        attributes
    }
}
```

Query entities by type and attributes

JSON

```
query {
    entities(
        where: {
            type: { typeName: "<entityType>" }
            attribute: { field: "<attrName>",operator: eq, value: "<attrValue>" }
        }
    ) {
        guid
        typeName
        qualifiedName
        attributes
    }
}
```

Query entities by type and business attributes

JSON

```
query {
    entities(
        where: {
            type: { typeName: "<entityType>" }
            businessAttribute: { field: "<BusinessMetadataName>.
<BusinessAttributeName>", operator: eq, value: "<BizAttrValue>" }
        }
    ) {
        guid
        typeName
        qualifiedName
        attributes
    }
}
```

Query entities by collection

Currently, this query pattern isn't supported for subassets.

JSON

```
query {
    entities(
        where: {
            type: { typeName: "<entityType>" }
            collectionID: "<collectionId>"
        }
    ) {
        guid
        typeName
        qualifiedName
        attributes
    }
}
```

Filter combination

Keys in an object(map) are combined as a logical AND.

JSON

```
query {
    entities(
        where: {
            type: { typeName: "<entityType>" }
            or: [
                {
                    and: [
                        { attribute: { field: "<attrName1>", value: "<attrValue1>"
} }
                        { attribute: { field: "<attrName2>", value: "<attrValue2>"
} }
                    ]
                }
                {
                    not: {
                        businessAttribute: {
                            field: "<BusinessMetadataName>.
<BusinessAttributeName>", value: "<BizAttrValue>"
                        }
                    }
                }
            ]
        }
    ) {
        guid
        typeName
        qualifiedName
        attributes
    }
}
```

Nested filter

Currently, this query pattern isn't supported for subassets.

Query entity by classification

JSON

```
query {
    entities(
        where: {
            classification: { type: { typeName: "<classificationType>",
includeSubTypes: true } }
        }
    ) {
        guid
        typeName
        qualifiedName
        attributes
    }
}
```

Query entity by related entity

JSON

```
query {
    entities(
        where: {
            relatedEntity: {
                relationshipAttributeName: "<relAttrName>"
                entity: {
                    type: { typeName: "<entityType>" }
                }
            }
        }
    ) {
        guid
        typeName
        qualifiedName
        attributes
    }
}
```

Query entity by glossary terms

JSON

```
query {
    entities(
        where: {
            assignedTerm: {
                term: {
                    qualifiedName: { eq: "<termName>" }
                }
            }
        }
    ) {
        guid
        typeName
        qualifiedName
        attributes
    }
}
```

Other queries

Get relationship

JSON

```
query {
    relationships(where: { guid: "<guid>" }) {
        guid
        typeName
        attributes
        end1 {
            guid
            typeName
            qualifiedName
            attributes
        }
        end2 {
            guid
            typeName
            qualifiedName
            attributes
        }
    }
}
```

Sample Response:

JSON

```
{
    "data": {
        "relationships": [
            {
                "guid": "...",
                "typeName": "ExampleRelationship",
                "attributes": {},
                "end1": {
                    "guid": "...",
                    "typeName": "column",
                    "qualifiedName": "...",
                    "attributes": {}
                },
                "end2": {
                    "guid": "...",
                    "typeName": "column",
                    "qualifiedName": "...",
                    "attributes": {}
                }
            }
        ]
    }
}
```

Lineage

Get dataset with downstream datasets

This query returns downstream datasets to 2 degrees.

JSON

```
query {
    entities(where: { guid: "<guid>" }) {#dataset
        guid
        typeName
        qualifiedName
        relatedEntities(where: { relationshipAttributeName: "inputToProcesses" })
{
            entity {#process
                guid
                typeName
                relatedEntities(where: { relationshipAttributeName: "outputs" }) {
                    entity {#dataset
                        guid
                        typeName
                        qualifiedName
                        relatedEntities(where: { relationshipAttributeName:
"inputToProcesses" }) {
                            entity {#process
```

```
                                guid
                                typeName
                                qualifiedName
                                relatedEntities(where: {
relationshipAttributeName: "outputs" }) {
                                    entity {#dataset
                                        guid
                                        typeName
                                        qualifiedName
                                    }
                                }
                            }
                        }
                    }
                }
            }
        }
    }
}
```

Sample Response:

JSON

```
{
    "data": {
        "entities": [
            {
                "guid": "...",
                "typeName": "Dataset",
                "qualifiedName": "...",
                "relatedEntities": [
                    {
                        "entity": {
                            "guid": "...",
                            "typeName": "Process",
                            "relatedEntities": [
                                {
                                    "entity": {
                                        "guid": "...",
                                        "typeName": "Dataset",

                                                    "guid": "...",
                                                    "typeName": "Process",
                                                    "relatedEntities": [
                                                        {
                                                            "entity": {
                                                                "guid": "...",
                                                                "typeName":
"Dataset",
```

```
                                                    "qualifiedName":
"..."
                                                        }
                                                    }
                                                ]
                                            }
                                        }
                                    ]
                                }
                            }
                        ]
                    }
                ]
            }
        }
    }
```

Limitations

Query fetch-depth limitation:

Queries are limited by query depth. The maximum depth is 5. For example, the following query will fail:

JSON

```
query {
    entities { #depth 1
        relatedEntities { #depth 2
            entity {
                relatedEntities { #depth 3
                    entity {
                        assignedTerms{ #depth 4
                            term {
                                classifications { #depth 5
                                    ...
                                }
                            }
                        }
                        relatedEntities { #depth 4
                            entity {
                                assignedTerms{ #depth 5
                                    term {
                                        classifications { #depth 6
                                            ...
                                        }
                                    }
                                }
```

```
                            }
                        }
                    }
                }
            }
        }
    }
}
```

Execution-time fetch-cost limitation:

Queries are constrained by the cost of query execution. The maximum allowable cost is set at 100 units.

The execution fetch cost is computed each time we aim to retrieve related entities, assigned terms, or classifications for a given entity or term.

Example

Consider a scenario where we query 3 entities, each with two related entities. The cost calculation would be as follows:

- One unit for the root query
- Three units for each level-1 entity

Hence, the total cost for this query would be `1 (root query) + 3 (level-1 entities) = 4`.

Filtering performance

Filtering is currently preview and has some limitations. See filtering for more information.

GraphQL queries begin with a root query that retrieves the top-level nodes. It then recursively fetches the related nodes.

The performance of a nested query is primarily determined by the root query because the related nodes are fetched from a known starting point, similar to a foreign key in SQL.

To optimize performance, it's crucial to avoid wildcard root queries that could trigger a table scan on the top-level nodes.

For instance, the following query could cause performance issues on large datasets because the `name` field isn't indexed:

JSON

```
query {
    entities(where: { name: { eq: "<value>" } }) {
        guid
        typeName
        attributes
        relatedEntities {
            entity {
                guid
                typeName
                attributes
            }
        }
    }
}
```

To prevent such performance issues, ensure that you apply a filter on `guid` or `qualifiedName`.

Cmdlet	Description
Add-AzPurviewAccountRootCollectionAdmin	Add the administrator for root collection associated with this account.
Get-AzPurviewAccount	Get an account
Get-AzPurviewAccountKey	List the authorization keys associated with this account.
Get-AzPurviewClassificationRule	Get a classification rule
Get-AzPurviewClassificationRuleVersion	Lists the rule versions of a classification rule
Get-AzPurviewDataSource	Get a data source
Get-AzPurviewDefaultAccount	Get the default account for the scope.
Get-AzPurviewFilter	Get a filter
Get-AzPurviewKeyVaultConnection	Gets key vault information
Get-AzPurviewScan	Gets a scan information
Get-AzPurviewScanResultScanHistory	Lists the scan history of a scan
Get-AzPurviewScanRuleset	Get a scan ruleset
Get-AzPurviewSystemScanRuleset	Get a system scan ruleset for a data source
Get-AzPurviewSystemScanRulesetLatest	Get the latest version of a system scan ruleset
Get-AzPurviewSystemScanRulesetVersion	List system scan ruleset versions in Data catalog
Get-AzPurviewTrigger	Gets trigger information
Invoke-AzPurviewTagClassificationRuleClassificationVersion	Sets Classification Action on a specific classificat rule version.
New-AzPurviewAccount	Creates or updates an account
New-AzPurviewAdlsGen1CredentialScanObject	Create an in-memory object for AdlsGen1CredentialScan.

Cmdlet	Description
New-AzPurviewAdlsGen1DataSourceObject	Create an in-memory object for AdlsGen1DataSource.
New-AzPurviewAdlsGen1MsiScanObject	Create an in-memory object for AdlsGen1MsiSc
New-AzPurviewAdlsGen1ScanRulesetObject	Create an in-memory object for AdlsGen1ScanRuleset.
New-AzPurviewAdlsGen2CredentialScanObject	Create an in-memory object for AdlsGen2CredentialScan.
New-AzPurviewAdlsGen2DataSourceObject	Create an in-memory object for AdlsGen2DataSource.
New-AzPurviewAdlsGen2MsiScanObject	Create an in-memory object for AdlsGen2MsiSc
New-AzPurviewAdlsGen2ScanRulesetObject	Create an in-memory object for AdlsGen2ScanRuleset.
New-AzPurviewAmazonAccountCredentialScanObject	Create an in-memory object for AmazonAccountCredentialScan.
New-AzPurviewAmazonAccountDataSourceObject	Create an in-memory object for AmazonAccountDataSource.
New-AzPurviewAmazonPostgreSqlCredentialScanObject	Create an in-memory object for AmazonPostgreSqlCredentialScan.
New-AzPurviewAmazonPostgreSqlDataSourceObject	Create an in-memory object for AmazonPostgreSqlDataSource.
New-AzPurviewAmazonPostgreSqlScanRulesetObject	Create an in-memory object for AmazonPostgreSqlScanRuleset.
New-AzPurviewAmazonS3CredentialScanObject	Create an in-memory object for AmazonS3CredentialScan.
New-AzPurviewAmazonS3DataSourceObject	Create an in-memory object for AmazonS3DataSource.
New-AzPurviewAmazonS3ScanRulesetObject	Create an in-memory object for AmazonS3ScanRuleset.
New-AzPurviewAmazonSqlCredentialScanObject	Create an in-memory object for AmazonSqlCredentialScan.
New-AzPurviewAmazonSqlDataSourceObject	Create an in-memory object for AmazonSqlDataSource.
New-AzPurviewAmazonSqlScanRulesetObject	Create an in-memory object for AmazonSqlScanRuleset.
New-AzPurviewAzureCosmosDbCredentialScanObject	Create an in-memory object for AzureCosmosDbCredentialScan.

Cmdlet	Description
New-AzPurviewAzureCosmosDbDataSourceObject	Create an in-memory object for AzureCosmosDbDataSource.
New-AzPurviewAzureCosmosDbScanRulesetObject	Create an in-memory object for AzureCosmosDbScanRuleset.
New-AzPurviewAzureDataExplorerCredentialScanObject	Create an in-memory object for AzureDataExplorerCredentialScan.
New-AzPurviewAzureDataExplorerDataSourceObject	Create an in-memory object for AzureDataExplorerDataSource.
New-AzPurviewAzureDataExplorerMsiScanObject	Create an in-memory object for AzureDataExplorerMsiScan.
New-AzPurviewAzureDataExplorerScanRulesetObject	Create an in-memory object for AzureDataExplorerScanRuleset.
New-AzPurviewAzureFileServiceCredentialScanObject	Create an in-memory object for AzureFileServiceCredentialScan.
New-AzPurviewAzureFileServiceDataSourceObject	Create an in-memory object for AzureFileServiceDataSource.
New-AzPurviewAzureFileServiceScanRulesetObject	Create an in-memory object for AzureFileServiceScanRuleset.
New-AzPurviewAzureKeyVaultObject	Create an in-memory object for AzureKeyVault.
New-AzPurviewAzureMySqlCredentialScanObject	Create an in-memory object for AzureMySqlCredentialScan.
New-AzPurviewAzureMySqlDataSourceObject	Create an in-memory object for AzureMySqlDataSource.
New-AzPurviewAzureMySqlScanRulesetObject	Create an in-memory object for AzureMySqlScanRuleset.
New-AzPurviewAzurePostgreSqlCredentialScanObject	Create an in-memory object for AzurePostgreSqlCredentialScan.
New-AzPurviewAzurePostgreSqlDataSourceObject	Create an in-memory object for AzurePostgreSqlDataSource.
New-AzPurviewAzurePostgreSqlScanRulesetObject	Create an in-memory object for AzurePostgreSqlScanRuleset.
New-AzPurviewAzureResourceGroupCredentialScanObject	Create an in-memory object for AzureResourceGroupCredentialScan.
New-AzPurviewAzureResourceGroupDataSourceObject	Create an in-memory object for AzureResourceGroupDataSource.
New-AzPurviewAzureResourceGroupMsiScanObject	Create an in-memory object for AzureResourceGroupMsiScan.

Cmdlet	Description
New-AzPurviewAzureSqlDatabaseCredentialScanObject	Create an in-memory object for AzureSqlDatabaseCredentialScan.
New-AzPurviewAzureSqlDatabaseDataSourceObject	Create an in-memory object for AzureSqlDatabaseDataSource.
New-AzPurviewAzureSqlDatabaseManagedInstanceCredentialScanObject	Create an in-memory object for AzureSqlDatabaseManagedInstanceCredentialS
New-AzPurviewAzureSqlDatabaseManagedInstanceDataSourceObject	Create an in-memory object for AzureSqlDatabaseManagedInstanceDataSource
New-AzPurviewAzureSqlDatabaseManagedInstanceMsiScanObject	Create an in-memory object for AzureSqlDatabaseManagedInstanceMsiScan.
New-AzPurviewAzureSqlDatabaseManagedInstanceScanRulesetObject	Create an in-memory object for AzureSqlDatabaseManagedInstanceScanRuleset
New-AzPurviewAzureSqlDatabaseMsiScanObject	Create an in-memory object for AzureSqlDatabaseMsiScan.
New-AzPurviewAzureSqlDatabaseScanRulesetObject	Create an in-memory object for AzureSqlDatabaseScanRuleset.
New-AzPurviewAzureSqlDataWarehouseCredentialScanObject	Create an in-memory object for AzureSqlDataWarehouseCredentialScan.
New-AzPurviewAzureSqlDataWarehouseDataSourceObject	Create an in-memory object for AzureSqlDataWarehouseDataSource.
New-AzPurviewAzureSqlDataWarehouseMsiScanObject	Create an in-memory object for AzureSqlDataWarehouseMsiScan.
New-AzPurviewAzureSqlDataWarehouseScanRulesetObject	Create an in-memory object for AzureSqlDataWarehouseScanRuleset.
New-AzPurviewAzureStorageCredentialScanObject	Create an in-memory object for AzureStorageCredentialScan.
New-AzPurviewAzureStorageDataSourceObject	Create an in-memory object for AzureStorageDataSource.
New-AzPurviewAzureStorageMsiScanObject	Create an in-memory object for AzureStorageMsiScan.
New-AzPurviewAzureStorageScanRulesetObject	Create an in-memory object for AzureStorageScanRuleset.
New-AzPurviewAzureSubscriptionCredentialScanObject	Create an in-memory object for AzureSubscriptionCredentialScan.
New-AzPurviewAzureSubscriptionDataSourceObject	Create an in-memory object for AzureSubscriptionDataSource.

Cmdlet	Description
New-AzPurviewAzureSubscriptionMsiScanObject	Create an in-memory object for AzureSubscriptionMsiScan.
New-AzPurviewAzureSynapseWorkspaceCredentialScanObject	Create an in-memory object for AzureSynapseWorkspaceCredentialScan.
New-AzPurviewAzureSynapseWorkspaceDataSourceObject	Create an in-memory object for AzureSynapseWorkspaceDataSource.
New-AzPurviewAzureSynapseWorkspaceMsiScanObject	Create an in-memory object for AzureSynapseWorkspaceMsiScan.
New-AzPurviewAzureSynapseWorkspaceScanRulesetObject	Create an in-memory object for AzureSynapseWorkspaceScanRuleset.
New-AzPurviewClassificationRule	Create a classification rule
New-AzPurviewCustomClassificationRuleObject	Create an in-memory object for CustomClassificationRule.
New-AzPurviewDataSource	Create a data source
New-AzPurviewFilter	Create a filter
New-AzPurviewFilterObject	Create an in-memory object for Filter.
New-AzPurviewKeyVaultConnection	Create an instance of a key vault connection
New-AzPurviewOracleDataSourceObject	Create an in-memory object for OracleDataSour
New-AzPurviewPowerBIDataSourceObject	Create an in-memory object for PowerBIDataSource.
New-AzPurviewPowerBIDelegatedScanObject	Create an in-memory object for PowerBIDelegatedScan.
New-AzPurviewPowerBIMsiScanObject	Create an in-memory object for PowerBIMsiScar
New-AzPurviewRegexClassificationRulePatternObject	Create an in-memory object for RegexClassificationRulePattern.
New-AzPurviewSapEccDataSourceObject	Create an in-memory object for SapEccDataSou
New-AzPurviewSapS4HanaDataSourceObject	Create an in-memory object for SapS4HanaDataSource.
New-AzPurviewSapS4HanaSapS4HanaCredentialScanObject	Create an in-memory object for SapS4HanaSapS4HanaCredentialScan.
New-AzPurviewScan	Create an instance of a scan
New-AzPurviewScanRuleset	Create a scan ruleset
New-AzPurviewSqlServerDatabaseCredentialScanObject	Create an in-memory object for SqlServerDatabaseCredentialScan.

Cmdlet	Description
New-AzPurviewSqlServerDatabaseDataSourceObject	Create an in-memory object for SqlServerDatabaseDataSource.
New-AzPurviewSqlServerDatabaseScanRulesetObject	Create an in-memory object for SqlServerDatabaseScanRuleset.
New-AzPurviewTeradataDataSourceObject	Create an in-memory object for TeradataDataSource.
New-AzPurviewTrigger	Create an instance of a trigger
New-AzPurviewTriggerObject	Create an in-memory object for Trigger.
Remove-AzPurviewAccount	Deletes an account resource
Remove-AzPurviewClassificationRule	Deletes a classification rule
Remove-AzPurviewDataSource	Deletes a data source
Remove-AzPurviewDefaultAccount	Removes the default account from the scope.
Remove-AzPurviewKeyVaultConnection	Deletes the key vault connection associated with the account
Remove-AzPurviewScan	Deletes the scan associated with the data source
Remove-AzPurviewScanRuleset	Deletes a scan ruleset
Remove-AzPurviewTrigger	Deletes the trigger associated with the scan
Set-AzPurviewDefaultAccount	Sets the default account for the scope.
Start-AzPurviewScanResultScan	Runs the scan
Stop-AzPurviewScanResultScan	Cancels a scan
Test-AzPurviewAccountNameAvailability	Checks if account name is available.
Update-AzPurviewAccount	Update an account
Update-AzPurviewClassificationRule	Update a classification rule
Update-AzPurviewDataSource	Update a data source
Update-AzPurviewFilter	Update a filter
Update-AzPurviewKeyVaultConnection	Update an instance of a key vault connection
Update-AzPurviewScan	Update an instance of a scan
Update-AzPurviewScanRuleset	Update a scan ruleset
Update-AzPurviewTrigger	Update an instance of a trigger

Microsoft Purview Resource Provider Rest API

Article • 10/31/2023

Microsoft Purview Microsoft Purview is a unified data governance service that helps you manage and govern your on-premises, multi-cloud, and software-as-a-service (SaaS) data. Easily create a holistic, up-to-date map of your data landscape with automated data discovery, sensitive data classification, and end-to-end data lineage. Empower data consumers to find valuable, trustworthy data. Manage user access to data in your estate securely and at scale.

Authorization Token

All Azure Resource Manager and Azure REST API calls require a valid authorization token in the request header to succeed. See Create the request: Acquire an access token for details on how to obtain this authorization token.

Type definitions and how to create custom types

Article • 05/14/2025

This tutorial will explain what type definitions are, how to create custom types, and how to initialize assets of custom types in Microsoft Purview.

In this tutorial, you'll learn:

- ✓ How Microsoft Purview uses the *type system* from *Apache Atlas*
- ✓ How to create a new custom type
- ✓ How to create relationships between custom types
- ✓ How to initialize new entities of custom types

Prerequisites

For this tutorial you'll need:

- An Azure account with an active subscription. If you don't have one, you can create an account for free.
- An active Microsoft Purview (formerly Azure Purview) account. If you don't have one, see the guide for getting started with Microsoft Purview for free.
- A bearer token to your Microsoft Purview account. To establish a bearer token and to call any APIs, see the documentation about how to authenticate APIs for Microsoft Purview.
- Your Apache Atlas endpoint of your Microsoft Purview account. It will be one of these two endpoints, depending on your environment:
  - If you're using the classic Microsoft Purview governance portal: `https://{{ACCOUNTNAME}}.purview.azure.com/catalog`
  - If you're using the new Microsoft Purview portal: `https://api.purview-service.microsoft.com/catalog`

> **Note**
>
> Before moving to the hands-on part of the tutorial, the first four sections will explain what a System Type is and how it is used in Microsoft Purview. All the REST API calls described further will use the **bearer token** and the **endpoint** which are described in the prerequisites.
>
> To skip directly to the steps, use these links:

- Create custom type definitions
- Initialize assets of custom types

What are *asset* and *type* in Microsoft Purview?

An *asset* is a metadata element that describes a digital or physical resource. The digital or physical resources that are expected to be cataloged as assets include:

- Data sources such as databases, files, and data feed.
- Analytical models and processes.
- Business policies and terms.
- Infrastructure like the server.

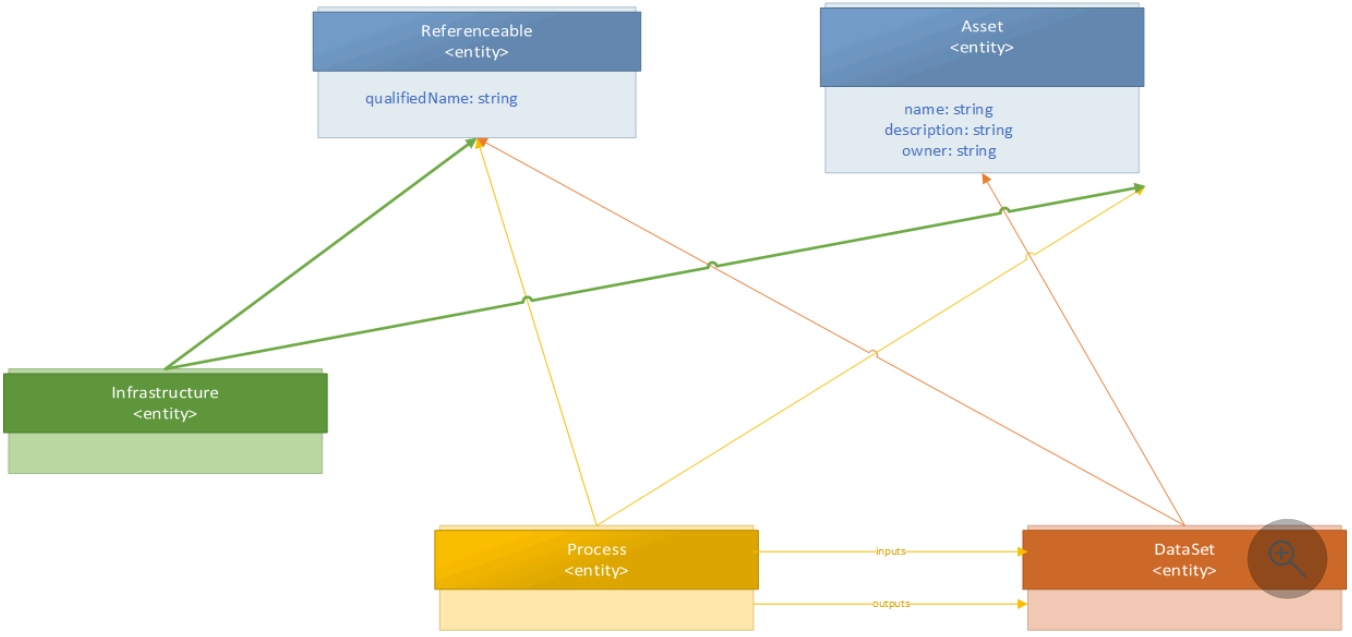
Microsoft Purview provides users a flexible *type system* to expand the definition of the asset to include new kinds of resources as they become relevant. Microsoft Purview relies on the Type System from Apache Atlas. All metadata objects (assets) managed by Microsoft Purview are modeled using type definitions. Understanding the Type System is fundamental to create new custom types in Microsoft Purview.

Essentially, a *Type* can be seen as a *Class* from Object Oriented Programming (OOP):

- It defines the properties that represent that type.
- Each type is uniquely identified by its *name*.
- A *type* can inherit from a *superType*. This is an equivalent concept as inheritance from OOP. A type that extends a superType will inherit the attributes of the superType.

You can see all type definitions in your Microsoft Purview account by sending a `GET` request to the All Type Definitions endpoint:

```
HTTP



GET https://{{ENDPOINT}}/catalog/api/atlas/v2/types/typedefs
```

Apache Atlas has few predefined system types that are commonly used as supertypes.

For example:

- **Referenceable**: This type represents all entities that can be searched for using a unique attribute called *qualifiedName*.
- **Asset**: This type extends from Referenceable and has other attributes such as: *name*, *description* and *owner*.

- **DataSet**: This type extends Referenceable and Asset. Conceptually, it can be used to represent a type that stores data. Types that extend DataSet can be expected to have a Schema. For example, a SQL table.
- **Lineage**: Lineage information helps one understand the origin of data and the transformations it may have gone through before arriving in a file or table. Lineage is calculated through *DataSet* and *Process*: DataSets (input of process) impact some other DataSets (output of process) through Process.

Example of a *Type* definition

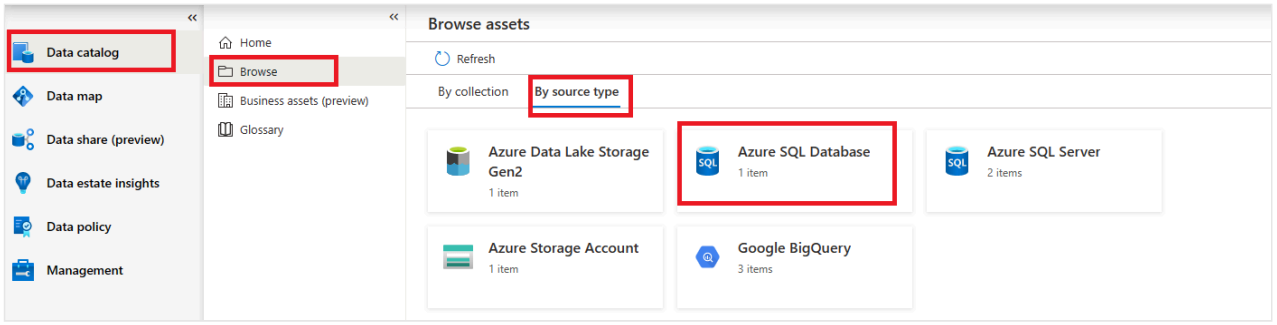
To better understand the Type system, let's look at an example and see how an **Azure SQL Table** is defined.

You can get the complete type definition by sending a `GET` request to the Type Definition endpoint:

HTTP

```
GET https://{{ENDPOINT}}/catalog/api/atlas/v2/types/typedef/name/{name}
```

> **Tip**
>
> The **{name}** property tells which definition you are interested in. In this case, you should use **azure_sql_table**.

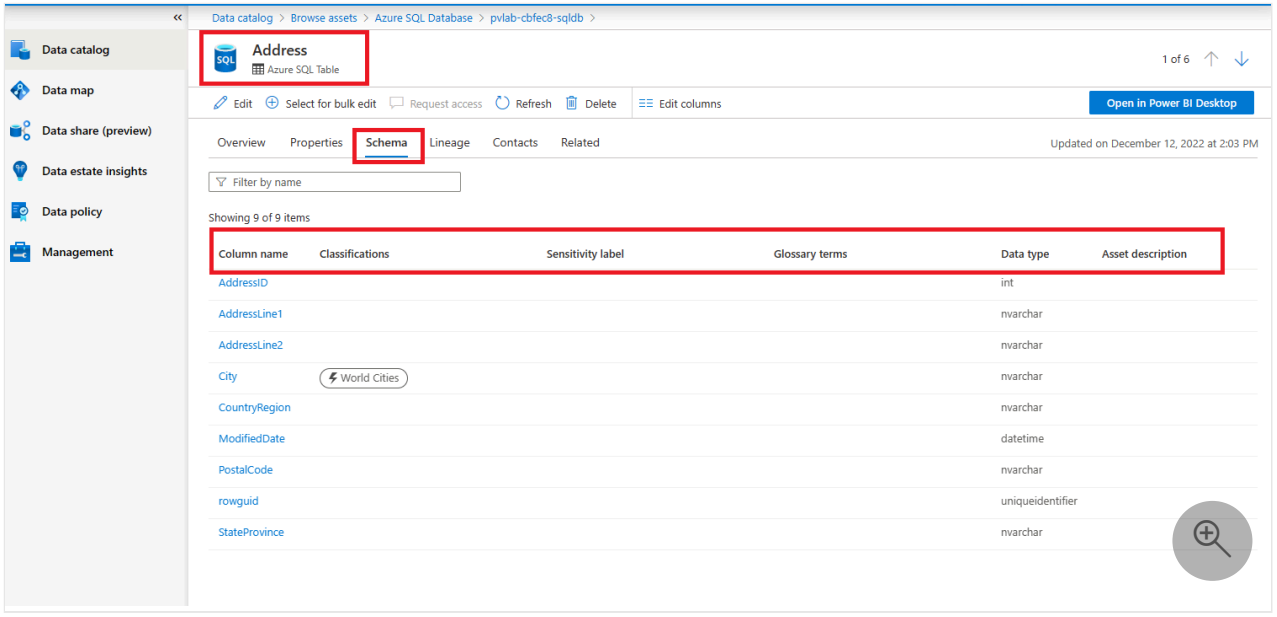


Below you can see a simplified JSON result:

JSON

```
{
  "category": "ENTITY",
  "guid": "7d92a449-f7e8-812f-5fc8-ca6127ba90bd",
  "name": "azure_sql_table",
  "description": "azure_sql_table",
  "typeVersion": "1.0",
  "serviceType": "Azure SQL Database",
  "options": {
    "schemaElementsAttribute": "columns",
  },
  "attributeDefs": [
    { "name": "principalId", ...},
    { "name": "objectType", ...},
    { "name": "createTime", ...},
    { "name": "modifiedTime", ... }
  ],
  "superTypes": [
    "DataSet",
    "Purview_Table",
    "Table"
  ],
  "subTypes": [],
  "relationshipAttributeDefs": [
    {
      "name": "dbSchema",
      "typeName": "azure_sql_schema",
      "isOptional": false,
      "cardinality": "SINGLE",
      "relationshipTypeName": "azure_sql_schema_tables",
    },
    {
      "name": "columns",
      "typeName": "array<azure_sql_column>",
      "isOptional": true,
      "cardinality": "SET",
      "relationshipTypeName": "azure_sql_table_columns",
    },
  ]
}
```

Based on the JSON type definition, let's look at some properties:



- **Category** field describes in what category your type is. The list of categories supported by Apache Atlas can be found here.
- **ServiceType** field is useful when browsing assets *by source type* in Microsoft Purview. The *service type* will be an entry point to find all assets that belong to the same *service type* - as defined on their type definition. In the below screenshot of Purview UI, the user limits the result to be the entities specified with *Azure SQL Database* in **serviceType**:

> **Note**
>
> **Azure SQL Database** is defined with the same *serviceType* as **Azure SQL Table**.

- **SuperTypes** describes the "*parent*" types you want to "*inherit*" from.
- **schemaElementsAttributes** from **options** influences what appears in the **Schema** tab of your asset in Microsoft Purview.

  Below you can see an example of how the **Schema** tab looks like for an asset of type Azure SQL Table:

- **relationshipAttributeDefs** are calculated through the relationship type definitions. In our JSON, we can see that **schemaElementsAttributes** points to the relationship attribute called **columns** - which is one of elements from **relationshipAttributeDefs** array, as shown below:

```JSON
...
"relationshipAttributeDefs": [
    ...
    {
```

```
        "name": "columns",
        "typeName": "array<azure_sql_column>",
        "isOptional": true,
        "cardinality": "SET",
        "relationshipTypeName": "azure_sql_table_columns",
      },
    ]
```

Each relationship has its own definition. The name of the definition is found in **relationshipTypeName** attribute. In this case, it's *azure_sql_table_columns*.

- The **cardinality** of this relationship attribute is set to *SET, which suggests that it holds a list of related assets.
- The related asset is of type *azure_sql_column*, as visible in the *typeName* attribute.

In other words, the *columns* relationship attribute relates the Azure SQL Table to a list of Azure SQL Columns that show up in the Schema tab.

Example of a *relationship Type definition*

Each relationship consists of two ends, called *endDef1* and *endDef2*.

In the previous example, *azure_sql_table_columns* was the name of the relationship that characterizes a table (endDef1) and its columns (endDef2).

For the full definition, you can do make a `GET` request to the following endpoint using *azure_sql_table_columns* as the name:

HTTP

```
GET
https://{{ENDPOINT}}/catalog/api/atlas/v2/types/typedef/name/azure_sql_table_colum
ns
```

Below you can see a simplified JSON result:

JSON

```
{
  "category": "RELATIONSHIP",
  "guid": "c80d0027-8f29-6855-6395-d243b37d8a93",
  "name": "azure_sql_table_columns",
  "description": "azure_sql_table_columns",
  "serviceType": "Azure SQL Database",
  "relationshipCategory": "COMPOSITION",
  "endDef1": {
    "type": "azure_sql_table",
    "name": "columns",
```

```
    "isContainer": true,
    "cardinality": "SET",
  },
  "endDef2": {
    "type": "azure_sql_column",
    "name": "table",
    "isContainer": false,
    "cardinality": "SINGLE",
  }
}
```

- **name** is the name of the relationship definition. The value, in this case *azure_sql_table_columns* is used in the *relationshipTypeName* attribute of the entity that has this relationship, as you can see it referenced in the json.
- **relationshipCategory** is the category of the relationship and it can be either COMPOSITION, AGGREGATION or ASSOCIATION as described here.
- **enDef1** is the first end of the definition and contains the attributes:
  - **type** is the type of the entity that this relationship expects as end1.
  - **name** is the attribute that will appear on this entity's relationship attribute.
  - **cardinality** is either SINGLE, SET or LIST.
  - **isContainer** is a boolean and applies to containment relationship category. When set to true in one end, it indicates that this end is the container of the other end. Therefore:
    - Only the *Composition* or *Aggregation* category relationships can and should have in one end *isContainer* set to true.
    - *Association* category relationship shouldn't have *isContainer* property set to true in any end.
- **endDef2** is the second end of the definition and describes, similarly to endDef1, the properties of the second part of the relationship.

Schema tab

What is *Schema* in Microsoft Purview?

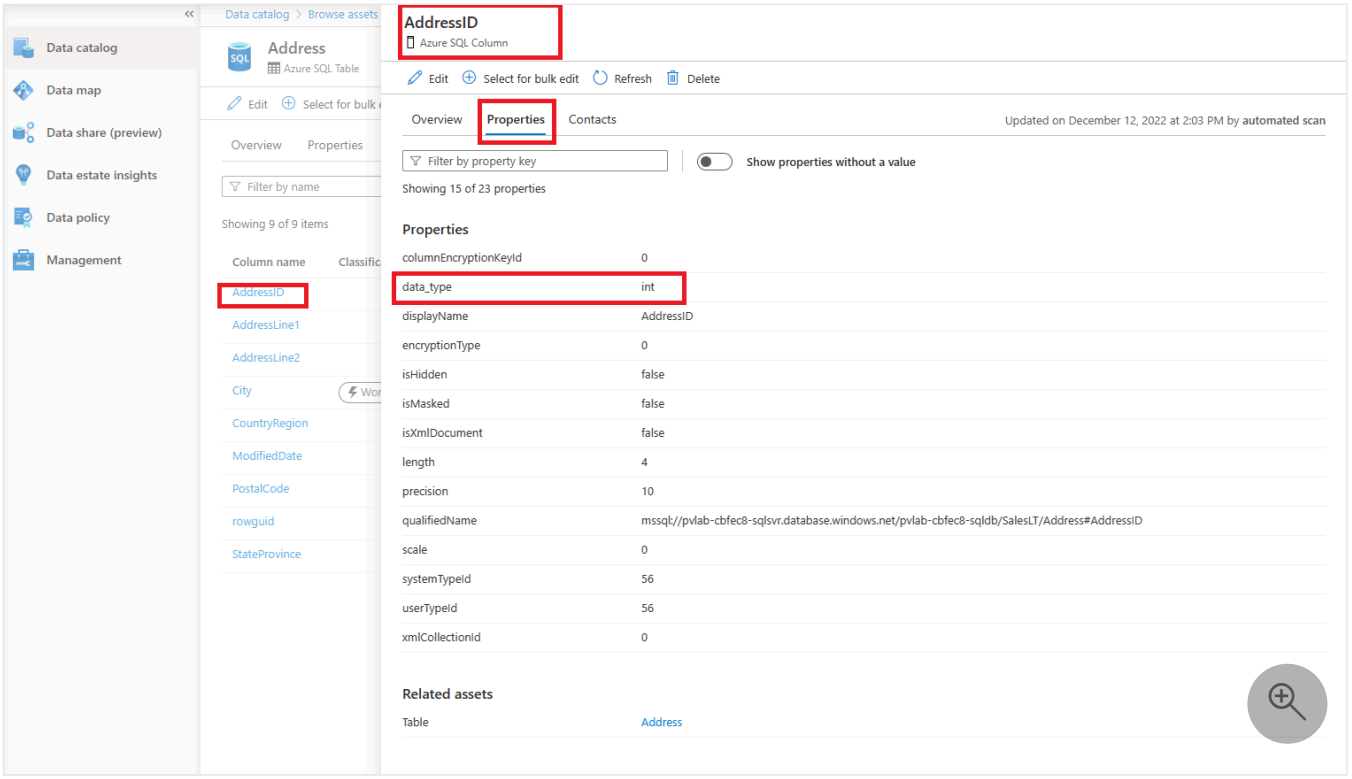
Schema is an important concept that reflects how data is stored and organized in the data store. It reflects the structure of the data and the data restrictions of the elements that construct the structure.

Elements on the same schema can be classified differently (due to their content). Also, different transformation (lineage) can happen to only a subset of elements. Due to these aspects, Purview can model schema and schema elements **as entities**, hence schema is usually a relationship attribute to the data asset entity. Examples of schema elements are: **columns** of a table, **json properties** of json schema, **xml elements** of xml schema etc.

There are two types of schemas:

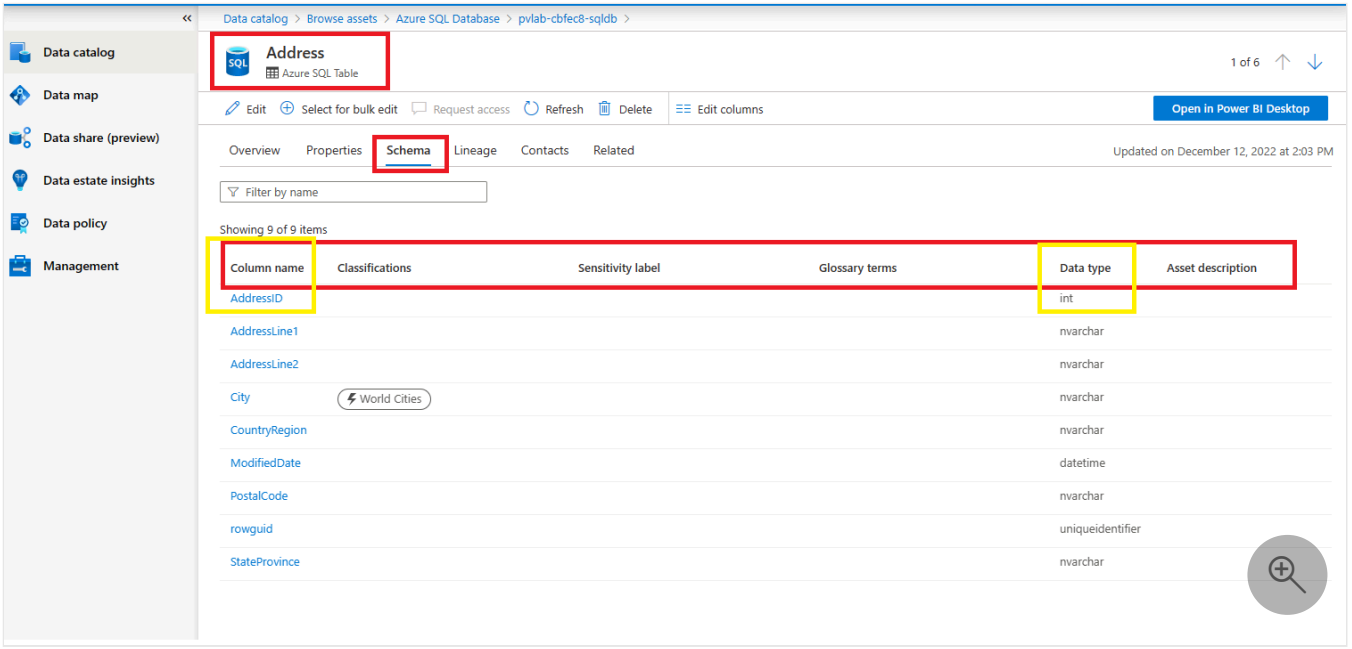
- **Intrinsic Schema** - Some systems are intrinsic to schema. For example, when you create a SQL Table, the system requires you to define the columns that construct the table; in this sense, schema of a table is reflected by its columns.

  For data store with predefined schema, Purview uses the corresponding relationship between the data asset and the schema elements to reflect the schema. This relationship attribute is specified by the keyword **schemaElementsAttribute** in **options** property of the entity type definition.



- **Non Intrinsic Schema** - Some systems don't enforce such schema restrictions, but users can use it to store structural data by applying some schema protocols to the data. For example, Azure Blobs store binary data and don't care about the data in the binary stream. Therefore, it's unaware of any schema, but the user can serialize their data with schema protocols like json before storing it in the blob. In this sense, schema is maintained by some extra protocols and corresponding validation enforced by the user.

  For data store without inherent schema, schema model is independent of this data store. For such cases, Purview defines an interface for schema and a relationship between DataSet and schema, called **dataset_attached_schemas** - this extends any entity type that inherits from DataSet to have an **attachedSchema** relationship attribute to link to their schema representation.



Example of *Schema tab*

The Azure SQL Table example from above has an intrinsic schema. The information that shows up in the Schema tab of the Azure SQL Table comes from the Azure SQL Column themselves.

Selecting one column item, we would see the following:

The question is, how did Microsoft Purview select the *data_tye* property from the column and showed it in the Schema tab of the table?

You can get the type definition of an Azure SQL Column by making a `GET` request to the endpoint:

HTTP

```
GET https://{{ENDPOINT}}/catalog/api/atlas/v2/types/typedef/name/{name}
```

> ⓘ **Note**

{name} in this case is: azure_sql_column

Here's a simplified JSON result:

JSON

```
{
  "category": "ENTITY",
  "guid": "58034a18-fc2c-df30-e474-75803c3a8957",
  "name": "azure_sql_column",
  "description": "azure_sql_column",
  "serviceType": "Azure SQL Database",
  "options": {
    "schemaAttributes": "[\"data_type\"]"
  },
  "attributeDefs":
  [
    {
      "name": "data_type",
      "typeName": "string",
      "isOptional": false,
      "cardinality": "SINGLE",
      "valuesMinCount": 1,
      "valuesMaxCount": 1,
      "isUnique": false,
      "isIndexable": false,
      "includeInNotification": false
    },
  ...
  ]
  ...
}
```

> **Note**
>
> serviceType is Azure SQL Database, the same as for the table

- *schemaAttributes* is set to **data_type**, which is one of the attributes of this type.

Azure SQL Table used *schemaElementAttribute* to point to a relationship consisting of a list of Azure SQL Columns. The type definition of a column has *schemaAttributes* defined.

In this way, the Schema tab in the table displays the attribute(s) listed in the *schemaAttributes* of the related assets.

Create custom type definitions

Why?

First, why would someone like to create a custom type definition?

There can be cases where there's no built-in type that corresponds to the structure of the metadata you want to import in Microsoft Purview.

In such a case, a new type definition has to be defined.

> **Note**
>
> The usage of built-in types should be favored over the creation of custom types, whenever possible.

Now that we gained an understanding of type definitions in general, let us create custom type definitions.

Scenario

In this tutorial, we would like to model a 1:n relationship between two types, called *custom_type_parent* and *custom_type_child*.

A *custom_type_child* should reference one parent, whereas a *custom_type_parent* can reference a list of children.

They should be linked together through a 1:n relationship.

> **Tip**
>
> Here you can find few tips when creating a new custom type.

Create definitions

1. Create the *custom_type_parent* type definition by making a `POST` request to one of the two following endpoints:

Classic Microsoft Purview governance portal:

```HTTP
POST https://{{ENDPOINT}}.purview.azure.com/catalog/api/atlas/v2/types/typedefs
```

New Microsoft Purview portal:

```HTTP
POST https://api.purview-service.microsoft.com/catalog/api/atlas/v2/types/typedefs
```

With the body:

```JSON
{
   "entityDefs":
   [
       {
           "category": "ENTITY",
           "version": 1,
           "name": "custom_type_parent",
           "description": "Sample custom type of a parent object",
           "typeVersion": "1.0",
           "serviceType": "Sample-Custom-Types",
           "superTypes": [
               "DataSet"
           ],
           "subTypes": [],
           "options":{
               "schemaElementsAttribute": "columns"
           }
       }
   ]
}
```

1. Create the *custom_type_child* type definition by making a `POST` request to one of the two following endpoints:

Classic Microsoft Purview governance portal:

```HTTP
POST https://{{ENDPOINT}}.purview.azure.com/catalog/api/atlas/v2/types/typedefs
```

New Microsoft Purview portal:

```HTTP
POST https://api.purview-service.microsoft.com/catalog/api/atlas/v2/types/typedefs
```

With the body:

JSON

```
{
   "entityDefs":
   [
       {
           "category": "ENTITY",
           "version": 1,
           "name": "custom_type_child",
           "description": "Sample custom type of a CHILD object",
           "typeVersion": "1.0",
           "serviceType": "Sample-Custom-Types",
           "superTypes": [
               "DataSet"
           ],
           "subTypes": [],
           "options":{
              "schemaAttributes": "data_type"
           }
       }
   ]
}
```

1. Create a custom type relationship definition by making a `POST` request to one of the two following endpoints:

Classic Microsoft Purview governance portal:

HTTP

```
POST https://{{ENDPOINT}}.purview.azure.com/catalog/api/atlas/v2/types/typedefs
```

New Microsoft Purview portal:

HTTP

```
POST https://api.purview-service.microsoft.com/catalog/api/atlas/v2/types/typedefs
```

With the body:

JSON

```
{
    "relationshipDefs": [
        {
            "category": "RELATIONSHIP",
            "endDef1" : {
                "cardinality" : "SET",
                "isContainer" : true,
```

```
                "name" : "Children",
                "type" : "custom_type_parent"
            },
            "endDef2" : {
                "cardinality" : "SINGLE",
                "isContainer" : false,
                "name" : "Parent",
                "type" : "custom_type_child"
            },
            "relationshipCategory" : "COMPOSITION",
            "serviceType": "Sample-Custom-Types",
            "name": "custom_parent_child_relationship"
        }
    ]
}
```

Initialize assets of custom types

1. Initialize a new asset of type *custom_type_parent* by making a `POST` request to one of the two following endpoints:

Classic Microsoft Purview governance portal:

HTTP

```
POST https://{{ENDPOINT}}.purview.azure.com/catalog/api/atlas/v2/entity
```

New Microsoft Purview portal:

HTTP

```
POST https://api.purview-service.microsoft.com/catalog/api/atlas/v2/entity
```

With the body:

JSON

```
{
    "entity": {
        "typeName":"custom_type_parent",
        "status": "ACTIVE",
        "version": 1,
         "attributes":{
            "name": "First_parent_object",
            "description": "This is the first asset of type custom_type_parent",
            "qualifiedName": "custom//custom_type_parent:First_parent_object"
         }
```

```
    }
}
```

Save the *guid* as you'll need it later.

1. Initialize a new asset of type *custom_type_child* by making a `POST` request to one of the two following endpoints:

Classic Microsoft Purview governance portal:

HTTP

```
POST https://{{ENDPOINT}}.purview.azure.com/catalog/api/atlas/v2/entity
```

New Microsoft Purview portal:

HTTP

```
POST https://api.purview-service.microsoft.com/catalog/api/atlas/v2/entity
```

With the body:

JSON

```
{
   "entity": {
       "typeName":"custom_type_child",
       "status": "ACTIVE",
       "version": 1,
       "attributes":{
           "name": "First_child_object",
           "description": "This is the first asset of type custom_type_child",
           "qualifiedName": "custom//custom_type_child:First_child_object"
        }
   }
}
```

Save the *guid* as you'll need it later.

1. Initialize a new relationship of type *custom_parent_child_relationship* by making a `POST` request to one of the two following endpoints:

Classic Microsoft Purview governance portal:

HTTP

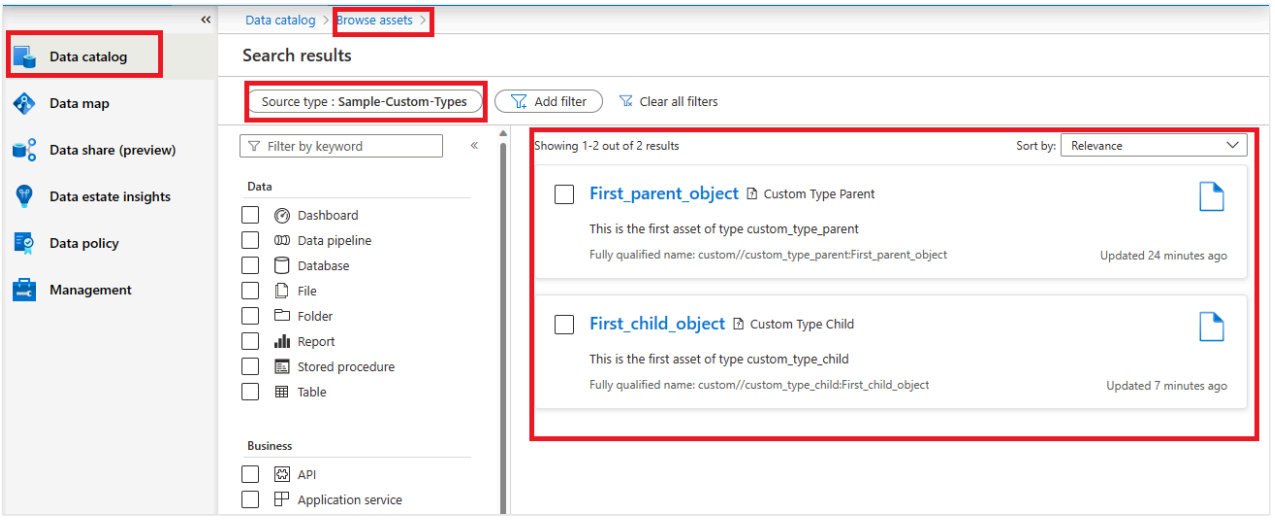
```
POST https://{{ENDPOINT}}.purview.azure.com/catalog/api/atlas/v2/relationship/
```

New Microsoft Purview portal:

HTTP

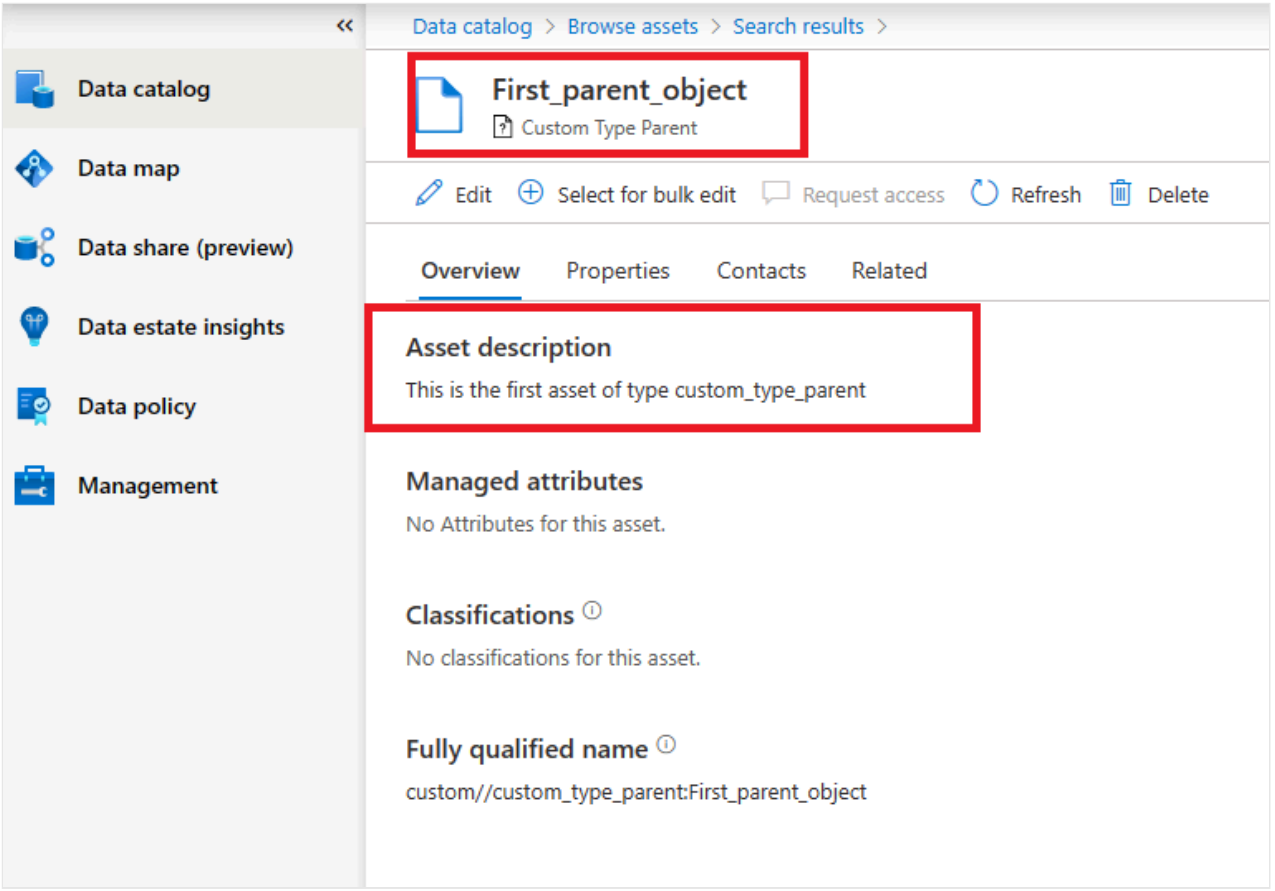
```
POST https://api.purview-service.microsoft.com/catalog/api/atlas/v2/relationship/
```

With the following body:



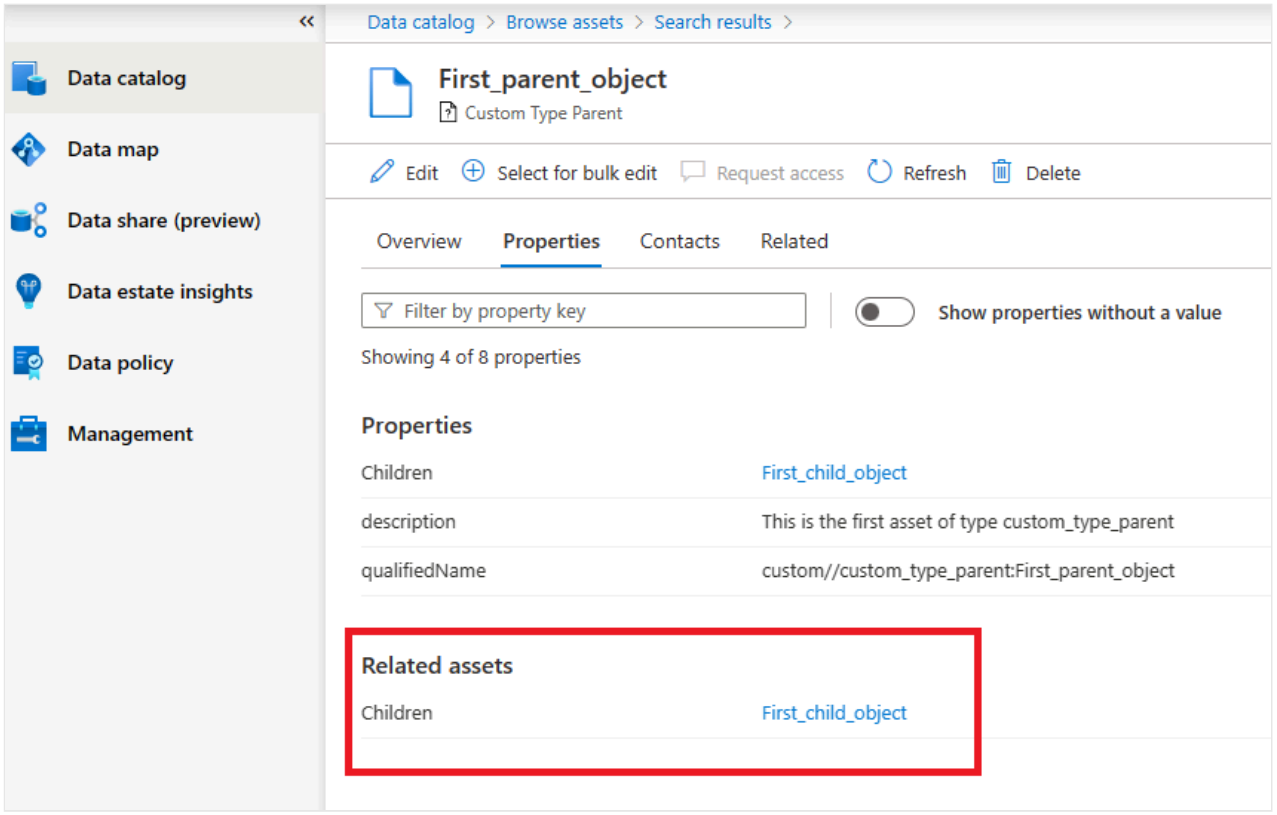
> **Note**
>
> The *guid* in end1 must be replaced with the the guid of the object created at step 6.1 The *guid* in end2 must be replaced with the guid of the object created at step 6.2

JSON



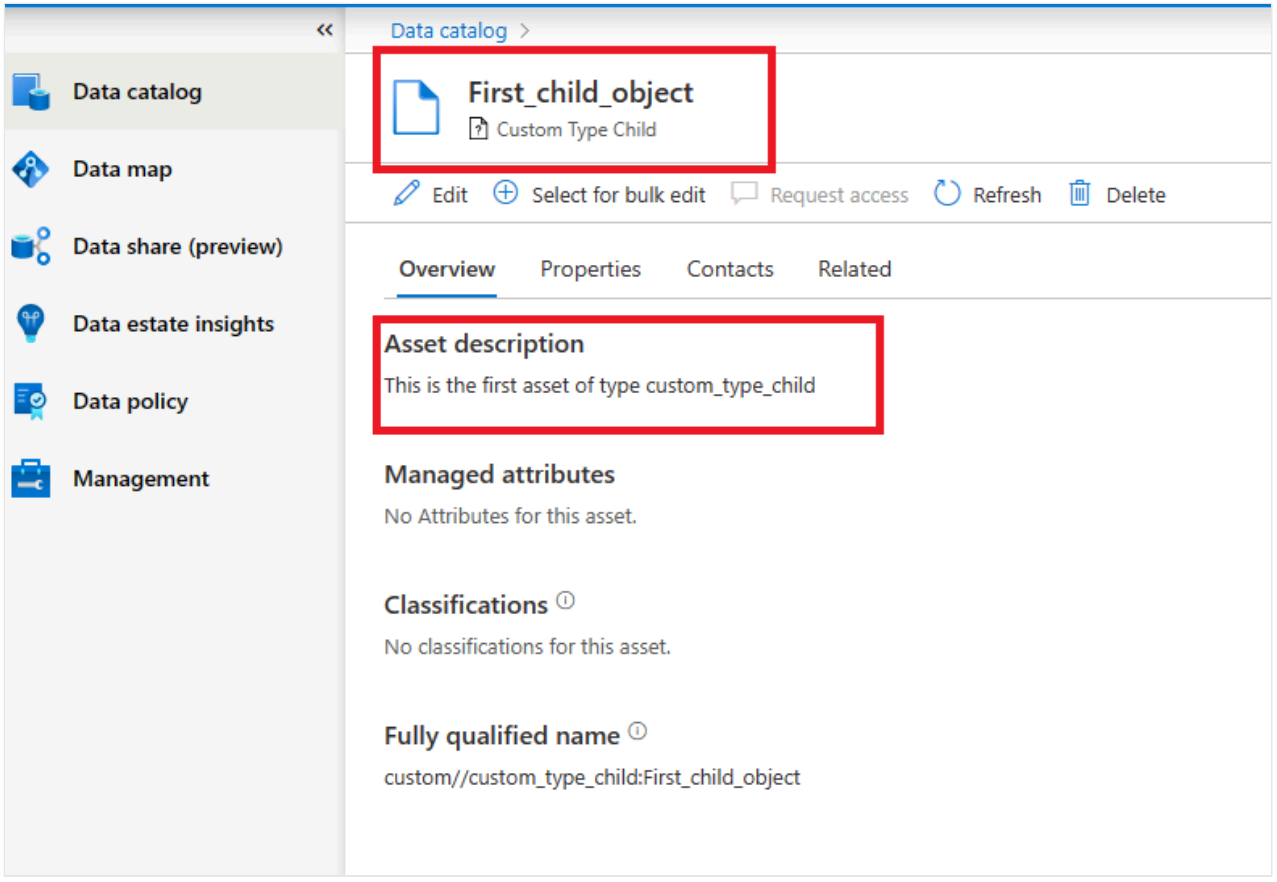
```
{
   "typeName": "custom_parent_child_relationship",
   "end1": {
         "guid": "...",
       "typeName": "custom_type_parent"
   },
   "end2": {
       "guid": "...",
       "typeName": "custom_type_child"
   }
}
```

View the assets in Microsoft Purview

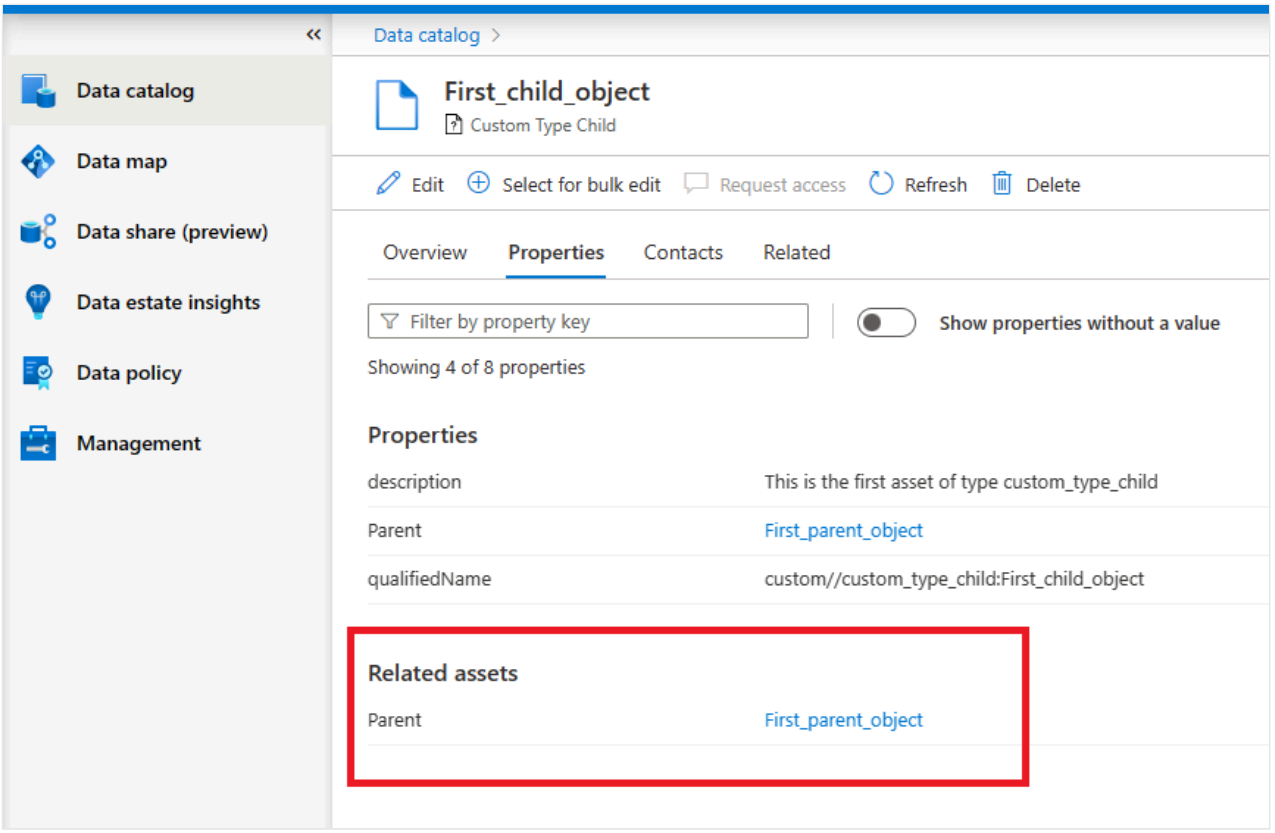


1. Go to *Unified Catalog* in Microsoft Purview.
2. Select *Browse*.
3. Select *By source type*.
4. Select *Sample-Custom-Types*.

5. Select the *First_parent_object*:

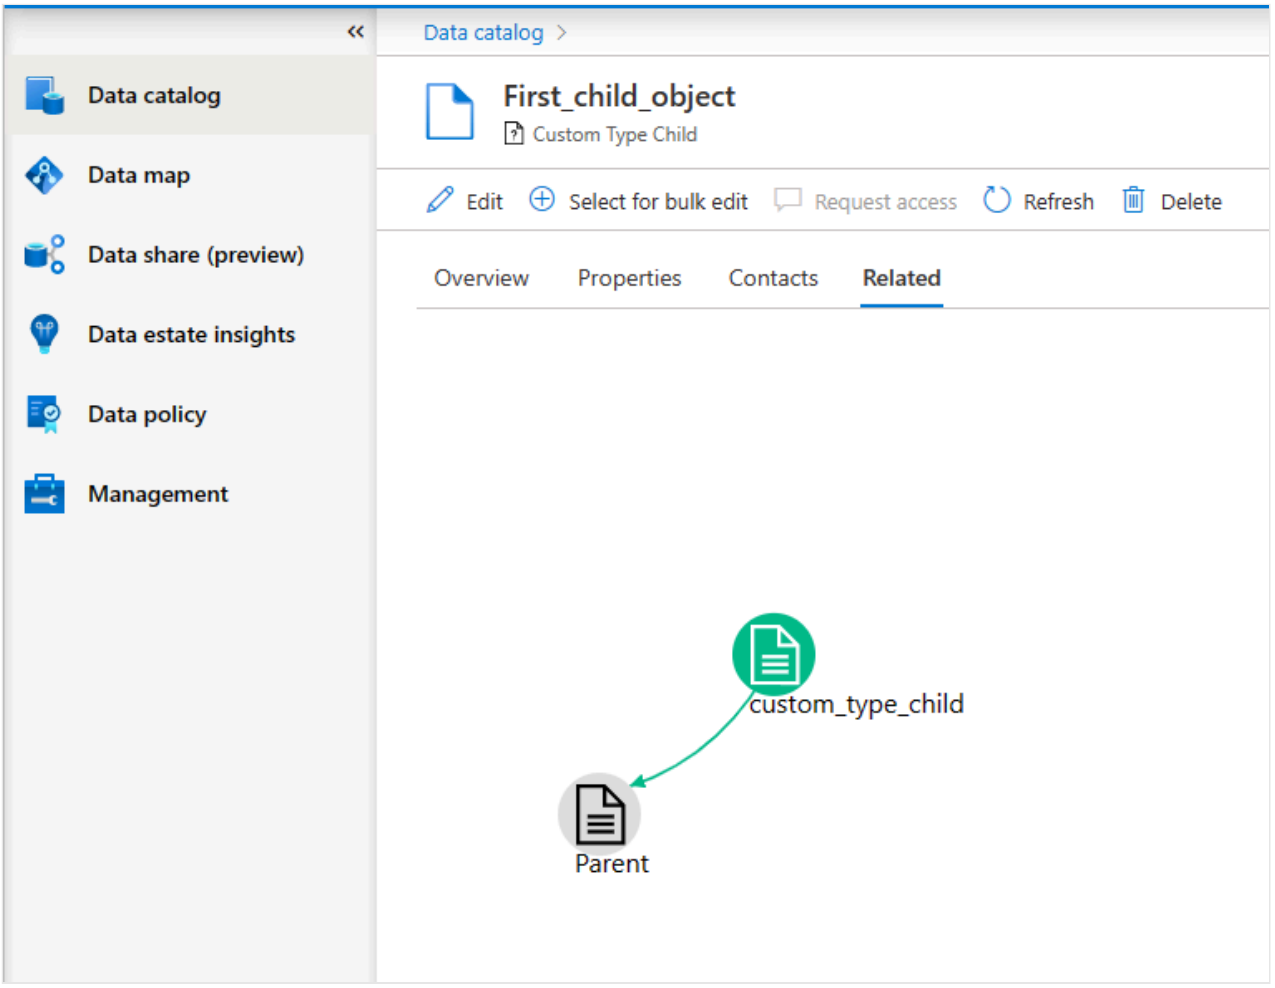


6. Select the *Properties* tab:

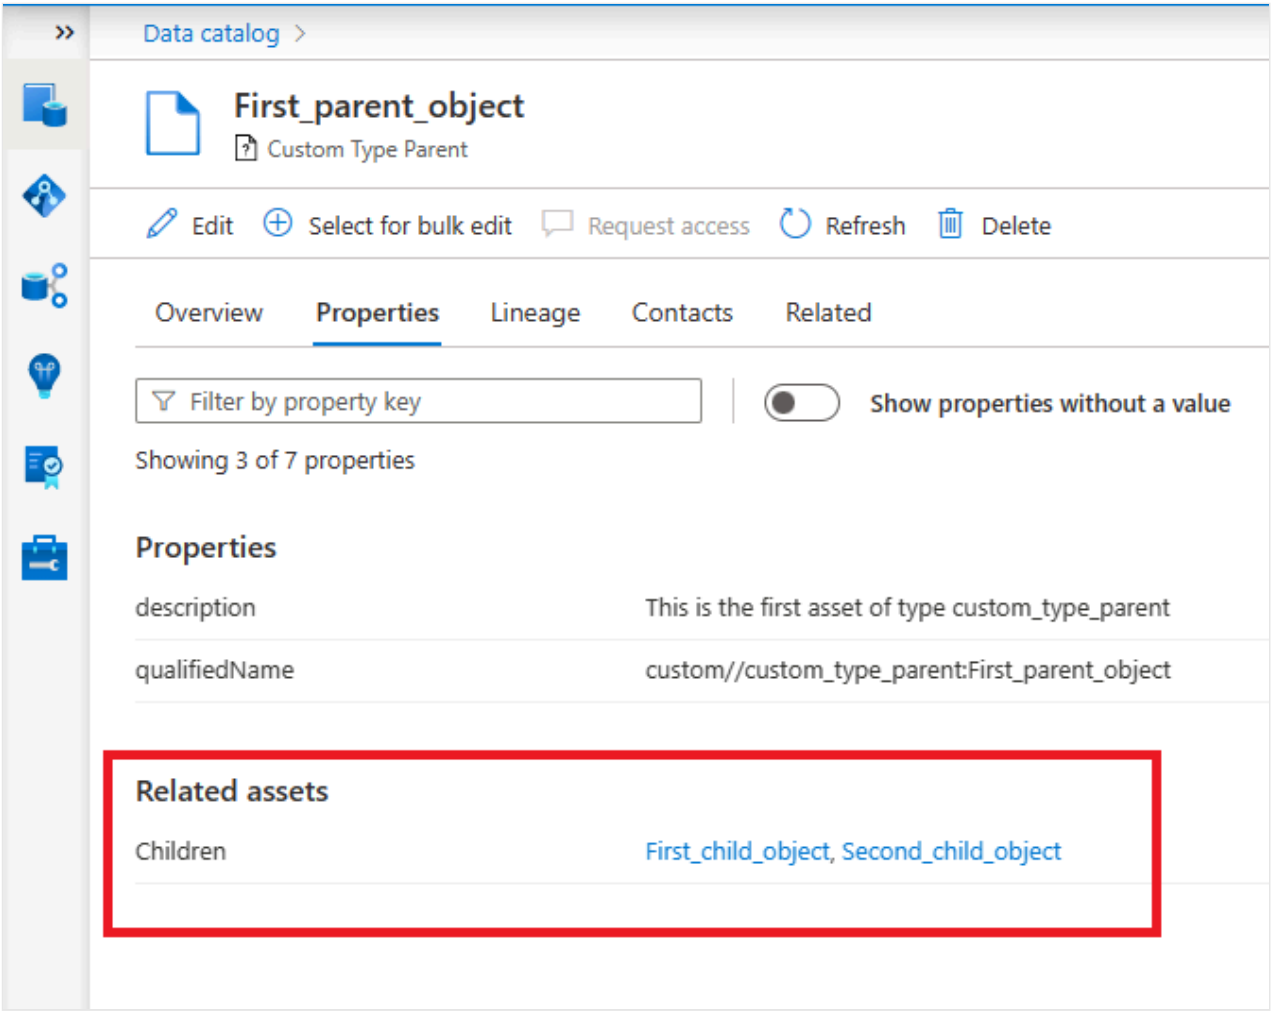


7. You can see the *First_child_object* being linked there.

8. Select the *First_child_object*:



9. Select the *Properties* tab:



10. You can see the Parent object being linked there.

11. Similarly, you can select the *Related* tab and will see the relationship between the two objects:

12. You can create multiple children by initializing a new child asset and inititialzing a relationship

> **Note**
>
> The *qualifiedName* is unique per asset, therefore, the second child should be called differently, such as: *custom//custom_type_child:Second_child_object*

> **Tip**
>
> If you delete the *First_parent_object* you will notice that the children will also be removed, due to the *COMPOSITION* relationship that we chose in the definition.

Limitations

There are several known limitations when working with custom types that will be enhanced in future, such as:

- Relationship tab looks different compared to built-in types

- Custom types have no icons
- Hierarchy isn't supported

Manage data sources | Microsoft Purview data plane REST APIs

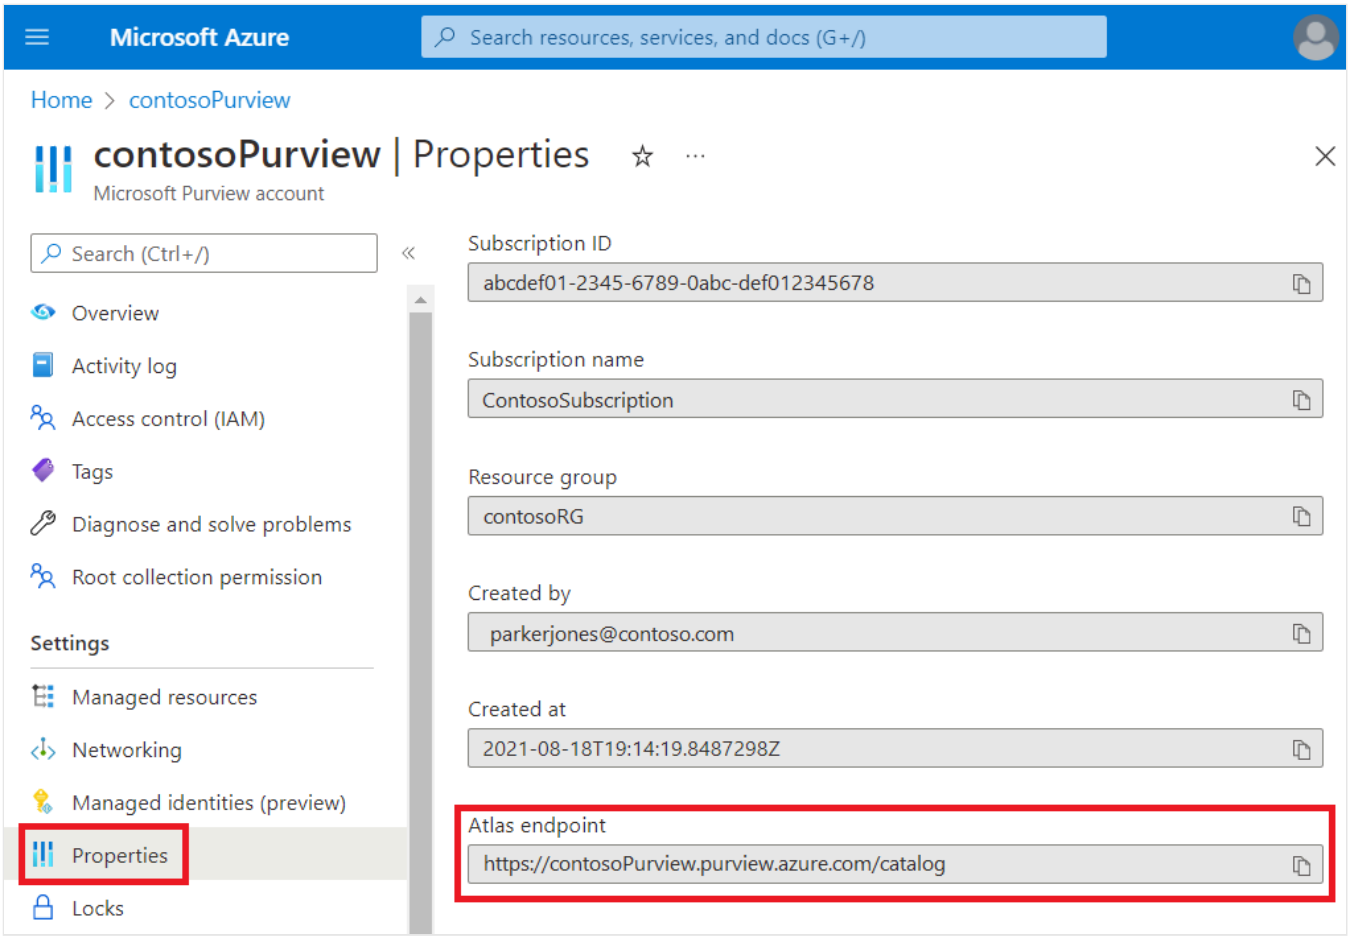
Tutorial: Atlas 2.2 functionality

Article • 05/14/2025

In this tutorial, learn to programmatically interact with new Atlas 2.2 APIs with Microsoft Purview Data Map.

Prerequisites

- If you don't have an Azure subscription, create a free account before you begin.
- You must have an existing Microsoft Purview account. If you don't have a catalog, see the quickstart for creating a Microsoft Purview account.
- To establish a bearer token and to call any APIs, see the documentation about how to authenticate APIs for Microsoft Purview.



Business metadata APIs

Business metadata is a template that contains custom attributes (key values). You can create these attributes globally and then apply them across multiple typedefs.

Atlas endpoint

For all the requests, you'll need the Atlas endpoint for your Microsoft Purview account.

1. Find your Microsoft Purview account in the Azure portal
2. Select the **Properties** page on the left side menu
3. Copy the **Atlas endpoint** value

Create business metadata with attributes

You can send a `POST` request to the following endpoint:

```
POST {{endpoint}}/api/atlas/v2/types/typedefs
```

> **Tip**
>
> The **applicableEntityTypes** property tells which data types the metadata will be applied to.

Sample JSON:

JSON

```
 {
"businessMetadataDefs": [
  {
    "category": "BUSINESS_METADATA",
    "createdBy": "admin",
    "updatedBy": "admin",
    "version": 1,
```

```
      "typeVersion": "1.1",
      "name": "<Name of Business Metadata>",
      "description": "",
      "attributeDefs": [
        {
          "name": "<Attribute Name>",
          "typeName": "string",
          "isOptional": true,
          "cardinality": "SINGLE",
          "isUnique": false,
          "isIndexable": true,
          "options": {
            "maxStrLength": "50",
            "applicableEntityTypes": "[\"Referenceable\"]"
          }
        }
      ]
    }
  ]
}
```

Add or update an attribute to existing business metadata

You can send a `PUT` request to the following endpoint:

```
PUT {{endpoint}}/api/atlas/v2/types/typedefs
```

Sample JSON:

JSON

```
 {
  "businessMetadataDefs": [
   {
     "category": "BUSINESS_METADATA",
     "createdBy": "admin",
     "updatedBy": "admin",
     "version": 1,
     "typeVersion": "1.1",
     "name": "<Name of Business Metadata>",
     "description": "",
     "attributeDefs": [
       {
         "name": "<Attribute Name>",
         "typeName": "string",
         "isOptional": true,
         "cardinality": "SINGLE",
         "isUnique": false,
```

```
          "isIndexable": true,
          "options": {
            "maxStrLength": "500",
            "applicableEntityTypes": "[\"Referenceable\"]"
          }
        },
        {
          "name": "<Attribute Name 2>",
          "typeName": "int",
          "isOptional": true,
          "cardinality": "SINGLE",
          "isUnique": false,
          "isIndexable": true,
          "options": {
            "applicableEntityTypes": "[\"Referenceable\"]"
          }
        }
      ]
    }
  ]
}
```

Get a business metadata definition

You can send a `GET` request to the following endpoint:

```
GET {endpoint}}/api/atlas/v2/types/typedef/name/{{Business Metadata Name}}
```

Set a business metadata attribute to an entity

You can send a `POST` request to the following endpoint:

```
POST {{endpoint}}/api/atlas/v2/entity/guid/{{GUID}}/businessmetadata?
isOverwrite=true
```

Sample JSON:

JSON

```
{
  "myBizMetaData1": {
        "bizAttr1": "I am myBizMetaData1.bizAttr1",
        "bizAttr2": 123,
```

```
  }
 }
```

Delete a business metadata attribute from an entity

You can send a `DELETE` request to the following endpoint:

```
'DELETE' {{endpoint}}/api/atlas/v2/entity/guid/{{GUID}}/businessmetadata?
isOverwrite=true
```

Sample JSON:

JSON

```
{
  "myBizMetaData1": {
    "bizAttr1": ""
  }
}
```

Delete a business metadata type definition

> **Note**
>
> You can only delete business metadata type definition if it has no references, i.e., if it has not been assigned to any assets in the catalog.

You can send a `DELETE` request to the following endpoint:

```
DELETE {{endpoint}}/api/atlas/v2/types/typedef/name/{{Business Metadata Name}}
```

Custom attribute APIs

Custom attributes are key/value pairs that can be directly added to an Atlas entity.

Set a custom attribute to an entity

You can send a `POST` request to the following endpoint:

```
POST {{endpoint}}/api/atlas/v2/entity
```

Sample JSON:

JSON

```
{
    "entity": {
        "typeName": "azure_datalake_gen2_path",
        "attributes": {

            "qualifiedName": "<FQN of the asset>",
            "name": "data6.csv"
        },
        "guid": "3ffb28ff-138f-419e-84ba-348b0165e9e0",
        "customAttributes": {
            "custAttr1": "attr1",
            "custAttr2": "attr2"
        }
    }
}
```

Label APIs

Labels are free text tags that can be applied to any Atlas entity.

Set labels to an entity

You can send a `POST` request to the following endpoint:

```
POST {{endpoint}}/api/atlas/v2/entity/guid/{{GUID}}/labels
```

Sample JSON:

JSON

```
[
  "label1",
```

```
  "label2"
]
```

Delete labels to an entity

You can send a `DELETE` request to the following endpoint:

```
DELETE {{endpoint}}/api/atlas/v2/entity/guid/{{GUID}}/labels
```

Sample JSON:

JSON

```
[
  "label2"
]
```

Manage data sources | Microsoft Purview data plane REST APIs

Tutorial: Authenticate for APIs

10/15/2025

In this tutorial, you learn how to authenticate for the Microsoft Purview data plane APIs. Anyone who wants to submit data to Microsoft Purview, include Microsoft Purview as part of an automated process, or build their own user experience on Microsoft Purview can use the APIs to do so.

Prerequisites

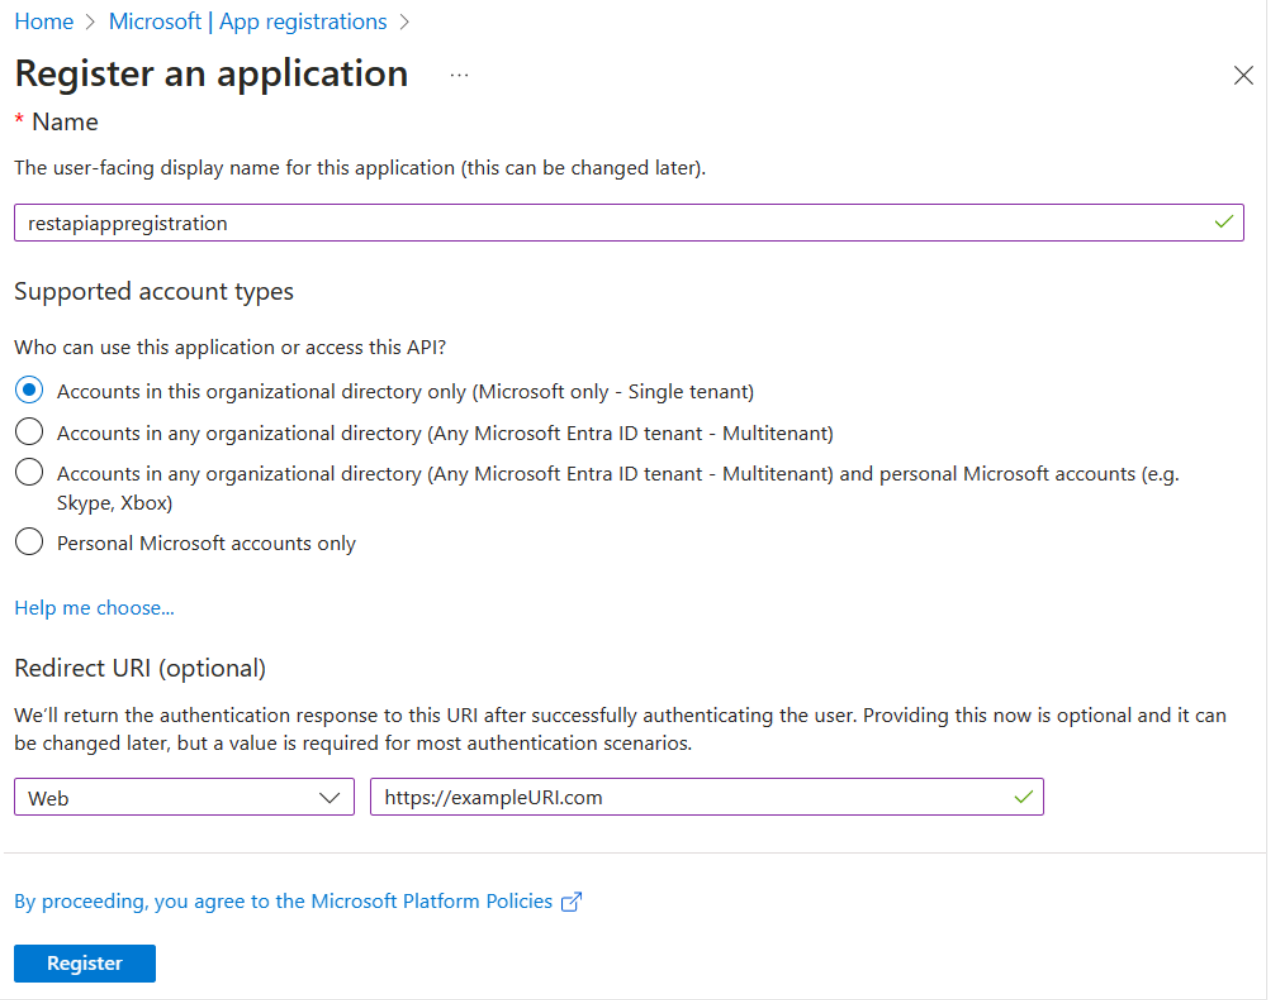
- To get started, you must have an existing Microsoft Purview account. If you don't have a catalog, see the quickstart for creating a Microsoft Purview account.

Create a service principal (application)

For an API client to access the Microsoft Purview data plane APIs, the client must have a service principal (application), and an identity that Microsoft Purview recognizes and is configured to trust. When you make API calls, that service principal's identity will be used for authorization.

Customers who have used existing service principals (application IDs) have had a high rate of failure. Therefore, we recommend creating a new service principal for calling APIs.

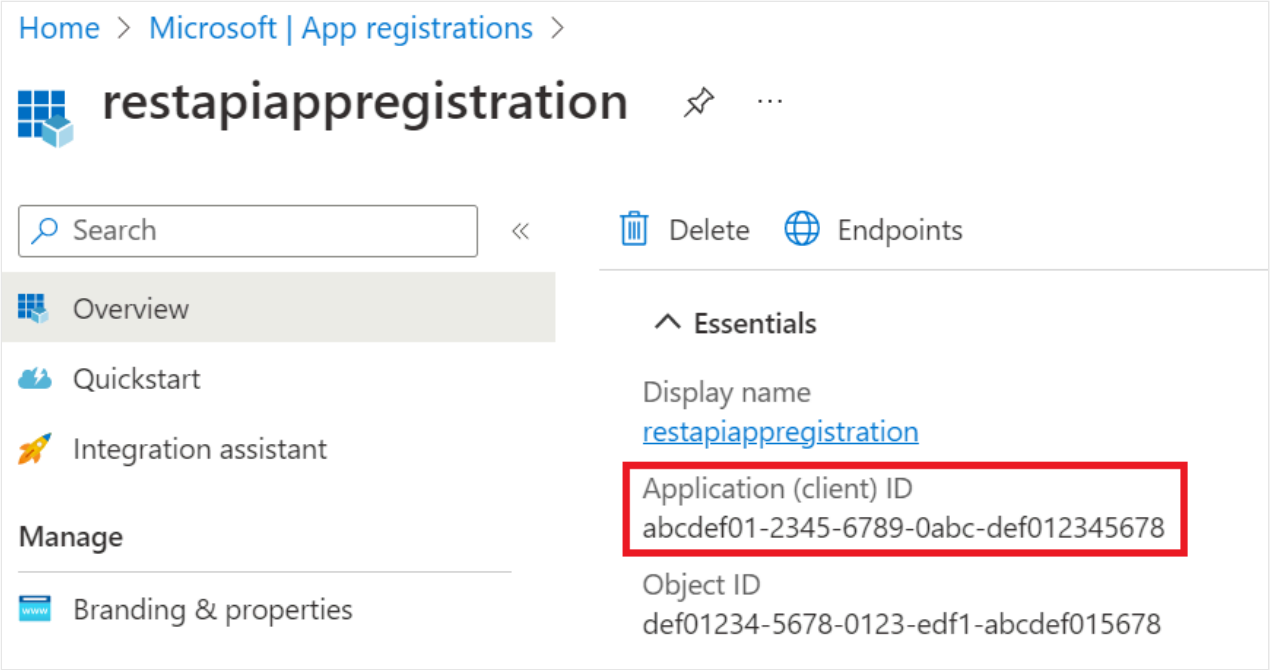
To create a new service principal:



1. Sign in to the Azure portal.
2. From the portal, search for and select **Microsoft Entra ID**.
3. From the **Microsoft Entra ID** page, select **App registrations** from the left pane.
4. Select **New registration**.
5. On the **Register an application** page:
   a. Enter a **Name** for the application (the service principal name).
   b. For *Who can use this application or access this API?*, select the kinds of user accounts you expect to use this API.

> **Tip**

If you expect only users from your current Microsoft Entra ID tenant to use the REST API, select, **Accounts in this organizational directory only (*<your tenant's name>* only - Single tenant)**. Otherwise, consider the other options.



c. For **Redirect URI (optional)**, select **Web** and enter a value. This value doesn't need to be a valid endpoint. `https://exampleURI.com` will do.

d. Select **Register**.

6. On the new service principal page, copy the values of the **Display name** and the **Application (client) ID** to save for later.

   The application ID is the `client_id` value in the sample code.

To use the service principal (application), you need to know the service principal's password that can be found by:

1. From the Azure portal, search for and select **Microsoft Entra ID**, and then select **App registrations** from the left pane.
2. Select your service principal (application) from the list.
3. Select **Certificates & secrets** from the left pane.
4. Select **New client secret**.
5. On the **Add a client secret** page, enter a **Description**, select an expiration time under **Expires**, and then select **Add**.

   On the **Client secrets** page, the string in the **Value** column of your new secret is your password. Save this value.

Set up authentication using service principal

Once the new service principal is created, you need to assign the data plane roles of your purview account to the service principal created above. Follow the steps below to assign the correct role to establish trust between the service principal and the Purview account:

Data Map

1. Navigate to your Microsoft Purview governance portal.
2. Select the Data Map in the left menu.
3. Select Collections.
4. Select the root collection in the collections menu. This will be the top collection in the list, and will have the same name as your Microsoft Purview account.

   > **Note**
   >
   > You can also assign your service principal permission to any sub-collections, instead of the root collection. However, all APIs will be scoped to that collection (and sub-collections that inherit permissions), and users trying to call the API for another collection will get errors.

5. Select the **Role assignments** tab.
6. Assign the following roles to the service principal created previously to access various data planes in Microsoft Purview. For detailed steps, see Assign Azure roles using the Microsoft Purview governance portal.

- Data Curator role to access Catalog Data plane.
- Data Source Administrator role to access Scanning Data plane.
- Collection Admin role to access Account Data Plane and Metadata policy Data Plane.
- Policy Author role to access the DevOps policies API

> **Note**
>
> Only members of the Collection Admin role can assign data plane roles in Microsoft Purview. For more information about Microsoft Purview roles, see Access Control in Microsoft Purview.

Get token

You can send a POST request to the following URL to get access token.

`https://login.microsoftonline.com/{your-tenant-id}/oauth2/token`

You can find your Tenant ID by searching for **Tenant Properties** in the Azure portal. The ID will be available on the tenant properties page.

The following parameters need to be passed to the above URL:

- **client_id**: client ID of the application registered in Microsoft Entra ID and is assigned to a data plane role for the Microsoft Purview account.
- **client_secret**: client secret created for the above application.
- **grant_type**: This should be 'client_credentials'.
- **resource**: 'https://purview.azure.net'

Here's a sample POST request in PowerShell:

Azure PowerShell

```
$tenantID = "12a345bc-67d1-ef89-abcd-efg12345abcde"

$url = "https://login.microsoftonline.com/$tenantID/oauth2/token"
$params = @{ client_id = "a1234bcd-5678-9012-abcd-abcd1234abcd"; client_secret =
"abcd~a1234bcd56789012abcdabcd1234abcd"; grant_type = "client_credentials";
resource = 'https://purview.azure.net' }

Invoke-WebRequest $url -Method Post -Body $params -UseBasicParsing | ConvertFrom-
Json
```

Sample response token:

JSON

```
{
    "token_type": "Bearer",
    "expires_in": "86399",
    "ext_expires_in": "86399",
    "expires_on": "1621038348",
    "not_before": "1620951648",
    "resource": "https://purview.azure.net",
    "access_token": "<<access token>>"
}
```

Tip

If you get an error message that reads: *Cross-origin token redemption is permitted only for the 'Single-Page Application' client-type.*

- Check your request headers and confirm that your request **doesn't** contain the 'origin' header.
- Confirm that your redirect URI is set to **web** in your service principal.
- Make sure your software is up to date for the application you're using to send your POST request.

Use the access token above to call the Data plane APIs.

Manage data sources | Microsoft Purview Data Plane REST APIs

Tutorial: Use REST APIs to manage role-based access control on Microsoft Purview collections

Article • 02/24/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

In August 2021, access control in Microsoft Purview moved from Azure Identity & Access Management (IAM) (control plane) to Microsoft Purview collections (data plane). This change gives enterprise data curators and administrators more precise, granular access control on their data sources scanned by Microsoft Purview. The change also enables organizations to audit right access and right use of their data.

This tutorial guides you through step-by-step usage of the Microsoft Purview Metadata Policy APIs to help you add users, groups, or service principals to a collection, and manage or remove their roles within that collection. REST APIs are an alternative method to using the Azure portal or Microsoft Purview governance portal to achieve the same granular role-based access control.

For more information about the built-in roles in Microsoft Purview, see the Microsoft Purview permissions guide. The guide maps the roles to the level of access permissions that are granted to users.

Metadata Policy API Reference summary

The following table gives an overview of the Microsoft Purview Metadata Policy API Reference.

> **Note**
>
> Replace {pv-acc-name} with the name of your Microsoft Purview account before running these APIs. For instance, if your Microsoft Purview account name is *FabrikamPurviewAccount*, your API endpoints will become *FabrikamPurviewAccount.purview.azure.com*. The "api-version" parameter is subject

to change. Please refer the Microsoft Purview Metadata policy REST API documentation for the latest "api-version" and the API signature.

Expand table

API function	REST method	API endpoint	Description
Read All Metadata Roles	GET	https://{pv-acc-name}.purview.azure.com /policystore/metadataroles?&api-version=2021-07-01	Reads all metadata roles from your Microsoft Purview account.
Read Metadata Policy By Collection Name	GET	https://{pv-acc-name}.purview.azure.com /policystore/collections/{collectionName}/metadataPolicy? &api-version=2021-07-01	Reads the metadata policy by using a specified collection name (the six character random name that's generated by Microsoft Purview when it creates the policy).
Read Metadata Policy By PolicyID	GET	https://{pv-acc-name}.purview.azure.com /policystore/metadataPolicies/{policyId}?&api-version=2021-07-01	Reads the metadata policy by using a specified policy ID. The policy ID is in GUID format.
Read All Metadata Policies	GET	https://{pv-acc-name}.purview.azure.com /policystore/metadataPolicies?&api-version=2021-07-01	Reads all metadata policies from your

API function	REST method	API endpoint	Description
			Microsoft Purview account. You can pick a certain policy to work with from the JSON output list that's generated by this API.
Update/PUT Metadata Policy	PUT	https://{pv-acc-name}.purview.azure.com /policystore/metadataPolicies/{policyId}?&api-version=2021-07-01	Updates the metadata policy by using a specified policy ID. The policy ID is in GUID format.

Microsoft Purview catalog collections API reference summary

The following table gives an overview of the Microsoft Purview collections APIs. For complete documentation about each API, select the API operation in the left column.

Expand table

Operation	Description
Create or update collection	Creates or updates a collection entity.
Delete collection	Deletes a collection entity.
Get collection	Gets a collection.
Get collection path	Gets the parent name and display name chains that represent the

Operation	Description
	collection path.
List child collection names	Lists the child collections names in the collection.
List collections	Lists the collections in the account.

- If you're using the API, the service principal, user, or group that executes the API should have a Collection Admin role assigned in Microsoft Purview to execute this API successfully.
- For all Microsoft Purview APIs that require {collectionName}, you'll need to use "*name*" (and not "*friendlyName*"). Replace {collectionName} with the actual six-character alphanumeric collection name string.

> **Note**
>
> This name is different from the friendly display name you supplied when you created the collection. If you don't have {collectionName} handy, use the List Collections API to select the six-character collection name from the JSON output.

Here's an example JSON file:

JSON

```
{
    "name": "74dhe7",
    "friendlyName": "Friendly Name",
    "parentCollection": {
        "type": "CollectionReference",
        "referenceName": "{your_purview_account_name}"
    },
    "systemData": {
        "createdBy": "{guid}",
        "createdByType": "Application",
        "createdAt": "2021-08-26T21:21:51.2646627Z",
        "lastModifiedBy": "7f8d47e2-330c-42f0-8744-fcfb1ecb3ea0",
        "lastModifiedByType": "Application",
        "lastModifiedAt": "2021-08-26T21:21:51.2646628Z"
    },
    "collectionProvisioningState": "Succeeded"
}
```

Policy JSON description

Here are some of the important identifiers in the JSON output that's received from the collection APIs:

Name: The name of the policy.

Id: The unique identifier for the policy.

Version: The latest version number of the policy.

> **ⓘ Important**
>
> The version number is incremented each time the Update-Metadata-Policy API is called. Be sure to fetch the latest copy of the policy by invoking the Get-Policy-by-Policy-ID API. Perform this refresh every time before you call the Update Policy (PUT) API, so that you always have the latest version of the JSON file.

DecisionRules: List the rules and effect of this policy. For metadata policies, the effect is always *"Permit"*.

Add or remove users from a collection or role

Use Microsoft Purview REST APIs to add or remove a user, group, or service principal from a collection or role. Detailed API usage is provided along with sample JSON outputs. We highly recommend that you follow the instructions in the next sections sequentially for best understanding of the Microsoft Purview metadata policy APIs.

Get all metadata roles

To list all the available metadata access permission roles, run one of the following commands, depending on the portal you are using:

Classic Microsoft Purview governance portal:

```ruby
GET
https://{your_purview_account_name}.purview.azure.com/policystore/metadataroles?api-version=2021-07-01
```

New Microsoft Purview portal:

Ruby

```
GET https://api.purview-service.microsoft.com/policystore/metadataroles?api-version=2021-07-01
```

The output JSON will describe the roles and their associated permissions in this format.

The default metadata roles are listed in the following table:

Expand table

Role ID	Permissions	Role description
purviewmetadatarole_builtin_data-source-administrator	Microsoft.Purview/accounts/scan/read Microsoft.Purview/accounts/scan/write Microsoft.Purview/accounts/collection/read	Grants access to others to read, write collection, register data sources, and trigger scans.
purviewmetadatarole_builtin_collection-administrator	Microsoft.Purview/accounts/collection/read Microsoft.Purview/accounts/collection/write	Administrator-level full access to the entire collection, including add or remove users and service principal names (SPNs) from the collection, management rights, and grant or revoke access. In some cases, the Collection Administrator might be different from the creator of the collection.

Role ID	Permissions	Role description
purviewmetadatarole_builtin_purview-reader	Microsoft.Purview/accounts/data/read Microsoft.Purview/accounts/collection/read	Grants only read access to data handling and all metadata, including classifications, sensitivity labels, insights, and read assets in a collection, except scan bindings.
purviewmetadatarole_builtin_data-curator	Microsoft.Purview/accounts/data/read Microsoft.Purview/accounts/data/write Microsoft.Purview/accounts/collection/read	Grants full access to data handling and all metadata, including classifications, sensitivity labels, insights, and read assets in a collection, except scan bindings.
purviewmetadatarole_builtin_data-share-contributor	Microsoft.Purview/accounts/share/read Microsoft.Purview/accounts/share/write	Grants access to data shares as a contributor.

JSON

```
{
  "values": [
    {
      "id": "purviewmetadatarole_builtin_data-curator",

        "cnfCondition": [
          [
            {
              "attributeName": "request.azure.dataAction",
              "attributeValueIncludedIn": [
                "Microsoft.Purview/accounts/data/read",
                "Microsoft.Purview/accounts/collection/read"
              ]
            }
          ]
        ],
        "version": 1
      }
    },
    {
      "id": "purviewmetadatarole_builtin_data-share-contributor",
      "name": "data-share-contributor",
      "type": "Microsoft.Purview/role",
      "properties": {
        "provisioningState": "Provisioned",
        "roleType": "BuiltIn",
        "friendlyName": "Data share contributor",
        "cnfCondition": [
          [
            {
              "attributeName": "request.azure.dataAction",
              "attributeValueIncludedIn": [
                "Microsoft.Purview/accounts/share/read",
                "Microsoft.Purview/accounts/share/write"
              ]
            }
          ]
        ],
        "version": 1
      }
    }
  ]
}
```

Get all metadata policies

Classic Microsoft Purview governance portal:

```
Ruby

GET
https://{your_purview_account_name}.purview.azure.com/policystore/metadataPolicies?api-version=2021-07-01
```

New Microsoft Purview portal:

```
Ruby

GET https://api.purview-service.microsoft.com/policystore/metadataPolicies?api-version=2021-07-01
```

The preceding command lists all available metadata policies across the entire collections hierarchy in tree format, from the root collection at the top to all its child policies. Each child collection contains each of its next level children.

Example:

```
JSON

{
  "values": [
    {
      "name": "policy_FabrikamPurview",
      "id": "9b2f1cb9-584c-4a16-811e-9232884b5cac",
      "version": 30,
      "properties": {
        "description": "",
        "decisionRules": [
          {
            "kind": "decisionrule",
            "effect": "Permit",
            "dnfCondition": [

                    "attributeName": "derived.purview.permission",
                    "attributeValueIncludes":
"purviewmetadatarole_builtin_collection-administrator:ukx7pq"
                  }
                ]
              ]
            },
            {
              "kind": "attributerule",
              "id": "permission:7wte2n",
              "name": "permission:7wte2n",
              "dnfCondition": [
                [
                  {
                    "fromRule": "purviewmetadatarole_builtin_collection-
administrator:7wte2n",
                    "attributeName": "derived.purview.permission",
                    "attributeValueIncludes":
"purviewmetadatarole_builtin_collection-administrator:7wte2n"
                  }
                ],
                [
                  {
                    "fromRule": "permission:ukx7pq",
                    "attributeName": "derived.purview.permission",
                    "attributeValueIncludes": "permission:ukx7pq"
                  }
                ]
              ]
            }
          ],
          "collection": {
            "type": "CollectionReference",
            "referenceName": "7wte2n"
          },
          "parentCollectionName": "ukx7pq"
        }
      }
    ]
}
```

Get the selected metadata policy

You can use either of two APIs to fetch a particular collection's metadata policy JSON structure by supplying either {collectionName} or {PolicyID}.

As described in the following two sections, both APIs serve the same purpose, and the JSON outputs of both are exactly the same.

Get the metadata policy of the collection by using the collection name

Classic Microsoft Purview governance portal:

```
GET
https://{your_purview_account_name}.purview.azure.com/policystore/collections/{collectionName}/metadataPolicy?api-version=2021-07-01
```

New Microsoft Purview portal:

```
GET https://api.purview-service.microsoft.com/policystore/collections/{collectionName}/metadataPolicy?api-version=2021-07-01
```

1. The Microsoft Purview account name is {your_purview_account_name}. Replace it with your Microsoft Purview account name.
2. In the JSON output of the previous API, "Get All Metadata Policies," look for the following section:

   { "type": "CollectionReference", "referenceName": "7xkdg2"}
3. Replace "{collectionName}" in the API URL with the value of "referenceName": "{6-char-collection-name}". For example, if your six-character collection name is "7xkdg2," the API URL will be formatted as:

   `https://{your_purview_account_name}.purview.azure.com/policystore/collections/7xkdg2/metadataPolicy?api-version=2021-07-01`
4. Execute the following API:

   ```
   {
     "name": "policy_qu45fs",
     "id": "c6639bb2-9c41-4be0-912b-775750e725de",
     "version": 0,
     "properties": {
       "description": "",
       "decisionRules": [
         {
           "kind": "decisionrule",
   ```

```
        "effect": "Permit",
        "dnfCondition": [
          [
            {
              "attributeName": "resource.purview.collection",
              "attributeValueIncludes": "qu45fs"
            },
            {
              "fromRule": "permission:qu45fs",
              "attributeName": "derived.purview.permission",
              "attributeValueIncludes": "permission:qu45fs"
            }
          ]
        ]
      }
    ],
    "attributeRules": [
      {
        "kind": "attributerule",
        "id": "purviewmetadatarole_builtin_collection-
administrator:qu45fs",
        "name": "purviewmetadatarole_builtin_collection-
administrator:qu45fs",
        "dnfCondition": [
          [
            {
              "attributeName": "principal.microsoft.id",
              "attributeValueIncludedIn": [
                "2f656762-e440-4b62-9eb6-a991d17d64b0"
              ]
            },
            {
              "fromRule": "purviewmetadatarole_builtin_collection-
administrator",
              "attributeName": "derived.purview.role",
              "attributeValueIncludes":
"purviewmetadatarole_builtin_collection-administrator"
            }
          ],
          [
            {
              "fromRule": "purviewmetadatarole_builtin_collection-
administrator:fabrikampurview",
              "attributeName": "derived.purview.permission",
              "attributeValueIncludes":
"purviewmetadatarole_builtin_collection-administrator:fabrikampurview"
            }
          ]
        ]
      },
      {
        "kind": "attributerule",
        "id": "permission:qu45fs",
        "name": "permission:qu45fs",
        "dnfCondition": [
```

```
          [
            {
              "fromRule": "purviewmetadatarole_builtin_collection-
administrator:qu45fs",
              "attributeName": "derived.purview.permission",
              "attributeValueIncludes":
"purviewmetadatarole_builtin_collection-administrator:qu45fs"
            }
          ],
          [
            {
              "fromRule": "permission:fabrikampurview",
              "attributeName": "derived.purview.permission",
              "attributeValueIncludes": "permission:fabrikampurview"
            }
          ]
        ]
      }
    ],
    "collection": {
      "type": "CollectionReference",
      "referenceName": "qu45fs"
    },
    "parentCollectionName": "fabrikampurview"
  }
}
```

Get the metadata policy of the collection by using the policy ID

Classic Microsoft Purview governance portal:

Ruby

```
GET
https://{your_purview_account_name}.purview.azure.com/policystore/metadataPo
licies/{policyId}?api-version=2021-07-01
```

New Microsoft Purview portal:

Ruby

```
GET https://api.purview-
service.microsoft.com/policystore/metadataPolicies/{policyId}?api-
version=2021-07-01
```

1. The Microsoft Purview account name is {your_purview_account_name}. Replace it with your Microsoft Purview account name.

2. In the JSON output of the previous API, "Get All Metadata Policies," look for the following section:

   {.... "name": "policy_qu45fs", "id": "{policy-guid}", "version": N ....}

3. Replace "{policyId}" in the API URL with the value of "id". For example, if your "{policy-guid}" is "c6639bb2-9c41-4be0-912b-775750e725de," the API URL will be formatted as:

   https://{your_purview_account_name}.purview.azure.com/policystore/metadataPolicies/c6639bb2-9c41-4be0-912b-775750e725de?api-version=2021-07-01

4. Now execute the following API:

> **Note**
>
> The output of this API call and the previous API call is the same. As mentioned previously, you can choose either one.

JSON

```
{
  "name": "policy_qu45fs",
  "id": "c6639bb2-9c41-4be0-912b-775750e725de",
  "version": 0,
  "properties": {
    "description": "",
    "decisionRules": [
      {
        "kind": "decisionrule",
        "effect": "Permit",
        "dnfCondition": [
          [
            {
              "attributeName": "resource.purview.collection",
              "attributeValueIncludes": "qu45fs"
            },
            {
              "fromRule": "permission:qu45fs",
              "attributeName": "derived.purview.permission",
              "attributeValueIncludes": "permission:qu45fs"
            }
          ]
        ]
      }
    ],
    "attributeRules": [
      {
        "kind": "attributerule",
```

```
        "id": "purviewmetadatarole_builtin_collection-administrator:qu45fs",
        "name": "purviewmetadatarole_builtin_collection-
administrator:qu45fs",
        "dnfCondition": [
          [
            {
              "attributeName": "principal.microsoft.id",
              "attributeValueIncludedIn": [
                "2f656762-e440-4b62-9eb6-a991d17d64b0"
              ]
            },
            {
              "fromRule": "purviewmetadatarole_builtin_collection-
administrator",
              "attributeName": "derived.purview.role",
              "attributeValueIncludes":
"purviewmetadatarole_builtin_collection-administrator"
            }
          ],
          [
            {
              "fromRule": "purviewmetadatarole_builtin_collection-
administrator:fabrikampurview",
              "attributeName": "derived.purview.permission",
              "attributeValueIncludes":
"purviewmetadatarole_builtin_collection-administrator:fabrikampurview"
            }
          ]
        ]
      },
      {
        "kind": "attributerule",
        "id": "permission:qu45fs",
        "name": "permission:qu45fs",
        "dnfCondition": [
          [
            {
              "fromRule": "purviewmetadatarole_builtin_collection-
administrator:qu45fs",
              "attributeName": "derived.purview.permission",
              "attributeValueIncludes":
"purviewmetadatarole_builtin_collection-administrator:qu45fs"
            }
          ],
          [
            {
              "fromRule": "permission:fabrikampurview",
              "attributeName": "derived.purview.permission",
              "attributeValueIncludes": "permission:fabrikampurview"
            }
          ]
        ]
      }
    ],
    "collection": {
```

```
      "type": "CollectionReference",
      "referenceName": "qu45fs"
    },
    "parentCollectionName": "fabrikampurview"
  }
}
```

Update the collection policy

Ruby

```
PUT
https://{your_purview_account_name}.purview.azure.com/policystore/metadataPo
licies/{policyId}?api-version=2021-07-01
```

In this section, you update the policy JSON that you obtained in the preceding step by adding or removing a user, group, or service principal from the collection. You then push it to the Microsoft Purview service by using a PUT REST method.

Whether you're adding or removing a user, group, or service principal, you'll follow the same API process.

1. Supply the user, group, or service principal object ID {guid} in the "attributeValueIncludedIn" array of the JSON.

2. Search the JSON output of the Get-Policy-by-ID API for the "attributeValueIncludedIn" array in the previous step, and either add or remove the user, group, or service principal object ID in the array. If you're unsure about how to fetch the user, group, or service principal object ID, see Get-MgUser.

3. There are multiple sections in the JSON mapping for each of the four roles. For the Collection Administrator permissions role, use the section bearing the ID called "purviewmetadatarole_builtin_collection-administrator". Likewise, use the corresponding section for the other roles.

4. To better understand the add/remove operation, carefully examine the difference between the JSON output from the previous API and the following output. In the JSON following output, we've added user ID "3a3a3a3a-2c2c-4b4b-1c1c-2a3b4c5d6e7f" As Collection Administrator.

JSON

```
{
  "name": "policy_qu45fs",
  "id": "c6639bb2-9c41-4be0-912b-775750e725de",
```

```
  "version": 0,
  "properties": {
    "description": "",
    "decisionRules": [
      {
        "kind": "decisionrule",
        "effect": "Permit",
        "dnfCondition": [
          [
            {
              "attributeName": "resource.purview.collection",
              "attributeValueIncludes": "qu45fs"
            },
            {
              "fromRule": "permission:qu45fs",
              "attributeName": "derived.purview.permission",
              "attributeValueIncludes": "permission:qu45fs"
            }
          ]
        ]
      }
    ],
    "attributeRules": [
      {
        "kind": "attributerule",
        "id": "purviewmetadatarole_builtin_collection-administrator:qu45fs",
        "name": "purviewmetadatarole_builtin_collection-
administrator:qu45fs",
        "dnfCondition": [
          [
            {
              "attributeName": "principal.microsoft.id",
              "attributeValueIncludedIn": [
                "2f656762-e440-4b62-9eb6-a991d17d64b0",
                "3a3a3a3a-2c2c-4b4b-1c1c-2a3b4c5d6e7f"
              ]
            },
            {
              "fromRule": "purviewmetadatarole_builtin_collection-
administrator",
              "attributeName": "derived.purview.role",
              "attributeValueIncludes":
"purviewmetadatarole_builtin_collection-administrator"
            }
          ],
          [
            {
              "fromRule": "purviewmetadatarole_builtin_collection-
administrator:fabrikampurview",
              "attributeName": "derived.purview.permission",
              "attributeValueIncludes":
"purviewmetadatarole_builtin_collection-administrator:fabrikampurview"
            }
          ]
        ]
```

```
      },
      {
        "kind": "attributerule",
        "id": "permission:qu45fs",
        "name": "permission:qu45fs",
        "dnfCondition": [
          [
            {
              "fromRule": "purviewmetadatarole_builtin_collection-
administrator:qu45fs",
              "attributeName": "derived.purview.permission",
              "attributeValueIncludes":
"purviewmetadatarole_builtin_collection-administrator:qu45fs"
            }
          ],
          [
            {
              "fromRule": "permission:fabrikampurview",
              "attributeName": "derived.purview.permission",
              "attributeValueIncludes": "permission:fabrikampurview"
            }
          ]
        ]
      }
    ],
    "collection": {
      "type": "CollectionReference",
      "referenceName": "qu45fs"
    },
    "parentCollectionName": "fabrikampurview"
  }
}
```

Add the Root Collection Administrator role

By default, the user who created the Microsoft Purview account is the Root Collection Administrator (that is, the administrator of the topmost level of the collection hierarchy). However, in some cases, an organization may want to change the Root Collection Administrator using the API.

Ruby

```
POST
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{
resourceGroupName}/providers/Microsoft.Purview/accounts/{accountName}/addRoo
tCollectionAdmin?api-version=2021-07-01
```

To run the preceding command, you need only to pass the new Root Collection Administrator's object ID. As we mentioned before, the object ID can be that of any

user, group, or service principal.

```JSON
{"objectId": "{guid}"}
```

> **Note**
>
> Users who call this API must have Owner or User Account and Authentication (UAA) permissions on the Microsoft Purview account to execute a write action on the account.

More resources

You may choose to execute Microsoft Purview REST APIs by using the PowerShell utility. It can be readily installed from PowerShell Gallery. With this utility, you can execute all the same commands, but from Windows PowerShell.

Create assets using the REST API

Article • 05/14/2025

In this tutorial, you'll learn how to create assets in Microsoft Purview Data Map that users are able to search and browse in Microsoft Purview Unified Catalog.

> **Note**
>
> If you're using the free version of Microsoft Purview, only users in the data curator role group will be able to access these assets.

If you already have your service principal and authentication token, you can skip directly to the steps to create assets using the REST API. Otherwise, follow this guide to call the REST API.

Prerequisites

- If you don't have an Azure subscription, create a free account before you begin.
- You must have an existing Microsoft Purview account. If you don't, check if your organization has access to the free version of Microsoft Purview, or use this quickstart to create a Microsoft Purview account.

Create a service principal (application)

For a REST API client to access Microsoft Purview to create entities, the client must have a service principal (application), and an identity that Microsoft Purview recognizes and is configured to trust.

Customers who have used existing service principals (application IDs) have had a high rate of failure. Therefore, we recommend creating a new service principal for calling APIs.

To create a new service principal:

1. Sign in to the Azure portal.
2. From the portal, search for and select **Microsoft Entra ID**.
3. From the **Microsoft Entra ID** page, select **App registrations** from the left pane.
4. Select **New registration**.
5. On the **Register an application** page:
   a. Enter a **Name** for the application (the service principal name).

b. Select **Accounts in this organizational directory only (<*your tenant's name*> only - Single tenant)**.
c. For **Redirect URI (optional)**, select **Web** and enter a value. This value doesn't need to be a valid endpoint. `https://exampleURI.com` will do.
d. Select **Register**.

6. On the new service principal page, copy the values of the **Display name** and the **Application (client) ID** to save for later.

   The application ID is the `client_id` value in the sample code.

To use the service principal (application), you need to know the service principal's password:

1. Select your service principal (application) in the **App registrations** list.
2. Select **Certificates & secrets** from the left pane.
3. Select **New client secret**.
4. On the **Add a client secret** page, enter a **Description**, select an expiration time under **Expires**, and then select **Add**.
5. On the **Client secrets** page, the string in the **Value** column of your new secret is your password. Save this value.

Set up authentication using service principal

Once the new service principal is created, you need to assign permissions so your service principal can access your Microsoft Purview account. The permissions you need to assign depend on whether you're using the classic Microsoft Purview experience or the new Microsoft Purview portal.

Select the tab for the experience you're using.

Classic governance portal

1. Navigate to your Microsoft Purview governance portal.
2. Select the Data Map in the left menu.
3. Select Collections.
4. Select the root collection in the collections menu. This is the top collection in the list, and will have the same name as your Microsoft Purview account.

> ⓘ **Note**

> You can also assign your service principal permission to any sub-collections, instead of the root collection. However, all APIs will be scoped to that collection (and sub-collections that inherit permissions), and users trying to call the API for another collection will get errors.

5. Select the **Role assignments** tab.
6. Assign the Data Curator role to the service principal created previously. For detailed steps, see Assign Azure roles using the Microsoft Purview governance portal.

After you've assigned permissions, you'll need to gather your authentication token.

1. Send a POST request to the following URL to get access token:

   `https://login.microsoftonline.com/{your-tenant-id}/oauth2/token`

   You can find your Tenant ID by searching for **Tenant Properties** in the Azure portal. The ID is available on the tenant properties page.

   The following parameters need to be passed to the above URL:

   - **client_id**: client ID of the application registered in Microsoft Entra ID and is assigned to a data plane role for the Microsoft Purview account.
   - **client_secret**: client secret created for the above application.
   - **grant_type**: This should be 'client_credentials'.
   - **resource**: This should be 'https://purview.azure.net'

   Here's a sample POST request in PowerShell:

   Azure PowerShell

   ```
   $tenantID = "12a345bc-67d1-ef89-abcd-efg12345abcde"

   $url = "https://login.microsoftonline.com/$tenantID/oauth2/token"
   $params = @{ client_id = "a1234bcd-5678-9012-abcd-abcd1234abcd";
   client_secret = "abcd~a1234bcd56789012abcdabcd1234abcd"; grant_type =
   "client_credentials"; resource = 'https://purview.azure.net' }

   Invoke-WebRequest $url -Method Post -Body $params      -UseBasicParsing |
   ConvertFrom-Json
   ```

   Sample response token:

   JSON

```
{
    "token_type": "Bearer",
    "expires_in": "86399",
    "ext_expires_in": "86399",
    "expires_on": "1621038348",
    "not_before": "1620951648",
    "resource": "https://purview.azure.net",
    "access_token": "<<access token>>"
}
```

> **Tip**
>
> If you get an error message that reads: *Cross-origin token redemption is permitted only for the 'Single-Page Application' client-type.*
>
> - Check your request headers and confirm that your request **doesn't** contain the 'origin' header.
> - Confirm that your redirect URI is set to **web** in your service principal.
> - Make sure your software is up to date for the application you're using to send your POST request.

2. Use the access token above to call the Data plane APIs.

Create assets using the REST API

Now that you have a token and can authenticate, you're ready to create your assets.

> **Important**
>
> Your request URL endpoints depend on what Microsoft Purview experience you're using: the classic Microsoft Purview experience or the new Microsoft Purview portal

Create Azure assets

Here's an example you can use to create your entities for Azure resources. This example covers an Azure Storage account, but you can use it for any other Azure sources.

> **Important**
>
> To use this example for your Azure resources, replace these values in the payload:

- typeName
- Owner
- qualifiedName
- name
- Expert ID
- Expert Info
- Owner ID
- Owner Info
- Createdby
- Updatedby

Classic governance portal

Request URL: `https://{accountName}.purview.azure.com/catalog/api/atlas/v2/entity`

Method: POST

Authentication: Use the token from the previous step as your bearer token.

Payload example:

JSON

```
{
  "referredEntities": {},
  "entity": {
    "typeName": "azure_storage_account",
    "attributes": {
      "owner": "ExampleOwner",
      "modifiedTime": 0,
      "createTime": 0,
      "qualifiedName": "https://exampleaccount.core.windows.net",
      "name": "ExampleStorageAccount",
      "description": null,
      "publicAccessLevel": null
    },
    "contacts": {
      "Expert": [
        {
          "id": "30435ff9-9b96-44af-a5a9-e05c8b1ae2d2",
          "info": "Example Expert Info"
        }
      ],
      "Owner": [
        {
          "id": " 30435ff9-9b96-44af-a5a9-e05c8b1ae2d2",
```

```
            "info": "Example Owner Info"
          }
        ]
      },
      "status": "ACTIVE",
      "createdBy": "ExampleCreator",
      "updatedBy": "ExampleUpdator",
      "version": 0
    }
  }
```

Create multicloud assets

Here's an example you can use to create your entities for multicloud resources. This example creates a Snowflake resource, but you can use it for any other sources

> ⓘ **Important**
>
> To use this example for your Azure resources, replace these values in the payload:
>
> - typeName
> - Owner
> - qualifiedName
> - name
> - type
> - Expert ID
> - Expert Info
> - Owner ID
> - Owner Info
> - Createdby
> - Updatedby

Classic governance portal

Request URL: `https://{accountName}.purview.azure.com/catalog/api/atlas/v2/entity`

Method: POST

Authentication: Use the token from the previous step as your bearer token.

Payload example:

JSON

```
{
  "referredEntities": {},
  "entity": {
    "typeName": "snowflake_table",
    "attributes": {
      "owner": "ExampleOwner",
      "modifiedTime": 0,
      "createTime": 0,
      "qualifiedName": "snowflake://microsoft_partner.east-us-
2.azure.snowflakecomputing.com/databases/AZUREPURVIEW_TESTDB/schemas/COMPANY/table
s/PROJECT_INFO",
      "name": "PROJECT_INFO",
      "description": null,
      "type": "TABLE"
    },
    "contacts": {
      "Expert": [
        {
          "id": "30435ff9-9b96-44af-a5a9-e05c8b1ae2d2",
          "info": "Example Expert Info"
        }
      ],
      "Owner": [
        {
          "id": "4b27e65f-6a15-4925-a4ef-2e640445079b",
          "info": "Example Owner Info"
        }
      ]
    },
    "status": "ACTIVE",
    "createdBy": "ExampleCreator",
    "updatedBy": "ExampleUpdator",
    "version": 0
  }
}
```

Manage data sources | Microsoft Purview Entity REST API reference

Create and get lineage relationships using the REST API

Article • 05/14/2025

In this tutorial, you learn how to use Microsoft Purview REST APIs to:

1. Create assets and lineage relationships between the data assets.
2. Query lineage relationships/paths.

APIs referenced in this article:

- Create Entity
- Create Relationship
- Get Lineage by GUID

Prerequisites

The use of these APIs requires Data Curator and Data Reader roles. Check this tutorial for details on how to obtain the access token.

Concepts

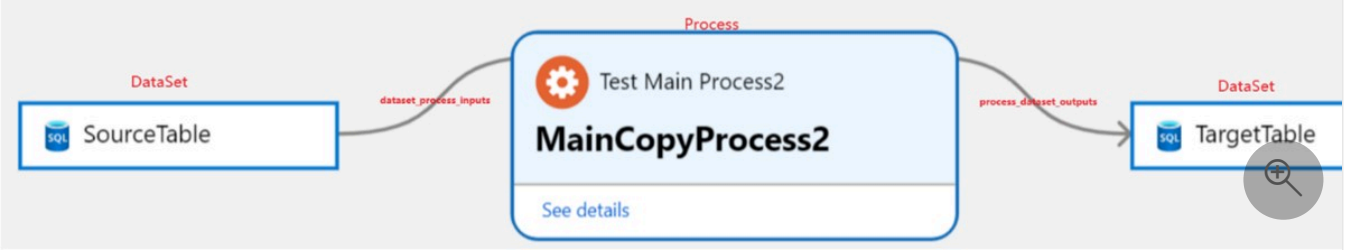
Asset

In Microsoft Purview, there are two types of base assets: DataSet and Process.

- DataSet Assets that contain data such as Azure SQL Table, Oracle Table etc. should be inherited from DataSet.
- Process Assets that process data, such as a data pipeline, query, function etc. should be inherited from Process.

Refer to assets and types to understand type definitions of DataSets and Processes.

Relationships and lineage



In Microsoft Purview, there are three types of relationships for lineage:

- *dataset_process_inputs*: connects DataSet to Process, which means the DataSet is the input of the Process
- *process_dataset_outputs*: connects Process to DataSet, which means the Process produces the DataSet

- *direct_lineage_dataset_dataset*: connects DataSet1 to DataSet2, which means DataSet1 is the upstream of DataSet2, although we wouldn't know exactly which Process is between them

Example 1: *Here's an example of lineage with 2 DataSets, one Process and two lineage relationships*:

Dataset ---> dataset_process_inputs ---> Process ---> process_dataset_outputs ---> DataSet

Example 2: *Another example of lineage with 2 DataSets and one lineage relationship:*

Dataset ---> direct_lineage_dataset_dataset ---> DataSet

Create assets and lineage relationships between the data assets

In the following sections, let's take hive_table as an example type for DataSet, and hive_query_process as an example type for Process. We'll create assets with those two types and create lineages between them. You can use any other type, which inherits from DataSet or Process to create lineages.

Example 1

Create assets via API

If the assets you want to create lineage for aren't created in Microsoft Purview yet, you can call the following API to create them.

API: Bulk Create Assets

Task: Create two hive_tables as datasets - table1 and table2, each with 2 hive_columns - column1 and column2.

HTTP

```
POST {endpoint}/datamap/api/atlas/v2/entity/bulk
```

With the body:

JSON

```
{
  "entities": [
    {
      "typeName": "hive_table",
      "attributes": {
        "qualifiedName": "test_lineage.table1",
        "name": "table1"
      },
      "relationshipAttributes": {
        "columns": [
          {
            "guid": "-11",
            "typeName": "hive_column"
          },{
            "guid": "-12",
            "typeName": "hive_column"
          }
        ]
      },
      "guid": "-1"
    },
    {
      "typeName": "hive_column",
      "attributes": {
        "qualifiedName": "test_lineage.table1#column1",
        "name": "column1",
        "type": "int"
      },
      "guid": "-11",
      "relationshipAttributes": {
        "table": {
          "guid": "-1",
          "typeName": "hive_table"
        }
      }
    },
    {
      "typeName": "hive_column",
      "attributes": {
```

```
      "qualifiedName": "test_lineage.table1#column2",
      "name": "column2",
      "type": "int"
    },
    "guid": "-12",
    "relationshipAttributes": {
      "table": {
        "guid": "-1",
        "typeName": "hive_table"
      }
    }
  },
  {
    "typeName": "hive_table",
    "attributes": {
      "qualifiedName": "test_lineage.table2",
      "name": "table2"
    },
    "relationshipAttributes": {
      "columns": [
        {
          "guid": "-21",
          "typeName": "hive_column"
        },{
          "guid": "-22",
          "typeName": "hive_column"
        }
      ]
    },
    "guid": "-2"
  },
  {
    "typeName": "hive_column",
    "attributes": {
      "qualifiedName": "test_lineage.table2#column1",
      "name": "column1",
      "type": "int"
    },
    "guid": "-21",
    "relationshipAttributes": {
      "table": {
        "guid": "-2",
        "typeName": "hive_table"
      }
    }
  },
  {
    "typeName": "hive_column",
    "attributes": {
      "qualifiedName": "test_lineage.table2#column2",
      "name": "column2",
      "type": "int"
    },
    "guid": "-22",
    "relationshipAttributes": {
```

```
        "table": {
          "guid": "-2",
          "typeName": "hive_table"
        }
      }
    }
  ]
}
```

Task: Create the process asset 'hive_view_query'

HTTP

```
POST {endpoint}/datamap/api/atlas/v2/entity/bulk
```

With the body:

JSON

```
{
  "entities": [
    {
      "typeName": "hive_view_query",
      "attributes": {
        "qualifiedName": "test_lineage.HiveQuery1",
        "name": "HiveQuery1",
        "columnMapping": "[{\"DatasetMapping\":
{\"Source\":\"test_lineage.table1\",\"Sink\":\"test_lineage.table2\"},\"ColumnMapp
ing\":[{\"Source\":\"column1\",\"Sink\":\"column1\"},
{\"Source\":\"column2\",\"Sink\":\"column2\"}]}]"
      },
      "guid": "-1"
    }
  ]
}
```

The above API calls result in creation of two hive_tables(Datasets) and one hive_view_query(Process).

Create lineage relationships between Datasets and the Process

API: Create Relationship

Task: Create lineage from table1 -> HiveQuery1 (that is, Dataset -> Process)

HTTP

```
POST {endpoint}/datamap/api/atlas/v2/relationship
```

With the body:

JSON

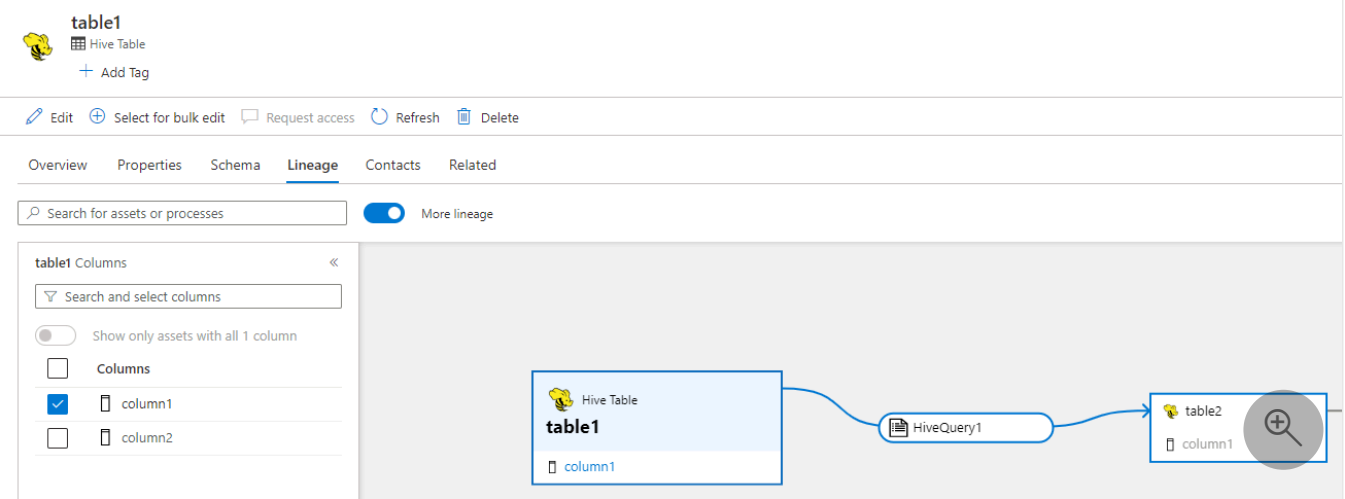
```
{
        "typeName": "dataset_process_inputs",
        "guid": "-1",
        "end1": {
            "typeName": "hive_table",
            "uniqueAttributes": {
                "qualifiedName": "test_lineage.table1"
            }
        },
        "end2": {
            "typeName": "Process",
            "uniqueAttributes": {
                "qualifiedName": "test_lineage.HiveQuery1"
            }
        }
}
```

Task: Create lineage from HiveQuery1 -> table2 (that is, Process -> Dataset)

HTTP

```
POST {endpoint}/datamap/api/atlas/v2/relationship
```

With the body:



JSON

```
{
        "typeName": "process_dataset_outputs",
        "guid": "-2",
        "end1": {
            "typeName": "Process",
            "uniqueAttributes": {
                "qualifiedName": "test_lineage.HiveQuery1"
            }
        },
        "end2": {
            "typeName": "hive_table",
            "uniqueAttributes": {
                "qualifiedName": "test_lineage.table2"
            }
```

```
        }
}
```

View lineage

Once the assets and lineage relationships are created, you can check the lineage graph in Microsoft Purview:

Example 2

Create a hive table, table3, with two columns

API: Bulk Create Assets

Task: Create table3, with 2 hive_columns, column1 and column2

HTTP

```
POST {endpoint}/datamap/api/atlas/v2/entity/bulk
```

With the body:

JSON

```
{
"entities": [
    {
      "typeName": "hive_table",
      "attributes": {
        "qualifiedName": "test_lineage.table3",
        "name": "table3"
      },
      "relationshipAttributes": {
```

```
        "columns": [
          {
            "guid": "-31",
            "typeName": "hive_column"
          },{
            "guid": "-32",
            "typeName": "hive_column"
          }
        ]
      },
      "guid": "-3"
    },
    {
      "typeName": "hive_column",
      "attributes": {
        "qualifiedName": "test_lineage.table3#column1",
        "name": "column1",
        "type": "int"
      },
      "guid": "-31",
      "relationshipAttributes": {
        "table": {
          "guid": "-3",
          "typeName": "hive_table"
        }
      }
    },
    {
      "typeName": "hive_column",
      "attributes": {
        "qualifiedName": "test_lineage.table3#column2",
        "name": "column2",
        "type": "int"
      },
      "guid": "-32",
      "relationshipAttributes": {
        "table": {
          "guid": "-3",
          "typeName": "hive_table"
        }
      }
    }
  ]
}
```

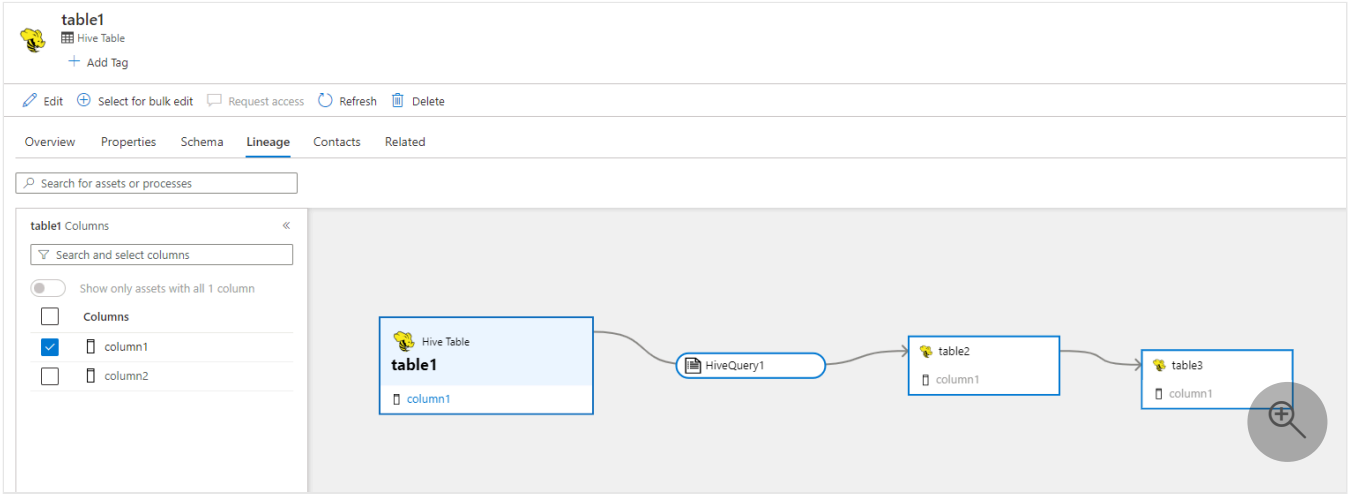
Create direct lineage between table 2 and table 3, with column mapping

API: Create Relationship

Task: Create lineage from table2 -> table3 (that is, Dataset -> Dataset) with column mapping

```
HTTP
```

```
POST {endpoint}/datamap/api/atlas/v2/relationship
```



With the body:

JSON

```
{
    "typeName": "direct_lineage_dataset_dataset",
    "guid": "-1",
    "end1": {
        "typeName": "hive_table",
        "uniqueAttributes": {
            "qualifiedName": "test_lineage.table2"
        }
    },
    "end2": {
        "typeName": " hive_table ",
        "uniqueAttributes": {
            "qualifiedName": "test_lineage.table3"
        }
    },
    "attributes": {
      "columnMapping": "[{\"Source\":\"column1\",\"Sink\":\"column1\"},
{\"Source\":\"column2\",\"Sink\":\"column2\"}]"
    }
}
```

View lineage

Now the lineage graph (together from Example 1 & Example 2 above) becomes:

Notice that table2 is directly linked to table3, without a HiveQuery between them.

Query lineage relationships/paths

API: Get Lineage by GUID

Task: Get lineage of table2 via REST API

HTTP

```
GET {{endpoint}}/api/atlas/v2/lineage/{{guid_of_table2}}?direction=BOTH
```

Below you can JSON response payload:

JSON

```
{
    "baseEntityGuid": "2a12b3ff-5816-4222-833a-035bf82e06e0",
    "lineageDirection": "BOTH",
    "lineageDepth": 3,
    "lineageWidth": -1,
    "childrenCount": -1,
    "guidEntityMap": {
        "16b93b78-8683-4f88-9651-24c4a9d797b0": {
            "typeName": "hive_table",
            "attributes": {
                "temporary": false,
                "lastAccessTime": 0,
                "createTime": 0,
                "qualifiedName": "test_lineage.table3",

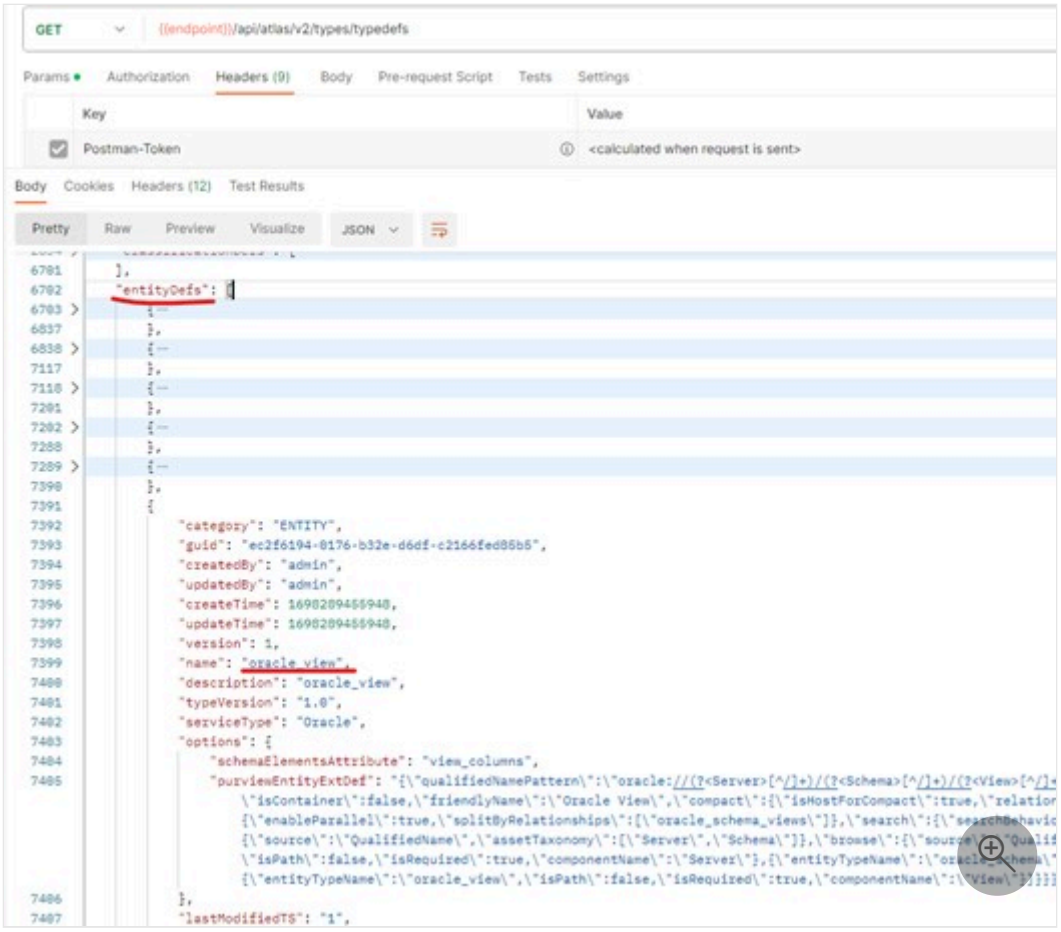
            "2a12b3ff-5816-4222-833a-035bf82e06e0": 1
        },
        "OUTPUT": {
            "16b93b78-8683-4f88-9651-24c4a9d797b0": 0,
            "2a12b3ff-5816-4222-833a-035bf82e06e0": 1
        }
    }
}
```



Other Resources

Type Definitions

All Assets/Entities and Relationships are defined in the type system.

Call list all type definitions API to get current type definitions in your Microsoft Purview instance. If you're not sure which typeName to use in the API calls described, you can check the type definitions API to find the appropriate Asset/Entity type.

Following is a sample response of this API:

You can see that in the entityDefs in the above response, asset types (such as oracle_table, oracle_view etc.) are defined. A further look at the definition of the asset (in this example, oracle_view) shows that the asset is inherited DataSet type.

Similarly, you can find that a process (for example, Oracle_function) is inherited from “Process” type as shown:

Create New Custom Types

If you want to create custom assets or processes, you can use the following APIs.

API: Create Typedef API

Task: Create a Custom Process Type

HTTP

```
POST {endpoint}/datamap/api/atlas/v2/types/typedefs
```

With the body:

JSON

```
{
  "enumDefs": [],
  "structDefs": [],
  "classificationDefs": [],
  "entityDefs": [
    {
      "name": "MyCustomServiceProcess",
      "superTypes": [
        "Process"
      ],
      "typeVersion": "1.0",
      "attributeDefs": []
    }
  ],
  "relationshipDefs": []
}
```

Task: Create a Custom DataSet Type

HTTP

```
POST {endpoint}/datamap/api/atlas/v2/types/typedefs
```

With the body:

JSON

```
{
  "enumDefs": [],
  "structDefs": [],
  "classificationDefs": [],
  "entityDefs": [
    {
      "name": "MyCustomDataSet",
      "superTypes": [
        "DataSet"
      ],
      "typeVersion": "1.0",
      "attributeDefs": []
    }
  ],
  "relationshipDefs": []
}
```

Microsoft Purview - Build custom lineage with the REST APIs

Article • 02/24/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

This article provides the steps to create data lineage entries using the REST API in the Microsoft Purview Data Catalog. In scenarios where the automatically generated lineage in Microsoft Purview is incomplete or missing, lineage can be custom built either manually in the Microsoft Purview portal or using the REST APIs. This article focuses on using REST APIs that can overcome manual lineage known limitations and provide more options.

Background

The ability to show the lineage between datasets is one of Microsoft Purview's important platform features. Systems like Data Factory, Data Share, and Power BI capture the lineage of data as it moves. In certain situations, Microsoft Purview's automatically generated lineage is incomplete or missing for practical visualization and enterprise reporting purposes. In those scenarios, custom lineage reporting is supported by Apache Atlas hooks and the REST API.

Using the REST APIs to build custom lineage allows you to overcome some of manual lineage's limitations as described in the following articles:

- Power BI lineage in Microsoft Purview
- Microsoft Purview manual lineage user guide
- Lineage - known limitations

The rest of this article explains the use of Microsoft Purview REST APIs to build and report custom lineage on Microsoft Purview.

Prerequisites

- For step-by-step guidance on how to use the Purview Python SDK Packages, refer Purview Python SDK Tutorial and Exploring Purview's REST API with Python
- For step-by-step guidance on how to use the *Purview REST APIs*, refer Purview Python SDK Tutorial

Scenarios

There are two use cases when building custom lineage becomes necessary:

A. Create new entities created and link them with lineage

B. Link existing entities or lineage to another existing entity or lineage

A. Create new entities and link them with lineage

As an example, lineage needs to be reported between entities A & B, but A & B don't exist currently.

To create the entities A & B, invoke the Microsoft Purview REST API: *Entity - Bulk Create Or Update - REST API*

HTTP

```
POST
https://{accountname}.purview.azure.com/datamap/api/atlas/v2/entity/bulk?
api-version=2023-09-01
```

Python

```
sample_entity_json = '{"entity": {"status": "ACTIVE","version": 0,"name":
ENTITY_A"}.......{"entity": ........}}'
#Send POST JSON containing entities to be created
CreateOrUpdateEntitesUrl =
'https://<purview_account_name>.purview.azure.com/datamap/api/atlas/v2/entit
y/bulk'
EntitiesResponse = requests.post(CreateOrUpdateEntitesUrl, json =
json.loads(sample_entity_json) ,headers=headers)
entitiesRes = json.loads(EntitiesResponse.text)
```

API Response "201 Created" indicates entities are successfully created and their respective GUIDs are contained in the output JSON.

Now that the entities A & B are created, move to step B to link the entities in the lineage chain using the same REST API.

B. Link existing entities or lineage to another existing entity or lineage

- If the number of entities to be linked isn't time or resource intensive (for example, less than 20-30 entities), you can connect the lineage manually in the Microsoft Purview portal. Follow the manual lineage user guide for steps to manually create lineage connections.
- If you have a high number of lineage connections to make, the process needs to be automated, or if manual lineage using the Microsoft Purview portal isn't feasible, proceed with the API process of linking and building custom lineage.

Custom Lineage JSON Payload:

Execute the *POST /entity/bulk* *Entity - Bulk Create Or Update - REST API* using the payload as illustrated:

HTTP

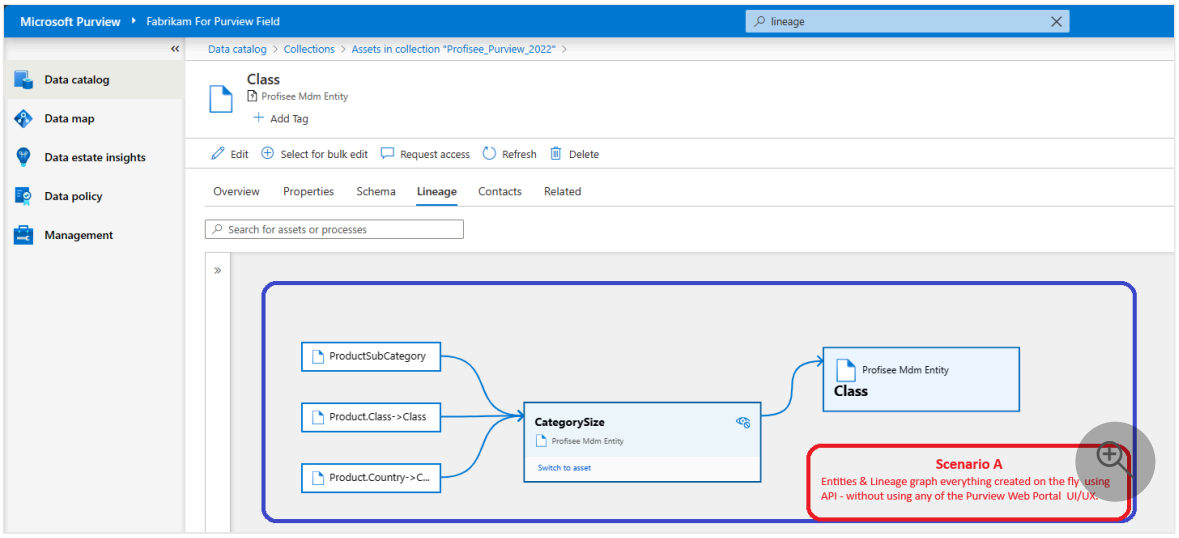
```
POST
https://{accountname}.purview.azure.com/datamap/api/atlas/v2/entity/bulk?
api-version=2023-09-01
```

Python

```
sample_entity_json = '{
  "entities": [
    {
      "status": "ACTIVE",
      "version": 1,
      "typeName": "Process",
      "attributes": {
        "inputs": [
          {
            "guid": "24558fd8-9cdc-47de-9310-56a58108bab0",
            “guid”: “27163581-9aca-212a-782a-213612639abc”
          }
        ],
        "outputs": [
          {
            "guid": "e33c694a-2c4f-4cae-8c27-06f6f6f60000"
          }
        ],
        "qualifiedName": "cassandra://query",
        "name": "query"
      }
    }
  ]
}'
```

```
#In this code snippet, we send the JSON as POST request containing the two GUIDs as input and "output" GUID as output. This creates lineage with 2 directional inputs and 1 directional output.
#Note: using the same API and SDK code you can create lineage with any number of inputs, any number of processes in between, any number of typedefs and any number of outputs.
#The API/SDK method is the most flexible and versatile menthod of creating lineage.

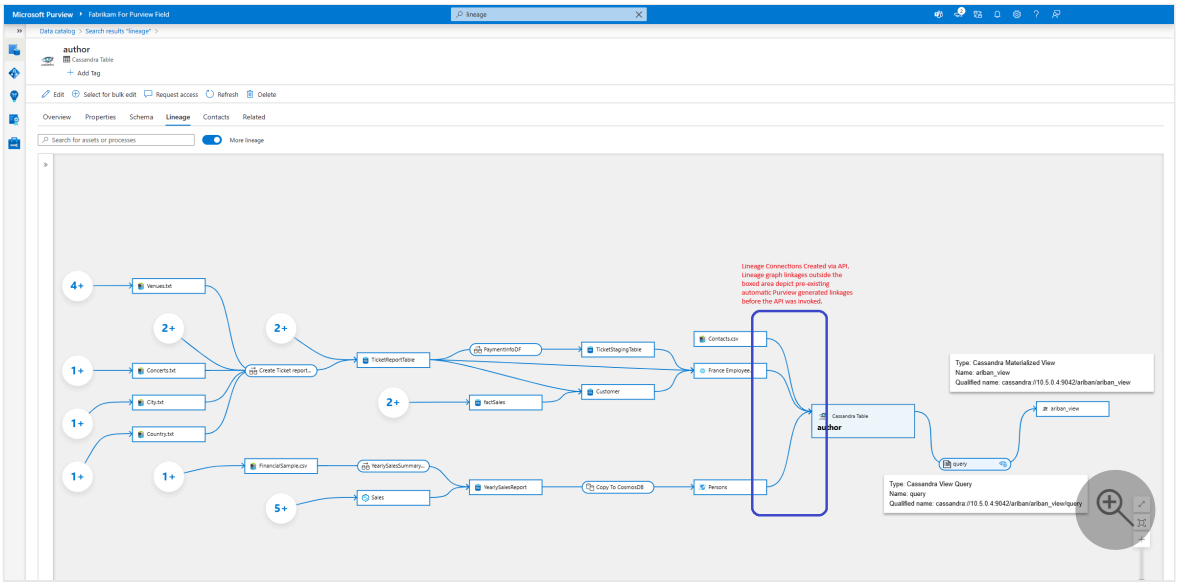
CreateLineageEntitesUrl = 'https://<purview_account_name>.purview.azure.com/datamap/api/atlas/v2/entity/bulk'
EntitiesResponse = requests.post(CreateLineageEntitesUrl, json = json.loads(sample_entity_json),headers=headers)
entitiesRes = json.loads(EntitiesResponse.text)
```



This JSON payload creates the custom lineage. It works for already existing assets whose GUIDs are supplied in the "inputs" JSON. For example "guid": "24558fd8-9cdc-47de-9310-56a58108bab0" and "27163581-9aca-212a-782a-213612639abc" refers to the directional input of the lineage and "guid": "e33c694a-2c4f-4cae-8c27-06f6f6f60000" refers to the directional output of the lineage, which was an existing asset automatically scanned by Purview. We just created the lineage between the two assets.

> ⓘ **Note**
>
> If the assets don't exist already, you need to run Bulk Entity create API before this step to create those entities before creating the lineage relationship. The bulk entity creation process using the POST /entity/bulk API and Python code snippet is described in step A.

Scenario Outcomes



API Response "201 Created" indicates successful lineage graph linkage creation and the created GUIDs are contained in the output JSON. Lineage appears in the Microsoft Purview portal:

- Scenario A: Custom built lineage from assets created via API:

- Scenario B: Custom built lineage from pre-existing assets linked via API.

> **Note**
>
> If the lineage is created from pre-existing entities, observe that the pre-existing lineage graph remains intact and the new linkage is created and displayed additionally.

Tutorial: Use the Microsoft Purview Python SDK

Article • 05/14/2025

This tutorial will introduce you to using the Microsoft Purview Python SDK. You can use the SDK to do all the most common Microsoft Purview operations programmatically, rather than through the Microsoft Purview governance portal.

In this tutorial, you'll learn how us the SDK to:

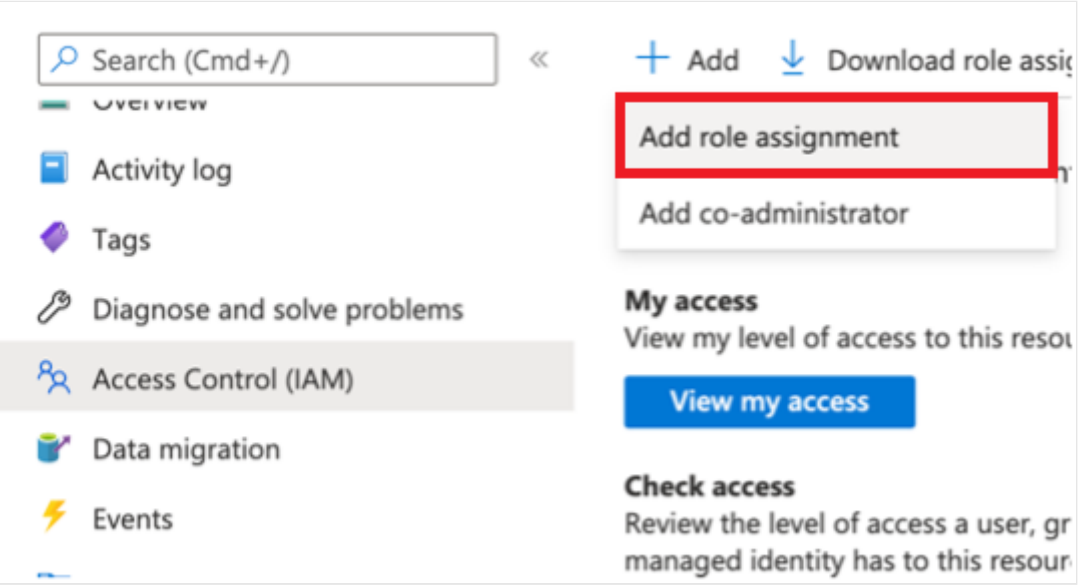
- ✓ Grant the required rights to work programmatically with Microsoft Purview
- ✓ Register a Blob Storage container as a data source in Microsoft Purview
- ✓ Define and run a scan
- ✓ Search the catalog
- ✓ Delete a data source

Prerequisites

For this tutorial, you'll need:

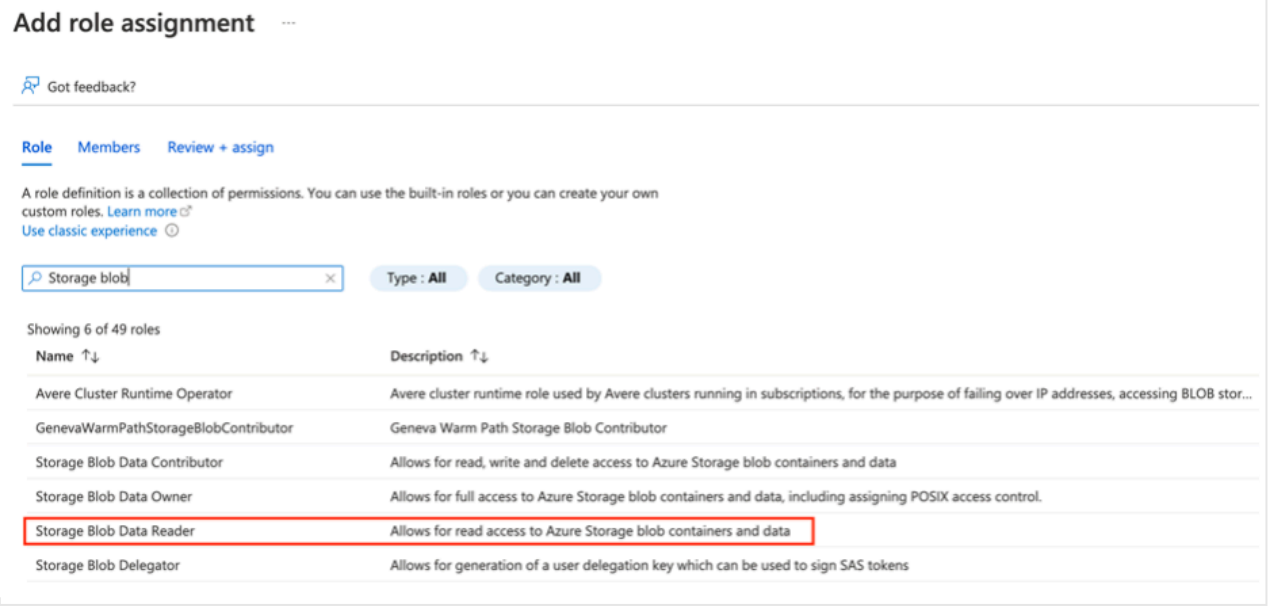
- Python 3.6 or higher
- An active Azure Subscription. If you don't have one, you can create one for free.
- A Microsoft Entra tenant associated with your subscription.
- An Azure Storage account. If you don't already have one, you can follow our quickstart guide to create one.
- A Microsoft Purview account. If you don't already have one, you can follow our quickstart guide to create one.
- A service principal with a client secret.

> **ⓘ Important**
>
> For these scripts your endpoint value will be different depending on which Microsoft Purview portal you are using. Endpoint for the classic Microsoft Purview governance portal: purview.azure.com/ Endpoint for the New Microsoft Purview portal: purview.microsoft.com/
>
> So if you're using the new portal, your endpoint value will be something like: "https://consotopurview.scan.purview.microsoft.com"



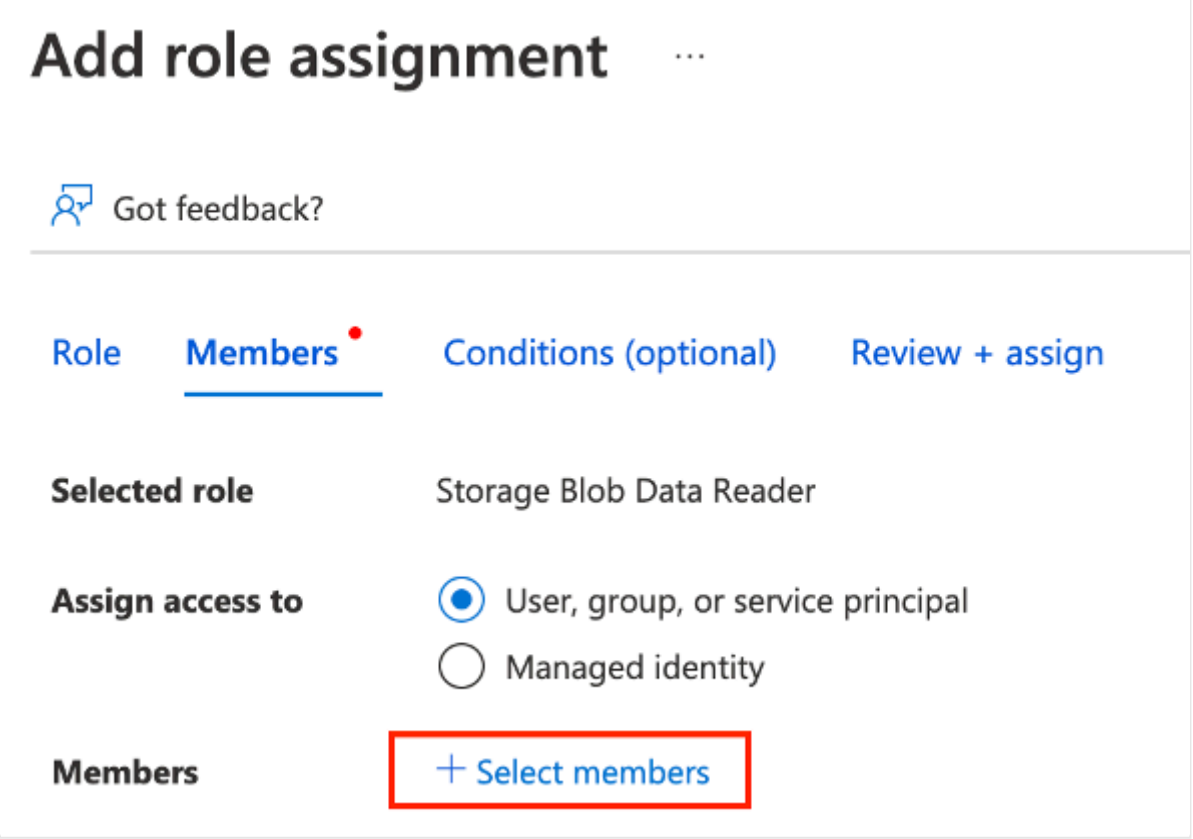
Give Microsoft Purview access to the Storage account

Before being able to scan the content of the Storage account, you need to give Microsoft Purview the right role.



1. Go to your Storage Account through the Azure portal.

2. Select Access Control (IAM).



3. Select the Add button and select **Add role assignment**.

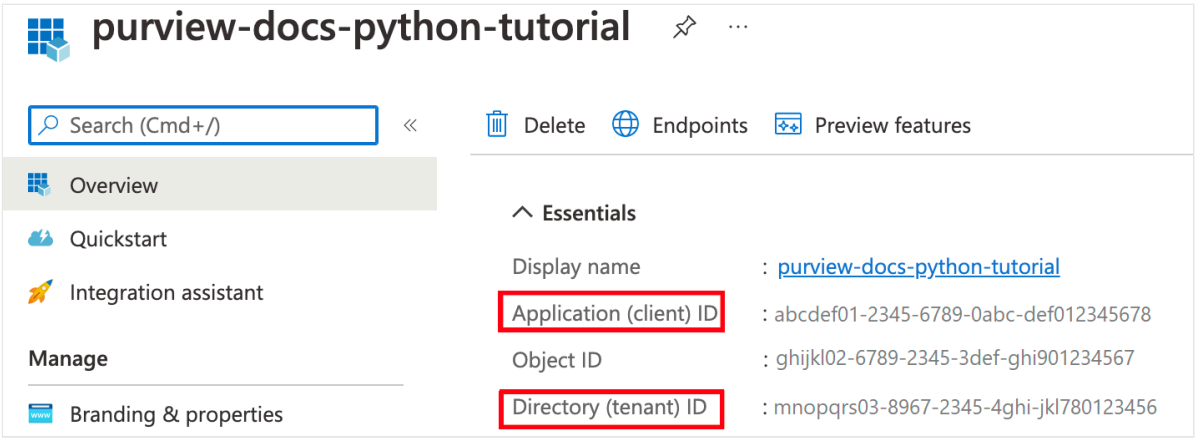
4. In the next window, search for the **Storage blob Reader** role and select it:

5. Then go on the **Members** tab and select **Select members**:

6. A new pane appears on the right. Search and select the name of your existing Microsoft Purview instance.

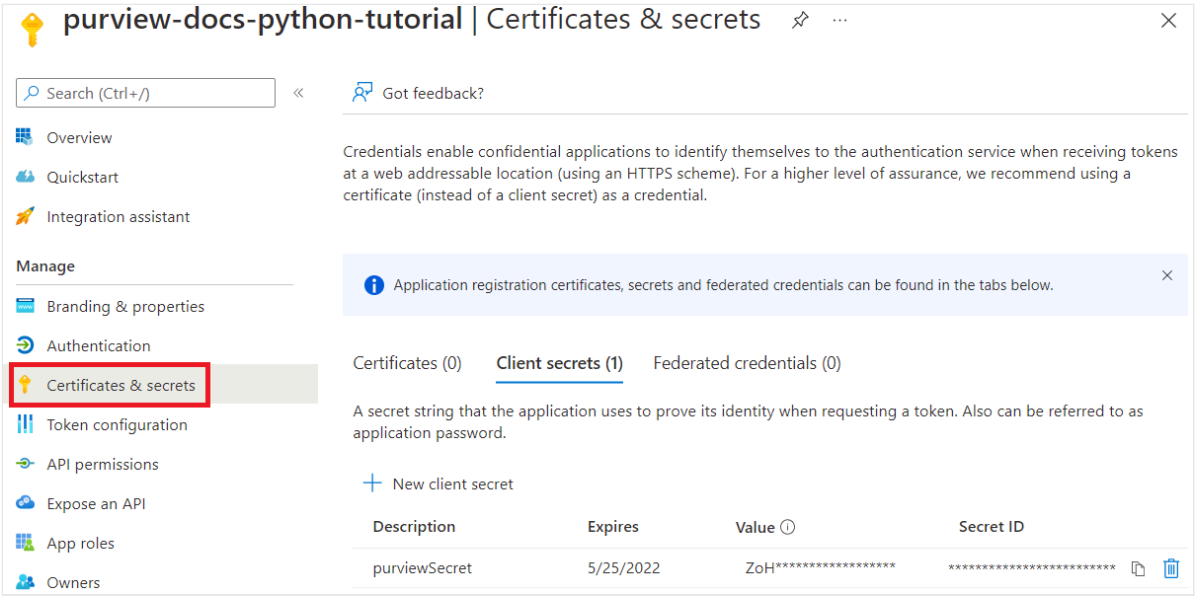
7. You can then select **Review + Assign**.

Microsoft Purview now has the required reading right to scan your Blob Storage.



Grant your application the access to your Microsoft Purview account

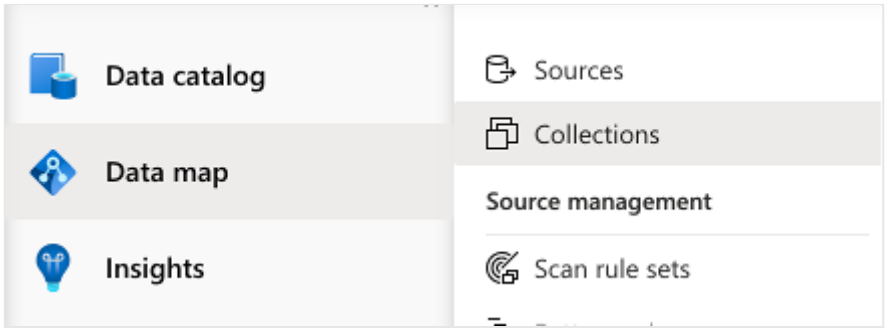
1. First, you'll need the Client ID, Tenant ID, and Client secret from your service principal. To find this information, select your **Microsoft Entra ID**.



2. Then, select **App registrations**.

3. Select your application and locate the required information:

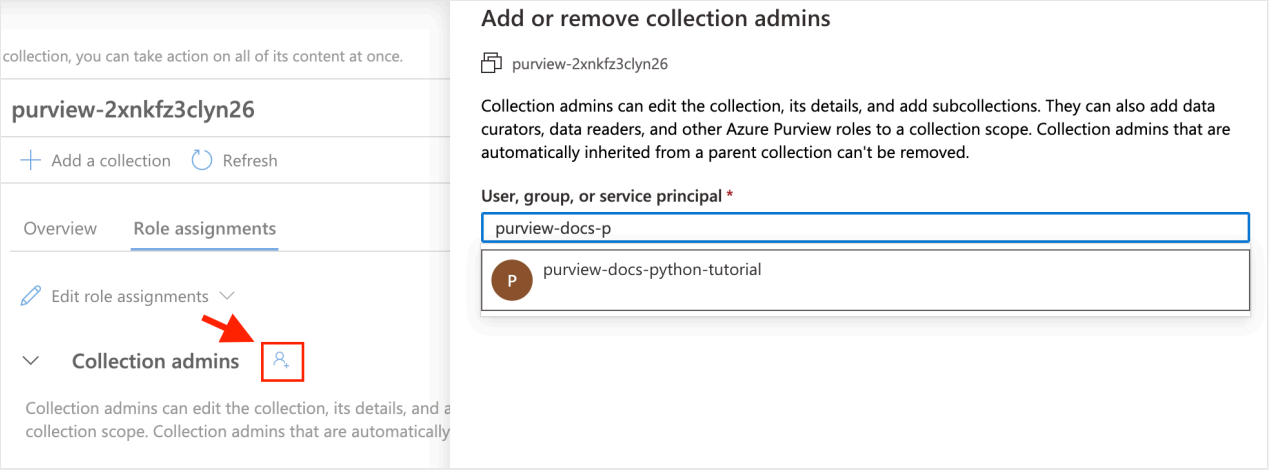
    - Name
    - Client ID (or Application ID)
    - Tenant ID (or Directory ID)



- Client secret

4. You now need to give the relevant Microsoft Purview roles to your service principal. To do so, access your Microsoft Purview instance. Select **Open Microsoft Purview governance portal** or open the Microsoft Purview's governance portal directly and choose the instance that you deployed.

5. Inside the Microsoft Purview governance portal, select **Data map**, then **Collections**:



6. Select the collection you want to work with, and go on the **Role assignments** tab. Add the service principal in the following roles:

    - Collection admins

- Data source admins
- Data curators
- Data readers

7. For each role, select the **Edit role assignments** button and select the role you want to add the service principal to. Or select the **Add** button next to each role, and add the service principal by searching its name or Client ID as shown below:

Install the Python packages

1. Open a new command prompt or terminal
2. Install the Azure identity package for authentication:

```
Bash

pip install azure-identity
```

3. Install the Microsoft Purview Scanning Client package:

```
Bash

pip install azure-purview-scanning
```

4. Install the Microsoft Purview Administration Client package:

```
Bash

pip install azure-purview-administration
```

5. Install the Microsoft Purview Client package:

```
Bash
```

```
pip install azure-purview-catalog
```

6. Install the Microsoft Purview Account package:

```Bash
pip install azure-purview-account
```

7. Install the Azure Core package:

```Bash
pip install azure-core
```

Create Python script file

Create a plain text file, and save it as a Python script with the suffix .py. For example: tutorial.py.

Instantiate a Scanning, Catalog, and Administration client

In this section, you learn how to instantiate:

- A scanning client useful to registering data sources, creating and managing scan rules, triggering a scan, etc.
- A catalog client useful to interact with the catalog through searching, browsing the discovered assets, identifying the sensitivity of your data, etc.
- An administration client is useful for interacting with the Microsoft Purview Data Map itself, for operations like listing collections.

First you need to authenticate to your Microsoft Entra ID. For this, you'll use the client secret you created.

1. Start with required import statements: our three clients, the credentials statement, and an Azure exceptions statement.

```Python
from azure.purview.scanning import PurviewScanningClient
from azure.purview.catalog import PurviewCatalogClient
from azure.purview.administration.account import PurviewAccountClient
```

```
from azure.identity import ClientSecretCredential
from azure.core.exceptions import HttpResponseError
```

2. Specify the following information in the code:

   - Client ID (or Application ID)
   - Tenant ID (or Directory ID)
   - Client secret

Python

```
client_id = "<your client id>"
client_secret = "<your client secret>"
tenant_id = "<your tenant id>"
```

3. Specify your endpoint:

> **ⓘ Important**
>
> Your endpoint value will be different depending on which Microsoft Purview portal you are using. Endpoint for the classic Microsoft Purview governance portal: `https://{your_purview_account_name}.purview.azure.com/` Endpoint for the New Microsoft Purview portal: `https://api.purview-service.microsoft.com`
>
> Scan endpoint for the classic Microsoft Purview governance portal: `https://{your_purview_account_name}.scan.purview.azure.com/` Endpoint for the New Microsoft Purview portal: `https://api.scan.purview-service.microsoft.com`

Python

```
purview_endpoint = "<endpoint>"

purview_scan_endpoint = "<scan endpoint>"
```

4. You can now instantiate the three clients:

Python

```
def get_credentials():
    credentials = ClientSecretCredential(client_id=client_id,
client_secret=client_secret, tenant_id=tenant_id)
    return credentials

def get_purview_client():
    credentials = get_credentials()
```

```
    client = PurviewScanningClient(endpoint=purview_scan_endpoint,
credential=credentials, logging_enable=True)
    return client

def get_catalog_client():
    credentials = get_credentials()
    client = PurviewCatalogClient(endpoint=purview_endpoint,
credential=credentials, logging_enable=True)
    return client

def get_admin_client():
    credentials = get_credentials()
    client = PurviewAccountClient(endpoint=purview_endpoint,
credential=credentials, logging_enable=True)
    return client
```

Many of our scripts will start with these same steps, as we'll need these clients to interact with the account.

Register a data source

In this section, you'll register your Blob Storage.

1. Like we discussed in the previous section, first you'll import the clients you'll need to access your Microsoft Purview account. Also import the Azure error response package so you can troubleshoot, and the ClientSecretCredential to construct your Azure credentials.

   Python

   ```
   from azure.purview.administration.account import PurviewAccountClient
   from azure.purview.scanning import PurviewScanningClient
   from azure.core.exceptions import HttpResponseError
   from azure.identity import ClientSecretCredential
   ```

2. Gather the resource ID for your storage account by following this guide: get the resource ID for a storage account.

3. Then, in your Python file, define the following information to be able to register the Blob storage programmatically:

   Python

   ```
   storage_name = "<name of your Storage Account>"
   storage_id = "<id of your Storage Account>"
   rg_name = "<name of your resource group>"
   rg_location = "<location of your resource group>"
   reference_name_purview = "<name of your Microsoft Purview account>"
   ```

4. Provide the name of the collection where you'd like to register your blob storage. (It should be the same collection where you applied permissions earlier. If it isn't, first apply permissions to this collection.) If it's the root collection, use the same name as your Microsoft Purview instance.

```
Python

collection_name = "<name of your collection>"
```

5. Create a function to construct the credentials to access your Microsoft Purview account:

```
Python

client_id = "<your client id>"
client_secret = "<your client secret>"
tenant_id = "<your tenant id>"

def get_credentials():
     credentials = ClientSecretCredential(client_id=client_id,
client_secret=client_secret, tenant_id=tenant_id)
     return credentials
```

6. All collections in the Microsoft Purview Data Map have a **friendly name** and a **name**.

   - The **friendly name** name is the one you see on the collection. For example: Sales.
   - The **name** for all collections (except the root collection) is a six-character name assigned by the data map.

   Python needs this six-character name to reference any sub collections. To convert your **friendly name** automatically to the six-character collection name needed in your script, add this block of code:

> **ⓘ Important**
>
> Your endpoint value will be different depending on which Microsoft Purview portal you are using. Endpoint for the classic Microsoft Purview governance portal: purview.azure.com/ Endpoint for the New Microsoft Purview portal: purview.microsoft.com/
>
> So if you're using the new portal, your endpoint value will be something like: "https://consotopurview.scan.purview.microsoft.com"

```
Python
```

```
def get_admin_client():
     credentials = get_credentials()
     client = PurviewAccountClient(endpoint=purview_endpoint,
credential=credentials, logging_enable=True)
     return client

try:
  admin_client = get_admin_client()
except ValueError as e:
    print(e)

collection_list = client.collections.list_collections()
 for collection in collection_list:
  if collection["friendlyName"].lower() == collection_name.lower():
      collection_name = collection["name"]
```

7. For both clients, and depending on the operations, you also need to provide an input body. To register a source, you'll need to provide an input body for data source registration:

Python

```
ds_name = "<friendly name for your data source>"

body_input = {
        "kind": "AzureStorage",
        "properties": {
            "endpoint": f"https://{storage_name}.blob.core.windows.net/",
            "resourceGroup": rg_name,
            "location": rg_location,
            "resourceName": storage_name,
            "resourceId": storage_id,
            "collection": {
                "type": "CollectionReference",
                "referenceName": collection_name
            },
            "dataUseGovernance": "Disabled"
        }
}
```

8. Now you can call your Microsoft Purview clients and register the data source.

> **ⓘ Important**
>
> Your endpoint value will be different depending on which Microsoft Purview portal you are using. Endpoint for the classic Microsoft Purview governance portal: `https://{your_purview_account_name}.purview.azure.com/` Endpoint for the New Microsoft Purview portal: `https://api.purview-service.microsoft.com`

If you're using the classic portal, your endpoint value will be: `https://{your_purview_account_name}.scan.purview.azure.com` If you're using the new portal, your endpoint value will be: `https://scan.api.purview-service.microsoft.com`

Python

```
def get_purview_client():
     credentials = get_credentials()
     client = PurviewScanningClient(endpoint={{ENDPOINT}},
credential=credentials, logging_enable=True)
     return client

try:
    client = get_purview_client()
except ValueError as e:
    print(e)

try:
    response = client.data_sources.create_or_update(ds_name, body=body_input)
    print(response)
    print(f"Data source {ds_name} successfully created or updated")
except HttpResponseError as e:
    print(e)
```

When the registration process succeeds, you can see an enriched body response from the client.

In the following sections, you'll scan the data source you registered and search the catalog. Each of these scripts will be similarly structured to this registration script.

Full code

Python

```
from azure.purview.scanning import PurviewScanningClient
from azure.identity import ClientSecretCredential
from azure.core.exceptions import HttpResponseError
from azure.purview.administration.account import PurviewAccountClient

client_id = "<your client id>"
client_secret = "<your client secret>"
tenant_id = "<your tenant id>"
purview_endpoint = "<endpoint>"
purview_scan_endpoint = "<scan endpoint>"
storage_name = "<name of your Storage Account>"
storage_id = "<id of your Storage Account>"
rg_name = "<name of your resource group>"
```

```
rg_location = "<location of your resource group>"
collection_name = "<name of your collection>"
ds_name = "<friendly data source name>"

def get_credentials():
    credentials = ClientSecretCredential(client_id=client_id,
client_secret=client_secret, tenant_id=tenant_id)
    return credentials

def get_purview_client():
    credentials = get_credentials()
    client = PurviewScanningClient(endpoint=purview_scan_endpoint,
credential=credentials, logging_enable=True)
    return client

def get_admin_client():
    credentials = get_credentials()
    client = PurviewAccountClient(endpoint=purview_endpoint,
credential=credentials, logging_enable=True)
    return client

try:
    admin_client = get_admin_client()
except ValueError as e:
        print(e)

collection_list = admin_client.collections.list_collections()
for collection in collection_list:
    if collection["friendlyName"].lower() == collection_name.lower():
        collection_name = collection["name"]

body_input = {
    "kind": "AzureStorage",
    "properties": {
        "endpoint": f"https://{storage_name}.blob.core.windows.net/",
        "resourceGroup": rg_name,
        "location": rg_location,
        "resourceName": storage_name,
        "resourceId": storage_id,
        "collection": {
            "type": "CollectionReference",
            "referenceName": collection_name
        },
        "dataUseGovernance": "Disabled"
    }
}

try:
    client = get_purview_client()
except ValueError as e:
        print(e)

try:
    response = client.data_sources.create_or_update(ds_name, body=body_input)
```

```
    print(response)
    print(f"Data source {ds_name} successfully created or updated")
except HttpResponseError as e:
    print(e)
```

Scan the data source

Scanning a data source can be done in two steps:

1. Create a scan definition
2. Trigger a scan run

In this tutorial, you'll use the default scan rules for Blob Storage containers. However, you can also create custom scan rules programmatically with the Microsoft Purview Scanning Client.

Now let's scan the data source you registered above.

1. Add an import statement to generate unique identifier, call the Microsoft Purview scanning client, the Microsoft Purview administration client, the Azure error response package to be able to troubleshoot, and the client secret credential to gather your Azure credentials.

   Python

   ```
   import uuid
   from azure.purview.scanning import PurviewScanningClient
   from azure.purview.administration.account import PurviewAccountClient
   from azure.core.exceptions import HttpResponseError
   from azure.identity import ClientSecretCredential
   ```

2. Create a scanning client using your credentials:

   Python

   ```
   client_id = "<your client id>"
   client_secret = "<your client secret>"
   tenant_id = "<your tenant id>"

   def get_credentials():
        credentials = ClientSecretCredential(client_id=client_id,
   client_secret=client_secret, tenant_id=tenant_id)
        return credentials

   def get_purview_client():
        credentials = get_credentials()
        client =
   PurviewScanningClient(endpoint=f"https://{reference_name_purview}.scan.purvie
   w.azure.com", credential=credentials, logging_enable=True)
   ```

```
     return client

try:
     client = get_purview_client()
except ValueError as e:
     print(e)
```

3. Add the code to gather the internal name of your collection. (For more information, see the previous section):

Python

```
collection_name = "<name of the collection where you will be creating the
scan>"

def get_admin_client():
     credentials = get_credentials()
     client = PurviewAccountClient(endpoint=purview_endpoint,
credential=credentials, logging_enable=True)
     return client

try:
    admin_client = get_admin_client()
except ValueError as e:
    print(e)

collection_list = client.collections.list_collections()
 for collection in collection_list:
  if collection["friendlyName"].lower() == collection_name.lower():
      collection_name = collection["name"]
```

4. Then, create a scan definition:

Python

```
ds_name = "<name of your registered data source>"
scan_name = "<name of the scan you want to define>"
reference_name_purview = "<name of your Microsoft Purview account>"

body_input = {
        "kind":"AzureStorageMsi",
        "properties": {
            "scanRulesetName": "AzureStorage",
            "scanRulesetType": "System", #We use the default scan rule set
            "collection":
                {
                    "referenceName": collection_name,
                    "type": "CollectionReference"
                }
        }
}
```

```
try:
    response = client.scans.create_or_update(data_source_name=ds_name,
scan_name=scan_name, body=body_input)
    print(response)
    print(f"Scan {scan_name} successfully created or updated")
except HttpResponseError as e:
    print(e)
```

5. Now that the scan is defined you can trigger a scan run with a unique ID:

Python

```
run_id = uuid.uuid4() #unique id of the new scan

try:
    response = client.scan_result.run_scan(data_source_name=ds_name,
scan_name=scan_name, run_id=run_id)
    print(response)
    print(f"Scan {scan_name} successfully started")
except HttpResponseError as e:
    print(e)
```

Full code

Python

```
import uuid
from azure.purview.scanning import PurviewScanningClient
from azure.purview.administration.account import PurviewAccountClient
from azure.identity import ClientSecretCredential

ds_name = "<name of your registered data source>"
scan_name = "<name of the scan you want to define>"
reference_name_purview = "<name of your Microsoft Purview account>"
client_id = "<your client id>"
client_secret = "<your client secret>"
tenant_id = "<your tenant id>"
collection_name = "<name of the collection where you will be creating the scan>"

def get_credentials():
    credentials = ClientSecretCredential(client_id=client_id,
client_secret=client_secret, tenant_id=tenant_id)
    return credentials

def get_purview_client():
    credentials = get_credentials()
    client = PurviewScanningClient(endpoint=purview_scan_endpoint,
credential=credentials, logging_enable=True)
    return client
```

```
def get_admin_client():
    credentials = get_credentials()
    client = PurviewAccountClient(endpoint=purview_endpoint,
credential=credentials, logging_enable=True)
    return client

try:
    admin_client = get_admin_client()
except ValueError as e:
        print(e)

collection_list = admin_client.collections.list_collections()
for collection in collection_list:
    if collection["friendlyName"].lower() == collection_name.lower():
        collection_name = collection["name"]

try:
    client = get_purview_client()
except AzureError as e:
    print(e)

body_input = {
    "kind":"AzureStorageMsi",
    "properties": {
        "scanRulesetName": "AzureStorage",
        "scanRulesetType": "System",
        "collection": {
            "type": "CollectionReference",
            "referenceName": collection_name
        }
    }
}

try:
    response = client.scans.create_or_update(data_source_name=ds_name,
scan_name=scan_name, body=body_input)
    print(response)
    print(f"Scan {scan_name} successfully created or updated")
except HttpResponseError as e:
    print(e)

run_id = uuid.uuid4() #unique id of the new scan

try:
    response = client.scan_result.run_scan(data_source_name=ds_name,
scan_name=scan_name, run_id=run_id)
    print(response)
    print(f"Scan {scan_name} successfully started")
except HttpResponseError as e:
    print(e)
```

Search catalog

Once a scan is complete, it's likely that assets have been discovered and even classified. This process can take some time to complete after a scan, so you may need to wait before running this next portion of code. Wait for your scan to show **completed**, and the assets to appear in Microsoft Purview Unified Catalog.

Once the assets are ready, you can use the Microsoft Purview Catalog client to search the whole catalog.

1. This time you need to import the **catalog** client instead of the scanning one. Also include the HTTPResponse error and ClientSecretCredential.

   Python

   ```
   from azure.purview.catalog import PurviewCatalogClient
   from azure.identity import ClientSecretCredential
   from azure.core.exceptions import HttpResponseError
   ```

2. Create a function to get the credentials to access your Microsoft Purview account, and instantiate the catalog client.

   Python

   ```
   client_id = "<your client id>"
   client_secret = "<your client secret>"
   tenant_id = "<your tenant id>"
   reference_name_purview = "<name of your Microsoft Purview account>"

   def get_credentials():
        credentials = ClientSecretCredential(client_id=client_id,
   client_secret=client_secret, tenant_id=tenant_id)
        return credentials

   def get_catalog_client():
       credentials = get_credentials()
       client =
   PurviewCatalogClient(endpoint=f"https://{reference_name_purview}.scan.purview
   .azure.com", credential=credentials, logging_enable=True)
       return client

   try:
       client_catalog = get_catalog_client()
   except ValueError as e:
       print(e)
   ```

3. Configure your search criteria and keywords in the input body:

Python

```
keywords = "keywords you want to search"

body_input={
    "keywords": keywords
}
```

Here you only specify keywords, but keep in mind you can add many other fields to further specify your query.

4. Search the catalog:

Python

```
try:
    response = client_catalog.discovery.query(search_request=body_input)
    print(response)
except HttpResponseError as e:
    print(e)
```

Full code

Python

```
from azure.purview.catalog import PurviewCatalogClient
from azure.identity import ClientSecretCredential
from azure.core.exceptions import HttpResponseError

client_id = "<your client id>"
client_secret = "<your client secret>"
tenant_id = "<your tenant id>"
reference_name_purview = "<name of your Microsoft Purview account>"
keywords = "<keywords you want to search for>"

def get_credentials():
    credentials = ClientSecretCredential(client_id=client_id,
client_secret=client_secret, tenant_id=tenant_id)
    return credentials

def get_catalog_client():
    credentials = get_credentials()
    client = PurviewCatalogClient(endpoint=purview_endpoint,
credential=credentials, logging_enable=True)
    return client

body_input={
    "keywords": keywords
}
```

```
try:
    catalog_client = get_catalog_client()
except ValueError as e:
    print(e)

try:
    response = catalog_client.discovery.query(search_request=body_input)
    print(response)
except HttpResponseError as e:
    print(e)
```

Delete a data source

In this section, you'll learn how to delete the data source you registered earlier. This operation is fairly simple, and is done with the scanning client.

1. Import the **scanning** client. Also include the HTTPResponse error and ClientSecretCredential.

   Python

   ```
   from azure.purview.scanning import PurviewScanningClient
   from azure.identity import ClientSecretCredential
   from azure.core.exceptions import HttpResponseError
   ```

2. Create a function to get the credentials to access your Microsoft Purview account, and instantiate the scanning client.

   Python

   ```
   client_id = "<your client id>"
   client_secret = "<your client secret>"
   tenant_id = "<your tenant id>"
   reference_name_purview = "<name of your Microsoft Purview account>"

   def get_credentials():
        credentials = ClientSecretCredential(client_id=client_id,
   client_secret=client_secret, tenant_id=tenant_id)
        return credentials

   def get_scanning_client():
       credentials = get_credentials()

   PurviewScanningClient(endpoint=f"https://{reference_name_purview}.scan.purvie
   w.azure.com", credential=credentials, logging_enable=True)
       return client

   try:
       client_scanning = get_scanning_client()
   ```

```
except ValueError as e:
    print(e)
```

3. Delete the data source:

Python

```
    ds_name = "<name of the registered data source you want to delete>"
    try:
        response = client_scanning.data_sources.delete(ds_name)
        print(response)
        print(f"Data source {ds_name} successfully deleted")
    except HttpResponseError as e:
        print(e)
```

Full code

Python

```
from azure.purview.scanning import PurviewScanningClient
from azure.identity import ClientSecretCredential
from azure.core.exceptions import HttpResponseError

client_id = "<your client id>"
client_secret = "<your client secret>"
tenant_id = "<your tenant id>"
reference_name_purview = "<name of your Microsoft Purview account>"
ds_name = "<name of the registered data source you want to delete>"

def get_credentials():
    credentials = ClientSecretCredential(client_id=client_id,
client_secret=client_secret, tenant_id=tenant_id)
    return credentials

def get_scanning_client():
    credentials = get_credentials()
    client =
PurviewScanningClient(endpoint=f"https://{reference_name_purview}.scan.purview.azu
re.com", credential=credentials, logging_enable=True)
    return client

try:
    client_scanning = get_scanning_client()
except ValueError as e:
    print(e)

try:
    response = client_scanning.data_sources.delete(ds_name)
    print(response)
    print(f"Data source {ds_name} successfully deleted")
```

```
except HttpResponseError as e:
    print(e)
```

Microsoft Purview governance services open-source tools and utilities

Article • 02/26/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

This article lists several open-source tools and utilities (command-line, python, and PowerShell interfaces) that help you get started quickly with Microsoft Purview governance services, like Microsoft Purview Data Map, Data Catalog, and Data Estate Insights in a matter of minutes! These tools have been authored & developed by collective effort of the Microsoft Purview Product Group and the open-source community. The objective of such tools is to make learning, starting up, regular usage, and long-term adoption of Microsoft Purview fast and easy.

Intended audience

- Microsoft Purview community including customers, developers, ISVs, partners, evangelists, and enthusiasts.
- The Microsoft Purview Data Catalog is based on Apache Atlas and extends full support for Apache Atlas APIs. We welcome Apache Atlas community, enthusiasts, and developers to wholeheartedly build on and evangelize Microsoft Purview.

Microsoft Purview customer journey stages

- *Microsoft Purview Learners*: Learners who are starting fresh with Microsoft Purview governance services and are keen to understand and explore how a multicloud unified data governance solution works. A section of learners includes users who want to compare and contrast Microsoft Purview with other competing solutions in the data governance market and try it before adopting for long-term usage.
- *Microsoft Purview Innovators*: Innovators who are keen to understand existing and latest features, ideate, and conceptualize features upcoming on Microsoft Purview. They're adept at building and developing solutions for customers, and have

futuristic forward-looking ideas for the next-gen cutting-edge data governance product.

- *Microsoft Purview Enthusiasts/Evangelists*: Enthusiasts who are a combination of Learners and Innovators. They have developed solid understanding and knowledge of Microsoft Purview, hence, are upbeat about adoption of Microsoft Purview. They can help evangelize Microsoft Purview as a service and educate several other Microsoft Purview users and probable customers across the globe.
- *Microsoft Purview Adopters*: Adopters who have migrated from starting up and exploring the Microsoft Purview governance portal and are smoothly using Microsoft Purview for more than a few months.
- *Microsoft Purview Long-Term Regular Users*: Long-term users who have been using the Microsoft Purview governance portal for more than one year and are now confident and comfortable using most advanced use cases on the Azure portal and Microsoft Purview governance portal; furthermore they have near perfect knowledge and awareness of the Microsoft Purview REST APIs and the other use cases supported via Microsoft Purview APIs.

Microsoft Purview open-source tools and utilities list

1. Purview-API-via-PowerShell

    - **Recommended customer journey stages**: *Learners, Innovators, Enthusiasts, Adopters, Long-Term Regular Users*
    - **Description**: This utility is based on and covers the entire set functionality described in the Microsoft Purview REST API reference. Download & Install from PowerShell Gallery. It helps you execute all the documented Microsoft Purview REST APIs through a breezy fast and easy to use PowerShell interface. Use and automate Microsoft Purview APIs for regular and long-term usage via command-line and scripted methods. This is an alternative for customers looking to do bulk tasks in automated manner, batch-mode, or scheduled cron jobs; as against the GUI method of using the Azure portal and Microsoft Purview governance portal. Detailed documentation, sample usage guide, self-help, and examples are available on GitHub:Azure-Purview-API-PowerShell.

2. Microsoft Purview Lab

    - **Recommended customer journey stages**: *Learners, Innovators, Enthusiasts*

- **Description**: A hands-on-lab introducing the myriad features of Microsoft Purview and helping you learn the concepts in a practical and hands-on approach where you execute each step on your own by hand to develop the best possible understanding of Microsoft Purview.

3. Microsoft Purview CLI

   - **Recommended customer journey stages**: *Innovators, Enthusiasts, Adopters, Long-Term Regular Users*
   - **Description**: Python-based tool to execute the Microsoft Purview APIs similar to Purview-API-via-PowerShell but has limited/lesser functionality than the PowerShell-based framework.

4. Microsoft Purview Demo

   - **Recommended customer journey stages**: *Learners, Innovators, Enthusiasts*
   - **Description**: An Azure Resource Manager (ARM) template-based tool to automatically set up and deploy fresh new Microsoft Purview account quickly and securely at the issue of just one command. It's similar to Purview-Starter-Kit, the extra feature being it deploys a few more pre-configured data sources - Azure SQL Database, Azure Data Lake Storage Gen2 Account, Azure Data Factory, Azure Synapse Analytics Workspace

5. PyApacheAtlas: Interface between Microsoft Purview and Apache Atlas using Atlas APIs

   - **Recommended customer journey stages**: *Innovators, Enthusiasts, Adopters, Long-Term Regular Users*
   - **Description**: A Python package to work with Microsoft Purview and Apache Atlas API. Supports bulk loading, custom lineage, and more from a Pythonic set of classes and Excel templates. The package supports programmatic interaction and an Excel template for low-code uploads.

6. Microsoft Purview Event Hubs Notifications Reader

   - **Recommended customer journey stages**: *Innovators, Enthusiasts, Adopters, Long-Term Regular Users*
   - **Description**: This tool demonstrates how to read Microsoft Purview's Event Hubs and catch real-time Kafka notifications from the Event Hubs in Atlas Notifications (https://atlas.apache.org/2.0.0/Notifications.html) format. Further, it generates an excel sheet CSV of the entities and assets on the fly that are discovered live during a scan, and any other notifications of interest that Microsoft Purview generates.

Feedback and disclaimer

None of the tools come with an express warranty from Microsoft verifying their efficacy or guarantees of functionality. They're certified to be free of any malicious activity or viruses, and guaranteed to not collect any private or sensitive data.

For feedback or questions about efficacy and functionality during usage, contact the respective tool owners and authors on the contact details mentioned in the respective GitHub repo.

Troubleshoot Microsoft Purview Data Map API request timeout exceptions

Article • 05/08/2025

Applies to Microsoft Purview Data Map API returned HTTP 408 request timeout.

Troubleshooting steps

The following list contains known patterns and solutions for request timeout exceptions.

If it doesn't match your case, or the failure can't be resolved after applied the solution, contact Microsoft Customer Support with all request history.

Time out to list all glossaries

```HTTP
# https://learn.microsoft.com/en-us/rest/api/purview/datamapdataplane/glossary/get-term
GET {endpoint}/datamap/api/atlas/v2/glossary?ignoreTermsAndCategories={ignoreTermsAndCategories}&limit={limit}&offset={offet}&sort={sort}
```

This API by default returns all glossaries together with all terms/categories under those glossaries. If there are 1000 glossaries, each glossary has 1000 terms and 1000 categories, it returns 1000 glossary with 1000 * (1000 terms + 1000 categories).

- The size of all related terms/categories could be too large to fetch via single API within a reasonable duration. Use query parameter `ignoreTermsAndCategories=true` to reduce total count to load in server side and shrink response size for network transfer. If terms/categories are still needed, you can combine with the below APIs to fetch them.
  - List terms under specific glossary

    ```HTTP
    # https://learn.microsoft.com/en-us/rest/api/purview/datamapdataplane/glossary/list-categories
    GET {endpoint}/datamap/api/atlas/v2/glossary/{glossaryGuid}/terms?limit={limit}&offset={offset}&sort={sort}
    ```

  - List categories under specific glossary

    ```HTTP
    ```

```
# https://learn.microsoft.com/en-us/rest/api/purview/datamapdataplane/glossary/list-terms
GET {endpoint}/datamap/api/atlas/v2/glossary/{glossaryGuid}/categories?limit={limit}&offset={offset}&sort={sort}
```

- The size of the all glossary count could be too large to fetch via a single API within a reasonable duration. Use query parameter `limit` and `offset` with small pagination size to get glossaries page by page.

Time out to get glossary with detailed info

HTTP

```
GET {endpoint}/datamap/api/atlas/v2/glossary/{glossaryGuid}/detailed
```

This API by default returns the glossary together with all terms/categories under the glossary.

- The size of all related terms/categories could be too large to fetch via single API within a reasonable duration. We recommend you use the below APIs to have a better pagination experience.
  - Get specific glossary

    HTTP

    ```
    # https://learn.microsoft.com/en-us/rest/api/purview/datamapdataplane/glossary/get
    GET {endpoint}/datamap/api/atlas/v2/glossary/{glossaryGuid}
    ```

  - List terms under specific glossary

    HTTP

    ```
    # https://learn.microsoft.com/en-us/rest/api/purview/datamapdataplane/glossary/list-terms
    GET {endpoint}/datamap/api/atlas/v2/glossary/{glossaryGuid}/terms?limit={limit}&offset={offset}&sort={sort}
    ```

  - List categories under specific glossary

    HTTP

    ```
    # https://learn.microsoft.com/en-us/rest/api/purview/datamapdataplane/glossary/list-categories
    ```

```
GET {endpoint}/datamap/api/atlas/v2/glossary/{glossaryGuid}/categories?
limit={limit}&offset={offset}&sort={sort}
```

Time out to list all terms under specific glossary

HTTP

```
# https://learn.microsoft.com/en-
us/rest/api/purview/datamapdataplane/glossary/list-terms
GET {endpoint}/datamap/api/atlas/v2/glossary/{glossaryGuid}/terms
```

By default, this API returns all terms under the glossary.

- The size of all terms under the glossary could be too large to fetch via single API within a reasonable duration. Use query parameters `limit` and `offset` with small pagination size to list terms page by page.

  HTTP

  ```
  # https://learn.microsoft.com/en-
  us/rest/api/purview/datamapdataplane/glossary/list-terms
  GET {endpoint}/datamap/api/atlas/v2/glossary/{glossaryGuid}/terms?limit=
  {limit}&offset={offset}&sort={sort}
  ```

Time out to get single term

HTTP

```
# https://learn.microsoft.com/en-
us/rest/api/purview/datamapdataplane/glossary/get-term
GET {endpoint}/datamap/api/atlas/v2/glossary/term/{termGuid}
```

This API by default returns the term together with its all relationships. For example, assignedEntities, parent/child terms.

- The size of assignedEntities on the term could be too large to fetch via single API within a reasonable duration. Use query parameter `excludeRelationshipTypes` to ignore assignedEntities relationship called `AtlasGlossarySemanticAssignment` in response. Then use another dedicated API to get assignedEntities with pagination.
  - Get specific term

    HTTP

```
# https://learn.microsoft.com/en-us/rest/api/purview/datamapdataplane/glossary/get-term
GET {endpoint}/datamap/api/atlas/v2/glossary/term/{termGuid}?excludeRelationshipTypes=AtlasGlossarySemanticAssignment
```

- List assignedEntities under specific term

```HTTP
# https://learn.microsoft.com/en-us/rest/api/purview/datamapdataplane/glossary/list-entities-assigned-with-term
GET {endpoint}/datamap/api/atlas/v2/glossary/terms/{termGuid}/assignedEntities?limit={limit}&offset={offset}&sort={sort}
```

Best practices for Microsoft Purview accounts merge scenarios

Article • 05/14/2025

Background

Microsoft Purview represents the next step towards unifying your organization's governance, policy, compliance, risk, and security. If you started using Microsoft Purview data governance with the classic experience, upgrading to the new experience is necessary to obtain the full set of capabilities and enhancements. For organizations with multiple accounts, this upgrade process involves merging existing accounts.

Merging Microsoft Purview accounts involves consolidating resources, configurations, and data governance policies from multiple accounts into a single, unified account. This process requires careful planning and consideration to ensure data integrity, security, and compliance.

It's recommended to follow this guide if you have more than one Microsoft Purview account under the classic experience.

Pre-merge assessment

- Conduct a thorough assessment to obtain the total number of Microsoft Purview accounts in your tenant, and the purpose of each account to identify which account to promote as primary. This account will be converted into your default domain in the new experience.
- Evaluate the remaining accounts to detect and resolve potential conflicts, such as duplicate resources or incompatible configurations.
- Currently, you can only have up to five domains (one default domain and four custom domains) inside the new experience. If your organization has more than five accounts in the classic mode, you need to select only five accounts to upgrade and retire the remaining accounts. For example, if your organization has multiple nonproduction accounts, you can consider merging one account into a custom domain and retire remaining accounts without using the merge tool. This process may include a combination of using the merge tool and manually migrating resources from other classic accounts under a nonprod account.
- Review Microsoft Purview limitations to reduce the risk of failure during the merge and ensure the unified experience has the capacity to merge resources.
- Evaluate resources in each account to determine what needs to be merged or can be excluded during the migration.

- Run the merge tool in assess mode to identify and resolve any issues before the merge, considering that the merge is a one-time irreversible process.

Conflict resolution

- Develop a strategy for resolving conflicts, such as renaming resources or excluding certain types from the merge. Handle name conflicts and consider the option to exclude certain object types.

What to do if conflicts happen

Use the following guidelines if conflicts are raised during the Microsoft Purview account merge process:

1. Identify Conflicts: During the premerge assessment, run the merge tool in assess mode to identify potential conflicts. This generates a list of conflicts that need to be resolved before proceeding with the merge. Conflicts may raise due any of these issues:

    - Conflicts may arise due to duplicate resources, such as assets, or glossary terms. For example, if two accounts have the same custom type definition name, you need to choose one and delete the other.
    - Conflicts could also occur due to incompatible configurations between accounts. This could include differences in data source configurations. For example, Advanced Resource Set feature may be turned on in the merging account but it's off in the primary account.

2. Resolve Conflicts:

    - If there are duplicate resources, consider renaming them to avoid conflicts. For example, you can rename conflicting assets or glossary term to ensure they have unique names across accounts.
        - You may choose to exclude certain types of resources from the merge if they're not essential or if they cause conflicts. This can help streamline the merge process and reduce the risk of errors.
        - For conflicts that can't be resolved automatically, manually delete the conflicting resources before proceeding with the merge. This ensures that only the necessary and nonconflicting resources are merged.

3. Re-Run Assessments:

    - After resolving conflicts, rerun the merge tool in assess mode to ensure that all issues are addressed. This step helps validate that the merge can proceed without

further conflicts.

4. Execute the Merge:

    - Run merge tool in assess mode until all conflicts are resolved.
    - Once all conflicts are resolved, proceed with the merge by following the step-by-step process outlined in the execution phase. This includes running assessments, performing prechecks, and executing the merge.

Perform the merge

- Consider the merge as a one-time process and irreversible.
- Make sure no major changes are happening in data map in the secondary account during the merge process.
- Follow a step-by-step process for the merge, starting with a precheck, running assessments, and then executing the merge.

Post-merge review

- After merge completion, conduct a review to ensure all resources are correctly integrated and that there are no outstanding issues.
- Manually migrate resources that weren't moved.
- Remove classic accounts that are merged.
- Review domains and collections roles to ensure proper role assignments are in place. Remove unnecessary roles that were added due to the merge process or assign the roles to lower-level collections when possible.

Next steps

Merge account to domain

Best practices for Microsoft Purview private endpoints during merging accounts

Article • 05/14/2025

Background

The new Microsoft Purview experience is single, organization-wide instance of Microsoft Purview that's the next step towards unifying your organization's governance, policy, compliance, risk, and security. It's a prerequisite to a single platform used to manage and govern any data, both structured and unstructured, across your data estate. Including Azure, Microsoft 365, Azure, on-premises, or multicloud and SaaS applications in future. For organizations with multiple accounts, this upgrade process involves merging existing accounts.

When merging Microsoft Purview accounts, it's important to consider the private endpoints. Private endpoints provide a secure and private connection to the Purview governance portal and other resources, ensuring that only users within your network can access them. During the merge process, resources, configurations, and data governance policies from multiple accounts are consolidated into a single, unified account. If one or more of your classic accounts have private endpoint connections, this requires careful planning to ensure that private endpoints are correctly configured and that all necessary connections are maintained. Failure to properly manage private endpoints during the merge can result in issues and potential failure in merge process.

This article contains information to guide you resolve conflict when merging accounts with private endpoints.

Private endpoints in Microsoft Purview accounts

Private endpoints in classic mode include the following capabilities:

- **Account private endpoints**: Allowed only client calls originating from within the private network to access the Microsoft Purview account.
- **Portal private endpoints**: Enabled secure access to the Microsoft Purview governance portal using private network connectivity.
- **Ingestion private endpoints**: Used to scan Azure IaaS and PaaS data sources inside Azure virtual networks and on-premises data sources through a private connection, to provide network isolation for metadata, flowing from data sources to the Microsoft Purview Data Map.

Private endpoints in unified experience include:

- **Platform private endpoints**: The Platform private endpoint is a new private endpoint concept in the unified portal that provides you organizational-level account private endpoint connection.
- **Ingestion private endpoints**: Used to scan Azure IaaS and PaaS data sources inside Azure virtual networks and on-premises data sources through a private connection.

Private endpoints conflict resolution during account merge

After you upgrade your primary account into unified experience, you may need to plan for account merge for the remaining classic accounts in your tenant. It's recommended to follow these guidelines to avoid conflicts during the merge process:

- Identify classic accounts that have any private endpoints, including accounts with Managed Vnet IRs. Remove unnecessary private endpoints, Managed VNet IR's or self-hosted integration runtimes from secondary accounts.
- If an account private endpoint is identified as a conflict and blocking the merge process, it's recommended to delete all private endpoints or filter them out during the merge process. The filtered configurations will not be merged into the unified experience.
- If there's a conflict in an ingestion private endpoint, the ingestion private endpoint in the secondary account can be abandoned. It's recommended to use the ingestion private endpoint in the primary account instead. If ingestion private endpoint is needed for a different VNet, you can create more ingestion private endpoints in the primary account. Create a new self-hosted integration runtime for full VNet isolation if needed.
- Portal private endpoint should be filtered out during the merge and be deleted in the secondary account after the merge, as portal private endpoint will be deprecated.

Conflicts on integration runtime

- If you're using Managed VNet IR and self-hosted integration runtimes in both accounts, it's recommended to delete Managed VNet IR and self-hosted integration runtime in the secondary account before merge. Create new Managed VNet IR or self-hosted integration runtime in the primary account after the merge. Alternatively, filtering out Managed VNET IR and self-hosted integration runtime is recommended. Scans using these will be filtered out and will need to be recreated after the merge.
- If the plan is to use the same self-hosted integration runtime virtual machines, uninstall self-hosted integration runtime in the secondary account before merge and install self-hosted integration runtime in the primary account after merging the secondary account. It's possible to reuse the same VMs and machines or use new ones.

Conflicts on managed private endpoint connections:

- Ensure Managed private endpoint connections to Platform private endpoint are properly set up in the primary account.
- Delete conflicting Managed VNet private endpoints from secondary accounts. After the merge, recreate or reuse existing Managed VNet IR in the primary account for connections to the sources that got merged.

Conflicting Azure Data Factory or ADS Lineage Connections

- It's recommended to filter out Azure Data Factory and ADS lineage connections during the merge. Work with the primary account's domain source admins to reconnect it.

Merge account to domain

Microsoft Purview automation best practices

Article • 05/14/2025

While Microsoft Purview governance solutions provide an out of the box user experience with the Microsoft Purview governance portal, not all tasks are suited to the point-and-click nature of the graphical user experience.

For example:

- Triggering a scan to run as part of an automated process.
- Monitoring for metadata changes in real time.
- Building your own custom user experience.

Microsoft Purview provides several tools in which we can use to interact with the underlying platform, in an automated, and programmatic fashion. Because of the open nature of the Microsoft Purview service, we can automate different aspects, from the control plane, made accessible via Azure Resource Manager, to Microsoft Purview's multiple data planes (catalog, scanning, administration, and more).

This article provides a summary of the options available, and guidance on what to use when.

Tools

Expand table

Tool Type	Tool	Scenario	Management	Catalog	Scanning	Logs
Resource Management	• ARM Templates • Terraform	Infrastructure as Code	✓			
Command Line	• Azure CLI	Interactive	✓			
Command Line	• Azure PowerShell	Interactive	✓	✓		
API	• REST API	On-Demand	✓	✓	✓	
Streaming (Apache Atlas)	• Event Hubs	Real-Time		✓		

Tool Type	Tool	Scenario	Management	Catalog	Scanning	Logs
Monitoring	• Azure Monitor	Monitoring				✓
SDK	• .NET • Java • JavaScript • Python	Custom Development	✓	✓	✓	

Command Line

Azure CLI and Azure PowerShell are command-line tools that enable you to manage Azure resources such as Microsoft Purview. While the list of commands will grow over time, only a subset of Microsoft Purview control plane operations is currently available. For an up-to-date list of commands currently available, check out the documentation (Azure CLI | Azure PowerShell).

- **Azure CLI** - A cross-platform tool that allows the execution of commands through a terminal using interactive command-line prompts or a script. Azure CLI has a **purview extension** that allows for the management of Microsoft Purview accounts. For example, `az purview account`.
- **Azure PowerShell** - A cross-platform task automation program, consisting of a set of cmdlets for managing Azure resources. Azure PowerShell has a module called **Az.Purview** that allows for the management of Microsoft Purview accounts. For example, `Get-AzPurviewAccount`.

When to use?

- Best suited for ad-hoc tasks and quick exploratory operations.

API

REST APIs are HTTP endpoints that surface different methods (`POST`, `GET`, `PUT`, `DELETE`), triggering actions such as create, read, update, or delete (CRUD). Microsoft Purview exposes a large portion of the Microsoft Purview platform via multiple service endpoints.

When to use?

- Required operations not available via Azure CLI, Azure PowerShell, or native client libraries.

- Custom application development or process automation.

Streaming (Apache Atlas)

Each Microsoft Purview account can configure Event Hubs that are accessible via their Atlas Kafka endpoint.

You can follow these steps to configure the Event Hubs namespaces.

> **Note**
>
> Enabling this Event Hubs namespace does incur a cost for the namespace. For specific details, see the pricing page.

Once the namespace is enabled, Microsoft Purview events can be monitored by consuming messages from the event hub. External systems can also use the event hub to publish events to Microsoft Purview as they occur.

- **Consume Events** - Microsoft Purview will send notifications about metadata changes to Kafka topic **ATLAS_ENTITIES**. Applications interested in metadata changes can monitor for these notifications. Supported operations include: `ENTITY_CREATE`, `ENTITY_UPDATE`, `ENTITY_DELETE`, `CLASSIFICATION_ADD`, `CLASSIFICATION_UPDATE`, `CLASSIFICATION_DELETE`.
- **Publish Events** - Microsoft Purview can be notified of metadata changes via notifications to Kafka topic **ATLAS_HOOK**. Supported operations include: `ENTITY_CREATE_V2`, `ENTITY_PARTIAL_UPDATE_V2`, `ENTITY_FULL_UPDATE_V2`, `ENTITY_DELETE_V2`.

When to use?

- Applications or processes that need to publish or consume Apache Atlas events in real time.

Monitoring

Microsoft Purview can send platform logs and metrics via "Diagnostic settings" to one or more destinations (Log Analytics Workspace, Storage Account, or Azure Event Hubs). Available metrics include `Data Map Capacity Units`, `Data Map Storage Size`, `Scan Canceled`, `Scan Completed`, `Scan Failed`, and `Scan Time Taken`.

Once configured, Microsoft Purview automatically sends these events to the destination as a JSON payload. From there, application subscribers that need to consume and act on these events can do so with the option of orchestrating downstream logic.

When to use?

- Applications or processes that need to consume diagnostic events.

SDK

Microsoft provides Azure SDKs to programmatically manage and interact with Azure services. Microsoft Purview client libraries are available in several languages (.NET, Java, JavaScript, and Python), designed to be consistent, approachable, and idiomatic.

- .NET
- Java
- JavaScript
- Python

When to use?

- Recommended over the REST API as the native client libraries (where available) will follow standard programming language conventions in line with the target language that will feel natural to the developer.

Microsoft Purview disaster recovery and migration best practices

Article • 05/14/2025

This article provides guidance on backup and recovery strategy when your organization has Microsoft Purview governance solutions in production deployment. You can also use this general guideline to implement account migration. The scope of this article is to cover manual business continuity and disaster recovery (BCDR) methods, where you could automate using APIs.

Azure data center outages are rare, but can last anywhere from a few minutes to hours. Data Center outages can cause disruption to environments that are being relied on for data governance. By following the steps detailed in this article, you can continue to govern your data in the event of a data center outage for the primary region of your Microsoft Purview account.

> **Tip**
>
> Find more information about reliability for Microsoft Purview.

Achieve business continuity for Microsoft Purview

BCDR in a Microsoft Purview instance refers to the mechanisms, policies, and procedures that enable your business to protect data loss and continue operating in the face of disruption, particularly to its scanning, classic catalog, and classic insights tiers. This page explains how to configure a disaster recovery environment for Microsoft Purview.

Today, Microsoft Purview doesn't support automated BCDR. Until that support is added, you're responsible to take care of backup and restore activities. You can manually create a secondary Microsoft Purview account as a warm standby instance in another region.

The following steps summarize how you can achieve disaster recovery manually:

1. Once the primary Microsoft Purview account is created, create one or more secondary Microsoft Purview accounts in a separate region.

   > **Important**
   >
   > Microsoft Purview currently supports a single Microsoft Purview instance per tenant. To create a second account for backup and disaster recovery, contact support

2. All activities performed on the primary Microsoft Purview account must be carried out on the secondary Microsoft Purview accounts as well. This includes:

    - Maintain Account information
    - Create and maintain custom scan rule sets, classifications, and classification rules
    - Register and scan sources
    - Create and maintain collections along with the association of sources with the collections
    - Create and maintain credentials used while scanning
    - Curate data assets
    - Create and maintain glossary terms

Specific steps to create and maintain a disaster recovery account are provided later in the article. Before you follow them, read through the limitations and considerations.

Limitations and considerations

As you create your manual BCDR plan, keep the following points in mind:

- You'll be charged for primary and secondary Microsoft Purview instances.
- The primary and secondary Microsoft Purview accounts can't be configured to the same Azure Data Factory, Azure Data Share and Synapse Analytics accounts, if applicable. As a result, the lineage from Azure Data Factory and Azure Data Share can't be seen in the secondary Microsoft Purview accounts. This limitation will be addressed when automated BCDR is supported.
- The integration runtimes are specific to a Microsoft Purview account. So, scans need to run in primary and secondary Microsoft Purview accounts in-parallel, multiple self-hosted integration runtimes must be maintained. This limitation will also be addressed when automated BCDR is supported.
- Parallel execution of scans from both primary and secondary Microsoft Purview accounts on the same source can affect the performance of the source. This can result in scan durations to vary across the Microsoft Purview accounts.
- It isn't advisable to back up "scanned" assets' details. You should only back up the curated data such as mapping of classifications and glossaries on assets. The only case when you need to back up assets' details is when you have custom assets via custom typeDef.
- The backed-up asset count should be fewer than 100,000 assets. The main driver is that you have to use the search query API to get the assets, which have limitation of 100,000

assets returned. However, if you're able to segment the search query to get smaller number of assets per API call, it's possible to back up more than 100,000 assets.

- If you want to continuously "sync" assets between two accounts, there are other steps that won't be covered in detail in this article. You have to use Microsoft Purview's Event Hubs to subscribe and create entities to another account. However, Event Hubs only has Atlas information. Microsoft Purview has added other capabilities such as **glossaries** and **contacts** that won't be available via Event Hubs.

Steps to achieve business continuity

Create the new account

- **If your organization already has multiple Microsoft Purview accounts**, you can create a new Microsoft Purview account by following this guide instruction: Quickstart: Create a Microsoft Purview account in the Azure portal
- **If your organization only has one tenant/organizational Microsoft Purview account**, to create an account for backup and recovery contact support.

Plan these configuration items that you can't change later:

- Account name
- Region
- Subscription
- Manage resource group name

Migrate configuration items

Below steps are referring to Microsoft Purview API documentation so that you can programmatically stand up the backup account quickly:

Expand table

Task	Description
Account information	Maintain Account information by granting access for the admin and/or service principal to the account at root level
Collections	Create and maintain Collections along with the association of sources with the Collections. You can call List Collections API and then get specific details of each collection via Get Collection API

Task	Description
Scan rule set	Create and maintain custom scan rule sets. You need to call List custom scan rule sets API and get details by calling Get scan rule set API
Manual classifications	Get a list of all manual classifications by calling get classifications APIs and get details of each classification
Resource set rule	Create and maintain resource set rule. You can call the Get resource set rule API to get the rule details
Data sources	Call the Get all data sources API to list data sources with details. You also have to get the triggers by calling Get trigger API. There's also Create data sources API if you need to re-create the sources in bulk in the new account.
Credentials	Create and maintain credentials used while scanning. There's no API to extract credentials, so this must be redone in the new account.
Self-hosted integration runtime (SHIR)	Get a list of SHIR and get updated keys from the new account then update the SHIRs. This must be done manually inside the SHIRs' hosts. These need to be running before you create scans.
ADF connections	Currently an ADF can be connected to one Microsoft Purview at a time. You must disconnect ADF from failed Microsoft Purview account and reconnect it to the new account later.

Run scans

> **Important**
>
> Make sure your self-hosted integration runtimes have been configured and are running and available before creating scans.

This will populate all assets with default `typedef`. There are several reasons to run the scans again vs. exporting the existing assets and importing to the new account:

- There's a limit of 100,000 assets returned from the search query to export assets.
- It's cumbersome to export assets with relationships.
- When you rerun the scans, you'll get all relationships and assets details up to date.
- Microsoft Purview comes out with new features regularly so you can benefit from other features when running new scans.

Running the scans is the most effective way to get all assets of data sources that Microsoft Purview is already supporting.

Migrate custom typedefs and custom assets

If your organization has created custom types in Microsoft Purview, you need to migrate those manually.

Custom typedefs

To identify all custom `typedef`, you can use the get all type definitions API. This will return each type. You need to identify the custom types in such format as `"serviceType": "<custom_typedef>"`

Custom assets

To export custom assets, you can search those custom assets and pass the proper custom `typedef` via the discovery API

> **Note**
>
> There is a 100,000 return limit per search result. You might have to break the search query so that it won't return more than 100,000 records.

There are several ways to scope down the search query to get a subset of assets:

- **Using `Keyword`**: Pass the parent FQN such as `Keyword: "<Parent String>/*"`
- **Using `Filter`**: Include `assetType` with the specific custom `typedef` in your search such as `"assetType": "<custom_typedef>"`

Here's an example of a search payload by customizing the `keywords` so that only assets in specific storage account (`exampleaccount`) are returned:

JSON

```
{
  "keywords": "adl://exampleaccount.azuredatalakestore.net/*",
  "filter": {
    "and": [
      {
        "not": {
          "or": [
            {
              "attributeName": "size",
              "operator": "eq",
              "attributeValue": 0
            },
```

```
            {
              "attributeName": "fileSize",
              "operator": "eq",
              "attributeValue": 0
            }
          ]
        }
      },
      {
        "not": {
          "classification": "MICROSOFT.SYSTEM.TEMP_FILE"
        }
      },
      {
        "not": {
          "or": [
            {
              "entityType": "AtlasGlossaryTerm"
            },
            {
              "entityType": "AtlasGlossary"
            }
          ]
        }
      }
    ]
  },
  "limit": 10,
  "offset": 0,
  "facets": [
    {
      "facet": "assetType",
      "count": 0,
      "sort": {
        "count": "desc"
      }
    },
    {
      "facet": "classification",
      "count": 10,
      "sort": {
        "count": "desc"
      }
    },
    {
      "facet": "contactId",
      "count": 10,
      "sort": {
        "count": "desc"
      }
    },
    {
      "facet": "label",
      "count": 10,
      "sort": {
```

```
        "count": "desc"
      }
    },
    {
      "facet": "term",
      "count": 10,
      "sort": {
        "count": "desc"
      }
    }
  ]
}
```

The returned assets will have some key/pair value that you can extract details:

JSON

```
{
    "referredEntities": {},
    "entity": {
    "typeName": "column",
    "attributes": {
        "owner": null,
        "qualifiedName":
"adl://exampleaccount.azuredatalakestore.net/123/1/DP_TFS/CBT/Extensions/DTTP.targ
ets#:xml/Project/Target/XmlPeek/@XmlInputPath",
        "name": "~XmlInputPath",
        "description": null,
        "type": "string"
    },
    "guid": "5cf8a9e5-c9fd-abe0-2e8c-d40024263dcb",
    "status": "ACTIVE",
    "createdBy": "ExampleCreator",
    "updatedBy": "ExampleUpdator",
    "createTime": 1553072455110,
    "updateTime": 1553072455110,
    "version": 0,
    "relationshipAttributes": {
        "schema": [],
        "inputToProcesses": [],
        "composeSchema": {
        "guid": "cc6652ae-dc6d-90c9-1899-252eabc0e929",
        "typeName": "tabular_schema",
        "displayText": "tabular_schema",
        "relationshipGuid": "5a4510d4-57d0-467c-888f-4b61df42702b",
        "relationshipStatus": "ACTIVE",
        "relationshipAttributes": {
            "typeName": "tabular_schema_columns"
        }
        },
        "meanings": [],
        "outputFromProcesses": [],
        "tabular_schema": null
```

```
    },
    "classifications": [
        {
        "typeName": "MICROSOFT.PERSONAL.EMAIL",
        "lastModifiedTS": "1",
        "entityGuid": "f6095442-f289-44cf-ae56-47f6f6f6000c",
        "entityStatus": "ACTIVE"
        }
    ],
    "contacts": {
        "Expert": [
        {
            "id": "30435ff9-9b96-44af-a5a9-e05c8b1ae2df",
            "info": "Example Expert Info"
        }
        ],
        "Owner": [
        {
            "id": "30435ff9-9b96-44af-a5a9-e05c8b1ae2df",
            "info": "Example Owner Info"
        }
        ]
    }
    }
}
```

> ⓘ Note
>
> You need to migrate the term templates from `typedef` output as well.

When you re-create the custom entities, you might need to prepare the payload prior to sending to the API:

> ⓘ Note
>
> The initial goal is to migrate all entities without any relationships or mappings. This will avoid potential errors.

- All `timestamp` value must be null such as `updateTime`, `updateTime`, and `lastModifiedTS`.
- The `guid` can't be regenerated exactly as before so you have to pass in a negative integer such as "-5000" to avoid error.
- The content of `relationshipAttributes` shouldn't be a part of the payload to avoid errors since it's possible that the `guids` aren't the same or haven't been created yet. You have to turn `relationshipAttributes` into an empty array prior to submitting the payload.

    - `meanings` contains all glossary mappings, which will be updated in bulk after the entities are created.

- Similarly, `classifications` needs to be an empty array as well when you submit the payload to create entities since you have to create classification mapping to bulk entities later using a different API.

Migrate relationships

To complete the asset migration, you must remap the relationships. There are three tasks:

1. Call the relationship API to get relationship information between entities by its `guid`
2. Prepare the relationship payload so that there's no hard reference to old `guids` in the old Microsoft Purview accounts. You need to update those `guids` to the new account's `guids`.
3. Finally, create a new relationship between entities

Migrate glossary terms

> **Note**
>
> Before migrating terms, you need to migrate the term templates. This step should be already covered in the custom `typedef` migration.

Using the Microsoft Purview governance portal

The quickest way to migrate glossary terms is to export terms to a .csv file. You can do this using the Microsoft Purview governance portal.

Using Microsoft Purview API

To automate glossary migration, you first need to get the glossary `guid` (`glossaryGuid`) via List Glossaries API. The `glossaryGuid` is the top/root level glossary `guid`.

The below sample response will provide the `guid` to use for subsequent API calls:

JSON

