevents people from seeing a cascade of policy tips.

To learn more about user notification and policy tip configuration and use, including how to customize the notification and tip text, see Send email notifications and show policy tips for DLP policies.

Policy tip considerations

- Policy tips aren't generated if the sensitivity label is in a compressed file.
- DLP has difficulty generating policy tips for encrypted files.

Policy tip references

Details on support for policy tips and notifications for different apps can be found here:

- Data loss prevention policy tip reference for Outlook for Microsoft 365
- Data loss prevention policy tip reference for Outlook on the Web
- Data loss prevention policy tip reference SharePoint in Microsoft 365 and OneDrive. web client

Block users in Exchange

> ⓘ **Note**

If you have policy tips enabled when the policy is configured to **Block only users outside your organization** is met, the policy tips notification blocks you from sending a message at all if there are external recipients. Therefore, you have to remove any external recipients before you can send the message to internal recipients.

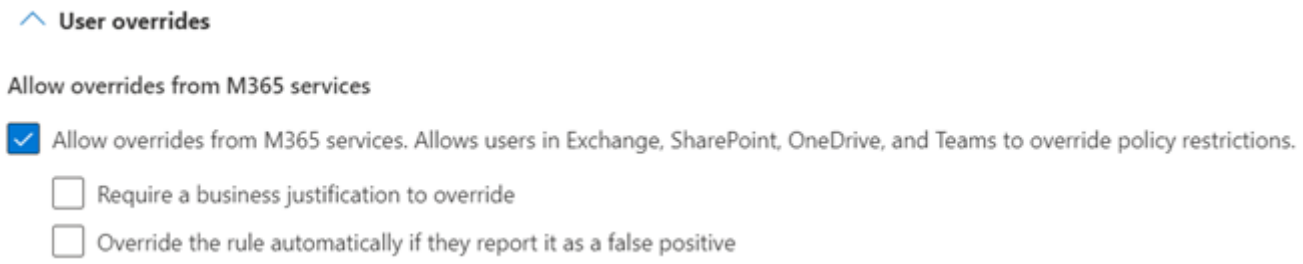
Blocking and notifications in SharePoint in Microsoft 365 and OneDrive

The following table shows the DLP blocking and notification behavior for policies that are scoped to SharePoint in Microsoft 365 and OneDrive. This isn't intended to be an exhaustive list, and there are more settings that aren't in scope for this article.

Conditions	Restrict access setting	Blocking and notification behavior
Content is shared from Microsoft 365- with people outside my organization	Not configured	User notification emails, policy tips, DLP alerts, and incident reports are sent when a file is shared with a guest or when a guest accesses the file.
Content is shared from Microsoft 365- only with people inside my organization	Not configured	User notification emails, policy tips, DLP alerts, and incident reports are sent when sensitive information is detected in the document.
Content is shared from Microsoft 365- only with people inside my organization	- **Restrict access or encrypt the content in Microsoft 365 locations** - **Block users from receiving email or accessing shared SharePoint, OneDrive, and Teams files** -**Block everyone**	- Access to sensitive files is blocked as soon as they're uploaded. - User notification emails, policy tips, DLP alerts, and incident reports are sent when a file is uploaded
Content is shared from Microsoft 365 - with people outside my organization	- **Restrict access or encrypt the content in Microsoft 365 locations** - **Block users from receiving email or accessing shared SharePoint, OneDrive, and Teams files**	- Access to a sensitive file is blocked as soon as it's uploaded, regardless of whether the document is shared or not for all guests. Policy Tips will be sent when the sensitive information is detected. - If the sensitive information is added to a file after it's shared and accessed by a user outside the organization, then alerts and incident reports will be sent. - If the document contains sensitive information before it's uploaded, external sharing will be blocked proactively. Because external sharing in this scenario is blocked when the

Conditions	Restrict access setting	Blocking and notification behavior
	- **Block only people outside your organization**	file is uploaded, no alerts or incident reports are sent. Suppression of the alerts and incident reports is designed to prevent a flood of alerts to the user for each blocked file. User notification emails, policy tips, DLP alerts, and incident reports are sent when a file is uploaded or sensitive information is added to the file. - Proactive blocking will show up as event in the Audit Log and Activity Explorer.
- **Content is shared from Microsoft 365** - **with people outside my organization**	- **Restrict access or encrypt the content in Microsoft 365 locations** - **Block users from receiving email or accessing shared SharePoint, OneDrive, and Teams files** - **Block everyone**	- When the first user outside the organization access the document, the event causes the document to be blocked. - It's expected that for a short time, the document is accessible by guests who have the link to the file. - User notification emails, policy tips, DLP alerts, and incident reports are sent when a file is shared with a guest or when a guest accesses that file.
Content is shared from Microsoft 365 - with people outside my organization	- **Restrict access or encrypt the content in Microsoft 365 locations** - **Block users from receiving email or accessing shared SharePoint, OneDrive, and Teams files** - **Block access for specific external domains or users** (in public preview, SPO/ODB only)	- Access is denied when a configured external user or domain attempts to open, preview, or download the file. - An audit record is generated per blocked access attempt (subject to preview limitations). - Events can be reviewed in DLP Alerts, Activity Explorer, and Audit logs. The event contains the blocked user's email. - Internal users and domains can't be blocked with this sub-option; use **Block everyone** to block internal users.

