Guidance to help you explore and get started with Microsoft Purview solutions in the Microsoft Purview portal.

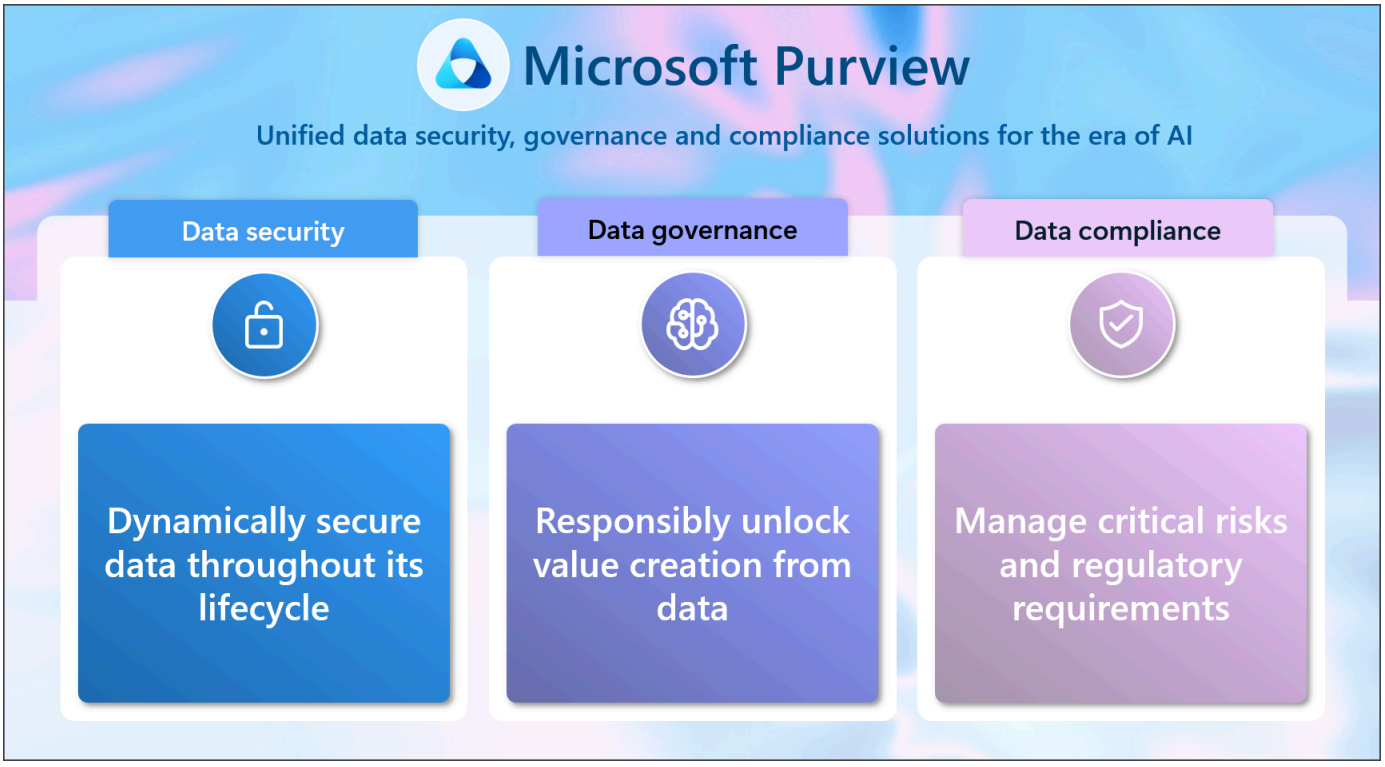
Microsoft Purview data governance solutions

- Unified Catalog
- Data Map
- Data governance planning
- Data governance roles and permissions

Microsoft Purview data security solutions

- Data Loss Prevention
- Data Security Investigations
- Data Security Posture Management
- Information Barriers
- Information Protection
- Insider Risk Management

Microsoft Purview data compliance solutions



- Audit
- Communication Compliance
- Compliance Manager
- Data Lifecycle Management
- eDiscovery
- Records Management

Learn about Microsoft Purview

Microsoft Purview is a comprehensive set of solutions that helps your organization govern, protect, and manage data in the era of AI, wherever your data lives. Microsoft Purview solutions provide integrated coverage and help address the fragmentation of data across organizations, the lack of visibility that hampers data protection and governance, the rapid acceleration of AI transformation, and the blurring of traditional IT management roles.

Microsoft Purview combines solutions and services into a unified platform that helps your organization:

- Gain visibility into data across your organization
- Safeguard and manage sensitive data across its lifecycle, wherever it lives
- Govern data seamlessly in new, comprehensive ways
- Manage critical data risks and regulatory requirements
- Protect against accidental oversharing and sensitive data leakage in generative AI

Unified data security, governance, and compliance solutions for the era of AI

Microsoft Purview provides organizations with a powerful platform for seamlessly securing and governing data. This unified approach helps organizations reduce complexity and improve

outcomes related to mitigating risks in the era of AI.

Adopt AI with confidence

AI transformation is accelerating at an incredible pace, which compounds organizations' challenges around securing their data. It's never been more important for organizations to mitigate and manage the risks associated with AI usage, and implement corresponding protection and governance controls.

Microsoft Purview data security and compliance protections for generative AI apps helps you protect data however you use AI, whether it's:

- Copilot experiences and agents,
- Enterprise AI apps that you build, or
- Other AI apps you use.

Explore the full range of Microsoft Purview capabilities for data security and compliance for AI.

Data security

Microsoft Purview provides a robust and coordinated set of data security solutions to help you dynamically secure data throughout its lifecycle. The solutions include:

- Microsoft Purview Data Loss Prevention
- Microsoft Purview Data Security Investigations
- Microsoft Purview Information Barriers
- Microsoft Purview Information Protection
- Microsoft Purview Insider Risk Management
- Microsoft Purview Privileged Access Management

Now in preview, Microsoft Data Security Posture Management (DSPM) helps you discover, protect, and investigate sensitive data risks across your digital estate. Unifying other Microsoft Purview solutions, DSPM provides visibility and control for both traditional applications and AI apps and agents, so you can monitor, assess, and remediate data risks regardless of where sensitive data resides.

Data governance

Microsoft Purview includes unified data governance solutions for managing data services across your data estate and developing a federated approach to governing your data and unlocking business innovation. The solutions include:

- Microsoft Purview Data Map
- Microsoft Purview Unified Catalog

Data compliance

Microsoft Purview includes data compliance compliance solutions to help your organization minimize compliance risks and meet regulatory requirements. The solutions include:

- Microsoft Purview Audit
- Microsoft Purview Communication Compliance
- Microsoft Purview Compliance Manager
- Microsoft Purview Data Lifecycle Management
- Microsoft Purview eDiscovery
- Microsoft Purview Records Management

Shared capabilities

Many capabilities that help you protect and govern data across Microsoft Purview are shared among multiple solutions. Some of these capabilities include:

- Classifiers
- Connectors
- Data explorer and activity explorer
- Sensitivity labels

The Microsoft Purview portal

The Microsoft Purview portal is designed to make securing and governing your data easy and efficient. The updated experience provides a consistent look and feel, a streamlined information architecture, and simplified navigation into Microsoft Purview solutions.

- **What's in the portal?** The Microsoft Purview portal provides access to data governance, data security, and data compliance solutions.
- **Start exploring**: Get details about accessing and navigating the portal by visiting Learn about the new Microsoft Purview portal.

Last updated on 05/15/2026

What's new in Microsoft Purview

Whether it's adding new solutions, updating existing features based on your feedback, or rolling out fresh and updated documentation, Microsoft Purview helps you stay on top of the ever-changing data governance, data security, and risk and compliance areas. Take a look at the following information to see what's new in Microsoft Purview.

What's planned for Microsoft Purview

Microsoft Purview continues to add new solutions and features to help with data governance, data security, and risk and compliance in your organization. Check out the following roadmap sites to learn more about what's planned for Microsoft Purview:

- Roadmap for data governance solutions.
- Roadmap for data security and risk and compliance solutions.

September 2026

Data Loss Prevention

- **General availability**: Integrate Microsoft Entra Global Secure Access with Purview to protect text, files, and AI interactions at the network layer, enforce restrictive actions based on DLP policies, and detect risky user activity through Insider Risk Management. It helps prevent sensitive data from being shared with untrusted cloud applications through browsers, apps, APIs, and add-ins, including generative AI platforms, social media, and collaborative platforms. See Learn about Microsoft Purview Network Data Security.

Information Barriers

- **New**: Create an Information Barriers policy compliance report to identify SharePoint sites, OneDrive accounts, and user-owned SharePoint Embedded containers that no longer comply after Information Barriers policy changes.

August 2026

Data Governance

- **Updated**: Data Quality capability requires the Microsoft Purview account and its data sources to be in the same Azure region.

Data Loss Prevention

- **In preview**: Use data loss prevention policies for non-Microsoft connected apps. Create DLP policies that protect sensitive data at rest in non-Microsoft connected applications, such as Box and Google Workspace. These policies use the existing Microsoft Defender for Cloud Apps connectors and support the same classification engine available for Microsoft 365 locations.
- **Updated**: The Endpoint DLP capability comparison now clarifies that policies for access by apps not included in a restricted apps list or restricted app group are supported on Windows but not on macOS.
- **Updated**: If an Exchange DLP policy uses sensitivity labels as a condition and policy tips while mandatory labeling is enabled, selecting a label from the mandatory-labeling prompt doesn't reevaluate the policy tip. The configured DLP action is still enforced.
- **Updated**: In cross-tenant Microsoft Teams chats and channels, DLP policy enforcement follows the tenant that initiated the conversation. A user's home-tenant DLP policies don't automatically apply when another tenant hosts the chat or thread.
- **In preview**: Prepare Endpoint DLP for permission changes in macOS 27. Deploy client version 101.26072 or later, configure protection modes, monitor permission status, and notify users if they disable the required **Device Control and Data Access** permission.
- **Updated**: Guidance for DLP policies in Microsoft Edge for Business now explains policy sync status, where to investigate managed and unmanaged app activity, and coverage limitations caused by duplicate app catalog entries, encoded traffic, dynamic endpoints, and shared consumer and enterprise URLs.

Data lifecycle management

- **Updated**: When you remove the last hold from an inactive mailbox, Microsoft 365 automatically applies a 30-day delay hold. Learn how to identify and remove delay holds before recalculating mailbox hold status.
- **New**: Remove a retention hold from an unlicensed OneDrive site by using Security & Compliance PowerShell. The guidance covers tenant-level and site-level holds, prerequisites, and common errors that can block site deletion.
- **In preview**: Permanently delete SharePoint and OneDrive files with Priority Cleanup. After simulation, review, and required approvals, selected files bypass the recycle bins and are no longer discoverable in SharePoint search, Microsoft 365 Copilot, or eDiscovery.

Data Security Posture Management

- **Updated**: Microsoft Purview support for Anthropic Claude Enterprise now includes data classification, Insider Risk Management, Communication Compliance, eDiscovery, Data Lifecycle Management, and Compliance Manager.

eDiscovery

- **Updated**: App-only authentication for eDiscovery cmdlets in Security & Compliance PowerShell is unsupported. Transition automations to Microsoft Graph APIs where available; the documented certificate-based authentication steps are best-effort guidance for existing automations and don't change the support status.

Sensitivity labels

- **New**: Before enforcing an auto-labeling policy, run it in simulation mode to identify which items it would label without making any changes. Review the match results and source distribution to determine whether the policy is ready to enforce.
- **New**: The **Insights** tab in the policy details panel provides an at-a-glance view of an auto-labeling policy's performance. The information shown varies depending on whether the policy is running in simulation or enforcement mode, helping you understand how it identifies or labels content.
- **In preview**: Sensitivity label policies for non-Microsoft connected apps. Create auto-labeling policies that protect sensitive data at rest in non-Microsoft connected apps, including Box and Google Workspace. These policies use the existing Microsoft Defender for Cloud Apps connectors and support the same classification engine available for Microsoft 365 locations.
- **Updated**: Added guidance describing how to provide external users access to open files protected by user-defined permissions sensitivity labels. For more information, see Limitations.
- **Updated**: Auto-labeling policies can target more than 100 SharePoint sites by using an existing adaptive scope with the SharePointAdaptiveScopes parameter with New-AutoSensitivityLabelPolicy.
- **New**: Review the minimum OneNote versions and supported sensitivity label capabilities for Windows, Mac, iOS, Android, and the web.
- **Updated**: If an active auto-labeling policy stops matching Exchange email because a rule failed to load, contact Microsoft Support to identify the affected rule.

Shared capabilities

- **New**: Run on-demand classification scans on Windows endpoints to discover sensitive information without waiting for files to be opened or modified. The new guidance covers billing and best practices, monitoring and troubleshooting, and frequently asked questions.
- **New**: Microsoft 365 audit log activities now include Microsoft Defender for Cloud activities, People Skills activities, Microsoft 365 Archive file-level policy activities, and Microsoft Purview permission activities.

July 2026

Data Governance

- **Updated**: Microsoft Purview protection policies no longer support Azure SQL Database.
- **New**: Configure a manual business continuity and disaster recovery environment for Microsoft Purview Data Map. The guidance covers creating a secondary account, mirroring scans, validating the environment, and requesting account promotion during a regional outage.

Data Loss Prevention

- **In preview**: Protect sensitive data in text and prompts by integrating with Microsoft Entra Global Secure Access (GSA). This integration enables organizations to intercept and inspect text and AI interactions at the network layer, enforce restrictive actions based on DLP policies, and detect risky user activity through Insider Risk Management. It helps prevent sensitive data from being shared with untrusted cloud applications through browsers, apps, APIs, and add-ins, including generative AI platforms, social media, and collaborative platforms. See Learn about Microsoft Purview Network Data Security.
- **In preview**: Exchange Online DLP policies can detect classification failures caused by timeouts, throttling, and other scanning errors. Administrators can enable classification-failure detection and use the **DocumentScanFailures** condition to apply different protection actions for specific failure types.
- **Updated**: Administrators can use Microsoft Fabric governance experiences in the OneLake catalog to understand DLP activity and adoption. These insights help identify evaluated workspaces, locate sensitive information, track policy adoption, and prioritize high-risk assets.

Data lifecycle management

- **Updated**: Priority cleanup policies now require three separate approvals before content can be permanently deleted: one Priority Cleanup administrator, one retention manager, and one eDiscovery administrator.

Information Protection

- **Updated**: Added a checklist to help administrators understand auditing, regional availability, label scope, encryption settings, sensitive information types, file eligibility, and required roles before creating an auto-labeling policy.
- **Updated**: Troubleshoot why a specific SharePoint or OneDrive file was or wasn't labeled. The diagnostic guidance covers unsupported formats, checked-out files, indexing delays, existing higher-priority labels, encryption prerequisites, transient failures, and unexpected labeling.
- **Updated**: Auto-labeling policies can remove or downgrade sensitivity labels. The documentation explains behaviors that are by design and often interpreted as bugs. These behaviors include activation results that differ from simulation, encryption restrictions, cross-tenant label identities, conflicts with label-application policies, and the effect of label removal on encryption.
- **Updated**: Auto-labeling simulation isn't a completely silent dry run. Simulation can generate activity alerts, duplicated policies start in simulation, management actions can remain unavailable during provisioning, and the review experience can mix auto-labeling and DLP results in test mode.
- **Updated**: Licensing and configuration locations are documented for client-side Office auto-labeling, service-side auto-labeling policies, and container-level labels. The guidance also describes common symptoms caused by missing licenses, roles, regional availability, or transient backend failures.
- **Updated**: Auto-labeling policy guidance now identifies supported and unsupported group types and explains membership-propagation delays. Mail-enabled security groups, distribution groups, and Microsoft 365 groups are supported, while mail-disabled, dynamic distribution, and deeply nested groups have limitations.

Insider Risk Management

- **In preview**: Unified alert experience combines the Triage Agent and Standard alert dashboards into a single alerts list page. View and manage both classic and agent-triaged alerts from one location, with the ability to preview agent summaries, alert and user details directly on the alerts list page.

- **In preview**: Expanded user profile details in the unified alert experience add additional user profile signals from Microsoft Entra, including office location, employee type, department, and last working date.
- **In preview**: Expanded note capabilities across alerts and cases. Analysts and investigators can now add and view notes on both alerts and cases. System-generated notes are automatically applied when there's a change in alert or case status, assigned user, closure, or case escalation.

Shared capabilities

- **Update**: Microsoft Purview role-group assignments can be configured with an expiration date so that access is revoked automatically. Temporary assignments can last from one day to two years and are supported by most built-in and custom role groups, except eDiscovery Administrator and eDiscovery Manager.

June 2026

Copilot Cowork

- **General availability (GA)**: Data security and compliance protections for Microsoft 365 Copilot Cowork

Data Loss Prevention

- **New**: Access Endpoint DLP device attribute data using Advanced Hunting. Query Endpoint DLP device configuration and policy sync attributes at scale through the DeviceInfo table's DlpInfo column in Advanced hunting in the Microsoft Defender portal, instead of relying on point-in-time exports from the Microsoft Purview portal.

- **New**: Create a DLP policy that uses device scoping. Scope an Endpoint DLP policy to specific device groups — for example, enforce policy only when Finance users access data from Windows devices, and not when the same users work from macOS — using dynamic device groups defined in Microsoft Entra ID.

- **In preview**: New **Email is received from** > **External users** condition for the **Microsoft 365 Copilot and Copilot Chat** policy location lets DLP policies prevent Copilot from using external email as grounding data, helping reduce prompt injection risk from untrusted senders. See Block external email from being processed (preview).

- **In preview**: Enhanced matched conditions for Exchange DLP events surfaces detailed non-sensitive information type (SIT) condition matches in DLP alerts and Activity Explorer for Exchange Online. Each matched condition includes the condition name, matched value, and source.

Data Security Investigations

- **In preview**: Endpoint DLP evidence collection is now available as a data source in Data Security Investigations. Investigators can query data captured by endpoint Data Loss Prevention (DLP) policies on onboarded devices and add the associated content to an investigation scope for AI-powered analysis. This integration enables aggregate analysis of endpoint exfiltration events instead of per-alert triage. For more information, see Search, review, and refine results in Data Security Investigations.
- **General availability (GA)**: Email and portal notifications for Data Security Investigations. Investigators receive notifications through the Microsoft Purview Notification Center and email when setup completes and investigations are ready to use.
- **Updated**: Data preparation in Data Security Investigations now runs automatically in the background as items are added to scope. You no longer need to manually initiate vectorization before using AI features.

Device Onboarding

- **New**: Monitor device health with the device health reports dashboard. Use the device health reports dashboard to monitor device onboarding status, policy update readiness, and feature readiness for Endpoint DLP.

eDiscovery

- **New**: A new *Convert supported file formats to HTML* option is available when adding search results to a review set and when exporting items from a review set in eDiscovery. When enabled, cloud-native file formats such as `.loop` and `.page` files are converted to HTML, making the content indexed and keyword searchable in the review set and easier to process in post-export workflows.

Information Protection client

- **In preview**: View and label files with the Information Protection client using macOS.

Insider Risk Management

- **General availability (GA)**: Select which generative AI apps to monitor in Insider Risk Management policy indicators. For Microsoft Copilot experiences and Enterprise AI apps, you can now select or deselect generative AI apps for monitoring, reducing alert noise, and avoiding unnecessary pay-as-you-go billing charges.

Sensitive information types

- **New**: Added definitions for the following sensitive information types:
  - China physical addresses
  - Colombia national ID
  - Colombia tax identification number
  - Greenland physical addresses
  - Russia physical addresses
  - Russia taxpayer identification number
  - Singapore physical addresses
  - South Africa physical addresses
  - Ukraine physical addresses

Sensitivity labels

- **Preview**: Rolling out, the sensitivity label setting to prevent connected experiences that analyze content now prevents all connected experiences in Word, Excel, and PowerPoint for Windows, rather than a subset of these experiences.
- **Preview**: Rolling out, the sensitivity label setting to prevent connected experiences that analyze content extends to Word, Excel, and PowerPoint across MacOS, iOS, and Android.

May 2026

Agent 365

- **General availability (GA)**: Data security and compliance protections for Microsoft Agent 365.

Data Governance

- **General availability (GA)**: Standalone data asset data quality scan is now generally available.
- **General availability (GA)**: Incremental data quality scan is now generally available.

- **General availability (GA)**: Configurable data quality thresholds for data quality rules and data assets are now generally available.

Data Loss Prevention

- **Updated**: Added the admin permissions (Directory Reader, Microsoft Edge administration, and Microsoft Intune administration) required to activate DLP policies for unmanaged cloud apps in Microsoft Edge for Business. For more information, see Learn about Data Loss Prevention for Cloud Apps in Edge for Business.
- **Updated**: Clarified Edge browser profile scope for cloud app DLP policies. Policies for unmanaged cloud apps on managed devices apply across all Edge profiles (work, personal, and InPrivate); policies for managed apps apply only in the Edge work profile. See Help prevent sharing via Microsoft Edge for Business to unmanaged AI apps from managed devices and Help prevent users from sharing sensitive info with cloud apps in Edge for Business.
- **Changed**: Removed DeepL and Zapier from the list of unmanaged AI apps supported by browser policies in Edge for Business.
- **In preview**: New **Block access for specific external domains or users** sub-option for the **Restrict access or encrypt the content in Microsoft 365 locations** action lets DLP policies for SharePoint and OneDrive block access to sensitive files for specific external domains or user SMTPs. See Actions and Help prevent sharing sensitive items via SharePoint and OneDrive with external users.

Data Security Investigations

- **New**: OCR support in Data Security Investigations. Image files are automatically processed with optical character recognition (OCR), and the extracted text is merged and vectorized for AI analysis.
- **New**: Custom examinations in Data Security Investigations. Define your own examination focus with custom prompts to analyze investigation content beyond the built-in examination areas.
- **Updated**: New guidance for working with large audit search results in Data Security Investigations. When audit searches exceed the approximately 3,000-item limit, use the Audit solution to analyze the full result volume, then split searches into smaller time-based slices for ingestion into an investigation.

Data Security Posture Management

- **General availability (GA)**: The new version of Data Security Posture Management is now generally available. Partner solutions for non-Microsoft data sources remain in preview, as does the Data Security Posture Agent. This current version provides guided workflows for proactive risk management and streamlines data security operations so you can more confidently adopt AI across your digital estate.
- **New**: Support for administrative units, to bring parity with the classic versions of DSPM and DSPM for AI.
- **New**: To optimize resources, processing is paused for Microsoft 365 data when tenants are inactive for more than 60 days, and automatically resume when you return to the solution. For more information, see Data updates paused for inactive tenants.
- **New**: The "Responsible AI FAQ for Data Security Posture Management" is replaced with the more detailed Application card for Data Security Posture Management to better help you understand this solution's AI capabilities, intended uses, limitations, evaluations, safety components, and best practices.
- **New**: Support for Anthropic Claude (Enterprise) when you add and configure the Anthropic Claude data connector, now in preview. Claude then displays as another AI application alongside Copilot, Copilot Studio, ChatGPT Enterprise, and other AI apps. Use activity explorer to see individual Claude interactions, such as who used Claude, when they used it, and what kinds of content were involved, just as you do for other AI apps. For more information about Purview support for Claude, see Use Microsoft Purview to manage data security & compliance for Anthropic Claude (Enterprise).

Information protection scanner

- **In preview**: Administrators can now enable, disable, and configure cluster-level scanner features from PowerShell.
- **In preview**: Custom Reporting populates additional columns and tables in the scanner cluster database so administrators can build their own reports directly against scan results in Power BI or any SQL-based reporting tool, without stitching together per-scan CSV reports.

Reports

- **Preview**: Custom posture reports let admins build tailored views of information protection and DLP activity. Assemble metric and chart cards in sections to answer organization-specific questions that complement the built-in posture reports.

Sensitivity labels

- **In preview**: Rolling out, manual labeling support for MP4 files in SharePoint and OneDrive. For more information, see Video support (MP4 files.
- **In preview**: Rolling out, a new label policy setting for meetings, **Apply meeting label to artifacts**, automatically applies the meeting's sensitivity label to recordings and their transcripts (.mp4 files), and to meeting notes (.loop files).
- **In preview**: You can now see the sync status of your sensitivity label publishing policies on the **Label policies** page, giving you visibility into when label policy updates are fully synced across Microsoft 365.
- **Updated**: The documentation section How to disable sensitivity labels for SharePoint and OneDrive (opt-out) now includes labeling behavior if you disable sensitivity labels for SharePoint and Onedrive after they've been enabled.
- **New**: For auto-labeling policies that are turned on and target SharePoint and OneDrive, per-policy review pages let you monitor daily labeling activity, spot-check labeled and failed files, and investigate labeling failures. For more information, see Policy-level labeling activity for SharePoint and OneDrive.

April 2026

Collection Policies

- **Preview**: Collection policies support sensitivity labels as a condition for scoping detection to items with specific sensitivity labels applied. This condition is supported with browser and network cloud apps detection.

Data Lifecycle Management

- **New**: Newly created Teams call data records (often abbreviated to CDRs, and sometimes also called *call detail records* or just *call records*) are no longer included with Teams chat retention policies. Instead, they are included in the new support for Teams call logs retention policies that you create by using PowerShell. These newly supported retention policies let you manage the deletion of calling-related data when this is required for compliance and regulatory requirements. Call data records previously included in Teams chat retention policies continue to be managed by those same policies.

Data Governance

- **In preview**: Use a one-time glossary migration and asset enablement process to curate data assets and columns with glossary terms. This process allows you to centralize the

management of glossary terms by migrating glossary terms created in the classic governance experience into Unified Catalog. When you complete the process, you can curate data assets and columns.

- **In preview**: New bulk import, editing, and moving capabilities can help you quickly scale operations in Unified Catalog:
  - Create data products in bulk
  - Create critical data elements in bulk
  - Create glossary terms in bulk and bulk edit glossary terms
  - Move multiple glossary terms between governance domains

- **General availability (GA)**: Now rolling out, the advanced resource sets capability is available to all customers. Pricing for advanced resource sets is consistent with existing rates for classic Microsoft Purview data governance.

- **In preview**: Data quality provides on-premises support for Oracle and SQL server. On-premises databases are scanned in on-premises infrastructure to ensure that data doesn't move beyond organizations' premises. You need to set up a Kubernetes cluster to host the runtime that scans these databases.

- **In preview**: Data quality thresholds help stakeholders and data consumers know when data quality scores fall below standards. You can configure alerts for a rule level threshold and a data asset level threshold.

Data Loss Prevention

- **Updated**: Restructured the just-in-time (JIT) protection documentation.
- **Updated**: The Get started with just-in-time protection article now focuses on deployment and configuration steps.
- **New**: A new conceptual article, Learn about just-in-time protection, now covers JIT concepts, terms, supported activities, device compatibility, and includes a detailed JIT workflow diagram.
- **Preview**: DLP policies for unmanaged cloud apps support a new URL contains text condition that detects when the URL of the cloud app contains specified text strings. You can use it as a condition to scope DLP rules to specific URLs, or as an exception to exclude specific URLs from policy enforcement.
- **Preview**: Email notifications for browser and network DLP rules notify end users via email when their activity is blocked. Notifications use a rolling 10-minute batching window to prevent excessive emails.

- **Preview**: Data loss prevention policy tip reference for Outlook for Android, iOS, and macOS. A new reference article covering DLP policy tips, supported conditions, oversharing dialogs, and override capabilities for Outlook on Android, iOS, and macOS.

Data Security Investigations

- **In preview**: Proactive AI insights from Data Security Posture Management (DSPM) automatically create and refresh a single investigation for your tenant every 24 hours. The DSPM exfiltration objective card displays risk counts across five fixed categories, giving security teams continuous visibility into recently exfiltrated sensitive data without manual investigation creation.
- **New**: A new Data Security Investigation Contributor role automatically provides Data Security Investigations access to members of several Microsoft Purview role groups. Members of the *Compliance Administrator* and *Organization Management* role groups have administrative and contributor access, while members of the *Data Security Management* and *Insider Risk Management* role groups have contributor access without needing explicit role assignment.

Data Security Posture Management (preview)

- **New**: Microsoft Sentinel with partner solutions now also supports Varonis to provide holistic data insights for Salesforce.

Developers

- **Documentation update:** Added *Scenarios and API overview* section. This new section helps developers identify which APIs to use for specific scenarios. For more information, see Scenarios and API overview.

eDiscovery

- **In preview**: Organizations using Customer Key can now enable customer-managed key (CMK) encryption for direct export packages in eDiscovery. When enabled, exported investigation data is encrypted at rest using tenant-specific encryption scopes backed by customer-managed keys.
- **Updated**: The maximum number of review sets per case has increased from 20 to 100 for eDiscovery with premium feature support.
- **New**: The Advanced review set explorer (preview) includes a new left navigation pane to browse the review set schema, insert KQL operators, and run sample queries, and a new

Getting started tab with basic and advanced query templates to help you build queries faster.

Insider Risk Management

- **In preview**: Preview content while triaging alerts to quickly identify false positives, confirm the presence of sensitive data, and decide whether the alert warrants escalation.

Sensitivity labels

- **General availability (GA)**: Auto-labeling policies introduce a new flow where you must decide whether to automatically apply a sensitivity label, or remove a label when the configured conditions apply for files in SharePoint and OneDrive. When you chose to automatically apply a sensitivity label, you can now optionally choose to always overriding an existing label that has a lower priority label, even if it was manually applied. This option was previously available for emails only and now extends to files in SharePoint and OneDrive.
- **New**: Rolling out, users can now apply sensitivity labels configured for user-defined permissions while using Office for the web. A prerequisite for this functionality is that co-authoring is enabled for the tenant. If this prerequisite isn't in place, users still see the message that they must use a desktop app to apply the label.
- **New**: The **Label policies** page for label publishing policies has a new **Export policies** option, where the **Export to CSV** selection acts similarly to **Export** on the **Sensitivity labels** page. The **Export to Zip** selection includes more detailed information about the policies and all sensitivity labels in your tenant. For more information, see Export policy configuration in Microsoft Purview.

Shared capabilities

- **General availability (GA)**: Export policy configuration as a ZIP file containing a point-in-time snapshot of all policy configurations in XML format for DLP and sensitivity label publishing policies. Use the export for support requests, configuration reference, and local analysis by using PowerShell or Microsoft 365 Copilot.

March 2026

Data Governance

- **General availability (GA)**: Authoring custom data quality rules using SQL expression language is now generally available. Users can create custom rules using both Azure Data Factory expression and SQL expression languages.
- **In preview**: Configurable Data Quality thresholds allows users to define minimum acceptable quality scores at the data quality rule and data asset levels to align quality evaluation with business criticality.

Data Loss Prevention

- **Preview**: DLP supports adaptive scopes for scoping SharePoint policies. SharePoint location scoping

Data Security Investigations

- **New**: Categorization now includes a **Standard** and **Advanced** option. **Standard** categorization can significantly reduce the time it takes to complete processing and the amount of Data Security Investigation Compute Units (compute unit) needed for categorization.
- **In preview**: New support for the Data Security Posture Agent in Microsoft Purview. The Data Security Posture agent (preview) in Data Security Investigations helps your organization proactively surface credentials buried in data across your organization at scale.
- **Updated**: New guidance for how categorization processes data in Data Security Investigations. Categorization uses relevance scoring to prioritize the most relevant content for each selected category. Updated documentation includes considerations for results, content volume effects, and recommendations for using examination tools for comprehensive analysis.
- **New**: Data Security Investigations now supports soft purge for Exchange mailbox items. Soft purge moves items to the recoverable items folder, preserving the ability to restore items based on retention settings. Updated documentation includes guidance for choosing between soft purge and hard purge methods.
- **New**: Audit search in Data Security Investigations is now generally available. Use audit search to identify and collect content based on user activities recorded in the Microsoft Purview unified audit log, such as accessing, copying, or downloading files, and pull the associated content into your investigation.
- **Updated**: Data Security Investigations searches now respect compliance boundaries configured with search permissions filters. Investigators whose accounts are scoped by a compliance boundary only see search results for content locations within their permitted boundary.

- **New**: Personal data examinations in Data Security Investigations identify and extract personally identifiable information from selected data items in an investigation scope. Quickly assess which personal data types were exposed after a data security incident, including names, email addresses, financial account numbers, and Social Security numbers, with severity classification and AI-generated reasoning to support regulatory compliance reporting.

Data Security Posture Management (preview)

- **New**: Extend coverage of data insights to third-party SaaS and IaaS platforms by using Microsoft Sentinel with partner solutions to provide holistic data insights across Google Cloud Platform, Snowflake, and Databricks.
- **New**: You can now use federated credentials as a more secure method of authentication to run Fabric data risk assessments. This change is also available for data risk assessments in Data Security Posture Management for AI (classic). For more information, see Prerequisites for Fabric data risk assessments.

Deployment models

- **Updated**: Expanded Microsoft Purview deployment models with comprehensive step-by-step inline guides for five deployment scenarios: Prevent data leak to shadow AI, Secure and govern Microsoft 365 Copilot agents, Deploy and use Data Security Posture Management, Lightweight guide to mitigate data leakage, and Reduce false positives with SITs and advanced classifiers. Previously available only as downloadable PPTX and PDF files, each model now includes detailed articles following a step-based workflow.

eDiscovery

- **In preview**: Use the new Advanced review set explorer to query review set data with Kusto Query Language (KQL). Build advanced queries with complex filtering, pattern-based text extraction, and data visualization to analyze and find key information in your review sets.
- **New**: Configure sampling options when adding search results to a review set in eDiscovery. Choose confidence-based or percentage-based sampling to add a statistically representative subset of search results instead of all items. Completing the **Generate statistics** process is required to enable sampling.

Insider Risk Management

- **In preview**: Disable content download to create cases without content to reduce triage time. To get started, see Enable or disable content download.
- **General availability (GA)**: Microsoft Fabric indicators now include Lakehouse indicators.
- **General availability (GA)**: A new quick policy template for detecting data theft from non-Microsoft 365 apps by users leaving your organization is now available.
- **General availability (GA)**: Pay-as-you-go usage reports provide transparency and enable more accurate budget planning and policy tuning.
- **In preview**: The agent summary tab in the Triage Agent in Insider Risk Management has been enhanced to intelligently distill user activity risk into meaningful risk pattern narratives, contextual filtering options, granular activity signals, and provide specific files within alerts.

Sensitivity labels

- **General availability (GA)**: Manual labeling for OneNote, supported at the section level. Because retention labels also support labeling at the section level, you might find it helpful to review the architecture diagram for retention policies and retention labels. To enable the support for sensitivity labels, SharePoint and OneDrive must already be enabled for sensitivity labels, and then run the following PowerShell command: *Set-SPOTenant -EnableSensitivityLabelforOneNote $true*
- **In preview**: Auto-labeling policies introduce a new flow where you must decide whether to automatically apply a sensitivity label, or remove a label when the configured conditions apply for files in SharePoint and OneDrive. When you chose to automatically apply a sensitivity label, you can now optionally choose to always overriding an existing label that has a lower priority label, even if it was manually applied. This option was previously available for emails only and now extends to files in SharePoint and OneDrive.
- **In preview**: Viva Engage communities now support sensitivity labels applied to their underlying Microsoft 365 groups and connected SharePoint sites. The container label settings supported are privacy and guest access controls, to help you manage consistent protection with other groups and sites that support sensitivity labels. You can manually apply the label in Engage communities, and configure it in label policies as a default label for newly created communities.
- **Documentation update**: Now that container-level support for sensitivity labels include new collaborative workspaces such as Viva Engage communities and Loop workspaces, the previously titled article "Use sensitivity labels to protect content in Microsoft Teams, Microsoft 365 groups, and SharePoint sites" is now renamed Use sensitivity labels to protect collaborative workspaces (groups and sites).

February 2026

Data Governance

- **In preview**: Microsoft Purview Data Quality supports incremental data quality scans by using time-based filtering. By using incremental scans, you can choose between full scans, incremental scans, or both when you run data quality rules on data assets.
- **In preview**: Data quality scans for standalone data assets enable organizations to measure and improve data quality immediately without associating a data asset to a data product, significantly speeding up governance adoption. By running scans on assets, organizations can decide whether to associate a data asset to a data product if the data asset is in poor quality.
- **General availability (GA)**: Azure SQL Managed Instance support (SQL MI) is now generally available. You can now measure, understand, and improve the quality of your data in your SQL MI. Both public network and private endpoint configurations are supported. To get started, create a connection similar to Azure SQL database with supported port number, and assess the quality of your data using the Microsoft Purview Data Quality scanner.

Developers

- Microsoft Purview enables software development companies to integrate governance, protection, and compliance capabilities into their applications using SDKs and APIs. A new list of partner integrations is now available, with links to partner documentation. For more information, see Software Developer Partner Integrations.

Insider Risk Management

- **In preview**: Microsoft Fabric indicators now include Lakehouse indicators.
- **In preview**: A new quick policy template for detecting data theft from non-Microsoft 365 apps by users leaving your organization is now available.

Sensitivity labels

- **New**: The client-side improvements for sensitivity labels that extend SharePoint permissions to downloaded documents that started to roll out to Windows version 2601+ in January for the Current Channel is complete, and now also available with the Monthly Enterprise Channel.

Where to start with Microsoft Purview

Microsoft Purview brings together data security, data governance, and data compliance solutions in a unified platform, the Microsoft Purview portal. These solutions share capabilities, exchange signals, and reinforce each other to give your organization comprehensive visibility and control over its data.

But with its breadth of solutions and capabilities, it can be hard to know where to begin with Purview. There's no single path that works for every organization because priorities differ based on your industry, regulatory requirements, and how far along you are in your AI adoption. However, most organizations follow a similar progression:

1. **Discover and understand your data**: Find out what data you have, where it lives, and how much of it is sensitive.
2. **Protect your sensitive data**: Apply labels, encryption, and policies to prevent data loss.
3. **Govern your data estate**: Catalog your assets, ensure data quality, and establish accountability.
4. **Control access and user behavior**: Make sure users can only reach the data they need and that they interact with it safely.
5. **Secure AI interactions**: Extend your protections and compliance controls to Copilot, agents, and other AI apps.

This article walks through each stage and explains which Purview solutions apply, how they connect, and where to start.

> **Tip**
>
> Before you begin configuring solutions, make sure the right people in your organization have the roles and permissions they need. Most exploration tasks, like viewing Data Security Posture Management dashboards, require only reader roles.

Discover and understand your data

Before you can protect or govern anything, you need to know what data you have and identify which data is sensitive. Discovery is the foundation for every other stage, and Purview provides several ways to build that picture.

Assess your data security posture

Data Security Posture Management (DSPM) brings together signals from across Purview to give you a unified view of sensitive data risks. DSPM helps you discover where sensitive data lives, identify oversharing risks, and get personalized recommendations for remediation. If your organization uses AI apps, DSPM provides extra visibility into how AI interacts with your data.

DSPM is a good starting point if you want a single dashboard that shows what needs attention first.

Classify sensitive data

Sensitive information types and trainable classifiers identify sensitive items across your Microsoft 365 environment by using pattern matching, machine learning, or examples of data you provide. These classifiers are *shared* across Purview, so a sensitive information type you configure here is also available to Data Loss Prevention policies, Insider Risk Management, Communication Compliance, and data classification reports.

Data classification provides dashboards and explorers that show how data is classified and used across your organization. Use activity explorer to see how users interact with sensitive data, including labeling activity and AI interactions.

To learn more, see Get started with data classification.

Scan and catalog data assets

Data Map scans your data sources and multicloud environments to capture metadata about your data assets. This process creates a comprehensive inventory that spans your entire data estate and feeds the Unified Catalog, where data owners and stewards curate data products and data consumers discover trusted datasets. Data Map and Purview share data to support various shared capabilities, as detailed in How data flows in Microsoft Purview.

To learn more, see Plan for data governance.

Protect your sensitive data

After you understand what sensitive data you have and where it lives, the next step is to apply protections. Purview data security solutions work together to protect data throughout its lifecycle.

Apply sensitivity labels

Sensitivity labels are the foundational protection mechanism in Purview. Labels provide visibility into the sensitivity of data and can apply encryption, access restrictions, and visual markings. When you apply a label to a document or email, the protection travels with the content wherever it goes - across services, devices, and into AI interactions.

Many solutions use sensitivity labels. Data Loss Prevention enforces them, AI apps honor them, Microsoft Purview Audit logs capture them, Microsoft Purview eDiscovery makes them searchable, and DSPM makes them visible. When you define and apply your labels, you build the foundation for protections that extend across the entire platform.

To learn more, see Get started with sensitivity labels.

Prevent data loss

Data Loss Prevention (DLP) policies monitor for sensitive information across Microsoft 365 services and endpoints. In a DLP policy, you define the sensitive information to monitor, the locations to monitor, the conditions that must be matched, and the actions to take when a match is found. DLP uses the same classifiers and sensitivity labels that other solutions rely on, so your protection policies are consistent across the platform.

To learn more, see Learn about data loss prevention.

Manage data retention and deletion

Data Lifecycle Management provides retention and deletion policies that help you keep content you need and delete content you don't. Retaining data often addresses compliance and regulatory requirements. Deleting data that no longer has business value reduces your exposure to cyberattacks and data breaches. These policies apply across Exchange, SharePoint, OneDrive, Teams, and other Microsoft 365 services.

To learn more, see Get started with data lifecycle management.

Govern your data estate

With sensitive data protected, your organization can focus on making sure all data is well-organized, trustworthy, and accessible to the right people. Purview data governance solutions help your organization establish a federated governance model where a central data office sets the rules and domain experts manage the data they know best.

Curate data in Unified Catalog

Unified Catalog is a searchable catalog powered by the metadata captured in Data Map. Data owners and stewards use it to curate data products, manage data quality, and grant access to data consumers. Data consumers discover trusted datasets through a self-service experience with natural language search.

Governance domains organize data products and business concepts to make data easier to find and use. Built-in data quality capabilities help data owners measure and improve the health of their data, which is especially important in the era of AI because AI systems that ingest trusted, high-quality data produce more accurate and reliable results.

How governance supports security and compliance

Governance and security complement each other. Data governance helps you understand *what* data you have and *where* it lives. Data security helps you *protect* that data. For example, when Data Map identifies sensitive data sources, your security team can prioritize applying sensitivity labels and DLP policies to those sources.

Governance also supports compliance. Data lineage capabilities in Unified Catalog help you see the relationships between data products and their sources, which is useful for responding to regulatory inquiries and demonstrating compliance.

To learn more, see Plan for data governance and Get started with data governance.

Control access and user behavior

Protecting data and governing data assets addresses the data itself. But you also need to make sure that *people* interact with data in safe, secure, and compliant ways. Purview provides several solutions that monitor user behavior, enforce access boundaries, and help you respond to incidents.

Detect and act on insider risks

Insider Risk Management identifies potentially risky user activities by correlating signals from Microsoft 365 and third-party sources. It can detect behaviors such as unusual data downloads, sensitive data sharing, and risky AI usage patterns. Insights from insider risk signals are integrated into Microsoft Defender XDR for a comprehensive view of security threats.

To learn more, see Learn about insider risk management.

Restrict communication and collaboration

Information Barriers restrict two-way communication and collaboration between groups and users in Teams, SharePoint, and OneDrive. Often used in highly regulated industries, Microsoft Purview Information Barriers help avoid conflicts of interest and safeguard internal information between users and organizational areas.

To learn more, see Learn about information barriers.

Limit privileged access

Privileged Access Management helps protect your organization by limiting standing access to sensitive data or critical configuration settings. Instead of administrators having constant access, just-in-time access rules are implemented for tasks that need elevated permissions.

To learn more, see Learn about privileged access management.

Monitor organizational activity

Audit captures, records, and retains user and admin activities across Microsoft 365 services. Audit logs are essential for security investigations, compliance obligations, and forensic analysis. Audit records include AI interactions, such as user prompts and responses with Copilot and other AI apps.

To learn more, see Get started with auditing solutions.

Detect inappropriate communications

Communication Compliance monitors email and Teams communications for regulatory violations, harassment, threats, and inappropriate sharing of sensitive information. You can also set policies to monitor interactions with generative AI apps.

For more information, see Learn about communication compliance.

Investigate data security incidents

Data Security Investigations uses generative AI to help your security team analyze and respond to data security incidents, identify risks from sensitive data exposure, and collaborate more effectively on remediation.

Meet regulatory requirements

Compliance Manager helps your organization assess its compliance posture against more than 360 industry and regional regulatory standards. It provides risk-based scoring, improvement actions, and prebuilt assessment templates, including templates for AI regulations.

eDiscovery helps your organization identify, collect, preserve, and export electronic information for legal cases and regulatory investigations. Records Management helps declare content as records or regulatory records, manage retention schedules, and conduct disposition reviews with proof of deletion.

For more information, see Get started with data compliance solutions.

Secure AI interactions

The rapid adoption of generative AI adds a new dimension to every stage described in this article. AI apps can surface content faster and at greater scale, which amplifies the risk of oversharing and sensitive data leakage. Purview provides data security and compliance capabilities for AI that span Copilot experiences and agents, enterprise AI apps, and other AI apps.

The protections you built in earlier stages carry forward into AI scenarios:

- **Sensitivity labels** applied to content are honored by AI apps. If a user doesn't have permission to access data, AI apps don't return that data. Users must have the EXTRACT usage right, as well as VIEW, for AI apps to return labeled, encrypted data.
- **DLP policies** can block sensitive information from being shared with third-party AI apps. Endpoint DLP policies can warn or block users from pasting sensitive data into AI sites accessed through a browser.
- **Insider Risk Management** includes a risky AI usage policy template that can detect prompt injection attacks and attempts to access protected materials.
- **DSPM** provides visibility into how AI is used across your organization, surfaces AI-specific risks, and offers one-click policies to address them.

- **Audit** captures user prompts and AI responses, and these records flow into activity explorer for monitoring and analysis.
- **Communication Compliance** can monitor AI-generated communications for regulatory violations.
- **Retention policies** from Data Lifecycle Management apply to AI interaction data, ensuring it's kept for the required period and then deleted.
- **Compliance Manager** provides assessment templates specifically for AI regulations.
- **Data governance** ensures the data feeding your AI apps is high quality, well-curated, and trustworthy, so AI systems produce accurate and reliable results.

To learn more, see Microsoft Purview data security and compliance for AI.

Shared capabilities across solutions

Purview solutions work well together because they share a common foundation of capabilities. When you configure these capabilities in one solution, they're available everywhere:

Expand table

Shared capability	How it's used
Classifiers (sensitive information types and trainable classifiers)	Used by DLP, Information Protection, Insider Risk Management, Communication Compliance, and data classification reports. Define once, use everywhere.
Sensitivity labels	Applied by Information Protection, enforced by DLP, honored by AI apps, captured by Audit, searchable in eDiscovery, and visible in DSPM.
Connectors	Bring third-party data into Microsoft 365 for compliance, governance, and security scenarios.
Activity explorer	Surfaces user and admin activities related to sensitive data, labeling, and AI interactions across solutions.

Iterate and improve over time

Deploying Purview isn't a one-time project. The deployment guides in Microsoft Purview deployment models consistently emphasize an operational phase where you expand scope, refine policies, and act on what you learn. You don't need to get everything right upfront. Start with foundational protections and improve over time.

As your deployment matures, revisit these key areas:

- **Refine your classifiers.** Start with built-in sensitive information types and expand to Exact Data Match, trainable classifiers, and document fingerprinting as you learn which detections produce false positives and which miss important content.
- **Enable Adaptive Protection.** Adaptive Protection connects Insider Risk Management signals to DLP policies so that protections adjust dynamically based on user risk level. This approach reduces friction for low-risk users while applying stricter controls when risk increases.
- **Expand to new locations and workloads.** Most organizations start with a subset of locations (for example, SharePoint and Exchange). Over time, expand DLP policies to endpoints, Teams chat, and third-party apps. Extend sensitivity labels retroactively to existing content using auto-labeling policies.
- **Use data security objectives.** DSPM provides guided data security objectives that group relevant Purview solutions into end-to-end workflows. Each objective focuses on a specific security goal, such as preventing oversharing or data exfiltration, with prioritized actions, progress tracking, and one-click policy configuration.

The key principle is to start simple, monitor results, and expand when ready. Each improvement you make builds on the foundation you already have in place.

Next steps

- Learn about Microsoft Purview and explore the full range of solutions.
- Get started with data security solutions to protect sensitive data.
- Plan for data governance and get started with Unified Catalog and Data Map.
- Get started with data compliance solutions to meet regulatory requirements.
- Explore Microsoft Purview data security and compliance for AI to secure your AI adoption.
- Explore Microsoft Purview deployment models for scenario-based step-by-step guides.

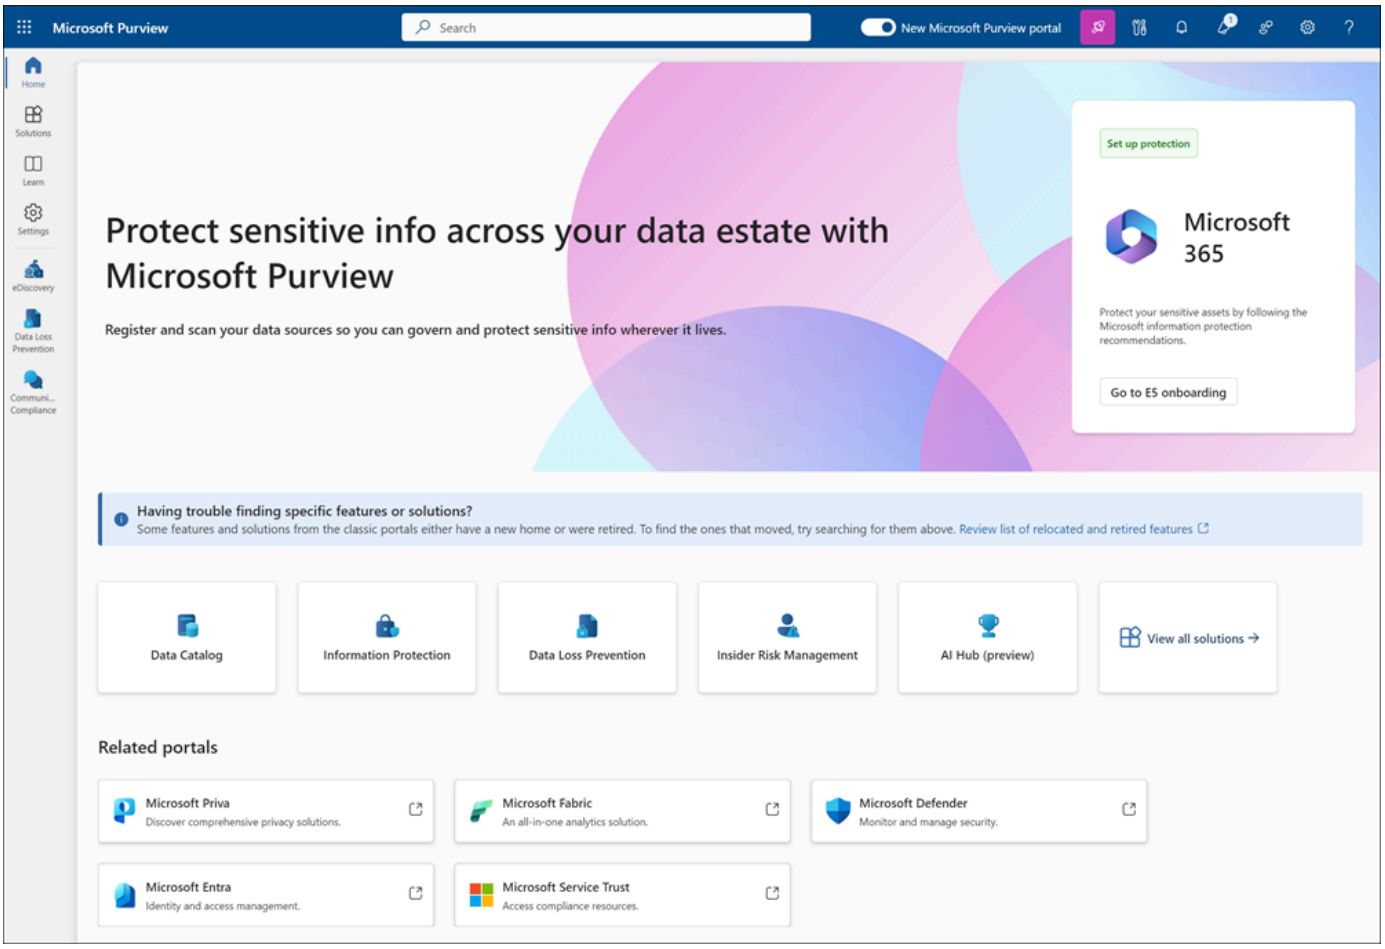
Learn about the Microsoft Purview portal



Microsoft Purview is a comprehensive set of solutions that helps you govern, protect, and manage data in your organization. The Microsoft Purview portal has a streamlined design and unified experience that helps you discover and access data security, data governance, and risk and compliance solutions for all your data, wherever it lives across your data estate. The unified experience streamlines navigation for all Purview solutions and provides a single-entry point for settings, search, and roles and permissions management.

Get started with the portal

When you first navigate to and open the Microsoft Purview portal, a welcome dialog appears that provides a brief overview of the new portal experience. After you agree to the terms and privacy conditions, select **Get started** to follow teaching bubbles that highlight key areas of the new portal experience.

Next, you see the new home page. The home page is your starting point for accessing all Microsoft Purview solutions, portal-wide settings, summary information about your data, and more.

Relocated portal features

Some features and capabilities that you're familiar with when using the retired Microsoft Purview compliance portal and the classic Microsoft Purview governance portal are relocated or retired in the Microsoft Purview portal.

Expand table

Feature or capability	Summary of changes
Classification	Classification is renamed to *Classifiers* and moved to the left-navigation area for each solution.
Content Search	Content Search features are now included as core components in eDiscovery.
Data asset search and browse	Data asset search and browse has moved to **Unified Catalog** > **Discovery** > **Data assets**.
Data Estate Insights	Data Estate Insights is renamed to *Reports* and moved to **Unified Catalog** > **Health management** > **Reports**.
Explorers	Explorers moved to the left-navigation area for each solution.
Glossary	The glossary moved to **Unified Catalog** > **Discovery** > **Enterprise glossary**.

Feature or capability	Summary of changes
Policies	Policies moved to the left-navigation area for each solution.
Privacy Risk Management	Privacy Risk Management is available in the Microsoft Priva portal.
Reports	Reports moved to the left-navigation area for each solution.
Roles and scopes	Roles and scopes are located in **Settings**.
Settings	Settings are located in the global left-navigation or at the top command bar of the portal. Select **Settings** to configure global and solution-level setting options.

Permissions and subscriptions

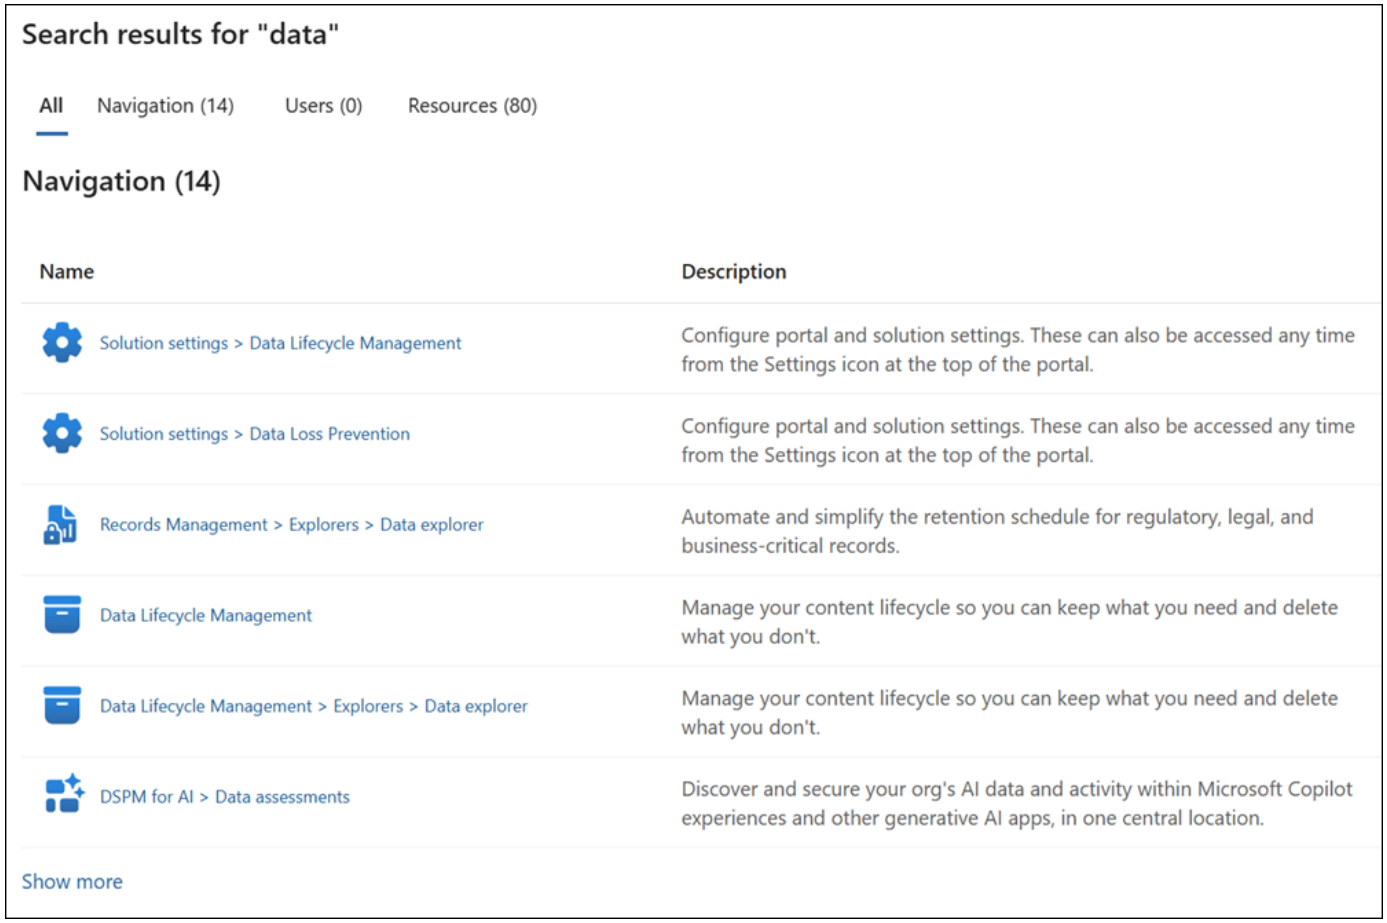
Depending on your permissions and your Microsoft Purview subscription, you see different solutions, home page cards, and features in the portal. For example, if you have permissions and a supported subscription to access a specific data governance or risk and compliance solution (such as **Data Loss Prevention**, **Insider Risk Management**, and others), you see these solution cards on the home page. If you don't have permissions or a supported subscription, you don't see these solution cards on the home page.

> **Note**
>
> You can grant Microsoft Purview permissions through security group membership. If you use Microsoft Entra Privileged Identity Management (PIM) for just-in-time membership for security groups in Microsoft Purview role groups, it can take up to two hours after activation for eligible administrators to have effective permissions applied in Microsoft Purview. For more information about PIM, see What is Microsoft Entra Privileged Identity Management.

For more information about permissions and role groups in Microsoft Purview, see:

- Permissions in the Microsoft Purview portal
- Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview portals

For more information about Microsoft Purview subscription requirements, see:



- Purview compliance solution requirements
- Purview governance solution plan requirements

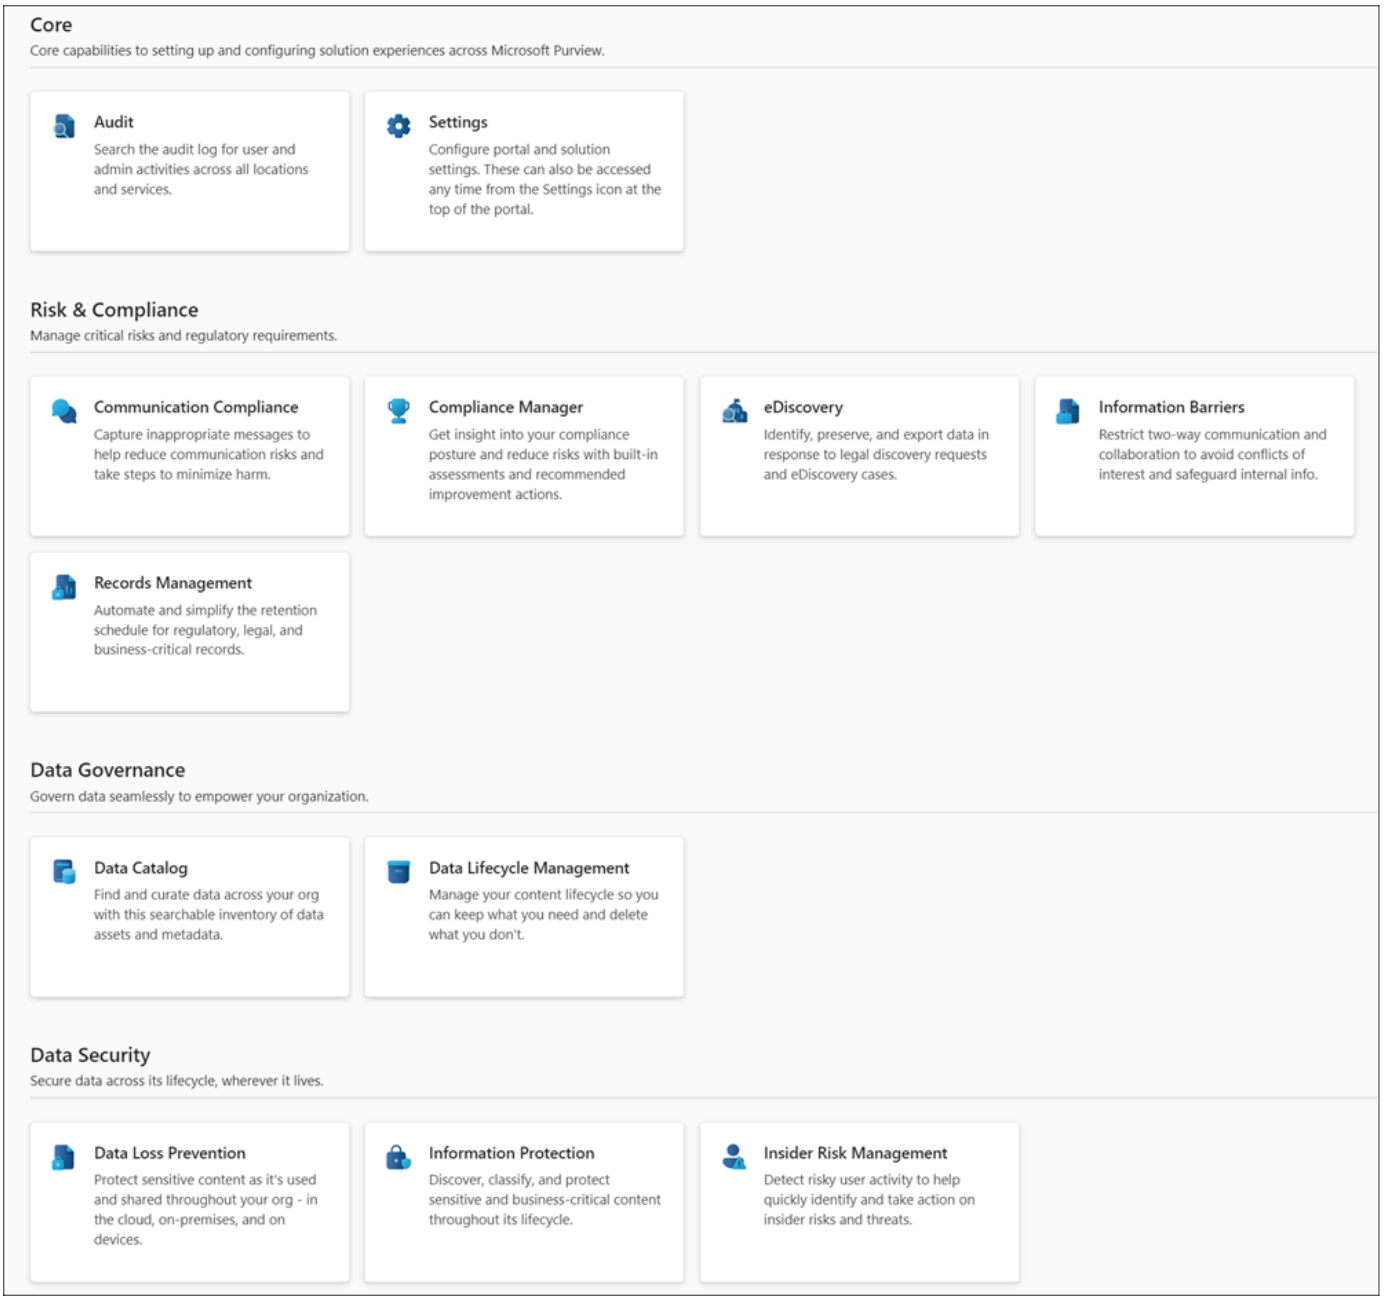
Global search

Use global search at the top of the portal to search for navigation, users, and resources across all your solutions and data estate. For terms you enter in the search bar, you see applicable results grouped by the following sections in the search results drop down:

- **Navigation**: Results for items associated with specific Microsoft Purview solutions and solution features.
- **Users**: Results for users included in your organization. When you select a user, you see user details, including email, role groups, and administrative units assigned. To view role groups for a user, you must have the *Role management* role assigned that isn't restricted to an administrative unit.
- **Resources**: Results for helpful resources associated with the searched term.

To view the consolidated search results page, select the links to view all results at the bottom of any section listed in the search results drop down or select the **Search** arrow on the right side of the search bar. To filter the displayed results by section on the search results page, select the **All**, **Navigation**, **Users**, or **Resources** link at the top of the page. To view all results in each section, select **Show more**.

The five most recently entered search terms are retained as quick links in the search bar for quick access to current results for these terms.

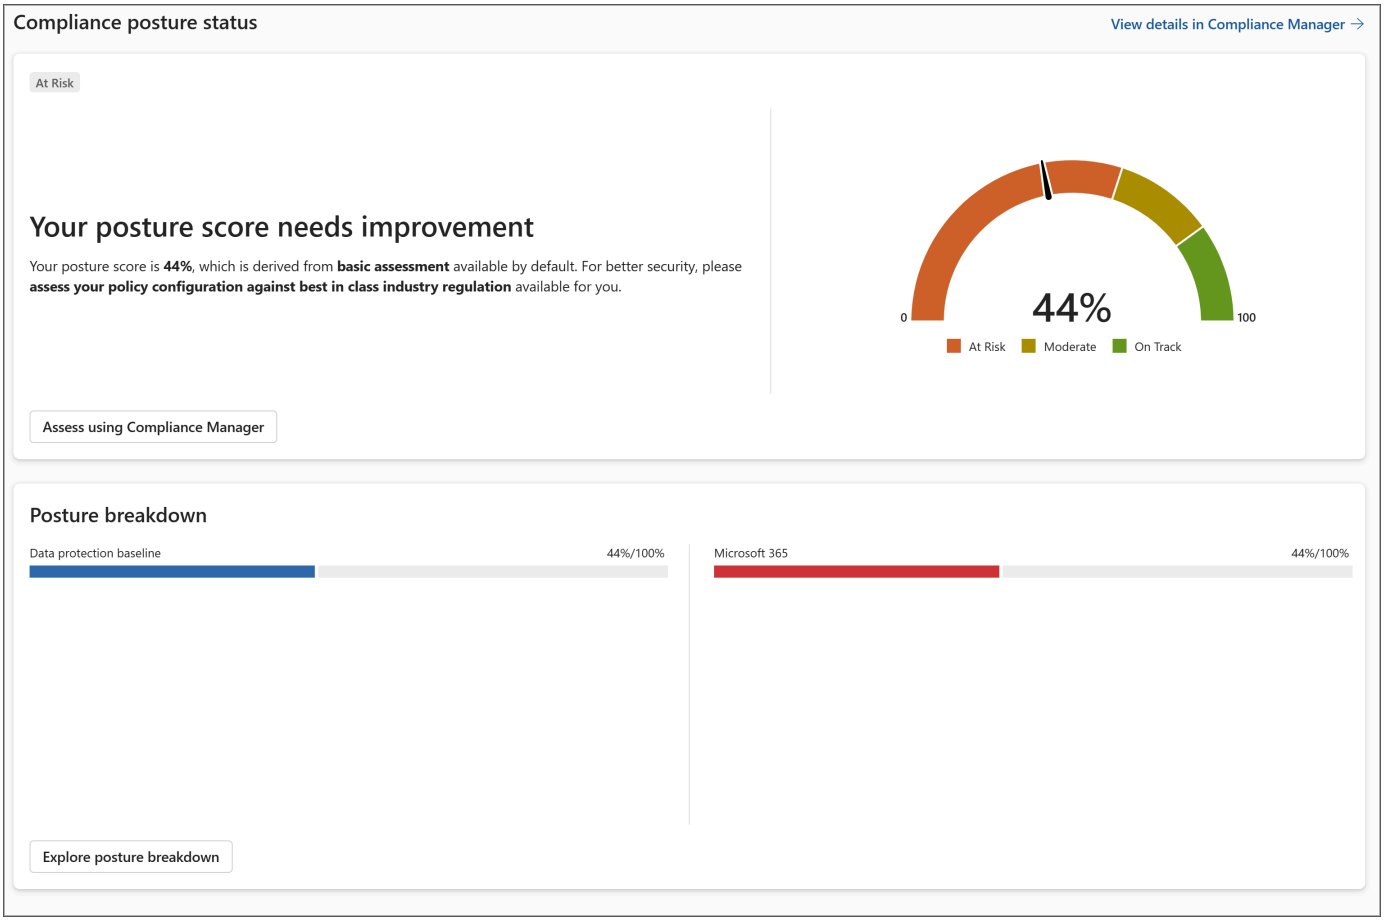


Sections and cards

Solution cards and the Solutions page

Solution cards on the portal home page allow you to quickly access and open the Microsoft Purview solutions that you have access to. You can't customize the displayed view for these cards.

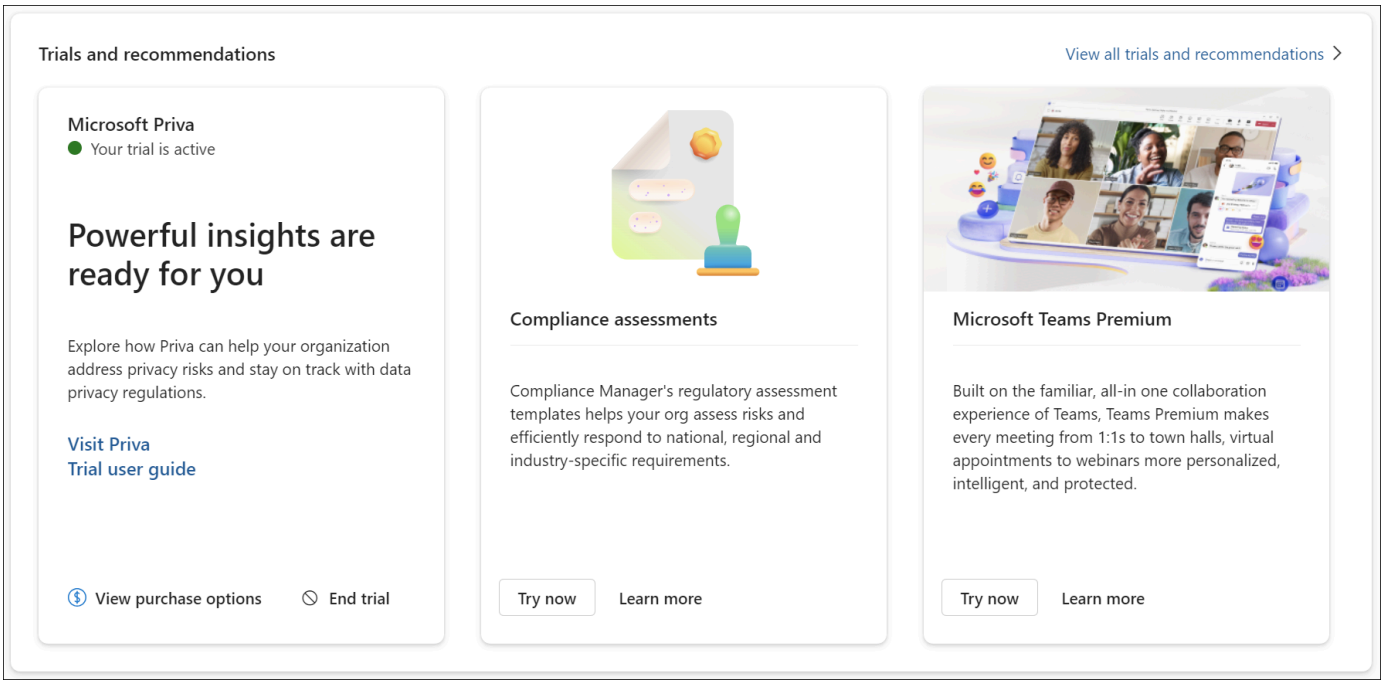
To view and manage all solutions you have access to that aren't listed in the solution card list, select **View all solutions**. From the **Solutions** page, you can select solutions in the **Core** section to set up and configure app experiences across Microsoft Purview. You can also use the **Risk & Compliance**, **Data Governance**, and **Data Security** sections to directly view and manage specific Microsoft Purview solutions. Use the predefined filters to view solutions by area, or use the search box to find a specific solution by keyword. To explore learning materials (documentation, blogs, videos, and tutorials), select **Knowledge Center** in the **Resources** section.



Related portals

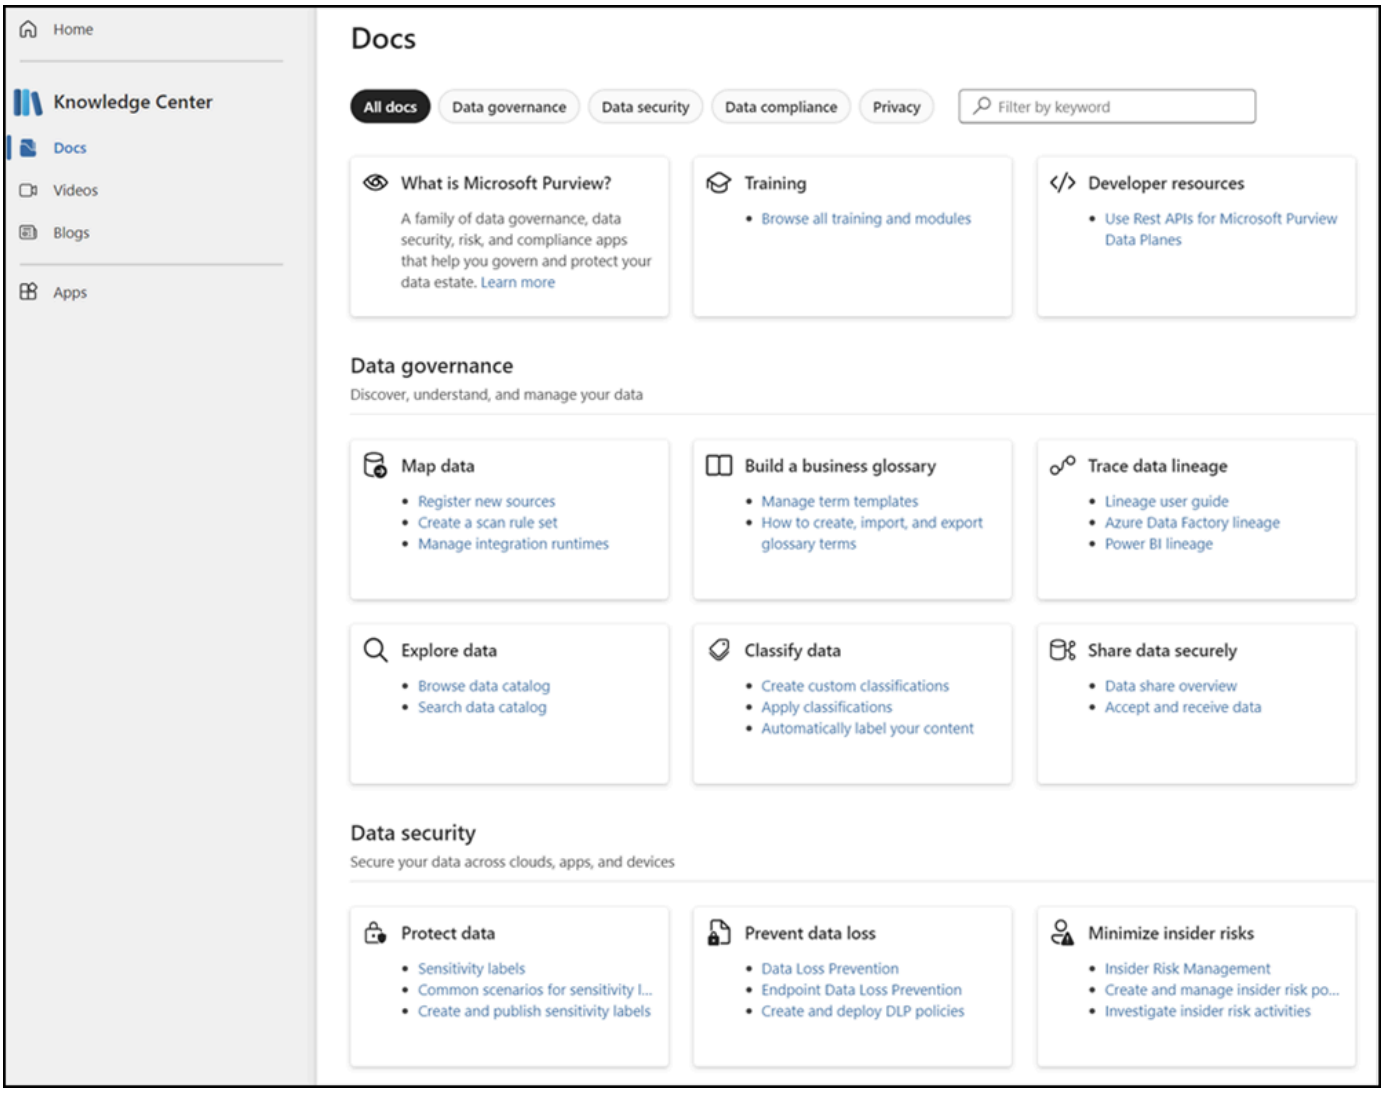
Access related portals and solutions to help you manage all aspects of data analytics, data privacy, user identity, and more in your organization. You can access the following management and resource portals by selecting **Solutions** > **Related portals** in the left navigation:

- Microsoft Defender
- Microsoft Entra
- Microsoft Fabric
- Microsoft Priva
- Microsoft Service Trust



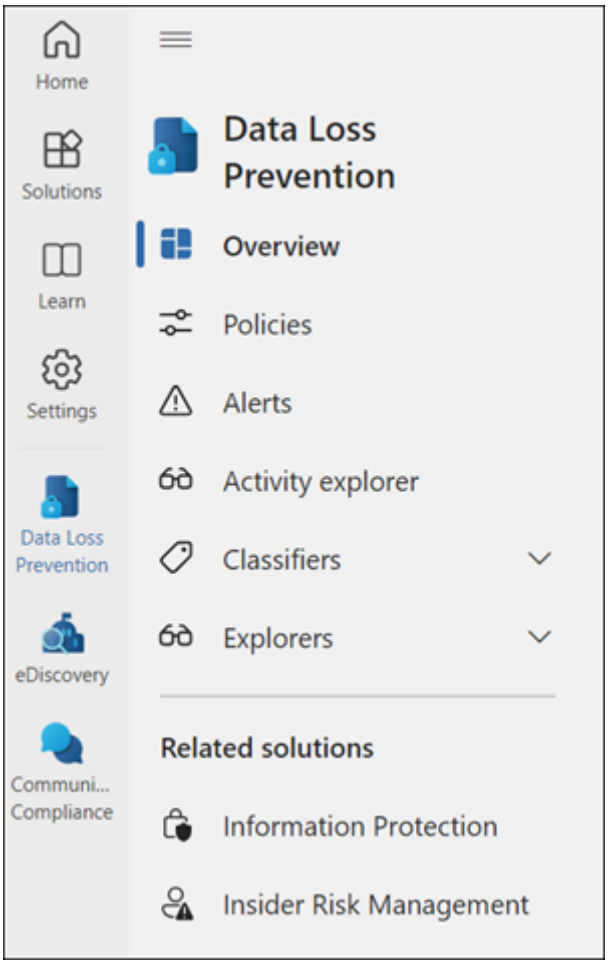
Compliance posture status

The **Compliance posture status** section includes cards that display summary information from the Compliance Manager solution about your organization's compliance posture. The compliance posture percentages reflect progress toward completing the requirements of regulatory assessments. The **Posture breakdown** section highlights completion rates for your organization's top assessments and the services covered by the assessments. Select **Assess using Compliance Manager** or **Explore posture breakdown** to visit Compliance Manager, where you can view, add, and manage assessments.



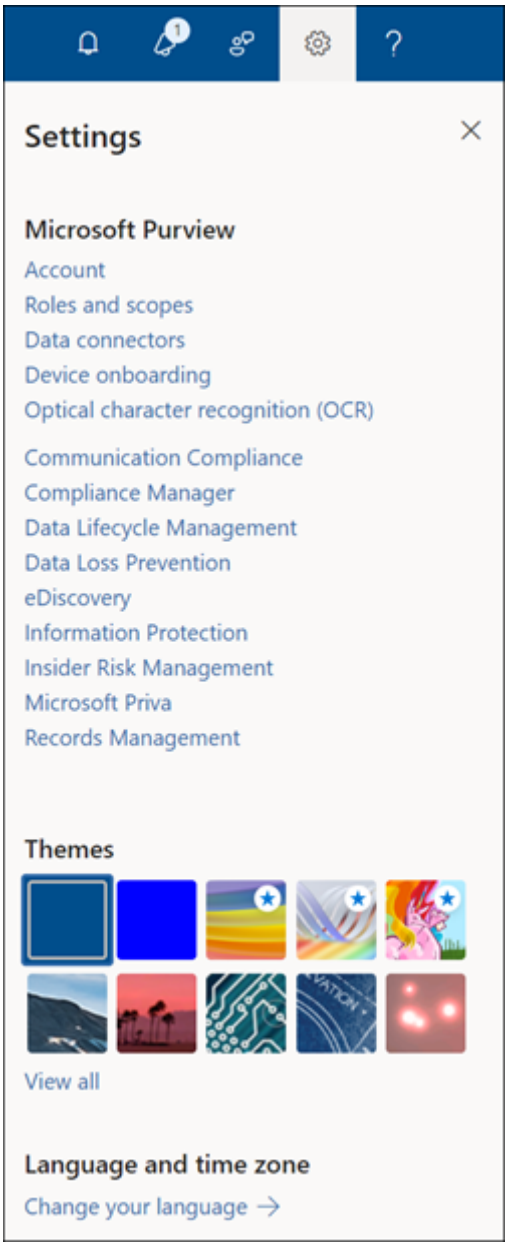
Trials and recommendations

The **Trials and recommendations** card displays information and links to help you get started with trial solutions for specific Microsoft Purview solutions. Select **View all trials and recommendations** to discover more security and compliance capabilities in Microsoft Purview you can try for free.



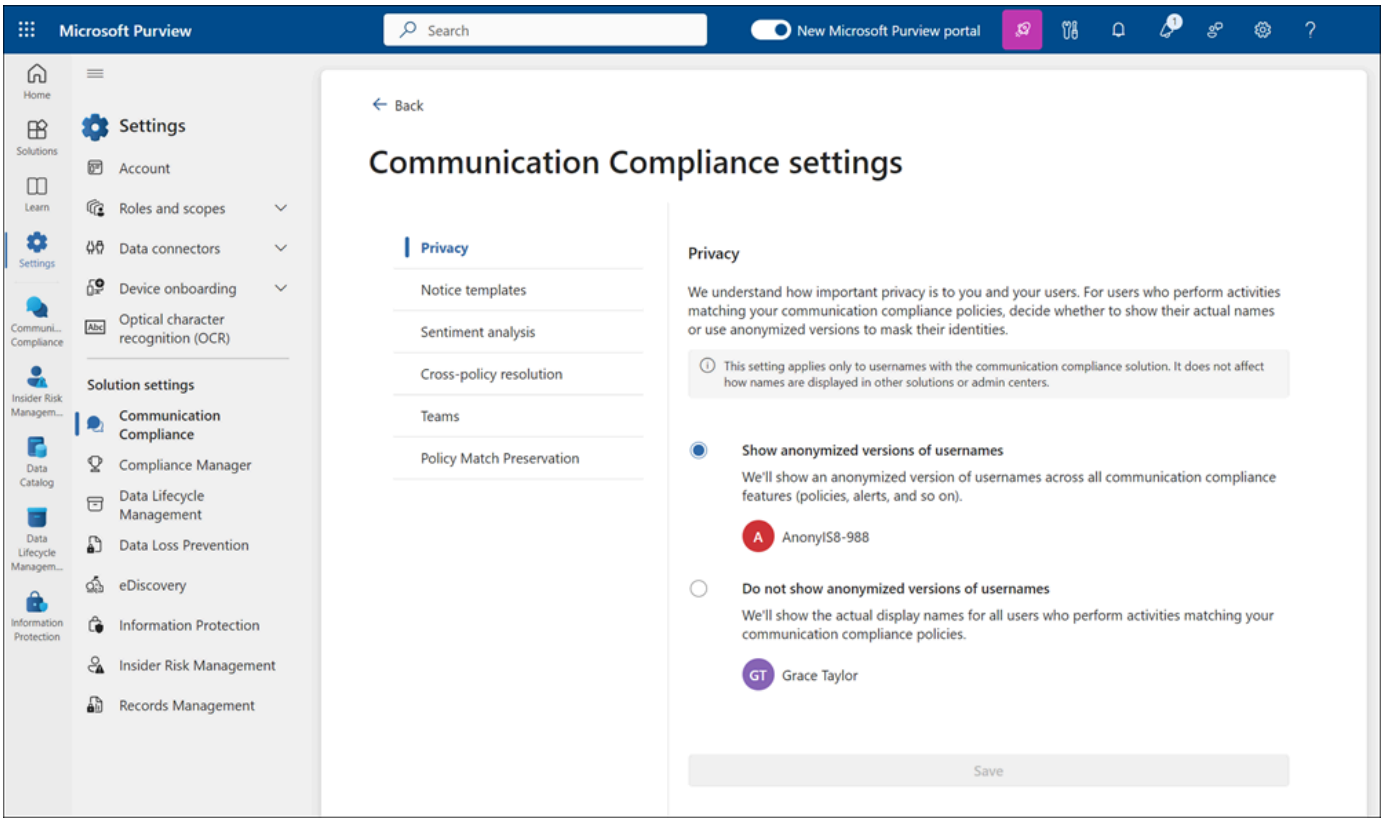
Knowledge Center

The **Knowledge Center** card highlights articles, product demos, tutorials, and other learning materials to help you succeed with Microsoft Purview. Select **Go to the Knowledge Center** to open the **Knowledge Center** page and view all available learning materials. Use the predefined filters to view knowledge center items by solution area, or use the search box to find a specific item by keyword.



New left navigation for solutions

When you select a Microsoft Purview solution in the portal, you see a solution-specific home page and a new left-navigation experience that lets you access all solution features, settings, and more. The new left-navigation displays links to the **Home**, **Solutions**, **Agents**, **Learn**, **Usage center**, and **Settings** pages for quick and easy access to these areas for managing solutions, learning more about Microsoft Purview, configuring solution settings, and more. Additionally, links to the five most recent Microsoft Purview solutions also display for quick access to these solutions.



Settings in the portal

Settings in the Microsoft Purview portal are now centralized in the portal. By selecting the **Settings** icon in the left navigation or at the top-right of the page, you can quickly manage solution and global portal-wide settings, no matter where you are in the portal.

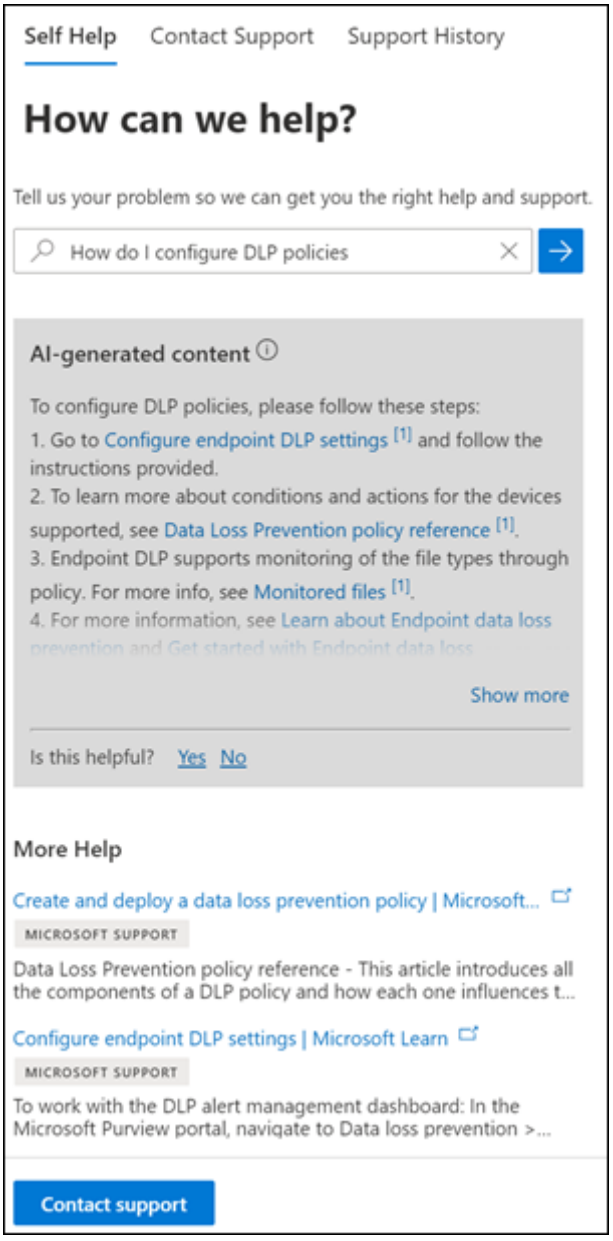
To view and manage portal-wide settings, select options in the **Themes**, **Language and time zone**, **Password**, and **Contact preferences** sections.

To view and manage solution settings, select a solution. This action opens the settings page for the solution where you can update settings for the selected solution. From any solutions settings page, you can also select other Microsoft Purview solutions in the **Solution settings** area in the left navigation to view and update settings in these solutions. To view and manage account settings, select **Account**.

Release notes and updates

View the latest release notes for Microsoft Purview solutions in a centralized location by selecting the **Release notes & updates** icon in the top right command bar. You can view Message center announcements for solutions that give you a high-level overview of a planned update or change and how it might affect your users or organization. Select the associated **Learn more** link to view the announcement and more details on the Message Center.

> **Note**
>
> You must have the `microsoft.office365.messageCenter/messages/read` permission to view release notes in the Microsoft Purview portal. The Message Center Reader, Global Reader, and Global Administrator roles include this permission. If you don't see an expected release note, check with your solution administrator or see What's new in Microsoft Purview.



Help and support

Select the **Help** icon in the upper-right command bar to access specific help and support options for Microsoft Purview solutions:

- **Guided tours**: Start an integrated dialog-driven overview of key features and capabilities in the Microsoft Purview portal.

- **Knowledge Center**: Quickly access the Knowledge Center that contains highlighted articles, product demos, tutorials, and other learning materials to help you succeed with Microsoft Purview.
- **Need help?**: Select specific solution areas for self-help or share what you need help with so the right help and support can be provided.

For solution-specific help and support, select a specific solution in the drop-down field in the **Need help** section and select **Get help**. For example, if you need help with data loss prevention (DLP) policies, select *Data Loss Prevention*, and then select **Get help**. On the **Help** tab, enter the details for your help request.

Depending on your request, you see AI-generated guidance customized for your request and links to articles scoped to your request. If neither of these options helps resolve your questions, select **Contact support** to select email or telephone options to get support from a Microsoft agent.

> **Note**
>
> AI and article suggestions in help and support might not be available for some Microsoft Purview solutions. Check back frequently for updates about upcoming availability for these solutions in help and support.

Submit feedback about the new portal

Select the **Feedback** icon in the upper-right command bar to provide your feedback to Microsoft about the new Microsoft Purview portal. Provide as much detail as you'd like, but don't include any private or sensitive information. After entering your feedback, select **Submit** to send your suggestions to Microsoft to help improve the portal experience.

Get started with data governance solutions

Getting started with data governance solutions in the Microsoft Purview portal depends on your organization's current relationship with Microsoft Purview data governance solutions.

- If your organization didn't create a Microsoft Purview account in the Azure portal, read about the new experience for new customers.
- If your organization has Microsoft Purview accounts in the Azure portal, read about the new experience for existing data governance customers.

New experience for new customers

If your organization doesn't have any Microsoft Purview accounts in any subscriptions under your Microsoft Entra tenant, you can get started with our governance solutions right away. Use the new Microsoft Purview portal to start your journey with the free version of Microsoft Purview.

Free version of Microsoft Purview data governance solutions

If you're new to Microsoft Purview data governance solutions, you can start in the free version of Microsoft Purview. Because the free version has limited capabilities, use it only for initial evaluation, development, and test scenarios. To use the full capabilities of Microsoft Purview data governance, upgrade to the enterprise version.

Only a core subset of Microsoft Purview's governance solutions with limited capabilities are currently available in the free version:

- Catalog: Browse and search for your data assets.
- Data Map history: A log of updates made to assets.

Currently, the free version of Microsoft Purview governance solutions supports these governance data sources using live view:

- Azure Blob Storage
- Azure Data Lake Storage Gen 2
- Azure SQL Database
- Azure subscriptions
- Microsoft Fabric

You can annotate and curate assets that are available via live view, or use our APIs to create new entities.

Check out the guide to getting started with the free version of Microsoft Purview data governance solutions.

Enterprise version

When you upgrade to the enterprise version of Microsoft Purview data governance, you have access to all Microsoft Purview data governance features, including:

- All data sources supported by Microsoft Purview data governance supported governance sources: Manage data sources across your data estate.
- Collections: Manage fine grained access control for users across your environment.
- Scanning: Gather your sources' technical metadata and lineage information.
- Automatic classification: Classify your data to identify important and sensitive information.
- Data owner policies: Govern data at the source from Microsoft Purview.
- All reports: Understand your data estate at a glance.
- Workflows: Automate governance in your environment.

Learn more about data governance in Microsoft Purview.

New experience for existing data governance customers

The new experience enhances the current Microsoft Purview data governance experience. It doesn't affect the information already stored in your accounts or your ability to use the APIs. When you upgrade to the new experience, you automatically get the enterprise version of Microsoft Purview. The enterprise version has all the features you already use, plus these new features:

- This new Microsoft Purview portal: the latest platform to manage your organization's data governance.
- Live view: view your Azure data assets in the Microsoft Purview Unified Catalog automatically and in real time with no need to register or set up a scan for the source.
- Tenant-level administration: roles that give you the ability to delegate administration from the tenant level, while maintaining fine-grained access control options to limit permissions by role and collections. This feature gives your team flexibility when managing access and responsibilities.
- Data Map history: a log of updates made to data assets, so you can audit changes in your Data Map.

For more information about the new experience, see Guide to getting started with data governance in the new Microsoft Purview portal.

Microsoft Purview setup guides

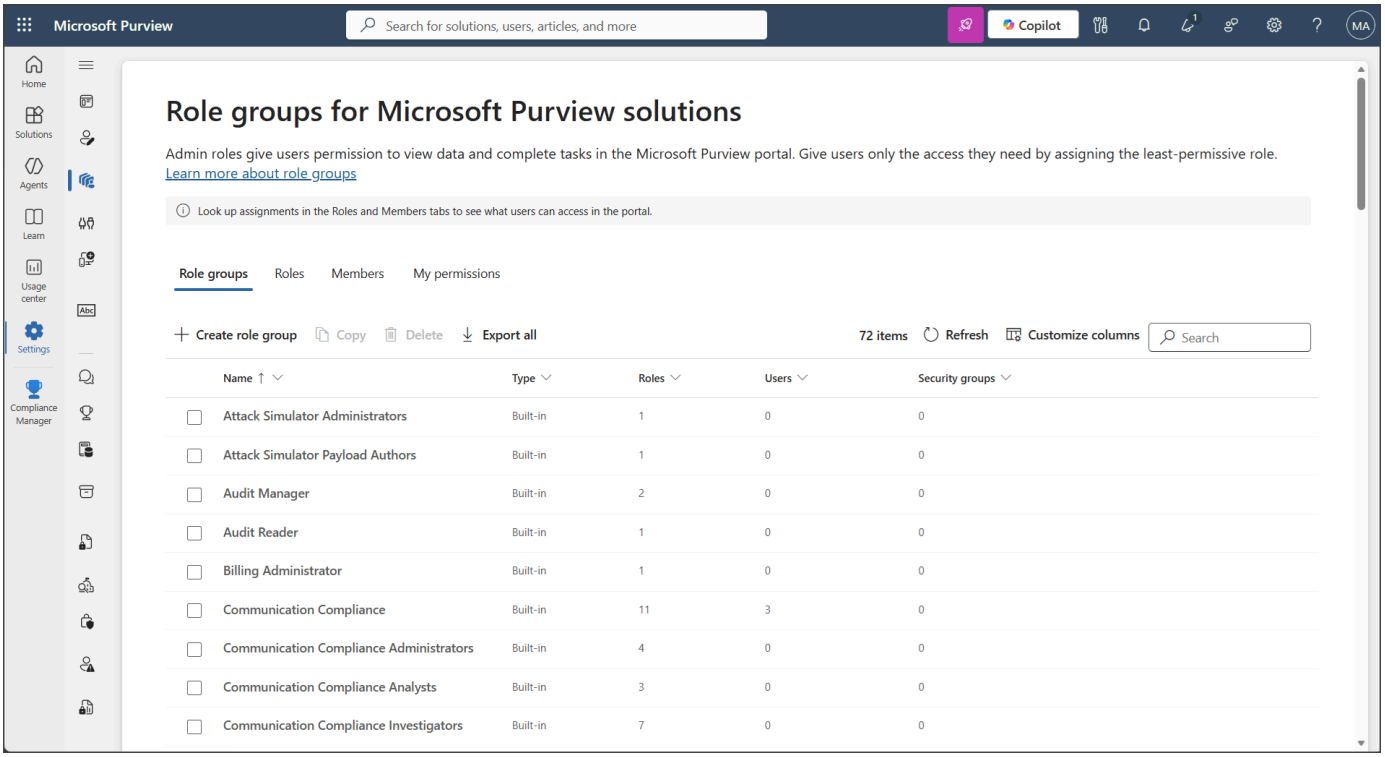
Microsoft Purview setup guides offer a guided experience for planning and deploying data security and compliance solutions in your organization.