```
"guid": "c018ddaf-7c21-4b37-a838-dae5f110c3d8"
```

Once you have the `glossaryGuid`, you can start to migrate the terms via two steps:

1. Export Glossary Terms As .csv
2. Import Glossary Terms Via .csv

Assign classifications to assets

> **Note**
>
> The prerequisite for this step is to have all classifications available in the new account from Migrate configuration items step.

You must call the discovery API to get the classification assignments to assets. This is applicable to all assets. If you've migrated the custom assets, the information about classification assignments is already available in `classifications` property. Another way to get classifications is to list classification per guid in the old account.

To assign classifications to assets, you need to associate a classification to multiple entities in bulk via the API.

Assign contacts to assets

If you have extracted asset information from previous steps, the contact details are available from the discovery API.

To assign contacts to assets, you need a list of `guids` and identify all `objectid` of the contacts. You can automate this process by iterating through all assets and reassign contacts to all assets using the Create Or Update Entities API.

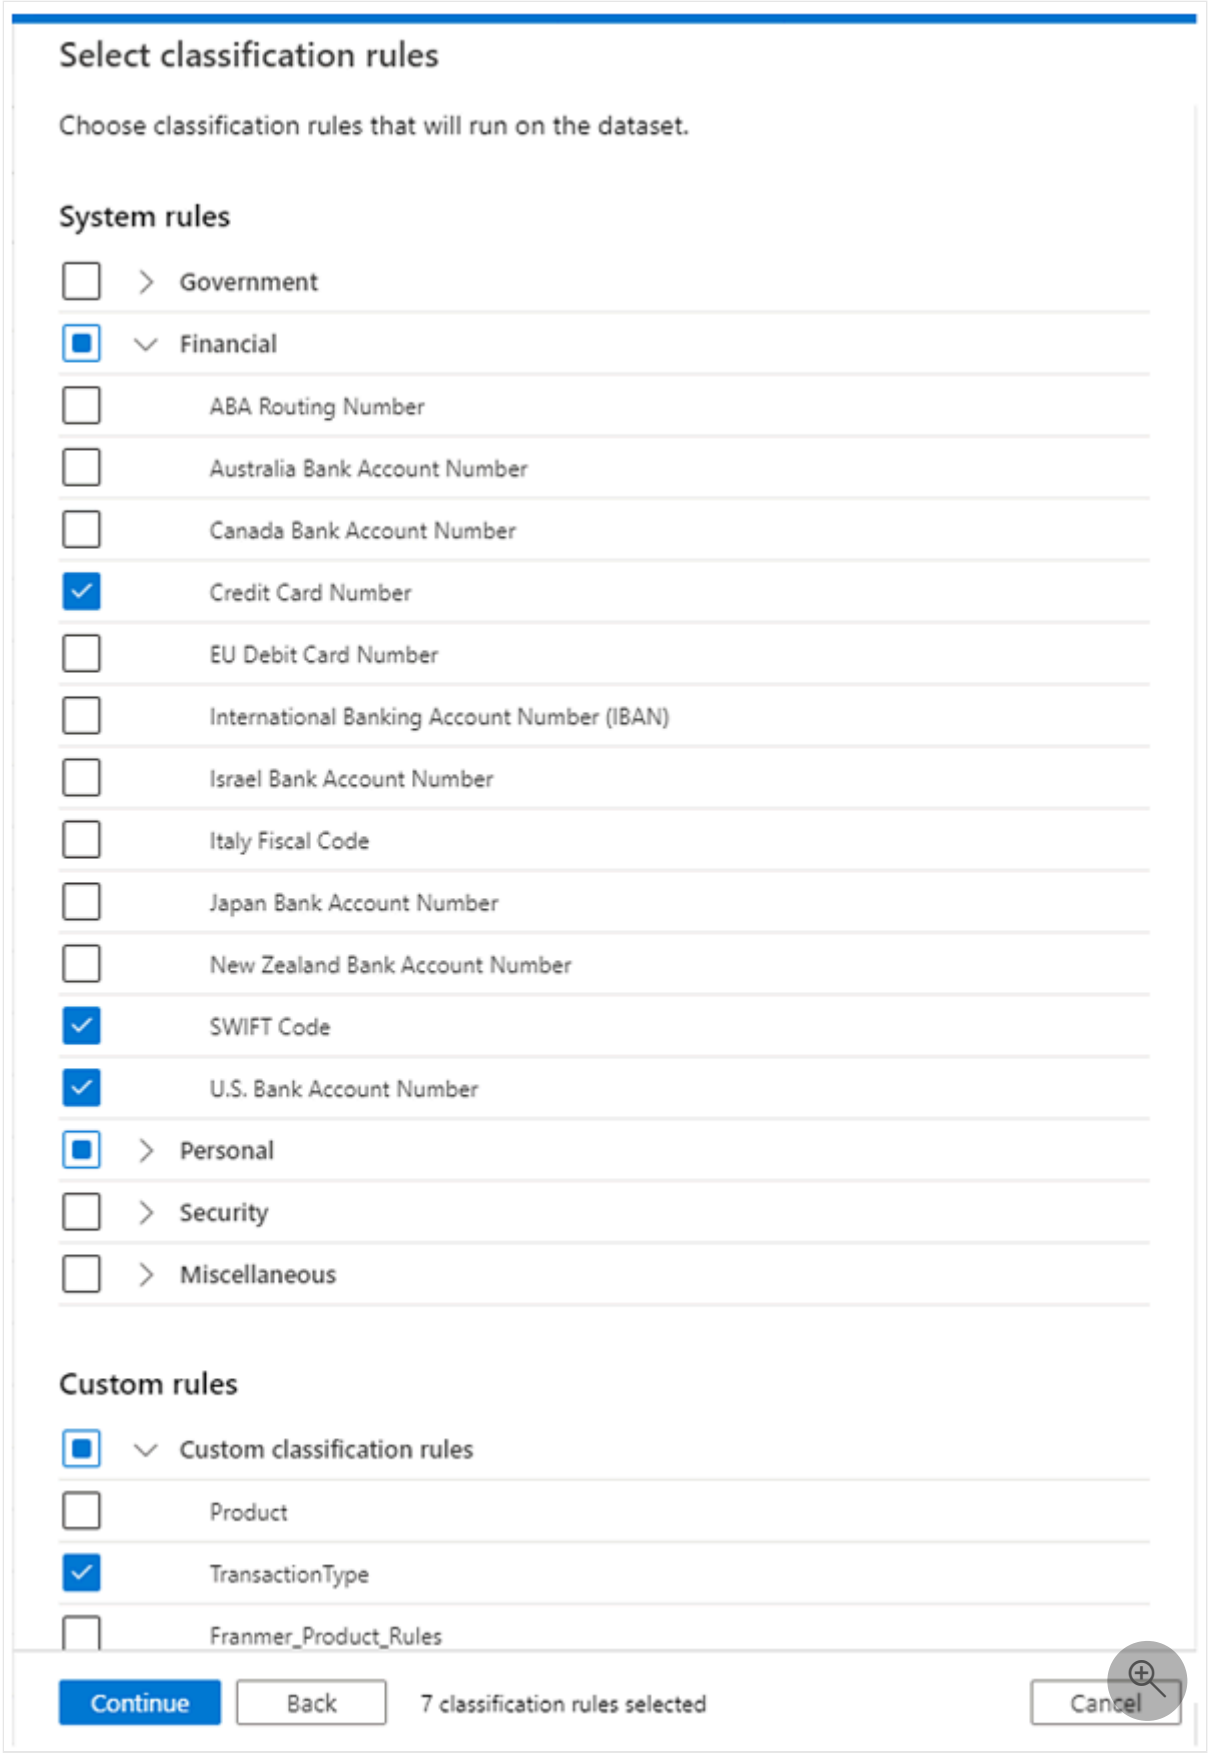
Classification best practices in the Microsoft Purview Data Map

Article • 05/14/2025



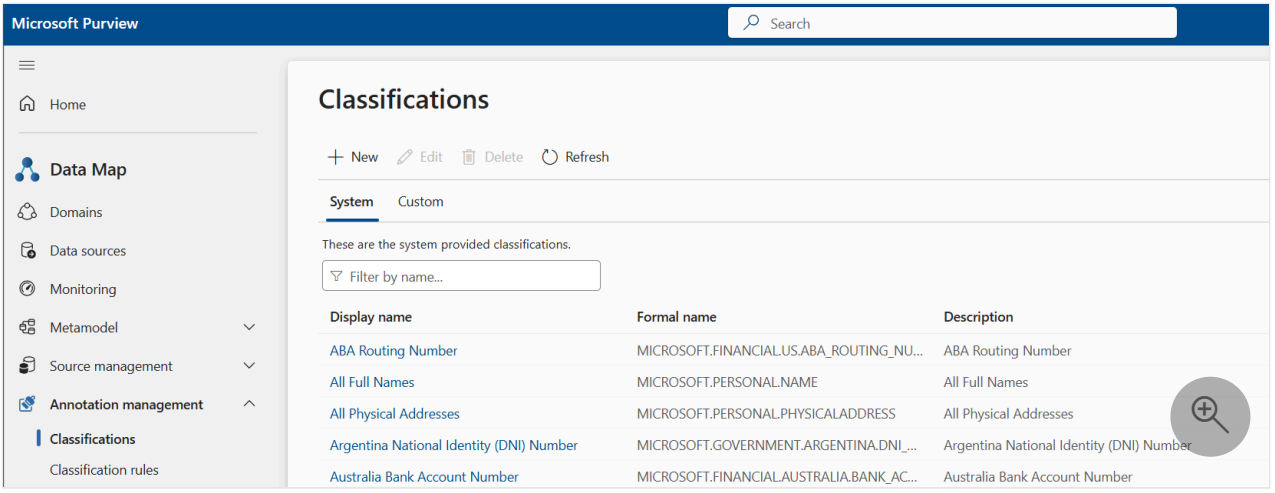
Data classification in the Microsoft Purview Data Map is a way of categorizing data assets by assigning unique logical labels or classes to the data assets. Classification is based on the business context of the data. For example, you might classify assets by *Passport Number*, *Driver's License Number*, *Credit Card Number*, *SWIFT Code*, *Person's Name*, and so on. Learn more about data classification in Data Map.

This article describes best practices to adopt when you're classifying data assets, so that your scans will be more effective and you have the most complete information possible about your entire data estate.

Scan rule set

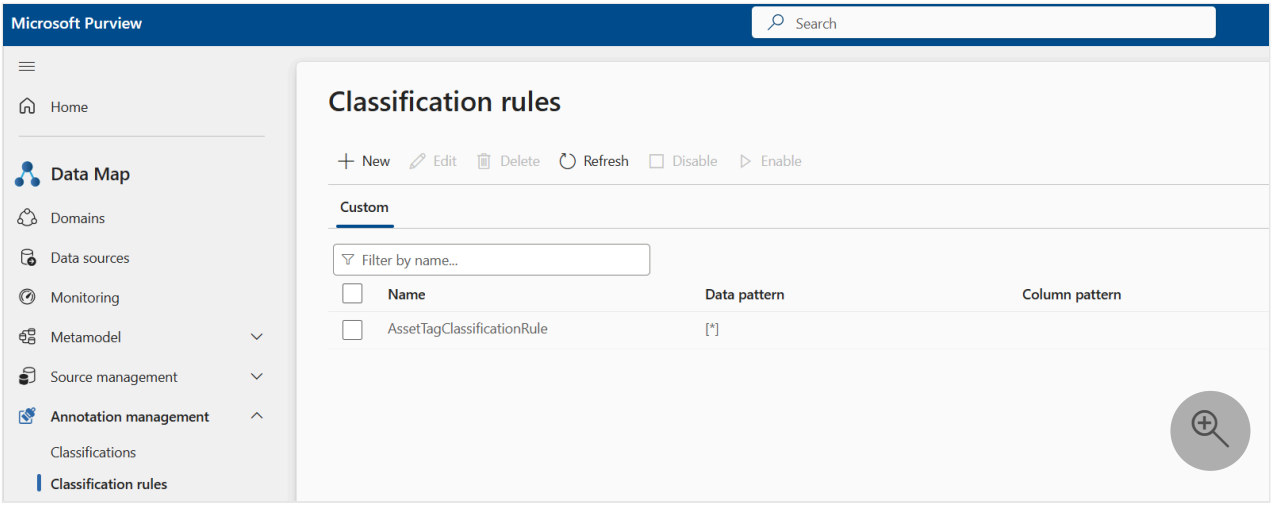
By using a *scan rule set*, you can configure the relevant classifications that should be applied to the particular scan for the data source. Select the relevant system classifications, or select custom classifications if you've created one for the data you're scanning.

For example, in the following image, only the specific selected system and custom classifications will be applied for the data source you're scanning (for example, financial data).



Annotation management

While you're deciding on which classifications to apply, we recommend that you:



- Go to **Data Map** > **Annotation management** > **Classifications** pane.

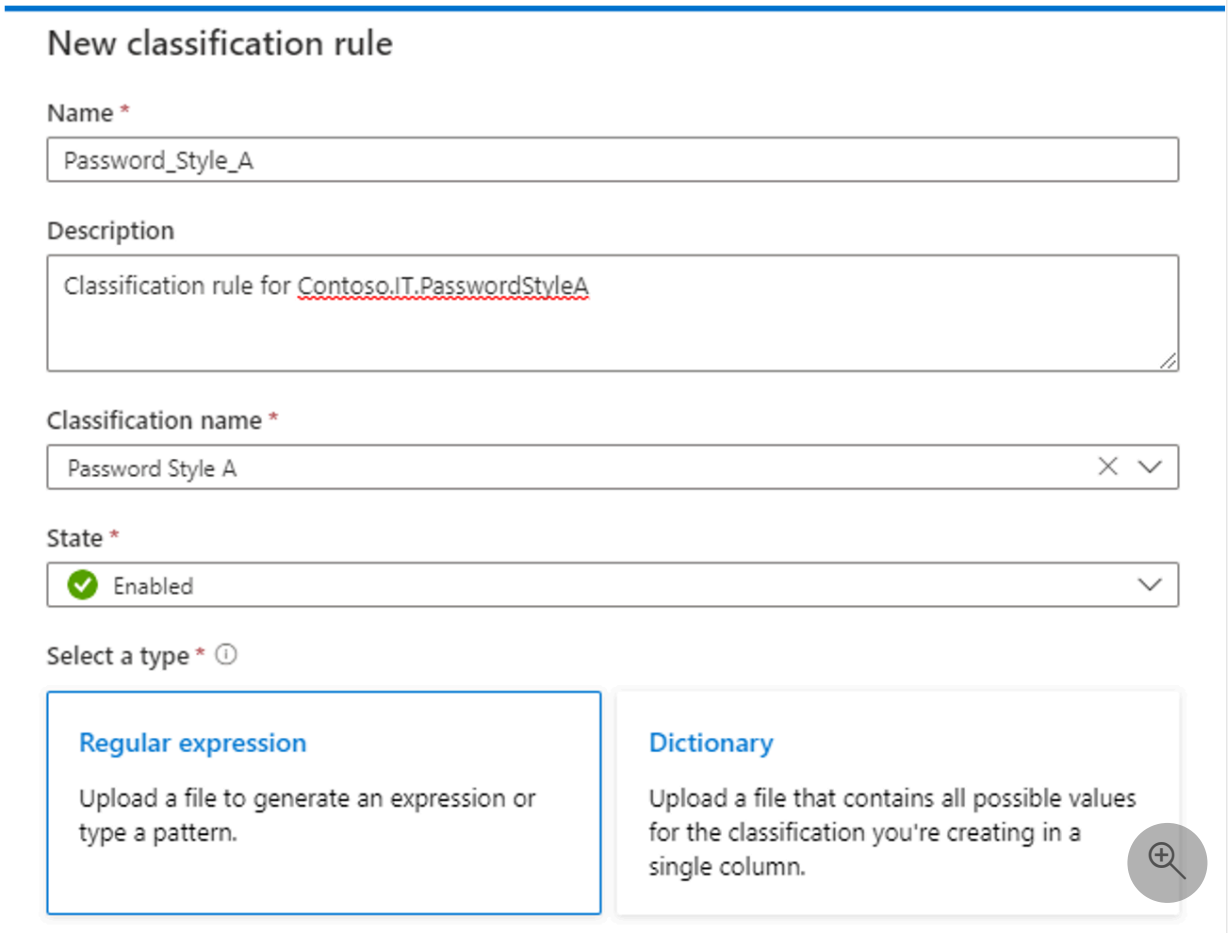
- Review the available system classifications to be applied on the data assets you're scanning. The formal names of system classifications have a *MICROSOFT* prefix.

- Create a custom classification, if necessary. Select the **Custom** tab, and then select **+ New**. Learn how to create a custom classification.

- Create the classification rule for the custom classification that you created in the preceding step. Go to **Data Map** > **Annotation management** > **Classification rules**. Here, you can create the classification rule for the custom classification name that you created in the preceding step.

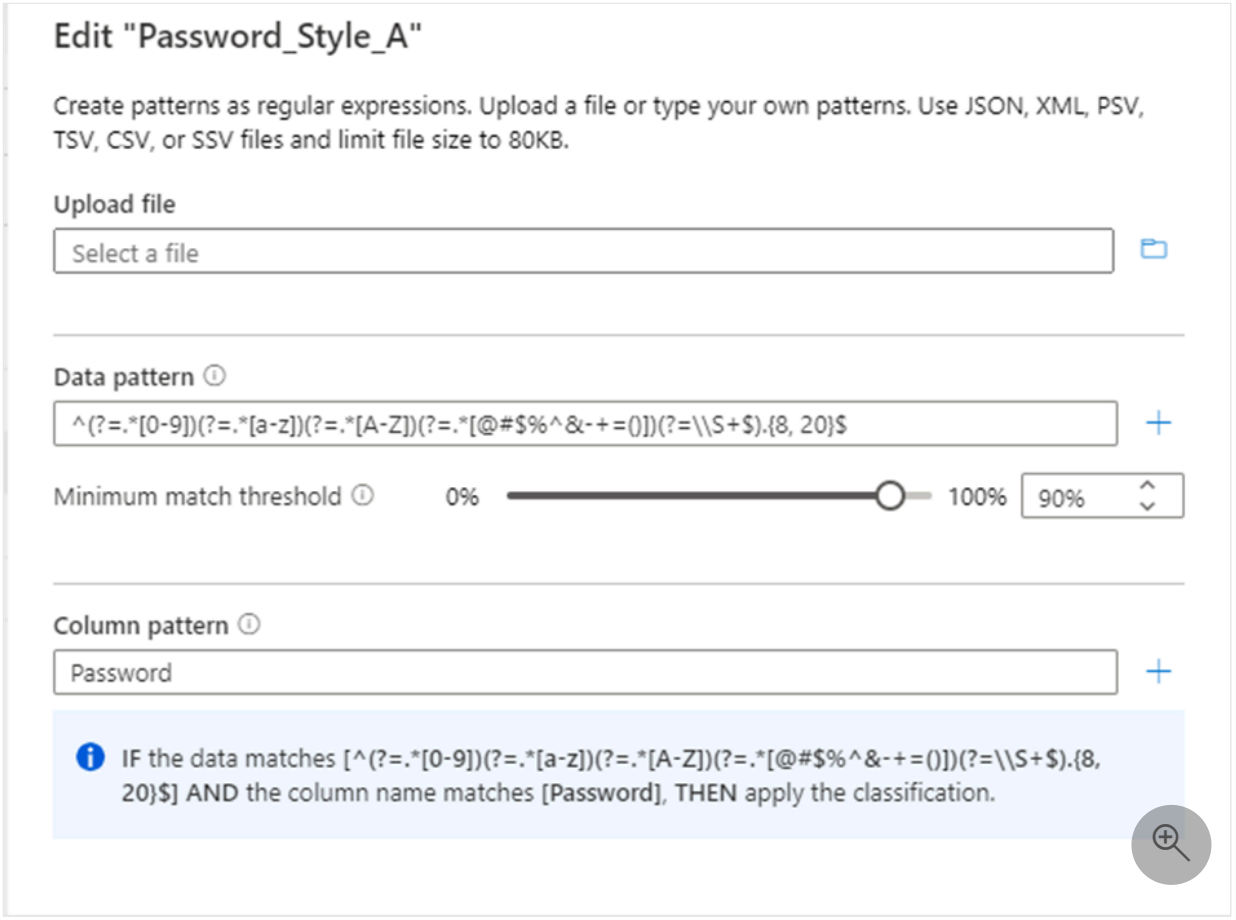
Custom classifications

Create custom classifications only if the available system classifications don't meet your needs.



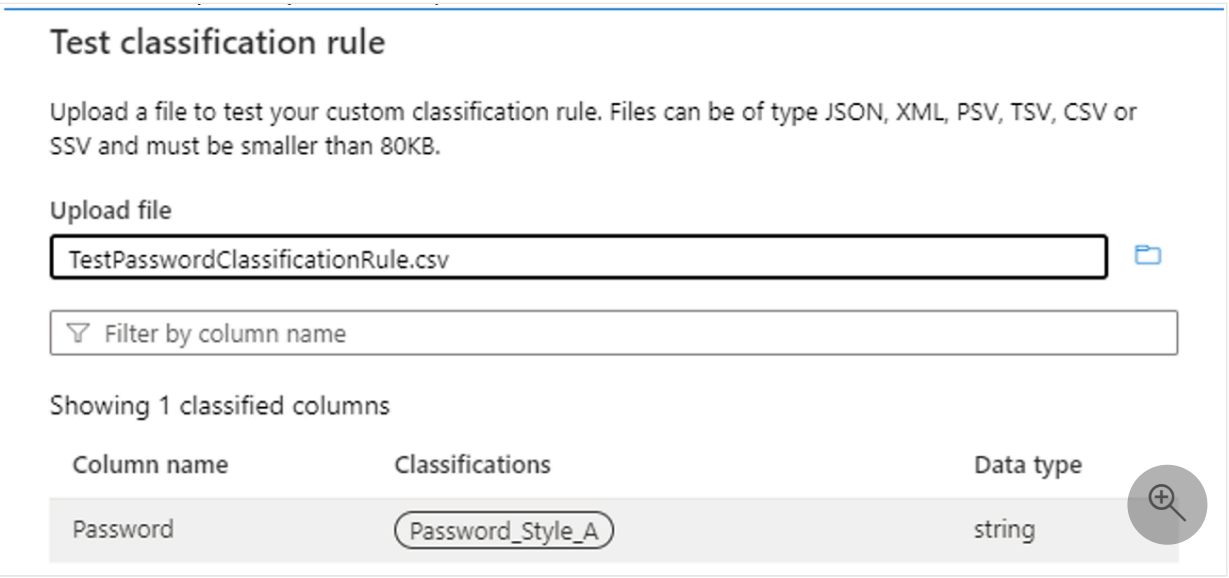
For the *name* of the custom classification, it's a good practice to use a namespace convention (for example, <*company name*>.<*business unit*>.<*custom classification name*>).

As an example, for the custom EMPLOYEE_ID classification for fictitious company Contoso, the name of your custom classification would be CONTOSO.HR.EMPLOYEE_ID, and the friendly name is stored in the system as HR.EMPLOYEE ID.



When you create and configure the classification rules for a custom classification, do the following:

- Select the appropriate classification name for which the classification rule is to be created.
- The Microsoft Purview Data Map supports the following two methods for creating custom classification rules:
    - Use the **Regular expression** (regex) method if you can consistently express the data element by using a regular expression pattern or you can generate the pattern by using a data file. Ensure that the sample data reflects the population.
    - Use the **Dictionary** method only if the list of values in the dictionary file represents all possible values of data to be classified and is expected to conform to a given set of data (considering future values as well).

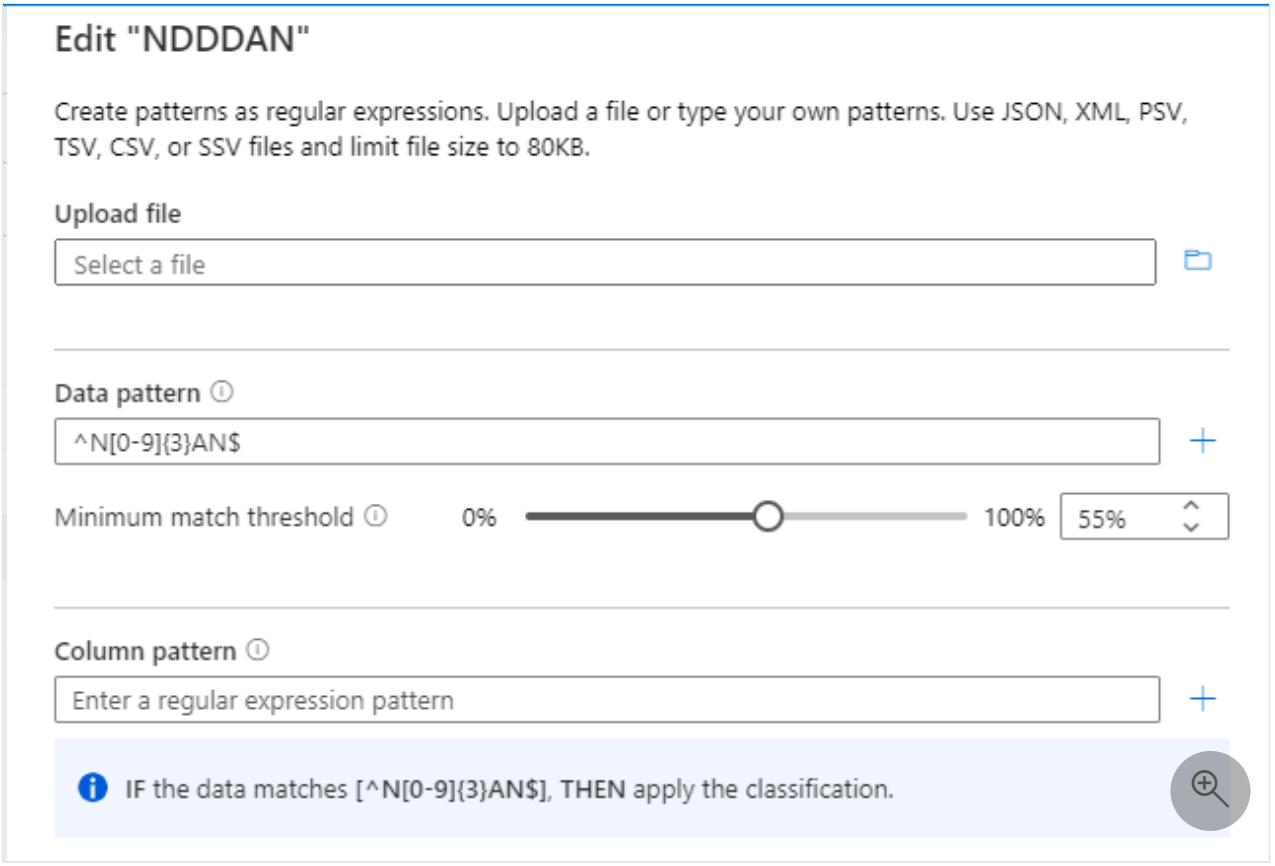


- Using the **Regular expression** method:
    - Configure the regex pattern for the data to be classified. Ensure that the regex pattern is generic enough to cater to the data being classified.

- Microsoft Purview also provides a feature to generate a suggested regex pattern. After you upload a sample data file, select one of the suggested patterns, and then select **Add to patterns** to use the suggested data and column patterns. You can modify the suggested patterns, or you can type your own patterns without having to upload a file.
- You can also configure the column name pattern, for the column to be classified to minimize false positives.
- Configure the *Minimum match threshold* parameter that's acceptable for your data that matches the data pattern to apply the classification. The threshold values can be from 1% through 100%. We suggest a value of at least 60% as the threshold to avoid false positives. However, you could configure as necessary for your specific classification scenarios. For example, your threshold might be as low as 1% if you want to detect and apply a classification for any value in the data if it matches the pattern.

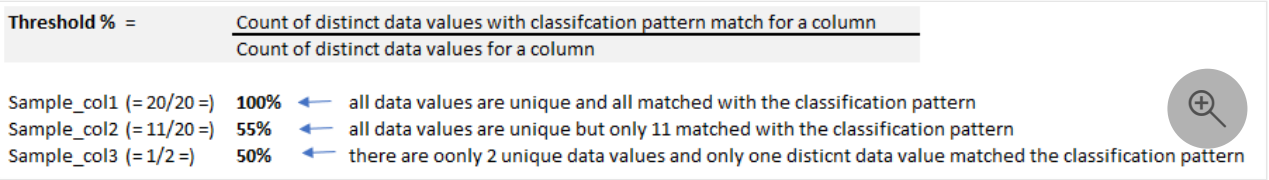
- The option to set a minimum match rule is automatically disabled if more than one data pattern is added to the classification rule.
- Use the *Test classification rule* and test with sample data to verify that the classification rule is working as expected. Ensure that in the sample data (for example, in a .csv file) at least three columns are present, including the column on which the classification is to be applied. If the test is successful, you should see the classification label on the column, as shown in the following image:

- Using the **Dictionary** method:
  - You can use the Dictionary method to fit enumeration data or if the dictionary list of possible values is available.
  - This method supports .csv and .tsv files, with a file size limit of 30 megabytes (MB).



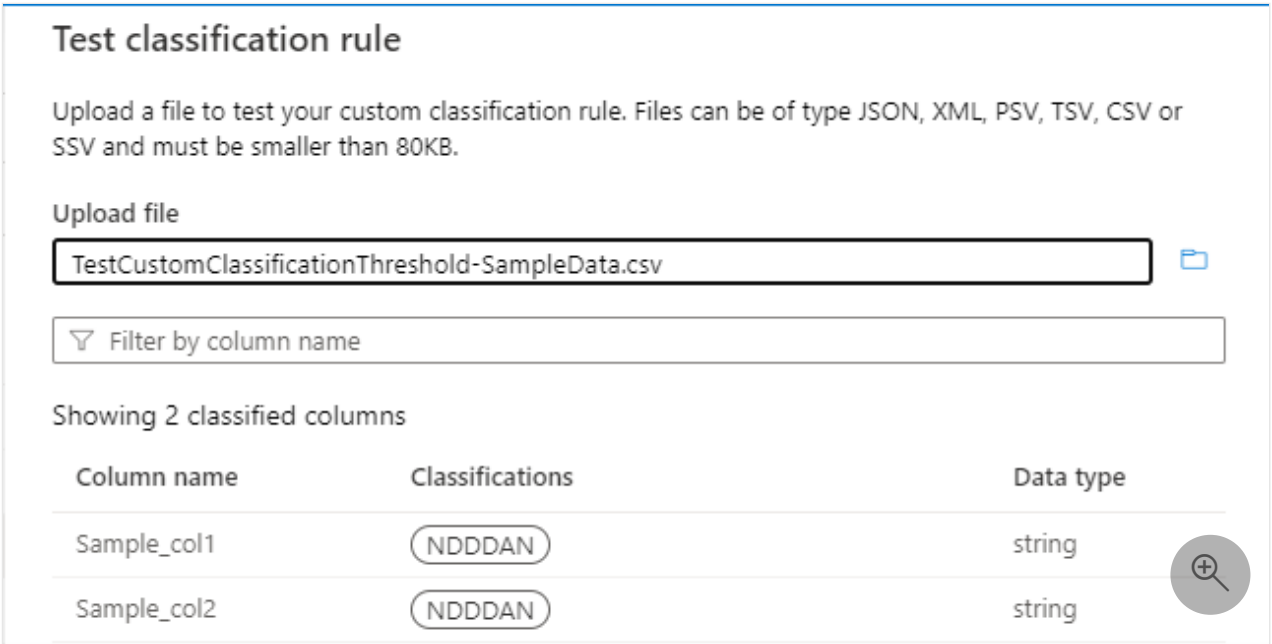
Custom classification archetypes

How the "threshold" parameter works in the regular expression



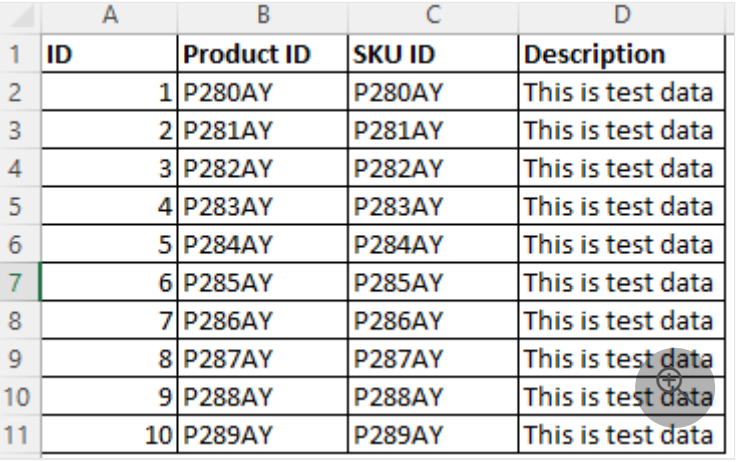
- Consider the sample source data in the following image. There are five columns, and the custom classification rule should be applied to columns **Sample_col1**, **Sample_col2**, and **Sample_col3** for the data pattern *N{Digit}{Digit}{Digit}AN*.

	A	B	C	D	E
1	ID	Sample_col1	Sample_col2	Sample_col3	Description
2	1	N280AN	N280AN	N280AN	This is test data
3	2	N857AN	N857AN	N280AN	This is test data
4	3	N471AN	N471AN	N280AN	This is test data
5	4	N670AN	N670AN	N280AN	This is test data
6	5	N240AN	N240AN	N280AN	This is test data
7	6	N809AN	N809AN	N280AN	This is test data
8	7	N638AN	N638AN	N280AN	This is test data
9	8	N519AN	N519AN	N280AN	This is test data
10	9	N499AN	N499AN	N280AN	This is test data
11	10	N853AN	N853AN	N280AN	This is test data
12	11	N565AN	N565AN	N280AN	This is test data
13	12	N535AN	XYZ123	XYZ123	This is test data
14	13	N825AN	XYZ124	XYZ123	This is test data
15	14	N891AN	XYZ125	XYZ123	This is test data
16	15	N239AN	XYZ126	XYZ123	This is test data
17	16	N889AN	XYZ127	XYZ123	This is test data
18	17	N823AN	XYZ128	XYZ123	This is test data
19	18	N249AN	XYZ129	XYZ123	This is test data
20	19	N637AN	XYZ130	XYZ123	This is test data
21	20	N999AN	XYZ131	XYZ123	This is test data

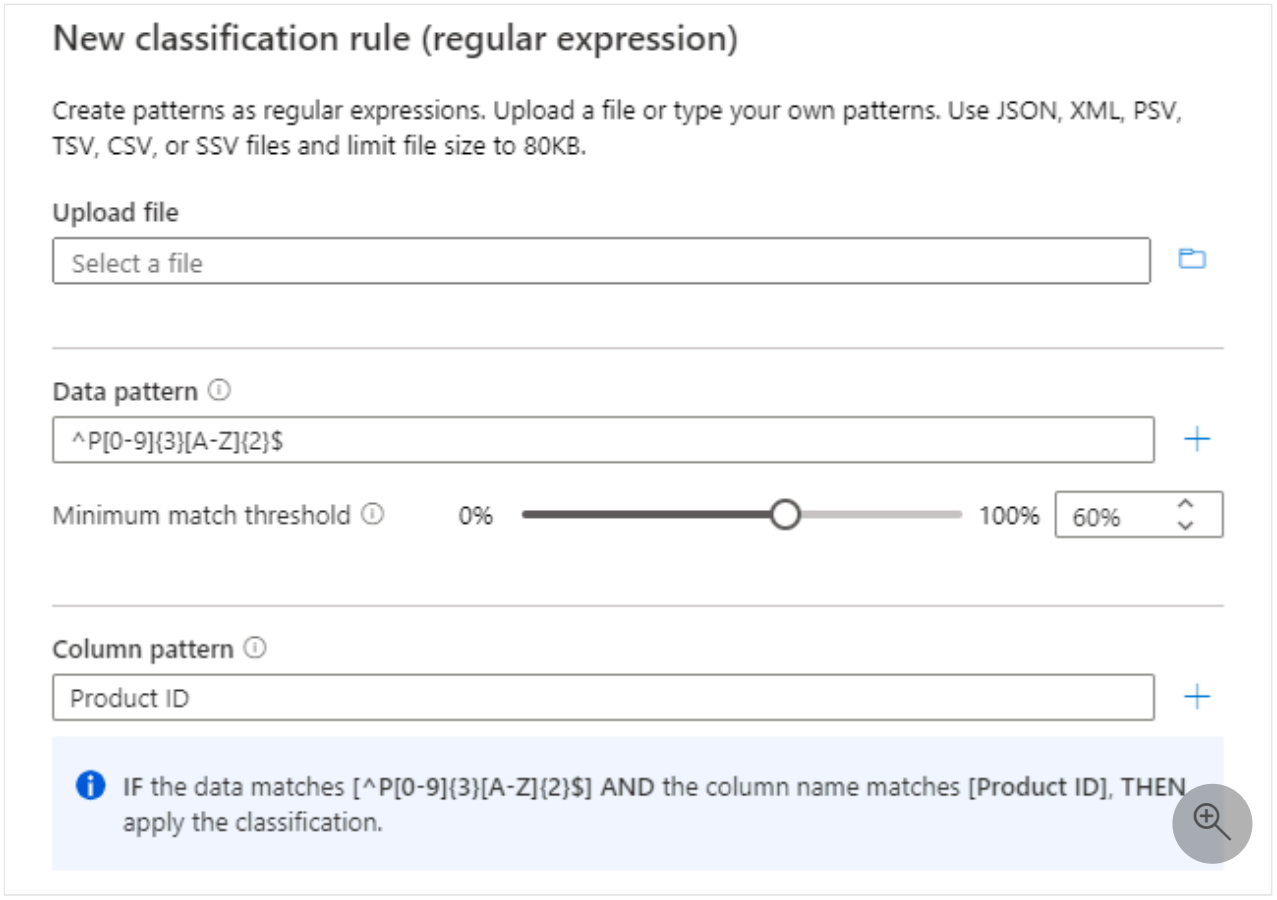


- The custom classification is named NDDDAN.
- The classification rule (regex for the data pattern) is ^N[0-9]{3}AN$.

- The threshold would be computed for the "^N[0-9]{3}AN$" pattern, as shown in the following image:



If you have a threshold of 55%, only columns **Sample_col1** and **Sample_col2** will be classified. **Sample_col3** won't be classified, because it doesn't meet the 55% threshold criterion.

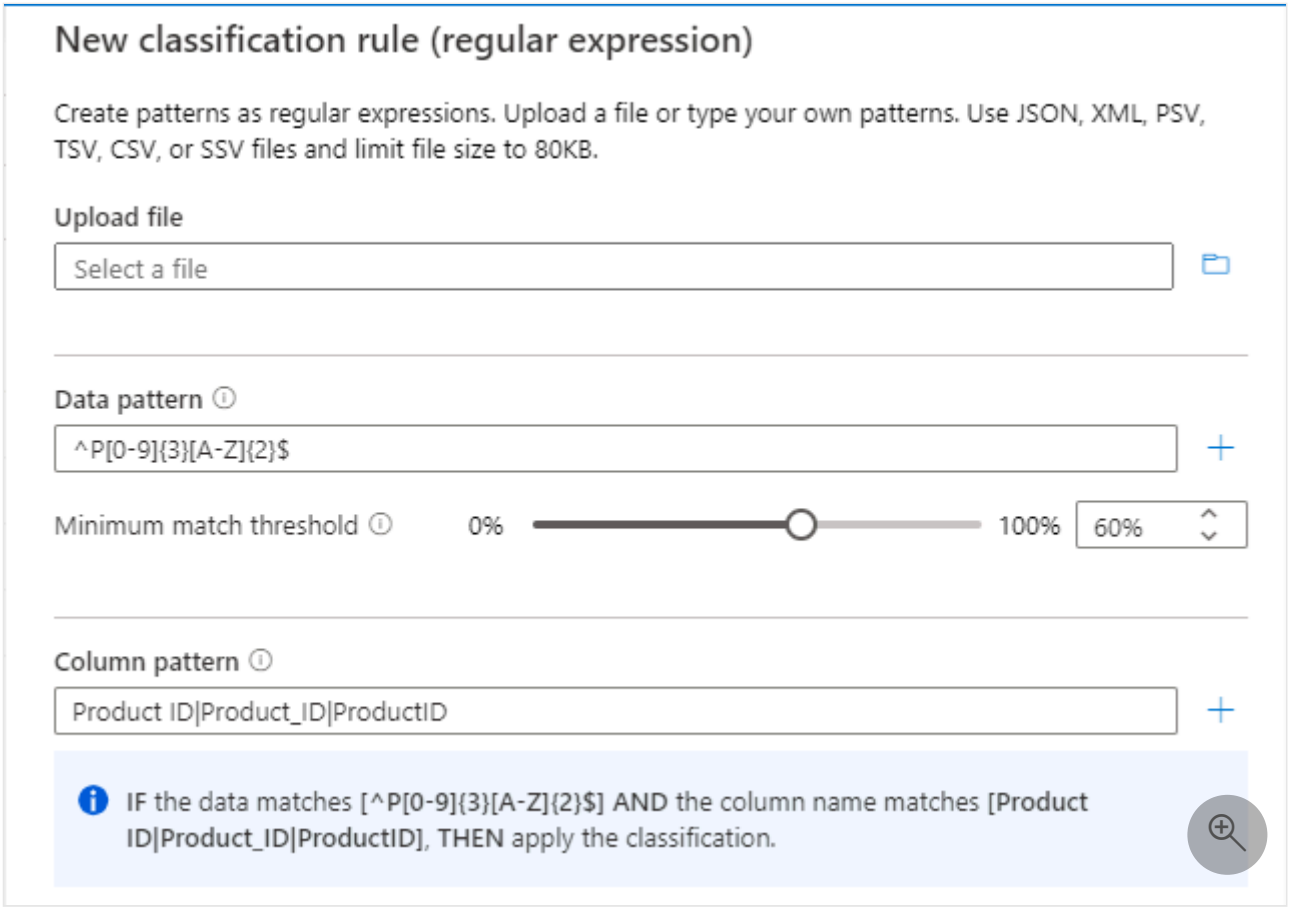


How to use both data and column patterns

- For the given sample data, where both column **B** and column **C** have similar data patterns, you can classify on column **B** based on the data pattern "^P[0-9]{3}[A-Z]{2}$".

	A	B	C	D
1	**ID**	**Product ID**	**SKU ID**	**Description**
2	1	P280AY	P280AY	This is test data
3	2	P281AY	P281AY	This is test data
4	3	P282AY	P282AY	This is test data
5	4	P283AY	P283AY	This is test data
6	5	P284AY	P284AY	This is test data
7	6	P285AY	P285AY	This is test data
8	7	P286AY	P286AY	This is test data
9	8	P287AY	P287AY	This is test data
10	9	P288AY	P288AY	This is test data
11	10	P289AY	P289AY	This is test data

- Use the column pattern along with the data pattern to ensure that only **Product ID** column is classified.



> **Note**
>
> The column pattern is verified as an AND condition with the data pattern.

- Use the *Test classification rule* and test with sample data to verify that the classification rule is working as expected.

How to use multiple column patterns

If there are multiple column patterns to be classified for the same classification rule, use pipe (|) character-separated column names. For example, for columns **Product ID**, **Product_ID**, **ProductID**, and so on, write the column pattern as shown in the following image:

For more information, see regex alternation construct.

Classification considerations

Here are some considerations to bear in mind as you're defining classifications:

- To decide what classifications are required to be applied to the assets prior to scanning, consider how your classifications are to be used. Unnecessary classification labels might look noisy and even misleading for data consumers. You can use classifications to:
  - Describe the nature of the data that exists in the data asset or schema that's being scanned. In other words, classifications should enable customers to identify the content of data asset or schema from the classification labels as they search the catalog.
  - Set priorities and develop a plan to achieve the security and compliance needs of an organization.
  - Describe the phases in the data preparation processes (raw zone, landing zone, and so on) and assign the classifications to specific assets to mark the phase in the process.

- You can assign classifications at the asset or column level automatically by including relevant classifications in the scan rule, or you can assign them manually after you ingest the metadata into the Microsoft Purview Data Map.
- For automatic assignment, see supported data stores for the Microsoft Purview Data Map.
- Before you scan your data sources in the Microsoft Purview Data Map, it's important to understand your data and configure the appropriate scan rule set for it (for example, by selecting relevant system classification, custom classifications, or a combination of both), because it could affect your scan performance. For more information, see supported classifications in Microsoft Purview Data Map.
- The Microsoft Purview scanner applies data sampling rules for deep scans (subject to classification) for both system and custom classifications. The sampling rule is based on the type of data sources. For more information, see the "Sampling within a file" section in Supported data sources and file types in Microsoft Purview.

  > ⓘ **Note**
  >
  > **Distinct data threshold**: This is the total number of distinct data values that need to be found in a column before the scanner runs the data pattern on it. Distinct data threshold has nothing to do with pattern matching but it is a pre-requisite for pattern matching. System classification rules require there to be at least 8 distinct values in each column to subject them to classification. The system requires this value to make sure that the column contains enough data for the scanner to accurately classify it. For example, a column that contains multiple rows that all contain the value 1 won't be classified. Columns that contain one row with a value and the rest of the rows have null values also won't get classified. If you specify multiple patterns, this value applies to each of them.

- The sampling rules apply to resource sets as well. For more information, see the "Resource set file sampling" section in supported data sources and file types in the Microsoft Purview Data Map.
- Custom classifications can't be applied on document type assets using custom classification rules. Classifications for such types can be applied manually only.
- Custom classifications aren't included in any default scan rules. Therefore, if automatic assignment of custom classifications is expected, you must deploy and use a custom scan rule that includes the custom classification to run the scan.
- If you apply classifications manually from the Microsoft Purview governance portal, such classifications are retained in subsequent scans.

- Subsequent scans won't remove any classifications from assets, if they were detected previously, even if the classification rules are inapplicable.
- For *encrypted source* data assets, Microsoft Purview picks only file names, fully qualified names, schema details for structured file types, and database tables. For classification to work, decrypt the encrypted data before you run scans.

Next steps

- Automatically apply classifications
- Manually apply classifications
- Create custom classification

Microsoft Purview domains and collections architectures and best practices

Article • 05/14/2025

At the core of Microsoft Purview data governance solutions, Data Map is a service that keeps an up-to-date map of assets and their metadata across your data estate. To hydrate the data map, you need to register and scan your data sources. In an organization, there might be thousands of sources of data managed and governed by either centralized or decentralized business units, teams, and environments. To manage this, you can use domains and collections in Microsoft Purview.

> **Note**
>
> The best practices recommendations in this article applies to Microsoft Purview accounts that are using a tenant-level account (https://purview.microsoft.com).

Domains

In Microsoft Purview, domains are foundational elements of the Data Map and represent a top-level hierarchy within a Microsoft Purview account. They enable the segregation of responsibilities, effective organization, and management of data governance within the organization specially when there are subsidiaries or business units that operate independently, but they share a common Entra ID tenant. By using domains, organizations can achieve several capabilities, including:

- Organization: Domains help logically group resources such as data sources, assets, scans, and security related resources that belong to a business unit or region.
- Delegation: Domains are a hierarchy above collections, allowing Microsoft Purview admins to delegate specific administrative tasks to subsets of components within Microsoft Purview data governance for specific business units or suborganization.
- Security: By isolating objects within domains, administrators can implement targeted security measures and control access more effectively. For example, resources such as connections, credentials and policies can be specific and visible for a certain domain.
- Lifecycle Management: Domains facilitate the separation of development, test, QA, preproduction, and production resources within the same tenant.
- Isolation of Resources: Domains help isolate resources due to regional, legal, or regulatory requirements.

Collections

Collections in Microsoft Purview support organizational or suborganizational mapping of metadata. By using collections, you can manage and maintain data sources, scans, and assets within a business unit in a hierarchy instead of a flat structure. Collections allow you to build a custom hierarchical model of your data landscape based on how your organization plans to use Microsoft Purview to govern your data.

A collection also provides a security boundary for your metadata in the data map. Access to collections, data sources, and metadata is set up and maintained based on the collections hierarchy in Microsoft Purview, following a least-privilege model:

- Users have the minimum amount of access they need to do their jobs.
- Users don't have access to sensitive data that they don't need.

Understanding the Relationship

- **Domains** are more strategic and policy-centric, while **collections** are more operational and access-centric. For example, in a large healthcare organization with several segments such as Hospitals, Clinics, Research, and Administration, all under the same Microsoft Entra ID tenant, domains, and collections can be defined as follows:
  - Domains: The organization creates domains for each segment. These domains are strategic and policy-centric, meaning they define high-level governance policies, compliance requirements, and data management strategies for each segment. For instance, the Hospitals domain might have policies related to patient data privacy and healthcare regulations, while the Research domain might focus on data sharing agreements and ethical guidelines for clinical trials. Each domain can have their own sets of credentials, scan rulesets, policies, and connections as well as collections, data sources, scans, and assets that aren't visible to users and admins in other domains.
  - Collections: Within the Hospitals domain, there are several operational tasks that need to be managed. The organization creates collections for different operational units such as Emergency Services, Inpatient Care, and Outpatient Services. These collections are more operational and access-centric, meaning they organize data sources, assets, and scan specific to each operational unit. Access to these collections is controlled based on the roles and responsibilities of the users within the Hospitals segment. For example, only emergency department staff might have access to the Emergency Services collection, while inpatient care managers have access to the Inpatient Care collection.
- **Collections** can exist within domains, inheriting the governance policies set at the domain level.
- In Microsoft Purview data governance, domains and collections have distinct functions. An account can have one default domain and up to four custom domains. Each domain can have its own collection hierarchy.

- A user member of **Purview Administrators** role can create and manage domains and delegate access to each business unit to manage their own domains by granting them access as **Purview Domain Manager** role.

Define a hierarchy

Design recommendations

- Start designing your domains and collections architecture based on your organization's legal, security requirements considering data management, and governance structure of your organization. Review the recommended archetypes in this article.
- Consider security and access management as part of your design decision-making process when you build domains and collections in Microsoft Purview.
- Start with default domain and build collection hierarchy inside the default domain. Use additional domains if you have any of the following requirements:
  - You need to build prod and non-prod environments under the same tenant.
  - You have multiple regions and need to logically separate resources and segregate responsibilities across these regions.
  - Your organization has multiple companies or business unit under the same tenant, and need to separate resources and segregate management and responsibilities.
- Each domain or collection has a name attribute and a friendly name attribute. If you use the Microsoft Purview governance portal to deploy a domain or collection, the system automatically assigns a random six-letter name to avoid duplication.
- Currently, a domain or collection name can contain up to 36 characters and a collection friendly name can have up to 100 characters.
- When you can, avoid duplicating your organizational structure into a deeply nested collection hierarchy. If you can't avoid doing so, be sure to use different names for every collection in the hierarchy to make the collections easy to distinguish.
- Automate deployment of domains and collections by using the API if you're planning to deploy domains and collections and role assignments in bulk.
- Use a dedicated service principal name (SPN) to run operations on Data Map for managing domains, collections and role assignments by using the API. Using an SPN

reduces the number of users who have elevated rights and follows least-privilege guidelines.

Design considerations

- Domains are available only to Microsoft Purview accounts using a tenant-level account.
- Consider that a Microsoft Purview account can have up to four domains in addition to the default domain. As part of consolidating your current Microsoft Purview accounts, the content of existing data maps including collections, data sources, assets and scans are migrated to a new domain.
- Create new domain if you're planning to onboard a new organization in your tenant that they have a different legal requirement.
- The following resources are deployed at tenant level and visible across all domains:
  - Typedefs
  - Managed attributes
  - Glossary terms
  - Classifications and classification rules
  - Metamodel
  - Integration runtimes
  - Workflows
- Domains provide separation of the following resources:
  - Credentials
  - Security connections
  - Custom scan rule sets
  - Advanced resource sets and pattern rules
  - Policies
  - ADF connections
  - Collections and all resources that can be scoped to a collection
- Collections provide separation of the following resources:
  - Data sources
  - Scans
  - Assets
- Each Microsoft Purview account is created with a default domain. The default domain name is the same as your Microsoft Purview account name. The default domain can't be removed, however, you can change the default domain's friendly name.

- A collection can have as many child collections as needed. But each collection can have only one domain and a parent collection.
- A collections hierarchy in a Microsoft Purview can support as many as 1000 collections, with a maximum of eight levels of depth. This doesn't include the root collection.
- By design, you can't register data sources multiple times in a single Microsoft Purview account. This architecture helps to avoid the risk of assigning different levels of access control to a single data source. If multiple teams consume the metadata of a single data source, you can register and manage the data source in a parent collection. You can then create corresponding scans under each subcollection so that relevant assets appear under each child collection.
- Lineage connections and artifacts are attached to the default domain even if the data sources are registered at lower-level collections.
- When you run a new scan, by default, the scan is deployed in the same collection as the data source. You can optionally select a different subcollection to run the scan. As a result, the assets belong under the subcollection.
- You can delete a domain if it's empty.
- You can delete a collection if it does not have any assets, associated scans, data sources or child collections.
- Moving data sources across collections is allowed if the user is granted the Data Source Admin role for the source and destination collections.
- Moving assets across collections is allowed if the user is granted the Data Curator role for the source and destination collections.
- To perform move and rename operations on a collection, review the following recommendations and considerations:

    1. To rename a collection, you must be member of collection admins role.
    2. To move a collection, you must be member of collection admins role on the source and destination collections.

Define an authorization model

Microsoft Purview contains roles in Microsoft Defender for Office 365 as well as roles that exist inside Microsoft Purview data plane. After you deploy a Microsoft Purview account, a default domain is automatically created and the creator of the Microsoft Purview account becomes

part of Purview Administrators role. For more information about permissions for the Microsoft Purview Data Map and Unified Catalog, see the roles and permissions documentation.

Design recommendations

- Consider implementing emergency access or a break-glass strategy for your tenant, so you can recover access to Microsoft Purview default domain when needed, to avoid Microsoft Purview account-level lockouts. Document the process for using emergency accounts.
- Minimize the number of Purview Administrators, domain admins and collection admins. Assign a maximum of three domain admin users at the default domain, including the SPN and your break-glass accounts. Assign your Collection Admin roles to the top-level collection or to subcollections instead.
- Assign roles to groups instead of individual users to reduce administrative overhead and errors in managing individual roles.
- Assign the service principal at the root collection for automation purposes.

To increase security, enable Microsoft Entra Conditional Access with multifactor authentication for purview administrators, domain admins and collection admins, data source admins, and data curators. Make sure emergency accounts are excluded from the Conditional Access policy.

Design considerations

- Microsoft Purview access management has moved into data plane and roles in Microsoft Defender for Office 365. Azure Resource Manager roles aren't used anymore, so you should use Microsoft Purview to assign roles.
- In Microsoft Purview, you can assign roles to users, security groups, and service principals (including managed identities) from Microsoft Entra ID on the same Microsoft Entra tenant where the Microsoft Purview account is deployed.
- You must first add guest accounts to your Microsoft Entra tenant as B2B users before you can assign Microsoft Purview roles to external users.
- By default, domain admins also obtain data source admins, data reader and data curator roles so they have access to read or modify assets.
- By default, Global Administrator is added as collection admins on the default domain.
- By default, all role assignments are automatically inherited by all child collections. But you can enable **Restrict inherited permissions** on any collection except for the root collection.

Restrict inherited permissions removes the inherited roles from all parent collections, except for the collection admin role.

- For Azure Data Factory connection: to connect to Azure Data Factory, you have to be a collection admin on the default domain.
- If you need to connect to Azure Data Factory for lineage, grant the Data Curator role to the data factory's managed identity at your Microsoft Purview root collection level. When you connect Data Factory to Microsoft Purview in the authoring UI, Data Factory tries to add these role assignments automatically. If you have the collection admin role on the Microsoft Purview default domain, this operation works.

Domains and collections archetypes

You can deploy your Microsoft Purview domains and collections based on centralized, decentralized, or hybrid data management and governance models. Base this decision on your business, legal and security requirements.

Example 1: Single organization with a single environment and shared legal requirements

This structure is suitable for organizations that:

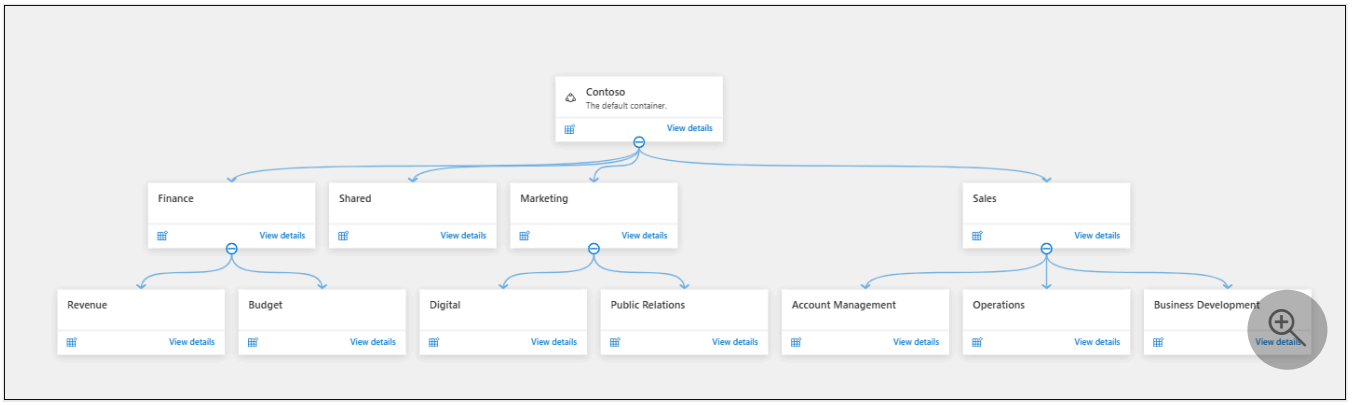
- Are based in a single geographic location and operate under same legal requirements.
- Have a centralized data management and governance team where the next level of data management falls into departments, teams, or projects.

The hierarchy consists of these verticals:

Domains:

- Default domain: Contoso

Collections under default domain:



- Departments (a delegated collection for each department)
- Teams or projects (further segregation based on projects)

There's no need for more domains, since there are no specific business or legal requirements to add more.

Organization-level shared data sources are registered and scanned in the Hub collection.

The department-level shared data sources are registered and scanned in the department collections.

Each data source is registered and scanned in its corresponding collection. So assets also appear in the same collection.

Example 2: Single multi-region organization with centralized management

This scenario is useful for organizations:

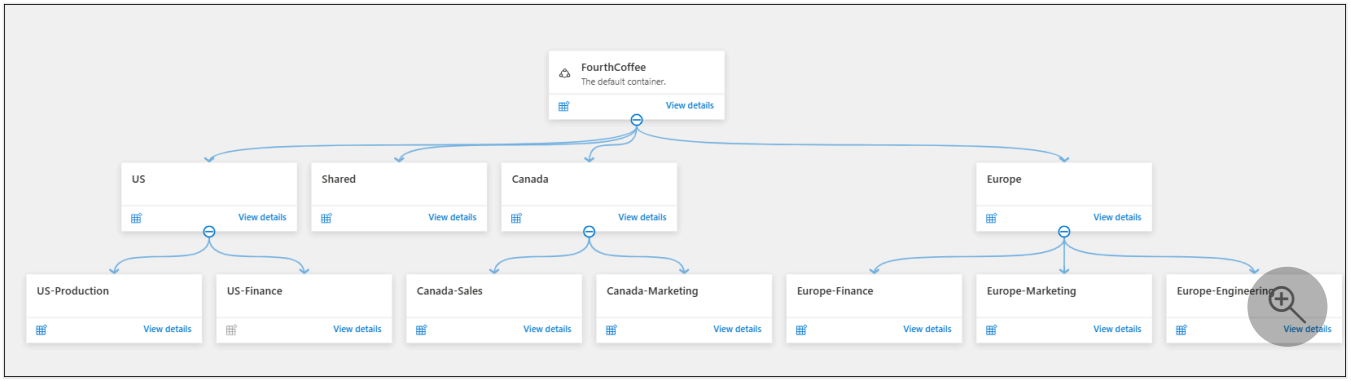
- That have presence in multiple regions.
- Where the data governance team is centralized or decentralized in each region.
- Where data management teams are distributed in each geographic location, and there's also a centralized federated management.
- Teams that need to manage their own data sources and resources

The domain and collection hierarchy consists of these verticals:

Domains:

- Default domain: FourthCoffee

Collections under default domain:



- Geographic locations (top-level collections based on geographic locations where data sources and data owners are located)
- Departments (a delegated collection for each department)
- Teams or projects (further segregation based on projects)

In this scenario, each region has a collection of its own under the default domain in the Microsoft Purview account. Data sources are registered and scanned in the corresponding collections in their own geographic locations. So assets also appear in the collection hierarchy for the region.

If you have centralized data management and governance teams, you can grant them access from the default domain. When you do, they gain oversight for the entire data estate in the data map. Optionally, the centralized team can register and scan any shared data sources. The centralized team can also manage security resources such as credentials and integration runtimes.

Region-based data management and governance teams can obtain access from their corresponding collections.

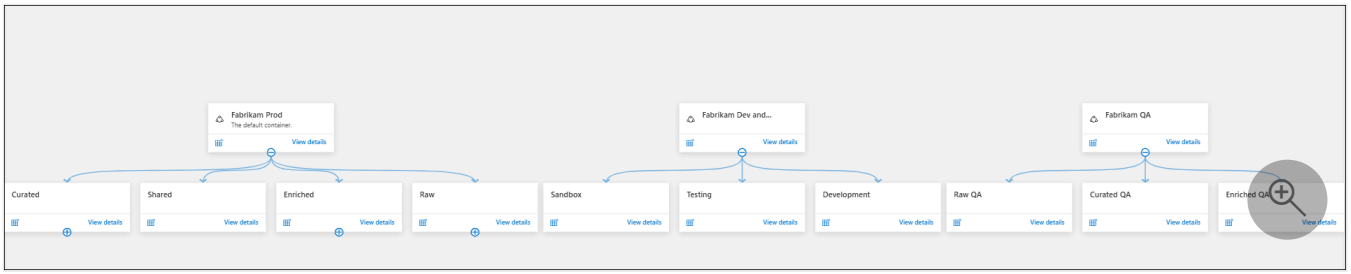
The department-level shared data sources are registered and scanned in the department collections.

Example 3: Single organization with multiple environments

This scenario can be useful if you have single tenant for all types of prod and non-prod environments and you need to isolate resources as much as possible. Data scientists and data engineers who can transform data to make it more meaningful, can manage Raw and Refine zones. They can then move the data into Produce or Curated zones in the corresponding environments.

The domain and collection hierarchy consists of these verticals:

Domains:



- Default domain: Fabrikam production
- Custom domain 1: Dev and Test
- Custom domain 2: QA

Collections under each domain could follow any of these verticals:

- Departments, Teams or projects (further segregation based on projects)
- Data transformation stages (Raw, Enriched, Produce/Curated, Development, etc.)

Data scientists and data engineers can have the Data Curators role on their corresponding zones so they can curate metadata. Data Reader access to the curated zone can be granted to

entire data personas and business users.

Example 4: Multiple organizations or companies, using the same Entra ID tenant with decentralized management

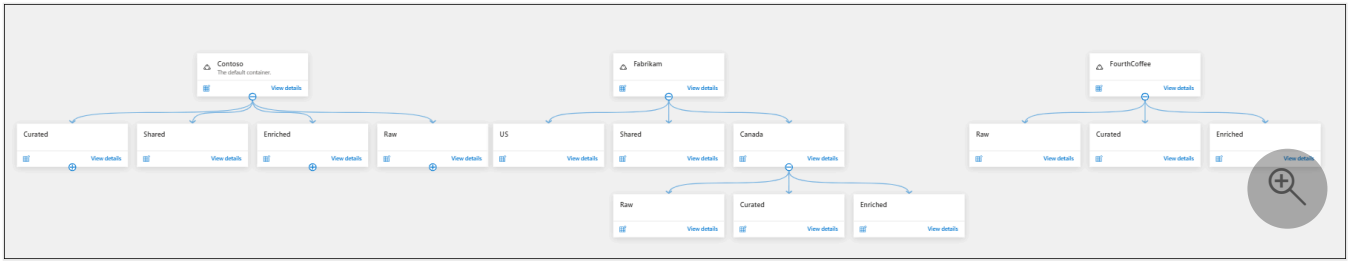
This option can be used for scenarios where multiple companies share the same Entra ID tenant and each organization need to organize metadata and manage their own resources

> ⓘ **Note**
>
> If you previously had multiple Microsoft Purview accounts in your tenant, the first account you select to migrate becomes default domain and you can upgrade the other accounts into separate domains.

The domain and collection hierarchy consists of these verticals:

Domains:

- Default domain: parent company or organization such as Contoso
- Custom domain 1: FourthCoffee
- Custom domain 2: Fabrikam



Collections under each domain could follow any of these verticals:

- Departments, teams or projects (further segregation based on projects)
- Data transformation stages (Raw, Enriched, Produce/Curated, Development, etc.)
- Regions within an organization

Each organization has a domain of its own with their own collections hierarchy in the Microsoft Purview account. Security resources are managed inside each domain and data sources are registered and scanned in the corresponding domains. Assets are added to the subcollection hierarchy for the specific domain.

If you have centralized data management and governance organization, that can be the default domain, so they can manage shared resources such as integration run-times, managed attributes, etc.

Organizational data management and governance teams can obtain access from their corresponding collections at a lower level, depending in centralized or decentralized management in each domain.

> **Note**
>
> A shared non-production domain can be created and used by multiple organizations, each org having their own top level collection in the non-prod domain.

Access management options

If you want to implement data democratization across an entire organization, use one domain and assign the Data Reader role at the default domain to data management, governance, and business users. Assign Data Source Admin and Data Curator roles at the subcollection levels to the corresponding data management and governance teams.

If you need to restrict access to metadata search and discovery in your organization, assign Data Reader and Data Curator roles at the specific collection level. For example, you could restrict US employees so they can read data only at the US collection level and not in the LATAM collection.

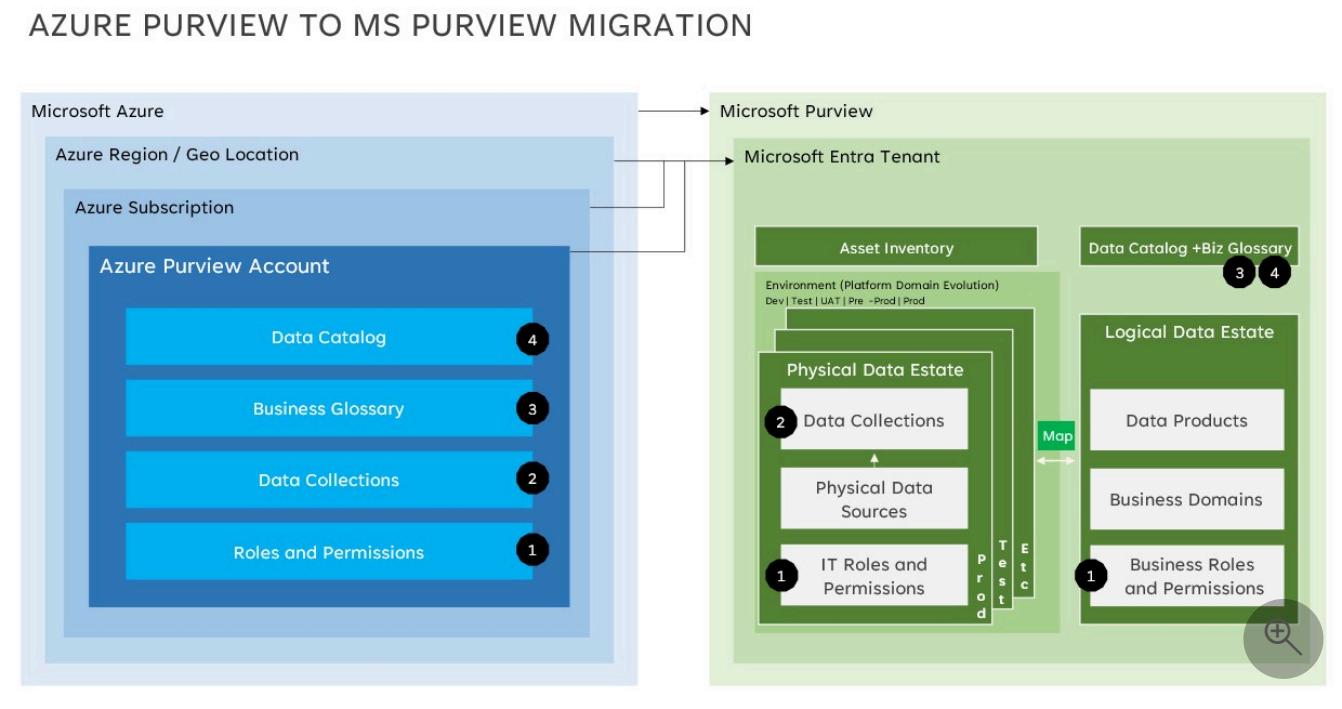
Create additional domains only if you need to, such as when separating prod and non-pro environments, upgrading multiple accounts into one unified account or have multiple companies inside the same tenant who have different security requirements.

You can apply a combination of these scenarios in your Microsoft Purview Data Map by using domains and collections.

Assign the domain admin role to the centralized data security and management team at the default collection. Delegate further domains or collection management of additional domains and lower-level collections to corresponding teams.

Next steps

- Manage domains and collections in the Microsoft Purview Data Map



- Governance roles and permissions in free and enterprise account types

Governance domains and domain recommendations

Article • 05/14/2025

> **ⓘ Important**
>
> - Domains in Data Map are limitied to 5 total.
> - Collections are limited to 1000 across all platform domains. (One domain can have 1000 collections; 5 plaform domains would have 200 collections each if spread evenly.)
> - Data sources are registered in one collection in one domain.
> - Assets from a scanned data source must be scanned in the same domain as the data source.
> - Merging an account will create a domain.
> - Fabric domains likey don't map to domains, as the number of Fabric domains will exceed the 5 domains limit.

General recommendations

- If true separation is required separate tenants are needed to enable different implementations of Microsoft Purview. Creating separate tenants isn't a likely solution for most organizations, but in some regulatory environments could be needed.

- Many organizations already have a SaaS model for deployment they can follow from Microsoft 365 or PBI/Fabric. Following that pattern within the organization can help resolve the SaaS deployment concerns.

Collections and domains

- Using collections offer access segmentation for most needs to different users to get only the access required to Data Map.
- Use collections for technical separation along IT teams and enable onboarding, the governance domains can be used for the business team separations and logical concept boundaries (glossary terms and data products).
- For data sources that don't have production and nonproduction separate resources, data sources that have both requires the use of collections for testing because each data source is registered to one domain and one collection.

Domains and governance domains

- Use dev, test, production governance domains (Finance.dev, Finance.prod, etc.) to separate testing with concepts and consumption experience. When testing isn't needed or shouldn't be made visible to consumers of the catalog, you can expire or repurpose the governance domain for production if concepts are ready for production.
- Plan to segment billing with governance domains not collections or platform domains.
- Governance domains can be mapped to platform domains and collections to build a logical relationship between the governance domains and the parts of Data Map that house their data assets.

Domain recommendations

Nonrecommended uses of the domains in Data Map

- Isolation of geo-residency segmentation.
- Domains don't scale to create boundaries along geo-residency segmentation needs.
- Domains don't enable separate storage locations for metadata.
- Business continuity and disaster recovery scenarios aren't recommended because if one domain is down all others are down.
- Metadata would need to be downloaded to an alternate source.
- Business unit isolation is best handled with Governance domains.
- Billing separation would follow the practice of using Governance domains.

Recommended uses of the domains in Data Map

- Lifecycle Management (Development, test, Quality Assurance, Production), most customers have nonproduction and production resources, which are intended to be kept separate from production resources. Separation can be achieved with either domains or collections. When there's nonproduction and production data in the same resource, the customer has to use collections.

Microsoft Purview (formerly Azure Purview) deployment best practices

> **Note**
>
> Microsoft Purview Data Catalog (classic), Data Health Insights (classic), and Purview Workflow (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Note**
>
> These best practices cover the deployment for classic Microsoft Purview governance solutions.
>
> For information about deploying the new Microsoft Purview data governance features, see our quickstart article.
>
> For more information about Microsoft Purview risk and compliance solutions, go here. For more information about Microsoft Purview in general, go here.

This article is a guide to successfully deploying Microsoft Purview (formerly Azure Purview) into production in your data estate. It's intended to help you strategize and phase your deployment from research to hardening your production environment, and is best used in tandem with our deployment checklist.

If you're looking for a strictly technical deployment guide, use the deployment checklist.

If you're creating a plan to deploy Microsoft Purview and want to consider best practices as you develop your deployment strategy, then follow the article below. This guide outlines tasks can be completed in phases over the course of a month or more to develop your deployment process for Microsoft Purview. Even organizations who have already deployed Microsoft Purview can use this guide to ensure they're getting the most out of their investment.

A well-planned deployment of your governance platform, can give the following benefits:

- Better data discovery
- Improved analytic collaboration

- Maximized return on investment

This guide provides insight on a full deployment lifecycle, from initial planning to a mature environment by following these stages:

Expand table

Stage	Description
Identify objectives and goals	Consider what your entire organization wants and needs from data governance.
Gathering questions	What questions might you and your team have as you get started, and where can you look to begin addressing them?
Create a process to move to production	Create a phased deployment strategy tailored to your organization.
Platform hardening	Continue to grow your deployment to maturity.

Many of Microsoft Purview's applications and features have their own individual best practices pages as well. They're referenced often throughout this deployment guide, but you can find all of them in the table of contents under **Concepts** and then **Best practices and guidelines**.

Identify objectives and goals

Many organizations have started their data governance journey by developing individual solutions that cater to specific requirements of isolated groups and data domains across the organization. Although experiences may vary depending on the industry, product, and culture, most organizations find it difficult to maintain consistent controls and policies for these types of solutions.

Some of the common data governance objectives that you might want to identify in the early phases to create a comprehensive data governance experience include:

- Maximizing the business value of your data
- Enabling a data culture where data consumers can easily find, interpret, and trust data
- Increasing collaboration amongst various business units to provide a consistent data experience
- Fostering innovation by accelerating data analytics to reap the benefits of the cloud
- Decreasing time to discover data through self-service options for various skill groups
- Reducing time-to-market for the delivery of analytics solutions that improve service to their customers

- Reducing the operational risks that are due to the use of domain-specific tools and unsupported technology

The general approach is to break down those overarching objectives into various categories and goals. Some examples are:

Expand table

Category	Goal
Discovery	Admin users should be able to scan Azure and non-Azure data sources (including on-premises sources) to gather information about the data assets automatically.
Classification	The platform should automatically classify data based on a sampling of the data and allow manual override using custom classifications.
Consumption	The business users should be able to find information about each asset for both business and technical metadata.
Lineage	Each asset must show a graphical view of underlying datasets so that the users understand the original sources and what changes have been made.
Collaboration	The platform must allow users to collaborate by providing additional information about each data asset.
Reporting	The users must be able to view reporting on the data estate including sensitive data and data that needs extra enrichment.
Data governance	The platform must allow the admin to define policies for access control and automatically enforce the data access based on each user.
Workflow	The platform must have the ability to create and modify workflow so that it's easy to scale out and automate various tasks within the platform.
Integration	Other third-party technologies such as ticketing or orchestration must be able to integrate into the platform via script or REST APIs.

Identify key scenarios

Microsoft Purview governance services can be used to centrally manage data governance across an organization's data estate spanning cloud and on-premises environments. To have a successful implementation, you must identify key scenarios that are critical to the business. These scenarios can cross business unit boundaries or affect multiple user personas either upstream or downstream.

These scenarios can be written up in various ways, but you should include at least these five dimensions:

1. Persona – Who are the users?
2. Source system – What are the data sources such as Azure Data Lake Storage Gen2 or Azure SQL Database?
3. Impact Area – What is the category of this scenario?
4. Detail scenarios – How the users use Microsoft Purview to solve problems?
5. Expected outcome – What is the success criteria?

The scenarios must be specific, actionable, and executable with measurable results. Some example scenarios that you can use:

Expand table

Scenario	Detail	Persona
Catalog business-critical assets	I need to have information about each data sets to have a good understanding of what it is. This scenario includes both business and technical metadata data about the data set in the catalog. The data sources include Azure Data Lake Storage Gen2, Azure Synapse DW, and/or Power BI. This scenario also includes on-premises resources such as SQL Server.	Business Analyst, Data Scientist, Data Engineer
Discover business-critical assets	I need to have a search engine that can search through all metadata in the catalog. I should be able to search using technical term, business term with either simple or complex search using wildcard.	Business Analyst, Data Scientist, Data Engineer, Data Admin
Track data to understand its origin and troubleshoot data issues	I need to have data lineage to track data in reports, predictions, or models back to its original source. I also need to understand the changes made to the data, and where the data has resided throughout the data life cycle. This scenario needs to support prioritized data pipelines Azure Data Factory and Databricks.	Data Engineer, Data Scientist
Enrich metadata on critical data assets	I need to enrich the data set in the catalog with technical metadata that is generated automatically. Classification and labeling are some examples.	Data Engineer, Domain/Business Owner
Govern data assets with friendly user experience	I need to have a Business glossary for business-specific metadata. The business users can use Microsoft Purview for self-service scenarios to annotate their data and enable the data to be discovered easily via search.	Domain/Business Owner, Business Analyst, Data Scientist, Data Engineer

Integration points with Microsoft Purview

It's likely that a mature organization already has an existing data catalog. The key question is whether to continue to use the existing technology and sync with the Microsoft Purview Data Map and Data Catalog or not. To handle syncing with existing products in an organization, Microsoft Purview provides Atlas REST APIs. Atlas APIs provide a powerful and flexible mechanism handling both push and pull scenarios. Information can be published to Microsoft Purview using Atlas APIs for bootstrapping or to push latest updates from another system into Microsoft Purview. The information available in Microsoft Purview can also be read using Atlas APIs and then synced back to existing products.

For other integration scenarios such as ticketing, custom user interface, and orchestration you can use Atlas APIs and Kafka endpoints. In general, there are four integration points with Microsoft Purview:

- **Data Asset** – This enables Microsoft Purview to scan a store's assets in order to enumerate what those assets are and collect any readily available metadata about them. So for SQL this could be a list of DBs, tables, stored procedures, views and config data about them kept in places like `sys.tables`. For something like Azure Data Factory (ADF) this could be enumerating all the pipelines and getting data on when they were created, last run, current state.
- **Lineage** – This enables Microsoft Purview to collect information from an analysis/data mutation system on how data is moving around. For something like Spark this could be gathering information from the execution of a notebook to see what data the notebook ingested, how it transformed it and where it outputted it. For something like SQL, it could be analyzing query logs to reverse engineer what mutation operations were executed and what they did. We support both push and pull based lineage depending on the needs.
- **Classification** – This enables Microsoft Purview to take physical samples from data sources and run them through our classification system. The classification system figures out the semantics of a piece of data. For example, we may know that a file is a Parquet file and has three columns and the third one is a string. But the classifiers we run on the samples will tell us that the string is a name, address, or phone number. Lighting up this integration point means that we've defined how Microsoft Purview can open up objects like notebooks, pipelines, parquet files, tables, and containers.
- **Embedded Experience** – Products that have a "studio" like experience (such as ADF, Synapse, SQL Studio, PBI, and Dynamics) usually want to enable users to discover data they want to interact with and also find places to output data. Microsoft Purview's catalog can help to accelerate these experiences by providing an embedding experience. This experience can occur at the API or the UX level at the partner's option. By embedding a call

to Microsoft Purview, the organization can take advantage of Microsoft Purview's map of the data estate to find data assets, see lineage, check schemas, look at ratings, contacts etc.

Gathering questions

Once your organization agrees on the high-level objectives and goals, there will be many questions from multiple groups. It's crucial to gather these questions in order to craft a plan to address all of the concerns. Make sure to include relevant groups as you gather these questions. You can use our documentation to start answering them.

Some example questions that you may run into during the initial phase:

- What are the main data sources and data systems in our organization?
- What data sources are supported?
- For data sources that aren't supported yet by Microsoft Purview, what are my options?
- How should we budget for Microsoft Purview?
- Who will use Microsoft Purview, and what roles will they have?
- Who can scan new data sources?
- Who can modify content inside of Microsoft Purview?
- What processes can I use to improve the data quality in Microsoft Purview?
- How to bootstrap the platform with existing critical assets, glossary terms, and contacts?
- How can we secure Microsoft Purview?
- How can we gather feedback and build a sustainable process?
- What can we do in a disaster situation?
- We're already using Azure Data Catalog, can we migrate to Microsoft Purview?

Even if you might not have the answer to most of these questions right away, gathering questions can help your organization to frame this project and ensure all "must-have" requirements can be met.

Include the right stakeholders

To ensure the success of implementing Microsoft Purview for your entire organization, it's important to involve the right stakeholders. Only a few people are involved in the initial phase. However, as the scope expands, you'll require more personas to contribute to the project and provide feedback.

Some key stakeholders that you may want to include:

Expand table

Persona	Roles
Chief Data Officer	The CDO oversees a range of functions that may include data management, data quality, master data management, data science, business intelligence, and creating data strategy. They can be the sponsor of the Microsoft Purview implementation project.
Domain/Business Owner	A business person who influences usage of tools and has budget control
Data Analyst	Able to frame a business problem and analyze data to help leaders make business decisions
Data Architect	Design databases for mission-critical line-of-business apps along with designing and implementing data security
Data Engineer	Operate and maintain the data stack, pull data from different sources, integrate and prepare data, set up data pipelines
Data Scientist	Build analytical models and set up data products to be accessed by APIs
DB Admin	Own, track, and resolve database-related incidents and requests within service-level agreements (SLAs); May set up data pipelines
DevOps	Line-of-Business application development and implementation; may include writing scripts and orchestration capabilities
Data Security Specialist	Assess overall network and data security, which involves data coming in and out of Microsoft Purview

Create a process to move to production

Below we've provided a potential four phase deployment plan that includes tasks, helpful links, and acceptance criteria for each phase:

1. Phase 1: Pilot
2. Phase 2: Minimum viable product
3. Phase 3: Pre-production
4. Phase 4: Production

Phase 1: Pilot

In this phase, Microsoft Purview must be created and configured for a small set of users. Usually, it's just a group of 2-3 people working together to run through end-to-end scenarios. They're

considered the advocates of Microsoft Purview in their organization. The main goal of this phase is to ensure key functionalities can be met and the right stakeholders are aware of the project.

Tasks to complete

Expand table

Task	Detail	Duration
Gather & agree on requirements	Discussion with all stakeholders to gather a full set of requirements. Different personas must participate to agree on a subset of requirements to complete for each phase of the project.	One Week
Navigating the Microsoft Purview governance portal	Understand how to use Microsoft Purview from the home page.	One Day
Configure ADF for lineage	Identify key pipelines and data assets. Gather all information required to connect to an internal ADF account.	One Day
Scan a data source such as Azure Data Lake Storage Gen2 or a SQL server.	Add the data source and set up a scan. Ensure the scan successfully detects all assets.	Two Day
Search and browse	Allow end users to access Microsoft Purview and perform end-to-end search and browse scenarios.	One Day

Other helpful links

- Create a Microsoft Purview account
- Create a collection
- Concept: Permissions and access
- Microsoft Purview product glossary

Acceptance criteria

- Microsoft Purview account is created successfully in organization subscription under the organization tenant.
- A small group of users with multiple roles can access Microsoft Purview.
- Microsoft Purview is configured to scan at least one data source.
- Users should be able to extract key values of Microsoft Purview such as:
  - Search and browse
  - Lineage
- Users should be able to assign asset ownership in the asset page.

- Presentation and demo to raise awareness to key stakeholders.
- Buy-in from management to approve more resources for MVP phase.

Phase 2: Minimum viable product

Once you have the agreed requirements and participated business units to onboard Microsoft Purview, the next step is to work on a Minimum Viable Product (MVP) release. In this phase, you'll expand the usage of Microsoft Purview to more users who will have more needs horizontally and vertically. There will be key scenarios that must be met horizontally for all users such as glossary terms, search, and browse. There will also be in-depth requirements vertically for each business unit or group to cover specific end-to-end scenarios such as lineage from Azure Data Lake Storage to Azure Synapse DW to Power BI.

Tasks to complete

Expand table

Task	Detail	Duration
Scan Azure Synapse Analytics	Start to onboard your database sources and scan them to populate key assets	Two Days
Create custom classifications and rules	Once your assets are scanned, your users may realize that there are other use cases for more classification beside the default classifications from Microsoft Purview.	2-4 Weeks
Scan Power BI	If your organization uses Power BI, you can scan Power BI in order to gather all data assets being used by Data Scientists or Data Analysts that have requirements to include lineage from the storage layer.	1-2 Weeks
Import glossary terms	In most cases, your organization may already develop a collection of glossary terms and term assignment to assets. This will require an import process into Microsoft Purview via .csv file.	One Week
Add contacts to assets	For top assets, you may want to establish a process to either allow other personas to assign contacts or import via REST APIs.	One Week
Add sensitive labels and scan	This might be optional for some organizations, depending on the usage of Labeling from Microsoft 365.	1-2 Weeks
Get classification and sensitive insights	For reporting and insight in Microsoft Purview, you can access this functionality to get various reports and provide presentation to management.	One Day
Onboard more users using Microsoft Purview	This step will require the Microsoft Purview Admin to work with the Microsoft Entra Admin to establish new Security Groups to	One Week

Task	Detail	Duration
managed users	grant access to Microsoft Purview.	

Other helpful links

- Collections architecture best practices
- Classification best practices
- Labeling best practices

Acceptance criteria

- Successfully onboard a larger group of users to Microsoft Purview (50+)
- Scan business critical data sources
- Import and assign all critical glossary terms
- Successfully test important labeling on key assets
- Successfully met minimum scenarios for participated business units' users

Phase 3: Pre-production

Once the MVP phase has passed, it's time to plan for pre-production milestone. You may want to include scanning on on-premises data sources such as SQL Server. If there's any gap in data sources not supported by Microsoft Purview, it's time to explore the Atlas API to understand other options.

Tasks to complete

Expand table

Task	Detail	Duration
Refine your scan using scan rule set	Your organization will have many data sources for pre-production. It's important to pre-define key criteria for scanning so that classifications and file extension can be applied consistently across the board.	1-2 Days
Assess region availability for scan for each of your sources by checking source pages	Depending on the region of the data sources and organizational requirements on compliance and security, you may want to consider what regions must be available for scanning.	One Day
Understand firewall concept when scanning	This step requires some exploration of how the organization configures its firewall and how Microsoft Purview can authenticate itself to access the data sources for scanning.	One Day

Task	Detail	Duration
Understand Private Link concept when scanning	If your organization uses Private Link, you must lay out the foundation of network security to include Private Link as a part of the requirements.	One Day
Scan on-premises SQL Server	This is optional if you have on-premises SQL Server. The scan will require setting up Self-hosted Integration Runtime and adding SQL Server as a data source.	1-2 Weeks
Use Microsoft Purview REST API for integration scenarios	If you have requirements to integrate Microsoft Purview with other third party technologies such as orchestration or ticketing system, you may want to explore REST API area.	1-4 Weeks
Understand Microsoft Purview pricing	This step will provide the organization important financial information to make decision.	1-5 Days

Other helpful links

- Labeling best practices
- Network architecture best practices

Acceptance criteria

- Successfully onboard at least one business unit with all of users
- Scan on-premises data source such as SQL Server
- POC at least one integration scenario using REST API
- Complete a plan to go to production, which should include key areas on infrastructure and security

Phase 4: Production

The above phases should be followed to create an effective data lifecycle management, which is the foundation for better governance programs. Data governance will help your organization prepare for the growing trends such as AI, Hadoop, IoT, and blockchain. It's just the start for many things data and analytics, and there's plenty more that can be discussed. The outcome of this solution would deliver:

- **Business Focused** - A solution that is aligned to business requirements and scenarios over technical requirements.
- **Future Ready** - A solution will maximize default features of the platform and use standardized industry practices for configuration or scripting activities to support the advancements/evolution of the platform.

Tasks to complete

Expand table

Task	Detail	Duration
Scan production data sources with Firewall enabled	If this is optional when firewall is in place but it's important to explore options to hardening your infrastructure.	1-5 Days
Enable Private Link	If this is optional when Private Link is used. Otherwise, you can skip this as it's a must-have criterion when Private is enabled.	1-5 Days
Create automated workflow	Workflow is important to automate process such as approval, escalation, review and issue management.	2-3 Weeks
Create operation documentation	Data governance isn't a one-time project. It's an ongoing program to fuel data-driven decision making and creating opportunities for business. It's critical to document key procedure and business standards.	One Week

Other helpful links

- Manage workflow runs
- Workflow requests and approvals
- Manage integration runtimes
- Request access to a data asset

Acceptance criteria

- Successfully onboard all business unit and their users
- Successfully meet infrastructure and security requirements for production
- Successfully meet all use cases required by the users

Platform hardening

More hardening steps can be taken:

- Increase security posture by enabling scan on firewall resources or use Private Link
- Fine-tune scope scan to improve scan performance
- Use REST APIs to export critical metadata and properties for backup and recovery
- Use workflow to automate ticketing and eventing to avoid human errors
- Use policies to manage access to data assets through the Microsoft Purview governance portal.

Lifecycle considerations

Another important aspect to include in your production process is how classifications and labels can be migrated. Microsoft Purview has over 90 system classifiers. You can apply system or custom classifications on file, table, or column assets. Classifications are like subject tags and are used to mark and identify content of a specific type found within your data estate during scanning. Sensitivity labels are used to identify the categories of classification types within your organizational data, and then group the policies you wish to apply to each category. It makes use of the same sensitive information types as Microsoft 365, allowing you to stretch your existing security policies and protection across your entire content and data estate. It can scan and automatically classify documents. For example, if you have a file named multiple.docx and it has a National ID number in its content, Microsoft Purview will add classification such as EU National Identification Number in the Asset Detail page.

In the Microsoft Purview Data Map, there are several areas where the Catalog Administrators need to ensure consistency and maintenance best practices over its life cycle:

- **Data assets** – Data sources will need to be rescanned across environments. It's not recommended to scan only in development and then regenerate them using APIs in Production. The main reason is that the Microsoft Purview scanners do a lot more "wiring" behind the scenes on the data assets, which could be complex to move them to a different Microsoft Purview instance. It's much easier to just add the same data source in production and scan the sources again. The general best practice is to have documentation of all scans, connections, and authentication mechanisms being used.
- **Scan rule sets** – This is your collection of rules assigned to specific scan such as file type and classifications to detect. If you don't have that many scan rule sets, it's possible to just re-create them manually again via Production. This will require an internal process and good documentation. However, if your rule sets change on a daily or weekly basis, this could be addressed by exploring the REST API route.
- **Custom classifications** – Your classifications may not also change regularly. During the initial phase of deployment, it may take some time to understand various requirements to come up with custom classifications. However, once settled, this will require little change. So the recommendation here's to manually migrate any custom classifications over or use the REST API.
- **Glossary** – It's possible to export and import glossary terms via the UX. For automation scenarios, you can also use the REST API.
- **Resource set pattern policies** – This functionality is advanced for any typical organizations to apply. In some cases, your Azure Data Lake Storage has folder naming conventions and

specific structure that may cause problems for Microsoft Purview to generate the resource set. Your business unit may also want to change the resource set construction with more customizations to fit the business needs. For this scenario, it's best to keep track of all changes via REST API, and document the changes through external versioning platform.

- **Role assignment** – This is where you control who has access to Microsoft Purview and which permissions they have. Microsoft Purview also has REST API to support export and import of users and roles but this isn't Atlas API-compatible. The recommendation is to assign an Azure Security Group and manage the group membership instead.

Moving tenants

Moving tenants is not currently supported for Microsoft Purview.

Moving subscriptions

It's possible to move your Microsoft Purview account between subscriptions. However, if your account was created before December 15, 2023 (or deployed using an API version previous to 2023-05-01-preview), or is using a managed Event Hubs, the managed storage account and managed Event Hubs associated with your Microsoft Purview account will not migrate with your instance. Your Microsoft Purview account will still be able to function, but you should not remove these resources.

If you need to remove the managed resources from the other subscription, you will need to create a new Microsoft Purview account and migrate your information to this new account, before removing the original and its managed resources.

Next steps

- Collections best practices
- Navigate the home page and search for an asset

Labeling best practices for Data Map

Article • 05/14/2025

> **Note**
>
> These best practices cover applying sensitivity labels to your data in Data Map. For more information about applying sensitivity labels in Microsoft Purview risk and compliance solutions, see Automatically apply a sensitivity label to Microsoft 365 data.

Microsoft Purview Data Map supports labeling structured and unstructured data stored across various data sources. Labeling data within Data Map allows users to easily find data that matches predefined autolabeling rules that were configured in the Microsoft Purview portal. Data Map extends the use of sensitivity labels from Microsoft Purview Information Protection to assets stored in infrastructure cloud locations and structured data sources.

Protect personal data with custom sensitivity labels for Microsoft Purview

Storing and processing personal data is subject to special protection. Labeling personal data is crucial to help you identify sensitive information. You can use the detection and labeling tasks for personal data in different stages of your workflows. Because personal data is ubiquitous and fluid in your organization, you need to define identification rules for building policies that suit your individual situation.

Why do you need to use labeling within Data Map

In Data Map, you can extend your organization's investment in sensitivity labels from Microsoft Purview Information Protection to assets that are stored in files and database columns within Azure, multicloud, and on-premises locations. These locations are defined in supported data sources. When you apply sensitivity labels to your content, you can keep your data secure by stating how sensitive certain data is in your organization. The Data Map also abstracts the data itself, so you can use labels to track the type of data, without exposing sensitive data on another platform.

Microsoft Purview Data Map labeling best practices and considerations

The following sections walk you through the process of implementing labeling for your assets.

Get started

- To enable sensitivity labeling in the data map, follow the steps in automatically apply sensitivity labels to your data in the Microsoft Purview Data Map.
- To find information on required licensing and helpful answers to other questions, see Sensitivity labels in the Microsoft Purview Data Map FAQ.

Label considerations

- If you already have sensitivity labels from Microsoft Purview Information Protection in use in your environment, continue to use your existing labels. Don't make duplicate or more labels for Data Map. This approach allows you to maximize the investment you've already made in the Microsoft Purview. It also ensures consistent labeling across your data estate.
- If you haven't created sensitivity labels in Microsoft Purview Information Protection, review the documentation to get started with sensitivity labels. Creating a classification schema is a tenant-wide operation. Discuss it thoroughly before you enable it within your organization.

Label recommendations

- When you configure sensitivity labels for the Microsoft Purview Data Map, you might define autolabeling rules for files, database columns, or both within the label properties. Microsoft Purview labels files within the Microsoft Purview Data Map. When the autolabeling rule is configured, Microsoft Purview automatically applies the label or recommends that the label is applied.

  > ⚠ **Warning**
  >
  > If you haven't configured autolabeling for items on your sensitivity labels, users might be affected within your Office and Microsoft 365 environment. You can test autolabeling on database columns without affecting users.

- If you're defining new autolabeling rules for files when you configure labels for the Microsoft Purview Data Map, make sure that you have the condition for applying the label set appropriately.

- You can set the detection criteria to **All of these** or **Any of these** in the upper right of the autolabeling for items page of the label properties.

- The default setting for detection criteria is **All of these**. This setting means that the asset must contain all the specified sensitive information types for the label to be applied.

While the default setting might be valid in some instances, many customers want to use **Any of these**. Then if at least one asset is found, the label is applied.

> **Note**
>
> Trainable classifiers from Microsoft Purview Information Protection aren't supported by Microsoft Purview Data Map.

- Maintain consistency in labeling across your data estate. If you use autolabeling rules for files, use the same sensitive information types for autolabeling database columns.
- Define your sensitivity labels via Microsoft Purview Information Protection to identify your personal data at a central place.
- Use policy templates as a starting point to build your rule sets.
- Combine data classifications to an individual rule set.
- Force labeling by using autolabel functionality.
- Build groups of sensitivity labels and store them as a dedicated sensitivity label policy. For example, store all required sensitivity labels for regulatory rules by using the same sensitivity label policy to publish.
- Capture all test cases for your labels. Test your label policies with all applications you want to secure.
- Promote sensitivity label policies to the Microsoft Purview Data Map.
- Run test scans from the Microsoft Purview Data Map on different data sources like hybrid cloud and on-premises to identify sensitivity labels.

- Gather and consider insights, for example, by using Microsoft Purview Data Estate Insights. Use alerting mechanisms to mitigate potential breaches of regulations.

By using sensitivity labels with Microsoft Purview Data Map, you can extend information protection beyond the border of your Microsoft data estate to your on-premises, hybrid cloud, multicloud, and software as a service (SaaS) scenarios.

Next steps

- Get started with sensitivity labels.
- How to automatically apply sensitivity labels to your data in the Microsoft Purview Data Map.

Microsoft Purview network architecture and best practices

Article • 02/24/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

Microsoft Purview governance solutions are a platform as a service (PaaS) solutions for data governance. Microsoft Purview accounts have public endpoints that are accessible through the internet to connect to the service. However, all endpoints are secured through Microsoft Entra logins and role-based access control (RBAC).

> **Note**
>
> These best practices cover the network architecture for **Microsoft Purview unified governance solutions**. For more information about Microsoft Purview risk and compliance solutions, **go here**. For more information about Microsoft Purview in general, **go here**.

For an added layer of security, you can create private endpoints for your Microsoft Purview account. You'll get a private IP address from your virtual network in Azure to the Microsoft Purview account and its managed resources. This address will restrict all traffic between your virtual network and the Microsoft Purview account to a private link for user interaction with the APIs and Microsoft Purview governance portal, or for scanning and ingestion.

Currently, the Microsoft Purview firewall provides access control for the public endpoint of your purview account. You can use the firewall to allow all access or to block all access through the public endpoint when using private endpoints. For more information see, Microsoft Purview firewall options

Based on your network, connectivity, and security requirements, you can set up and maintain Microsoft Purview accounts to access underlying services or ingestion. Use this best practices guide to define and prepare your network environment so you can access Microsoft Purview and scan data sources from your network or cloud.

This guide covers the following network options:

- Use Azure public endpoints.
- Use private endpoints.
- Use private endpoints and allow public access on the same Microsoft Purview account.
- Use Azure public endpoints to access Microsoft Purview governance portal and private endpoints for ingestion.

This guide describes a few of the most common network architecture scenarios for Microsoft Purview. Though you're not limited to those scenarios, keep in mind the limitations of the service when you're planning networking for your Microsoft Purview accounts.

Prerequisites

To understand which network option is best for your environment, we suggest that you perform the following actions first:

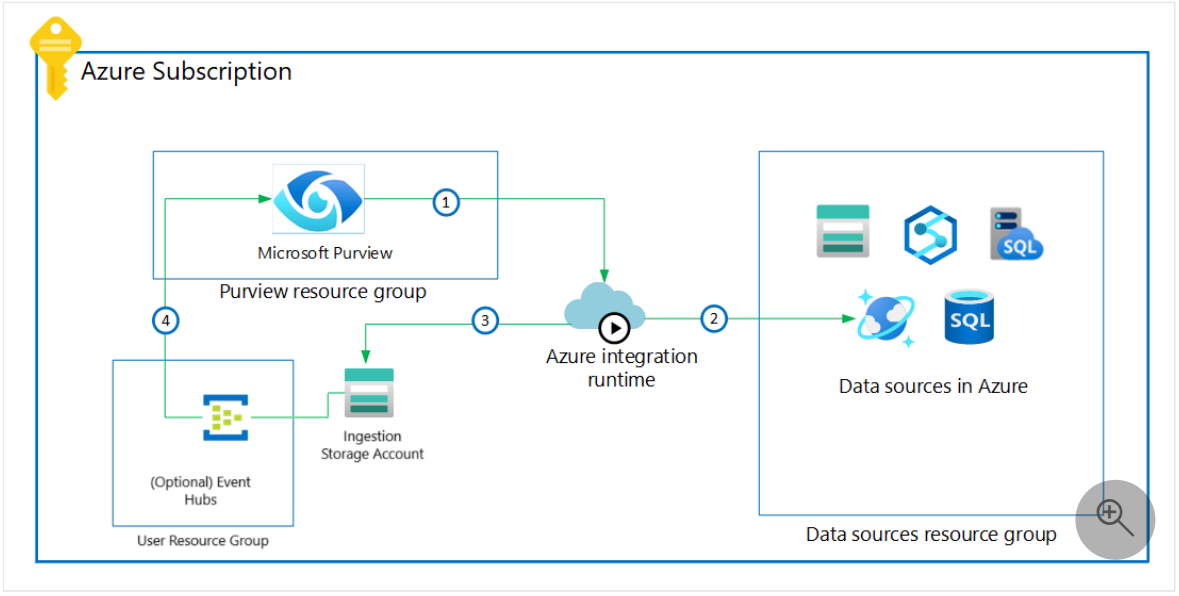
- Review your network topology and security requirements before registering and scanning any data sources in Microsoft Purview. For more information, see: Define an Azure network topology.

- Define your network connectivity model for PaaS services.

Option 1: Use public endpoints

By default, you can use Microsoft Purview accounts through the public endpoints accessible over the internet. Allow public networks in your Microsoft Purview account if you have the following requirements:

- No private connectivity is required when scanning or connecting to Microsoft Purview endpoints.
- All data sources are software-as-a-service (SaaS) applications only.
- All data sources have a public endpoint that's accessible through the internet.
- Business users require access to a Microsoft Purview account and the Microsoft Purview governance portal through the internet.



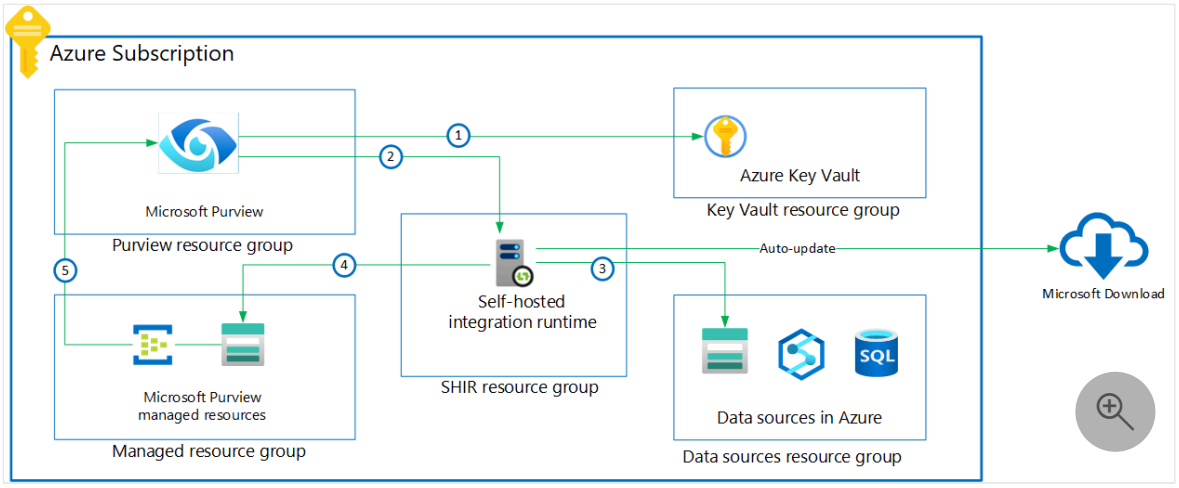
Integration runtime options

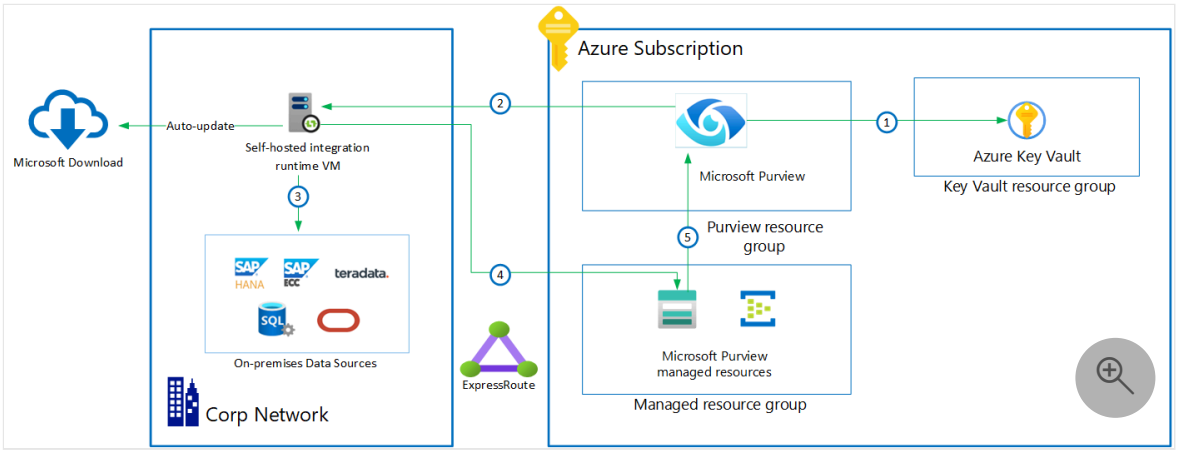
To scan data sources while the Microsoft Purview account firewall is set to allow public access, you can use all the integration runtime types - the Azure integration runtime,

Managed VNet integration runtime, and a self-hosted integration runtime. Learn more from Choose the right integration runtime configuration for your scenario.

Here are some best practices:

- Whenever applicable, we recommend that you use the Azure integration runtime or Managed VNet integration runtime to scan data sources, to reduce cost and administrative overhead.
- The following steps show the communication flow at a high level when you're using the Azure integration runtime to scan a data source:





> **Note**
>
> This graphic only applies to Microsoft Purview accounts created after December 15, 2023 (or deployed using API version 2023-05-01-preview onwards).

1. A manual or automatic scan is initiated from the Microsoft Purview Data Map through the Azure integration runtime.
2. The Azure integration runtime connects to the data source to extract metadata.
3. Metadata is queued in the Microsoft Purview ingestion storage account and stored in Azure Blob Storage temporarily.
4. Metadata is sent to the Microsoft Purview Data Map.

- Scanning on-premises and VM-based data sources always requires using a self-hosted integration runtime. The Azure integration runtime isn't supported for

these data sources. The following steps show the communication flow at a high level when you're using a self-hosted integration runtime to scan a data source. The first diagram shows a scenario where resources are within Azure or on a VM in Azure. The second diagram shows a scenario with on-premises resources. The steps between the two are the same from Microsoft Purview's perspective:

1. A manual or automatic scan is triggered. Microsoft Purview connects to Azure Key Vault to retrieve the credential to access a data source.

2. The scan is initiated from the Microsoft Purview Data Map through a self-hosted integration runtime.

3. The self-hosted integration runtime service from the VM or on-premises machine connects to the data source to extract metadata.

4. Metadata is processed in the machine's memory for the self-hosted integration runtime. Metadata is queued in Microsoft Purview ingestion storage and then stored in Azure Blob Storage temporarily. Actual data never leaves the boundary of your network.

5. Metadata is sent to the Microsoft Purview Data Map.

Authentication options

When you're scanning a data source in Microsoft Purview, you need to provide a credential. Microsoft Purview can then read the metadata of the assets from the data source by using the integration runtime. Refer to each data source article for details about the supported authentication types and the needed permissions. Authentication options and requirements vary based on the following factors:

- **Data source type**. For example, if the data source is Azure SQL Database, you need to use a login with db_datareader access to each database. This can be a user-assigned managed identity or a Microsoft Purview managed identity. Or it can be a service principal in Microsoft Entra ID added to SQL Database as db_datareader.

  If the data source is Azure Blob Storage, you can use a Microsoft Purview managed identity, or a service principal in Microsoft Entra ID added as a Blob Storage Data Reader role on the Azure storage account. Or use the storage account's key.

- **Authentication type**. We recommend that you use a Microsoft Purview managed identity to scan Azure data sources when possible, to reduce administrative overhead. For any other authentication types, you need to set up credentials for source authentication inside Microsoft Purview:

  1. Generate a secret inside an Azure key vault.
  2. Register the key vault inside Microsoft Purview.
  3. Inside Microsoft Purview, create a new credential by using the secret saved in the key vault.

- **Runtime type that's used in the scan**. Currently, you can't use a Microsoft Purview managed identity with a self-hosted integration runtime.

Other considerations

- If you choose to scan data sources using public endpoints, your self-hosted integration runtime VMs must have outbound access to data sources and Azure endpoints.
- Your self-hosted integration runtime VMs must have outbound connectivity to Azure endpoints.

Option 2: Use private endpoints

Similar to other PaaS solutions, Microsoft Purview doesn't support deploying directly into a virtual network. So you can't use certain networking features with the offering's

resources, such as network security groups, route tables, or other network-dependent appliances such as Azure Firewall. Instead, you can use private endpoints that can be enabled on your virtual network. You can then disable public internet access to securely connect to Microsoft Purview.

You must use private endpoints for your Microsoft Purview account if you have any of the following requirements:

- You need to have end-to-end network isolation for Microsoft Purview accounts and data sources.
- You need to block public access to your Microsoft Purview accounts.
- Your platform-as-a-service (PaaS) data sources are deployed with private endpoints, and you've blocked all access through the public endpoint.
- Your on-premises or infrastructure-as-a-service (IaaS) data sources can't reach public endpoints.

Design considerations

- To connect to your Microsoft Purview account privately and securely, you need to deploy an account and a portal private endpoint. For example, this deployment is necessary if you intend to connect to Microsoft Purview through the API or use the Microsoft Purview governance portal.
- If you need to connect to the Microsoft Purview governance portal by using private endpoints, you have to deploy both account and portal private endpoints.
- To scan data sources through private connectivity, you need to configure at least one account and one ingestion private endpoint for Microsoft Purview.
- Review DNS requirements. If you're using a custom DNS server on your network, clients must be able to resolve the fully qualified domain name (FQDN) for the Microsoft Purview account endpoints to the private endpoint's IP address.

Integration runtime options

To scan data sources through private connectivity, you can use Managed VNet integration runtime or self-hosted integration runtime. Learn more from Choose the right integration runtime configuration for your scenario.

- Whenever applicable, we recommend that you use the Managed VNet integration runtime to scan data sources, to reduce cost and administrative overhead.

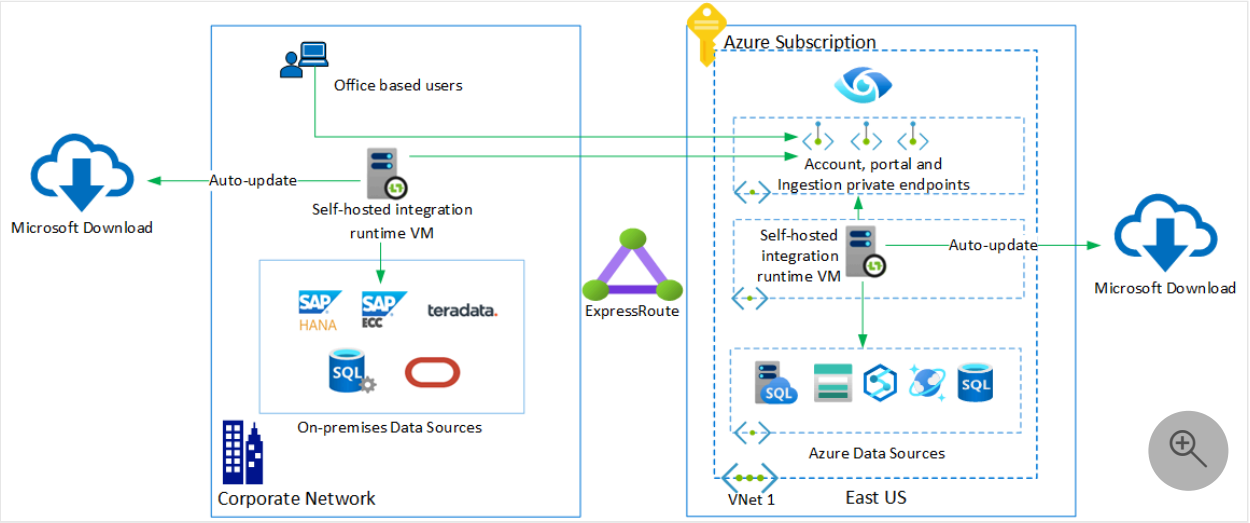
- If using self-hosted integration runtime, you need to set up and use a self-hosted integration runtime on a Windows virtual machine that's deployed inside the same or a peered virtual network where Microsoft Purview ingestion private endpoints are deployed.
- To scan on-premises data sources, you can also install a self-hosted integration runtime either on an on-premises Windows machine or on a VM inside an Azure virtual network.
- When you're using private endpoints with Microsoft Purview, you need to allow network connectivity from data sources to the self-hosted integration VM on the Azure virtual network where Microsoft Purview private endpoints are deployed.
- We recommend allowing automatic upgrade of the self-hosted integration runtime. Make sure you open required outbound rules in your Azure virtual network or on your corporate firewall to allow automatic upgrade. For more information, see Self-hosted integration runtime networking requirements.

Authentication options

- Make sure that your credentials are stored in an Azure key vault and registered inside Microsoft Purview.
- You must create a credential in Microsoft Purview based on each secret that you create in the Azure key vault. You need to assign, at minimum, *get* and *list* access for secrets for Microsoft Purview on the Key Vault resource in Azure. Otherwise, the credentials won't work in the Microsoft Purview account.

Current limitations

- Scanning multiple Azure sources by using the entire subscription or resource group through ingestion private endpoints and a self-hosted integration runtime or Managed VNet integration runtime isn't supported when you're using private endpoints for ingestion. Instead, you can register and scan data sources individually.
- For limitations related to Microsoft Purview private endpoints, see Known limitations.
- For limitations related to the Private Link service, see Azure Private Link limits.



Private endpoint scenarios

Single virtual network, single region

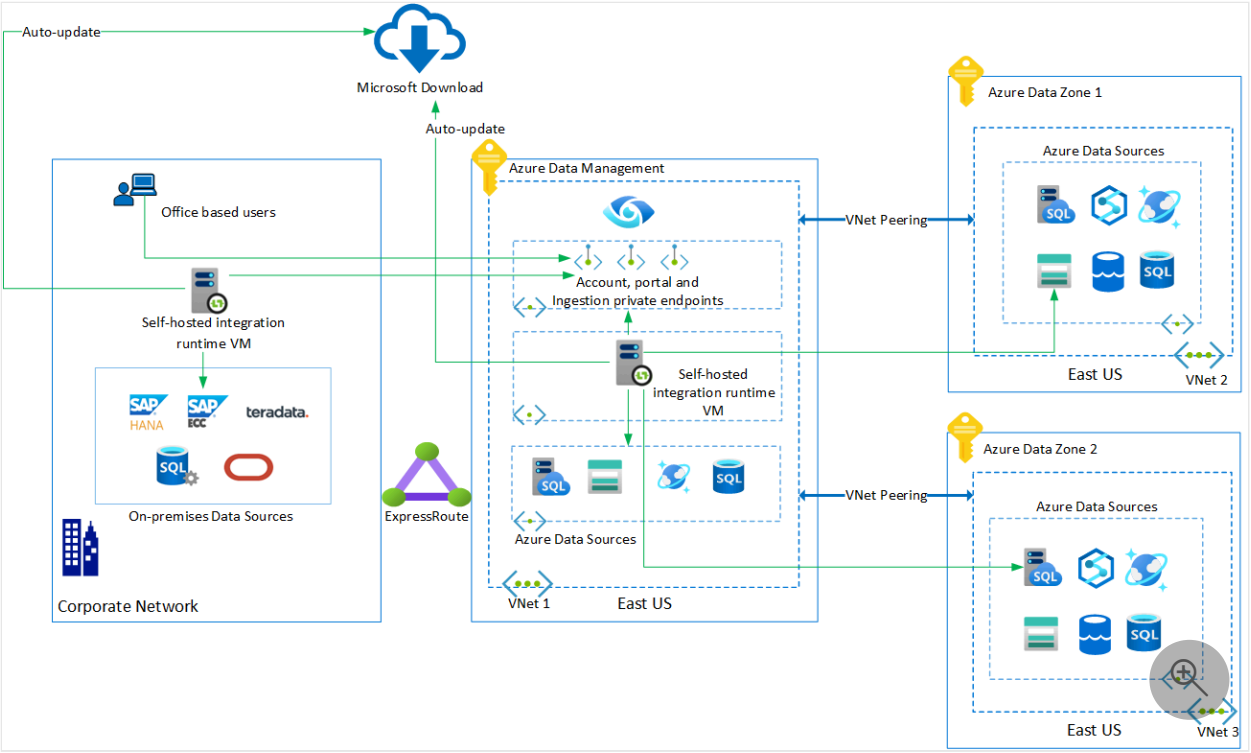
In this scenario, all Azure data sources, self-hosted integration runtime VMs, and Microsoft Purview private endpoints are deployed in the same virtual network in an Azure subscription.

If on-premises data sources exist, connectivity is provided through a site-to-site VPN or Azure ExpressRoute connectivity to an Azure virtual network where Microsoft Purview private endpoints are deployed.

This architecture is suitable mainly for small organizations or for development, testing, and proof-of-concept scenarios.

Single region, multiple virtual networks

To connect two or more virtual networks in Azure together, you can use virtual network peering. Network traffic between peered virtual networks is private and is kept on the Azure backbone network.



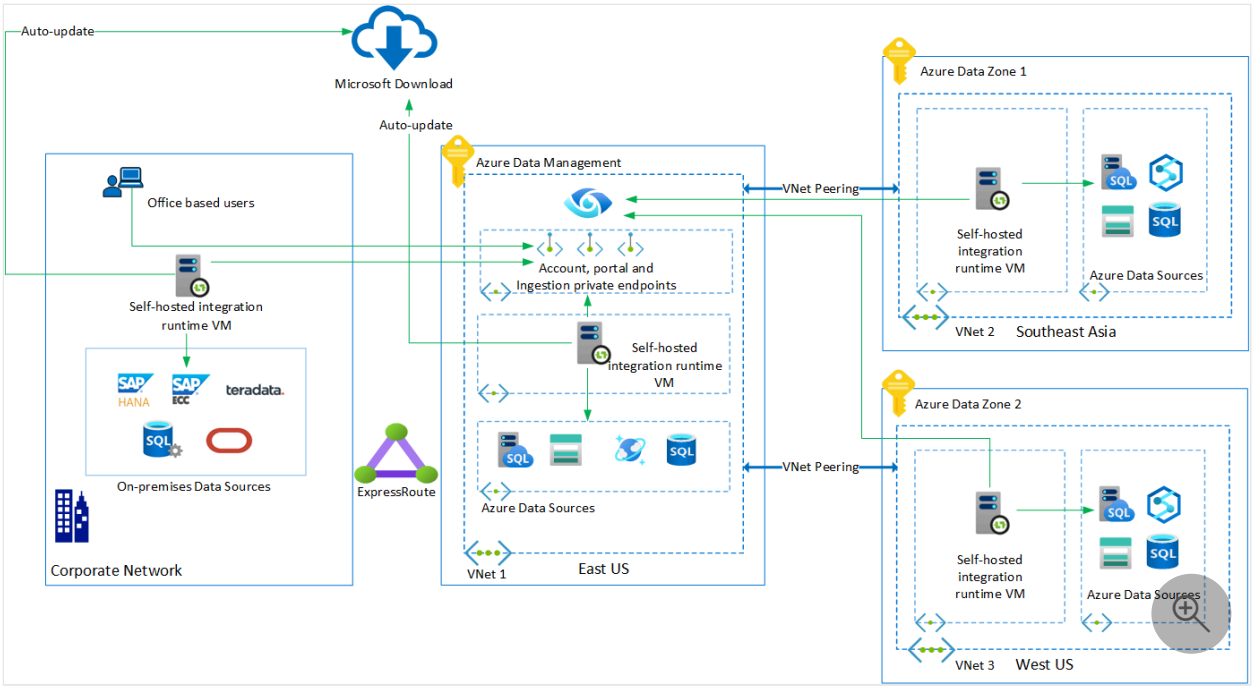
Many customers build their network infrastructure in Azure by using the hub-and-spoke network architecture, where:

- Networking shared services (such as network virtual appliances, ExpressRoute/VPN gateways, or DNS servers) are deployed in the hub virtual network.
- Spoke virtual networks consume those shared services via virtual network peering.

In hub-and-spoke network architectures, your organization's data governance team can be provided with an Azure subscription that includes a virtual network (hub). All data services can be located in a few other subscriptions connected to the hub virtual network through a virtual network peering or a site-to-site VPN connection.

In a hub-and-spoke architecture, you can deploy Microsoft Purview and one or more self-hosted integration runtime VMs in the hub subscription and virtual network. You can register and scan data sources from other virtual networks from multiple subscriptions in the same region.

The self-hosted integration runtime VMs can be deployed inside the same Azure virtual network or a peered virtual network where the account and ingestion private endpoints are deployed.

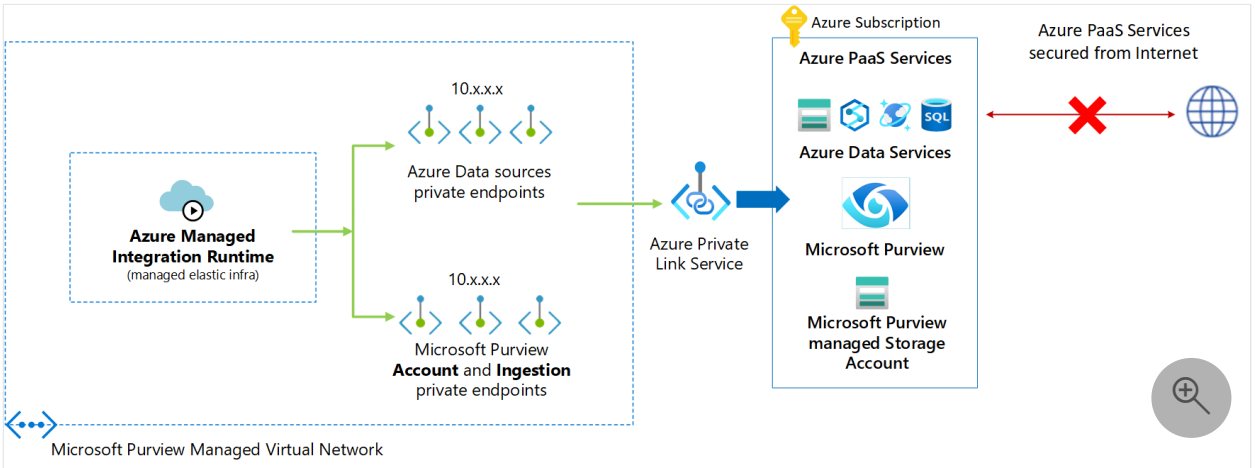


You can optionally deploy another self-hosted integration runtime in the spoke virtual networks.

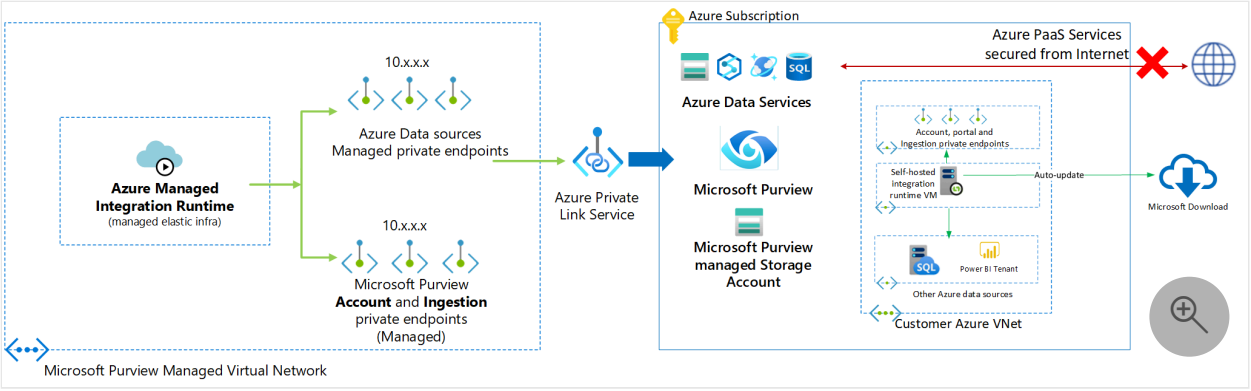
Multiple regions, multiple virtual networks

If your data sources are distributed across multiple Azure regions in one or more Azure subscriptions, you can use this scenario.

For performance and cost optimization, we highly recommended deploying one or more self-hosted integration runtime VMs in each region where data sources are located.



Scan using Managed Vnet Runtime



You can use Managed VNet Runtime to scan data sources in a private network. Learn more from Use a Managed VNet with your Microsoft Purview account.

Using Managed VNet Runtime helps to minimize the administrative overhead of managing the runtime and reduce overall scan duration.

To scan any Azure data sources over private network using Managed VNet Runtime, a managed private endpoint must be deployed within Microsoft Purview Managed Virtual Network, even if the data source already has a private network in your Azure subscription.

If you need to scan on-premises data sources or additional data sources in Azure that are not supported by Managed VNet Runtime, you can deploy both Managed VNet Runtime and Self-hosted integration runtime.

If Microsoft Purview isn't available in your primary region

Microsoft Purview is an Azure platform as a service solution. You can deploy a Microsoft Purview account inside your Azure subscription in any supported Azure regions.

If Microsoft Purview isn't available in your primary Azure region, consider the following factors when choosing a secondary region to deploy your Microsoft Purview account:

- Review the latency between your primary Azure region where data sources are deployed and your secondary Azure region, where Microsoft Purview account will be deployed. For more information, see Azure network round-trip latency statistics.
- Review your data residency requirements. When you scan data sources in the Microsoft Purview Data Map, information related to your metadata is ingested and stored inside your data map in the Azure region where your Microsoft Purview account is deployed. For more information, see Where is metadata stored.
- Review your network and security requirements if private network connectivity for user access or metadata ingestion is required. For more information, see If Microsoft Purview isn't available in your primary region.

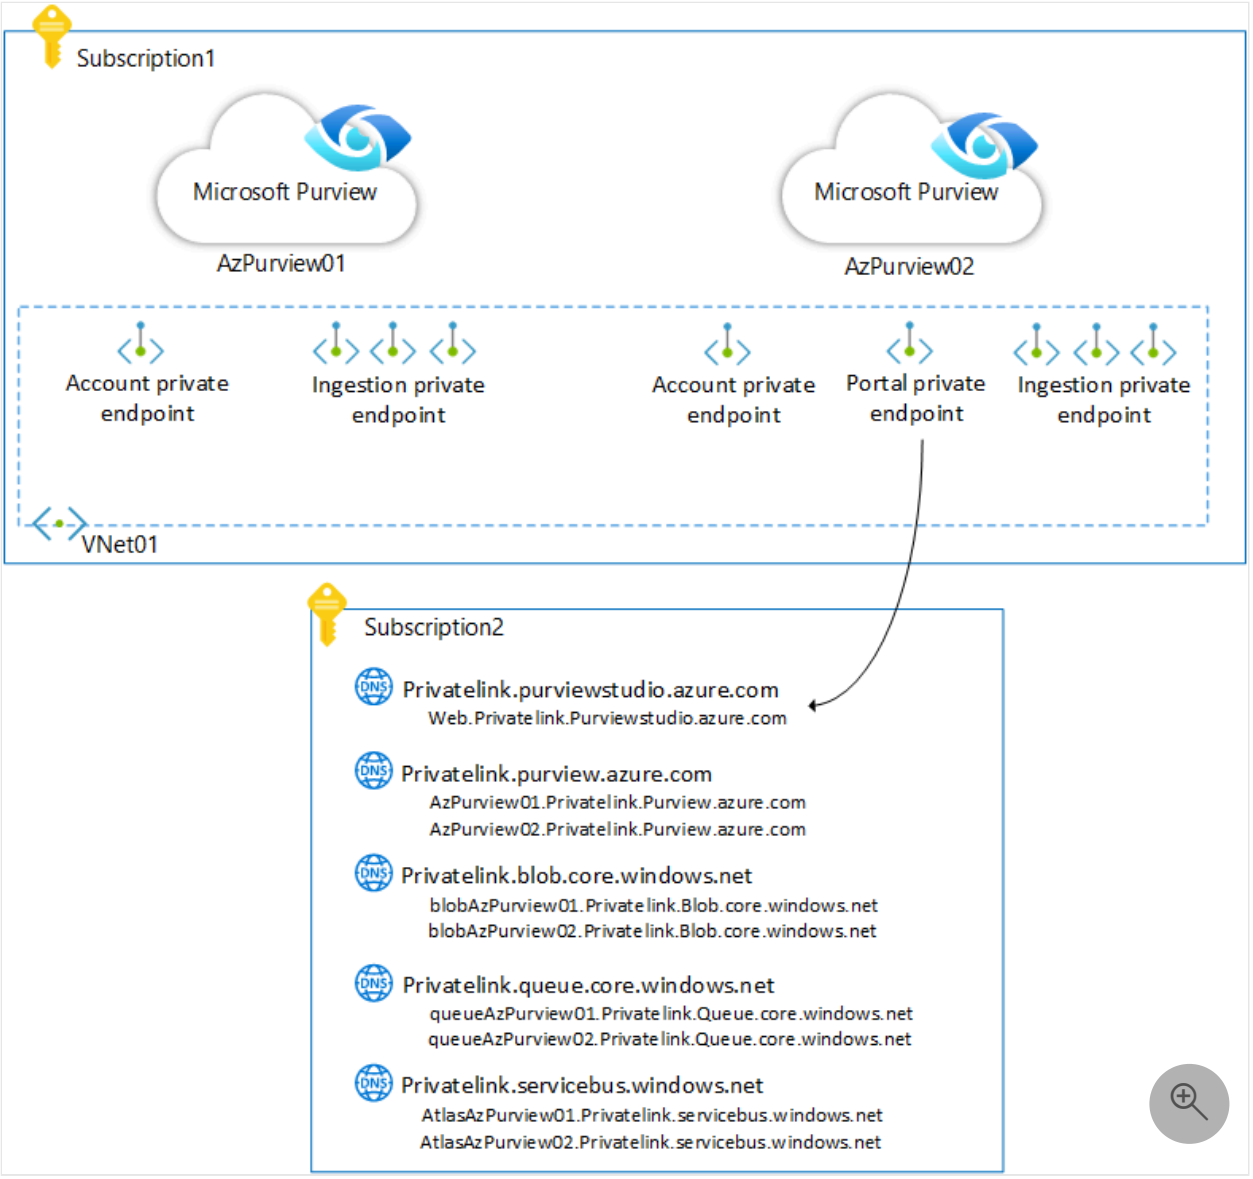
Option 1: Deploy your Microsoft Purview account in a secondary region and deploy all private endpoints in the primary region, where your Azure data sources are located. For this scenario:

- This is the recommended option, if Australia Southeast is the primary region for all your data sources and you have all network resources deployed in your primary region.
- Deploy a Microsoft Purview account in your secondary region (for example, Australia East).
- Deploy all Microsoft Purview private endpoints including account, portal and ingestion in your primary region (for example, Australia Southeast).
- Deploy all [Microsoft Purview self-hosted integration runtime](../ manage-integration-runtimes.md) VMs in your primary region (for example, Australia Southeast). This helps to reduce cross region traffic as the Data Map scans will

happen in the local region where data sources are located and only metadata is ingested int your secondary region where your Microsoft Purview account is deployed.
- If you use Microsoft Purview Managed VNets for metadata ingestion, Managed VNet Runtime and all managed private endpoints will be automatically deployed in the region where your Microsoft Purview is deployed (for example, Australia East).

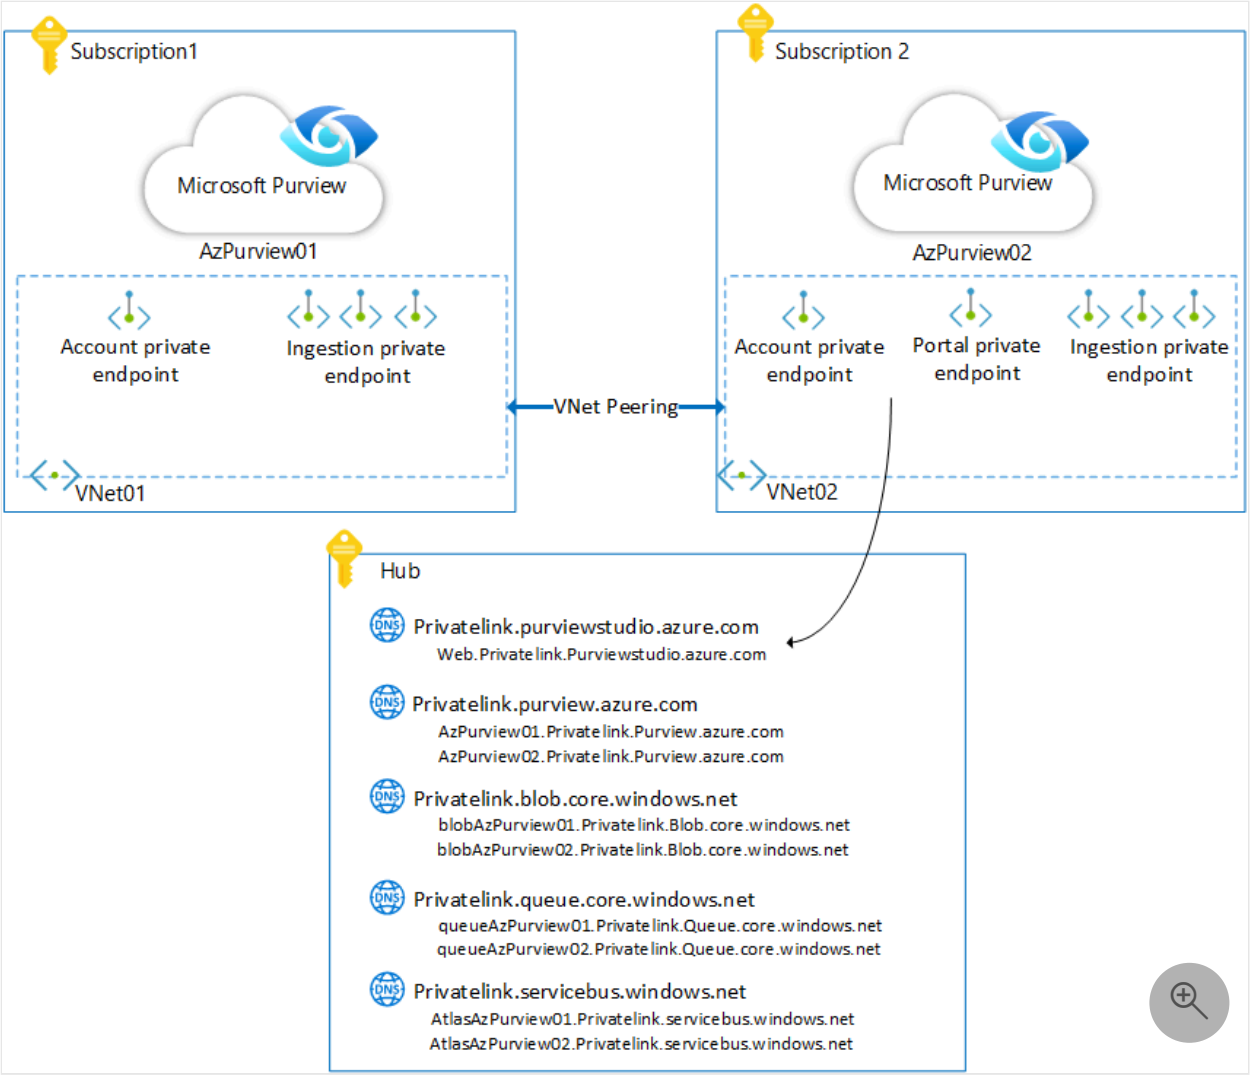
Option 2: Deploy your Microsoft Purview account in a secondary region and deploy private endpoints in the primary and secondary regions. For this scenario:

- This option is recommended if you have data sources in both primary and secondary regions and users are connected through the primary region.
- Deploy a Microsoft Purview account in your secondary region (for example, Australia East).
- Deploy Microsoft Purview governance portal private endpoint in the primary region (for example, Australia Southeast) for user access to Microsoft Purview governance portal.
- Deploy Microsoft Purview account and ingestion private endpoints in your primary region (for example, Australia southeast) to scan data sources locally in the primary region.
- Deploy Microsoft Purview account and ingestion private endpoints in your secondary region (for example, Australia East) to scan data sources locally in the secondary region.
- Deploy [Microsoft Purview self-hosted integration runtime](../ manage-integration-runtimes.md) VMs in both primary and secondary regions. This will help to keep data Map scan traffic in the local region and send only metadata to Microsoft Purview Data Map where is configured in your secondary region (for example, Australia East).
- If you use Microsoft Purview Managed VNets for metadata ingestion, Managed VNet Runtime and all managed private endpoints will be automatically deployed in the region where your Microsoft Purview is deployed (for example, Australia East).



DNS configuration with private endpoints

Name resolution for multiple Microsoft Purview accounts



It's recommended to follow these recommendations, if your organization needs to deploy and maintain multiple Microsoft Purview accounts using private endpoints:

1. Deploy at least one *account* private endpoint for each Microsoft Purview account.

2. Deploy at least one set of *ingestion* private endpoints for each Microsoft Purview account.
3. Deploy one *portal* private endpoint for one of the Microsoft Purview accounts in your Azure environments. Create one DNS A record for *portal* private endpoint to resolve `web.purview.azure.com`. The *portal* private endpoint can be used by all purview accounts in the same Azure virtual network or virtual networks connected through VNet peering.

This scenario also applies if multiple Microsoft Purview accounts are deployed across multiple subscriptions and multiple VNets that are connected through VNet peering. *Portal* private endpoint mainly renders static assets related to the Microsoft Purview governance portal, thus, it's independent of Microsoft Purview account, therefore, only one *portal* private endpoint is needed to visit all Microsoft Purview accounts in the Azure environment if VNets are connected.

> **Note**
>
> You may need to deploy separate *portal* private endpoints for each Microsoft Purview account in the scenarios where Microsoft Purview accounts are deployed in isolated network segmentations. Microsoft Purview *portal* is static contents for all customers without any customer information. Optionally, you can use public network, (without portal private endpoint) to launch `web.purview.azure.com` if your end users are allowed to launch the Internet.

Option 3: Use both private and public endpoints

You might choose an option in which a subset of your data sources uses private endpoints, and at the same time, you need to scan either of the following:

- Other data sources that are configured with a service endpoint
- Data sources that have a public endpoint that's accessible through the internet

If you need to scan some data sources by using an ingestion private endpoint and some data sources by using public endpoints or a service endpoint, you can:

1. Use private endpoints for your Microsoft Purview account.
2. Set **Public network access** to **Enabled from all networks** on your Microsoft Purview account.

Integration runtime options

- To scan an Azure data source that's configured with a private endpoint, you need to set up and use a self-hosted integration runtime on a Windows virtual machine that's deployed inside the same or a peered virtual network where Microsoft Purview account and ingestion private endpoints are deployed.

  When you're using a private endpoint with Microsoft Purview, you need to allow network connectivity from data sources to a self-hosted integration VM on the Azure virtual network where Microsoft Purview private endpoints are deployed.

- To scan an Azure data source that's configured to allow a public endpoint, you can use the Azure integration runtime.

- To scan on-premises data sources, you can also install a self-hosted integration runtime on either an on-premises Windows machine or a VM inside an Azure virtual network.

- We recommend allowing automatic upgrade for a self-hosted integration runtime. Make sure you open required outbound rules in your Azure virtual network or on your corporate firewall to allow automatic upgrade. For more information, see Self-hosted integration runtime networking requirements.

Authentication options

- To scan an Azure data source that's configured to allow a public endpoint, you can use any authentication option, based on the data source type.

- If you use an ingestion private endpoint to scan an Azure data source that's configured with a private endpoint:

  - You can't use a Microsoft Purview managed identity. Instead, use a service principal, an account key, or SQL authentication, based on the data source type.

  - Make sure that your credentials are stored in an Azure key vault and registered inside Microsoft Purview.

- You must create a credential in Microsoft Purview based on each secret that you create in Azure Key Vault. At minimum, assign *get* and *list* access for secrets for Microsoft Purview on the Key Vault resource in Azure. Otherwise, the credentials won't work in the Microsoft Purview account.

Option 4: Use private endpoints for ingestion only

You might choose this option if you need to:

- Scan all data sources using ingestion private endpoint.
- Managed resources must be configured to disable public network.
- Enable access to Microsoft Purview governance portal through public network.

To enable this option:

1. Configure ingestion private endpoint for your Microsoft Purview account.
2. Set **Public network access** to **Disabled for ingestion only (Preview)** on your Microsoft Purview account.

Integration runtime options

Follow recommendation for option 2.

Authentication options

Follow recommendation for option 2.

Self-hosted integration runtime network and proxy recommendations

For scanning data sources across your on-premises and Azure networks, you may need to deploy and use one or multiple self-hosted integration runtime virtual machines inside an Azure VNet or an on-premises network, for any of the scenarios mentioned earlier in this document.

- To simplify management, when possible, use Azure IR and Microsoft Purview Managed VNet IR to scan data sources.

- The Self-hosted integration runtime service can communicate with Microsoft Purview through public or private network over port 443. For more information,

see, self-hosted integration runtime networking requirements.

- One self-hosted integration runtime VM can be used to scan one or multiple data sources in Microsoft Purview, however, self-hosted integration runtime must be only registered for Microsoft Purview and can't be used for Azure Data Factory or Azure Synapse at the same time.
- You can register and use one or multiple self-hosted integration runtimes in one Microsoft Purview account. It's recommended to place at least one self-hosted integration runtime VM in each region or on-premises network where your data sources reside.
- It's recommended to define a baseline for required capacity for each self-hosted integration runtime VM and scale the VM capacity based on demand.
- It's recommended to set up network connection between self-hosted integration runtime VMs and Microsoft Purview and its managed resources through private network, when possible.
- Allow outbound connectivity to download.microsoft.com, if auto-update is enabled.
- The self-hosted integration runtime service doesn't require outbound internet connectivity, if self-hosted integration runtime VMs are deployed in an Azure VNet or in the on-premises network that is connected to Azure through an ExpressRoute or Site to Site VPN connection. In this case, the scan and metadata ingestion process can be done through private network.
- Self-hosted integration runtime can communicate Microsoft Purview and its managed resources directly or through a proxy server. Avoid using proxy settings if self-hosted integration runtime VM is inside an Azure VNet or connected through ExpressRoute or Site to Site VPN connection.
- Review supported scenarios, if you need to use self-hosted integration runtime with proxy setting.

Next steps

- Use private endpoints for secure access to Microsoft Purview

Manage and increase quotas for classic data governance resources

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

This article highlights the limits that currently exist in the classic Microsoft Purview Data Governance service. These limits are also known as quotas.

> **Note**
>
> These are limits for the classic data governance experience.

Classic Microsoft Purview Data Governance limits

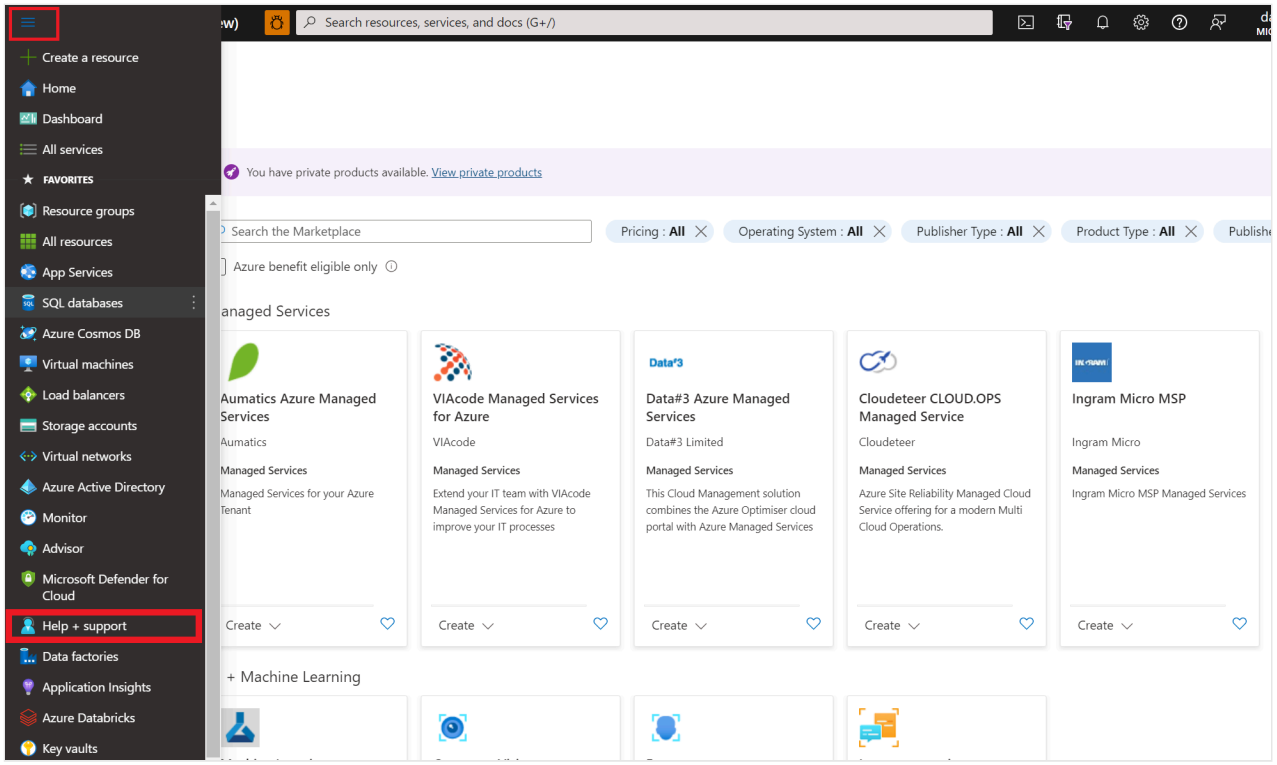
Expand table

Resource	Default limit	Maximum limit
Microsoft Purview accounts per region, per tenant (all subscriptions combined)	3* (dependent)	Contact Support
Data Map throughput There's no default limit on the Data Map metadata storage	10 capacity units 250 operations per second	100 capacity units 2,500 operations per second
vCores available for scanning, per account**	160	160
Concurrent scans per Purview account. The limit is based on the type of data sources scanned*	5	10
Maximum time that a scan can run for	7 days	7 days
Size of assets per account	100M physical assets	Contact support
Maximum size of an asset in a catalog	2 MB	2 MB
Maximum length of an asset name and classification name	4 KB	4 KB
Maximum length of asset property name and value	32 KB	32 KB

Resource	Default limit	Maximum limit
Maximum length of classification attribute name and value	32 KB	32 KB
Maximum number of glossary terms, per glossary	100K	100K
Maximum number of self-service policies, per account	3K	3K
Maximum number of collections	256	256
Maximum ingestion of child objects and contacts	Doesn't apply	20,000 entities

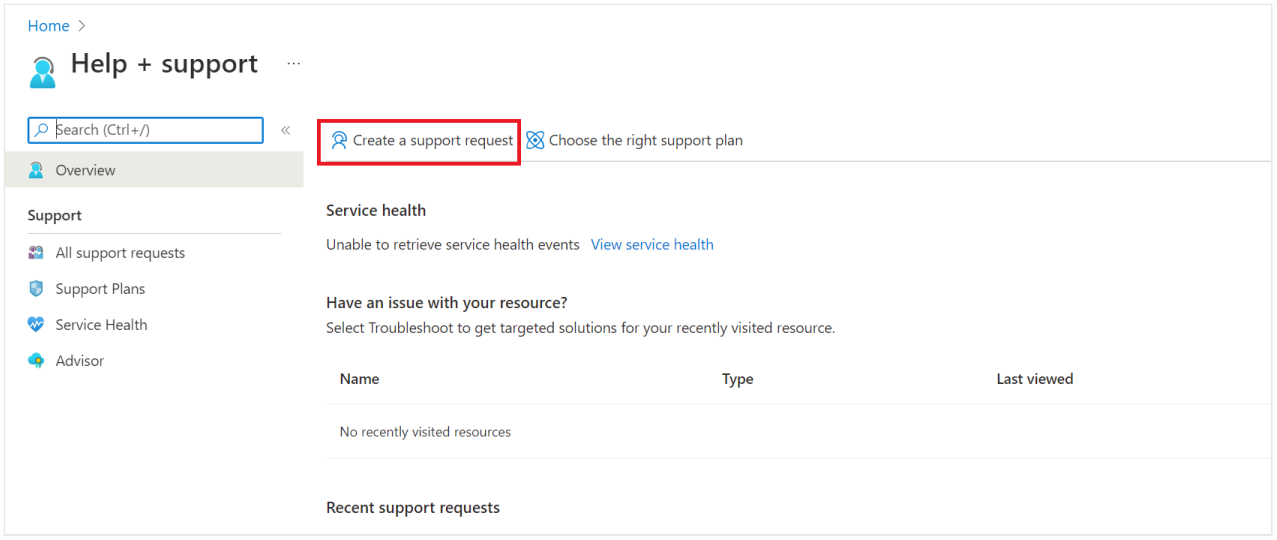
* Accounts limit is dependent on your organization. For full information, see the FAQ.

** Self-hosted integration runtime scenarios aren't included in the limits defined in the above table.



^ Increasing the Data Map throughput limit also increases the minimum number of capacity units with no usage. TO increase Data Map throughput, you can request a capacity until upgrade. See Data Map throughput for more info about Data Map in general.

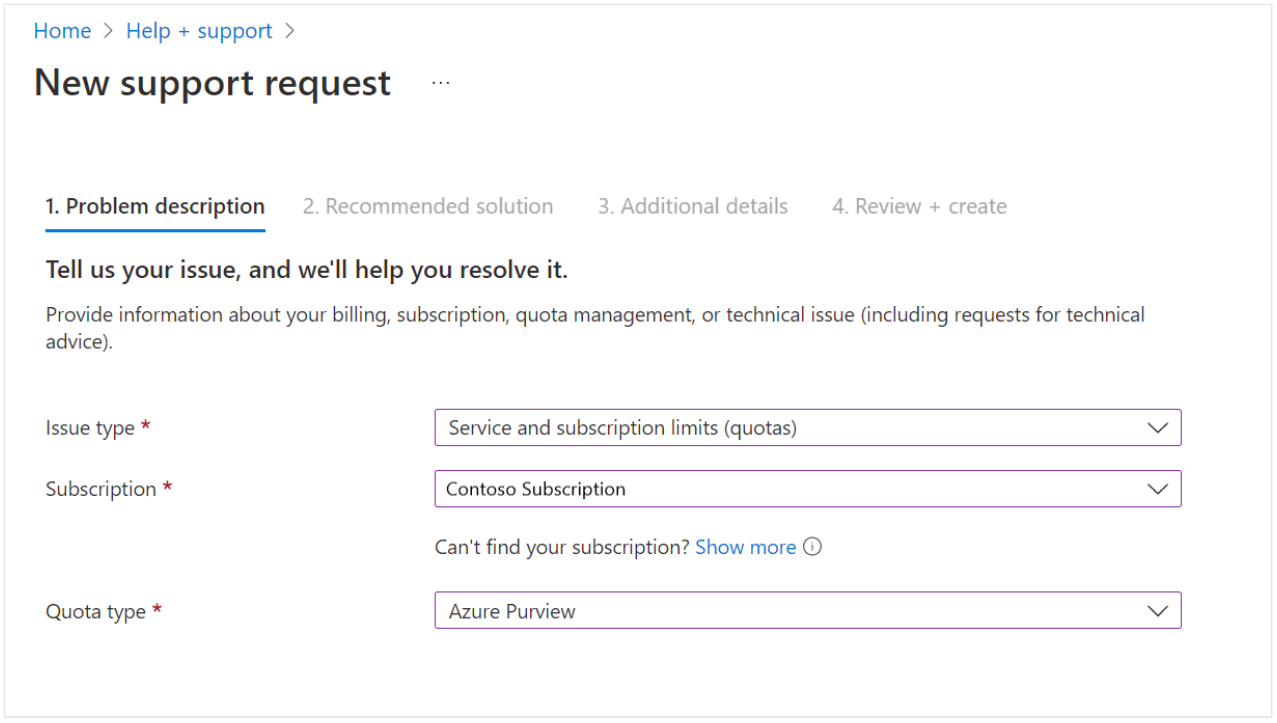
Request quota increase



Use the following steps to create a new support request from the Azure portal to increase quota for Microsoft Purview. You can create a quota request for Microsoft Purview accounts in a subscription or tenant (dependent on your organization), and the Data Map throughput (capacity units) of a specific account.

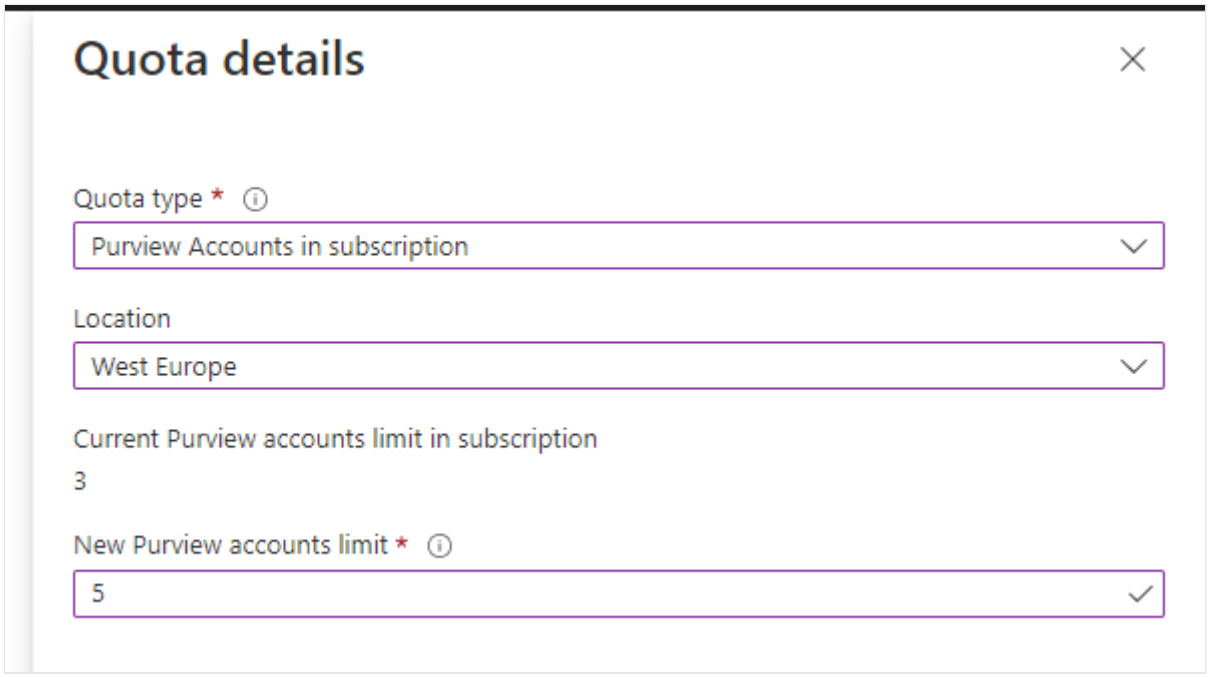
> **⊗ Caution**
>
> Once you have upgraded your Data Map throughput, you can't downgrade.

1. On the Azure portal menu, select **Help + support**.



2. In **Help + support**, select **New support request**.

3. For **Issue type**, select **Service and subscription limits (quotas)**.



4. For **Subscription**, select the subscription whose quota you want to increase.

5. For **Quota type**, select Microsoft Purview. Then select **Next**.

6. In the **Details** window, select **Enter details** to enter additional information.

7. Choose your **Quota type**, scope (either location or account) and what you wish the new limit to be

8. Enter the rest of the required support information. Review and create the support request

Frequently asked questions (FAQ) about Microsoft Purview data governance solutions

Overview

Many organizations lack a holistic understanding of their data. It's challenging to understand what data exists, where data is located, and how to find and access relevant data. Data lacks context such as lineage, classification, and comprehensive metadata, making it difficult for business users to search for the right data and use that data appropriately. As a result, only a small fraction of collected data is used to inform business decisions. Finally, identifying data security issues and protecting sensitive data is inconsistent. It requires ongoing time and effort, especially while maintaining data agility.

Microsoft Purview data governance solutions help customers gain deep knowledge of all their data while maintaining control over its use. With our tools, organizations discover and curate data. They gain insights into their data estate and centrally govern access to data.

Purpose of this FAQ

This FAQ answers common questions that customers and field teams often ask about Microsoft Purview data governance solutions: Microsoft Purview Data Map and Microsoft Purview Unified Catalog.

Where can I submit feedback or feature requests?

If you have an issue with Microsoft Purview Data Map or Unified Catalog, reach out to support.

If you have feedback about the documentation, reach out using the feedback button at the bottom of every documentation page.

What are the source types available for metadata scanning and classification?

There are many sources available, and we're adding more all the time. For a full list of sources and all their available capabilities, see our supported data sources article.

Does the Microsoft Purview Data Map support scanning zipped files?

Currently, the Microsoft Purview Data Map supports scanning GZIP files that contain a single CSV. For more information, see supported file types for scanning.

Do scans in the Microsoft Purview Data Map impact operational database performance?

It depends. The amount of load on a database will be dependent on the number of assets being scanned, and complexity of the table schema (like number of columns, etc.). The Microsoft Purview Data Map only samples a subset of the data to determine classification. For sampling related details, see the supported data sources documentation. It's recommended to schedule scans outside of normal business hours. For scanning best practices, see the scanning best practices documentation.

Can I customize the number of rows scanned?

No. Number of rows scanned is determined by the data source being scanned. For more information, see our sampling documentation.

What data systems/processors can we connect and get lineage?

Our lineage offering updates often. For a full list of systems, see our lineage user guide.

How are Azure Unified Catalog (ADC) Gen 2, Azure Information Protection, and Microsoft Purview (formerly Azure Purview) related?

Microsoft Purview (formerly Azure Purview) originally began as ADC Gen 2 but has since broadened in scope. It now embraces the advanced catalog capabilities of ADC Gen 2 combined

with the data classification, labeling, and compliance policy enforcement capabilities of Azure Information Protection. Microsoft Purview now houses compliance and data governance tools to manage your full data estate. For more information, see our overview documentation.

What happens to customers using ADC Gen 1?

Microsoft Purview is the focus of all product innovation in the catalog solution space for Microsoft. ADC Gen 1 is being retired in 2024.

How do I migrate existing ADC Gen 1 data assets to Microsoft Purview?

Use the Microsoft Purview APIs to extract from ADC Gen 1 and ingest into Microsoft Purview. For the glossary, we support bulk tools based on CSV.

How do I encrypt sensitive data for SQL tables using Microsoft Purview?

Data encryption is done at the data source level. Microsoft Purview stores only the metadata. It doesn't preview data.

What's the difference between a glossary and classification?

A glossary uses a naming convention followed by non-technical/business users of the data, also known as data consumers. These types of people are business analysts or data scientists who use Microsoft Purview to search for certain types of data, based on business usage. For instance, supply chain analysts might need to search for the terms *SKU types* and *shipment details*. They search the glossary for these terms to find relevant data. Classification is a tag applied to a data asset at the table, column, or file level that identifies what data exists in the asset. Classification can be applied automatically or manually, based on the type of data found. Typically, you use classification tags to identify whether an asset contains sensitive data, and what type of sensitive data that might be.

Can the Microsoft Purview Data Map scan and classify emails, PDFs etc. in my SharePoint and OneDrive?

Scanning for on-premises SharePoint sites and libraries is provided through the Microsoft Purview Information Protection scanner. The scanner is available for use through a customer's Microsoft 365 subscription with the following SKUs: AIP P1, EMS E3, and Microsoft 365 E3. If you have any one of these SKUs, you should have the right entitlements to start using the Microsoft Purview Information Protection scanner. However, currently, the Microsoft Purview Data Map doesn't support scanning SharePoint and OneDrive into the Microsoft Purview Unified Catalog. Follow these links for supported file types for the Microsoft Purview Information Protection scanner, and supported file types for the Microsoft Purview Unified Catalog.

What is the compute used for the scan?

There's a Microsoft-managed scanning infrastructure. For most Azure/AWS resources that we support, you don't need to deploy a scanning infrastructure.

Is there a way to create a Microsoft Purview account programatically? For example, using Azure Resource Manager (ARM) template / CLI / PowerShell?

Yes, PowerShell commands, a .NET script, a Python script, an ARM template, and a Bicep template are all available.

I'm already using Atlas, can I easily move to Microsoft Purview?

Microsoft Purview is compatible with Atlas API. If you're migrating from Atlas, it's recommended to scan your data sources first using Microsoft Purview. Once the assets are available in your account, you can use similar Atlas APIs to integrate such as updating assets or adding custom lineage. Microsoft Purview modifies the Search API to use Azure Search so you should be able to use Advance Search.

Can I register multiple tenants within a single Microsoft Purview account?

No, currently in order to scan another tenant's data source, you need to create a separate Microsoft Purview account in that tenant.

Does Microsoft Purview support column level lineage?

Yes, Microsoft Purview supports column level lineage.

Does Microsoft Purview support Soft-Delete?

Yes, Microsoft Purview supports Soft Delete for Azure subscription status management perspective. Microsoft Purview can read subscription states (disabled/warned etc.) and put the account in soft-delete state until the account is restored/deleted. All the data plane API calls will be blocked when the account is in soft delete state and only GET/DELETE control plane API calls will be allowed. You can find additional information in Azure subscription states page Azure Subscription Status.

Does Microsoft Purview Data Map support data loss prevention (DLP) capabilities?

No, the data map doesn't currently provide the data loss prevention capabilities that are supported for Microsoft 365 apps and services.

Read about Data Loss Prevention in Microsoft Purview Information Protection if you're interested in data loss prevention for Microsoft 365 apps and services.

Can I use the same self-hosted integration runtime (SHIR) for both Microsoft Purview and Azure Data Factory?

No. For more information about the SHIR, see our self-hosted integration runtime documentation.

How do I use the REST API for Microsoft Purview?

You can follow our documentation for examples: using the REST API to access the Unified Catalog, and using the REST API to manage access control. We also have a tutorial for using the Python SDK, and Atlas 2.2 APIs.

What network, security, and firewall configurations are recommended for Microsoft Purview?

For network, security, and firewall configuration recommendations, see our security best practices documentation.

Microsoft Purview (formerly Azure Purview) deployment checklist

Article • 10/28/2024

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Tip**
>
> Microsoft Purview has a new experience! If you're a new Microsoft Purview customer, or if you want more information, see our article on the new portal or the article about our new data governance experience.
>
> If you're planning on deploying Microsoft Purview governance solutions in your organization, use our new portal and check out our data governance quickstart and best practices.

This article lists prerequisites that help you get started quickly on planning and deployment for your Microsoft Purview (formerly Azure Purview) account.

If you're creating a plan to deploy Microsoft Purview, and also want to consider best practices as you develop your deployment strategy, then use our deployment best practices guide to get started.

If you're looking for a strictly technical deployment guide, this deployment checklist is for you.

Expand table

No.	Prerequisite / Action	Required permission	More guidance and recommendations
1	Microsoft Entra tenant	N/A	An Microsoft Entra tenant should be associated with your subscription. • *Information Protection Administrator* role is required, if you plan to extend Microsoft 365 Sensitivity Labels to

No.	Prerequisite / Action	Required permission	More guidance and recommendations
			the Microsoft Purview Data Map for files and db columns • *Power BI Administrator* role is required, if you're planning to scan Power BI tenants.
2	An active Azure Subscription	*Subscription Owner*	An Azure subscription is needed to deploy Microsoft Purview and its managed resources. If you don't have an Azure subscription, create a free subscription before you begin.
3	Define whether you plan to deploy a Microsoft Purview with a managed event hub	N/A	You can choose to deploy configure an existing Event Hubs namespace during Microsoft Purview account creation, see Microsoft Purview account creation. With this managed namespace you can publish messages to the event hub kafka topic ATLAS_HOOK and Microsoft Purview will consume and process it. Microsoft Purview will notify entity changes to the event hub kafka topic ATLAS_ENTITIES and user can consume and process it. You can enable or disable this feature any time after account creation.
4	Register the following resource providers: • Microsoft.Storage • Microsoft.EventHub (optional) • Microsoft.Purview	*Subscription Owner* or custom role to register Azure resource providers (*/register/action*)	Register required Azure Resource Providers in the Azure Subscription that is designated for Microsoft Purview Account. Review Azure resource provider operations.
5	Update Azure Policy to allow deployment of the following resources in your Azure subscription: • Microsoft Purview • Azure Storage	*Subscription Owner*	Use this step if an existing Azure Policy prevents deploying such Azure resources. If a blocking policy exists and needs to remain in place, follow our Microsoft Purview exception tag guide and follow the steps to create an exception for Microsoft Purview accounts.
6	Define your network security requirements.	Network and Security architects.	• Review Microsoft Purview network architecture and best practices to define what scenario is more relevant to your network requirements.

No.	Prerequisite / Action	Required permission	More guidance and recommendations
			• If private network is needed, use Microsoft Purview Managed IR to scan Azure data sources when possible to reduce complexity and administrative overhead.
7	An Azure Virtual Network and Subnets for Microsoft Purview private endpoints.	*Network Contributor* to create or update Azure virtual network.	Use this step if you're planning to deploy private endpoint connectivity with Microsoft Purview: • Private endpoints for **Ingestion**. • Private endpoint for Microsoft Purview **Account**. • Private endpoint for Microsoft Purview **Portal**. Deploy Azure Virtual Network if you need one.
8	Deploy private endpoint for Azure data sources.	*Network Contributor* to set up private endpoints for each data source.	Perform this step, if you're planning to use Private Endpoint for Ingestion.
9	Define whether to deploy new or use existing Azure Private DNS Zones.	Required Azure Private DNS Zones can be created automatically during Purview Account deployment using Subscription Owner / Contributor role	Use this step if you're planning to use Private Endpoint connectivity with Microsoft Purview. Required DNS Zones for Private Endpoint: • privatelink.purview.azure.com • privatelink.purview-service.microsoft.com • privatelink.purviewstudio.azure.com • privatelink.blob.core.windows.net • privatelink.queue.core.windows.net • privatelink.servicebus.windows.net
10	A management machine in your CorpNet or inside Azure virtual network to launch the Microsoft Purview governance portal.	N/A	Use this step if you're planning to set **Allow Public Network** to **deny** on your Microsoft Purview Account.

No.	Prerequisite / Action	Required permission	More guidance and recommendations
11	Deploy a Microsoft Purview Account	Subscription Owner / Contributor	Purview account is deployed with one Capacity Unit and will scale up based on demand.
12	Deploy a Managed Integration Runtime and Managed private endpoints for Azure data sources.	*Data source admin* to set up Managed virtual network inside Microsoft Purview. *Network Contributor* to approve managed private endpoint for each Azure data source.	Perform this step if you're planning to use Managed virtual network. within your Microsoft Purview account for scanning purposes.
13	Deploy Self-hosted integration runtime VMs inside your network.	Azure: *Virtual Machine Contributor* On-premises: Application owner	Use this step if you're planning to perform any scans using Self-hosted Integration Runtime.
14	Create a Self-hosted integration runtime inside Microsoft Purview.	Data curator VM Administrator or application owner	Use this step if you're planning to use Self-hosted Integration Runtime instead of Managed Integration Runtime or Azure Integration Runtime. download
15	Register your Self-hosted integration runtime	Virtual machine administrator	Use this step if you have **on-premises** or **VM-based data sources** (for example, SQL Server). Use this step are using **Private Endpoint** to scan to **any** data sources.
16	Grant Azure RBAC **Reader** role to **Microsoft Purview MSI** at data sources' Subscriptions	*Subscription owner* or *User Access Administrator*	Use this step if you're planning to register multiple or **any** of the following data sources: • Azure Blob Storage • Azure Data Lake Storage Gen1 • Azure Data Lake Storage Gen2 • Azure SQL Database

No.	Prerequisite / Action	Required permission	More guidance and recommendations
			• Azure SQL Managed Instance • Azure Synapse Analytics
17	Grant Azure RBAC **Storage Blob Data Reader** role to **Microsoft Purview MSI** at data sources Subscriptions.	*Subscription owner* or *User Access Administrator*	**Skip** this step if you're using Private Endpoint to connect to data sources. Use this step if you have these data sources: • Azure Blob Storage • Azure Data Lake Storage Gen2
18	Enable network connectivity to allow AzureServices to access data sources: for example, Enable "**Allow trusted Microsoft services to access this storage account**".	*Owner* or *Contributor* at Data source	Use this step if **Service Endpoint** is used in your data sources. (Don't use this step if Private Endpoint is used)
19	Enable **Microsoft Entra authentication** on **Azure SQL Servers**, **Azure SQL Managed Instance** and **Azure Synapse Analytics**	Azure SQL Server Contributor	Use this step if you have **Azure SQL DB** or **Azure SQL Managed Instance** or **Azure Synapse Analytics** as data source.
20	Grant **Microsoft Purview MSI** account with **db_datareader** role to Azure SQL databases and Azure SQL Managed Instance databases	Azure SQL Administrator	Use this step if you have **Azure SQL DB** or **Azure SQL Managed Instance** as data source. **Skip** this step if you're using **Private Endpoint** to connect to data sources.
21	Grant Azure RBAC **Storage Blob Data Reader** to **Synapse SQL Server** for staging Storage Accounts	Owner or User Access Administrator at data source	Use this step if you have **Azure Synapse Analytics** as data sources. **Skip** this step if you're using Private Endpoint to connect to data sources.
22	Grant Azure RBAC **Reader** role to **Microsoft Purview MSI** at **Synapse workspace** resources	Owner or User Access Administrator at data source	Use this step if you have **Azure Synapse Analytics** as data sources. **Skip** this step if you're using Private Endpoint to connect to data sources.
23	Grant Azure **Purview MSI account** with **db_datareader** role	Azure SQL Administrator	Use this step if you have **Azure Synapse Analytics (Dedicated SQL databases)**.

No.	Prerequisite / Action	Required permission	More guidance and recommendations
			Skip this step if you're using **Private Endpoint** to connect to data sources.
24	Grant **Microsoft Purview MSI** account with **sysadmin** role	Azure SQL Administrator	Use this step if you have Azure Synapse Analytics (Serverless SQL databases). **Skip** this step if you're using **Private Endpoint** to connect to data sources.
25	Create an app registration or service principal inside your Microsoft Entra tenant	Microsoft Entra ID *Application Administrator*	Use this step if you're planning to perform a scan on a data source using Delegated Author Service Principal.
26	Create an **Azure Key Vault** and a **Secret** to save data source credentials or service principal secret.	*Contributor* or *Key Vault Administrator*	Use this step if you have **on-premises** or **VM-based data sources** (for example, SQL Server). Use this step are using **ingestion private endpoints** to scan a data source.
27	Grant Key **Vault Access Policy** to Microsoft Purview MSI: **Secret: get/list**	*Key Vault Administrator*	Use this step if you have **on-premises** / **VM-based data sources** (for example, SQL Server) Use this step if **Key Vault Permission Model** is set to Vault Access Policy.
28	Grant **Key Vault RBAC role** Key Vault Secrets User to Microsoft Purview MSI.	*Owner* or *User Access Administrator*	Use this step if you have **on-premises** or **VM-based data sources** (for example, SQL Server) Use this step if **Key Vault Permission Model** is set to Azure role-based access control.
29	Create a new connection to Azure Key Vault from the Microsoft Purview governance portal	*Data source admin*	Use this step if you're planning to use any of the following authentication options to scan a data source in Microsoft Purview: • Account key • Basic Authentication • Delegated Auth • SQL Authentication • Service Principal • Consumer Key
30	Deploy a private endpoint for Power BI tenant	*Power BI Administrator* *Network contributor*	Use this step if you're planning to register a Power BI tenant as data source and your Microsoft Purview account is set to **deny public access**.

No.	Prerequisite / Action	Required permission	More guidance and recommendations
			For more information, see How to configure private endpoints for accessing Power BI.
31	Connect Azure Data Factory to Microsoft Purview from Azure Data Factory Portal. **Manage** -> **Microsoft Purview**. Select **Connect to a Purview account**. Validate if Azure resource tag **catalogUri** exists in ADF Azure resource.	Azure Data Factory Contributor / Data curator	Use this step if you have **Azure Data Factory**.
32	Verify if you have at least one **Microsoft 365 required license** in your Microsoft Entra tenant to use sensitivity labels in Microsoft Purview.	Microsoft Entra ID *Global Reader*	Perform this step if you're planning to extend **sensitivity labels to Microsoft Purview Data Map** For more information, see licensing requirements to use sensitivity labels on files and database columns in Microsoft Purview
33	Consent "**Extend labeling to assets in Microsoft Purview Data Map**"	Compliance Administrator Azure Information Protection Administrator	Use this step if you're interested in extending sensitivity labels to your data in the data map. For more information, see Labeling in the Microsoft Purview Data Map.
34	Create new collections and assign roles in Microsoft Purview	*Collection admin*	Create a collection and assign permissions in Microsoft Purview.
36	Govern Data Sources in Microsoft Purview	*Data Source admin* *Data Reader* or *Data Curator*	For more information, see supported data sources and file types
35	Grant access to data roles in the organization	*Collection admin*	Provide access to other teams to use Microsoft Purview: • Data curator • Data reader • Collection admin • Data source admin • Policy Author • Workflow admin

No.	Prerequisite / Action	Required permission	More guidance and recommendations
			For more information, see Access control in Microsoft Purview.

Feature availability for Microsoft Purview

07/15/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

Learn what which Microsoft Purview features are partially available or unavailable in Azure Government and Azure China 21Vianet regions.

In the list of global Azure regions, there are several regions that serve specific markets in addition to the public cloud regions. Microsoft Purview is deployed into the following regions.

- Azure China 21Vianet region: China North 3.
- Azure Government regions: US GOV Virginia

The information in the rest of this document provides information on the feature availability for Microsoft Purview. To see more detailed information about a feature's regional support, select the link to that feature.

Azure China 21Vianet cloud

Feature support is represented by the following symbols:

Expand table

Symbol	Meaning	Description
❌	Unsupported	Unsupported means that the feature isn't available in that particular region.
✅	Supported	Supported means that the feature is available in that particular region and in no way differs from the public cloud offering.
⚠	Partial support	Partial support indicates that the feature offered for the public cloud is available, but with perhaps some modifications. See the guidance and recommended sections for more information about partially supported features.

Reliability in Microsoft Purview

Summarize this article for me

This article describes reliability support in Purview for governance experiences. It covers both regional resiliency with availability zones and disaster recovery and business continuity. For a more detailed overview of reliability principles in Microsoft Azure, see Azure reliability.

Availability zone support

Availability zones are physically separate groups of datacenters within an Azure region. When one zone fails, services can fail over to one of the remaining zones.

Microsoft Purview makes commercially reasonable efforts to support zone-redundant availability zones, where resources automatically replicate across zones, without any need for you to set up or configure.

Prerequisites

- Microsoft Purview governance experience currently provides partial availability zone support in a limited number of regions. This partial availability zone support covers experiences and certain functionalities within an experience.
- Zone availability might or might not be available for Microsoft Purview governance experiences or features and functionalities that are in preview.

Supported regions

The table below lists availability zone support:

Expand table

Region	Microsoft Purview Data Map	Scan	Policy	Insights

China North 3	✅	✅	✅	✅
West Europe		✅	✅	✅

Disaster recovery and business continuity

Disaster recovery refers to practices that organizations use to recover from events such as natural disasters or failed deployments that result in downtime and data loss. Regardless of the cause, the best remedy for a disaster is a well-defined and tested disaster recovery plan and an application design that actively supports disaster recovery. Before you start creating your disaster recovery plan, see Recommendations for designing a disaster recovery strategy.

For disaster recovery, Microsoft uses the shared responsibility model. In this model, Microsoft ensures that the baseline infrastructure and platform services are available. However, many Azure services don't automatically replicate data or fall back from a failed region to cross-replicate to another enabled region. For those services, you're responsible for setting up a disaster recovery plan that works for your workload. Most services that run on Azure platform

as a service (PaaS) offerings provide features and guidance to support disaster recovery. Use service-specific features to support fast recovery to help develop your disaster recovery plan.

> **Important**
>
> Classic Microsoft Purview doesn't support automated disaster recovery. You're responsible for backup and restore activities. You can manually create a secondary Purview account as a warm standby instance in another region. This standby instance in another region doesn't support Microsoft Purview data governance.

To implement disaster recovery for Microsoft Purview classic data governance, see disaster recovery and migration best practices.

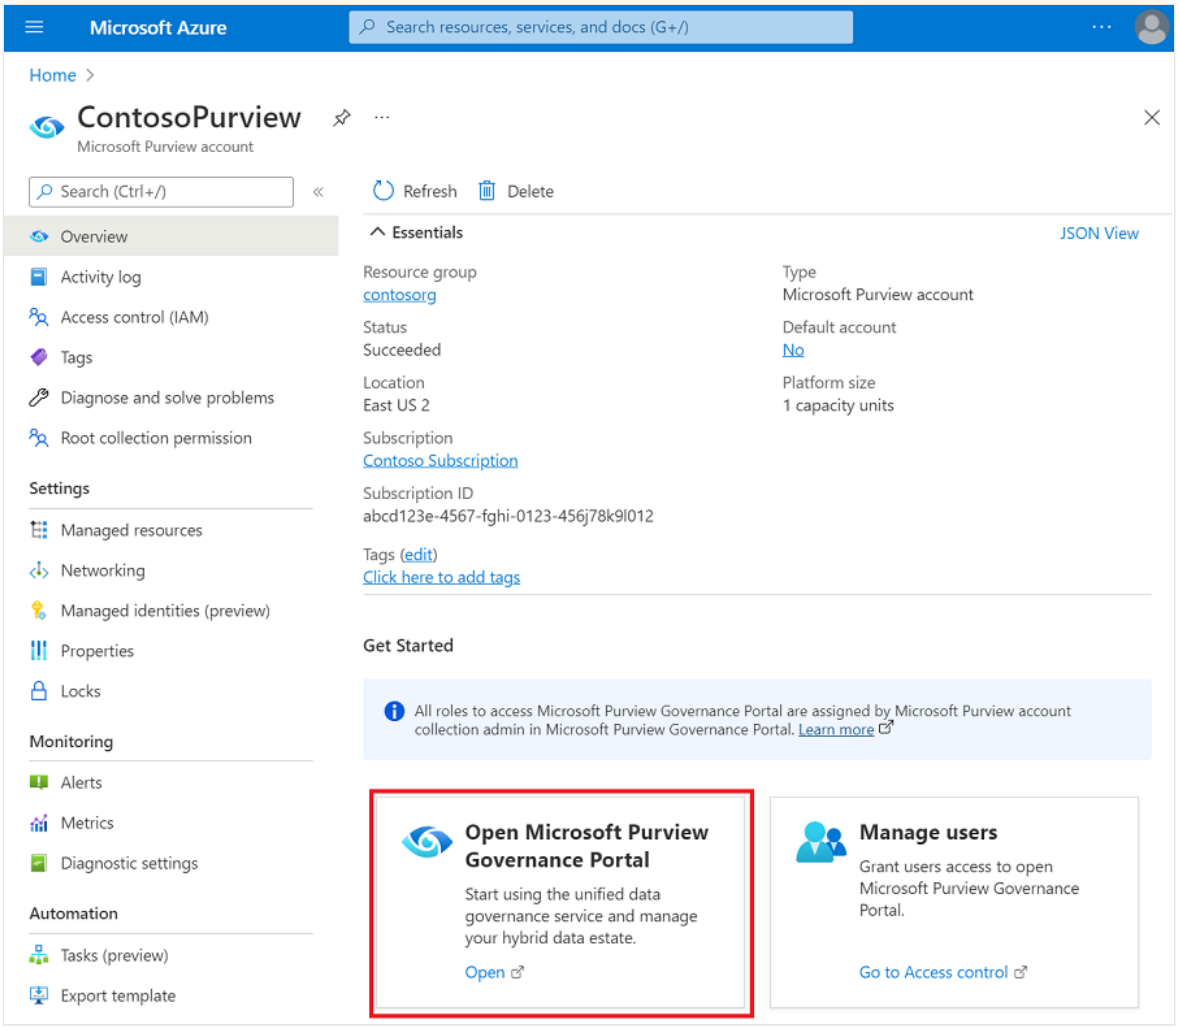
Classic Microsoft Purview governance portal

Article • 01/28/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

This article gives an overview of some of the features in the classic Microsoft Purview governance portal.

> **Tip**
>
> Microsoft Purview has a new experience! If you're a new Microsoft Purview customer, or if you want more information, see our **article on the new portal** or the article about our new **data governance experience**.

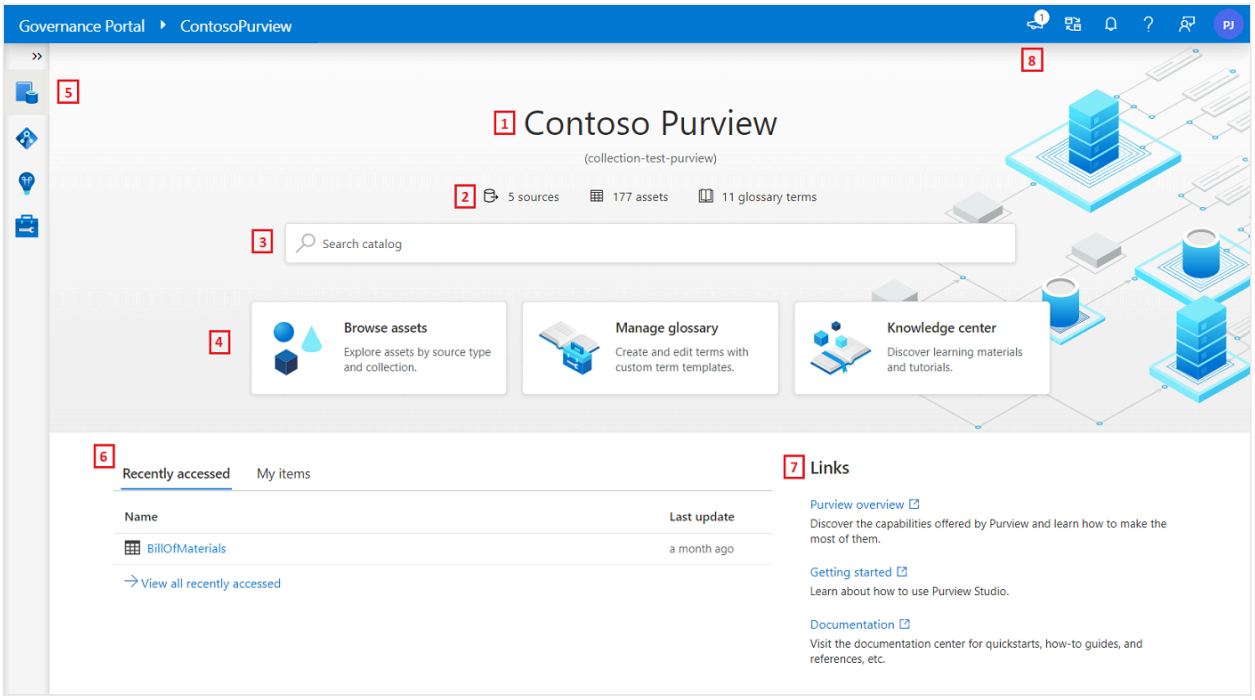


Prerequisites

- An Active Microsoft Purview account is already created in Azure portal
- The user has permissions to access the classic Microsoft Purview governance portal.

Launch Microsoft Purview account

- You can launch the Microsoft Purview account directly by going to `https://web.purview.azure.com`, selecting **Microsoft Entra ID** and the account name. Or by going to `https://web.purview.azure.com/resource/yourpurviewaccountname`



- To launch your Microsoft Purview account from the Azure portal, go to Microsoft Purview accounts in Azure portal, select the account you want to launch and launch the account.

> **Tip**
>
> If you can't access the portal, confirm you have the necessary permissions.

Home page

Home is the starting page for the Microsoft Purview governance portal.

The following list summarizes the main features of **Home page**. Each number in the list corresponds to a highlighted number in the preceding screenshot.

1. Friendly name of the catalog. You can set catalog name in **Management** > **Account information**.

2. Catalog analytics shows the number of:

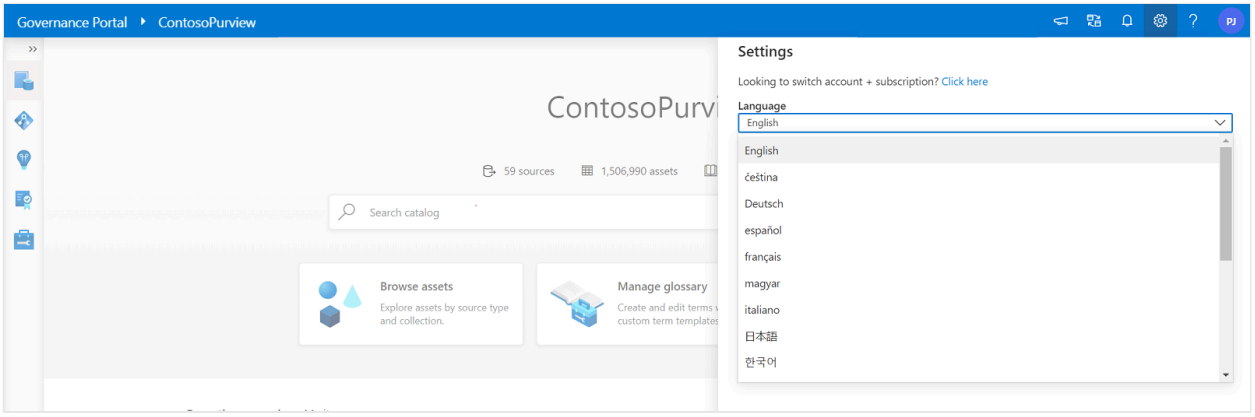
    - Data sources
    - Assets
    - Glossary terms

3. The search box allows you to search for data assets across the data catalog.

4. The quick access buttons give access to frequently used functions of the application. The buttons that are presented, depend on the role assigned to your user account at the root collection.

    - For *collection admin*, the available button is **Knowledge center**.
    - For *data curator*, the buttons are **Browse assets**, **Manage glossary**, and **Knowledge center**.
    - For *data reader*, the buttons are **Browse assets**, **View glossary**, and **Knowledge center**.
    - For *data source admin* + *data curator*, the buttons are **Browse assets**, **Manage glossary**, and **Knowledge center**.
    - For *data source admin* + *data reader*, the buttons are **Browse assets**, **View glossary**, and **Knowledge center**.

> **Note**
>
> For more information about Microsoft Purview roles, see Access control in Microsoft Purview.

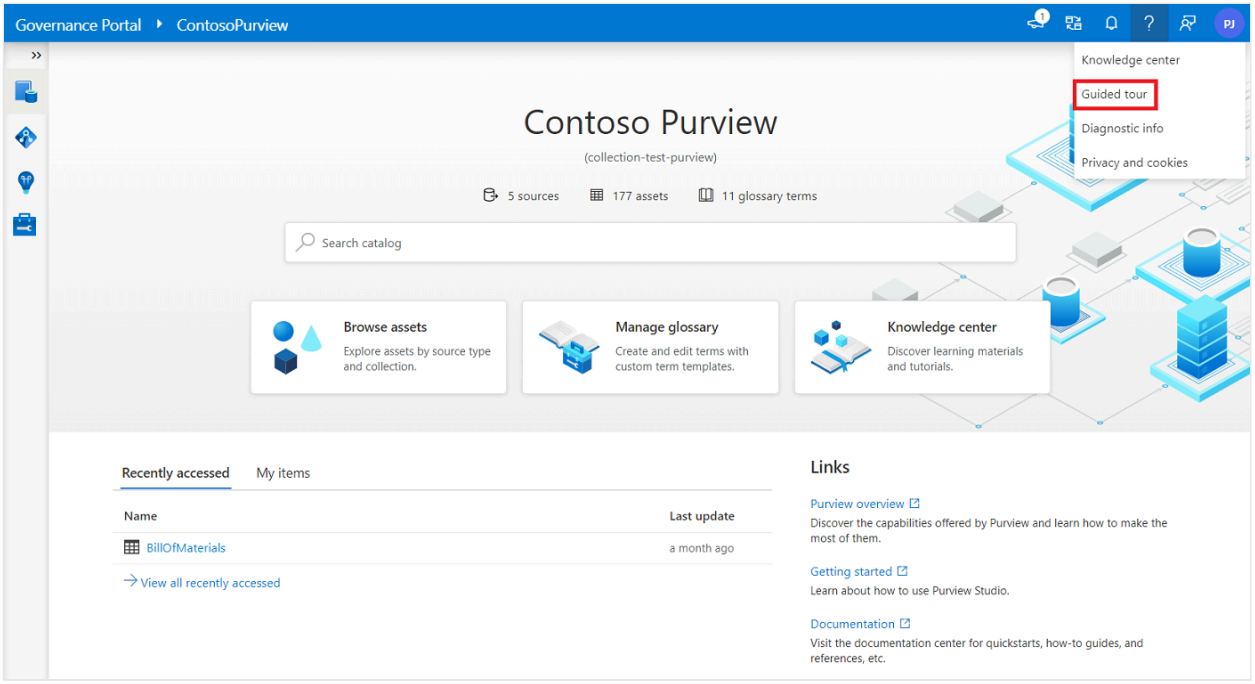


5. The left navigation bar helps you locate the main pages of the application.
6. The **Recently accessed** tab shows a list of recently accessed data assets. For information about accessing assets, see Search the Data Catalog and Browse by asset type. **My items** tab is a list of data assets owned by the logged-on user.
7. **Links** contains links to region status, documentation, pricing, overview, and Microsoft Purview status
8. The top navigation bar contains information about release notes/updates, change purview account, notifications, help, and feedback sections.

Knowledge center

The knowledge center is where you can find all the videos and tutorials related to Microsoft Purview.

Localization



Microsoft Purview is localized in 18 languages. To change the language used, go to the **Settings** from the top bar and select the desired language from the dropdown.

> **Note**
>
> Only generally available features are localized. Features still in preview are in English regardless of which language is selected.

Guided tours

Each UX in the Microsoft Purview governance portal will have guided tours to give overview of the page. To start the guided tour, select **help** on the top bar and select **guided tours**.

Next steps

Scan data

Access control in the classic Microsoft Purview governance portal

Article • 05/20/2025

The Microsoft Purview governance portal uses **Collections** in the Microsoft Purview Data Map to organize and manage access across its sources, assets, and other artifacts. This article describes collections and access management for your account in the classic Microsoft Purview governance portal.

> **Important**
>
> This article covers Microsoft Purview data governance permissions in the classic Microsoft Purview governance portal.
>
> - For governance permissions the Microsoft Purview portal see governance permissions in the portal.
> - For general permissions in the new Microsoft Purview portal see permissions in the portal.

Permissions to access the classic Microsoft Purview governance portal

There are two main ways to access the classic Microsoft Purview governance portal, both of which require permissions:

- To access your Microsoft Purview governance portal directly at https://web.purview.azure.com, you'll need at least a reader role on a collection in your Microsoft Purview Data Map.
- To access your Microsoft Purview governance portal through the Azure portal by searching for your Microsoft Purview account, opening it, and selecting **Open Microsoft Purview governance portal**, you'll need at least a **Reader** role under **Access Control (IAM)**.

> **Note**
>
> If you created your account using a service principal, to be able to access the Microsoft Purview governance portal you will need to grant a user collection admin permissions on the root collection.

Collections

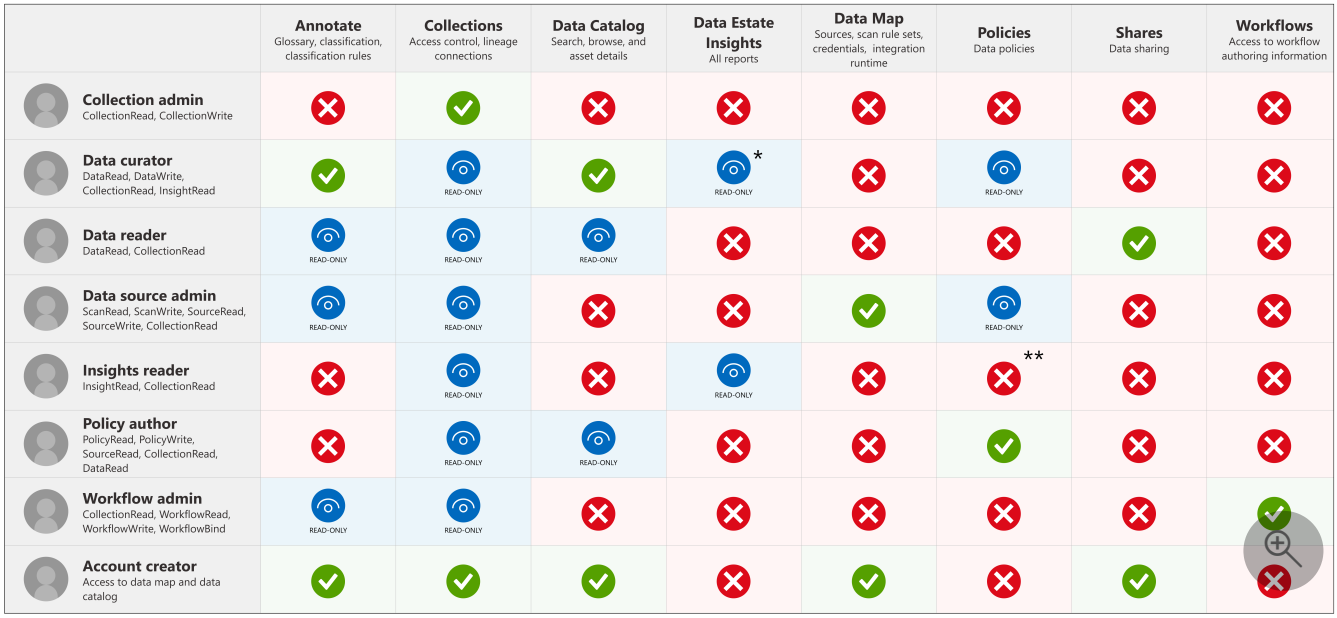
A collection is a tool that the Microsoft Purview Data Map uses to group assets, sources, and other artifacts into a hierarchy to manage access control. All accesses to the Microsoft Purview governance portal's resources are managed from collections in the Microsoft Purview Data Map.

Roles

The Microsoft Purview governance portal uses a set of predefined roles to control who can access what within the account. These roles are currently:

- **Domain admin** (domain level only) - Can assign permissions within a domain and manage its resources.
- **Collection administrator** - a role for users that will need to assign roles to other users in the Microsoft Purview governance portal or manage collections. Collection admins can add users to roles on collections where they're admins. They can also edit collections, their details, and add subcollections. A collection administrator on the root collection also automatically has permission to the Microsoft Purview governance portal. If your **root collection administrator** ever needs to be changed, you can follow the steps in the section below.
- **Data curators** - a role that provides access to the Microsoft Purview Unified Catalog to manage assets, configure custom classifications, create and manage glossary terms, and view data estate insights. Data curators can create, read, modify, move, and delete assets. They can also apply annotations to assets.
- **Data readers** - a role that provides read-only access to data assets, classifications, classification rules, collections and glossary terms.
- **Data source administrator** - a role that allows a user to manage data sources and scans. If a user is granted only to **Data source admin** role on a given data source, they can run new scans using an existing scan rule. To create new scan rules, the user must be also granted as either **Data reader** or **Data curator** roles.
- **Insights reader** - a role that provides read-only access to insights reports for collections where the insights reader also has at least the **Data reader** role. For more information, see insights permissions.
- **Policy author** - a role that allows a user to view, update, and delete Microsoft Purview policies through the Data policy app within Microsoft Purview.
- **Workflow administrator** - a role that allows a user to access the workflow authoring page in the Microsoft Purview governance portal, and publish workflows on collections where they have access permissions. Workflow administrator only has access to authoring, and

so will need at least Data reader permission on a collection to be able to access the Purview governance portal.



> **Note**
>
> At this time, Microsoft Purview policy author role is not sufficient to create policies. The Microsoft Purview data source admin role is also required.

Who should be assigned to what role?

Expand table

User Scenario	Appropriate Role(s)
I just need to find assets, I don't want to edit anything	Data reader
I need to edit and manage information about assets	Data curator
I want to create custom classifications	Data curator **or** data source administrator
I need to edit the business glossary	Data curator
I need to view Data Estate Insights to understand the governance posture of my data estate	Data curator
My application's Service Principal needs to push data to the Microsoft Purview Data Map	Data curator
I need to set up scans via the Microsoft Purview governance portal	Data curator on the collection **or** data curator **and** data source administrator where the source is registered.
I need to enable a Service Principal or group to set up and monitor scans in the Microsoft Purview Data Map without allowing them to access the catalog's information	Data source administrator
I need to put users into roles in the Microsoft Purview governance portal	Collection administrator
I need to create and publish access policies	Data source administrator and policy author
I need to create workflows for my Microsoft Purview account in the governance portal	Workflow administrator
I need to share data from sources registered in Microsoft Purview	Data reader

User Scenario	Appropriate Role(s)
I need to receive shared data in Microsoft Purview	Data reader
I need to view insights for collections I'm a part of	Insights reader **or** data curator
I need to create or manage our self-hosted integration runtime (SHIR)	Data source administrator
I need to create managed private endpoints	Data source administrator

> ⓘ Note
>
> ***Data curator** - Data curators can read insights only if they are assigned data curator at the root collection level.
>
> ****Data source administrator permissions on Policies** - Data source administrators are also able to publish data policies.

Understand how to use the Microsoft Purview governance portal's roles and collections

All access control is managed through collections in the Microsoft Purview Data Map. The collections can be found in the Microsoft Purview governance portal. Open your account in the Azure portal and select the Microsoft Purview governance portal tile on the Overview page. From there, navigate to the data map on the left menu, and then select the 'Collections' tab.

When a Microsoft Purview (formerly Azure Purview) account is created, it starts with a root collection that has the same name as the account itself. The creator of the account is automatically added as a Collection Admin, Data Source Admin, Data Curator, and Data Reader on this root collection, and can edit and manage this collection.

Sources, assets, and objects can be added directly to this root collection, but so can other collections. Adding collections will give you more control over who has access to data across your account.

All other users can only access information within the Microsoft Purview governance portal if they, or a group they're in, are given one of the above roles. This means, when you create an account, no one but the creator can access or use its APIs until they're added to one or more of the above roles in a collection.

Users can only be added to a collection by a collection admin, or through permissions inheritance. The permissions of a parent collection are automatically inherited by its subcollections. However, you can choose to restrict permission inheritance on any collection. If you do this, its subcollections will no longer inherit permissions from the parent and will need to be added directly, though collection admins that are automatically inherited from a parent collection can't be removed.

You can assign roles to users, security groups, and service principals from your Microsoft Entra ID that is associated with your subscription.

Assign permissions to your users

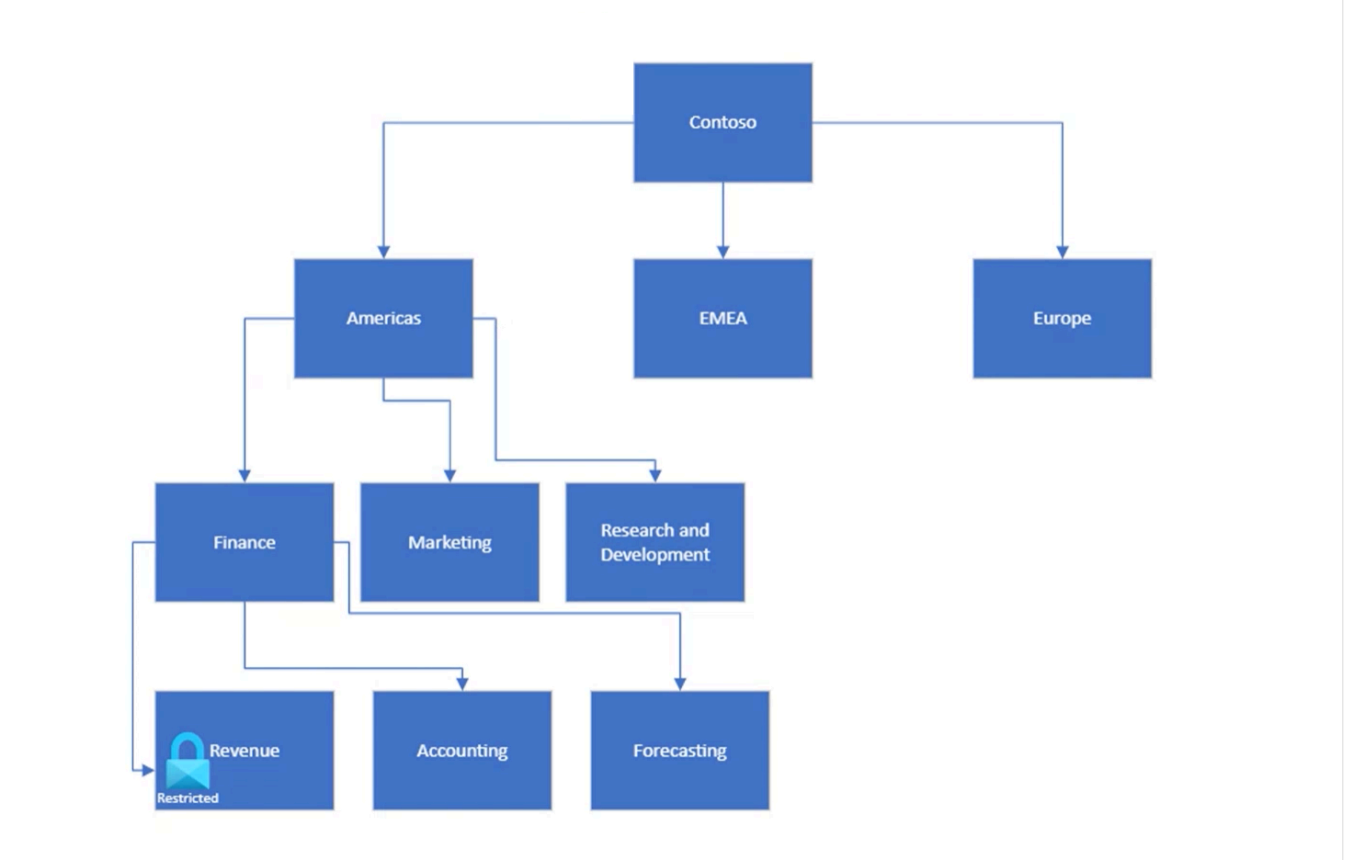
After creating a Microsoft Purview (formerly Azure Purview) account, the first thing to do is create collections and assign users to roles within those collections.

> ⓘ **Note**
>
> If you created your account using a service principal, to be able to access the Microsoft Purview governance portal and assign permissions to users, you will need to **grant a user collection admin permissions on the root collection**.

Create collections

Collections can be customized for structure of the sources in your Microsoft Purview Data Map, and can act like organized storage bins for these resources. When you're thinking about the collections you might need, consider how your users will access or discover information. Are your sources broken up by departments? Are there specialized groups within those

departments that will only need to discover some assets? Are there some sources that should be discoverable by all your users?

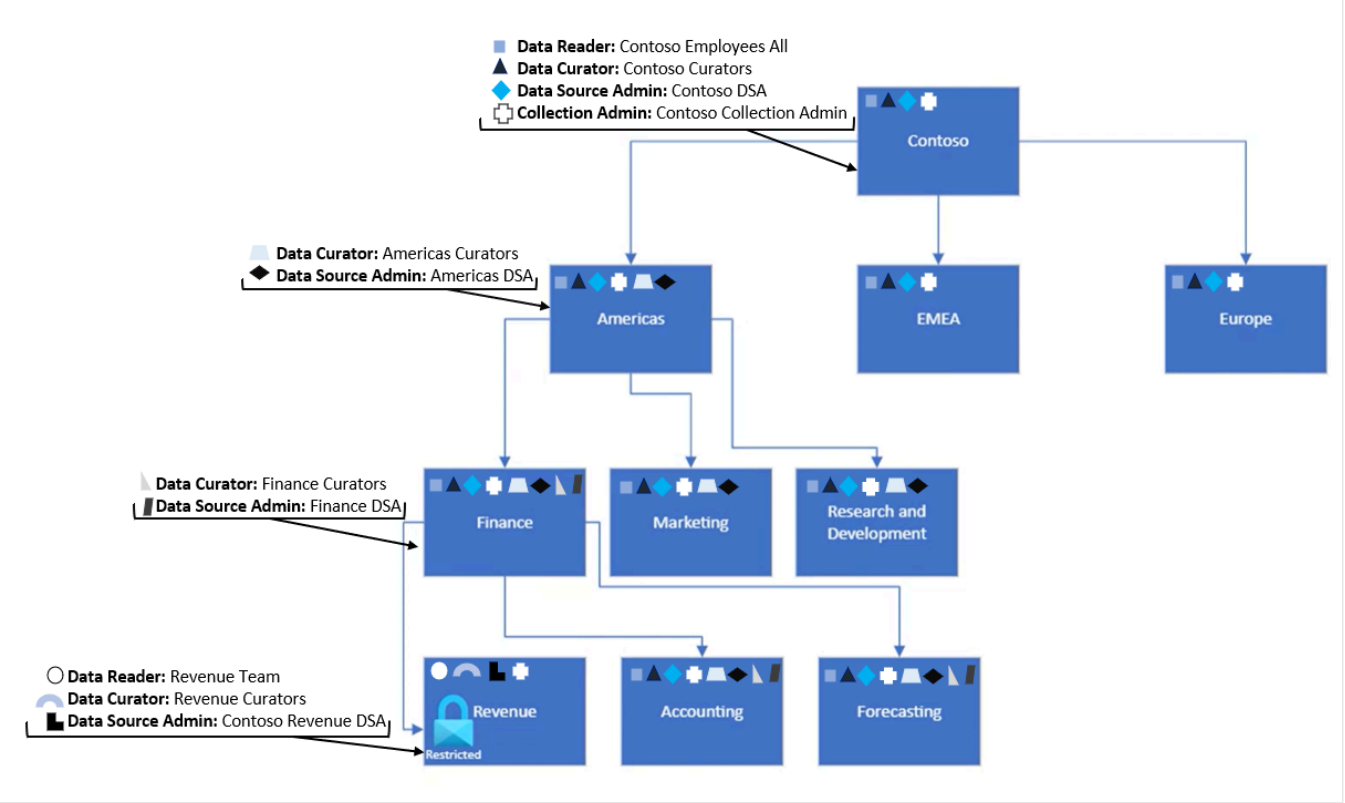


This will inform the collections and subcollections you may need to most effectively organize your data map.

New collections can be added directly to the data map where you can choose their parent collection from a drop-down, or they can be added from the parent as a sub collection. In the data map view, you can see all your sources and assets ordered by the collections, and in the list, the source's collection is listed.

For more instructions and information, you can follow our guide for creating and managing collections.

A collections example



Now that we have a base understanding of collections, permissions, and how they work, let's look at an example.

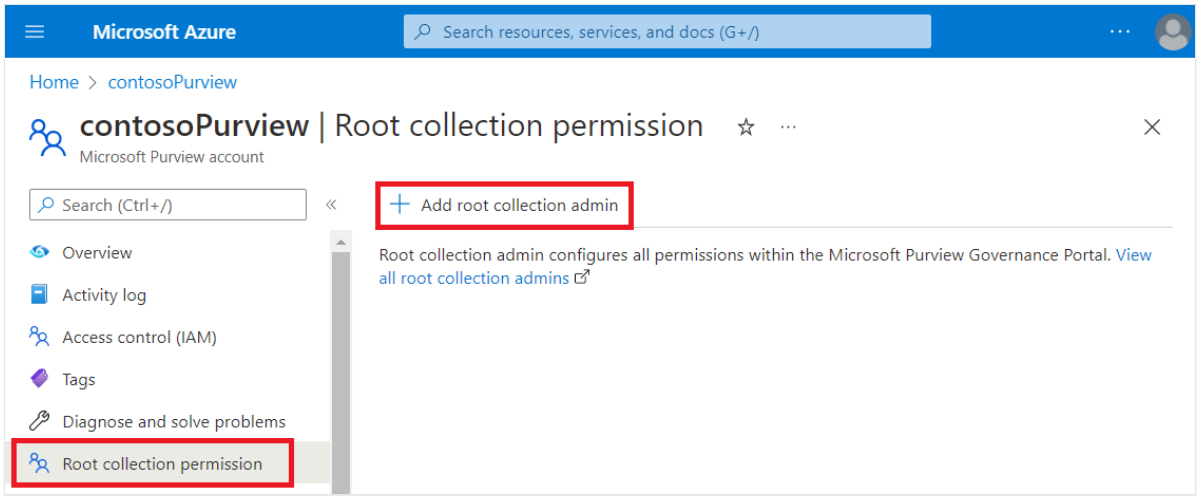
This is one way an organization might structure their data: Starting with their root collection (Contoso, in this example) collections are organized into regions, and then into departments and subdepartments. Data sources and assets can be added to any one these collections to organize data resources by these regions and department, and manage access control along

those lines. There's one subdepartment, Revenue, that has strict access guidelines so permissions will need to be tightly managed.

The data reader role can access information within the catalog, but not manage or edit it. So for our example above, adding the Data Reader permission to a group on the root collection and allowing inheritance will give all users in that group reader permissions on sources and assets in the Microsoft Purview Data Map. This makes these resources discoverable, but not editable, by everyone in that group. Restricting inheritance on the Revenue group will control access to those assets. Users who need access to revenue information can be added separately to the Revenue collection. Similarly with the Data Curator and Data Source Admin roles, permissions for those groups will start at the collection where they're assigned and trickle down to subcollections that haven't restricted inheritance. Below we have assigned permissions for several groups at collections levels in the Americas sub collection.

Add users to roles

Role assignment is managed through the collections. Only a user with the collection admin role can grant permissions to other users on that collection. When new permissions need to be added, a collection admin will access the Microsoft Purview governance portal, navigate to data map, then the collections tab, and select the collection where a user needs to be added. From the Role Assignments tab, they'll be able to add and manage users who need permissions.



For full instructions, see our how-to guide for adding role assignments.

Administrator change

There may be a time when your root collection admin needs to change, or an admin needs to be added after an account is created by an application. By default, the user who creates the account is automatically assigned collection admin to the root collection. To update the root collection admin, there are four options:

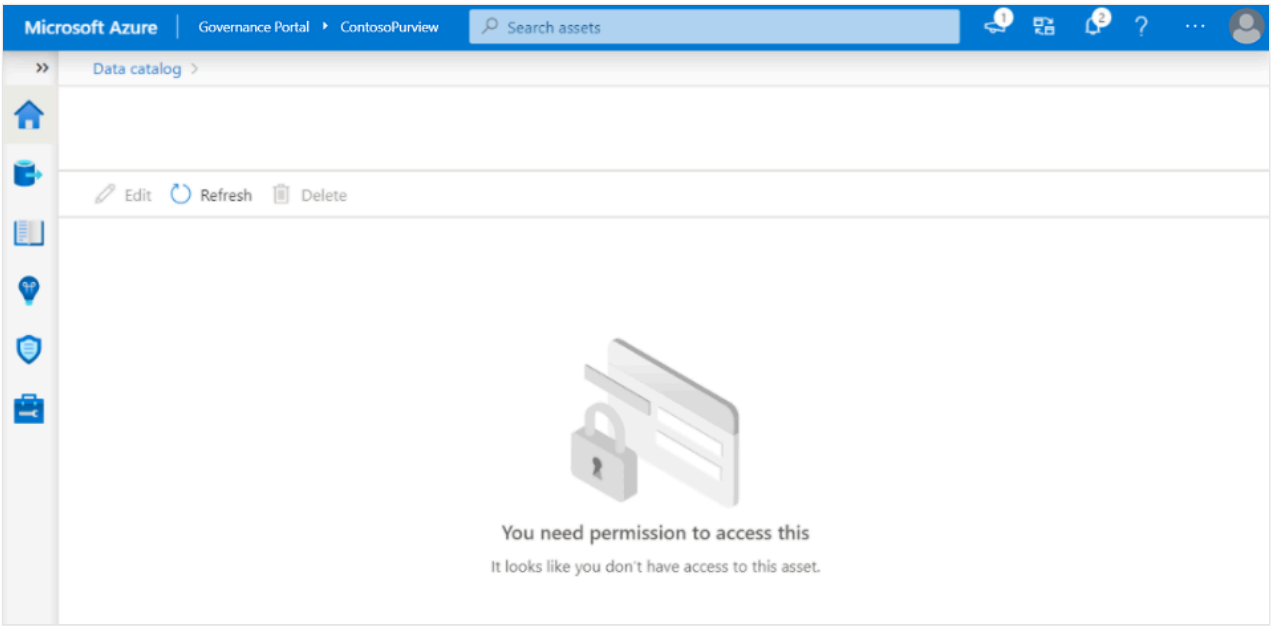
- You can manage root collection administrators in the Azure portal:

    1. Sign in to the Azure portal and search for your Microsoft Purview account.
    2. Select **Root collection permission** from the left-side menu on your Microsoft Purview account page.
    3. Select **Add root collection admin** to add an administrator.

    4. You can also select **View all root collection admins** to be taken to the root collection in the Microsoft Purview governance portal.

- You can assign permissions through the Microsoft Purview governance portal as you have for any other role.

- You can use the REST API to add a collection administrator. Instructions to use the REST API to add a collection admin can be found in our REST API for collections documentation. For additional information, you can see our REST API reference.

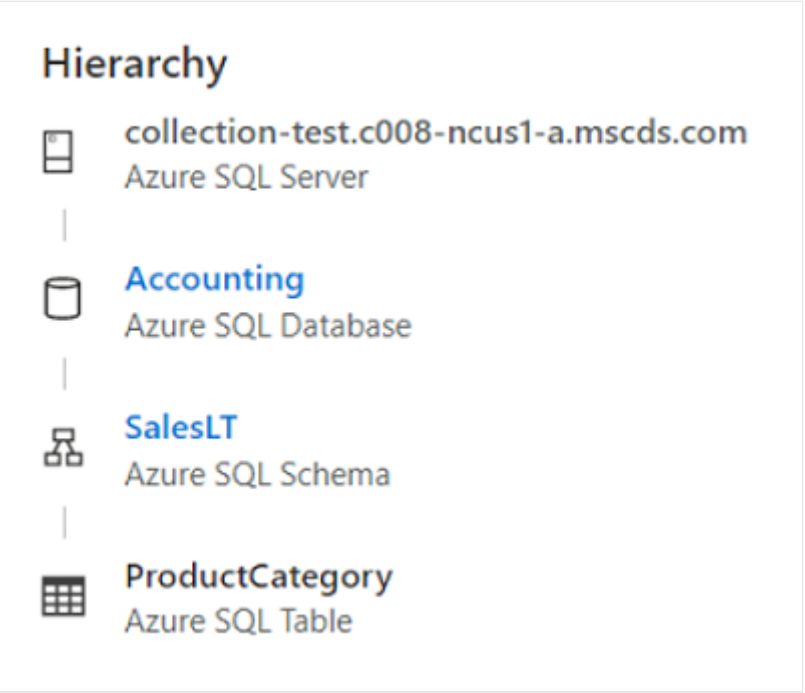


- You can also use the below Azure CLI command. The object-id is optional. For more information and an example, see the CLI command reference page.

    Azure CLI

    ```
    az purview account add-root-collection-admin --account-name [Microsoft
    Purview Account Name] --resource-group [Resource Group Name] --object-id
    [User Object Id]
    ```

Permissions on assets



1. If you don't have read permission on a collection, the assets under that collection won't be listed in search results. If you get the direct URL of one asset and open it, you'll see the no access page. Contact your collection admin to grant you the access. You can select the **Refresh** button to check the permission again.

2. If you have the read permission to one collection but don't have the write permission, you can browse the asset details page, but the following operations are disabled:

    - Edit the asset. The **Edit** button will be disabled.
    - Delete the asset. The **Delete** button will be disabled.
    - Move asset to another collection. The ellipsis button on the right-top corner of Collection path section will be hidden.

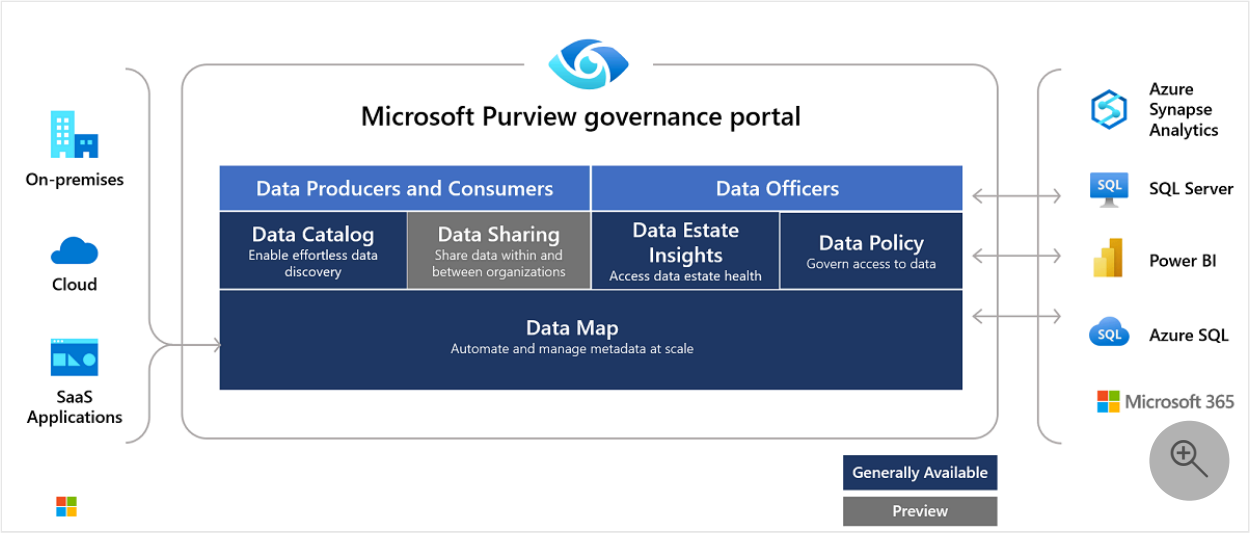
3. The assets in **Hierarchy** section are also affected by permissions. Assets without read permission will be grayed.

Next steps

Now that you have a base understanding of collections, and access control, follow the guides below to create and manage those collections, or get started with registering sources into your Microsoft Purview Data Map.

- How to create and manage collections
- Supported data sources in the Microsoft Purview Data Map

What are Microsoft Purview's classic governance solutions?



Article • 01/28/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Note**
>
> Data governance in Microsoft Purview has a new experience! This article covers functionality and features in the classic experience. For more information about the latest tools and features, see the overview for data governance using the data catalog.

Microsoft Purview's classic data governance solutions created one place for you to manage your on-premises, multicloud, and software-as-a-service (SaaS) data. Using the Microsoft Purview Data Catalog, Data Map, Data Estate Insights, and Policies you could:

- Create an up-to-date map of your business' entire data landscape.
- Empower your users to find useful, trustworthy data.
- Classify your sensitive information, so it's visible and you can manage it.
- Automatically map your data's lineage so you can see where it's coming from and where it's going.
- Enable your business' data curators and security administrators with the tools they need to manage and secure your data estate.

> **Tip**
>
> Looking to govern your data in Microsoft 365 by keeping what you need and deleting what you don't? Use Microsoft Purview Data Lifecycle Management.

Data Map

Microsoft Purview automates data discovery by providing data scanning and classification for assets across your data estate. Metadata and descriptions of discovered data assets are integrated into a holistic map of your data estate. Microsoft Purview Data Map provides the foundation for data discovery and data governance. Microsoft Purview Data Map is a cloud native PaaS service that captures metadata about enterprise data present in analytics and operation systems on-premises and cloud. Microsoft Purview Data Map is automatically kept up to date with built-in automated scanning and classification system. Business users can configure and use the data map through an intuitive UI and developers can programmatically interact with the Data Map using open-source Apache Atlas 2.2 APIs. Microsoft Purview Data Map powers the Microsoft Purview Data Catalog, the Microsoft Purview Data Estate Insights and the Microsoft Purview Data Policy as unified experiences within the Microsoft Purview governance portal.

For more information, see our introduction to Data Map.

Atop the Data Map, there are purpose-built apps that create environments for data discovery, access management, and insights about your data landscape.

Expand table

App	Description
Classic Data Catalog	Finds trusted data sources by browsing and searching your data assets. The data catalog aligns your assets with friendly business terms and data classification to identify data sources.
Data Estate Insights	Gives you an overview of your data estate to help you discover what kinds of data you have and where it is.
Data Policy	A set of central, cloud-based experiences that help you provision access to data securely and at scale.

Classic Data Catalog

With the classic Microsoft Purview Data Catalog, business and technical users can quickly and easily find relevant data using a search experience with filters based on lenses such as glossary terms, classifications, sensitivity labels and more. For subject matter experts, data stewards and officers, the Microsoft Purview Data Catalog provides data curation features such as business glossary management and the ability to automate tagging of data assets with glossary terms. Data consumers and producers can also visually trace the lineage of data assets: for example, starting from operational systems on-premises, through movement, transformation & enrichment with various data storage and processing systems in the cloud, to consumption in an analytics system like Power BI. For more information, see our introduction to search using Data Catalog.

Data Estate Insights

With the Microsoft Purview Data Estate Insights, the chief data officers and other governance stakeholders can get a bird's eye view of their data estate and can gain actionable insights into the governance gaps that can be resolved from the experience itself.

For more information, see our introduction to Data Estate Insights.

Data Policy

Microsoft Purview Data Policy is a set of central, cloud-based experiences that help you manage access to data sources and datasets securely and at scale.

- Manage access to data sources from a single-pane of glass, cloud-based experience
- Enables at-scale access provisioning
- Introduces a new data-plane permission model that is external to data sources
- It's seamlessly integrated with Microsoft Purview Data Map and Catalog:
  - Search for data assets and grant access only to what is required via fine-grained policies.
  - Path to support SaaS, on-premises, and multicloud data sources.
  - Path to create policies that leverage any metadata associated to the data objects.
- Based on role definitions that are simple and abstracted (for example: Read, Modify)

For more information, see our introductory guides:

- Data owner access policies (preview): Provision fine-grained to broad access to users and groups via intuitive authoring experience.
- Self-service access policies (preview): Self-Service: Workflow approval and automatic provisioning of access requests initiated by business analysts that discover data assets in Microsoft Purview's catalog.
- DevOps policies: Provision IT operations personnel access to SQL system metadata, so that they can monitor performance, health and audit security, while limiting the insider threat.

Here are the benefits of the Data Policy app:

Expand table

Principle	Benefit
Simplify	Permissions are bundled into role definitions that are abstracted and consistent across data source types, like Read and Modify.
	Reduce the need of permission expertise for each data source type.
Reduce effort	Graphical interface lets you navigate the data object hierarchy quickly.
	Supports policies on entire Azure resource groups and subscriptions.
Enhance security	Access is granted centrally and can be easily reviewed and revoked.
	Reduces the need for privileged accounts to configure access directly at the data source.

Principle	Benefit
	Supports the Principle of Least Privilege via data resource scopes and common role definitions.

Traditional challenges that Microsoft Purview seeks to address

Challenges for data consumers

Traditionally, discovering enterprise data sources has been an organic process based on communal knowledge. For companies that want the most value from their information assets, this approach presents many challenges:

- Because there's no central location to register data sources, users might be unaware of a data source unless they come into contact with it as part of another process.
- Unless users know the location of a data source, they can't connect to the data by using a client application. Data-consumption experiences require users to know the connection string or path.
- The intended use of the data is hidden to users unless they know the location of a data source's documentation. Data sources and documentation might live in several places and be consumed through different kinds of experiences.
- If users have questions about an information asset, they must locate the expert, or team responsible for that data and engage them offline. There's no explicit connection between the data and the experts that understand the data's context.
- Unless users understand the process for requesting access to the data source, discovering the data source and its documentation won't help them access the data.

Challenges for data producers

Although data consumers face the previously mentioned challenges, users who are responsible for producing and maintaining information assets face challenges of their own:

- Annotating data sources with descriptive metadata is often a lost effort. Client applications typically ignore descriptions that are stored in the data source.

- Creating documentation for data sources can be difficult and it's an ongoing responsibility to keep documentation in sync with data sources. Users might not trust documentation that's perceived as being out of date.
- Creating and maintaining documentation for data sources is complex and time-consuming. Making that documentation readily available to everyone who uses the data source can be even more so.
- Restricting access to data sources and ensuring that data consumers know how to request access is an ongoing challenge.

When such challenges are combined, they present a significant barrier for companies that want to encourage and promote the use and understanding of enterprise data.

Challenges for security administrators

Users who are responsible for ensuring the security of their organization's data may have any of the challenges listed above as data consumers and producers, and the following extra challenges:

- An organization's data is constantly growing and being stored and shared in new directions. The task of discovering, protecting, and governing your sensitive data is one that never ends. You need to ensure that your organization's content is being shared with the correct people, applications, and with the correct permissions.
- Understanding the risk levels in your organization's data requires diving deep into your content, looking for keywords, RegEx patterns, and sensitive data types. For example, sensitive data types might include Credit Card numbers, Social Security numbers or Bank Account numbers. You must constantly monitor all data sources for sensitive content, as even the smallest amount of data loss can be critical to your organization.
- Ensuring that your organization continues to comply with corporate security policies is a challenging task as your content grows and changes, and as those requirements and policies are updated for changing digital realities. Security administrators need to ensure data security in the quickest time possible.

Microsoft Purview advantages

Microsoft Purview is designed to address the issues mentioned in the previous sections and to help enterprises get the most value from their existing information assets. The catalog makes data sources easily discoverable and understandable by the users who manage the data.

Microsoft Purview provides a cloud-based service into which you can register data sources. During registration, the data remains in its existing location, but a copy of its metadata is added to Microsoft Purview, along with a reference to the data source location. The metadata is also indexed to make each data source easily discoverable via search and understandable to the users who discover it.

After you register a data source, you can then enrich its metadata. Either the user who registered the data source or another user in the enterprise can add more metadata. Any user can annotate a data source by providing descriptions, tags, or other metadata for requesting data source access. This descriptive metadata supplements the structural metadata, such as column names and data types that are registered from the data source.

Discovering and understanding data sources and their use is the primary purpose of registering the sources. Enterprise users might need data for business intelligence, application development, data science, or any other task where the correct data is required. They can use the data catalog discovery experience to quickly find data that matches their needs, understand the data to evaluate its fitness for purpose, and consume the data by opening the data source in their tool of choice.

At the same time, users can contribute to the catalog by tagging, documenting, and annotating data sources that have already been registered. They can also register new data sources, which are then discovered, understood, and consumed by the community of catalog users.

Lastly, Microsoft Purview Data Policy app provides a superior solution to keep your data secure.

In-region data residency

Microsoft Purview processes data and stores metadata information, but does not store customer data. Data is processed in its data region, and customer metadata stays within the region where Microsoft Purview is deployed. For regions with data residency requirements, customer data stays within its region, and customer metadata is always kept within the same region where Microsoft Purview is deployed.

Next steps

Tip

Check if Microsoft Purview is available in your region on the **regional availability page**.

To get started with Microsoft Purview, see Create a Microsoft Purview account. For pricing information see, Pricing for Microsoft Purview.

Overview of pricing for classic data governance solutions in Microsoft Purview

Article • 05/20/2025

Classic data governance solutions in Microsoft Purview in the classic governance portal provided a single pane of glass for managing data governance by enabling automated scanning and classifying data.

> **Tip**
>
> For specific price details for governance in the classic portal, see the Microsoft Purview (formerly Azure Purview) pricing page. This article will guide you through the features and factors that will affect pricing.

Why do you need to understand the components of pricing?

- While the pricing for classic data governance solutions in Microsoft Purview is on a subscription-based **Pay-As-You-Go** model, there are various dimensions that you can consider while budgeting
- This guideline is intended to help you plan the budgeting for classic data governance solutions by providing a view on the control factors that impact the budget

Factors impacting Azure Pricing

There are **direct** and **indirect** costs that need to be considered while planning budgeting and cost management.

Direct costs impacting Microsoft Purview pricing are based on these applications:

- The Microsoft Purview Data Map
- Data Estate Insights

Indirect costs

Indirect costs impacting classic data governance solutions in Microsoft Purview pricing are:

- Managed resources

    - An Event Hubs namespace can be configured at creation or enabled in the Azure portal on the Kafka configuration page of the account to enable monitoring with *Atlas Kafka* topics events. The Event Hubs will be charged separately.

- Azure private endpoint
    - Azure private end points are used for classic data governance solutions in Microsoft Purview, where it's required for users on a virtual network (virtual network) to securely access the catalog over a private link
    - The prerequisites for setting up private endpoints could result in extra costs, for example, costs if you deploy a virtual network.

- Self-hosted integration runtime related costs
    - Self-hosted integration runtime requires infrastructure, which results in extra costs
    - It's required to deploy and register Self-hosted integration runtime (SHIR) inside the same virtual network where Microsoft Purview ingestion private endpoints are deployed
    - Other memory requirements for scanning
        - Certain data sources such as SAP require more memory on the SHIR machine for scanning

- Virtual Machine Sizing
    - Plan virtual machine sizing in order to distribute the scanning workload across VMs to optimize the v-cores utilized while running scans

- Microsoft 365 license
    - Microsoft Purview Information Protection sensitivity labels can be automatically applied to your Azure assets in the Microsoft Purview Data Map.
    - Microsoft Purview Information Protection sensitivity labels are created and managed in the Microsoft Purview portal.
    - To create sensitivity labels for use in Microsoft Purview, you must have an active Microsoft 365 license, which offers the benefit of automatic labeling. For the full list of licenses, see the Sensitivity labels in Microsoft Purview FAQ.

- Azure Alerts
    - Azure Alerts can notify customers of issues found with infrastructure or applications using the monitoring data in Azure Monitor
    - The pricing for Azure Alerts is available here

- Cost Management Budgets & Alerts
    - Automatically generated cost alerts are used in Azure to monitor Azure usage and spending based on when Azure resources are consumed
    - Azure allows you to create and manage Azure budgets. Refer tutorial

- Multicloud egress charges
  - Consider the egress charges (minimal charges added as a part of the multicloud subscription) associated with scanning multicloud (for example AWS, Google) data sources running native services excepting the S3 and RDS sources

Pricing for the Microsoft Purview Data Map

Article • 05/20/2025

This guide covers pricing guidelines for Microsoft Purview Data Map in the classic Microsoft Purview governance portal.

For a full pricing guideline details for Microsoft Purview (formerly Azure Purview), see the pricing guideline overview.

For specific price details, see the Microsoft Purview (formerly Azure Purview) pricing page. This article will guide you through the features and factors that will affect pricing for Data Map.

Direct costs impacting pricing for Data Map are based on the following three dimensions:

- **Elastic data map**
- **Automated scanning & classification**
- **Advanced resource sets**

Elastic Data Map

- The **Data Map** is the foundation of the Microsoft Purview governance portal architecture and so needs to be up to date with asset information in the data estate at any given point.
- The data map is charged in terms of **Capacity Unit** (CU). The data map is provisioned at one CU if the catalog is storing up to 10 GB of metadata storage and serves up to 25 data map operations/sec.
- The data map is always provisioned at one CU when an account is first created.
- However, the data map scales automatically between the minimal and maximal limits of that elasticity window, to cater to changes in the data map with respect to two key factors - **operation throughput** and **metadata storage**.

Operation throughput

- An event driven factor based on the Create, Read, Update, Delete operations performed on the data map
- Some examples of the data map operations would be:
  - Creating an asset in Data Map
  - Adding a relationship to an asset such as owner, steward, parent, lineage
  - Editing an asset to add business metadata such as description, glossary term
  - Keyword-search returning results to search result page

    - Importing or exporting information using API
- If there are multiple queries executed on the Data Map, the number of I/O operations also increases resulting in the scaling up of the data map
- The number of concurrent users also forms a factor governing the data map capacity unit
- Other factors to consider are type of search query, API interaction, workflows, approvals, and so on
- Data burst level
    - When there's a need for more operations/second throughput, the Data map can autoscale within the elasticity window to cater to the changed load
    - This constitutes the **burst characteristic** that needs to be estimated and planned for
    - The burst characteristic comprises the **burst level** and the **burst duration** for which the burst exists
        - The **burst level** is a multiplicative index of the expected consistent elasticity under steady state
        - The **burst duration** is the percentage of the month that such bursts (in elasticity) are expected because of growing metadata or higher number of operations on the data map

Metadata storage

- If the number of assets reduces in the data estate, and are then removed in the data map through subsequent incremental scans, the storage component automatically reduces and so the data map scales down

Automated scanning, classification, and ingestion

There are two major automated processes that can trigger ingestion of metadata into the Microsoft Purview Data Map:

- Automatic scans using native connectors. This process includes three main steps:
    - Metadata scan
    - Automatic classification
    - Ingestion of metadata into the Microsoft Purview Data Map

- Automated ingestion using Azure Data Factory and/or Azure Synapse pipelines. This process includes:
    - Ingestion of metadata and lineage into the Microsoft Purview Data Map if the account is connected to any Azure Data Factory or Azure Synapse pipelines.

Automatic scans using native connectors

- A **full scan** processes all assets within a selected scope of a data source whereas an **incremental scan** detects and processes assets, which have been created, modified, or deleted since the previous successful scan
- All scans (full or Incremental scans) will pick up **updated, modified, or deleted** assets
- It's important to consider and avoid the scenarios when multiple people or groups belonging to different departments set up scans for the same data source resulting in more pricing for duplicate scanning
- Schedule **frequent incremental scans** post the initial full scan aligned with the changes in the data estate. This will ensure the data map is kept up to date always and the incremental scans consume lesser v-core hours as compared to a full scan
- The **"View Details"** link for a data source will enable users to run a full scan. However, consider running incremental scans after a full scan for optimized scanning excepting when there's a change to the scan rule set (classifications/file types)
- **Register the data source at a parent collection** and **Scope scans at child collection** with different access controls to ensure there are no duplicate scanning costs being entailed
- Curtail the users who are allowed to register data sources for scanning through **fine grained access control** and **Data Source Administrator** role using Collection authorization. This will ensure only valid data sources are allowed to be registered and scanning v-core hours is controlled resulting in lower costs for scanning
- Consider that the **type of data source** and the **number of assets** being scanned affect the scan duration
- **Create custom scan rule sets** to include only the subset of **file types** available in your data estate and **classifications** that are relevant to your business requirements to ensure optimal use of the scanners
- While creating a new scan for a data source, follow the **order of preparation** recommended before actually running the scan. This includes gathering the requirements for **business specific classifications** and **file types** (for storage accounts) to enable appropriate scan rule sets to be defined to avoid multiple scans and control unnecessary costs for multiple scans through missed requirements
- Align your scan schedules with Self-Hosted Integration Runtime (SHIR) VMs (Virtual Machines) size to avoid extra costs linked to virtual machines

Automated ingestion using Azure Data Factory and/or Azure Synapse pipelines

- Metadata and lineage are ingested from Azure Data Factory or Azure Synapse pipelines every time the pipelines run in the source system.

Advanced resource sets

- The Microsoft Purview Data Map uses **resource sets** to address the challenge of mapping large numbers of data assets to a single logical resource by providing the ability to scan all the files in the data lake and find patterns (GUID, localization patterns, etc.) to group them as a single asset in the data map

- **Advanced Resource Set** is an optional feature, which allows for customers to get enriched resource set information computed such as Total Size, Partition Count, etc., and enables the customization of resource set grouping via pattern rules. If Advanced Resource Set feature isn't enabled, Unified Catalog will still contain resource set assets, but without the aggregated properties. There will be no "Resource Set" meter billed to the customer in this case.

- Use the basic resource set feature, before switching on the Advanced Resource Sets in the Microsoft Purview Data Map to verify if requirements are met

- Consider turning on Advanced Resource Sets if:
  - Your data lakes schema is constantly changing, and you're looking for more value beyond the basic Resource Set feature to enable the Microsoft Purview Data Map to compute parameters such as #partitions, size of the data estate, etc., as a service
  - There's a need to customize how resource set assets get grouped.

- It's important to note that billing for Advanced Resource Sets is based on the compute used by the offline tier to aggregate resource set information and is dependent on the size/number of resource sets in your catalog

Pricing for Data Estate Insights

Article • 01/28/2025

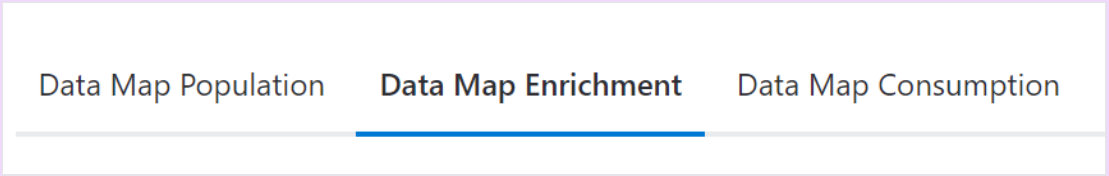
> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

This guide covers pricing guidelines for the classic Data Estate Insights features in the classic Microsoft Purview governance portal.

> **Tip**
>
> There's a **new data estate health experience** in the new Microsoft Purview Data Catalog.

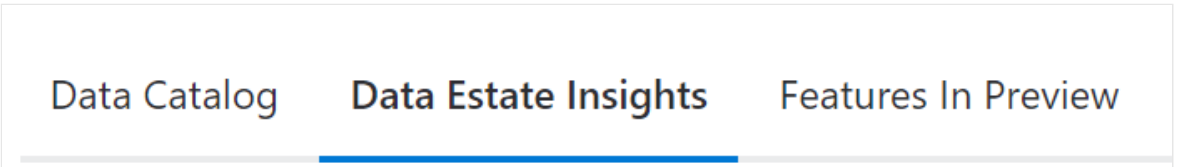
For a full pricing guideline details for classic data governance solutions in Microsoft Purview, see the pricing guideline overview.

For specific price details, see the classic data governance solutions in Microsoft Purview pricing page. This article guides you through the features and factors that affect pricing for Data Estate Insights.



Guidelines

Data Estate Insights in the classic Microsoft Purview governance portal is billed on two dimensions:



- **Report generation** - this incorporates the job that checks for any changes in your environment and the jobs that aggregate metrics about your Microsoft Purview account that will appear in specific reports.
  - If you have set your reports to refresh on a schedule, at the time of refresh there will be a job to check if any updates have been made to your environment. You'll always be billed a small amount for this check.
  - If updates have been made to your environment, you're billed for the jobs that aggregate metrics and generate your report.

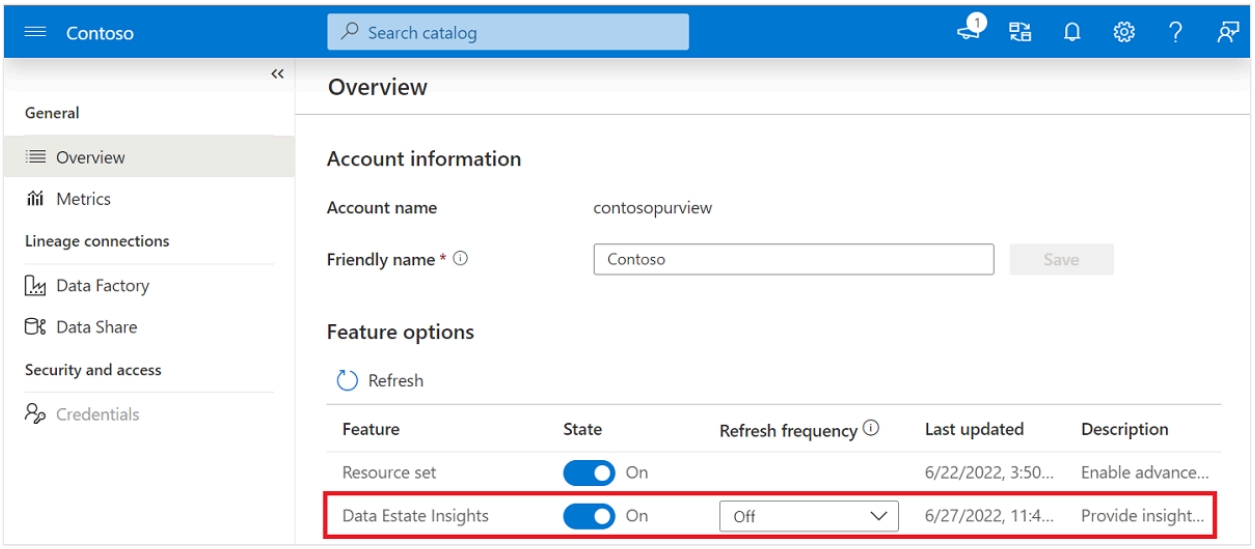
    > **Note**

On the pricing page, you can find details for report generation pricing under Data Map Enrichment.

- **Report consumption** - This incorporates access of the report features (currently served through the UX). On the pricing page, you can find details for report generation pricing under Data Estate Insights.

> **Important**
>
> The Data Estate Insights application is **on** by default when you create a Microsoft Purview account. This means, "State" is on and "Refresh Frequency" is set to automatic*.
>
> * At this time automatic refresh is weekly.

If you want to reschedule or reduce how often your reports are refreshed, you can schedule your Data Estate Insights reports.



If you don't plan on using Data Estate Insights for a while, a **data curator** on the **root collection** can disable Data Estate Insights features in one of two ways:

- Disable the Data Estate Insights application - this stops billing from both report generation and report consumption.
- Disable report refresh - insights readers have access to current reports, but reports won't be refreshed. Billing occurs for report consumption but not report generation.

> **Note**
>
> The application or report refresh can be enabled again later at any time.

A **data curator** on your account's **root collection** can make these changes in the Management section of the Microsoft Purview governance portal in **Overview**, under

Feature options. For specific steps, see the disable Data Estates Insights article

Schedule Report Refresh

Your reports can be scheduled to refresh daily, weekly, or monthly depending on your needs, and this will affect billing.

Firstly, on the date/time of your scheduled refresh, insights runs a job to check if any changes have been made in your environment since the last refresh. You'll always be billed for this job.

If changes have been made since the last report refresh, billing is calculated based on the amount of compute power that is used to generate the report, and is billed at the time of report generation. For more information about specific pricing, see the pricing page **under Data Map Enrichment.**

For more information about setting your refresh schedule, see the schedule Data Estate Insights reports article.

Disable the Data Estate Insights application

Disabling Data Estate Insights disables the entire application, including these reports:

- Stewardship
- Asset
- Glossary
- Classification
- Labeling

The application icon will still show in the menu, but insights readers won't have access to reports at all, and report generation jobs are stopped. The Microsoft Purview account

won't receive any bill for Data Estate Insights.

For steps to disable the Data Estate Insights application, see the disable article.

Disable report refresh

You can choose to disable report refreshes instead of disabling the entire Data Estate Insights application.

When you disable report refreshes, insight readers will be able view reports but they'll see a banner on top of each report, warning that the report might not be current. It will also indicate the date the report was last generated.

In this case, graphs showing data from last 30 days will appear blank after 30 days. Graphs showing snapshot of the data map will continue to show graph and details. When an insights readers accesses an insight report, report consumption meter will be triggered, and the Microsoft Purview account will be billed.

For steps to disable report refresh see the disable article.

Create a Microsoft Purview account

Article • 10/28/2024

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> You can only create one Microsoft Purview account per tenant. If your organization already has a Microsoft Purview account, you won't be able to create a new Microsoft Purview account unless your organization already had multiple accounts and is still under the the preexisting quota. For more information, see the FAQ.

> **Tip**
>
> If your organization hasn't created a Microsoft Purview account in Azure before, start in the new Microsoft Purview portal: https://purview.microsoft.com. You can use the free version to test capabilities, and upgrade to the enterprise version for the full data governance in Microsoft Purview features.

This quickstart describes the steps to create a Microsoft Purview (formerly Azure Purview) account through the Azure portal. Then we'll get started on the process of classifying, securing, and discovering your data in the Microsoft Purview Data Map!

The Microsoft Purview governance portal surfaces tools like the Microsoft Purview Data Map and Microsoft Purview Data Catalog that help you manage and govern your data landscape. By connecting to data across your on-premises, multicloud, and software-as-a-service (SaaS) sources, the Microsoft Purview Data Map creates an up-to-date map of your data estate. It identifies and classifies sensitive data, and provides end-to-end linage. Data consumers are able to discover data across your organization, and data administrators are able to audit, secure, and ensure right use of your data.

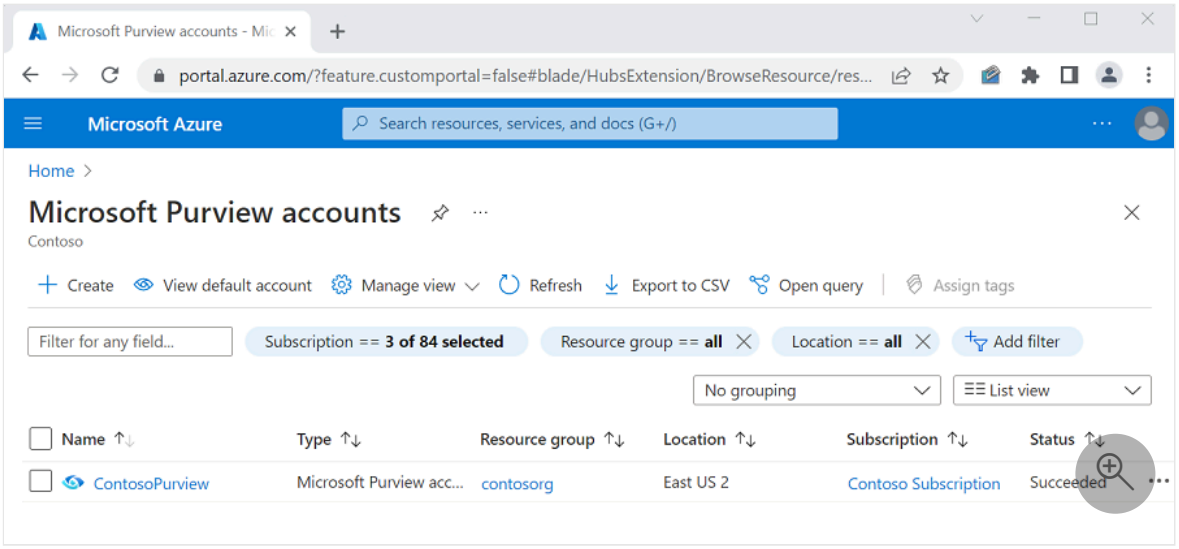
For more information about the governance capabilities of Microsoft Purview, see our governance solutions overview page.

Prerequisites

- If you don't have an Azure subscription, create a free subscription before you begin.
- A Microsoft Entra tenant associated with your subscription.
- The user account that you use to sign in to Azure must be a member of the *contributor* or *owner* role, or an *administrator* of the Azure subscription. To view the permissions that you have in the subscription, follow these steps:

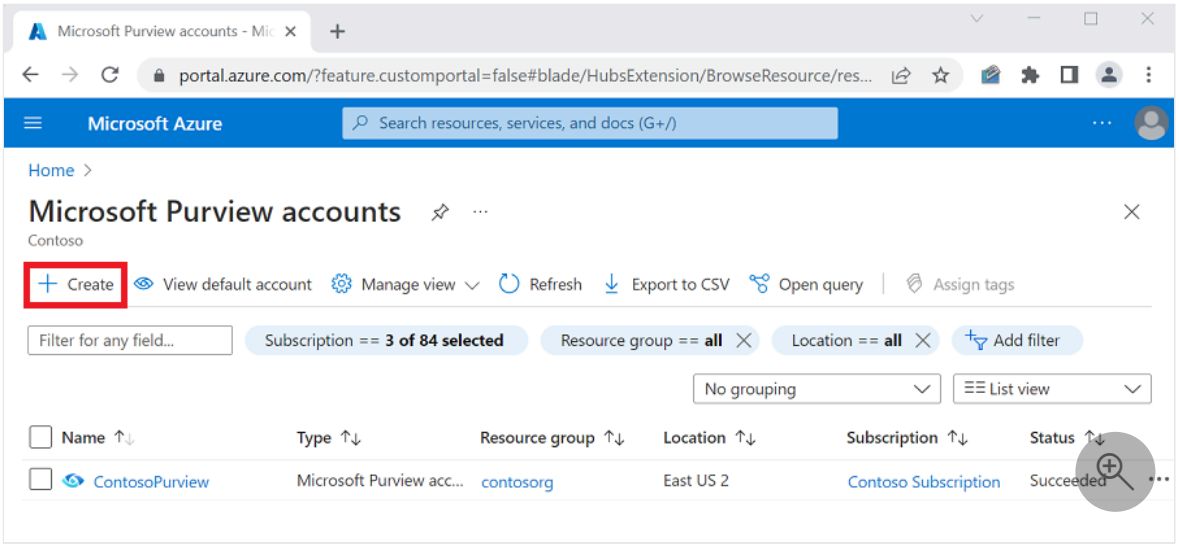
    1. Go to the Azure portal
    2. Select your username in the upper-right corner.
    3. Select the ellipsis button ("...") for more options.
    4. Then select **My permissions**.
    5. If you have access to multiple subscriptions, select the appropriate subscription.

Sign in to Azure



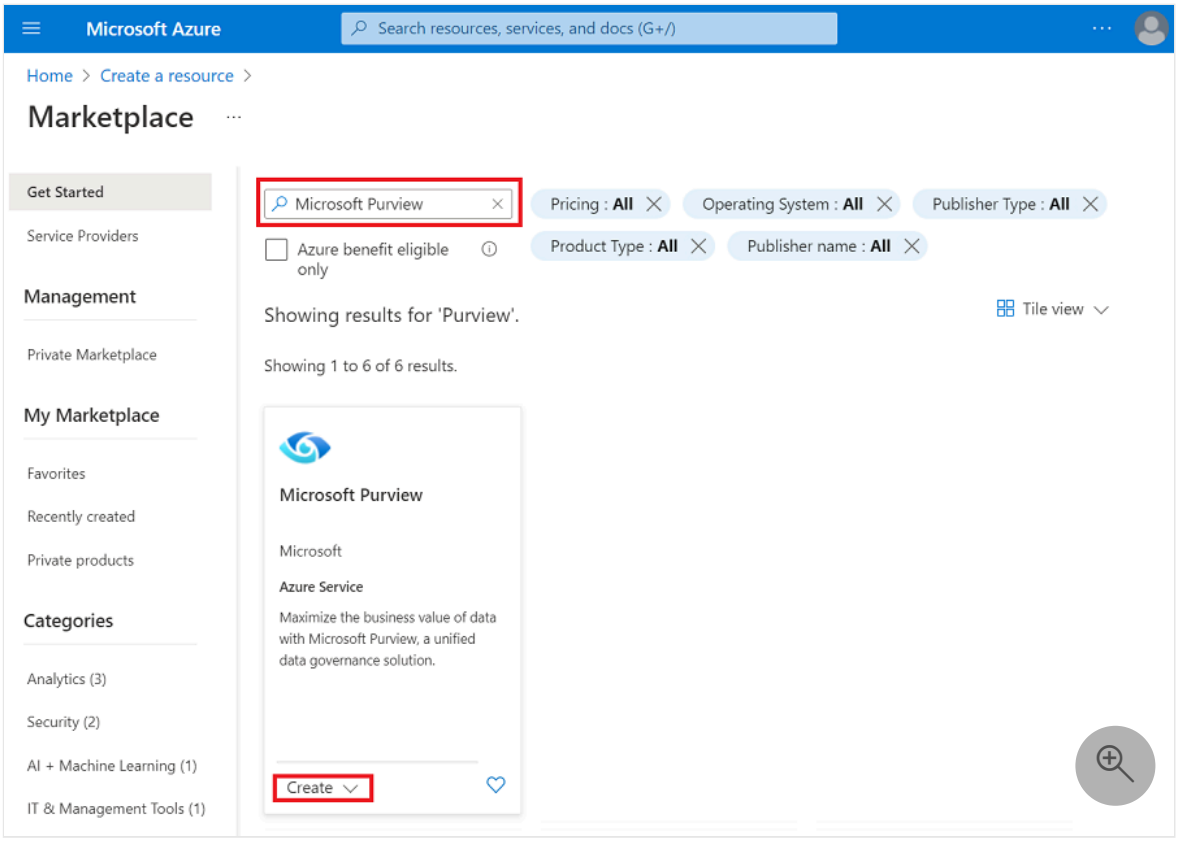
Sign in to the Azure portal with your Azure account.

Create an account



> **Tip**
>
> If you're creating the first Microsoft Purview account in your tenant, you don't need to set anything up and you should use **the free version of Microsoft Purview governance solutions** at **https://purview.microsoft.com**.

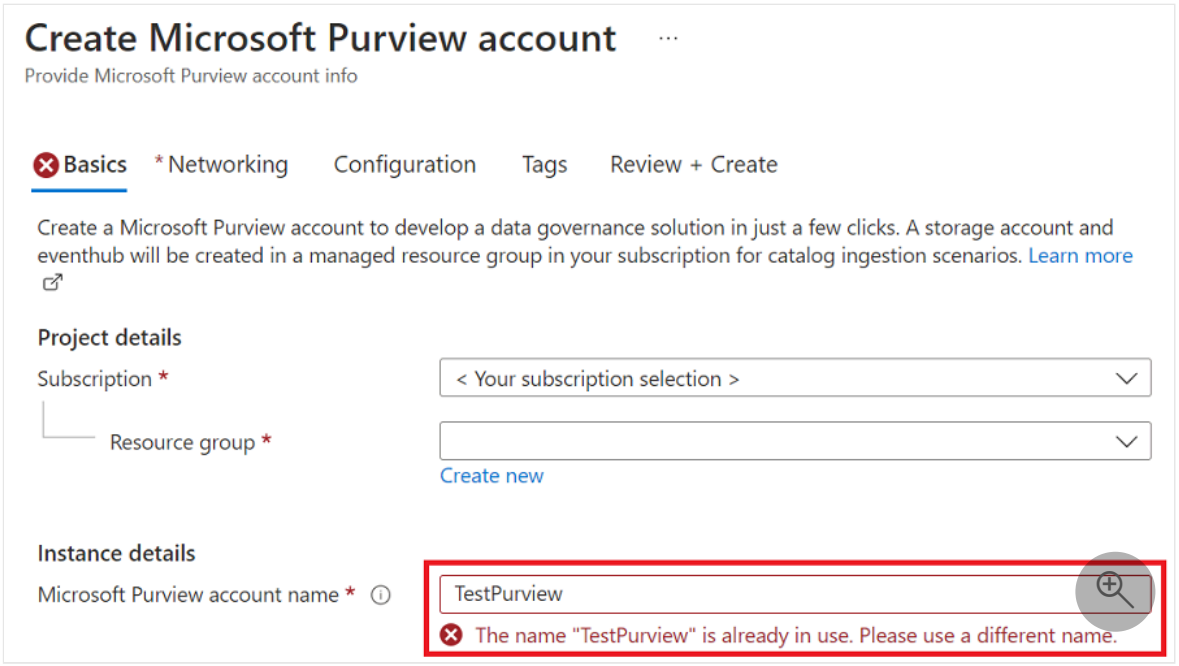
> **Important**
>
> If you have any **Azure Policies** preventing creation of **Storage accounts** or **Event Hub namespaces**, or preventing **updates to Storage accounts** first follow the **Microsoft Purview exception tag guide** to create an exception for Microsoft Purview accounts. Otherwise you will not be able to deploy Microsoft Purview.



1. Search for **Microsoft Purview** in the Azure portal.

2. Select **Create** to create a new Microsoft Purview account.

Or instead, you can go to the marketplace, search for **Microsoft Purview**, and select **Create**.



3. On the new Create Microsoft Purview account page under the **Basics** tab, select the Azure subscription where you want to create your account.

4. Select an existing **resource group** or create a new one to hold your account.

   To learn more about resource groups, see our article on using resource groups to manage your Azure resources.

5. Enter a **Microsoft Purview account name**. Spaces and symbols aren't allowed.

   The name of the Microsoft Purview account must be globally unique. If you see the following error, change the name of Microsoft Purview account and try creating again.

6. Choose a **location**.

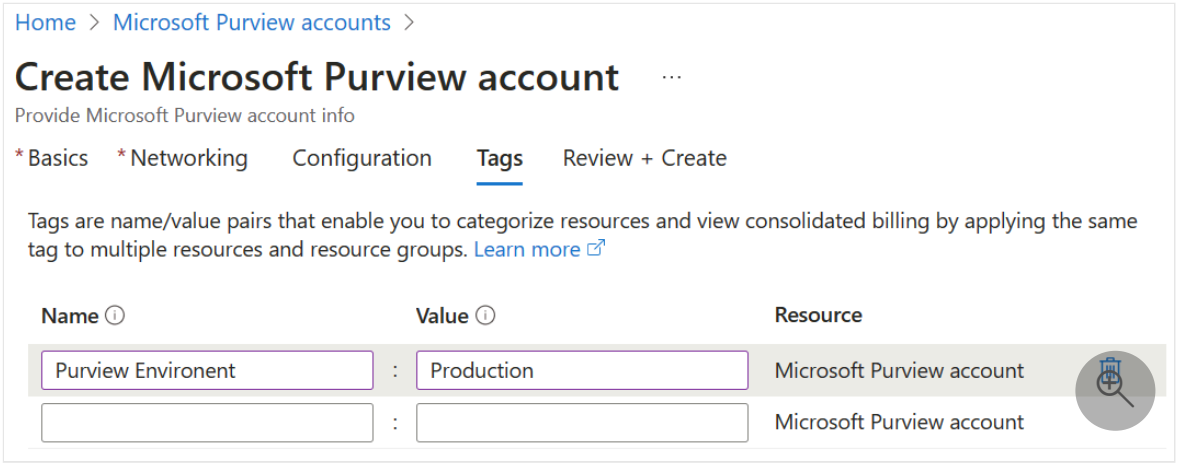
   The list shows only locations that support the Microsoft Purview governance portal, and if this is your organization's first Microsoft Purview account, the location is restricted to the one that matches your Microsoft Entra ID home region. This location is the region where your Microsoft Purview account and metadata are stored. Sources can be housed in other regions.

   > **Note**
   >
   > The Microsoft Purview, formerly Azure Purview, does not support moving accounts across regions, so be sure to deploy to the correction region. You can find out more information about this in move operation support for resources.

7. On the **Networking** tab you can choose to connect to all networks, or to use private endpoints. For more information and configuration options, see Configure firewall settings for your Microsoft Purview account and private endpoints for Microsoft Purview articles.

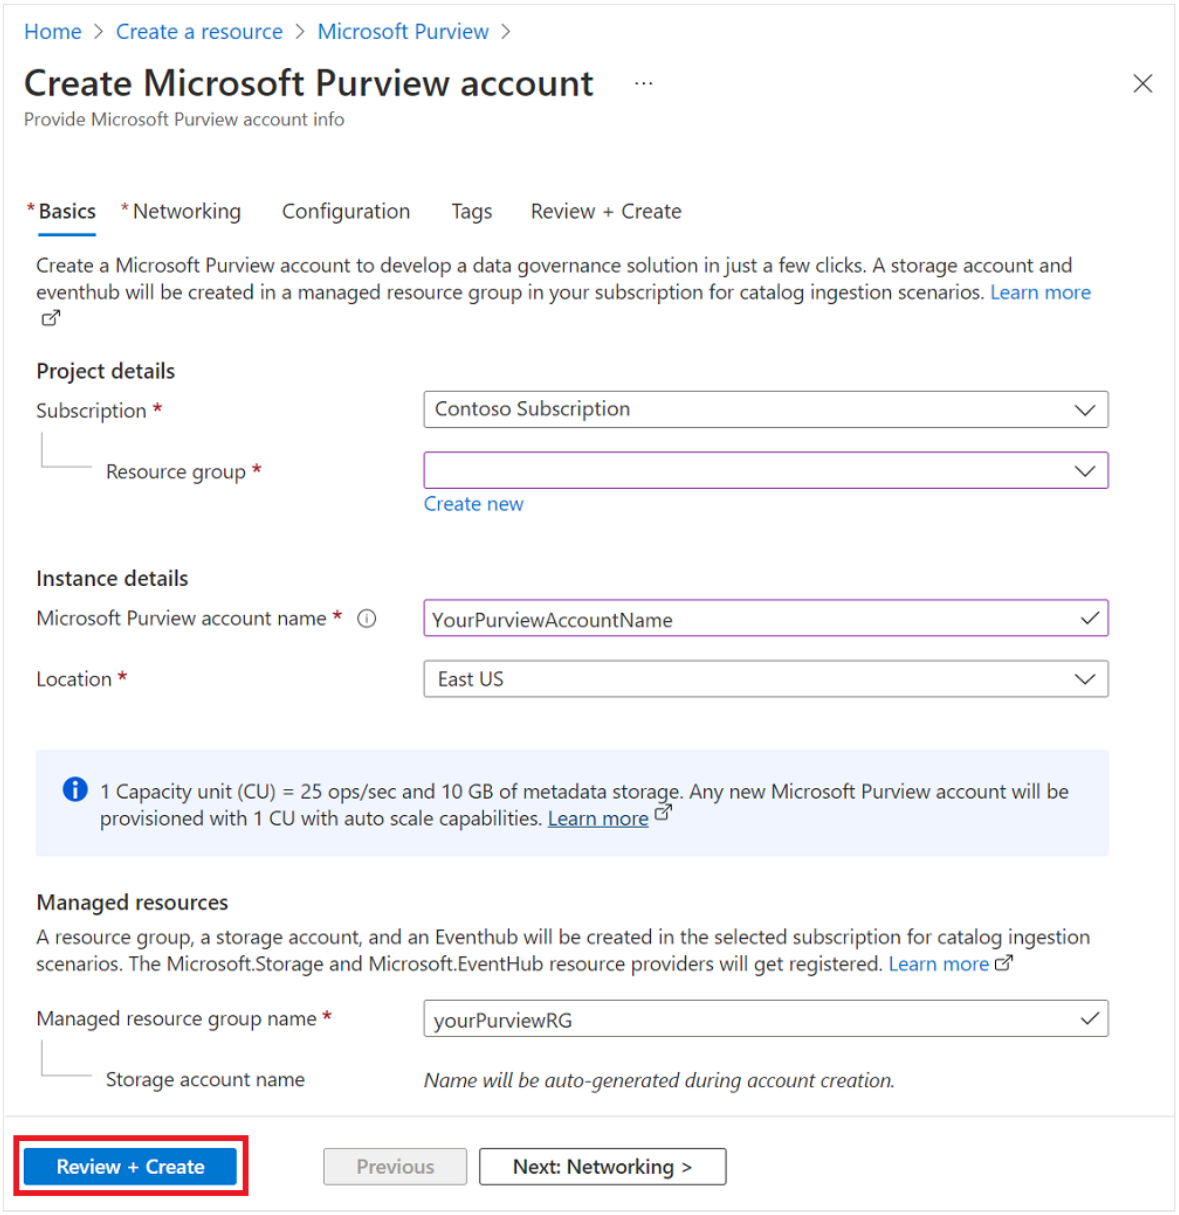
8. On **Configuration** tab you can choose to configure Event Hubs namespaces to programmatically monitor your Microsoft Purview account using Event Hubs and Atlas Kafka.

   - Steps to configure Event Hubs namespaces
   - Send and receive Atlas Kafka topics messages



> **Note**
>
> These options can be configured after you have created your account in **Kafka configuration** under settings on your Microsoft Purview account page in the Azure Portal.
>
> 
>

9. On the **Tags** tab, add a tag called **Purview environment**, and give it one of the below values:



Expand table

Value	Meaning
Production	This account is being used or will be used in the future to support all my cataloging and governance requirements in production.
Pre-Production	This account is being used or will be used in the future to validate cataloging and governance requirements before making it available to my users in production.
Test	This account is being used or will be used in the future to test out capabilities in Microsoft Purview Governance.
Dev	This account is being used or will be used in the future to test out capabilities or develop custom code, scripts etc. in Microsoft Purview

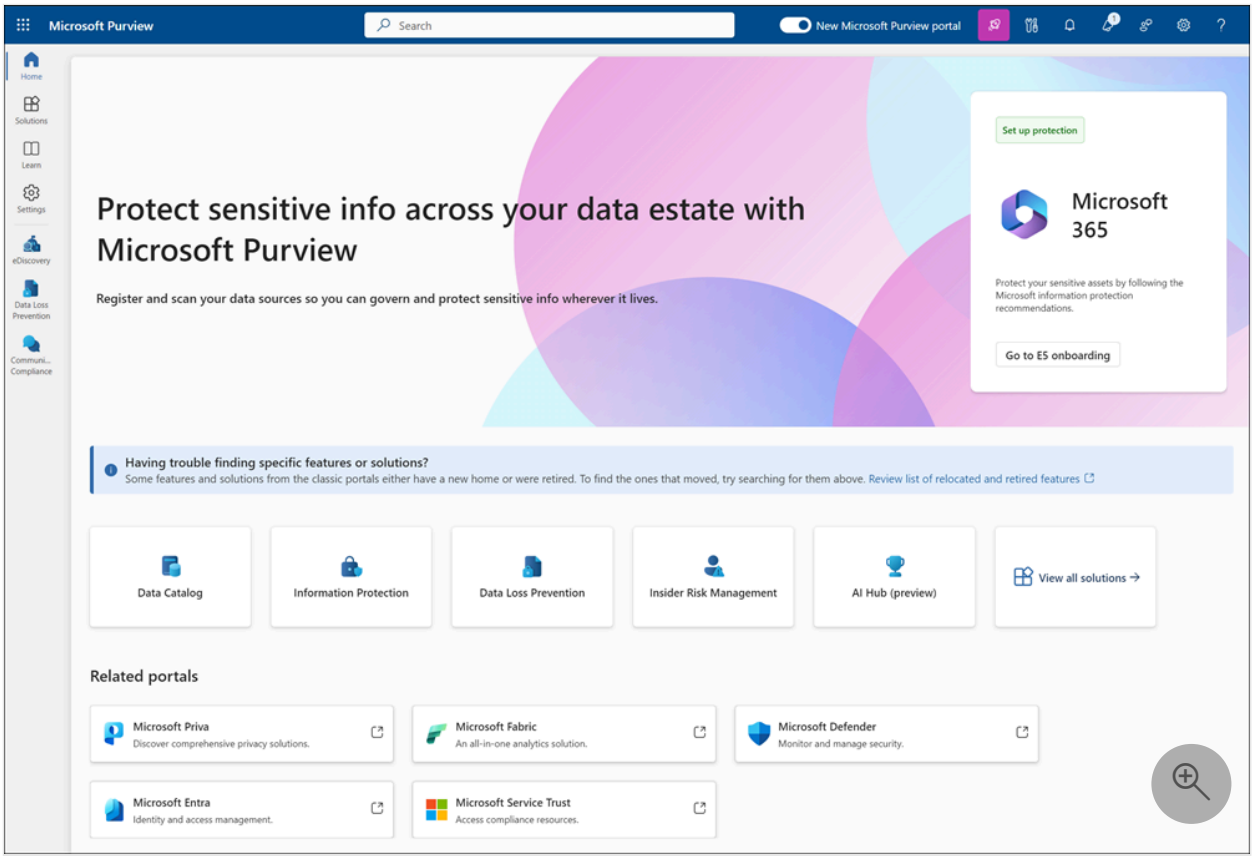
Value	Meaning
	Governance.
Proof of Concept	This account is being used or will be used in the future to test out capabilities or develop custom code, scripts etc. in Microsoft Purview Governance.

10. Select **Review & Create**, and then select **Create**. It takes a few minutes to complete the creation. The newly created account appears in the list on your **Microsoft Purview accounts** page.

Protect your account

To protect your Microsoft Purview Account from accidental deletion, Microsoft recommends that you create the Azure policy ['DenyAction'](/azure/governance/policy/concepts/effect-deny-action#denyaction-example)

JSON



```
{
  "if": {
    "allOf": [
      {
        "field": "type",
        "equals": "Microsoft.Purview/accounts"
      },
      {
        "field": "tags.environment",
        "equals": "Production"
      }
```

```
      ]
    },
    "then": {
      "effect": "denyAction",
      "details": {
        "actionNames": [
          "delete"
        ],
        "cascadeBehaviors": {
          "resourceGroup": "deny"
        }
      }
    }
  }
```

Open the Microsoft Purview portal

After your account is created, you can use the Microsoft Purview portal to access and manage it.

In a browser, navigate directly to https://purview.microsoft.com to access the portal.

For more information about using the portal, see our documentation on the Microsoft Purview portal.

Next steps

In this quickstart, you learned how to create a Microsoft Purview (formerly Azure Purview) account, and how to access it.

Next, you can create a user-assigned managed identity (UAMI) that will enable your new Microsoft Purview account to authenticate directly with resources using Microsoft Entra authentication.

To create a UAMI, follow our guide to create a user-assigned managed identity.

Follow these next articles to learn how to navigate the Microsoft Purview governance portal, create a collection, and grant access to the Microsoft Purview Data Map:

- Using Microsoft Purview portal
- Get started with data governance in Microsoft Purview
- Add users to your Microsoft Purview account

Quickstart: Create a Microsoft Purview (formerly Azure Purview) account using Azure PowerShell/Azure CLI

Article • 02/26/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> You can only create one Microsoft Purview account per tenant. If your organization already has a Microsoft Purview account, you won't be able to create a new Microsoft Purview account unless your organization already had multiple accounts and is still under the the preexisting quota. For more information, see the FAQ.

In this Quickstart, you'll create a Microsoft Purview account using Azure PowerShell/Azure CLI. PowerShell reference for Microsoft Purview is available, but this article will take you through all the steps needed to create an account with PowerShell.

The Microsoft Purview governance portal surfaces tools like the Microsoft Purview Data Map and Microsoft Purview Data Catalog that help you manage and govern your data landscape. By connecting to data across your on-premises, multi-cloud, and software-as-a-service (SaaS) sources, the Microsoft Purview Data Map creates an up-to-date map of your information. It identifies and classifies sensitive data, and provides end-to-end linage. Data consumers are able to discover data across your organization, and data administrators are able to audit, secure, and ensure right use of your data.

For more information about the classic governance capabilities of Microsoft Purview, see our governance solutions overview page.

Prerequisites

- If you don't have an Azure subscription, create a free subscription before you begin.

- A Microsoft Entra tenant associated with your subscription.
- The user account that you use to sign in to Azure must be a member of the *contributor* or *owner* role, or an *administrator* of the Azure subscription. To view the permissions that you have in the subscription, follow these steps:

    1. Go to the Azure portal
    2. Select your username in the upper-right corner.
    3. Select the ellipsis button ("...") for more options.
    4. Then select **My permissions**.
    5. If you have access to multiple subscriptions, select the appropriate subscription.

Sign in to Azure

Sign in to the Azure portal with your Azure account.

Install PowerShell

Install either Azure PowerShell or Azure CLI in your client machine to deploy the template: Command-line deployment

Create an account

1. Sign in with your Azure credential

    PowerShell

    Azure PowerShell

    ```
    Connect-AzAccount
    ```

2. If you have multiple Azure subscriptions, select the subscription you want to use:

    PowerShell

    Azure PowerShell

    ```
    Set-AzContext [SubscriptionID/SubscriptionName]
    ```

3. Create a resource group for your account. You can skip this step if you already have one:

PowerShell

Azure PowerShell

```
New-AzResourceGroup -Name myResourceGroup -Location 'East US'
```

4. Create or Deploy the account:

PowerShell

Use the New-AzPurviewAccount cmdlet to create the Microsoft Purview account:

Azure PowerShell

```
New-AzPurviewAccount -Name yourPurviewAccountName -
ResourceGroupName myResourceGroup -Location eastus -IdentityType
SystemAssigned -SkuCapacity 4 -SkuName Standard -
PublicNetworkAccess Enabled
```

5. The deployment command returns results. Look for `ProvisioningState` to see whether the deployment succeeded.

6. If you deployed the account using a service principal, instead of a user account, you'll also need to run the below command in the Azure CLI:

Azure CLI

```
az purview account add-root-collection-admin --account-name [Microsoft
Purview Account Name] --resource-group [Resource Group Name] --object-
id [User Object Id]
```

This command will grant the user account collection admin permissions on the root collection in your Microsoft Purview account. This allows the user to access the Microsoft Purview governance portal and add permission for other users. For more information about permissions in Microsoft Purview, see our permissions guide. For more information about collections, see our manage collections article.

Next steps

In this quickstart, you learned how to create a Microsoft Purview (formerly Azure Purview) account.

Follow these next articles to learn how to navigate the Microsoft Purview governance portal, create a collection, and grant access to the Microsoft Purview governance portal.

- How to use the Microsoft Purview governance portal
- Grant users permissions to the governance portal
- Create a collection

Quickstart: Create a Microsoft Purview (formerly Azure Purview) account using .NET SDK

Article • 02/26/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> You can only create one Microsoft Purview account per tenant. If your organization already has a Microsoft Purview account, you won't be able to create a new Microsoft Purview account unless your organization already had multiple accounts and is still under the the preexisting quota. For more information, see the FAQ.

In this quickstart, you'll use the .NET SDK to create a Microsoft Purview (formerly Azure Purview) account.

The Microsoft Purview governance portal surfaces tools like the Microsoft Purview Data Map and Microsoft Purview Data Catalog that help you manage and govern your data landscape. By connecting to data across your on-premises, multicloud, and software-as-a-service (SaaS) sources, the Microsoft Purview Data Map creates an up-to-date map of your information. It identifies and classifies sensitive data, and provides end-to-end linage. Data consumers are able to discover data across your organization, and data administrators are able to audit, secure, and ensure right use of your data.

For more information about the classic governance capabilities of Microsoft Purview, see our governance solutions overview page.

Prerequisites

- If you don't have an Azure subscription, create a free subscription before you begin.
- A Microsoft Entra tenant associated with your subscription.

- The user account that you use to sign in to Azure must be a member of the *contributor* or *owner* role, or an *administrator* of the Azure subscription. To view the permissions that you have in the subscription, follow these steps:

    1. Go to the Azure portal
    2. Select your username in the upper-right corner.
    3. Select the ellipsis button ("...") for more options.
    4. Then select **My permissions**.
    5. If you have access to multiple subscriptions, select the appropriate subscription.

Sign in to Azure

Sign in to the Azure portal with your Azure account.

Visual Studio

The walkthrough in this article uses Visual Studio 2019. The procedures for Visual Studio 2013, 2015, or 2017 may differ slightly.

Azure .NET SDK

Download and install Azure .NET SDK on your machine.

Create an application in Microsoft Entra ID

1. In Create a Microsoft Entra application, create an application that represents the .NET application you're creating in this tutorial. For the sign-on URL, you can provide a dummy URL as shown in the article (`https://contoso.org/exampleapp`).
2. In Get values for signing in, get the **application ID** and **tenant ID**, and note down these values that you use later in this tutorial.
3. In Certificates and secrets, get the **authentication key**, and note down this value that you use later in this tutorial.
4. In Assign the application to a role, assign the application to the **Contributor** role at the subscription level so that the application can create data factories in the subscription.

Create a Visual Studio project

Next, create a C# .NET console application in Visual Studio:

1. Launch **Visual Studio**.
2. In the Start window, select **Create a new project** > **Console App (.NET Framework)**. .NET version 4.5.2 or above is required.
3. In **Project name**, enter **PurviewQuickStart**.
4. Select **Create** to create the project.

Install NuGet packages

1. Select **Tools** > **NuGet Package Manager** > **Package Manager Console**.

2. In the **Package Manager Console** pane, run the following commands to install packages. For more information, see the Microsoft.Azure.Management.Purview NuGet package.

```
PowerShell
```

```
Install-Package Microsoft.Azure.Management.Purview
Install-Package Microsoft.Azure.Management.ResourceManager -
IncludePrerelease
Install-Package Microsoft.IdentityModel.Clients.ActiveDirectory
```

Tip

If you are getting an error that reads: **Package <package name> is not found in the following primary sources(s):** and it is listing a local folder, you need to update your package sources in Visual Studio to include the nuget site as an online source.

1. Go to **Tools**
2. Select **NuGet Package Manager**
3. Select **Package Manage Settings**
4. Select **Package Sources**
5. Add https://nuget.org/api/v2/ as a source.

Create a Microsoft Purview client

1. Open **Program.cs**, include the following statements to add references to namespaces.

```
C#
```

```
using System;
using System.Collections.Generic;
using System.Linq;
using Microsoft.Rest;
using Microsoft.Rest.Serialization;
   using Microsoft.Azure.Management.ResourceManager;
using Microsoft.Azure.Management.Purview;
   using Microsoft.Azure.Management.Purview.Models;
   using Microsoft.IdentityModel.Clients.ActiveDirectory;
```

2. Add the following code to the **Main** method that sets the variables. Replace the placeholders with your own values. For a list of Azure regions in which Microsoft Purview is currently available, search on **Microsoft Purview** and select the regions that interest you on the following page: Products available by region.

C#

```
// Set variables
string tenantID = "<your tenant ID>";
string applicationId = "<your application ID>";
string authenticationKey = "<your authentication key for the
application>";
string subscriptionId = "<your subscription ID where the data factory
resides>";
string resourceGroup = "<your resource group where the data factory
resides>";
string region = "<the location of your resource group>";
string purviewAccountName =
    "<specify the name of purview account to create. It must be
globally unique.>";
```

3. Add the following code to the **Main** method that creates an instance of **PurviewManagementClient** class. You use this object to create a Microsoft Purview Account.

C#

```
// Authenticate and create a purview management client
var context = new AuthenticationContext("https://login.windows.net/" +
tenantID);
ClientCredential cc = new ClientCredential(applicationId,
authenticationKey);
AuthenticationResult result = context.AcquireTokenAsync(
"https://management.azure.com/", cc).Result;
ServiceClientCredentials cred = new
TokenCredentials(result.AccessToken);
var client = new PurviewManagementClient(cred)
{
```

```
    SubscriptionId = subscriptionId
};
```

Create an account

Add the following code to the **Main** method that will create the **Microsoft Purview Account**.

C#

```
// Create a purview Account
Console.WriteLine("Creating Microsoft Purview Account " + purviewAccountName
+ "...");
Account account = new Account()
{
Location = region,
Identity = new Identity(type: "SystemAssigned"),
Sku = new AccountSku(name: "Standard", capacity: 4)
};
try
{
  client.Accounts.CreateOrUpdate(resourceGroup, purviewAccountName,
account);
  Console.WriteLine(client.Accounts.Get(resourceGroup,
purviewAccountName).ProvisioningState);
}
catch (ErrorResponseModelException purviewException)
{
Console.WriteLine(purviewException.StackTrace);
  }
  Console.WriteLine(
    SafeJsonConvert.SerializeObject(account, client.SerializationSettings));
  while (client.Accounts.Get(resourceGroup,
purviewAccountName).ProvisioningState ==
         "PendingCreation")
  {
    System.Threading.Thread.Sleep(1000);
  }
Console.WriteLine("\nPress any key to exit...");
Console.ReadKey();
```

Run the code

Build and start the application, then verify the execution.

The console prints the progress of creating Microsoft Purview Account.

Sample output

JSON

```
Creating Microsoft Purview Account testpurview...
Succeeded
{
  "sku": {
    "capacity": 4,
    "name": "Standard"
  },
  "identity": {
    "type": "SystemAssigned"
  },
  "location": "southcentralus"
}

Press any key to exit...
```

Verify the output

Go to the **Microsoft Purview accounts** page in the Azure portal and verify the account created using the above code.

Delete Microsoft Purview account

To programmatically delete a Microsoft Purview account, add the following lines of code to the program:

C#

```
Console.WriteLine("Deleting the Microsoft Purview Account");
client.Accounts.Delete(resourceGroup, purviewAccountName);
```

Check if Microsoft Purview account name is available

To check availability of a purview account, use the following code:

C#

```
CheckNameAvailabilityRequest checkNameAvailabilityRequest =
newCheckNameAvailabilityRequest()
{
```

```
    Name = purviewAccountName,
    Type =  "Microsoft.Purview/accounts"
};
Console.WriteLine("Check Microsoft Purview account name");
Console.WriteLine(client.Accounts.CheckNameAvailability(checkNameAvailabilit
yRequest).NameAvailable);
```

The above code with print 'True' if the name is available and 'False' if the name isn't available.

Next steps

In this quickstart, you learned how to create a Microsoft Purview (formerly Azure Purview) account, delete the account, and check for name availability. You can now download the .NET SDK and learn about other resource provider actions you can perform for a Microsoft Purview account.

Follow these next articles to learn how to navigate the Microsoft Purview governance portal, create a collection, and grant access to the Microsoft Purview governance portal.

- How to use the Microsoft Purview governance portal
- Grant users permissions to the governance portal

Quickstart: Create a Microsoft Purview (formerly Azure Purview) account using Python

Article • 01/28/2025

> **Note**
>
> Microsoft Purview Data Map (classic), Data Catalog (classic), Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> You can only create one Microsoft Purview account per tenant. If your organization already has a Microsoft Purview account, you will not be able to create a new Microsoft Purview account unless your organization already had multiple accounts and is still under the the pre-existing quota. For more information, see the FAQ.

In this quickstart, you'll create a Microsoft Purview (formerly Azure Purview) account programatically using Python. The Python reference for Microsoft Purview is available, but this article will take you through all the steps needed to create an account with Python.

The Microsoft Purview governance portal surfaces tools like the Microsoft Purview Data Map and Microsoft Purview Data Catalog that help you manage and govern your data landscape. By connecting to data across your on-premises, multi-cloud, and software-as-a-service (SaaS) sources, the Microsoft Purview Data Map creates an up-to-date map of your information. It identifies and classifies sensitive data, and provides end-to-end linage. Data consumers are able to discover data across your organization, and data administrators are able to audit, secure, and ensure right use of your data.

For more information about the classic governance capabilities of Microsoft Purview, see our governance solutions overview page.

Prerequisites

- If you don't have an Azure subscription, create a free subscription before you begin.
- A Microsoft Entra tenant associated with your subscription.
- The user account that you use to sign in to Azure must be a member of the *contributor* or *owner* role, or an *administrator* of the Azure subscription. To view the permissions that you have in the subscription, follow these steps:

    1. Go to the Azure portal
    2. Select your username in the upper-right corner.
    3. Select the ellipsis button ("...") for more options.
    4. Then select **My permissions**.
    5. If you have access to multiple subscriptions, select the appropriate subscription.

Sign in to Azure

Sign in to the Azure portal with your Azure account.

Install the Python package

1. Open a terminal or command prompt with administrator privileges.
2. First, install the Python package for Azure management resources:

    ```
    Python
    ```

    ```
    pip install azure-mgmt-resource
    ```

3. To install the Python package for Microsoft Purview, run the following command:

    ```
    Python
    ```

    ```
    pip install azure-mgmt-purview
    ```

    The Python SDK for Microsoft Purview supports Python 2.7, 3.3, 3.4, 3.5, 3.6 and 3.7.

4. To install the Python package for Azure Identity authentication, run the following command:

    ```
    Python
    ```

```
pip install azure-identity
```

> **Note**
>
> The "azure-identity" package might have conflicts with "azure-cli" on some common dependencies. If you meet any authentication issue, remove "azure-cli" and its dependencies, or use a clean machine without installing "azure-cli" package.

Create a purview client

1. Create a file named **purview.py**. Add the following statements to add references to namespaces.

```Python
from azure.identity import ClientSecretCredential
 from azure.mgmt.resource import ResourceManagementClient
 from azure.mgmt.purview import PurviewManagementClient
 from azure.mgmt.purview.models import *
 from datetime import datetime, timedelta
 import time
```

2. Add the following code to the **Main** method that creates an instance of PurviewManagementClient class. You'll use this object to create a purview account, delete purview accounts, check name availability, and other resource provider operations.

```Python
def main():

# Azure subscription ID
subscription_id = '<subscription ID>'

 # This program creates this resource group. If it's an existing resource group, comment out the code that creates the resource group
rg_name = '<resource group>'

# The purview name. It must be globally unique.
purview_name = '<purview account name>'

# Location name, where Microsoft Purview account must be created.
location = '<location name>'
```

```
# Specify your Active Directory client ID, client secret, and tenant ID
credentials = ClientSecretCredential(client_id='<service principal
ID>', client_secret='<service principal key>', tenant_id='<tenant ID>')
# resource_client = ResourceManagementClient(credentials,
subscription_id)
purview_client = PurviewManagementClient(credentials, subscription_id)
```

Create a purview account

1. Add the following code to the **Main** method that creates a **purview account**. If your resource group already exists, comment out the first `create_or_update` statement.

Python

```
 # create the resource group
 # comment out if the resource group already exits
 resource_client.resource_groups.create_or_update(rg_name, rg_params)

 #Create a purview
 identity = Identity(type= "SystemAssigned")
 sku = AccountSku(name= 'Standard', capacity= 4)
 purview_resource = Account(identity=identity,sku=sku,location
=location )

 try:
     pa = (purview_client.accounts.begin_create_or_update(rg_name,
purview_name, purview_resource)).result()
     print("location:", pa.location, " Microsoft Purview Account Name:
", pa.name, " Id: " , pa.id ," tags: " , pa.tags)
 except:
     print("Error")
     print_item(pa)

 while (getattr(pa,'provisioning_state')) != "Succeeded" :
     pa = (purview_client.accounts.get(rg_name, purview_name))
     print(getattr(pa,'provisioning_state'))
     if getattr(pa,'provisioning_state') == "Failed" :
         print("Error in creating Microsoft Purview account")
         break
     time.sleep(30)
```

2. Now, add the following statement to invoke the **main** method when the program is run:

Python

```
# Start the main method
main()
```

Full script

Here's the full Python code:

Python

```
from azure.identity import ClientSecretCredential
from azure.mgmt.resource import ResourceManagementClient
from azure.mgmt.purview import PurviewManagementClient
from azure.mgmt.purview.models import *
from datetime import datetime, timedelta
import time

def main():

    # Azure subscription ID
    subscription_id = '<subscription ID>'

    # This program creates this resource group. If it's an existing resource
group, comment out the code that creates the resource group
    rg_name = '<resource group>'

    # The purview name. It must be globally unique.
    purview_name = '<purview account name>'

    # Location for your resource group and your Microsoft Purview account.
    location ="<location>"

    # Specify your Active Directory client ID, client secret, and tenant ID
    credentials = ClientSecretCredential(client_id='<service principal ID>',
client_secret='<service principal key>', tenant_id='<tenant ID>')
    resource_client = ResourceManagementClient(credentials, subscription_id)
    purview_client = PurviewManagementClient(credentials, subscription_id)

    # create the resource group
    # comment out if the resource group already exits
    resource_client.resource_groups.create_or_update(rg_name, {"location":
location})

    #Create a purview
    identity = Identity(type= "SystemAssigned")
    sku = AccountSku(name= 'Standard', capacity= 4)
    purview_resource = Account(identity=identity,sku=sku,location =location)

    try:
        pa = (purview_client.accounts.begin_create_or_update(rg_name,
purview_name, purview_resource)).result()
```

```
        print("location:", pa.location, " Microsoft Purview Account Name: ",
purview_name, " Id: " , pa.id ," tags: " , pa.tags)
    except:
        print("Error in submitting job to create account")
        print_item(pa)

    while (getattr(pa,'provisioning_state')) != "Succeeded" :
        pa = (purview_client.accounts.get(rg_name, purview_name))
        print(getattr(pa,'provisioning_state'))
        if getattr(pa,'provisioning_state') == "Failed" :
            print("Error in creating Microsoft Purview account")
            break
        time.sleep(30)

# Start the main method
main()
```

Run the code

Build and start the application. The console prints the progress of Microsoft Purview account creation. Wait until it's completed. Here's the sample output:

Console

```
location: southcentralus  Microsoft Purview Account Name:  purviewpython7
Id:  /subscriptions/8c2c7b23-848d-40fe-b817-
690d79ad9dfd/resourceGroups/Demo_Catalog/providers/Microsoft.Purview/account
s/purviewpython7  tags:  None
Creating
Creating
Succeeded
```

Verify the output

Go to the **Microsoft Purview accounts** page in the Azure portal and verify the account created using the above code.

Delete Microsoft Purview account

To delete purview account, add the following code to the program, then run:

Python

```
pa = purview_client.accounts.begin_delete(rg_name, purview_name).result()
```

Next steps

In this quickstart, you learned how to create a Microsoft Purview (formerly Azure Purview) account, delete the account, and check for name availability. You can now download the Python SDK and learn about other resource provider actions you can perform for a Microsoft Purview account.

Follow these next articles to learn how to navigate the Microsoft Purview governance portal, create a collection, and grant access to the Microsoft Purview governance portal.

Quickstart: Create a Microsoft Purview (formerly Azure Purview) account using a Bicep file

Article • 02/26/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> You can only create one Microsoft Purview account per tenant. If your organization already has a Microsoft Purview account, you won't be able to create a new Microsoft Purview account unless your organization already had multiple accounts and is still under the the preexisting quota. For more information, see the FAQ.

This quickstart describes the steps to deploy a Microsoft Purview (formerly Azure Purview) account using a Bicep file.

After you've created the account, you can begin registering your data sources, and using the Microsoft Purview governance portal to understand and govern your data landscape. By connecting to data across your on-premises, multicloud, and software-as-a-service (SaaS) sources, the Microsoft Purview Data Map creates an up-to-date map of your information. It identifies and classifies sensitive data, and provides end-to-end data linage. Data consumers are able to discover data across your organization and data administrators are able to audit, secure, and ensure right use of your data.

For more information about the classic governance capabilities of Microsoft Purview, see our governance solutions overview page.

To deploy a Microsoft Purview account to your subscription using a Bicep file, follow the guide below.

Prerequisites

- If you don't have an Azure subscription, create a free subscription before you begin.
- A Microsoft Entra tenant associated with your subscription.
- The user account that you use to sign in to Azure must be a member of the *contributor* or *owner* role, or an *administrator* of the Azure subscription. To view the permissions that you have in the subscription, follow these steps:

    1. Go to the Azure portal
    2. Select your username in the upper-right corner.
    3. Select the ellipsis button ("...") for more options.
    4. Then select **My permissions**.
    5. If you have access to multiple subscriptions, select the appropriate subscription.

Sign in to Azure

Sign in to the Azure portal with your Azure account.

Review the Bicep file

The Bicep file used in this quickstart is from Azure Quickstart Templates.

Bicep

```
@description('Specify a name for the Azure Purview account.')
param purviewName string = 'azurePurview${uniqueString(resourceGroup().id)}'

@description('Specify a region for resource deployment.')
param location string = resourceGroup().location

resource purview 'Microsoft.Purview/accounts@2021-12-01' = {
  name: purviewName
  location: location
  sku: {
    name: 'Standard'
    capacity: 1
  }
  identity: {
    type: 'SystemAssigned'
  }
  properties: {
    publicNetworkAccess: 'Enabled'
    managedResourceGroupName: 'managed-rg-${purviewName}'
```

```
  }
}
```

The following resources are defined in the Bicep file:

- Microsoft.Purview/accounts

The Bicep file performs the following tasks:

- Creates a Microsoft Purview account in a specified resource group.

Deploy the Bicep file

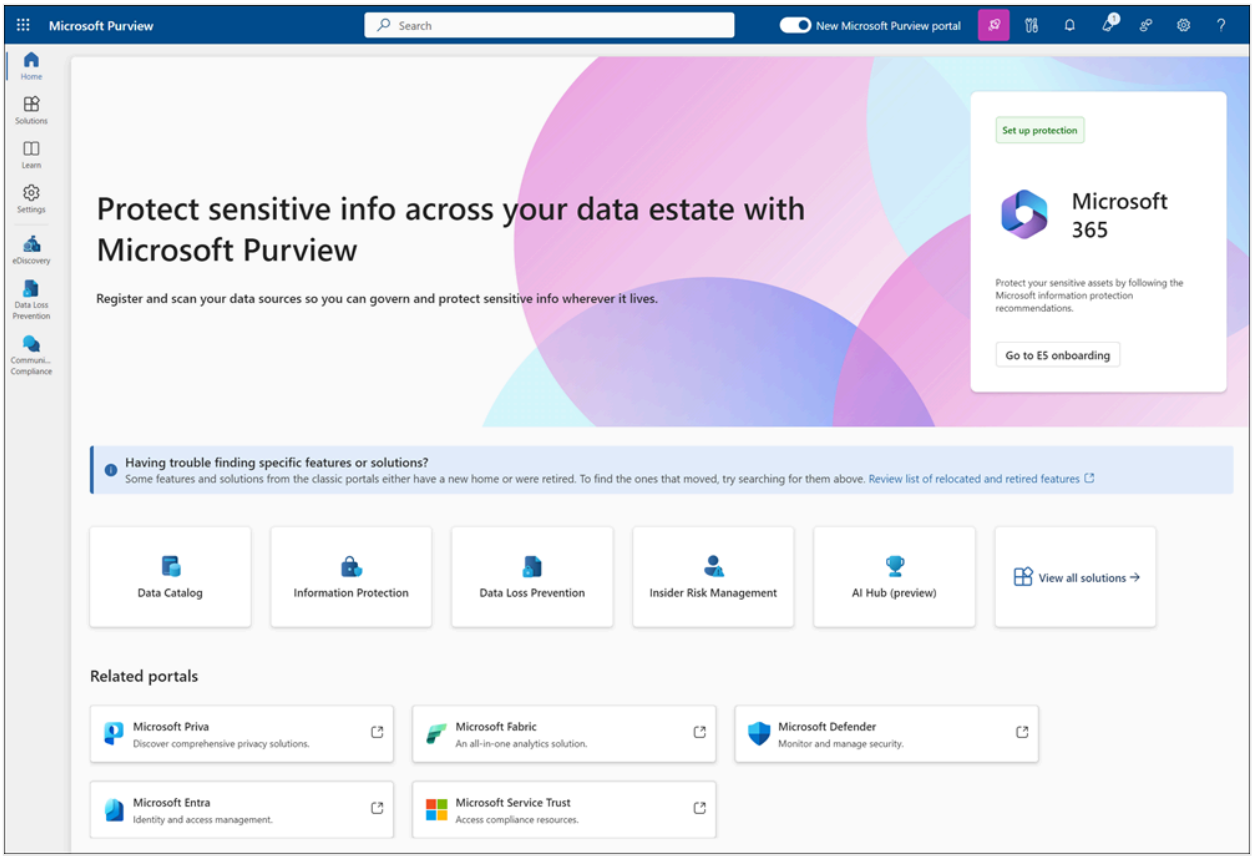
1. Save the Bicep file as **main.bicep** to your local computer.
2. Deploy the Bicep file using either Azure CLI or Azure PowerShell.

CLI

Azure CLI

```
az group create --name exampleRG --location eastus
az deployment group create --resource-group exampleRG --template-
file main.bicep
```

You'll be prompted to enter the following values:



- **Purview name**: enter a name for the Microsoft Purview account.

When the deployment finishes, you should see a message indicating the deployment succeeded.

Open the Microsoft Purview governance portal

After your account is created, you can use the Microsoft Purview portal to access and manage it.

In a browser, navigate directly to https://purview.microsoft.com to access the portal.

For more information about using the portal, see our documentation on the Microsoft Purview portal.

Get started with your Purview resource

After deployment, the first activities are usually:

- Create a collection
- Register a resource
- Scan the resource

At this time, these actions aren't able to be taken through a Bicep file. Follow the guides above to get started!

Clean up resources

When you no longer need them, use the Azure portal, Azure CLI, or Azure PowerShell to remove the resource group, firewall, and all related resources.

CLI

Azure CLI

```
az group delete --name exampleRG
```

Next steps

In this quickstart, you learned how to create a Microsoft Purview (formerly Azure Purview) account and how to access the Microsoft Purview governance portal.

Next, you can create a user-assigned managed identity (UAMI) that will enable your new Microsoft Purview account to authenticate directly with resources using Microsoft Entra authentication.

To create a UAMI, follow our guide to create a user-assigned managed identity.

Follow these next articles to learn how to navigate the Microsoft Purview governance portal, create a collection, and grant access to Microsoft Purview:

Quickstart: Create a Microsoft Purview (formerly Azure Purview) account using an ARM template

Article • 05/20/2025

> **Important**
>
> You can only create one Microsoft Purview account per tenant. If your organization already has a Microsoft Purview account, you won't be able to create a new Microsoft Purview account unless your organization already had multiple accounts and is still under the the preexisting quota. For more information, see the FAQ.

This quickstart describes the steps to deploy a Microsoft Purview (formerly Azure Purview) account using an Azure Resource Manager (ARM) template.

After you've created the account, you can begin registering your data sources and using the Microsoft Purview governance portal to understand and govern your data landscape. By connecting to data across your on-premises, multicloud, and software-as-a-service (SaaS) sources, the Microsoft Purview Data Map creates an up-to-date map of your information. It identifies and classifies sensitive data, and provides end-to-end data linage. Data consumers are able to discover data across your organization and data administrators are able to audit, secure, and ensure right use of your data.

For more information about the classic governance capabilities of Microsoft Purview, see our governance solutions overview page.

To deploy a Microsoft Purview account to your subscription using an ARM template, follow the guide below.

Prerequisites

- If you don't have an Azure subscription, create a free subscription before you begin.
- A Microsoft Entra tenant associated with your subscription.
- The user account that you use to sign in to Azure must be a member of the *contributor* or *owner* role, or an *administrator* of the Azure subscription. To view the permissions that you have in the subscription, follow these steps:

    1. Go to the Azure portal

2. Select your username in the upper-right corner.
3. Select the ellipsis button ("...") for more options.
4. Then select **My permissions**.
5. If you have access to multiple subscriptions, select the appropriate subscription.

Sign in to Azure

Sign in to the Azure portal with your Azure account.

Deploy a custom template

If your environment meets the prerequisites and you're familiar with using ARM templates, select the **Deploy to Azure** button. The template will open in the Azure portal where you can customize values and deploy. The template will deploy a Microsoft Purview account into a new or existing resource group in your subscription.

Review the template

The template used in this quickstart is from Azure Quickstart Templates.

JSON

```
{
  "$schema": "https://schema.management.azure.com/schemas/2019-04-
01/deploymentTemplate.json#",
  "contentVersion": "1.0.0.0",
  "metadata": {
    "_generator": {
      "name": "bicep",
      "version": "0.11.1.770",
      "templateHash": "10388724958841997784"
    }
  },
  "parameters": {
    "purviewName": {
      "type": "string",
      "defaultValue": "[format('azurePurview{0}',
uniqueString(resourceGroup().id))]",
      "metadata": {
        "description": "Specify a name for the Azure Purview account."
      }
    },
    "location": {
```

```
      "type": "string",
      "defaultValue": "[resourceGroup().location]",
      "metadata": {
        "description": "Specify a region for resource deployment."
      }
    }
  },
  "resources": [
    {
      "type": "Microsoft.Purview/accounts",
      "apiVersion": "2021-12-01",
      "name": "[parameters('purviewName')]",
      "location": "[parameters('location')]",
      "sku": {
        "name": "Standard",
        "capacity": 1
      },
      "identity": {
        "type": "SystemAssigned"
      },
      "properties": {
        "publicNetworkAccess": "Enabled",
        "managedResourceGroupName": "[format('managed-rg-{0}',
parameters('purviewName'))]"
      }
    }
  ]
}
```

The following resources are defined in the template:

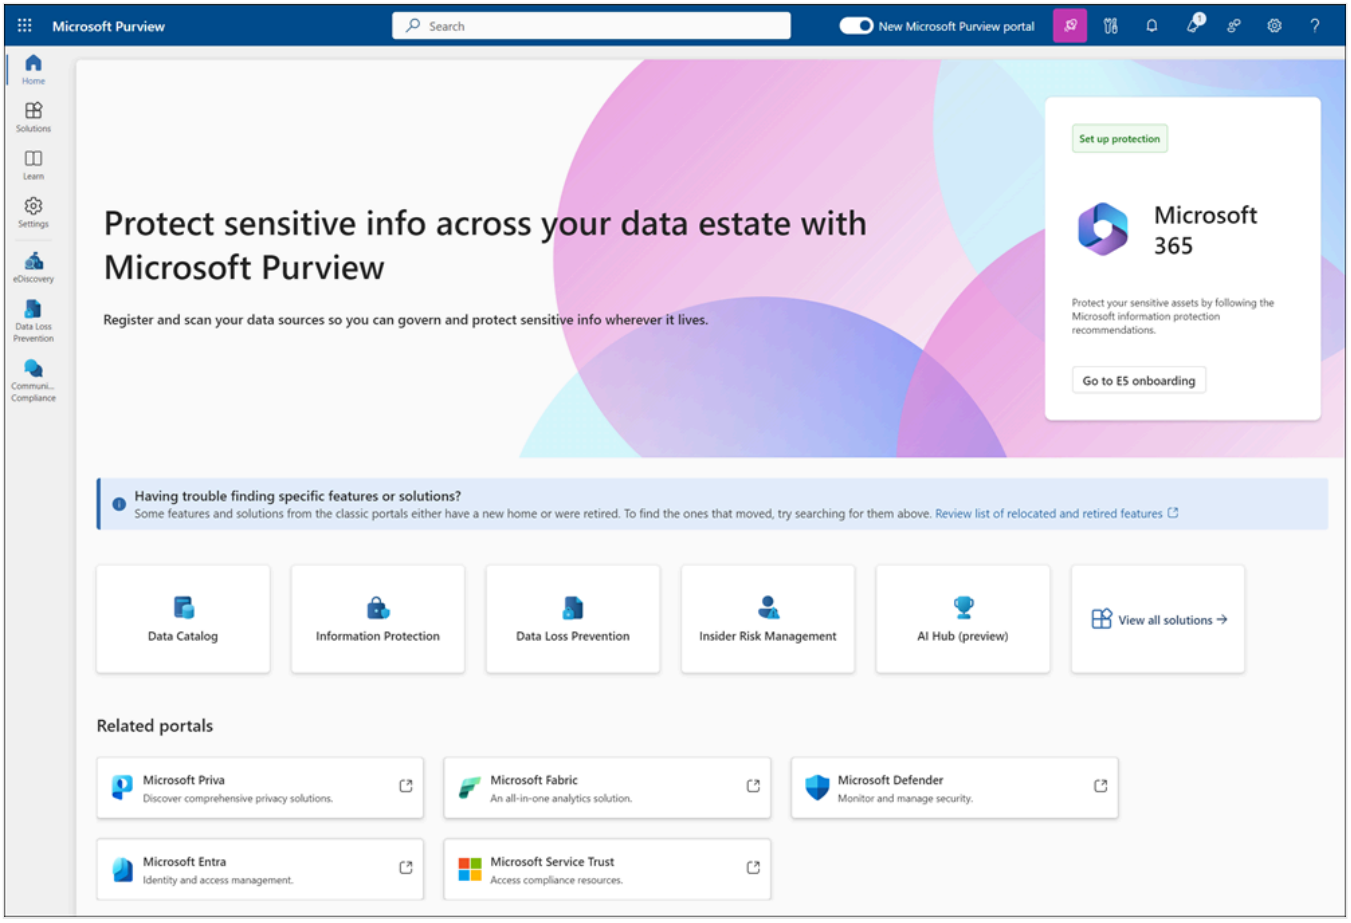
- Microsoft.Purview/accounts

The template performs the following tasks:

- Creates a Microsoft Purview account in a specified resource group.

Customize network settings for your account

When you're deploying your ARM template, you can also use the following settings in the template to manage your public network access settings:



- **Enabled for all networks** `"publicNetworkAccess": "Enabled", "managedResourcesPublicNetworkAccess": "Enabled"`
- **Disabled for ingestion only (Preview)** `"publicNetworkAccess": "Enabled", "managedResourcesPublicNetworkAccess": "Disabled"`
- **Disabled from all networks** `"publicNetworkAccess": "Disables", "managedResourcesPublicNetworkAccess": "Disabled"`

For example: `"resources": [{ "type": "Microsoft.Purview/accounts", "apiVersion": "2021-12-01", "name": "[parameters('purviewName')]", "location": "[parameters('location')]", "sku": { "name": "Standard", "capacity": 1 }, "identity": { "type": "SystemAssigned" }, "properties": { "publicNetworkAccess": "Enabled", "managedResourcesPublicNetworkAccess": "Enabled" "managedResourceGroupName": "[format('managed-rg-{0}', parameters('purviewName'))]" } }]`

Open the Microsoft Purview governance portal

After your account is created, you can use the Microsoft Purview portal to access and manage it.

In a browser, navigate directly to https://purview.microsoft.com to access the portal.

For more information about using the portal, see our documentation on the Microsoft Purview portal.

Get started with your Purview resource

After deployment, the first activities are usually:

- Create a collection

- Register a resource
- Scan the resource

At this time, these actions aren't able to be taken through an Azure Resource Manager template. Follow the guides above to get started!

Clean up resources

To clean up the resources deployed in this quickstart, delete the resource group, which deletes all resources in the group. You can delete the resources either through the Azure portal, or using the PowerShell script below.

Azure PowerShell

```
$resourceGroupName = Read-Host -Prompt "Enter the resource group name"
Remove-AzResourceGroup -Name $resourceGroupName
Write-Host "Press [ENTER] to continue..."
```

Next steps

In this quickstart, you learned how to create a Microsoft Purview (formerly Azure Purview) account and how to access the Microsoft Purview governance portal.

Next, you can create a user-assigned managed identity (UAMI) that will enable your new Microsoft Purview account to authenticate directly with resources using Microsoft Entra authentication.

To create a UAMI, follow our guide to create a user-assigned managed identity.

Follow these next articles to learn how to navigate the Microsoft Purview governance portal, create a collection, and grant access to Microsoft Purview:

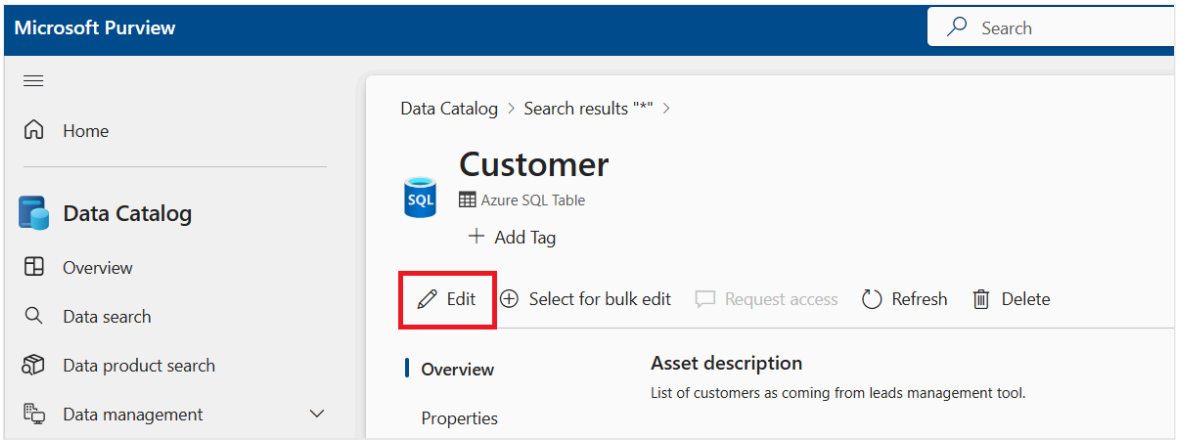
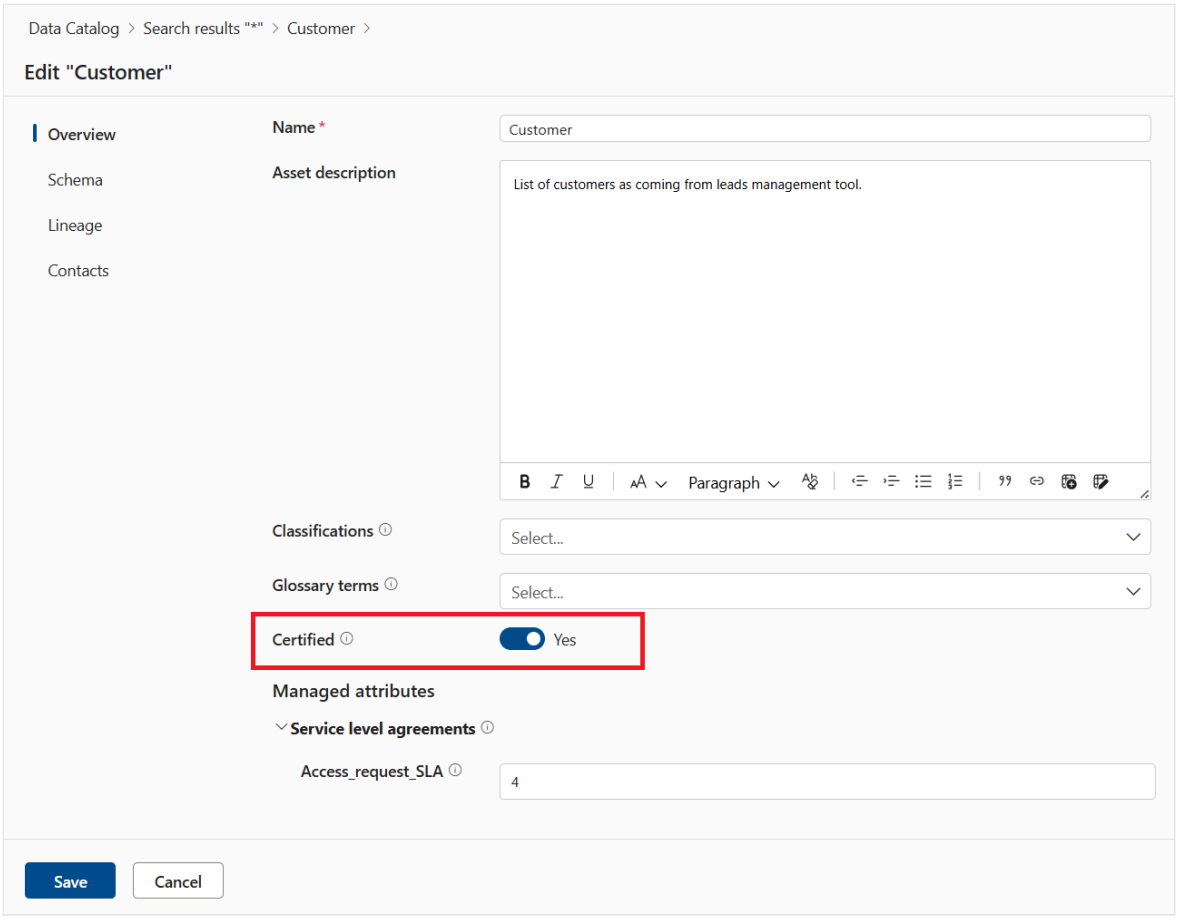
Asset certification in the Microsoft Purview Data Catalog

Article • 01/28/2025



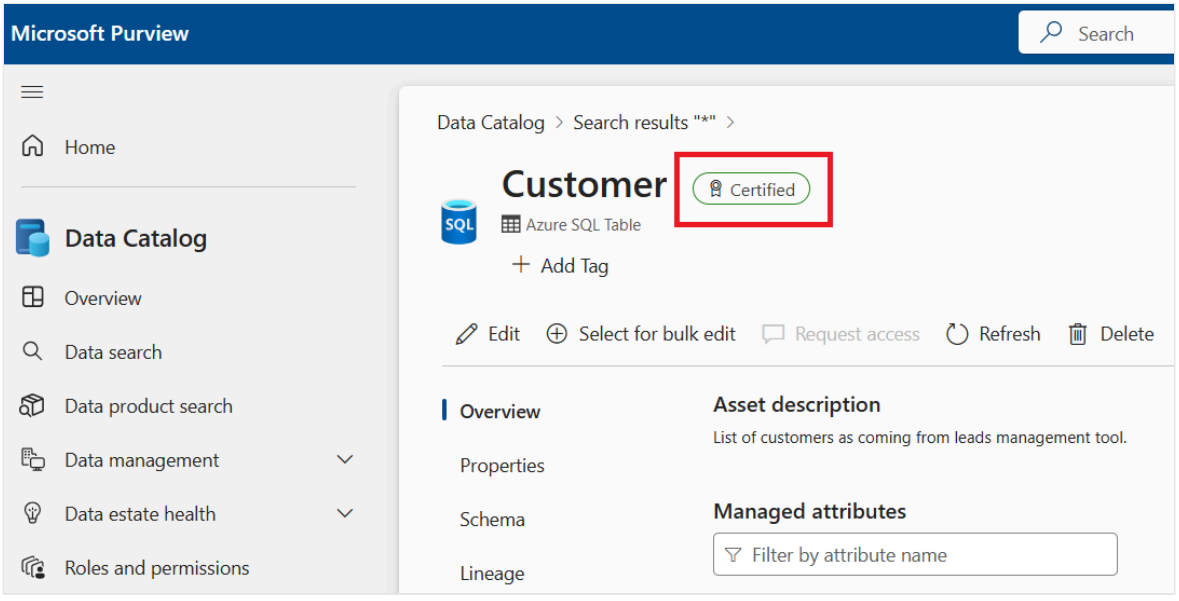
> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

As a Microsoft Purview Data Catalog grows in size, it becomes important for data consumers to understand what assets they can trust. Data consumers must know if an asset meet their organization's quality standards and can be regarded as reliable. Microsoft Purview allows data stewards to manually endorse assets to indicate that they're ready to use across an organization or business unit. This article describes how data stewards can certify assets and data consumers can view certification labels.



How to certify an asset

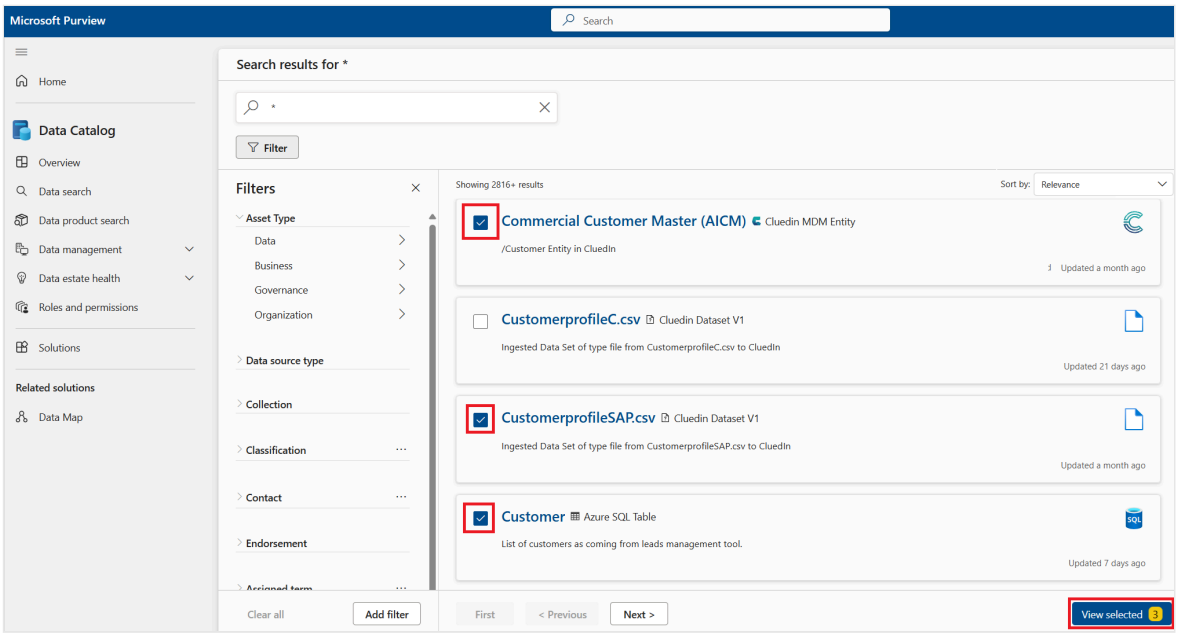
To certify an asset, you must be a **data curator** for the collection containing the asset. For steps to assign this role, see our permissions documentation.



1. Navigate to the [asset details]classic-catalog-asset-details.md) of the desired asset. Select **Edit**.

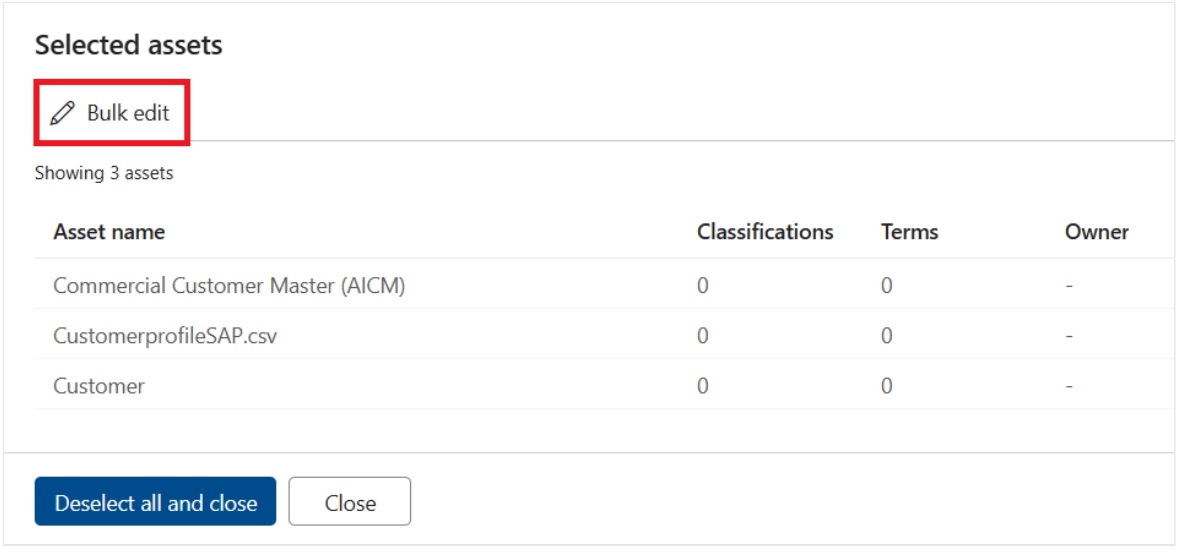
2. Toggle the **Certified** field to **Yes**.

3. Save your changes. The asset has a "Certified" label next to the asset name.



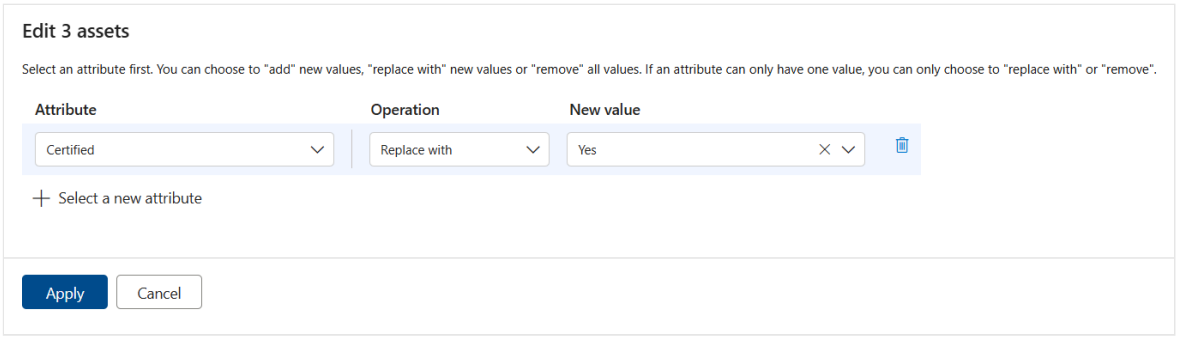
> **Note**
>
> PowerBI assets can only be certified in a PowerBI workspace. PowerBI endorsement labels are displayed in Microsoft Purview's search and browse experiences.

Certify assets in bulk



You can use the Microsoft Purview bulk edit experience to certify multiple assets at once.

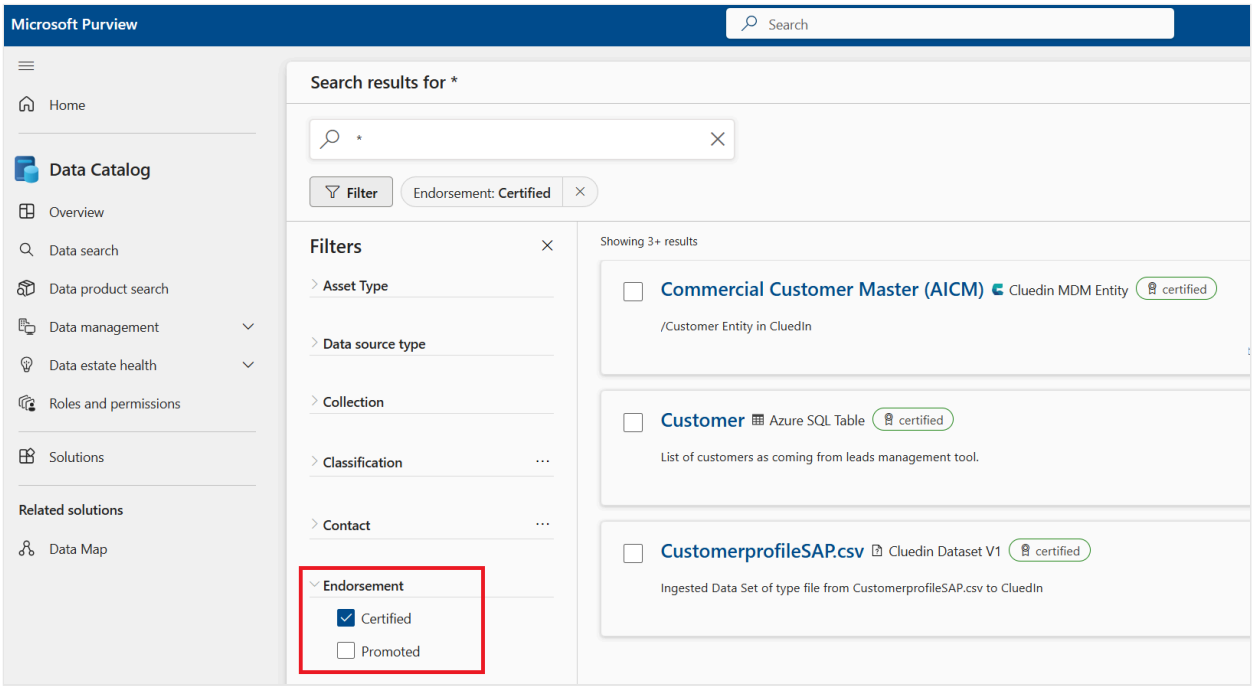
1. After searching or browsing the data catalog, select checkbox next to the assets you wish to certify.



2. Select **View selected**.

3. Select **Bulk edit**

4. Choose attribute **Certified**, operation **Replace with**, and new value **Yes**.



5. Select **Apply**

All assets selected have the "Certified" label.

Viewing certification labels in Search

When search or browsing the data catalog, you see a certification label on any asset that is certified. Certified assets boosted in search results to help data consumers discover them easily.

Next steps

Discover your assets in the Microsoft Purview Data Catalog by either:

- Browsing the data catalog
- Searching the data catalog

Asset normalization

Article • 05/20/2025

When ingesting assets into the Microsoft Purview Data Map, different sources updating the same data asset may send similar, but slightly different qualified names. While these qualified names represent the same asset, slight differences such as an extra character may cause these assets on the surface to appear different and cause duplicate entries in Microsoft Purview. To avoid storing duplicate entries and causing confusion when consuming the Unified Catalog, Microsoft Purview automatically applies normalization during ingestion to ensure all fully qualified names of the same entity type are in the same format.

For example, you scan in an Azure Blob with the qualified name `https://myaccount.file.core.windows.net/myshare/folderA/folderB/my-file.parquet`. This blob is also consumed by an Azure Data Factory pipeline that will then add lineage information to the asset. The ADF (Azure Data Factory) pipeline may be configured to read the file as `https://myAccount.file.core.windows.net//myshare/folderA/folderB/my-file.parquet`. While the qualified name is different, this ADF pipeline is consuming the same piece of data. Normalization ensures that all the metadata from both Azure Blob Storage and Azure Data Factory is visible on a single asset, `https://myaccount.file.core.windows.net/myshare/folderA/folderB/my-file.parquet`.

> **Important**
>
> The rules listed below are the only kinds of potential duplication Microsoft Purview currently recognizes. If you are experiencing accidental asset duplication, compare the assets fully qualified names to check for capitalization differences or extra characters. Update any ingestion points, for example your ADF pipelines, so that the qualified names match.

Normalization rules

These are the normalization rules that Microsoft Purview automatically applies.

Encode curly brackets

Applies to: All Assets

Before: `https://myaccount.file.core.windows.net/myshare/{folderA}/folder{B/`

After: `https://myaccount.file.core.windows.net/myshare/%7BfolderA%7D/folder%7BB/`

Trim section spaces

Applies to: Azure Blob, Azure Files, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Azure Data Factory, Azure SQL Database, Azure SQL Managed Instance, Azure SQL pool, Azure Cosmos DB, Azure Cognitive Search, Azure Data Explorer, Azure Data Share, Amazon S3

Before: `https://myaccount.file.core.windows.net/myshare/ folder A/folderB /`

After: `https://myaccount.file.core.windows.net/myshare/folder A/folderB/`

Remove hostname spaces

Applies to: Azure Blob, Azure Files, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Azure SQL Database, Azure SQL Managed Instance, Azure SQL pool, Azure Cosmos DB, Azure Cognitive Search, Azure Data Explorer, Azure Data Share, Amazon S3

Before: `https://myaccount .file. core.win dows. net/myshare/folderA/folderB/`

After: `https://myaccount.file.core.windows.net/myshare/folderA/folderB/`

Remove square brackets

Applies to: Azure SQL Database, Azure SQL Managed Instance, Azure SQL pool

Before: `mssql://foo.database.windows.net/[bar]/dbo/[foo bar]`

After: `mssql://foo.database.windows.net/bar/dbo/foo%20bar`

> ⓘ **Note**
>
> Spaces between two square brackets will be encoded

Lowercase scheme

Applies to: Azure Blob, Azure Files, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Azure SQL Database, Azure SQL Managed Instance, Azure SQL pool, Azure Cosmos DB, Azure Cognitive Search, Azure Data Explorer, Amazon S3

Before: `HTTPS://myaccount.file.core.windows.net/myshare/folderA/folderB/`

After: `https://myaccount.file.core.windows.net/myshare/folderA/folderB/`

Lowercase hostname

Applies to: Azure Blob, Azure Files, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Azure SQL Database, Azure SQL Managed Instance, Azure SQL pool, Azure Cosmos DB, Azure Cognitive Search, Azure Data Explorer, Amazon S3

Before: `https://myAccount.file.Core.Windows.net/myshare/folderA/folderB/`

After: `https://myaccount.file.core.windows.net/myshare/folderA/folderB/`

Lowercase file extension

Applies to: Azure Blob, Azure Files, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Amazon S3

Before: `https://myAccount.file.core.windows.net/myshare/folderA/data.TXT`

After: `https://myaccount.file.core.windows.net/myshare/folderA/data.txt`

Remove duplicate slash

Applies to: Azure Blob, Azure Files, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Azure Data Factory, Azure SQL Database, Azure SQL Managed Instance, Azure SQL pool, Azure Cosmos DB, Azure Cognitive Search, Azure Data Explorer, Azure Data Share, Amazon S3

Before: `https://myAccount.file.core.windows.net//myshare/folderA////folderB/`

After: `https://myaccount.file.core.windows.net/myshare/folderA/folderB/`

Convert to ADL scheme

Applies to: Azure Data Lake Storage Gen1

Before: `https://mystore.azuredatalakestore.net/folderA/folderB/abc.csv`

After: `adl://mystore.azuredatalakestore.net/folderA/folderB/abc.csv`

Remove Trailing Slash

Remove the trailing slash from higher level assets for Azure Blob, ADLS Gen1, and ADLS Gen2.

Applies to: Azure Blob, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2

Asset types: "azure_blob_container", "azure_blob_service", "azure_storage_account", "azure_datalake_gen2_service", "azure_datalake_gen2_filesystem", "azure_datalake_gen1_account".

Before: `https://myaccount.core.windows.net/`

After: `https://myaccount.core.windows.net`

Troubleshooting

If your data isn't being normalized, and you're experiencing accidental asset duplication, compare the assets fully qualified names to check for capitalization differences or additional characters.

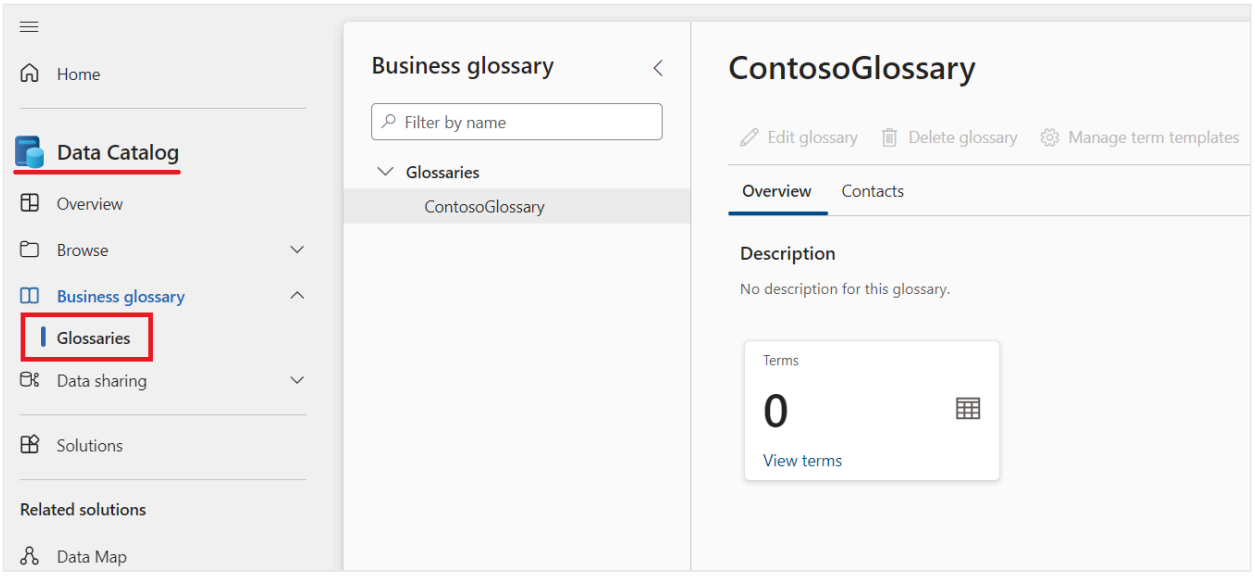
The rules listed above are the only types of duplication Microsoft Purview currently recognizes. If your data is falling outside of these rules, update any ingestion points, for example your ADF pipelines, so that the qualified names match.

If your assets meet the rules but aren't being normalized, contact support.

Next steps

Scan in an Azure Blob Storage account into the Microsoft Purview data map.

Understand business glossary features in the classic Microsoft Purview governance portal



Article • 01/28/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Tip**
>
> Microsoft Purview has a new experience! If you're a new Microsoft Purview customer, or if you want more information, see our **article on the new portal** or the article about our new **data governance experience** and our new **glossary terms**.

A **glossary** provides vocabulary for business users. It consists of business terms that can be related to each other and allows them to be categorized so that they can be understood in different contexts. These terms can be then mapped to assets like a database, tables, columns etc. This helps in abstracting the technical jargon associated with the data repositories and allows the business user to discover and work with data in the vocabulary that is more familiar to them.

You can find Microsoft Purview's classic glossaries in the classic Microsoft Purview governance portal in the Data Catalog under **Business Glossary**.

A **business glossary** is a collection of terms. Each term represents an object in an organization and it's highly likely that there are multiple terms representing the same object. A customer could also be referred to as client, purchaser, or buyer. These multiple terms have a relationship with each other. The relationship between these terms could be:

- synonyms - different terms with the same definition
- related - different name with similar definition

The same term can also imply multiple business objects. It's important that each term is well-defined and clearly understood within the organization.

Relationships between terms

Microsoft Purview supports these out-of-the-box relationships for terms:

- Parent/child term
- Acronym
- Synonyms
- Related terms

Relationship definitions in the glossary are bi-directional: Every relationship between terms is a two-way relationship. This means that if term A is related to term B, then term B is also related to term A.

Anytime you populate a relationship in one direction, Purview automatically adds the reverse relationship for you. For example, if you add term A as a synonym for term B, Purview automatically adds term B as a synonym for term A.

Glossary vs classification vs sensitivity labels

While glossary terms, classifications and labels are annotations to a data asset, each one of them has a different meaning in the context of catalog.

Glossary

As stated above, Business glossary term defines the business vocabulary for an organization and helps in bridging the gap between various departments in your company.

Classifications

Classifications are annotations that can be assigned to entities. The flexibility of classifications enables you to use them for multiple scenarios such as:

- understanding the nature of data stored in the data assets
- defining access control policies

Microsoft Purview has more than 200 system classifiers today and you can define your own classifiers in catalog. As part of the scanning process, we automatically detect these classifications and apply them to data assets and schemas. However, you can override them at any point of time. The human overrides are never replaced by automated scans.

Sensitivity labels

Sensitivity labels are a type of annotation that allows you to classify and protect your organization's data, without hindering productivity and collaboration. Sensitivity labels are used to identify the categories of classification types within your organizational data, and group the policies that you wish to apply to each category. Microsoft Purview makes use of the same sensitive information types as Microsoft 365, which allows you to stretch your existing security policies and protection across your entire content and data estate. The same labels can be shared across Microsoft Office products and data assets in Microsoft Purview.

For more information about sensitivity labels, see: Learn about sensitivity labels

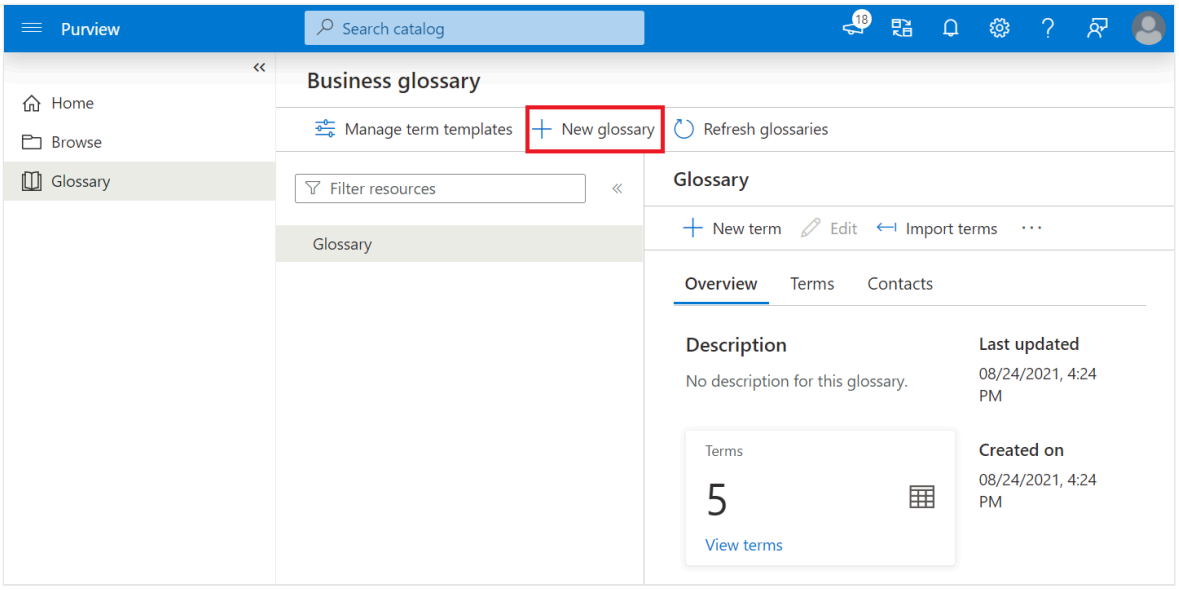
Create and manage classic business glossaries

Article • 01/28/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.



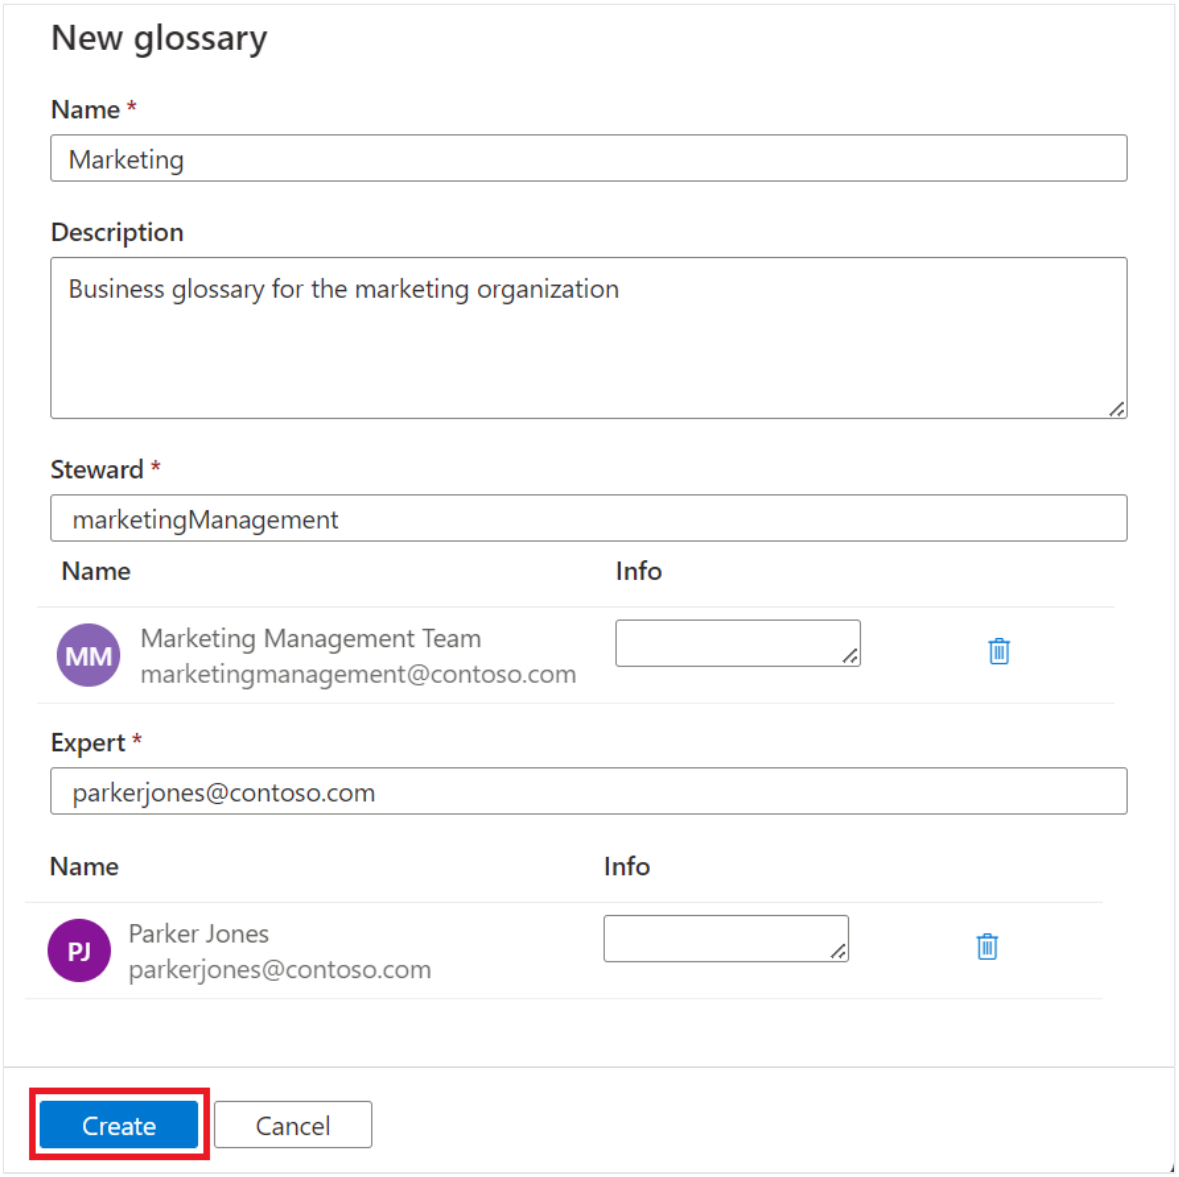
> **Tip**
>
> The new Microsoft Purview Data Catalog has a new glossary experience. For more information, see the glossary terms in the data catalog article.

In the classic Microsoft Purview data governance experience, you can create multiple business glossaries to support separate glossaries for any context in your business. This article provides the steps to create and manage business glossaries in the classic Microsoft Purview Data Catalog.

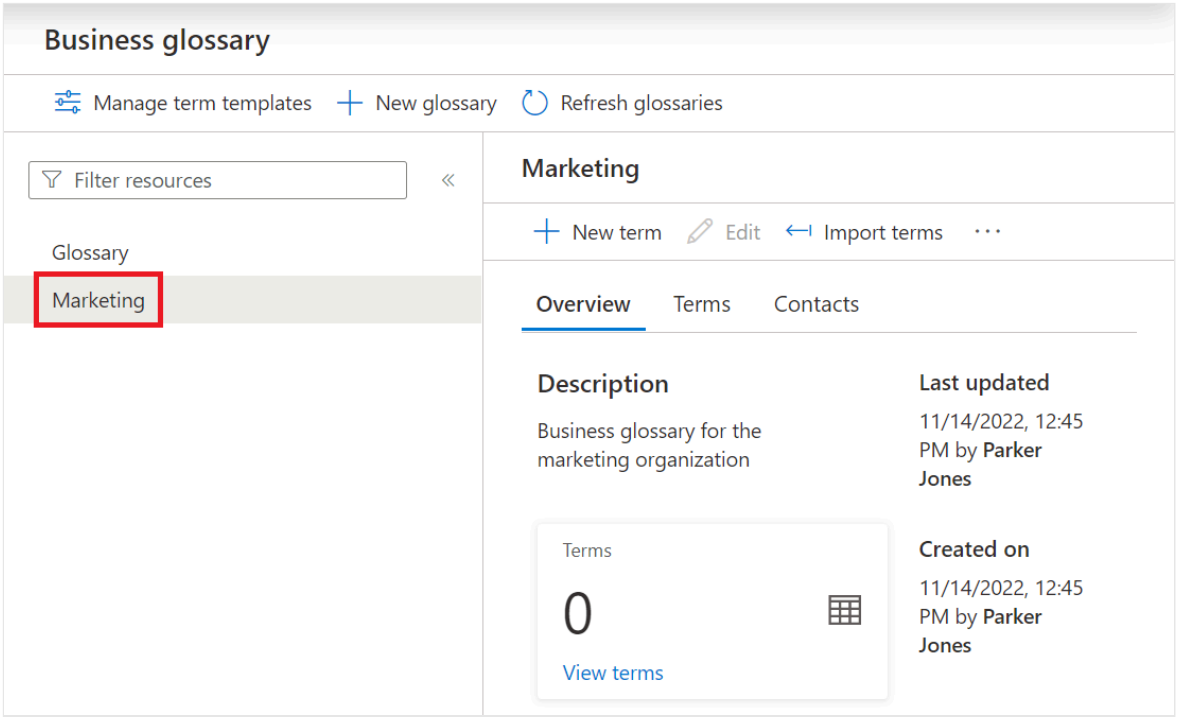
Create a new glossary

To create a classic business glossary, follow these steps:

1. Open the **Data catalog**
2. In the classic Microsoft Purview portal, select **Glossary**.
3. On the **Business glossary** page, select **+ New glossary**.



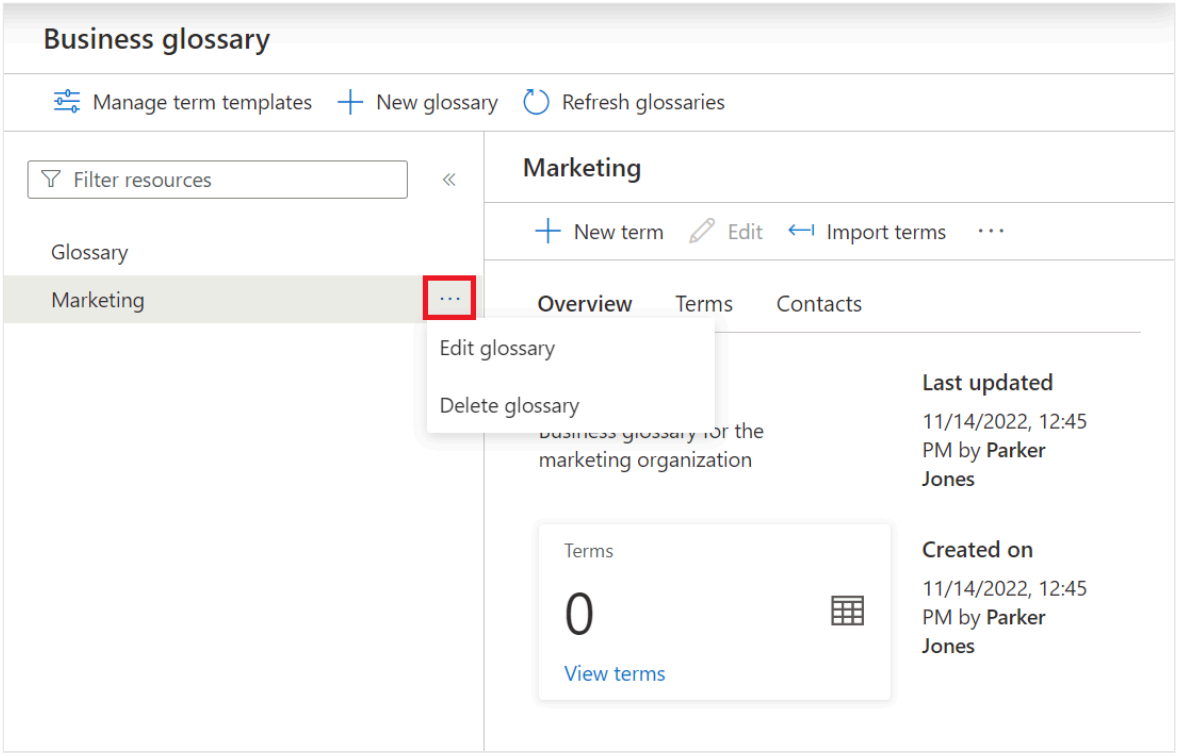
4. Give your glossary a **Name** and a **Description**.



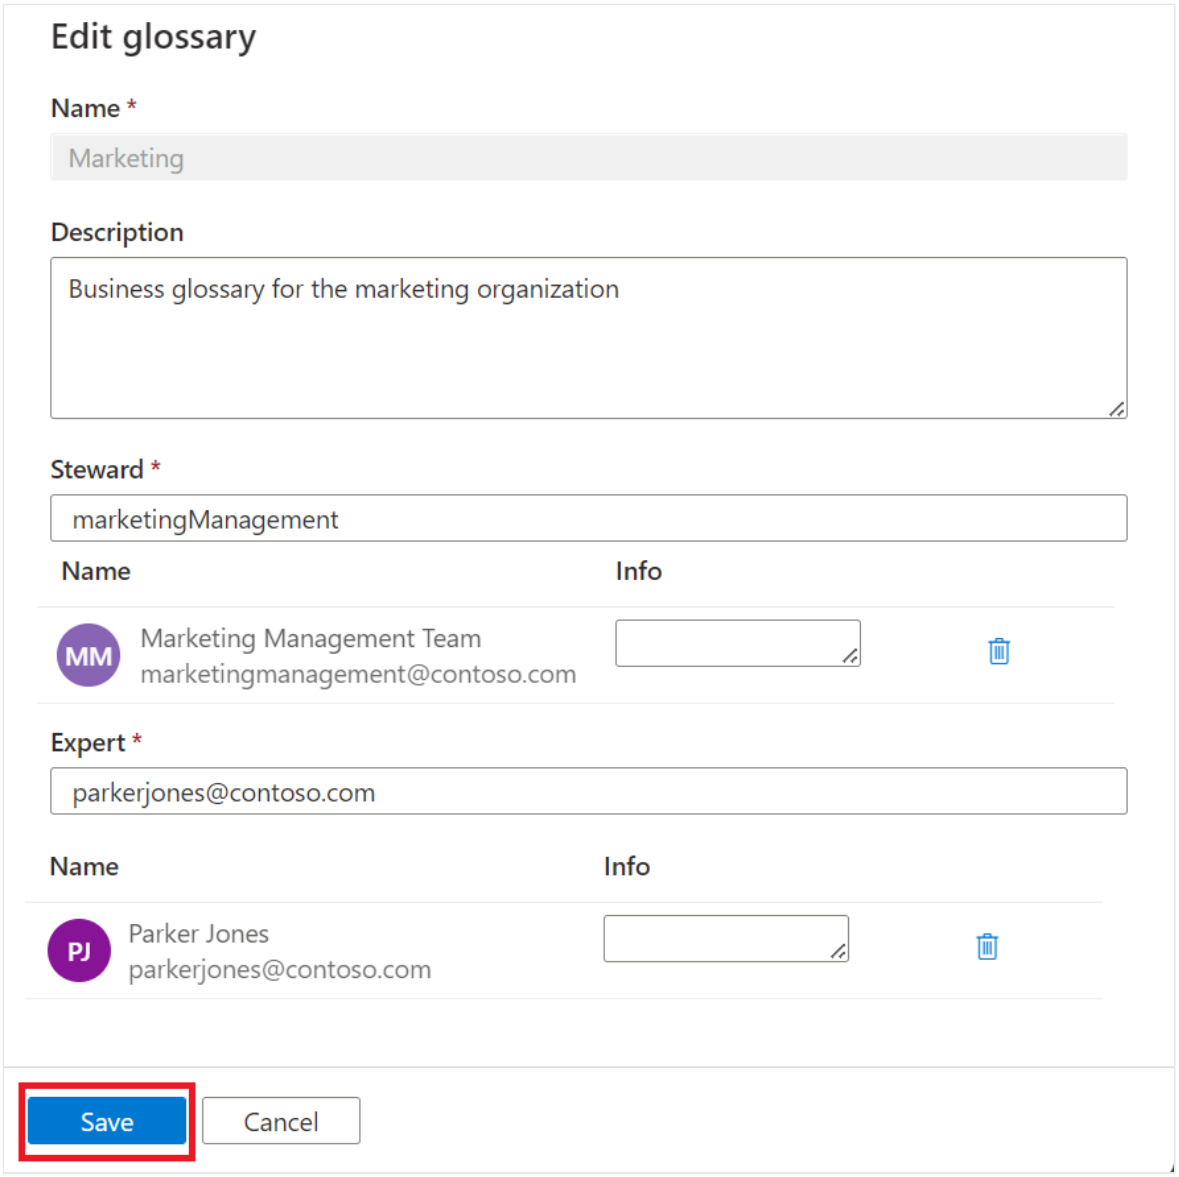
5. You need to select at least one **Steward**, a Microsoft Entra user or group who will manage the glossary.

6. You'll also need to select at least one **Expert**, a Microsoft Entra user or group who can be contacted for more information about the glossary.

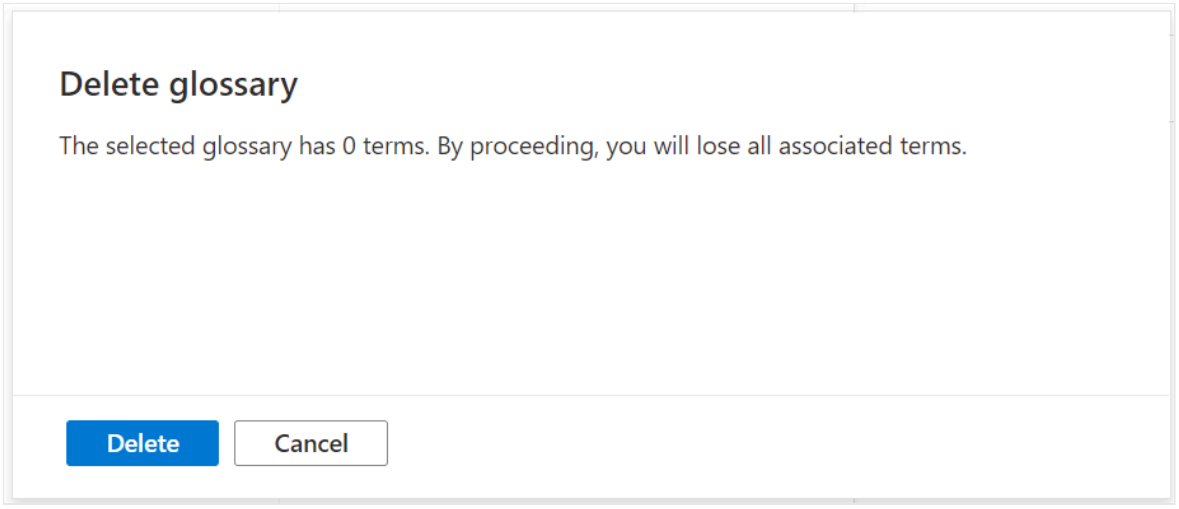
7. You can give additional information about the stewards or experts here, and when you're finished, select **Create**.



8. Once your new glossary is created, you'll be able to see it in the list of glossaries. You can switch between glossaries by selecting their names.



Manage or delete a glossary



1. To edit or delete a glossary, hover over the glossary and select the ellipsis button next to the glossary's name.

2. If you select **Edit glossary**, you can edit the description and the steward or the expert, but at this time you can't change the glossary name. Select **Save** to save the changes.

3. If you select **Delete glossary**, you'll be asked to confirm the deletion. All terms associated with the glossary will be deleted if you delete the glossary. Select **Delete** again to delete the glossary.

Next steps

- For more information about creating and managing glossary terms, see the glossary terms article.
- For information about glossary terms in the new experience, see glossary terms in the new Microsoft Purview Data Catalog experience

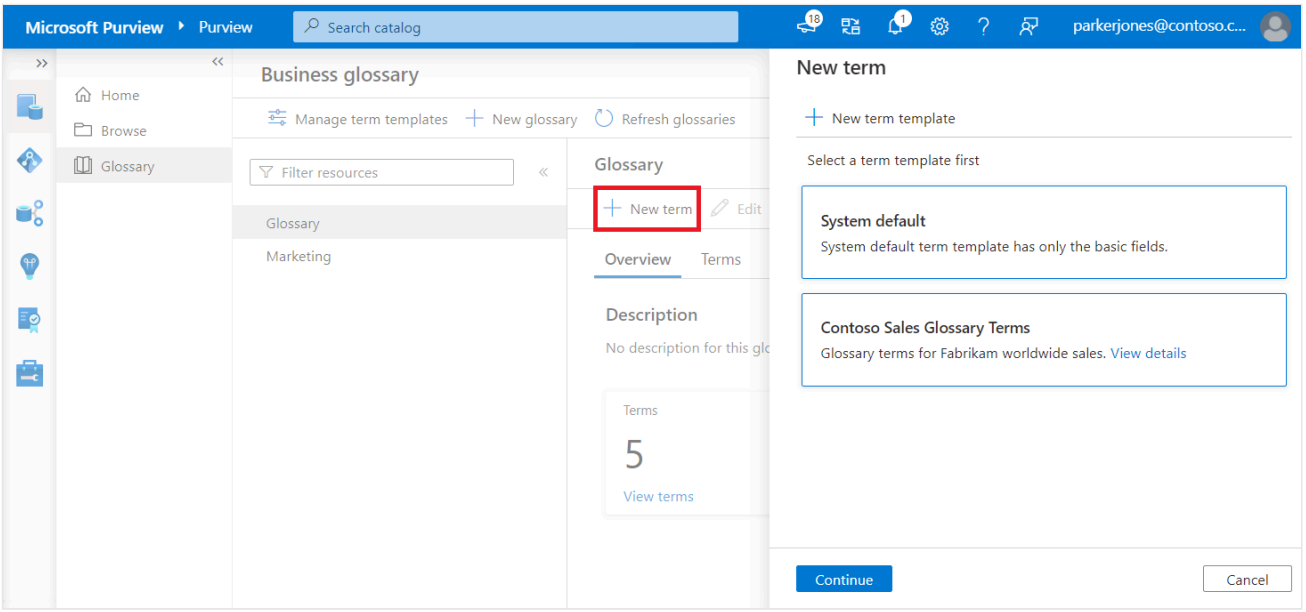
Creating glossary terms in the classic experience

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

This article describes how to work with the business glossary in Microsoft Purview. It provides steps to create a business glossary term in the Microsoft Purview Data Catalog. It also shows you how to import and export glossary terms by using .CSV files, and how to delete terms that you no longer need.

> **Tip**
>
> Take advantage of the unified glossary experience. Migrate your existing glossary terms from the classic data governance experience so that you can apply any glossary term to both a business concept and a data asset. Learn how to migrate classic glossary terms (preview).

Create a term



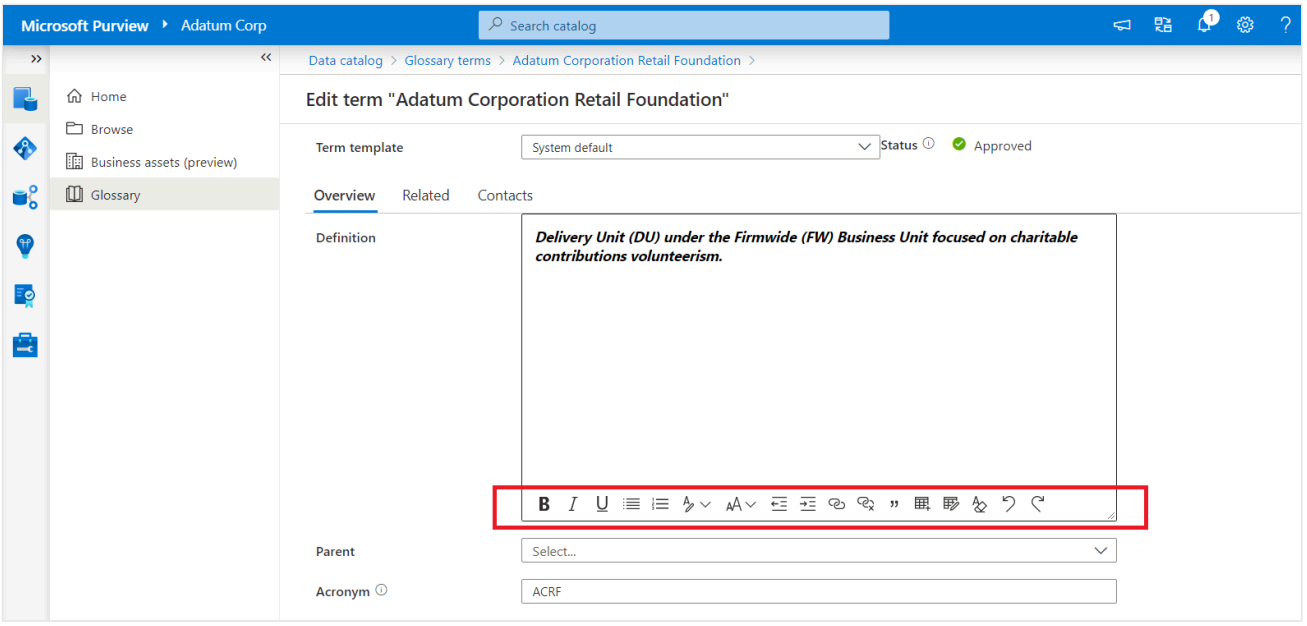
To create a glossary term, follow these steps:

1. Open the Microsoft Purview Data Catalog.
2. If you're using the classic Microsoft Purview portal, select **Glossary**. If you're using the new Microsoft Purview portal under **Business glossary**, select **Glossaries**.
3. Select the glossary you would like to create the new term for, then select **+ New term**. A term can only be added to one glossary at a time.

   > **Note**

Each glossary supports a maximum of 100,000 terms. For more information about creating and managing glossaries see the manage glossaries page.

A pane opens with the **System default** template selected. Choose the template, or templates, that you want to use to create a glossary term, and then select **Continue**.



4. If you selected multiple templates, you can select and deselect templates from the **Term template** dropdown at the top of the page.

5. Give your new term a name, which must be unique in the catalog.

> **Note**
>
> Term names are case-sensitive. For example, **Sample** and **sample** could both exist in the same glossary.

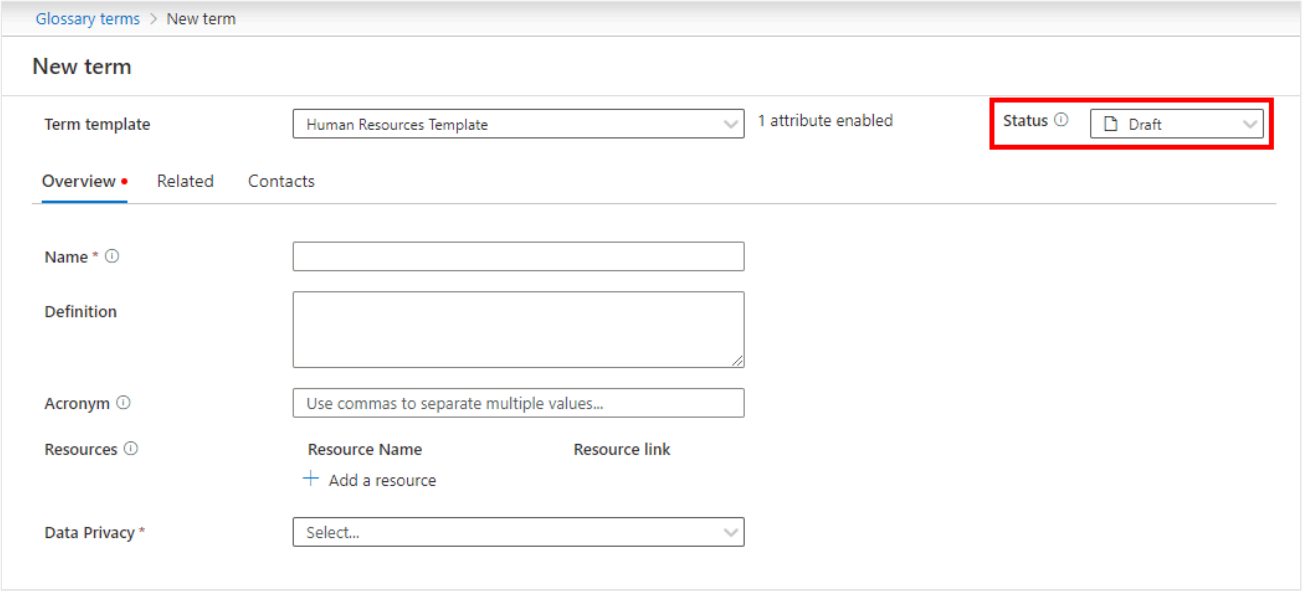
6. For **Definition**, add a definition for the term.

   Microsoft Purview enables you to add rich formatting to term definitions. For example, you can add bold, underline, or italic formatting to text. You can also create tables, bulleted lists, or hyperlinks to external resources.

Here are the options for rich text formatting:

Expand table

Name	Description	Keyboard shortcut
Bold	Make your text bold. Adding the asterisk (*) character around text will also make it bold.	Ctrl+B
Italic	Make your text italic. Adding the underscore (_) character around text will also make it italic.	Ctrl+I
Underline	Underline your text.	Ctrl+U
Bullets	Create a bulleted list. Adding the hyphen (-) character before text will also create a bulleted list.	
Numbering	Create a numbered list. Adding the 1 character before text will also create a numbered list.	
Heading	Add a formatted heading.	
Font size	Change the size of your text. The default size is 12.	
Decrease indent	Move your paragraph closer to the margin.	
Increase indent	Move your paragraph farther away from the margin.	
Add hyperlink	Create a link for quick access to webpages and files.	
Remove hyperlink	Change a link to plain text.	



Name	Description	Keyboard shortcut
Quote	Add quote text.	
Add table	Add a table to your content.	
Edit table	Insert or delete a column or row from a table.	
Clear formatting	Remove all formatting from a selection of text.	
Undo	Undo changes that you made to the content.	Ctrl+Z
Redo	Redo changes that you made to the content.	Ctrl+Y

> **Note**
>
> Updating a definition with the rich text editor adds the attribute `"microsoft_isDescriptionRichText": "true"` in the term payload. This attribute is not visible on the user experience and is automatically populated when you take any rich text action. The right text definition is populated in the following snippet of a term's JSON message:

JSON