Learn more URL



Users may want to learn why their activity is being blocked. You can configure a site or a page that explains more about your policies. In the rule's user notification settings, select **Provide a compliance URL for the end user to learn more about your organization's policies**, and then enter the URL.

- For Outlook Win32, the *Learn more* link in the policy tip points to the site URL that you provide. This URL has priority over the global compliance URL configured with Set-PolicyConfig -ComplianceURL.
- For Microsoft Copilot and Copilot Chat, the **Learn about access restrictions** link in the standard block message points to the URL that you provide. Only the link destination changes; the message text and enforcement action remain unchanged. For more information, see Customize the link in Copilot policy tips.

> **Important**
>
> You must configure the site or page that the link points to from scratch. Microsoft Purview doesn't provide this functionality out of the box.

User overrides

The intent of **User overrides** is to give users a way to bypass, with justification, DLP policy blocking actions on sensitive items in Exchange, SharePoint, OneDrive, or Teams, so that they can continue their work. User overrides are enabled only when **Notify users in Office 365 services with a policy tip** is enabled, so user overrides go hand-in-hand with Notifications and Policy tips.

> **Note**
>
> User overrides aren't available for the On-premises repositories location.

Typically, user overrides are useful when your organization is first rolling out a policy. The feedback that you get from any override justifications and identifying false positives helps in tuning the policy.

- If the policy tips in the most restrictive rule allow people to override the rule, then overriding this rule also overrides any other rules that the content matched.

User override behavior

When a user selects the **Allow** option to override a block action for these activities:

- Print
- Copy to a removable USB device
- Copy to a network share

Within 30 seconds of the popup notification showing, the activity is allowed to continue. If the user doesn't select the **Allow** option within 30 seconds, the activity is blocked.

For all other activities, the user must repeat the activity after selecting the **Allow** option in order for it to complete

Business justification X-Header

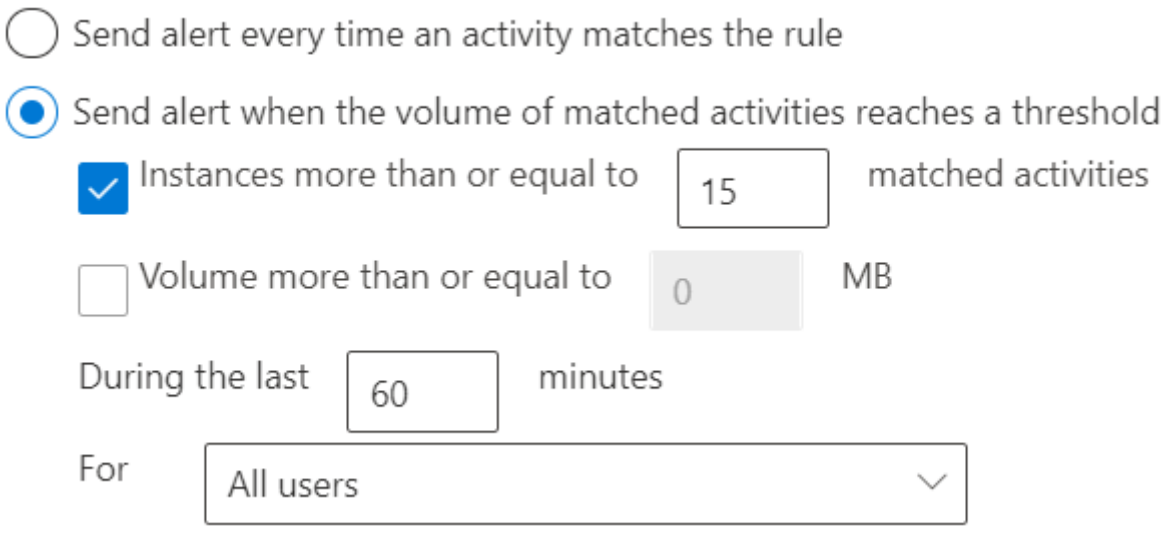
When a user overrides a block with override action on an email, the override option and the text that they provide are stored in the Audit log and in the email X-header. To view the business justification overrides, search the audit log for `ExceptionInfo` value for the details. Here's an example of the audit log values:

XML

```
{
    "FalsePositive"; false,
    "Justification"; My manager approved sharing of this content",
    "Reason"; "Override",
    "Rules": [
         "<message guid>"
    ]
}
```

If you have an automated process that makes use of the business justification values, the process can access that information programmatically in the email X-header data.