These guides organize the basic solution configuration steps and help point you directly to primary guidance for these steps in Microsoft Purview documentation. By using the authenticated experience in the admin center guides, you can also use automation for some solution configuration steps to help you quickly get started with your solution deployment.

Setup guides in the admin center require authentication to Microsoft Purview as an administrator or other role with access to the Microsoft 365 admin center. However, anyone can access the guides in the Microsoft 365 Setup portal.

Setup guides

Expand table



Guide: Setup Portal	Guide: Admin Center	Description
Audit setup guide	Audit setup guide	**Microsoft Purview Auditing Solutions setup guide** provides guidance to enable and configure auditing in Microsoft 365. The guide covers verifying licensing, assigning permissions, enabling Audit (Premium) events, creating audit retention policies, and using the unified audit log to search and review user and admin activities for investigations.
Manage data exfiltration with Purview	Manage data exfiltration with Purview	The **Manage data exfiltration with Microsoft Purview setup guide** provides steps to configure Insider Risk Management policies, link Data Loss Prevention alerts, and enable auditing and labeling features to prevent unauthorized data transfers. The guide highlights built-in tools that streamline permission setup for Microsoft 365 groups, reducing manual steps and improving configuration efficiency.
Secure by default with Purview	Secure by default with Purview	The **Secure by default with Microsoft Purview setup guide** provides guidance to enable default security configurations and apply encryption and sensitivity labels automatically across Microsoft 365. The guide covers publishing default labels, configuring auto-labeling for Office apps, setting contextual defaults for SharePoint and Microsoft Teams, and enabling built-in labeling for Office for the web to achieve broad coverage with minimal user interaction.

Last updated on 04/01/2026

Permissions in the Microsoft Purview portal

The Microsoft Purview portal supports direct management of permissions for users who perform tasks within Microsoft Purview. By using the **Roles and scopes** area in **Settings** for the portal, you can manage permissions for users across your Purview data security, data governance, and risk and compliance solutions. You can limit users to perform only specific tasks that you explicitly grant them access to.

> **Important**
>
> To view **Role groups** in the **Roles and scopes** area in the Microsoft Purview portal, users need to be a global administrator or need to be assigned the *Role Management* role (assigned only to the *Organization Management* role group). The *Role Management* role allows users to view, create, and modify role groups.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. When planning your access control strategy, follow the best practice to manage access with the least privilege for your users.

Microsoft Purview permissions

The Microsoft Purview portal uses the role-based access control (RBAC) permissions model. Most Microsoft 365 services use RBAC, so if you're familiar with the permission structure in these services, granting permissions in the Microsoft Purview portal is similar. The permissions you manage in the Microsoft Purview portal don't cover the management of all the permissions needed in each individual service. You still need to manage certain service-specific permissions in the admin center for the specific service. For example, if you need to assign permissions for archiving, auditing, and MRM retention policies, you need to manage these permissions in the Exchange admin center.

Solution-specific permissions

For specific Microsoft Purview solution permission guidance, see the following articles:

Data security

- Data Loss Prevention
- Data Security Investigations
- Data Security Posture Management

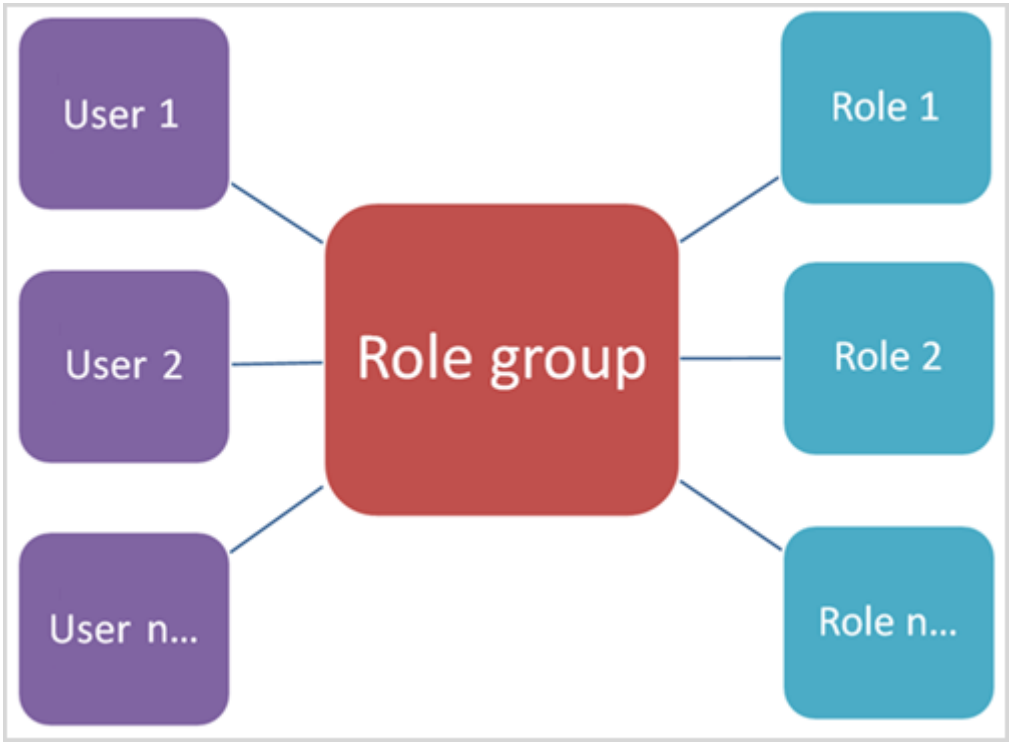
- Privileged Access Management

AI and Copilot

- Data Security Posture Management for AI
- Security Copilot for Purview
- Triage Agent in Data Loss Prevention
- Triage Agent in Insider Risk Management

To view all of the default role groups that are available in the Microsoft Purview portal and the roles that are assigned to the role groups by default, see Roles and role groups in the Microsoft Defender XDR and Microsoft Purview portals.



Managing permissions in the Microsoft Purview portal only gives users access to the compliance and governance features that are available within the Microsoft Purview portal. To grant permissions to other features that aren't in the Microsoft Purview portal, such as Exchange mail flow rules (also known as transport rules), use the Exchange admin center.

The current governance roles and role groups cover only broad access to the Microsoft Purview Data Map and Unified Catalog. For more access, Microsoft Purview governance uses a combination of role groups, data access, and solution-specific permissions.

Relationship of members, roles, and role groups

A role grants permissions to perform a set of tasks. For example, the *Case Management* role lets users work with eDiscovery cases.

A role group is a set of roles that enable users to do their jobs across compliance and governance solutions in the Microsoft Purview portal. For example, by adding users to the *Insider Risk Management* role group, designated administrators, analysts, investigators, and auditors get the necessary insider risk management permissions in a single group. The Microsoft Purview portal includes default role groups for tasks and functions for each compliance and governance solution that you need to assign people to. Generally, add individual users as members to the default role groups as needed.

Microsoft Entra roles in the Microsoft Purview portal

The roles that appear in the Microsoft Entra ID section of the **Roles and scopes** area are Microsoft Entra roles, and global administrators can see this section. These roles align with job functions in your organization's IT group, making it easy to give a person all the permissions necessary to get their job done. You can view the users currently assigned to each role by selecting an admin role and viewing the role panel details. To manage members of a Microsoft Entra role, select **Manage members** in Microsoft Entra ID. This choice redirects you to the Azure management portal.

For more information about Microsoft Entra roles, see Microsoft Entra built-in roles.

Expand table

Entra role	Description	Mapped Purview role groups
AI Administrator	Manage all aspects of Microsoft 365 Copilot and AI-related enterprise services in Microsoft 365. For more information, see AI Administrator.	Compliance Manager Administrators Data Security AI Admins Data Security AI Viewers

Entra role	Description	Mapped Purview role groups
Attack Payload Author	Create attack payloads but not actually launch or schedule them. For more information, see Attack Payload Author.	Attack Simulator Payload Authors
Attack Simulation Administrator	Create and manage all aspects of attack simulation creation, launch/scheduling of a simulation, and the review of simulation results. For more information, see Attack Simulation Administrator.	Attack Simulator Administrators
Compliance Administrator	Help your organization stay compliant with any regulatory requirements, manage eDiscovery cases, and maintain data governance policies across Microsoft 365 locations, identities, and apps. For more information, see Compliance Administrator.	Compliance Administrator
Compliance Data Administrator	Keep track of your organization's data across Microsoft 365, make sure it's protected, and get insights into any issues to help mitigate risks. For more information, see Compliance Data Administrator.	Compliance Data Administrator
Global Administrator	Access to all administrative features in all Microsoft 365 services. Only global administrators can assign other administrator roles. For more information, see Global Administrator / Company Administrator.	Data Catalog Curators Data Estate Insights Readers Organization Management Purview Administrators
Global Reader	The read-only version of the **Global administrator** role. View all settings and administrative information across Microsoft 365. For more information, see Global Reader.	Global Reader
Security Administrator	Control your organization's overall security by managing security policies, reviewing security analytics and reports across Microsoft 365 products, and staying up-to-speed on the threat landscape. For more information, see Security Administrator.	Security Administrator
Security Operator	View, investigate, and respond to active threats to your Microsoft 365 users, devices, and content. For more information, see Security Operator.	Security Operator
Security Reader	View and investigate active threats to your Microsoft 365 users, devices, and content, but (unlike the Security operator) they don't have permissions to respond by taking action. For more information, see Security Reader.	Security Reader

For more information about other Entra roles and user assignment synchronization from Purview for authorizing long-running operations, see the Purview Role Assignment Migrator.

Privileged Identity Management for Groups in the Microsoft Purview portal

Microsoft Entra Privileged Identity Management (PIM) for Groups provides user eligibility for just-in-time membership to groups assigned to Microsoft Entra roles. By using PIM for Groups, you can assign Microsoft Entra security groups to Microsoft Purview role groups in the Microsoft Purview portal. This assignment allows users to activate just-in-time access and then perform tasks in the Microsoft Purview portal. Unlike Microsoft Entra role assignments with Privileged Identity Management (PIM) in Microsoft Entra ID, you can't manage just-in-time activations by using direct user assignments to role groups in the Microsoft Purview portal.

Role precedence and scope behavior

If you assign both an Entra role and a scoped Microsoft Purview role group assignment to a user or group (for example, a role group scoped to an Administrative Unit), the Entra role takes precedence at runtime. As a result, the user's effective permissions are unscoped, even if a scoped Microsoft Purview role group assignment also exists.

- **Example 1**: If you assign the *Compliance Administrator* role in Entra to a user and also assign a scoped *Compliance Administrator* role in Microsoft Purview, the Entra role overrides the scoped assignment. The user's effective access is *unscoped*, and they can access all entities available to that role without Administrative Unit scoping.
- **Example 2**: If you assign the *Global Reader* role in Entra to a user and assign a scoped *DLP Compliance Management* role in Microsoft Purview, any features or APIs that overlap between these roles grant the user *unscoped access* to the corresponding data.
- **Example 3**: When both scoped Microsoft Purview role assignments and Entra roles are present, Entra roles always take precedence, and scoping applied through Administrative Units doesn't restrict the user's effective permissions for overlapping capabilities.

Temporary permissions

You can assign role groups and grant temporary access that automatically revokes permissions when they're no longer needed. Automatically expiring permissions let administrators assign an expiration date to Microsoft Purview role group assignments. When the configured expiration date is reached, the assignment is automatically removed and access is revoked without requiring

manual action from an administrator. Actions that are already completed or in progress aren't affected, but any new operation is denied after the assignment expires. This approach helps organizations implement least-privilege access by reducing long-term access that's no longer needed.

Automatic expiring permissions are optional and are configured on a per-user assignment basis. Administrators can create temporary assignments with an expiration date, update an existing expiration date, extend an assignment, or remove the expiration to make the assignment permanent. A minimum expiration period of one day and maximum expiration period of two years can be selected from the current date in the local time zone of the administrator who sets the expiration.

Role group assignments are evaluated independently. If a user receives the same role group through both an individual assignment and a security group assignment, each assignment retains its own expiration date. Access remains active as long as one of the assignments is still valid. Assigning a role group to a security group also means changes to that group's membership update any added users with the expiration date associated with the assigned role group. The **My Permissions** page displays the latest expiration date across active assignments. The expiration date is recorded as part of the audit logs for Microsoft Purview permissions when the date is added or updated by the admin. You don't receive a notification before permissions expire, nor are any additional audit logs are generated when a user's temporary permissions expires.

> ⓘ **Important**
>
> All built-in and custom role groups except the following support automatic expiring permissions:
>
> - eDiscovery Administrator
> - eDiscovery Manager

Manage role groups

The following sections describe how to add, remove, create, update, and delete role groups in the Microsoft Purview portal.

Add users or groups to a Microsoft Purview built-in role group

Complete the following steps to add users or groups to a Microsoft Purview role group:

1. Sign in to the Microsoft Purview portal by using credentials for an admin account assigned the *Role management* role. Go to **Settings** > **Roles and scopes** to view and manage compliance and governance roles in your organization.
2. Select **Role groups**.
3. On **Role groups for Microsoft Purview solutions**, select a Microsoft Purview role group you want to add users to. Select **Edit** on the control bar.
4. On **Edit members of the role group**, select **Choose users** or **Choose groups**.

   > **Important**
   >
   > Security groups are supported only in Microsoft 365 commercial cloud organizations.

5. Select the check box for all users or groups you want to add to the role group.
6. Select **Select**.
7. If the selected users or groups need organization-wide access as part of this role group assignment, go to step 11.
8. If the selected users or groups need temporary access, select the users or groups and select **Edit expiration**.
9. If the selected users or groups need to be assigned to administrative units, select the users or groups and select **Assign admin units**.
10. On **Assign admin units**, select the check box for all the administrative units you want to assign to the users or groups. Select **Select**.
11. Select **Next** and **Save** to add the users or groups to the role group. Select **Done** to complete the steps.

Remove users or groups from a Microsoft Purview built-in role group

To remove users or groups from a Microsoft Purview role group, complete the following steps:

1. Sign in to the Microsoft Purview portal by using credentials for an admin account assigned the *Role management* role. Go to **Settings** > **Roles and scopes** to view and manage compliance and governance roles in your organization.

2. Select **Role groups**.
3. On **Role groups for Microsoft Purview solutions**, select a Microsoft Purview role group that you want to remove users or groups from. Select **Edit** on the control bar.
4. On **Edit members of the role group**, select the check box for all users or groups you want to remove from the role group.
5. Select **Remove members**, and then select **Next**.
6. Select **Save** to remove the users or groups from the role group. Select **Done** to complete the steps.

Create a custom Microsoft Purview role group

Complete the following steps to create a custom Microsoft Purview role group:

1. Sign in to the Microsoft Purview portal by using credentials for an admin account assigned the *Role management* role. Go to **Settings** > **Roles and scopes** to view and manage compliance and governance roles in your organization.

2. Select **Role groups**.

3. On **Role groups for Microsoft Purview solutions**, select **Create role group**.

4. On **Name the role group**, enter a name for the custom role group in the **Name** field. You can't change the name of the role group after you create it. If needed, enter a description for the custom role group in the **Description** field. Select **Next** to continue.

5. On **Add roles to the role group**, select **Choose roles**.

6. Select the checkboxes for the roles to add to the custom role group. Select **Select**.

7. Select **Next** to continue.

8. On **Add members to the role group**, select **Choose users** (or **Choose groups** if applicable).

   > **Important**
   >
   > Security groups are supported only in Microsoft 365 commercial cloud organizations.

9. Select the checkboxes for the users (or groups) to add to the custom role group. Select **Select**.

10. Select **Next** to continue.

11. If the selected users or groups need organization-wide access as part of this role group assignment, go to step 15.

12. If the selected users or groups need temporary access, select the users or groups and select **Edit expiration**.

13. If the selected users or groups need to be assigned to administrative units, select the users or groups and select **Assign admin units**.

14. On **Assign admin units**, select the check box for all the administrative units you want to assign to the users or groups. Select **Select**.

15. Select **Next**.

16. On **Review the role group and finish**, review the details for the custom role group. If you need to edit the information, select **Edit** in the appropriate section. When all the settings are correct, select **Create** to create the custom role group or select **Cancel** to discard the changes and not create the custom role group.

Update a custom Microsoft Purview role group

Complete the following steps to update a custom Microsoft Purview role group:

1. Sign in to the Microsoft Purview portal by using credentials for an admin account assigned the *Role management* role. Go to **Settings** > **Roles and scopes** to view and manage compliance and governance roles in your organization.
2. Select **Role groups**.
3. On **Role groups for Microsoft Purview solutions**, select a Microsoft Purview role group you want to update, and then select **Edit** on the control bar.
4. On **Name the role group**, update the description for the custom role group in the **Description** field. You can't change the name of the custom role group. Select **Next**.
5. On **Edit roles of the role group**, select **Choose roles** to add roles to update the roles assigned to the role group. You can also select any of the currently assigned roles and select **Remove roles** to remove the roles from the role group. After you update the roles, select **Next**.
6. On **Edit members of the role group**, select **Choose users** or **Choose groups** to add users or groups assigned to the role group.
   a. To change the expiration for the selected users or groups, select any of the currently assigned user or groups and select **Edit expiration**.

b. To update the administrative units for users or groups, select any of the currently assigned user or groups and select **Assign admin units**. You can also select any of the currently assigned users and groups and select **Remove members** to remove the users or groups from the role group. After you update the members, select **Next**.

7. On **Review the role group and finish**, review the details for the custom role group. If you need to edit the information, select **Edit** in the appropriate section. When all the settings are correct, select **Save** to update the custom role group or select **Cancel** to discard the changes and not update the custom role group.

Delete a custom Microsoft Purview role group

Complete the following steps to delete a custom Microsoft Purview role group:

1. Sign in to the Microsoft Purview portal by using credentials for an admin account assigned the *Role management* role. Go to **Settings** > **Roles and scopes** to view and manage compliance and governance roles in your organization.
2. Select **Role groups**.
3. On **Role groups for Microsoft Purview solutions**, select a Microsoft Purview role group you want to delete, then select **Delete** on the control bar.
4. On **Delete role group**, select **Delete** to delete the role group or select **Cancel** to cancel the deletion process.

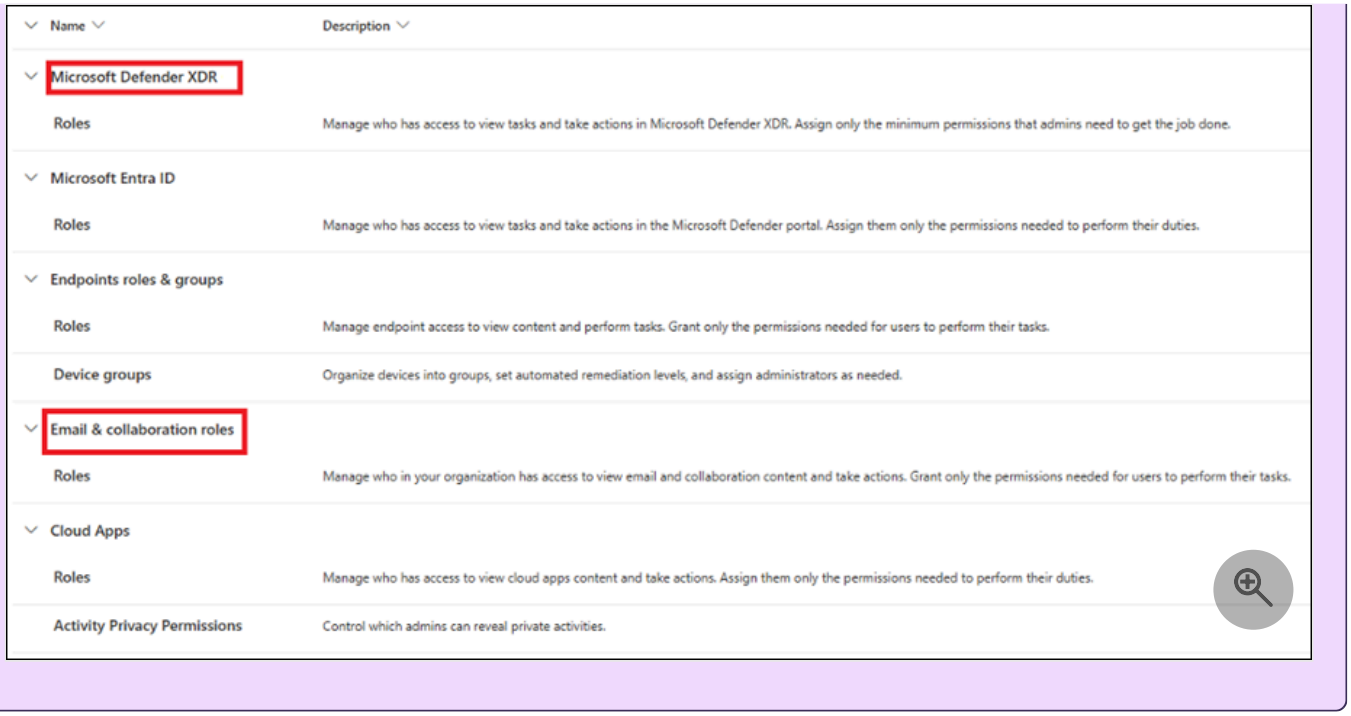
Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview



> **Tip**
>
> *Did you know you can try the features in Microsoft Defender for Office 365 Plan 2 for free?* Use the 90-day Defender for Office 365 trial at the Microsoft Defender portal trials hub. Learn about who can sign up and trial terms on Try Microsoft Defender for Office 365.

This article lists the default roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

Permissions in these products are based on role-based access control (RBAC). Users need to be a global admin or a member of one or more role groups to access the Microsoft Defender portal or Microsoft Purview portals. RBAC is the same permissions model that's used by Exchange Online, but role groups in Exchange Online don't share membership or permissions with role groups in Defender for Office 365 or Purview.

The Security Dashboard for AI at `ai.security.microsoft.com` is also available to eligible tenants and provides a unified, real-time view of AI-related risk signals from Microsoft Defender, Microsoft Entra, and Microsoft Purview.

> **Note**
>
> Microsoft Defender unified role-based access control (Unified RBAC) is a separate permissions model that's also available. It's also the recommended permission model for Microsoft Defender for Office 365 Plan 2, and it's the default for new Defender for Office 365 Plan 2 organizations starting July 2026. The permissions in this RBAC model are different from the Defender for Office 365 permissions as described in this article. For more information, see Microsoft Defender XDR role-based access control (RBAC).
>
> **If you activate Defender XDR RBAC for Email & collaboration, the permissions page at https://security.microsoft.com/emailandcollabpermissions is no longer available in the Defender portal, so you need to ensure that you configure or import your roles *before* you activate Defender unified RBAC.**

For more information about permissions, see the following articles:

- Email & collaboration permissions in the Microsoft Defender portal
- Microsoft Defender unified role-based access control (RBAC)
- Permissions in the Microsoft Purview portal
- Permissions in Microsoft Purview solutions
- Permissions in the Microsoft Purview governance portal

Role groups in Microsoft Defender for Office 365 and Microsoft Purview

The table in this section lists the default role groups that are available in the Microsoft Defender portal and the Microsoft Purview portals, and the roles that are assigned to the role groups by default. To grant permissions to a user to perform tasks in Defender for Office 365 or Microsoft Purview, add them to the appropriate role group.

Managing permissions in Defender for Office 365 or Microsoft Purview gives users access to security and compliance and governance features that are available within their respective portals. To grant permissions to other features, such as Exchange mail flow rules (also known as transport rules), you need to grant permissions in Exchange Online. For more information, see Permissions in Exchange Online.

> ⓘ **Note**

To view the **Permissions** tab as described in this article, you need to be an admin. Specifically, you need to be assigned the **Role Management** role, and that role is assigned only to the **Organization Management** and **Purview Administrators** role groups by default. The **Role Management** role also allows you to view, create, and modify role groups.

Insider Risk Management Session Approvers	For internal approval use only.	Insider Risk Management Sessions
IRM Contributors	This role group is visible, but is used by background services only.	Insider Risk Management Permanent contribution Insider Risk Management Temporary contribution
Knowledge Administrators	Configure knowledge, learning, assign trainings and other intelligent features.	Knowledge Admin
MailFlow Administrator	Members can monitor and view mail flow insights and reports in the Defender portal. Global admins can add ordinary users to this group, but, if the user isn't a member of the Exchange Admin group, the user doesn't have access to Exchange admin-related tasks.	Exchange Administrator View-Only Recipients

Role group	Description	Default roles assigned
Organization Management[1]	Members can control permissions for accessing features in these portals, and also manage settings for device management, data loss prevention, reports, and preservation. Users who aren't global administrators must be Exchange administrators to see and take action on devices that are managed by Basic Mobility and Security for Microsoft 365 (formerly known as Mobile Device Management or MDM). Global admins are automatically added as members of this role group, but you don't see them in the output of the Get-RoleGroupMember cmdlet in Security & Compliance PowerShell. **Important**: Microsoft strongly advocates for the principle of least privilege. Assigning accounts only the minimum permissions necessary to perform their tasks helps reduce security risks and strengthens your organization's overall protection. Global Administrator is a highly privileged role that you should limit to emergency scenarios or when you can't use a different role. Quarantine Administrator	Members can access all Quarantine actions. For more information, see Manage quarantined messages and files as an admin	Quarantine
Records Management	Members can configure all aspects of records management, including retention labels and disposition reviews.	Disposition Management RecordManagement

Role group	Description	Default roles assigned
		Retention Management Scope Manager
Reviewer	Members can access review sets in eDiscovery (Premium) cases. Members of this role group can see and open the list of cases on the **eDiscovery** > **Advanced** page in the Microsoft Purview portal that they're members of. After the user accesses an eDiscovery (Premium) case, they can select **Review sets** to access case data. This role doesn't allow the user to preview the results of a collection search that's associated with the case or do other search or case management tasks. Members of this role group can only access the data in a review set.	Review
Security Administrator	Members have access to many security features of Identity Protection Center, Privileged Identity Management, Monitor Microsoft 365 Service Health, and the Defender and compliance portals. By default, this role group may not appear to have any members. However, the Security Administrator role from Microsoft Entra ID is assigned to this role group. Therefore, this role group inherits the capabilities and membership of the Security Administrator role from Microsoft Entra ID. To manage permissions centrally, add and remove group members in the Microsoft Entra admin center. For more information, see Microsoft Entra built-in roles. If you edit this role group in these portals (membership or roles), those changes apply only to the security and compliance areas and not to any other services. This role group includes all of the read-only permissions of the Security reader role, plus many additional administrative permissions for the same services: Azure Information Protection, Identity Protection Center, Privileged Identity Management, Monitor Microsoft 365 Service Health, and the Defender and compliance portals. Compliance Manager Reader Security Reader Sensitivity Label Reader Tag Reader View-Only Device Management View-Only DLP Compliance Management View-Only IB Compliance Management View-Only Manage Alerts
Service Assurance User	Members can access the Service assurance section in the Microsoft Purview portal. Service assurance provides reports and documents that describe Microsoft's security practices for customer data that's stored in Microsoft 365. It also provides independent non-Microsoft audit reports on Microsoft 365. For more information, see Service assurance in the Microsoft Purview portal.	Service Assurance View
Subject Rights Request Administrators	Create subject rights requests.	Case Management Compliance Manager Contribution Compliance Manager Reader Compliance Search

Role group	Description	Default roles assigned
		Custodian Export Manage Review Set Tags Preview Review Subject Rights Request Admin View-Only Case
Subject Rights Request Approvers	Approvers who are able to approve subject rights requests.	Compliance Manager Reader Compliance Search Custodian Export Manage Review Set Tags Preview Review Subject Rights Request Approver
Supervisory Review	Members can create and manage the policies that define which communications are subject to review in an organization. For more information, see Configure communication compliance policies for your organization.	Supervisory Review Administrator

Note

[1] This role group doesn't assign members the permissions necessary to search the audit log or to use any reports that might include Exchange data, such as the DLP or Defender for Office 365 reports. To search the audit log or to view all reports, a user has to be assigned permissions in Exchange Online. This action is required because the underlying cmdlet that's

used to search the audit log is an Exchange Online cmdlet. Global admins can search the audit log and view all reports because they're automatically added as members of the Organization Management role group in Exchange Online. For more information, see Search the audit log in the Microsoft Purview portal.

> **Note**
>
> [2] This role or role group is in preview. While it may be visible in commercial Microsoft 365 tenants, it is not supported and has no operational effect outside the M365 ABAC private preview. At this time, support is planned only for Microsoft U.S. government cloud environments (GCC High and DoD, see Understand Microsoft U.S. government cloud environments for Microsoft 365 and Microsoft Copilot).

Roles in Microsoft Defender for Office 365 and Microsoft Purview

The table in this section lists the available roles and the role groups that they're assigned to by default.

Roles that aren't assigned to the Organization Management role group by default are marked with *

Expand table

Role	Description	Default role group assignments
Admin Unit Extension Manager	Assigns permissions to use AUE.	Compliance Administrator Organization Management Purview Administrators
***AI Administrator**	In addition to the capabilities listed for this role in Microsoft Entra built-in roles, use this role for read-only access to all pages in Data Security Posture Management for AI (classic) and for read-only access to AI-related data in the preview version of Data Security Posture	AI Administrators

Role	Description	Default role group assignments
	Management. This role does not have access to read prompts and responses of AI interactions.	
*Attack Simulator Admin	Don't use this role. Use the Attack Simulation Administrator role in Microsoft Entra ID.	Attack Simulator Administrators
*Attack Simulator Payload Author	Don't use this role in the portals. Use the corresponding role in Microsoft Entra ID.	Attack Simulator Payload Authors
Audit Logs	Turn on and configure auditing for the organization, view the organization's audit reports, and then export these reports to a file.	Audit Manager Organization Management Security Administrator
*Billing Admin	Allows billing admin for selected feature.	Billing Administrator
Case Management	Create, edit, delete, and control access to eDiscovery cases.	Communication Compliance Communication Compliance Investigators Compliance Administrator Data Security Management eDiscovery Manager Insider Risk Management Insider Risk Management Admins Insider Risk Management Analysts Insider Risk

Purview Role Assignment Migrator

The **Microsoft Purview Role Assignment Migrator** is a Microsoft first-party enterprise application in Microsoft Entra ID that runs the background synchronization *from* Microsoft Purview role assignments *to* corresponding Entra roles. Microsoft 365 services use these Entra roles to verify that the administrator has the correct level of permissions before allowing long-running Microsoft Purview operations, such as content search and export, to proceed.

Role mapping

The following table shows which Purview roles map to each of the following Entra roles. These Entra roles only grant the ability to run Purview operations, and no other operations outside Purview are granted.

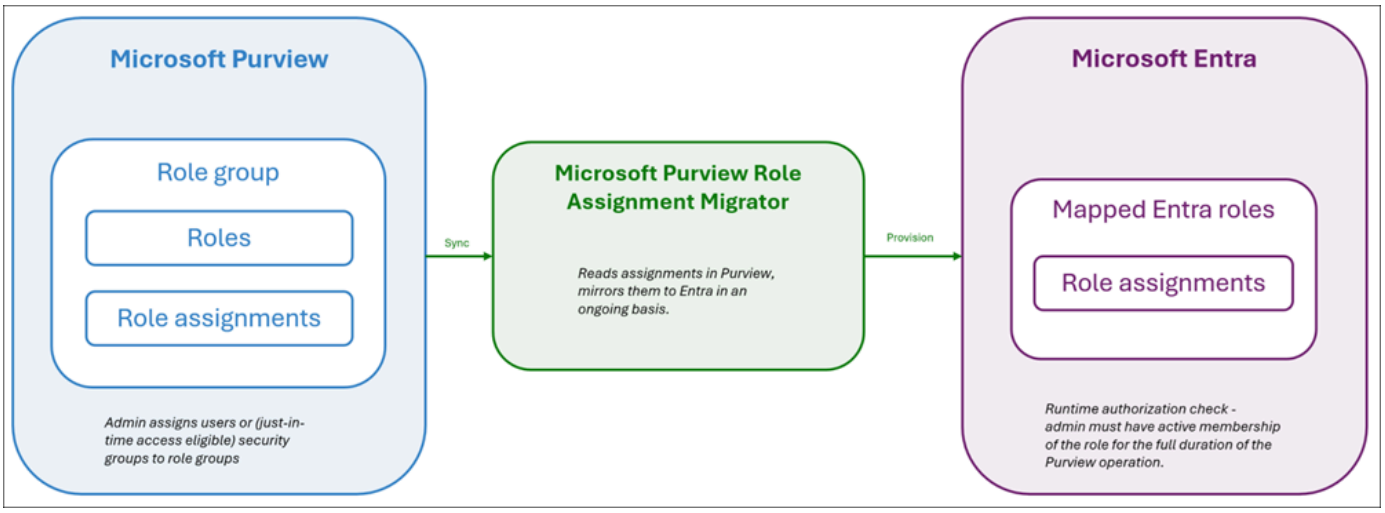
Expand table

Purview roles	Mapped Entra role	Description
Insider Risk Management Analysis Insider Risk Management Investigation Compliance Search Export Privacy Management Admin Privacy Management Analysis Privacy Management Investigation Privacy Management Permanent Contribution Privacy Management	Purview Workload Content Reader	Allows Microsoft Purview operations to read content from Microsoft 365 services (for example, read a file in SharePoint).

Purview roles	Mapped Entra role	Description
Temporary Contribution Privacy Management Viewer Data Security Investigation Reviewer		
Hold Privacy Management Investigation Data Security Investigation Investigator	Purview Workload Content Writer	Allows Microsoft Purview operations to read and write content to Microsoft 365 services (for example, store mail items in Exchange).
Search and Purge Data Security Investigation Admin Data Security Investigation Analyst	Purview Workload Content Administrator	Allows Microsoft Purview operations to read, write, and delete content in Microsoft 365 services (for example, purge messages in Microsoft Teams).

If an administrator holds multiple Purview roles that map to different Entra roles, they receive the highest-privilege Entra role. The precedence order is: **Administrator** > **Writer** > **Reader**.

> ⓘ **Note**
>
> The Purview Role Assignment Migrator manages the Purview Workload Content Reader, Purview Workload Content Writer, and Purview Workload Content Administrator Entra roles, and only the listed Purview roles synchronize to Entra. Don't assign the Entra roles in the Entra portal. These roles don't appear in the Microsoft Purview portal like the ones that are shown on the settings page.



Synchronization audit logs

The Purview Role Assignment Migrator works in two modes:

- **Initial bulk sync:** When the Purview Role Assignment Migrator first activates for your tenant, it syncs all existing Purview role assignments to Microsoft Entra in a single pass. This process

generates a burst of activity in your Microsoft Entra audit logs.

- **Continuous sync:** All subsequent changes to Purview role memberships trigger synchronization to Microsoft Entra.

> **Important**
>
> Keep the Purview Role Assignment Migrator enterprise application enabled in Microsoft Entra ID. The application ID is `7fe3d988-4f3b-4f33-83bd-1fb921a35ed2`. Disabling this app stops synchronization. New Purview role assignments don't propagate to Microsoft Entra, and long-running Purview operations fail authorization checks at runtime.

The Purview Role Assignment Migrator synchronization activity appears in Microsoft Entra audit logs with the display name **PurviewRoleAssignmentMigrator**. The **New Value** field for each log entry shows the Microsoft Entra role that was assigned.

You see two distinct patterns of activity:

Expand table

Activity pattern	When it occurs	Volume
Bulk sync	Once, when the Purview Role Assignment Migrator first activates for your tenant	High — all existing Purview role assignments sync at once
Continuous sync	Ongoing, after each change to a Purview role membership	Low — proportional to the rate of Purview role changes in your tenant

If you see a sudden spike of `PurviewRoleAssignmentMigrator` entries in your Microsoft Entra audit logs, this spike in audit log entries comes from the initial bulk sync and isn't a sign of

unauthorized activity.

> **Important**
>
> Don't assign users to these Microsoft Entra roles directly in Microsoft Entra ID. The Purview Role Assignment Migrator manages these assignments exclusively from Purview and it overwrites any manual assignments in Microsoft Entra at the next synchronization.

Just-in-time access

By default, the Purview Role Assignment Migrator synchronizes the role assignments to the Microsoft Entra roles as **active (permanent)** assignments. Microsoft Entra Privileged Identity Management (PIM) for Groups allows eligible users to activate just-in-time membership to groups. When you add these Microsoft Entra **security groups** with eligible assignments to Purview roles, the Purview Role Assignment Migrator synchronizes that same security group membership into the corresponding Microsoft Entra roles. This process allows organizations that require role assignments to be just-in-time in Microsoft Entra to apply the same model for Microsoft Purview and enforce role activation.

> **Important**
>
> Size your just-in-time membership activation window on the security group to cover the full duration of your operations. If an activation expires while a long-running operation is still running, the operation might fail at its next runtime authorization check. For example, to identify how long your eDiscovery operations typically take, use **Process Manager in eDiscovery** and set activation durations accordingly.

Learn about Microsoft Purview billing models

Microsoft Purview offers a set of integrated solutions that help customers secure and govern their data. It's composed of data security and data governance solutions for:

- Microsoft 365 and non-Microsoft 365 workloads and data systems.
- Microsoft 365 and non-Microsoft 365 endpoints.
- Compliance solutions for data used with Generative AI applications.

Microsoft Purview supports two complementary billing models to support this diverse environment:

- Per-user license for Microsoft 365 and Windows/macOS endpoint sources
- Pay-as-you-go model for non-Microsoft 365 data sources and certain other capabilities

This article takes you through:

- An overview of the two billing models.
- Links to information on the solution specific capabilities.

> **Note**
>
> The pay-as-you-go billing model builds on the per-user licensing model. The two are complementary, not mutually exclusive.

Per-user licensing model

The per-user licensing model is the familiar Microsoft 365 E3/E5/A5/F5/G5 model. It remains unchanged. This licensing model enables you to apply Microsoft Purview controls and protections to Microsoft 365 and Windows/macOS endpoint-based assets. It's described in the Microsoft Purview service description.

Pay-as-you-go billing model

The pay-as-you-go billing model is a consumption billing model. It extends Microsoft Purview data security, data governance, and data risk and compliance protection capabilities beyond Microsoft 365 and Windows/macOS environments to non-Microsoft 365 locations. The billing mechanisms are Azure based, so you must associate your Microsoft 365 tenant with an active

Azure subscription. It also protects data moving through networks, DataOps, application architectures, and AI apps and agents, as well as certain other user-agnostic capabilities.

In the pay-as-you-go model, you're charged based on your usage of various pay-as-you-go features, based on the unit of consumption for the feature. An Azure bill is generated at the end of the month for the total number of pay-as-you-go charges across all Microsoft solutions.

> **Note**
>
> For guidance on how to associate a Microsoft 365 tenant to an Azure subscription, see Enable Microsoft Purview pay-as-you-go features for new customers.

Capabilities that use the pay-as-you-go billing model

> **Note**
>
> Some Microsoft Purview solutions use the per-user licensing model. Some require the per-user licensing model to be enabled before you can use the pay-as-you-go billing model. Some are pay-as-you-go only and don't require a per-user license.

Data Security and Data Governance

The pay-as-you-go billing model extends Microsoft Purview data security and governance capabilities beyond Microsoft 365 and Windows/macOS to environments like:

- Amazon Web Services (AWS)
- Azure ADLS
- Azure SQL
- Box
- Dropbox
- Google Drive
- Microsoft Fabric

For details on data governance assets, see Microsoft Purview data governance billing.

Data security capabilities

Expand table

Solution	Applies to	Unit of Measure	Details
Data Security Investigations	Data storage meter based on the storage associated each investigation	Number of gigabytes of stored data for all investigations/month Number of Security Compute units consumed	Learn more about billing for Data Security Investigations
Information Protection	Sensitivity labels that you apply to non-Microsoft 365 data sources	Number of assets in scope of protection policy/day	Refer to details below on how assets are defined and calculated
Insider Risk Management	Detect risky behavior for non-Microsoft 365 locations when using Cloud and generative AI policy indicators	Data Security processing unit as measured on a daily basis	Learn more about Insider Risk Management policy indicators

Data governance capabilities

Expand table

Solution	Applies	Unit of Measure	Details
Unified Catalog data curation	Applies when you actively curate and manage the technical assets in Microsoft Purview Unified Catalog	Number of unique assets governed/day	Learn more about data governance billing
Unified Catalog data health management	Applies when you manage data quality and take health management actions	Number of data governance processing units (DGPUs) consumed	Learn more about data governance billing

Data governance processing units: For more information on data governance processing units, see Data governance processing units explained.

Data risk and compliance capabilities

For generative AI apps and agents, Microsoft Purview offers the following capabilities on a pay-as-you-go billing model. Microsoft 365 Copilot experiences aren't charged.

Expand table

Solution	Applies to	Unit of Measure	Details
Audit solutions	Audit logs for user interactions with non-Microsoft generative AI applications	Number of audit records processed	Learn more about generative AI applications supported by Audit solutions.
Communication compliance	Detect inappropriate or risky interactions for non-Microsoft 365 AI interactions when using AI policy indicators	Number of text records scanned	Billing meters for communication compliance are broken down into two categories, standard, and premium. Learn more about the channels and generative AI applications supported by Communication Compliance
Data Lifecycle Management	Retention policies for AI interactions	Number of non-Microsoft 365 Copilot or AI App interactions (prompts and responses) under a retention policy	Each non-Microsoft 365 generative AI prompt and response count as a separate interaction and is retained and deleted according to the retention policy settings you configure in Microsoft Purview. For more information on retention policies in DLM for Microsoft 365 Copilot and AI apps, see Learn about retention for Copilot & AI apps
eDiscovery	Storage of non-Microsoft 365 AI application data and usage of Microsoft Graph APIs for standard licensed tenants	Number gigabytes stored/day for storage of non-Microsoft 365 AI data. Gigabytes/export for usage of Export API by Standard licensed tenants	Learn more about eDiscovery billing

Other Microsoft Purview solutions that use pay-as-you-go pricing

Expand table

Solution	Applies to	Unit of Measure	Details
On-demand classification (preview)	Applies when you run a scan to identify and classify sensitive content in data stored in SharePoint and OneDrive	Asset, based on the number classified per scan	Learn more about On-demand classification (preview)

Solution	Applies to	Unit of Measure	Details
Microsoft Security Copilot	Applies for all Security Copilot functions	Security Compute Units	Get started with Security Copilot
Network Data Security (preview)	Requests from an endpoint device to a website, cloud app, or generative AI app	Number of requests sent from the endpoint device to the website, cloud app, or generative AI app	Network data security only counts requests that are outbound from the device.
Data Security for Gen AI Applications	Applies to classification and protection of sensitive content for non-M365 AI interactions (prompts/responses)	Number of requests or messages for non-Microsoft 365 AI interactions (prompts or responses)	Learn more about data security for AI interactions
Data Loss Prevention for Cloud Apps in Edge for Business browser	Applies to requests from the Edge for Business browser to a website, cloud app, or generative AI app	Number of requests sent from the Edge for Business browser to the website, cloud app, or generative AI app	Data loss prevention for cloud apps only counts requests for unmanaged cloud apps.

Cost estimator tools

Understand pricing and estimate your expected monthly costs for pay-as-you-go capabilities:

- Microsoft pay-as-you-go pricing
- Estimate your costs for Microsoft Purview pay-as-you-go feature use

Units of measure for pay-as-you-go capabilities

Assets

An asset is any Microsoft 365 item that a Microsoft Purview policy protects. Some examples are a table for structured data or any file for unstructured data. You're charged for each day that a policy covers an asset. For Microsoft Data Lifecycle Management, assets include interactions (prompts and responses) between a user and a Copilot or AI App.

Here are some examples of assets for Microsoft Purview Data Security and Governance and the protection policies that you can apply to them.

Expand table

Cloud provider	Data source	Asset	Can be protected by
Azure	SQL DB	Table	Protection policy and auto-labeling policy from Microsoft Purview Information Protection
Azure	ADLS	File or resource set	Protection policy and auto-labeling policy from Microsoft Purview Information Protection
Azure	Blob	File or resource set	Protection policy and auto-labeling policy from Microsoft Purview Information Protection
Azure	Fabric	Supported item types	Protection policies from Microsoft Purview Information Protection
Azure	Fabric	Supported item types	Microsoft Purview Data Loss Prevention

For details on data governance assets, see Microsoft Purview data governance billing.

Counting assets

Assets are counted based on the number of items that are in the scope of a policy. The asset doesn't have to match a policy's conditions to be counted, it just has to be in a location that's in the scope of a policy. An asset is only counted once, regardless of how many solutions or protection policies cover it.

Here are some examples:

- **Protection policy**: A tenant has SQL server with 100 tables, and 50 of those tables are labeled **Confidential** and 20 are labeled **General**. The protection policy only applies to assets labeled with **Confidential**, so the asset count is 50.
- **Data Loss Prevention policy**: A tenant has 10 Fabric workspaces, each with 50 assets. The policy only applies to five of these Fabric workspaces. The asset count for this policy is 250.

Processing units

A processing unit measures the amount of compute resources used to process signals from workloads that are included in pay-as-you-go.

- **Data governance processing units**: A data governance processing unit (DGPU) is a fully managed compute unit that runs compute capabilities such as data quality and data health management. Each DGPU is 60 minutes of compute time that runs across varying

sets of nodes based on the workload need. For more information on data governance processing units, see Data governance processing units explained.

- **Data security processing units**: Microsoft Purview data security processing units represent the compute required to process user activities from non-Microsoft 365 data sources to generate insights. The number of units required can vary depending on the Purview solution and the complexity of the data being processed. Insider risk management is a pay-as-you-go feature that uses a processing unit based meter. It includes pay-as-you-go indicators. For more information, see Configure policy indicators in insider risk management.
- **Compute units**: Data Security Investigation compute units (compute units) represent the compute required to process and generate AI-based insights in Data Security Investigations. The number of units required can vary depending on the process and is a pay-as-you-go feature that uses a processing unit based meter.For more information, see Billing in Data Security Investigations.

Counting processing units

The number of processing units you need varies depending on the Microsoft Purview solution and the complexity of the data being processed.

For example, Insider Risk Management processes user activities corresponding to the non-Microsoft 365 indicators selected in data theft and data leak policies to generate insights, alerts, and cases. For Insider Risk Management, a processing unit represents the compute required to process 10,000 such user activities. Billing is based on the number of processing units utilized. Insider Risk Management indicators that detect activity in cloud storage apps (Box, Dropbox, Google Drive), cloud services (AWS, Azure), and Microsoft Fabric (Power BI) are billed on data security processing units.

Data storage meter (GBs)

Microsoft Purview data storage meter is defined by a gigabyte per month storage amount billed at a specific rate for applicable solutions. The total amount of data within a solution subject to data storage meter is automatically calculated from the current amount of data in solution-related containers. For example, pay-as-you-go in Data Security Investigations and eDiscovery use the data storage meter.

eDiscovery also uses a storage meter defined by the gigabytes per export through Graph API for E3 eDiscovery licensed customers. Each organization receives an included amount of free storage per month, with additional usage billed at a set price per GB.

For more information about API storage and pricing, see Microsoft Purview pricing.

Text records

Microsoft Purview text records meter is defined by text records, where one text record equals 1,000 characters. Each message converts into multiple text records based on character length. For example, pay-as-you-go in Communication Compliance uses a text records-based meter.

1 text record = 1,000 characters

If a message has more than 1,000 characters, it counts as one text record for each unit of 1,000 characters. For instance, if a message contains 7,500 characters, it counts as eight text records. If a message contains 500 characters, it counts as one text record.

Counting text records for Communication Compliance Premium

Counting text records for premium is based on the type of detections that the messages are being evaluated for. If the evaluation includes the following detections, they're charged at the premium rate:

1. **Code of conduct**: Hate, self-harm, violence, sexual
2. **Risky Gen AI:** Prompt shields, protected materials

Calculating text records for Communication Compliance Standard

If messages are evaluated positive for any other detections, such as other trainable classifiers or sensitive info types, you pay standard charges. Messages that evaluate messages for both premium and standard detections are charged only for premium detections.

Security Compute Units (SCU)

A security compute unit (SCU) is a bundled unit of measure. It combines all the resources, like network, processor, and storage, that Microsoft Security Copilot needs to provide service into a single, billable quantity.

For more information on SCUs, see Get started with security compute units.

Counting SCUs

The number of SCUs you have available is your capacity. Your available capacity consists of two types:

- **Provisioned SCUs:** These are units that you pre-allocate. You use the cost estimators to project the number of SCUs you anticipate using. Use of provisioned SCUs is measured in hourly blocks. For example, if you provision an SCU at 9:05 a.m., then deprovision it at 9:35 am, and then provision another SCU at 9:45 am, you are charged for two units within the 9:00 a.m. to 10:00 a.m. hour. To maximize usage, make SCU provisioning changes at the beginning of the hour. For more information, see Manage usage.
- **Overage SCUs:** These units cover unexpected spikes in usage. To manage unexpected demand spikes, you can allocate an overage amount to ensure that additional SCUs are available when you run out of provisioned units. Overage units are billed on-demand. You can set limits for overage units as unlimited or set a maximum upper amount. This approach enables predictable billing while providing the flexibility to handle both regular and unexpected usage.

Requests

For pay-as-you-go billing, a request is each network call a device or browser makes to a website or API. This definition doesn't include the responses to the requests. Azure counts requests in the monthly pay-as-you-go bill you receive. Microsoft Purview network data security pay-as-you-go uses requests as its unit of measure. Here are some examples:

Expand table

Activity	Data type	Example
Text sent to or shared with cloud or AI app	human readable strings transmitted inline	- submitting a form with textual information - Sending raw text or a prompt to a generative AI - the body of an email - sending JDSON data to an API
File uploaded to or shared with cloud or AI app	Byte streams, including text based file, binary files, txt files, source code, documents, images, videos, .exe's, .pdf's, archive files	- Uploading a profile picture to social media - sending a document or PDF file as an email attachment - sharing a document with generative AI - transferring a document or .ZIP files to a cloud storage solution

Consent to use use pay-as-you-go capabilities

Article • 04/08/2025

Applies to:

- Existing Azure Purview customers who are using the classic data governance pricing model.
- Microsoft Purview customers using Data Security pay-as-you-go features in free public preview.

> **Important**
>
> You can only use this procedure if your organization is in one of the above categories.

This feature is in preview.

Consent to use pay-as-you-go capabilities

If your organization is in one of the above categories, you must give your consent to switch from your current billing model to the pay-as-you-go model.

If you aren't familiar with the pay-as-you-go model see, Learn about Microsoft Purview billing models.

Prerequisites for pay-as-you-go

To consent to changing to the pay-as-you-go model, you must have these prerequisites.

Roles and permissions to consent to the pay-as-you-go pricing structure

Only an account in the Global Administrator role can provide consent to switch to the pay-as-you-go model.

Consent experience

Microsoft Purview has a single unified consent experience that applies to all pay-as-you-go apps and capabilities. Your consent applies to all current and future pay-as-you-go features, as

they transition from free to paid public preview.

> **Note**
>
> Although the consent experience is common for all apps and capabilities, certain apps may not be available in all regions. For instance, data governance is currently available in specific regions. For more information on region availability, see Supported regions for Microsoft Purview Data Governance.

1. Open the Microsoft Purview portal > **Settings** > **Account overview** in the new Microsoft Purview portal.
2. Select **Review Consent** and switch to the pay-as-you-go model.
3. Microsoft Purview Unified Catalog app customers can learn more here.
4. A confirmation is displayed that you've successfully switched to the new business model.

See also

- Learn about Microsoft Purview billing models

Enable Microsoft Purview pay-as-you-go features for new customers

Applies to:

- Organizations that aren't current Azure Purview customers using the classic data governance pricing model customers.

In this procedure, you enable the Microsoft Purview pay-as-you-go features by associating your Microsoft 365 tenant with an Azure subscription for billing purposes.

If you aren't familiar with the pay-as-you-go model see, Learn about Microsoft Purview billing models.

This featue is in preview.

Prerequisites for pay-as-you-go

To enable pay-as-you go, you must have:

- An Azure subscription in the same tenant as Microsoft Purview.
- An Azure resource group in that subscription.
- Either of the following service plan
  - MIP_S_Exchange
  - EXCHANGE_S_FOUNDATION

If you already have these resources, you can use them with Microsoft Purview.

If you don't already have these resources, see:

- Create your initial Azure subscriptions
- Manage Azure resource groups by using the Azure portal.

Roles and permissions to consent to the new pricing structure

Only an account in the Global Administrator role can enable the pay-as-you-go model:

Subscription based

The enablement flow requires you to associate your Microsoft Purview tenant to an Azure subscription. All consumption and billing information is available in the Azure portal under **Cost Management + Billing**.

You can use an existing Azure subscription and resource group or create a new one. The Azure subscription must be active to bill against before you can enable the pay-as-you-go billing model.

1. Open the Microsoft Purview portal and select the rocket icon on the top right in the header pane, near the **Settings** icon.
2. Select **Get Started** in the ribbon menu to start the process. This can also be done from **Settings** > **Account details**.
3. Select your active Azure subscription from the list. If you don't have an active Azure subscription, you must create a new one before you can proceed. See Create your initial Azure subscriptions.
4. Select the resource group. If you don't have a **Resouce group** in your Azure tenant, you must create a new one before you can proceed. See - Manage Azure resource groups by using the Azure portal. The billing resource is created under the resource group. This is where the pay-as-you-go version of Microsoft Purview is hosted in the Azure portal.

The *Country/Region* value is fixed for the tenant.

Upon completion, it can take a few hours for changes to complete. When completed, you can use pay-as-you-go features to protect your non-Microsoft 365 assets on the **Solutions** page.

- Learn about Microsoft Purview billing models
- Consent to use use pay-as-you-go capabilities

Last updated on 02/03/2026

Manage pay-as-you-go and per-user licensing usage

> **Note**
>
> The Microsoft Purview **Usage center** feature is in preview.

Microsoft Purview solutions are licensed through the **Premium licensing model**, which is the per-seat model, the **pay-as-you-go billing model** model, or a combination of both. If you need to understand the billing models in Microsoft Purview, see Learn about Microsoft Purview billing models.

The **Usage center** in the Microsoft Purview portal helps you understand and manage your usage for both billing models. You can view your pay-as-you-go billing usage and your per-user licensing usage for Microsoft Purview capabilities.

Permissions

To access the **Usage center** > **Pay-as-you-go** and **Usage center** > **Premium usage** pages, the account you use must have one of the following roles:

- Global Reader
- Security Reader
- Global Admin

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Pay-as-you-go usage

The **Usage center** provides detailed information on **Total Units Used** about your pay-as-you-go billing usage by feature and by workload. For definitions on the **Unit of Measure** see Units of measure for pay-as-you-go capabilities. The pay-as-you-go usage page also lets you toggle the features listed between paused and active states.

Expand table

Feature name	Pausable	Detailed report available
Communication compliance Standard	Yes	Yes
Communication compliance Premium	Yes	Yes
Enterprise Data Management Basic	No	Yes
Enterprise Data Management Standard	No	Yes
Enterprise Data Management Advanced	No	Yes
Audit	Yes	Yes
Insider Risk Management	No	Yes
On-Demand Classification	Yes	Yes
Information Protection	Yes	Yes
Data lifecycle management	Yes	Yes
Data Catalogue Governed Assets	No	Yes
Data Security Investigations	No	No
In-transit protection of data to AI apps	No	Yes
In-transit protection of data through Browser	No	Yes
In-transit protection of data at the network layer	No	Yes
eDiscovery	Yes	No

Premium usage model

The **Premium usage** model is useful for identifying underlicensing situations and under utilization of purchased licenses.

Policy Scoping

Use the **Policy Scoping** card tells you how many unlicensed users are in scope of one or more Microsoft Purview premium features. This helps you identify potential under-licensing situations so you can optimize your licensing usage.

The **Policy Scoping** card shows three key metrics:

- Policy scoped users: The total number of users in scope of one or more Microsoft Purview premium features.
- Policy scope users with assigned licenses: The number of users in scope of one or more, which are licensed one or more of Microsoft Purview premium features.
- Policy scoped users without assigned licenses: The number of users in scope of one or more Microsoft Purview premium features, which aren't licensed for any of those features.

The unlicensed user metric is calculated like this:

Policy scoped users - **Policy scoped users with assigned licenses** = **Policy scoped users without assigned licenses**

License Assignment

There may be users who are assigned licenses for Microsoft Purview premium features but aren't in scope of any of the features. So essentially, you're paying for usage of a feature, but not using the feature. The **License Assignment** card helps you identify these users so you can optimize your licensing usage.

The **License Assignment** card shows two key metrics:

- **License assigned users**: The number of users that are assigned Microsoft Purview Premium licenses.
- **License assigned users not under policy scope**: The number of users that are assigned Microsoft Purview Premium licenses but aren't in scope of any Microsoft Purview premium features.

The **License assigned users not under policy scope** metric is calculated like this:

License assigned users - **Policy scoped users with assigned licenses** = **License assigned users not under policy scope**

Free version of Microsoft Purview data governance solutions

Article • 04/04/2025

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

Microsoft Purview offers your administrators the ability to govern your data estate and your users the ability to discover data across your organization. The free version of Microsoft Purview governance solutions is an automatically available instance, ready for your users without needing to set it up. It allows your organization to try Microsoft Purview's basic capabilities and begin your governance journey.

The free version of Microsoft Purview governance solutions uses a single, organization-wide instance of Microsoft Purview that users can access to explore their Azure and Microsoft Fabric resources. Metadata for these resources is automatically inventoried and can be searched using the catalog.

Access to this version of Microsoft Purview depends on your organization's current relationship with Microsoft Purview; whether you're a new Microsoft Purview user, if you have existing accounts, or if you're already using other services like Microsoft Fabric. For more information, see, how to access the free version of Microsoft Purview governance solutions.

Free version limitations

- In the free version of Microsoft Purview governance solutions, there's a limitation of 1,000 annotated assets. An annotated asset applies both to live view assets that have been curated, or custom assets added using the Microsoft Purview Data Map REST APIs. For example, if your account has 50 live view data assets, and you add descriptions and classifications to 15 of those assets, you have 15 annotated assets, and can have 985 more before you reach your limit. A description and a classification on the same asset count only as one annotated asset.
- In the free version, only data curators are able to access any resources added to the data map using the REST APIs.

- If your free version tenant shows three months of no activity, we have the right to clean up the account and might remove the unused resources.

What's available in the free version

Users who have access to data stored in supported Azure resources have access to its metadata in Microsoft Purview. Data readers can search for and browse this metadata and data owners can augment the metadata to provide more context.

Only a core subset of Microsoft Purview's governance solutions with limited capabilities are currently available in the free version:

- Catalog: Browse and search for your data assets.
- Data Map history: A log of updates made to assets.

Catalog

Users can browse and search for their data assets in Azure. You can explore your Azure assets to discover reliable data sources in their environment using live view without any setup needed. The catalog automatically records data schema so users can explore data sources before accessing them. Data owners can add metadata and information to their assets, such as description, classifications, and contacts, so users have a more complete picture of their data estate.

Supported data sources

Currently, the free version of Microsoft Purview governance solutions supports these governance data sources using live view:

- Azure Blob Storage
- Azure Data Lake Storage Gen 2
- Azure SQL Database
- Azure subscriptions
- Microsoft Fabric

You can annotate and curate assets that are available via live view, or use our APIs to create new entities.

Access the free version of Microsoft Purview governance solutions

The free version of Microsoft Purview governance solutions uses a single, organization-wide instance of Microsoft Purview. Access to the latest Microsoft Purview experience depends on your current relationship with Microsoft Purview; whether you're a new Microsoft Purview customer or an existing Microsoft Purview customer.

The free version of Microsoft Purview governance solutions uses the same location mappings as Microsoft 365, and maps to a location based on your Microsoft Entra ID home region. For more information, see the FAQ.

New Microsoft Purview customers

If you're an Azure Enterprise, Dynamics 365, Microsoft 365 Enterprise, Microsoft Fabric, Power Apps, or Power BI customer, to access the free version of Microsoft Purview governance solutions for your organization go to https://purview.microsoft.com. For more information about this access, see the FAQ.

If you're not an Azure Enterprise, Dynamics 365, Microsoft 365 Enterprise, Microsoft Fabric, Power Apps, or Power BI customer, we're currently making the free version of Microsoft Purview governance solutions available to organizations in batches. Go to https://purview.microsoft.com to check if it's available to your organization. If not:

- You can create a Microsoft Purview account to access the **enterprise** version of Microsoft Purview.
- You can wait until the free version of Microsoft Purview governance solutions is available to your organization, and check this document for updates.

Existing Microsoft Purview customers

If you're already using Microsoft Purview, your account is likely already upgraded to the enterprise version of Microsoft Purview.

You can check your organization's account type in the Microsoft Purview portal under the **Settings** gear icon, and **View all settings**.

Permissions

Access control in the free version of Microsoft Purview governance solutions is managed at the organization/tenant level. All users are able to view data assets for sources where they have at least **Read** permissions already. For other functionality, like metadata curation, you can assign this role:

Expand table

Role	Description
Data Catalog Curator	Catalog curators can perform the create, read, modify, and delete actions on catalog data objects and establish relationships between objects.

Get details about governance roles and permissions.

Upgrade to enterprise

The enterprise version of Microsoft Purview has access to the rest of Microsoft Purview applications and data sources. Learn how to upgrade to the enterprise version of Microsoft Purview data governance.

When you upgrade, all your data from the free version of Microsoft Purview governance solutions will be migrated into the enterprise version. The enterprise version will be hosted in the same location as the free version of Microsoft Purview governance solutions.

What's in the the free and enterprise versions

Here's a brief comparison of the free and enterprise versions of Microsoft Purview data governance:

Expand table

Free	Enterprise
Auto discovery of Azure data sources	Collections, and glossary terms to organize your data map
Role group access control to platform and apps	Fine-grained, collection-level access control to platform and apps
Definition and manual application of classifications and terms	Automated application of classifications and terms
Manual descriptions, tags, and contacts	Manual and Bulk descriptions, tags, and contacts.
Manual creation of assets using the data map APIs	Full use of Microsoft Purview's REST APIs
	Automated scans for the hybrid data estate

Free	Enterprise
	Workflows
	Business rules
	Support for business assets and managed attributes

Applications supported between versions of Microsoft Purview:

Expand table

Application	Free	Enterprise	Notes
Catalog	x	x	Free supports browse and search, while enterprise supports advanced search and self-service data access.
Data Estate Insights		x	Enterprise supports all available reports
Data Policy		x	
Data Map	x	x	Data map history is available in both the free and enterprise versions of Microsoft Purview.

For more information about the applications available in the enterprise version of Microsoft Purview, see the overview article.

Support for the free version of Microsoft Purview governance solutions

With the free version of Microsoft Purview governance solutions, you can't open support tickets for Microsoft Purview. You need to upgrade to the enterprise version of Microsoft Purview for support.

Next steps

- Get started with the free version of Microsoft Purview governance solutions
- New Microsoft Purview portal
- Upgrade to enterprise

Get started with the free version of Microsoft Purview data governance solutions

Article • 04/04/2025

> **Important**
>
> This feature is currently in preview. The Supplemental Terms of Use for Microsoft Azure Previews include additional legal terms that apply to Azure features that are in beta, in preview, or otherwise not yet released into general availability.

The free version of Microsoft Purview governance solutions provides an automatically available Microsoft Purview instance, ready for your users without setup. It allows your organization to try Microsoft Purview's basic governance capabilities and begin your governance journey. This article offers some best practices to help you quickly get started with Microsoft Purview data governance solutions, the Data Map, and the catalog.

Access to this version of Microsoft Purview depends on your organization's current relationship with Microsoft Purview; whether you're a new Microsoft Purview user, if you have existing accounts, or if you're using other services like Microsoft Fabric. For more information, see how to access the free version of Microsoft Purview governance solutions..

How to start your governance journey

The free version of Microsoft Purview governance solutions lets you get started on your governance journey even as you begin planning. Once your organization has access to the free version of Microsoft Purview governance solutions, use this guide to build your governance experience.

1. Explore the Microsoft Purview portal.
2. See what metadata for supported Azure sources is already available in the catalog.
3. Search or browse the catalog to understand your initial assets.
4. Engage your data owners, and add data curators to manage metadata in your environment.

5. Work with your data owners and curators to augment the metadata for existing data sources. This gives your users more context and information about their data sources.

6. Add your other critical Azure resources to the data map using our REST APIs.

   > **Important**
   >
   > Only **data curators** will be able to access any resources added to the data map using the **REST APIs**. In order for other users to be able to access, **upgrade to the enterprise version of Microsoft Purview**.

7. Engage your users to discover your users to access your resources in the catalog.

When you're ready to expand

Once you've added and curated your critical Azure resources in the Microsoft Purview portal, if you're looking for more governance features, you're ready to upgrade to the enterprise version of Microsoft Purview.

When you upgrade, all the information you have and have added to the free version of Microsoft Purview governance solutions will be available in the enterprise version of Microsoft Purview within minutes, so you can get started using all of the enterprise features right away. Here's some steps you can take to prepare your environment for upgrade.

1. Review our deployment best practices to start the right conversations in your organization.
2. Consider your network architecture for Microsoft Purview.
3. Plan your collections architecture for your data map.
4. Upgrade to the enterprise version of Microsoft Purview.
5. Review our scanning and classification.

> **Tip**
>
> If you used the **REST APIs** to add sources and assets in the free version of Microsoft Purview governance solutions that you can now scan in the enterprise version, Microsoft Purview will **normalize** the newly scanned information and add it to your existing resources.

Next steps

- New Microsoft Purview portal
- Upgrade to enterprise
- Roles and permissions

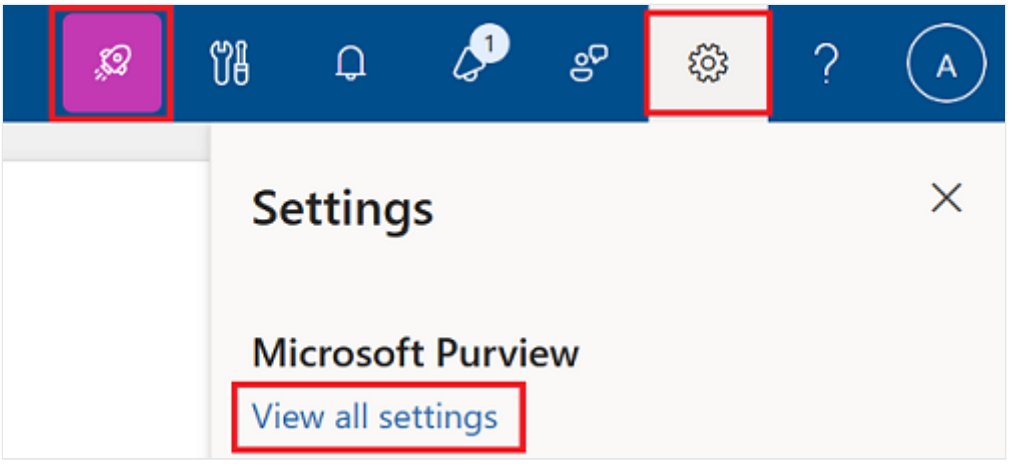
Upgrade from the free to enterprise version of Microsoft Purview data governance

Article • 05/01/2025

> **Note**
>
> If you already have a Microsoft Purview account and enabled the new Microsoft Purview portal experience, you are using the enterprise version of Microsoft Purview. You can check your account type in the Microsoft Purview portal by selecting the **Settings** gear icon, then selecting **View all settings**.

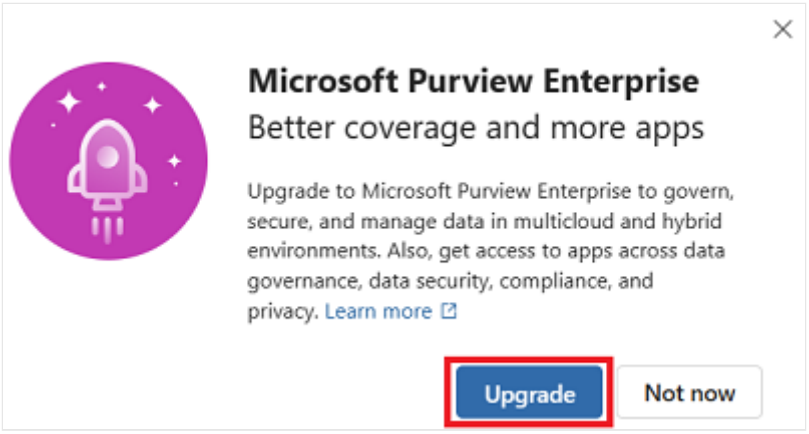
When you upgrade from the free version of Microsoft Purview governance solutions to the enterprise version, the data in the free version will automatically be available in the enterprise version within minutes. Your experience in the portal remains the same, and you gain access to all Microsoft Purview data governance solutions' capabilities, including:

- All Microsoft Purview supported sources
- Collections
- Scanning
- Automatic classification
- Microsoft Purview policies
- All reports in Data Estate Insights
- Workflows

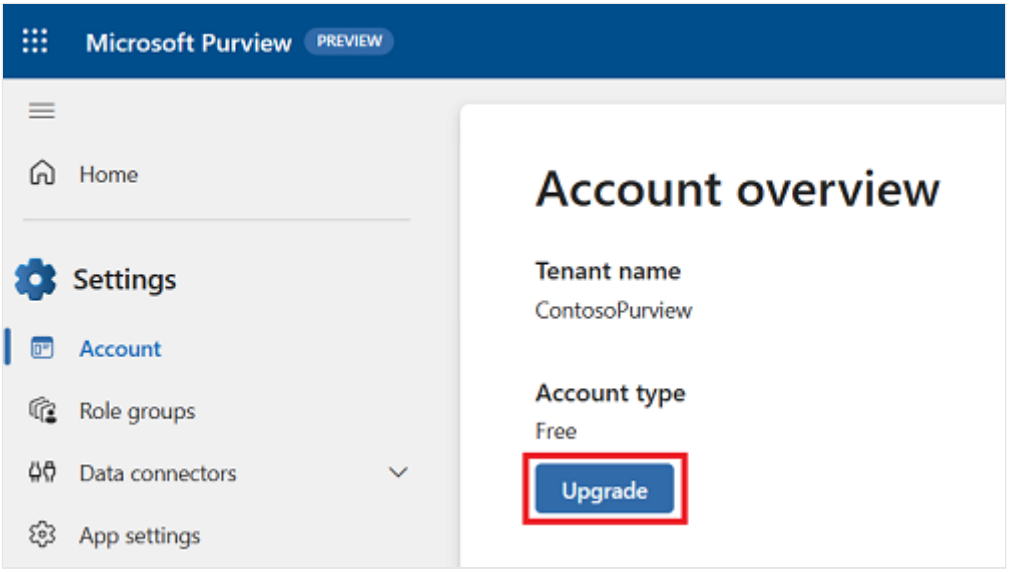


Learn more about getting started with Microsoft Purview data governance solutions.

> **Important**
>
> If you create a classic Microsoft Purview instance for the first time in your organization, the instance will automatically be upgraded to the enterprise version of Microsoft Purview.



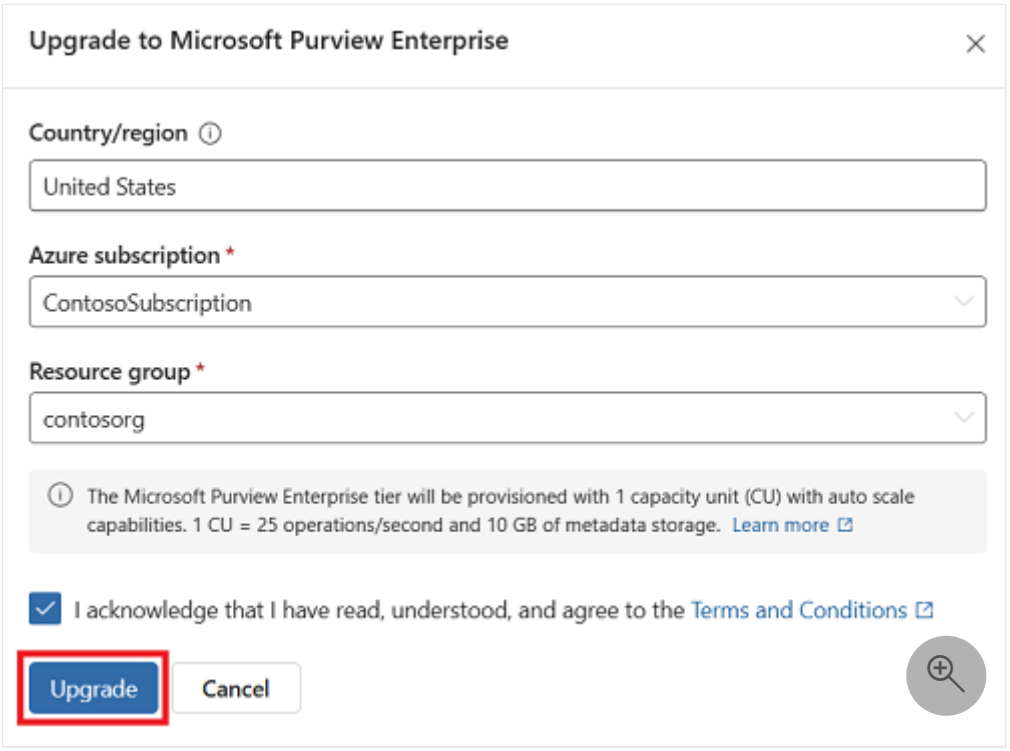
Upgrade



You can upgrade to the enterprise version of Microsoft Purview using these steps:

1. Open the Microsoft Purview portal
2. Select the upgrade button in the ribbon menu, or select **Settings**, then **View all settings**.

3. Select **Upgrade**



4. Your region is the same region as the free version of your Microsoft Purview account. For more information, see the FAQ.

5. Select the Azure subscription where you would like to house the Azure linked Microsoft Purview resource.

6. Select the resource group where you would like to house the Azure linked resource.

7. Select the check box to acknowledge terms and conditions.

8. Select **Upgrade**

9. You've upgraded! Select **Use default settings** to get started, or **Continue with setup** to manage settings.

Protect your account

In order to protect your Microsoft Purview account from accidental deletion, we recommend creation of the Azure Policy 'DenyAction'

JSON

```
{
  "if": {
    "allOf": [
      {
        "field": "type",
        "equals": "Microsoft.Purview/accounts"
      },
      {
        "field": "tags.environment",
        "equals": "Production"
      }
    ]
  },
  "then": {
    "effect": "denyAction",
    "details": {
      "actionNames": [
        "delete"
      ],
```

```
        "cascadeBehaviors": {
          "resourceGroup": "deny"
        }
      }
    }
  }
```

Settings

Governance settings in the new Microsoft Purview portal include:

- Account type - either free or enterprise. The free version only includes a subset of applications and sources. The enterprise version of Microsoft Purview includes all available governance applications and sources.
- Kafka configurations - configure Microsoft Purview to be able to send and receive Atlas Kafka topics events with Azure Event Hubs

Possible exceptions

When you're upgrading to the enterprise version of Microsoft Purview, there are a few possible exceptions you can encounter. These guides address them.

Private endpoints

If your Microsoft Purview account had disabled all public network access and is using private endpoints, you can still upgrade to the new experience.

You can continue to use your *ingestion* private endpoints as is, but the new experience also uses a *platform* private endpoint.

After upgrading to the new experience, you can follow this guide to set up platform the private endpoint for governance solutions in the Microsoft Purview portal.

For more information, see what to do if your account has disabled all public network access.

Resource providers

Before upgrading to the enterprise version of Microsoft Purview, you need to have these resource providers registered in Azure:

- Microsoft.Purview
- Microsoft.Storage
- Microsoft.EventHub

If all of them aren't already registered, you might receive an error.

Default name isn't allowed

It's possible that default names have been disallowed in your organization, and you need to enter a new resource name.

To resolve, enter a new resource name and then complete the upgrade process.

For more information about default naming policies, you can see the resource naming guidance documentation.

Region

If your account is in a different region than your tenant, an admin needs to confirm setup.

> **Note**
>
> If you want to use a different region, you will either need to cancel and wait for upcoming region related features, or cancel and create a new Microsoft Purview account in one of the available regions.

Nonadmin request

If a user who isn't a Purview Admin selects the upgrade button, a request to upgrade is sent to an administrator. The administrator can update from directly within the request email, or they can upgrade using the above steps.

If you don't have access to the Microsoft 365 role groups to assign Purview Admins, contact support.

Switch back to classic portal

Even after upgrading to the enterprise version of Microsoft Purview, you can switch back to the classic portal at any time using the toggle.

Billing

> **Note**
>
> The enterprise version of Microsoft Purview uses the same pricing dimensions as the classic Microsoft Purview governance portal experience. You can check your account type in the Microsoft Purview portal under **Settings**, then **View all settings**.

Billing for the enterprise version of Microsoft Purview is pay-as-you-go.

For more information, see these articles:

- Pricing guidelines
- Microsoft Purview elastic data map
- Pricing calculator

Linked resource

The enterprise version of Microsoft Purview is hosted by a linked resource in the Azure portal. If you delete this linked resource in the Azure portal, you lose all your Microsoft Purview information.

After deletion, you can reinstate the free version for your environment if it's been enabled for your organization by going to the Microsoft Purview portal. But you're starting your environment from scratch.

Learn about the Microsoft Purview Suite trial

The Microsoft Purview Suite trial is a free and easy way to try compliance capabilities of Microsoft Purview solutions. After a quick setup taking only a couple of minutes, the features of the Microsoft E5 license package are available for you to use for up to 90 days.

Where to sign up

Sign up in the Microsoft Purview portal. When you start a trial, the trial is effective immediately for 90 days. It can take up to two hours for all Microsoft Purview solutions to appear in your left navigation. Sign out and sign back in to see the updates.

- Sign in to the Microsoft Purview portal.
- On the home page, go to the **Trials and recommendations** section and select **View all trials and recommendations**.
- In the **Purview and Priva trials** section, find the **Microsoft Purview setup** card and select **Get started**.

At the hub you can see the status of your trials, sign up for other trials, and view purchase options.

Eligibility and licensing

Customers who don't already have a Microsoft E5 license package are eligible for the trial if they meet one of these two requirements:

- Have Microsoft 365 E3, **or**
- Have Office 365 E3 **and** Enterprise Mobility and Security E3

The trial isn't available for Microsoft 365 Government customers.

As part of the trial setup, 25 Microsoft Purview Suite (formerly known as Microsoft 365 E5 Compliance) licenses are automatically applied to your organization. The licenses are active for 90 days. You might want to refer to the Microsoft Purview service description for licensing details for each solution.

Roles for starting the trial

A user with one of the roles listed below can start or end a trial:

- Billing Administrator
- Compliance Administrator
- Compliance Data Administrator
- Global Administrator

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Get more details about roles for starting trials.

Getting started, finding support, and ending the trial

Getting started

You can start using Microsoft Purview solutions as soon as you see them in the Microsoft Purview portal. Nothing is created automatically and users won't be affected. When you navigate to each solution, you may be guided to make extra setup configurations to start using features.

Finding support

Organizations can use FastTrack for trial deployment support if the tenant has at least 150 licenses. Get more details about FastTrack.

Extending the trial

You can extend the trial within the last 15 days of the trial period. You're limited to a maximum of two trial periods. If you don't extend by the time your trial period ends, you need to wait at least 30 days before signing up for a second trial.

Ending the trial

Admins can disable the trial anytime by selecting **End trial** on the **Purview setup** card on the **Microsoft Purview trials and recommendations** page in the Microsoft Purview portal.

If you decide not to upgrade to the E5 level solutions, unless stated otherwise for the solution your trial data will be maintained for a period of time, usually 180 days, before being permanently deleted. You may continue to access the data gathered during the trial until that time.

Learn more about Microsoft Purview solutions

The Microsoft Purview Suite trial includes the solutions listed below.

> **Note**
>
> Certain Microsoft Purview features may appear in other Microsoft products for which a license is needed. Refer to each Microsoft Purview solution's licensing details at **Microsoft 365 licensing guidance for security & compliance**.

- **Audit**

  Microsoft Purview Audit (Premium) helps organizations to conduct forensic and compliance investigations by increasing audit log retention required to conduct an investigation, providing access to intelligent insights that help determine scope of compromise, and faster access to Office 365 Management Activity API. Learn more about Audit (Premium).

- **Communication Compliance**

  Microsoft Purview Communication Compliance helps you overcome modern compliance challenges associated with internal and external communications by helping you automatically capture inappropriate messages, investigate possible policy violations, and take steps to remediate. Learn more about Communication Compliance.

- **Compliance Manager**

  Microsoft Purview Compliance Manager can help you throughout your compliance journey, from taking inventory of your data protection risks to managing the complexities of implementing controls, staying current with regulations and certifications, and reporting to auditors. Learn more about Compliance Manager.

- **Data Lifecycle Management**

  Automate your retention coverage by using adaptive policy scopes. This feature allows you to dynamically target policies for retention to specific users, groups, or sites. These policies automatically update when changes occur in your organization. In addition,

policies that use adaptive scopes aren't subject to location limits. Learn more about adaptive policy scopes.

Learn more about Microsoft Purview Data Lifecycle Management.

- **Data Loss Prevention**

  Microsoft Purview Data Loss Prevention (DLP) helps you control sharing and use of sensitive info on devices, apps, and services. With trials, you can extend coverage of DLP policies to Teams and devices, protect even more sensitive content using trainable classifiers and exact data match (EDM), and get started quickly with our recommended DLP policies. Learn more about Data Loss Prevention.

  When the trial ends:
  - Your existing policies stay turned on unless you turn them off.
  - You won't be able to edit or add Teams or Devices locations in existing or new policies.

- **Data Security Posture Management**

  Microsoft Purview Data Security Posture Management (DSPM) helps organizations discover, protect, and investigate sensitive data risks across their digital estate. This solution provides unified visibility and control for both traditional applications and AI apps and agents, supporting data governance across Microsoft 365 and integrated third-party SaaS platforms. Monitor, assess, and remediate data risks, regardless of where sensitive data resides.

  Learn more about Microsoft Purview Data Security Posture Management.

- **eDiscovery**

  Take advantage of an end-to-end workflow for preserving, collecting, analyzing, and exporting content that's responsive to your organization's internal and external investigations. Legal teams can also manage the entire legal hold notification process by communicating with custodians involved in a case. Learn more about eDiscovery.

- **Information Protection**

  Implement Microsoft Purview Information Protection with sensitivity labels to help you discover, classify, and protect your sensitive content wherever it lives or travels. With the trials, you can recommend users apply sensitivity labels to their emails and docs, discover and automatically label sensitive content, take advantage of machine learning based classifiers, and get started quickly with some recommended labels and policies.

  When the trial ends:

    - All files and emails labeled during your trial stay labeled. You can manually remove the labels.
    - Your existing policies stay turned on unless you turn them off.
    - Any autolabeling policies can't be edited after the trial ends, but can be deleted.

    For more information about each of these preconfigured features and how they affect users, see Learn about the free trial for Microsoft Purview Information Protection.

Get more information about the full range of features for Microsoft Purview Information Protection.

- **Insider Risk Management**

  Use artificial intelligence to help you quickly identify, triage, and remediate internal risks. Using logs from Microsoft 365 and Azure services, you can define policies that monitor for risk signals, then take remediation actions such as promoting user education or initiating an investigation. Learn more about Insider Risk Management.

- **Records Management**

  Use integrated Microsoft Purview Records Management features to automate the retention schedule for organizational regulatory, legal, and business-critical records. Get full content lifecycle support, from creation to collaboration, record declaration, retention, and disposition:
    - Classify content as a record to prevent users from editing, as required by regulations, laws, or organizational policy
    - Apply retention labels to content automatically when it matches criteria you specify, using autoapply label policies
    - Use adaptive scope policies to dynamically target your retention label policies to locations, with no limit on how many locations are included
    - Get full content lifecycle support, including the ability to perform disposition review on contents before they're permanently deleted at the end

Get more information on the full range of features for Microsoft Purview Records Management.

Terms and conditions

See the terms and conditions for Microsoft 365 trials.

Last updated on 03/30/2026

Learn about the Microsoft Purview Compliance Manager premium assessments trial

07/24/2025

Compliance Manager helps you automatically assess and manage compliance across your multicloud environment. The assessments you build are based on templates that correspond to governmental regulations and industry standards around the world.

Your licensing agreement to use Compliance Manager may include one or more built-in regulatory templates for building assessments. An extensive library of premium regulations is also available for building assessments specific to your organization's needs. To try out these regulatory templates before purchasing licenses, sign up for the free Compliance Manager premium assessments trial.

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the **Microsoft Purview trials hub**. Learn details about **signing up and trial terms**.

Trial setup instructions

- Sign in to the Microsoft Purview portal.
- On the home page, go to the [**Trials and recommendations**](purview-portal.md#trials-and-recommendations section and select **View all trials and recommendations**.
- In the **Purview and Priva trials** section, find the **Compliance assessments** card and select **Try now**.

The premium assessment trial is available to organizations using Compliance Manager under a commercial license. For GCC and DOD information and trial options, see Learn about regulations in Compliance Manager.

Full access to Compliance Manager features depends on your licensing agreement for Compliance Manager. To learn more about the free compliance trial that includes Compliance Manager, see Learn about the Microsoft Purview risk and compliance solutions trial.

> **Note**
>
> Check your Microsoft 365 admin center settings to facilitate enrollment in the trial. In the Microsoft 365 admin center, go to the **Settings** > **Org settings** > **Services** page, and select **User owned apps and services**. Then check the box to let users start trials on behalf of your organization. When setup finishes in about two minutes, you can go back and uncheck the box to disable this setting. You can also start the trial without adjusting your org settings by going to the **Billing** > **Purchase services** page and searching for the Compliance Manager premium assessment trial.

Regulations available to use during the trial

When you start your one-time trial for premium assessments, you can use 25 premium regulatory templates of your choice for free for 90 days. You can create as many assessments from the 25 regulations as you wish. View the full list of Compliance Manager regulations.

After starting your trial, go to your **Assessments** tab in Compliance Manager and view the **Purchased regulation licenses used** counter to see how many regulations are available and are in use. This counter shows your 25 licensed regulatory templates. As you create assessments for these regulations, your activated number updates. Multiple assessments based on the same regulation count as one regulatory template use. For more information, see Learn about regulations in Compliance Manager.

Roles for starting the trial

A user with one of the roles listed below can start or end a trial:

- Billing Administrator
- Compliance Administrator
- Compliance Data Administrator
- Global Administrator

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Get more details about roles for starting trials.

During your trial

Throughout your trial, you can review the **Trial summary** section of the **Overview** page in Compliance Manager to see how many assessments you created, the number of improvement actions taken, how your compliance score has changed, and how much time remains in your trial. From here, you can also review the list of available regulations and learn more about purchasing them for ongoing use.

After the trial

After your trial ends, the regulatory templates you used won't receive automatic updates and might fall out of date with any regulatory changes. We recommend that you delete assessments built from regulatory templates that you don't intend to purchase.

Ending the trial

Admins can disable the trial anytime by selecting **End trial** on the **Compliance assessments trial** card on the **Microsoft Purview trials and recommendations** page in the Microsoft Purview portal.

Learn more and explore other trials

To learn more about the features of Compliance Manager and how it can help your organization meet compliance and regulatory requirements, see Microsoft Purview Compliance Manager.

You can also learn about other Microsoft Purview solutions and how to start trials at Learn about the Microsoft Purview risk and compliance solutions trial.

Terms and conditions

See the terms and conditions for Microsoft 365 trials.

How data flows in Microsoft Purview

This article describes how Microsoft Purview shares data between Purview solutions. This information supplements the commitments made to you in the relevant sections of the Microsoft Product Terms and the Microsoft Products and Services Data Protection Addendum.

The Data Map provides a unified map of your data assets and can identify the assets' relationships for effective governance. Microsoft Defender for Cloud Apps gives you full visibility of your SaaS app landscape to help protect your apps.

When you create an enterprise account, either by upgrading a free tier account or by creating a new enterprise account, you can register data sources within your data estate. By registering data sources, users in the enterprise account can scan the registered data sources. After you complete registration and scan activities for a data source, data flows between Data Map and some Microsoft Purview solutions.

> **Important**
>
> If you don't want to authorize data flows throughout Microsoft Purview, don't register or scan any of the data sources in your data estate into Data Map.

The following table describes how Microsoft Purview solutions share data with Data Map and receive data from Data Map and Microsoft Defender for Cloud Apps.

Expand table

Microsoft Purview Solution	What gets shared to Data Map	What is received from Data Map	What is received from Microsoft Defender for Cloud Apps
Microsoft Purview Audit	N/A	- Service configuration data - Audited activities data (including audit records and log query permissions) - Admin operations data	N/A
Microsoft Purview Unified Catalog	N/A	- Asset details, including asset metadata, classification data,	N/A

Microsoft Purview Solution	What gets shared to Data Map	What is received from Data Map	What is received from Microsoft Defender for Cloud Apps
		and label data	
Microsoft Purview Data Loss Prevention (DLP)	- DLP policies and configuration	- Classification data - Policy hit audit events and policy distribution acknowledgment status	N/A
Microsoft Purview Information Protection	- Label definitions, policies, and configurations -Label insights and aggregations for Microsoft 365 - Microsoft Information Protection policies and configurations - Classification data for Microsoft 365 - Asset metadata for Microsoft 365 - Telemetry data for protection policies and labels	- Label insights and aggregations - Classification data - Tenant roles, role groups, and license information - Scan setup and execution details - Asset metadata (owner and additional information including name, path, consent status) - Policy hit audit events and policy distribution acknowledgment status	N/A
Microsoft Purview Insider Risk Management	N/A	N/A	- Cloud app events (activity log) and connection status
Microsoft Purview Policy	N/A	- Label names, policies and Ids - Policy definition	N/A

Last updated on 04/01/2026

Microsoft Purview extensibility and Development Partners

Microsoft Purview solutions help organizations intelligently assess their compliance risks, govern and protect sensitive data, and effectively respond to regulatory requirements. Microsoft Purview offers many extensibility scenarios and enables organizations to adapt, extend, integrate, accelerate, and support their compliance solutions.

Three key building blocks support extensibility in Microsoft Purview:

- **Data connectors**. Use these connectors to import and archive non-Microsoft data so you can apply Microsoft 365 protection and governance capabilities to third-party data.
- **APIs**. APIs enable programmatic access to Microsoft Purview capabilities.
- **Software Developer Partner Integrations:** Microsoft Purview enables software development companies to embed advanced data security capabilities directly into their applications.

Data connectors

Microsoft provides third-party data connectors that you can configure in the Microsoft Purview portal. For a list of data connectors provided by Microsoft, see the Third-party data connectors table. The table of third-party data connectors also summarizes the compliance solutions that you can apply to third-party data after you import and archive data in Microsoft 365, and links to the step-by-step instructions for each connector.

Prerequisites for data connectors

Many of the data connectors available in the Microsoft Purview portal allow you to import and archive third-party data but require you to prepare and perform configuration tasks in the third-party data source. The documentation details these prerequisites for each third-party data connector.

For data connectors in the Microsoft Purview portal or the Microsoft Purview portal provided by one of Microsoft's partners, your organization needs a business relationship with the partner before you can deploy a connector.

For guidance and requirements for third-party data connectors, see the "Data connectors" section in Microsoft 365 guidance for security & compliance.

APIs

Microsoft Purview and Microsoft Priva APIs are available in the Microsoft Information Protection SDK, Microsoft Graph API, and the Office 365 Management Activity API. Some compliance APIs are part of a new set of security and compliance APIs that enable developers for Microsoft 365 customers, independent software publishers, system integrators, and managed security service providers to build high-value security and compliance solutions.

To learn more about how to access Graph APIs, see Overview of Microsoft Graph.

Microsoft Information Protection (MIP) SDK

The MIP SDK exposes the labeling and encryption services from the Microsoft Purview portal to third-party applications and services. Developers can use the SDK to build native support for applying labels and protection to files. Developers can determine which actions to take when specific labels are detected, and reason over MIP-encrypted information.

High-level MIP SDK use cases include:

- A line-of-business application that applies classification labels to files on export.
- A CAD/CAM design application that provides native support for sensitivity labels.
- A cloud access security broker or data loss prevention solution that can encrypt data with rights management.

For more information about the MIP SDK, prerequisites, additional scenarios, and samples, see MIP SDK Overview.

Microsoft Graph API for Teams DLP

Data loss prevention (DLP) capabilities are widely used in Microsoft Teams, particularly as organizations shift to remote work. Recently, we announced the general availability of the Microsoft Graph Change Notification API for messages in Teams. This API enables developers to build apps that can listen to Microsoft Teams messages in near-real time and then implement DLP scenarios for both customers and partners. Additionally, Microsoft Graph Patch API lets you apply DLP actions to Teams messages.

These two APIs form the Microsoft Graph API for Teams DLP. You can get started by trying out the sample app. For more information about Microsoft Teams messaging webhooks, see the documentation.

For the licensing requirements for Teams DLP, see Microsoft 365 licensing guidance for security & compliance.

Microsoft Graph API for eDiscovery

With eDiscovery, organizations can discover data where it lives and manage more end-to-end eDiscovery workflows with intelligent machine learning and analytics capabilities to reduce data to the relevant set – all while the data stays within the Microsoft 365 security and compliance boundary.

You can use Graph APIs for eDiscovery to create and manage cases, review sets, and review set queries in a scalable and repeatable manner. This approach enables customers and partners to create apps and workflows to automate common and repetitive processes such as creating cases and managing custodians and legal holds.

For the licensing requirements for eDiscovery and the API, see the "eDiscovery" section in the Microsoft 365 licensing guidance for security & compliance.

Microsoft Graph API for Teams Export

Enterprise Information Archiving (EIA) for Microsoft Teams is a key scenario for our customers as it allows them to solve for regulatory requirements. In addition to our built-in capabilities for archiving content in Microsoft Teams, customers and partners can now use Teams Export APIs to solve for custom application and integration scenarios. The Teams Export APIs support bulk-export (up to 200 requests per second/per app/per tenant) of Teams messages and message attachments. Deleted messages are also accessible by the API for up to 30 days after they're deleted. For more information about these Teams Export APIs and how to use them in your applications, see Export content with the Microsoft Teams Export APIs.

For the licensing requirements for the use of the Teams Export APIs, see Microsoft 365 licensing guidance for security & compliance.

Microsoft Graph Connector APIs (preview)

With Microsoft Graph connectors, organizations can index third-party data so it appears in Microsoft Search results. This feature expands the types of content sources that are searchable in

your Microsoft 365 productivity apps and the broader Microsoft ecosystem. The third-party data can be hosted on-premises or in public or private clouds. Starting with eDiscovery (Premium), we're enabling developer preview of built-in compliance value of Microsoft 365 connected apps. This capability enables compliance for apps integrating into the Microsoft 365 ecosystem to empower users with seamless compliance experiences. To learn more about how to incorporate Microsoft Graph Connector APIs in your apps, see Create, update, and delete connections in the Microsoft Graph.

Microsoft Graph API for records management

Organizations of all types need a records management solution to manage critical records across their data. Microsoft Purview Records Management helps an organization manage its legal obligations, provides the ability to demonstrate compliance with regulations, and increases efficiency with regular disposition of items that are no longer required.

Organizations use the records management solution to protect, label, retain, or delete their data. The Microsoft Graph APIs for records management help organizations manage retention labels and their associated actions more efficiently, automate repetitive tasks, and equip customers with flexibility in options.

The first release of Graph APIs for records management supports the management of retention labels and event-based retention. Example scenarios include:

- **Managing retention labels**

  Record management admins and developers need to maintain their record management systems with labels that they periodically create, update, and delete.

  Developers and compliance admins use the Graph APIs for records management to perform CRUD operations on the label entity to maintain their systems.

- **Triggering an event for an existing label**

  When an employee leaves an organization, the information is updated in the HR management system. From the date of leaving, confidential documents need to be retained for seven years. These documents already have the retention label "Employee_departure" applied to them.

  Developers and compliance admins use the Graph APIs for records management to read the label “Employee_departure” and look up the associated event type "Event-employee_departure".

They then use the Graph APIs for records management to create an event for the associated event type. The retention period for the confidential documents starts after this event is created.

For more information about the Graph APIs for records management, see Use the Microsoft Graph Records Management API.

For licensing requirements to use these APIs, see the records management information from the Microsoft 365 guidance for security & compliance, Microsoft Purview Data Lifecycle Management & Microsoft Purview Records Management section.

Microsoft Graph API for retention labels in SharePoint and OneDrive for Business

Retention labels are part of the Microsoft Purview Data Lifecycle Management solution and apply governance at the driveitem level. Retention labels support more capabilities than retention policies and can handle exceptions within a location. For more information on retention labels, see Create retention labels for exceptions to your retention policies.

With the Microsoft Graph APIs for retention labels, organizations can programmatically apply and manage these labels on items in SharePoint and OneDrive for Business to automate their processes.

These Graph APIs support the following tasks:

- **Apply a retention label to an item**
- **Remove a retention label from an item**
- **Get metadata information on the retention label applied to an item**
- **Lock or unlock the record label applied to an item**

For licensing requirements to use these APIs, see the records management information from the Microsoft 365 guidance for security & compliance, Microsoft Purview Data Lifecycle Management & Microsoft Purview Records Management section.

Software Developer Partner Integrations

Microsoft Purview enables software development companies to embed advanced data security capabilities directly into their applications. Using available SDKs and APIs, developers can build solutions that apply classification, labeling, protection, and retention policies natively within their workflows. These integrations enable automation, consistent policy enforcement, and unified

governance across diverse environments—helping companies meet regulatory requirements and streamline compliance processes at scale.

Network Data Security

Microsoft Purview Network Data Security enables real-time protection by intercepting and inspecting network traffic using the Purview DLP engine. Through deep integration with SASE and next-generation firewall platforms, it extends Purview classification and policy enforcement capabilities to the network layer based on customer-defined data loss prevention and collection policies. This enables:

- Granular control over sensitive data flows across both sanctioned and unsanctioned applications.
- Blocking exfiltration and unauthorized sharing with generative AI tools, cloud services, storage platforms, and social media.
- Deep integration with Purview insights and solutions, including Data Security Posture Management (DSPM) and Insider Risk Management (IRM).
- Stronger compliance for AI interactions through content capture that supports eDiscovery, retention, deletion, and related regulatory workflows.