```
{
     "additionalAttributes": {
     "microsoft_isDescriptionRichText": "true"
     }
 }
```

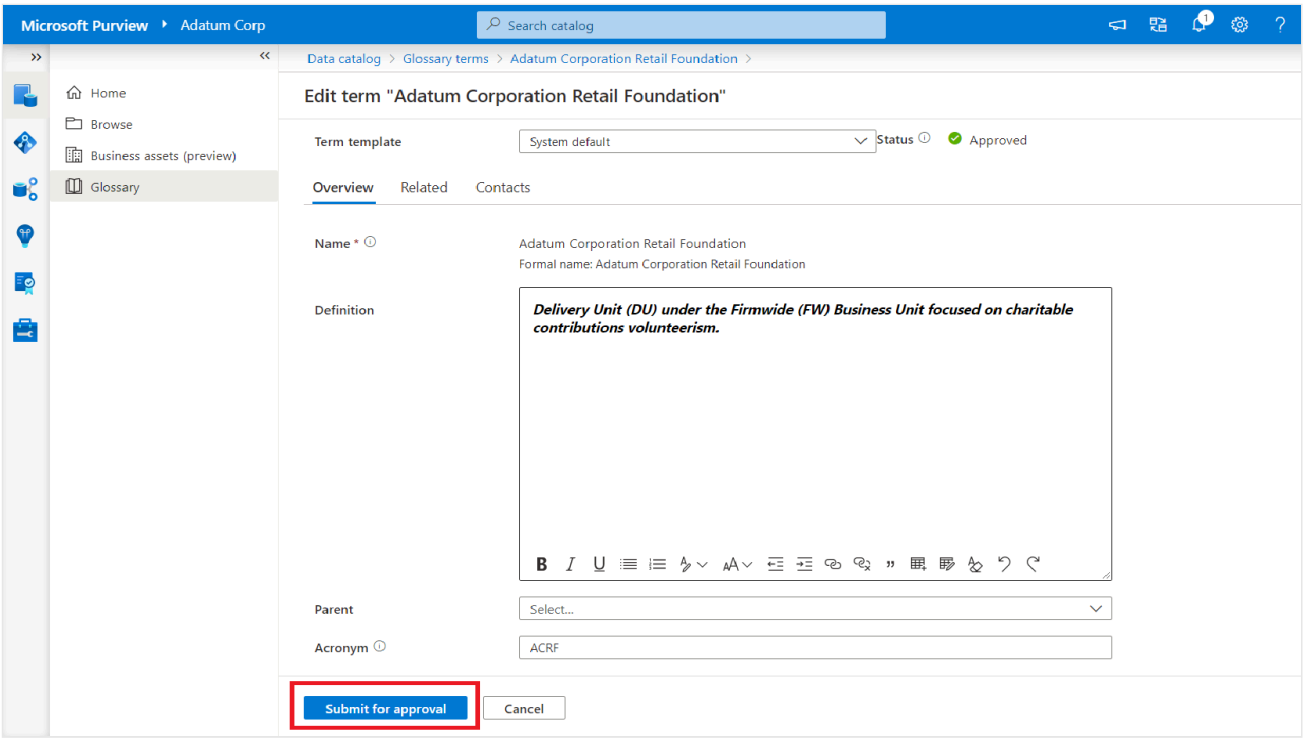
7. For **Status**, select the status for the term. New terms default to **Draft**.

Status markers are metadata associated with the term. Currently, you can set the following status on each term:

- **Draft**: This term isn't yet officially implemented.
- **Approved**: This term is officially approved.
- **Expired**: This term should no longer be used.
- **Alert**: This term needs attention.

> ⓘ **Important**
>
> If an approval workflow is enabled on the term hierarchy, a new term will go through the approval process when it's created. The term is stored in the catalog only when it's approved. To learn about how to manage approval workflows for a business glossary, see Approval workflow for business terms.

8. Add **Resources** and **Acronym** information. If the term is part of a hierarchy, you can add parent terms at **Parent** on the **Overview** tab.



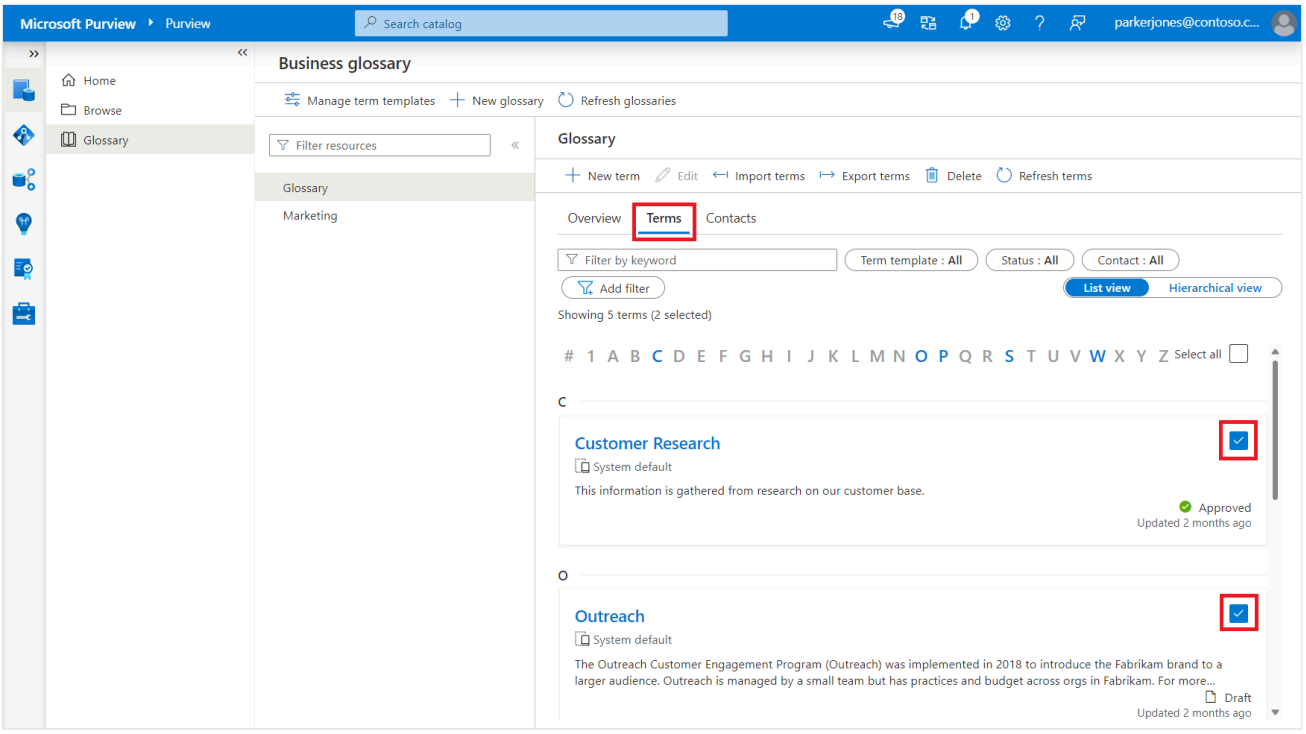
9. To establish relationships with other terms, add **Synonyms** and **Related terms** information on the **Related** tab, and then select **Apply**.

10. Optionally, select the **Contacts** tab to add experts and stewards to your term.

11. Select **Create** to create your term.

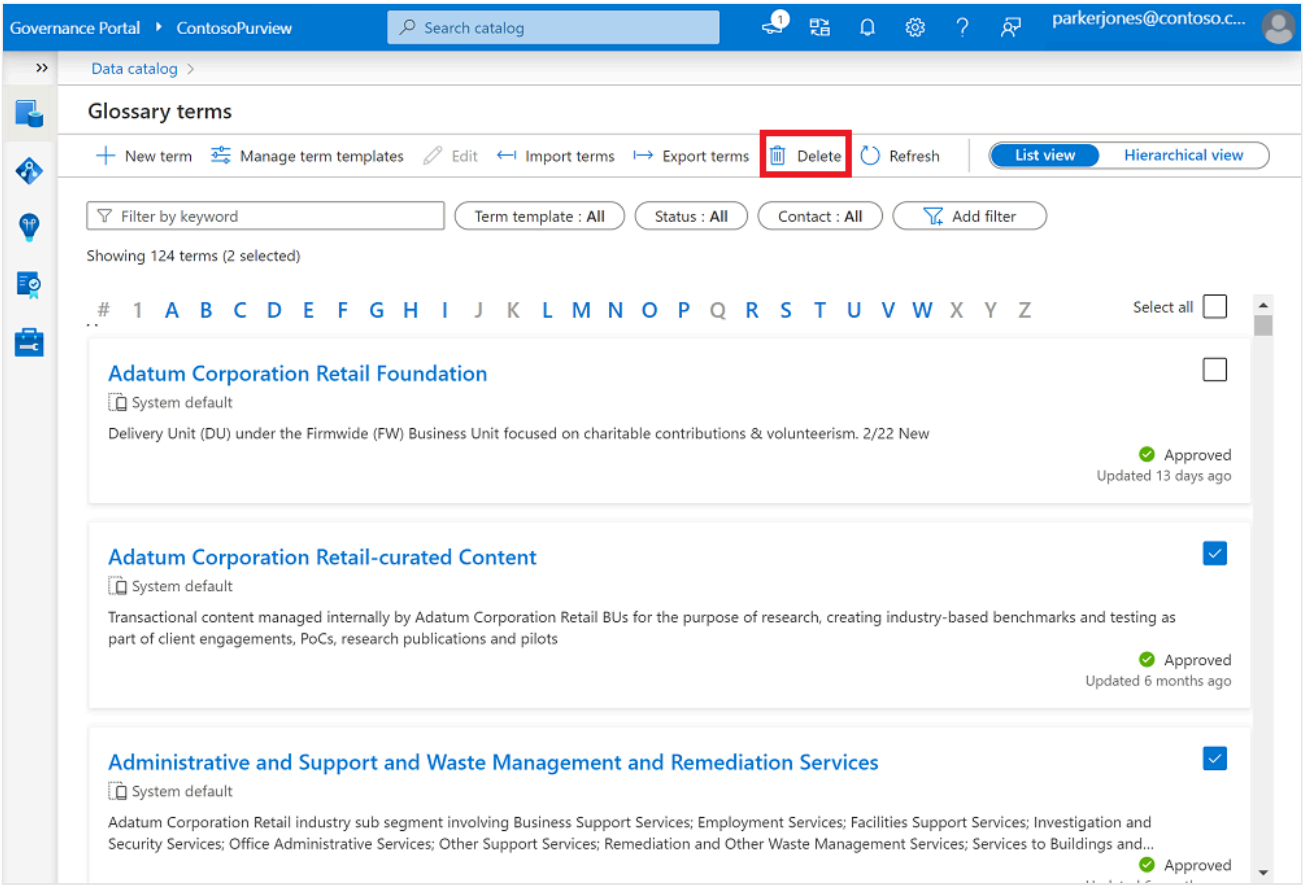
> ⓘ **Important**

If an approval workflow is enabled on the term's hierarchy path, you'll see **Submit for approval** instead of the **Create** button. Selecting **Submit for approval** will trigger the approval workflow for this term.



Delete terms

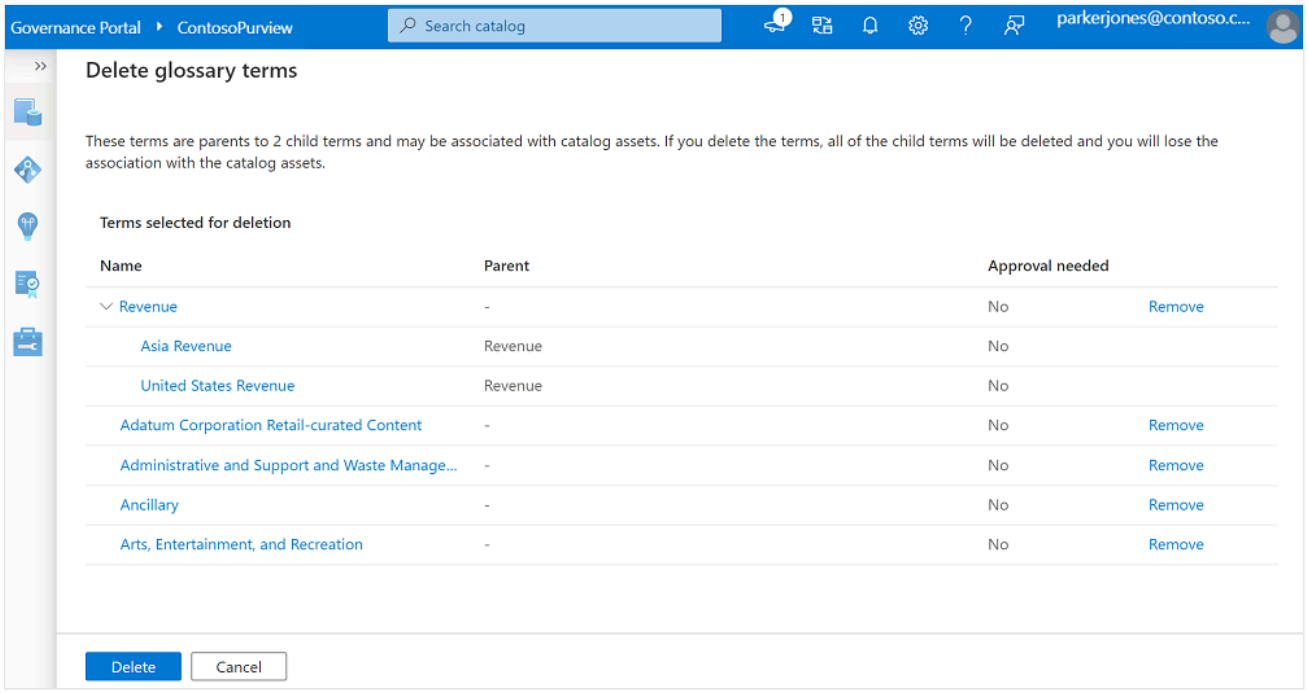
1. Open the **Data catalog**.



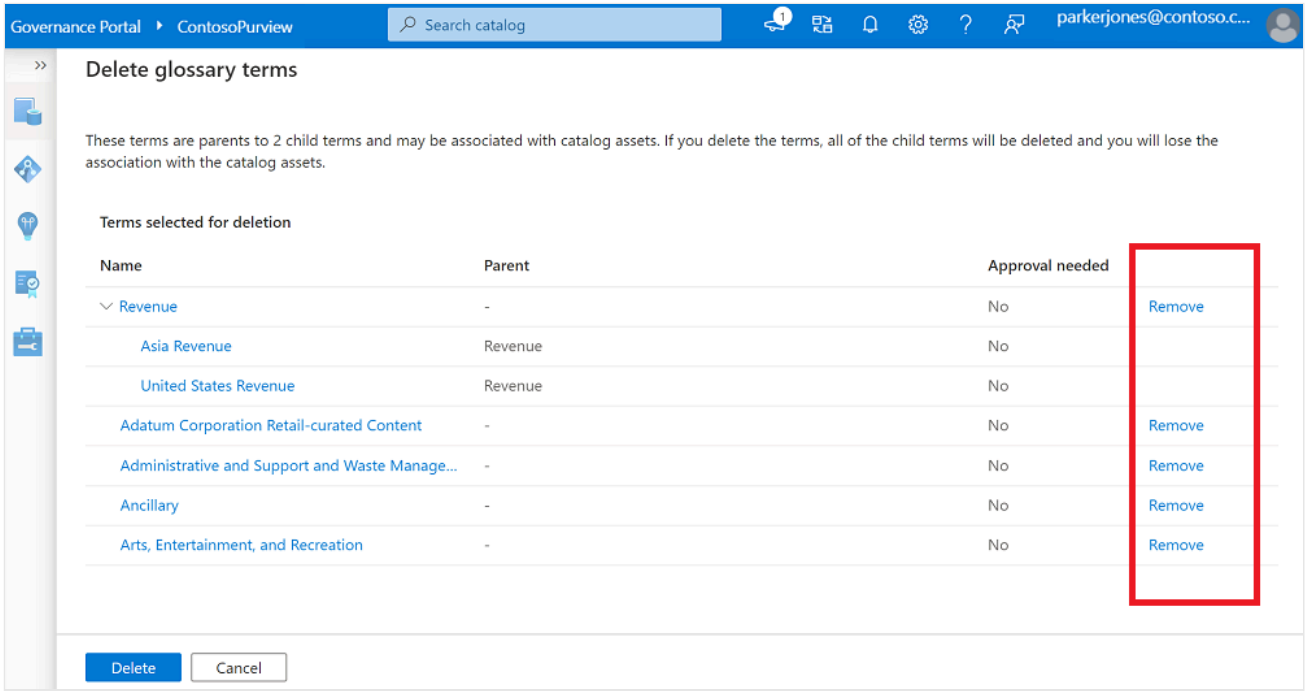
2. If you're using the classic Microsoft Purview portal, select **Glossary**. If you're using the new Microsoft Purview portal under **Business glossary**, select **Glossaries**.

3. Select the glossary that has the terms you want to delete, and select the **Terms** tab.

4. Select checkboxes for the terms that you want to delete. You can select a single term or multiple terms for deletion.



5. Select the **Delete** button on the top menu.

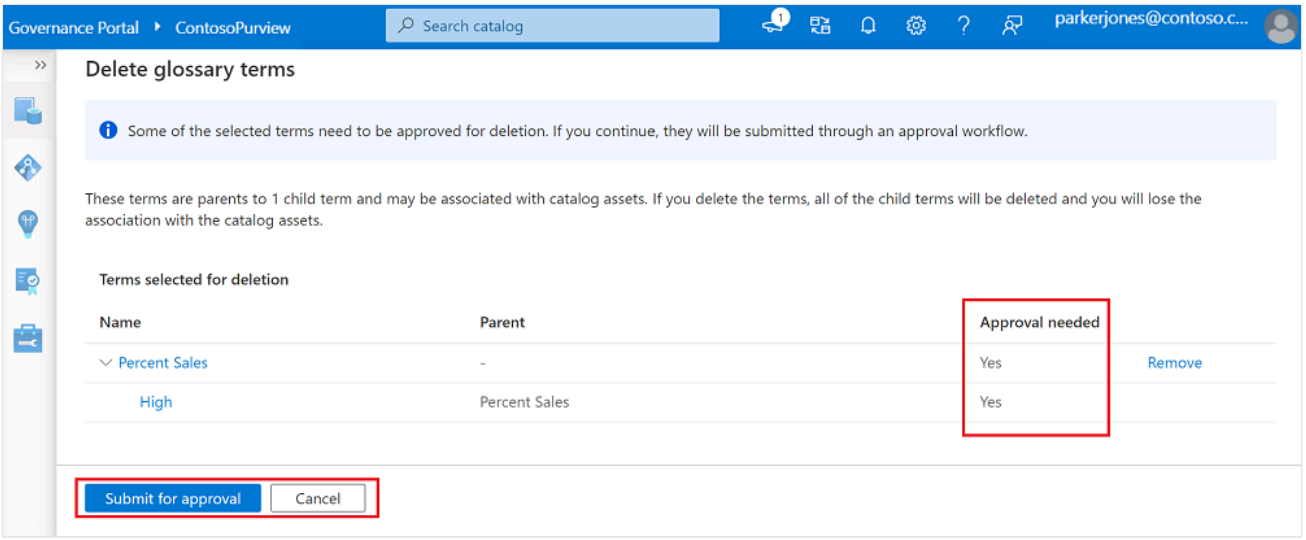


6. A new window shows all the terms selected for deletion. In the following example, the list of terms to be deleted are the parent term **Revenue** and its two child terms.

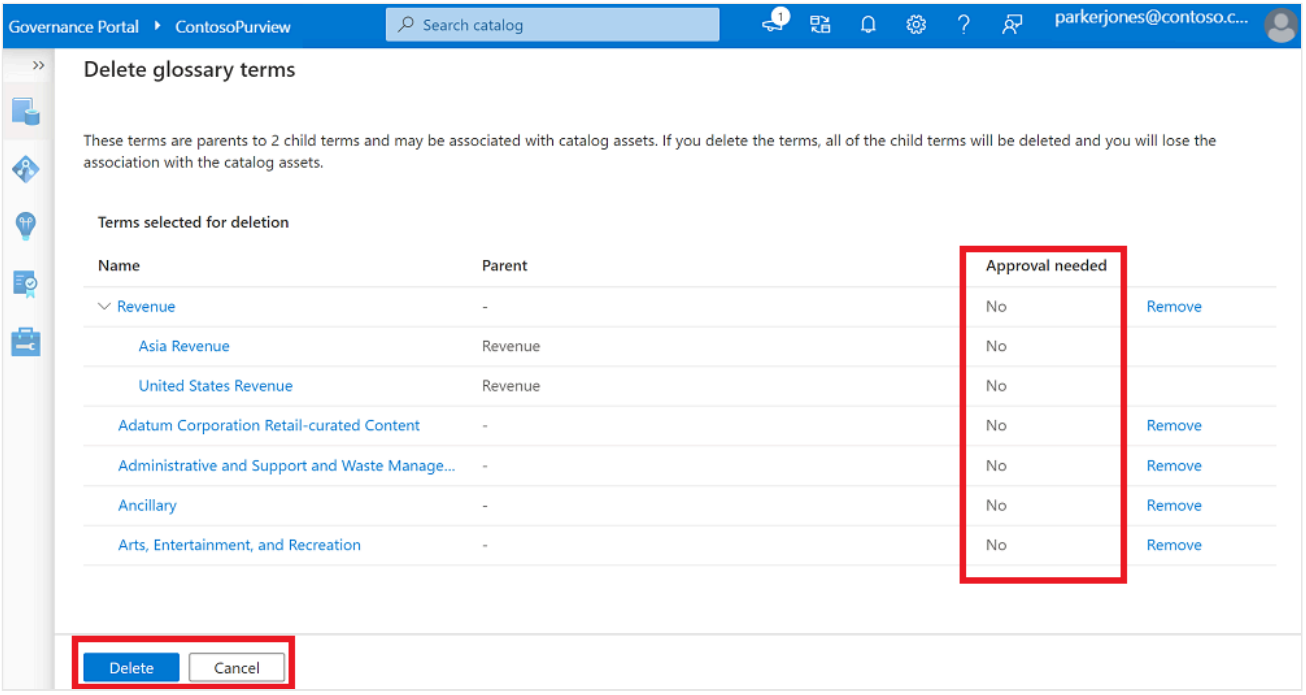
> **Note**

If a parent is selected for deletion, all the children for that parent are automatically selected for deletion.

Review the list. You can remove the terms that you don't want to delete by selecting **Remove**.



7. The **Approval needed** column shows which terms require an approval process. If the value is **Yes**, the term will go through an approval workflow before deletion. If the value is **No**, the term will be deleted without any approvals.



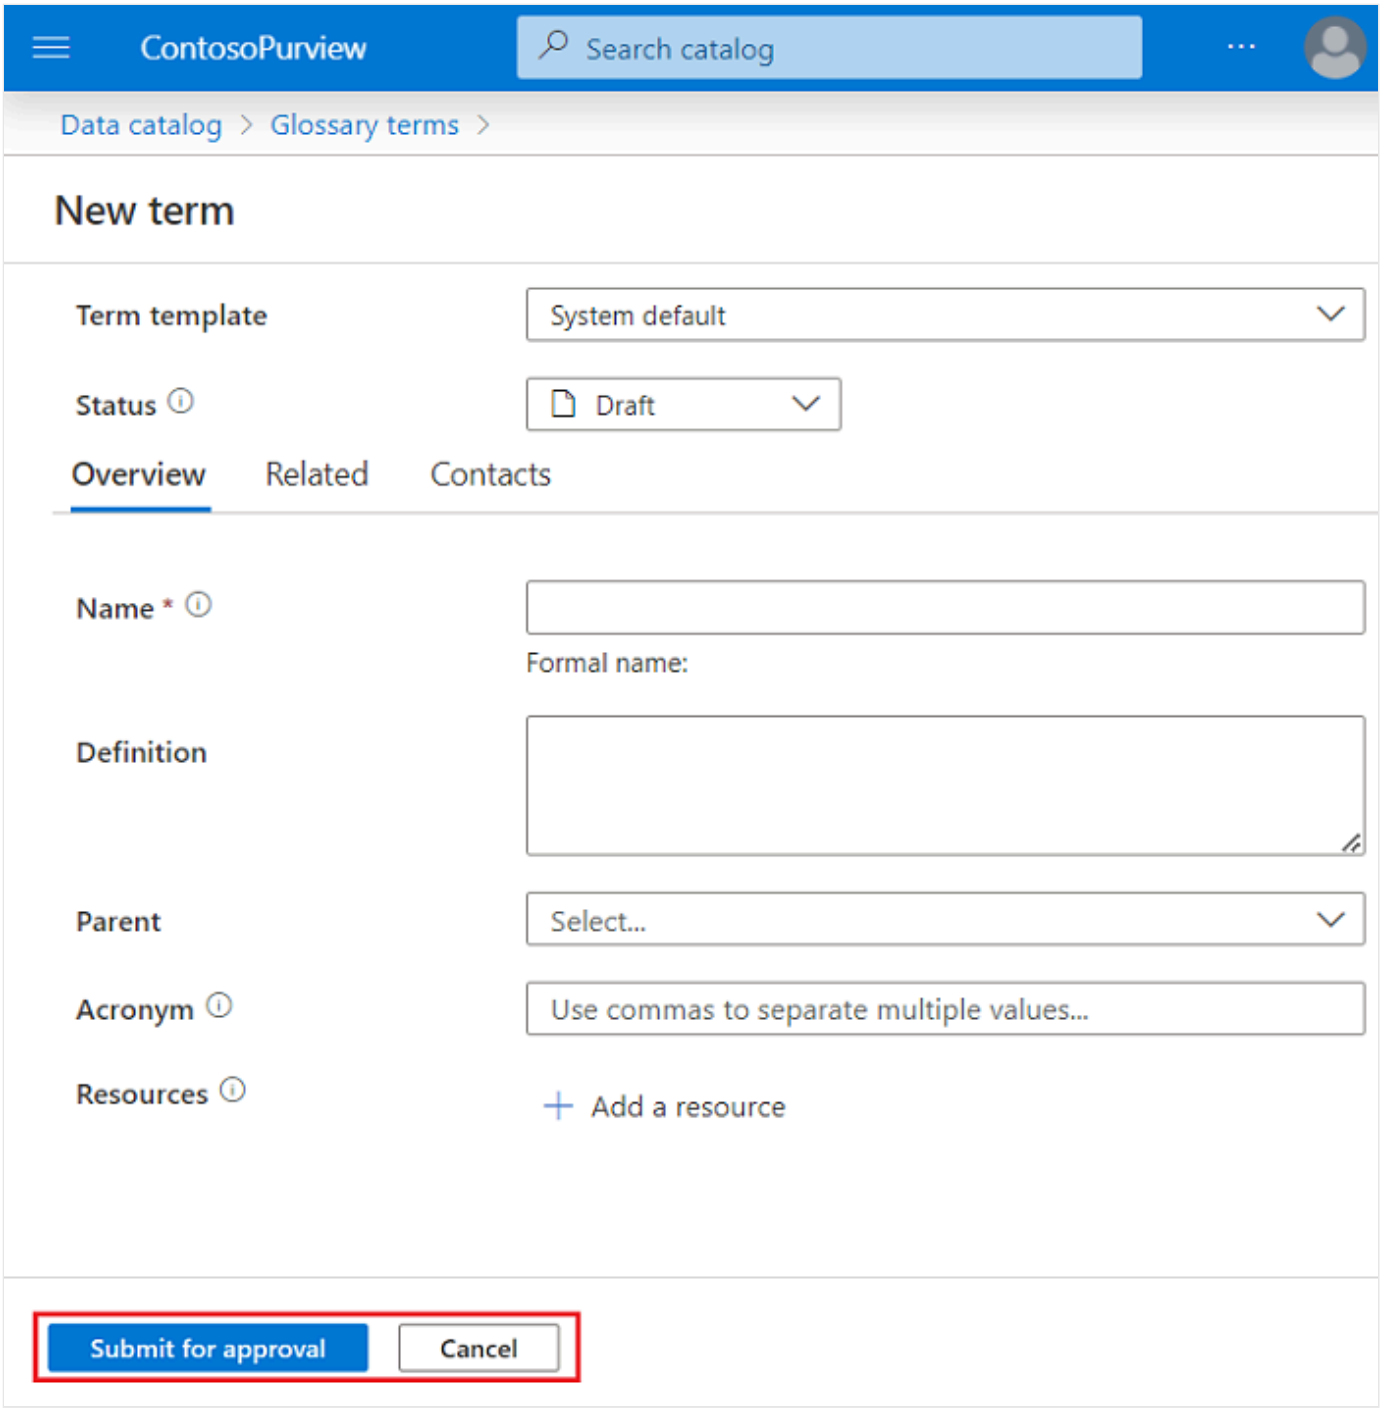
> ⓘ Note

If a parent has an associated approval process but its child doesn't, the workflow for deleting the parent term will be triggered. This is because the selection is done on the parent, and you're acknowledging the deletion of child terms along with parent.

If at least one term needs to be approved, **Submit for approval** and **Cancel** buttons appear. Selecting **Submit for approval** will delete all the terms where approval isn't needed and will trigger approval workflows for terms that require it.

If no terms need to be approved, **Delete** and **Cancel** buttons appear. Selecting **Delete** will delete all the selected terms.

Business terms with approval workflow enabled



If workflows are enabled on a term, then any create, update, or delete actions for the term will go through an approval before they're saved in the data catalog.

- **New terms**: When a create approval workflow is enabled on a parent term, you see **Submit for approval** instead of **Create** after you enter all the details in the creation process. Selecting **Submit for approval** triggers the workflow. You'll get a notification when your request is approved or rejected.

- **Updates to existing terms**: When an update approval workflow is enabled on a parent term, you see **Submit for approval** instead of **Save** when you're updating the term. Selecting **Submit for approval** triggers the workflow. The changes won't be saved in catalog until all the approvals are met.

- **Deletion**: When a delete approval workflow is enabled on the parent term, you see **Submit for approval** instead of **Delete** when you're deleting the term. Selecting **Submit for approval** triggers the workflow. However, the term won't be deleted from the catalog until all the approvals are met.

- **Importing terms**: When an import approval workflow is enabled for the Microsoft Purview glossary, you see **Submit for approval** instead of **OK** in the **Import** window when you're importing terms via .CSV file. Selecting **Submit for approval** triggers the workflow. However, the terms in the file won't be updated in the catalog until all the approvals are met.

Next steps

- For more information about glossary terms, see the glossary reference.
- For more information about approval workflows of the business glossary, see Approval workflow for business terms.

Import and export glossary terms

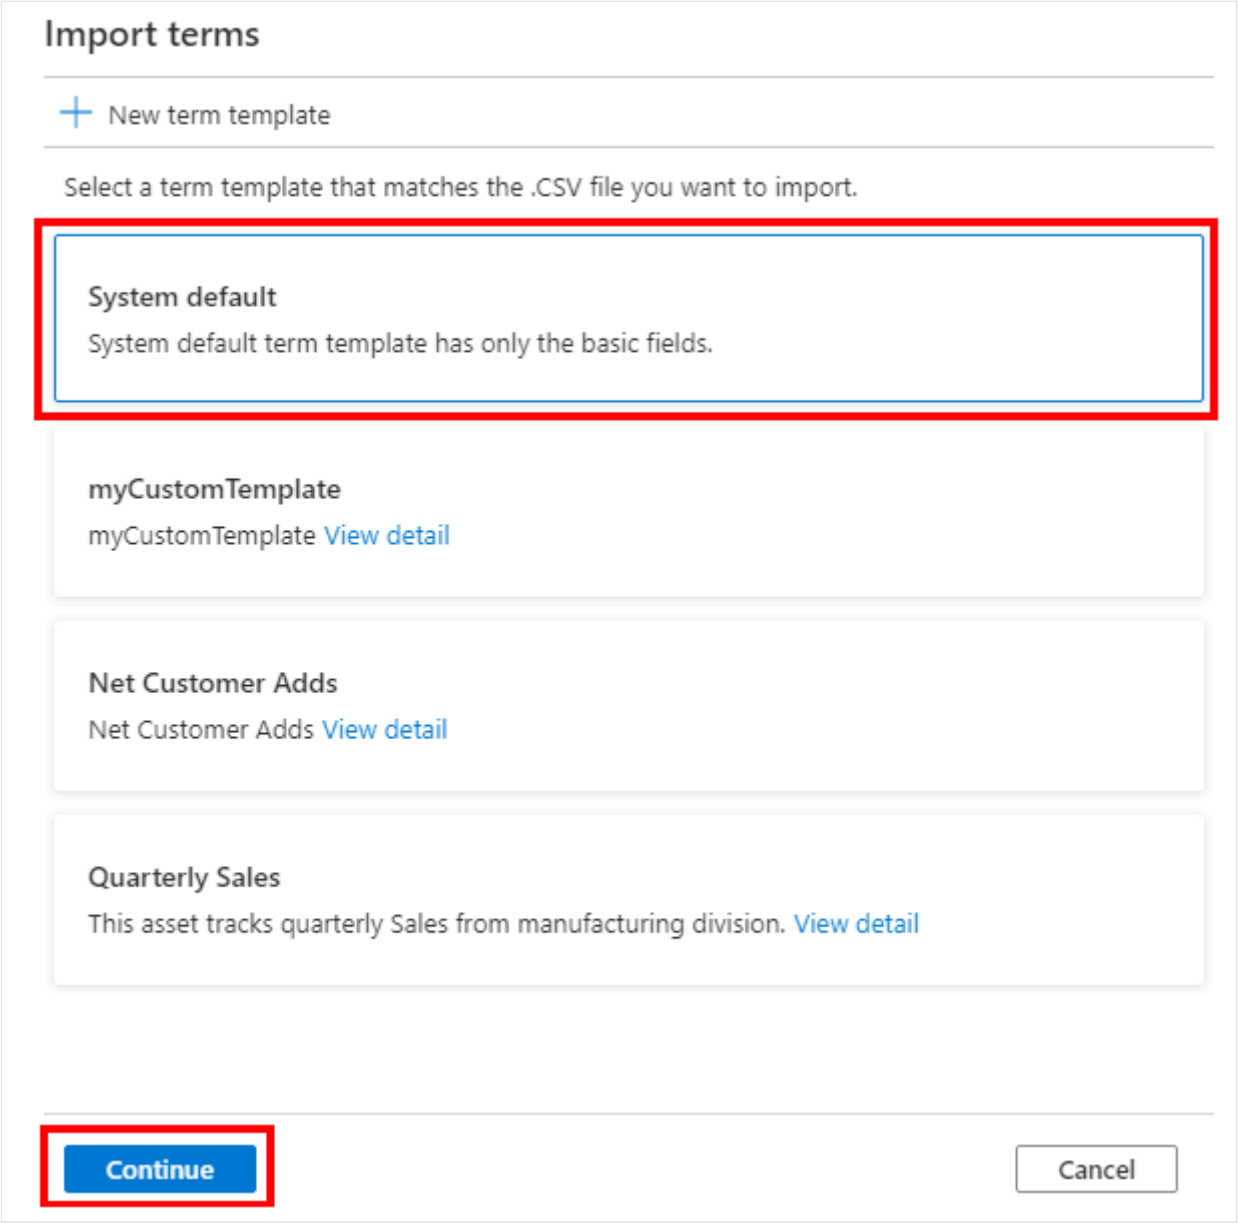
> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

This article describes how to work with the business glossary in Microsoft Purview. It provides steps to create a business glossary term in the Microsoft Purview Data Catalog. It also shows you how to import and export glossary terms by using .CSV files.

> **Note**
>
> To edit the glossary, and import or export terms, you need to have data curator permissions.

Import terms into the glossary

The Microsoft Purview Data Catalog provides a template .CSV file for you to import terms from the catalog into your glossary. Duplicate terms include both spelling and capitalization, because term names are case-sensitive.



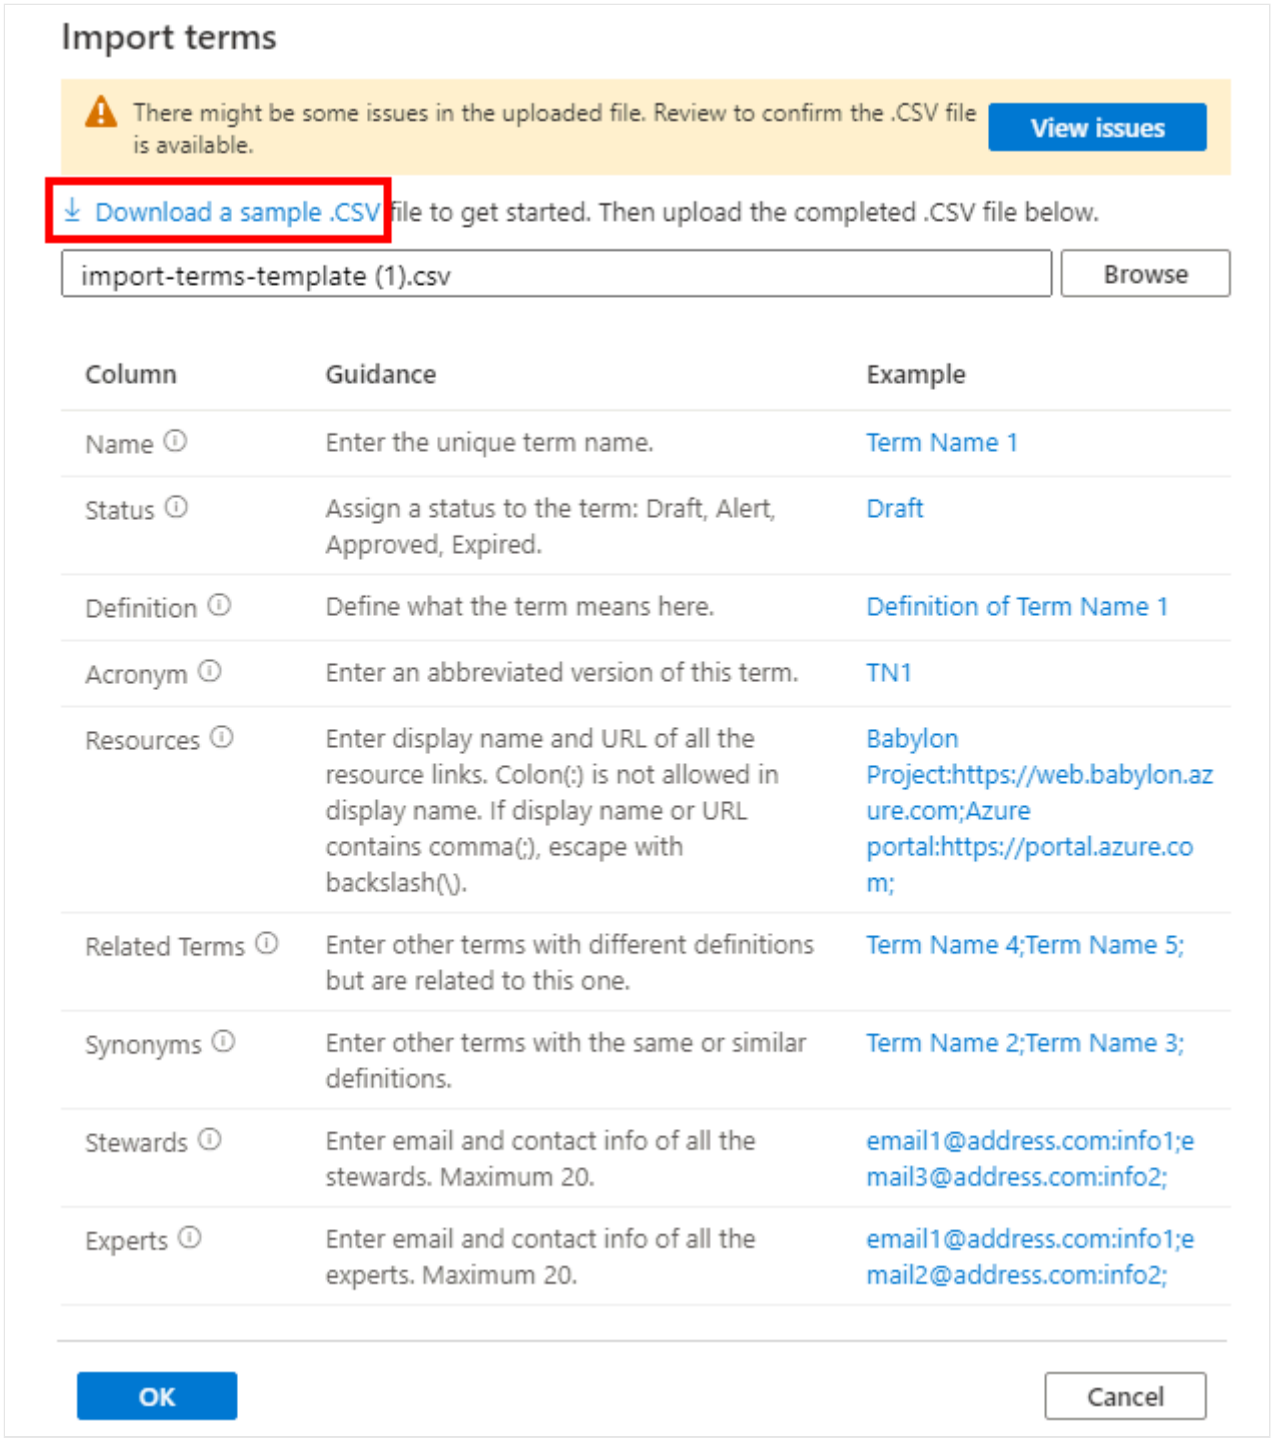
1. Open the Microsoft Purview Data Catalog.

2. If you're using the classic Microsoft Purview portal, select **Glossary**. If you're using the new Microsoft Purview portal under **Business glossary**, select **Glossaries**.

3. Select the glossary where you want to import terms.
   a. In the Microsoft Purview portal, select **View terms** and then select **Import terms**.
   b. In the classic governance portal, select **Import terms**.

4. Select the template, or templates, for the terms you want to import, and then select **Continue**.

   You can select multiple templates and import terms for different templates from a single .csv file.



5. Download the .csv template and use it to enter the terms that you want to add.

   Give your template file a name that starts with a letter and includes only letters, numbers, spaces, an underscore (_), or other non-ASCII Unicode characters. Special characters in the file name will create an error.

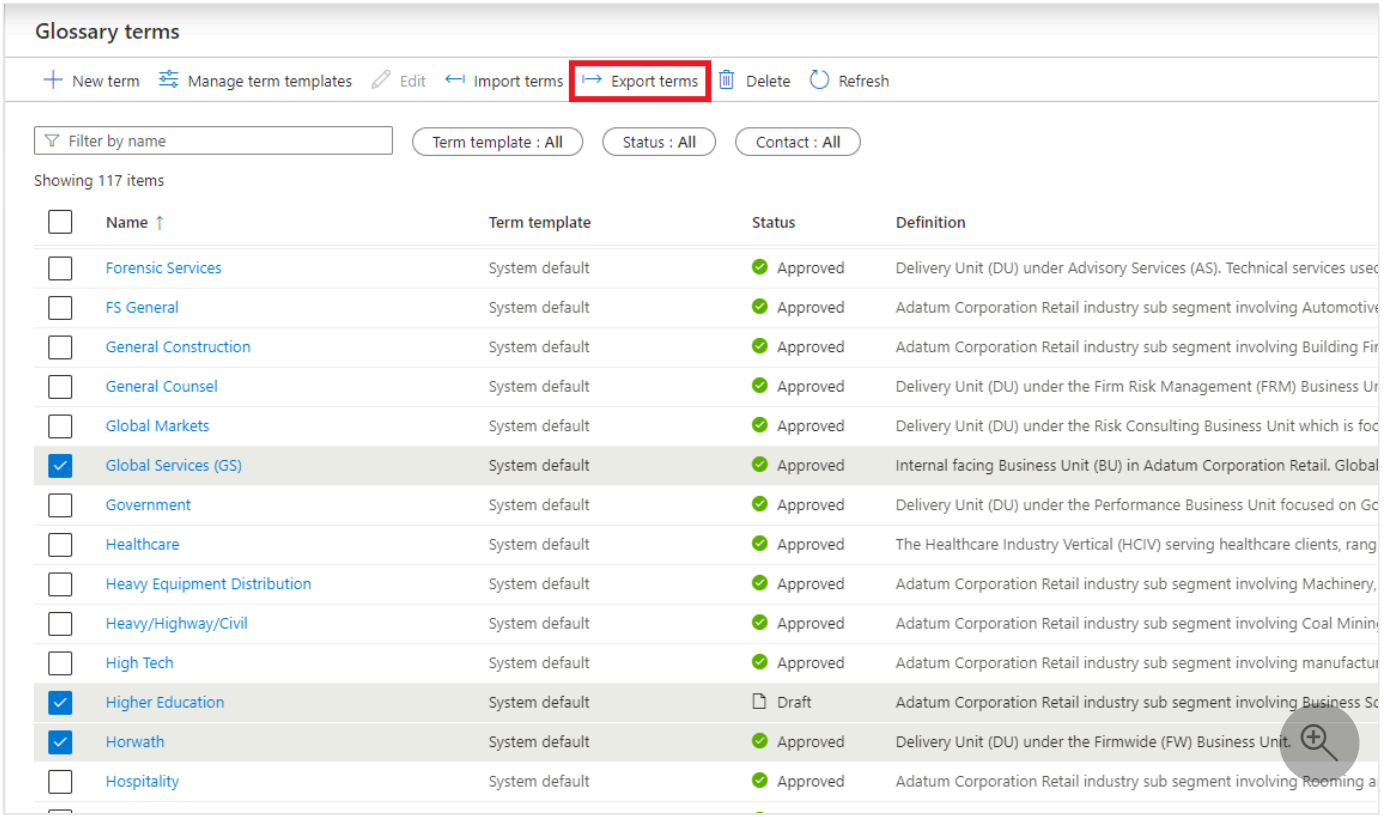
> ⓘ **Important**
>
> The system supports only importing columns that are available in the template. The **System default** template will have all the default attributes.
>
> Custom term templates define out-of-the box attributes and additional custom attributes. Therefore, the .CSV file differs in the total number of columns and the column names, depending on the term template that you select. You can also review the file for problems after upload.

If you want to upload a file with a rich text definition, be sure to enter the definition with markup tags and populate the column `IsDefinitionRichText` to `true` in the .CSV file.

6. After you finish filling out your .CSV file, select your file to import, and then select **OK**.

The system will upload the file and add all the terms to your selected glossary.

> **Important**



The email address for an expert or steward should be the primary address of the user from the Microsoft Entra group. Alternate emails, user principal names, and non-Microsoft Entra ID emails are not yet supported.

Export terms from the glossary

When you're in any of your glossaries, the **Export terms** button is disabled by default. After you select the terms that you want to export, the **Export terms** button is enabled.

> **Note**
>
> Selected terms **don't** need to be from the same term template to be able to export them.

Select **Export terms** to download the selected terms.

> **Important**
>
> The import process currently doesn't support updating the parent of a term.

Business terms with approval workflow enabled

If workflows are enabled on a term, then any import actions for the term will go through an approval before they're saved in the data catalog.

When an import approval workflow is enabled for the Microsoft Purview glossary, you'll see **Submit for approval** instead of **OK** in the **Import** window when you're importing terms via .CSV file. Selecting **Submit for approval** triggers the workflow. However, the terms in the file won't be updated in the catalog until all the approvals are met.

Next steps

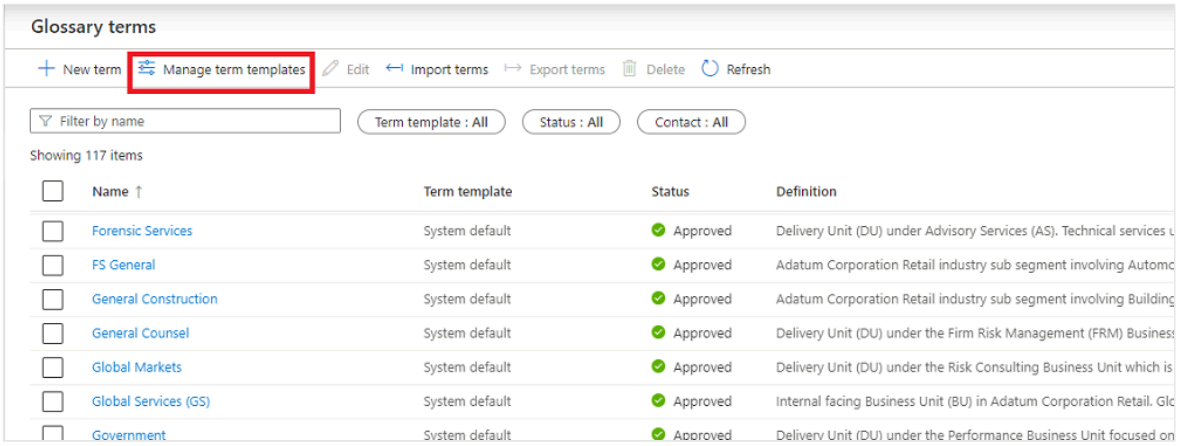
- For more information about glossary terms, see the glossary reference.
- For more information about approval workflows of the business glossary, see Approval workflow for business terms.

Last updated on 04/22/2026

How to manage term templates for business glossary

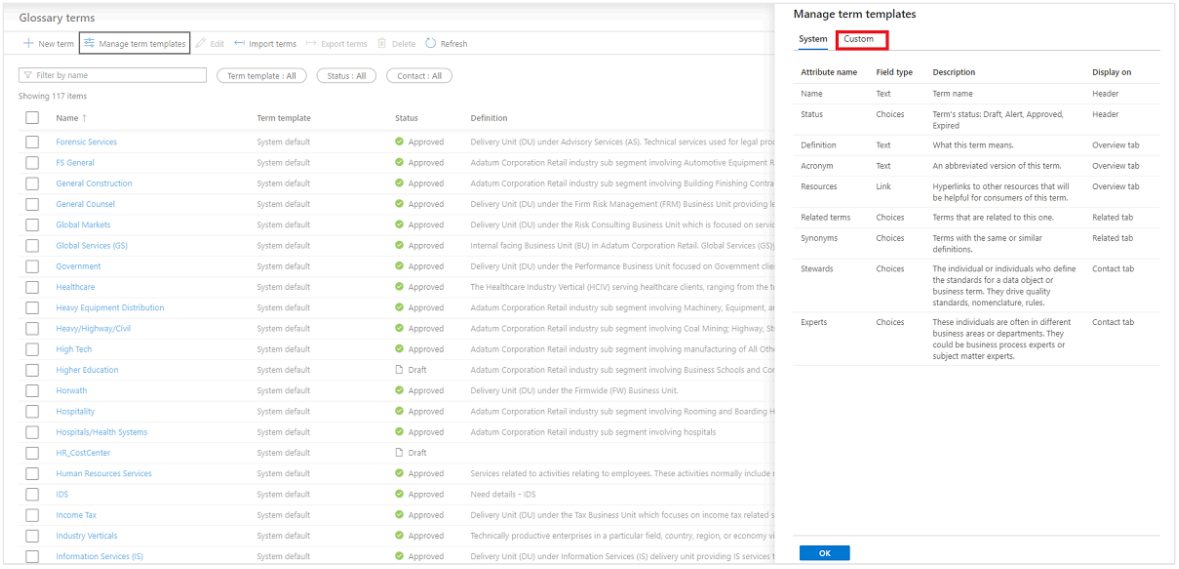
Article • 01/28/2025

> **Note**
>
> Microsoft Purview Data Map (classic), Data Catalog (classic), Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.



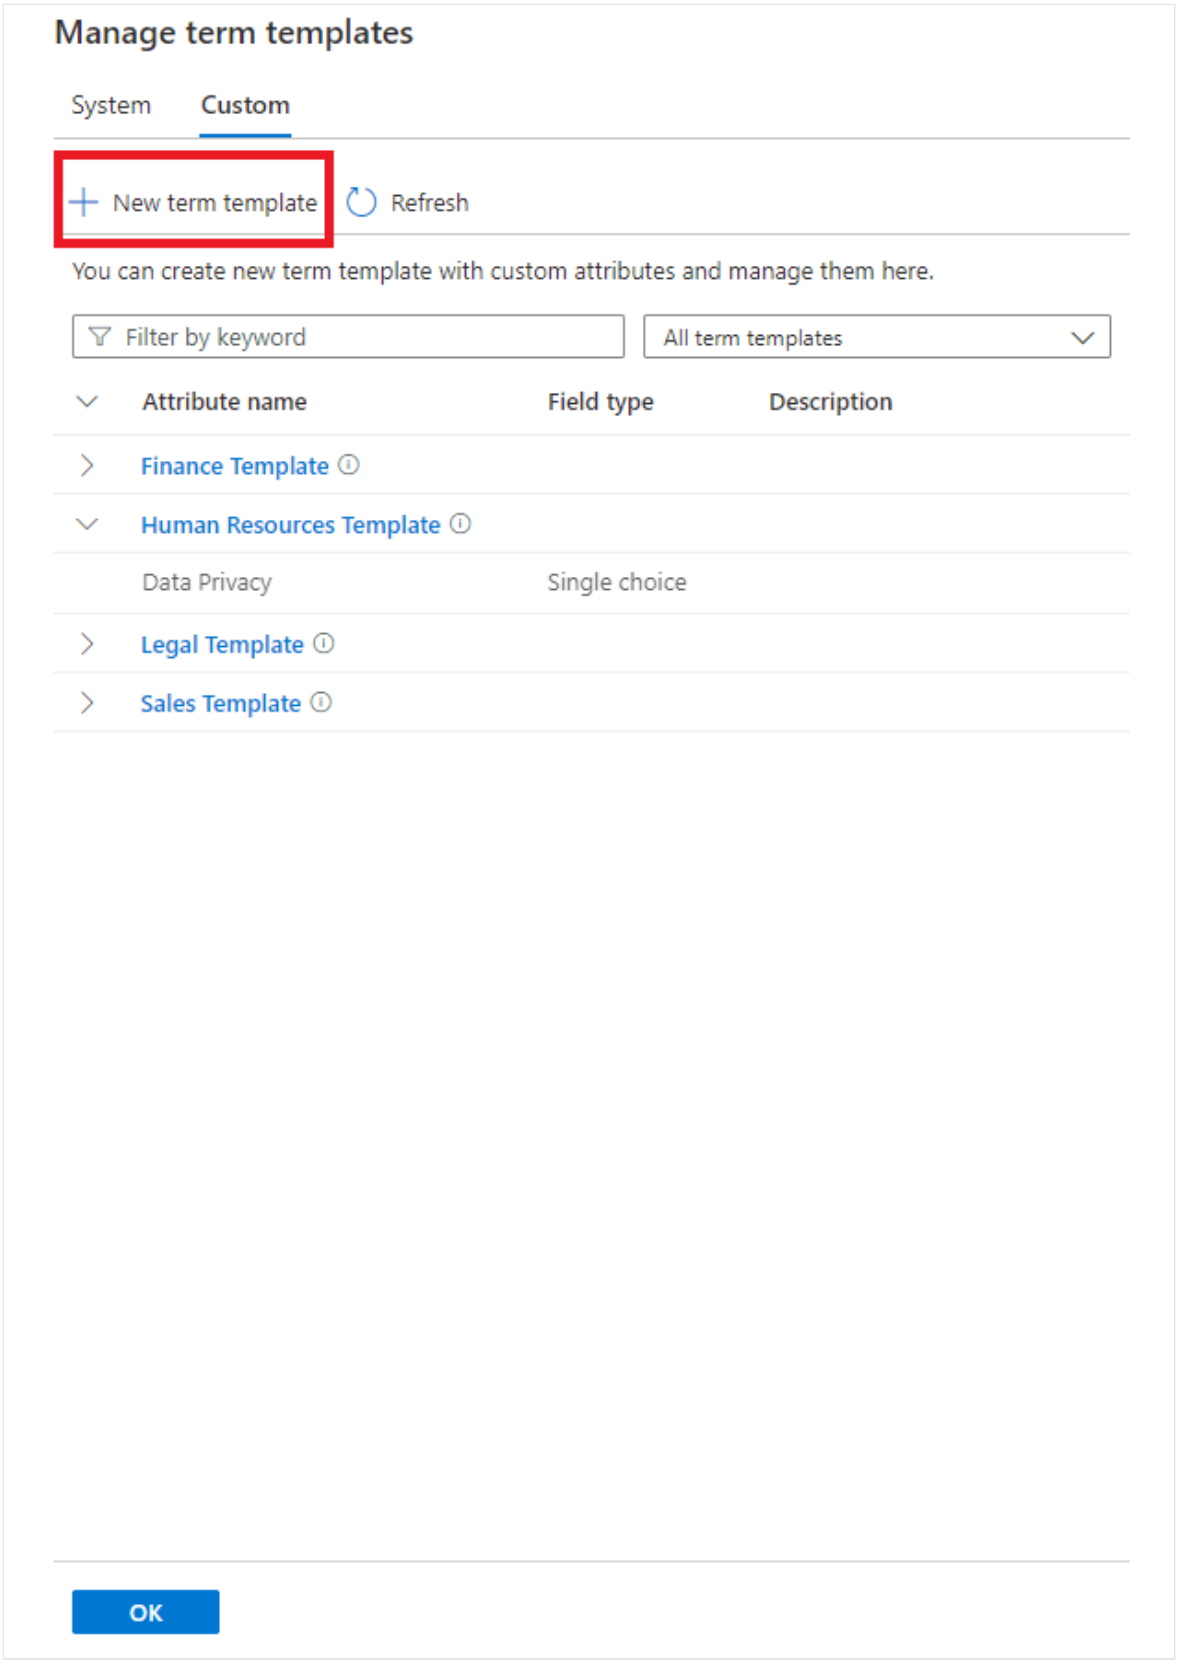
Microsoft Purview allows you to create a glossary of terms that are important for enriching your data. Each new term added to your Microsoft Purview Data Catalog Glossary is based on a term template that determines the fields for the term. This article describes how to create a term template and custom attributes that can be associated to glossary terms.

Manage term templates and custom attributes



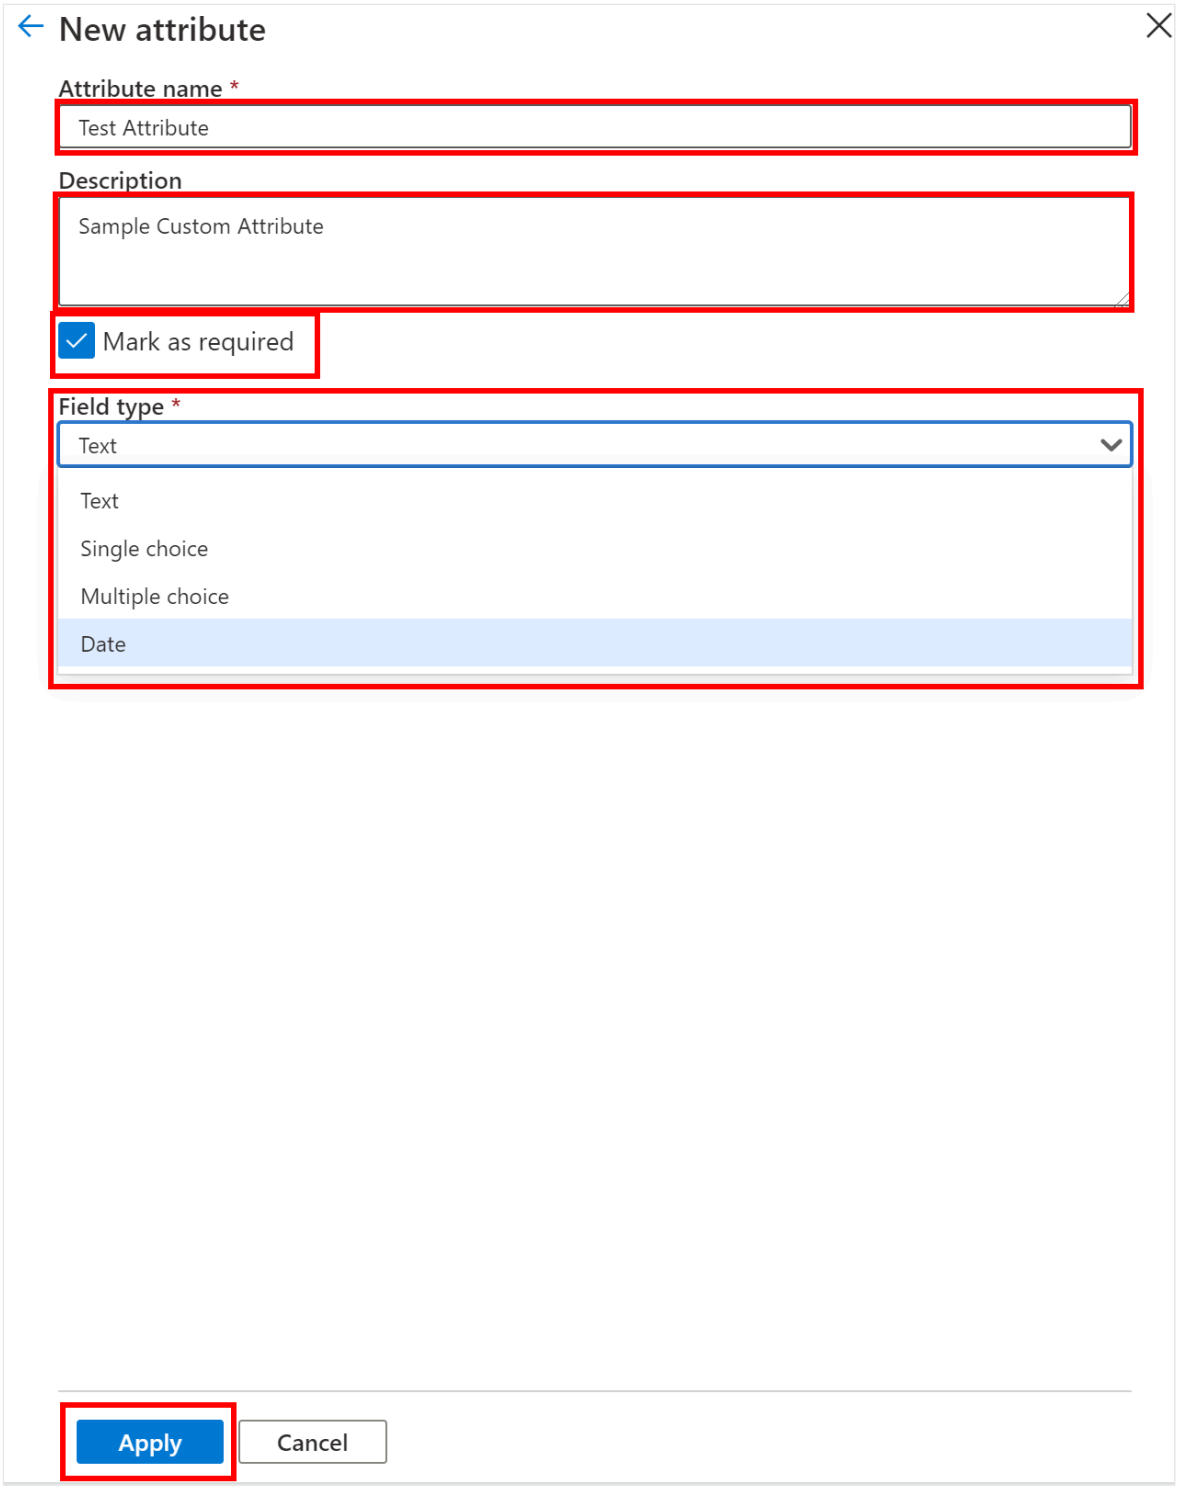
Using term templates, you can create custom attributes, group them together and apply a template while creating terms.

> **Note**
>
> Once a term is created, the template associated with the term can't be changed.

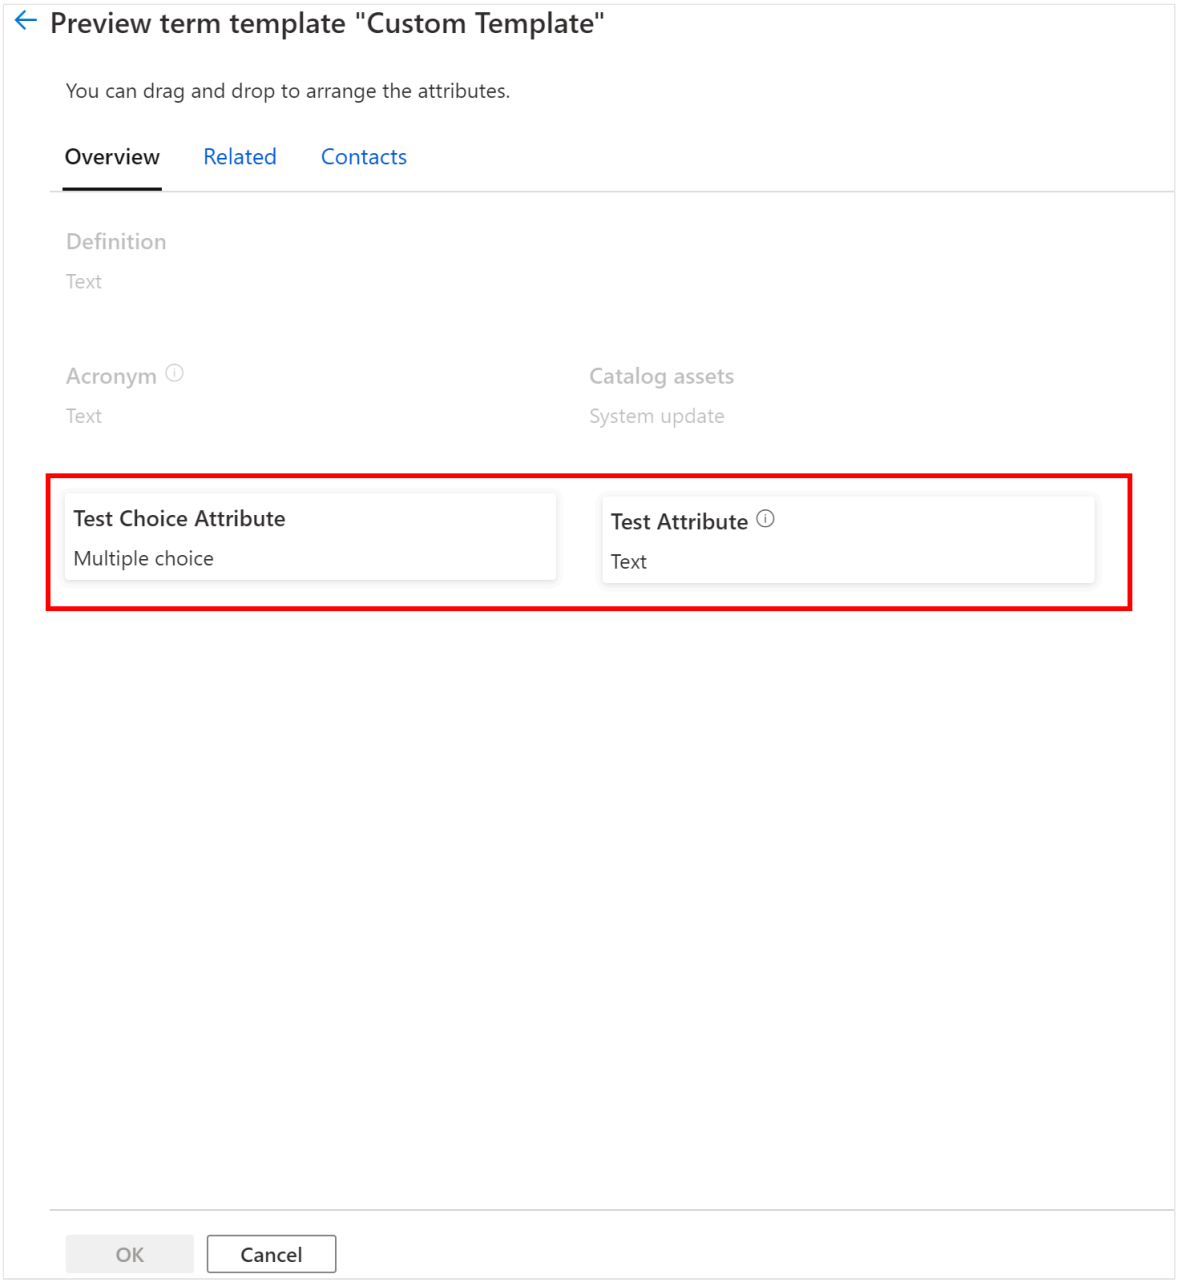


1. Open the Microsoft Purview Data Catalog.
2. If you're using the classic Microsoft Purview portal, select **Glossary**. If you're using the new Microsoft Purview portal under **Business glossary**, select **Glossaries**.
3. Select **Manage term templates**.

4. The page shows both system and custom attributes. Select the **Custom** tab to create or edit term templates.

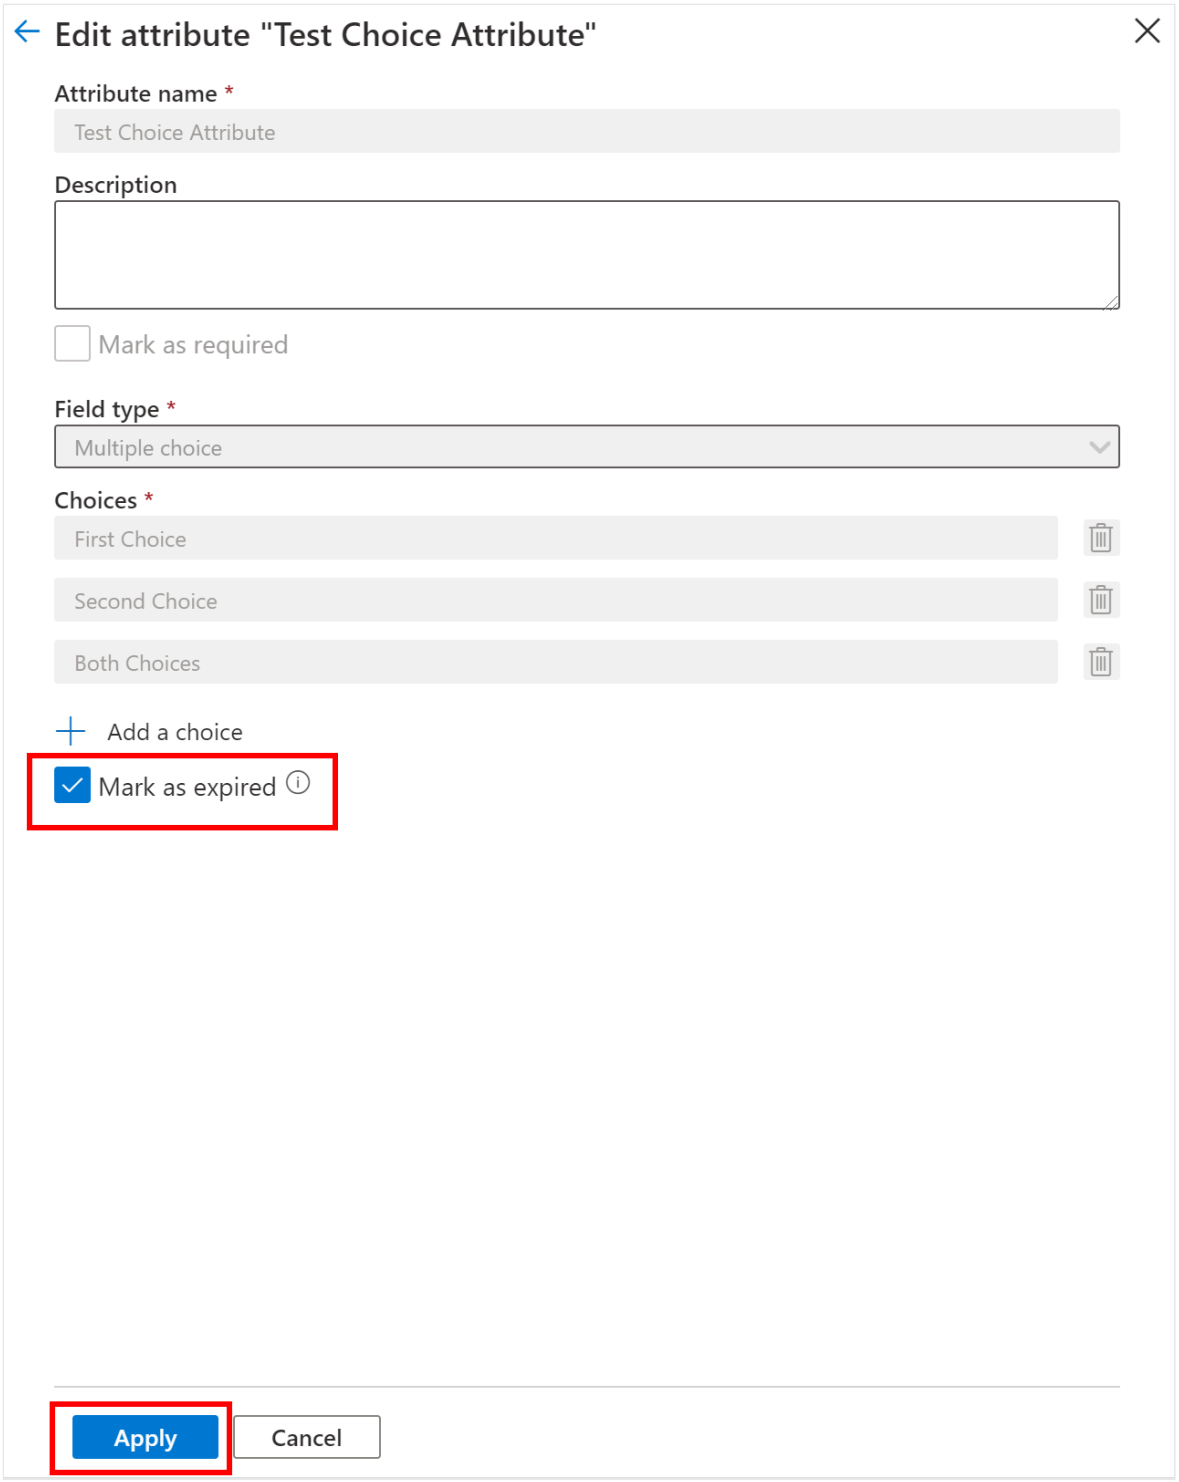


5. Select + **New term template** and enter a template name and description.



6. Select + **New attribute** to create a new custom attribute for the term template. Enter an attribute name, description. The custom attribute name must be unique within a term template but can be same name can be reused across templates.

   Choose the field type from the list of options **Text**, **Single choice**, **Multi choice**, or **Date**. You can also provide a default value string for Text field types. The attribute can also be marked as **required**.



7. Once all the custom attributes are created, select **Preview** to arrange the sequence of custom attributes. You can drag and drop custom attributes in the desired sequence.

8. Once all the custom attributes are defined, select **Create** to create a term template with custom attributes.

9. Existing custom attributes can be marked as expired by checking **Mark as Expired**. Once expired, the attribute can't be reactivated. The expired attribute is greyed out for existing terms. Future new terms created with this term template will no longer show the attribute that has been marked expired.

10. To delete a term template, open the template and select **Delete**. Note, if the term template is in use, you can't delete it until you remove the glossary terms to which it's assigned.

Next steps

Follow the Tutorial: Create and import glossary terms to learn more.

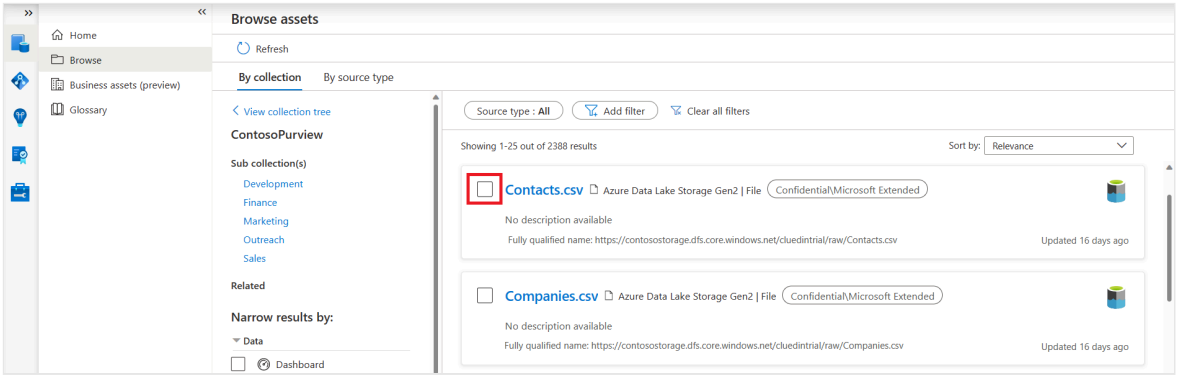
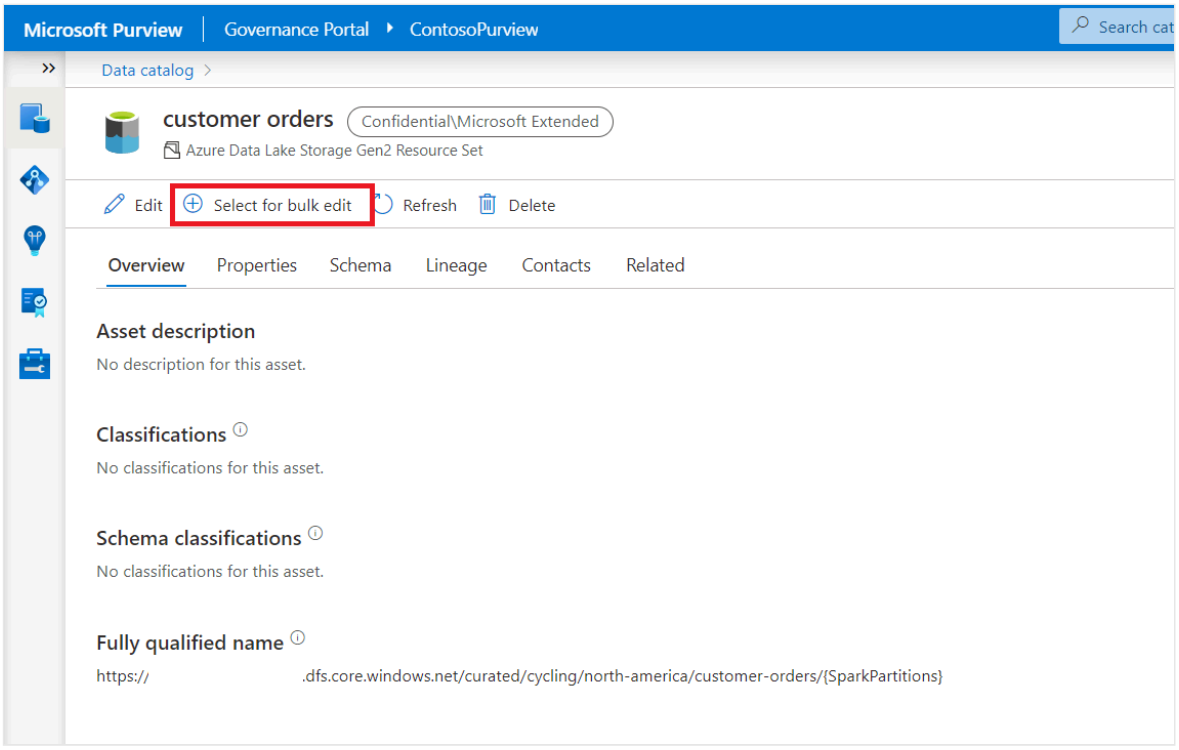
How to bulk edit assets

Article • 02/26/2025



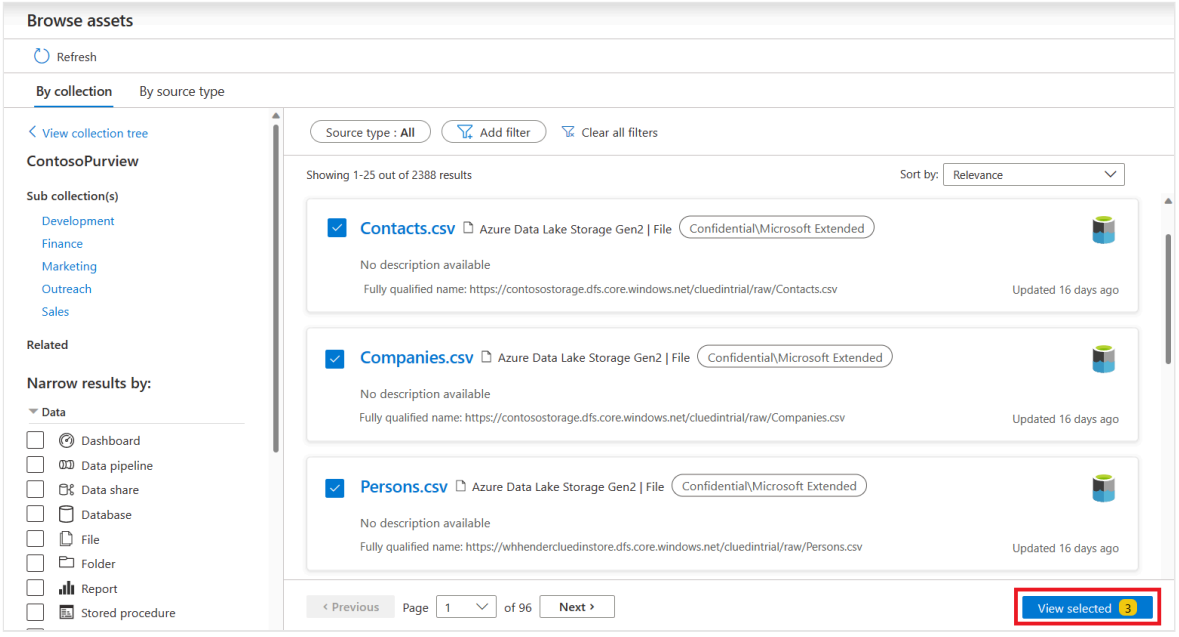
> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

This article describes how you can update assets in bulk to add glossary terms, classifications, owners, and experts on multiple assets at once.



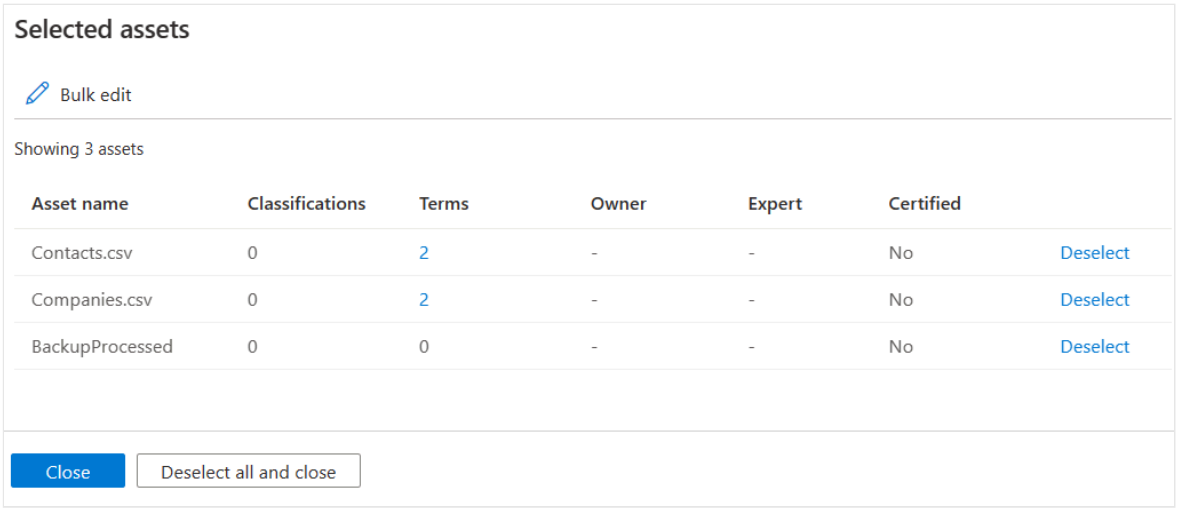
> **Note**
>
> Bulk editing as described here is for data assets. Other assets like classifications and glossary terms can't be added to the bulk edit list.

Select assets to bulk edit

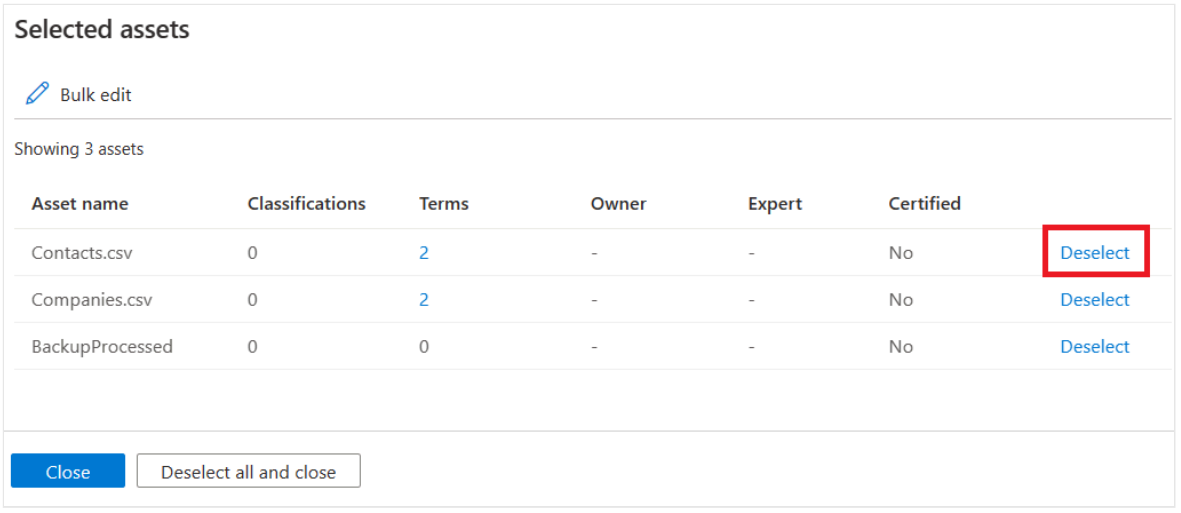


1. Use Microsoft Purview search or browse to discover assets you wish to edit.
2. In the search results, each data asset has a checkbox you can select to add the asset to the selection list.

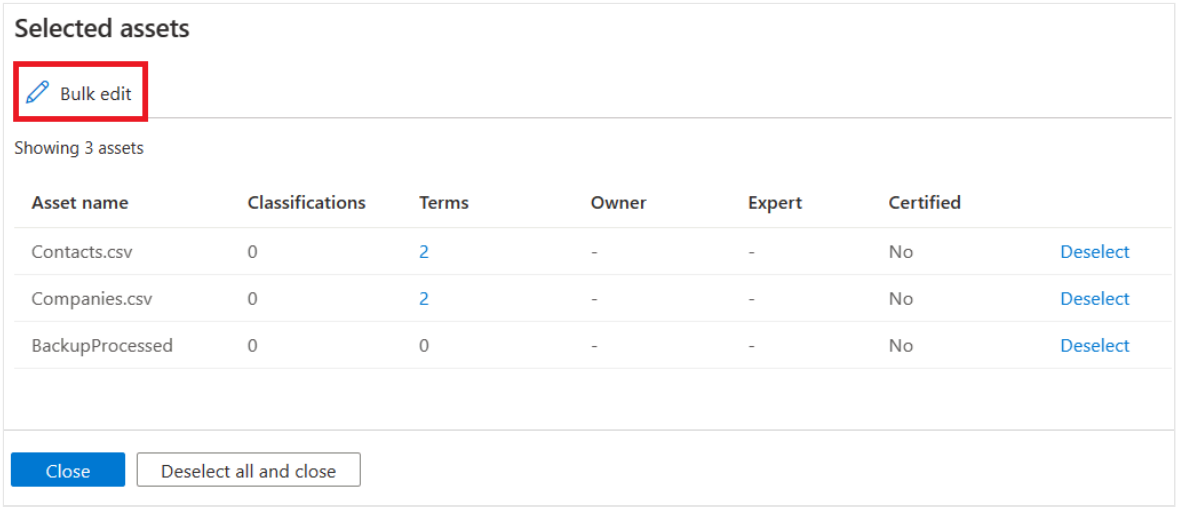
3. You can also add an asset to the bulk edit list from the asset detail page. Select **Select for bulk edit** to add the asset to the bulk edit list.



4. Select the checkbox to add it to the bulk edit list. You can see the selected assets by selecting the **View selected** button.

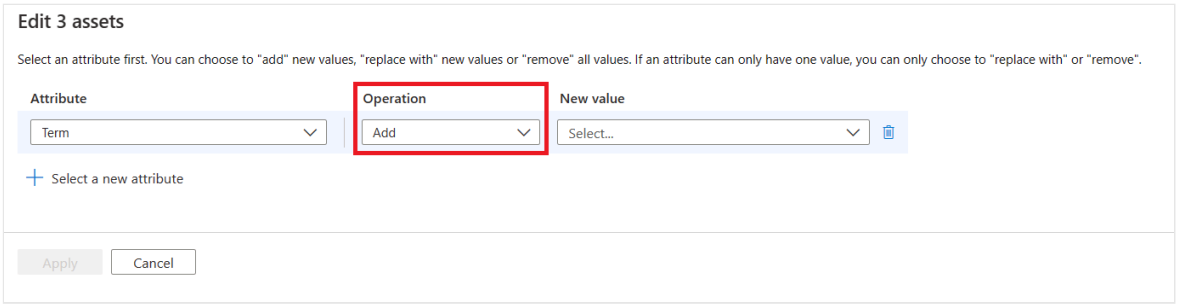


Bulk edit assets



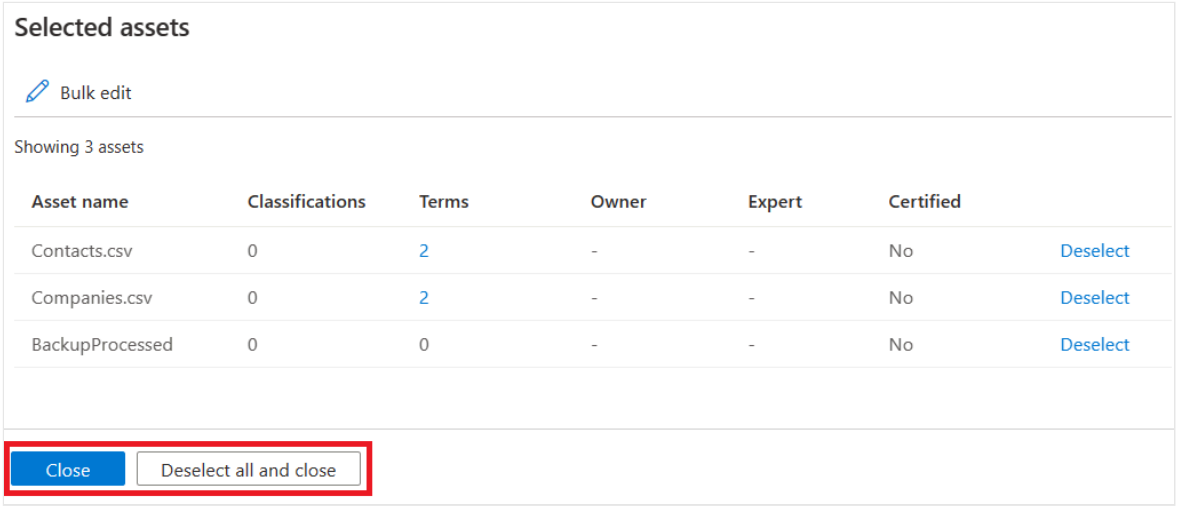
1. When all assets have been chosen, select **View selected** to pull up the selected assets.

2. Review the list and select **Deselect** if you want to remove any assets from the list.



3. Select **Bulk edit** to add, remove, or replace an annotation for all the selected assets. You can edit the glossary terms, classifications, owners, or experts of an asset.

4. For each attribute selected, you can choose which edit operation to apply
   a. **Add** will append a new annotation to the selected data assets.



b. **Replace with** will replace all of the annotations for the selected data assets with the annotation selected.
c. **Remove** will remove all annotations for selected data assets.

You can edit multiple assets at once by selecting **Select a new attribute**.

5. When you have made all your updates, select **Apply**.

6. Once complete, close the bulk edit blade by selecting **Close** or **Remove all and close**. Close won't remove the selected assets whereas remove all and close will remove all the selected assets.

> **Important**
>
> In the UI you can currently only select up to 25 assets. The **View Selected** box will be visible only if there is at least one asset selected.

Governance roles and permissions for classic Data Catalog in free and enterprise account types

Article • 05/20/2025

> **Important**
>
> This article explains governance permissions in the free and enterprise versions of Microsoft Purview data governance solutions using the classic Microsoft Purview Data Catalog.
>
> - For permissions using the new Microsoft Purview Unified Catalog, see the data governance permissions article.
> - For general permissions in the Microsoft Purview portal see permissions in the portal.
> - For classic data governance permissions, see the permissions in the Microsoft Purview governance portal article.

Microsoft Purview data governance has two solutions in the Microsoft Purview portal, the Data Map and the catalog. These solutions use tenant/organizational-level permissions, existing data access permissions, and domain/collection permissions to provide users access to governance tools and data assets. The kind of permissions available to use depends on your Microsoft Purview account type. You can check your account type in the Microsoft Purview portal under the **Settings** card, and **Account**.

Expand table

Account Type	Tenant/Organization permissions	Data access permissions	Domain and collection permissions
Free	x	x	
Enterprise	x	x	x

For more information about each permission type, see these guides:

- Tenant/organization permissions - assigned at the organizational level, they provide general and administrative permissions.
- Domain and collection level permissions - permissions in the Microsoft Purview Data Map that grant access to data assets in Microsoft Purview.
- Data access permissions - permissions users already have on their Azure data sources.

For more information about permission based on account type, see these guides:

- Free
- Enterprise

> **Important**
>
> For users newly created in Microsoft Entra ID, it could take some time for permissions to propagate even after correct permissions have been applied.

Tenant level role groups

Assigned at the organizational level, tenant level role groups provide general, and administrative permissions for both the Microsoft Purview Data Map and classic Data Catalog. If you're managing your Microsoft Purview account or your organization's data governance strategy, you probably need one or several of these roles.

The currently available governance tenant-level role groups are:

Expand table

Role group	Description	Account type availability
Purview administrator	Create, edit, and delete domains and perform role assignments.	Free and enterprise accounts
Data Source Administrators	Manage data sources and data scans in the Microsoft Purview Data Map.	Enterprise accounts
Data Catalog Curators	Perform create, read, modify, and delete actions on catalog data objects and establish relationships between objects in the classic Data Catalog.	Enterprise accounts
Data Estate Insights Readers	Provides read-only access to all insights reports across platforms and providers in the classic Data Catalog.	Enterprise accounts
Data Estate Insights Admins	Provides admin access to all insights reports across platforms and providers in the classic Data Catalog.	Enterprise accounts

For a full list of all available roles and role groups, not just for data governance, see roles, and role groups in the Microsoft Defender XDR and Microsoft Purview portals.

How to assign and manage role groups

> **Note**
>
> Users must hold the role management role or the Global Administrator role for the organization in order to assign roles.

> **Important**

Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview **roles and permissions**.

To assign and manage roles in Microsoft Purview, follow the permissions in Microsoft Purview guide.

Permissions to search the classic Data Catalog

No specific permissions are needed in the catalog to be able to search it. However, searching the catalog will only return relevant data assets that you have permissions to view in the Data Map.

Users can find a data asset in the catalog when:

- The user has at least read permissions on an available Azure or Microsoft Fabric resource
- The user has data reader permissions on a domain or collection in the Microsoft Purview Data Map where the asset is stored

Permissions to these assets are managed at the resource level and at the Data Map level.

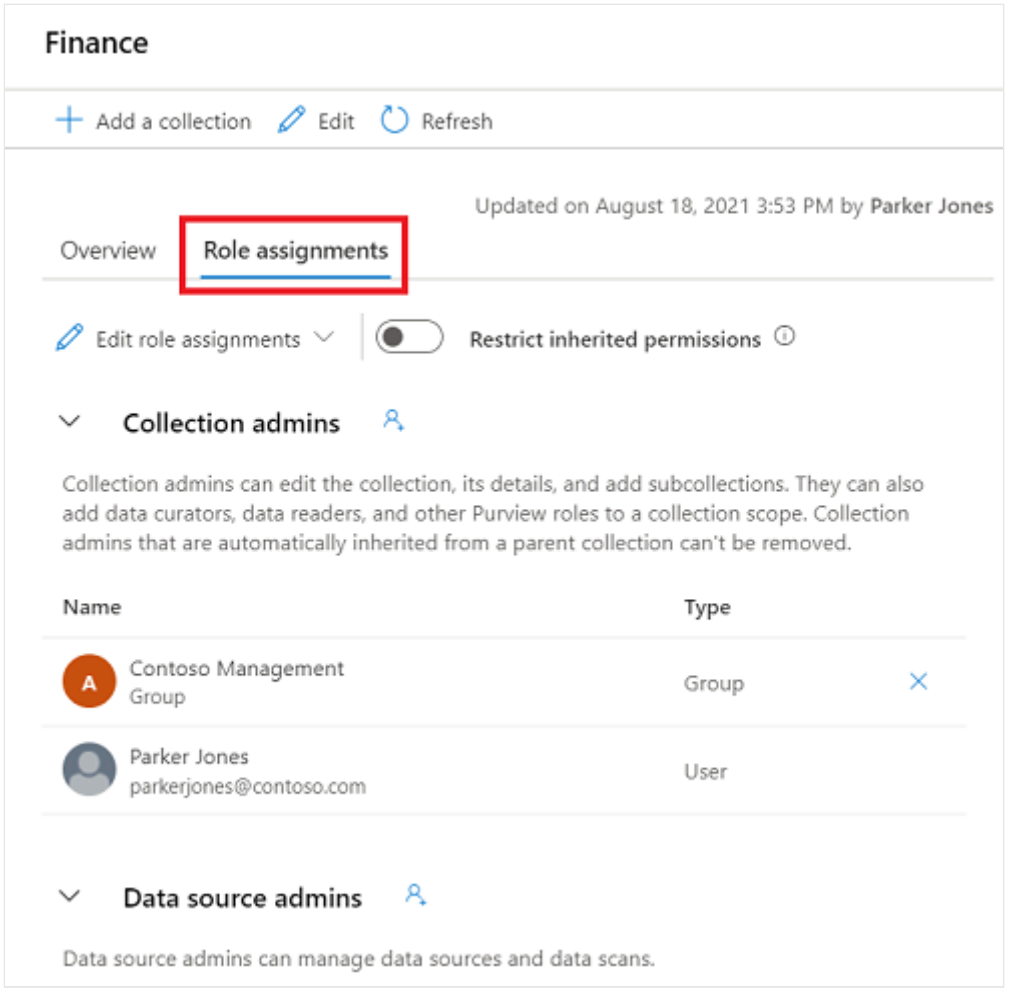
Domain and collection permissions

Domains and collections are tools that the Microsoft Purview Data Map uses to group assets, sources, and other artifacts into a hierarchy for discoverability and to manage access control within the Microsoft Purview Data Map.

Domain and collection roles

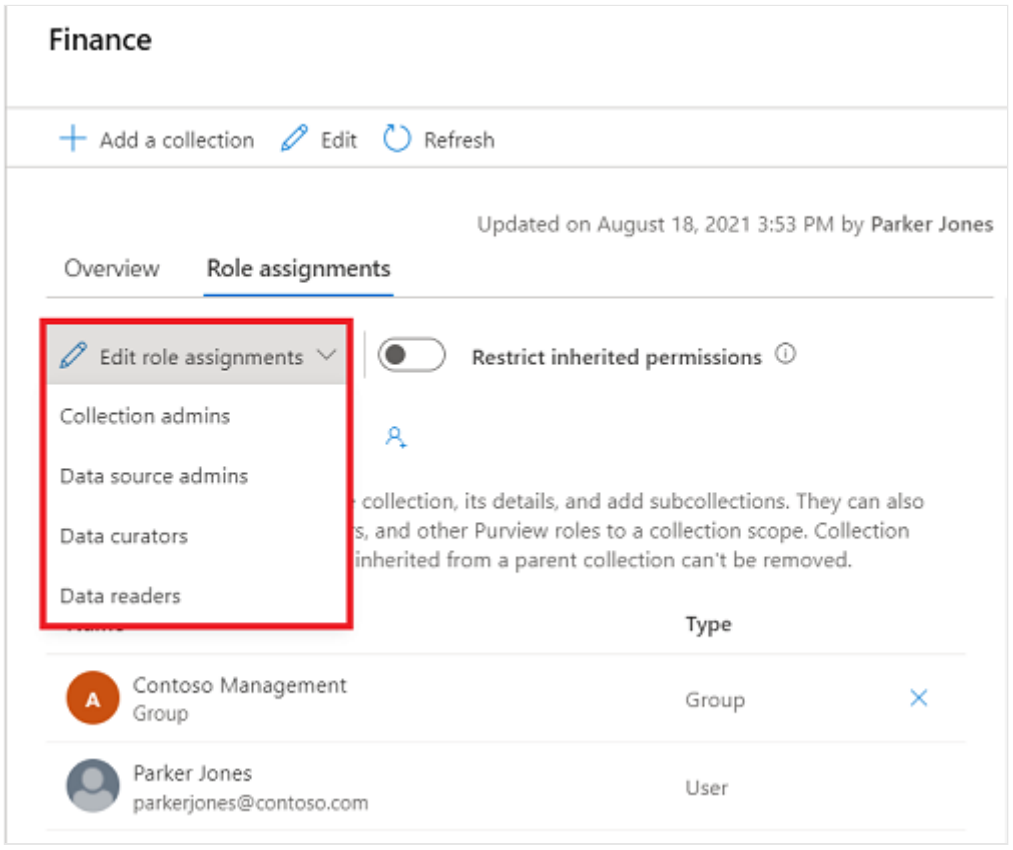
The Microsoft Purview Data Map uses a set of predefined roles to control who can access what within the account. These roles are currently:

- **Domain admin** (domain level only) - Can assign permissions within a domain and manage its resources.
- **Collection administrator** - a role for users that will need to assign roles to other users in the Microsoft Purview governance portal or manage collections. Collection admins can add users to roles on collections where they're admins. They can also edit collections, their details, and add subcollections. A collection administrator on the root collection also automatically has permission to the Microsoft Purview governance portal. If your **root collection administrator** ever needs to be changed, you can follow the steps in the section below.



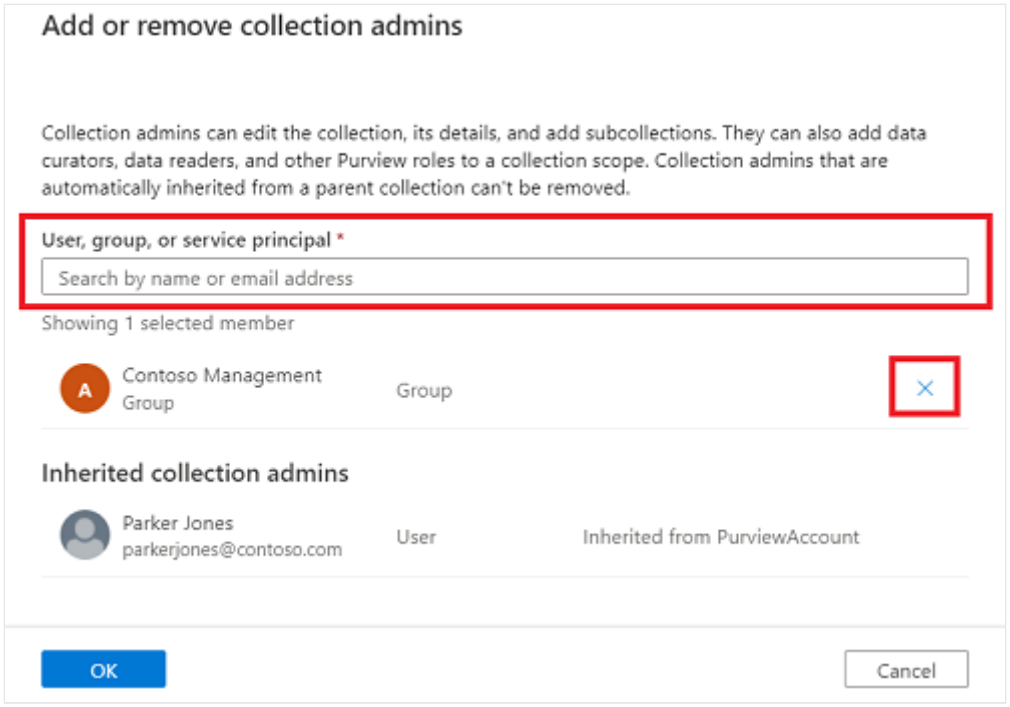
- **Data curators** - a role that provides access to the Microsoft Purview Unified Catalog to manage assets, configure custom classifications, create and manage glossary terms, and view data estate insights. Data curators can create, read, modify, move, and delete assets. They can also apply annotations to assets.
- **Data readers** - a role that provides read-only access to data assets, classifications, classification rules, collections and glossary terms.
- **Data source administrator** - a role that allows a user to manage data sources and scans. If a user is granted only to **Data source admin** role on a given data source, they can run new scans using an existing scan rule. To create new scan rules, the user must be also granted as either **Data reader** or **Data curator** roles.
- **Insights reader** - a role that provides read-only access to insights reports for collections where the insights reader also has at least the **Data reader** role. For more information, see insights permissions.
- **Policy author** - a role that allows a user to view, update, and delete Microsoft Purview policies through the Data policy app within Microsoft Purview.
- **Workflow administrator** - a role that allows a user to access the workflow authoring page in the Microsoft Purview governance portal, and publish workflows on collections where they have access permissions. Workflow administrator only has access to authoring, and so will need at least Data reader permission on a collection to be able to access the Purview governance portal.

> ⓘ **Note**
>
> At this time, Microsoft Purview policy author role is not sufficient to create policies. The Microsoft Purview data source admin role is also required.



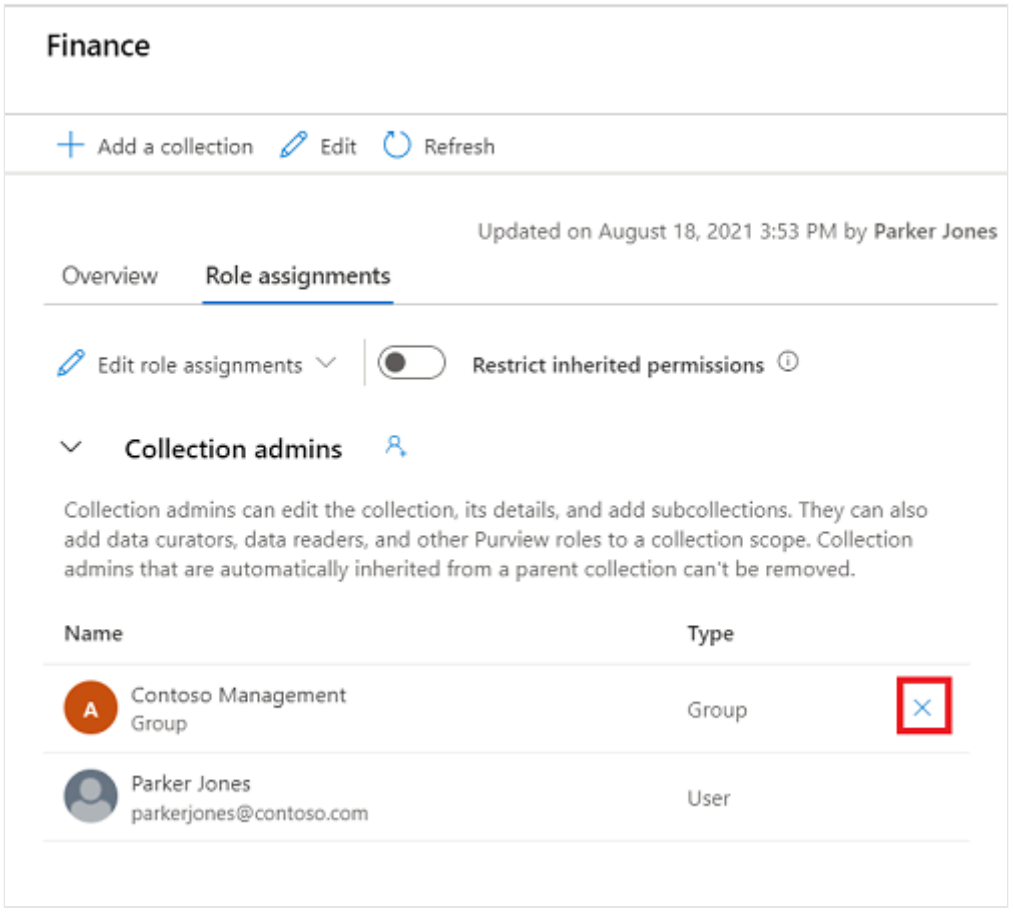
> ⓘ **Important**
>
> The user that created the account is automatically assigned domain admin on the default domain and collection admin on the root collection.

Add role assignments

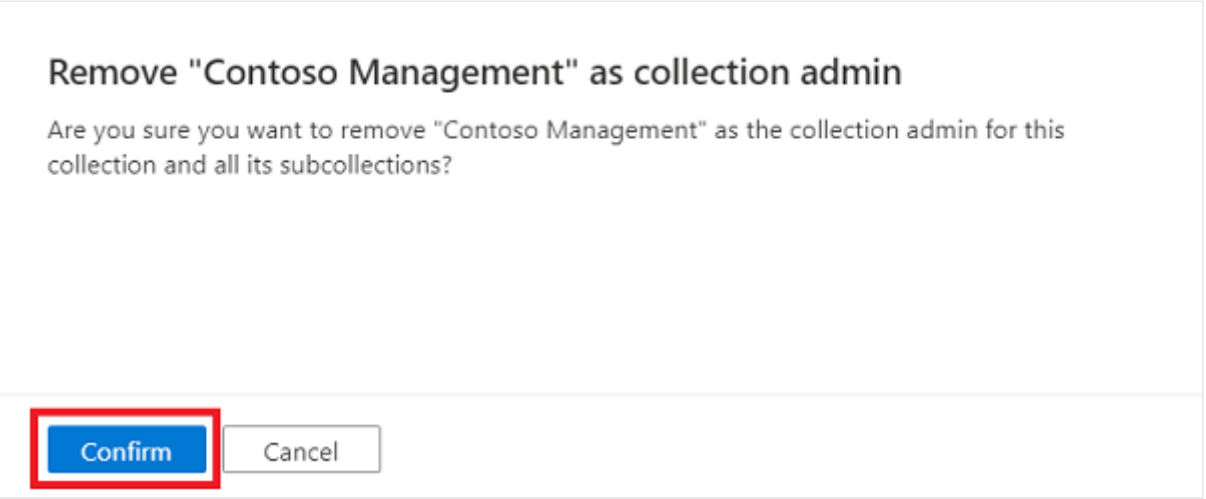


1. Open the Microsoft Purview Data Map.
2. Select the domain or collection where you want to add your role assignment.
3. Select the **Role assignments** tab to see all the roles in a collection or a domain. Only a collection admin or domain admin can manage role assignments.

4. Select **Edit role assignments** or the person icon to edit each role member.



5. Type in the textbox to search for users you want to add to the role member. Select **X** to remove members you don't want to add.



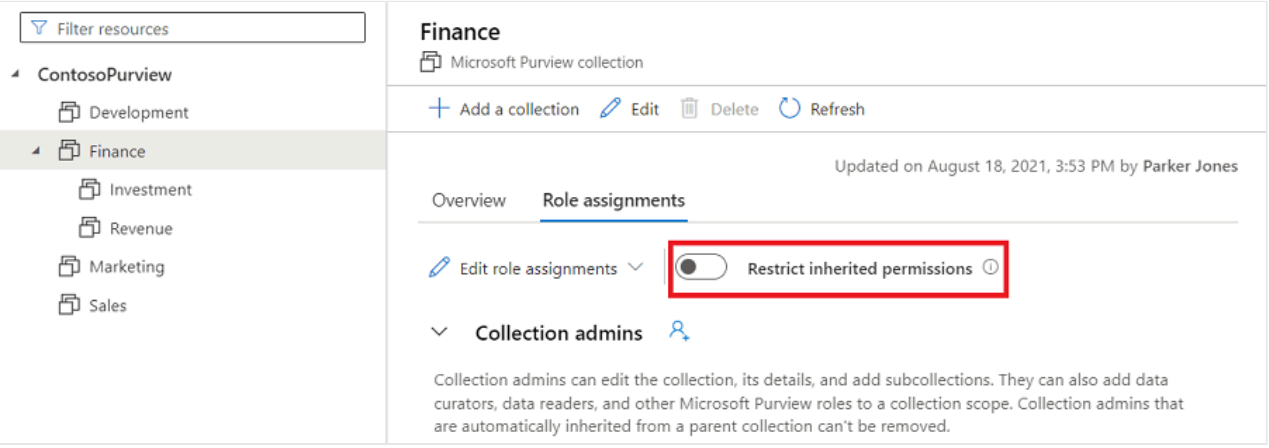
6. Select **OK** to save your changes, and you'll see the new users reflected in the role assignments list.

Remove role assignments

1. Select **X** button next to a user's name to remove a role assignment.

2. Select **Confirm** if you're sure to remove the user.

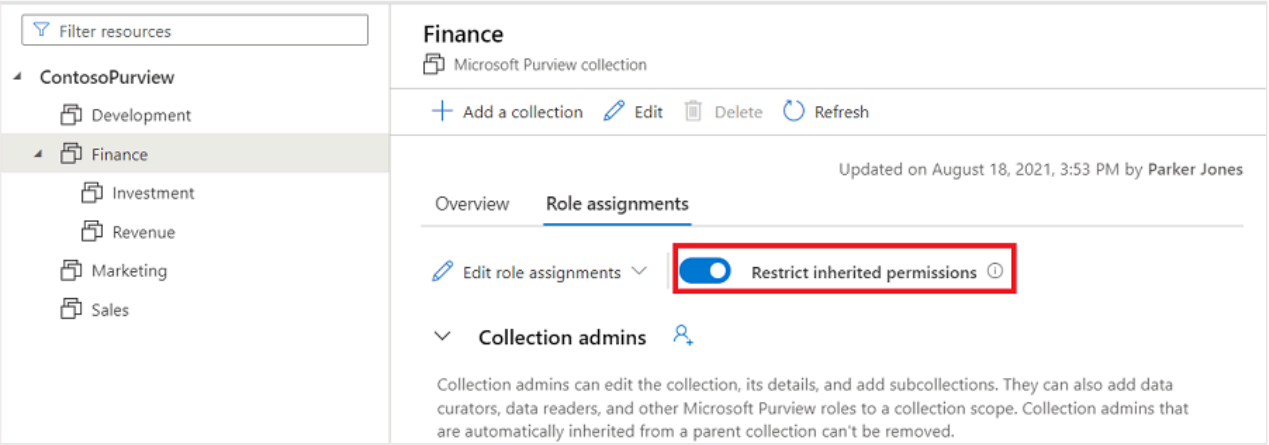
Restrict inheritance



Collection permissions are inherited automatically from the parent collection. You can restrict inheritance from a parent collection at any time, using the restrict inherited permissions option.

> **Note**
>
> Currently permissions from the default domain cannot be restricted. Any permissions assigned at the default domain will be inherited by the domain's direct subcollections.

Once you restrict inheritance, you'll need to add users directly to the restricted collection to grant them access.



1. Navigate to the collection where you want to restrict inheritance and select the **Role assignments** tab.

2. Select **Restrict inherited permissions** and select **Restrict access** in the popup dialog to remove inherited permissions from this collection and any subcollections. Collection admin permissions won't be affected.

3. After restriction, inherited members are removed from the roles expect for collection admin.

4. Select the **Restrict inherited permissions** toggle button again to revert.

> **Tip**
>
> For more detailed information about the roles available in collections see the who should be assigned what roles table or the collections example.

Data access permissions

Data access permissions are permissions users already have on their Azure data sources. These existing permissions also grant permission to access and manage the metadata for those sources, depending on the level of permissions:

- Reader permissions
- Owner permissions

Currently, these features are only available for some Azure sources:

Expand table

Data source	Reader permission
Azure SQL Database	Reader role in Azure
Azure Blob Storage	Reader role in Azure
Azure Data Lake Storage Gen2	Reader role in Azure
Azure Subscription	Read permission on subscription

The reader role contains enough permissions, but if you're building a custom role, your users need to have these actions included:

Expand table

Data source	Reader permission
Azure SQL Database	"Microsoft.Sql/servers/read", "Microsoft.Sql/servers/databases/read", "Microsoft.Sql/servers/databases/schemas/read", "Microsoft.Sql/servers/databases/schemas/tables/read", "Microsoft.Sql/servers/databases/schemas/tables/columns/read"
Azure Blob Storage	"Microsoft.Storage/storageAccounts/read", "Microsoft.Storage/storageAccounts/blobServices/read", "Microsoft.Storage/storageAccounts/blobServices/containers/read"
Azure Data Lake Storage Gen2	"Microsoft.Storage/storageAccounts/read", "Microsoft.Storage/storageAccounts/blobServices/read", "Microsoft.Storage/storageAccounts/blobServices/containers/read"
Azure Subscription	"Microsoft.Resources/subscriptions/resourceGroups/read"

Reader permissions

Users who have at least the reader role on available Azure resources are also able to access those resources metadata in the free and enterprise account types.

Users can search and browse for assets from these sources in the classic Data Catalog and view their metadata.

These are the permissions needed on the resources for users to be considered readers:

Expand table

Data source	Reader permission
Azure SQL Database	Reader role in Azure
Azure Blob Storage	Reader role in Azure
Azure Data Lake Storage Gen2	Reader role in Azure
Azure Subscription	Read permission on subscription

Owner permissions

Users who have the owner role or write permissions on available Azure resources can access and edit metadata for those resources in free and enterprise account types.

Owning users can search and browse for assets from these sources in the catalog and view metadata. Users can also update and manage the metadata for those resources. Learn more about metadata curation.

These are the permissions needed on the resources for users to be considered owners:

Expand table

Data source	Owner permission
Azure SQL Database	"Microsoft.Sql/servers/write", "Microsoft.Sql/servers/databases/write", "Microsoft.Authorization/roleAssignments/write"
Azure Blob Storage	"Microsoft.Storage/storageAccounts/write", "Microsoft.Authorization/roleAssignments/write"
Azure Data Lake Storage Gen2	"Microsoft.Storage/storageAccounts/write", "Microsoft.Authorization/roleAssignments/write"

Permissions in the free version

All users are able to view data assets for available sources where they have at least **Read** permissions already. Owning users are able to manage the metadata for available assets where they have at least **Owner/Write** permissions already. For more information, see the data access permissions section.

Extra permissions can also be assigned using tenant level role groups.

> **Important**
>
> For users newly created in Microsoft Entra ID, it may take some time for permissions to propagate even after correct permissions have been applied.

Permissions in enterprise version of Microsoft Purview

All users are able to view data assets for available sources where they have at least **Read** permissions already. Owning users are able to manage the metadata for assets where they

have at least **Owner/Write** permissions already. For more information, see the data access permissions section.

Extra permissions can also be assigned using tenant level role groups.

Permissions can also be assigned in the Microsoft Purview Data Map so users can browse assets in the Data Map or classic Data Catalog search that they don't already have data access to.

Azure Storage in-place data sharing with Microsoft Purview (preview)

Article • 01/28/2025

> **Note**
>
> Microsoft Purview Data Map (classic), Data Catalog (classic), Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently being retired, with support provided until September 2025 to allow for migration to Microsoft Fabric external data sharing.

Traditionally, organizations have shared data with internal teams or external partners by generating data feeds, requiring investment in data copy and refresh pipelines. The result is higher cost for data storage and movement, data proliferation (that is, multiple copies of data), and delay in access to time-sensitive data.

With Microsoft Purview Data Sharing, data providers can now share data **in-place** from Azure Data Lake Storage Gen2 and Azure Storage accounts, both within and across organizations. Share data directly with users and partners without data duplication and centrally manage your sharing activities from within Microsoft Purview.

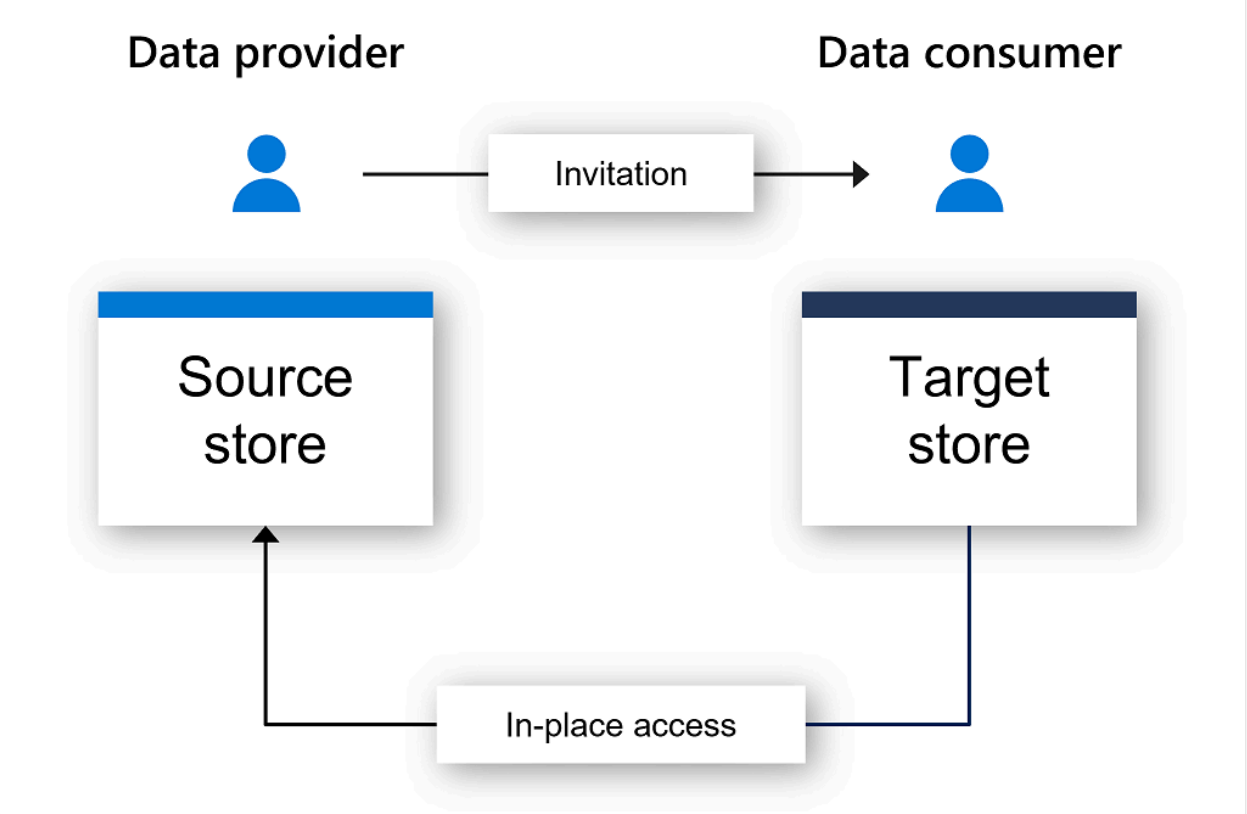
With Microsoft Purview Data Sharing, data consumers can now have near real-time access to shared data. Storage data access and transactions are charged to the data consumers based on what they use, and at no more cost to the data providers.

Get started

Get started with Microsoft Purview in-place data sharing for Azure Storage by reviewing the next steps or following the Data Sharing Quickstart.

> **Important**

Data sharing is accessed through the classic Microsoft Purview governance portal: https://web.purview.azure.com



Available sources

Expand table

Supported data store	Data Sharing
Azure Blob Storage	Yes
Azure Data Lake Storage Gen2	Yes

How in-place data sharing works

Microsoft Purview enables sharing of files and folders in-place from ADLS Gen2 and Blob storage accounts.

A data provider creates a share by selecting a data source that is registered in Microsoft Purview, choosing which files and folders to share, and who to share them with. Microsoft Purview then sends an invitation to each data consumer.

When a consumer accepts the invitation, they specify a target storage account in their own Azure subscription that they'll use to access the shared data. This establishes a

sharing relationship between the provider and consumer storage accounts. This sharing relationship provides data consumer read-only access to shared data through the consumer's storage account. Any changes to the data in the provider's source storage account is reflected in near real-time in the consumer's storage account.

The data provider pays for data storage and their own data access, while the data consumer pays for their own data access transactions.

Data providers can revoke access to the shared data at any time, or set a share expiration time for time-bound access to data. Data consumers can also terminate access to the share at any time.

Where data is stored

Microsoft Purview Data Sharing only stores metadata about your share. It doesn't store a copy of the shared data itself. The data is stored in the underlying source storage account that is being shared. You can have your storage accounts in a different Azure region than your Microsoft Purview account.

Key capabilities

- Share data within the organization or with partners and customers outside of the organization (within the same Azure tenant or across different Azure tenants).
- Share data from ADLS Gen2 or Blob storage in-place without data duplication.
- Share data with multiple recipients.
- Access shared data in near real time.
- Manage sharing relationships and keep track of who the data is shared with/from, for each ADLSGen2 or Blob Storage account.
- Terminate share access at any time.
- Flexible experience through Microsoft Purview governance portal or via REST APIs.

Data sharing scenarios

Microsoft Purview Data Sharing can help with various data sharing scenarios, including:

- Collaborate with external business partners while maintaining data security in your own environment.
- Outsource data transformation and processing to third party ISVs or data aggregators by sharing raw data and receiving normalized data and analytics results back.

- Automate sharing of big data (for example: IoT data, scientific data, satellite and surveillance images or videos, financial market data) in near real time and without data duplication.
- Share data between different departments within the organization.

Support

If you have any questions, please reach out to your account manager or customer support. If you have a support plan and you need technical help, create a support request.

1. For **Issue type**, select *Technical*.
2. For **Subscription**, select your subscription.
3. For **Service**, select *My services*, then select *Service type*.
4. Select the Microsoft Purview resource that you are creating a support request for.
5. For **Summary**, type a description of your issue or question.
6. For **Problem type**, select *Data Share*.
7. For **Problem subtype**, select appropriately.

Share Azure Storage data in-place with Microsoft Purview Data Sharing (preview)

Article • 01/28/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently being retired, with support provided until September 2025 to allow for migration to Microsoft Fabric external data sharing.

Microsoft Purview Data Sharing supports in-place data sharing from Azure Data Lake Storage (ADLS Gen2) to ADLS Gen2, and Blob storage account to Blob storage account. This article explains how to share data using Microsoft Purview.

Prerequisites to share data

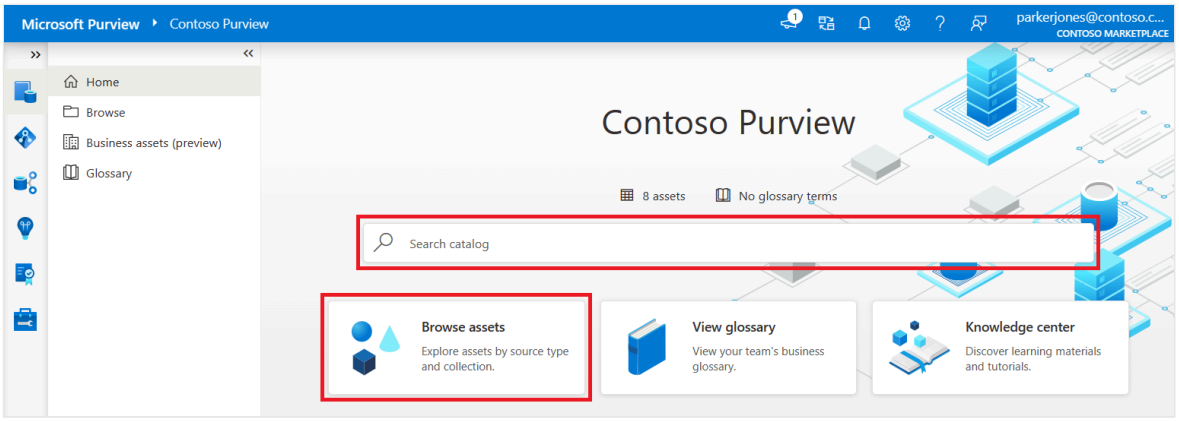
Microsoft Purview prerequisites

- A Microsoft Purview account.
- A minimum of Data Reader role is needed on a Microsoft Purview collection to use data sharing in the governance portal. Refer to Microsoft Purview permissions to learn more about the Microsoft Purview collection and roles.
- To use the SDK, no Microsoft Purview permissions are needed.
- Your data recipient's Azure sign-in email address, or the object ID and tenant ID of the recipient application, that you'll use to send the invitation to receive a share. The recipient's email alias won't work.

Azure Storage account prerequisites

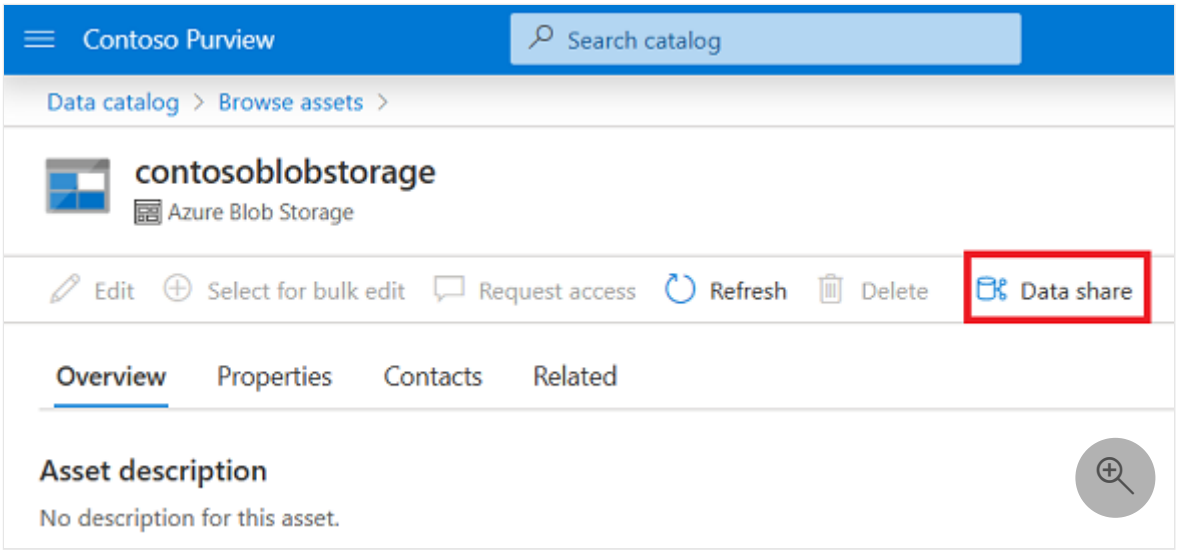
- Your Azure subscription must be registered for the **AllowDataSharing** preview feature. (If you haven't already registered this preview feature, consider using Microsoft Fabric external data sharing instead, since Microsoft Purview Data Sharing will be retired in September 2025.) Or, contact support.
- A source storage account **created after the registration step is completed**. Source storage account can be in a different Azure region from your Microsoft Purview account, but needs to follow the available configurations.
- You need the **Owner** or **Storage Blob Data Owner** role on the source storage account to be able to share data. You can find more details on the ADLS Gen2 or Blob storage data source page.
- If the source storage account is in a different Azure subscription than the one for Microsoft Purview account, the Microsoft. Purview resource provider needs to be registered in the Azure subscription where the Storage account is located. It's automatically registered at the time of share provider adding an asset if the user has permission to do the `/register/action` operation and therefore, Contributor or Owner roles to the subscription where the Storage account is located. This registration is only needed the first time when sharing or receiving data into a storage account in the Azure subscription.
- A storage account needs to be registered in the collection to create a share using the Microsoft Purview portal experience. For instructions to register, see the ADLS Gen2 or Blob storage data source pages. This step isn't required to use the SDK.

Create a share



There are two ways you can create a data share:

- Directly from the data asset
- Use the data sharing application



Create share from asset

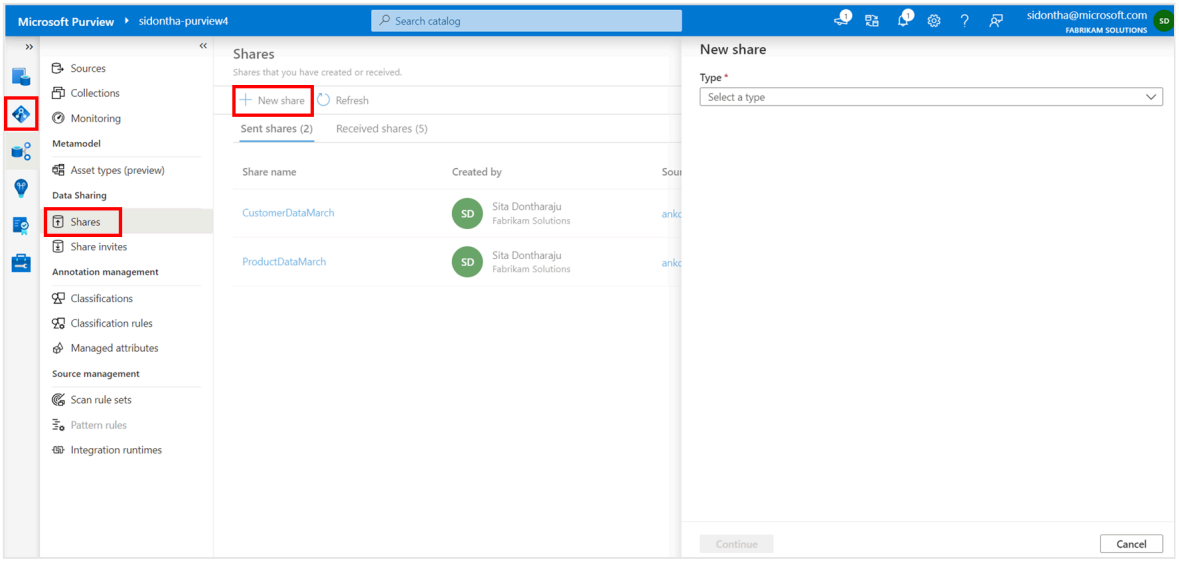
1. You can create a share by starting from **Data Catalog**

   Within the classic Microsoft Purview governance portal or the new Microsoft Purview portal, find the Azure Storage or Azure Data Lake Storage (ADLS) Gen 2 data asset you would like to share data from using either the data catalog search or browse.

2. Once you have found your data asset, select the **Data Share** button.

3. Select **+New Share**.

4. Follow the rest of the steps to create your data share.



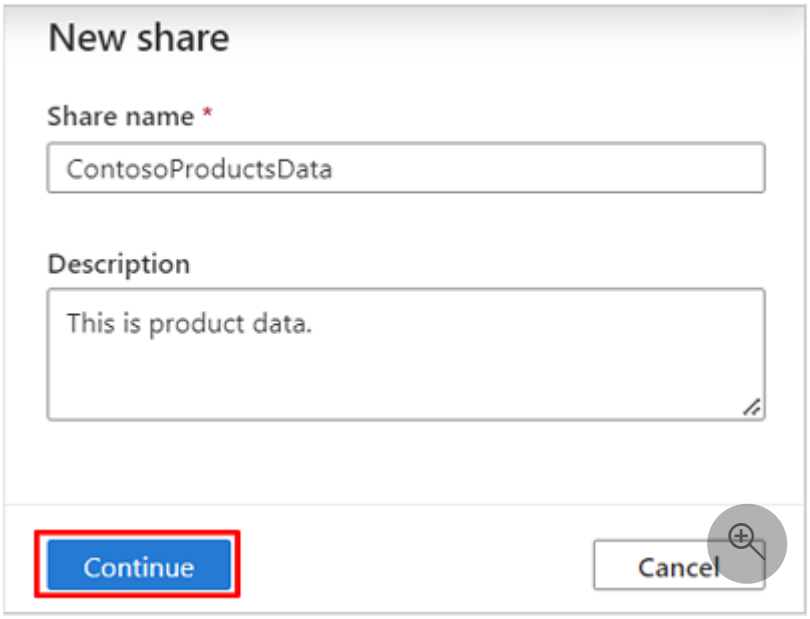
Create share from application

1. If you're using the new Microsoft Purview experience You can create a share by starting from the **Data Catalog**.

   Open the Microsoft Purview portal. Navigate to the **Data Catalog** application. Then select **Shares**. Select **+New Share**.

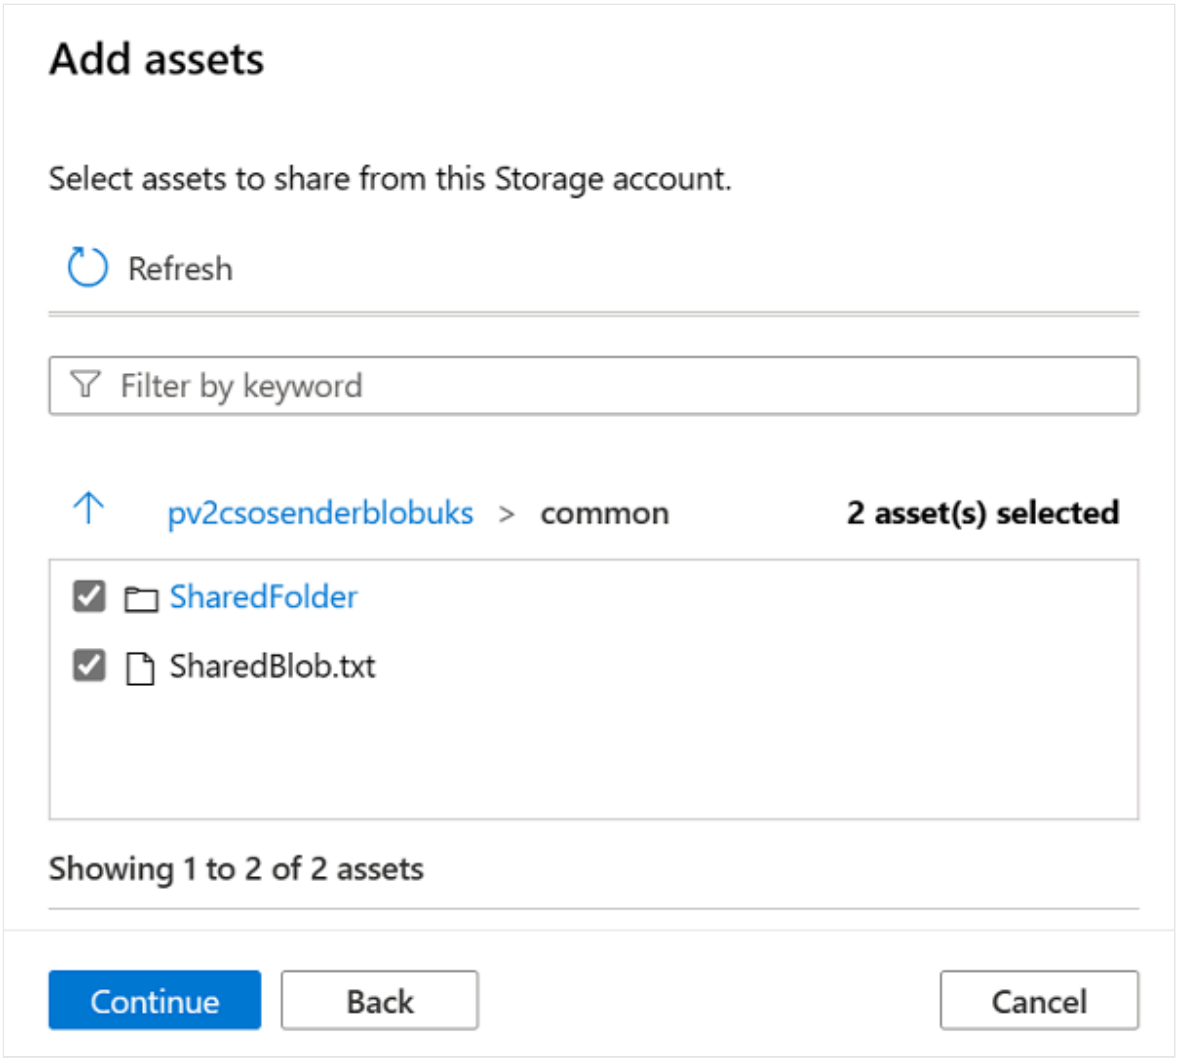
2. If you're using the classic Microsoft Purview experience You can create a share by starting from the **Data Map**.

   Open the Microsoft Purview governance portal. Select the **Data Map** icon from the left navigation. Then select **Shares**. Select **+New Share**.



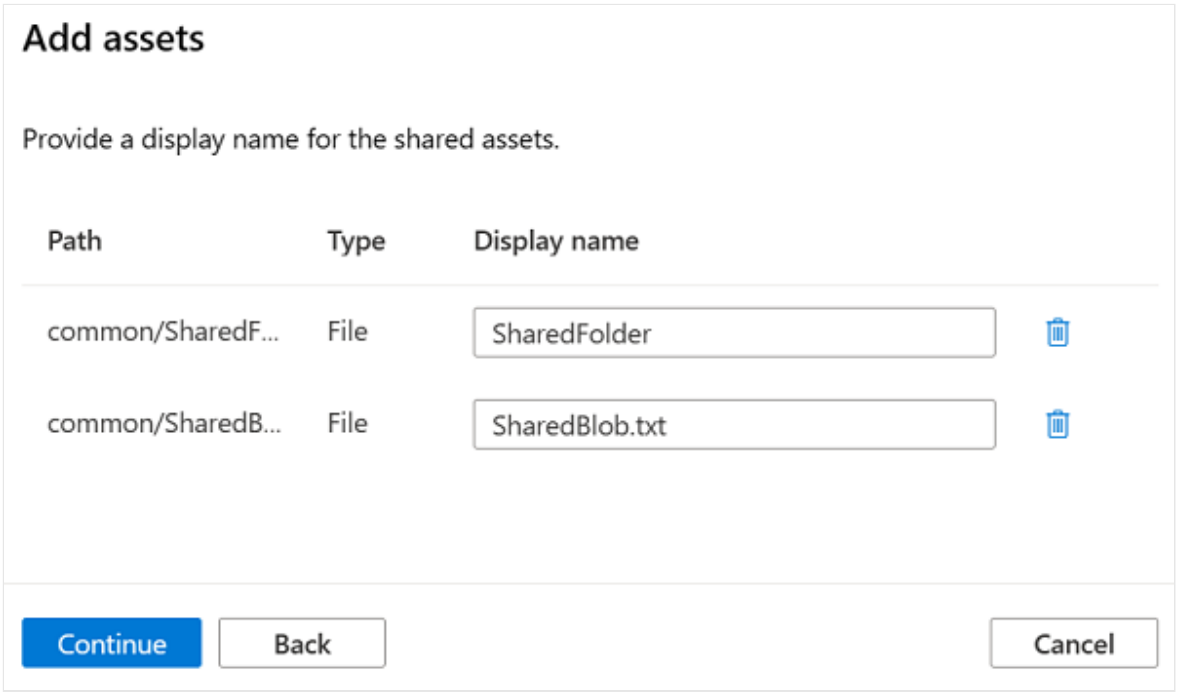
3. From either location, select the Storage account type and the Storage account you want to share data from. Then select **Continue**.

4. Follow the rest of the steps to create your data share.



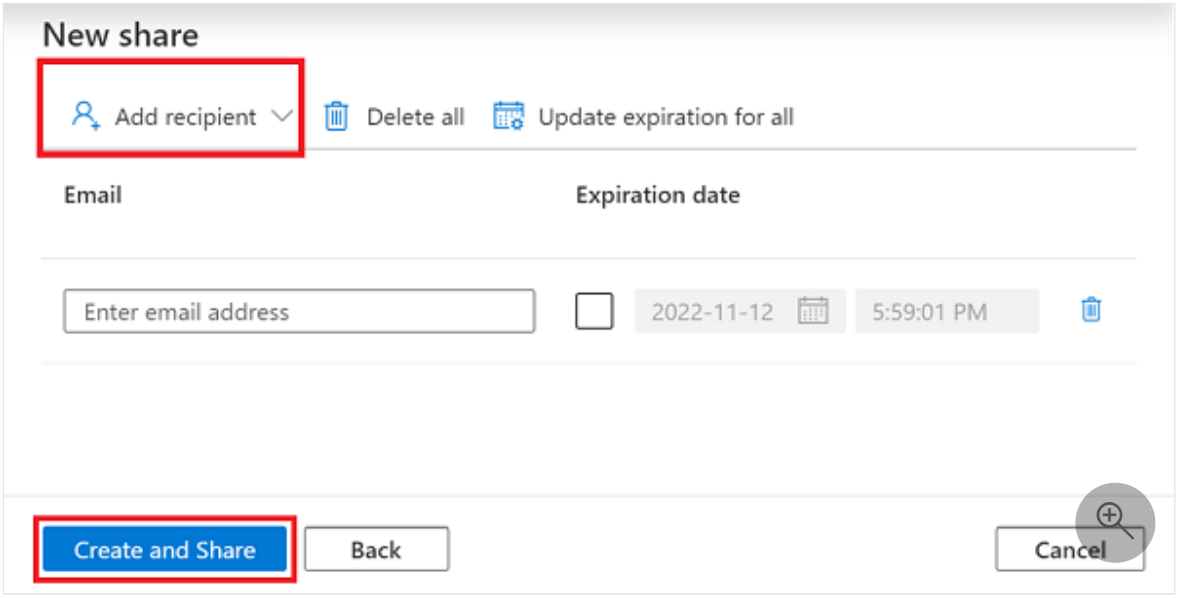
Create share

1. Specify a name and a description of share contents (optional). Then select **Continue**.

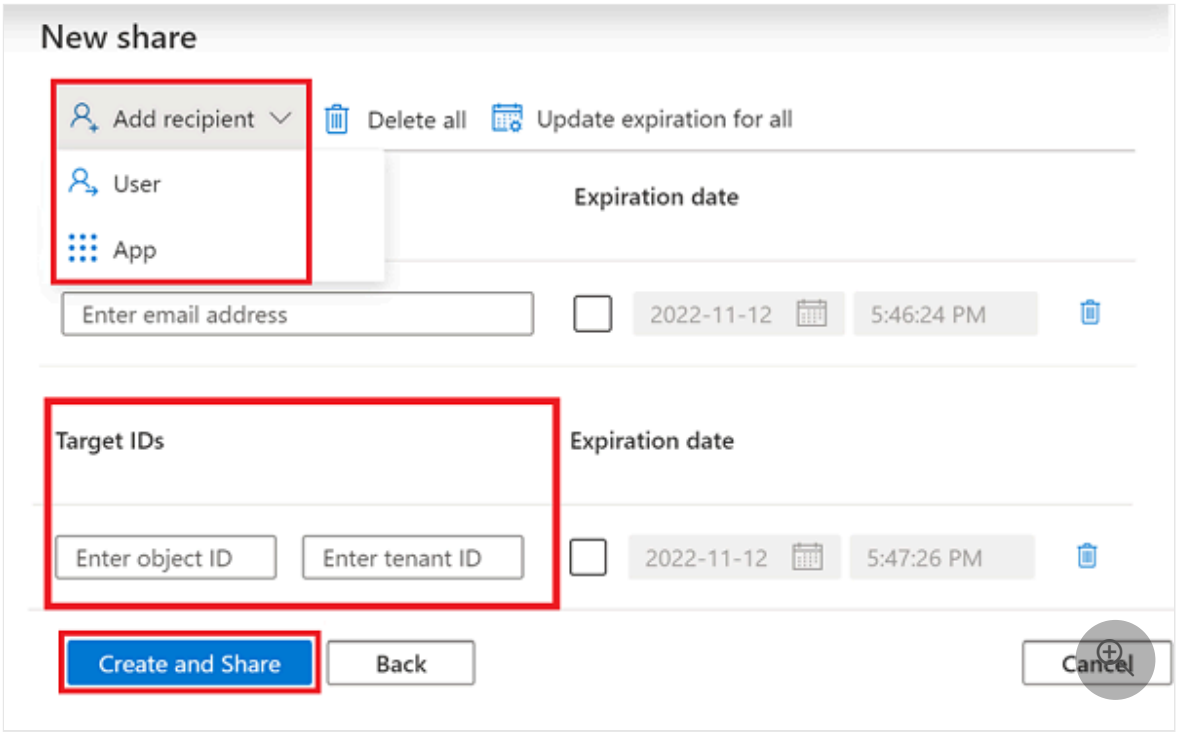


2. Search for and add all the assets you'd like to share out at the container, folder, and file level, and then select **Continue**.

> **Important**
>
> Only containers, files, and folders that belong to the current Blob or ADLSGen2 Storage account can be added to the share.



3. You can edit the display names the shared data will have, if you like. Then select **Continue**.



4. Select **Add Recipient** and select **User** or **App**.

To share data to a user, select **User**, then enter the Azure sign-in email address of who you want to share data with. By default, the option to enter email address of user is shown.

To to share data with a service principal, select **App**. Enter the object ID and tenant ID of the recipient you want to share data with.

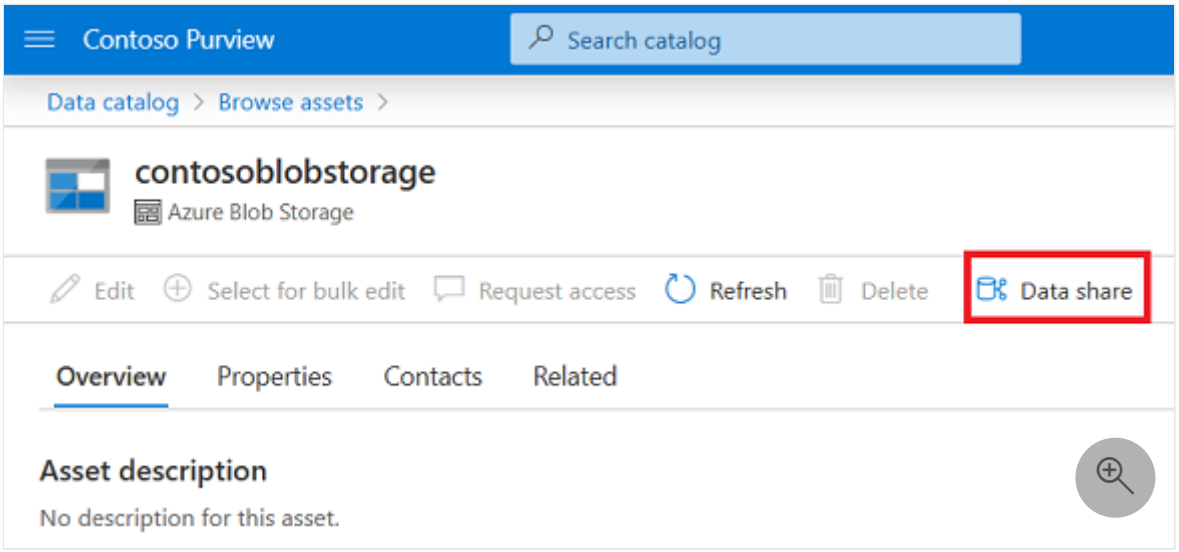
5. Select **Create and Share**. Optionally, you can specify an **Expiration date** for when to terminate the share. You can share the same data with multiple recipients by selecting **Add Recipient** multiple times.

You've now created your share. The recipients of your share will receive an invitation and they can view the share invitation in their Microsoft Purview account.

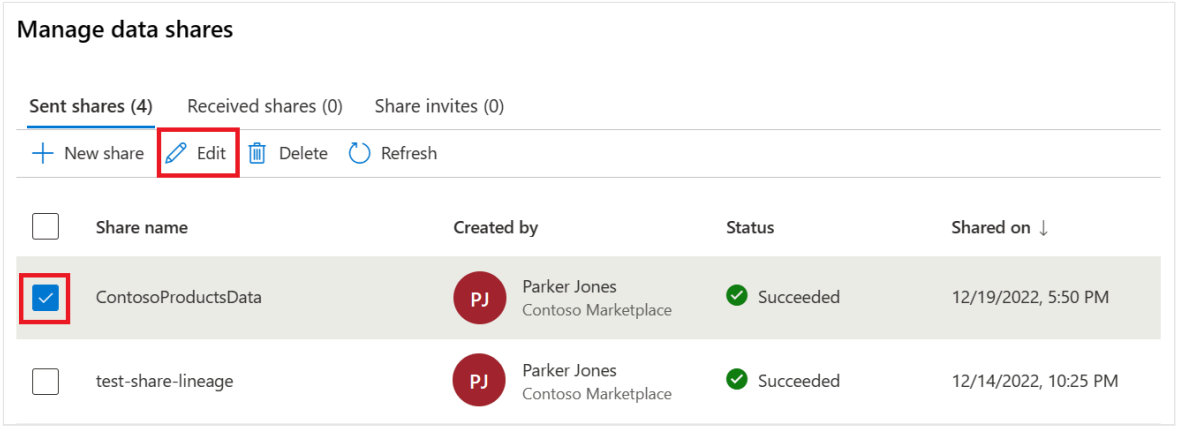
When a share is created, a new asset of type sent share is ingested into the Microsoft Purview catalog, in the same collection as the storage account from which you created the share. You can search for it like any other asset in the data catalog.

You can also track lineage for data shared using Microsoft Purview. See, Microsoft Purview Data Sharing lineage to learn more about share assets and data sharing lineage.

> ⓘ **Note**
>
> Shares created using the SDK without registering the storage account with Microsoft Purview will not be ingested into the catalog. User can register their storage account if desired. If a storage account is un-registered or re-registered to a different collection, share assets of that storage account continue to be in the initial collection.

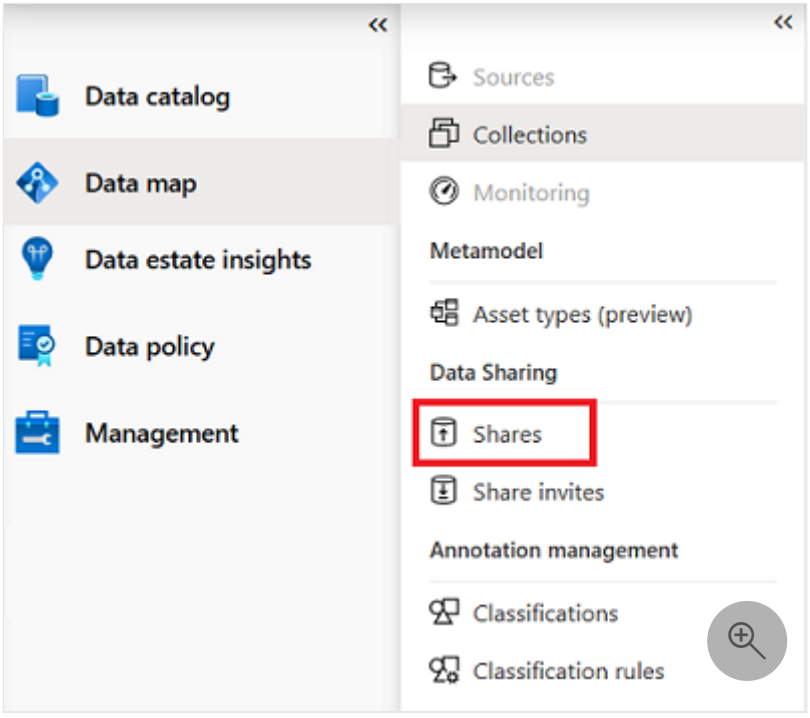


Update a sent share



Once a share is created, you can update description, assets, and recipients.

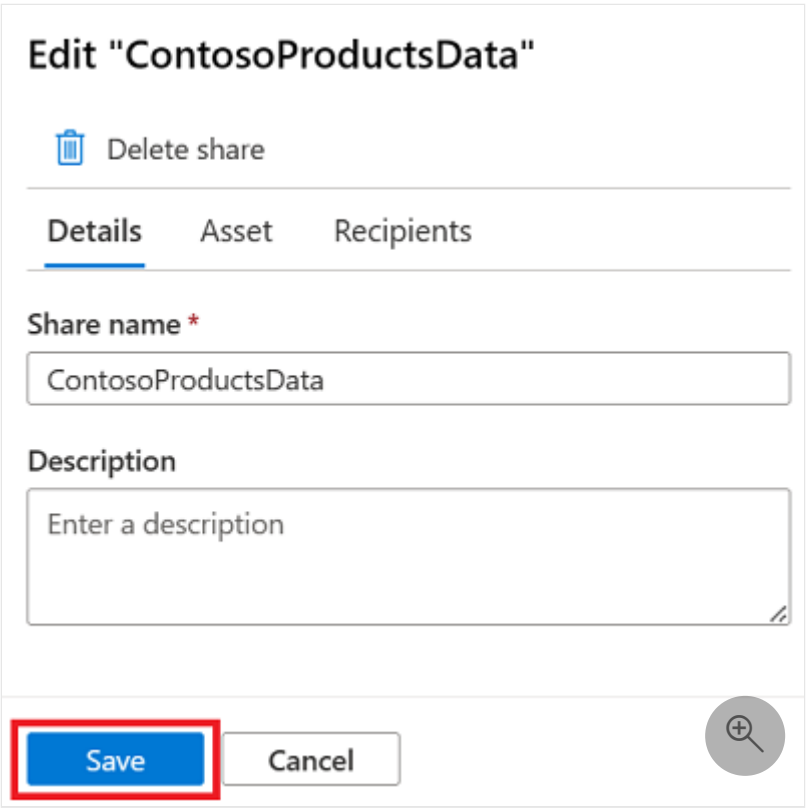
> ⓘ **Note**
>
> If you only have the **Reader** role on the source storage account, you will be able to view list of sent shares and received shares but not edit. You can find more details on the ADLS Gen2 or Blob storage data source page.



You can find your sent shares one of two ways:

- Access the blob storage or ADLS Gen2 asset where the data was shared from in the data catalog. Open it, then select **Data Share**. There you're able to see all the shares for that asset. Select a share, and then select the **Edit** option.

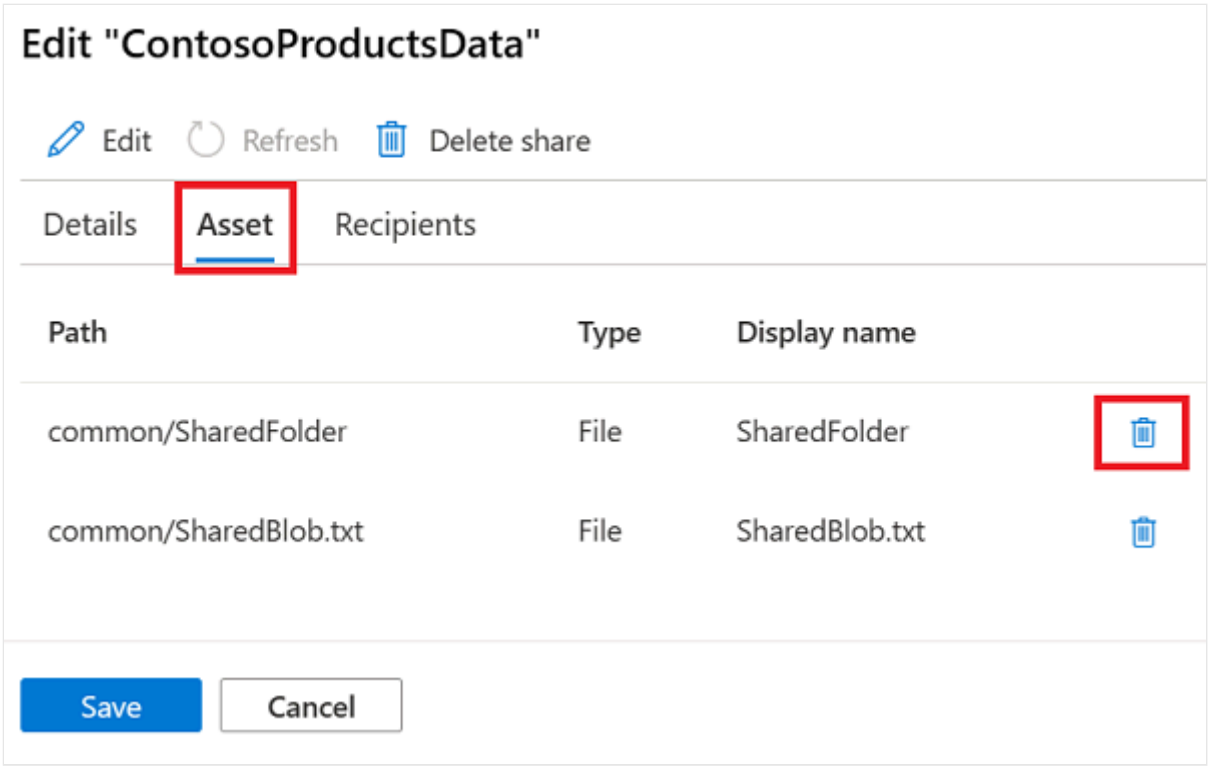
- For shares that you sent, in the classic Microsoft Purview governance portal you can find them in the **Shares** menu in the Microsoft Purview Data Map. In the new Microsoft Purview portal you can find them in the **Data Catalog** application in the **Shares** menu. There you're able to see all the shares you have sent. Select a share, and then select the **Edit** option.



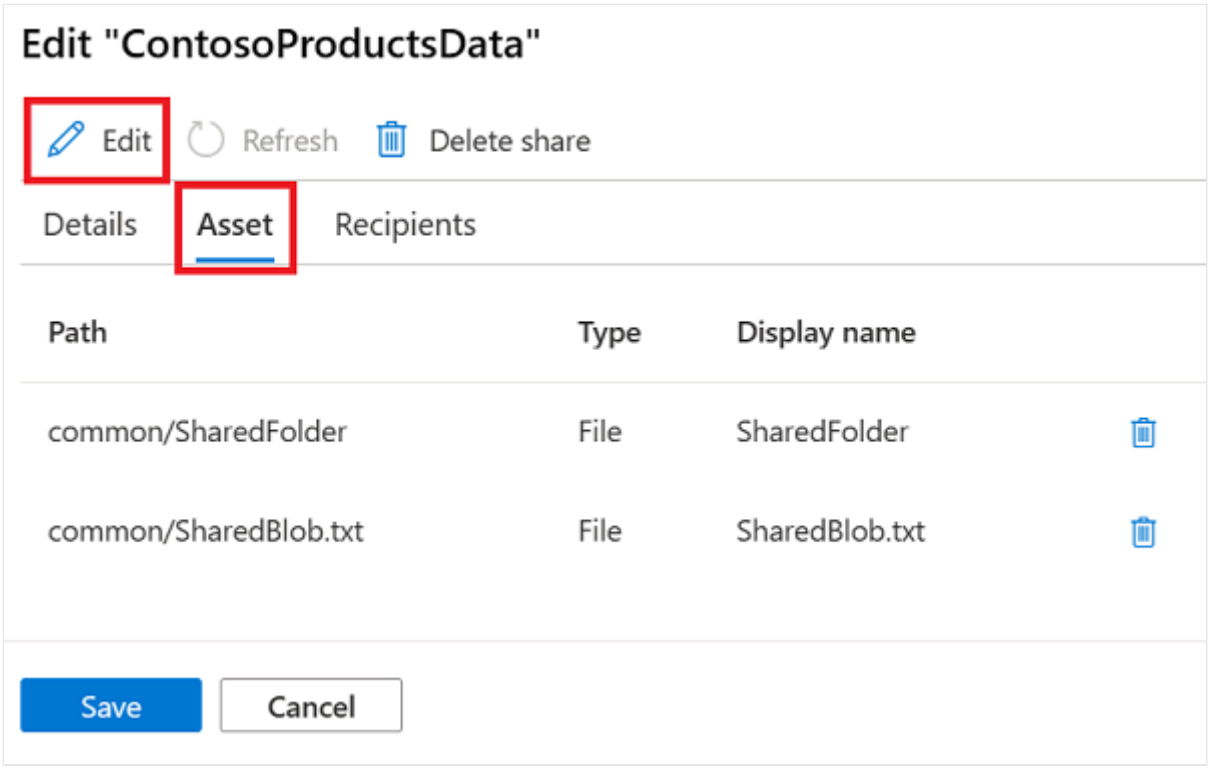
From any of these places you can:

- Edit share details
- Edit shared assets
- Edit share recipients
- Delete your share

Edit details



On the **Details** tab of the edit share page, you can update the share name and description. Save any changes by selecting **Save**.



Edit assets

On the **Asset** tab of the edit share page you can see all the shared files and folders.

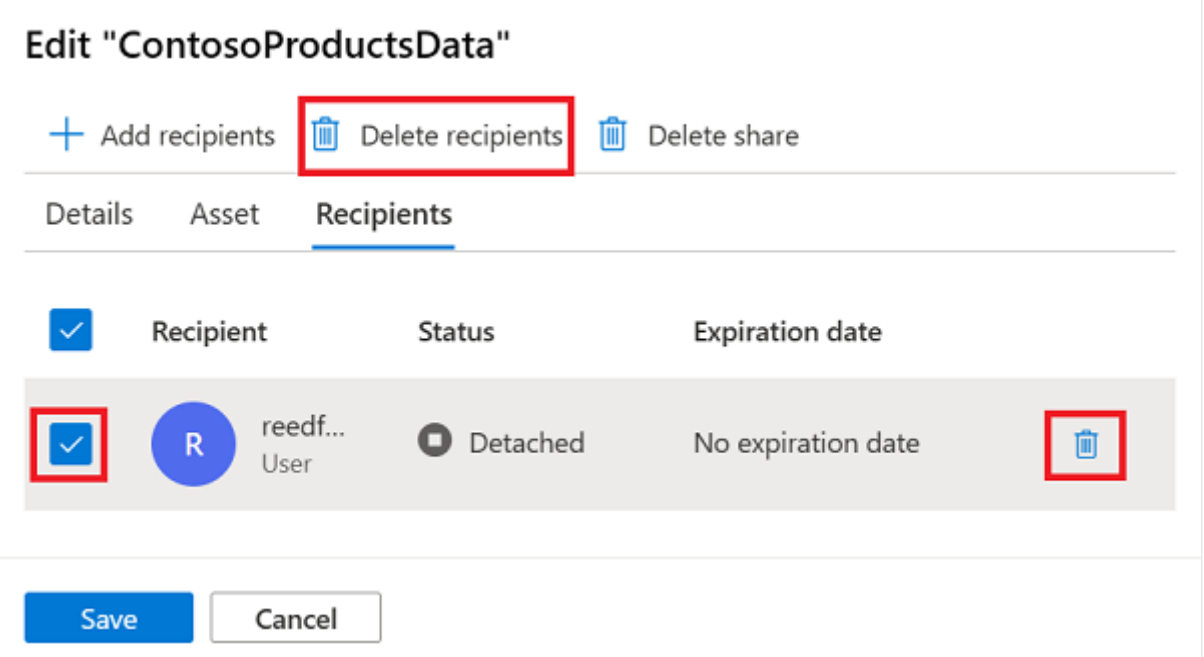
You can **remove** any containers, files, or folders from the share by selecting the delete button in the asset's row however you can't remove all the assets of a sent share.

You can **add new assets** by selecting the **Edit** button and then searching for and selecting any other containers, files, and folders in the asset that you would like to add.

Once you've selected your assets, select **Add**, and you'll see your new asset in the Asset tab.

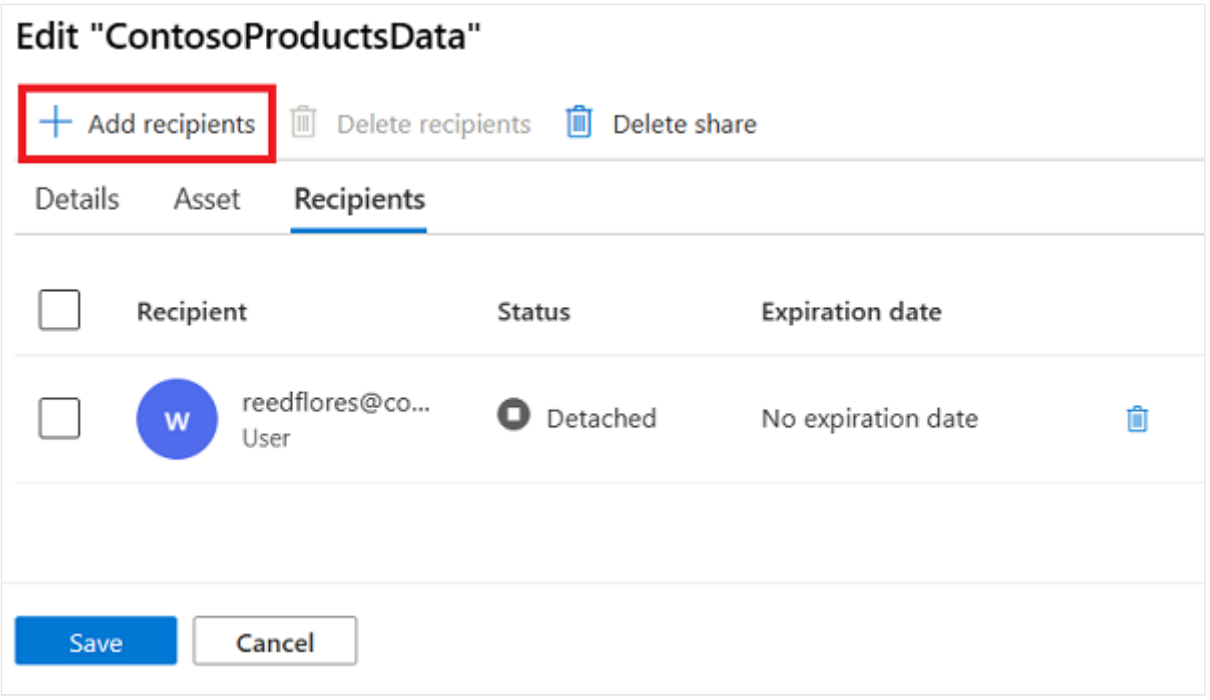
Save all your changes by selecting the **Save** button.

Edit recipients



On the **Recipients** tab of the edit share page you can see all the users and groups that are receiving your shares, their status, and the expiration date for their share.

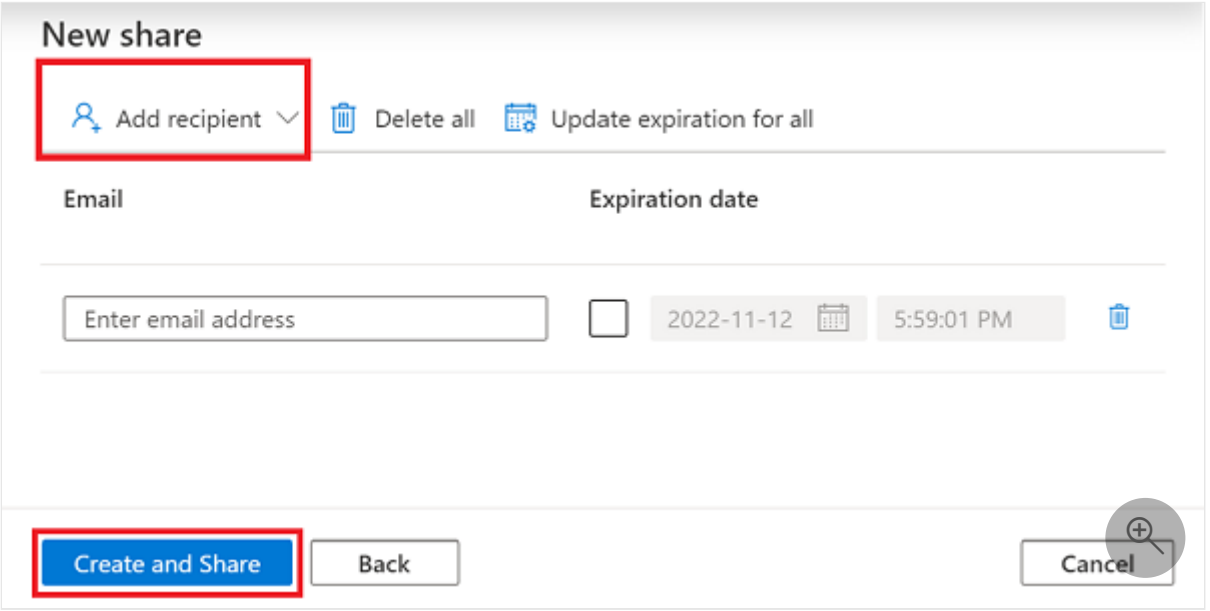
Here are what each of the recipient statuses mean:



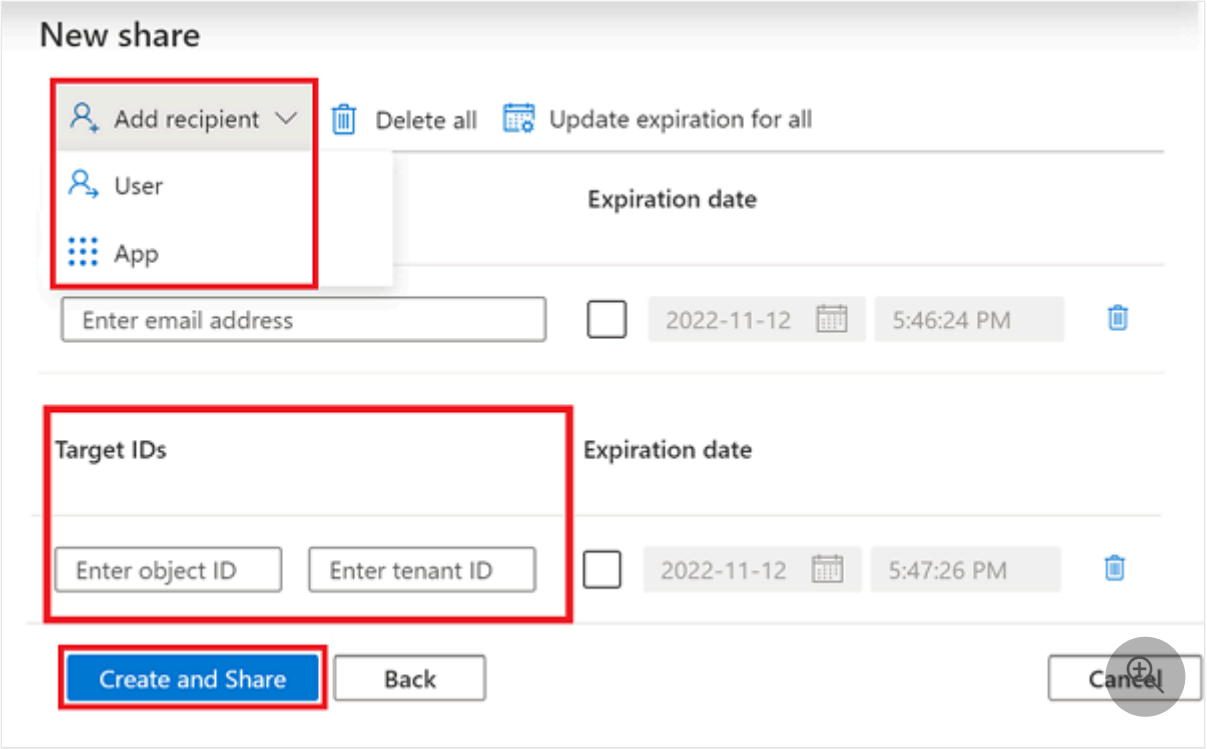
Expand table

Status	Meaning
Attached	The share has been accepted and the recipient has access to the shared data.
Detached	The recipient hasn't accepted the invitation or is no longer active. They aren't receiving the share.

You can **remove or delete recipients** by either selecting the delete button on the recipient's row, or selecting multiple recipients and then selecting the **Delete recipients** button at the top of the page.



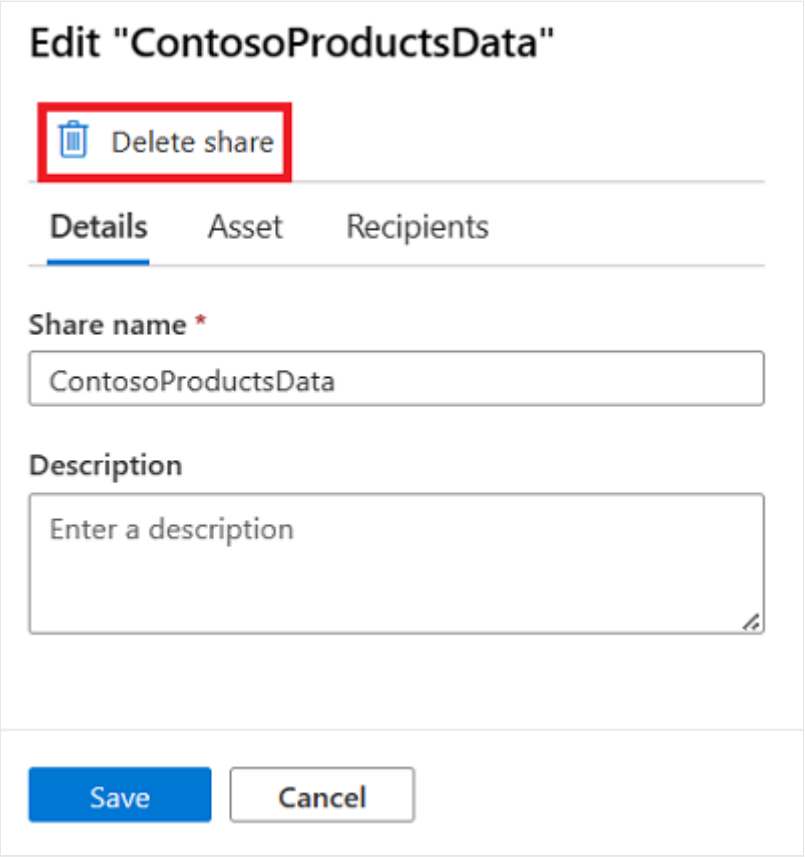
You can **add recipients** by selecting the **Add recipients** button.



Select **Add Recipient** again and select **User** or **App**.

To share data to a user, select **User**, then enter the Azure sign-in email address of who you want to share data with. By default, the option to enter email address of user is shown.

To to share data with a service principal, select **App**. Enter the object ID and tenant ID of the recipient you want to share data with.



Optionally, you can specify an **Expiration date** for when to terminate the share. You can share the same data with multiple recipients by clicking on **Add Recipient** multiple times.

When you're finished, select the **Add recipients** confirmation button at the bottom of the page.

Save all your changes by selecting the **Save** button.

Delete share

To delete your share, on any tab in the edit share page, select the **Delete share** button.

Confirm that you would like to delete in the pop-up window and the share will be removed.

Troubleshoot

Here are some common issues for sharing data and how to troubleshoot.

Can't create Microsoft Purview account

If you're getting an error related to *quota* when creating a Microsoft Purview account, it means your organization has exceeded Microsoft Purview service limit. If you require an increase in limit, contact support.

Can't find my Storage account asset in the Catalog

There are a couple possible reasons:

- The data source isn't registered in Microsoft Purview. Refer to the registration steps for Blob Storage and ADLSGen2 respectively. Performing a scan isn't necessary.
- Data source is registered to a Microsoft Purview collection that you don't have a minimum of Data Reader permission to. Refer to Microsoft Purview catalog permissions and reach out to your collection admin for access.

Can't create shares or edit shares

- You don't have permission to the data store where you want to share data from. Check the prerequisites for required data store permissions.

Can't view list of shares in the storage account asset

- You don't have enough permissions the data store that you want to see shares of. You need a minimum of **Reader** role on the source storage account to see a read-only view of sent shares and received shares. You can find more details on the ADLS Gen2 or Blob storage data source page.
- Review storage account prerequisites and make sure your storage account region, performance, and redundancy options are all supported.

Receive Azure Storage in-place share with Microsoft Purview Data Sharing (preview)

Article • 10/28/2024

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently being retired, with support provided until September 2025 to allow for migration to Microsoft Fabric external data sharing.

Microsoft Purview Data Sharing supports in-place data sharing from Azure Data Lake Storage (ADLS Gen2) to ADLS Gen2, and Blob storage account to Blob storage account. This article explains how to receive a share and access shared data.

Prerequisites to receive shared data

Microsoft Purview prerequisites

- A Microsoft Purview account.
- A minimum of Data Reader role on a Microsoft Purview collection to use data sharing user experience in the Microsoft Purview governance portal. Refer to Microsoft Purview permissions to learn more about the Microsoft Purview collection and roles.
- To use the SDK, no Microsoft Purview permission is needed.

Azure Storage account prerequisites

- Your Azure subscription must be registered for the **AllowDataSharing** preview feature. Follow the below steps using Azure portal or PowerShell.

Portal

1. In the Azure portal, select the Azure subscription that you use to create the source and target storage account.
2. From the left menu, select **Preview features** under *Settings*.
3. Select **AllowDataSharing** and *Register*.
4. Refresh the *Preview features* screen to verify the *State* is **Registered**. It could take 15 minutes to 1 hour for registration to complete.
5. In addition, to use data share for storage accounts in East US, East US2, North Europe, South central US, West Central US, West Europe, West US, West US2, West US3: Select AllowDataSharingInHeroRegion and Register

For more information, see the register preview feature article.

The *RegistrationState* should be **Registered**. It could take 15 minutes to 1 hour for registration to complete. For more information, see the register preview feature article.

> **Note**
>
> The following are supported storage account configurations:
> - Azure regions: Canada Central, Canada East, UK South, UK West, Australia East, Japan East, Korea South, and South Africa North
> - Additional Azure Regions: East US, East US2, North Europe, Southcentral US, West Central US, West Europe, West US, West US2, West US3
> - Performance: Standard
> - Redundancy options: LRS

- A target storage account **created after** the registration step is completed. **The target storage account must be in the same Azure region as the source storage account.** If you don't know the Azure region of the source storage account, you can find out during the share attaching step later in the process. Target storage account can be in a different Azure region from your Microsoft Purview account.

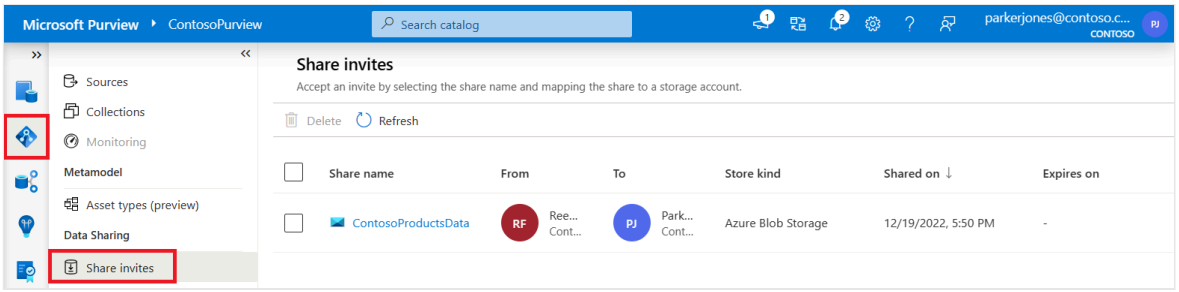
> **Important**
>
> The target storage account must be in the same Azure region as the source storage account.

- You need the **Contributor** or **Owner** or **Storage Blob Data Owner** or **Storage Blob Data Contributor** role on the target storage account. You can find more details on the ADLS Gen2 or Blob storage data source pages.

- If the target storage account is in a different Azure subscription than the one for Microsoft Purview account, the `Microsoft.Purview` resource provider needs to be registered in the Azure subscription where the Storage account is located. It's automatically registered at the time of share consumer attaching the share and if the user has permission to do the `/register/action` operation and therefore, Contributor or Owner roles to the subscription where the Storage account is located. This registration is only needed the first time when sharing or receiving data into a storage account in the Azure subscription.

- A storage account needs to be registered in the collection where you receive the share. For instructions to register, see the ADLS Gen2 or Blob storage data source pages. This step isn't required to use the SDK.

- Latest version of the storage SDK, PowerShell, CLI, and Azure Storage Explorer. Storage REST API version must be February 2020 or later.



Receive share

1. You can view your share invitations in any Microsoft Purview account. Open the Microsoft Purview governance portal by browsing directly to the classic portal or the new Microsoft Purview portal and selecting your Microsoft Purview account.

2. In the classic portal, select the **Data Map** icon from the left navigation. In the new portal, navigate to the **Data Catalog** application.

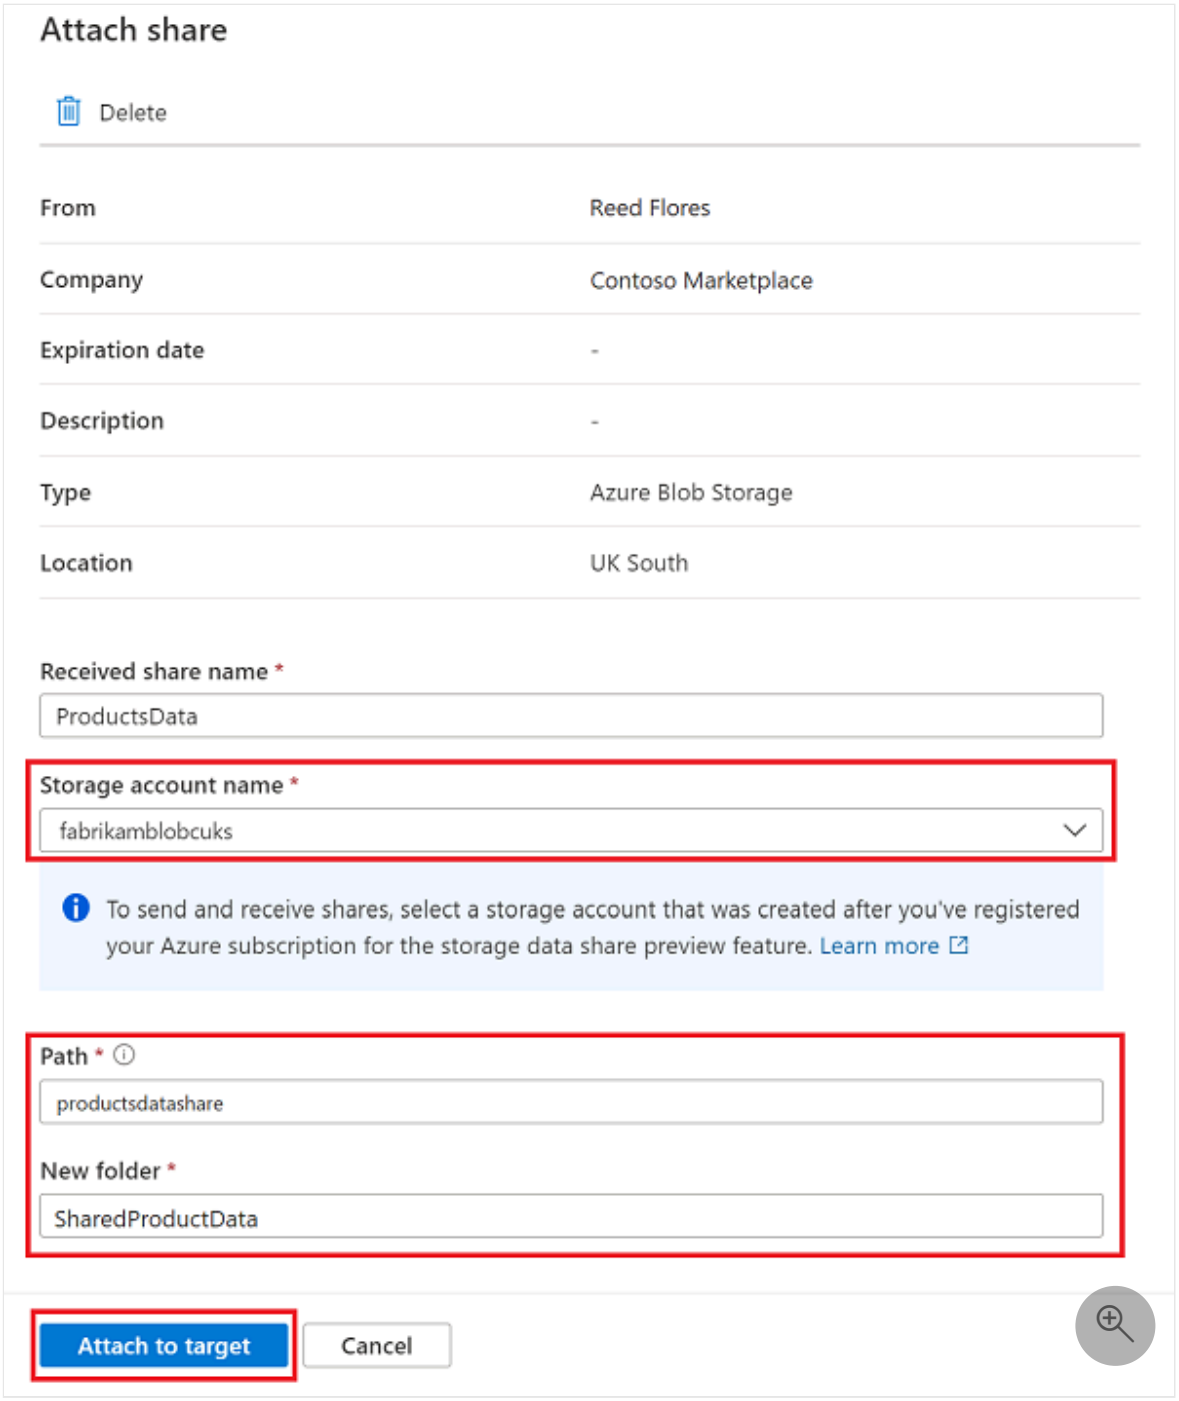
3. Select **Share invites**. If you received an email invitation, you can also select the **View share invite** link in the email to select a Microsoft Purview account.

   If you're a guest user of a tenant, you are asked to verify your email address for the tenant before viewing share invitation for the first time. You can see our guide below for steps. Once verified, it's valid for 12 months.

4. Alternately, within the Microsoft Purview portal, find the Azure Storage or Azure Data Lake Storage (ADLS) Gen 2 data asset you would like to receive the share into using either the data catalog search or browse. Select the **Data Share** button. You can see all the invitations in the **Share invites** tab.

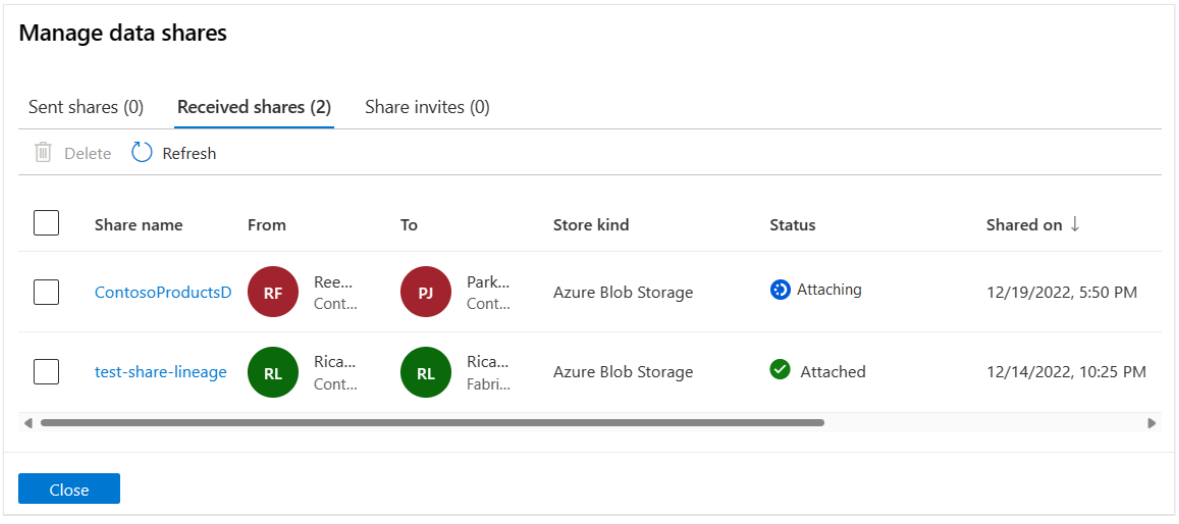
5. Select name of the share invite to view or configure.

6. If you don't want to accept the invitation, select **Delete**.



> **Note**
>
> If you delete an invitation, if you want to accept the share in future it needs to be resent. To deselect the share without deleting select the **Cancel** button instead.

7. You can edit the **Received share name** if you like. Then select a **Storage account name** for a target storage account in the same region as the source. You can choose to **Register a new storage account to attach the share** in the drop-down as well.



> **Important**
>
> The target storage account needs to be in the same Azure region as the source storage account.

8. Configure the **Path** (either a new container name, or the name of an existing share container) and, **New folder** (a new folder name for the share within in your container).

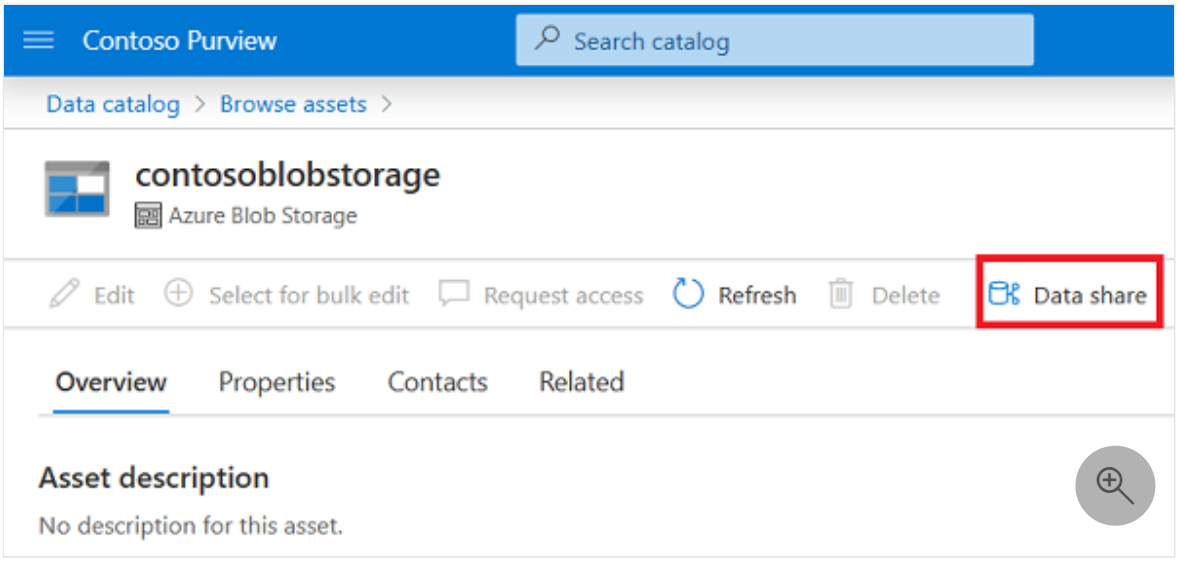
9. Select **Attach to target**.

10. On the Manage data shares page, you see the new share with the status of **Attaching** until it has completed and is attached.

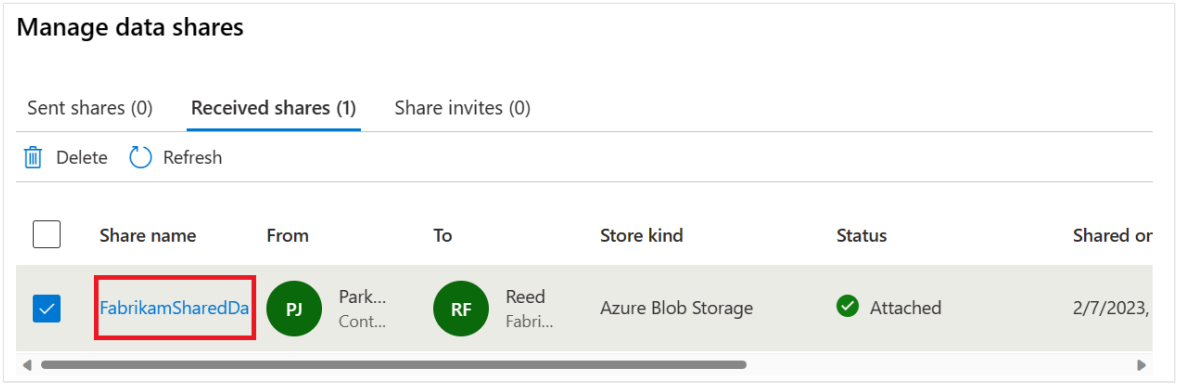
11. You can access shared data from the target storage account through Azure portal, Azure Storage Explorer, Azure Storage SDK, PowerShell, or CLI. You can also analyze the shared data by connecting your storage account to Azure Synapse Analytics Spark or Databricks.

When a share is attached, a new asset of type received share is ingested into the Microsoft Purview catalog, in the same collection as the storage account to which you attached the share is registered. You can search or browse for it like any other asset.

Refer to Microsoft Purview Data Sharing lineage to learn more about share assets and data sharing lineage.

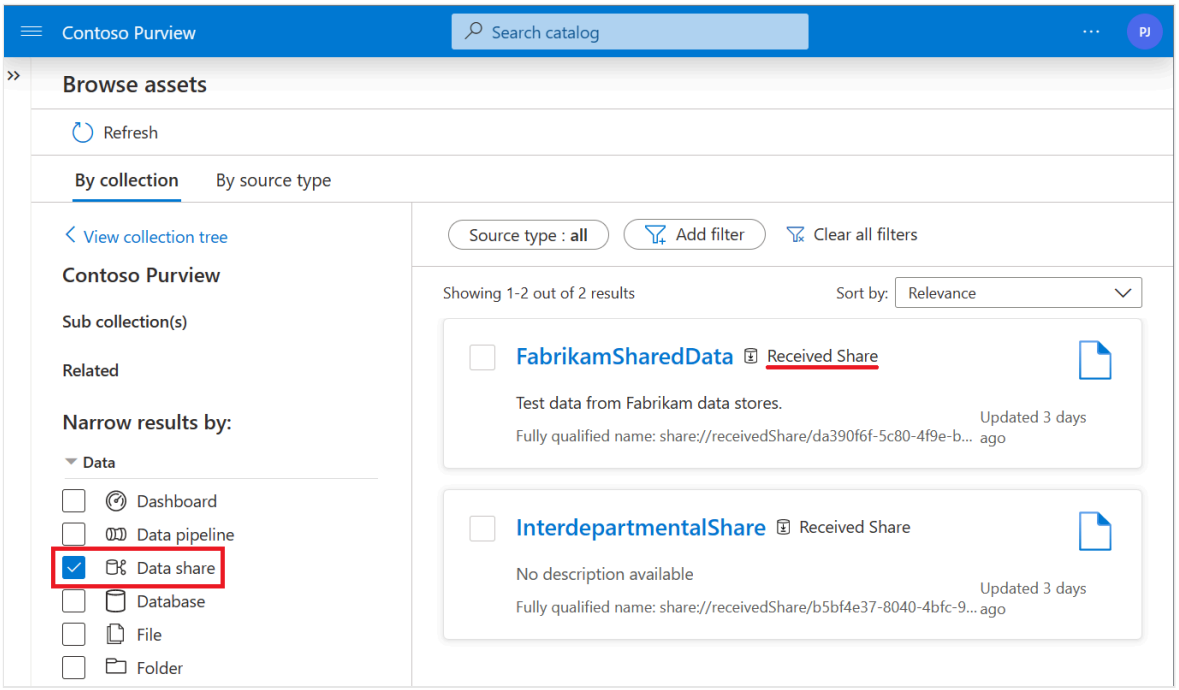


> ⓘ **Note**
>
> Shares attached using the SDK without registering the storage account with Microsoft Purview won't be ingested into the catalog. User can register their storage account if desired. If a storage account is unregistered or re-registered to a different collection, share assets of that storage account continue to be in the initial collection.



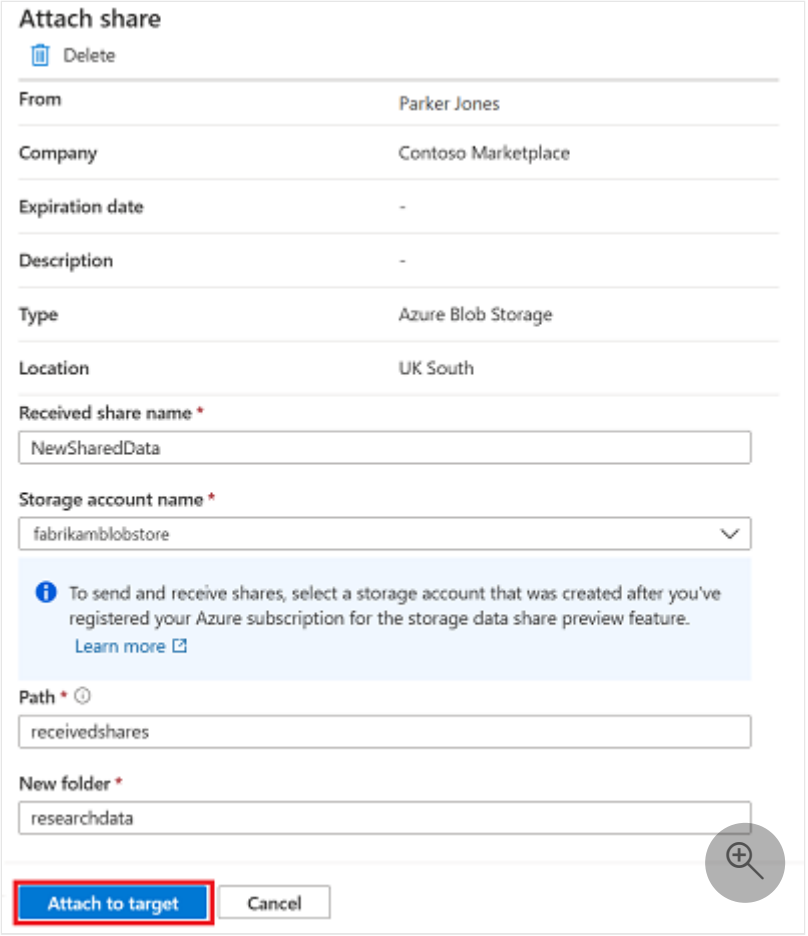
Update received share

Once you attach a share, you can edit the received share by reattaching the share to a new storage account, or stop the sharing relationship by deleting the received share.



You can find and edit received share asset one of two ways:

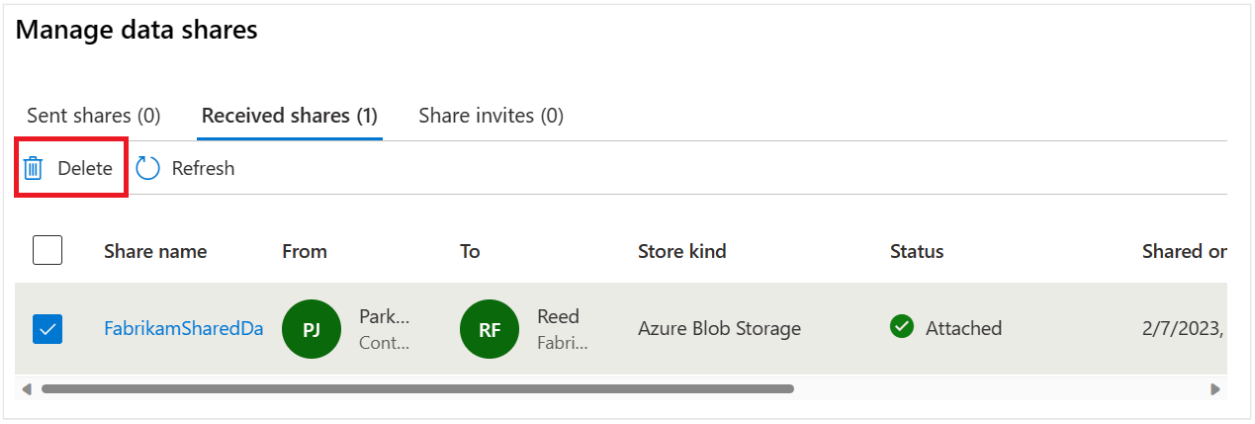
- Access the blob storage or ADLS Gen2 asset where the data was received in the data catalog and open it, then select **Data Share** and **Manage data shares**. There you're able to see all the shares for that asset. Select the **Received shares** tab, select a share, and then select your share.

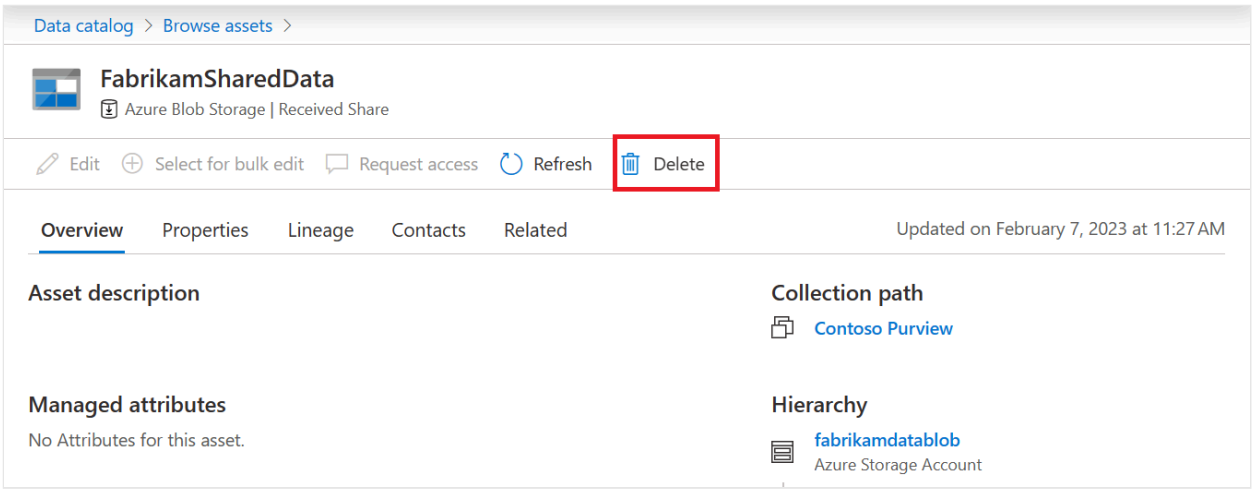


- Search or browse the data catalog for data share assets and select your received share. Then select the **Edit** button.

Reattach share

After you've selected your data share to edit, you can reattach the share to a new storage account or path in your current storage account by selecting a storage account, providing a path, and providing the folder.



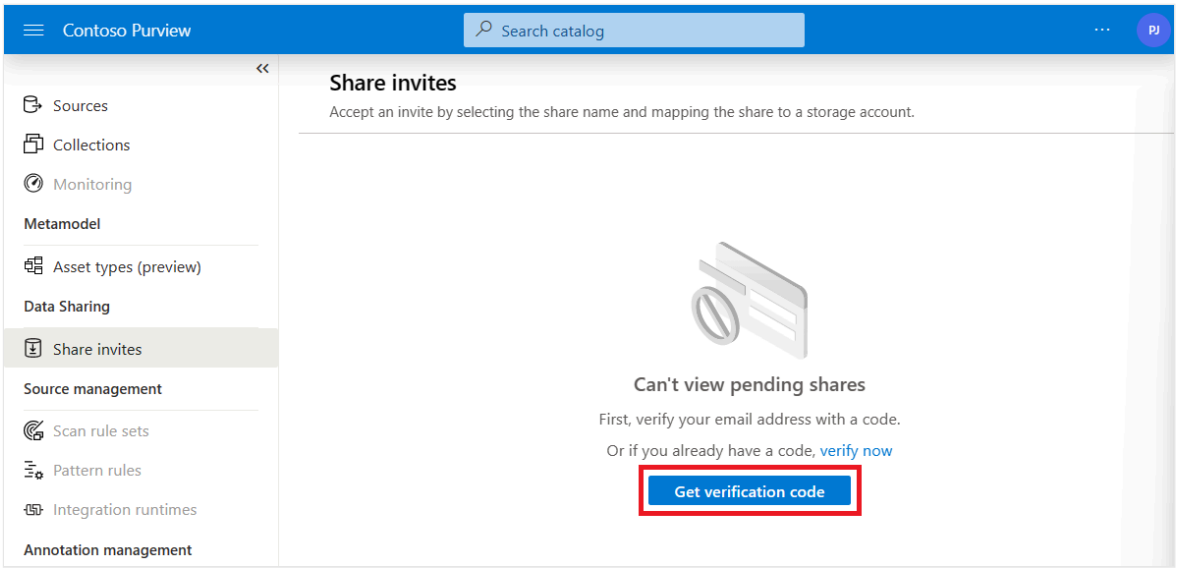


If you're updating the target, select **Attach to target** to save your changes. Attaching can take a couple minutes to complete after the process has been started.

> **Note**
>
> While reattaching, if you selected a storage account that is registered to a collection that you don't have permissions to or a storage account that isn't registered in Microsoft Purview, you'll be shown the appropriate message. You'll see the shared data in your target data store.

Delete received share

To delete a received share, select the share and then select **Delete**.



Deleting a received share stops the sharing relationship, and you won't be able to access shared data. Deleting a received share can take a few minutes.

Guest user verification

If you're a guest user in Azure, to be able to receive shares your account must first be associated with the Microsoft Entra ID. You can start this process from within Microsoft Purview.

1. In the Microsoft Purview Governance Portal, select the Data Map and then **Share invites**.

2. You see text indicating that you need to be associated with Microsoft Entra ID. Select the **Get verification code** button.

3. You'll receive an email from Microsoft Azure with the verification code. Copy it.

4. Return to the **Share invites** page in the Microsoft Purview Governance Portal, select **Verify**, and enter the code you received.

Troubleshoot

Here are some common issues for receiving share and how to troubleshoot them.

Can't create Microsoft Purview account

If you're getting an error related to *quota* when creating a Microsoft Purview account, it means your organization has exceeded Microsoft Purview service limit. If you require an increase in limit, contact support.

Can't find my Storage account asset in the Catalog

- Data source isn't registered in Microsoft Purview. Refer to the registration steps for Blob Storage and ADLSGen2 respectively. Performing a scan isn't necessary.
- Data source is registered to a Microsoft Purview collection that you don't have a minimum of Data Reader permission to. Refer to Microsoft Purview catalog permissions and reach out to your collection admin for access.

Can't view list of shares in the storage account asset

- Permission issue to the data store that you want to see shares for. You need a minimum of **Reader** role on the source storage account to see a read-only view of

sent shares and received shares. You can find more details on the ADLS Gen2 or Blob storage data source page.

Can't view received share in the storage account asset

- You might have selected a different storage account to attach the share to, that might not be registered in Microsoft Purview or maybe registered to a collection you don't have permissions to. Refer to the registration steps for Blob Storage and ADLSGen2 respectively. Refer to Microsoft Purview catalog permissions and reach out to your collection admin for access to collections.

Can't view share invite

If you've been notified that you've received a share, but can't view share invite in your Microsoft Purview account, it could be due to the following reasons:

- You don't have a minimum of **Data Reader** role to any collections in this Microsoft Purview account. Contact your *Microsoft Purview Collection Admin* to grant you access to **Data Reader** role to view, accept, and configure the received share.
- Share invitation is sent to your email alias or an email distribution group instead of your Azure sign-in email. Contact your data provider and ensure that they've sent the invitation to your Azure sign-in e-mail address.
- Share has already been accepted. If you already accepted the share, it will no longer show up in *Share invites* tab. Select *Received shares* in any Storage account that you have permissions to and see your active shares.
- You're a guest user of the tenant. If you're a guest user of a tenant, you need to verify your email address for the tenant in order to view a share invitation for the first time. Once verified, it's valid for 12 months.

Can't see target storage account in the list when attaching a share

When you attach a share to a target, if your storage account isn't listed for you to select, it's likely due to the following reasons:

- You don't have required permissions to the storage account. Check prerequisites for details on required storage permissions.

Failed to attach share

If you failed to attach a share, it's likely due to the following reasons:

- Permission issue to the target data store. Check prerequisites for required data store permissions.
- The storage account isn't supported. Microsoft Purview Data share only supports storage accounts with specific configurations.
- The *Path* you specified includes container created outside of Microsoft Purview Data Sharing. You can only receive data into containers created while attaching.
- The *New Folder* you specified to receive storage data isn't empty.
- Source and target storage account is the same. Sharing from the same source storage account to the same target isn't supported.
- Exceeding limit. Source storage account can support up to 20 targets, and target storage account can support up to 100 sources. If you require an increase in limit, contact support.

Can't access shared data in the target data store

If you can't access shared data, it's likely due to the following reasons:

- After share attaching is successful, it could take some time for the data to appear in the target data store. Try again in a few minutes. Likewise, after you delete a share, it can take a few minutes for the data to disappear in the target data store.
- You're accessing shared data using a storage API version prior to February 2020. Only storage API version February 2020 and later are supported for accessing shared data. Ensure you're using the latest version of the storage SDK, PowerShell, CLI, and Azure Storage Explorer.
- You're accessing shared data using an analytics tool that uses a storage API version February 2020. You can access shared data from Azure Synapse Analytics Spark and Databricks. You won't be able to access shared data usingprior to Azure Data Factory, Power BI, or AzCopy.

Quickstart: Share and receive Azure Storage data in-place with Microsoft Purview Data Sharing (preview)

> **Note**
>
> Microsoft Purview Data Catalog (classic), Data Health Insights (classic), and Purview Workflow (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently being retired, with support provided until September 2025 to allow for migration to Microsoft Fabric external data sharing.

This article provides a quick guide on how to share data and receive shares from Azure Data Lake Storage (ADLS Gen2) or Blob storage accounts.

> **Important**
>
> Data sharing is accessed through the classic Microsoft Purview governance portal: https://web.purview.azure.com

Prerequisites

Microsoft Purview prerequisites

- A Microsoft Purview account. You can also use two Microsoft Purview accounts, one for data provider and one for data consumer to test both scenarios.
- Your recipient's Azure sign-in email address that you can use to send the invitation to. The recipient's email alias won't work.

Azure Storage account prerequisites

- Your Azure subscription must be registered for the **AllowDataSharing** preview feature. (If you haven't already registered this preview feature, consider using Microsoft Fabric external data sharing instead, since Microsoft Purview Data Sharing will be retired in September 2025.) Or, contact support.
- Source and target storage accounts **created after** the registration step is completed. **Both storage accounts must be in the same Azure region as each other**. Both storage accounts need to be ADLS Gen2 or Blob Storage accounts. Your storage accounts can be in a different Azure region from your Microsoft Purview account.
- Latest version of the storage SDK, PowerShell, CLI, and Azure Storage Explorer. Storage REST API version must be February 2020 or later.
- The storage accounts need to be registered in the collections where you'll send or receive the share. If you're using one Microsoft Purview account, this can be two different collections, or the same collection. For instructions to register, see the ADLS Gen2 or Blob storage data source pages.
- If the source or target storage accounts are in a different Azure subscription than the one for Microsoft Purview account, the Microsoft. Purview resource provider is automatically registered in the Azure subscription where the data store is located at the time of share provider adding an asset or share consumer mapping an asset and **ONLY** if the user has permission to do the /register/action operation for the resource provider. The permission is included in the Contributor and Owner roles.

> **Note**
>
> This registration is only needed the first time when sharing or receiving data into a storage account in the Azure subscription.

Required roles

Here are required roles for sharing data and receiving shares.

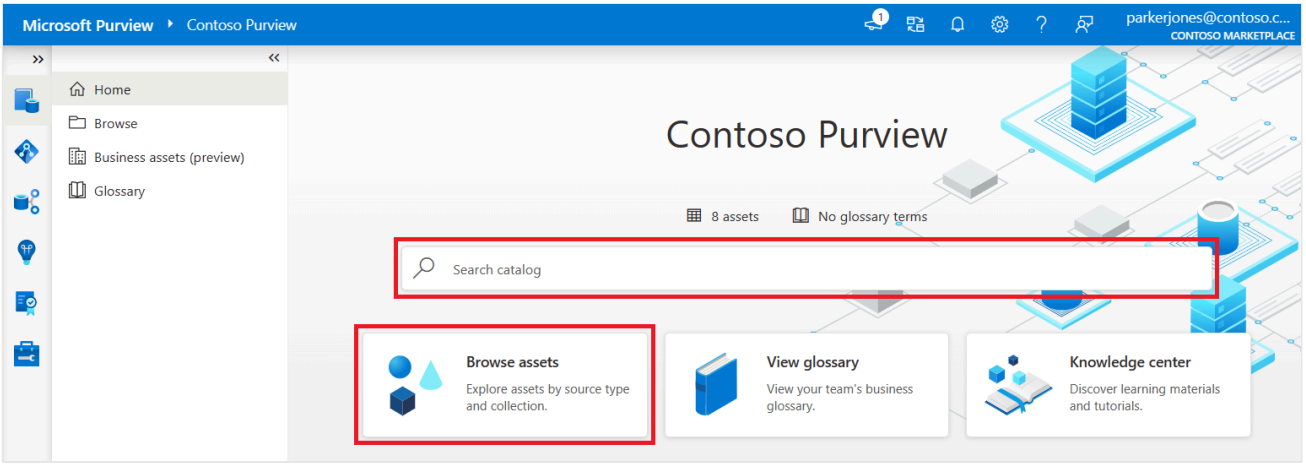
Expand table

	Azure Storage account roles	Microsoft Purview collection roles
Data provider	One of the following roles: • Owner • Storage Blob Data Owner	Data Reader
Data consumer	One of the following roles:	Data Reader

	Azure Storage account roles	Microsoft Purview collection roles
	• Contributor • Owner • Storage Blob Data Contributor • Storage Blob Data Owner	

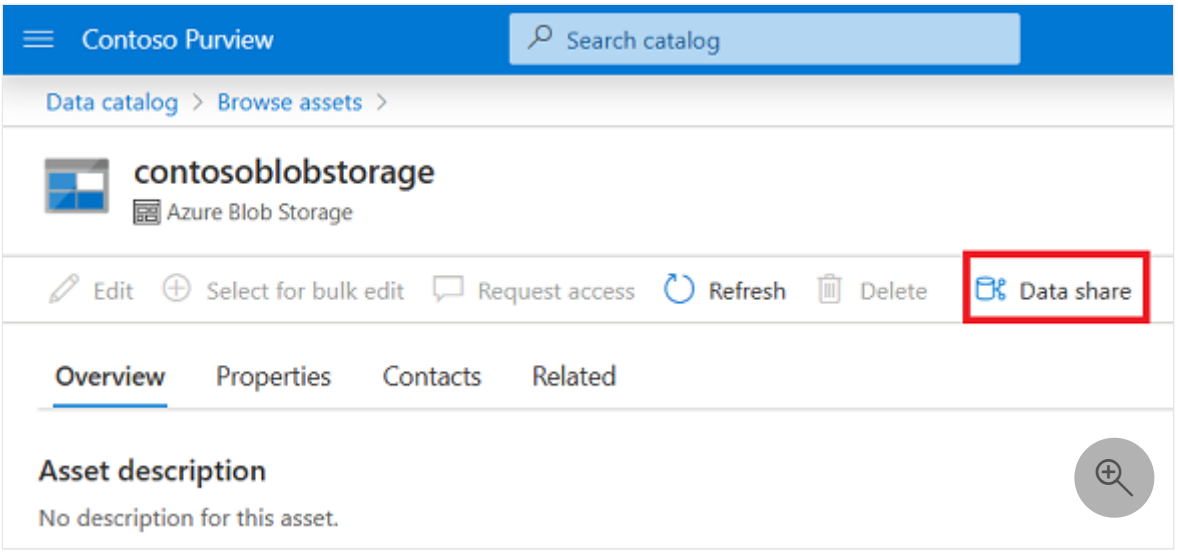
> **Note**
>
> If you created the Microsoft Purview account, you're automatically assigned all the roles to the root collection. Refer to Microsoft Purview permissions to learn more about the Microsoft Purview collection and roles.

Create a share



There are two ways you can create a data share:

- Directly from the data asset
- Use the data sharing application



Create share from asset

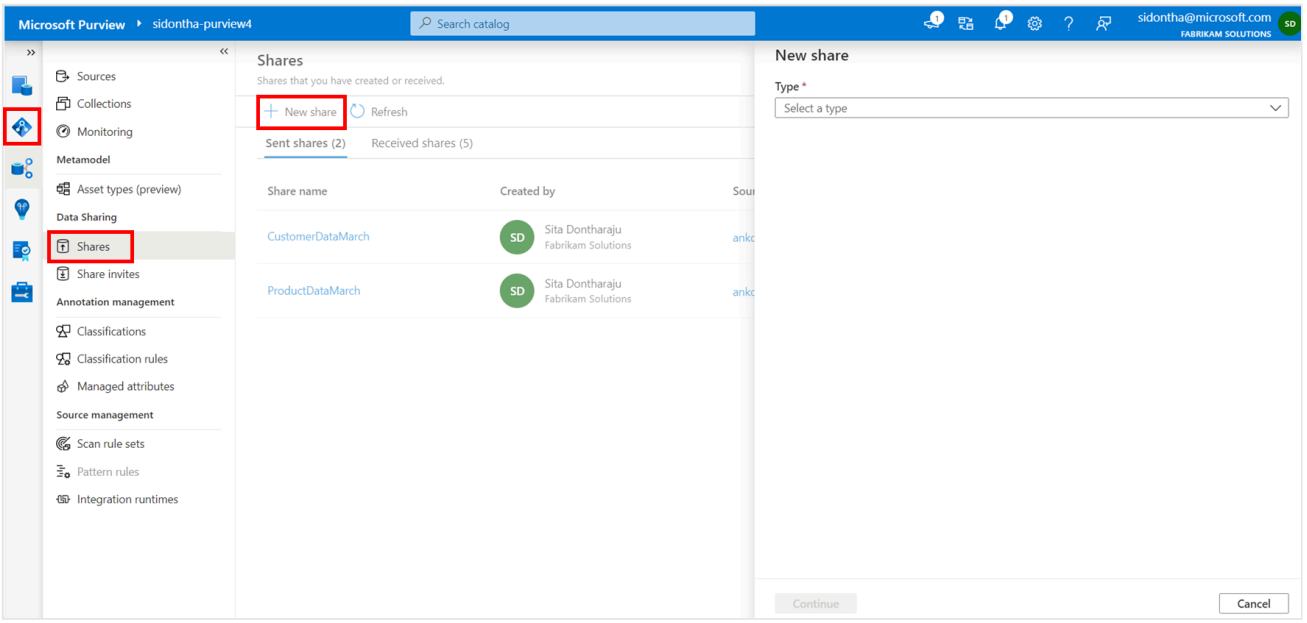
1. You can create a share by starting from **Data Catalog**

   Within the classic Microsoft Purview governance portal or the new Microsoft Purview portal, find the Azure Storage or Azure Data Lake Storage (ADLS) Gen 2 data asset you would like to share data from using either the data catalog search or browse.

2. Once you have found your data asset, select the **Data Share** button.

3. Select **+New Share**.

4. Follow the rest of the steps to create your data share.



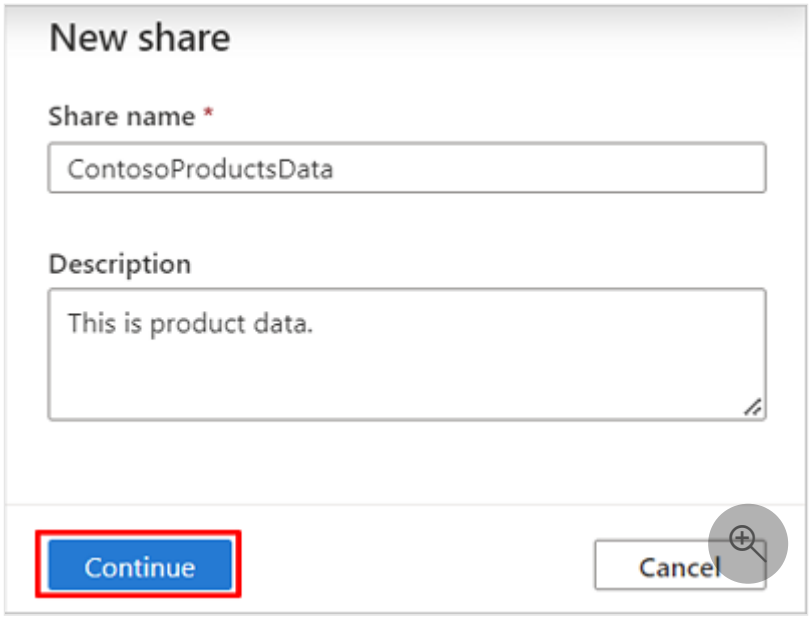
Create share from application

1. If you're using the new Microsoft Purview experience You can create a share by starting from the **Data Catalog**.

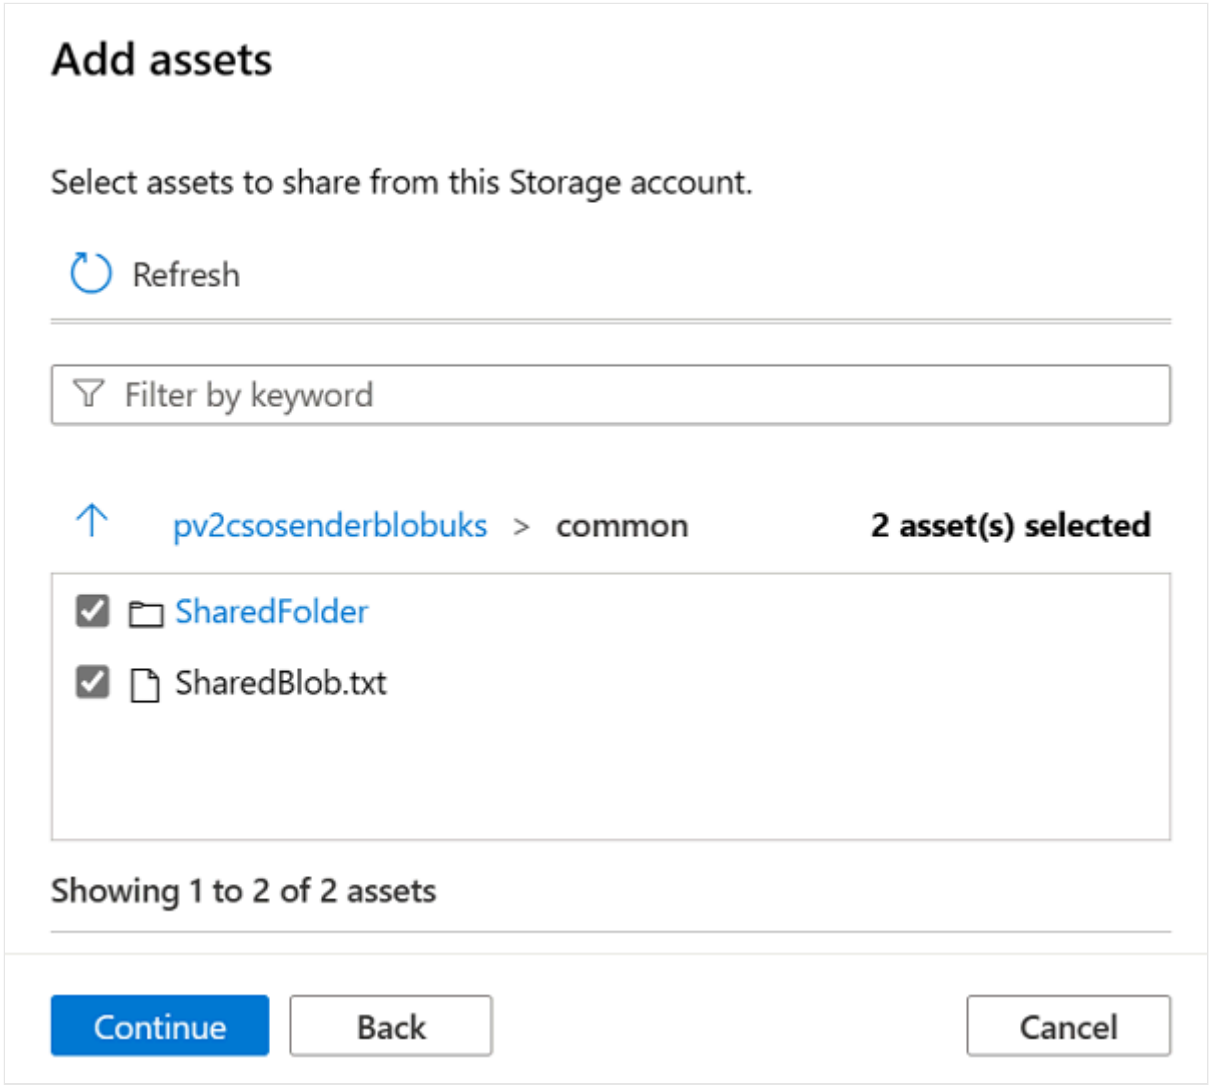
   Open the Microsoft Purview portal. Navigate to the **Data Catalog** application. Then select **Shares** from the left navigation. Select **+New Share**.

2. If you're using the classing Microsoft Purview experience You can create a share by starting from the **Data Map**.

   Open the Microsoft Purview governance portal. Select the **Data Map** icon from the left navigation. Then select **Shares**. Select **+New Share**.

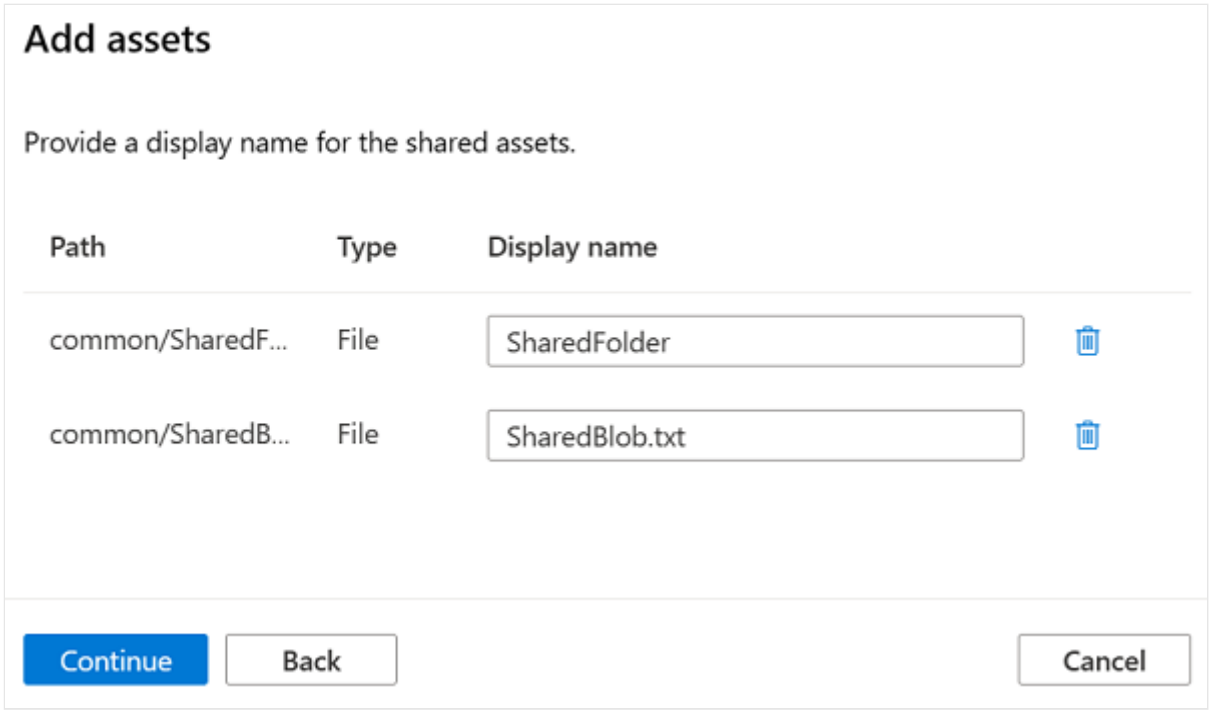


3. From either location, select the Storage account type and the Storage account you want to share data from. Then select **Continue**.



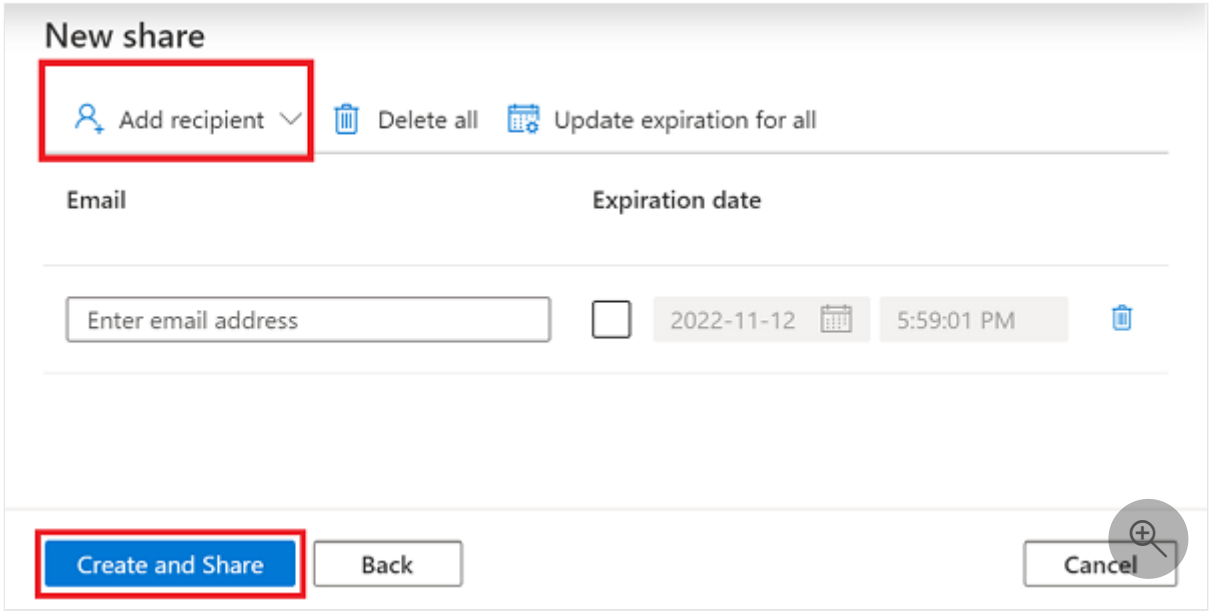
4. Follow the rest of the steps to create your data share.

Create share

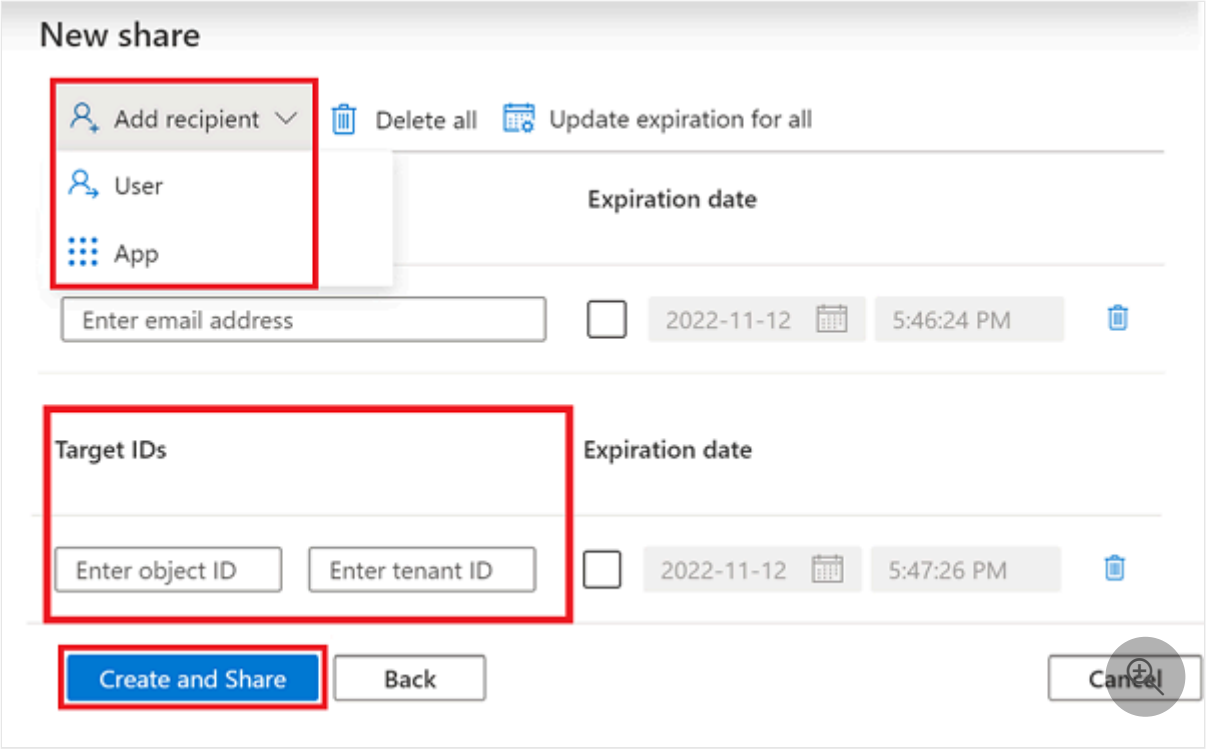


1. Specify a name and a description of share contents (optional). Then select **Continue**.

2. Search for and add all the assets you'd like to share out at the container, folder, or file level, and then select **Continue**.



3. You can edit the display names the shared data will have, if you like. Then select **Continue**.



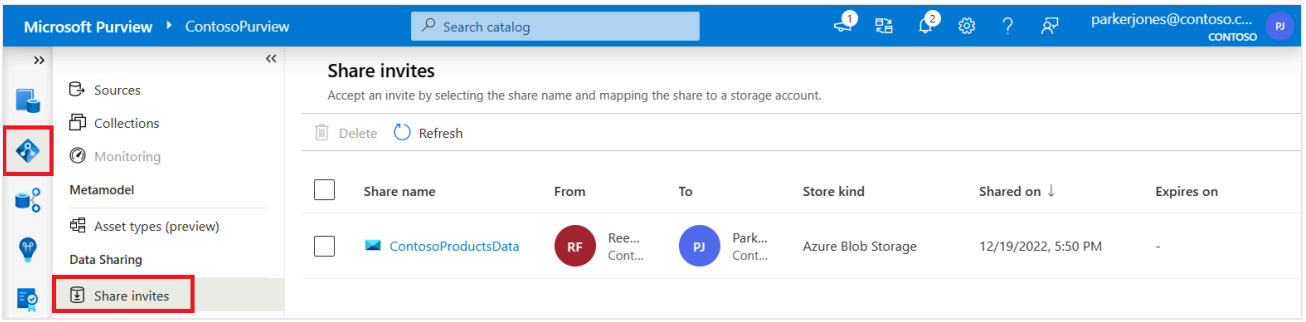
4. Select **Add Recipient** and select **User** or **App**.

   To share data to a user, select **User**, then enter the Azure sign-in email address of who you want to share data with. By default, the option to enter email address of user is shown.

   To to share data with a service principal, select **App**. Enter the object ID and tenant ID of the recipient you want to share data with.

5. Select **Create and Share**. Optionally, you can specify an **Expiration date** for when to terminate the share. You can share the same data with multiple recipients by selecting **Add Recipient** multiple times.

You've now created your share. The recipients of your share will receive an invitation and they can view the pending share in their Microsoft Purview account.



Receive share

1. You can view your share invitations in any Microsoft Purview account. Open the Microsoft Purview governance portal by browsing directly to the classic portal or the new Microsoft Purview portal and selecting your Microsoft Purview account.

2. In the classic portal, select the **Data Map** icon from the left navigation. In the new portal, navigate to the **Data Catalog** application.

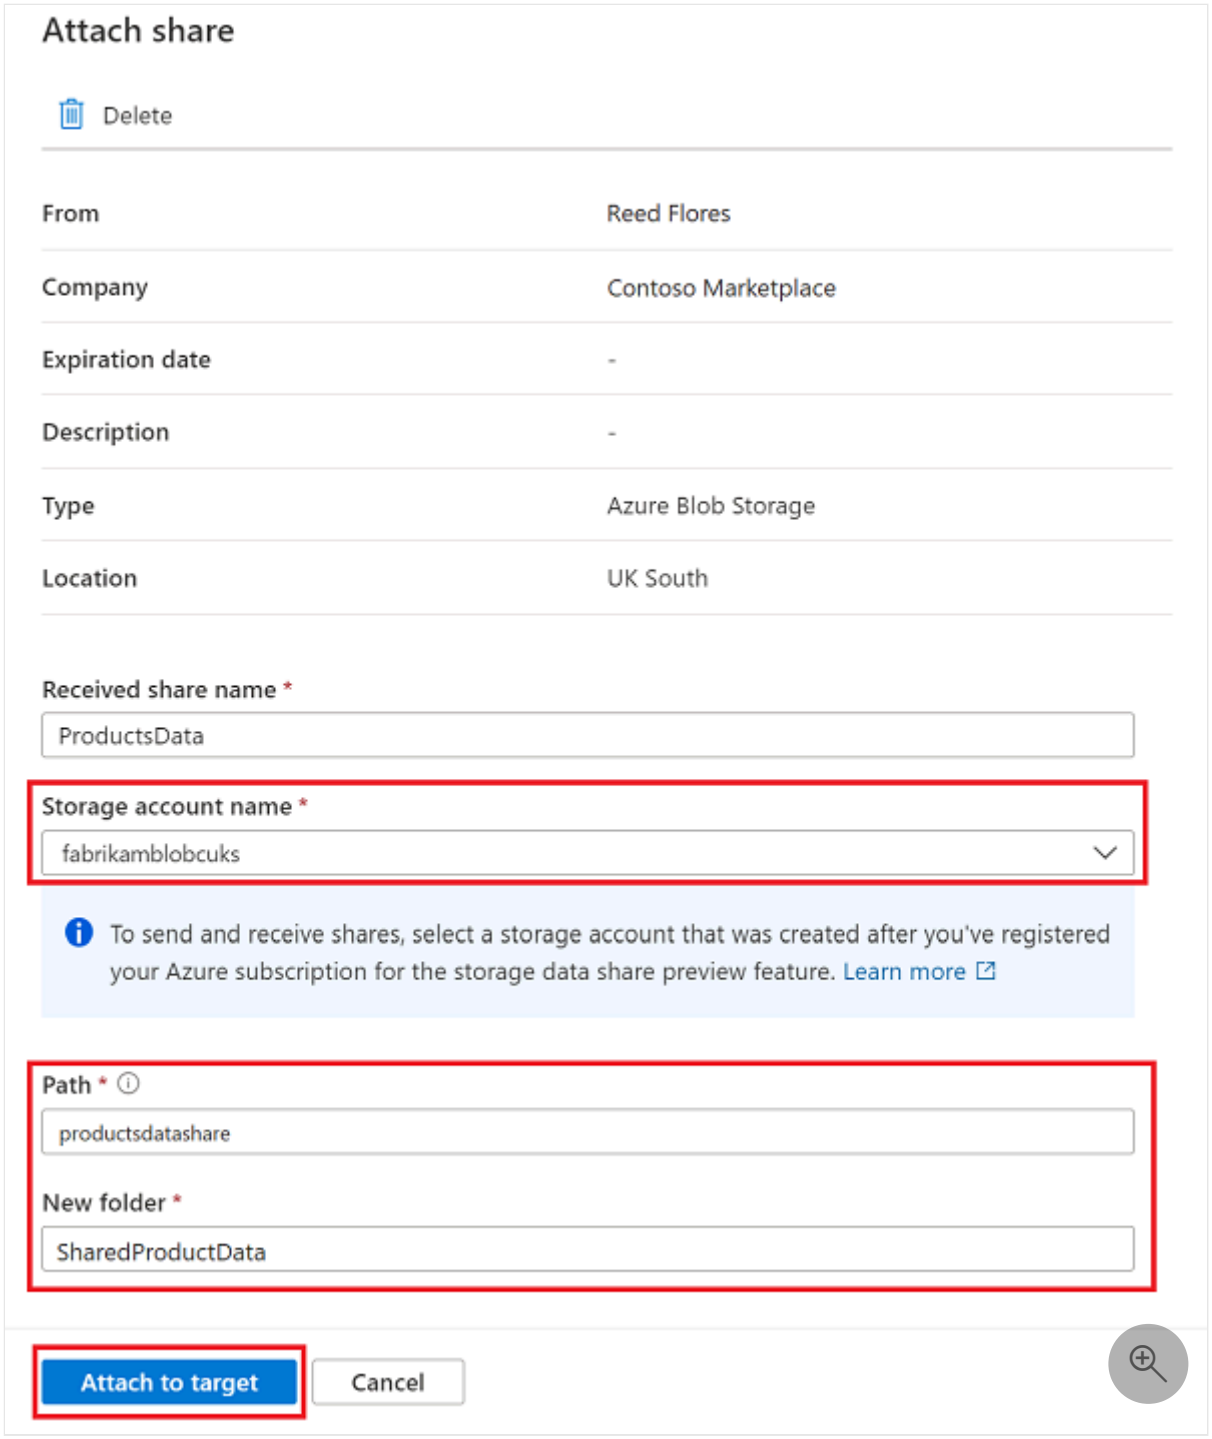
3. Select **Share invites**. If you received an email invitation, you can also select the **View share invite** link in the email to select a Microsoft Purview account.

   If you're a guest user of a tenant, you'll be asked to verify your email address for the tenant before viewing share invitation for the first time. You can see our guide for steps. Once verified, it's valid for 12 months.

4. Alternately, within the Microsoft Purview portal, find the Azure Storage or Azure Data Lake Storage (ADLS) Gen 2 data asset you would like to receive the share into using either the data catalog search or browse. Select the **Data Share** button. You can see all the invitations in the **Share invites** tab.

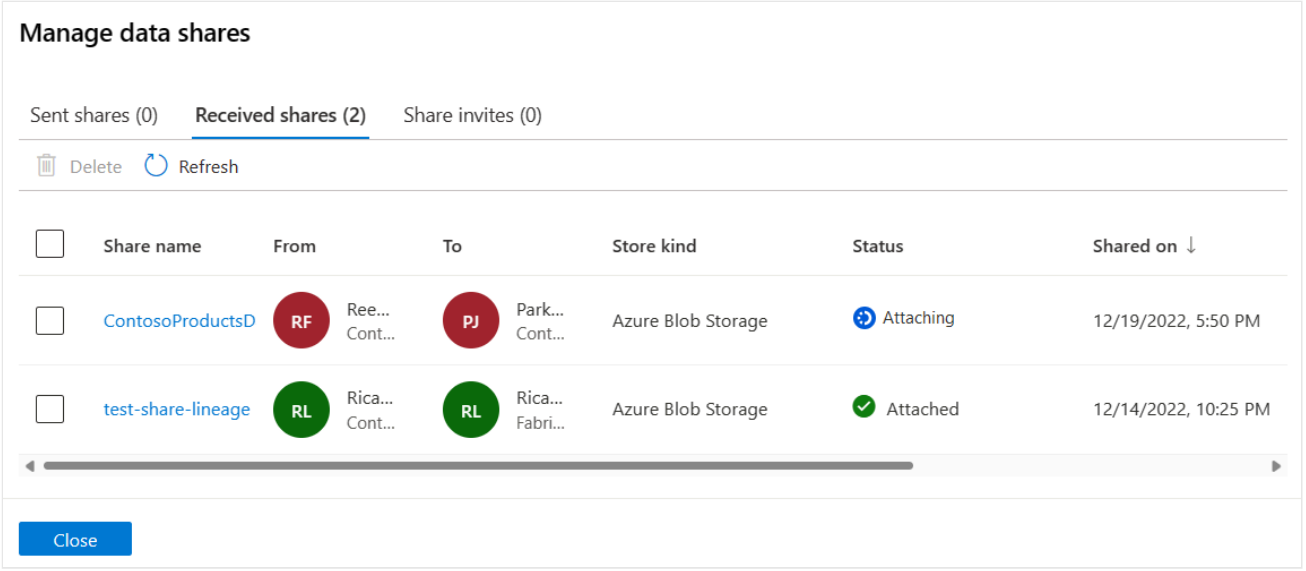
5. Select name of the share to view or configure.

6. If you don't want to accept the invitation, select **Delete**.



> **Note**
>
> If you delete an invitation, if you want to accept the share in future it will need to be resent. To deselect the share without deleting select the **Cancel** button instead.

7. You can edit the **Received share name** if you like. Then select a **Storage account name** for a target storage account in the same region as the source. You can choose to **Register a new storage account to attach the share** in the drop-down as well.



> **Important**
>
> The target storage account needs to be in the same Azure region as the source storage account.

8. Configure the **Path** (either a new container name, or the name of an existing share container) and, **New folder** (a new folder name for the share within in your container).

9. Select **Attach to target**.

10. On the Manage data shares page, you'll see the new share with the status of **Attaching** until it has completed and is attached.

11. You can access shared data from the target storage account through Azure portal, Azure Storage Explorer, Azure Storage SDK, PowerShell or CLI. You can also analyze the shared data by connecting your storage account to Azure Synapse Analytics Spark or Databricks.

Clean up resources

To clean up the resources created for the quick start, follow the steps below:

1. Within Microsoft Purview portal, delete the sent share.
2. Also delete your received share.
3. Once the shares are successfully deleted, delete the target container and folder Microsoft Purview created in your target storage account when you received shared data.

Troubleshoot

To troubleshoot issues with sharing data, refer to the troubleshooting section of the how to share data article. To troubleshoot issues with receiving share, refer to the troubleshooting section of the how to receive shared data article.

Quickstart: Share and receive data with the Microsoft Purview Data Sharing .NET SDK

Article • 10/28/2024

> **Note**
>
> Microsoft Purview Data Map (classic), Data Catalog (classic), Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently being retired, with support provided until September 2025 to allow for migration to Microsoft Fabric external data sharing.

In this quickstart, you'll use the .NET SDK to share data and receive shares from Azure Data Lake Storage (ADLS Gen2) or Blob storage accounts. The article includes code snippets that allow you to create, accept, and manage shares using Microsoft Purview Data Sharing.

For an overview of how data sharing works, watch this short demo.

> **Note**
>
> This feature has been updated in February 2023, and the SDK and permissions needed to view and manage data shares in Microsoft Purview have changed.
>
> - No permissions are now required in Microsoft Purview to use the SDK to create and manage shares. (Reader permissions are needed to use the Microsoft Purview Governance Portal for sharing data.)
> - Permissions are still required on storage accounts.
>
> See the updated NuGet package and updated code snippets to use the updated SDK.

Prerequisites

Microsoft Purview prerequisites

- A Microsoft Purview account. You can also use two Microsoft Purview accounts, one for data provider and one for data consumer to test both scenarios.
- Your recipient's Azure sign-in email address that you can use to send the invitation to. The recipient's email alias won't work.

Azure Storage account prerequisites

- Your Azure subscription must be registered for the **AllowDataSharing** preview feature. (If you haven't already registered this preview feature, consider using Microsoft Fabric external data sharing instead, since Microsoft Purview Data Sharing will be retired in September 2025.) Or, contact support.
- Source and target storage accounts **created after** the registration step is completed. **Both storage accounts must be in the same Azure region as each other**. Both storage accounts need to be ADLS Gen2 or Blob Storage accounts. Your storage accounts can be in a different Azure region from your Microsoft Purview account.
- Latest version of the storage SDK, PowerShell, CLI, and Azure Storage Explorer. Storage REST API version must be February 2020 or later.
- The storage accounts need to be registered in the collections where you'll send or receive the share. If you're using one Microsoft Purview account, this can be two different collections, or the same collection. For instructions to register, see the ADLS Gen2 or Blob storage data source pages.
- If the source or target storage accounts are in a different Azure subscription than the one for Microsoft Purview account, the Microsoft. Purview resource provider is automatically registered in the Azure subscription where the data store is located at the time of share provider adding an asset or share consumer mapping an asset and **ONLY** if the user has permission to do the /register/action operation for the resource provider. The permission is included in the Contributor and Owner roles.

  > ⓘ **Note**
  >
  > This registration is only needed the first time when sharing or receiving data into a storage account in the Azure subscription.

Required roles

Here are required roles for sharing data and receiving shares.

Expand table

	Azure Storage account roles	Microsoft Purview collection roles
Data provider	One of the following roles: • Owner • Storage Blob Data Owner	Data Reader
Data consumer	One of the following roles: • Contributor • Owner • Storage Blob Data Contributor • Storage Blob Data Owner	Data Reader

> **Note**
>
> If you created the Microsoft Purview account, you're automatically assigned all the roles to the root collection. Refer to Microsoft Purview permissions to learn more about the Microsoft Purview collection and roles.

Visual Studio

The walkthrough in this article uses Visual Studio 2022. The procedures for Visual Studio 2013, 2015, 2017, or 2019 may differ slightly.

Azure .NET SDK

Download and install Azure .NET SDK on your machine.

Use a service principal

In the code snippets in this tutorial, you can authenticate either using your own credentials or using a service principal. To set up a service principal, follow these instructions:

1. In Create a Microsoft Entra application, create an application that represents the .NET application you're creating in this tutorial. For the sign-on URL, you can provide a dummy URL as shown in the article (`https://contoso.org/exampleapp`).

2. In Get values for signing in, get the **application ID**,**tenant ID**, and **object ID**, and note down these values that you use later in this tutorial.

3. In Certificates and secrets, get the **authentication key**, and note down this value that you use later in this tutorial.

4. assign the application to these roles:

Expand table

User	Azure Storage account roles	Microsoft Purview collection roles
Data provider	One of the following roles: • Owner • Blob Storage Data Owner	Data Share Contributor
Data consumer	One of the following roles: • Contributor • Owner • Storage Blob Data Contributor • Blob Storage Data Owner	Data Share Contributor

Create a Visual Studio project

Next, create a C# .NET console application in Visual Studio:

1. Launch **Visual Studio**.
2. In the Start window, select **Create a new project** > **Console App**. .NET version 6.0 or above is required.
3. In **Project name**, enter **PurviewDataSharingQuickStart**.
4. Select **Create** to create the project.

Install NuGet packages

1. Select **Tools** > **NuGet Package Manager** > **Package Manager Console**.

2. In the **Package Manage Console** run the .NET cli add package command shown on this page to add the NuGet package: Microsoft.Azure.Analytics.Purview.Sharing NuGet package.

3. In the **Package Manager Console** pane, run the following commands to install packages.

```PowerShell
Install-Package Azure.Analytics.Purview.Sharing -IncludePrerelease
Install-Package Azure.Identity
```

> **Tip**
>
> If you get an error that reads "Could not find any project in..." when attempting these commands, you may just need to move a folder level down in your project. Try the command `dir` to list folders in your directory, then use 'cd <name of the project folder>' to move down a level to your project folder. Then try again.

Create a sent share

This script creates a data share that you can send to internal or external users. To use it, be sure to fill out these variables:

- **SenderTenantId** - the Azure Tenant ID for the sender's identity.
- **SenderPurviewAccountName** - the name of the Microsoft Purview account where the data will be sent from.
- **ShareName** - A display name for your sent share.
- **ShareDescription** - (optional) A description for your sent share.
- **SenderStorageKind** - either BlobAccount or AdlsGen2Account.
- **SenderStorageResourceId** - the resource ID for the storage account where the data will be sent from.
- **SenderStorageContainer** - the name of the container where the data to be shared is stored.
- **SenderPathToShare** - the file/folder path to the data to be shared.
- **UseServiceTokenCredentials** - (optional) If you want to use a service principal to create the shares, set this to **true**.
- **SenderClientId** - (optional) If using a service principal to create the shares, this is the Application (client) ID for the service principal.
- **SenderClientSecret** - (optional) If using a service principal to create the shares, add your client secret/authentication key.
- **SentShareID** - (optional) This option must be a GUID, and the current value generates one for you, but you can replace it with a different value if you would

like.

- **ReceiverVisiblePath** - (optional) The name for the share the receiver will see. Currently set to a GUID, but GUID is not required.
- **SenderPurviewEndPoint** - If you're using If you're using the classic Microsoft purview experience, use `$"https://{SenderPurviewAccountName}.purview.azure.com"`; If you're using the new Microsoft Purview experience, use `https://api.purview-service.microsoft.com/`

C#

```
using Azure;
using Azure.Analytics.Purview.Sharing;
using Azure.Core;
using Azure.Identity;
using System.ComponentModel;

public static class PurviewDataSharingQuickStart
{
    // [REQUIRED INPUTS] Set To Actual Values.
    private static string SenderTenantId = "<Sender Identity's Tenant ID>";
    private static string SenderPurviewAccountName = "<Sender Purview
Account Name>";

Send invitation to a user

This script sends an email invitation for a share to a user. If you want to send an invitation to a service principal, see the next code example. To use it, be sure to fill out these variables:

- **RecipientUserEmailId** - Email address for the user to send the invitation to.
- **SenderTenantId** - the Azure Tenant ID for the share sender's identity.
- **SenderPurviewAccountName** - the name of the Microsoft Purview account where the data will be sent from.
- **SenderStorageResourceId** - the resource ID for the storage account where the data will be sent from.
- **SentShareDisplayName** - the name of the sent share you're sending an invitation for.
- **UseServiceTokenCredentials** - (optional) If you want to use a service principal to create the shares, set this to **true**.

- **SenderClientId** - (optional) If using a service principal to create the shares, this is the Application (client) ID for the service principal.
- **SenderClientSecret** - (optional) If using a service principal to create the shares, add your client secret/authentication key.
- **InvitationId** - (optional) This option must be a GUID, and the current value generates one for you, but you can replace it with a different value if you would like.
- **SenderPurviewEndPoint** - If you're using If you're using the classic Microsoft purview experience, use `$"https://{SenderPurviewAccountName}.purview.azure.com"`; If you're using the new Microsoft Purview experience, use `https://api.purview-service.microsoft.com/`

        }

        return list;
    }
}
```

Delete recipient

This script removes a share invitation, and therefore the share, for a recipient. To use it, be sure to fill out these variables:

- **SenderTenantId** - the Azure Tenant ID for the share sender's identity.
- **SenderPurviewAccountName** - the name of the Microsoft Purview account where the data was sent from.
- **SentShareDisplayName** - the name of the sent share you're removing a recipient for.
- **SenderStorageResourceId** - the resource ID for the storage account where the data will be sent from.
- **RecipientUserEmailId** - Email address for the user you want to delete.
- **UseServiceTokenCredentials** - (optional) If you want to use a service principal to create the shares, set this to **true**.
- **SenderClientId** - (optional) If using a service principal to create the shares, this is the Application (client) ID for the service principal.
- **SenderClientSecret** - (optional) If using a service principal to create the shares, add your client secret/authentication key.
- **SenderPurviewEndPoint** - If you're using If you're using the classic Microsoft purview experience, use `$"https://{SenderPurviewAccountName}.purview.azure.com"`; If you're using the new Microsoft Purview experience, use `https://api.purview-service.microsoft.com/`

Create a received share

This script allows you to receive a data share. To use it, be sure to fill out these variables:

- **ReceiverTenantId** - the Azure Tenant ID for the user/service that is receiving the shared data.
- **ReceiverPurviewAccountName** - the name of the Microsoft Purview account where the data will be received.
- **ReceiverStorageKind** - either BlobAccount or AdlsGen2Account.
- **ReceiverStorageResourceId** - the resource ID for the storage account where the data will be received.
- **ReceiverStorageContainer** - the name of the container where the shared data will be stored.
- **ReceiverTargetFolderName** - the folder path to where the shared data will be stored.
- **ReceiverTargetMountPath** - the mount path you'd like to use to store your data in the folder.
- **UseServiceTokenCredentials** - (optional) If you want to use a service principal to receive the shares, set this to **true**.
- **ReceiverClientId** - (optional) If using a service principal to receive the shares, this is the Application (client) ID for the service principal.
- **ReceiverClientSecret** - (optional) If using a service principal to receive the shares, add your client secret/authentication key.
- **ReceivedShareId** - (optional) This option must be a GUID, and the current value will generate one for you, but you can replace it with a different value if you would like.
- **ReceiverVisiblePath** - (optional) Name you want to use for the path for your received share.
- **ReceivedShareDisplayName** - (optional) A display name for your received share.
- **ReceiverPurviewEndPoint** - If you're using If you're using the classic Microsoft purview experience, use `$"https://{ReceiverPurviewAccountName}.purview.azure.com"`; If you're using the new Microsoft Purview experience, use `https://api.purview-service.microsoft.com/`

Update received share

This script allows you to update the storage location for a received share. Just like creating a received share, you add the information for the storage account where you want the data to be housed. To use it, be sure to fill out these variables:

- **ReceiverTenantId** - the Azure Tenant ID for the user/service that is receiving the shared data.
- **ReceiverPurviewAccountName** - the name of the Microsoft Purview account where the data will be received.
- **ReceiverStorageKind** - either BlobAccount or AdlsGen2Account.
- **ReceiverStorageResourceId** - the resource ID for the storage account where the data has been shared.
- **ReAttachStorageResourceId** - the resource ID for the storage account where the data will be received.
- **ReceiverStorageContainer** - the name of the container where the shared data will be stored.
- **ReceiverTargetFolderName** - the folder path to where the shared data will be stored.
- **ReceiverTargetMountPath** - the mount path you'd like to use to store your data in the folder.
- **ReceivedShareDisplayName** - The display name for your received share.
- **UseServiceTokenCredentials** - (optional) If you want to use a service principal to receive the shares, set this to **true**.
- **ReceiverClientId** - (optional) If using a service principal to receive the shares, this is the Application (client) ID for the service principal.
- **ReceiverClientSecret** - (optional) If using a service principal to receive the shares, add your client secret/authentication key.
- **ReceiverPurviewEndPoint** - If you're using If you're using the classic Microsoft purview experience, use `$"https://{ReceiverPurviewAccountName}.purview.azure.com"`; If you're using the new Microsoft Purview experience, use `https://api.purview-service.microsoft.com/`

                    {
                        containerName = ReceiverStorageContainer,
                        folder = ReceiverTargetFolderName,
                        mountPath = ReceiverTargetMountPath
                    },
                    storeReference = new
                    {
                        referenceName = ReAttachStorageResourceId,
                        type = "ArmResourceReference"
                    }
                }
            }
        };

        var allReceivedShares = await
receivedSharesClient.GetAllAttachedReceivedSharesAsync(ReceiverStorageResour
ceId).ToResultList();

        var myReceivedShare = allReceivedShares.First(recShareDoc =>
        {
            var doc = JsonDocument.Parse(recShareDoc).RootElement;
            var props = doc.GetProperty("properties");
            return props.GetProperty("displayName").ToString() ==
ReceivedShareDisplayName;
        });

        Console.ForegroundColor = ConsoleColor.Green;
        Console.WriteLine("My Received Share Id: " +
JsonDocument.Parse(myReceivedShare).RootElement.GetProperty("id").ToString()
);
        Console.ForegroundColor = Console.ForegroundColor;
```

```
        var ReceivedShareId =
JsonDocument.Parse(myReceivedShare).RootElement.GetProperty("id").ToString()
;

        var receivedShare = await
receivedSharesClient.CreateOrReplaceReceivedShareAsync(WaitUntil.Completed,
ReceivedShareId, RequestContent.Create(attachedReceivedShareData));

        Console.ForegroundColor = ConsoleColor.Green;
        Console.WriteLine(receivedShare.Value);
        Console.ForegroundColor = Console.ForegroundColor;

        return receivedShare.Value;
    }

    public static async Task<List<T>> ToResultList<T>(this AsyncPageable<T>
asyncPageable)
    {
        List<T> list = new List<T>();

        await foreach (T item in asyncPageable)
        {
            list.Add(item);
        }

        return list;
    }
}
```

Delete received share

This script deletes a received share. To use it, be sure to fill out these variables:

- **ReceiverTenantId** - the Azure Tenant ID for the user/service that is receiving the shared data.
- **ReceiverPurviewAccountName** - the name of the Microsoft Purview account where the data will be received.
- **ReceivedShareDisplayName** - The display name for your received share.
- **ReceiverStorageResourceId** - the resource ID for the storage account where the data has been shared.
- **UseServiceTokenCredentials** - (optional) If you want to use a service principal to receive the shares, set this to **true**.
- **ReceiverClientId** - (optional) If using a service principal to receive the shares, this is the Application (client) ID for the service principal.
- **ReceiverClientSecret** - (optional) If using a service principal to receive the shares, add your client secret/authentication key.

- **ReceiverPurviewEndPoint** - If you're using If you're using the classic Microsoft purview experience, use `$"https://{ReceiverPurviewAccountName}.purview.azure.com"`; If you're using the new Microsoft Purview experience, use `https://api.purview-service.microsoft.com/`

C#

```
using Azure;
using Azure.Analytics.Purview.Sharing;
using Azure.Core;
using Azure.Identity;
using System.Text.Json;

public static class PurviewDataSharingQuickStart
{
    // [REQUIRED INPUTS] Set To Actual Values.
    private static string ReceiverTenantId = "<Receiver Indentity's Tenant ID>";
    private static string ReceiverPurviewAccountName = "<Receiver Purview Account Name>";

    private static string ReceivedShareDisplayName = "<Display name of your received share>";

    private static string ReceiverStorageResourceId = "<Storage Account Resource Id for the account where the share is currently attached.>";

    //Use if using a service principal to delete share.
    private static bool UseServiceTokenCredentials = false;
    private static string ReceiverClientId = "<Receiver Caller Application (Client) Id>";
    private static string ReceiverClientSecret = "<Receiver Caller Application (Client) Secret>";

    // General Configs
    private static string ReceiverPurviewEndPoint = $"https://{ReceiverPurviewAccountName}.purview.azure.com";
    private static string ReceiverShareEndPoint = $"{ReceiverPurviewEndPoint}/share";

    private static async Task Main(string[] args)
    {
        try
        {
            TokenCredential receiverCredentials = UseServiceTokenCredentials
            ? new ClientSecretCredential(ReceiverTenantId, ReceiverClientId, ReceiverClientSecret)
            : new DefaultAzureCredential(new DefaultAzureCredentialOptions { AuthorityHost = new Uri("https://login.windows.net"), TenantId = ReceiverTenantId });
```

```
            ReceivedSharesClient? receivedSharesClient = new
ReceivedSharesClient(ReceiverShareEndPoint, receiverCredentials);

            var allReceivedShares = await
receivedSharesClient.GetAllAttachedReceivedSharesAsync(ReceiverStorageResour
ceId).ToResultList();

            var myReceivedShare = allReceivedShares.First(recShareDoc =>
            {
                var doc = JsonDocument.Parse(recShareDoc).RootElement;
                var props = doc.GetProperty("properties");
                return props.GetProperty("displayName").ToString() ==
ReceivedShareDisplayName;
            });

            Console.ForegroundColor = ConsoleColor.Green;
            Console.WriteLine("My Received Share Id: " +
JsonDocument.Parse(myReceivedShare).RootElement.GetProperty("id").ToString()
);
            Console.ForegroundColor = Console.ForegroundColor;

            var ReceivedShareId =
JsonDocument.Parse(myReceivedShare).RootElement.GetProperty("id").ToString()
;

            await
receivedSharesClient.DeleteReceivedShareAsync(WaitUntil.Completed,
ReceivedShareId);

            Console.ForegroundColor = ConsoleColor.Green;
            Console.WriteLine("Delete Complete");
            Console.ForegroundColor = Console.ForegroundColor;
        }
        catch (Exception ex)
        {
            Console.ForegroundColor = ConsoleColor.Red;
            Console.WriteLine(ex);
            Console.ForegroundColor = Console.ForegroundColor;
        }
    }
    public static async Task<List<T>> ToResultList<T>(this AsyncPageable<T>
asyncPageable)
    {
        List<T> list = new List<T>();

        await foreach (T item in asyncPageable)
        {
            list.Add(item);
        }

        return list;
    }
}
```

Clean up resources

To clean up the resources created for the quick start, use the following guidelines:

1. Within Microsoft Purview portal, delete the sent share.
2. Also delete your received share.
3. Once the shares are successfully deleted, delete the target container and folder Microsoft Purview created in your target storage account when you received shared data.

FAQ: Azure Storage in-place data share with Microsoft Purview Data Sharing (preview)

Article • 10/28/2024

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

Here are some frequently asked questions for Microsoft Purview Data Sharing.

Is data sharing going to be retired?

Yes, Microsoft Purview Data Sharing will be retired in September 2025. To share data, use Microsoft Fabric external data sharing.

Is data sharing available in the new Microsoft Purview Data Catalog?

No, data sharing is accessed through the classic Microsoft Purview governance portal: https://web.purview.azure.com

What are the key terms related to data sharing?

- **Data Provider** - Organization that shares data.
- **Data Consumer** - Organization that receives shared data from a data provider.
- **Asset** - For storage in-place sharing, an asset is a storage account, and the list of files and folders you want to share from the storage account.
- **Share** - A share is a set of data that can be shared from provider to consumer. It's a set of assets. You can have one asset with files/folders from one storage account, and another asset with files/folders from a different storage account.
- **Collection** - A collection is a tool Microsoft Purview uses to group assets, sources, shares, and other artifacts into a hierarchy for discoverability and to manage access control. A root collection is created automatically when you create your Microsoft

Purview account and you're granted all the roles to the root collection. You can use the root collection (default) or create child collections for data sharing.

- **Recipient** - A recipient is a user or service principal to which the share is sent.

Can I use the API or SDK for storage in-place sharing?

Yes, you can use REST API or .NET SDK for programmatic experience to share data.

We have a guide for getting started with the .NET SDK.

What are the roles and permissions required to share data or receive shares?

Expand table

Operations	Roles and Permissions
Data provider: create share, add asset and recipients, revoke access	**Microsoft Purview collection role**: minimum of Data Reader to use the Microsoft Purview portal experience, none to use API or SDK
	Storage account role checked when adding and updating asset: Owner or Storage Blob Data Owner
	Storage account permissions checked when adding and updating asset: Microsoft.Authorization/roleAssignments/write OR Microsoft.Storage/storageAccounts/blobServices/containers/blobs/modifyPermissions/
Data consumer: Receive share, attach share, delete share	**Microsoft Purview collection role**: minimum of Data Reader to use the Microsoft Purview portal experience, none to use API or SDK
	Storage account role checked when attaching share: Contributor OR Owner OR Storage Blob Data Contributor OR Storage Blob Data Owner

Operations	Roles and Permissions
	Storage account permissions checked when attaching share: Microsoft.Storage/storageAccounts/write OR Microsoft.Storage/storageAccounts/blobServices/containers/write
Data consumer: Access shared data	No share-specific role required. You can access shared data with regular storage account permission just like any other data. Data consumer's ability to apply ACLs for shared data is currently not supported.

How can I share data from containers?

When adding assets, you can select the container(s) that you would like to share.

Can I share data in-place with storage account in a different Azure region?

Cross-region in-place data sharing isn't currently supported for storage account. Data provider and data consumer's storage accounts need to be in the same Azure region.

Is there support for read-write shares?

Storage in-place sharing supports read-only shares. Data consumer can't write to the shared data.

To share data back to the data provider, the data consumer can create a share and share with the data provider.

Can I access shared data from analytics tools like Azure Synapse?

You can access shared data from storage clients like Azure Synapse Analytics Spark and Databricks. You won't be able to access shared data using Azure Data Factory, Power BI, or AzCopy.

Does the recipient of the share need to be a user's email address or can I share data with an

application?

Through the UI, you can share data with recipient's Azure sign-in email or using service principal's object ID and tenant ID.

Through API and SDK, you also send invitation to object ID of a user principal or service principal. Also, you can optionally specify a tenant ID that you want the share to be received into.

Is the recipient accepting the share only for themselves?

When the recipient attaches the share to a target storage account, any user or application that has access to the target storage account will be able to access shared data.

If the recipient leaves the organization, what happens to the received share?

Once the received share is accepted and attached to a target storage account, any users with appropriate permissions to the target storage account can continue to access the shared data even after the recipient has left the organization.

Once the received share is accepted, any user with data reader permission to the Microsoft Purview collection that the share is received into can view and update the received share.

How do I request an increase in limits for the number of shares?

Data provider's source storage account can support up to 20 targets, and data consumer's target storage account can support up to 100 sources. To request a limit increase, contact support.

How do I troubleshoot data sharing issues?

To troubleshoot issues with sharing data, refer to the troubleshooting section of the how to share data article. To troubleshoot issues with receiving share, refer to the

troubleshooting section of the how to receive share article.

Is there support for Private endpoints, VNET and IP restrictions?

Private endpoints, VNET, and IP restrictions are supported for data share for storage. Blob should be chosen as the target subresource when creating a private endpoint for storage accounts.

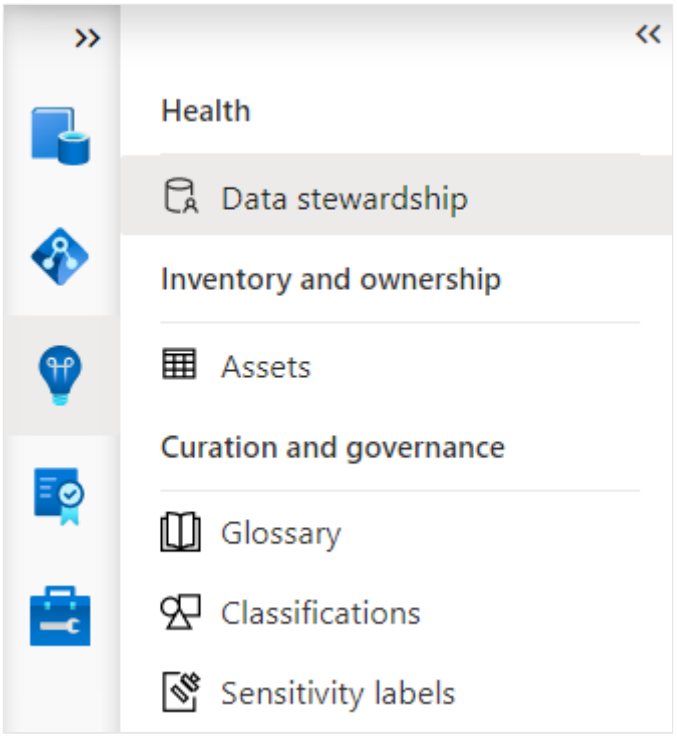
Understand the Microsoft Purview Data Estate Insights application

Article • 02/24/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

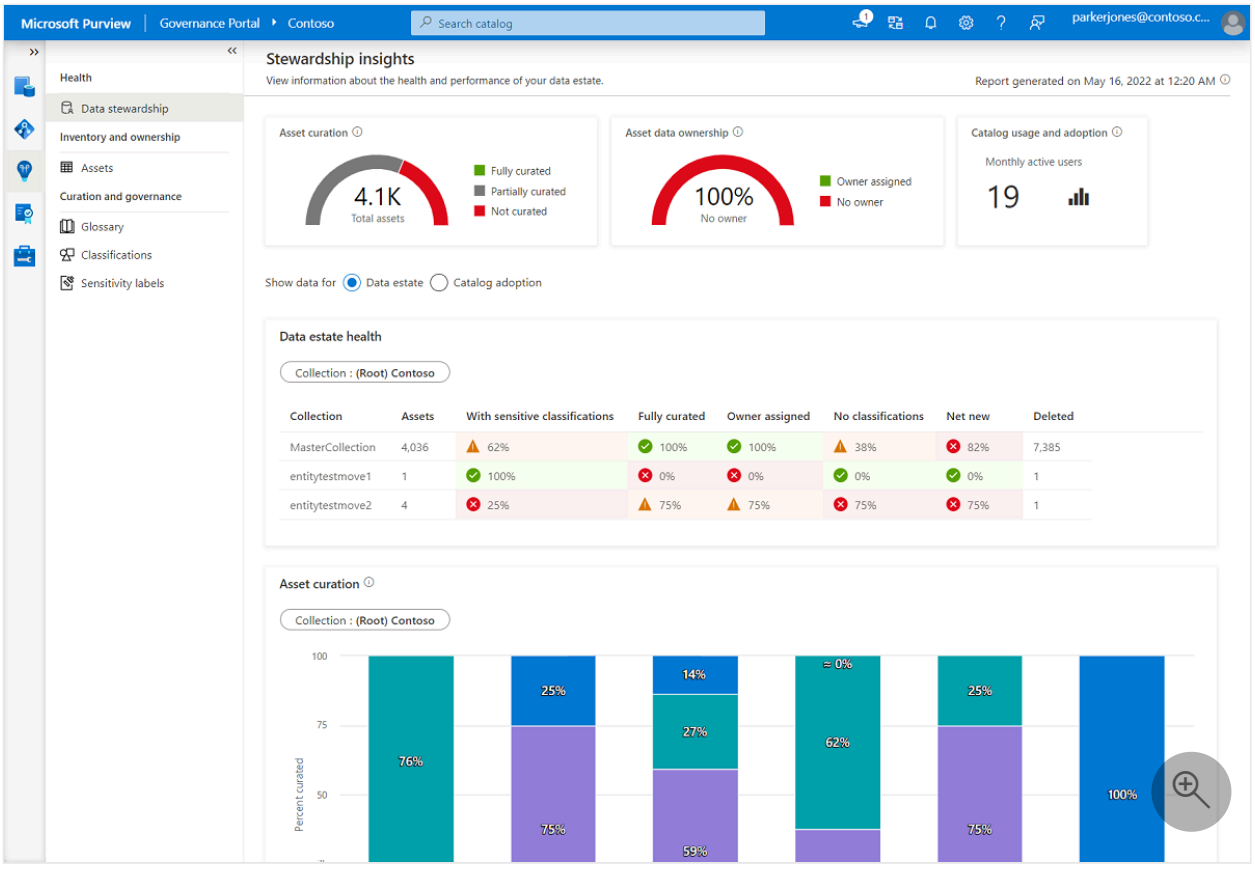


This article provides an overview of the Data Estate Insights application in Microsoft Purview.

The Data Estate Insights application is purpose-built for governance stakeholders, primarily for roles focused on data management, compliance, and data use: like a Chief Data Officer. The application provides actionable insights into the organization's data estate, catalog usage, adoption, and processes. As organizations scan and populate their Microsoft Purview Data Map, the Data Estate Insights application automatically extracts valuable governance gaps and highlights them in its top metrics. Then it also provides drill-down experience that enables all stakeholders, such as data owners and data stewards, to take appropriate action to close the gaps.

All the reports within the Data Estate Insights application are automatically generated and populated, so governance stakeholders can focus on the information itself, rather than building the reports.

The dashboards and reports available within Microsoft Purview Data Estate Insights are categorized in three sections:



- Health
- Inventory and Ownership
- Curation and governance

> **Note**
>
> If you're using the new Microsoft Purview portal, these same reports are still available, but are accessed inside the **Data Catalog**.

Health

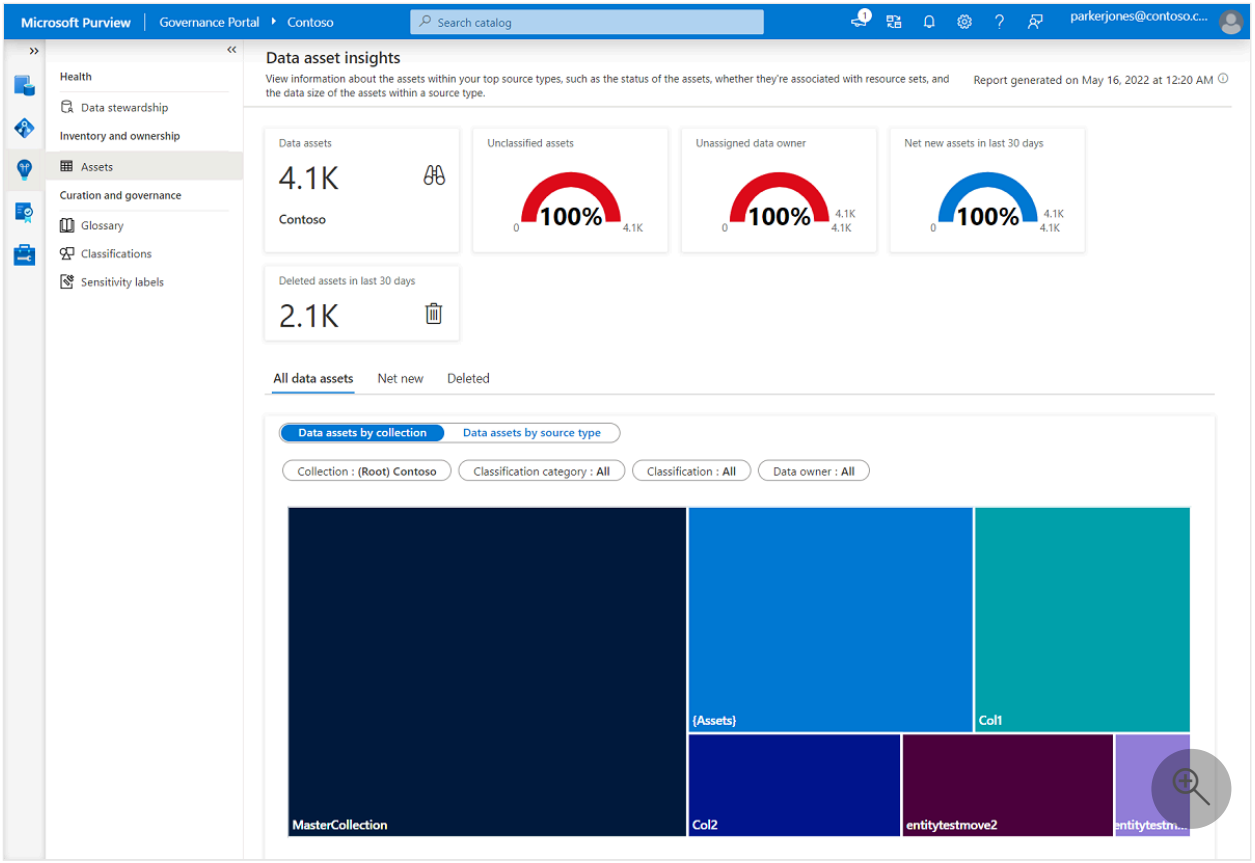
Data, governance, and quality focused users like chief data officers and data stewards can start at the health dashboards to understand the current health status of their data estate, current return on investment on their catalog, and begin to address any outstanding issues.

Data stewardship

The data stewardship dashboard highlights key performing indicators that the governance stakeholders need to focus on, to attain a clean and governance-ready data estate. Information like asset curation rates, data ownership rates, and classification rates are calculated out of the box and trended over time.

Management-focused users, like a Chief Data Officer, can also get a high-level understanding of weekly and monthly active users of their catalog, and information about how the catalog is being used. Is the catalog being adopted across their organization, as better adoption leads to better overall governance penetration in the organization?

For more information about these dashboards, see the data Stewardship documentation.



Catalog adoption

The catalog adoption dashboard highlights active users, searches, viewed assets, and top searched keywords. This report helps you understand how and if your data catalog is being used, so you can see the impact it's having on data usage and discoverability.

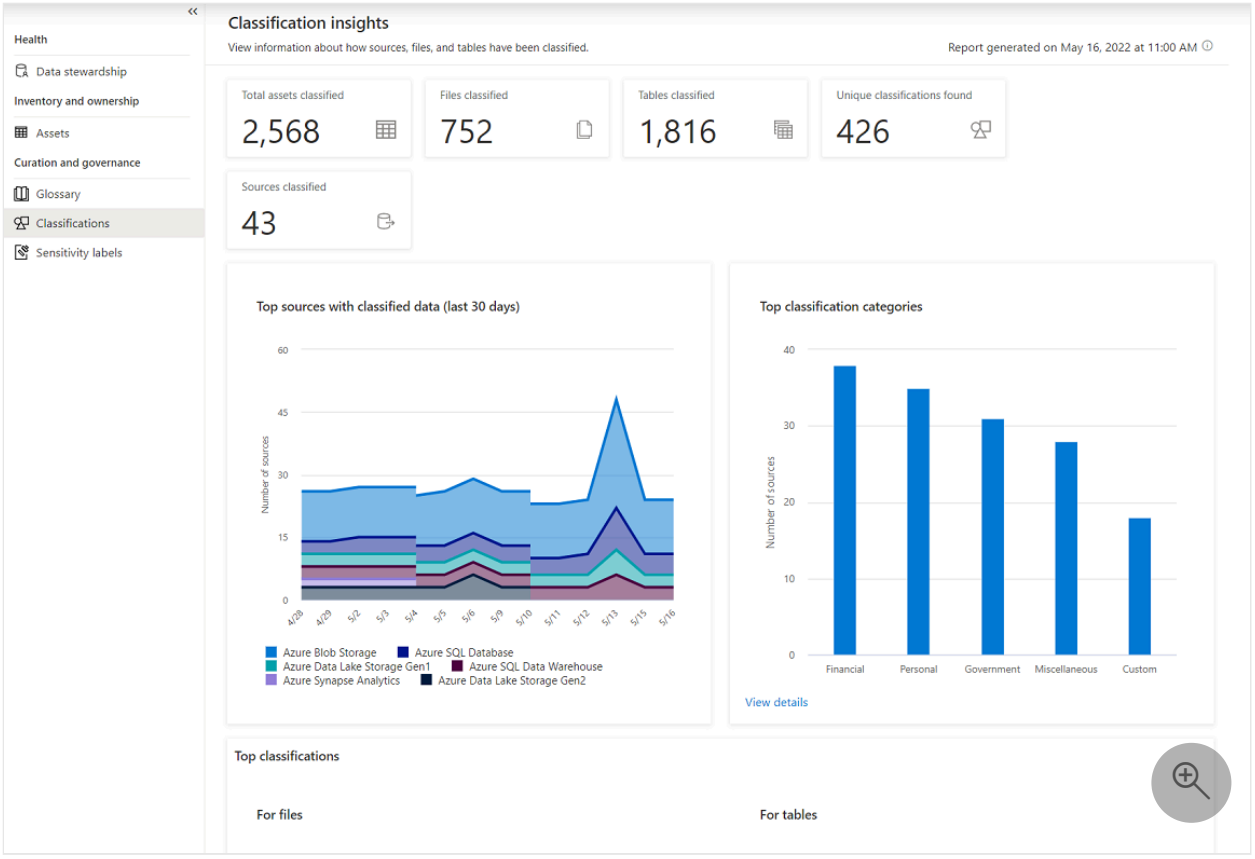
For more information about these dashboards, see the catalog adoption documentation.