> ⓘ Note
>
> The `msip_justification` values are stored in the following order:
>
> `False Positive; Recipient Entitled; Manager Approved; I Acknowledge; JustificationText_[free text]`.
>
> Notice that the values are separated by semicolons. The maximum free text allowed is 500 characters.



Incident reports

When a rule is matched, you can send an *Alert* email to your compliance officer (or any people you choose) with details of the event and you can view them in the Microsoft Purview Data Loss Prevention **Alerts** dashboard and in the Microsoft Defender XDR portal. An alert includes information about the item that was matched, the actual content that matched the rule, and the name of the person who last modified the content.

In preview, admin alert emails include details such as:

- The alert severity
- The time the alert occurred
- The activity.
- The sensitive data that were detected.
- The alias of the user whose activity triggered the alert.
- The policy that was matched.
- The alert ID
- The endpoint operation that was attempted if the **Devices** location is in the scope of the policy.
- The app that was being used.
- The device name, if the match occurred on an endpoint device.

DLP feeds incident information to other Microsoft Purview Information Protection services, like insider risk management. In order to get incident information to insider risk management, you must set the **Incident reports** severity level to **High**.

Alert types

Alerts can be sent every time an activity matches a rule, which can be noisy. To help cut down on the noise, they can be aggregated based on number of matches or volume of items over a set period of time. There are two types of alerts that can be configured in DLP policies.

- **Single-event alerts** are typically used in policies that monitor for highly sensitive events that occur in a low volume, like a single email with 10 or more customer credit card numbers being sent outside your organization. In preview user based alert aggregation (preview) modifies the behavior of single event alerts.
- **Aggregate-event alerts** are typically used in policies that monitor for events that occur in a higher volume over a period of time. For example, an aggregate alert can be triggered when 10 individual emails each with one customer credit card number is sent outside your org over 48 hours.

> **Note**
>
> For rules with Alerts configured on Sharepoint, or OneDrive workloads we only send one alert per file per rule. This is true, even if the same violation has been committed by multiple users.

Other alert options

When you select **Use email incident reports to notify you when a policy match occurs** you can choose to include:

- The name of the person who last modified the content.
- The types of sensitive content that matched the rule.
- The rule's severity level.
- The content that matched the rule, including the surrounding text.
- The item containing the content that matched the rule.

For more information on alerts, see:

- Alerts in DLP policies: Describes alerts in the context of a DLP policy.
- Get started with data loss prevention alerts: Covers the necessary licensing, permissions, and prerequisites for DLP alerts and alert reference details.
- Create and deploy data loss prevention policies: Includes guidance on alert configuration in the context of creating a DLP policy.

- Learn about investigating data loss prevention alerts: Covers the various methods for investigating of DLP alerts.
- Investigate data loss incidents with Microsoft Defender XDR: How to investigate DLP alerts in Microsoft Defender portal.

Evidence collection for file activities on devices

If you've enabled **Setup evidence collection for file activities on devices** and added Azure storage accounts, you can select **Collect original file as evidence for all selected file activities on Endpoint** and the Azure storage account you want to copy the items to. You must also choose the activities you want to copy items for. For example, if you select **Print** but not **Copy to a network share**, then only items that are printed from monitored devices will be copied to the Azure storage account.

Additional options

If you have multiple rules in a policy, you can use the **Additional options** to control further rule processing if there's a match to the rule you're editing as well as setting the priority for evaluation of the rule. This is only supported for Exchange and Teams locations

What the DLP policy templates include

07/18/2025

Microsoft Purview Data Loss Prevention (DLP) in the Microsoft Purview portal includes ready-to-use policy templates that address common compliance requirements, such as helping you to protect sensitive information subject to the U.S. Health Insurance Act (HIPAA), U.S. Gramm-Leach-Bliley Act (GLBA), or U.S. Patriot Act. This article lists all of the policy templates, what types of sensitive information they look for, and what the default conditions and actions are. This article doesn't include every detail of how each policy template is configured; instead, the article presents with you enough information to help you decide which template is the best starting point for your scenario. Remember, you can customize these policy templates to meet your specific requirements.