The following list of partners have successfully built a Network Data Security integration:

Partner	Partner documentation	Description
iboss	iboss deployment guide	iboss Zero Trust Integrates with Purview DLP for secure access and network data classification.
Netskope	Netskope deployment guide	Netskope One Integrates with Purview DLP to inspect and classify network traffic for data protection.

For more information on building integrations with Microsoft Purview, see Use Microsoft Purview APIs to support data security and governance in your apps. To get listed in the above table of integration partners, register your interest using the following form: Microsoft Purview Network Data Security partner integration checklist.

Microsoft Purview for Generative AI Apps integration

As generative AI tools become embedded in business processes, Microsoft Purview enables security, compliance, and data teams to discover and monitor AI usage, safeguard sensitive information in prompts and outputs, and enforce organizational policies—helping organizations innovate responsibly while reducing risk and meeting regulatory requirements. Developers can use the Microsoft Purview SDK to integrate these protections directly into their AI solutions, extending Purview's coverage across the enterprise AI ecosystem. Visit the following documentation for guidance on building this integration: Use the Microsoft Purview SDK with Agent Framework.

Implementing Zero Trust with Microsoft Purview

Microsoft Purview solutions can help you implement a Zero Trust security strategy that is based on the following security principles:

Expand table

Verify explicitly	Use least privilege access	Assume breach
Always authenticate and authorize based on all available data points.	Limit user access with Just-In-Time and Just-Enough-Access (JIT/JEA), risk-based adaptive policies, and data protection.	Minimize blast radius and segment access. Verify end-to-end encryption and use analytics to get visibility, drive threat detection, and improve defenses.

Microsoft Purview is a primary component of the **Use least privilege access** principle by providing data protection solutions. Use Purview capabilities to help you safeguard your data across platforms, apps, and clouds.

Zero Trust to protect data

Microsoft Purview provides the following capabilities and options for a data defense in depth strategy and a Zero Trust implementation for data protection:

- **Data classification**: So you can know your data

  Discover and detect sensitive data across your entire organization, so that you can better protect it. For more information, see Classifiers overview and Reports.

- **Information protection**: So you can protect your data

  Apply sensitivity labels to integrate with Microsoft 365 Copilot and other apps and services to provide access control guardrails, and encryption with rights management for your most sensitive data. Content markings, such as footers and watermarks, can increase awareness and security policy compliance. While users create or update content, the highly visible labels and labeling recommendations support user education about sensitive data. For more information, see Learn about sensitivity labels.

  When you use sensitivity labels with protection policies, you can automatically enforce access restrictions across your data estate the moment sensitive information is detected.

- **Data loss prevention (DLP)**: So you can prevent data loss

Users sometimes take risks with your organization's sensitive data, which might result in a data security or compliance incident. Data loss prevention helps you monitor for and protect against risky oversharing of sensitive data. As with sensitivity labeling, policy tips support user education about sensitive data. For more information, see Learn about data loss prevention.

- **Insider Risk Management**: So you can identify and take action against risky security-related user activities and data activity patterns

  Correlate various signals to identify and take action on potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. For more information, see Learn about Insider Risk Management.

- **Data lifecycle management**: So you can delete what you don't need, and safeguard important data

  Deploy policies to manage the lifecycle of sensitive data to reduce data exposure. Limit the number of copies or propagation of sensitive data by automatically and permanently deleting it when it's no longer needed. Or conversely, protect important data from malicious or accidental deletes by automatically retaining a copy in a secured location after a user deletes the data. For more information, see Learn about data lifecycle management.

Supporting tools and technologies:

> **Note**
>
> Now in preview, use Microsoft Data Security Posture Management (DSPM) to help you discover, protect, and investigate sensitive data risks across your digital estate. Unifying other Microsoft Purview solutions, DSPM provides visibility and control for both traditional applications and AI apps and agents, so you can monitor, assess, and remediate data risks regardless of where sensitive data resides.

- As you implement these capabilities, use appropriate role-based permissions and administrative units to provide Just-Enough-Access and segment access. Augment these protective measures with privileged access management for Just-In-Time access.

- Consider your encryption requirements for specific scenarios, for example:
  - Microsoft 365 Copilot
  - Use your sensitivity labels to apply Double Key Encryption to selected documents and emails when only your organization and no cloud services should be able to decrypt them.

    - Use Advanced Message Encryption if you need to keep sensitive content within your organization boundary, log external mail access, or revoke access to encrypted emails.
    - Use Customer Key if you need to control the root encryption keys for Microsoft 365 data at-rest.
    - If you use Conditional Access or cross-tenant access settings, these services need specific configurations to support encrypted content.

- For high-value documents and emails, records management supports additional restrictions and a disposition review process.

- Consider using information barriers if you need to segment access between specific users by restricting two-way communication and collaboration between groups and users in Microsoft Teams, SharePoint, and OneDrive.

- Additional governance options:
    - Access policies in the Microsoft Purview Unified Catalog allow users to request access to data, but also give you the tools to ensure they only have access to the data they need, and only for as long as they need it.
    - Use the data sharing app to minimize data duplication and instead, provide read-only access that you can time-limit or remove the access.

- Consider using Compliance Manager to help drive the adoption of and monitor the implementation of security features and configurations. Easy-to-build assessments with automatic monitoring help you stay on track with requirements across your multicloud environment.

- Use auditing solutions to help you monitor Microsoft 365 data and respond to security events.

- Use Customer Lockbox to ensure Microsoft service engineers must obtain approval before accessing any Microsoft 365 data you own during a support investigation.

Next steps

Solution guidance to help you implement a Zero Trust strategy for data protection by using Microsoft Purview:

- Deploy an information protection solution with Microsoft Purview
- Deploy a data governance solution with Microsoft Purview

Because data protection helps protect personal data stored and managed by your organization, see also Manage data privacy and data protection with Microsoft Priva and Microsoft Purview.

Help dynamically mitigate risks with Adaptive Protection

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Adaptive protection in Microsoft Purview uses machine learning to identify the most critical risks and proactively and dynamically apply protection controls from:

- Microsoft Purview Data Loss Prevention (DLP)
- Microsoft Purview Data Lifecycle Management (preview)
- Microsoft Entra Conditional Access (preview)

Integration with data loss prevention, data lifecycle management, and Conditional Access helps organizations automate their response to insider risks and reduces the time required to identify and remediate potential threats. By using the capabilities of all four solutions, organizations can create a more comprehensive security framework that addresses both internal and external threats.

> **Important**
>
> To learn about licensing requirements for using Adaptive Protection with data loss prevention, data lifecycle management, and Conditional Access, see Microsoft 365, Office 365, Enterprise Mobility + Security, and Windows 11 Subscriptions.

Adaptive protection helps mitigate potential risks by using:

- **Context-aware detection**. Helps identify the most critical risks with ML-driven analysis of both content and user activities.
- **Dynamic controls**. Helps enforce effective controls on high-risk users while others maintain productivity.

- **Automated mitigation**. Helps minimize the impact of potential data security incidents and reduce admin overhead.

Adaptive protection dynamically assigns appropriate data loss prevention, data lifecycle management, and Conditional Access policies to users based on the insider risk levels defined and analyzed by the machine learning models in Insider Risk Management. Policies become adaptive based on user context, ensuring that the most effective policy, such as blocking data sharing through data loss prevention or blocking application access through Conditional Access, is applied only to high-risk users while low-risk users maintain productivity. Data loss prevention and Conditional Access policy controls constantly adjust, so when a user's insider risk level changes, an appropriate policy dynamically applies to match the insider new risk level. In the case of data lifecycle management, Insider Risk Management detects *Elevated risk level* users and preserves their deleted data for 120 days by using an automatically created data lifecycle management retention label policy.

> **Important**
>
> Insider Risk Management is currently available in tenants hosted in geographical regions and countries supported by Azure service dependencies. To verify that the Insider Risk Management solution is supported for your organization, see Azure dependency availability by country/region. Insider Risk Management is available for commercial clouds but isn't available for US Government cloud programs at this time.

Watch the following video for a summary of how Adaptive Protection can help identify and mitigate the most critical risks in your organization:

https://learn-video.azurefd.net/vod/player?id=9487d97b-4306-4a17-abb8-1008d4c63325&locale=en-us&embedUrl=%2Fpurview%2Finsider-risk-management-adaptive-protection

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Insider risk levels and preventive controls

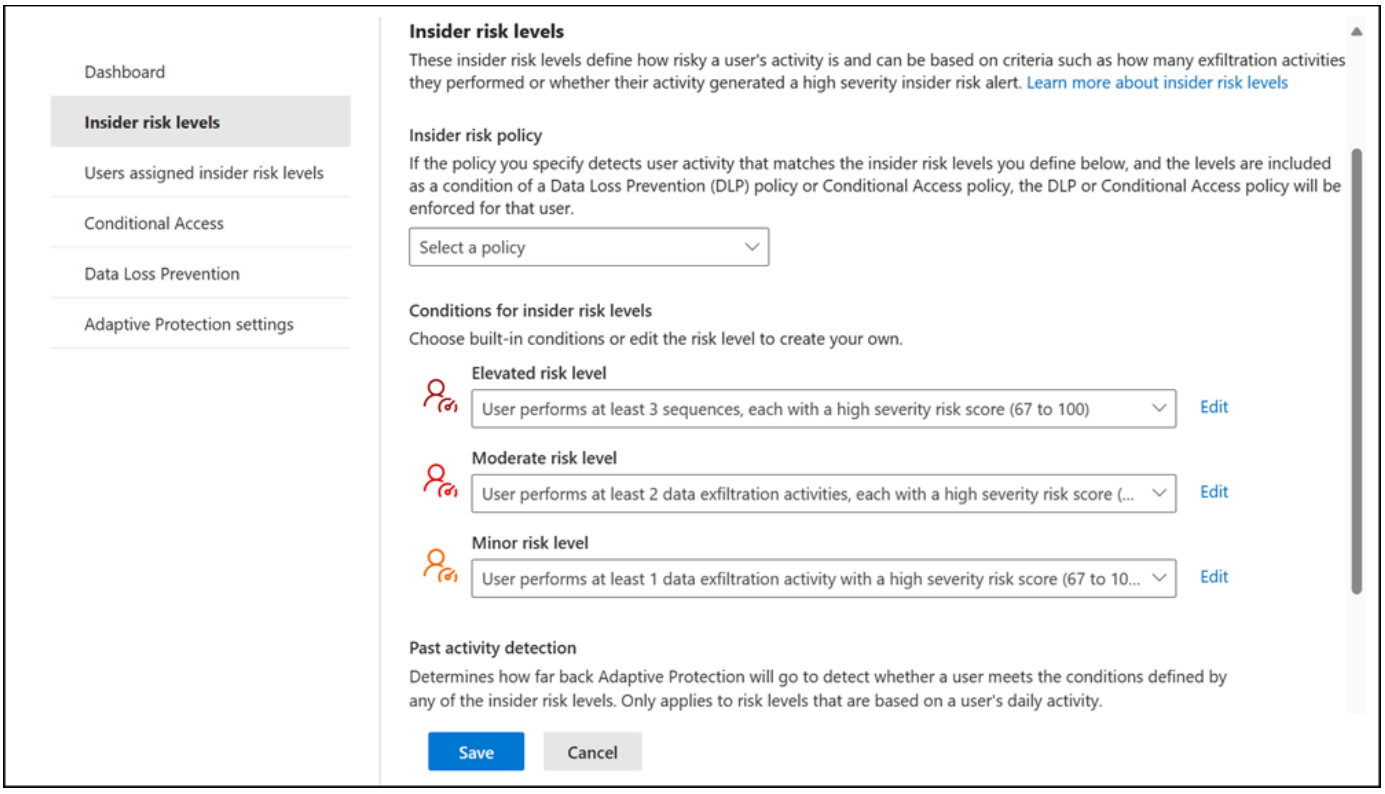
With Adaptive Protection, administrators can configure risk factors or activities for customizable insider risk levels based on your organization's needs. The insider risk levels for Adaptive Protection update continuously and automatically based on the users' risk factors and insights. When users' data security risks increase or decrease, their insider risk levels adjust accordingly. Based on the insider risk levels, data loss prevention policies and Conditional Access policies automatically apply the right level of preventative controls as configured by admins, such as *block*, *block with override*, or *warning*.

> **Tip**
>
> *Insider risk levels* in Adaptive Protection differ from *alert severity levels* that assign Insider Risk Management users based on activity detected in Insider Risk Management policies.
>
> - Insider risk levels (Elevated, Moderate, or Minor), as described in this article, measure risk determined by admin-defined conditions such as the number of exfiltration activities users perform in a day or whether their activity generated a high-severity insider risk alert.
> - Alert severity levels (Low, Medium, or High) assign to users based on activity detected in Insider Risk Management policies. These levels calculate based on alert risk scores assigned to all active alerts associated with the user. These levels help insider risk analysts and investigators prioritize and respond to user activity accordingly.

For data lifecycle management, the data lifecycle management policy monitors users that assign an *Elevated risk level* by Insider Risk Management Adaptive Protection. When a risky user deletes any content from SharePoint, OneDrive, or Exchange Online, the contents are automatically preserved for 120 days. Admins can contact Microsoft support to restore any preserved content.

Depending on the Insider Risk Management policy assigned in Adaptive Protection, different criteria (users, groups, indicators, thresholds, etc.) are used to determine applicable insider risk levels. Insider risk levels are based on user insights, not solely on the number of instances of specific user activities. Insights are a calculation of the aggregate number of activities and the severity level of these activities.

For example, insider risk levels for User A wouldn't be determined by User A performing a potentially risky activity more than three times. The insider risk levels for User A would be determined by an insight of the aggregate number of activities and risk scores would be assigned to the activity based on the thresholds configured in the selected policy.



Insider risk levels

Insider risk levels in Adaptive Protection define how risky a user's activity is and can base on criteria such as how many exfiltration activities they performed or whether their activity generated a high severity insider risk alert. These insider risk levels have built-in insider risk level definitions, but you can customize these definitions as needed:

- **Elevated risk level**: This risk level includes built-in definitions for users with high severity alerts, users with at least three sequence insights that each have a high severity alert for specific risk activities, or one or more confirmed high severity alerts.
- **Moderate risk level**: This risk level includes built-in definitions for users with medium severity alerts or users with at least two data exfiltration activities with high severity scores.
- **Minor risk level**: This risk level includes built-in definitions for users with low severity alerts or users with at least one data exfiltration activity with a high severity score.

For an insider risk level to assign to a user, the number of insights and the severity assigned to the activity need to match the definition for the insider risk level. The number of activities for an insight might be a single activity or multiple activities accruing to the single insight. The number of insights evaluates for the insider risk level definition, not the number of activities contained in an insight.

For example, suppose the conditions in the Insider Risk Management policy assigned to Adaptive Protection scope for identifying downloads from SharePoint sites in your organization. If the policy detects that a user downloaded 10 files from a SharePoint site in a single day that are determined to be high severity, this counts as a single insight that consists of 10 activity events. To qualify for assigning an *Elevated risk level* to the user, two additional insights (with high severity) require for the user. The additional insights might or might not contain one or more activities.

Customizing insider risk levels

Custom insider risk levels enable you to create insider risk levels that fit your organization's needs. You can customize the criteria for the insider risk level and define conditions for when to assign the insider risk level to users.

Consider the following examples for using Adaptive Protection together with data loss prevention, data lifecycle management, and Conditional Access policies.

- **Data loss prevention policies**:
  - Allow users with the *Minor risk level* or *Medium risk level* to receive policy tips and education on best practices for handling sensitive data. With this approach, you can influence positive behavior changes over time and reduce organizational data risks.
  - Block users with the *Elevated risk level* from saving or sharing sensitive data to minimize the impact of potential data incidents.
- **Data lifecycle management policy**:
  - Preserve any SharePoint, OneDrive, or Exchange Online content deleted by a risky user for 120 days. A risky user in this case is a user that Adaptive Protection assigns the *Elevated risk level*.
- **Conditional Access policies**:
  - Require *Minor risk level* users to acknowledge Terms of Use before using an application.
  - Block *Medium risk level* users from accessing certain applications.

- Completely block *Elevated risk level* users from using *any* applications. Learn more about commonly applied Conditional Access policies

Insider risk level criteria and conditions

You can customize insider risk level criteria and conditions based on the following areas:

- **Alerts generated or confirmed for a user**: Choose conditions based on the severity level for alerts that the selected Insider Risk Management policy generates or confirms for a user. Conditions for alerts aren't additive. The insider risk level is assigned to a user if one of the conditions is met.
- **Specific user activity**: Choose conditions for activity to detect, its severity, and the number of daily occurrences during the past activity detection window (optional). Conditions for user activity are additive. The insider risk level is assigned to a user only if all the conditions are met.

Past activity detection

The **Past activity detection** setting determines how many days back Adaptive Protection examines to detect whether a user meets the conditions defined by any of the insider risk levels. The default setting is 7 days, but you can choose between 5 and 30 days of previous activity to apply insider risk level conditions. This setting only applies to insider risk levels that are based on a user's daily activity and excludes insider risk levels based on alerts.

The following example illustrates how past activity detection settings and insider risk levels interact to determine if a user's past activity is in-scope:

- **Elevated risk level** setting: User performs at least three sequences, each with a high severity risk score (67 to 100)
- **Past activity detection** setting: 3 days

Expand table

User activity	Activity in-scope for insider risk level
User has 1 high severity sequence each day on Day T-3, T-2, T-1	Yes
User has 1 high severity sequence on Day T-4 and 2 high severity sequences on Day T-3	No
User has 3 high severity sequences on Day T-3	Yes

Insider risk level timeframe

The **Insider risk level timeframe** setting determines how long an insider risk level remains assigned to a user before it's automatically reset. The default setting is 7 days, but you can choose between 5 and 30 days before resetting the insider risk level for a user.

Insider risk levels also reset for a user when:

- The associated alert for the user is dismissed.
- The associated case for the user is resolved.
- The insider risk level end date is manually expired.

> **Note**
>
> If a user is currently assigned an insider risk level and that user meets the criteria again for that insider risk level, the insider risk level timeframe extends for the defined number of days for the user.

Risk level expiration options

When you enable the automatic expiration option (enabled by default), Adaptive Protection risk levels for a user automatically expire when the associated alert for a user is dismissed or the associated case for the user is closed. If you want to keep the Adaptive Protection risk level for a user even if the alert is dismissed or the case is closed, disable the option.

Permissions for Adaptive Protection

> **Important**
>
> To learn about licensing requirements for using Adaptive Protection with data loss prevention, data lifecycle management, and Conditional Access, see Microsoft 365, Office 365, Enterprise Mobility + Security, and Windows 11 Subscriptions.

Depending on how you use Insider Risk Management built-in role groups and role groups for data loss prevention or Conditional Access, you might need to update Insider Risk Management permissions for administrators, analysts, and investigators in your organization.

The following table describes the permissions required for specific Adaptive Protection tasks.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Expand table

Task	Required role group
Configure Adaptive Protection and update settings	*Insider Risk Management* or *Insider Risk Management Admins*
Create and manage Conditional Access policies with the Adaptive Protection condition	One of the following: *Global administrator*, *Conditional Access Administrator*, *Security Administrator*
Create and manage data loss prevention policies with the Adaptive Protection condition	One of the following: *Compliance Administrator*, *Compliance Data Administrator*, *DLP Compliance Management*, *Global Administrator*
View details on users' or agents' assigned insider risk levels	*Insider Risk Management*, *Insider Risk Management Analysts*, or *Insider Risk Management Investigators*

> **Important**
>
> The four categories of role groups correspond to the following tabs on the Adaptive Protection page: **Insider risk levels**, **Users assigned insider risk levels**, **Data Loss Prevention**, **Conditional Access**. If you're not assigned to the appropriate role group, the tab doesn't appear on the **Adaptive protection** page.

Learn more about role groups in Microsoft Defender for Office 365 and Microsoft Purview compliance

Configure Adaptive Protection

Depending on the needs of your organization or where you're currently configured with Insider Risk Management, data loss prevention, data lifecycle management, and Conditional Access, you have two options to get started with Adaptive Protection:

- Quick setup

- Custom setup

Quick setup

The quick setup option is the fastest way to get started with Adaptive Protection. With this option, you don't need any preexisting Insider Risk Management, data loss prevention, data lifecycle management, or Conditional Access policies. You also don't need to preconfigure any settings or features. If your organization doesn't have a current subscription or license that supports Insider Risk Management, data loss prevention, or data lifecycle management, sign up for a Microsoft Purview risk and compliance solutions trial before starting the quick setup process. You can also sign up for a Microsoft Entra trial for Conditional Access.

To get started, select **Turn on Adaptive Protection** from the Adaptive Protection cards on the Microsoft Purview portal home page or the data loss prevention Overview page. You can also start the quick setup process by going to **Insider Risk Management** > **Adaptive protection** > **Dashboard** > **Quick setup**.

> **Note**
>
> If you're already a scoped admin for Microsoft Purview, you can't turn on quick setup.

Here's what the quick setup process configures for Adaptive Protection:

Expand table

Area	Configuration
A new insider risk policy	- Policy template: Data leaks - Policy name: Adaptive Protection policy for Insider Risk Management - Policy scope for users and groups: All users and groups - Priority content: None - Triggering events: Selected exfiltration events (you can view in Insider Risk Management settings) - Policy indicators: A subset of Office indicators (you can view in Insider Risk Management settings) - Risk score boosters: Activity is over user's usual activity for that day
Adaptive protection insider risk levels	- *Elevated risk level*: Users must have at least three high severity exfiltration sequences - *Moderate risk level*: Users must have at least two high severity activities (excluding some types of downloads) - *Minor risk level*: Users must have at least one high severity activity (excluding some types of downloads)

Area	Configuration
Insider risk settings (if already configured)	- Policy indicators: Office indicators not already configured (you can view in Insider Risk Management settings) - All other settings previously configured aren't updated or changed. - Analytics: On (thresholds for triggering events in policies are the default settings determined by Analytics recommendations)
Insider risk settings (if not already configured)	- Privacy: Show anonymized versions of user names. **Note:** User names aren't anonymized in Conditional Access or data loss prevention. - Policy timeframes: Defaults - Policy indicators: A subset of Office indicators (you can view in Insider Risk Management settings) - Risk score boosters: All - Intelligent Detections: Alert Volume = Default volume - Analytics: On - Admin notifications: Send notification email when first alert is generated to all
New Conditional Access policy (created in Report-only mode so users won't be blocked)	**1-Block access for users with Insider Risk (Preview)** - Included users: All users - Excluded guest or external users: B2bDirectConnect User; OtherExternalUser; ServiceProvider - Cloud apps: Office 365 apps - Insider risk levels: *Elevated* - Block access: Selected
New data lifecycle management policy	An organization-wide autoapply label policy that monitors users assigned the *Elevated risk level*. Any SharePoint, OneDrive, or Exchange Online content deleted by a risky user is preserved for 120 days. If you haven't already turned on Adaptive Protection, the policy is automatically created and applied when you turn on Adaptive Protection. If you have already turned on Adaptive Protection, you need to explicitly opt in to the data lifecycle management policy that's created automatically.
Two new data loss prevention policies	Adaptive Protection policy for Endpoint DLP - *Elevated risk level* rule: Blocked - *Moderate/Minor risk level* rule: Audit - Policy starts in test mode (audit only) Adaptive Protection policy for Teams and Exchange DLP - *Elevated risk level* rule: Blocked - *Moderate/Minor risk level* rules: Audit - Policy starts in test mode (audit only)

After you start the quick setup process, it can take up to 72 hours before the following items are completed:

- Analytics
- Associated Insider Risk Management, data loss prevention, data lifecycle management, and Conditional Access policies
- Adaptive Protection insider risk levels, data loss prevention, data lifecycle management, and Conditional Access actions applied to applicable user activities.

> **Note**
>
> Once you enable Adaptive Protection, don't disable it before the setup process completes. Disabling Adaptive Protection before the setup process completes might lead to policy errors.

Administrators receive a notification email when the quick setup process completes.

Custom setup

The custom setup option lets you customize the Insider Risk Management policy, the insider risk levels, and the data loss prevention and Conditional Access policies configured for Adaptive Protection.

> **Note**
>
> For data lifecycle management, if you don't turn on Adaptive Protection, the policy isn't created and applied automatically. If you turn on Adaptive Protection for your organization, you need to **explicitly opt in to apply the data lifecycle management policy**.

The custom setup option also lets you configure these items before enabling the Adaptive Protection connections between Insider Risk Management and data loss prevention. In most cases, use this option if your organization already has Insider Risk Management and data loss prevention policies in place.

Complete the following steps to configure Adaptive Protection by using the custom setup.

Step 1: Create Insider Risk Management policy

Assign insider risk levels to users or agents when a policy assigned in Adaptive Protection either detects user or agent activity or generates alerts that match the insider risk level conditions you define in the next step. If you don't want to use an existing Insider Risk Management policy,

create a new Insider Risk Management policy. Your Insider Risk Management policy for Adaptive Protection should include:

- **Users whose activity you want to detect**. This group can include all users and groups in your organization or just a subset for specific risk mitigation scenarios or testing purposes.
- **Activities you consider risky and custom thresholds that influence an activity's risk score**. Risky activities might include emailing people outside your organization or copying files to USB devices.

Select **Create insider risk policy** to start the new policy workflow. The Data leaks policy template is automatically selected in the workflow, but you can select any policy template.

> **Important**
>
> Depending on the policy template you select, you might need to configure additional settings for the policy to properly detect potentially risky activities and to create applicable alerts.

Step 2: Configure insider risk level settings

Select the **Insider risk levels** tab. Start by selecting the Insider Risk Management policy you want to use for Adaptive Protection. This policy can be the new policy you created in Step 1 or an existing policy or policies that you already configured.

Next, accept the applicable built-in insider risk level conditions or create your own. Depending on the type of policy you select, the insider risk level conditions reflect the applicable conditions associated with indicators and activities you configure in the policy.

For example, if you choose a policy based on the Data leaks policy template, the built-in insider risk level condition choices apply to indicators and activities available in that policy. If you select a policy based on the Security policy violations policy template, the built-in insider risk level conditions automatically scope to indicators and activities available in that policy.

Customize an insider risk level for your policy

1. Sign in to the Microsoft Purview portal by using credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Adaptive protection** in the left navigation, then select **Insider risk levels**.

4. On the **Insider risk levels** page, select **Edit** for the insider risk level you want to customize (*Elevated*, *Moderate*, or *Minor*).

5. On the **Custom insider risk level** pane, select an option in the **Insider risk level based on** section:

   - **Alert generated or confirmed for a user**
   - **Specific user activity**

6. If you select the **Alert generated or confirmed for a user** option, choose the severity levels for alerts that are generated or confirmed for a user that should use this insider risk level. You can keep the *Severity for generated alerts* and the *Severity for confirmed alerts* conditions or remove one of these conditions if you only want to use one. If you need to add one of these conditions back, select **Add condition**, then select the condition. For each condition, choose the severity level that should be applied for the condition (*High*, *Medium*, or *Low*). If the **any** of the conditions are met, the insider risk level is assigned to a user.

7. If you select the **Specific user activity** option, choose the activity to detect, its severity, and number of daily occurrences during the past activity detection window. You must configure the *Activities*, *Activity severity*, and *Activity occurrences during detection window* conditions for this insider risk level.

   For the *Activities* condition, the options you can choose from automatically update for the types of activities you define with the indicators configured in the associated policy. If needed, select the **Assign this insider risk level to any user who has a future alert confirmed, even if conditions above aren't met** checkbox. If the **all** of the conditions are met, the insider risk level is assigned to a user.

   For the *Activity severity* condition, specify the severity level for the activities included in the daily activity insight. The options are *High*, *Medium*, and *Low*, and are based on risk score ranges.

   For the *Activity occurrences during detection window* condition, specify the number of times selected activities must be detected within the specified *Past activity detection* period. This number isn't related to the number of events that might occur for an activity. For example, if the policy detects that a user downloaded 20 files from SharePoint in one day, that count is one daily activity insight consisting of 20 events.

8. Select **Confirm** to apply the custom insider risk level conditions.

How insider risk level is assigned if a user is in scope for multiple policies

If a user is in scope for multiple policies and receives alerts of different severity levels, the user is assigned the highest severity level received. For example, consider a policy that assigns an *Elevated risk level* if users receive a high severity alert. If a user receives a low-severity alert from policy 1, a medium-severity alert from policy 2, and a high-severity alert from policy 3, the user is assigned an *Elevated risk level* - the level for the highest alert severity received.

Insider risk level conditions must be present in selected policies to be detected. For example, if you select the *Copy to USB* activity to assign a *Moderate risk level*, but the activity is selected in just one of three selected policies, then only activity from that one policy assigns a *Moderate risk level* for that activity.

Step 3: Create or edit a data loss prevention policy

Next, create a new data loss prevention policy or edit an existing policy to restrict actions for users who match your insider risk level conditions in Adaptive Protection. Use the following guidelines for your data loss prevention policy configuration:

- You must include the *User's insider risk level for Adaptive Protection is* condition in your data loss prevention policy. This data loss prevention policy can include other conditions as needed.
- Although you can include other locations in the data loss prevention policy, Adaptive Protection currently supports only Exchange, Microsoft Teams, and devices.

Select **Create policy** to start the data loss prevention policy workflow and create a new data loss prevention policy. If you have an existing data loss prevention policy that you'd like to configure for Adaptive Protection, go to **Data loss prevention** > **Policies** in the Microsoft Purview portal and select the data loss prevention policy you'd like to update for Adaptive Protection. For guidance on how to configure a new data loss prevention policy or update an existing data loss prevention policy for Adaptive Protection, see Learn about Adaptive Protection in data loss prevention: Manual configuration.

> **Tip**
>
> We recommend testing the data loss prevention policy (with policy tips) so you can review data loss prevention alerts to verify that the policy is working as expected before enabling Adaptive Protection.

Step 4: Create or edit a Conditional Access policy

Next, create a new Conditional Access policy or edit an existing policy to restrict actions for users who match your insider risk level conditions in Adaptive Protection. Use the following guidelines for your Conditional Access policy configuration:

- On the Conditional Access page where you control access based on signals from conditions, set the *Insider risk* condition to *Yes*, and then select an insider risk level (*Elevated*, *Moderate*, or *Minor*). This is the insider risk level that users must have in order for the policy to be enforced.

Select **Create policy** to start the Conditional Access policy workflow and create a new Conditional Access policy. If you have an existing Conditional Access policy that you'd like to configure for Adaptive Protection, go to **Protection** > **Conditional Access** in the Microsoft Entra admin center and select the Conditional Access policy you'd like to update for Adaptive Protection. For guidance on how to configure a new Conditional Access policy or update an existing Conditional Access policy for Adaptive Protection, see Common Conditional Access policy: Insider risk based policy.

Step 5: Turn on Adaptive Protection

After you complete the Insider Risk Management policy, insider risk level, DLP policy, and Conditional Access policy configuration steps, you're ready to enable Adaptive Protection. When you turn on Adaptive Protection:

- The Insider Risk Management policy starts looking for user activity matching your insider risk level conditions. If detected, the insider risk levels are assigned to users.
- Users who are assigned insider risk levels appear on the **Users assigned insider risk levels** tab in Adaptive Protection.
- The data loss prevention policy applies protection actions for any user assigned to insider risk levels included in the data loss prevention policy. The data loss prevention policy is added to the **Data Loss Prevention** tab in **Adaptive protection**. You can view details about the data loss prevention policy and edit policy conditions from the dashboard.
- The data lifecycle management policy, which is automatically created, applies protection actions for any user assigned to the *Elevated risk level*. The following message appears with a green background on the **Adaptive Protection** tab to let users know that proactive data preservation is being applied: "Your organization is also being dynamically protected from users who might potentially delete critical data." The message also provides a link to the

data lifecycle management setting where you can turn off the proactive data preservation feature, if desired.

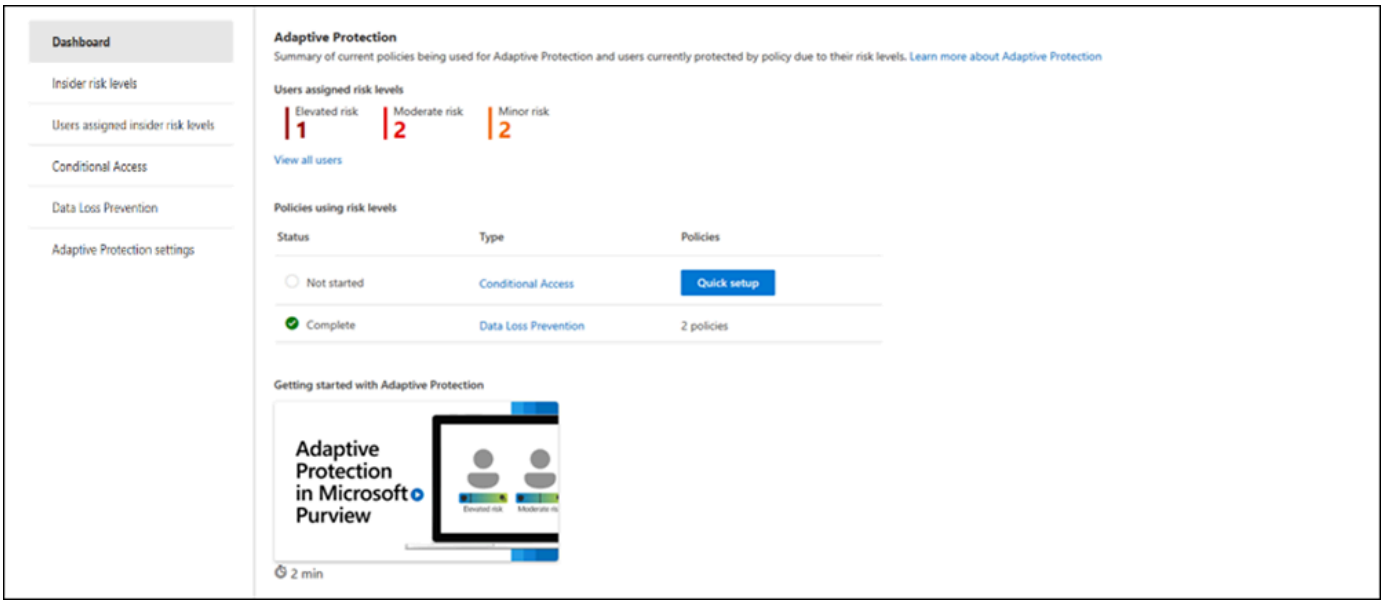
- The Conditional Access policy applies protection actions for any user assigned to insider risk levels included in the Conditional Access policy. The Conditional Access policy is added to the **Conditional Access policies** tab in **Adaptive protection**. You can view details about the Conditional Access policy and edit policy conditions from the dashboard.

To enable Adaptive Protection, select the **Adaptive Protection settings** tab, and then turn **Adaptive Protection** to *On*. It might take up to 36 hours before you can expect to see Adaptive Protection insider risk levels and data loss prevention, data lifecycle management, and Conditional Access actions applied to applicable user activities.

Watch the following video on the Microsoft Mechanics channel to see how Adaptive Protection can automatically adjust the strength of data protection based on calculated data security insider risk levels of users.

Manage Adaptive Protection

When you enable Adaptive Protection and configure your Insider Risk Management, data loss prevention, and Conditional Access policies, you can access information about policy metrics, users currently included, and insider risk levels currently in scope.



> **Note**
>
> Data lifecycle management metrics don't currently appear on the dashboard. However, if proactive data preservation is turned on, you see the following message on the **Adaptive Protection** tab: "Your organization is also being dynamically protected from users who might potentially delete critical data."

Use the Adaptive Protection dashboard

After you complete either the Quick setup or Custom setup process, the **Dashboard** tab in **Adaptive protection** displays widgets for summary information about user insider risk levels, Conditional Access policies, and data loss prevention policies.

- **Users assigned insider risk levels**: Shows the number of users for each insider risk level (*Elevated*, *Moderate*, and *Minor*).
- **Policies using insider risk levels**: Shows the status of policies (*Not started* or *Complete*), the type of policy (*Conditional Access* or *Data Loss Prevention*), and the number of configured

policies for each type of policy. If a policy type isn't configured, select **Quick setup** to configure the policy.

View users assigned insider risk levels

The **Users assigned insider risk levels** tab shows users assigned an insider risk level in Adaptive Protection. You can review the following information for each user:

- **Users**: Lists the user name. For data loss prevention policies, if the Show anonymized versions of usernames option is selected in Insider Risk Management settings, you see anonymized user names. For Conditional Access policies, user names aren't anonymized even if the **Show anonymized versions of usernames** setting is selected.

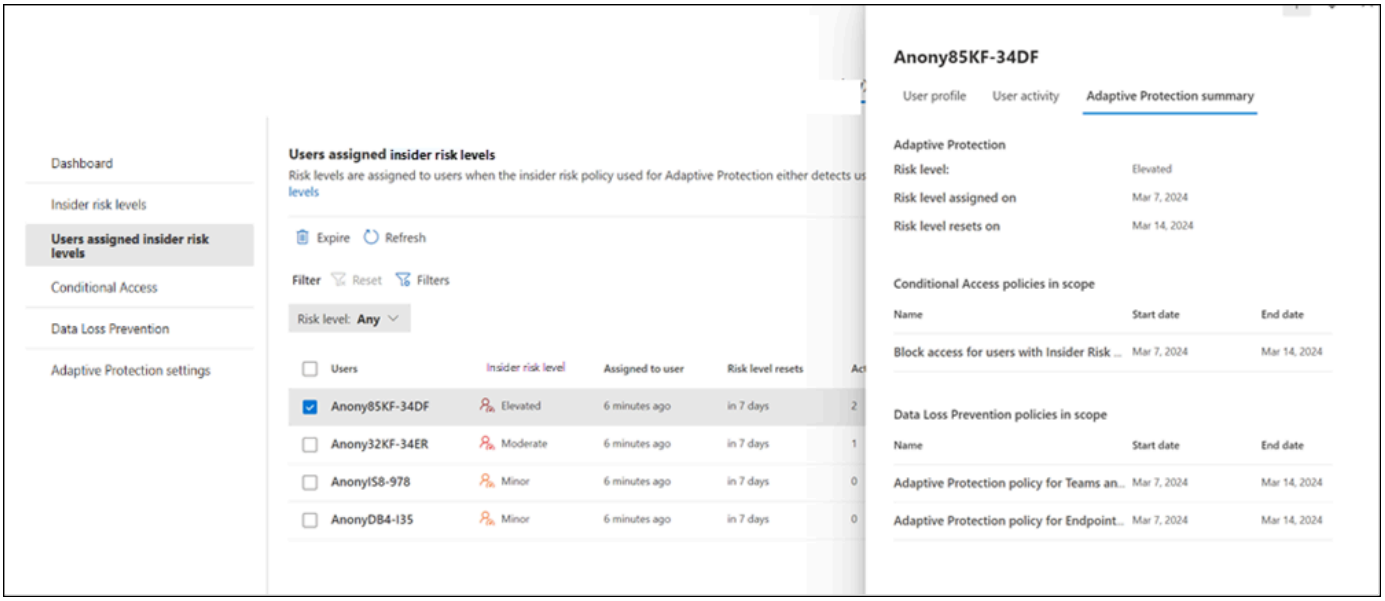
  > **Important**
  >
  > To maintain referential integrity, anonymization of usernames (if turned on) isn't preserved for users from Adaptive Protection who have alerts or activity that appear outside Insider Risk Management. Actual usernames appear in related data loss prevention alerts and the activity explorer.

- **Insider risk level**: The current insider risk level assigned to the user.
- **Assigned to user**: The number of days or months that pass since assigning an insider risk level to the user.
- **Insider risk level resets**: The number of days until the insider risk level automatically resets for the user.

To manually reset the insider risk level for a user, select the user, then select **Expire**. This user no longer has an assigned insider risk level. Existing alerts or cases for this user aren't removed. If this user is included in the selected Insider Risk Management policy, an insider risk level is assigned again if a triggering event is detected.

- **Active alerts**: The number of current Insider Risk Management alerts for the user.
- **Cases confirmed as violation**: The number of confirmed cases for the user.
- **Case**: The name of the case.

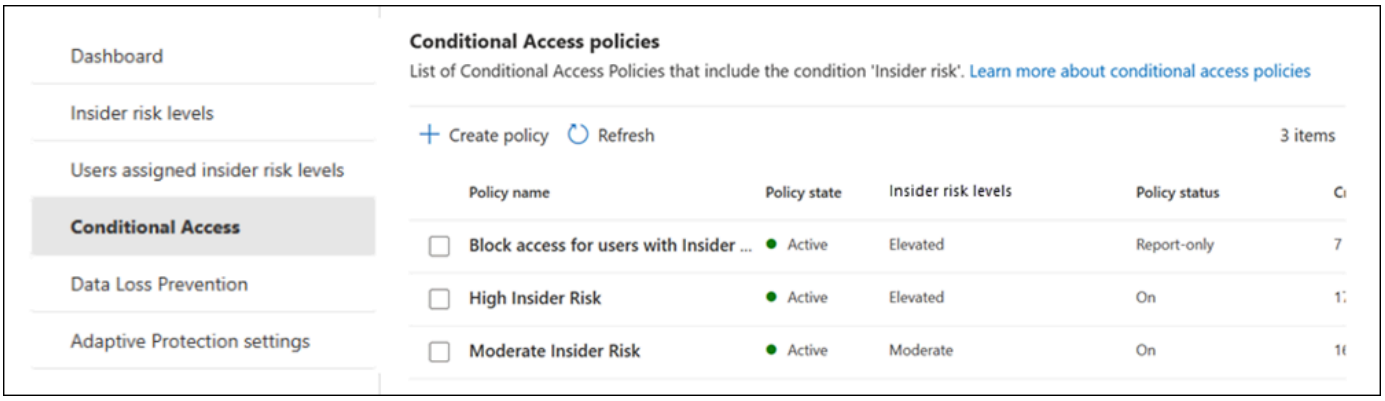
You can filter users by *Insider risk level*.



To view detailed insider risk and Adaptive Protection information for a specific user, select the user to open the user details pane. The details pane contains three tabs: **User profile**, **User activity**, and **Adaptive protection summary**. For information about the **User profile** and **User activity** tabs, see View user details.

The **Adaptive protection summary** tab aggregates information in four sections:

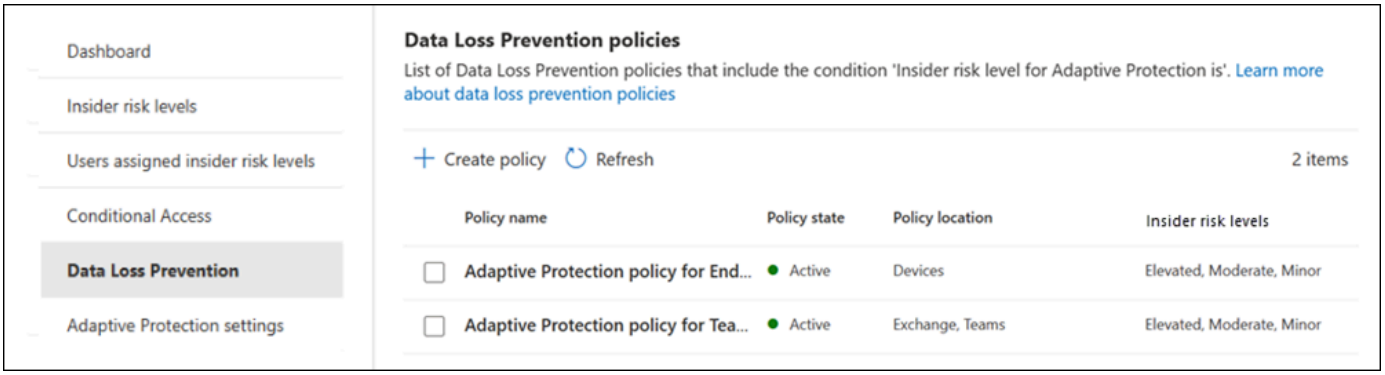
- **Adaptive protection**: Displays information about the current *Risk level*, *Risk level assigned on*, and *Risk level reset on* for the user.
- **Data Loss Prevention policies in scope (dynamic)**: Displays all the data loss prevention policies currently in scope for the user and the start and end date for the policy. This information is based on the insider risk level for the user and data loss prevention policy configuration for insider risk levels. For example, if a user has activities that are defined as *Elevated risk level* for Insider Risk Management policies, and two data loss prevention policies are configured with the *Elevated risk level* condition, these two data loss prevention policies are displayed here for the user.



- **Conditional Access policies in scope (dynamic)**: Displays all the Conditional Access policies currently in scope for the user and the start and end date for the policy. This information is based on the insider risk level for the user and Conditional Access policy configuration for insider risk levels. For example, if a user has activities that are defined as *Elevated risk level* for Insider Risk Management policies, and a Conditional Access policy is configured with the *Elevated risk level* condition, the Conditional Access policy is displayed here for the user.
- **Insider risk policy for Adaptive protection**: Displays any Insider Risk Management policy where the user is currently in-scope.

Manage Conditional Access policies for Adaptive Protection

The **Conditional Access policies** page shows all Conditional Access policies that use the **Insider risk** condition. You can review the following information for each policy:



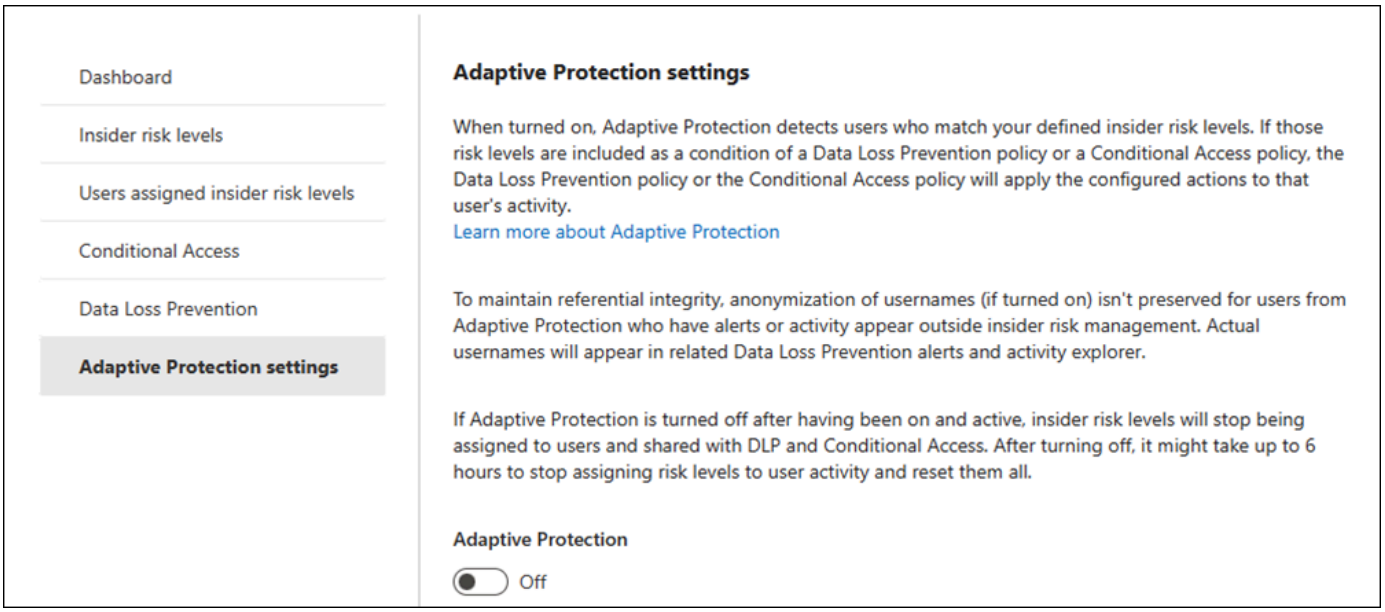
- **Policy name**: The name of the Conditional Access policy.
- **Policy state**: The current state of the policy. Values are *Active* or *Inactive*.
- **Insider risk levels**: The insider risk levels included in the Conditional Access policy by using the **Insider Risk** condition. The options are *Elevated*, *Moderate*, or *Minor*.
- **Policy status**: The current status of the Conditional Access policy. The options are *On* or *Test with notifications*.
- **Created on**: The date you created the Conditional Access policy.
- **Last modified**: The date you last edited the Conditional policy.

Manage Data Loss Prevention policies for Adaptive Protection

The **Data Loss Prevention policies** page shows all data loss prevention policies that use the **User's insider risk level for Adaptive Protection is** condition. You can review the following information for each policy:

- **Policy name**: The name of the data loss prevention policy.
- **Policy state**: The current state of the policy. Values are *Active* or *Inactive*.
- **Policy location**: The DLP policy locations included in the data loss prevention policy. Currently, Adaptive Protection supports Exchange, Teams, and Devices.
- **Insider risk levels**: The insider risk levels included in the data loss prevention policy by using the **Insider risk level for Adaptive Protection is** condition. The options are *Elevated*, *Moderate*, or *Minor*.
- **Policy status**: The current status of the data loss prevention policy. The options are *On* or *Test with notifications*.
- **Created**: The date you created the data loss prevention policy.
- **Last modified**: The date you last edited the data loss prevention policy.

Tune your insider risk level settings



After reviewing users with insider risk levels, you might find too many or too few users assigned an insider risk level. Use these two methods to tune your policy configurations and adjust the number of users assigned insider risk levels:

- Modify insider risk level settings. Adjust your thresholds to assign an insider risk level to a user:
  - Increase or decrease the severity of the activity required to assign an insider risk level. For example, reduce the activity or alert severity if you're seeing too few users with insider risk levels.
  - If the insider risk level is based on a specific user activity, increase or decrease the activity occurrences during the detection window. For example, reduce the activity occurrences if you're seeing too few users with insider risk levels.
  - Change what the insider risk level is based on. For example, assign an insider risk level only if the alert is confirmed to decrease the number of users if you're seeing too many users with insider risk levels.
- Modify policy thresholds. Since policy detections assign insider risk levels, modify your policy to change the requirements to assign an insider risk level. Modify a policy by increasing or decreasing the policy thresholds that lead to high, medium, or low severity activities and alerts.

Disable Adaptive Protection

In certain scenarios, you might need to temporarily disable Adaptive Protection. To disable Adaptive Protection, select the **Adaptive Protection settings** tab and turn **Adaptive Protection** *Off*.

If you turn off Adaptive Protection after it's been on and active, the system stops assigning insider risk levels to users and stops sharing them with data loss prevention, data lifecycle management, and Conditional Access. All existing insider risk levels for users are reset. After turning off Adaptive Protection, it might take up to six hours to stop assigning insider risk levels to user activity and reset them all. The Insider Risk Management, data loss prevention, data lifecycle management, and Conditional Access policies aren't automatically deleted.

> **Note**
>
> You can opt out of data lifecycle management protection without disabling Insider Risk Management Adaptive Protection by turning off the **Adaptive protection in Data Lifecycle Management** setting in data lifecycle management. If you turn off this setting, the data lifecycle management policy is deleted. The setting isn't enabled again unless you turn it back on. Learn about Adaptive Protection in Data Loss Prevention

Article • 03/31/2025

Adaptive Protection in Microsoft Purview integrates Microsoft Purview Insider Risk Management with Microsoft Purview Data Loss Prevention (DLP). When insider risk identifies a user who is engaging in risky behavior, they are dynamically assigned to a inside risk level. Then Adaptive Protection can automatically create a DLP policy to help protect the organization against the risky behavior that's associated with that inside risk level. As users insider risk levels change in insider risk management, the DLP policies applied to users can adjust.

You can manually create DLP policies that help protect against risky behaviors that insider risk identifies too.

Refer to Help dynamically mitigate risks with Adaptive Protection to learn about Adaptive Protection and how to configure it.

How Adaptive Protection shows up in DLP policies

If you're unfamiliar with DLP policies, you should review these articles before working with Adaptive Protection:

- Learn about data loss prevention
- Plan for data loss prevention (DLP)
- Data Loss Prevention policy reference
- Design a data loss prevention policy

Once Adaptive Protection is configured in insider risk, a condition called **User's risk level for Adaptive Protection is** will be available to use in rules that are configured for policies scoped to Exchange Online, Devices, and Teams locations.

The condition **Insider risk level for Adaptive Protection is** has three values:

- **Elevated risk level**
- **Moderate risk level**
- **Minor risk level**

These insider risk level profiles are defined in insider risk. You can select one, two or all three in a policy rule. Learn more about insider risk levels.

You can manually configure DLP policies that are part of Adaptive Protection and also use the quick setup configuration in insider risk to create DLP policies automatically from a template.

Manual configuration

You manually configure an Adaptive Protection DLP policy just like you would configure any other policy. Just select the **Insider risk level for Adaptive Protection is** condition and the insider risk level profiles that you want, configure all the other policy options and deploy the policy according to your normal procedures.

Quick setup configuration

If quick setup is used to configure Adaptive Protection in insider risk, DLP policies are created automatically, so you should be on the lookout for them. Quick setup will create one policy for Teams and Exchange Online with two rules, one for the elevated risk profile and one for the moderate and minor insider risk levels. It will also create one policy for Devices with two rules, one for the elevated risk profile and one for the moderate and minor insider risk levels.

> **Tip**
>
> Insider risk presents a view of just the DLP policies that use the **Insider risk level for Adaptive Protection is** condition. Open **Microsoft Purview portal** > **Insider risk management** > **Adaptive protection** to see the list. You'll need DLP to be in one of these roles to access the insider risk node:

- Compliance administrator
- Compliance Data administrator
- Organization management (Users who are not global administrators must be Exchange administrators to see and take action on devices that are managed by Basic Mobility and Security for Microsoft 365)
- Global administrator
- DLP compliance management
- View-only DLP compliance management

> **Important**

Microsoft recommends that you use roles with the fewest permissions. This helps improve security for your organization. Global Administrator is a highly privileged role that should only be used in scenarios where a lesser privileged role can't be used.

Policy values for Teams and Exchange online DLP policy

This is the configuration for the Teams and Exchange DLP policy created during Quick Setup. The policy name is **Adaptive Protection policy for Teams and Exchange DLP**.

Rule: Adaptive Protection block rule for Teams and Exchange DLP

Expand table

DLP policy element	Configured value
Conditions	**Insider risk level for Adaptive Protection is** **- Elevated Risk Level** AND **- Content is Shared from Microsoft 365 With people outside my organization**

Adaptive Protection configuration guide

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Adaptive Protection is highly configurable, from defining risk levels to setting up mitigation actions in data loss prevention (DLP) or conditional access policies. How you configure your risk levels and your policies that use the Adaptive Protection condition depends on your organization's security posture and your willingness to disrupt the end user experience for users and agents in your organization. You can define separate risk levels for users and agents by selecting the appropriate tab.

This configuration is our recommendation for organizations wanting to minimize false positives and potential disruptions to users and agents.

Expand table

Adaptive Protection settings	Elevated	Moderate	Minor
Risk level configuration	Confirmed alert of any severity for a user	High severity alert generated for a user	Low or medium severity alert generated for a user

Data loss prevention

Teams and Exchange configuration

With this configuration, your organization creates two DLP policies for Teams and Exchange locations. One policy is for elevated risk users and agents, and the other is for moderate and minor risk users and agents.

Elevated risk users and agents can't share content on Teams and Exchange with people outside of your organization. Moderate and minor risk users and agents have their attempts to share content externally on Teams and Exchange audited. Users and agents of all risk levels receive

an email notification that their attempt to share content externally conflicts with your organization's policy.

You can modify these configurations to fit your organization's security posture and policies. Policy tips aren't currently supported for Adaptive Protection in DLP.

Expand table

DLP policy element	Elevated	Moderate
Actions	Restrict access or encrypt the content in Microsoft 365 locations - Block only people outside your organization	None
Additional options	Off	Off
Conditions	Insider risk level for Adaptive Protection is - Elevated Risk AND - Content is Shared from Microsoft 365 with people outside my organization	Insider risk level for Adaptive Protection is - Moderate Risk AND - Content is Shared from Microsoft 365 with people outside my organization

Status	Run the policy in simulation mode - Policy tips not selected	Run the policy in simulation mode - Policy tips not selected
User notification	On - Notify the user who sent, shared, or last modified the content	On - Notify the user who sent, shared, or last modified the content
User override	Off	Off

Endpoint configuration

With this configuration, your organization creates two policies for devices. One policy is for elevated risk users and the other is for moderate and minor risk users.

Elevated risk users are blocked from uploading to restricted cloud service domains or accessing content from unallowed browsers. They're also blocked from copying content to the clipboard, removable USB devices, and network share. They're blocked from printing content that matches the policy conditions. They can't access content with restricted apps. For moderate and minor risk users, all of these activities are audited.

Expand table

DLP policy element	Elevated	Moderate
Actions	Audit or restrict activities on devices - Upload to a restricted cloud service domain or access from unallowed browsers (Block) File activities for all apps - Apply restrictions to specific activity - Copy to clipboard (Block) - Copy to removable USB device (Block) - Copy to network share (Block) - Print (Block) Restricted App activities - Access by restricted apps (Block)	Audit or restrict activities on devices - Upload to a restricted cloud service domain or access from unallowed browsers (Audit) File activities for all apps - Apply restrictions to specific activity - Copy to clipboard (Audit) - Copy to removable USB device (Audit) - Copy to network share (Audit) - Print (Audit) Restricted App activities - Access by restricted apps (Audit)

Insider Risk Management

Conditional access policy configuration

To minimize disruption to user productivity while protecting against risky users, we recommend creating the following Conditional Access policies with the Insider risk condition when configuring Adaptive Protection.

Elevated

For elevated risk users and agents, minimize potential impact by taking a multipronged approach to limit how they can access sensitive data. Depending on your organization's risk posture, choose any combination of these policies.

- Block from Office 365 Apps: When used with the Insider risk condition, this configuration blocks elevated risk users from signing in to Office 365 apps.
- Block from access to specific labeled sites: When used with the Conditional Access Insider risk condition, this configuration blocks elevated users and agents from accessing those SharePoint sites and prevents Copilot from generating content grounded on these sites. By using the authentication context in Conditional Access, this configuration helps limit how risky users and agents can exploit access to sensitive information by using generative AI.
- Block downloads using Conditional Access application control: Prevent data exfiltration by using the Insider risk condition with this configuration to block elevated risk users and agents from downloading from specific cloud applications. This configuration might be useful for organizations that don't want to block access from cloud apps entirely but still want to apply additional controls to elevated users and agents.

Moderate

- Require Terms of Use at sign-in to Microsoft Admin Portals: Use the Insider risk condition in Conditional Access with a Terms of Use requirement to remind moderate risk users and agents of their security and privacy commitments while preserving productivity.

Minor

Get Conditional Access insights for minor risk users and agents while protecting their productivity. Using a policy with the Insider risk condition in Report-Only mode provides increased visibility on minor risk users and agents while preserving their productivity.

- Conditional Access insights and reporting workbook

Adaptive scopes

> *Microsoft Purview service description*

When you create a communication compliance policy, a policy for retention, or an auto-labeling policy, you can add an adaptive scope for your policy. A single policy can have one or many adaptive scopes.

- An adaptive scope uses a query that you specify, so you can define the membership of users or groups included in that query. These dynamic queries run daily against the attributes or properties that you specify for the selected scope. You can use one or more adaptive scopes with a single policy.
- For example, you can assign different policy settings to users according to their department by using existing Microsoft Entra attributes without the administrative overhead of creating and maintaining groups for this purpose.

Advantages of using adaptive scopes

The advantages of using adaptive scopes include:

- No limits on the number of items per policy. Although adaptive policies are still subject to the maximum number of policies per tenant limitations, the more flexible configuration likely results in far fewer policies.
- More powerful targeting for your policies. For example, you can assign different settings to users according to their geographical location without the administrative overhead of creating and maintaining groups.
- Query-based scopes provide resilience against business changes that might not be reliably reflected in group membership or external processes that rely on cross-department communication.
- A single policy can include locations for both Microsoft Teams and Viva Engage, whereas when you don't use an adaptive scope, each location requires its own policy.
- Support for Microsoft Entra administrative units.

For additional advantages of using adaptive scopes specific to policies for retention, see Adaptive or static policy scopes for retention.

For configuration information, see Configuring adaptive scopes.

How adaptive scopes work with Microsoft Entra administrative units

Whereas adaptive scopes are created and configured in Microsoft Purview to support the dynamic targeting of policies for compliance, administrative units are created and configured in Microsoft Entra ID. They provide the ability to assign admins to one or more administrative units, with the result that these now restricted admins can manage only the users in their assigned administrative units. This configuration supports the security best practice of least privilege. Typically, administrative units are designed around specific geography, department, or business divisions.

This boundary of management flows into Microsoft Purview for supported solutions to ensure that restricted admins can manage only the users they have been assigned to manage.

As an example to show how administrative units integrate with adaptive scopes, consider a restricted compliance admin who wants to create an adaptive user scope just for users in France:

1. A compliance admin is assigned two administrative units, **All users in Europe** and **All users in North America**. When they create an adaptive scope, they can select and assign only these administrative units. They can't create an adaptive scope to manage users from other administrative units.
2. They create a new adaptive scope for users and select the administrative unit **All users in Europe**. Then, because they want the adaptive scope to be only for users in France, they use the Microsoft Entra ID **Country or region** attribute to specify France (CountryOrRegion = France). If they misconfigure this attribute and specify a valid value in Microsoft Entra ID, such as India, but the users with that value aren't included in the **All users in Europe** administrative unit, the scope won't contain any users.
3. When just this adaptive scope is selected for a policy that's targeted to all users, the policy is applied just to users in France.
4. As a reusable configuration element, the same adaptive scope can be used for other compliance policies.

If the compliance admin adds both of the administrative units to this adaptive scope, the end result is still the same because users in the North America administrative scope don't have France specified as their country or region attribute. However, the compliance admin knows that they need to target just users in France, so it's more efficient to run the query against just the Europe administrative unit. If requirements change, you can always add or remove administrative units from an existing adaptive scope.

Maximums for adaptive policy scopes

There's no limit to the number of adaptive policy scopes that you can add to a policy, but there are some maximum limits for the query that defines each adaptive scope:

- String length for attribute or property values: 200
- Number of attributes or properties without a group, or within a group: 10
- Number of groups: 10
- Number of characters in an advanced query: 10,000
- Grouping attributes or properties within a group isn't supported. This limitation means that the maximum number of properties or attributes supported within a single adaptive scope is 100.
- For auto-labeling policies, a SharePoint adaptive scope supports up to 50,000 sites per policy.

Configure adaptive scopes

When you choose to use adaptive scopes, you're prompted to select the type of adaptive scope you want. There are three different types of adaptive scopes, and each one supports different attributes or properties:

Expand table

Adaptive scope type	Attributes or properties supported
Users - applies to: - Exchange mailboxes - OneDrive accounts - Teams chats and Copilot interactions - Teams private channel messages (applicable pre-migration only) - Viva Engage user messages - Team chats - Teams call logs - Microsoft Copilot experiences - Enterprise AI apps - Other AI apps	First Name Last name Display name Job title Department Office Street address City State or province Postal code Country or region Email addresses Alias Exchange custom attributes: CustomAttribute1 - CustomAttribute15 Exchange Extension custom attributes: ExtensionCustomAttribute1 - ExtensionCustomAttribute5

Adaptive scope type	Attributes or properties supported
SharePoint sites * - applies to: - SharePoint sites and OneDrive accounts for retention policies - SharePoint sites for auto-labeling policies	Site URL Site name Site template Custom properties (SharePoint only): RefinableString00 - RefinableString99
Microsoft 365 Groups - applies to: - Microsoft 365 Group mailboxes & sites - Teams channel messages (standard, shared, and private post-migration) - Viva Engage community messages	Name Display name Description Email addresses Alias Exchange custom attributes: CustomAttribute1 - CustomAttribute15 Exchange Extension custom attributes: ExtensionCustomAttribute1 - ExtensionCustomAttribute5

* Records Center sites (legacy feature) in SharePoint aren't supported.

> **Note**
>
> For communication compliance policies:
>
> - SharePoint sites and OneDrive accounts aren't supported.
> - Excluded users and Microsoft 365 groups are supported.

The property names for sites are based on SharePoint site managed properties. For information about the custom attributes, see Using Custom SharePoint Site Properties to Apply Microsoft 365 Retention with Adaptive Policy Scopes.

The attribute names for users and groups are based on filterable recipient properties that map to Microsoft Entra attributes. For example:

- **Alias** maps to the LDAP name **mailNickname** that displays as **Email** in the Microsoft Entra admin center.
- **Email addresses** maps to the LDAP name **proxyAddresses** that displays as **Proxy address** in the Microsoft Entra admin center.

You can easily specify the attributes and properties listed in the table when you configure an adaptive scope by using the simple query builder. The advanced query builder supports additional attributes and properties, as described in the following section.

How to configure an adaptive scope

Before you configure your adaptive scope, use the previous section to identify what type of scope to create and what attributes and values to use. You might need to work with other administrators to confirm this information.

You need to assign the correct role groups to admins to create an adaptive scope. Any role group with the *Scope Manager* role can create an adaptive scope. The *Scope Manger* role is included in the following built-in role groups:

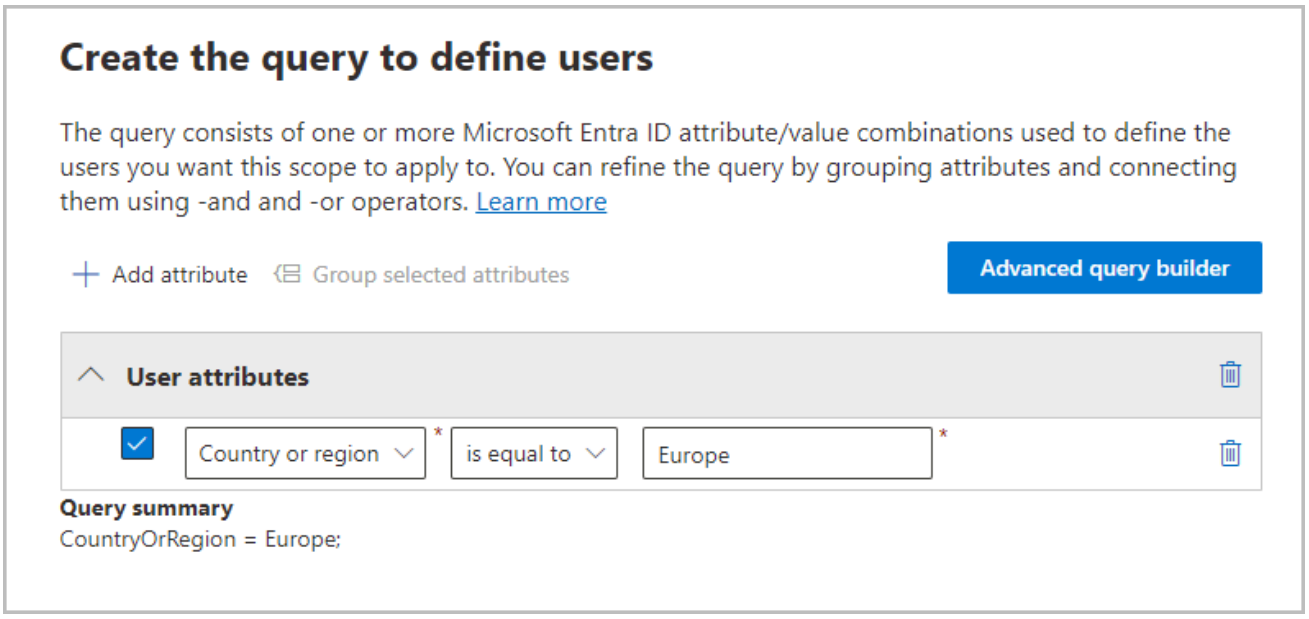
- Compliance Administrator
- Compliance Data Administrator
- Organization Management
- Records Management
- Communication Compliance
- Communication Compliance Admins

For SharePoint sites, there might be additional SharePoint configuration needed if you plan to use custom site properties.

To create and configure adaptive scopes, use the following instructions.

1. Sign in to the Microsoft Purview portal > **Settings** > **Roles and scopes** > **Adaptive scopes**.

2. On the **Adaptive scopes** page, select **+ Create scope**.

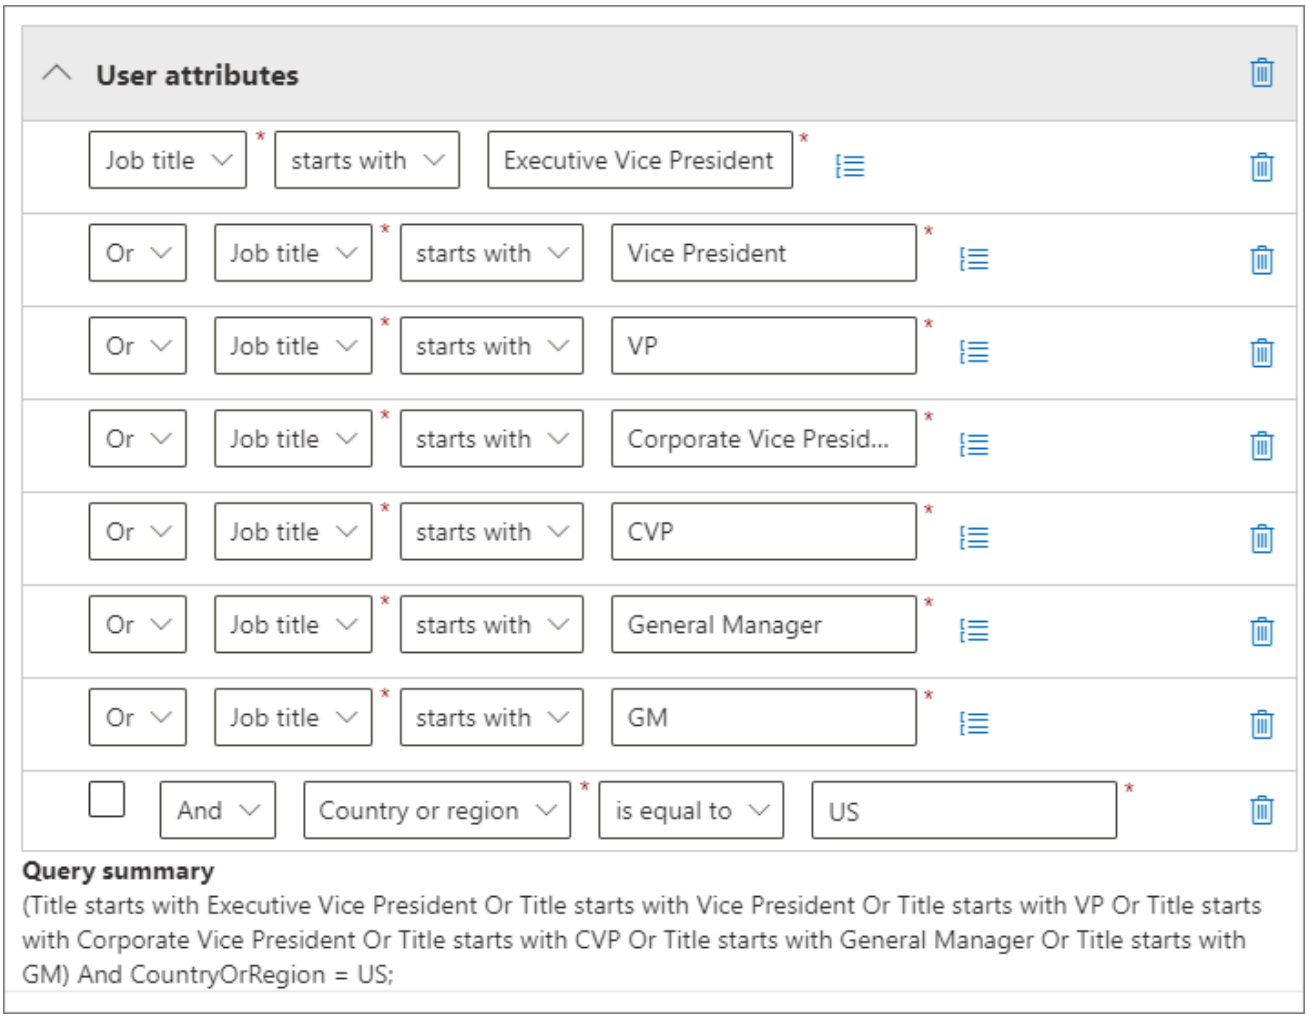


3. Follow the prompts in the configuration where you're first asked to assign an administrative unit. If your account is assigned administrative units, you must select one administrative unit that restricts the scope membership.

   > **Note**
   >
   > Because administrative units don't yet support SharePoint sites, you can't create an adaptive scope for SharePoint sites if you select administrative units.

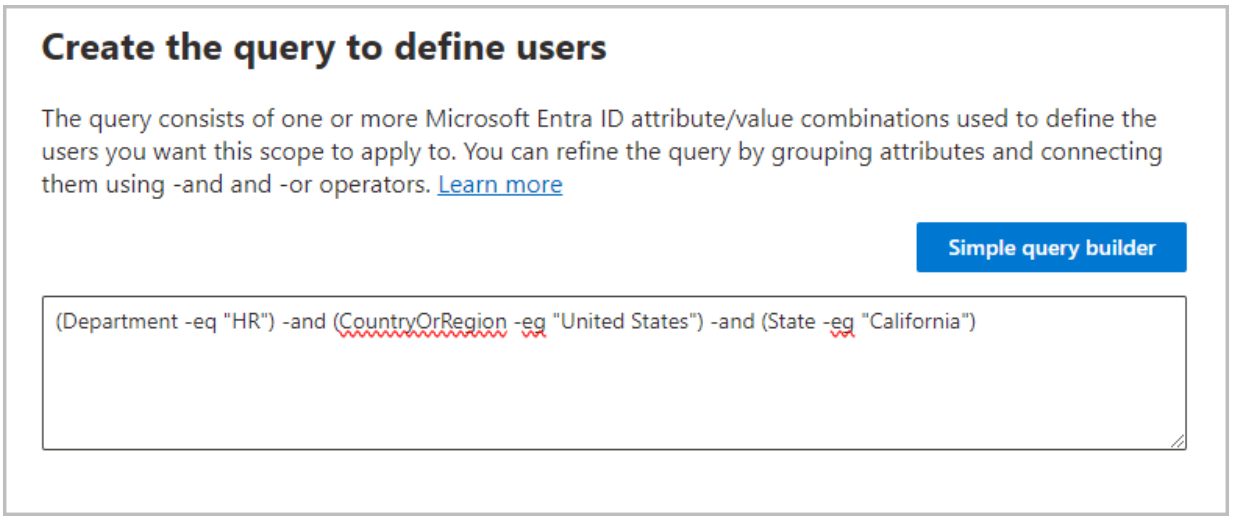
   If you don't want to restrict the adaptive scope by using administrative units, or your organization hasn't configured administrative units, keep the default of **Full directory**.

4. Select the type of scope, and then select the attributes or properties you want to use to build the dynamic membership. Type in the attribute or property values.



For example, to configure an adaptive scope that identifies users in Europe, first select **Users** as the scope type. Then select the **Country or region** attribute, and type in **Europe**:

Once daily, this query runs against Entra ID and identifies all users who have the value **Europe** specified for in their account for the **Country or region** attribute.



> **Important**
>
> Because the query doesn't run immediately, there's no validation that you typed in the value correctly.

Select **Add attribute** (for users and groups) or **Add property** (for sites) to use any combination of attributes or properties that are supported for their scope type. Use logical operators to build queries. The operators supported are **is equal to**, **is not equal to**, **starts with**, and **not starts with**. You can group selected attributes or properties. For example:

Alternatively, you can select **Advanced query builder** to specify your own queries:

- For **User** and **Microsoft 365 Group** scopes: Use OPATH filtering syntax. For example, to create a user scope that defines its membership by department, country/region, and state:

  One of the advantages of using the advanced query builder for these scopes is a wider choice of query operators:

  - **and**

- **or**
- **not**
- **eq** (equals)
- **ne** (not equals)
- **lt** (less than)
- **gt** (greater than)
- **like** (string comparison)
- **notlike** (string comparison)

- For **SharePoint sites** scopes: Use Keyword Query Language (KeyQL). You might already be familiar with using KeyQL to search SharePoint by using indexed site properties. To help you specify these KeyQL queries, see Keyword Query Language (KeyQL) syntax reference.

  For example, because SharePoint site scopes automatically include all SharePoint site types, which include Microsoft 365 group-connected and OneDrive sites, you can use the indexed site property **SiteTemplate** to include or exclude specific site types. The templates you can specify:

  - `SITEPAGEPUBLISHING` for modern communication sites
  - `GROUP` for Microsoft 365 group-connected sites
  - `TEAMCHANNEL` for Microsoft Teams private channel sites
  - `STS` for a classic SharePoint team site
  - `SPSPERS` for OneDrive sites

  So to create an adaptive scope that includes only modern communication sites and excludes Microsoft 365 group-connected and OneDrive sites, specify the following KeyQL query:

  ```
  Console
  SiteTemplate=SITEPAGEPUBLISHING
  ```

  You can validate these advanced queries independently from the scope configuration.

  > **Note**
  >
  > You must use the advanced query builder if you want to exclude inactive mailboxes. Or conversely, target just inactive mailboxes. For this configuration, use the OPATH property *IsInactiveMailbox*:

- To exclude inactive mailboxes, make sure the query includes: `(IsInactiveMailbox -eq "False")`
- To target just inactive mailboxes, specify: `(IsInactiveMailbox -eq "True")`

5. Create as many adaptive scopes as you need. You can select one or more adaptive scopes when you create your policy.

It can take up to five days for the queries to fully populate and changes aren't immediate. Factor in this delay by waiting a few days before you add a newly created scope to a policy.

> **Tip**
>
> For the data lifecycle management and records management solutions, use the **policy lookup option** to help you identify policies that are currently assigned to specific users, sites, and Microsoft 365 groups.

Validate advanced queries

You can manually validate advanced queries by using PowerShell and SharePoint search:

- Use PowerShell for the scope types **Users** and **Microsoft 365 Groups**
- Use SharePoint search for the scope type **SharePoint sites**

To run a query by using PowerShell

1. Connect to Exchange Online PowerShell by using an account with appropriate Exchange Online Administrator permissions.

2. Use either Get-Recipient, Get-Mailbox, or Get-User with the *-Filter* parameter and your OPATH query for the adaptive scope enclosed in curly brackets (`{`,`}`). If your attribute values are strings, enclose these values in double or single quotes.

   You can determine whether to use Get-Mailbox, Get-Recipient, or Get-User for validation by identifying which cmdlet is supported by the OPATH property that you choose for your query.

   > **Important**

Get-Mailbox doesn't support the *MailUser* recipient type, so you must use Get-Recipient or Get-User to validate queries that include on-premises mailboxes in a hybrid environment.

To validate a **User** scope, use the appropriate command:

- `Get-Mailbox` with *-RecipientTypeDetails UserMailbox,SharedMailbox,RoomMailbox,EquipmentMailbox*
- `Get-Recipient` with *-RecipientTypeDetails UserMailbox,MailUser,SharedMailbox,RoomMailbox,EquipmentMailbox*

To validate a **Microsoft 365 Group** scope, use:

- `Get-Mailbox` with *-GroupMailbox* or `Get-Recipient` with *-RecipientTypeDetails GroupMailbox*

For example, to validate a **User** scope related to the **Department** attribute set to the value **Marketing**, you could use:

PowerShell

```
Get-Recipient -RecipientTypeDetails UserMailbox,MailUser -Filter {Department -eq "Marketing"} -ResultSize Unlimited
```

To validate a **User** scope related to the **EmailAddresses** attribute generally requires the value to include the **smtp:** prefix. For example to **exclude** a user where EmailAddresses includes **admin@contoso.com**:

PowerShell

```
Get-Mailbox -RecipientTypeDetails UserMailbox -Filter {EmailAddresses -notlike "smtp:admin@contoso.com"} -ResultSize Unlimited
```

To validate a **Microsoft 365 Group** scope related to the group's **CustomAttribute15** attribute set to **Marketing** as the value, you could use:

PowerShell

```
Get-Mailbox -RecipientTypeDetails GroupMailbox -Filter {CustomAttribute15 -eq "Marketing"} -ResultSize Unlimited
```

> **Tip**
>
> When you use these commands to validate a user scope, if the number of recipients returned is higher than expected, it might be because it includes users who don't have a valid license for adaptive scopes. These users don't have the policy settings applied to them.
>
> For example, in a hybrid environment, you might have unlicensed synchronized user accounts without an Exchange mailbox on-premises or in Exchange Online. You can identify these users by running the following command: `Get-User -RecipientTypeDetails User`

3. Verify that the output matches the expected users or groups for your adaptive scope. If it doesn't, check your query and the values with the relevant administrator for Microsoft Entra ID or Exchange.

> **Note**
>
> The output from these commands might not match the member list for the same filter within the scope details on the Adaptive Scopes page. The member list in scope details shows arbitration mailboxes in scope whereas the command output doesn't. Moreover, adaptive scope query changes can take up to five days to become effective and reflected in the scope details view of the Adaptive Scopes page.

To run a query by using SharePoint search

1. Using an account that has the SharePoint admin role, go to `https://<your_tenant>.sharepoint.com/search`.
2. Use the search bar to specify your KeyQL query.
3. Verify that the search results match the expected site URLs for your adaptive scope. If they don't, check your query and the URLs with the relevant administrator for SharePoint.

View adaptive scope membership details

After creating a query for an adaptive scope in Microsoft Purview, you can view the member details of the scope.

Complete the following steps to access the member details page of an adaptive scope in Microsoft Purview:

1. Sign in to the Microsoft Purview portal, if you're not already signed in.
2. Select **Settings** > **Roles and scopes** > **Adaptive scopes**.
3. Select an existing adaptive scope from the list.
4. From the **Details** flyout pane, select **Scope details**.
5. A list of scope members is shown. Review the **State** column in the list that shows **Added** for members within the adaptive scope or **Removed** if the member was previously in the adaptive scope but removed now they no longer match the scope query.
6. Optionally, use the **Export** option to download a list of the displayed scope members to a CSV file.

   If the scope membership is large (1,000 or more), or you want to customize the export, use the PowerShell cmdlet Get-AdaptiveScopeMembers.

> **Note**
>
> It might take up to five days for the member details list to update added or removed members. The adaptive scope can apply to more than 1 million members. However, the member details can only show up to 1 million members across both added and removed members.

Administrative units in Microsoft Purview

By using administrative units in Microsoft Entra ID, you can subdivide your organization into smaller units and restrict administrative permissions to specific parts of your Microsoft Entra organization. You can create, delete, and edit administrative units in Microsoft Entra, and manage the users or groups that are members of each unit.

Microsoft Purview integrates with administrative units by enabling you to assign role group members to specific units. Microsoft Purview solutions that support administrative units restrict visibility and management permissions to members of the assigned unit.

For example, you can use administrative units to delegate permissions to administrators for each geographic region in a large multinational organization or to group administrator access by department. You can then create region-specific or department-specific policies, and view user activity as a result of those policies and administrative unit assignments. You can also use administrative units as an initial scope for a policy, where the users eligible for the policy depend on administrative unit membership.

If you're using adaptive scopes for compliance policies, see How adaptive scopes work with Microsoft Entra administrative units.

Supported solutions

The following Microsoft Purview solutions support administrative units:

Expand table

Solution	Configuration support
Data lifecycle management	Role groups, retention policies, and retention label policies
Data Loss Prevention (DLP)	Role groups and DLP policies
Communication Compliance	Role groups and policies
Insider Risk Management	Role groups and policies
Records management	Role groups, retention policies, retention label policies, and adaptive scopes
Sensitivity labeling	Role groups, sensitivity label policies, and auto-labeling policies

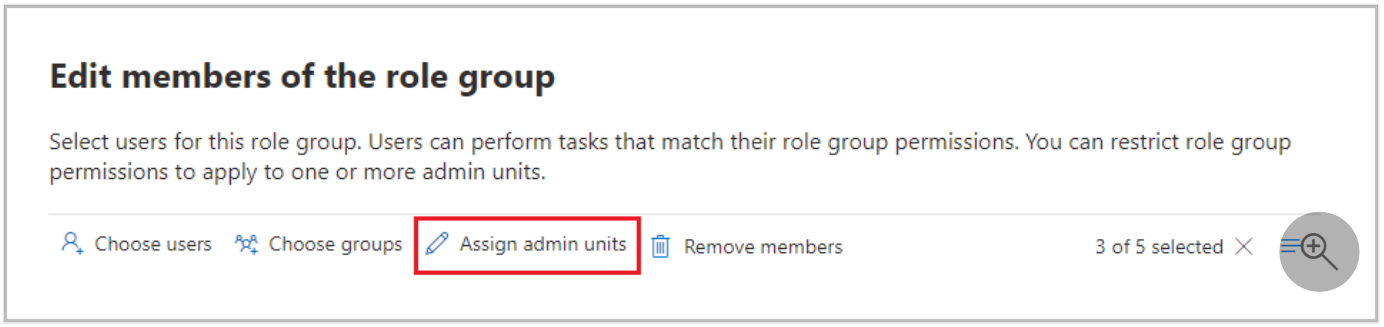
The configuration for administrative units automatically flows down to the following features:

- **Alerts**:
  - DLP alerts are visible only to users in assigned administrative units.
- **Activity explorer**:
  - Activity events are visible only to users in assigned administrative units.
- **Adaptive scopes**:
  - Restricted administrators can select, create, edit, and view adaptive scopes only for users in those administrators' assigned administrative units.
  - When a restricted administrator configures a policy that uses adaptive scopes, the administrator can select only adaptive scopes that are assigned to their administrative units.
- **Audit log**:
  - Search access.
- **Communication Compliance**:
  - Policy lookup and configuration: Restricted administrators can create or manage policies only for users assigned to their administrative units.
  - Alerts and policy matches: Restricted administrators can investigate user activities only for users within their assigned administrative units.
- **Data lifecycle management and records management**:
  - Policy lookup: Restricted administrators see policies only from users within their assigned administrative units.
  - Disposition review and verification: Restricted administrators can add reviewers only from within their assigned administrative units, and see disposition reviews and items disposed only from users within their assigned administrative units.
- **Insider Risk Management**:
  - Policy lookup and configuration: Restricted administrators can create or manage policies only for users assigned to their administrative units.
  - User activities: Restricted administrators can start scoring activities or investigate user activities only for users within their assigned administrative units.
  - Alerts and cases: Restricted administrators can view and investigate alerts and cases only for users within their assigned administrative units.

> **Note**
>
> Although DLP and Insider Risk Management both surface **alerts** in Microsoft Defender XDR, Microsoft Defender XDR only supports administrative units for DLP. Microsoft Defender XDR supports up to 100 administrative units.

Permissions for administrative units

To assign a role group member to an administrative unit, administrators must be assigned the *Role management* role. For more information about managing role groups and roles in Microsoft Purview, see Permissions in the Microsoft Purview portal. To view the complete list of default role groups and the roles assigned to each, see Role groups in Microsoft Purview.



You can assign role group members to administrative units within the following built-in role groups:

Expand table

Role group	Solution area
Communication Compliance	Communication Compliance
Communication Compliance Administrators	Communication Compliance
Communication Compliance Analysts	Communication Compliance
Communication Compliance Investigators	Communication Compliance
Compliance Administrator	Cross-solution
Compliance Data Administrators	Cross-solution
Global Reader	Cross-solution
Information Protection	Information Protection
Information Protection Admins	Information Protection
Information Protection Analyst	Information Protection
Information Protection Investigators	Information Protection
Information Protection Readers	Information Protection
Insider Risk Management	Insider Risk Management
Insider Risk Management Admins	Insider Risk Management
Insider Risk Management Analysts	Insider Risk Management
Insider Risk Management Approvers	Insider Risk Management
Insider Risk Management Investigators	Insider Risk Management
Insider Risk Management Session Approvers	Insider Risk Management

Role group	Solution area
Organization Management	Cross-solution
Records Management	Records Management
Security Administrator	Cross-solution
Security Operator	Cross-solution
Security Reader	Cross-solution

When you assign role groups, you can select individual members or groups, and then select the **Assign admin units** option to select administrative units that you define in Microsoft Entra ID:

> **Important**
>
> **Assign admin units** is always available when you create custom role groups. You can assign administrative units for any custom role group.

These administrators, referred to as *restricted administrators*, can select one or more of their assigned administrative units to automatically define the initial scope of policies that they create or edit. If administrators don't have administrative units assigned (*unrestricted administrators*), they can assign policies to the entire directory without being required to select individual administrative units.

> **Important**
>
> After you assign administrative units to members of the role groups, these restricted administrators can't see and edit existing policies. However, there's no operational change to these policies and they remain visible and can be edited by unrestricted administrators.
>
> Restricted administrators also can't see historical data by using features that support administrative units, such as activity explorer and alerts. They remain visible to unrestricted

administrators. Going forward, restricted administrators can see this related data for their assigned administrative units only.

Prerequisites for administrative units

Before configuring administrative units for Microsoft Purview solutions, make sure your organization and users meet the following subscription and licensing requirements:

- Microsoft Entra ID P1 or P2 licensing
- Microsoft Purview licensing (one of the following subscriptions):
  - Microsoft 365 E5/A5/G5
  - Microsoft 365 E5/A5/G5/F5 Compliance or F5 Security & Compliance
  - Microsoft 365 E5/A5/G5/F5 Information Protection & Governance
  - Microsoft 365 E5/A5/F5 Insider Risk Management

  For more information about licensing options for Microsoft Purview features, see the Microsoft Purview service description.

Configure administrative units

Complete the following steps to configure and use administrative units with Microsoft Purview solutions:

1. Create administrative units to restrict the scope of role permissions in Microsoft Entra ID.
2. Add users and distribution groups to administrative units.

   > **Important**
   >
   > Members of Dynamic Distribution Groups don't automatically become members of an administrative unit.

3. If you create geographic region or department-based administrative units, configure administrative units by using dynamic membership rules.

   > **Note**

> You can't add groups to an administrative unit that uses dynamic membership rules. If needed, create two administrative units, one for users and one for groups.

4. Use any of the role groups from the Microsoft Purview solutions that support administrative units to assign administrative units to members.

When restricted administrators create or edit policies that support administrative units, they can select administrative units so that only the users in those administrative units are eligible for the policy:

- *Unrestricted administrators* don't have to select administrative units as part of the policy configuration. They can keep the default of the entire directory or select one or more administrative units.
- *Restricted administrators* must select one or more administrative units as part of the policy configuration.

Later in the policy configuration, administrators who select administrative units must include or exclude (if supported) individual users and groups from the administrative units that they previously selected for the policy.

For information about administrative units that is specific to each supported solution, see the following sections:

- For audit: Scoping access to audit logs using administrative units
- For communication compliance: Consider administrative units if you want to scope user permissions to a region or department
- For data lifecycle management: Support for administrative units
- For DLP: Administrative Unit restricted policies
- For insider risk management: Consider administrative units if you want to scope user permissions to a region or department
- For records management: Support for administrative units
- For sensitivity labeling: Support for administrative units

SharePoint site support for administrative units

Microsoft Purview now supports adding SharePoint sites to administrative units. By using this feature, you can tailor visibility and management control of Microsoft Purview administrators within the Microsoft Purview portal. This support is only available for Microsoft Information

Protection auto-labeling policies and Microsoft Data Loss Prevention policies that support application to SharePoint sites.

> **Note**
>
> You manage administrative unit creation, deletion, and Microsoft Entra resource membership from Microsoft Entra ID. Any administrative unit you create appears in the listing for Microsoft Purview.

It can take up to five days for a SharePoint site query to fully populate. Changes aren't immediate. Wait until the query fully populates before you associate a policy with an administrative unit.

Configure SharePoint sites for administrative units

Complete the following steps to configure administrative units. These steps guide you through administrative unit creation, how to associate resources to that administrative unit, and how to assign Microsoft Purview role group members to administrative units. After you create administrative units, use the following steps to associate SharePoint sites to the administrative unit.

Microsoft Purview customers entitled to this feature can now access **Administrative units** under the **Roles and scopes** in Microsoft Purview portal settings. Within **Administrative units**, select an administrative unit and edit it to associate SharePoint sites to the administrative unit.

To complete the following steps to configure SharePoint sites within administrative units for use in Microsoft Purview, you must have the admin unit extension manager role assigned. An administrator with role management rights in Microsoft Purview assigns this role, either by using a built-in role group with this role or by using a custom role group.

1. Go to the Microsoft Purview portal.
2. Select **Settings** and select **Roles and scopes**.
3. Select **Administrative units**.
4. Select an existing administrative unit from the list.
5. Select **Edit**.
6. Create a query to associate SharePoint sites with the administrative unit.
7. Use any of the role groups from the Microsoft Purview solutions that support administrative units to assign administrative units to members.

Queries to associate SharePoint sites with administrative units support site properties for Site URL, site name, and `RefinableString00`-`RefinableString99`. These queries apply both to SharePoint sites and OneDrive accounts, with the exception of shared channel SharePoint sites. The property names for sites are based on SharePoint site managed properties. For more information about associating custom properties to managed properties (`RefinableString00`-`RefinableString99`), see Using Custom SharePoint Site Properties to Apply Microsoft 365 Retention with Adaptive Policy Scopes.

Test your query

To test your query by using SharePoint search, complete the following steps:

1. With an account assigned the SharePoint admin role, go to `https://<your_tenant>.sharepoint.com/search`.
2. Use the search bar to enter the query shown in the **query summary** for your SharePoint sites in the administrative unit.
3. Verify that the search results match the expected site URLs for your administrative unit. If they don't, check your query and the URLs with the relevant administrator for SharePoint.

The same restricted and unrestricted administrator behavior that applies to user-scoped policies also applies to policies that include SharePoint sites. Additionally, administrators selecting administrative units can't include or exclude individual SharePoint sites. SharePoint sites support application to all sites associated with the administrative unit.

> **Important**
>
> To remove associated sites from an administrative unit, edit a SharePoint query for an administrative unit to result in no site memberships. To clear site membership, make the query result in no sites.

View SharePoint site membership

After you create a SharePoint query for an administrative unit in Microsoft Purview, you can view the site members of the administrative unit. You can only view user and group membership of an administrative unit from the Microsoft Entra ID portal.

Complete the following steps to access the member details page and see SharePoint site members of an administrative unit in Microsoft Purview:

1. Go to the Microsoft Purview portal.
2. Select **Settings** and select **Roles and scopes**.
3. Select **Administrative units**.
4. Select an existing administrative unit from the list.
5. Select **Member Details**.
6. View the list of SharePoint site members.
7. Check the **State** column in the list, which shows *Added* for sites added to the administrative unit or *Removed* if the site was previously in the administrative unit but is removed after it's no longer a match for the SharePoint query.
8. Use the **Export** function to download a list of the displayed sites to a CSV file.

> **Note**
>
> It might take up to five days for the member details list to update added or removed sites.

For information about administrative units and the SharePoint site in Microsoft Purview solutions, see:

- **DLP**: Administrative Unit restricted policies
- **Sensitivity labels**: Support for administrative units

Get started with data explorer

Data explorer allows you to natively view the items that were summarized on the overview page.

Document preview and download is disabled if the document is encrypted to mitigate security risks.

Prerequisites

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions

> **Important**
>
> Access to data explorer is highly restricted because it lets you read the contents of scanned files. These permissions supersede permissions that are locally assigned to the items, which allow viewing of the content.

Microsoft Entra ID roles to access the data explorer tab

In order to get access to the data explorer tab, an account must be assigned membership in any one of these roles or role groups. Membership in these roles doesn't allow you to view the list of items in content explorer or to view the contents of the items in data explorer.

- Compliance administrator
- Security administrator
- Compliance data administrator
- Global administrator

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your

organization. Learn more about Microsoft Purview roles and permissions.

Required Microsoft Purview permissions to access items in data explorer

Access to data explorer is configured in the Microsoft Purview portal. There are two roles that grant access to data explorer. **Data Explorer List viewer** and **Data Explorer Content viewer**.

These are independent role groups and the permissions they grant aren't cumulative. For example, if you want to grant an account the ability to view the items and their locations only, grant Data Explorer List viewer rights. If you want that same account to also be able to view the contents of the items in the list, grant Data Explorer Content viewer rights as well.

You can also assign either or both of the roles to a custom role group to tailor access to content explorer.

- **Data Explorer List viewer**: Membership in this role group allows you to see each item and its location in list view. The `data classification list viewer` role has been pre-assigned to this role group.
- **Data Explorer Content viewer**: Membership in this role group allows you to view the contents of each item in the list. The `data classification content viewer` role has been pre-assigned to this role group. Additionally, this role is also required to view name of items in list view, which may contain sensitive data.

> **Note**
>
> In preview, data explorer supports administrative units. Members of role groups that have the *data classification list viewer* or *data classification content viewer* role will receive these respective role permissions can be restricted by administrative unit assignments within data explorer. For more on administrative unit support in Purview, see Administrative units support in Microsoft Purview.

Role management role holders in Microsoft Purview can assign the necessary data explorer list viewer, and data explorer content viewer role group membership.

Fine tune Microsoft Purview Roles and Role Groups

There are roles and role groups that you use to fine tune your access controls.

Here's a list of applicable roles. To learn more about them, see Permissions in the Microsoft Purview portal.

- Information Protection Admin
- Information Protection Analyst
- Information Protection Investigator
- Information Protection Reader

Here's a list of applicable role groups. To learn more, see Permissions in the Microsoft Purview portal.

- Information Protection
- Information Protection Admins
- Information Protection Analysts
- Information Protection Investigators
- Information Protection Readers

Data explorer

Data explorer shows a current snapshot of the items that have a sensitivity label, a retention label or have been classified as a sensitive information type in your organization.

Sensitive information types

A DLP policy can help protect sensitive information, which is defined as a **sensitive information type**. Microsoft 365 includes definitions for many common sensitive information types from across many different regions that are ready for you to use. For example, a credit card number, bank account numbers, and national ID numbers.

Sensitivity labels

A sensitivity label is simply a tag that indicates the value of the item to your organization. It can be applied manually, or automatically. Once applied, the label gets embedded in the document and will follow the document everywhere it goes. A sensitivity label enables various protective behaviors, such as mandatory watermarking or encryption.

Sensitivity labels must be enabled for files that are in SharePoint and OneDrive in order for the corresponding data to surface in the data classification page. For more information, see Enable sensitivity labels for files in SharePoint and OneDrive.