Inventory and ownership

This area focuses on summarizing data estate inventory for data quality and management focused users, like data stewards and data curators. These dashboards provide key metrics and overviews to give users the ability to find and resolve gaps in their assets, all from within the data estate insights application.

Assets

This report provides a summary of your data estate and its distribution by collection and source type. You can also view new assets, deleted assets, updated assets, and stale assets from the last 30 days.



Explore your data by classification, investigate why assets didn't get classified, and see how many assets exist without a data owner assigned. To take action, the report provides a “View Detail” button to view and edit the specific assets that need treatment.

You can also view data asset trends by asset count and data size, as we record this metadata during the data map scanning process.

For more information, see the asset insights documentation.

Curation and governance

This area focuses on giving a summary of how curated your assets are by several curation contexts. Currently we focus on showcasing assets with glossary, classification, and sensitivity labels.

Glossary

Data, governance, and quality focused users like chief data officers and data stewards a status check on their business glossary. Data maintenance and collection focused users like Data Stewards can view this report to understand distribution of glossary terms by status, learn how many glossary terms are attached to assets, and how many aren't yet attached to any asset. Business users can also learn about completeness of their glossary terms.

This report summarizes top items that use needs to focus on to create a complete and usable glossary for their organization. Users can also navigate into the "Glossary" experience from "Glossary Insights" experience, to make changes on a specific glossary term.

For more information, see the glossary insights in Microsoft Purview documentation.

Classifications

This report provides details about where classified data is located, the classifications found during a scan, and a drill-down to the classified files themselves. It enables data quality and data security focused users like data stewards, data curators, and security administrators to understand the types of information found in their organization's data estate.

In Microsoft Purview, classifications are similar to subject tags, and are used to mark and identify content of a specific type in your data estate.

Use the classification insights report to identify content with specific classifications and understand required actions, such as adding extra security to the repositories, or moving content to a more secure location.

For more information, see the classification insights about your data from Microsoft Purview documentation.

Sensitivity Labels

This report provides details about the sensitivity labels found during a scan and a drill-down to the labeled files themselves. It enables security administrators to ensure the security of the data found in their organization's data estate by identifying where sensitive data is stored.

In Microsoft Purview, sensitivity labels are used to identify classification type categories, and the group security policies that you want to apply to each category.

Use the labeling insights report to identify the sensitivity labels found in your content and understand required actions, such as managing access to specific repositories or files.

For more information, see the sensitivity label insights about your data in Microsoft Purview documentation.

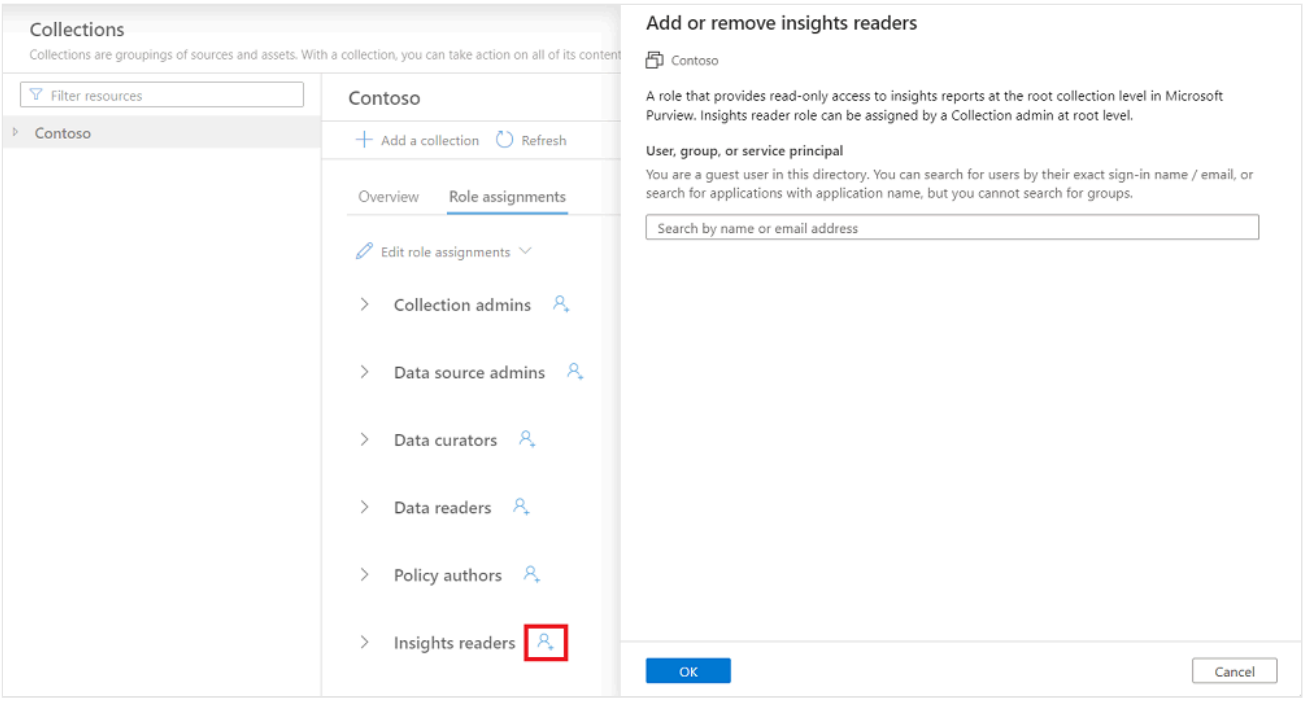
Access control in Data Estate Insights within Microsoft Purview

> **Note**
>
> Microsoft Purview Data Catalog (classic), Data Health Insights (classic), and Purview Workflow (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

Like all other permissions in Microsoft Purview, Data Estate Insights access is given through collections. This article describes what permissions are needed to access Data Estate Insights in Microsoft Purview.



Insights reader role

The insights reader role gives users read permission to the Data Estate Insights application in Microsoft Purview. However, a user with this role will only have access to information for collections that they also have at least data reader access to.

As Data Estate Insights application gives a bird's eye view of your data estate and catalog usage from a governance and risk perspective, it's intended for users who need to manage and report on this high-level information, like a Chief Data Officer. You may not want, or need, all your data readers to have access to the Data Estate Insights dashboards.

Role assignment

- **Insights Reader** role can be assigned to any Data Map user, by the **Data Curator of the root collection**. Users assigned the Data Curator role on subcollections don't have the privilege of assigning insights reader.

- A **Data Curator** of any collection also has read permission to Data Estate Insights application. Their scope of insights will be limited to the metadata assigned to collections. In other words, a Data Curator at a subcollection will only view KPIs and aggregations on collections they have access to. A Data Curator can still view and edit assets from Data Estate Insights app, without any extra permissions.

- A **Data Reader** at any collection node, can see Data Estate Insights app on the left navigation bar, however, when they hover on the icon, they'll receive a message saying they need to contact Data Curator at root collection for access. Once a Data Reader has been assigned the Insights Reader role, they can view KPIs and aggregations based on the collections they have Data Reader permission on. A Data Reader can't edit assets or select "***Export to CSV***" from the app.

> ⓘ **Note**
>
> All roles other than Data Curator, will need explicit role assignment as **Insights Reader** to be able to click into the Data Estate Insights app.

Disable Data Estate Insights or report refresh

> **Note**
>
> Microsoft Purview Data Catalog (classic), Data Health Insights (classic), and Purview Workflow (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

Microsoft Purview Data Estate Insights automatically aggregates metrics and creates reports about your Microsoft Purview account and your data estate. When you scan registered sources and populate your Microsoft Purview Data Map, the Data Estate Insights application automatically identifies governance gaps and highlights them in its top metrics. It also provides drill-down experience that enables all stakeholders, such as data owners and data stewards, to take appropriate action to close the gaps.

These features are optional and can be enabled or disabled at any time. This article provides the specific steps required to enable or disable Microsoft Purview Data Estate Insights features.

To reschedule without disabling, see the article to schedule Data Estate Insights reports.

> **Important**
>
> The Data Estate Insights application is **on** by default when you create a Microsoft Purview account.
>
> **State** is set to On.
>
> **Refresh Schedule** is set to a weekly refresh that begins 7 days after the account is created.
>
> As the Data Map is populated and curated, Insights App shows data in the reports. The reports are ready for consumption to anyone with Insights Reader role.

If you don't plan on using Data Estate Insights for a time, a **data curator** **on the** **root collection** can disable the Data Estate Insights in one of two ways:

- Disable the Data Estate Insights application - this will stop billing from both report generation and report consumption.
- Disable report refresh - Insights readers have access to current reports, but reports won't be refreshed. Billing will occur for report consumption but not report generation.

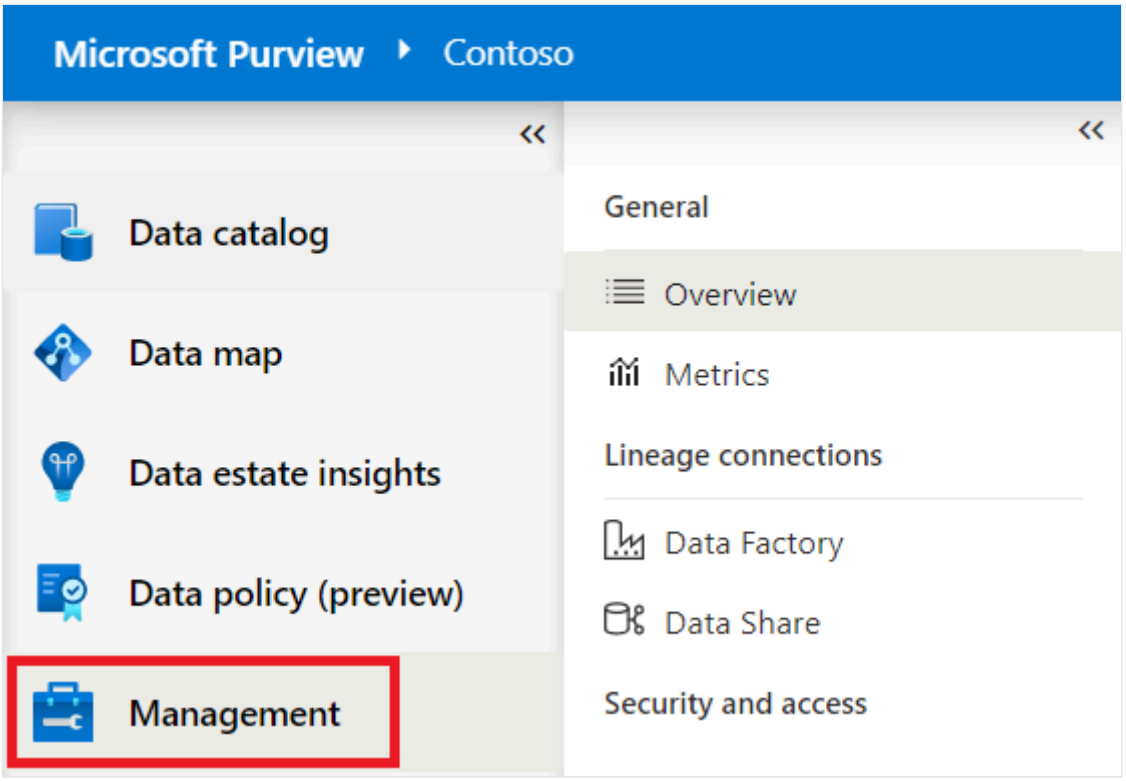
Steps for both methods, and for re-enablement, are below.

For more information about billing for Data Estates Insights, see our pricing guidelines.

Disable the Data Estate Insights application

> **Note**
>
> To be able to disable this application, you will need to have the **data curator role** on your account's **root collection.**

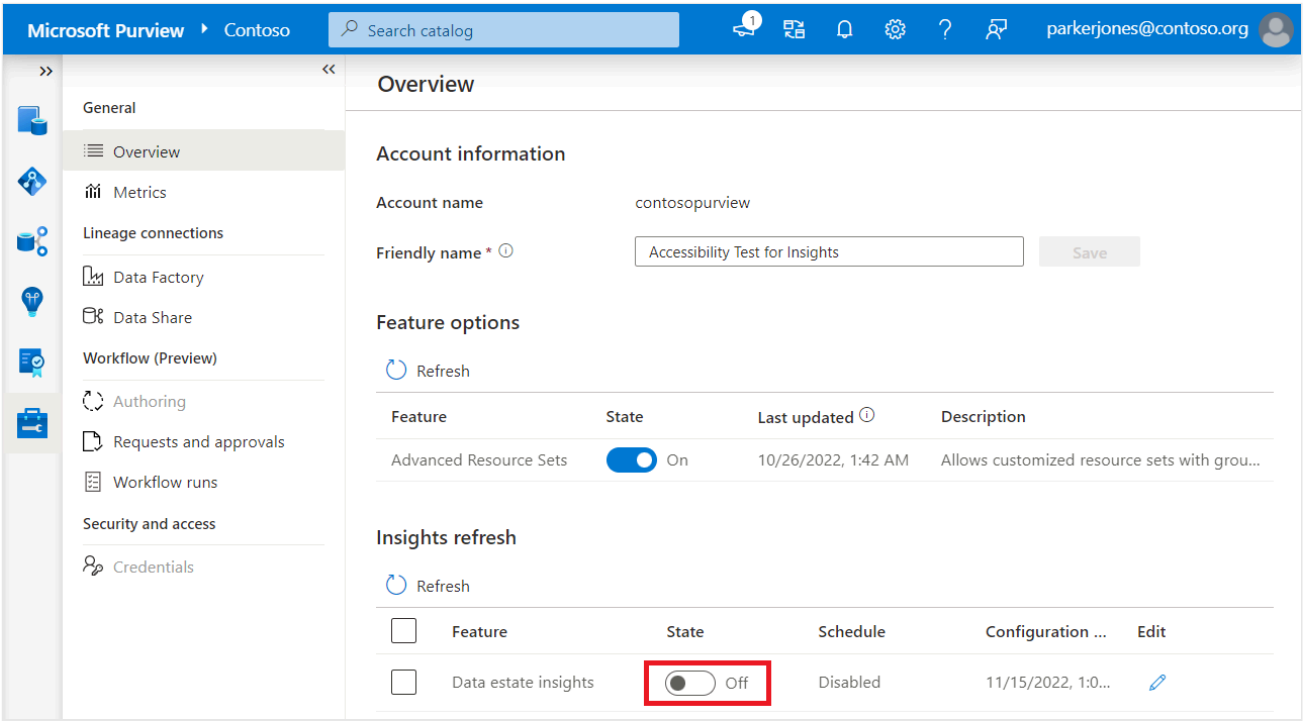
Disabling Data Estate Insights will disable the entire application, including these reports:



- Stewardship
- Asset
- Glossary
- Classification
- Labeling

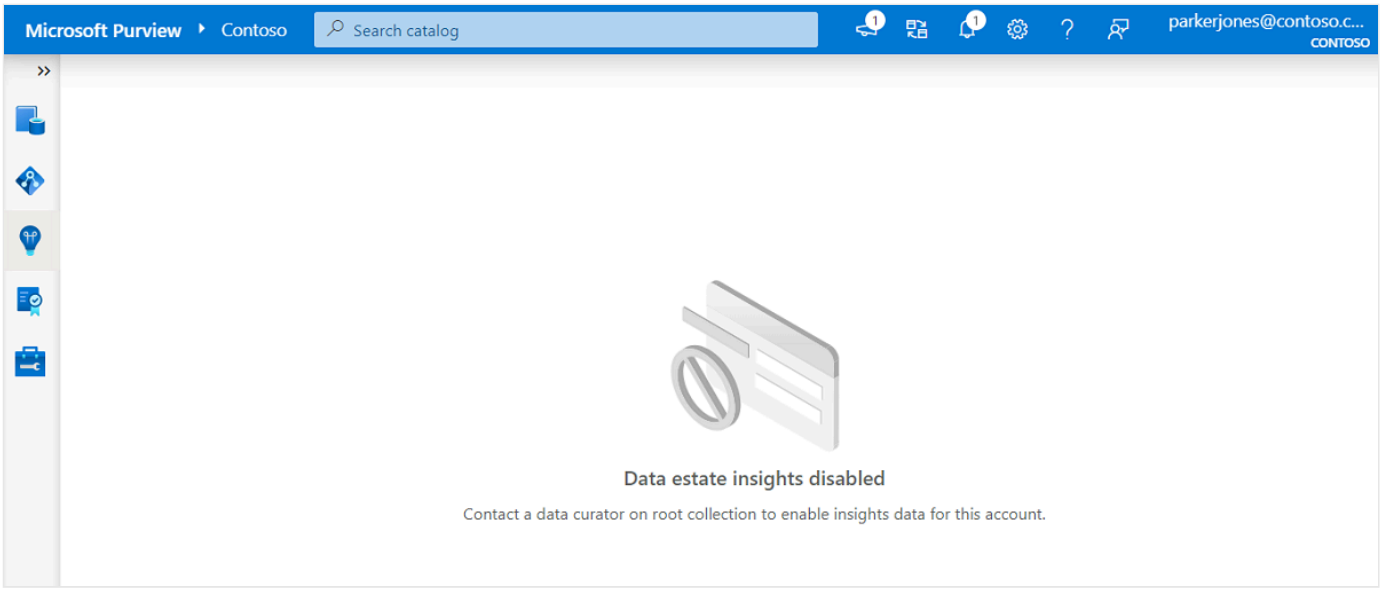
The application icon will still show in the menu, but insights readers won't have access to reports at all, and report generation jobs will be stopped. The Microsoft Purview account won't receive any bill for Data Estate Insights.

To disable the Data Estate Insights application, a user with the data curator role at the root collection can follow these steps:



1. If you're using the Microsoft Purview portal, the schedule can't be changed; all classic reports are set to refresh weekly by default. Classic reports in the new Microsoft Purview don't impact your billing.

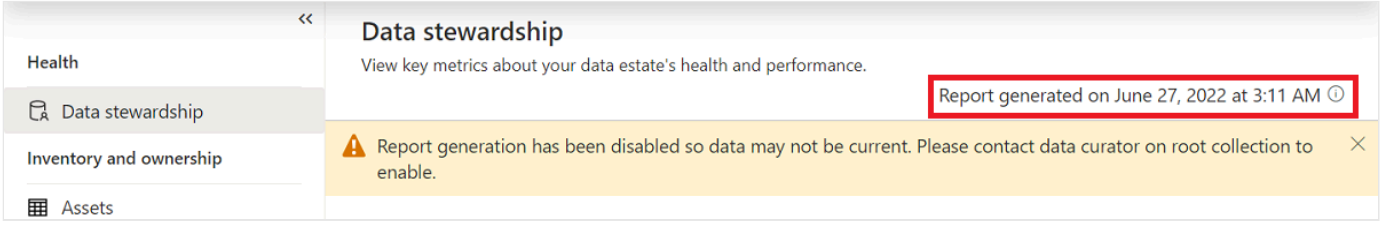
2. In the Microsoft Purview governance portal, go to the **Management** section.



3. Then select **Overview**.

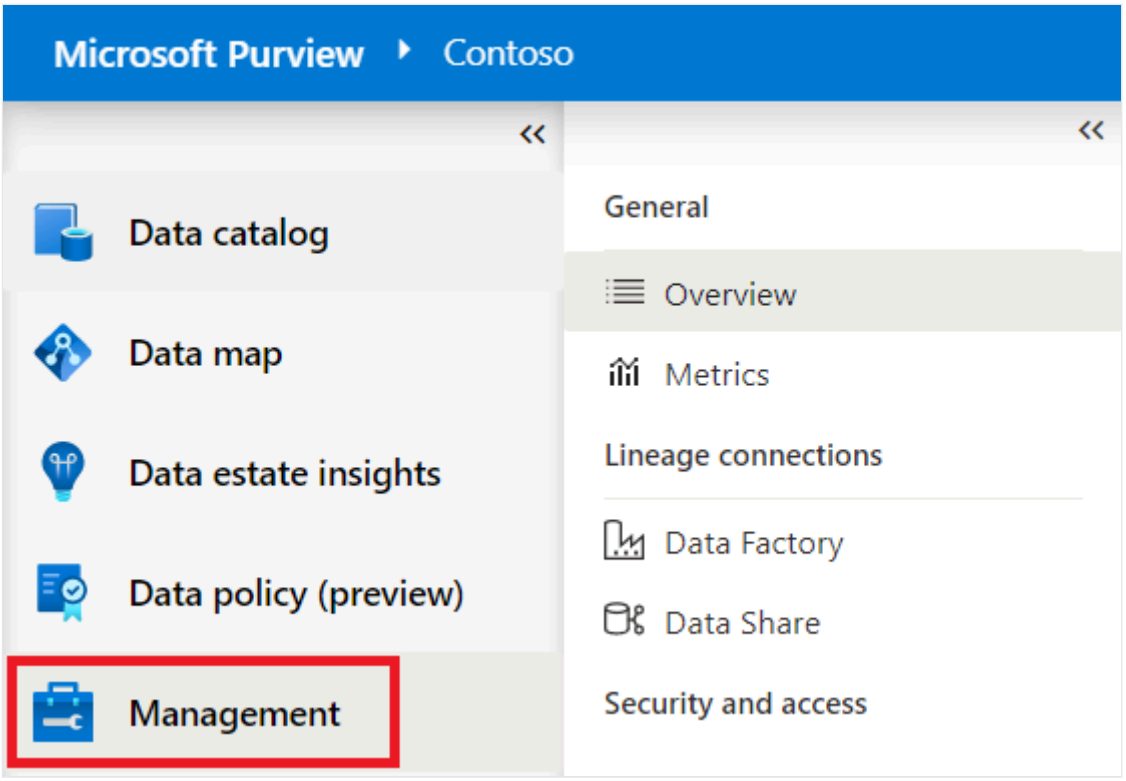
4. In the **Feature options** menu, locate Data Estate Insights, and select the **State** toggle to change it to **Off**.

Once you have disabled Data Estate Insights, the icon will still appear in the left hand menu, but users will receive a warning stating that the application has been disabled when attempting to access it.



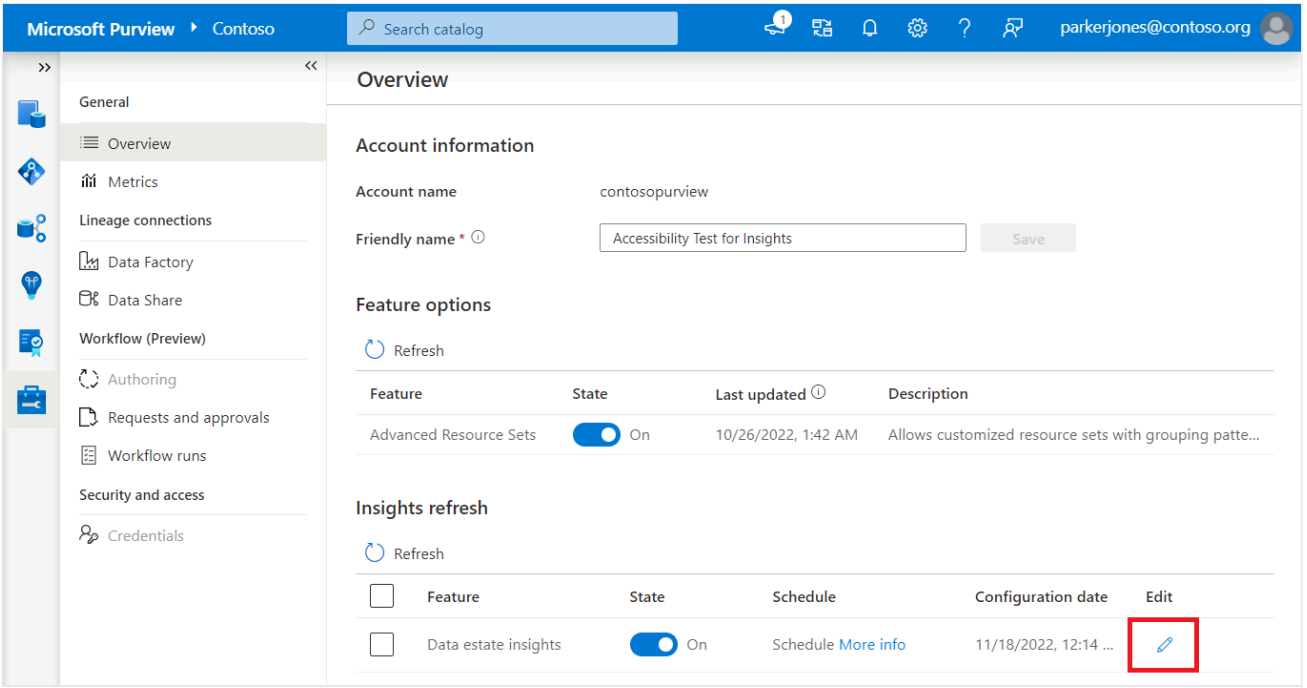
Disable report refresh

> **Note**
>
> To be able to disable or edit report refresh, you will need to have the data curator role on your account's root collection.



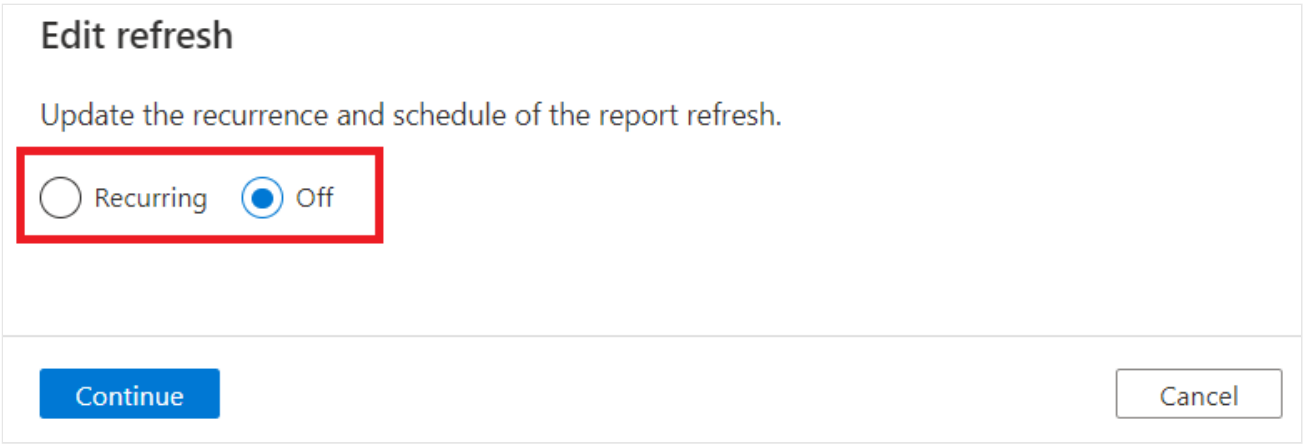
You can choose to disable report refreshes instead of disabling the entire Data Estate Insights application. When you disable report refreshes, users with the insights reader role will still be able view reports, but they'll see warning at the top of each report indicating that the data may not be current and the date of the last refresh.

Graphs that show data from the last 30 days will appear blank after 30 days while graphs showing snapshot of the data map will continue to show graphs and details.



To disable the Data Estate Insights report refresh, a user with the data curator role at the root collection can follow these steps:

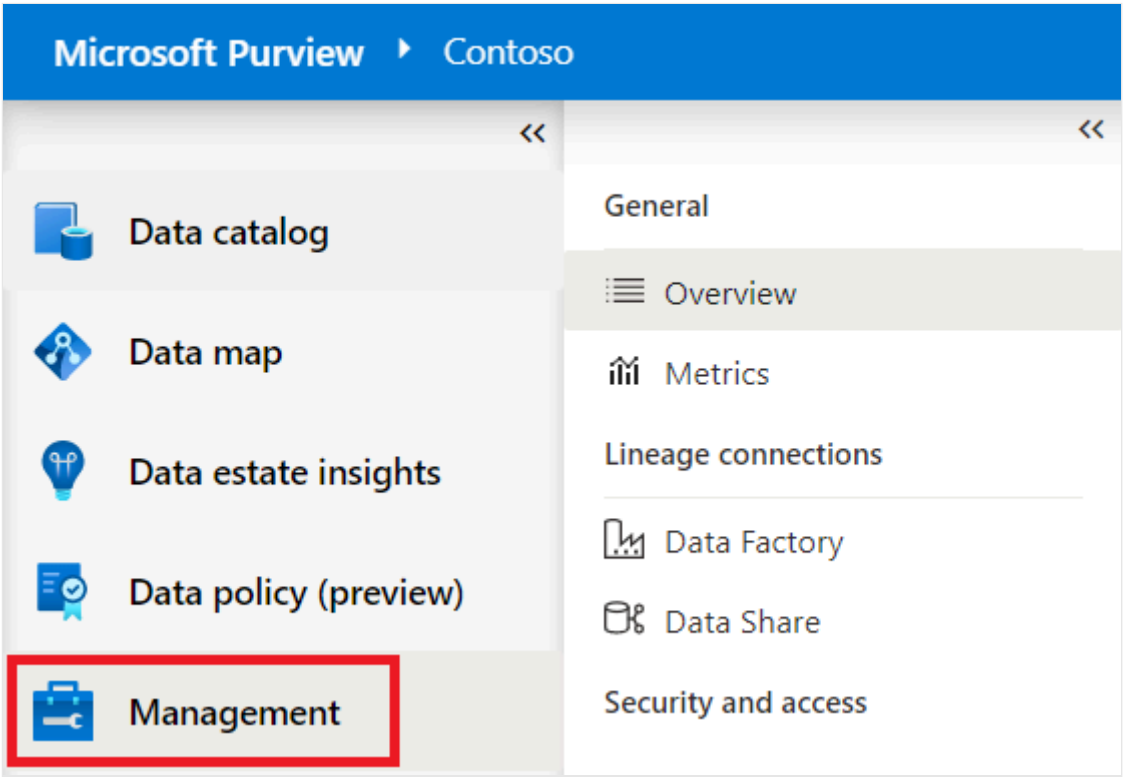
1. In the Microsoft Purview governance portal, go to the **Management** section.



2. Then select **Overview**.

3. In the **Insights refresh** menu, locate Data Estate Insights and select the **Edit pencil**

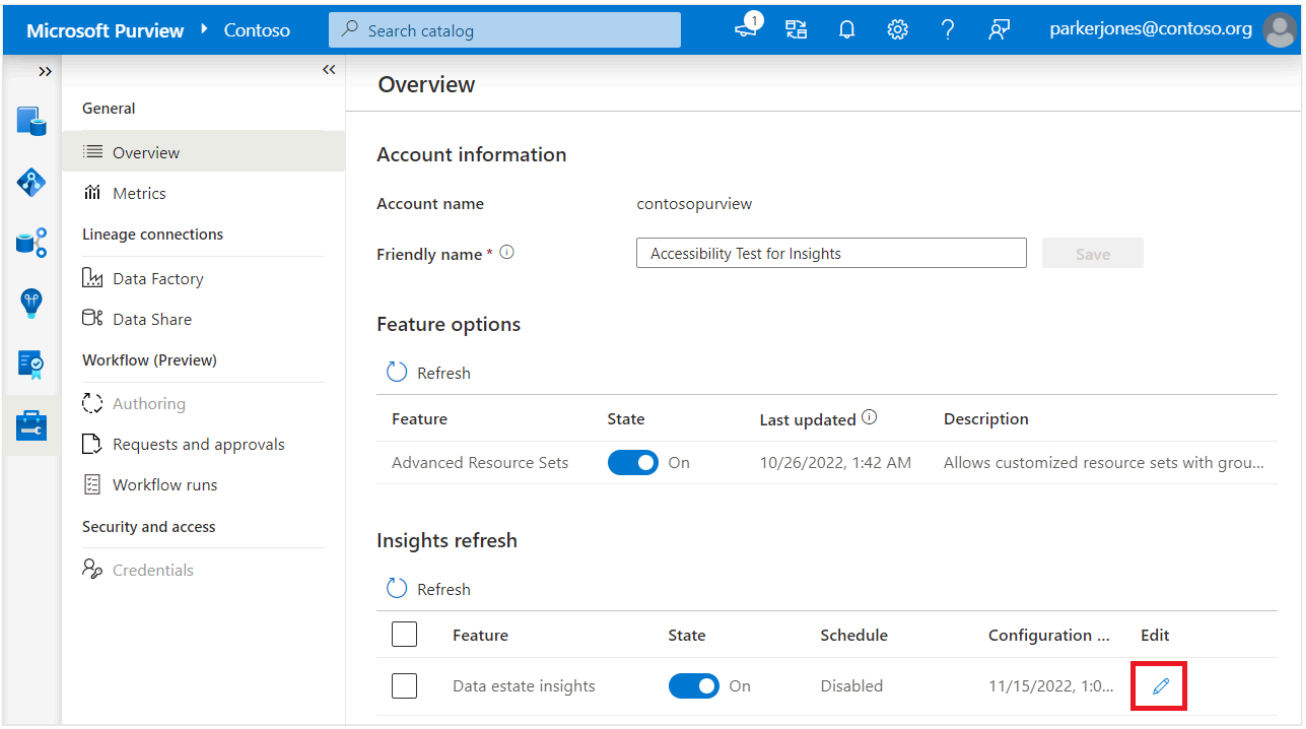
4. Select the **Off** radio button and select **Continue**. If prompted, review your edits and select **Save.**



5. You can now see under the **Schedule** column, the refresh schedule reads as **Disabled**.

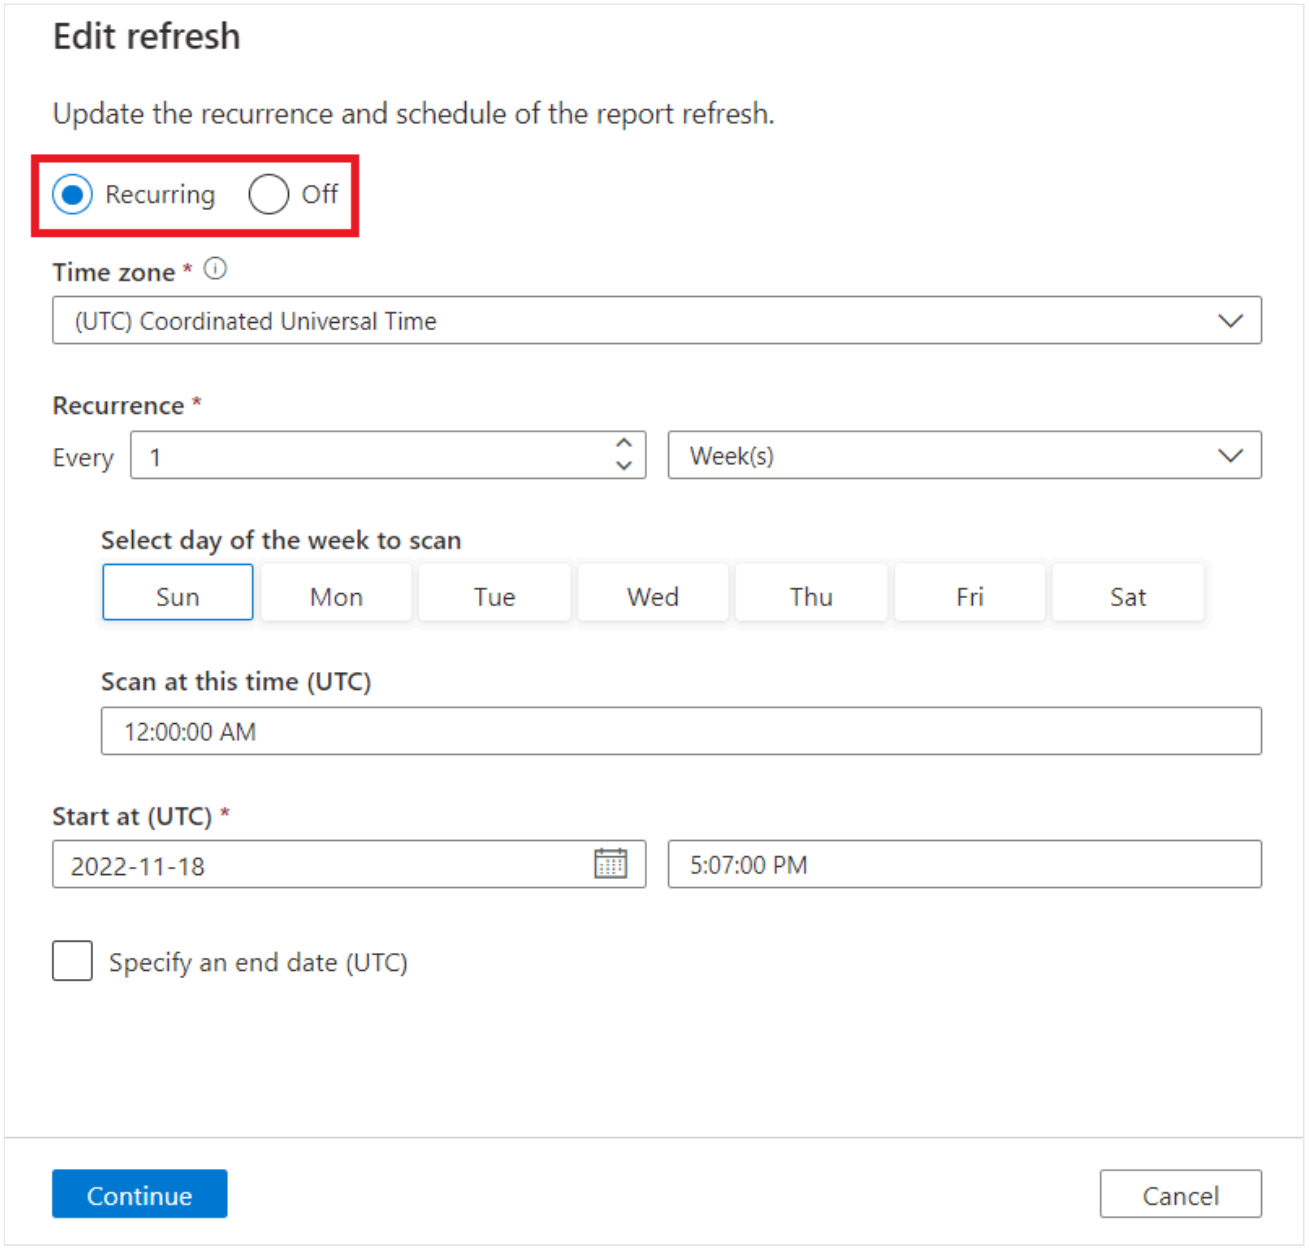
Re-enable Data Estate Insights and report refresh

> **Note**
>
> To enable Data Estate Insights, enable report refresh, or edit report refresh, you will need to have the data curator role on your account's root collection.



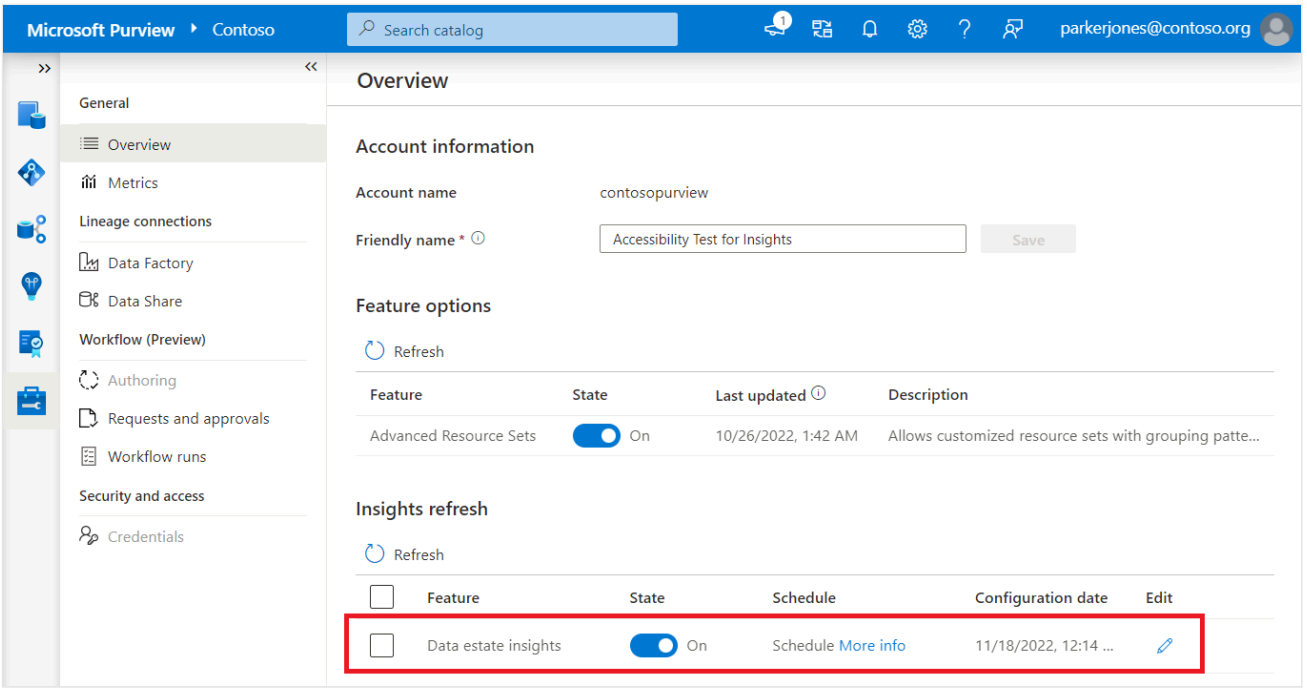
If Data Estate Insights or report refresh has been disabled in your Microsoft Purview governance portal environment, a user with the data curator role at the root collection can re-enable either at any time by following these steps:

1. In the Microsoft Purview governance portal, go to the **Management** section.



2. Then select **Overview**.

3. In the **Insights refresh** menu, locate Data Estate Insights, and select the **Edit** pencil.



4. In the **Edit** menu, select **Recurring**.

5. Then select your time zone, set your recurrence to **Month(s)** or **Weeks(s)**, select your day and time to run, specify a start time, and optionally specify an end time. For more information about the available options, see the article to schedule Data Estate Insights reports.

6. Select **Continue**. If prompted, review the updates and select **Save**.

7. Now you can see your schedule is set. Selecting **More info** in the schedule columns will give you the recurrence details.

Schedule Data Estate Insights reports refresh

Article • 02/24/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

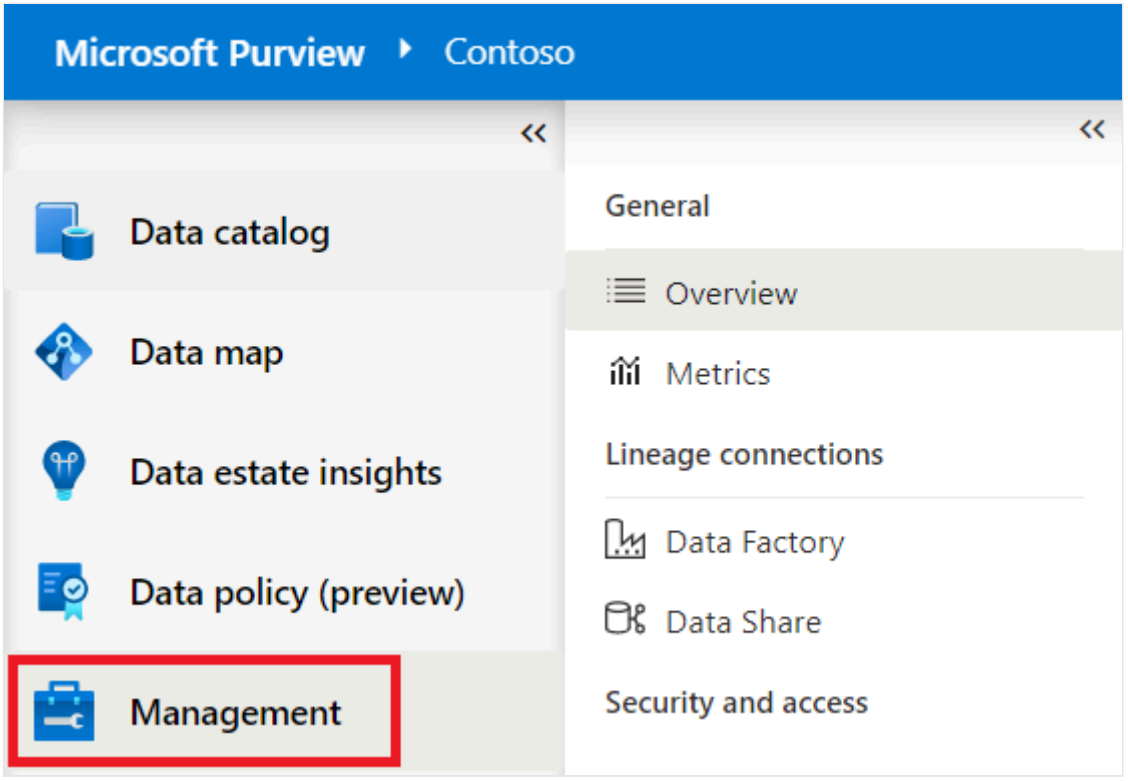
Microsoft Purview Data Estate Insights automatically creates reports that help you to identify governance gaps in your data estate. However, you can set the schedule for this automatic refresh to fit your reporting patterns and needs. In this article, we'll describe how you can schedule your refresh and what options are available.

If you would like to disable Data Estate Insights for a time, you can follow our article to disable Data Estate Insights.

> **Important**
>
> The Data Estate Insights application is **on** by default when you create a Microsoft Purview account.
>
> **Refresh Schedule** is set to a weekly refresh that begins 7 days after the account is created.
>
> As the Data Map is populated and curated, Insights App shows data in the reports. The reports are ready for consumption to anyone with Insights Reader role.

Permissions needed

To update the report refresh schedule for Data Estate Insights, you need **data curator permissions** on the **root collection**.

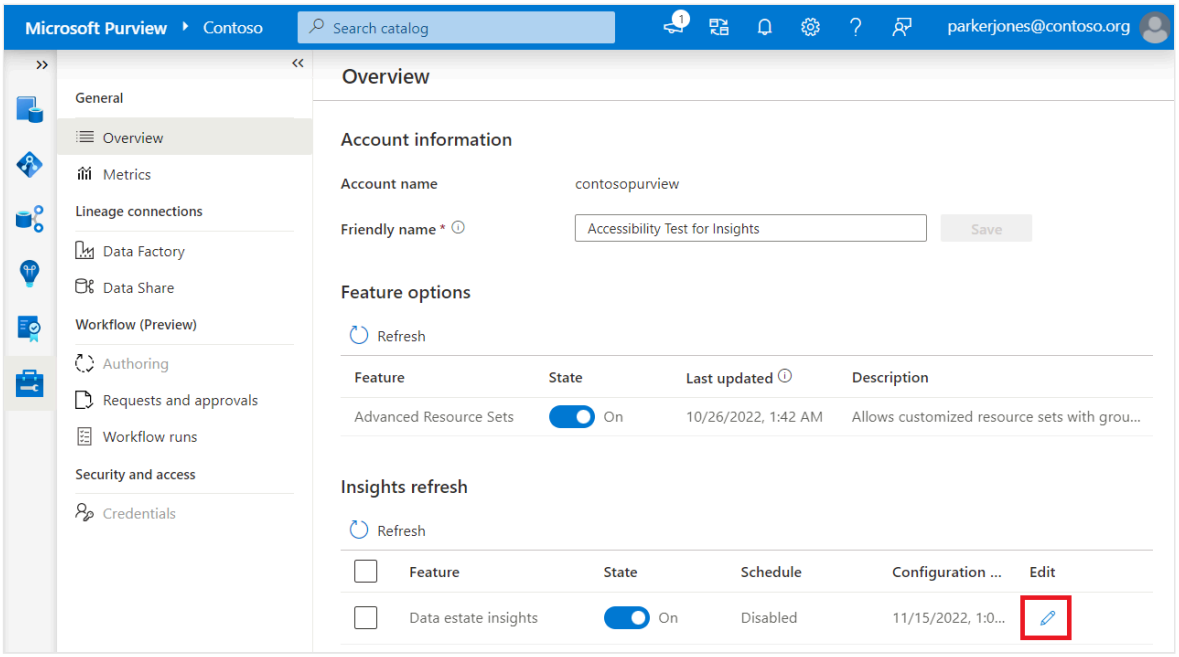


How to update the refresh schedule

> **Important**

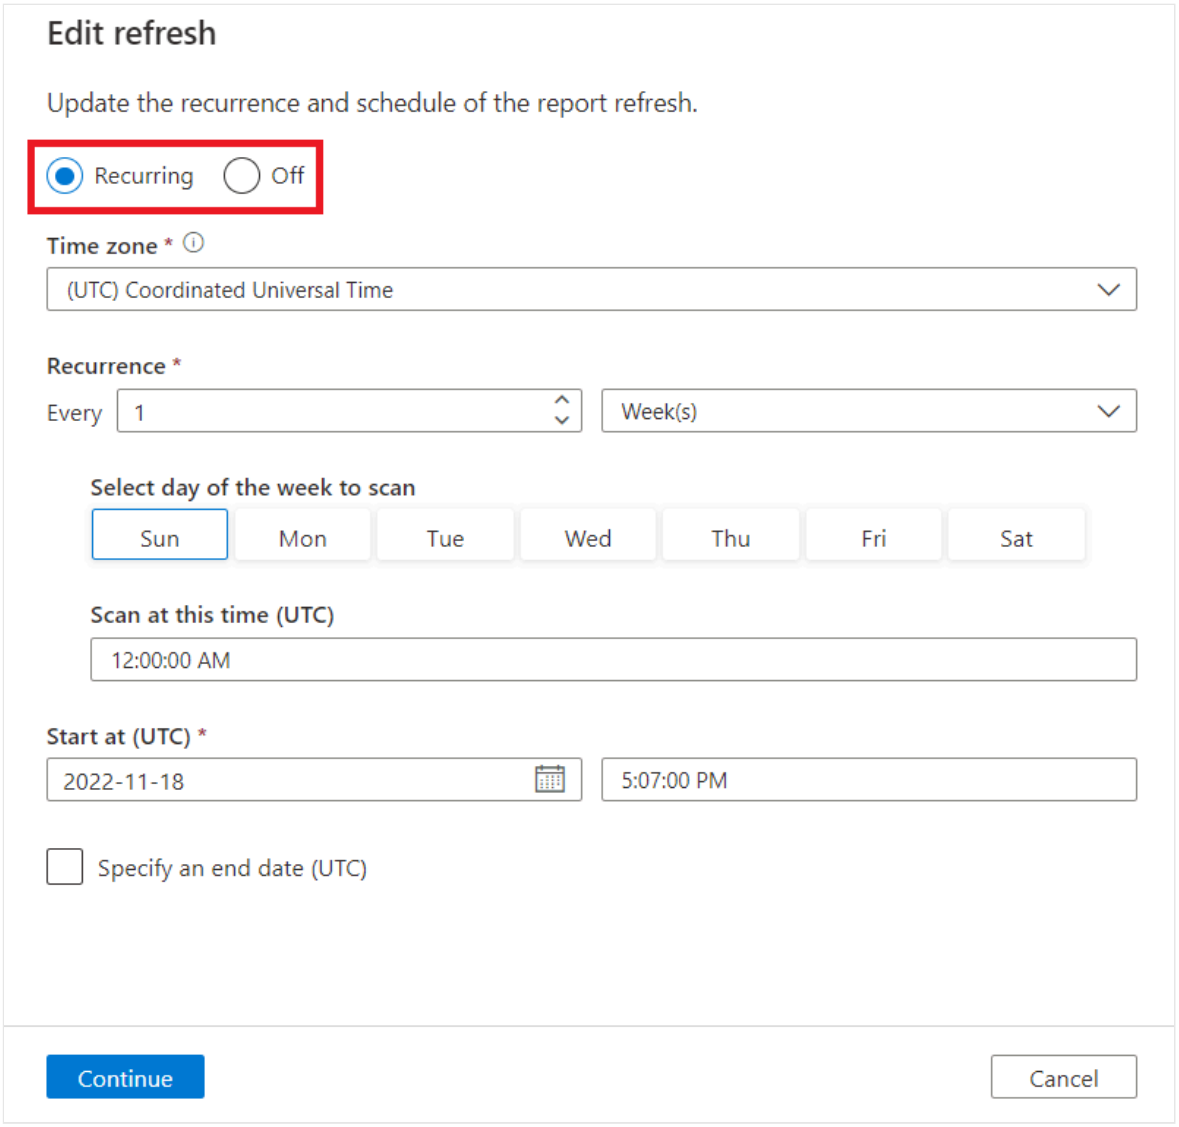
Report refresh rate does impact your billing.

1. If you're using the Microsoft Purview portal, the schedule can't be changed; all classic reports are set to refresh weekly by default. Classic reports in the new Microsoft Purview don't impact your billing.



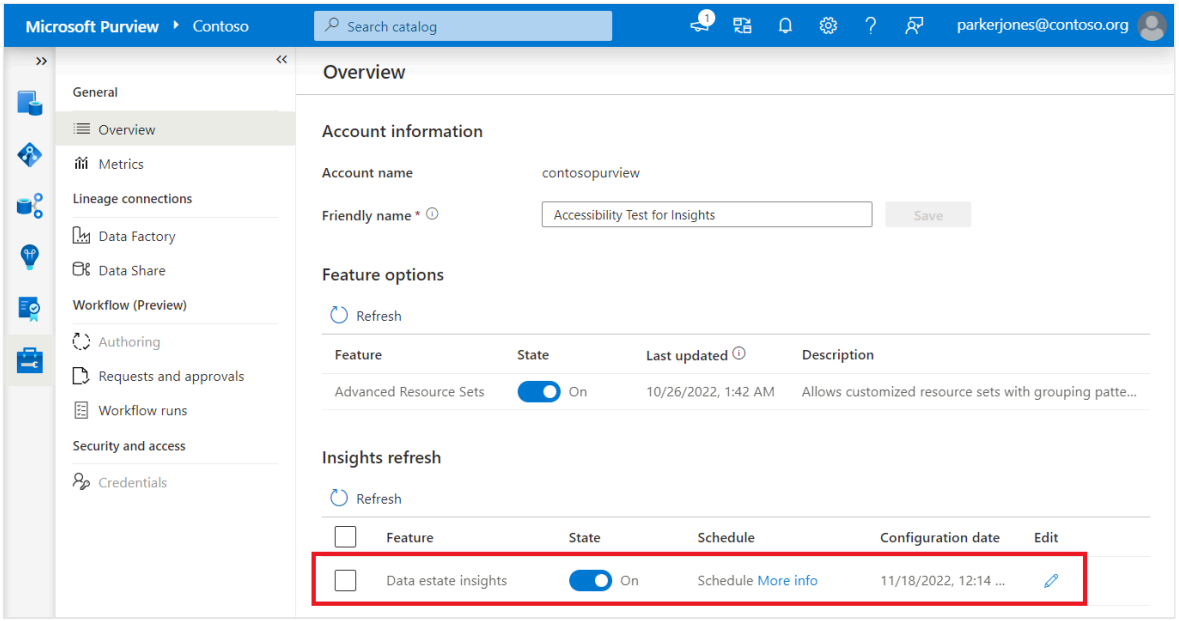
2. In the Microsoft Purview governance portal, go to the **Management** section.

3. Then select **Overview**.



4. In the **Insights refresh** menu, locate Data Estate Insights, and select the **Edit** pencil. For more information about the insights refresh menu, see the insights refresh menu section below.

> **Note**
>
> If the State is currently set to **Off** you need to first turn it **On** before you can update the refresh schedule.



5. In the **Edit** menu, select **Recurring**.

6. Then select your time zone, set your recurrence to **Month(s)**, **Weeks(s)**, or **Days(s)**, select your day and time to run, specify a start time, and optionally specify an end time. For more information about the schedule options, see the schedule options section below.

7. Select **Continue**. If prompted, review the updates and select **Save**.

8. Now you can see your schedule is set. Selecting **More info** in the schedule columns give you the recurrence details.

Does the refresh schedule affect billing?

Yes. You're billed when Microsoft Purview Data Estate Insights checks for updates in your environment and when a report is generated.

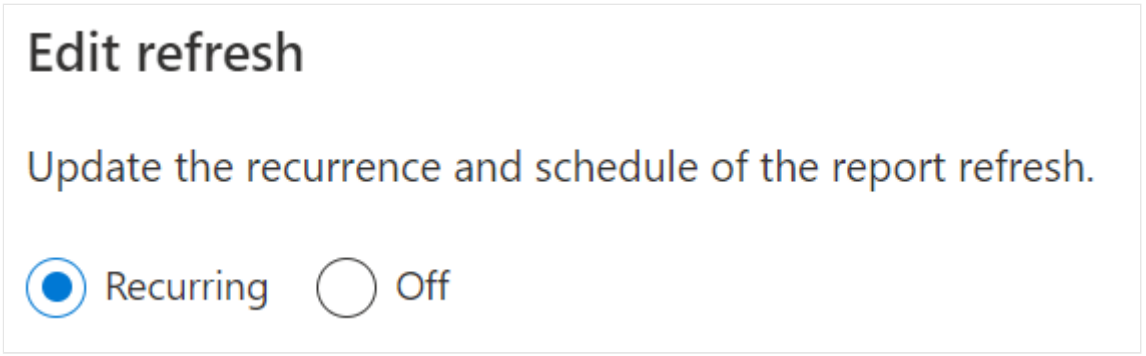
1. A check for updates to your Microsoft Purview instance is made at your scheduled report refresh time. You'll always be billed for this check at your report refresh time.

2. If updates have been made, you'll be billed to generate your insights report. If no updates were made since the last report, you'll not be billed to generate a report.

   > ⓘ **Note**
   >
   > An asset is considered to be **updated** if it's updated in Microsoft Purview. An update in Microsoft Purview means a change in the following properties: asset name, description, schema, classifications, experts, owners, etc. New rows in a data asset and a re-scan won't result in an update to your insights reports if the metadata properties haven't changed.

For more information about billing for Data Estates Insights, see our pricing guidelines.

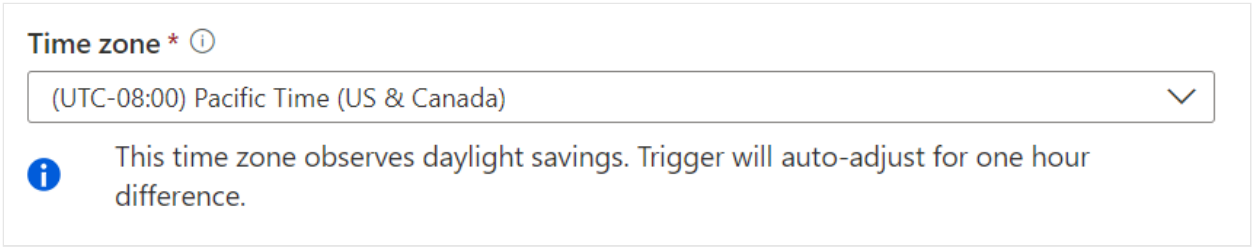
Schedule options



Below are listed all the schedule options currently available when you modify your refresh schedule:

- Recurring or off
- Time zone
- Recurrence
- Start at
- End date (optional)

Recurring or off

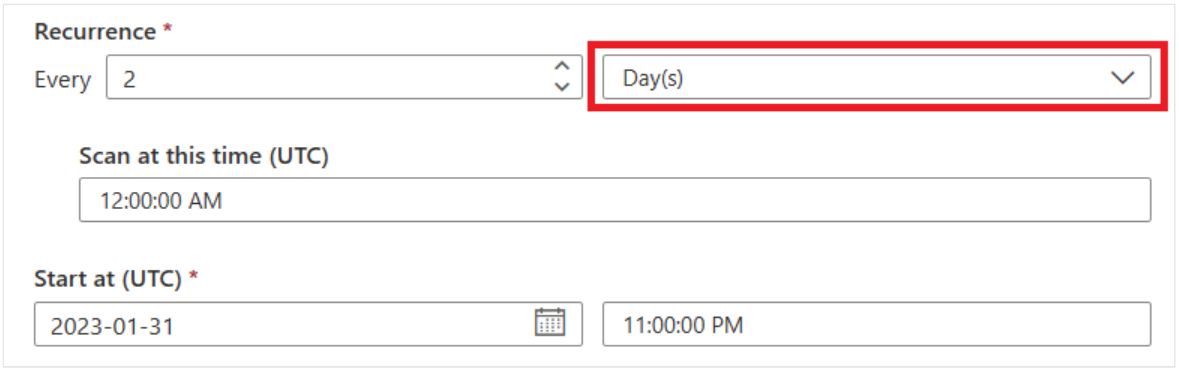


- **Recurring** - your Data Estate Insights report refreshes on the recurrence schedule you specify below, based on the time zone you indicate.

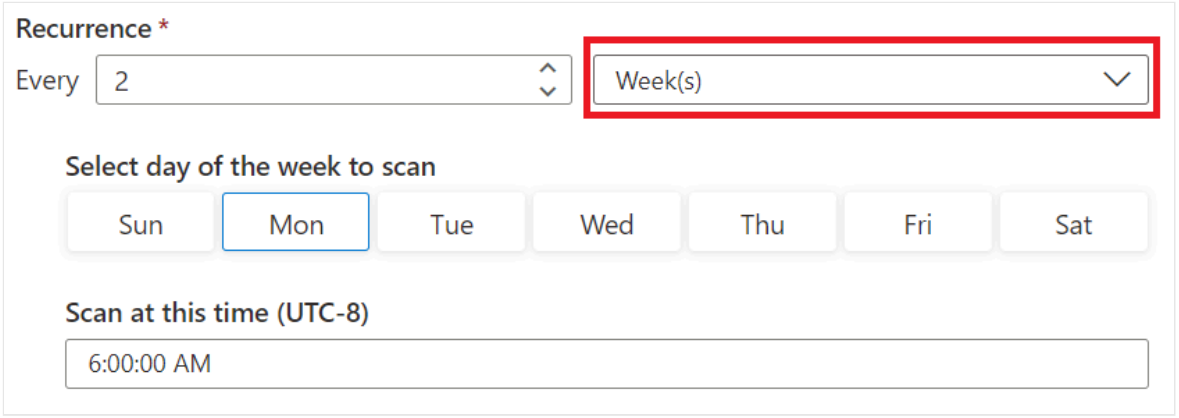
- **Off** - your Data Estate Insights reports will no longer refresh information, but the current reports remain available. For more information, see our disable Data Estate Insights article.

Time zone

Select the time zone you'd like to align your refresh schedule with. If the time zone you select observes daylight savings, your trigger auto-adjusts for the difference.

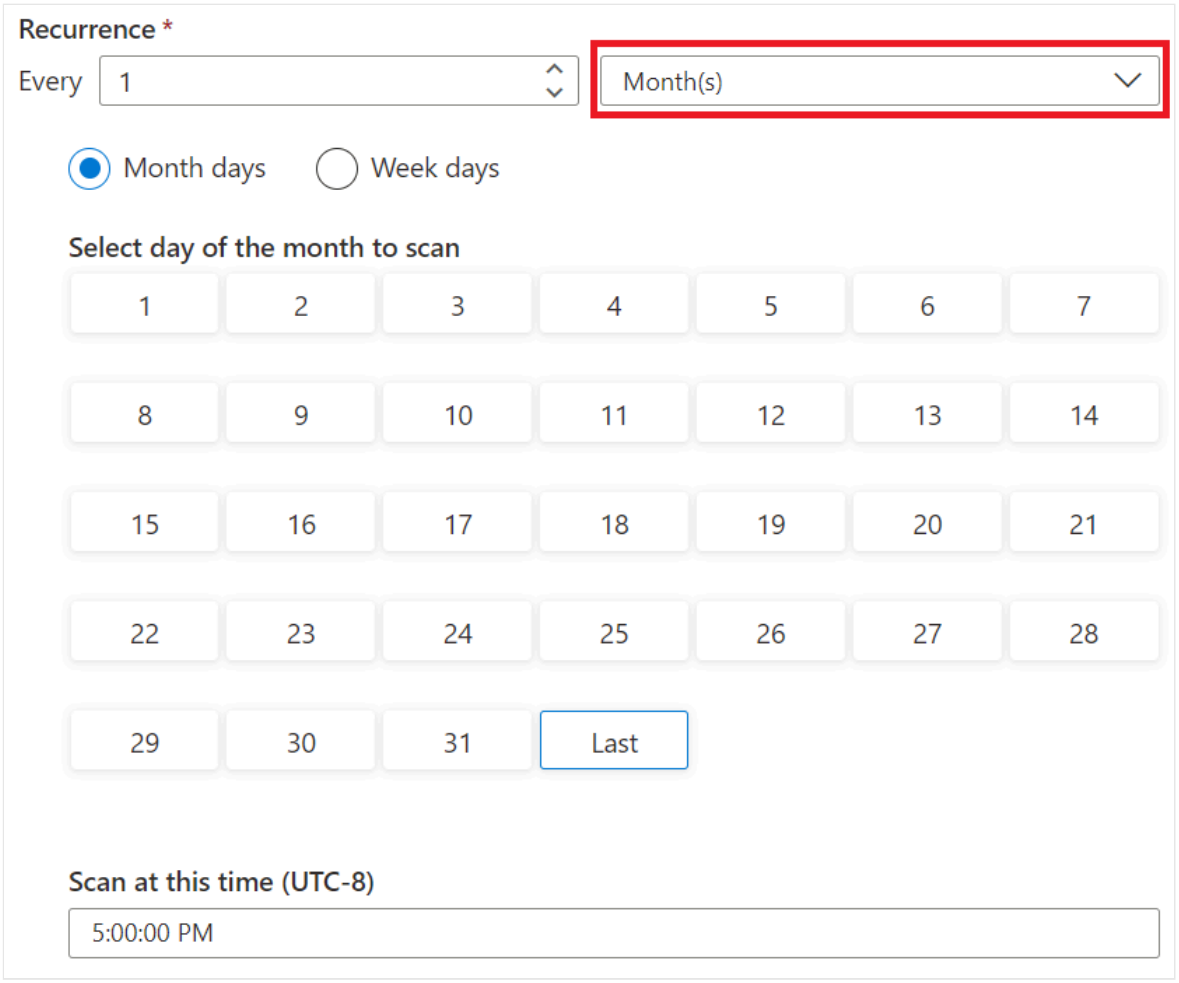


Recurrence



You can select a daily, weekly, or monthly refresh recurrence.

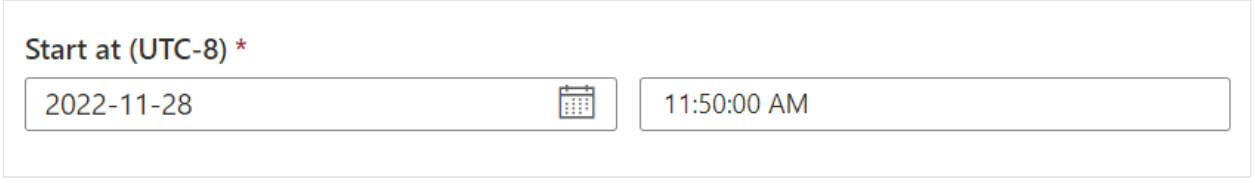
> **Important**
>
> No matter what you set your refresh recurreance to, Data Estate Insights run a check before refreshing to see if any updates have been made to the assets. If no update has been made, the reports won't refresh.
>
> An asset is considered to be **updated** only if it is updated in Microsoft Purview. An update in Microsoft Purview means a change in the following properties: asset name, description, schema, classifications, experts, owners, etc... New rows in a data asset and a re-scan won't result in an update to your insights reports if the metadata properties of the asset have not changed.



- **Daily recurrence** - schedule daily recurrence by setting recurrence to every (1-5) days, and choosing the time of day you would like to refresh the report. For example, the below report refreshes every other day at 12 AM UTC.

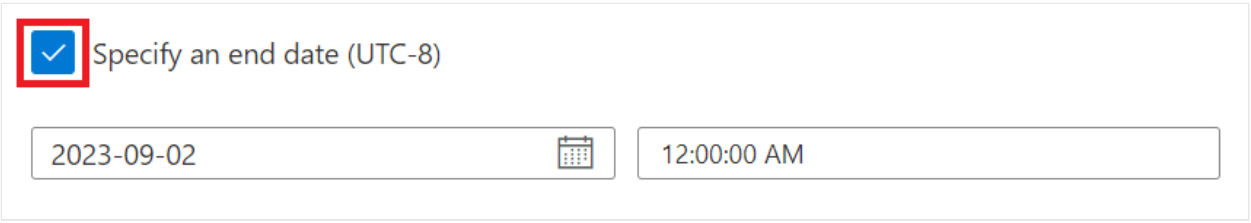
- **Weekly recurrence** - schedule weekly recurrence by setting recurrence to every (1-5) weeks, and choosing the day of the week and time of day you would like to refresh the report. For example, the below report refreshes on Monday every two weeks, at six AM.

- **Monthly recurrence** - schedule monthly recurrence by setting recurrence to every (1-5) months, and choosing the day of the month and time of day you would like to refresh the report. Choose **Last** to always run on the last day of the month, and **1** to always run on the first day of the month. For example, the below report refreshes on the last day of every month at five PM.



Set **Scan at this time** to the time of day you'd like to begin your refresh.

> **Tip**
>
> The time you select will be the time that the report begins its refresh. Microsoft Purview will adjust compute for the amount of data being aggregated, but **schedule your recurrence a little before you will need the report** so the report has time to fully refresh and will be ready.

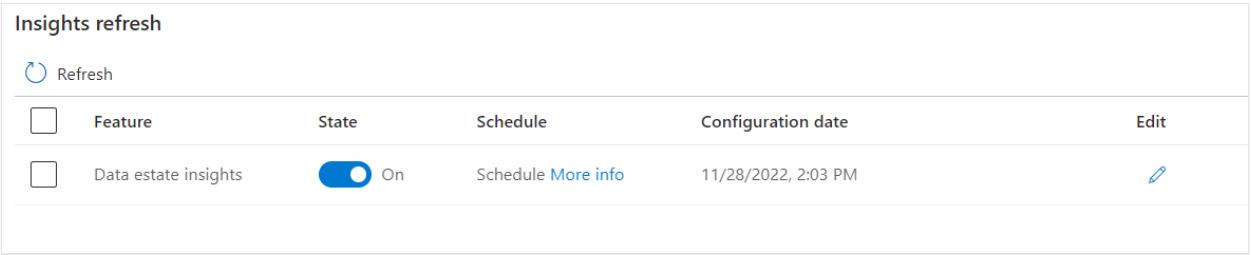


Start at

The **Start at** option allows you to set when your reports will begin their refresh schedule, and is relative to the time zone you selected. Set it for the current date and time to set the schedule immediately.

Specify an end date

If you want your reports to stop refreshing after a certain amount of time, you can enable this option by selecting the check box and providing an end date. For example: a monthly recurrence schedule refreshing on the first of the month with the below end date would refresh on September 1 2023, and wouldn't refresh again in October.



Insights refresh menu

In the management menu of the Microsoft Purview governance portal, you'll find the Insights refresh menu that lets you set your Data Estate Insights report availability. Here's all the information you can find there:

Expand table

Feature	State	Schedule	Configuration date	Edit
Lists the feature your settings are for	Either **On** or **Off**. For more information about turning off reports, see our disable Data Estate Insights article.	Select **More info** to see your recurrence schedule, start time, and end time.	The day your recurrence schedule was last set. By default this will be the creation date of your Microsoft Purview account.	Allows you to update your recurrence schedule when reports are turned on.

Understand the classic data stewardship report in Unified Catalog

As described in the insights concepts, the data stewardship report is part of the "Health" section of Data Estate Insights. This report offers a one-stop shop experience for data, governance, and quality focused users like chief data officers and data stewards to get actionable insights into key areas of gap in their data estate.

In this guide, you learn how to:

- ✓ Navigate and view data stewardship report from your Microsoft Purview account.
- ✓ Drill down for more asset count details.

Prerequisites

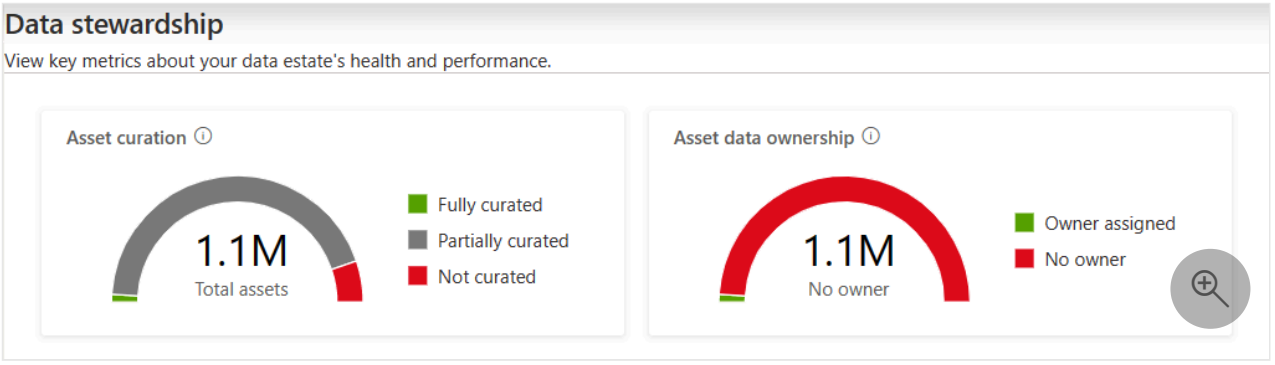
Before getting started with Data Estate Insights, make sure that you complete the following steps:

- Set up a storage resource and populate the account with data.
- Set up and complete a scan your storage source. For more information on how to create and complete a scan, see Manage data sources in Microsoft Purview.
- Permissions depending on your current experience:
  - If using the classic Microsoft Purview Catalog, you need the data curator role or insight reader role.
  - If using the new Microsoft Purview Unified Catalog, you need data health reader permissions.

Understand your data estate and catalog health in Data Estate Insights

In Data Estate Insights, you can get an overview of all assets inventoried in Data Map, and any key gaps that governance stakeholders can close for better governance of the data estate.

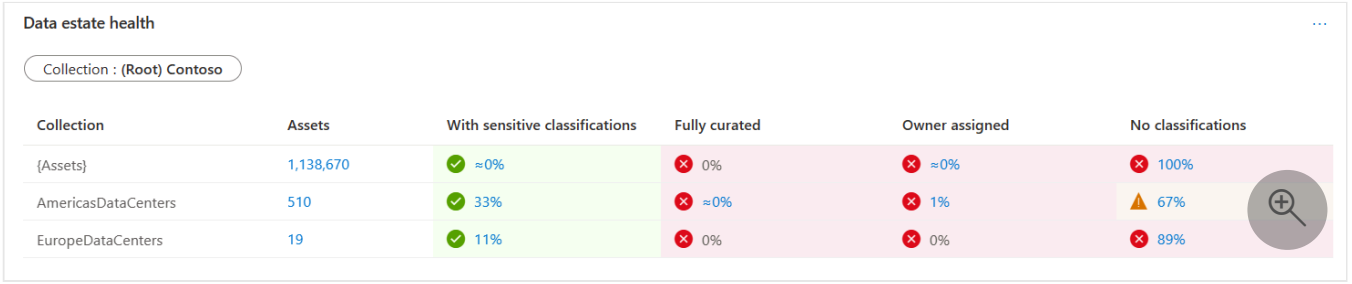
1. Open the Microsoft Purview portal.



2. If you're using the classic Microsoft Purview portal, select **Data estate insights**. If you're using the new Microsoft Purview portal open **Unified Catalog**, select **Health Management**, then select **Reports**.

3. Select **Classic data stewardship**.

View data stewardship dashboard

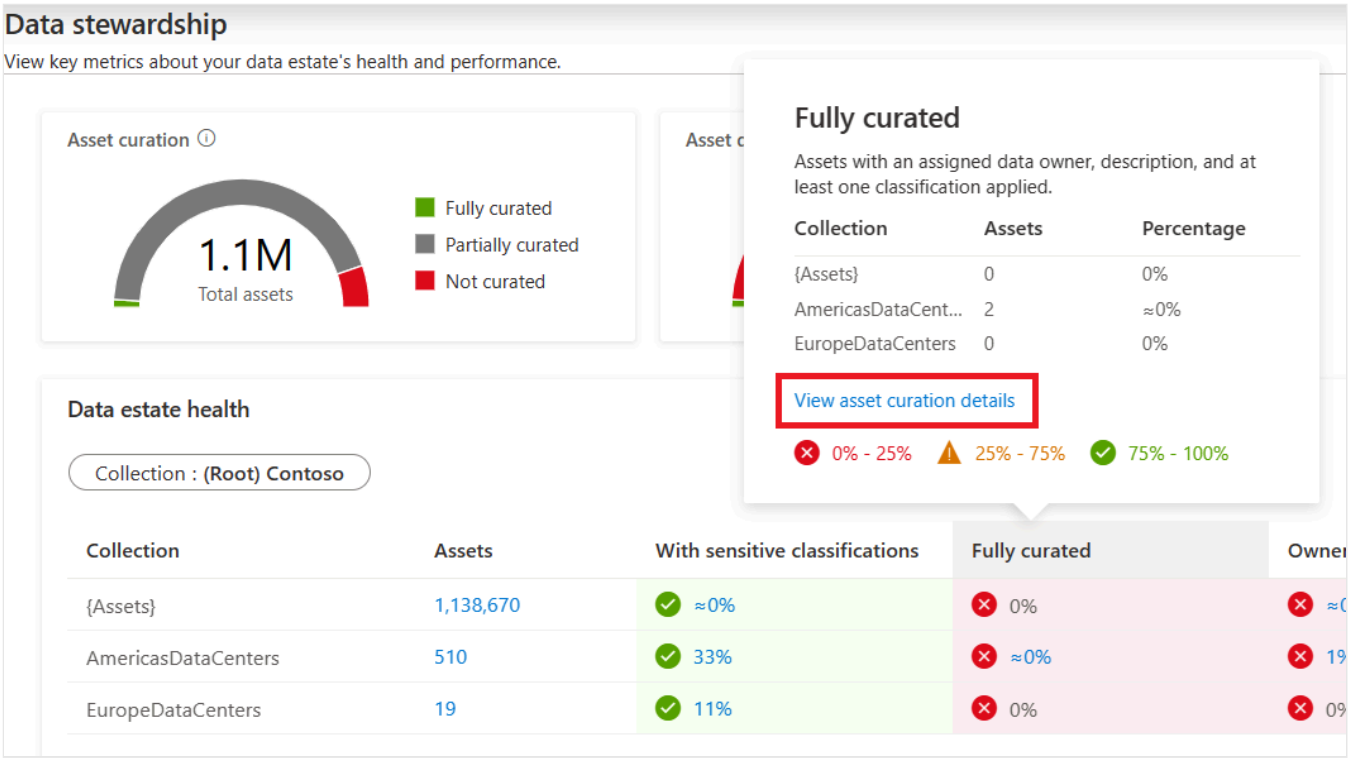


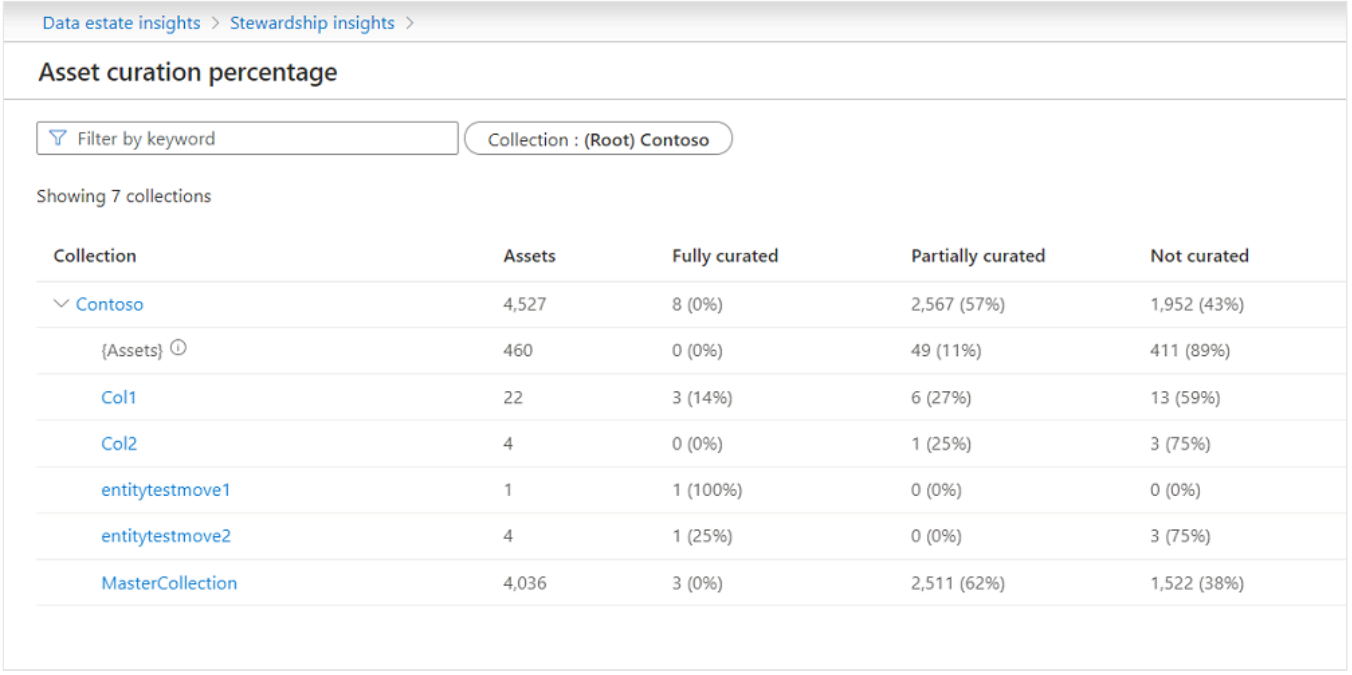
The dashboard is purpose-built for governance and quality-focused users, like data stewards and chief data officers, to understand the health management of their organization. The dashboard shows high-level KPIs that help reduce governance risks:

- **Asset curation**: The dashboard categorizes all data assets into three areas: "Fully curated," "Partially curated," and "Not curated," based on certain attributes of assets being present. An asset is "Fully curated" if it has at least one classification tag, an assigned data owner, and a description. If any of these attributes is missing, but not all, then the asset is categorized as "Partially curated" and if all of them are missing, then it's "Not curated."
- **Asset data ownership**: The dashboard categorizes assets that have the owner attribute within the "Contacts" tab as blank as "No owner". Otherwise, it categorizes them as "Owner assigned".

Health management

Health management is a scorecard view that helps management and governance focused users, like chief data officers, understand critical governance metrics that can be looked at by collection hierarchy.

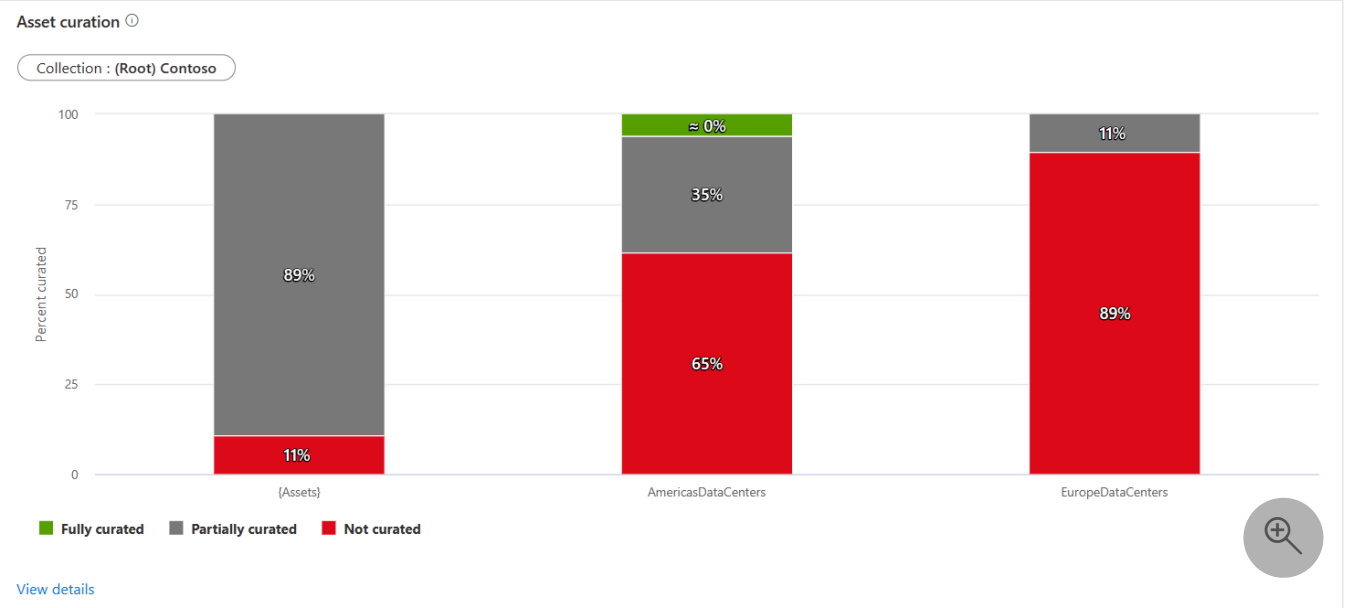




You can view the following metrics:

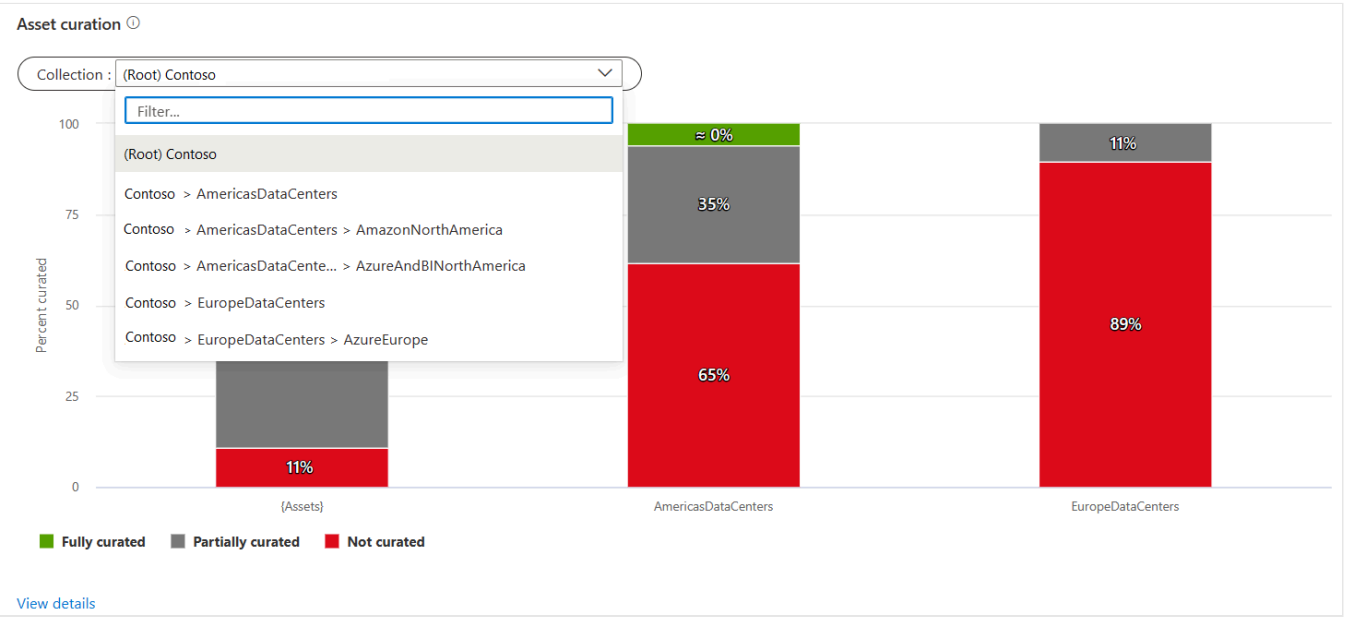
- **Assets**: Count of assets by collection drill-down.
- **With sensitive classifications**: Count of assets with any system classification applied.
- **Fully curated assets**: Count of assets that have a data owner, at least one classification, and a description.

- **Owner assigned**: Count of assets with data owner assigned on them.
- **No classifications**: Count of assets with no classification tag.
- **Out of date**: Percentage of assets that haven't been updated in over 365 days.
- **New**: Count of new assets pushed in the Data Map in the last 30 days.
- **Updated**: Count of assets updated in the Data Map in the last 30 days.
- **Deleted**: Count of deleted assets from the Data Map in the last 30 days.

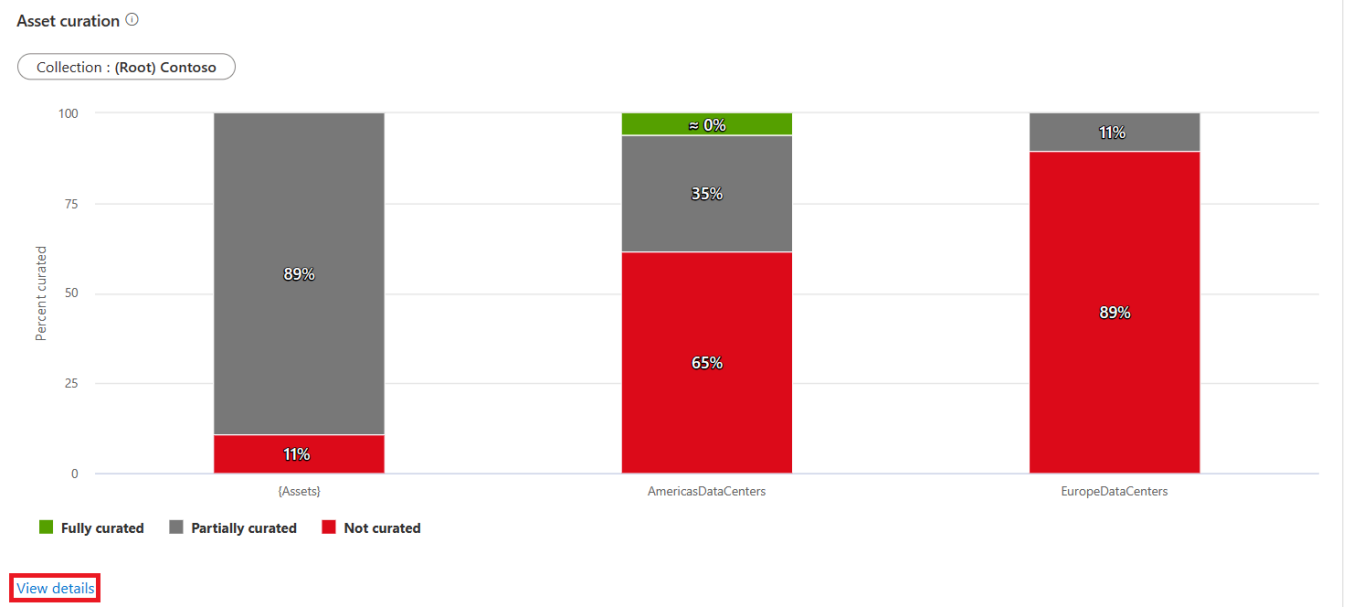


You can also drill down by collection paths. As you hover on each column name, it provides description of the column, provides recommended percentage ranges, and takes you to the detailed graph for further drill-down.

Asset curation

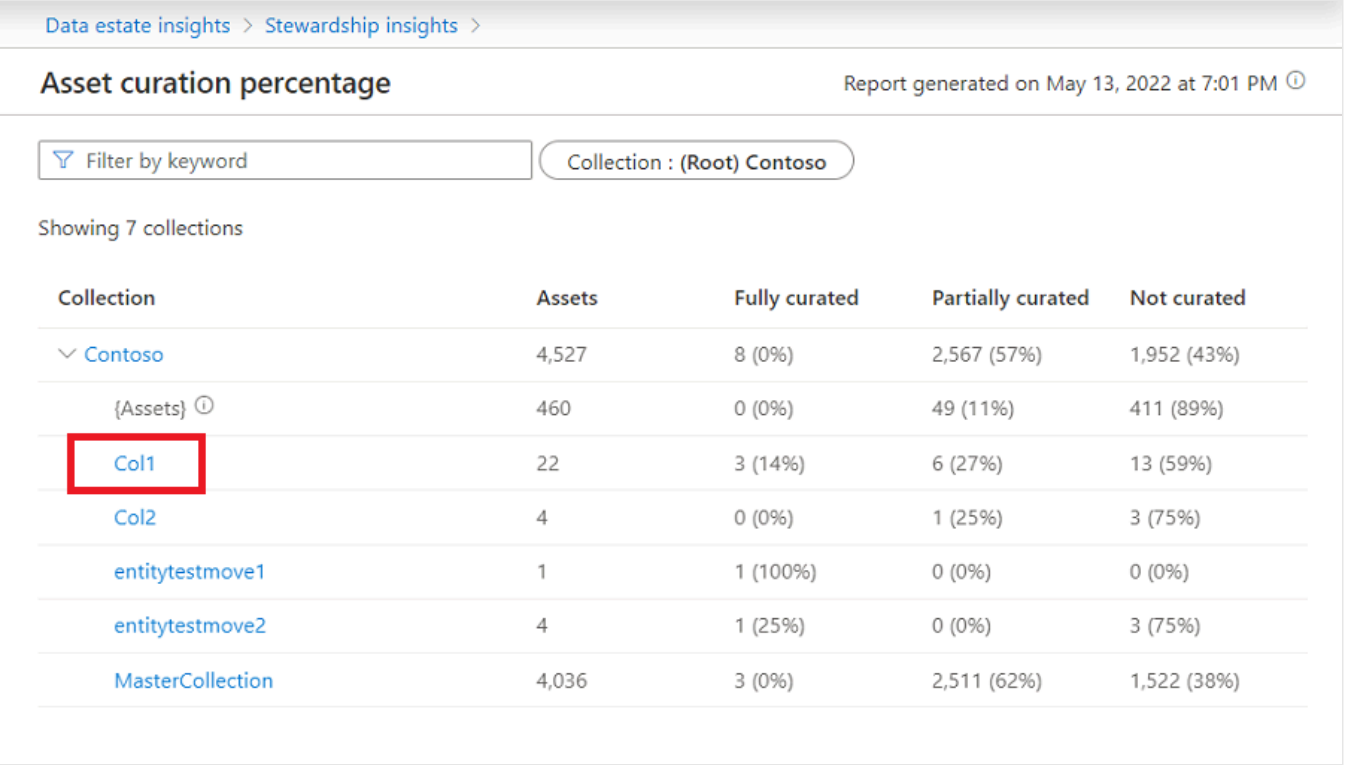


The system categorizes all data assets into three areas: **Fully curated**, **Partially curated**, and **Not curated**, based on whether assets have certain attributes.



An asset is ***Fully curated*** if it has at least one classification tag, an assigned data owner, and a description.

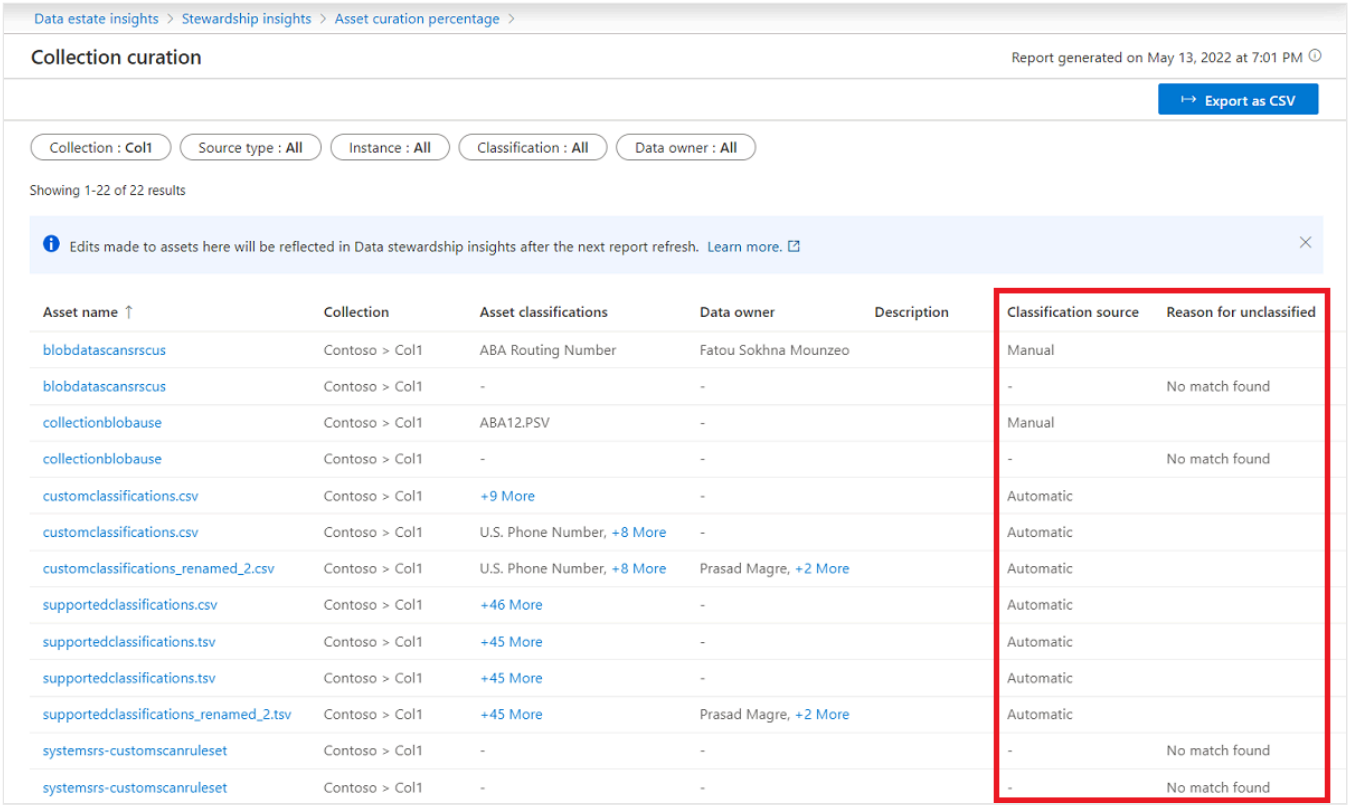
If an asset is missing any of these attributes, but not all, the system categorizes it as **Partially curated**. If an asset is missing all of these attributes, the system lists it as **Not curated**.



You can drill down by collection hierarchy.

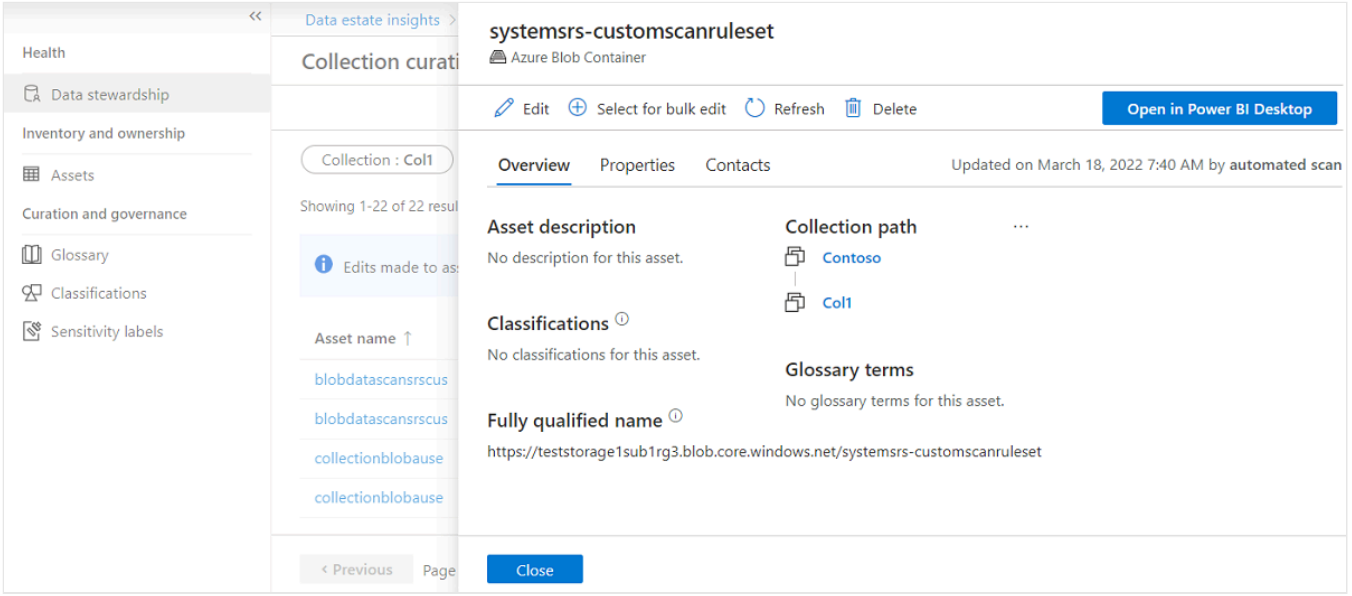
For further information about which assets aren't fully curated, you can select **View details** link that takes you into the deeper view.

In the **View details** page, if you select a specific collection, it lists all assets with attribute values or blanks that make up the ***fully curated*** assets.



The detail page shows two key pieces of information:

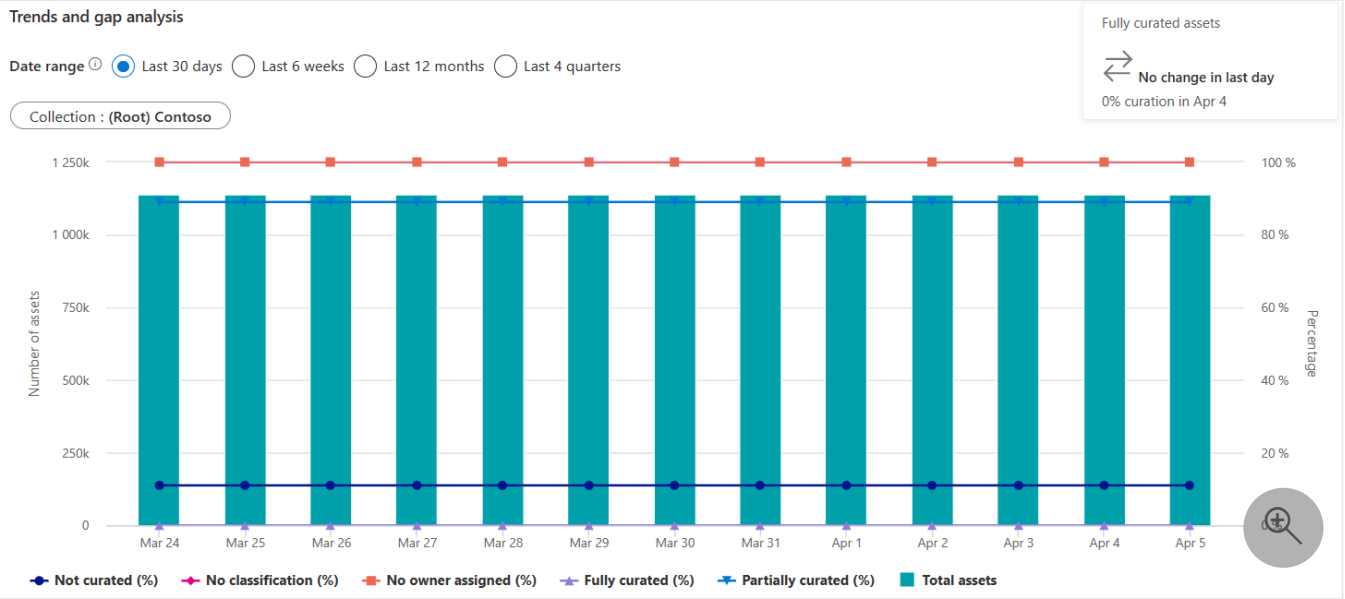
First, it tells you what the ***classification source*** is, if the asset is classified. It's **Manual** if a curator or data owner applies the classification manually. It's **Automatic** if the system classifies the asset during scanning. This page only provides the last applied classification state.



Second, if an asset is unclassified, it tells us why it's not classified, in the column ***Reasons for unclassified***. Currently, Data Estate Insights can provide one of the following reasons:

- No match found

- Low confidence score
- Not applicable



You can select any asset and add missing attributes, without leaving the **Data estate insights** app.

Trends and gap analysis

This graph shows how the assets and key metrics have been trending over different time periods:

- Last 30 days: The graph uses the last run of the day or the recording of the last run across days as a data point.
- Last six weeks: The graph uses the last run of the week, with the week ending on Sunday. If there's no run on Sunday, the graph uses the last recorded run.
- Last 12 months: The graph uses the last run of the month.
- Last four quarters: The graph uses the last run of the calendar quarter.

Understand the classic catalog adoption report in Unified Catalog

As described in the insights concepts, the catalog adoption report is part of the "Health" section of classic Microsoft Purview Data Estate Insights. This report offers a one-stop shop experience for administrators to determine if and how the classic Microsoft Purview Data Catalog is being used. It helps answer questions like:

- What are my users searching for?
- How many people used the catalog last month?
- What are the most used data assets?

Prerequisites

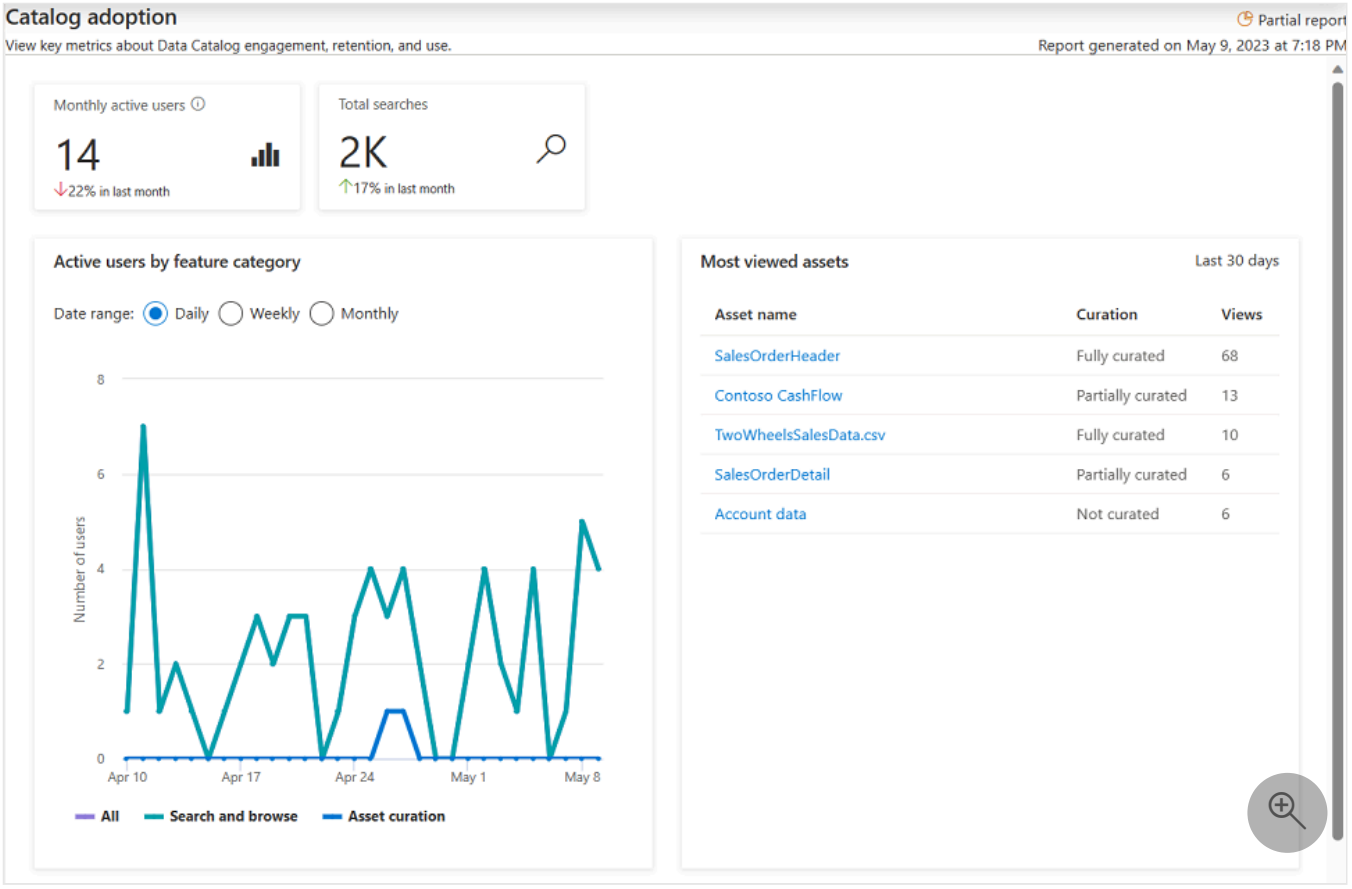
Before getting started with Data Estate Insights, make sure that you complete the following steps:

- Set up a storage resource and populate the account with data.
- Set up and complete a scan of your storage source. For more information about creating and completing a scan, see manage data sources in Microsoft Purview.
- Have the right permissions depending on your current experience:
  - If using the classic Microsoft Purview Data Catalog, you need the data curator role or insight reader role.
  - If using the new Microsoft Purview Unified Catalog, you need data health reader permissions.

Understand your data estate and catalog health in Data Estate Insights

In Data Estate Insights, you can get an overview of all assets inventoried in the Data Map, and any key gaps that governance stakeholders can close for better governance of the data estate.

1. Open the Microsoft Purview portal.



2. If you're using the classic Microsoft Purview portal, select **Data estate insights**. If you're using the new Microsoft Purview portal open **Unified Catalog**, select **Health Management**, then select **Reports**.

3. Select **Classic catalog adoption**.

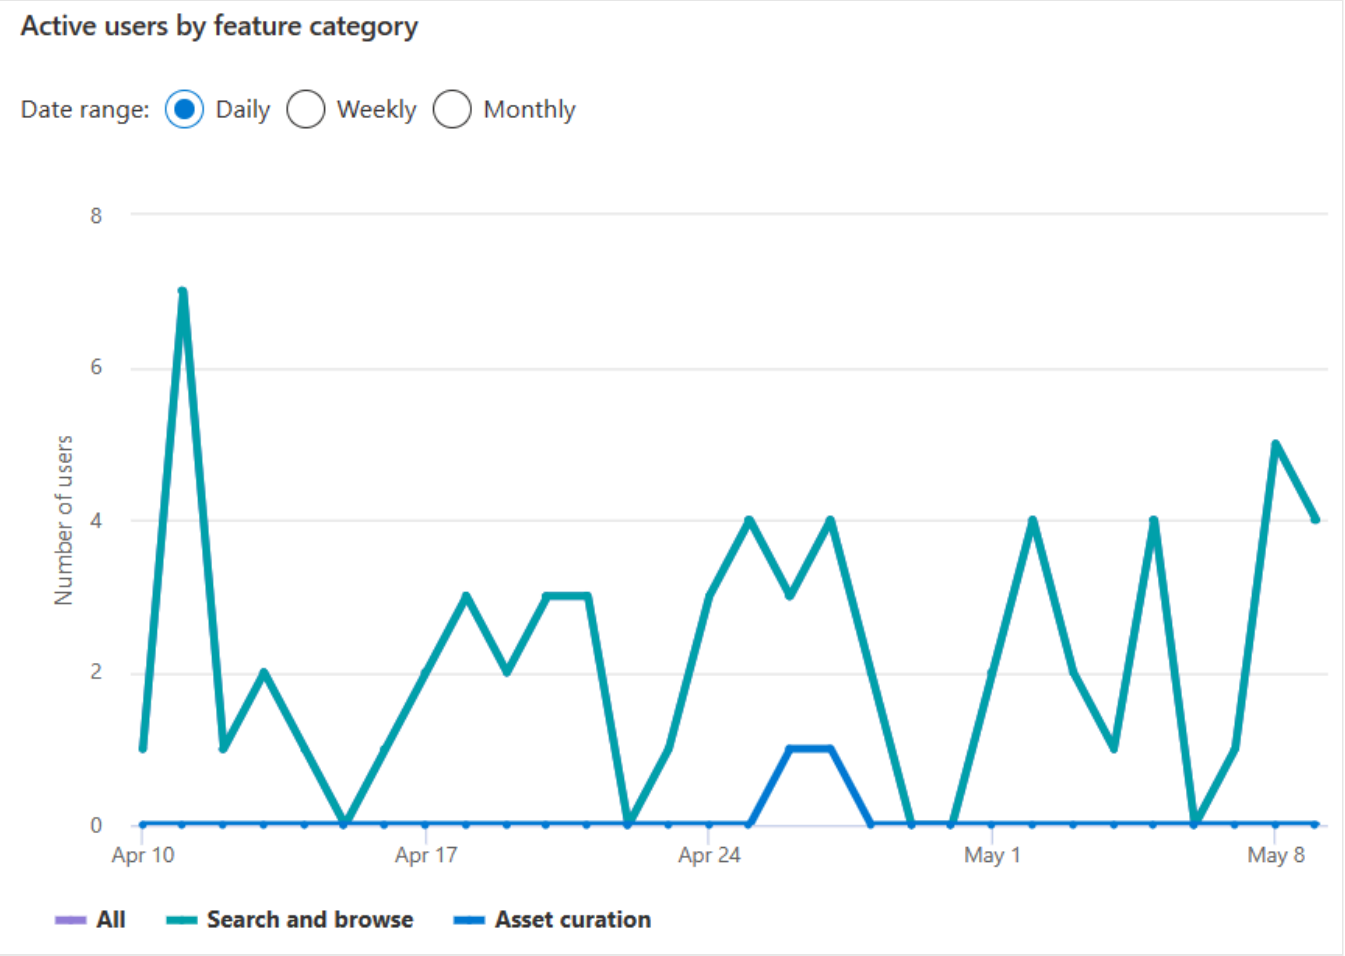
View catalog adoption dashboard

The catalog adoption dashboard has several curated tiles and charts to identify:

- How many active users your catalog had in the last month.
- How many total searches were performed in the last month.
- Which catalog features are being used.
- Most viewed assets.
- Top searched keywords in catalog.

Monthly active users

The **Monthly active users** count is the number of unique users who perform any action, such as search, browse, or curation.



The **Monthly active users** tile shows how many users took at least one action in the catalog in the last 30 days. An action in the catalog includes searching for a term, browsing in the catalog, and updating an asset in the catalog. This tile also includes an indicator of a percentage increase or decrease in users from the previous month.

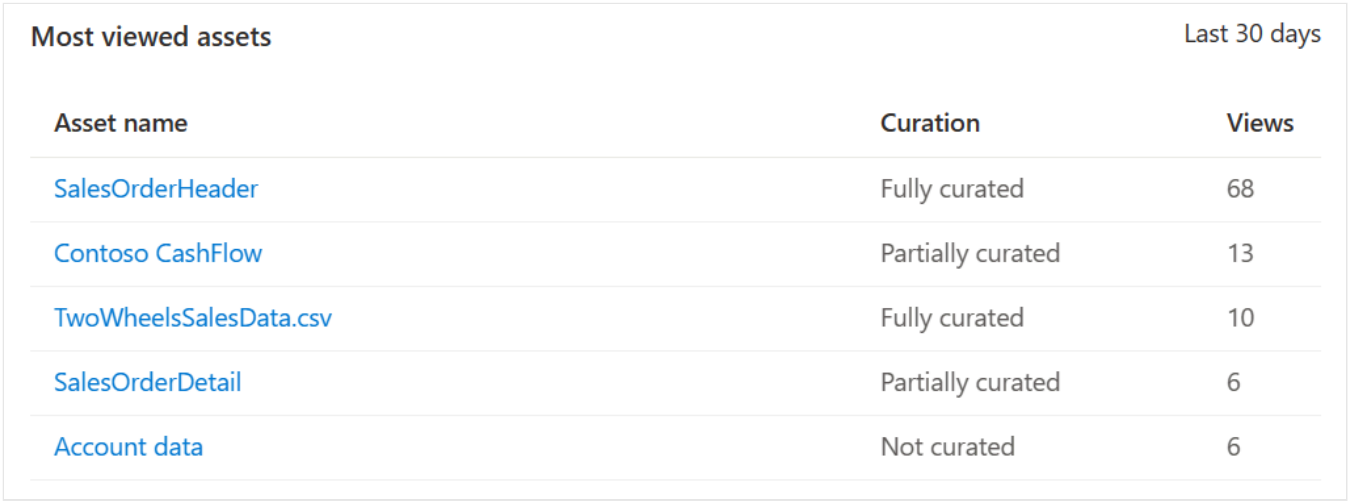
Total searches

The **Total searches** tile shows a count of all searches performed in the catalog over the last 30 days. The tile also shows the percentage increase or decrease in the number of searches from the previous month.

Active users by feature category

The **Active users by feature category** chart helps you monitor user activity trends in the catalog. Here's an example of the chart:

At the top of the chart, select your date range to view user activity on a daily, weekly, or monthly basis.



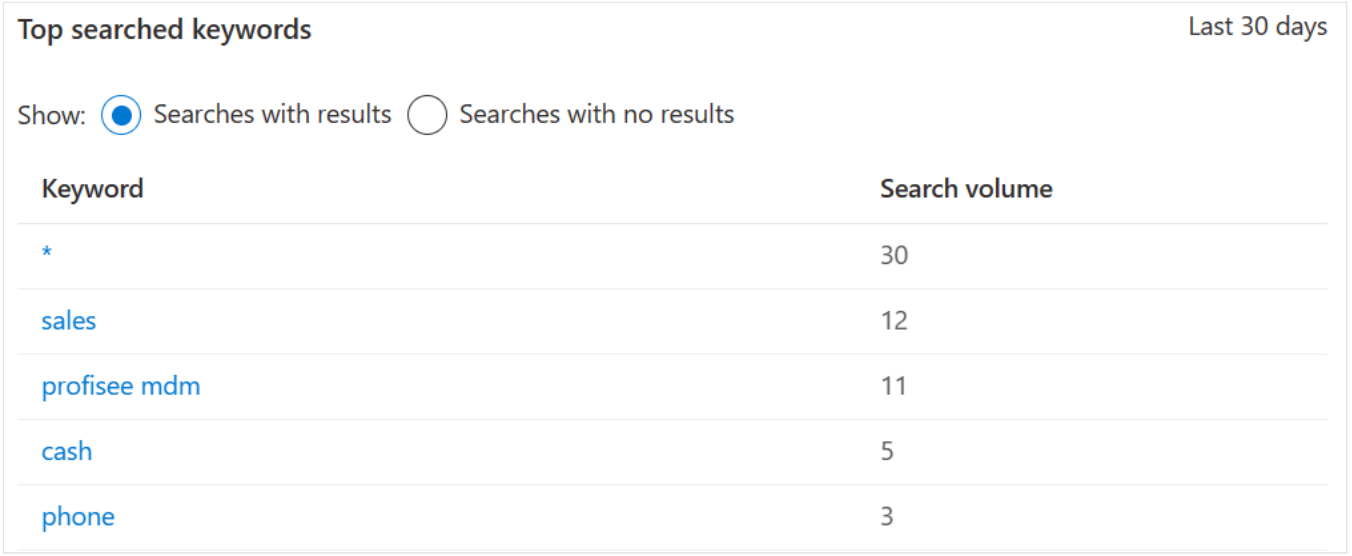
The chart shows the number of users in the date range who perform actions in one of three categories:

- **Search and browse**: The count of users per action category (search or browse). A user may appear in both counts if they perform both actions. For example, if a user performs both search and browse, the same user is counted twice in this number (once under search, once under browse). One user can contribute two counts in Search/Browse, but still counts as one in Monthly Active Users. This is why **Search and browse** can be higher than **Monthly active users**.

- **Asset curation**: The count of users who performed at least any one of these actions on an asset:
  - Added, removed, or updated a rating
  - Added or removed a tag
  - Added or removed a glossary term
  - Added or removed a classification
  - Edited an asset's name or description
  - Added or removed a certification
  - Added or removed a column level classification, glossary term, description, name, or data type
  - Added or removed manual lineage
  - Added or removed a contact
- **All**: The count of users who performed both a search or browse action, *and* at least one asset curation action within the date range.

Most viewed assets

The most viewed assets table shows the top assets in the catalog, by sum of views in the last 30 days.



This table allows you to select through to your most viewed assets for more information, but the table also provides these other details:

- Curation status - There are three possible statuses: **Fully curated**, **Partially curated**, and **Not curated**, based on certain attributes of assets being present. An asset is **Fully curated** if it has at least one classification tag, an assigned Data Owner, and a description. If any of these attributes is missing, but not all, then the asset is categorized as **Partially curated** and if all of them are missing, then it's **Not curated**. For more information about the curation status of your data assets, see the data stewardship dashboard.
- Views - count of the number of views the asset received in the last 30 days.

Top searched keywords

The top searched keywords table shows your top keywords both for searches that produced results, and searches that didn't. That way you can know what users are finding with the catalog, and what they're still looking for.

At the top of the table, you can select one of the two radio buttons to select whether to show keywords for searches with results, or searches without results.

You can select any of the keywords to run the search in the catalog and see the results for yourself as well.

The table also provides search volume, which is the number of times that keyword was searched in the last 30 days.

Report generated timestamp

The timestamp displayed, such as, "Report generated on December 4, 2025 at 11:37 AM", indicates when the page was loaded or refreshed. It doesn't represent the time when the backend actually computed the KPI data. The actual calculation time comes from the backend timePoint field (for example, 2025-11-05T06:59:48) from the API response.

Monthly aggregation behavior for usage metrics

The **Monthly active users** and **Total searches** metrics display data from the previous fully completed month. For example, December views show November data. The KPI is updated during the job run after the month changes, even though the job runs every week.

Understand the classic assets report in Unified Catalog

This article describes how to access, view, and filter data asset insight reports for your data.

In this article, you learn how to:

- ✓ View data estate insights from your Microsoft Purview account.
- ✓ Get a bird's eye view of your data.
- ✓ Drill down for more asset count details.

Prerequisites

Before getting started with Microsoft Purview Data Estate Insights, make sure that you've completed the following steps:

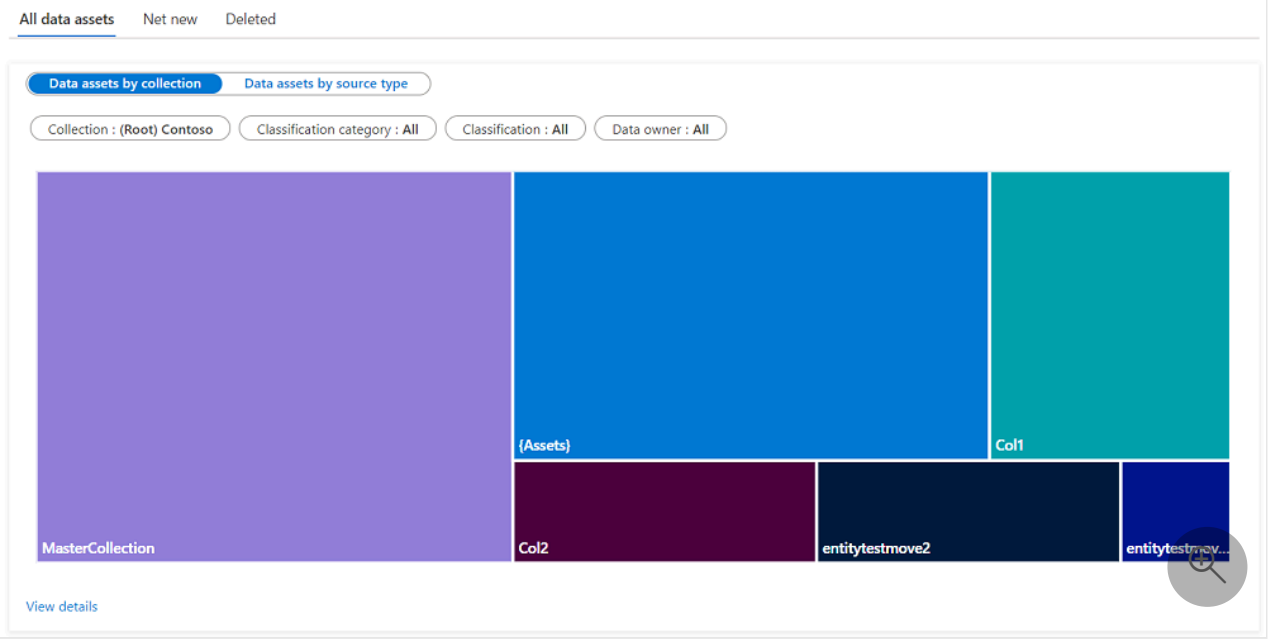
- Set up a storage resource and populated the account with data.
- Set up and completed a scan your storage source. For more information to create and complete a scan, see Manage data sources in Microsoft Purview.
- Permissions depending on your current experience:
  - If using the classic Microsoft Purview Catalog, you need the data curator role or insight reader role.
  - If using the new Microsoft Purview Unified Catalog, you need data health reader permissions.

Understand your asset inventory in Data Estate Insights

In Microsoft Purview Data Estate Insights, you can get an overview of the assets that you scanned into the Data Map. You can also view key gaps that governance stakeholders can close for better governance of the data estate.

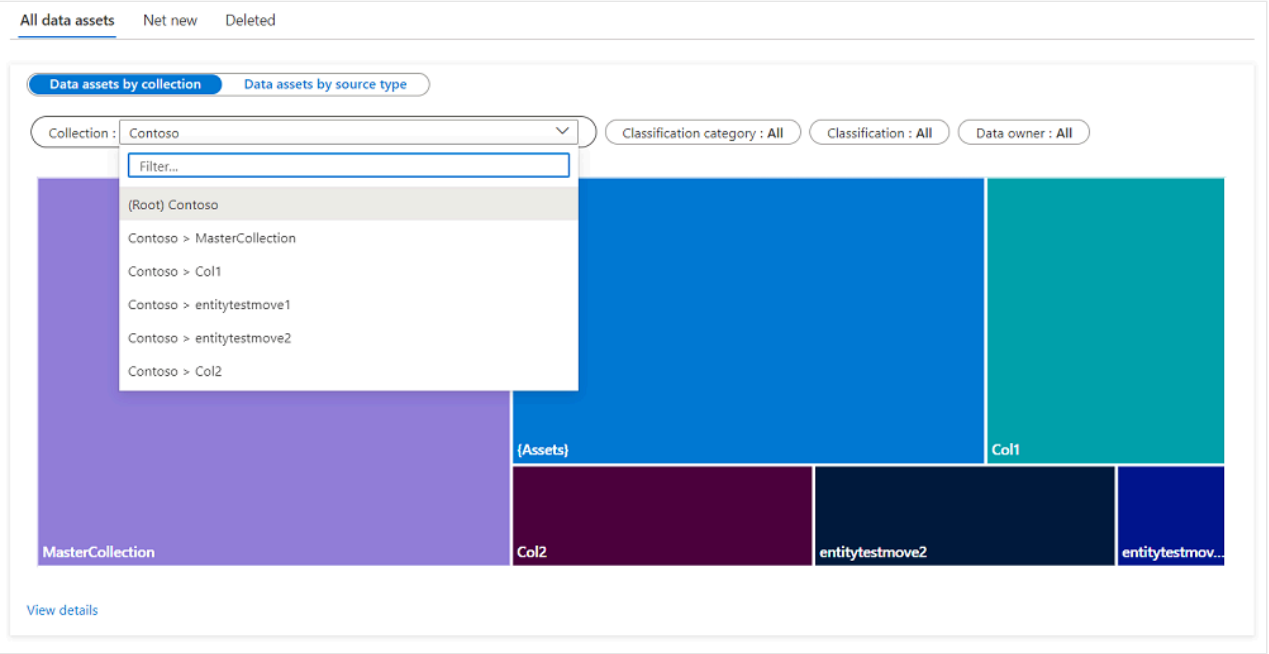
1. Open the Microsoft Purview portal.

2. If you're using the classic Microsoft Purview portal, select **Data estate insights**. If you're using the new Microsoft Purview portal open **Unified Catalog**, select **Health Management**, then select **Reports**.



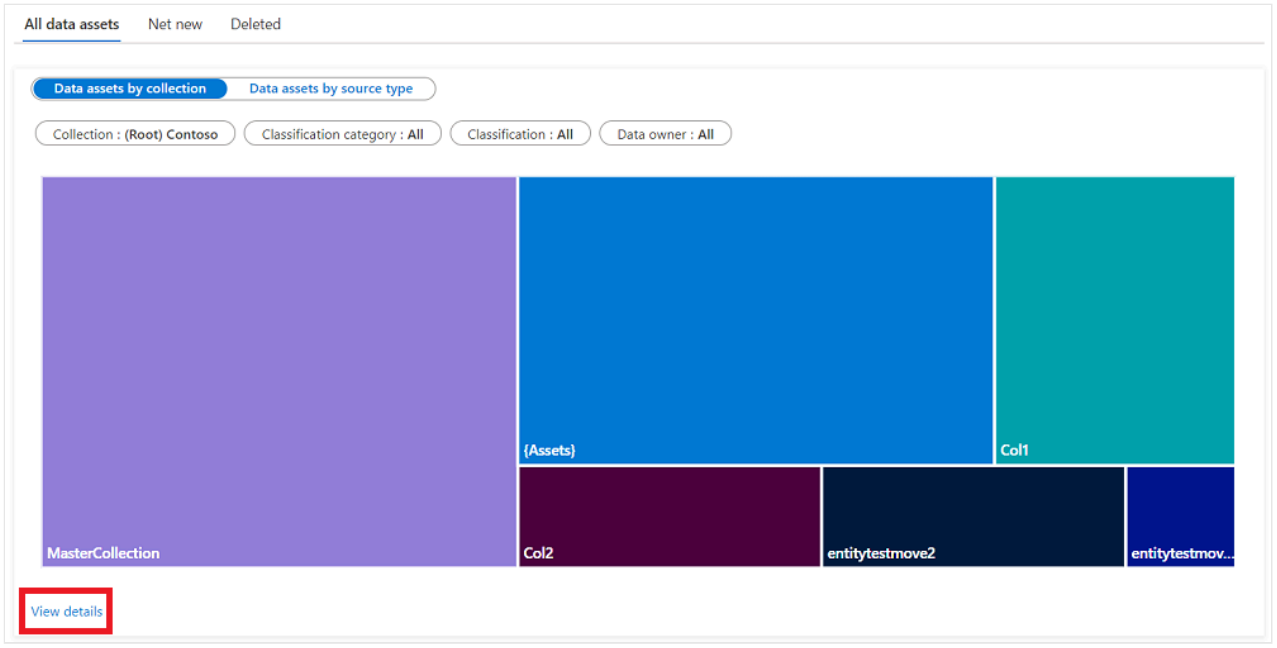
3. Select the **Classic assets** report.

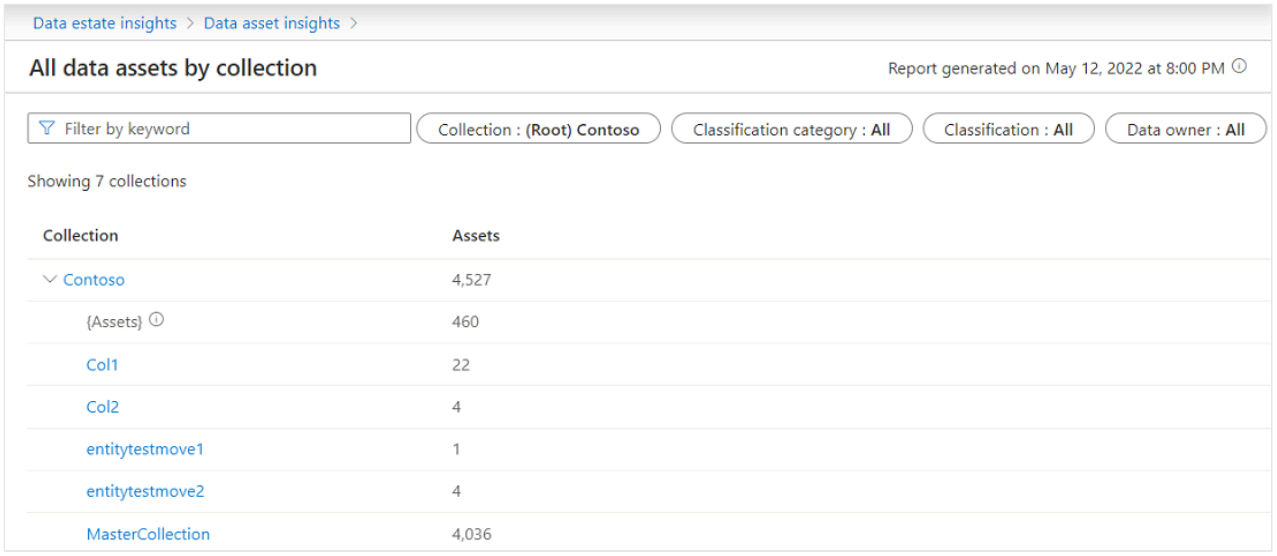
4. The **Assets Summary** report provides several high-level KPIs, with these graphs:



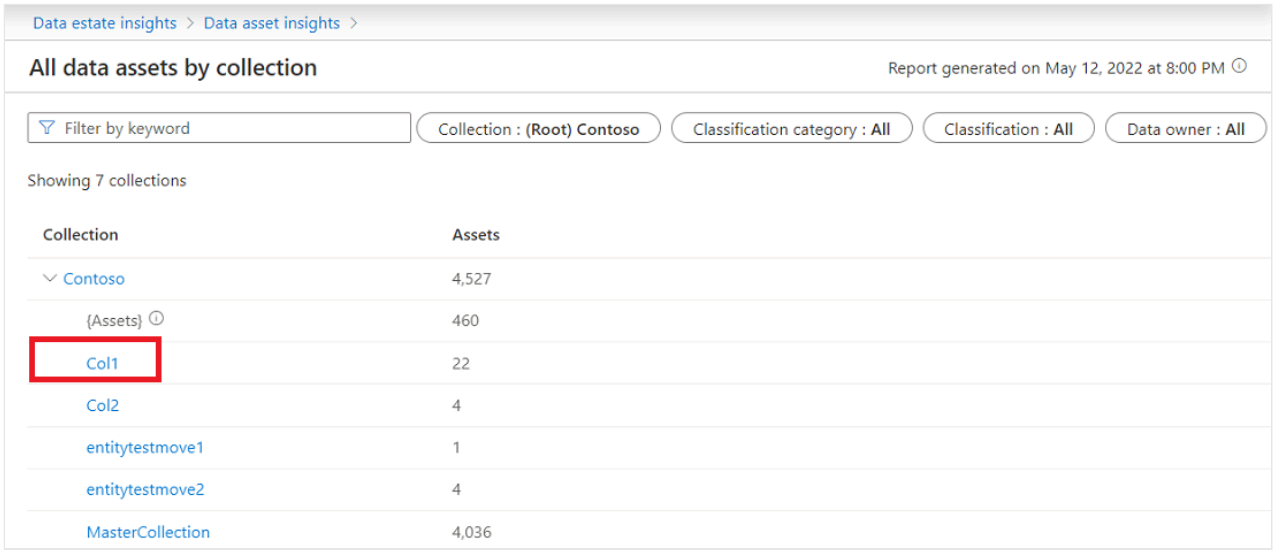
- **Unclassified assets**: Assets with no system or custom classification on the entity or its columns.
- **Unassigned data owner**: Assets that have the owner attribute within "Contacts" tab as blank.
- **Net new assets in last 30 days**: Assets that you added to the Purview account, via data scan or Atlas API pushes.
- **Deleted assets in last 30 days**: Assets that you deleted from the Purview account, as a result of deletion from data sources.

5. Below these KPIs, you can also view your data asset distribution by collection.

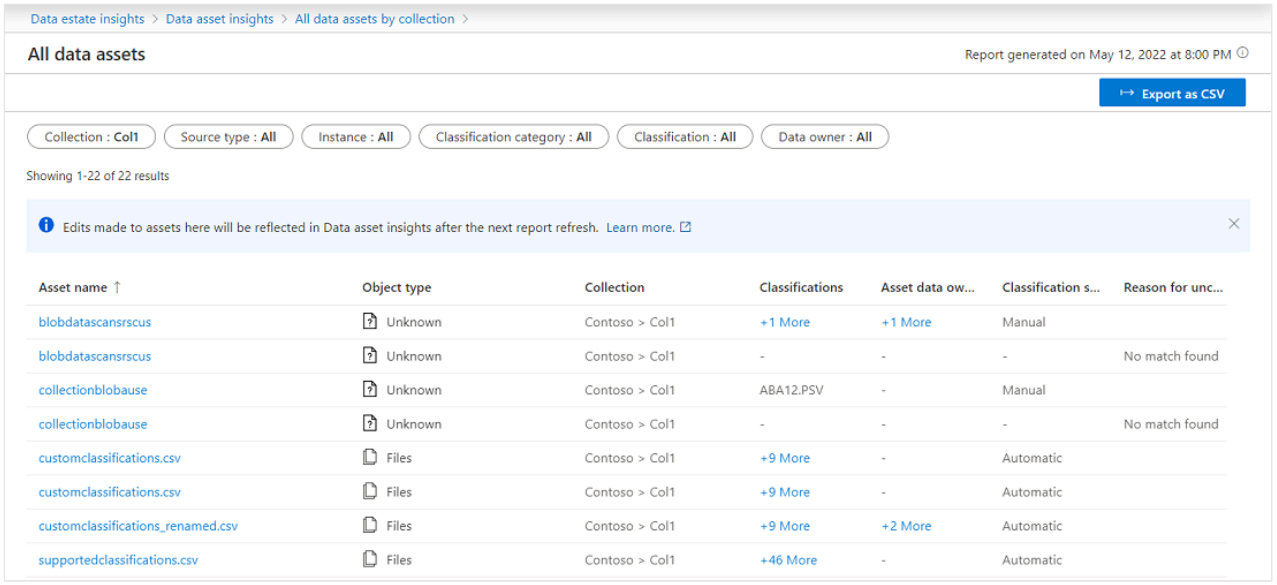




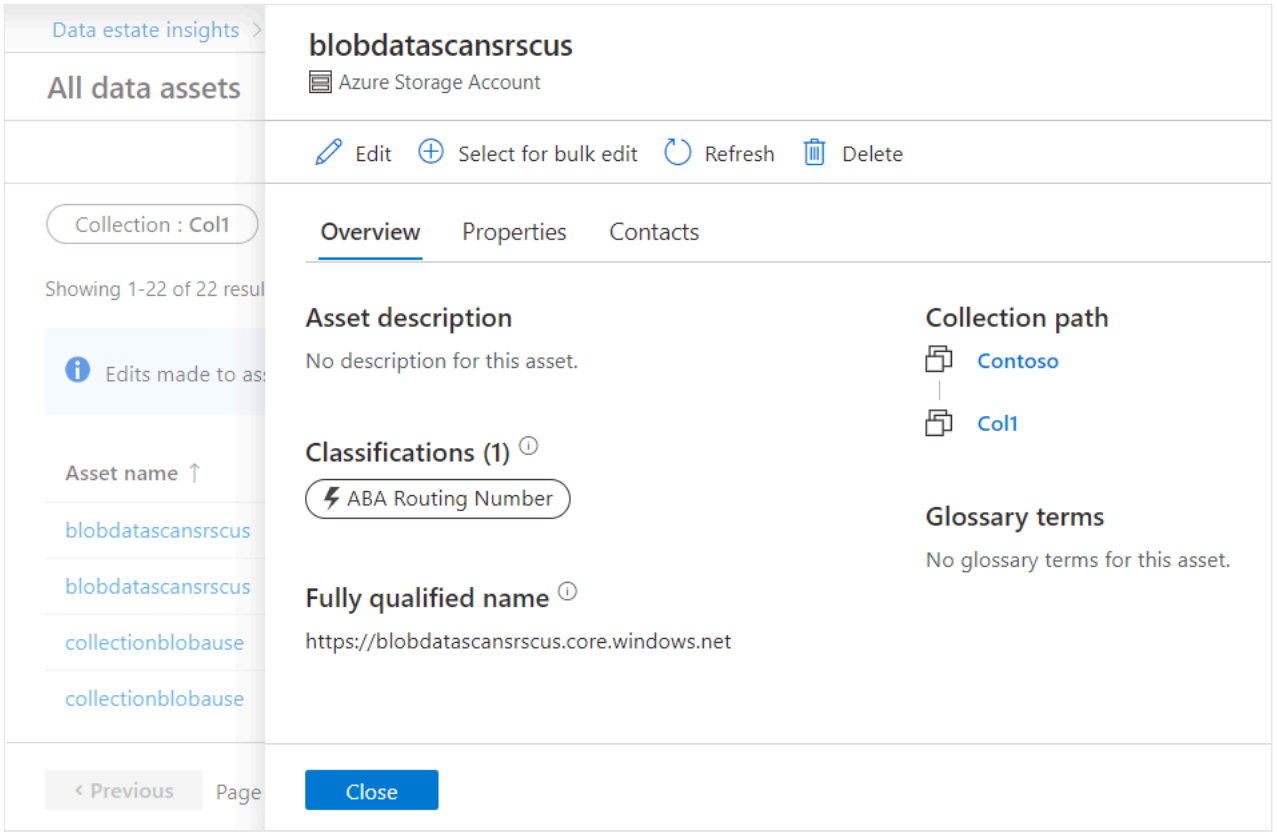
6. Using filters you can drill down to assets within a specific collection or classification category.



> ⓘ Note
>
> ***Each classification filter has some common values:***
>
> - **Applied**: Any filter value is applied
> - **Not Applied**: No filter value is applied. For example, if you pick a classification filter with value as "Not Applied", the graph shows all assets with no classification.
> - **All**: Filter values are cleared. Meaning the graph shows all assets, with or without classification.
> - **Specific**: You pick a specific classification from the filter, and only that classification is shown.



7. To learn more about which specific assets are shown in the graph, select **View details**.



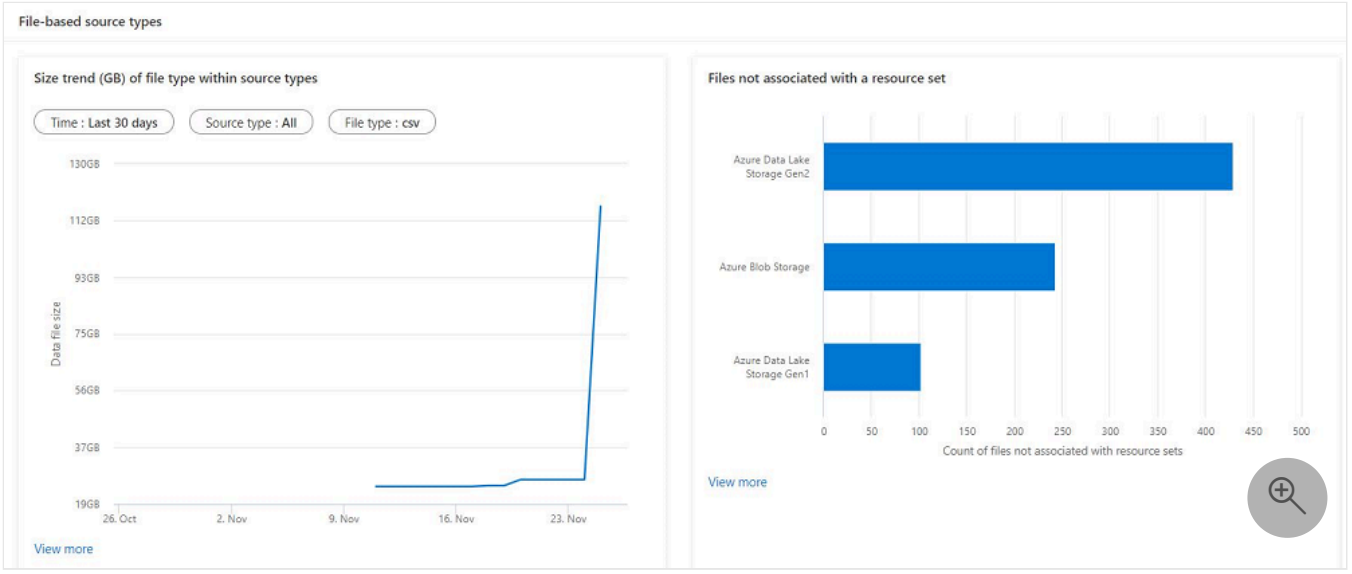
8. You can select any collection to view the collection's asset list.

9. You can also select an asset to edit without leaving the Data Estate Insights App.

File-based source types

The next graphs in asset insights show a distribution of file-based source types. The first graph, **Size trend (GB) of file type within source types**, shows top file type size trends over the last 30 days.

1. Pick your source type to view the file type within the source.



2. Select **View details** to see the current data size, change in size, current asset count, and change in asset count.

> **Note**
>
> If the scan runs only once in the last 30 days, or any catalog change such as classification addition or removal happens only once in 30 days, then the change information appears blank.

3. See the top folders with change top asset counts when you select source type.

4. Select the path to see the asset list.

The second graph in file-based source types is **Files not associated with a resource set**. If you expect that all files should roll up into a resource set, this graph can help you understand which assets aren't rolled up. Missing assets can be an indication of the wrong file-pattern in the folder. You can select **View details** below the graph for more information.

Understand the classic glossary report in Unified Catalog

This article describes how to access, view, and filter Microsoft Purview glossary insight reports for your data. In this how-to guide, you learn how to:

- ✓ Find Data Estate Insights.
- ✓ Get a bird's eye view of your data.

Prerequisites

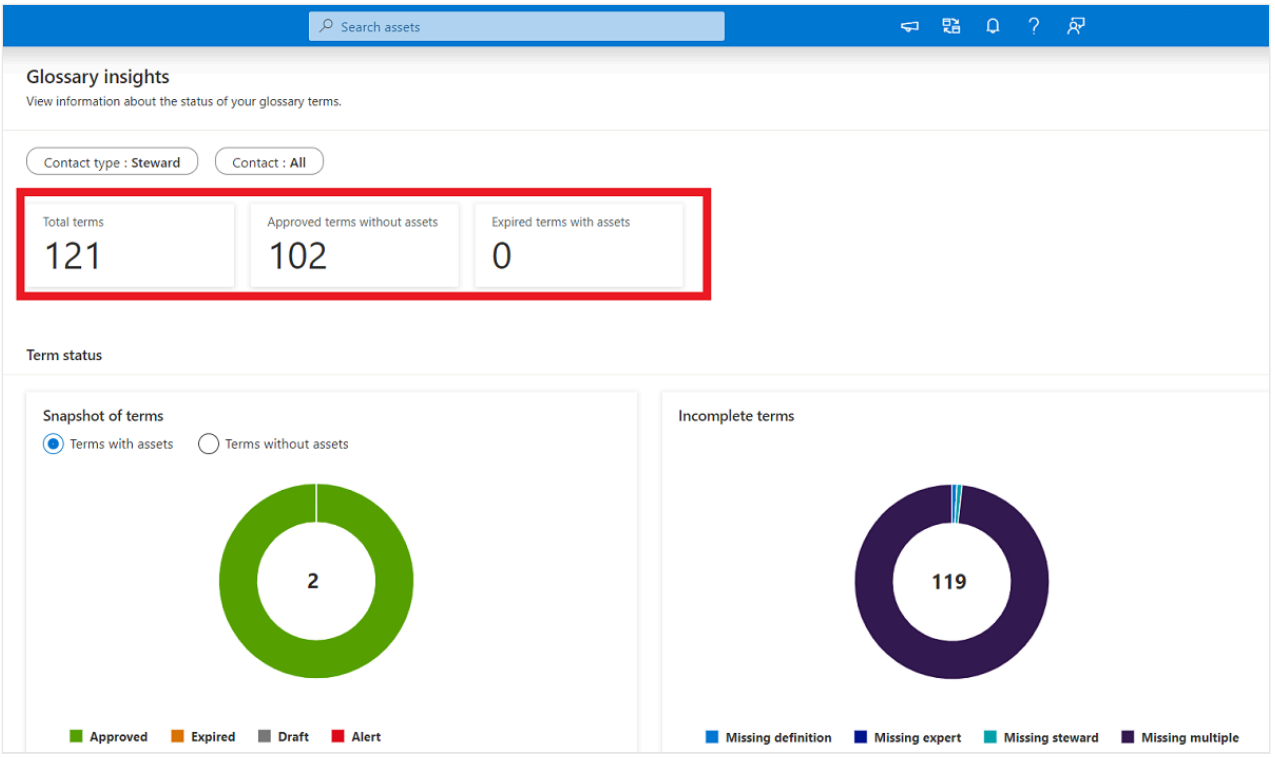
Before getting started with Data Estate Insights glossary insights, make sure that you complete the following steps:

- Set up a storage resource and populate the account with data.
- Set up and complete a scan your storage source.
- Set up at least one business glossary term and attach it to an asset.
- Permissions depending on your current experience:
  - If using the classic Microsoft Purview Catalog, you need the data curator role or insight reader role.
  - If using the new Microsoft Purview Unified Catalog, you need data health reader permissions.

Use Microsoft Purview glossary insights

In Microsoft Purview, you can create glossary terms and attach them to assets. As you make use of these terms in your data map, you can view the glossary distribution in glossary insights. These insights give you the state of your glossary based on:

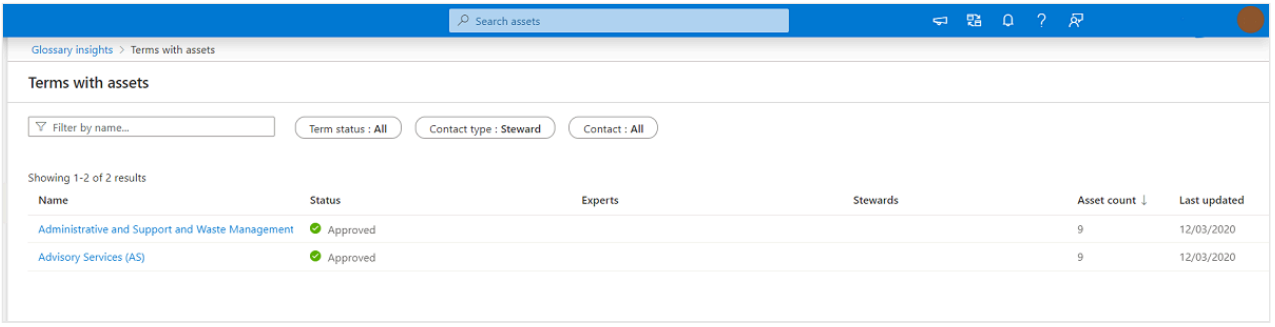
- Number of terms attached to assets.
- Status of terms.
- Distribution of roles by users.



View glossary insights

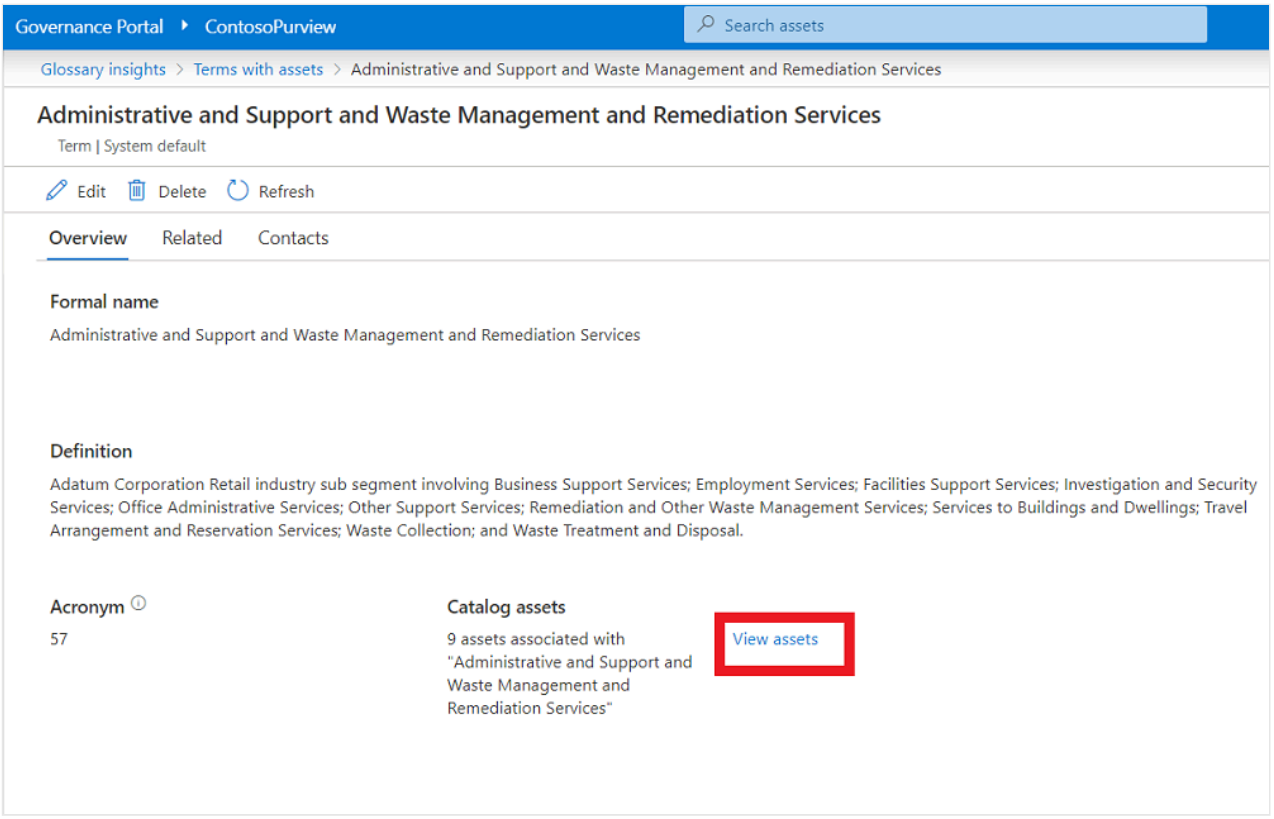
1. Open the Microsoft Purview portal.

2. If you're using the classic Microsoft Purview portal, select **Data estate insights**. If you're using the new Microsoft Purview portal open **Unified Catalog**, select **Health Management**, then select **Reports**.



3. Select the **Classic glossary** report.

4. The report starts with **High-level KPIs** that shows ***Total terms*** in your Microsoft Purview account, ***Approved terms without assets***, and ***Expired terms with assets***. Each of these values helps you understand the current health of your Glossary.



5. The **Snapshot of terms** section (displayed above) shows the term status as ***Draft***, ***Approved***, ***Alert***, and ***Expired*** for terms with assets and terms without assets.

6. Select **View details** to see the term names with various status and more details about ***Stewards*** and ***Experts***.

7. When you select "View more" for ***Approved terms with assets***, Data Estate Insights allows you to navigate to the **Glossary** term detail page, from where you can further navigate to the list of assets with the attached terms.

8. In Glossary insights page, view a distribution of **Incomplete terms** by type of information missing. The graph shows count of terms with ***Missing definition***, ***Missing expert***, ***Missing steward***, and ***Missing multiple*** fields.

9. Select ***View more*** from **Incomplete terms**, to view the terms that have missing information. You can navigate to Glossary term detail page to input the missing information and ensure the glossary term is complete.

Last updated on 11/14/2025

Understand the classic classifications report in Unified Catalog

This article describes how to access, view, and filter the classic classifications report for your data.

In this article, you learn how to:

- ✓ Launch your Microsoft Purview account from Microsoft Azure.
- ✓ View classification insights on your data.
- ✓ Drill down for more classification details on your data.

Prerequisites

Before getting started with Data Estate Insights, make sure you complete the following steps:

- Set up a storage resource and populate the account with data.
- Set up and complete a scan on the data in each data source. For more information, see Manage data sources in Microsoft Purview and Create a scan rule set.
- Permissions depending on your current experience:
  - If using the classic Microsoft Purview Catalog, you need the data curator role or insight reader role.
  - If using the new Microsoft Purview Unified Catalog, you need data health reader permissions.

Use Data Estate Insights for classifications

In Microsoft Purview, classifications are similar to subject tags, and are used to mark and identify data of a specific type that's found within your data estate during scanning.

Microsoft Purview uses the same sensitive information types as Microsoft 365, allowing you to stretch your existing security policies and protection across your entire data estate.

> ⓘ **Note**
>
> After you scan your source types, wait a couple of hours for the classic classifications report to reflect the new assets.

View classification insights

1. Open the Microsoft Purview portal.
2. If you're using the classic Microsoft Purview portal, select **Data estate insights**. If you're using the new Microsoft Purview portal open **Unified Catalog**, select **Health management**, then select **Reports**.
3. Select the **Classic classifications** report. The **Classification insights** page displays the following areas:

Expand table

Area	Description
Overview of sources with classifications	Displays tiles that provide: - The number of subscriptions found in your data - The number of unique classifications found in your data - The number of classified sources found - The number of classified files found - The number of classified tables found
Top sources with classified data (last 30 days)	Shows the trend, over the past 30 days, of the number of sources found with classified data.
Top classification categories by sources	Shows the number of sources found by classification category, such as **Financial** or **Government**.
Top classifications for files	Shows the top classifications applied to files in your data, such as credit card numbers or national/regional identification numbers.
Top classifications for tables	Shows the top classifications applied to tables in your data, such as personal identifying information.
Classification activity (files and tables)	Displays separate graphs for files and tables, each showing the number of files or tables classified over the selected timeframe. **Default**: 30 days Select the **Time** filter above the graphs to select a different time frame to display.

Classification insights drilldown

In any of the following **Classification insights** graphs, select the **View details** link to drill down for more details:

- **Top classification categories by sources**
- **Top classifications for files**
- **Top classifications for tables**

- **Classification activity > Classification data**

To learn more, use the following options:

Expand table

Option	Description
Filter your data	Use the filters above the grid to filter the data shown, including the classification name, subscription name, or source type. If you're not sure of the exact classification name, enter part or all of the name in the **Filter by keyword** box.
Sort the grid	Select a column header to sort the grid by that column.
Edit columns	To display more or fewer columns in your grid, select **Edit Columns**, then select the columns you want to view or change the order.
Drill down further	To drill down to a specific classification, select a name in the **Classification** column to view the **Classification by source** report. This report displays data for the selected classification, including the source name, source type, subscription ID, and the numbers of classified files and tables.
Browse assets	To browse through the assets found with a specific classification or source, select a classification or source, depending on the report you're viewing, then select **Browse assets** above the filters. The search results display all of the classified assets found for the selected filter. For more information, see Search the Microsoft Purview Unified Catalog.

Next steps

Learn how to use Data Estate Insights with the following resources:

- Learn how to use Asset insights.
- Learn how to use Data Stewardship.

Last updated on 11/14/2025

Understand the classic sensitivity labels report in Unified Catalog

This article describes how to access, view, and filter security insights provided by sensitivity labels applied to your data.

Supported data sources include: Azure Blob Storage, Azure Data Lake Storage (ADLS) GEN 1, Azure Data Lake Storage (ADLS) GEN 2, SQL Server, Azure SQL Database, Azure SQL Managed Instance, Amazon S3 buckets, Amazon RDS databases (public preview), Power BI.

In this article, you learn how to:

- ✓ Launch your Microsoft Purview account from Microsoft Azure.
- ✓ View sensitivity labeling insights on your data.
- ✓ Drill down for more sensitivity labeling details on your data.

Prerequisites

Before getting started with Data Estate Insights, make sure that you complete the following steps:

- Set up your Azure resources and populate the relevant accounts with test data.
- Extended sensitivity labels to assets in Microsoft Purview Data Map, and create or select the labels you want to apply to your data.
- Set up and complete a scan on the test data in each data source. For more information, see Manage data sources in Microsoft Purview and Create a scan rule set.
- Permissions depending on your current experience:
  - If using the classic Microsoft Purview Catalog, you need the data curator role or insight reader role.
  - If using the new Microsoft Purview Unified Catalog, you need data health reader permissions.

For more information, see Manage data sources in Microsoft Purview and Automatically label your data in Microsoft Purview.

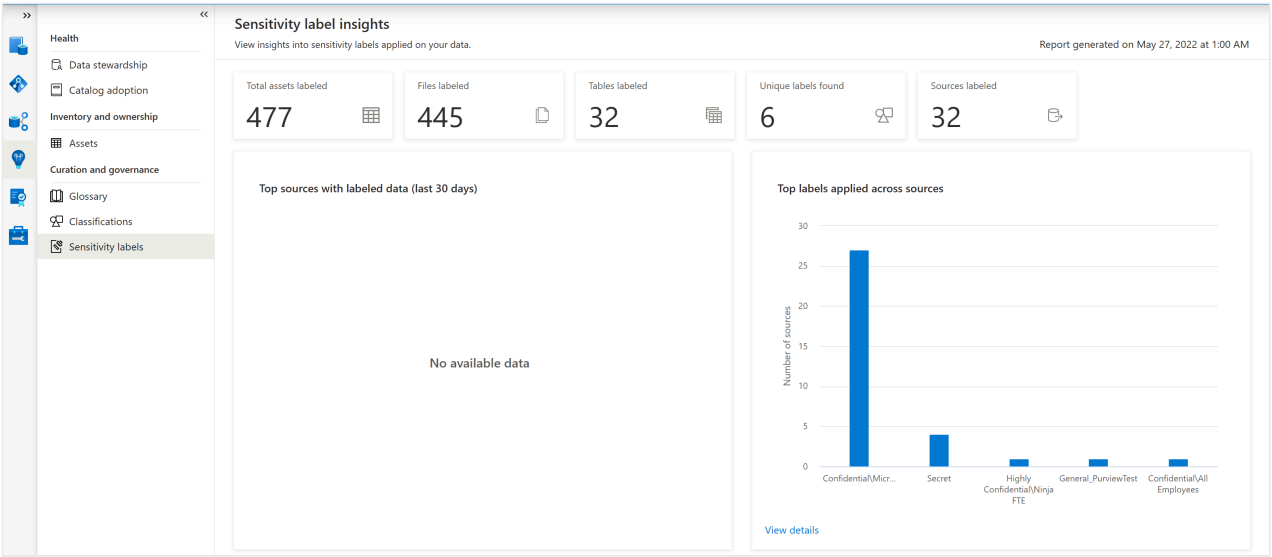
Use Data Estate Insights for sensitivity labels

Classifications are similar to subject tags. Use them to mark and identify data of a specific type that you find within your data estate during scanning.

Sensitivity labels enable you to state how sensitive certain data is in your organization. For example, a specific project name might be highly confidential within your organization, while that same term isn't confidential to other organizations.

Classifications match directly, such as a social security number, which has a classification of **Social Security Number**.

In contrast, sensitivity labels are applied when one or more classifications and conditions are found together. In this context, conditions refer to all the parameters that you can define for unstructured data, such as **proximity to another classification**, and **% confidence**.



Data Estate Insights uses the same classifications, also known as sensitive information types, as those used with Microsoft 365 apps and services. This enables you to extend your existing sensitivity labels to assets in Data Map.

> ⓘ **Note**
>
> After you scan your source types, wait a couple of hours for the **Classic sensitivity labels** report to reflect the new assets.

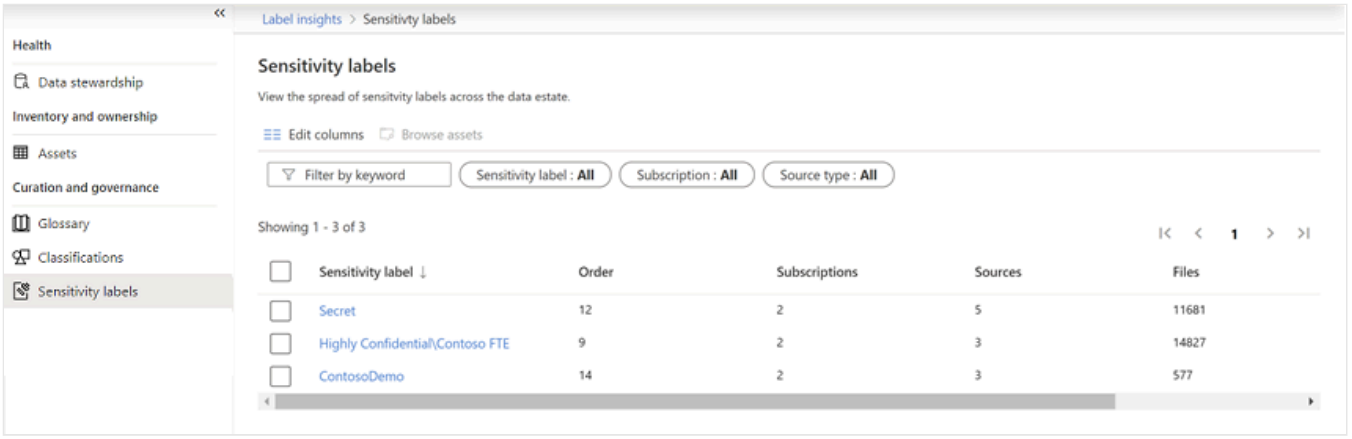
View sensitivity labeling insights

1. Open the Microsoft Purview portal.
2. If you're using the classic Microsoft Purview portal, select **Data estate insights**. If you're using the new Microsoft Purview portal open **Unified Catalog**, select **Health Management**, then select **Reports**.
3. Select the **Classic sensitivity labels** report.

   > ⓘ **Note**
   >
   > If this report is empty, you might not have extended your sensitivity labels to Data Map. For more information, see Learn about sensitivity labels in Data Map.

The main **Sensitivity labeling insights** page displays the following areas:

Expand table



Area	Description
Overview of sources with sensitivity labels	Displays tiles that provide: - The number of subscriptions found in your data. - The number of unique sensitivity labels applied on your data - The number of sources with sensitivity labels applied - The number of files and tables found with sensitivity labels applied
Top sources with labeled data (last 30 days)	Shows the trend, over the past 30 days, of the number of sources with sensitivity labels applied.
Top labels applied across sources	Shows the top labels applied across all of your Microsoft Purview data resources.
Top labels applied on files	Shows the top sensitivity labels applied to files in your data.
Top labels applied on tables	Shows the top sensitivity labels applied to database tables in your data.
Labeling activity	Displays separate graphs for files and tables, each showing the number of files or tables labeled over the selected time frame. **Default**: 30 days Select the **Time** filter above the graphs to select a different time frame to display.

Sensitivity labeling insights drilldown

In any of the following **Sensitivity labeling insights** graphs, select the **View more** link to drill down for more details:

- **Top labels applied across sources**
- **Top labels applied on files**
- **Top labels applied on tables**
- **Labeling activity > Labeled data**

For example:

To learn more, use the following options:

Expand table

Option	Description
Filter your data	Use the filters above the grid to filter the data shown, including the label name, subscription name, or source type. If you're not sure of the exact label name, enter part or all of the name in the **Filter by keyword** box.
Sort the grid	Select a column header to sort the grid by that column.
Edit columns	To display more or fewer columns in your grid, select **Edit Columns**, then select the columns you want to view or change the order. Select a column header to sort the grid by that column.
Drill down further	To drill down to a specific label, select a name in the **Sensitivity label** column to view the **Label by source** report. This report displays data for the selected label, including the source name, source type, subscription ID, and the numbers of classified files and tables.
Browse assets	To browse through the assets found with a specific label or source, select one or more labels or sources, depending on the report you're viewing, then select **Browse assets** above the filters.

Option	Description
	The search results display all of the labeled assets found for the selected filter. For more information, see Search the Microsoft Purview Unified Catalog.

Sensitivity label integration with Microsoft Purview Information Protection

Close integration with Microsoft Purview Information Protection means that you have direct ways to extend visibility into your data estate, and classify and label your data. For more information about sensitivity labels, see: Learn about sensitivity labels.

To extend sensitivity labels to your assets in Data Map, you must turn on this capability in the Microsoft Purview portal.

For more information, see Apply sensitivity labels to your data in Data Map.

Managed attributes in Microsoft Purview Data Map

07/16/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

Managed attributes are user-defined attributes that provide a business or organization level context to an asset. When applied to assets, managed attributes enable data consumers using the data catalog to gain context on the role an asset plays in a business.

Terminology

> **Important**
>
> Attributes for data assets are referred to by different names, depending on which portal you're using.
>
> - In the Microsoft Purview portal, https://purview.microsoft.com, they're called **Data asset attributes**.
> - In the classic Microsoft Purview governance portal, https://web.purview.azure.com, they're called **Managed attributes**.
>
> This article explains working with **Managed attributes** in the classic governance portal (although the process for working with data asset attributes in the Microsoft Purview portal is the same).

- **Managed attribute:** A set of user-defined attributes that provide a business or organization level context to an asset. A managed attribute has a name and a value. For example, 'Department' is an attribute name and 'Finance' is its value.
- **Attribute group:** A grouping of managed attributes that allow for easier organization and consumption.

Create managed attributes

1. Access managed attributes by following the steps corresponding to the portal you're using:

    - In the Microsoft Purview portal (https://purview.microsoft.com):
        a. Under **Solutions**, select **Unified Catalog**.
        b. Under **Catalog management**, select **Custom metadata**, then select the **Data asset attributes** tab.
    - In the classic Microsoft Purview governance portal (https://web.purview.azure.com):
        a. Open **Data Map**.
        b. Under the **Annotation management**, select **Managed attributes**.

2. Select **New**, then select either **New attribute** or **New attribute group**.

3. To create an attribute group, enter a name and a description.

4. Managed attributes have a name, attribute group, data type, and associated asset types. They also have a required flag that can only be enabled when created as part of creating a new attribute group. Associated asset types are the data asset types you can apply the attribute to. For example, if you select "Azure SQL Table" for an attribute, it will be applied to Azure SQL Table assets, but not Azure Synapse Dedicated Table assets.

5. Select **Create** to save your attribute.

These attributes will be automatically applied to the specified resources without a value. You'll need to apply a value for each asset.

Required managed attributes

When you create a managed attribute as part of a managed attribute group, you can add the **required** flag. The required flag means that a value must be provided for this managed attribute. When you edit a data asset, the required attribute must be filled out before you can close the editor.

> **Important**
>
> - You can only add the **required** flag when you create an attribute during the process of creating an attribute group. You can't add the **required** flag while creating a new attribute outside of an attribute group.
> - If an existing attribute doesn't have the **required** flag, you can't add it during the editing process.

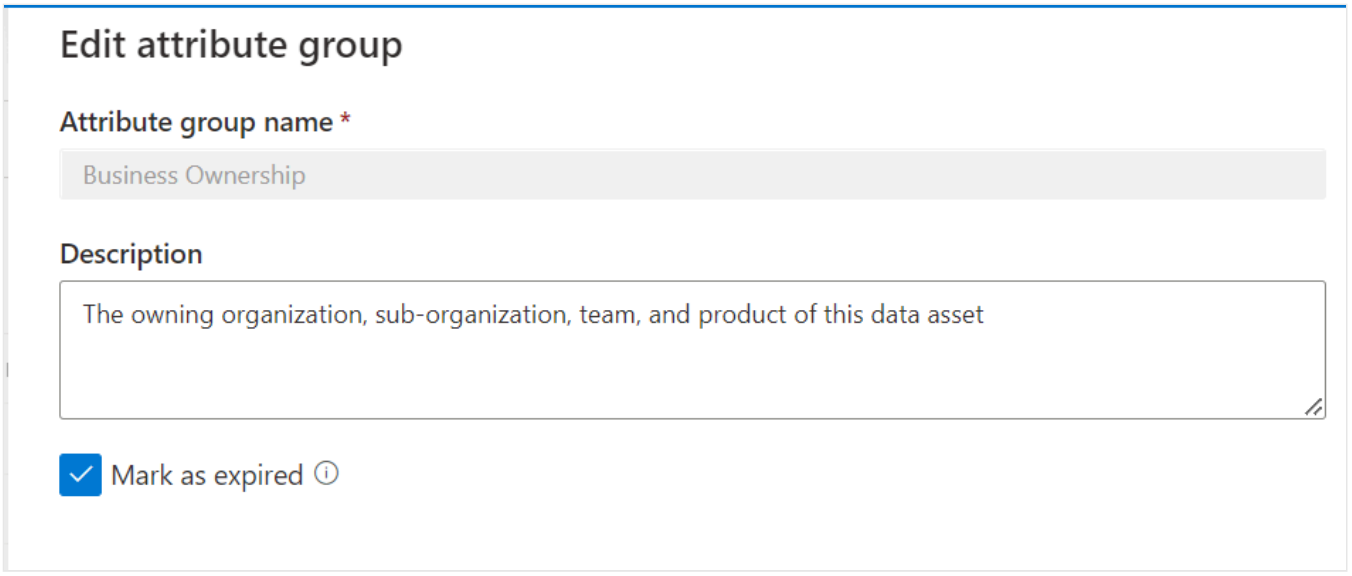
- Once you add the **required** flag, you can't remove it from the attribute.

1. Open Data Map and navigate to **Managed attributes** in the **Annotation management** section.
2. Select **New** and select **Attribute group**.
3. Select **New attribute**.
4. Fill out your attribute details, and select **Mark as required**.
5. Select **Apply** and finish adding other attributes to complete your attribute group.

Add value for managed attribute

Once a managed attribute has been created, you'll need to add a value for each of your assets. You can add values to your assets by:

1. Search for your data asset.
2. On the overview for your asset, see the **Managed attributes** section with all attributes that have values. (You can see attributes without values by using the **Show attributes without a value** toggle.)
3. Select the **Edit** button.
4. Under **Managed attributes**, add values for each of your attributes.
5. If any attributes are **Required**, you won't be able to save until you add a value for that attribute.



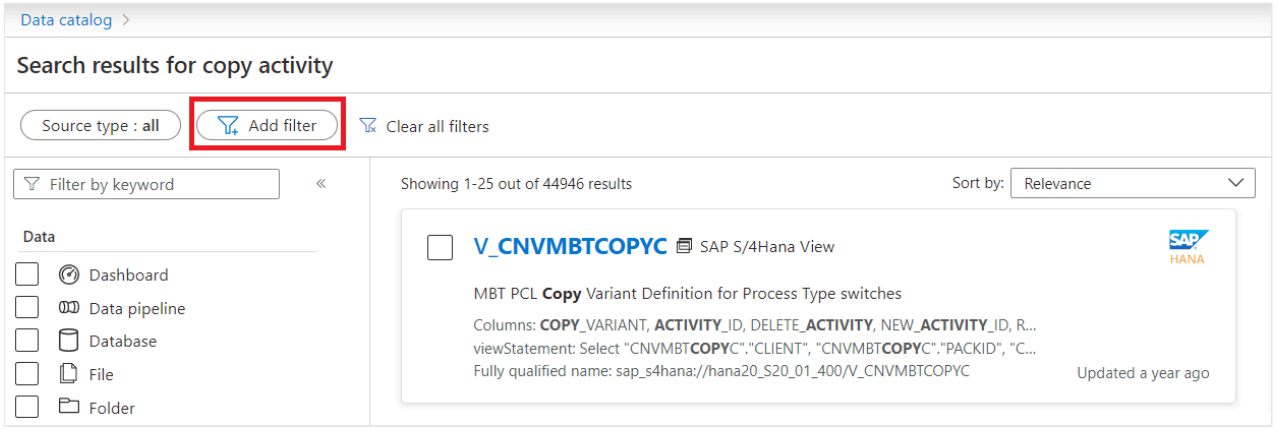
Expiring managed attributes

In the managed attribute management experience, managed attributes can't be deleted, only expired. Expired attributes can't be applied to any assets and are, by default, hidden in the user experience. By default, expired managed attributes aren't removed from an asset. If an asset has an expired managed attribute applied, it can only be removed, not edited.

Both attribute groups and individual managed attributes can be expired. To mark an attribute group or managed attribute as expired, select the **Edit** icon.

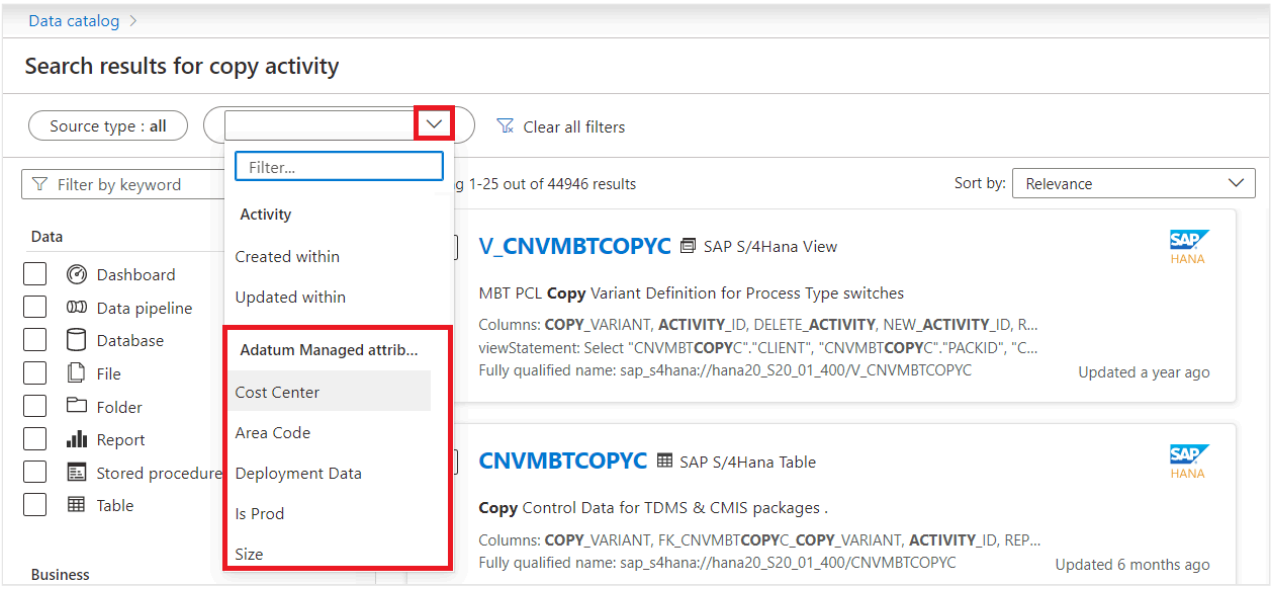
Name	Description	Type	Associated asset types
Business Ownership	The owning organization, sub-organization, team, a...	-	-
Organization	-	Single choice	Azure SQL Table

Select **Mark as expired** and confirm your change. Once expired, attribute groups and managed attributes can't be reactivated.



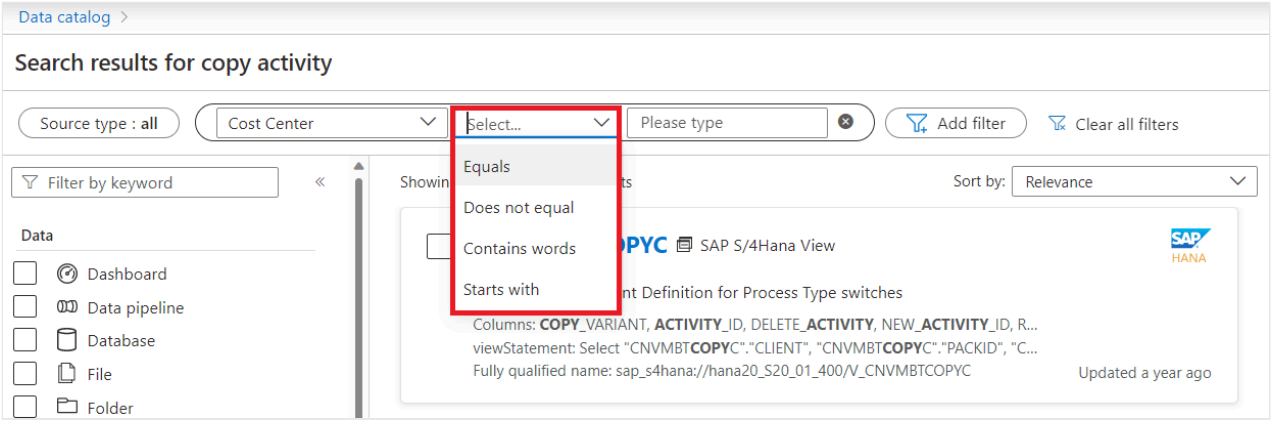
Create managed attributes using APIs

Managed attributes can be programmatically created and applied using the business metadata APIs in Apache Atlas 2.2. For more information, see the Use Atlas 2.2 APIs tutorial.



Searching by managed attributes

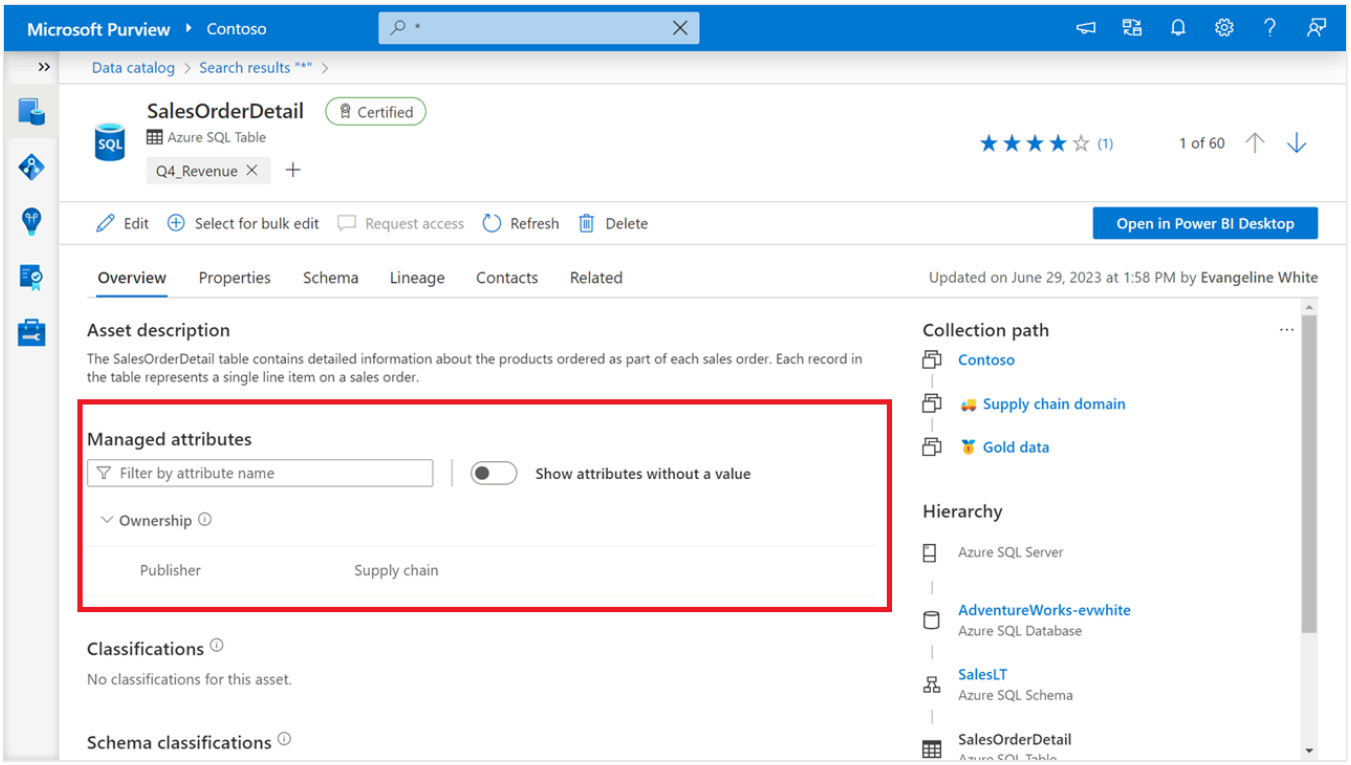
Once you have created managed attributes, you can refine your data catalog searches using these attributes.



1. In a data catalog search, to refine by a managed attribute, first select **Add filter** at the top of the search.

2. Select the drop-down, scroll to your list of managed attributes, and select one.

3. Select your operator, which will be different based on the kinds of values allowed by the attribute. In this example, we've selected Cost Center, which is a text value, so we can compare Cost Center with the text we'll enter.



4. Enter your values, and the search runs with your new filter.

Best practices for using managed attributes

Use managed attributes to extend the fields available for an asset in the Microsoft Purview Data Catalog. Managed attributes are key-value pairs that add structured metadata to your data catalog. When Microsoft Purview scans data, it adds technical information about the data like data type, classification, etc. If you want to add more fields, you need to define managed attributes.

In the following example, a managed attribute lets me tag tables with the department that publishes them. I use a managed attribute because I want to make sure assets are always tagged in exactly the same way with this information. I also want to filter by the publisher field when I search for data.

The managed attribute in this example helps people quickly find all data published by the supply chain team, but doesn't help someone understand the definition of a publisher or what it means if supply chain is the publisher of the data. For any information that needs a business explanation, use terms.

Known limitations

Below are the known limitations of the managed attribute feature as it currently exists in Microsoft Purview.

- Managed attributes can only be expired.
- Managed attributes can't be applied via the bulk edit experience.
- After creating an attribute group, you can't edit the name of the attribute group.
- After creating a managed attribute, you can't update the attribute name, attribute group, or the field type.
- A managed attribute can only be marked as required during the creation of an attribute group.

Asset management in the Microsoft Purview Data Catalog

Article • 02/24/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

This article discusses how assets are displayed in the Microsoft Purview Data Catalog, and all the features and details available to them. It describes how you can view relevant information or take action on assets in your catalog.

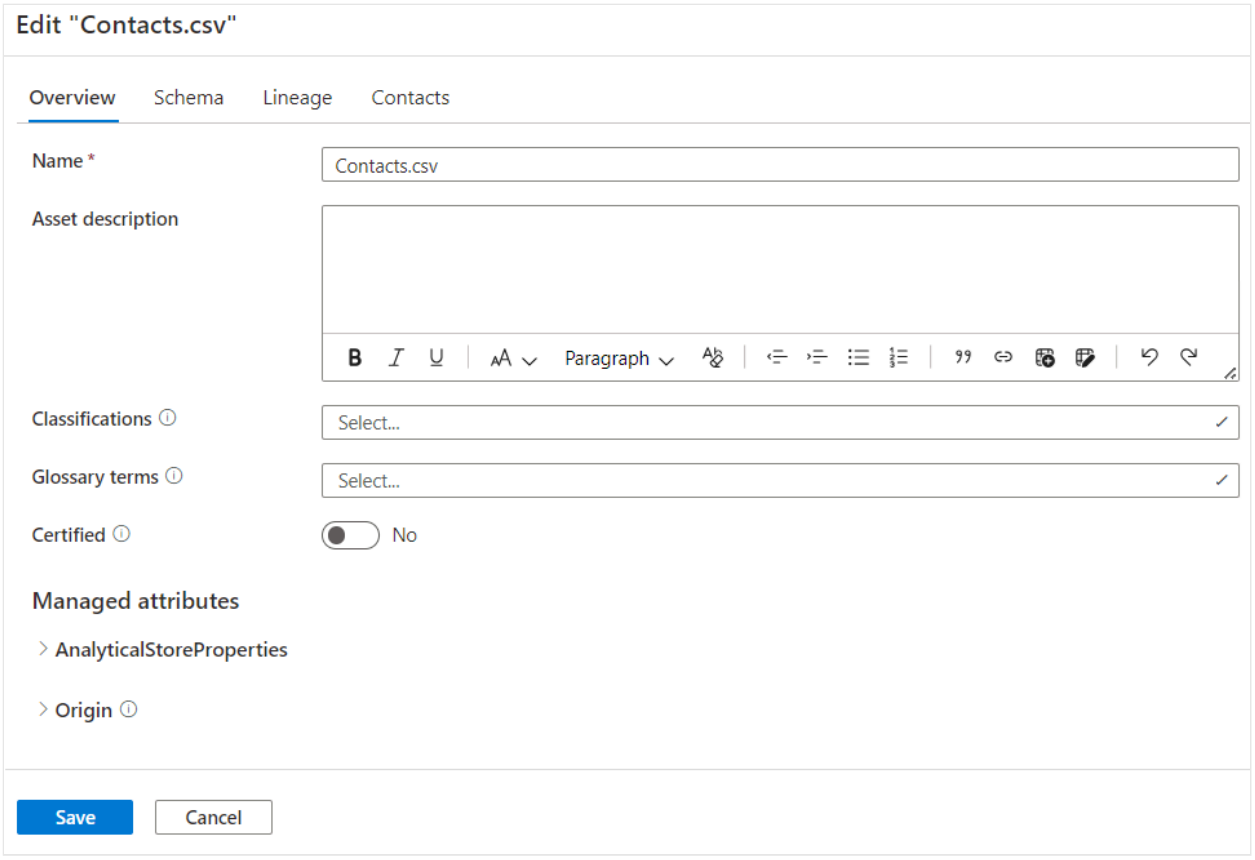
Prerequisites

- Set up your data sources and scan the assets into your catalog.
- *Or* Use the Microsoft Purview Atlas APIs to ingest assets into the catalog.

Discover assets

You can discover your assets in the Microsoft Purview Data Catalog by either:

- Browsing the data catalog
- Searching the data catalog



Once you've discovered an asset, select it to view the asset details page, which contains all the asset details, and more actions you can take.

Edit assets

To edit an asset, other than adding a rating, you will need the data curator role on the collection where the asset is housed.

To edit assets you can either:

- Select multiple assets in the catalog to bulk edit assets
- Select a single asset and select the **Edit** button at the top of the asset details page

When you're editing an asset you can manage nearly all its information including:

- Overview: Manually update name, description, classification, and glossary terms.
- Schema: Manually update column name, classification, glossary terms, data types, and description.
- Lineage: Manually add lineage connections to other resources.
- Contacts: Add experts and owners users can contact for more information on this resource.

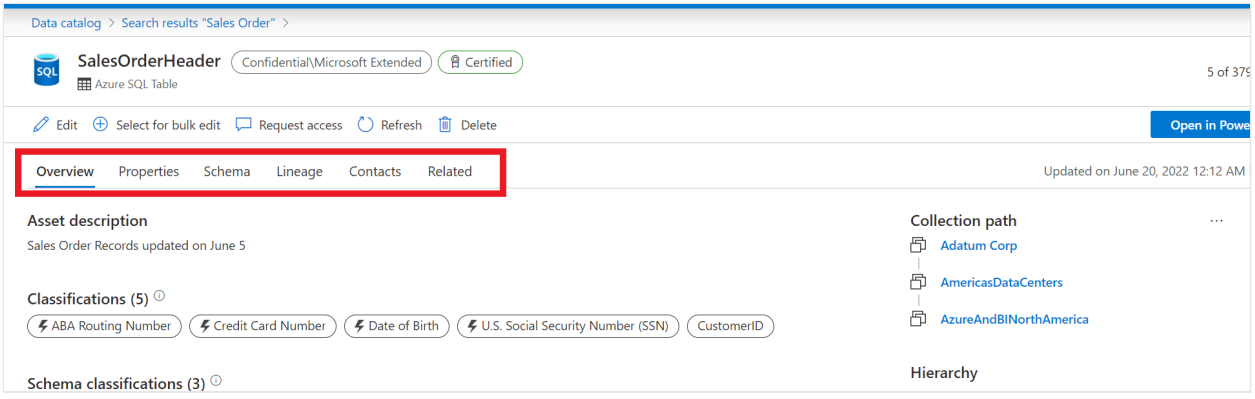
Scan behavior after editing assets

Microsoft Purview works to reflect the truth of the source system whenever possible. For example, if you edit a column and later it's deleted from the source table. A scan will remove the column metadata from the asset in Microsoft Purview.

Both column-level and asset-level updates such as adding a description, glossary term or classification don't impact scan updates. Scans will update new columns and classifications regardless if these changes are made.

Delete asset

If you're a data curator on the collection containing an asset, you can delete an asset by selecting the delete icon under the name of the asset.



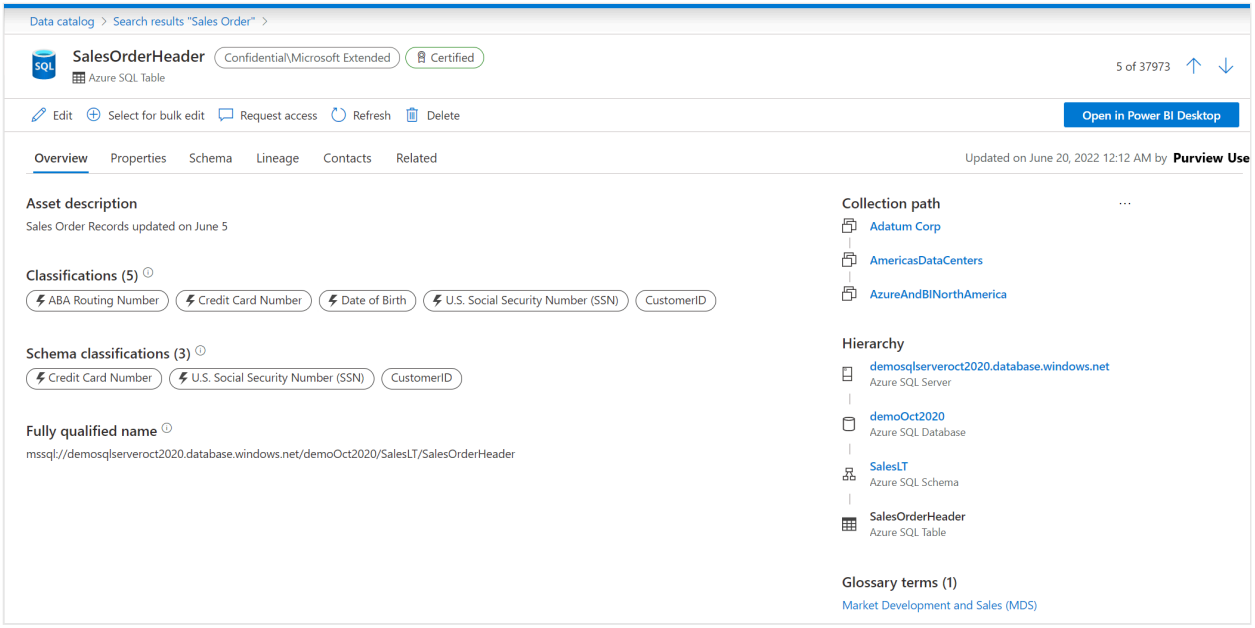
> **Important**
>
> Deleting the asset using the delete button will also delete all the child assets under the hierarchy. For example, if you attempt to delete a storage account asset in your catalog, all the assets under it - containers, folders and files - will also be deleted together.

Any asset you delete using the delete button is permanently deleted in Microsoft Purview. However, if you run a **full scan** on the source from which the asset was ingested into the catalog, then the asset is reingested and you can discover it using the Microsoft Purview Data Catalog.

When you run an incremental scan on the source, the **deleted asset won't get re-ingested** into the catalog unless the asset is modified by an end user since the previous run of the scan. For example, say you manually delete a SQL table from the Microsoft Purview Data Map. Later, a data engineer adds a new column to the source table. When Microsoft Purview scans the database, the table will be reingested into the data map and be discoverable in the data catalog.

Asset details page

At the top of the asset details page there are several tabs:



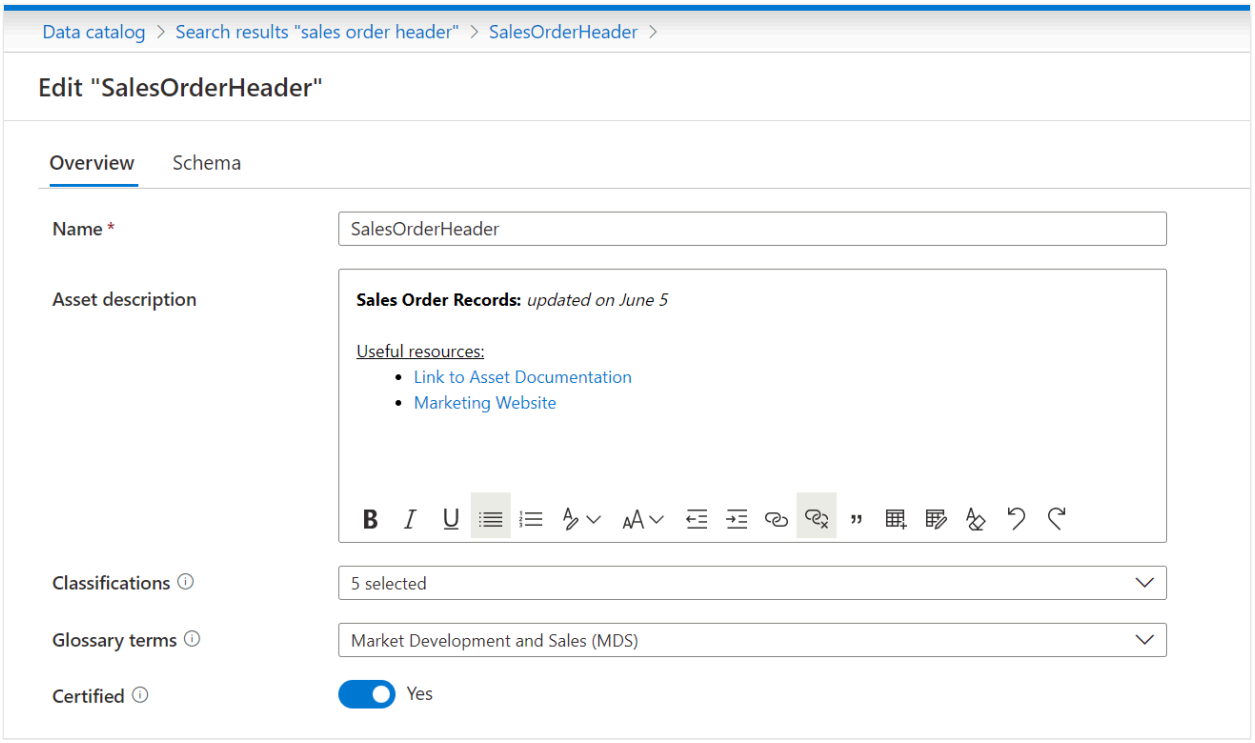
- **Overview** - An asset's basic details like description, classification, hierarchy, and glossary terms.
- **Properties** - The technical metadata and relationships discovered in the data source.
- **Schema** - The schema of the asset including column names, data types, column level classifications, terms, and descriptions are represented in the schema tab.
- **Lineage** - This tab contains lineage graph details for assets where it's available.
- **Contacts** - Every asset can have an assigned owner and expert that can be viewed and managed from the contacts tab.

- **Related** - This tab lets you navigate through the technical hierarchy of assets that are related to the current asset you're viewing.

> **Tip**
>
> You can information on all these tabs by editing the asset.

Asset overview

The overview section of the asset details gives a summarized view of an asset. The sections that follow explains the different parts of the overview page.



Asset description

An asset description gives a synopsis of what the asset represents. You can add or update an asset description by editing the asset.

Adding rich text to a description

Microsoft Purview enables users to add rich formatting to asset descriptions such as adding bolding, underlining, or italicizing text. Users can also create tables, bulleted lists, or hyperlinks to external resources.

Below are the rich text formatting options:

Expand table

Name	Description	Shortcut key
Bold	Make your text bold. Adding the '*' character around text will also bold it.	Ctrl+B
Italic	Italicize your text. Adding the '_' character around text will also italicize it.	Ctrl+I
Underline	Underline your text.	Ctrl+U
Bullets	Create a bulleted list. Adding the '-' character before text will also create a bulleted list.	
Numbering	Create a numbered list Adding the '1' character before text will also create a bulleted list.	
Heading	Add a formatted heading	
Font size	Change the size of your text. The default size is 12.	
Decrease indent	Move your paragraph closer to the margin.	
Increase indent	Move your paragraph farther away from the margin.	
Add hyperlink	Create a link in your document for quick access to web pages and files.	

Name	Description	Shortcut key
Remove hyperlink	Change a link to plain text.	
Quote	Add quote text	
Add table	Add a table to your content.	
Edit table	Insert or delete a column or row from a table	
Clear formatting	Remove all formatting from a selection of text, leaving only the normal, unformatted text.	
Undo	Undo changes you made to the content.	Ctrl+Z
Redo	Redo changes you made to the content.	Ctrl+Y

> **Note**
>
> Updating a description with the rich text editor updates the `userDescription` field of an entity. If you have already added an asset description before the release of this feature, that description is stored in the `description` field. When overwriting a plain text description with rich text, the entity model will persist both `userDescription` and `description`. The asset details overview page will only show `userDescription`. The `description` field can't be edited in the Microsoft Purview studio user experience.

Classifications

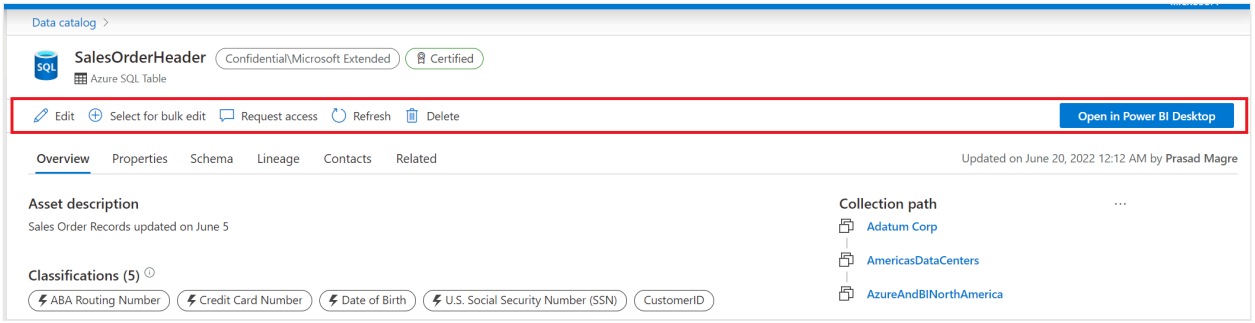
Classifications identify the kind of data being represented by an asset or column such as "ABA routing number", "Email Address", or "U.S. Passport number". These attributes can be assigned during scans or added manually. For a full list of classifications, see the supported classifications in Data Map. You can see classifications assigned both to the asset and columns in the schema from the overview page.which you can also view as part of the schema.

Glossary terms

Glossary terms are a managed vocabulary for business terms that can be used to categorize and relate assets across your organization. For more information, see the business glossary page. You can view the assigned glossary terms for an asset in the

overview section. If you're a data curator on the asset, you can add or remove a glossary term on an asset by editing the asset.

Collection hierarchy



In Microsoft Purview, collections organize assets and data sources. They also manage access across the Microsoft Purview governance portal. You can view an assets containing collection under the **Collection path** section.

Asset hierarchy

You can view the full asset hierarchy within the overview tab. As an example: if you navigate to a SQL table, then you can see the schema, database, and the server the table belongs to.

Asset actions

Below are a list of actions you can take from an asset details page. Actions available to you vary depending on your permissions and the type of asset you're looking at. Available actions are generally available on the global actions bar.

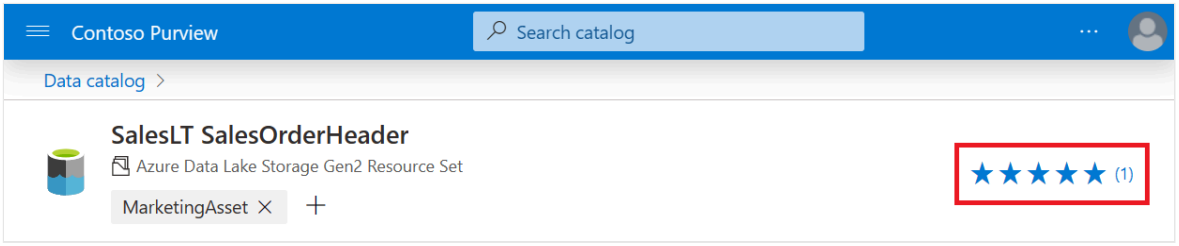
Request access to data

If a self-service data access workflow has been created, you can request access to a desired asset directly from the asset details page! To learn more about Microsoft Purview's data policy applications, see how to enable data policy enforcement.

Open in Power BI

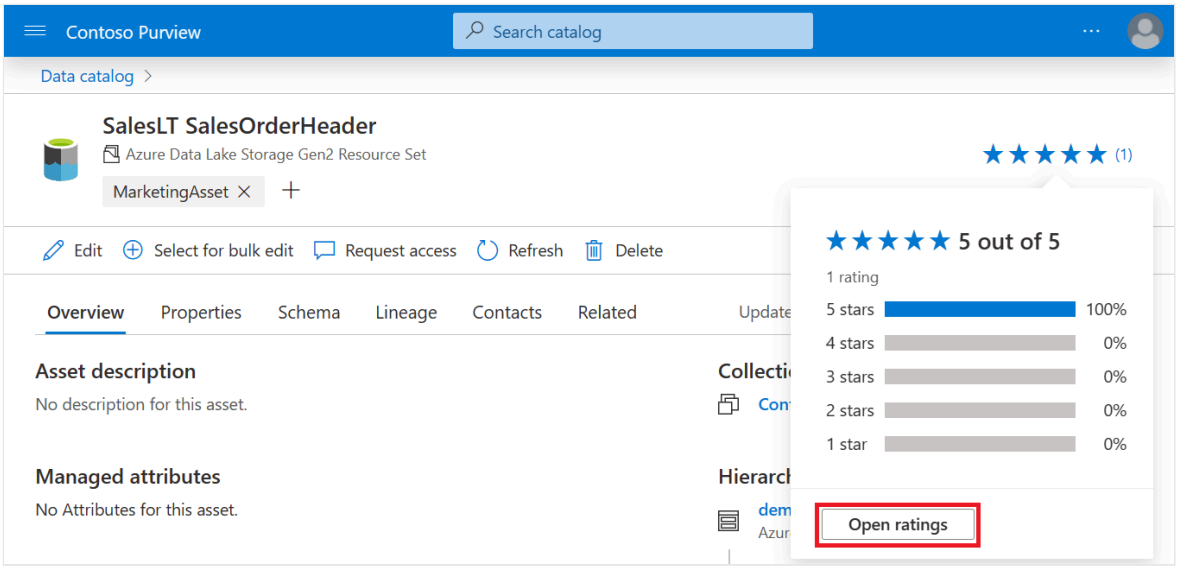
Microsoft Purview makes it easy to work with useful data you find the data catalog. You can open certain assets in Power BI Desktop from the asset details page. Power BI Desktop integration is supported for the following sources.

- Azure Blob Storage
- Azure Cosmos DB
- Azure Data Lake Storage Gen2
- Azure Dedicated SQL pool (formerly SQL DW)
- Azure SQL Database
- Azure SQL Managed Instance
- Azure Synapse Analytics
- Azure Database for MySQL
- Azure Database for PostgreSQL
- Oracle DB
- SQL Server
- Teradata



Ratings

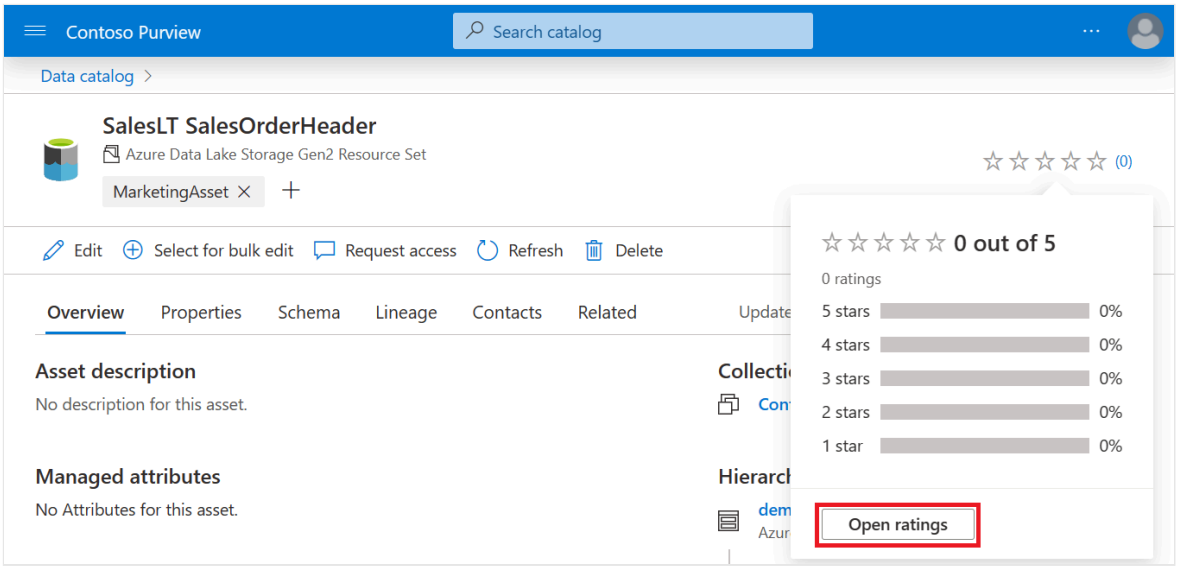
Assets can be rated by all users with read access, or better, to that asset in Microsoft Purview. Ratings allow users to give an asset a rating from 1 to 5 stars, and leave a comment about the asset.



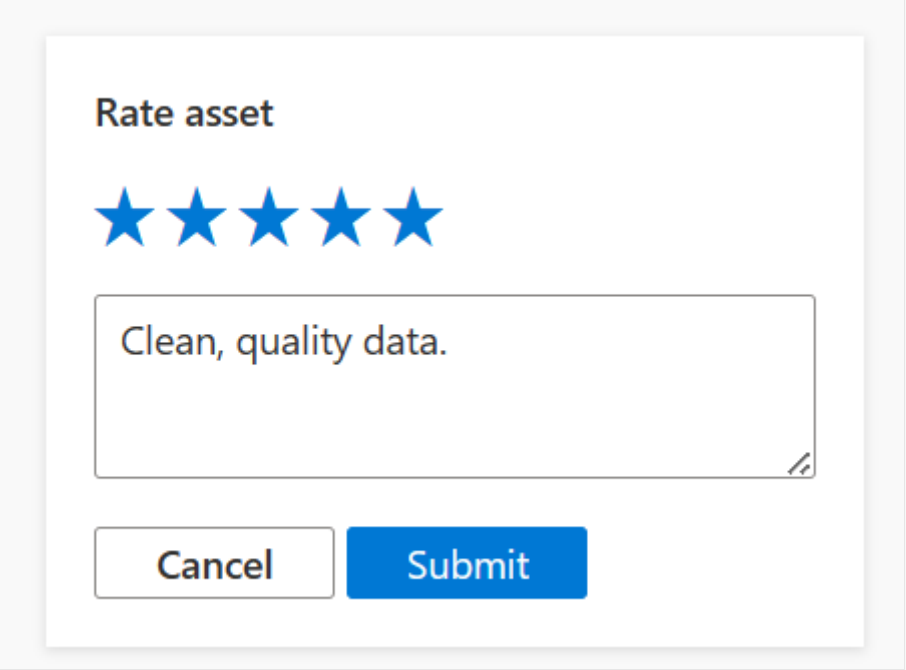
These ratings can be seen by all users with read access, and rating can be added as a filter when searching the data catalog so users can find assets with a certain rating.

View ratings

1. Search or browse for your asset in Microsoft Purview and select it.
2. In the header of the asset you can see a rating, which will show an aggregate star rating of the asset, and the number of reviews.

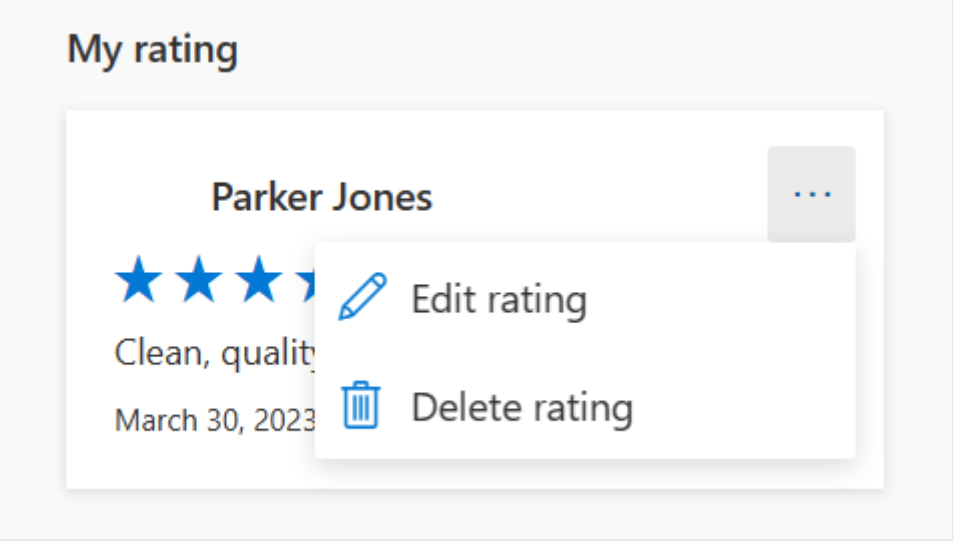


3. To see a percentage breakdown of the ratings, select the rating.
4. To see specific ratings and their comments, or to add your own rating, select **Open ratings**.



Add a rating to an asset

1. Search or browse for your asset in Microsoft Purview and select it.
2. Select the ratings button in the asset's header.
3. Select the **Open ratings** button.



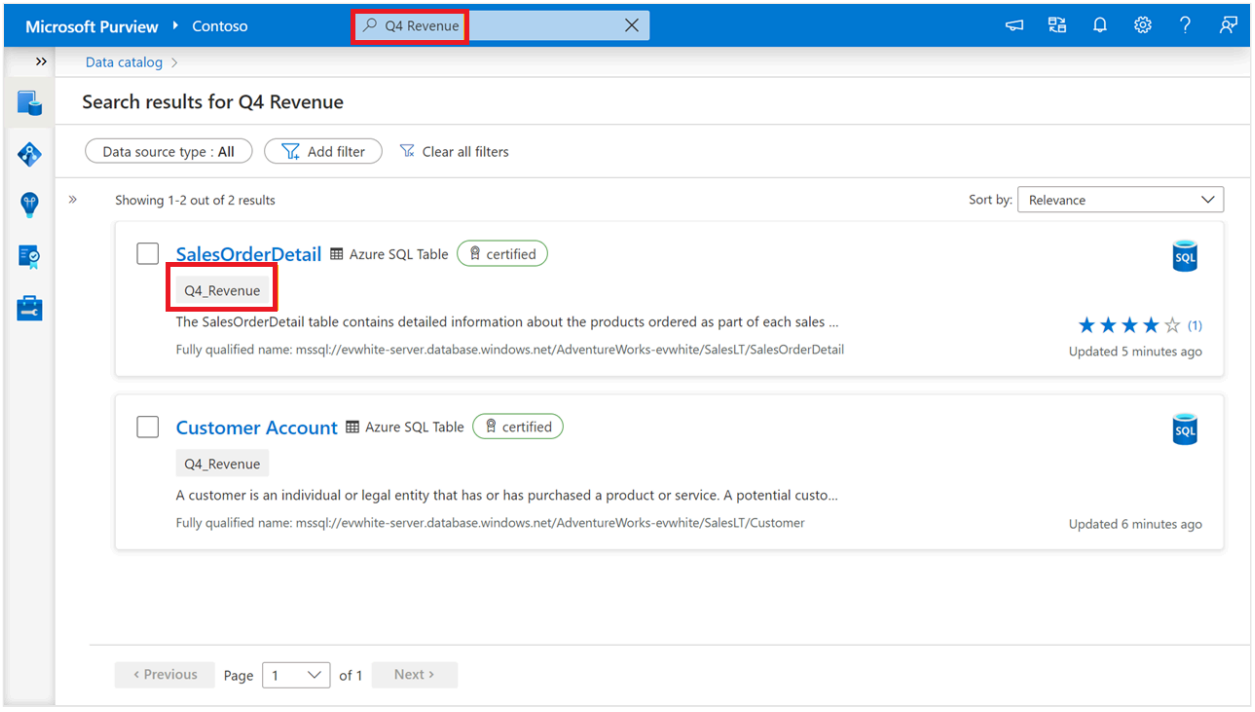
4. Choose a star rating, add a comment, and select **Submit**.

Edit or delete your rating

1. Select the ratings button in the asset's header.
2. Select the **Open ratings** button.
3. Under **My rating** select the ellipsis button in your rating.

4. To delete your rating, select **Delete rating**.
5. To edit your rating, select **Edit rating**, then update your score and comment and select **Submit**.

Tags

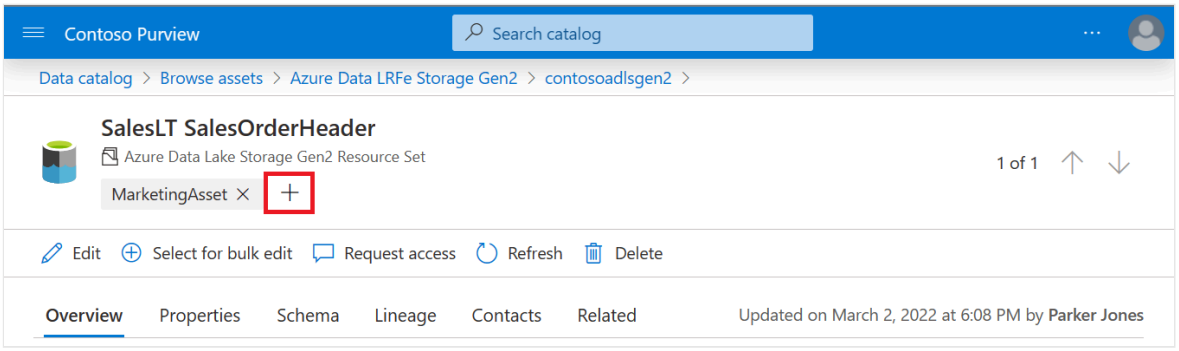


Asset can be tagged by users with data curator permissions or better, and any users with reader permissions on these assets in Microsoft Purview can see these tags. Users can

add tags as a filter when searching the data catalog, so users can see all assets with certain tags.

> **Note**
>
> Tag limitations:
>
> - An asset can only have up to 50 tags
> - Tags can only be 50 characters
> - Allowed characters: numbers, letters, -, and _

Use tags when you want to quickly label your data assets without the need for consistency or control. Tags are simple keywords or phrases that can be applied to data assets to provide informal metadata. They're useful for categorizing data assets, making them easier to discover and understand. They're also a great way to see how your data consumers describe your data so you can incorporate this language into your business glossary over time.

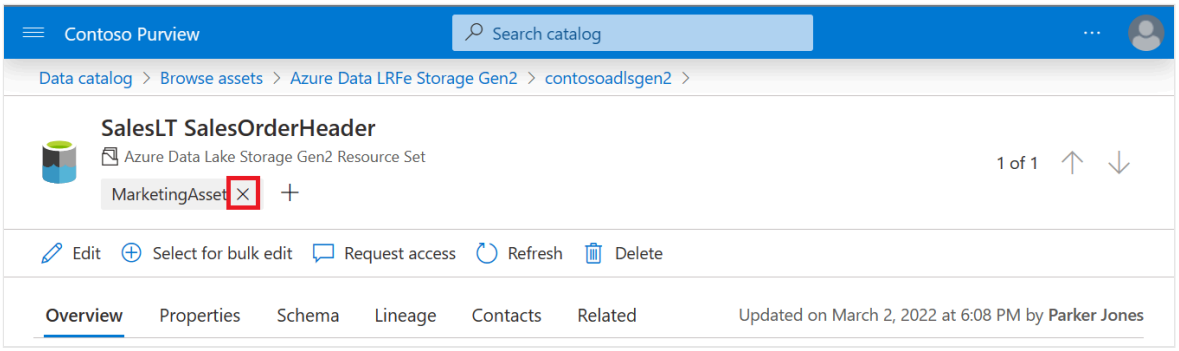


In the following example, a few assets with Q4 Revenue so users can easily find the data assets to use for a new report with this information. Searching the keyword returns all data with that tag applied:

Add a tag to an asset

If you have data curator permissions Microsoft Purview, you can add a tag to an asset by:

1. Search or browse for your asset in Microsoft Purview and select it.
2. Select the + **Add Tag** button under the asset's name.



3. Select an existing available tag, or input a new tag.

Remove a tag from an asset

If you have data curator permissions Microsoft Purview, you can remove a tag from an asset by:

1. Search or browse for your asset in Microsoft Purview and select it.
2. Select the **X** button next to an existing tag under the asset's name.

3. Confirm the removal of the tag.

Duplicate assets

If you notice duplicate assets in your Microsoft Purview Data Catalog, review the asset normalization documentation. Microsoft Purview normalizes assets to prevent duplication, but not all possible scenarios are covered.

Compare the fully qualified asset names for duplicate assets, and update ingestion points to resolve capitalization or character differences. Then, delete the duplicated asset in your catalog.

Next steps

- Browse the Microsoft Purview Data Catalog
- Search the Microsoft Purview Data Catalog

- Asset normalization

Metadata curation in Microsoft Purview Data Map

Article • 05/20/2025

This article describes how users can update and curate the metadata of an asset in the Microsoft Purview Data Map. Data assets in the map automatically have technical metadata like name and schema, but users can also add other information like descriptions and contacts. This extra information allows other users to better understand data assets so they can discover, govern, and use them.

Who can update metadata?

- Users who have the owner role or write permissions on available, live Azure resources can access and edit those resources in free and enterprise account types. For more information about data owner metadata curation, see the data owner curation section on this page.
- Users who have data curator permissions on a collection in a Microsoft Purview account can edit the metadata details for all data assets in that collection. This is only available in the enterprise version of Microsoft Purview.
- Users who are using the classic Microsoft Purview Unified Catalog and have been assigned to the the data curator role group can edit the metadata details for all data assets in a Microsoft Purview account. For more information, see the role group curation section on this page.

Data owner curation

If a user is a data owner on an available, live Azure resource, they're able to access and manage that asset's metadata in Microsoft Purview. In this case, a 'data owner' isn't limited to users who have the Azure RBAC owner role on a resource. It also applies to users who have certain write permissions on the available Azure resources. The permissions needed are listed in the supported live sources section.

With those permissions, data owners able to update these aspects of a data asset:

- Description
- Contacts
- Column descriptions

> **Tip**
>
> Any of these updates are tracked by Microsoft Purview and can be viewed in **Data Map history**.

Role group curation

If a user has been added to the data curator role group in the classic Microsoft Purview Unified Catalog, they're able to access and manage asset metadata in Microsoft Purview depending on the version of Microsoft Purview they're using.

With the free version of Microsoft Purview governance solutions you can update these aspects:

- Display name
- Description
- Contacts
- Column descriptions
- Column names
- Column data types
- Source classifications
- Column classifications

With the enterprise version of Microsoft Purview, after extending live view, or registering and scanning an asset, you can edit all the other aspects of that asset, including adding glossary terms.

> **Tip**
>
> Any of these updates are tracked by Microsoft Purview and can be viewed in **Data Map history**.

Collection-level role curation

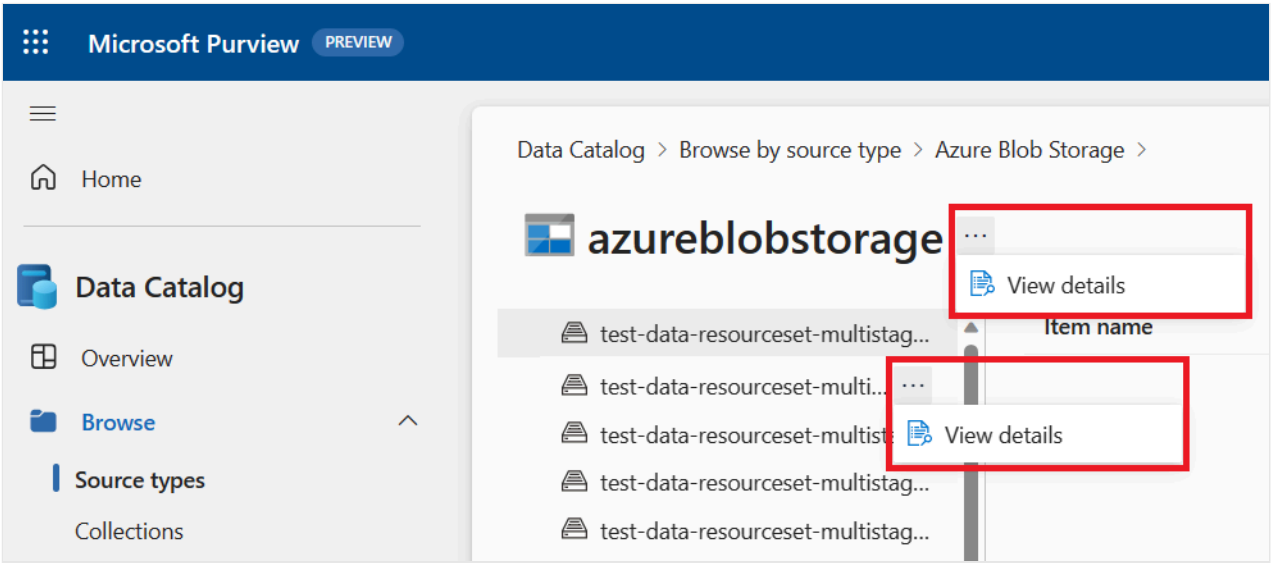
If a user has been given the data curator role on a collection in Data Map, they're able to access and manage metadata for any assets in that collection.

> **Note**

A user can only be assigned the data curator role on a collection in the enterprise version of Microsoft Purview.

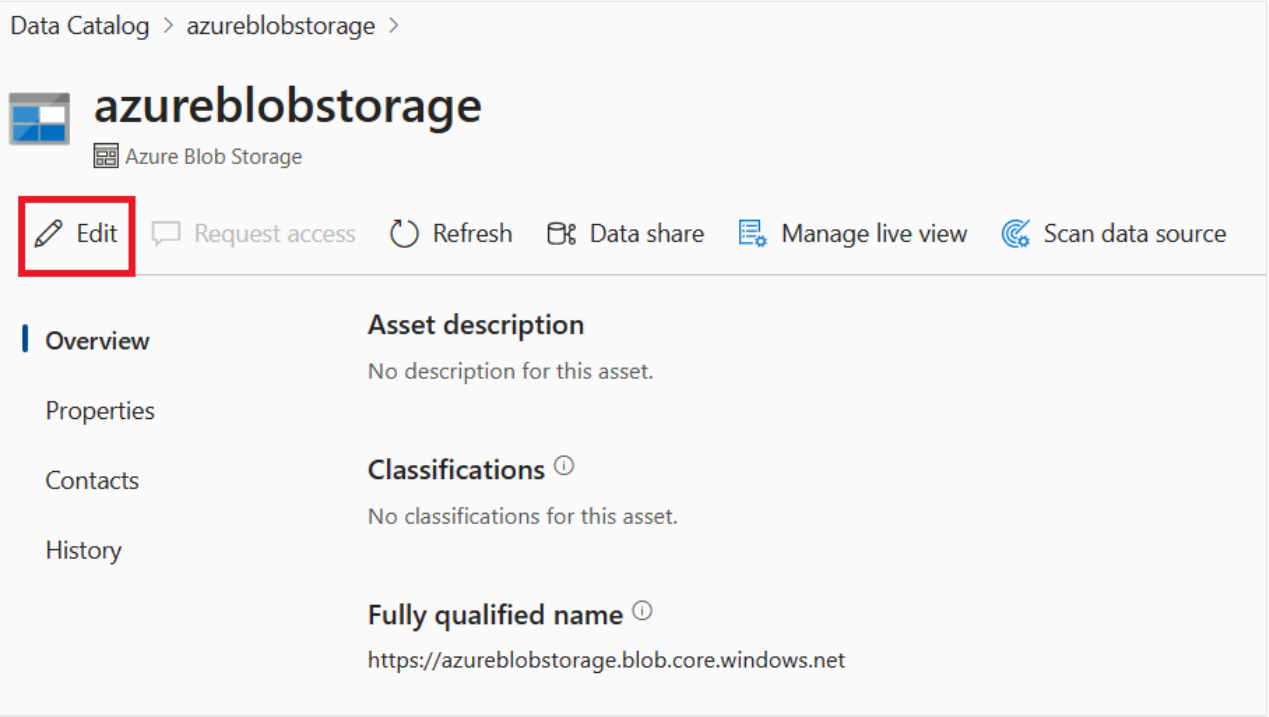
With the data curator role, a user can update aspects of their data assets depending on the kind of asset it is.

If an asset is only available as a live view asset you can edit:



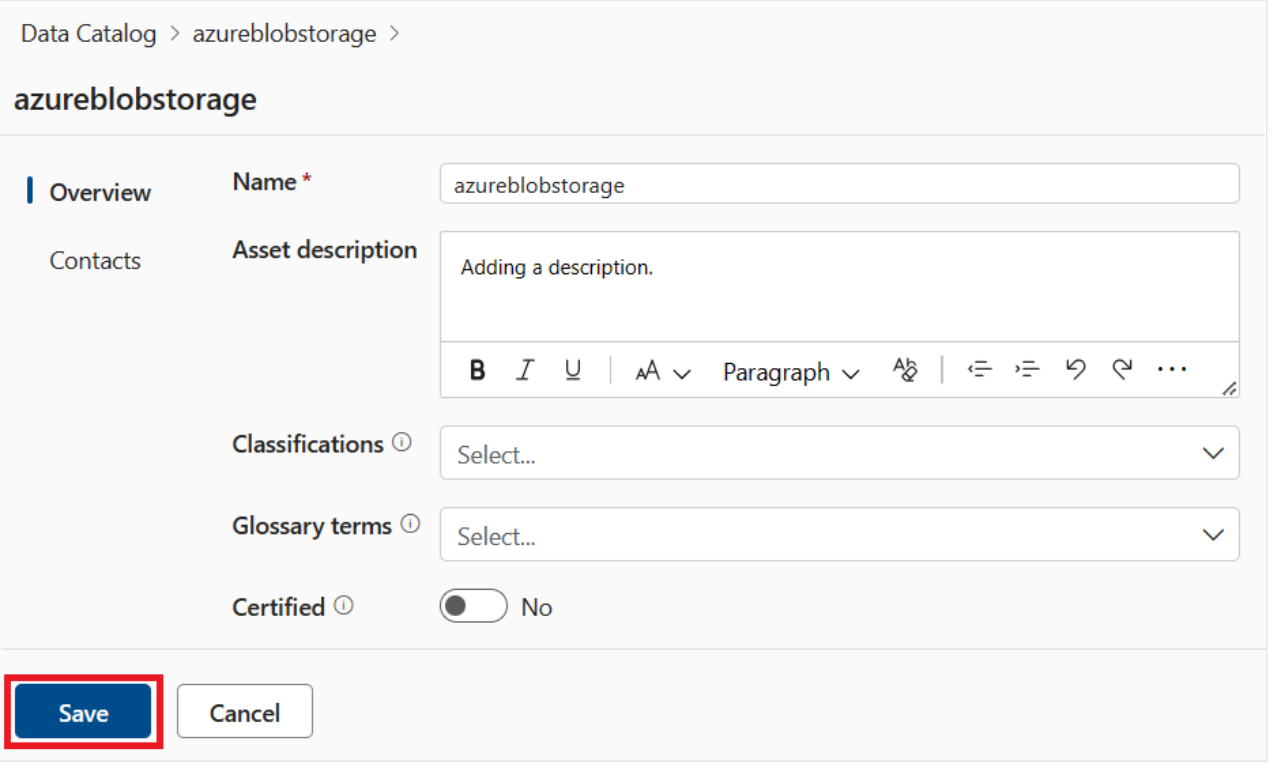
- Display name
- Description
- Contacts
- Column descriptions
- Column names
- Column data types
- Source classifications
- Column classifications

Once an asset has had live view extended for all users, or if an asset has been registered and scanned, you can edit all the other aspects of an asset, including adding glossary terms.



How to edit assets

1. In the Microsoft Purview portal (or the classic Microsoft Purview governance portal) search or browse for a data source or asset.



2. Select the asset to view details.

3. Select **Edit**.

4. Make any changes to the metadata, and select **Save** when you're finished.

For more information about editing assets, including rich text editing for descriptions, see the [manage assets in the Unified Catalog article]classic-catalog-asset-details.md).

Supported live sources

Expand table

Data source	Owner permission
Azure SQL Database	"Microsoft.Sql/servers/write", "Microsoft.Sql/servers/databases/write", "Microsoft.Authorization/roleAssignments/write"
Azure Blob Storage	"Microsoft.Storage/storageAccounts/write", "Microsoft.Authorization/roleAssignments/write"
Azure Data Lake Storage Gen2	"Microsoft.Storage/storageAccounts/write", "Microsoft.Authorization/roleAssignments/write"

Limitations

These are the current limitations for metadata curation in Microsoft Purview:

- When a user in the data curator role group edits a live mode asset for the first time, it will not work. If you edit a second time with a different edit than the first attempt, then it works.

Next steps

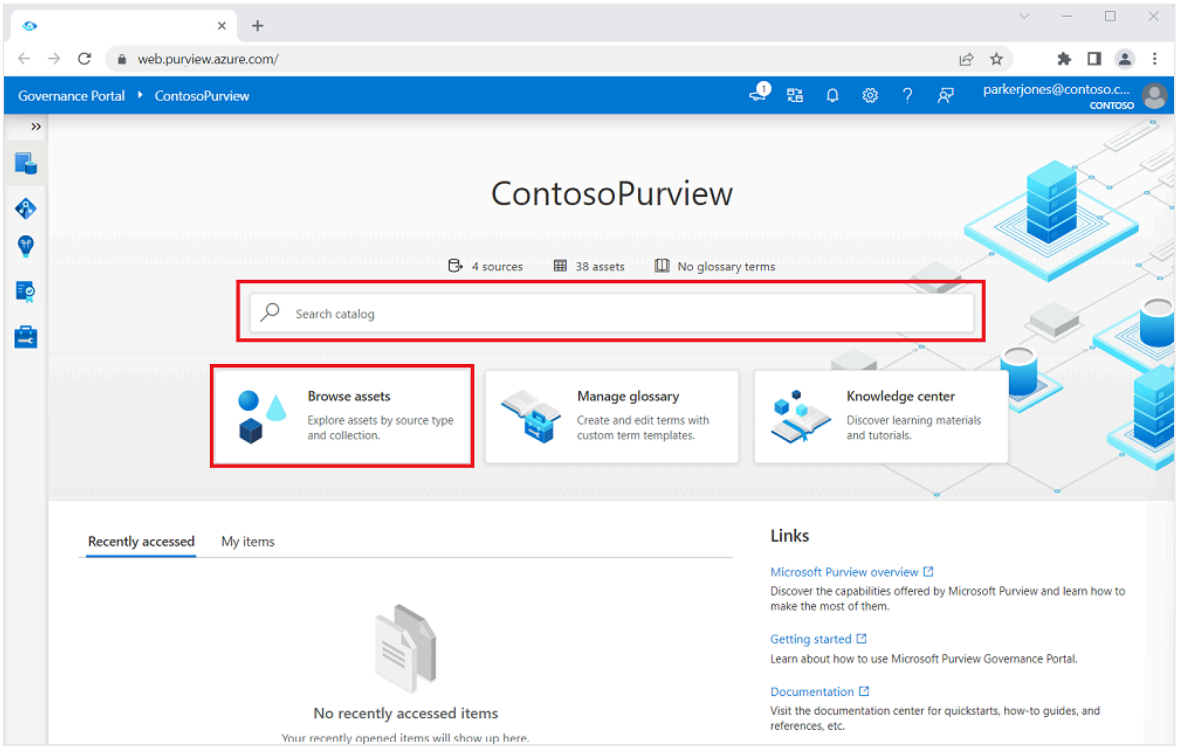
- What is live view?
- The new Microsoft Purview portal
- Roles and permissions

How to request access for a data asset

Article • 02/26/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

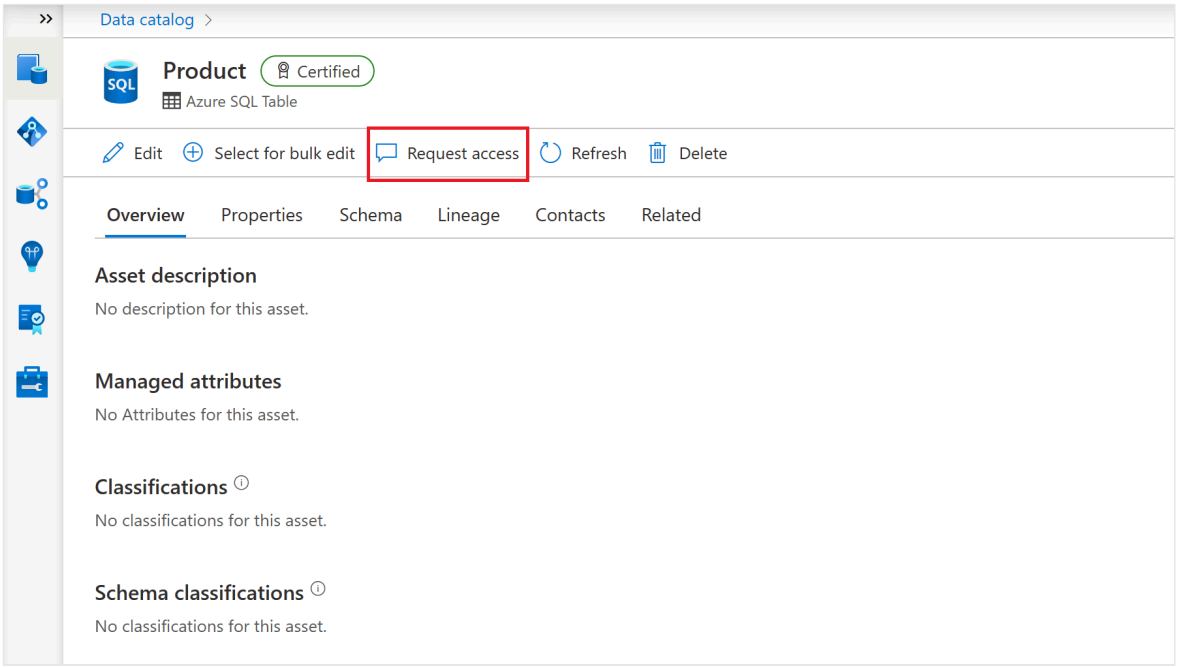
> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.



If you discover a data asset in the catalog that you would like to access, you can request access directly through Microsoft Purview. The request will trigger a workflow that will request that the owners of the data resource grant you access to that data source.

This article outlines how to make an access request.

> **Note**
>
> For this option to be available for a resource, a self-service access workflow needs to be created and assigned to the collection where the resource is registered. Contact the collection administrator, data source administrator, or workflow administrator of your collection for more information. Or, for information on how to create a self-service access workflow, see our self-service access workflow documentation.

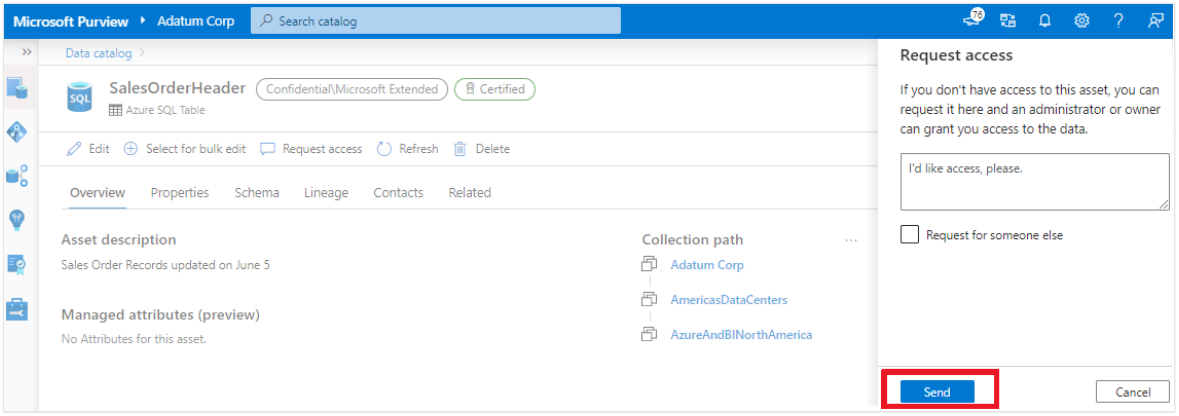


Request access

1. To find a data asset, use Microsoft Purview's search or browse functionality.

2. Select the asset to go to asset details.

3. Select **Request access**.



> **Note**
>
> If this option isn't available, a self-service access workflow either hasn't been created, or hasn't been assigned to the collection where the resource is registered. Contact the collection administrator, data source administrator, or workflow administrator of your collection for more information. Or, for

information on how to create a self-service access workflow, see our self-service access workflow documentation.

4. The **Request access** window will open. You can provide comments on why data access is requested.

5. Select **Send** to trigger the self-service data access workflow.

> ⓘ Note
>
> If you want to request access on behalf of another user, select the checkbox **Request for someone else** and populate the email id of that user.

> ⓘ Note
>
> A request access to resource set will actually submit the data access request for the folder one level up which contains all these resource set files.

6. Data owners will be notified of your request and will either approve or reject the request.

Next steps

- What are Microsoft Purview workflows
- Approval workflow for business terms
- Self-service data access workflow for hybrid data estates
- Self-service policies

Search for data assets

After data is scanned and ingested into the Microsoft Purview Data Map, data consumers need to easily find the data they need for their analytics or governance workloads. Data discovery can be time consuming because you might not know where to find the data that you want. Even after finding the data, you might have doubts about whether you can trust the data and take a dependency on it.

This article outlines how to search Microsoft Purview Unified Catalog to quickly find the data you're looking for. You can search across all data assets, or focus on governed assets that have been curated with governance metadata such as glossary terms, data products, critical data elements, or data quality scores.

Permissions to search the Unified Catalog

Searching Unified Catalog only returns relevant data assets that you have permissions to view.

You can find a data asset in Unified Catalog when:

- You have at least read permissions on an available Azure or Microsoft Fabric resource.
- You have at least data reader permissions on a domain or collection in the Microsoft Purview Data Map where the asset is stored.

Manage permissions to these assets at the resource level and at the Microsoft Purview Data Map level, respectively. For more information on providing this access, see the links above.

To search for curated, ready-to-use data assets, search for data products your organization has developed.

> **Tip**
>
> If your Unified Catalog is well-curated, day-to-day business users shouldn't need to search the full catalog. They should be able to find data they need in data products, or by using the governed assets search to find curated data. For more information about setting up Unified Catalog, see Get started with data governance, and plan for Unified Catalog.

Permissions to search governed assets

Governed assets are visible to users with the Global Catalog Reader role. Local Catalog Readers can view governed assets in the governance domain they have access to. Published governance concepts, such as glossary terms, data products, and critical data elements, are also visible to catalog readers. Draft concepts are visible only to Data Product Owners and Data Stewards.

Existing Data Map reader and curator roles aren't changed by the governed assets search experience.

Searching the catalog

To search for data assets in Unified Catalog:

1. In the Microsoft Purview portal, open **Unified Catalog**.
2. Under **Discovery**, select **Data assets**.
3. In the search bar, enter keywords to narrow your search, such as name, data type, classifications, and glossary terms. Search suggestions appear as you enter keywords. Your search history is also presented so you can resume a previous data exploration.
4. To complete your search, select **View search results** or select **Enter**. For full search syntax information, see keyword search syntax.

The search results page shows a list of data assets and glossary terms that match the search terms. The keyword is highlighted in the return results, so you can see where the term was found in the asset. The **Governed assets** tab displays only governed assets search results, and the **All assets** tab displays the search results in all assets in your data estate, whether they're governed or not.

> **Note**
>
> Search only returns items in collections where you're a data reader or curator. For more information, see roles and permissions in collections.

The Microsoft Purview relevance engine sorts through all the matches and ranks them based on what it believes is useful to a user. For example, a data consumer is likely more interested in a table curated by a data steward that matches on multiple keywords than an unannotated folder. Many factors determine an asset's relevance score. The Microsoft Purview search team constantly tunes the relevance engine to ensure the top search results have value to you.

Keywords and keyword search syntax

Search queries consist of keywords and operators such as `AND`, `OR`, `NOT`, exact phrase quotes, field-scoped search, and parentheses for grouping. You can combine these operators to build precise queries that return exactly the assets you need.

For the full list of supported operators, field names, and detailed syntax guidance, see Keyword search syntax.

Filter results

If the top results don't include the assets you're looking for, you can filter your results by using the filter pane to the left of the search results.

On the search results page, select **Filter** to open and close the filter pane. With the filter pane open, select a filter category, then select the checkbox next to the values you want to filter on. For some filters, you can select the ellipsis to choose **Or** or **And**.

Available filters

You can add filters by selecting **Add filter** on the filter pane and selecting one of the following options:

- **Activity**: Refine your search to attributes created or updated within a certain timeframe.
- **Asset type**: Refine your search to specified asset types. For example: dashboards, files, glossary terms, or metamodel assets.
- **Assigned term**: Refine your search to assets with the selected terms applied.
- **Classification**: Refine your search to assets with certain classifications.
- **Collection**: Refine your search by assets in a specific collection.
- **Contact**: Refine your search to assets that have selected users listed as a contact.
- **Data source type**: Refine your search to assets from specified source types. For example: Azure Blob Storage or Power BI.
- **Endorsement**: Refine your search to assets with specified endorsements, like **Certified** or **Promoted**.
- **Label**: Refine your search to assets with specific security labels.
- **Data asset attributes**: Refine your search to assets with specified data asset attributes. Attributes are listed under their attribute group, and use operators to help search for specific values. For example: Equals or Doesn't equal.
- **Rating**: Refine your search to only data assets with a specified rating.
- **Tags**: Refine your search to assets with selected tags.

Search for governed assets (preview)

The governed assets search provides a focused view of data assets that are actively governed in Unified Catalog. Instead of searching across all assets, you can search only for assets that have governance metadata, such as glossary terms, data products, critical data elements, or data quality scores. Learn more about governed assets.

The governed assets search is helpful because organizations have large data estates but only a small percentage of assets are curated and ready for consumption. Data consumers can use this search to find meaningful, governed data without navigating the entire data estate.

To search for governed assets:

1. In the Microsoft Purview portal, open **Unified Catalog**.
2. Under **Discovery**, select **Data assets**.
3. Enter keywords in the search bar and select **Enter** or **View search results**.
4. On the search results page, select the **Governed assets** tab.

The search results show only assets that are governed in Unified Catalog. Each asset has a **Governed** label next to its name. Governed assets search supports semantic search, so you can use natural language queries to find assets.

Search capabilities

Governed assets search includes the following capabilities:

- **Partial keyword match**: Enter a partial keyword, and the search returns results that match the partial term. For example, entering *cust* returns results that match *customer*.
- **Exact match with double quotes**: Use double quotes to search for an exact phrase. For example, "*customer profile*" searches for the phrase as a single unit, rather than matching *customer* and *profile* separately.
- **Search highlights**: Hover over a search result to see why it was returned. The highlight shows which attributes matched your search query, such as name, description, or term.

> **Note**
>
> Search isn't case sensitive, but spaces within search terms matter. Underscores and other non-space characters are treated as part of the keyword.

Filter governed asset results

You can filter governed asset search results by using the following filters (see filter definitions):

- Asset type
- Data source type
- Classification
- Contact
- Glossary term
- Data product
- Critical data element

> **Note**
>
> The **Terms** filter in governed assets search uses Unified Catalog terms. After you migrate glossary terms and enable data asset curation, the **Assigned term** filter is no longer available in the all data assets search, and classic terms no longer appear on asset details pages.

View governed asset details

Select a governed asset from the search results to view its details. On the asset details page, select the **Governance** tab to see how the asset is governed. The **Governance** tab shows:

- Data products the asset is part of.
- Glossary terms linked to the asset.
- Critical data elements associated with columns in the asset.
- The latest data quality score, if a data quality run was performed on the asset.

The **Governance** tab follows existing permission models. If you have a Catalog Reader role, you see only published governance concepts. Draft concepts, such as draft glossary terms, are visible only to Data Product Owners and Data Stewards.

If an asset is deleted from Data Map, a warning icon appears next to the asset in search results. The asset continues to appear until the Data Product Owner removes it.

> **Note**

If an asset is ungoverned (all links to data products, glossary terms, and critical data elements are removed), the asset currently still appears in governed assets search results.

Bulk edit search results

If you want to make changes to multiple assets returned by search, you can modify glossary terms, classifications, and contacts in bulk. For more information, see How to bulk edit assets.

View assets

From the search results page, select an asset to view details, such as description, attributes, schema, lineage, and classifications.

Browse the Unified Catalog

Unified Catalog offers a browse experience that enables users to explore what data is available to them either by collection or by exploring the hierarchy of each data source in the catalog.

In Unified Catalog, go to **Discovery** > **Data assets**. Under **Explore your data**, select a card for how you want to explore your data: in Azure, in Microsoft Fabric, by source type, or by collection.

You can only see the data sources you have permission to view.

Searching Microsoft Purview in connected services

After you register your Microsoft Purview instance to an Azure Data Factory or an Azure Synapse Analytics workspace, you can search Unified Catalog directly from those services. For more information, see Discover data in ADF using Microsoft Purview and Discover data in Synapse using Microsoft Purview.

Link glossary terms to assets and columns (preview)

You can add business context to your data by linking glossary terms to data assets and columns.

Users need two roles in order to attach terms to assets and columns:

1. **Data Curator**: All users need to hold this role in the collection where the asset belongs. Only Data Curators can edit data assets. Learn more about this role and collections permissions in Data Map.

2. In addition, users need either one of these roles:
    a. **Data Steward**: Users can be a Data Steward in any governance domian. These users can see published and unpublished glossary terms, and can attach both kinds of terms to assets and columns.
    b. **Global Asset Curator**: This role allows users to attach published glossary terms to assets and columns. Users with this role can only see published terms and attach published terms to assets and columns.

See Data governance roles and permissions for role descriptions and how to assign roles.

Link terms to a data asset:

1. Search for an asset or column in Unified Catalog.
2. Select the data asset to open its details page.
3. Select **Edit**.
4. On the **Overview** page, at **Glossary terms**, select **Add term**.
5. Search for a term by entering keywords, or select the checkbox next to a term listed on the page. You can select multiple terms.
6. Select **Add**.
7. Select **Save**.

The terms are attached to the asset.

Link terms to a column within an asset:

1. Search for an asset or column in Unified Catalog.
2. Select the data asset to open its details page.
3. Select **Edit**.
4. On the **Schema** page, find the row for the column you want to add a term to, and select **Add term**.
5. Search for a term by entering keywords, or select the checkbox next to a term listed on the page. You can select multiple terms.
6. Select **Add**.
7. Select **Save**.

The terms are attached to the column.

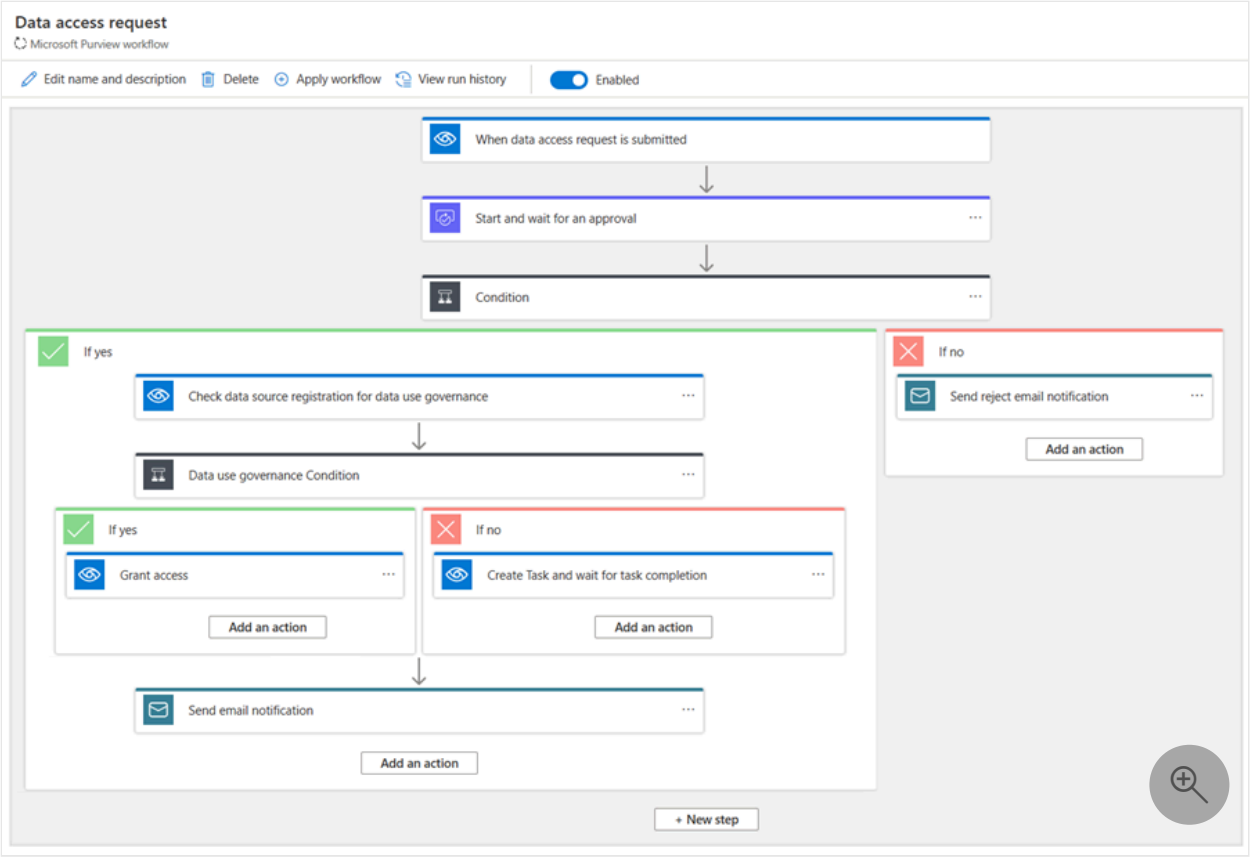
Workflows in Microsoft Purview

Article • 02/24/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.



> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Workflows are automated, repeatable business processes that users can create within Microsoft Purview to validate and orchestrate CUD (create, update, delete) operations on their data entities. Enabling these processes allows organizations to track changes, enforce policy compliance, and ensure quality data across their data landscape.

Workflows automate the approval process for updates your data assets, so you can ensure quality updates.

What are workflows?

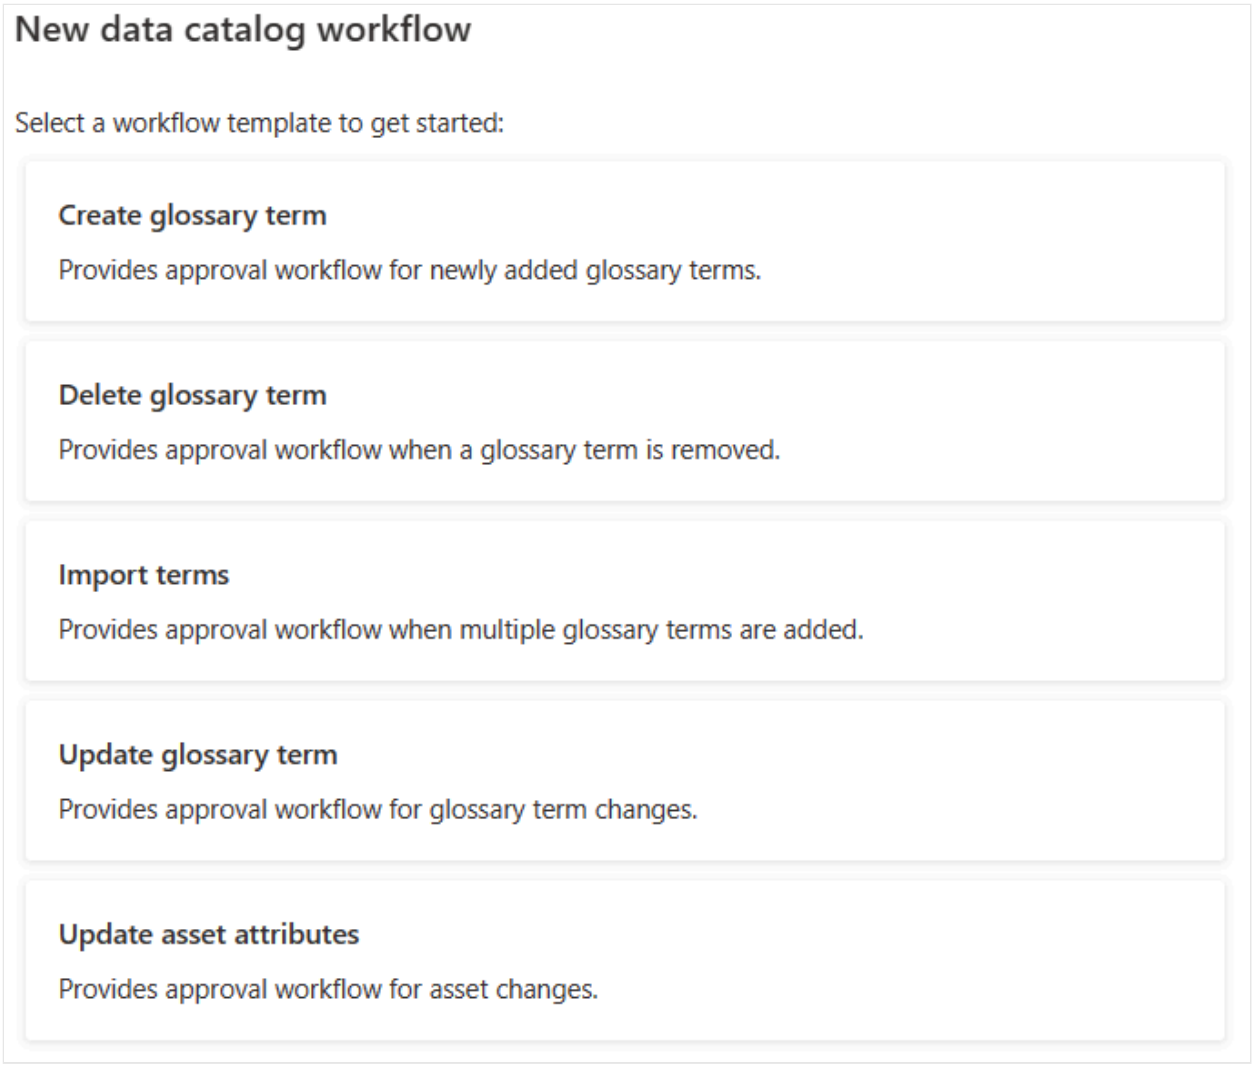
Workflows are automated processes that are made up of connectors that contain a common set of pre-established actions and are run when specified operations occur in your data catalog.

For example: A user attempts to delete a business glossary term that is bound to a workflow. When the user submits this operation, the workflow runs through its actions instead of, or before, the original delete operation.

Workflow actions include things like generating approval requests or sending a notification, that allow users to automate validation and notification systems across their organization.

Currently, there are two kinds of workflows:

- **Data governance** - for data policy, access governance, and loss prevention. Scoped at the collection level.
- **Data catalog** - to manage approvals for CUD (create, update, delete) operations for glossary terms. Scoped at the glossary level.



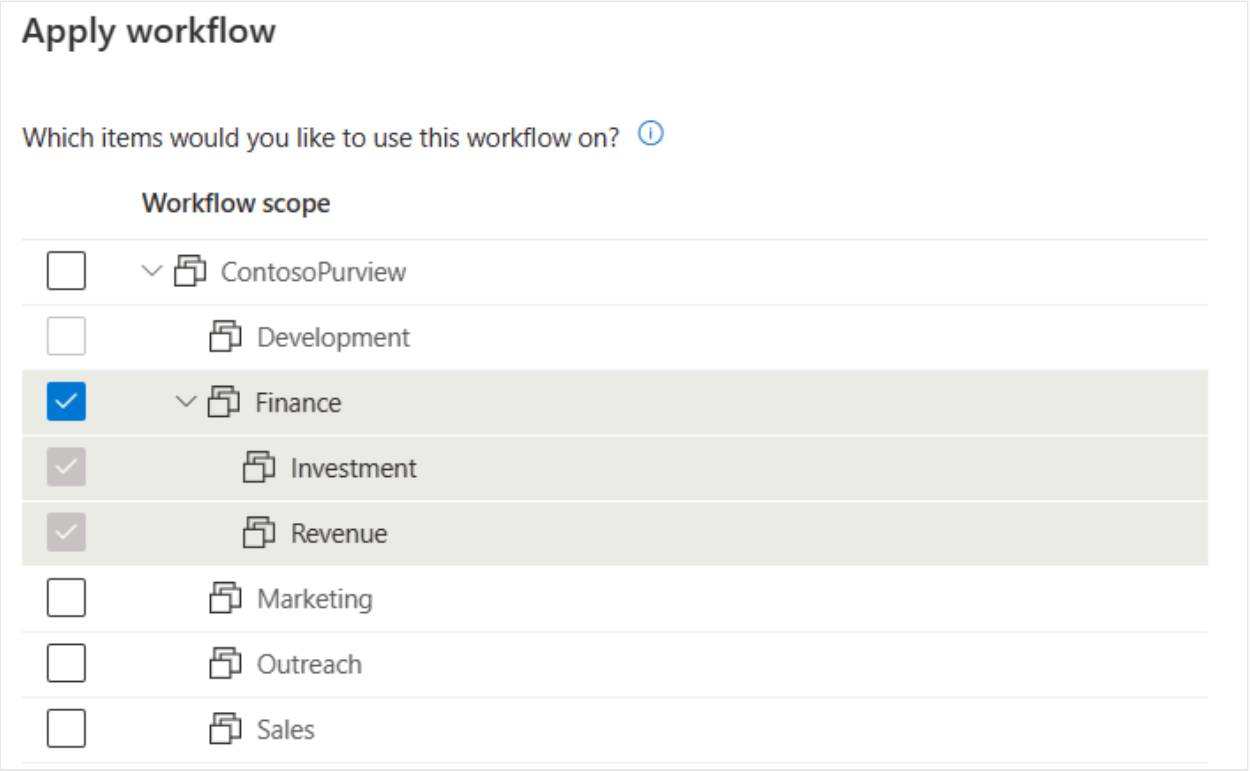
These workflows can be built from pre-established workflow templates provided in the Microsoft Purview governance portal, but are fully customizable using the available workflow connectors.

Workflow templates

For all the different types of user defined workflows enabled and available for your use, Microsoft Purview provides templates to help workflow administrators create workflows without needing to build them from scratch. The templates are built into the authoring

experience and automatically populate based on the workflow being created, so there's no need to search for them.

Templates are available to launch the workflow authoring experience. However, a workflow admin can customize the template to meet the requirements in their organization.



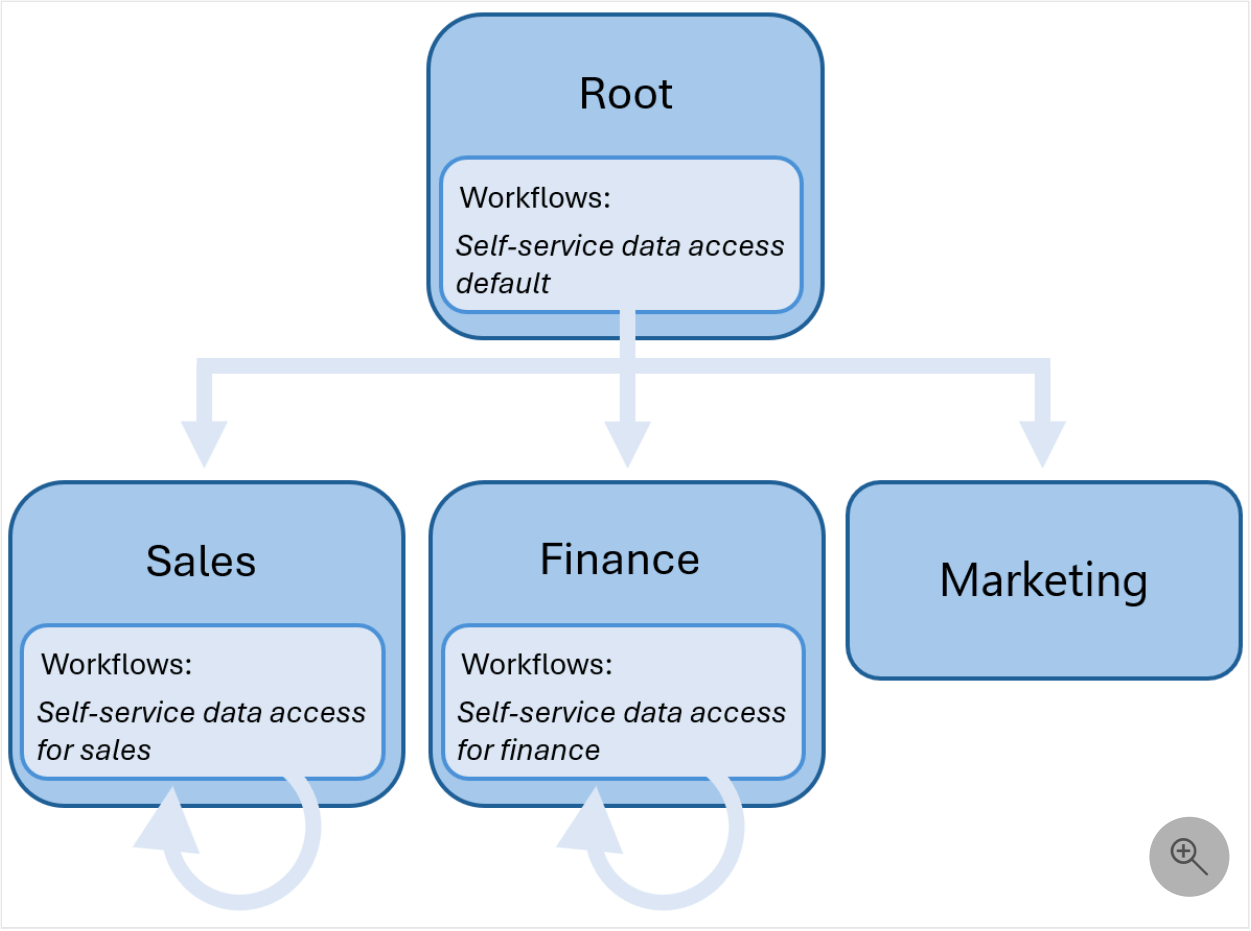
Workflow connectors

Workflow connectors are a common set of actions applicable across some workflows. They can be used in any workflow in Microsoft Purview to create processes customized to your organization. To view the list of existing workflow connectors in Microsoft Purview, see the workflow connectors documentation..

Workflow scope

Once a workflow is created and enabled, it can be bound to a particular scope. This gives you the flexibility to run different workflows for different areas/departments in your organization.

Data governance workflows are scoped to collections, and can be bound to the root collection to govern the whole Microsoft Purview catalog, or any subcollection.



Data catalog workflows are scoped to the glossary and can be bound to the entire glossary, any single term, or any parent term to manage child-terms.

If there's no workflow directly associated with a scope, the workflow engine will traverse upward in the scope hierarchy to determine closest workflow, and run that workflow for the operation.

For example, the AdatumCorp Purview account has the following collection hierarchy:

Root Collection > Sales | Finance | Marketing

- **Root collection** has the workflow *Self-Service data access default* defined and bound.
- **Sales** has *Self-Service data access for sales* defined and bound.
- **Finance** has *Self-Service data access for finance* defined and bound.
- **Marketing** has no workflows directly bound.

When an access request is made for a data asset in Finance collection, the *Self-Service data access for finance collection* workflow is run.

However, when a request access is made for a data asset in Marketing collection, *Self-Service data access default workflow* is triggered. Because there are no workflows bound at the Marketing scope, the workflow engine traverses to the next level in the scope hierarchy, which is Marketing's parent: the root collection. The workflow at the parent scope, the root collection scope, is run.

Who can manage workflows?

A new role, **Workflow Admin** is being introduced with workflow functionality.

A Workflow admin defined for a collection can create self-service workflows and bind these workflows to the collections they have access to.

A Workflow admin defined for any collection can create approval workflows for the business glossary. In order to bind the glossary workflows to a term you need to have at least Data reader permissions.

Next steps

Now that you understand what workflows are, you can follow these guides to use them in your Microsoft Purview account:

- Self-service data access workflow for hybrid data estates
- Approval workflow for business terms
- Manage workflow requests and approvals

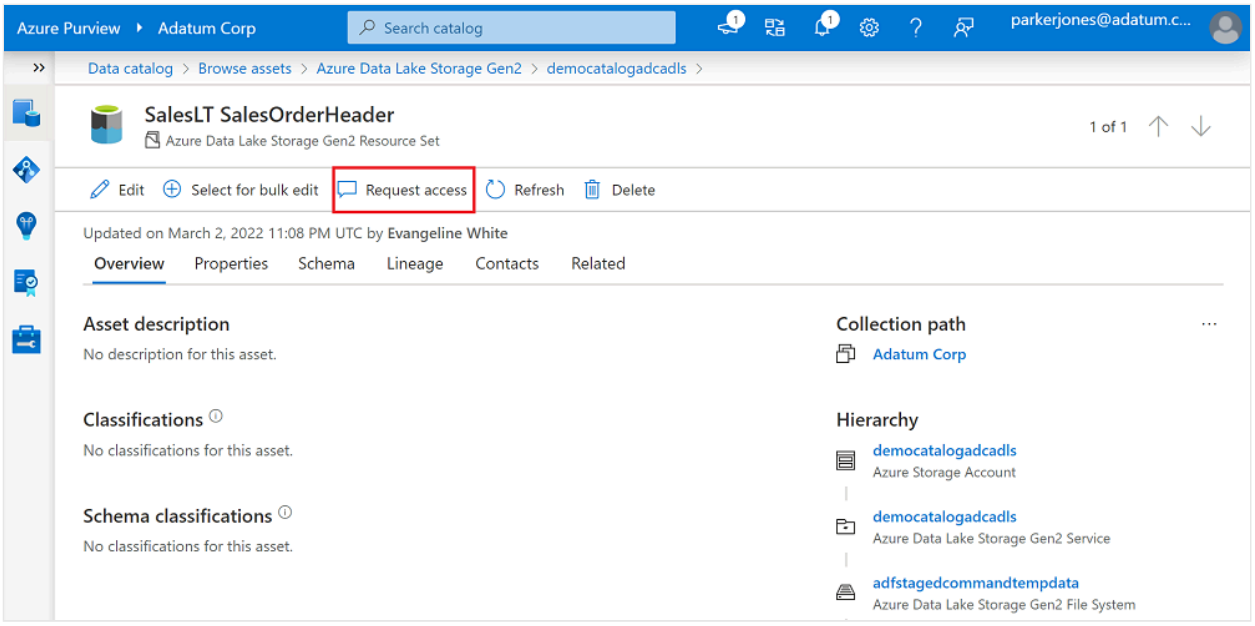
Self-service access workflows for hybrid data estates

Article • 02/26/2025



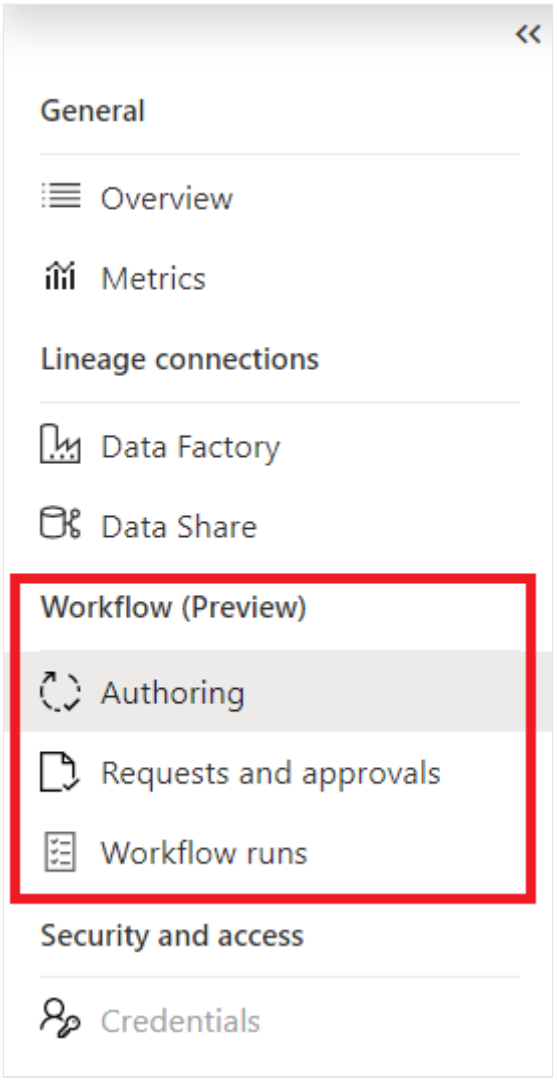
> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

You can use workflows to automate some business processes through Microsoft Purview. Self-service access workflows allow you to create a process for your users to request access to datasets they've discovered in Microsoft Purview.

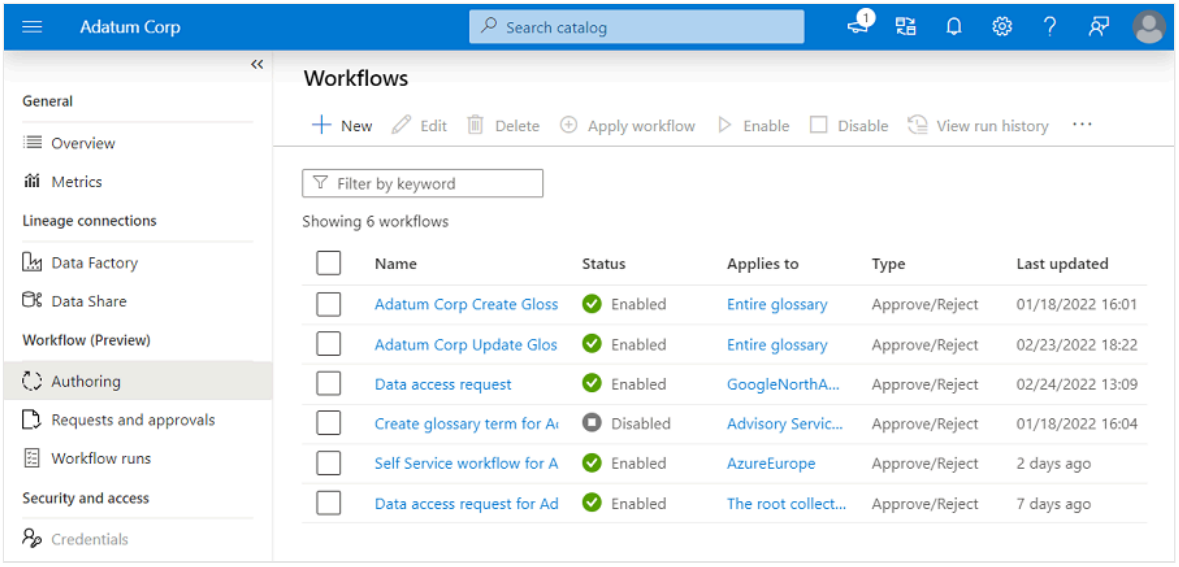
Let's say your team has a new data analyst who will do some business reporting. You add that data analyst to your department's collection in Microsoft Purview. From there, they can browse through the data assets and read descriptions about the data that your department has available.

The data analyst notices that one of the Azure Data Lake Storage Gen2 accounts seems to have the exact data that they need to get started. Because a self-service access workflow has been set up for that resource, they can request access to that Azure Data Lake Storage account from within Microsoft Purview.



You can create these workflows for any of your resources across your data estate to automate the access request process. Workflows are assigned at the collection level, so they automate business processes along the same organizational lines as your permissions.

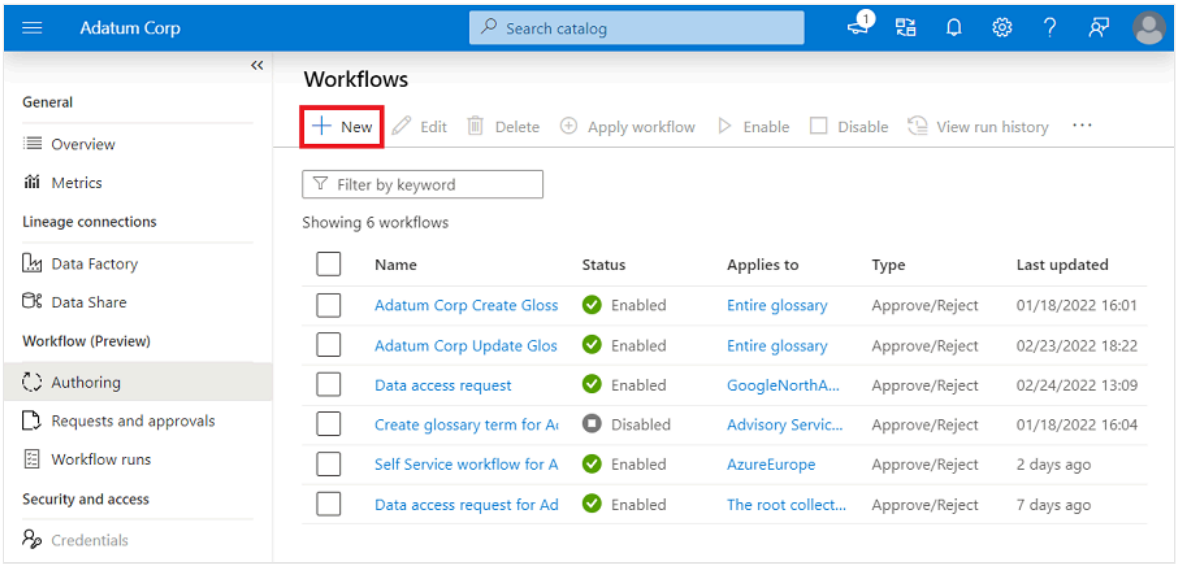
This guide shows you how to create and manage self-service access workflows in Microsoft Purview.



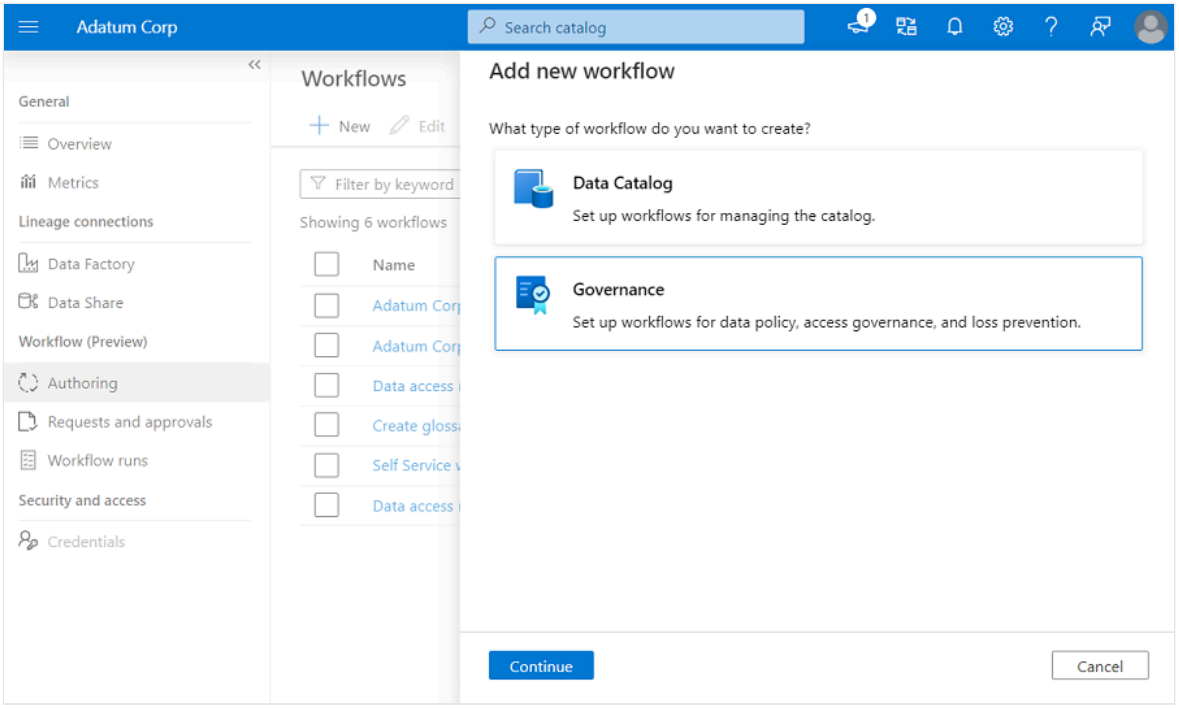
> **Note**
>
> To create or edit a workflow, you need the workflow admin role in Microsoft Purview. You can also contact the workflow admin in your collection, or reach out to your collection administrator, for permissions.

Create and enable the self-service access workflow

1. Sign in to the Microsoft Purview governance portal and select the management center. Three new icons appear in the table of contents.

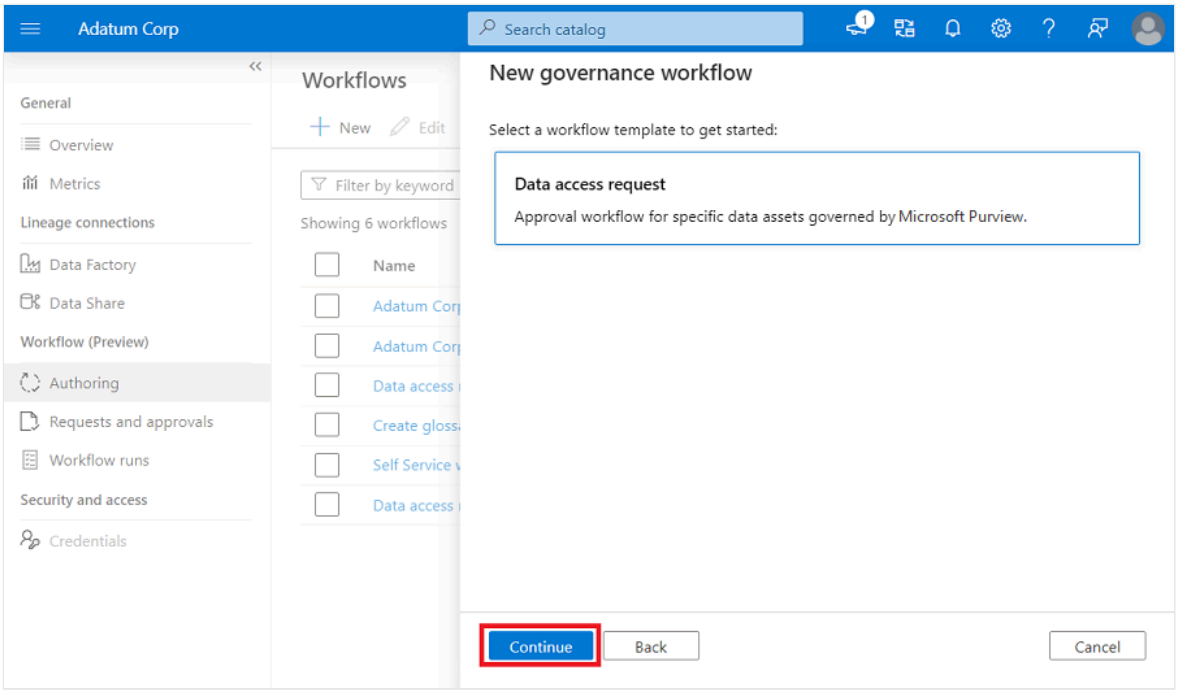


2. To create new workflows, select **Authoring**. This step takes you to the workflow authoring experience.

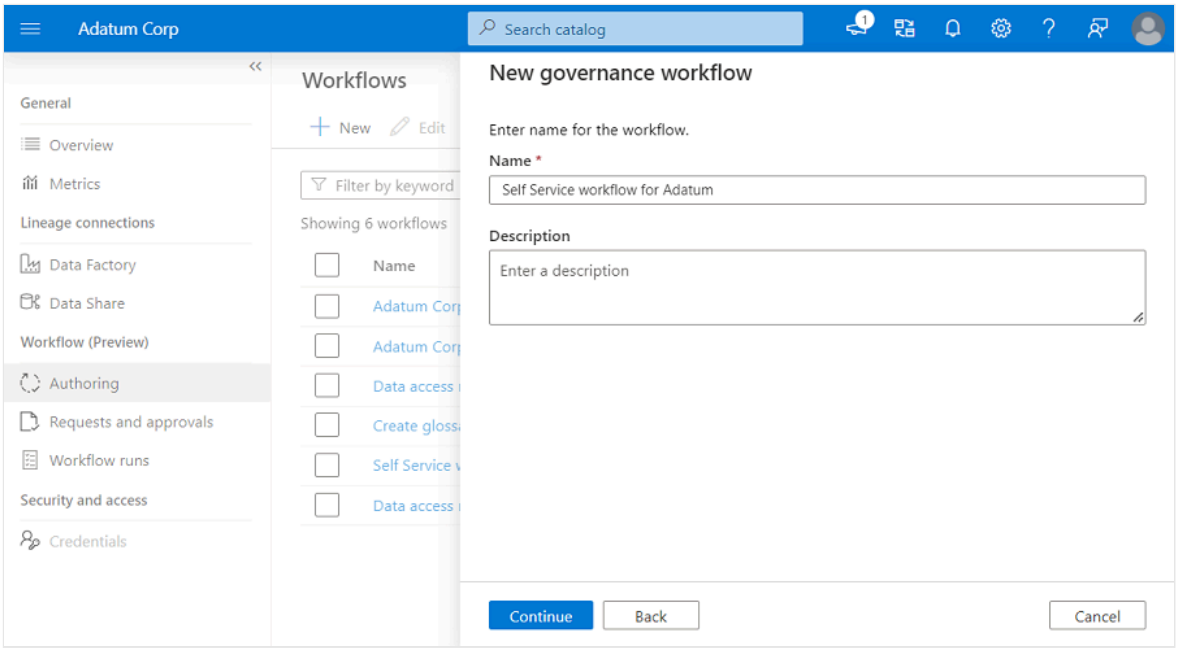


> **Note**

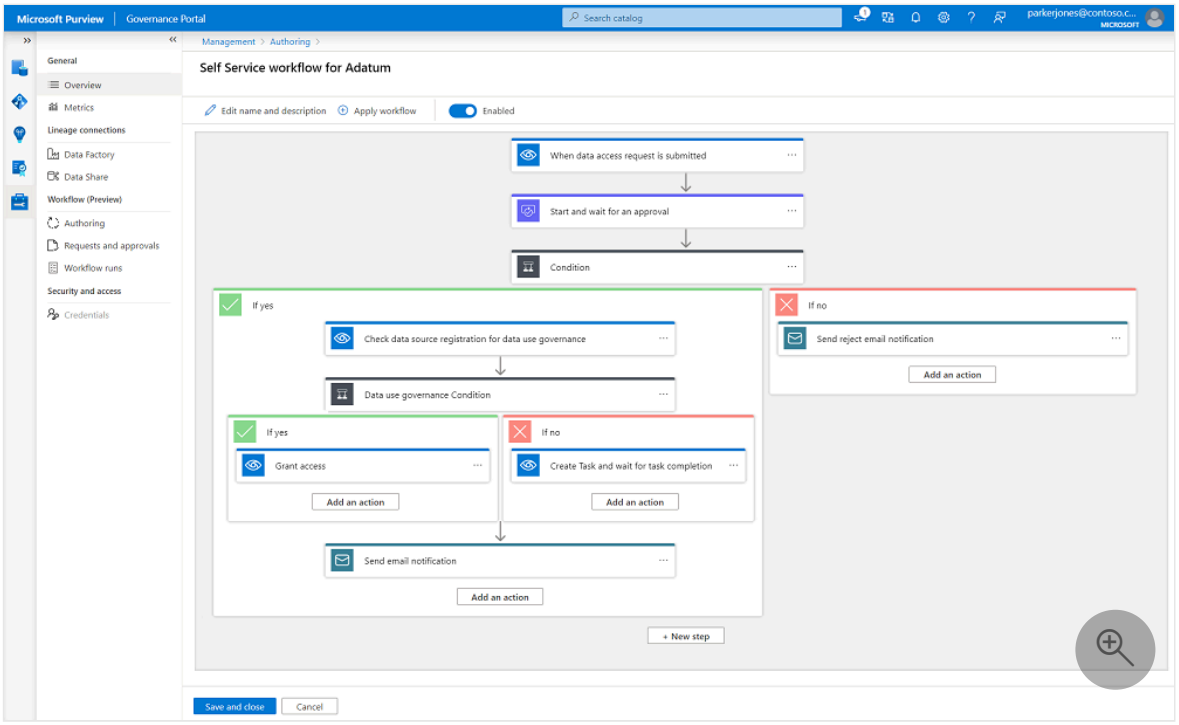
If the **Authoring** tab is unavailable, you don't have the permissions to author workflows. You need the workflow admin role.



3. To create a new self-service workflow, select the **+New** button.



4. You're presented with categories of workflows that you can create in Microsoft Purview. To create an access request workflow, select **Governance**, and then select **Continue**.



5. The next screen shows all the templates that Microsoft Purview provides to create a self-service data access workflow. Select the **Data access request** template, and then select **Continue**.

6. Enter a workflow name, optionally add a description, and then select **Continue**.

7. You're presented with a canvas where the selected template is loaded by default.

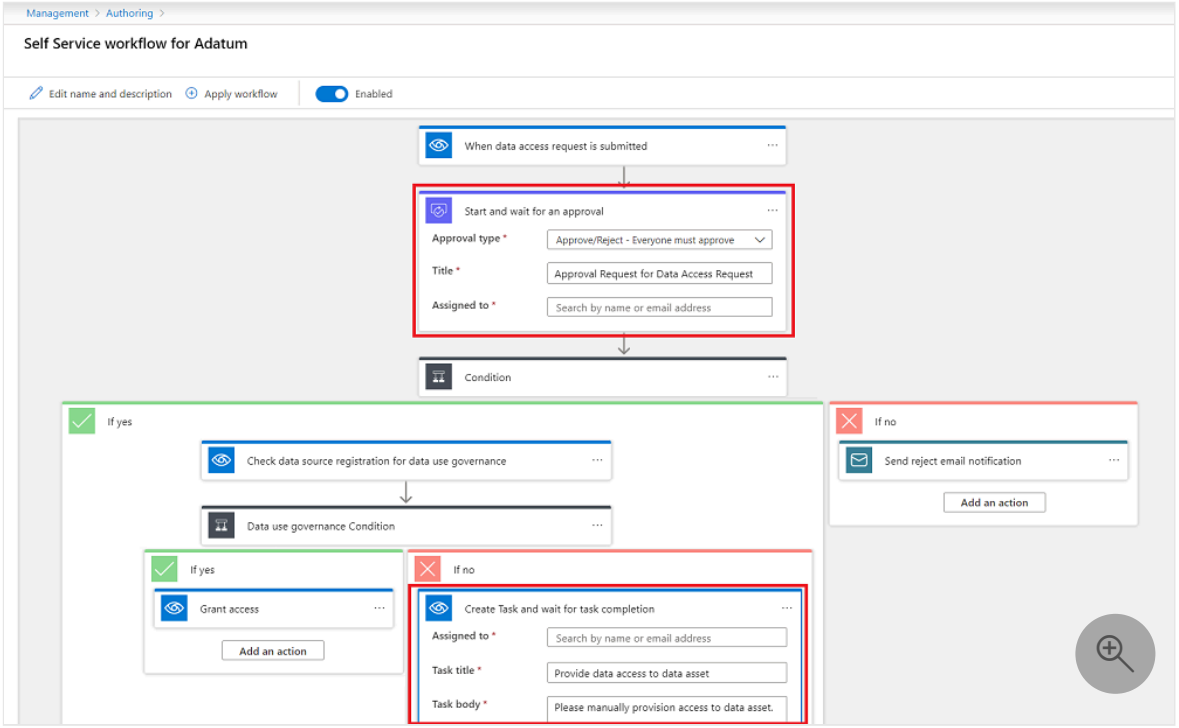
The template has the following steps:

a. Trigger when a data access request is made.

b. Get an approval connector that specifies a user or group that will be contacted to approve the request.

Assign data owners as approvers. Using the dynamic variable **Asset.Owner** as approvers in the approval connector will send approval requests to the data owners on the entity.

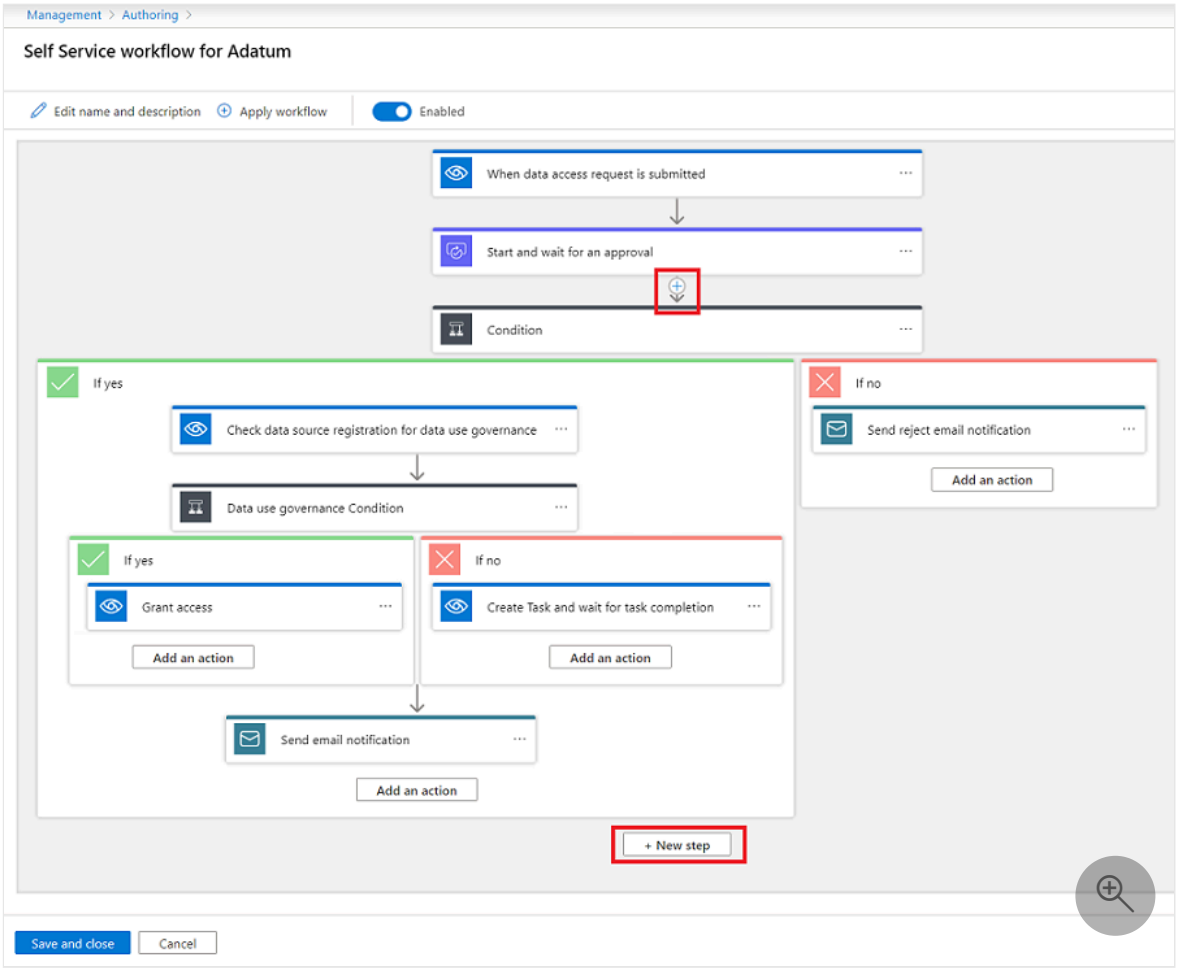
> **Note**
>
> Using the **Asset.Owner** variable might result in errors if an entity doesn't have a data owner.



8. If the condition to check approval status is approved, take the following steps:

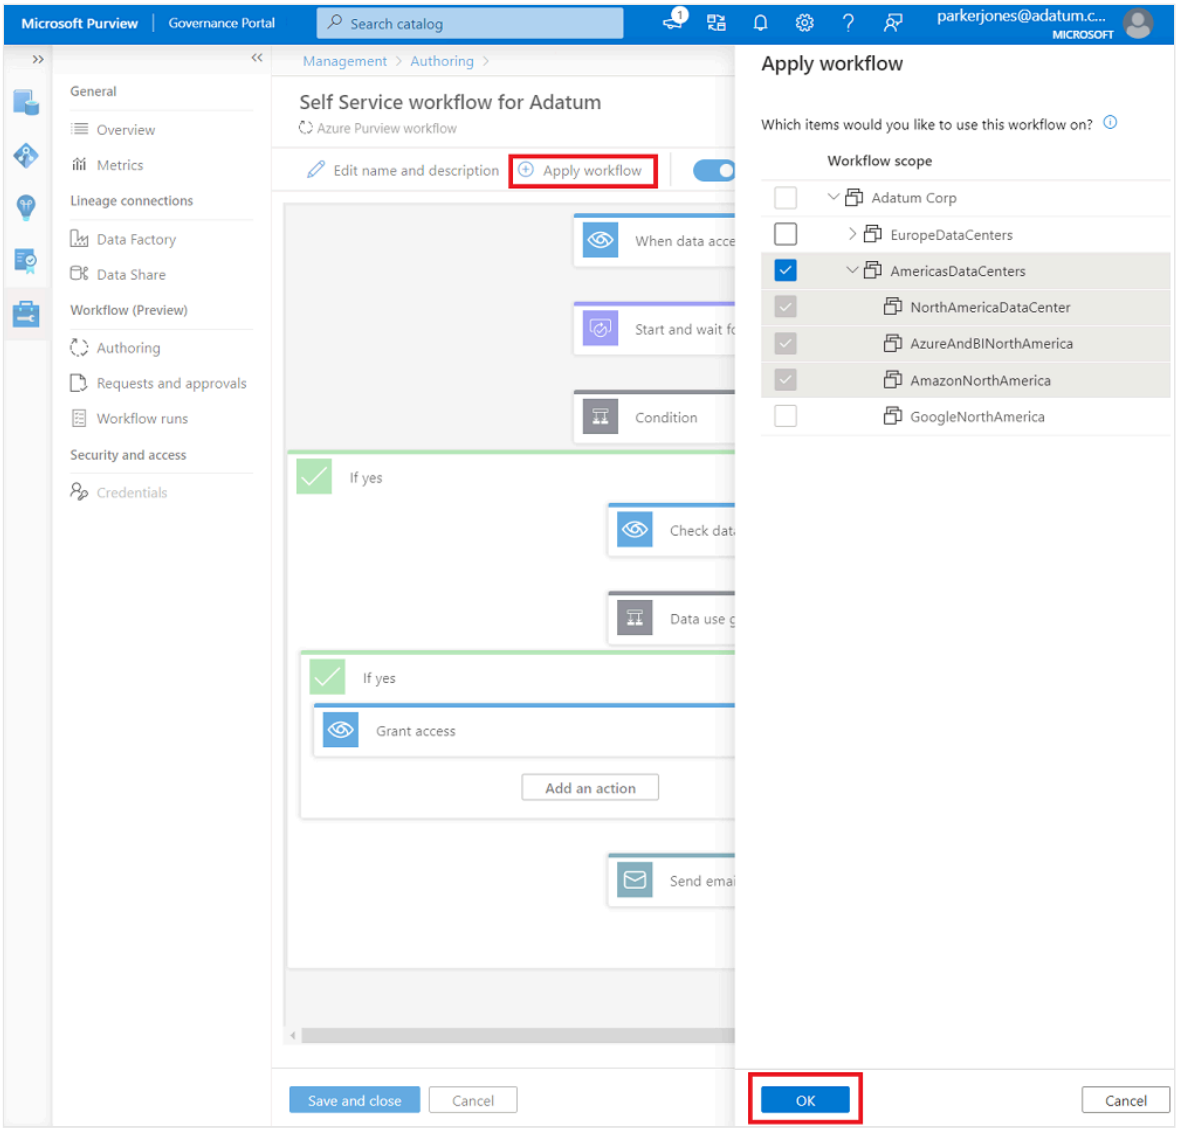
   - If a data source is registered for data policy enforcement with the policy:
     a. Create a self-service policy.
     b. Send email to the requestor that confirms access.
   - If a data source isn't registered with the policy:
     a. Use a connector to assign a task to a user or a Microsoft Entra group to manually provide access to the requestor.
     b. Send an email to requestor to explain that access is provided after the task is marked as complete.

   If the condition to check approval status is rejected, send an email to the requestor to say that the data access request is denied.



9. You can use the default template as it is by populating two fields:

   - Add an approver's email address or Microsoft Entra group in the **Start and wait for an approval** connector.
   - Add a user's email address or Microsoft Entra group in the **Create task and wait for task completion** connector to denote who is responsible for manually providing access if the source isn't registered with the policy.

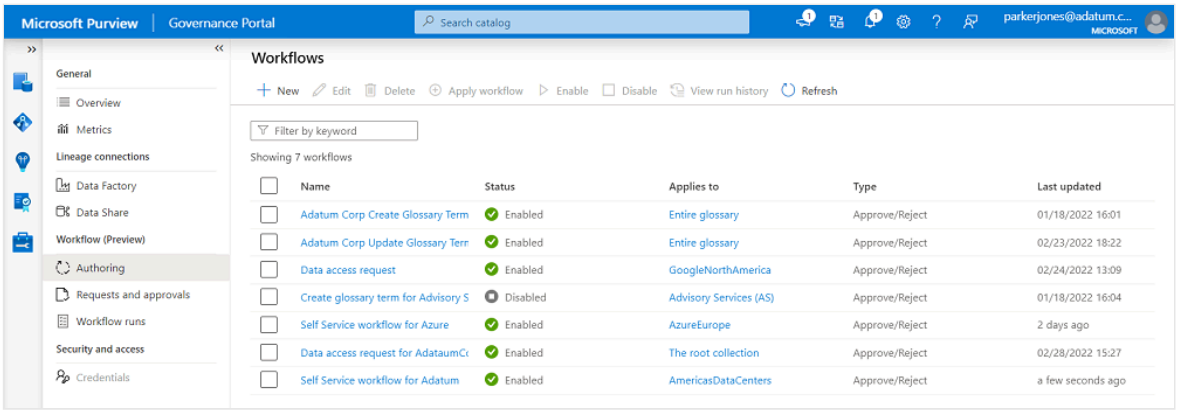


> **Note**
>
> Configure the workflow to create self-service policies only for sources that the Microsoft Purview policy supports. To see what the policy supports, check the documentation about data owner policies.
>
> If the Microsoft Purview policy doesn't support your source, use the **Create task and wait for task completion** connector to assign tasks to users or groups that can provide access.

You can also modify the template by adding more connectors to suit your organizational needs.

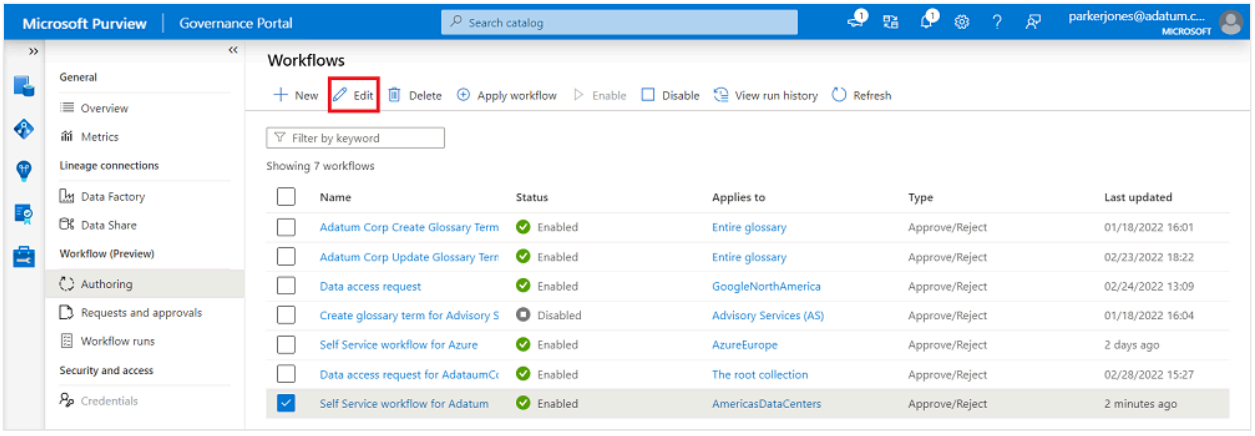
10. After you define a workflow, you need to bind the workflow to a collection hierarchy path. The binding (or scoping) implies that this workflow is triggered only for data access requests in that collection.

    To bind a workflow or to apply a scope to a workflow, select **Apply workflow**. Select the scope that you want to associate with this workflow, and then select **OK**.



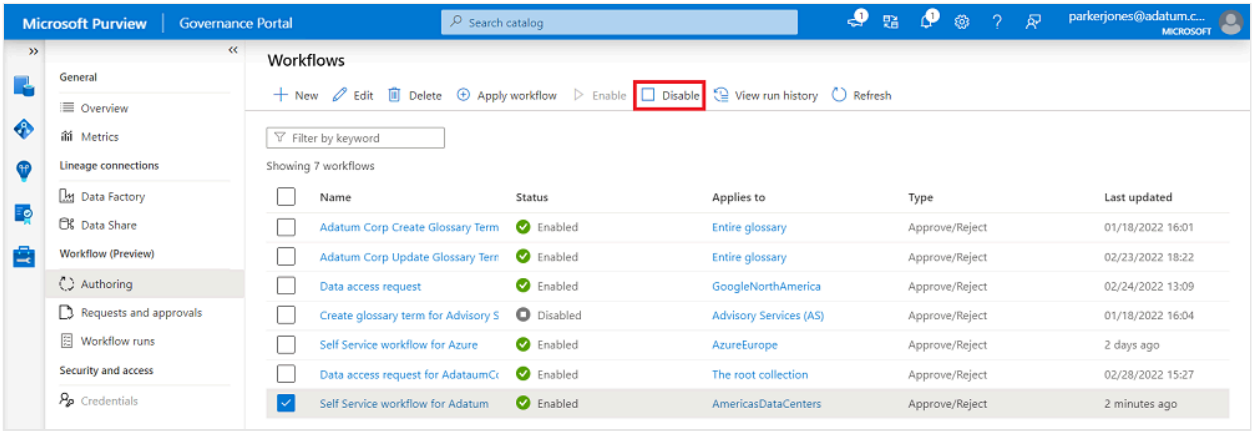
> **Note**
>
> The Microsoft Purview workflow engine will always resolve to the closest workflow that the collection hierarchy path is associated with. If the workflow engine doesn't find a direct binding, it will look for the workflow that's associated with the closest parent in the collection tree.

11. Make sure that the **Enable** toggle is on. The workflow should be enabled by default.



12. Select **Save and close** to create and enable the workflow.

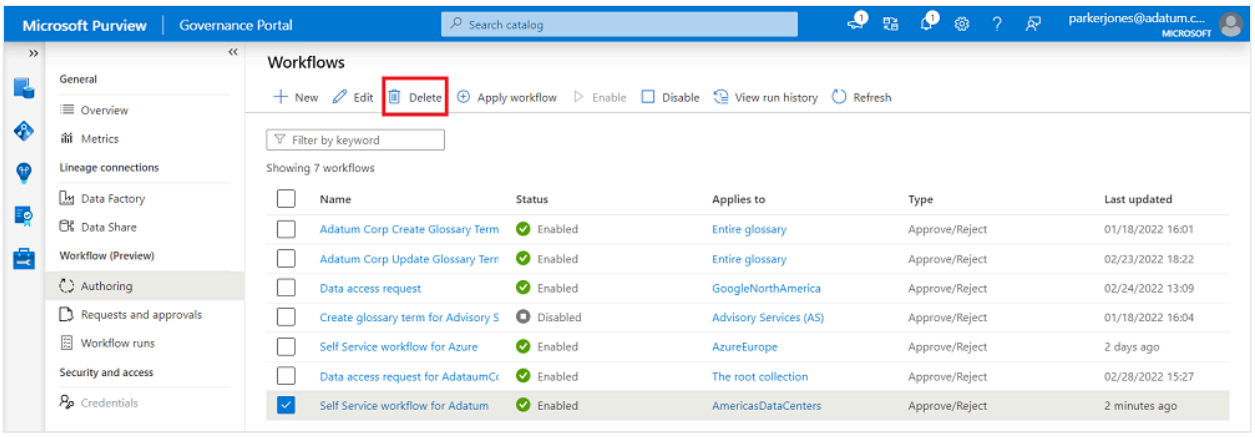
    Your new workflow now appears in the list of workflows.



Edit an existing workflow

To modify an existing workflow, select the workflow, and then select the **Edit** button. You're presented with the canvas that contains the workflow definition. Modify the workflow, and then select **Save** to commit the changes.

Disable a workflow



To disable a workflow, select the workflow, and then select **Disable**.

Another way is to select the workflow, select **Edit**, turn off the **Enable** toggle in the workflow canvas, and then select **Save and close**.

Delete a workflow

To delete a workflow, select the workflow, and then select **Delete**.

Next steps

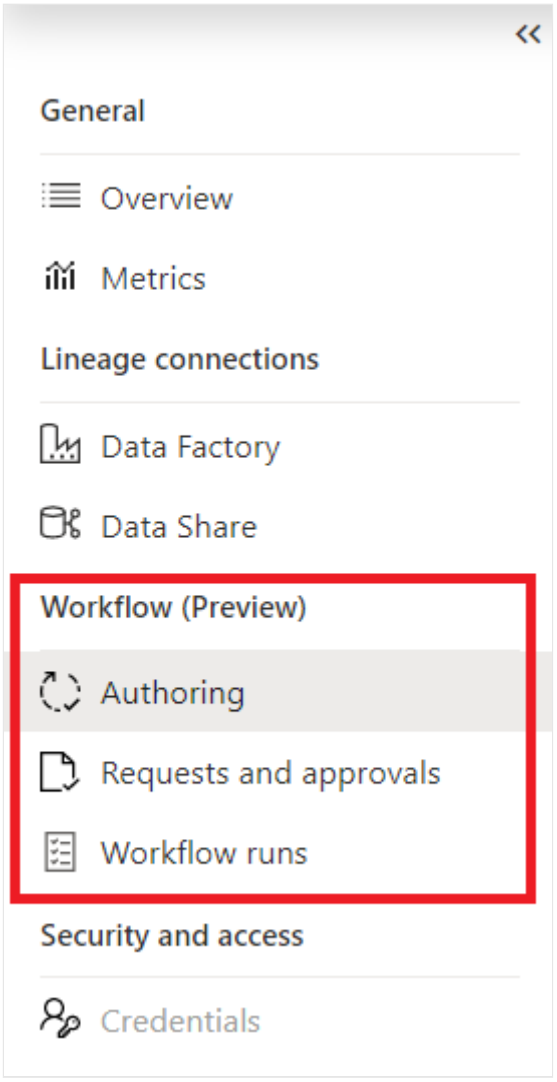
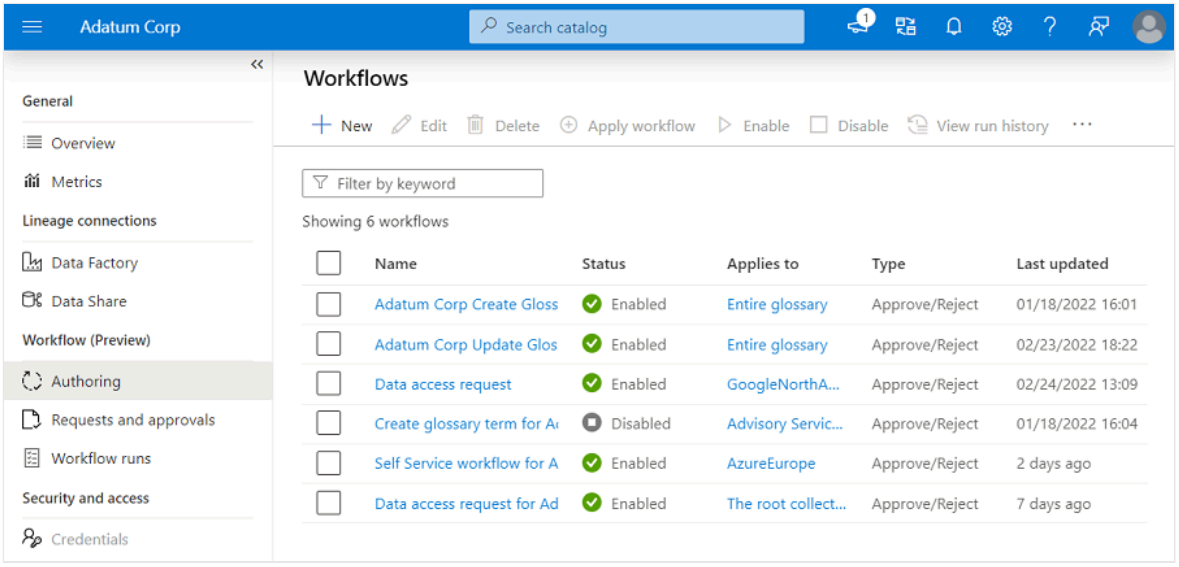
Approval workflow for business terms

Article • 02/26/2025



> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

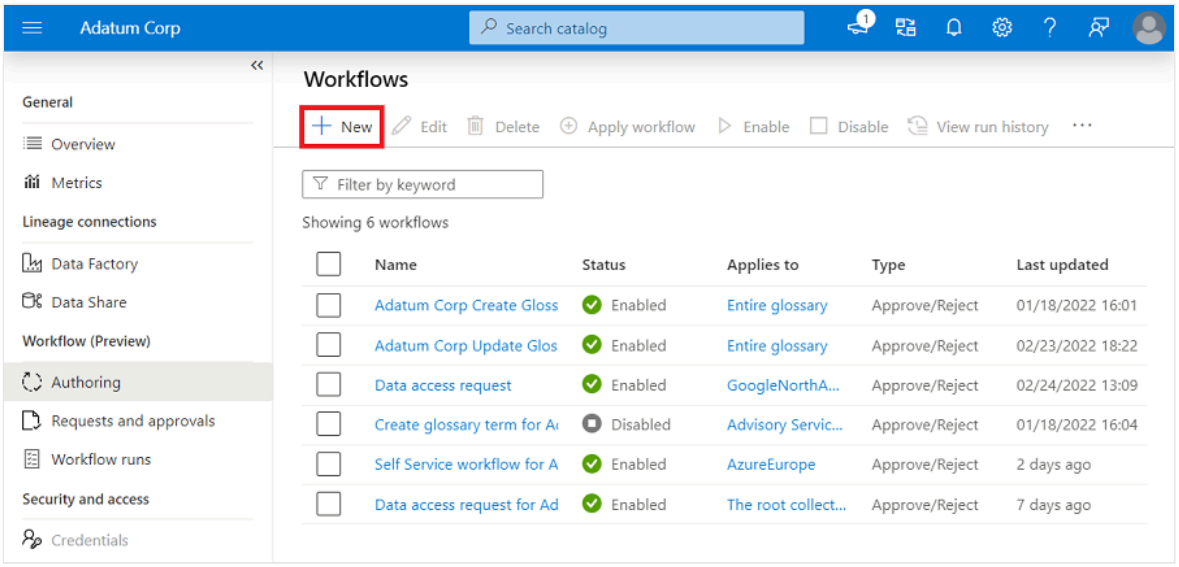
> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.



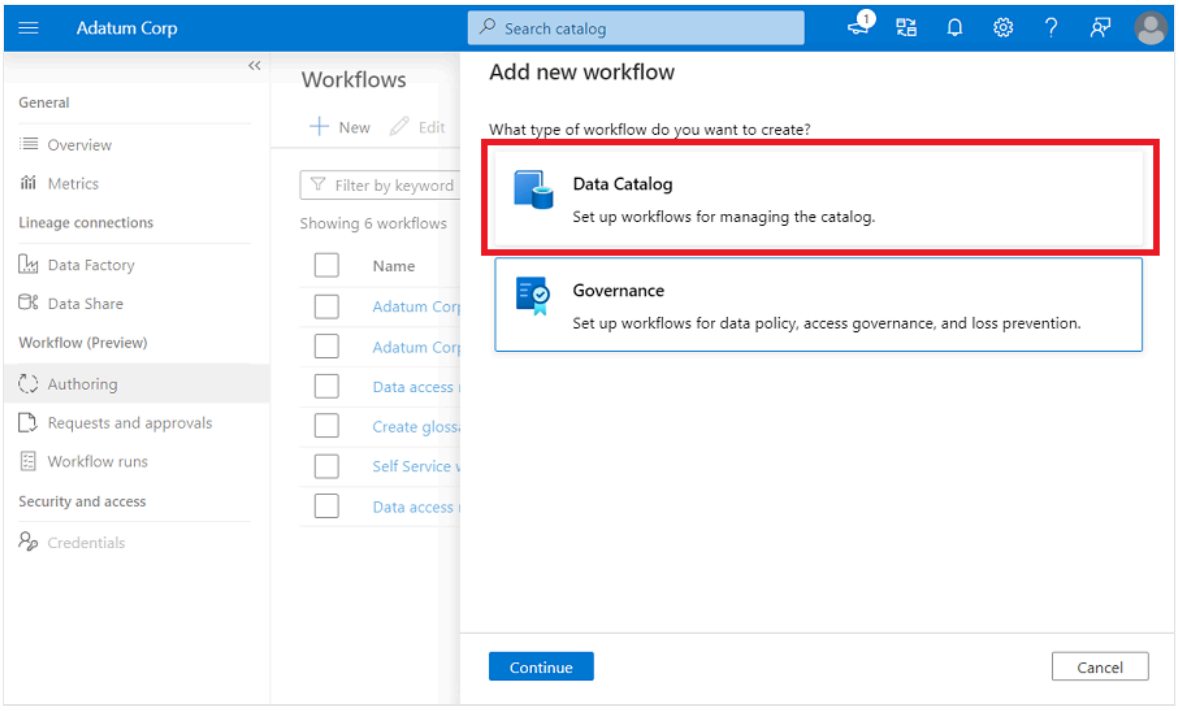
This guide will take you through the creation and management of approval workflows for business terms.

Create and enable a new approval workflow for business terms

1. Sign in to the Microsoft Purview governance portal and select the Management center. You'll see three new icons in the table of contents.



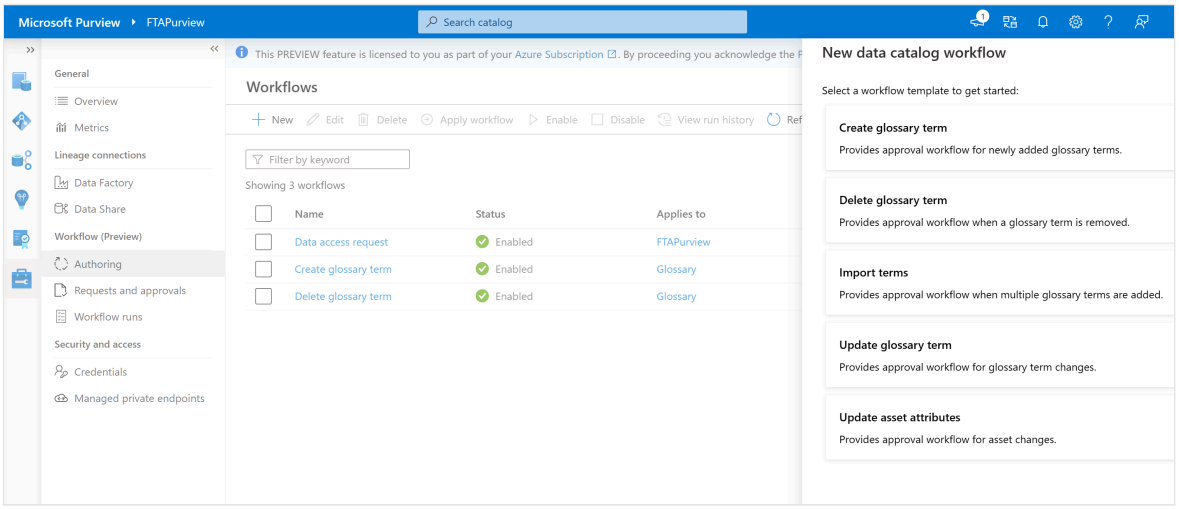
2. To create new workflows, select **Authoring** in the workflow section. This will take you to the workflow authoring experiences.



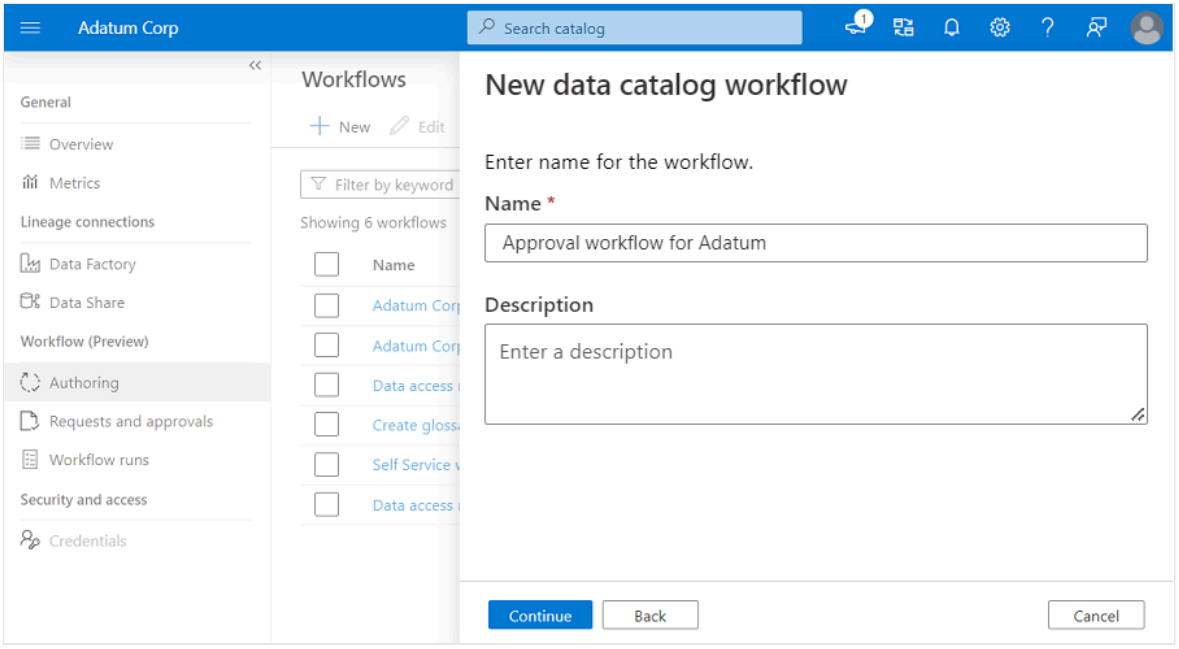
> **Note**

If the authoring tab is greyed out, you don't have the permissions to be able to author workflows. You'll need the workflow admin role.

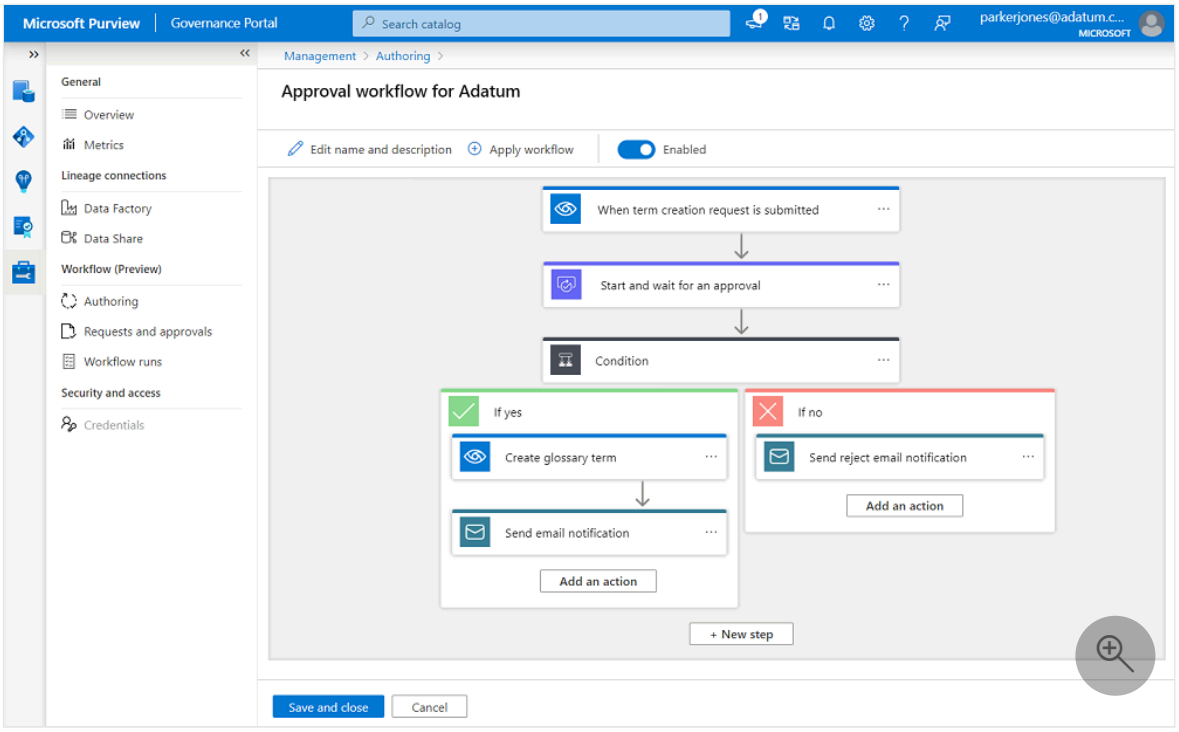
3. To create a new workflow, select **+New** button.



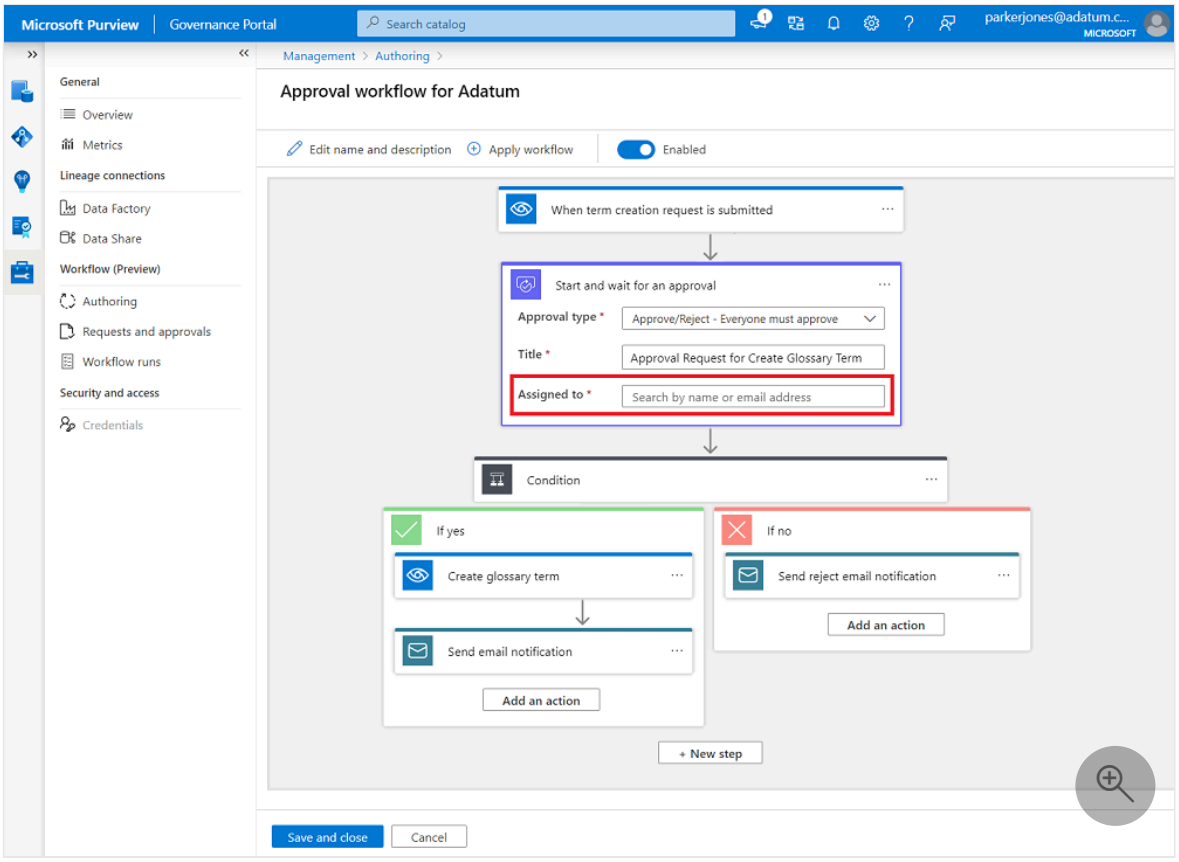
4. To create **Approval workflows for business terms** Select **Data Catalog** and select **Continue**



5. In the next screen, you'll see all the templates provided by Microsoft Purview to create a workflow. Select the template using which you want to start your authoring experiences and select **Continue**. Each of these templates specifies the kind of action that will trigger the workflow. In the screenshot below we've selected **Create glossary term**. The four different templates available for business glossary are:



- Create glossary term - when a term is created, approval will be requested.
- Update glossary term - when a term is updated, approval will be requested.
- Delete glossary term - when a term is deleted, approval will be requested.
- Import terms - when terms are imported, approval will be requested.

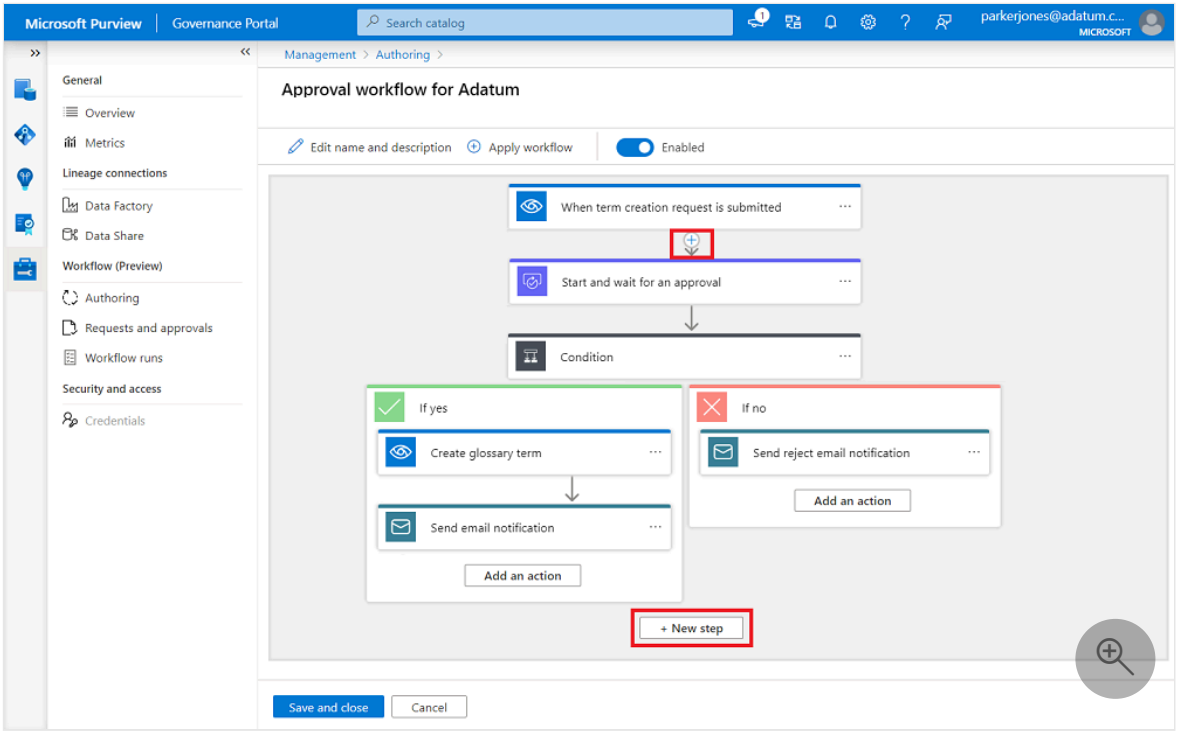


6. Next, enter a workflow name and optionally add a description. Then select **Continue**.

7. You'll now be presented with a canvas where the selected template is loaded by default.

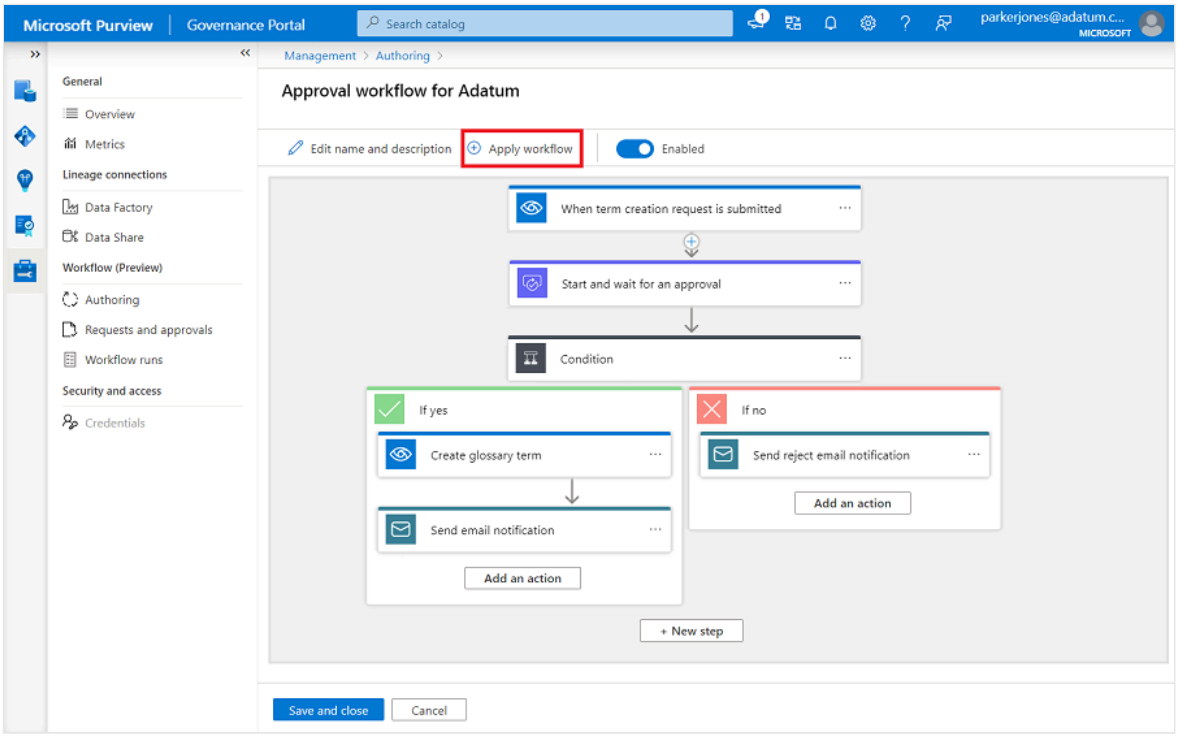
8. The default template can be used as it is by populating the approver's email address in **Start and Wait for approval** Connector.

The default template has the following steps:

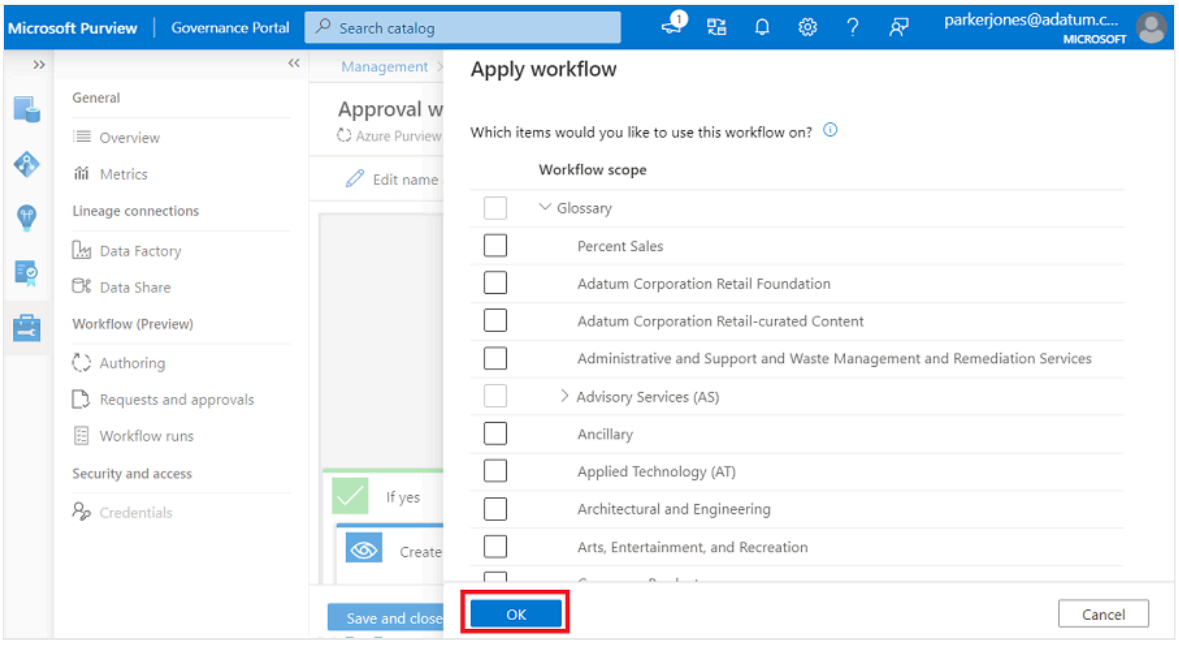


a. Trigger when a glossary term is created/updated/deleted/imported depending on the template selected.

b. Approval connector that specifies a user or group that will be contacted to approve the request.



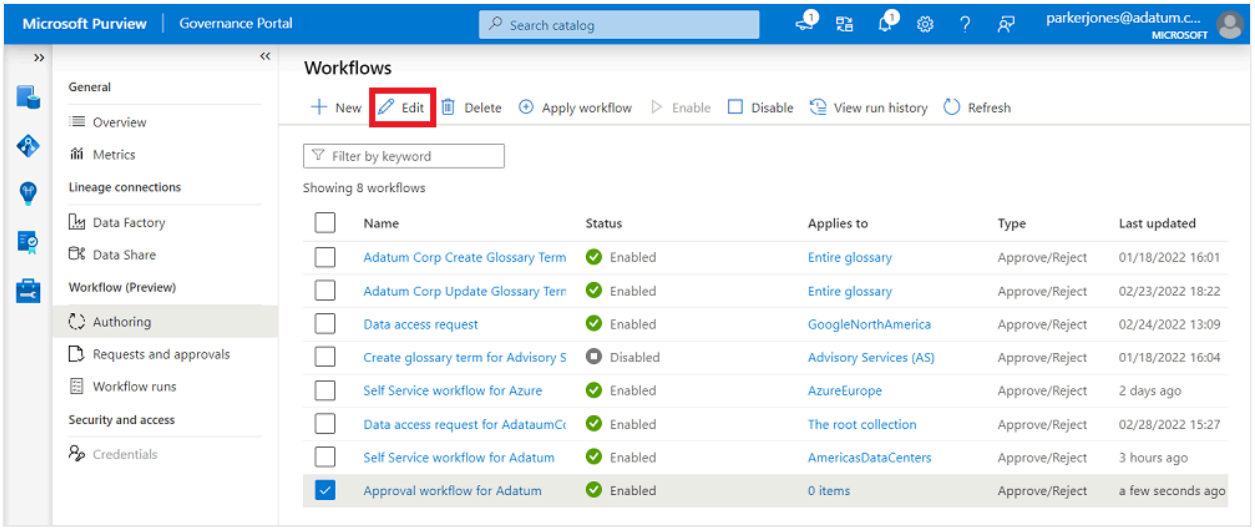
c. Condition to check approval status



- If approved:
  i. Create/update/delete/import the glossary term
  ii. Send an email to requestor that their request is approved, and term CUD (create, update, delete) operation is successful.
- If rejected:
  i. Send email to requestor that their request is denied.

9. You can also modify the template by adding more connectors to suit your organizational needs. Add a new step to the end of the template by selecting the **New step** button. Add steps between any already existing steps by selecting the arrow icon between any steps.

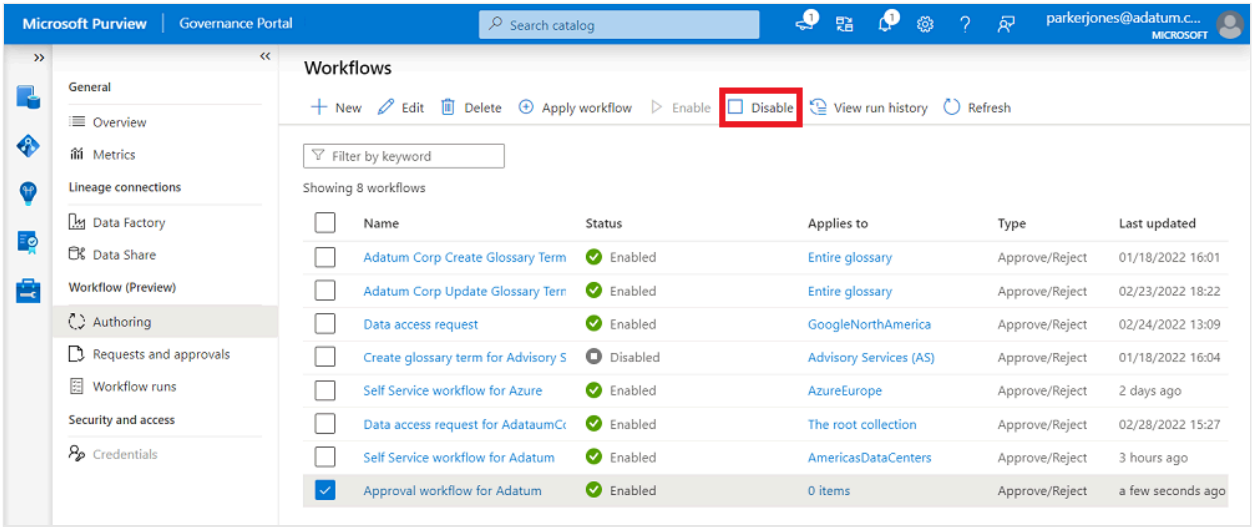
10. Once you're done defining a workflow, you need to bind the workflow to a glossary hierarchy path. The binding implies that this workflow is triggered only for CUD operations within the specified glossary hierarchy path. A workflow can be bound to only one hierarchy path. To bind a workflow or to apply a scope to a workflow, you need to select 'Apply workflow'. Select the scopes you want this workflow to be associated with and select **OK**.



> **Note**
>
> - The Microsoft Purview workflow engine will always resolve to the closest workflow that the term hierarchy path is associated with. In case a direct binding is not found, it will traverse up in the tree to find the workflow associated with the closest parent in the glossary tree.
> - Import terms can only be bound to root glossary path as the .CSV can contain terms from different hierarchy paths.

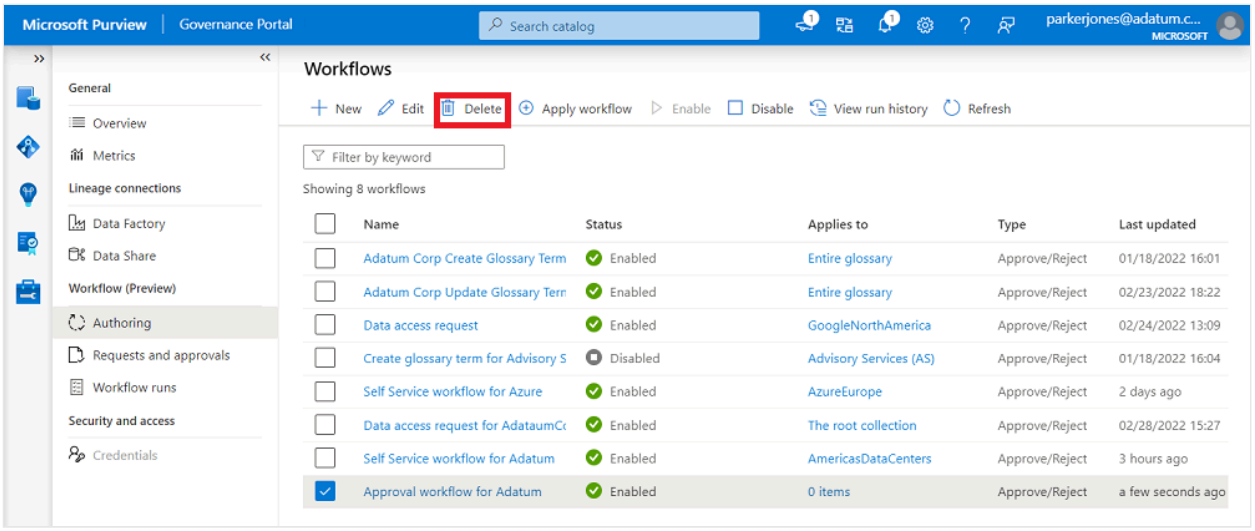
11. By default, the workflow will be enabled. To disable, toggle the Enable button in the top menu.

12. Finally select **Save and close** to create the workflow.



Edit an existing workflow

To modify an existing workflow, select the workflow and then select **Edit** in the top menu. You'll then be presented with the canvas containing workflow definition. Modify the workflow and select **Save** to commit changes.



Disable a workflow

To disable a workflow, select the workflow and then select **Disable** in the top menu. You can also disable the workflow by selecting **Edit** and changing the enable toggle in workflow canvas.

Delete a workflow

To delete a workflow, select the workflow and then select **Delete** in the top menu.

Limitations for business terms with approval workflow enabled

- Non-approved glossary terms aren't saved in Purview catalog.
- The behavior of tagging terms to assets/schemas is same as today. That is, previously created draft terms can be tagged to assets/schemas.

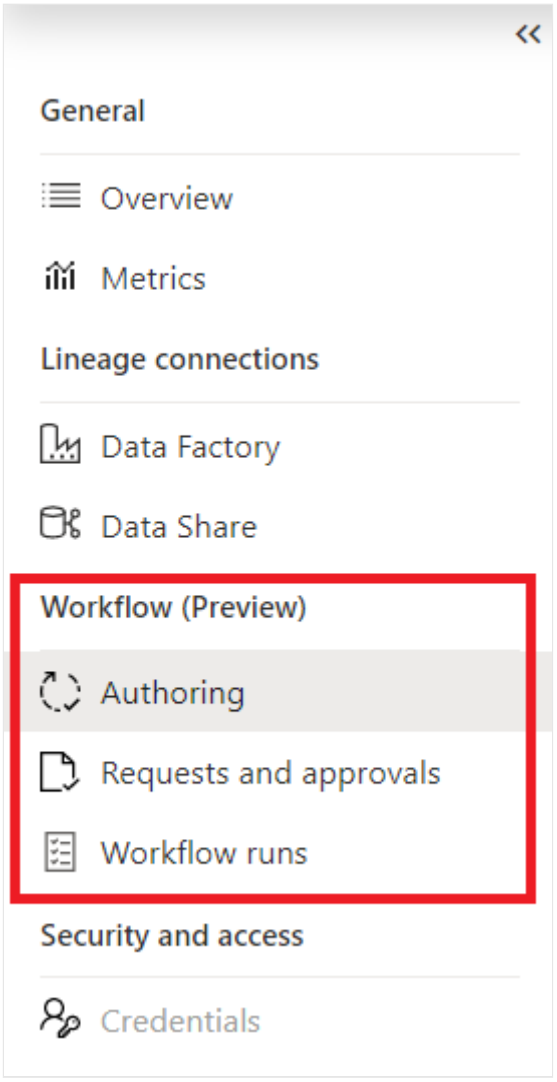
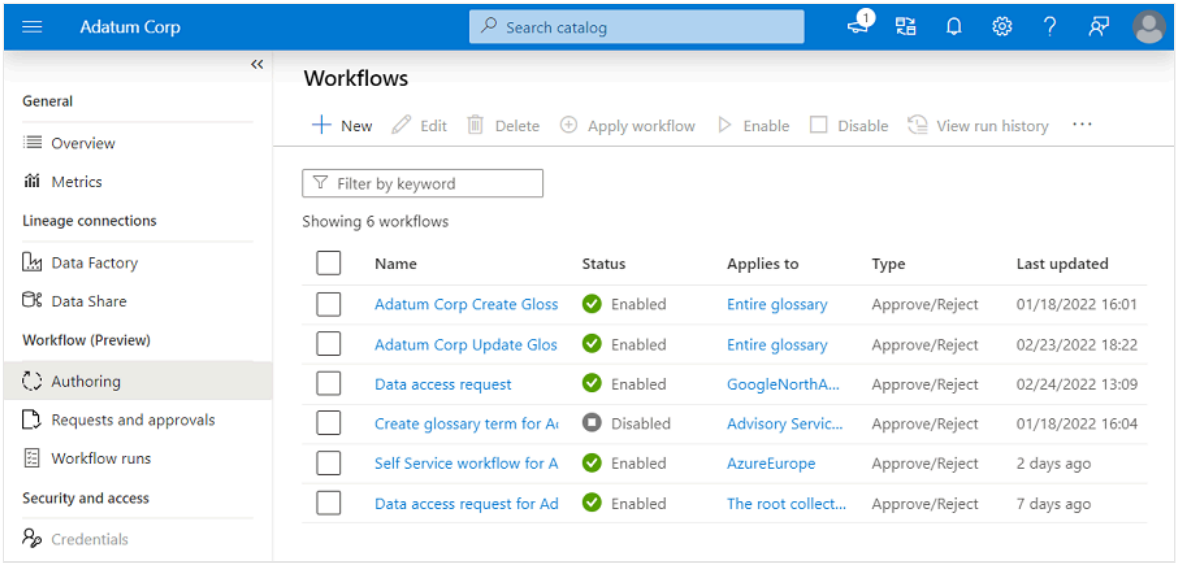
Approval workflow for asset curation

Article • 02/26/2025



> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

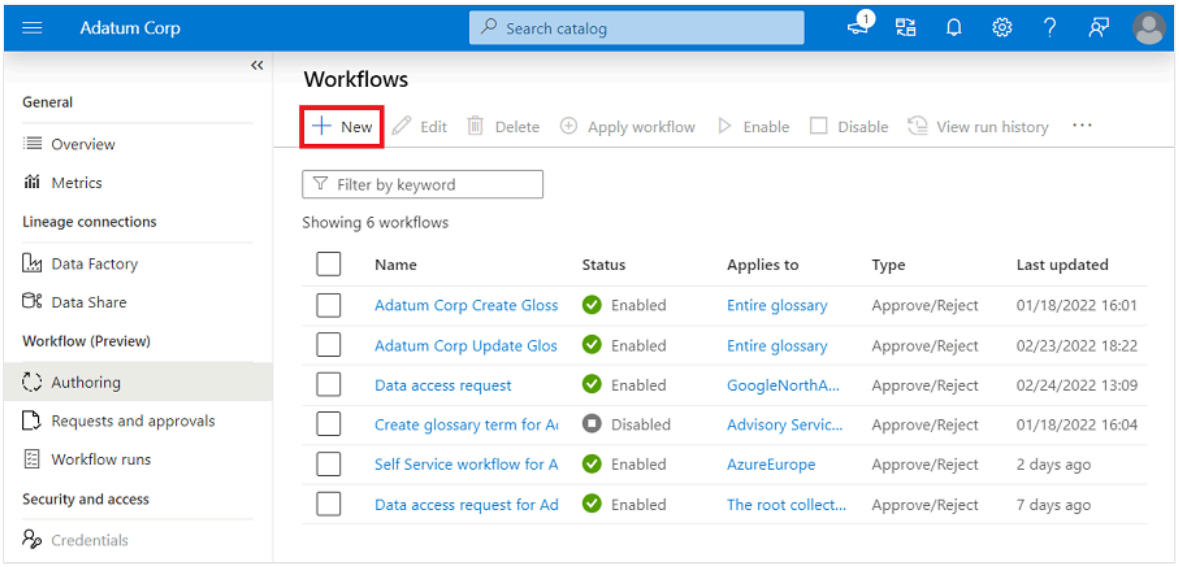
> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.



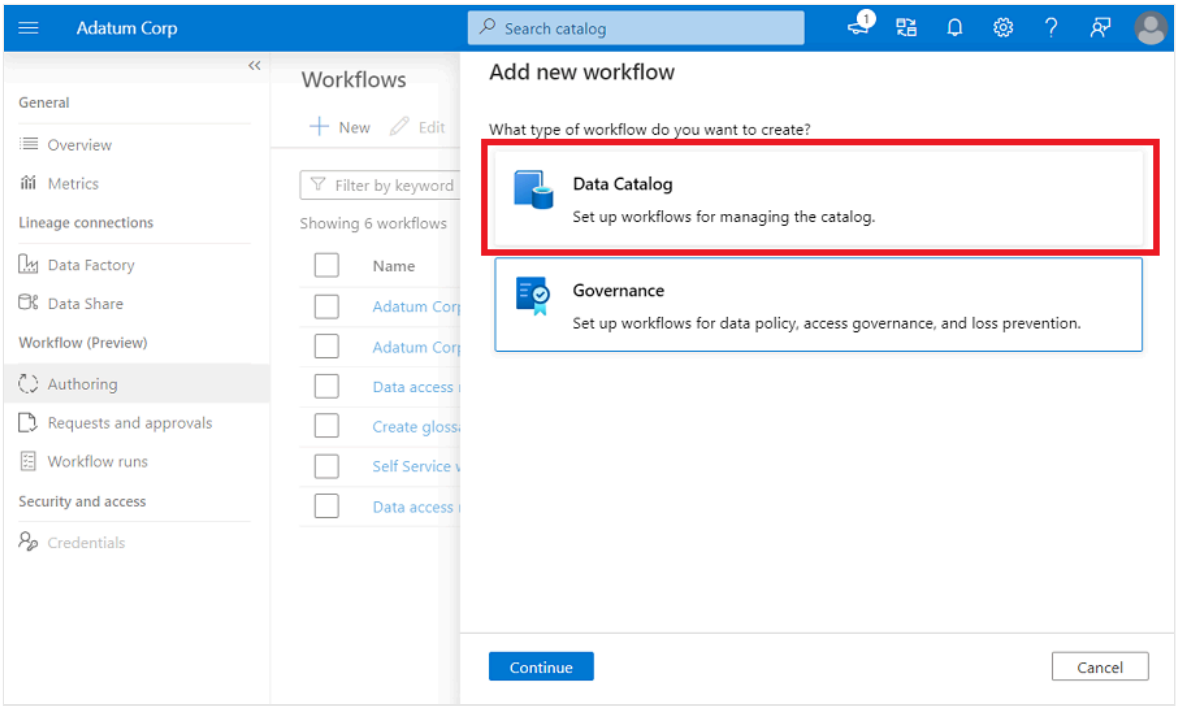
This guide will take you through the creation and management of approval workflows for asset curation.

Create and enable a new approval workflow for asset curation

1. Sign in to the Microsoft Purview governance portal and select the Management center. You'll see three new icons in the table of contents.

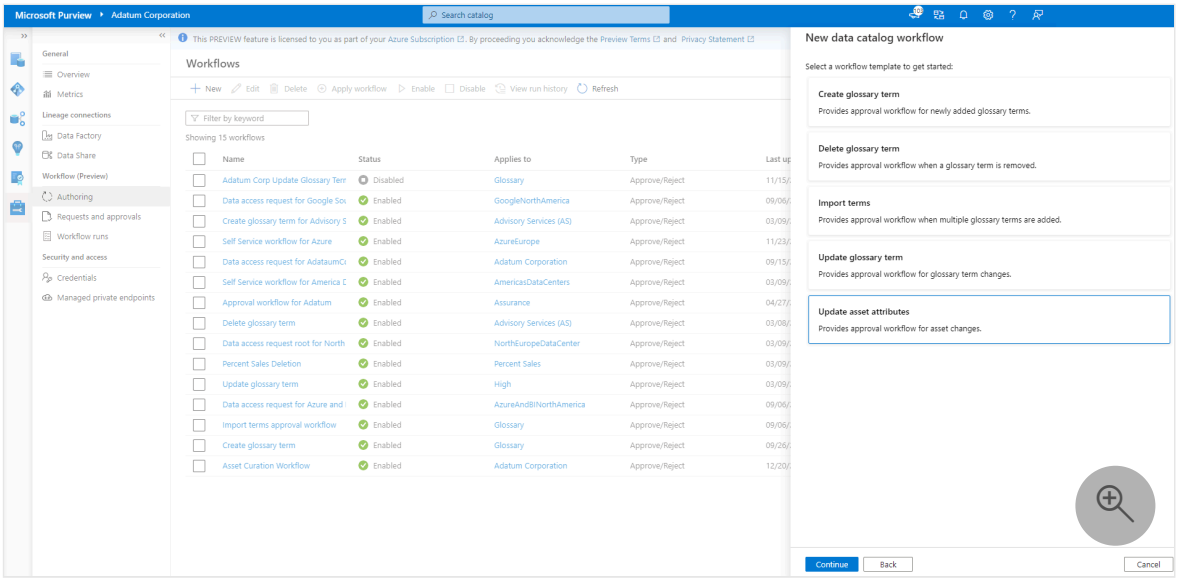


2. To create new workflows, select **Authoring** in the workflow section. This will take you to the workflow authoring experiences.

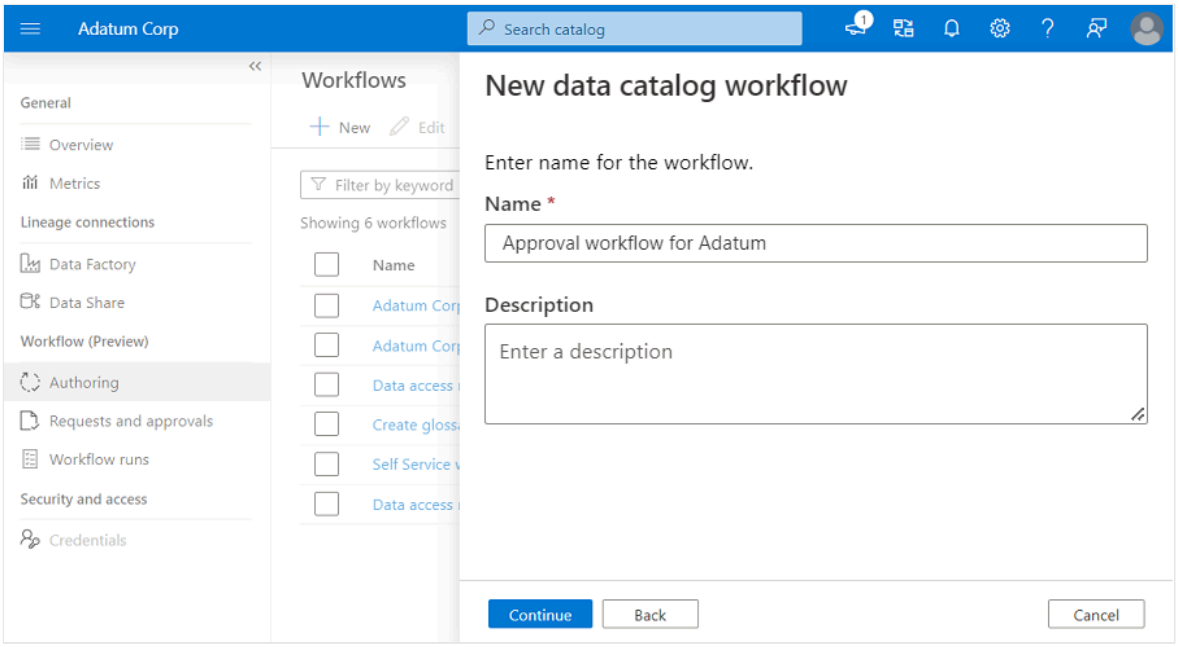


> **Note**

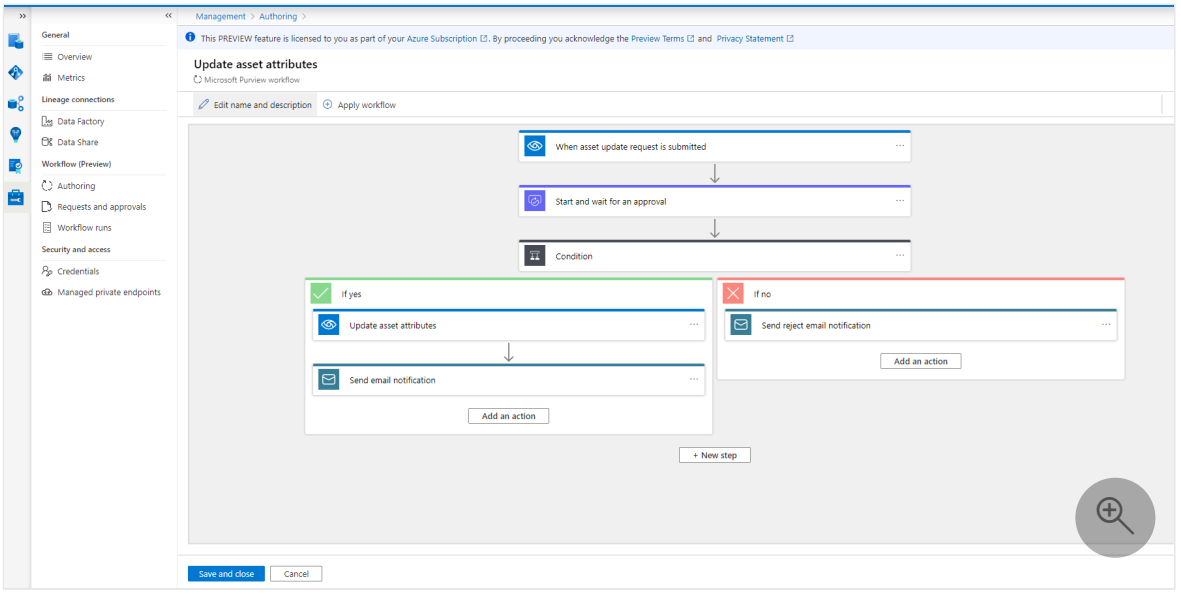
If the authoring tab is greyed out, you don't have the permissions to be able to author workflows. You'll need the workflow admin role.



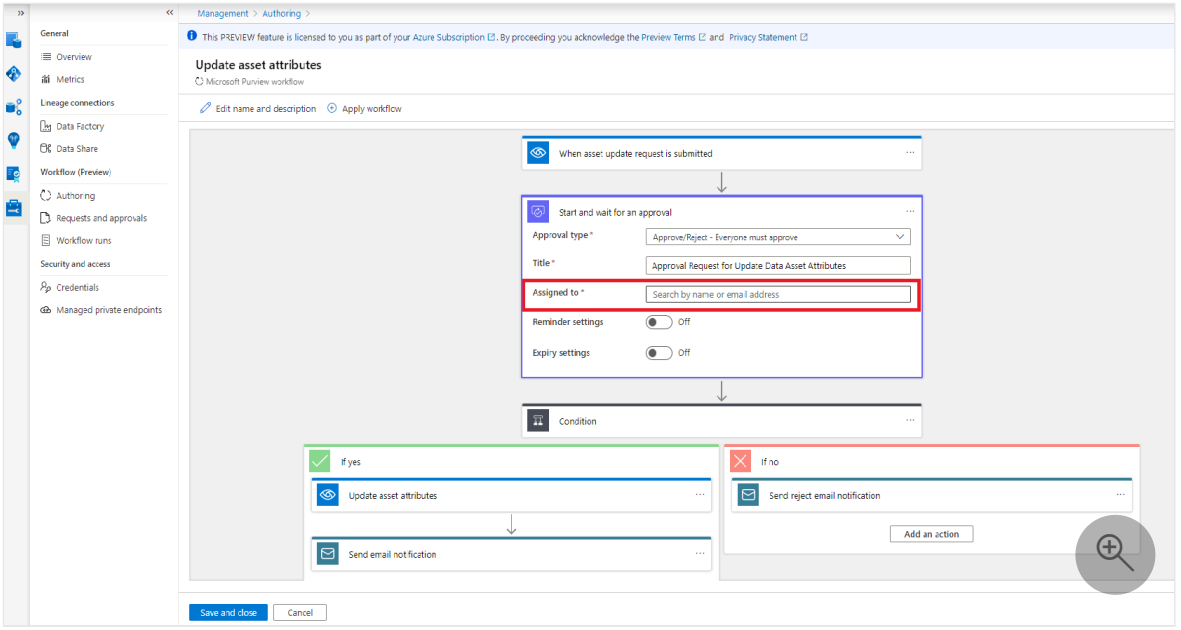
3. To create a new workflow, select the **+New** button.



4. To create **Approval workflows for asset curation** Select **Data Catalog** and select **Continue**



5. In the next screen, you'll see all the templates provided by Microsoft Purview to create a workflow. Select the template using which you want to start your authoring experiences and select **Continue**. Each of these templates specifies the kind of action that will trigger the workflow. In the screenshot below we've selected **Update asset attributes** to create approval workflow for asset updates.

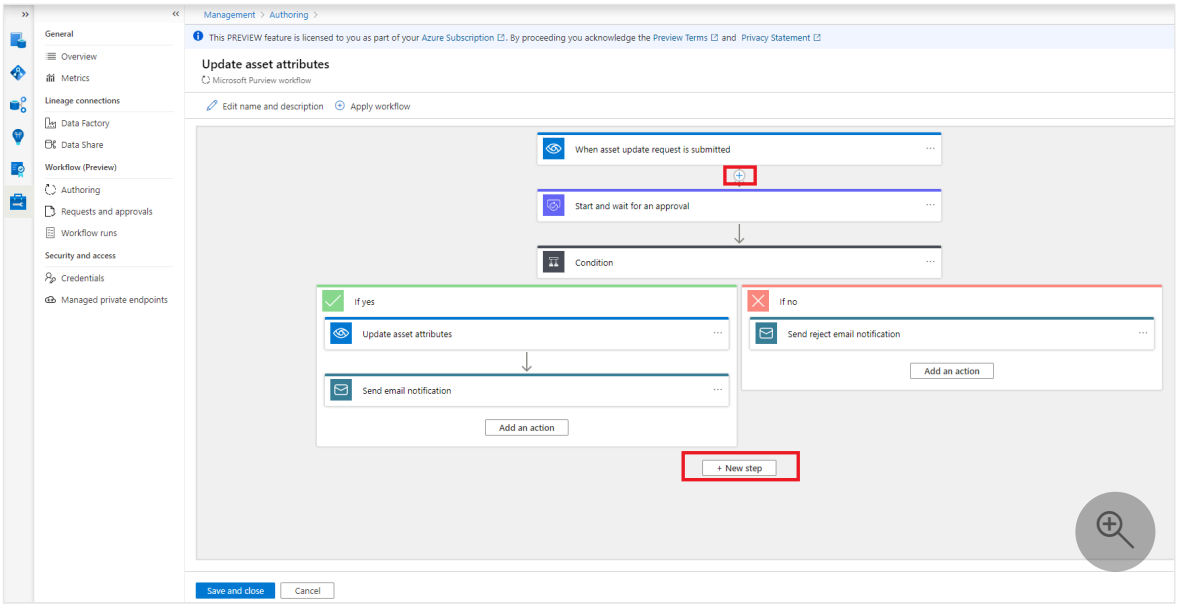


6. Next, enter a workflow name and optionally add a description. Then select **Continue**.

7. You'll now be presented with a canvas where the selected template is loaded by default.

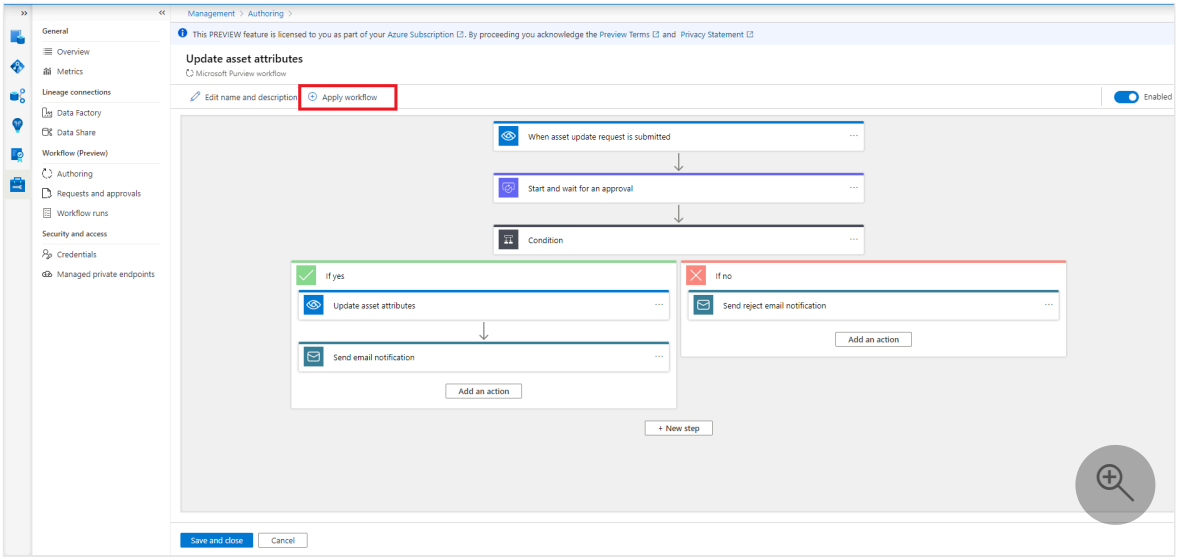
8. The default template can be used as it is by populating the approver's email address in **Start and Wait for approval** Connector.

The default template has the following steps:

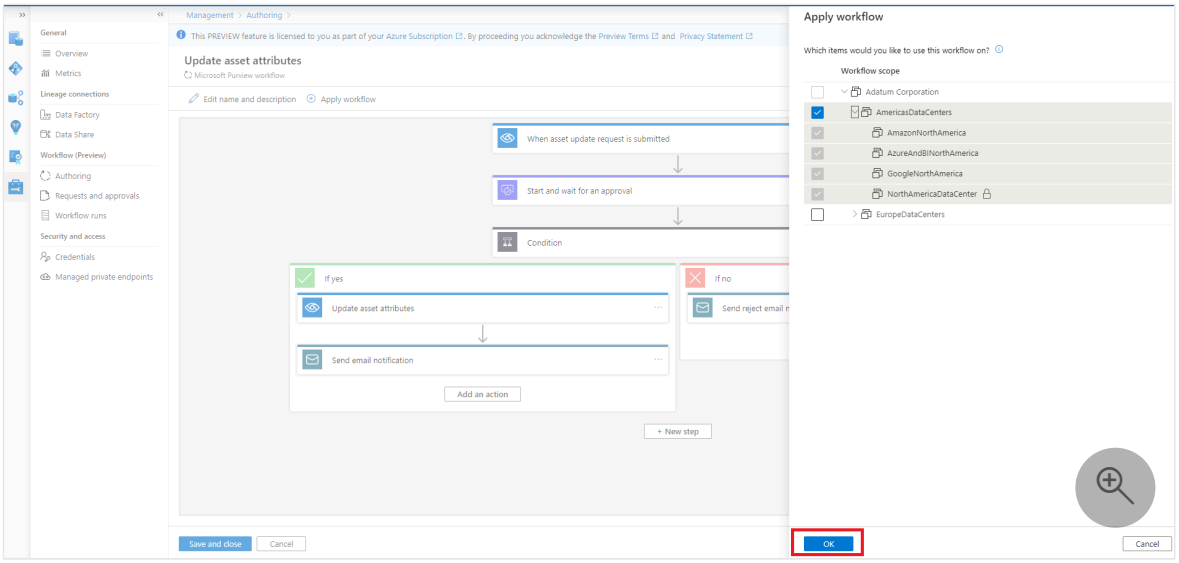


a. Trigger when an asset is updated. The update can be done in overview, schema or contacts tab.

b. Approval connector that specifies a user or group that will be contacted to approve the request.



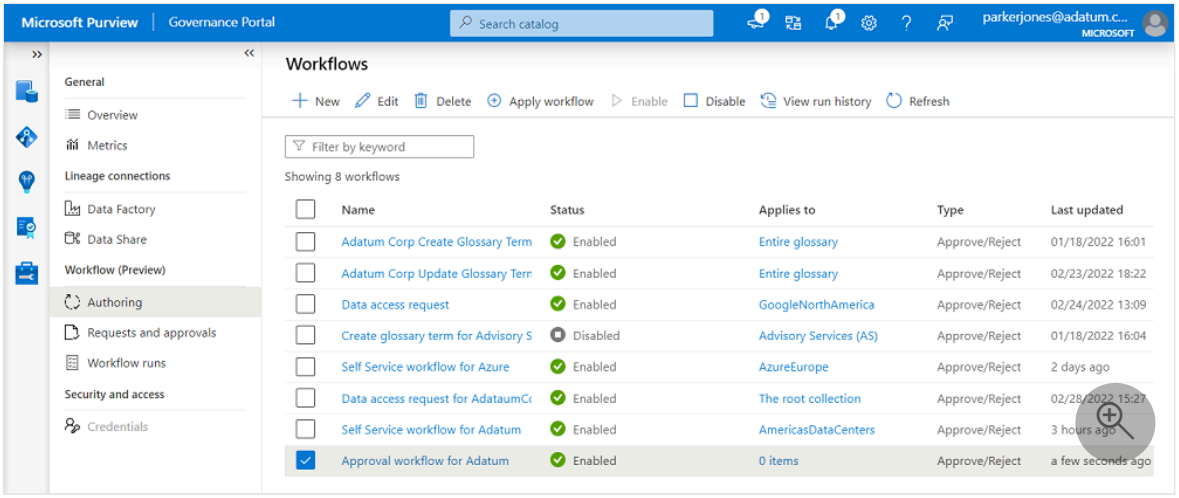
c. Condition to check approval status



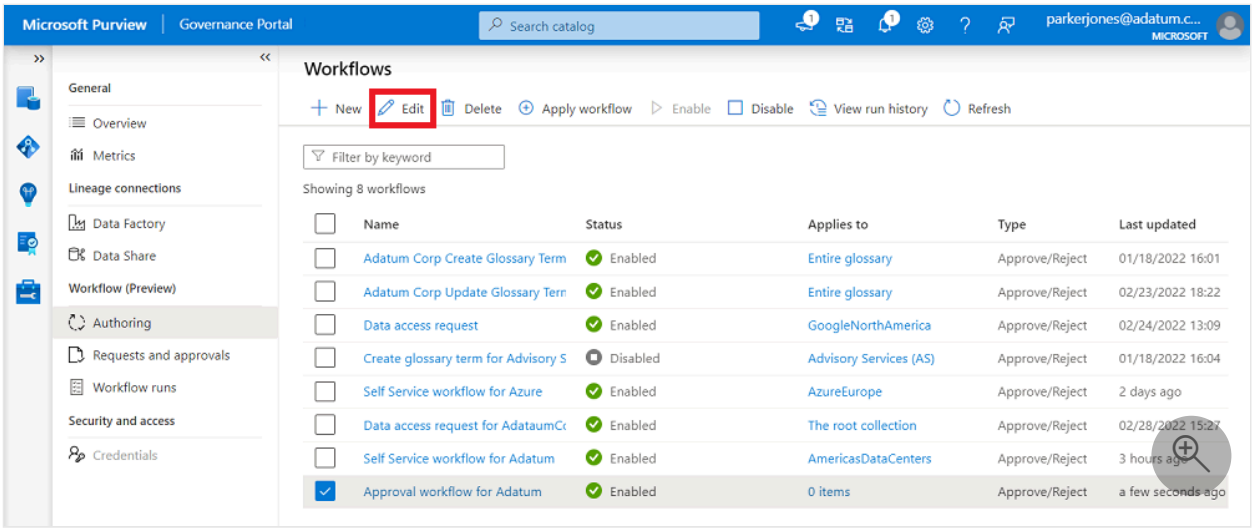
- If approved:
  i. Update the asset in Purview data catalog.
  ii. Send an email to requestor that their request is approved, and asset update operation is successful.
- If rejected:
  i. Send email to requestor that their asset update request is denied.

9. You can also modify the template by adding more connectors to suit your organizational needs. Add a new step to the end of the template by selecting the **New step** button. Add steps between any already existing steps by selecting the arrow icon between any steps.

10. Once you're done defining a workflow, you need to bind the workflow to a collection hierarchy path. The binding implies that this workflow is triggered only for update operation on data assets in that collection. A workflow can be bound to only one hierarchy path. To bind a workflow or to apply a scope to a workflow, you need to select 'Apply workflow'. Select the scopes you want this workflow to be associated with and select **OK**.

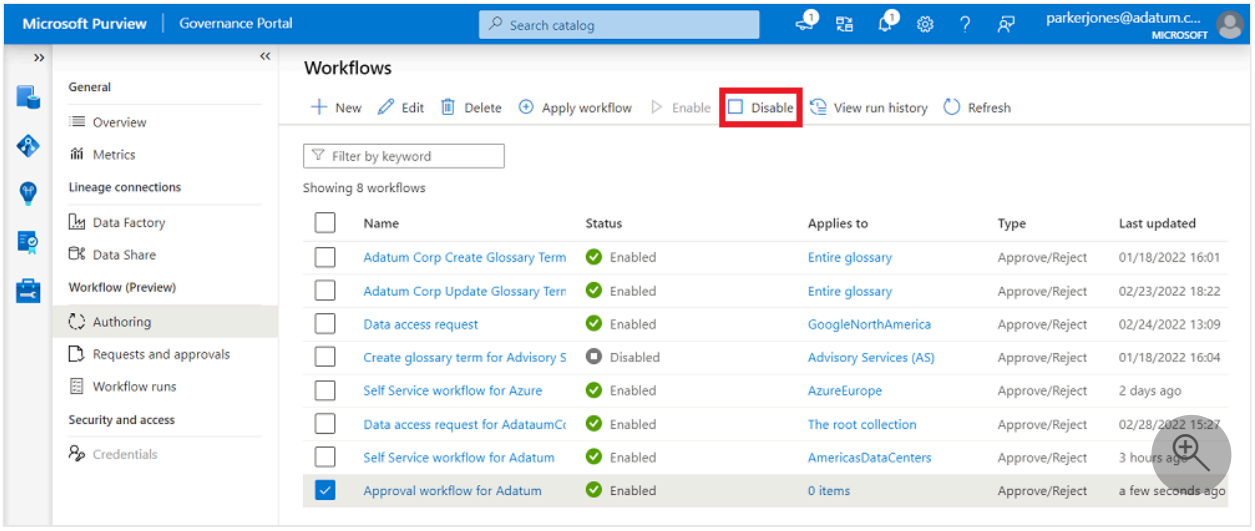


> **Note**
>
> The Microsoft Purview workflow engine will always resolve to the closest workflow that the collection hierarchy path is associated with. In case a direct binding is not found, it will traverse up in the tree to find the workflow associated with the closest parent in the collection tree.



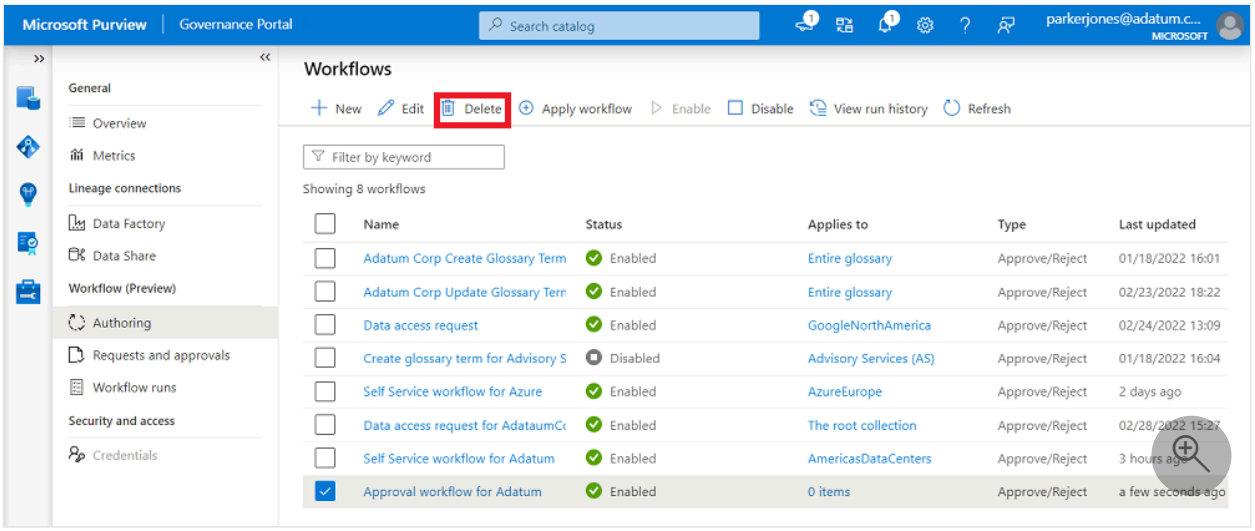
11. By default, the workflow will be enabled. To disable, toggle the Enable button in the top menu.

12. Finally select **Save and close** to create and the workflow.



Edit an existing workflow

To modify an existing workflow, select the workflow and then select **Edit** in the top menu. You'll then be presented with the canvas containing workflow definition. Modify the workflow and select **Save** to commit changes.



Disable a workflow

To disable a workflow, select the workflow and then select **Disable** in the top menu. You can also disable the workflow by selecting **Edit** and changing the enable toggle in workflow canvas.

Delete a workflow

To delete a workflow, select the workflow and then select **Delete** in the top menu.

Limitations for asset curation with approval workflow enabled

- Lineage updates are directly stored in Purview data catalog without any approvals.

Next steps

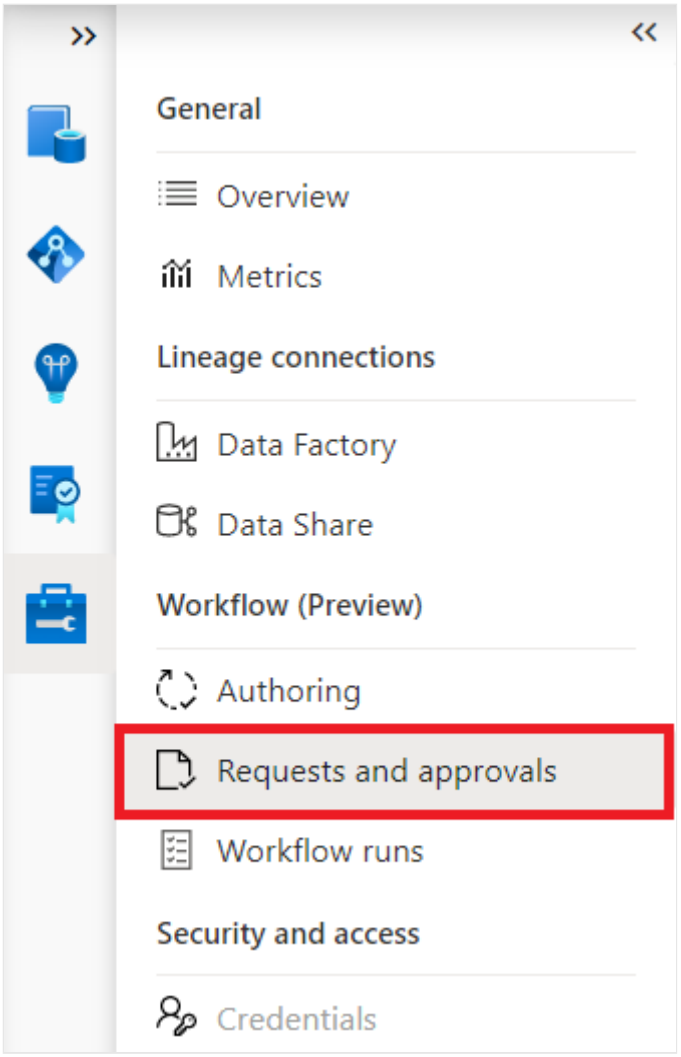
Manage workflow requests and approvals



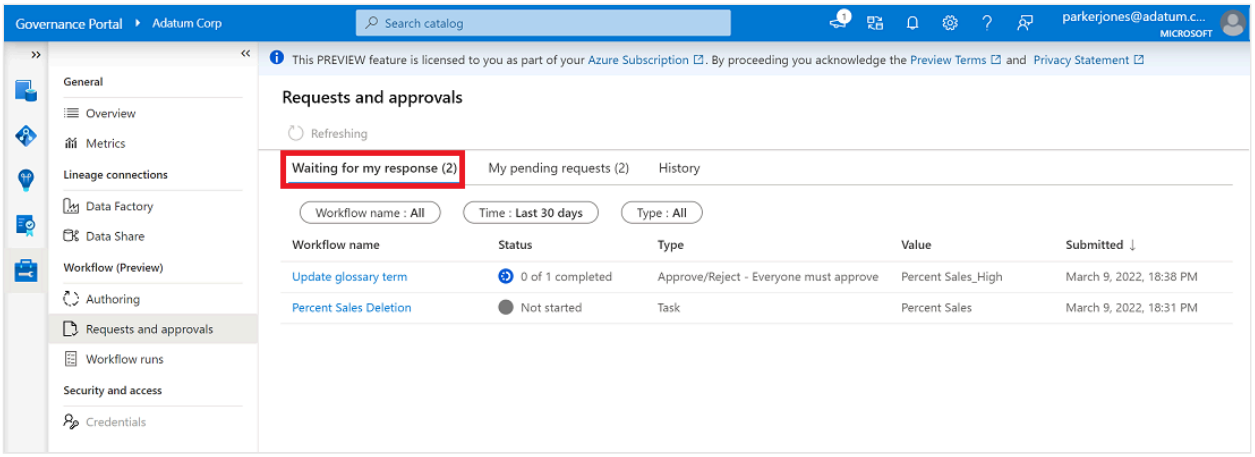
Article • 02/26/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

This article outlines how to manage requests and approvals that generated by a workflow in Microsoft Purview.

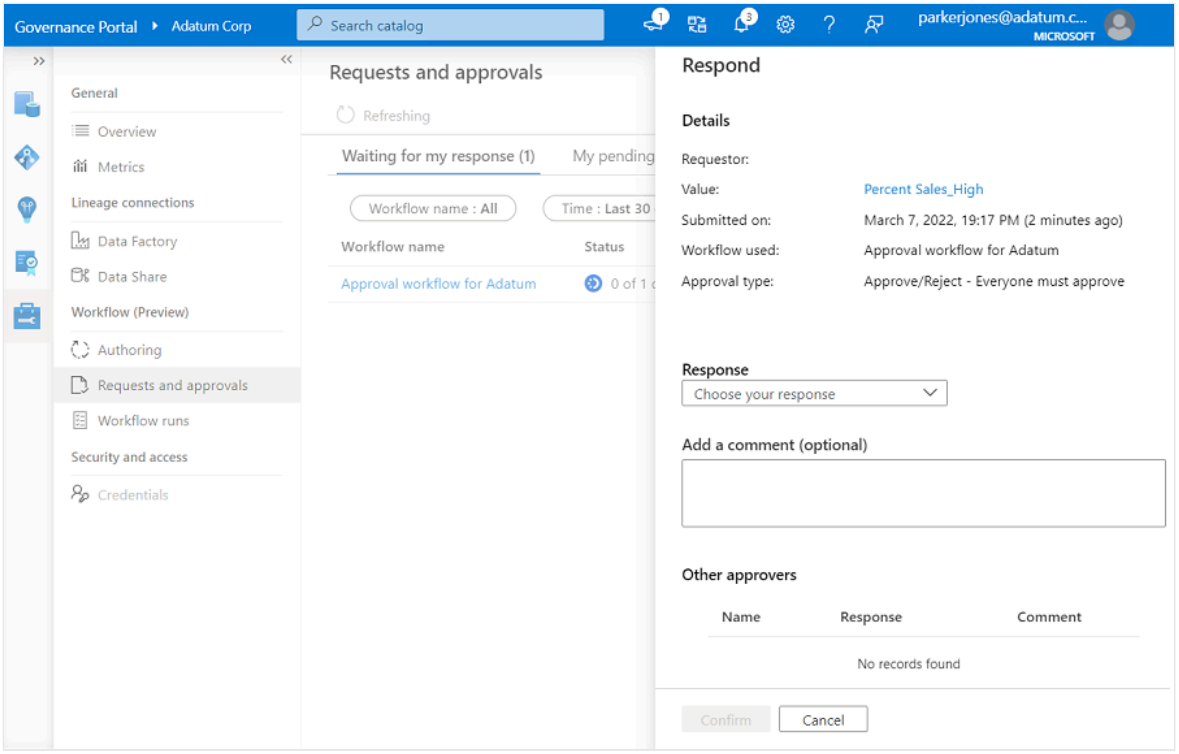
To view requests you've made or request for approvals that have been sent to you by a workflow instance, navigate to management center in the Microsoft Purview governance portal, and select **Requests and Approvals**.



You'll be presented with three tabs:

- Waiting for a response - This tab shows the requests (tasks) and approvals that are waiting for you to act on.
- Pending requests - You can view all the approval requests and tasks you've submitted in this tab.
- History - All the completed approvals and tasks are moved to this tab.

Waiting for a response

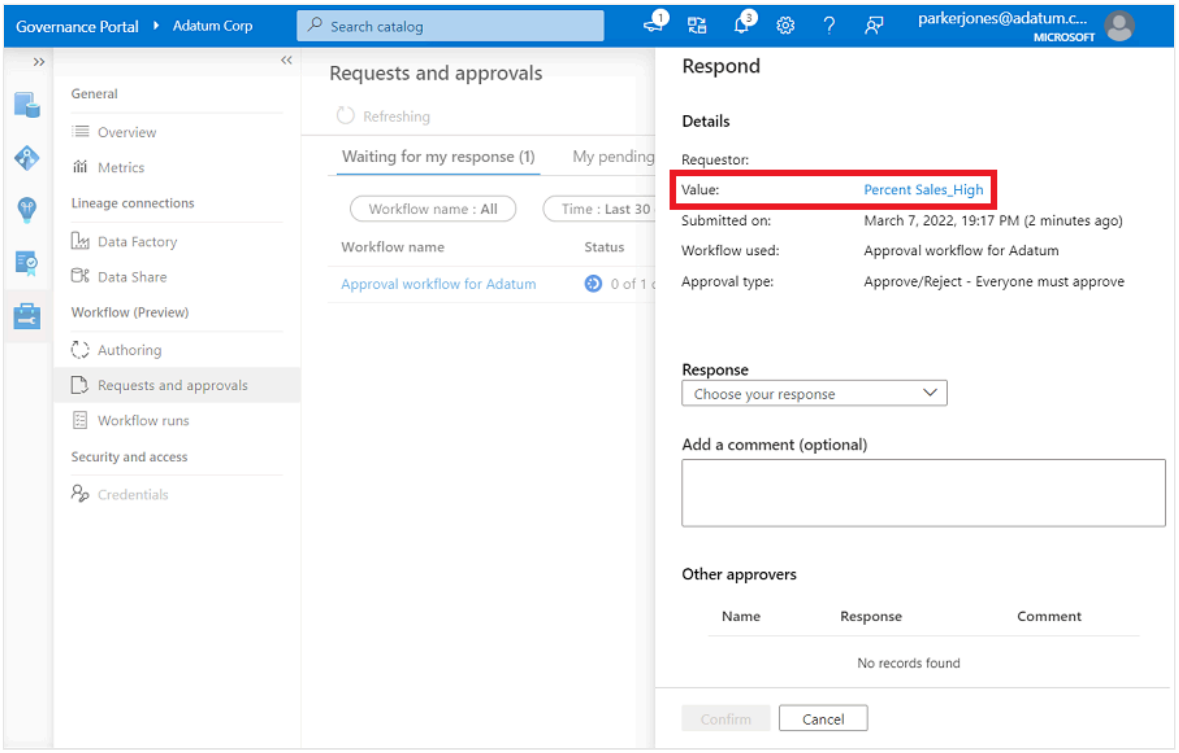


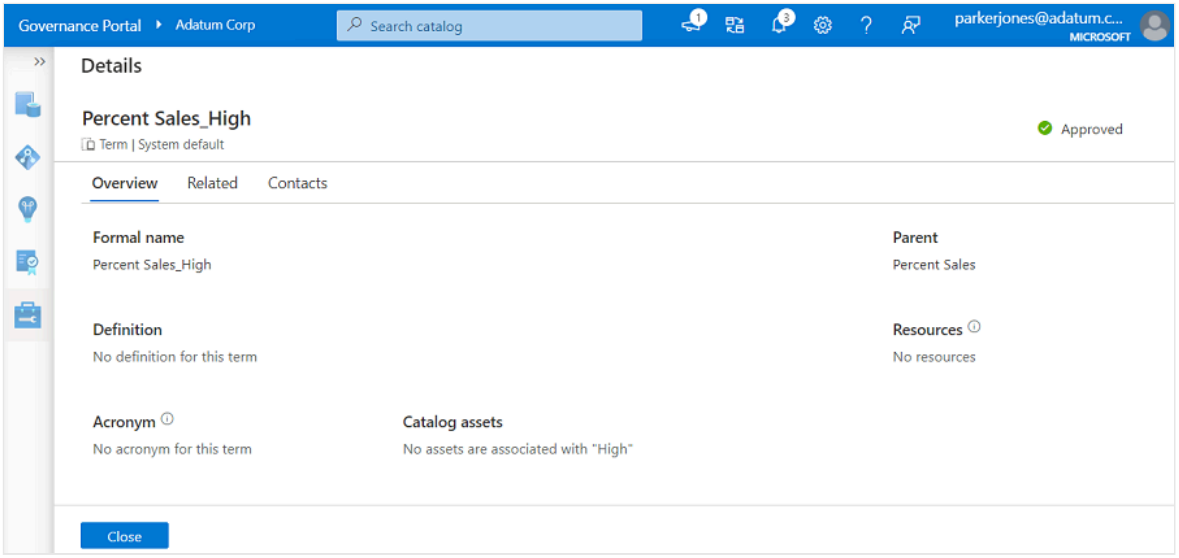
This tab shows the requests (tasks) and approvals that are waiting for your action.

Select the request to take action.

Approvals

1. To approve/reject a request, select the request and you'll be presented with the following window:

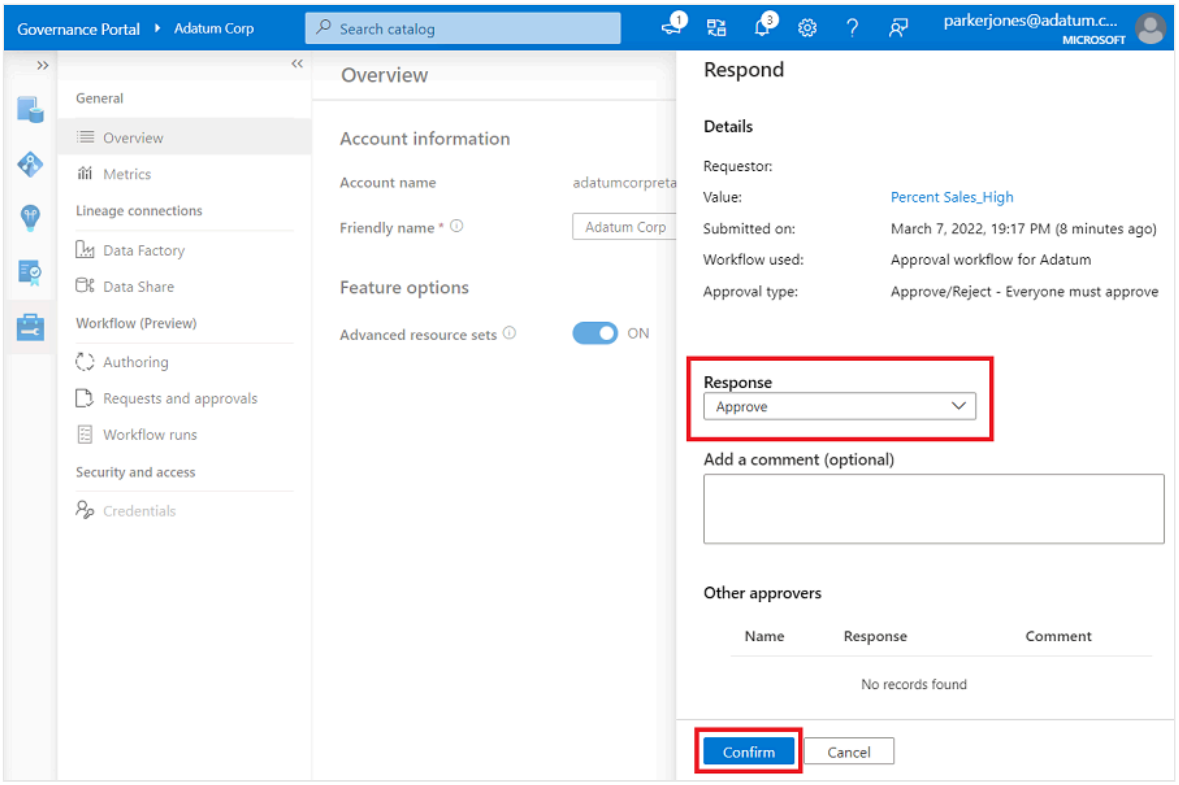




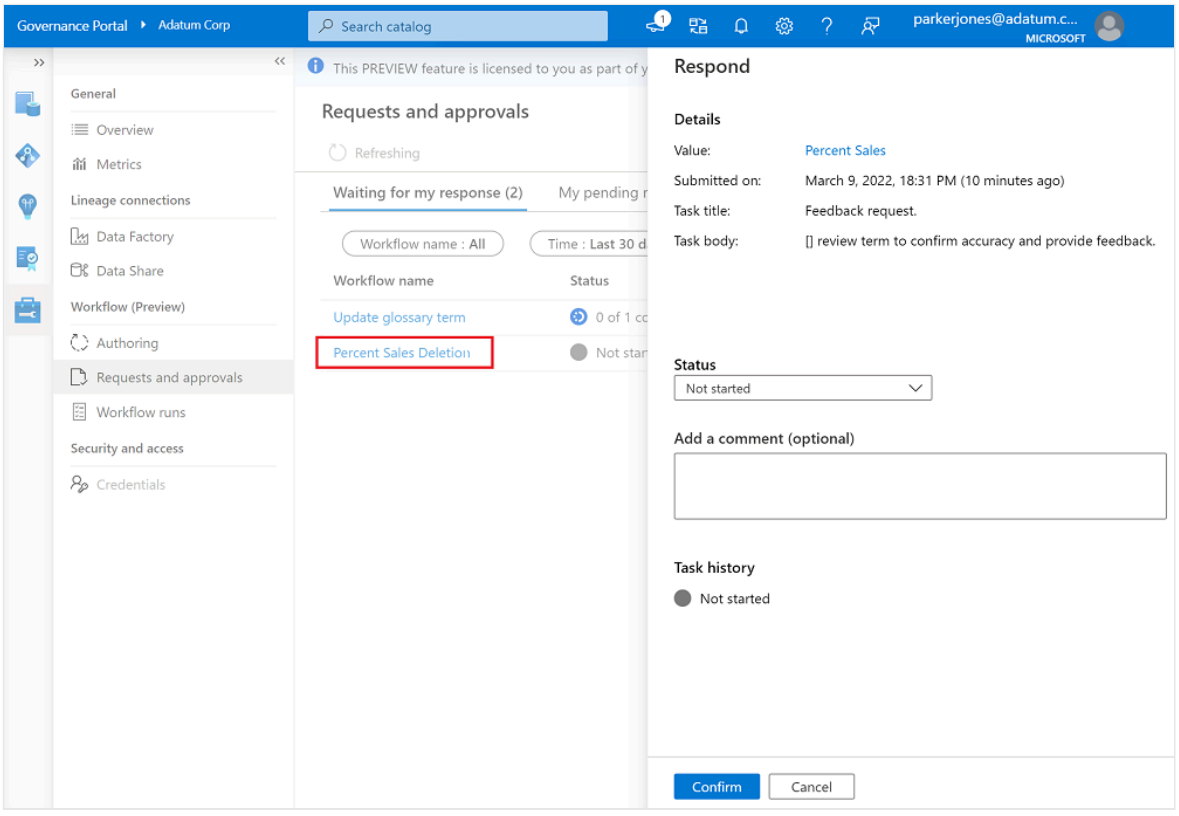
2. An approval activity has the following available responses:

   - **Approved** – An approver can mark the response as **Approved** indicating their approval for the changes proposed by the requestor.
   - **Rejected** - An approver can mark the response as **Rejected** indicating that they don't approve the changes proposed by the requestor.

3. Optionally, select the value to see details of the request. In the screenshot below, it shows the term details. If the approval is for a data asset, you'll be able to view the



details, as shown below.



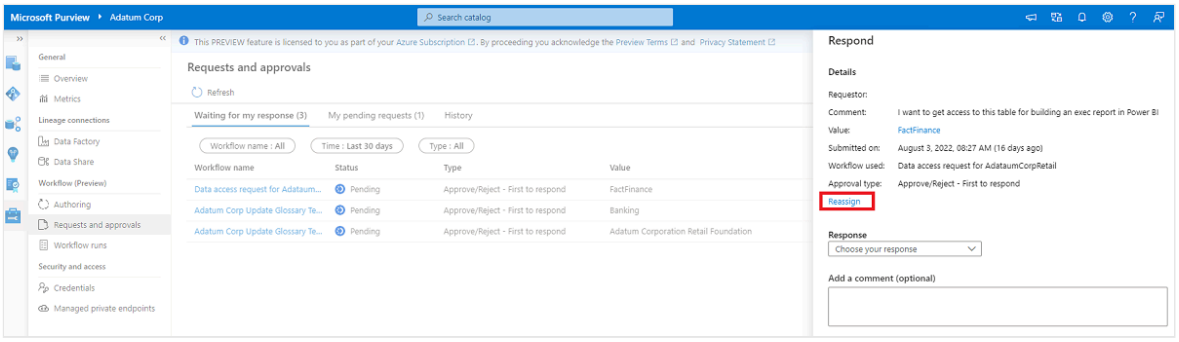
4. If there are updates, you'll also to be able to see the current value and proposed value.

5. Choose your response, optionally add comments, and select **Confirm**.

Tasks

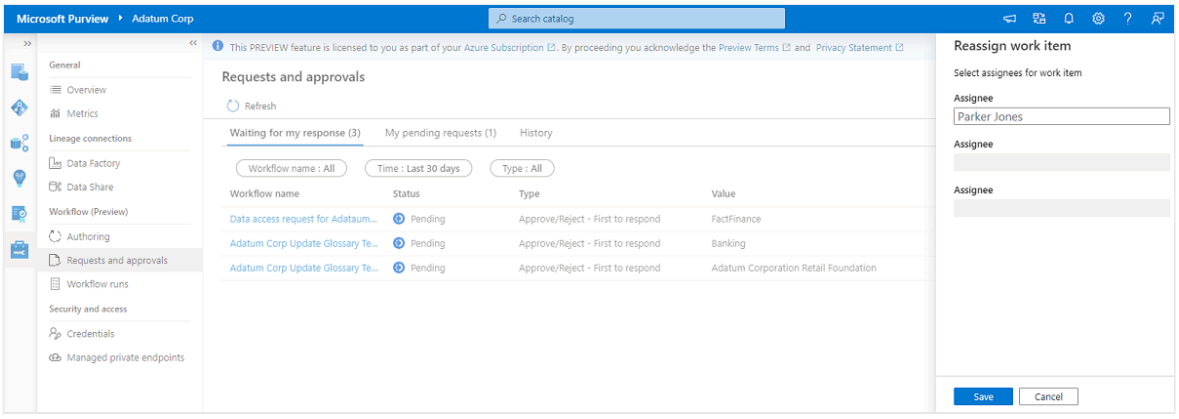
1. To complete a task, select the task request and you'll be presented with the following window:

2. A task has the following statues:



- Not started – This is the status of the task when it's initially created by a workflow.
- In Progress – A task owner can mark the task as **In progress** to indicate that they're currently working on it.
- Complete – Once the task is complete, a task owner can change the status as **Complete**. This marks the completion of task activity, and the workflow will now move to the next step.

3. Select the correct status, add any comments, and select **Confirm**.

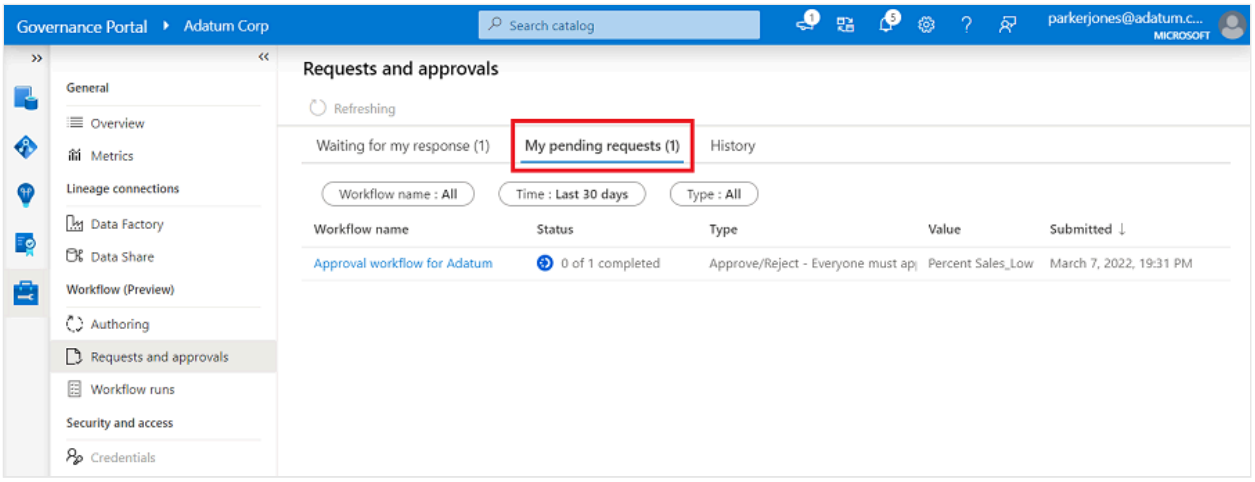


Reassign requests

You can reassign requests both approvals and tasks that are assigned to you to a different user.

1. To reassign, select the request or task you're assigned and select **Reassign** in the following window.

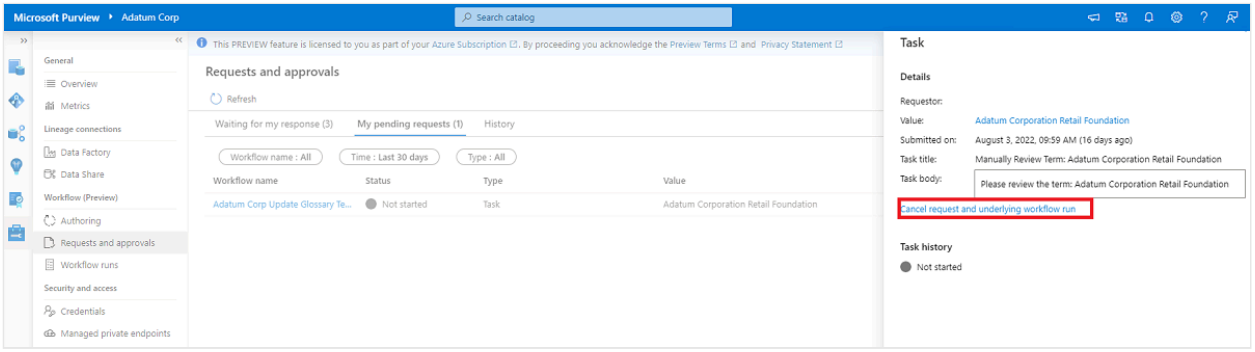
2. You'll be presented with a list of all the users who are assigned to the request. Select **Assignee** where your user name or the group you're part of is displayed and change it from your user name to the new user name. Select **Save** to complete the reassignment.



> **Note**

You can only re-assign your user ID or group you are part of to another user or group. The other assignees will be greyed out and will not available for re-assignment.

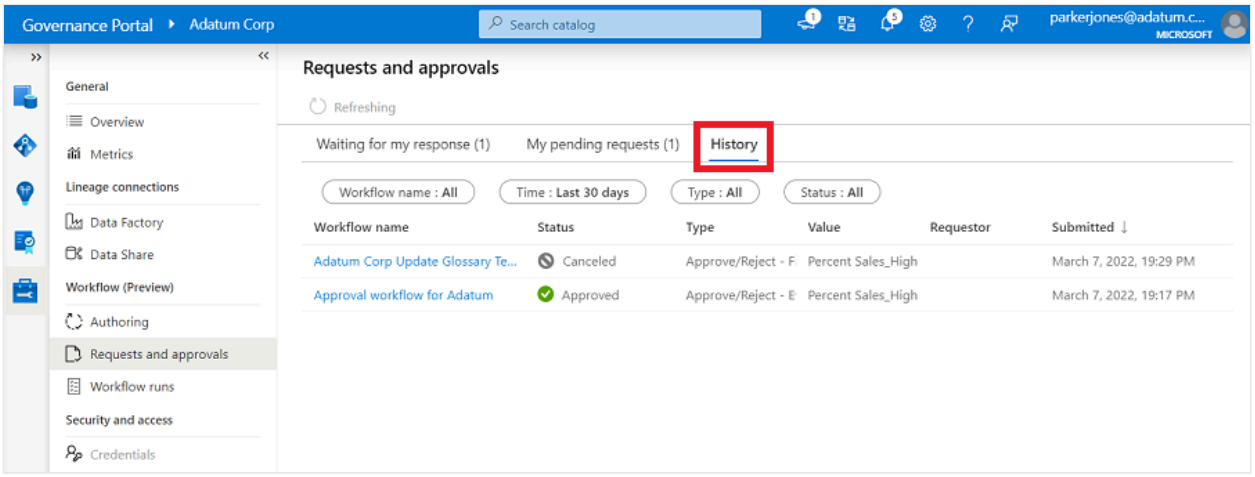
Pending requests



In this tab you can view all the approval requests and tasks that you've submitted.

Select the request to see the status and the outcomes for each approver/task owner.

Cancel workflows



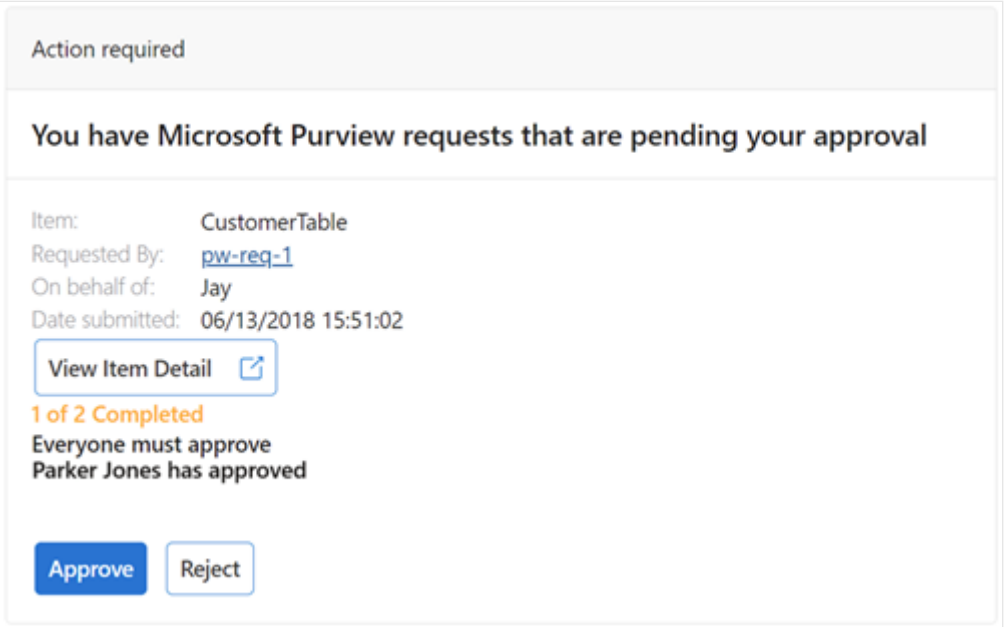
You can cancel a submitted request and its underlying workflow by selecting **Cancel request and its underlying workflow run**.

> **Note**
>
> You can only cancel workflows that are in progress. When you cancel a request from the **requests and approvals** section, it will cancel the underlying workflow run.

History

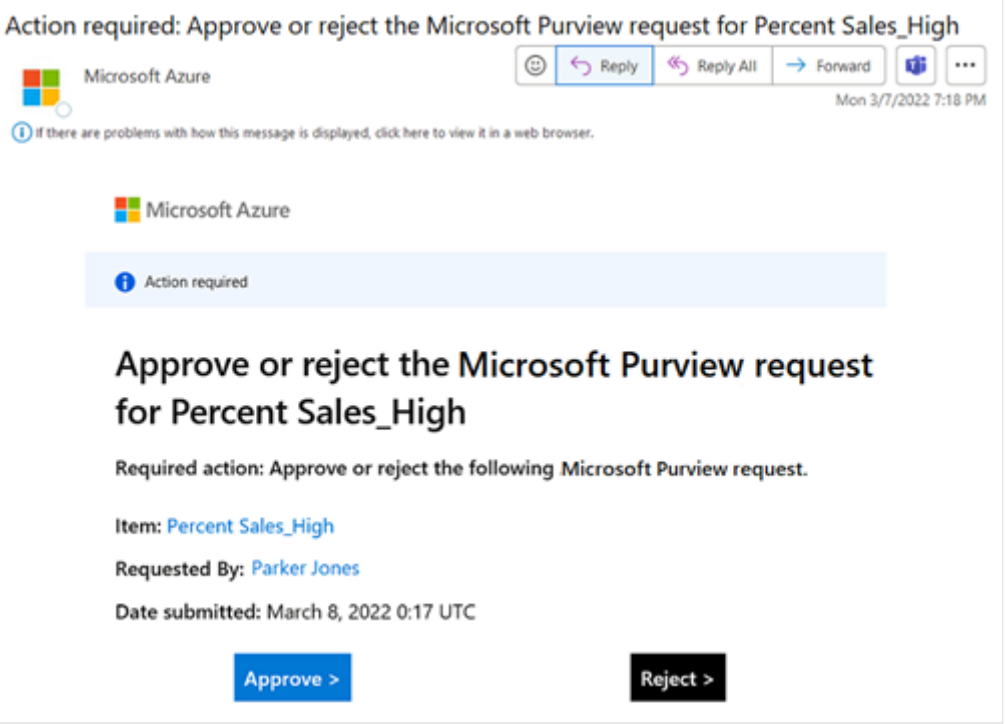
All the completed approvals and tasks are moved to this tab.

Select an approval or task to see details and responses from all approvals or task owners.



Email notifications

Purview approvals and task connectors have in-built email capabilities. Every time an approval/task action is triggered in workflow; it sends email to all the users who need to act on it.



There are two kinds of emails that can be sent:

- **Actionable messages** - if your workflow and email client meet the requirements, your approvers can receive single and aggregated actionable approval emails where they can leave comments and reject or approve requests within outlook. For more information, the approver can also select the approval item in the message to be taken to request details in the Microsoft Purview portal.

  > **ⓘ Important**
  >
  > If your workflow or email client don't meet the **requirements**, your users might receive 400/401/403 errors when using actionable messages.

- **Standard messages** - if your workflow and email client don't meet the requirements, your approvers will receive single and aggregated approval emails that will direct them to the approval experience in the Microsoft Purview portal.

Users can respond by selecting the links in the email, for **actionable messages** they can submit responses directly in the email, or by navigating to the Microsoft Purview governance portal and viewing their pending tasks.

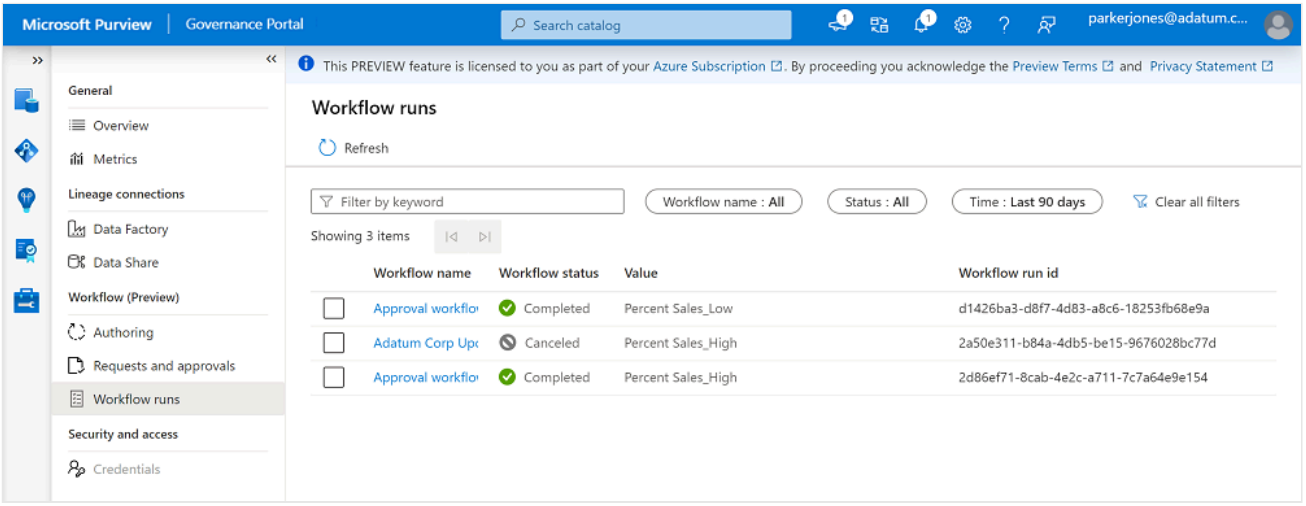
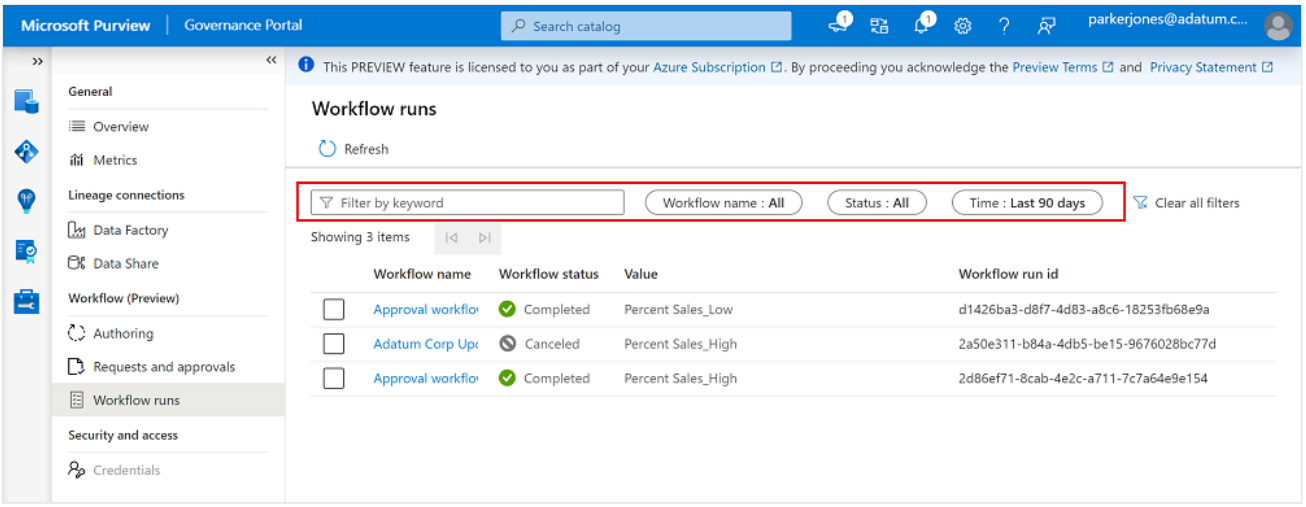
Manage workflow runs

> **Note**
>
> Microsoft Purview Data Catalog (classic), Data Health Insights (classic), and Purview Workflow (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.



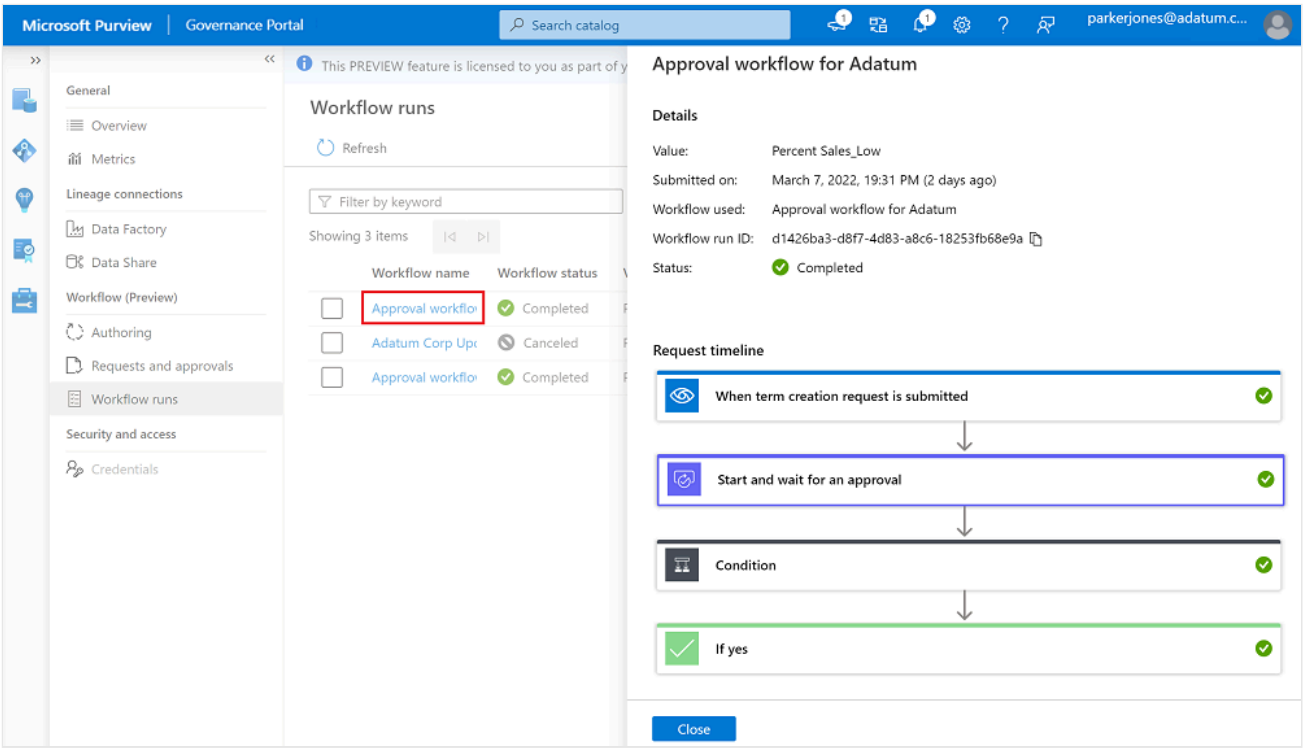
> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

This article outlines how to manage workflows that are already running.

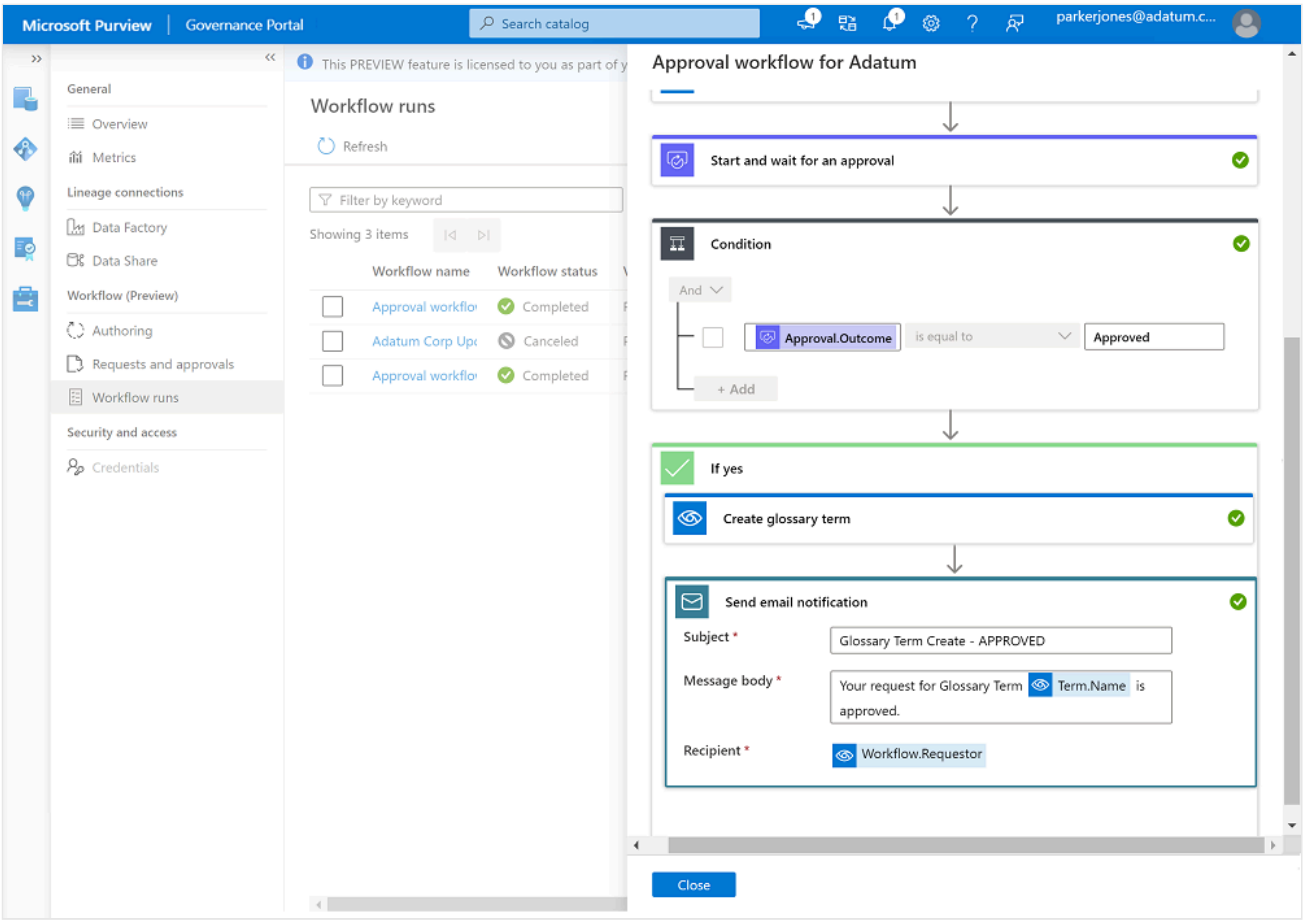


1. To view workflow runs you triggered, sign in to the Microsoft Purview governance portal, select the Management center, and select **Workflow runs**.

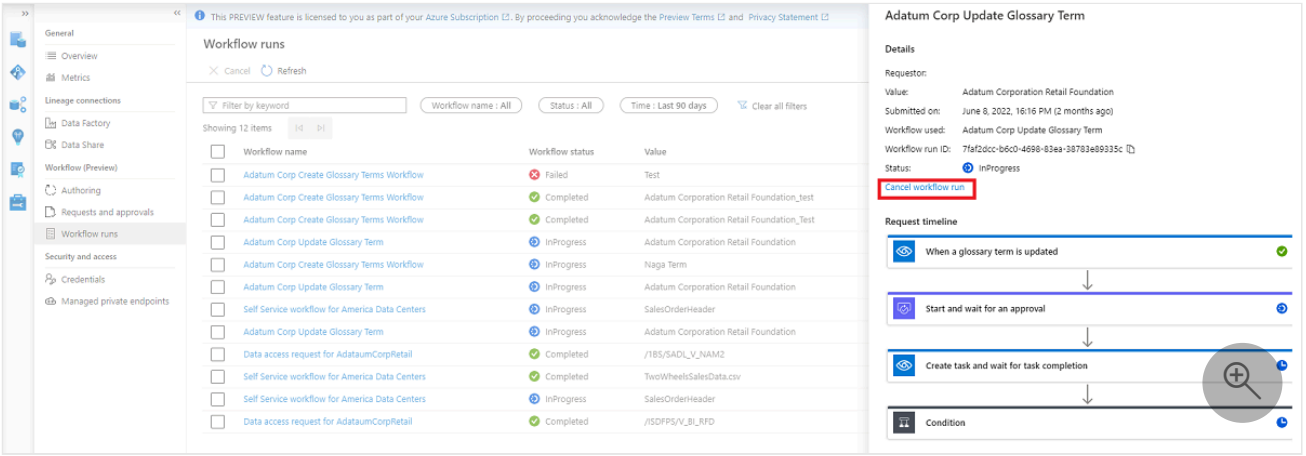
2. You'll be presented with the list of workflow runs and their statuses.



3. You can filter the results by using workflow name, status, or time.



4. Select a workflow name to see the details of the workflow run.



5. This will present a window that shows all the actions that are completed, actions that are in-progress, and the next action for that workflow run.

6. You can select any of the actions in the request timeline to see the specific status and sub steps details.

7. You can cancel a running workflow by selecting **Cancel workflow run**.

> **Note**
>
> You can only cancel workflows that are in progress.

ServiceNow actions in Microsoft Purview workflows

Article • 02/24/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

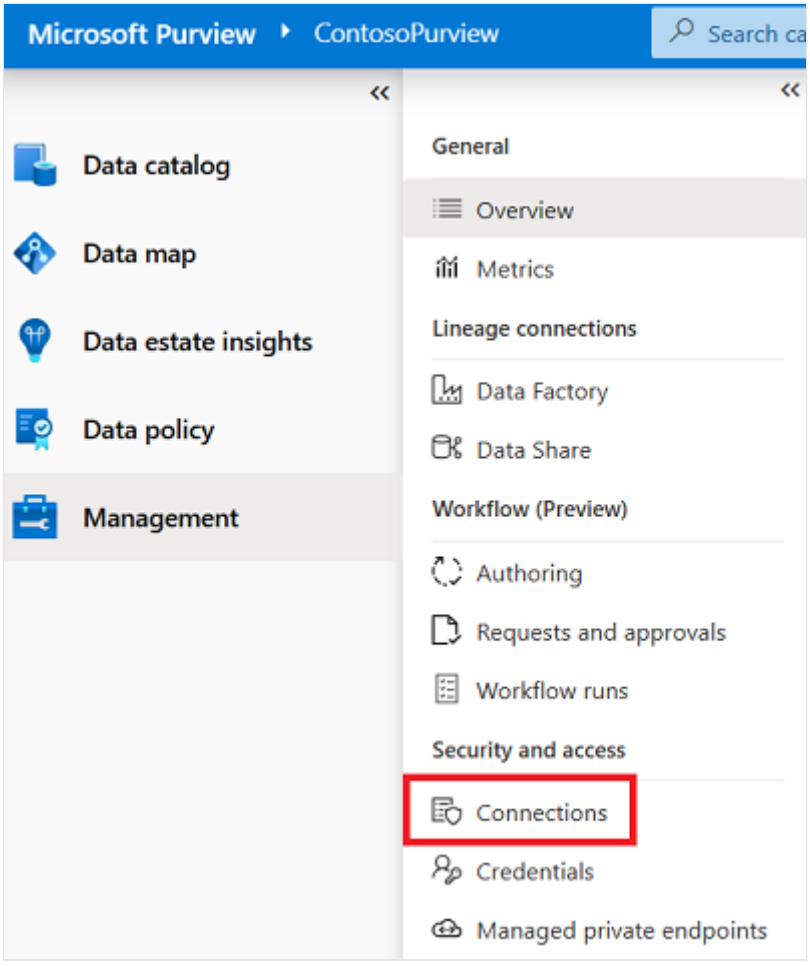
You can use ServiceNow actions in Microsoft Purview workflows to manage and update your ServiceNow records during your data catalog and data governance workflows.

For a list of all available workflow actions, see our workflow actions page. To connect to your ServiceNow instance, follow the instructions below.

Set up authentication

Microsoft Purview uses Azure Key Vault to securely store the credentials it uses to connect to other services. Before we can connect to ServiceNow we need to create our ServiceNow credential in the Azure Key vault. Follow these steps:

1. If you don't have an Azure Key Vault, you can follow this documentation to create one.
2. Create a secret in your key vault. The value will be your ServiceNow basic authentication password.
3. Grant Microsoft Purview access to your Azure Key Vault.
4. Create a connection in Microsoft Purview to your Azure Key Vault.
5. Create a new basic authentication credential in Microsoft Purview, providing your ServiceNow username and your key vault secret.



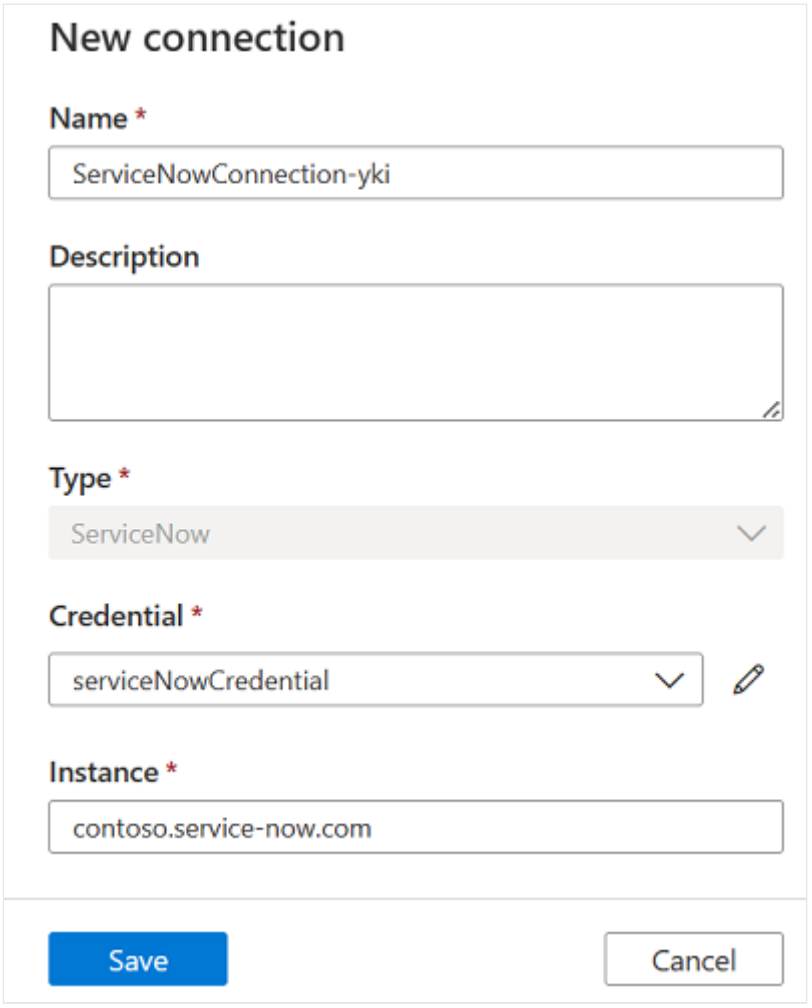
Now we have all the authentication pieces in place to connect to your ServiceNow instance.

Connect to ServiceNow

To access to your ServiceNow instance from Microsoft Purview workflows, first we'll create a connection. This allows Microsoft Purview to authenticate with ServiceNow.

Microsoft Purview uses basic auth credentials to connect to ServiceNow.

1. In the Microsoft Purview governance portal, select the **Management** menu, and then select **Connections**.

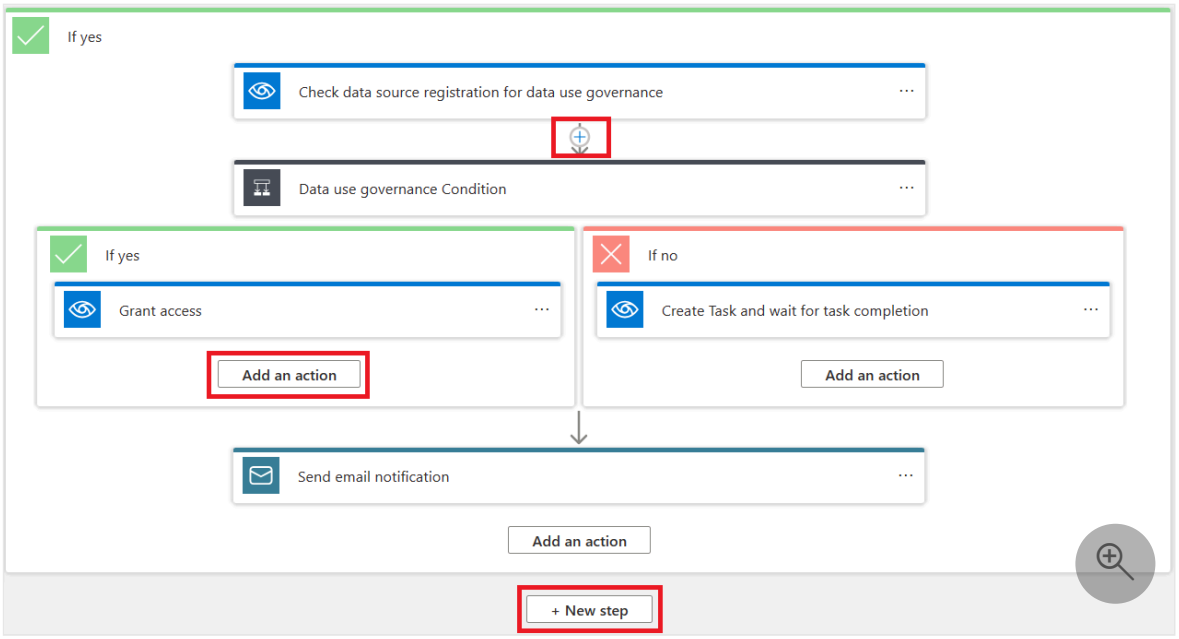


2. Select the + **New** button to create a new connection.

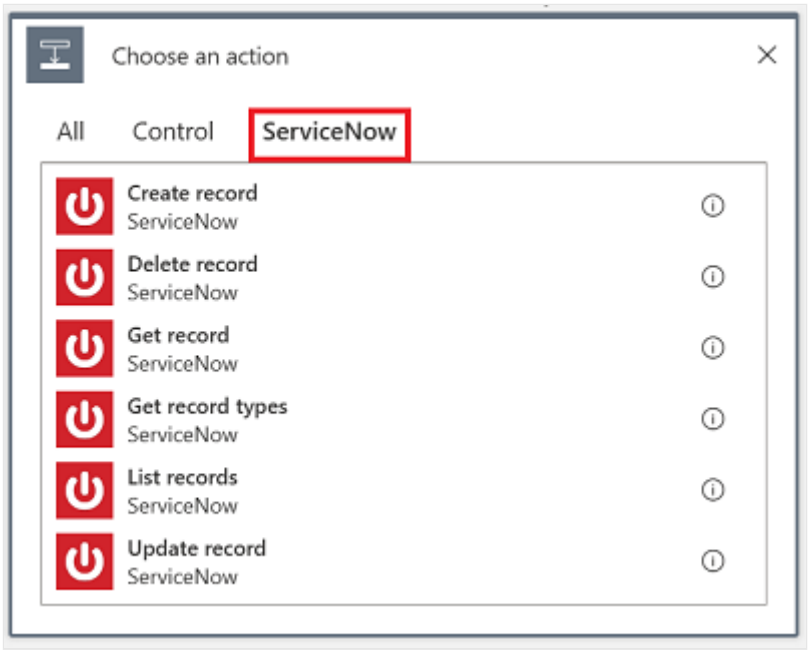
3. Select the **ServiceNow** data source.

4. Name your connection, select the credential you created when you set up authentication, and provide your ServiceNow instance in this format:

   `<instance>.service-now.com`



5. Select **Save**



Create ServiceNow action

When you're authoring any workflow (for example an approval workflow for business terms), you can add a ServiceNow action by following these steps.

1. Add an action to your workflow by selecting the + button on the arrow between actions, select the **Add an action** button, or the + **New Step** button at the end of the flow. Where you add the action is where it will be executed in the workflow.

2. In the **Choose an action** menu, select **ServiceNow**.

3. Select the ServiceNow action you'd like to use, and fill out the parameters. For more information about each action, see the available ServiceNow actions list.

4. Select **Save** to save your additions to the workflow.

Available actions

Expand table

Connector Type	Functionality	Parameters	Customizable	Workflow templates
Create record	Create a record for a ServiceNow object type.	-Connection (your ServiceNow connection) -Record type -Record body -Display system references toggle -Exclude reference links toggle	- Renamable: Yes - Deletable: Yes - Multiple per workflow	All workflows templates
Delete record	Delete a record for a ServiceNow object type.	-Connection (your ServiceNow connection) -Record type -System ID	- Renamable: Yes - Deletable: Yes - Multiple per workflow	All workflows templates
Get record	Get a record for a ServiceNow object type.	-Connection (your ServiceNow connection) -Record type -System ID -Display system references toggle -Exclude reference links toggle	- Renamable: Yes - Deletable: Yes - Multiple per workflow	All workflows templates
Get record types	List available record types.	-Connection (your ServiceNow connection)	- Renamable: Yes - Deletable: Yes - Multiple per workflow	All workflows templates
List records	Get records of a ServiceNow object type.	-Connection (your ServiceNow connection) -Record type -Display system references toggle -Exclude reference links toggle -Query -Limit (default is 10000) -Offset	- Renamable: Yes - Deletable: Yes - Multiple per workflow	All workflows templates
Update record	Updates a record for a ServiceNow object	-Connection (your ServiceNow	- Renamable: Yes	All workflows templates

Connector Type	Functionality	Parameters	Customizable	Workflow templates
	type.	connection) -Record type -System ID -Record body -Display system references toggle -Exclude reference links toggle	- Deletable: Yes - Multiple per workflow

>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

You can use workflows to automate some business processes through Microsoft Purview. A Connector in a workflow provides a way to connect to different systems and apply a set of prebuilt actions and triggers.

Current workflow connectors and actions

Currently the following connectors and actions are available for a workflow in Microsoft Purview:

Expand table

Connector Type	Functionality	Parameters	Customizable	Workflow templates
Apply to each	Apply an action or set of actions to all returned values in an output.	-Output to process -Actions	- Renamable: Yes - Deletable: Yes - Multiple per workflow	All workflows templates
Check data source registration for data use governance	Validate if data source has been registered with Data policy enforcement enabled.	None	- Renamable: Yes - Deletable: Yes - Multiple per workflow	Data access request

Connector Type	Functionality	Parameters	Customizable	Workflow templates
Condition	Evaluate a value to true or false. Based on the evaluation the workflow will be redirected to different branches	- Add row - Title - Add group	- Renamable: Yes - Deletable: Yes - Multiple per workflow	All workflows templates
Create Glossary Term	Create a new glossary term	None	- Renamable: Yes - Deletable: Yes - Multiple per workflow	Create glossary term template
Create task and wait for task completion	Creates, assigns, and tracks a task to a user or Microsoft Entra group as part of a workflow. - Reminder settings - You can set reminders to periodically remind the task owner until they complete the task. - Expiry settings - You can set an expiration or deadline for the task activity. Also, you can set who needs to be notified (user/AAD group) after the expiry. - Email aggregation available	- Assigned to - Task title - Task body	- Renamable: Yes - Deletable: Yes - Multiple per workflow	All workflows templates
Delay	Delay the next action until a specified number of units has passed.	-Count: Number of units that need to pass until the delay resolves -Unit: Month, Week, Day, Hour, Minute, Second	- Renamable: Yes - Deletable: Yes - Multiple per workflow	All workflows templates
Delete glossary term	Delete an existing glossary term	None	- Renamable: Yes - Deletable: Yes - Multiple per workflow	Delete glossary term

Connector Type	Functionality	Parameters	Customizable	Workflow templates
Grant access	Create an access policy to grant access to the requested user.	None	- Renamable: Yes - Deletable: Yes - Multiple per workflow	Data access request
Http	Integrate with external applications through http or https call. For more information, see Workflows HTTP connector	- Host - Method - Path - Headers - Queries - Body - Authentication	- Renamable: Yes - Deletable: Yes - Settings: Secured Input and Secure outputs (Enabled by default) - Multiple per workflow	All workflows templates
Import glossary terms	Import one or more glossary terms	None	- Renamable: Yes - Deletable: No - Multiple per workflow	Import terms
Parse JSON	Parse an incoming JSON to extract parameters	- Content - Schema	- Renamable: Yes - Deletable: No - Multiple per workflow	All workflows templates
Send email notification	Send email notification to one or more recipients	- Subject - Message body - Recipient	- Renamable: Yes - Deletable: Yes - Settings: Secured Input and Secure outputs (Enabled by default), Single or aggregated emails - Multiple per workflow	All workflows templates
ServiceNow actions	Connect to an instance of	Depending. See ServiceNow in workflows	- Renamable: Yes	All workflows

Connector Type	Functionality	Parameters	Customizable	Workflow templates
	ServiceNow and complete one of these actions: -Create record -Delete record -Get record -Get record types -List records -Update record	for more information.	- Deletable: Yes - Multiple per workflow	templates
Start and wait for an approval	Generates approval requests and assigns the requests to individual users or Microsoft Entra groups. There are two approval types: - First to Respond – First approver's outcome (Approve/Reject) is considered final. - Everyone must approve – This implies everyone identified as an approver must approve. If one approver rejects the request, the request is rejected. - Email aggregation available	- Approval Type - Title - Assigned To	- Renamable: Yes - Deletable: Yes - Multiple per workflow	All workflows templates
Switch	Evaluates a dynamic content expression and chooses the case that matches the result, running specific actions for only that case. **Currently up to 15 cases are supported.**	- On: Dynamic content to evaluate. (string, integer) - Equals: Value to evaluate 'on' against. When matched, the workflow diverts to this case. (string, integer)	- Renamable: Yes - Deletable: Yes - Multiple per workflow	All workflows templates
Until	Repeat actions within the until control until the and/or condition	-Actions: Actions to repeat -Count: Default 60,	- Renamable: Yes - Deletable: Yes	All workflows templates

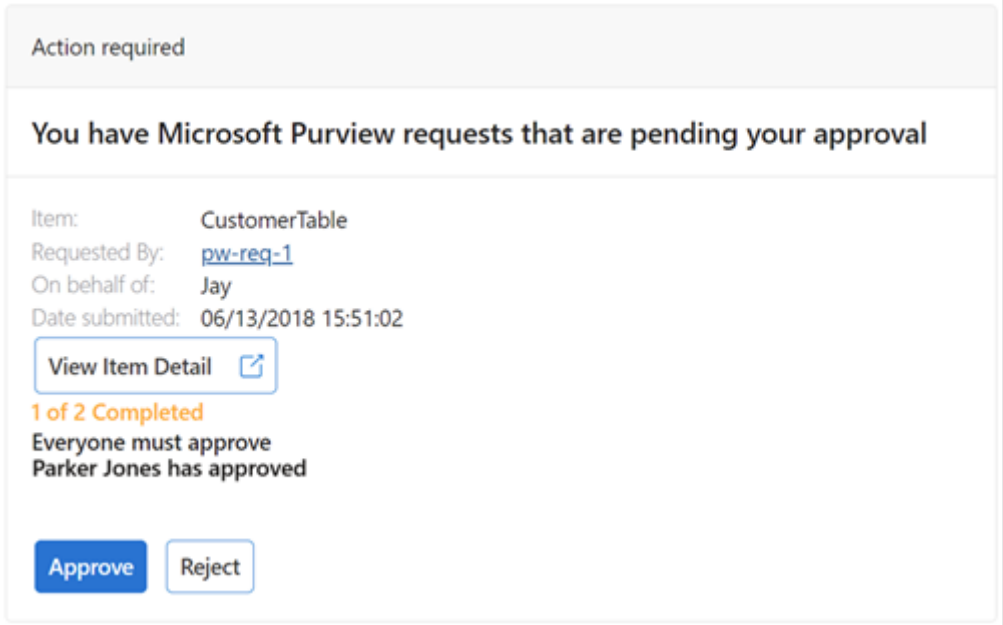
Connector Type	Functionality	Parameters	Customizable	Workflow templates
	is satisfied, or the count or time out limits have been reached.	Minimum 1, Maximum 1000 The number of cycles that an Until loop can have during a workflow run. -Time-out: Default PT1H(1 hour), Maximum PT1H(1 hour) The amount of time that the Until loop can run before exiting and is specified in ISO 8601 format. If cumulative time counted for all actions and iterations within Until action takes longer than the time-out limit, the current cycle doesn't stop. However, the next cycle doesn't start because the limit condition isn't met.	- Multiple per workflow	
Update glossary term	Update an existing glossary term	None	- Renamable: Yes - Deletable: Yes - Multiple per workflow	Update glossary term
Variable actions	Define and update custom variables with these actions: -Initialize variable -Set variable -Increment variable -Decrement variable -Append array to variable -Append string to variable	Depending. See the variable actions section for more information.	- Renamable: Yes - Deletable: Yes - Multiple per workflow	All workflows templates
When term creation request is submitted	Triggers a workflow with all term details when a new term request is submitted	None	- Renamable: Yes - Deletable: No	Create glossary term template

Connector Type	Functionality	Parameters	Customizable	Workflow templates
			- Only one per workflow	
When term deletion request is submitted	Triggers a workflow with all term details when a request to delete an existing term is submitted	None	- Renamable: Yes - Deletable: No - Only one per workflow	Delete glossary term
When term Import request is submitted	Triggers a workflow with all term details in a csv file, when a request to import terms is submitted	None	- Renamable: Yes - Deletable: No - Only one per workflow	Import terms
When term update request is submitted	Triggers a workflow with all term details when a request to update an existing term is submitted	None	- Renamable: Yes - Deletable: No - Only one per workflow	Update glossary term

Start and wait for an approval

The start and wait for an approval connector generates approval requests and assigns the requests to individual users or Microsoft Entra groups.

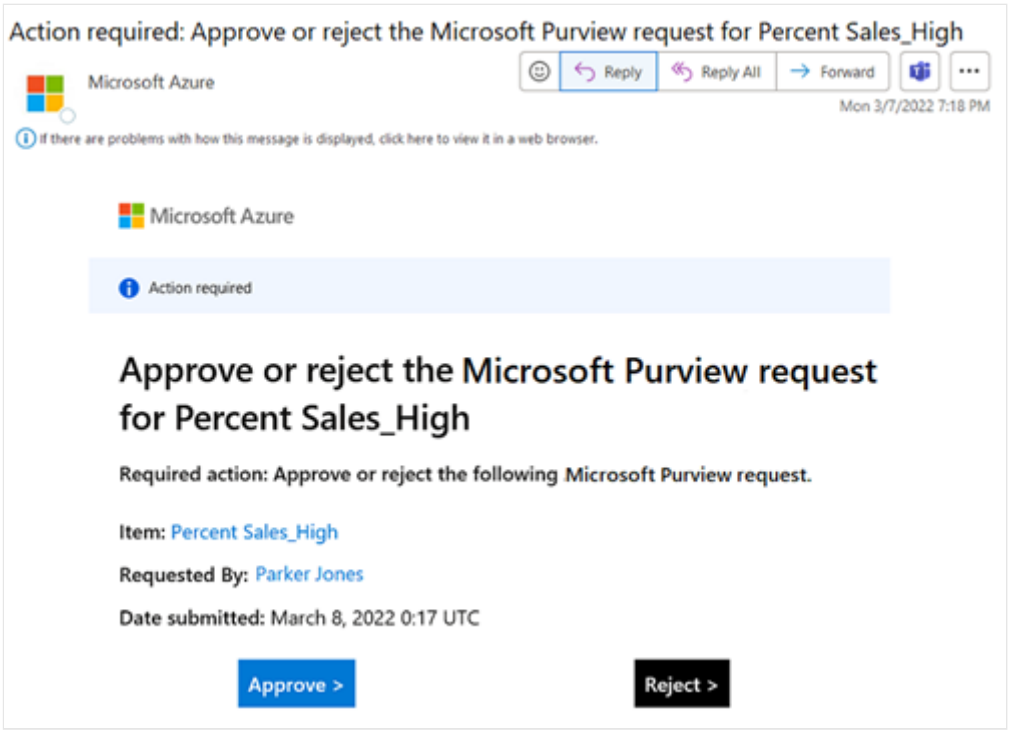
Currently, the connector supports two types of approval types:



- **First to Respond** – This implies that the first approver's outcome (Approve/Reject) is considered final.
- **Everyone must approve** – This implies everyone identified as an approver must approve the request for the request to be considered approved. If one approver rejects the request, regardless of other approvers, the request is rejected.

You can also set reminders to periodically remind the approver until they approve or reject, or set an expiration or deadline for the approval activity. When the request expires, you can choose who will receive a notification about the expiration.

Approval requests



Approval requests are sent as emails to the groups or users specified in the approval connector. There are two types of possible approval emails depending on whether your workflow and your email client meet some requirements.

- **Actionable messages** - if your workflow and email client meet the requirements, your approvers can receive single and aggregated actionable approval emails where they can leave comments and reject or approve requests within outlook. For more information, the approver can also select the approval item in the message to be taken to request details in the Microsoft Purview portal.

> **ⓘ Important**
>
> If your workflow or email client don't meet the **requirements**, your users might receive 400/401/403 errors when using actionable messages.

- **Standard messages** - if your workflow and email client don't meet the requirements, your approvers receive single and aggregated approval emails that direct them to the approval experience in the Microsoft Purview portal.

Actionable approval requirements

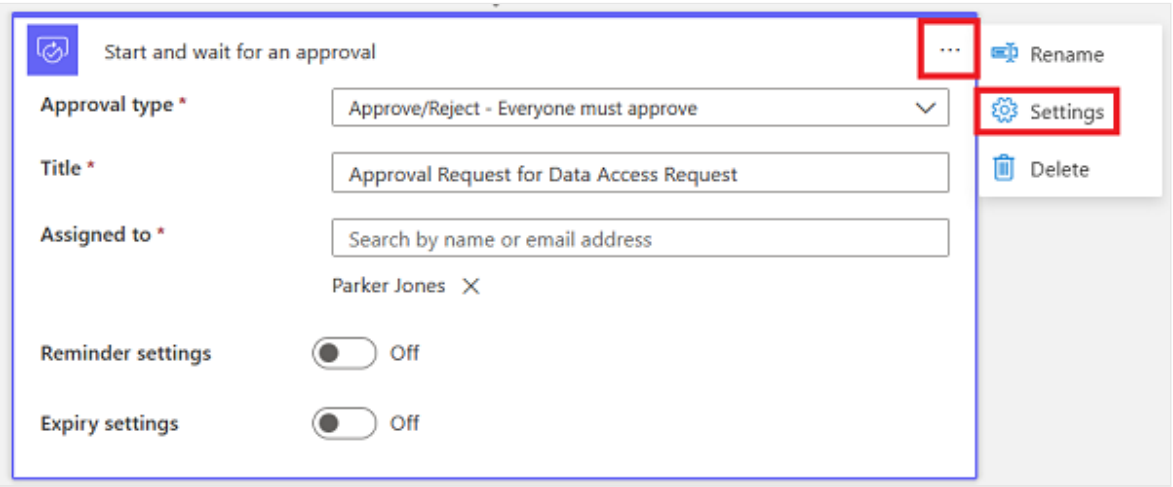
For your approvers to use actionable messages in Outlook, your Microsoft Purview, workflow, and email client must meet these requirements:

- Your Microsoft Purview account must have public network access enabled.
- When the user submits an approval from the actionable email, they need to be logged into the same tenant where the Microsoft Purview account resides.
- The **Assigned to** configured in the Start and Wait for approval Connector must be an individual not a group.
- The **Assigned to** configured in the Start and Wait for approval Connector must have a mailbox on Outlook.com or Exchange Online in Office 365.
- The email client used to open the approval request email must be Outlook with these versions: Outlook version requirements for actionable messages.
- The Microsoft Purview account isn't in an Azure Government and Azure China 21Vianet region.

> **Tip**
>
> If users receive a 403 message when attempting to approve an item from an actionable email, your Microsoft Purview account likely has network settings that are rejecting the request.

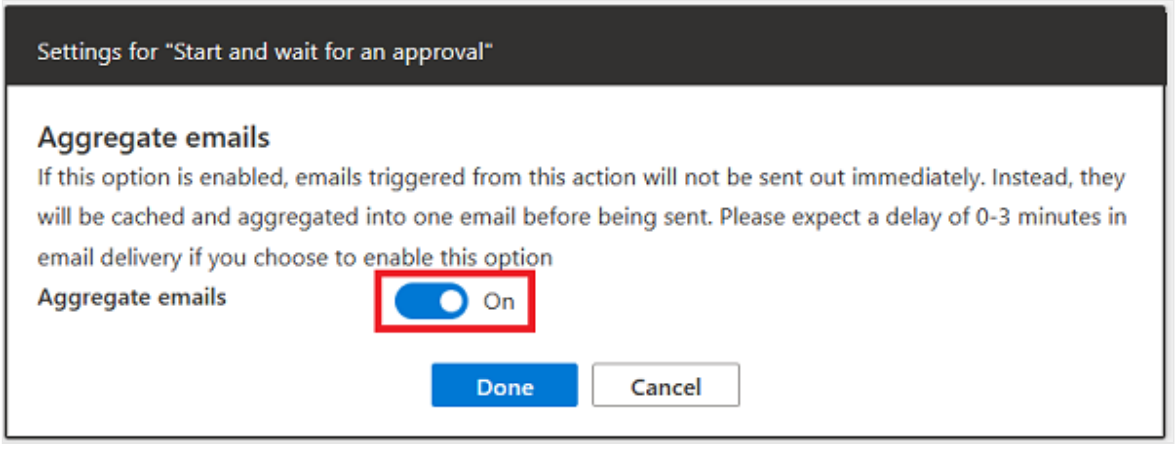
Send email notification

When you send an email notification in a workflow, either using the send email activity or another activity, by default individual emails are sent to each user specified. However, for some activities there's also an option to aggregate emails to be sent to batches of users. This can greatly reduce the number of emails sent from activities.



These activities are available to aggregate emails:

- Start and wait for an approval
- Send email notification
- Create task and wait for task completion



How to aggregate emails

When you're using one of the available activities and want to aggregate your emails, follow these steps.

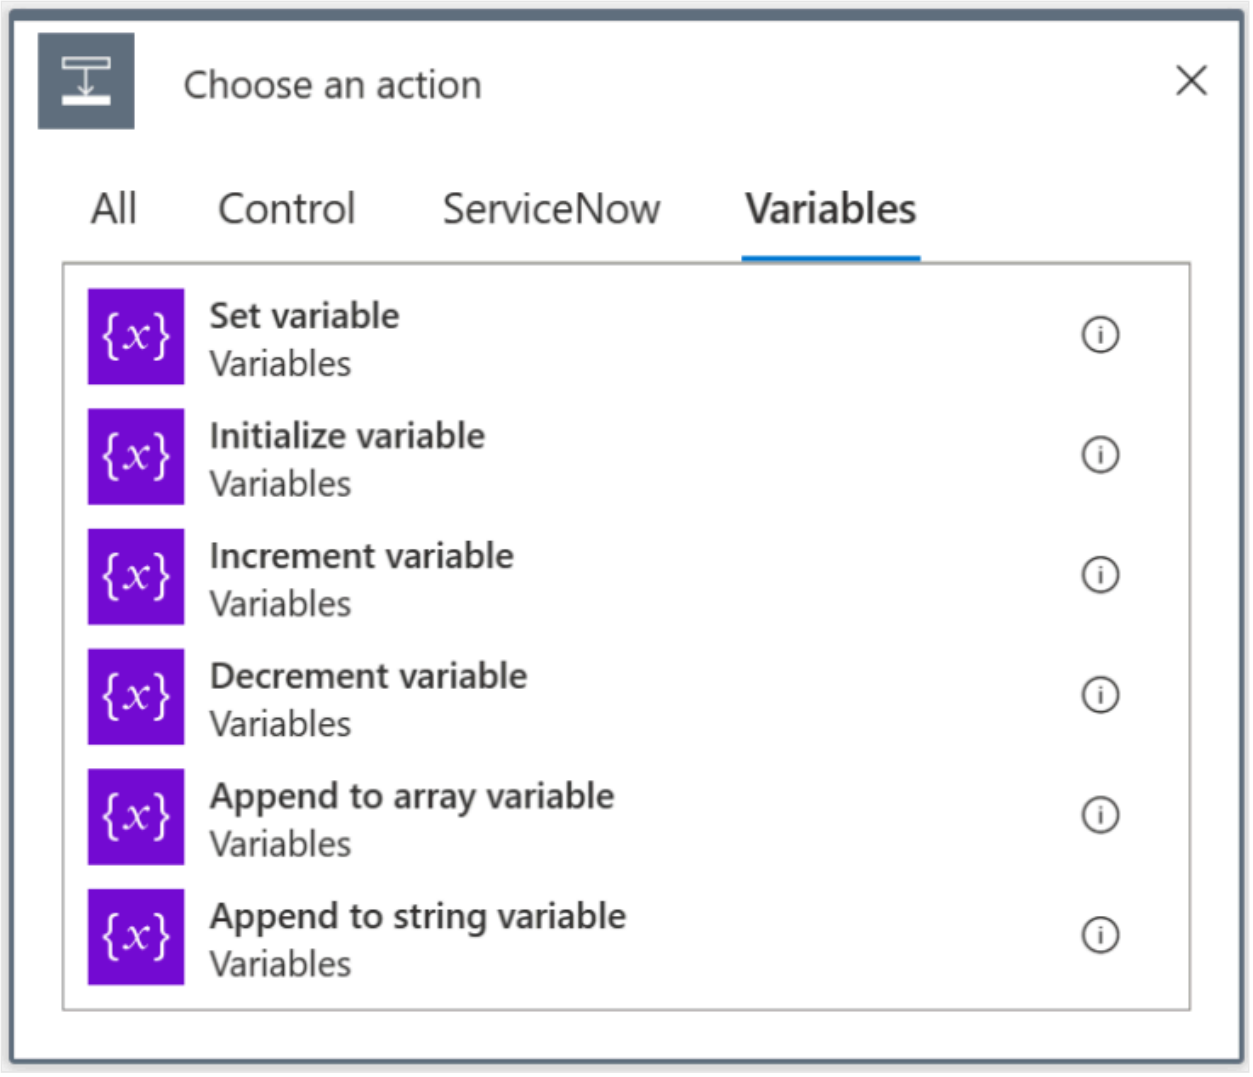
1. Open your activity settings by selecting the ellipsis button in the activity, and then the **Settings** option.

2. Select the **Aggregate emails** toggle to switch it to **On**.

3. Select **Done**

4. Finish making any other edits needed to your workflow, and then select **Save** to save the changes to your workflow.

Aggregation information



When you enable aggregation, the emails sent during this action are sent immediately. Instead the individual emails would be aggregated into one email and sent to receivers. The aggregation causes a slight delay in email delivery, between 0-3 minutes.

Aggregated emails are batched in groups of at most, 20. That is, if there are 110 emails that need to be aggregated, in the end 6 emails would be sent.

Variable actions

Create, update, and reference custom variables that you can reference in workflows in any places that support dynamic content. You can create variables of these data types:

- Integer
- Float
- Boolean
- Array
- String
- Object

Here are all the actions available and their parameters and descriptions:

Expand table

Action	Functionality	Parameters
Initialize variable	Create a new variable of one of the available types	-Name -Type -Value: Appropriate value based on variable type
Set variable	Update variable to specified value	-Name: Variable name selected from drop-down -Value: New value for variable
Increment variable	Increase integer and float variables by a specified value	-Name: Variable name selected from drop-down -Value: Amount to increment variable
Decrement variable	Reduce integer and float variables by a specified value	-Name: Variable name selected from drop-down

Action	Functionality	Parameters
		-Value: Amount to decrement variable
Append to array variable	Append specified value to array variable	-Name: Variable name selected from drop-down -Value: New value to append
Append to string variable	Append specified value to array variable	-Name: Variable name selected from drop-down -Value: New value to append

Variable limitations

- 50 variables per workflow
- Numeric variable range is $[-(2^{53}-1), 2^{53}-1]$
- names are limited to 46 characters
- Self-references aren't allowed in actions that update variable values: set, increment, decrement, append to array, append to string
- Initialize variable can't be used in local scope actions like "apply to each," "condition," or "until."
- Set variable can't be used in "apply to each" actions.

Workflow dynamic content

Article • 02/26/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

You can use dynamic content inside Microsoft Purview workflows to associate certain variables in the workflow or add other expressions to process these values.

When you add dynamic content to your workflows, you're building expressions from provided building blocks that reference and process information in your workflow so you can get the values you need in real-time.

In the dynamic content menu, the currently available options are:

- Built-in variables - variables that represent values coming to the workflow from the items that triggered it
- Expressions - formulas built from functions and variables that can process values in-workflow.

Built-in variables

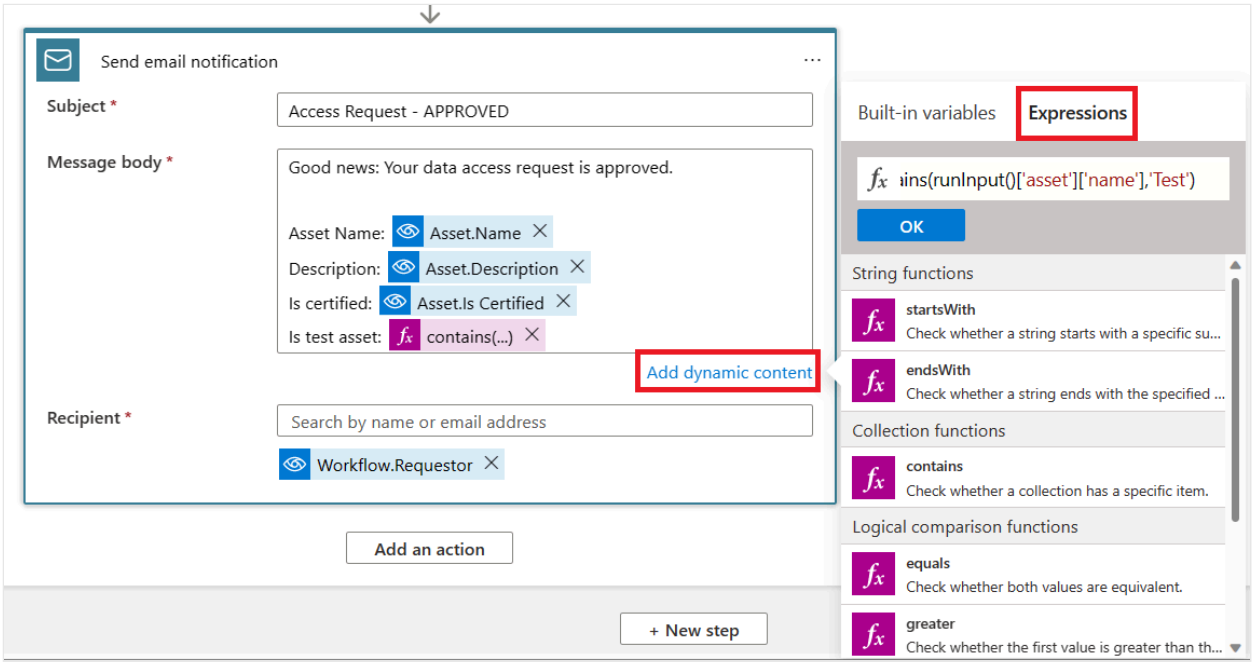
Currently, the following variables are available for a workflow connector in Microsoft Purview:

Expand table

Prerequisite connector	Built-in variable	Functionality	Type	Possible values
When data access request is submitted When asset update request is submitted	Workflow.Requestor	The ID of the requestor of the workflow	*string*	
	Asset.Name	The name of the asset	*string*	
	Asset.Description	The description of the asset	*string* or *null*	
	Asset.Type	The type of the asset	*string*	
	Asset.Fully Qualified Name	The fully qualified name of the asset	*string*	
	Asset.Owner	The IDs of the data owners of the asset	*array* of *string*s	
	Asset.Classification	The display names of classifications of the asset	*array* of *string*s	
	Asset.Schema.Classification	The display names of classifications applied to a column in the asset schema	*array* of *string*s	
	Asset.Is Certified	The indicator of whether the asset meets your organization's quality standards and can be regarded as reliable	*boolean*	`true` or `false`
When data access request is submitted	Workflow.Request Recipient	The ID of the request recipient of the workflow	*string*	
Start and wait for an approval	Approval.Outcome	The outcome of the approval	*string*	`'Approved'` or `'Rejected'`
	Approval.Assigned To	The IDs of the approvers	*array* of *string*s	

Prerequisite connector	Built-in variable	Functionality	Type	Possible values
	Approval.Comments	The names of the approvers and their comments	*string*	
Check data source registration for data use governance	Data Use Governance	The result of the data use governance check	*boolean*	`true` or `false`
When term creation request is submitted	Workflow.Requestor	The ID of the requestor of the workflow	*string*	
	Term.Name	The name of the term	*string*	
	Term.Formal Name	The formal name of the term	*string*	
	Term.Definition	The definition of the term	*string*	
	Term.Experts	The IDs of the experts of the term	*array* of *string*s	
	Term.Stewards	The IDs of the stewards of the term	*array* of *string*s	
	Term.Parent.Name	The name of parent term if exists	*string*	
	Term.Parent.Formal Name	The formal name of parent term if exists	*string*	
When term update request is submitted When term deletion request is submitted	Workflow.Requestor	The requestor of the workflow	*string*	
	Term.Name	The name of the term	*string*	
	Term.Formal Name	The formal name of the term	*string*	
	Term.Definition	The definition of the term	*string* or *null*	

Prerequisite connector	Built-in variable	Functionality	Type	Possible values
	Term.Experts	The IDs of the experts of the term	*array* of *string*s	
	Term.Stewards	The IDs of the stewards of the term	*array* of *string*s	
	Term.Parent.Name	The name of parent term if exists	*string*	
	Term.Parent.Formal Name	The formal name of parent term if exists	*string*	
	Term.Created By	The ID of the creator of the term	*string*	
	Term.Last Updated By	The ID of the last updater of the term	*string*	
When term import request is submitted	Workflow.Requestor	The ID of the requestor of the workflow	*string*	
	Import File.Name	The name of the file to import	*string*	
Http	Http.Body	HTTP response body	*object* or *string*	
	Http.Headers	HTTP response headers	*object*	
	Http.Status Code	HTTP status code	*string*	
Apply to each	Item	The current item of Apply to Each action	Any	
Until	Index	The current iteration index of Until action	*integer*	
Create record Delete record Get record Update record	Result	The result of ServiceNow action	*object*	
Get record types List records	Result	The result of ServiceNow action	*array* of *object*s	



Expressions

Workflow definitions in Microsoft Purview allow you to use functions in your expressions to process values in your workflows.

To find functions based on their general purpose, review the following tables. Or, for detailed information about each function, see the alphabetical list.

When you're building a workflow and want to add a function to your expressions, follow these steps:

1. Select the value you're going to edit.
2. Select the **Add dynamic content** button that appears underneath the textbox.
3. Select the **Expressions** tab in the dynamic content window and scroll to select your value.
4. Update your expression and select **OK** to add it.

Considerations

- Function parameters are evaluated from left to right.
- Functions that appear inline with plain text require enclosing curly braces ({}) to use the expression's interpolated format instead. This format helps avoid parsing problems. If your function expression doesn't appear inline with plain text, no curly braces are necessary.

  The following example shows the correct and incorrect syntax:

  Correct: `"<text>/@{<function-name>('<parameter-name>')}/<text>"`

Incorrect: `"<text>/@<function-name>('<parameter-name>')/<text>"`

- Functions may have overloads, which are multiple versions of a function with the same name but different ways of doing a task, depending on the input you give them.

The following sections organize functions based on their general purpose, or you can browse these functions in alphabetical order.

String functions

To work with strings, you can use these string functions and also some collection functions. String functions work only on strings.

Expand table

String function	Task
endsWith	Check whether a string ends with the specified substring.
startsWith	Check whether a string starts with a specific substring.

Collection functions

To work with collections, generally arrays, strings, and sometimes, dictionaries, you can use these collection functions.

Expand table

Collection function	Task
contains	Check whether a collection has a specific item.
length	Return the number of items in a collection, or the length of a string.

Logical comparison functions

To work with conditions, compare values and expression results, or evaluate various kinds of logic, you can use these logical comparison functions. For the full reference about each function, see the alphabetical list.

Expand table

Logical comparison function	Task
not	Check whether an expression is false. Return true when the expression is false, or return false when true.
and	Check whether all expressions are true. Return true when all expressions are true, or return false when at least one expression is false.
or	Check whether at least one expression is true. Return true when at least one expression is true, or return false when all are false.
equals	Check whether both values are equivalent.
greater	Check whether the first value is greater than the second value.
greaterOrEquals	Check whether the first value is greater than or equal to the second value.
less	Check whether the first value is less than the second value.
lessOrEquals	Check whether the first value is less than or equal to the second value.

User functions

To work with users, their relationships with other users and groups, and the resources they access for example their mails, calendars, files, administrative roles, group memberships. For the full reference about each function, see the alphabetical list.

Expand table

User function	Task
getUserName	Get the name of the user.
getManager	Get the ID of the user's manager.
memberOfGroup	Check whether the user is a member of the group.

Conversion functions

To change a value's type or format, you can use these conversion functions. For the full reference about each function, see the alphabetical list.

Expand table

Conversion function	Task
createArray	Return an array from any number of inputs.
createObject	Return an empty object.
string	Return the string version for a value.
int	Try to convert the input value into an integer number.
float	Try to convert the input value into a float number..
bool	Try to convert the input value into a boolean value.
object	Try to convert the input value into an object.
array	Try to convert the input value into an array.
nullOrElse	Give a default value to a nullable value.

All functions - alphabetical list

and

Check whether all expressions are true. Return true when all expressions are true, or return false when at least one expression is false.

Expand table

Parameter	Type	Description
value	*boolean*	The first expression to check
values...	*boolean*	The rest expressions to check

Expand table

Return value type	Description
boolean	Return true when all expressions are true. Return false when at least one expression is false.

Examples

These examples check whether the specified expressions are false:

```
and(equals(1, 1), equals(2, 2))
and(equals(1, 1), equals(1, 2))
and(equals(1, 2))
```

And returns these results:

- First example: Both expressions are true, so returns `true`.
- Second example: One expression is false, so returns `false`.
- Third example: The expression is false, so returns `false`.

array

This function tries to convert the input value into an array. It is used to cast the value from a broader type to *array*. To create an array from items, see createArray.

Expand table

Parameter	Type	Description
value	Any	The value to convert

Expand table

Return value type	Description
array	The converted array value

Example

This example asserts **Item** of an "Apply to each" action to be of *array* type:

```
array(items('Appy to each'))
```

bool

This function tries to convert the input value into a boolean value. It is used to cast the value from a broader type to *boolean*.

Expand table

Parameter	Type	Description
value	Any	The value to convert

Expand table

Return value type	Description
boolean	The converted boolean value

Example

This example asserts **Item** of an "Apply to each" action to be of *boolean* type:

```
bool(items('Appy to each'))
```

contains

Check whether a collection has a specific item. Return true when the item is found, or return false when not found.

Overload 1: A *string* to find a substring

This overload is case-sensitive.

Expand table

Parameter	Type	Description
collection	*string*	The string to check
value	*string*	The substring to find

Expand table

Return value type	Description
boolean	Return true when the substring is found. Return false when not found.

Overload 2: A *array* to find a value

Expand table

Parameter	Type	Description
collection	*array*	The collection to check
value	Any	The item to find

Expand table

Return value type	Description
boolean	Return true when the item is found. Return false when not found.

Example 1

This example checks the string "hello world" for the substring "world" and returns `true`:

```
contains('hello world', 'world')
```

Example 2

This example checks the variable **Asset.Owner** for the item equal to the variable **Workflow.Requestor**:

```
contains(runInput()['asset']['dataOwner'], runInput()['requestor'])
```

createArray

Return an array from any number of inputs. This function doesn't require the input values to be of a same type.

Expand table

Parameter	Type	Description
values...	Any	Values to create the array.

Expand table

Return value type	Description
array	The array created from all the input items

Examples

These examples create an array from inputs:

```
createArray('h', 'e', 'l', 'l', 'o')
createArray(true, null)
createArray()
```

createObject

Return an empty object.

Expand table

Return value type	Description
object	An empty object

Example

This example creates an array from inputs, and returns {}.

```
createObject()
```

endsWith

Check whether a string ends with a specific substring. Return true when the substring is found, or return false when not found. This function is case-sensitive.

Expand table

Parameter	Type	Description
text	*string*	The string to check
searchText	*string*	The ending substring to find

Expand table

Return value type	Description
boolean	Return true when the ending substring is found. Return false when not found.

Example 1

This example checks whether the "hello world" string ends with the "world" string:

```
endsWith('hello world', 'world')
```

And returns this result: `true`

Example 2

This example checks whether the "hello world" string ends with the "universe" string:

```
endsWith('hello world', 'universe')
```

And returns this result: `false`

equals

Check whether both values, expressions, or objects are equivalent. Return true when both are equivalent, or return false when they're not equivalent.

Expand table

Parameter	Type	Description
value	Any	The values, expressions, or objects to compare
compareTo	Any	The comparison values, expressions, or objects

Expand table

Return value type	Description
boolean	Return true when both are equivalent. Return false when not equivalent.

Examples

These examples check whether the specified inputs are equivalent.

```
equals(true, 1)
equals('abc', 'abcd')
```

And returns these results:

- First example: Both values are equivalent, so the function returns `true`.
- Second example: Both values aren't equivalent, so the function returns `false`.

float

This function tries to convert the input value into a float number. It is used to cast the value from a broader type to *float*.

Expand table

Parameter	Type	Description
value	Any	The value to convert

Expand table

Return value type	Description
float	The converted float value

Example

This example asserts **Item** of an "Apply to each" action to be of *float* type:

```
float(items('Appy to each'))
```

getManager

Get the ID of the user's manager in Microsoft Entra ID.

Overload 1: Get for a single user

Expand table

Parameter	Type	Description
userId	*string*	The ID of the input user

Expand table

Return value type	Description
string or *null*	The ID of the input user's manager or null if not exist

Overload 2: Get for multiple users

Expand table

Parameter	Type	Description
userId	*array*	The IDs of the input users

Expand table

Return value type	Description
array	The union of IDs of the input users' managers

Examples

These examples get the manager(s) of the input user(s):

```
getManager(runInput()['requestor'])
getManager(runInput()['term']['stewards'])
```

- First example: The input parameter is a string, so returns the ID of the manager of **Workflow.Requestor**

- Second example: the input parameter is an array, so returns the union set of IDs of managers of **Term.Stewards**.

getUserName

Get the name of the user in Microsoft Entra ID.

Overload 1: Get for a single user

Expand table

Parameter	Type	Description
userId	*string*	The ID of the input user

Expand table

Return value type	Description
string	The name of the input user

Overload 2: Get for multiple users

Expand table

Parameter	Type	Description
userId	*array*	The IDs of the input users

Expand table

Return value type	Description
array	The names of the input users

Examples

These examples get the name(s) of the input user(s):

```
getUserName(runInput()['requestor'])
getUserName(runInput()['term']['stewards'])
```

- First example: The input parameter is a string, so returns the name of **Workflow.Requestor**
- Second example: The input parameter is an array, so returns an array of names of **Term.Stewards**.

greater

Check whether the first value is greater than the second value. Return true when the first value is more, or return false when less.

Overload 1: Compare numbers

Expand table

Parameter	Type	Description
value	*integer* or *float*	The first value to check whether greater than the second value
compareTo	*integer* or *float*	The comparison value

Expand table

Return value type	Description
boolean	Return true when the first value is greater than the second value. Return false when the first value is equal to or less than the second value.

Overload 2: Compare strings

Expand table

Parameter	Type	Description
value	*string*	The first value to check whether greater than the second value
compareTo	*string*	The comparison value

Expand table

Return value type	Description
boolean	Return true when the first value is greater than the second value. Return false when the first value is equal to or less than the second value.

Examples

These examples check whether the first value is greater than the second value:

```
greater(10, 5)
greater('apple', 'banana')
```

And return these results:

- First example: `true`
- Second example: `false`

greaterOrEquals

Check whether the first value is greater than or equal to the second value. Return true when the first value is greater or equal, or return false when the first value is less.

Overload 1: Compare numbers

Expand table

Parameter	Type	Description
value	*integer* or *float*	The first value to check whether greater than or equal to the second value
compareTo	*integer* or *float*	The comparison value

Expand table

Return value type	Description
boolean	Return true when the first value is greater than or equal to the second value. Return false when the first value is less than the second value.

Overload 2: Compare strings

Expand table

Parameter	Type	Description
value	*string*	The first value to check whether greater than or equal to the second value
compareTo	*string*	The comparison value

Expand table

Return value type	Description
boolean	Return true when the first value is greater than or equal to the second value. Return false when the first value is less than the second value.

Examples

These examples check whether the first value is greater or equal than the second value:

```
greaterOrEquals(5, 5)
greaterOrEquals('apple', 'banana')
```

And return these results:

- First example: `true`
- Second example: `false`

int

This function tries to convert the input value into an integer number. It is used to cast the value from a broader type to *integer*.

Expand table

Parameter	Type	Description
value	Any	The value to convert

Expand table

Return value type	Description
integer	The converted integer value

Example

This example asserts **Item** of an "Apply to each" action to be of *integer* type:

```
int(items('Appy to each'))
```

length

Return the number of items in a collection, or the length of a string.

Expand table

Parameter	Type	Description
value	*string* or *array*	The string or the collection with the items to count

Expand table

Return value type	Description
boolean	The number of items in the collection or the length of the string

Examples

These examples count the number of items in these collections:

```
length('abcd')
length(createArray(0, 1, 2, 3))
```

And both return this result: `4`

less

Check whether the first value is less than the second value. Return true when the first value is less, or return false when the first value is more.

Overload 1: Compare numbers

Expand table

Parameter	Type	Description
value	*integer* or *float*	The first value to check whether less than the second value
compareTo	*integer* or *float*	The comparison value

Expand table

Return value type	Description
boolean	Return true when the first value is less than the second value. Return false when the first value is equal to or greater than the second value.

Overload 2: Compare strings

Expand table

Parameter	Type	Description
value	*string*	The first value to check whether greater than the second value
compareTo	*string*	The comparison value

Expand table

Return value type	Description
boolean	Return true when the first value is less than the second value. Return false when the first value is equal to or greater than the second value.

Examples

These examples check whether the first value is less than the second value.

```
less(5, 10)
less('banana', 'apple')
```

And return these results:

- First example: `true`
- Second example: `false`

lessOrEquals

Check whether the first value is less than or equal to the second value. Return true when the first value is less than or equal, or return false when the first value is more.

Overload 1: Compare numbers

Expand table

Parameter	Type	Description
value	*integer* or *float*	The first value to check whether less than or equal to the second value
compareTo	*integer* or *float*	The comparison value

Expand table

Return value type	Description
boolean	Return true when the first value is less than or equal to the second value. Return false when the first value is greater than the second value.

Overload 2: Compare strings

Expand table

Parameter	Type	Description
value	*string*	The first value to check whether less than or equal to the second value
compareTo	*string*	The comparison value

Expand table

Return value type	Description
boolean	Return true when the first value is less than or equal to the second value. Return false when the first value is greater than the second value.

Examples

These examples check whether the first value is less or equal than the second value.

```
lessOrEquals(10, 10)
lessOrEquals('apply', 'apple')
```

And return these results:

- First example: `true`
- Second example: `false`

memberOfGroup

Check whether the user is a member of the group in Microsoft Entra ID. Group ID can be found on Microsoft Entra group management page.

Expand table

Parameter	Type	Description
userId	*string*	The ID of the input user
groupId	*string*	The ID of the group to check

Expand table

Return value type	Description
boolean	Return true when the user is a member of the group. Return false when the user is not a member of the group or the group doesn't exist.

Example

This example check whether **Workflow.Requestor** is a member of the specified group:

```
memberOfGroup(runInput()['requestor'], '00000000-0000-0000-0000-
111111111111')
```

not

Check whether an expression is false. Return true when the expression is false, or return false when true.

Expand table

Parameter	Type	Description
value	*boolean*	The expression to check

Expand table

Return value type	Description
boolean	Return true when the expression is false. Return false when the expression is true.

Examples

These examples check whether the specified expressions are false:

```
not(equals(1, 2))
not(equals(1, 1))
```

And return these results:

- First example: The expression is false, so the function returns `true`.
- Second example: The expression is true, so the function returns `false`.

nullOrElse

Give a default value to a nullable value. Return a non-nullable value.

Overload 1: String version

Expand table

Parameter	Type	Description
value	*string* or *null*	The nullable value
defaultValue	*string*	The fallback value

Expand table

Return value type	Description
string	Return the input value if it is not null. Return the default value if the input value is null.

Overload 2: Integer version

Expand table

Parameter	Type	Description
value	*integer* or *null*	The nullable value
defaultValue	*integer*	The fallback value

Expand table

Return value type	Description
integer	Return the input value if it is not null. Return the default value if the input value is null.

Overload 3: Float version

Expand table

Parameter	Type	Description
value	*float* or *null*	The nullable value
defaultValue	*float*	The fallback value

Expand table

Return value type	Description
float	Return the input value if it is not null. Return the default value if the input value is null.

Overload 4: Boolean version

Expand table

Parameter	Type	Description
value	*boolean* or *null*	The nullable value
defaultValue	*boolean*	The fallback value

Expand table

Return value type	Description
boolean	Return the input value if it is not null. Return the default value if the input value is null.

Overload 5: Array version

Expand table

Parameter	Type	Description
value	*array* or *null*	The nullable value
defaultValue	*array*	The fallback value

Expand table

Return value type	Description
array	Return the input value if it is not null. Return the default value if the input value is null.

Overload 6: Object version

Expand table

Parameter	Type	Description
value	*object* or *null*	The nullable value
defaultValue	*object*	The fallback value

Expand table

Return value type	Description
object	Return the input value if it is not null. Return the default value if the input value is null.

Example

This example gives the nullable variable **Term.Definition** a default value `'Empty'`:

```
nullOrElse(runInput()['term']['definition'], 'Empty')
```

object

This function tries to convert the input value into an object value. It is used to cast the value from a broader type to *object*.

Expand table

Parameter	Type	Description
value	Any	The value to convert

Expand table

Return value type	Description
boolean	The converted object value

Example

This example asserts **Item** of an "Apply to each" action to be of *object* type:

```
object(items('Appy to each'))
```

or

Check whether at least one expression is true. Return true when at least one expression is true, or return false when all are false.

Expand table

Parameter	Type	Description
value	*boolean*	The first expression to check
values...	*boolean*	The rest expressions to check

Expand table

Return value type	Description
boolean	Return true when at least one expression is true. Return false when all expressions are false.

Examples

These examples check whether at least one expression is true:

```
or(equals(1, 1), equals(1, 2))
or(equals(1, 2), equals(1, 3))
or(equals(1, 2))
```

And return these results:

- First example: At least one expression is true, so the function returns `true`.
- Second example: Both expressions are false, so the function returns `false`.
- Third example: The expression is false, so the function returns `false`.

startsWith

Check whether a string starts with a specific substring. Return true when the substring is found, or return false when not found. This function is case-sensitive.

Expand table

Parameter	Type	Description
text	*string*	The string to check
searchText	*string*	The starting substring to find

Expand table

Return value type	Description
boolean	Return true when the starting substring is found. Return false when not found.

Example 1

This example checks whether the "hello world" string starts with the "hello" substring:

```
startsWith('hello world', 'hello')
```

And returns this result: `true`

Example 2

This example checks whether the "hello world" string starts with the "greetings" substring:

```
startsWith('hello world', 'greetings')
```

And returns this result: `false`

string

This function returns the string version of the value.

Expand table

Parameter	Type	Description
value	Any	The value to convert

Expand table

Return value type	Description
string	The string version for the specified value. If the value parameter is null, this value is returned as an empty string ("") value.

Examples

These examples convert the input value into a string:

```
string('abc')
string(true)
string(createArray())
```

And return these results:

- First example: The input value is a string, so returns an identity value `'abc'`.
- Second example: String version of boolean values are capitalized, so the function returns `'True'`.
- Third example: Arrays or objects are converted to JSON form, so the function returns `'[]'`.

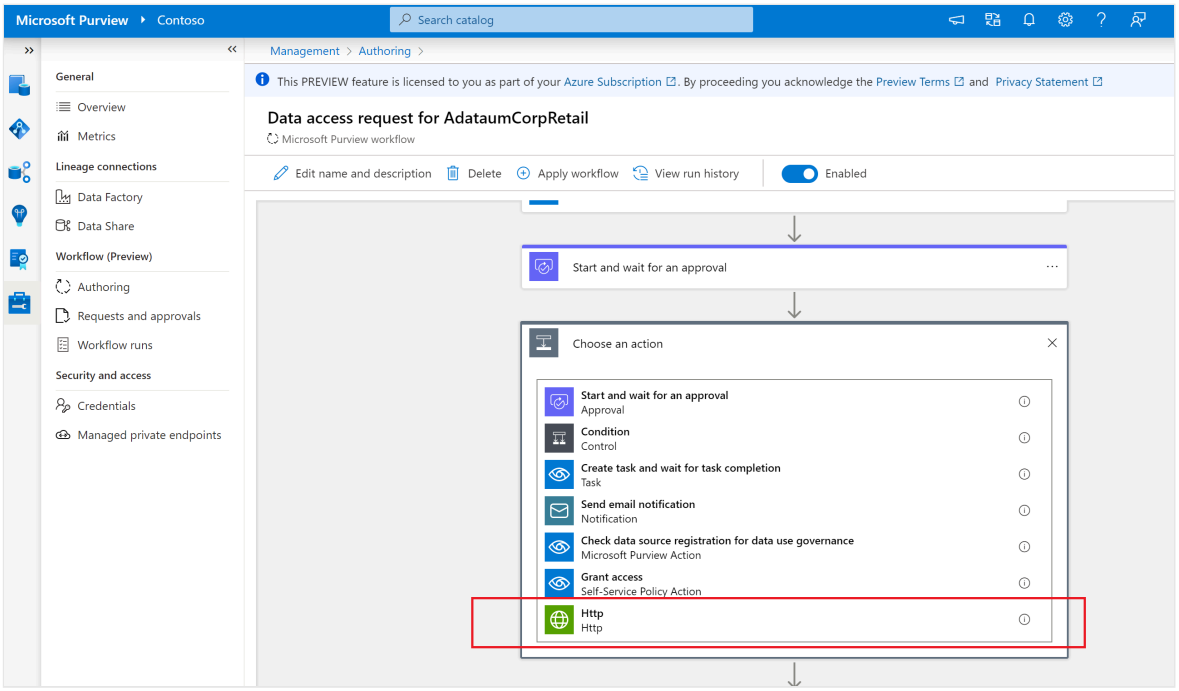
Use external APIs in Workflows

Article • 02/26/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

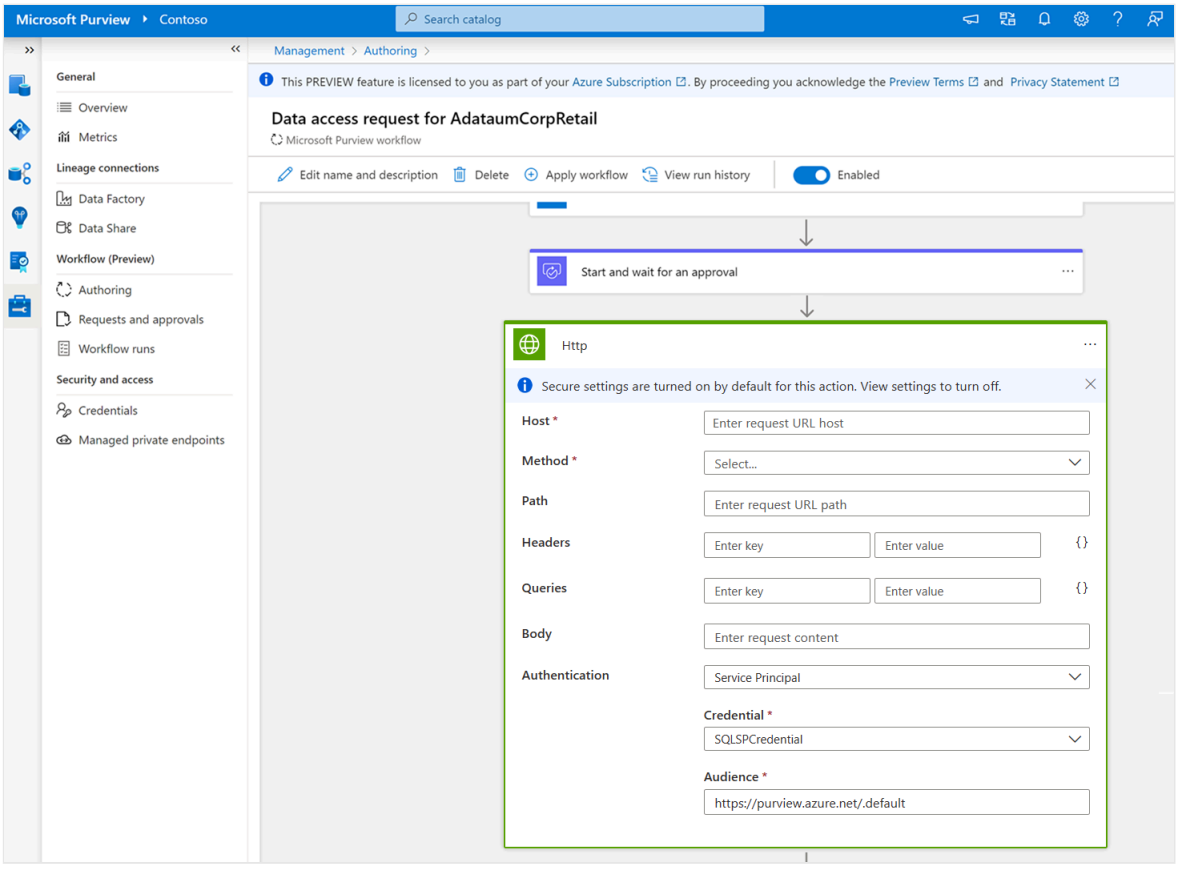
> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

You can use workflows to automate some business processes through Microsoft Purview, and the HTTP connector and parse JSON action allow you to integrate your workflows with external applications.



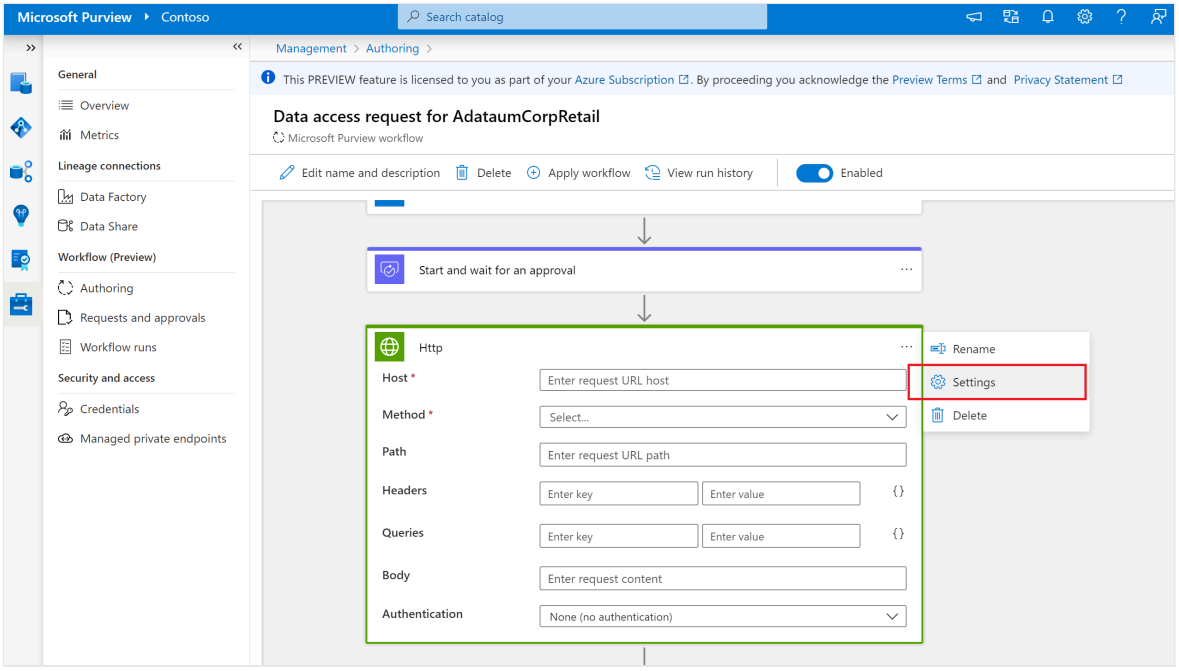
HTTP connector

HTTP connectors use Representational State Transfer (REST) architecture, which allows Microsoft Purview workflows to interact directly with non-Microsoft applications using web requests.

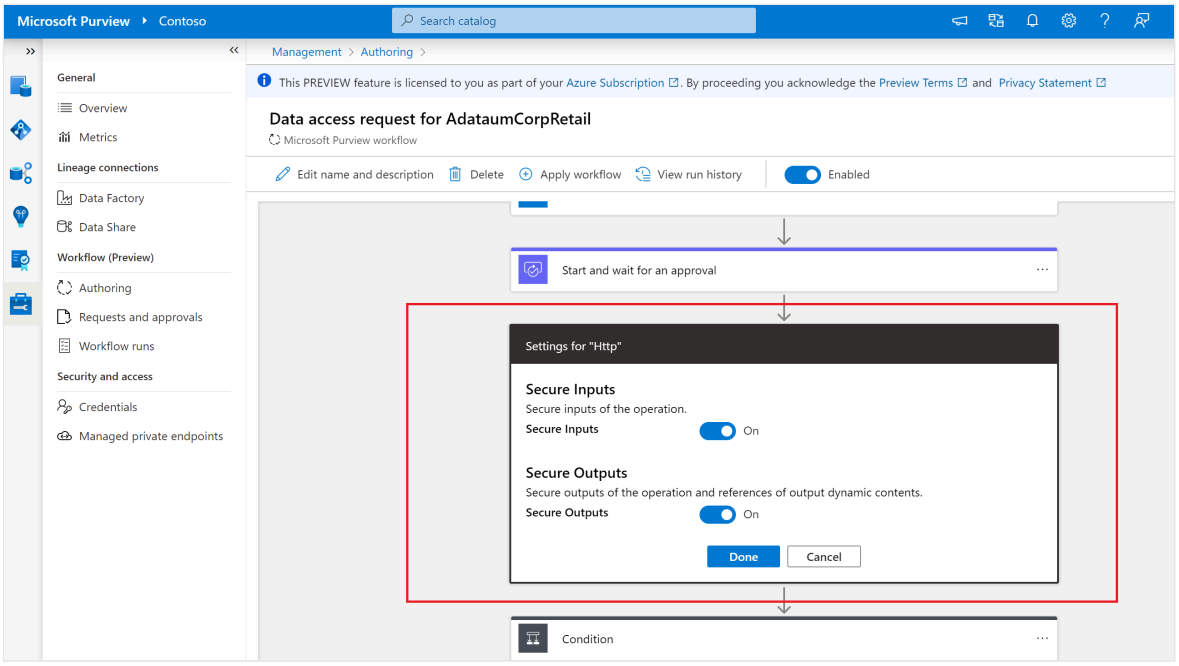


HTTP connector is available in all workflow templates.

> **Note**
>
> To create or edit a workflow, you need the workflow admin role in Microsoft Purview. You can also contact the workflow admin in your collection, or reach out to your collection administrator, for permissions.



1. To add an HTTP connector, select the + icon in the template where you want to add and select HTTP connector.



2. Once you select HTTP connector, fill the following parameters:
    a. **Host** - Request URL you want to call when this connector is executed.
    b. **Method** - Select one of the following methods. GET, PUT, PATCH, POST and DELETE. These methods correspond to create, read, update and delete operations.
    c. **Path** - Optionally you can enter request URL Path. You can use dynamic content for this parameter.
    d. **Headers** - Optionally, you can enter HTTP headers. HTTP headers let the client and the server pass additional information with an HTTP request or response
    e. **Queries** - Optionally, you can pass queries.
    f. **Body** - Optionally, you can pass HTTP body while invoking the URL
    g. **Authentication** - HTTP connector is integrated with your Microsoft Purview credentials. Depending on the URL, you can invoke one of these three types:
        i. **None** (no authentication)
        ii. **Basic authentication** - using a basic authentication credential you've already created.
        iii. **Service principal** - using a service principal credential you've already created, and an audience. The audience will be the intended consumer of the access token. The Microsoft Purview audience for example: `https://purview.azure.net/.default` Make sure your service principal is authorized to call corresponding services, like ARM.

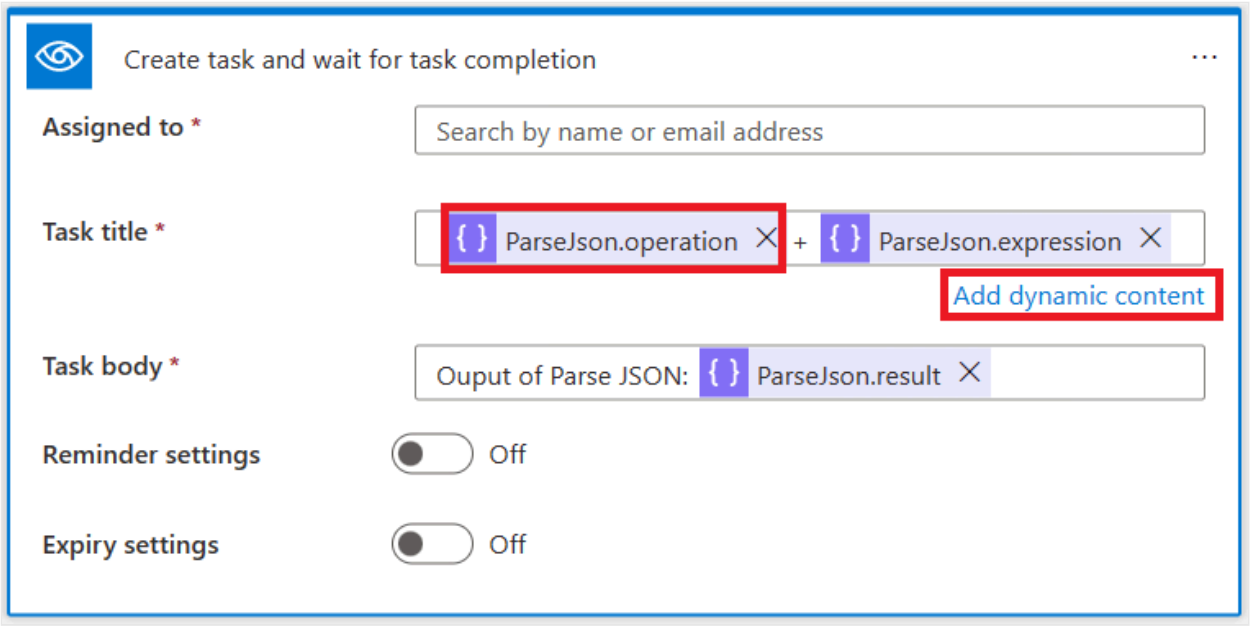
3. By default, secure settings are turned on for HTTP connectors. To turn OFF secure inputs and outputs select the ellipsis icon (...) to go to settings.

4. You're now presented with the settings for HTTP connector and you can turn secure inputs and outputs OFF.

Parse JSON action

The parse JSON action in workflows allows you to take an incoming JSON from HTTP (or any other action/connector), and parse the JSON to extract values for use in your workflow.

The parse JSON action is available in all workflows.



The parse JSON action has two parameters:

- Content - a variable that should contain the JSON you want to parse.
- Schema - the schema of the incoming JSON, which allows the workflow to parse the incoming information. You can supply your own, or use the **Generate from**

sample button. If you generate from a sample, you'll enter a sample JSON payload and a schema will be automatically generated for you.

Actions and connectors in the workflow after the parse JSON action will be able to use the values extracted from the JSON by selecting **Add dynamic content** for any parameters.

Concepts for Microsoft Purview Data owner policies (preview)

Article • 02/24/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

This article discusses concepts related to managing read or modify access to assets in your data estate from within the Microsoft Purview governance portal.

> **Note**
>
> This capability does not offer access control for Microsoft Purview itself. Granting access to Microsoft Purview internal roles is described in Access control in Microsoft Purview. This capability is used to grant data plane access, i.e., access to the data itself in data systems like Azure Storage. It does not allow you to grant control plane access. Control plane access provides visibility and ability manage resources in your subscription. You can manage control plane access via Identity and Access Management (IAM)

Overview

Access policies in Microsoft Purview enable you to manage access to different data systems across your entire data estate. For example:

A user needs read access to an Azure Storage account that has been registered in Microsoft Purview. You can grant this access directly in Microsoft Purview by creating a

data access policy through the **Data policy** app in the Microsoft Purview governance portal.

Data owner policies can be enforced only on data systems that have been enabled for policy enforcement in Microsoft Purview i.e., with the **Data policy enforcement** option turned on in data source registration.

Concepts

Data owner policy

A **Data owner policy** is a named set of policy statements. When a policy is published to one or more data systems under Microsoft Purview's governance, it's then enforced by them. A policy definition includes a policy name, description, and a list of one or more policy statements.

> ⓘ **Note**
>
> Currently only a single policy statement is supported per policy.

Policy statement

A **policy statement** is a human readable instruction that dictates how the data source should handle a specific data access operation. The policy statement comprises **Effect**, **Action, Data Resource** and **Subject**.

Action

An **action** is the operation being permitted or denied as part of this policy. For example: Read or Modify. These high-level logical actions map to one (or more) data actions in the data system where they are enforced.

Effect

The **effect** indicates what should be outcome if there is a match on the Data resource and Subject of the policy statement. Currently, the only supported value is **Allow**.

Data resource

The **data resource** is the fully qualified data asset path to the object the policy statement applies. It conforms to the following format:

/subscription/<subscription-id>/resourcegroups/<resource-group-name>/providers/<provider-name>/<data-asset-path>

Azure Storage data-asset-path format:

Microsoft.Storage/storageAccounts/<account-name>/blobservice/default/containers/<container-name>

Azure SQL DB data-asset-path format:

Microsoft.Sql/servers/<server-name>

Subject

It is a list of the end-user identities from Microsoft Entra ID for whom this policy statement is applicable. Each identity can be a service principal, an individual user, a group, or a managed service identity (MSI).

Example

Allow Read on Data Asset:
/subscription/finance/resourcegroups/prod/providers/Microsoft.Storage/storageAccounts/finDataLake/blobservice/default/containers/FinData to group Finance-analyst

In the above policy statement, the effect is *Allow*, the action is *Read*, the data resource is Azure Storage container *FinData*, and the subject is Microsoft Entra group *Finance-analyst*. If any user that belongs to this group attempts to read data from the storage container *FinData*, the request will be allowed.

Hierarchical enforcement of policies

The data resource specified in a policy statement is hierarchical by default. This means that the policy statement applies to the data object itself and to **all** the children objects contained by the data object. For example, a policy statement on Azure Storage container applies to all the blobs contained within it.

Policy combining algorithm

A data source combines all the applicable local policies with all policies from Microsoft Purview and provides a consolidated decision when a user tries to access an asset. The combining strategy picks the most restrictive policy.

For example, let's assume two different policies on an Azure Storage container *FinData* as follows,

Policy 1 - *Allow Read on Data Asset /subscription/..../containers/FinData to group Finance-analyst*

Policy 2 - *Deny Read on Data Asset /subscription/..../containers/FinData to group Finance-contractors*

Then let's assume that user 'user1', who is part of two groups: *Finance-analyst* and *Finance-contractors*, executes a call to the blob read API. Since both policies will be applicable, Azure Storage will choose the most restrictive one, which is *Deny* of *Read*. Thus, the access request will be denied.

Policy publishing

A newly created policy exists in the draft mode state, only visible in Microsoft Purview. The act of publishing initiates enforcement of a policy in the specified data systems. It's an asynchronous action that can take between 5 minutes and 2 hours to be effective, depending on the data source type. For more information, consult the Data owner policies how-to guides related to each data source type.

A policy published to a data source could contain policy statements that refer to a different data source. Such references will be ignored since the asset in question does not exist in the data source where the policy is applied.

Next steps

Check the guides on how to create policies in Microsoft Purview that get enforced in specific data systems. Beyond the UI, you can now try the Data owner policies API.

Provision access to system metadata in Azure SQL Database using Microsoft Purview DevOps policies

Article • 10/28/2024

> **Note**
>
> Microsoft Purview Data Map (classic), Data Catalog (classic), Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

DevOps policies are a type of Microsoft Purview access policies. They allow you to manage access to system metadata on data sources that have been registered for *Data policy enforcement* in Microsoft Purview. These policies are configured directly from the Microsoft Purview governance portal, and after they're saved, they get automatically published and then enforced by the data source. Microsoft Purview policies only manage access for Microsoft Entra principals.

This how-to guide covers how to configure Azure SQL Database to enforce policies created in Microsoft Purview. It covers the configuration steps for Azure SQL Database and the ones in Microsoft Purview to provision access to Azure SQL Database system metadata (DMVs and DMFs) using the DevOps policies actions *SQL Performance Monitoring* or *SQL Security Auditing*.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- A new or existing Microsoft Purview account. Follow this quickstart guide to create one.
- Create a new Azure SQL Database instance, or use an existing one, in one of the currently available regions for this feature. You can follow this guide to create an Azure SQL Database instance.

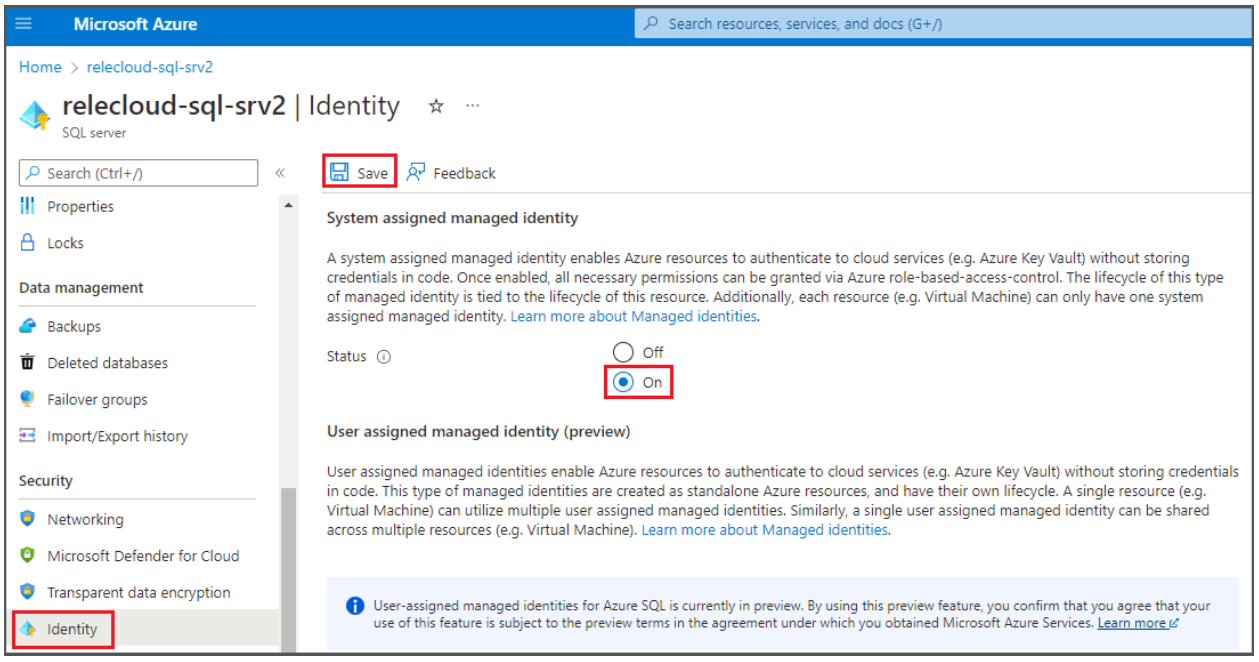
Region support

All Microsoft Purview regions are supported.

Enforcement of Microsoft Purview policies is available only in the following regions for Azure SQL Database:

Public cloud:

- East US
- East US2
- South Central US
- West Central US
- West US3
- Canada Central
- Brazil South
- West Europe
- North Europe
- France Central
- UK South
- South Africa North
- Central India
- South East Asia
- East Asia
- Australia East



Sovereign clouds:

- USGov Virginia
- China North 3

Configure the Azure SQL Database instance for policies from Microsoft Purview

For the logical server associated with Azure SQL Database to honor policies from Microsoft Purview, you need to configure a Microsoft Entra admin. In the Azure portal, go to the logical server that hosts the Azure SQL Database instance. On the side menu, select **Microsoft Entra ID**. Set an admin name to any Microsoft Entra user or group that you prefer, and then select **Save**.

Then, on the side menu, select **Identity**. Under **System assigned managed identity**, turn the status to **On**, and then select **Save**.

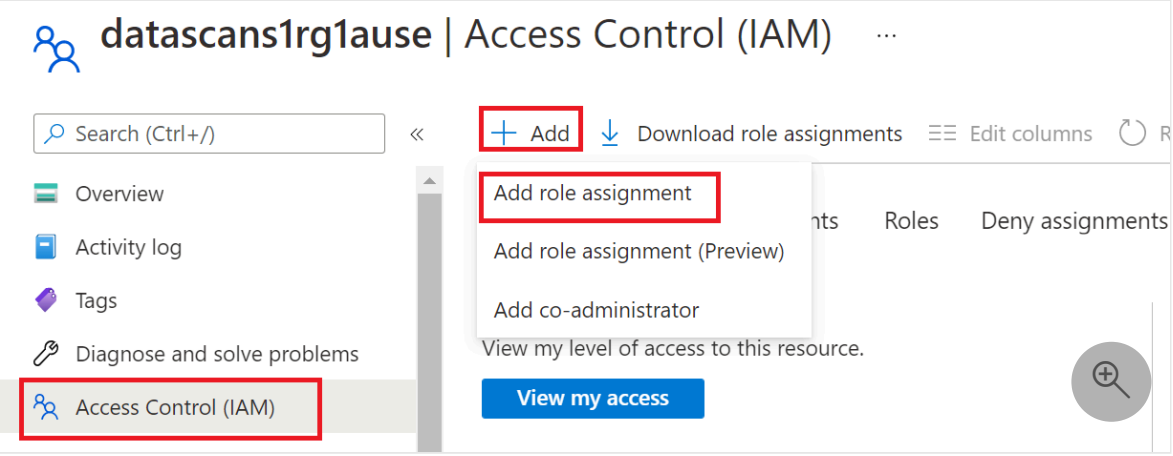
Microsoft Purview Configuration

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.

> **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

Configure permissions to enable Data policy enforcement on the data source

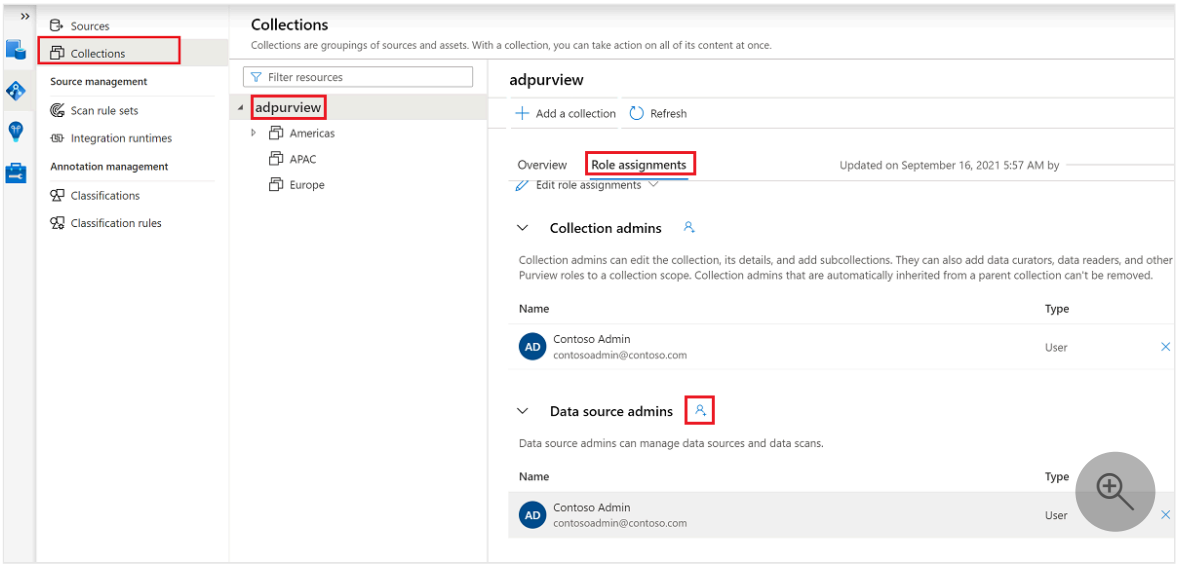


Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission

inheritance):

- IAM Owner
- Both IAM Contributor and IAM User Access Administrator



To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.

> **Note**
>
> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before

a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

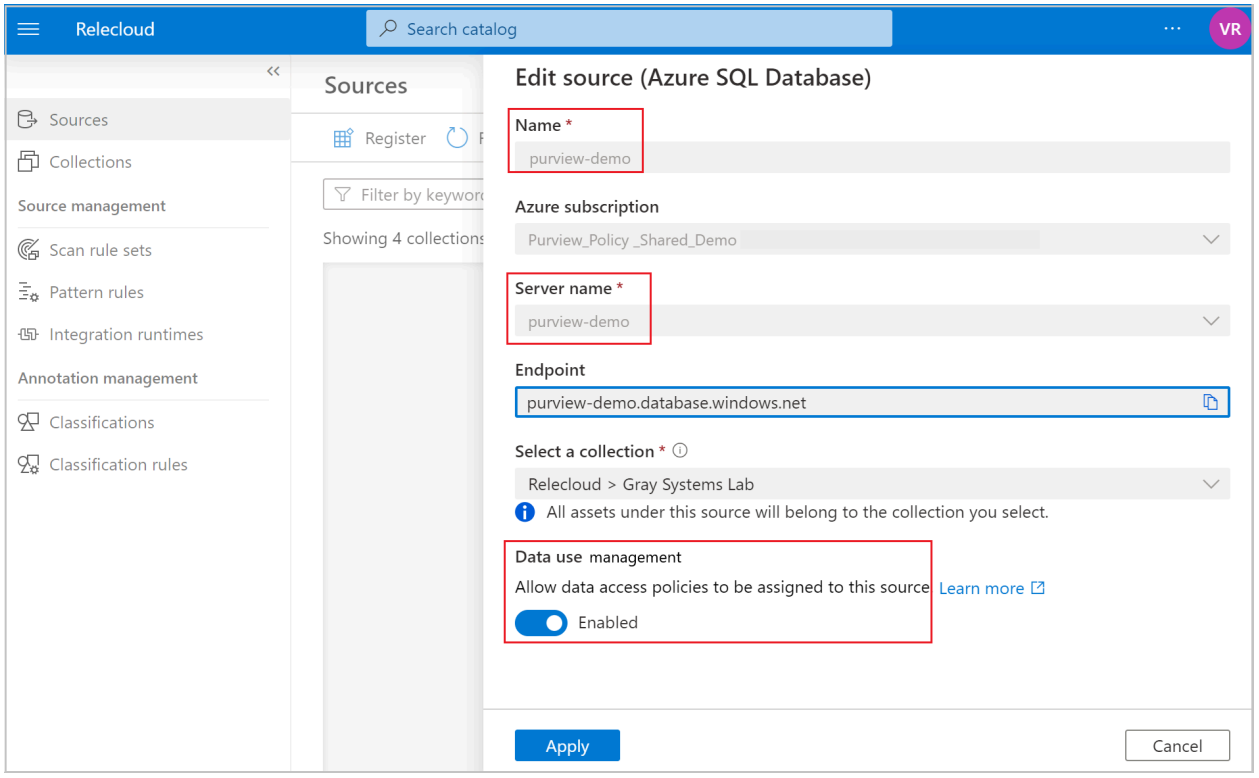
> ⓘ **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

Delegate access provisioning responsibility to roles in Microsoft Purview

After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> ⓘ **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin* role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.

If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.



Register the data sources in Microsoft Purview

The Azure SQL Database data source needs to be registered first with Microsoft Purview, before access policies can be created. You can follow these guides:

Register and scan Azure SQL Database.

After you've registered your resources, you'll need to enable Data policy enforcement. Data policy enforcement needs certain permissions and can affect the security of your data, as it delegates to certain Microsoft Purview roles the ability to manage access to data sources. **Go through the secure practices related to Data policy enforcement in this guide**: How to enable Data policy enforcement

Once your data source has the **Data policy enforcement** toggle *Enabled*, it looks like this screenshot. This enables the access policies to be used with the given data source.

Return to the Azure portal for Azure SQL Database to verify it's now governed by Microsoft Purview:

1. Sign in to the Azure portal through this link
2. Select the Azure SQL Server that you want to configure.
3. Go to **Microsoft Entra ID** on the left pane.
4. Scroll down to **Microsoft Purview access policies**.
5. Select the button to **Check for Microsoft Purview Governance**. Wait while the request is processed. It could take a few minutes.

6. Confirm that the Microsoft Purview Governance Status shows `Governed`. Note that **it could take a few minutes** after you enable *Data policy enforcement* in Microsoft Purview for the correct status to be reflected.

> **Note**
>
> If you disable Data policy enforcement for this Azure SQL Database data source, it might take up to 24 hours for the Microsoft Purview Governance Status to be updated automatically to `Not Governed`. This can be accelerated by selecting **Check for Microsoft Purview Governance**. Before you enable *Data policy enforcement* for the data source in another Microsoft Purview account, ensure that the Purview Governance Status shows as `Not Governed`. Then repeat the steps above with the new Microsoft Purview account.

Create a new DevOps policy

Follow this link for the steps to create a new DevOps policy in Microsoft Purview.

List DevOps policies

Follow this link for the steps to list DevOps policies in Microsoft Purview.

Update a DevOps policy

Follow this link for the steps to update a DevOps policies in Microsoft Purview.

Delete a DevOps policy

Follow this link for the steps to delete a DevOps policies in Microsoft Purview.

> **Important**

DevOps policies are auto-published and changes can take up to **5 minutes** to be enforced by the data source.

Test the DevOps policy

See how to test the policy you created.

Role definition detail

See the mapping of DevOps role to data source actions.

Next steps

What can I accomplish with Microsoft Purview DevOps policies?

Article • 02/24/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

This article describes how to manage access to data sources in your data estate by using the Microsoft Purview governance portal. It focuses on basic concepts of DevOps policies. That is, it provides background information about DevOps policies that you should know before you follow other articles to get configuration steps.

> **Note**
>
> This capability is different from the internal access control in the Microsoft Purview governance portal.

Access to system metadata is crucial for IT and DevOps personnel to ensure that critical database systems are healthy, are performing to expectations, and are secure. You can grant and revoke that access efficiently and at scale through Microsoft Purview DevOps policies.

Any user who holds the Policy Author role at the root collection level in Microsoft Purview can create, update, and delete DevOps policies. After DevOps policies are saved, they're published automatically.

Access policies vs. DevOps policies

Microsoft Purview access policies enable customers to manage access to data systems across their entire data estate, all from a central location in the cloud. You can think of these policies as access grants that can be created through Microsoft Purview Studio, avoiding the need for code. They dictate whether a list of Microsoft Entra principals, such as users and groups, should be allowed or denied a specific type of access to a data source or an asset within it. Microsoft Purview communicates these policies to the data sources, where they're natively enforced.

DevOps policies are a special type of Microsoft Purview access policies. They grant access to database system metadata instead of user data. They simplify access provisioning for IT operations and security auditing personnel. DevOps policies only grant access. They don't deny access.

Elements of a DevOps policy

Three elements define a DevOps policy:

- **Subject**

  This is a list of Microsoft Entra users, groups, or service principals that are granted access.

- **Data resource**

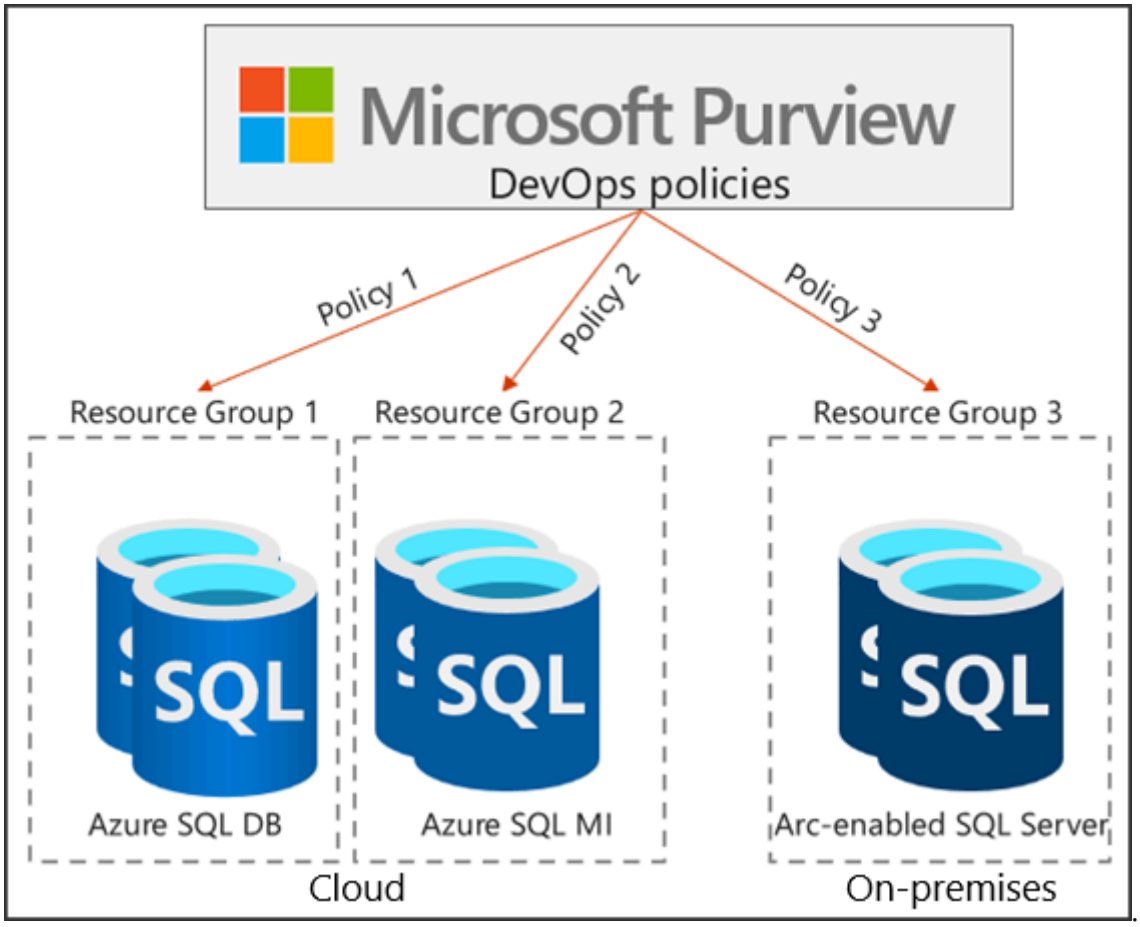
  This is the scope where the policy is enforced. The data resource path is the composition of subscription > resource group > data source.

  Microsoft Purview DevOps policies currently support SQL-type data sources. You can configure them on individual data sources and on entire resource groups and subscriptions. You can create DevOps policies only after you register the data resource in Microsoft Purview with the **Data policy enforcement** option turned on.

- **Role**

  A role maps to a set of actions that the policy permits on the data resource. DevOps policies support the SQL Performance Monitor and SQL Security Auditor roles. Both of these roles provide access to SQL system metadata, and more specifically to dynamic management views (DMVs) and dynamic management functions (DMFs). But the set of DMVs and DMFs that these roles grant is different. We provide some popular examples later in this article.

  The Create, list, update, and delete Microsoft Purview DevOps policies article details the role definition for each data source type. That is, it provides a mapping of roles in Microsoft Purview to the actions that are permitted in that type of data source. For example, the role definition for SQL Performance Monitor and SQL Security Auditor includes *Connect* actions at the server and database level on the data source side.



In essence, the DevOps policy assigns the role's related permissions to the subject and is enforced in the scope of the data resource's path.

Hierarchical enforcement of policies

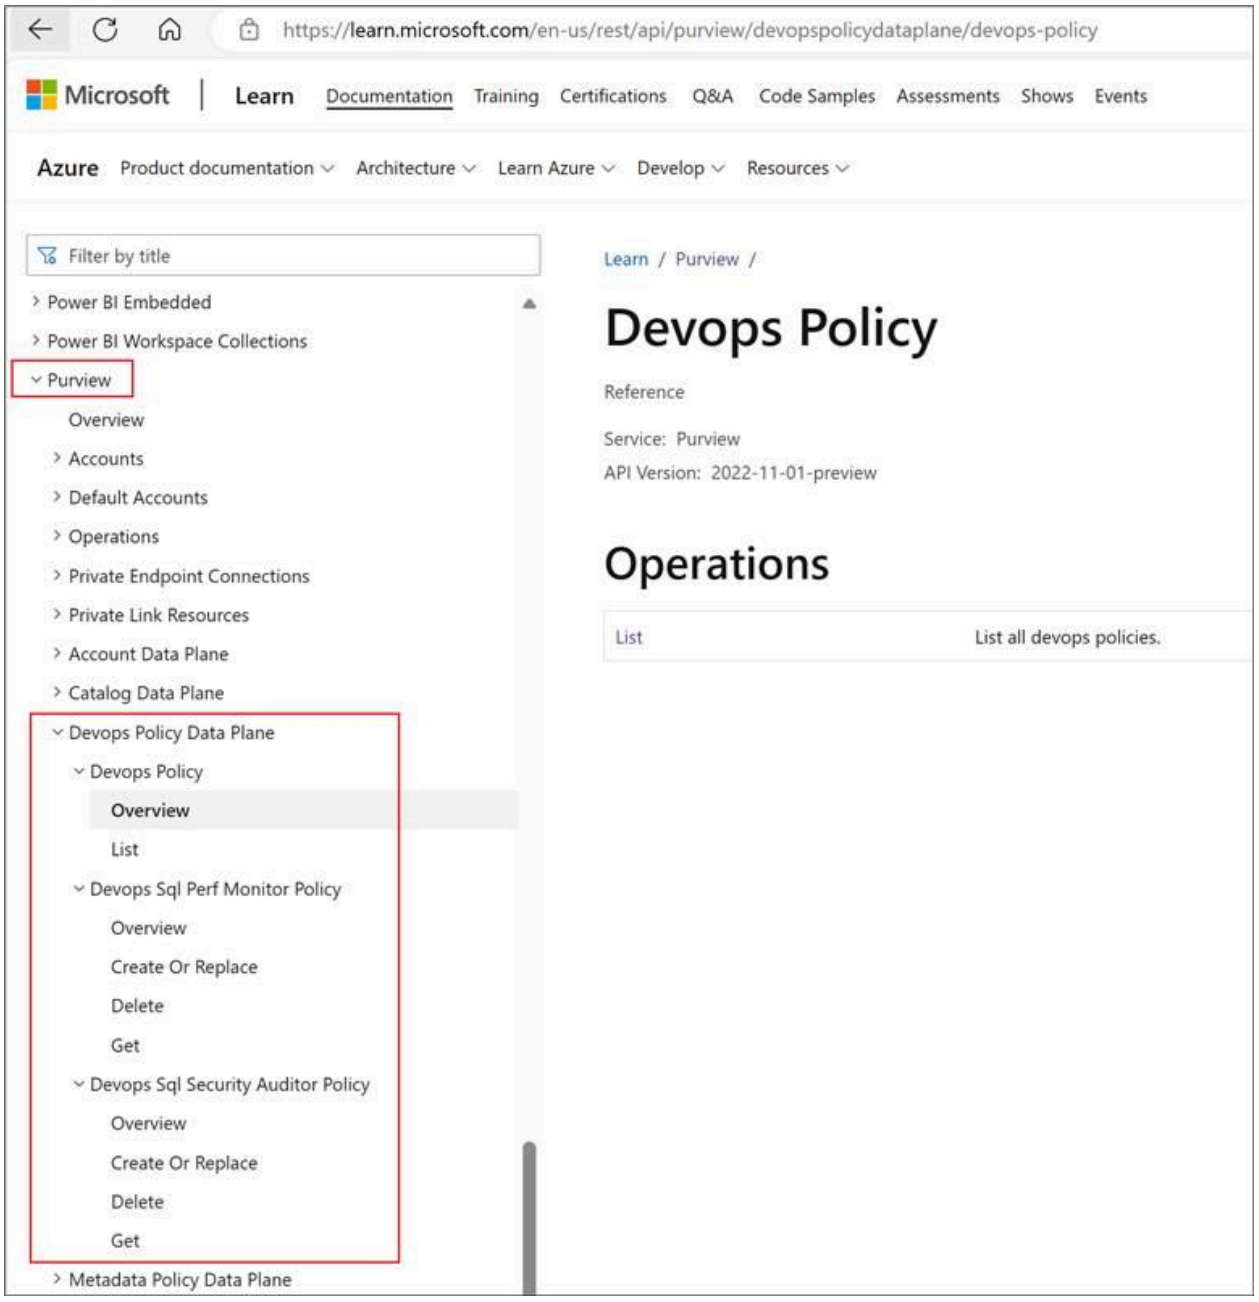
A DevOps policy on a data resource is enforced on the data resource itself and all child resources that it contains. For example, a DevOps policy on an Azure subscription applies to all resource groups, to all policy-enabled data sources within each resource group, and to all databases within each data source.

Example scenario to demonstrate the concept and the benefits

Bob and Alice are involved with the DevOps process at their company. They need to log in to dozens of SQL Server instances on-premises and Azure SQL logical servers to monitor their performance so that critical DevOps processes don't break. Their manager, Mateo, puts all these SQL data sources into Resource Group 1. He then creates a Microsoft Entra group and includes Alice and Bob. Next, he uses Microsoft Purview DevOps policies (Policy 1 in the following diagram) to grant this Microsoft Entra group access to Resource Group 1, which hosts the logical servers.

These are the benefits:

- Mateo doesn't have to create local logins in each server.



- The policies from Microsoft Purview improve security by limiting local privileged access. They support the principle of least privilege. In the scenario, Mateo grants only the minimum access that Bob and Alice need to perform the task of monitoring system health and performance.
- When new servers are added to the resource group, Mateo doesn't need to update the policy in Microsoft Purview for it to be enforced on the new servers.
- If Alice or Bob leaves the organization and the job is backfilled, Mateo just updates the Microsoft Entra group. He doesn't have to make any changes to the servers or to the policies that he created in Microsoft Purview.
- At any point in time, Mateo or the company's auditor can see all the permissions that were granted directly in Microsoft Purview Studio.

Expand table

Principle	Benefit
Simplify	The role definitions SQL Performance Monitor and SQL Security Auditor capture the permissions that typical IT and DevOps personas need to execute their job.
	There's less need for permission expertise on each data source type.
Reduce effort	A graphical interface lets you move through the data object hierarchy quickly.
	Microsoft Purview supports policies on entire Azure resource groups and subscriptions.
Enhance security	Access is granted centrally and can be easily reviewed and revoked.
	There's less need for privileged accounts to configure access directly at the data source.
	DevOps policies support the principle of least privilege via data resource scopes and role definitions.

DevOps policies API

Many sophisticated customers prefer to interact with Microsoft Purview via scripts rather than via the UI. Microsoft Purview DevOps policies now support a REST API that offers full create, read, update, and delete (CRUD) capability. This capability includes listing, policies for SQL Performance Monitor, and policies for SQL Security Auditor. For more information, see the API specification.

.

Mapping of popular DMVs and DMFs

SQL dynamic metadata includes a list of more than 700 DMVs and DMFs. The following table illustrates some of the most popular ones. The table maps the DMVs and DMFs to their role definitions in Microsoft Purview DevOps policies. It also provides links to reference content.

Expand table

DevOps role	Category	Example DMV or DMF
SQL Performance Monitor	Query system parameters to understand your system	sys.configurations

DevOps role	Category	Example DMV or DMF
		sys.dm_os_sys_info
	Identify performance bottlenecks	sys.dm_os_wait_stats
	Analyze currently running queries	sys.dm_exec_query_stats
	Analyze blocking issues	sys.dm_tran_locks
		sys.dm_exec_requests
		sys.dm_os_waiting_tasks
	Analyze memory usage	sys.dm_os_memory_clerks
	Analyze file usage and performance	sys.master_files
		sys.dm_io_virtual_file_stats
	Analyze index usage and fragmentation	sys.indexes
		sys.dm_db_index_usage_stats
		sys.dm_db_index_physical_stats
	Manage active user connections and internal tasks	sys.dm_exec_sessions
	Get procedure execution statistics	sys.dm_exec_procedure_stats
	Use the Query Store	sys.query_store_plan
		sys.query_store_query
		sys.query_store_query_text
	Get Error Log (not yet supported)	sys.sp_readerrorlog
SQL Security Auditor	Get audit details	sys.dm_server_audit_status
Both SQL Performance Monitor and SQL Security Auditor		sys.dm_audit_actions
		sys.dm_audit_class_type_map

DevOps role	Category	Example DMV or DMF

For more information on what IT support personnel can do when you grant them access via the Microsoft Purview roles, see the following resources:

- SQL Performance Monitor: Use Microsoft Purview to provide at-scale access to performance data in Azure SQL and SQL Server
- SQL Security Auditor: Security-related dynamic management views and functions

Microsoft Purview Self-service data discovery and access (Preview)

Article • 02/26/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

This article helps you understand Microsoft Purview Self-service data access policy.

> **Important**
>
> Microsoft Purview Self-service data access policy is currently in PREVIEW. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

Important limitations

The self-service data access policy is only supported when the prerequisites mentioned in Data Policy Enforcement are satisfied.

Overview

Microsoft Purview Self-service data access workflow allows data consumer to request access to data when browsing or searching for data. Once the data access request is approved, a policy gets auto-generated to grant access to the requestor provided the data source is enabled for Data Policy Enforcement. Currently, self-service data access policy is supported for storage accounts, containers, folders, and files.

A **workflow admin** needs to map a self-service data access workflow to a collection. Collection is logical grouping of data sources that are registered within Microsoft Purview. **Only data source(s) that are registered** for Data Policy Enforcement has self-service policies auto-generated.

Terminology

- **Data consumer** is anyone who uses the data. Example, a data analyst accessing marketing data for customer segmentation. Data consumer and data requestor will be used interchangeably within this document.
- **Collection** is logical grouping of data sources that are registered within Microsoft Purview.
- **Self-service data access workflow** is the workflow that is initiated when a data consumer requests access to data.
- **Approver** is either a security group, a Microsoft Entra user, or a Microsoft Entra group that can approve self-service access requests.

How to use Microsoft Purview self-service data access policy

Microsoft Purview allows organizations to catalog metadata about all registered data assets. It allows data consumers to search for or browse to the required data asset.

With self-service data access workflow, data consumers can not only find data assets but also request access to the data assets. When the data consumer requests access to a data asset, the associated self-service data access workflow is triggered.

A default self-service data access workflow template is provided with every Microsoft Purview account. The default template can be amended to add more approvers and/or set the approver's email address. For more details, refer Create and enable self-service data access workflow.

Whenever a data consumer requests access to a dataset, the notification is sent to the workflow approver(s). The approver(s) can view the request and approve it either from Microsoft Purview governance portal or from within the email notification. When the request is approved, a policy is auto-generated and applied against the respective data source. Self-service data access policy gets auto-generated only if the data source is registered for **Data Policy Enforcement**. The prerequisites mentioned within the Data Policy Enforcement have to be satisfied.

Data consumer can access the requested dataset using tools such as Power BI or Azure Synapse Analytics workspace.

> ⓘ **Note**

Users won't be able to browse to the asset using the Azure portal or Storage explorer if the only permission granted is read/modify access at the file or folder level of the storage account.

⊗ Caution

Folder level permission is required to access data in ADLS Gen 2 using Power BI. Additionally, resource sets aren't supported by self-service policies. Hence, folder level permission needs to be granted to access resource set files such as CSV or parquet.

Next steps

If you would like to preview these features in your environment, follow the link below.

- Enable Data Policy Enforcement
- create self-service data access workflow
- working with policies at file level
- working with policies at folder level
- self-service policies for Azure SQL Database tables and views

Impact of deleting Microsoft Purview account on access policies

> **Note**
>
> Microsoft Purview Data Catalog (classic), Data Health Insights (classic), and Purview Workflow (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

Important considerations

Deleting a Microsoft Purview account that has active (that is, published) policies removes those policies. Any access to a data source or a dataset that was previously provisioned from Microsoft Purview gets revoked. This can lead to outages, that is, users or groups in your organization not able to access critical data. Review the decision to delete the Microsoft Purview account with the people in Policy Author role at root collection level before proceeding. To find out who holds that role in the Microsoft Purview account, review the section on managing role assignments in this guide.

Before deleting the Microsoft Purview account, it's advisable that you provision access to the users in your organization that need access to datasets using an alternate mechanism or a different Purview account. Then orderly delete or unpublish any active policies

- Deleting DevOps policies - You need to delete DevOps policies for them to be unpublished.
- Unpublishing Data Owner policies.
- Deleting Self-service access policies - You need to delete Self-service access policies for them to be unpublished.

Role definitions SQL Performance Monitor and SQL Security Auditor supported only from DevOps policies experience

> **Note**
>
> Microsoft Purview Data Catalog (classic), Data Health Insights (classic), and Purview Workflow (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

This guide discusses actions that have been retired from Data owner policies experience and are now supported only from the DevOps policies experience.

Important considerations

The following two actions that were previously available in the Microsoft Purview Data owner policies experience are now supported only from the Microsoft Purview DevOps policies, which is a more focused experience.

- SQL Performance Monitor
- SQL Security Auditor

If you currently have Data owner policies with these actions we encourage you to give the DevOps policies experience a try. Creating new policies or editing existing policies that involve these two actions is now unsupported from the Data owner experience.

Enable data policy enforcement on your Microsoft Purview sources

Article • 02/24/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

Data policy enforcement is an option within the data source registration in Microsoft Purview. This option lets Microsoft Purview manage data access for your resources. The high level concept is that the data owner allows its data resource to be available for access policies by enabling *data policy enforcement*.

Currently, a data owner can enable data policy enforcement on a data resource, which enables it for these types of access policies:

- DevOps policies
- Data owner access policies
- Self-service access policies - access policies automatically generated by Microsoft Purview after a self-service access request is approved.
- Protection-policies

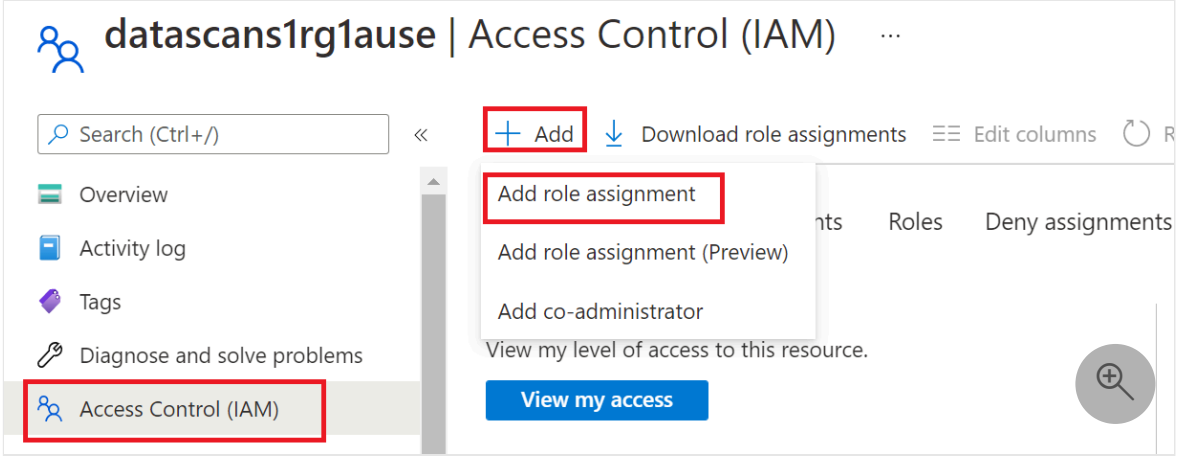
To be able to create any data policy on a resource, data policy enforcement must first be enabled on that resource. This article will explain how to enable data policy enforcement on your resources in Microsoft Purview.

> **Important**
>
> Because data policy enforcement directly affects access to your data, it directly affects your data security. Review additional considerations and best practices below before enabling data policy enforcement in your environment.

Prerequisites

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.



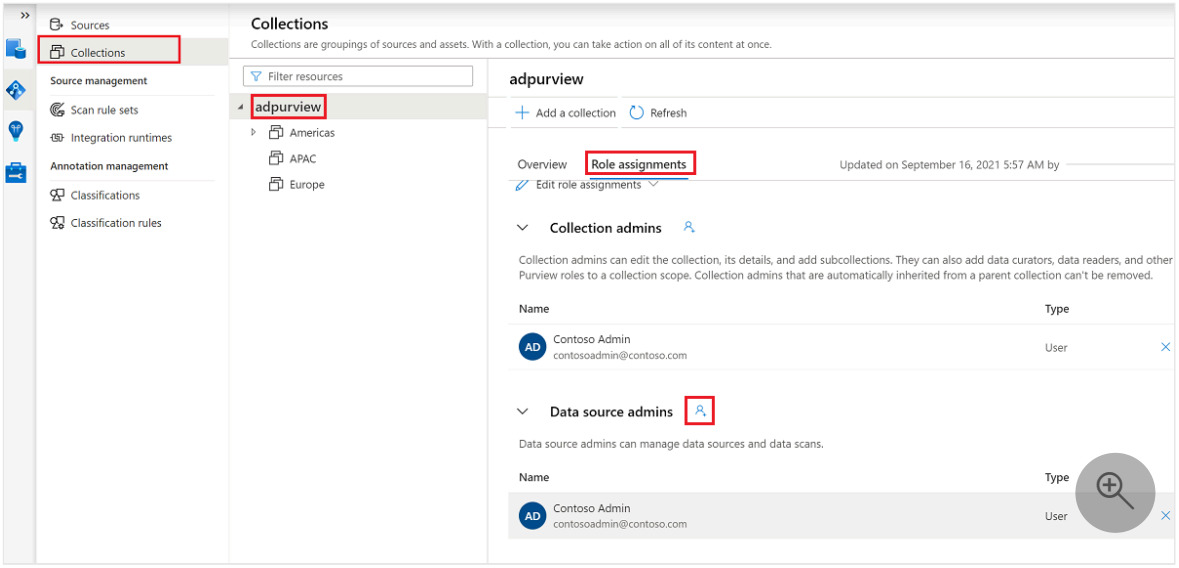
> **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

Configure permissions to enable Data policy enforcement on the data source

Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission inheritance):
  - IAM Owner
  - Both IAM Contributor and IAM User Access Administrator

  To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.



> **Note**

> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> ⓘ **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

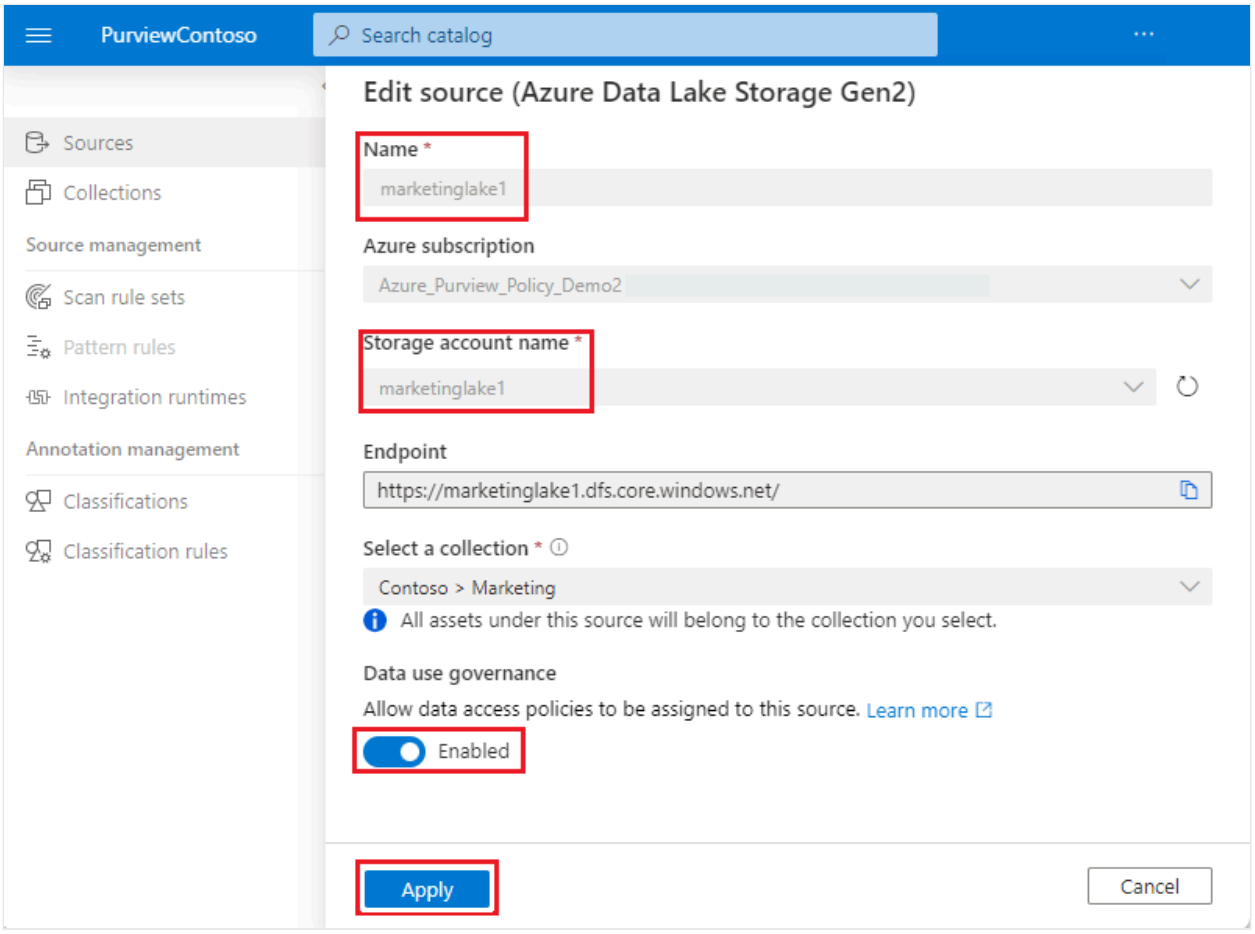
Delegate access provisioning responsibility to roles in Microsoft Purview

After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> ⓘ **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin*

role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.

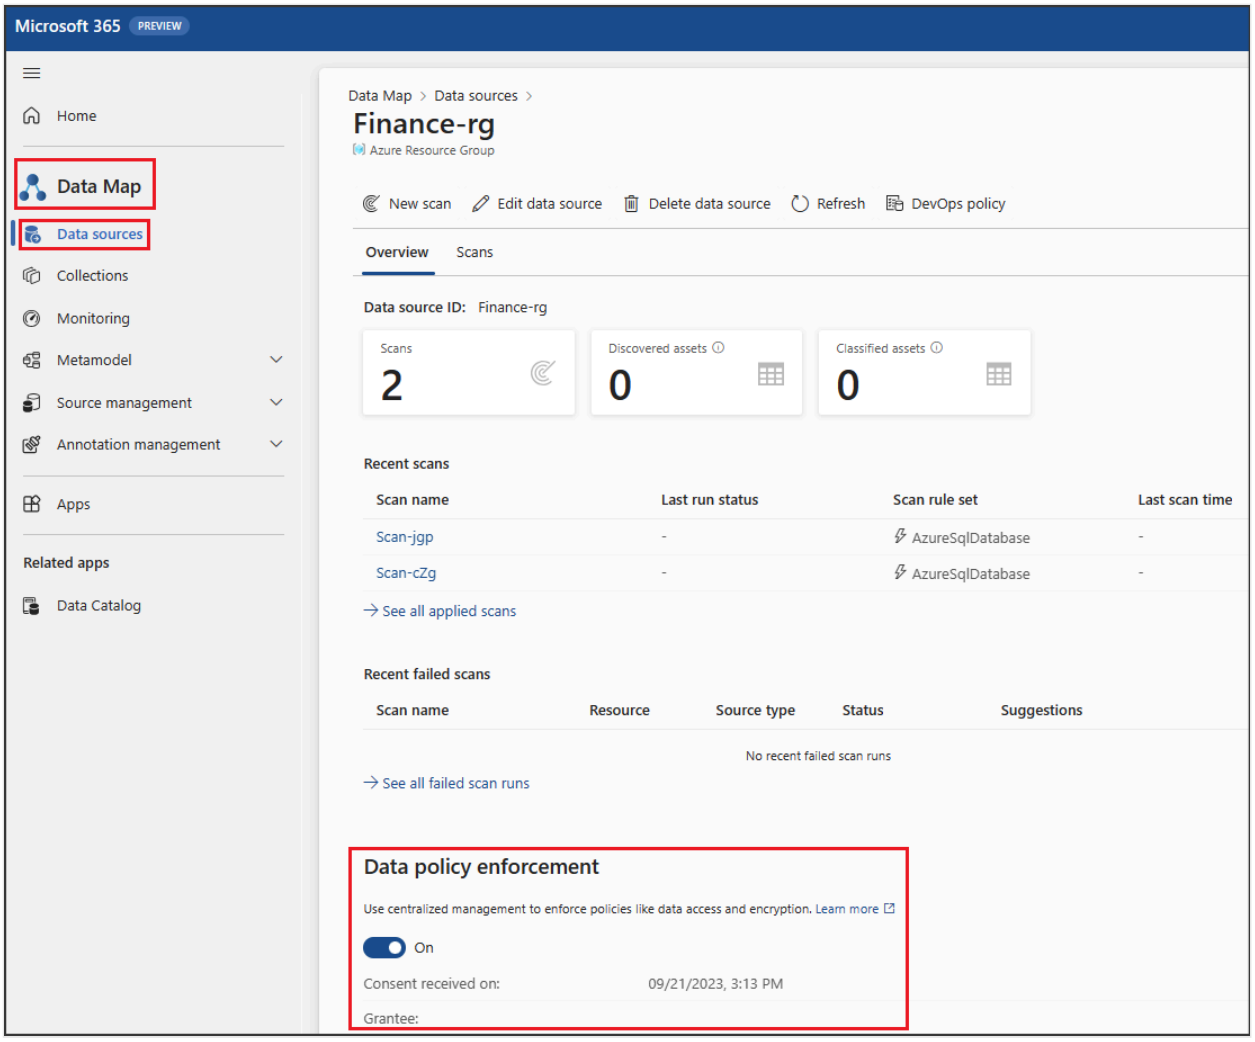
If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.



Enable data policy enforcement

To enable *data policy enforcement* for a resource, the resource will first need to be registered in Microsoft Purview. To register a resource, follow the **Prerequisites** and **Register** sections of the source pages for your resources.

Once you have your resource registered, follow the rest of the steps to enable an individual resource for *data policy enforcement*.



From the classic Microsoft Purview governance portal

1. Go to the classic Microsoft Purview governance portal.
2. Select the **Data map** tab in the left menu.
3. Select the **Sources** tab in the left menu.
4. Select the source where you want to enable *data policy enforcement*.
5. At the top of the source page, select **Edit source**.
6. Set the **Data policy enforcement** toggle to **Enabled**, as shown in the image below.

From the new Microsoft Purview portal

1. Go to the new Microsoft Purview portal.
2. Select the **Data Map** tab in the left menu.
3. Select the **Data sources** tab in the left menu.
4. Select the source where you want to enable *data policy enforcement*.
5. Set the **Data policy enforcement** toggle to **On**, as shown in the image below.

Disable data policy enforcement

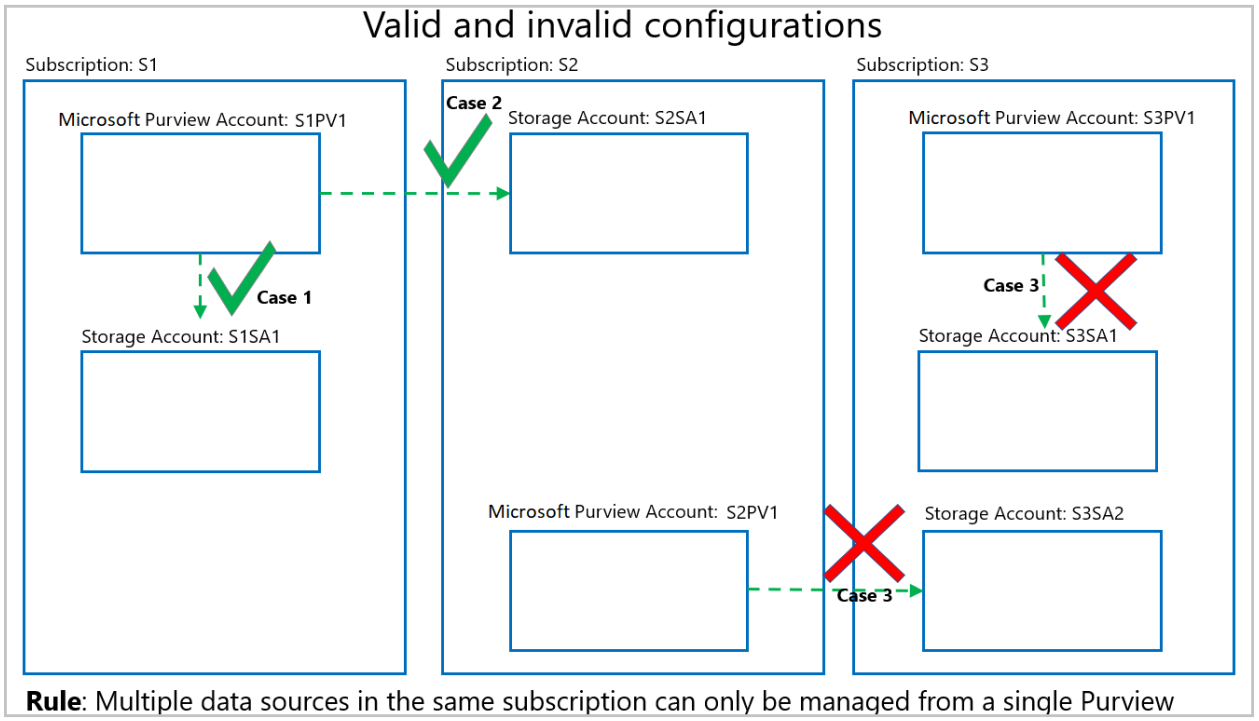
To disable data policy enforcement for a source, resource group, or subscription, a user needs to either be a resource IAM **Owner** or a Microsoft Purview **Data source admin**. Once you have those permissions follow these steps:

From the classic Microsoft Purview governance portal

1. Go to the Microsoft Purview governance portal.
2. Select the **Data map** tab in the left menu.
3. Select the **Sources** tab in the left menu.
4. Select the source you want to disable data policy enforcement for.
5. At the top of the source page, select **Edit source**.
6. Set the **Data policy enforcement** toggle to **Disabled**.

From the new Microsoft Purview portal

1. Go to the new Microsoft Purview portal.
2. Select the **Data map** tab in the left menu.
3. Select the **Sources** tab in the left menu.
4. Select the source you want to disable data policy enforcement for.
5. Set the **Data policy enforcement** toggle to **Off**.



Additional considerations related to data policy enforcement

- Make sure you write down the **Name** you use when registering in Microsoft Purview. You will need it when you publish a policy. The recommended practice is to make the registered name exactly the same as the endpoint name.
- To disable a source for *data policy enforcement*, you first have to remove any published policies on that data source.
- While user needs to have both data source *Owner* and Microsoft Purview *Data source admin* to enable a source for *data policy enforcement*, **any** Data Source admin for the collection can disable it.
- Disabling *data policy enforcement* for a subscription will disable it also for all assets registered in that subscription.

> ⚠ **Warning**
>
> **Known issues** related to source registration
>
> - Moving data sources to a different resource group or subscription is not supported. If want to do that, de-register the data source in Microsoft Purview before moving it and then register it again after that happens. Note that policies are bound to the data source ARM path. Changing the data source subscription or resource group makes policies ineffective.
> - Once a subscription gets disabled for *data policy enforcement* any underlying assets that are enabled for *data policy enforcement* will be disabled, which is the right behavior. However, policy statements based on those assets will still be allowed after that.

Data policy enforcement best practices

- We highly encourage registering data sources for *data policy enforcement* and managing all associated access policies in a single Microsoft Purview account.
- Should you have multiple Microsoft Purview accounts, be aware that **all** data sources belonging to a subscription must be registered for *data policy enforcement* in a single Microsoft Purview account. That Microsoft Purview account can be in any subscription in the tenant. The *data policy enforcement* toggle will become greyed out when there are invalid configurations. Some examples of valid and invalid configurations follow in the diagram below:
  - **Case 1** shows a valid configuration where a Storage account is registered in a Microsoft Purview account in the same subscription.
  - **Case 2** shows a valid configuration where a Storage account is registered in a Microsoft Purview account in a different subscription.
  - **Case 3** shows an invalid configuration arising because Storage accounts S3SA1 and S3SA2 both belong to Subscription 3, but are registered to different Microsoft Purview accounts. In that case, the *data policy enforcement* toggle will only enable in the Microsoft Purview account that wins and registers a data source in that subscription first. The toggle will then be greyed out for the other data source.
- If the *data policy enforcement* toggle is greyed out and cannot be enabled, hover over it to know the name of the Microsoft Purview account that has registered the data resource first.

Next steps

- Create data owner policies for your resources
- Enable Microsoft Purview data owner policies on all data sources in a subscription or a resource group
- Enable Microsoft Purview data owner policies on an Azure Storage account

Tutorial: Troubleshoot Microsoft Purview policies for SQL data sources

Article • 02/26/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

In this tutorial, you learn how issue SQL commands to inspect the Microsoft Purview policies that have been communicated to the SQL instance, where they'll be enforced. You'll also learn how to force a download of the policies to the SQL instance. These commands are only used for troubleshooting and aren't required during the normal operation of Microsoft Purview policies. These commands require a higher level of privileges in the SQL instance.

For more information about Microsoft Purview policies, see the concept guides listed in the Next steps section.

Prerequisites

- An Azure subscription. If you don't already have one, create a free subscription.
- A Microsoft Purview account. If you don't have one, see the quickstart for creating a Microsoft Purview account.
- Register a data source, enable *Data policy enforcement*, and create a policy. To do so, use one of the Microsoft Purview policy guides. To follow along with the examples in this tutorial, you can create a DevOps policy for Azure SQL Database.

Test the policy

Once you create a policy, the Microsoft Entra principals referenced in the Subject of the policy should be able to connect to any database in the server to which the policies are published.

Force policy download

It's possible to force an immediate download of the latest published policies to the current SQL database by running the following command. The minimal permission required to run it's membership in ##MS_ServerStateManager##-server role.

SQL

```
-- Force immediate download of latest published policies
exec sp_external_policy_refresh reload
```

Analyze downloaded policy state from SQL

The following DMVs can be used to analyze which policies have been downloaded and are currently assigned to Microsoft Entra principals. The minimal permission required to run them is VIEW DATABASE SECURITY STATE - or assigned Action Group *SQL Security Auditor*.

SQL

```
-- Lists generally supported actions
SELECT * FROM sys.dm_server_external_policy_actions

-- Lists the roles that are part of a policy published to this server
SELECT * FROM sys.dm_server_external_policy_roles

-- Lists the links between the roles and actions, could be used to join the
two
SELECT * FROM sys.dm_server_external_policy_role_actions

-- Lists all Azure AD principals that were given connect permissions
SELECT * FROM sys.dm_server_external_policy_principals

-- Lists Azure AD principals assigned to a given role on a given resource
scope
SELECT * FROM sys.dm_server_external_policy_role_members

-- Lists Azure AD principals, joined with roles, joined with their data
actions
SELECT * FROM sys.dm_server_external_policy_principal_assigned_actions
```

Create, list, update, and delete Microsoft Purview DevOps policies

Article • 02/26/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

DevOps policies are a type of Microsoft Purview access policies. You can use them to manage access to system metadata on data sources that have been registered for **Data policy enforcement** in Microsoft Purview.

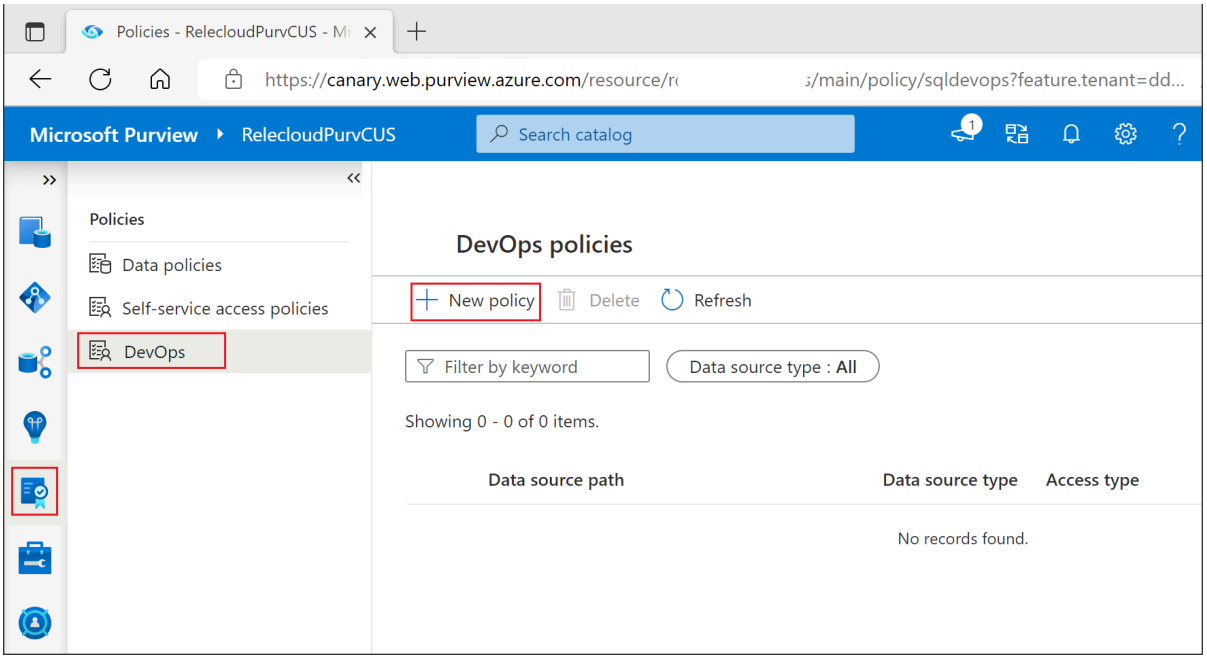
You can configure DevOps policies directly from the Microsoft Purview governance portal. After they're saved, they're automatically published and then enforced by the data source. Microsoft Purview policies manage only access for Microsoft Entra principals.

This guide covers the configuration steps in Microsoft Purview to provision access to database system metadata by using the DevOps policy actions for the SQL Performance Monitor and SQL Security Auditor roles. It shows how to create, list, update, and delete DevOps policies.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- A new or existing Microsoft Purview account. Follow this quickstart guide to create one.

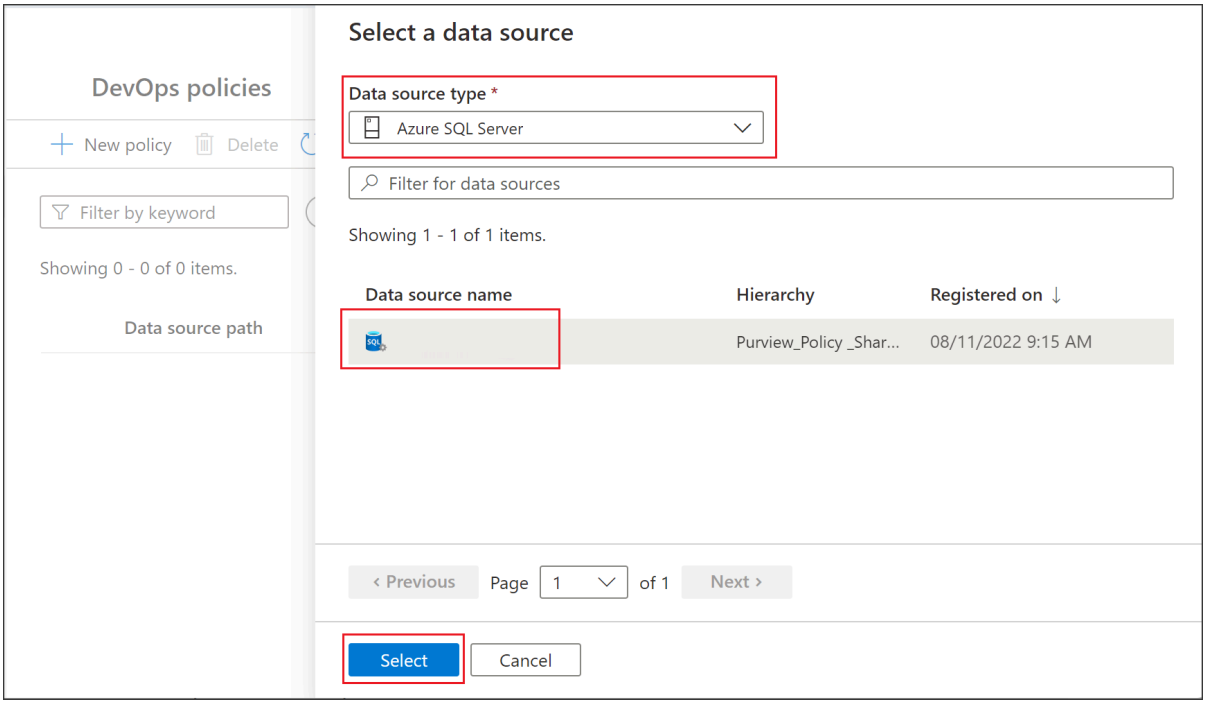
Configuration



Before you author policies in the Microsoft Purview policy portal, you need to configure the data sources so that they can enforce those policies:

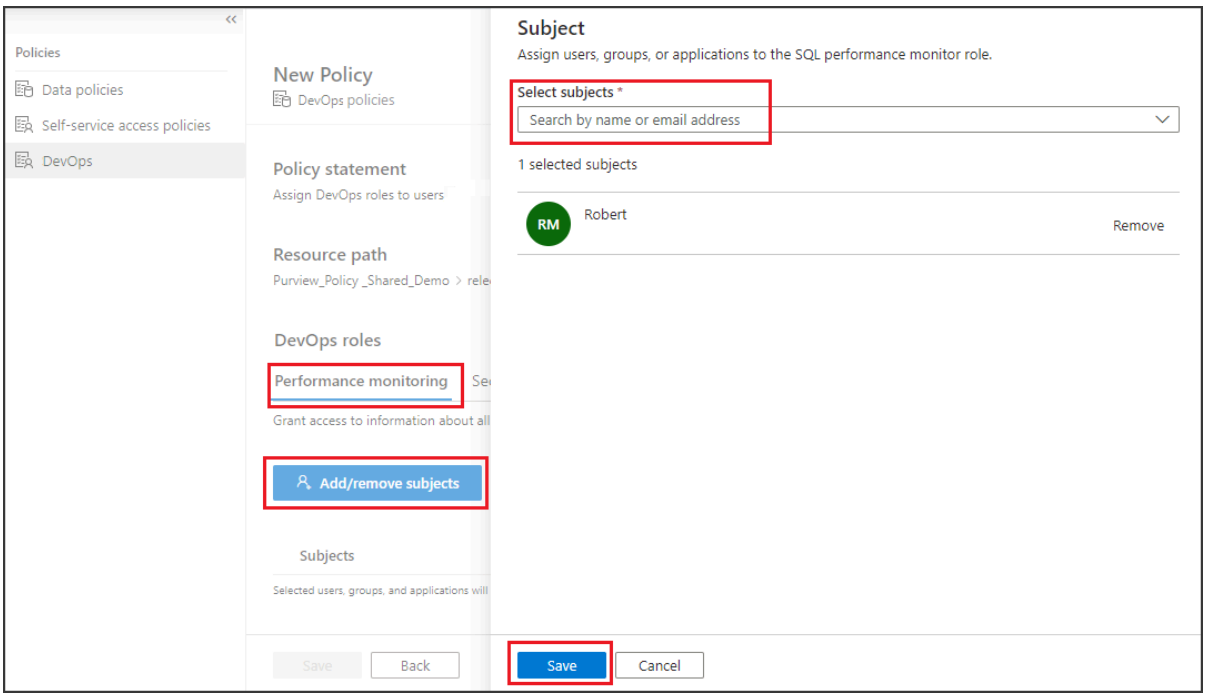
1. Follow any policy-specific prerequisites for your source. Check the table of Microsoft Purview supported data sources and select the link in the **Access policy** column for sources where access policies are available. Follow any steps listed in the "Access policy" and "Prerequisites" sections.
2. Register the data source in Microsoft Purview. Follow the "Prerequisites" and "Register" sections of the source pages for your resources.
3. Turn on the **Data policy enforcement** toggle in the data source registration. For more information, including additional permissions that you need for this step, see Enable Data policy enforcement on your Microsoft Purview sources.

Create a new DevOps policy



To create a DevOps policy, first ensure that you have the Microsoft Purview Policy Author role at the root collection level. Check the section on managing Microsoft Purview role assignments in this guide. Then, follow these steps:

1. Sign in to the Microsoft Purview governance portal.
2. On the left pane, select **Data policy**. Then select **DevOps policies**.
3. Select the **New policy** button.



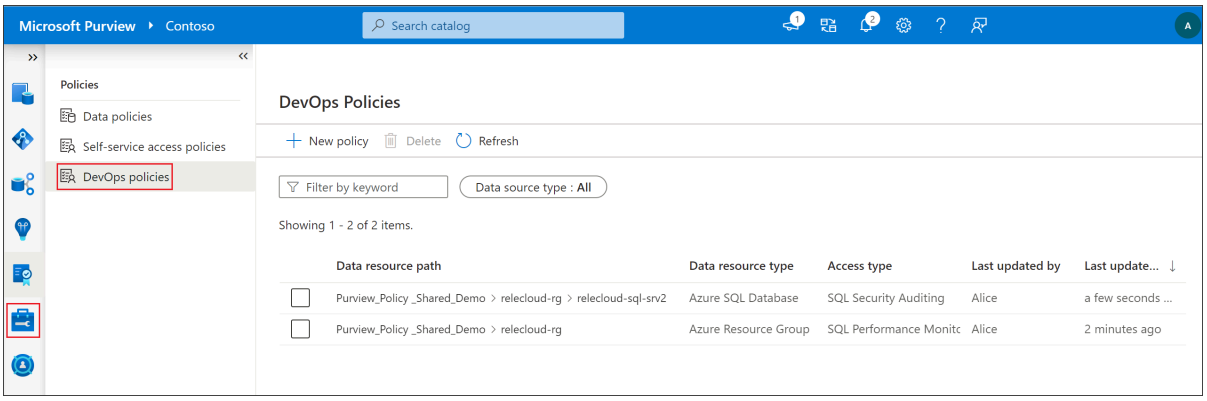
The policy detail panel opens.

4. For **Data source type**, select a data source. Under **Data source name**, select one of the listed data sources. Then click **Select** to return to the **New Policy** pane.

5. Select one of two roles, **Performance monitoring** or **Security auditing**. Then select **Add/remove subjects** to open the **Subject** panel.

   In the **Select subjects** box, enter the name of a Microsoft Entra principal (user, group, or service principal). Microsoft 365 groups are supported, but updates to group membership take up to one hour to be reflected in Microsoft Entra ID. Keep adding or removing subjects until you're satisfied, and then select **Save**.

6. Select **Save** to save the policy. The policy is published automatically. Enforcement starts at the data source within five minutes.



List DevOps policies

To list DevOps policies, first ensure that you have one of the following Microsoft Purview roles at the root collection level: Policy Author, Data Source Admin, Data Curator, or Data Reader. Check the section on managing Microsoft Purview role assignments in this guide. Then, follow these steps:

1. Sign in to the Microsoft Purview governance portal.

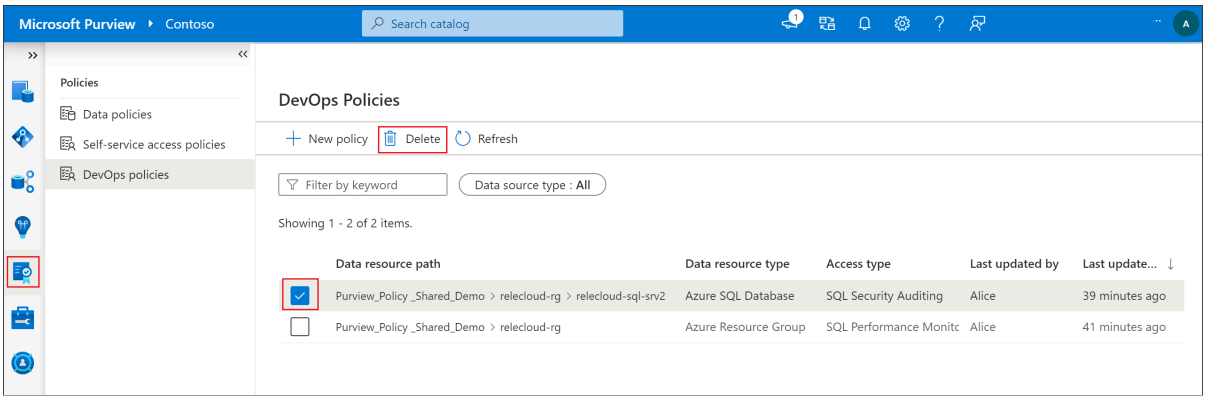
2. On the left pane, select **Data policy**. Then select **DevOps policies**.

   The **DevOps Policies** pane lists any policies that have been created.

Update a DevOps policy

To update a DevOps policy, first ensure that you have the Microsoft Purview Policy Author role at the root collection level. Check the section on managing Microsoft Purview role assignments in this guide. Then, follow these steps:

1. Sign in to the Microsoft Purview governance portal.
2. On the left pane, select **Data policy**. Then select **DevOps policies**.
3. On the **DevOps Policies** pane, open the policy details for one of the policies by selecting it from its data resource path.



4. On the pane for policy details, select **Edit**.
5. Make your changes, and then select **Save**.

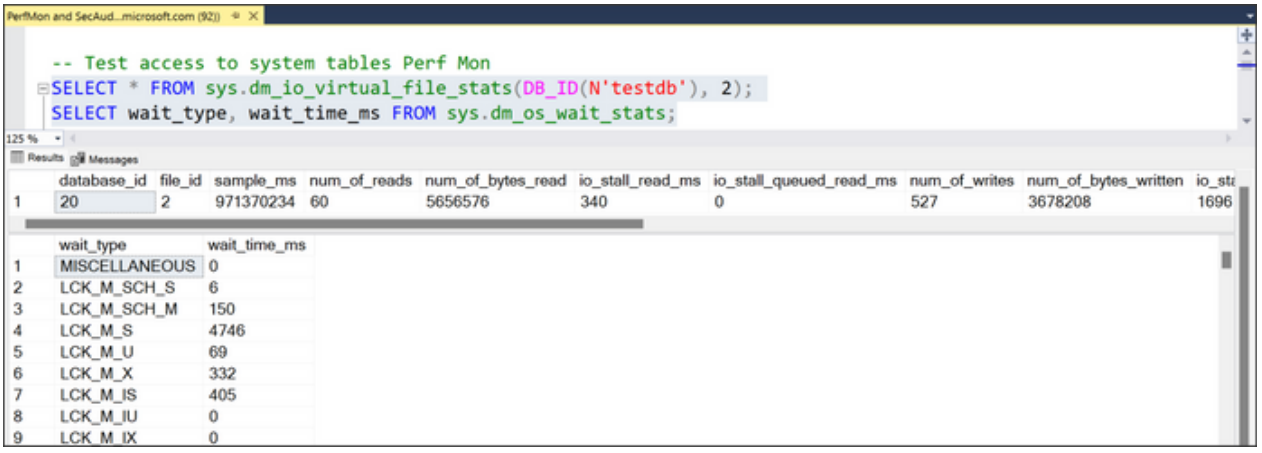
Delete a DevOps policy

To delete a DevOps policy, first ensure that you have the Microsoft Purview Policy Author role at the root collection level. Check the section on managing Microsoft Purview role assignments in this guide. Then, follow these steps:

1. Sign in to the Microsoft Purview governance portal.
2. On the left pane, select **Data policy**. Then select **DevOps policies**.
3. Select the checkbox for one of the policies, and then select **Delete**.

Test the DevOps policy

After you create a policy, any of the Microsoft Entra users that you selected as subjects can now connect to the data sources in the scope of the policy. To test, use SQL Server Management Studio (SSMS) or any SQL client and try to query some dynamic management views (DMVs) and dynamic management functions (DMFs). The following sections list a few examples. For more examples, consult the mapping of popular DMVs and DMFs in What can I accomplish with Microsoft Purview DevOps policies?.



If you require more troubleshooting, see the Next steps section in this guide.

Test SQL Performance Monitor access

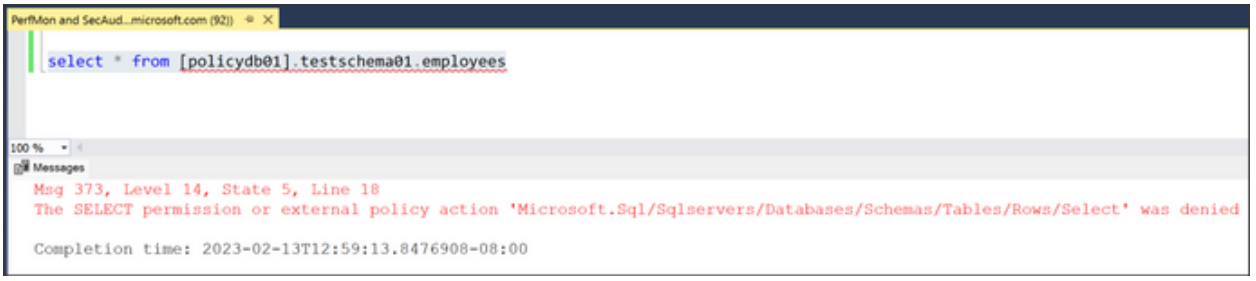
If you provided the subjects of the policy for the SQL Performance Monitor role, you can issue the following commands:

SQL

```
-- Returns I/O statistics for data and log files
SELECT * FROM sys.dm_io_virtual_file_stats(DB_ID(N'testdb'), 2)
-- Waits encountered by threads that executed. Used to diagnose performance issues
SELECT wait_type, wait_time_ms FROM sys.dm_os_wait_stats
```

Test SQL Security Auditor access

If you provided the subjects of the policy for the SQL Security Auditor role, you can issue the following commands from SSMS or any SQL client:



```sql
-- Returns the current state of the audit
SELECT * FROM sys.dm_server_audit_status
-- Returns information about the encryption state of a database and its associated database encryption keys
SELECT * FROM sys.dm_database_encryption_keys
```

Ensure no access to user data

Try to access a table in one of the databases by using the following command:

```sql
-- Test access to user data
SELECT * FROM [databaseName].schemaName.tableName
```

The Microsoft Entra principal that you're testing with should be denied, which means the data is protected from insider threats.