Encrypted sensitivity labels are not surfaced on content explorer for SharePoint and OneDrive.

Retention labels

A retention label allows you to define how long a labeled item is kept and the steps to be taken prior to deleting it. They're applied manually or automatically via policies. They can play a role in helping your organization stay in compliance with legal and regulatory requirements.

Trainable Classifiers

A trainable classifiers allows you to identify sensitive data by using examples of the data you're interested in rather than identifying elements in the item (pattern matching). You can use built-in classifiers or train a classifier with your own content.

How to use data content explorer

1. Sign in to the Microsoft Purview portal > **Solutions** > **Information Protectionn** > **Explorers** > **Data explorer**.
2. If you know the name of the label, classifiers or the sensitive information type, you can type that into the filter box.
3. Alternately, you can browse for the item by expanding the type and selecting the type from the list.
4. Select a data source under **Data source** and drill down the folder structure to the item.
5. Double-click to open the item natively in data explorer.

Export

The **Export** control will create a .csv file that contains a listing of whatever the focus of the pane is.

> **Note**
>
> It can take up to *seven days* for counts to be updated in data content explorer, *fourteen days* for files that are in SharePoint.

Filter

When you drill down into a location, such as an Exchange or Teams folder, or a SharePoint or OneDrive site, the **Filter** tool appears.

The scope of the search tool is what is displaying in the **All locations** pane and what you can search on varies depending on the selected location.

When **Exchange** or **Teams** is the selected location, you can search on the full email address of the mailbox, for example `user@domainname.com`.

When either **SharePoint** or **OneDrive** are selected location, the search tool will appear when you drill down to site names, folders and files.

You can search on:

Expand table

value	example
full site name	`https://contoso.onmicrosoft.com/sites/sitename`
file name	`RES_Resume_1234.txt`
text at the beginning of file name	`RES`
text after an underscore character (_) in file name	`Resume` or `1234`
file extension	`txt`

Provide match/not a match accuracy feedback in data explorer

You can view the number of matches a SIT or trainable classifier has in **Data explorer**. You can also provide feedback on whether an item is actually a match or not using the **Match**, **Not a Match** feedback mechanism and use that feedback to tune your classifiers. See, Increase classifier accuracy for more information.

Get started with Content Explorer (classic)

Content Explorer (classic) lets you natively view the items summarized on the overview page. When a document is encrypted, you can't access the document preview, and download is disabled to mitigate any security risks.

Prerequisites

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions

One set of permissions grants access to the content explorer tab, and a more restrictive set grants access to the items in content explorer.

Permissions to access the content explorer tab

To access the content explorer tab, assign an account membership in any one of these Entra ID roles or Purview roles. Membership in these roles doesn't grant permission to view the list of items in content explorer or to view the contents of the items in content explorer.

Entra ID roles

- Compliance administrator
- Security administrator
- Compliance data administrator

Microsoft Purview Roles and Role Groups

You can use roles and role groups to fine tune your access controls beyond the above guidance. Here's a list of applicable roles. To learn more about them, see Permissions in the Microsoft Purview portal.

- Information Protection Admin
- Information Protection Analyst

- Information Protection Investigator
- Information Protection Reader

Here's a list of applicable role groups. To learn more, see Permissions in the Microsoft Purview portal.

- Information Protection
- Information Protection Admins
- Information Protection Analysts
- Information Protection Investigators
- Information Protection Readers

Required permissions to access items in content explorer

Access to content explorer is highly restricted because it lets you read the contents of scanned files. Therefore, you need additional permissions to access content explorer data.

These permissions supersede permissions that are locally assigned to the items, which allow viewing of the content. The roles that grant access to content explorer are:

- **Content Explorer List viewer**: Membership in this role group allows you to see each item and its location in list view. The `data classification list viewer` role is preassigned to this role group.

- **Content Explorer Content viewer**: Membership in this role group allows you to view the contents of each item in the list. The `data classification content viewer` role is preassigned to this role group. Additionally, this role is also required to view name of items in list view, which might contain sensitive data.

The account you use to access content explorer **must be in one or both of the role groups**. These are independent role groups and aren't cumulative. For example, if you want to grant an account the ability to view the items and their locations only, grant Content Explorer List viewer rights. If you want that same account to also be able to view the contents of the items in the list, grant Content Explorer Content viewer rights as well.

You can also assign either or both of the roles to a custom role group to tailor access to content explorer.

Role management role holders in Microsoft Purview can assign the necessary Content Explorer List Viewer, and Content Explorer Content Viewer role group membership.

> **Note**
>
> Content Explorer support administrative units. Members of role groups that have the *data classification list viewer* or *data classification content viewer* role receive these respective role permissions can be restricted by administrative unit assignments within content explorer. For more on administrative unit support in Purview, see Administrative units support in Microsoft Purview.

Content explorer

Content explorer shows a current snapshot of the items that have a sensitivity label, a retention label, or are classified as a sensitive information type in your organization.

Sensitive information types

A DLP policy helps protect sensitive information, which is defined as a **sensitive information type**. Microsoft 365 includes definitions for many common sensitive information types from across many different regions that are ready for you to use. For example, credit card numbers, bank account numbers, and national ID numbers.

Sensitivity labels

A sensitivity label is a tag that indicates the value of the item to your organization. You can apply it manually or automatically. Once applied, the label gets embedded in the document and follows the document everywhere it goes. A sensitivity label enables various protective behaviors, such as mandatory watermarking or encryption.

You must enable sensitivity labels for files in SharePoint and OneDrive for the corresponding data to surface in the data classification page. For more information, see Enable sensitivity labels for files in SharePoint and OneDrive.

Encrypted sensitivity labels don't surface on content explorer for SharePoint and OneDrive.

Retention labels

A retention label lets you define how long to keep a labeled item and the steps to take before deleting it. You can apply them manually or automatically through policies. They help your organization stay in compliance with legal and regulatory requirements.

How to use content explorer

1. Sign in to the Microsoft Purview portal > **Solutions** > **Data Lifecycle Management** > **Explorers** > **Content explorer**.
2. If you know the name of the label or the sensitive information type, type it into the filter box.
3. Alternately, you can browse for the item by expanding the label type and selecting the label from the list.
4. Select a location under **All locations** and drill down the folder structure to the item.
5. Double-click to open the item natively in content explorer.

Export

The **export** control creates a .csv file that contains a listing of whatever the focus of the pane is.

> **Note**
>
> It can take up to *seven days* for counts to update in content explorer and *14 days* for files that are in SharePoint.

Filter

When you drill down into a location, such as an Exchange or Teams folder, or a SharePoint or OneDrive site, the **Filter** tool appears.

The scope of the search tool is what displays in the **All locations** pane. What you can search on varies depending on the selected location.

When you select **Exchange** or **Teams**, you can search on the full email address of the mailbox, for example `user@domainname.com`.

When you select **SharePoint** or **OneDrive**, you can search on site names, folders, and files.

You can search on:

Expand table

Value	Example
Full site name	`https://contoso.onmicrosoft.com/sites/sitename`

Value	Example
File name	`RES_Resume_1234.txt`
Text at the beginning of file name	`RES`
Text after an underscore character (_) in file name	`Resume` or `1234`
File extension	`txt`

Save views in Content Explorer

You can create customized views in content explorer, by configuring what SITs, Sensitivity Labels, Trainable Classifiers, and Retention Labels which are important for you. A view can be made default, to quickly load the view next time content explorer is opened.

Provide match or not a match accuracy feedback in content explorer

In **Content explorer**, you can see how many matches a sensitive information type (SIT) or trainable classifier has. You can also give feedback on whether an item is actually a match by using the **Match** and **Not a Match** feedback options. Use this feedback to improve your classifiers. For more information, see Increase classifier accuracy.

> **Note**
>
> Updating a custom sensitive information type (SIT) definition doesn't by itself reclassify unchanged historical files. For SharePoint and OneDrive files that need updated classification, use on-demand classification, and review its scope, costs, and active-policy effects first. A file's last-modified date alone doesn't establish when it was classified. For the distinction between classification results and auto-labeling policy matches, see Auto-labeling classification and simulation concepts.

Email attachment preview

For Exchange items, content explorer supports the preview of email attachments without the need to download the email. The following email attachment file types are supported: `.doc, .docx, .xlsx, .xls, .xlsm, .xlsb, .pptx, .pdf, .txt, .csv, .html, .xml, .json, .rtf, .cpp, .cs, .py, .jpg, .png, .jpeg, and .eml`

Content explorer document preview supports Excel files up to 25 MB.

Last updated on 10/14/2026

Get started with activity explorer

Activity explorer lets you monitor what's being done with your labeled content. Activity explorer provides a historical view of activities on your labeled content. The activity information comes from the Microsoft 365 unified audit logs. It's transformed and then made available in the activity explorer UI. Activity explorer reports on up to 30 days worth of data.

Activity explorer gives you multiple ways to sort and view the data.

When activities appear

Activity explorer isn't a real-time view. Because its data comes from the Microsoft 365 unified audit log, activities appear on the same schedule as audit records — not the moment they occur.

- For core services (Exchange, SharePoint, OneDrive, and Teams), allow 60 to 90 minutes after an activity for it to appear in activity explorer. Other services can take longer, and Microsoft doesn't guarantee a specific time for an activity to become available. For more information, see Search the audit log.
- After you enable or change a policy, allow time for the policy to reach the workload *and* for the resulting activities to flow in. An empty view right after you turn on a policy usually means the data pipeline hasn't caught up yet, not that the policy failed.
- Devices report endpoint activities only while they're online. An offline device backfills its activities after it reconnects.

> **Note**
>
> If a recent activity isn't showing yet, confirm that it falls within the 30 days of data that activity explorer reports on, and allow the audit-log availability time described earlier before you treat a missing activity as a defect. To confirm an activity independently, search for it in Audit.

Filters

Filters are the building blocks of activity explorer. Each filter focuses on a different dimension of the collected data. You can use about 50 different individual filters, including:

- Date range

- Activity type
- Location
- Sensitivity label
- User
- Client IP
- Device name
- Is protected

To see all the filters, open the filter pane in activity explorer and look at the dropdown list.

> **Note**
>
> Filter options are generated based on the first 500 records to ensure optimal performance. This limitation might cause some values to not appear in the filter dropdown. For endpoint events, only the most restrictive DLP rule appears. Filters you apply in activity explorer also operate based on this most restrictive rule.

Filter sets

Activity explorer comes with predefined sets of filters to help save time when you want to focus on a specific activity. Use filter sets to quickly provide you with a view of higher level activities than individual filters do. Some of the predefined filter sets are:

- Endpoint DLP activities
- Sensitivity labels applied, changed, or removed
- Egress activities
- DLP policies that detected activities
- Network DLP activities
- Protected Browser

You can also create and save your own filter sets by combining individual filters.

Microsoft Security Copilot in activity explorer (preview)

In *preview*, Microsoft Security Copilot in Microsoft Purview is embedded in activity explorer. It can help efficiently drill down into Activity data and help you identify activities, files with sensitive info, users, and other details that are relevant to an investigation.

> **Important**
>
> Be sure to check the responses from Security Copilot for accuracy and completeness before taking any action based on the information provided. You can provide feedback to help improve the accuracy of the responses.

Data hunting

Security Copilot skills use all the data available to Microsoft Purview, filters, and filter sets available in activity explorer and use machine learning to provide you with insights into the activity (sometimes referred to as *data hunting*) on your data that is most important to you.

- **Show me the top 5 activities from the past week**
- **Filter and investigate activities**
- **Find files used in specific activities**

Selecting a prompt automatically opens the Security Copilot side card and shows you the results of the query. You can then further refine the query.

Natural language to filter set generation

Use the prompt box to enter complex natural language queries to generate filter sets. For example, you can enter:

```
Filter and investigate files copied to cloud with sensitive info type credit card number for past 30 days.
```

Security Copilot generates a filter set for your query. Review the filter to make sure it fits your needs, then apply it to the data.

Prerequisites

SKU/subscriptions licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions

An account must be explicitly assigned membership in any one of these role groups, or must be explicitly granted the role.

Roles and role groups

Use roles and role groups to fine-tune your access controls. For more information, see Permissions in the Microsoft Purview portal.

Microsoft Purview roles

- Information Protection Admin
- Information Protection Analyst
- Information Protection Investigator
- Information Protection Reader

Microsoft Purview role groups

- Information Protection
- Information Protection Investigators
- Information Protection Analysts
- Information Protection Admins & Information Protection Readers (both role groups needs to be assigned)

Microsoft 365 roles

- Compliance Admins
- Security Admins
- Compliance Data Admins

Microsoft 365 role groups

- Compliance Administrator
- Security Administrator
- Security Reader

Activity types

Activity explorer gathers information from the audit logs of multiple sources of activities.

Some examples of the **Sensitivity label activities** and **Retention labeling activities** from applications native to Microsoft Office, the Microsoft Purview Information Protection client and

scanner, SharePoint, Exchange (sensitivity labels only), and OneDrive include:

- Label applied
- Label changed (upgraded, downgraded, or removed)
- Auto-labeling simulation
- File read

For the current list of activities listed in Activity explorer, go into Activity explorer and open the activity filter. The list of activities is available in the dropdown list.

Labeling activity specific to the Microsoft Purview Information Protection client and scanner that comes into Activity explorer includes:

- Protection applied
- Protection changed
- Protection removed
- Files discovered

For more detailed information on what labeling activity makes it into Activity explorer, see Labeling events available in Activity explorer.

Additionally, Activity Explorer gathers DLP policy match events from Microsoft 365 workloads such as Exchange, SharePoint, OneDrive, Teams chat and channels, and on-premises SharePoint folders, libraries, and file shares. When you enable Endpoint data loss prevention (DLP), Activity Explorer also includes device-level activities from onboarded Windows 10, Windows 11, and the three most recent major macOS versions.

Enhanced matched conditions for Exchange DLP events (preview)

For Exchange Online DLP events, Activity Explorer surfaces enhanced matched condition details for non-sensitive information type (SIT) conditions in addition to SIT matches. Every non-SIT condition that contributed to a DLP policy match is displayed with three levels of detail:

- **Condition name**: The specific policy condition that was matched, for example, *Sender domain is* or *Attachment's file extension is*.
- **Matched value**: The actual value that triggered the condition match, for example, `contoso.com` or `.docx`.
- **Source**: The part of the message where the match was found, for example, the message header, envelope, or attachment.

Enhanced matched condition details appear on the event detail flyout for Exchange DLP events in Activity Explorer and the DLP Alerts dashboard. The following condition categories are supported:

- **Sender conditions**: Sender is, Sender domain is, Sender address contains words, Sender address matches patterns, Sender is a member of, Sender IP address is, Sender AD attribute
- **Recipient conditions**: Recipient is, Recipient domain is, Recipient address contains words, Recipient address matches patterns, Recipient is a member of, Recipient AD attribute
- **Attachment conditions**: Attachment's file extension is, Document name contains words, Document name matches patterns, Document property is, Document size equals or is greater than, Document is password protected, Document could not be scanned, Document didn't complete scanning
- **Content conditions**: Content character set contains words, Content is shared from M365, Content is received from
- **Header conditions**: Header contains words, Header matches patterns
- **Message property conditions**: Message size over, Message type is, Message importance is, Subject contains words, Subject matches patterns, Subject or body contains words, Subject or body matches patterns, Has sender overridden the policy tip

For the full reference of Exchange DLP conditions, see Data loss prevention Exchange conditions and actions reference.

Some example events gathered from devices include the following actions taken on files:

- Deletion
- Creation
- Copy to clipboard
- Modify
- Read
- Print
- Rename
- Copy to network share
- Access by an unallowed app

Understanding the actions that are taken on content with sensitivity labels helps you determine whether the controls that you have in place, such as Microsoft Purview Data Loss Prevention policies, are effective. If not, or if you discover something unexpected (such as a large number of items labeled `highly confidential` that are downgraded to `general`), you can manage your policies and take new actions to restrict the undesired behavior.

> **Note**
>
> - Activity explorer doesn't monitor retention activities for Exchange.
> - Legacy Azure Information Protection (AIP) labels are not supported; as a result, they may appear as GUIDs in Activity Explorer.

> **Note**
>
> If a user reports the Teams DLP verdict as a false positive, the activity shows as **DLP info** in the list on Activity explorer. The entry doesn't have any rule and policy match details but shows synthetic values. There's also no incident report generated for false positive reporting.

Activity type events and alerts

This table shows the events that Activity Explorer triggers for three sample policy configurations. The events depend on whether a policy match is detected.

Expand table

Policy configuration	Activity Explorer event triggered for this action type	Activity Explorer event triggered when a DLP rule is matched	Activity Explorer alert triggered
Policy contains a single rule allowing the activity without auditing it.	Yes	No	No
Policy contains two rules: Matches for Rule #1 are allowed; policy matches for Rule #2 are audited.	Yes (Rule #2 only)	Yes (Rule #2 only)	Yes (Rule #2 only)
Policy contains two rules: Matches for both rules are allowed and not audited.	Yes	No	No

> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Microsoft Purview capabilities can help your organization manage data security and compliance needs. Start now at the Microsoft Purview trials hub. Learn details about signing up and trial terms.

Sensitivity label applied

This event is generated each time you label an unlabeled document or send an email with a sensitivity label.

- Activity explorer captures this event when you save a labeled document in native Microsoft Office applications and web applications.
- It captures this event when you apply a label for the Microsoft Purview Information Protection client.
- You can also monitor upgrade and downgrade label actions through the *Label event type* field and filter.

Expand table

Source	Reported in Activity explorer	Note
Word, Excel, PowerPoint	Yes	
Outlook	Yes	If you apply a sensitivity label to any email in an email thread, the same label is automatically applied to subsequent replies on the thread. These labeling events appear in activity explorer as automatic labeling events, even when automatic labeling isn't configured.
SharePoint, OneDrive	Yes	
Exchange	Yes	

Source	Reported in Activity explorer	Note
Microsoft Purview Information Protection client and scanner	Yes	The *new label* action maps to *label applied* in activity explorer
Microsoft Information Protection (MIP) SDK	Yes	The *new label* action maps to *label applied* in activity explorer
Rights Management Service (RMS)	Not applicable	
Power BI desktop and web	No	Accessible in the Microsoft 365 audit logs
Microsoft Defender for Cloud Apps	No	

Sensitivity label changed

This event is generated each time a sensitivity label is updated on the document or email.

- For the Microsoft Purview Information Protection client and scanner, and MIP SDK sources, the *upgrade label* and *downgrade label* action maps to Activity explorer *label changed*.
- The event is captured when the action is saved in native Microsoft Office applications and web applications.
- The event is captured when the action occurs for the Microsoft Purview Information Protection client and scanner enforcements.
- You can also monitor upgrade and downgrade labels actions via the *Label event type* field and filter. The *justification* text is also captured, except for SharePoint and OneDrive.
- Sensitivity labeling in Microsoft Office apps: Outlook collects the last action that was generated before *file save/email send* actions. For example, if the user changes label on an email multiple times before sending, the last label found on the email when it is sent is captured in the audit log and then reported in activity explorer.

Microsoft Defender for Cloud Apps	No	

Sensitivity label removed

This event is generated each time you remove a sensitivity label from a file or document.

- Microsoft Office applications and web applications capture this event when you save the document.
- Microsoft Purview Information Protection client captures this event when you remove the label.
- Sensitivity labeling in Microsoft Office: Outlook collects the last labeling event that was generated before *file save/email send* actions.

Data loss prevention (DLP) policy matched

This event is generated each time a DLP policy matches a document or an email.

Expand table

Source	Reported in Activity explorer
Exchange	Yes
SharePoint	Yes
OneDrive	Yes
Teams	Yes
Windows 10, Windows 11, and macOS devices	Yes
MAC	No
On-premises	No
Microsoft Defender for Cloud Apps	No

The Endpoint DLP events for devices running Windows 10, Windows 11, and any of the three most recently released major versions of macOS are:

- File deleted
- File created
- File copied to clipboard
- File modified
- File read
- File printed
- File renamed
- File copied to network share
- File accessed by unallowed app

Retention label applied

This event is generated each time you label an unlabeled document or send an email with a retention label.

- The event is captured when you save a document or send an email.

Expand table

Source	Reported in Activity explorer
Exchange	No
SharePoint	Yes

Source	Reported in Activity explorer
OneDrive	Yes

Retention label changed

This event is generated each time you update a label on a document or email.

- The event is captured when you save a document or send an email.

Expand table

Source	Reported in Activity explorer
Exchange	No
SharePoint	Yes
OneDrive	Yes

Retention label removed

This event is generated each time you remove a label from a file or document.

- The event is captured when you save a document or send an email.

Expand table

Source	Reported in Activity explorer
Exchange	No
SharePoint	Yes
OneDrive	Yes

Considerations

- When the recommended label tool tip appears to an end user, the event isn't captured. However, if the user chooses to apply the recommended label, the label appears under the *How applied* field as *Recommended*.
- Sensitive information types aren't currently available for auto-labeling activities from Word, Excel, PowerPoint, and Outlook, SharePoint, and OneDrive.

- When you label items with a sensitivity label and then delete that label, any events involving those items still appear in activity explorer. Instead of showing the name of the deleted sensitivity label, the GUID of the deleted sensitivity label appears.

Learn about connectors for third-party data

Microsoft 365 lets administrators use data connectors to import and archive non-Microsoft, third-party data from social media platforms, instant messaging platforms, and document collaboration platforms, to mailboxes in your Microsoft 365 organization. One primary benefit of using data connectors to import and archive third-party data in Microsoft 365 is that you can apply various Microsoft Purview solutions to the data after you import it. This approach helps you ensure that your organization's non-Microsoft data complies with the regulations and standards that affect your organization.

This article describes the available third-party data connectors, the Microsoft Purview solutions that support imported third-party data, and how to provision a service principal for partner connectors.

Third-party data connectors

The Microsoft Purview portal provides native third-party data connectors from Microsoft to import data from various data sources, such as LinkedIn, Instant Bloomberg, and Twitter. It also provides data connectors that support the Insider risk management solution.

In addition to these native data connectors, Microsoft works with the following partners to provide many more third-party data connectors in the Microsoft Purview portal. Your organization works with these partners to set up their archiving service before creating a corresponding data connector in the Microsoft Purview portal.

- TeleMessage
- 17a-4 LLC
- CellTrust

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

The third-party data connectors described in this article (except for HR data and physical badging data that the Microsoft Purview Insider Risk Management solution uses) import into user mailboxes. The Microsoft Purview solutions that support third-party data apply to the user mailbox where the data is stored.

> **Important**
>
> All Veritas data connectors in Microsoft Purview were retired on June 30, 2024. Non-Veritas data connectors in your organization aren't affected by this change. Contact your Veritas account representative if you have questions about Veritas archiving services.

Microsoft Purview data connectors

The following table lists the native third-party data connectors available in the Microsoft Purview portal. The table also summarizes the compliance solutions that you can apply after you import and archive third-party data in Microsoft 365. For a more detailed description of each compliance solution and how it supports third-party data, see the Overview of compliance solutions that support third-party data section.

Select the link in the **Third-party data** column to go to the step-by-step instructions for creating a connector for that data type.

Expand table

TeleMessage data connectors

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

The following table lists the third-party data connectors available through the partnership with TeleMessage. The table also summarizes the compliance solutions you can apply to third-party data after you import and archive it in Microsoft 365. For more information about each compliance solution and how it supports third-party data, see the Overview of compliance solutions that support third-party data section.

Before you can archive third-party data in Microsoft 365, you need to work with TeleMessage to set up their archiving service for your organization. For more information, select the link in the

Third-party data column to go to the step-by-step instructions for creating a connector for that data type.

You can also use TeleMessage data connectors in GCC environments in the Microsoft 365 US Government cloud. For more information, see the Data connectors in the US Government cloud section in this article.

17a-4 data connectors

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

The following table lists the third-party data connectors available through a partnership with 17a-4 LLC. The table also summarizes the compliance solutions you can apply to third-party data after you import and archive it in Microsoft 365. For a detailed description of each compliance solution and how it supports third-party data, see the Overview of compliance solutions that support third-party data section.

Before you can archive third-party data in Microsoft 365, you need to work with 17a-4 LLC to set up their archiving service (called *DataParser*) for your organization. For more information, select the link in the **Third-party data** column to go to the step-by-step instructions for creating a connector for that data type.

You can also use 17a-4 data connectors in GCC environments in the Microsoft 365 US Government cloud. For more information, see the Data connectors in the US Government cloud section in this article.

CellTrust data connectors

> ⓘ **Important**

All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.

To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

The following table lists the third-party data connector available through a partnership with CellTrust. The table also summarizes the compliance solutions you can apply to third-party data after you import and archive it in Microsoft 365. For a more detailed description of each compliance solution and how it supports third-party data, see the Overview of compliance solutions that support third-party data section.

Before you can archive third-party data in Microsoft 365, you need to work with CellTrust to set up their archiving service, *CellTrust SL2*, for your organization. For more information, select the link in the **Third-party data** column to go to the step-by-step instructions for creating a CellTrust SL2 connector.

Expand table

Third-party data	Litigation Hold	eDiscovery	Retention settings	Records management	Communication Compliance	Insider Risk Management
CellTrust SL2	✔	✔	✔	✔	✔	

The CellTrust SL2 data connector is also available in GCC environments in the Microsoft 365 US Government cloud. For more information, see the Data connectors in the US Government cloud section in this article.

Provision a service principal for third-party data connectors

For partner third-party data connectors, you must configure a service principal. Before you begin, confirm the Azure CLI is installed on your computer.

Complete the following steps to configure a service principal for your organization:

1. Open PowerShell and verify the Azure CLI installation:

```
PowerShell
```

```
az version
```

2. Sign in with the administrator account for your organization:

```PowerShell
az login
```

3. Run the following cmdlet to create the service principal for your organization. Replace `<PartnerAppId>` with the application ID provided by the partner (TeleMessage, 17a-4 LLC, or CellTrust):

```PowerShell
az ad sp create --id <PartnerAppId>
```

Overview of Microsoft Purview solutions that support third-party data

The following sections describe how Microsoft Purview solutions help you manage imported third-party data, including Communication Compliance, eDiscovery, Insider Risk Management, Litigation Hold, Records management, and Retention settings.

Communication Compliance

Use Microsoft Purview Communication Compliance to examine third-party data to make sure it complies with your organization's data standards. You can detect, capture, and take remediation actions for inappropriate messages in your organization. For example, you can monitor the third-party data that you import for offensive language, sensitive information, and regulatory compliance.

eDiscovery

Microsoft Purview eDiscovery is the primary legal investigation tool in Microsoft 365. Use eDiscovery to add custodians to a case, place a custodian's data on hold, and load a custodian's third-party data into a review set for further analysis such as themes and duplicate detection. After you load third-party data into a review set, you can query and filter it to a narrow result set. Use eDiscovery to manage third-party data that might be relevant to your organization's legal or internal investigations.

You can also use eDiscovery to search for and create query-based holds to preserve third-party data. To search for third-party data imported to user mailboxes, use the `kind:externaldata` property in your search query. To search for a specific type of third-party data, use the `itemclass:ipm.externaldata.<third-party data type>` mailbox property. For more information, see Find content in mailboxes and Use Keyword Query Language to create search queries.

Insider Risk Management

By using signals from third-party data, such as selective HR data, Microsoft Purview Insider Risk Management helps you minimize internal risks by detecting, investigating, and acting on risky activities in your organization. For example, data imported by the HR data connector is used as risk indicators to help detect departing user data theft. The healthcare data connector supports risk indicators for patient data misuse, and the third-party insider risk detections connector lets you extend detections to non-Microsoft workloads.

Litigation Hold

Place a Litigation Hold on a user mailbox to retain third-party data. When you create a hold, specify a hold duration (also called a *time-based hold*) so that deleted and modified third-party data is retained for a specified period and then permanently deleted from the mailbox. Or retain content indefinitely (called an *infinite hold*) or until the Litigation Hold is removed.

Records management

The Microsoft Purview Records Management solution lets you declare third-party data as a record. Users can manually apply a retention label that marks third-party data in their mailbox as a record. Or you can auto-apply retention labels by identifying sensitive information, keywords, or content types in third-party data.

Retention settings

Apply a retention policy to user mailboxes to retain and then delete third-party data (and other mailbox content) after the retention period expires. Use retention policies to delete third-party data of a certain age or use retention labels to trigger a disposition review when the retention period for third-party data expires.

Data connectors in the US Government cloud

Some data connectors are available in the US Government cloud. The following tables show the specific government environments that support third-party data connectors. For more information about US Government clouds, see Microsoft 365 US Government.

Microsoft data connectors in the US Government cloud

The following table lists Microsoft data connectors available in US Government cloud environments.

Expand table

Data connector	GCC	GCC High	DoD
Human resources (HR)	Yes	Yes	Yes

TeleMessage data connectors in the US Government cloud

The following table lists TeleMessage data connectors available in US Government cloud environments.

Set up a connector to manage Anthropic Claude data

Use a connector to manage the activity feed and chat conversations from Anthropic Claude. After you set up and configure the connector, it connects by using the Anthropic Compliance API. Microsoft Purview ingests the data, which begins showing up in Data Security Posture Management reports after about one day.

Before you begin

Before you set up the Anthropic Claude data connector, make sure the following prerequisites are in place.

Subscription

To learn more about Microsoft 365 tenant-level services licensing requirements, see Microsoft 365 Security.

Anthropic Enterprise plan

Your organization must have an **Enterprise** plan from Anthropic. The primary owner must enable the Compliance API in **Organization Settings** > **Data and Privacy**. On this page, you can also retrieve your Compliance Access Key by going to **Compliance access keys** > **Create key**. You need this key in the next section where you set up the connector.

For more information about the Anthropic Compliance API, see Access the Compliance API.

Permissions

Assign the Data Connector Admin role to the user who creates the Anthropic Claude data connector in the Microsoft Purview portal. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

Set up the Anthropic Claude data connector

To set up the Anthropic Claude data connector, perform the following steps.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **All connectors**.
4. From the list, select **Anthropic Claude**.
5. On the **Anthropic Claude** product description page, select **Add connector**.
6. On the **Terms of service** page, review and select **Accept**.
7. On the **Connector name** page, enter a descriptive name for the connector and select **Next**.
8. On the **Authentication** page, enter the following information:
    - **API Key**: Enter the Compliance API key generated from your Anthropic Organization Settings. Select **Validate connection**.
    - **Organization IDs**: Select your Anthropic organization identifier.
    - **API Base URL**: Confirm the Anthropic API base URL (the default is `https://api.anthropic.com`).
9. Select **Next**.
10. On the **Data scope** page, select the data types to import:
    - **Activity Feed** — Authentication events, chat interactions, file uploads, admin actions, and compliance audit events across Claude.ai, Console, and API. *(Scope: read:compliance_activities)*
    - **Chat Conversations** — Full message history between users and Claude, including user prompts, AI responses, and metadata for DSPM analysis. *(Scope: read:compliance_user_data)*
    - Select a **Sync frequency** to determine how often the connector pulls new data from the Anthropic Compliance API.
11. Select **Next**.
12. On the **Review your connector** page, verify your connector configuration and select **Finish**.

After you create the connector, you can see the following data:

- **Ongoing sync**: View new activities and chats that the connector imports based on your selected frequency.
- **DSPM**: View Claude interaction data in the DSPM Dashboard and Activity Explorer.
- **Monitoring**: View connector health and sync status in **Data connectors** > **My connectors**.

ⓘ **Note:** The author created this article with assistance from AI. Learn more

Set up a connector to archive Bloomberg Message data

Use a data connector to import and archive financial services email data from the Bloomberg Message collaboration tool. After you set up and configure a connector, it connects to your organization's Bloomberg secure FTP (SFTP) site once every day, and imports email items to mailboxes in Microsoft 365.

After storing Bloomberg Message data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, In-Place Archiving, Auditing, Communication Compliance, and Microsoft 365 retention policies to Bloomberg Message data. For example, you can search Bloomberg Message emails by using eDiscovery or associate the mailbox that contains the Bloomberg Message data with a custodian in an eDiscovery (Premium) case. Using a Bloomberg Message connector to import and archive data in Microsoft 365 can help your organization stay compliant with government and regulatory policies.

Overview of archiving Bloomberg Message data

The following overview explains the process of using a connector to archive Bloomberg Message data in Microsoft 365.

1. Your organization works with Bloomberg to set up a Bloomberg SFTP site. You also work with Bloomberg to configure Bloomberg Message to copy email messages to the

Bloomberg SFTP site.

2. Every 24 hours, Bloomberg Message copies email messages to the Bloomberg SFTP site.

3. The Bloomberg Message connector that you create in the Microsoft Purview portal connects to the Bloomberg SFTP site every day and transfers the email messages from the previous 24 hours to a secure Azure Storage area in the Microsoft Cloud.

4. The connector imports the email message items to the mailbox of a specific user. A new folder named BloombergMessage is created in the specific user's mailbox and the items are imported to it.

   The connector uses the value of the CorporateEmailAddress property. Every email message contains this property, which is populated with the email address of every participant of the email message. In addition to automatic user mapping by using the value of the *CorporateEmailAddress* property, you can also define a custom mapping by uploading a CSV mapping file. This mapping file contains a Bloomberg UUID and the corresponding Microsoft 365 mailbox address for each user in your organization. If you enable automatic user mapping and provide a custom mapping, for every email item the connector first looks at the custom-mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's Bloomberg UUID, the connector uses the *CorporateEmailAddress* property of the email item. If the connector doesn't find a valid Microsoft 365 user in either the custom-mapping file or the *CorporateEmailAddress* property of the email item, the item won't be imported.

Before you begin

Some of the implementation steps for archiving Bloomberg Message data are external to Microsoft 365. You must complete these steps before you create the connector in the Microsoft Purview portal.

- To set up a Bloomberg Message connector, you need keys and key passphrases for Pretty Good Privacy (PGP) and Secure Shell (SSH). Use these keys to configure the Bloomberg SFTP site. The connector uses these keys to connect to the Bloomberg SFTP site and import data to Microsoft 365. Use the PGP key to configure the encryption of data that's transferred from the Bloomberg SFTP site to Microsoft 365. Use the SSH key to configure secure shell to enable a secure remote authentication when the connector connects to the Bloomberg SFTP site.

  When setting up a connector, you can use public keys and key passphrases provided by Microsoft or use your own private keys and passphrases. We recommend that you use the public keys provided by Microsoft. However, if your organization already configured a

Bloomberg SFTP site by using private keys, you can create a connector by using these same private keys.

- Subscribe to Bloomberg Anywhere. This subscription is required so that you can sign in to Bloomberg Anywhere to access the Bloomberg SFTP site that you set up and configure.

- Set up a Bloomberg SFTP (Secure file transfer protocol) site. After working with Bloomberg to set up the SFTP site, data from Bloomberg Message is uploaded to the SFTP site every day. The connector you create in Step 2 connects to this SFTP site and transfers the email data to Microsoft 365 mailboxes. SFTP also encrypts the Bloomberg Message data that is sent to mailboxes during the transfer process.

  For information about Bloomberg SFTP (also called *BB-SFTP*):

  - See the "SFTP Connectivity Standards" document at Bloomberg Support.
  - Contact Bloomberg customer support.

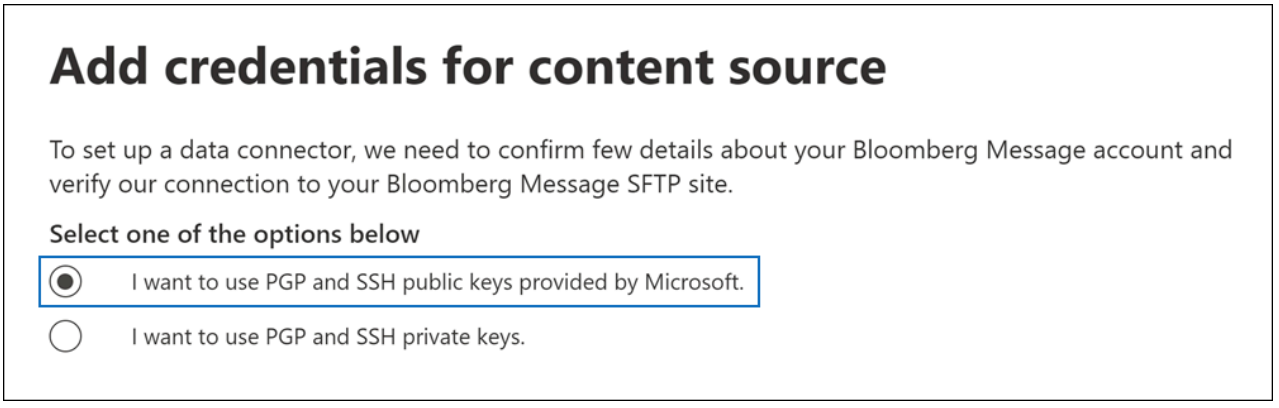
- After you work with Bloomberg to set up an SFTP site, Bloomberg provides some information to you after you respond to the Bloomberg implementation email message. Save a copy of the following information. You use it to set up a connector in Step 3.

  - Firm code, which is an ID for your organization and is used to sign in to the Bloomberg SFTP site.
  - Password for your Bloomberg SFTP site
  - URL for Bloomberg SFTP site (for example, sftp.bloomberg.com). In addition, Bloomberg might also provide a corresponding IP address for the Bloomberg SFTP site, which you can also use to set up the connector.
  - Port number for Bloomberg SFTP site

- The Bloomberg Message connector can import a total of 200,000 items in a single day. If there are more than 200,000 items on the SFTP site, none of those items are imported to Microsoft 365.

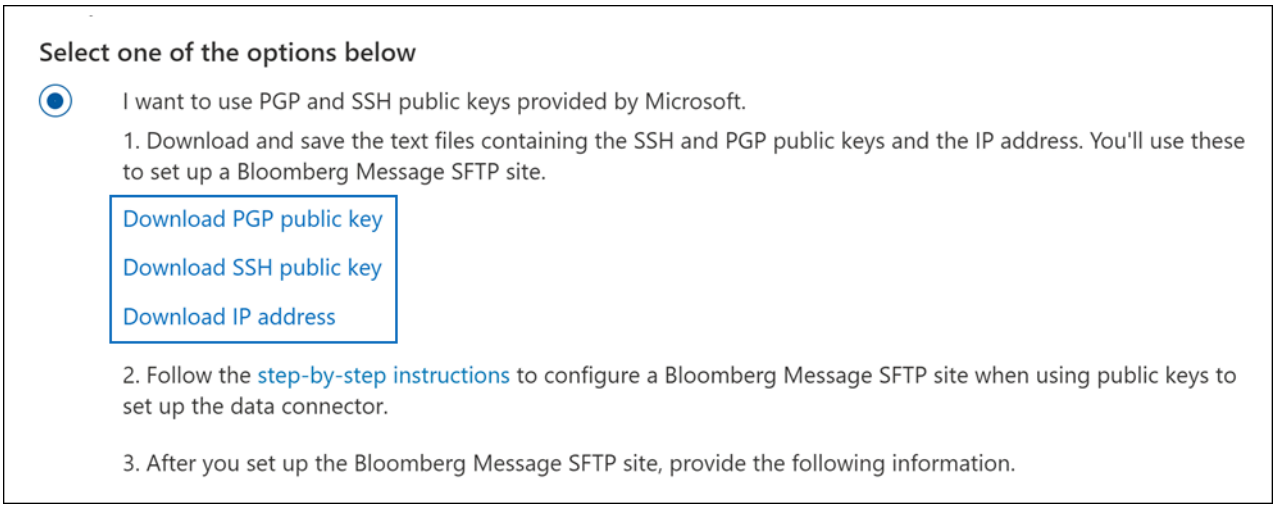
- The user who creates a Bloomberg Message connector in Step 3 (and who downloads the public keys and IP address in Step 1) must be assigned the Data Connector Admin role. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For

instructions, see:- Permissions in the Microsoft Purview portal - Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview compliance



Set up a connector by using public keys

The following steps show you how to set up a Bloomberg Message connector by using the public keys for Pretty Good Privacy (PGP) and Secure Shell (SSH).



Step 1: Obtain PGP and SSH public keys

First, get a copy of the PGP and SSH public keys. You use these keys in Step 2 to set up the Bloomberg SFTP site so it allows the connector (that you create in Step 3) to connect to the SFTP site and transfer the Bloomberg Message email data to Microsoft 365 mailboxes. You also get an IP address in this step, which you use when configuring the Bloomberg SFTP site.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, choose **Bloomberg Message**, select **View**.
5. On the **Bloomberg Message** product description page, select **Add connector**.
6. On the **Terms of service** page, select **Accept**.
7. On the **Add credentials for content source** page, select **I want to use PGP and SSH public keys provided by Microsoft**.

8. Under step 1, select the **Download SSH key**, **Download PGP key**, and **Download IP address** links to save a copy of each file to your local computer.

These files contain the following items that you use to configure the Bloomberg SFTP site in Step 2:

- PGP public key: Use this key to configure the encryption of data that's transferred from the Bloomberg SFTP site to Microsoft 365.
- SSH public key: Use this key to configure secure shell to enable a secure remote authentication when the connector connects to the Bloomberg SFTP site.
- IP address: Configure the Bloomberg SFTP site to accept connection requests from this IP address. The same IP address is used by the Bloomberg Message connector to connect to the SFTP site and transfer Bloomberg Message data to Microsoft 365.

9. Select **Cancel** to close the workflow. You come back to this workflow in Step 3 to create the connector.

Step 2: Configure the Bloomberg SFTP site

> **Note**
>
> If your organization previously set up a Bloomberg SFTP site to archive Instant Bloomberg data by using public PGP and SSH keys, you don't need to set up another one. You can specify the same SFTP site when you create the connector in Step 3.

Use the PGP and SSH public keys and the IP address that you got in Step 1 to configure PGP encryption and SSH authentication for the Bloomberg SFTP site. This configuration lets the Bloomberg Message connector that you create in Step 3 connect to the Bloomberg SFTP site and transfer Bloomberg Message data to Microsoft 365. You need to work with Bloomberg customer support to set up your Bloomberg SFTP site. Contact Bloomberg customer support for assistance.

> **Important**
>
> Bloomberg recommends that you attach the three files that you download in Step 1 to an email message and send it to their customer support team when working with them to set up your Bloomberg SFTP site.

Step 3: Create a Bloomberg Message connector

In this step, you create a Bloomberg Message connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the Bloomberg SFTP site and transfer email messages to the corresponding user mailboxes in Microsoft 365.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. Choose **Bloomberg Message** from the list.
5. On the **Terms of service** page, select **Accept**.
6. On the **Add credentials for content source** page, select **I want to use PGP and SSH public keys provided by Microsoft**.
7. Under Step 3, enter the required information in the following boxes and then select **Validate connection**.
   - **Name:** The name for the connector. It must be unique in your organization.
   - **Firm code:** The ID for your organization that is used as the username for the Bloomberg SFTP site.
   - **Password:** The password for your organization's Bloomberg SFTP site.
   - **SFTP URL:** The URL for the Bloomberg SFTP site (for example, `sftp.bloomberg.com`). You can also use an IP address for this value.
   - **SFTP port:** The port number for the Bloomberg SFTP site. The connector uses this port to connect to the SFTP site.
8. After the connection is successfully validated, select **Next**.
9. On the **Define user** page, specify the users to import data for.
   - **All users in your organization**. Select this option to import data for all users.
   - **Only users on Litigation hold**. Select this option to import data only for users whose mailboxes are placed on Litigation hold. This option imports data to user mailboxes

that have the LitigationHoldEnabled property set to True. For more information, see Create a Litigation hold.

10. On the **Map Bloomberg Message users to Microsoft 365 users** page, enable automatic user mapping and provide custom user mapping as required.

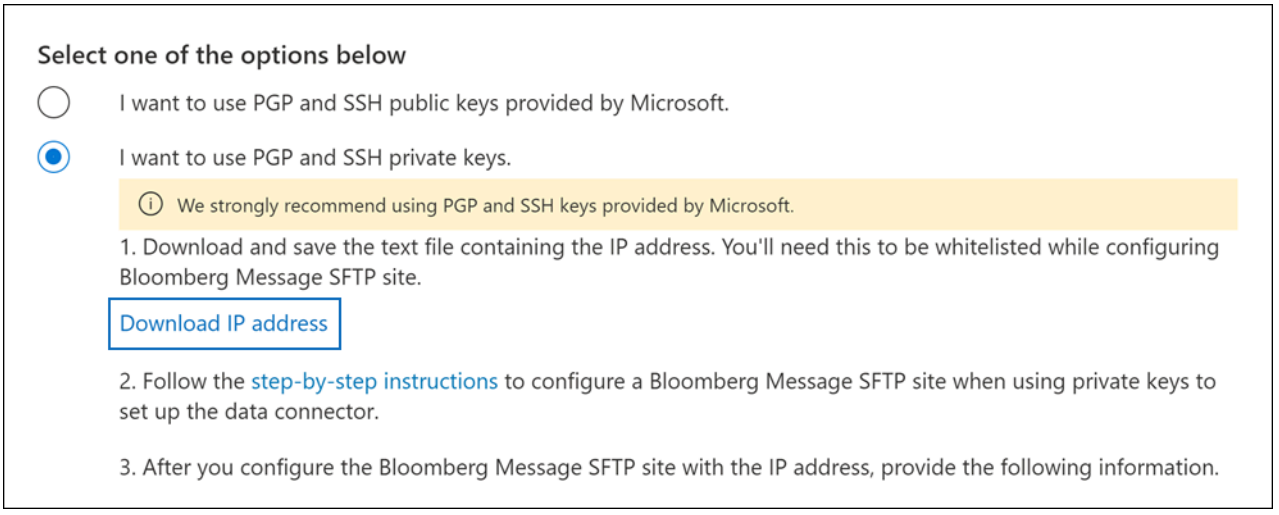
    > **Note**
    >
    > The connector imports message items to the mailbox of a specific user. A new folder named **BloombergMessage** is created in the specific user's mailbox and the items are imported to it. The connector uses the value of the *CorporateEmailAddress* property. Every chat message contains this property, and the property is populated with the email address of every participant of the chat message. In addition to automatic user mapping using the value of the *CorporateEmailAddress* property, you can also define custom mapping by uploading a CSV mapping file. The mapping file should contain the Bloomberg UUID and corresponding Microsoft 365 mailbox address for each user. If you enable automatic user mapping and provide a custom mapping, for every message item the connector will first look at custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's Bloomberg UUID, the connector will use the *CorporateEmailAddress* property of the chat item. If the connector doesn't find a valid Microsoft 365 user in either the custom mapping file or the *CorporateEmailAddress* property of the message item, the item won't be imported.

11. Select **Next**, review your settings, and then select **Finish** to create the connector.

Set up a connector by using private keys

The steps in this section show you how to set up a Bloomberg Message connector by using PGP and SSH private keys. Use this connector setup option if your organization already configured a Bloomberg SFTP site by using private keys.

Step 1: Obtain an IP address to configure the Bloomberg SFTP site



> **Note**

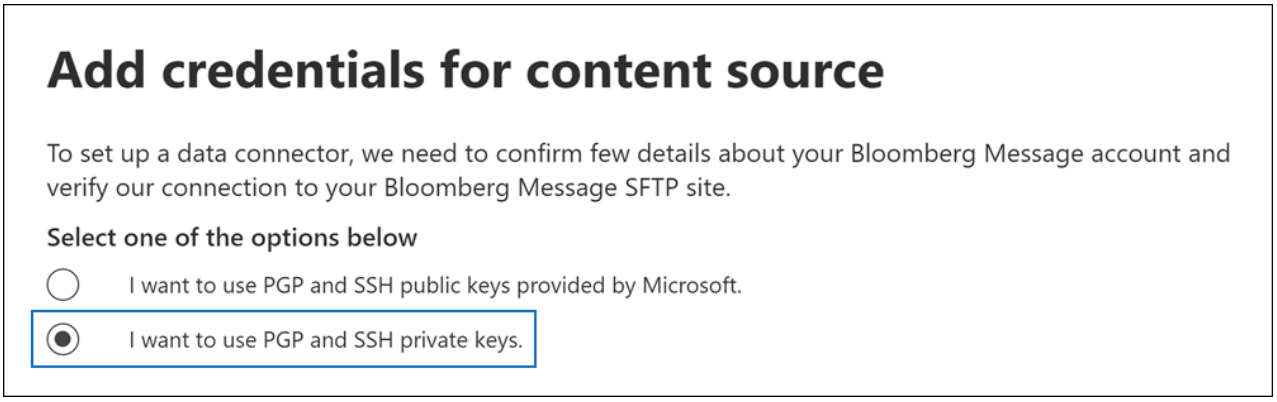
If your organization previously configured a Bloomberg SFTP site to archive Instant Bloomberg data by using PGP and SSH private keys, you don't need to configure another one. You can specify the same SFTP site when you create the connector in Step 2.

If your organization used PGP and SSH private keys to set up a Bloomberg SFTP site, you need to obtain an IP address and provide it to Bloomberg customer support. The Bloomberg SFTP site must be configured to accept connection requests from this IP address. The same IP address is used by the Bloomberg Message connector to connect to the SFTP site and transfer Bloomberg Message data to Microsoft 365.

To obtain the IP address:

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. Choose **Bloomberg Message** from the list.
5. On the **Terms of service** page, select **Accept**.
6. On the **Add credentials for content source** page, select **I want to use PGP and SSH private keys**.
7. Under step 1, select **Download IP address** to save a copy of the IP address file to your local computer.

8. Select **Cancel** to close the workflow. You come back to this workflow in Step 4 to create the connector.



You need to work with Bloomberg customer support to configure your Bloomberg SFTP site to accept connection requests from this IP address. Contact Bloomberg customer support for

assistance.

Step 2: Create a Bloomberg Message connector

After configuring your Bloomberg SFTP site, create a Bloomberg Message connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the Bloomberg SFTP site and transfer email messages to the corresponding user mailboxes in Microsoft 365. To complete this step, have copies of the same private keys and key passphrases that you used to set up your Bloomberg SFTP site.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. Choose **Bloomberg Message** from the list.
5. On the **Terms of service** page, select **Accept**.
6. On the **Add credentials for content source** page, select **I want to use PGP and SSH private keys**.

7. Under Step 3, enter the required information in the following boxes and then select **Validate connection**.

   - **Name:** The name for the connector. It must be unique in your organization.
   - **Firm code:** The ID for your organization that is used as the username for the Bloomberg SFTP site.
   - **Password:** The password for your organization's Bloomberg SFTP site.
   - **SFTP URL:** The URL for the Bloomberg SFTP site (for example, `sftp.bloomberg.com`). You can also use an IP address for this value.
   - **SFTP port:** The port number for the Bloomberg SFTP site. The connector uses this port to connect to the SFTP site.

- **PGP private key:** The PGP private key for the Bloomberg SFTP site. Include the entire private key value, including the beginning and ending lines of the key block.
- **PGP key passphrase:** The passphrase for the PGP private key.
- **SSH private key:** The SSH private key for the Bloomberg SFTP site. Include the entire private key value, including the beginning and ending lines of the key block.
- **SSH key passphrase:** The passphrase for the SSH private key.

8. After the connection is successfully validated, select **Next**.

9. On the **Define user** page, specify the users to import data for.

   - **All users in your organization**. Select this option to import data for all users.
   - **Only users on Litigation hold**. Select this option to import data only for users whose mailboxes are placed on Litigation hold. This option imports data to user mailboxes that have the LitigationHoldEnabled property set to True. For more information, see Create a Litigation hold.

10. On the **Map Bloomberg Message users to Microsoft 365 users** page, enable automatic user mapping and provide custom user mapping as required.

    > ⓘ Note
    >
    > The connector imports message items to the mailbox of a specific user. A new folder named **BloombergMessage** is created in the specific user's mailbox and the items are imported to it. The connector uses the value of the *CorporateEmailAddress* property. Every chat message contains this property, and the property is populated with the email address of every participant of the chat message. In addition to automatic user mapping using the value of the *CorporateEmailAddress* property, you can also define custom mapping by uploading a CSV mapping file. The mapping file should contain the Bloomberg UUID and corresponding Microsoft 365 mailbox address for each user. If you enable automatic user mapping and provide a custom mapping, for every message item the connector will first look at custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's Bloomberg UUID, the connector will use the *CorporateEmailAddress* property of the chat item. If the connector doesn't find a valid Microsoft 365 user in either the custom mapping file or the *CorporateEmailAddress* property of the message item, the item won't be imported.

11. Select **Next**, review your settings, and then select **Finish** to create the connector.

Limits

- Microsoft 365 doesn't support threading for Bloomberg Message email. The system imports individual messages sent to a person, but it doesn't show them in a threaded conversation.

Last updated on 03/30/2026

Set up a connector to archive Facebook data (preview)

Use a connector to import and archive data from Facebook Business pages to Microsoft 365. After you set up and configure the connector, it connects to the Facebook Business page on a scheduled basis, converts the content of Facebook items to an email message format, and then imports those items to a mailbox in Microsoft 365.

After the Facebook data is imported, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, In-Place Archiving, Auditing, Communication Compliance, and Microsoft 365 retention policies to the Facebook data. For example, when you place a mailbox on Litigation Hold or assign it to a retention policy, the Facebook data is preserved. You can search third-party data by using eDiscovery or associate the mailbox where the Facebook data is stored with a custodian in a Microsoft Purview eDiscovery (Premium) case. Using a connector to import and archive Facebook data in Microsoft 365 can help your organization stay compliant with government and regulatory policies.

Before you begin for setting up a connector for Facebook Business pages

Complete the following prerequisites before setting up and configuring a connector in the Microsoft Purview portal to import and archive data from your organization's Facebook Business pages.

- You need a Facebook account for your organization's business pages. You need to sign in to this account when setting up the connector. Currently, you can only archive data from Facebook Business pages; you can't archive data from individual Facebook profiles.
- Your organization must have a valid Azure subscription. If you don't have an existing Azure subscription, you can sign up for one of these options:
  - Sign up for a free one year Azure subscription
  - Sign up for a Pay-As-You-Go Azure subscription
- The connector for Facebook Business pages can import a total of 200,000 items in a single day. If there are more than 200,000 Facebook Business items in a day, none of those items

are imported to Microsoft 365.

- The user who sets up the custom connector in the Microsoft Purview portal (in Step 5) must be assigned the Data Connector Admin role. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

Step 1: Create an app in Microsoft Entra ID

First, register a new app in Microsoft Entra ID. This app corresponds to the Azure web app resource used by the Facebook connector, which you deploy in Step 2 and configure in Step 4.

For more information, see Create an app in Microsoft Entra ID.

When you complete this step, save the following information to a text file. You'll use these values in later steps in the deployment process.

- Microsoft Entra application ID
- Microsoft Entra application secret
- Tenant Id

Step 2: Deploy the connector web service from GitHub to your Azure account

Next, deploy the source code for the Facebook Business pages connector app. This app uses the Facebook API to connect to your Facebook account and extract data so you can import it to Microsoft 365. The Facebook connector that you deploy for your organization uploads the items from your Facebook Business pages to the Azure Storage location that you create in this step. After you create a Facebook business pages connector in the Microsoft Purview portal (in Step 5), the Import service copies the Facebook business pages data from the Azure Storage location to a mailbox in your Microsoft 365 organization. As explained in the Before you begin section, you must have a valid Azure subscription to create an Azure Storage account.

For more information, see Deploy the connector web service from GitHub to your Azure account.

When you complete this step, provide the following information:

- APISecretKey: Create this secret during the completion of this step. It's used in Step 5.
- TenantId: The tenant ID of your Microsoft 365 organization that you copied after creating the Facebook connector app in Microsoft Entra ID in Step 1.

After you complete this step, copy the Azure app service URL (for example, `https://fbconnector.azurewebsites.net`). You need to use this URL to complete Step 3, Step 4, and Step 5.

Step 3: Register the web app on Facebook

Create and configure a new app on Facebook. The Facebook business pages connector that you create in Step 5 uses the Facebook web app to interact with the Facebook API to obtain data from your organization's Facebook Business pages.

For more information, see Register the Facebook app.

When you complete this step, save the following information to a text file. You use these values to configure the Facebook connector app in Step 4.

- Facebook application ID
- Facebook application secret
- Facebook webhooks verify token

Step 4: Configure the Facebook connector app

Add configuration settings to the Facebook connector app that you deployed as an Azure web app resource in Step 2. Go to the home page of the Facebook connector Azure web app and configure the connector app.

For more information, see Configure the Facebook connector app.

When you complete this step, provide the following information (that you copied to a text file after completing the previous steps):

- Facebook application ID (obtained in Step 3)
- Facebook application secret (obtained in Step 3)
- Facebook webhooks verify token (obtained in Step 3)
- Microsoft Entra application ID (the Microsoft Entra application ID obtained in Step 1)
- Microsoft Entra application secret (the Microsoft Entra application secret obtained in Step 1)

Step 5: Set up a Facebook Business pages connector in the Microsoft Purview portal

In this step, you set up the connector in the Microsoft Purview portal that imports data from your Facebook Business pages to a specified mailbox in Microsoft 365. When you finish this step, the Microsoft 365 Import service starts importing data from your Facebook Business pages to Microsoft 365.

For more information, see Step 5: Set up a Facebook connector in the Microsoft Purview portal.

As you complete this step, you provide the following information, which you copy to a text file after completing the steps:

- Microsoft Entra application ID (obtained in Step 1)
- Azure app service URL (obtained in Step 2; for example, `https://fbconnector.azurewebsites.net`)
- APISecretKey (created in Step 2)

Set up a connector to import healthcare EHR audit data (preview)

You can set up a data connector to import auditing data for user activity in your organization's Electronic Healthcare Records (EHR) system. Auditing data from your healthcare EHR system includes data for events related to accessing a patient's health records. Microsoft Purview Insider Risk Management solution uses healthcare EHR auditing data to help protect your organization from unauthorized access to patient information.

Setting up a Healthcare connector consists of the following tasks:

- Creating an app in Microsoft Entra ID to access an API endpoint that accepts a tab-separated text file containing healthcare EHR auditing data.
- Creating a text file with all the required fields as defined in the connector schema.
- Creating a Healthcare connector instance in the Microsoft Purview portal.
- Running a script to push healthcare EHR auditing data to the API endpoint.
- Optionally, scheduling the script to run automatically to import the auditing data.

Before you begin

- Assign the Data Connector Admin role to the user who creates the Healthcare connector in Step 3. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see:- Permissions in the Microsoft Purview portal - Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview compliance

- Determine how to retrieve or export the data from your organization's healthcare EHR system (on a daily basis) and create a text file that's described in Step 2. The script that you run in Step 4 pushes the data in the text file to the API endpoint.

- Understand that the sample script you run in Step 4 pushes the healthcare EHR auditing data from a text file to the connector API so that the insider risk management solution can use it. This sample script isn't supported under any Microsoft standard support program or service. The sample script is provided AS IS without warranty of any kind. Microsoft further disclaims all implied warranties including, without limitation, any implied warranties of merchantability or of fitness for a particular purpose. You assume all risk arising from the use or performance of the sample script and documentation. In no event shall Microsoft, its authors, or anyone else involved in the creation, production, or delivery

of the scripts be liable for any damages whatsoever (including, without limitation, damages for loss of business profits, business interruption, loss of business information, or other pecuniary loss) arising out of the use of or inability to use the sample scripts or documentation, even if Microsoft has been advised of the possibility of such damages.

Step 1: Create an app in Microsoft Entra ID

First, create and register a new app in Microsoft Entra ID. The app corresponds to the Healthcare connector that you create in Step 3. When you create the app, Microsoft Entra ID can authenticate the push request for a text file containing healthcare EHR auditing data. During the creation of this Microsoft Entra app, save the following information. You use these values in later steps.

- Microsoft Entra application ID (also called the *app Id* or *client Id*)
- Microsoft Entra application secret (also called the *client secret*)
- Tenant Id (also called the *directory Id*)

For step-by-step instructions for creating an app in Microsoft Entra ID, see Register an application with the Microsoft identity platform.

Step 2: Prepare a text file with healthcare EHR auditing data

Next, create a text file that contains information about employees' access to patient health records in your organization's healthcare EHR system. As previously explained, determine how to generate this text file from your healthcare EHR system. The Healthcare connector workflow requires a text file with tab-separated values to map that data in the text file with required connector schema. The supported file formats are comma (.csv), pipe (.psv), or tab (.tsv) separated text files.

> **Note**
>
> The maximum size of the text file that contains the auditing data is 3 GB. The maximum number of rows is 5 million. Also, be sure to only include the relevant auditing data from your healthcare EHR system.

The following table lists the fields that are required to enable insider risk management scenarios. A subset of these fields is mandatory. These fields are highlighted with an asterisk (*). If the text file is missing any of the mandatory fields, the file isn't validated and the data in the file isn't imported.

Expand table

Field	Category
Creation Time* Event Name* Workstation Id Event Section Event Category	These fields are used to identify access activity events in your healthcare EHR system.
Patient Reg Id Patient First Name* Patient Middle Name Patient Last Name* Patient Address Line 1* Patient Address Line 2 Patient City* Patient Zip Code* Patient State Patient Country Patient Department	These fields are used to identify patient profile information.
Restricted Access Reason* Restricted Access Comment	These fields are used to identify access to restricted records.
Email Address (UPN) or SamAccountName* Employee User Name Employee Id Employee Last Name [1] Employee First Name [1]	These fields are used to identify employee profile information for address and name matching required to determine access to Family/Neighbor/Employee records.

> **Note**
>
> [1]This field might not be available by default in your healthcare EHR system. You need to configure the export to ensure the text file contains this field.

Step 3: Create the Healthcare connector

In this step, you create a Healthcare connector in the Microsoft Purview portal. After you run the script in Step 4, the connector processes the text file you created in Step 2 and pushes it to the API endpoint you set up in Step 1. Be sure to copy the JobId generated when you create the connector. You need the JobId when you run the script.

1. Sign in to the Microsoft Purview portal.

2. Select **Settings** > **Data connectors**.

3. Select **My connectors**, then select **Add connector**.

4. From the list, choose **Healthcare (preview)**.

5. Accept the terms of service.

6. On the **Authentication credentials** page, enter the following information and select **Next**:
   a. Enter or paste the Microsoft Entra application ID for the Azure app that you created in Step 1.
   b. Enter a name for the healthcare connector.

7. On the **File mapping method** page, select one of the following options and select **Next**:

   - **Upload a sample file**. Select **Upload sample file** to upload the file that you prepared in Step 2. With this option, you can quickly select column names in your text file from a drop-down list to map the columns to the required schema for the healthcare connector.

   Or

   - **Manually provide the mapping details**. Type the name of the columns in your text file to map the columns to the required schema for the healthcare connector.

8. On the **File mapping details** page, complete one of the following steps, depending on whether you uploaded a sample file in the previous step:

   - Use the dropdown lists to map the columns from the sample file to each required field for the healthcare connector.

   Or

   - For each field, type the column name from the file that you prepared in Step 2 that corresponds to the field for the healthcare connector.

9. On the **Review** page, review your settings and select **Finish** to create the connector.

   A status page confirms the connector was created. This page contains two important items that you need to complete the next step to run the sample script to upload your healthcare EHR auditing data.

   - **Job ID.** You need this job ID to run the script in the next step. You can copy it from this page or from the connector flyout page.
   - **Link to sample script.** Select the **here** link to go to the GitHub site to access the sample script. The link opens a new window. Keep this window open so that you can

copy the script in Step 4. Alternatively, you can bookmark the destination or copy the URL so you can access it again when you run the script. This link is also available on the connector flyout page.

10. Select **Done**.

    The new connector appears in the list on the **Connectors** tab.

11. Select the Healthcare connector that you just created to display the flyout page, which contains properties and other information about the connector.

If you haven't already done so, copy the values for the **Azure App ID** and **Connector job ID**. You need these values to run the script in the next step. You can also download the script from the flyout page or using the link in the next step.

Select **Edit** to change the Azure App ID or the column header names that you defined on the **File mapping** page.

Step 4: Run the sample script to upload your healthcare EHR auditing data

The last step in setting up a Healthcare connector is to run a sample script that uploads the healthcare EHR auditing data in the text file (that you created in Step 1) to the Microsoft cloud. Specifically, the script uploads the data to the Healthcare connector. After you run the script, the Healthcare connector that you created in Step 3 imports the healthcare EHR auditing data to your Microsoft 365 organization where other compliance tools, such as the Insider Risk Management solution, can access it. After you run the script, consider scheduling a task to run it automatically on a daily basis so the most current employee termination data is uploaded to the Microsoft cloud. For more information, see (Optional) Step 6: Schedule the script to run automatically.

> **Note**
>
> As previously stated, the maximum size of the text file that contains the auditing data is 3 GB. The maximum number of rows is 5 million. The script that you run in this step takes about 30 to 40 minutes to import the auditing data from large text files. Additionally, the script divides large text files into smaller blocks of 100K rows, and then imports those blocks sequentially.

1. Go to the window that you left open from the previous step to access the GitHub site with the sample script. Alternatively, open the bookmarked site or use the URL that you

copied. You can also access the script here.

2. Select the **Raw** button to display the script in text view.
3. Copy all the lines in the sample script and save them to a text file.
4. Modify the sample script for your organization, if necessary.
5. Save the text file as a Windows PowerShell script file by using a filename suffix of `.ps1`; for example, `HealthcareConnector.ps1`.
6. Open a Command Prompt on your local computer, and go to the directory where you saved the script.
7. Run the following command to upload the healthcare audit data in the text file to Microsoft cloud; for example:

```
PowerShell

.\HealthcareConnector.ps1 -tenantId <tenantId> -appId <appId>  -appSecret
<appSecret>  -jobId <jobId>  -filePath '<filePath>'
```

The following table describes the parameters to use with this script and their required values. Use the information you obtained in the previous steps for these values.

Expand table

Parameter	Description
tenantId	This is the Id for your Microsoft 365 organization that you obtained in Step 1. You can also obtain the tenant Id for your organization on the **Overview** blade in the Microsoft Entra admin center. This value identifies your organization.
appId	This is the Microsoft Entra application Id for the app that you created in Microsoft Entra ID in Step 1. Microsoft Entra ID uses this value for authentication when the script attempts to access your Microsoft 365 organization.
appSecret	This is the Microsoft Entra application secret for the app that you created in Microsoft Entra ID in Step 1. This value is also used for authentication.
jobId	This is the job ID for the Healthcare connector that you created in Step 3. This value associates the healthcare EHR auditing data that you upload to the Microsoft cloud with the Healthcare connector.
filePath	This is the file path for the text file (stored on the same system as the script) that you created in Step 2. Try to avoid spaces in the file path; otherwise use single quotation marks.

Here's an example of the syntax for the Healthcare connector script using actual values for each parameter:

```PowerShell
.\HealthcareConnector.ps1 -tenantId aaaabbbb-0000-cccc-1111-dddd2222eeee -appId 00001111-aaaa-2222-bbbb-3333cccc4444 -appSecret Aa1Bb~2Cc3.-Dd4Ee5Ff6Gg7Hh8Ii9_Jj0Kk1Ll2 -jobId 00001111-aaaa-2222-bbbb-3333cccc4444 -filePath 'C:\Users\contosoadmin\Desktop\Data\healthcare_audit_records.csv'
```

If the upload is successful, the script displays the **Upload Successful** message.

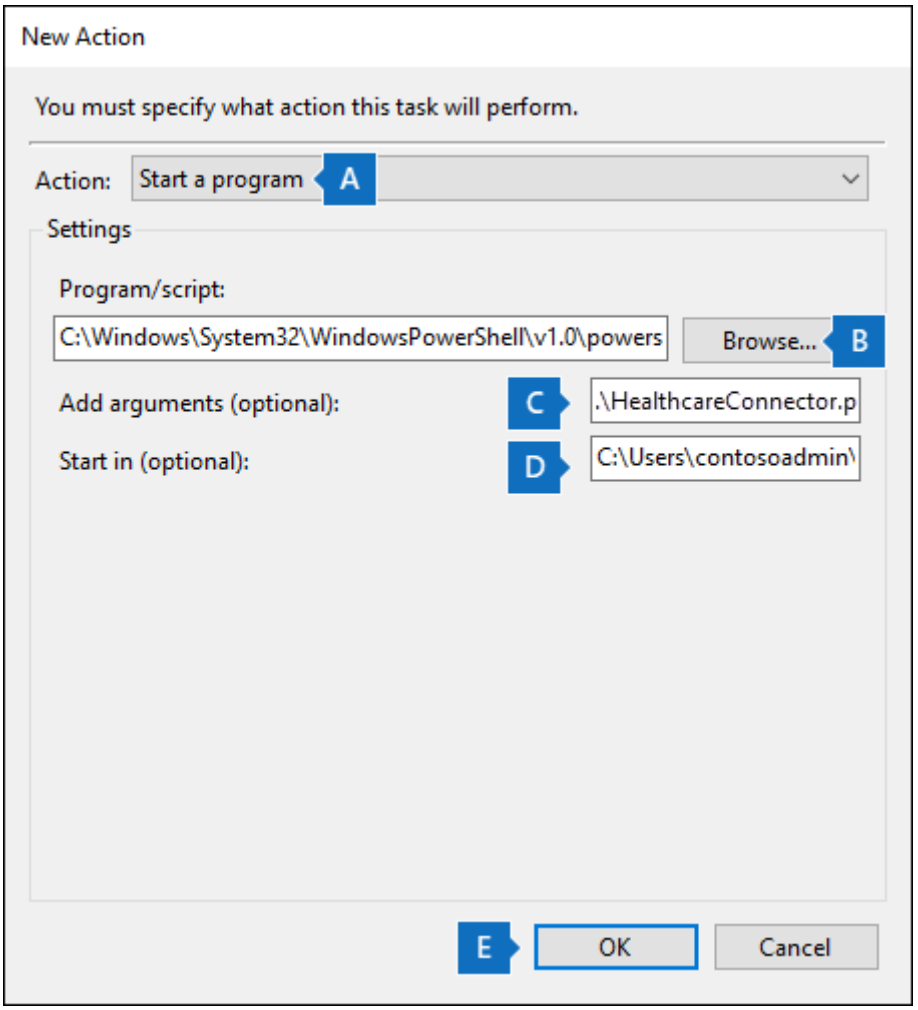
> **Note**
>
> If you have problems running the previous command because of execution policies, see About Execution Policies and Set-ExecutionPolicy for guidance about setting execution policies.

Step 5: Monitor the Healthcare connector

After you create the Healthcare connector and push your EHR auditing data, you can view the connector and upload status in the Microsoft Purview portal. If you schedule the script to run automatically on a regular basis, you can also view the current status after the last time the script runs.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select the Healthcare connector that you created to display the flyout page. This page contains the properties and information about the connector.
4. Under **Last import**, select the **Download log** link to open (or save) the status log for the connector. This log contains information about each time the script runs and uploads the data from the text file to the Microsoft cloud.

   The `RecordsSaved` field indicates the number of rows in the text file that the script uploads. For example, if the text file contains four rows, the value of the `RecordsSaved` fields is 4, if the script successfully uploads all the rows in the text file.

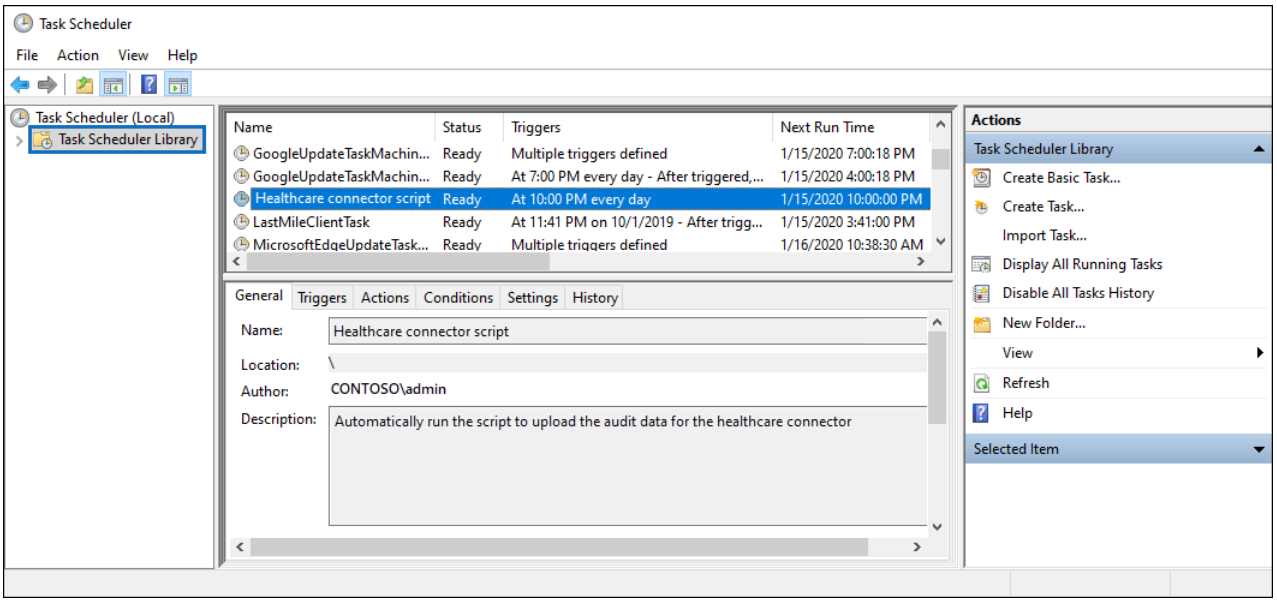


If you don't run the script in Step 4, a link to download the script appears under **Last import**. You can download the script and then follow the steps to run the script.

(Optional) Step 6: Schedule the script to run automatically

To make sure tools like the Insider Risk Management solution always have the latest auditing data from your healthcare EHR system, schedule the script to run automatically every day. You also need to update the EHR auditing data in the same text file on a similar schedule so it contains the latest information about patient records access activities by your employees. The goal is to upload the most current auditing data so the Healthcare connector can make it available to the insider risk management solution.

Use the Task Scheduler app in Windows to automatically run the script every day.



1. On your local computer, select the Windows **Start** button and type **Task Scheduler**.
2. Select the **Task Scheduler** app to open it.
3. In the **Actions** section, select **Create Task**.
4. On the **General** tab, type a descriptive name for the scheduled task, such as **Healthcare connector script**. You can also add an optional description.
5. Under **Security options**, do the following things:
   a. Decide whether to run the script only when you're logged on to the computer or run it when you're logged on or not.
   b. Make sure the **Run with the highest privileges** checkbox is selected.
6. Select the **Triggers** tab, select **New**, and then do the following things:
   a. Under **Settings**, select the **Daily** option, then choose a date and time to run the script for the first time. The script runs every day at the same specified time.
   b. Under **Advanced settings**, make sure the **Enabled** checkbox is selected.
   c. Select **Ok**.
7. Select the **Actions** tab, select **New**, and then do the following things:

a. In the **Action** dropdown list, make sure that **Start a program** is selected.
b. In the **Program/script** box, select **Browse**, go to the following location, and select it so the path is displayed in the box: `C:\Windows\System32\WindowsPowerShell\v1.0\powershell.exe`.
c. In the **Add arguments (optional)** box, paste the same script command that you ran in Step 4. For example, `.\HealthcareConnector.ps1 -tenantId "aaaabbbb-0000-cccc-1111-dddd2222eeee" -appId "00001111-aaaa-2222-bbbb-3333cccc4444" -appSecret "Aa1Bb~2Cc3.-Dd4Ee5Ff6Gg7Hh8Ii9_Jj0Kk1Ll2" -jobId "00001111-aaaa-2222-bbbb-3333cccc4444" -filePath "C:\Healthcare\audit\records.txt"`
d. In the **Start in (optional)** box, paste the folder location of the script that you ran in Step 4. For example, C:\Healthcare\audit.
e. Select **Ok** to save the settings for the new action.

8. In the **Create Task** window, select **Ok** to save the scheduled task. You might be prompted to enter your user account credentials.

   The new task appears in the Task Scheduler Library.

The last time the script ran and the next time it's scheduled to run is displayed. You can double-select the task to edit it.

You can also verify the last time the script ran on the flyout page of the corresponding Healthcare connector in the Microsoft Purview portal.

Set up a connector to import HR data

You can set up a data connector to import human resources (HR) data related to events such as a user's resignation or a change in a user's job level. The insider risk management solution uses the HR data to generate risk indicators that help you identify possible malicious activity or data theft by users inside your organization.

Setting up a connector for HR data that insider risk management policies use to generate risk indicators involves creating a CSV file that contains the HR data, creating an app in Microsoft Entra for authentication, creating an HR data connector in the Microsoft Purview portal, and running a script (on a scheduled basis) that ingests the HR data in CSV files to the Microsoft cloud so it's available to the insider risk management solution.

Before you begin

- Determine which HR scenarios and data to import to Microsoft 365. This determination helps you decide how many CSV files and HR connectors you need to create, and how to generate and structure the CSV files. The insider risk management policies you want to implement determine the HR data you import. For more information, see Step 1.
- Determine how to retrieve or export the data from your organization's HR system (regularly) and add it to the CSV files that you create in Step 1. The script that you run in Step 4 uploads the HR data in the CSV files to the Microsoft cloud.
- Assign the Data Connector Admin role to the user who creates the HR connector in Step 3. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see:- Permissions in the Microsoft Purview portal - Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview compliance
- Understand that the sample script you run in Step 4 uploads your HR data to the Microsoft cloud so that the insider risk management solution can use it. This sample script isn't supported under any Microsoft standard support program or service. The sample script is provided AS IS without warranty of any kind. Microsoft further disclaims all implied warranties including, without limitation, any implied warranties of merchantability or of fitness for a particular purpose. You assume all risk arising from the use or performance of the sample script and documentation. In no event shall Microsoft, its authors, or anyone else involved in the creation, production, or delivery of the scripts be liable for any damages whatsoever (including, without limitation, damages for loss of

business profits, business interruption, loss of business information, or other pecuniary loss) arising out of the use of or inability to use the sample scripts or documentation, even if Microsoft has been advised of the possibility of such damages.

- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant. For step-by-step instructions for setting up an HR connector in a GCC environment, see Set up a connector to import HR data in US Government.
- Add the *webhook.ingestion.office.com* domain to your firewall allowlist for your organization.

Step 1: Prepare a CSV file with your HR data

First, create a CSV file that contains the HR data the connector imports to Microsoft 365. The insider risk solution uses this data to generate potential risk indicators. You can import data for the following HR scenarios to Microsoft 365:

- Employee resignation. Information about employees who leave your organization.
- Job level changes. Information about job level changes for employees, such as promotions and demotions.
- Performance reviews. Information about employee performance.
- Performance improvement plans. Information about performance improvement plans for employees.
- Employee profile (preview). General information about an employee.

The type of HR data to import depends on the insider risk management policy and corresponding policy template you want to implement. The following table shows which HR data type each policy template requires:

Expand table

Policy template	HR data type
Data theft by departing users	Employee resignations

Policy template	HR data type
Data leaks	Not applicable
Data leaks by priority users	Not applicable
Data leaks by risky users	Job level changes, Performance reviews, Performance improvement plans
Security policy violations	Not applicable
Security policy violations by departing users	Employee resignations
Security policy violations by priority users	Not applicable
Security policy violations by risky users	Job level changes, Performance reviews, Performance improvement plans
Offensive language in email	Not applicable
Healthcare policy	Employee profile

For more information about policy templates for insider risk management, see Insider risk management policies.

For each HR scenario, provide the corresponding HR data in one or more CSV files. The number of CSV files to use for your insider risk management implementation is discussed later in this section.

After you create the CSV file with the required HR data, store it on the local computer where you run the script in Step 4. Implement an update strategy to make sure the CSV file always contains the most current information so that whatever you run the script, the most current HR data is uploaded to the Microsoft cloud and accessible to the insider risk management solution.

> **ⓘ Important**
>
> The column names described in the following sections aren't required parameters, but only examples. You can use any column name in your CSV files. However, you *must* map the column names you use in a CSV file to the data type when you create the HR connector in Step 3. Also note that the sample CSV files in the following sections are shown in NotePad view. It's much easier to view and edit CSV files in Microsoft Excel. The following sections describe the required CSV data for each HR scenario.

CSV file for employee resignation data

Here's an example of a CSV file for employee resignation data.

text

```
UserPrincipalName,ResignationDate,LastWorkingDate
sarad@contoso.com,2019-04-23T15:18:02.4675041+05:30,2019-04-
29T15:18:02.4675041+05:30
pilarp@contoso.com,2019-04-24T09:15:49Z,2019-04-29T15:18:02.7117540
```

The following table describes each column in the CSV file for employee resignation data.

Expand table

Column	Description
UserPrincipalName	The Microsoft Entra UserPrincipalName (UPN) used to identify the terminated user.
ResignationDate	Specifies the date the user's employment is officially terminated or the user resigns from your organization. For example, this date might be when the user gives their notice about leaving your organization. This date might be different from the date of the person's last day of work. Use the following date format: `yyyy-mm-ddThh:mm:ss.nnnnnn| -hh:mm`, which is the ISO 8601 date and time format.
LastWorkingDate	Specifies the last day of work for the terminated user. This date can't be more than six months prior or one year in advance from the time of upload. Use the following date format: `yyyy-mm-ddThh:mm:ss.nnnnnn| -hh:mm`, which is the ISO 8601 date and time format.

CSV file for job level changes data

Here's an example of a CSV file for job level changes data.

text

```
UserPrincipalName,EffectiveDate,OldLevel,NewLevel
sarad@contoso.com,2019-04-23T15:18:02.4675041+05:30,Level 61 - Sr. Manager,Level
60- Manager
pillar@contoso.com,2019-04-23T15:18:02.4675041+05:30,Level 62 - Director,Level 60-
Sr. Manager
```

The following table describes each column in the CSV file for job level changes data.

Expand table

Column	Description
UserPrincipalName	The Microsoft Entra UserPrincipalName (UPN) used to specify the user's email address.
EffectiveDate	Specifies the date that the user's job level is officially changed. Use the following date format: `yyyy-mm-ddThh:mm:ss.nnnnnn+ | -hh:mm`, which is the ISO 8601 date and time format.
Remarks	Specifies the remarks that evaluator provides about the change of job level. You can enter a limit of 200 characters. This parameter is optional. You don't have to include it in the CSV file.
OldLevel	Specifies the user's job level before it was changed. This is a free-text parameter and can contain hierarchical taxonomy for your organization. This parameter is optional. You don't have to include it in the CSV file.
NewLevel	Specifies the user's job level after it was changed. This is a free-text parameter and can contain hierarchical taxonomy for your organization. This parameter is optional. You don't have to include it in the CSV file.

CSV file for performance review data

Here's an example of a CSV file for performance data.

text

```
UserPrincipalName,EffectiveDate,Remarks,Rating
sarad@contoso.com,2019-04-23T15:18:02.4675041+05:30,Met expectations but bad
attitude,2-Below expectation
pillar@contoso.com,2019-04-23T15:18:02.4675041+05:30, Multiple conflicts with the
team
```

The following table describes each column in the CSV file for performance review data.

Expand table

Column	Description
UserPrincipalName	The Microsoft Entra UserPrincipalName (UPN) used to specify the user's email address.
EffectiveDate	Specifies the date that the user is officially informed about the result of their performance review. This date can be the date when the performance review cycle ends. Use the following date format: `yyyy-mm-ddThh:mm:ss.nnnnnn+ | -hh:mm`, which is the ISO 8601 date and time format.

Column	Description
Remarks	Specifies any remarks that evaluator provides to the user for the performance review. This is a text parameter with a limit of 200 characters. This parameter is optional. You don't have to include it in the CSV file.
Rating	Specifies the rating provided for the performance review. This is a text parameter and can contain any free-form text that your organization uses to recognize the evaluation. For example, "3 Met expectations" or "2 Below average". This is a text parameter with a limit of 25 characters. This parameter is optional. You don't have to include it in the CSV file.

CSV file for performance improvement plan data

Here's an example of a CSV file for the data for the performance improvement plan data.

text

```
UserPrincipalName,EffectiveDate,ImprovementRemarks,PerformanceRating
sarad@contoso.com,2019-04-23T15:18:02.4675041+05:30,Met expectation but bad
attitude,2-Below expectation
pillar@contoso.com,2019-04-23T15:18:02.4675041+05:30, Multiple conflicts with the
team
```

The following table describes each column in the CSV file for performance review data.

Expand table

Column	Description
UserPrincipalName	The Microsoft Entra UserPrincipalName (UPN) used to specify the user's email address.
EffectiveDate	Specifies the date when the user is officially informed about their performance improvement plan. You must use the following date format: `yyyy-mm-ddThh:mm:ss.nnnnnn+ | -hh:mm`, which is the ISO 8601 date and time format.
Remarks	Specifies any remarks that evaluator provides about the performance improvement plan. This is a text parameter with a limit of 200 characters. This is an optional parameter. You don't have to include it in the CSV file.
Rating	Specifies any rating or other information related to the performance review. This is a text parameter and can contain any free form text that your organization uses to recognize the evaluation. For example, "3 Met expectations" or "2 Below average". This is a text parameter with limit of 25 characters. This is an optional parameter. You don't have to include it in the CSV file.

CSV file for employee profile data (preview)

> **Note**
>
> The capability to create an HR connector for employee profile data is in public preview. To create an HR connector that supports employee profile data, go to the **Data connectors** page in the Microsoft Purview portal, select the **Connectors** tab, then select **Add a connector** > **HR**. Follow the steps to create a connector in Step 3: Create the HR connector.

Here's an example of a CSV file for employee profile data.

text

```
UserPrincipalName,UserName,EmployeeFirstName,EmployeeLastName,EmployeeAddLine1,Empl
oyeeAddLine2,EmployeeCity,EmployeeState,EmployeeZipCode,EmployeeDept,EmployeeType,E
mployeeRole
jackq@contoso.com,jackq,jack,qualtz,50 Oakland
Ave,#206,City,Florida,32104,Orthopaedic,Regular,Nurse
```

The following table describes each column in the CSV file for employee profile data.

Expand table

Column	Description
UserPrincipalName*	The Microsoft Entra UserPrincipalName (UPN) used to specify the user's email address.
EmployeeFirstName*	First name of the employee.
EmployeeLastName*	Last name of the employee.
EmployeeAddressLine1*	Street address of the employee.
EmployeeAddressLine2	Secondary address information, such as apartment number, for employee.
EmployeeCity	City of residence for employee.
EmployeeState	State of residence for employee.
EmployeeZipCode*	Zip code of residence for employee.
EmployeeCountry	Country of residence for employee.
EmployeeDepartment	Employee's department in the organization.

Column	Description
EmployeeType	Employment type for employee, such as Regular, Exempt, or Contractor.
EmployeeRole	Employees's role, designation, or job title in the organization.

> **Note**
>
> * This column is mandatory. If a mandatory column is missing, the CSV file isn't validated and other data in the file isn't imported.

We recommend that you create an HR connector that only imports employee profile data. For this connector, frequently refresh the employee profile data, preferably every 15 to 20 days. Employee profile records are deleted if you don't update them in the past 30 days.

Determining how many CSV files to use for HR data

In Step 3, you can choose to create separate connectors for each HR data type or a single connector for all data types. You can use separate CSV files that contain data for one HR scenario (like the examples of the CSV files described in the previous sections). Alternatively, you can use a single CSV file that contains data for two or more HR scenarios. Here are some guidelines to help you determine how many CSV files to use for HR data.

- If the insider risk management policy that you want to implement requires multiple HR data types, consider using a single CSV file that contains all the required data types.
- The method for generating or collecting the HR data might determine the number of CSV files. For example, if the different types of HR data used to configure an HR connector are located in a single HR system in your organization, then you might be able to export the data to a single CSV file. But if data is distributed across different HR systems, then it might be easier to export data to different CSV files. For example, employee resignation data might be located in a different HR system than job level or performance review data. In this case, it might be easier to have separate CSV files rather than having to manually combine the data into a single CSV file. So, how you retrieve or export data from your HR systems might determine how many CSV files you need.
- As a general rule, the data types in a CSV file determine the number of HR connectors that you need to create. For example, if a CSV file contains all the data types required to support your insider risk management implementation, then you only need one HR connector. But if you have two separate CSV files that each contain a single data type, then you have to create two HR connectors. An exception to this rule is that if you add an

HRScenario column to a CSV file (see the next section), you can configure a single HR connector that can process different CSV files.

- For each CSV file, you can ingest up to 500 records at once. To ingest a larger number of records, upload multiple CSV files, each with fewer than 500 records.

Configuring a single CSV file for multiple HR data types

You can add multiple HR data types to a single CSV file. This configuration is useful if the insider risk management solution you're implementing requires multiple HR data types or if the data types are located in a single HR system in your organization. Having fewer CSV files always allows you to have fewer HR connectors to create and manage.

Here are requirements for configuring a CSV file with multiple data types:

- Add the required columns (and optional columns if you use them) for each data type and the corresponding column name in the header row. If a data type doesn't correspond to a column, leave the value blank.

- Add an **HRScenario** column to the CSV file. The HR connector uses this column to identify which rows in the CSV file contain which type HR data. The values in this column identify the type of HR data in each row. For example, values that correspond to the HR scenarios could be `Resignation`, `Job level change`, `Performance review`, `Performance improvement plan`, and `Employee profile`.

- If you have multiple CSV files that contain an **HRScenario** column, make sure that each file uses the same column name and the same values that identify the specific HR scenarios.

The following example shows a CSV file that contains the **HRScenario** column. The values in the HRScenario column identify the type of data in the corresponding row. The following sample covers four HR scenarios `Resignation`, `Job level change`, `Performance review`, and `Performance improvement plan`.

text

```

> **Note**
>
> You can use any name for the column that identifies HR data type because you map the name of the column in your CSV file as the column that identifies the HR data type when you set up the connector in Step 3. You also map the values used for the data type column when you set up the connector.

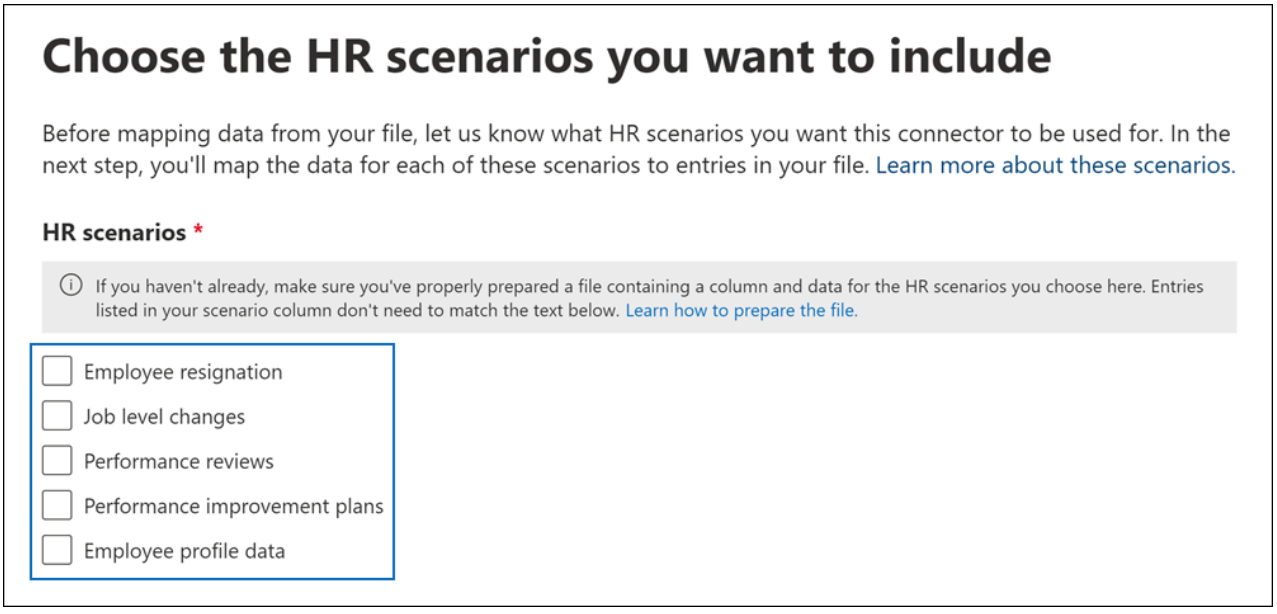
Adding the HRScenario column to a CSV file that contains a single data type

Based on your organization's HR systems and how you export HR data to a CSV file, you might need to create multiple CSV files that each contain a single HR data type. In this case, you can still create a single HR connector to import data from different CSV files. To do this, add an HRScenario column to the CSV file and specify the HR data type. Then, you can run the script for each CSV file but use the same job ID for the connector. For more information, see Step 4.

Step 2: Create an app in Microsoft Entra ID

Next, create and register a new app in Microsoft Entra ID. The app corresponds to the HR connector that you create in Step 3. When you create this app, Microsoft Entra ID can authenticate the HR connector when it runs and attempts to access your organization. This app also authenticates the script that you run in Step 4 to upload your HR data to the Microsoft cloud. During the creation of this Microsoft Entra app, save the following information. You use these values in Step 3 and Step 4.

- Microsoft Entra application ID (also called the *app ID* or *client ID*)
- Microsoft Entra application secret (also called the *client secret*)
- Tenant ID (also called the *directory Id*)



For step-by-step instructions for creating an app in Microsoft Entra ID, see Register an application with the Microsoft identity platform.

Step 3: Create the HR connector

The next step is to create an HR connector in the Microsoft Purview portal. After you run the script in Step 4, the HR connector that you create will ingest the HR data from the CSV file to your Microsoft 365 organization. Before you create a connector, be sure that you have a list of the HR scenarios and the corresponding CSV column names for each one. You have to map the data required for each scenario to the actual column names in your CSV file when configuring the connector. Alternatively, you can upload a sample CSV file when configuring the connector and the workflow help you map the name of the columns to the required data types.

After you complete this step, be sure to copy the job ID that's generated when you create the connector. You use the job ID when you run the script.

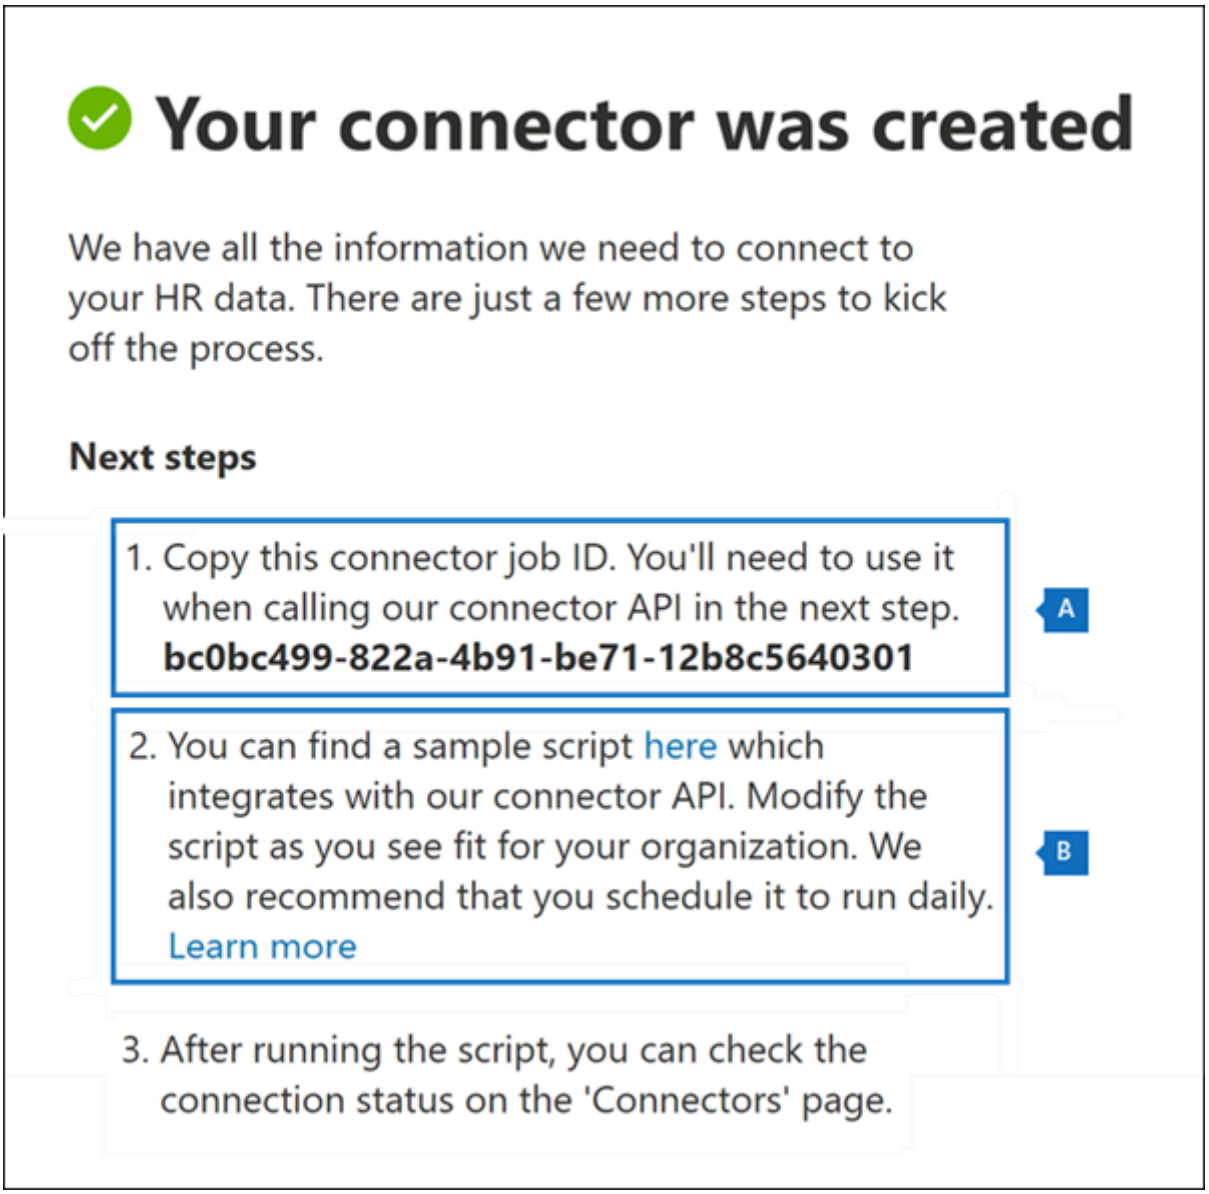
1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, choose **HR (preview)**.
5. On the **Setup the connection** page, do the following and then select **Next**:
   a. Type or paste the Microsoft Entra application ID for the Azure app that you created in Step 2.
   b. Type a name for the HR connector.
6. On the HR scenarios page, select one or more HR scenarios that you want to import data for and then select **Next**.

7. On the file mapping method page, select a file type if necessary, and then select one of the following options and then select **Next**.

- **Upload a sample file**. If you select this option, select **Upload sample file** to upload the CSV file that you prepared in Step 1. This option allows you to quickly select column names in your CSV file from a drop-down list to map them to the data types for the HR scenarios that you previously selected.

OR

- **Manually provide the mapping details**. If you select this option, you have to type the name of the columns in your CSV file to map them to the data types for the HR scenarios that you previously selected.



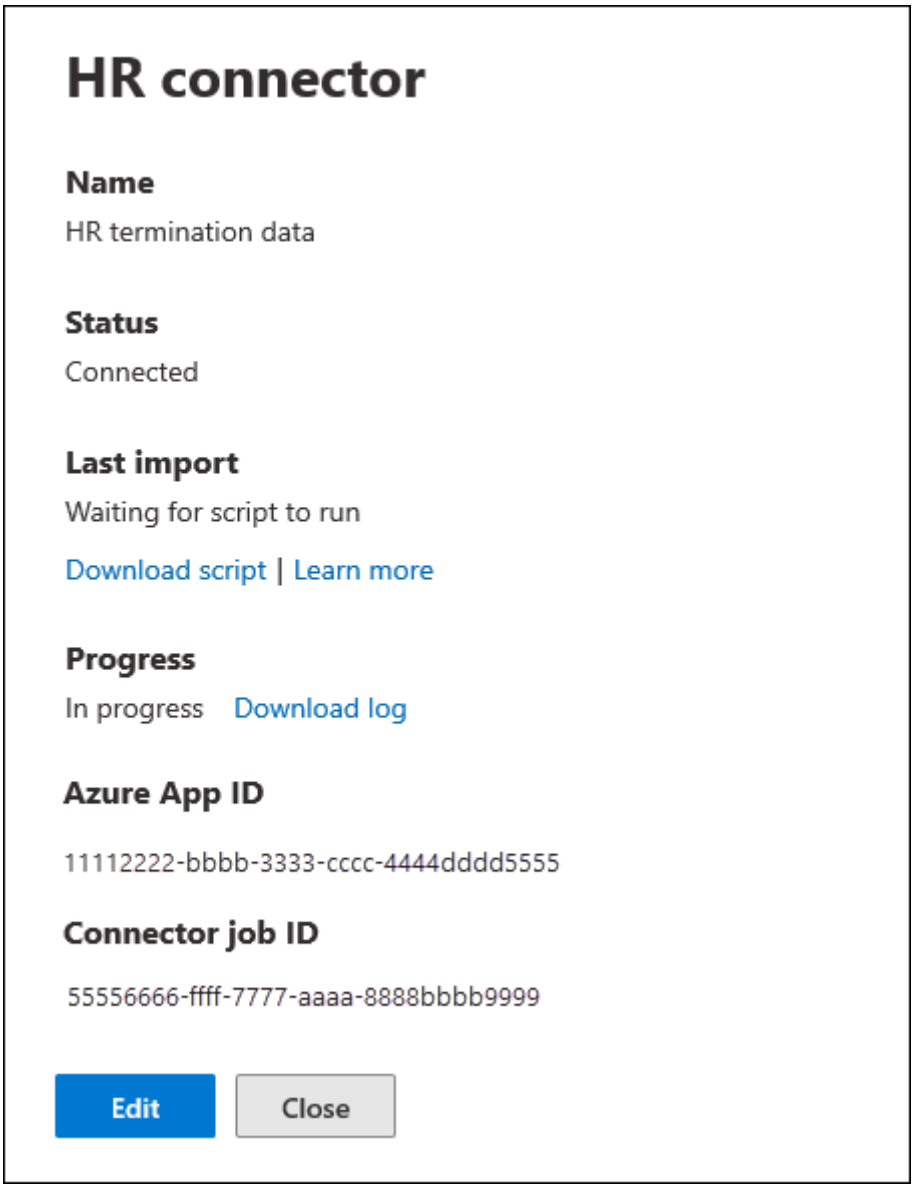
8. On the File mapping details page, do one of the following, depending on whether you uploaded a sample CSV file and whether you're configuring the connector for a single HR scenario or for multiple scenarios. If you uploaded a sample file, you don't have to type the column names. You pick them from a dropdown list.

   - If you selected a single HR scenario in the previous step, then type the column header names (also called *parameters*) from the CSV file that you created in Step 1 in each of the appropriate boxes. The column names that you type aren't case-sensitive, but be sure to include spaces if the column names in your CSV file include spaces. As previously explained, the names you type in these boxes must match the parameter names in your CSV file. For example, the following screenshot shows the parameter names from the sample CSV file for the employee resignation HR scenario shown in Step 1.

   - If you selected multiple data types in the previous step, then you need to enter identifier column name that will identify the HR data type in your CSV file. After entering the identifier column name, type the value that identifies this HR data type, and type the column header names for selected data types from the CSV file(s) that you created in Step 1 in each of the appropriate boxes for each selected data type. As previously explained, the names that you type in these boxes must match the column names in your CSV file.

9. On the **Review** page, review your settings and then select **Finish** to create the connector.

   A status page is displayed that confirms the connector was created. This page contains two important things that you need to complete the next step to run the sample script to upload your HR data.



a. **Job ID.** You'll need this job ID to run the script in the next step. You can copy it from this page or from the connector flyout page.

b. **Link to sample script.** Select the **here** link to go to the GitHub site to access the sample script (the link opens a new window). Keep this window open so that you can copy the script in Step 4. Alternatively, you can bookmark the destination or copy the URL so you can access it again when you run the script. This link is also available on the connector flyout page.

10. Select **Done**.

    The new connector is displayed in the list on the **Connectors** tab.

11. Select the HR connector that you just created to display the flyout page, which contains properties and other information about the connector.

If you haven't already done so, you can copy the values for the **Azure App ID** and **Connector job ID**. You'll need these to run the script in the next step. You can also download the script from the flyout page (or download it using the link in the next step.)

You can also select **Edit** to change the Azure App ID or the column header names that you defined on the **File mapping** page.

Step 4: Run the sample script to upload your HR data

> **Important**
>
> You must add the *webhook.ingestion.office.com* domain to your firewall allowlist for your organization. If you block this domain, the script doesn't run.

The last step in setting up an HR connector is to run a sample script that uploads the HR data in the CSV file (that you created in Step 1) to the Microsoft cloud. Specifically, the script uploads the data to the HR connector. After you run the script, the HR connector that you created in Step 3 imports the HR data to your Microsoft 365 organization where other compliance tools, such as the Insider risk management solution, can access it. After you run the script, consider scheduling a task to run it automatically on a daily basis so the most current employee termination data is uploaded to the Microsoft cloud. For more information, see Schedule the script to run automatically.

1. Go to the window that you left open from the previous step to access the GitHub site with the sample script. Alternatively, open the bookmarked site or use the URL that you copied. You can also access the script here.
2. Select the **Raw** button to display the script in text view.
3. Copy all the lines in the sample script and save them to a text file.
4. Modify the sample script for your organization, if necessary.
5. Save the text file as a Windows PowerShell script file by using a filename suffix of `.ps1`; for example, `HRConnector.ps1`. Alternatively, you can use the GitHub filename for the script, which is `upload_termination_records.ps1`.
6. Open a command prompt on your local computer, and go to the directory where you saved the script.
7. Run the following command to upload the HR data in the CSV file to the Microsoft cloud; for example:

   PowerShell

   ```
   .\HRConnector.ps1 -tenantId <tenantId> -appId <appId>  -appSecret <appSecret>
   -jobId <jobId>  -filePath '<filePath>'
   ```

   The following table describes the parameters to use with this script and their required values. The information you obtained in the previous steps is used in the values for these parameters.

   Expand table

Parameter	Description
`tenantId`	This is the ID for your Microsoft 365 organization that you obtained in Step 2. You can also obtain the tenant ID for your organization on the **Overview** blade in the Microsoft Entra admin center. This value identifies your organization.

Parameter	Description
`appId`	This is the Microsoft Entra application ID for the app that you created in Microsoft Entra ID in Step 2. This value is used by Microsoft Entra ID for authentication when the script attempts to access your Microsoft 365 organization.
`appSecret`	This is the Microsoft Entra application secret for the app that you created in Microsoft Entra ID in Step 2. This value is also used for authentication.
`jobId`	This is the job ID for the HR connector that you created in Step 3. This value associates the HR data that is uploaded to the Microsoft cloud with the HR connector.
`filePath`	This is the file path for the file (stored on the same system as the script) that you created in Step 1. Try to avoid spaces in the file path; otherwise use single quotation marks.

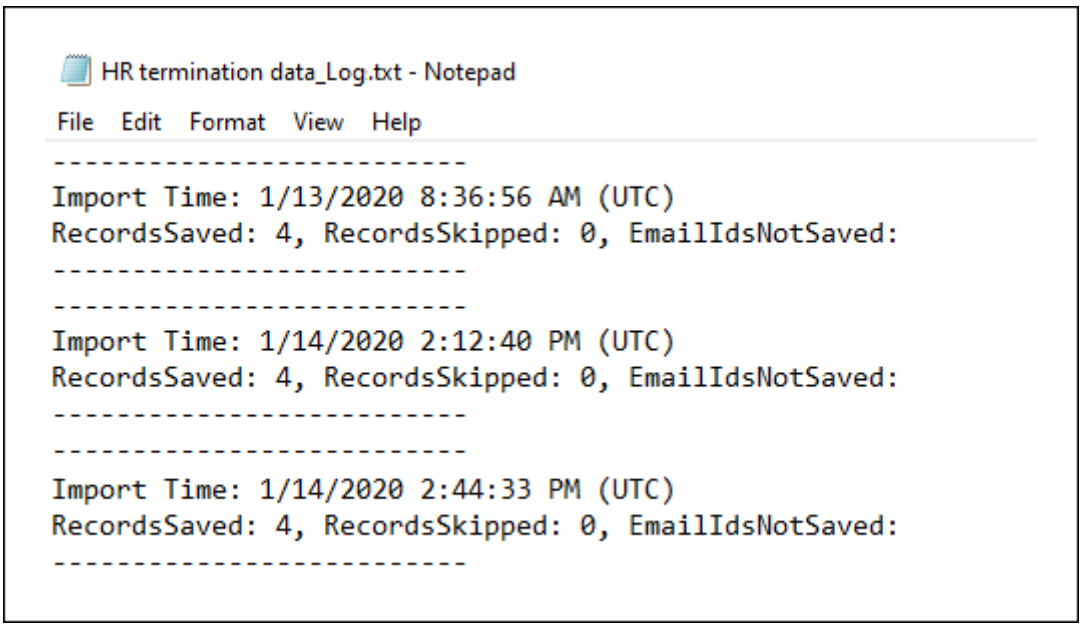
Here's an example of the syntax for the HR connector script using actual values for each parameter:

PowerShell

```
.\HRConnector.ps1 -tenantId aaaabbbb-0000-cccc-1111-dddd2222eeee -appId
00001111-aaaa-2222-bbbb-3333cccc4444 -appSecret Aa1Bb~2Cc3.-
Dd4Ee5Ff6Gg7Hh8Ii9_Jj0Kk1Ll2 -jobId 00001111-aaaa-2222-bbbb-3333cccc4444 -
filePath 'C:\Users\contosoadmin\Desktop\Data\employee_termination_data.csv'
```

If the upload is successful, the script displays the **Upload Successful** message.

> **Note**
>
> If you have problems running the previous command because of execution policies, see About Execution Policies and Set-ExecutionPolicy for guidance about setting execution policies.



Step 5: Monitor the HR connector

After you create the HR connector and run the script to upload your HR data, you can view the connector and upload status in the Microsoft Purview portal. If you schedule the script to run automatically on a regular basis, you can also view the current status after the last time the script ran.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.

3. Select **My connectors**, then select the HR connector that you created to display the flyout page. This page contains the properties and information about the connector.

4. Under **Progress**, select the **Download log** link to open (or save) the status log for the connector. This log contains information about each time the script runs and uploads the data from the CSV file to the Microsoft cloud.

   The `RecordsSaved` field indicates the number of rows in the CSV file that you uploaded. For example, if the CSV file contains four rows, the value of the `RecordsSaved` fields is 4, if the script successfully uploads all the rows in the CSV file.

If you didn't run the script in Step 4, a link to download the script is displayed under **Last import**. You can download the script and then follow the steps to run the script.

(Optional) Step 6: Schedule the script to run automatically

To make sure tools like the insider risk management solution always have access to the latest HR data from your organization, schedule the script to run automatically on a recurring basis, such as once a day. This schedule requires updating the HR data in the CSV file on a similar (if not the same) schedule so that it contains the latest information about employees who leave your organization. The goal is to upload the most current HR data so that the HR connector can make it available to the insider risk management solution.

Use the Task Scheduler app in Windows to automatically run the script every day.

1. On your local computer, select the Windows **Start** button and then type **Task Scheduler**.

2. Select the **Task Scheduler** app to open it.

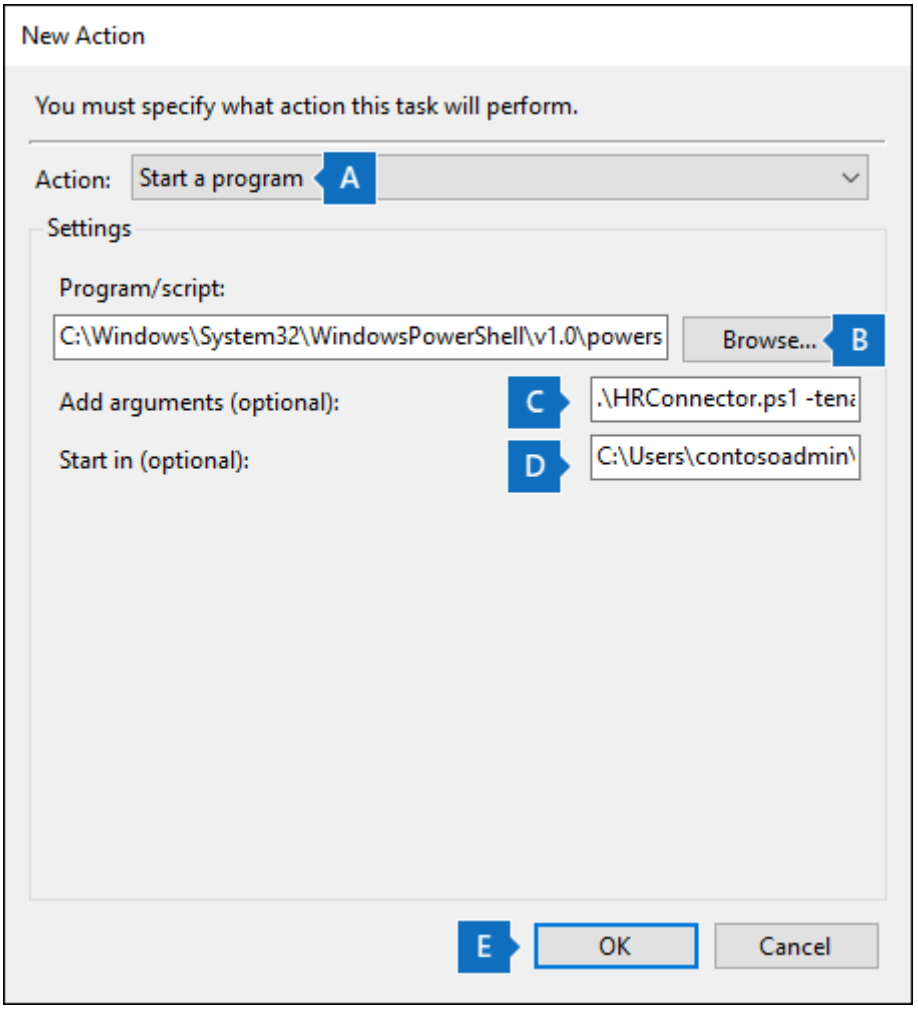
3. In the **Actions** section, select **Create Task**.

4. On the **General** tab, type a descriptive name for the scheduled task, such as **HR Connector Script**. You can also add an optional description.

5. Under **Security options**, do the following steps:

   a. Decide whether to run the script only when you're logged on to the computer or run it when you're logged on or not.

   b. Make sure that the **Run with the highest privileges** checkbox is selected.



6. Select the **Triggers** tab, select **New**, and then do the following steps:

   a. Under **Settings**, select the **Daily** option, then choose a date and time to run the script for the first time. The script runs every day at the same specified time.

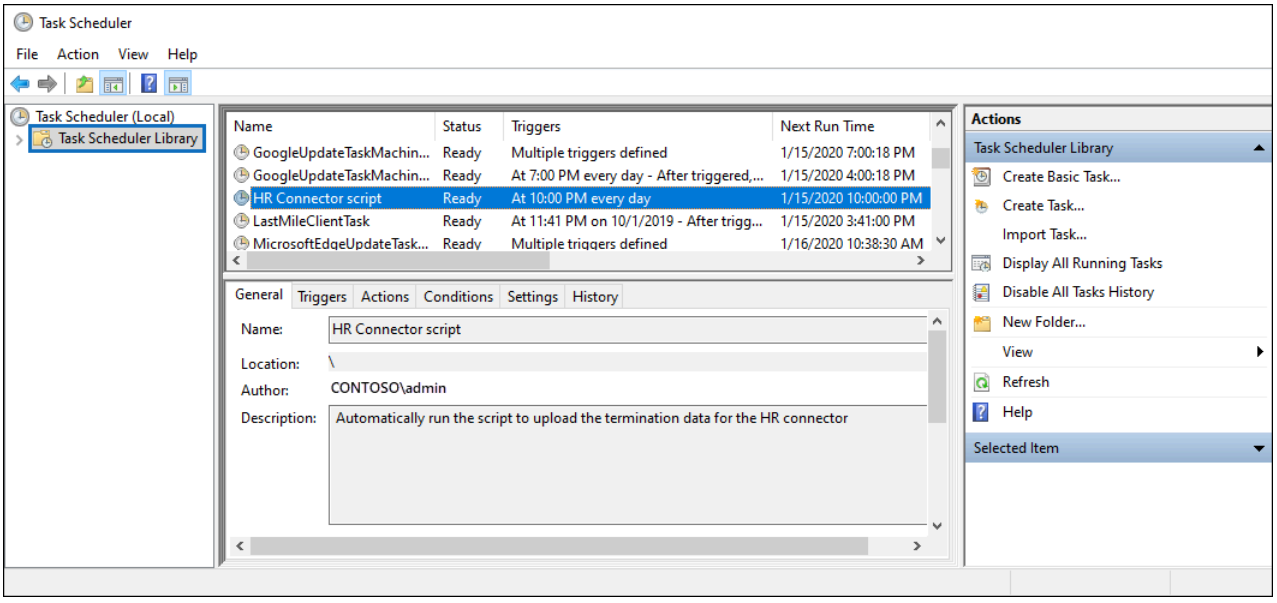
   b. Under **Advanced settings**, make sure the **Enabled** checkbox is selected.

   c. Select **Ok**.

7. Select the **Actions** tab, select **New**, and then do the following steps:

   a. In the **Action** dropdown list, make sure that **Start a program** is selected.

b. In the **Program/script** box, select **Browse**, go to the following location, and select it so the path displays in the box: `C:\Windows\System32\WindowsPowerShell\v1.0\powershell.exe`.



c. In the **Add arguments (optional)** box, paste the same script command that you ran in Step 4. For example, `.\HRConnector.ps1 -tenantId "aaaabbbb-0000-cccc-1111-dddd2222eeee" -appId "00001111-aaaa-2222-bbbb-3333cccc4444" -appSecret "Aa1Bb~2Cc3.-Dd4Ee5Ff6Gg7Hh8Ii9_Jj0Kk1Ll2" -jobId "00001111-aaaa-2222-bbbb-3333cccc4444" -filePath "C:\Users\contosoadmin\Desktop\Data\employee_termination_data.csv"`

d. In the **Start in (optional)** box, paste the folder location of the script that you ran in Step 4. For example, `C:\Users\contosoadmin\Desktop\Scripts`.

e. Select **Ok** to save the settings for the new action.

8. In the **Create Task** window, select **Ok** to save the scheduled task. You might be prompted to enter your user account credentials.

   The new task appears in the Task Scheduler Library.

   The last time the script ran and the next time it's scheduled to run displays. You can double-select the task to edit it.

   You can also verify the last time the script ran on the flyout page of the corresponding HR connector in the Microsoft Purview portal.

(Optional) Step 7: Upload data by using Power Automate templates

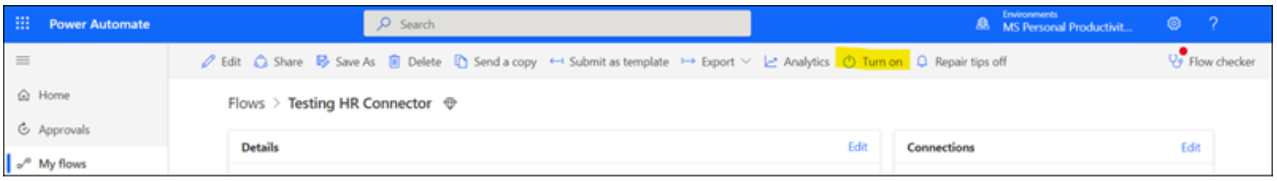
You can upload HR data by using Power Automate templates and define triggers. For example, you can configure a Power Automate template to trigger when new HR connector files are available in SharePoint or OneDrive locations. You can also streamline this process by storing confidential information like Microsoft Entra application secret (created in **Step 2**) in Azure Key Vault and use it with Power Automate for authentication.

Complete the following steps to automatically upload HR data when new files become available on OneDrive for Business:

1. Download the *ImportHRDataforIRM.zip* package from the GitHub site.
2. In Power Automate, go to **My flows**.
3. Select **Import** and upload the *ImportHRDataforIRM.zip* package.
4. After the package is uploaded, update the content (name and OneDrive for Business connection), and select **Import**.

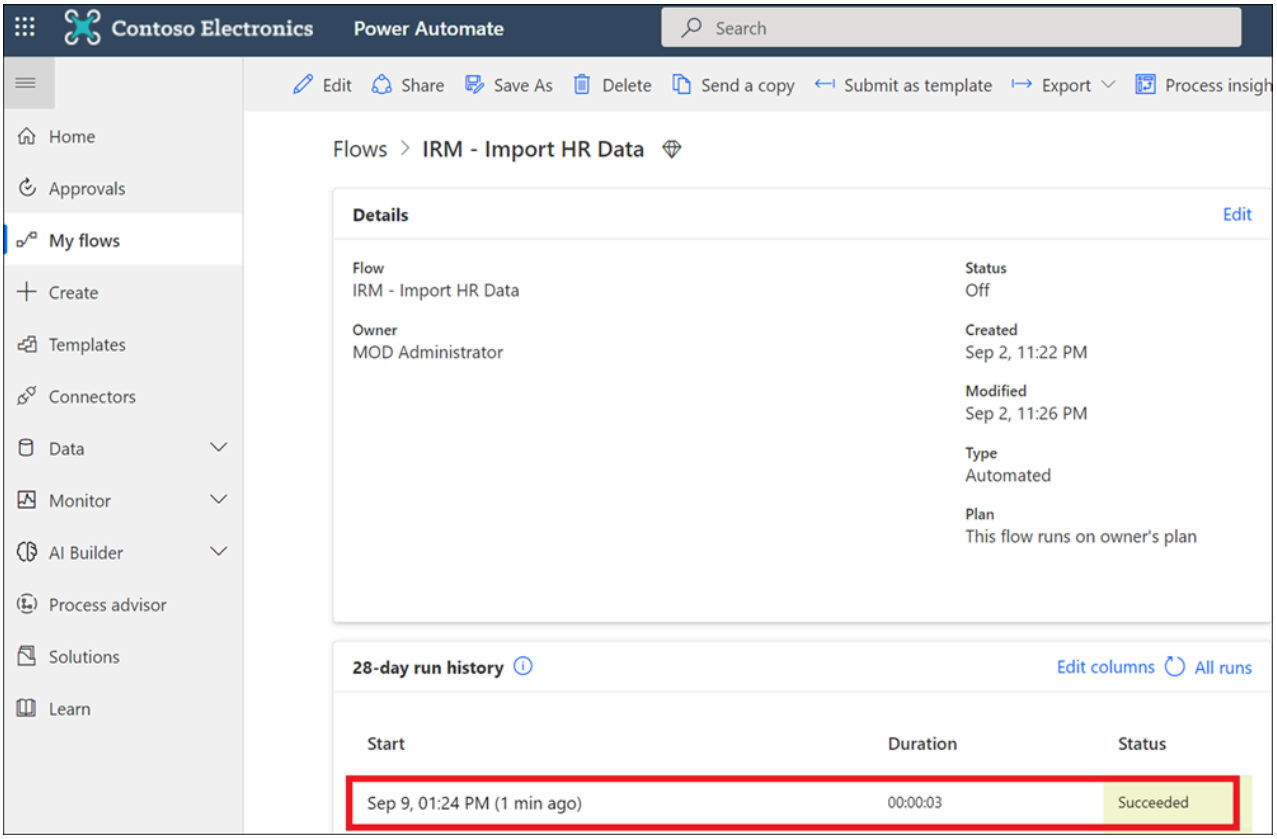
5. Select **Open flow** and update the parameters. The following table describes the parameters to use in this Power Automate Flow and their required values. Use the information you obtained in the previous steps for these values.

Expand table



Parameter	Description
App ID	This is the Microsoft Entra application ID for the app that you created in Microsoft Entra ID in **Step 2**. Microsoft Entra ID uses this application ID for authentication when the script attempts to access your Microsoft 365 organization.
App Secret	This is the Microsoft Entra application secret for the app that you created in Microsoft Entra ID in **Step 2**. This application secret is used for authentication.

Parameter	Description
File location	This is the OneDrive for Business location where Power Automate monitors for 'new file created' activities to trigger this flow.
Job ID	Identifier for the HR connector created in **Step 3**. This identifier associates the HR data uploaded to the Microsoft cloud with the HR connector.
Tenant ID	Identifier for your Microsoft 365 organization obtained in **Step 2**. You can also obtain the tenant ID for your organization on the **Overview** blade in the Microsoft Entra admin center. This identifier is used to identify your organization.
URI	Verify that the value for this parameter is *https://webhook.ingestion.office.com/api/signals*



1. Select **Save**.

2. Go to **Flow overview** and select **Turn on**.

3. Test the flow manually by uploading a new file to your OneDrive for Business folder and verify that it ran successfully. This process might take a few minutes after the upload before the flow is triggered.

4. You can now monitor the HR connector as described in **Step 5**.

If needed, you can update the flow to create triggers based on file availability and modification events on SharePoint and other data sources supported by Power Automate Flows.

Existing HR connectors

On December 13, 2021, we released the employee profile data scenario for HR connectors. If you created an HR connector before this date, we migrate the existing instances or your organization's HR connectors so your HR data continues to be imported to the Microsoft cloud. You don't have to do anything to maintain this functionality. You can keep using these connectors without disruption.

If you want to implement the employee profile data scenario, create a new HR connector and configure it as required. After you create a new HR connector, run the script by using the job ID

of the new connector and CSV files with employee profile data previously described in this article.

Last updated on 03/30/2026

Set up a connector to import HR data in US Government

You can set up a data connector to import human resources (HR) data to your US Government organization. HR-related data includes the date an employee submitted their resignation and date of the employee's last day. Microsoft information protection solutions, such as the insider risk management solution, use this HR data to help protect your organization from malicious activity or data theft inside your organization. Setting up an HR connector consists of creating an app in Microsoft Entra that's used for authentication by connector, creating a CSV mapping files that contains your HR data, creating a data connector in the Microsoft Purview portal, and then running a script (on a scheduled basis) that ingests the HR data in the CSV file to the Microsoft cloud. Then the data connector is used by the insider risk management tool to access the HR data that you imported to your Microsoft 365 US Government organization.

Before you begin

- The user who creates the HR connector in Step 3 must be assigned the Data Connector Admin role. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

  > **Note**
  >
  > The Data Connector Admin role currently isn't supported in US Government GCC High and DoD environments. Therefore, the user who creates the HR connector in GCC High and DoD environments must be assigned the Mailbox Import Export role in Exchange Online. By default, no role group in Exchange Online has this role assigned. You can add the Mailbox Import Export role to the Organization Management role group in Exchange Online. Or you can create a new role group, assign the Mailbox Import Export role, and then add the appropriate users as members. For more information, see

the Create role groups or Modify role groups sections in the article "Manage role groups in Exchange Online".

- Determine how to retrieve or export the data from your organization's HR system (on a regular basis) and add it to the CSV file that's described in Step 2. The script that you run in Step 4 uploads the HR data in the CSV file to the Microsoft cloud.

- The sample script that you run in Step 4 uploads HR data to the Microsoft cloud so that other Microsoft tools, such as the insider risk management solution, can use it. This sample script isn't supported under any Microsoft standard support program or service. The sample script is provided AS IS without warranty of any kind. Microsoft further disclaims all implied warranties including, without limitation, any implied warranties of merchantability or of fitness for a particular purpose. You assume all risk arising from the use or performance of the sample script and documentation. In no event shall Microsoft, its authors, or anyone else involved in the creation, production, or delivery of the scripts be liable for any damages whatsoever (including, without limitation, damages for loss of business profits, business interruption, loss of business information, or other pecuniary loss) arising out of the use of or inability to use the sample scripts or documentation, even if Microsoft has been advised of the possibility of such damages.

Step 1: Create an app in Microsoft Entra ID

First, create and register a new app in Microsoft Entra ID. The app corresponds to the HR connector that you create in Step 3. When you create the app, Microsoft Entra ID can authenticate the HR connector. The app also authenticates the script that you run in Step 4 to upload your HR data to the Microsoft cloud. During the creation of this Microsoft Entra app, save the following information. You use these values in later steps.

- Microsoft Entra application ID (also called the *app Id* or *client Id*)
- Microsoft Entra application secret (also called the *client secret*)
- Tenant Id (also called the *directory Id*)

For step-by-step instructions for creating an app in Microsoft Entra ID, see Register an application with the Microsoft identity platform.

Step 2: Prepare a CSV file with your HR data

In this step, you create a CSV file that contains information about employees who left your organization. As explained in the Before You Begin section, you need to decide how to generate

this CSV file from your organization's HR system. The following example shows a completed CSV file (opened in Note Pad) that contains the three required parameters (columns). It's much easier to edit the CSV file in Microsoft Excel.

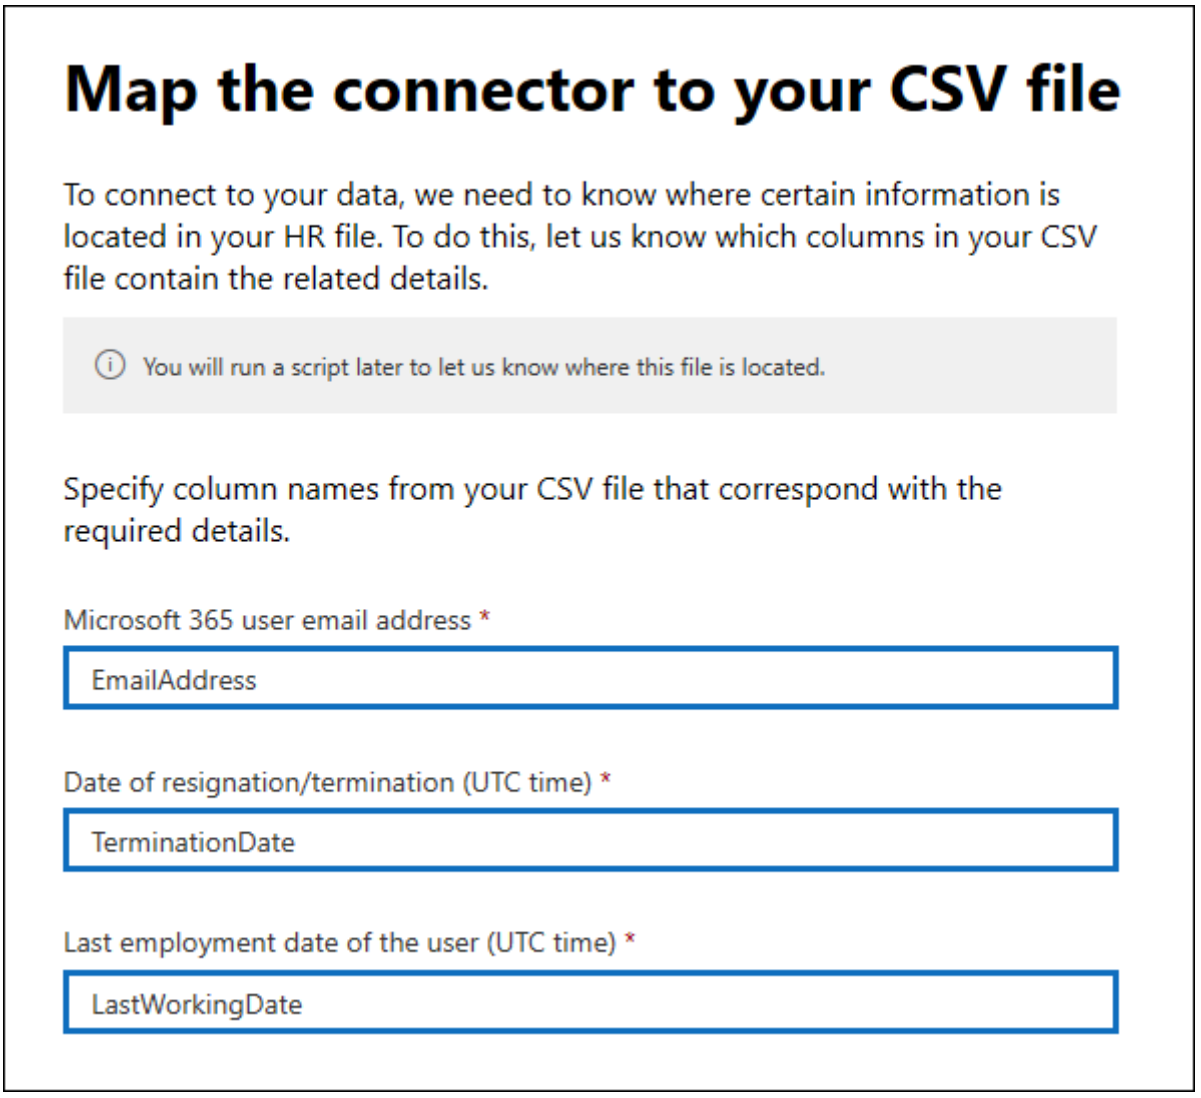
```text
EmailAddress,TerminationDate,LastWorkingDate
sarad@contoso.com,2019-04-23T15:18:02.4675041+05:30,2019-04-29T15:18:02.4675041+05:30
pilarp@contoso.com,2019-04-24T09:15:49Z,2019-04-29T15:18:02.7117540
```

The first row, or header row, of the CSV file lists the required column names. You choose the name used in each column header (the ones in the following example are suggestions). However, you must specify the same column names when you create the HR connector in Step 3. Don't include spaces in the column names.

The following table describes each column in the CSV file:

Expand table

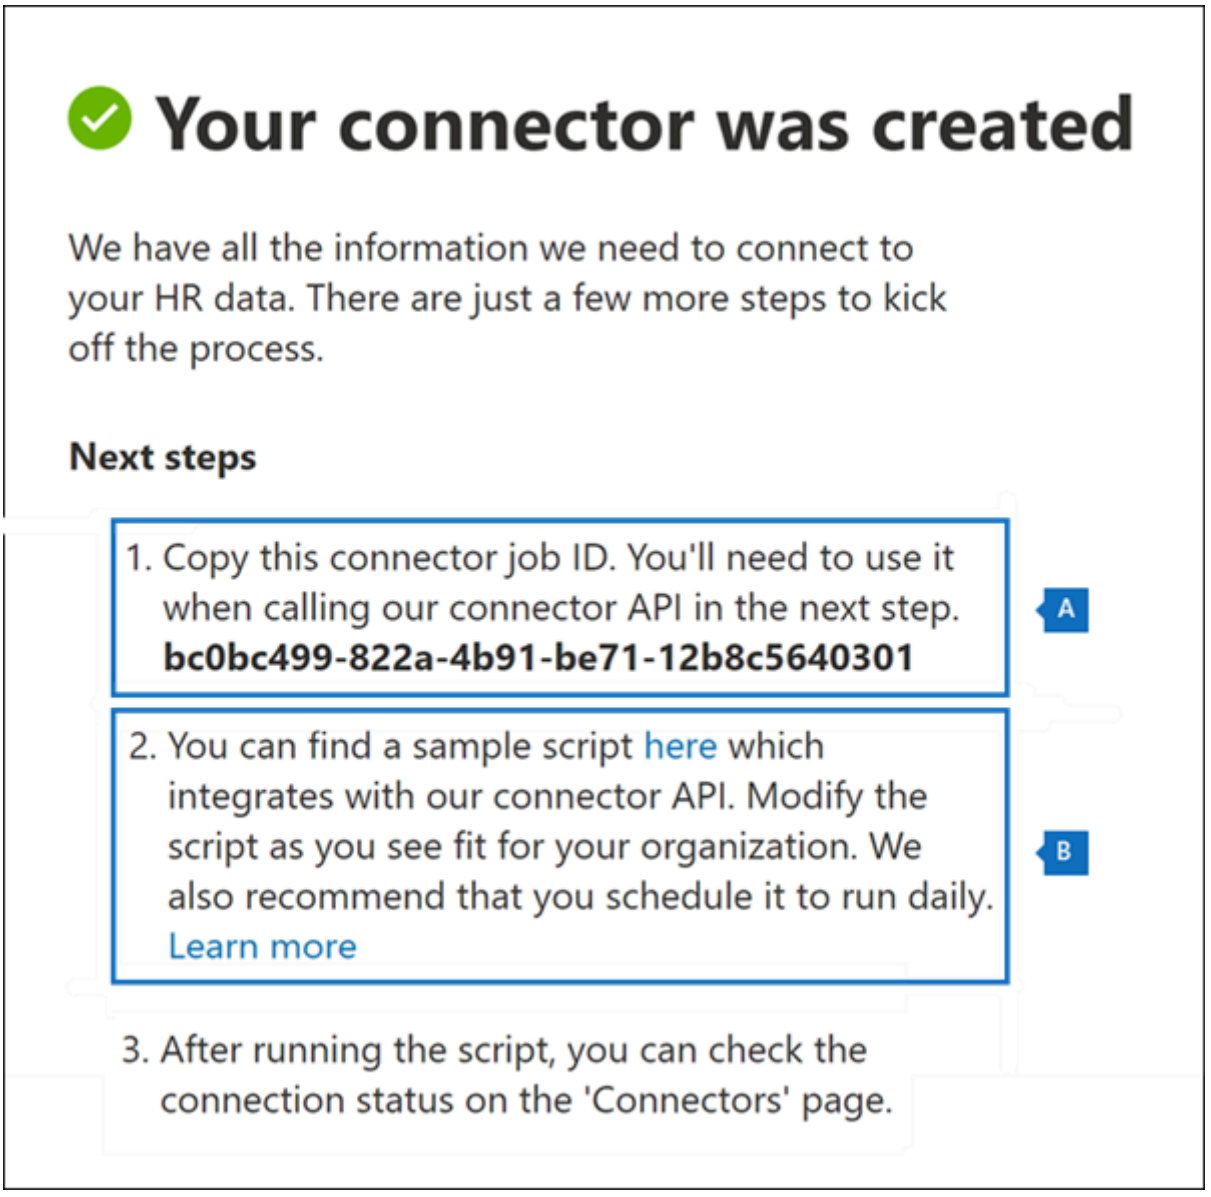
Column name	Description
EmailAddress	Specifies the email address of the terminated employee.
TerminationDate	Specifies the date the person's employment was officially terminated in your organization. For example, this date might be when the employee gives their notice about leaving your organization. This date might be different from the date of the person's last day of work. Use the following date format: `yyyy-mm-ddThh:mm:ss.nnnnnn+|-hh:mm`, which is the ISO 8601 date and time format.
LastWorkingDate	Specifies the last day of work for the terminated employee. Use the following date format: `yyyy-mm-ddThh:mm:ss.nnnnnn+|-hh:mm`, which is the ISO 8601 date and time format.



After you create the CSV file with the required HR data, store it on the same system as the script that you run in Step 4. Be sure to implement an update strategy so the CSV file always contains the most current information. This strategy ensures that whatever script you run, the most current employee termination data is uploaded to the Microsoft cloud.

Step 3: Create the HR connector

In this step, you create an HR connector in the Microsoft Purview portal. When you run the script in Step 4, the HR connector ingests the HR data from the CSV file to your Microsoft 365

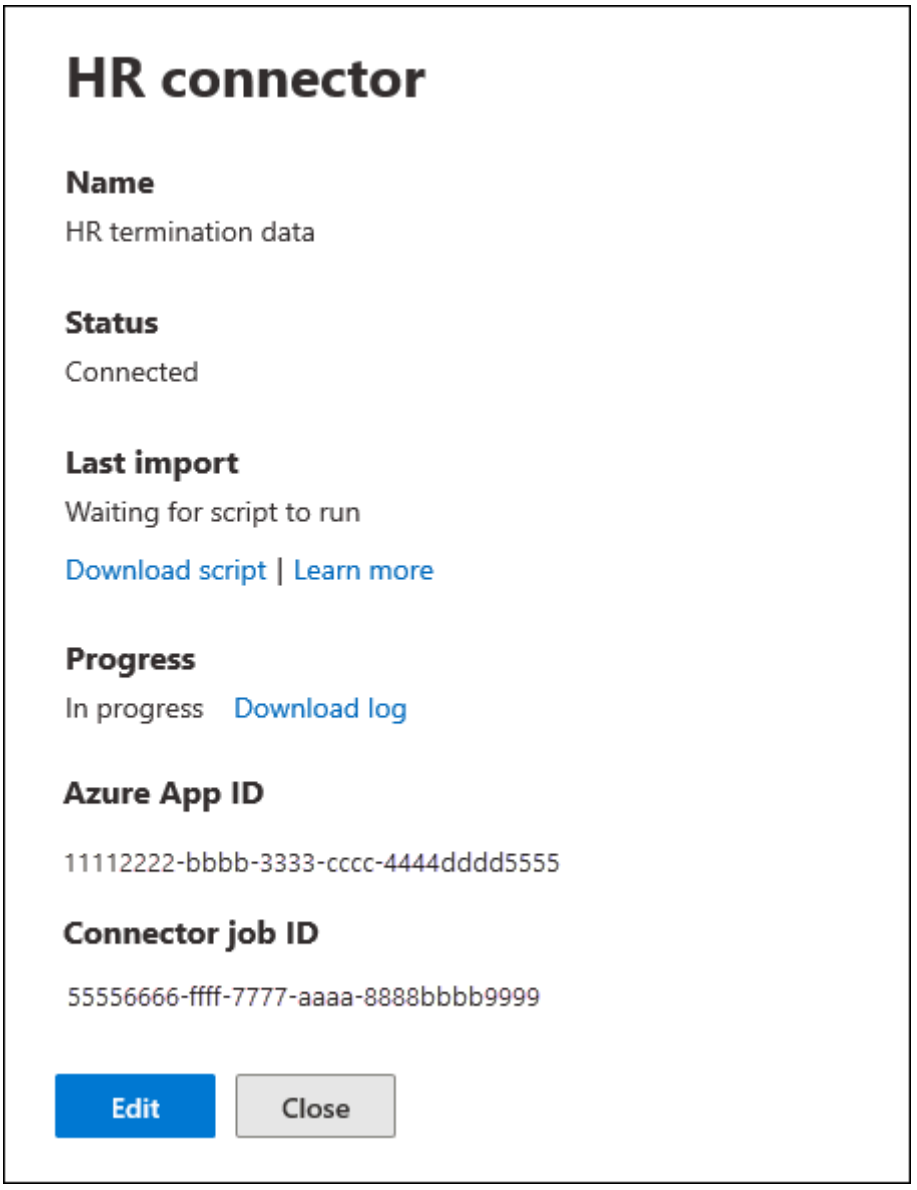


organization. Be sure to copy the job ID that's generated when you create the connector. You'll use the job ID when you run the script.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **HR**.
5. On the **Authentication credentials** page, enter the following information and then select **Next**:
   a. Enter or paste the Microsoft Entra application ID for the Azure app that you created in Step 1.
   b. Enter a name for the HR connector.
6. On the **File mapping** page, enter the names of the three column headers (also called *parameters*) from the CSV file that you created in Step 2 in each of the appropriate boxes. The names aren't case-sensitive. As previously explained, the names that you enter in these boxes must match the parameter names in your CSV file. For example, the following screenshot shows the parameter names from the example in sample CSV file shown in Step 2.

7. On the **Review** page, review your settings and then select **Finish** to create the connector.

   A status page is displayed that confirms the connector was created. This page contains two important things that you need to complete the next step to run the sample script to upload your HR data.



a. **Job ID.** You need this job ID to run the script. You can copy it from this page or from the connector flyout page.

b. **Link to sample script.** Select the **here** link to go to the GitHub site to access the sample script (the link opens a new window). Keep this window open so that you can copy the script in Step 4. Alternatively, you can bookmark the destination or copy the URL so you can access it again in Step 4. This link is also available on the connector flyout page.

8. Select **Done**.

   The new connector is displayed in the list on the **Connectors** tab.

9. Select the HR connector that you just created to display the flyout page, which contains properties and other information about the connector.

If you didn't already, copy the values for the **Azure App ID** and **Connector job ID**. You need these values to run the script in the next step. You can also download the script from the flyout page (or download it using the link in the next step).

Select **Edit** to change the Azure App ID or the column header names that you defined on the **File mapping** page.

Step 4: Run the sample script to upload your HR data

To set up an HR connector, run a sample script that uploads the HR data in the CSV file (created in Step 2) to the Microsoft cloud. The script specifically uploads the data to the HR connector. After you run the script, the HR connector that you created in Step 3 imports the HR data to your Microsoft 365 organization where other compliance tools, such as the Insider risk management solution, can access it. Consider scheduling a task to run the script automatically on a daily basis so the most current employee termination data is uploaded to the Microsoft cloud. For more information, see Schedule the script to run automatically.

1. Go to the window you left open from the previous step to access the GitHub site with the sample script. Alternatively, open the bookmarked site or use the URL that you copied.
2. Select the **Raw** button to display the script in text view.
3. Copy all the lines in the sample script and save them to a text file.
4. Modify the sample script for your organization, if necessary.
5. Save the text file as a Windows PowerShell script file by using a filename suffix of `.ps1`; for example, `HRConnector.ps1`.
6. Open a Command Prompt on your local computer, and go to the directory where you saved the script.
7. Run the following command to upload the HR data in the CSV file to the Microsoft cloud; for example:

PowerShell

```
.\HRConnector.ps1 -tenantId <tenantId> -appId <appId>  -appSecret <appSecret>  -jobId <jobId>  -csvFilePath '<csvFilePath>'
```

The following table describes the parameters to use with this script and their required values. Use the information you obtained in the previous steps for these values.

Expand table

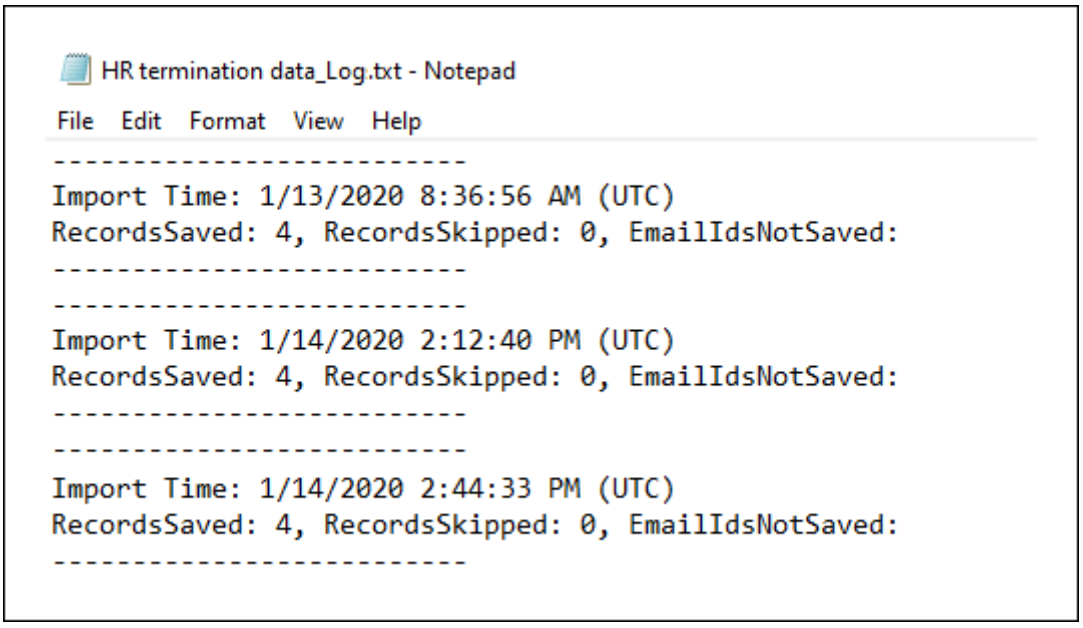
Parameter	Description
`tenantId`	The Id for your Microsoft 365 organization that you obtained in Step 1. You can also get the tenant Id for your organization on the **Overview** blade in the Microsoft Entra admin center. This value identifies your organization.
`appId`	The Microsoft Entra application Id for the app that you created in Microsoft Entra ID in Step 1. Microsoft Entra ID uses this value for authentication when the script attempts to access your Microsoft 365 organization.
`appSecret`	The Microsoft Entra application secret for the app that you created in Microsoft Entra ID in Step 1. This value is also used for authentication.
`jobId`	The job ID for the HR connector that you created in Step 3. This value associates the HR data that you upload to the Microsoft cloud with the HR connector.
`csvFilePath`	The file path for the CSV file (stored on the same system as the script) that you created in Step 2. Try to avoid spaces in the file path; otherwise use single quotation marks.

Parameter	Description

Here's an example of the syntax for the HR connector script using actual values for each parameter:

PowerShell

```
 .\HRConnector.ps1 -tenantId aaaabbbb-0000-cccc-1111-dddd2222eeee -appId
00001111-aaaa-2222-bbbb-3333cccc4444 -appSecret Aa1Bb~2Cc3.-
Dd4Ee5Ff6Gg7Hh8Ii9_Jj0Kk1Ll2 -jobId 00001111-aaaa-2222-bbbb-3333cccc4444 -
csvFilePath 'C:\Users\contosoadmin\Desktop\Data\employee_termination_data.csv'
```



If the upload is successful, the script displays the **Upload Successful** message.

> **Note**
>
> If you have problems running the previous command because of execution policies, see About Execution Policies and Set-ExecutionPolicy for guidance about setting execution policies.

Step 5: Monitor the HR connector

After you create the HR connector and run the script to upload your HR data, you can view the connector and upload status in the Microsoft Purview portal. If you schedule the script to run automatically on a regular basis, you can also view the current status after the last time the script ran.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select the HR connector that you created to display the flyout page. This page contains the properties and information about the connector.
4. Under **Progress**, select the **Download log** link to open (or save) the status log for the connector. This log contains information about each time the script runs and uploads the data from the CSV file to the Microsoft cloud.

The `RecordsSaved` field indicates the number of rows in the CSV file that uploaded. For example, if the CSV file contains four rows, the value of the `RecordsSaved` fields is 4, if the script successfully uploaded all the rows in the CSV file.

If you didn't run the script in Step 4, a link to download the script is displayed under **Last import**. You can download the script and then follow the steps in Step 4 to run it.

(Optional) Step 6: Schedule the script to run automatically

To make sure tools like the insider risk management solution always have the latest HR data from your organization, schedule the script to run automatically on a recurring basis, such as once a day. This schedule requires that you update the HR data in the CSV file on a similar (if not the same) schedule so that it contains the latest information about employees who leave your organization. The goal is to upload the most current HR data so that the HR connector can make it available to the insider risk management solution.

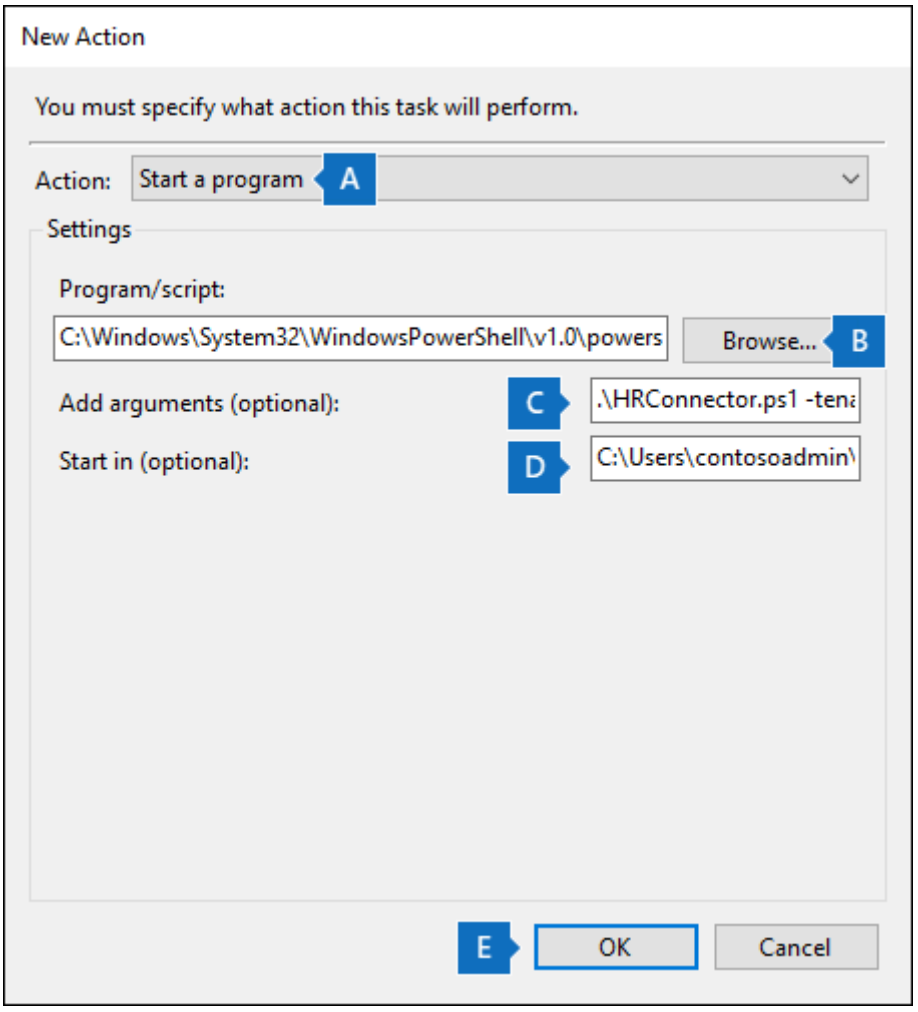
Use the Task Scheduler app in Windows to automatically run the script every day.

1. On your local computer, select the Windows **Start** button and then type **Task Scheduler**.
2. Select the **Task Scheduler** app to open it.
3. In the **Actions** section, select **Create Task**.
4. On the **General** tab, type a descriptive name for the scheduled task, such as **HR Connector Script**. You can also add an optional description.

5. Under **Security options**, complete the following steps:

   a. Decide whether to run the script only when you're logged on to the computer or run it when you're logged on or not.

   b. Make sure that the **Run with the highest privileges** checkbox is selected.



6. Select the **Triggers** tab, select **New**, and then complete the following steps:

   a. Under **Settings**, select the **Daily** option, and then select a date and time to run the script for the first time. The script runs every day at the same specified time.

   b. Under **Advanced settings**, make sure the **Enabled** checkbox is selected.

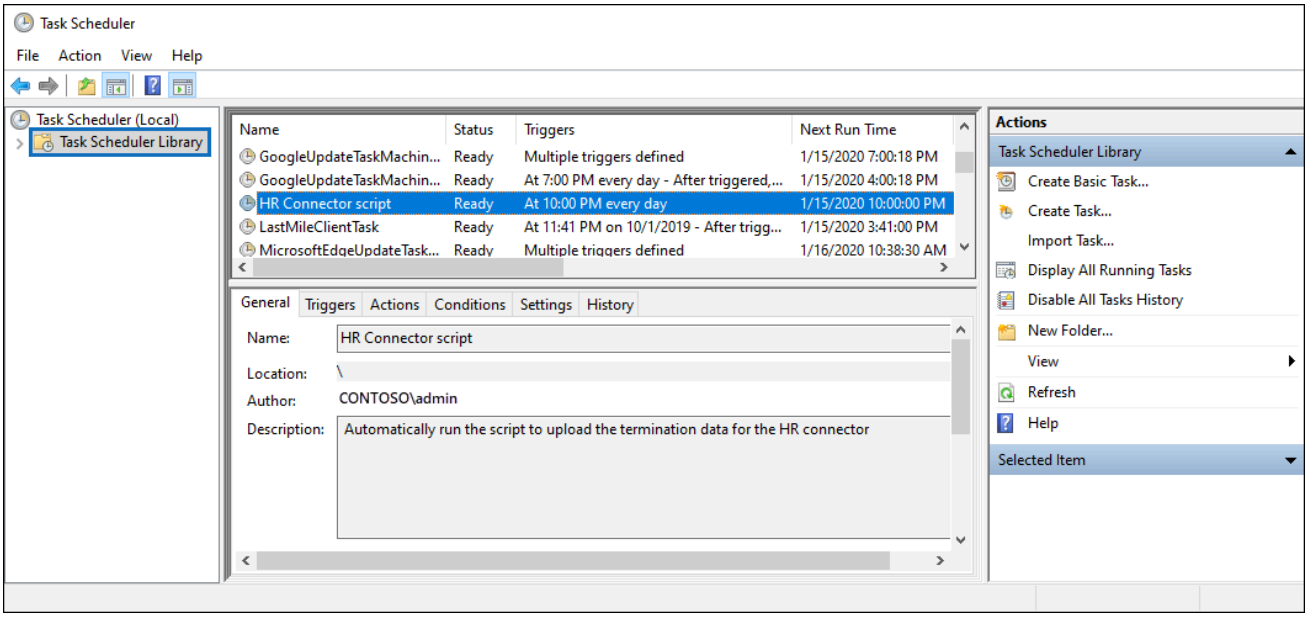
   c. Select **Ok**.

7. Select the **Actions** tab, select **New**, and then complete the following steps:

   a. In the **Action** dropdown list, make sure that **Start a program** is selected.

   b. In the **Program/script** box, select **Browse**, and go to the following location and select it so the path is displayed in the box:

`C:\Windows\System32\WindowsPowerShell\v1.0\powershell.exe`.



c. In the **Add arguments (optional)** box, paste the same script command that you ran in Step 4. For example, `.\HRConnector.ps1 -tenantId "aaaabbbb-0000-cccc-1111-dddd2222eeee" -appId "00001111-aaaa-2222-bbbb-3333cccc4444" -appSecret "Aa1Bb~2Cc3.-Dd4Ee5Ff6Gg7Hh8Ii9_Jj0Kk1Ll2" -jobId "00001111-aaaa-2222-bbbb-3333cccc4444" -csvFilePath "C:\Users\contosoadmin\Desktop\Data\employee_termination_data.csv"`

d. In the **Start in (optional)** box, paste the folder location of the script that you ran in Step 4. For example, `C:\Users\contosoadmin\Desktop\Scripts`.

e. Select **Ok** to save the settings for the new action.

8. In the **Create Task** window, select **Ok** to save the scheduled task. You might be prompted to enter your user account credentials.

   The new task is displayed in the Task Scheduler Library.

   The last time the script ran and the next time it's scheduled to run is displayed. You can double-select the task to edit it.

   You can also verify the last time the script ran on the flyout page of the corresponding HR connector in the Microsoft Purview portal.

Set up a connector to archive ICE Chat data

Use a native connector to import and archive financial services chat data from the ICE Chat collaboration tool. After you set up and configure a connector, it connects to your organization's ICE Chat secure FTP (SFTP) site once every day, converts the content of chat messages to an email message format, and then imports those items to mailboxes in Microsoft 365.

After storing ICE Chat data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, In-Place Archiving, Auditing, Communication Compliance, and Microsoft 365 retention policies to ICE Chat data. For example, you can search ICE Chat messages by using eDiscovery or associate the mailbox that contains the ICE Chat data in an eDiscovery case. Using an ICE Chat connector to import and archive data in Microsoft 365 can help your organization stay compliant with government and regulatory policies.

Overview of archiving ICE Chat data

The following overview explains the process of using a connector to archive ICE chat data in Microsoft 365.

1. Your organization works with ICE Chat to set up an ICE Chat SFTP site. You also work with ICE Chat to configure ICE Chat to copy chat messages to your ICE Chat SFTP site.

2. Once every 24 hours, ICE Chat copies chat messages to your ICE Chat SFTP site.

3. The ICE Chat connector that you create in the Microsoft Purview portal connects to the ICE Chat SFTP site every day and transfers the chat messages from the previous 24 hours to a secure Azure Storage location in the Microsoft cloud. The connector also converts the content of a chat massage to an email message format.

4. The connector imports chat message items to the mailboxes of specific users. A new folder named **ICE Chat** is created in the user mailboxes and the chat message items are imported to that folder. The connector uses the value of the *SenderEmail* and *RecipientEmail* properties. Every chat message contains these properties, which are populated with email address of the sender and every recipient/participant of the chat message.

   In addition to automatic user mapping that uses the values of the *SenderEmail* and *RecipientEmail* property (which means that the connector imports a chat message to the sender's mailbox and the mailboxes of every recipient), you can also define custom user mapping by uploading a CSV mapping file. This mapping file contains the ICE Chat *ImId* and the corresponding Microsoft 365 mailbox address for every user in your organization. If you enable automatic user mapping and provide a custom-mapping file, for every chat item the connector first looks at the custom-mapping file. If it doesn't find a valid Microsoft 365 user account that corresponds to a user's ICE Chat ImId, the connector uses the *SenderEmail* and *RecipientEmail* properties of the chat item to import the item to the mailboxes of the chat participants. If the connector doesn't find a valid Microsoft 365 user in either the custom-mapping file or the *SenderEmail* and *RecipientEmail* properties, the item won't be imported.

Before you begin

Some implementation steps for archiving ICE Chat data are external to Microsoft 365. You must complete these steps before you create the connector in the Microsoft Purview portal.

- ICE Chat charges customers a fee for external compliance. Your organization should contact the ICE Chat sales group to discuss and sign the ICE Chat data services agreement, which you can get at ICE Data Services Agreement (PDF). This agreement is between ICE Chat and your organization and doesn't involve Microsoft. After you set up an ICE Chat SFTP site (see Configure the ICE Chat SFTP site), ICE Chat provides the FTP credentials directly to your organization. Then you provide those credentials to Microsoft when you create the connector (see Create an ICE Chat connector).

- You must set up an ICE Chat SFTP site before creating the connector (see Create an ICE Chat connector). After working with ICE Chat to set up the SFTP site, data from ICE Chat is uploaded to the SFTP site every day. The connector you create in the Create an ICE Chat connector step connects to this SFTP site and transfers the chat data to Microsoft 365 mailboxes. SFTP also encrypts the ICE Chat data that's sent to mailboxes during the transfer process.

- To set up an ICE Chat connector, you need keys and key passphrases for Pretty Good Privacy (PGP) and Secure Shell (SSH). These keys configure the ICE Chat SFTP site and help the connector connect to the ICE Chat SFTP site to import data to Microsoft 365. The PGP key configures the encryption of data that's transferred from the ICE Chat SFTP site to Microsoft 365. The SSH key configures secure shell to enable a secure remote authentication when the connector connects to the ICE Chat SFTP site.

  When setting up a connector, you can use public keys and key passphrases provided by Microsoft or your own private keys and passphrases. Use the public keys provided by Microsoft. However, if your organization already configured an ICE Chat SFTP site by using private keys, you can create a connector by using these same private keys.

- The ICE Chat connector can import up to 200,000 items in a single day. If there are more than 200,000 items on the SFTP site, none of those items are imported to Microsoft 365.

- The admin who creates the ICE Chat connector in Step 3 (and who downloads the public keys and IP address in Step 1) must be assigned the Data Connector Admin role. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

Set up a connector by using public keys

The steps in this section show you how to set up an ICE Chat connector by using the public keys for Pretty Good Privacy (PGP) and Secure Shell (SSH).

Step 1: Obtain PGP and SSH public keys

First, get a copy of the public keys for Pretty Good Privacy (PGP) and Secure Shell (SSH). You use these keys in Step 2 to configure the ICE Chat SFTP site to allow the connector (that you create in Step 3) to connect to the SFTP site and transfer the ICE Chat data to Microsoft 365 mailboxes. You also get an IP address during the public-key download process, which you use when configuring the ICE Chat SFTP site.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. Select **ICE Chat** from the list.
5. On the **Terms of service** page, select **Accept**.
6. On the **Add credentials for content source** page, select **I want to use PGP and SSH public keys provided by Microsoft**.
7. Under step 1, select the **Download SSH key**, **Download PGP key**, and **Download IP address** links to save a copy of each file to your local computer.

   These files contain the following items that you use to configure the ICE Chat SFTP site in Step 2:

   - PGP public key: Use this key to configure the encryption of data that's transferred from the ICE Chat SFTP site to Microsoft 365.
   - SSH public key: Use this key to configure Secure SSH to enable a secure remote authentication when the connector connects to the ICE Chat SFTP site.
   - IP address: Configure the ICE Chat SFTP site to accept a connection request only from this IP address, which is used by the ICE Chat connector that you create in Step 3.
8. Select **Cancel** to close the workflow. You return to this workflow in the Create an ICE Chat connector section to create the connector.

Step 2: Configure the ICE Chat SFTP site

Next, use the PGP and SSH public keys and the IP address that you obtained in the Obtain PGP and SSH public keys step to configure PGP encryption and SSH authentication for the ICE Chat SFTP site. This configuration lets the ICE Chat connector that you create in the Create an ICE Chat connector section connect to the ICE Chat SFTP site and transfer ICE Chat data to Microsoft 365. You need to work with ICE Chat customer support to set up your ICE Chat SFTP site.

Step 3: Create an ICE Chat connector

In the last step, you create an ICE Chat connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the ICE Chat SFTP site and transfer chat messages to the corresponding user mailboxes in Microsoft 365.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. Select **ICE Chat** from the list.
5. On the **Terms of service** page, select **Accept**.
6. On the **Add credentials for content source** page, select **I want to use PGP and SSH public keys**.
7. Under Step 3, enter the required information in the following boxes and then select **Validate connection**.
    - **Firm code:** The ID for your organization, which you use as the username for the ICE Chat SFTP site.
    - **Password:** The password for your ICE Chat SFTP site.
    - **SFTP URL:** The URL for the ICE Chat SFTP site (for example, `sftp.theice.com`). You can also use an IP address for this value.
    - **SFTP port:** The port number for the ICE Chat SFTP site. The connector uses this port to connect to the SFTP site.
8. After the connection is successfully validated, select **Next**.
9. On the **Define user** page, specify the users to import data for.
    - **All users in your organization**. Select this option to import data for all users.
    - **Only users on Litigation hold**. Select this option to import data only for users whose mailboxes are placed on Litigation hold. This option imports data to user mailboxes that have the LitigationHoldEnabled property set to True. For more information, see Create a Litigation hold.
10. On the **Map external users to Microsoft 365 users** page, enable automatic user mapping and provide custom user mapping as required. You can download a copy of the user-

mapping CSV file on this page. You can add the user mappings to the file and then upload it.

> **Note**
>
> The custom mapping file contains the ICE Chat imid and corresponding Microsoft 365 mailbox address for each user. If you enable automatic user mapping and provide a custom mapping, for every chat item, the connector first looks at the custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's ICE Chat imid, the connector imports the item to the mailboxes for the users specified in the *SenderEmail* and *RecipientEmail* properties of the chat item. If the connector doesn't find a valid Microsoft 365 user by either automatic or custom user mapping, the item isn't imported.

11. Select **Next**, review your settings, and then select **Finish** to create the connector.

Set up a connector by using private keys

The steps in this section show you how to set up an ICE Chat connector by using PGP and SSH private keys. Use this connector setup option if your organization already configured an ICE Chat SFTP site by using private keys.

Step 1: Get an IP address to configure the ICE Chat SFTP site

If your organization uses PGP and SSH private keys to set up an ICE Chat SFTP site, get an IP address and give it to ICE Chat customer support. The ICE Chat SFTP site must accept connection requests from this IP address. The IP address you download in this step is also used by the ICE Chat connector to connect to the SFTP site and transfer ICE Chat data to Microsoft 365.

To get the IP address:

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. Select **ICE Chat** from the list.
5. On the **Terms of service** page, select **Accept**.
6. On the **Add credentials for content source** page, select **I want to use PGP and SSH private keys**.

7. Under step 1, select **Download IP address** to save a copy of the IP address file to your local computer.
8. Select **Cancel** to close the workflow. You return to this workflow in the Create an ICE Chat connector section to create the connector.

Work with ICE Chat customer support to configure your ICE Chat SFTP site to accept connection requests from this IP address.

Step 2: Create an ICE Chat connector

After you configure your ICE Chat SFTP site, create an ICE Chat connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the ICE Chat SFTP site and transfer email messages to the corresponding user mailboxes in Microsoft 365. To complete this step, make sure you have copies of the same private keys and key passphrases that you used to set up your ICE Chat SFTP site.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. Select **ICE Chat** from the list.
5. On the **Terms of service** page, select **Accept**.
6. On the **Add credentials for content source** page, select **I want to use PGP and SSH private keys**.
7. Under Step 3, enter the required information in the following boxes and then select **Validate connection**.
    - **Name:** The name for the connector. It must be unique in your organization.
    - **Firm code:** The ID for your organization that is used as the username for the ICE Chat SFTP site.
    - **Password:** The password for your organization's ICE Chat SFTP site.
    - **SFTP URL:** The URL for the ICE Chat SFTP site (for example, `sftp.theice.com`). You can also use an IP address for this value.
    - **SFTP port:** The port number for the ICE Chat SFTP site. The connector uses this port to connect to the SFTP site.

- **PGP private key:** The PGP private key for the ICE Chat SFTP site. Include the entire private key value, including the beginning and ending lines of the key block.
- **PGP key passphrase:** The passphrase for the PGP private key.
- **SSH private key:** The SSH private key for the ICE Chat SFTP site. Include the entire private key value, including the beginning and ending lines of the key block.
- **SSH key passphrase:** The passphrase for the SSH private key.

8. After the connection is successfully validated, select **Next**.

9. On the **Define user** page, specify the users to import data for.

   - **All users in your organization**. Select this option to import data for all users.
   - **Only users on Litigation hold**. Select this option to import data only for users whose mailboxes are placed on Litigation hold. This option imports data to user mailboxes that have the LitigationHoldEnabled property set to True. For more information, see Create a Litigation hold.

10. On the **Map ICE Chat users to Microsoft 365 users** page, enable automatic user mapping and provide custom user mapping as required.

    > ⓘ Note
    >
    > The custom mapping file contains the ICE Chat imid and corresponding Microsoft 365 mailbox address for each user. If you enable automatic user mapping and provide a custom mapping, for every chat item, the connector first looks at the custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's ICE Chat imid, the connector imports the item to the mailboxes for the users specified in the *SenderEmail* and *RecipientEmail* properties of the chat item. If the connector doesn't find a valid Microsoft 365 user by either automatic or custom user mapping, the item isn't imported.

11. Select **Next**, review your settings, and then select **Finish** to create the connector.

Set up a connector to import third-party insider risk detections (preview)

You can set up a connector to extend the Microsoft Purview Insider Risk Management solution to include third-party (non-Microsoft) detections. For example, you might want to extend your detections to include Salesforce and Dropbox activities and use them alongside the built-in detections provided by insider risk management, which focuses on Microsoft services like SharePoint Online and Exchange Online.

To bring your own detections to the insider risk management solution, import preprocessed, aggregated detections from security information and event management (SIEM) solutions such as Microsoft Sentinel or Splunk. Import a sample file into the Insider Risk Indicators connector workflow. The connector workflow analyzes the sample file and configures the required schema for insider risk management.

> ⓘ **Note**
>
> Currently, you can't import "raw" detection signals into insider risk management. You can only import preprocessed aggregations as a file.

Overall process

Bringing your own detections to insider risk management is a three-step process:

1. In Microsoft Purview, create the Insider Risk Indicators (preview) connector as described in this article.
2. In the insider risk management solution, create custom indicators.
3. In the insider risk management solution, use the custom indicators in policies as triggers or indicators and define thresholds.

When user activity crosses the threshold value that you specify for the policy, the user is brought into scope of the insider risk management policy and is scored for risk. An alert is generated and analysts can investigate the alert using custom indicator details.

> ⓘ **Note**
>
> You can only use custom indicators with the *Data theft* and *Data leaks* templates.

Before you begin

- **Determine the scenarios and data you want to import to Microsoft 365**. This determination helps you decide how many CSV files and Insider Risk Indicator connectors you need to create and how to structure the CSV files. The types of triggers and indicators you want to create determine the imported data. See Determining how many CSV files to prepare for indicator data.
- **Determine how to retrieve or export the data from your internal system and add it to the CSV files that you prepare in Step 2**. The script that you run in Step 4 uploads the data in the CSV files to the insider risk management solution.
- **Assign the *Data Connector Admin* role** to the user who creates the connector in Step 3. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see:- Permissions in the Microsoft Purview portal - Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview compliance

> ⓘ **Important**
>
> The sample script that you run in Step 4 uploads your data to the Microsoft cloud so that the insider risk management solution can use it. This sample script isn't supported under any Microsoft standard support program or service. The sample script is provided AS IS without warranty of any kind. Microsoft further disclaims all implied warranties including, without limitation, any implied warranties of merchantability or of fitness for a particular purpose. You assume all risk arising from the use or performance of the sample script and documentation. In no event shall Microsoft, its authors, or anyone else involved in the creation, production, or delivery of the scripts be liable for any damages whatsoever (including, without limitation, damages for loss of business profits, business interruption, loss of business information, or other pecuniary loss) arising out of the use of or inability to use the sample scripts or documentation, even if Microsoft has been advised of the possibility of such damages.

Determining how many CSV files to prepare for indicator data

In Step 3, you can prepare separate CSV files that contain data for each indicator or prepare a single CSV file that contains data for two or more indicators.

Here are some guidelines to help you determine how many CSV files to prepare:

- If the insider risk management policy you want to implement requires multiple indicators, consider using a single CSV file that contains the data for all the indicators. As a general

rule, the number of connectors that you need to create is determined by the services in a CSV file. For example, if a CSV file contains all the services required to support your insider risk management implementation, you only need one connector. Having fewer CSV files allows you to have fewer connectors to create and manage. If you have two separate CSV files that each contain a single service, you need to create two connectors.

- The method for generating or collecting the data might determine the number of CSV files. For example, if the different types of data used to configure a connector are located in a single system in your organization, you might be able to export the data to a single CSV file. But if data is distributed across different systems, it might be easier to export data to different CSV files. How you retrieve or export data from your systems might determine the number of CSV files you need.

Step 1: Create an app in Microsoft Entra ID

First, create and register a new app in Microsoft Entra ID for the connector that you create in Step 3. When you create this app, Microsoft Entra ID can authenticate the connector when it runs and attempts to access your organization. Use this app to authenticate the script that you run in Step 4 to upload your data to the Microsoft cloud. When you create the Microsoft Entra app, save the following information:

- Microsoft Entra application ID (app ID or client ID)
- Microsoft Entra application secret (client secret)
- Tenant ID (directory ID)

Use these values in Steps 3 and 4. For step-by-step instructions on creating an app in Microsoft Entra ID, see Register an application with the Microsoft identity platform.

Step 2: Prepare CSV file(s) with your insider risk indicators data

Next, prepare a CSV file that contains the indicator data that the connector imports to Microsoft 365. The insider risk management solution uses this data. You can import data for the following scenarios:

- Create a trigger that, when activated, brings a user into scope for a policy. Example 1 below shows how to prepare a CSV file for a 'home-grown' trigger that predicts the probability of an employee leaving an organization.
- Create a policy indicator that monitors user activities. Example 2 below shows how to prepare a single CSV file for multiple indicators (one for Dropbox and one for Salesforce).

For each scenario, provide the corresponding indicator data in one or more CSV files. See Determining how many CSV files to use for indicator data.

After you create the CSV file with the required indicator data, store it on the local computer that you run the script on in Step 4. Implement an update strategy to make sure that the CSV file always contains the most current information so that whenever you run the script, the most current indicator data is uploaded to the Microsoft cloud and accessible to the insider risk management solution.

> **Important**
>
> The column names described in the following sections are examples, not required parameters. You can use any column names in your CSV files. However, the column names that you use in a CSV file must be mapped to a data type when you create the connector in Step 3. Also note that the sample CSV files in the following sections are shown in NotePad. It's much easier to view and edit CSV files in Microsoft Excel.

Example 1: Prepare a CSV file for a simple trigger that brings a user into scope for a policy

This example shows how to structure a CSV file to create a 'home-grown' trigger that could be used to predict the probability of an employee leaving an organization. This example uses the following sample data:

text

```
UserPrincipalName,PredictionTime,PredictionScore,ModelInfo
sarad@contoso.com,2023-04-20T05:52:56.962686Z,6,Model accuracy: 67%, Model name:
LeaverPrediction_M1
sarad@contoso.com,2023-04-24T05:52:56.962686Z,9,Model accuracy: 67%, Model name:
LeaverPrediction_M1
sarad@contoso.com,2023-04-24T05:52:56.962686Z,3,Model accuracy: 67%, Model name:
LeaverPrediction_M1
```

The following table describes each column in the CSV file.

Expand table

Column	Description
UserPrincipalName	The Microsoft Entra UserPrincipalName (UPN) used to identify the user.
Prediction Time	Mandatory field that displays the date/time that the activity occurred. Use the following date format: `yyyy-mm-ddThh:mm:ss.nnnnnn+|-hh:mm`, which is the ISO 8601

Column	Description
	date and time format
Prediction Score	Risky activity score. This field is used for the trigger threshold setting. Only *Number* fields can be used for threshold settings.
Model Info	Extra field used to track information about the prediction model.

> **Note**
>
> Only the UserPrincipalName and date/time fields are mandatory. All other fields are optional but can be helpful for the analyst or investigator in decision making when they triage alerts (these fields appear in the Activity explorer and in alerts and cases).

When you create the connector in Step 3, you'll use the data in the `PredictionScore` field as a threshold value for the trigger. If a user crosses the threshold value that you set later in the policy, the user is brought into the scope of the policy.

Example 2: Prepare a single CSV file to create multiple policy indicators

This example shows how to create multiple policy indicators (one for Dropbox and one for Salesforce) from a single CSV file. This example uses the following sample data:

text

```
User_Principal_Name,Display_Name,Alert_Severity,Alert_Count,Aggregation_Date,Source
_Workload,AdditionalInfo_Salesforce,AdditionalInfo_Dropbox
sarad@contoso.com,Salesforce - Sensitive report downloaded and emailed
externally,High,10,2023-04-24T05:52:56.962686Z,Salesforce,text,text
sarad@contoso.com,Salesforce - Anomalous download of sales lead
reports,Medium,6,2023-04-24T05:52:56.962686Z,Salesforce,text,text
bradh@contoso.com,Salesforce - Printing sales reports,Low,50,2023-04-
24T05:52:56.962686Z,Salesforce,text,text
bradh@contoso.com,Salesforce - Excessive modifications to sensitive
reports,Medium,3,2023-04-24T05:52:56.962686Z,Salesforce,text,text
sarad@contoso.com,Dropbox - Sensitive files saved to personal Dropbox,High,14,2023-
04-24T05:52:56.962686Z,Dropbox,text,text
bradh@contoso.com,Dropbox - Anomalous file copy activity,Medium,5,2023-04-
24T05:52:56.962686Z,Dropbox,text,text
```

The following table describes each column in the CSV file.

Expand table

Column	Description
UserPrincipalName	The Microsoft Entra UserPrincipalName (UPN) used to identify the user.
Display Name	Name of the risky activity.
Alert Severity	Severity categories: *Low*, *Medium*, and *High*.
Alert Count	Number of incidences of each activity. Data in this field is used for the indicator threshold setting.
Aggregation Date	Mandatory field that displays the date/time that the activity occurred. Use the following date format: `yyyy-mm-ddThh:mm:ss.nnnnnn+|-hh:mm`, which is the ISO 8601 date and time format
Source Workload	This is the key field for the multiple indicators scenario. Select this field for the **Source column** field when you create the connector, and use the values in this field (**Dropbox** and **Salesforce**) in the **Related values in source column** field in the connector.
Additional Info Salesforce	Any additional info that you want to note about the Salesforce indicator
Additional Info Dropbox	Any additional info that you want to note about the Dropbox indicator

See the following example to see how you use this CSV file when creating the data connector.

Step 3: Create the Insider Risk Indicators connector

Create a connector in the Microsoft Purview portal. After you run the script in Step 4, the connector imports the data from the CSV file and uploads it to your Microsoft 365 organization.

> **Note**
>
> Before you create a connector, make sure that you have a list of the scenarios and the corresponding CSV column names for each scenario.

Example 1: Create a connector file for a simple trigger

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.

4. From the list, choose **Insider Risk Indicators (preview)**.

5. Review the terms of service, then select **Accept** if you want to continue creating the connector.

6. On the **Authentication** page, complete the following steps:
   a. Enter a name for the connector.
   b. Paste the Microsoft Entra application ID for the Azure app that you created in Step 1.
   c. Select **Next**.

7. On the **Sample file** page:
   a. Select **Upload sample file**, then select the CSV file that you want to upload.
   b. In the **Source column** list, select **None (Single source)**.
   c. In the **Verify sample data and data type** section, review each field to make sure that the right data types are assigned to each field. If a field is used later as a threshold value, make sure that it has a *Number* data type. For example, in this scenario, the `PredictionScore` field is used as a threshold value and the data type is set appropriately to *Number*.

8. Select **Next**.

9. On the **Data mapping** page:
   a. Enter the values for **Event time (UTC time)** and **Microsoft 365 user email address** based on the appropriate values from the CSV file. These fields are mandatory for the connector.
   b. In the **Default** field, use the list to select each field you want to include from the CSV file. For example, select a Number field to use later as a threshold value for the indicator or select other fields to use as supporting information.

10. Select **Next**.

11. On the **Finish** page, review all the information, and if everything looks correct, select **Finish**.

12. Copy the job ID for the connector. You need it for the next step.

13. Go to Step 4 to run the script that uploads the data to Microsoft 365.

Example 2: Create a connector that includes multiple policy indicators

This example shows how to set up a single connector to create multiple policy indicators for Salesforce and Dropbox. You could create two separate connectors, but creating a single connector that works for both can reduce overall file maintenance.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, choose **Insider Risk Indicators (preview)**.
5. Review the terms of service, then select **Accept** if you want to continue creating the connector.
6. On the **Authentication** page, enter the following information:
   a. Enter a name for the connector.
   b. Paste the Microsoft Entra application ID for the Azure app that you created in Step 2.
   c. Select **Next**.
7. On the **Sample file** page:
   a. Select **Upload sample file**, then select the CSV file that you want to upload.
   b. In the **Source column** list, select the column to use as the source. In the example CSV file, the source column is `SourceWorkload`, since it stores the values for the two separate workloads (Salesforce and Dropbox).
   c. In the **Related values in source column** field, enter the related values. For this example, enter `Salesforce,Dropbox`. Don't include spaces between values.

   > **Important**
   >
   > Make sure that the values you enter in the **Related values in source column** field match the values in the **Source column** list. The connector fails if the column values don't match.

   a. In the **Verify sample data and data type** section, review each field to make sure that the right data types are assigned for each field. If a field is used later as a threshold value, make sure that it has a Number data type. For example, in this example scenario, the `AlertCount` field is used as a threshold value and the data type is set appropriately to *Number*.
   b. Select **Next**.
8. On the **Data mapping** page:
   a. Enter the values for **Event time (UTC time)** and **Microsoft 365 user email address** based on the appropriate values from the CSV file. These fields are mandatory and common to both indicators you're creating for this example.
   b. Select the columns from your sample file that you want to map to the two workloads, Salesforce and Dropbox.

> **Tip**
>
> You can use the same process described previously to create multiple policy indicators based on severity levels. For example, you can use a single connector to create separate Low, Medium, and High indicators. In the **Source column** list, select the field that holds the values for the separate workloads (Low, Medium, High). Enter those workload values in the **Related values in source column** field. Map the appropriate fields in the **Data mapping** page.

9. Select **Next**.
10. On the **Finish** page, review all the information, and if everything looks correct, select **Finish**.
11. Copy the job ID for the connector. You need it for the next step.
12. Go to the next step (Step 4) to run the script that uploads the data to Microsoft 365.

Step 4: Run the sample script to upload your data

The last step in setting up a connector is running a sample script that uploads the data in the CSV file. When you run the script, the connector you created in Step 3 imports the data to your Microsoft 365 organization where the insider risk management solution can access it. After you run the script, consider scheduling a task to run it automatically on a daily basis so the most current data is uploaded to the Microsoft cloud. For more information, see Schedule the script to run automatically.

Before running the script

- Make sure to add the *webhook.ingestion.office.com* domain to your firewall allowlist for your organization. If this domain is blocked, the script doesn't run.
- Make sure to wait 24 hours before uploading the data after you update the custom indicators and the associated policies. This waiting period ensures all components sync. If you immediately upload the data while the updates are syncing, some data might not be scored for risk.
- Make sure that all combinations of UPN and timestamp to be imported are unique. If any record in the uploaded CSV file contains the same timestamp and UPN as other records in the file, the record is dropped.

Run the sample script

1. Go to the window that you left open from the previous step to access the GitHub site with the sample script. Alternatively, open the bookmarked site or use the URL that you copied. You can also access the script at https://github.com/microsoft/m365-compliance-connector-sample-scripts/blob/main/sample_script.ps1 .
2. Select the **Raw** button to display the script in text view.
3. Copy all the lines in the sample script, and save them to a text file.
4. Modify the sample script for your organization, if necessary.
5. Save the text file as a Windows PowerShell script file by using a filename suffix of `.ps1`; for example, `HRConnector.ps1`. Alternatively, you can use the GitHub filename for the script, which is `upload_termination_records.ps1`.
6. Open a command prompt on your local computer, and then go to the directory where you saved the script.
7. Run the following command to upload the data in the CSV file to the Microsoft cloud; for example:

   PowerShell

   ```
   .\HRConnector.ps1 -tenantId <tenantId> -appId <appId>  -appSecret <appSecret>
   -jobId <jobId>  -filePath '<filePath>'
   ```

   The following table describes the parameters to use with this script and their required values. The information you obtained in the previous steps is used in the values for these parameters.

   Expand table

Parameter	Description
`tenantId`	This is the ID for your Microsoft 365 organization that you obtained in Step 1. You can also obtain the tenant ID for your organization on the **Overview** blade in the Microsoft Entra admin center. This value identifies your organization.
`appId`	This is the Microsoft Entra application ID for the app that you created in Microsoft Entra ID in Step 1. This value is used by Microsoft Entra ID for authentication when the script attempts to access your Microsoft 365 organization.
`appSecret`	This is the Microsoft Entra application secret for the app that you created in Microsoft Entra ID in Step 1. This value is also used for authentication.
`jobId`	This is the job ID for the connector that you created in Step 3. This value associates

Parameter	Description
	the data that is uploaded to the Microsoft cloud with the connector.
`filePath`	This is the file path for the file (stored on the same system as the script) that you created in Step 1. Try to avoid spaces in the file path; otherwise use single quotation marks.

Here's an example of the syntax for the connector script using actual values for each parameter:

PowerShell