Role definition detail

The following table maps Microsoft Purview data policy roles to specific actions in SQL data sources.

Expand table

Microsoft Purview policy role	Actions in data sources
SQL Performance Monitor	Microsoft.Sql/Sqlservers/Connect
	Microsoft.Sql/Sqlservers/Databases/Connect
	Microsoft.Sql/Sqlservers/Databases/SystemViewsAndFunctions/DatabasePerformanceState/Rows/Select

Microsoft Purview policy role	Actions in data sources
	Microsoft.Sql/Sqlservers/SystemViewsAndFunctions/ServerPerformanceState/Rows/Select
	Microsoft.Sql/Sqlservers/Databases/SystemViewsAndFunctions/DatabaseGeneralMetadata/Rows/Select
	Microsoft.Sql/Sqlservers/SystemViewsAndFunctions/ServerGeneralMetadata/Rows/Select
	Microsoft.Sql/Sqlservers/Databases/DBCCs/ViewDatabasePerformanceState/Execute
	Microsoft.Sql/Sqlservers/DBCCs/ViewServerPerformanceState/Execute
	Microsoft.Sql/Sqlservers/Databases/ExtendedEventSessions/Create
	Microsoft.Sql/Sqlservers/Databases/ExtendedEventSessions/Options/Alter
	Microsoft.Sql/Sqlservers/Databases/ExtendedEventSessions/Events/Add
	Microsoft.Sql/Sqlservers/Databases/ExtendedEventSessions/Events/Drop
	Microsoft.Sql/Sqlservers/Databases/ExtendedEventSessions/State/Enable
	Microsoft.Sql/Sqlservers/Databases/ExtendedEventSessions/State/Disable
	Microsoft.Sql/Sqlservers/Databases/ExtendedEventSessions/Drop
	Microsoft.Sql/Sqlservers/Databases/ExtendedEventSessions/Target/Add
	Microsoft.Sql/Sqlservers/Databases/ExtendedEventSessions/Target/Drop
	Microsoft.Sql/Sqlservers/ExtendedEventSessions/Create
	Microsoft.Sql/Sqlservers/ExtendedEventSessions/Options/Alter
	Microsoft.Sql/Sqlservers/ExtendedEventSessions/Events/Add
	Microsoft.Sql/Sqlservers/ExtendedEventSessions/Events/Drop
	Microsoft.Sql/Sqlservers/ExtendedEventSessions/State/Enable
	Microsoft.Sql/Sqlservers/ExtendedEventSessions/State/Disable
	Microsoft.Sql/Sqlservers/ExtendedEventSessions/Drop
	Microsoft.Sql/Sqlservers/ExtendedEventSessions/Target/Add
	Microsoft.Sql/Sqlservers/ExtendedEventSessions/Target/Drop
SQL Security Auditor	Microsoft.Sql/Sqlservers/Connect
	Microsoft.Sql/Sqlservers/Databases/Connect
	Microsoft.Sql/sqlservers/SystemViewsAndFunctions/ServerSecurityState/rows/select
	Microsoft.Sql/Sqlservers/Databases/SystemViewsAndFunctions/DatabaseSecurityState/rows/select

Microsoft Purview policy role	Actions in data sources
	Microsoft.Sql/sqlservers/SystemViewsAndFunctions/ServerSecurityMetadata/rows/select
	Microsoft.Sql/Sqlservers/Databases/SystemViewsAndFunctions/DatabaseSecurityMetadata/rows/select

Provision access to system metadata in Azure SQL Database using Microsoft Purview DevOps policies

Article • 10/28/2024

> **Note**
>
> Microsoft Purview Data Map (classic), Data Catalog (classic), Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

DevOps policies are a type of Microsoft Purview access policies. They allow you to manage access to system metadata on data sources that have been registered for *Data policy enforcement* in Microsoft Purview. These policies are configured directly from the Microsoft Purview governance portal, and after they're saved, they get automatically published and then enforced by the data source. Microsoft Purview policies only manage access for Microsoft Entra principals.

This how-to guide covers how to configure Azure SQL Database to enforce policies created in Microsoft Purview. It covers the configuration steps for Azure SQL Database and the ones in Microsoft Purview to provision access to Azure SQL Database system metadata (DMVs and DMFs) using the DevOps policies actions *SQL Performance Monitoring* or *SQL Security Auditing*.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- A new or existing Microsoft Purview account. Follow this quickstart guide to create one.
- Create a new Azure SQL Database instance, or use an existing one, in one of the currently available regions for this feature. You can follow this guide to create an Azure SQL Database instance.

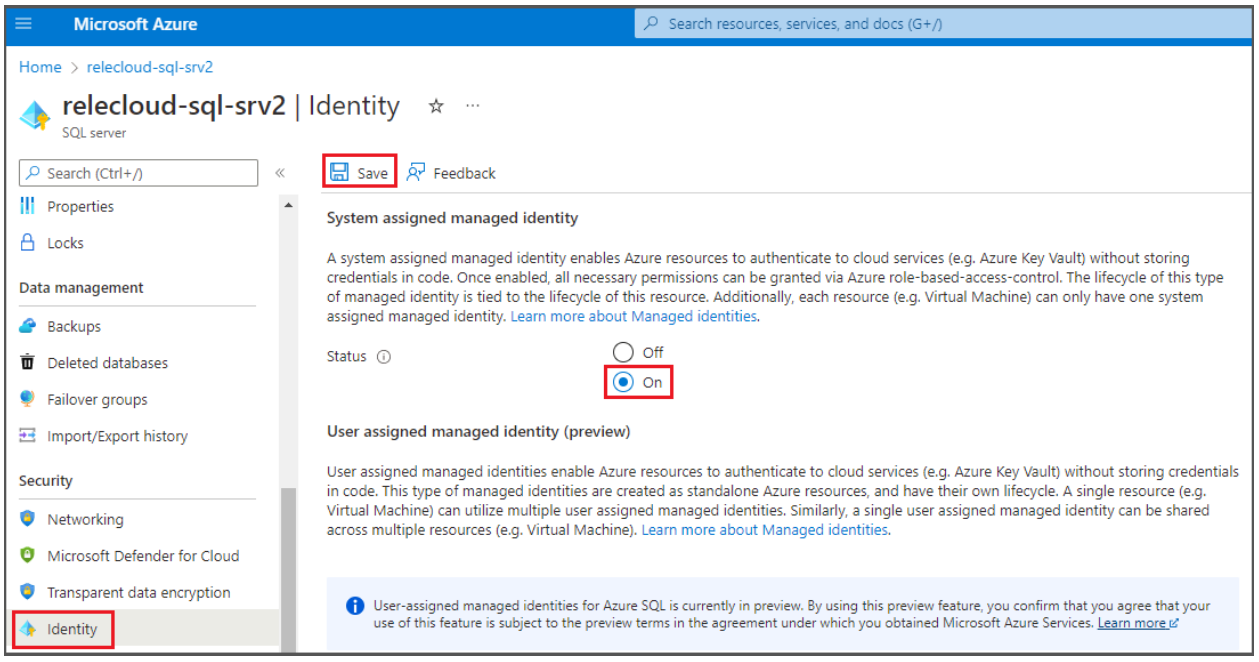
Region support

All Microsoft Purview regions are supported.

Enforcement of Microsoft Purview policies is available only in the following regions for Azure SQL Database:

Public cloud:

- East US
- East US2
- South Central US
- West Central US
- West US3
- Canada Central
- Brazil South
- West Europe
- North Europe
- France Central
- UK South
- South Africa North
- Central India
- South East Asia
- East Asia
- Australia East



Sovereign clouds:

- USGov Virginia
- China North 3

Configure the Azure SQL Database instance for policies from Microsoft Purview

For the logical server associated with Azure SQL Database to honor policies from Microsoft Purview, you need to configure a Microsoft Entra admin. In the Azure portal, go to the logical server that hosts the Azure SQL Database instance. On the side menu, select **Microsoft Entra ID**. Set an admin name to any Microsoft Entra user or group that you prefer, and then select **Save**.

Then, on the side menu, select **Identity**. Under **System assigned managed identity**, turn the status to **On**, and then select **Save**.

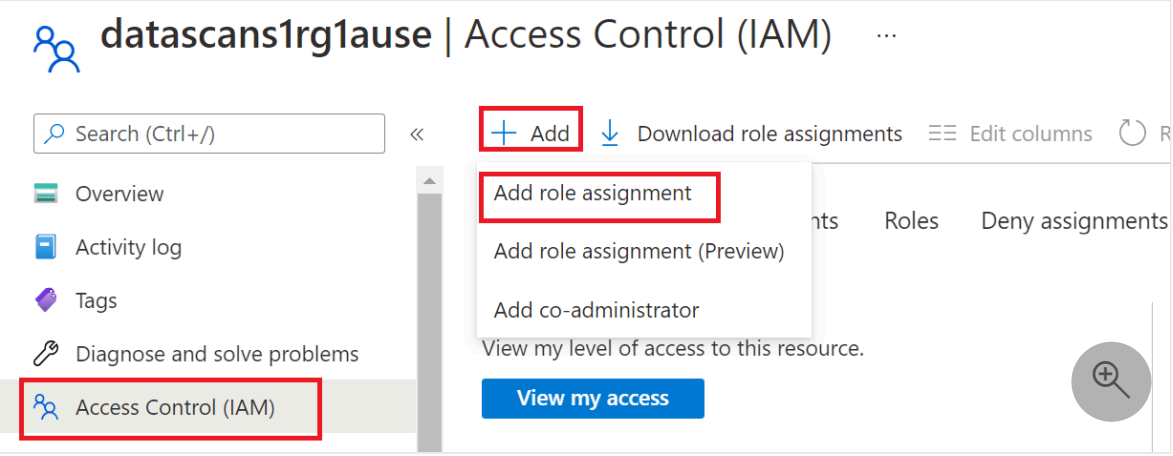
Microsoft Purview Configuration

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.

> **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

Configure permissions to enable Data policy enforcement on the data source

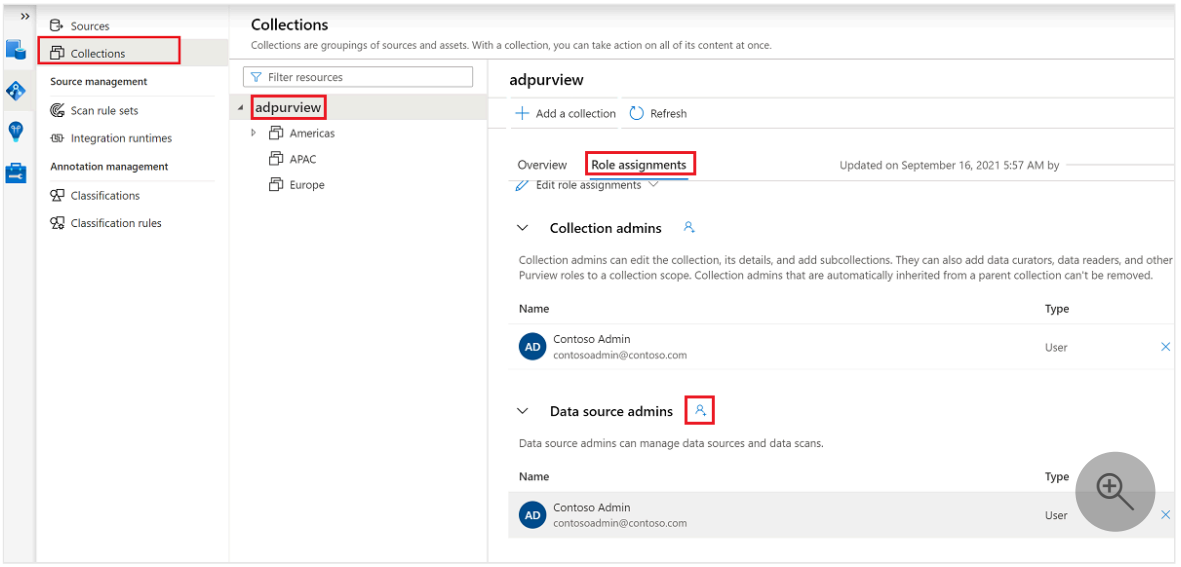


Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission

inheritance):

- IAM Owner
- Both IAM Contributor and IAM User Access Administrator



To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.

> **Note**
>
> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before

a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

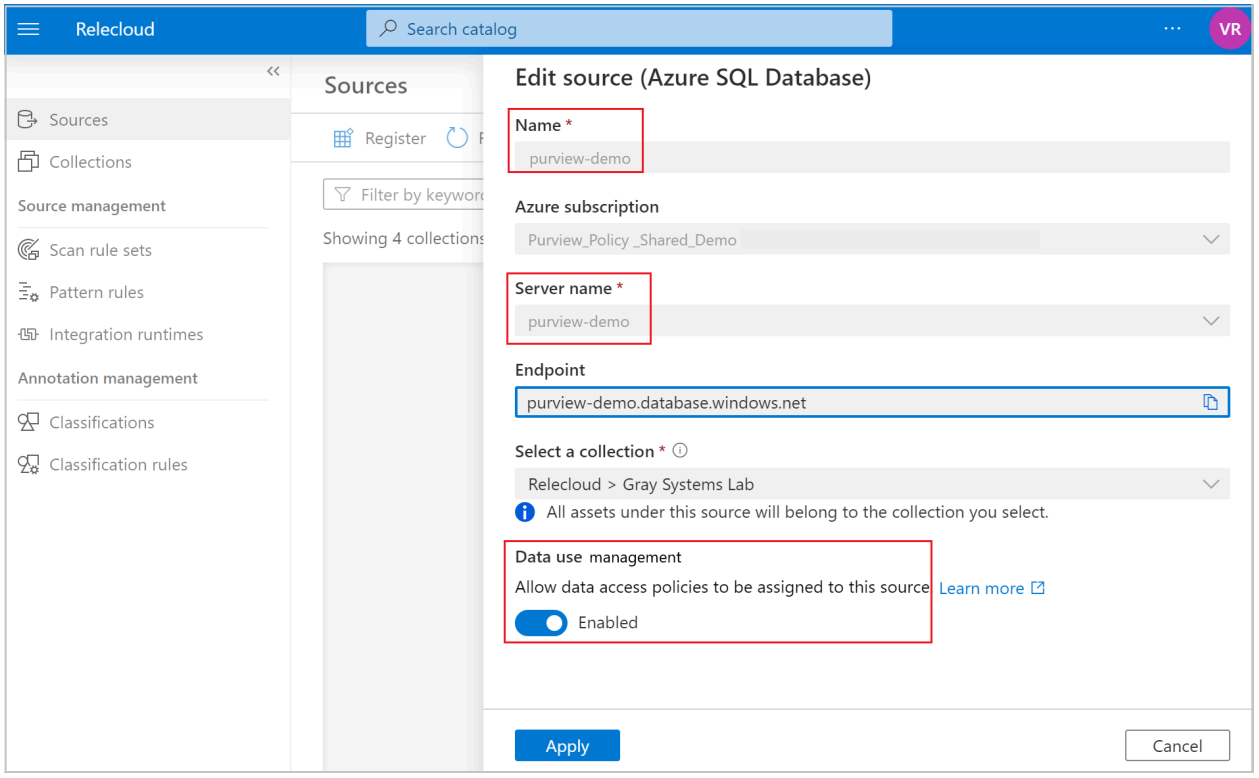
> ⓘ **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

Delegate access provisioning responsibility to roles in Microsoft Purview

After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> ⓘ **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin* role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.

If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.



Register the data sources in Microsoft Purview

The Azure SQL Database data source needs to be registered first with Microsoft Purview, before access policies can be created. You can follow these guides:

Register and scan Azure SQL Database.

After you've registered your resources, you'll need to enable Data policy enforcement. Data policy enforcement needs certain permissions and can affect the security of your data, as it delegates to certain Microsoft Purview roles the ability to manage access to data sources. **Go through the secure practices related to Data policy enforcement in this guide**: How to enable Data policy enforcement

Once your data source has the **Data policy enforcement** toggle *Enabled*, it looks like this screenshot. This enables the access policies to be used with the given data source.

Return to the Azure portal for Azure SQL Database to verify it's now governed by Microsoft Purview:

1. Sign in to the Azure portal through this link
2. Select the Azure SQL Server that you want to configure.
3. Go to **Microsoft Entra ID** on the left pane.
4. Scroll down to **Microsoft Purview access policies**.
5. Select the button to **Check for Microsoft Purview Governance**. Wait while the request is processed. It could take a few minutes.

6. Confirm that the Microsoft Purview Governance Status shows `Governed`. Note that **it could take a few minutes** after you enable *Data policy enforcement* in Microsoft Purview for the correct status to be reflected.

> **Note**
>
> If you disable Data policy enforcement for this Azure SQL Database data source, it might take up to 24 hours for the Microsoft Purview Governance Status to be updated automatically to `Not Governed`. This can be accelerated by selecting **Check for Microsoft Purview Governance**. Before you enable *Data policy enforcement* for the data source in another Microsoft Purview account, ensure that the Purview Governance Status shows as `Not Governed`. Then repeat the steps above with the new Microsoft Purview account.

Create a new DevOps policy

Follow this link for the steps to create a new DevOps policy in Microsoft Purview.

List DevOps policies

Follow this link for the steps to list DevOps policies in Microsoft Purview.

Update a DevOps policy

Follow this link for the steps to update a DevOps policies in Microsoft Purview.

Delete a DevOps policy

Follow this link for the steps to delete a DevOps policies in Microsoft Purview.

> **Important**

DevOps policies are auto-published and changes can take up to **5 minutes** to be enforced by the data source.

Test the DevOps policy

See how to test the policy you created.

Role definition detail

Provision access to system metadata in Azure SQL Managed Instance using Microsoft Purview DevOps policies

Article • 10/28/2024

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

DevOps policies are a type of Microsoft Purview access policies. They allow you to manage access to system metadata on data sources that have been registered for *data policy enforcement* in Microsoft Purview. These policies are configured directly from the Microsoft Purview governance portal, and after they're saved, they get automatically published and then enforced by the data source. Microsoft Purview policies only manage access for Microsoft Entra principals.

This how-to guide covers how to configure Azure SQL Managed Instance to enforce policies created in Microsoft Purview. It covers the configuration steps for Azure SQL MI and the ones in Microsoft Purview to provision access to Azure SQL MI system metadata (DMVs and DMFs) using the DevOps policies actions *SQL Performance Monitoring* or *SQL Security Auditing*.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- A new or existing Microsoft Purview account. Follow this quickstart guide to create one.
- Create a new Azure SQL MI or use an existing one in one of the currently available regions for this feature. You can follow this guide to create a new Azure SQL MI.

Region support

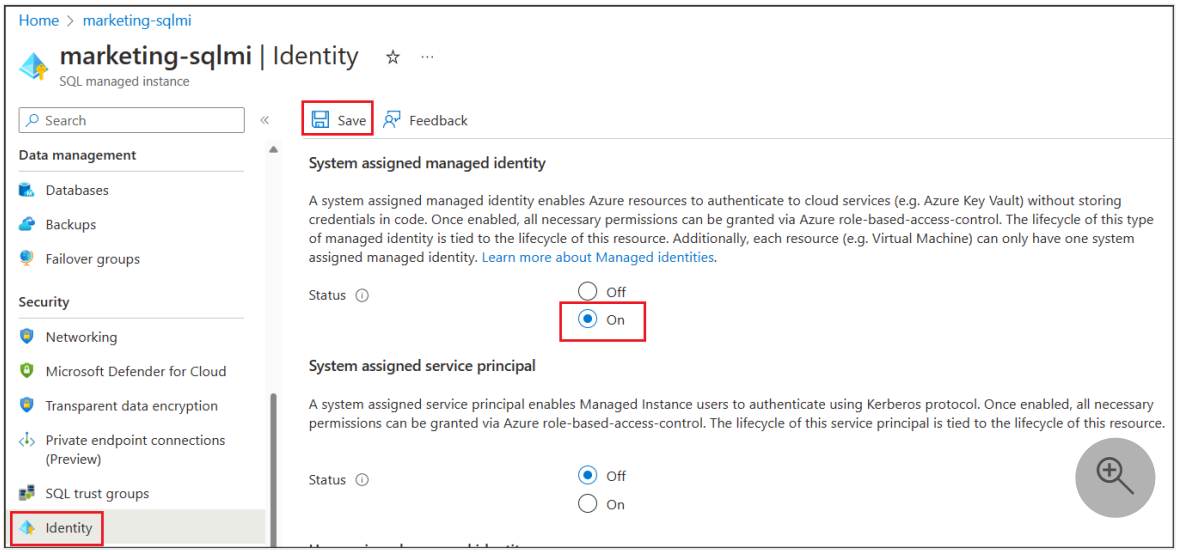
All Microsoft Purview regions are supported.

Enforcement of Microsoft Purview policies is available only in the following regions for Azure SQL MI:

Public cloud:

- East US
- East US2
- South Central US
- West Central US
- West US3
- Canada Central
- Brazil South
- West Europe
- North Europe
- France Central
- UK South
- South Africa North
- Central India
- South East Asia
- East Asia
- Australia East

Azure SQL MI configuration

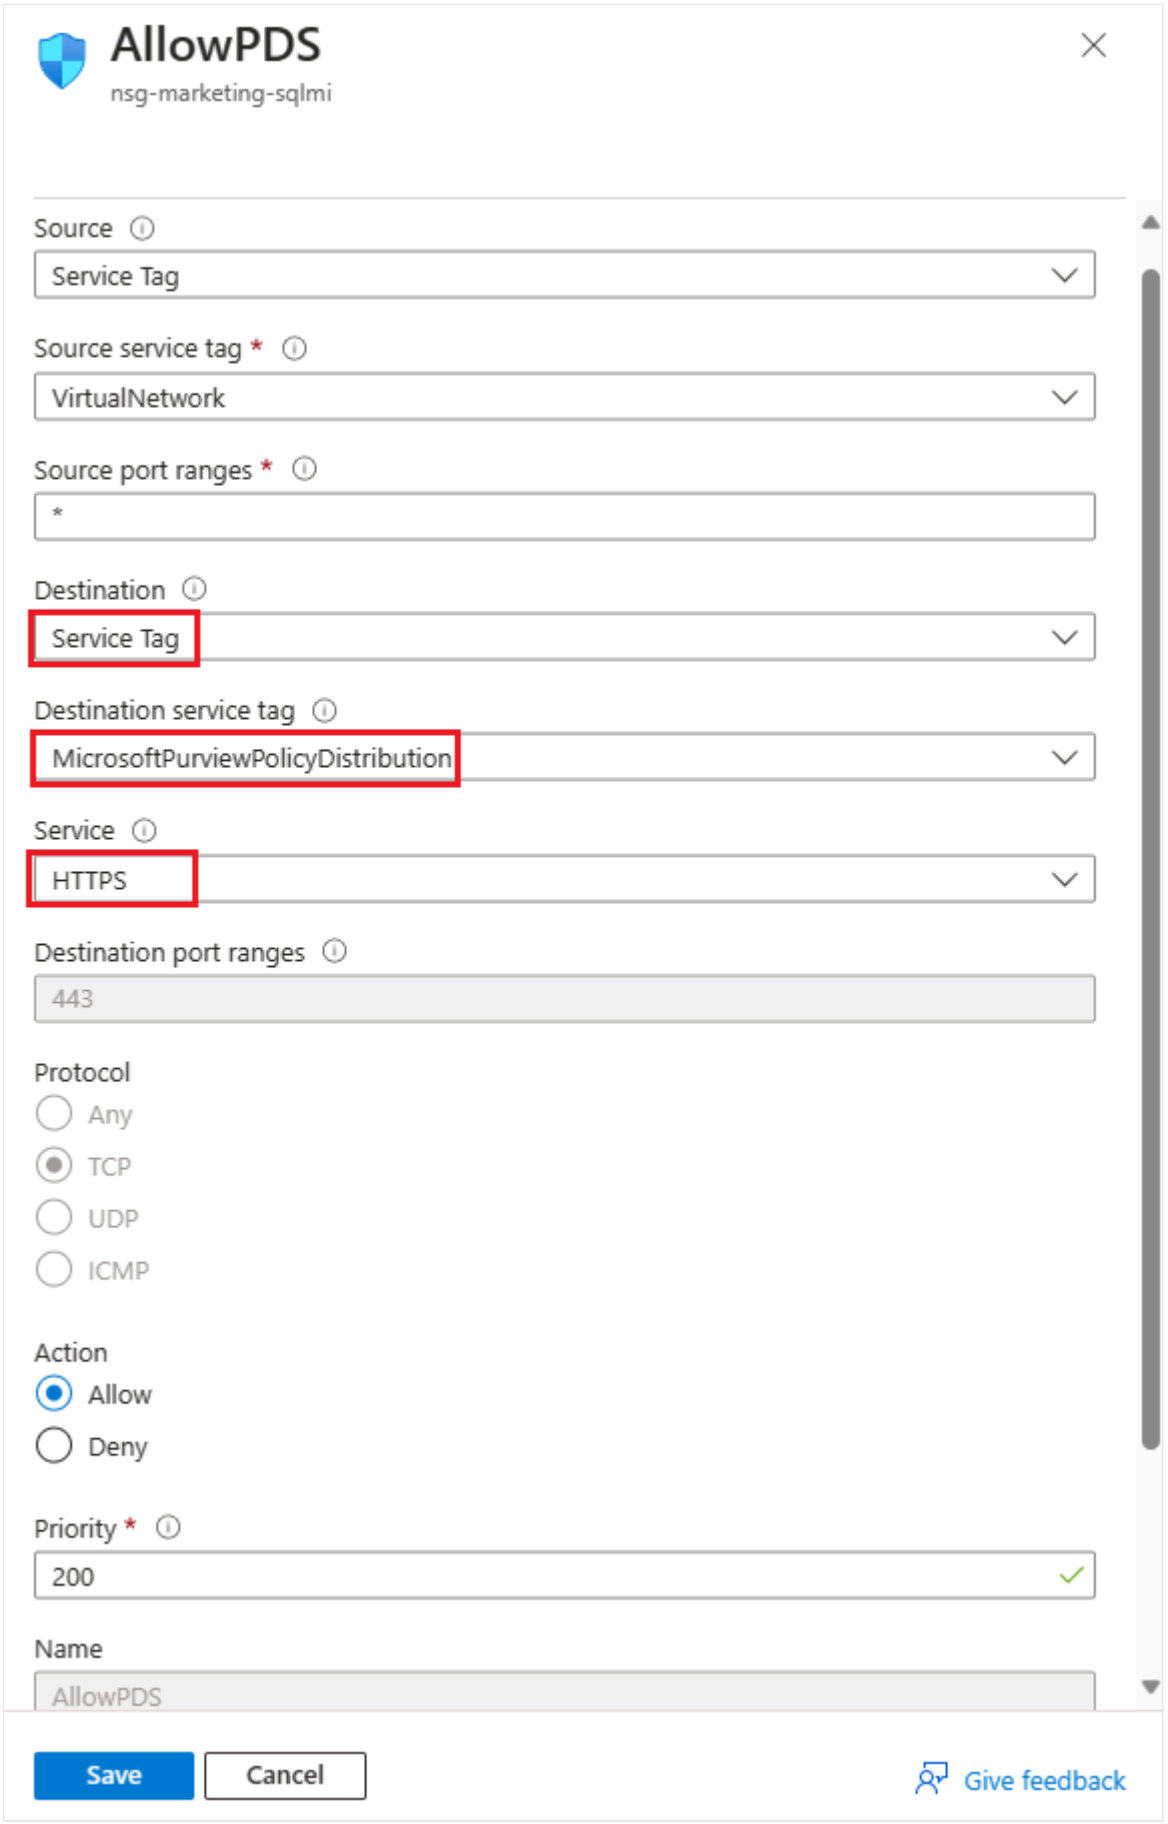


This section explains how you can set up Azure SQL MI to honor policies from Microsoft Purview. Check first whether Azure SQL MI is configured for public or private endpoint. This guide explains how to do so.

Configuration for SQL MI public endpoint

If Azure SQL MI is configured for public endpoint, follow these steps:

- Configure a Microsoft Entra Admin. In Azure portal navigate to the Azure SQL MI then navigate to Microsoft Entra ID on the side menu (formerly called Active Directory admin). Set an Admin name and then select **Save**.



- Then navigate to Identity on the side menu. Under System assigned managed identity check status to *On* and then select **Save**. See screenshot:

Configuration for SQL MI private endpoint

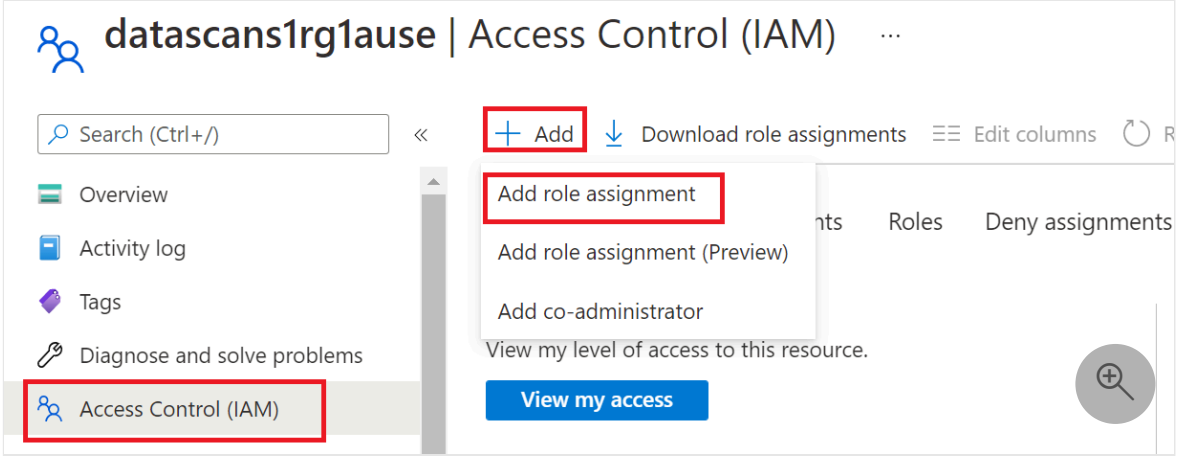
If Azure SQL MI is configured to use private endpoint, execute the same steps outlined in the configuration for public endpoint, and in addition, do the following:

- Navigate to the Network Security Group (NSG) associated to your Azure SQL MI.
- Add an outbound security rule similar to the one in the following screenshot. *Destination = Service Tag, Destination service tag = MicrosoftPurviewPolicyDistribution, Service = HTTPS, Action = Allow.* Ensure also that this rule's priority is lower than the one for the *deny_all_outbound* rule.

Microsoft Purview Configuration

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.



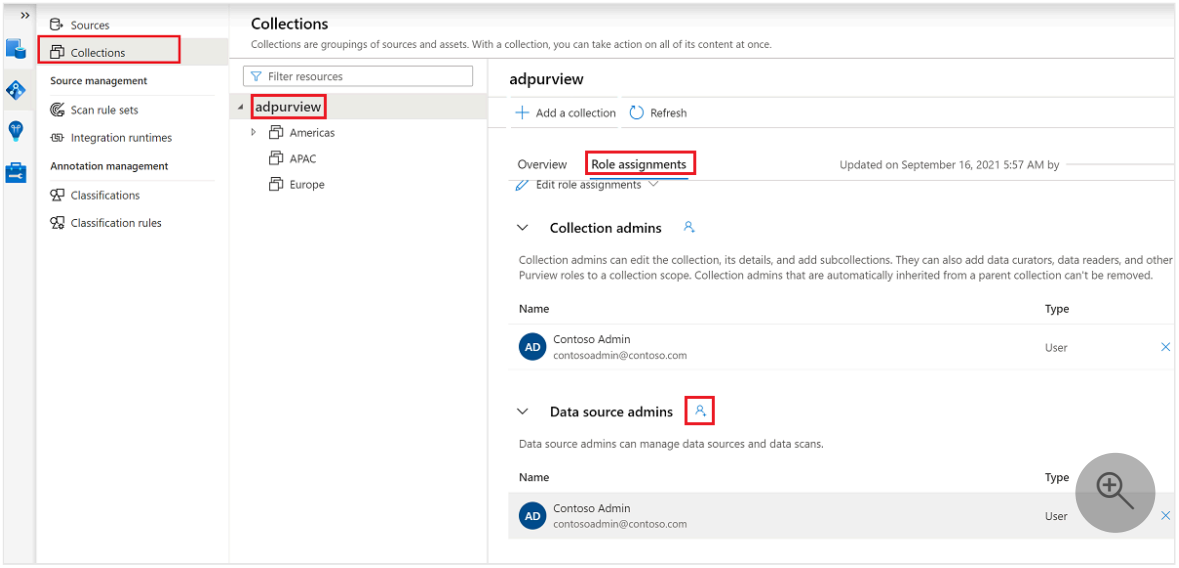
> **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

Configure permissions to enable Data policy enforcement on the data source

Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission inheritance):
  - IAM Owner
  - Both IAM Contributor and IAM User Access Administrator

  To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.



> **Note**

> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

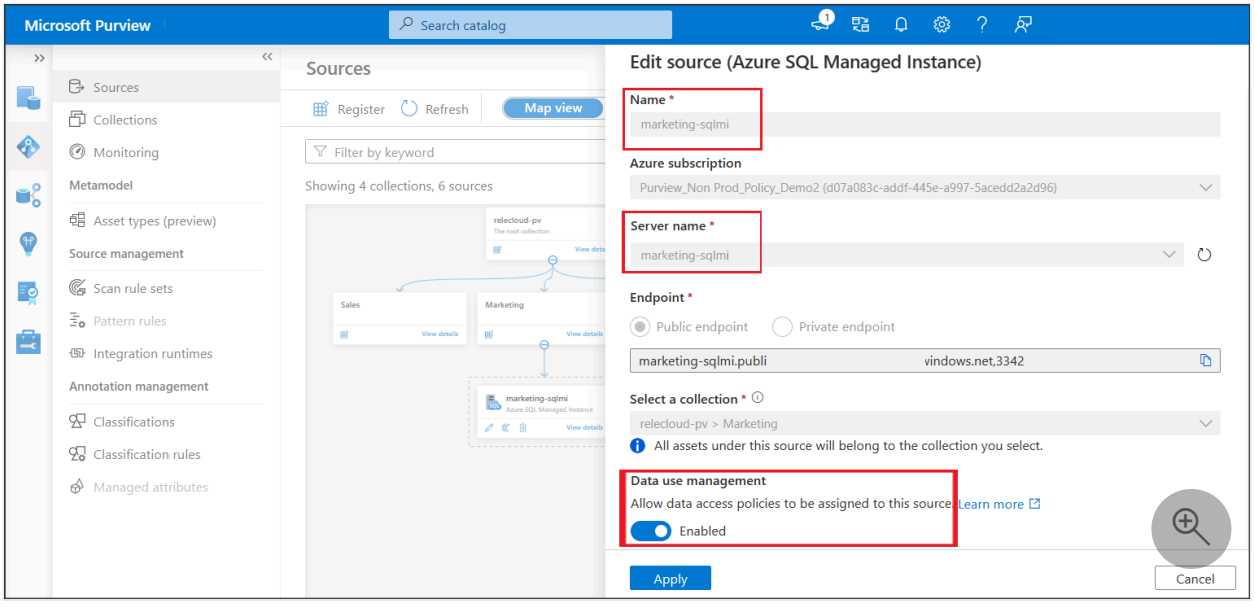
> ⓘ **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

Delegate access provisioning responsibility to roles in Microsoft Purview

After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> ⓘ **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin*

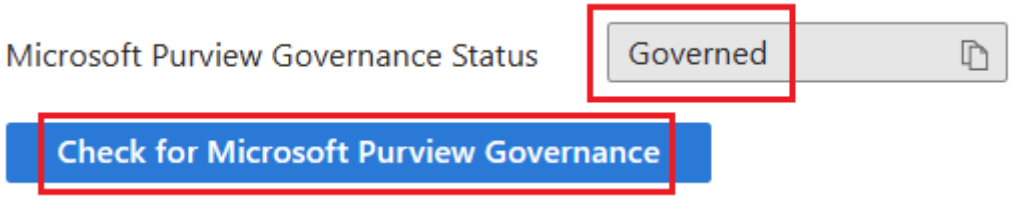
role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.



If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.

Register the data sources in Microsoft Purview

The Azure SQL Managed Instance data source needs to be registered first with Microsoft Purview, before you can create access policies. You can follow the "Prerequisites" and "Register the data source" sections in this guide: Register and scan Azure SQL MI.



After you've registered your resources, you'll need to enable data policy enforcement (formerly Data Use Management). Data policy enforcement needs certain permissions and can affect the security of your data, as it delegates to certain Microsoft Purview roles the ability to manage access to data sources. **Go through the secure practices related to data policy enforcement in this guide**: How to enable policy enforcement

Once your data source has the **Data policy enforcement** toggle *Enabled*, it will look like this screenshot. This will enable the access policies to be used with the given data source.

Return to the Azure portal for Azure SQL Database to verify it's now governed by Microsoft Purview

1. Sign in to the Azure portal through this link
2. Select the Azure SQL Managed Instance that you want to configure.
3. Go to **Microsoft Entra ID admin** on the left pane.
4. Scroll down to **Microsoft Purview access policies**.
5. Select the button to **Check for Microsoft Purview Governance**. Wait while the request is processed. It could take a few minutes.

6. Confirm that the Microsoft Purview Governance Status shows `Governed`. Note that **it could take a few minutes** after you enable *data policy enforcement* in Microsoft Purview for the correct status to be reflected.

> **Note**
>
> If you disable data policy enforcement for this Azure SQL MI in Microsoft Purview, select **Check for Microsoft Purview Governance** for the Microsoft Purview Governance Status to be updated to `Not Governed`. This step must be done for the impacted Azure SQL MI each time data policy enforcement status is changed for an existing or new access policy in Microsoft Purview. Before you enable *data policy enforcement* for the data source in another Microsoft Purview account, ensure that the Purview Governance Status shows as `Not Governed`. Then repeat the steps above with the new Microsoft Purview account.

Create a new DevOps policy

Follow this link for the steps to create a new DevOps policy in Microsoft Purview.

List DevOps policies

Follow this link for the steps to list DevOps policies in Microsoft Purview.

Update a DevOps policy

Follow this link for the steps to update a DevOps policies in Microsoft Purview.

Delete a DevOps policy

Follow this link for the steps to delete a DevOps policies in Microsoft Purview.

> **Important**
>
> DevOps policies are auto-published and changes can take up to **5 minutes** to be enforced by the data source.

Test the DevOps policy

See how to test the policy you created.

Role definition detail

Provision access to system metadata in SQL Server 2022 (Azure Arc-enabled) using Microsoft Purview DevOps policies

Article • 10/28/2024

[Dev> [!NOTE] > Microsoft Purview Data Map (classic), Data Catalog (classic), Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

Ops policies](../concept-policies-devops.md) are a type of Microsoft Purview access policies. They allow you to manage access to system metadata on data sources that have been registered for *Data policy enforcement* in Microsoft Purview. These policies are configured directly from the Microsoft Purview governance portal, and after they're saved, they get automatically published and then enforced by the data source. Microsoft Purview policies only manage access for Microsoft Entra principals.

This how-to guide covers how to configure SQL Server 2022 to enforce policies created in Microsoft Purview. It covers onboarding with Azure Arc, enabling Microsoft Entra ID on the SQL Server, and provisioning access to its system metadata (DMVs and DMFs) using the DevOps policies actions *SQL Performance Monitoring* or *SQL Security Auditing*.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- A new or existing Microsoft Purview account. Follow this quickstart guide to create one.
- Get SQL Server on-premises version 2022 and install it. Versions 2022 or more recent are supported on both Windows and Linux. You can try the free Developer edition.
- Configure your permissions and then register a list of resource providers in the subscription you'll use to onboard the SQL Server instance to Azure Arc.
- Complete prerequisites and onboard the SQL Server instance with Azure Arc. A simple configuration for Windows SQL Server is here. An alternate configuration for Linux SQL Server is here.
- Enable Microsoft Entra authentication in SQL Server. For a simpler setup, complete the prerequisites and process outlined in this article.

- Remember to grant application permissions and grant admin consent
- You need to configure a Microsoft Entra admin for the SQL Server instance, but it isn't necessary to set up other Microsoft Entra logins or users. You'll grant access to those users by using Microsoft Purview policies.

Region support

Data policy enforcement is available in all Microsoft Purview regions except:

- West US2
- East Asia
- US Gov Virginia
- China North 3

Security considerations for Azure Arc-enabled SQL Server

- The server admin can turn off the Microsoft Purview policy enforcement.
- Azure Arc admin and server admin permissions provide the ability to change the Azure Resource Manager path of the server. Because mappings in Microsoft Purview use Resource Manager paths, it can lead to wrong policy enforcements.
- A SQL Server admin (database admin) can gain the power of a server admin and can tamper with the cached policies from Microsoft Purview.
- The recommended configuration is to create a separate app registration for each SQL server instance. This configuration prevents the second SQL Server instance from reading the policies meant for the first SQL Server instance, in case a rogue admin in the second SQL Server instance tampers with the Resource Manager path.

Verify the prerequisites

1. Sign in to the Azure portal through this link
2. Navigate to **SQL servers** on the left pane. You'll see a list of SQL Server instances on Azure Arc.
3. Select the SQL Server instance that you want to configure.
4. Go to **Microsoft Entra ID** on the left pane.
5. Ensure that Microsoft Entra authentication is configured with an admin login. If not, refer to the access policy prerequisites section in this guide.

6. Ensure that a certificate has been provided to for SQL Server to authenticate to Azure. If not, refer to the access policy prerequisites section in this guide.

7. Ensure that an app registration has been entered to create a trust relationship between SQL Server and Microsoft Entra ID. If not, refer to the access policy prerequisites section in this guide.

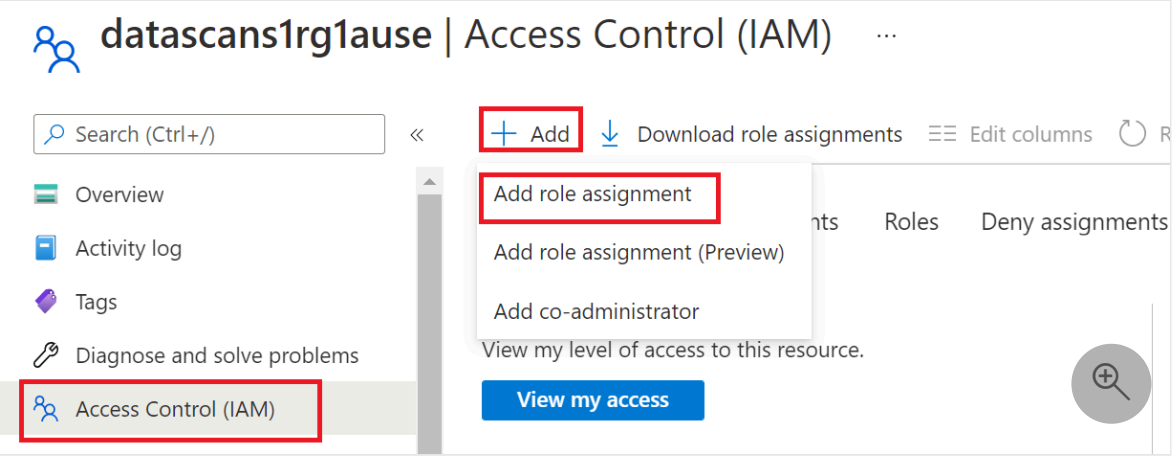
8. If you made any changes, select the **Save** button to save the configuration and wait until the operation completes successfully. This could take a few minutes. The message "*Saved successfully*" will be displayed at the top of the page in green background. You might need to scroll up to see it.

Microsoft Purview configuration

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.

> ⓘ **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

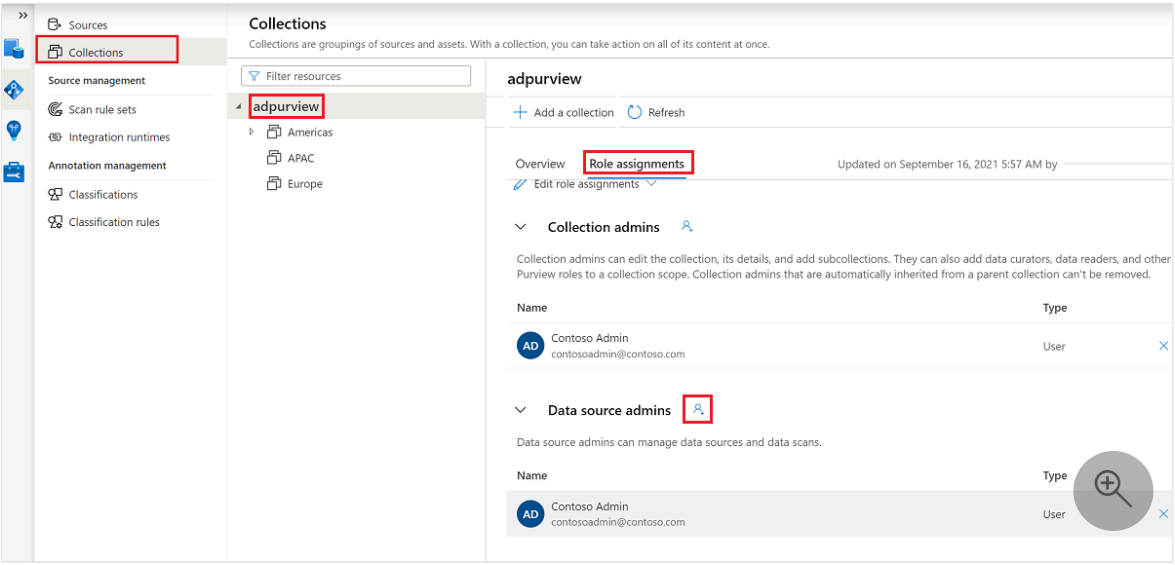


Configure permissions to enable Data policy enforcement on the data source

Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission inheritance):
  - IAM Owner

- Both IAM Contributor and IAM User Access Administrator



To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.

> **Note**
>
> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

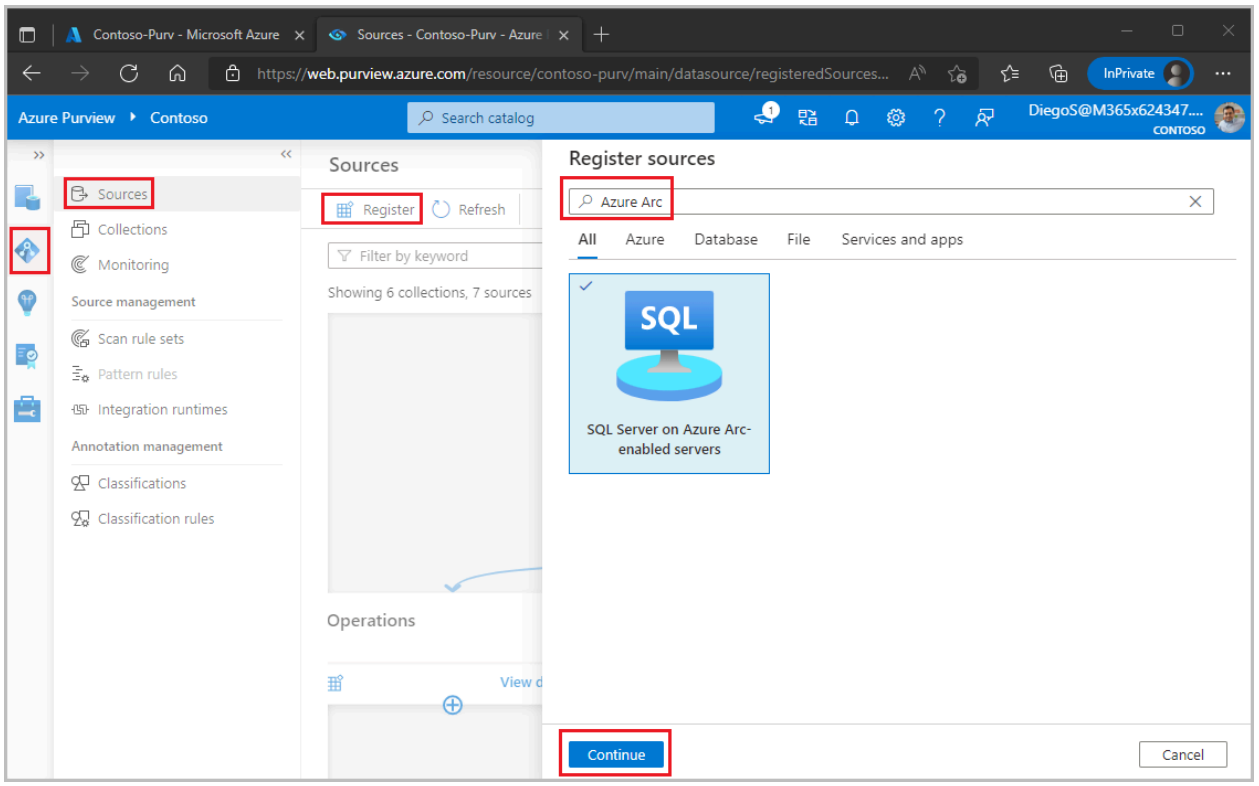
For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**

To publish Data owner policies, the Data source admin role must be configured at the root collection level.

Delegate access provisioning responsibility to roles in Microsoft Purview

After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.



> **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin* role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.

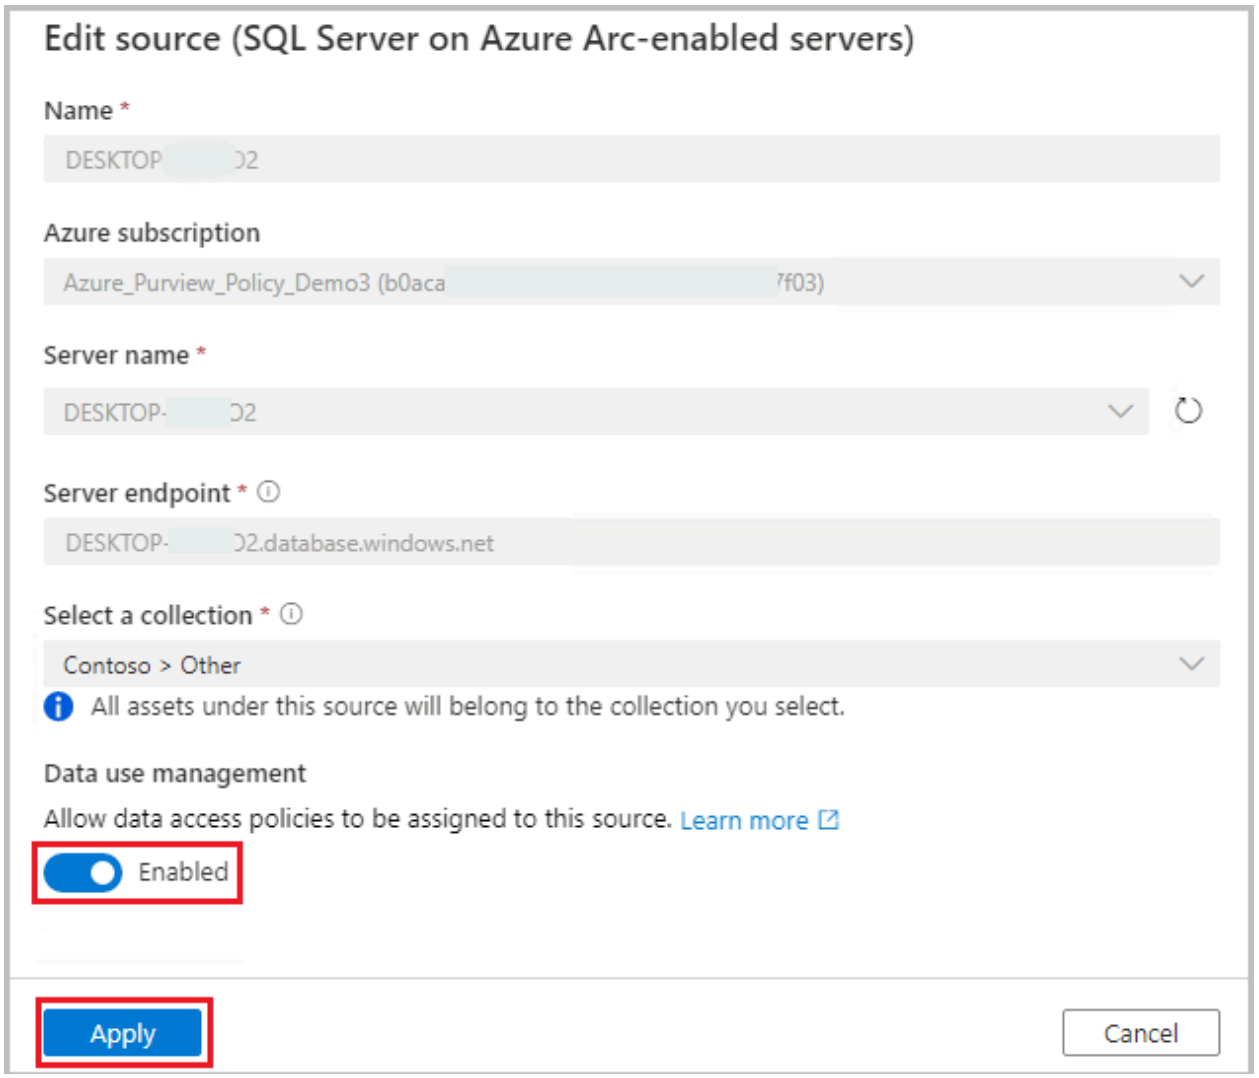
If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.

Register data sources in Microsoft Purview

The Azure Arc-enabled SQL Server data source needs to be registered first with Microsoft Purview, before policies can be created.

1. Sign in to Microsoft Purview Studio.
2. Navigate to the **Data map** feature on the left pane, select **Sources**, then select **Register**. Type "Azure Arc" in the search box and select **SQL Server on Azure Arc**. Then select **Continue**.

1. Enter a **Name** for this registration. It's best practice to make the name of the registration the same as the server name in the next step.



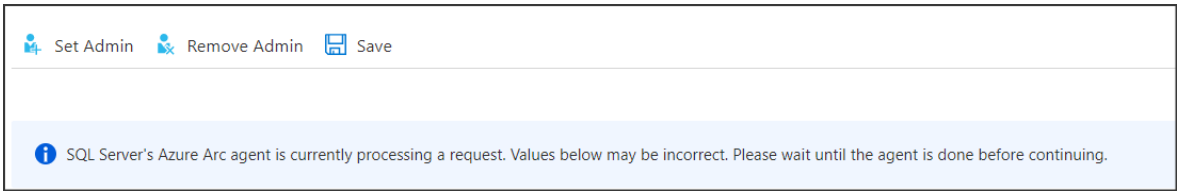
2. select an **Azure subscription**, **Server name**, and **Server endpoint**.

3. **Select a collection** to put this registration in.

4. Enable Data Policy Enforcement. Data Policy Enforcement needs certain permissions and can affect the security of your data, as it delegates to certain Microsoft Purview roles to manage access to the data sources. **Go through the secure practices related to Data Policy Enforcement in this guide**: How to enable Data Policy Enforcement

5. Select **Register** or **Apply** at the bottom.

Once your data source has the **Data policy enforcement** toggle *Enabled*, it will look like this picture.



Enable policies in Azure Arc-enabled SQL Server

This section describes the steps to configure SQL Server on Azure Arc to use Microsoft Purview. Execute these steps after you enable the *Data policy enforcement* option for this data source in the Microsoft Purview account.

1. Sign in to the Azure portal through this link
2. Navigate to **SQL servers** on the left pane. You'll see a list of SQL Server instances on Azure Arc.
3. Select the SQL Server instance that you want to configure.
4. Go to **Microsoft Entra ID** on the left pane.
5. Scroll down to **Microsoft Purview access policies**.
6. Select the button to **Check for Microsoft Purview Governance**. Wait while the request is processed. While that happens, this message will be displayed at the top

of the page. You might need to scroll up to see it.

7. At the bottom of the page, confirm that the Microsoft Purview Governance Status shows `Governed`. Note that **it may take up to 30 minutes** for the correct status to be reflected. Continue doing a browser refresh until that happens.

8. Confirm that the Microsoft Purview Endpoint points to the Microsoft Purview account where you registered this data source and enabled the *data policy enforcement*

Create a new DevOps policy

Follow this link for the steps to create a new DevOps policy in Microsoft Purview.

List DevOps policies

Follow this link for the steps to list DevOps policies in Microsoft Purview.

Update a DevOps policy

Follow this link for the steps to update a DevOps policies in Microsoft Purview.

Delete a DevOps policy

Follow this link for the steps to delete a DevOps policies in Microsoft Purview.

> **Important**
>
> DevOps policies are auto-published and changes can take up to **5 minutes** to be enforced by the data source.

Test the DevOps policy

See how to test the policy you created.

Provision access to system metadata on entire resource groups or subscriptions using Microsoft Purview DevOps policies

Article • 10/28/2024

> **Note**
>
> Microsoft Purview Data Map (classic), Data Catalog (classic), Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

DevOps policies are a type of Microsoft Purview access policies. They allow you to manage access to system metadata on data sources that have been registered for *Data policy enforcement* in Microsoft Purview. These policies are configured directly in the Microsoft Purview governance portal, and after they're saved, they get automatically published and then enforced by the data source. Microsoft Purview policies only manage access for Microsoft Entra principals.

This how-to guide covers how to register an entire resource group or subscription and then create a single policy that will provision access to **all** data sources in that resource group or subscription. That single policy will cover all existing data sources and any data sources that are created afterwards. And provisioning access to its system metadata (DMVs and DMFs) using the DevOps policies actions *SQL Performance Monitoring* or *SQL Security Auditing*.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- A new or existing Microsoft Purview account. Follow this quickstart guide to create one.

Only these data sources are enabled for access policies on resource group or subscription. Follow the **Prerequisites** section that is specific to the data sources in these guides:

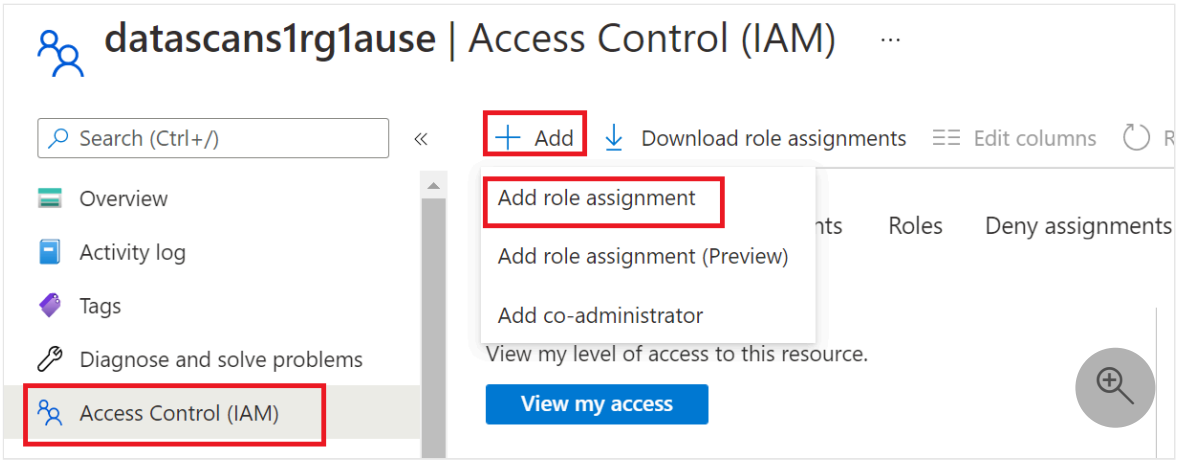
- DevOps policies on an Azure SQL Database

- DevOps policies on an Azure Arc-enabled SQL Server

Microsoft Purview Configuration

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.



> ⓘ **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

Configure permissions to enable Data policy enforcement on the data source

Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission inheritance):
  - IAM Owner
  - Both IAM Contributor and IAM User Access Administrator

  To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.

> **Note**
>
> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

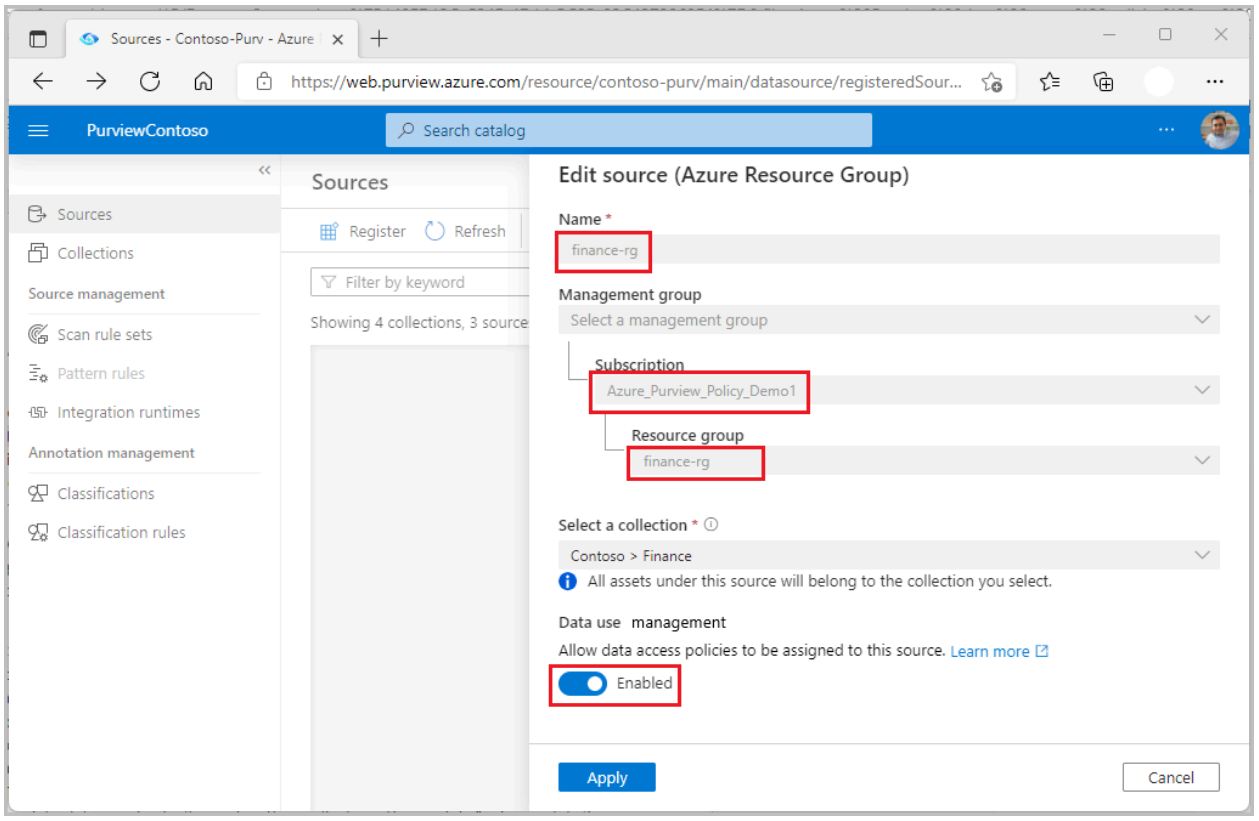
> **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

Delegate access provisioning responsibility to roles in Microsoft Purview

After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin* role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.

If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.



Register the subscription or resource group for Data Policy Enforcement

The subscription or resource group needs to be registered with Microsoft Purview before you can create access policies. To register your subscription or resource group, follow the **Prerequisites** and **Register** sections of this guide:

- Register multiple sources in Microsoft Purview

After you've registered your resources, you'll need to enable the Data Policy Enforcement option. Data Policy Enforcement needs certain permissions and can affect the security of your data, as it delegates to certain Microsoft Purview roles to manage access to the data sources. **Go through the secure practices related to Data Policy Enforcement in this guide**: How to enable Data Policy Enforcement

In the end, your resource will have the **Data Policy Enforcement** toggle **Enabled**, as shown in the screenshot:

Create a new DevOps policy

Follow this link for the steps to create a new DevOps policy in Microsoft Purview.

List DevOps policies

Follow this link for the steps to list DevOps policies in Microsoft Purview.

Update a DevOps policy

Follow this link for the steps to update a DevOps policies in Microsoft Purview.

Delete a DevOps policy

Follow this link for the steps to delete a DevOps policies in Microsoft Purview.

Test the DevOps policy

See how to test the policy you created.

Role definition detail

See the mapping of DevOps role to data source actions.

Next steps

See related videos, blogs, and documents.

Tutorial: Access provisioning by data owner to Azure Storage datasets (preview)

Article • 02/26/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Policies in Microsoft Purview allow you to enable access to data sources that have been registered to a collection. This tutorial describes how a data owner can use Microsoft Purview to enable access to datasets in Azure Storage through Microsoft Purview.

In this tutorial, you learn how to:

- ✓ Prepare your Azure environment
- ✓ Configure permissions to allow Microsoft Purview to connect to your resources
- ✓ Register your Azure Storage resource for Data Policy Enforcement
- ✓ Create and publish a policy for your resource group or subscription

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- A new or existing Microsoft Purview account. Follow this quickstart guide to create one.

Region support

- All Microsoft Purview regions are supported.

- Storage accounts in the following regions are supported without the need for additional configuration. However, zone-redundant storage (ZRS) accounts are not supported.
  - Australia Central
  - Australia East
  - Australia Southeast
  - Brazil South
  - Canada Central
  - Canada East
  - Central India
  - Central US
  - East Asia
  - East US 2
  - East US
  - France Central
  - Germany West Central
  - Japan East
  - Japan West
  - Korea Central
  - North Central US
  - North Europe
  - Norway East
  - Poland Central
  - Qatar Central
  - South Central US
  - South Africa North
  - Southeast Asia
  - South India
  - Sweden Central
  - Switzerland North
  - West Central US
  - West Europe
  - West US
  - West US 2
  - West US 3
  - UAE North
  - UK South
  - UK West
- Storage accounts in other regions in Public Cloud are supported after setting feature flag *AllowPurviewPolicyEnforcement*, as outlined in the next section. Newly

created ZRS Storage accounts are supported, if created after setting the feature flag *AllowPurviewPolicyEnforcement*.

If needed, you can create a new Storage account by following this guide.

Configure the subscription where the Azure Storage account resides for policies from Microsoft Purview

This step is only necessary in certain regions (see prior section). To enable Microsoft Purview to manage policies for one or more Azure Storage accounts, execute the following PowerShell commands in the subscription where you'll deploy your Azure Storage account. These PowerShell commands will enable Microsoft Purview to manage policies on all Azure Storage accounts in that subscription.

If you're executing these commands locally, be sure to run PowerShell as an administrator. Alternatively, you can use the Azure Cloud Shell in the Azure portal: https://shell.azure.com.

PowerShell

```
# Install the Az module
Install-Module -Name Az -Scope CurrentUser -Repository PSGallery -Force
# Login into the subscription
Connect-AzAccount -Subscription <SubscriptionID>
# Register the feature
Register-AzProviderFeature -FeatureName AllowPurviewPolicyEnforcement -
ProviderNamespace Microsoft.Storage
```

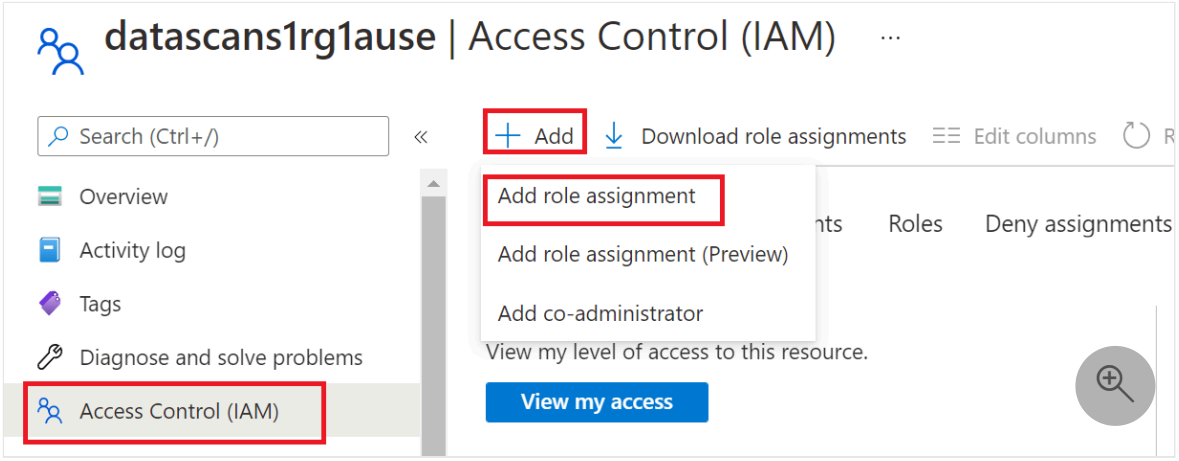
If the output of the last command shows *RegistrationState* as *Registered*, then your subscription is enabled for access policies. If the output is *Registering*, wait at least 10 minutes, and then retry the command. **Do not continue unless the RegistrationState shows as *Registered***.

Configuration

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.

Note



Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

Configure permissions to enable Data policy enforcement on the data source

Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission inheritance):
  - IAM Owner
  - Both IAM Contributor and IAM User Access Administrator

  To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.

> **Note**
>
> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

Delegate access provisioning responsibility to roles in Microsoft Purview

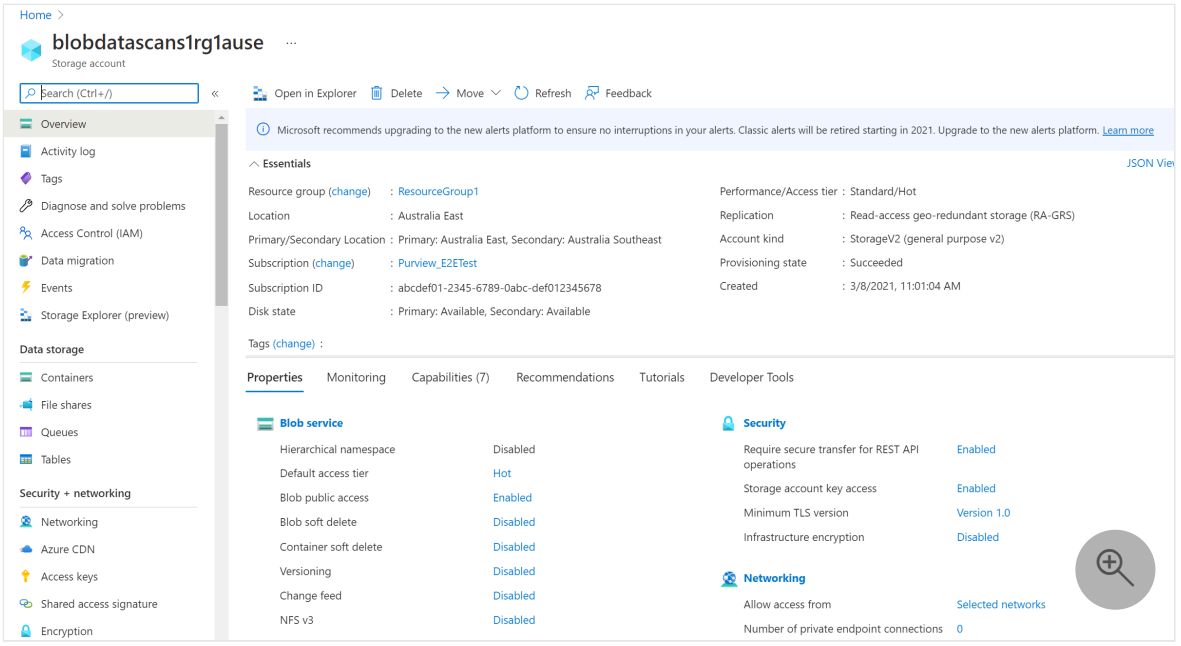
After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin* role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.

If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to

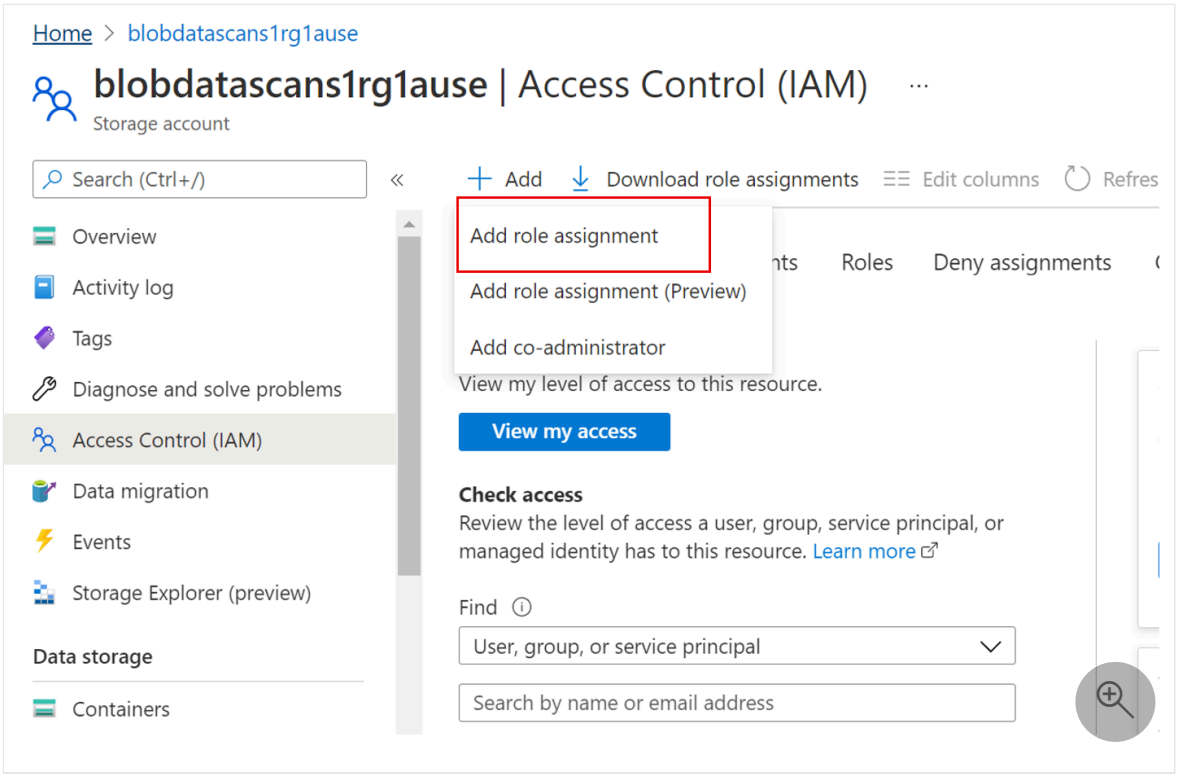
prevent the Microsoft Purview account from being deleted through Resource Manager locks.

Register the data sources in Microsoft Purview for Data Policy Enforcement



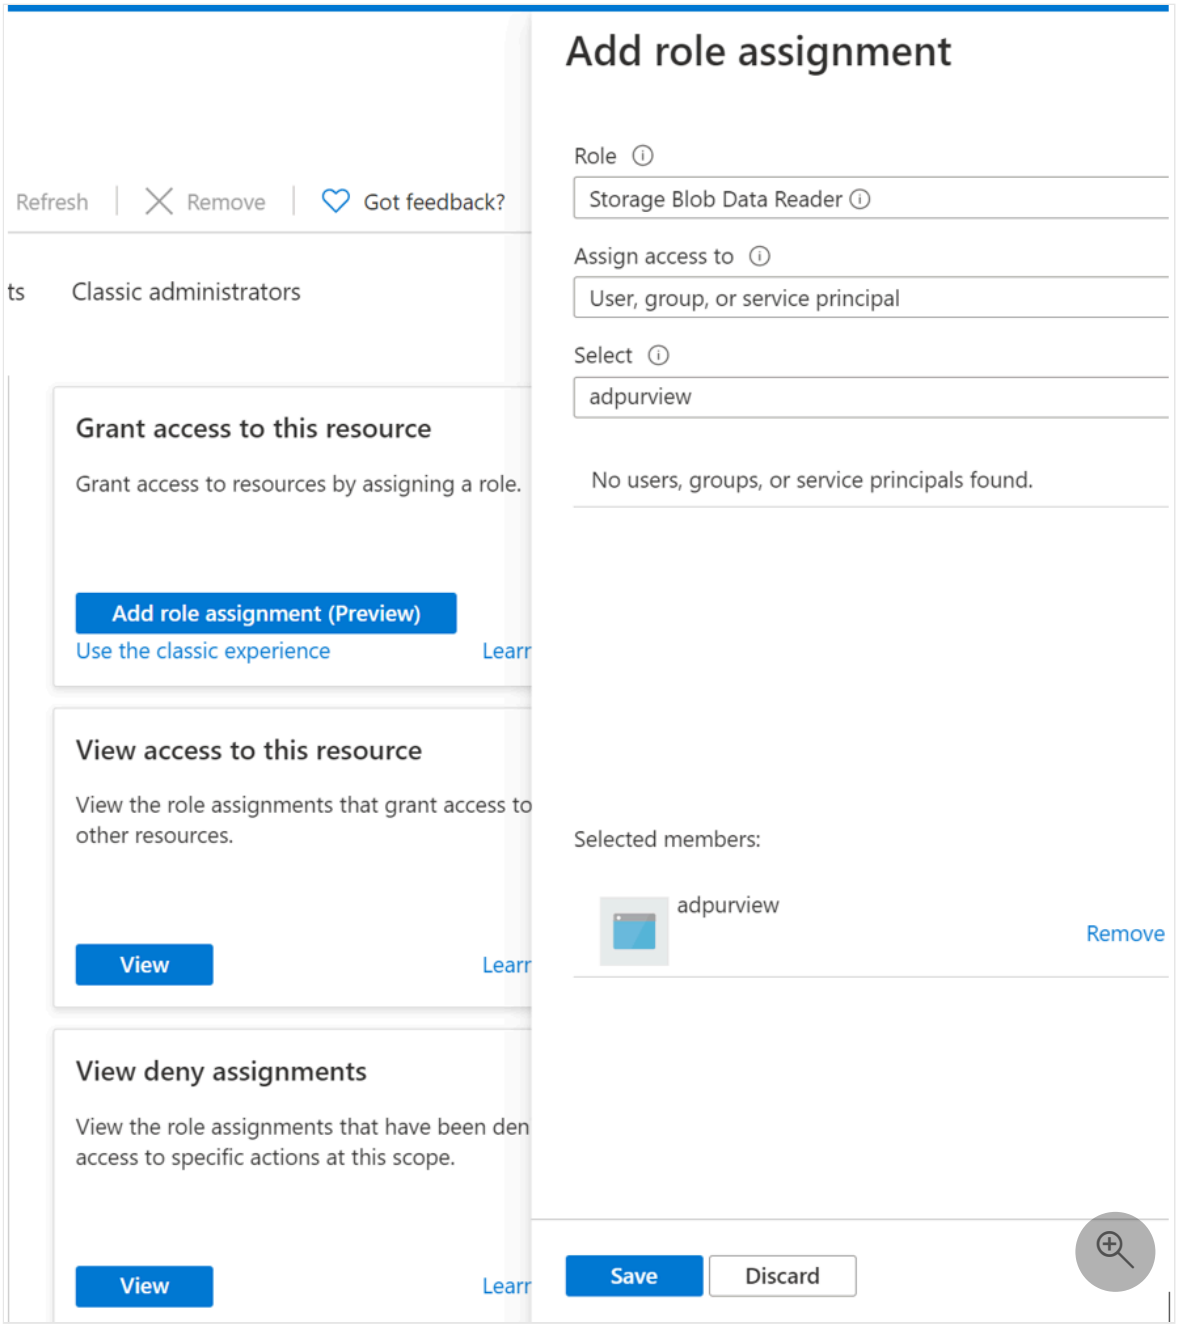
Your Azure Storage account needs to be registered in Microsoft Purview to later define access policies, and during registration we'll enable Data Policy Enforcement. **Data Policy Enforcement** is an available feature in Microsoft Purview that allows users to manage access to a resource from within Microsoft Purview. This allows you to centralize data discovery and access management, however it's a feature that directly impacts your data security.

> ⚠ **Warning**
>
> Before enabling Data Policy Enforcement for any of your resources, read through our **Data Policy Enforcement article**.
>
> This article includes Data Policy Enforcement best practices to help you ensure that your information is secure.



To register your resource and enable Data Policy Enforcement, follow these steps:

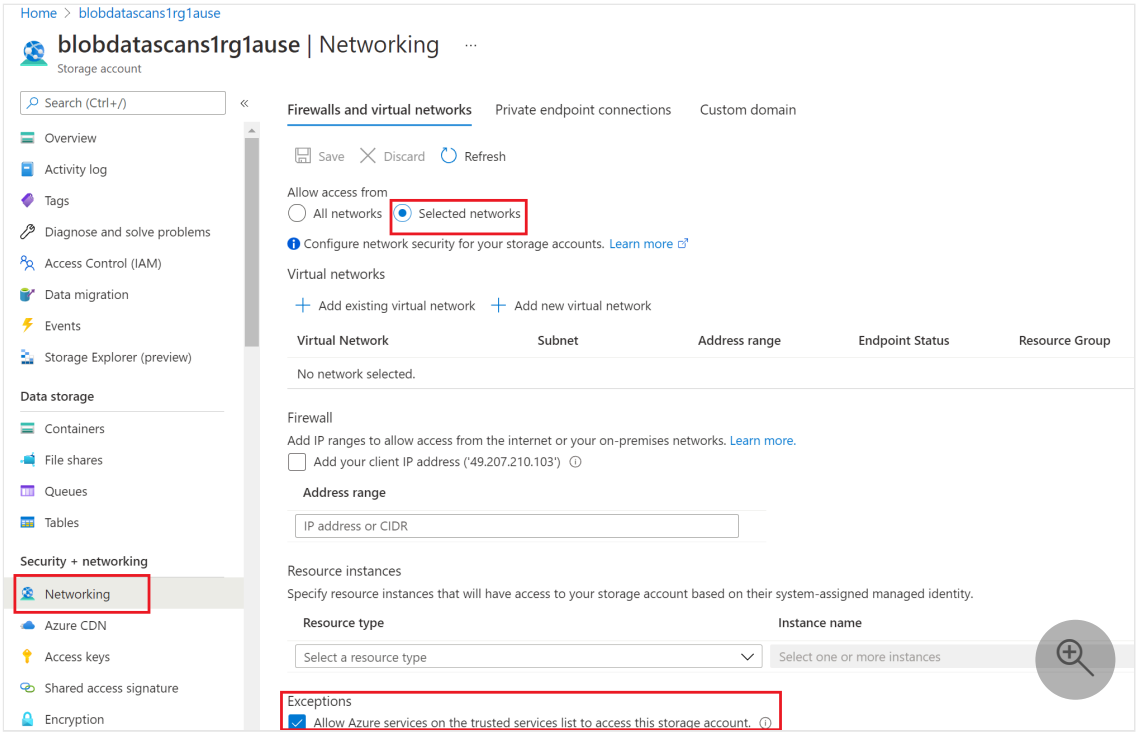
> ⓘ **Note**
>
> You need to be an owner of the subscription or resource group to be able to add a managed identity on an Azure resource.



1. From the Azure portal, find the Azure Blob storage account that you would like to register.

2. Select **Access Control (IAM)** in the left navigation and then select **+ Add** --> **Add role assignment**.

3. Set the **Role** to **Storage Blob Data Reader** and enter your *Microsoft Purview account name* under the **Select** input box. Then, select **Save** to give this role assignment to your Microsoft Purview account.



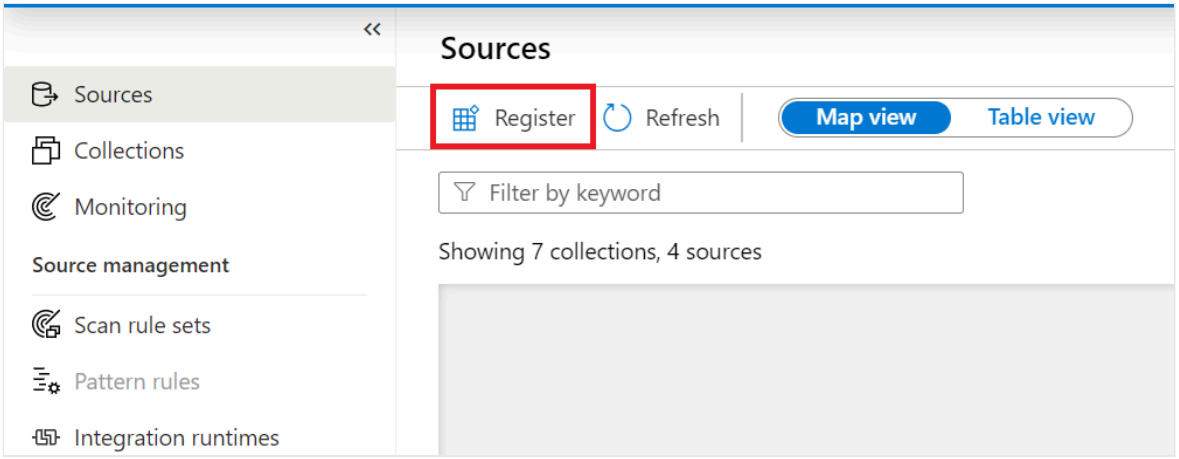
4. If you have a firewall enabled on your Storage account, follow these steps as well:

   a. Go into your Azure Storage account in Azure portal.

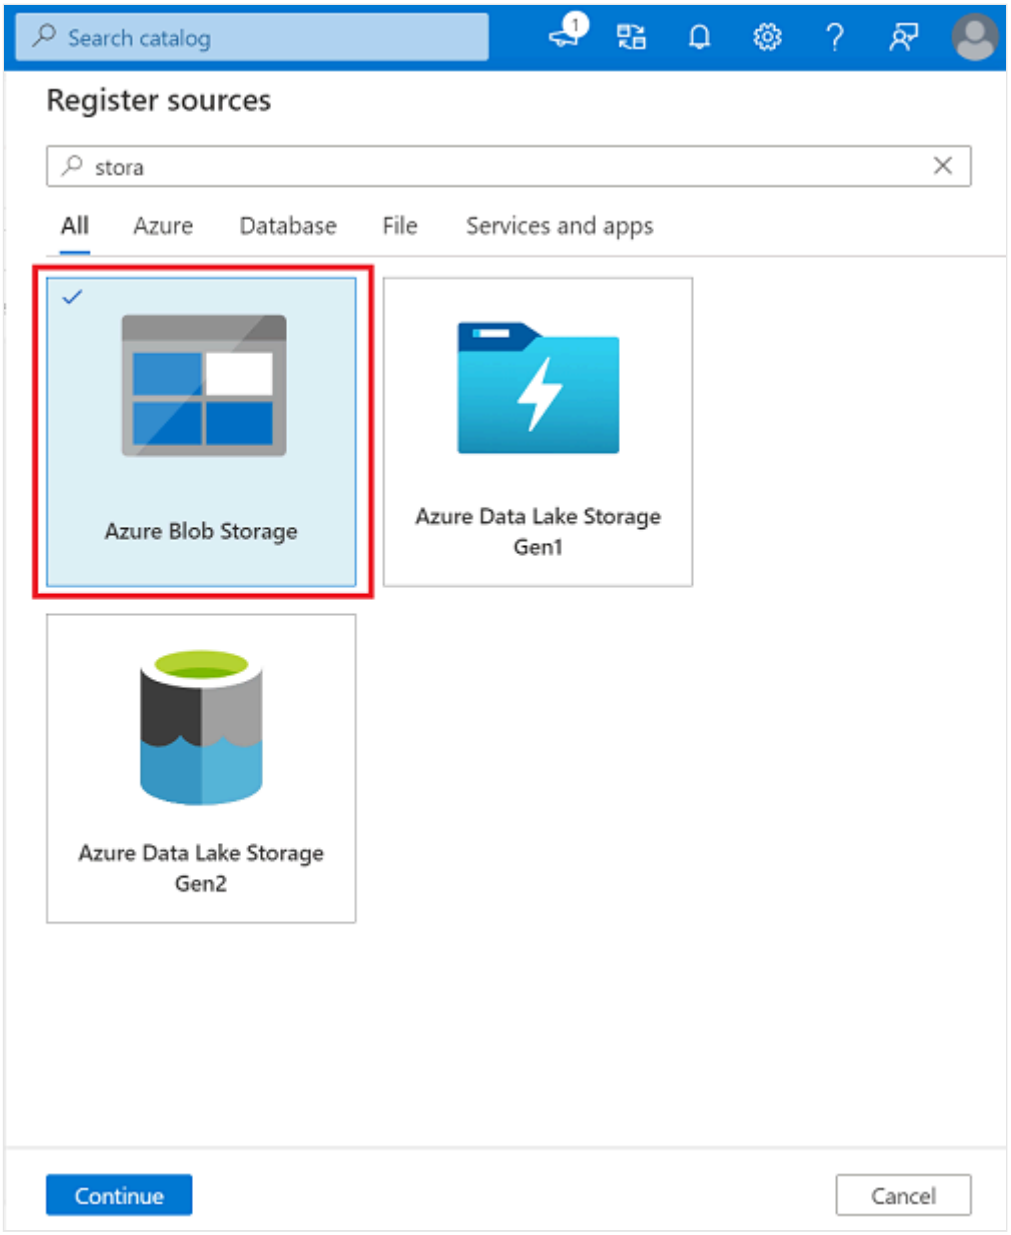
   b. Navigate to **Security + networking** > **Networking**.

   c. Choose **Selected Networks** under **Allow access from**.

   d. In the **Exceptions** section, select **Allow trusted Microsoft services to access this storage account** and select **Save**.



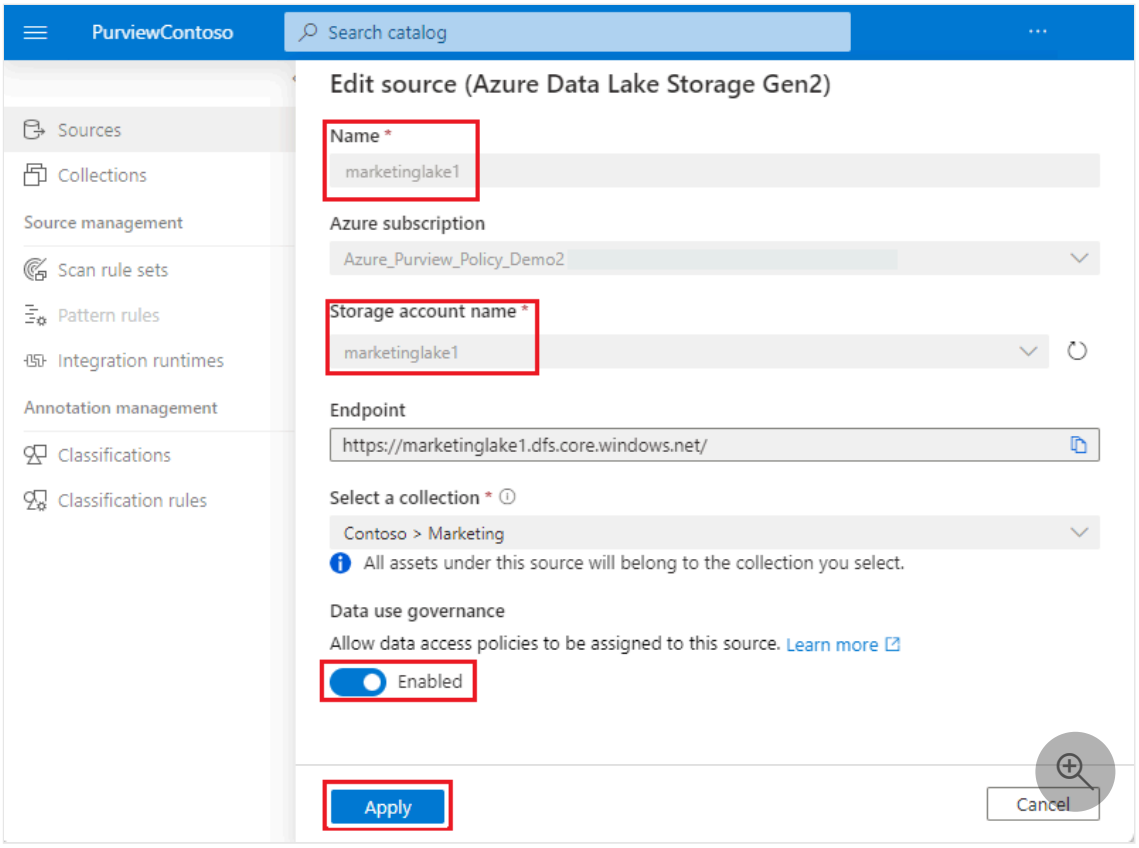
5. Once you have set up authentication for your storage account, go to the Microsoft Purview governance portal.



6. Select **Data Map** on the left menu.

7. Select **Register**.

8. On **Register sources**, select **Azure Blob Storage**.



9. Select **Continue**.

10. On the **Register sources (Azure)** screen, do the following:

    a. In the **Name** box, enter a friendly name that the data source will be listed with in the catalog.

    b. In the **Subscription** dropdown list boxes, select the subscription where your storage account is housed. Then select your storage account under **Storage account name**. In **Select a collection** select the collection where you'd like to register your Azure Storage account.

c. In the **Select a collection** box, select a collection or create a new one (optional).

d. Set the *Data Policy Enforcement* toggle to **Enabled**, as shown in the image below.

> **Tip**

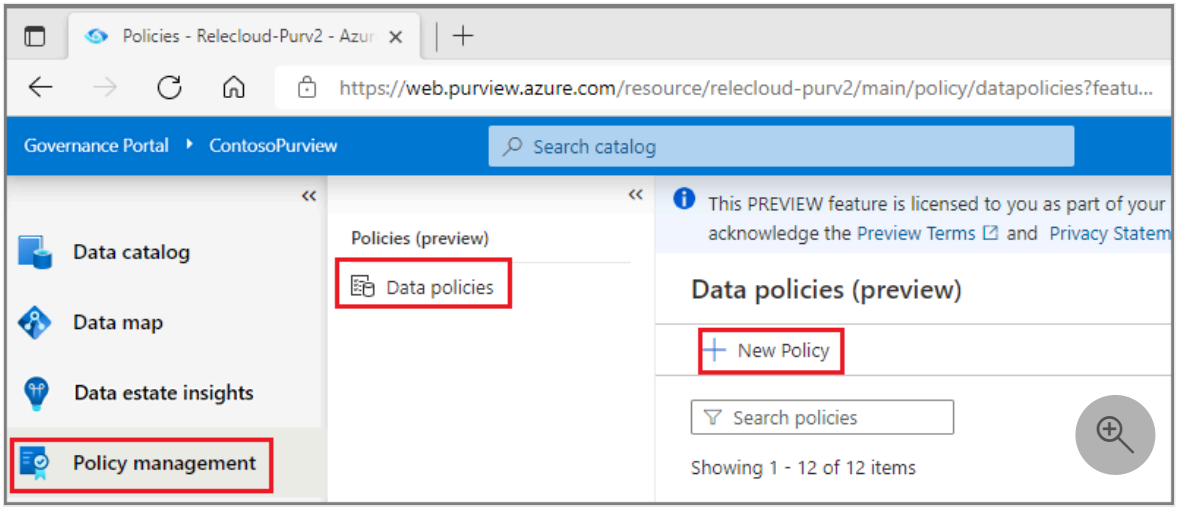
If the Data Policy Enforcement toggle is greyed out and unable to be selected:

i. Confirm you have followed all prerequisites to enable Data Policy Enforcement across your resources.

ii. Confirm that you have selected a storage account to be registered.

iii. It may be that this resource is already registered in another Microsoft Purview account. Hover over it to know the name of the Microsoft Purview account that has registered the data resource.first. Only one Microsoft Purview account can register a resource for Data Policy Enforcement at at time.

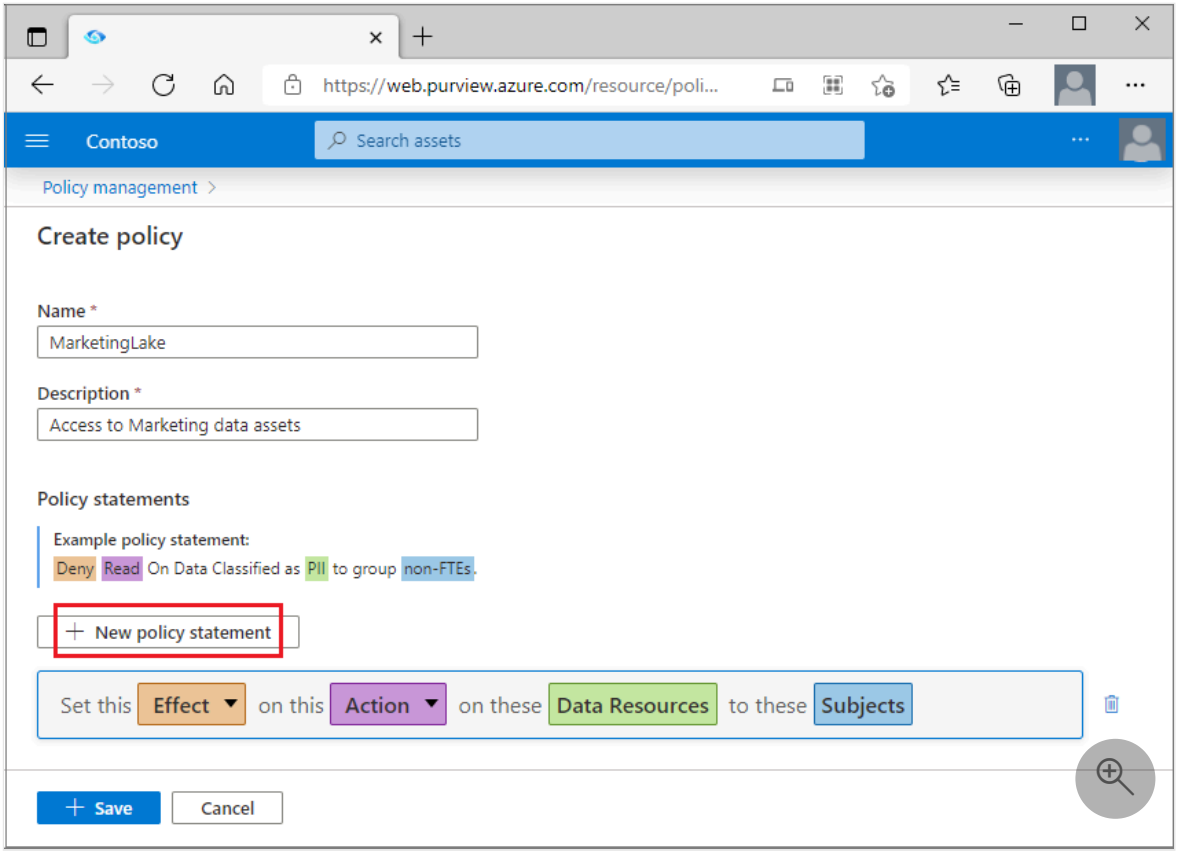
e. Select **Register** to register the resource group or subscription with Microsoft Purview with Data Policy Enforcement enabled.



> **Tip**
>
> For more information about Data Policy Enforcement, including best practices or known issues, see our Data Policy Enforcement article.

Create a data owner policy

1. Sign in to the Microsoft Purview governance portal.

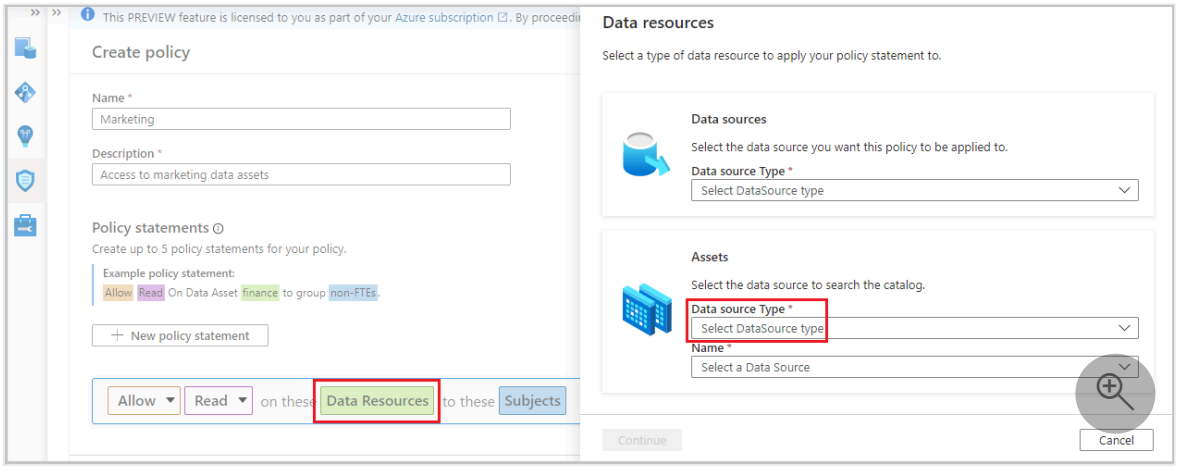


2. Navigate to the **Data policy** feature using the left side panel. Then select **Data policies**.

3. Select the **New Policy** button in the policy page.

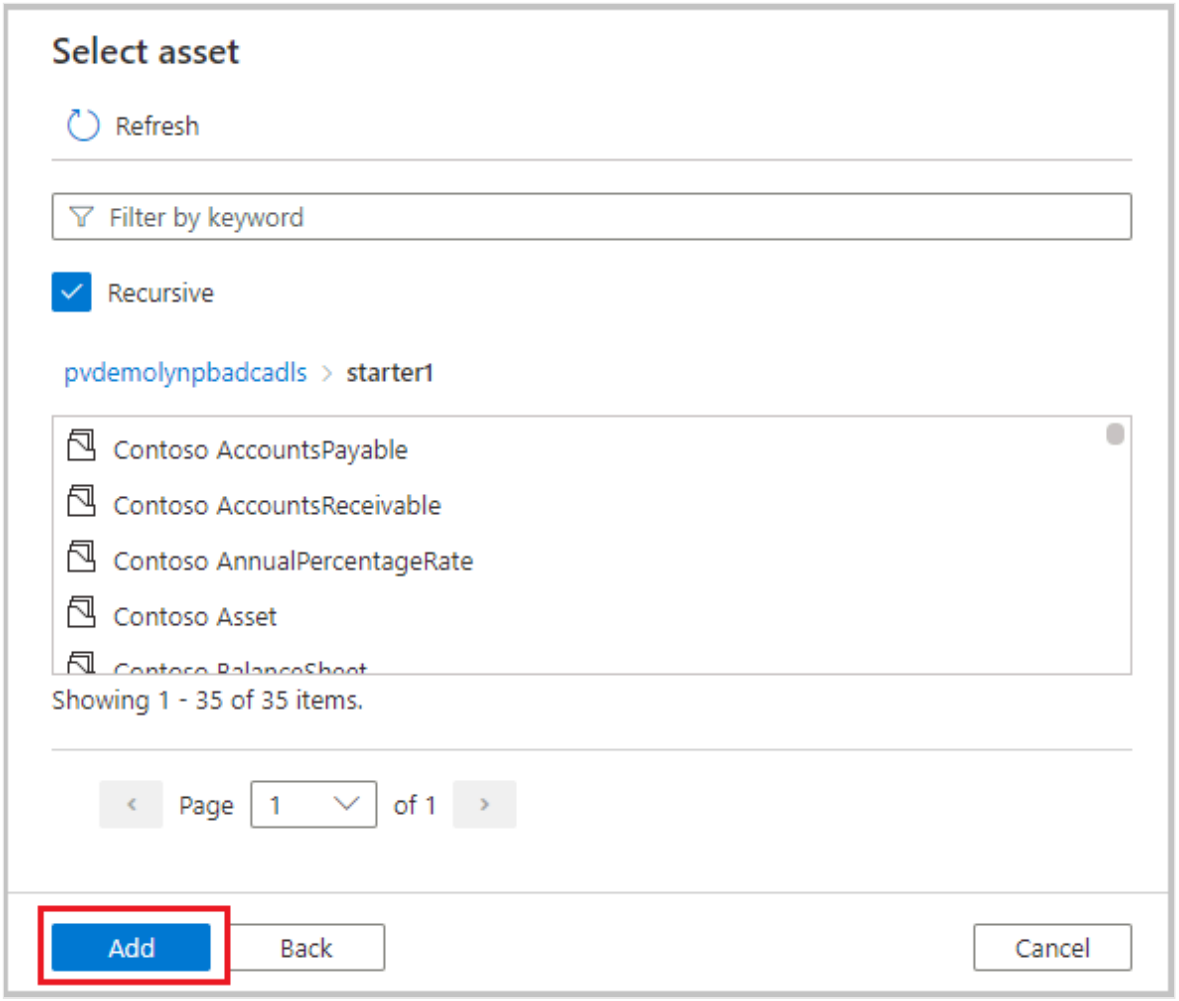
4. The new policy page will appear. Enter the policy **Name** and **Description**.

5. To add a policy statement to the new policy, select the **New policy statement** button. This will bring up the policy statement builder.



6. Select the **Effect** button and choose *Allow* from the drop-down list.

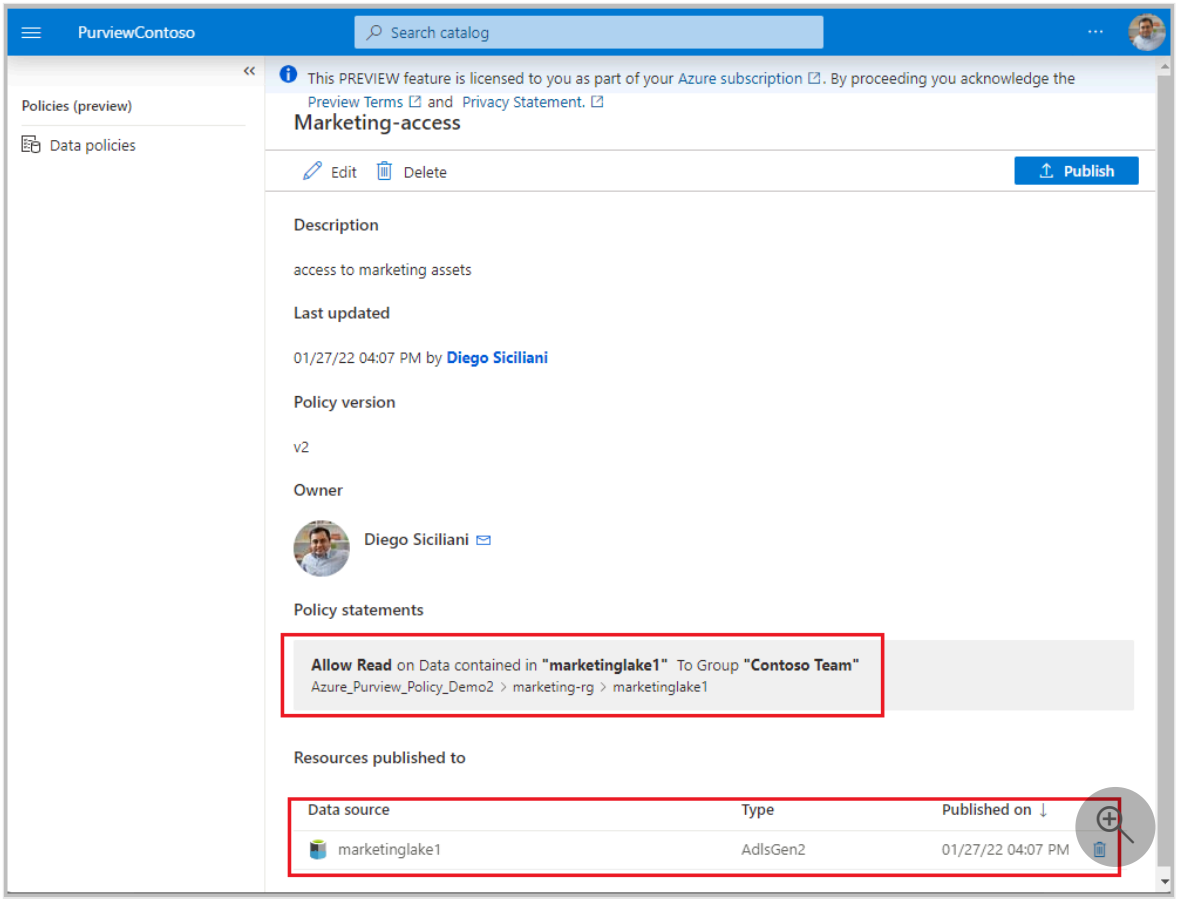
7. Select the **Action** button and choose *Read* or *Modify* from the drop-down list.



8. Select the **Data Resources** button to bring up the window to enter Data resource information, which will open to the right.

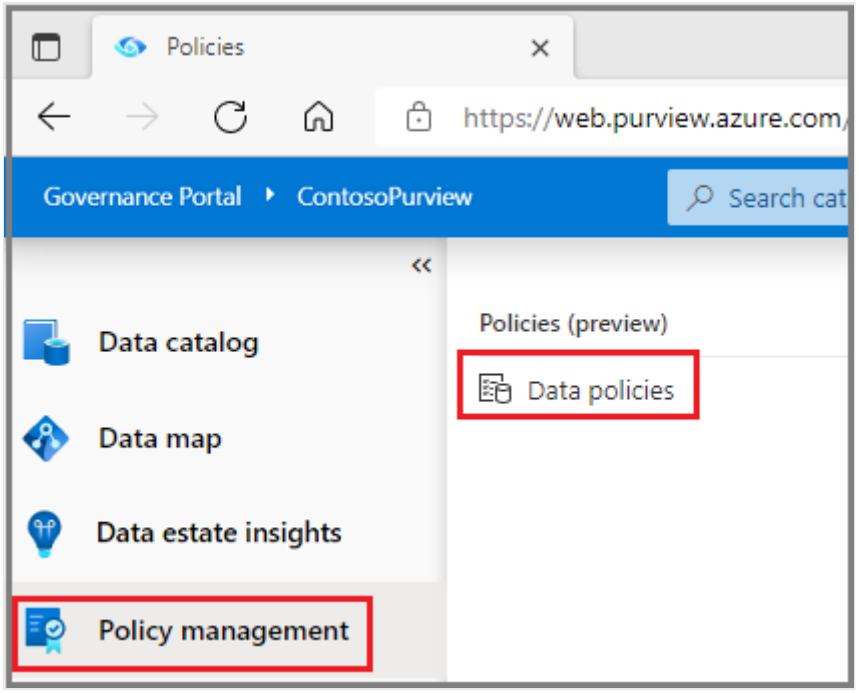
9. Under the **Data Resources** Panel do one of two things depending on the granularity of the policy:

    - To create a broad policy statement that covers an entire data source, resource group, or subscription that was previously registered, use the **Data sources** box and select its **Type**.
    - To create a fine-grained policy, use the **Assets** box instead. Enter the **Data Source Type** and the **Name** of a previously registered and scanned data source. See example in the image.

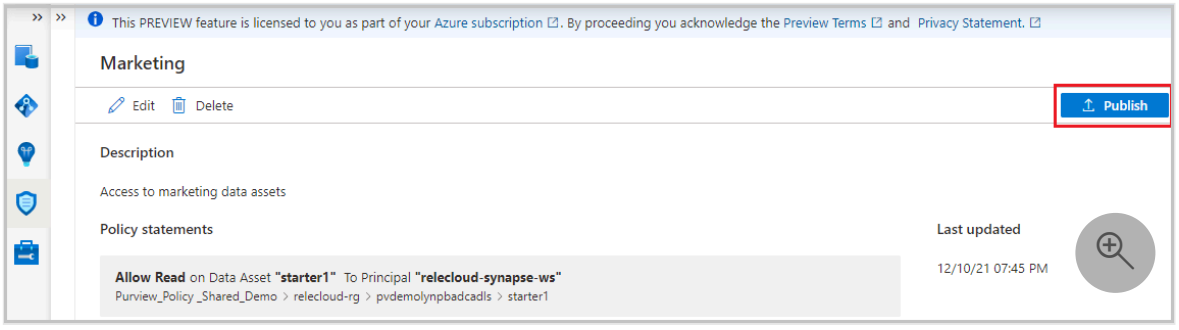


10. Select the **Continue** button and traverse the hierarchy to select and underlying data-object (for example: folder, file, etc.). Select **Recursive** to apply the policy from that point in the hierarchy down to any child data-objects. Then select the **Add** button. This will take you back to the policy editor.

11. Select the **Subjects** button and enter the subject identity as a principal, group, or MSI. Then select the **OK** button. This will take you back to the policy editor

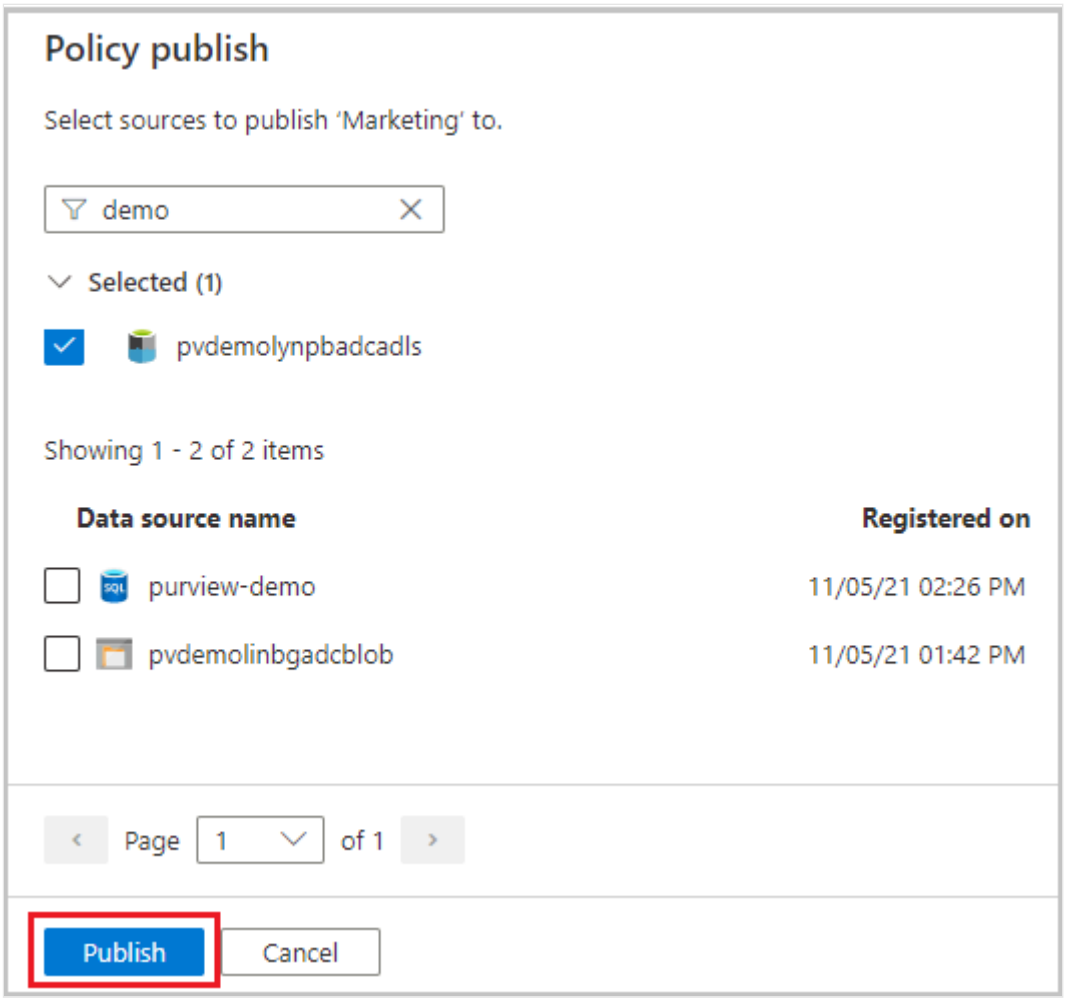


12. Select the **Save** button to save the policy.



Publish a data owner policy

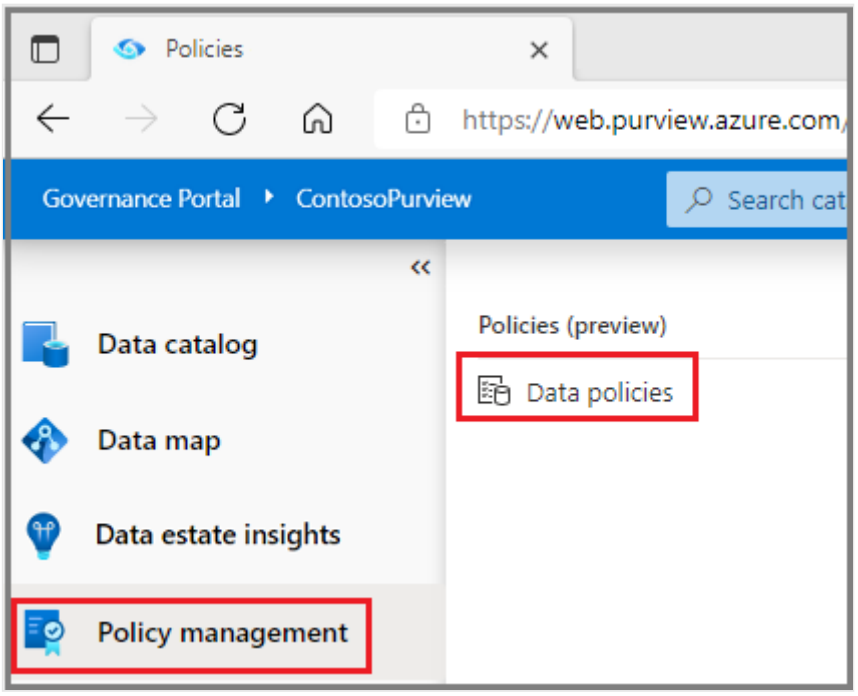
1. Sign in to the Microsoft Purview governance portal.



2. Navigate to the **Data policy** feature using the left side panel. Then select **Data policies**.

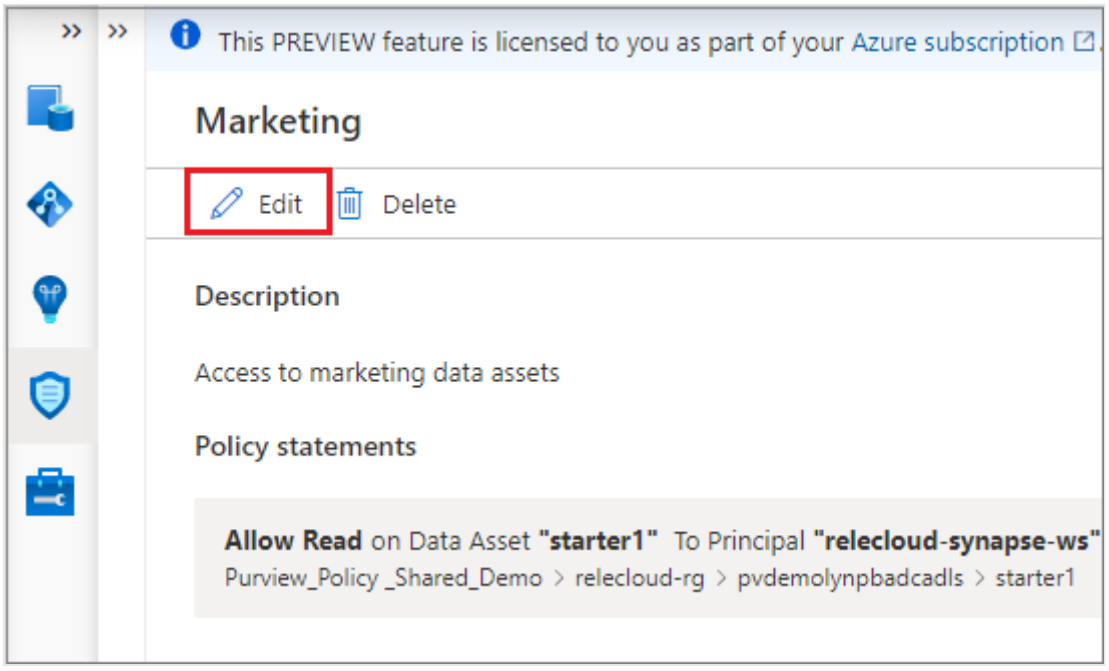
3. The Policy portal will present the list of existing policies in Microsoft Purview. Locate the policy that needs to be published. Select the **Publish** button on the right top corner of the page.

4. A list of data sources is displayed. You can enter a name to filter the list. Then, select each data source where this policy is to be published and then select the **Publish** button.



> **ⓘ Important**
>
> - Publish is a background operation. It can take up to **2 hours** for the changes to be reflected in Storage account(s).

Clean up resources



To delete a policy in Microsoft Purview, follow these steps:

1. Sign in to the Microsoft Purview governance portal.
2. Navigate to the **Data policy** feature using the left side panel. Then select **Data policies**.

3. The Policy portal will present the list of existing policies in Microsoft Purview. Select the policy that needs to be updated.

4. The policy details page will appear, including Edit and Delete options. Select the **Edit** button, which brings up the policy statement builder. Now, any parts of the statements in this policy can be updated. To delete the policy, use the **Delete** button.

Authoring and publishing Microsoft Purview Data owner policies (preview)

Article • 02/24/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Data owner policies are a type of Microsoft Purview access policies. They allow you to manage access to user data in sources that have been registered for *Data Policy Enforcement* in Microsoft Purview. These policies can be authored directly in the Microsoft Purview governance portal, and after publishing, they get enforced by the data source.

This guide describes how to create, update, and publish data owner policies in the Microsoft Purview governance portal.

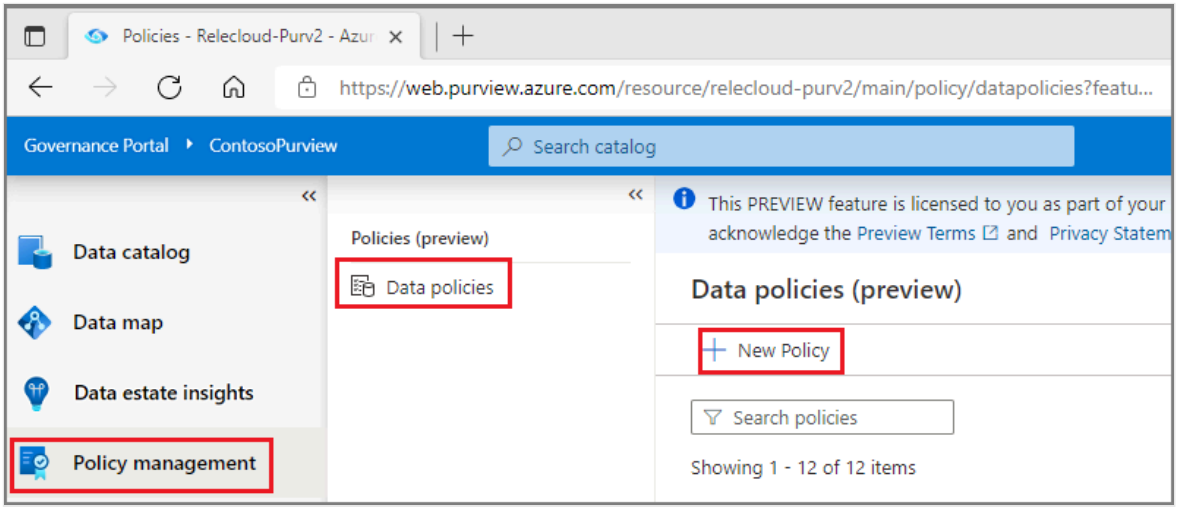
Prerequisites

- An Azure account with an active subscription. Create an account for free.
- A new or existing Microsoft Purview account. Follow this quickstart guide to create one.

Configuration

Before authoring policies in the Microsoft Purview policy portal, you'll need to configure Microsoft Purview and the data sources so that they can enforce those policies.

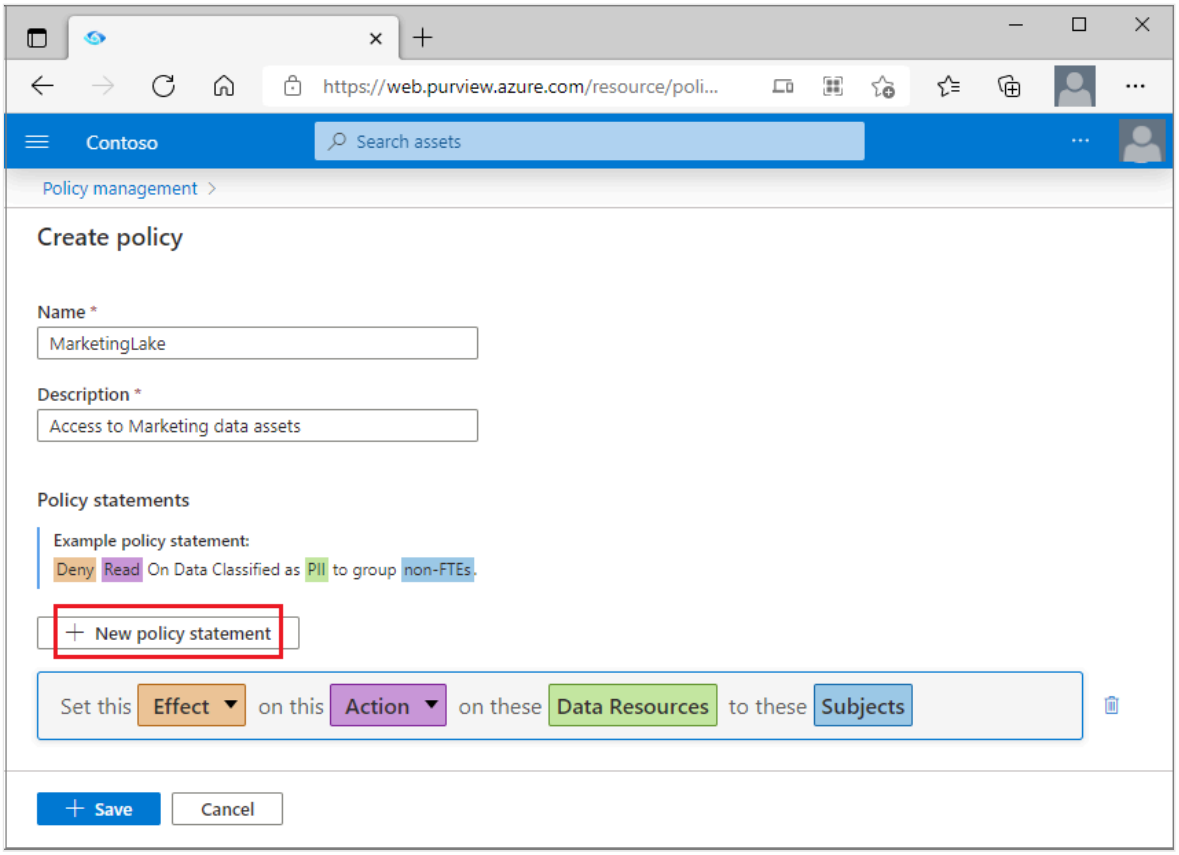
1. Follow any policy-specific prerequisites for your source. Check the Microsoft Purview supported data sources table and select the link in the **Access Policy** column for sources where access policies are available. Follow any steps listed in the Access policy or Prerequisites sections.
2. Register the data source in Microsoft Purview. Follow the **Prerequisites** and **Register** sections of the source pages for your resources.
3. Enable the Data policy enforcement option on the data source registration. Data Policy Enforcement needs certain permissions and can affect the security of your data, as it delegates to certain Microsoft Purview roles to manage access to the data sources. **Go through the secure practices related to Data Policy Enforcement in this guide**: How to enable Data Policy Enforcement



Create a new policy

This section describes the steps to create a new policy in Microsoft Purview. Ensure you have the *Policy Author* permission as described here.

1. Sign in to the Microsoft Purview governance portal.

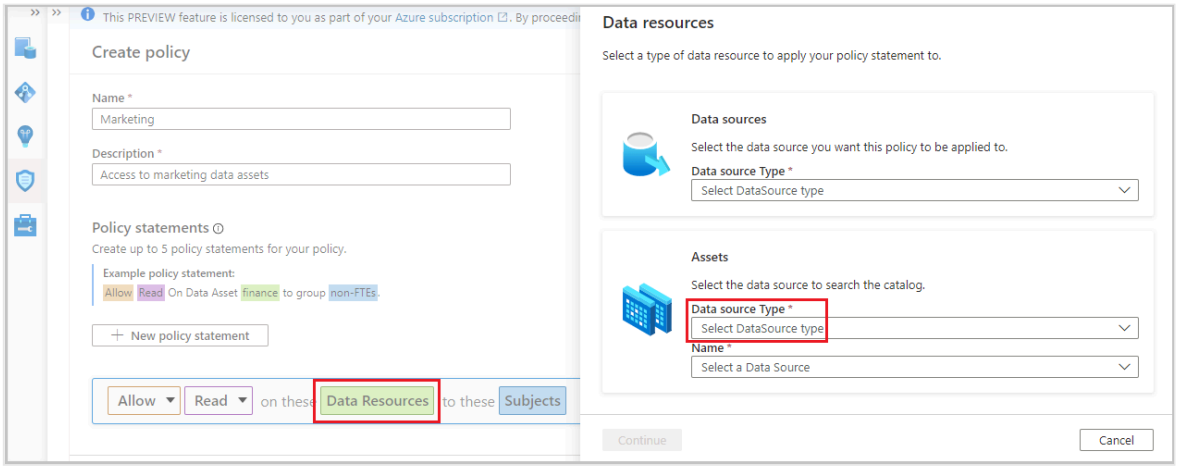


2. Navigate to the **Data policy** feature using the left side panel. Then select **Data policies**.

3. Select the **New Policy** button in the policy page.

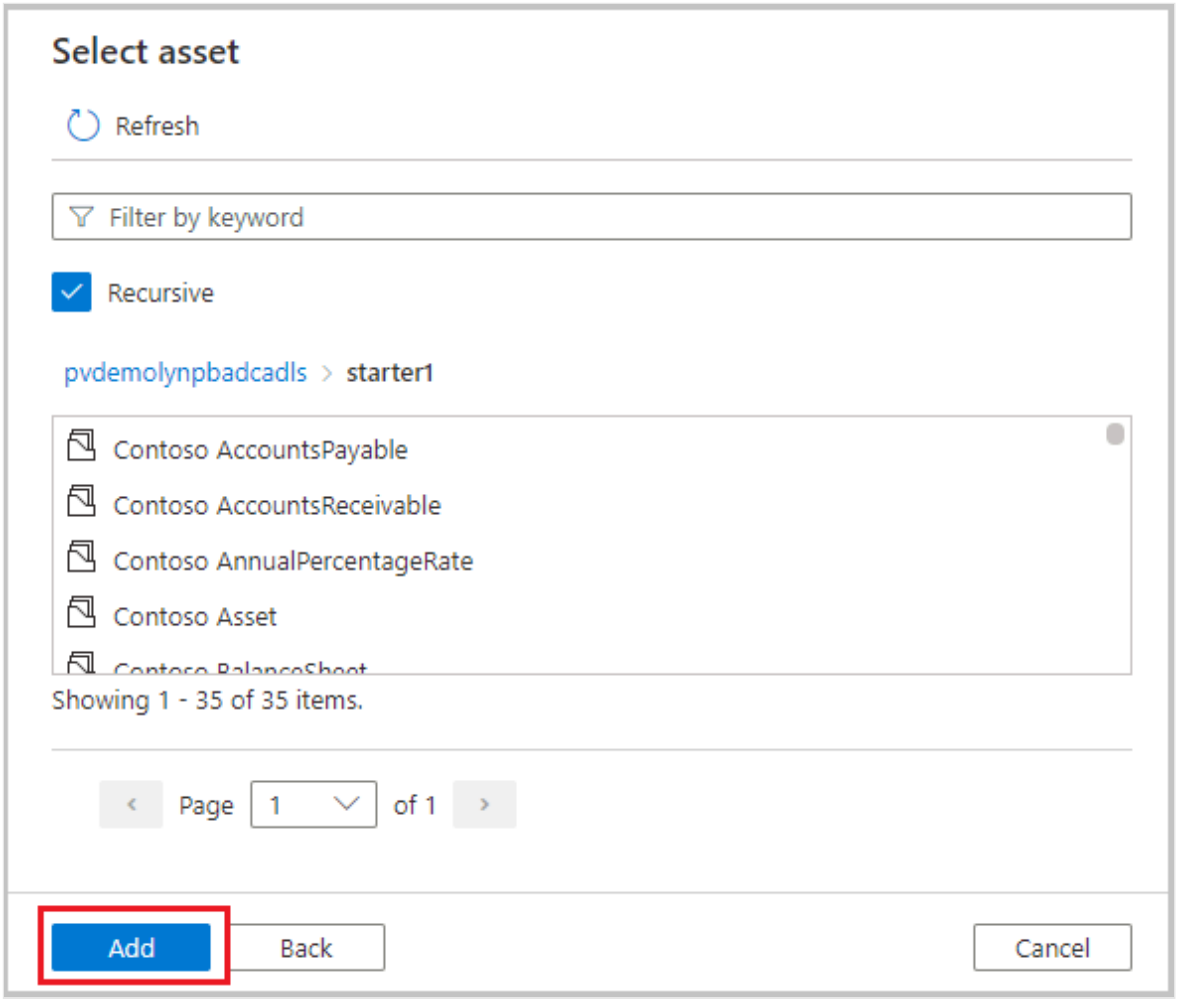
4. The new policy page will appear. Enter the policy **Name** and **Description**.

5. To add a policy statement to the new policy, select the **New policy statement** button. This will bring up the policy statement builder.



6. Select the **Effect** button and choose *Allow* from the drop-down list.

7. Select the **Action** button and choose *Read* or *Modify* from the drop-down list.



8. Select the **Data Resources** button to bring up the window to enter Data resource information, which will open to the right.

9. Under the **Data Resources** Panel do **one of two things** depending on the granularity of the policy:

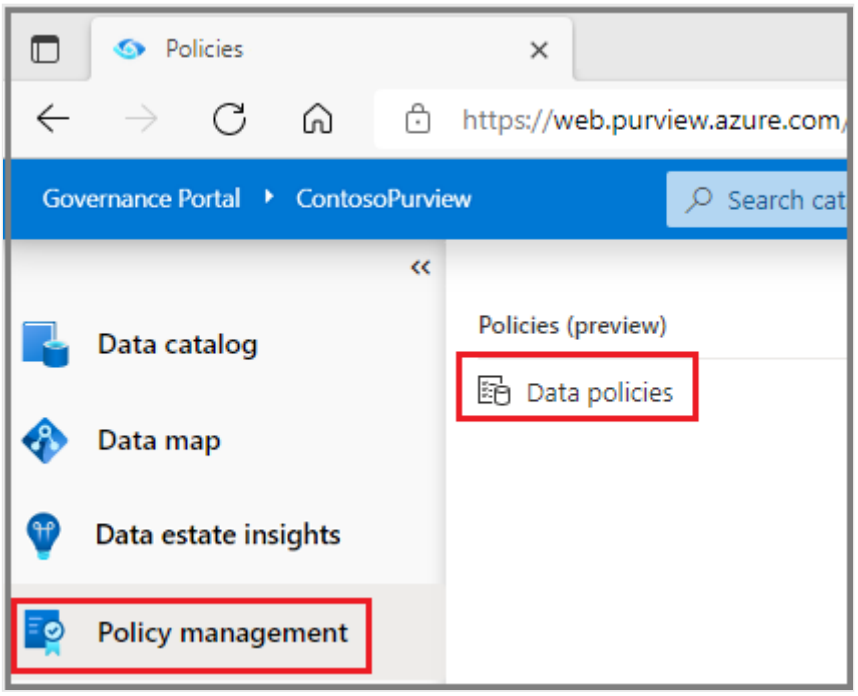
    - To create a broad policy statement that covers an entire data source, resource group, or subscription that was previously registered, use the **Data sources** box and select its **Type**.
    - To create a fine-grained policy, use the **Assets** box instead. Enter the **Data Source Type** and the **Name** of a previously registered and scanned data source. See example in the image.

10. Select the **Continue** button and transverse the hierarchy to select and underlying data-object (for example: folder, file, etc.). Select **Recursive** to apply the policy from that point in the hierarchy down to any child data-objects. Then select the **Add** button. This will take you back to the policy editor.

11. Select the **Subjects** button and enter the subject identity as a principal, group, or MSI. Note that Microsoft 365 groups are supported but updates to group membership take up to 1 hour to get reflected by Microsoft Entra ID. Then select the **OK** button. This will take you back to the policy editor.

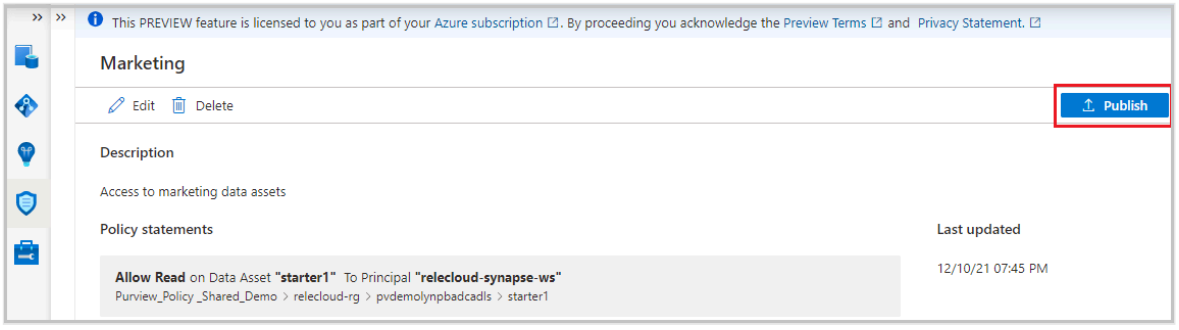
12. Select the **Save** button to save the policy.

Now that you have created your policy, you will need to publish it for it to become active.



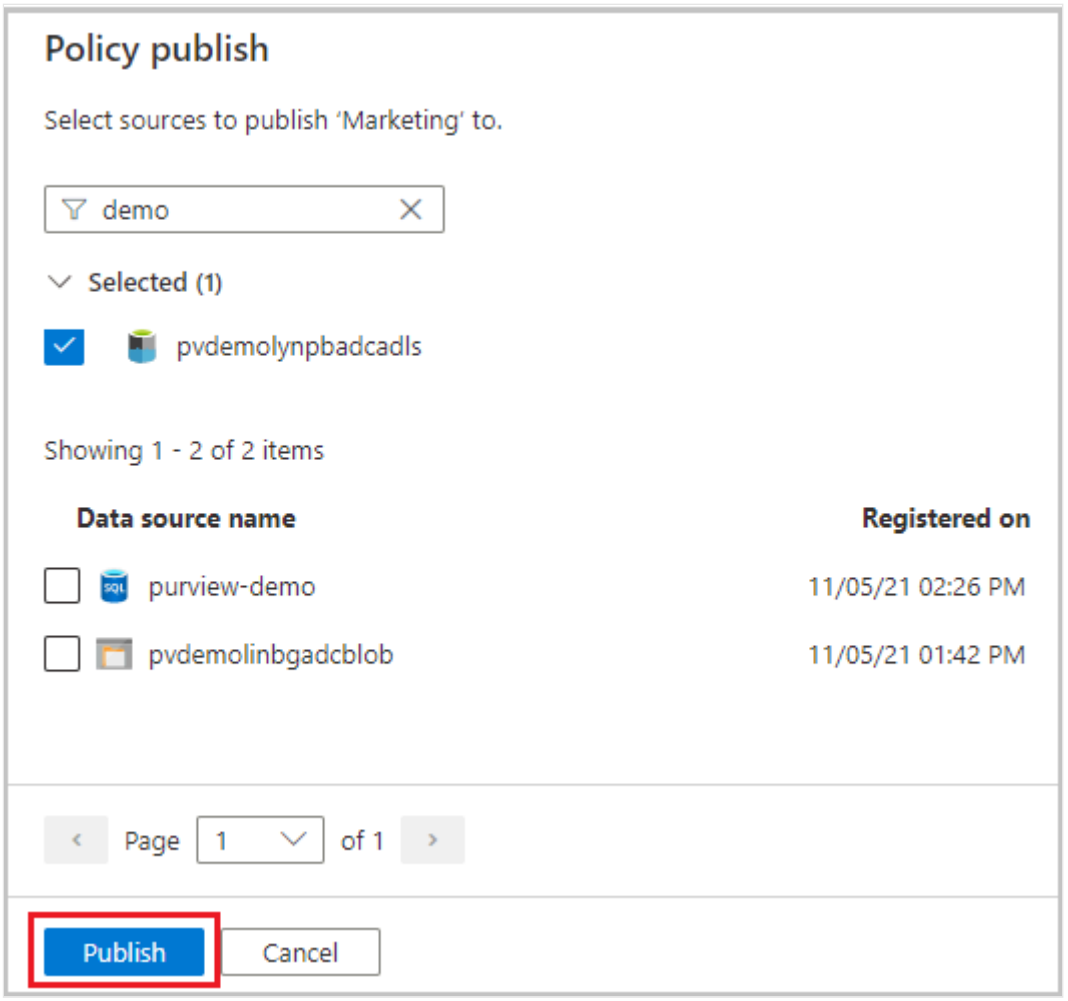
Publish a policy

A newly created policy is in the **draft** state. The process of publishing associates the new policy with one or more data sources under governance. This is called "binding" a policy to a data source.



Ensure you have the *Data Source Admin* permission as described here

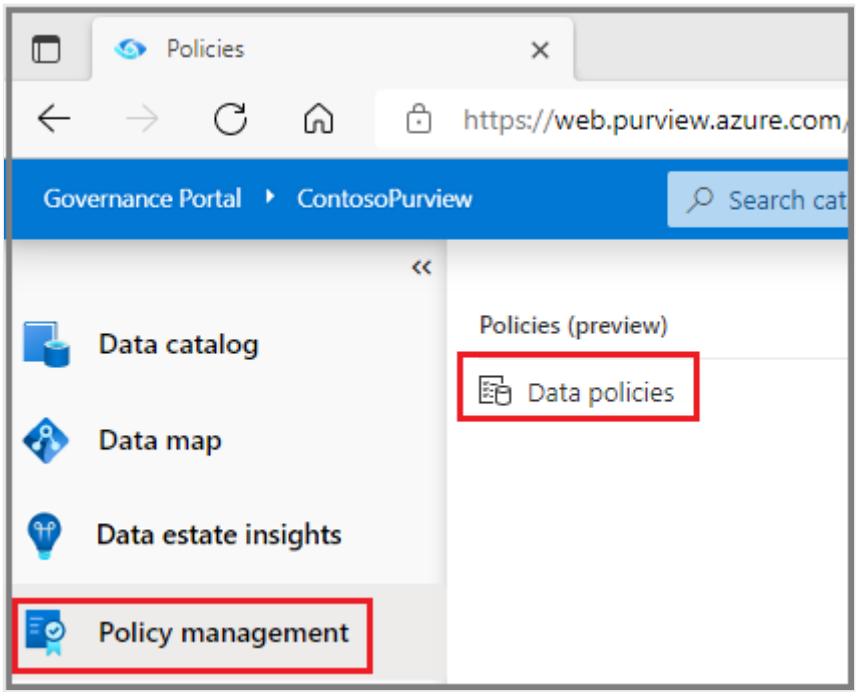
The steps to publish a policy are as follows:



1. Sign in to the Microsoft Purview governance portal.
2. Navigate to the **Data policy** feature using the left side panel. Then select **Data policies**.

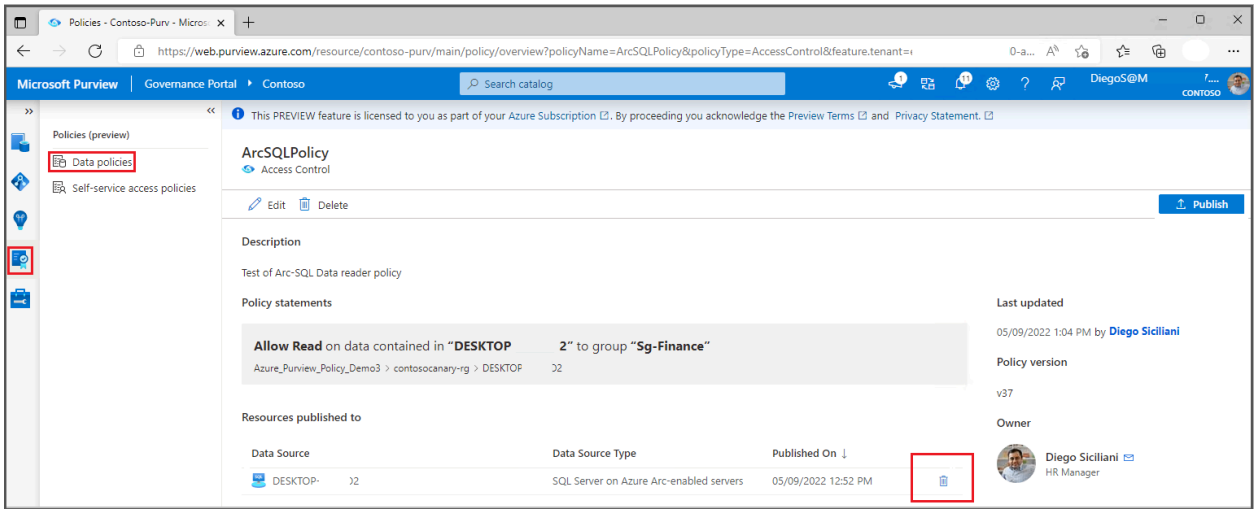
3. The Policy portal will present the list of existing policies in Microsoft Purview. Locate the policy that needs to be published. Select the **Publish** button on the right top corner of the page.

4. A list of data sources is displayed. You can enter a name to filter the list. Then, select each data source where this policy is to be published and then select the **Publish** button.



> ⓘ Note
>
> After making changes to a policy, there is no need to publish it again for it to take effect if the data source(s) continues to be the same.

Unpublish a policy

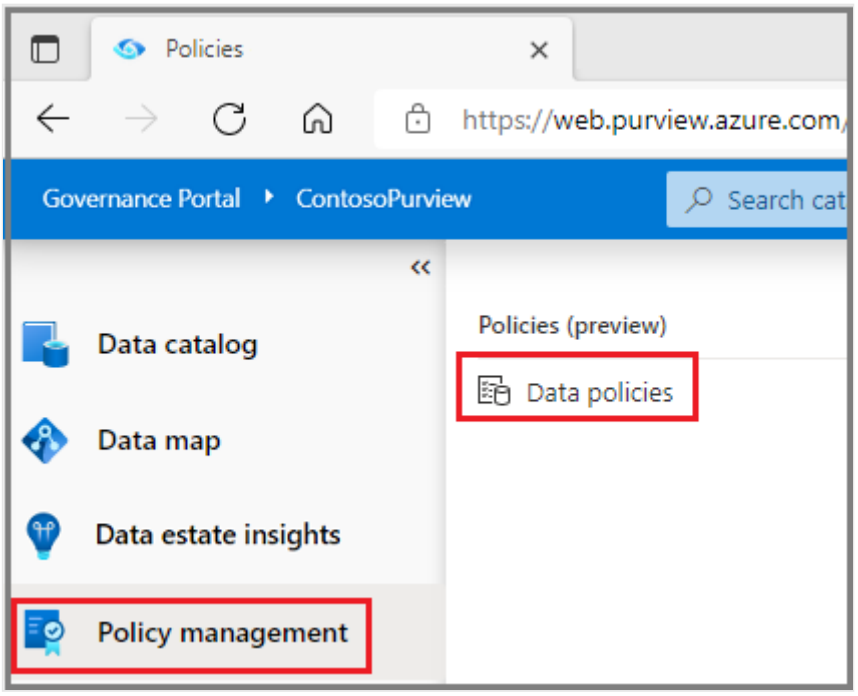


Ensure you have the *Data Source Admin* permission as described here

The steps to publish a policy are as follows:

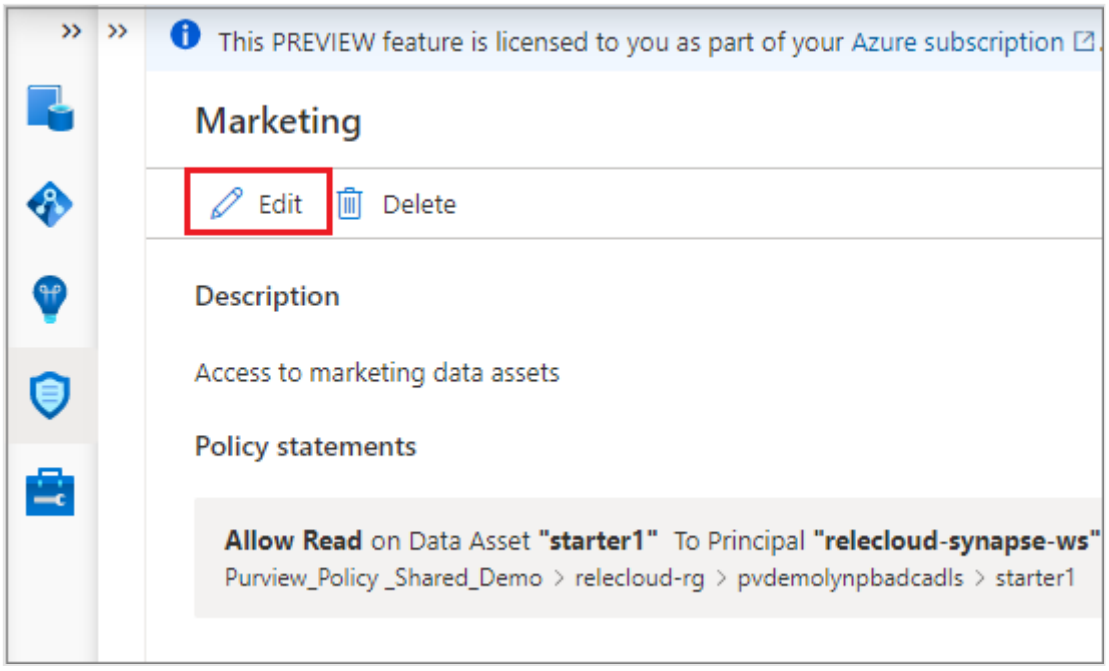
1. Sign in to the Microsoft Purview governance portal.
2. Navigate to the **Data policy** feature using the left side panel. Then select **Data policies**.

3. The Policy portal will present the list of existing policies in Microsoft Purview. Locate the policy that needs to be unpublished. Select the trash can icon.



Update or delete a policy

Steps to update or delete a policy in Microsoft Purview are as follows. Ensure you have the *Policy Author* permission as described here



1. Sign in to the Microsoft Purview governance portal.

2. Navigate to the **Data policy** feature using the left side panel. Then select **Data policies**.

3. The Policy portal will present the list of existing policies in Microsoft Purview. Select the policy that needs to be updated.

4. The policy details page will appear, including Edit and Delete options. Select the **Edit** button, which brings up the policy statement builder. Now, any parts of the statement in this policy can be updated. To delete the policy, use the **Delete** button.

Next steps

For specific guides on creating policies, you can follow these tutorials:

- Doc: Microsoft Purview data owner policies on all data sources in a subscription or a resource group
- Doc: Microsoft Purview data owner policies on an Azure Storage account

Provision read access to Azure Storage using Microsoft Purview Data owner policies (preview)

Article • 10/28/2024

> **Note**
>
> Microsoft Purview Data Map (classic), Data Catalog (classic), Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Data owner policies are a type of Microsoft Purview access policies. They allow you to manage access to user data in sources that have been registered for *Data Policy Enforcement* in Microsoft Purview. These policies can be authored directly in the Microsoft Purview governance portal, and after publishing, they get enforced by the data source.

This guide covers how a data owner can delegate in Microsoft Purview management of access to Azure Storage datasets. Currently, these two Azure Storage sources are supported:

- Blob storage
- Azure Data Lake Storage (ADLS) Gen2

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- A new or existing Microsoft Purview account. Follow this quickstart guide to create one.

Region support

- All Microsoft Purview regions are supported.
- Storage accounts in the following regions are supported without the need for additional configuration. However, zone-redundant storage (ZRS) accounts are not supported.
  - Australia Central
  - Australia East
  - Australia Southeast
  - Brazil South
  - Canada Central
  - Canada East
  - Central India
  - Central US
  - East Asia
  - East US 2
  - East US
  - France Central
  - Germany West Central
  - Japan East
  - Japan West
  - Korea Central
  - North Central US
  - North Europe
  - Norway East
  - Poland Central
  - Qatar Central
  - South Central US
  - South Africa North
  - Southeast Asia
  - South India
  - Sweden Central
  - Switzerland North
  - West Central US
  - West Europe
  - West US
  - West US 2
  - West US 3
  - UAE North
  - UK South
  - UK West

- Storage accounts in other regions in Public Cloud are supported after setting feature flag *AllowPurviewPolicyEnforcement*, as outlined in the next section. Newly created ZRS Storage accounts are supported, if created after setting the feature flag *AllowPurviewPolicyEnforcement*.

If needed, you can create a new Storage account by following this guide.

Configure the subscription where the Azure Storage account resides for policies from Microsoft Purview

This step is only necessary in certain regions (see prior section). To enable Microsoft Purview to manage policies for one or more Azure Storage accounts, execute the following PowerShell commands in the subscription where you'll deploy your Azure Storage account. These PowerShell commands will enable Microsoft Purview to manage policies on all Azure Storage accounts in that subscription.

If you're executing these commands locally, be sure to run PowerShell as an administrator. Alternatively, you can use the Azure Cloud Shell in the Azure portal: https://shell.azure.com.

PowerShell

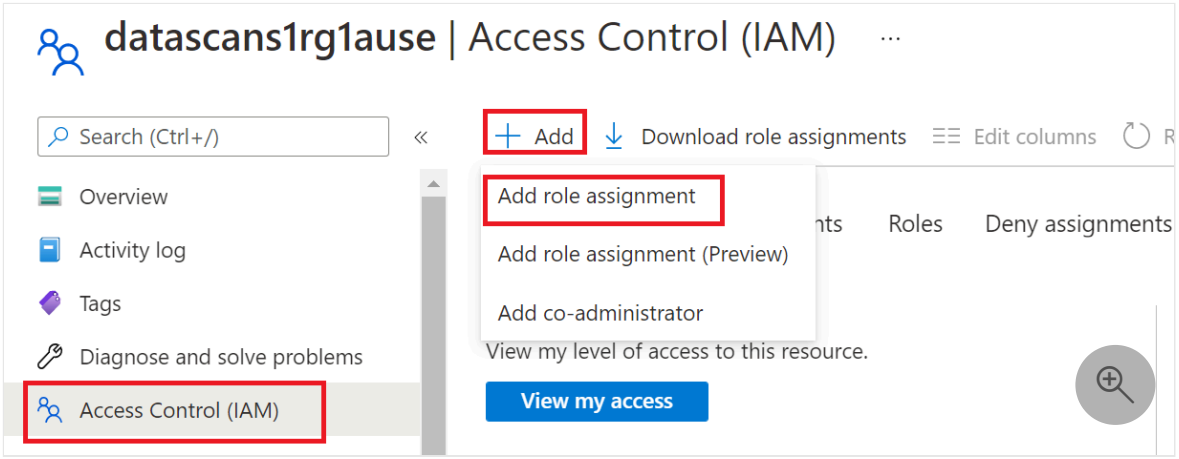
```
# Install the Az module
Install-Module -Name Az -Scope CurrentUser -Repository PSGallery -Force
# Login into the subscription
Connect-AzAccount -Subscription <SubscriptionID>
# Register the feature
Register-AzProviderFeature -FeatureName AllowPurviewPolicyEnforcement -
ProviderNamespace Microsoft.Storage
```

If the output of the last command shows *RegistrationState* as *Registered*, then your subscription is enabled for access policies. If the output is *Registering*, wait at least 10 minutes, and then retry the command. **Do not continue unless the RegistrationState shows as *Registered***.

Microsoft Purview configuration

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.



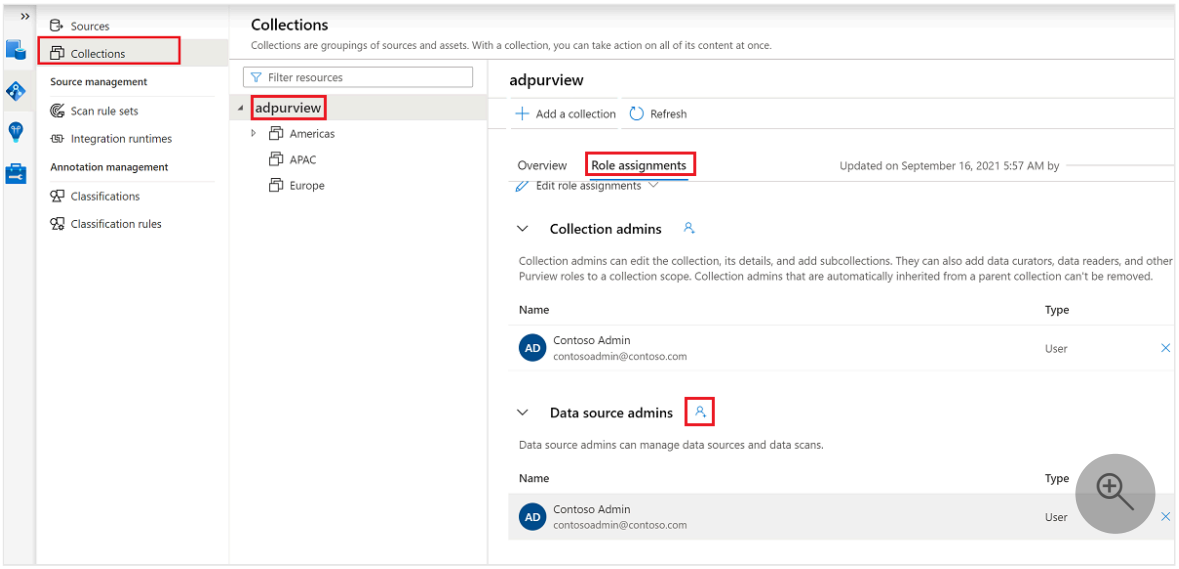
> **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

Configure permissions to enable Data policy enforcement on the data source

Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission inheritance):
  - IAM Owner
  - Both IAM Contributor and IAM User Access Administrator

  To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.



> **Note**
>
> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check

which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers

permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

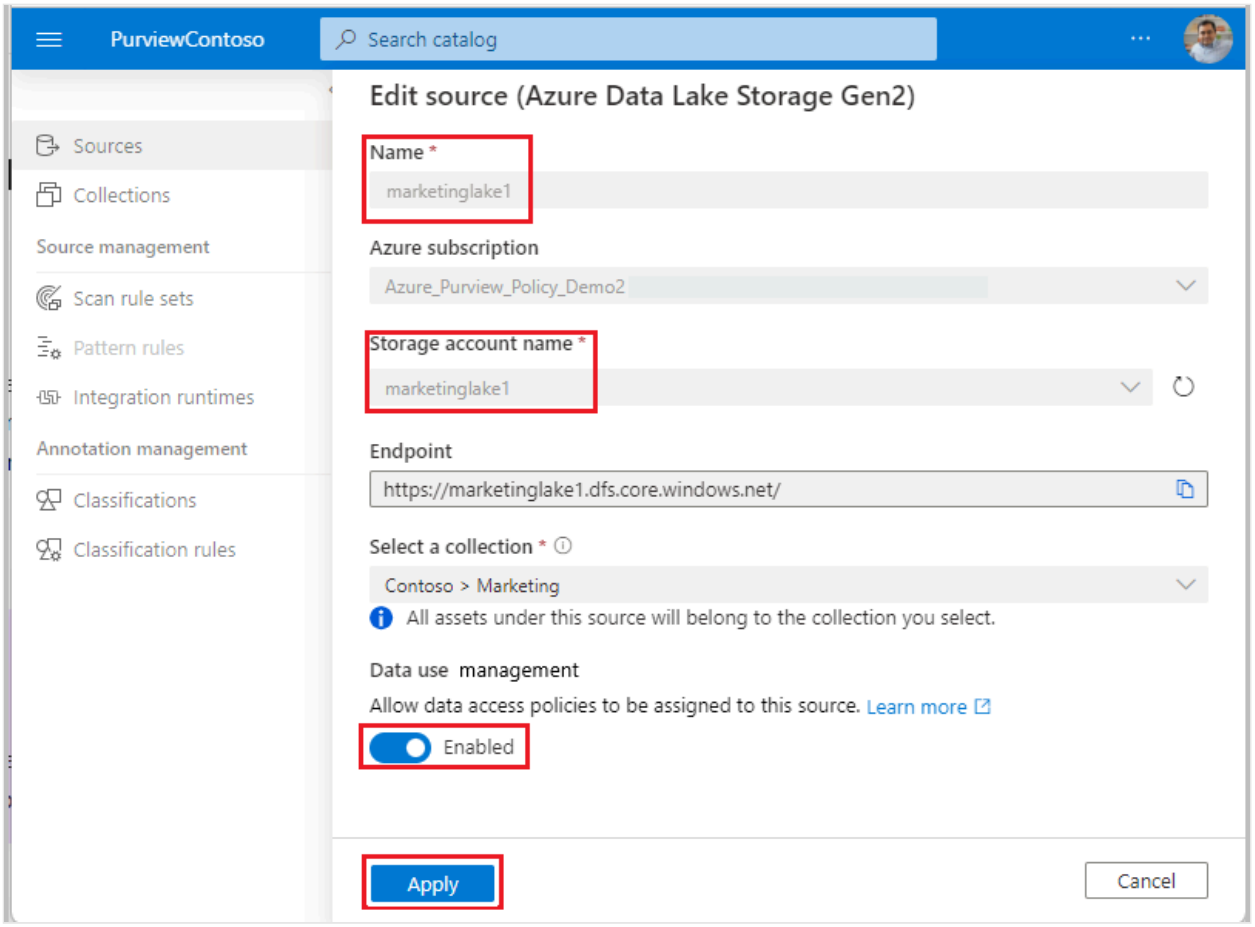
Delegate access provisioning responsibility to roles in Microsoft Purview

After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin* role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.

If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.

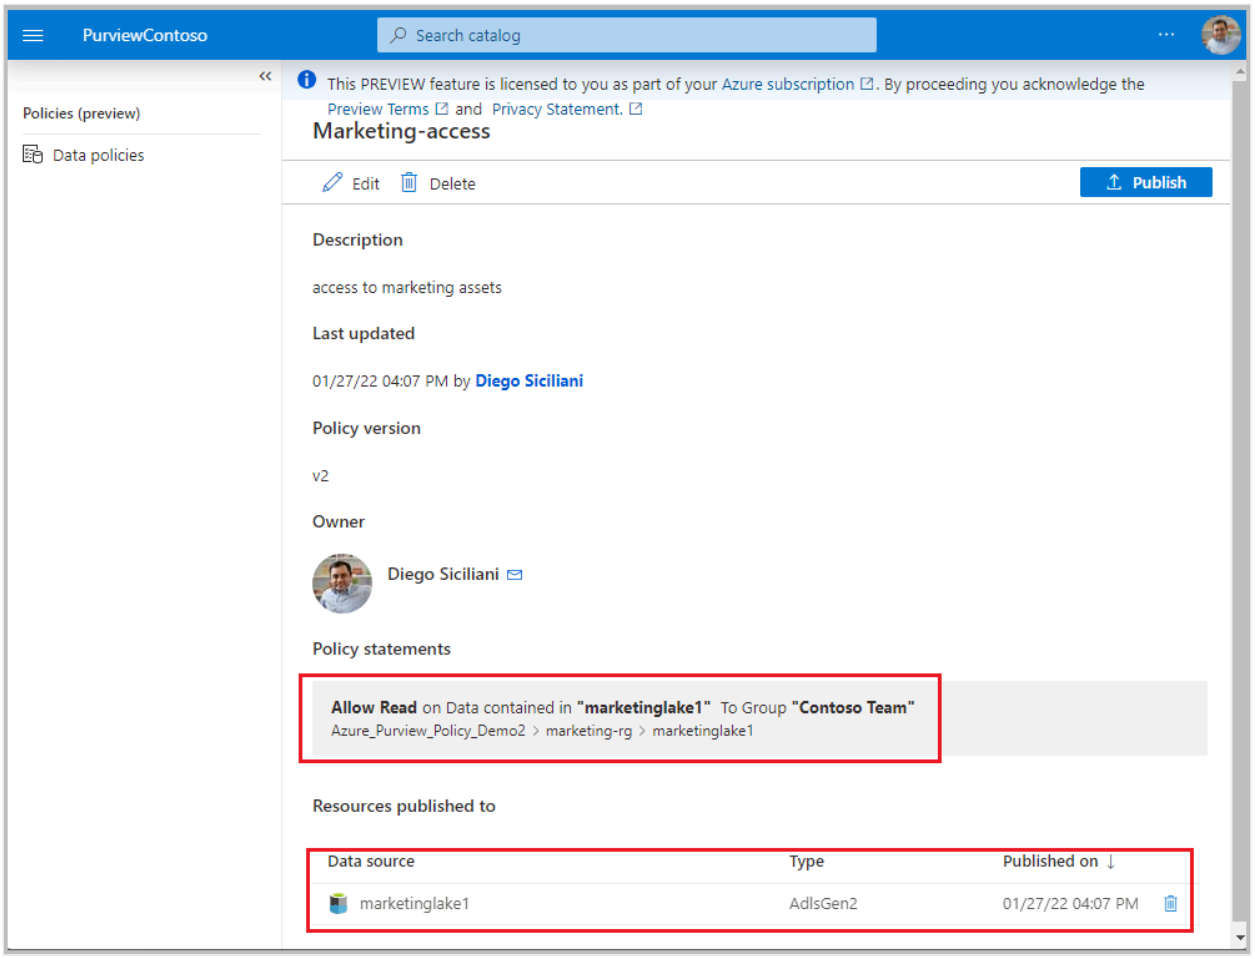
Register the data sources in Microsoft Purview for Data Policy Enforcement



The Azure Storage resources need to be registered first with Microsoft Purview to later define access policies.

To register your resources, follow the **Prerequisites** and **Register** sections of these guides:

- Register and scan Azure Storage Blob - Microsoft Purview
- Register and scan Azure Data Lake Storage (ADLS) Gen2 - Microsoft Purview



After you've registered your resources, you'll need to enable Data Policy Enforcement. Data Policy Enforcement needs certain permissions and can affect the security of your data, as it delegates to certain Microsoft Purview roles to manage access to the data sources. **Go through the secure practices related to Data Policy Enforcement in this guide**: How to enable Data Policy Enforcement

Once your data source has the **Data Policy Enforcement** toggle **Enabled**, it will look like this screenshot:

Create and publish a data owner policy

Execute the steps in the **Create a new policy** and **Publish a policy** sections of the data-owner policy authoring tutorial. The result will be a data owner policy similar to the example shown in the image: a policy that provides group *Contoso Team read* access to Storage account *marketinglake1*:

> **Important**
>
> - Publish is a background operation. Azure Storage accounts can take up to **2 hours** to reflect the changes.

Unpublish a data owner policy

Follow this link for the steps to unpublish a data owner policy in Microsoft Purview.

Update or delete a data owner policy

Follow this link for the steps to update or delete a data owner policy in Microsoft Purview.

Data Consumption

- Data consumer can access the requested dataset using tools such as Power BI or Azure Synapse Analytics workspace.

- The Copy and Clone commands in Azure Storage Explorer require other IAM permissions to work in addition to the Allow Modify policy from Purview. Provide Microsoft.Storage/storageAccounts/blobServices/generateUserDelegationKey/action permission in IAM to the Microsoft Entra principal.
- Subcontainer access: Policy statements set below container level on a Storage account are supported. However, users won't be able to browse to the data asset using Azure portal's Storage Browser or Microsoft Azure Storage Explorer tool if access is granted only at file or folder level of the Azure Storage account. This is because these apps attempt to crawl down the hierarchy starting at container level, and the request fails because no access has been granted at that level. Instead, the App that requests the data must execute a direct access by providing a fully qualified name to the data object. The following documents show examples of how to perform a direct access. See also the blogs in the *Next steps* section of this how-to-guide.
  - *abfs* for ADLS Gen2
  - *az storage blob download* for Blob Storage

Additional information

- Creating a policy at Storage account level enables the Subjects to access system containers, for example *$logs*. If this is undesired, first scan the data sources and then create finer-grained policies for each (that is, at container or subcontainer level).
- The root blob in a container will be accessible to the Microsoft Entra principals in a Microsoft Purview *allow*-type RBAC policy if the scope of such policy is either subscription, resource group, Storage account or container in Storage account.
- The root container in a Storage account will be accessible to the Microsoft Entra principals in a Microsoft Purview *allow*-type RBAC policy if the scope of such policy is either subscription, resource group, or Storage account.

Limits

- The limit for Microsoft Purview policies that can be enforced by Storage accounts is 100 MB per subscription, which roughly equates to 5,000 policies.

Known issues

Known issues related to Policy creation

- Don't create policy statements based on Microsoft Purview resource sets. Even if displayed in Microsoft Purview policy authoring UI, they aren't yet enforced. Learn more about resource sets.

Policy action mapping

This section contains a reference of how actions in Microsoft Purview data policies map to specific actions in Azure Storage.

Expand table

Microsoft Purview policy action	Data source specific actions
Read	Microsoft.Storage/storageAccounts/blobServices/containers/read
	Microsoft.Storage/storageAccounts/blobServices/containers/blobs/read
Modify	Microsoft.Storage/storageAccounts/blobServices/containers/blobs/read
	Microsoft.Storage/storageAccounts/blobServices/containers/blobs/write
	Microsoft.Storage/storageAccounts/blobServices/containers/blobs/add/action
	Microsoft.Storage/storageAccounts/blobServices/containers/blobs/move/action
	Microsoft.Storage/storageAccounts/blobServices/containers/blobs/delete
	Microsoft.Storage/storageAccounts/blobServices/containers/read
	Microsoft.Storage/storageAccounts/blobServices/containers/write
	Microsoft.Storage/storageAccounts/blobServices/containers/delete

Provision read access to Azure SQL Database using Microsoft Purview Data owner policies (preview)

Article • 10/28/2024

> **Note**
>
> Microsoft Purview Data Map (classic), Data Catalog (classic), Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Data owner policies are a type of Microsoft Purview access policies. They allow you to manage access to user data in sources that have been registered for *Data Policy Enforcement* in Microsoft Purview. These policies can be authored directly in the Microsoft Purview governance portal, and after publishing, they get enforced by the data source.

This guide covers how a data owner can delegate authoring policies in Microsoft Purview to enable access to Azure SQL Database. The following actions are currently enabled: *Read*. *Modify* isn't supported at this point.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- A new or existing Microsoft Purview account. Follow this quickstart guide to create one.
- Create a new Azure SQL Database instance, or use an existing one, in one of the currently available regions for this feature. You can follow this guide to create an Azure SQL Database instance.

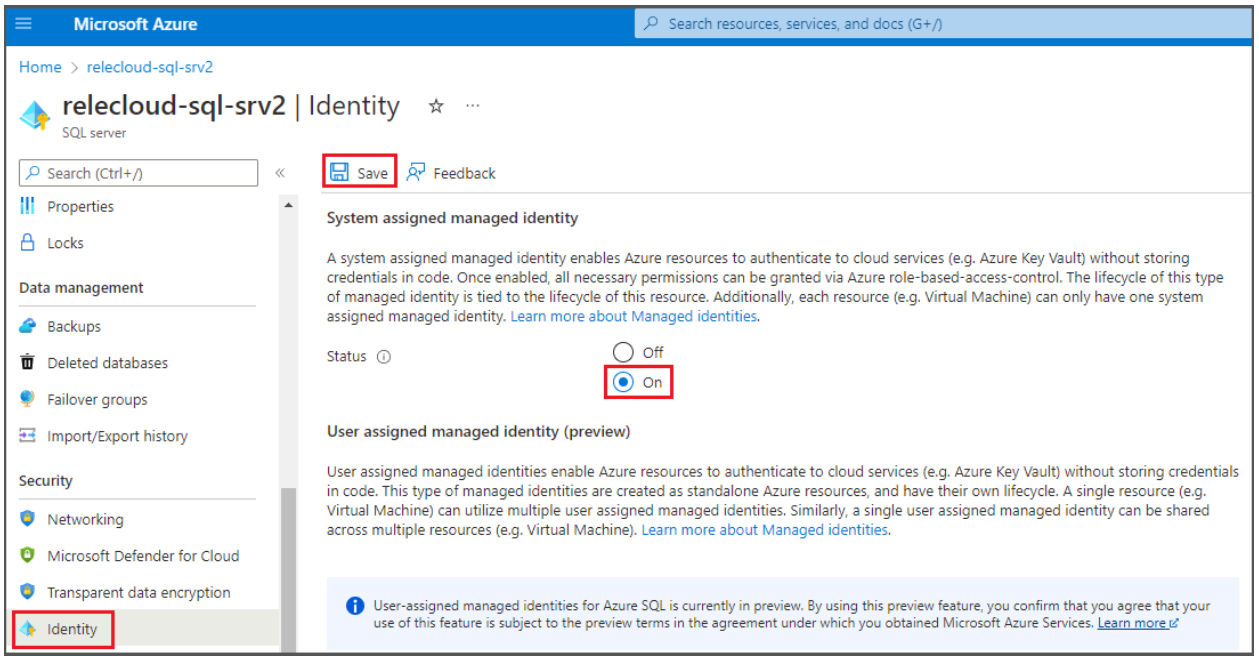
Region support

All Microsoft Purview regions are supported.

Enforcement of Microsoft Purview policies is available only in the following regions for Azure SQL Database:

Public cloud:

- East US
- East US2
- South Central US
- West Central US
- West US3
- Canada Central
- Brazil South
- West Europe
- North Europe
- France Central
- UK South
- South Africa North
- Central India
- South East Asia
- East Asia
- Australia East



Sovereign clouds:

- USGov Virginia
- China North 3

Configure the Azure SQL Database instance for policies from Microsoft Purview

For the logical server associated with Azure SQL Database to honor policies from Microsoft Purview, you need to configure a Microsoft Entra admin. In the Azure portal, go to the logical server that hosts the Azure SQL Database instance. On the side menu, select **Microsoft Entra ID**. Set an admin name to any Microsoft Entra user or group that you prefer, and then select **Save**.

Then, on the side menu, select **Identity**. Under **System assigned managed identity**, turn the status to **On**, and then select **Save**.

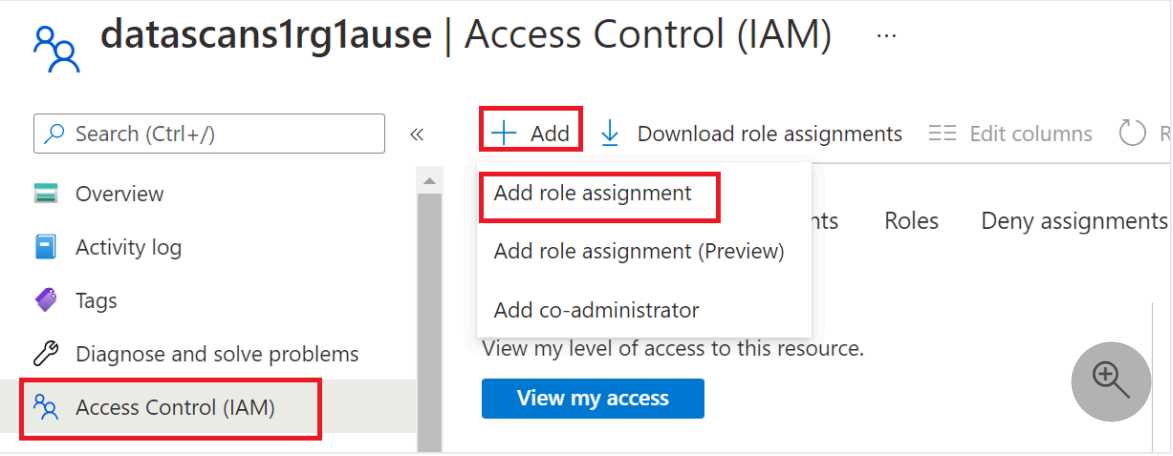
Microsoft Purview configuration

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.

> **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

Configure permissions to enable Data policy enforcement on the data source

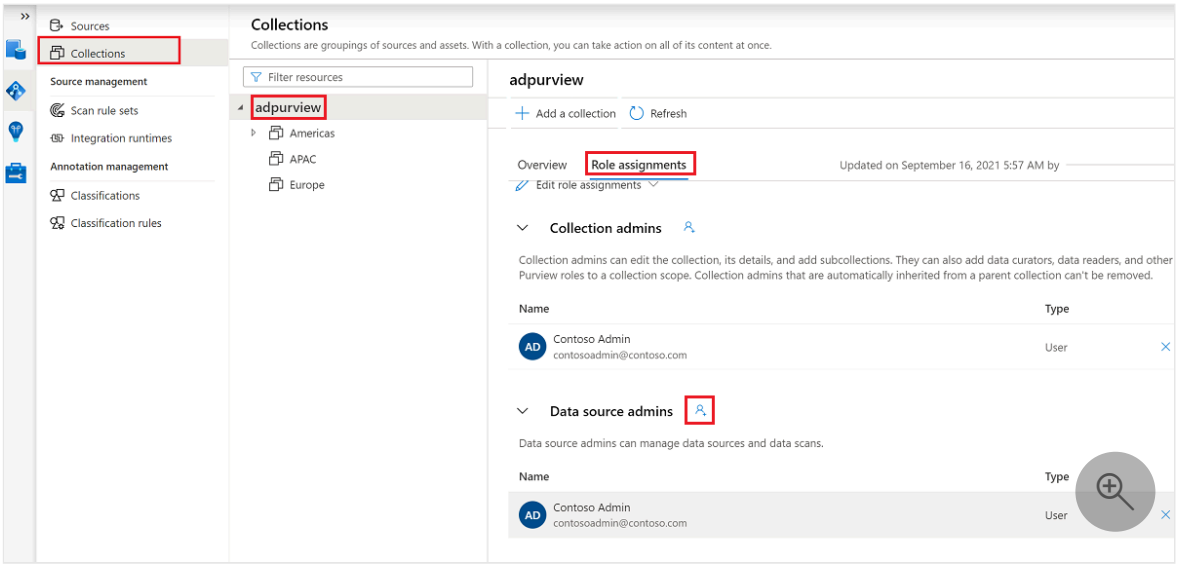


Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission

inheritance):

- IAM Owner
- Both IAM Contributor and IAM User Access Administrator



To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.

> **Note**
>
> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before

a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

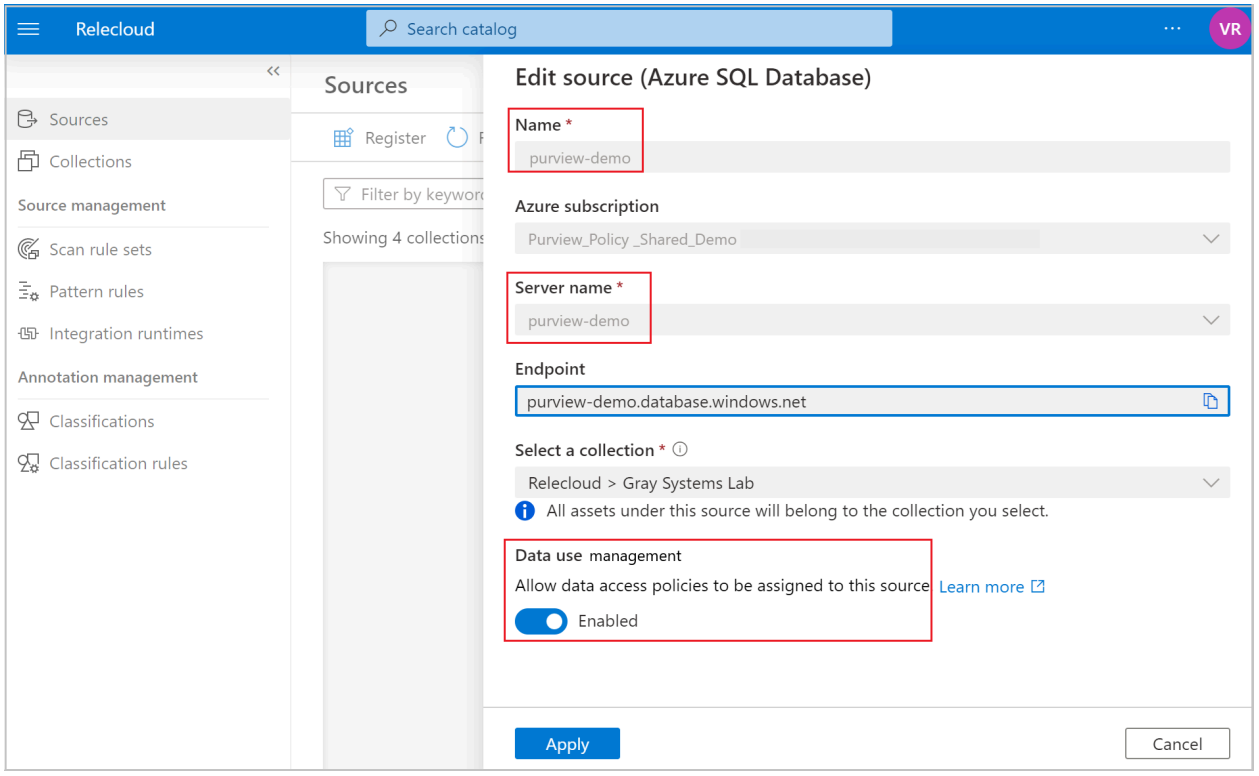
> ⓘ **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

Delegate access provisioning responsibility to roles in Microsoft Purview

After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> ⓘ **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin* role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.

If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.



Register the data sources in Microsoft Purview

The Azure SQL Database data source needs to be registered first with Microsoft Purview before creating access policies. You can follow these guides:

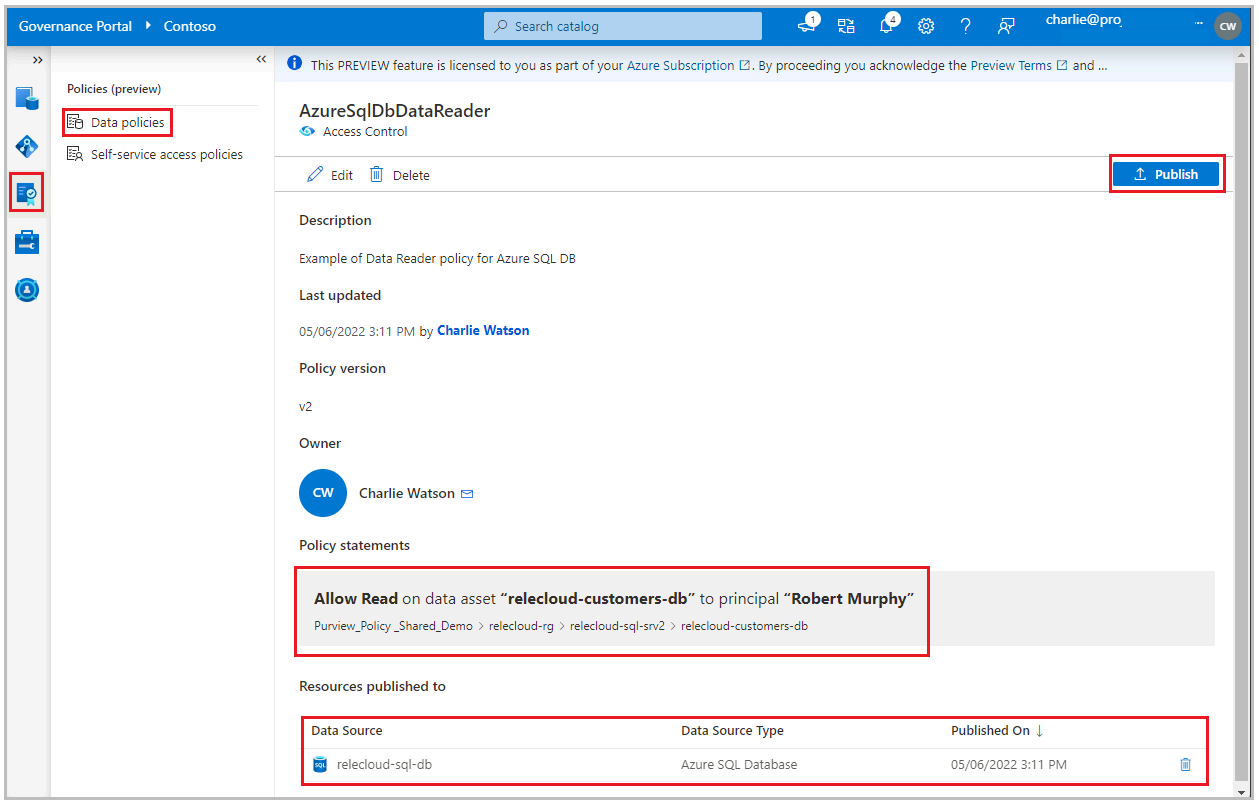
Register and scan Azure SQL Database

After you've registered your resources, you'll need to enable Data Policy Enforcement. Data Policy Enforcement can affect the security of your data, as it delegates to certain Microsoft Purview roles to manage access to the data sources. **Go through the secure practices related to Data Policy Enforcement in this guide**: How to enable Data Policy Enforcement

Once your data source has the **Data policy enforcement** toggle *Enabled*, it will look like this screenshot. This will enable the access policies to be used with the given Azure SQL server and all its contained databases.

Return to the Azure portal for Azure SQL Database to verify it's now governed by Microsoft Purview:

1. Sign in to the Azure portal through this link
2. Select the Azure SQL Server that you want to configure.
3. Go to **Microsoft Entra ID** on the left pane.
4. Scroll down to **Microsoft Purview access policies**.
5. Select the button to **Check for Microsoft Purview Governance**. Wait while the request is processed. It could take a few minutes.



6. Confirm that the Microsoft Purview Governance Status shows `Governed`. Note that **it could take a few minutes** after you enable *Data policy enforcement* in Microsoft Purview for the correct status to be reflected.

> **Note**
>
> If you disable Data policy enforcement for this Azure SQL Database data source, it might take up to 24 hours for the Microsoft Purview Governance Status to be updated automatically to `Not Governed`. This can be accelerated by selecting **Check for Microsoft Purview Governance**. Before you enable *Data policy enforcement* for the data source in another Microsoft Purview account, ensure that the Purview Governance Status shows as `Not Governed`. Then repeat the steps above with the new Microsoft Purview account.

Create and publish a data owner policy

Execute the steps in the **Create a new policy** and **Publish a policy** sections of the data-owner policy authoring tutorial. The result will be a data owner policy similar to the example shown.

Example: Read policy. This policy assigns the Microsoft Entra principal 'Robert Murphy' to the *SQL Data reader* action, in the scope of SQL server *relecloud-sql-srv2*. This policy has also been published to that server. Note that policies related to this action are supported below server level (for example, database, table).

> **Important**
>
> - Publish is a background operation. It can take up to **5 minutes** for the changes to be reflected in this data source.
> - Changing a policy does not require a new publish operation. The changes will be picked up with the next pull.

Unpublish a data owner policy

Follow this link for the steps to unpublish a data owner policy in Microsoft Purview.

Update or delete a data owner policy

Follow this link for the steps to update or delete a data owner policy in Microsoft Purview.

Test the policy

After you create the policy, any of the Microsoft Entra users in the Subject should now be able to connect to the data sources in the scope of the policy. To test, use SSMS or any SQL client and try to query. Attempt access to a SQL table you have provided read access to.

If you require more troubleshooting, see the Next steps section in this guide.

Role definition detail

This section contains a reference of how relevant Microsoft Purview data policy roles map to specific actions in SQL data sources.

Expand table

Microsoft Purview policy role definition	Data source specific actions
Read	Microsoft.Sql/sqlservers/Connect
	Microsoft.Sql/sqlservers/databases/Connect
	Microsoft.Sql/Sqlservers/Databases/Schemas/Tables/Rows
	Microsoft.Sql/Sqlservers/Databases/Schemas/Views/Rows

Provision read access to Azure Arc-enabled SQL Server 2022 using Microsoft Purview Data owner policies (preview)

Article • 02/24/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Data owner policies are a type of Microsoft Purview access policies. They allow you to manage access to user data in sources that have been registered for *Data Policy Enforcement* in Microsoft Purview. These policies can be authored directly in the Microsoft Purview governance portal, and after publishing, they get enforced by the data source.

This guide covers how a data owner can delegate authoring policies in Microsoft Purview to enable access to Azure Arc-enabled SQL Server. The following actions are currently enabled: *Read*. This action is only supported for policies at server level. *Modify* is not supported at this point.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- A new or existing Microsoft Purview account. Follow this quickstart guide to create one.

- Get SQL Server on-premises version 2022 and install it. Versions 2022 or more recent are supported on both Windows and Linux. You can try the free Developer edition.
- Configure your permissions and then register a list of resource providers in the subscription you'll use to onboard the SQL Server instance to Azure Arc.
- Complete prerequisites and onboard the SQL Server instance with Azure Arc. A simple configuration for Windows SQL Server is here. An alternate configuration for Linux SQL Server is here.
- Enable Microsoft Entra authentication in SQL Server. For a simpler setup, complete the prerequisites and process outlined in this article.
- Remember to grant application permissions and grant admin consent
- You need to configure a Microsoft Entra admin for the SQL Server instance, but it isn't necessary to set up other Microsoft Entra logins or users. You'll grant access to those users by using Microsoft Purview policies.

Region support

Data policy enforcement is available in all Microsoft Purview regions except:

- West US2
- East Asia
- US Gov Virginia
- China North 3

Security considerations for Azure Arc-enabled SQL Server

- The server admin can turn off the Microsoft Purview policy enforcement.
- Azure Arc admin and server admin permissions provide the ability to change the Azure Resource Manager path of the server. Because mappings in Microsoft Purview use Resource Manager paths, it can lead to wrong policy enforcements.
- A SQL Server admin (database admin) can gain the power of a server admin and can tamper with the cached policies from Microsoft Purview.
- The recommended configuration is to create a separate app registration for each SQL server instance. This configuration prevents the second SQL Server instance from reading the policies meant for the first SQL Server instance, in case a rogue admin in the second SQL Server instance tampers with the Resource Manager path.

Verify the prerequisites

1. Sign in to the Azure portal through this link

2. Navigate to **SQL servers** on the left pane. You'll see a list of SQL Server instances on Azure Arc.

3. Select the SQL Server instance that you want to configure.

4. Go to **Microsoft Entra ID** on the left pane.

5. Ensure that Microsoft Entra authentication is configured with an admin login. If not, refer to the access policy prerequisites section in this guide.

6. Ensure that a certificate has been provided to for SQL Server to authenticate to Azure. If not, refer to the access policy prerequisites section in this guide.

7. Ensure that an app registration has been entered to create a trust relationship between SQL Server and Microsoft Entra ID. If not, refer to the access policy prerequisites section in this guide.

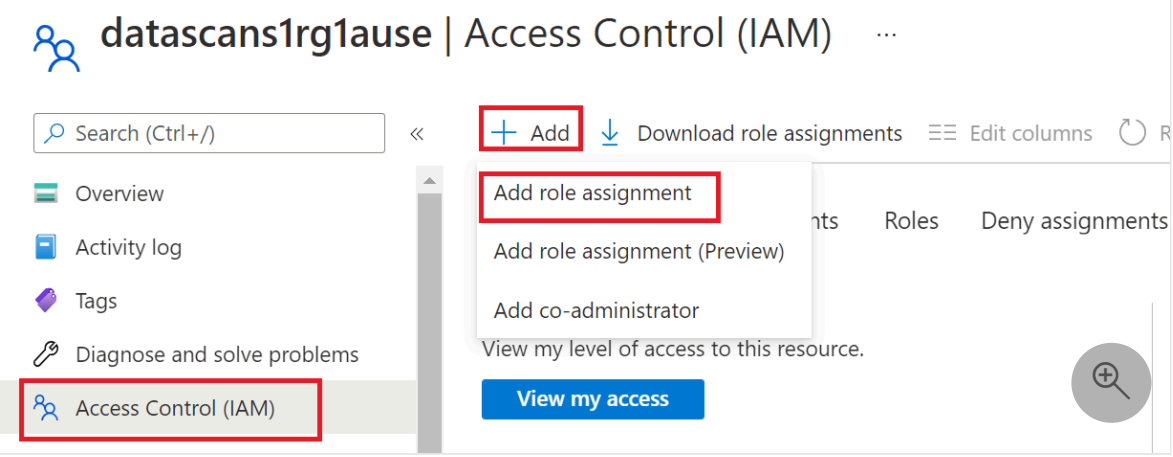
8. If you made any changes, select the **Save** button to save the configuration and wait until the operation completes successfully. This could take a few minutes. The message "*Saved successfully*" will be displayed at the top of the page in green background. You might need to scroll up to see it.

Microsoft Purview configuration

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.

> ⓘ **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.



Configure permissions to enable Data policy enforcement on the data source

Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to

enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission inheritance):
  - IAM Owner
  - Both IAM Contributor and IAM User Access Administrator

  To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.

> **Note**
>
> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before

a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

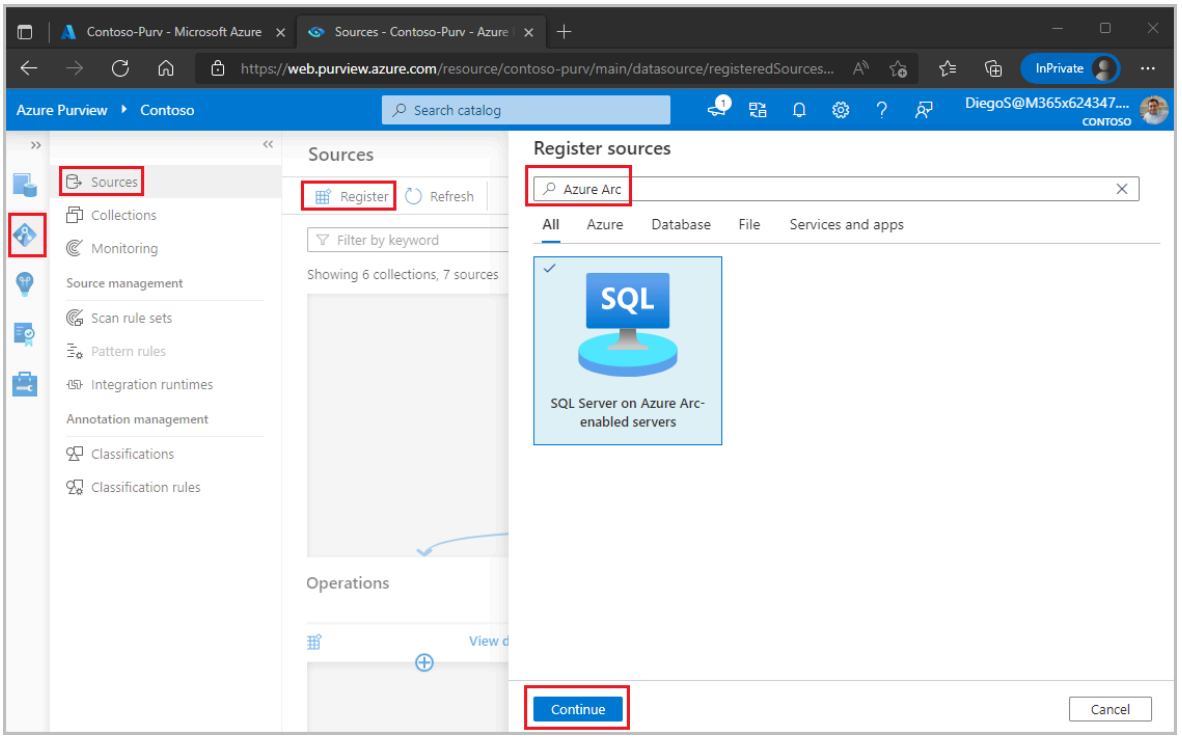
For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> ⓘ **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

Delegate access provisioning responsibility to roles in Microsoft Purview

After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> ⓘ **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin* role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.



If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.

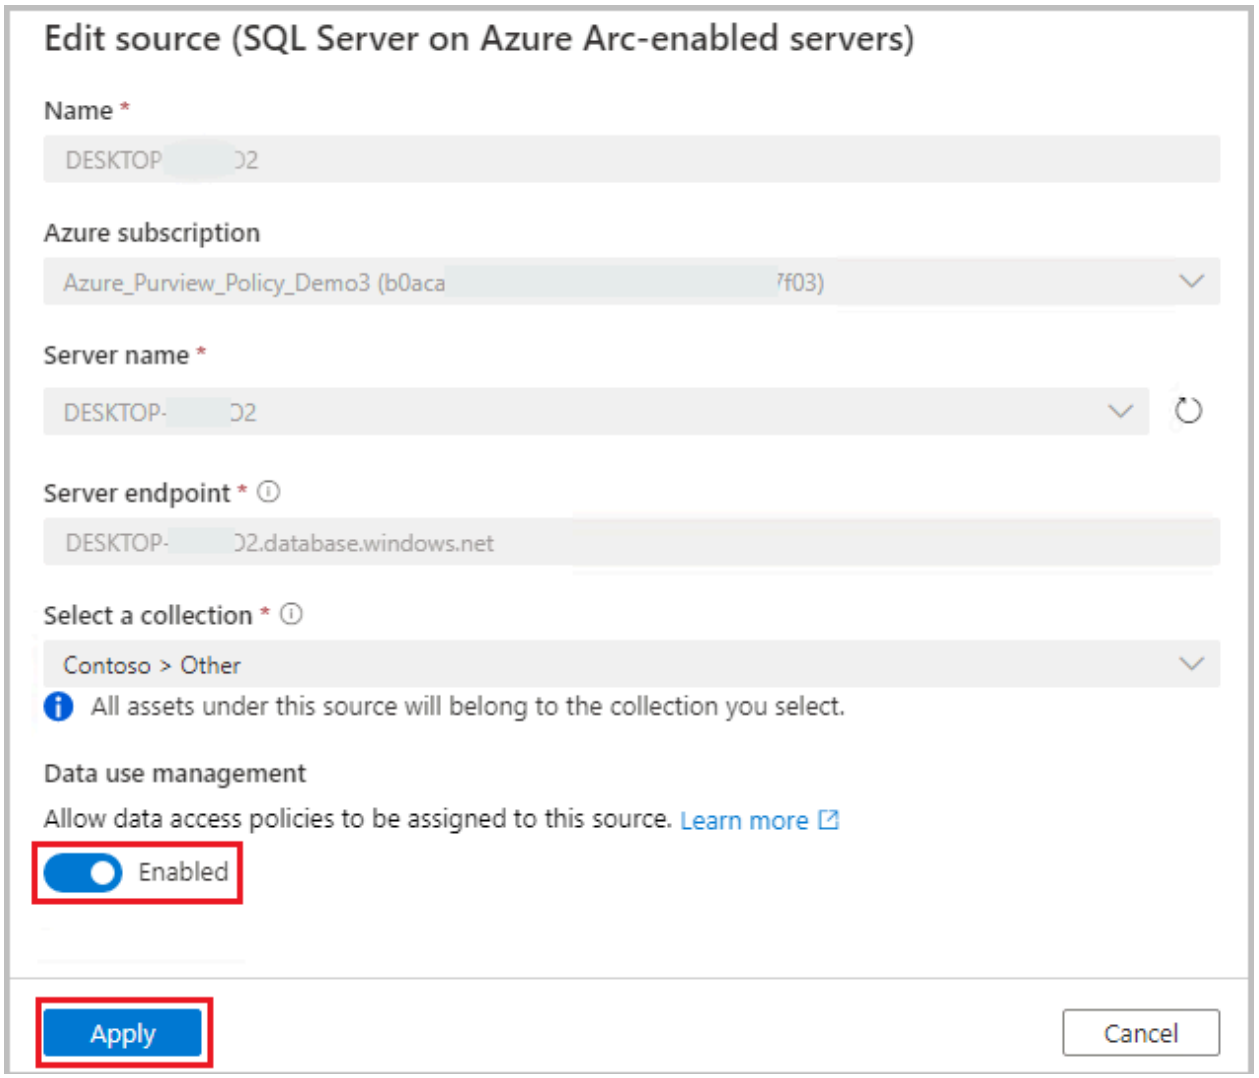
Register data sources in Microsoft Purview

Register each data source with Microsoft Purview to later define access policies.

1. Sign in to Microsoft Purview Studio.

2. Navigate to the **Data map** feature on the left pane, select **Sources**, then select **Register**. Type "Azure Arc" in the search box and select **SQL Server on Azure Arc**. Then select **Continue**.

3. Enter a **Name** for this registration. It is best practice to make the name of the registration the same as the server name in the next step.



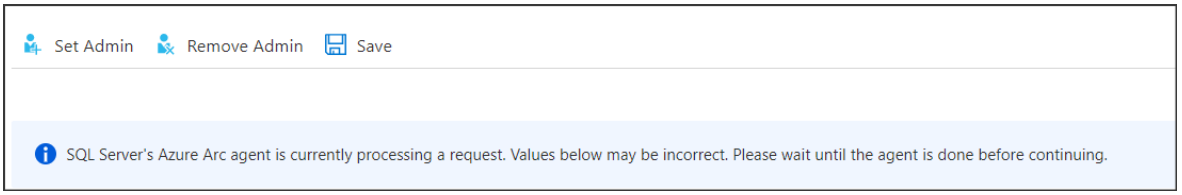
4. Select an **Azure subscription**, **Server name** and **Server endpoint**.

5. **Select a collection** to put this registration in.

6. Enable Data Policy Enforcement. Data Policy Enforcement needs certain permissions and can affect the security of your data, as it delegates to certain Microsoft Purview roles to manage access to the data sources. **Go through the secure practices related to Data Policy Enforcement in this guide**: How to enable Data Policy Enforcement

7. Select **Register** or **Apply** at the bottom.

Once your data source has the **Data policy enforcement** toggle *Enabled*, it will look like this picture.

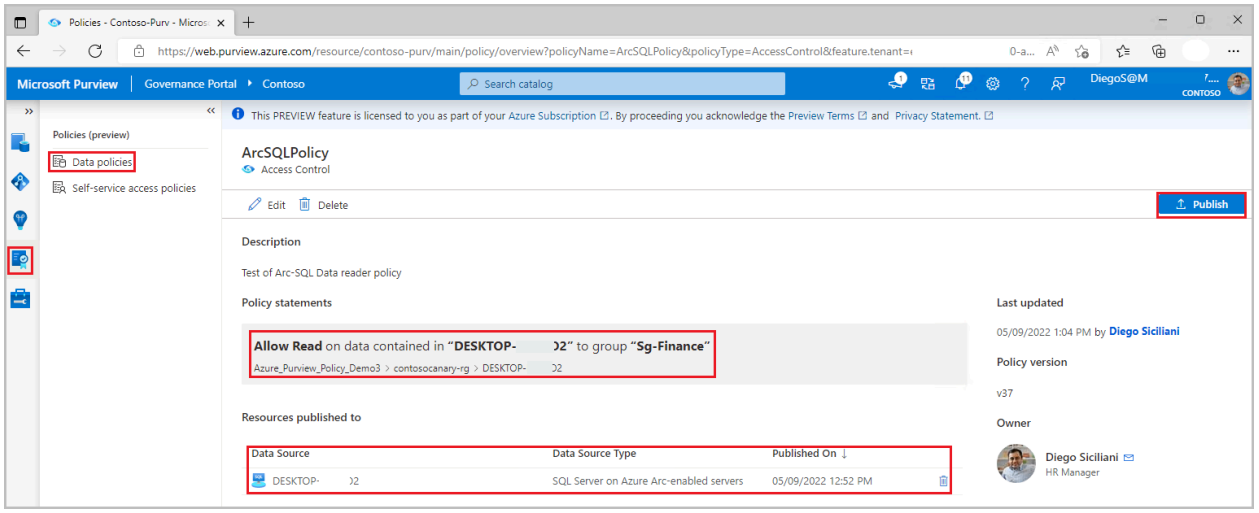


Enable policies in Azure Arc-enabled SQL Server

This section describes the steps to configure SQL Server on Azure Arc to use Microsoft Purview. Execute these steps after you enable the *Data policy enforcement* option for this data source in the Microsoft Purview account.

1. Sign in to the Azure portal through this link
2. Navigate to **SQL servers** on the left pane. You'll see a list of SQL Server instances on Azure Arc.
3. Select the SQL Server instance that you want to configure.
4. Go to **Microsoft Entra ID** on the left pane.
5. Scroll down to **Microsoft Purview access policies**.
6. Select the button to **Check for Microsoft Purview Governance**. Wait while the request is processed. While that happens, this message will be displayed at the top

of the page. You might need to scroll up to see it.



7. At the bottom of the page, confirm that the Microsoft Purview Governance Status shows `Governed`. Note that **it may take up to 30 minutes** for the correct status to be reflected. Continue doing a browser refresh until that happens.

8. Confirm that the Microsoft Purview Endpoint points to the Microsoft Purview account where you registered this data source and enabled the *data policy enforcement*

Create and publish a Data owner policy

Execute the steps in the **Create a new policy** and **Publish a policy** sections of the data-owner policy authoring tutorial. The result will be a data owner policy similar to the example:

Example: Read policy. This policy assigns the Microsoft Entra principal 'sg-Finance' to the *SQL Data reader* action, in the scope of SQL server *DESKTOP-xxx*. This policy has also been published to that server. Note that policies related to this action are not supported below server level.

> **Note**
>
> - Given that scan is not currently available for this data source, data reader policies can only be created at server level. Use the **Data sources** box instead of the Asset box when authoring the **data resources** part of the policy.

- There is a know issue with SQL Server Management Studio that prevents right-clicking on a table and choosing option “Select Top 1000 rows”.

> **Important**
>
> - Publish is a background operation. It can take up to **5 minutes** for the changes to be reflected in this data source.
> - Changing a policy does not require a new publish operation. The changes will be picked up with the next pull.

Unpublish a data owner policy

Follow this link for the steps to unpublish a data owner policy in Microsoft Purview.

Update or delete a data owner policy

Follow this link for the steps to update or delete a data owner policy in Microsoft Purview.

Test the policy

After the policy is published and has been communicated to the data source, any of the Microsoft Entra users in the Subject should be able to connect and execute a query that targets the assets to which the policy granted access. To test, use SSMS or any SQL client and try to query. For example, attempt access to a SQL table you have provided read access to.

If you require additional troubleshooting, see the Next steps section in this guide.

Role definition detail

This section contains a reference of how relevant Microsoft Purview data policy roles map to specific actions in SQL data sources.

Provision access to entire resource groups or subscriptions using Microsoft Purview Data owner policies (preview)

Article • 02/24/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Data owner policies are a type of Microsoft Purview access policies. They allow you to manage access to user data in sources that have been registered for *Data Policy Enforcement* in Microsoft Purview. These policies can be authored directly in the Microsoft Purview governance portal, and after publishing, they get enforced by the data source.

In this guide we cover how to register an entire resource group or subscription and then create a single policy that will manage access to **all** data sources in that resource group or subscription. That single policy will cover all existing data sources and any data sources that are created afterwards.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- A new or existing Microsoft Purview account. Follow this quickstart guide to create one.

Only these data sources are enabled for access policies on resource group or subscription. Follow the **Prerequisites** section that is specific to the data source(s) in these guides:

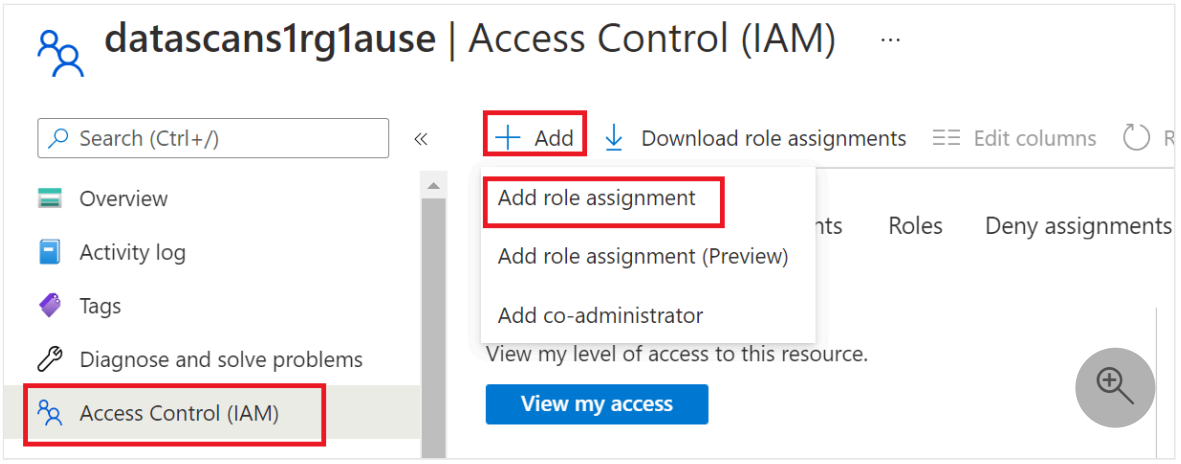
- Data owner policies on an Azure Storage account
- Data owner policies on an Azure SQL Database(*)
- Data owner policies on an Azure Arc-enabled SQL Server(*)

(*) The *Modify* action is not currently supported for SQL-type data sources.

Microsoft Purview configuration

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.



> ⓘ **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

Configure permissions to enable Data policy enforcement on the data source

Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission inheritance):
  - IAM Owner
  - Both IAM Contributor and IAM User Access Administrator

  To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.

> **Note**
>
> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

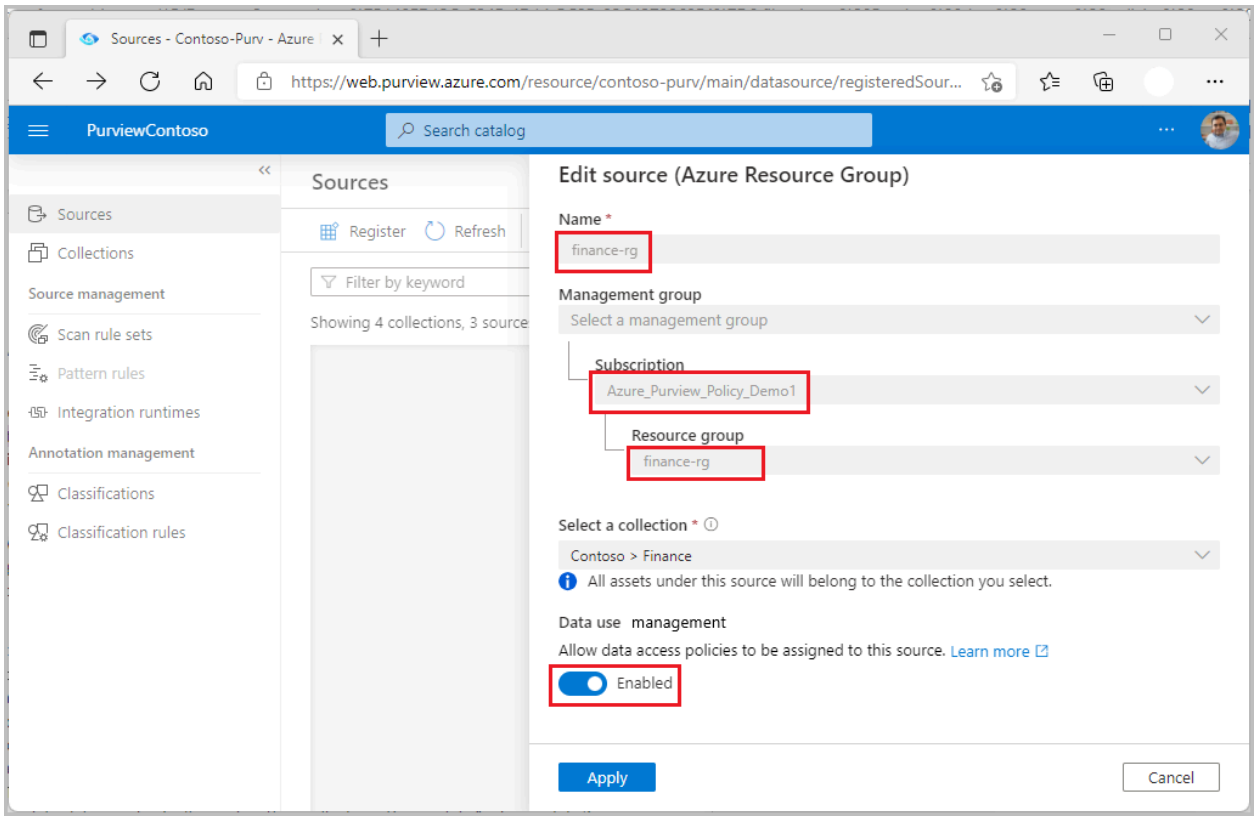
> **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

Delegate access provisioning responsibility to roles in Microsoft Purview

After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin* role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.

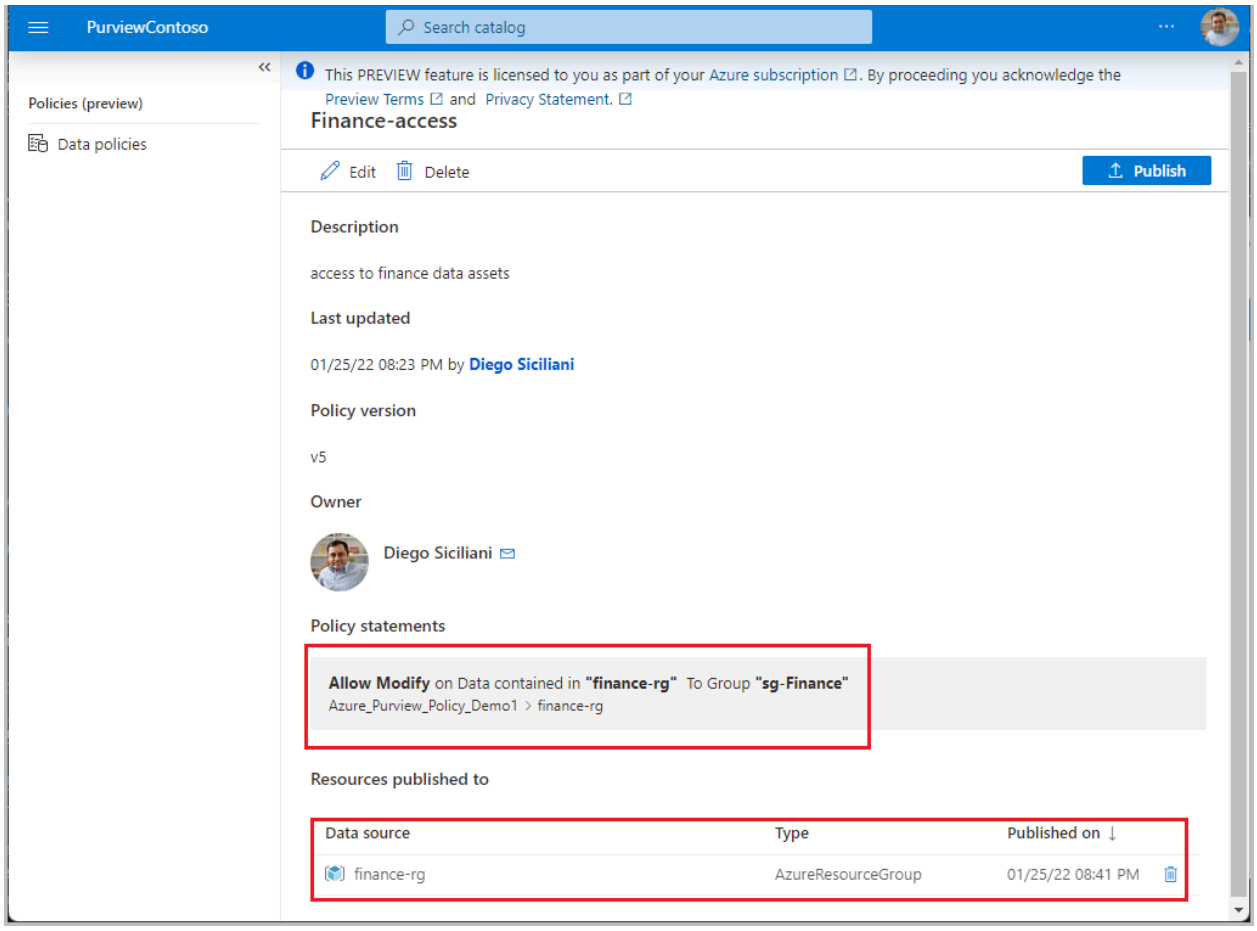
If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.



Register the subscription or resource group for Data Policy Enforcement

The subscription or resource group needs to be registered with Microsoft Purview before you can create access policies. To register your subscription or resource group, follow the **Prerequisites** and **Register** sections of this guide:

- Register multiple sources in Microsoft Purview



After you've registered your resources, you'll need to enable Data Policy Enforcement. Data Policy Enforcement needs certain permissions and can affect the security of your data, as it delegates to certain Microsoft Purview roles to manage access to the data sources. **Go through the secure practices related to Data Policy Enforcement in this guide**: How to enable Data Policy Enforcement

In the end, your resource will have the **Data Policy Enforcement** toggle **Enabled**, as shown in the screenshot:

Create and publish a data owner policy

Execute the steps in the **Create a new policy** and **Publish a policy** sections of the data-owner policy authoring tutorial. The result will be a data owner policy similar to the example shown in the image: a policy that provides security group *sg-Finance modify* access to resource group *finance-rg*. Use the Data source box in the Policy user experience.

> **Important**
>
> - Publish is a background operation. For example, Azure Storage accounts can take up to **2 hours** to reflect the changes.
> - Changing a policy does not require a new publish operation. The changes will be picked up with the next pull.

Unpublish a data owner policy

Follow this link for the steps to unpublish a data owner policy in Microsoft Purview.

Update or delete a data owner policy

Follow this link for the steps to update or delete a data owner policy in Microsoft Purview.

Additional information

- Creating a policy at subscription or resource group level will enable the Subjects to access Azure Storage system containers, for example, *$logs*. If this is undesired, first scan the data source and then create finer-grained policies for each (that is, at container or sub-container level).

Limits

The limit for Microsoft Purview policies that can be enforced by Storage accounts is 100 MB per subscription, which roughly equates to 5000 policies.

How to view self-service data access policies

Article • 01/28/2025

> **Note**
>
> Microsoft Purview Data Map (classic), Data Catalog (classic), Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

In a Microsoft Purview catalog, you can now request access to data assets. If policies are currently available for the data source type and the data source has Data Policy Enforcement enabled, a self-service policy is generated when a data access request is approved.

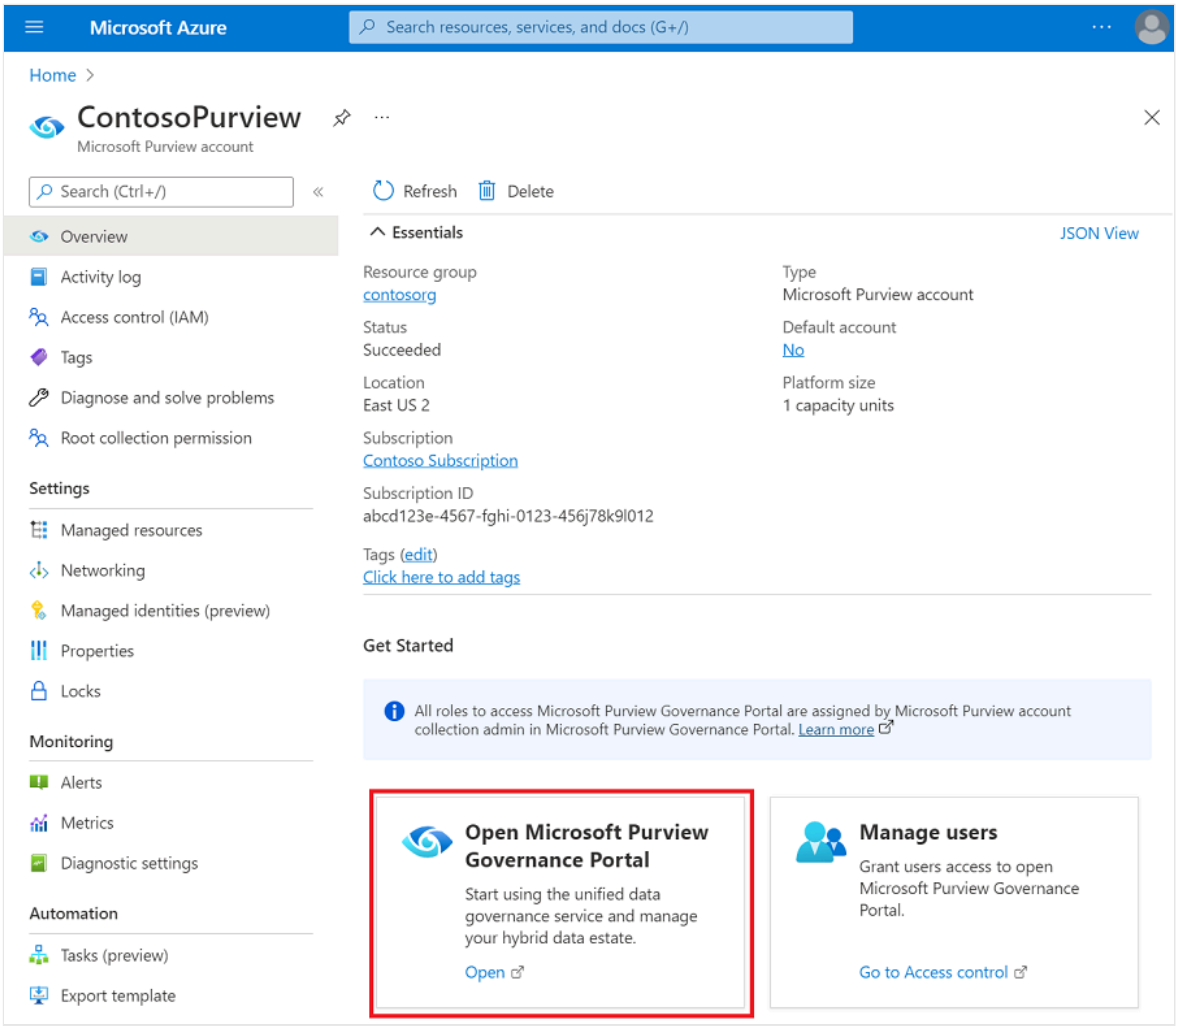
This article describes how to view self-service data access policies that have been autogenerated by approved access requests.

Prerequisites

> **Important**
>
> To view self-service policies, make sure that the below prerequisites are completed.

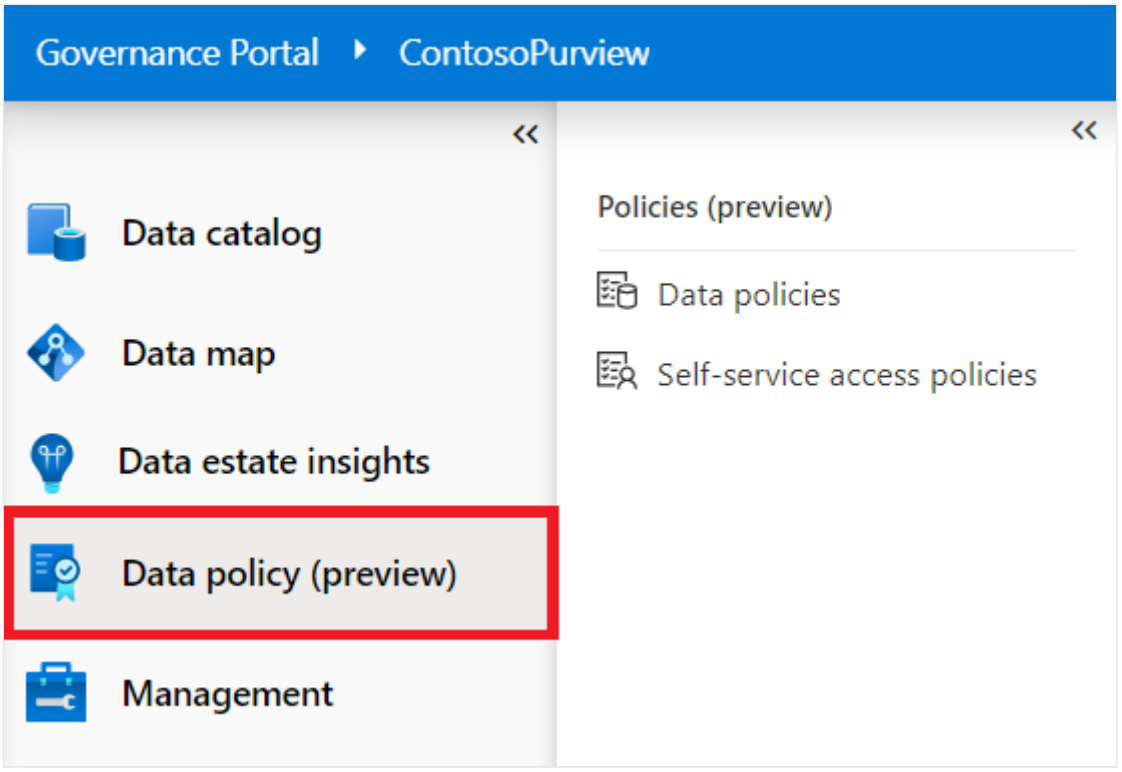
Self-service policies must exist for them to be viewed. To enable and create self-service policies, follow these articles:

1. Enable Data Policy Enforcement - this will allow Microsoft Purview to create policies for your sources.
2. Create a self-service data access workflow - this will enable users to request access to data sources from within Microsoft Purview.
3. Approve a self-service data access request - after approving a request, if your workflow from the previous step includes the ability to create a self-service data policy, your policy will be created and will be viewable.



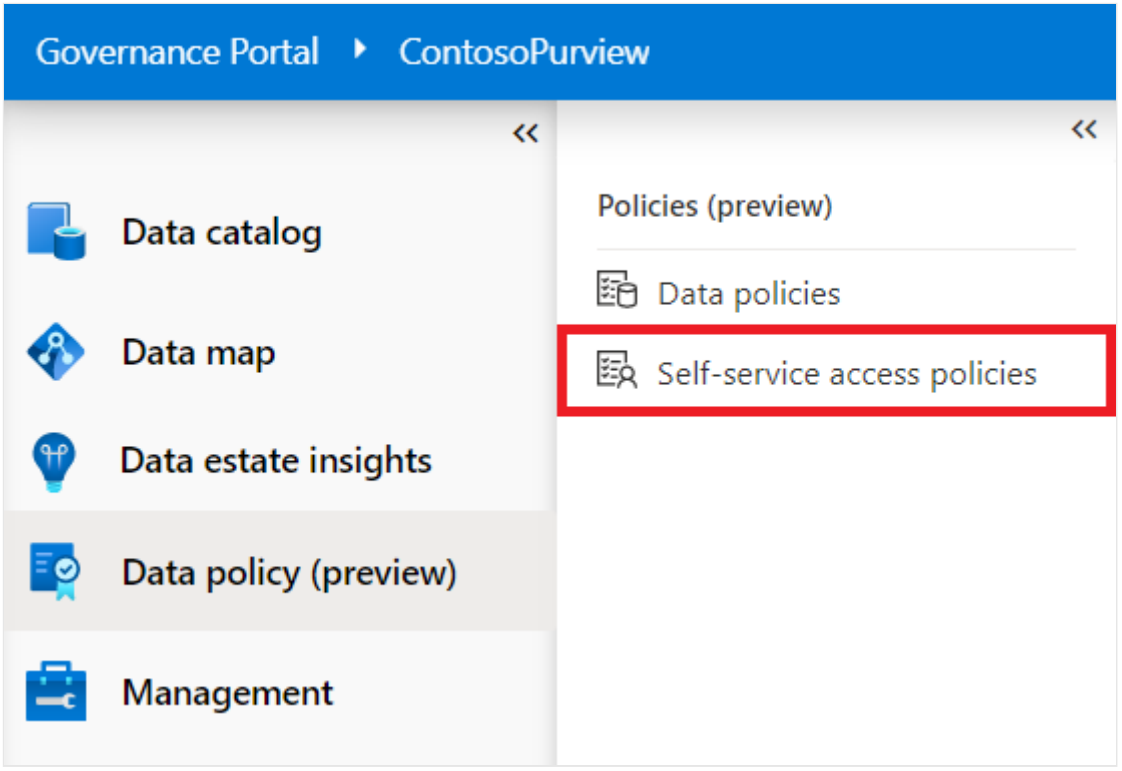
Permission

Only the creator of your Microsoft Purview account, or users with **Policy Admin** permissions can view self-service data access policies.



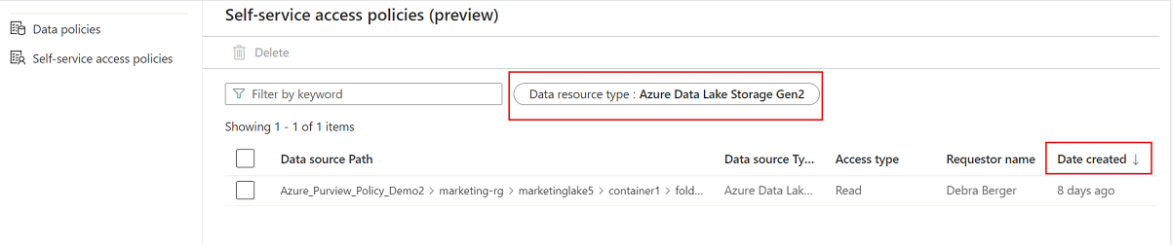
If you need to add or request permissions, follow the Microsoft Purview permissions documentation.

Steps to view self-service data access policies



1. Launch the Microsoft Purview governance portal. The Microsoft Purview governance portal can be launched as shown below or by using the url directly.

2. Select the policy management tab to launch the self-service access policies.



3. Open the self-service access policies tab.

4. Here you'll see all your policies. The policies can be sorted and filtered by any of the displayed columns to improve your search.

> ⓘ Note
>
> The only policies listed here will be policies from access requests that have already been approved. Access policies are not created until a self-service

access request has been submitted and approved.

5. Each policy has these details to tell you more about it. These details make up the simple rules of the policy: A user has been granted specific access to a specific data source.

    - **Data source path** - the full path of the data source in your Azure subscription that a user now has access to.
    - **Access type** - what kind of access the user has.
    - **Requestor name** and **On behalf of** - Who requested the access and whom the access was for.
    - **Date created** - when the policy was created (when the access request was approved.)

You can also delete existing self-service access policies, if you're ready to remove access for a user.

How to delete self-service data access policies

Article • 02/26/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

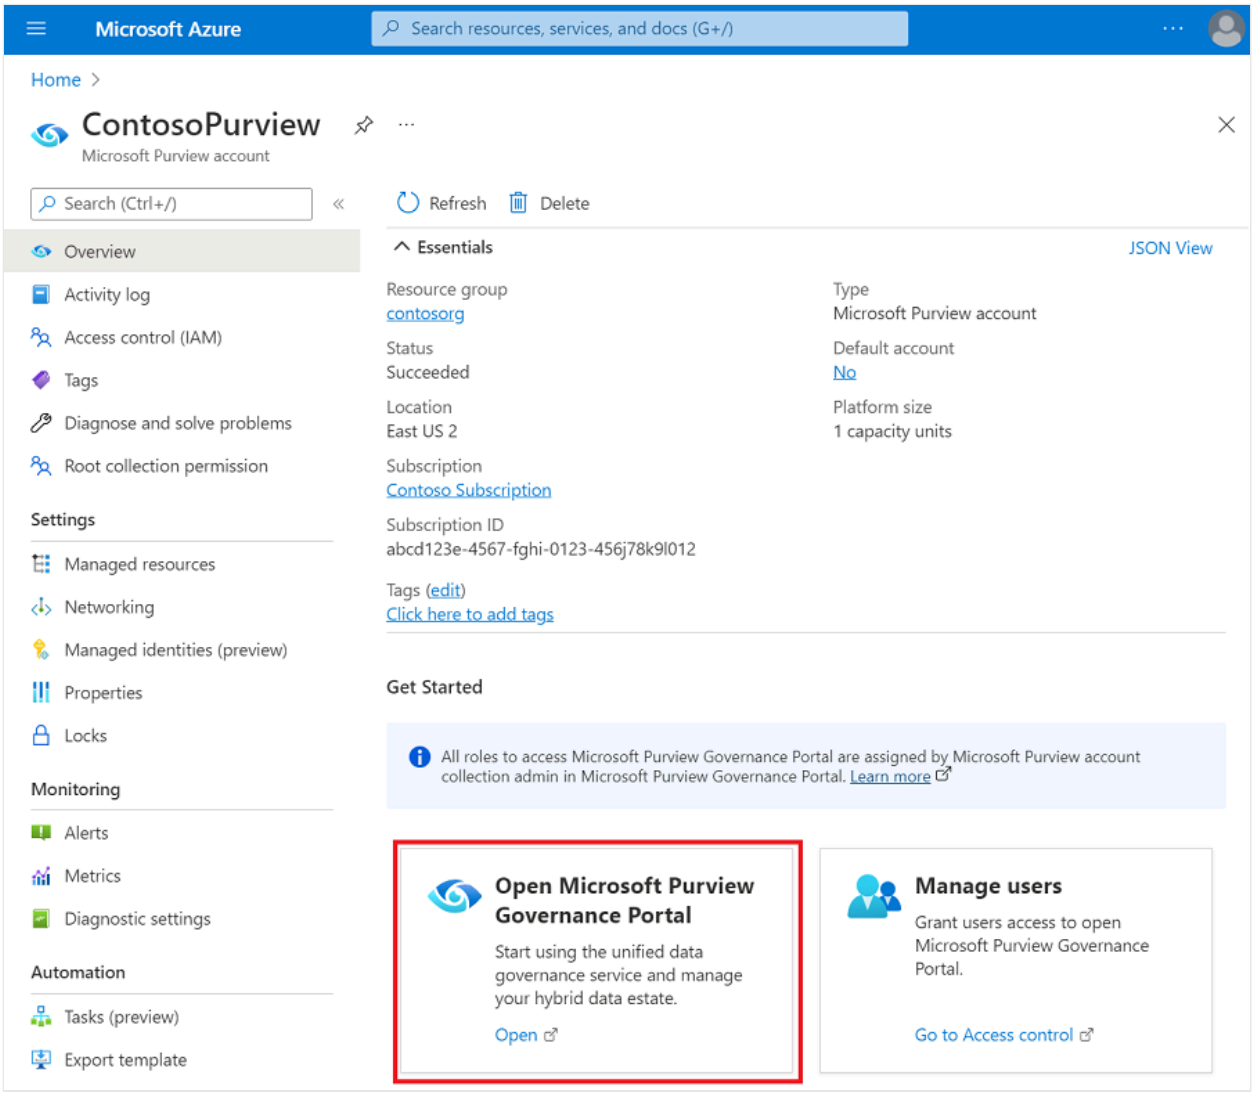
In a Microsoft Purview catalog, you can now request access to data assets. If policies are currently available for the data source type and the data source has Data Policy Enforcement enabled, a self-service policy is generated when a data access request is approved.

This article describes how to delete self-service data access policies that have been auto-generated by approved access requests.

Prerequisites

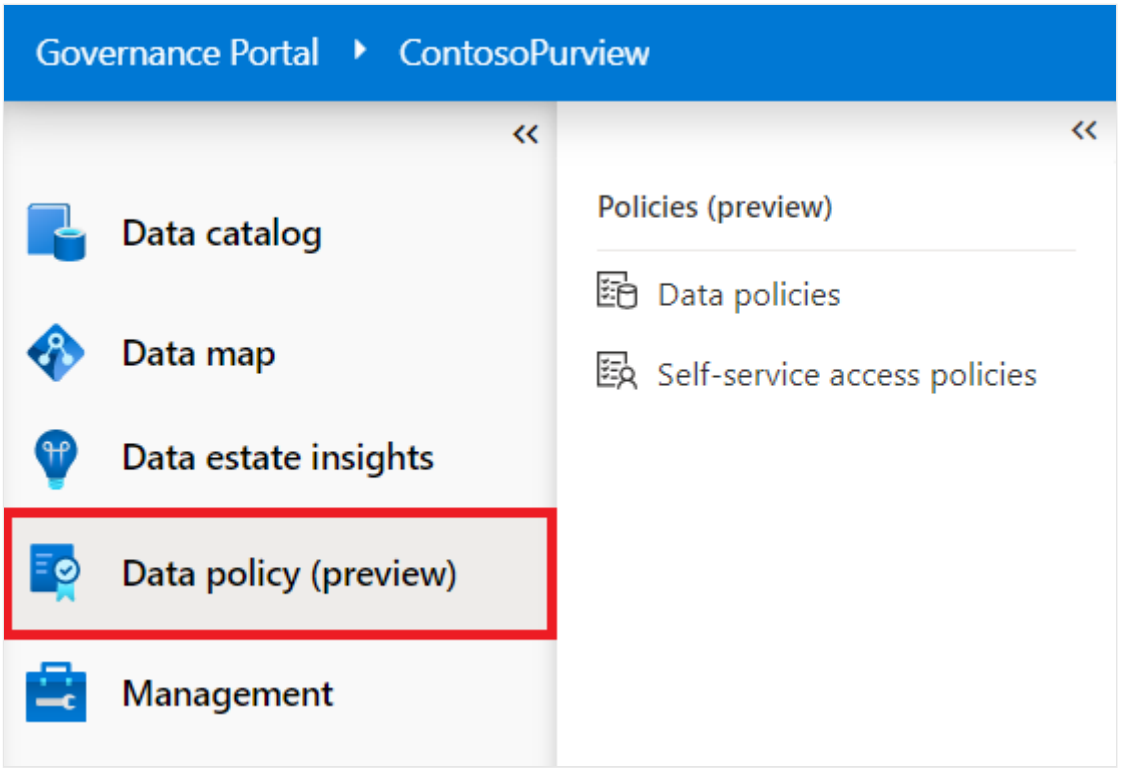
> **Important**
>
> To delete self-service policies, make sure that the below prerequisites are completed.

Self-service policies must exist to be deleted. To enable and create self-service policies, follow these articles:



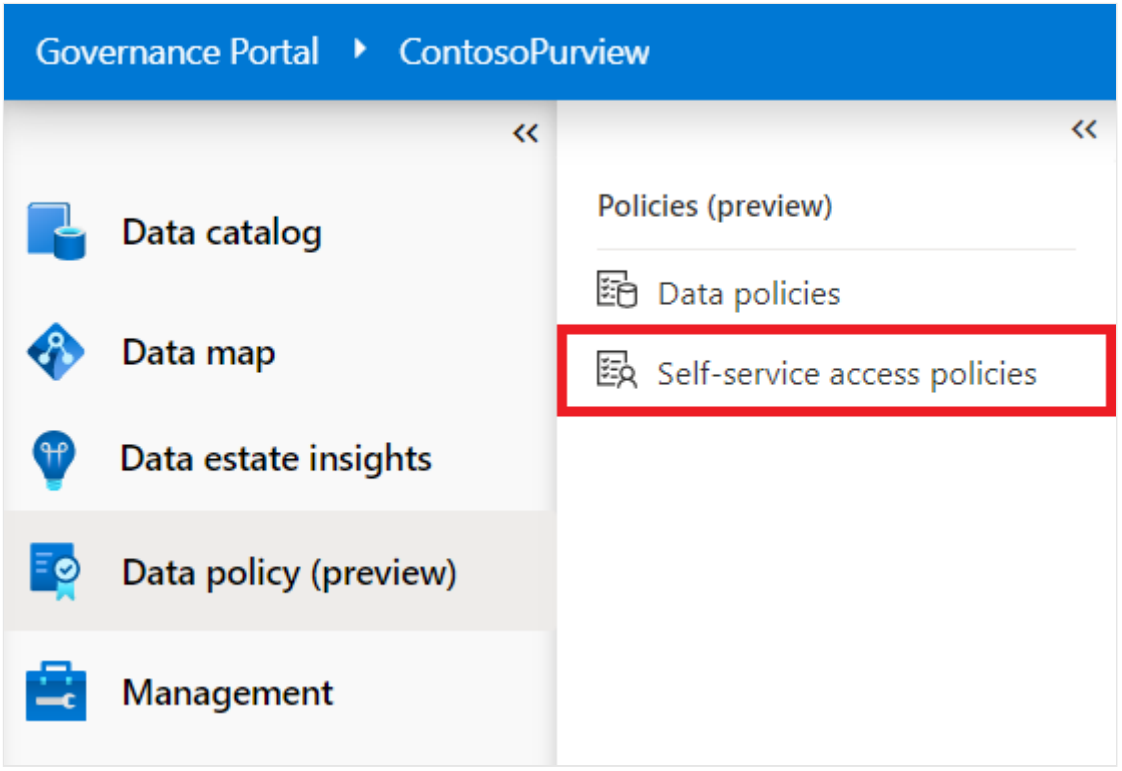
1. Enable Data Policy Enforcement - this will allow Microsoft Purview to create policies for your sources.
2. Create a self-service data access workflow - this will enable users to request access to data sources from within Microsoft Purview.
3. Approve a self-service data access request - after approving a request, if your workflow from the previous step includes the ability to create a self-service data policy, your policy will be created and will be viewable.

Permission

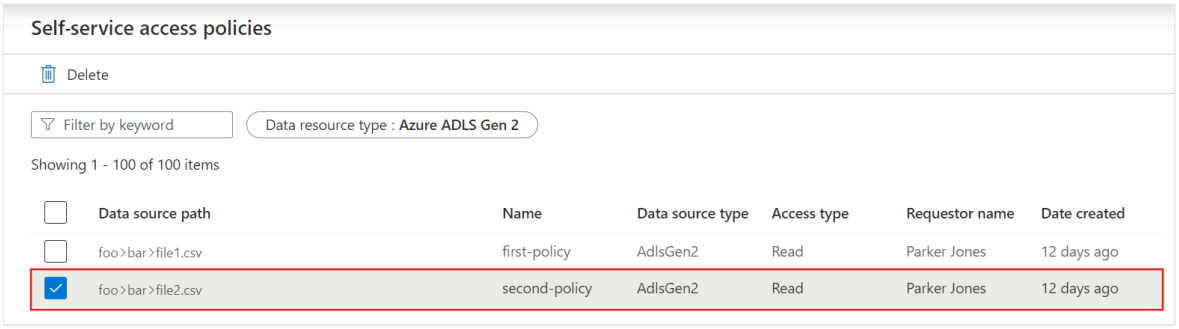


Only users with **Policy Admin** privilege can delete self-service data access policies.

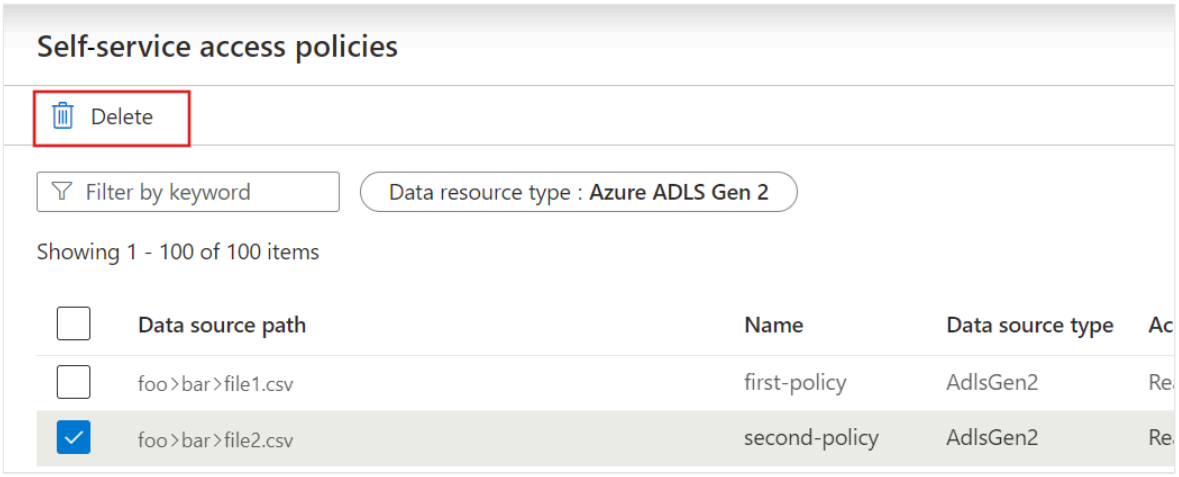
Steps to delete self-service data access policies



The Microsoft Purview governance portal can be launched as shown below from the Azure portal or by using the url directly.



1. Select the policy management tab to launch the self-service access policies.



2. Open the self-service access policies tab.

3. Here you'll see all your policies. Select the policies that need to be deleted. The policies can be sorted and filtered by any of the displayed columns to improve your search.

4. Select the delete button to delete all selected policies.

5. Select **OK** on the confirmation dialog box to delete the policy. Refresh the screen to confirm that the policies have been deleted.

Self-service policies for Azure SQL Database (preview)

Article • 02/26/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Self-service policies allow you to manage access from Microsoft Purview to data sources that have been registered for **Data Policy Enforcement**.

This how-to guide describes how self-service policies get created in Microsoft Purview to enable access to Azure SQL Database. The following actions are currently enabled: *Read Tables*, and *Read Views*.

> **Caution**
>
> *Ownership chaining* must exist for *select* to work on Azure SQL Database *views*.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- A new or existing Microsoft Purview account. Follow this quickstart guide to create one.
- Create a new Azure SQL Database instance, or use an existing one, in one of the currently available regions for this feature. You can follow this guide to create an Azure SQL Database instance.

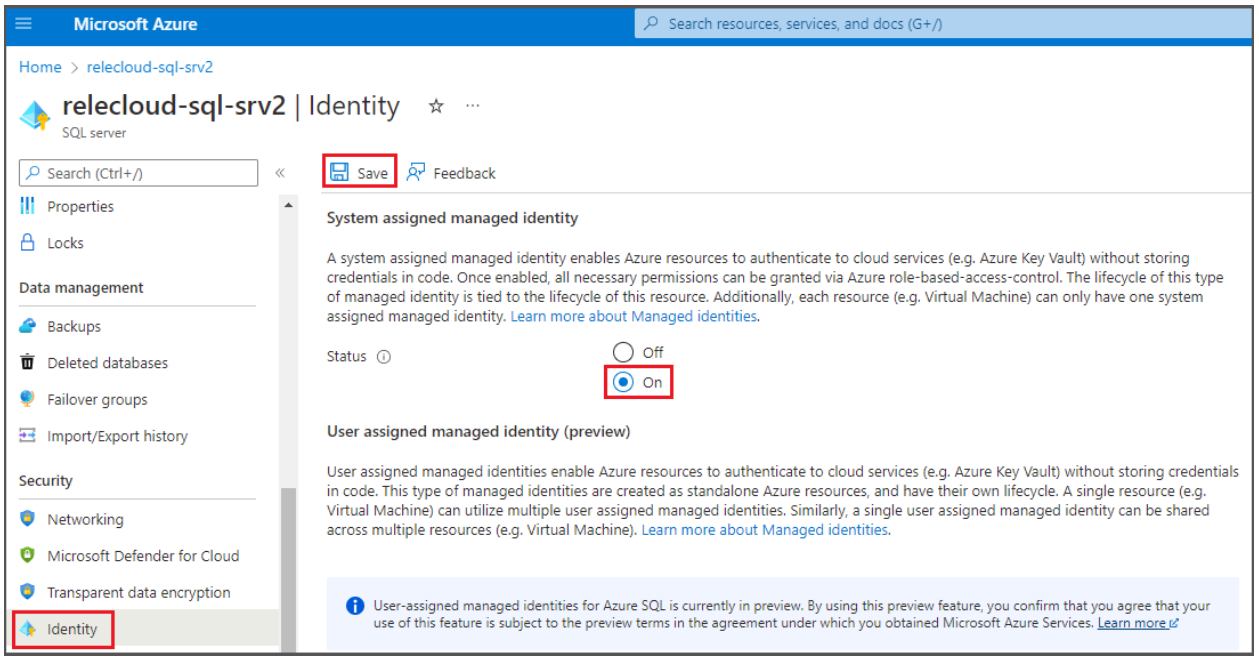
Region support

All Microsoft Purview regions are supported.

Enforcement of Microsoft Purview policies is available only in the following regions for Azure SQL Database:

Public cloud:

- East US
- East US2
- South Central US
- West Central US
- West US3
- Canada Central
- Brazil South
- West Europe
- North Europe
- France Central
- UK South
- South Africa North
- Central India
- South East Asia
- East Asia
- Australia East



Sovereign clouds:

- USGov Virginia
- China North 3

Configure the Azure SQL Database instance for policies from Microsoft Purview

For the logical server associated with Azure SQL Database to honor policies from Microsoft Purview, you need to configure a Microsoft Entra admin. In the Azure portal, go to the logical server that hosts the Azure SQL Database instance. On the side menu, select **Microsoft Entra ID**. Set an admin name to any Microsoft Entra user or group that you prefer, and then select **Save**.

Then, on the side menu, select **Identity**. Under **System assigned managed identity**, turn the status to **On**, and then select **Save**.

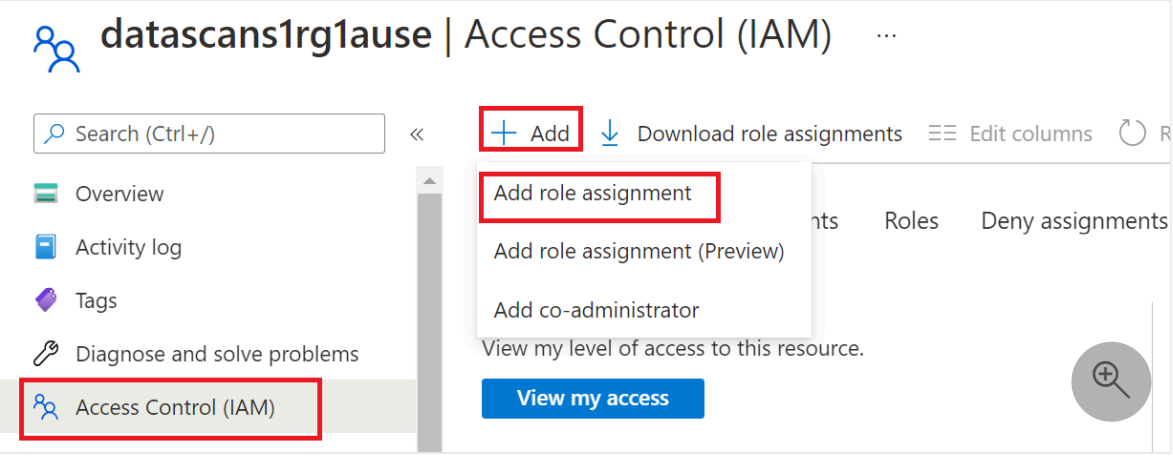
Microsoft Purview Configuration

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.

> **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and then registered again in Microsoft Purview.

Configure permissions to enable Data policy enforcement on the data source

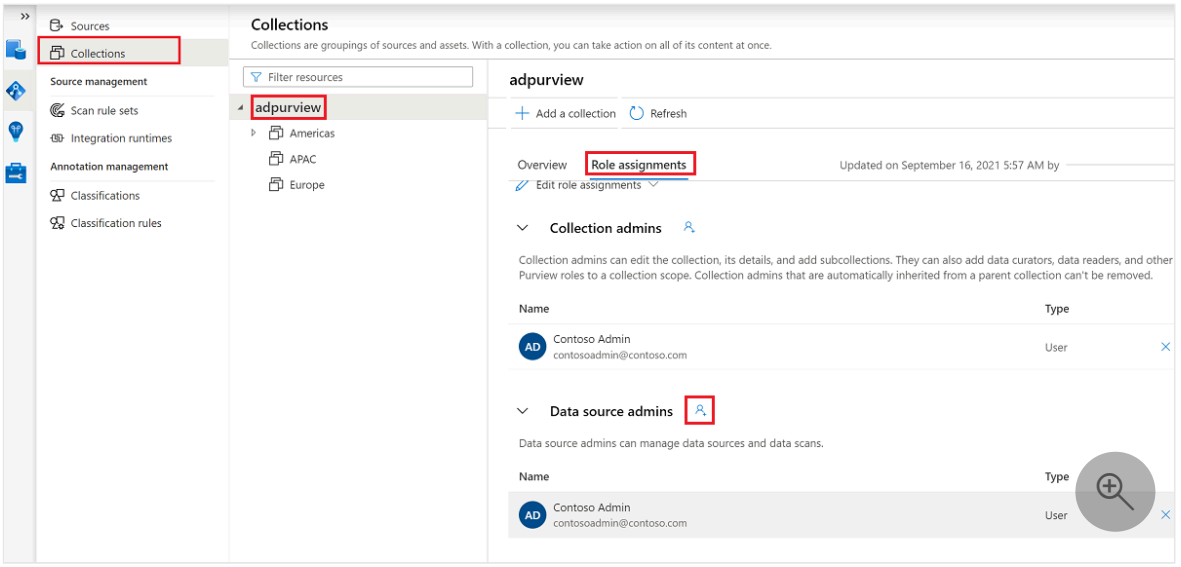


Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission

inheritance):

- IAM Owner
- Both IAM Contributor and IAM User Access Administrator



To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.

> **Note**
>
> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information, see the guide on managing Microsoft Purview role assignments.

  The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before

a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> ⓘ **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

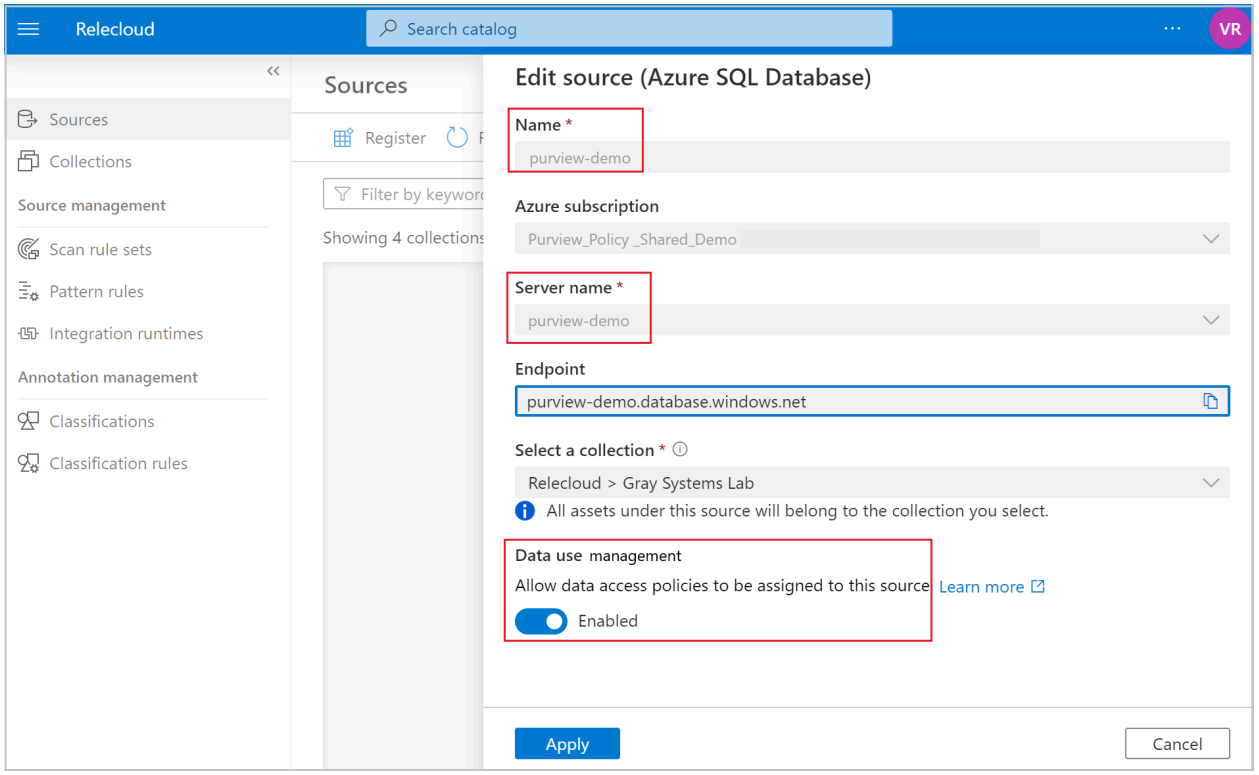
Delegate access provisioning responsibility to roles in Microsoft Purview

After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> ⓘ **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin* role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.

If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to prevent the Microsoft Purview account from being deleted through Resource Manager locks.

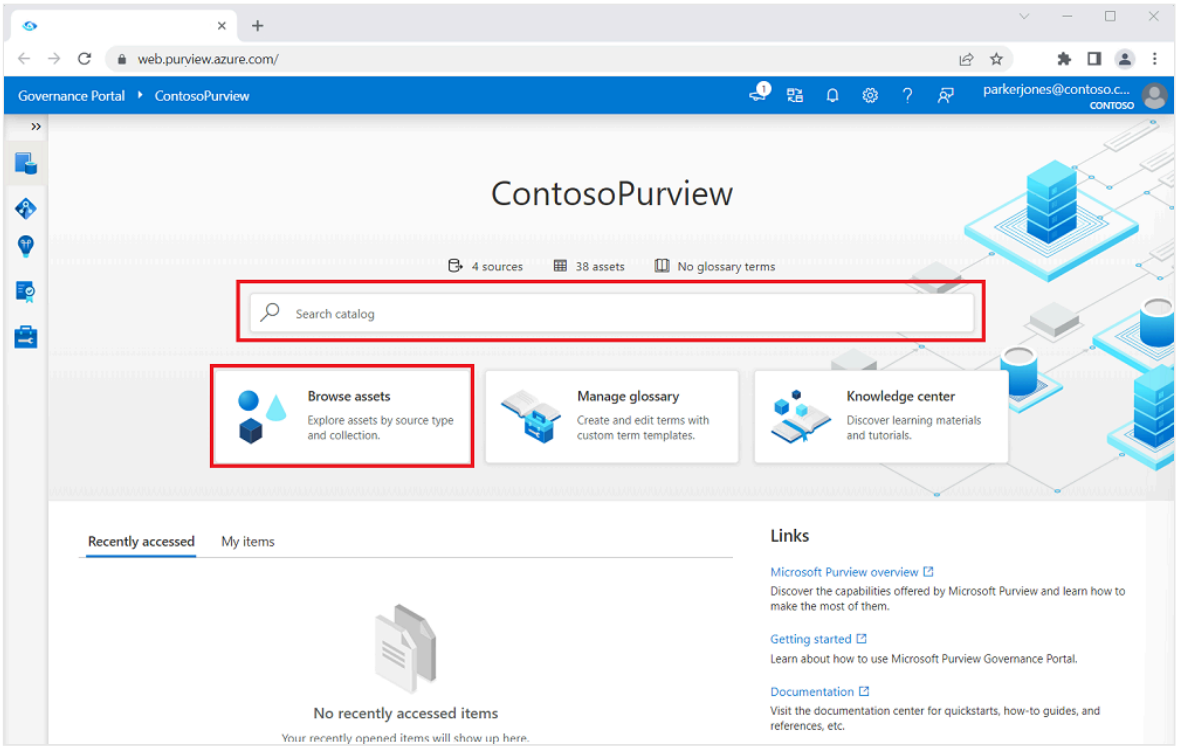
Register the data sources in Microsoft Purview



The Azure SQL Database resources need to be registered first with Microsoft Purview to later define access policies. You can follow these guides:

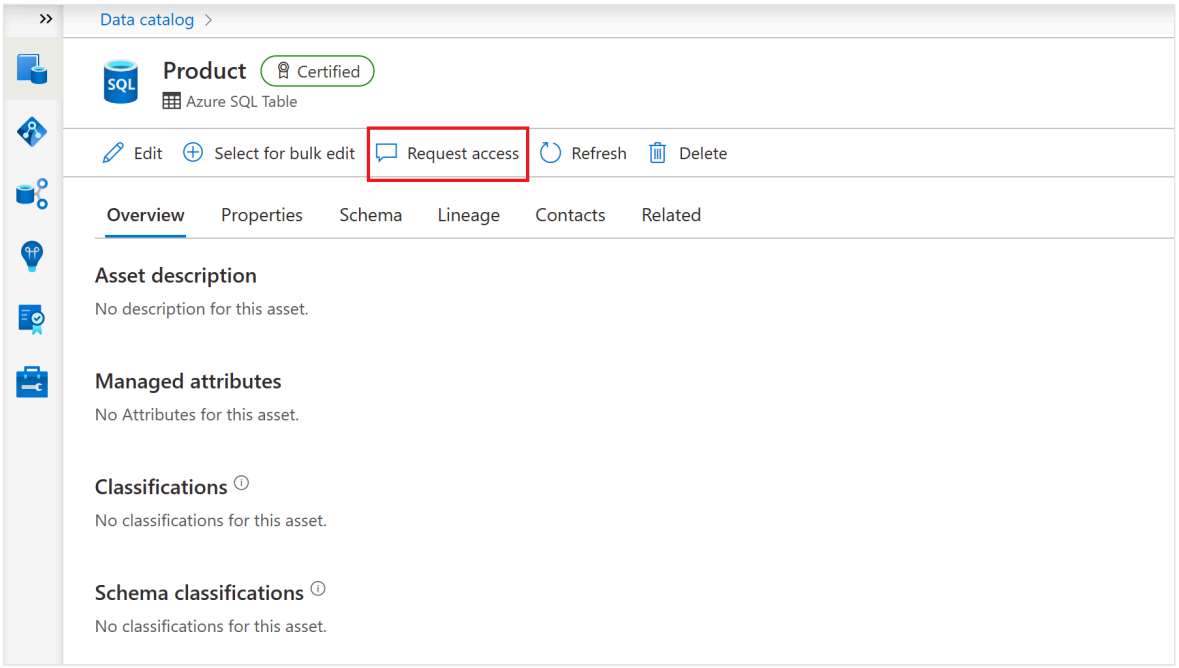
Register and scan Azure SQL DB

After you've registered your resources, you'll need to enable data policy enforcement. Data policy enforcement can affect the security of your data, as it delegates to certain Microsoft Purview roles to manage access to the data sources. **Go through the secure practices related to data policy enforcement in this guide**:



How to enable data policy enforcement

Once your data source has the **Data policy enforcement** toggle *Enabled*, it will look like this picture. This will enable the access policies to be used with the given SQL server and all its contained databases.

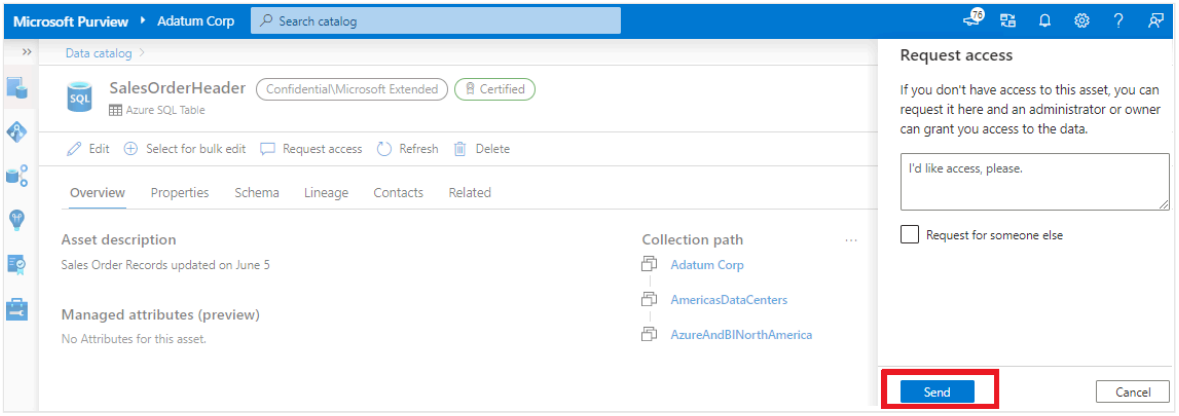


Create a self-service data access request

1. To find a data asset, use Microsoft Purview's search or browse functionality.

2. Select the asset to go to asset details.

3. Select **Request access**.



> **Note**
>
> If this option isn't available, a self-service access workflow either hasn't been created, or hasn't been assigned to the collection where the resource is registered. Contact the collection administrator, data source administrator, or workflow administrator of your collection for more information. Or, for

information on how to create a self-service access workflow, see our [self-service access workflow documentation](#).

4. The **Request access** window will open. You can provide comments on why data access is requested.

5. Select **Send** to trigger the self-service data access workflow.

> **Note**
>
> If you want to request access on behalf of another user, select the checkbox **Request for someone else** and populate the email id of that user.

> **Note**
>
> A request access to resource set will actually submit the data access request for the folder one level up which contains all these resource set files.

6. Data owners will be notified of your request and will either approve or reject the request.

> **Important**
>
> - Publish is a background operation. It can take up to **5 minutes** for the changes to be reflected in this data source.
> - Changing a policy does not require a new publish operation. The changes will be picked up with the next pull.

View a self-service Policy

To view the policies you've created, follow the article to view the self-service policies.

Test the policy

The Microsoft Entra account, group, MSI, or SPN for which the self-service policies were created, should now be able to connect to the database on the server and execute a select query against the requested table or view.

Force policy download

It's possible to force an immediate download of the latest published policies to the current SQL database by running the following command. The minimal permission required to run the command is membership in the ##MS_ServerStateManager##-server role.

SQL

```
-- Force immediate download of latest published policies
exec sp_external_policy_refresh reload
```

Analyze downloaded policy state from SQL

The following DMVs can be used to analyze which policies have been downloaded and are currently assigned to Microsoft Entra accounts. The minimal permission required to run them is VIEW DATABASE SECURITY STATE - or assigned Action Group *SQL Security Auditor*.

SQL

```
-- Lists generally supported actions
SELECT * FROM sys.dm_server_external_policy_actions

-- Lists the roles that are part of a policy published to this server
SELECT * FROM sys.dm_server_external_policy_roles

-- Lists the links between the roles and actions, could be used to join the
two
SELECT * FROM sys.dm_server_external_policy_role_actions

-- Lists all Azure AD principals that were given connect permissions
SELECT * FROM sys.dm_server_external_policy_principals

-- Lists Azure AD principals assigned to a given role on a given resource
scope
```

```
SELECT * FROM sys.dm_server_external_policy_role_members

-- Lists Azure AD principals, joined with roles, joined with their data
actions
SELECT * FROM sys.dm_server_external_policy_principal_assigned_actions
```

Additional information

Policy action mapping

This section contains a reference of how actions in Microsoft Purview data policies map to specific actions in Azure SQL Database.

Self-service access provisioning for Azure Storage datasets (Preview)

Article • 02/26/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Access policies allow you to manage access from Microsoft Purview to data sources that have been registered for *Data Policy Enforcement*.

This how-to guide describes how self-service policies get created in Microsoft Purview to enable access to Azure storage datasets. Currently, these two Azure Storage sources are supported:

- Blob storage
- Azure Data Lake Storage (ADLS) Gen2

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- A new or existing Microsoft Purview account. Follow this quickstart guide to create one.

Region support

- All Microsoft Purview regions are supported.
- Storage accounts in the following regions are supported without the need for additional configuration. However, zone-redundant storage (ZRS) accounts are not

supported.
    - Australia Central
    - Australia East
    - Australia Southeast
    - Brazil South
    - Canada Central
    - Canada East
    - Central India
    - Central US
    - East Asia
    - East US 2
    - East US
    - France Central
    - Germany West Central
    - Japan East
    - Japan West
    - Korea Central
    - North Central US
    - North Europe
    - Norway East
    - Poland Central
    - Qatar Central
    - South Central US
    - South Africa North
    - Southeast Asia
    - South India
    - Sweden Central
    - Switzerland North
    - West Central US
    - West Europe
    - West US
    - West US 2
    - West US 3
    - UAE North
    - UK South
    - UK West
- Storage accounts in other regions in Public Cloud are supported after setting feature flag *AllowPurviewPolicyEnforcement*, as outlined in the next section. Newly created ZRS Storage accounts are supported, if created after setting the feature flag *AllowPurviewPolicyEnforcement*.

If needed, you can create a new Storage account by following this guide.

Configure the subscription where the Azure Storage account resides for policies from Microsoft Purview

This step is only necessary in certain regions (see prior section). To enable Microsoft Purview to manage policies for one or more Azure Storage accounts, execute the following PowerShell commands in the subscription where you'll deploy your Azure Storage account. These PowerShell commands will enable Microsoft Purview to manage policies on all Azure Storage accounts in that subscription.

If you're executing these commands locally, be sure to run PowerShell as an administrator. Alternatively, you can use the Azure Cloud Shell in the Azure portal: https://shell.azure.com.

PowerShell

```
# Install the Az module
Install-Module -Name Az -Scope CurrentUser -Repository PSGallery -Force
# Login into the subscription
Connect-AzAccount -Subscription <SubscriptionID>
# Register the feature
Register-AzProviderFeature -FeatureName AllowPurviewPolicyEnforcement -
ProviderNamespace Microsoft.Storage
```

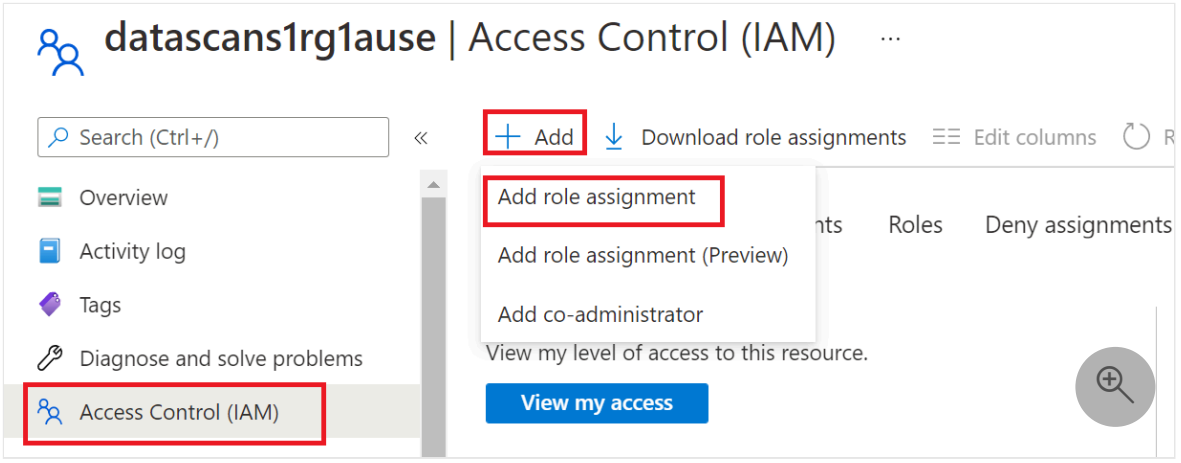
If the output of the last command shows *RegistrationState* as *Registered*, then your subscription is enabled for access policies. If the output is *Registering*, wait at least 10 minutes, and then retry the command. **Do not continue unless the RegistrationState shows as *Registered***.

Configuration

Register the data source in Microsoft Purview

Before a policy can be created in Microsoft Purview for a data resource, you must register that data resource in Microsoft Purview Studio. You will find the instructions related to registering the data resource later in this guide.

> **Note**
>
> Microsoft Purview policies rely on the data resource ARM path. If a data resource is moved to a new resource group or subscription it will need to be de-registered and



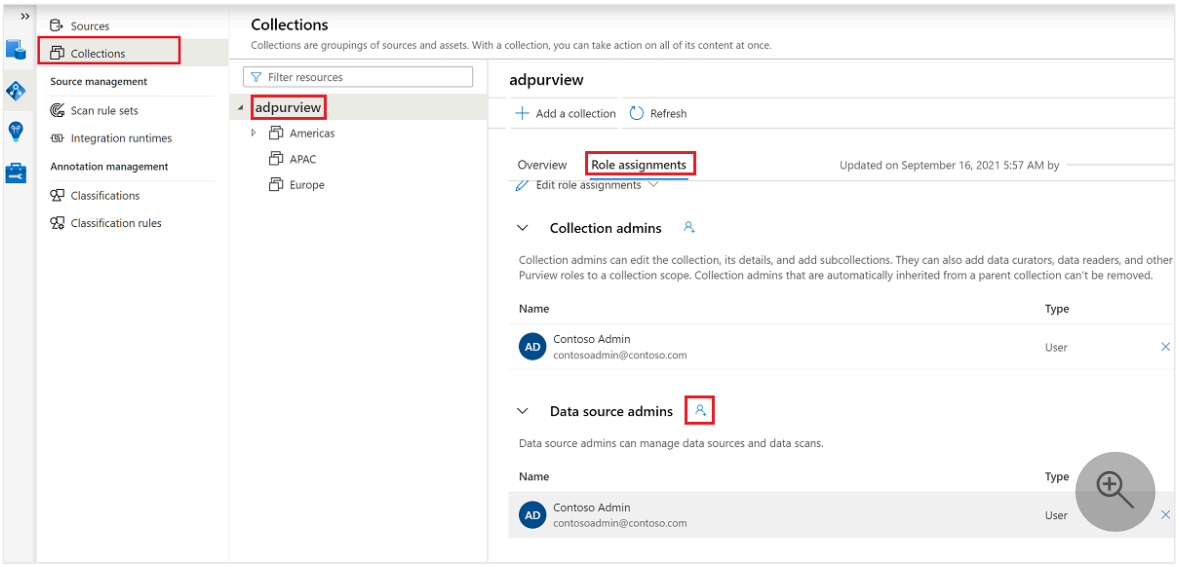
then registered again in Microsoft Purview.

Configure permissions to enable Data policy enforcement on the data source

Once a resource is registered, but before a policy can be created in Microsoft Purview for that resource, you must configure permissions. A set of permissions are needed to enable the **Data policy enforcement**. This applies to data sources, resource groups, or subscriptions. To enable *Data policy enforcement*, you must have *both* specific Identity and Access Management (IAM) privileges on the resource as well as specific Microsoft Purview privileges:

- You must have *either one* of the following IAM role combinations on the resource's Azure Resource Manager path or any parent of it (that is, using IAM permission inheritance):
  - IAM Owner
  - Both IAM Contributor and IAM User Access Administrator

  To configure Azure role-based access control (RBAC) permissions, follow this guide. The following screenshot shows how to access the **Access Control** section in the Azure portal for the data resource to add a role assignment.



> **Note**
>
> The *IAM Owner* role for a data resource can be inherited from a parent resource group, a subscription, or a subscription management group. Check which Microsoft Entra users, groups, and service principals hold or are inheriting the *IAM Owner* role for the resource.

- You also need to have the Microsoft Purview *Data source admin* role for the collection or a parent collection (if inheritance is enabled). For more information,

see the guide on managing Microsoft Purview role assignments.

The following screenshot shows how to assign the *Data source admin* role at the root collection level.

Configure Microsoft Purview permissions to create, update, or delete access policies

To create, update or delete policies, you need to get the *Policy author* role in Microsoft Purview at *root collection level*:

- The *Policy author* role can create, update, and delete DevOps and Data Owner policies.
- The *Policy author* role can delete self-service access policies.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> Policy author role must be configured at the root collection level.

In addition, to easily search Microsoft Entra users or groups when creating or updating the subject of a policy, you can greatly benefit from getting the Directory Readers permission in Microsoft Entra ID. This is a common permission for users in an Azure tenant. Without the Directory Reader permission, the Policy Author will have to type the complete username or email for all the principals included in the subject of a data policy.

Configure Microsoft Purview permissions for publishing Data Owner policies

Data Owner policies allow for checks and balances if you assign the Microsoft Purview *Policy author* and *Data source admin* roles to different people in the organization. Before a Data owner policy takes effect, a second person (*Data source admin*) must review it and explicitly approve it by publishing it. This does not apply to DevOps or Self-service access policies as publishing is automatic for them when those policies are created or updated.

To publish a Data owner policy you need to get the *Data source admin* role in Microsoft Purview at *root collection level*.

For more information about managing Microsoft Purview role assignments, see Create and manage collections in the Microsoft Purview Data Map.

> **Note**
>
> To publish Data owner policies, the Data source admin role must be configured at the root collection level.

Delegate access provisioning responsibility to roles in Microsoft Purview

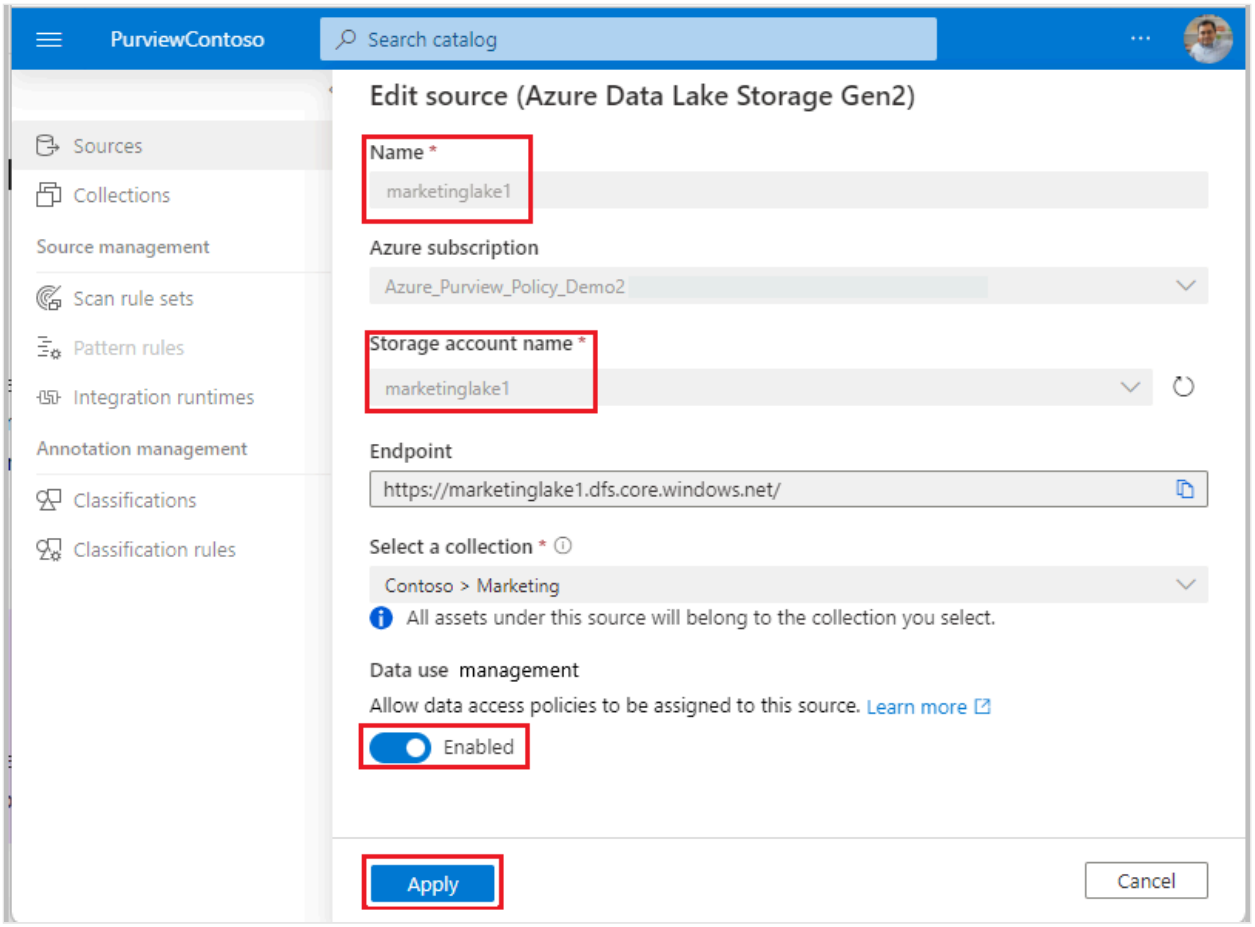
After a resource has been enabled for **Data policy enforcement**, any Microsoft Purview user with the *Policy author* role at the root collection level can provision access to that data source from Microsoft Purview.

> **Note**
>
> Any Microsoft Purview root *Collection admin* can assign new users to root *Policy author* roles. Any *Collection admin* can assign new users to a *Data source admin* role under the collection. Minimize and carefully vet the users who hold Microsoft Purview *Collection admin*, *Data source admin*, or *Policy author* roles.

If a Microsoft Purview account with published policies is deleted, such policies will stop being enforced within an amount of time that depends on the specific data source. This change can have implications on both security and data access availability. The Contributor and Owner roles in IAM can delete Microsoft Purview accounts. You can check these permissions by going to the **Access control (IAM)** section for your Microsoft Purview account and selecting **Role Assignments**. You can also use a lock to

prevent the Microsoft Purview account from being deleted through Resource Manager locks.

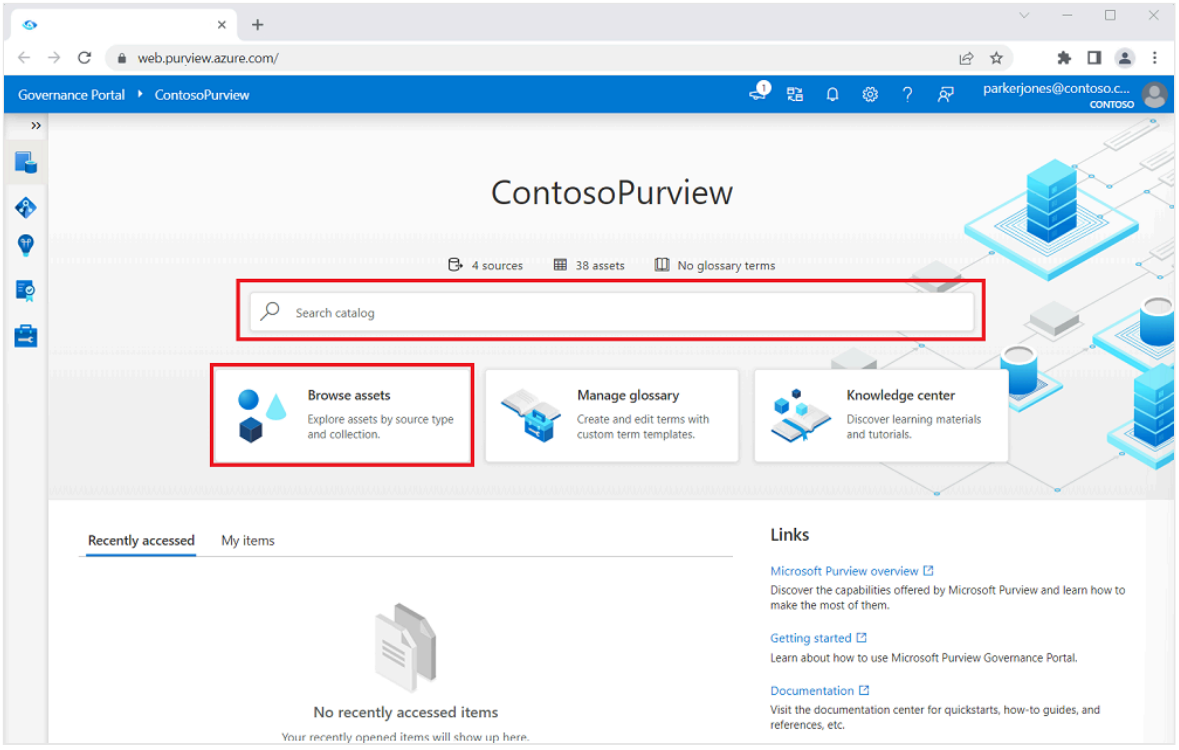
Register the data sources in Microsoft Purview for Data Policy Enforcement



The Azure Storage resources need to be registered first with Microsoft Purview to later define access policies.

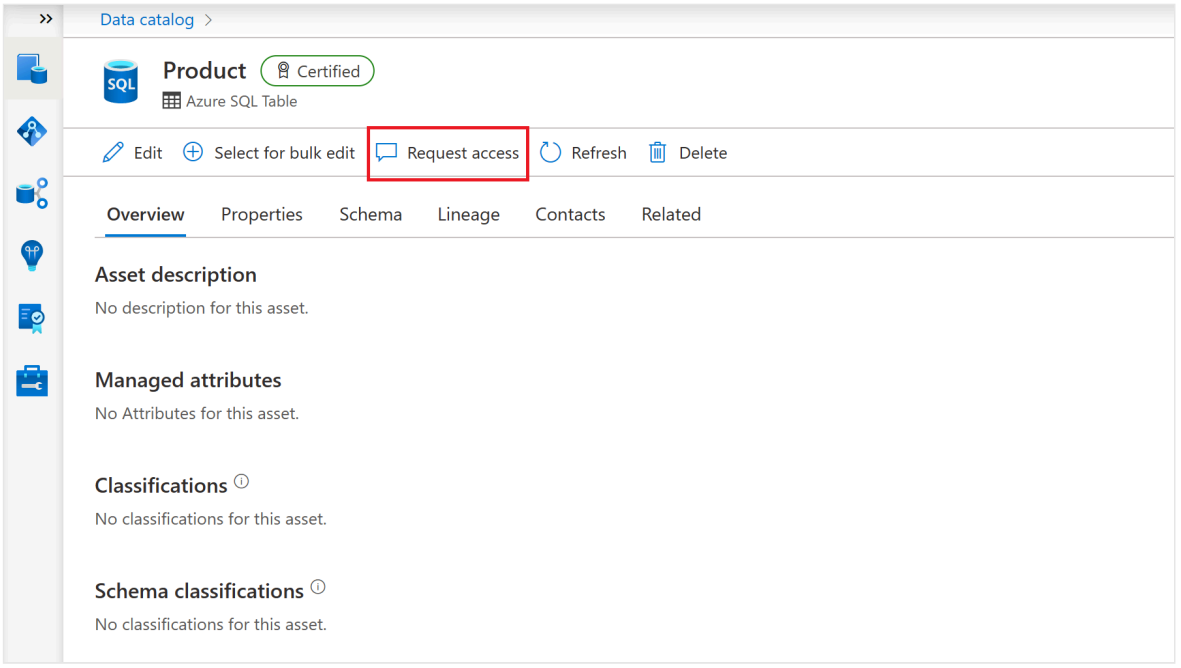
To register your resources, follow the **Prerequisites** and **Register** sections of these guides:

- Register and scan Azure Storage Blob - Microsoft Purview
- Register and scan Azure Data Lake Storage (ADLS) Gen2 - Microsoft Purview



After you've registered your resources, you'll need to enable data policy enforcement. Data policy enforcement needs certain permissions and can affect the security of your data, as it delegates to certain Microsoft Purview roles to manage access to the data sources. **Go through the secure practices related to Data Policy Enforcement in this guide**: How to enable data policy enforcement

Once your data source has the **Data Policy Enforcement** toggle **Enabled**, it will look like this picture:

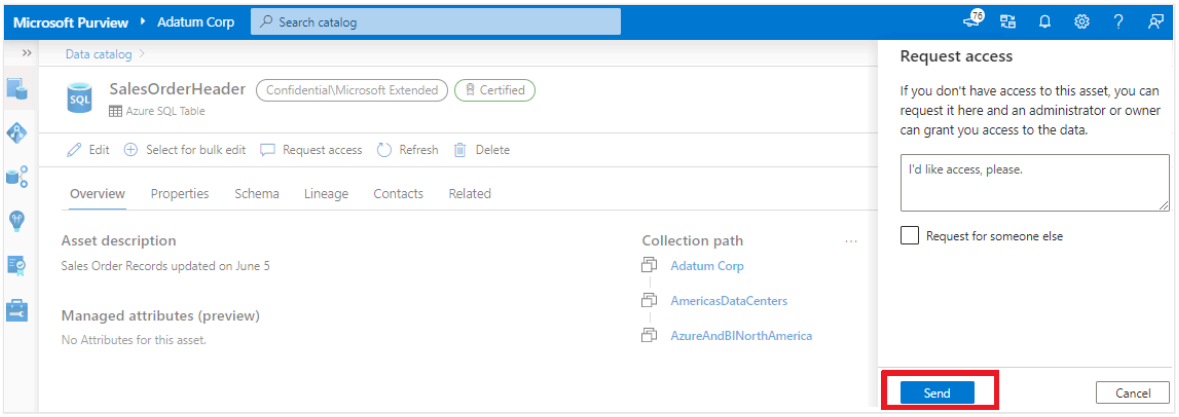


Create a self-service data access request

1. To find a data asset, use Microsoft Purview's search or browse functionality.

2. Select the asset to go to asset details.

3. Select **Request access**.



> **Note**
>
> If this option isn't available, a self-service access workflow either hasn't been created, or hasn't been assigned to the collection where the resource is registered. Contact the collection administrator, data source administrator, or workflow administrator of your collection for more information. Or, for information on how to create a self-service access workflow, see our self-service access workflow documentation.

4. The **Request access** window will open. You can provide comments on why data access is requested.

5. Select **Send** to trigger the self-service data access workflow.

> **Note**
>
> If you want to request access on behalf of another user, select the checkbox **Request for someone else** and populate the email id of that user.

> **Note**
>
> A request access to resource set will actually submit the data access request for the folder one level up which contains all these resource set files.

6. Data owners will be notified of your request and will either approve or reject the request.

> **Important**
>
> - Publish is a background operation. Azure Storage accounts can take up to **2 hours** to reflect the changes.

View a self-service policy

To view the policies you've created, follow the article to view the self-service policies.

Data consumption

- Data consumer can access the requested dataset using tools such as Power BI or Azure Synapse Analytics workspace.

> **Note**
>
> Users won't be able to browse to the asset using the Azure portal or Storage explorer if the only permission granted is read/modify access at the file or folder level of the storage account.

> **Caution**

Folder level permission is required to access data in ADLS Gen 2 using Power BI. Additionally, resource sets aren't supported by self-service policies. Hence, folder level permission needs to be granted to access resource set files such as CSV or parquet.

Known issues

Known issues related to Policy creation

- self-service policies aren't supported for Microsoft Purview resource sets. Even if displayed in Microsoft Purview, it isn't yet enforced. Learn more about resource sets.

Get started with protection policies (preview)

Protection policies help organizations automatically protect sensitive data across data sources. Microsoft Purview already scans data assets and identifies sensitive data elements. Protection policies help you automatically restrict access to that data by using sensitivity labels from Microsoft Purview Information Protection.

Protection policies ensure that enterprise admins must authorize data access for a sensitivity label. After you enable these policies, access control is automatically imposed whenever Information Protection detects sensitive information.

Actions supported

- Restrict access on labeled data assets so that only users and groups you select can access them.
- Configure action on sensitivity labels in the Information Protection solution.

Data sources supported

- Azure Sources:
  - Azure Blob storage
  - Azure Data Lake Storage Gen2
- Microsoft Fabric

> **Tip**
>
> This article covers general steps for all protection policies. The available data source articles cover specifics like available regions, limitations, and specific features for those data sources.

Prerequisites

- Microsoft 365 E5 license and setup of the pay-as-you-go billing model. To understand pay-as-you-go billing by assets protected, see the pay-as-you-go billing model. For information about the specific licenses required, see sensitivity label licensing information. To get a Microsoft 365 E5 trial license for your tenant, sign up from your environment.

Azure sources

- Configure users and permissions.
- Create or extend sensitivity labels from Microsoft Purview Information Protection to Data Map assets.
- Register sources - register any of these sources you like:
  - Azure Blob Storage
  - Azure Data Lake Storage Gen2

  > **Note**
  >
  > To continue, you need to be a data source administrator in the collection where your Azure storage source is registered.

- Enable data policy enforcement:
  - Go to the new Microsoft Purview portal.
  - Select the **Data Map** tab in the left menu.
  - Select the **Data sources** tab in the left menu.
  - Select the source where you want to enable *data policy enforcement*.
  - Set the **Data policy enforcement** toggle to **On**.
- Scan sources - register any of the sources you've registered:
  - Azure Blob Storage
  - Azure Data Lake Storage Gen2

  > **Note**
  >
  > Wait at least 24 hours after scanning.

Users and permissions for Azure sources

There are several types of users you need, and you need to set up the corresponding roles and permissions for these users:

1. Microsoft Purview Information Protection Admin - Broad rights to manage Information Protection solution: reviewing / creating / updating / deleting protection policies, sensitivity labels and label/auto-labeling policies, all classifier types. They should also have full access to data explorer, activity explorer, Microsoft Purview Information Protection insights, and reports.

    - User needs the roles from within the built-in role group “Information Protection”, along with new roles for data map reader, insights reader, scan reader, source reader. Full permissions would be:
        - Information Protection reader
        - Data Map Reader
        - Insights Reader
        - Source Reader
        - Scan Reader
        - Information Protection admin
        - Information Protection analyst
        - Information protection investigator
        - Data classification list viewer
        - Data classification content viewer
        - Microsoft Purview evaluation administrator
    - **Option 1** - Recommended:
        a. Within the Microsoft Purview role groups panel, search for **Information Protection**.
        b. Select the Information Protection role group, select **Copy**.
        c. Name it: "Preview - Information Protection", and select **Create copy**.
        d. Select **Preview - Information Protection** and select **Edit**.
        e. On the **Roles** page, **+ Choose roles** and search for “reader”.
        f. Select these four roles: Data map reader, insights reader, scan reader, source reader.
        g. Add the Microsoft Purview Information Protection admin test user account to this new copied group and complete the wizard.
    - **Option 2**- uses built-in groups (will provide more permissions than needed)
        a. Place a new Microsoft Purview Information Protection admin test user account within the built-in groups for Information Protection, Data Estate Insights Readers, Data Source Administrators.

2. Data Owner/Admin - This user will enable your source for data policy enforcement in Microsoft Purview for Azure and Amazon S3 sources.

Create protection policy

After you check the prerequisites and prepare your Microsoft Purview instance and source for protection policies and wait at least 24 hours after your most recent scan, complete the following steps to create your protection policies:

1. Sign in to the Microsoft Purview portal > **Information Protection** card > **Policies**. If the **Information Protection** solution card isn't displayed, select **View all solutions** and then select **Information Protection** from the **Data Security** section.

2. Select **Protection policies**.

3. Select **+ New protection policy**.

4. Enter a name and description, and select **Next**.

5. Select **+ Add sensitivity label** to add sensitivity labels to detect for the policy, and select all the labels you want the policy to apply to.

6. Select **Add** and then select **Next**.

7. Select the sources you want to apply the policy to.
   a. For Microsoft Fabric sources, select only Fabric and select **Next**. (For more information, see the Fabric documentation.)
   b. For Azure sources, you can select multiple sources. Select the **Edit** button to manage the scope for each source you select.

8. Depending on your source, select the **+ Include** button at the top to add up to 10 resources to your scope list. The policy applies to all the resources you select.

   > **Note**
   >
   > Currently, a maximum of 10 resources are supported, and you must select them under **Edit** for them to be enabled. If the Azure storage account enables a customer-managed key, the storage account doesn't work for protection policies.

9. Select **Add** and then select **Done** when your list of sources is complete.

10. Depending on your source, select the type of protection policy you want to create.
    a. For Fabric sources, follow the protection policies for Fabric documentation.
    b. For other sources, select the users who are **NOT** denied access based on the label. Everyone in your org is denied access to labeled items except for the users and groups you add here.

> **Important**
>
> Ensure that you include any service principal accounts running Microsoft Purview Data Governance Scans for the scoped sources in a security group. Add this security group to the allowed list of your protection policies. This action prevents future scans from being blocked by access restrictions on labeled files.

1. Select **Next**.
2. Select whether to turn on the policy right away or not, and select **Next**.
3. Select **Submit**.
4. Select **Done**.
5. You should now see your new policy in the list of protection policies. Select it to confirm that all the details are correct.

Manage protection policy

To edit or delete an existing protection policy, follow these steps:

1. Open the Microsoft Purview portal.
2. Open the **Information Protection** solution.
3. Select **Policies**, then select **Protection policies**.
4. Select the policy you want to manage.
5. To change any of the details, select the **Edit policy** button.
6. To delete the policy, select **Delete policy**.

Authoring and publishing protection policies for Azure sources (preview)

Protection access control policies (protection policies) enable organizations to automatically protect sensitive data across data sources. Microsoft Purview already scans data assets and identifies sensitive data elements. This new feature allows you to automatically restrict access to that data by using sensitivity labels from Microsoft Purview Information Protection.

Protection policies ensure that Enterprise Admins must authorize data access for a sensitivity type. After you enable these policies, access control is automatically imposed whenever Information Protection detects sensitive information.

Actions supported

- Restrict access on labeled data assets so that only users and groups you select can access them.
- Configure action on Sensitivity Labels in the Information Protection solution.

Sources supported

- Azure Blob Storage
- Azure Data Lake Storage Gen2

Prerequisites

- Microsoft 365 E5 license and setup of the pay-as-you-go billing model. To understand pay-as-you-go billing by assets protected, see the pay-as-you-go billing model. For information about the specific licenses required, see sensitivity label licensing information. To get a Microsoft 365 E5 trial license for your tenant, sign up from your environment.

- Existing Purview accounts upgraded to Microsoft Purview single tenant model and new Portal experience, using the enterprise version of Microsoft Purview.

- Configure users and permissions.

- Create or extend sensitivity labels from Microsoft Purview Information Protection to Data Map assets.

- Register sources - register any of these sources you like:
  - Azure Blob Storage
  - Azure Data Lake Storage Gen2

  > ⓘ **Note**
  >
  > To continue, you need to be a **data source administrator** in the collection where your Azure storage source is registered.

- Enable data policy enforcement:
  - Go to the new Microsoft Purview portal.
  - Select the **Data Map** tab in the left menu.
  - Select the **Data sources** tab in the left menu.
  - Select the source where you want to enable *data policy enforcement*.
  - Set the **Data policy enforcement** toggle to **On**.

- Scan sources - register any of the sources you've registered:
  - Azure Blob Storage
  - Azure Data Lake Storage Gen2

  > ⓘ **Note**
  >
  > Wait at least 24 hours after scanning.

Users and permissions

There are several types of users you need, and you need to set up the corresponding roles and permissions for these users:

1. Microsoft Purview Information Protection Admin - Broad rights to manage Information Protection solution: reviewing / creating / updating / deleting protection policies, sensitivity labels and label/auto-labeling policies, all classifier types. They should also have full access to data explorer, activity explorer, Microsoft Purview Information Protection insights, and reports.

   - User needs the roles from within the built-in role group “Information Protection”, along with new roles for data map reader, insights reader, scan reader, source reader. Full permissions would be:

    - Information Protection reader
    - Data Map Reader
    - Insights Reader
    - Source Reader
    - Scan Reader
    - Information Protection admin
    - Information Protection analyst
    - Information protection investigator
    - Data classification list viewer
    - Data classification content viewer
    - Microsoft Purview evaluation administrator
- **Option 1** - Recommended:
    a. Within the Microsoft Purview role groups panel, search for **Information Protection**.
    b. Select the Information Protection role group, select **Copy**.
    c. Name it: "Preview - Information Protection", and select **Create copy**.
    d. Select **Preview - Information Protection** and select **Edit**.
    e. On the **Roles** page, **+ Choose roles** and search for “reader”.
    f. Select these four roles: Data map reader, insights reader, scan reader, source reader.
    g. Add the Microsoft Purview Information Protection admin test user account to this new copied group and complete the wizard.
- **Option 2**- uses built-in groups (will provide more permissions than needed)
    a. Place a new Microsoft Purview Information Protection admin test user account within the built-in groups for Information Protection, Data Estate Insights Readers, Data Source Administrators.

2. Data Owner/Admin - This user will enable your source for data policy enforcement in Microsoft Purview for Azure and Amazon S3 sources.

Create protection policy

After you check the prerequisites and prepare your Microsoft Purview instance and source for protection policies and wait at least 24 hours after your most recent scan, complete the following steps to create your protection policies:

1. Sign in to the Microsoft Purview portal and select the **Information Protection** card. If the **Information Protection** solution card isn't displayed, select **View all solutions** and then select **Information Protection** from the **Data Security** section.

2. On the left navigation, select select **Policies**, then select **Protection policies**.

3. Select **New protection policy**.
4. Provide a name and description and select **Next**.
5. Select + **Add sensitivity label** to add sensitivity label(s) to detect for the policy, and select all the labels you want the policy to apply to.
6. Select **Add** then select **Next**.
7. Select the sources you want to apply the policy to. You can select multiple sources. Select **Edit** to manage the scope for each you select.
8. Depending on your source, select the + **Include** button at the top to add up to 10 resources your scope list. The policy will be applied to all the resources you select.

   > ⓘ **Note**
   >
   > Currently a maximum of 10 resources is supported, and they must be selected under **Edit** for them to be enabled.

9. Select **Add** and then select **Done** when your list of sources is complete.
10. Depending on your source, select the type of protection policy you want to create.
11. Select the users who will **NOT** be denied access based on the label. Everyone in your org will be denied access to labeled items except for the users and groups you add here.

    > ⓘ **Important**
    >
    > Ensure that any service principal accounts running data governance scans for the scoped sources are included in a Security Group. Add this Security Group to the allowed list of your protection policies. This will prevent future scans from being blocked by access restrictions on labeled files.

12. Select **Next**.
13. Choose whether turn on the policy right away or not, and select **Next**.
14. Select **Submit**.
15. Select **Done**.

You should now see your new policy in the list of protection policies. Select it to confirm that all the details are correct.

Manage protection policy

To edit or delete an existing protection policy, follow these steps:

1. Open the Microsoft Purview portal.
2. Open the **Information Protection** solution.
3. Select **Policies**, then select **Protection policies**.
4. Select the policy you want to manage.
5. To change any of the details, select the **Edit policy** button.
6. To delete the policy, select **Delete policy**.

Next steps

- Get started with protection policies: Learn about protection policies across all supported data sources.
- Register and scan Azure Data Lake Storage Gen2: Register your ADLS Gen2 source and apply protection policies.

Protection policies in Microsoft Fabric

Microsoft Purview protection access control policies (protection policies) enable organizations to control access to items in Fabric using sensitivity labels.

The target audience for this article is security and compliance admins, Fabric admins and users, and anyone else who wants to learn about how protection policies control access to items in Fabric. If you want to see how to create a protection policy for Fabric, see Create and manage protection policies for Fabric.

How do protection policies for Fabric work?

Each protection policy for Fabric is associated with a sensitivity label. The policy controls access to an item that has the associated label by allowing users and groups specified in the policy to retain permissions they have on the item, while blocking access for everyone else.

The policy can allow specified users and groups to retain full control on the labeled item if they currently have it. All other users and groups are blocked from accessing the item.

> **Note**
>
> A protection policy doesn't apply to a label issuer. That is, the user that last applied a label associated with a protection policy to an item won't be denied access to that item, even if they aren't specified in the policy. For example, if a protection policy is associated with label A, and a user applies label A to an item, that user will be able to access the item even if they're not specified in the policy.

View an item's restricted users

In the Fabric admin portal, you can use the OneLake catalog to view an item's permissions and determine which users are restricted from accessing it. The Permissions tab in the item's details is visible to you if you have a role of Admin or Member in the workspace containing the item.

To view an item's permissions in the Fabric admin portal, open the **OneLake catalog**, locate the item (optionally filter by workspace), and select its name to open the item details. Then, select the **Permissions** tab to see the list of users and groups that have access to the item, including those restricted by a protection policy.

Use cases

Protection policies are useful in scenarios where organizations need to restrict access to sensitive items. For example, an organization might want to ensure that only specific internal users can access items labeled as "Confidential," while blocking access for everyone else.

Who creates protection policies for Fabric?

Protection policies for Fabric are generally configured by an organization's Purview security and compliance teams. The protection policy creator must have role of Information Protection Admin or higher. For more information, see Create and manage protection policies for Fabric.

Requirements

- A Microsoft 365 E3/E5 license is required for sensitivity labels from Microsoft Purview Information Protection. For more information, see Microsoft Purview Information Protection: Sensitivity labeling.
- At least one "appropriately configured" sensitivity label from Microsoft Purview Information Protection must exist in the tenant. "Appropriately configured" in the context of protection policies for Fabric means that when the label was configured, it was scoped to **Files & other data assets**, and its protection settings were set to include **Control access** (for information about sensitivity label configuration, see Create and configure sensitivity labels and their policies). Only such "appropriately configured" sensitivity labels can be used to create the protection policies for Fabric.
- For protection policies to be enforced in Fabric, the Fabric tenant setting **Allow users to apply sensitivity labels for content** must be enabled. This setting is required for all sensitivity label related policy enforcement in Fabric, so if sensitivity labels are already being used in Fabric, this setting will already be on. For more information about enabling sensitivity labels in Fabric, see Enable sensitivity labels.

Supported item types

Protection policies are supported for all native Fabric item types, including lakehouses, notebooks, pipelines, and other core Fabric assets.

Additionally, protection policies are supported for Power BI semantic models. Other Power BI item types, such as reports and dashboards, aren't currently supported.

Considerations and limitations

- Up to 50 protection policies can be created.
- Up to 100 users and groups can be added to a protection policy.
- Protection policies for Fabric don't support guest/external users.
- Protection policies don't integrate with Fabric CI/CD solutions. Deployment pipelines and Git integration use only workspace permissions, not item-level permissions from protection policy labels.
- After a policy has been created, it can take up to 24 hours for it to start detecting and protecting items labeled with the sensitivity label that was associated with the policy.
- For native Fabric item types, if the label is applied automatically by the system—such as in the case of downstream inheritance—and there is no designated label issuer, the user who created the artifact will not be restricted by protection policies.

Microsoft Purview metamodel

Article • 01/28/2025

> **Note**
>
> Microsoft Purview Data Map (classic), Data Catalog (classic), Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

> **Note**
>
> On April 22, 2024 asset types moved to be under the Microsoft Purview Data Catalog feature in the Microsoft Purview portal. Access instructions have been updated.

Metamodel is a feature in the Microsoft Purview Data Catalog that helps add rich business context to your data catalog. It tells a story about how your data is grouped in data domains, how it's used in business processes, what projects are impacted by the data, and ultimately how the data fits in the day to day of your business.

The context metamodel provides is important because business users, the people who are consuming the data, often have nontechnical questions about the data. Questions like: What department produces this dataset? Are there any projects that are using this dataset? Where does this report come from?

When you scan data into Microsoft Purview, the technical metadata can tell you what the data looks like, if the data has been classified, or if it has glossary terms assigned, but it can't tell you where and how that data is used. The metamodel gives your users that information. It can tell you what data is mission critical for a product launch or used by a high performing sales team to convert leads to prospects.

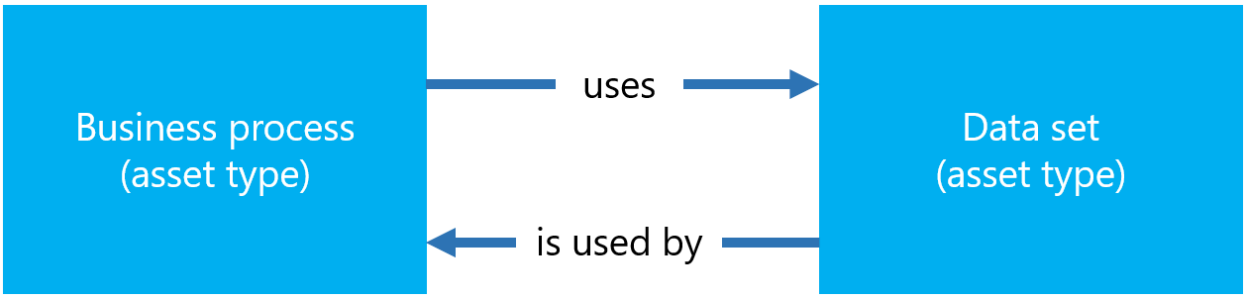
So the metamodel not only helps data consumers find the data they're looking for, but it also tells your data managers what data is critical and how healthy that critical data is,

so you can better manage and govern it. For example: you could have different privacy obligations if you use personal information for marketing activities vs. analytics that improve a product or service, and metamodel can help you determine where data is being used.

So what is the metamodel?

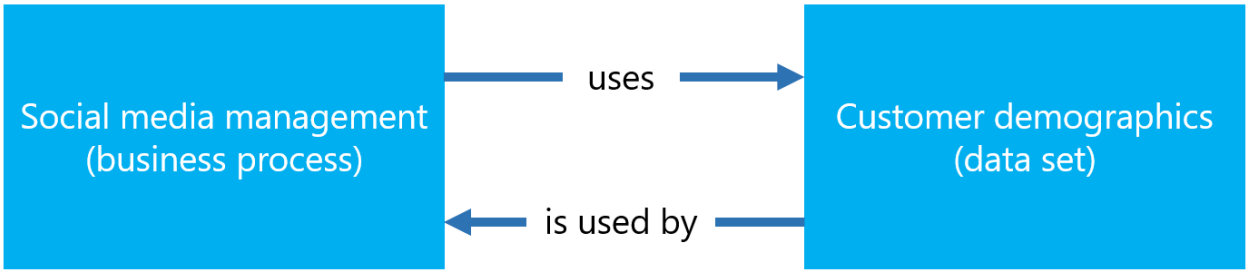
What does it look like? The metamodel is built from **assets** and the **relationships** between them.

For example, you might have a sales reporting team (asset) that consumes data (relationship) from some SQL tables (assets).



When you scan data sources into the data map, you already have the technical data assets like SQL tables available for your metamodel. But what about assets like a sales reporting team, or a marketing strategy that represent processes or people instead of a data source? Metamodel provides **asset types** that allow you to describe other important parts of your business.

An **asset type** is a template for important concepts like business processes, departments, lines of business, or even products. They're the building blocks you'll use to describe how data is used in your business. The **asset type** creates a template you can use over and over to describe specific assets. For example, you can define an asset type "department" and then create new department assets for each of your business departments. These new assets are stored in Microsoft Purview like any other data assets that were scanned in the data map, so you can search and browse for them in the data catalog.

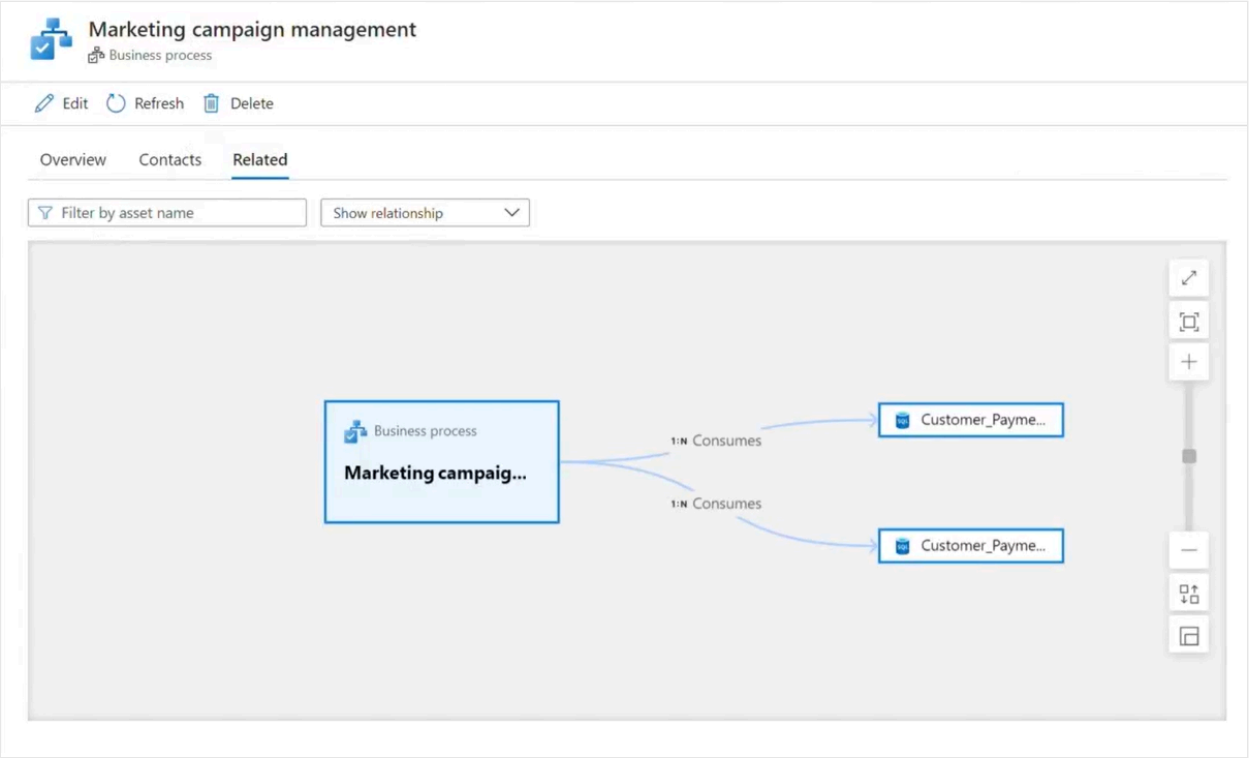


Metamodel includes several predefined asset types to help you get started, but you can also create your own.

Similarly a **relationship definition** is the template for the kinds of interactions between assets that you want to represent. For example, a department *manages* a business process. An organization *has* departments. The business process, organization, and departments are the assets, "manages" and "has" are the relationships between them.

For example, if we want to use Microsoft Purview to show how key data sets are used in our business processes, we can represent that information as a template:

Which we can then use to describe how a specific business process uses a specific data set:



Metamodel example

For a simple example of a metamodel, let's consider marketing campaign management in a business. This process is an asset that we'll add to our metamodel. It's not a data source we can scan, since it's a set of business processes, but during this process real data will be used and referenced. It's important to show what data is being used and how, so we can properly manage and govern it. We'll create an asset for the marketing campaign management from the asset type "Business Process".

We know there are two tables in SQL that the marketing campaign management team uses. These are assets too, but they were data source assets created when the SQL database was scanned into the Microsoft Purview Data Map.

The relationship between the marketing campaign management asset and the SQL table assets is that campaign management **consumes**, or uses, the SQL tables when developing campaigns. We can record that in our metamodel, so now anyone that looks at those SQL tables can see that they're being used to develop marketing campaigns. We'll also be able to see if there are any other teams that use this data, or maybe which department develops this data as well. So now, with metamodel, we know not only what the data is, but we have a story about how it's being used that helps us understand and manage it.

And now that marketing campaign management is an asset in your data catalog like any other asset, so you can find it in a search. A user could search for that process and quickly know what data it uses and produces, without needing to know anything about the data beforehand.

Next steps

If you're ready to get started, follow the how to create a metamodel article.

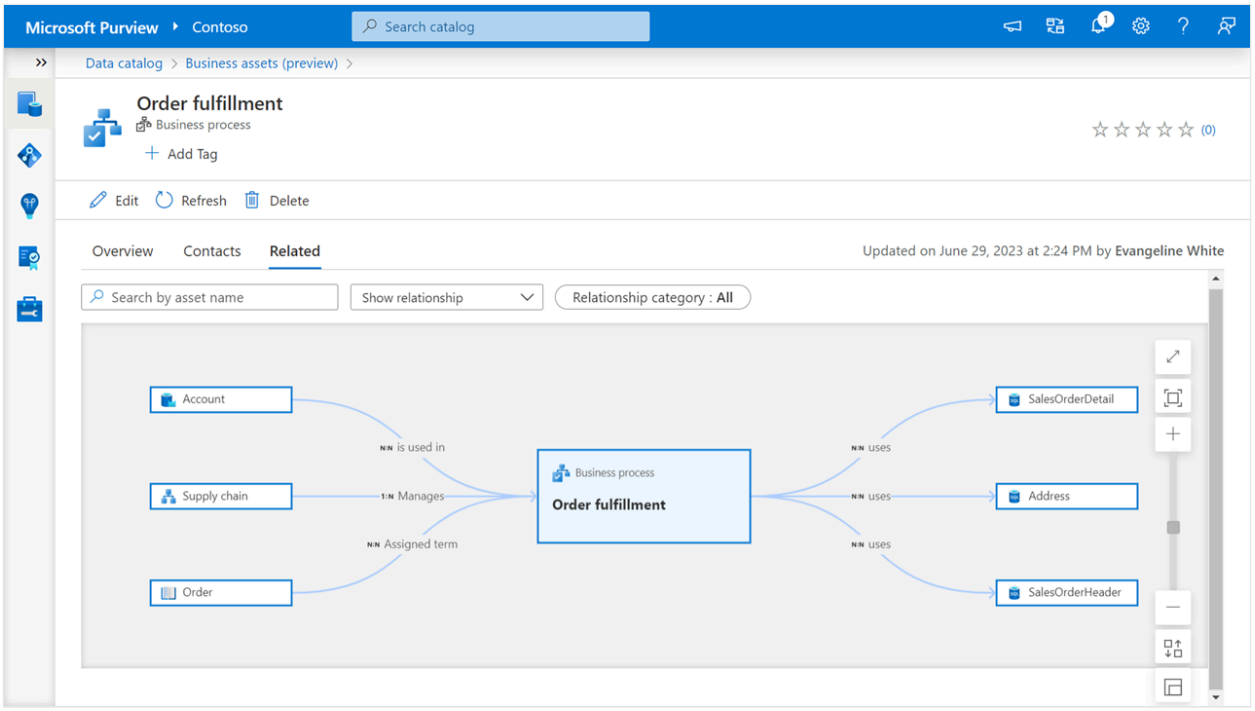
Manage assets with metamodel

Article • 10/28/2024

> **Note**
>
> Microsoft Purview Data Map (classic), Data Catalog (classic), Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.



> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

> **Note**
>
> On April 22, 2024 asset types moved to be under the Microsoft Purview Data Catalog feature in the Microsoft Purview portal. Access instructions have been updated.

Metamodel is a feature in the Microsoft Purview Data Map that gives the technical data in your data map relationships and reference points to make it easier to navigate and understand in the day to day. Like adding streets and cities to a map, the metamodel orients users so they know where they're and can discover the information they need.

Create additional asset types for describing real-world things in your organization such as departments, projects, products, and lines of business. When you look at your data estate, it's often helpful to understand how your data fits into your business. Use business assets whenever you want to associate data assets to specific organizational structures, business processes, or other anything else that could be convincingly modeled as an entity.

In the example below, I describe more business context for the SalesOrderDetail table by showing that the Supply chain department (a business asset) manages the order fulfillment business process (a business asset) which uses the SalesOrderDetail table. Visualizing business context in this way can help others identify the “official” dataset that's used for a particular business purpose and understand whether data is being used compliantly.

This article will get you started in building a metamodel for your Microsoft Purview Data Map.

Prerequisites

- An Azure account with an active subscription. Create an account for free.
- Create a new, or use an existing Microsoft Purview account. You can follow our quick-start guide to create one.
- Data Curator role on the collection where the data asset is housed and/or the root collection, depending on what you need. See the guide on managing Microsoft Purview role assignments.
  - Create and modify asset types, modify assets - Data Curator on the collection where the data asset is housed. An asset will need to be moved to your collection after creation for you to be able to modify it.
  - Create and modify assets - Data curator on the root collection.

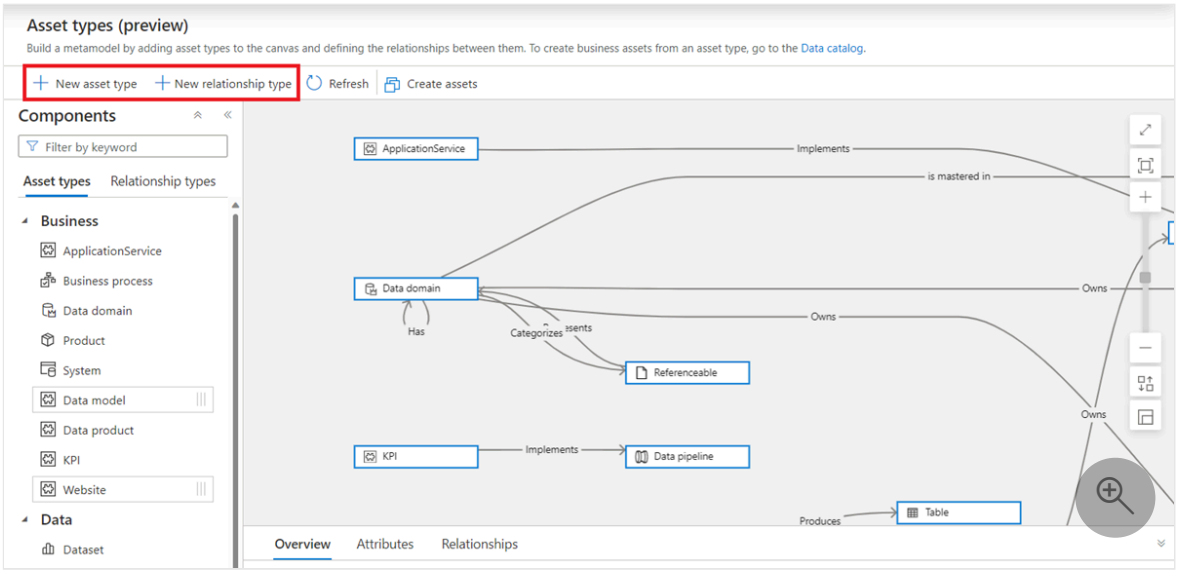
> **Note**
>
> Even if you are using the new data catalog experience these permissions are required.

Current limitations

> **Note**

Since this feature is in preview, available abilities are regularly updated.

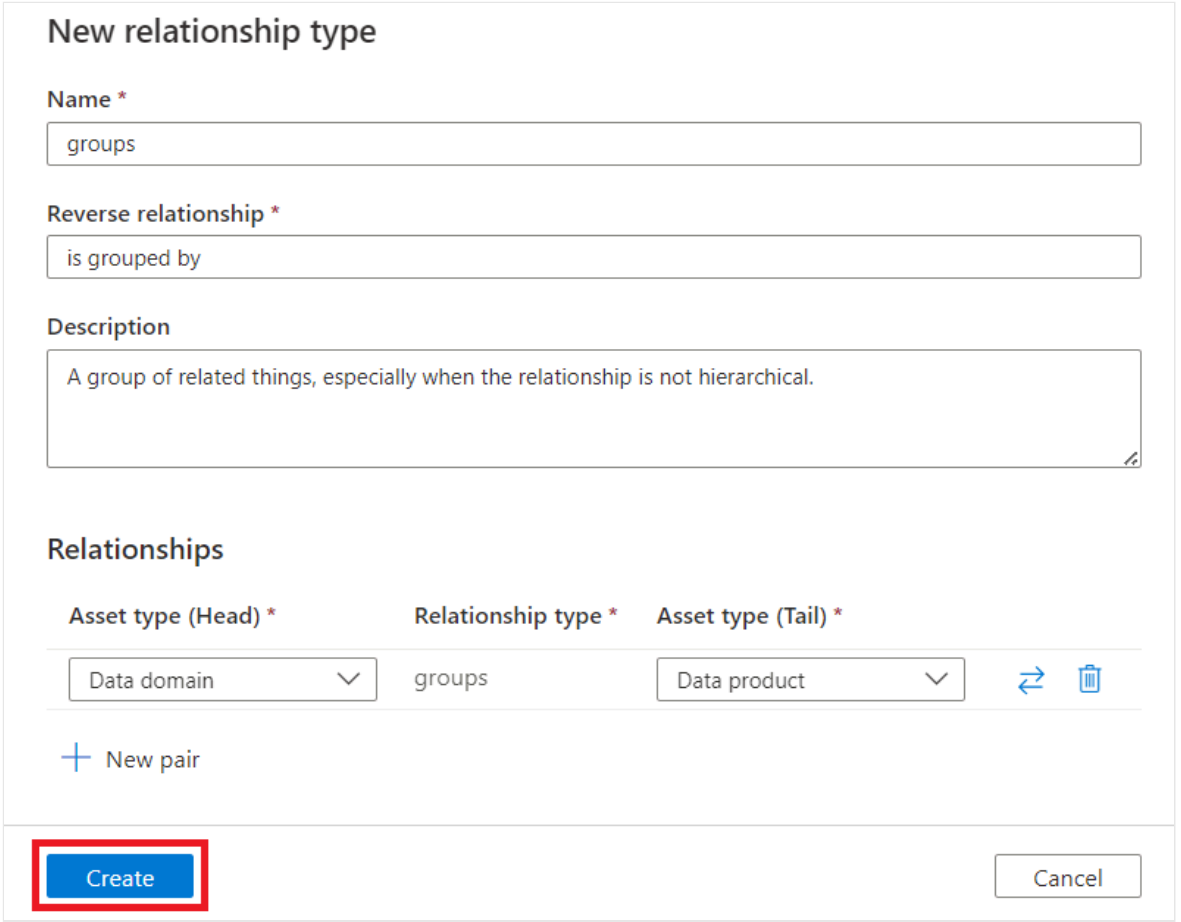
- When a new asset created, you have to refresh the asset to see relationships
- You can't set relationships between two data assets in the Microsoft Purview governance portal
- The related tab only shows a "business lineage" view for business assets, not data assets



Create and modify asset types

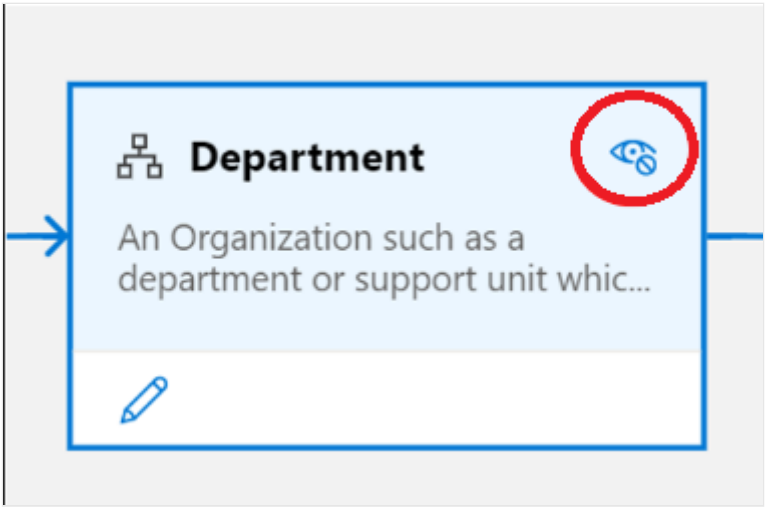
1. To open asset types in the Microsoft Purview Data Catalog:

    - If you're using the new data catalog experience in the Microsoft Purview portal (https://purview.microsoft.com):
        a. Open the data catalog application
        b. Select the **Data management** dropdown
        c. Select **Governance domains**
        d. Select a domain where you want to add your managed attribute.
        e. Select the **Governance domains** header
        f. Select **Asset types**
    - If you're using the classic data catalog experience in the Microsoft Purview portal (https://purview.microsoft.com):
        a. Open the data catalog application
        b. Select the **Metamodel** dropdown
        c. Select **Asset types**
    - If you're using the classic Microsoft Purview governance portal (https://web.purview.azure.com):
        a. Open the Microsoft Purview Data Map
        b. Select **Asset types** under the **Metamodel** section.

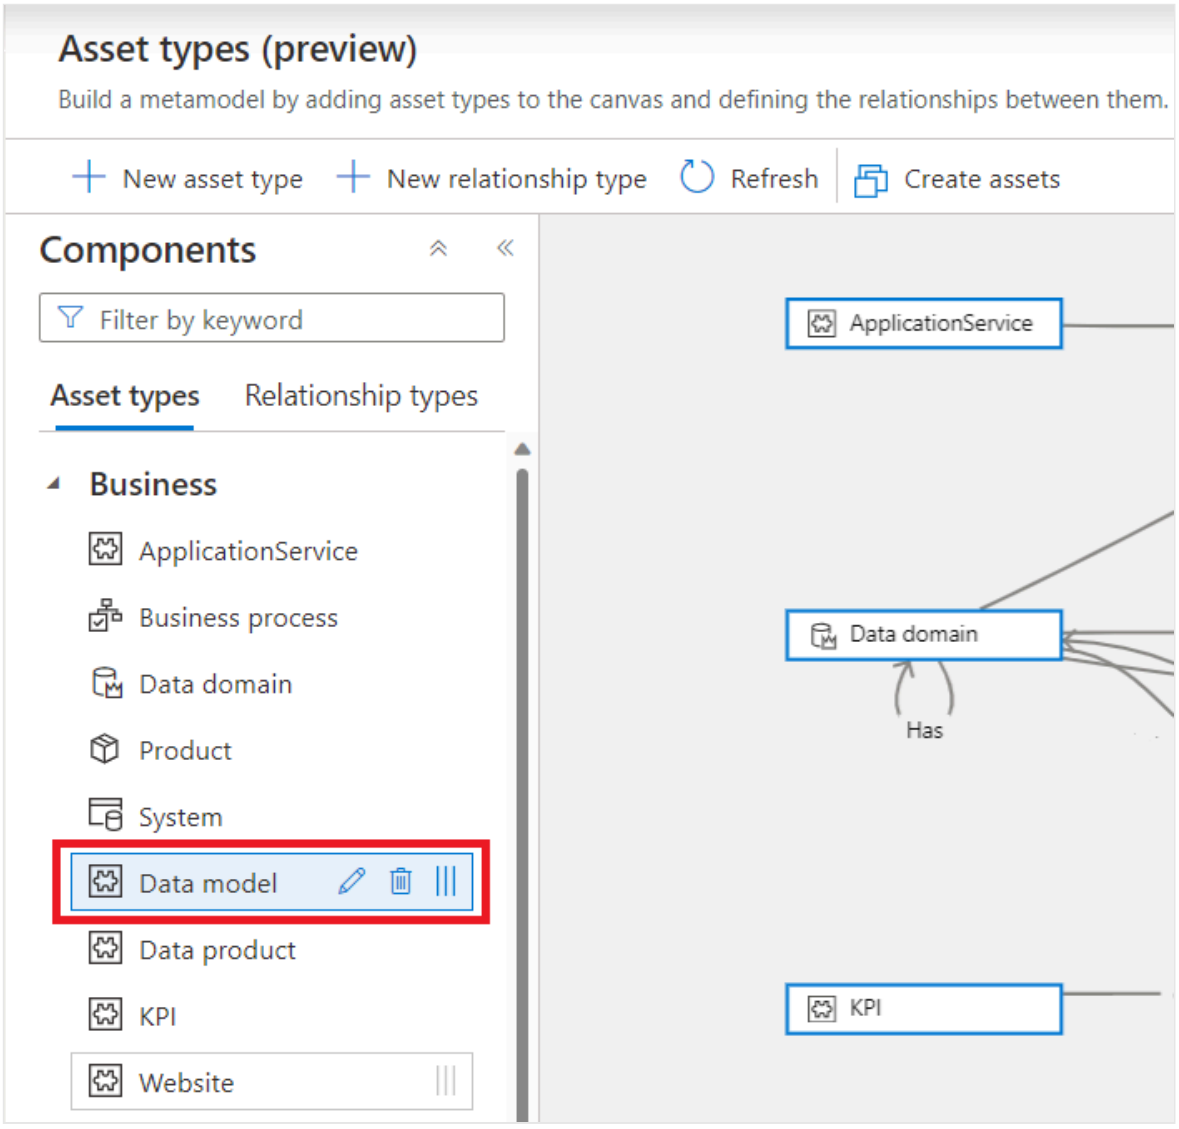


2. You'll see a list of available asset types. Predefined asset types will have unique icons. All custom assets are designated with a puzzle piece icon.

3. To create a new asset type, select **New asset type** and add a name, description, and attributes.



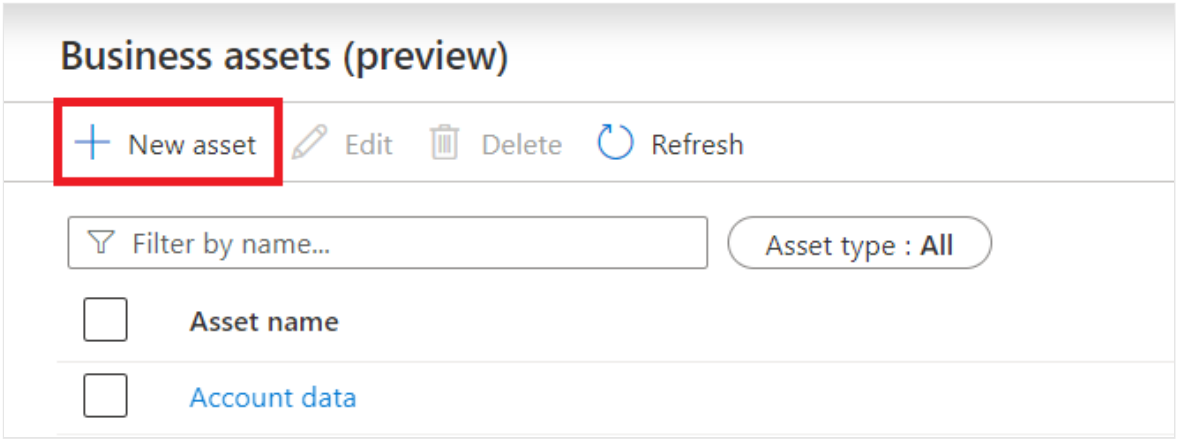
4. To define a relationship between two asset types, select **New relationship type**.



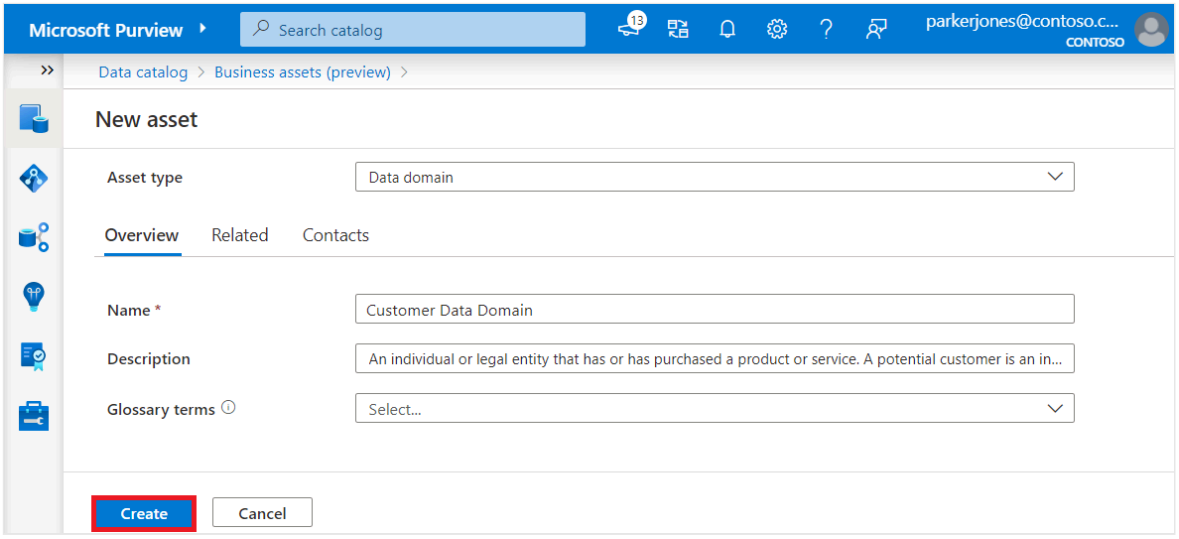
5. Give the relationship a name and define its reverse direction. Assign it to one or more pairs of assets. Select **Create** to save your new relationship type.

6. As you create more asset types, your canvas might get crowded with asset types. To hide an asset from the canvas, select the eye icon on the asset card.

7. To add an asset type back to the canvas, drag it from the left panel.

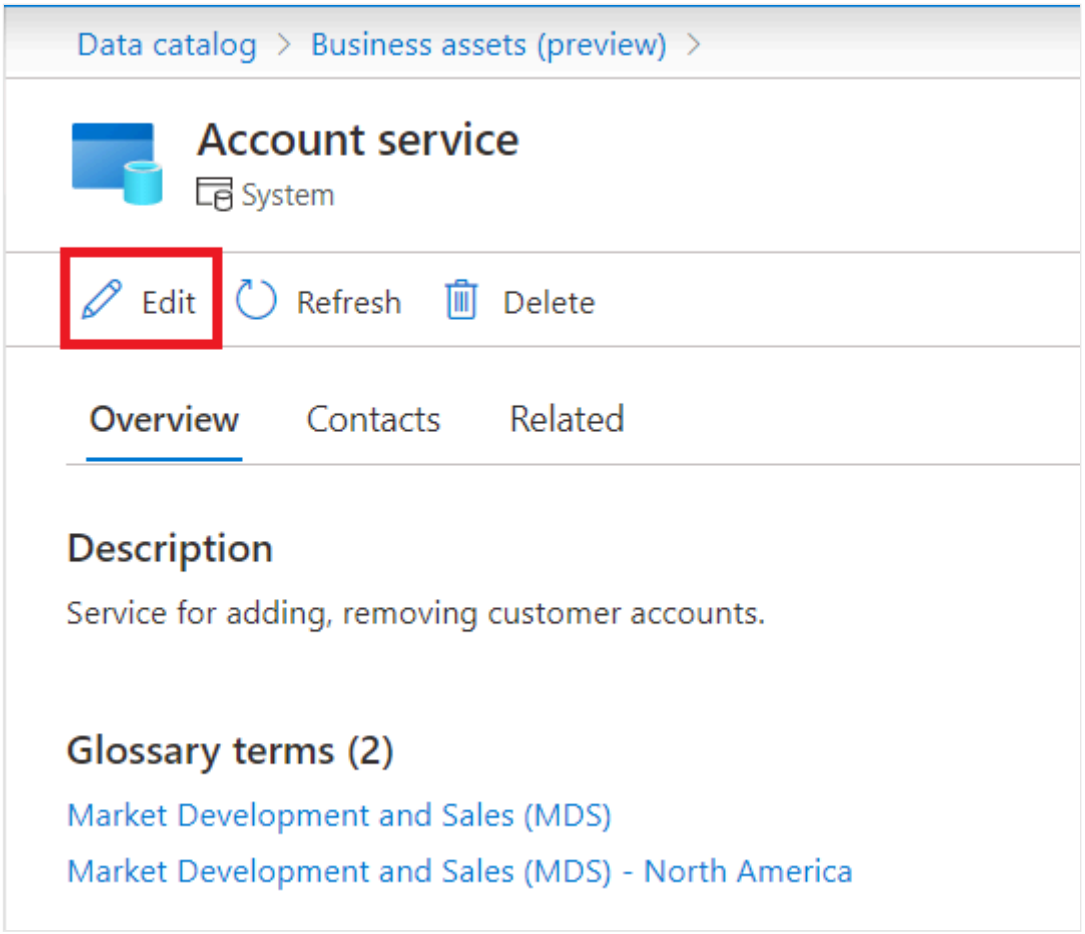


Create and modify assets

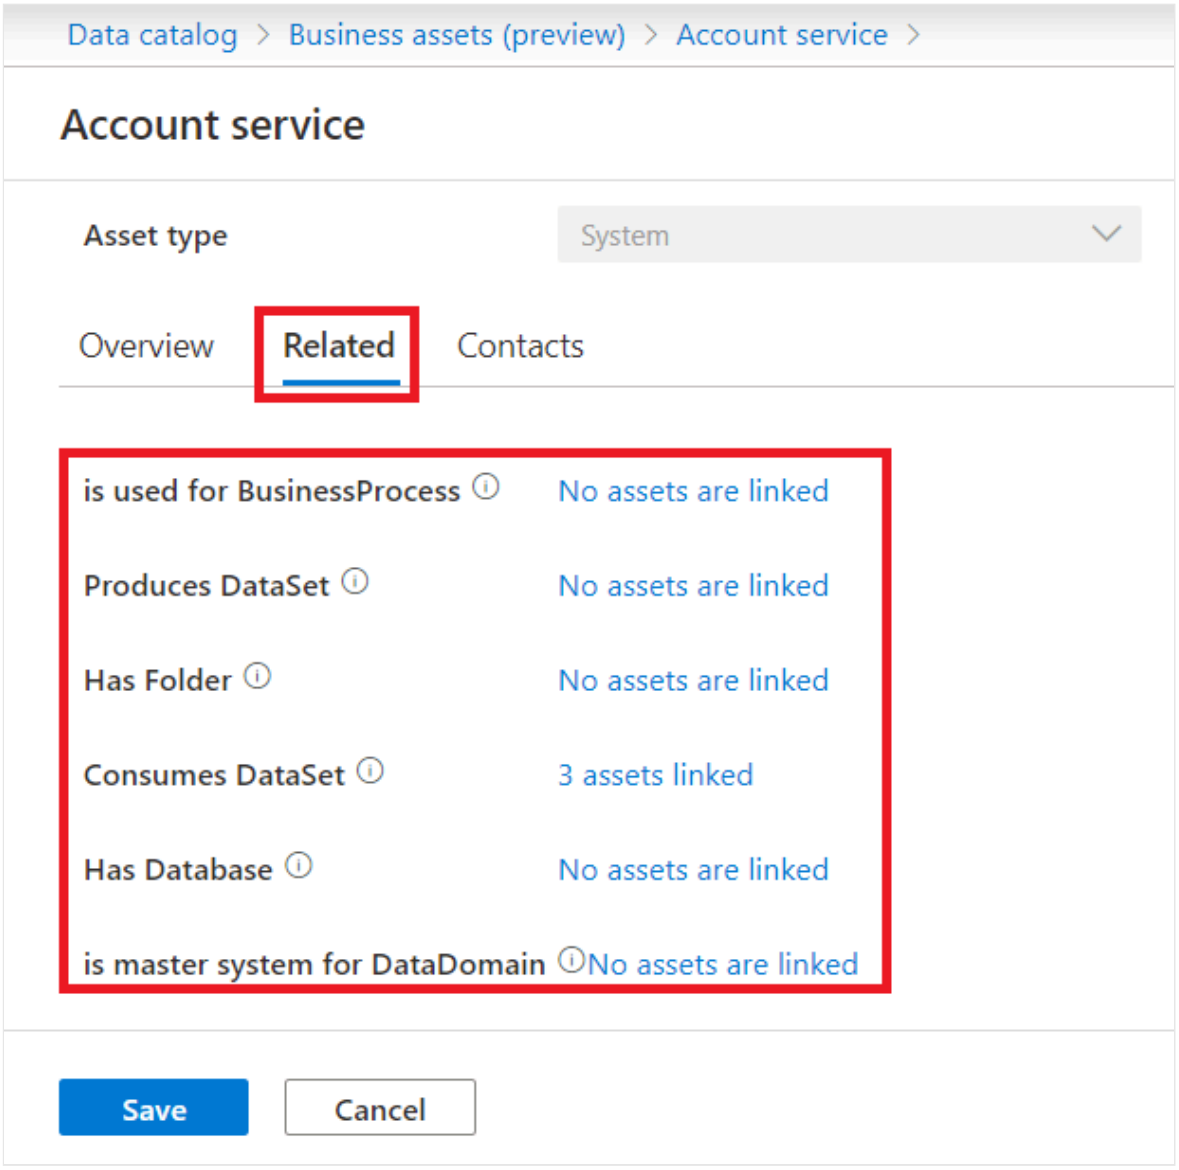


1. When you're ready to begin working with assets, navigate to your data catalog. If you're using the classic Microsoft Purview portal, select **Business assets**. If you're

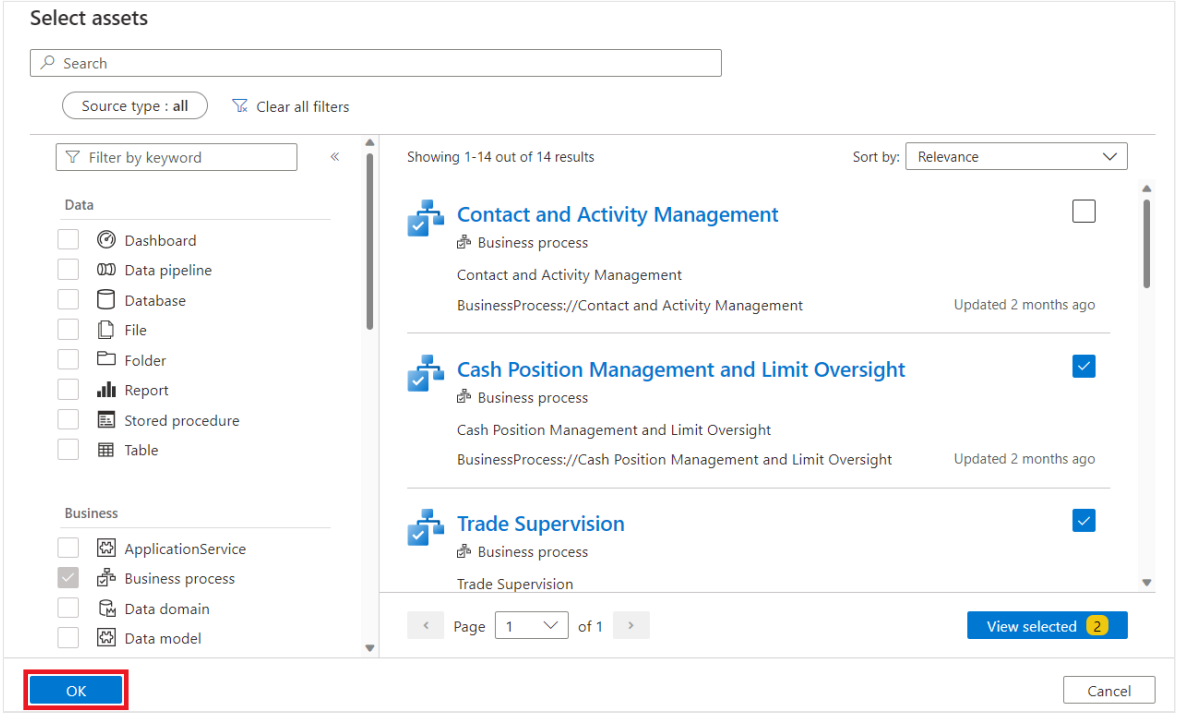
using the new Microsoft Purview portal under **Business glossary** select **Business assets**.



> **Note**
>
> If you're using the new data catalog experience, you'll need to switch back to the original experience to update your business assets.

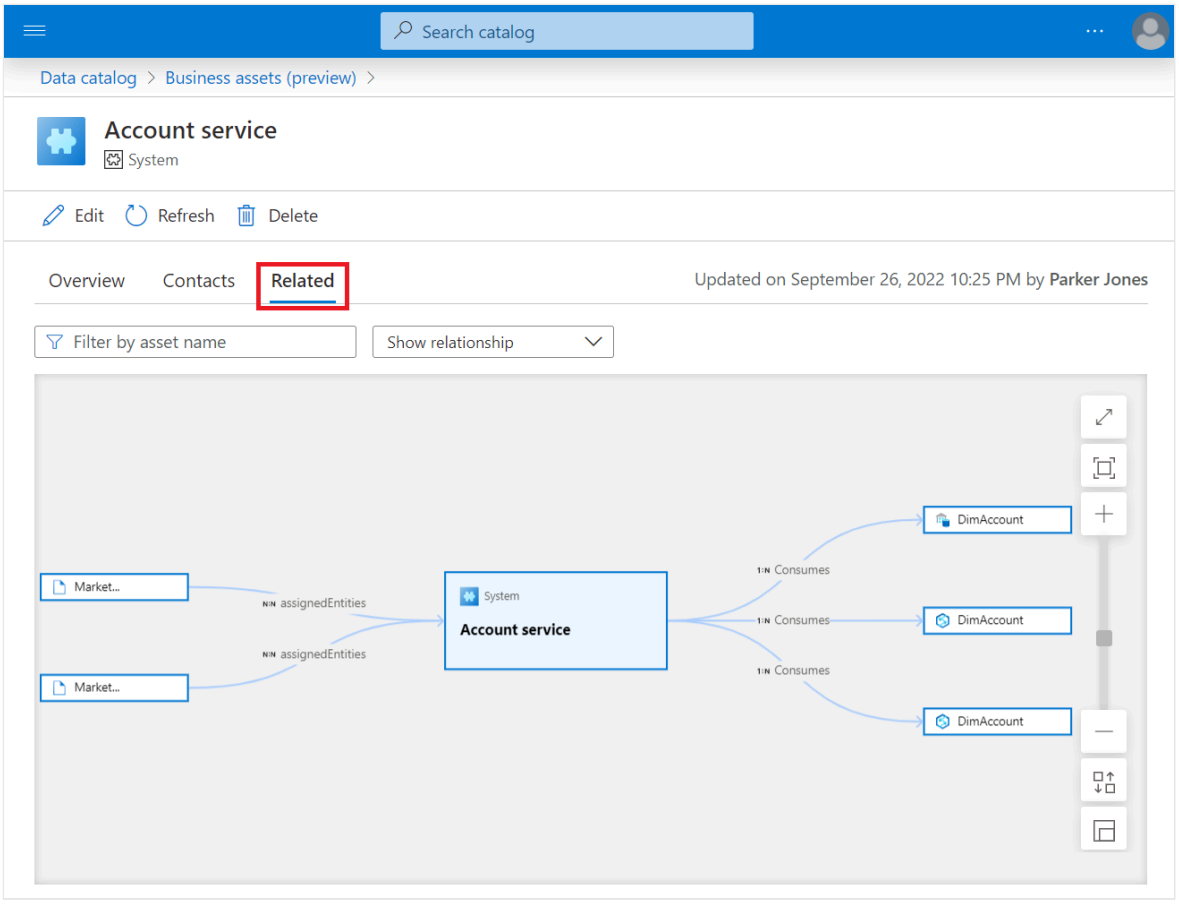


2. To create a new asset, select **New asset**, select the asset type from the drop-down menu, give it a name, description, and complete any required attributes. Select **Create** to save your new asset.



3. To establish a relationship between two assets, go to the asset detail page and select **Edit** > **Related**, and the relationship you'd like to populate.

Data catalog > Business assets (preview) >
Account service
System
Edit
Refresh
Delete
Overview
Contacts
Related
Description
Service for adding, removing customer accounts.
Glossary terms (2)
Market Development and Sales (MDS)
Market Development and Sales (MDS) - North America



4. Select the assets or assets you'd like to link from the data catalog and select **OK**.

5. Save your changes. You can see the relationships you established in the asset overview.

6. In the **Related** tab of the asset you can also explore a visual representation of related assets.

> **Note**
>
> This is the experience provided by default from Atlas.

Predefined asset types

An asset type is a template for storing a concept that's important to your organization—anything you might want to represent in your data map alongside your physical metadata. You can create your own, but Purview also comes with a prepackaged set of business asset types you can modify to meet your needs.

Expand table

Asset Type	Description
Application service	A well-defined software component, especially one that implements a specific business function such as on-boarding a new customer, taking an order, or sending an invoice.
Business process	A set of activities that are performed in coordination in an organizational or technical environment that jointly realizes a business goal.
Data Domain	A category of data that is governed or explicitly managed for master data management.
Department	An organizational subunit that only has full recognition within the context of that organization. A department wouldn't be regarded as a legal entity in its own right.
Line of business	An organization subdivision focused on a single product or family of products.
Organization	A collection of people organized together into a community or other social, commercial, or political structure. The group has some common purpose or reason for existence that goes beyond the set of people belonging to it and can act as a unit. Organizations are often decomposable into hierarchical structures.
Product	Any offered product or service.
Project	A specific activity used to control the use of resources and associated costs so they're used appropriately in order to successfully achieve the project's goals, such as building a new capability or improving an existing capability.
System	An IT system including hardware and software.

Next steps

For more information about the metamodel, see the metamodel concept page.

Audit logs, diagnostics, and activity history

Article • 05/20/2025

This tutorial lists the step-by-step configuration required to enable and capture audit and diagnostics logs for the Microsoft Purview Data Map via Azure Event Hubs.

A Microsoft Purview administrator or Microsoft Purview data-source admin needs the ability to monitor audit and diagnostics logs captured from Data Map. Audit and diagnostics information consists of the timestamped history of actions taken and changes made to a Microsoft Purview account by every user. Captured activity history includes actions made using the Microsoft Purview portal, or using the REST API.

This tutorial takes you through the steps to enable audit logging. It also shows you how to configure and capture streaming audit events from the Microsoft Purview portal via Azure Diagnostics event hubs.

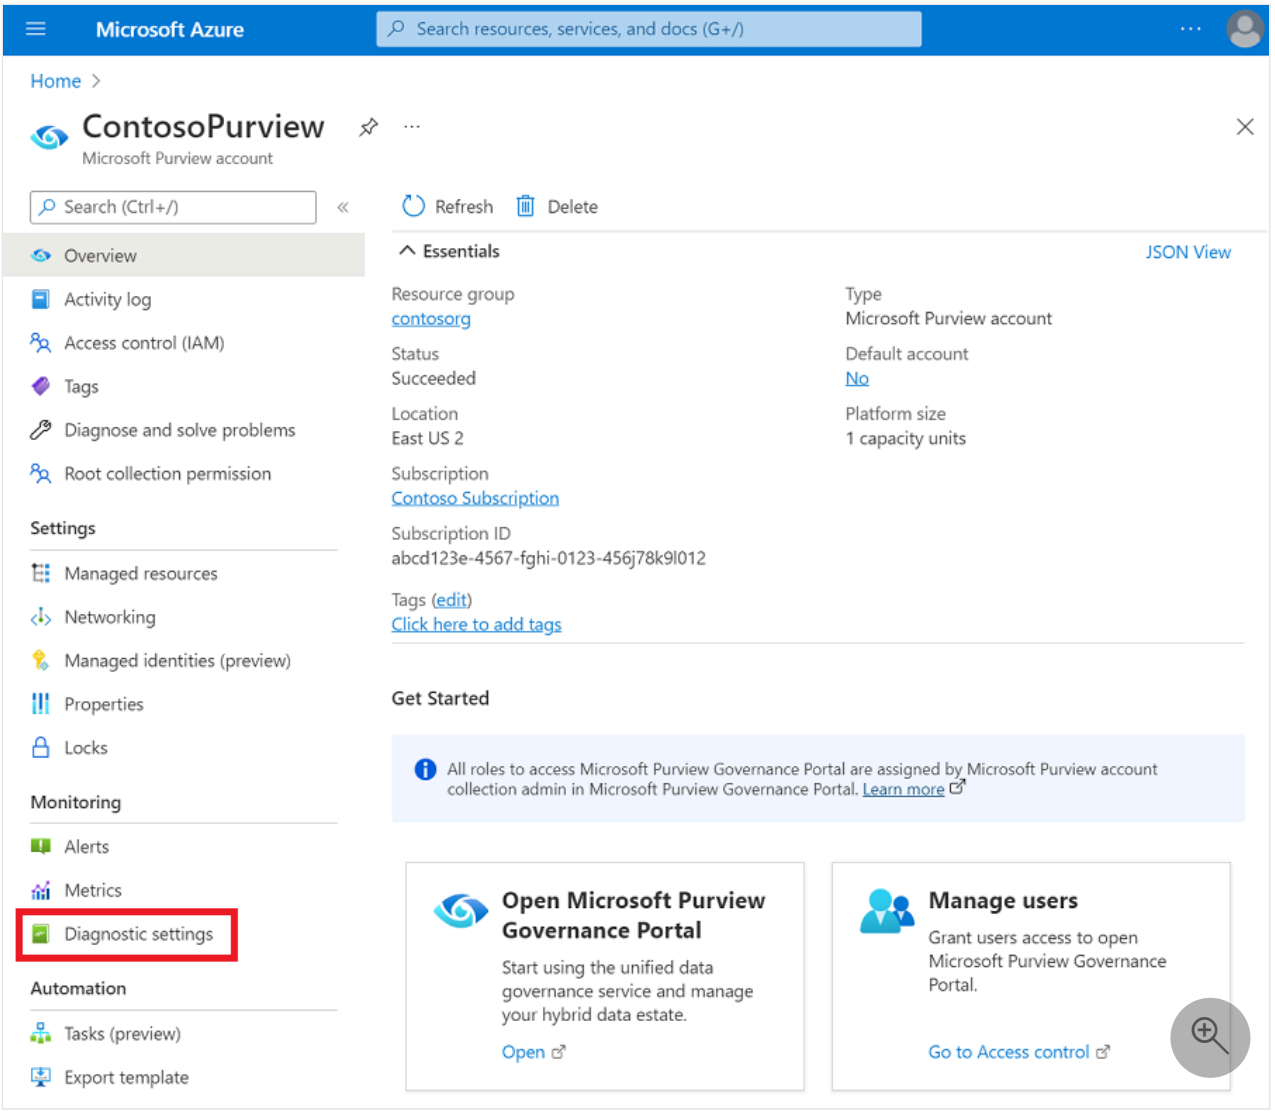
Enable audit and diagnostics

The following sections walk you through the process of enabling audit and diagnostics.

Configure Event Hubs

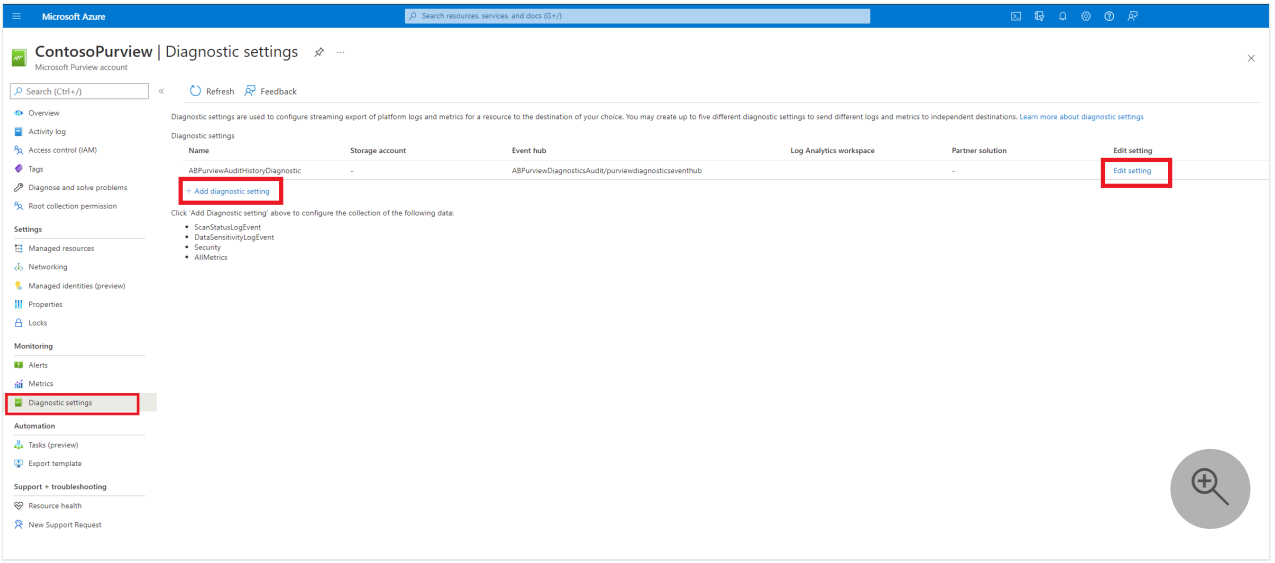
Create an Azure Event Hubs namespace by using an Azure Resource Manager (ARM) template (GitHub). This automated Azure ARM template will deploy and finish creating your Event Hubs instance with the required configuration.

For step-by-step explanations and manual setup:



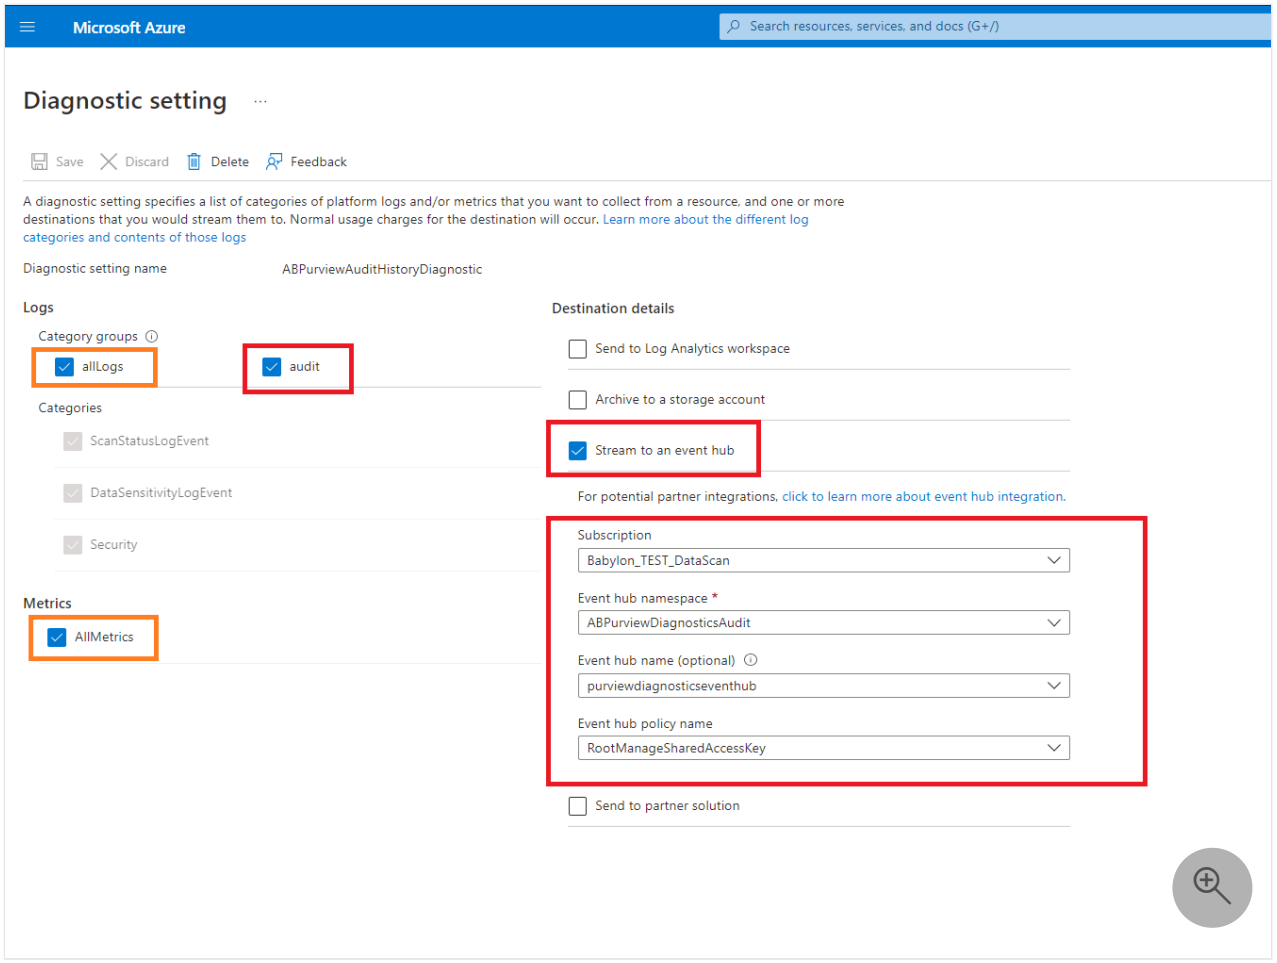
- Event Hubs: Use an ARM template to enable Event Hubs capture
- Event Hubs: Enable capturing of events streaming manually by using the Azure portal

Connect a Microsoft Purview account to Diagnostics event hubs



Now that Event Hubs is deployed and created, connect your Microsoft Purview account diagnostics audit logging to Event Hubs.

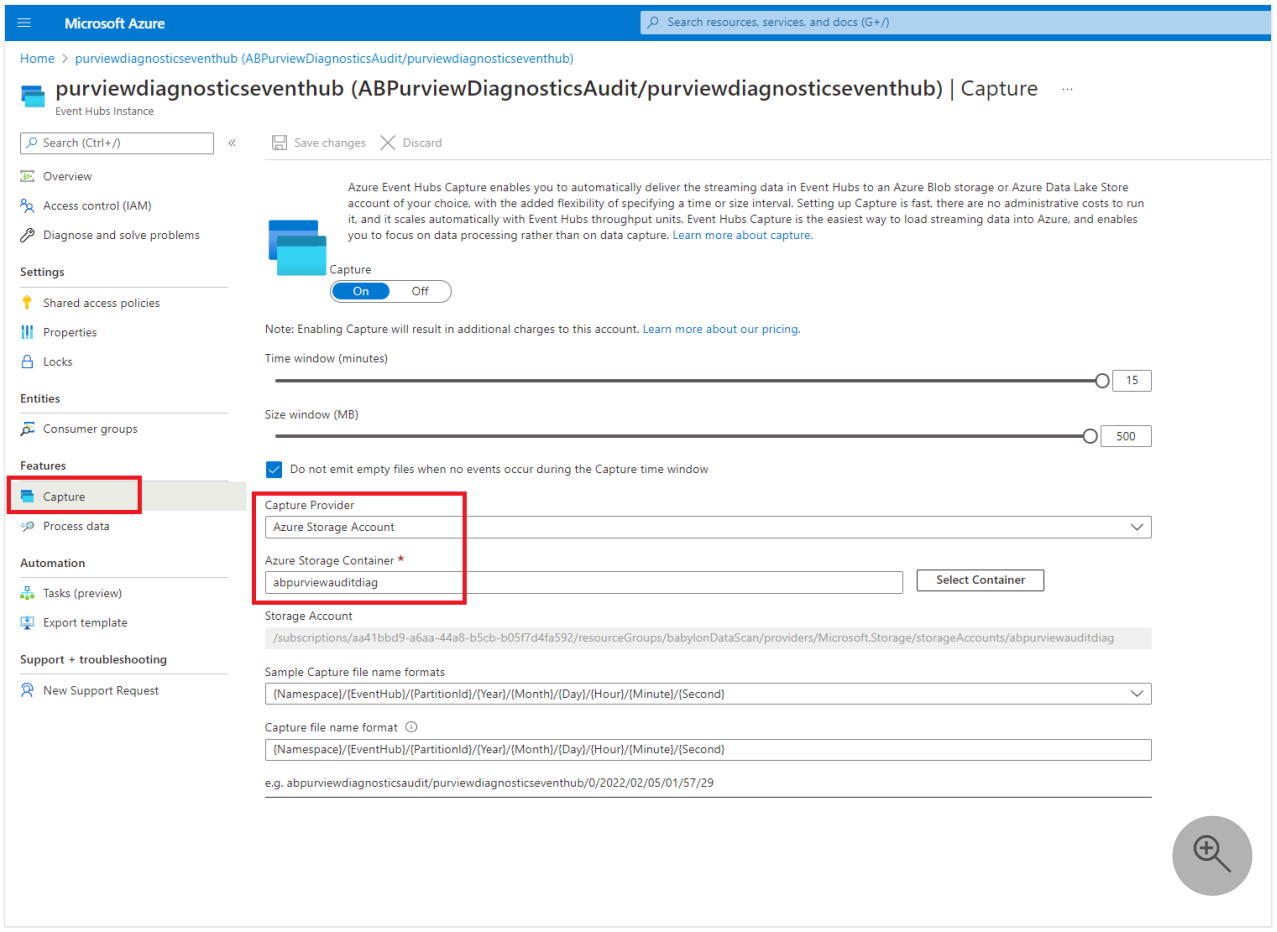
1. Go to your Microsoft Purview account home page. This page is where the overview information is displayed in the Azure portal. It's not the Microsoft Purview governance portal home page.



2. On the left menu, select **Monitoring** > **Diagnostic settings**.

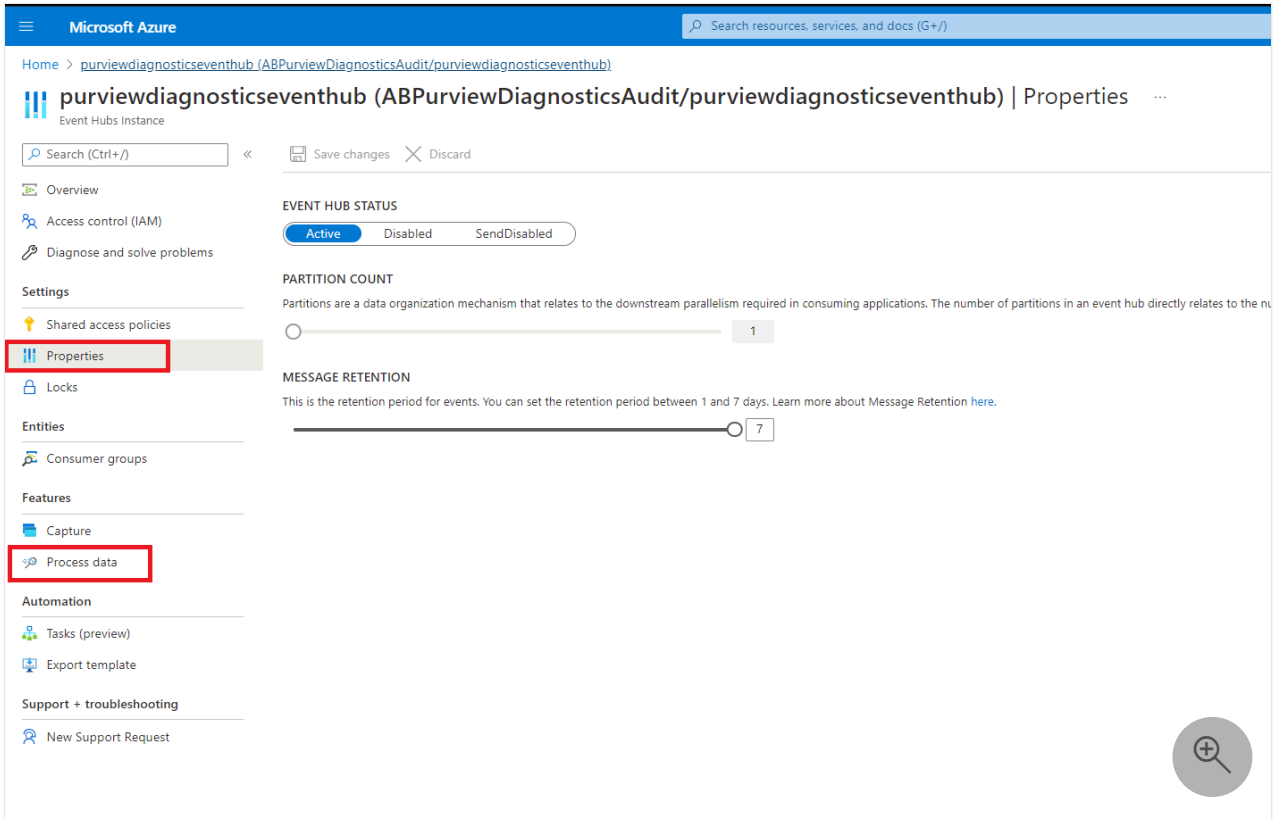
3. Select **Add diagnostic setting** or **Edit setting**. Adding more than one diagnostic setting row in the context of Microsoft Purview isn't recommended. In other words, if you already have a diagnostic setting row, don't select **Add diagnostic**. Select **Edit** instead.

4. Select the **audit** and **allLogs** checkboxes to enable collection of audit logs. Optionally, select **AllMetrics** if you also want to capture Data Map capacity units and Data Map size metrics of the account.



Diagnostics configuration on the Microsoft Purview account is complete.

Now that diagnostics audit logging configuration is complete, configure the data capture and data retention settings for Event Hubs.

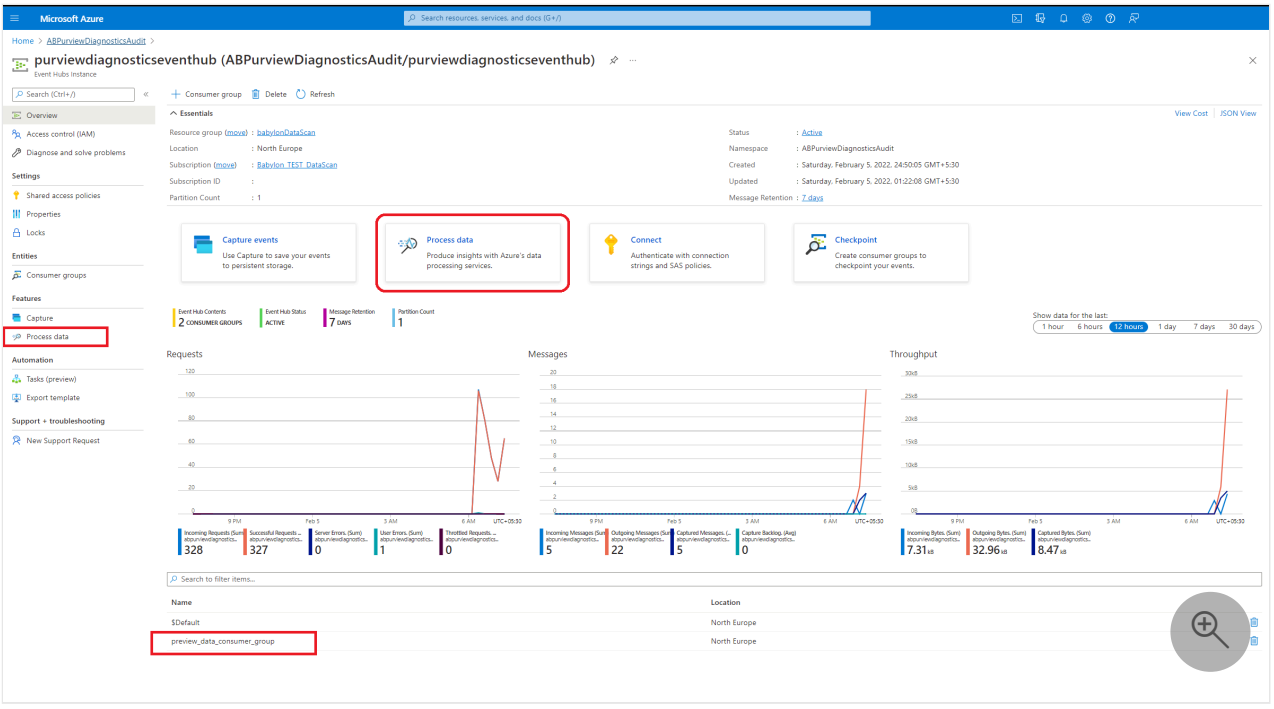


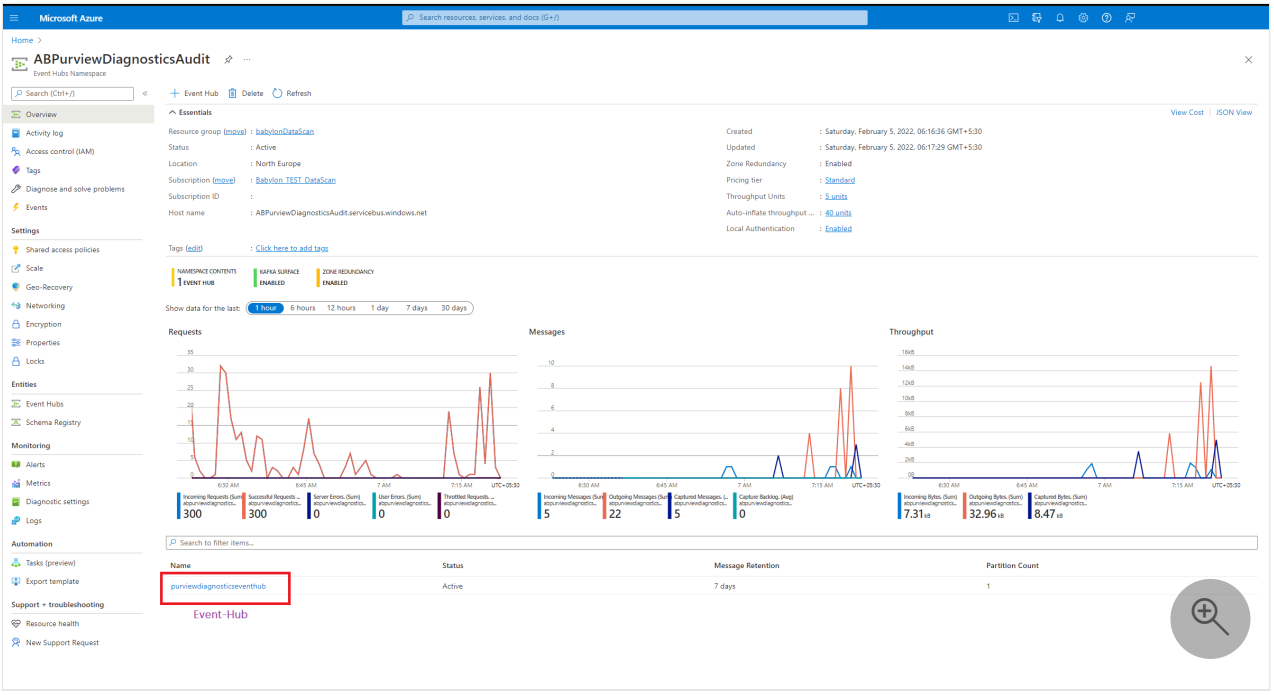
1. Go to the Azure portal home page, and search for the name of the Event Hubs namespace you created earlier.

2. Go to the Event Hubs namespace. Select **Event Hubs** > **Capture Data**.

3. Supply the name of the Event Hubs namespace and the event hub where you want the audit and diagnostics to be captured and streamed. Modify the **Time Window** and **Size Window** values for the retention period of the streaming events. Select **Save**.

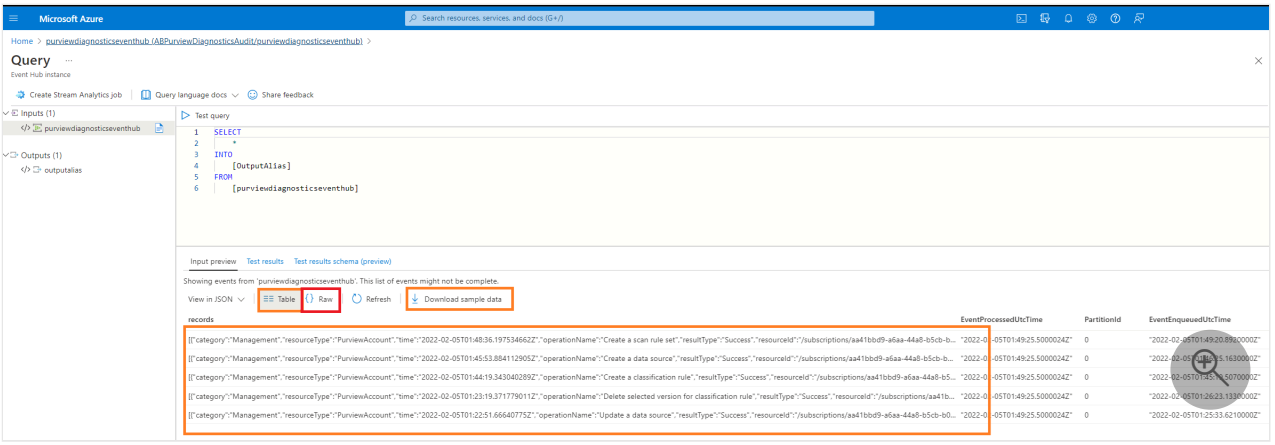
4. Optionally, on the left menu, go to **Properties** and change **Message Retention** to any value between one and seven days. The retention period value depends on the frequency of scheduled jobs or the scripts you've created to continuously listen and capture the streaming events. If you schedule a capture once every week, move the slider to seven days.





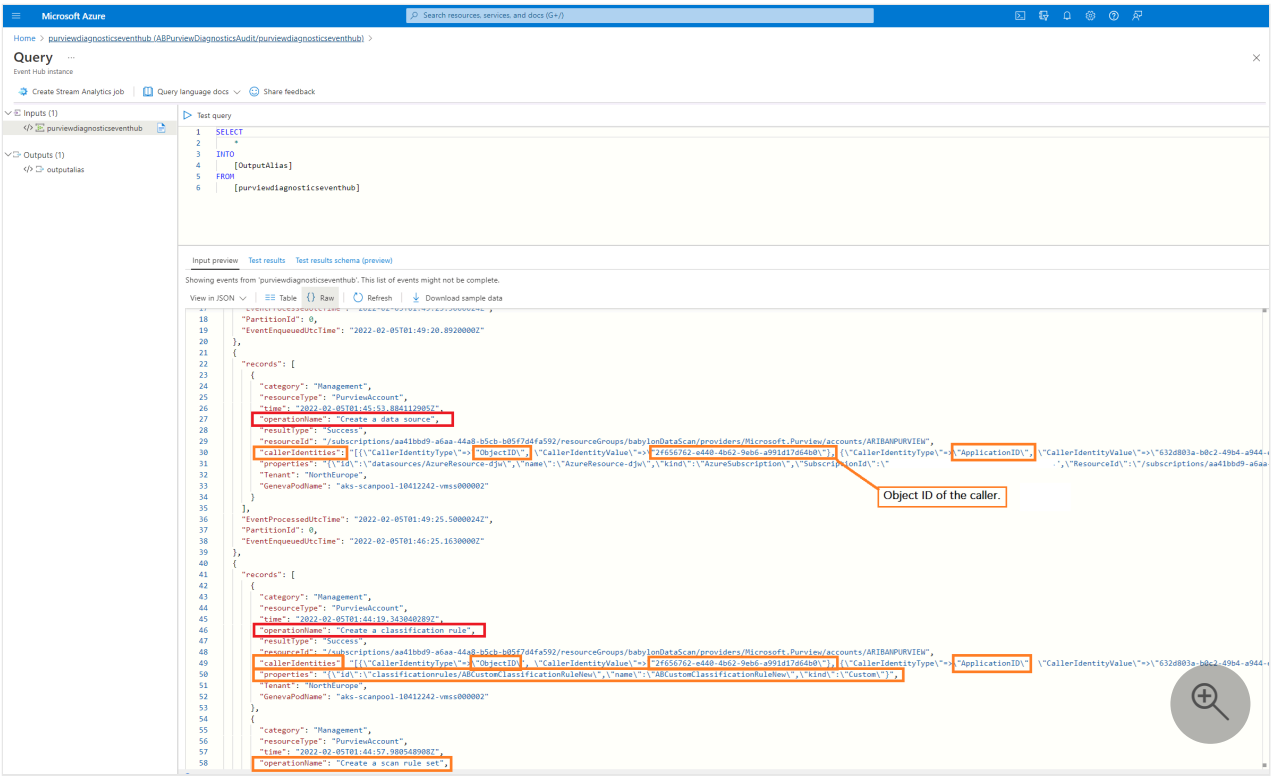
5. At this stage, the Event Hubs configuration is complete. The Microsoft Purview governance portal will start streaming all its audit history and diagnostics data to this event hub. You can now proceed to read, extract, and perform further analytics and operations on the captured diagnostics and audit events.

Read captured audit events



To analyze the captured audit and diagnostics log data:

1. Go to **Process data** on the Event Hubs page to see a preview of the captured audit logs and diagnostics.



2. Switch between the **Table** and **Raw** views of the JSON output.

3. Select **Download sample data** and analyze the results carefully.

Now that you know how to gather this information, you can use automatic, scheduled scripts to extract, read, and perform further analytics on the Event Hubs audit and diagnostics data. You can even build your own utilities and custom code to extract business value from captured audit events.

These audit logs can also be transformed to Excel, any database, Dataverse, or Synapse Analytics database for analytics and reporting by using Power BI.

While you're free to use any programming or scripting language of your choice to read the event hubs, here's a ready-made Python-based script. See this Python tutorial on how to capture Event Hubs data in Azure Storage and read it by using Python (azure-eventhub).

Audit event categories

Some of the important categories of Microsoft Purview governance portal audit events that are currently available for capture and analysis are listed in the table.

More types and categories of activity audit events will be added.

Create an Azure policy exclusion for Microsoft Purview

Article • 05/14/2025

Many subscriptions have Azure Policies in place that restrict the creation or update of some resources. This is to maintain subscription security and cleanliness. However, Microsoft Purview accounts created before December 15, 2023 (or deployed using API version previous to 2023-05-01-preview) deployed an Azure Storage account when it was created. It's managed by Azure, so you don't need to maintain it, but it's necessary for Microsoft Purview to run correctly. Existing policies could block Microsoft Purview from updating this Azure Storage account, which can cause errors during scanning.

Overall, your approach to resolving this error is going to be dependent on your organizations needs and policies, but here are a few ways you could update your policies to resolve this issue.

To maintain your policies in your subscription, but still allow the creation and updates to these managed resources, you can create an exclusion. For example, adding an exclusion for the resource group where your Microsoft Purview account is being deployed.

For steps to create an exclusion for your policies, see these steps to add an exclusion to your policy.

Use resource selectors on a created policy

Depending on other policies deployed in your subscription, or depending on your region, you could need to add **Resource selectors** under the **Advanced** tab when assigning a policy. For example, you might need to add a resource selector for **resourceLocation** set to the region where you'll deploy your Microsoft Purview account. For more information about these conditions, see our documentation on location conditions.

Create an exemption

Exemptions are recommended for time-bound or specific scenarios where a resource or resource hierarchy should still be tracked and would otherwise be evaluated, but there's a specific reason it shouldn't be assessed for compliance. It would allow a temporary exception to your policy for a resource to exist for a finite amount of time.

For more information, see the documentation for policy exemptions.

Next steps

To set up Microsoft Purview by using Private Link, see Use private endpoints for your Microsoft Purview account.

Conditional Access with Microsoft Purview

Article • 05/20/2025

Microsoft Purview governance solutions support Microsoft Conditional Access.

The following steps show how to configure Microsoft Purview to enforce a Conditional Access policy.

Prerequisites

- When multi-factor authentication is enabled, to sign in to the Microsoft Purview governance portal, you must perform multi-factor authentication.

Configure conditional access

1. Sign in to the Azure portal, select **Microsoft Entra ID**.
2. Browse to **Security** > **Conditional Access**. For more information, see Microsoft Entra Conditional Access technical reference.
3. Select **Create new policy**, provide a name, and then select **Configure rules**.
4. Under **Assignments**, select **Users and groups**, check **Select users and groups**, and then select the user or group for Conditional Access. Select **Select**, and then select **Done** to accept your selection.
5. Select **Cloud apps**, select **Select apps**. You see all apps available for Conditional Access. Select **Azure Purview**, at the bottom select **Select**, and then select **Done**.
6. Select **Access controls**, select **Grant**, and then check the policy you want to apply.
7. Set **Enable policy** to **On** and select **Create**.

Next steps

- Use the Microsoft Purview governance portal
- More information about conditional access

Microsoft Purview metrics in Azure Monitor

Article • 05/20/2025

This article describes how to configure metrics, alerts, and diagnostic settings for Microsoft Purview using Azure Monitor.

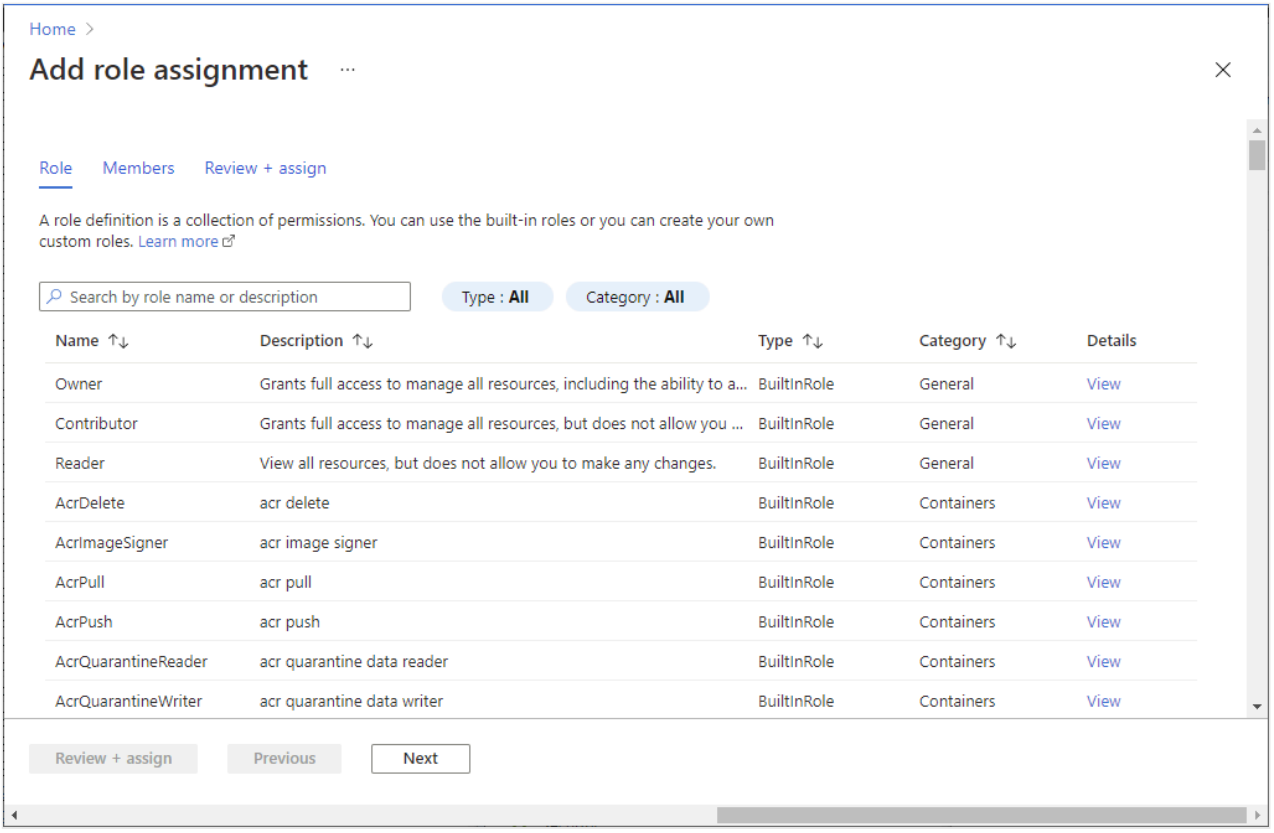
Monitor Microsoft Purview

Microsoft Purview admins can use Azure Monitor to track the operational state of Microsoft Purview account. Metrics are collected to provide data points for you to track potential problems, troubleshoot, and improve the reliability of the Microsoft Purview account. The metrics are sent to Azure monitor for events occurring in Microsoft Purview.

Aggregated metrics

The metrics can be accessed from the Azure portal of a Microsoft Purview account. Access to the metrics is controlled by the role assignment of Microsoft Purview account. Users need to be part of the "Monitoring Reader" role in Microsoft Purview to see the metrics. Learn more about Monitoring role permissions.

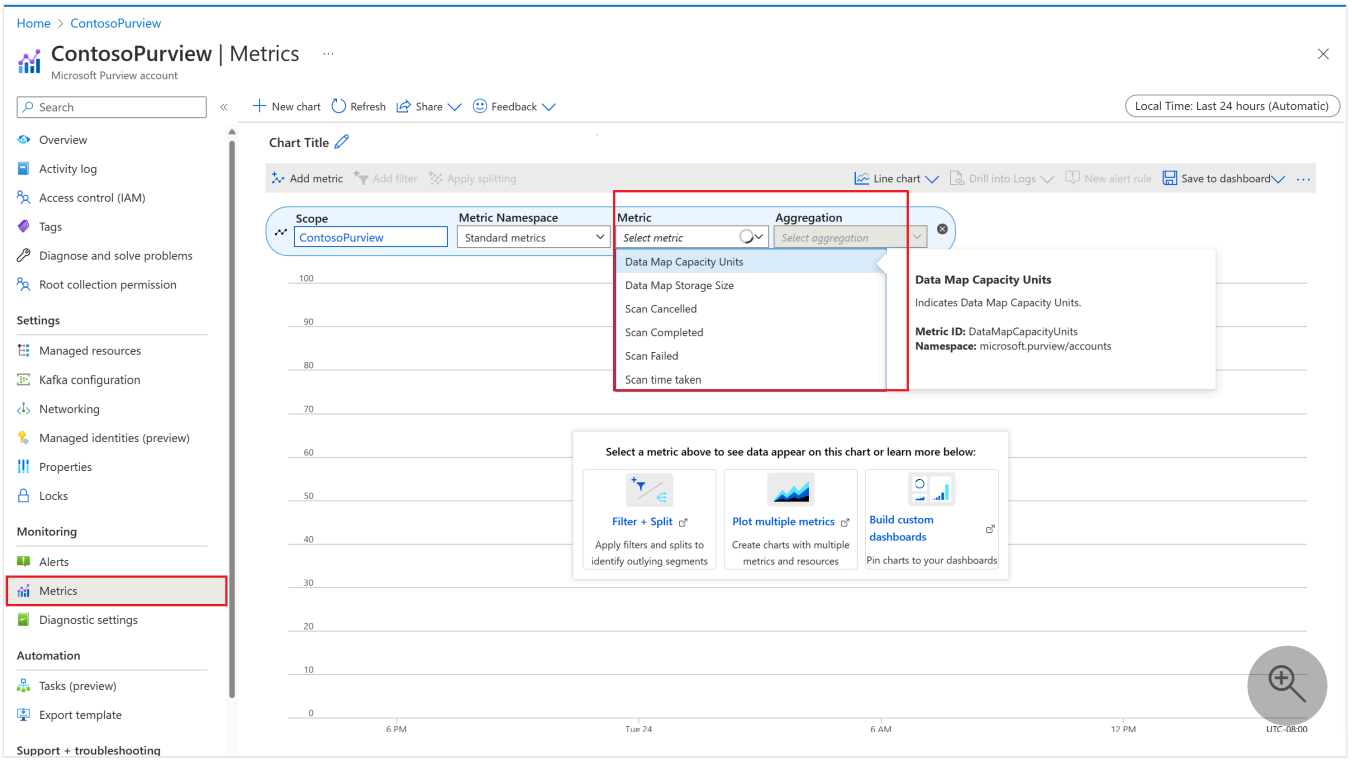
The person who created the Microsoft Purview account automatically gets permissions to view metrics. If anyone else wants to see metrics, add them to the **Monitoring Reader** role, by following these steps:



Add a user to the Monitoring Reader role

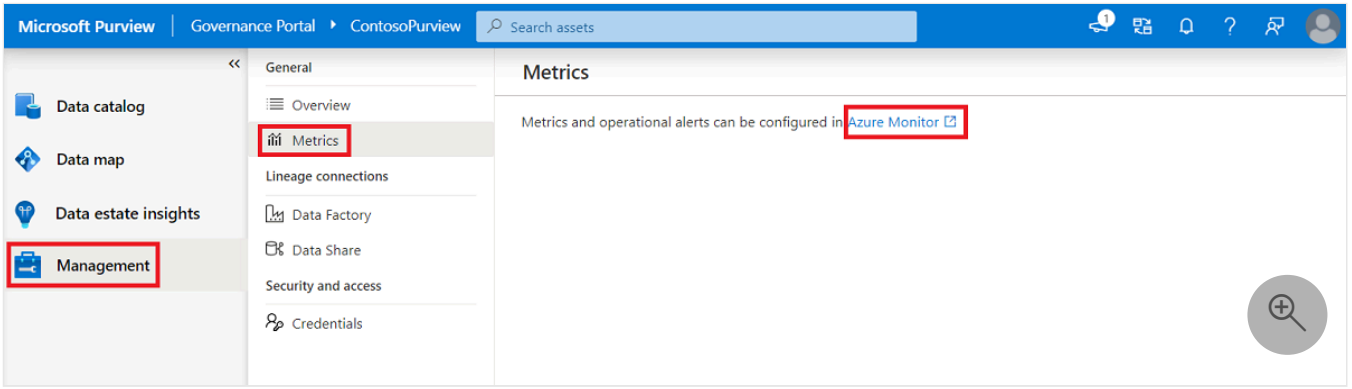
To add a user to the **Monitoring Reader** role, the owner of Microsoft Purview account or the Subscription owner can follow these steps:

1. Go to the Azure portal and search for the Microsoft Purview account name.
2. Select **Access control (IAM)**.
3. Select **Add** > **Add role assignment** to open the **Add role assignment** page.
4. Assign the role listed below. Get details on assigning Azure roles.



Expand table

Setting	Value
Role	Monitoring Reader
Assign access to	User, group, or service principal
Members	<Microsoft Entra account user>



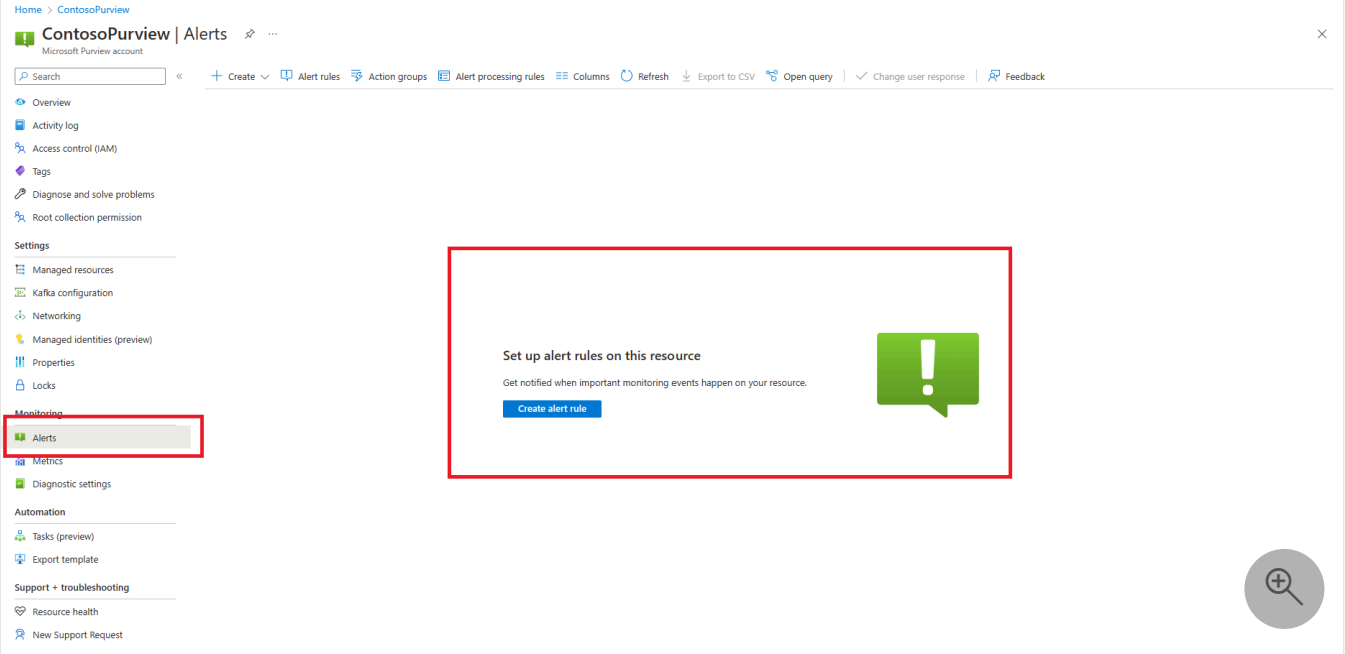
Metrics visualization

Users in the **Monitoring Reader** role can see the aggregated metrics and diagnostic logs sent to Azure Monitor. The metrics are listed in the Azure portal for the corresponding Microsoft Purview account. In the Azure portal, select the Metrics section to see the list of all available metrics.

Microsoft Purview users can also access the metrics page directly from the management center of the Microsoft Purview account. Select Azure Monitor in the main page of Microsoft Purview management center to launch Azure portal.

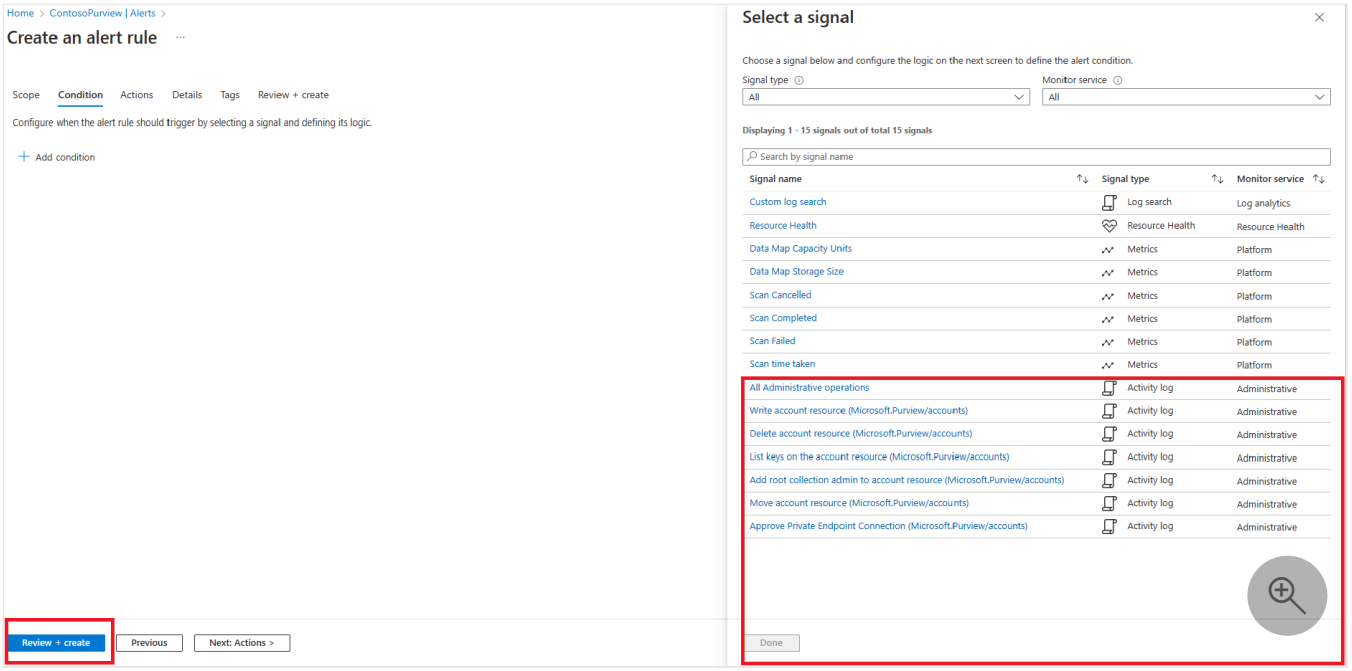
Available metrics

To get familiarized with how to use the metric section in the Azure portal pre read the following two documents. Getting started with Metric Explorer and Advanced features of Metric Explorer.



The following table contains the list of metrics available to explore in the Azure portal:

Expand table

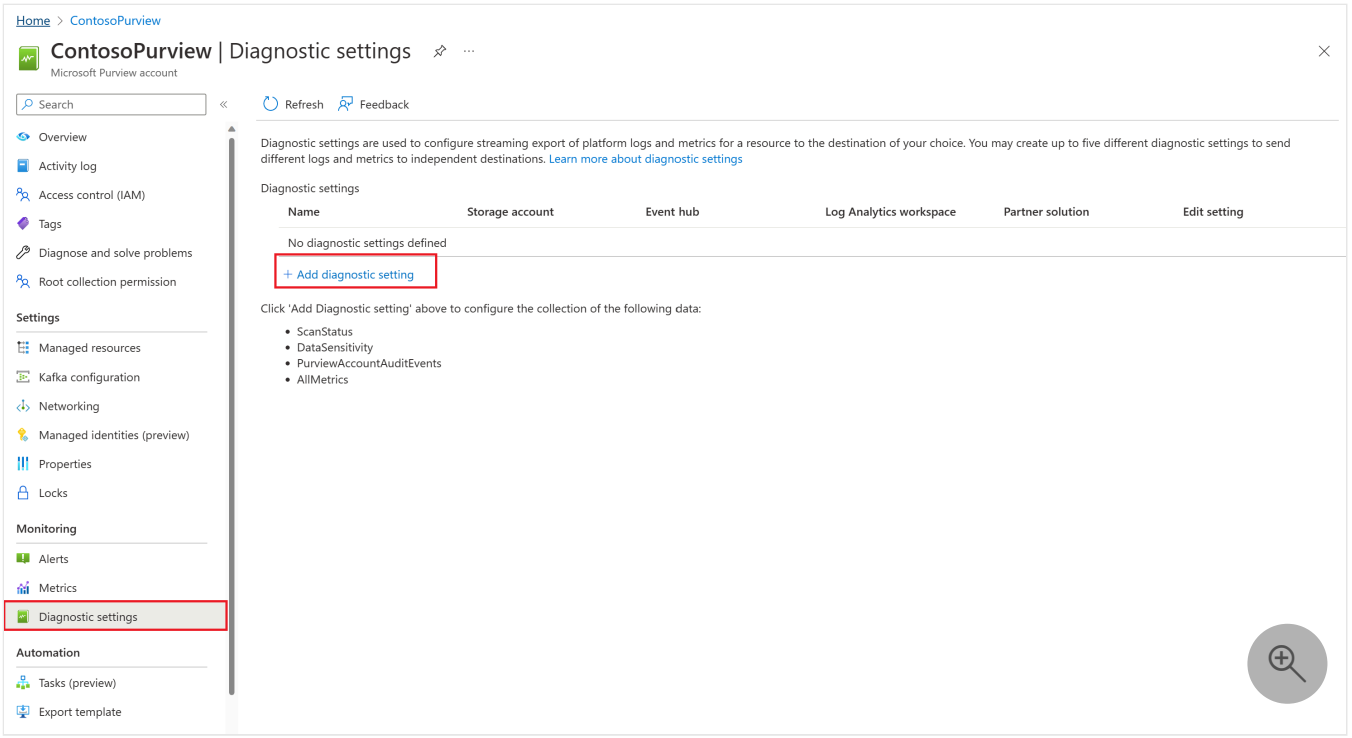


Metric Name	Metric Namespace	Aggregation type	Description
Data Map Capacity Units	Elastic data map	Sum Count	Aggregate the elastic data map capacity units over time period
Data Map Storage Size	Elastic data map	Sum Avg	Aggregate the elastic data map storage size over time period
Scan Canceled	Automated scan	Sum Count	Aggregate the canceled data source scans over time period
Scan Completed	Automated scan	Sum Count	Aggregate the completed data source scans over time period
Scan Failed	Automated scan	Sum Count	Aggregate the failed data source scans over time period
Scan time taken	Automated scan	Min Max Sum Avg	Aggregate the total time taken by scans over time period

Monitoring alerts

Alerts can be accessed from the Azure portal of a Microsoft Purview account. Access to the alerts is controlled by the role assignment of Microsoft Purview account just like metrics. A user can setup alert rules in their purview account to get notified when important monitoring events happen.

The user can also create specific alert rules and conditions for signals within purview.

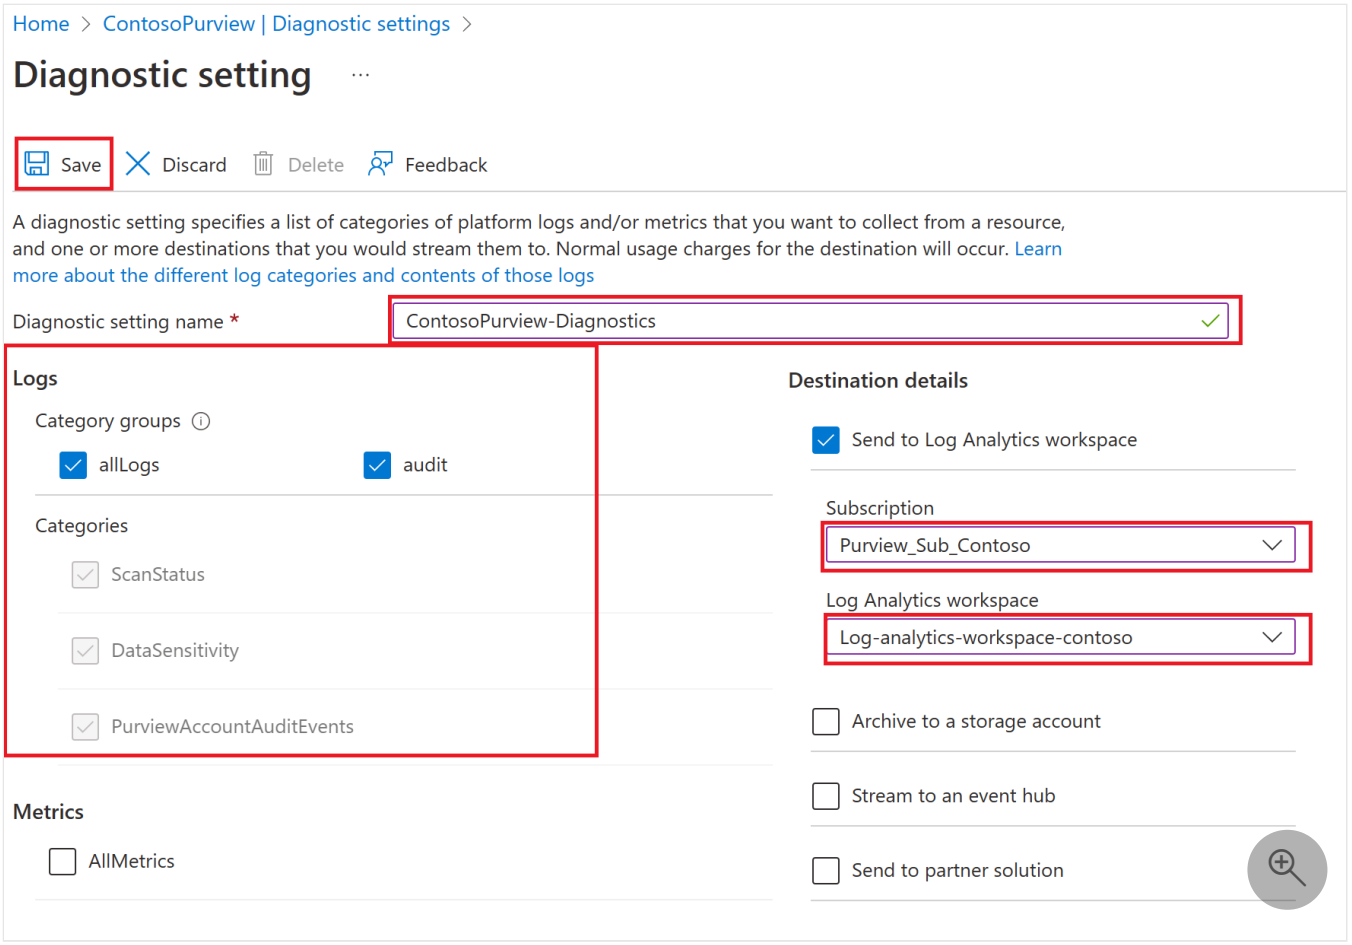


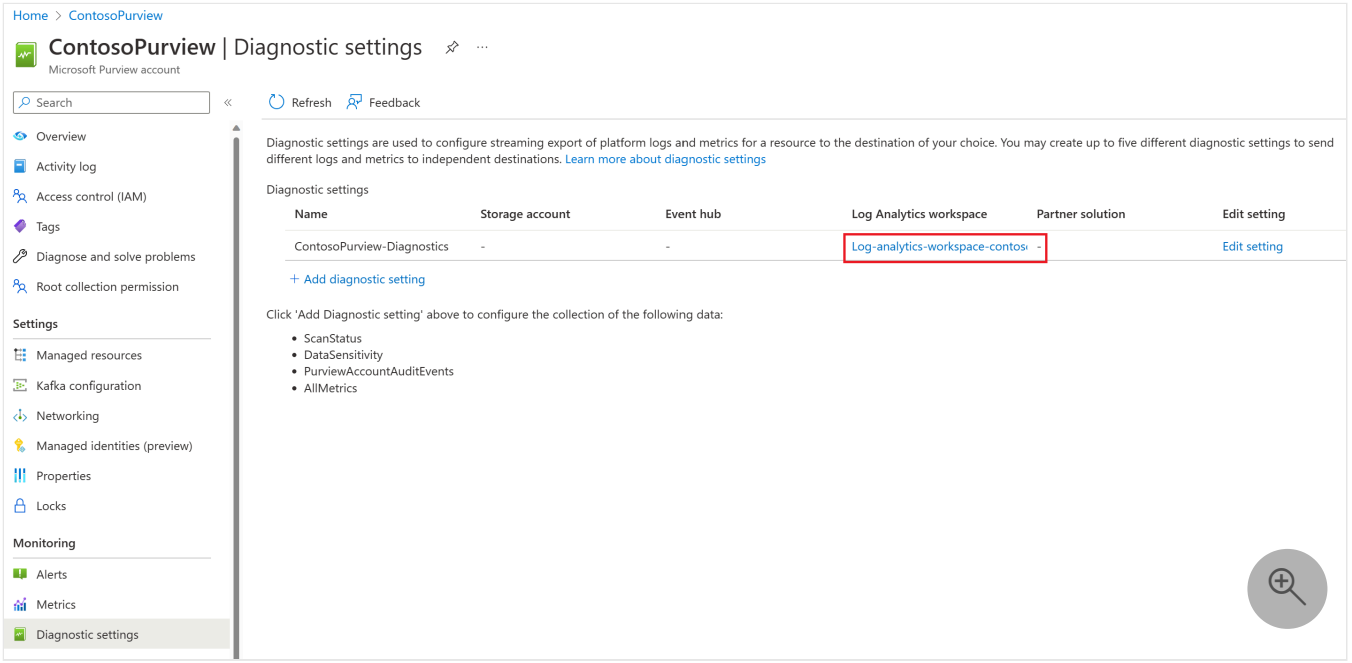
Sending diagnostic logs

Raw telemetry events are sent to Azure Monitor. Events can be sent to a Log Analytics Workspace, archived to a customer storage account of choice, streamed to an event hub, or sent to a partner solution for further analysis. Exporting of logs is done via the Diagnostic settings for the Microsoft Purview account on the Azure portal.

Follow these steps to create a diagnostic setting for your Microsoft Purview account and send to your preferred destination:

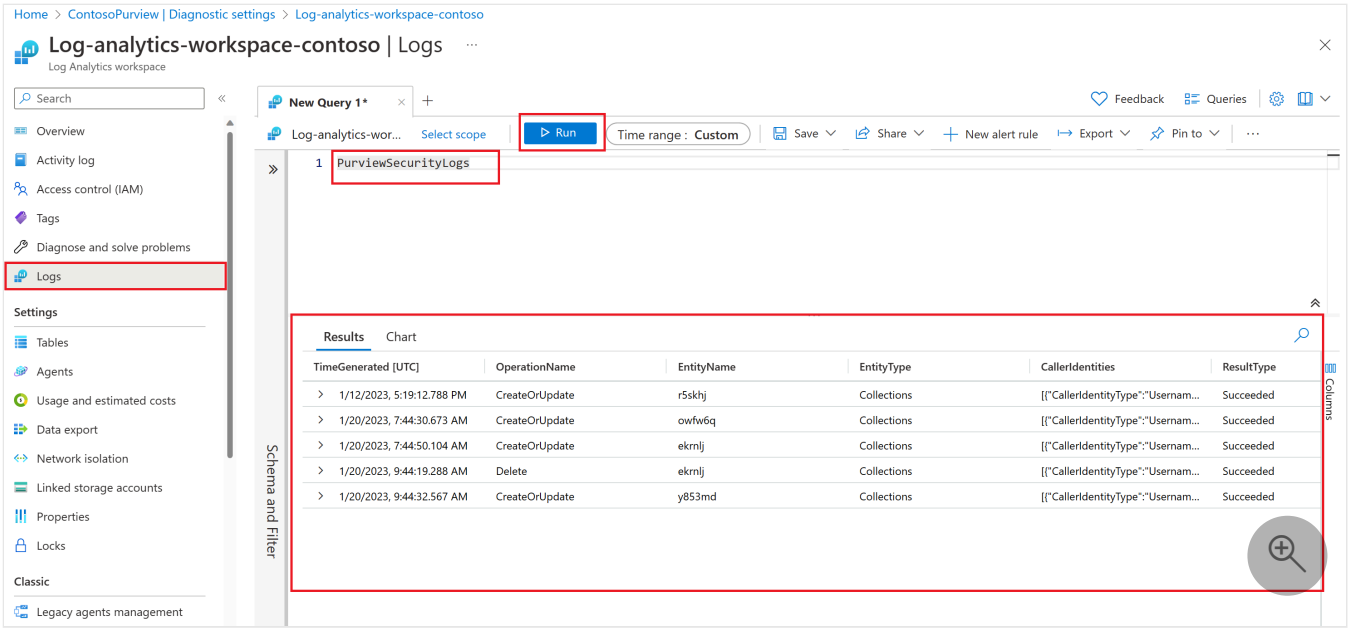
1. Locate your Microsoft Purview account in the Azure portal.
2. In the menu under **Monitoring** select **Diagnostic settings**.
3. Select **Add diagnostic setting** to create a new diagnostic setting to collect platform logs and metrics. For more information about these settings and logs, see the Azure Monitor documentation..





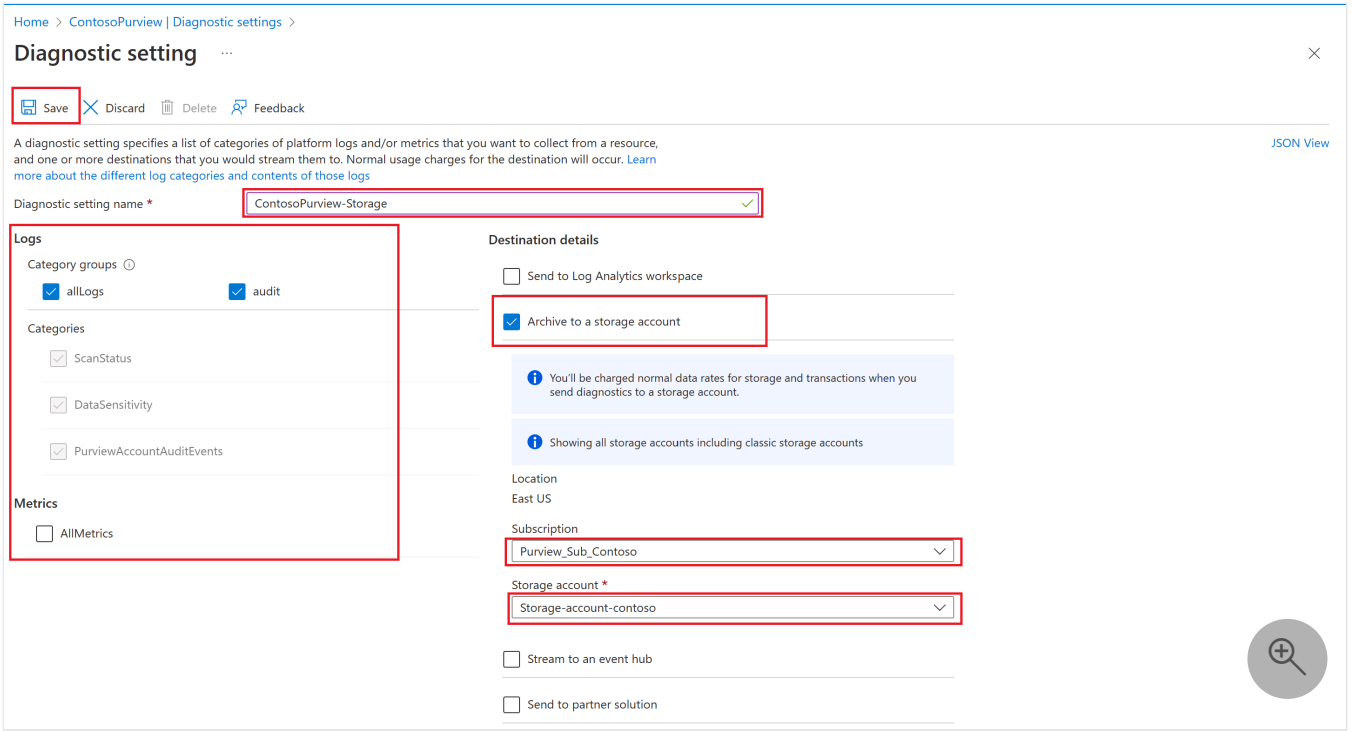
4. You can send your logs to:

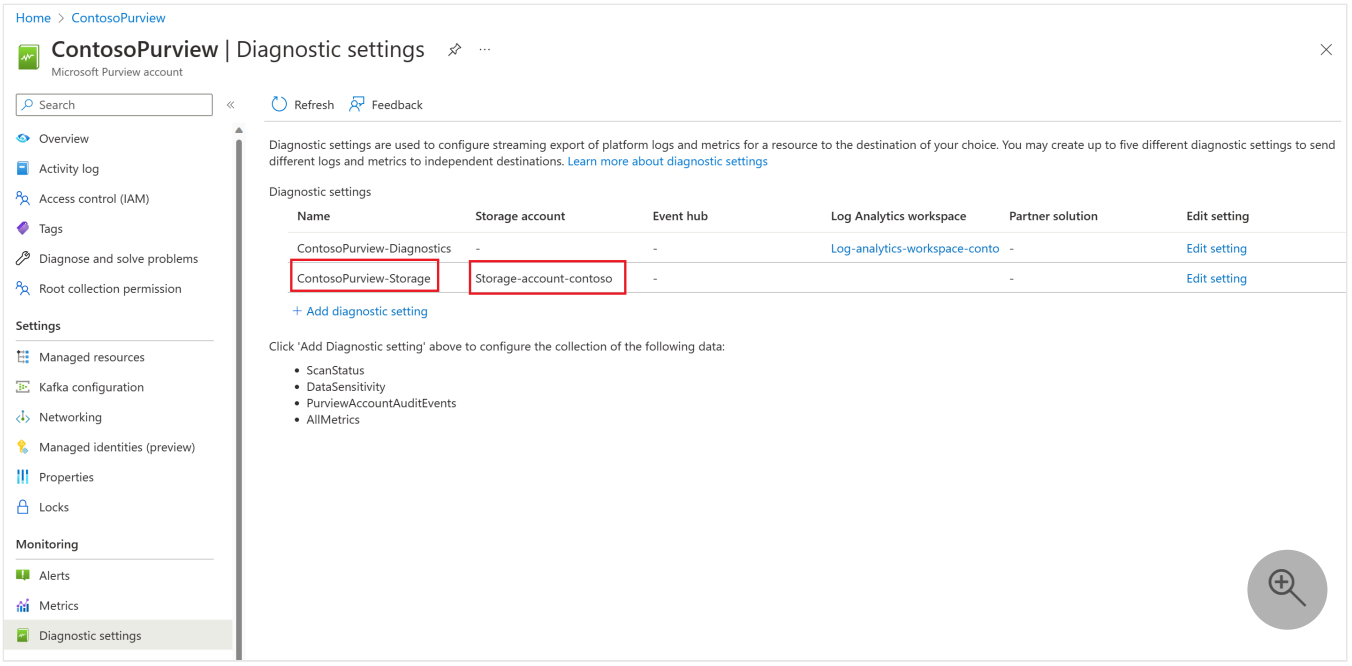
- A log analytics workspace
- A storage account
- An event hub



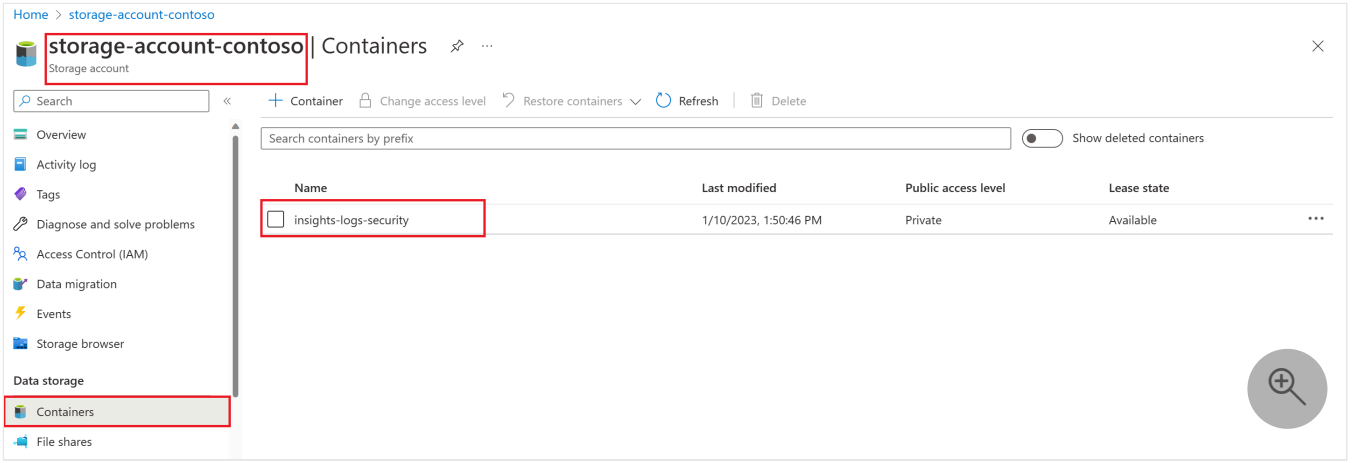
Destination - Log Analytics Workspace

1. In the **Destination details**, select **Send to Log Analytics workspace**.
2. Create a name for the diagnostic setting, select the applicable log category group and select the right subscription and workspace, then select save. The workspace doesn't have to be in the same region as the resource being monitored. You to create a new workspace, you can follow this article: Create a New Log Analytics Workspace.



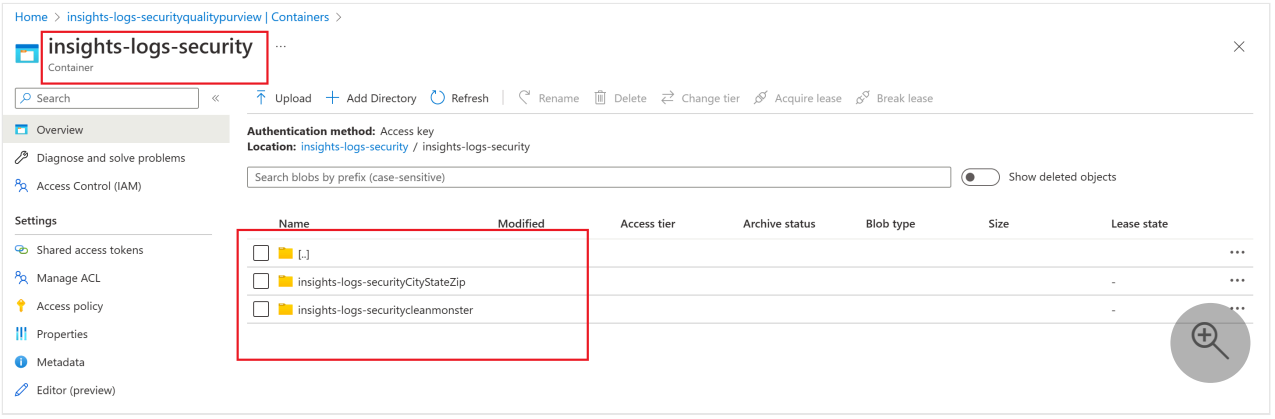


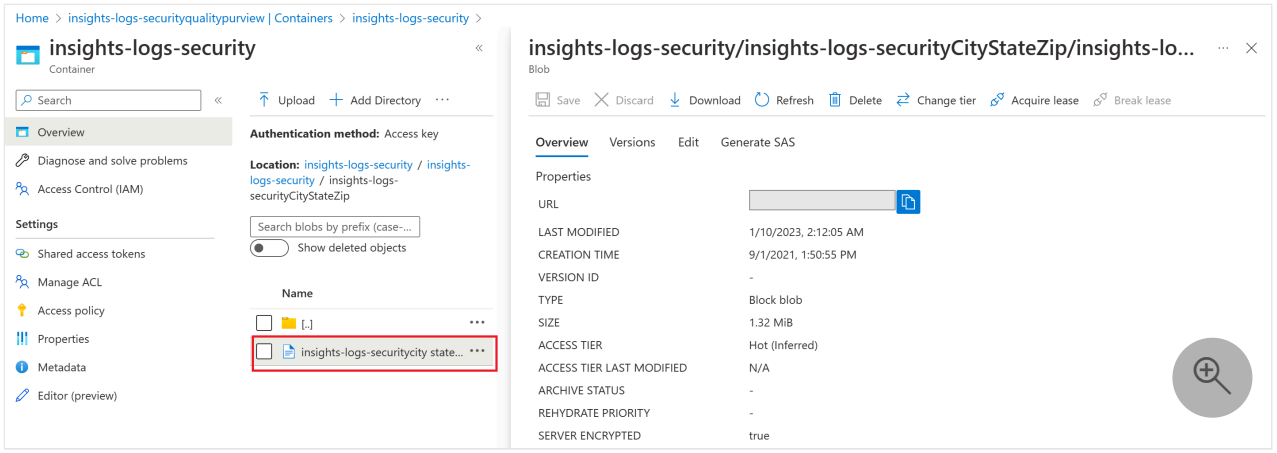
3. Verify the changes in your Log Analytics Workspace by performing some operations to populate data. For example, creating/updating/deleting a policy. After which you can open the **Log Analytics Workspace**, navigate to **Logs**, enter query filter as "**purviewsecuritylogs**", then select "**Run**" to execute the query.



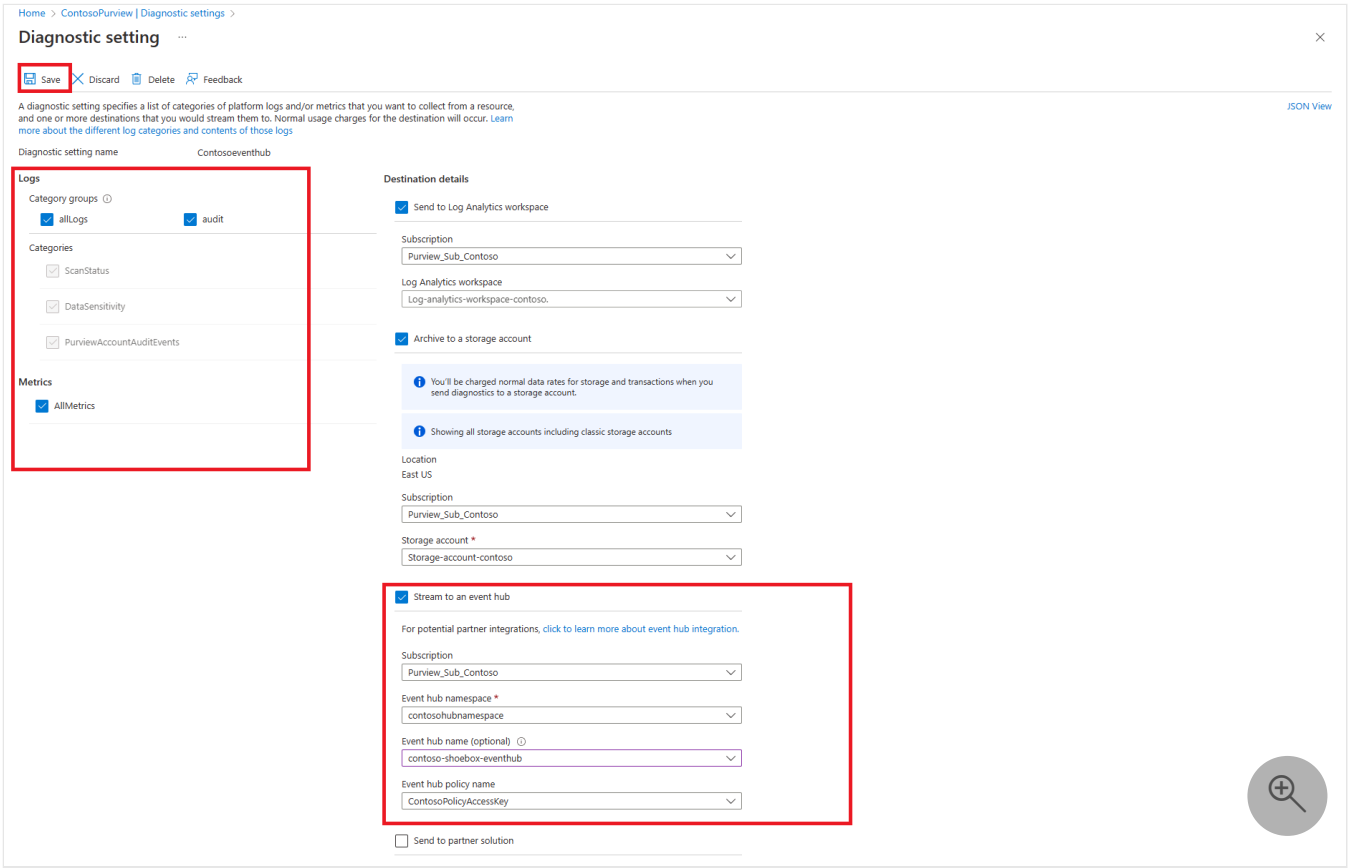
Destination - Storage account

1. In the **Destination details**, select **Archive to a storage account**.
2. Create a diagnostic setting name, select the log category, select the destination as archive to a storage account, select the right subscription and storage account then select save. A dedicated storage account is recommended for archiving the diagnostic logs. If you need a storage account, you can follow this article: Create a storage account.

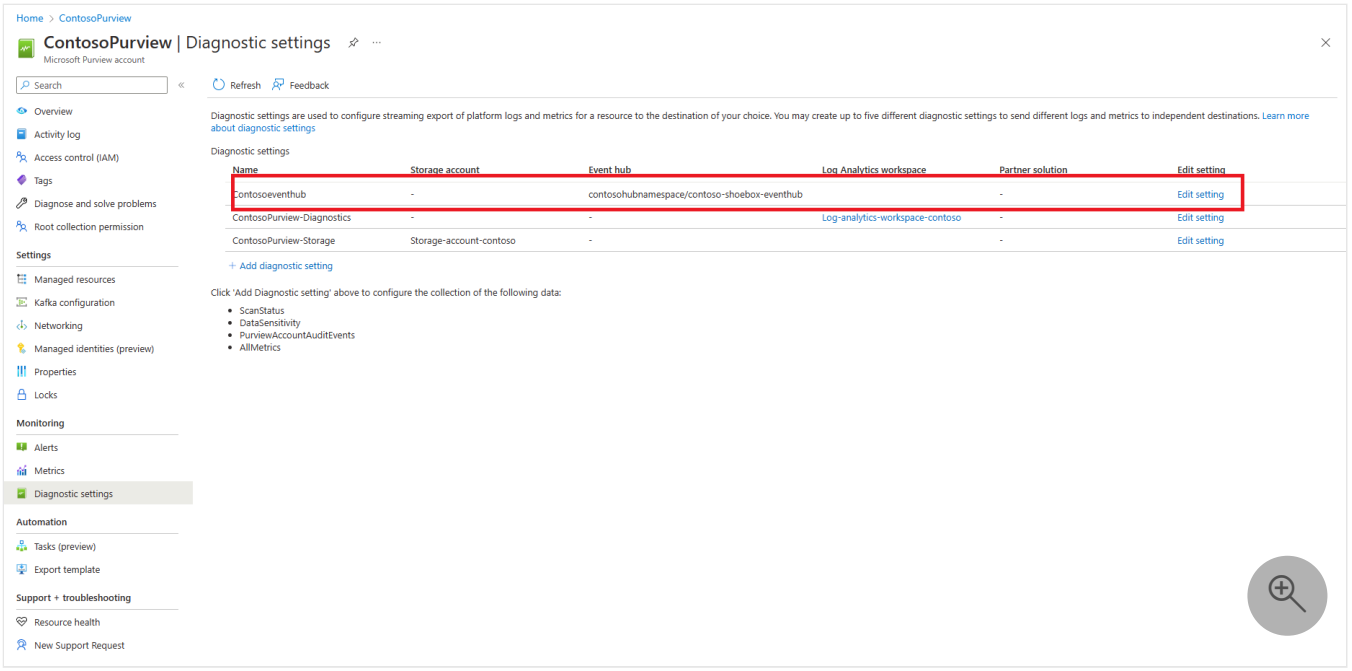


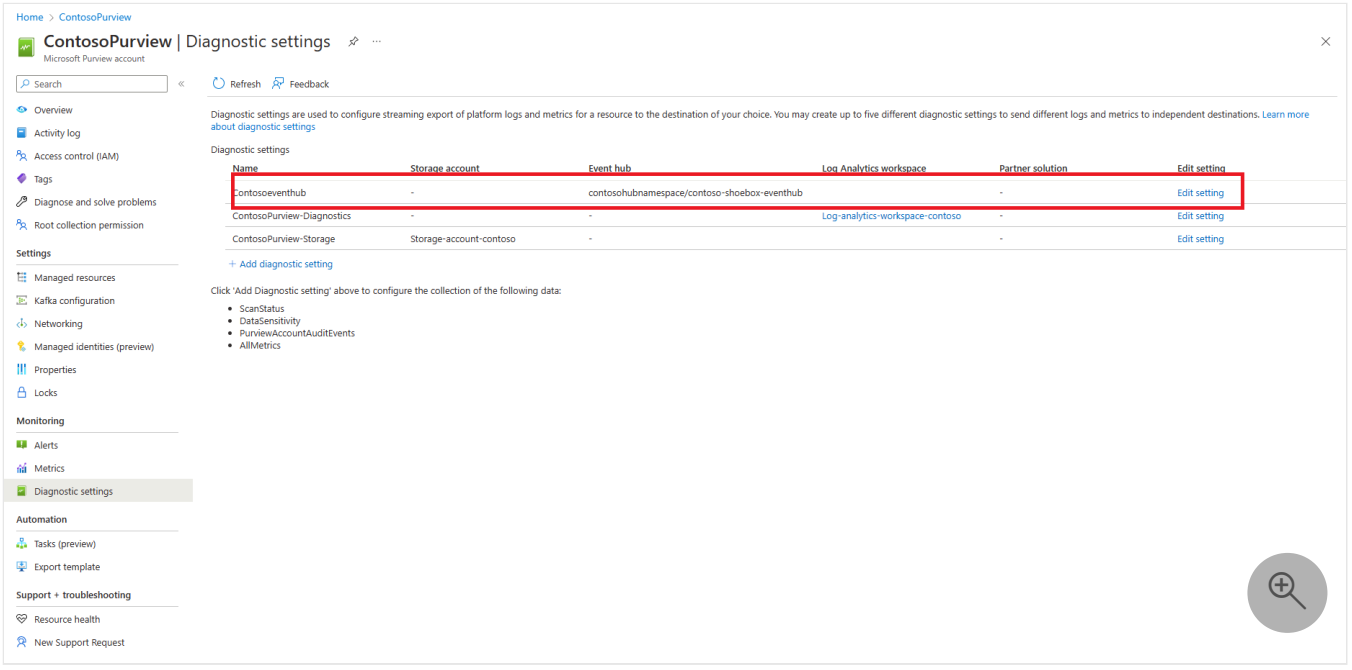


3. To see logs in the **Storage Account**, perform a sample action (for example: create/update/delete a policy), then open the **Storage Account**, navigate to **Containers**, and select the container name.



4. Navigate to the file and download it to see the logs.





Destination - Event hub

1. In the **Destination details**, select **Stream to an event hub**.
2. Create a diagnostic setting name, select the log category, select the destination as stream to event hub, select the right subscription, event hubs namespace, event hub name and event hub policy name then select save. An event hub name space is required before you can stream to an event hub. If you need to create an event hub namespace, you can follow this article: Create an event hub & event hubs namespace storage account

3. To see logs in the **Event Hubs Namespace**, Go to the Azure portal, and search for the name of the event hubs namespace you created earlier, go the Event Hubs Namespace and click on overview. To find our more about capturing and reading captured audit events in the event hubs namespace, you can follow this article: Audit Logs & diagnostics

Sample Log

Here's a sample log you'd receive from a diagnostic setting.

The event tracks the scan life cycle. A scan operation follows progress through a sequence of states, from Queued, Running and finally a terminal state of Succeeded | Failed | Canceled. An event is logged for each state transition and the schema of the event will have the following properties.

JSON

```
{
  "time": "<The UTC time when the event occurred>",
  "properties": {
    "dataSourceName": "<Registered data source friendly name>",
    "dataSourceType": "<Registered data source type>",
    "scanName": "<Scan instance friendly name>",
    "assetsDiscovered": "<If the resultType is succeeded, count of assets
discovered in scan run>",
    "assetsClassified": "<If the resultType is succeeded, count of assets
classified in scan run>",
    "scanQueueTimeInSeconds": "<If the resultType is succeeded, total seconds the
scan instance in queue>",
    "scanTotalRunTimeInSeconds": "<If the resultType is succeeded, total seconds
the scan took to run>",
    "runType": "<How the scan is triggered>",
    "errorDetails": "<Scan failure error>",
    "scanResultId": "<Unique GUID for the scan instance>"
  },
  "resourceId": "<The azure resource identifier>",
  "category": "<The diagnostic log category>",
  "operationName": "<The operation that cause the event Possible values for
ScanStatusLogEvent category are:
                    |AdhocScanRun
                    |TriggeredScanRun
                    |StatusChangeNotification>",
  "resultType": "Queued - indicates a scan is queued.
                 Running - indicates a scan entered a running state.
                 Succeeded - indicates a scan completed successfully.
                 Failed - indicates a scan failure event.
                 Cancelled - indicates a scan was cancelled. ",
  "resultSignature": "<Not used for ScanStatusLogEvent category. >",
  "resultDescription": "<This will have an error message if the resultType is
Failed. >",

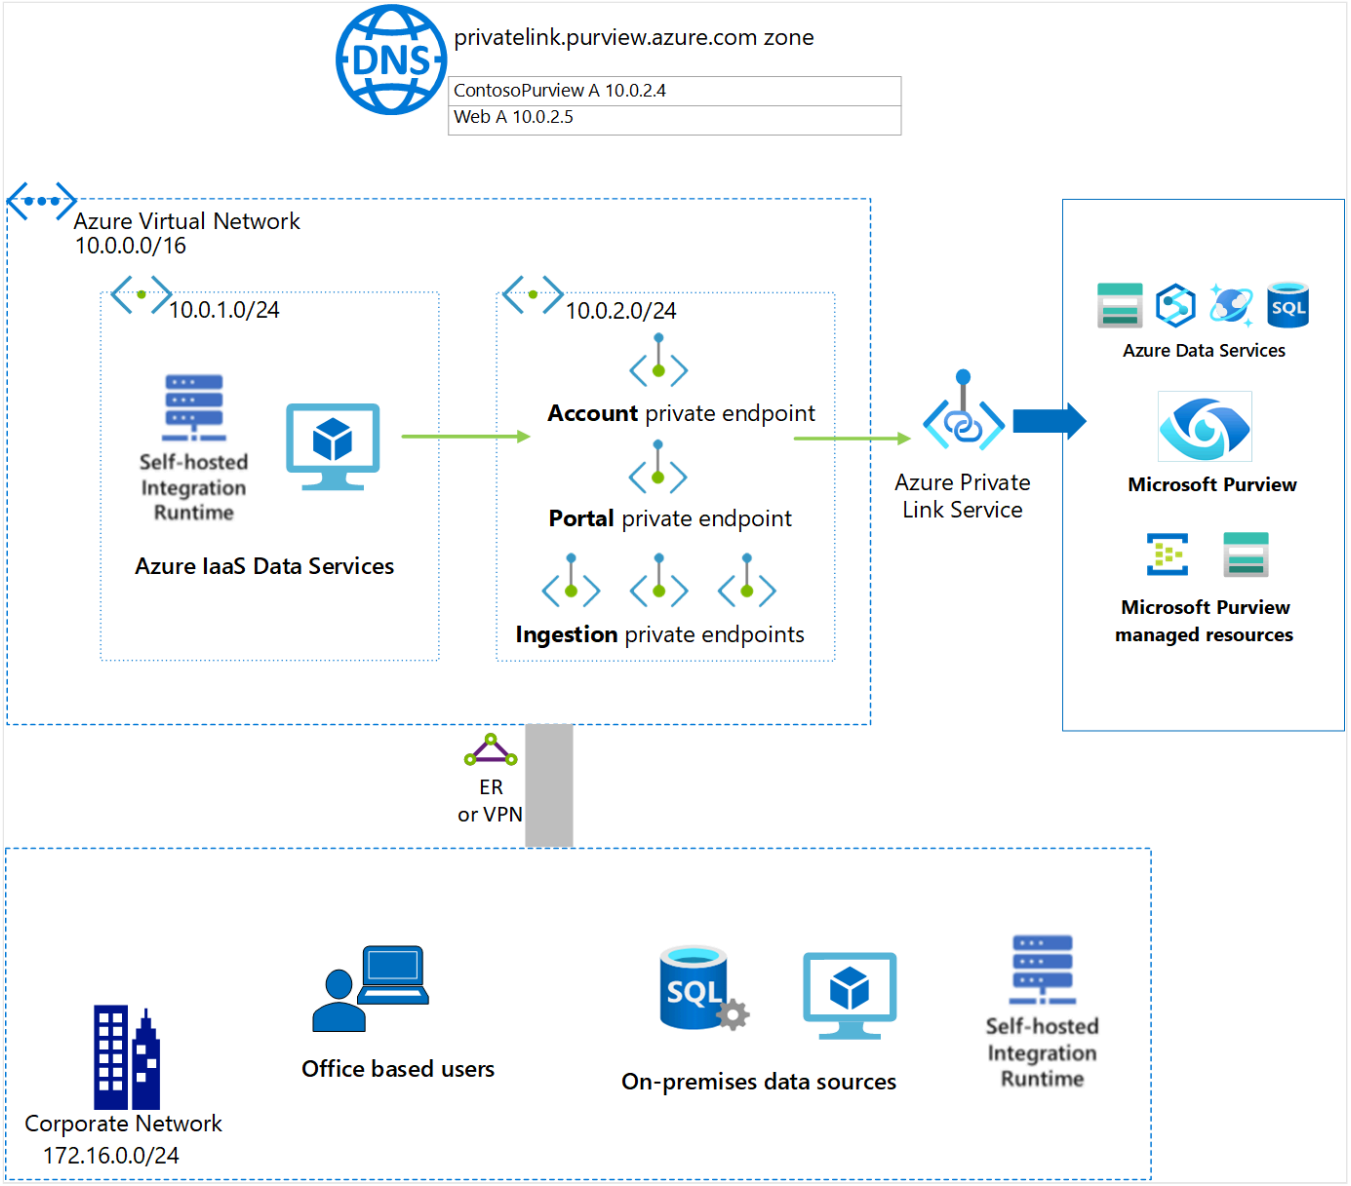
Microsoft Purview Data Map

Use private endpoints for your Microsoft Purview account

Article • 05/09/2025



> **Important**
>
> This article covers private endpoints for the classic Microsoft Purview governance portal (https://web.purview.azure.com). If you're using the new Microsoft Purview portal (https://purview.microsoft.com/), follow the documentation for private endpoints in the Microsoft Purview portal.

Conceptual Overview

You can use Azure private endpoints for your Microsoft Purview accounts to allow users on a virtual network (VNet) to securely access the catalog over a Private Link. A private endpoint uses an IP address from the VNet address space for your Microsoft Purview account. Network traffic between the clients on the VNet and the Microsoft Purview account traverses over the VNet and a private link on the Microsoft backbone network.

If you're still using the classic portal experience, you can deploy Microsoft Purview *account* private endpoint, to allow only client calls to Microsoft Purview that originate from within the private network. To connect to the classic governance portal using a private network connectivity, you can deploy *portal* private endpoint.

For both the new and classic experience, you can deploy *ingestion* private endpoints if you need to scan Azure IaaS and PaaS data sources inside Azure virtual networks and on-premises data sources through a private connection. This method ensures network isolation for your metadata flowing from the data sources to Microsoft Purview Data Map.

Prerequisites

Before deploying private endpoints for Microsoft Purview account, ensure you meet the following prerequisites:

1. An Azure account with an active subscription. Create an account for free.
2. An existing Azure Virtual network. Deploy a new Azure virtual network if you don't have one.

Microsoft Purview private endpoint deployment scenarios

Use the following recommended checklist to perform deployment of Microsoft Purview account with private endpoints:

Expand table

Scenario	Objectives
Scenario 1 - Connect to your Microsoft Purview and scan data sources privately and securely	You need to restrict access to your Microsoft Purview account only via a private endpoint, including access to the classic governance portal, Atlas APIs and scan data sources in on-premises and Azure (but inside a virtual network) using self-hosted integration runtime ensuring end to end network isolation. (Deploy *account*, _portal, and *ingestion* private endpoints.)
Scenario 2 - Connect privately and securely to your Microsoft Purview account	You need to enable access to your Microsoft Purview account, including access to *the Microsoft Purview governance portal* and Atlas API through private endpoints. (Deploy *account* and *portal* private endpoints).
Scenario 3 - Scan data source securely using Managed Virtual Network	You need to scan Azure data sources securely, without having to manage a virtual network or a self-hosted integration runtime VM. (Deploy managed private endpoints for Microsoft Purview Azure data sources).
Scenario 4 - Using the new Microsoft Purview portal	If you're using the new portal experience, you can set up ingestion and platform private endpoints.

Frequently Asked Questions

For FAQs related to private endpoint deployments in Microsoft Purview, see FAQ about Microsoft Purview private endpoints.

Troubleshooting guide

For troubleshooting private endpoint configuration for Microsoft Purview accounts, see Troubleshooting private endpoint configuration for Microsoft Purview accounts.

Known limitations

To view list of current limitations related to Microsoft Purview private endpoints, see Microsoft Purview private endpoints known limitations.

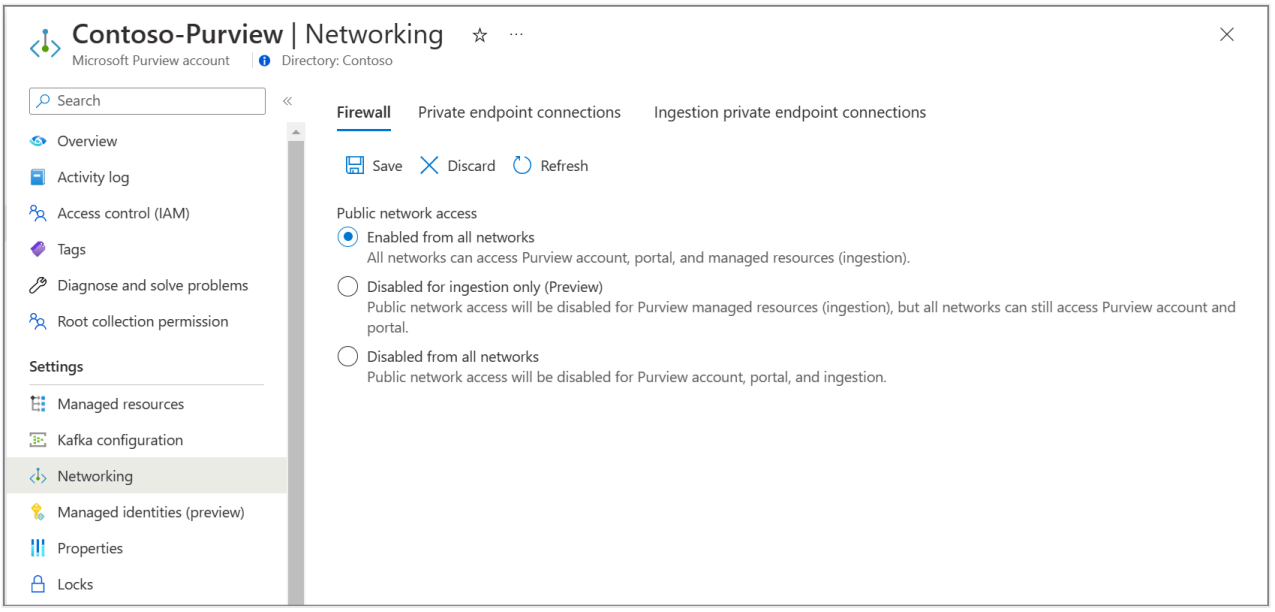
Configure firewall settings for your Microsoft Purview account

Article • 05/09/2025

> **Important**
>
> This article covers private endpoints for the classic Microsoft Purview governance portal (https://web.purview.azure.com). If you're using the new Microsoft Purview portal (https://purview.microsoft.com/), follow the documentation for private endpoints in the Microsoft Purview portal.

Prerequisites

To configure Microsoft Purview account firewall settings, ensure you meet the following prerequisites:



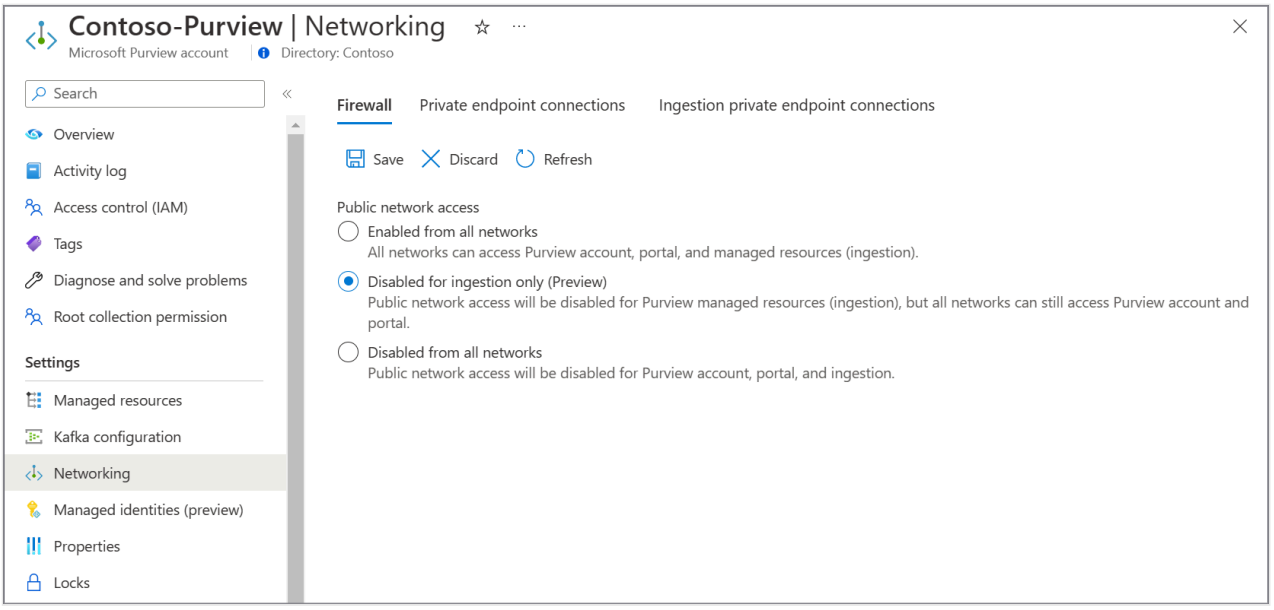
1. An Azure account with an active subscription. Create an account for free.
2. An existing Microsoft Purview account.
3. Must have IAM Contributor role on the Microsoft Purview account.
4. Must have IAM Reader role on the Azure subscription that hosts the Microsoft Purview account.

Microsoft Purview firewall deployment scenarios

To configure Microsoft Purview firewall, follow these steps:

1. Sign in to the Azure portal.
2. Navigate to your Microsoft Purview account in the portal.
3. Under *Settings*, choose **Networking**.
4. In the **Firewall** tab, under **Public network access**, change the firewall settings to the option that suits your scenario:

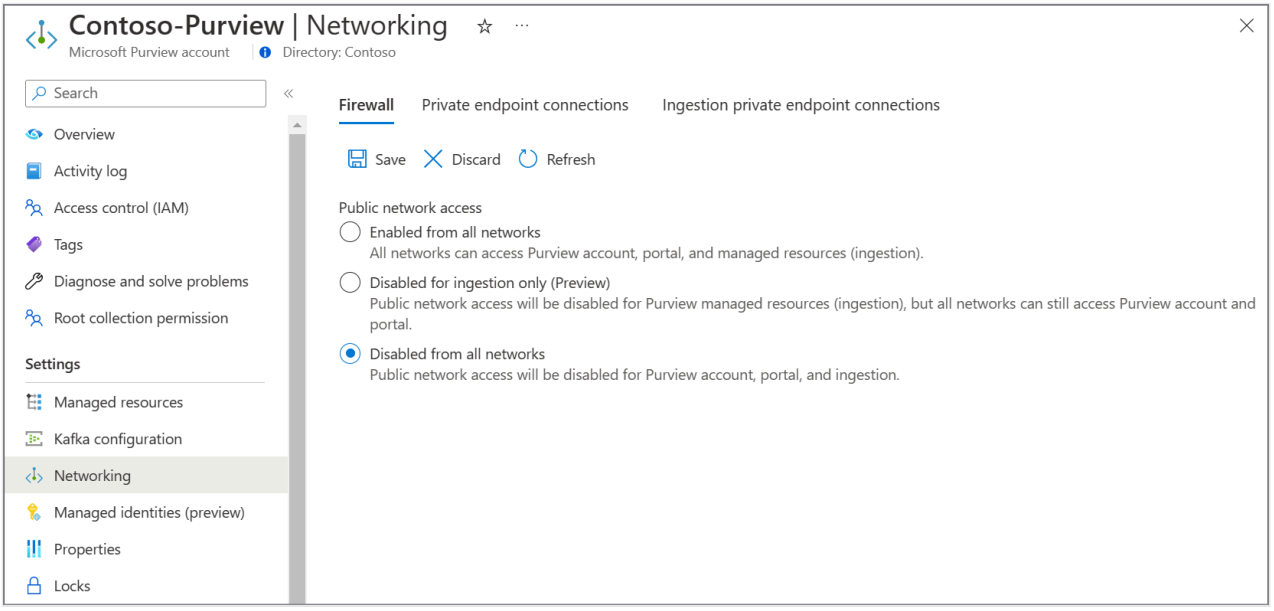
- **Enabled from all networks**



By choosing this option:

- All public network access into your Microsoft Purview account is allowed.
- If you're using a managed Event Hubs for kafka notifications, public network access is set to *All networks* on your Microsoft Purview account's Event Hubs.
- If you have an account created before December 15, 2023, public network access is set to *Enabled from all networks* on your Microsoft Purview account's managed storage account. If you have an account created after that date (or deployed using API version 2023-05-01-preview onwards), the public network access on your Microsoft Purview account's ingestion storage account *Enabled from all networks*.

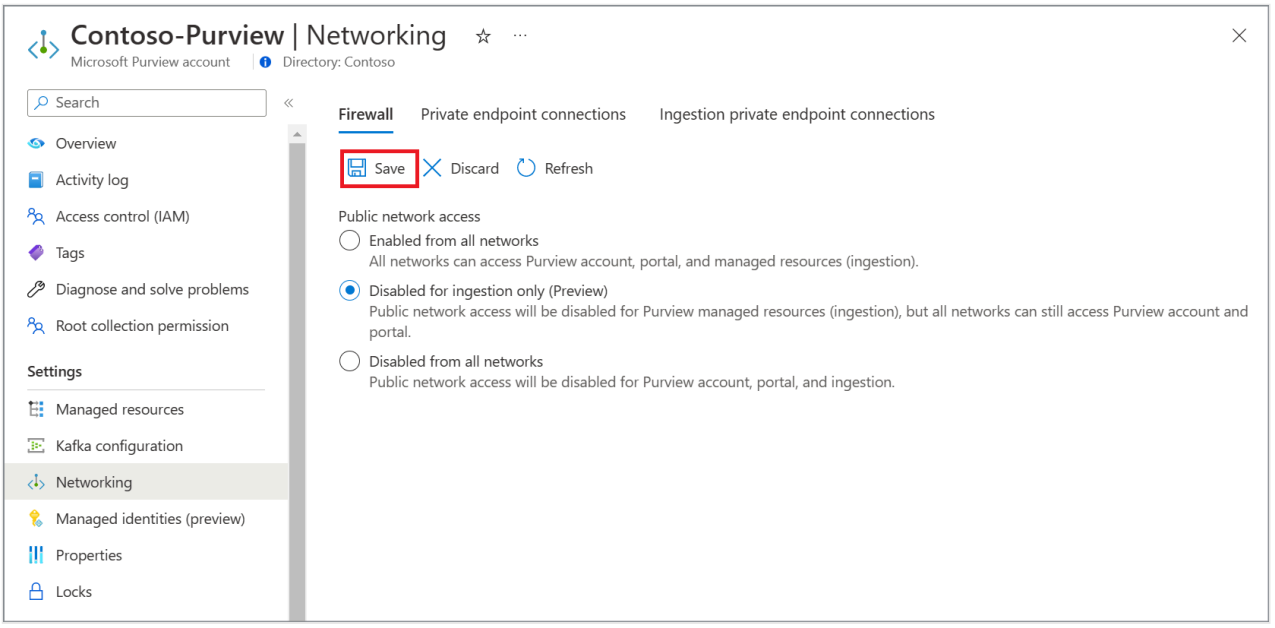
> **Note**
>
> Even though the network access is enabled through public internet, to gain access to the classic governance portal, users must be first authenticated and authorized.



- **Disabled for ingestion only (preview)**

By choosing this option:

- Public network access to your Microsoft Purview account through API and the classic governance portal is allowed.
- All public network traffic for ingestion is disabled. In this case, you must configure a private endpoint for ingestion before setting up any scans. For more information, see Use private endpoints for your Microsoft Purview account.
- If you're using a managed Event Hubs for kafka notifications, public network access is set to *Disabled* on your Microsoft Purview account's Event Hubs.
- If you have an account created before December 15, 2023, public network access is set to *Disabled* on your Microsoft Purview account's managed storage account. If you have an account created after that date (or deployed using API version 2023-05-01-preview onwards), the public network access on your Microsoft Purview account's ingestion storage account *Disabled*.



- **Disabled from all networks**

By choosing this option:

- All public network access into your Microsoft Purview account is disabled.
- All network access to your Microsoft Purview account through APIs or the classic governance portal including traffic to run scans is allowed only through private network using private endpoints. For more information, see Connect to your Microsoft Purview and scan data sources privately and securely.
- If you're using a managed Event Hubs for kafka notifications, public network access is set to *Disabled* on your Microsoft Purview account's Event Hubs.
- If you have an account created before December 15, 2023, public network access is set to *Disabled* on your Microsoft Purview account's managed storage account. If you have an account created after that date (or deployed using API version 2023-05-01-preview onwards), the public network access on your Microsoft Purview account's ingestion storage account is set to *Disabled*.

5. Select **Save**.

Connect to your Microsoft Purview and scan data sources privately and securely

Article • 05/09/2025

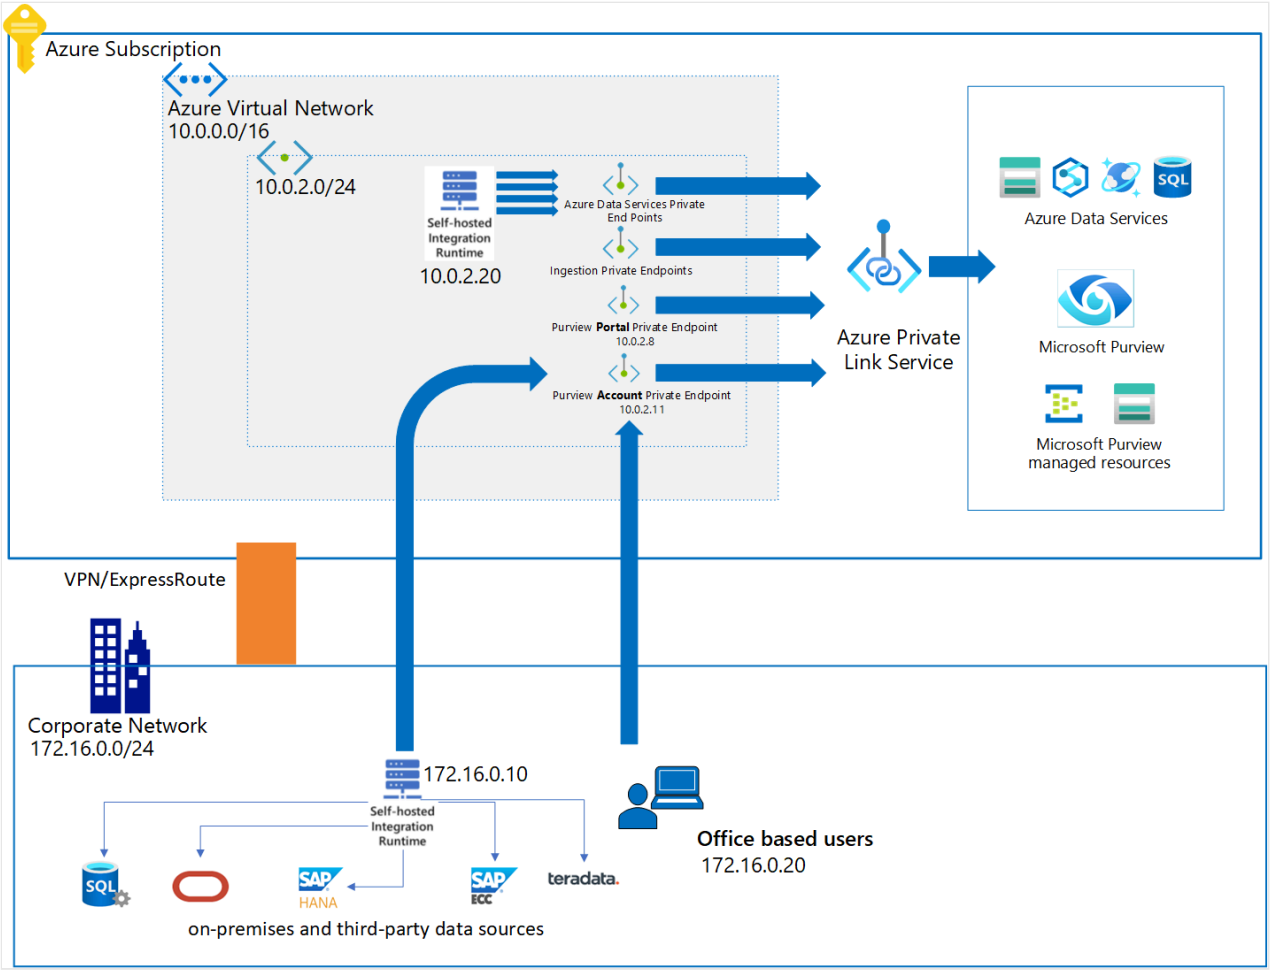
>
> This article covers private endpoints for the classic Microsoft Purview governance portal (https://web.purview.azure.com). If you're using the new Microsoft Purview portal (https://purview.microsoft.com/), follow the documentation for private endpoints in the Microsoft Purview portal.



In this guide, you'll learn how to deploy *account*, _portal, and *ingestion* private endpoints for your Microsoft Purview account to access purview account and scan data sources using a self-hosted integration runtime securely and privately, enabling end-to-end network isolation.=

The Microsoft Purview *account* private endpoint is used to add another layer of security by enabling scenarios where only client calls that originate from within the virtual network are allowed to access the Microsoft Purview account. This private endpoint is also a prerequisite for the portal private endpoint.

The Microsoft Purview *portal* private endpoint is required to enable connectivity to the classic Microsoft Purview governance portal using a private network.

Microsoft Purview can scan data sources in Azure or an on-premises environment by using *ingestion* private endpoints. Depending on your accounts deployment date and configuration, up to three private endpoint resources are required to be deployed and linked to Microsoft Purview configured resources when ingestion private endpoint is deployed:

- If you're using a managed Event Hubs for kafka notifications, a namespace private endpoint is linked to a Microsoft Purview configured Event Hubs namespace.
- If your account was created before December 15, 2023:
  - Blob private endpoint is linked to a Microsoft Purview managed storage account.
  - Queue private endpoint is linked to a Microsoft Purview managed storage account.
- If your account was created after December 15, 2023 (or deployed using API version 2023-05-01-preview onwards):
  - Blob private endpoint is linked to a Microsoft Purview ingestion storage.
  - Queue private endpoint is linked to a Microsoft Purview ingestion storage.

Deployment checklist

Following the instructions further in this guide, you can deploy these private endpoints for an existing Microsoft Purview account:

1. Choose an appropriate Azure virtual network and a subnet to deploy Microsoft Purview private endpoints. Select one of the following options:

    - Deploy a new virtual network in your Azure subscription.
    - Locate an existing Azure virtual network and a subnet in your Azure subscription.

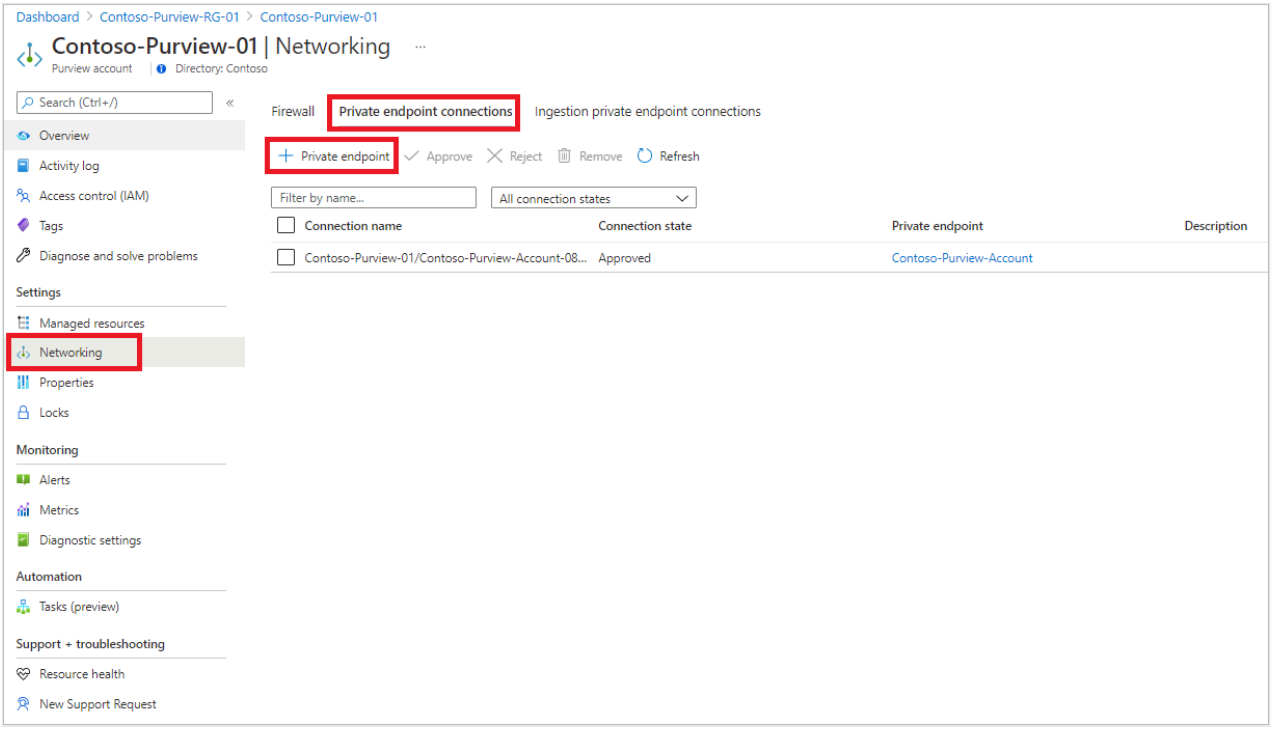
2. Define an appropriate DNS name resolution method, so you can access Microsoft Purview account and scan data sources using private network. You can use any of the following options:

    - Deploy new Azure DNS zones using the steps explained further in this guide.
    - Add required DNS records to existing Azure DNS zones using the steps explained further in this guide.
    - After completing the steps in this guide, add required DNS A records in your existing DNS servers manually.

3. Deploy private endpoints for an existing Microsoft Purview account.

4. Enable access to Microsoft Entra ID if your private network has network security group rules set to deny for all public internet traffic.

5. Deploy and register Self-hosted integration runtime inside the same virtual network or a peered virtual network where Microsoft Purview account and ingestion private endpoints are deployed.



6. After completing this guide, adjust DNS configurations if needed.

7. Validate your network and name resolution between management machine, self-hosted IR VM and data sources to Microsoft Purview.

> **Note**
>
> If you configure your own Event Hubs namespace or enable a managed Event Hubs namespace after deploying your ingestion private endpoint, you'll need to redeploy the ingestion private endpoint.

Enable *account* and *portal* private endpoint

1. Go to the Azure portal, and then select your Microsoft Purview account, and under **Settings** select **Networking**, and then select **Private endpoint connections**.

2. Select + **Private endpoint** to create a new private endpoint.

3. Fill in the basic information.

4. On the **Resource** tab, for **Resource type**, select **Microsoft.Purview/accounts**.

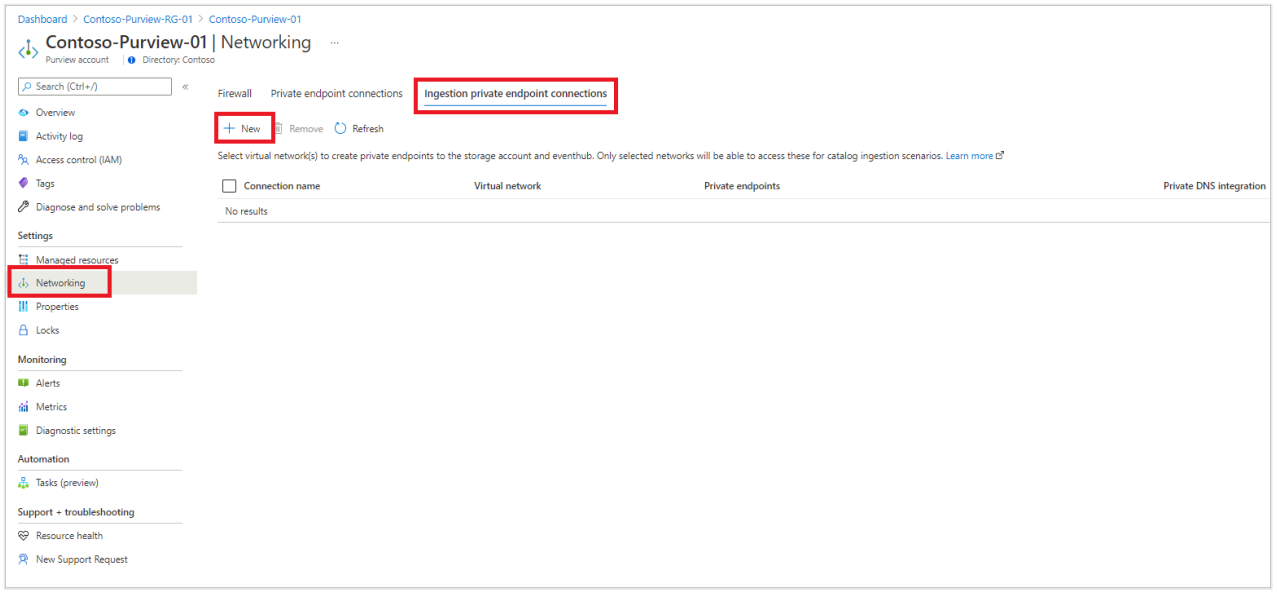
5. For **Resource**, select the Microsoft Purview account, and for **Target sub-resource**, select **account**.

6. On the **Configuration** tab, select the virtual network and optionally, select Azure Private DNS zone to create a new Azure DNS Zone.

   > **Note**
   >
   > For DNS configuration, you can also use your existing Azure Private DNS Zones from the dropdown list or add the required DNS records to your DNS Servers manually later. For more information, see Configure DNS Name Resolution for private endpoints

7. Go to the summary page, and select **Create** to create the account private endpoint.

8. Repeat steps 2 through 7 to create the portal private endpoint. Make sure you select **portal** for **Target sub-resource**.



Deploy *ingestion* private endpoint

Ingestion private endpoints are deployed from the Azure portal for all Microsoft Purview instances, regardless of whether you're using the Microsoft Purview portal or the classic governance portal.

1. Go to the Azure portal, and then search for and select your Microsoft Purview account.

2. From your Microsoft Purview account, under **Settings** select **Networking**, and then select **Ingestion private endpoint connections**.

3. Under Ingestion private endpoint connections, select **+ New** to create a new ingestion private endpoint.

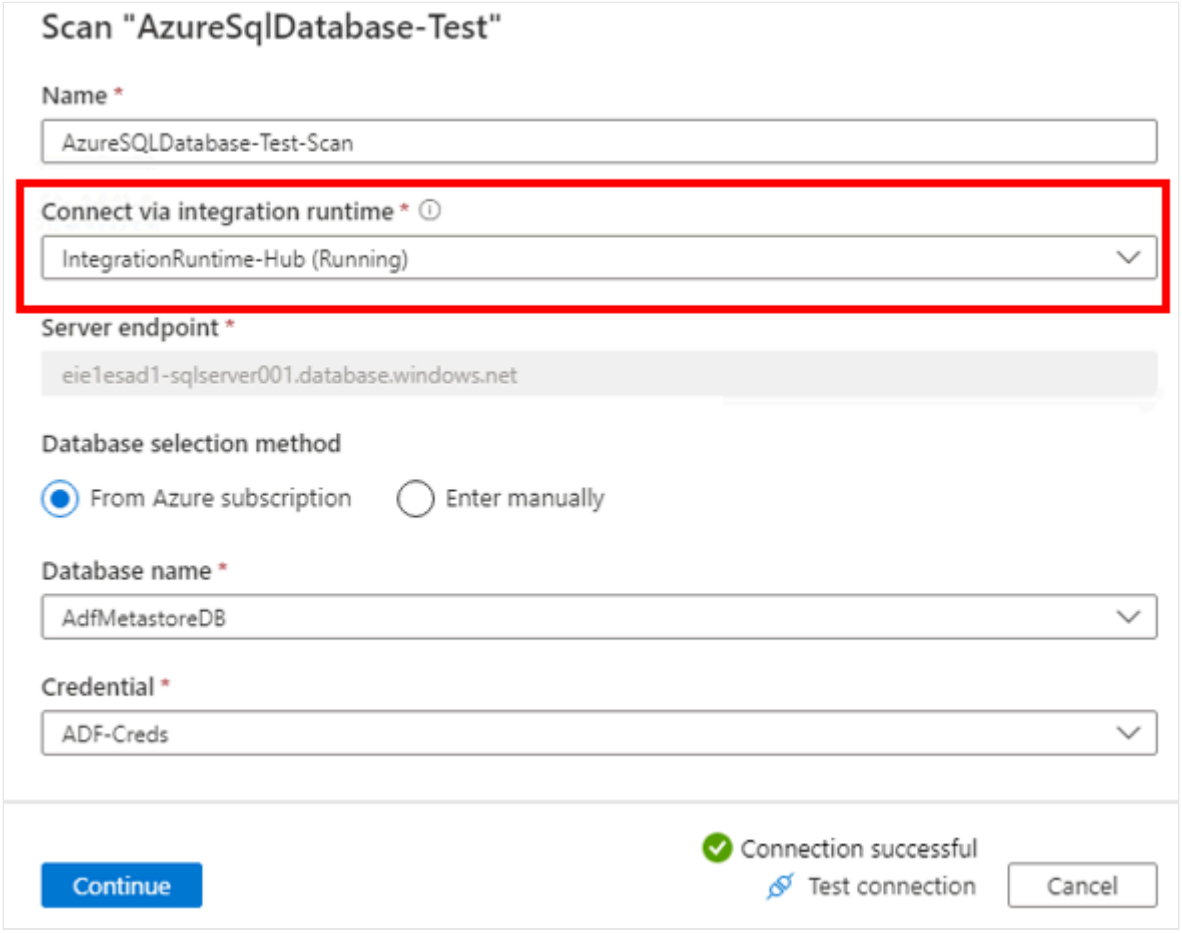
4. Fill in the basic information, selecting your existing virtual network and a subnet details. Optionally, select **Private DNS integration** to use Azure Private DNS Zones. Select correct Azure Private DNS Zones from each list.

   > **Note**
   >
   > You can also use your existing Azure Private DNS zones or create DNS records in your DNS Servers manually later. For more information, see Configure DNS Name Resolution for private endpoints

5. Select **Create** to create the private endpoint.

6. If you don't have one already, you need to deploy a self-hosted integration runtime to connect to the sources with private endpoints.

Configure networking for Event Hubs namespace



If you've configured an Event Hubs to send/receive events to/from Microsoft Purview's Apache Atlas Kafka topics, you need to confirm your Event Hubs network settings allow communication.

Deploy self-hosted integration runtime (IR) and scan your data sources

Once you deploy ingestion private endpoints for your Microsoft Purview, you need to setup and register at least one self-hosted integration runtime (IR):

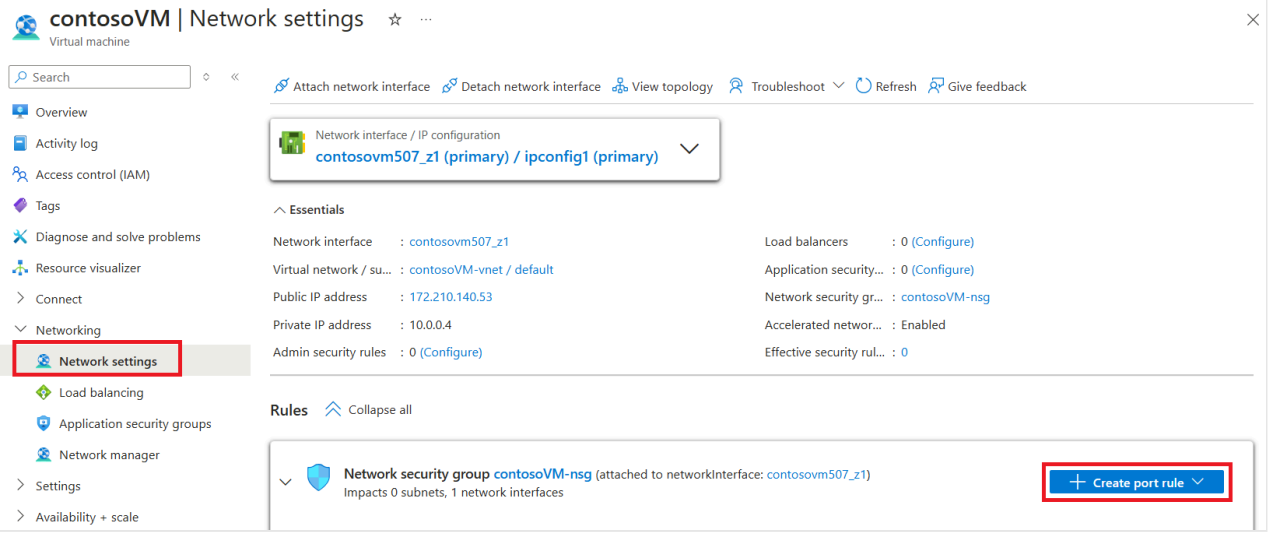
- All on-premises source types like Microsoft SQL Server, Oracle, SAP, and others are currently supported only via self-hosted IR-based scans. The self-hosted IR must run within your private network and then be peered with your virtual network in Azure.
- For all Azure source types like Azure Blob Storage and Azure SQL Database, you must explicitly choose to run the scan by using a self-hosted integration runtime that is deployed in the same virtual network or a peered virtual network where Microsoft Purview account and ingestion private endpoints are deployed.

Follow the steps in Create and manage a self-hosted integration runtime to set up a self-hosted IR. Then set up your scan on the Azure source by choosing that self-hosted IR in the **Connect via integration runtime** dropdown list to ensure network isolation.

> **Important**
>
> Make sure you download and install the latest version of self-hosted integration runtime from Microsoft download center.

Enable access to Microsoft Entra ID

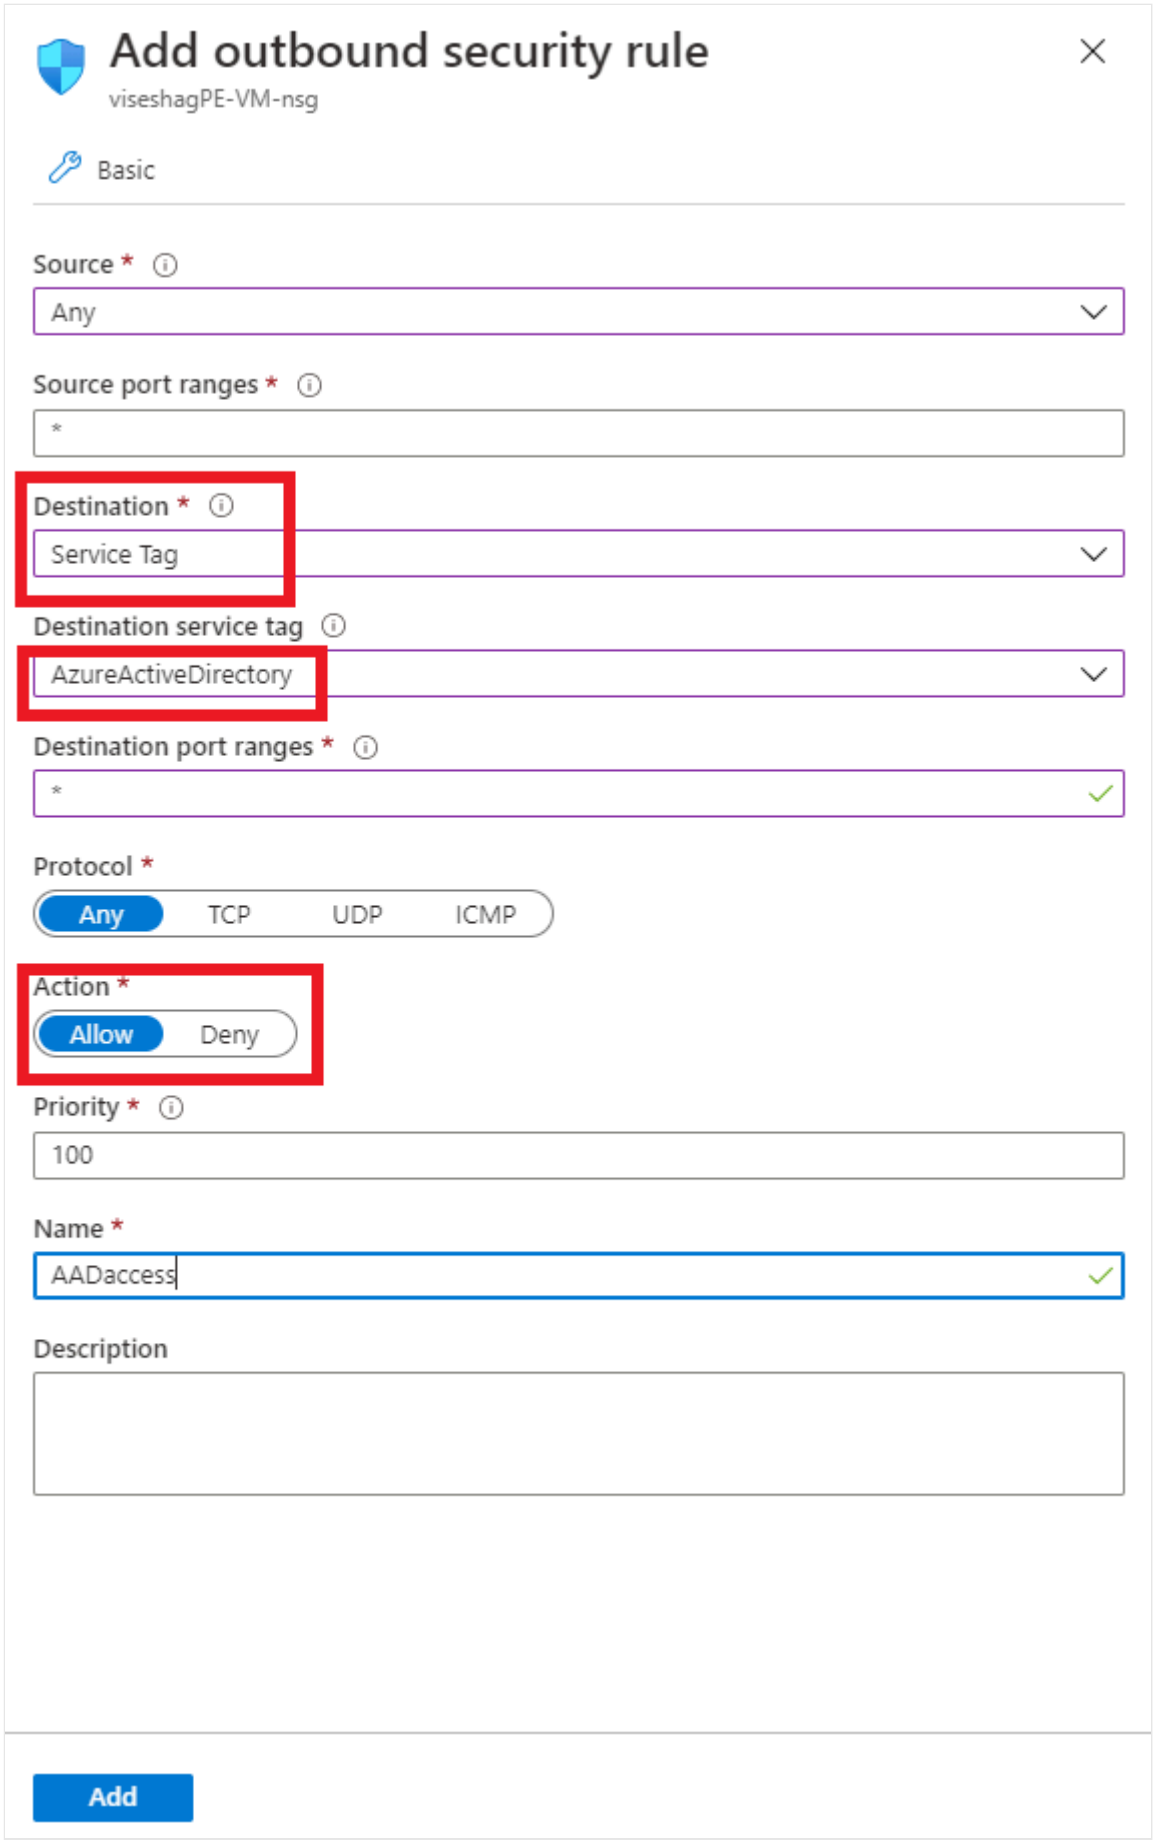
> **Note**



If your VM, VPN gateway, or VNet Peering gateway has public internet access, it can access the classic Microsoft Purview governance portal and the Microsoft Purview account enabled with private endpoints. For this reason, you don't have to follow the rest of the instructions. If your private network has network security group rules set to deny all public internet traffic, you'll need to add some rules to enable Microsoft Entra ID access. Follow the instructions to do so.

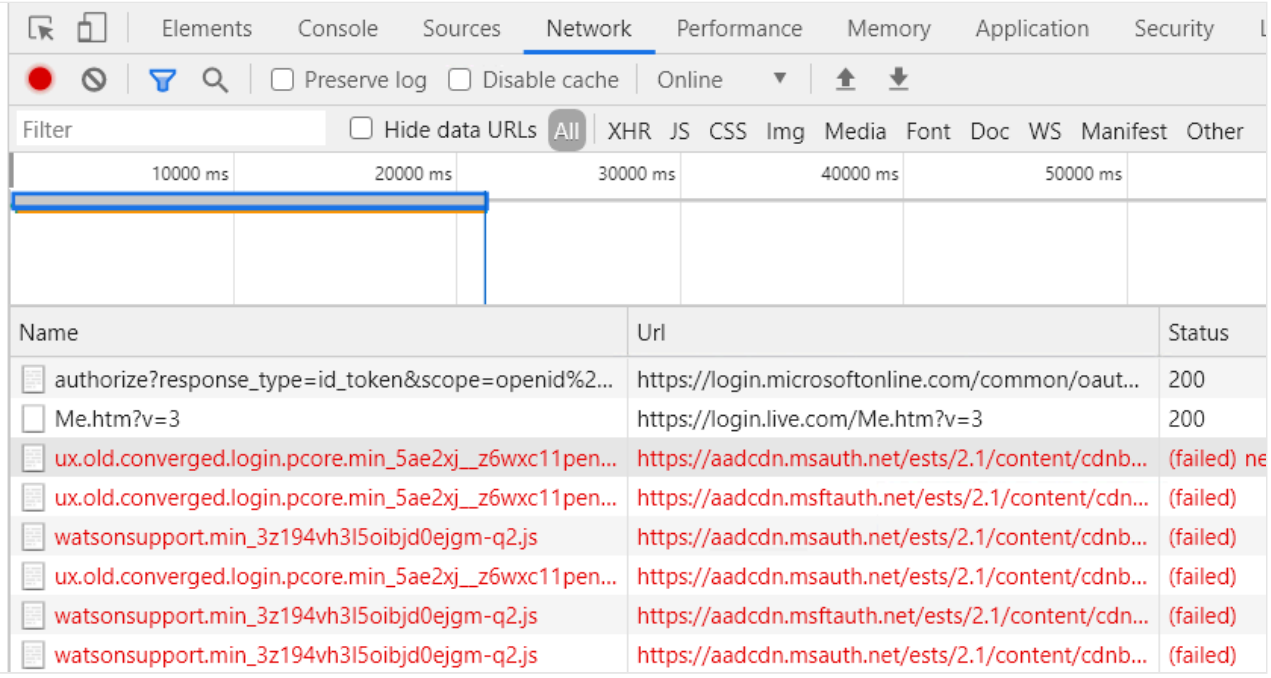
These instructions are provided for accessing Microsoft Purview securely from an Azure VM. Similar steps must be followed if you're using VPN or other virtual network Peering gateways.

1. Go to your virtual machine in the Azure portal, and under **Networking**, select **Network settings**.



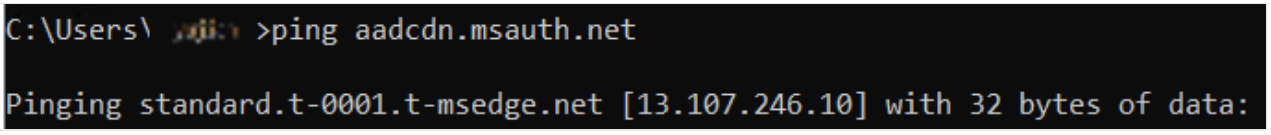
2. Select **+ Create port rule**

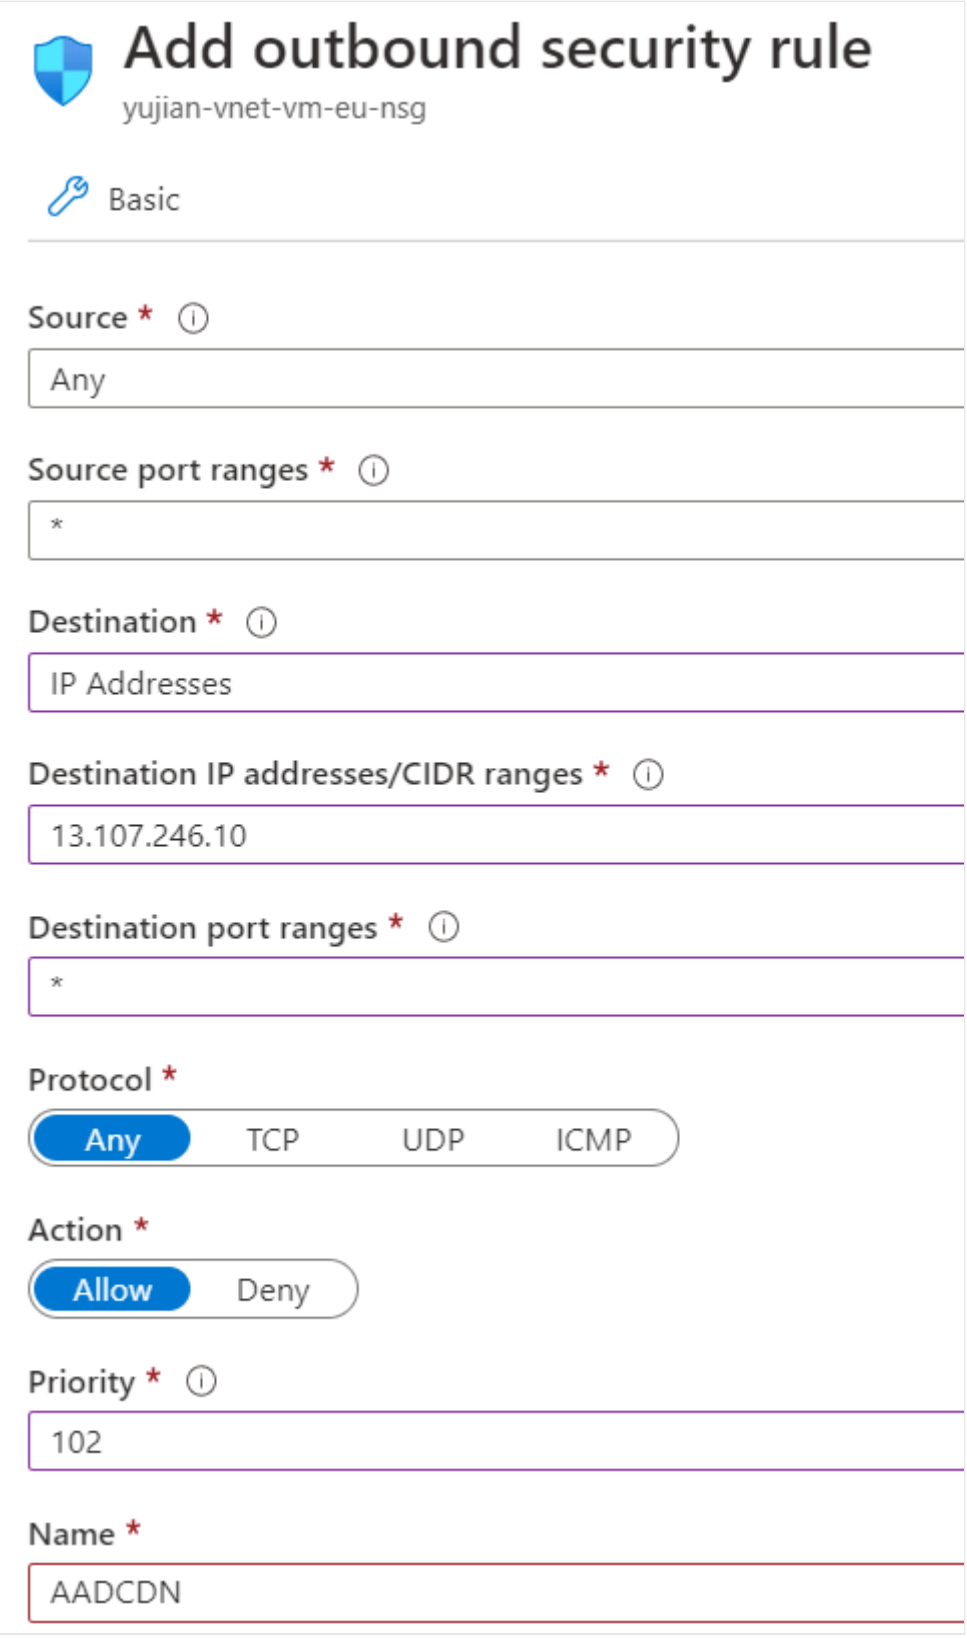
3. Select **Outbound port rule**



4. On the **Add outbound security rule** pane:
   a. Under **Destination**, select **Service Tag**.
   b. Under **Destination service tag**, select **AzureActiveDirectory**.
   c. Under **Destination port ranges**, select *.
   d. Under **Action**, select **Allow**.
   e. Under **Priority**, the value should be higher than the rule that denied all internet traffic.

   Create the rule.





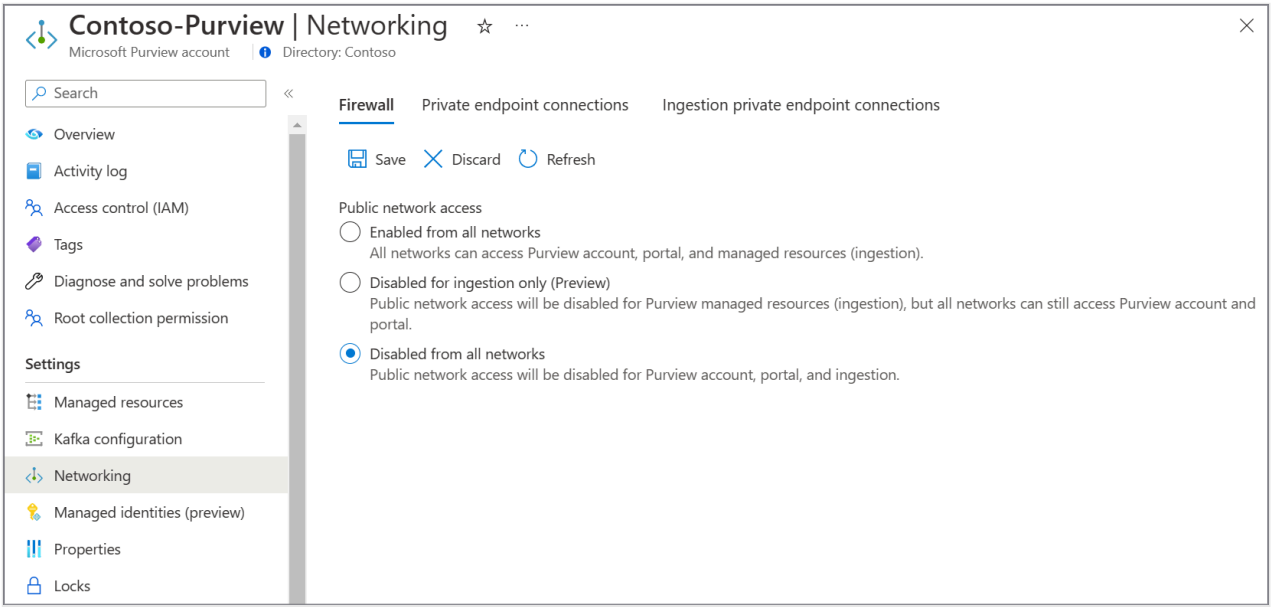
5. Follow the same steps to create another rule to allow the **AzureResourceManager** service tag. If you need to access the Azure portal, you can also add a rule for the **AzurePortal** service tag.

6. Connect to the VM and open the browser. Go to the browser console by selecting Ctrl+Shift+J, and switch to the network tab to monitor network requests. Enter web.purview.azure.com in the URL box, and try to sign in by using your Microsoft Entra credentials. Sign-in will probably fail, and on the **Network** tab on the console, you can see Microsoft Entra ID trying to access aadcdn.msauth.net but getting blocked.

7. In this case, open a command prompt on the VM, ping aadcdn.msauth.net, get its IP, and then add an outbound port rule for the IP in the VM's network security rules. Set the **Destination** to **IP Addresses** and set **Destination IP addresses** to the aadcdn IP. Because of Azure Load Balancer and Azure Traffic Manager, the Microsoft Entra Content Delivery Network IP might be dynamic. After you get its IP, it's better to add it into the VM's host file to force the browser to visit that IP to get the Microsoft Entra Content Delivery Network.

8. After the new rule is created, go back to the VM and try to sign in by using your Microsoft Entra credentials again. If signin succeeds, then the classic Microsoft Purview governance portal is ready to use. But in some cases, Microsoft Entra ID redirects to other domains to sign in based on a customer's account type. For example, for a live.com account, Microsoft Entra ID redirects to live.com to sign in, and then those requests are blocked again. For Microsoft employee accounts, Microsoft Entra ID accesses msft.sts.microsoft.com for sign-in information.

Check the networking requests on the browser **Networking** tab to see which domain's requests are getting blocked, redo the previous step to get its IP, and add outbound port rules in the network security group to allow requests for that IP. If possible, add the URL and IP to the VM's host file to fix the DNS resolution. If you know the exact sign-in domain's IP ranges, you can also directly add them into networking rules.



9. Now your Microsoft Entra sign-in should be successful. The classic Microsoft Purview governance portal will load successfully, but listing all the Microsoft Purview accounts won't work because it can only access a specific Microsoft Purview account. Enter `web.purview.azure.com/resource/{PurviewAccountName}` to directly visit the Microsoft Purview account that you successfully set up a private endpoint for.

Firewalls to restrict public access

To cut off access to the Microsoft Purview account completely from the public internet, follow these steps. This setting applies to both private endpoint and ingestion private endpoint connections.

1. From the Azure portal, go to the Microsoft Purview account, and under **Settings**, select **Networking**.

2. Go to the **Firewall** tab, and ensure that the toggle is set to **Disable from all networks**.

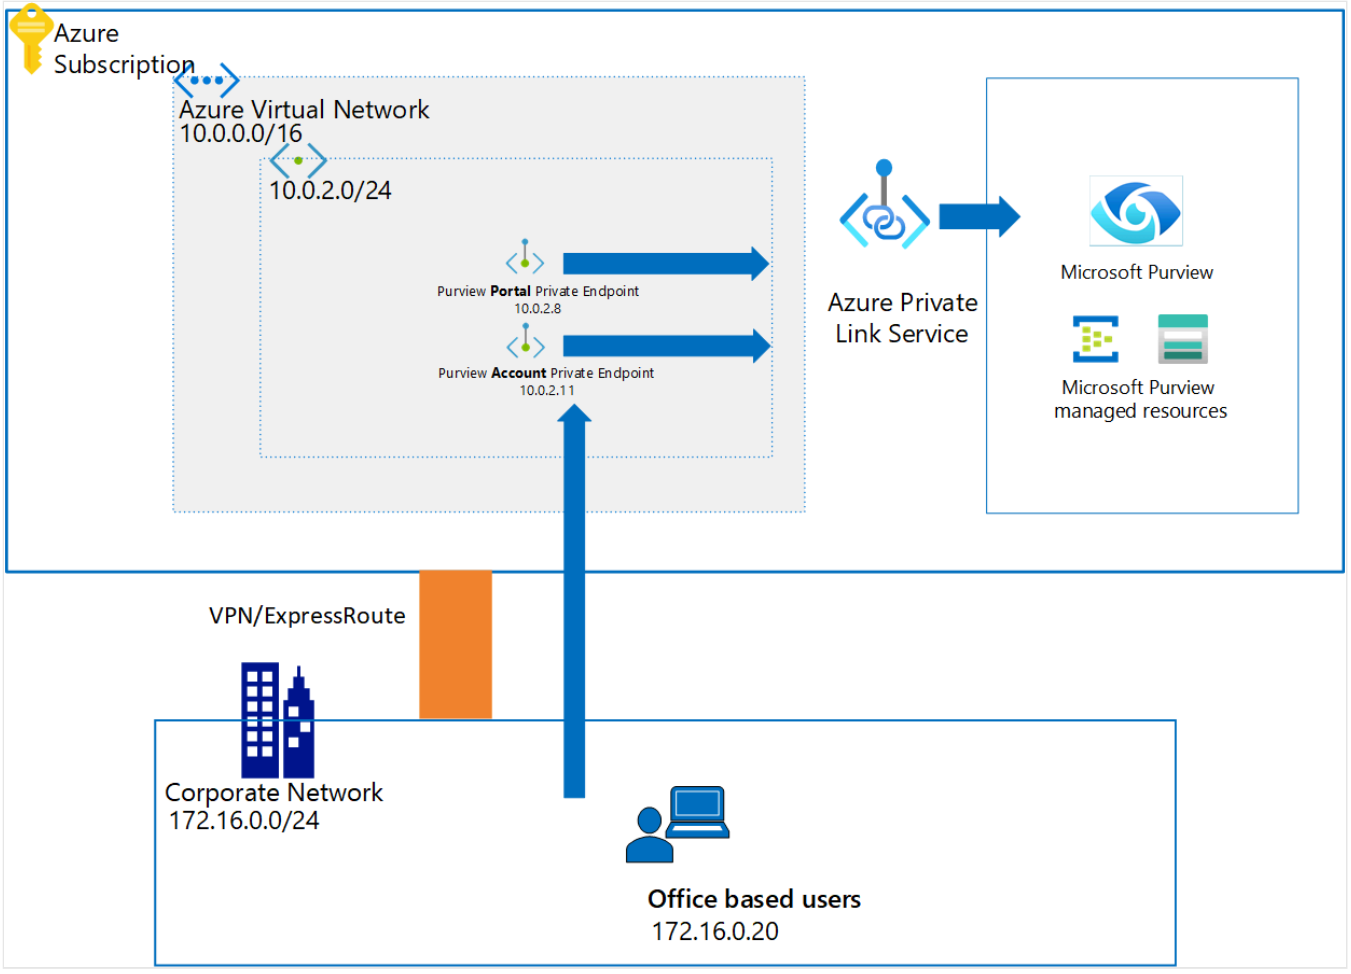
Connect privately and securely to your Microsoft Purview account

Article • 05/09/2025

> **Important**
>
> This article covers private endpoints for the classic Microsoft Purview governance portal (https://web.purview.azure.com). If you're using the new Microsoft Purview portal (https://purview.microsoft.com/), follow the documentation for private endpoints in the Microsoft Purview portal.



In this guide, you'll learn how to deploy private endpoints for your Microsoft Purview account to allow you to connect to your Microsoft Purview account only from VNets and private networks. To achieve this goal, you need to deploy *account* and *portal* private endpoints for your Microsoft Purview account.

> **Important**
>
> Microsoft Purview instances using the new Microsoft Purview portal can only use ingestion private endpoints.

The Microsoft Purview *account* private endpoint is used to add another layer of security by enabling scenarios where only client calls that originate from within the virtual network are allowed to access the Microsoft Purview account. This private endpoint is also a prerequisite for the portal private endpoint.

The Microsoft Purview *portal* private endpoint is required to enable connectivity to the classic Microsoft Purview governance portal using a private network.

> **Note**
>
> If you only create *account* and *portal* private endpoints, you won't be able to run any scans. To enable scanning on a private network, you will also need to create an ingestion private endpoint.

For more information about Azure Private Link service, see private links and private endpoints to learn more.

Deployment checklist

Using this guide, you can deploy these private endpoints for an existing Microsoft Purview account:

1. Choose an appropriate Azure virtual network and a subnet to deploy Microsoft Purview private endpoints. Select one of the following options:

    - Deploy a new virtual network in your Azure subscription.
    - Locate an existing Azure virtual network and a subnet in your Azure subscription.

2. Define an appropriate DNS name resolution method, so Microsoft Purview account and web portal can be accessible through private IP addresses. You can use any of the following options:

    - Deploy new Azure DNS zones using the steps explained further in this guide.
    - Add required DNS records to existing Azure DNS zones using the steps explained further in this guide.

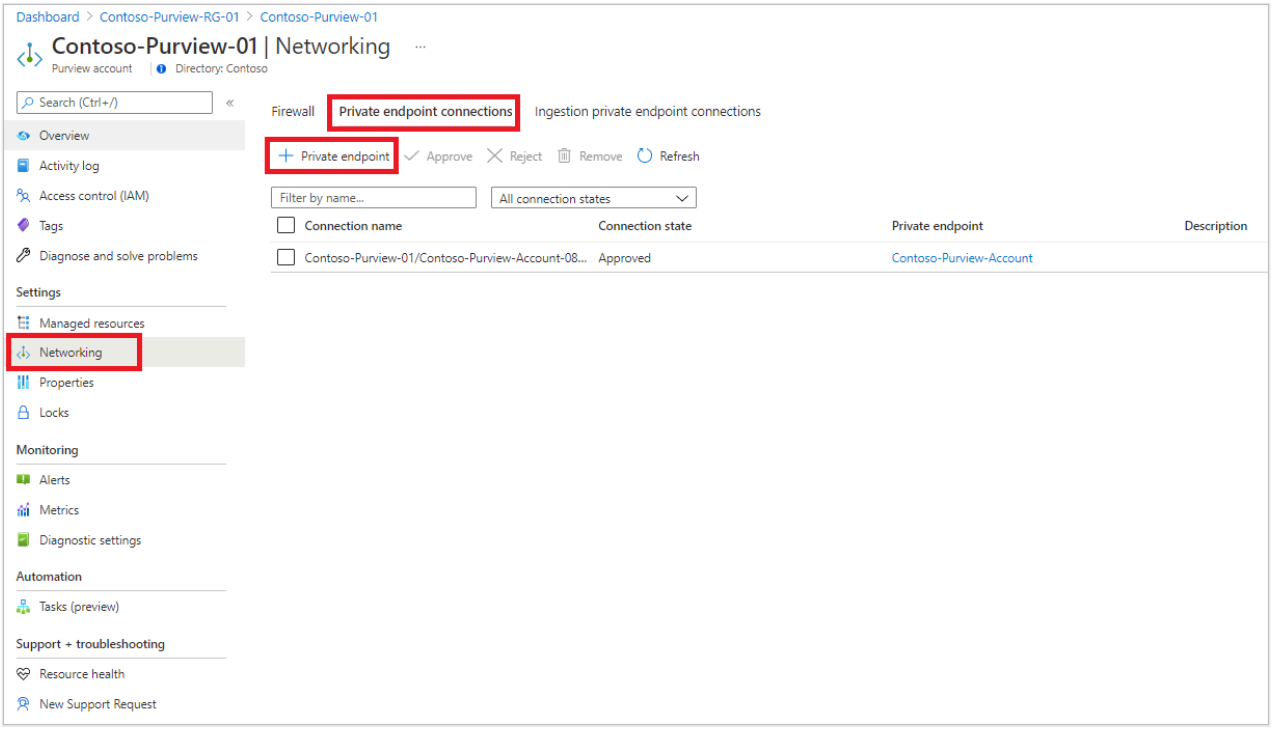
- After completing the steps in this guide, add required DNS A records in your existing DNS servers manually.

3. Deploy account and portal private endpoints for an existing Microsoft Purview account.

4. Enable access to Microsoft Entra ID if your private network has network security group rules set to deny for all public internet traffic.

5. After completing this guide, adjust DNS configurations if needed.

6. Validate your network and name resolution from management machine to Microsoft Purview.



Enable *account* and *portal* private endpoint

There are two ways you can add Microsoft Purview *account* and *portal* private endpoints for an existing Microsoft Purview account:

- Use the Azure portal (Microsoft Purview account).
- Use the Private Link Center.

Use the Azure portal (Microsoft Purview account)

1. Go to the Azure portal, and then select your Microsoft Purview account, and under **Settings** select **Networking**, and then select **Private endpoint connections**.

2. Select + **Private endpoint** to create a new private endpoint.

3. Fill in the basic information.

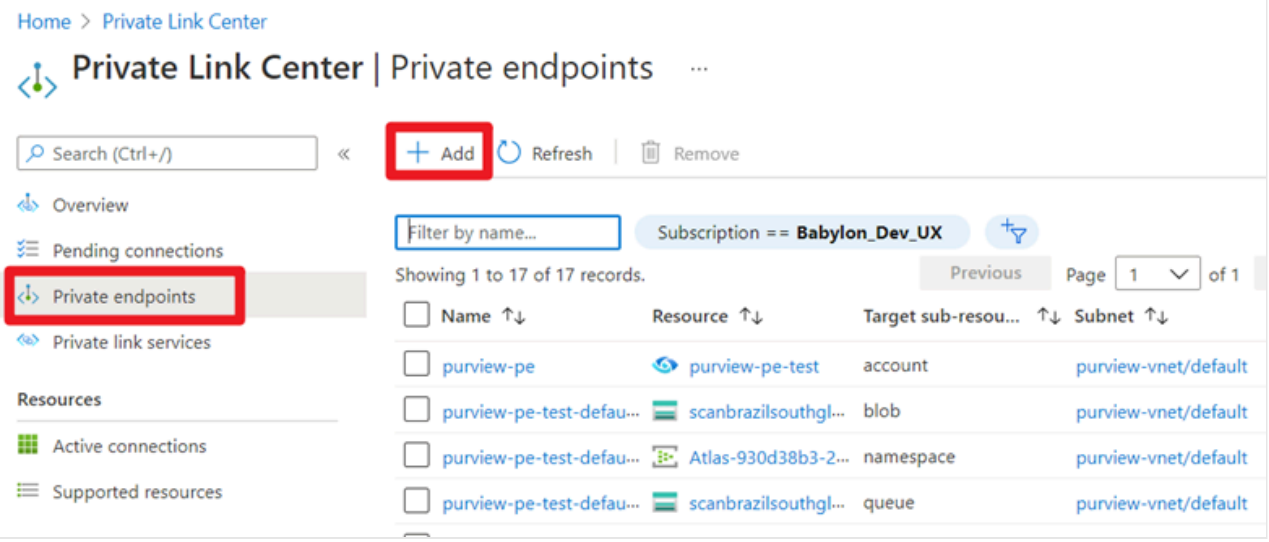
4. On the **Resource** tab, for **Resource type**, select **Microsoft.Purview/accounts**.

5. For **Resource**, select the Microsoft Purview account, and for **Target sub-resource**, select **account**.

6. On the **Configuration** tab, select the virtual network and optionally, select Azure Private DNS zone to create a new Azure DNS Zone.

   > **Note**
   >
   > For DNS configuration, you can also use your existing Azure Private DNS Zones from the dropdown list or add the required DNS records to your DNS Servers manually later. For more information, see Configure DNS Name Resolution for private endpoints

7. Go to the summary page, and select **Create** to create the portal private endpoint.



8. Follow the same steps when you select **portal** for **Target sub-resource**.

Use the Private Link Center

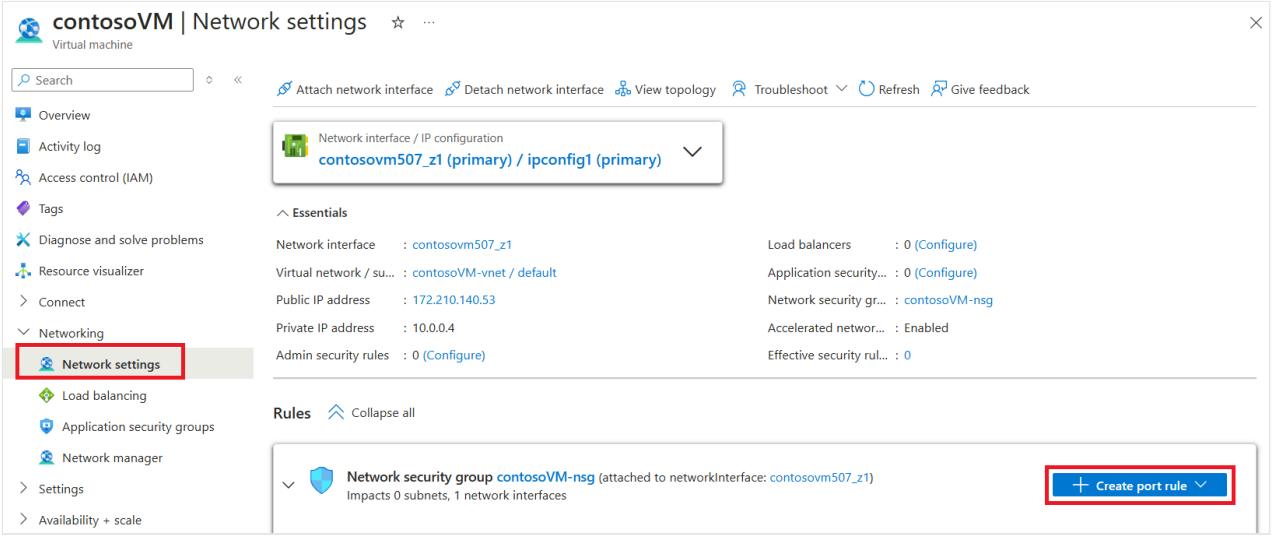
1. Go to the Azure portal.

2. In the search bar at the top of the page, search for **private link** and go to the **Private Link** pane by selecting the first option.

3. Select + **Add**, and fill in the basic details.

4. For **Resource**, select the already created Microsoft Purview account. For **Target sub-resource**, select **account**.

5. On the **Configuration** tab, select the virtual network and private DNS zone. Go to the summary page, and select **Create** to create the account private endpoint.

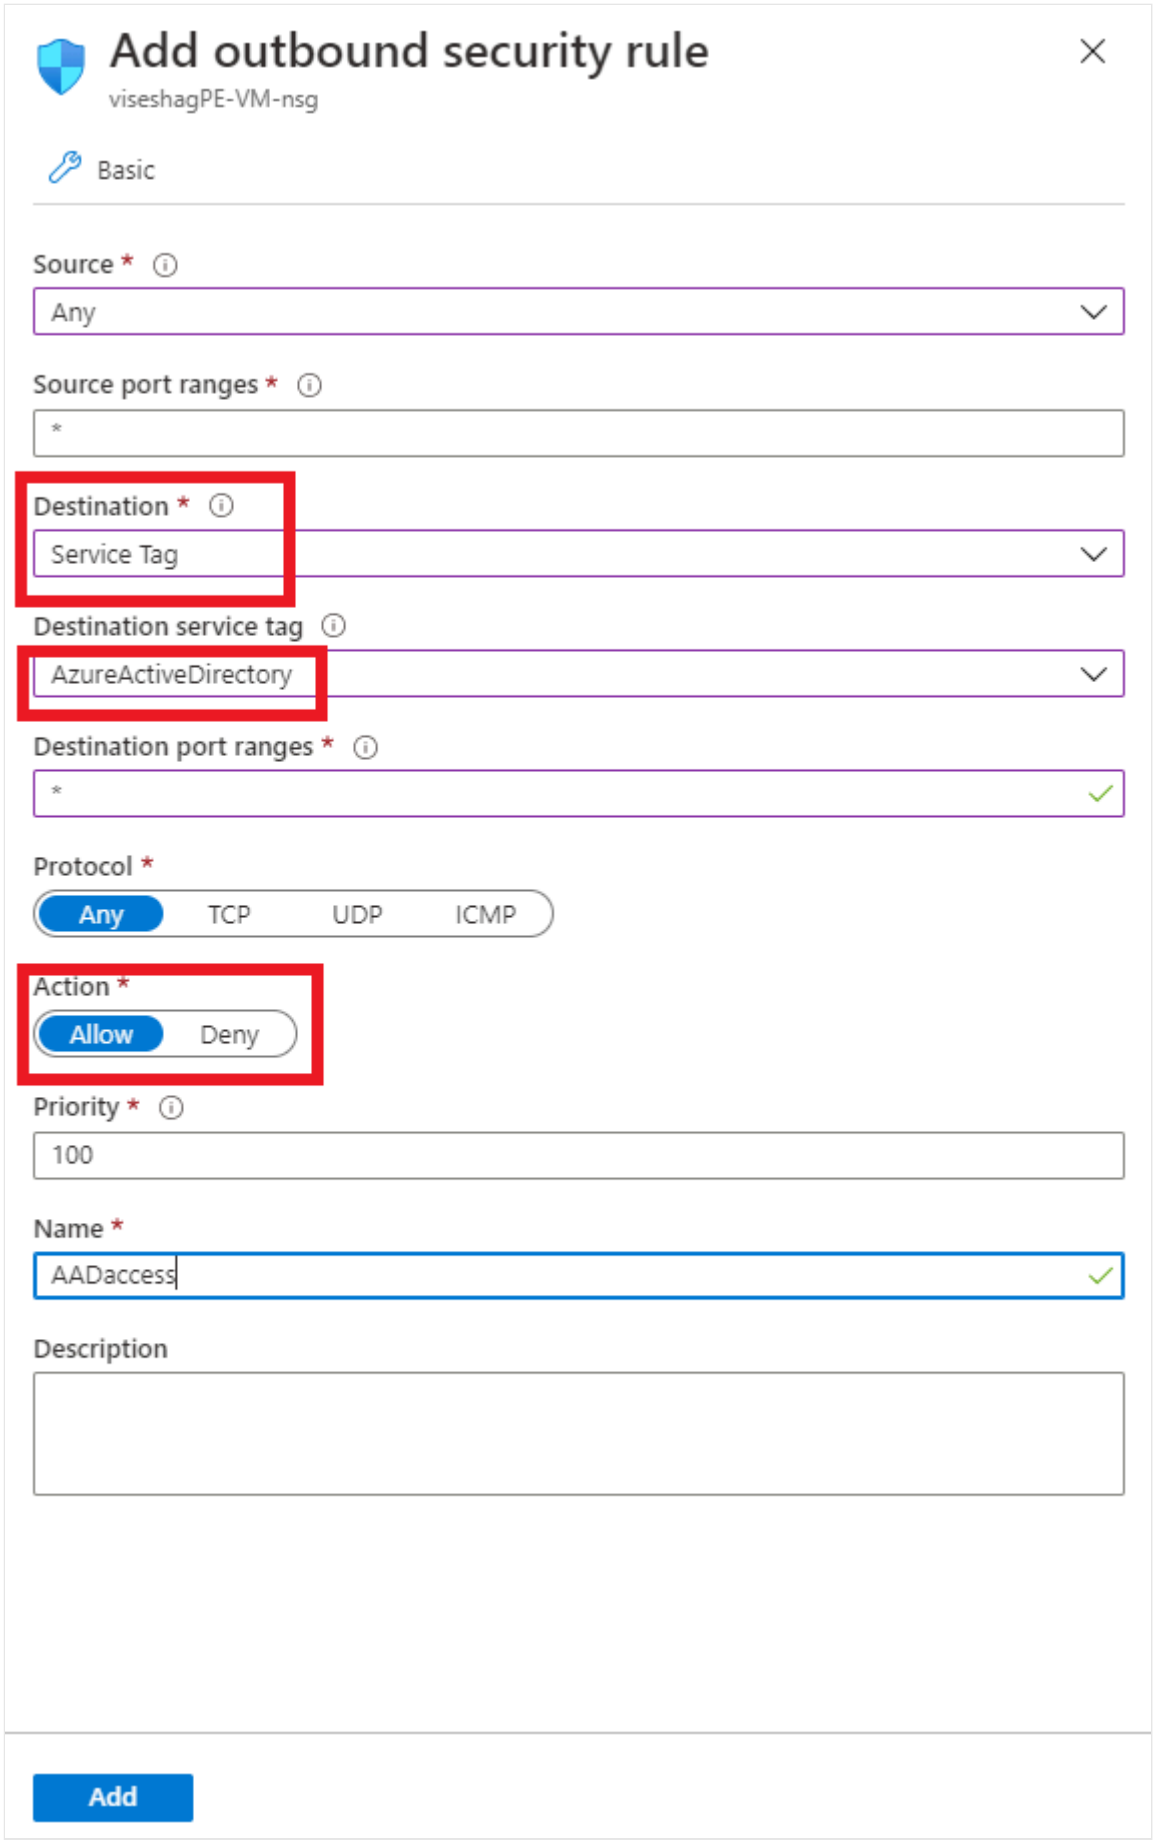


> **Note**
>
> Follow the same steps when you select **portal** for **Target sub-resource**.

Enable access to Microsoft Entra ID

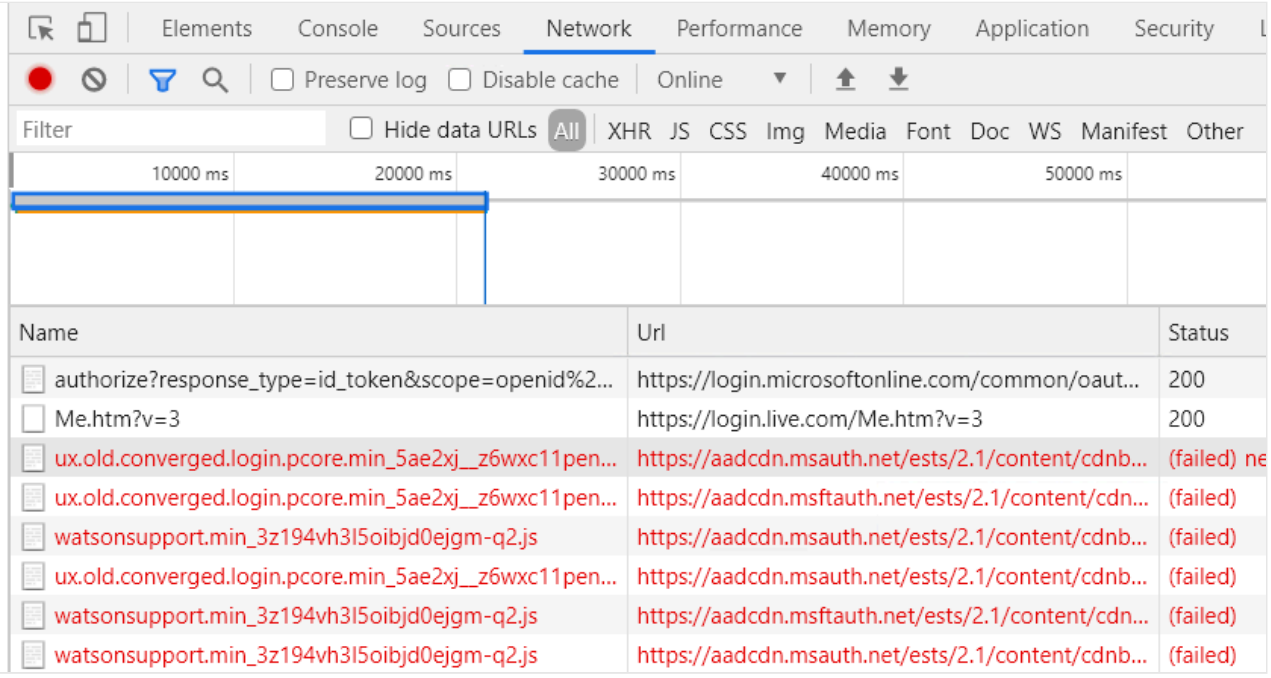
> **Note**
>
> If your VM, VPN gateway, or VNet Peering gateway has public internet access, it can access the Microsoft Purview portal and the Microsoft Purview account enabled with private endpoints. For this reason, you don't have to follow the rest of the instructions. If your private network has network security group rules set to deny all public internet traffic, you'll need to add some rules to enable Microsoft Entra ID access. Follow the instructions to do so.

These instructions are provided for accessing Microsoft Purview securely from an Azure VM. Similar steps must be followed if you're using VPN or other virtual network Peering gateways.



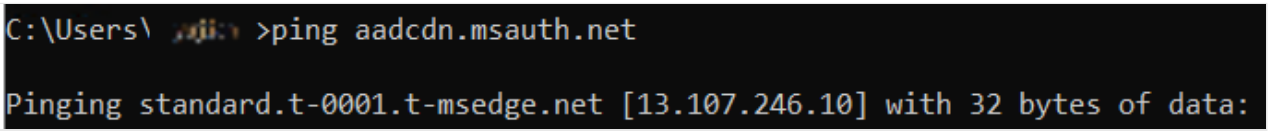
1. Go to your VM in the Azure portal, and under **Settings**, select **Networking**. Then select **Outbound port rules**, **Add outbound port rule**.

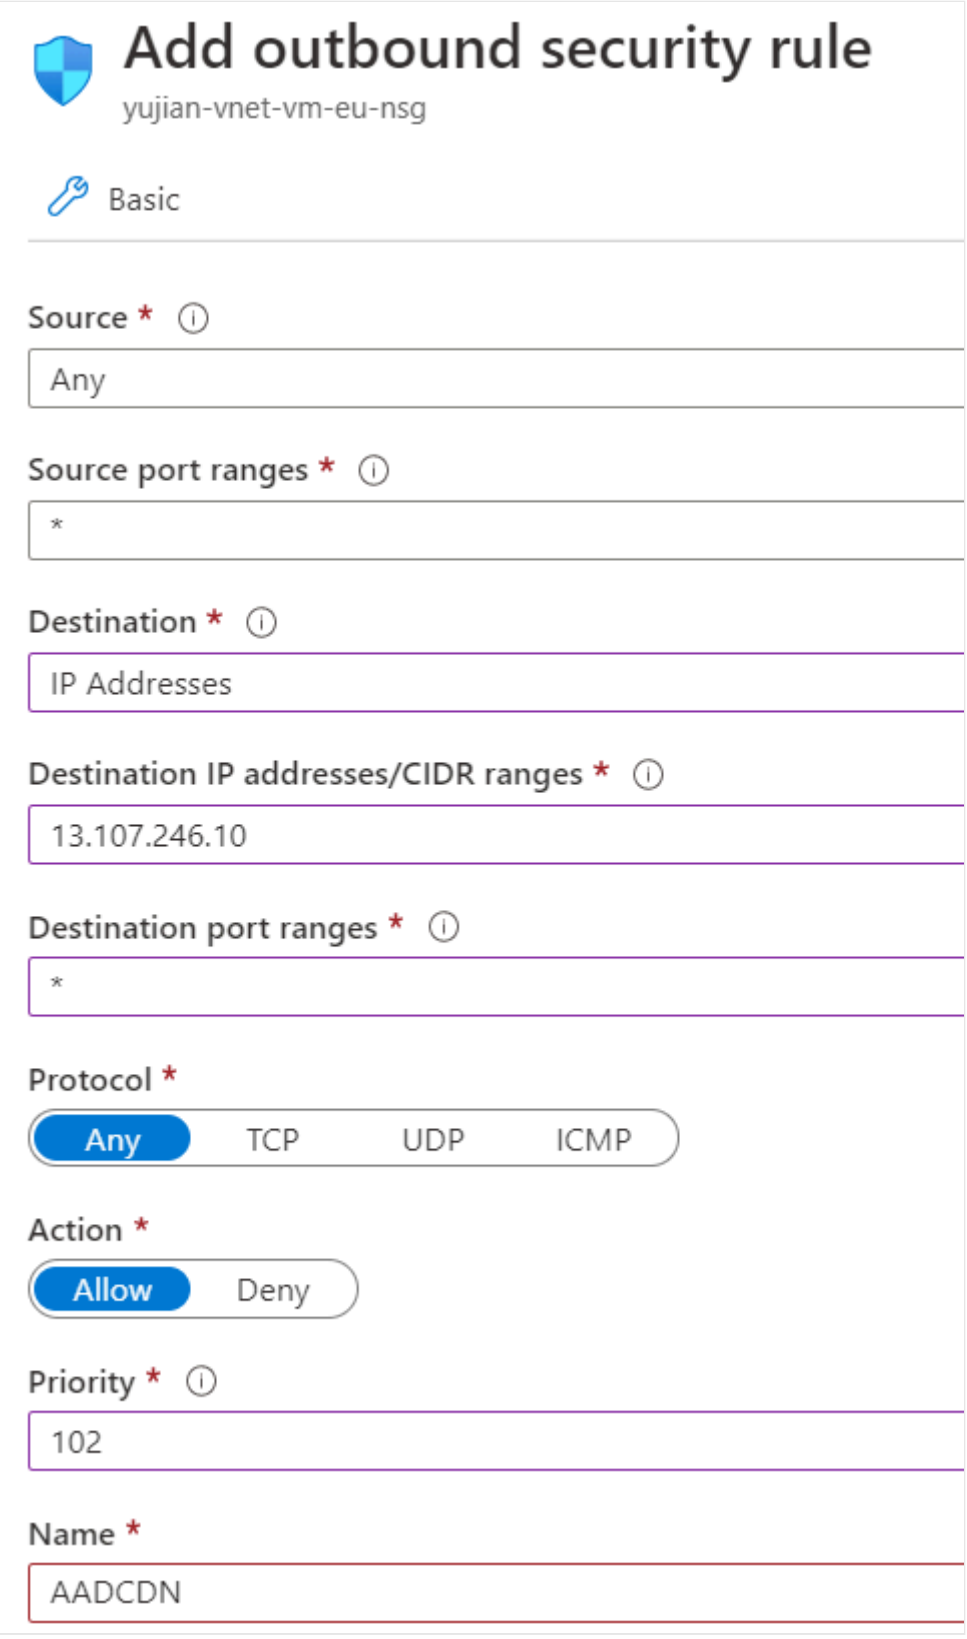
2. On the **Add outbound security rule** pane:
   a. Under **Destination**, select **Service Tag**.



b. Under **Destination service tag**, select **AzureActiveDirectory**.
c. Under **Destination port ranges**, select *.
d. Under **Action**, select **Allow**.
e. Under **Priority**, the value should be higher than the rule that denied all internet traffic.

Create the rule.





3. Follow the same steps to create another rule to allow the **AzureResourceManager** service tag. If you need to access the Azure portal, you can also add a rule for the **AzurePortal** service tag.

4. Connect to the VM and open the browser. Go to the browser console by selecting Ctrl+Shift+J, and switch to the network tab to monitor network requests. Enter web.purview.azure.com in the URL box, and try to sign in by using your Microsoft Entra credentials. Sign-in will probably fail, and on the **Network** tab on the console, you can see Microsoft Entra ID trying to access aadcdn.msauth.net but getting blocked.

5. In this case, open a command prompt on the VM, ping aadcdn.msauth.net, get its IP, and then add an outbound port rule for the IP in the VM's network security rules. Set the **Destination** to **IP Addresses** and set **Destination IP addresses** to the aadcdn IP. Because of Azure Load Balancer and Azure Traffic Manager, the Microsoft Entra Content Delivery Network IP might be dynamic. After you get its IP, it's better to add it into the VM's host file to force the browser to visit that IP to get the Microsoft Entra Content Delivery Network.

6. After the new rule is created, go back to the VM and try to sign in by using your Microsoft Entra credentials again. If sign-in succeeds, then the Microsoft Purview portal is ready to use. But in some cases, Microsoft Entra ID redirects to other domains to sign in based on a customer's account type. For example, for a live.com account, Microsoft Entra ID redirects to live.com to sign in, and then those requests are blocked again. For Microsoft employee accounts, Microsoft Entra ID accesses msft.sts.microsoft.com for sign-in information.

Check the networking requests on the browser **Networking** tab to see which domain's requests are getting blocked, redo the previous step to get its IP, and add outbound port rules in the network security group to allow requests for that IP. If possible, add the URL and IP to the VM's host file to fix the DNS resolution. If you know the exact sign-in domain's IP ranges, you can also directly add them into networking rules.

7. Now your Microsoft Entra sign-in should be successful. The Microsoft Purview portal will load successfully, but listing all the Microsoft Purview accounts won't work because it can only access a specific Microsoft Purview account. Enter `web.purview.azure.com/resource/{PurviewAccountName}` to directly visit the Microsoft Purview account that you successfully set up a private endpoint for.

Next steps

- Verify resolution for private endpoints
- Manage data sources in Microsoft Purview
- Troubleshooting private endpoint configuration for your Microsoft Purview account

Configure and verify DNS Name Resolution for Microsoft Purview private endpoints

Article • 05/09/2025

> **Important**
>
> This article covers private endpoints for the classic Microsoft Purview governance portal (https://web.purview.azure.com). If you're using the new Microsoft Purview portal (https://purview.microsoft.com/), follow the documentation for private endpoints in the Microsoft Purview portal.

Conceptual overview

Accurate name resolution is a critical requirement when setting up private endpoints for your Microsoft Purview accounts.

You might need to enable internal name resolution in your DNS settings to resolve the private endpoint IP addresses to the fully qualified domain name (FQDN) from data sources and your management machine to Microsoft Purview account and self-hosted integration runtime, depending on scenarios that you're deploying.

> **Tip**
>
> When you deploy your DNS Zones, don't use specific IP addresses. IP addresses for Azure resources are not static, and building your DNS Zones with static IP addresses will eventually cause errors.

Deployment options

Use any of the following options to set up internal name resolution when using private endpoints for your Microsoft Purview account:

- Deploy new Azure Private DNS Zones in your Azure environment part of private endpoint deployment. (Default option)
- Use existing Azure Private DNS Zones. Use this option if you're using a private endpoint in a hub-and-spoke model from a different subscription or even within the same subscription.
- Use your own DNS Servers if you don't use DNS forwarders and instead you manage A records directly in your on-premises DNS servers.

> **Tip**
>
> - Classic Microsoft Purview governance portal (https://web.purview.azure.com): *account*, *portal*, and *ingestion* private endpoints are supported.
> - New Microsoft Purview portal (https://purview.microsoft.com/): *platform* and *ingestion* private endpoints are supported.

Option 1 - Deploy new Azure Private DNS Zones

Deploy new Azure Private DNS Zones

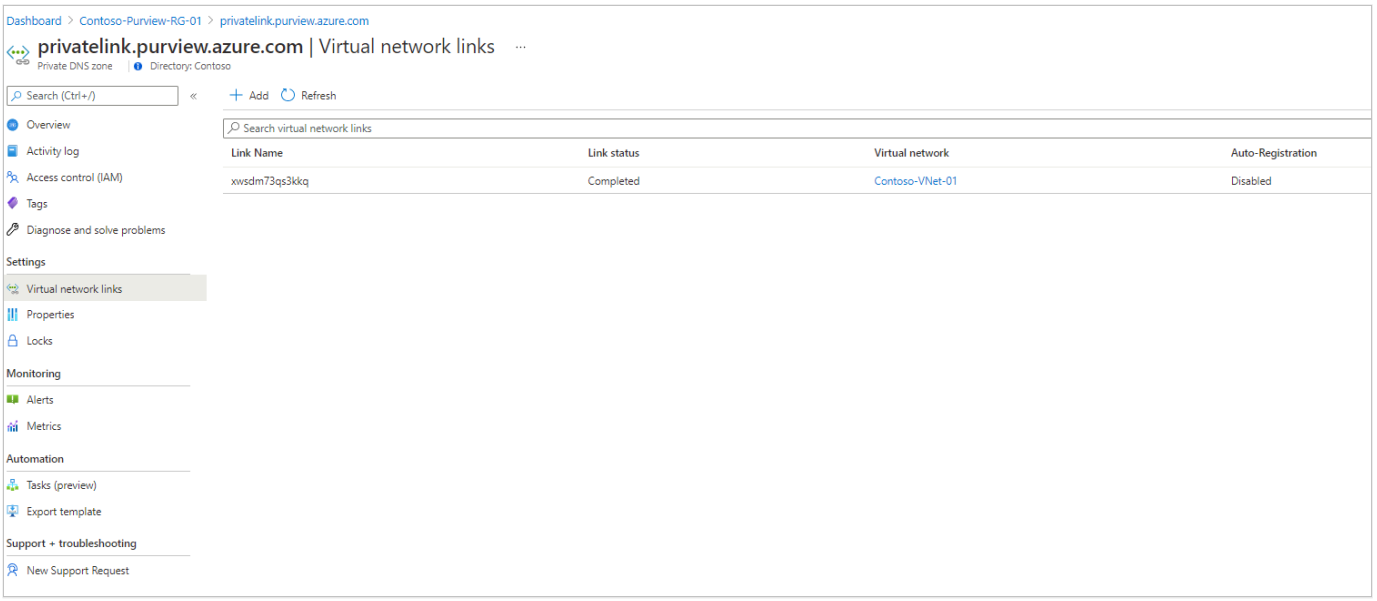
To enable internal name resolution, you can deploy the required Azure DNS Zones inside your Azure subscription where Microsoft Purview account is deployed.

Name	Type	Location
privatelink.blob.core.windows.net	Private DNS zone	Global
privatelink.purview.azure.com	Private DNS zone	Global
privatelink.purviewstudio.azure.com	Private DNS zone	Global
privatelink.queue.core.windows.net	Private DNS zone	Global
privatelink.servicebus.windows.net	Private DNS zone	Global

When you create ingestion, portal and account private endpoints, the DNS CNAME resource records for Microsoft Purview is automatically updated to an alias in few subdomains with the prefix `privatelink`:

- By default, during the deployment of *account* or *platform* private endpoints for your Microsoft Purview account, we also create a private DNS zone that corresponds to the `privatelink` subdomain for Microsoft Purview as `privatelink.purview.azure.com` for the classic Microsoft Purview governance portal and `privatelink.purview-service.microsoft.com` for the Microsoft Purview portal, including DNS A resource records for the private endpoints.
- During the deployment of *portal* private endpoint for your Microsoft Purview account, we also create a new private DNS zone that corresponds to the `privatelink` subdomain for Microsoft Purview as `privatelink.purviewstudio.azure.com` including DNS A resource records for *Web*.
- If you enable ingestion private endpoints, other DNS zones are required for managed or configured resources.

The following table shows an example of Azure Private DNS zones and DNS A Records that are deployed as part of configuration of private endpoint for a Microsoft Purview account if you enable *Private DNS integration* during the deployment:



Expand table

Private endpoint	Private endpoint associated to	Portal availability	DNS Zone (new)	A Record (example)
Account	Microsoft Purview	`privatelink.purview.azure.com`	Contoso-Purview	
Platform	Microsoft Purview	`privatelink.purview-service.microsoft.com`	Contoso-Purview	
Portal	Microsoft Purview	`privatelink.purviewstudio.azure.com`	Web	
Platform	Microsoft Purview	`privatelink.purview-service.microsoft.com`	Web	
Ingestion	Microsoft Purview ingestion - Blob*	`privatelink.blob.core.windows.net`	ingestioneus2eastusksqky	
Ingestion	Microsoft Purview ingestion - Blob*	`privatelink.blob.storage.azure.net`	ingestioneus2eastusksqky	
Ingestion	Microsoft Purview ingestion - Queue*	`privatelink.queue.core.windows.net`	ingestioneus2eastusksqky	
Ingestion	Microsoft Purview ingestion - Queue*	`privatelink.queue.storage.azure.net`	ingestioneus2eastusksqky	
Ingestion	Microsoft Purview configured Event Hubs - Event Hubs**	`privatelink.servicebus.windows.net`	atlas-12345678-1234-1234-abcd-123456789abc	

> **Note**
>
> *If your account was created before December 15, 2023, the endpoint is deployed to your managed storage account. If it was created after November 10 (or deployed using API version 2023-05-01-preview onwards), it points to the ingestion storage.
>
> **Your account only has an associated Event Hubs namespace if it is configured for kafka notifications or created before December 15, 2022.

Validate virtual network links on Azure Private DNS Zones

Once the private endpoint deployment is completed, make sure there's a Virtual network link on all corresponding Azure Private DNS zones to Azure virtual network where private endpoint was deployed.

For more information, see Azure private endpoint DNS configuration.

Verify internal name resolution

When you resolve the Microsoft Purview endpoint URL from outside the virtual network with the private endpoint, it resolves to the public endpoint of Microsoft Purview. When resolved from the virtual network hosting the private endpoint, the Microsoft Purview endpoint URL resolves to the private endpoint's IP address.

As an example, if a Microsoft Purview account name is 'Contoso-Purview', when it's resolved from outside the virtual network that hosts the private endpoint, it will be:

Expand table

Name	Type	Value
`Contoso-Purview.purview.azure.com`	CNAME	`Contoso-Purview.privatelink.purview.azure.com`
`Contoso-Purview.privatelink.purview.azure.com`	CNAME	<Microsoft Purview public endpoint>
<Microsoft Purview public endpoint>	A	<Microsoft Purview public IP address>
`Web.purview.azure.com`	CNAME	<Microsoft Purview governance portal public endpoint>

The DNS resource records for Contoso-Purview, when resolved in the virtual network hosting the private endpoint, will be:

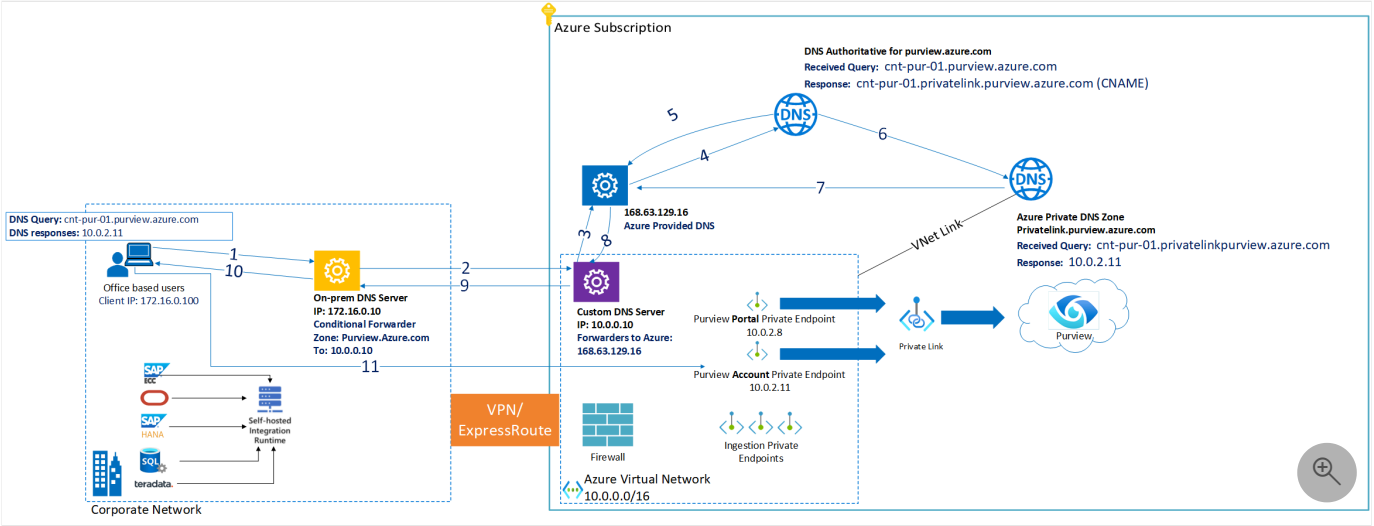
Expand table

Name	Type	Value
`Contoso-Purview.purview.azure.com`	CNAME	`Contoso-Purview.privatelink.purview.azure.com`
`Contoso-Purview.privatelink.purview.azure.com`	A	<Microsoft Purview account private endpoint IP address>
`Web.purview.azure.com`	CNAME	<Microsoft Purview portal private endpoint IP address>

Option 2 - Use existing Azure Private DNS Zones

Use existing Azure Private DNS Zones

During the deployment of Microsoft Purview private endpoints, you can choose *Private DNS integration* using existing Azure Private DNS zones. This is common case for organizations where private endpoint is used for other services in Azure. In this case, during the deployment of private endpoints, make sure you select the existing DNS zones instead of creating new ones.



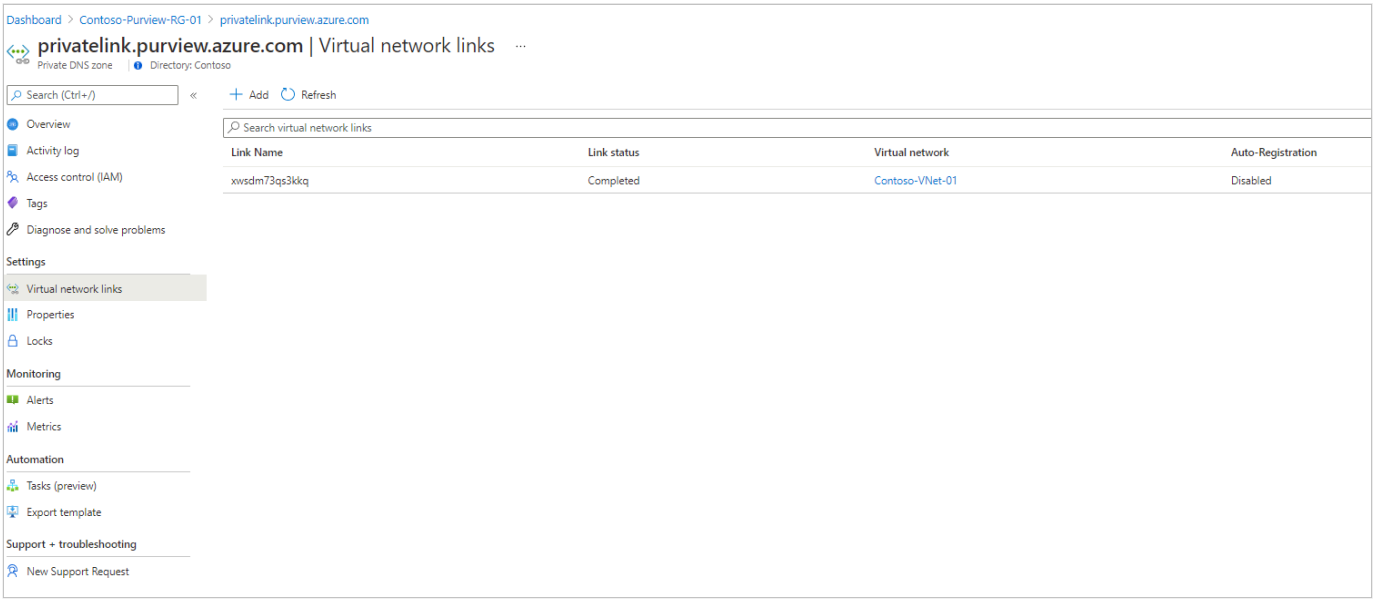
This scenario also applies if your organization uses a central or hub subscription for all Azure Private DNS Zones.

The following list shows the required Azure DNS zones and A records for Microsoft Purview private endpoints:

> **Important**
>
> Update all names with `Contoso-Purview`,`ingestioneus2eastusksqky` and `atlas-12345678-1234-1234-abcd-123456789abc` with corresponding Azure resources name in your environment.
>
> - `Contoso-Purview` is the name of your Microsoft Purview account.
> - You only need the endpoints associated with the portal you're using:
>   - Classic Microsoft Purview governance portal (https://web.purview.azure.com): *account*, *portal*, and *ingestion* private endpoints are supported.
>   - New Microsoft Purview portal (https://purview.microsoft.com/): *platform* and *ingestion* private endpoints are supported.
> - If your account is configured for kafka notifications or was created before December 15, 2022, `atlas-12345678-1234-1234-abcd-123456789abc` is your Event Hubs namespace.
> - If your account was created **before** December 15, 2023, for `ingestioneus2eastusksqky` use the name of your Microsoft Purview managed storage account.
> - If your account was created **after** December 15, 2023 (or deployed using API version 2023-05-01-preview onwards), leave `ingestioneus2eastusksqky` as is.

Expand table

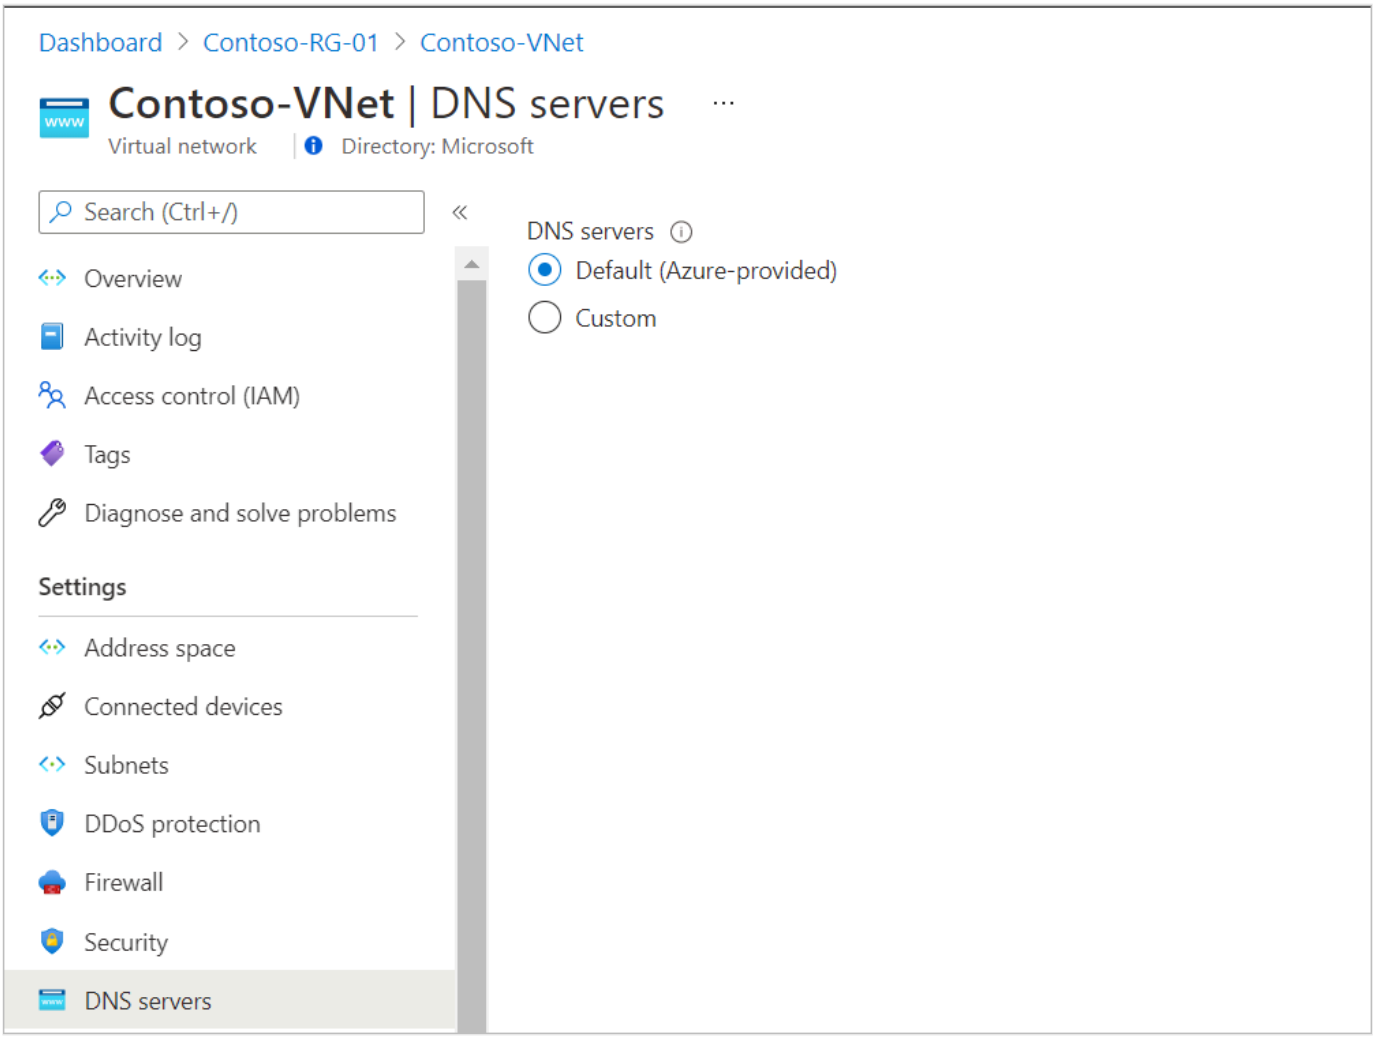
Private endpoint	Private endpoint associated to	Portal availability	DNS Zone (existing)	A Record (example)
Account	Microsoft Purview	`privatelink.purview.azure.com`	Contoso-Purview	
Platform	Microsoft Purview	`privatelink.purview-service.microsoft.com`	Contoso-Purview	
Portal	Microsoft Purview	`privatelink.purviewstudio.azure.com`	Web	
Ingestion	Microsoft Purview ingestion - Blob*	`privatelink.blob.core.windows.net`	ingestioneus2eastusksqky	
Ingestion	Microsoft Purview ingestion - Blob*	`privatelink.blob.storage.azure.net`	ingestioneus2eastusksqky	
Ingestion	Microsoft Purview ingestion - Queue*	`privatelink.queue.core.windows.net`	ingestioneus2eastusksqky	
Ingestion	Microsoft Purview ingestion - Queue*	`privatelink.queue.storage.azure.net`	ingestioneus2eastusksqky	
Ingestion	Microsoft Purview configured Event Hubs**	`privatelink.servicebus.windows.net`	atlas-12345678-1234-1234-abcd-123456789abc	



> **Note**
>
> *If your account was created before December 15, 2023, the endpoint is deployed to your managed storage account. If it was created after November 10 (or deployed using API version 2023-05-01-preview onwards), it points to the ingestion storage. **Your account only has an associated Event Hubs namespace if it is configured for kafka notifications or created before December 15, 2022.

For more information, see Virtual network workloads without custom DNS server and On-premises workloads using a DNS forwarder scenarios in Azure Private Endpoint DNS configuration.

Verify virtual network links on Azure Private DNS Zones



Once the private endpoint deployment is completed, make sure there's a Virtual network link on all corresponding Azure Private DNS zones to Azure virtual network where private endpoint was deployed.

For more information, see Azure private endpoint DNS configuration.

Configure DNS Forwarders if custom DNS is used

Additionally it's required to validate your DNS configurations on Azure virtual network where self-hosted integration runtime VM or management PC is located.

- If it's configured to *Default*, no further action is required in this step.
- If custom DNS server is used, you should add corresponding DNS forwarders inside your DNS servers for the following zones:
  - Purview.azure.com
  - purviewstudio.azure.com
  - Blob.core.windows.net
  - Queue.core.windows.net
  - Blob.storage.azure.net
  - Queue.storage.azure.net
  - Servicebus.windows.net

Verify internal name resolution

When you resolve the Microsoft Purview endpoint URL from outside the virtual network with the private endpoint, it resolves to the public endpoint of Microsoft Purview. When resolved from the virtual network hosting the private endpoint, the Microsoft Purview endpoint URL resolves to the private endpoint's IP address.

As an example, if a Microsoft Purview account name is 'Contoso-Purview', when it's resolved from outside the virtual network that hosts the private endpoint, it will be:

Expand table

Name	Type	Value
`Contoso-Purview.purview.azure.com`	CNAME	`Contoso-Purview.privatelink.purview.azure.com`
`Contoso-Purview.privatelink.purview.azure.com`	CNAME	<Microsoft Purview public endpoint>

Name	Type	Value
<Microsoft Purview public endpoint>	A	<Microsoft Purview public IP address>
`Web.purview.azure.com`	CNAME	<Microsoft Purview governance portal public endpoint>

The DNS resource records for Contoso-Purview, when resolved in the virtual network hosting the private endpoint, will be:

Expand table

Name	Type	Value
`Contoso-Purview.purview.azure.com`	CNAME	`Contoso-Purview.privatelink.purview.azure.com`
`Contoso-Purview.privatelink.purview.azure.com`	A	<Microsoft Purview account private endpoint IP address>
`Web.purview.azure.com`	CNAME	<Microsoft Purview portal private endpoint IP address>

Option 3 - Use your own DNS Servers

If you don't use DNS forwarders and instead you manage A records directly in your on-premises DNS servers to resolve the endpoints through their private IP addresses, you might need to create the following A records in your DNS servers.

> **Important**
>
> Update all names with `Contoso-Purview`, `ingestioneus2eastusksqky` and `atlas-12345678-1234-1234-abcd-123456789abc` with corresponding Azure resources name in your environment.
>
> - `Contoso-Purview` is the name of your Microsoft Purview account.
> - You only need the endpoints associated with the portal you're using:
>   - Classic Microsoft Purview governance portal (https://web.purview.azure.com): *account*, *portal*, and *ingestion* private endpoints are supported.
>   - New Microsoft Purview portal (https://purview.microsoft.com/): *platform* and *ingestion* private endpoints are supported.
> - If your account is configured for kafka notifications or was created before December 15, 2022, `atlas-12345678-1234-1234-abcd-123456789abc` is your Event Hubs namespace.
> - If your account was created **before** December 15, 2023, for `ingestioneus2eastusksqky` use the name of your Microsoft Purview managed storage account.
> - If your account was created **after** December 15, 2023 (or deployed using API version 2023-05-01-preview onwards), leave `ingestioneus2eastusksqky` as is.

Expand table

Name	Type	Value	Portal availability
`web.purview.azure.com`	A	<portal private endpoint IP address of Microsoft Purview>	Classic portal
`ingestioneus2eastusksqky.blob.core.windows.net`, `ingestioneus2eastusksqky.blob.storage.azure.net`	A	<blob-ingestion private endpoint IP address of Microsoft Purview>	Classic and new portals
`ingestioneus2eastusksqky.queue.core.windows.net`, `ingestioneus2eastusksqky.queue.storage.azure.net`	A	<queue-ingestion private endpoint IP address of Microsoft Purview>	Classic and new portals
`atlas-12345678-1234-1234-abcd-123456789abc.servicebus.windows.net`	A	<namespace-ingestion private endpoint IP address of Microsoft Purview>	Classic and new portals

Name	Type	Value	Portal availability
`Contoso-Purview.Purview.azure.com`	A	<account/platform private endpoint IP address of Microsoft Purview>	Classic and new portals
`Contoso-Purview.scan.Purview.azure.com`	A	<account/platform private endpoint IP address of Microsoft Purview>	Classic and new portals
`Contoso-Purview.catalog.Purview.azure.com`	A	<account/platform private endpoint IP address of Microsoft Purview>	Classic and new portals
`Contoso-Purview.proxy.purview.azure.com`	A	<account/platform private endpoint IP address of Microsoft Purview>	Classic and new portals
`Contoso-Purview.guardian.purview.azure.com`	A	<account/platform private endpoint IP address of Microsoft Purview>	Classic and new portals
`gateway.purview.azure.com`	A	<account/platform private endpoint IP address of Microsoft Purview>	Classic and new portals

`manifest.prod.ext.web.purview.azure.com`	A	<portal private endpoint IP address of Microsoft Purview>	Classic portal
`cdn.prod.ext.web.purview.azure.com`	A	<portal private endpoint IP address of Microsoft Purview>	Classic portal
`hub.prod.ext.web.purview.azure.com`	A	<portal private endpoint IP address of Microsoft Purview>	Classic portal
`catalog.prod.ext.web.purview.azure.com`	A	<portal private endpoint IP address of Microsoft Purview>	Classic portal
`cseo.prod.ext.web.purview.azure.com`	A	<portal private endpoint IP address of Microsoft Purview>	Classic portal
`datascan.prod.ext.web.purview.azure.com`	A	<portal private endpoint IP address of Microsoft Purview>	Classic portal
`datashare.prod.ext.web.purview.azure.com`	A	<portal private endpoint IP address of Microsoft Purview>	Classic portal
`datasource.prod.ext.web.purview.azure.com`	A	<portal private endpoint IP address of Microsoft Purview>	Classic portal
`policy.prod.ext.web.purview.azure.com`	A	<portal private endpoint IP address of Microsoft Purview>	Classic portal
`sensitivity.prod.ext.web.purview.azure.com`	A	<portal private endpoint IP address of Microsoft Purview>	Classic portal
`web.privatelink.purviewstudio.azure.com`	A	<portal private endpoint IP address of Microsoft Purview>	Classic portal
`workflow.prod.ext.web.purview.azure.com`	A	<portal private endpoint IP address of Microsoft Purview>	Classic portal

Verify and DNS test name resolution and connectivity

1. If you're using Azure Private DNS Zones, make sure the following DNS Zones and the corresponding A records are created in your Azure Subscription:

Expand table

Private endpoint	Private endpoint associated to	Portal availability	DNS Zone (existing)	A Record (example)
Account	Microsoft Purview	Classic portal	`privatelink.purview.azure.com`	Contoso-Purview
Platform	Microsoft Purview	New portal	`privatelink.purview-service.microsoft.com`	Contoso-Purview
Portal	Microsoft Purview	Classic portal	`privatelink.purviewstudio.azure.com`	Web
Ingestion	Microsoft Purview ingestion - Blob*	Classic and new portals	`privatelink.blob.core.windows.net`, `privatelink.blob.storage.azure.net`	ingestioneus2eastusksqky
Ingestion	Microsoft Purview ingestion - Queue*	Classic and new portals	`privatelink.queue.core.windows.net`, `privatelink.queue.storage.azure.net`	ingestioneus2eastusksqky
Ingestion	Event Hubs**	Classic and new portals	`privatelink.servicebus.windows.net`	atlas-12345678-1234-1234-abcd-123456789abc

> **Note**
>
> *If your account was created before December 15, 2023, the endpoint is deployed to your managed storage account. If it was created after November 10 (or deployed using API version 2023-05-01-preview onwards), it points to the ingestion storage. **Your account only has an associated Event Hubs namespace if it is configured for kafka notifications or created before December 15, 2022.

2. Create Virtual network links in your Azure Private DNS Zones for your Azure Virtual Networks to allow internal name resolution.

3. From your management PC and self-hosted integration runtime VM, test name resolution and network connectivity to your Microsoft Purview account using tools such as Nslookup.exe and PowerShell

To test name resolution you need to resolve the following FQDNs through their private IP addresses: (Instead of Contoso-Purview, ingestioneus2eastusksqky or atlas-12345678-1234-1234-abcd-123456789abc, use the hostname associated with your purview account name and managed or configured resources names)

- `Contoso-Purview.purview.azure.com`
- `web.purview.azure.com`
- `ingestioneus2eastusksqky.blob.core.windows.net`
- `ingestioneus2eastusksqky.queue.core.windows.net`
- `atlas-12345678-1234-1234-abcd-123456789abc.servicebus.windows.net`

To test network connectivity, from self-hosted integration runtime VM you can launch PowerShell console and test connectivity using `Test-NetConnection`. You must resolve each endpoint by their private endpoint and obtain TcpTestSucceeded as True. (Instead of Contoso-Purview, ingestioneus2eastusksqky or atlas-12345678-1234-1234-abcd-123456789abc, use the hostname associated with your purview account name and managed or configured resources names)

- `Test-NetConnection -ComputerName Contoso-Purview.purview.azure.com -port 443`
- `Test-NetConnection -ComputerName web.purview.azure.com -port 443`
- `Test-NetConnection -ComputerName ingestioneus2eastusksqky.blob.core.windows.net -port 443`
- `Test-NetConnection -ComputerName ingestioneus2eastusksqky.queue.core.windows.net -port 443`

- `Test-NetConnection -ComputerName atlas-12345678-1234-1234-abcd-123456789abc.servicebus.windows.net -port 443`

The following example shows Microsoft Purview DNS name resolution from outside the virtual network or when an Azure private endpoint isn't configured.

```
C:\>nslookup.exe
Default Server:  UnKnown
Address:  168.63.129.16

> Contoso-Purview-01.purview.azure.com
Server:  UnKnown
Address:  168.63.129.16

Non-authoritative answer:
Name:    purview-gateway-prod.eastus.cloudapp.azure.com
Address:  52.226.150.205
Aliases:  Contoso-Purview-01.purview.azure.com
          contoso-purview-01.privatelink.purview.azure.com
          gateway-prod-eastus.babylon-service.azure.com

> web.purview.azure.com
Server:  UnKnown
Address:  168.63.129.16

Non-authoritative answer:
Name:    waws-prod-blu-655b4fde.cloudapp.net
Address:  40.117.171.112
Aliases:  web.purview.azure.com
          web.privatelink.purviewstudio.azure.com
          web.privatelink.purview.azure.com
          purviewstudio-prod-tm.trafficmanager.net
          purviewstudio-prod-wa-prod-shell-eastus.purviewstudio-prod-ase-eastus.p.azurewebsites.net
          waws-prod-blu-655b4fde.sip.p.azurewebsites.windows.net
```

The following example shows Microsoft Purview DNS name resolution from inside the virtual network.

```
C:\>nslookup.exe
Default Server:  UnKnown
Address:  168.63.129.16

> Contoso-Purview-01.purview.azure.com
Server:  UnKnown
Address:  168.63.129.16

Non-authoritative answer:
Name:    contoso-purview-01.privatelink.purview.azure.com
Address:  10.40.0.4
Aliases:  Contoso-Purview-01.purview.azure.com

> web.purview.azure.com
Server:  UnKnown
Address:  168.63.129.16

Non-authoritative answer:
Name:    web.privatelink.purviewstudio.azure.com
Address:  10.40.0.5
Aliases:  web.purview.azure.com
```

Troubleshooting private endpoint configuration for Microsoft Purview accounts

Article • 05/09/2025

> **Important**
>
> This article covers private endpoints for the classic Microsoft Purview governance portal (https://web.purview.azure.com). If you're using the new Microsoft Purview portal (https://purview.microsoft.com/), follow the documentation for private endpoints in the Microsoft Purview portal.

This article summarizes known limitations related to using private endpoints for Microsoft Purview and provides a list of steps and solutions for troubleshooting some of the most common relevant issues.

Known limitations

- We currently don't support ingestion private endpoints that work with your AWS sources.
- Scanning Azure Multiple Sources using self-hosted integration runtime isn't supported.
- Using Azure integration runtime to scan data sources behind private endpoint isn't supported.
- The ingestion private endpoints can be created via the classic Microsoft Purview governance portal experience described in the steps here. They can't be created from the Private Link Center.
- Creating a DNS record for ingestion private endpoints inside existing Azure DNS Zones, while the Azure Private DNS Zones are located in a different subscription than the private endpoints isn't supported via the classic Microsoft Purview governance portal experience. A record can be added manually in the destination DNS Zones in the other subscription.
- If you configure your own Event Hubs namespace or enable a managed Event Hubs namespace after deploying an ingestion private endpoint, you'll need to redeploy the ingestion private endpoint.
- Self-hosted integration runtime machine must be deployed in the same virtual network or a peered virtual network where Microsoft Purview account and ingestion private endpoints are deployed.
- For limitation related to Private Link service, see Azure Private Link limits.
- Currently, Microsoft Purview instances using the new Microsoft Purview portal can only use ingestion private endpoints.

Recommended troubleshooting steps

1. Once you deploy private endpoints for your Microsoft Purview account, review your Azure environment to make sure private endpoint resources are deployed successfully. Depending on your scenario, one or more of the following Azure private endpoints must be deployed in your Azure subscription:

Expand table

Private endpoint	Private endpoint assigned to	Example
Account	Microsoft Purview Account	mypurview-private-account
Portal	Microsoft Purview Account	mypurview-private-portal
Ingestion	Storage (Blob)*	mypurview-ingestion-blob
Ingestion	Storage (Queue)*	mypurview-ingestion-queue
Ingestion	Event Hubs Namespace**	mypurview-ingestion-namespace

> **Note**
>
> *If your account was created before December 15, 2023, the endpoint is deployed to your managed storage account. If it was created after November 10 (or deployed using API version 2023-05-01-preview onwards), it points to the ingestion storage.
>
> **Your account only has an associated Event Hubs namespace if it is configured for kafka notifications or created before December 15, 2022.

2. If portal private endpoint is deployed, make sure you also deploy account private endpoint.

3. If portal private endpoint is deployed, and public network access is set to deny in your Microsoft Purview account, make sure you launch the classic Microsoft Purview governance portal from internal network.

    - To verify the correct name resolution, you can use a **NSlookup.exe** command line tool to query `web.purview.azure.com`. The result must return a private IP address that belongs to portal private endpoint.
    - To verify network connectivity, you can use any network test tools to test outbound connectivity to `web.purview.azure.com` endpoint to port **443**. The connection must be successful.

4. If Azure Private DNS Zones are used, make sure the required Azure DNS Zones are deployed and there's DNS (A) record for each private endpoint.

5. Test network connectivity and name resolution from management machine to Microsoft Purview endpoint and purview web url. If account and portal private endpoints are deployed, the endpoints must be resolved through private IP addresses.

   PowerShell

   ```
   Test-NetConnection -ComputerName web.purview.azure.com -Port 443
   ```

   Example of successful outbound connection through private IP address:

   ```
   ComputerName     : web.purview.azure.com
   RemoteAddress    : 10.9.1.7
   RemotePort       : 443
   InterfaceAlias   : Ethernet 2
   SourceAddress    : 10.9.0.10
   TcpTestSucceeded : True
   ```

   PowerShell

   ```
   Test-NetConnection -ComputerName purview-test01.purview.azure.com -Port 443
   ```

   Example of successful outbound connection through private IP address:

   ```
   ComputerName     : purview-test01.purview.azure.com
   RemoteAddress    : 10.9.1.8
   RemotePort       : 443
   InterfaceAlias   : Ethernet 2
   SourceAddress    : 10.9.0.10
   TcpTestSucceeded : True
   ```

6. If you've created your Microsoft Purview account after 18 August 2021, make sure you download and install the latest version of self-hosted integration runtime from Microsoft download center.

7. From self-hosted integration runtime VM, test network connectivity and name resolution to Microsoft Purview endpoint.

8. From self-hosted integration runtime, test network connectivity and name resolution to Microsoft Purview managed resources such as blob queue, and secondary resources like Event Hubs through port 443 and private IP addresses. (If either are needed, replace the managed storage account and Event Hubs namespace with corresponding resource names).