```
 .\HRConnector.ps1 -tenantId aaaabbbb-0000-cccc-1111-dddd2222eeee -appId
00001111-aaaa-2222-bbbb-3333cccc4444 -appSecret Aa1Bb~2Cc3.-
Dd4Ee5Ff6Gg7Hh8Ii9_Jj0Kk1Ll2 -jobId 00001111-aaaa-2222-bbbb-3333cccc4444 -
filePath 'C:\Users\contosoadmin\Desktop\Data\insider_risk_indicator_data.csv'
```

If the upload is successful, the script displays the **Upload Successful** message.

> ⓘ Note
>
> If you have problems running the previous command because of execution policies, see About Execution Policies and Set-ExecutionPolicy for guidance about setting execution policies.

Step 5: Monitor the connector

After you create the connector and run the script to upload your data, view the connector and upload status in the Microsoft Purview portal. If you schedule the script to run automatically on a regular basis, you can view the current status after the last time the script runs.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select the HR connector that you created to display the flyout page. This page contains the properties and information about the connector.
4. Under **Progress**, select the **Download log** link to open (or save) the status log for the connector. This log contains information about each time the script runs and uploads the data from the CSV file to the Microsoft cloud.

The `RecordsSaved` field indicates the number of rows in the CSV file that uploaded. For example, if the CSV file contains four rows, the value of the `RecordsSaved` field is 4 if the script successfully uploads all the rows in the CSV file.

If you don't run the script in Step 4, a link to download the script is displayed under **Last import**. You can download the script and then follow the steps to run the script.

(Optional) Step 6: Schedule the script to run automatically

To make sure the insider risk management solution always has the latest data from your organization, schedule the script to run automatically on a recurring basis, such as once a day. This schedule requires updating the data in the CSV file on a similar (if not the same) schedule so that it contains the latest information. The goal is to upload the most current data so that the connector can make it available to the insider risk management solution.

Use the Task Scheduler app in Windows to automatically run the script every day.

1. On your local computer, select the Windows **Start** button and type **Task Scheduler**.
2. Select the **Task Scheduler** app.
3. In the **Actions** section, select **Create Task**.
4. On the **General** tab, enter a descriptive name for the scheduled task. For example, **HR Connector Script**. You can also add an optional description.
5. Under **Security options**, complete the following steps:
   a. Decide whether to run the script only when you're logged on to the computer or when you're logged on or not.
   b. Make sure that the **Run with the highest privileges** check box is selected.
6. Select the **Triggers** tab, select **New**, and complete the following steps:
   a. Under **Settings**, select the **Daily** option, and choose a date and time to run the script for the first time. The script runs every day at the same specified time.
   b. Under **Advanced settings**, make sure that the **Enabled** check box is selected.
   c. Select **OK**.
7. Select the **Actions** tab, select **New**, and complete the following steps:
   a. In the **Action** dropdown list, make sure that **Start a program** is selected.
   b. In the **Program/script** box, select **Browse**, then go to the following location and select it so the path is displayed in the box:

`C:\Windows\System32\WindowsPowerShell\v1.0\powershell.exe`.

c. In the **Add arguments (optional)** box, paste the same script command that you ran in Step 4. For example, `.\HRConnector.ps1 -tenantId "aaaabbbb-0000-cccc-1111-dddd2222eeee" -appId "00001111-aaaa-2222-bbbb-3333cccc4444" -appSecret "Aa1Bb~2Cc3.-Dd4Ee5Ff6Gg7Hh8Ii9_Jj0Kk1Ll2" -jobId "00001111-aaaa-2222-bbbb-3333cccc4444" -filePath "C:\Users\contosoadmin\Desktop\Data\insider_risk_indicator_data.csv"`

d. In the **Start in (optional)** box, paste the folder location of the script that you ran in Step 4. For example, `C:\Users\contosoadmin\Desktop\Scripts`.

e. Select **OK** to save the settings for the new action.

8. In the **Create Task** window, select **OK** to save the scheduled task. You might be prompted to enter your user account credentials.

   The new task appears in the Task Scheduler Library. You see the last time the script ran and the next time it's scheduled to run. Double-click the task to edit it.

   You can also verify the last time the script ran on the flyout page of the corresponding connector in the Microsoft Purview portal.

(Optional) Step 7: Upload data using Power Automate templates

You can upload the CSV data by using Power Automate templates and define triggers. For example, you can configure a Power Automate template to trigger when new connector files are available in SharePoint or OneDrive locations. You can also streamline this process by storing confidential information like the Microsoft Entra application secret (created in Step 1) in Azure Key Vault and use it with Power Automate for authentication.

Complete the following steps to automatically upload data when new files become available on OneDrive for Business:

1. Download the *ImportHRDataforIRM.zip* package from the GitHub site.
2. In Power Automate, go to **My flows**.
3. Select **Import** and upload the *ImportHRDataforIRM.zip* package.
4. After the package is uploaded, update the content (name and OneDrive for Business connection) and select **Import**.
5. Select **Open flow** and update the parameters. The following table describes the parameters to use in this Power Automate flow and their required values. The information

you obtained in the previous steps is used in the values for these parameters.

Expand table

Parameter	Description
`appId`	This is the Microsoft Entra application ID for the app that you created in Microsoft Entra ID in Step 1. This value is used by Microsoft Entra ID for authentication when the script attempts to access your Microsoft 365 organization.
`appSecret`	This is the Microsoft Entra application secret for the app that you created in Microsoft Entra ID in Step 1. This secret is used for authentication.
`fileLocation`	This is the OneDrive for Business location where Power Automate monitors for 'new file created' activities to trigger this flow.
`jobId`	Identifier for the connector created in Step 3. This identifier associates the data uploaded to the Microsoft cloud with the connector.
`tenantId`	Identifier for your Microsoft 365 organization obtained in Step 1. You can also obtain the tenant ID for your organization on the **Overview** blade in the Microsoft Entra admin center. Microsoft uses this tenant ID to identify your organization.
`URI`	Verify that the value for this parameter is *https://webhook.ingestion.office.com/api/signals*

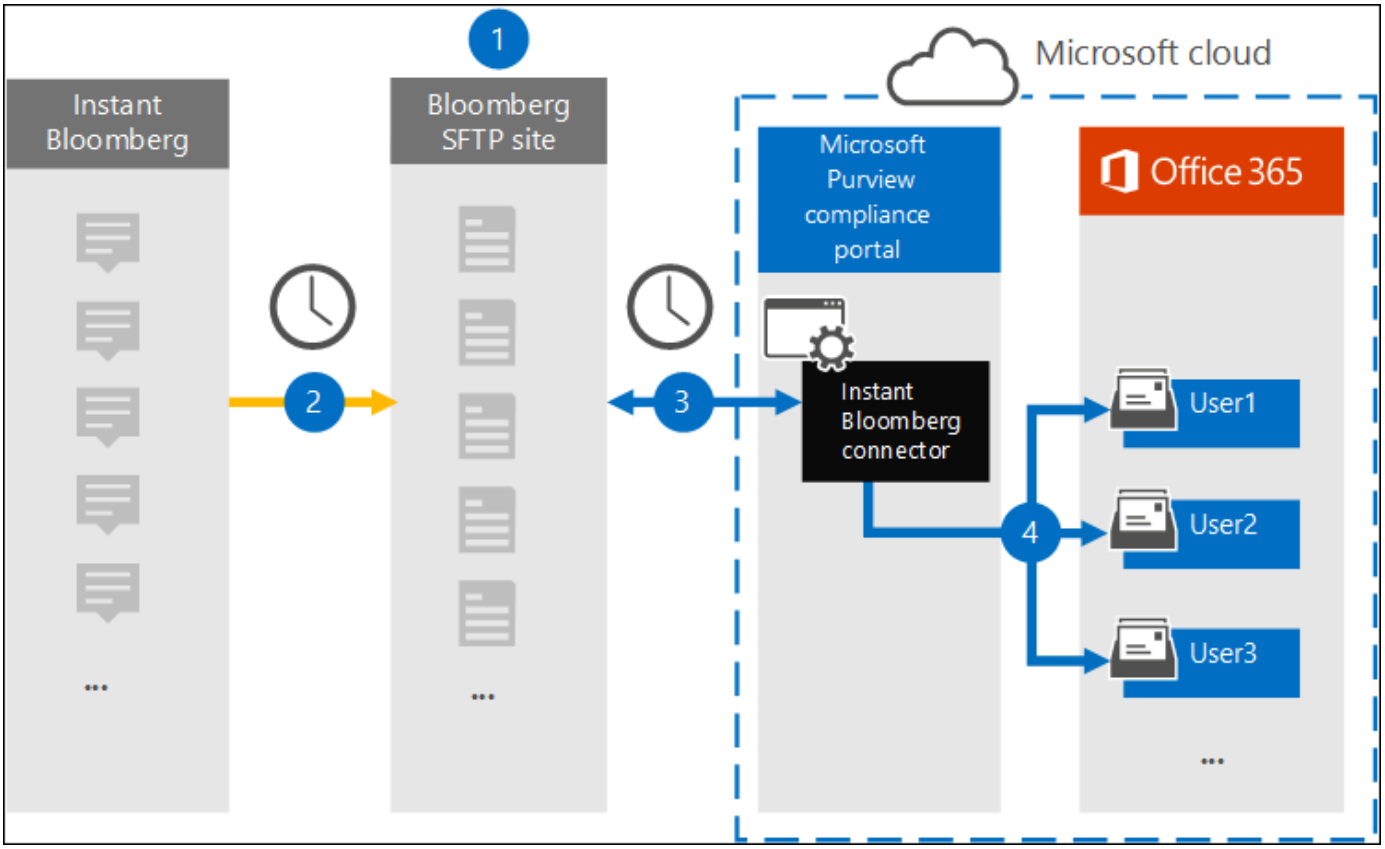
1. Select **Save**.
2. Go to **Flow overview** and select **Turn on**.
3. Test the flow manually by uploading a new file to your OneDrive for Business folder and verify that it runs successfully. This process might take a few minutes after the upload before the flow is triggered.
4. You can now monitor the connector as described in Step 5.

If needed, you can update the flow to create triggers based on file availability and modification events on SharePoint and other data sources supported by Power Automate flows.

Next steps

- Create custom indicators in insider risk management
- Use the custom indicators in policies as triggers or indicators and define thresholds

Last updated on 03/30/2026



Set up a connector to archive Instant Bloomberg data

Use a connector to import and archive financial services chat data from the Instant Bloomberg collaboration tool. After you set up and configure a connector, it connects to your organization's Bloomberg secure FTP site (SFTP) once every day, converts the content of chat messages to an email message format, and then imports those items to mailboxes in Microsoft 365.

After storing Instant Bloomberg data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, In-Place Archiving, Auditing, Communication Compliance, and Microsoft 365 retention policies to Instant Bloomberg data. For example, you can search Instant Bloomberg chat messages by using eDiscovery or associate the mailbox that contains the Instant Bloomberg data with a custodian in a Microsoft Purview eDiscovery (Premium) case. By using an Instant Bloomberg connector to import and archive data in Microsoft 365, you can help your organization stay compliant with government and regulatory policies.

Overview of archiving Instant Bloomberg data

The following overview explains the process of using a connector to archive Instant Bloomberg chat data in Microsoft 365.

1. Your organization works with Bloomberg to set up a Bloomberg SFTP site. You also work with Bloomberg to configure Instant Bloomberg to copy chat messages to your Bloomberg SFTP site.

2. Every 24 hours, Instant Bloomberg copies chat messages to the Bloomberg SFTP site.

3. The Instant Bloomberg connector that you create in the Microsoft Purview portal connects to the Bloomberg SFTP site every day and transfers the chat messages from the previous 24 hours to a secure Azure Storage area in the Microsoft Cloud. The connector also converts the content of a chat massage to an email message format.

4. The connector imports the chat message items to the mailbox of a specific user. A new folder named InstantBloomberg is created in the specific user's mailbox and the items are imported to it. The connector uses the value of the *CorporateEmailAddress* property. Every chat message contains this property, which is populated with the email address of every participant of the chat message. In addition to automatic user mapping by using the value of the *CorporateEmailAddress* property, you can also define a custom mapping by uploading a CSV mapping file. This mapping file should contain a Bloomberg UUID and the corresponding Microsoft 365 mailbox address for each user. If you enable automatic user mapping and provide a custom mapping, for every chat item the connector first looks at custom-mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's Bloomberg UUID, the connector uses the *CorporateEmailAddress* property of the chat item. If the connector doesn't find a valid Microsoft 365 user in either the custom-mapping file or the *CorporateEmailAddress* property of the chat item, the item isn't imported.

Before you begin

Some of the implementation steps required to archive Instant Bloomberg data are external to Microsoft 365. You must complete these steps before you can create the connector in the Microsoft Purview portal.

- To set up an Instant Bloomberg connector, you need keys and key passphrases for Pretty Good Privacy (PGP) and Secure Shell (SSH). Use these keys to configure the Bloomberg SFTP site. The connector uses these keys to connect to the Bloomberg SFTP site and import data to Microsoft 365. Use the PGP key to configure the encryption of data that's transferred from the Bloomberg SFTP site to Microsoft 365. Use the SSH key to configure secure shell to enable a secure remote authentication when the connector connects to the Bloomberg SFTP site.

When setting up a connector, you can use public keys and key passphrases provided by Microsoft or use your own private keys and passphrases. Use the public keys provided by Microsoft. However, if your organization already configured a Bloomberg SFTP site by using private keys, you can create a connector by using these same private keys.

- Subscribe to Bloomberg Anywhere. This subscription is required so that you can sign in to Bloomberg Anywhere to access the Bloomberg SFTP site that you set up and configure.

- Set up a Bloomberg SFTP (Secure file transfer protocol) site. After working with Bloomberg to set up the SFTP site, data from Instant Bloomberg is uploaded to the SFTP site every day. The connector you create in Step 2 connects to this SFTP site and transfers the chat data to Microsoft 365 mailboxes. SFTP also encrypts the Instant Bloomberg chat data that you send to mailboxes during the transfer process.

  For external information about Bloomberg SFTP (also called *BB-SFTP*), use the following resources:
  - See the "SFTP Connectivity Standards" document at Bloomberg Support.
  - Contact Bloomberg customer support.

  After you work with Bloomberg to set up an SFTP site, Bloomberg provides some information to you after you respond to the Bloomberg implementation email message. Save a copy of the following information. You use it to set up a connector in Step 3.
  - Firm code, which is an ID for your organization and is used to sign in to the Bloomberg SFTP site.
  - Password for your Bloomberg SFTP site
  - URL for Bloomberg SFTP site (for example, sftp.bloomberg.com)
  - Port number for Bloomberg SFTP site

- The Instant Bloomberg connector can import a total of 200,000 items in a single day. If there are more than 200,000 items on the SFTP site, none of those items are imported to Microsoft 365.

- The user who downloads the public keys and IP address in the "Get PGP and SSH and public keys" procedure and creates the connector in the "Create an Instant Bloomberg connector" procedure must be assigned the Data Connector Admin role. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview

portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

Set up a connector by using public keys

The steps in this section show you how to set up an Instant Bloomberg connector by using the public keys for Pretty Good Privacy (PGP) and Secure Shell (SSH).

Step 1: Get PGP and SSH and public keys

First, get a copy of the public keys for Pretty Good Privacy (PGP) and Secure Shell (SSH). You use these keys to configure the Bloomberg SFTP site and to allow the Instant Bloomberg connector that you create later to connect to the SFTP site and transfer the Instant Bloomberg chat data to Microsoft 365 mailboxes. You also download an IP address during this key-download procedure, which you use when configuring the Bloomberg SFTP site.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **Instant Bloomberg**.
5. On the **Terms of service** page, select **Accept**.
6. On the **Add credentials for content source** page, select **I want to use PGP and SSH public keys provided by Microsoft**.
7. Under step 1, select the **Download SSH key**, **Download PGP key**, and **Download IP address** links to save a copy of each file to your local computer.

   These files contain the following items that you use to configure the Bloomberg SFTP site in Step 2:

   - PGP public key: Use this key to configure the encryption of data that's transferred from the Bloomberg SFTP site to Microsoft 365.
   - SSH public key: Use this key to configure secure shell to enable a secure remote authentication when the connector connects to the Bloomberg SFTP site.
   - IP address: Configure the Bloomberg SFTP site to accept connection requests from this IP address. The same IP address is used by the Instant Bloomberg connector to connect to the SFTP site and transfer Instant Bloomberg data to Microsoft 365.

8. Select **Cancel** to close the Add credentials workflow. You return to this connector setup workflow later to create the Instant Bloomberg connector.

Step 2: Configure the Bloomberg SFTP site

Use the PGP and SSH public keys and the IP address that you downloaded earlier to set up PGP encryption and SSH authentication for the Bloomberg SFTP site. The PGP encryption and SSH authentication configuration lets the Instant Bloomberg connector connect to the Bloomberg SFTP site and transfer Instant Bloomberg data to Microsoft 365 after you create the connector later in this procedure. You need to work with Bloomberg customer support to set up your Bloomberg SFTP site. Contact Bloomberg customer support for assistance.

> **Important**
>
> Bloomberg recommends that you attach the downloaded SSH key, PGP key, and IP address files to an email message and send them to their customer support team when working with them to set up your Bloomberg SFTP site.

Step 3: Create an Instant Bloomberg connector

In this step, you create an Instant Bloomberg connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the Bloomberg SFTP site and transfer chat messages to the corresponding user mailboxes in Microsoft 365.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **Instant Bloomberg**.
5. On the **Terms of service** page, select **Accept**.
6. On the **Add credentials for Bloomberg SFTP site** page, in the SFTP credentials section, enter the required information in the following boxes and then select **Next**.
    - **Firm code:** The ID for your organization that Bloomberg uses as the username for the SFTP site.
    - **Password:** Password for Bloomberg SFTP site.

- **SFTP URL:** The URL for Bloomberg SFTP site (for example, `sftp.bloomberg.com`). You can also use an IP address for this value.
- **SFTP port:** The port number for Bloomberg SFTP site. The connector uses this port to connect to the SFTP site.

7. On the **Define user** page, select one of the following options to specify the users whose data you want to import.

   - **All users in your organization**. Select this option to import data for all users.
   - **Only users on Litigation hold**. Select this option to import data only for users whose mailboxes are placed on Litigation hold. This option imports data to user mailboxes that have the LitigationHoldEnabled property set to True. For more information, see Create a Litigation hold.

8. On the **Select data types to import** page, select the required data types to be imported apart from **Messages**

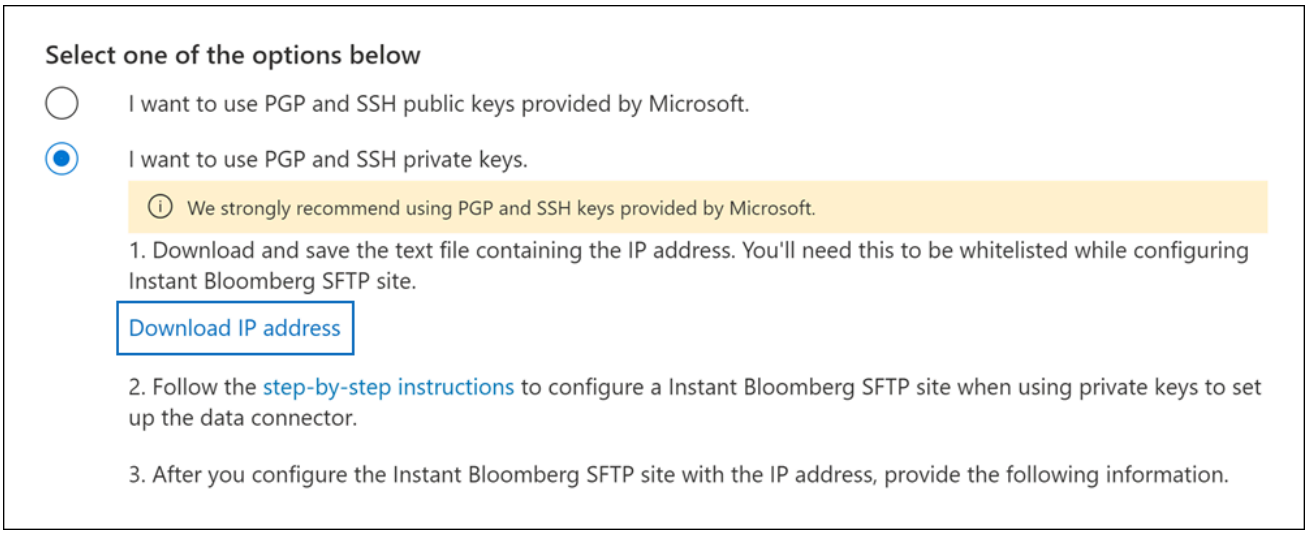
9. On the **Map Instant Bloomberg users to Microsoft 365 users** page, enable automatic user mapping and provide custom user mapping as required

   > ⓘ **Note**
   >
   > The connector imports the chat message items to the mailbox of a specific user. A new folder named **InstantBloomberg** is created in the specific user's mailbox and the items are imported to it. The connector uses the value of the *CorporateEmailAddress* property. Every chat message contains this property, and the property is populated with the email address of every participant of the chat message. In addition to automatic user mapping using the value of the *CorporateEmailAddress* property, you can also define custom mapping by uploading a CSV mapping file. The mapping file should contain the Bloomberg UUID and corresponding Microsoft 365 mailbox address for each user. If you enable automatic user mapping and provide a custom mapping, for every chat item the connector first looks at custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's Bloomberg UUID, the connector uses the *CorporateEmailAddress* property of the chat item. If the connector doesn't find a valid Microsoft 365 user in either the custom mapping file or the *CorporateEmailAddress* property of the chat item, the item won't be imported.

10. Select **Next**, review your settings, and then select **Finish** to create the connector.

Set up a connector by using private keys

The following procedure shows how to set up an Instant Bloomberg connector by using PGP and SSH private keys. Use this connector setup option if your organization already configured a Bloomberg SFTP site by using private keys.



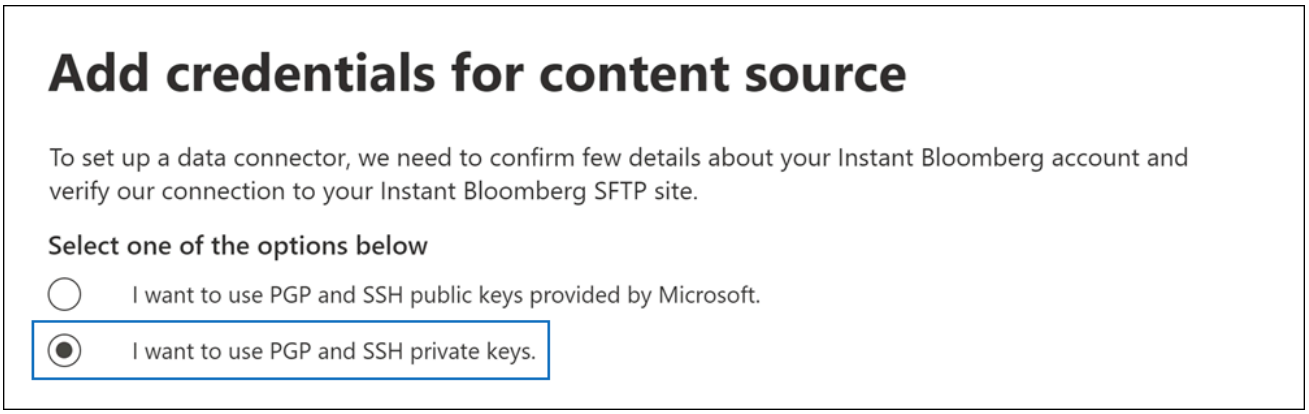
Step 1: Get an IP address to configure the Bloomberg SFTP site

> **Note**
>
> If your organization previously configured a Bloomberg SFTP site to archive Bloomberg Message data by using PGP and SSH private keys, you don't need to configure another one. You can specify the previously configured Bloomberg SFTP site when you create the Instant Bloomberg connector later in this procedure.

If your organization uses PGP and SSH private keys to set up a Bloomberg SFTP site, you need to get an IP address and give it to Bloomberg customer support. The Bloomberg SFTP site must accept connection requests from this IP address. The same IP address is used by the Instant Bloomberg connector to connect to the SFTP site and transfer Instant Bloomberg data to Microsoft 365.

To get the IP address:

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **Instant Bloomberg**.
5. On the **Terms of service** page, select **Accept**.
6. On the **Add credentials for content source** page, select **I want to use PGP and SSH private keys**.
7. Under step 1, select **Download IP address** to save a copy of the IP address file to your local computer.



8. Select **Cancel** to close the workflow. You return to this workflow in Step 2 to create the connector.

Work with Bloomberg customer support to configure your Bloomberg SFTP site to accept connection requests from this IP address. Contact Bloomberg customer support for assistance.

Step 2: Create an Instant Bloomberg connector

After you configure your Bloomberg SFTP site, create an Instant Bloomberg connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the Bloomberg SFTP site and transfer email messages to the corresponding user mailboxes in Microsoft 365. Before creating the connector, be sure to have copies of the PGP and SSH private keys and key passphrases that you used to set up your Bloomberg SFTP site.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **Instant Bloomberg**.
5. On the **Terms of service** page, select **Accept**.
6. On the **Add credentials for content source** page, select **I want to use PGP and SSH private keys**.

7. In the connection details section, enter the required information in the following boxes and then select **Validate connection**.

    - **Name:** The name for the connector. It must be unique in your organization.
    - **Firm code:** The ID for your organization that Bloomberg uses as the username for the SFTP site.
    - **Password:** The password for your organization's Bloomberg SFTP site.
    - **SFTP URL:** The URL for the Bloomberg SFTP site (for example, `sftp.bloomberg.com`). You can also use an IP address for this value.
    - **SFTP port:** The port number for the Bloomberg SFTP site. The connector uses this port to connect to the SFTP site.
    - **PGP private key:** The PGP private key for the Bloomberg SFTP site. Be sure to include the entire private key value, including the beginning and ending lines of the key block.
    - **PGP key passphrase:** The passphrase for the PGP private key.
    - **SSH private key:** The SSH private key for the Bloomberg SFTP site. Be sure to include the entire private key value, including the beginning and ending lines of the key block.
    - **SSH key passphrase:** The passphrase for the SSH private key.

8. After the connection is successfully validated, select **Next**.

9. On the **Define user** page, select one of the following options to specify the users whose data you want to import.

    - **All users in your organization**. Select this option to import data for all users.
    - **Only users on Litigation hold**. Select this option to import data only for users whose mailboxes are placed on Litigation hold. This option imports data to user mailboxes that have the LitigationHoldEnabled property set to True. For more information, see Create a Litigation hold.

10. On the **Map Instant Bloomberg users to Microsoft 365 users** page, enable automatic user mapping and provide custom user mapping as required.

> **Note**
>
> The connector imports the chat message items to the mailbox of a specific user. A new folder named **InstantBloomberg** is created in the specific user's mailbox and the items are imported to it. The connector uses the value of the *CorporateEmailAddress* property. Every chat message contains this property, and the property is populated with the email address of every participant of the chat message. In addition to automatic user mapping using the value of the *CorporateEmailAddress* property, you can also define custom mapping by uploading a CSV mapping file. The mapping file should contain the Bloomberg UUID and corresponding Microsoft 365 mailbox address for each user. If you enable automatic user mapping and provide a custom mapping, for every chat item the connector first looks at custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's Bloomberg UUID, the connector uses the *CorporateEmailAddress* property of the chat item. If the connector doesn't find a valid Microsoft 365 user in either the custom mapping file or the *CorporateEmailAddress* property of the chat item, the item won't be imported.

11. Select **Next**, review your settings, and then select **Finish** to create the connector.

Set up a connector to archive LinkedIn data

Use a connector to import and archive data from LinkedIn Company pages. After you set up and configure a connector, it connects to the account for the specific LinkedIn Company page once every 24 hours. The connector converts the messages posted to the Company page to an email message, then imports those items to a mailbox in Microsoft 365.

After storing the LinkedIn Company page data in a mailbox, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, In-Place Archiving, Auditing, and Microsoft 365 retention policies to LinkedIn data. For example, you can search for these items by using eDiscovery or associate the storage mailbox with a custodian in a Microsoft Purview eDiscovery (Premium) case. Creating a connector to import and archive LinkedIn data in Microsoft 365 can help your organization stay compliant with government and regulatory policies.

Before you begin

Before you create the connector, make sure you meet the following requirements:

- Assign the Data Connector Admin role to the user who creates a LinkedIn Company Page connector. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.
- Have the sign-in credentials (email address or phone number and password) of a LinkedIn user account that is an admin for the LinkedIn Company Page that you want to archive. You use these credentials to sign into LinkedIn when setting up the connector.
- Understand that the LinkedIn connector can import a total of 200,000 items in a single day. If there are more than 200,000 LinkedIn items in a day, none of those items are imported to Microsoft 365.

Create a LinkedIn connector

Perform the following steps to create a LinkedIn connector in Microsoft Purview.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. Select **LinkedIn company pages** from the list.
5. On the **Terms of service** page, select **Accept**.
6. On the **Sign in with LinkedIn** page, select **Sign in with LinkedIn**.
7. On the LinkedIn sign in page, enter the email address (or phone number) and password for the LinkedIn account associated with the company page that you want to archive, then select **Sign in**. A workflow page displays with a list of all LinkedIn Company Pages associated with the account that you signed in to. You can only configure a connector for one company page. If your organization has multiple LinkedIn Company Pages, you need to create a connector for each one.
8. Select the company page that you want to archive items from, then select **Next**.
9. On the **Choose storage location** page, select the email address of a Microsoft 365 mailbox that the LinkedIn items will be imported to, then select **Next**. Items are imported to the inbox folder in this mailbox. The mailbox used must have an Exchange Online Plan 1 or Plan 2 license.
10. Select **Next** to review the connector settings and then select **Finish** to complete the connector setup.

> **Note**
>
> LinkedIn items are imported to the LinkedIn subfolder in the inbox of the storage mailbox in Microsoft 365. They appear as email messages.

Set up a connector to import physical badging data

Set up a data connector to import physical badging data, such as an employee's raw physical access events or any physical access alarms generated by your organization's badging system. Examples of physical access points are an entry to a building or an entry to server room or data center. Microsoft Purview Insider Risk Management solution uses physical badging data to help protect your organization from malicious activity or data theft inside your organization.

Setting up a physical badging connector consists of the following tasks:

- Create an app in Microsoft Entra ID to access an API endpoint that accepts a JSON payload that contains physical badging data.
- Create the JSON payload with a schema defined by physical badging data connector.
- Create a physical badging data connector in the Microsoft Purview portal.
- Run a script to push the physical badging data to the API endpoint.
- Optionally, schedule the script to run automatically to import currently physical badging data.

Before you begin

- Assign the Data Connector Admin role to the user who creates the physical badging connector in Step 3. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see:- Permissions in the Microsoft Purview portal - Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview compliance

  > ⓘ **Note**
  >
  > The Data Connector Admin role isn't currently supported in US Government GCC High and DoD environments. Therefore, assign the Mailbox Import Export role in Exchange Online to the user who creates the HR connector in GCC High and DoD environments. By default, no role group in Exchange Online has this role assigned. You can add the Mailbox Import Export role to the Organization Management role group in Exchange Online. Or, you can create a new role group, assign the Mailbox Import Export role, and add the appropriate users as members. For more

information, see the **Create role groups** or **Modify role groups** sections in the article "Manage role groups in Exchange Online".

- Determine how to retrieve or export data from your organization's physical badging system (on a daily basis) and create a JSON file as described in Step 2. The script that you run in Step 4 pushes the data in the JSON file to the API endpoint.
- Understand that the sample script you run in Step 4 pushes the physical badging data from a JSON file to the connector API so the insider risk management solution can use it. This sample script isn't supported under any Microsoft standard support program or service. The sample script is provided AS IS without warranty of any kind. Microsoft further disclaims all implied warranties including, without limitation, any implied warranties of merchantability or of fitness for a particular purpose. You assume all risk arising from the use or performance of the sample script and documentation. In no event shall Microsoft, its authors, or anyone else involved in the creation, production, or delivery of the scripts be liable for any damages whatsoever (including, without limitation, damages for loss of business profits, business interruption, loss of business information, or other pecuniary loss) arising out of the use of or inability to use the sample scripts or documentation, even if Microsoft has been advised of the possibility of such damages.
- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Step 1: Create an app in Microsoft Entra ID

First, create and register a new app in Microsoft Entra ID. The app corresponds to the physical badging connector that you create in Step 3. When you create the app, Microsoft Entra ID can authenticate the push request for a JSON payload containing physical badging data. During the creation of this Microsoft Entra app, save the following information. You use these values in later steps.

- Microsoft Entra application ID (also called the *app Id* or *client Id*)
- Microsoft Entra application secret (also called the *client secret*)
- Tenant Id (also called the *directory Id*)

For step-by-step instructions for creating an app in Microsoft Entra ID, see Register an application with the Microsoft identity platform.

Step 2: Prepare a JSON file with physical badging data

In this step, you create a JSON file that contains information about employees' physical access data. As explained in the before you begin section, you need to determine how to generate this JSON file from your organization's physical badging system.

> **Note**
>
> Don't add non-English characters to the JSON file. The connector supports only English characters. If the JSON contains non-English characters, data ingestion might fail.

The JSON file must conform to the schema definition required by the connector. The following table describes the required schema properties for the JSON file:

Expand table

Property	Description	Data type
UserId	An employee can have multiple digital identities across the systems. The input needs to have the Microsoft Entra ID already resolved by the source system.	UPN or email address
AssetId	The reference ID of the physical asset or physical access point.	Alphanumeric string
AssetName	The friendly name of the physical asset or physical access point.	Alphanumeric string
EventTime	The time stamp of access.	Date and time, in UTC format
AccessStatus	Value of `Success` or `Failed`	String

The following example shows a JSON file that conforms to the required schema:

JSON

```
[
    {
        "UserId":"sarad@contoso.com",
```

```
        "AssetId":"Mid-Sec-7",
        "AssetName":"Main Building 1st Floor Mid Section",
        "EventTime":"2019-07-04T01:57:49",
        "AccessStatus":"Failed"
    },
    {
        "UserId":"pilarp@contoso.com",
        "AssetId":"Mid-Sec-7",
        "AssetName":"Main Building 1st Floor Mid Section",
        "EventTime":"2019-07-04T02:57:49",
        "AccessStatus":"Success"
    }
]
```

You can also download the schema definition for the JSON file from the workflow when you create the physical badging connector in Step 3.

text

```
{
   "title" : "Physical Badging Signals",
   "description" : "Access signals from physical badging systems",
   "DataType" : {
      "description" : "Identify what is the data type for input signal",
      "type" : "string",
   },
   "type" : "object",
   "properties": {
      "UserId" : {
         "description" : "Unique identifier AAD Id resolved by the source system",
         "type" : "string",
      },
      "AssetId": {
         "description" : "Unique ID of the physical asset/access point",
         "type" : "string",
      },
      "AssetName": {
         "description" : "friendly name of the physical asset/access point",
         "type" : "string",
      },
      "EventTime" : {
         "description" : "timestamp of access",
         "type" : "string",
      },
      "AccessStatus" : {
         "description" : "what was the status of access attempt - Success/Failed",
         "type" : "string",
      },
   }
   "required" : ["UserId", "AssetId", "EventTime" "AccessStatus"]
}
```

Step 3: Create the physical badging connector

In this step, you create a physical badging connector in the Microsoft Purview portal. When you run the script in Step 4, it processes the JSON file you created in this step and pushes it to the API endpoint you configured in Step 1. Be sure to copy the JobId generated when you create the connector. You'll use the JobId when you run the script.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, choose **Physical badging**.
5. On the **Authentication credentials** page, enter the following information, then select **Next**:
   a. Enter or paste the Microsoft Entra application ID for the Azure app that you created in Step 1.
   b. Download the sample schema for your reference to create the JSON file.
   c. Enter a unique name for the physical badging connector.
6. On the **Review** page, review your settings and select **Finish** to create the connector.
7. View the status page that confirms the connector was created. This page also contains the job ID. You can copy the job ID from this page or from the flyout page for the connector. You need this job ID when running the script.

   The status page also contains a link to the script. Refer to this script to understand how to post the JSON file to the API endpoint.
8. Select **Done**.

   The new connector appears in the list on the **Connectors** tab.
9. Select the physical badging connector that you just created to display the flyout page, which contains properties and other information about the connector.

Step 4: Run the script to upload your physical badging data

To set up a physical badging connector, run a script that pushes the physical badging data in the JSON file (created in Step 2) to the API endpoint (created in Step 1). We provide a sample script for your reference. You can choose to use it or create your own script to post the JSON file to the API endpoint.

After you run the script, the JSON file containing the physical badging data is pushed to your Microsoft 365 organization where the insider risk management solution can access it. We recommend you post physical badging data daily. You can automate the process to generate the JSON file every day from your physical badging system and then schedule the script to push the data.

> **Note**
>
> The API can process a JSON file with up to 50,000 records.

1. Go to this GitHub site to access the sample script.
2. Select the **Raw** button to display the script in text view.
3. Copy all the lines in the sample script and save them to a text file.
4. Modify the sample script for your organization, if necessary.
5. Save the text file as a Windows PowerShell script file by using a filename suffix of .ps1; for example, PhysicalBadging.ps1.
6. Open a Command Prompt on your local computer, and go to the directory where you saved the script.
7. Run the following command to push the physical badging data in the JSON file to the Microsoft cloud; for example:

   PowerShell

   ```
   .\PhysicalBadging.ps1 -tenantId "<Tenant Id>" -appId "<Azure AD App Id>" -appSecret "<Azure AD App Secret>" -jobId "Job Id" -jsonFilePath "<records file path>"
   ```

   The following table describes the parameters to use with this script and their required values. Use the information you obtained in the previous steps for these values.

Expand table

Parameter	Description
tenantId	This is the Id for your Microsoft 365 organization that you obtained in Step 1. You can also get the tenantId for your organization on the **Overview** blade in the Microsoft Entra admin center. This value identifies your organization.
appId	This is the Microsoft Entra application Id for the app that you created in Microsoft Entra ID in Step 1. Microsoft Entra ID uses this value for authentication when the script attempts to access your Microsoft 365 organization.
appSecret	This is the Microsoft Entra application secret for the app that you created in Microsoft Entra ID in Step 1. Microsoft Entra ID also uses this value for authentication.
jobId	This is the Job Id for the physical badging connector that you created in Step 3. The script uses this value to associate the physical badging data that it pushes to the Microsoft cloud with the physical badging connector.
JsonFilePath	This is the file path on the local computer (the one you're using to run the script) for the JSON file that you created in Step 2. This file must follow the sample schema described in Step 3.

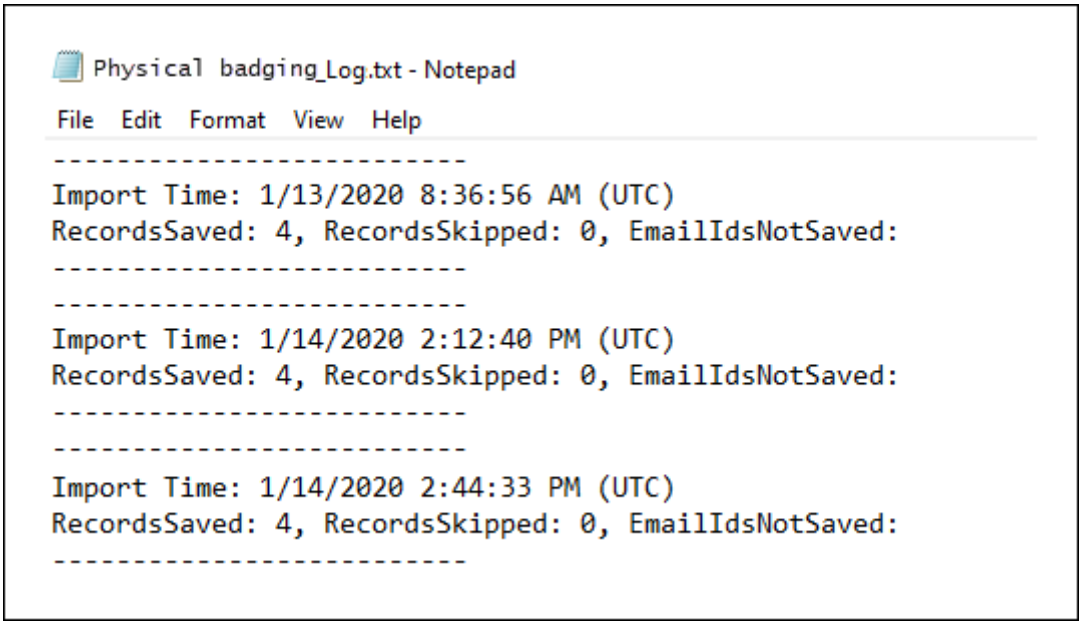
Here's an example of the syntax for the physical badging connector script using actual values for each parameter:

PowerShell

```
.\PhysicalBadging.ps1 -tenantId aaaabbbb-0000-cccc-1111-dddd2222eeee -appId
00001111-aaaa-2222-bbbb-3333cccc4444 -appSecret Aa1Bb~2Cc3.-
Dd4Ee5Ff6Gg7Hh8Ii9_Jj0Kk1Ll2 -jobId 00001111-aaaa-2222-bbbb-3333cccc4444 -
jsonFilePath 'C:\Users\contosoadmin\Desktop\Data\physical_badging_data.json'
```

If the upload is successful, the script displays the **Upload Successful** message.

If you have multiple JSON files, run the script for each file.



Step 5: Monitor the physical badging connector

After you create the physical badging connector and push your physical badging data, you can view the connector and upload status in the Microsoft Purview portal. If you schedule the script to run automatically on a regular basis, you can also view the current status after the last time the script runs.

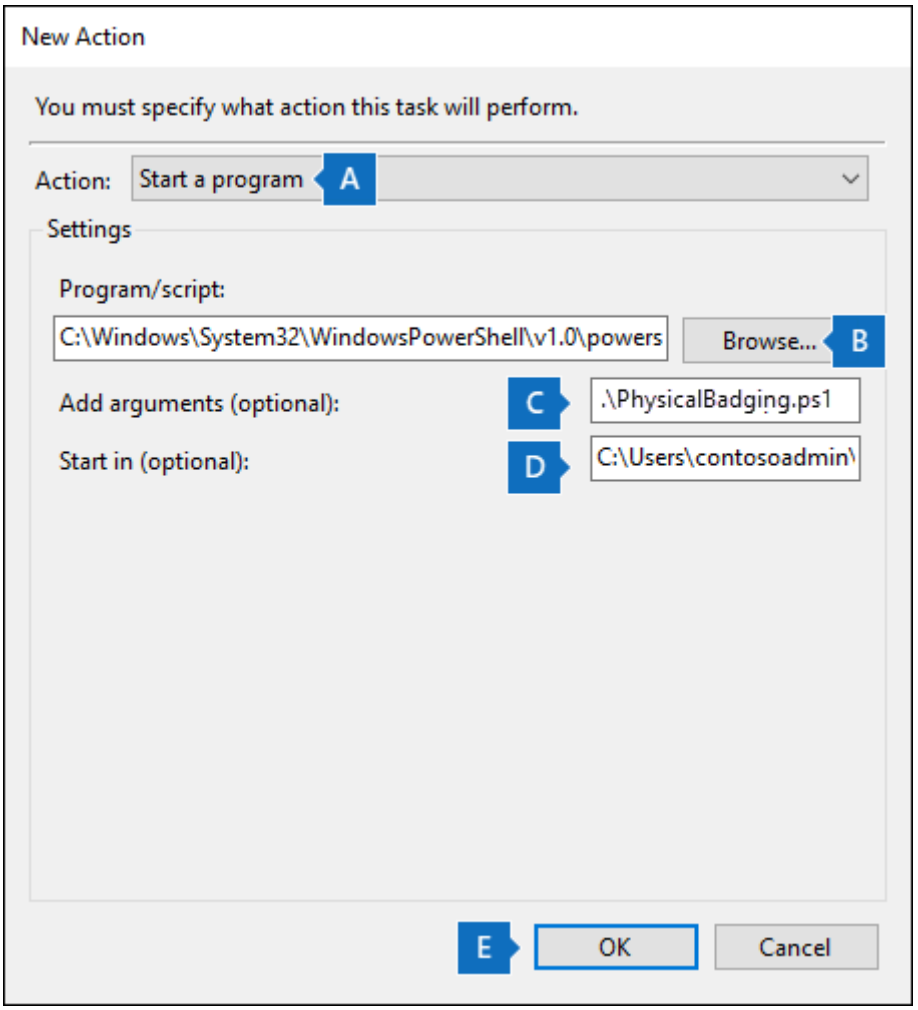
1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.

3. Select **My connectors**, then select the physical badging connector that you created to display the flyout page. This page contains the properties and information about the connector.

4. Under **Last import**, select the **Download log** link to open (or save) the status log for the connector. This log contains information about each time the script runs and uploads the data from the JSON file to the Microsoft cloud.

   The **RecordsSaved** field shows the number of records in the JSON file that the script uploads. For example, if the JSON file contains four records, the value of the **RecordsSaved** fields is 4 when the script successfully uploads all the records in the JSON file. The **RecordsSkipped** field shows the number of records in the JSON file that the script skips. Before uploading records in the JSON file, the script validates the Email IDs. Any record with an invalid Email ID is skipped and the corresponding Email ID displays in the field **EmailIdsNotSaved**.

If you didn't run the script in Step 4, a link to download the script appears under **Last import**. You can download the script and then follow the steps in Step 4 to run it.



(Optional) Step 6: Schedule the script to run automatically

To make sure tools like the insider risk management solution always have the latest physical badging data from your organization, schedule the script to run automatically on a recurring basis, such as once a day. This schedule requires updating the physical badging data to JSON file on a similar (if not the same) schedule so that it contains the latest information about employees who leave your organization. The goal is to upload the most current physical

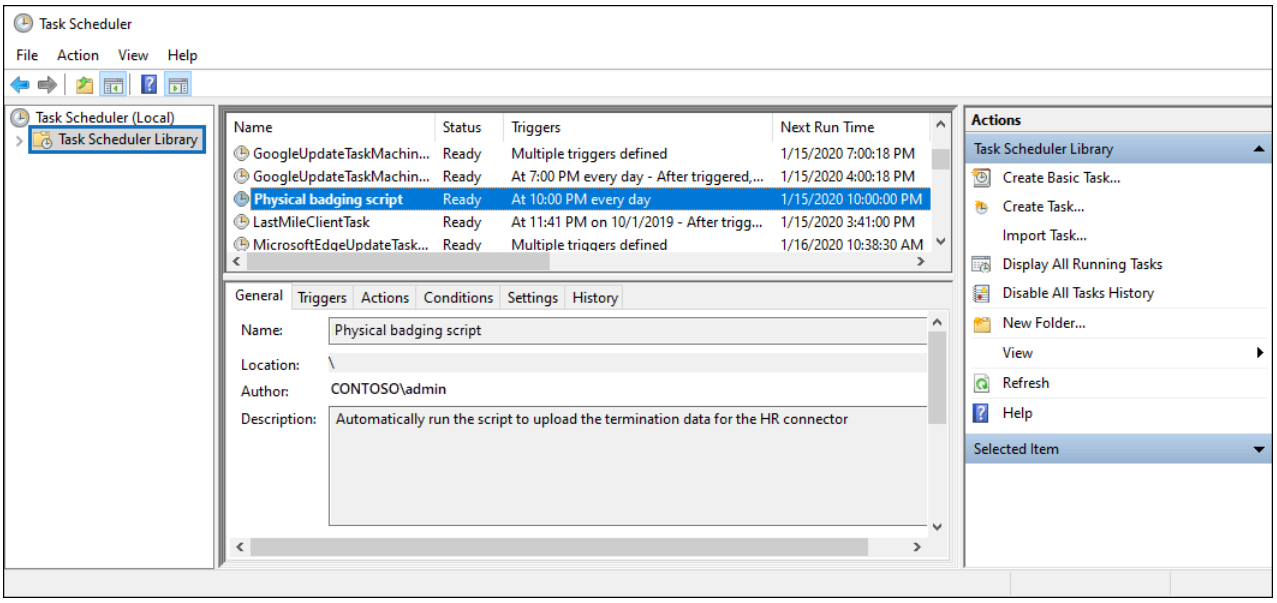
badging data so that the physical badging connector can make it available to the insider risk management solution.

Use the Task Scheduler app in Windows to automatically run the script every day.

1. On your local computer, select the Windows **Start** button and then type **Task Scheduler**.
2. Select the **Task Scheduler** app to open it.
3. In the **Actions** section, select **Create Task**.
4. On the **General** tab, type a descriptive name for the scheduled task, such as **physical badging connector Script**. You can also add an optional description.
5. Under **Security options**, do the following things:
    a. Decide whether to run the script only when you're logged on to the computer or run it when you're logged on or not.
    b. Make sure that the **Run with the highest privileges** checkbox is selected.
6. Select the **Triggers** tab, select **New**, and then do the following things:
    a. Under **Settings**, select the **Daily** option, and then choose a date and time to run the script for the first time. The script runs every day at the same specified time.
    b. Under **Advanced settings**, make sure the **Enabled** checkbox is selected.
    c. Select **Ok**.
7. Select the **Actions** tab, select **New**, and then do the following things:

a. In the **Action** dropdown list, make sure that **Start a program** is selected.

b. In the **Program/script** box, select **Browse**, and go to the following location and select it so the path is displayed in the box: `C:\Windows\System32\WindowsPowerShell\v1.0\powershell.exe`.



c. In the **Add arguments (optional)** box, paste the same script command that you ran in Step 4. For example, `.\PhysicalBadging.ps1 -tenantId "aaaabbbb-0000-cccc-1111-dddd2222eeee" -appId "00001111-aaaa-2222-bbbb-3333cccc4444" -appSecret "Aa1Bb~2Cc3.-Dd4Ee5Ff6Gg7Hh8Ii9_Jj0Kk1Ll2" -jobId "00001111-aaaa-2222-bbbb-3333cccc4444" -jsonFilePath "C:\Users\contosoadmin\Desktop\Data\physical_badging_data.json"`

d. In the **Start in (optional)** box, paste the folder location of the script that you ran in Step 4. For example, `C:\Users\contosoadmin\Desktop\Scripts`.

e. Select **Ok** to save the settings for the new action.

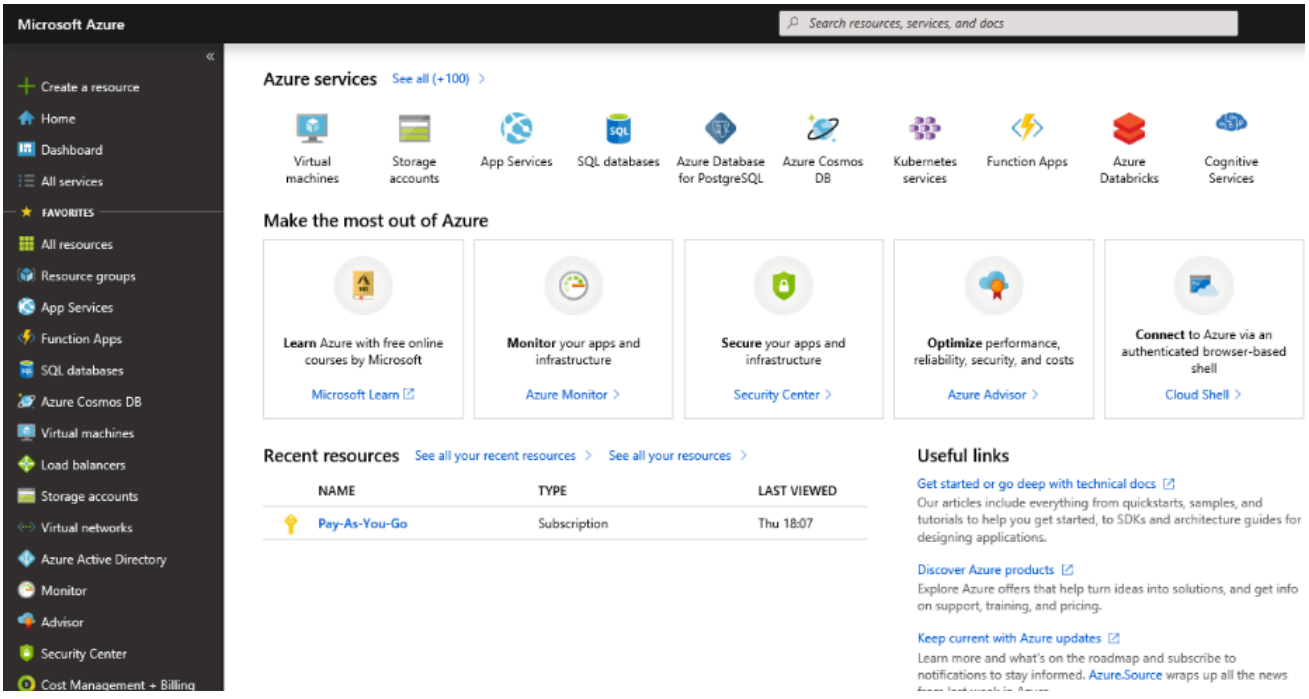
8. In the **Create Task** window, select **Ok** to save the scheduled task. You might be prompted to enter your user account credentials.

   The new task is displayed in the Task Scheduler Library.

The last time the script ran and the next time it's scheduled to run is displayed. You can double-select the task to edit it.

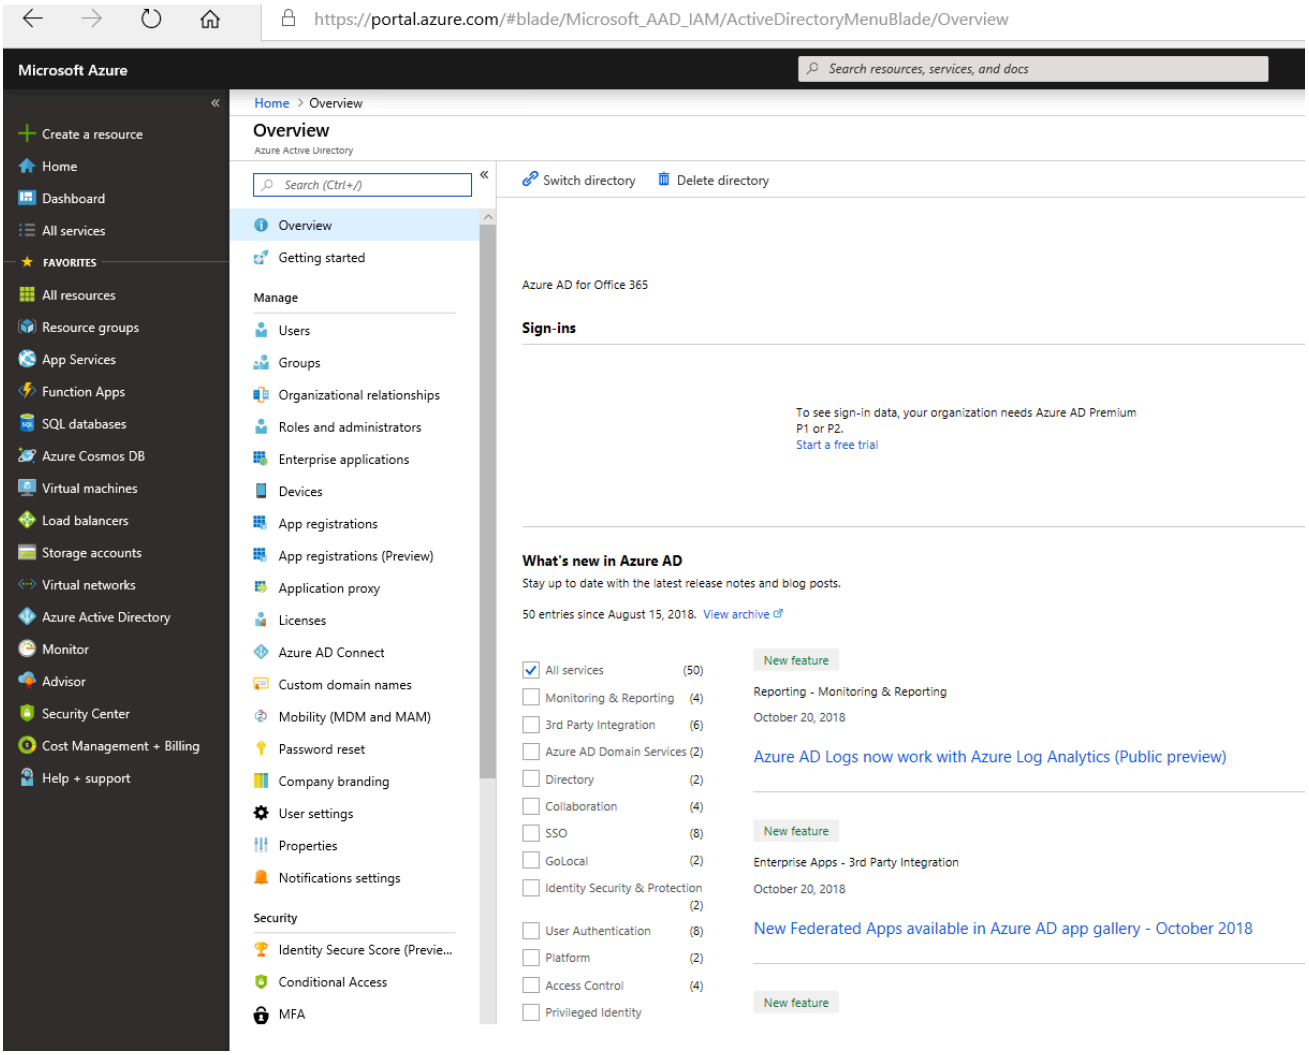
You can also verify the last time the script ran on the flyout page of the corresponding physical badging connector in the Microsoft Purview portal.

Last updated on 03/30/2026



Deploy a connector to archive Twitter data

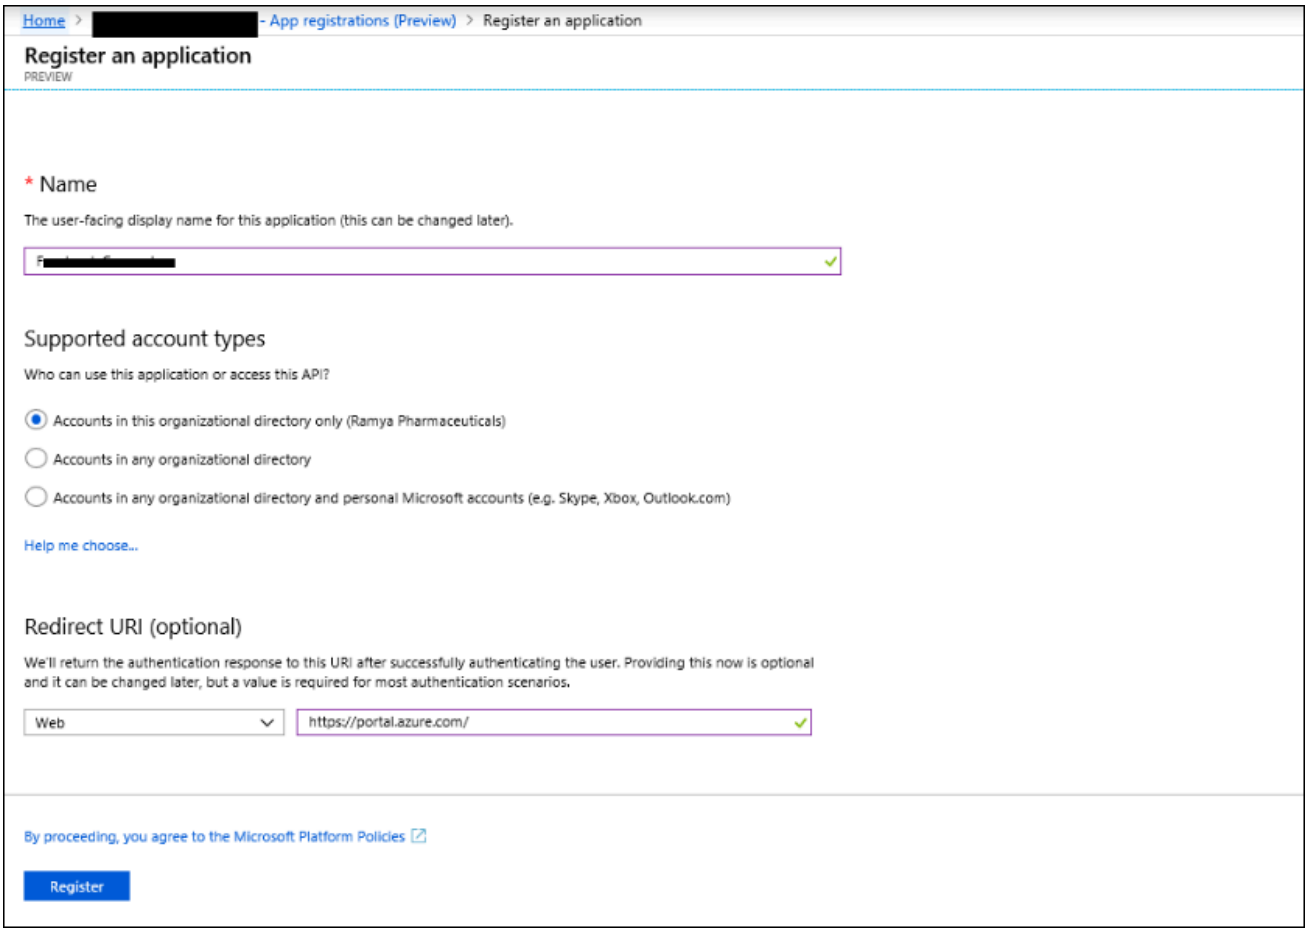
This article describes the process to deploy a connector that uses the Microsoft 365 Import service to import data from your organization's Twitter account to Microsoft 365. For a high-level overview of this process and a list of prerequisites required to deploy a Twitter connector, see Set up a connector to archive Twitter data.



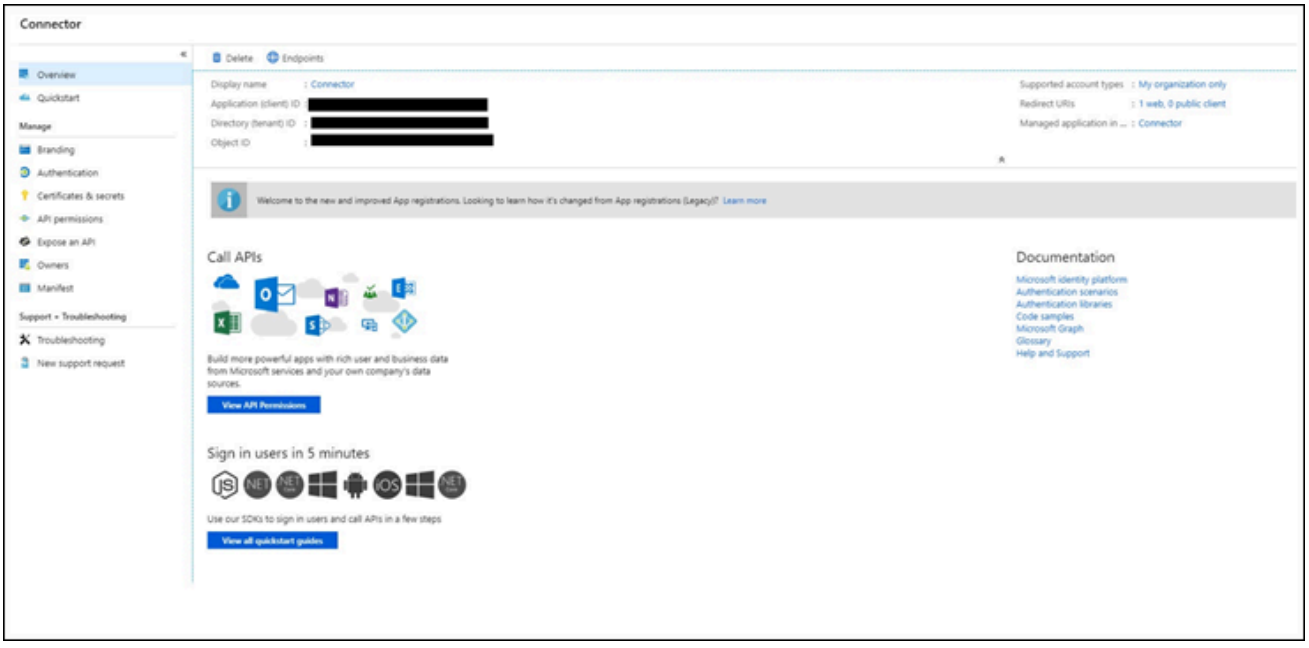
Step 1: Create an app in Microsoft Entra ID

1. Go to https://portal.azure.com and sign in with the credentials of a global admin account.

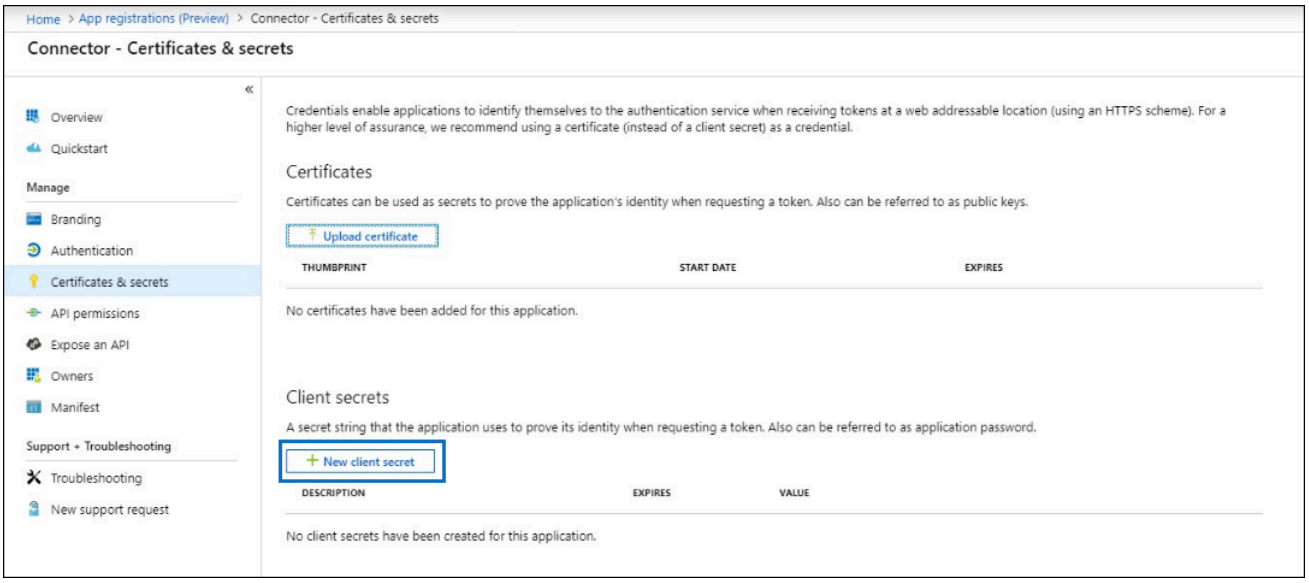
   > **Important**
   >
   > Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.



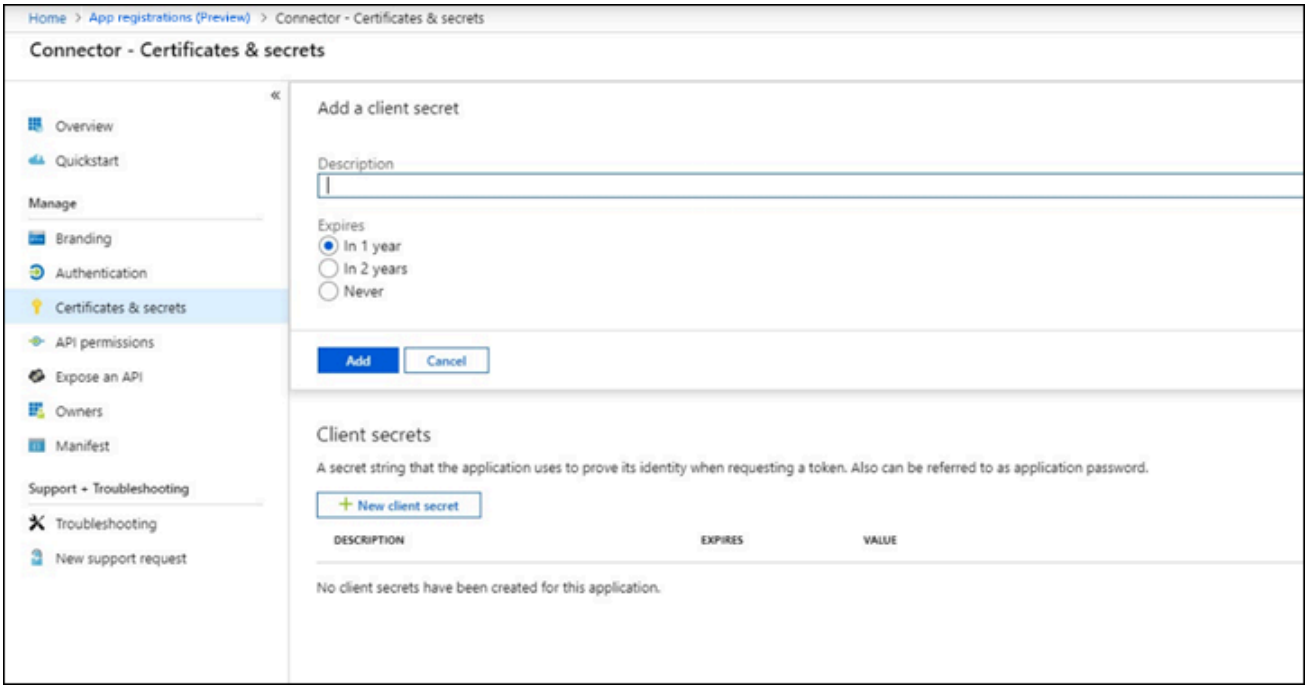
2. In the left navigation, select **Microsoft Entra ID**.



3. In the left navigation, select **App registrations (Preview)**, then select **New registration**.



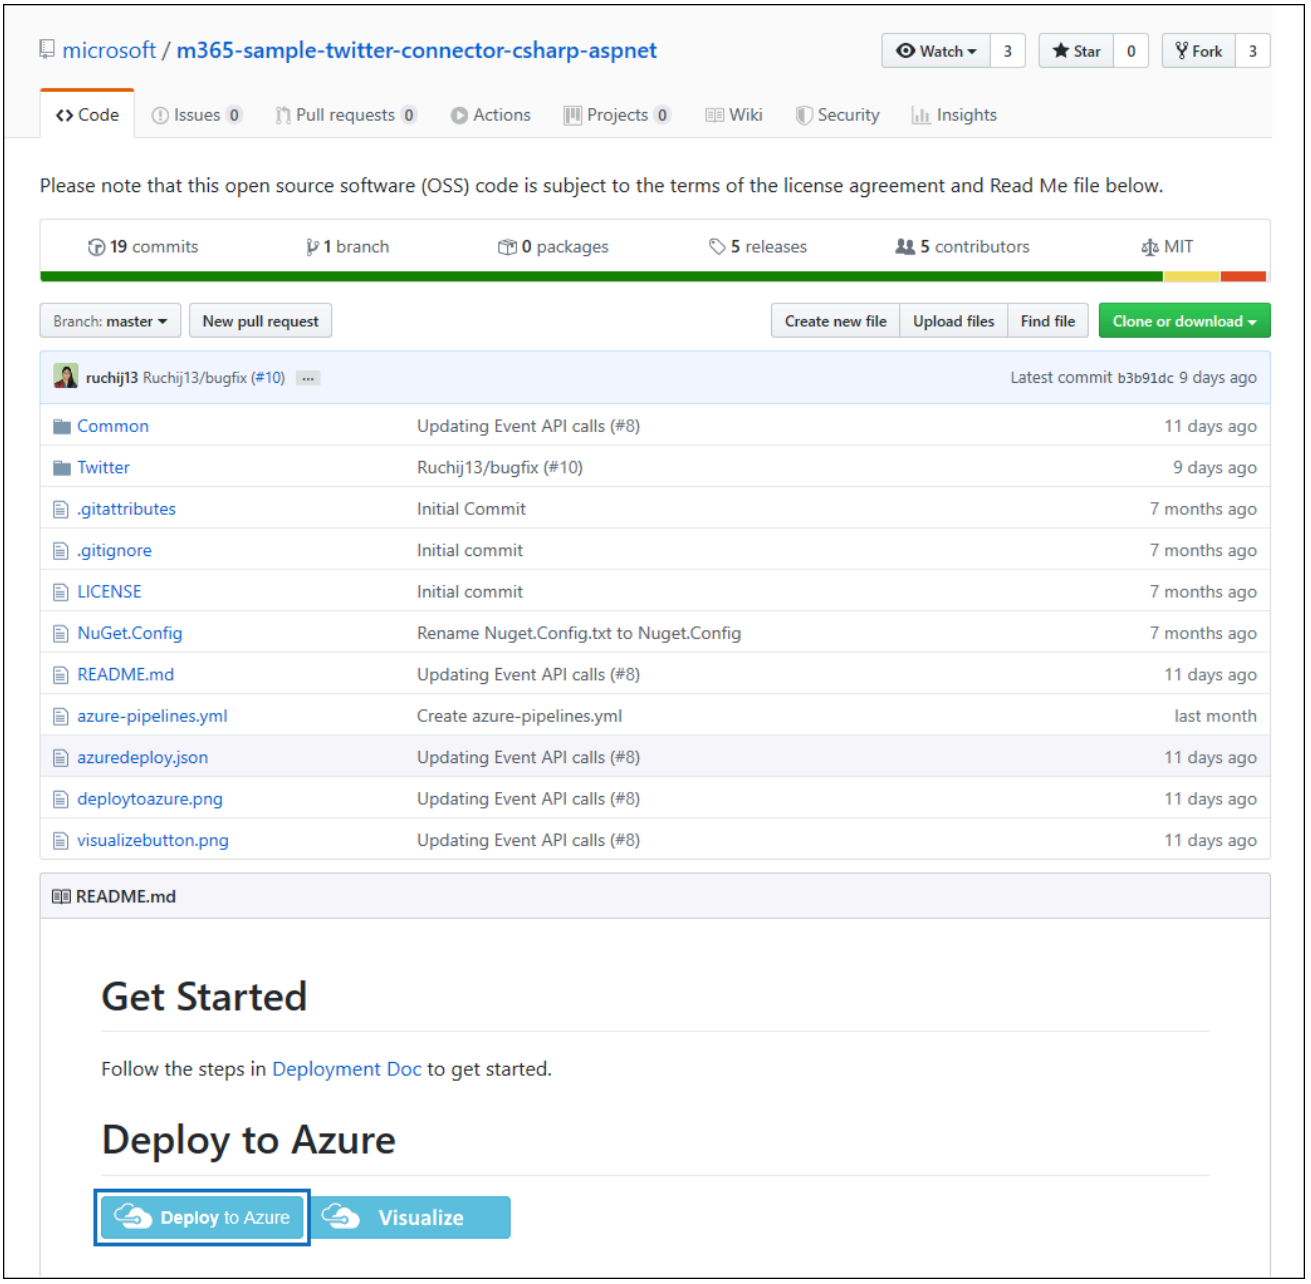
4. Register the application. Under **Redirect URI (optional)**, select **Web** in the application type dropdown list, then type `https://portal.azure.com` in the box for the URI.



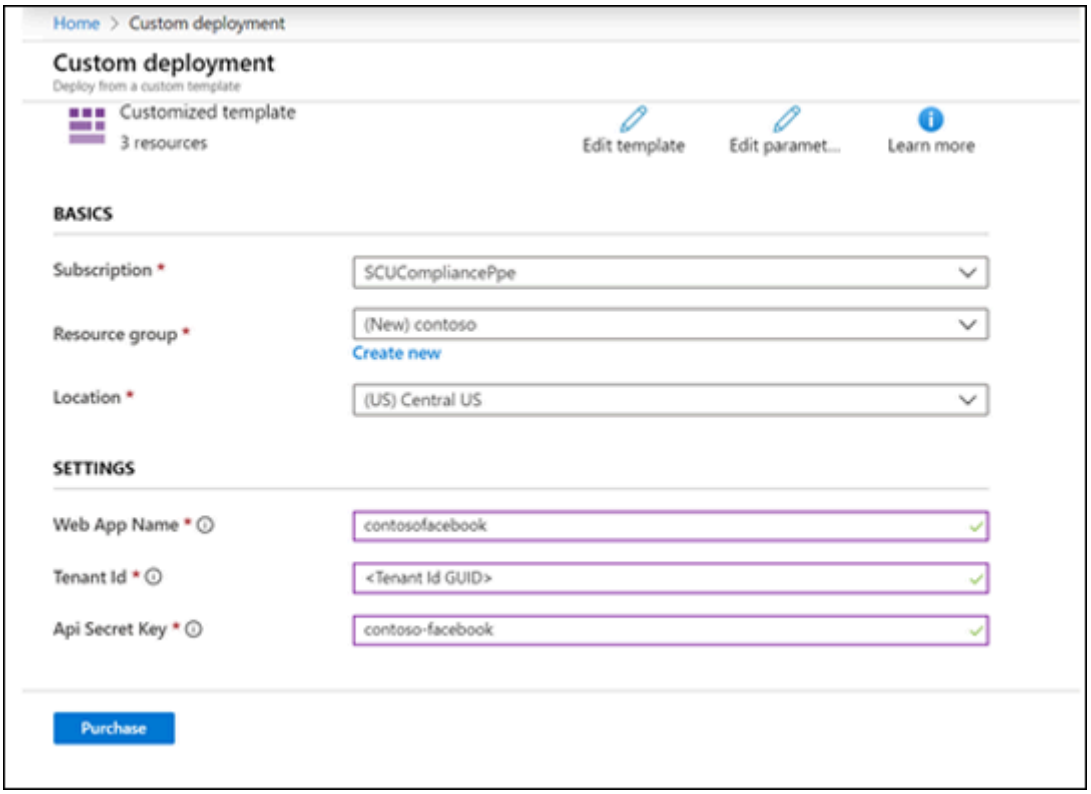
5. Copy the **Application (client) ID** and **Directory (tenant) ID** and save them to a text file or other safe location. You use these IDs in later steps.

6. Go to **Certificates & secrets for the new app** and under **Client secrets**, select **New client secret**.

7. Create a new secret. In the description box, type the secret and then select an expiration period.

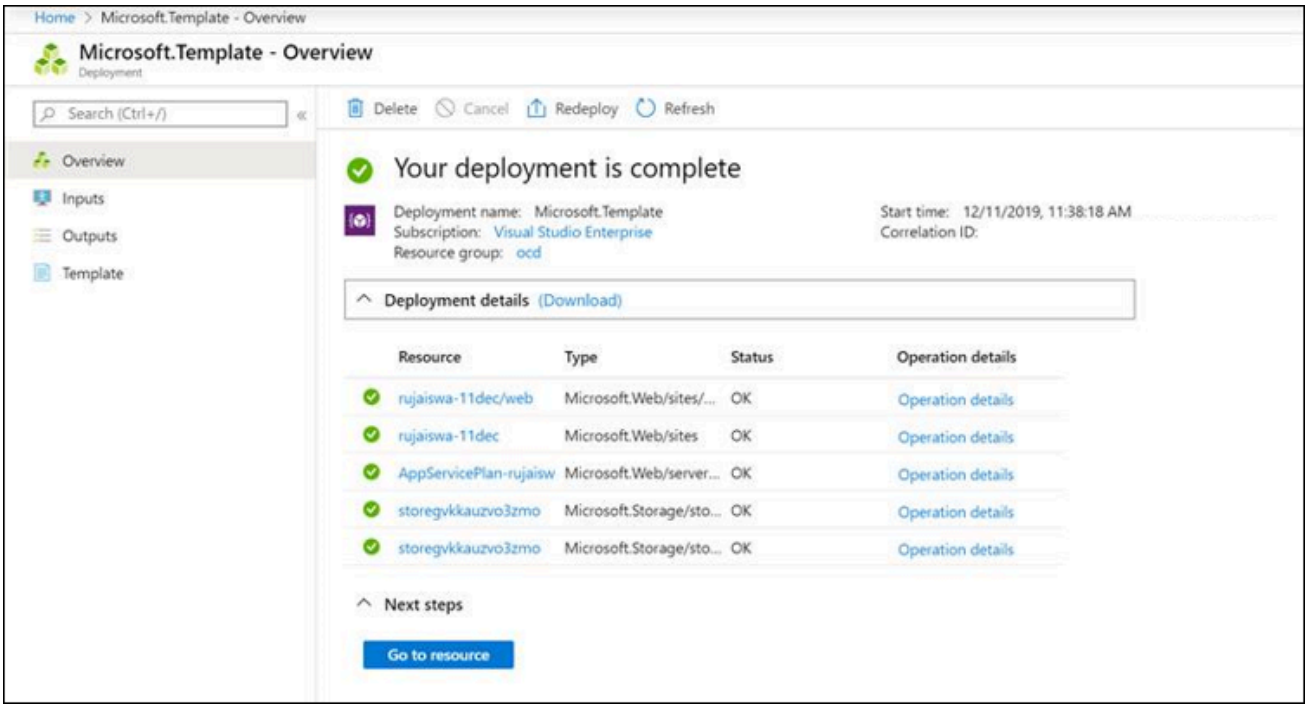


8. Copy the value of the secret and save it to a text file or other storage location. This is the Microsoft Entra application secret that you use in later steps.

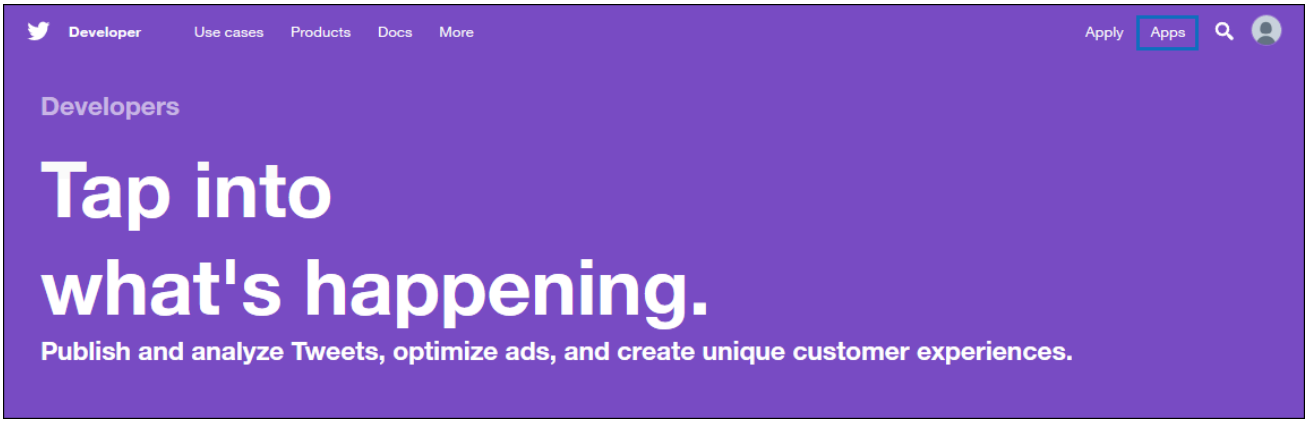


Step 2: Deploy the connector web service from GitHub to your Azure account

1. Go to this GitHub site and select **Deploy to Azure**.

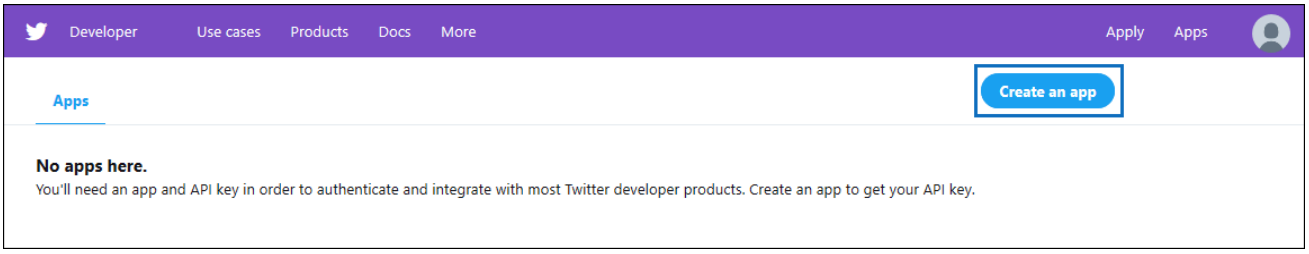


2. After you select **Deploy to Azure**, you're redirected to an Azure portal with a custom template page. Fill in the **Basics** and **Settings** details, then select **Purchase**.

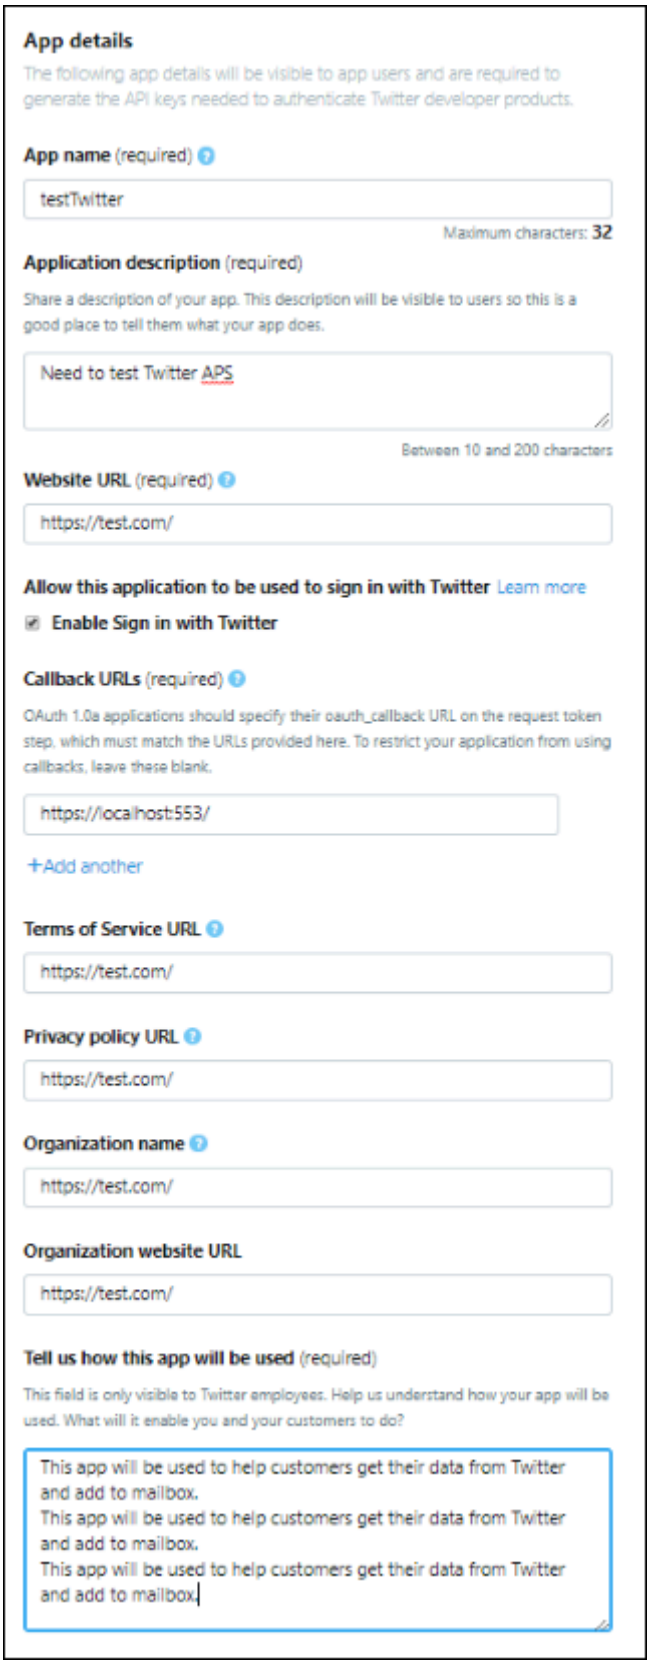


- **Subscription:** Select your Azure subscription that you want to deploy the Twitter connector web service to.
- **Resource group:** Select or create a new resource group. A resource group is a container that holds related resources for an Azure solution.
- **Location:** Select a location.
- **Web App Name:** Provide a unique name for the connector web app. The name must be between 3 and 18 characters in length. This name is used to create the Azure app service URL; for example, if you provide the Web app name of **twitterconnector** then the Azure app service URL is **twitterconnector.azurewebsites.net**.
- **tenantId:** The tenant ID of your Microsoft 365 organization that you copied after creating the Twitter connector app in Microsoft Entra ID in Step 1.
- **APISecretKey:** You can type any value as the secret. This value is used to access the connector web app in Step 5.

3. When the deployment succeeds, the page looks similar to the following screenshot:

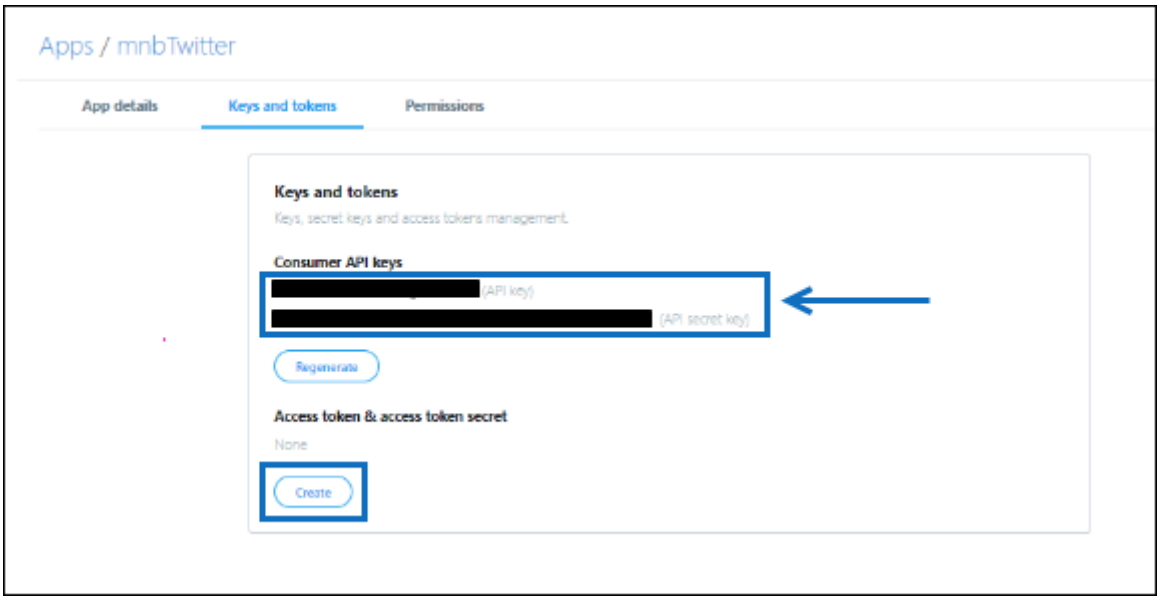


Step 3: Create the Twitter app



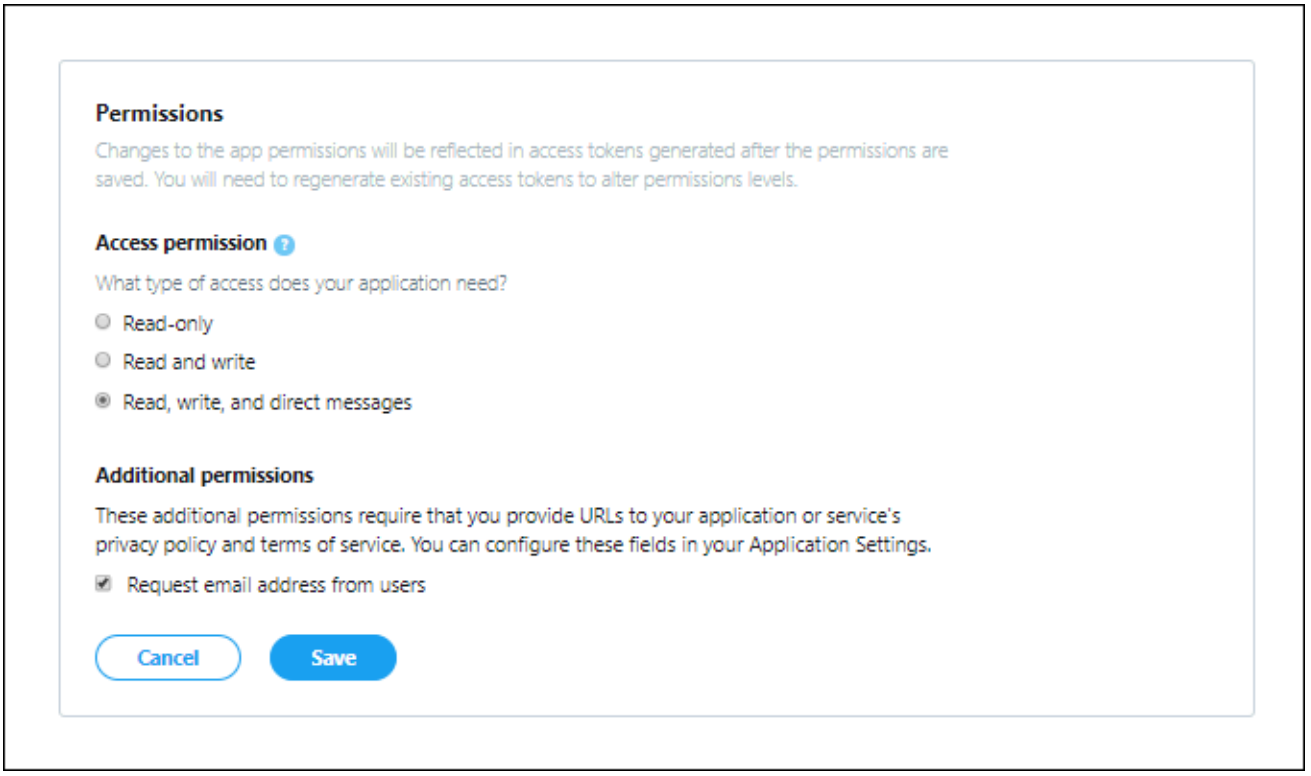
1. Go to https://developer.twitter.com , sign in with the credentials for the developer account for your organization, and select **Apps**.

2. Select **Create an app**.

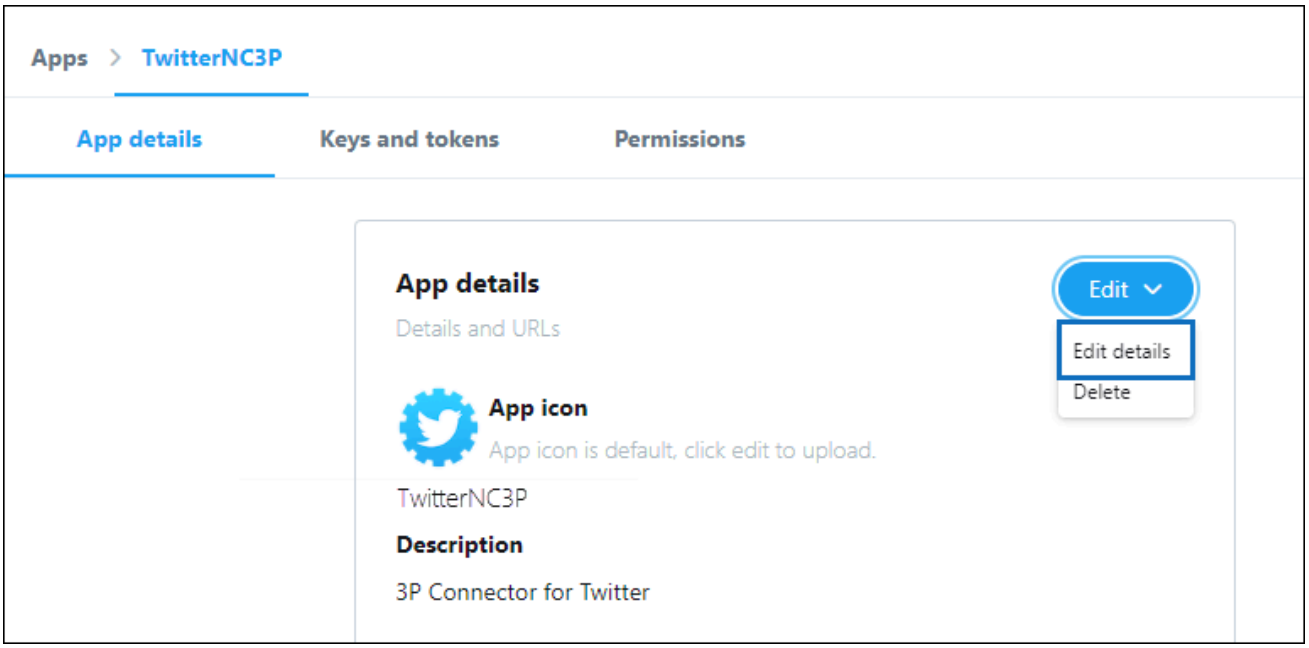


3. Under **App details**, enter information about the application.

4. On the Twitter developer dashboard, select the app that you just created, then select **Details**.

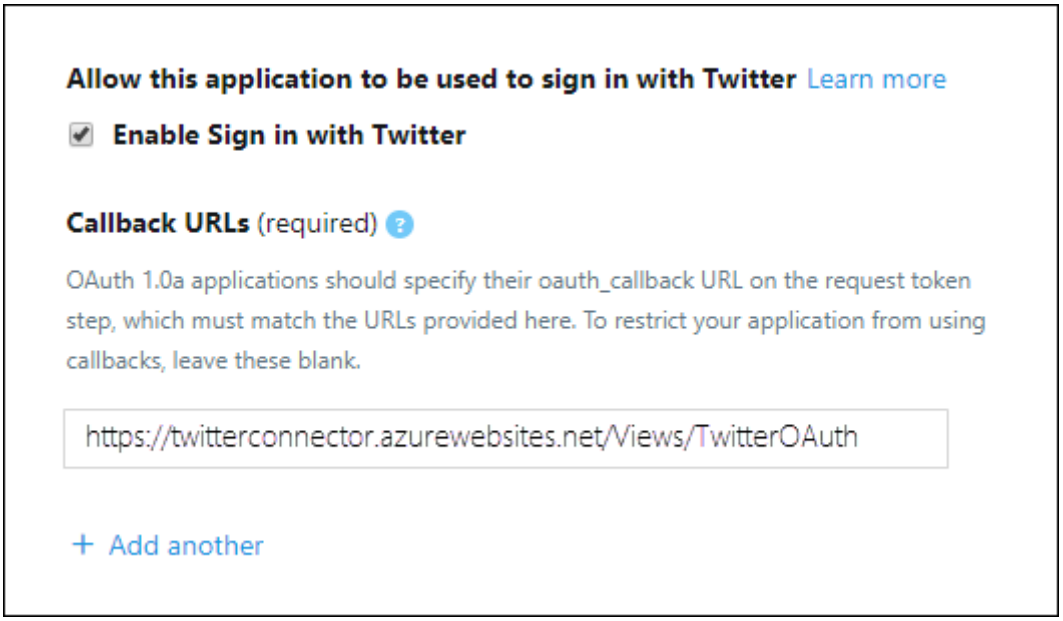


5. On the **Keys and tokens** tab, under **Consumer API keys**, copy both the API Key and the API secret key and save them to a text file or other storage location. Then select **Create** to generate an access token and an access token secret and copy these to a text file or other storage location.



Select **Create** to generate an access token and an access token secret, and copy these to a text file or other storage location.

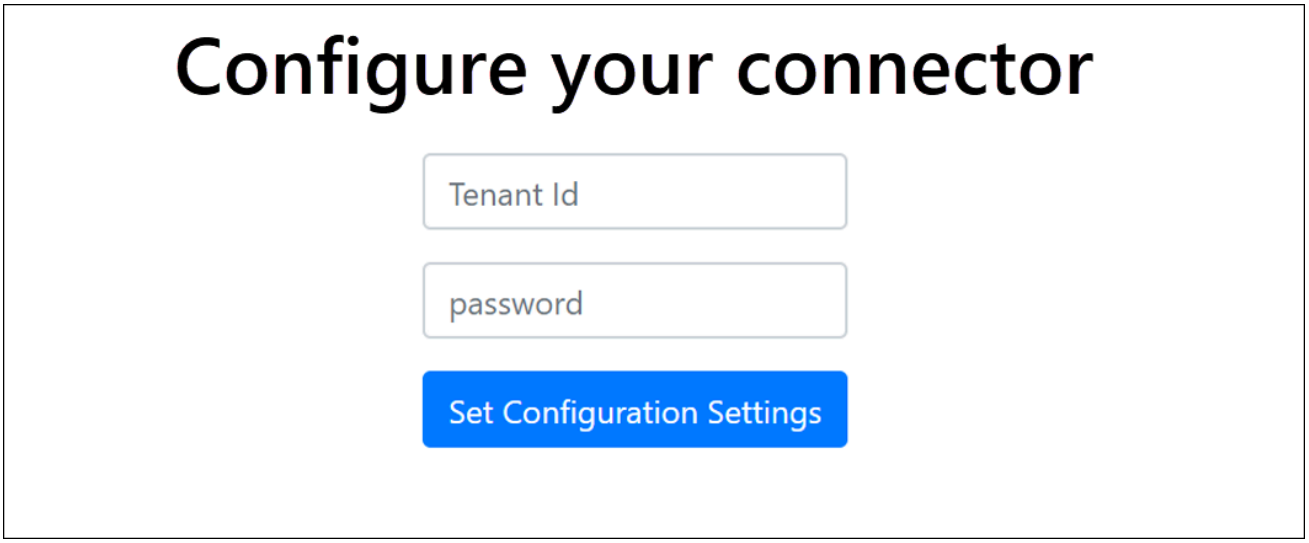
6. Select the **Permissions** tab and configure the permissions as shown in the following screenshot:



7. After you save the permission settings, select the **App details** tab, then select **Edit** > **Edit details**.

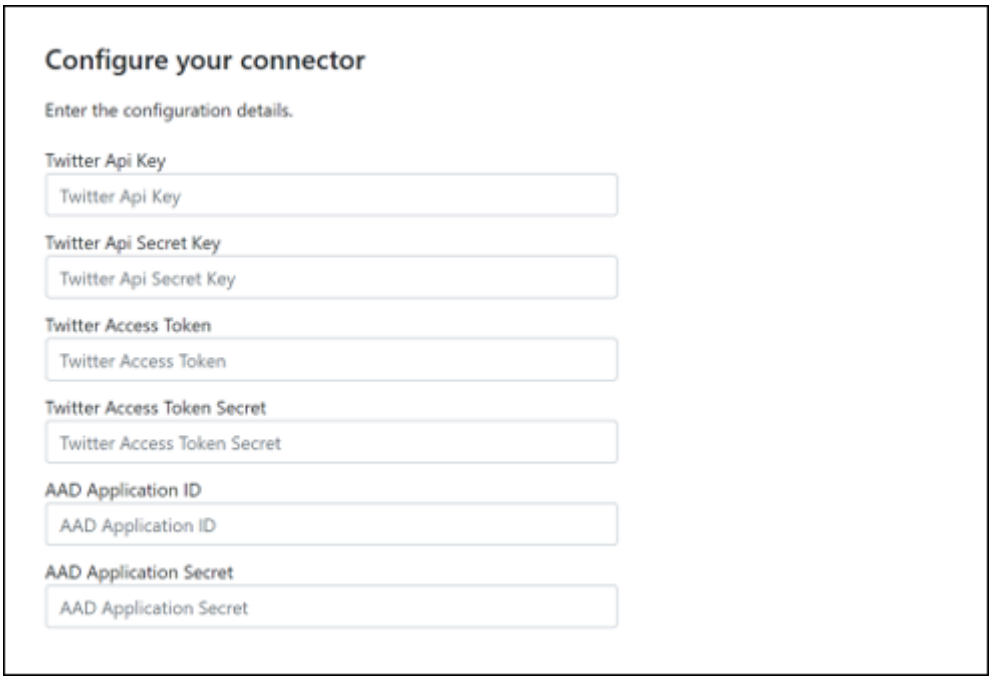
8. Complete the following tasks:

   - Select the checkbox to allow the connector app to sign in to Twitter.
   - Add the OAuth redirect Uri using the following format: **<connectorserviceuri>/Views/TwitterOAuth**, where the value of *connectorserviceuri* is the Azure app service URL for your organization.



The Twitter developer app is now ready to use.

Step 4: Configure the connector web app



1. Go to `https://<AzureAppResourceName>.azurewebsites.net` (where **AzureAppResourceName** is the name of your Azure app resource that you named in Step 2). The home page of the app looks like the following screenshot:

2. Select **Configure** to display a sign in page.

3. In the Tenant Id box, type or paste your Microsoft Entra tenant ID (the Directory (tenant) ID from the Microsoft Entra app registration). In the password box, type or paste the APISecretKey value from the Azure deployment template settings, then select **Set Configuration Settings** to display the configuration details page.

4. Enter the following configuration settings:

   - **Twitter Api Key:** The API key for the Twitter application that you created in Step 3.
   - **Twitter Api Secret Key:** The API secret key for the Twitter application that you created in Step 3.
   - **Twitter Access Token:** The access token that you created in Step 3.
   - **Twitter Access Token Secret:** The access token secret that you created in Step 3.
   - **Microsoft Entra Application ID:** The application ID for the Microsoft Entra app that you created in Step 1
   - **Microsoft Entra Application Secret:** The value of the Microsoft Entra application client secret that you created during the app registration in Microsoft Entra ID.

5. Select **Save** to save the connector settings.

Step 5: Set up a Twitter connector

1. Sign in to the Microsoft Purview portal.

2. Select **Settings** > **Data connectors**.

3. Select **My connectors**, then select **Add connector**.

4. From the list, select **Twitter**.

5. On the **Terms of service** page, select **Accept**.

6. On the **Add credentials for your connector app** page, enter the following information and then select **Validate connection**.

    - In the **Name** box, type a name for the connector, such as **Twitter help handle**.
    - In the **Connector URL** box, type or paste the Azure app service URL.
    - In the **Password** box, type or paste the APISecretKey value from the Azure deployment template settings.
    - In the **Azure App ID** box, type or paste the value of the Azure Application App Id (also called the *client ID*) that you obtained in Step 1.

7. After the connection is successfully validated, select **Next**.

8. On the **Authorize Microsoft 365 to import data** page, type or paste the APISecretKey again and then select **Login web app**.

9. Select **Login with Twitter**.

10. On the Twitter sign in page, sign in by using the credentials for your organization's Twitter account. After you sign in, the Twitter page displays the following message, "Twitter Connector Job Successfully set up."

11. Select **Continue** to complete setting up the Twitter connector.

12. On the **Set filters** page, you can apply a filter to initially import items that are a certain age. Select an age, and then select **Next**.

13. On the **Choose storage location** page, type the email address of Microsoft 365 mailbox that the Twitter items are imported to, and then select **Next**.

14. Select **Next** to review the connector settings and then select **Finish** to complete the connector setup.

Set up a Microsoft connector to archive Twitter data (preview)

Use a connector to import and archive data from Twitter to Microsoft 365. After you set up and configure the connector, it connects to your organization's Twitter account (on a scheduled basis), converts the content of an item to an email message format, and then imports those items to a mailbox in Microsoft 365. Before you begin, make sure you have a Twitter account for your organization, a valid Azure subscription, and the Data Connector Admin role in the Microsoft Purview portal.

After Twitter data is imported, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, In-Place Archiving, Auditing, Communication Compliance, and Microsoft 365 retention policies to the data stored in the mailbox. For example, you can search Twitter data using eDiscovery or associate the mailbox where the data is stored with a custodian in an eDiscovery case. Using a connector to import and archive Twitter data in Microsoft 365 can help your organization stay compliant with government and regulatory policies.

Before you begin

Complete the following prerequisites before you set up and configure a connector in the Microsoft Purview portal to import and archive data from your organization's Twitter account.

- You need a Twitter account for your organization. You need to sign in to this account when setting up the connector.
- Your organization must have a valid Azure subscription. If you don't have an existing Azure subscription, you can sign up for one of these options:
  - Sign up for a free one year Azure subscription
  - Sign up for a Pay-As-You-Go Azure subscription
- The Twitter connector can import a total of 200,000 items in a single day. If there are more than 200,000 Twitter items in a day, none of those items are imported to Microsoft 365.
- The user who sets up the Twitter connector in the Microsoft Purview portal (in Step 5) must be assigned the Data Connector Admin role. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role

by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

Step 1: Create an app in Microsoft Entra ID

First, register a new app in Microsoft Entra ID. This app corresponds to the web app resource that you implement in Step 2 for the Twitter connector.

For more information, see Create an app in Microsoft Entra ID.

When you complete this step, save the following information to a text file. You'll use these values in later steps in the deployment process.

- Microsoft Entra application ID
- Microsoft Entra application secret
- Tenant Id

Step 2: Deploy connector web service from GitHub repository to your Azure account

Next, deploy the source code for the Twitter connector app that uses the Twitter API to connect to your Twitter account and extract data so you can import it to Microsoft 365. The Twitter connector that you deploy for your organization uploads the items from your organization's Twitter account to the Azure Storage location that you create in this step. After you create a Twitter connector in the Microsoft Purview portal (in Step 5), the Microsoft 365 Import service copies the Twitter data from the Azure Storage location to a mailbox in Microsoft 365. You must have a valid Azure subscription to create an Azure Storage account.

To deploy the source code for the Twitter connector app:

1. Go to the Microsoft 365 sample Twitter connector repository on GitHub.
2. Select **Deploy to Azure**.

For more information, see Deploy the connector web service from GitHub to your Azure account.

When you complete this step, provide the following information:

- APISecretKey: Create this secret during the completion of this step. You use it in Step 5.

- tenantId: The tenant ID of your Microsoft 365 organization that you copied after creating the Twitter app in Microsoft Entra ID in Step 1.

After you complete this step, be sure to copy the app Service URL (for example, `https://twitterconnector.azurewebsites.net`). You need to use this URL to complete Step 3, Step 4, and Step 5.

Step 3: Create developer app on Twitter

Create and configure a developer app on Twitter. The custom connector you create in Step 7 uses the Twitter app to interact with the Twitter API and obtain data from your organization's Twitter account.

For step-by-step instructions, see Create the Twitter app.

When you complete this step, save the following information to a text file. You'll use these values to configure the Twitter connector app in Step 4.

- Twitter API Key
- Twitter API Secret Key
- Twitter Access Token
- Twitter Access Token Secret

Step 4: Configure the Twitter connector app

Add configuration settings to the Twitter connector app that you deployed in Step 2. Go to the home page of your connector app and configure it.

For step-by-step instructions, see Configure the connector web app.

When you complete this step, provide the following information. You copied this information to a text file after completing the previous steps:

- Twitter API Key (obtained in Step 3)
- Twitter API Secret Key (obtained in Step 3)
- Twitter Access Token (obtained in Step 3)
- Twitter Access Token Secret (obtained in Step 3)
- Microsoft Entra application ID (the Microsoft Entra application ID obtained in Step 1)
- Microsoft Entra application secret (the Microsoft Entra application secret obtained in Step 1)

Step 5: Set up a Twitter connector in the Microsoft Purview portal

In this step, you set up the Twitter connector in the Microsoft Purview portal. The connector imports data from your organization's Twitter account to a specified mailbox in Microsoft 365. When you finish this step, the Microsoft 365 Import service starts importing data from your organization's Twitter account to Microsoft 365.

For step-by-step instructions, see Set up a Twitter connector.

As you complete this step, provide the following information and save it in a text file:

- Azure app service URL (obtained in Step 2; for example, `https://twitterconnector.azurewebsites.net`)
- APISecretKey (created in Step 2)

Set up a connector to archive Android mobile data

Use a TeleMessage connector to import and archive SMS, MMS, voice calls, and call logs from Android mobile phones. After you set up and configure a connector, it connects to your organization's TeleMessage account once every day and imports the mobile communication of employees using the TeleMessage Android Archiver to mailboxes in Microsoft 365.

After storing data from Android mobile phones in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, and Microsoft 365 retention policies to Android Archiver data. For example, you can search Android Archiver mobile communication by using eDiscovery or associate the mailbox that contains the Android Archiver connector data with a custodian in an eDiscovery (Premium) case. Using an Android Archiver connector to import and archive data in Microsoft 365 can help your organization stay compliant with government and regulatory policies.

Overview of archiving Android mobile data

The following overview explains the process of using a connector to archive Android mobile data in Microsoft 365.

1. Your organization works with TeleMessage to set up an Android Archiver connector. For more information, see Android Archiver.

2. In real time, SMS, MMS, voice calls, and call logs from your organization's Android mobile phones are copied to the TeleMessage site.

3. The Android Archiver connector that you create in the Microsoft Purview portal connects to the TeleMessage site every day and transfers the Android data from the previous 24 hours to a secure Azure Storage location in the Microsoft cloud. The connector also converts the Android data to an email message format.

4. The connector imports the mobile communication items to the mailbox of a specific user. A new folder named Android Archiver is created in the specific user's mailbox, and the items are imported to the folder. The connector does mapping by using the value of the *User's Email address* property. Every email message contains this property, which is populated with the email address of every participant of the email message. In addition to automatic user mapping by using the value of the *User's Email address* property, you can also define a custom mapping by uploading a CSV mapping file. This mapping file should contain the mobile number and corresponding Microsoft 365 mailbox address for each user. If you enable automatic user mapping and provide a custom mapping, for every email item the connector first looks at custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's mobile number, the connector uses the user's email address property of the email item. If the connector doesn't find a valid Microsoft 365 user in either the custom mapping file or the *User's email address* property of the email item, the item won't be imported.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

Some of the implementation steps required to archive Android communication data are external to Microsoft 365. You must complete these steps before you can create the connector in the

Microsoft Purview portal.

- Order the Android Archiver service from TeleMessage and get a valid administration account for your organization. You need to sign in to this account when you create the connector.
- Register all users that require the Android Archiver service in the TeleMessage account. When registering users, use the same email address that's used for their Microsoft 365 account.
- Install and activate the TeleMessage Android Archiver app on the mobile phones of your employees.
- Assign the Data Connector Admin role to the user who creates a Android Archiver connector. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.
- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Create an Android Archiver connector

After completing the prerequisite tasks, create an Android Archiver connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the TeleMessage site and transfer Android communication to the corresponding user mailboxes in Microsoft 365.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.

4. From the list, select **Android Archiver**.
5. On the **Terms of service** page, select **Accept**.
6. On the **Login to TeleMessage** page, enter the required information in the following boxes and then select **Next**.
    - **Username:** Your TeleMessage username.
    - **Password:** Your TeleMessage password.
7. After you create the connector, close the pop-up window and select **Next**.
8. On the **User mapping** page, enable automatic user mapping and select **Next**. If you need custom mapping, upload a CSV file, and select **Next**.
9. Review your settings, then select **Finish** to create the connector.

Android Archiver connector limits

The connector supports importing attachments or items up to 10 MB.

ⓘ**Note:** The author created this article with assistance from AI. Learn more

Set up a connector to archive AT&T SMS/MMS data

Use a TeleMessage connector to import and archive SMS and MMS data from the AT&T Mobile Network. After you set up and configure a connector, it connects to your organization's AT&T Network once every day and imports SMS and MMS data to mailboxes in Microsoft Purview.

After storing SMS and MMS messages in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, and Microsoft 365 retention policies to AT&T Network data. For example, you can search AT&T Network data by using eDiscovery or associate the mailbox that contains the AT&T Network connector data with a custodian in an eDiscovery (Premium) case. Using an AT&T Network connector to import and archive data in Microsoft 365 can help your organization stay compliant with government and regulatory policies.

Overview of archiving AT&T Network data

The following overview explains the process of using a connector to archive AT&T Network data in Microsoft 365.

1. Your organization works with TeleMessage to set up an AT&T Network connector. For information, see AT&T Network Archiver.

2. In real time, SMS and MMS messages from your organization's AT&T Network are copied to the TeleMessage site.

3. The AT&T Network connector that you create in the Microsoft Purview portal connects to the TeleMessage site every day and transfers the SMS and MMS messages from the previous 24 hours to a secure Azure Storage location in the Microsoft cloud. The connector also converts the content of SMS and MMS messages to an email message format.

4. The connector imports the mobile communication items to the mailbox of specific users. A new folder named **AT&T SMS/MMS Network Archiver** is created in the user's mailbox and the items are imported to it. The connector does this mapping by using the value of the *User's Email address* property. Every SMS and MMS message contains this property, which is populated with the email address of every participant of the message.

   In addition to automatic user mapping by using the value of the *User's Email address* property, you can also define a custom mapping by uploading a CSV mapping file. This mapping file contains the mobile phone number and corresponding Microsoft 365 email address for users in your organization. If you enable both automatic user mapping and custom mapping, for every email item the connector first looks at the custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a mobile phone number, the connector uses the values in the email address property of the item it's trying to import. If the connector doesn't find a valid Microsoft 365 user in either the custom mapping file or in the email address property of the email item, the item won't be imported.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

Some of the implementation steps required to archive AT&T Network data are external to Microsoft 365. You must complete these steps before you can create the connector in the Microsoft Purview portal.

- Order the mobile archiver service from TeleMessage and get a valid administration account for your organization. You need to sign in to this account when you create the connector in the Microsoft Purview portal.
- Obtain your AT&T account and billing contact details so you can fill out the TeleMessage onboarding forms and order the message archiving service from AT&T.
- Register all users that require AT&T SMS/MMS Network archiving in the TeleMessage account. When registering users, use the same email address that's used for their Microsoft 365 account.
- Ensure your employees have corporate-owned and corporate-liable mobile phones on the AT&T mobile network. Archiving messages in Microsoft 365 isn't available for employee-owned or "Bring Your Own Devices (BYOD) devices.
- Assign the Data Connector Admin role to the user who creates a AT&T Network connector. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see:- Permissions in the Microsoft Purview portal - Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview compliance
- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Create an AT&T Network connector

After you complete the prerequisites described in the previous section, you can create an AT&T Network connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the TeleMessage site and transfer SMS and MMS messages to the corresponding user mailboxes in Microsoft 365.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.

3. Select **My connectors**, then select **Add connector**.
4. From the list, choose **AT&T Network**.
5. On the **Terms of service** page, select **Accept**.
6. On the **Login to TeleMessage** page, under Step 3, enter the required information in the following boxes and then select **Next**.
    - **Username:** Your TeleMessage username.
    - **Password:** Your TeleMessage password.
7. After the connector is created, you can close the pop-up window and go to the next page.
8. On the **User mapping** page, enable automatic user mapping. To enable custom mapping, upload a CSV file that contains the user mapping information, and then select **Next**.
9. Review your settings, and then select **Finish** to create the connector.

Limits

Importing attachments or items supports files up to 10 MB.

Set up a connector to archive Bell Network data

Use a TeleMessage connector to import and archive Short Messaging Service (SMS) and Multimedia Messaging Service (MMS) messages from the Bell Network. After you set up and configure a connector, it connects to your organization's Bell Network once every day, and imports SMS and MMS messages to mailboxes in Microsoft 365.

After storing the SMS and MMS messages in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, and Microsoft 365 retention policies to Bell Network data. For example, you can search Bell Network SMS/MMS using eDiscovery or associate the mailbox that contains the Bell Network connector data with a custodian in an eDiscovery (Premium) case. Using a Bell Network connector to import and archive data in Microsoft 365 can help your organization stay compliant with government and regulatory policies.

Overview of archiving Bell Network data

The following overview explains the process of using a connector to archive Bell Network data in Microsoft 365.

1. Your organization works with TeleMessage and Bell to set up a Bell Network connector. For more information, see Bell Network Archiver.

2. In real time, SMS and MMS messages from your organization's Bell Network are copied to the TeleMessage site.

3. The Bell Network connector that you create in the Microsoft Purview portal connects to the TeleMessage site every day and transfers the SMS and MMS messages from the previous 24 hours to a secure Azure Storage location in the Microsoft cloud. The connector also converts the content of SMS and MMS messages to an email message format.

4. The connector imports the mobile communication items to the mailbox of specific users. A new folder named **Bell SMS/MMS Network Archiver** is created in a specific user's mailbox and the items are imported to it. The connector does this mapping by using the value of the *User's Email address* property. Every SMS and MMS message contains this property, which is populated with the email address of every participant of the message.

   In addition to automatic user mapping by using the value of the *User's Email address* property, you can also define a custom mapping by uploading a CSV mapping file. This mapping file contains the mobile phone number and corresponding Microsoft 365 email address for users in your organization. If you enable both automatic user mapping and custom mapping, for every Bell Network item the connector first looks at custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's mobile phone number, the connector uses the values in the email address property of the item it's trying to import. If the connector doesn't find a valid Microsoft 365 user in either the custom mapping file or in the email address property of the Bell Network item, the item won't be imported.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

Some of the implementation steps required to archive Bell Network data are external to Microsoft 365. You must complete these steps before you can create a connector in the Microsoft Purview portal.

- Order the Bell Network Archiver service from TeleMessage and get a valid administration account for your organization. You need to sign in to this account when you create the connector in the Microsoft Purview portal.
- Obtain your Bell Network account and billing contact details so you can fill out the TeleMessage onboarding forms and order the message archiving service from Bell.
- Register all users that require Bell SMS/MMS Network archiving in the TeleMessage account. When registering users, use the same email address that's used for their Microsoft 365 account.
- Ensure your employees have corporate-owned and corporate-liable mobile phones on the Bell mobile network. Archiving messages in Microsoft 365 isn't available for employee-owned or "Bring Your Own Devices (BYOD) devices.
- Assign the Data Connector Admin role to the user who creates a Bell Network connector. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see:- Permissions in the Microsoft Purview portal - Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview compliance
- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Create a Bell Network connector

The last step is to create a Bell Network connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the TeleMessage site and transfer SMS and MMS messages to the corresponding user mailboxes in Microsoft 365.

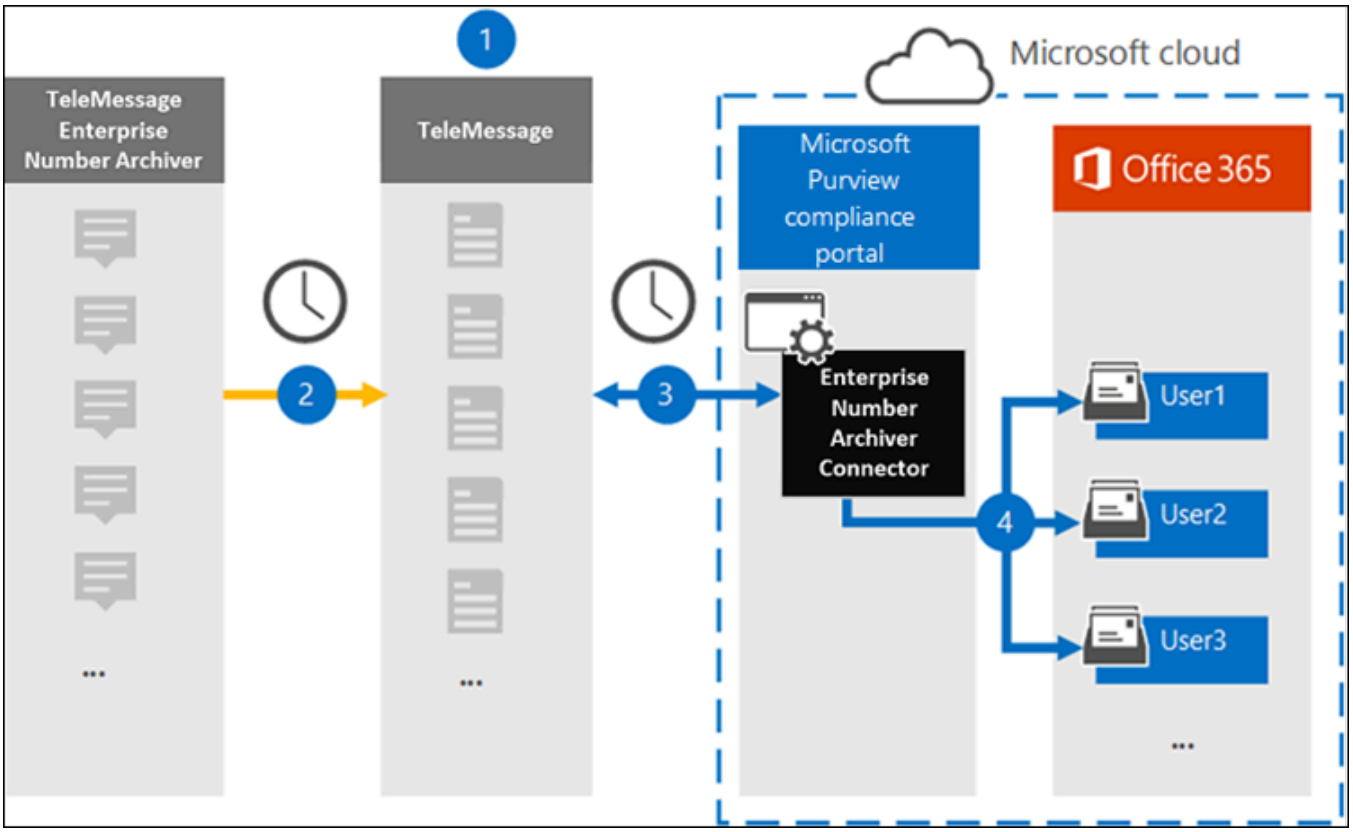
1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.

4. From the list, choose **Bell SMS/MMS Network Archiver**.
5. On the **Terms of service** page, select **Accept**.
6. On the **Login to TeleMessage** page, under Step 3, enter the required information in the following boxes and then select **Next**.
    - **Username:** Your TeleMessage username.
    - **Password:** Your TeleMessage password.
7. After the connector is created, you can close the pop-up window and go to the next page.
8. On the **User mapping** page, enable automatic user mapping. To enable custom mapping, upload a CSV file that contains the user mapping information, and then select **Next**.
9. Review your settings, and then select **Finish** to create the connector.

Limits

Importing attachments or items supports files up to 10 MB.

Last updated on 03/13/2026



Set up a connector to archive Enterprise Number data

Use a TeleMessage connector to import and archive Short Messaging Service (SMS) and Multimedia Messaging Service (MMS) messages, chat messages, voice call recordings, and voice call logs from the Enterprise Number Archiver. After you set up and configure a connector, it connects to your organization's TeleMessage account once every day and imports the mobile communication data of employees using the TeleMessage Enterprise Number Archiver to mailboxes in Microsoft 365.

After storing the TeleMessage Enterprise Number Archiver connector data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, In-Place Archiving, Auditing, Communication Compliance, and Microsoft 365 retention policies to Enterprise Number Archiver data. For example, you can search the TeleMessage Enterprise Number Archiver SMS, MMS, and Voice Call using eDiscovery or associate the mailbox that contains the Enterprise Number Archiver connector data with a custodian in an eDiscovery (Premium) case. Using an Enterprise Number Archiver connector to import and archive data in Microsoft 365 can help your organization stay compliant with government and regulatory policies.

Overview of archiving Enterprise Number data

The following overview explains the process of using a connector to archive Enterprise Network data in Microsoft 365.

1. Your organization works with TeleMessage to set up an Enterprise Number Archiver connector. For more details refer to here.
2. The Enterprise Number Archiver connector that you create in the Microsoft Purview portal connects to the TeleMessage site every day and transfers the email messages from the previous 24 hours to a secure Azure Storage area in the Microsoft Cloud.
3. The connector imports the mobile communication items to the mailbox of a specific user. A new folder named Enterprise Number Archiver is created in the specific user's mailbox and the items are imported to it. The connector does mapping by using the value of the *User's Email address* property. Every email message contains this property, which is populated with the email address of every participant of the email message. In addition to automatic user mapping using the value of the *User's Email address* property, you can also define a custom mapping by uploading a CSV mapping file. This mapping file should contain User's mobile Number and the corresponding Microsoft 365 mailbox address for each user. If you enable automatic user mapping and provide a custom mapping, for every email item the connector will first look at custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's mobile number, the connector will use the User 's email address property of the email item. If the connector doesn't find a valid Microsoft 365 user in either the custom mapping file or the *user's email address* property of the email item, the item won't be imported.

Before you begin

Important

All partner third-party data connector configurations require a provisioned **service principal** for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.

To provision a service principal using PowerShell, see **Provision a service principal for partner third-party data connectors**.

Some of the implementation steps required to archive Enterprise Number Archiver data are external to Microsoft 365. You must complete these steps before you can create the connector in the Microsoft Purview portal.

- Order the Enterprise Number Archiver service from TeleMessage and get a valid administration account for your organization. You need to sign in to this account when you create the connector in the Microsoft Purview portal.
- Register all users that require Enterprise Number SMS/MMS Network archiving in the TeleMessage account. When registering users, use the same email address that's used for their Microsoft 365 account.
- Install and activate the TeleMessage Enterprise Number Archiver app on the mobile phones of your employees.
- Assign the Data Connector Admin role to the user who creates a Enterprise Number Archiver connector. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see:- Permissions in the Microsoft Purview portal - Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview compliance
- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Create an Enterprise Number Archiver connector

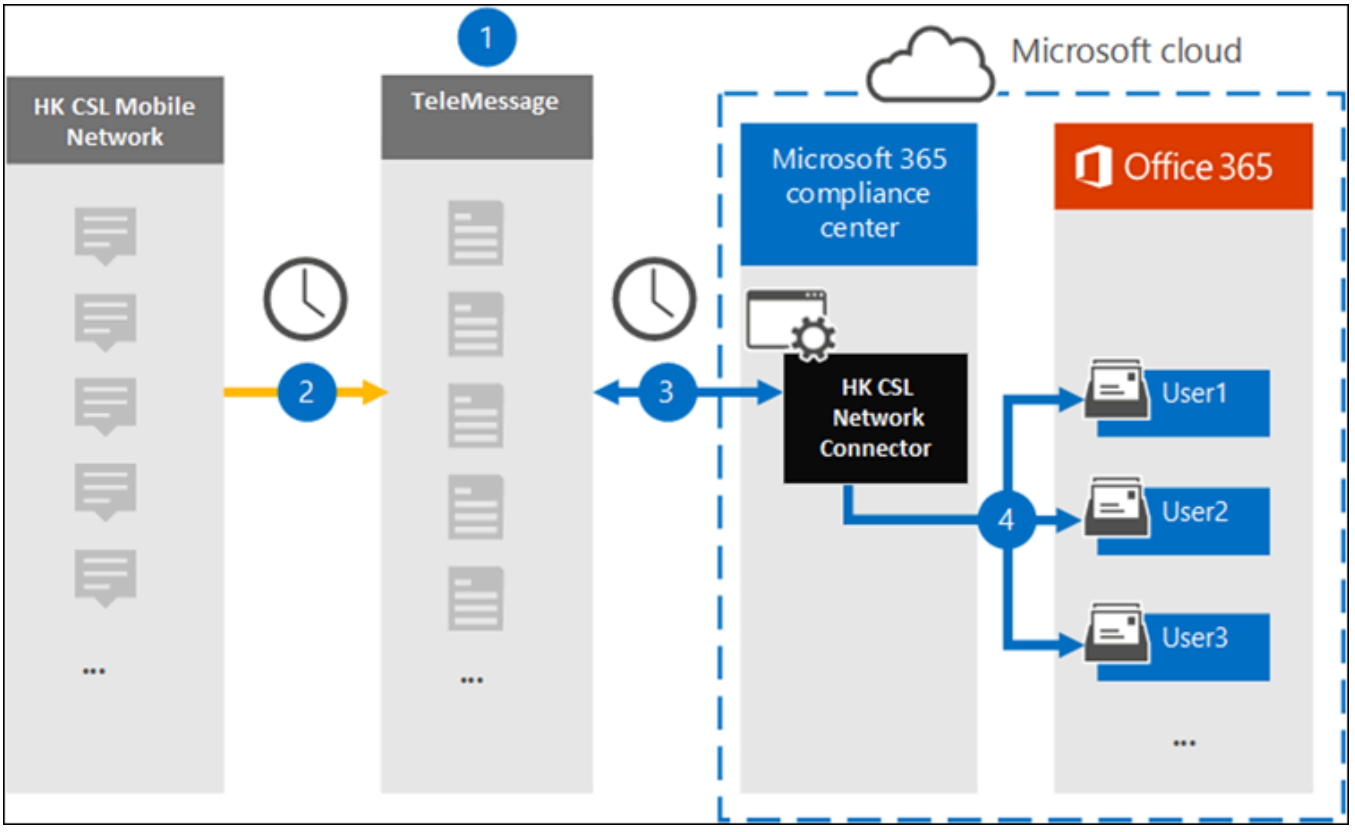
After you complete the prerequisites described in the previous section, create an Enterprise Number Archiver connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the TeleMessage site and transfer SMS, MMS, and voice call messages to the corresponding user mailboxes in Microsoft 365.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, choose **Enterprise Number Archiver**.
5. On the **Terms of service** page, select **Accept**.
6. On the **Login to TeleMessage** page, under Step 3, enter the required information in the following boxes and then select **Next**.
    - **Username:** Your TeleMessage username.
    - **Password:** Your TeleMessage password.
7. After the connector is created, you can close the pop-up window and go to the next page.
8. On the **User mapping** page, enable automatic user mapping. To enable custom mapping, upload a CSV file that contains the user mapping information, and then select **Next**.
9. Review your settings, and then select **Finish** to create the connector.

Limits

Importing attachments or items supports files up to 10 MB.

Last updated on 03/13/2026



Set up a connector to archive Hong Kong CSL SMS/MMS data

Use a TeleMessage connector in the Microsoft Purview portal to import and archive SMS and MMS data from the Hong Kong (HK) CSL Mobile Network. After you set up and configure a connector, it connects to your organization's HK CSL Network once every day, and imports SMS and MMS data to mailboxes in Microsoft Purview.

After storing SMS and MMS messages in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold and Microsoft 365 retention policies to HK CSL Network data. For example, you can search HK CSL Network data or associate the mailbox that contains the HK CSL Network connector data with a custodian in an eDiscovery case. Using a HK CSL Network connector to import and archive data in Microsoft 365 can help your organization stay compliant with government and regulatory policies.

Overview of archiving HK CSL Network data

The following overview explains the process of using a connector to archive HK CSL Network data in Microsoft 365.

1. Your organization works with TeleMessage to set up a HK CSL Network connector. For information, see HK CSL Network Archiver.

2. In real time, SMS and MMS messages from your organization's HK CSL Network are copied to the TeleMessage site.
3. The HK CSL Network connector that you create in the Microsoft Purview portal connects to the TeleMessage site every day and transfers the SMS and MMS messages from the previous 24 hours to a secure Azure Storage location in the Microsoft cloud. The connector also converts the content of SMS and MMS messages to an email message format.
4. The connector imports the mobile communication items to the mailbox of specific users. A new folder named **HK CSL SMS/MMS Network Archiver** is created in the user's mailbox and the items are imported to it. The connector does this mapping by using the value of the *User's Email address* property. Every SMS and MMS message contains this property, which is populated with the email address of every participant of the message.

In addition to automatic user mapping by using the value of the *User's Email address* property, you can also define a custom mapping by uploading a CSV mapping file. This mapping file contains the mobile phone number and corresponding Microsoft 365 email address for users in your organization. If you enable both automatic user mapping and custom mapping, for every email item the connector first looks at the custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a mobile phone number, the connector uses the values in the email address property of the item it's trying to import. If the connector doesn't find a valid Microsoft 365 user in either the custom mapping file or in the email address property of the email item, the item won't be imported.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

Some of the implementation steps required to archive HK CSL Network data are external to Microsoft 365. You must complete these steps before you can create the connector in the Microsoft Purview portal.

- Order the mobile archiver service from TeleMessage and get a valid administration account for your organization. You need to sign in to this account when you create the connector in the Pruview portal.

- Obtain your HK CSL account and billing contact details so you can fill out the TeleMessage onboarding forms and order the message archiving service from HK CSL.
- Register all users that require HK CSL SMS/MMS Network archiving in the TeleMessage account. When registering users, be sure to use the same email address that's used for their Microsoft 365 account.
- Ensure users have corporate-owned and corporate-liable mobile phones on the HK CSL mobile network. Archiving messages in Microsoft 365 isn't available for employee-owned or "Bring Your Own Devices (BYOD) devices.
- Assign the Data Connector Admin role to the user who creates a HK CSL Network connector. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see:- Permissions in the Microsoft Purview portal - Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview compliance

This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Create an HK CSL Network connector

After you complete the prerequisites described in the previous section, you can create an HK CSL Network connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the TeleMessage site and transfer SMS and MMS messages to the corresponding user mailboxes in Microsoft 365.

1. Go to the Microsoft Purview portal and select **Data connectors** > **HK CSL Network**.

2. On the **HK CSL Network product** description page, select **Add connector**.

3. On the **Terms of service** page, select **Accept**.

4. On the **Login to TeleMessage** page, under Step 3, enter the required information in the following boxes and select **Next**.

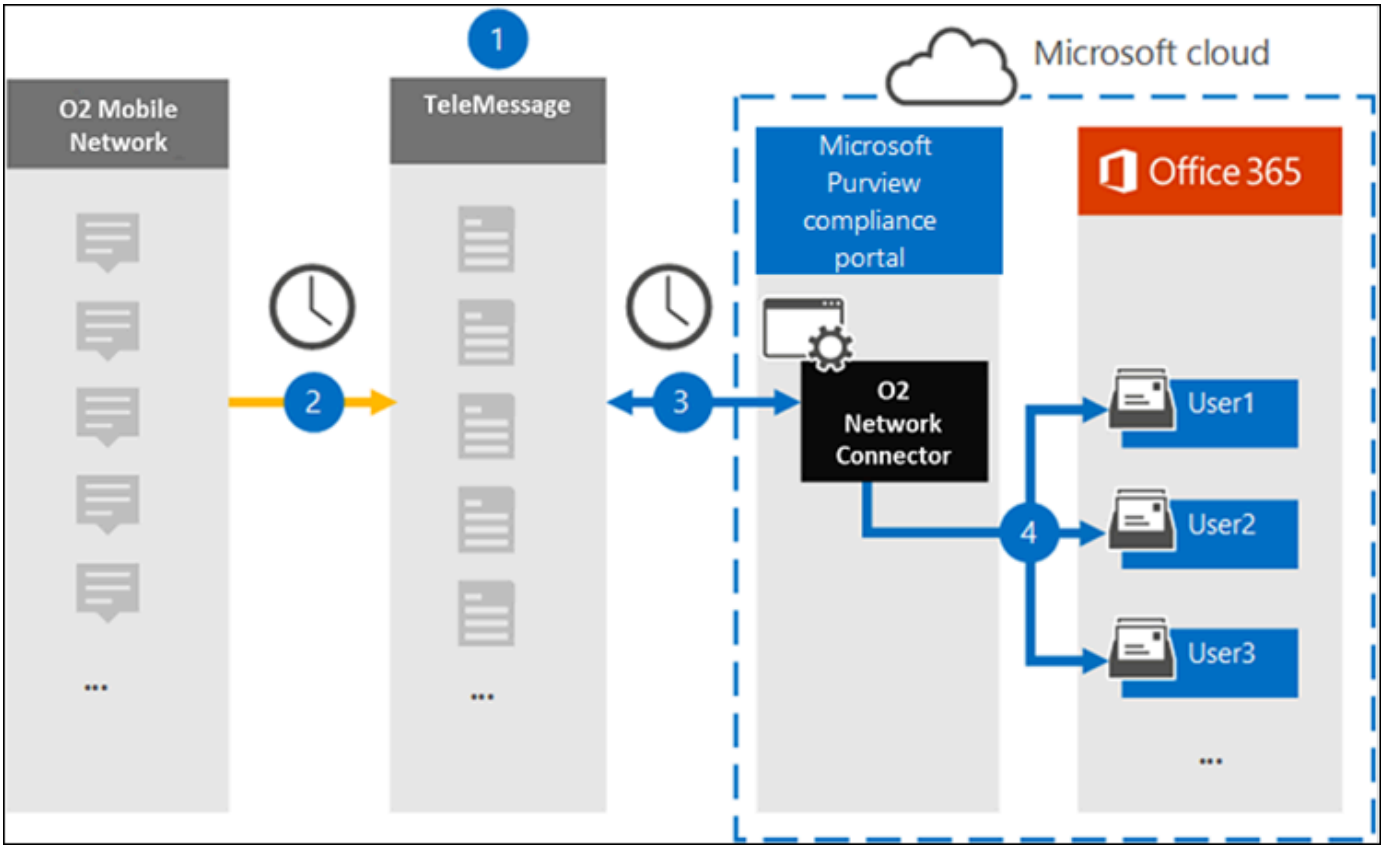
    - **Username:** Your TeleMessage username.
    - **Password:** Your TeleMessage password.

5. After you create the connector, you can close the pop-up window and go to the next page.
6. On the **User mapping** page, enable automatic user mapping. To enable custom mapping, upload a CSV file that contains the user mapping information, and select **Next**.
7. Review your settings, and select **Finish** to create the connector.
8. Go to the **Connectors** tab on the **Data connectors** page in the Microsoft Purview portal to see the progress of the import process for the new connector.

Limits

Importing attachments or items supports files up to 10 MB.

Last updated on 03/13/2026



Set up a connector to archive O2 Network data

Use a TeleMessage connector to import and archive Short Messaging Service (SMS) messages and voice calls from the O2 mobile network. After you set up and configure a connector, it connects to your organization's O2 Network once every day, and imports SMS and voice calls to mailboxes in Microsoft 365.

After you store SMS messages and voice calls in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, and Microsoft 365 retention policies to O2 Network data. For example, you can search O2 Network SMS messages and voice calls by using eDiscovery or associate the mailbox that contains O2 Network data with a custodian in an eDiscovery (Premium) case. Using an O2 Network connector to import and archive data in Microsoft 365 can help your organization stay compliant with government and regulatory policies.

Overview of archiving O2 Network data

The following overview explains the process of using a connector to archive O2 Network data in Microsoft 365.

1. Your organization works with TeleMessage and O2 to set up an O2 Network connector. For more information, see O2 Network Archiver.

2. Once every 24 hours, the TeleMessage site copies SMS messages and voice calls from your organization's O2 Network.

3. The O2 Network connector that you create in the Microsoft Purview portal connects to the TeleMessage site every day and transfers the SMS messages and voice calls from the previous 24 hours to a secure Azure Storage location in the Microsoft cloud. The connector also converts the content of SMS messages and voice calls to an email message format.

4. The connector imports the mobile communication items to the mailbox of specific users. A new folder named **O2 SMS and Voice Network Archiver** is created in a specific user's mailbox and the items are imported to it. The connector does this mapping by using the value of the *User's Email address* property. Every SMS message and voice call contains this property, which is populated with the email address of every participant of the message.

   In addition to automatic user mapping by using the value of the *User's Email address* property, you can also define a custom mapping by uploading a CSV mapping file. This mapping file contains the mobile phone number and corresponding Microsoft 365 email address for users in your organization. If you enable both automatic user mapping and custom mapping, for every O2 item the connector first looks at custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's mobile phone number, the connector uses the values in the email address property of the item it's trying to import. If the connector doesn't find a valid Microsoft 365 user in either the custom mapping file or in the email address property of the O2 item, the item won't be imported.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

Some of the implementation steps required to archive O2 Network data are external to Microsoft 365. You must complete these steps before you can create a connector in the Microsoft Purview portal.

- Order the O2 Network Archiver service from TeleMessage and get a valid administration account for your organization. You need to sign in to this account when you create the connector in the Microsoft Purview portal.
- Get your O2 Network account and billing contact details so you can fill out the TeleMessage onboarding forms and order the message archiving service from O2.
- Register all users that require O2 SMS and Voice Network archiving in the TeleMessage account. When registering users, be sure to use the same email address that's used for their Microsoft 365 account.
- Ensure your employees have corporate-owned and corporate-liable mobile phones on the O2 mobile network. Archiving messages in Microsoft 365 isn't available for employee-owned or "Bring Your Own Devices (BYOD) devices.
- Assign the Data Connector Admin role to the user who creates an O2 Network connector. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.
- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Create an O2 Network connector

After you complete the prerequisites described in Before you begin, you can create an O2 Network connector in the Microsoft Purview portal. The connector uses the information you

provide to connect to the TeleMessage site and transfer SMS messages and voice calls to the corresponding user mailboxes in Microsoft 365.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. Select **O2 Network** from the list.
5. On the **Terms of service** page, select **Accept**.
6. On the **Login to TeleMessage** page, under Step 3, enter the required information in the following boxes and then select **Next**.
    - **Username:** Your TeleMessage username.
    - **Password:** Your TeleMessage password.
7. After the connector is created, you can close the pop-up window and go to the next page.
8. On the **User mapping** page, enable automatic user mapping and select **Next**. If you need custom mapping, upload a CSV file, and select **Next**.
9. Review your settings, and then select **Finish** to create the connector.

O2 Network connector limits

Importing attachments or items supports files up to 10 MB.

Set up a connector to archive Rogers Network data

Use the TeleMessage connector to import and archive SMS and MMS data from the Rogers mobile network. When you set up and configure a Rogers Network Archiver connector, it connects to your organization's Rogers mobile network and imports SMS and MMS data to mailboxes in Microsoft 365. Before you set up the connector, you need a TeleMessage account, Rogers account details, and the Data Connector Admin role. For the full list of prerequisites, see Before you begin.

After storing data from the Rogers mobile network in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, and Microsoft 365 retention policies to the data. For example, you can search for SMS and MMS messages from the Rogers mobile network by using eDiscovery or a search associated with a Microsoft Purview eDiscovery case. Using a Rogers Network Archiver connector to import and archive data in Microsoft 365 can help your organization stay compliant with corporate governance regulations and regulatory policies.

Overview of archiving Rogers mobile network data

The following overview explains the process of using a connector to archive Rogers SMS and MMS data in Microsoft 365.

1. Your organization works with TeleMessage to set up a Rogers Network Archiver connector. For more information, see Activating the TeleMessage Rogers Network Archiver for Microsoft 365.

2. In real time, your organization's Rogers mobile network copies data to the TeleMessage site.

3. The Rogers Network Archiver connector that you create in the Microsoft Purview portal connects to the TeleMessage site every day and transfers the email messages from the previous 24 hours to a secure Azure Storage area in the Microsoft Cloud.

4. The connector imports the mobile communication items to the mailbox of a specific user. A new folder named Rogers SMS/MMS Network Archiver is created in the specific user's mailbox and the items are imported to it. The connector does the mapping by using the value of the *User's Email address* property. Every email message contains this property, which is populated with the email address of every participant of the email message.

   In addition to automatic user mapping by using the value of the *User's Email address* property, you can also define a custom mapping by uploading a CSV mapping file. This mapping file should contain User's mobile Number and the corresponding Microsoft 365 mailbox address for each user. If you enable automatic user mapping and provide a custom mapping, for every email item the connector first looks at custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's mobile number, the connector uses the user's email address property of the email item. If the connector doesn't find a

valid Microsoft 365 user in either the custom mapping file or the *user's email address* property of the email item, the item isn't imported.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

- Order the Rogers Network Archiver service from TeleMessage and get a valid administration account for your organization. You need to sign in to this account when you create the connector in the Microsoft Purview portal.
- Register all users that require Rogers Network archiving in the TeleMessage account. When registering users, use the same email address that's used for their Microsoft 365 account.
- Ensure your employees have corporate-owned and corporate-liable mobile phones on the O2 mobile network. Archiving messages in Microsoft 365 isn't available for employee-owned or "Bring Your Own Devices (BYOD) devices.
- Get the Rogers account and billing contact details for your organization so that you can complete the onboarding forms and order the message archiving service from Rogers.
- Assign the Data Connector Admin role to the user who creates the Rogers Network Archiver connector in Create a Rogers Network Archiver connector. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.
- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and

processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Create a Rogers Network Archiver connector

After you complete the prerequisites described in Before you begin, you can create the Rogers Network Archiver connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the TeleMessage site and transfer Rogers SMS/MMS data to the corresponding user mailboxes in Microsoft 365.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **Rogers Network Archiver**.
5. On the **Terms of service** page, select **Accept**.
6. On the **Login to TeleMessage** page, in the credentials section of the login form, enter the required information in the following boxes and then select **Next**.
   - **Username:** Your TeleMessage username.
   - **Password:** Your TeleMessage password.
7. After the connector is created, you can close the pop-up window and go to the next page.
8. On the **User mapping** page, enable automatic user mapping. To enable custom mapping, upload a CSV file that contains the user mapping information, and then select **Next**.
9. Review your settings, and then select **Finish** to create the connector.

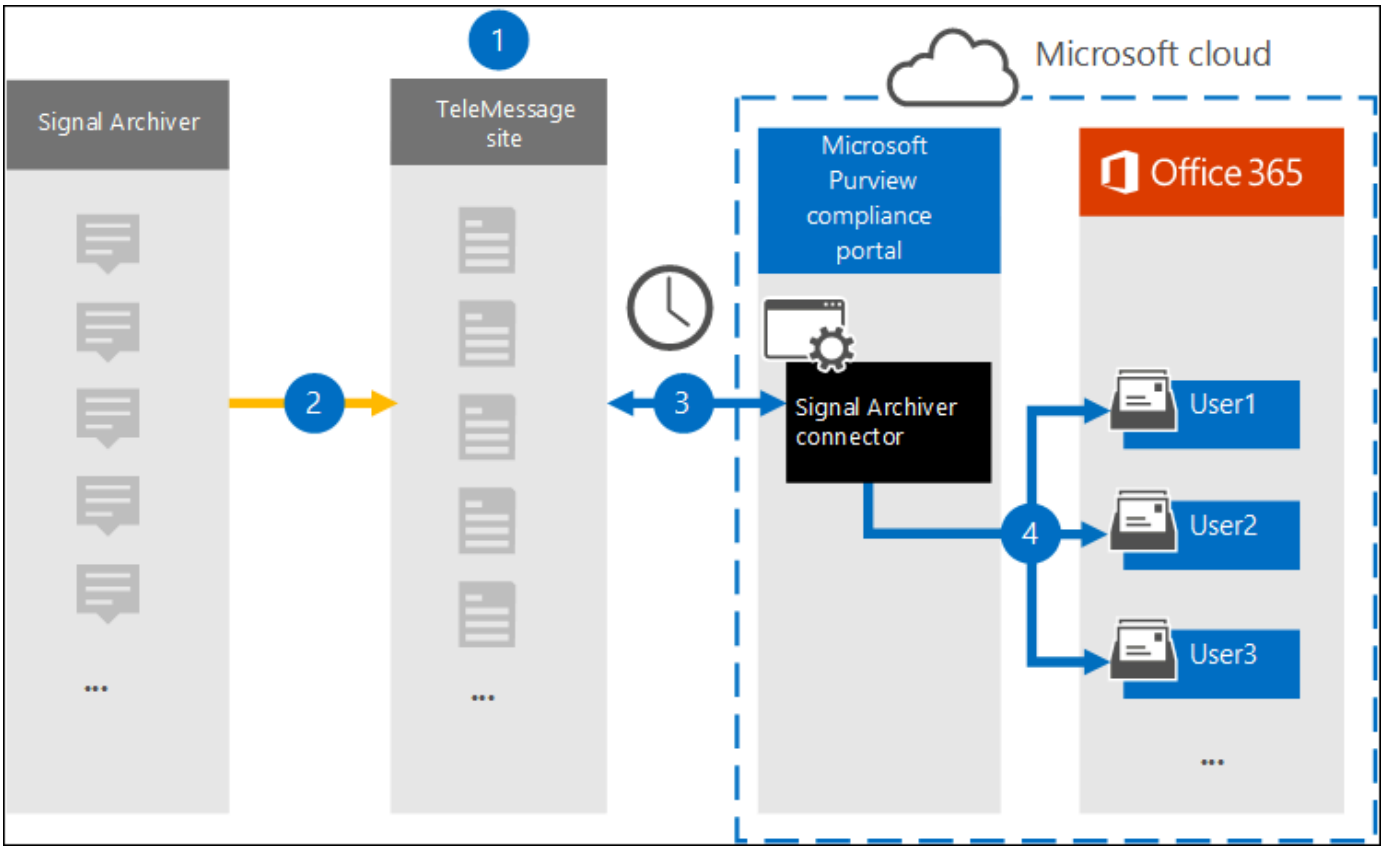
Set up a connector to archive Signal communications data



Signal Archiver connector for TeleMessage

Use the TeleMessage connector to import and archive Signal chats, attachments, files, and deleted messages and calls. After you set up and configure a connector, it connects to your organization's TeleMessage account and imports the mobile communication of employees using the TeleMessage Signal Archiver to mailboxes in Microsoft 365.

After Signal Archiver connector data is stored in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, and Microsoft 365 retention policies to Signal communications data. For example, you can search Signal communication by using eDiscovery or associate the mailbox that contains the Signal Archiver connector data with a custodian in an eDiscovery (Premium) case. Using a Signal Archiver connector to import and archive data in Microsoft 365 can help your organization stay compliant with corporate governance regulations and regulatory policies.

Overview of archiving Signal communications data

The following overview explains the process of using a connector to archive Signal communication data in Microsoft 365.

1. Your organization works with TeleMessage to set up a Signal Archiver connector. For more information, see Activating the TeleMessage Signal Archiver for Microsoft 365.

2. In real time, your organization's Signal data is copied to the TeleMessage site.

3. The Signal Archiver connector that you create in the Microsoft Purview portal connects to the TeleMessage site every day and transfers the email messages from the previous 24 hours to a secure Azure Storage area in the Microsoft Cloud.

4. The connector imports the mobile communication items to the mailbox of a specific user. A new folder named Signal Archiver is created in the specific user's mailbox and the items are imported to it. The connector uses the value of the *User's Email address* property for mapping. Every email message contains this property, which is populated with the email address of every participant of the email message.

   In addition to automatic user mapping by using the value of the *User's Email address* property, you can also define a custom mapping by uploading a CSV mapping file. This mapping file should contain User's mobile Number and the corresponding Microsoft 365 mailbox address for each user. If you enable automatic user mapping and provide a custom mapping, for every email item the connector first looks at custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's mobile number, the connector uses the User's email address property of the email item. If the connector doesn't find a

valid Microsoft 365 user in either the custom mapping file or the *user's email address* property of the email item, the item won't be imported.

Before you begin

> **Important**

Set up a connector to archive T-Mobile SMS/MMS data

Use a TeleMessage connector in the Microsoft Purview portal to import and archive SMS and MMS data from T-Mobile Mobile Network. After you set up and configure a connector, it connects to your organization's T-Mobile Network once every day, and imports SMS and MMS data to mailboxes in Microsoft Purview. Before you begin, you'll need a TeleMessage account, T-Mobile account details, corporate-owned devices on the T-Mobile network, and the appropriate Microsoft Purview permissions. For the full list of prerequisites, see Before you begin.

After storing SMS and MMS messages in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, and Microsoft 365 retention policies to T-Mobile Network data. For example, you can search T-Mobile Network data by using eDiscovery or associate the mailbox that contains the T-Mobile Network connector data with a custodian in an eDiscovery (Premium) case. Using a T-Mobile Network connector to import and archive data in Microsoft 365 can help your organization stay compliant with government and regulatory policies.

Overview of archiving T-Mobile Network data

The following overview explains the process of using a connector to archive T-Mobile Network data in Microsoft 365.

1. Your organization works with TeleMessage to set up a T-Mobile Network connector. For information, see T-Mobile Network Archiver.
2. In real time, SMS and MMS messages from your organization's T-Mobile Network are copied to the TeleMessage site.
3. The T-Mobile Network connector that you create in the Microsoft Purview portal connects to the TeleMessage site every day and transfers the SMS and MMS messages from the previous 24 hours to a secure Azure Storage location in the Microsoft cloud. The connector also converts the content of SMS and MMS messages to an email message format.
4. The connector imports the mobile communication items to the mailbox of specific users. A new folder named **T-Mobile SMS/MMS Network Archiver** is created in the user's mailbox and the items are imported to it. The connector does this mapping by using the value of the *User's Email address* property. Every SMS and MMS message contains this property, which is populated with the email address of every participant of the message.

In addition to automatic user mapping by using the value of the *User's Email address* property, you can also define a custom mapping by uploading a CSV mapping file. This mapping file contains the mobile phone number and corresponding Microsoft 365 email address for users in your organization. If you enable both automatic user mapping and custom mapping, for every email item the connector first looks at the custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a mobile phone number, the connector uses the values in the email address property of the item it's trying to import. If the connector doesn't find a valid Microsoft

365 user in either the custom mapping file or in the email address property of the email item, the item won't be imported.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

Some of the implementation steps required to archive T-Mobile Network data are external to Microsoft 365. You must complete these steps before you can create the connector in the Microsoft Purview portal.

- Order the mobile archiver service from TeleMessage and get a valid administration account for your organization. You need to sign in to this account when you create the connector in the Microsoft Purview portal.
- Obtain your T-Mobile account and billing contact details so you can fill out the TeleMessage onboarding forms and order the message archiving service from T-Mobile.
- Register all users that require T-Mobile SMS/MMS Network archiving in the TeleMessage account. When registering users, be sure to use the same email address that's used for their Microsoft 365 account.
- Ensure users have corporate-owned and corporate-liable mobile phones on the T-Mobile mobile network. Archiving messages in Microsoft 365 isn't available for user-owned or "Bring Your Own Devices (BYOD)" devices.
- Assign the Data Connector Admin role to the user who creates a T-Mobile Network connector. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Create a T-Mobile Network connector

After you complete the prerequisites described in Before you begin, you can create a T-Mobile Network connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the TeleMessage site and transfer SMS and MMS messages to the corresponding user mailboxes in Microsoft 365.

1. Go to Microsoft Purview portal and then select **Data connectors** > **T-Mobile Network**.
2. On the **T-Mobile Network product** description page, select **Add connector**.
3. On the **Terms of service** page, select **Accept**.
4. On the **Login to TeleMessage** page, under Step 3, enter the required information in the following boxes and then select **Next**.
    - **Username:** Your TeleMessage username.
    - **Password:** Your TeleMessage password.
5. After the connector is created, you can close the pop-up window and go to the next page.
6. On the **User mapping** page, enable automatic user mapping. To enable custom mapping, upload a CSV file that contains the user mapping information, and then select **Next**.
7. Review your settings, and then select **Finish** to create the connector.
8. Go to the **Connectors** tab on the **Data connectors** page in the Microsoft Purview portal to see the progress of the import process for the new connector.

Set up a connector to archive Telegram communications data

Use the TeleMessage connector to import and archive Telegram chats, attachments, files, and deleted messages and calls. After you set up and configure a connector, it connects to your organization's TeleMessage account and imports the mobile communication of employees using the Telegram Archiver to mailboxes in Microsoft 365.

After storing Telegram Archiver connector data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, and Microsoft 365 retention policies to Telegram communication data. For example, you can search Telegram communication by using eDiscovery or associate the mailbox that contains the Telegram Archiver connector data with a custodian in an eDiscovery (Premium) case. By using a Telegram Archiver connector to import and archive data in Microsoft 365, your organization can stay compliant with corporate governance regulations and regulatory policies.

Overview of archiving Telegram communications data

The following overview explains the process of using a connector to archive Telegram communications data in Microsoft 365.

1. Your organization works with TeleMessage to set up a Telegram Archiver connector. For more information, see Activating the TeleMessage Telegram Archiver for Microsoft 365.

2. In real time, your organization's Telegram data is copied to the TeleMessage site.

3. The Telegram Archiver connector that you create in the Microsoft Purview portal connects to the TeleMessage site every day and transfers the email messages from the previous 24 hours to a secure Azure Storage area in the Microsoft Cloud.

4. The connector imports the mobile communication items to the mailbox of a specific user. A new folder named Telegram Archiver is created in the specific user's mailbox and the items are imported to it. The connector uses the value of the *User's Email address* property for this mapping. Every email message contains this property, which is populated with the email address of every participant of the email message.

> In addition to automatic user mapping by using the value of the *User's Email address* property, you can also define a custom mapping by uploading a CSV mapping file. This mapping file should contain User's mobile Number and the corresponding Microsoft 365 mailbox address for each user. If you enable automatic user mapping and provide a custom mapping, for every email item the connector will first look at custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's mobile number, the connector will use the User's email address property of the email item. If the connector doesn't find a valid Microsoft 365 user in either the custom mapping file or the *user's email address* property of the email item, the item won't be imported.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned **service principal** for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see **Provision a service principal for partner third-party data connectors**.

- Order the Telegram archiving service from TeleMessage and get a valid administration account for your organization. You need to sign in to this account when you create the connector in the Microsoft Purview portal.

- Register all users that require Telegram archiving in the TeleMessage account. When registering users, use the same email address that's used for their Microsoft 365 account.
- Install the Telegram Archiver app on the mobile phones of your employees and activate it. The Telegram Archiver app allows them to communicate and chat with other Telegram users.
- Assign the Data Connector Admin role to the user who creates a Telegram Archiver connector in Create a Telegram Archiver connector. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.
- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Create a Telegram Archiver connector

After you complete the prerequisites described in Before you begin, create the Telegram Archiver connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the TeleMessage site and transfers Telegram communications data to the corresponding user mailboxes in Microsoft 365.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **Telegram Archiver**.
5. On the **Terms of service** page, select **Accept**.

6. On the **Login to TeleMessage** page, under Step 3, enter the required information in the following boxes and then select **Next**.

    - **Username:** Your TeleMessage username.
    - **Password:** Your TeleMessage password.

7. After the connector is created, you can close the pop-up window and go to the next page.

8. On the **User mapping** page, enable automatic user mapping. To enable custom mapping, upload a CSV file that contains the user mapping information, and then select **Next**.

9. Review your settings, and then select **Finish** to create the connector.

Set up a connector to archive TELUS Network data

Use the TeleMessage connector to import and archive Short Messaging Service (SMS) data from your organization's TELUS Network. After you set up and configure a connector, it connects to your organization's TELUS Network once every day and imports SMS data to mailboxes in Microsoft 365.

After storing SMS messages in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, and Microsoft 365 retention policies to TELUS data. For example, you can search TELUS SMS messages by using eDiscovery or associate the mailbox that contains the TELUS data with a custodian in an eDiscovery (Premium) case. Using a TELUS Network connector to import and archive data in Microsoft 365 can help your organization stay compliant with government and regulatory policies.

Overview of archiving TELUS Network data

The following overview explains the process of using a connector to archive TELUS Network data in Microsoft 365.

1. Your organization works with TeleMessage and TELUS to set up a TELUS Network connector. For more information, see TELUS Network Archiver.

2. In real time, SMS messages from your organization's TELUS Network are copied to the TeleMessage site.

3. The TELUS Network connector that you create in the Microsoft Purview portal connects to the TeleMessage site every day and transfers the SMS messages from the previous 24 hours to a secure Azure Storage location in the Microsoft cloud. The connector also converts the content of SMS messages to an email message format.

4. The connector imports the mobile communication items to the mailbox of a specific user. A new folder named **TELUS SMS Network Archiver** is created in the specific user's mailbox and the items are imported to it. The connector does mapping by using the value of the *User's Email address* property. Every SMS message contains this property, which is populated with the email address of every participant of the SMS message.

   In addition to automatic user mapping by using the value of the *User's Email address* property, you can also implement custom mapping by uploading a CSV mapping file. This mapping file contains the mobile phone number and corresponding Microsoft 365 email address for users in your organization. If you enable both automatic user mapping and custom mapping, for every TELUS item the connector first looks at custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's mobile phone number, the connector uses the values in the email address property of the item it's trying to import. If the connector doesn't find a valid Microsoft 365 user in either the custom mapping file or in the email address property of the TELUS item, the item won't be imported.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

Some of the implementation steps required to archive TELUS Network data are external to Microsoft 365. You must complete these steps before you can create a connector in the Microsoft Purview portal.

- Order the TELUS Network Archiver service from TeleMessage and get a valid administration account for your organization. You need to sign in to this account when you create the connector in the Microsoft Purview portal.
- Obtain your TELUS Network account and billing contact details so you can fill out the TeleMessage onboarding forms and order the message archiving service from TELUS.
- Register all users that require TELUS SMS Network archiving in the TeleMessage account. When registering users, be sure to use the same email address that's used for their Microsoft 365 account.
- Ensure your employees have corporate-owned and corporate-liable mobile phones on the TELUS mobile network. Archiving messages in Microsoft 365 isn't available for employee-owned or Bring Your Own Devices (BYOD) devices.
- Assign the Data Connector Admin role to the user who creates a TELUS Network connector. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.
- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Create a TELUS Network connector

After you complete the prerequisites described in Before you begin, create a TELUS Network connector in the Microsoft Purview portal. The connector uses the information you provide to

connect to the TeleMessage site and transfer SMS messages to the corresponding user mailboxes in Microsoft 365.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **TELUS Network**.
5. On the **Terms of service** page, select **Accept**.
6. On the **Login to TeleMessage** page, under Step 3, enter the required information in the following boxes and then select **Next**.
    - **Username:** Your TeleMessage username.
    - **Password:** Your TeleMessage password.
7. After you create the connector, close the pop-up window.
8. On the **User mapping** page, enable automatic user mapping and select **Next**. To use custom mapping, upload a CSV file, and select **Next**.
9. Review your settings, and then select **Finish** to create the connector.

TELUS Network connector limits

Importing attachments or items supports files up to 10 MB.

Set up a connector to archive Verizon Network data

Use the TeleMessage connector to import and archive Short Messaging Service (SMS) and Multimedia Messaging Service (MMS) data from Verizon Network. Before you begin, review the prerequisites for setting up the Verizon Network connector. After you set up and configure a connector, it connects to your organization's Verizon Network once every day and imports SMS and MMS data to mailboxes in Microsoft 365.

After storing Verizon Network connector data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, and Microsoft 365 retention policies to Verizon data. For example, you can search Verizon SMS and MMS messages by using eDiscovery or associate the mailbox that contains Verizon Network data with a custodian in a Microsoft Purview eDiscovery (Premium) case. Using a Verizon Network connector to import and archive data in Microsoft 365 can help your organization stay compliant with government and regulatory policies.

Overview of archiving Verizon Network data

The following overview explains the process of using a connector to archive Verizon Network data in Microsoft 365.

1. Your organization works with TeleMessage and Verizon to set up a Verizon Network connector. For more information, see Verizon Network Archiver.

2. Once every 24 hours, your organization's Verizon Network copies SMS and MMS messages to the TeleMessage site.

3. The Verizon Network connector that you create in the Microsoft Purview portal connects to the TeleMessage site every day and transfers the SMS and MMS messages from the previous 24 hours to a secure Azure Storage location in the Microsoft cloud. The connector also converts the content of SMS and MMS messages to an email message format.

4. The connector imports the mobile communication items to the mailbox of a specific user. A new folder named **Verizon SMS/MMS Network Archiver** is created in the specific user's mailbox and the items are imported to it. The connector does this mapping by using the value of the *User's Email address* property. Every SMS and MMS message contains this property, which is populated with the email address of every participant of the message.

   In addition to automatic user mapping by using the value of the *User's Email address* property, you can also implement custom mapping by uploading a CSV mapping file. This mapping file contains the mobile phone number and corresponding Microsoft 365 email address for users in your organization. If you enable both automatic user mapping and custom mapping, for every Verizon item the connector first looks at custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's mobile phone number,

the connector uses the values in the email address property of the item it's trying to import. If the connector doesn't find a valid Microsoft 365 user in either the custom mapping file or in the email address property of the Verizon item, the item won't be imported.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

Some of the implementation steps required to archive Verizon Network data are external to Microsoft 365. You must complete these steps before you can create a connector in the Microsoft Purview portal.

- Order the Verizon Network Archiver service from TeleMessage and get a valid administration account for your organization. You need to sign in to this account when you create the connector in the Microsoft Purview portal.
- Obtain your Verizon Network account and billing contact details so you can fill out the TeleMessage onboarding forms and order the message archiving service from Verizon.
- Register all users that require Verizon SMS and MMS archiving in the TeleMessage account. When registering users, use the same email address that's used for their Microsoft 365 account.
- Ensure your employees have corporate-owned and corporate-liable mobile phones on the Verizon mobile network. Archiving messages in Microsoft 365 isn't available for employee-owned or Bring Your Own Devices (BYOD) devices.
- Assign the Data Connector Admin role to the user who creates a Verizon Network connector. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions,

see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Create a Verizon Network connector

After you complete the prerequisites described in Before you begin, you can create a Verizon Network connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the TeleMessage site and transfer SMS and MMS messages to the corresponding user mailboxes in Microsoft 365.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **Verizon Network**.
5. On the **Terms of service** page, select **Accept**.
6. On the **Login to TeleMessage** page, under Step 3, enter the required information in the following boxes and then select **Next**.
    - **Username:** Your TeleMessage username.
    - **Password:** Your TeleMessage password.
7. After the connector is created, you can close the pop-up window and go to the next page.
8. On the **User mapping** page, enable automatic user mapping and select **Next**. If you need custom mapping, upload a CSV file, and select **Next**.
9. Review your settings, and then select **Finish** to create the connector.

Limits for archiving Verizon Network data

Importing attachments or items supports files up to 10 MB.

Set up a connector to archive WeChat data

Use the TeleMessage connector to import and archive WeChat and WeCom calls, chats, attachments, files, and recalled messages. When you set up and configure a connector, it connects to your organization's TeleMessage account and imports the mobile communication of employees who use the TeleMessage WeChat Archiver to mailboxes in Microsoft 365.

After storing WeChat Archiver connector data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, In-Place Archiving, Auditing, Communication Compliance, and Microsoft 365 retention policies to WeChat communication data. For example, you can search WeChat communication by using eDiscovery or associate the mailbox that contains the WeChat Archiver connector data with a custodian in an eDiscovery (Premium) case. Using a WeChat Archiver connector to import and archive data in Microsoft 365 can help your organization stay compliant with corporate governance regulations and regulatory policies.

Overview of archiving WeChat communication data

The following overview explains the process of using a connector to archive WeChat communications data in Microsoft 365.

1. Your organization works with TeleMessage to set up a WeChat Archiver connector.

2. In real time, your organization's WeChat data is copied to the TeleMessage site.

3. The WeChat Archiver connector that you create in the Microsoft Purview portal connects to the TeleMessage site every day and transfers the email messages from the previous 24 hours to a secure Azure Storage area in the Microsoft Cloud.

4. The connector imports the mobile communication items to the mailbox of a specific user. A new folder named WeChat Archiver is created in the specific user's mailbox and the items are imported to it. The connector does mapping by using the value of the *User's Email address* property. Every email message contains this property, which is populated with the email address of every participant of the email message. In addition to automatic user mapping using the value of the *User's Email address* property, you can also define a custom mapping by uploading a CSV mapping file. This mapping file should contain User's mobile Number and the corresponding Microsoft 365 mailbox address for each user. If you enable automatic user mapping and provide a custom mapping, for every email item the connector will first look at custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's mobile number, the connector will use the User ‘s email address property of the email item. If the connector doesn't find a valid Microsoft 365 user in either the custom mapping file or the *user's email address* property of the email item, the item won't be imported.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

- Work with TeleMessage to set up a WeChat archive connector. For activation steps, see Activating the TeleMessage WeChat Archiver for Microsoft 365.

- Set up a TeleMessage connector for Microsoft 365 and get a valid company administration account. To purchase the service, see Order Microsoft 365 Mobile Archiving.

- Register all users that require WeChat archiving in the TeleMessage account with the same email address that is used for the user's Microsoft 365 account.
- Install the Tencent WeCom app on the mobile phones of users in your organization and activate it. The WeCom app lets users communicate and chat with other WeChat and WeCom users.
- Assign the Data Connector Admin role to the user who creates a WeChat Archiver connector in the Microsoft Purview portal. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.
- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Create a WeChat Archiver connector

Complete the following steps to create a WeChat Archiver connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the TeleMessage site and transfer WeChat communications data to the corresponding user mailboxes in Microsoft 365.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **WeChat Archiver**.
5. On the **Terms of service** page, select **Accept**.

6. On the **Login to TeleMessage** page, under Step 3, enter the required information in the following boxes and then select **Next**.

    - **Username**: Your TeleMessage user name.
    - **Password**: Your TeleMessage password.

7. After you create the connector, you can close the TeleMessage sign-in pop-up window.

8. On the **User mapping** page, enable automatic user mapping. You can also upload a custom user mapping CSV file.

9. Select **Next**, review your settings, and then select **Finish** to create the connector.

WeChat connector limits

Importing attachments or items supports files up to 10 MB.

Set up a connector to archive WhatsApp data

Use the TeleMessage connector to import and archive WhatsApp calls, chats, attachments, files, and deleted messages. After you set up and configure a connector, it connects to your organization's TeleMessage account once every day, and imports the mobile communication of employees using the TeleMessage WhatsApp Phone Archiver or TeleMessage WhatsApp Cloud Archiver to mailboxes in Microsoft 365.

After WhatsApp data is stored in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, and Microsoft 365 retention policies to WhatsApp data. For example, you can search WhatsApp messages using eDiscovery or associate the mailbox that contains WhatsApp messages with a custodian in an eDiscovery (Premium) case. Using a WhatsApp connector to import and archive data in Microsoft 365 can help your organization stay compliant with government and regulatory policies.

Overview of archiving WhatsApp data

The following overview explains the process of using a connector to archive WhatsApp data in Microsoft 365. A connector is a configuration in Microsoft Purview that connects to TeleMessage and imports WhatsApp data into Microsoft 365 mailboxes.

1. Your organization works with TeleMessage to set up a WhatsApp Archiver connector. For more information, see WhatsApp Archiver.

2. In real time, your organization's WhatsApp data is copied to the TeleMessage site.

3. The WhatsApp connector that you create in the Microsoft Purview portal connects to the TeleMessage site every day and transfers WhatsApp data from the previous 24 hours to a secure Azure Storage location in the Microsoft cloud. The connector also converts the content WhatsApp data to an email message format.

4. The connector imports WhatsApp data to the mailbox of a specific user. A new folder named **WhatsApp Archiver** is created in the specific user's mailbox and the items are imported to it. The connector does this mapping by using the value of the *User's Email address* property. Every WhatsApp message contains this property, which is populated with the email address of every participant of the message.

   In addition to automatic user mapping using the value of the *User's Email address* property, you can also implement custom mapping by uploading a CSV mapping file. This mapping file contains the mobile phone number and corresponding Microsoft 365 email address for users in your organization. If you enable both automatic user mapping and custom mapping, for every WhatsApp item the connector first looks at custom mapping file. If it doesn't find a valid Microsoft 365 user that corresponds to a user's mobile phone number, the connector will use the values in the email address property of the item it's trying to

import. If the connector doesn't find a valid Microsoft 365 user in either the custom mapping file or in the email address property of the WhatsApp item, the item won't be imported.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

You need to complete some implementation steps before you can create the connector in the Microsoft Purview portal. These steps are external to Microsoft 365.

- Order the WhatsApp Archiver service from TeleMessage and get a valid administration account for your organization. You need to sign in to this account when you create the connector in the Microsoft Purview portal.
- Register all users that require WhatsApp archiving in the TeleMessage account. When registering users, use the same email address that's used for their Microsoft 365 account.
- Install the TeleMessage WhatsApp Phone Archiver app on the mobile phones of your employees and activate it. Alternatively, you can install the regular WhatsApp or WhatsApp Business apps on the mobile phones of your employees and activate the WhatsApp Cloud Archiver service by scanning a QR code on the TeleMessage website. For more information, see WhatsApp Cloud Archiver.
- Assign the Data Connector Admin role to the user who creates a WhatsApp Archiver connector. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Create a WhatsApp Archiver connector

After you complete the prerequisites described in Before you begin, create the WhatsApp connector in the Microsoft Purview portal. The connector uses the information you provide to connect to the TeleMessage site and transfer the WhatsApp data to the corresponding user mailboxes in Microsoft 365.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **WhatsApp Archiver**.
5. On the **Terms of service** page, select **Accept**.
6. On the **Login to TeleMessage** page, under Step 3, enter the required information in the following boxes and then select **Next**.
    - **Username:** Your TeleMessage username.
    - **Password:** Your TeleMessage password.
7. After the connector is created, you can close the pop-up window and go to the next page.
8. On the **User mapping** page, enable automatic user mapping and select **Next**. If you need custom mapping, upload a CSV file, and select **Next**.
9. Review your settings, and then select **Finish** to create the connector.

Limits for archiving WhatsApp data

Importing attachments or items supports files up to 10 MB.

Set up a connector to archive BlackBerry data

Use the BlackBerry DataParser from 17a-4 LLC to import and archive BlackBerry enterprise data to user mailboxes in your Microsoft 365 organization. The DataParser includes a BlackBerry connector that you configure to capture items from a third-party data source and import those items to Microsoft 365. The BlackBerry DataParser connector converts BlackBerry data to an email message format and then imports those items to user mailboxes in Microsoft 365.

After you store BlackBerry data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, retention policies and retention labels, and Communication Compliance. By using a BlackBerry connector to import and archive data in Microsoft 365, your organization can stay compliant with government and regulatory policies.

Overview of archiving BlackBerry data

The following overview explains the process of using a data connector to archive BlackBerry data in Microsoft 365.

1. Your organization works with 17a-4 to set up and configure the BlackBerry DataParser.

2. The DataParser regularly collects BlackBerry items and converts the content of a message to an email message format.

3. You create the BlackBerry DataParser connector in the Microsoft Purview portal. The connector connects to DataParser and transfers the messages to a secure Azure Storage location in the Microsoft cloud.

4. The connector creates a subfolder in the Inbox folder named **BlackBerry DataParser** in the user mailboxes and imports the BlackBerry items to that folder. The connector uses the value of the *Email* property to determine which mailbox to import items to. Every BlackBerry item contains the *Email* property, which is populated with the email address of every participant.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

- Create a DataParser account for Microsoft connectors. To create an account, contact 17a-4 LLC. You need to sign in to this account when you create the connector.

- Assign the Data Connector Admin role to the user who creates the BlackBerry DataParser connector and completes the connector setup. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the

Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Step 1: Set up a BlackBerry DataParser connector

Create a 17a-4 connector for BlackBerry data in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. Select **BlackBerry DataParser** from the list.
5. Select **Accept** on the **Terms of service** page.
6. Enter a unique name that identifies the connector in the **Name** field and select **Next**.
7. Sign in to your 17a-4 account and complete the steps in the BlackBerry DataParser connection workflow.

Step 2: Configure the BlackBerry DataParser connector

Work with 17a-4 Support to configure the BlackBerry DataParser connector.

Step 3: Map users

The BlackBerry DataParser connector automatically maps users to their Microsoft 365 email addresses before importing data to Microsoft 365.

Step 4: Monitor the BlackBerry DataParser connector

After you create a BlackBerry DataParser connector, you can view the connector status in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select the BlackBerry DataParser connector that you created to display the flyout page, which contains the properties and information about the connector.

Set up a connector to archive Bloomberg data

Use the Bloomberg DataParser from 17a-4 LLC to import and archive data from Bloomberg to user mailboxes in your Microsoft 365 organization. The DataParser includes a Bloomberg connector that's configured to capture items from a third-party data source and import those items to Microsoft 365. The Bloomberg DataParser connector converts Bloomberg data to an email message format and then imports those items to user mailboxes in Microsoft 365.

After you store Bloomberg data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, retention policies and retention labels, and Communication Compliance. By using a Bloomberg connector to import and archive data in Microsoft 365, you can help your organization stay compliant with government and regulatory policies.

Overview of archiving Bloomberg data

The following overview explains the process of using a data connector to archive Bloomberg data in Microsoft 365.

1. Your organization works with 17a-4 to set up and configure the Bloomberg DataParser.

2. The DataParser regularly collects Bloomberg items and converts the content of a message to an email message format.

3. You create the Bloomberg DataParser connector in the Microsoft Purview portal. The connector connects to DataParser and transfers the converted Bloomberg messages to a secure Azure Storage location in the Microsoft cloud.

4. The connector creates a subfolder in the Inbox folder named **Bloomberg DataParser** in the user mailboxes and imports the Bloomberg items to that folder. The connector uses the value of the *Email* property to determine which mailbox to import items to. Every Bloomberg item contains the *Email* property, which is populated with the email address of every participant.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

- Create a DataParser account for Microsoft connectors. To create an account, contact 17a-4 LLC. You need to sign in to this account when you create the connector.

- Assign the Data Connector Admin role to the user who creates the Bloomberg DataParser connector. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the

Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Step 1: Set up a Bloomberg DataParser connector

Create a 17a-4 connector for Bloomberg data in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. Select **Bloomberg DataParser** from the list.
5. Select **Accept** on the **Terms of service** page.
6. Enter a unique name that identifies the connector and select **Next**.
7. Sign in to your 17a-4 account and complete the steps in the Bloomberg DataParser connection workflow.

Step 2: Configure the Bloomberg DataParser connector

Work with 17a-4 Support to configure the Bloomberg DataParser connector.

Step 3: Map Bloomberg users to Microsoft 365 users

The Bloomberg DataParser connector automatically maps users to their Microsoft 365 email addresses before importing data to Microsoft 365.

Step 4: Monitor the Bloomberg DataParser connector

After you create a Bloomberg DataParser connector, you can view the connector status in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select the Bloomberg DataParser connector that you created to display the flyout page, which contains the properties and information about the connector.
4. Under **Connector status with source**, select the **Download log** link to open (or save) the status log for the connector. This log contains information about the data that's imported to the Microsoft cloud. For more information, see View admin logs for data connectors.

ⓘ**Note:** The author created this article with assistance from AI. Learn more

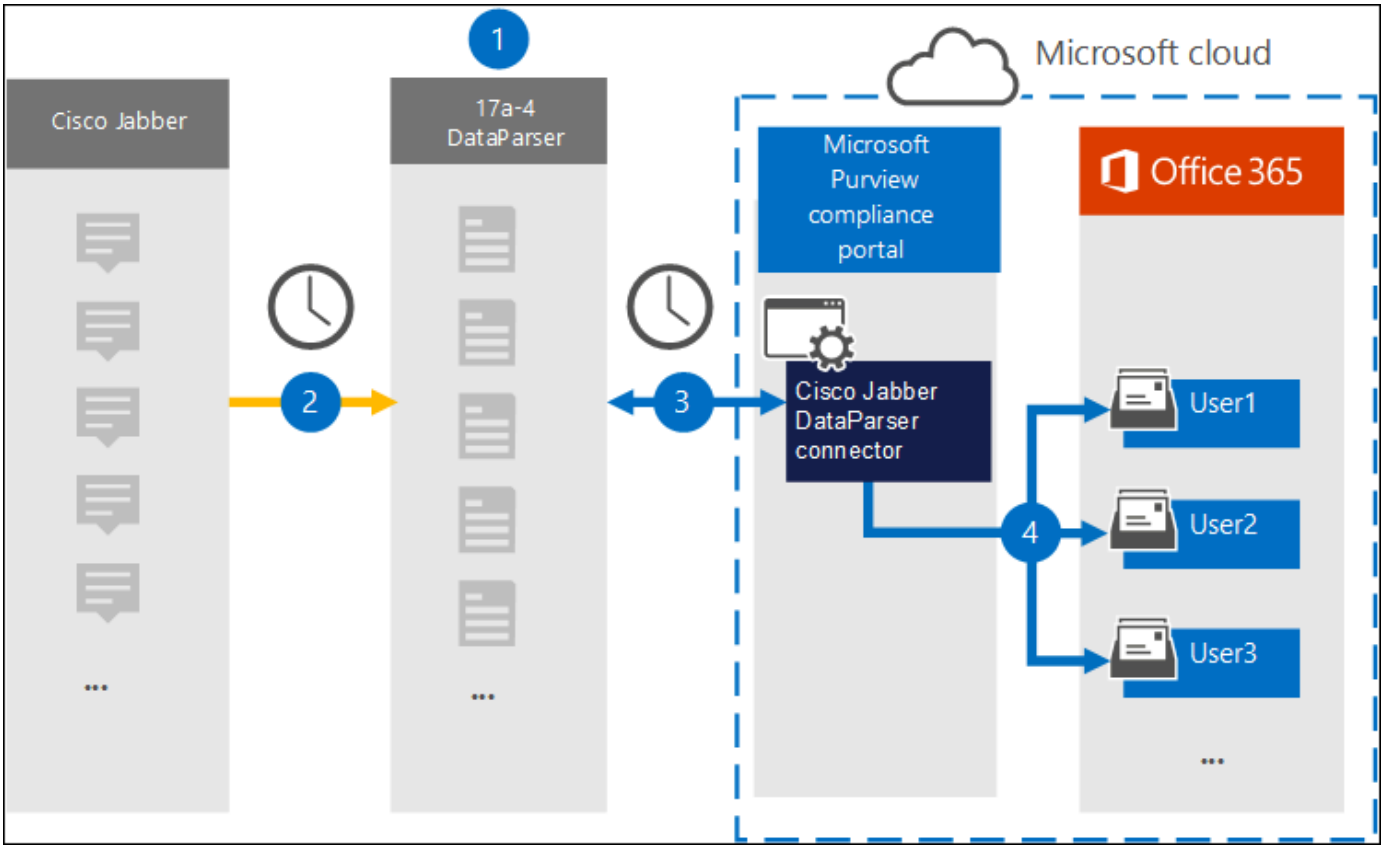
Last updated on 06/24/2026



Set up a connector to archive Cisco Jabber data

Use the Cisco Jabber DataParser from 17a-4 LLC to import and archive data from Cisco Jabber to user mailboxes in your Microsoft 365 organization. The DataParser includes a Cisco Jabber connector that you configure to capture items from a third-party data source and import those items to Microsoft 365. The Cisco Jabber DataParser connector converts Cisco Jabber data to an email message format and then imports those items to user mailboxes in Microsoft 365.

After you store Cisco Jabber data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, retention policies and retention labels, and Communication Compliance. By using a Cisco Jabber connector to import and archive data in Microsoft 365, your organization can stay compliant with government and regulatory policies.

Overview of archiving Cisco Jabber data

The following overview explains the process of using a data connector to archive Cisco Jabber data in Microsoft 365.

1. Your organization works with 17a-4 to set up and configure the Cisco Jabber DataParser.

2. The DataParser regularly collects Cisco Jabber items and converts the content of a message to an email message format.

3. You create the Cisco Jabber DataParser connector in the Microsoft Purview portal. The connector connects to DataParser and transfers the messages to a secure Azure Storage location in the Microsoft cloud.

4. The connector creates a subfolder in the Inbox folder named **Cisco Jabber DataParser** in the user mailboxes and imports the Cisco Jabber items to that folder. The connector uses the value of the *Email* property to determine which mailbox to import items to. Every Cisco Jabber item contains this property, which is populated with the email address of every participant.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

- Create a DataParser account for Microsoft connectors. To create an account, contact 17a-4 LLC. You need to sign in to this account when you set up the Cisco Jabber DataParser connector in the Microsoft Purview portal.

- Assign the Data Connector Admin role to the user who sets up the Cisco Jabber DataParser connector in the Microsoft Purview portal and completes the user mapping configuration. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Step 1: Set up a Cisco Jabber DataParser connector

Create a 17a-4 connector for Cisco Jabber data in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **Cisco Jabber DataParser**.
5. On the **Terms of service** page, select **Accept**.
6. Enter a unique name that identifies the connector and then select **Next**.
7. Sign in to your 17a-4 account and complete the steps in the Cisco Jabber DataParser connection workflow.

Step 2: Configure the Cisco Jabber DataParser connector

Work with 17a-4 Support to configure the Cisco Jabber DataParser connector.

Step 3: Map Cisco Jabber users to Microsoft 365 users

The Cisco Jabber DataParser connector automatically maps users to their Microsoft 365 email addresses before importing data to Microsoft 365.

Step 4: Monitor the Cisco Jabber DataParser connector

After you create a Cisco Jabber DataParser connector, you can view the connector status in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.

3. Select **My connectors**, then select the Cisco Jabber DataParser connector that you created to display the flyout page, which contains the properties and information about the connector.
4. Under **Connector status with source**, select the **Download log** link to open (or save) the status log for the connector. This log contains information about the data that's been imported to the Microsoft cloud. For more information, see View admin logs for data connectors.

Set up a connector to archive Cisco Webex data

Use the Cisco Webex DataParser from 17a-4 LLC to import and archive data from the Cisco Webex platform to user mailboxes in your Microsoft 365 organization. The DataParser includes a Cisco Webex connector that you configure to capture items from a third-party data source and import those items to Microsoft 365. The Cisco Webex DataParser connector converts Cisco Webex data to an email message format and then imports those items to user mailboxes in Microsoft 365.

After you store Cisco Webex data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, retention policies and retention labels, and Communication Compliance. By using a Cisco Webex connector to import and archive data in Microsoft 365, you can help your organization stay compliant with government and regulatory policies.

Overview of archiving Cisco Webex data

The following overview explains the process of using a data connector to archive Cisco Webex data in Microsoft 365.

1. Your organization works with 17a-4 to set up and configure the Cisco Webex DataParser.
2. The DataParser regularly collects Cisco Webex items and converts the content of a message to an email message format.

3. You create the Cisco Webex DataParser connector in the Microsoft Purview portal. The connector connects to DataParser and transfers the messages to a secure Azure Storage location in the Microsoft cloud.

4. The connector creates a subfolder in the Inbox folder named **Cisco Webex DataParser** in the user mailboxes and imports the Cisco Webex items to that folder. The connector uses the value of the *Email* property to determine which mailbox to import items to. Every Cisco Webex item contains this property, which is populated with the email address of every participant.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

- Create a DataParser account for Microsoft connectors. To create an account, contact 17a-4 LLC. You need to sign in to this account when you create the connector in Step 1.

- Assign the Data Connector Admin role to the user who creates the Cisco Webex DataParser connector in Step 1 (and completes it in Step 3). This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see:- Permissions in the Microsoft Purview portal - Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview compliance

- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Step 1: Set up a Cisco Webex DataParser connector

Create a 17a-4 connector for Cisco Webex data in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, choose **Cisco Webex DataParser**.
5. On the **Terms of service** page, select **Accept**.
6. Enter a unique name that identifies the connector and then select **Next**.
7. Sign in to your 17a-4 account and complete the steps in the Cisco Webex DataParser connection workflow.

Step 2: Configure the Cisco Webex DataParser connector

Work with 17a-4 Support to configure the Cisco Webex DataParser connector.

Step 3: Map users

The Cisco Webex DataParser connector automatically maps users to their Microsoft 365 email addresses before importing data to Microsoft 365.

Step 4: Monitor the Cisco Webex DataParser connector

After you create a Cisco Webex DataParser connector, you can view the connector status in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select the Cisco Webex DataParser connector that you created to display the flyout page, which contains the properties and information about the connector.
4. Under **Connector status with source**, select the **Download log** link to open (or save) the status log for the connector. This log contains information about the data that's imported to the Microsoft cloud. For more information, see View admin logs for data connectors.

Limits

Importing attachments or items supports files up to 10 MB.

Set up a connector to archive FactSet data

Use the FactSet DataParser from 17a-4 LLC to import and archive data from the FactSet platform to user mailboxes in your Microsoft 365 organization. The DataParser includes a FactSet connector that you configure to capture items from a third-party data source and import those items to Microsoft 365. The FactSet DataParser connector converts FactSet data to an email message format and then imports those items to user mailboxes in Microsoft 365.

After storing FactSet data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, retention policies and retention labels, and Communication Compliance. By using a FactSet connector to import and archive data in Microsoft 365, your organization can stay compliant with government and regulatory policies.

Overview of archiving FactSet data

The following overview explains the process of using a data connector to archive FactSet data in Microsoft 365.

1. Your organization works with 17a-4 to set up and configure the FactSet DataParser.

2. The DataParser regularly collects FactSet items and converts the content of a message to an email message format.

3. You create the FactSet DataParser connector in the Microsoft Purview portal. The connector connects to DataParser and transfers the messages to a secure Azure Storage location in the Microsoft cloud.

4. The connector creates a subfolder in the Inbox folder named **FactSet DataParser** in the user mailboxes and imports the FactSet items to that folder. The connector uses the value of the *Email* property to determine which mailbox to import items to. Every FactSet item contains this property, which is populated with the email address of every participant.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

- Create a DataParser account for Microsoft connectors. To do this, contact 17a-4 LLC. You need to sign in to this account when you create the connector in the Microsoft Purview portal.

- Assign the Data Connector Admin role to the user who creates the FactSet DataParser connector in the Microsoft Purview portal and completes the user-mapping configuration. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and

processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Step 1: Set up a FactSet DataParser connector

Create a 17a-4 connector for FactSet data in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **FactSet DataParser**.
5. On the **Terms of service** page, select **Accept**.
6. Enter a unique name that identifies the connector and then select **Next**.
7. Sign in to your 17a-4 account and complete the steps in the FactSet DataParser connection workflow.

Step 2: Configure the FactSet DataParser connector

Work with 17a-4 Support to configure the FactSet DataParser connector.

Step 3: Map FactSet users to Microsoft 365 users

The FactSet DataParser connector automatically maps users to their Microsoft 365 email addresses before importing data to Microsoft 365.

Step 4: Monitor the FactSet DataParser connector

After you create a FactSet DataParser connector, you can view the connector status in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select the FactSet DataParser connector that you created to display the connector properties and information.
4. Under **Connector status with source**, select the **Download log** link to open or save the status log for the connector. This log contains information about the data imported to the

Microsoft cloud. For more information, see View admin logs for data connectors.

Data connector limits for FactSet archiving

Importing attachments or items supports files up to 10 MB.

Set up a connector to archive FX Connect data

Use the FX Connect DataParser from 17a-4 LLC to import and archive data from FX Connect to user mailboxes in your Microsoft 365 organization. The DataParser includes a FX Connect connector that's configured to capture items from a third-party data source and import those items to Microsoft 365. The FX Connect DataParser connector converts FX Connect data to an email message format and then imports those items to user mailboxes in Microsoft 365.

After you store FX Connect data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, retention policies and retention labels, and Communication Compliance. By using a FX Connect connector to import and archive data in Microsoft 365, your organization can stay compliant with government and regulatory policies.

Overview of archiving FX Connect data

The following overview explains the process of using a data connector to archive FX Connect data in Microsoft 365.

1. Your organization works with 17a-4 to set up and configure the FX Connect DataParser.

2. The DataParser regularly collects FX Connect items. The DataParser also converts the content of a message to an email message format.

3. You create the FX Connect DataParser connector in the Microsoft Purview portal. The connector connects to DataParser and transfers the messages to a secure Azure Storage location in the Microsoft cloud.

4. The connector creates a subfolder in the Inbox folder named **FX Connect DataParser** in the user mailboxes, and imports the FX Connect items to that folder. The connector uses the value of the *Email* property to determine which mailbox to import items to. Every FX Connect item contains this property, which is populated with the email address of every participant.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned **service principal** for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see **Provision a service principal for partner third-party data connectors**.

- Create a DataParser account for Microsoft connectors. To do this, contact 17a-4 LLC. You need to sign in to this account when you create the connector in the Set up a FX Connect DataParser connector procedure.

- Assign the Data Connector Admin role to the user who creates the FX Connect DataParser connector in Step 1 (and completes it in Step 3). This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and

processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Step 1: Set up a FX Connect DataParser connector

Create a 17a-4 connector for FX Connect data in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **FX Connect DataParser**.
5. On the **Terms of service** page, select **Accept**.
6. Enter a unique name that identifies the connector and then select **Next**.
7. Sign in to your 17a-4 account and complete the steps in the FX Connect DataParser connection workflow.

Step 2: Configure the FX Connect DataParser connector

Work with 17a-4 Support to configure the FX Connect DataParser connector.

Step 3: Map FX Connect users to Microsoft 365 users

The FX Connect DataParser connector automatically maps users to their Microsoft 365 email addresses before importing data to Microsoft 365.

Step 4: Monitor the FX Connect DataParser connector

After you create a FX Connect DataParser connector, you can view the connector status in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select the FX Connect DataParser connector that you created to display the flyout page, which contains the properties and information about the connector.
4. Under **Connector status with source**, select the **Download log** link to open (or save) the status log for the connector. This log contains information about the data that's been

imported to the Microsoft cloud. For more information, see View admin logs for data connectors.

Connector limits for archiving FX Connect data

Importing attachments or items supports files up to 10 MB.

Set up a connector to archive ICE Connect Chat data

Use the ICE DataParser from 17a-4 LLC to import and archive data from ICE Connect Chat to user mailboxes in your Microsoft 365 organization. The DataParser includes an ICE Chat connector that's configured to capture items from a third-party data source and import those items to Microsoft 365. The ICE DataParser connector converts ICE Connect Chat data to an email message format and then imports those items to user mailboxes in Microsoft 365.

After you store ICE Connect Chat data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, retention policies and retention labels, and Communication Compliance. By using an ICE DataParser connector to import and archive data in Microsoft 365, you can help your organization stay compliant with government and regulatory policies.

Overview of archiving ICE Chat data

The following overview explains the process of using a data connector to archive ICE Connect Chat data in Microsoft 365.

1. Your organization works with 17a-4 to set up and configure the ICE DataParser.
2. The DataParser regularly collects ICE Connect Chat items. The DataParser also converts the content of a message to an email message format.
3. You create the ICE DataParser connector in the Microsoft Purview portal. The connector connects to DataParser and transfers the messages to a secure Azure Storage location in the Microsoft cloud.
4. The connector creates a subfolder in the Inbox folder named **ICE DataParser** in the user mailboxes, and imports the ICE Connect Chat items to that folder. The connector uses the value of the *Email* property to determine which mailbox to import items to. Every ICE Connect Chat item contains this property, which is populated with the email address of every participant.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see **Provision a service principal for partner third-party data connectors**.

- Create a DataParser account for Microsoft connectors. To create an account, contact 17a-4 LLC. You need to sign in to this account when you set up the ICE DataParser connector in the Microsoft Purview portal.
- Assign the Data Connector Admin role to the user who creates the ICE DataParser connector in the Microsoft Purview portal and completes the user-mapping configuration. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Step 1: Set up an ICE DataParser connector

Create a 17a-4 connector for ICE Connect Chat data in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. Select **ICE DataParser** from the list.
5. Select **Accept** on the **Terms of service** page.
6. Enter a unique name that identifies the connector, then select **Next**.
7. Sign in to your 17a-4 account and complete the steps in the ICE DataParser connection workflow.

Step 2: Configure the ICE DataParser connector

Work with 17a-4 Support to configure the ICE DataParser connector.

Step 3: Map ICE Connect Chat users to Microsoft 365 users

The ICE DataParser connector automatically maps users to their Microsoft 365 email addresses before importing data to Microsoft 365.

Step 4: Monitor the ICE DataParser connector

After you create an ICE DataParser connector, you can view the connector status in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.

3. Select **My connectors**, then select the ICE DataParser connector that you created to display the flyout page, which contains the properties and information about the connector.
4. Under **Connector status with source**, select the **Download log** link to open (or save) the status log for the connector. This log contains information about the data that's been imported to the Microsoft cloud. For more information, see View admin logs for data connectors.

ICE Connect Chat connector limits

Importing attachments or items supports files up to 10 MB.

Set up a connector to archive InvestEdge data

Use the InvestEdge DataParser from 17a-4 LLC to import and archive data from InvestEdge to user mailboxes in your Microsoft 365 organization. The DataParser includes an InvestEdge connector that's configured to capture items from a third-party data source and import those items to Microsoft 365. The InvestEdge DataParser connector converts InvestEdge data to an email message format and then imports those items to user mailboxes in Microsoft 365.

After storing InvestEdge data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, retention policies and retention labels, and Communication Compliance. By using an InvestEdge connector to import and archive data in Microsoft 365, your organization can stay compliant with government and regulatory policies.

Overview of archiving InvestEdge data

The following overview explains the process of using a data connector to archive InvestEdge data in Microsoft 365.

1. Your organization works with 17a-4 to set up and configure the InvestEdge DataParser.

2. The DataParser regularly collects InvestEdge items and converts the content of a message to an email message format.

3. You create the InvestEdge DataParser connector in the Microsoft Purview portal. The connector connects to DataParser and transfers the messages to a secure Azure Storage location in the Microsoft cloud.

4. The connector creates a subfolder in the Inbox folder named **InvestEdge DataParser** in the user mailboxes and imports the InvestEdge items to that folder. The connector uses the value of the *Email* property to determine which mailbox to import items to. Every InvestEdge item contains this property, which is populated with the email address of every participant.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

- Create a DataParser account for Microsoft connectors. To create an account, contact 17a-4 LLC. You need to sign in to this account when you set up the InvestEdge DataParser connector in the Microsoft Purview portal.

- Assign the Data Connector Admin role to the user who sets up the InvestEdge DataParser connector in the Microsoft Purview portal and completes the user-mapping configuration. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Step 1: Set up an InvestEdge DataParser connector

Create a 17a-4 connector for InvestEdge data in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **InvestEdge DataParser**.
5. On the **Terms of service** page, select **Accept**.
6. Enter a unique name that identifies the connector and then select **Next**.
7. Sign in to your 17a-4 account and complete the steps in the InvestEdge DataParser connection workflow.

Step 2: Configure the InvestEdge DataParser connector

Work with 17a-4 Support to configure the InvestEdge DataParser connector.

Step 3: Map InvestEdge users to Microsoft 365 users

The InvestEdge DataParser connector automatically maps users to their Microsoft 365 email addresses before importing data to Microsoft 365.

Step 4: Monitor the InvestEdge DataParser connector

After you create an InvestEdge DataParser connector, you can view the connector status in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select the InvestEdge DataParser connector that you created to display the flyout page, which contains the properties and information about the connector.

4. Under **Connector status with source**, select the **Download log** link to open (or save) the status log for the connector. This log contains information about the data that's imported to the Microsoft cloud. For more information, see View admin logs for data connectors.

InvestEdge DataParser connector limits

Importing attachments or items supports files up to 10 MB.

Set up a connector to archive LivePerson Conversational Cloud data

Use the LivePerson Conversational Cloud DataParser from 17a-4 LLC to import and archive data from LivePerson Conversational Cloud to user mailboxes in your Microsoft 365 organization. The DataParser includes a LivePerson Conversational Cloud connector that's configured to capture items from a third-party data source and import those items to Microsoft 365. The LivePerson Conversational Cloud DataParser connector converts data to an email message format and then imports those items to user mailboxes in Microsoft 365.

After you store data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, retention policies and retention labels, and Communication Compliance. By using a LivePerson Conversational Cloud connector to import and archive data in Microsoft 365, you help your organization stay compliant with government and regulatory policies.

Overview of archiving LivePerson Conversational Cloud data

The following overview explains the process of using a data connector to archive LivePerson Conversational Cloud data in Microsoft 365.

1. Your organization works with 17a-4 to set up and configure the LivePerson Conversational Cloud DataParser.

2. The DataParser regularly collects LivePerson Conversational Cloud items and converts the content of a message to an email message format.

3. You create the LivePerson Conversational Cloud DataParser connector in the Microsoft Purview portal. The connector connects to DataParser and transfers the messages to a secure Azure Storage location in the Microsoft cloud.

4. The connector creates a subfolder in the Inbox folder named **LivePerson Conversational Cloud DataParser** in the user mailboxes and imports the items to that folder. The connector uses the value of the *Email* property to determine which mailbox to import items to. Every item contains this property, which is populated with the email address of every participant.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.

To provision a service principal using PowerShell, see **Provision a service principal for partner third-party data connectors**.

- Create a DataParser account for Microsoft connectors. To create an account, contact 17a-4 LLC. You need to sign in to this account when you set up the LivePerson Conversational Cloud DataParser connector in the Microsoft Purview portal.
- Assign the Data Connector Admin role to the user who sets up and completes the LivePerson Conversational Cloud DataParser connector configuration in the Microsoft Purview portal. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.
- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Step 1: Set up a LivePerson Conversational Cloud DataParser connector

Create a 17a-4 connector for LivePerson Conversational Cloud data in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **LivePerson Conversational Cloud DataParser**.
5. On the **Terms of service** page, select **Accept**.
6. Enter a unique name that identifies the connector and then select **Next**.

7. Sign in to your 17a-4 account and complete the steps in the LivePerson Conversational Cloud DataParser connection workflow.

Step 2: Configure the LivePerson Conversational Cloud DataParser connector

Work with 17a-4 Support to configure the LivePerson Conversational Cloud DataParser connector.

Step 3: Map LivePerson Conversational Cloud users to Microsoft 365 users

The LivePerson Conversational Cloud DataParser connector automatically maps users to their Microsoft 365 email addresses before importing data to Microsoft 365.

Step 4: Monitor the LivePerson Conversational Cloud DataParser connector

After you create a LivePerson Conversational Cloud DataParser connector, you can view the connector status in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select the LivePerson Conversational Cloud DataParser connector that you created to display the flyout page, which contains the properties and information about the connector.
4. Under **Connector status with source**, select the **Download log** link to open (or save) the status log for the connector. This log contains information about the data that's been imported to the Microsoft cloud. For more information, see View admin logs for data connectors.

Connector limits for archiving LivePerson Conversational Cloud data

Importing attachments or items supports files up to 10 MB.

Set up a connector to archive Quip data

Use the Quip DataParser from 17a-4 LLC to import and archive data from Quip to user mailboxes in your Microsoft 365 organization. The DataParser includes a Quip connector that's configured to capture items from a third-party data source and import those items to Microsoft 365. The Quip DataParser connector converts Quip data to an email message format and then imports those items to user mailboxes in Microsoft 365.

After storing Quip data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, retention policies and retention labels, and Communication Compliance. By using a Quip connector to import and archive data in Microsoft 365, your organization can stay compliant with government and regulatory policies.

Overview of archiving Quip data

The following overview explains the process of using a data connector to archive Quip data in Microsoft 365.

1. Your organization works with 17a-4 to set up and configure the Quip DataParser.

2. The DataParser regularly collects Quip items and converts the content of a message to an email message format.

3. You create the Quip DataParser connector in the Microsoft Purview portal. The connector connects to DataParser and transfers the messages to a secure Azure Storage location in the Microsoft cloud.

4. The connector creates a subfolder in the Inbox folder named **Quip DataParser** in the user mailboxes and imports the Quip items to that folder. The connector uses the value of the *Email* property to determine which mailbox to import items to. Every Quip item contains the *Email* property, which is populated with the email address of every participant.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

- Create a DataParser account for Microsoft connectors. To create an account, contact 17a-4 LLC. You need to sign in to the DataParser account when you create the connector in Step 1.

- Assign the Data Connector Admin role to the user who creates the Quip DataParser connector in Step 1 (and completes it in Step 3). This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the

Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Step 1: Set up a Quip DataParser connector

Create the Quip DataParser connector

Create a 17a-4 connector for Quip data in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **Quip DataParser**.
5. On the **Terms of service** page, select **Accept**.
6. Enter a unique name that identifies the connector and then select **Next**.
7. Sign in to your 17a-4 account and complete the steps in the Quip DataParser connection workflow.

Step 2: Configure the Quip DataParser connector

Work with 17a-4 Support to configure the Quip DataParser connector.

Step 3: Map Quip users to Microsoft 365 users

The Quip DataParser connector automatically maps users to their Microsoft 365 email addresses before importing data to Microsoft 365.

Step 4: Monitor the Quip DataParser connector

After you create a Quip DataParser connector, you can view the connector status in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select the Quip DataParser connector that you created to display the flyout page, which contains the properties and information about the connector.

4. Under **Connector status with source**, select the **Download log** link to open (or save) the status log for the connector. This log contains information about the data that's been imported to the Microsoft cloud. For more information, see View admin logs for data connectors.

Set up a connector to archive Refinitiv Eikon Messenger data

Use the Refinitiv Eikon Messenger DataParser from 17a-4 LLC to import and archive data from Refinitiv Eikon Messenger to user mailboxes in your Microsoft 365 organization. The DataParser includes a Refinitiv Eikon Messenger connector that's configured to capture items from a third-party data source and import those items to Microsoft 365. The Refinitiv Eikon Messenger DataParser connector converts Refinitiv Eikon Messenger data to an email message format and then imports those items to user mailboxes in Microsoft 365.

After you store Refinitiv Eikon Messenger data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, retention policies and retention labels, and Communication Compliance. By using a Refinitiv Eikon Messenger connector to import and archive data in Microsoft 365, you can help your organization stay compliant with government and regulatory policies.

Overview of archiving Refinitiv Eikon Messenger data

The following overview explains the process of using a data connector to archive Refinitiv Eikon Messenger data in Microsoft 365.

1. Your organization works with 17a-4 to set up and configure the Refinitiv Eikon Messenger DataParser.
2. The DataParser regularly collects Refinitiv Eikon Messenger items. The DataParser also converts the content of a message to an email message format.
3. The Refinitiv Eikon Messenger DataParser connector that you create in the Microsoft Purview portal connects to DataParser and transfers the messages to a secure Azure Storage location in the Microsoft cloud.
4. The connector creates a subfolder in the Inbox folder named **Refinitiv Eikon Messenger DataParser** in the user mailboxes and imports the Refinitiv Eikon Messenger items to that folder. The connector uses the value of the *Email* property to determine which mailbox to import items to. Every Refinitiv Eikon Messenger item contains this property, which is populated with the email address of every participant.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

- Create a DataParser account for Microsoft connectors. To create an account, contact 17a-4 LLC. You need to sign in to this account when you create the connector in the Microsoft Purview portal.
- Assign the Data Connector Admin role to the user who creates and completes the Refinitiv Eikon Messenger DataParser connector setup in the Microsoft Purview portal. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the

Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Set up a connector to archive Slack data

Use DataParser from 17a-4 LLC to import and archive data from the Slack platform to user mailboxes in your Microsoft 365 organization. DataParser includes a Slack connector that's configured to capture items from a third-party data source and import those items to Microsoft 365. The Slack DataParser connector converts Slack data to an email message format and then imports those items to user mailboxes in Microsoft 365.

After you store Slack data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, retention policies and retention labels, and Communication Compliance. By using a Slack connector to import and archive data in Microsoft 365, you help your organization stay compliant with government and regulatory policies.

Overview of archiving Slack data

The following overview explains the process of using a data connector to archive Slack data in Microsoft 365.

1. Your organization works with 17a-4 to set up and configure the Slack DataParser.

2. The DataParser regularly collects Slack items and converts the content of a message to an email message format.

3. You create the Slack DataParser connector in the Microsoft Purview portal. The connector connects to DataParser and transfers the messages to a secure Azure Storage location in the Microsoft cloud.

4. The connector creates a subfolder in the Inbox folder named **Slack DataParser** in the user mailboxes and imports the Slack items to that folder. The connector uses the value of the *Email* property to determine which mailbox to import items to. Every Slack item contains this property, which is populated with the email address of every participant.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

- Create a DataParser account for Microsoft connectors. To do this, contact 17a-4 LLC. You need to sign in to this account when you create the connector in the Microsoft Purview portal.

- Assign the Data Connector Admin role to the user who creates the Slack DataParser connector in the Microsoft Purview portal and completes the user-mapping configuration. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and

processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Step 1: Set up a Slack DataParser connector

Create a 17a-4 connector for Slack data in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. Select **Slack DataParser** from the list.
5. Select **Accept** on the **Terms of service** page.
6. Enter a unique name that identifies the connector, then select **Next**.
7. Sign in to your 17a-4 account and complete the steps in the Slack DataParser connection workflow.

Step 2: Configure the Slack DataParser connector

Work with 17a-4 Support to configure the Slack DataParser connector.

Step 3: Map Slack users to Microsoft 365 users

The Slack DataParser connector automatically maps users to their Microsoft 365 email addresses before importing data to Microsoft 365.

Step 4: Monitor the Slack DataParser connector

After you create a Slack DataParser connector, you can view the connector status in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select the Slack DataParser connector that you created to display the flyout page, which contains the properties and information about the connector.
4. Under **Connector status with source**, select the **Download log** link to open (or save) the status log for the connector. This log contains information about the data that's been

imported to the Microsoft cloud. For more information, see View admin logs for data connectors.

Connector limits for archiving Slack data

Importing attachments or items supports files up to 10 MB.

Set up a connector to archive SQL data

Use the SQL DataParser from 17a-4 LLC to import and archive data from a SQL database. The connector stores that data in user mailboxes in your Microsoft 365 organization. The DataParser captures items from the SQL source and converts them to an email message format. It then imports those items to Microsoft 365.

After SQL data is stored in user mailboxes, you can apply Microsoft Purview features. These features include Litigation Hold, eDiscovery, retention policies, retention labels, and Communication Compliance. A SQL connector helps your organization stay compliant with government and regulatory policies.

Overview of archiving SQL data

The following overview explains the process of using a data connector to archive SQL data in Microsoft 365.

1. Your organization works with 17a-4 to set up and configure the SQL DataParser.
2. The DataParser regularly collects SQL items and converts the content of a message to an email message format.

3. You create the SQL DataParser connector in the Microsoft Purview portal. The connector connects to DataParser and transfers the messages to a secure Azure Storage location in the Microsoft cloud.

4. The connector creates a subfolder in the Inbox folder named **SQL DataParser** in the user mailboxes and imports the SQL items to that folder. The connector uses the value of the *Email* property to determine which mailbox to import items to. Every SQL item contains this property, which is populated with the email address of every participant.

Before you begin

Complete the following prerequisites before you create the SQL DataParser connector:

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

- Create a DataParser account for Microsoft connectors. To create an account, contact 17a-4 LLC. You need to sign in to this account when you create the connector in the Microsoft Purview portal.

- Assign the Data Connector Admin role to the user who creates the SQL DataParser connector in the Microsoft Purview portal and completes the user mapping configuration. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the

Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Step 1: Set up a SQL DataParser connector

Create a 17a-4 connector for SQL data in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **SQL DataParser**.
5. On the **Terms of service** page, select **Accept**.
6. Enter a unique name that identifies the connector and then select **Next**.
7. Sign in to your 17a-4 account and complete the steps in the SQL DataParser connection workflow.

Step 2: Configure the SQL DataParser connector

Work with 17a-4 Support to configure the SQL DataParser connector.

Step 3: Map SQL source users to Microsoft 365 users

The SQL DataParser connector automatically maps users to their Microsoft 365 email addresses before importing data to Microsoft 365.

Step 4: Monitor the SQL DataParser connector

After you create a SQL DataParser connector, you can view the connector status in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select the SQL DataParser connector that you created to display the flyout page, which contains the properties and information about the connector.
4. Under **Connector status with source**, select the **Download log** link to open or save the status log for the connector. This log contains information about the data that's been

imported to the Microsoft cloud. For more information, see View admin logs for data connectors.

SQL data connector limits

Importing attachments or items supports files up to 10 MB.

Set up a connector to archive Symphony data

Use the Symphony DataParser from 17a-4 LLC to import and archive Symphony communications data to user mailboxes in your Microsoft 365 organization. The DataParser includes a Symphony connector that you configure to capture items from a third-party data source and import those items to Microsoft 365. The Symphony DataParser connector converts Symphony data to an email message format and then imports those items to user mailboxes in Microsoft 365.

After storing Symphony data in user mailboxes, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, retention policies and retention labels, and Communication Compliance. By using a Symphony connector to import and archive data in Microsoft 365, you help your organization stay compliant with government and regulatory policies.

Overview of archiving Symphony data

The following overview explains the process of using a data connector to archive Symphony data in Microsoft 365.

1. Your organization works with 17a-4 to set up and configure the Symphony DataParser.
2. The DataParser regularly collects Symphony items and converts the content of a message to an email message format.
3. You create the Symphony DataParser connector in the Microsoft Purview portal. The connector connects to DataParser and transfers the messages to a secure Azure Storage location in the Microsoft cloud.
4. The connector creates a subfolder in the Inbox folder named **Symphony DataParser** in the user mailboxes and imports the Symphony items to that folder. The connector uses the value of the *Email* property to determine which mailbox to import items to. Every Symphony item contains this property, which is populated with the email address of every participant.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

- Create a DataParser account for Microsoft connectors. To create an account, contact 17a-4 LLC. You need to sign in to this account when you set up the Symphony DataParser connector.
- Assign the Data Connector Admin role to the user who sets up the Symphony DataParser connector and completes the user-mapping configuration. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Step 1: Set up a Symphony DataParser connector

Create a 17a-4 connector for Symphony data in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. From the list, select **Symphony DataParser**.
5. On the **Terms of service** page, select **Accept**.
6. Enter a unique name that identifies the connector and then select **Next**.
7. Sign in to your 17a-4 account and complete the steps in the Symphony DataParser connection workflow.

Step 2: Configure the Symphony DataParser connector

Work with 17a-4 Support to configure the Symphony DataParser connector.

Step 3: Map Symphony users to Microsoft 365 users

The Symphony DataParser connector automatically maps users to their Microsoft 365 email addresses before importing data to Microsoft 365.

Step 4: Monitor the Symphony DataParser connector

After you create a Symphony DataParser connector, you can view the connector status in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select the Symphony DataParser connector that you created to display the flyout page, which contains the properties and information about the connector.

4. Under **Connector status with source**, select the **Download log** link to open (or save) the status log for the connector. This log contains information about the data that's been imported to the Microsoft cloud. For more information, see View admin logs for data connectors.

Connector limits for archiving Symphony data

Importing attachments or items supports files up to 10 MB.

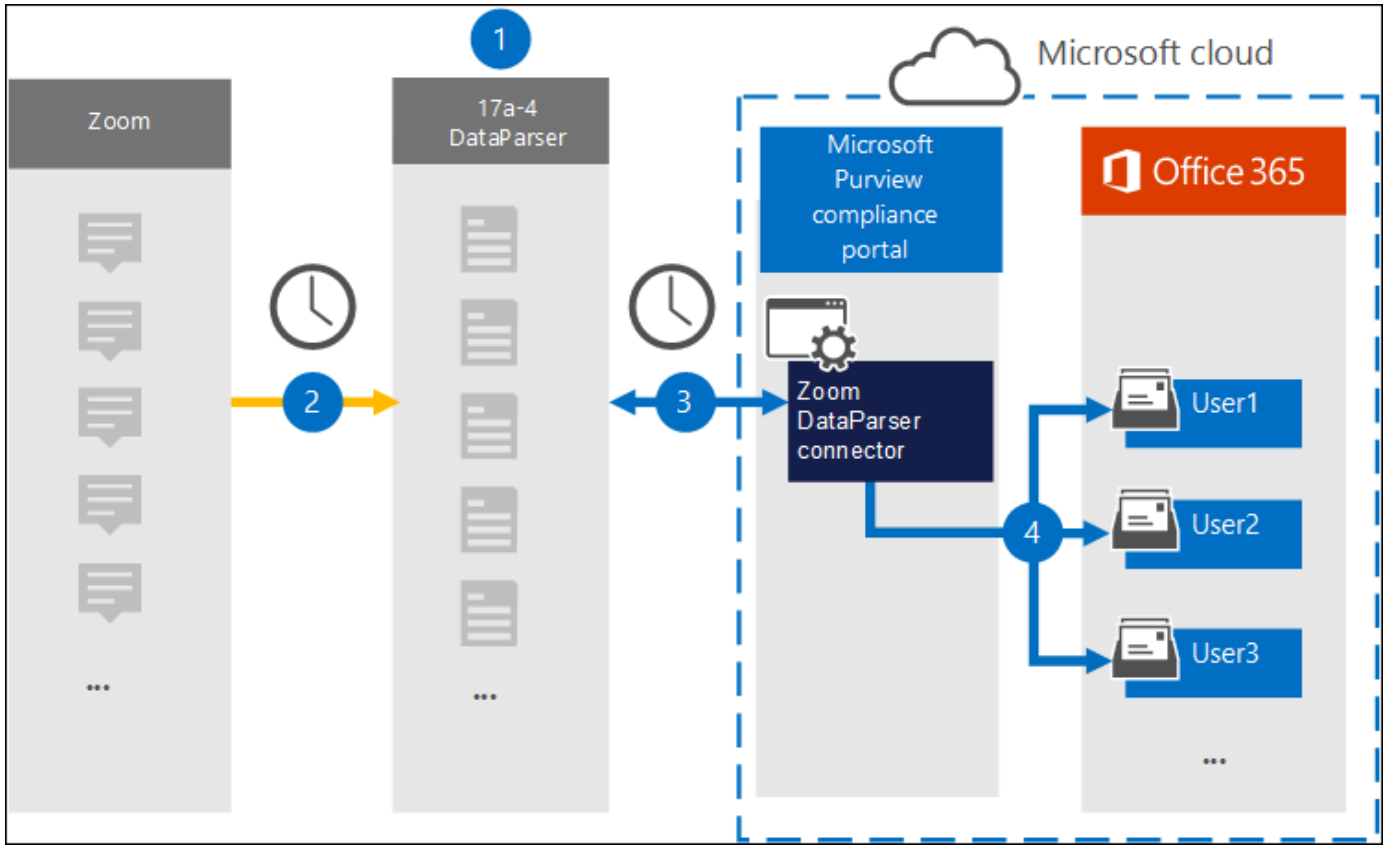
Set up a connector to archive Zoom data



Archive Zoom data with the 17a-4 Zoom DataParser connector

Use the Zoom DataParser from 17a-4 LLC to import and archive data from the Zoom platform to user mailboxes in your Microsoft 365 organization. The DataParser includes a Zoom connector that captures items from a third-party data source. It then converts Zoom data to an email message format and imports those items to user mailboxes in Microsoft 365.

After Zoom data is stored in user mailboxes, you can apply Microsoft Purview features. These features include Litigation Hold, eDiscovery, retention policies, retention labels, and Communication Compliance. Using a Zoom connector to import and archive data in Microsoft 365 helps your organization stay compliant with government and regulatory policies.

Overview of archiving Zoom data

The following overview explains the process of using a data connector to archive Zoom data in Microsoft 365.

1. Your organization works with 17a-4 to set up and configure the Zoom DataParser.
2. The DataParser regularly collects Zoom items and converts the content of a message to an email message format.
3. You create the Zoom DataParser connector in the Microsoft Purview portal. The connector connects to DataParser and transfers the messages to a secure Azure Storage location in the Microsoft cloud.
4. The connector creates a subfolder in the Inbox folder named **Zoom DataParser** in the user mailboxes and imports the Zoom items to that folder. The connector uses the value of the *Email* property to determine which mailbox to import items to. Every Zoom item contains this property, which is populated with the email address of every participant.

Before you begin

> **Important**
>
> All partner third-party data connector configurations require a provisioned service principal for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.
>
> To provision a service principal using PowerShell, see Provision a service principal for partner third-party data connectors.

- Create a DataParser account for Microsoft connectors. To do this, contact 17a-4 LLC. You need to sign in to this account when you create the connector in Step 1: Set up a Zoom DataParser connector.
- Assign the Data Connector Admin role to the user who creates the Zoom DataParser connector in Step 1 (and completes it in Step 3). This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.
- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and

processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.

Step 1: Set up a Zoom DataParser connector

Create a 17a-4 connector for Zoom data in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. Select **Zoom DataParser** from the list.
5. Select **Accept** on the **Terms of service** page.
6. Enter a unique name that identifies the connector, then select **Next**.
7. Sign in to your 17a-4 account and complete the steps in the Zoom DataParser connection workflow.

Step 2: Configure the Zoom DataParser connector

Work with 17a-4 Support to configure the Zoom DataParser connector.

Step 3: Map Zoom users to Microsoft 365 users

The Zoom DataParser connector automatically maps users to their Microsoft 365 email addresses before importing data to Microsoft 365.

Step 4: Monitor the Zoom DataParser connector

After you create a Zoom DataParser connector, you can view the connector status in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select the Zoom DataParser connector that you created to display the flyout page, which contains the properties and information about the connector.
4. Under **Connector status with source**, select the **Download log** link to open (or save) the status log for the connector. This log contains information about the data that's imported to

the Microsoft cloud. For more information, see View admin logs for data connectors.

Zoom data connector limits

Zoom items are the messages and related content imported by the connector. Importing attachments or items supports files up to 10 MB.

Archive data from CellTrust SL2 to Microsoft 365

CellTrust SL2 captures mobile communications data and integrates with the leading archiving technologies to meet the electronic discovery requirements for regulations such as FINRA, HIPAA, FOIA, and TCPA. The SL2 Data Connector imports mobile communication items to Microsoft 365. This article describes the process for integrating SL2 with Microsoft 365 by using the CellTrust SL2 Data Connector for archiving. To complete this process, you need a subscription to the CellTrust SL2 service and familiarity with the SL2 architecture. For information about CellTrust SL2, see https://www.celltrust.com.

After you import data to user mailboxes in Microsoft 365, you can apply Microsoft Purview features such as Litigation Hold, eDiscovery, Microsoft 365 retention policies, and Communication Compliance. By using the CellTrust SL2 Data Connector to import and archive data in Microsoft 365, your organization can stay compliant with government and regulatory policies.

Overview of archiving with the CellTrust SL2 Data Connector

CellTrust's SL2 platform captures communication data from multiple sources. SL2 data sources are either Person-to-Person (P2P) or Application-to-Person (A2P). The process described in this article pertains only to P2P data sources. For all P2P data sources, at least one party in the collaboration is an SL2 user who subscribes to the SL2 service. The following overview explains the process of using the CellTrust SL2 Data Connector in Microsoft 365.

1. SL2 users send and receive data to and from SL2 services in Microsoft Azure.

2. Your organization has an SL2 domain in CellTrust's SL2 Cloud Service environment. Your domain can have one or more organizational units (OUs). The SL2 Cloud Service transfers your data to a highly secure area in the Microsoft Azure platform, so that your data never leaves the Microsoft Azure environment. Depending on your SL2 plan (Enterprise, SMB, or Government), Microsoft Azure Global or Microsoft Azure Government hosts your domain.

3. After you create the CellTrust SL2 Data Connector in the Microsoft Purview portal, your domain and OUs (regardless of your SL2 plan) begin sending data to Microsoft 365. The data feed is structured to support reporting based on data sources, OUs, or the domain by itself. As a result, your organization needs only one connector to feed all your data sources to Microsoft 365.

4. The connector creates a folder under each mapped user with an appropriate Microsoft 365 license titled **CellTrust SL2**. This mapping connects a CellTrust SL2 user to an Microsoft 365 mailbox by using an email address. If a user ID in CellTrust SL2 has no match in Microsoft 365, the user's data isn't archived.

Before you begin

> **Important**

All partner third-party data connector configurations require a provisioned **service principal** for the partner application. This requirement isn't applicable for native Microsoft third-party data connector configurations.

To provision a service principal using PowerShell, see **Provision a service principal for partner third-party data connectors**.

- Verify that you have a domain in the CellTrust SL2 cloud service environment. For more information about obtaining a production or trial SL2 domain, Contact CellTrust.
- Get the credentials to access the administrator account for your SL2 domain.
- Assign the Data Connector Admin role to the user who creates the CellTrust SL2 data connector in the Microsoft Purview portal and completes the connector setup, including user mapping. This role is required to add connectors on the **Data connectors** page in the Microsoft Purview portal. Multiple role groups include this role by default. For a list of these role groups, see Roles in Microsoft Defender for Office 365 and Microsoft Purview. Alternatively, an admin in your organization can create a custom role group, assign the Data Connector Admin role, and then add the appropriate users as members. For instructions, see Permissions in the Microsoft Purview portal and Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.
- This data connector is available in GCC environments in the Microsoft 365 US Government cloud. Third-party applications and services might involve storing, transmitting, and processing your organization's customer data on third-party systems that are outside of the Microsoft 365 infrastructure and therefore aren't covered by the Microsoft Purview and data protection commitments. Microsoft makes no representation that use of this product to connect to third-party applications implies that those third-party applications are FedRAMP compliant.
- A domain administrator can set up a connector for the domain or any OUs in that domain. If you use the OU Administrator account, you can only set up a connector for that specific OU.
- To successfully complete the setup steps, you must be assigned a Microsoft 365 E5 license and have the proper Microsoft Office admin rights.

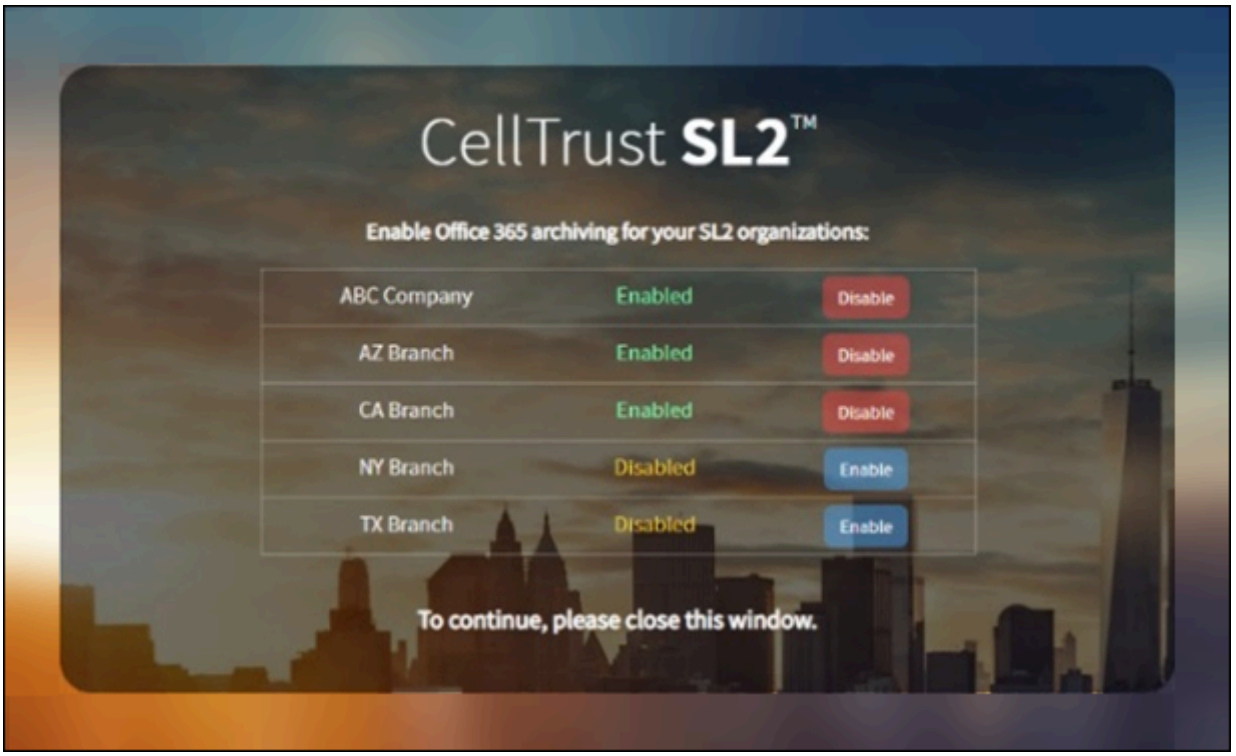
Step 1: Create a CellTrust SL2 connector

Create a data connector for CellTrust SL2 data in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select **My connectors**, then select **Add connector**.
4. Select **CellTrust SL2 (preview)** from the list.
5. Select **Accept** on the **Terms of service** page.
6. Enter a unique name that identifies the connector and select **Next**. The name you enter identifies the connector on the **Data connectors** page after you create it.
7. Select **Sign into CellTrust** on the **Sign in to your CellTrust account** page. You're redirected to the **CellTrust Portal for Microsoft 365** in a new browser window.

Step 2: Select the domains or OUs to archive

To select domains and OUs for archiving, sign in to an administrator account for your CellTrust SL2 domain and choose which domains and OUs to archive in Microsoft 365.



1. On the CellTrust **Microsoft 365 Connector** page, select your environment in the SL2 cloud service to display a sign-in page.

   Typically, you see one option representing your environment. However, if you have domains in more than one environment, you see options for each environment. After you make a selection, you're redirected to the SL2 authentication page.

2. Sign in with your Domain or OU Administrator account credentials.

   If you sign in as an SL2 domain administrator, you see the name of your domain and the OUs in that domain. If you don't have OUs, you only see the name of your domain. If you sign in as OU Administrator, you only see the name of your OU.

3. Enable the business units you want to archive. Selecting the domain doesn't automatically select the OUs. You must enable each OU separately to archive it.

4. When you finish your selections, close the browser window and return to the workflow page in Microsoft Purview portal. After a few seconds, the workflow automatically advances to the **User mapping** page.

Step 3: Map users and complete the connector setup

To complete the connector setup, map users and finalize the configuration in the Microsoft Purview portal.

1. On the **User mapping** page, select **Enable automatic user mapping** if the email address for users is the same in both SL2 and Microsoft 365. Otherwise, manually provide user email addresses by uploading a CSV file that maps users' SL2 address to their Microsoft 365 address.

2. Select **Next**, review your settings, and then select **Finish** to create the connector.

   The new connector is added to the list on the **Data connectors** page.

> **Tip**
>
> To test the new connector, send a text message using your SL2 mobile app or from your SL2 portal. Go to your Microsoft 365 mailbox and open the **CellTrust SL2** folder in your Inbox. It might take a few minutes for the text messages to show up in your mailbox.

Get help from CellTrust

For details about contacting CellTrust for help with setting up a CellTrust SL2 data connector, see the CellTrust Customer Support page.

Use Content Search to search third-party data imported by a custom partner connector

> **⊗ Caution**
>
> Microsoft retired all classic eDiscovery experiences on August 31, 2025. This retirement includes classic Content Search, classic eDiscovery (Standard), and classic eDiscovery (Premium).
>
> The guidance in this article only applies to organizations hosted in Microsoft 365 operated by 21Vianet (China). If your organization isn't hosted by 21Vianet, use the guidance for the new eDiscovery experience in the Microsoft Purview portal.

You can use the Content search eDiscovery tool in the Microsoft Purview portal to search for items imported to mailboxes in Microsoft 365 from a third-party data source. You can create a query to search all imported third-party data items or you can create a query to search specific third-party data items. Also, you can also create a query-based retention policy or a query-based eDiscovery hold to preserve third-party data.

> **ⓘ Important**
>
> The guidance in this article only applies to third-party data imported by a custom partner connector. This article doesn't apply to third-party data that is imported by using the third-party data connectors in the Microsoft Purview portal.

Creating a query to search all third-party data

To search (or place on hold) any type of third-party data that you've imported to Office 365, you can use the `kind:externaldata` message property-value pair in the keyword box for a Content Search or when creating a query-based hold. For example, to search for items imported from any third-party data source and contain the word "contoso" in the Subject property of the imported item, you would use the following query:

PowerShell