```
PowerShell

Test-NetConnection -ComputerName
`scansoutdeastasiaocvseab`.blob.core.windows.net -Port 443
```

Example of successful outbound connection to managed blob storage through private IP address:

```

ComputerName     : scansoutdeastasiaocvseab.blob.core.windows.net
RemoteAddress    : 10.15.1.6
RemotePort       : 443
InterfaceAlias   : Ethernet 2
SourceAddress    : 10.15.0.4
TcpTestSucceeded : True
```

```
PowerShell

Test-NetConnection -ComputerName
`scansoutdeastasiaocvseab`.queue.core.windows.net -Port 443
```

Example of successful outbound connection to managed queue storage through private IP address:

```

ComputerName     : scansoutdeastasiaocvseab.blob.core.windows.net
RemoteAddress    : 10.15.1.5
RemotePort       : 443
InterfaceAlias   : Ethernet 2
SourceAddress    : 10.15.0.4
TcpTestSucceeded : True
```

```
PowerShell

Test-NetConnection -ComputerName `Atlas-1225cae9-d651-4039-86a0-
b43231a17a4b`.servicebus.windows.net -Port 443
```

Example of successful outbound connection to Event Hubs namespace through private IP address:

```
ComputerName     : Atlas-1225cae9-d651-4039-86a0-
b43231a17a4b.servicebus.windows.net
RemoteAddress    : 10.15.1.4
RemotePort       : 443
InterfaceAlias   : Ethernet 2
SourceAddress    : 10.15.0.4
TcpTestSucceeded : True
```

9. From the network where data source is located, test network connectivity and name resolution to Microsoft Purview endpoint and managed or configured resources endpoints.

10. If data sources are located in on-premises network, review your DNS forwarder configuration. Test name resolution from within the same network where data sources are located to self-hosted integration runtime, Microsoft Purview endpoints and managed or configured resources. It's expected to obtain a valid private IP address from DNS query for each endpoint.

    For more information, see Virtual network workloads without custom DNS server and On-premises workloads using a DNS forwarder scenarios in Azure Private Endpoint DNS configuration.

11. If management machine and self-hosted integration runtime VMs are deployed in on-premises network and you have set up DNS forwarder in your environment, verify DNS and network settings in your environment.

12. If ingestion private endpoint is used, make sure self-hosted integration runtime is registered successfully inside Microsoft Purview account and shows as running both inside the self-hosted integration runtime VM and in the classic Microsoft Purview governance portal .

Common errors and messages

Issue

You could receive the following error message when running a scan:

`Internal system error. Please contact support with correlationId:xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx System Error, contact support.`

Cause

This can be an indication of issues related to connectivity or name resolution between the VM running self-hosted integration runtime and Microsoft Purview's managed storage account or configured Event Hubs.

Resolution

Validate if name resolution is successful between the VM running the Self-Hosted Integration Runtime and the Microsoft Purview managed blob queue or configured Event Hubs through port 443 and private IP addresses (step 8 above.)

Issue

You could receive the following error message when running a new scan:

`message: Unable to setup config overrides for this scan. Exception:'Type=Microsoft.WindowsAzure.Storage.StorageException,Message=The remote server returned an error: (404) Not Found.,Source=Microsoft.WindowsAzure.Storage,StackTrace= at Microsoft.WindowsAzure.Storage.Core.Executor.Executor.EndExecuteAsync[T](IAsyncResult result)`

Cause

This can be an indication of running an older version of self-hosted integration runtime. You'll need to use the self-hosted integration runtime version 5.9.7885.3 or greater.

Resolution

Upgrade self-hosted integration runtime to 5.9.7885.3.

Issue

Microsoft Purview account with private endpoint deployment failed with Azure Policy validation error during the deployment.

Cause

This error suggests that there might be an existing Azure Policy Assignment on your Azure subscription that is preventing the deployment of any of the required Azure resources.

Resolution

Review your existing Azure Policy Assignments and make sure deployment of the following Azure resources are allowed in your Azure subscription.

> ⓘ **Note**
>
> Depending on your scenario, you may need to deploy one or more of the following Azure resource types:
>
> - Microsoft Purview (Microsoft.Purview/Accounts)
> - Private Endpoint (Microsoft.Network/privateEndpoints)
> - Private DNS Zones (Microsoft.Network/privateDnsZones)
> - Event Hub Name Space (Microsoft.EventHub/namespaces)
> - Storage Account (Microsoft.Storage/storageAccounts)

Issue

Not authorized to access this Microsoft Purview account. This Microsoft Purview account is behind a private endpoint. Access the account from a client in the same virtual network (virtual network) that has been configured for the Microsoft Purview account's private endpoint.

Cause

User is trying to connect to Microsoft Purview from a public endpoint or using Microsoft Purview public endpoints where **Public network access** is set to **Deny**.

Resolution

In this case, to open the classic Microsoft Purview governance portal, either use a machine that is deployed in the same virtual network as the classic Microsoft Purview governance portal private endpoint or use a VM that is connected to your CorpNet in which hybrid connectivity is allowed.

Issue

You could receive the following error message when scanning a SQL server, using a self-hosted integration runtime:

```
Message=This implementation is not part of the Windows Platform FIPS validated cryptographic algorithms
```

Cause

Self-hosted integration runtime machine has enabled the FIPS mode. Federal Information Processing Standards (FIPS) defines a certain set of cryptographic algorithms that are allowed to be used. When FIPS mode is enabled on the machine, some cryptographic classes that the invoked processes depend on are blocked in some scenarios.

Resolution

Disable FIPS mode on self-hosted integration server.

FAQ about Microsoft Purview private endpoints and managed virtual networks

Article • 05/09/2025

> **Important**
>
> This article covers private endpoints for the classic Microsoft Purview governance portal (https://web.purview.azure.com). If you're using the new Microsoft Purview portal (https://purview.microsoft.com/), follow the documentation for private endpoints in the Microsoft Purview portal.

This article answers common questions that customers and field teams often ask about Microsoft Purview network configurations by using Azure Private Link or Microsoft Purview Managed VNets. It's intended to clarify questions about Microsoft Purview firewall settings, private endpoints, DNS configuration, and related configurations.

To set up Microsoft Purview by using Private Link, see Use private endpoints for your Microsoft Purview account. To configure Managed VNets for a Microsoft Purview account, see Use a Managed virtual network with your Microsoft Purview account.

When should I use a self-hosted integration runtime, Managed virtual network IR, or Azure IR?

Learn more from Choose the right integration runtime configuration for your scenario.

Can I use both self-hosted integration runtime and Managed virtual network IR inside a Microsoft Purview account?

Yes. You can use one or all of the runtime options in a single Microsoft Purview account: Azure IR, Managed virtual network IR, and self-hosted integration runtime. You can use only one runtime option in a single scan.

What's the purpose of deploying the Microsoft Purview account private endpoint?

The Microsoft Purview account private endpoint is used to add another layer of security by enabling scenarios where only client calls that originate from within the virtual network are allowed to access the account. This private endpoint is also a prerequisite for the portal private endpoint.

What's the purpose of deploying the Microsoft Purview portal private endpoint?

The Microsoft Purview portal private endpoint provides private connectivity to the classic Microsoft Purview governance portal.

What's the purpose of deploying the Microsoft Purview ingestion private endpoints?

Microsoft Purview can scan data sources in Azure or an on-premises environment by using ingestion private endpoints. Three other private endpoint resources are deployed and linked to Microsoft Purview managed or configured resources when ingestion private endpoints are created:

- If you're using a managed Event Hubs for kafka notifications, **namespace** is linked to a Microsoft Purview configured Event Hubs namespace.
- If your account was created before December 15, 2023:
  - **Blob** is linked to a Microsoft Purview managed storage account.
  - **Queue** is linked to a Microsoft Purview managed storage account.
- If your account was created after December 15, 2023 (or deployed using API version 2023-05-01-preview onwards):
  - **Blob** is linked to a Microsoft Purview ingestion storage.
  - **Queue** is linked to a Microsoft Purview ingestion storage.

Can I scan a data source through a public endpoint if a private endpoint is enabled on my Microsoft Purview account?

Yes. Data sources that aren't connected through a private endpoint can be scanned by using a public endpoint while Microsoft Purview is configured to use a private endpoint.

Can I scan a data source through a service endpoint if a private endpoint is enabled?

Yes. Data sources that aren't connected through a private endpoint can be scanned by using a service endpoint while Microsoft Purview is configured to use a private endpoint. Learn more from Choose the right integration runtime configuration for your scenario.

Can I access the classic Microsoft Purview governance portal from a public network if Public network access is set to Deny in Microsoft Purview account networking?

No. Connecting to Microsoft Purview from a public endpoint where **Public network access** is set to **Deny** results in the following error message:

"Not authorized to access this Microsoft Purview account. This Microsoft Purview account is behind a private endpoint. Access the account from a client in the same virtual network (virtual network) that has been configured for the Microsoft Purview account's private endpoint."

In this case, to open the classic Microsoft Purview governance portal, either use a machine that's deployed in the same virtual network as the Microsoft Purview portal private endpoint or use a VM that's connected to your CorpNet in which hybrid connectivity is allowed.

Is it possible to restrict access to the Microsoft Purview managed storage account or ingestion storage account and Event Hubs namespace (for private endpoint ingestion only) but keep portal access enabled for users across the web?

> **Note**
>
> Your account only has a managed storage account if it was created before December 15, 2023 (or deployed using API version previous to 2023-05-01-preview). Your account only has an associated Event Hubs namespace if it is configured for kafka notifications or was created before December 15, 2022.

Yes. You can configure Microsoft Purview firewall setting to Disabled for ingestion only (Preview). By choosing this option, public network access to your Microsoft Purview account through API and classic Microsoft Purview governance portal is allowed, however public network access is set to disabled on your Microsoft Purview account's Managed storage account. You also need to confirm your Event Hubs network settings allow communication.

If public network access is set to Allow, does it mean the managed storage account or ingestion storage account and Event Hubs namespace are accessible by anyone?

> **Note**
>
> Your account only has a managed storage account if it was created before December 15, 2023 (or deployed using API version previous to 2023-05-01-preview). Your account only has an associated Event Hubs namespace if it is **configured for kafka notifications** or was created before December 15, 2022.

No. As protected resources, access to the Microsoft Purview managed storage account and any Event Hubs namespace is restricted to Microsoft Purview only using RBAC authentication schemes. These resources are deployed with a deny assignment to all principals, which prevents any applications, users, or groups from gaining access to them.

To read more about Azure deny assignment, see Understand Azure deny assignments.

What private DNS zones are required for Microsoft Purview for a private endpoint?

For Microsoft Purview *account*, *portal*, and *platform* private endpoints:

- `privatelink.purview.azure.com` - for the classic Microsoft Purview governance portal.
- `privatelink.purview-service.microsoft.com` - for the Microsoft Purview portal.

For Microsoft Purview *ingestion* private endpoints:

- `privatelink.blob.core.windows.net`
- `privatelink.queue.core.windows.net`
- `privatelink.servicebus.windows.net`

Do I have to use a dedicated virtual network and dedicated subnet when I deploy Microsoft Purview private endpoints?

No. However, `PrivateEndpointNetworkPolicies` must be disabled in the destination subnet before you deploy the private endpoints. Consider deploying Microsoft Purview into a virtual network that has network connectivity to data source virtual networks through virtual network Peering and access to an on-premises network if you plan to scan data sources cross-premises.

Read more about Disable network policies for private endpoints.

Can I deploy Microsoft Purview private endpoints and use existing private DNS zones in my subscription to register the A records?

Yes. Your private endpoint DNS zones can be centralized in a hub or data management subscription for all internal DNS zones required for Microsoft Purview and all data source records. We recommend this method to allow Microsoft Purview to resolve data sources by using their private endpoint internal IP addresses.

You're also required to set up a virtual network link for virtual networks for the existing private DNS zone.

What are the outbound ports and firewall requirements for virtual machines with self-hosted integration runtime for Microsoft Purview when you use a private endpoint?

The VMs in which self-hosted integration runtime is deployed must have outbound access to Azure endpoints and a Microsoft Purview private IP address through port 443.

Do I need to enable outbound internet access from the virtual machine running self-hosted integration runtime if a private endpoint is enabled?

No. However, it's expected that the virtual machine running self-hosted integration runtime can connect to your instance of Microsoft Purview through an internal IP address by using port 443. Use common troubleshooting tools for name resolution and connectivity testing, such as nslookup.exe and Test-NetConnection.

Do I still need to deploy private endpoints for my Microsoft Purview account if I'm using Managed virtual network?

At least one account and portal private endpoints are required, if public access in Microsoft Purview account is set to **deny**. At least one account, portal and ingestion private endpoint are required, if public access in Microsoft Purview account is set to **deny** and you're planning to scan more data sources using a self-hosted integration runtime.

What inbound and outbound communications are allowed through public endpoint for Microsoft Purview Managed VNets?

No inbound communication is allowed into a Managed virtual network from public network. All ports are opened for outbound communications. In Microsoft Purview, a Managed virtual network can be used to privately connect to Azure data sources to extract metadata during scan.

Why do I receive the following error message when I try to launch the classic Microsoft Purview governance portal from my machine?

"This Microsoft Purview account is behind a private endpoint. Access the account from a client in the same virtual network (virtual network) that has been configured for the Microsoft Purview account's private endpoint."

It's likely your Microsoft Purview account is deployed by using Private Link and public access is disabled on your Microsoft Purview account. As a result, you have to browse the clssic Microsoft Purview governance portal from a virtual machine that has internal network connectivity to Microsoft Purview.

If you're connecting from a VM behind a hybrid network or using a jump machine connected to your virtual network, use common troubleshooting tools for name resolution and connectivity testing, such as nslookup.exe and Test-NetConnection.

1. Validate if you can resolve the following addresses through your Microsoft Purview account's private IP addresses.

   - `Web.Purview.Azure.com`
   - `<YourPurviewAccountName>.Purview.Azure.com`

2. Verify network connectivity to your Microsoft Purview account by using the following PowerShell command:

   PowerShell

   ```
   Test-NetConnection -ComputerName <YourPurviewAccountName>.Purview.Azure.com -Port 443
   ```

3. Verify your cross-premises DNS configuration if you use your own DNS resolution infrastructure.

For more information about DNS settings for private endpoints, see Azure private endpoint DNS configuration.

Can I move private endpoints associated with Microsoft Purview account or its managed resources to another Azure subscription or resource group?

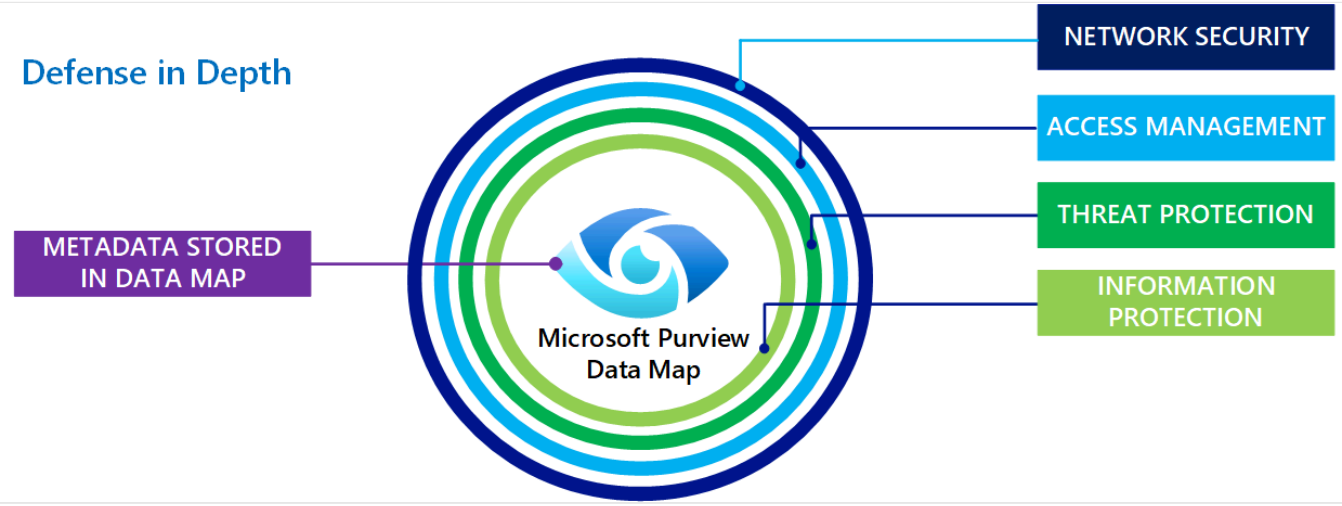
No. Move operations for Account, Portal, or Ingestion private endpoints aren't supported. For more information, see Move networking resources to new resource group or subscription.

Can I create multiple managed virtual networks in different regions?

Yes. You can create multiple managed virtual networks across different regions in a single Microsoft Purview instance so you can access data sources available in different regions. This feature provides the ability to:

- Create multiple managed virtual networks (five maximum) across different regions within a single Microsoft Purview instance.
- Network isolation within your own organization to address potential data residency or scan performance concerns.

Next steps



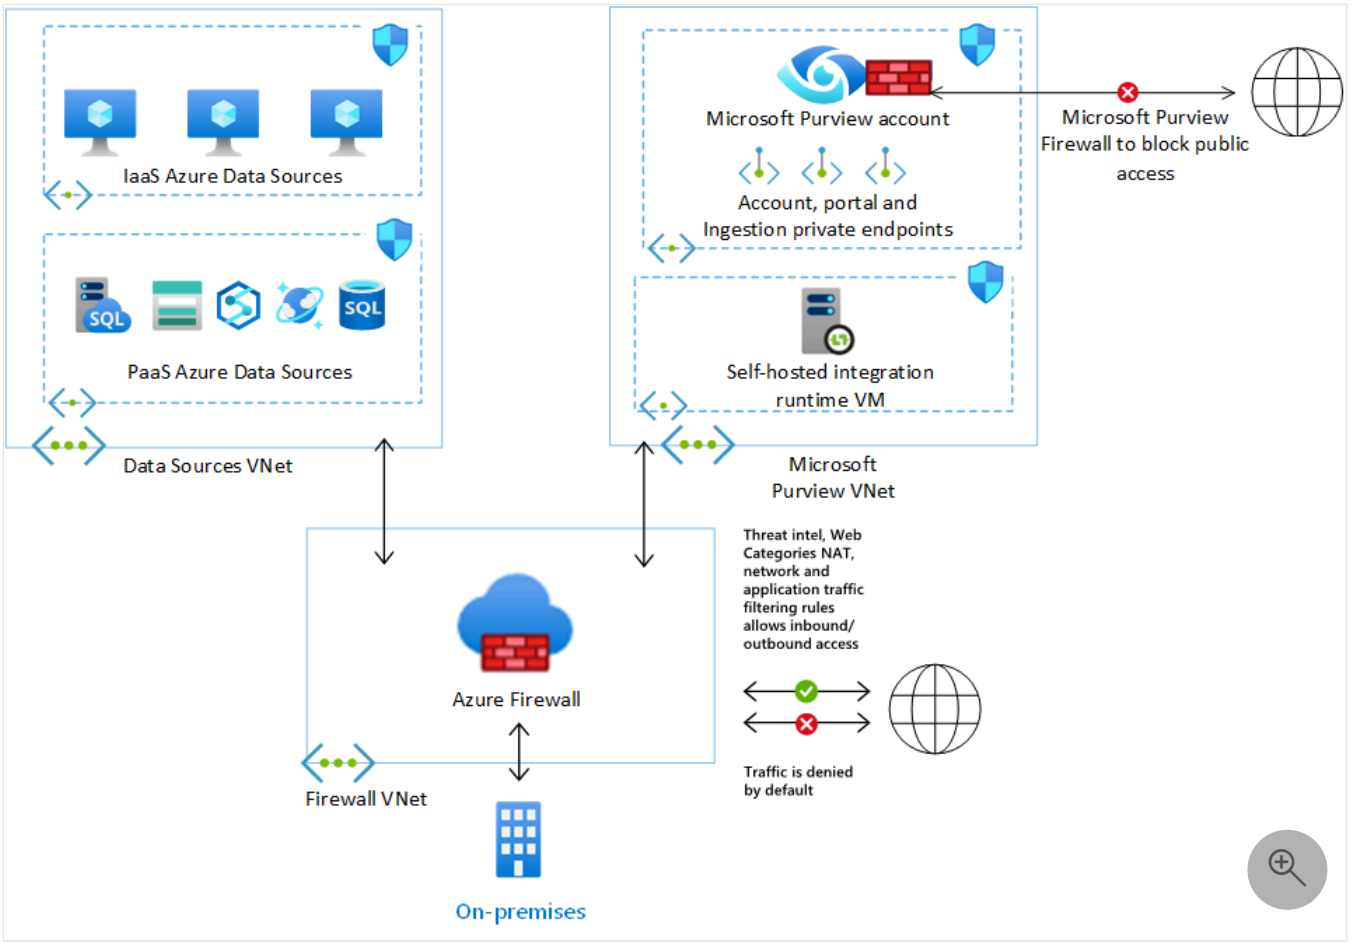
To set up Microsoft Purview by using Private Link, see Use private endpoints for your Microsoft Purview account.

Data governance best practices for security

Article • 05/20/2025

This article provides best practices for common security requirements for classic Microsoft Purview governance solutions. The security strategy described follows the layered defense-in-depth approach.

> **Note**
>
> These best practices cover security for Microsoft Purview data governance solutions. Learn more about Microsoft Purview in general, or about risk and compliance solutions specifically.



Before applying these recommendations to your environment, you should consult your security team as some may not be applicable to your security requirements.

Network security

You can enable the following network security capabilities for the Microsoft Purview data map:

- Enable end-to-end network isolation using Private Link Service.
- Use Microsoft Purview Firewall to disable Public access.
- Deploy Network Security Group (NSG) rules for subnets where Azure data sources private endpoints, Microsoft Purview private endpoints and self-hosted runtime VMs are deployed.
- Implement Microsoft Purview with private endpoints managed by a Network Virtual Appliance, such as Azure Firewall for network inspection and network filtering.

For more information, see Best practices related to connectivity to Azure PaaS Services.

Deploy private endpoints for Microsoft Purview accounts

If you need to use Microsoft Purview from inside your private network, it's recommended to use Azure Private Link Service with your Microsoft Purview accounts for partial or end-to-end isolation to connect to Microsoft Purview governance portal, access Microsoft Purview endpoints and to scan data sources.

The Microsoft Purview *account* private endpoint is used to add another layer of security, so only client calls that are originated from within the virtual network are allowed to access the Microsoft Purview account. This private endpoint is also a prerequisite for the portal private endpoint.

The Microsoft Purview *portal* private endpoint is required to enable connectivity to Microsoft Purview governance portal using a private network.

Microsoft Purview can scan data sources in Azure or an on-premises environment by using ingestion private endpoints.

For more information, see Microsoft Purview network architecture and best practices.

Block public access using Microsoft Purview firewall

You can disable Microsoft Purview Public access to cut off access to the Microsoft Purview account completely from the public internet. In this case, you should consider the following requirements:

- Microsoft Purview must be deployed based on end-to-end network isolation scenario.
- To access Microsoft Purview governance portal and Microsoft Purview endpoints, you need to use a management machine that is connected to private network to access Microsoft Purview through private network.
- Review known limitations.

For more information, see Firewalls to restrict public access.

Use Network Security Groups

You can use an Azure network security group to filter network traffic to and from Azure resources in an Azure virtual network. A network security group contains security rules that allow or deny inbound network traffic to, or outbound network traffic from, several types of Azure resources. For each rule, you can specify source and destination, port, and protocol.

Network Security Groups can be applied to network interface or Azure virtual networks subnets, where Microsoft Purview private endpoints, self-hosted integration runtime VMs and Azure data sources are deployed.

For more information, see apply NSG rules for private endpoints.

The following NSG rules are required on **data sources** for Microsoft Purview scanning:

Expand table

Direction	Source	Source port range	Destination	Destination port	Protocol	Action
Inbound	Self-hosted integration runtime VMs' private IP addresses or subnets	*	Data Sources private IP addresses or Subnets	443	Any	Allow

The following NSG rules are required on from the **management machines** to access Microsoft Purview governance portal:

Expand table

Direction	Source	Source port range	Destination	Destination port	Protocol	Action
Outbound	Management machines' private IP addresses or subnets	*	Microsoft Purview account and portal private endpoint IP addresses or subnets	443	Any	Allow
Outbound	Management machines' private IP addresses or subnets	*	Service tag: `AzureCloud`	443	Any	Allow

The following NSG rules are required on **self-hosted integration runtime VMs** for Microsoft Purview scanning and metadata ingestion:

> **Important**
>
> Consider adding additional rules with relevant Service Tags, based on your data source types.

Expand table

Direction	Source	Source port range	Destination	Destination port	Protocol	Action
Outbound	Self-hosted integration runtime VMs' private IP addresses or subnets	*	Data Sources private IP addresses or subnets	443	Any	Allow
Outbound	Self-hosted integration runtime VMs' private IP addresses or subnets	*	Microsoft Purview account and ingestion private endpoint IP addresses or Subnets	443	Any	Allow
Outbound	Self-hosted integration runtime VMs' private IP	*	Service tag: `Servicebus`	443	Any	Allow

Direction	Source	Source port range	Destination	Destination port	Protocol	Action
	addresses or subnets					
Outbound	Self-hosted integration runtime VMs' private IP addresses or subnets	*	Service tag: `Storage`	443	Any	Allow
Outbound	Self-hosted integration runtime VMs' private IP addresses or subnets	*	Service tag: `AzureActiveDirectory`	443	Any	Allow
Outbound	Self-hosted integration runtime VMs' private IP addresses or subnets	*	Service tag: `DataFactory`	443	Any	Allow
Outbound	Self-hosted integration runtime VMs' private IP addresses or subnets	*	Service tag: `KeyVault`	443	Any	Allow

The following NSG rules are required on for **Microsoft Purview account, portal and ingestion private endpoints**:

Expand table

Direction	Source	Source port range	Destination	Destination port	Protocol	Action
Inbound	Self-hosted integration runtime VMs' private IP addresses or subnets	*	Microsoft Purview account and ingestion private endpoint IP addresses or subnets	443	Any	Allow

Direction	Source	Source port range	Destination	Destination port	Protocol	Action
Inbound	Management machines' private IP addresses or subnets	*	Microsoft Purview account and ingestion private endpoint IP addresses or subnets	443	Any	Allow

For more information, see Self-hosted integration runtime networking requirements.

Access management

Identity and Access Management provides the basis of a large percentage of security assurance. It enables access based on identity authentication and authorization controls in cloud services. These controls protect data and resources and decide which requests should be permitted.

Related to roles and access management in Microsoft Purview, you can apply the following security best practices:

- Define roles and responsibilities to manage Microsoft Purview in control plane and data plane:
  - Define roles and tasks required to deploy and manage Microsoft Purview inside an Azure subscription.
  - Define roles and task needed to perform data management and governance using Microsoft Purview.
- Assign roles to Microsoft Entra groups instead of assigning roles to individual users.
- Use Azure Active Directory Entitlement Management to map user access to Microsoft Entra groups using Access Packages.
- Enforce multifactor authentication for Microsoft Purview users, especially, for users with privileged roles such as collection admins, data source admins or data curators.

Manage a Microsoft Purview account in control plane and data plane

Control plane refers to all operations related to Azure deployment and management of Microsoft Purview inside Azure Resource Manager.

Data plane refers to all operations, related to interacting with Microsoft Purview inside Data Map and Unified Catalog.

You can assign control plane and data plane roles to users, security groups and service principals from your Microsoft Entra tenant that is associated to Microsoft Purview instance's Azure subscription.

Examples of control plane operations and data plane operations:

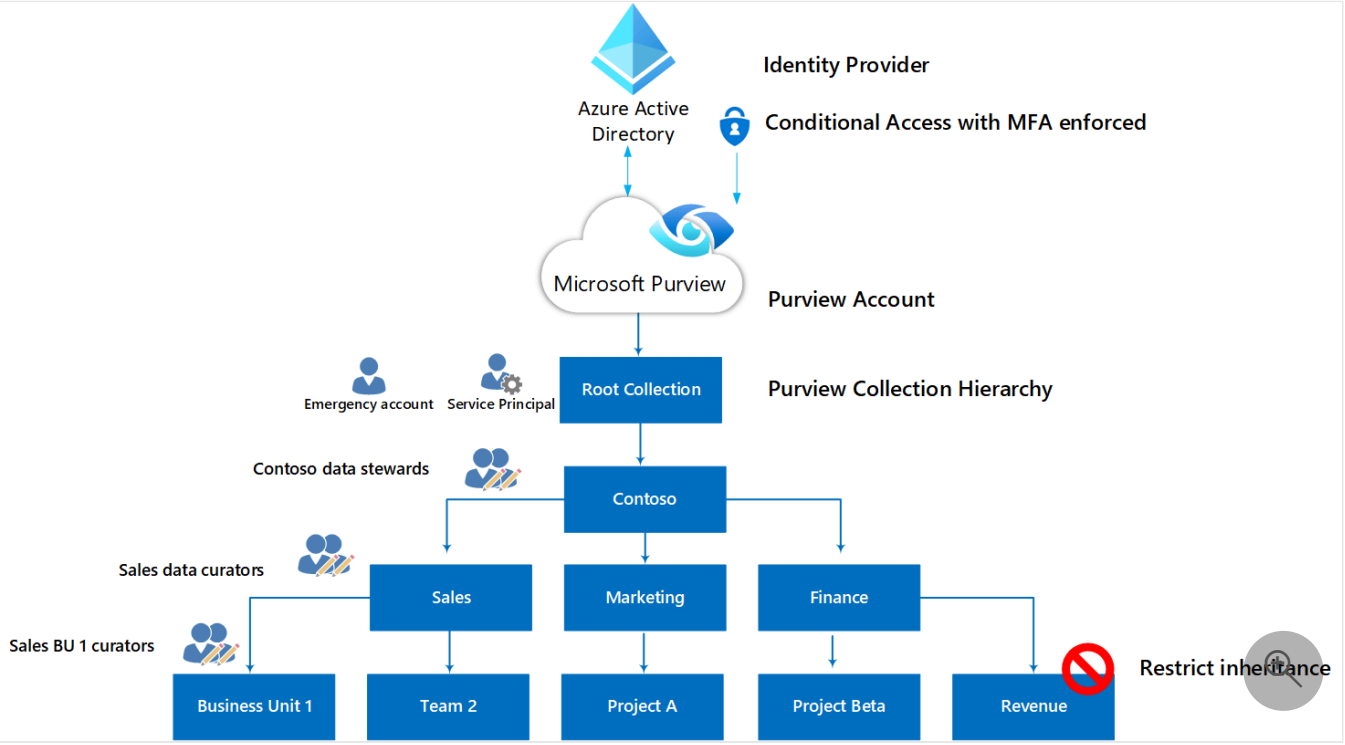
Expand table

Task	Scope	Recommended role	What roles to use?
Deploy a Microsoft Purview account	Control plane	Azure subscription owner or contributor	Azure RBAC roles
Set up a Private Endpoint for Microsoft Purview	Control plane	Contributor	Azure RBAC roles
Delete a Microsoft Purview account	Control plane	Contributor	Azure RBAC roles
Add or manage a self-hosted integration runtime (SHIR)	Control plane	Data source administrator	Microsoft Purview roles
View Microsoft Purview metrics to get current capacity units	Control plane	Reader	Azure RBAC roles
Create a collection	Data plane	Collection Admin	Microsoft Purview roles
Register a data source	Data plane	Collection Admin	Microsoft Purview roles
Scan a SQL Server	Data plane	Data source admin and data reader or data curator	Microsoft Purview roles
Search inside Microsoft Purview Unified Catalog	Data plane	Data source admin and data reader or data curator	Microsoft Purview roles

Microsoft Purview plane roles are defined and managed inside Microsoft Purview instance in Microsoft Purview collections. For more information, see Access control in Microsoft Purview.

Follow Microsoft Purview Data Governance roles for guidance on users' roles and permissions to manage in Unified Catalog.

Follow Azure role-based access recommendations for Azure control plane tasks.



Authentication and authorization

To gain access to Microsoft Purview, users must be authenticated and authorized. Authentication is the process of proving the user is who they claim to be. Authorization refers to controlling access inside Microsoft Purview assigned on collections.

We use Microsoft Entra ID to provide authentication and authorization mechanisms for Microsoft Purview inside Collections. You can assign Microsoft Purview roles to the following security principals from your Microsoft Entra tenant that is associated with Azure subscription where your Microsoft Purview instance is hosted:

- Users and guest users (if they're already added into your Microsoft Entra tenant)
- Security groups
- Managed Identities
- Service Principals

Microsoft Purview fine-grained roles can be assigned to a flexible Collections hierarchy inside the Microsoft Purview instance.

Define Least Privilege model

As a general rule, restrict access based on the need to know and least privilege security principles is imperative for organizations that want to enforce security policies for data access.

In Microsoft Purview, data sources, assets and scans can be organized using Microsoft Purview Collections. Collections are hierarchical grouping of metadata in Microsoft Purview, but at the same time they provide a mechanism to manage access across Microsoft Purview. Roles in Microsoft Purview can be assigned to a collection based on your collection's hierarchy.

Use Microsoft Purview collections to implement your organization's metadata hierarchy for centralized or delegated management and governance hierarchy based on least privileged model.

Follow least privilege access model when assigning roles inside Microsoft Purview collections by segregating duties within your team and grant only the amount of access to users that they need to perform their jobs.

For more information how to assign least privilege access model in Microsoft Purview, based on Microsoft Purview collection hierarchy, see Access control in Microsoft Purview.

Lower exposure of privileged accounts

Securing privileged access is a critical first step to protecting business assets. Minimizing the number of people who have access to secure information or resources, reduces the chance of a malicious user getting access, or an authorized user inadvertently affecting a sensitive resource.

Reduce the number of users with write access inside your Microsoft Purview instance. Keep the number of collection admins and data curator roles minimum at root collection.

Use multifactor authentication and conditional access

Microsoft Entra multifactor authentication provides another layer of security and authentication. For more security, we recommend enforcing conditional access policies for all privileged accounts.

By using Microsoft Entra Conditional Access policies, apply Microsoft Entra multifactor authentication at sign-in for all individual users who are assigned to Microsoft Purview roles with modify access inside your Microsoft Purview instances: Collection Admin, Data Source Admin, Data Curator.

Enable multifactor authentication for your admin accounts and ensure that admin account users have registered for MFA.

You can define your Conditional Access policies by selecting Microsoft Purview as a Cloud App.

Prevent accidental deletion of Microsoft Purview accounts

In Azure, you can apply resource locks to an Azure subscription, a resource group, or a resource to prevent accidental deletion or modification for critical resources.

Enable Azure resource lock for your Microsoft Purview accounts to prevent accidental deletion of Microsoft Purview instances in your Azure subscriptions.

Adding a `CanNotDelete` or `ReadOnly` lock to Microsoft Purview account doesn't prevent deletion or modification operations inside Microsoft Purview data plane, however, it prevents any operations in control plane, such as deleting the Microsoft Purview account, deploying a private endpoint or configuration of diagnostic settings.

For more information, see Understand scope of locks.

Resource locks can be assigned to Microsoft Purview resource groups or resources, however, you can't assign an Azure resource lock to Microsoft Purview Managed resources or managed Resource Group.

Implement a break glass strategy

Plan for a break glass strategy for your Microsoft Entra tenant, Azure subscription and Microsoft Purview accounts to prevent tenant-wide account lockout.

For more information about Microsoft Entra ID and Azure emergency access planning, see Manage emergency access accounts in Microsoft Entra ID.

For more information about Microsoft Purview break glass strategy, see Microsoft Purview collections best practices and design recommendations.

Threat protection and preventing data exfiltration

Microsoft Purview provides rich insights into the sensitivity of your data, which makes it valuable to security teams using Microsoft Defender for Cloud to manage the organization's security posture and protect against threats to their workloads. Data resources remain a popular target for malicious actors, making it crucial for security teams to identify, prioritize, and secure sensitive data resources across their cloud environments. To address this challenge, we're announcing the integration between Microsoft Defender for Cloud and Microsoft Purview in public preview.

Integrate with Microsoft 365 and Microsoft Defender for Cloud

Often, one of the biggest challenges for security organization in a company is to identify and protect assets based on their criticality and sensitivity. Microsoft recently announced integration between Microsoft Purview and Microsoft Defender for Cloud in Public Preview to help overcome these challenges.

If you've extended your Microsoft 365 sensitivity labels for assets and database columns in Microsoft Purview, you can keep track of highly valuable assets using Microsoft Defender for

Cloud from inventory, alerts and recommendations based on assets detected sensitivity labels.

- For recommendations, we've provided **security controls** to help you understand how important each recommendation is to your overall security posture. Microsoft Defender for Cloud includes a **secure score** value for each control to help you prioritize your security work. Learn more in Security controls and their recommendations.
- For alerts, we've assigned **severity labels** to each alert to help you prioritize the order in which you attend to each alert. Learn more in How are alerts classified?.

For more information, see Integrate Microsoft Purview with Azure security products.

Information Protection

Secure metadata extraction and storage

Microsoft Purview is a data governance solution in cloud. You can register and scan different data sources from various data systems from your on-premises, Azure, or multicloud environments into Microsoft Purview. While data source is registered and scanned in Microsoft Purview, the actual data and data sources stay in their original locations, only metadata is extracted from data sources and stored in Microsoft Purview Data Map, which means you don't need to move data out of the region or their original location to extract the metadata into Microsoft Purview.

If your account was created **before** December 15, 2023, then your account was deployed with a managed resource group and an Azure Storage account was deployed in that group. These resources are consumed by Microsoft Purview and can't be accessed by any other users or principals. An Azure role-based access control (RBAC) deny assignment is added automatically to this resource group when the Microsoft Purview account was deployed, and that prevents access by other users or any CRUD operations that aren't initiated by Microsoft Purview.

Accounts deployed **after** December 15, 2023 (or deployed using API version 2023-05-01-preview onwards) use an ingestion storage account which is deployed in internal Microsoft Azure subscriptions. Since these resources are not on the Microsoft Purview's Azure subscription, they can't be accessed by any other users or principals, except the Microsoft Purview account.

(If you've deployed your accounts using the API, accounts deployed using the API version 2023-05-01-preview onwards will use an ingestion storage account deployed on internal Microsoft Azure subscriptions, instead of a managed storage account deployed on your Azure subscription.)

Where is metadata stored?

Microsoft Purview extracts only the metadata from different data source systems into Microsoft Purview Data Map during the scanning process.

You can deploy a Microsoft Purview account inside your Azure subscription in any supported Azure regions.

All metadata is stored inside Data Map inside your Microsoft Purview instance. This means the metadata is stored in the same region as your Microsoft Purview instance.

How metadata is extracted from data sources?

Microsoft Purview allows you to use any of the following options to extract metadata from data sources:

- **Azure runtime**. Metadata data is extracted and processed inside the same region as your data sources.

    1. A manual or automatic scan is initiated from the Microsoft Purview Data Map through the Azure integration runtime.
    2. The Azure integration runtime connects to the data source to extract metadata.
    3. Metadata is queued in Microsoft Purview managed or ingestion storage and stored in Azure Blob Storage.
    4. Metadata is sent to the Microsoft Purview Data Map.

- **Self-hosted integration runtime**. Metadata is extracted and processed by self-hosted integration runtime inside self-hosted integration runtime VMs' memory before they're sent to Microsoft Purview Data Map. In this case, customers have to deploy and manage one or more self-hosted integration runtime Windows-based virtual machines inside their Azure subscriptions or on-premises environments. Scanning on-premises and VM-based data sources always requires using a self-hosted integration runtime. The Azure integration runtime isn't supported for these data sources. The following steps show the communication flow at a high level when you're using a self-hosted integration runtime to scan a data source.

    1. A manual or automatic scan is triggered. Microsoft Purview connects to Azure Key Vault to retrieve the credential to access a data source.
    2. The scan is initiated from the Microsoft Purview Data Map through a self-hosted integration runtime.

3. The self-hosted integration runtime service from the VM connects to the data source to extract metadata.

4. Metadata is processed in VM memory for the self-hosted integration runtime. Metadata is queued in Microsoft Purview ingestion storage and then stored in Azure Blob Storage.

5. Metadata is sent to the Microsoft Purview Data Map.

If you need to extract metadata from data sources with sensitive data that can't leave the boundary of your on-premises network, it's highly recommended to deploy the self-hosted integration runtime VM inside your corporate network, where data sources are located, to extract and process metadata in on-premises, and send only metadata to Microsoft Purview.

1. A manual or automatic scan is triggered. Microsoft Purview connects to Azure Key Vault to retrieve the credential to access a data source.

2. The scan is initiated through the on-premises self-hosted integration runtime.

3. The self-hosted integration runtime service from the VM connects to the data source to extract metadata.

4. Metadata is processed in VM memory for the self-hosted integration runtime. Metadata is queued in Microsoft Purview ingestion storage and then stored in Azure Blob Storage. Actual data never leaves the boundary of your network.

5. Metadata is sent to the Microsoft Purview Data Map.

Information protection and encryption

Azure offers many mechanisms for keeping data private in rest and as it moves from one location to another. For Microsoft Purview, data is encrypted at rest using Microsoft-managed keys and when data is in transit, using Transport Layer Security (TLS) v1.2 or greater.

Transport Layer Security (Encryption-in-transit)

Data in transit (also known as data in motion) is encrypted in Microsoft Purview.

To add another layer of security in addition to access controls, Microsoft Purview secures customer data by encrypting data in motion with Transport Layer Security (TLS) and protect data in transit against 'out of band' attacks (such as traffic capture). It uses encryption to make sure attackers can't easily read or modify the data.

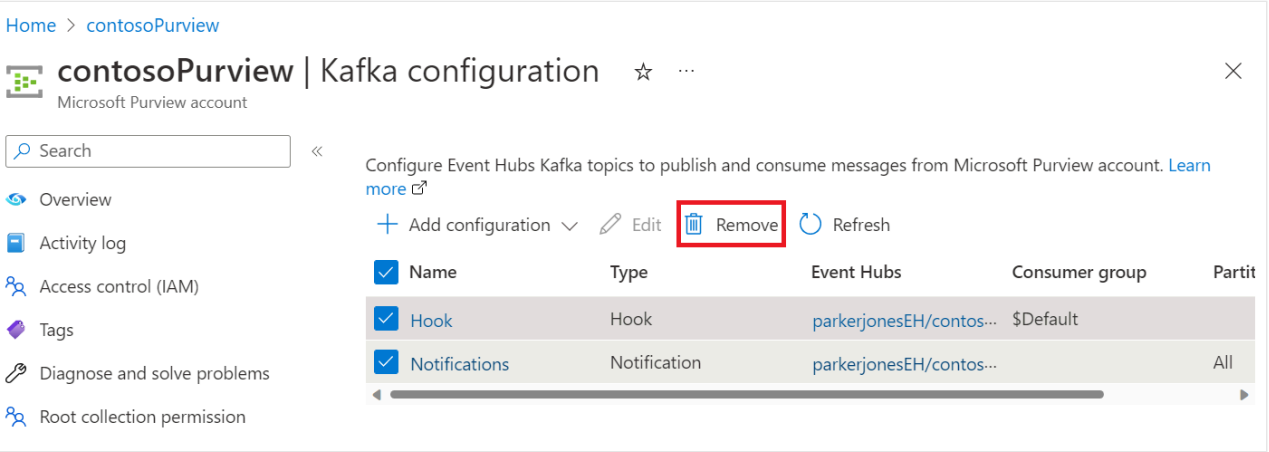
Microsoft Purview supports data encryption in transit with Transport Layer Security (TLS) v1.2 or greater.

For more information, see, Encrypt sensitive information in transit.

Transparent data encryption (Encryption-at-rest)

Data at rest includes information that resides in persistent storage on physical media, in any digital format. The media can include files on magnetic or optical media, archived data, and data backups inside Azure regions.

To add another layer of security in addition to access controls, Microsoft Purview encrypts data at rest to protect against 'out of band' attacks (such as accessing underlying storage). It uses encryption with Microsoft-managed keys. This practice helps make sure attackers can't easily read or modify the data.



For more information, see Encrypt sensitive data at rest.

Optional Event Hubs namespace configuration

Each Microsoft Purview account can configure Event Hubs that are accessible via their Atlas Kafka endpoint. This can be enabled at creation under *Configuration*, or from the Azure portal under *Kafka configuration*. It's recommended to only enable optional managed event hub if it's used to distribute events into or outside of Microsoft Purview account Data Map. To remove this information distribution point, either don't configure these endpoints, or remove them.

To remove configured Event Hubs namespaces, you can follow these steps:

1. Search for and open your Microsoft Purview account in the Azure portal.
2. Select **Kafka configuration** under settings on your Microsoft Purview account page in the Azure portal.
3. Select the Event Hubs you want to disable. (Hook hubs send messages to Microsoft Purview. Notification hubs receive notifications.)
4. Select **Remove** to save the choice and begin the disablement process. This can take several minutes to complete.

> **Note**
>
> If you have an ingestion private endpoint when you disable this Event Hubs namespace, after disabling the ingestion private endpoint may show as disconnected.

For more information about configuring these Event Hubs namespaces, see: Configure Event Hubs for Atlas Kafka topics

Credential management

To extract metadata from a data source system into Microsoft Purview Data Map, it's required to register and scan the data source systems in Microsoft Purview Data Map. To automate this process, we have made available connectors for different data source systems in Microsoft Purview to simplify the registration and scanning process.

To connect to a data source Microsoft Purview requires a credential with read-only access to the data source system.

It's recommended prioritizing the use of the following credential options for scanning, when possible:

1. Microsoft Purview Managed Identity
2. User Assigned Managed Identity
3. Service Principals
4. Other options such as Account key, SQL Authentication, etc.

If you use any options rather than managed identities, all credentials must be stored and protected inside an Azure key vault. Microsoft Purview requires get/list access to secret on the Azure Key Vault resource.

As a general rule, you can use the following options to set up integration runtime, and credentials to scan data source systems:

Expand table

Scenario	Runtime option	Supported Credentials
Data source is an Azure Platform as a Service, such as Azure Data Lake Storage Gen 2 or Azure SQL inside public network	Option 1: Azure Runtime	Microsoft Purview Managed Identity, Service Principal or Access Key / SQL Authentication (depending on Azure data source type)
Data source is an Azure Platform as a Service, such as Azure Data Lake Storage Gen 2 or Azure SQL inside public network	Option 2: Self-hosted integration runtime	Service Principal or Access Key / SQL Authentication (depending on Azure data source type)
Data source is an Azure Platform as a Service, such as Azure Data Lake Storage Gen 2 or Azure SQL inside private network using Azure Private Link Service	Self-hosted integration runtime	Service Principal or Access Key / SQL Authentication (depending on Azure data source type)
Data source is inside an Azure IaaS VM such as SQL Server	Self-hosted integration runtime deployed in Azure	SQL Authentication or Basic Authentication (depending on Azure data source type)
Data source is inside an on-premises system such as SQL Server or Oracle	Self-hosted integration runtime deployed in Azure or in the on-premises network	SQL Authentication or Basic Authentication (depending on Azure data source type)
Multicloud	Azure runtime or self-hosted integration runtime based on data source types	Supported credential options vary based on data sources types
Power BI tenant	Azure Runtime	Microsoft Purview Managed Identity

Use this guide to read more about each source and their supported authentication options.

Other recommendations

Apply security best practices for Self-hosted runtime VMs

Consider securing the deployment and management of self-hosted integration runtime VMs in Azure or your on-premises environment, if self-hosted integration runtime is used to scan data sources in Microsoft Purview.

For self-hosted integration runtime VMs deployed as virtual machines in Azure, follow security best practices recommendations for Windows virtual machines.

- Lock down inbound traffic to your VMs using Network Security Groups and Azure Defender access Just-in-Time.
- Install antivirus or antimalware.
- Deploy Azure Defender to get insights around any potential anomaly on the VMs.
- Limit the amount of software in the self-hosted integration runtime VMs. Although it isn't a mandatory requirement to have a dedicated VM for a self-hosted runtime for Microsoft Purview, we highly suggest using dedicated VMs especially for production environments.
- Monitor the VMs using Azure Monitor for VMs. By using Log analytics agent, you can capture content such as performance metrics to adjust required capacity for your VMs.
- By integrating virtual machines with Microsoft Defender for Cloud, you can you prevent, detect, and respond to threats.
- Keep your machines current. You can enable Automatic Windows Update or use Update Management in Azure Automation to manage operating system level updates for the OS.
- Use multiple machines for greater resilience and availability. You can deploy and register multiple self-hosted integration runtimes to distribute the scans across multiple self-hosted integration runtime machines or deploy the self-hosted integration runtime on a Virtual Machine Scale Set for higher redundancy and scalability.
- Optionally, you can plan to enable Azure backup from your self-hosted integration runtime VMs to increase the recovery time of a self-hosted integration runtime VM if there's a VM level disaster.

Microsoft Purview data security solutions

> *Microsoft Purview service description*

Microsoft Purview data security solutions help you manage and monitor your data and protect information. This article helps you learn about Microsoft Purview data security solutions and quickly get started with deploying these solutions to meet specific security needs for your organization.

Protect sensitive data across clouds, apps, and devices

Your information protection strategy should be driven by your business needs, but every organization has a requirement to protect some or all of its data. Use the capabilities from Microsoft Purview Information Protection (formerly Microsoft Information Protection) to help you discover, classify, protect, and govern sensitive information wherever it lives or travels.

Know your data

Your organization likely has information residing across the Microsoft 365 services, other cloud services, and on-premises. Identifying which items are sensitive and gaining visibility into how they're being used is central to your information protection practice. Microsoft Purview includes:

- Sensitive information types to identify sensitive items by using built-in or custom regular expressions, or a function.
- Trainable classifiers to identify sensitive items by using examples of the data you're interested in rather than identifying elements in the item.
- Data classification provides a graphical identification of items in your organization that have a sensitivity label, a retention label, or have been classified and the actions your users are taking on them

Protect your data

There are many capabilities that you can use from the Microsoft Purview Information Protection solution to help protect your data, wherever it's stored and however it's accessed. However, sensitivity labels are the foundational capability that both provide protection actions and interact with other Purview solutions and capabilities.

Sensitivity labels provide users and admins with visibility into the sensitivity of the data that they're using, and the labels themselves can apply protection actions that include encryption, access restrictions, and visual markings. For more information about the range of labeling scenarios supported, see the Common scenarios for sensitivity labels section from the getting started documentation. For more information about sensitivity labels, see Learn about sensitivity labels.

Encrypt your data and control your encryption keys

Encryption is an important part of your information protection strategy. The encryption process encodes your data (referred to as plaintext) into ciphertext. Unlike plaintext, ciphertext can't be used by people or computers unless and until the ciphertext is decrypted. Decryption requires an encryption key that only authorized users have. Encryption helps ensure that only authorized recipients can decrypt your content.

Microsoft Purview Double Key Encryption helps secure your most sensitive data that is subject to the strictest protection requirements. Microsoft Purview Customer Key helps you meet regulatory or compliance obligations for controlling root keys. You explicitly authorize Microsoft 365 services to use your encryption keys to provide value added cloud services, such as eDiscovery, anti-malware, anti-spam, search indexing, and so on.

Prevent data loss

Unintentional sharing of sensitive items can cause financial harm to your organization and may result in a violation of laws and regulations. Microsoft Purview Data Loss Prevention can help protect your organization against unintentional or accidental sharing of sensitive information both inside and outside of your organization. In a data loss prevention policy, you:

- Define the sensitive information you want to monitor for, like financial, health, medical, and privacy data.
- Where to monitor, like Microsoft 365 services or Windows and macOS devices.
- The conditions that must be matched for a policy to be applied to an item, like items containing credit card, driver's license, or social security numbers.
- The actions to take when a match is found, like audit, block the activity, and block the activity with override.

Address your data security objectives with Data Security Posture Management

Microsoft Data Security Posture Management (DSPM) helps you discover, protect, and investigate sensitive data risks across your digital estate. Unifying other Microsoft Purview solutions by focusing on data security objectives with remediation plans that have guided workflows and reports, DSPM provides visibility and control for both traditional applications and AI apps and agents, regardless of where sensitive data resides.

Analyze and respond to data security incidents with Data Security Investigations

Microsoft Purview Data Security Investigations helps cybersecurity teams in your organization harness generative artificial intelligence (AI) to analyze and respond to data security incidents, risky insiders, and data breaches. Investigations help you quickly identify risks from sensitive data exposure and more effectively collaborate with your partner teams to remediate the issues and simplify tasks that traditionally are time consuming and complex.

Detect and act on risk activities with Insider Risk Management

Microsoft Purview Insider Risk Management uses the full breadth of service and 3rd-party indicators to help you quickly identify, triage, and act on risky user activity in your organization. By using logs from Microsoft 365 and Microsoft Graph, insider risk management allows you to define specific policies to identify risk indicators. After identifying risky activities, you can take action to mitigate these risks.

Restrict communication and collaboration between users with Information Barriers

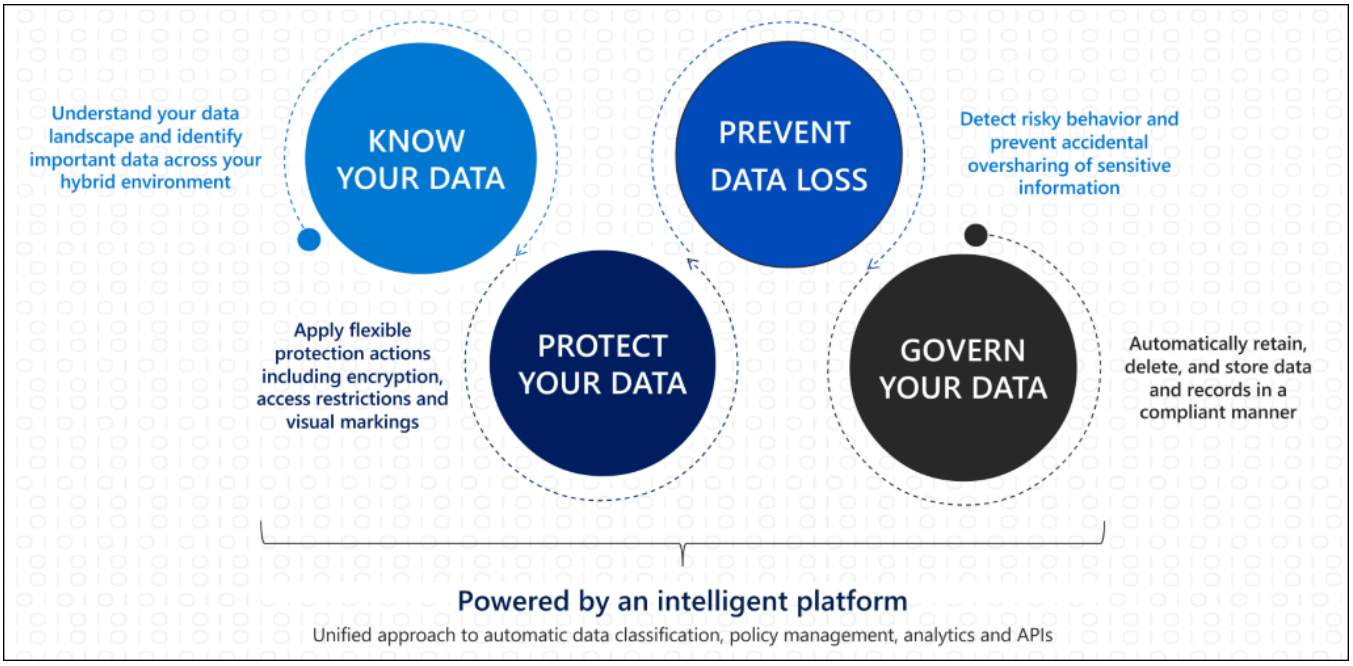
Microsoft Purview Information Barriers (IB) is a compliance solution that allows you to restrict two-way communication and collaboration between groups and users in Microsoft Teams, SharePoint, and OneDrive. Often used in highly regulated industries, IB can help to avoid conflicts of interest and safeguard internal information between users and organizational areas.

Limit access to sensitive data with Privileged Access Management

Having standing access by some users to sensitive information or critical network configuration settings in Microsoft Exchange is a potential pathway for compromised accounts or internal

threat activities. Microsoft Purview Privileged Access Management helps protect your organization from breaches and helps to meet compliance best practices by limiting standing access to sensitive data or access to critical configuration settings. Instead of administrators having constant access, just-in-time access rules are implemented for tasks that need elevated permissions.

Last updated on 05/01/2026



Protect your sensitive data with Microsoft Purview

Summarize this article for me

> *Microsoft Purview service description*

Implement capabilities from **Microsoft Purview Information Protection** (formerly Microsoft Information Protection) to help you discover, classify, and protect sensitive information wherever it lives or travels.

These information protection capabilities give you the tools to know your data, protect your data, and prevent data loss.

Use the following sections to learn more about the available capabilities and how to get started with each one. However, if you're looking for a guided deployment, see Deploy an information protection solution with Microsoft Purview.

For information about governing your data for compliance or regulatory requirements, see Govern your data with Microsoft Purview.

Know your data

To understand your data landscape and identify sensitive data across your hybrid environment, use the following capabilities:

Expand table

Capability	What problems does it solve?	Get started
Sensitive information types	Identifies sensitive data by using built-in or custom regular expressions or a function. Corroborative evidence includes keywords, confidence levels, and proximity.	Customize a built-in sensitive information type
Trainable classifiers	Identifies sensitive data by using examples of the data you're interested in rather than identifying elements in the item (pattern matching). You can use built-in classifiers or train a classifier with your own content.	Get started with trainable classifiers
Data classification	A graphical identification of items in your organization that have a sensitivity label, a retention label, or have been classified. You can also use this information to gain insights into the actions that your users are taking on these items.	Get started with content explorer Get started with activity explorer

Protect your data

To apply flexible protection actions that include encryption, access restrictions, and visual markings, use the following capabilities:

Expand table

Capability	What problems does it solve?	Get started
Sensitivity labels	A single labeling solution across apps, services, and devices to protect your data as it travels inside and outside your organization. Example scenarios: - Manage sensitivity labels for Office apps - Encrypt documents and emails - Protect calendar items, Teams meetings, and chat For a comprehensive list of supported scenarios for sensitivity labels, see the Get started documentation.	Get started with sensitivity labels
Microsoft Purview Information Protection client	For Windows computers, extends labeling to File Explorer and PowerShell	Extend sensitivity labeling on Windows
Double Key Encryption	Under all circumstances, only your organization can ever decrypt protected content or for regulatory requirements, you must hold encryption keys within a geographical boundary.	Deploy Double Key Encryption

Capability	What problems does it solve?	Get started
Message Encryption	Encrypts email messages and attached documents that are sent to any user on any device, so only authorized recipients can read emailed information. Example scenario: Revoke email encrypted by Advanced Message Encryption	Set up Message Encryption
Service encryption with Customer Key	Protects against viewing of data by unauthorized systems or personnel, and complements BitLocker disk encryption in Microsoft datacenters.	Set up Customer Key
SharePoint Information Rights Management (IRM)	Protects SharePoint lists and libraries so that when a user checks out a document, the downloaded file is protected so that only authorized people can view and use the file according to policies that you specify.	Set up Information Rights Management (IRM) in SharePoint admin center
Rights Management connector	Protection-only for existing on-premises deployments that use Exchange or SharePoint Server, or file servers that run Windows Server and File Classification Infrastructure (FCI).	Steps to deploy the RMS connector
Information protection scanner	Discovers, labels, and protects sensitive information that resides in data stores that are on premises.	Configuring and installing the information protection scanner
Microsoft Defender for Cloud Apps	Discovers, labels, and protects sensitive information that resides in data stores that are in the cloud.	Discover, classify, label, and protect regulated and sensitive data stored in the cloud
Microsoft Purview Data Map	Identifies sensitive data and applies automatic labeling to content in Microsoft Purview Data Map assets. These include files in storage such as Azure Data Lake and Azure Files, and schematized data such as columns in Azure SQL DB and Azure Cosmos DB.	Labeling in Microsoft Purview Data Map
Microsoft Information Protection SDK	Extends sensitivity labels to third-party apps and services. Example scenario: Set and get a sensitivity label (C++)	Microsoft Information Protection (MIP) SDK setup and configuration

Prevent data loss

To help prevent accidental oversharing of sensitive information, use the following capabilities:

Expand table

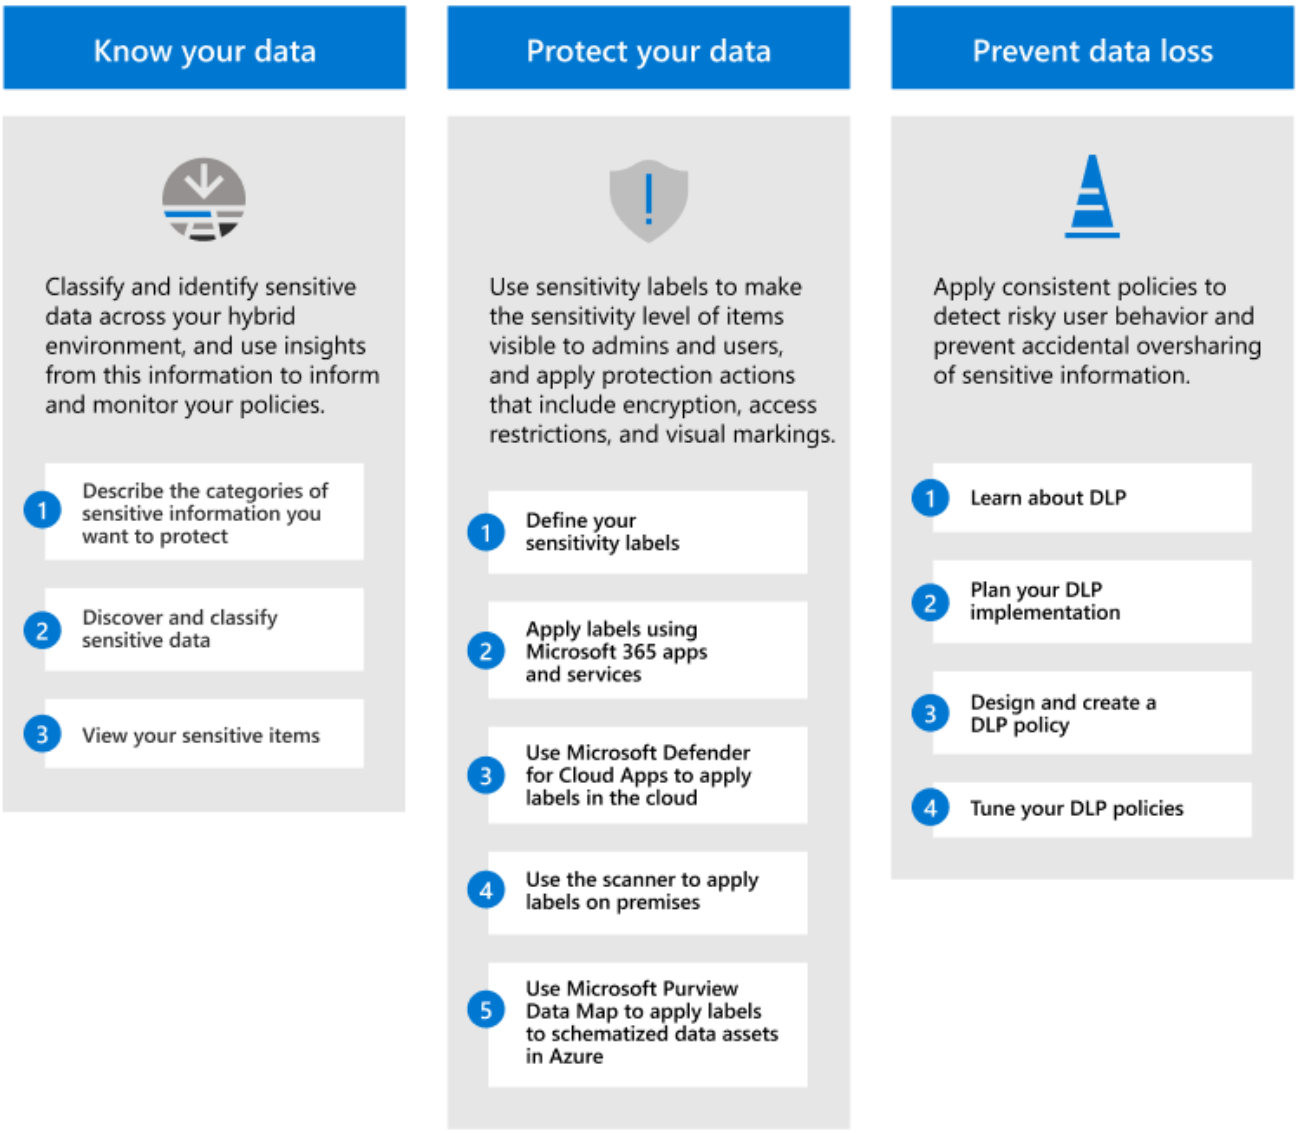
Capability	What problems does it solve?	Get started
Microsoft Purview Data Loss Prevention	Helps prevent unintentional sharing of sensitive items.	Learn about data loss prevention
Endpoint data loss prevention	Extends DLP capabilities to items that are used and shared on Windows 10 computers.	Get started with Endpoint data loss prevention
Microsoft Purview extension for Chrome	Extends DLP capabilities to the Chrome browser	Get started with the Microsoft Purview extension for Chrome
Microsoft Purview data loss prevention on-premises repositories	Extends DLP monitoring of file activities and protective actions for those files to on-premises file shares and SharePoint folders and document libraries.	Get started with Microsoft Purview data loss prevention on-premises repositories
Protect sensitive information in Microsoft Teams chat and channel messages	Extends some DLP functionality to Teams chat and channel messages	Learn about the default data loss prevention policy in Microsoft Teams

Licensing requirements

License requirements to protect your sensitive data depend on the scenarios and features you use. Rather than set licensing requirements for each capability listed on this page, for more information, see the Microsoft Purview service description and the related PDF download for feature-level licensing requirements.

Last updated on 02/27/2026

Deploy an information protection solution with Microsoft Purview



> *Microsoft Purview service description*

Your information protection strategy is driven by your business needs. Many organizations must comply with regulations, laws, and business practices. Additionally, organizations need to protect proprietary information, such as data for specific projects.

Microsoft Purview Information Protection (formerly Microsoft Information Protection) provides a framework, process, and capabilities you can use to protect sensitive data across clouds, apps, and devices.

Microsoft Purview Information Protection framework

Use Microsoft Purview Information Protection to help you discover, classify, protect, and govern sensitive information wherever it lives or travels.

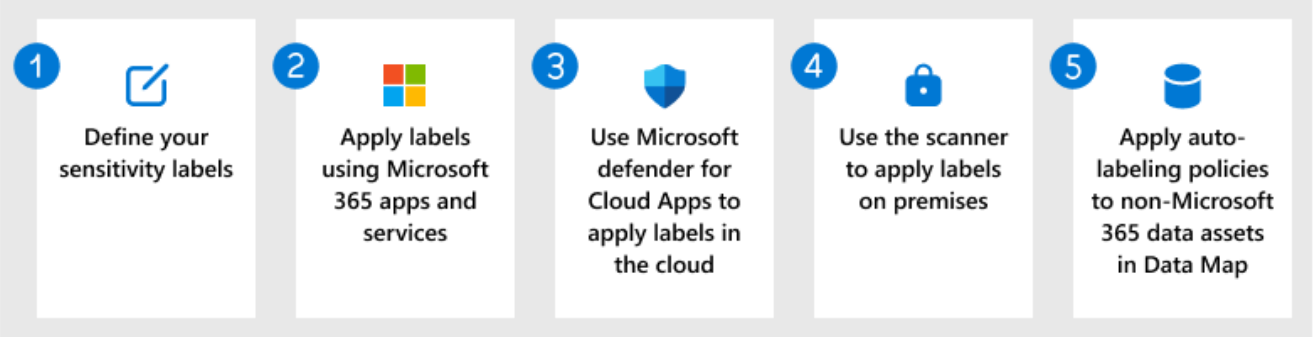
For data governance, see Deploy a data governance solution with Microsoft Purview.

> **Tip**
>
> Consider using the new version of Data Security Posture Management (DSPM) to supplement the information on this page and jumpstart securing your data with Microsoft Purview Information Protection.
>
> DSPM helps you discover, protect, and investigate sensitive data risks across your digital estate by unifying Microsoft Purview Information Protection with other Microsoft Purview solutions and capabilities. With a focus on data security objectives with guided workflows that offer default sensitivity labels, default policies, and more, DSPM helps you monitor, assess, and remediate data risks regardless of where sensitive data resides.

Licensing

Microsoft Purview Information Protection capabilities are included with Microsoft Purview. The licensing requirements can vary even within capabilities, depending on configuration options. To identify licensing requirements and options, see the Microsoft Purview service description.

Know your data



Knowing where your sensitive data resides is often the biggest challenge for many organizations. Microsoft Purview Information Protection data classification helps you to discover and accurately classify ever-increasing amounts of data that your organization creates. Graphical representations help you gain insights into this data so you can set up and monitor policies to protect and govern it.

Expand table

Step	Description	More information
1	Describe the categories of sensitive information you want to protect. You already have an idea of what types of information are most valuable to your org and what types aren't. Work with stakeholders to describe these categories that are your starting point.	Learn about sensitive information types Learn about trainable classifiers
2	Discover and classify sensitive data. Sensitive data in items can be found by using many different methods that include default DLP policies, manual labeling by users, and automated pattern recognition using sensitive information types or machine learning.	Classifiers overview
3	View your sensitive items. Use content explorer and activity explorer for a deeper analysis of sensitive items and the actions that users are taking on these items.	Get started with content explorer Get started with activity explorer

Protect your data

Use the information from knowing where your sensitive data resides to help you more efficiently protect it. However, there's no need to wait—you can start to protect your data immediately with a combination of manual, default, and automatic labeling. Then, use content explorer and activity explorer from the previous section to confirm what items are labeled and how your labels are being used.

Expand table

Step	Description	More information
1	Define your sensitivity labels and policies that will protect your organization's data. In addition to identifying the sensitivity of content, these labels can apply protection actions such as content markings (headers, footers, watermarks), encryption, and other access controls. Example sensitivity labels: **Personal** **Public** **General** - **Anyone (unrestricted)** - **All Employees (unrestricted)** **Confidential** - **Anyone (unrestricted)** - **All Employees** - **Trusted People** **Highly Confidential** - **All Employees** - **Specific People** Example sensitivity label policy: 1. Publish all labels to all users in the tenant 2. Default label of **General \ All Employees (unrestricted)** for items	Get started with sensitivity labels Create and configure sensitivity labels and their policies Restrict access to content by using sensitivity labels to apply encryption

Step	Description	More information
	3. Users must provide a justification to remove a label or lower its classification	
2	Label and protect data for Microsoft 365 apps and services. Sensitivity labels are supported for Microsoft 365 Word, Excel, PowerPoint, Outlook, Teams meetings, and also containers that include SharePoint and OneDrive sites, and Microsoft 365 groups. Use a combination of labeling methods such as manual labeling, automatic labeling, a default label, and mandatory labeling. Example configuration for client-side auto-labeling: 1. Recommend **Confidential \ Anyone (unrestricted)** if 1-9 credit card numbers 2. Recommend **Confidential \ All Employees** if 10+ credit card numbers -- typical end user experience, and the user selects the button to show sensitive content (Word only) Example configuration for service-side auto-labeling: Apply to all locations (Exchange, SharePoint, OneDrive) 1. Apply **Confidential \ Anyone (unrestricted)** if 1-9 credit card numbers 2. Apply **Confidential \ All Employees** if 10+ credit card numbers 3. Apply **Confidential \ Anyone (unrestricted)** if 1-9 US personal data and full names 4. Apply **Confidential \ All Employees** if 10+ US personal data and full names	Manage sensitivity labels in Office apps Enable sensitivity labels for files in SharePoint and OneDrive Enable co-authoring for files encrypted with sensitivity labels Configure a default sensitivity label for a SharePoint document library Automatically apply a sensitivity label to Microsoft 365 data Use sensitivity labels to protect collaborative workspaces (groups and sites) Use sensitivity labels to protect calendar items, Teams meetings, and chat Use sensitivity labels with Microsoft Loop Use sensitivity labels to set the default sharing link for sites and documents in SharePoint and OneDrive Apply a sensitivity label to a model in Microsoft Syntex Sensitivity labels in Power BI
3	Discover, label, and protect sensitive items that reside in data stores in the cloud (Box, GSuite, SharePoint, and OneDrive) by using Microsoft Defender for Cloud Apps with your sensitivity labels.	Discover, classify, label, and protect regulated and sensitive data stored in the cloud

Step	Description	More information
	Example configuration for a file policy: Looks for credit card numbers in files stored in a Box account, and then applies a sensitivity label to identify the highly confidential info and encrypt it.	
4	Discover, label, and protect sensitive items that reside in data stores on premises by deploying the information protection scanner with your sensitivity labels.	Configuring and installing the information protection scanner
5	Auto-apply sensitivity labels in Microsoft Purview Data Map to discover and label items for Azure Blob Storage, Azure files, and Azure Data Lake Storage Gen2.	Learn about sensitivity labels in Microsoft Purview Data Map

If you're a developer who wants to extend sensitivity labels to line-of-business apps or third-party SaaS apps, see Microsoft Information Protection (MIP) SDK setup and configuration.

Additional protection capabilities

Microsoft Purview includes additional capabilities to help protect data. Not every customer needs these capabilities, and some might be superseded by more recent releases.

Refer to the Protect your data with Microsoft Purview page for the full list of protection capabilities.

Prevent data loss

Deploy Microsoft Purview Data Loss Prevention (DLP) policies to govern and prevent the inappropriate sharing, transfer, or use of sensitive data across apps and services. These policies help users make the right decisions and take the right actions when they're using sensitive data.

Expand table

Step	Description	More information
1	Learn about DLP. Organizations have sensitive information under their control, such as financial data, proprietary data, credit card numbers, health records, and social security numbers. To help protect this sensitive data and reduce risk, they need a way to prevent their users from inappropriately sharing it with people who shouldn't have it. This practice is called data loss prevention (DLP).	Learn about data loss prevention
2	Plan your DLP implementation. Every organization will plan for and implement data loss prevention (DLP) differently, because every organization's business needs, goals, resources, and situation are unique to them. However, there are elements that are common to all successful DLP implementations.	Plan for data loss prevention
3	Design and create a DLP policy. Creating a data loss prevention (DLP) policy is quick and easy, but getting a policy to yield the intended results can be time consuming if you have to do a lot of tuning. Taking the time to design a policy before you implement it gets you to the desired results faster, and with fewer unintended issues, than tuning by trial and error alone. Help prevent sharing credit card numbers through email: Prevents emails being sent if they contain credit card numbers or the email has a specific sensitivity label that identities highly confidential info.	Design a DLP policy DLP policy reference Create and deploy data loss prevention policies
4	Tune your DLP policies. After you deploy a DLP policy, you'll see how well it meets the intended purpose. Use that information to adjust your policy settings for better performance.	Create and deploy data loss prevention policies

Deployment strategies

The credit card number examples are often helpful for initial testing and end user education. Even if your organization doesn't typically need to protect credit card numbers, the concept of these being sensitive items that need protection is easily understood by users. Many websites provide credit card numbers that are suitable for testing purposes only. You can also search for sites that provide credit card number generators so that you can paste the numbers into documents and emails.

When you're ready to move your automatic labeling and DLP policies into production, change to classifiers and configurations that are suitable for the type of data used by your organization. For example, you might need to use trainable classifiers for intellectual property and specific types of documents, or exact data match (EDM) sensitive information types for privacy data that's related to customers or employees.

Or, you might want to start by discovering and protecting IT-related information that is frequently the target of security attacks. Then, supplement this by checking for and preventing the sharing of passwords with DLP policies for email and Teams chat:

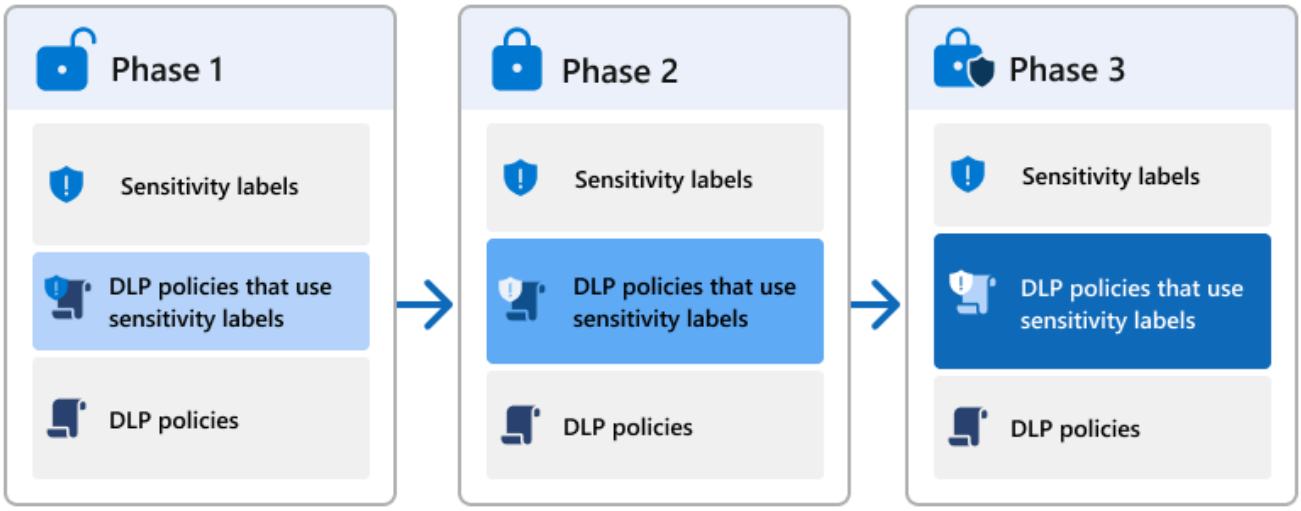
- Use the trainable classifiers **IT** and **IT Infra and Network Security Documents**
- Use the built-in sensitive info type **General Password** and create a custom sensitive info type for "password is" for the different languages used by your users

Deploying an information protection solution isn't a linear deployment but iterative, and often circular. The more you know your data, the more accurately you can label it, and prevent data leakage. The results of those applied labels and policies flow into the Reports and tools, which in turn makes more sensitive data visible for you to protect. Or, if you're already protecting that sensitive data, consider whether it requires additional protective actions.

You can start to manually label data as soon as you've defined sensitivity labels. The same classifiers that you use for DLP can be used to automatically find and label more data. You can even use sensitivity labels as a classifier, for example, block sharing items that are labeled highly confidential.

Most customers already have some solutions in place to protect their data. Your deployment strategy might be to build on what you already have, or focus on gaps that offer the most business value or addresses high risk areas.

To help you plan your unique deployment strategy, reference Get started with sensitivity labels and Plan for data loss prevention.



Consider a phased deployment

You might prefer to deploy information protection by using a phased deployment that implements progressively restrictive controls. This approach gradually introduces new protection measures for users as you gain familiarity and confidence with the technology. For example:

- From default labels and no encryption, to recommending labels that apply encryption when sensitive data is found, and then automatically applying labels when sensitive data is found.

- DLP policies that progress from auditing oversharing actions, to more restrictive blocking with warning to educate users, and then blocking all sharing.

Details of such a phased deployment might look something like the following plan, where sensitivity labels and DLP policies become more integrated with each other to provide greater data protection than if they were used independently:

Phase 1

Sensitivity label configurations:

- **General\All Employees**: Default label for email. No encryption. If applied on emails, block users from over-sharing.
- **Confidential\All Employees**: Default label for documents. No encryption. If applied on emails, block users from over-sharing.
- **Highly Confidential\All Employees**: No encryption. If applied on emails, block users from over-sharing.

DLP policy A:

- If 1-2 instances of credit cards are found, block external sharing except if the item is labeled as **Personal** or **Confidential\Anyone (unrestricted)**. Use logging and reporting for analysis.

DLP policy B:

- If 3-9 instances of credit cards are found, block external sharing, cloud egress, and copy to removable drives except if the item is labeled as **Confidential\Anyone (unrestricted)**. Use logging and reporting for analysis.

DLP policy C:

- If 10+ instances of credit cards are found, block external sharing, cloud egress, and copy to removable drives with no exceptions. Use logging and reporting for analysis.

Configuration details for this example phased deployment:

- Default sublabel for a parent label or label group
- Data loss prevention Exchange conditions and actions reference
- Confidence levels and other elements of a sensitivity type
- Use sensitivity labels as conditions in DLP policies
- Encryption that lets users assign permissions
- Encryption for specific usage rights
- Configure and view alerts for data loss prevention policies

For other deployment guidance that includes a phased deployment strategy, see Secure by default with Microsoft Purview and protect against oversharing from our Product Engineering team.

Training resources

Interactive guides: Microsoft Purview Information Protection

Learning modules for consultants and admins:

- Introduction to information protection and data lifecycle management in Microsoft Purview
- Classify data for protection and governance
- Protect information in Microsoft Purview
- Prevent data loss in Microsoft Purview

To help train your users to apply and use the sensitivity labels that you configure for them, see End-user documentation for sensitivity labels.

When you deploy data loss prevention policies for Teams, you might find the following end-user guidance useful as an introduction to this technology. It includes some potential messages that users might see: Teams messages about data loss prevention (DLP) and communication compliance policies.

Last updated on 03/31/2026

Microsoft Purview Information Protection for Office 365 operated by 21Vianet

09/02/2025

This article covers the differences between Microsoft Purview Information Protection support for Office 365 operated by 21Vianet and commercial offerings that are limited to offering previously known as Azure Information Protection (AIP), as well as specific configuration instructions for customers in China— including how to install the information protection scanner and manage content scan jobs.

Differences between 21Vianet and commercial offerings

While our goal is to deliver all commercial features and functionality to customers in China with our Microsoft Purview Information Protection support for Office 365 operated by 21Vianet offer, there's some missing functionality:

- Active Directory Rights Management Services (AD RMS) encryption is supported only in Microsoft 365 Apps for enterprise (build 11731.10000 or later). Office Professional Plus doesn't support AD RMS.
- Migration from AD RMS to the Azure Rights Management service isn't currently available.
- Sharing of encrypted emails with users in the commercial cloud is supported.
- Sharing of documents and email attachments with users in the commercial cloud isn't currently available. This includes Office 365 operated by 21Vianet users in the commercial cloud, non-Office 365 operated by 21Vianet users in the commercial cloud, and users with an RMS for Individuals license.
- IRM with SharePoint (IRM-protected sites and libraries) isn't currently available.
- The Mobile Device Extension for AD RMS isn't currently available.
- The Microsoft Purview Information Protection viewer for iOS and Android isn't supported by Azure China 21Vianet.
- The scanner area of the Microsoft Purview portal is unavailable to customers in China. Use PowerShell commands instead of performing actions in the portal, such as managing and running your content scan jobs.

- Network endpoints for the Microsoft Purview Information Protection client within the 21Vianet environment are different than the endpoints required for other cloud services. Network connectivity from clients to the following endpoints is required:
  - Download label and label policies: `*.protection.partner.outlook.cn`
  - Azure Rights Management service: `*.aadrm.cn`

- Document Tracking and Revocation *by users* isn't currently available.

Configuration for customers in 21Vianet

To configure Microsoft Purview Information Protection support for Office 365 operated by 21Vianet:

1. Enable Rights Management for the tenant.
2. Add the Microsoft Information Protection Sync Service service principal.
3. Configure DNS encryption.
4. Install and configure the Microsoft Purview Information Protection client.
5. Configure Windows settings.
6. Install the information protection scanner and manage content scan jobs.

Step 1: Enable Rights Management for the tenant

For the encryption to work correctly, the Azure Rights Management service must be enabled for the tenant.

1. Check if this service is enabled:
   a. Launch PowerShell as an administrator.
   b. If the AIPService module isn't installed, run `Install-Module AipService`.
   c. Import the module using `Import-Module AipService`.
   d. Connect to the service using `Connect-AipService -environmentname azurechinacloud`.
   e. Run `(Get-AipServiceConfiguration).FunctionalState` and check if the state is `Enabled`.
2. If the functional state is `Disabled`, run `Enable-AipService`.

Step 2: Add the Microsoft Information Protection Sync Service service principal

The **Microsoft Information Protection Sync Service** service principal isn't available in Azure China tenants by default, and is required for Microsoft Purview Information Protection. Create this service principal manually via the Azure Az PowerShell module.

1. If you don't have the Azure Az module installed, install it or use a resource where the Azure Az module comes preinstalled, such as Azure Cloud Shell. For more information, see Install the Azure Az PowerShell module.

2. Connect to the service using the Connect-AzAccount cmdlet and the `azurechinacloud` environment name:

   PowerShell

   ```
   Connect-azaccount -environmentname azurechinacloud
   ```

3. Create the **Microsoft Information Protection Sync Service** service principal manually using the New-AzADServicePrincipal cmdlet and the `870c4f2e-85b6-4d43-bdda-6ed9a579b725` application ID for the Microsoft Purview Information Protection Sync Service:

   PowerShell

   ```
   New-AzADServicePrincipal -ApplicationId 870c4f2e-85b6-4d43-bdda-6ed9a579b725
   ```

4. After adding the service principal, add the relevant permissions required to the service.

Step 3: Configure DNS encryption

For encryption to work correctly, Office client applications must connect to the China instance of the service and bootstrap from there. To redirect client applications to the right service instance, the tenant admin must configure a DNS SRV record with information about the URL for the Azure Rights Management service. Without the DNS SRV record, the client application attempts to connect to the public cloud instance by default and will fail.

Also, the assumption is that users will log in with a username based off the tenant-owned domain (for example, `joe@contoso.cn`), and not the `onmschina` username (for example, `joe@contoso.onmschina.cn`). The domain name from the username is used for DNS redirection to the correct service instance.

Configure DNS encryption - Windows

1. Get the Azure Rights Management service ID:

a. Launch PowerShell as an administrator.
b. If the AIPService module isn't installed, run `Install-Module AipService`.
c. Connect to the service using `Connect-AipService -environmentname azurechinacloud`.
d. Run `(Get-AipServiceConfiguration).RightsManagementServiceId` to get the service ID.

2. Log in to your DNS provider, navigate to the DNS settings for the domain, and then add a new SRV record.

   - Service = `_rmsredir`
   - Protocol = `_http`
   - Name = `_tcp`
   - Target = `[GUID].rms.aadrm.cn` (where GUID is the Azure Rights Management service ID)
   - Priority, Weight, Seconds, TTL = default values

3. Associate the custom domain with the tenant in the Azure portal. This adds an entry in DNS, which might take several minutes to get verified after you add the value to the DNS settings.

4. Log in to the Microsoft 365 admin center with the corresponding global admin credentials and add the domain (for example, `contoso.cn`) for user creation. In the verification process, additional DNS changes might be required. Once verification is done, users can be created.

Configure DNS encryption - Mac, iOS, Android

Log in to your DNS provider, navigate to the DNS settings for the domain, and then add a new SRV record.

- Service = `_rmsdisco`
- Protocol = `_http`
- Name = `_tcp`
- Target = `api.aadrm.cn`
- Port = `80`
- Priority, Weight, Seconds, TTL = default values

Step 4: Install and configure the labeling client

Download and install the Microsoft Purview Information Protection client from the Microsoft Download Center.

For more information, see:

- Extend sensitivity labeling on Windows
- Microsoft Purview Information Protection client - Release management and supportability

Step 5: Configure Windows settings

Windows needs the following registry key for authentication to point to the correct sovereign cloud for Azure China:

- Registry node = `HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Microsoft\MSIP`
- Name = `CloudEnvType`
- Value = `6` (default = 0)
- Type = `REG_DWORD`

> **Important**
>
> Make sure you don't delete the registry key after an uninstall. If the key is empty, incorrect, or non-existent, the functionality will behave as the default value (default value = 0 for the commercial cloud). If the key is empty or incorrect, a print error is also added to the log.

Step 6: Install the information protection scanner and manage content scan jobs

Install the Microsoft Purview Information Protection scanner to scan your network and content shares for sensitive data, and apply classification and protection labels as configured in your organization's policy.

When configuring and managing your content scan jobs, use the following procedure instead of the Microsoft Purview portal that's used by the commercial offerings.

For more information, see Learn about the information protection scanner and Manage your content scan jobs using PowerShell only.

To install and configure your scanner:

1. Sign in to the Windows Server computer that will run the scanner. Use an account that has local administrator rights and that has permissions to write to the SQL Server master database.

2. Start with PowerShell closed. If you've previously installed the information protection scanner, make sure the Microsoft Purview Information Protection Scanner service is stopped.

3. Open a Windows PowerShell session with the **Run as an administrator** option.

4. Run the Install-Scanner cmdlet, specifying your SQL Server instance on which to create a database for the Microsoft Purview Information Protection scanner, and a meaningful name for your scanner cluster.

   ```PowerShell
   Install-Scanner -SqlServerInstance <name> -Cluster <cluster name>
   ```

   > **Tip**
   >
   > You can use the same cluster name in the **Install-Scanner** command to associate multiple scanner nodes to the same cluster. Using the same cluster for multiple scanner nodes enables multiple scanners to work together to perform your scans.

5. Verify that the service is now installed by using **Administrative Tools** > **Services**.

   The installed service is named **Microsoft Purview Information Protection Scanner** and is configured to run by using the scanner service account that you created.

6. Get an Azure token to use with your scanner. A Microsoft Entra token allows the scanner to authenticate to the Azure Information Protection service, enabling the scanner to run non-interactively.

   a. Open the Azure portal and create a Microsoft Entra application to specify an access token for authentication. For more information, see Run information protection labeling cmdlets unattended.

      > **Tip**
      >
      > When creating and configuring Microsoft Entra applications for the **Set-Authentication** command, the **Request API permissions** pane shows the **APIs my organization uses** tab instead of the **Microsoft APIs** tab. Select the **APIs my organization uses** to then select **Azure Rights Management Services**.

   b. From the Windows Server computer, if your scanner service account has been granted the **Log on locally** right for the installation, sign in with this account and start a PowerShell session.

      If your scanner service account can't be granted the **Log on locally** right for the installation, use the *OnBehalfOf* parameter with Set-Authentication, as described in

Run information protection labeling cmdlets unattended.

c. Run Set-Authentication, specifying values copied from your Microsoft Entra application:

```
PowerShell

Set-Authentication -AppId <ID of the registered app> -AppSecret <client
secret sting> -TenantId <your tenant ID> -DelegatedUser <Azure AD account>
```

For example:

```
PowerShell

$pscreds = Get-Credential CONTOSO\scanner
Set-Authentication -AppId "77c3c1c3-abf9-404e-8b2b-4652836c8c66" -AppSecret
"OAkk+rnuYc/u+]ah2kNxVbtrDGbS47L4" -DelegatedUser scanner@contoso.com -
TenantId "9c11c87a-ac8b-46a3-8d5c-f4d0b72ee29a" -OnBehalfOf $pscreds
Acquired application access token on behalf of CONTOSO\scanner.
```

The scanner now has a token to authenticate to Microsoft Entra ID. This token is valid for one year, two years, or never, according to your configuration of the **Web app /API** client secret in Microsoft Entra ID. When the token expires, you must repeat this procedure.

7. Run the Set-ScannerConfiguration cmdlet to set the scanner to function in offline mode. Run:

```
PowerShell

Set-ScannerConfiguration -OnlineConfiguration Off
```

8. Run the Set-ScannerContentScanJob cmdlet to create a default content scan job.

The only required parameter in the **Set-ScannerContentScanJob** cmdlet is **Enforce**. However, you may want to define other settings for your content scan job at this time. For example:

```
PowerShell

Set-ScannerContentScanJob -Schedule Manual -DiscoverInformationTypes
PolicyOnly -Enforce Off -DefaultLabelType PolicyDefault -RelabelFiles Off -
PreserveFileDetails On -IncludeFileTypes '' -ExcludeFileTypes '.msg,.tmp' -
DefaultOwner <account running the scanner>
```

The syntax above configures the following settings while you continue the configuration:

- Keeps the scanner run scheduling to *manual*
- Sets the information types to be discovered based on the sensitivity labeling policy
- Does *not* enforce a sensitivity labeling policy
- Automatically labels files based on content, using the default label defined for the sensitivity labeling policy
- Does *not* allow for relabeling files
- Preserves file details while scanning and auto-labeling, including *date modified*, *last modified*, and *modified by* values
- Sets the scanner to exclude .msg and .tmp files when running
- Sets the default owner to the account you want to use when running the scanner

9. Use the Add-ScannerRepository cmdlet to define the repositories you want to scan in your content scan job. For example, run:

```
PowerShell

Add-ScannerRepository -OverrideContentScanJob Off -Path 'c:\repoToScan'
```

Use one of the following syntaxes, depending on the type of repository you're adding:

- For a network share, use `\\Server\Folder`.
- For a SharePoint library, use `http://sharepoint.contoso.com/Shared%20Documents/Folder`.
- For a local path: `C:\Folder`
- For a UNC path: `\\Server\Folder`

> **Note**
>
> Wildcards aren't supported and WebDav locations aren't supported.
>
> To modify the repository later on, use the Set-ScannerRepository cmdlet instead.

Continue with the following steps as needed:

- Run a discovery cycle and view reports for the scanner
- Use PowerShell to configure the scanner to apply classification and protection
- Use PowerShell to configure a DLP policy with the scanner

The following table lists PowerShell cmdlets that are relevant for installing the scanner and managing your content scan jobs:

Expand table

Cmdlet	Description
Add-ScannerRepository	Adds a new repository to your content scan job.
Get-ScannerConfiguration	Returns details about your cluster.
Get-ScannerContentScan	Gets details about your content scan job.
Get-ScannerRepository	Gets details about repositories defined for your content scan job.
Remove-ScannerContentScan	Deletes your content scan job.
Remove-ScannerRepository	Removes a repository from your content scan job.
Set-ScannerContentScan	Defines settings for your content scan job.
Set-ScannerRepository	Defines settings for an existing repository in your content scan job.

For more information, see:

- Learn about the information protection scanner
- Configuring and installing the information protection scanner
- Manage your content scan jobs using PowerShell only

Default sensitivity labels and policies to protect your data

> *Microsoft Purview service description*

When you use Data Security Posture Management or Data Security Posture Management for AI (classic), you can activate some default sensitivity labels and their policies for Microsoft Purview Information Protection:

- Sensitivity labels and a sensitivity label publishing policy
- Client-side auto-labeling
- Service-side auto-labeling

> **Note**
>
> The default labels and policies are now automatically created for new customers who have an eligible license for Microsoft Purview.

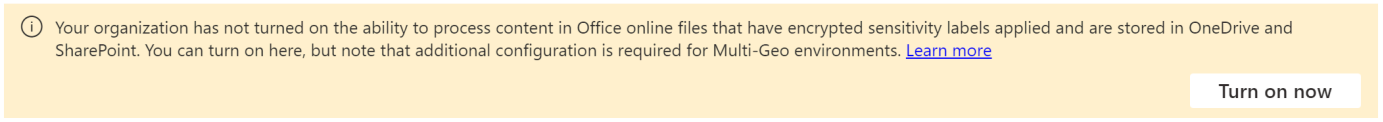
These default configurations get you up and running quickly with Microsoft Purview Information Protection to help you protect your data in Microsoft 365. You can use them as-is, make just a few changes, or fully customize them to better suit your business requirements. Then, extend the labels beyond Microsoft 365, to protect data in other sources, such as Microsoft Azure and Microsoft Foundry.

If you're an existing customer who wasn't eligible for the automatic creation of the default labels and policies, you can activate the default configurations that are supported by your licenses if you haven't yet configured an equivalent:

Expand table

Default configuration	Equivalent
Sensitivity labels and a sensitivity label policy	Published sensitivity labels
Client-side auto-labeling	One or more sensitivity labels configured to automatically apply (or recommend to users) in Office apps

Default configuration	Equivalent
Service-side auto-labeling	At least one auto-labeling policy that's turned on



Activate the default labels and policies

If the default labels and polices aren't automatically created for you, you can activate them:

- From the current version of Data Security Posture Management > **Actions** > **Setup tasks**, select **Protect your data with sensitivity labels**
- From Data Security Posture Management for AI (classic) > **Recommendations**, select **Protect your data with sensitivity labels**

After the labels and policies are created, you'll need to enable sensitivity labels for SharePoint and OneDrive. This one-time, manual step is a prerequisite to use sensitivity labels in Office for the web, and auto-labeling policies for SharePoint and OneDrive.

To do this step, use the following banner at the top of the **Information Protection** > **Overview** page, and select **Turn on now**. If you don't see this banner, sensitivity labels for SharePoint and OneDrive have already been enabled for your tenant.

For more information about this capability, see Enable sensitivity labels for files in SharePoint and OneDrive.

Default sensitivity labels

When you don't have sensitivity labels that are published, we'll create the following labels for you:

Expand table

Label name	Label description for users	Settings
Personal	Non-business data, for personal use only.	**Scope**: Files & other data assets, Emails, Meetings* **Content marking**: No **Auto-labeling**: No

Label name	Label description for users	Settings
		Group settings: No **Site settings**: No **Auto-labeling for database columns**: None
Public	Business data that is specifically prepared and approved for public consumption.	**Scope**: Files & other data assets, Emails, Meetings* **Content marking**: No **Auto-labeling**: No **Group settings**: No **Site settings**: No **Auto-labeling for database columns**: None
General	Business data that is not intended for public consumption. However, this can be shared with external partners, as required. Examples include a company internal telephone directory, organizational charts, internal standards, and most internal communication.	**Scope**: Files & other data assets, Emails **Content marking**: No **Auto-labeling**: No **Group settings**: No **Site settings**: No **Auto-labeling for database columns**: None
General \ Anyone (unrestricted)	Organization data that isn't intended for public consumption but can be shared with external partners if appropriate. Examples include customer conversations that don't include sensitive info or released marketing materials.	**Scope**: Files & other data assets, Emails, Meetings* **Content marking**: No **Auto-labeling**: No

Label name	Label description for users	Settings
		Group settings: No **Site settings**: No **Auto-labeling for database columns**: None
General \ All Employees (unrestricted)	Organization data that isn't intended for public consumption. If you need to share this content with external partners, confirm with other data owners that it's OK to share and then change the label to General \ Anyone (unrestricted) . Examples include a company internal telephone directory, organizational charts, internal standards, and most internal communication.	**Scope**: Files & other data assets, Emails, Meetings* **Content marking**: No **Auto-labeling**: No **Group settings**: No **Site settings**: No **Auto-labeling for database columns**: None
Confidential	Sensitive business data that could cause damage to the business if shared with unauthorized people. Examples include contracts, security reports, forecast summaries, and sales account data.	**Scope**: Files & other data assets, Emails **Content marking**: No **Auto-labeling**: No **Group settings**: No **Site settings**: No **Auto-labeling for database columns**: None
Confidential \ Anyone (unrestricted)	Confidential data that doesn't need to be encrypted. Use this option with care and appropriate business justification.	This label is selected for client-side auto-labeling and service-side auto-labeling. **Scope**: Files & other data assets, Emails, Meetings*

Label name	Label description for users	Settings
		Content marking: Footer: Classified as Confidential **Auto-labeling**: Recommend that users apply the label **Group settings**: No **Site settings**: No **Auto-labeling for database columns**: None
Confidential \ All Employees	Confidential data that requires protection, which allows all employees full permissions. Data owners can track and revoke content.	This label is selected for client-side auto-labeling and service-side auto-labeling. **Scope**: Files & other data assets, Emails, Meetings* **Encryption**: All users and groups in the org: Co-Author **Content marking**: Footer: Classified as Confidential **Auto-labeling**: Recommend that users apply the label **Group settings**: No **Site settings**: No **Auto-labeling for database columns**: None
Confidential \ Trusted People	Confidential data that can be shared with trusted people inside and outside your organization. These people can also reshare the data as needed.	**Scope**: Files & other data assets, Emails, Meetings*

Label name	Label description for users	Settings
		Encryption: Let users assign permissions: - Encrypt-Only for Outlook - Prompt users in Word, PowerPoint, and Excel **Content marking**: Footer: Classified as Confidential **Auto-labeling**: No **Group settings**: No **Site settings**: No **Auto-labeling for database columns**: None
Highly Confidential	Very sensitive business data that would cause damage to the business if it was shared with unauthorized people. Examples include employee and customer information, passwords, source code, and pre-announced financial reports.	**Scope**: Files & other data assets, Emails **Content marking**: Watermark: HIGHLY CONFIDENTIAL **Auto-labeling**: No **Group settings**: No **Site settings**: No **Auto-labeling for database columns**: None
Highly Confidential \ All Employees	Highly confidential data that allows all employees view, edit, and reply permissions to this content. Data owners can track and revoke content.	**Scope**: Files & other data assets, Emails, Meetings* **Encryption**: All users and groups in the org: Co-Author **Content marking**:

Label name	Label description for users	Settings
		Footer: Classified as Highly Confidential **Auto-labeling**: No **Group settings**: No **Site settings**: No **Auto-labeling for database columns**: None
Highly Confidential \ Specific People	Highly confidential data that requires protection and can be viewed only by people you specify and with the permission level you choose.	**Scope**: Files & other data assets, Emails, Meetings* **Encryption**: Let users assign permissions: - Do Not Forward for Outlook - Prompt users in Word, PowerPoint, and Excel **Content marking**: Footer: Classified as Highly Confidential **Auto-labeling**: No **Group settings**: No **Site settings**: No **Auto-labeling for database columns**: None

* The **Meetings** scope is included for customers starting October 2024 if the tenant has licenses to manually apply a label for scheduled meetings. Additionally:

- The sensitivity label policy includes a default Teams meeting label.
- If the tenant has licenses to manually apply the label to Teams meetings, some of the sensitivity labels also have settings configured to protect these meetings.

> **Note**
>
> The label names and descriptions are automatically available for the following locales: US English, Chinese Simplified and Traditional, French, German, Italian, Japanese, Korean, Portuguese Brazilian, Russian, and Spanish.
>
> If you need additional languages, you can specify your translations by using PowerShell.

For more information about these configuration settings and what sensitivity labels can do, see What sensitivity labels can do.

If you need to edit these default sensitivity labels, see Create and configure sensitivity labels.

Default sensitivity label policy

The default sensitivity label policy makes the labels available for users to start labeling their documents and emails with sensitivity labels. It has the following configuration:

- Publish the default labels to all users in your tenant
- Default label of **General \ All Employees (unrestricted)** for unlabeled documents, email, and meetings
- Users must provide a justification to remove a label or lower its classification

For more information about these policy settings, and other policy settings that are available, see What label policies can do.

If you need to edit these default policy settings, see Publish sensitivity labels by creating a label policy.

When you use these labels in Office apps on Windows, macOS, iOS, and Android, users see new labels within four hours, and within one hour for Word, Excel, and PowerPoint on the web when you refresh the browser. However, you might need to allow up to 24 hours for changes to replicate to all apps and services.

Client-side auto-labeling

The default client-side auto-labeling configuration automatically recommends users apply a sensitivity label when we detect credit card numbers in documents or emails they're working with. As a recommendation rather than automatically applied, this configuration serves as a good

first step for highlighting concerning content and introduces users to the practice of labeling their documents and emails.

Client-side auto-labeling only works for documents and emails in use by the Office apps Word, Excel, PowerPoint, and Outlook.

The default client-side auto-labeling has the following configuration:

- If there are 1-9 instances of credit card numbers found in a document or email, recommend the user applies the sensitivity label **Confidential \ Anyone (unrestricted)**
- If there are 10 or more instances of credit card numbers found in a document or email, recommend the user applies the sensitivity label **Confidential \ All Employees**

> **Note**
>
> If we detected you have your own sensitivity labels published, we'll prompt you to select one of your own labels for auto-labeling and configure it for you.

If you want to edit the client-side auto-labeling configuration, see How to configure auto-labeling for Office apps.

Service-side auto-labeling

Service-side auto-labeling helps label sensitive documents at rest, and emails in transit. The default service-side auto-labeling policy creates policies that run in simulation mode for documents stored in all SharePoint or OneDrive sites, and all emails that are sent via Exchange Online.

In simulation mode, items aren't actually labeled until the policy is turned on. You can manually turn on the policy. Alternatively, if you don't change the default setting, the policy will be automatically turned on for you if there aren't any changes to the policy within a set number of days from when the simulation completes.

In most cases, the number of days before an unedited policy is automatically turned on is 7. However, specific to new customers from June 23, 2022, the initial number of days is 25, and then 7 after the policy is edited.

Simulation mode allows you to preview what items would get labeled when the policy is turned on, so you can have confidence in the labeling feature before you deploy the policy to your

tenant for actual labeling.

The default service-side auto-labeling policies have the following configuration: For all customers:

- If there are 1-9 instances of credit card numbers found in a document or email, apply the sensitivity label **Confidential \ Anyone (unrestricted)**
- If there are 10 or more instances of credit card numbers found in a document or email, apply the sensitivity label **Confidential \ All Employees**

> **Note**
>
> If we detected you have your own sensitivity labels published, we'll prompt you to select one of your own labels for your auto-labeling policy.

There are two auto-labeling policies for each setting. One policy is for the Exchange location, and the other for the SharePoint and OneDrive locations. Although the policies are created at the same time, simulation isn't immediately turned on for SharePoint and OneDrive:

- Exchange location: The auto-labeling policy is created and immediately starts simulation.
- SharePoint and OneDrive locations: The auto-labeling policy is created but waits 25 days before it automatically starts simulation. This delay ensures that there is time for files to be created and saved to these locations.

When the simulation is complete, review the results. If you are happy with them, turn on the policies.

For more information about simulation mode, see Learn about simulation mode.

If you want to edit the service-side auto-labeling policy, see How to configure auto-labeling policies for SharePoint, OneDrive, and Exchange.

Additional resources

To learn more about sensitivity labels and all the capabilities available with Microsoft Purview Information Protection, see the following resources:

Last updated on 05/01/2026

Microsoft Purview posture reports overview

> **Note**
>
> Information Protection posture reports, Data Loss Prevention posture reports, and Custom posture reports are in preview. The capabilities, terminology, and UX may change before general availability.

Prerequisites

Permissions

To access **Reports**, your account must belong to one of the following Microsoft 365 role groups, Microsoft Purview roles, or Microsoft Purview role groups.

Microsoft 365 role groups

- Compliance administrator
- Security administrator
- Compliance data administrator
- Global administrator

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Microsoft Purview roles

To fine-tune access controls, use Microsoft Purview roles. To learn more, see Permissions in the Microsoft Purview portal.

- Information Protection Admin
- Information Protection Analyst
- Information Protection Investigator

- Information Protection Reader

Microsoft Purview role groups

To grant access through role groups, use the following Microsoft Purview role groups. To learn more, see Permissions in the Microsoft Purview portal.

- Information Protection
- Information Protection Admins
- Information Protection Analysts
- Information Protection Investigators
- Information Protection Readers

Posture reports

Microsoft Purview collects and analyzes large volumes of data about how information in your organization is used and protected. This data surfaces through audit logs, Activity explorer, Content explorer, solution-level dashboards, and reports. Posture reports give SOC admins and solution-level admins prebuilt views that turn that data into key insights about your information protection and DLP posture.

Posture reports help you answer questions for executives and operations teams, such as:

- Is Purview doing what we intend it to do?
- Are our policies effective?
- Where are the gaps in our protection strategy?

You find **Posture Reports** in the Microsoft Purview portal:

- **Information Protection** > **Reports**
- **Data Loss Prevention** > **Reports**

> **Note**
>
> The data shown in posture reports is gathered on a 30-day rolling-window basis. Save any reports (as .PDF) that you want to keep for future reference. You can also configure and save your preferred filter settings for future use.

Information Protection posture reports

These reports are in preview.

- Label distribution and adoption
- Auto-labeling policy coverage
- Sensitivity label activity

Data Loss Prevention posture reports

These reports are in preview.

- Most triggered DLP rules and activities
- DLP policies with highest trigger volume
- Top DLP policy violators

> **Note**
>
> DLP policies in simulation mode don't show up in posture reports.

How the Reports tool works

As a Microsoft 365 administrator or compliance administrator, you can evaluate and then tag content in your organization to control where it goes, protect it no matter where it is, and ensure that it's preserved and deleted according to your organization's needs. You do this through the application of sensitivity labels, retention labels, sensitive information types (SIT) classification, and classification by trainable classifiers. There are various ways to do the discovery, evaluation, and tagging, but the end result is that you might have large numbers of documents and emails that are tagged and classified with one or more of these labels. You need to see:

- How labels are used across your tenant and what's done with those items.
- The protections placed on items.
- The most common activities.

The **Reports** tool, available in the **Information Protection** and **Data Loss Prevention (DLP)** solutions, provides visibility into that information and more. The reports include information from both Microsoft 365 source services (Exchange, SharePoint, OneDrive) and non-Microsoft 365 sources.

For example, the **Reports** tool shows you:

- Information on protection policies (preview).

- The trainable classifiers detected most often across your cloud platforms.
- The number of items classified as a sensitive information type and what those classifications are.
- The SITs detected most often across your cloud platforms.
- The top applied sensitivity labels and activities.
- A summary of activities users take on your sensitive content.
- The locations of your sensitive and retained data.
- Summary information on email encryption.

The sections in the **Reports** page are interactive, so you can drill down for more detail. The **Reports** page also links to:

- Activity explorer
- Data explorer
- Content explorer (classic)

Custom posture reports

> **Note**
>
> Custom posture reports are in preview. The capabilities, terminology, and UX may change before general availability.

Custom posture reports work alongside the built-in posture reports to give your team flexibility. Use the built-in reports for ready-made insights that cover common information-protection and DLP scenarios, and create custom reports to assemble the metrics, charts, and filters that answer questions specific to your organization.

Use custom posture reports to answer questions such as:

- Are sensitivity labels being adopted consistently across workloads?
- Where is sensitive content concentrated, and is that concentration growing?
- Are DLP policies reducing risk for specific data types?

To create or open a custom posture report, go to one of the following locations in the Microsoft Purview portal:

- **Information Protection** > **Reports** > **Add report**
- **Data Loss Prevention** > **Reports** > **Add report**

Key concepts

A custom report is a container that holds the cards you use to visualize labeling, classification, and protection activity. Every custom report includes:

- A **report name** and description that state the report's purpose.
- One or more **sections** that group cards by purpose, audience, or theme.
- One or more **cards** within each section that each answer a specific question.

Sections

Sections give a report structure by grouping related cards. They make multi-card reports easier to read and navigate. A report can contain one or more sections, and each section can hold multiple cards.

Add sections before you add cards—sections are the layout framework for the report.

Card types

Cards are the building blocks of a custom report. You can mix and match built-in cards within the same report, or add a custom card.

Expand table

Card type	Description	Use for
Metric card	Displays a single, high-level value or KPI.	Pairing a primary metric with its historical trend. Common uses include adoption, growth, and compliance-health indicators.
Chart card	Provides richer visualizations that reveal patterns and trends.	Distributions, breakdowns, and trend analysis across locations, labels, or workloads.

Custom card configuration

Custom cards let you tailor views to the specific questions your organization needs to answer. They complement built-in cards by adding organization-specific perspectives to the foundation that built-in cards already provide.

Metric-based custom cards support these configuration options:

- **Time range**: Choose any window up to 30 days, extending the 7-day view that built-in metric cards provide.
- **Display format**: **Number** (a raw count), **Percentage** (a proportional view), or **Compound** (a value combined with a trend direction).
- **Filters**: Limit data to specific criteria, such as a sensitivity label, location, or workload.

Chart-based custom cards support these chart types:

- **Vertical bar**: Compares values across categories using vertical bars.
- **Horizontal bar**: Compares values across categories using horizontal bars. Useful when category labels are long.
- **Pie**: Shows the proportional distribution of values across categories.
- **Donut**: Similar to a pie chart, with a central area that improves readability.
- **Line chart**: Shows trends or changes over time.

Apply filters and pivot by grouping dimensions—such as **Activity** or **Sensitive info type**—to tailor chart-based cards to specific scenarios.

Example: configure a custom card

This example tracks adoption of the *Confidential* sensitivity label over the last 30 days.

Expand table

Setting	Value
Card type	Metric card
Metric	Number of items labeled *Confidential*
Time range	Last 30 days (custom)
Display format	**Compound** (total count with trend direction)
Sensitivity label filter	*Confidential*
Workload filter	SharePoint

What the card shows:

- The current total number of items labeled *Confidential*.
- Whether labeling activity is increasing or decreasing over the last 30 days.
- A focused view of adoption for one label and one workload.

Best practices

- Start with clear questions, then choose the cards that answer them.
- Avoid overcrowding a report. A few well-chosen cards are more effective than many.
- Use metric cards for status at a glance and chart cards for deeper analysis.
- Treat custom reports as living assets and iterate as needs evolve.
- For larger reports, save after every two sections.

Microsoft Purview classifiers overview

Microsoft Purview classifiers help administrators identify sensitive content so they can protect and manage it. The Classifiers page brings classification types together in one experience where you can discover, create, inspect, and manage classifiers.

Search and filtering help you find classifiers. When you create a new classifier, you can view how each classifier type works. This helps you understand the available options and choose a classifier for your scenario.

The **Classified items** count shows how many items were found with that specific classification. You can also see how many policies use a classifier and inspect those dependencies before changing it.

In the Microsoft Purview portal, you can access **Classifiers** under **Information Protection**, **Data Loss Prevention**, or **DSPM** (Data Security Posture Management).

Classification types and capabilities

> **Important**
>
> The new Classifiers experience in Microsoft Purview is in preview and is available alongside the existing classification experiences. Classifiers you create, edit, or delete in either experience are reflected in the other. Features and functionality in the new experience might change before general availability.

Explore the following classification types and related capabilities.

Sensitive information types

Sensitive information types (SITs) identify content that matches patterns of sensitive information, such as social security, credit card, or bank account numbers. You can use preexisting sensitive information types or create your own.

For more information, see Learn about sensitive information types. For information about predefined types, see Sensitive information type entity definitions.

Named entities

Named entities are sensitive information types that use dictionaries and patterns to detect person names, physical addresses, and medical terms and conditions.

For more information, see Learn about named entities.

Exact data match

Exact data match identifies sensitive content by matching exact values.

For more information, see Learn about exact data match based sensitive information types.

Trainable classifiers

Microsoft Purview provides pretrained trainable classifiers that are ready to use. You can also create custom trainable classifiers by providing samples of the content you want to recognize.

For more information, see Learn about trainable classifiers.

Credentials

Credential sensitive information types detect credentials in content. The **All credentials** sensitive information type groups individual credential types to detect credentials from supported services and environments.

For more information, see All credential types.

Fingerprinting

Document fingerprinting recognizes content that is a variation of a template.

For more information, see Document fingerprinting.

Optical character recognition

Optical character recognition (OCR) lets Microsoft Purview scan images for sensitive information. You can enable OCR to extend classification to images without creating separate classifiers.

For setup requirements and supported locations, see Learn about optical character recognition.

On-demand classification

On-demand classification identifies and classifies sensitive content in files at rest, including files that haven't been classified or need updated classification.

For more information, see Create and analyze an on-demand classification scan.

Explore classified content

The Classifiers page helps you manage classifiers. Use Data Explorer to review items with classification matches and see where those items are located. Access to item lists and item contents requires the appropriate Data Explorer permissions.

You can find Data Explorer on the Microsoft Purview portal > **Information Protection** > **Explorers** page.

For supported content, access requirements, and instructions, see Get started with Data Explorer.

Permissions

Access to the Classifiers page can come from a Microsoft Entra administrator role or a Microsoft Purview role group.

> **Note**
>
> As a best practice, always use the role with least privilege to grant access to the Classifiers page.

Microsoft Entra administrator roles

The following Microsoft Entra roles provide access:

- Global administrator
- Compliance administrator
- Security administrator
- Compliance data administrator

Microsoft Purview roles and role groups

In Microsoft Purview, a **role** defines permissions, and a **role group** contains a set of roles. Adding a user to a role group grants the permissions of the roles in that group. For details, see Permissions in the Microsoft Purview portal.

Applicable Microsoft Purview roles

- Information Protection Admin
- Information Protection Analyst
- Information Protection Investigator
- Information Protection Reader

Applicable Microsoft Purview role groups

Use the following role groups to assign access. Their permissions differ; choose the group that matches the user's responsibilities. For assignment guidance, see Permissions in the Microsoft Purview portal.

- Information Protection
- Information Protection Admins
- Information Protection Analysts
- Information Protection Investigators
- Information Protection Readers

Learn about sensitive information types

Identifying and classifying sensitive items that are under your organization's control is the first step in the Information Protection discipline. Microsoft Purview provides three ways of identifying items so that they can be classified:

- manually, by users
- via automated pattern recognition, as with sensitive information types
- via machine learning

Sensitive information types (SITs) are pattern-based classifiers. They detect sensitive information like social security, credit card, or bank account numbers to identify sensitive items, see Sensitive information type entity definitions for a complete list of all SITs.

Microsoft provides a large number of preconfigured SITs or you can create your own.

Licensing

E5 license is required to make use of credential scanning SITs. For a list of all the credential scanning SITs, see All credentials sensitive information types. This SIT contains all the credential scanning SITs that are available in the portal. Each member of this SIT is a credential scanning SIT and can be used as a standalone. For a list of many Microsoft created SITs, see Sensitive information type entity definitions.

Sensitive information types are used in

- Microsoft Purview Data Loss Prevention policies
- Sensitivity labels
- Retention labels
- Insider risk management
- Communication compliance
- Auto-labeling policies
- Microsoft Priva

Categories of sensitive information types

Built in sensitive information types

Microsoft created these SITs and they show up in the Purview portal by default. These SITs can't be edited, but you can use them as templates by copying them to create custom sensitive information types. See, Sensitive information type entity definitions for a full list of all SITs.

Named entity sensitive information types

Named entity SITs also show up in the Purview portal by default. They detect person names, physical addresses, and medical terms and conditions. They can't be edited or copied. For more information, see Learn about named entities.

Named entity SITs come in two types:

un-bundled

These named entity SITs have a narrower focus, such as a single country or region, or a single class of terms. Use them when you need a data loss prevention (DLP) policy with a narrower detection scope. See, Examples of named entity SITs.

bundled

Bundled named entity SITs detect all possible matches in a class, such as *All physical addresses*. Use them as broad criteria in your DLP policies for detecting sensitive items. See, Examples of named entity SITs.

> **Tip**
>
> You must enable **Advanced classification scanning and protection**if you want to use a bundled SIT in an endpoint DLP policy. This requirement is specific to the combination of bundled SITS andendpoint DLP policies.

Custom sensitive information types

If the preconfigured sensitive information types don't meet your needs, you can create your own custom sensitive information types that you fully define or you can copy one of the built-in ones and modify it. For more information, see

Create a custom sensitive information type in the Microsoft Purview portal.

Exact data match sensitive information types

All exact data match (EDM)-based SITs are created from scratch. You use them to detect items that have exact values, which you define in a database of sensitive information. For more information, see Learn about exact data match based sensitive information types.

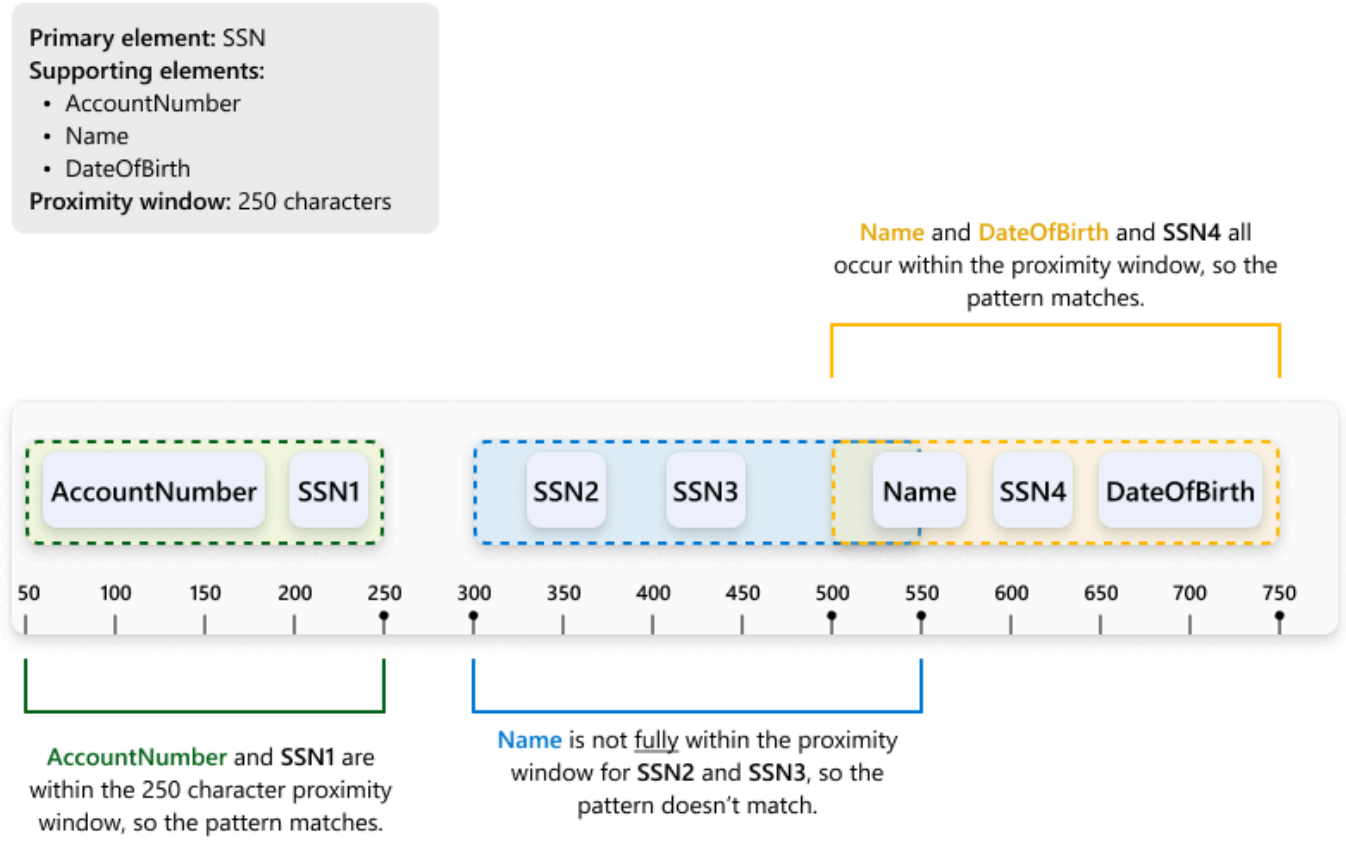
Fundamental parts of a sensitive information type

Every sensitive information type (SIT) entity consists of the following fields:

- ***Name:*** Indicates how the sensitive information type is referred to.
- ***Description:*** Explanation of what the sensitive information type is looking for.
- ***Pattern:*** Defines what a SIT detects. It consists of the following components: primary element, supporting elements, confidence level, and proximity.

The following table describes each component of the patterns used in defining sensitive information types.

Expand table



Pattern component	Description
Primary element	The main element that the sensitive information type is looking for. It can be a **regular expression** with or without a checksum validation, a **keyword list**, a **keyword dictionary**, or a **function**.Each of these types of elements can either be selected from the list of existing SITs or can be custom-defined by a user with admin permissions. Once an element is defined, it appears in the list of existing elements, along with those that come built-in.
Supporting element	An element that acts as corroborative evidence. When included, supporting elements help increase the confidence level with respect to the accuracy of detected matches. For example, if the primary element is defined as `SSN` (composed of nine digits), and the keyword *Social Security Number (SSN)* is used as a supporting element when found in proximity to `SSN`, the confidence that the `SSN` detected is truly a Social Security number is higher than if the *Social Security Number (SSN)* keyword is not present. A supporting element can be a regular expression (with or without a checksum validation), a keyword list, or a keyword dictionary.
Confidence Level	There are three confidence levels with respect to detected matches: high, medium, and low. The confidence level reflects how much supporting evidence is detected along with the primary element. The more supporting evidence a detected item contains, the higher the confidence that a matched item contains the sensitive info you're looking for. For more information about confidence levels, see the video included later in this article.
Proximity	Specifies how close a supporting element is to a primary element, in terms of the number of characters between them.

Understanding proximity

The following diagram shows how match detection works with respect to proximity. In this example, the primary element is the `SSN` field and the SIT definition requires that each instance of an `SSN` value must be within a specified proximity to at least one of the following elements:

- `AccountNumber`
- `Name`
- `DateOfBirth`

In the diagram, we see that the data being checked includes three different instances of the `SSN` field: `SSN1`, `SSN2`, `SSN3`, and `SSN4`.

.

To understand how proximity works, let's start by taking a look at some sample detection criteria. Here, were want to detect nine-digit social security numbers. The detection criteria require that a nine-digit regular expression (primary element) is found in conjunction with supporting evidence (among the `AccountNumber`, `Name`, and `DateOfBirth` fields) that appears within 250 characters (the *proximity*).

As illustrated in the diagram, only the primary elements `SSN1` and `SSN4` meet the detection criteria described. Let's take a closer look.

- In the case of `SSN1`, the `AccountNumber` value is within the specified proximity window of 250 characters, so a match is detected.
- In both the cases of `SSN2` and `SSN3`, none of the supporting elements occur within 250 characters of the primary element, so those values aren't detected as a match. However, as you look at the proximity window for `SSN2` in the diagram, you might ask: *Why isn't there a match for `SSN2`? Doesn't the `SSN2` proximity window extend to the `Name` element?* This is a good question. The answer is: *Not quite*. While the proximity window ***extends into*** the `Name` value, it doesn't include the ***entire*** value, so the pattern doesn't match.
- Finally, in the case of `SSN4`, there are two supporting elements within the proximity window, both `Name` and `DateOfBirth`, so this pattern matches as well.

Learn more about confidence levels in this short video.

https://learn-video.azurefd.net/vod/player?id=ace82ff5-4e4c-4542-b0f4-09d8d3335486&locale=en-us&embedUrl=%2Fpurview%2Fsit-sensitive-information-type-learn-about

Example sensitive information type

Argentina national identity (DNI) number

Format

Eight digits separated by periods

Pattern

Eight digits:

- two digits
- a period
- three digits
- a period
- three digits

Checksum

No

Definition

A DLP policy has medium confidence that it has detected this type of sensitive information if, within a proximity of 250 characters:

- The regular expression Regex_argentina_national_id finds content that matches the pattern.
- A keyword from Keyword_argentina_national_id is found.

XML

```
<!-- Argentina National Identity (DNI) Number -->
<Entity id="00aa00aa-bb11-cc22-dd33-44ee44ee44ee" recommendedConfidence="75"
patternsProximity="250">
   <Pattern confidenceLevel="75">
      <IdMatch idRef="Regex_argentina_national_id"/>
      <Match idRef="Keyword_argentina_national_id"/>
  </Pattern>
</Entity>
```

Keywords

Keyword_argentina_national_id

- Argentina National Identity number
- Identity
- Identification National Identity Card
- DNI
- National Registry of Persons (NIC)
- Documento Nacional de Identidad
- Registro Nacional de las Personas
- Identidad
- Identificación

More on confidence levels

In a sensitive information type entity definition, **confidence level** reflects how much supporting evidence is detected in addition to the primary element. The more supporting evidence an item contains, the higher the confidence that a matched item contains the sensitive info you're looking for. For example, matches with a high confidence level contain more supporting evidence in close proximity to the primary element, whereas matches with a low confidence level would contain little to no supporting evidence in close proximity.

A high confidence level returns the fewest false positives but might result in more false negatives. Low or medium confidence levels return more false positives but few to zero false negatives.

- **low confidence**: Matched items contain the fewest false negatives but the most false positives. Low confidence returns all low, medium, and high confidence matches. The low confidence level has a value of 65.
- **medium confidence**: Matched items contain an average number of false positives and false negatives. Medium confidence returns all medium, and high confidence matches. The medium confidence level has a value of 75.
- **high confidence**: Matched items contain the fewest false positives but the most false negatives. High confidence only returns high confidence matches and has a value of 85.

You should use high confidence level patterns with low counts, say five to 10, and low confidence patterns with higher counts, say 20 or more.

> ⓘ **Note**
>
> If you have existing policies or custom sensitive information types (SITs) defined using number-based confidence levels (also known as *accuracy*), they'll automatically be mapped to the three discrete confidence levels; low confidence, medium confidence, and high confidence, across the Security @ Compliance Center UI.
>
> - All policies with minimum accuracy or custom SIT patterns with confidence levels of between 76 and 100 will be mapped to high confidence.
> - All policies with minimum accuracy or custom SIT patterns with confidence levels of between 66 and 75 will be mapped to medium confidence.
> - All policies with minimum accuracy or custom SIT patterns with confidence levels less than or equal to 65 will be mapped to low confidence.

Creating custom sensitive information types

You can choose from several options to create custom sensitive information types.

- **Use the UI** - You can set up a custom sensitive information type using the Purview portal UI. With this method, you can use regular expressions, keywords, and keyword dictionaries. To learn more, see Create a custom sensitive information type.

- **Use EDM** - You can set up custom sensitive information types using Exact Data Match (EDM)-based classification. This method enables you to create a dynamic sensitive information type using a secure database that you can refresh periodically. See Learn about exact data match based sensitive information types.

- **Use PowerShell** - You can set up custom sensitive information types using PowerShell. Although this method is more complex than using the UI, you have more configuration options. See Create a custom sensitive information type in Security & Compliance PowerShell.

Tuning trainable classifiers

Endpoint DLP classifies files based on all sensitive information types available in the tenant, including custom sensitive information types, regardless of their utilization in any DLP policies. This can cause excessive classification traffic if the sensitive information types aren't well tuned and end up matching many files. You should optimize all custom sensitive information types. Do this by removing unused sensitive information types and redesigning SITs if they match most of the files in your organization. For guidance on utilizing SIT Regex validators to tune SITs, see: Sensitive information type REGEX validators and additional check

Double byte character set support

Improved confidence levels are available for immediate use within Microsoft Purview Data Loss Prevention services, information protection, Communication Compliance, data lifecycle management, and records management.

- Information Protection now supports double byte character set languages for:
- Chinese (simplified)
- Chinese (traditional)
- Korean
- Japanese

This support is available for sensitive information types. For more information, see Information protection support for double byte character sets release notes.

Single byte character set support

To detect patterns containing Chinese/Japanese characters and single byte characters or to detect patterns containing Chinese/Japanese and English, define two variants of the keyword or regex.

For example, to detect a keyword like "机密的document", use two variants of the keyword; one with a space between the Japanese and English text and another without a space between the Japanese and English text. So, the keywords to be added in the SIT should be "机密的 document"

and "机密的document". Similarly, to detect a phrase "東京オリンピック2020", two variants should be used; "東京オリンピック 2020" and "東京オリンピック2020".

Along with Chinese/Japanese/double byte characters, if the list of keywords/phrases also contains non-Chinese/Japanese words also (for instance, English only), you should create two dictionaries/keyword lists. One for keywords containing Chinese/Japanese/double byte characters and another one for English-only keywords. For example, if you want to create a keyword dictionary/list with three phrases "Highly confidential", "機密性が高い" and "机密的document", the you should create two keyword lists.

- Highly confidential
- 機密性が高い, 机密的document and 机密的 document While creating a regex using a double byte hyphen or a double byte period, make sure to escape both the characters like you would escape a hyphen or period in a regex. Here's a sample regex for reference: `(?<!\d)([4][0-9]{3}[\-?\-\t]*[0-9]{4}`

> We recommend using string match instead of word match in a keyword list.

Detection differences across workloads

The same sensitive information type can produce different results depending on where content is evaluated—for example, email in transit (Exchange), files at rest (SharePoint and OneDrive), and files on managed devices (Endpoint DLP). Endpoint DLP classifies files against *all* sensitive information types available in the tenant, and using a bundled SIT in an endpoint DLP policy requires Advanced classification scanning and protection.

Before you rely on a custom SIT in production, test it and validate detection in each workload where you intend to use it—for example, a mail flow rule, a SharePoint or OneDrive policy, and an endpoint policy. Detection can also be affected by content-extraction limits such as maximum file size and the number of characters scanned; see DLP platform considerations.

Test sensitive information type

You can test the SIT by uploading a sample file. The test results show the number of matches for each confidence level. You can test built-in SITs, custom SITs, trainable classifiers, and exact data match.

Test Built-in and Custom sensitive information type

Test exact data match sensitive information type.

To test any custom or default SIT tenant, there must be at least one Exchange Online license added to the tenant. Otherwise, the Test SIT option will be greyed out when any SIT is selected.

Provide match/not a match accuracy feedback in sensitive info types

You can view the number of matches a SIT has in **Sensitive info types** and **Content explorer**. You can also provide feedback on whether an item is actually a match or not using the **Match**, **Not a Match** feedback mechanism and use that feedback to tune your SITs. For more information, see Increase classifier accuracy.

For further information

- Sensitive information type entity definitions
- Create a custom sensitive information type
- Create a custom sensitive information type in PowerShell

To learn how to use sensitive information types to comply with data privacy regulations, see Deploy information protection for data privacy regulations with Microsoft 365 (aka.ms/m365dataprivacy).

Create custom sensitive information types

If the preconfigured sensitive information types (SITs) don't meet your needs, you can create and define customized SITs that meet your needs. You can also copy and then edit a built-in SIT.

The custom SITs are added to the `Microsoft.SCCManaged.CustomRulePack` rule package.

There are two methods for creating a new SIT:

- Create a new SIT from scratch
- Copy and modify an existing SIT

Before you begin

- You should be familiar with sensitive information types and what they're composed of. To get this understanding, see, Learn about sensitive information types. It's critical to understand the roles of:
  - regular expressions - Microsoft 365 sensitive information types uses the Boost.RegEx 5.1.3 engine
  - keyword lists - you can create your own as you define your sensitive information type or choose from existing keyword lists
  - keyword dictionary
  - Sensitive information type functions
  - confidence levels
- Familiarize yourself with Sensitive information type limits.

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

> **Important**
>
> Microsoft Customer Service & Support can't assist with creating custom classifications or regular expression patterns. Support engineers can provide limited support for the feature, such as, providing sample regular expression patterns for simulation purposes, or helping to troubleshoot an existing regular expression pattern that's not triggering as expected.

However, they can't provide assurances that any custom content-matching development fulfills your requirements or obligations.

Create a custom SIT from scratch

> **Note**
>
> Microsoft Purview supports creating custom SITs that use double-byte character languages, such as Chinese, Japanese, and Korean. Because these languages don't use delimiters the way that single-byte languages do, Purview adds a space between each word in languages that use double-byte characters. It also removes special characters, such as punctuation.

Use the following procedure to fully define a brand new sensitive information type.

1. Sign in to the Microsoft Purview portal.
2. In the Microsoft Purview portal, navigate to **Information Protection** > **Classifiers** > **Sensitive info types** and choose **Create sensitive info type**.
3. Fill in values for **Name** and **Description** and choose **Next**.
4. Choose **Create pattern**. You can create multiple patterns, each with different elements and confidence levels, as you define your new sensitive information type.
5. Choose the default confidence level for the pattern. The values are **Low confidence**, **Medium confidence**, and **High confidence**.
6. Choose and define the **Primary element**. The primary element can be a **Regular expression** with an optional validator, a **Keyword list**, a **Keyword dictionary**, or one of the preconfigured **Functions**. For more information on the SIT functions used for data loss prevention, see Sensitive information type functions. For more information on the date and the checksum validators, see Sensitive Information Type regular expression validators.

   > **Important**
   >
   > Custom SIT regex patterns must follow these rules:
   >
   > - **Don't use positional anchors** like `^` and `$`. When content is scanned, there are no guarantees about where in the content the starting and ending anchors correspond to.

- Use **one primary capturing group** (the only capturing group), for example: `(?:prefix)(primary capturing group)(?:suffix)` (use noncapturing groups for any additional grouping).
- Handle all match variants **inside** that single group using `|` (alternation). Multiple capturing groups separated by `|` at the top level are **not supported** and are blocked during validation.

Invalid pattern (three top-level capturing groups):

```
(?:[\s,;])([A-Z]{2}[0-9]{3})(?:[\s,;])|(?:[\s,;])([A-Z]{2}[A-Z]{4}[0-9])(?:[\s,;])|(?:[\s,;])([A-Z]{2}[0-9]{5})(?:[\s,;])
```

Valid pattern (single capturing group with alternation):

```
(?:[\s,;])([A-Z]{2}[0-9]{3}|[A-Z]{2}[A-Z]{4}[0-9]|[A-Z]{2}[0-9]{5})(?:[\s,;])
```

For more information on limits, see Sensitive information type limits.

7. Fill in a value for **Character proximity**.
8. (Optional) Add supporting elements if you have any. Supporting elements can be a regular expression with an optional validator, a keyword list, a keyword dictionary or one of the predefined functions. Supporting elements can have their own **Character proximity** configuration.
9. (Optional) Add any **sensitive information type additional checks** from the list of available checks.
10. Choose **Create**.
11. Choose **Next**.
12. Choose the **recommended confidence level** for this sensitive information type.
13. Check your settings and choose **Save**.

> ⓘ **Important**
>
> Microsoft 365 uses the search crawler to identify and classify sensitive information in SharePoint and OneDrive sites. To identify your new custom sensitive information type in existing content, the content must be recrawled. Content is crawled based on a schedule, but you can manually recrawl content for a site collection, list, or library. For

more information, see Manually request crawling and reindexing of a site, a library, or a list.

14. The **Sensitive info types** tab of the **Classifiers** page, lists all of the sensitive information types. Choose **Refresh** and then or use the search tool or browse the list to find your new SIT.

Copy and modify an existing SIT

This procedure explains how to copy and modify an existing SIT using the Purview Portal.

Alternatively, you can copy and modify custom SITs using PowerShell and using Purview's Exact Data Match (EDM) capabilities. To learn more about those methods, see:

- Create a custom sensitive information type in Microsoft Purview PowerShell
- Learn about exact data match based sensitive information types

> **Note**
>
> These SITs can't be copied:
>
> - Canada driver's license number
> - EU driver's license number
> - EU national identification number
> - EU passport number
> - EU social security number or equivalent identification
> - EU tax identification number
> - International classification of diseases (ICD-10-CM)
> - International classification of diseases (ICD-9-CM)
> - U.S. driver's license number

When you have 10 text processors or restricted text processors, such as keyword lists, regex, keyword dictionaries, or functions, you won't be able to copy the SIT from the UI directly. Instead, you need to use PowerShell for this task. To learn more about how to clone or copy your SIT using PowerShell, see Modify a custom sensitive information type using PowerShell

Copy and modify an existing SIT using the Microsoft Purview portal

1. Sign in to the Microsoft Purview portal.

2. **Information Protection** > **Classifiers** > **Sensitive info types** and select the sensitive information type that you want to copy.

3. The overview page for the sensitive information type opens. Choose **Copy**. When the copy is ready, a message stating that the copy was created appears with an option to edit it. Choose **Yes**.

4. Give your new sensitive information type a new **Name** and **Description**.

5. You can choose to create a new pattern, or edit or remove some or all of the existing patterns.
   a. To create a new pattern, choose **Create**.
   b. To edit an existing pattern, choose the **Edit** (pencil) icon next to the pattern you want to change.
   c. To remove a pattern, choose the **Delete** icon next to the pattern you want to remove.

6. When creating or editing a pattern, choose the default confidence level for the pattern. The values are **Low confidence**, **Medium confidence**, and **High confidence**.

7. Choose and define **Primary element**. The primary element can be a **Regular expression**, a **Keyword list**, a **Keyword dictionary**, or one of the preconfigured **Functions**. See, Sensitive information type functions.

8. Fill in a value for **Character proximity**.

9. (Optional) If you have **Supporting elements** or any sensitive information type additional checks you want to run, add them. If needed, you can organize your **Supporting elements** into groups.

10. If you're creating a new pattern, choose **Create**. If you're editing an existing pattern, choose **Update**.

11. Choose **Next**.

12. Confirm the confidence level selection for this sensitive information type and then choose **Next**.

13. Review your settings and then choose **Save**.

14. Your new sensitive information type is created. At the confirmation message, choose **Done*

> ⓘ **Note**

Microsoft Purview Information Protection supports double byte character set languages for:

- Chinese (simplified)
- Chinese (traditional)
- Korean
- Japanese

This support is available for sensitive information types. For more information, see Information protection support for double byte character sets release notes (preview).

Tip

To detect patterns containing Chinese/Japanese characters and single byte characters, or to detect patterns containing Chinese/Japanese and English, define two variants of the keyword or regex.

- For example, to detect a keyword like "机密的document", use two variants of the keyword; one with a space between the Japanese and English text and another without a space between the Japanese and English text. So, the keywords to be added in the SIT should be "机密的 document" and "机密的document". Similarly, to detect a phrase "東京オリンピック2020", two variants should be used; "東京オリンピック 2020" and "東京オリンピック2020".

Along with Chinese/Japanese/double byte characters, if the list of keywords/phrases also contain non Chinese/Japanese words also (for instance, English only), creating two dictionaries/keyword lists is recommended. Create one for keywords containing Chinese/Japanese/double byte characters and another for English-only.

- For example, if you want to create a keyword dictionary/list with three phrases "Highly confidential", "機密性が高い", and "机密的document", you should create two keyword lists.

    1. Highly confidential
    2. 機密性が高い, 机密的document and 机密的 document

While creating a regex using a double byte hyphen or a double byte period, make sure to escape both the characters in the same way that you would escape a hyphen or period in a regex. Here's a sample regex for reference:

```
(?<!\d)([4][0-9]{3}[\-?\-\t]*[0-9]{4})
```

Double-byte special characters shouldn't be used in the keyword.

We recommend using a string match instead of a word match in a keyword list.

Test sensitive information types

At any time during the life of a sensitive information type (SIT), you can test how it performs. This article explains how to do that in the Microsoft Purview portal.

Before you begin

Before you test a sensitive information type, make sure you have the following background knowledge and preparation.

- You should be familiar with sensitive information types and what they're composed of. For more information, see, Learn about sensitive information types.
- It's critical to understand the roles of:
  - regular expressions - Microsoft 365 sensitive information types uses the Boost.RegEx 5.1.3 engine
  - keyword lists - you can create your own as you define your sensitive information type or choose from existing keyword lists
  - keyword dictionary
  - Sensitive information type functions
  - confidence levels
- Familiarize yourself with Sensitive information type limits.

> **Important**
>
> Microsoft Customer Service & Support can't assist with creating custom classifications or regular expression patterns. Support engineers can provide limited support for the feature, such as, providing sample regular expression patterns for simulation purposes, or helping to troubleshoot an existing regular expression pattern that's not triggering as expected. However, they can't provide assurances that any custom content-matching development fulfills your requirements or obligations.

Permissions and role groups

The account you use to perform tests of SITs must be assigned one of these roles in the Microsoft Purview *and* one of these roles or role groups in Exchange.

Role groups assignments in the Microsoft Purview portal

The account you use must be assigned one of these role groups in the Microsoft Purview portal:

- Compliance Administrator
- Compliance Data Administrator
- Security Administrator
- Communication Compliance Admins
- Information Protection Admins
- Information Protection Investigators
- Organization Management

To assign a user to a role group in the Microsoft Purview portal, follow the steps in Add users or groups to a Microsoft Purview built-in role group.

Microsoft Entra Roles in Exchange Online

The following roles can be assigned either in the Exchange Admin center or in Microsoft Entra.

- Communication Compliance Admin
- Communication Compliance Investigation
- Compliance Admin
- Data Loss Prevention
- Information Protection Admin
- Information Protection Investigator
- Information Protection Reader
- Insider Risk Management Admin
- Insider Risk Management Investigation
- Privacy Management Admin
- Privacy Management Investigation
- Security Admin

Microsoft Entra Role Groups in Exchange Online

The following Exchange Online role groups satisfy this requirement:

- Communication Compliance
- Communication Compliance Administrators
- Compliance Administrator
- Organization Management
- Compliance Management
- Information Protection

- Information Protection Admins
- Information Protection Investigators
- Information Protection Readers
- Insider Risk Management
- Insider Risk Management Admins
- Insider Risk Management Investigators
- Privacy Management
- Privacy Management Administrators
- Privacy Management Investigators
- Security Administrator

Enable access to simulation mode

To enable access to simulation mode, your account must be assigned one of the following role groups:

Applies to these role groups:

- Communication Compliance Admins
- Information Protection Admins
- Information Protection Investigators
- Organization Management

Test the effects of a sensitive information type

You can test the effects of any sensitive information type in the **Sensitive info types** list. Test each sensitive information type that you create before using it in a policy.

This uploaded-file test is different from auto-labeling policy simulation. It tests the SIT against the file you upload; it doesn't refresh classification for existing SharePoint or OneDrive files. A policy simulation uses available classification results for those files. See Auto-labeling classification and simulation concepts for how to interpret differences and when classification needs updating.

> ⓘ **Note**
>
> This procedure is only supported for unencrypted files.

1. Prepare two files, for example, two Word documents. One should have content that matches the elements you specified in your sensitive information type. The other should

have content that doesn't match.

2. Sign in to the Microsoft Purview portal > **Information Protection** > **Classifiers** > **Sensitive info types** and choose the sensitive information type from the list to open the details pane. Choose **Test**.
3. Upload a file and choose **Test**. (You can only upload and test one file at a time.)
4. On the **Match results** page, review the results and choose **Finish**.
5. Perform the same steps for the second file.

Note: The author created this article with assistance from AI. Learn more

Customize a built-in sensitive information type

When looking for sensitive information in content, you need to describe that information in what's called a *rule*. Microsoft Purview Data Loss Prevention (DLP) includes rules for the most common sensitive information types (SITs). You can use these rules right away. To use them, you must include them in a policy. You can adjust these built-in rules to meet your organization's specific needs by creating a custom sensitive information type. This topic shows you how to customize the XML file that contains the existing rule collection so you can detect a wider range of potential credit card information.

You can take this example, which modifies the Credit Card Number SIT, and apply this approach to other built-in sensitive information types. For a list of default SITs and XML definitions, see Sensitive information type entity definitions.

Export the XML file of the current rules

To export the XML, you need to connect to Security & Compliance PowerShell.

1. In the PowerShell, type the following to display your organization's rules on screen. If you haven't created your own, you'll only see the default, built-in rules, labeled "Microsoft Rule Package."

   PowerShell

   ```
   Get-DlpSensitiveInformationTypeRulePackage
   ```

2. Store your organization's rules in a variable by typing the following. Storing something in a variable makes it easily available later in a format that works for PowerShell commands.

   PowerShell

   ```
   $ruleCollections = Get-DlpSensitiveInformationTypeRulePackage
   ```

3. Make a formatted XML file with all that data by typing the following.

   PowerShell

```
[System.IO.File]::WriteAllBytes('C:\custompath\exportedRules.xml',
$ruleCollections.SerializedClassificationRuleCollection)
```

> **Important**
>
> Make sure that you use the file location where your rule pack is actually stored. `C:\custompath\` is a placeholder.

Find the rule that you want to modify in the XML

The cmdlets above exported the entire *rule collection*, which includes the default rules that Microsoft provides. Next, you'll need to look specifically for the Credit Card Number rule that you want to modify.

1. Use a text editor to open the exported XML file (for example, `exportedRules.xml`) that you created in the preceding procedure.

2. Scroll down to the `<Rules>` tag, which marks the start of the rules section. Because this XML file contains the information for the entire rule collection, it contains other information at the top that you need to scroll past to get to the rules.

3. Look for *Func_credit_card* to find the Credit Card Number rule definition. In the XML, rule names can't contain spaces, so the spaces are usually replaced with underscores, and rule names are sometimes abbreviated. An example of this is the U.S. Social Security number rule, which is abbreviated *SSN*. The XML for the Credit Card Number rule should look like the following code sample:

XML

```
<Entity id="50842eb7-edc8-4019-85dd-5a5c1f2bb085"
       patternsProximity="300" recommendedConfidence="85">
      <Pattern confidenceLevel="85">
       <IdMatch idRef="Func_credit_card" />
        <Any minMatches="1">
          <Match idRef="Keyword_cc_verification" />
          <Match idRef="Keyword_cc_name" />
          <Match idRef="Func_expiration_date" />
        </Any>
      </Pattern>
    </Entity>
```

Now that you have located the Credit Card Number rule definition in the XML, you can customize the rule's XML to meet your needs. For a refresher on the XML definitions, see the Term glossary later in this article.

Modify the XML and create a new sensitive information type

First, you need to create a new sensitive information type because you can't directly modify the default rules. You can do a wide variety of things with custom sensitive information types, which are outlined in Create a custom sensitive information type in Security & Compliance PowerShell. For this example, we'll keep it simple and only remove corroborative evidence and add keywords to the Credit Card Number rule.

All XML rule definitions are built on the following general template. You need to copy and paste the Credit Card Number definition XML in the template, modify some values (notice the ". . ." placeholders in the following example), and then upload the modified XML as a new rule that can be used in policies.

XML

```
<?xml version="1.0" encoding="utf-16"?>
<RulePackage xmlns="https://schemas.microsoft.com/office/2011/mce">
  <RulePack id=". . .">
    <Version major="1" minor="0" build="0" revision="0" />
    <Publisher id=". . ." />
    <Details defaultLangCode=". . .">
      <LocalizedDetails langcode=" . . . ">
         <PublisherName>. . .</PublisherName>
         <Name>. . .</Name>
         <Description>. . .</Description>
      </LocalizedDetails>
    </Details>
  </RulePack>

 <Rules>
   <!-- Paste the Credit Card Number rule definition here.-->
      <LocalizedStrings>
         <Resource idRef=". . .">
           <Name default="true" langcode=" . . . ">. . .</Name>
           <Description default="true" langcode=". . .">  . . .</Description>
         </Resource>
      </LocalizedStrings>
   </Rules>
</RulePackage>
```

Now, you have something that looks similar to the following XML. Because rule packages and rules are identified by their unique GUIDs, you need to generate two GUIDs: one for the rule package and one to replace the GUID for the Credit Card Number rule. The GUID for the entity ID in the following code sample is the GUID for the built-in rule definition, which you need to replace with a new GUID. There are several ways to generate GUIDs, but you can do it easily in PowerShell by typing **[guid]::NewGuid()**.

XML

```
<?xml version="1.0" encoding="utf-16"?>
<RulePackage xmlns="https://schemas.microsoft.com/office/2011/mce">
  <RulePack id="8aac8390-e99f-4487-8d16-7f0cdee8defc">
    <Version major="1" minor="0" build="0" revision="0" />
    <Publisher id="..." />
    <Details defaultLangCode="en">
      <LocalizedDetails langcode="en">
        <PublisherName>Contoso Ltd.</PublisherName>
        <Name>Financial Information</Name>
        <Description>Modified versions of the Microsoft rule package</Description>
      </LocalizedDetails>
    </Details>
  </RulePack>

 <Rules>
    <Entity id="00aa00aa-bb11-cc22-dd33-44ee44ee44ee"
       patternsProximity="300" recommendedConfidence="85">
      <Pattern confidenceLevel="85">
        <IdMatch idRef="Func_credit_card" />
        <Any minMatches="1">
          <Match idRef="Keyword_cc_verification" />
          <Match idRef="Keyword_cc_name" />
          <Match idRef="Func_expiration_date" />
        </Any>
      </Pattern>
    </Entity>
      <LocalizedStrings>
         <Resource idRef="00aa00aa-bb11-cc22-dd33-44ee44ee44ee">
<!-- This is the GUID for the preceding Credit Card Number entity because the
following text is for that Entity. -->
           <Name default="true" langcode="en-us">Modified Credit Card Number</Name>
           <Description default="true" langcode="en-us">Credit Card Number that looks
for additional keywords, and another version of Credit Card Number that doesn't
require keywords (but has a lower confidence level)</Description>
         </Resource>
      </LocalizedStrings>
   </Rules>
</RulePackage>
```

Remove the corroborative evidence requirement from a sensitive information type

Now you have a new sensitive information type that you're able to upload to the Microsoft Purview portal. The next step is to make the rule more specific. Modify the rule so that it only looks for a 16-digit number that passes the checksum but that doesn't require additional (corroborative) evidence, such as keywords. To require only a 16-digit number that passes the checksum, remove the part of the XML that looks for corroborative evidence. Corroborative evidence is very helpful in reducing false positives. When detecting credit card numbers, there are usually certain keywords or an expiration date near the credit card number. If you remove that evidence, you should also adjust how confident you are that you found a credit card number by lowering the `confidenceLevel`, which is 85 in the example.

XML

```
<Entity id="00aa00aa-bb11-cc22-dd33-44ee44ee44ee" patternsProximity="300"
      <Pattern confidenceLevel="85">
        <IdMatch idRef="Func_credit_card" />
      </Pattern>
    </Entity>
```

Look for keywords that are specific to your organization

You might want to require corroborative evidence but want different or additional keywords, and perhaps you want to change where to look for that evidence. You can adjust the `patternsProximity` to expand or shrink the window for corroborative evidence around the 16-digit number. To add your own keywords, you must define a keyword list and reference it within your rule. The following XML adds the keywords "company card" and "Contoso card", so that any message that contains those phrases within 150 characters of a credit card number will be identified as a credit card number.

XML

```
<Rules>
<! -- Modify the patternsProximity to be "150" rather than "300." -->
    <Entity id="00aa00aa-bb11-cc22-dd33-44ee44ee44ee" patternsProximity="150"
recommendedConfidence="85">
      <Pattern confidenceLevel="85">
        <IdMatch idRef="Func_credit_card" />
        <Any minMatches="1">
          <Match idRef="Keyword_cc_verification" />
```

```
          <Match idRef="Keyword_cc_name" />
<!-- Add the following XML, which references the keywords at the end of the XML
sample. -->
          <Match idRef="My_Additional_Keywords" />
          <Match idRef="Func_expiration_date" />
        </Any>
      </Pattern>
    </Entity>
<!-- Add the following XML, and update the information inside the <Term> tags with the
keywords that you want to detect. -->
    <Keyword id="My_Additional_Keywords">
      <Group matchStyle="word">
        <Term caseSensitive="false">company card</Term>
        <Term caseSensitive="false">Contoso card</Term>
      </Group>
    </Keyword>
```

Upload your rule

Before you begin, make sure you can connect to Security & Compliance PowerShell.

To upload your rule, you need to do the following.

1. Save it as an .xml file with Unicode encoding. Saving the file with Unicode encoding is important because the rule won't work if the file is saved with a different encoding.

2. Connect to Security & Compliance PowerShell.

3. In the PowerShell, type the following.

   PowerShell

   ```
   New-DlpSensitiveInformationTypeRulePackage -FileData
   ([System.IO.File]::ReadAllBytes('C:\custompath\MyNewRulePack.xml'))
   ```

   > **ⓘ Important**
   >
   > Make sure that you use the file location where your rule pack is actually stored. `C:\custompath\` is a placeholder.

4. To confirm, type Y, and then press **Enter**.

5. Verify the display name of your new rule and that it was uploaded, by entering:

   PowerShell

```
Get-DlpSensitiveInformationType
```

To start using the new rule to detect sensitive information, you need to add the rule to a DLP policy. To learn how to add the rule to a policy, see Create and Deploy data loss prevention policies.

Term glossary

These are the definitions for the terms you encountered during this procedure.

Expand table

Term	Definition
Entity	*Entities* are what we call sensitive information types, such as credit card numbers. Each entity has a unique GUID as its ID. If you copy a GUID and search for it in the XML, you'll find the XML rule definition and all the localized translations of that XML rule. You can also find this definition by locating the GUID for the translation and then searching for that GUID.
Functions	The XML file references `Func_credit_card`, which is a function in compiled code. Functions are used to run complex regexes and verify that checksums match for our built-in rules. Because this happens in the code, some of the variables don't appear in the XML file.
IdMatch	This is the identifier that the pattern is to trying to match—for example, a credit card number.
Keyword lists	The XML file also references `keyword_cc_verification` and `keyword_cc_name`, which are lists of keywords that we are looking to match within the `patternsProximity` for the entity. These aren't currently displayed in the XML.
Pattern	The *pattern* contains the list of what the sensitive type is looking for. This includes keywords, regexes, and internal functions, which perform tasks like verifying checksums. Sensitive information types can have multiple patterns with unique confidence levels. This is useful when creating a sensitive information type that returns a high confidence if corroborative evidence is found and a lower confidence if little or no corroborative evidence is found.
Pattern confidenceLevel	This is the level of confidence that the DLP engine found a match. This level of confidence is associated with a match for the pattern if the pattern's requirements are met. This is the confidence measure you should consider when using Exchange mail flow rules (also known as transport rules).

Term	Definition
patternsProximity	When we find what looks like a credit card number pattern, `patternsProximity` is the distance around that number where we'll look for corroborative evidence.
recommendedConfidence	This is the confidence level we recommend for this rule. The recommended confidence level applies to entities and affinities. For entities, this number is never evaluated against the `confidenceLevel` for the pattern. It's merely a suggestion to help you choose a confidence level if you want to apply one. For affinities, the `confidenceLevel` of the pattern must be higher than the `recommendedConfidence` number for a mail flow rule action to be invoked. The `recommendedConfidence` is the default confidence level used in mail flow rules that invokes an action. If you want, you can manually change the mail flow rule to be invoked based off the pattern's confidence level, instead.

Manage custom sensitive information types

This article walks you through the steps to modify and remove an existing custom sensitive information type.

Modify custom sensitive information types

To modify a custom sensitive information type, perform the following steps:

1. Sign in to the Microsoft Purview portal > **Information Protection** > **Classifiers** > **Sensitive info types** and choose the sensitive information type from the list that you want to modify.
2. Choose **Edit**.
3. You can add other patterns, with unique primary and supporting elements, confidence levels, character proximity, and **additional checks** or edit/remove the existing ones.

Delete custom sensitive information types

> **Note**
>
> You can only remove custom sensitive information types; you can't remove built-in sensitive information types.

> **Important**
>
> Before your remove a custom sensitive information type, verify that no DLP policies or Exchange mail flow rules (also known as *transport rules*) still reference the custom sensitive information type that you plan to remove.

1. Sign in to the Microsoft Purview portal > **Information Protection** > **Classifiers** > **Sensitive info types** and choose the sensitive information type that you want to delete.

Sensitive information type regex validators and additional checks

> **Important**
>
> Microsoft Customer Service & Support can't assist with creating custom classifications or regular expression patterns. Support engineers can provide limited support for the feature, such as providing sample regular expression patterns for testing the feature, or assisting with troubleshooting an existing regular expression pattern that's not triggering as expected. However, support engineers can't assure you that any custom content-matching development fulfills your requirements or obligations.

Sensitive Information Type regular expression validators

Checksum validator

To run a checksum on a digit in a regular expression, you can use the *checksum validator*. For example, if you need to create a SIT for an eight-digit license number where the last digit is a checksum digit validated using a mod 9 calculation, set up the checksum algorithm as shown in the following example:

Console

```
Sum = digit 1 * Weight 1 + digit 2 * weight 2 + digit 3 * weight 3 + digit 4 * weight
4 + digit 5 * weight 5 + digit 6 * weight 6 + digit 7 * weight 7 + digit 8 * weight 8
Mod value = Sum % 9
If Mod value == digit 8
    Account number is valid
If Mod value != digit 8
    Account number is invalid
```

1. Define the primary element with a regular expression that matches any eight-digit number:

   Console

   ```
   \d{8}
   ```

2. Add the checksum validator.

3. Add the weight values separated by commas, the position of the check digit, and the mod value. For more information on the Modulo operation, see Modulo operation.

> **Note**
>
> If the check digit isn't part of the checksum calculation, use 0 as the weight for the check digit. For example, in the eight-digit license number example, weight 8 is equal to 0 if the check digit won't be used for calculating the check digit.

Parameters

The following parameters define how the checksum validator performs its calculation:

- **Weights:** To define the series of numbers with which each digit starting from position 1 to last position of the regex needs to be multiplied. This calculates the sum product. Weight

positions refer to the order of the digits only, it doesn't consider any nondigit characters like dashes.
- **Mod:** Perform Modulo operation on the result from previous operation.
- **ModCoefficient:** Perform addition or subtraction on the modulo result.
- **CheckDigit:** Define the position of the check digit with which the calculated number will be compared against.

Advanced Checksum Validator

Advanced Checksum can be used without the need of scripting, by using parameters such as PositionBasedUpdate, UseAscii, MultiDigitResult, CheckDigitValue.

- **Digit Replacement Before Computation:** Define rules to replace digits based on position or value before checksum calculation.
- **Letter-to-ASCII Conversion:** Nondigit characters can now be converted to their ASCII values instead of being ignored, enabling checksum support for alphanumeric inputs.
- **Single-Digit Reduction of Multi-Digit Results:** Intermediate results can now be reduced to a single digit by summing their digits (12 → 1+2 = 3), allowing for more compact and consistent outputs.
- **Post-Processing of Two-Digit Results:** Apply mathematical operations like division or modulo to two-digit results to derive final values.
- **Exclusion of Specific Check Digit Values:** Define a list of disallowed check digit values. If the computed result matches one, the system modifies the input and rerun the checksum logic.
- **Final Check Digit Substitution:** Post-computation, specific check digit values can be substituted with alternatives.

Advanced Checksum Validator Parameters

The following parameters control advanced checksum validator behavior:

- **UseAscii:** Replace alphabets with their ascii value
- **PositionBasedUpdate:** Pre checksum computation. We update the digits based on the attributes, match-position-replacewith.
- **CheckDigitValue:** Post checksum computation. If checksum calculated is part of repeat list, perform defined operation on it.

- ltiDigitResult:** Post/Intermediate checksum computation. If Post/intermediate calculation result is of multiple digits, perform the defined operation on it until it's a single digit.

For example, in the XML below, we have passed the following parameters: weights, mod, checkdigit, and ascii.

Console

```
<Validators id="Validator_test_id_card_number">
<Validator type="Checksum">
<Param name="Weights">1,1,2,1,1,1,1,1,1,1,1,1,1,1,1,1</Param>
<Param name="Mod">9</Param>
<Param name="CheckDigit">7</Param>
<Param name="UseAscii">1</Param>
</Validator>
</Validators>
```

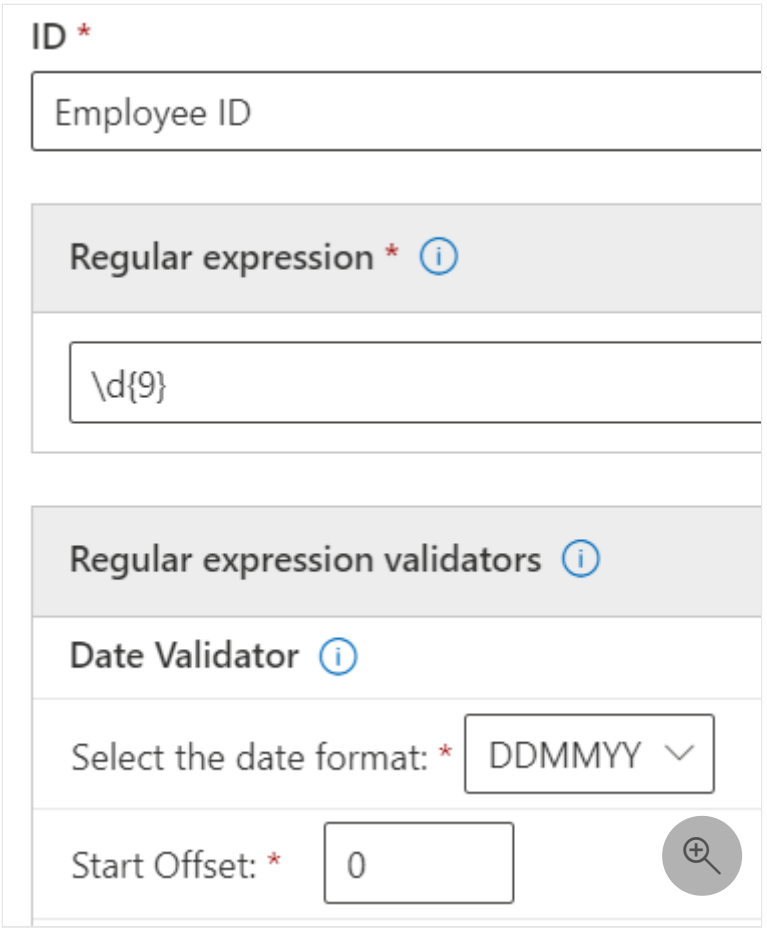
Limitations

Be aware of the following limitations when using advanced checksum validation:

- No UI Support Creating or editing SITs with advanced checksum logic isn't available via the UX.
- In alphanumeric SITs, letters are skipped if no weights are defined for them.

Date validator

If a date value that's embedded in a regular expression is part of a new pattern you're creating, you can use the *date validator* to test whether that date value meets your criteria. For example, you want to create a SIT for a nine-digit employee identification number. The first six digits are the date of hire in DDMMYY format and the last three are randomly generated numbers. Use these steps to validate that the first six digits are in the correct format:



1. Define the primary element with this regular expression:

   Console

   ```
   \d{9}
   ```

2. Add the date validator.

3. Select the date format and the start offset. Since the date string is the first six digits, the offset is `0`.

Functional processors as validators

You can use function processors for some of the most commonly used SITs as validators. Using function processors allows you to define your own regular expressions while ensuring that they pass the additional checks required by the SIT. For example, Func_India_Aadhar ensures that the custom regular expression you defined passes the validation logic required for the Indian Aadhar card. For more information on the DLP functions that you can use as validators, see Sensitive information type functions.

Luhn check validator

You can use the Luhn check validator if you have a custom sensitive information type that includes a regular expression, which should pass the Luhn algorithm.

Sensitive information type additional checks

Here are the definitions and some examples for the available additional checks.

Exclude specific matches: This check lets you define keywords to exclude when detecting matches for the pattern you're editing. For example, you might exclude test credit card numbers like '4111111111111111' so that they're not matched as a valid number.

Starts or doesn't start with characters: This check lets you define the characters that the matched items must or must not start with. For example, if you want the pattern to detect only credit card numbers that start with 41, 42, or 43, select **Starts with** and add 41, 42, and 43 to the list, separated by commas.

Ends or doesn't end with characters: This check lets you define the characters that the matched items must or must not end with. For example, if your Employee ID number can't end with 0 or 1, select **Doesn't end with** and add 0 and 1 to the list, separated by commas.

Exclude duplicate characters: This check lets you ignore matches in which all the digits are the same. For example, if the six digit employee ID number can't have all the digits be the same, you can select **Exclude duplicate characters** to exclude 111111, 222222, 333333, 444444, 555555, 666666, 777777, 888888, 999999, and 000000 from the list of valid matches for the employee ID.

Include or exclude prefixes: This check lets you define the keywords that must or must not be found immediately before the matching entity. Depending on your selection, entities are matched or not matched if they're preceded by the prefixes you include here. For example, if you **Exclude** the prefix `GUID`, any entity that's preceded by **GUID:** won't match.

Include or exclude suffixes: This check lets you define the keywords that must or must not be found immediately after the matching entity. Depending on your selection, entities match or not match if they're followed by the suffixes you include here. For example, if you **Exclude** the suffix `GUID`, any text that's followed by `:GUID` won't match.

Create a custom sensitive information type using PowerShell

This article shows you how to create an XML *rule package* file that defines custom sensitive information types. This article describes a custom sensitive information type that detects employee ID numbers. You can use the sample XML in this article as a starting point for your own XML file.

For more information about sensitive information types, see Learn about sensitive information types.

After you've created a well-formed XML file, you can upload it to Microsoft 365 using PowerShell. Then, you're ready to use your custom sensitive information type in policies. You can test its effectiveness in detecting the sensitive information as you intended.

> **Note**
>
> If you don't need the fine-grained control that PowerShell provides, you can create custom sensitive information types in the Microsoft Purview portal. For more information, see **Create a custom sensitive information type**.

Important disclaimer

Microsoft Support can't help you create content-matching definitions.

For custom content-matching development, testing, and debugging, you need to use your own internal IT resources, or use consulting services, such as Microsoft Consulting Services (MCS). Microsoft Support engineers can provide limited support for this feature, but they can't guarantee that custom content-matching suggestions will fully meet your needs.

MCS can provide regular expressions for testing purposes. They can also provide assistance in troubleshooting an existing RegEx pattern that's not working as expected with a single specific content example.

For more information, see the Potential validation issues to be aware of section.

For more information about the Boost.RegEx (formerly known as RegEx++) engine that's used for processing the text, see Boost.Regex 5.1.3 .

> **Note**
>
> If you use an ampersand character (&) as part of a keyword in your custom sensitive information type, you need to add an additional term with spaces around the character. For example, use `L & P` *not* `L&P`.

Sample XML of a rule package

Here's the sample XML of the rule package that we create in this article. Elements and attributes are explained in the sections on Rule, Entity, and Pattern elements; Match elements; evidence combinations; proximity; confidence levels; LocalizedStrings; and RulePack markup.

XML

```
<?xml version="1.0" encoding="UTF-16"?>

      </Description>
    </Resource>
  </LocalizedStrings>
</Rules>
</RulePackage>
```

What are your key requirements? [Rule, Entity, Pattern elements]

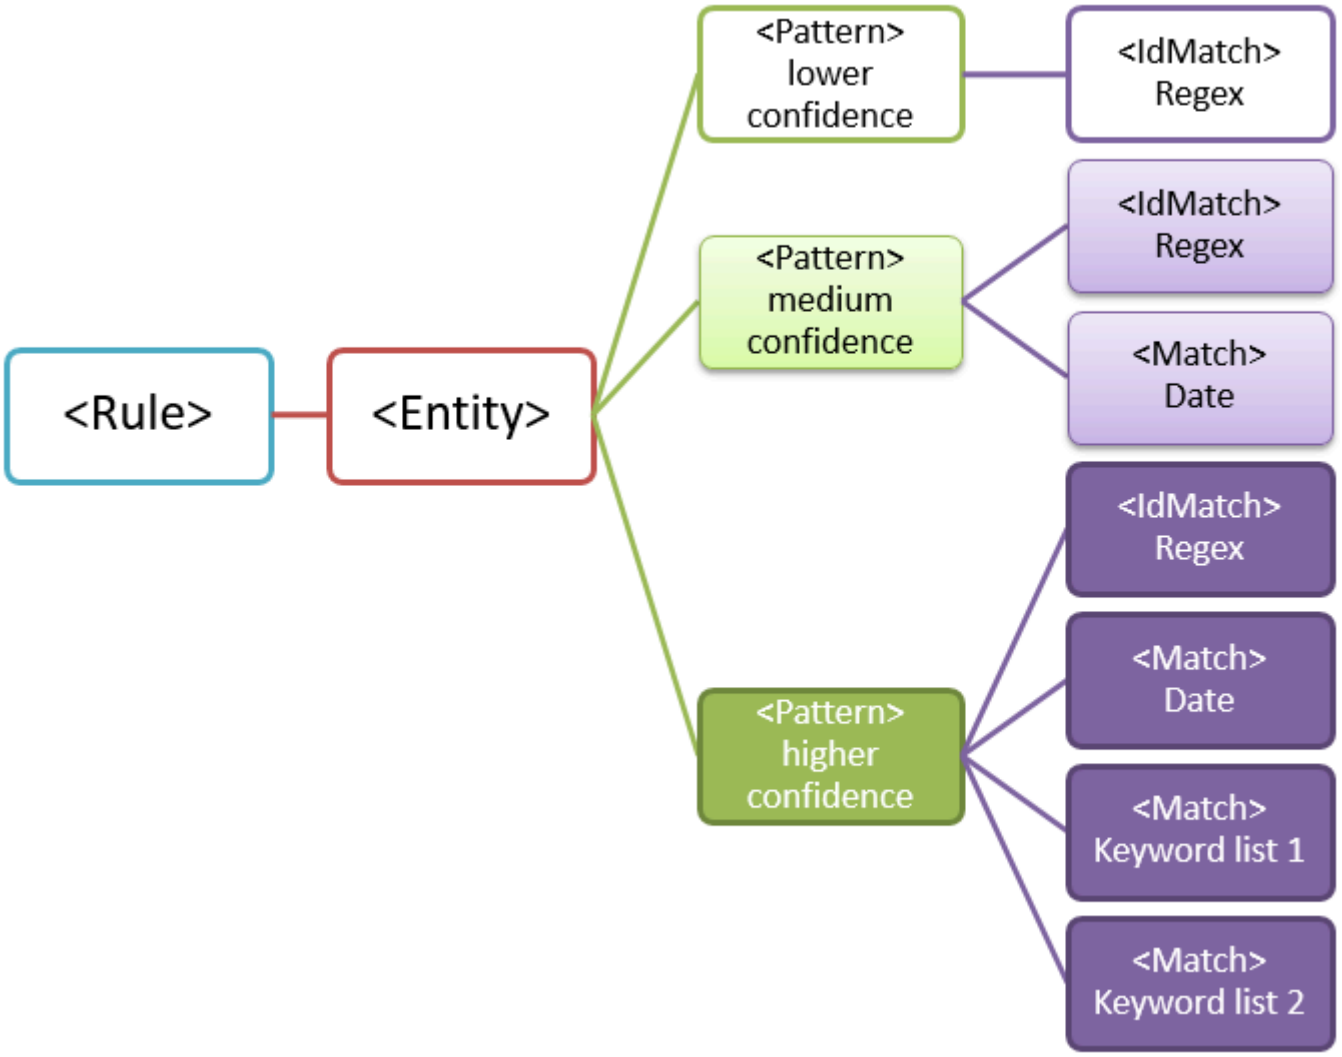
It's important that you understand the basic structure of the XML schema for a rule. Your understanding of the structure helps your custom sensitive information type to identify the right content.

A rule defines one or more entities (also known as sensitive information types). Each entity defines one or more patterns. A pattern is what a policy looks for when it evaluates content (for example, email and documents).

In XML markup, "rules" mean the patterns that define the sensitive information type. Don't associate references to rules in this article with "conditions" or "actions" that are common in other Microsoft features.

Simplest scenario: entity with one pattern

Here's a simple scenario: You want your policy to identify content that contains nine-digit employee IDs that are used in your organization. A pattern refers to the regular expression in the rule that identifies nine-digit numbers. Any content that contains a nine-digit number satisfies the pattern.



But, this pattern might identify **any** nine-digit number, including longer numbers or other types of nine-digit numbers that aren't employee IDs. This type of unwanted match is known as a *false positive*.

More common scenario: entity with multiple patterns

Because of the potential for false positives, you typically use more than one pattern to define an entity. Multiple patterns provide supporting evidence for the target entity. For example, additional keywords, dates, or other text can help identify the original entity (for example, the nine-digit employee number).

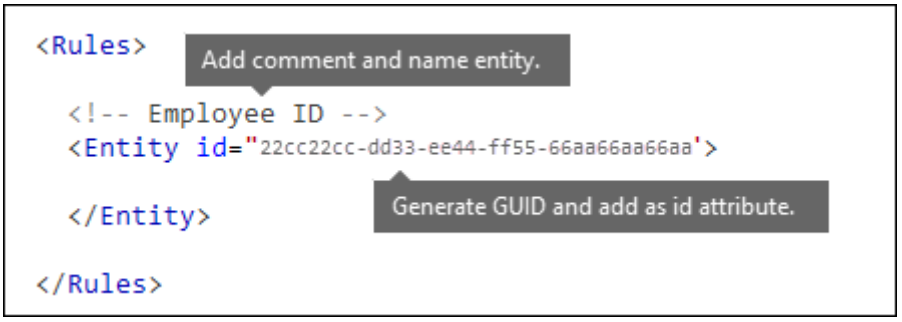
For example, to increase the likelihood of identifying content that contains an employee ID, you can define other patterns to look for:

- A pattern that identifies a hire date.
- A pattern that identifies both a hire date and the "employee ID" keyword.

There are important points to consider for multiple-pattern matches:

- Patterns that require more evidence have a higher confidence level. Based on the confidence level, you can take the following actions:
  - Use more restrictive actions (such as block content) with higher-confidence matches.
  - Use less restrictive actions (such as send notifications) with lower-confidence matches.

- The supporting `IdMatch` and `Match` elements reference RegExes and keywords that are actually children of the `Rule` element, not the `Pattern`. The `Pattern` references supporting elements, but they're included in the `Rule`. This behavior means that a single definition of a supporting element, such as a regular expression or a keyword list, can be referenced by multiple entities and patterns.



What entity do you need to identify? [Entity element, ID attribute]

An entity is a sensitive information type, such as a credit card number, that has a well-defined pattern. Each entity has a unique GUID as its ID.

Name the entity and generate its GUID

Use the following steps to create the entity markup and generate its unique identifier:

1. In your XML editor of choice, add the `Rules` and `Entity` elements.
2. Add a comment that contains the name of your custom entity, such as Employee ID. Later, you add the entity name to the localized strings section, and that name appears in the admin center when you create a policy.
3. Generate a unique GUID for your entity. For example, in Windows PowerShell, you can run the command `[guid]::NewGuid()`. Later, you'll also add the GUID to the localized strings section of the entity.

```
<Rules>
  <!-- Employee ID -->
  <Entity id="22cc22cc-dd33-ee44-ff55-66aa66aa66aa">
  </Entity>
</Rules>
```

What pattern do you want to match? [Pattern element, IdMatch element, Regex element]

The pattern contains the list of what the sensitive information type is looking for. The pattern can include RegExes, keywords, and built-in functions. Functions do task like running RegExes to find dates or addresses. Sensitive information types can have multiple patterns with unique confidences.

In the following diagram, all of the patterns reference the same regular expression. This RegEx looks for a nine-digit number `(\d{9})` surrounded by white space `(\s) ... (\s)`. The `IdMatch` element references this regular expression, and it's the common requirement for all patterns that look for the Employee ID entity. `IdMatch` is the identifier that the pattern is to trying to match. A `Pattern` element must have exactly one `IdMatch` element.

```
<Rules>

  <!-- Employee ID -->
  <Entity id="                                    ">

    <Pattern>
      <IdMatch idRef="Regex_employee_id" />
    </Pattern>

    <Pattern>
      <IdMatch idRef="Regex_employee_id" />
    </Pattern>

    <Pattern>
      <IdMatch idRef="Regex_employee_id" />
    </Pattern>

  </Entity>

  <Regex id="Regex_employee_id">(\s)(\d{9})(\s)</Regex>

</Rules>
```

Each Pattern has exactly one required IdMatch element, which references the same regex.

Regex defines the identifier the pattern is trying to match.

A satisfied pattern match returns a count and confidence level, which you can use in the conditions in your policy. When you add a condition for detecting a sensitive information type to a policy, you can edit the count and confidence level as shown in the following diagram. Confidence level (also called match accuracy) is explained in the confidenceLevel and recommendedConfidence attributes section.

Regular expressions are powerful, so there are issues that you need to know about. For example, a RegEx that identifies too much content can affect performance. To learn more about regular expression validation and performance issues, see the Potential validation issues to be aware of section.

Do you want to require additional evidence? [Match element, minCount attribute]

In addition to `IdMatch`, a pattern can use the `Match` element to require additional supporting evidence, such as a keyword, RegEx, date, or address.

A `Pattern` might include multiple `Match` elements:

- Directly in the `Pattern` element.
- Combined by using the `Any` element.

`Match` elements are joined with an implicit AND operator. In other words, all `Match` elements must be satisfied for the pattern to be matched.

You can use the `Any` element to introduce AND or OR operators. For details, see the Different combinations of evidence section.

You can use the optional `minCount` attribute to specify how many instances of a match need to be found for each `Match` element. For example, you can specify that a pattern is satisfied only when at least two keywords from a keyword list are found.

```
<Rules>

  <!-- Employee ID -->
  <Entity id="                                    ">

    <Pattern>
      <IdMatch idRef="Regex_employee_id" />
    </Pattern>

    <Pattern>
      <IdMatch idRef="Regex_employee_id" />
    </Pattern>

    <Pattern>
      <IdMatch idRef="Regex_employee_id" />
      <Match idRef="Keyword_employee" />
      <Match idRef="Keyword_badge" minCount="2" />
    </Pattern>

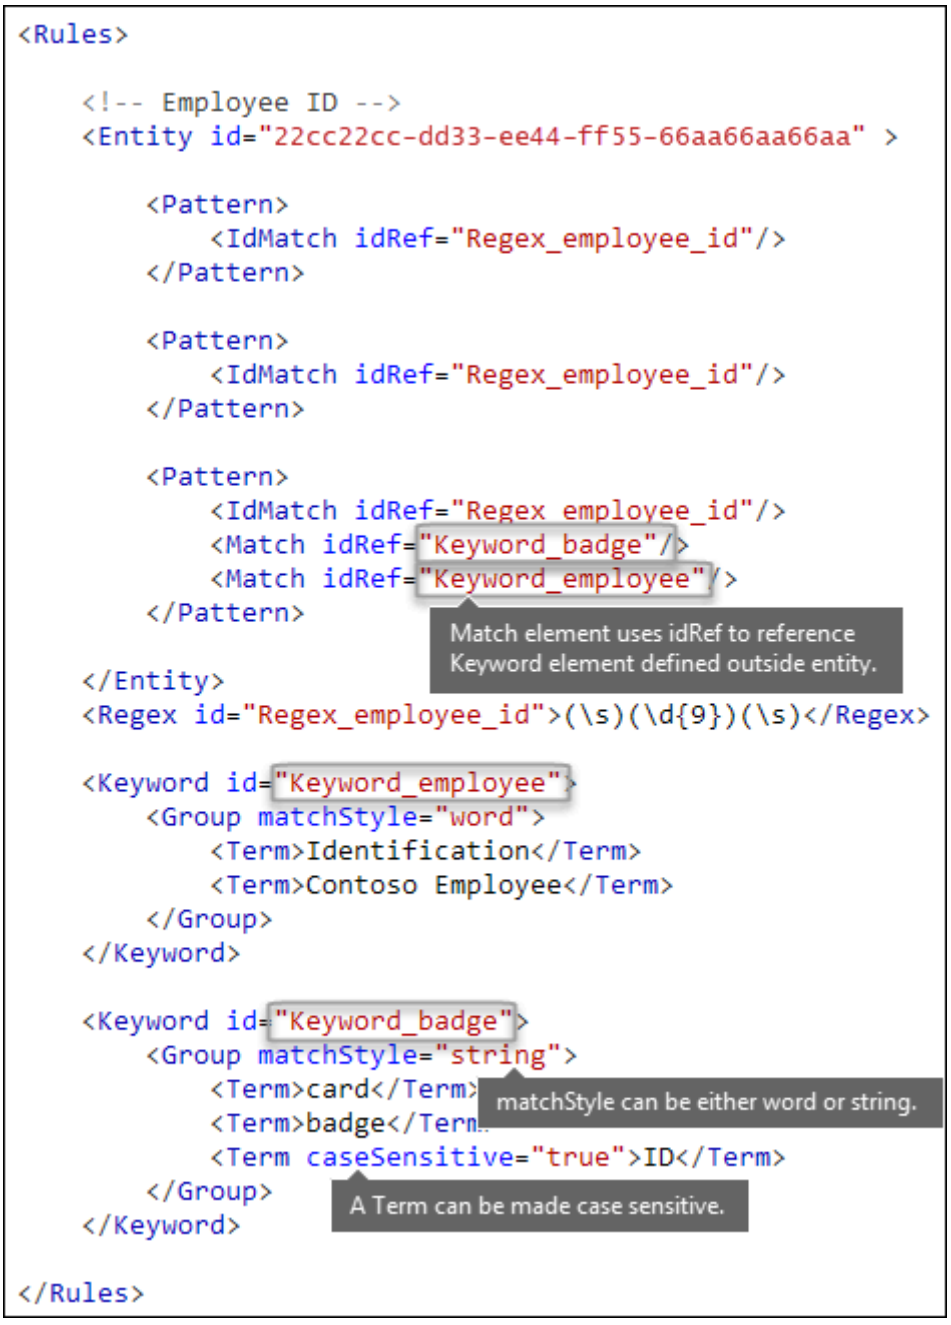
  </Entity>

  <Regex id="Regex_employee_id">(\s)(\d{9})(\s)</Regex>
```

Use minCount to make the Match require more evidence.

Use the Match element to require corroborative evidence.

Keywords [Keyword, Group, and Term elements, matchStyle, and caseSensitive attributes]



Identifying sensitive information often requires additional keywords as corroborative evidence. For example, in addition to matching a nine-digit number, you can look for words like "card", "badge", or "ID" using the Keyword element. The `Keyword` element has an `ID` attribute that can be referenced by multiple `Match` elements in multiple patterns or entities.

Keywords are included as a list of `Term` elements in a `Group` element. The `Group` element has a `matchStyle` attribute with two possible values:

- **matchStyle="word"**: A word match identifies whole words surrounded by white space or other delimiters. You should always use **word** unless you need to match parts of words or words in Asian languages.

- **matchStyle="string"**: A string match identifies strings no matter what they're surrounded by. For example, "ID" matches both "b**id**" and "**id**ea". Use `string` only when you need to match Asian words or if your keyword might be included in other strings.

Finally, you can use the `caseSensitive` attribute of the `Term` element to specify that the content must match the keyword exactly, including lower-case and upper-case letters.

```
<Rules>

    <!-- Employee ID -->
    <Entity id="22cc22cc-dd33-ee44-ff55-66aa66aa66aa" >

        <Pattern>
            <IdMatch idRef="Regex_employee_id"/>
        </Pattern>

        <Pattern>
            <IdMatch idRef="Regex_employee_id"/>
        </Pattern>

        <Pattern>
            <IdMatch idRef="Regex_employee_id"/>
            <Match idRef="Keyword_badge"/>
            <Match idRef="Keyword_employee"/>
        </Pattern>

    </Entity>
    <Regex id="Regex_employee_id">(\s)(\d{9})(\s)</Regex>

    <Keyword id="Keyword_employee">
        <Group matchStyle="word">
            <Term>Identification</Term>
            <Term>Contoso Employee</Term>
        </Group>
    </Keyword>

    <Keyword id="Keyword_badge">
        <Group matchStyle="string">
            <Term>card</Term>
            <Term>badge</Term>
            <Term caseSensitive="true">ID</Term>
        </Group>
    </Keyword>

</Rules>
```

Regular expressions [Regex element]

In this example, the employee `ID` entity already uses the `IdMatch` element to reference a regular expression for the pattern: a nine-digit number surrounded by whitespace. In addition, a pattern can use a `Match` element to reference an additional `Regex` element to identify corroborative evidence, such as a five-digit or nine-digit number in the format of a US postal code.

Additional patterns such as dates or addresses [built-in functions]

Sensitive information types can also use built-in functions to identify corroborating evidence. For example, a US date, EU date, expiration date, or US address. Microsoft 365 doesn't support uploading your own custom functions. But, when you create a custom sensitive information type, your entity can reference built-in functions.

For example, an employee ID badge has a hire date on it, so this custom entity can use the built-in `Func_us_date` function to identify a date in the format that's commonly used in the US.

For more information, see Sensitive information type functions.

Different combinations of evidence [Any element, minMatches, and maxMatches attributes]

In a `Pattern` element, all `IdMatch` and `Match` elements are joined with an implicit AND operator. In other words, all of the matches must be satisfied before the pattern can be satisfied.

You can create more flexible matching logic by using the `Any` element to group `Match` elements. For example, you can use the `Any` element to match all, none, or an exact subset of its child `Match` elements.

The `Any` element has optional `minMatches` and `maxMatches` attributes that you can use to define how many of the child `Match` elements must be satisfied before the pattern is matched. The

`minMatches` and `maxMatches` attributes define the *number* of `Match` elements, not the number of instances of evidence found for the matches. To define a minimum number of instances for a specific match, such as two keywords from a list, use the `minCount` attribute for a `Match` element, as described in the Match element, minCount attribute section.

Match at least one child Match element

To require only a minimum number of `Match` elements, you can use the `minMatches` attribute. In effect, these `Match` elements are joined with an implicit OR operator. This `Any` element is satisfied if a US-formatted date or a keyword from either list is found.

XML

```
<Any minMatches="1" >
     <Match idRef="Func_us_date" />
     <Match idRef="Keyword_employee" />
     <Match idRef="Keyword_badge" />
</Any>
```

Match an exact subset of any children Match elements

To require an exact number of `Match` elements, set `minMatches` and `maxMatches` to the same value. This `Any` element is satisfied only if exactly one date or keyword is found. If there are any more matches, the pattern isn't matched.

XML

```
<Any minMatches="1" maxMatches="1" >
     <Match idRef="Func_us_date" />
     <Match idRef="Keyword_employee" />
     <Match idRef="Keyword_badge" />
</Any>
```

Match none of children "Match" elements

If you want to require the absence of specific evidence for a pattern to be satisfied, you can set both minMatches and maxMatches to 0. This can be useful if you have a keyword list or other evidence that is likely to indicate a false positive.

For example, the employee ID entity looks for the keyword "card" because it might refer to an "ID card". However, if card appears only in the phrase "credit card", "card" in this content is unlikely

to mean "ID card". So you can add "credit card" as a keyword to a list of terms that you want to exclude from satisfying the pattern.

XML

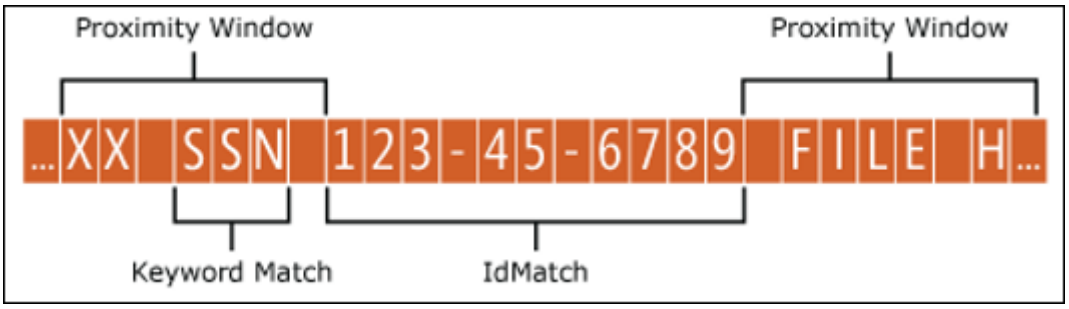
```
<Any minMatches="0" maxMatches="0" >
    <Match idRef="Keyword_false_positives_local" />
    <Match idRef="Keyword_false_positives_intl" />
</Any>
```

Match several unique terms

If you want to match several unique terms, use the *uniqueResults* parameter, set to *true*, as shown in the following example:

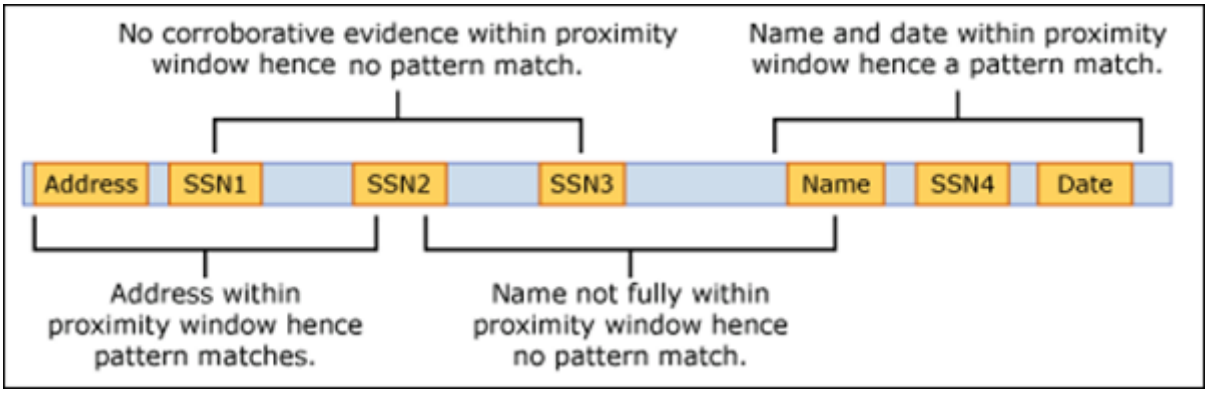
XML

```
<Pattern confidenceLevel="75">
    <IdMatch idRef="Salary_Revision_terms" />
    <Match idRef=" Salary_Revision_ID " minCount="3" uniqueResults="true" />
</Pattern>
```



In this example, a pattern is defined for salary revision using at least three unique matches.

How close to the entity must the other evidence be? [patternsProximity attribute]



Your sensitive information type is looking for a pattern that represents an employee ID, and as part of that pattern it's also looking for corroborative evidence like a keyword such as "ID". It makes sense that the closer together this evidence is, the more likely the pattern is to be an actual employee ID. You can determine how close other evidence in the pattern must be to the entity by using the required patternsProximity attribute of the Entity element.

For each pattern in the entity, the patternsProximity attribute value defines the distance (in Unicode characters) from the IdMatch location for all other Matches specified for that Pattern. The proximity window is anchored by the IdMatch location, with the window extending to the left and right of the IdMatch.

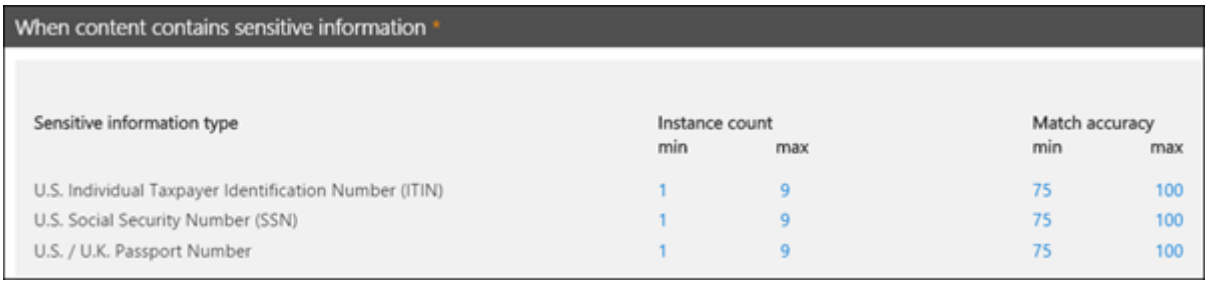
The example below illustrates how the proximity window affects the pattern matching where IdMatch element for the employee ID custom entity requires at least one corroborating match of keyword or date. Only ID1 matches because for ID2 and ID3, either no or only partial corroborating evidence is found within the proximity window.

For email, the message body and each attachment are treated as separate items. This means that the proximity window doesn't extend beyond the end of each of these items. For each item (attachment or body), both the idMatch and corroborative evidence needs to reside in that item.

What are the right confidence levels for different patterns? [confidenceLevel attribute, recommendedConfidence attribute]

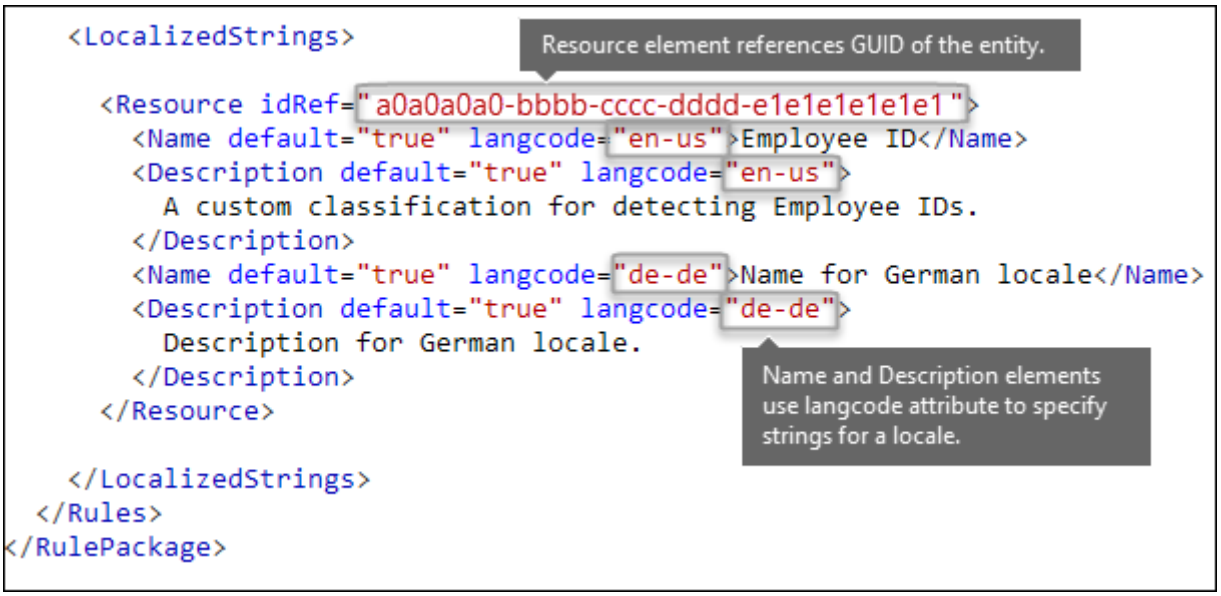
The more evidence that a pattern requires, the more confidence you have that an actual entity (such as employee ID) has been identified when the pattern is matched. For example, you have more confidence in a pattern that requires a nine-digit ID number, hire date, and keyword in close proximity, than you do in a pattern that requires only a nine-digit ID number.

The Pattern element has a required confidenceLevel attribute. You can think of the value of confidenceLevel (a value among 65/75/85 indicating Low/Medium/High confidence levels) as a unique ID for each pattern in an entity. After you upload your custom sensitive information type and then create a policy, you can reference these confidence levels in the conditions of the rules that you create.



```
<!--  Employee ID  -->
<Entity id="33dd33dd-ee44-ff55-aa66-77bb77bb77bb" patternsProximity="300">
  <Pattern confidenceLevel="65">
    <IdMatch idRef="Regex_employee_id"/>
  </Pattern>
  <Pattern confidenceLevel="75">
    <IdMatch idRef="Regex_employee_id"/>
    <Match idRef="Func_us_date"/>
  </Pattern>
  <Pattern confidenceLevel="85">
    <IdMatch idRef="Regex_employee_id"/>
    <Match idRef="Func_us_date"/>
    <Any minMatches="1">
      <Match idRef="Keyword_badge" minCount="2"/>
      <Match idRef="Keyword_employee"/>
    </Any>
    <Any minMatches="0" maxMatches="0">
      <Match idRef="Keyword_false_positives_local"/>
      <Match idRef="Keyword_false_positives_intl"/>
    </Any>
  </Pattern>
</Entity>
```

The more evidence the Pattern requires, the higher the confidence level.



In addition to confidenceLevel for each Pattern, the Entity has a recommendedConfidence attribute. The recommended confidence attribute can be thought of as the default confidence level for the rule. When you create a rule in a policy, if you don't specify a confidence level for the rule to use, that rule matches based on the recommended confidence level for the entity. The recommendedConfidence attribute is mandatory for each Entity ID in the Rule Package, if missing you won't be able to save policies that use the Sensitive Information Type.

Do you want to support other languages in the UI of the Purview portal? [LocalizedStrings element]

If your compliance team uses the Microsoft Purview portal to create policies in different locales and in different languages, you can provide localized versions of the name and description of your custom sensitive information type. When your compliance team uses Microsoft 365 in a language that you support, they see the localized name in the UI.

The Rules element must contain a LocalizedStrings element, which contains a Resource element that references the GUID of your custom entity. In turn, each Resource element contains one or more Name and Description elements that each use the `langcode` attribute to provide a localized string for a specific language.

```
    <LocalizedStrings>
      <Resource idRef="a0a0a0a0-bbbb-cccc-dddd-e1e1e1e1e1e1">
        <Name default="true" langcode="en-us">Employee ID</Name>
        <Description default="true" langcode="en-us">
          A custom classification for detecting Employee IDs.
        </Description>
        <Name default="true" langcode="de-de">Name for German locale</Name>
        <Description default="true" langcode="de-de">
          Description for German locale.
        </Description>
      </Resource>
    </LocalizedStrings>
  </Rules>
</RulePackage>
```

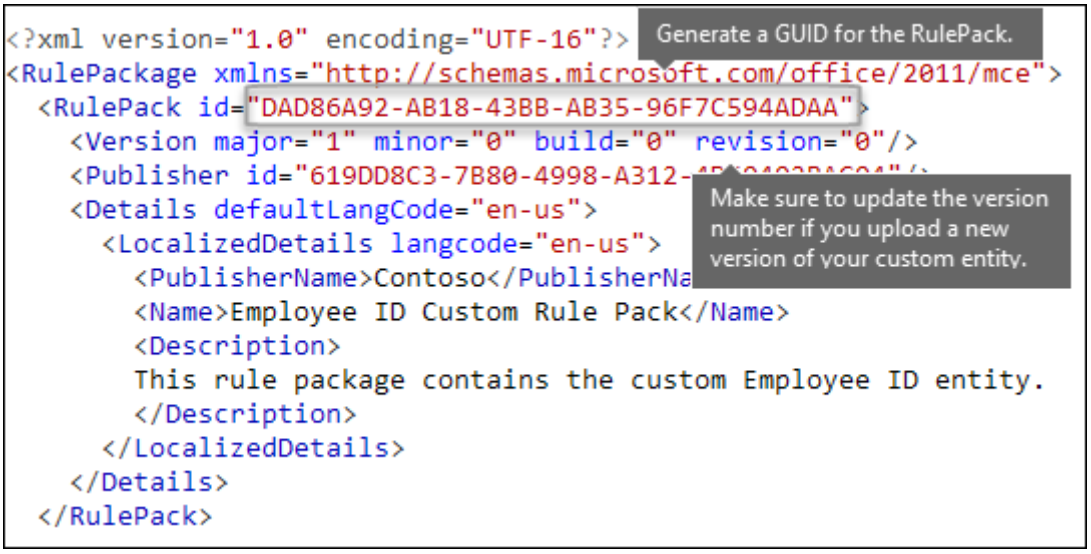
You use localized strings only for how your custom sensitive information type appears in the UI of the Compliance center. You can't use localized strings to provide different localized versions of a keyword list or regular expression.

Other rule package markup [RulePack GUID]

Finally, the beginning of each RulePackage contains some general information that you need to fill in. You can use the following markup as a template and replace the ". . ." placeholders with your own info.

Most importantly, you need to generate a GUID for the RulePack. Earlier, you generated a GUID for the entity; this is a second GUID for the RulePack. There are several ways to generate GUIDs, but you can do it easily in PowerShell by typing [guid]::NewGuid().

The Version element is also important. When you upload your rule package for the first time, Microsoft 365 notes the version number. Later, if you update the rule package and upload a new



version, make sure to update the version number or Microsoft 365 won't deploy the rule package.

XML

```
<?xml version="1.0" encoding="utf-16"?>
<RulePackage xmlns="http://schemas.microsoft.com/office/2011/mce">
  <RulePack id=". . .">
    <Version major="1" minor="0" build="0" revision="0" />
    <Publisher id=". . ." />
    <Details defaultLangCode=". . .">
      <LocalizedDetails langcode=" . . . ">
         <PublisherName>. . .</PublisherName>
         <Name>. . .</Name>
         <Description>. . .</Description>
      </LocalizedDetails>
    </Details>
  </RulePack>

 <Rules>
  . . .
 </Rules>
</RulePackage>
```

When complete, your RulePack element should look like this.

Validators

Microsoft 365 exposes function processors for commonly used SITs as validators. Here's a list of them.

List of currently available validators

The following validator functions are currently available for use in custom sensitive information type definitions:

- `Func_credit_card`
- `Func_ssn`
- `Func_unformatted_ssn`
- `Func_randomized_formatted_ssn`
- `Func_randomized_unformatted_ssn`
- `Func_aba_routing`
- `Func_south_africa_identification_number`
- `Func_brazil_cpf`
- `Func_iban`
- `Func_brazil_cnpj`
- `Func_swedish_national_identifier`
- `Func_india_aadhaar`
- `Func_uk_nhs_number`
- `Func_Turkish_National_Id`
- `Func_australian_tax_file_number`
- `Func_usa_uk_passport`
- `Func_canadian_sin`
- `Func_formatted_itin`
- `Func_unformatted_itin`
- `Func_dea_number_v2`
- `Func_dea_number`
- `Func_japanese_my_number_personal`
- `Func_japanese_my_number_corporate`

This gives you the ability to define your own RegEx and validate them. To use validators, define your own RegEx and use the `Validator` property to add the function processor of your choice. Once defined, you can use this RegEx in an SIT.

In the example below, a regular expression - Regex_credit_card_AdditionalDelimiters is defined for Credit card, which is then validated using the checksum function for credit card by using Func_credit_card as a validator.

XML

```
<Regex id="Regex_credit_card_AdditionalDelimiters" validators="Func_credit_card">
(?:^|[\s,;\:\(\)\[\]"'])([0-9]{4}[ -_][0-9]{4}[ -_][0-9]{4}[ -_][0-9]{4})(?:$|[\s,;\:\
(\)\[\]"'])</Regex>
```

```
<Entity id="675634eb7-edc8-4019-85dd-5a5c1f2bb085" patternsProximity="300"
recommendedConfidence="85">
<Pattern confidenceLevel="85">
<IdMatch idRef="Regex_credit_card_AdditionalDelimiters" />
<Any minMatches="1">
<Match idRef="Keyword_cc_verification" />
<Match idRef="Keyword_cc_name" />
<Match idRef="Func_expiration_date" />
</Any>
</Pattern>
</Entity>
```

Microsoft 365 provides two generic validators

Checksum validator

In this example, a checksum validator for employee ID is defined to validate the RegEx for EmployeeID.

XML

```
<Validators id="EmployeeIDChecksumValidator">
<Validator type="Checksum">
<Param name="Weights">2, 2, 2, 2, 2, 1</Param>
<Param name="Mod">28</Param>
<Param name="CheckDigit">2</Param> <!-- Check 2nd digit -->
<Param name="AllowAlphabets">1</Param> <!– 0 if no Alphabets -->
</Validator>
</Validators>
<Regex id="Regex_EmployeeID" validators="ChecksumValidator">(\d{5}[A-Z])</Regex>
<Entity id="675634eb7-edc8-4019-85dd-5a5c1f2bb085" patternsProximity="300"
recommendedConfidence="85">
<Pattern confidenceLevel="85">
<IdMatch idRef="Regex_EmployeeID"/>
</Pattern>
</Entity>
```

Date Validator

In this example, a date validator is defined for a RegEx part of which is date.

XML

```
<Validators id="date_validator_1"> <Validator type="DateSimple"> <Param
name="Pattern">DDMMYYYY</Param> <!–supported patterns DDMMYYYY, MMDDYYYY, YYYYDDMM,
YYYYMMDD, DDMMYYYY, DDMMYY, MMDDYY, YYDDMM, YYMMDD --> </Validator> </Validators>
<Regex id="date_regex_1" validators="date_validator_1">\d{8}</Regex>
```

Changes for Exchange Online

Previously, you might have used Exchange Online PowerShell to import your custom sensitive information types for DLP. Now your custom sensitive information types can be used in both the Exchange admin center and the Microsoft Purview portal. As part of this improvement, you should use Security & Compliance PowerShell to import your custom sensitive information types—you can't import them from Exchange Online PowerShell anymore. Your custom sensitive information types will continue to work just like before; however, it may take up to one hour for changes made to custom sensitive information types in the Compliance center to appear in the Exchange admin center.

Note that in the Compliance center, you use the **New-DlpSensitiveInformationTypeRulePackage** cmdlet to upload a rule package. (Previously, in the Exchange admin center, you used the **ClassificationRuleCollection**` cmdlet.)

Upload your rule package

To upload your rule package, do the following steps:

1. Save it as an .xml file with Unicode encoding.
2. Connect to Security & Compliance PowerShell
3. Use the following syntax:

   PowerShell

   ```
   New-DlpSensitiveInformationTypeRulePackage -FileData
   ([System.IO.File]::ReadAllBytes('PathToUnicodeXMLFile'))
   ```

   This example uploads the Unicode XML file named MyNewRulePack.xml from C:\My Documents.

   PowerShell

   ```
   New-DlpSensitiveInformationTypeRulePackage -FileData
   ([System.IO.File]::ReadAllBytes('C:\My Documents\MyNewRulePack.xml'))
   ```

   For detailed syntax and parameter information, see New-DlpSensitiveInformationTypeRulePackage.

> **Note**
>
> The maximum number of rule packages supported is 10, but each package can contain the definition of multiple sensitive information types.

4. To verify that you've successfully created a new sensitive information type, do any of the following steps:

   - Run the Get-DlpSensitiveInformationTypeRulePackage cmdlet to verify the new rule package is listed:

     ```
     PowerShell
     Get-DlpSensitiveInformationTypeRulePackage
     ```

   - Run the Get-DlpSensitiveInformationType cmdlet to verify the sensitive information type is listed:

     ```
     PowerShell
     Get-DlpSensitiveInformationType
     ```

     For custom sensitive information types, the Publisher property value will be something other than Microsoft Corporation.

   - Replace <Name> with the Name value of the sensitive information type (example: Employee ID) and run the Get-DlpSensitiveInformationType cmdlet:

     ```
     PowerShell
     Get-DlpSensitiveInformationType -Identity "<Name>"
     ```

Potential validation issues to be aware of

When you upload your rule package XML file, the system validates the XML and checks for known bad patterns and obvious performance issues. Here are some known issues that the validation checks for a regular expression:

- Lookbehind assertions in the regular expression should be of fixed length only. Variable length assertions results in errors.

For example, `"(?<=^|\s|_)"` won't pass validation. The first pattern (`^`) is zero length, while the next two patterns (`\s` and `_`) have a length of one. An alternate way to write this regular expression is `"(?:^|(?<=\s|_))"`.

- Can't begin or end with alternator `|`, which matches everything because it's considered an empty match.

  For example, `|a` or `b|` won't pass validation.

- Can't begin or end with a `.{0,m}` pattern, which has no functional purpose and only impairs performance.

  For example, `.{0,50}ASDF` or `ASDF.{0,50}` won't pass validation.

- Can't have `.{0,m}` or `.{1,m}` in groups, and can't have `.\*` or `.+` in groups.

  For example, `(.{0,50000})` won't pass validation.

- Can't have any character with `{0,m}` or `{1,m}` repeaters in groups.

  For example, `(a\*)` won't pass validation.

- Can't begin or end with `.{1,m}`; instead, use `.`.

  For example, `.{1,m}asdf` won't pass validation. Instead, use `.asdf`.

- Can't have an unbounded repeater (such as `*` or `+`) on a group.

  For example, `(xx)\*` and `(xx)+` won't pass validation.

- The regex pattern must contain exactly one primary capturing group (the only capturing group). Use noncapturing groups for any prefix/suffix (for example: `(?:prefix)(primary capturing group)(?:suffix)`). Consolidate match variants inside the single capturing group using `|`; patterns like `(group1)|(group2)` are rejected.

  For example, `(?:[\s,;])([A-Z]{2}[0-9]{3})(?:[\s,;])|(?:[\s,;])([A-Z]{2}[A-Z]{4}[0-9])(?:[\s,;])` won't pass validation because it contains multiple capturing groups. Instead, use `(?:[\s,;])([A-Z]{2}[0-9]{3}|[A-Z]{2}[A-Z]{4}[0-9])(?:[\s,;])`.

- Keywords have a maximum of 50 characters in Length. If you have a keyword within a Group exceeding this, a suggested solution is to create the Group of terms as a Keyword Dictionary and reference the GUID of the Keyword Dictionary within the XML structure as part of the Entity for Match or idMatch in the file.

- Each Custom Sensitive Information Type can have a maximum of 2,048 keywords total.
- The maximum size of Keyword Dictionaries in a single tenant is 480 KB compressed to comply with AD Schema limits. Reference the same dictionary as many times as necessary when creating custom sensitive information types. Start with creating custom keyword lists in the sensitive information type and use keyword dictionaries if you have more than 2048 keywords in a keyword list or a keyword is larger than 50 characters in length.
- A maximum of 50 keyword dictionary based sensitive information types are allowed in a tenant.
- Ensure each Entity element contains a recommendedConfidence attribute.
- When using the PowerShell Cmdlet, there's a maximum return size of the Deserialized Data of approximately 1 megabyte. This affects the size of your rule pack XML file. Keep the uploaded file limited to a 770 kilobyte maximum as a suggested limit for consistent results without error when processing.
- The XML structure doesn't require formatting characters such as spaces, tabs, or carriage return/linefeed entries. Take note of this when optimizing for space on uploads. Tools such as Microsoft Visual Code provide join line features to compact the XML file.

If a custom sensitive information type contains an issue that may affect performance, it won't be uploaded and you may see one of these error messages:

- `Generic quantifiers which match more content than expected (e.g., '+', '*')`
- `Lookaround assertions`
- `Complex grouping in conjunction with general quantifiers`

Recrawl your content to identify the sensitive information

Microsoft 365 uses the search crawler to identify and classify sensitive information in site content. Content in SharePoint Online and OneDrive for Business sites is recrawled automatically whenever it's updated. But to identify your new custom type of sensitive information in all existing content, that content must be recrawled.

To re-evaluate content across multiple locations at once, you can create a scan using On-demand classification. Learn more about On-demand classification\

Reference: Rule package XML schema definition

You can copy this markup, save it as an XSD file, and use it to validate your rule package XML file.

XML

```xml
<?xml version="1.0" encoding="utf-8"?>
<xs:schema xmlns:mce="http://schemas.microsoft.com/office/2011/mce"
           targetNamespace="http://schemas.microsoft.com/office/2011/mce"

Remove a custom sensitive information type using PowerShell

In Security & Compliance PowerShell, there are two methods to remove custom sensitive information types:

- **Remove individual custom sensitive information types**: Use the method documented in Modify a custom sensitive information type using PowerShell. Export the custom rule package containing the custom sensitive information type. Remove the sensitive information type from the XML file, and then import the updated XML file back into the existing custom rule package.
- **Remove a custom rule package and all custom sensitive information types that it contains**: Removing an entire custom rule package is documented in this section.

> **Note**
>
> Before your remove a custom sensitive information type, verify that no DLP policies or Exchange mail flow rules (also known as transport rules) still reference the sensitive information type.

1. Security & Compliance PowerShell
2. To remove a custom rule package, use the Remove-DlpSensitiveInformationTypeRulePackage cmdlet. Run the following command to remove the specified rule package when you no longer need it or want to replace it:

   ```
   PowerShell
   Remove-DlpSensitiveInformationTypeRulePackage -Identity "RulePackageIdentity"
   ```

   You can use the Name value (for any language) or the `RulePack id` (GUID) value to identify the rule package.

   The following example removes a custom rule package named "Employee ID Custom Rule Pack":

   ```
   PowerShell
   ```

```
Remove-DlpSensitiveInformationTypeRulePackage -Identity "Employee ID Custom Rule Pack"
```

For detailed syntax and parameter information, see the Remove-DlpSensitiveInformationTypeRulePackage cmdlet reference.

3. To verify that you've successfully removed a custom sensitive information type, do any of the following steps:

   - Run the Get-DlpSensitiveInformationTypeRulePackage cmdlet and verify the rule package is no longer listed:

     PowerShell

     ```
     Get-DlpSensitiveInformationTypeRulePackage
     ```

   - Run the Get-DlpSensitiveInformationType cmdlet to verify the sensitive information types in the removed rule package are no longer listed:

     PowerShell

     ```
     Get-DlpSensitiveInformationType
     ```

     For custom sensitive information types, the Publisher property value will be something other than "Microsoft Corporation".

   - Replace <Name> with the Name value of the sensitive information type (for example, Employee ID) and run the Get-DlpSensitiveInformationType cmdlet to verify the sensitive information type is no longer listed:

     PowerShell

     ```
     Get-DlpSensitiveInformationType -Identity "<Name>"
     ```

Modify a custom sensitive information type using PowerShell

Before you begin, connect to Security & Compliance PowerShell. For instructions, see Security & Compliance PowerShell.

In Security & Compliance PowerShell, modifying a custom sensitive information type requires you to:

1. Export the existing rule package that contains the custom sensitive information type to an XML file (or use the existing XML file if you have it).
2. Modify the custom sensitive information type in the exported XML file.
3. Import the updated XML file back into the existing rule package.

To connect to Security & Compliance PowerShell, see Security & Compliance PowerShell.

Step 1: Export the existing rule package to an XML file

Use the following steps to export the existing rule package to an XML file.

> **Note**
>
> If you have a copy of the XML file (for example, if you just created and imported it), you can skip to Step: 2 Modify the sensitive information type in the exported XML file.

1. If you don't already know the name of the custom rule package, run the Get-DlpSensitiveInformationTypeRulePackage cmdlet to find it:

   PowerShell

   ```
   Get-DlpSensitiveInformationTypeRulePackage
   ```

   > **Note**
   >
   > The built-in rule package that contains the built-in sensitive information types is named *Microsoft Rule Package*. The rule package that contains the custom sensitive

information types that you created in the Compliance center UI is named *Microsoft.SCCManaged.CustomRulePack*.

2. Use the Get-DlpSensitiveInformationTypeRulePackage cmdlet to store the custom rule package to a variable:

```
PowerShell
$rulepak = Get-DlpSensitiveInformationTypeRulePackage -Identity "RulePackageName"
```

For example, if the name of the rule package is "Employee ID Custom Rule Pack", run the following cmdlet:

```
PowerShell
$rulepak = Get-DlpSensitiveInformationTypeRulePackage -Identity "Employee ID Custom Rule Pack"
```

3. Use the following syntax to export the custom rule package to an XML file:

```
PowerShell
[System.IO.File]::WriteAllBytes('XMLFileAndPath', $rulepak.SerializedClassificationRuleCollection)
```

This example exports the rule package to the file named ExportedRulePackage.xml in the C:\My Documents folder.

```
PowerShell
[System.IO.File]::WriteAllBytes('C:\My Documents\ExportedRulePackage.xml', $rulepak.SerializedClassificationRuleCollection)
```

Step 2: Modify the sensitive information type in the exported XML file

For XML schema details and editing guidance, see Customize a built-in sensitive information type.

Step 3: Import the updated XML file back into the existing rule package

To import the updated XML back into the existing rule package, use the Set-DlpSensitiveInformationTypeRulePackage cmdlet:

PowerShell

```
Set-DlpSensitiveInformationTypeRulePackage -FileData
([System.IO.File]::ReadAllBytes('C:\My Documents\External Sensitive Info Type Rule
Collection.xml'))
```

For detailed syntax and parameter information, see Set-DlpSensitiveInformationTypeRulePackage.

Create a keyword dictionary

Microsoft Purview can identify, monitor, and protect your sensitive items. Identifying sensitive items sometimes requires looking for keywords, particularly when identifying generic content (such as healthcare-related communication), or inappropriate or explicit language. Although you can create keyword lists when you create custom sensitive information types, keyword lists are limited in size and if you're creating custom sensitive information types in PowerShell, require modifying XML to create or edit them.

In contrast, keyword dictionaries provide simpler management of keywords and at a larger scale, supporting up to 1 MB of terms (post-compression) in the dictionary. Additionally, keyword dictionaries can support any language. The tenant limit is also 1 MB after compression. A post-compression limit of 1 MB means that all dictionaries combined across a tenant can have close to one million characters.

Keyword dictionary limits

You can create keyword dictionary, subject to a combined size limit of 1MB (post compression) per tenant. To find out how many keyword dictionaries you have in your tenant, connect to Security & Compliance PowerShell and then run this PowerShell script:

PowerShell

```
$rawFile = $env:TEMP + "\rule.xml"

$kd = Get-DlpKeywordDictionary
$ruleCollections = Get-DlpSensitiveInformationTypeRulePackage
[System.IO.File]::WriteAllBytes((Resolve-Path $rawFile),
$ruleCollections.SerializedClassificationRuleCollection)
$UnicodeEncoding = New-Object System.Text.UnicodeEncoding
$FileContent = [System.IO.File]::ReadAllText((Resolve-Path $rawFile),
$unicodeEncoding)

if($kd.Count -gt 0)
{
$count = 0
$entities = $FileContent -split "Entity id"
for($j=1;$j -lt $entities.Count;$j++)
{
for($i=0;$i -lt $kd.Count;$i++)
{
$Matches = Select-String -InputObject $entities[$j] -Pattern $kd[$i].Identity -
AllMatches
```

```
$count = $Matches.Matches.Count + $count
if($Matches.Matches.Count -gt 0) {break}
}
}

Write-Output "Total Keyword Dictionary SIT:"
$count
}
else
{
$Matches = Select-String -InputObject $FileContent -Pattern $kd.Identity -AllMatches
Write-Output "Total Keyword Dictionary SIT:"
$Matches.Matches.Count
}

Remove-Item $rawFile
```

Basic steps to creating a keyword dictionary

Most commonly you compile your keywords for your dictionary in a file, such as a .csv or .txt list. You upload the dictionary file into a SIT during creation or editing or import them via a PowerShell cmdlet. Alternatively, you can start from an existing keyword dictionary. Lastly, you can enter keywords manually in the **Add keyword dictionary** dialog. When you create a keyword dictionary, you follow the same core steps:

Create a keyword dictionary using the Microsoft Purview portal

Use these steps to create or import keywords for a custom dictionary:

1. Sign in to the Microsoft Purview portal **Information Protection** > **Classifiers** > **Sensitive info types**.
2. Select + **Create sensitive info type** and then enter a **Name** and **Description** for your sensitive info type. Choose **Next**.
3. On the **Define patterns for this sensitive info type** page, choose + **Create pattern**.
4. In the **New pattern** window, select a **Confidence level**.
5. Choose **Add a Primary element** and select **Keyword dictionary**.
6. On the **Add a keyword dictionary** flyout, you can:
   a. **Upload a dictionary** file in **TXT** or **CSV** format.
   b. **Choose from existing dictionaries**.

c. or create a new dictionary by entering keywords manually and giving it a name.

7. Still in the **New Pattern** window, for **Character proximity**, specify how far away (in number of characters) that any supporting elements must be to be detected. The closer the primary and supporting elements are to each other, the more likely the detected content is going to be what you're looking for.

8. Add the **Supporting elements** you wish to use to increase the accuracy of detecting what you're looking for.

9. Add any **Additional checks** and then choose **Create**.

10. Choose **Next** to continue creating your sensitive information type. When you're finished, choose **Done**.

Create a keyword dictionary from a file using PowerShell

Often when you need to create a large dictionary, it's so you can use keywords from a file or a list exported from some other source. This procedure creates a keyword dictionary containing a list of diseases to screen in external email. To begin, you need to connect to Security & Compliance PowerShell.

1. Copy your keywords into a text file and make sure that each keyword is on a separate line.

2. Save the text file with Unicode encoding. In Notepad, navigate to > **Save As** > **Encoding** > **Unicode**.

3. Read the file into a variable by running this cmdlet:

```
PowerShell
$fileData = [System.IO.File]::ReadAllBytes('<filename>')
```

4. Create the dictionary by running this cmdlet:

```
PowerShell
New-DlpKeywordDictionary -Name <name> -Description <description> -FileData
$fileData
```

Using keyword dictionaries in custom sensitive information types and DLP policies

Keyword dictionaries can be used as part of the match requirements for a custom sensitive information type, or as a sensitive information type themselves. Both require you to create a custom sensitive information type using PowerShell. Follow the instructions in Create a custom sensitive information type using PowerShell to create a sensitive information type. Once you have the XML, you need the GUID identifier from the XML in order to use the keyword dictionary.

XML

```
<Entity id="00aa00aa-bb11-cc22-dd33-44ee44ee44ee" patternsProximity="300"
recommendedConfidence="75">
    <Pattern confidenceLevel="75">
        <IdMatch idRef=". . ."/>
    </Pattern>
</Entity>
```

To get the identity of your dictionary, run this command and copy the **Identity** property value:

PowerShell

```
Get-DlpKeywordDictionary -Name "Diseases"
```

The output of the command looks like this:

```
RunspaceId : 138e55e7-ea1e-4f7a-b824-79f2c4252255
Identity : 8d2d44b0-91f4-41f2-94e0-21c1c5b5fc9f
Name : Diseases
Description : Names of diseases and injuries from ICD-10-CM lexicon
KeywordDictionary : aarskog's syndrome, abandonment, abasia, abderhalden-kaufmann-lignac,
abdominalgia, abduction contracture, abetalipo proteinemia, abiotrophy, ablatio, ablation,
ablepharia,abocclusion, abolition, aborter, abortion, abortus, aboulomania, abrami's
disease, abramo
IsValid : True
ObjectState : Unchanged
```

Paste the **identity** value into the XML for your custom sensitive information type as the **idRef**. Next, upload the XML file. Your dictionary now appears in your list of sensitive information types and you can use it right in your policy, specifying how many keywords are required to match.

XML

```
<Entity id="11bb11bb-cc22-dd33-ee44-55ff55ff55ff" patternsProximity="300"
recommendedConfidence="85">
      <Pattern confidenceLevel="85">
        <IdMatch idRef="8d2d44b0-91f4-41f2-94e0-21c1c5b5fc9f" />
      </Pattern>
    </Entity>
    <LocalizedStrings>
      <Resource idRef="11bb11bb-cc22-dd33-ee44-55ff55ff55ff">
        <Name default="true" langcode="en-us">Diseases</Name>
        <Description default="true" langcode="en-us">Detects various
diseases</Description>
      </Resource>
    </LocalizedStrings>
```

> **Note**
>
> Microsoft 365 Information Protection supports double-byte character set languages for:
>
> - Chinese (simplified)
> - Chinese (traditional)
> - Korean
> - Japanese
>
> This support is available for sensitive information types. See, Information protection support for double byte character sets release notes (preview) for more information.

> **Tip**
>
> To detect patterns containing Chinese/Japanese characters and single byte characters or to detect patterns containing Chinese/Japanese and English, define two variants of the keyword or regex.
>
> - For example, to detect a keyword like "机密的document", use two variants of the keyword; one with a space between the Japanese and English text and another without a space between the Japanese and English text. So, the keywords to be added in the SIT should be "机密的 document" and "机密的document". Similarly, to detect a phrase "東京オリンピック2020", two variants should be used; "東京オリンピック 2020" and "東京オリンピック2020".
>
> Along with Chinese/Japanese/double byte characters, if the list of keywords/phrases also contains non-Chinese/Japanese words also (for instance, stand-alone English words), you

should create two dictionaries/keyword lists. One for keywords containing Chinese/Japanese/double byte characters and another one for English words.

- For example, if you want to create a keyword dictionary/list with three phrases "Highly confidential", "機密性が高い" and "机密的document", you should create two keyword lists.

    1. Highly confidential
    2. 機密性が高い, 机密的document and 机密的 document

While creating a regex using a double byte hyphen or a double byte period, make sure to escape both the characters like one would escape a hyphen or period in a regex. Here's a sample regex for reference:

- `(?<!\d)([4][0-9]{3}[\-?\-\t]*[0-9]{4}`

We recommend using a string match instead of a word match in a keyword list.

Modify a keyword dictionary

This article explains how to modify keywords in custom or built-in keyword dictionaries used by sensitive information types (SITs) in Microsoft Purview. You can modify a keyword dictionary by using the Microsoft Purview portal or PowerShell.

Modify a keyword dictionary in the portals

Keyword dictionaries can be used as **Primary elements** or **Supporting elements** in sensitive information type (SIT) patterns. You can edit a keyword dictionary while creating a SIT or in an existing custom SIT. For example to edit an existing keyword dictionary:

1. Sign in to the Microsoft Purview portal > **Information Protection** > **Classifiers** > **Sensitive info types**.
2. Choose the SIT that uses the keyword dictionary you want to update.
3. Select **Edit**.
4. Choose **Next**.
5. **Edit** the pattern that has the keyword dictionary you want to update.
6. Edit the keyword dictionary in the **Primary element** or the **Supporting element** sections. Make your edits, using one keyword per line.

7. Choose **Done**.

Modify a keyword dictionary using PowerShell

For example, we'll modify some terms in PowerShell, save the terms locally where you can modify them in an editor, and then update the previous terms in place.

First, retrieve the dictionary object:

PowerShell

```
$dict = Get-DlpKeywordDictionary -Name "Diseases"
```

Printing `$dict` will show the various properties. The keywords themselves are stored in an object on the backend, but `$dict.KeywordDictionary` contains a string representation of them, which you'll use to modify the dictionary.

Before you modify the dictionary, you need to turn the string of terms back into an array using the `.split(',')` method. Then you'll clean up the unwanted spaces between the keywords with the `.trim()` method, leaving just the keywords to work with.

PowerShell

```
$terms = $dict.KeywordDictionary.split(',').trim()
```

Now you'll remove some terms from the dictionary. Because the example dictionary has only a few keywords, you could as easily skip to exporting the dictionary and editing it in Notepad, but dictionaries generally contain a large amount of text, so you'll first learn this way to edit them easily in PowerShell.

In the previous command, you saved the keywords to the `$terms` array. There are several ways to remove items from an array, but as a straightforward approach, you'll create an array of the terms you want to remove from the dictionary, and then copy only the dictionary terms to it that aren't in the list of terms to remove.

Run the command `$terms` to show the current list of terms. The output of the command looks like this:

PowerShell

```
aarskog's syndrome
abandonment
abasia
abderhalden-kaufmann-lignac
abdominalgia
abduction contracture
abetalipoproteinemia
abiotrophy
ablatio
ablation
ablepharia
abocclusion
abolition
aborter
abortion
abortus
aboulomania
abrami's disease
```

Run this command to specify the terms that you want to remove:

PowerShell

```
$termsToRemove = @('abandonment','ablatio')
```

Run this command to actually remove the terms from the list:

PowerShell

```
$updatedTerms = $terms | Where-Object {$_ -notin $termsToRemove}
```

Run the command `$updatedTerms` to show the updated list of terms. The output of the command looks like this (the specified terms have been removed):

PowerShell

```
aarskog's syndrome
abasia
abderhalden-kaufmann-lignac
abdominalgia
abduction contracture
abetalipoproteinemia
abiotrophy
ablation
ablepharia
abocclusion
abolition
aborter
abortion
abortus
aboulomania
abrami's disease
```

Now save the dictionary locally and add a few more terms. You could add the terms right here in PowerShell, but you'll still need to export the file locally to ensure it's saved with Unicode encoding and contains the BOM.

Save the dictionary locally by running the following:

PowerShell

```
Set-Content $updatedTerms -Path "C:\myPath\terms.txt"
```

Now open the file, add your other terms, and save with Unicode encoding (UTF-16). Now you'll upload the updated terms and update the dictionary in place.

PowerShell

```
Set-DlpKeywordDictionary -Identity "Diseases" -FileData
([System.IO.File]::ReadAllBytes('C:myPath\terms.txt'))
```

Now the dictionary has been updated in place. The `Identity` field takes the name of the dictionary. If you wanted to also change the name of your dictionary using the `Set-` cmdlet, you would just need to add the `-Name` parameter to the `Set-DlpKeywordDictionary` command with your new dictionary name.

Common usage scenarios for sensitive information types

This article describes how to implement some common sensitive information type (SIT) use case scenarios. You can use these procedures as examples and adapt them to your specific needs.

Protect credit card numbers

Contoso Bank needs to classify the credit card numbers that they issue as sensitive. Their credit cards start with a set of six-digit patterns. They would like to customize the out-of-the-box credit card definition to detect only those credit card numbers starting with their six-digit patterns.

Suggested solution

1. Create a copy of the credit card SIT. Use the steps to copy and modify an existing SIT to copy the credit card SIT.
2. Edit the high confidence pattern. Follow the steps in Edit or delete a SIT pattern.
3. Add the **starts with** check and add the list of pattern digits (formatted & unformatted). For example to ensure that the SIT only considers credit cards starting with 411111 & 433512 should be considered valid, add the following to the list 4111 11, 4111-11, 411111, 4335 12, 4335-12, 433512.
4. Repeat step 2 & 3 for the low confidence pattern.

Test numbers similar to Social Security numbers

Contoso has identified a few nine-digit test numbers that trigger false positive matches in the Social Security Number (SSN) Microsoft Purview Data Loss Prevention (DLP) policy. They would like to exclude these numbers from the list of valid matches SSN matches.

Suggested solution

1. Create a copy of the SSN SIT. Use the steps to copy and modify an existing SIT to copy the SSN SIT.
2. Edit the high confidence pattern. Follow the steps in Edit or delete a SIT pattern.
3. Add the numbers you want to exclude in the **exclude specific values** check. For example, to exclude 239-23-532 & 23923532, just adding 23923532 is sufficient.
4. Repeat step 2 & 3 for other confidence patterns as well

Prevent phone numbers in signatures from triggering matches

Australia-based Contoso finds that phone numbers in email signatures are triggering a match for their Australia company number DLP policy.

Suggested solution

Add a 'NOT' group in supporting elements using a keyword list containing commonly used keywords in email signatures, such as *Phone*, *Mobile*, *email*, *Thanks and regards*, etc. Keep the proximity of this keyword list to a smaller value (for instance, 50 characters) for better accuracy. For more information, see Get started with custom sensitive information types.

Troubleshoot why an ABA routing policy doesn't trigger

DLP policy is unable to trigger ABA routing number policy in large excel files because the required keyword isn't within 300 characters.

Suggested solution

Create a copy of the built-in SIT and edit it to change the proximity of the keyword list from *300 characters* to *Anywhere in the document*.

> **Tip**
>
> You may edit the keyword list to include/exclude keywords that are relevant to your organization.

Unable to detect credit card numbers with unusual delimiters

Contoso Bank has noticed some of their employees share credit card numbers with '/' as a delimiter, for example, 4111/1111/1111/1111, which the out-of-the-box credit card definition doesn't detect. Contoso would like to define their own regex and validate it using LuhnCheck.

Suggested solution

1. Create a copy of the credit card SIT using the steps in Customize a built-in sensitive information type

2. Add a new pattern
3. In the primary element, select **regular expression**
4. Define the regular expression that includes '/' as part of the regular expression; choose **validator** and then select **luhncheck** or **func_credit_card** to ensure the regex also passes the LuhnCheck.

Ignore disclaimer notices when configuring sensitive information type detection

Many organizations add legal disclaimers, disclosure statements, signatures, or other information to the top or bottom of email messages that enter or leave their organizations. In some cases, emails sent within an organization itself can contain such text. For example, employees might add signatures with motivational quotes, social messages, and so on. A disclaimer or signature can contain the terms that are present in the lexicon of a CC and might generate many false positives.

For example, a typical disclaimer might contain words like *sensitive*, or *confidential*. Policies looking for sensitive info will detect such disclaimers as incidents, leading to lot of false positives. Thus, providing customers with an option to ignore disclaimers can reduce the number of false positives and increase the efficiency of the compliance team.

Review an example disclaimer notice

Consider the following disclaimer:

"IMPORTANT NOTICE: This e-mail message is intended to be received only by persons entitled to receive the confidential information it may contain. E-mail messages to clients of Contoso may contain information that is confidential and legally privileged. Please do not read, copy, forward, or store this message unless you are an intended recipient. If you have received this message in error, please forward it to the sender and delete it completely from your computer system."

If the SIT is configured to detect *confidential* as a keyword, the SIT pattern invokes a match every time an email includes the disclaimer, leading to considerable number of false positives.

Ignore disclaimer using prefix and suffix in SIT

One way to ignore keyword instances in disclaimer text is to exclude keywords that are preceded by a specific prefix and followed by a specific suffix.

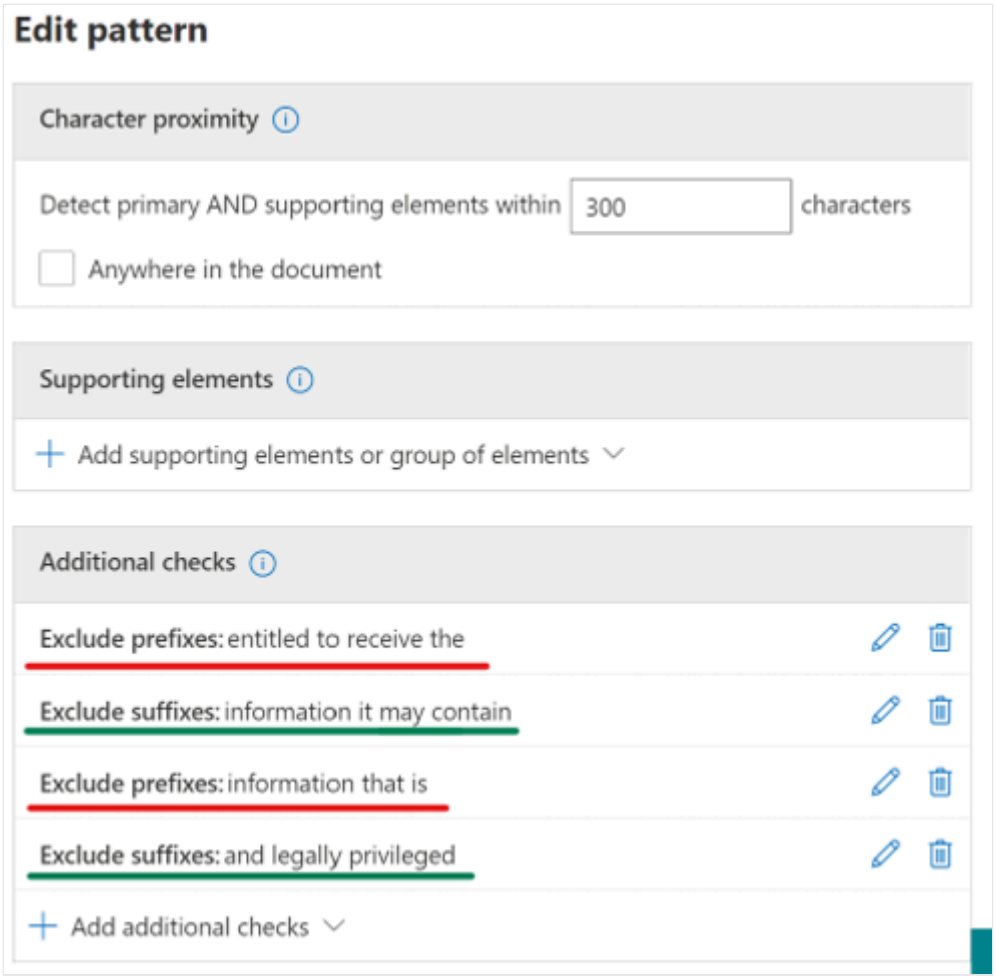
Consider this disclaimer:

"IMPORTANT NOTICE: This e-mail message is intended to be received only by persons *entitled to receive the* confidential **information it may contain**. E-mail messages to clients of Contoso may contain information that is confidential and legally privileged. Please do not read, copy, forward, or store this message unless you are an intended recipient. If you have received this message in error, please forward it to the sender and delete it completely from your computer system."

Say we have two instances of the keyword *confidential*. If we configure the SIT to ignore instances of the keyword *confidential* that are preceded by prefixes (italicized in the example) and followed by suffixes (bolded in the example), then we can successfully ignore disclaimers in most cases.

To ignore the disclaimer using prefix and suffix:

1. Add additional checks in the current SIT to exclude prefix and suffix text to the keyword that we want to ignore in the disclaimer.
2. Choose to exclude the prefix and in the **Prefixes** text box enter **contain information that is**.
3. Choose to exclude the suffix and in the **Suffixes** text box enter **and legally privileged**.
4. Repeat this process for other instances of the keywords in the disclaimer, as shown in the following graphic.



Ignore disclaimer by excluding secondary elements

Another way to add a list of supporting elements (keyword instances found in disclaimer text) that need to be excluded is to exclude secondary elements.

Consider this disclaimer:

"IMPORTANT NOTICE: This e-mail message is intended to be received only by persons entitled to receive the confidential information it may contain. E-mail messages to clients of Contoso may contain information that is confidential and legally privileged. Please do not read, copy, forward, or store this message unless you are an intended recipient. If you have received this message in error, please forward it to the sender and delete it completely from your computer system."

We have two instances of the keyword “confidential” in this example. If we configure the SIT to ignore instances of this keyword in the disclaimer (underlined as red in the following image), we can achieve ignoring disclaimers in most of the cases.

To ignore the disclaimer using secondary elements:

1. Select **Not any of these** group in the supporting elements.
2. Add the instances of disclaimer that we want to ignore as a keyword list/dictionary.
3. Add the keywords as a new line that we want to ignore. Remember that the length of each text can't be more than 50 characters.
4. Set the proximity of this element to be within 50-60 characters of the primary element.

ABA routing number

Article • 08/19/2024

Format

nine digits that may be in a formatted or unformatted pattern

Pattern

- two digits in the ranges 00-12, 21-32, 61-72, or 80
- two digits
- an optional hyphen
- four digits
- an optional hyphen
- a digit

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function Func_aba_routing finds content that matches the pattern.
- A keyword from Keyword_ABA_Routing is found.

A DLP policy has low confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function Func_aba_routing finds content that matches the pattern.

XML

```
    <!-- ABA Routing Number -->
    <Entity id="cb353f78-2b72-4c3c-8827-92ebe4f69fdf"
patternsProximity="300" recommendedConfidence="75">
      <Pattern confidenceLevel="75">
        <IdMatch idRef="Func_aba_routing" />
        <Match idRef="Keyword_ABA_Routing" />
      </Pattern>
      <Pattern confidenceLevel="65">
        <IdMatch idRef="Func_aba_routing" />
      </Pattern>
    </Entity>
```

All credentials sensitive information types

"All credentials" is a bundled-entity sensitive information type (SIT). It detects credentials from all supported services and environments, which include Amazon, Azure, GitHub, Google, Microsoft general, Slack and more.

> **Important**
>
> Because the **All Credetials** SIT is a bundled SIT, it ***does not*** contain any keywords. The keywords that it detects are based on the individual SITs it contains. Refer to the individual SITs for keyword information.

For information about implementing bundled SITs, see Learn about named entities.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a bundled SIT in an endpoint DLP policy. This requirement is specific to the combination of bundled SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Keyword Highlighting

Not supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Description

The All credentials SIT is a bundled SIT that scans for individual credential types. This includes checksum evaluated values and keyword/pattern combinations. The All credential entity scans for any of the underlying credential information type checksums and/or patterns are detected in a document.

Contains

This bundled entity SIT contains these individual SITs:

- Amazon S3 Client Secret Access Key
- ASP.NET Machine Key
- Microsoft Entra Client Access Token
- Microsoft Entra Client Secret
- Microsoft Entra user Credentials
- Azure App Service Deployment Password
- Azure Batch Shared Access Key
- Azure Bot Framework Secret Key
- Azure Bot Service App Secret
- Azure Cognitive Search API Key
- Azure Cognitive Service Key
- Azure Container Registry Access Key
- Azure COSMOS DB Account Access Key
- Azure Databricks Personal Access Token

- Azure DevOps App Secret
- Azure DevOps Personal Access Token
- Azure EventGrid Access Key
- Azure Function Master / API Key
- Azure IoT Shared Access Key
- Azure Logic App Shared Access Signature
- Azure Machine Learning Web Service API Key
- Azure Maps Subscription Key
- Azure Redis Cache Connection String Password
- Azure Service Bus Shared Access Signature
- Azure Shared Access Key / Web Hook Token
- Azure SignalR Access Key
- Azure SQL Connection String
- Azure Storage Account Access Key
- Azure Storage Account Shared Access Signature
- Azure Storage Account Shared Access Signature for High Risk Resources
- Azure Subscription Management Certificate
- Client Secret / API Key
- General Password

> **Tip**
>
> General Password detects password related keywords in English only.

- General Symmetric Key
- GitHub Personal Access Token
- Google API key
- Http Authorization Header
- Microsoft Bing Maps Key
- Slack Access Token
- User Login Credentials
- X.509 Certificate Private Key

Cloud support is available for the following:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

Description

This named entity SIT matches personal names that a human would identify as a name with high confidence. For example, if a string is found consisting of a given name and is followed by a family name then a match is made with high confidence. It uses three primary resources:

- A dictionary of given names.
- A dictionary of family names.
- Patterns of how names are formed.

The three resources are different for each country/region. The strings *Olivia Wilson* would trigger a match. Common given/family names are given a higher confidence than rarer names. However, the pattern also allows partial matches. If a given name from the dictionary is found and it's followed by a family name that isn't in the dictionary, then a partial match is triggered. For example, *Tomas Richard* would trigger a partial match. Partial matches are given lower confidence.

In addition, patterns that a human would see as indicative of names are also matched with appropriate confidence. Like *O. Wilson*, *O.P. Wilson*, *Dr. O. P. Wilson*, *Wilson, O.P.* or *T. Richard, Jr.* would be matches.

Cloud Support

Cloud support is available for the following:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

Description

This bundled named entity matches text that mentions medical conditions that are present in curated dictionaries. There's one curated dictionary per supported language. The dictionaries are from many international medical resources. The dictionaries include as many medical conditions as possible without risking a large number of false positives. Each entry contains the different forms that a single condition is commonly written in to ensure coverage, for example:

- *TB*
- *tuberculosis*
- *phthisis pulmonalis*

Contains

This bundled named entity SIT contains these individual SITs.

- Blood test terms
- Types of medication
- Diseases
- Generic medication names
- Impairments listed in the U.S. Disability Evaluation Under Social Security
- Lab test terms
- Lifestyles that relate to medical conditions
- Medical specialties
- Surgical procedures
- Brand medication names

Description

The matching of street addresses is designed to match strings that a human would identify as a street address. To achieve this matching, it uses several primary resources:

- A dictionary of settlements, counties, and regions.
- A dictionary of street suffixes, like Road, Street, or Avenue.
- Patterns of postal codes.
- Patterns of address formats.

The resources are different for each country/region. The primary resources are the patterns of address formats that are used in a given country/region. Different formats are chosen to make sure that as many addresses as possible are matched. These formats allow flexibility, for example, an address may omit the postal code or omit a town name or have a street with no street suffix. In all cases, such matches are used to increase the confidence of the match.

The patterns are designed to match individual single addresses, not generic locations. So strings such as *Redmond, WA 98052*, or *Main Street, Albuquerque* aren't matched.

Contains

This bundled named entity SIT contains these individual SITs:

- Australia physical addresses
- Austria physical addresses
- Belgium physical addresses
- Brazil physical addresses
- Bulgaria physical addresses
- Canada physical addresses
- China physical addresses
- Croatia physical addresses
- Cyprus physical addresses
- Czech Republic physical addresses
- Denmark physical addresses

- Estonia physical addresses
- Finland physical addresses
- France physical addresses
- Germany physical addresses
- Greece physical addresses
- Greenland physical addresses
- Hungary physical addresses
- Iceland physical addresses
- Ireland physical addresses
- Italy physical addresses
- Japan physical addresses
- Latvia physical addresses
- Liechtenstein physical addresses
- Lithuania physical addresses
- Luxembourg physical addresses
- Malta physical addresses
- Netherlands physical addresses
- New Zealand physical addresses
- Norway physical addresses
- Poland physical addresses
- Portugal physical addresses
- Romania physical addresses
- Russia physical addresses
- Singapore physical addresses
- Slovakia physical addresses
- Slovenia physical addresses
- South Africa physical addresses
- Spain physical addresses
- Sweden physical addresses
- Switzerland physical addresses
- Turkey physical addresses
- Ukraine physical addresses
- United Kingdom physical addresses
- United States physical addresses

Supported languages

- English
- Bulgarian
- Chinese

Amazon S3 client secret access key

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

A combination of 40 characters consisting of letters, digits, and special characters.

Pattern

13-digit number:

A combination of 40 characters consisting of:

- a-z (case insensitive)
- 0-9
- forward slash (/) or plus sign (+)

for example:

`Aa1Bb~2Cc3.-Dd4Ee5Ff6Gg7Hh8Ii9_Jj0Kk1Ll2`

Credential example

Expand table

Confidence Band	Example
High	`Amazon AWS Access Key: Aa1Bb~2Cc3.-Dd4Ee5Ff6Gg7Hh8Ii9_Jj0Kk1Ll2`
Medium	`Client secret (AWS): Aa1Bb~2Cc3.-Dd4Ee5Ff6Gg7Hh8Ii9_Jj0Kk1Ll2`

Confidence Band	Example
Low	N/A

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used to access Amazon Web Services.

It uses several primary resources:

- Patterns of Base64 encoded 240-bits symmetric key.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName.
- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary words.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Keywords

Keyword_SymmetricKey240:

- secret
- key

Argentina national identity (DNI) number

Article • 08/19/2024

Format

Eight digits with or without periods

Pattern

Eight digits:

- two digits
- an optional period
- three digits
- an optional period
- three digits

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression Regex_argentina_national_id finds content that matches the pattern.
- A keyword from Keyword_argentina_national_id is found.

XML

```xml
<!-- Argentina National Identity (DNI) Number -->
<Entity id="eefbb00e-8282-433c-8620-8f1da3bffdb2" recommendedConfidence="75"
patternsProximity="300">
   <Pattern confidenceLevel="75">
      <IdMatch idRef="Regex_argentina_national_id"/>
      <Match idRef="Keyword_argentina_national_id"/>
  </Pattern>
</Entity>
```

Keywords

Keyword_argentina_national_id

- Argentina National Identity number
- cedula
- cédula
- dni
- documento nacional de identidad
- documento número
- documento numero
- registro nacional de las personas
- rnp

Argentina Unique Tax Identification Key (CUIT/CUIL)

Article • 08/19/2024

Format

11 digits with dash

Pattern

11 digits with a dash:

- two digits in 20, 23, 24, 27, 30, 33 or 34
- a hyphen (-)
- eight digits
- a hyphen (-)
- one check digit

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_Argentina_Unique_Tax_Key` finds content that matches the pattern.
- A keyword from `Keyword_Argentina_Unique_Tax_Key` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_Argentina_Unique_Tax_Key` finds content that matches the pattern.

XML

```
    <!-- Argentina Unique Tax Identification Key (CUIT/CUIL) -->
      <Entity id="98da3da1-9199-4571-b7c4-b6522980b507"
patternsProximity="300" recommendedConfidence="75" relaxProximity="true">
        <Pattern confidenceLevel="85">
          <IdMatch idRef="Func_Argentina_Unique_Tax_Key" />
          <Match idRef="Keyword_Argentina_Unique_Tax_Key" />
        </Pattern>
        <Pattern confidenceLevel="75">
          <IdMatch idRef="Func_Argentina_Unique_Tax_Key" />
        </Pattern>
      </Entity>
```

Keywords

ASP.NET machine key

This sensitive information type (SIT) is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

Symmetric keys in XML configuration.

Pattern

Various symmetric key formats in XML, for example:

XML

```
<machineKey decryptionKey="******** </br>
<machineKey validationKey="********
```

Credential example

XML

```
<configuration>
    <system.web>
        <machineKey
            validationKey="Validation Key here"
            decryptionKey="Decryption key here"
            validation="SHA1"
            decryption="AES" />
    </system.web>
</configuration>
```

See **How to generate a `<machineKey> element`** in the Resolving view state message authentication code (MAC) errors support article for information on generating keys.

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used to encrypt or hash data in ASP.NET forms authentication and view state.

It uses several primary resources:

- Patterns of Symmetric key context in xml files.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Keywords

Keyword_SymmetricKeyContextInXml:

- password

- key
- connectionstring

Austria identity card

Article • 08/19/2024

Format

A 24-character combination of letters, digits, and special characters

Pattern

24 characters:

- 22 letters (not case-sensitive), digits, backslashes, forward slashes, or plus signs
- two letters (not case-sensitive), digits, backslashes, forward slashes, plus signs, or equal signs

Checksum

Not applicable

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_austria_eu_national_id_card` finds content that matches the pattern.
- A keyword from `Keywords_austria_eu_national_id_card` is found.

XML

```
      <!-- Austria Identity Card -->
      <Entity id="5ec06c3b-007e-4820-8343-7ff73b889735"
patternsProximity="300" recommendedConfidence="75">
        <Pattern confidenceLevel="75">
          <IdMatch idRef="Regex_austria_eu_national_id_card" />
          <Match idRef="Keywords_austria_eu_national_id_card" />
        </Pattern>
      </Entity>
```

Keywords

Keywords_austria_eu_national_id_card

- identity number
- national id
- personalausweis republik österreich

Austria passport number

Article • 08/19/2024

Format

One letter followed by an optional space and seven digits

Pattern

A combination of one letter, seven digits, and one space:

- one letter (not case-sensitive)
- one space (optional)
- seven digits

Checksum

not applicable

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_austria_eu_passport_number` finds content that matches the pattern.
- A keyword from `Keywords_eu_passport_number` or `Keywords_austria_eu_passport_number` is found.
- The regular expression `Regex_eu_passport_date1` finds date in the format DD.MM.YYYY or a keyword from `Keywords_eu_passport_date` is found

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_austria_eu_passport_number` finds content that matches the pattern.
- A keyword from `Keywords_eu_passport_number` or `Keywords_austria_eu_passport_number` is found.

XML

Austria physical addresses

Article • 08/19/2024

This unbundled named entity detects patterns related to physical address from Austria. It's also included in the All Physical Addresses bundled named entity SIT.

Confidence level

Medium

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Cloud Support

Cloud support is available for the following:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

Austria social security number

Article • 01/27/2025

Format

10 digits in the specified format

Pattern

10 digits:

- three digits that correspond to a serial number
- one check digit
- six digits that correspond to the birth date (DDMMYY with valid MM value of 01 to 12)

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_austria_eu_ssn_or_equivalent` finds content that matches the pattern.
- a keyword from `Keywords_austria_eu_ssn_or_equivalent` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_austria_eu_ssn_or_equivalent` finds content that matches the pattern.

XML

Austria tax identification number

Article • 08/19/2024

Format

nine digits with optional hyphen and forward slash

Pattern

nine digits with optional hyphen and forward slash:

- two digits
- a hyphen (optional)
- three digits
- a forward slash (optional)
- four digits

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_austria_eu_tax_file_number` finds content that matches the pattern.
- A keyword from `Keywords_austria_eu_tax_file_number` is found.

A DLP policy has low confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_austria_eu_tax_file_number` finds content that matches the pattern.

XML

Azure App Service deployment password

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

A combination of 60 characters consisting of letters, digits, and special characters.

Pattern

Any combination of 60 characters consisting of:

- a-z (not case-sensitive)
- 0-9
- forward slashes (/)
- or plus signs (+)

format example:

```
Ee5Ff~6Gg7.-Hh8Ii9Jj0Kk1Ll2Mm3_Nn4Oo5Pp6
```

Credential format example

```
userPWD=Ff6Gg~7Hh8.-Ii9Jj0Kk1Ll2Mm3Nn4_Oo5Pp6Qq7
```

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used to secure Azure App Service deployment from a local computer.

It uses several primary resources:

- Patterns of Base64 encoded 360-bits symmetric key.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName.
- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Keywords

Keyword_SymmetricKey360:

- password
- pw

Azure Batch Shared Access Key

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

A combination of 43 characters consisting of letters, digits, and special characters ending in an equals (=) sign that isn't part of the pattern.

Pattern

A combination of 43 characters consisting of:

- a-z (not case-sensitive)
- 0-9
- forward slashes (/)
- or plus signs (+)

format example:

```
A1bC2dE3fH4iJ5kL6mN7oP8qR9sT0u/+=
```

Credential format example

```
Account=account.batch.azure.net;AccountKey=A1bC2dE3fH4iJ5kL6mN7oP8qR9sT0u/+
```

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Definition

This SIT is designed to match the security information that's used to access Azure Batch accounts.

It uses several primary resources:

- Patterns of Base64 encoded 256-bits symmetric key.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName, ID.
- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Keywords

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used to access Azure Container Registry services as an admin account.

It uses several primary resources:

- Patterns of Base64 encoded 192-bits symmetric key.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName.
- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Keywords

Keyword_SymmetricKey192:

- password
- -p
- azurecr

Last updated on 11/18/2025

Azure Cosmos DB account access key

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

A combination of 88 characters consisting of letters, digits, and special characters.

Pattern

Any combination of 86 characters consisting of:

- a-z (not case-sensitive)
- 0-9
- forward slashes (/)
- or plus signs (+)
- ends with two equal signs (=)

format example:

```
C2dE3fH4iJ5kL6mN7oP8qR9sT0uV1w/+C2dE3fH4iJ5kL6mN7oP8qR9sT0uV1w==
```

Credential example

```
AccountEndpoint=https://account.documents.azure.com;AccountKey=C2dE3fH4iJ5kL6mN7oP8qR9sT0uV1w/+C2dE3fH4iJ5kL6mN7oP8qR9sT0uV1w==
```

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used to provide access to administrative resources for Azure Cosmos DB accounts.

It uses several primary resources:

- Patterns of Base64 encoded 512-bits symmetric key.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName, ID, AccountName.
- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Format

A combination of 56 characters consisting of letters, digits, and special characters.

or

A combination of up to 90 characters consisting of letters, digits, and special characters.

Pattern

Any combination of 54 characters consisting of:

- a-z (not case-sensitive)
- 0-9
- forward slashes (/)
- or plus signs (+)
- ends with two equal signs (=)

format example:

```
A1bC2dE3fH4iJ5kL6mN7oP8qR9sT0u/==
```

or

A combination of 54 to 84 characters consisting of:

- a-z (not case-sensitive)

- 0-9
- or percent signs (%)
- ends with a suffix '%3d%3d' (not case-sensitive)

for example:

abcdefghijklmnopqrstuvwxyz0123456789%2F%2BABCDEF0123456789%3D%3D

Credential example

`https://account.azurewebsites.net/api/function?code=A1bC2dE3fH4iJ5kL6mN7oP8qR9sT0u/==`

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used to request Azure Function API when its authorization level is set a value other than anonymous.

It uses several primary resources:

- Patterns of Base64 encoded 320-bits symmetric key.
- Patterns of URL Encoded 320-bits symmetric key.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName.
- Patterns of mockup values, redactions, and placeholders.

- A dictionary of vocabulary.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. - SharedAccessKey
- AccountKey

Last updated on 11/18/2025

Azure Maps subscription key

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

A combination of 43 characters consisting of letters, digits, and special characters.

Pattern

Any combination of 43 characters consisting of:

- a-z (not case-sensitive)
- 0-9
- dashes (-)
- or underlines (_)

format example:

```
C2dE3fH4iJ5kL6mN7oP8qR9sT0uV1w-
```

Credential example

```
host: atlas.microsoft.com; key: C2dE3fH4iJ5kL6mN7oP8qR9sT0uV1w-;
```

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used to access resources in Azure Maps accounts.

It uses several primary resources:

- Patterns of Base64 URL encoded 256-bits symmetric key.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName.
- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Azure publish setting password

Article • 02/10/2025

Format

The string `userpwd=` followed by an alphanumeric string.

Pattern

- the string `userpwd=`
- any combination of 60 lowercase letters or digits
- a quotation mark (")

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `CEP_Regex_AzurePublishSettingPasswords` finds content that matches the pattern.
- The regular expression `CEP_CommonExampleKeywords` doesn't find content that matches the pattern.

XML

```
<!--Azure Publish Setting Password-->
<Entity id="75f4cc8a-a68e-49e5-89ce-fa8f03d286a5" patternsProximity="300"
recommendedConfidence="85">

Azure Redis cache connection string

Article • 02/10/2025

Format

The string `redis.cache.windows.net` followed by the characters and strings outlined in the pattern below, including the string `password` or `pwd`.

Pattern

- the string `redis.cache.windows.net`
- any combination of between 1-200 lower- or uppercase letters, digits, symbols, special characters, or spaces
- the string `password` or `pwd`
- zero to two whitespace characters
- an equal sign (=)
- zero to two whitespace characters
- any combination of 43 characters that are lower- or uppercase letters, digits, forward slash (/), or plus sign (+)
- an equal sign (=)

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `CEP_Regex_AzureRedisCacheConnectionString` finds content that matches the pattern.
- The regular expression `CEP_CommonExampleKeywords` doesn't find content that matches the pattern.

XML

```

Azure Redis cache connection string password

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> Because credential scanning SITs are a type of advanced classifier, you must enable advanced classification before implementing them. For information about enabling advanced classification, and about configuring endpoints and the supported file types, see Advanced classification scanning and protection.

Format

A combination of up to 20,000-characters consisting of letters, digits, and special characters.

or

A combination of 44-characters consisting of letters, digits, and special characters.

Pattern

Any combination of up to 20,000 characters consisting of:

- a-z (not case-sensitive)
- 0-9
- forward slashes (/)
- or plus signs (+)
- Up to 2 equal signs (=)

format example:

```
aB1cD2eF/3gH4iJ5kL6-mN7oP8qR=
```

or

Any combination of 43 characters consisting of:

- a-z (not case-sensitive)
- 0-9
- forward slashes (/)
- or plus signs (+)
- ends with an equal sign (=)

format example:

`iJ5kL6mN7oP8qR9sT0+uV1wX2yZ==`

Credential example

`HostName=account.redis.cache.windows.net;Password=****************************

Checksum

Yes

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used to connect to Azure Cache for Redis servers.

It uses several primary resources:

- Patterns of Base64 encoded string literal.
- Patterns of Base64 encoded 256-bits symmetric key.

- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName, ID.
- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Format

A combination of 44-characters consisting of letters, digits, and special characters ending with an equals sign (=) that isn't part of the pattern.

or

A combination of up to 76-characters consisting of letters, digits, and special characters ending with an equals sign (=) that isn't part of the pattern.

Pattern

Any combination of 43 characters consisting of:

- a-z (not case-sensitive)
- 0-9
- forward slashes (/)
- or plus signs (+)
- ends with an equal sign (=) that isn't part of the pattern

format example:

```
kL6mN7oP8qR9sT0uV1+wX2yZ3aB=
```

or

Any combination of 43 to 73 characters consisting of:

- a-z (not case-sensitive)
- 0-9
- or percent signs (%)
- ends with a suffix '%3d' (not case-sensitive)

format example:

`mN7oP8qR9sT0uV1wX2%yZ3aB4dE%3D`

Credential example

`Endpoint=sb://account.servicebus.windows.net;SharedAccessKey=mN7oP8qR9sT0uV1wX2%yZ3aB4dE%3D`

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used to grant a user access to Azure Service Bus resources with specific rights.

It uses several primary resources:

- Patterns of Base64 encoded 256-bits symmetric key.
- Patterns of URL Encoded 256-bits symmetric key.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName, ID.

- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `CEP_Regex_AzureStorageAccountKeyGeneric` finds content that matches the pattern.

XML

```
<!--Azure Storage Account Key (Generic)-->
<Entity id="7ff41bd0-5419-4523-91d6-383b3a37f084" patternsProximity="300"
recommendedConfidence="85">
  <Pattern confidenceLevel="85">
        <IdMatch idRef="CEP_Regex_AzureStorageAccountKeyGeneric" />
  </Pattern>
</Entity>
```

Azure Storage account shared access signature

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

A combination of 44 characters consisting of letters, digits, and special characters.

or

A combination of up to 76 characters consisting of letters, digits, and special characters.

Pattern

Any combination of 43 characters consisting of:

- a-z (not case-sensitive)
- 0-9
- forward slashes (/)
- or plus signs (+)
- ends with an equal sign (=)

format example:

```
aB1cD2eF+3gH4iJ5kL6/mN7oP8qR=
```

or

A combination of 43 to 73 characters consisting of:

- a-z (not case-sensitive)
- 0-9
- or percent signs (%)
- ends with a suffix '%3d' (not case-sensitive)

for example:

`aB1cD2eF3gH4iJ5kL6mN7oP8q%R%3D`

Credential example

`https://account.blob.core.windows.net/?`

`sr=...&sv=...&st=...&se=...&sp=...&sig=aB1cD2eF3gH4iJ5kL6mN7oP8q%R%3D`

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used to grant restricted access rights to Azure Storage resources.

It uses several primary resources:

- Patterns of Base64 encoded 256-bits symmetric key.
- Patterns of URL Encoded 256-bits symmetric key.

- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName, ID.
- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Keywords

>
> This example has been truncated. It's not a detectable example of this SIT.

Checksum

Yes

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used to authenticate with the classic deployment model provided by Azure. Many programs and tools, like Visual Studio or the Azure SDK, use these certificates to automate configuration and deployment of various Azure services.

It uses several primary resources:

- Patterns of Base64 encoded string literal.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Canada physical addresses

Article • 08/19/2024

This unbundled named entity detects patterns related to physical address from Canada. It's also included in the All Physical Addresses bundled named entity SIT.

Confidence level

Medium

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Cloud Support

Cloud support is available for the following:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

Canada social insurance number

Article • 08/19/2024

Format

nine digits with optional hyphens or spaces

Pattern

Formatted:

- three digits
- a hyphen or space
- three digits
- a hyphen or space
- three digits

Unformatted: nine digits

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function Func_canadian_sin finds content that matches the pattern.
- At least one of the following patterns:
  - A keyword from Keyword_sin is found.

    - A keyword from Keyword_sin_collaborative is found.
- The checksum passes.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function Func_unformatted_canadian_sin finds content that matches the pattern.
- A keyword from Keyword_sin is found.
- The checksum passes.

China resident identity card (PRC) number

Article • 08/19/2024

Format

18 digits

Pattern

18 digits:

- six digits that are an address code
- eight digits in the form YYYYMMDD, which are the date of birth
- three digits that are an order code
- one digit that is a check digit

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_china_resident_id` finds content that matches the pattern.
- A keyword from `Keyword_china_resident_id` is found.
- The checksum passes.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_china_resident_id` finds content that matches the pattern.
- The checksum passes.

XML

Client secret / API key

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

A client secret or refresh token used in OAuth 2.0 protocol.

or

A combination of 24 characters consisting of letters, digits, and special characters.

or

A combination of 32 characters consisting of letters and digits.

or

A combination of 40 characters consisting of letters and digits.

or

A combination of 44 characters consisting of letters, digits, and special characters.

or

A combination of 56 characters consisting of letters, digits, and special characters

or

A combination of 88 characters consisting of letters, digits, and special characters.

Pattern

Various client secret or refresh token formats for example:

`ClientSecret:********`

`AppSecret=********`

`ConsumerKey:=********`

`Refresh_Token:********`

or

A combination of 22 characters:

- a-z (not case-sensitive)
- digits, forward slashes, or plus signs
- ends with two equal signs (=)

for example:

`abcdefgh0123456789/+AB==`

or

A combination of 32 characters:

- a-f or A-F (case-sensitive)
- or 0-9

for example:

`abcdef0123456789abcdef0123456789`

or

A combination of 40 characters:

- a-f or A-F (case-sensitive)

or

- 0-9

for example:

`Aa1Bb~2Cc3.-Dd4Ee5Ff6Gg7Hh8Ii9_Jj0Kk1Ll2`

or

A combination of 43 characters:

- a-z (not case-sensitive)
- 0-9
- forward slashes (/)
- or plus signs (+)
- ends with an equal sign (=)

for example:

`abcdefghijklmnopqrstuvwxyz0123456789/+ABCDE=`

or

A combination of 54 characters:

- a-z (not case-sensitive)
- 0-9
- forward slashes (/) or plus signs (+)
- ends with two equal signs (==)

for example:

`abcdefghijklmnopqrstuvwxyz0123456789/+ABCDEFGHIJKLMNOP==`

or

A combination of 86 characters:

- a-z (not case-sensitive)
- 0-9
- forward slashes (/) or plus signs (+)
- ends with two equal signs (=)

for example:

`abcdefghijklmnopqrstuvwxyz0123456789/+ABCDEabcdefghijklmnopqrstuvwxyz0123456789/+ABCDE==`

Credential example

`client_secret=abcdefghijklmnopqrstuvwxyz0123456789/+ABCDE=`

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's known only to the OAuth application and the authorization server to exchange for an access token at runtime.

It uses several primary resources:

- Patterns of Client secret context.
- Patterns of Base64 encoded 128 bits symmetric key.
- Patterns of Hex encoded 128 bits symmetric key.
- Patterns of Hex encoded 160 bits Symmetric Key.
- Patterns of Base64 encoded 256 bits symmetric key.
- Patterns of Base64 encoded 320 bits symmetric key.
- Patterns of Base64 encoded 512 bits symmetric key.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName, Id, AccountName.
- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Keywords

Keyword_ClientSecretContext:

- key

Keyword_SymmetricKey512:

- SharedAccessKey
- AccountKey

Last updated on 11/18/2025

Colombia national ID

Format

Eight to 10 digits with optional separators (dots or commas).

Pattern

Eight to 10 digits:

- Two digits followed by six digits (with optional dot or comma separators between groups of three), or
- The digit 1 followed by nine digits (with optional dot or comma separators between groups of three)

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Checksum

No

Definition

A data loss prevention (DLP) policy has medium confidence that it detects this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_colombia_national_id_number` finds content that matches the pattern.
- A keyword from `Keywords_colombia_national_id_number` is found.

XML

```
    <!-- Colombia National ID -->

Credit card number

Article • 04/23/2025

Format

14 to 19 digits that can be formatted or unformatted (ddddddddddddddd).

- Must pass the Luhn test.
- Must match number formats used by major credit card companies.

Pattern

Detects cards from all major brands. This includes Visa, MasterCard, Discover Card, JCB, American Express, gift cards, diner's cards, Rupay, and China UnionPay.

This sensitive information type doesn't flag reserved credit card numbers, such as the ones financial institutions use for testing

Checksum

Yes - the Luhn test, and verify match with number formats of major credit card companies.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it detects this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_credit_card` finds content that matches the pattern.
- One of the following conditions is true:
  - A keyword from `Keyword_cc_verification` is found.
  - A keyword from `Keyword_cc_name` is found.
  - The function `Func_expiration_date` finds a date in the right date format.

- The checksum passes.

A DLP policy has low confidence that it detects this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_credit_card` finds content that matches the pattern.
- The checksum passes.

XML

```
<!-- Credit Card Number -->

Croatia drivers license number

Article • 08/19/2024

Format

eight digits without spaces and delimiters

Pattern

eight digits

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_croatia_eu_driver's_license_number` finds content that matches the pattern.
- A keyword from `Keywords_eu_driver's_license_number` or `Keywords_croatia_eu_driver's_license_number` is found.

XML

```
      <!-- Croatia Driver's License Number -->
      <Entity id="005b3ef1-47dd-4e68-bb02-c6db484d00f2"
patternsProximity="300" recommendedConfidence="75">
        <Pattern confidenceLevel="75">
          <IdMatch idRef="Regex_croatia_eu_driver's_license_number" />
```

```
          <Any minMatches="1">
            <Match idRef="Keywords_eu_driver's_license_number" />
            <Match idRef="Keywords_croatia_eu_driver's_license_number" />
          </Any>
        </Pattern>
      </Entity>
```

Croatia identity card number

Article • 08/19/2024

This entity is included in the EU National Identification Number sensitive information type. It's available as a stand-alone sensitive information type entity.

Format

nine digits

Pattern

nine consecutive digits

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_croatia_id_card` finds content that matches the pattern.
- A keyword from `Keyword_croatia_id_card` is found.

XML

```
<!--Croatia Identity Card Number-->
<Entity id="ff12f884-c20a-4189-b185-34c8e7258d47" recommendedConfidence="75"
patternsProximity="300">
  <Pattern confidenceLevel="75">
```

```
      <IdMatch idRef="Func_croatia_id_card"/>
      <Match idRef="Keyword_croatia_id_card"/>
    </Pattern>
  </Entity>
```

Czech personal identity number

Article • 08/19/2024

Format

nine digits with optional forward slash (old format)

10 digits with optional forward slash (new format)

Pattern

nine digits (old format):

- six digits that represent date of birth
- an optional forward slash
- three digits

10 digits (new format):

- six digits that represent date of birth
- an optional forward slash
- four digits where last digit is a check digit

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_czech_id_card` finds content that matches the pattern.
- A keyword from `Keyword_czech_id_card` is found.
- The checksum passes.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_czech_id_card_new_format` finds content that matches the pattern.
- The checksum passes.

Denmark personal identification number

Article • 08/19/2024

Format

10 digits containing a hyphen

Pattern

10 digits:

- six digits in the format DDMMYY, which are the date of birth
- an optional space or hyphen
- four digits where the final digit is a check digit

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Func_denmark_eu_tax_file_number` finds content that matches the pattern.
- A keyword from `Keyword_denmark_id` is found.
- The checksum passes.

A DLP policy has low confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Func_denmark_eu_tax_file_number` finds content that matches the pattern.
- The checksum passes.

- Microsoft 365 Department of Defense

Drug Enforcement Agency (DEA) number

Article • 08/19/2024

Format

two letters followed by seven digits

Pattern

Pattern must include all of the following:

- one letter (not case-sensitive) from this set of possible letters: A/B/F/G/M/P/R, which is a registrant code
- one letter (not case-sensitive), which is the first letter of the registrant's last name or digit '9'
- seven digits, the last of which is the check digit

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_dea_number` finds content that matches the pattern.
- A keyword from `Keyword_dea_number` is found
- The checksum passes.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_dea_number` finds content that matches the pattern.
- The checksum passes.

Estonia personal identification code

Article • 08/19/2024

Format

11 digits without spaces and delimiters

Pattern

11 digits:

- one digit that corresponds to sex and century of birth (odd number male, even number female; 1-2: 19th century; 3-4: 20th century; 5-6: 21st century)
- six digits that correspond to date of birth (YYMMDD)
- three digits that correspond to a serial number separating persons born on the same date
- one check digit

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_estonia_eu_national_id_card` finds content that matches the pattern.
- A keyword from `Keywords_estonia_eu_national_id_card` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_estonia_eu_national_id_card` finds content that matches the pattern.

Estonia physical addresses

Article • 08/19/2024

This unbundled named entity detects patterns related to physical address from Estonia. It's also included in the All Physical Addresses bundled named entity SIT.

Confidence level

Medium

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Cloud Support

Cloud support is available for the following:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

EU debit card number

Article • 08/19/2024

Format

16 to 19 digits

Pattern

16 to 19 formatted or unformatted digits

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_eu_debit_card` finds content that matches the pattern.
- At least one of the following cases is true:
  - A keyword from `Keyword_eu_debit_card` is found.
  - A keyword from `Keyword_card_terms_dict` is found.
  - A keyword from `Keyword_card_security_terms_dict` is found.
  - A keyword from `Keyword_card_expiration_terms_dict` is found.
  - The function `Func_expiration_date` finds a date in the right date format.
- The checksum passes.

A DLP policy has low confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function Func_eu_debit_card finds content that matches the pattern.
- The checksum passes.

Finland drivers license number

Article • 08/19/2024

Format

10 digits containing a hyphen

Pattern

10 digits containing a hyphen:

- six digits
- a hyphen
- three digits
- a digit or letter

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_finland_eu_driver's_license_number` finds content that matches the pattern.
- A keyword from `Keywords_eu_driver's_license_number` or `Keywords_finland_eu_driver's_license_number` is found.

Finland passport number

Article • 08/19/2024

This entity is available in the EU Passport Number sensitive information type and is available as a stand-alone sensitive information type entity.

Format

combination of nine letters and digits

Pattern

combination of nine letters and digits:

- two letters (not case-sensitive)
- seven digits

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_finland_passport_number` finds content that matches the pattern.
- A keyword from `Keywords_eu_passport_number` or `Keyword_finland_passport_number` is found.

- The regular expression `Regex_eu_passport_date1` finds date in the format DD.MM.YYYY or a keyword from `Keywords_eu_passport_date` is found

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_finland_passport_number` finds content that matches the pattern.
- A keyword from `Keywords_eu_passport_number` or `Keyword_finland_passport_number` is found.

France drivers license number

Article • 08/19/2024

This entity is available in the EU Driver's License Number sensitive information type and is available as a stand-alone sensitive information type entity.

Format

12 digits

Pattern

12 digits with validation to discount similar patterns such as French telephone numbers

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- the function `Func_french_drivers_license` finds content that matches the pattern.
- a keyword from `Keyword_french_drivers_license` is found.

XML

```

France passport number

Article • 08/19/2024

This entity is available in the EU Passport Number sensitive information type. It's also available as a stand-alone sensitive information type entity.

Format

nine digits and letters

Pattern

nine digits and letters:

- two digits
- two letters (not case-sensitive)
- five digits

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_fr_passport` finds content that matches the pattern.
- A keyword from `Keywords_eu_passport_number` or `Keywords_france_eu_passport_number` is found.

- The regular expression `Regex_eu_passport_date3` finds date in the format DD MM YYYY or a keyword from `Keywords_eu_passport_date` is found

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_fr_passport` finds content that matches the pattern.
- A keyword from `Keywords_eu_passport_number` or `Keywords_france_eu_passport_number` is found.

XML

France physical addresses

Article • 08/19/2024

This unbundled named entity detects patterns related to physical address from France. It's also included in the All Physical Addresses bundled named entity SIT.

Confidence level

Medium

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Cloud Support

Cloud support is available for the following:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

France social security number (INSEE)

Article • 08/19/2024

Format

15 digits

Pattern

Must match one of two patterns:

- 13 digits followed by a space followed by two digits

  or

- 15 consecutive digits

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_french_insee` finds content that matches the pattern.
- A keyword from `Keyword_fr_insee` is found.
- The checksum passes.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_french_insee` or `Func_fr_insee` finds content that matches the pattern.
- The checksum passes.

General Password

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

Up to 20,000-character combination of letters, digits, and special characters.

or

Sign in credentials used in command lines

or

Plain-text password used in code snippets

or

Plain-text password used in script

or

Plain-text password used in XML configuration

or

A combination of 24 characters consisting of letters, digits, and special characters.

or

A combination of 32 characters consisting of letters and digits.

or

A combination of 32 characters consisting of letters, digits, and special characters.

or

A combination of 44 characters consisting of letters, digits, and special characters.

or

An 88-character combination of letters, digits, and special characters.

Patterns

1. Any combination of up to 20,000 characters consisting of:

    - a-z (case insensitive)
    - 0-9
    - forward slashes (/) or plus signs (+)
    - Up to two equal signs (=)

2. Various command line sign-in credentials formats

3. Various password formats in code snippets

4. Various password formats in script

5. Various password formats in XML

6. Any combination of 22 characters consisting of:

    - a-z (case insensitive)
    - digits, forward slashes, or plus signs
    - ends with two equal signs (=)

7. Any combination of 32 characters consisting of:

    - a-f or A-F (case-sensitive) or 0-9

8. Any combination of 32 characters consisting of:

    - a-z (case insensitive)
    - 0-9
    - forward slashes (/) or plus signs (+)

9. Any combination of 43 characters consisting of:

- a-z (case insensitive)
- 0-9
- forward slashes (/) or plus signs (+)
- ends with an equal sign (=)

10. Any combination of 86 characters consisting of:

    - a-z (case insensitive)
    - 0-9
    - forward slashes (/) or plus signs (+)
    - ends with two equal signs (=)

Credential example

Expand table

Confidence Band	Example
High	`password = D3m0P@sswd!`
Medium	`secret : DemoPasswd!`
Low	`password = demopasswd2`

Checksum

Yes

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Description

This SIT is designed to match security information, such as usernames and passwords, that are used in the sign-in process user login process. It uses several primary resources:

- Patterns of Base64 encoded string literal.
- Patterns of Password context in command line.
- Patterns of Password context in code.
- Patterns of Password context in script.
- Patterns of Password context in XML.
- Patterns of Base64 encoded 128-bits symmetric key.
- Patterns of Hex encoded 128-bits symmetric key.
- Patterns of Base64 encoded 192-bits symmetric key.
- Patterns of Base64 encoded 256-bits symmetric key.
- Patterns of Base64 encoded 512-bits symmetric key.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName, ID, AccountName.
- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary words.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. For instance, mockup values, redacted values, and placeholders, like credential type or usage descriptions, that are in the position where an actual secret value should present aren't matched.

General Symmetric key

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

A combination of 44 characters consisting of letters, digits, and special characters.

or

A combination of 88 characters consisting of letters, digits, and special characters.

Pattern

A combination of 43 characters:

- a-z (not case-sensitive)
- 0-9
- forward slashes (/) or plus signs (+)
- ends with an equal sign (=)

format example:

```
Cc3Dd4Ee5Ff6Gg7Hh8Ii9Jj0Kk1Ll2Mm34/+Nn=
```

or

A combination of 86 characters:

- a-z (not case-sensitive)
- 0-9

- forward slashes (/) or plus signs (+)
- ends with two equal signs (=)

format example:

`Cc3Dd4Ee5Ff6Gg7Hh8Ii9Jj0Kk1Ll2Mm3Nn4/+==`

Credential example

Expand table

Confidence Band	Example
High	`N/A`
Medium	`N/A`
Low	`key=Cc3Dd4Ee5Ff6Gg7Hh8Ii9Jj0Kk1Ll2Mm34/+Nn=;`

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used in general authentication process.

It uses several primary resources:

- Patterns of Base64 encoded 256-bits symmetric key.
- Patterns of Base64 encoded 512-bits symmetric key.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName, Id, AccountName.
- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Generic medication names

Article • 08/19/2024

This unbundled named entity detects names of generic medications, such as *acetaminophen*. It supports English terms only. It's also included in the All medical terms and conditions bundled named entity SIT.

Confidence level

High

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Cloud Support

Cloud support is available for the following:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

German Driver's License Number

This sensitive information type entity is included in the EU Driver's License Number sensitive information type. It's also available as a stand-alone sensitive information type entity.

Format

Combination of 11 digits and letters

Pattern

Eleven digits and letters (not case-sensitive):

- a digit or letter
- two digits
- six digits or letters
- a digit
- a digit or letter

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A data loss prevention (DLP) policy has medium confidence that it detects this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_german_drivers_license` finds content that matches the pattern.
- A keyword from `Keyword_german_drivers_license_number` is found.

- The checksum passes.

XML

```

Germany identity card number

Article • 01/24/2025

Format

since 1 November 2010: Nine to 11 letters and digits

from 1 April 1987 until 31 October 2010: 10 digits

Pattern

since 1 November 2010: 9 to 11 characters alphanumeric pattern

- one L, M, N, P, R, T, V, W, X, Y (case insensitive)
- eight digits or letters in C, F, G, H, J, K, L, M, N, P, R, T, V, W, X, Y and Z (case insensitive)
- optional check digit
- Optional d/D

from 1 April 1987 until 31 October 2010:

- 10 digits

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_german_id_card_with_check` finds content that matches the pattern (10 to 11 characters alphanumeric pattern (post 2010)).
- A keyword from `Keyword_germany_id_card` is found.
- The checksum passes.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_germany_id_card` finds content that matches the pattern (9 characters without check digit issued post-2010 or 10 digits pattern issued pre-2010).
- A keyword from `Keyword_germany_id_card` is found.

A DLP policy has low confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_german_id_card_with_check` finds content that matches the pattern (10 to 11 characters alphanumeric pattern (post 2010)).
- The checksum passes.

XML

```
      <!-- Germany Identity Card Number -->

German Passport Number

Format

9 to 11 characters

Pattern

- one letter in C, F, G, H, J, K (case insensitive)
- eight digits or letters in C, F, G, H, J, K, L, M, N, P, R, T, V, W, X, Y, and Z (case insensitive)
- optional check digit
- Optional d/D

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A data loss prevention (DLP) policy has high confidence that it detects this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_german_passport_checksum` finds content that matches the pattern.
- A keyword from `Keyword_german_passport` or `Keywords_eu_passport_number_common` is found.
- The checksum passes.

A DLP policy has medium confidence that it detects this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_german_passport` finds content that matches the nine characters pattern (without check digit and optional d/D).
- A keyword from `Keyword_german_passport` or `Keywords_eu_passport_number_common` is found.

A DLP policy has low confidence that it detects this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_german_passport_checksum` finds content that matches the pattern.
- The checksum passes.

Germany physical addresses

Article • 08/19/2024

This unbundled named entity detects patterns related to physical address from Germany. It's also included in the All Physical Addresses bundled named entity SIT.

Confidence level

Medium

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Cloud Support

Cloud support is available for the following:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

Germany tax identification number

Article • 08/19/2024

Format

GitHub personal access token

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

A combination of 40 characters consisting of letters, digits, and special characters.

or

Paired username and password used in URL.

or

A combination of 40 characters consisting of letters and digits.

Pattern

- A token prefix (case-sensitive) 'ghp_', 'gho_', 'ghu_', 'ghs_', or 'ghr_'
- Any combination of 36 a-z (not case-sensitive) or 0-9

format example:

`ghp_A1bC2dE3fH4iJ5kL6mN7oP8qR9sT0u`

or

Various URL username and password formats for example:

`https://username:********@contoso.com/`

`ftp://username:********@contoso.com:20/`

or

A combination of 40 characters:

- a-f or A-F (case-sensitive) or 0-9

format example:

`A1bC2dE3fH4iJ5kL6mN7oP8qR9sT0u`

Credential format example

`pat=ghp_A1bC2dE3fH4iJ5kL6mN7oP8qR9sT0u`

Checksum

Yes

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used as an alternate password for authentication to GitHub when using GitHub API or the command line.

It uses several primary resources:

- Patterns of Identifiable GitHub PAT.
- Patterns of User Login Credentials in URL.
- Patterns of Hex encoded 160 bits Symmetric Key.

- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName.
- Patterns of mockup values, redactions, and placeholders.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Keywords

Keyword_GitHubPatIdentifiableSecret:

- gh_

Keyword_LoginCredentialsInUrl:

- ://

Keyword_SymmetricKey160Hex:

- token

Last updated on 11/18/2025

Google API key

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

A combination of 39 characters consisting of letters, digits, and special characters.

Pattern

A token prefix (case-sensitive) 'AIza'

A combination of 35 characters:

- a-z (not case-sensitive)
- 0-9
- hyphen (-)
- underline (_)
- or backward slashes (\)

format example:

```
A1bC2dE3f-4iJ5_L6mN\oP8qR9sT0u
```

Credential format example

```
apiKey=A1bC2dE3f-4iJ5_L6mN\oP8qR9sT0u;
```

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used as a simple encrypted string that identifies a Google REST API client without any principal that is used to associate API requests with your project for quota and billing.

It uses several primary resources:

- Patterns of Base64 encoded 210 bits symmetric key.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName.
- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Greece physical addresses

Article • 08/19/2024

This unbundled named entity detects patterns related to physical address from Greece. It's also included in the All Physical Addresses bundled named entity SIT.

Confidence level

Medium

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Cloud Support

Cloud support is available for the following:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

Greece Social Security Number (AMKA)

Article • 08/19/2024

Format

11 digits without spaces and delimiters

Pattern

- Six digits as date of birth YYMMDD
- Four digits
- a check digit

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_greece_eu_ssn` finds content that matches the pattern.
- A keyword from `Keywords_greece_eu_ssn_or_equivalent` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_greece_eu_ssn` finds content that matches the pattern.

Greek Tax Identification Number

Format

Nine digits without spaces and delimiters

Pattern

Nine digits

Checksum

Not applicable

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A data loss prevention (DLP) policy has medium confidence that it detects this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_greece_eu_tax_file_number` finds content that matches the pattern.
- A keyword from `Keywords_greece_eu_tax_file_number` is found.

XML

```
      <!-- Greek Tax Identification Number -->
      <Entity id="15a54a5a-53d4-4080-ad43-a2a4fe1d3bf7" patternsProximity="300"
recommendedConfidence="75">
        <Pattern confidenceLevel="75">
          <IdMatch idRef="Regex_greece_eu_tax_file_number" />
          <Match idRef="Keywords_greece_eu_tax_file_number" />
```

```
        </Pattern>
      </Entity>
```

Keywords

The following keywords are used for detection. These include the Greek tax file number (AFM) and related terms.

Hong Kong identity card (HKID) number

Article • 08/19/2024

Format

Combination of 8-9 letters and numbers plus optional parentheses around the final character

Pattern

Combination of 8-9 letters:

- 1-2 letters (not case-sensitive)
- Six digits
- optional space
- a check character (any digit or the letter A) which is optionally enclosed in parentheses

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_hong_kong_id_card` finds content that matches the pattern.
- A keyword from `Keyword_hong_kong_id_card` is found.
- The checksum passes.

A DLP policy has low confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_hong_kong_id_card` finds content that matches the pattern.
- The checksum passes.

XML

Http authorization header

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

An authorization header used in HTTP request.

Pattern

Various authentication header formats for example:

```
authorization: basic ********
authorization: bearer ********
authorization: digest ********
authorization: negotiate ********
```

Credential example

```
Authorization: Basic ABCDEFGHIJKLMNOPQRS0123456789;
```

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used in the header of an HTTP request for authentication and authorization.

It uses several primary resources:

- Patterns of Http authorization header.
- Patterns of CredentialName, CredentialFeatures, ResourceType.
- Patterns of mockup values, redactions, and placeholders.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Keywords

Keyword_HttpAuthorizationHeader:

- authorization

Iceland physical addresses

Article • 08/19/2024

This unbundled named entity detects patterns related to physical address from Iceland. It's also included in the All Physical Addresses bundled named entity SIT.

Confidence level

Medium

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Cloud Support

Cloud support is available for the following:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

Impairments Listed In The U.S. Disability Evaluation Under Social Security

Article • 08/19/2024

This unbundled named entity detects names of impairments listed in the U.S. Disability Evaluation Under Social Security, such as *muscular dystrophy*. It supports English terms only. It's also included in the All medical terms and conditions bundled named entity SIT.

Confidence level

High

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

For **IPv4**, a DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_ipv4_address` finds content that matches the pattern.
- A keyword from `Keyword_ipaddress` is found.

For **IPv6**, a DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_ipv6_address` finds content that matches the pattern.
- No keyword from `Keyword_ipaddress` is found.

XML

```

IP Address v4

Article • 08/19/2024

Format

Complex pattern that accounts for formatted (periods) and unformatted (no periods) versions of the IPv4 addresses.

Pattern

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_ipv4_address` finds content that matches the pattern.
- A keyword from `Keyword_ipaddress` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_ipv4_address` finds content that matches the pattern.

XML

```
      <!-- IP Address v4-->

Ireland personal public service (PPS) number

Article • 08/19/2024

Format

Old format (until 31 December 2012):

- seven digits followed by 1-2 letters

New format (1 January 2013 and after):

- seven digits followed by two letters

Pattern

Old format (until 31 December 2012):

- seven digits
- one to two letters (not case-sensitive)

New format (1 January 2013 and after):

- seven digits
- a letter (not case-sensitive) which is an alphabetic check digit
- An optional letter in the range A-I, or "W"

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_ireland_pps finds` content that matches the pattern.
- A keyword from `Keywords_ireland_eu_national_id_card` is found.
- The checksum passes.

A DLP policy has low confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_ireland_pps` finds content that matches the pattern.
- The checksum passes.

XML

```
      <!-- Ireland Personal Public Service (PPS) Number -->

Italy fiscal code

Article • 08/19/2024

Format

a 16-character combination of letters and digits in the specified pattern

Pattern

A 16-character combination of letters and digits:

- three letters that correspond to the first three consonants in the family name
- three letters that correspond to the first, third, and fourth consonants in the first name
- two digits that correspond to the last digits of the birth year
- one letter that corresponds to the letter for the month of birth—letters are used in alphabetical order, but only the letters A to E, H, L, M, P, R to T are used (so, January is A and October is R)
- two digits that correspond to the day of the month of birth in order to differentiate between genders, 40 is added to the day of birth for women
- four digits that correspond to the area code specific to the municipality where the person was born (country/region-wide codes are used for foreign countries/regions)
- one parity digit

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_italy_eu_national_id_card` finds content that matches the pattern.
- A keyword from `Keywords_italy_eu_national_id_card` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_italy_eu_national_id_card` finds content that matches the pattern.

Italy passport number

Article • 08/19/2024

Format

two letters or digits followed by seven digits with no spaces or delimiters

Pattern

two letters or digits followed by seven digits:

- two digits or letters (not case-sensitive)
- seven digits

Checksum

Not applicable

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_italy_eu_passport_number` finds content that matches the pattern.
- A keyword from `Keywords_eu_passport_number` or `Keywords_italy_eu_passport_number` is found.
- The regular expression `Regex_italy_eu_passport_date` finds date in the format DD MMM/MMM YYYY (Example - 01 GEN/JAN 1988) or a keyword from `Keywords_eu_passport_date` is found

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_italy_eu_passport_number` finds content that matches the pattern.
- A keyword from `Keywords_eu_passport_number` or `Keywords_italy_eu_passport_number` is found.

Italy physical addresses

Article • 08/19/2024

This unbundled named entity detects patterns related to physical address from Italy. It's also included in the All Physical Addresses bundled named entity SIT.

Confidence level

Medium

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Cloud Support

Cloud support is available for the following:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

Italy value added tax number

Article • 08/19/2024

Format

13 character alphanumeric pattern with optional delimiters

Pattern

13 character alphanumeric pattern with optional delimiters:

- I or i
- T or t
- optional space, dot, hyphen, or comma
- 11 digits

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_italy_value_added_tax_number` finds content that matches the pattern.
- A keyword from `Keywords_italy_value_added_tax_number` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_italy_value_added_tax_number` finds content that matches the pattern.

Latvia passport number

Article • 08/19/2024

Format

two letters or digits followed by seven digits with no spaces or delimiters

Pattern

two letters or digits followed by seven digits:

- two digits or letters (not case-sensitive)
- seven digits

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_latvia_eu_passport_number` finds content that matches the pattern.
- A keyword from `Keywords_eu_passport_number` or `Keywords_latvia_eu_passport_number` is found.
- The regular expression `Regex_eu_passport_date1` finds date in the format DD.MM.YYYY or a keyword from `Keywords_eu_passport_date` is found

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The regular expression `Regex_latvia_eu_passport_number` finds content that matches the pattern.
- A keyword from `Keywords_eu_passport_number` or `Keywords_latvia_eu_passport_number` is found.

XML

Latvia personal code

Article • 08/19/2024

Format

11 digits and an optional hyphen

Pattern

Old format

11 digits and a hyphen:

- six digits that correspond to the birth date (DDMMYY)
- a hyphen
- one digit that corresponds to the century of birth ("0" for 19th century, "1" for 20th century, and "2" for 21st century)
- four digits, randomly generated

New format

11 digits

- Two digits "32"
- Nine digits

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_latvia_eu_national_id_card` or the regex `Regex_latvia_eu_national_id_card_new_format` finds content that matches the pattern.
- A keyword from `Keywords_latvia_eu_national_id_card` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_latvia_eu_national_id_card` or the regex `Regex_latvia_eu_national_id_card_new_format` finds content that matches the pattern.

Latvia physical addresses

Article • 08/19/2024

This unbundled named entity detects patterns related to physical address from Latvia. It's also included in the All Physical Addresses bundled named entity SIT.

Confidence level

Medium

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Cloud Support

Cloud support is available for the following:

- Microsoft Commercial Cloud
- Microsoft Government Community Cloud
- Microsoft 365 Government Community Cloud High
- Microsoft 365 Department of Defense

Liechtenstein physical addresses

Article • 08/19/2024

This unbundled named entity detects patterns related to physical address from Liechtenstein. It's also included in the All Physical Addresses bundled named entity SIT.

Confidence level

Medium

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Luxemburg national identification number (non-natural persons)

Article • 08/19/2024

Format

11 digits

Pattern

11 digits

- two digits
- an optional space
- three digits
- an optional space
- three digits
- an optional space
- two digits
- one check digit

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_luxemburg_eu_tax_file_number_non_natural` finds content that matches the pattern.
- A keyword from `Keywords_luxemburg_eu_tax_file_number` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_luxemburg_eu_tax_file_number_non_natural` finds content that matches the pattern.

- six digits indicating a valid date
- a letter - H/h or M/m
- two letters indicating a valid Mexican state code
- three letters
- one letter or digit
- one digit

Checksum

No

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_mexico_population_registry_code` finds content that matches the pattern.

- A keyword from `Keyword_mexico_population_registry_code` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_mexico_population_registry_code` finds content that matches the pattern.

XML

```
    <!-- Mexico Unique Population Registry Code (CURP) -->
      <Entity id="e905ad4d-5a74-406d-bf36-b1efca798af4"
patternsProximity="300" recommendedConfidence="75" relaxProximity="true">
        <Pattern confidenceLevel="85">
          <IdMatch idRef="Func_mexico_population_registry_code" />
          <Match idRef="Keyword_mexico_population_registry_code" />
        </Pattern>
        <Pattern confidenceLevel="75">
          <IdMatch idRef="Func_mexico_population_registry_code" />
        </Pattern>
      </Entity>
```

Microsoft Bing maps key

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

A combination of 64 characters consisting of letters, digits, and special characters.

Pattern

A combination of 64 characters:

- a-z (not case-sensitive)
- 0-9
- underlines (_)
- or hyphens (-)

format example:

```
aB1cD2eF-3gH4iJ5kL6_mN7oP8qR
```

Credential format example

```
bingMapsKey=aB1cD2eF-3gH4iJ5kL6-mN7oP8qR
```

Checksum

No

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used to call Bing Maps API.

It uses several primary resources:

- Patterns of Base64 URL encoded 384-bits symmetric key.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName.
- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Keywords

Keyword_SymmetricKey384Url:

This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

A combination of up to 10,000 characters consisting of letters, digits, and special characters.

or

A client secret or refresh token used in OAuth2.0 protocol.

or

A combination of up to 1,000 characters consisting of letters, digits, and special characters.

Pattern

Any combination of:

- up to 10,000
- a-z (not case-sensitive)
- 0-9
- forward slashes (/)
- or plus signs (+)
- Up to 2
- equal signs (=)

for example:

`"VersionProfile": null, "TokenCache": { "CacheData": A1bC2dE3fH4iJ5kL6mN7oP8qR9sT0u

or

Variant client secret or refresh token formats for example.
`ClientSecret:********`
`AppSecret=********`
`ConsumerKey:=********`
`Refresh_Token:********`

or

3 letters: eyJ (case-sensitive)

And

A combination of up to 1,000 characters consisting

- a-z (not case-sensitive)
- 0-9
- dashes (-)
- underlines (_)

- or dots (.)

format example:

`A1bC2dE3fH4iJ5kL6mN7oP8qR9sT0u`

This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's contains claims that one can use in Azure Active Directory B2C (Azure AD B2C) to identify the granted permissions to Azure resources.

It uses several primary resources:

- Patterns of Azure PowerShell Token Cache
- Patterns of Client secret context
- Patterns of Json Web Token
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName
- Patterns of mockup values, redactions, and placeholders
- A dictionary of vocabulary

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Low	N/A

Checksum

Yes

SITs that have checksums use a unique calculation to check if the information is valid. This means when the **Checksum** value is **Yes**, the service can make a positive detection based on the sensitive data alone. When the **Checksum** value is **No** additional (secondary) elements must also be detected for the service to make a positive detection.

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

This SIT is designed to match the security information that's used to secure Microsoft Entra service principals.

It uses several primary resources:

- Patterns of Client Secret with specific format.
- Patterns of CredentialName, CredentialFeatures, AccountIdentityName, AccountIdentityValue, ResourceType, ResourceName.
- Patterns of mockup values, redactions, and placeholders.
- A dictionary of vocabulary.

The patterns are designed to match actual credentials with reasonable confidence. The patterns don't match credentials formatted as examples. Mockup values, redacted values, and placeholders, like credential type or usage descriptions, in the position where an actual secret value should present won't be matched.

Keywords

Keyword_AppSecret:

This SIT is also included in the All credentials bundled SIT.

> **Important**
>
> You must enable Advanced classification scanning and protection if you want to use a credential scanning SIT in an endpoint DLP policy. This requirement is specific to the combination of credential scanning SITS and endpoint DLP policies. The advanced classification article gives you information about enabling advanced classification, and about configuring endpoints and the supported file types.

Format

A paired username and password related to *.onmicrosoft.com domain.

or

Plain-text password used in code snippets.

or

Plain-text password used in XML configuration.

Pattern

Various username and password formats, for example:

`username=...password=********`

`/user:.../pass:********`

`SharePointOnlineAuthenticatedContext`

`sign_in`

or

Various password formats in code snippets, for example:

`new X509Certificates2( ...`

`ConvertTo-SecureString -String ********...`

`password = "********"...`

`"password" : "********"...`

`UserPasswordCredential( ...`

or

Various password formats in XML, for example:

```xml
... <secret>********</secret> ...
... <password>********</password> ...
... <setting name="password" value="********" > ...
... <setting name="password">********</setting> ...
... <setting name="password"><value>********</value></setting> ...
```

Credential example

`username=user@contoso.onmicrosoft.com;password=********`

Checksum

No

- an optional hyphen or space
- two to three digits
- an options hyphen or space

Checksum

Yes

Keyword Highlighting

Supported

When keyword highlighting is supported in the contextual summary for a sensitive information type or a trainable classifier, in the **Contextual Summary** view of activity explorer, the keywords in a document that were matched to a policy are highlighted.

Definition

A DLP policy has high confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_new_zealand_bank_account_number` finds content that matches the pattern.

- A keyword from `Keywords_new_zealand_bank_account_number` is found.

A DLP policy has medium confidence that it's detected this type of sensitive information if, within a proximity of 300 characters:

- The function `Func_new_zealand_bank_account_number` finds content that matches the pattern.

XML

```
      <!-- New Zealand Bank Account Number -->
      <Entity id="1a97fc2b-dd2f-48f1-bc4e-2ddf25813956"
patternsProximity="300" recommendedConfidence="85">
        <Pattern confidenceLevel="85">
          <IdMatch idRef="Func_new_zealand_bank_account_number" />
          <Match idRef="Keywords_new_zFealand_bank_account_number" />
        </Pattern>
        <Pattern confidenceLevel="75">
          <IdMatch idRef="Func_new_zealand_bank_account_number" />
        </Pattern>
      </Entity>
```