```
kind:externaldata AND subject:contoso
```

When creating queries to search and hold third-party data, you can also use conditions to narrow the search results. For more information about creating Content Search queries, see Keyword queries and search conditions for Content Search.

Creating a query to search specific types of third-party data

Instead of searching all types of third-party data, you can create queries that only search for a specify type of third-party data by using the following message *property: value* pair in the keyword box for a Content Search:

```
PowerShell
itemclass:ipm.externaldata.<third-party data type>*
```

For example, to search Facebook data that contains the word "contoso" in the Subject property, you would use the following query:

```
PowerShell
itemclass:ipm.externaldata.Facebook* AND subject:contoso
```

The following table lists the third-party data types that you can search, and the value to use for the `itemclass:` message property to specifically search for that type of third-party data. The query syntax isn't case-sensitive.

Expand table

Third-party data type	Value for `itemclass:` property
AIM	`ipm.externaldata.AIM*`
American Idol	`ipm.externaldata.AmericanIdol*`

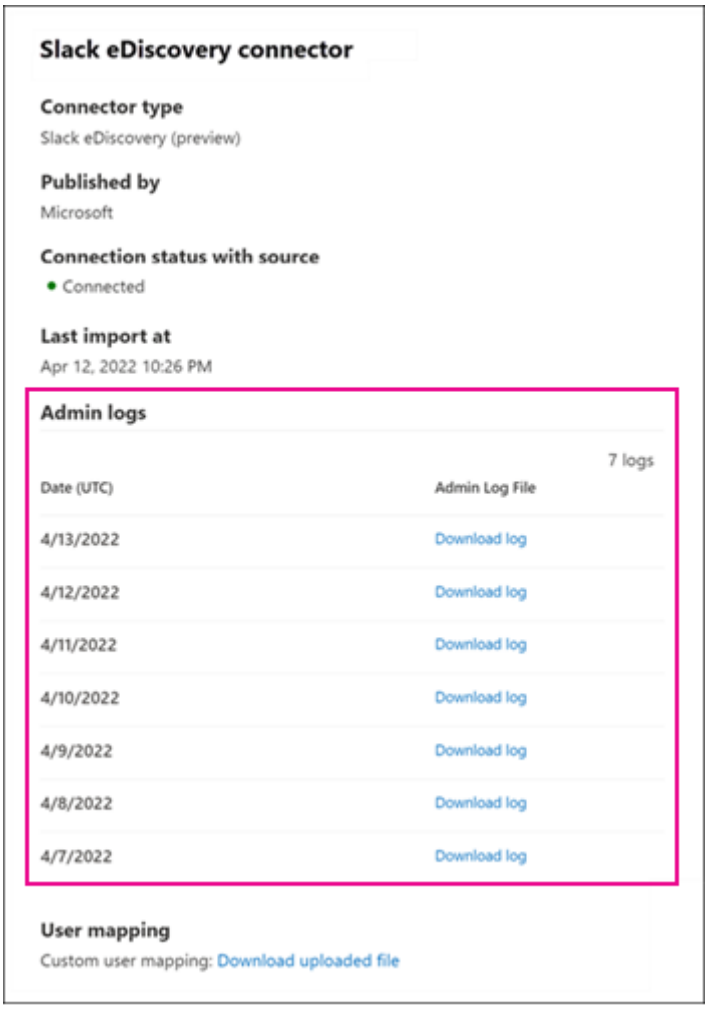
View admin logs for data connectors

09/26/2025

After you create a data connector to import non-Microsoft data to Microsoft Purview, you can monitor the daily import status of the connector by downloading the admin logs for the data connector.

Before you view admin logs

> **Important**
>
> We highly recommended that you review admin logs daily to ensure any data ingestion failures caused by erroneous data or service issues are detected early and remediated. Without daily monitoring, you could end up with irreversible loss of data.



Before you can view admin logs, make sure that you've confirmed the following:

- Auditing must be enabled for your organization to generate and view admin log for your organization. Auditing is enabled by default in Microsoft Purview. However, we recommend that you verify auditing status of your organization. For instructions, see Verify the auditing status for your organization. If you need to enable auditing for your organization, see Turn on auditing.
- After auditing is turned on, it could take up to 48 hours to generate admin logs for data connectors. We recommend that you enable auditing before you create data connectors.
- After a data connector is created, it can take up to 72 hours to generate admin logs that contain import status summary.
- Admin logs are available for the previous seven days.

Download admin logs for data connectors

To download admin logs for date connectors, complete the following steps:

1. Sign into the Microsoft Purview portal.
2. Select **Settings** > **Data connectors**.
3. Select the **My connectors** tab and then select a data connector to display the fly out page, which contains information and properties about the data connector.
4. Under **Admin logs**, select the **Download log** link to open an admin log.

5. View the following import status information in the admin log:

- **Import completion time**: timestamp (in UTC) when connector completes import from data source and all the below events are computed/updated against the import.
- **Items available from source**: count of items downloaded by Connector from data source.
- **Items available for import**: count of items available for import by Connector after fanout. Fanout represents the act of writing a message to all associated participants (sender, receiver etc.).
- **Items imported successfully**: count of items imported successfully by Connector into user mailboxes after fanout.
- **Items partially imported**: count of items imported successfully by Connector into user mailboxes after fanout but had attachments dropped.
- **Items skipped**: count of items skipped from being imported into user mailboxes after fanout due to it being duplicate items.
- **Items failed**: count of items that failed to be imported into user mailboxes after fanout due to it errors (like user mapping, item size exceeded etc.). Event is logged once per user for user mapping failures.

> **Note**
>
> Items available for import should be a sum of items imported successfully, partially imported, skipped, and failed.

- Summary of Failed item details:
  - **Item ID**: unique identifier of the item
  - **Source User ID**: user ID at source application
  - **Microsoft 365 User ID**: User Principal Name in Microsoft 365
  - **Failure Reason**: indicates the reason why the connector couldn't import the item

> **Note**
>
> If no items are imported on a particular day, the admin log contains the following message: `No items ingested on mm/dd/yyyy.`

Reingesting data after failures

Reingesting of data after failures is supported if completed within 90 days. To reingest data, select the **Help** icon in the Microsoft Purview portal to open a support case. Be prepared to provide all relevant logs to help troubleshoot any issues more quickly.

Collection Policies solution overview

Collection policies are an event collection and filtering tool in Microsoft Purview that enables monitoring and classification of events from apps and locations that lay both inside of and beyond your organizations trust boundaries. They let you filter which events from both untrusted and trusted sources are ingested into Purview. Once ingested, that data can be classified and used by various Microsoft Purview signal consuming solutions, such as Microsoft Purview Activity explorer, Microsoft Purview Insider Risk Management, Microsoft Purview eDiscovery, Microsoft Purview Data Lifecycle Management.

Collection policies can help you achieve these data security outcomes:

Only ingest the events that you want

The primary purpose of collection policies is to enable you to define the events that your organization wants to bring into Microsoft Purview, so you can focus on the data that you care about. Here are some examples of how this capability can help you.

Regulatory compliance by geopolitical location

Your organization may span geopolitical and regulatory boundaries with different regions having different data security and privacy requirements. One may require all events be ingested into Purview, while another area may be subject to restrictions on what events can be collected. Collection policies let you define the events that are collected for each region. This allows you to meet the data security and privacy requirements of each region while still having a single consolidated view into your organization's sensitive information.

Filter out unnecessary events

Your organization may have many events that are being collected, but you only want to see the events that are relevant to your needs. For example, say your organization has onboarded all devices and enabled **Always audit file activity for devices** in Endpoint DLP settings. This means that all file activity is being collected and placed into activity explorer. Sifting through all events may slow event investigation as you sort out the unwanted data to get to the data you need. With collection policies, you can filter out the events that you don't want to see before they get to activity explorer. This can help reduce noise and make it easier to find the events that are relevant to your organization.

How collection policies work

The key to understanding collection policies is to know what an event is.

An *event* is made up of two things:

- A *condition*, like **Content contains**, or **File extension is**. This requires the use of classifiers, like sensitive information types. For example, a condition could be **Content contains** a sensitive information type, like **U.S. Social Security Number** or **File extension is** > **.docx**.
- An *activity* that a user can take on a sensitive item, like **File copied to removable media**

Collection policies filter events based on:

- A match to one or more conditions and activities defined in the event.
- A match to the *data source* or location where the event is happening. For example, a collection policy can be scoped to only collect events from devices, or only collect events from Copilot in Fabric.

A policy is considered matched when one or more of the conditions are met (unless you AND the conditions) and the activity is matched on the data source.

Multiple collection policies for single data source

It's possible your organization will need to create multiple collection policies for any given data source. Collection policies handle the multiple policy scenario differently than DLP or other Purview policies, which assign a priority to policy evaluation based on the order in which the policies are created.

On the collection polices page, you see all the individual policies that have been created. But on the back end, during policy evaluation, Microsoft Purview combines all the collection policies for a data source into a single collection policy for that data source. So all the conditions for a data source are used when identifying matches.

Accessing collection policies

Collection policies are a component of the Microsoft Purview portal **Classifiers** feature. You can access them from anywhere in the Purview portal where the **Classifiers** feature is available. For example,

- In the Microsoft Purview portal, select **Solutions** > **Data Loss Prevention** > **Classifiers** > **Collection policies**.

- Alternately, you can access collection policies in the Microsoft Purview portal from **Solutions** > **Information Protection** > **Classifiers** > **Collection policies**.

Collection policy configuration overview

You have flexibility in how you create and configure your collection policies. All collection policies require the same information from you. You must know this information *before* you start creating a collection policy. For additional details about each step, including supported configuration, see Collection policies policy reference.

1. Define **data to detect** by configuring conditions required for a policy match. There are four supported conditions:

    - **Content contains classifiers**, which makes use of sensitive information types and trainable classifiers. Can be scoped to all classifiers, all classifiers except selected ones, or only specific classifiers.

      > ⓘ Note
      >
      > The devices location doesn't support using trainable classifiers.

    - **Document size equals or is greater than**, as measured in bytes, kilobytes (KB), megabytes (MB), gigabytes (GB), or terabytes (TB).
    - **Document is equal to or smaller than**, as measured in bytes, kilobytes (KB), megabytes (MB), gigabytes (GB), or terabytes (TB).
    - **File extension is**, which makes use of file extensions.

2. Choose the **activities** required for a policy match - The supported activities are specific for the data source. For devices, there are 19 supported activities, such as **File copied to removable media**, **File printed**, and **File uploaded to cloud**. A full list of the supported activities is available in the Collection policies policy reference.

3. Choose **where to apply** the policy by selecting a data source.

4. Depending on the policy settings you choose, you may have additional settings to configure, such as whether or not to enable content capture for AI interactions and the cloud apps detection method.

Content capture for AI interactions

To help comply with regulatory requirements, you can decide whether to capture and store all detected prompts and responses from any generative AI data sources added to the policy. This makes it easy to discover and protect the captured content later with additional Microsoft Purview policies and solutions. This capability doesn't include content in files shared with generative AI, and only applies to:

- Copilot experiences
- Enterprise AI
- Unmanaged cloud apps categorized as generative AI
- All unmanaged AI apps adaptive app scope

Without the setting enabled, content detected in prompts and responses are limited to sensitive information only.

> ⓘ **Note**
>
> To capture AI content, you must have the **Content contains classifiers** condition set to **All**.

Collection Policies and Microsoft Purview Insider Risk Management

Depending on your configuration, Microsoft Purview Insider Risk Management policy behavior might be impacted by collection policies. When an insider risk policy is configured, it monitors service and third-party indicators to help you quickly identify, triage, and act on risk activity. Using logs from Microsoft 365 and Microsoft Graph, Insider Risk Management allows you to define specific policies to identify risk indicators. These policies allow you to identify risky activities and to act to mitigate these risks.

> ⚠ **Warning**
>
> When a device collection policy is configured and deployed, if there's a conflict between what the Insider Risk Management policy is configured to monitor and what the collection policy is configured to filter for, the collection policy configuration takes precedence. This means that if an Insider Risk Management policy is configured to monitor a specific activity, but the collection policy is configured to filter out that activity, the activity isn't collected and isn't available for review in Insider Risk Management. This only applies to device indicators in Insider Risk Management policies, and only when a device collection policy is deployed. If a collection policy is configured to collect something that an Insider Risk Management policy isn't configured for, then the indicator is collected, but Insider Risk Management ignores it.

Collection policies and Endpoint Data Loss Prevention

When **Always audit file activity for devices** is enabled all activities for Office, PDF, and CSV files are collected by default. If you want to modify which activities are collected for devices in this case, you can do so by configuring a collection policy targeted to devices. If **Always audit file activity for devices** isn't enabled, activities aren't collected from devices, even if a collection policy is created scoped to devices.

Collection policies can't impact the behavior of DLP policies, only what is collected and recorded for audit file events on devices.

Collection policies and Microsoft Purview Data Security Posture Management and Purview Data Security Posture Management for AI

When you use one-click policies in Microsoft Data Security Posture Management or Microsoft Data Security Posture Management for AI (DSPM for AI), you can take action on recommendations that automatically create collection policies on your behalf.

You can view and monitor the outcomes of these policies in tailored experiences within DSPM and DSPM for AI, as well as in activity explorer. These policies are named automatically by the quick policy experience. Post-creation, these collection policies can be viewed and edited in the same manner as collection policies created using the workflow.

Last updated on 11/12/2025

Create and deploy collection policies

There are many configuration options in a Microsoft Purview collection policy. Each option changes the policy's behavior. This article presents some common intent scenarios for policies that map to configuration options. Then it walks you through configuring those options. Once you familiarize yourself with the scenarios in this article, you'll have the foundational skills that you need to use the collection policy creation UX to create your own policies.

Before you begin

If you're new to Microsoft Purview collection policies, here's a list of the core articles you should be familiar before.

- Collection policies solution overview.
- Collection policies policy reference

SKU/subscriptions licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Learn about Microsoft Purview billing models

Billing for collection policies

This feature uses pay-as-you-go billing or per-user licensing for Microsoft Purview capabilities or both. To help you understand and manage your usage, Microsoft Purview provides a **Usage center** in the Microsoft Purview portal. For more information, see Manage pay-as-you-go and per-user licensing usage. To learn more about Purview billing, see Purview billing models..

Granular Roles and Role Groups

There are roles and role groups that you can use to fine tune your access controls.

Here's a list of applicable roles.

- DLP Compliance Management

To learn more, see Permissions in the Microsoft Purview portal.

Here's a list of applicable role groups.

- Organization Management
- Compliance Administrator
- Insider Risk Management Admin
- Information Protection Admins
- Data Security Viewers (read-only support)

Policy creation scenarios

There are so many configuration options in the policy creation flow that it's not possible to cover every, or even most configurations. So this article covers the most common collection policy scenarios. Going through the following scenarios gives you hands-on experience across a broad range of configurations.

- Scenario 1 Detect sensitive data shared with unmanaged cloud apps via network

Scenario 1 Detect sensitive data shared with unmanaged cloud apps via network

This scenario detects sensitive data shared with unmanaged cloud apps at the network level. Visibility into the network traffic is provided by an integrated Secure Access Service Edge (SASE) or non-Microsoft secure browser provider, so it requires the integration to be configured and enabled. The steps to configure and enable the integration are covered in this scenario.

> **Note**
>
> This is a hypothetical scenario with hypothetical values. It's only for illustrative purposes. You should substitute your own sensitive information types, sensitivity labels, distribution groups and users.

Scenario 1 prerequisites and assumptions

- You either have an existing relationship with one or more supported SASE or non-Microsoft secure browser providers or are interested in procuring one as part of your deployment. See the Security Store in Microsoft Purview Data Loss Prevention to understand which providers are supported.

- If you choose a non-Microsoft SASE or secure browser integration, you have configured Microsoft Purview pay-as-you-go billing for your Microsoft 365 tenant. Pay-as-you-go is not required for integration with Entra Global Secure Access. For more information, see Learn about Microsoft Purview Network Data Security.

Configuring network data security is a multi-phase process.

1. Setup Purview integration with one or more SASE providers.
2. Configure a collection policy to detect sensitive data shared with unmanaged cloud apps at the network level.
3. Viewing the network data security data

Scenario 1 policy intent statement and mapping

We need to detect data that is sensitive to our organization in text or files shared by any user in the "US Sales" group through browsers, applications, add-ins, APIs, and more, with unmanaged cloud apps, such as ChatGPT, Dropbox, Slack, or Gmail.

Expand table

Statement	Configuration question answered and configuration mapping
"We need to detect data that is sensitive to our organization"	- Data to detect: **All classifiers** excluding **All Full Names** and **All Physical Addresses**
"...in text or files..."	- Activities to detect: **Text sent to or shared with cloud or AI app** and **File uploaded to or shared with cloud or AI app**
"...shared by any user in the "US Sales" group through browsers, applications, add-ins, APIs, and more, with unmanaged cloud apps, such as ChatGPT, Dropbox, Slack, or Gmail..."	- Where to apply: **Unmanaged cloud apps: ChatGPT, Dropbox, Slack, Gmail** - Scope: **Include "US Sales" group**

Steps to create policy for scenario 1

SASE provider integration

Perform the following steps to integrate a supported SASE or secure browser provider with Microsoft Purview:

1. In the Microsoft Purview portal, open the **Data Loss Prevention** solution and choose **Security Store** in the left navigation bar.

2. Select **Get solution** for the SASE or non-Microsoft secure browser solution provider you want to integrate with.
3. Complete the steps required by the integration. The steps vary depending on the SASE provider you choose. For Entra Global Secure Access integration, see Create content policies for network content filtering.

Configure collection policy for network data security

Perform the following steps to create the collection policy for network data security:

1. Sign in to the Microsoft Purview portal.
2. Open the **Data loss prevention** solution and navigate to **Classifiers** > **Collection policies**.
3. Select + **Create policy**.
4. Give the policy a **Name** and an optional **Description**. You can use the policy intent statement here.
5. Choose **Next**.
6. Select + **Add condition** and choose **Content contains**.
7. Select **Classifiers** and then **Edit**.
8. In the **Scope for classifiers** flyout, check **Exclude classifiers** and then select + **Exclude classifiers**.
9. In the **Choose Classifiers** flyout, select **All Full Names** and **All Physical Addresses** then select **Done**.
10. Select **Done** then select **Next**.

> **Tip**
>
> You can also add **Sensitivity labels** as a condition under **Content contains** to scope detection to items with specific sensitivity labels applied. For example, you can focus detection on items labeled as "Internal" or "Confidential" while excluding publicly labeled content. Sensitivity labels are only supported with browser and network cloud apps detection.

11. Select + **Add activities**.

12. Select **Text sent to or shared with cloud or AI app** and **File uploaded to or shared with cloud or AI app**.
13. Select **Add** then **Next**.
14. Select **+ Add data source**.
15. Select the **Unmanaged cloud apps** tab.
16. Search for and select **ChatGPT**, **Dropbox**, **Slack**, and **Gmail** and select **Add**.
17. Select **Edit scope** on the **Unmanaged cloud apps** row.
18. Select the **Include only specific** option, and on the **Included** tab select **+ Add inclusions**.
19. Search for the **US Sales** group, select it, and select **Add**.
20. Select **Save and close** then select **Next**.
21. Leave the default option of **Don't capture content** and select **Next**.
22. Ensure **Network and non-Microsoft secure browsers** is enabled and select **Next**.
23. Ensure **Turn on** is enabled and select **Next**.
24. Review the policy settings and select **Create policy**.
25. Review the **Next steps** and select **Done**.

Viewing the network data security data

You can view network sensitive data matches in two Purview tools:

- Activity explorer in Data loss prevention
- Data Security Posture Management (DSPM).

Activity explorer

Use the following steps to view network data security matches in Activity explorer:

1. Open the **Data loss prevention** solution and navigate to **Explorers** > **Activity explorer**.
2. Select **+ Add filter** and choose **Enforcement plane**.
3. Click the **Enforcement plane** filter and select **Network**.
4. Select **Apply**.

DSPM

Use the following steps to review collection policy results in DSPM for AI:

1. Open the DSPM solution.
2. Navigate to **Reports** to see high level reports and graphs breaking down the interactions detected by the collection policy.
3. Navigate to **Activity explorer** to see individual AI interactions and sensitive information detection events.

> **Note**
>
> Unless you've enabled content capture for AI interactions in the collection policy, only sensitive content matches will be available to view.

Note: The author created this article with assistance from AI. Learn more

Collection policy reference

Microsoft Purview collection policies have many components to configure. To create an effective policy, you need to understand the purpose of each component and how its configuration alters the behavior of the policy. This article provides a detailed anatomy of a collection policy.

Before you begin

If you're new to collection policies, here's a list of the core articles you need as you implement them in your organization:

1. Collection Policies solution overview
2. Collection policy reference - this article that you're reading now introduces all the components of a DLP policy and how each one influences the behavior of a policy
3. Create and Deploy collection policies.

Conditions

Specify conditions to define what **data to detect**. Conditions are optional, but some might be required for other settings. If you don't add conditions, what gets detected depends on the data sources you select later:

- **Devices**: All data is detected, even if it doesn't match your organization's classifiers.
- **All other data sources**: Only data that matches your organization's classifiers is detected.

Collection policies support five conditions:

Expand table

Condition	More information
Content contains classifiers	Sensitive information types and trainable classifiers to detect. Can be scoped to all classifiers, all classifiers except selected ones, or specific classifiers. The devices data source *doesn't support trainable classifiers*. If you select one, it's ignored.
Content contains sensitivity labels	Sensitivity labels to scope detection to items with specific sensitivity labels applied. Only supported with browser and network cloud apps detection.
Document size equals or is greater than	Detect files with a size that is greater than a specified number of bytes, kilobytes (KB), megabytes (MB), gigabytes (GB), or terabytes (TB).

Condition	More information
Document is equal to or smaller than	Detect files with a size that is smaller than a specified number of bytes, kilobytes (KB), megabytes (MB), gigabytes (GB), or terabytes (TB).
File extension is	Detect files with specified file extensions.

Activities

Choose which **activities to detect**. Supported activities are specific to the data sources you want to include.

> **Tip**
>
> You can mix activities that support different data sources in a single policy, but you must add all applicable data sources to the policy to support the selected activities.

Expand table

Activity	Description	Data source
Text sent to or shared with cloud or AI app	When raw text is uploaded to a cloud app, including generative AI prompts, form submissions, and messages	- Cloud apps - Generative AI
File uploaded to or shared with cloud or AI app	When a binary file is uploaded to a cloud app or generative AI services	- Cloud apps - Generative AI
Text received from cloud or AI app	When raw text is downloaded from a cloud app, including generative AI responses	- Cloud apps - Generative AI
File downloaded from cloud or AI app	When a binary file is downloaded from a cloud app or generative AI service	- Cloud apps - Generative AI
Archive created	When an archive file is created on an onboarded endpoint device	Devices
File accessed by unallowed app	When a file is accessed by a restricted app or app group on an onboarded endpoint device	Devices

Activity	Description	Data source
File archived	When a file is added to an archive on an onboarded endpoint device	Devices
File copied to network share	When a file is copied to a network share on an onboarded endpoint device	Devices
File copied to remote desktop session	When a file is copied to a remote computer through a remote desktop session on an onboarded endpoint device	Devices
File copied to removable media	When a file is copied to a removable media, such as a USB flash drive, on an onboarded endpoint device	Devices
File created	When a file is created on an onboarded endpoint device	Devices
File created on network share	When a file is created on a network share from an onboarded endpoint device	Devices
File created on removable media	When a file is created on removable media, such as a USB flash drive, from an onboarded endpoint device	Devices
File deleted	When a file is deleted from an onboarded endpoint device	Devices
File modified	When a file is modified from an onboarded endpoint device	Devices
File printed	When a file is printed from an onboarded endpoint device	Devices
File read	When a file is read from an onboarded endpoint device	Devices
File renamed	When a file is renamed from an onboarded endpoint device	Devices
File transferred by Bluetooth	When a file is transferred by Bluetooth from an onboarded endpoint device	Devices
File uploaded to cloud	When a file is uploaded to the cloud from an onboarded endpoint device	Devices
Removable media mount	When removable media, such as a USB flash drive, is mounted on an onboarded endpoint device	Devices
Removable media unmount	When removable media, such as a USB flash drive, is unmounted on an onboarded endpoint device	Devices

Data sources

Data sources define **where to apply** the policy, and directly correlate to the activities added to the policy.

The following data sources are supported:

Expand table

Data source	More information	Supported activities
Devices	Devices onboarded to Microsoft 365 and managed by your org.	Windows devices onboarded into Microsoft 365.
Copilot experiences	Includes Copilot in Microsoft Fabric and Microsoft Security Copilot only, with support for more experiences coming soon.	- Text sent to or shared with cloud or AI app - Text received from cloud or AI app
Enterprise AI	Non-Copilot AI apps that are onboarded or connected to your org by using methods like Microsoft Entra registration, Microsoft Foundry, or Microsoft Purview Data Map connectors. Policies can be applied to all Enterprise AI apps or scoped to specific apps.	- Text sent to or shared with cloud or AI app - Text received from cloud or AI app
Unmanaged cloud apps	Cloud apps sourced in the Defender for Cloud Apps catalog that aren't set up for single sign-on (SSO), allowing users to access personal data through a browser, app, add-in, or API. Policies only detect data while its being shared or transferred (data in motion) via browser and network detection.	**Browser & Network**: - Text sent to or shared with cloud or AI app - File uploaded to or shared with cloud or AI app **Network only**: - Text received from cloud or AI app -File downloaded from cloud or AI app
Adaptive app scopes	Groups of apps, whose membership is determined based on app metadata, such as category. Currently only "All unmanaged AI apps" - unmanaged cloud apps categorized as generative AI - is supported via browser and network detection.	**Browser & Network**: - Text sent to or shared with cloud or AI app - File uploaded to or shared with cloud or AI app **Network only**:

Data source	More information	Supported activities
		- Text received from cloud or AI app -File downloaded from cloud or AI app

> **Note**
>
> Some unmanaged AI apps aren't supported in Edge for Business. Adaptive app scopes apply only to the supported unmanaged apps in Edge for Business. To learn more, see Learn more about which apps are supported.

Scoping data sources to users and groups

For each data source, you can choose to scope by:

- **All** users and groups (default)
- **Specific** users and groups
- **All except** specific users and groups

> **Note**
>
> Excluded users and groups take precedence over any included users or groups.

Other collection policy settings

Depending on the conditions, activities, and data sources you specify, you might need to configure other collection policy settings. When these settings are disabled or grayed out, the policy configuration isn't compatible with the setting.

Content capture for AI interactions

To help comply with regulatory requirements, you can decide whether to capture and store all detected prompts and responses from any generative AI data sources you add to the policy. This feature is called *content capture*. By using this feature, you can easily discover and protect the captured content later by using other Microsoft Purview policies and solutions. This capability

doesn't include content in files shared with generative AI, and only applies to the following data sources:

- Copilot experiences
- Enterprise AI
- Unmanaged cloud apps categorized as generative AI
- All unmanaged AI apps adaptive app scope

Without this setting enabled, content detected in prompts and responses is limited to sensitive information only.

> **Note**
>
> To capture AI content, you must set the **Content contains classifiers** condition to `All`.

Cloud apps detection

If you add unmanaged cloud apps or adaptive app scopes data sources to the policy, including generative AI, you must choose how to detect this data. You can choose from the following options:

- **Browser** - Detect sensitive data shared with unmanaged cloud apps through the Microsoft Edge browser when on Intune-managed work devices. See supported unmanaged apps that can be targeted in policies, see supported activities for what user activities can be captured, and see supported browsers to confirm your version of the Microsoft Edge browser supports browser detection.
- **Network** - Detect sensitive data shared with unmanaged cloud apps through browsers, apps, APIs, and more, by using an integrated Secure Service Edge (SSE) provider and Microsoft Purview network data security.

> **Important**
>
> Microsoft Purview browser and network data security policies don't apply to B2B guest users.

Considerations for unmanaged cloud apps policies

Review this information when you configure policies that include unmanaged cloud apps, or when you troubleshoot unexpected policy behavior:

- When multiple catalog entries exist for the same app with differences in the entry name (for example, QwenAI and Qwen Chat), include all entries for the app to avoid unintended coverage gaps.
- Some unmanaged AI apps like Runway and Meta AI might intermittently send content in encoded form to dynamically generated endpoints, which can impact policy enforcement.
- Policies that target unmanaged apps can capture interactions from both the consumer and enterprise versions of an app when the app's URL is shared across instances (for example, ChatGPT consumer and ChatGPT enterprise).
- When you target an unmanaged cloud app in an Edge for Business browser policy, detection is based on the destination app's traffic, which isn't always exactly the same as the originating app.
- Inline evaluation size limits: Microsoft Purview evaluates up to 4 MB of content for uploadText and downloadText, and files up to 3 MB for uploadFile and downloadFile.

> **Note**
>
> The unmanaged cloud app features only apply to the consumer version of Microsoft 365 Copilot. For more information on the enterprise version and available Purview features see, Learn more about Microsoft 365 Copilot Enterprise protections.

Next steps

After creating a collection policy, you might need to take additional steps depending on the configured settings.

- If you enable **Browser** detection, the Microsoft Edge management service automatically creates the required configuration policies to activate collection policies in Edge for Business. To learn more, see Activate your Microsoft Purview policy in Microsoft Edge.
- If you enable **Network** detection, you must add and configure one or more Secure Access Service Edge (SASE) or non-Microsoft secure enterprise browser integrations to begin detecting network traffic. To learn more, see SASE provider integrations.

> **Important**

If the **automatic behaviors** fail to sync for browser detection, Microsoft Purview shows an error message and policies aren't applied in Edge for Business. An admin with the **required permissions** must resync to resolve the error. For more information, see **activate your Microsoft Purview policy in Microsoft Edge**.

Pay-as-you-go features

Some collection policy data sources and features are pay-as-you-go and require an Azure subscription to be linked before creating a policy. Learn more about Microsoft Purview features that use pay-as-you-go-billing here..

- Copilot experiences
- Enterprise AI
- Unmanaged cloud app activity detected through non-Microsoft SASE and secure enterprise browser integrations via Microsoft Purview network data security
  - Microsoft Entra Global Secure Access integration with Purview network data security is licensed per seat and does not require pay-as-you-go. For more information, see Learn about Microsoft Purview Network Data Security.
- Unmanaged cloud app activity detected through Microsoft Purview policies using inline data protections for the browser.

Privacy notice for Enterprise AI and Network Data Security

Enterprise AI data sources and network data security integrations might require integration with a third-party app or provider. If you choose to enable any third-party integration, it gains access to and might store some policy configuration, including user identifiers. In this case, the third party's terms, conditions, and privacy policy govern the usage and storage of this data.

Monitor device health with the device health reports dashboard

The device health reporting dashboard in Microsoft Purview gives compliance and security administrators a centralized view of device readiness for Endpoint Data Loss Prevention (Endpoint DLP). Use the dashboard to monitor device onboarding status, policy update readiness, and feature readiness for Endpoint DLP.

The dashboard helps you find devices that might not be ready to receive or enforce Endpoint DLP policies because of configuration, connectivity, or version issues. It consolidates device health insights, reducing manual troubleshooting across multiple pages.

Before you begin

To access the device health reporting dashboard, you must have one of the following roles:

- Compliance Administrator
- Security Administrator
- Global Administrator

> **Tip**
>
> Use the least-privileged role that meets your needs. For most organizations, the Compliance Administrator or Security Administrator role is sufficient.

Devices must also:

- Be onboarded to Endpoint DLP
- Be actively reporting device telemetry

For information about onboarding devices, see Get started with Endpoint data loss prevention.

Open the device health reporting dashboard

To open the device health reporting dashboard, follow these steps:

1. Go to the Microsoft Purview portal.

2. Select **Settings** > **Device onboarding** > **Device report**.

What the dashboard shows

The dashboard displays data from devices that reported within the past 30 days. It updateevery hour. Each section is interactive — select **View devices** to open a side pane with device categories, then select a category to open a filtered list of matching devices.

Expand table

Visualization	Description	Use case
Device onboarding	Provides an overview of onboarded devices, including: total onboarded devices, onboarded devices running Endpoint DLP, onboarded devices with configuration issues.	Use this section to quickly understand overall onboarding coverage and identify devices that may require configuration remediation.
Device readiness to receive policy updates	Shows devices that may not be ready to receive future Endpoint DLP policy updates because of: offline status during the past day, outdated Microsoft Defender Antivirus versions, configuration issues. These indicators don't confirm whether a device failed to receive a policy update, but instead highlight devices that may be at risk of not receiving future updates.	Use this section to proactively identify devices that may require remediation to remain ready for future policy updates.
Last time devices were seen online	Provides a breakdown of devices based on when each device was last seen online. Devices are grouped based on recency of activity, including devices seen in the last 24 hours, past 3 days, past 7 days, and past 30 days. This visualization helps you understand how recently devices have been active across your organization and provides visibility into overall device connectivity and reporting recency.	Use this section to understand how recently devices have been active or reporting activity across your organization.
Device readiness for feature	Displays readiness information for supported Endpoint DLP features. Currently, this section supports readiness reporting for: Just-in-time protection, Paste to supported browsers. This section shows how many devices are ready for each feature, and how many require updates before a feature can be used. Additional Endpoint DLP features will be added to this section in future releases.	Use this section to validate readiness before enabling or deploying Endpoint DLP features across devices.

Monitor device readiness

Use the dashboard to monitor device posture at scale, find misconfigured devices, detect devices that might not receive Endpoint DLP policy updates, and validate readiness before deploying new features.

To investigate device health issues, follow this typical workflow:

1. Review dashboard summaries to identify problem areas.
2. Select a dashboard segment to open a filtered list of affected devices.
3. Investigate individual devices.
4. Identify root cause issues such as:
    - Outdated versions
    - Connectivity issues
    - Invalid configurations

Common scenarios

Monitor device posture across your organization

Organizations need to monitor device health and readiness at scale to ensure devices remain ready to receive the latest policies and supported Endpoint DLP features. Use the dashboard to continuously monitor onboarding status, policy update readiness, feature readiness, and recent device activity. The dashboard helps you find devices that need remediation.

Identify onboarded devices with configuration issues

Onboarded devices may still have configuration issues that affect Endpoint DLP enforcement or feature readiness. Use the **Device onboarding** visualization to review Endpoint DLP coverage and find devices with configuration issues that need remediation.

Identify devices that may not be ready to receive policy updates

Some devices may not be ready to receive Endpoint DLP policy updates because of connectivity, Defender version, or configuration issues. These indicators don't confirm whether a device failed to receive an update, but highlight devices at risk of not receiving future updates. Use the **Device readiness to receive policy updates** visualization to find these devices and plan remediation.

Monitor device connectivity

Device connectivity affects readiness for policy updates and Endpoint DLP features. Use the **Last time devices were seen** visualization to view when devices were last seen online — in the past 24 hours, 3 days, 7 days, or 30 days. This breakdown helps you evaluate device activity patterns across your organization.

Validate readiness before enabling Endpoint DLP features

Some Endpoint DLP features require devices to meet specific configuration or version requirements. Use the **Device readiness for feature** visualization to validate whether devices are ready for supported features, including Just-in-time protection and Paste to supported browsers.

Best practices

- **Review the dashboard regularly.** Frequent checks help you catch device health trends before they become widespread issues.
- **Investigate devices that haven't reported recently.** Devices offline for extended periods may miss critical policy updates.
- **Validate readiness before deploying new policies or features.** Confirm that devices meet configuration and version requirements to avoid failed deployments.
- **Prioritize remediation for devices with outdated Defender versions.** Outdated Microsoft Defender Antivirus versions can prevent devices from receiving Endpoint DLP policies.

Onboard Windows devices into Microsoft 365 overview

Applies to:

- Endpoint data loss prevention (DLP)
- Insider risk management

Endpoint data loss prevention (Endpoint DLP) and insider risk management require that Windows 10 and Windows 11 devices be onboarded into the service so that they can send monitoring data to the services.

Endpoint DLP allows you to monitor Windows 10 or Windows 11 devices and detect when sensitive items are used and shared. This gives you the visibility and control you need to ensure that they're used and protected properly, and to help prevent risky behavior that might compromise them. For more information about all of Microsoft's DLP offerings, see Learn about data loss prevention. To learn more about Endpoint DLP, see Learn about Endpoint data loss prevention.

Endpoint DLP also allows you to onboard devices running Windows Server 2019 and later versions.

> **Note**
>
> Installing the supported Windows Server KBs disables the *Classification* feature on the server. This means that Endpoint DLP won't classify files on the server. However, Endpoint DLP will still protect those files on the server that were classified before those KBs were installed on server. To ensure this protection, install Microsoft Defender version 4.18.23100 (October 2023) or later.

By default, Endpoint DLP isn't enabled for Windows servers when they're initially onboarded. Before you can see Endpoint DLP events for your servers in Activity Explorer, you must first turn on Endpoint DLP support for onboarded servers.

Once properly configured, the same data loss protection policies can be automatically applied to both Windows PCs and Windows servers.

Insider risk management uses the full breadth of service and 3rd-party indicators to help you quickly identify, triage, and act on risky user activity. By using logs from Microsoft 365 and Microsoft Graph, insider risk management allows you to define specific policies to identify risk indicators and to take action to mitigate these risks. For more information, see Learn about insider risk management.

Device onboarding is shared across Microsoft 365 and Microsoft Defender for Endpoint (MDE). If you've already onboarded devices to MDE, they appear in the managed devices list and no further steps are necessary to onboard those specific devices. Onboarding devices in Microsoft Purview portal also onboards them into MDE.

Before you begin

SKU/subscriptions licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

> **Important**
>
> For information on managing user licensing for devices see Available plans.

Permissions

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. This helps improve security for your organization. Global Administrator is a highly privileged role that should only be used in scenarios where a lesser privileged role can't be used.

To enable device management, the account you use must be a member of any one of these roles:

- Security admin
- Compliance admin
- Global admin

If you want to use a custom account to view the device management settings, it must be in one of these roles:

- Compliance admin
- Compliance data admin
- Global reader
- Security admin
- Global admin

If you want to use a custom account to access the onboarding/offboarding page, it must be in one of these roles:

- Compliance admin
- Security admin
- Global admin

If you want to use a custom account to turn on/off device monitoring, it must be in one of these roles:

- Compliance admin
- Security admin
- Global admin

Prepare your Windows devices

Make sure that the Windows devices that you need to onboard meet these requirements.

1. Must be running one of the following builds of Windows or Windows Server:

    a. Windows (X64):
        i. Windows 11 24H2 (See update details)
        ii. Windows 11 23H2 (See update details)
        iii. Windows 11 22H2 update (See update details)
        iv. Windows 11 21H2 (See update details)
        v. Windows 10 22H2 update (See update details)

    b. Windows (ARM64):
        i. Windows 11 24H2 (See update details)
        ii. Windows 11 23H2 (See update details)
        iii. Windows 11 22H2 update (See update details)
        iv. Windows 11 21H2 (See update details)

c. Windows Server 2019 OS: 1809 onwards or Windows Server 2022 OS: 21H2 onwards.

d. Anti-malware Client Version is 4.18.2110 or newer. Check your current version by opening Windows Security app, select the Settings icon, and then select About. The version number is listed under anti-malware Client Version. Update to the latest anti-malware Client Version by installing Windows Update KB4052623. For more information, see: Microsoft Defender Antivirus in Windows. After a new anti-malware Client version or a new anti-malware Engine version is released, versions older than N-2 are no longer supported.

> ⓘ **Important**
>
> None of Windows Security components need to be active, but the **Real-time protection and Behavior monitor** must be enabled.
>
> After a new anti-malware Client version or a new anti-malware Engine version is released, versions older than N-2 are no longer supported.

2. All devices must be one of these:

   - Microsoft Entra joined
   - Microsoft Entra hybrid joined
   - Microsoft Entra registered

3. A supported version of Microsoft 365 Apps is installed and up to date. For the most robust protection and user experience, ensure Microsoft 365 Apps version 16.0.14701.0 or later is installed.

> ⓘ **Note**
>
> - If you're running Office 365 - KB 4577063 is required.
> - If you are on Monthly Enterprise Channel of Microsoft 365 Apps versions 2004-2008, you need to update to version 2009 or later. See **Update history for Microsoft 365 Apps (listed by date)** for current versions. To learn more about known issue, see the Office Suite section of **Release notes for Current Channel releases in 2020**.

4. If you have endpoints that use a device proxy to connect to the internet, follow the procedures in Configure device proxy and internet connection settings for Microsoft Purview Endpoint DLP.

   > **Important**
   >
   > Make sure you allow *MpDlpService.exe* through your firewall, third-party antivirus software, or application control.

5. Here are the prerequisites for each feature.

Expand table

Feature	Prerequisite
Add hyperlink support in warn and block toast messages (Roadmap ID 480733)	Anti-malware Client Version 4.18.25010 or newer is required.
IP or IP address ranges support within Sensitive service domain groups (Roadmap ID 479759)	Anti-malware Client Version 4.18.25010 or newer is required.
Allow and Off modes in the policy (Roadmap ID 481356)	anti-malware Client Version 4.18.25010 or newer is required.
Device and Device group-based policy scoping support for Endpoint DLP (Roadmap ID 480732)	Windows 10: See update details Windows 11 22H2: See update details Windows 11 23H2: See update details Windows 11 24H2: See update details
Full file evidence support for restricted apps (Roadmap ID 479757)	Anti-malware Client Version 4.18.25020 or newer is required.
Pause and Resume support for printer (Roadmap ID 486369)	Anti-malware Client Version 4.18.25030 or newer is required.
Increase file type coverage to 100+ (Roadmap ID 416481)	Windows 10: See update details Windows 11 22H2: See update details Windows 11 23H2: See update details Windows 11 24H2: See update details

Feature	Prerequisite
Endpoint DLP support for Teams	Anti-malware Client Version 4.18.25050 or newer is required.
Advanced label-based protection for all files on devices (Roadmap ID 487859)	Information protection client version: 3.1.309 or newer is required. Anti-malware Client Version 4.18.25050 or newer is required. Windows 10: See update details Windows 11 22H2: See update details Windows 11 23H2: See update details Windows 11 24H2: See update details
Network share/Removable media/Printer group support on Edge (Roadmap ID 486370)	Edge: 137 or newer is required. Anti-malware Client Version 4.18.25050 or newer is required.
OneDrive shadow file protection support (Roadmap ID 489842)	Anti-malware Client Version 4.18.26020 or newer is required.
Restricted apps and app groups support on Edge (Roadmap ID 485769)	Anti-malware Client Version 4.18.25080 or newer is required.
Logged-in user details (user email) on the device onboarding page (Roadmap ID 548669)	Anti-malware Client Version 4.18.26030 or newer is required. Windows 10: See update details Windows 11 22H2: See update details Windows 11 23H2: See update details Windows 11 24H2: See update details
Device health details in the export function on the device onboarding page and in Advanced hunting on Security portal (Roadmap ID 542792)	Anti-malware Client Version 4.18.26030 or newer is required. Windows 10: See update details Windows 11 22H2: See update details Windows 11 23H2: See update details Windows 11 24H2: See update details
Network share/Removable media/Printer group support on Edge (Roadmap ID 486370)	Edge: 137 or newer is required. Anti-malware Client Version

Feature	Prerequisite
	4.18.25050 or newer is required.
Hyperlink within toast messages for the Edge browser (Roadmap ID 558688)	Anti-malware Client Version 4.18.26040 or newer is required.
Print resume support for Just-in-time protection (JIT)	Anti-malware Client Version 4.18.26040 or newer is required.

Onboarding Windows 10 or Windows 11 devices

You must enable device monitoring and onboard your endpoints before you can monitor and protect sensitive items on a device. Both of these actions are done in the Microsoft Purview portal.

When you want to onboard devices that haven't been onboarded yet, you download the appropriate script and deploy it to those devices. Follow the device onboarding procedures below.

If you already have devices onboarded into Microsoft Defender for Endpoint, they'll already appear in the managed devices list.

In this deployment scenario, you onboard Windows 10 or Windows 11 devices that haven't been onboarded yet.

1. Open the Microsoft Purview portal. Choose **Settings** > **Device onboarding** > **Devices**.

   > **Note**
   >
   > If you have previously deployed Microsoft Defender for Endpoint, all the devices that were onboarded during that process will be listed in the **Devices** list. There's no need to onboard them again. While it usually takes about 60 seconds for device onboarding to be enabled, allow up to 30 minutes before engaging with Microsoft support.

2. Choose **Turn on device onboarding**.

3. Choose **Onboarding** to begin the onboarding process.

4. Choose the way you want to deploy to these other devices from the **Deployment method** list and then **download package**.

5. Choose the appropriate procedure to follow from the table below:

Expand table

Article	Description
Intune	Use Mobile Device Management tools or Microsoft Intune to deploy the configuration package on device.
Configuration Manager	You can use either use Microsoft Endpoint Configuration Manager (current branch) version 1606 or Microsoft Endpoint Configuration Manager (current branch) version 1602 or earlier to deploy the configuration package on devices.
Group Policy	Use Group Policy to deploy the configuration package on devices.
Local script	Learn how to use the local script to deploy the configuration package on endpoints.
Virtual desktop infrastructure (VDI) devices	Learn how to use the configuration package to configure VDI devices.

Check device status

After onboarding your devices, you can monitor **Configuration status** and **Policy Sync status** to ensure devices are properly set up to receive policy updates. To learn what Configuration status and Policy sync status mean, see: Understand device configuration and policy sync status values

To view these details, go to **Device onboarding** > **Devices**. From there, you can review each device's current configuration state and confirm whether policies have successfully synced. For guidance on resolving **Configuration status** or **Policy Sync status** issues, see: Troubleshooting endpoint data loss prevention configuration and policy sync

> **Note**
>
> Onboarded devices will continue to appear for 180 days after the device is offline.

Onboard Windows 10 and Windows 11 devices using Mobile Device Management tools

09/26/2025

Applies to:

- Endpoint data loss prevention (DLP)
- Insider risk management

You can use mobile device management (MDM) solutions to configure devices. Microsoft 365 information protection supports MDM solutions by providing OMA-URIs to create policies to manage devices.

Before you begin

If you're using Microsoft Intune, the device must be enrolled in MDM.

For more information on enabling MDM with Microsoft Intune, see Device enrollment (Microsoft Intune).

Onboard devices using Microsoft Intune

Follow the instructions from Intune.

> **Note**
>
> The **Health Status for onboarded devices** policy uses read-only properties and can't be remediated.

Offboard and monitor devices using Mobile Device Management tools

For security reasons, the package used to offboard devices will expire 30 days after the date it was downloaded. Expired offboarding packages sent to a device will be rejected. When you download an offboarding package, you're notified of the package's expiry date. The expiry date is also included in the package name.

> **Note**
>
> Onboarding and offboarding policies must not be deployed on the same device at the same time. If they are, unpredictable collisions result.

1. Get the offboarding package from the Microsoft Purview portal.
2. In the navigation pane, select **Settings** > **Device onboarding** > **Offboarding**.
3. In the **Deployment method** field, select **Mobile Device Management / Microsoft Intune**.
4. Select **Download package**, and save the .zip file.
5. Extract the contents of the .zip file to a shared, read-only location that can be accessed by the network administrators who deploy the package. You should have a file named *DeviceCompliance_valid_until_YYYY-MM-DD.offboarding*.
6. Use the Microsoft Intune custom configuration policy to deploy the following supported OMA-URI settings.

   ```
   Console

   OMA-URI: ./Device/Vendor/MSFT/WindowsAdvancedThreatProtection/Offboarding
   Date type: String
   Value: [Copy and paste the value from the content of the
   DeviceCompliance_valid_until_YYYY-MM-DD.offboarding file]
   ```

   > **Note**
   >
   > If Microsoft Defender for Endpoint is already configured, you can **Turn on device onboarding**. If you do this, step 6 isn't required.

> **Note**
>
> The **Health Status for offboarded devices** policy uses read-only properties and can't be remediated.

> **Important**

Offboarding causes the device to stop sending sensor data to the portal. However, data from the device, including reference to any alerts received, will be retained for up to six months.

Onboard Windows 10 and Windows 11 devices using Microsoft Configuration Manager

Article • 02/18/2025

Applies to:

- Endpoint data loss prevention (DLP)
- Insider risk management

Supported client operating systems

You can onboard the following operating systems using Configuration Manager:

- Windows 11
- Windows 10, version 1709 or newer

> **Important**
>
> When onboarding systems to Microsoft Purview for endpoint, they will also report to Defender for Endpoint, even if a different antivirus or anti-malware solution is in use. In such cases, these systems will report to Defender for Endpoint in **passive mode**, ensuring there is no interference with the existing antivirus or anti-malware solution.

Onboarding to Microsoft Purview for Endpoint with Configuration Manager

In Configuration Manager, configure the Endpoint Protection settings as follows to ensure the client recognizes the configuration file.

- Set **Manage Endpoint protection client on the computers** to **Yes**.
- The **Install Endpoint Protection Client on Client computers** can be set to **No**.

> **Note**

This is to allow clients to receive the configuration file from Configuration Manager. If you do not turn this on the Configuration file may not deploy on to the clients.

- Set the Microsoft Defender for Endpoint client on Windows server 2012 R2 and Windows Server 2016 to **MDE client (recommended)**.

Deploy this Client Settings configuration to the collections that are used to onboard systems.

Onboard devices using Configuration Manager

1. Get the configuration package .zip file (*DeviceComplianceOnboardingPackage.zip*) from Microsoft Purview portal.
2. In the navigation pane, select **Settings** > **Device Onboarding** > **Onboarding**.
3. In the **Select Operating system to start onboarding process**: select **Windows 10** and then in the **Deployment method** field, select **Microsoft Endpoint Configuration Manager**.
4. Select **Download package** and save the .zip file.
5. Extract the contents of the .zip file to a shared, read-only location accessible by the Configuration Manager console for deployment. Ensure the file named ***DeviceCompliance.onboarding*** is present.

Onboard the devices

1. In the Configuration Manager console, navigate to **Assets and Compliance** > **Endpoint Protection** > **Microsoft Defender for Endpoint Policies**.

   > **Note**
   >
   > Microsoft Purview and Microsoft Defender for Endpoint use the same method to connect to Microsoft cloud security environments.

2. Select **Create Microsoft Defender for Endpoint Policy** to open the policy wizard.
3. Select **I accept these license terms and automatic updates of both Agents**. Then type the **Name** and **Description** for the Microsoft Defender for Endpoint policy and select **Onboarding**.

4. Select **Browse** and browse to the configuration file you extracted from the downloaded .zip file.

   > ⓘ **Note**
   >
   > You do not need the Workspace key and Workspace ID for Windows 10 and 11.

   Select **Next**.

5. Specify the file samples that are collected and shared from managed devices for analysis.

   - **None**
   - **All file types**

6. Review the summary and complete the wizard.

7. Right-click on the policy you created, select **Deploy**, and then choose a collection to which you want to deploy the Microsoft Defender for Endpoint policy.

Monitor

1. In the Configuration Manager console, navigate **Monitoring** > **Deployments** and then select the deployment you created for the **Defender for Endpoint policy** deployment.

2. Click on **View Status** to review the information. Under **Compliant** you can see the status of the onboarded systems. Systems that have not yet been onboarded may appear under the **Unknown** tab.

> ⓘ **Note**
>
> This process may take some time, and the system might need to reboot for the changes to take effect.

Offboard devices using Configuration Manager

For security reasons, the package used to Offboard devices will expire 30 days after the date it was downloaded. Expired offboarding packages sent to a device will be rejected.

When downloading an offboarding package, you'll be notified of the packages expiry date and it will also be included in the package name.

> **Note**
>
> Onboarding and offboarding policies must not be deployed on the same device at the same time, otherwise this causes unpredictable collisions.

Offboard devices using Microsoft Configuration Manager current branch

If you use Microsoft Configuration Manager current branch, see Create an offboarding configuration file.

Create an offboarding configuration file

1. Sign in to the Microsoft Purview console.
2. Select **Settings**, then select **Device onboarding** and then select **Offboarding** under the onboarding heading.
3. Select **Windows 10** for the operating system and **Microsoft Endpoint Configuration Manager** for the deployment method.
    - Using the **Windows 10** option ensures that all devices in the collection are off boarded, and the MMA is uninstalled when needed.
4. Download the compressed archive (.zip) file and extract the contents. Offboarding files are valid for 30 days.
5. In the Configuration Manager console, navigate to **Assets and Compliance** > **Endpoint Protection** > **Microsoft Defender For Endpoint Policies** and select **Create Microsoft Defender for Endpoint Policy**. The policy wizard opens.
6. Type the **Name** and **Description** for the Microsoft Defender for Endpoint policy and select **Offboarding**.
7. **Browse** to the configuration file you extracted from the downloaded .zip file.
8. Review the summary and complete the wizard.
9. Select Deploy to target the Microsoft Defender for Endpoint policy to clients you wish to offboard from Purview.

> **Important**
>
> The Microsoft Purview for Endpoint configuration files contains sensitive information which should be kept secure.

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the **Microsoft Purview trials hub**. Learn details about **signing up and trial terms**.

Monitor device configuration

With Microsoft Configuration Manager current branch, use the built-in Microsoft Defender for Endpoint dashboard in the Configuration Manager console. For more information, see Microsoft Defender Advanced Threat Protection - Monitor.

Check that the devices are compliant with the Endpoint data loss prevention service

You can set a compliance rule for configuration item in Configuration Manager to monitor your deployment.

> **Note**
>
> This procedure and registry entry applies to Endpoint DLP and Defender for Endpoint.

This rule should be a *non-remediating* compliance rule configuration item that monitors the value of a registry key on targeted devices.

Monitor the following registry key entry:

Console

```
Path: "HKLM\SOFTWARE\Microsoft\Windows Advanced Threat Protection\Status"
Name: "OnboardingState"
Value: "1"
```

For more information, see Plan for and configure compliance settings.

Was this page helpful? Yes No

Onboard Windows 10 devices and Windows 11 using Group Policy

Applies to:

- Endpoint data loss prevention (DLP)
- Insider risk management
- Group Policy

> **Note**
>
> To use Group Policy (GP) updates to deploy the package, you must be on Windows Server 2008 R2 or later.
>
> For Windows Server 2019, you may need to replace NT AUTHORITY\Well-Known-System-Account with NT AUTHORITY\SYSTEM of the XML file that the Group Policy preference creates.

This article explains how to use Group Policy to deploy the Microsoft Purview device configuration package on Windows 10 and Windows 11 devices. After onboarding, devices can be monitored by endpoint data loss prevention and insider risk management features. The procedures cover both onboarding and offboarding scenarios. This guidance is intended for IT administrators who manage device policies through Group Policy Objects (GPOs).

Onboard devices using Group Policy

Use the following steps to download and deploy the Group Policy onboarding package:

1. Open the Purview portal.
2. In the navigation pane, select **Settings** > **Device Onboarding**.
3. In the **Deployment method** field, select **Group policy**.
4. Click **Download package** and save the .zip file.
5. Extract the contents of the .zip file to a shared, read-only location that can be accessed by the device. You should have a folder called *OptionalParamsPolicy* and the file

DeviceComplianceLocalOnboardingScript.cmd.

6. Open the Group Policy Management Console (GPMC), right-click the Group Policy Object (GPO) you want to configure and click **Edit**.

7. In the **Group Policy Management Editor**, go to **Computer configuration**, then **Preferences**, and then **Control panel settings**.

8. Right-click **Scheduled tasks**, point to **New**, and then click **Immediate Task (At least Windows 7)**.

9. In the **Task** window that opens, go to the **General** tab. Under **Security options** click **Change User or Group** and type SYSTEM and then click **Check Names** then **OK**. NT AUTHORITY\SYSTEM appears as the user account the task will run as.

10. Select **Run whether user is logged on or not** and check the **Run with highest privileges** check box.

11. Go to the **Actions** tab and click **New...** Ensure that **Start a program** is selected in the **Action** field. Enter the file name and location of the shared *WindowsDefenderATPOnboardingScript.cmd* file.

12. Click **OK** and close any open GPMC windows.

Offboard devices using Group Policy

For security reasons, the package used to offboard devices will expire 30 days after the date it was downloaded. Expired offboarding packages sent to a device will be rejected. When downloading an offboarding package you will be notified of the packages expiry date and it will also be included in the package name.

> **ⓘ Important**
>
> Offboarding causes the device to stop sending sensor data to the portal. However, data from the device, including references to any alerts it has had, will be retained for up to six months.

> **ⓘ Note**

Onboarding and offboarding policies must not be deployed on the same device at the same time. Deploying both policies simultaneously causes unpredictable collisions.

1. Get the offboarding package from Microsoft Purview portal.
2. In the navigation pane, select **Settings** > **//Device onboarding** > **Offboarding**.
3. In the **Deployment method** field, select **Group policy**.
4. Click **Download package** and save the .zip file.
5. Extract the contents of the .zip file to a shared, read-only location that can be accessed by the device. You should have a file named *DeviceComplianceOffboardingScript_valid_until_YYYY-MM-DD.cmd*.
6. Open the Group Policy Management Console (GPMC), right-click the Group Policy Object (GPO) you want to configure and click **Edit**.
7. In the **Group Policy Management Editor**, go to **Computer configuration,** then **Preferences**, and then **Control panel settings**.
8. Right-click **Scheduled tasks**, point to **New**, and then click **Immediate task**.
9. In the **Task** window that opens, go to the **General** tab. Choose the local SYSTEM user account (BUILTIN\SYSTEM) under **Security options**.
10. Select **Run whether user is logged on or not** and check the **Run with highest privileges** check-box.
11. Go to the **Actions** tab and click **New...**. Ensure that **Start a program** is selected in the **Action** field. Enter the file name and location of the shared *DeviceComplianceOffboardingScript_valid_until_YYYY-MM-DD.cmd* file.
12. Click **OK** and close any open GPMC windows.

Monitor device configuration

With Group Policy there isn't an option to monitor deployment of policies on the devices. Monitoring can be done directly in the Microsoft Purview portal, or by using other deployment tools such as Microsoft Endpoint Configuration Manager or Mobile Device Management tools.

Monitor devices using the portal

To verify that onboarded devices are reporting correctly, use the following steps:

1. Go to the Microsoft Purview portal.
2. Click **Devices** list.
3. Verify that devices are appearing.

> **Note**
>
> It can take several days for devices to start showing on the **Devices list**. This includes the time it takes for the policies to be distributed to the device, the time it takes before the user logs on, and the time it takes for the endpoint to start reporting.

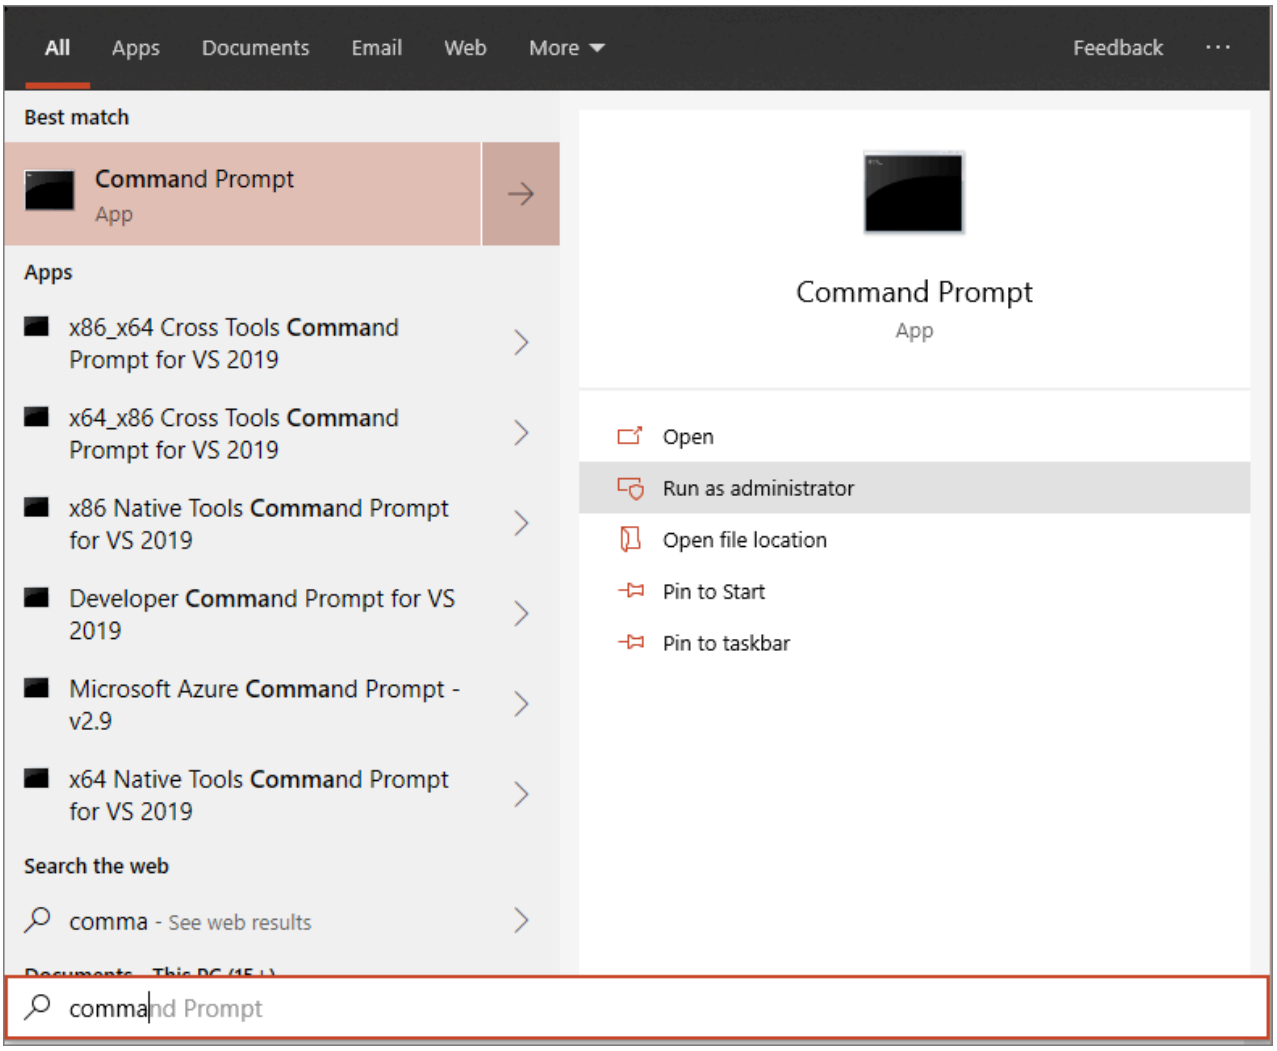
Onboard Windows 10 and Windows 11 devices using a local script

09/26/2025

Applies to:



- Endpoint data loss prevention (DLP)
- Insider risk management

You can also manually onboard individual devices to Microsoft 365. You might want to do this first when testing the service before you commit to onboarding all devices in your network.

> **Important**
>
> This script has been optimized for use on up to 10 devices.
>
> To deploy at scale, use other deployment options. For example, you can deploy an onboarding script to more than 10 devices in production with the script available in Onboard Windows 10 devices using Group Policy.

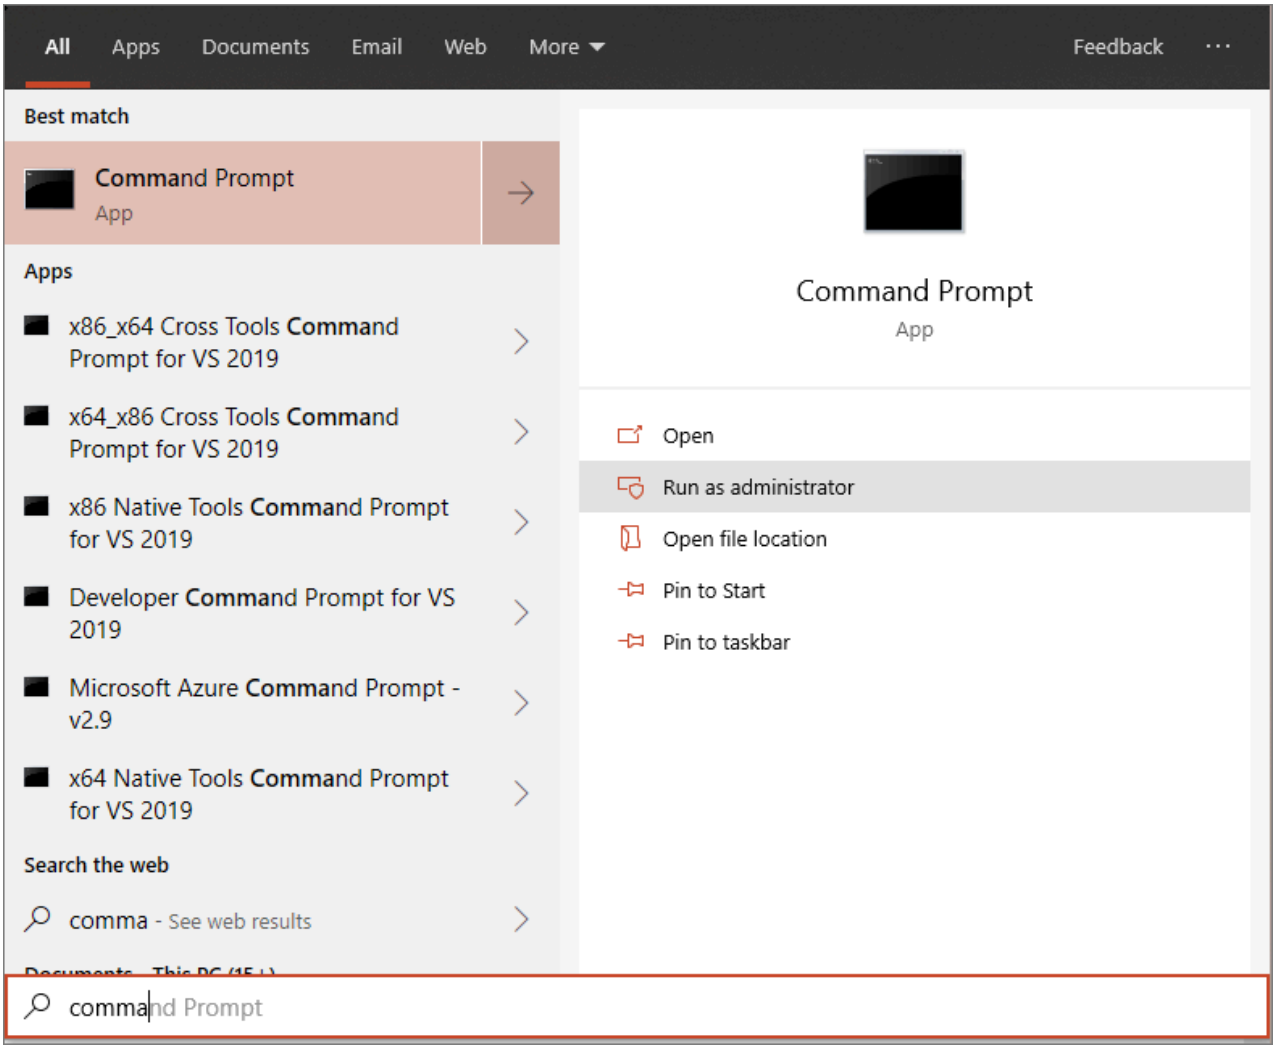
Onboard devices

1. Get the configuration package .zip file (*DeviceComplianceOnboardingPackage.zip*) package from Microsoft Purview portal
2. In the navigation pane, select **Settings** > **Device onboarding**.
3. In the **Deployment method** field, select **Local Script**.
4. Click **Download package** and save the .zip file.
5. Extract the contents of the configuration package to a location on the device you want to onboard (for example, the Desktop). You should have a file named *DeviceComplianceLocalOnboardingScript.cmd*.
6. Open an elevated command-line prompt on the device and run the script:
7. Go to **Start** and type **cmd**.
8. Right-click **Command prompt** and select **Run as administrator**.

9. Type the location of the script file. If you copied the file to the desktop, type: *%userprofile%\Desktop\DeviceComplianceLocalOnboardingScript.cmd*

10. Press the **Enter** key or click **OK**.

For information on how you can manually validate that the device is compliant and correctly reports sensor data see, Troubleshoot Microsoft Defender Advanced Threat Protection onboarding issues.



Offboard devices using a local script

For security reasons, the package used to Offboard devices will expire 30 days after the date it was downloaded. Expired offboarding packages sent to a device will be rejected. When downloading an offboarding package you will be notified of the packages expiry date and it will also be included in the package name.

> ⓘ **Note**

Onboarding and offboarding policies must not be deployed on the same device at the same time, otherwise this will cause unpredictable collisions.

1. Get the offboarding package from Microsoft Purview portal.
2. In the navigation pane, select **Settings** > **Device offboarding**.
3. In the **Deployment method** field, select **Local Script**.
4. Click **Download package** and save the .zip file.
5. Extract the contents of the .zip file to a shared, read-only location that can be accessed by the devices. You should have a file named *DeviceComplianceOffboardingScript_valid_until_YYYY-MM-DD.cmd*.
6. Open an elevated command-line prompt on the device and run the script:
7. Go to **Start** and type **cmd**.
8. Right-click **Command prompt** and select **Run as administrator**.

9. Type the location of the script file. If you copied the file to the desktop, type: *%userprofile%\Desktop\WindowsDefenderATPOffboardingScript_valid_until_YYYY-MM-DD.cmd*

10. Press the **Enter** key or click **OK**.

> **Important**
>
> Offboarding causes the device to stop sending sensor data to the portal.

Monitor device configuration

You can follow the different verification steps in the [Troubleshoot onboarding issues] ((/windows/security/threat-protection/microsoft-defender-atp/troubleshoot-onboarding) to verify that the script completed successfully and the agent is running.

Monitoring can also be done directly on the portal, or by using the different deployment tools.

Monitor devices using the portal

1. Go to Microsoft Purview portal.

2. Choose **Settings** > **Device onboarding** > **Devices**.

3. Go to Microsoft Purview portal, and select **Settings** > **Device onboarding** > **Devices**.

4. Verify that devices are appearing.

- Troubleshoot Microsoft Defender Advanced Threat Protection onboarding issues

Onboard non-persistent virtual desktop infrastructure devices

09/26/2025

Applies to:

- Endpoint data loss prevention (DLP)
- Insider risk management
- Virtual desktop infrastructure (VDI) devices

Onboard VDI devices

Microsoft 365 supports non-persistent virtual desktop infrastructure (VDI) session onboarding.

> **Note**
>
> To onboard non-persistent VDI sessions, VDI devices must be on Windows 10 1809 or higher.

There might be associated challenges when onboarding VDIs. The following are typical challenges for this scenario:

- Instant early onboarding of short-lived sessions, which must be onboarded to Microsoft 365 prior to the actual provisioning.
- The device name is typically reused for new sessions.

VDI devices can appear in the Microsoft Purview portal as either:

- Single entry for each device. In this case, the *same* device name must be configured when the session is created, for example using an unattended answer file.
- Multiple entries for each device - one for each session.

The following steps guide you through onboarding VDI devices and will highlight steps for single and multiple entries.

> **Warning**
>
> Endpoint data loss prevention support for Windows Virtual Desktop supports both single session and multi-session scenarios. For environments where there are low resource

configurations, the VDI boot procedure might slow the device onboarding process.

1. Get the VDI configuration package .zip file (*DeviceCompliancePackage.zip*) from Microsoft Purview portal.
2. In the navigation pane, select **Settings** > **Device onboarding** > **Onboarding**.
3. In the **Deployment method** field, select **VDI onboarding scripts for non-persistent endpoints**.
4. Select **Download package** and save the .zip file.
5. Copy the files from the DeviceCompliancePackage folder extracted from the .zip file into the `golden` image under the path `C:\WINDOWS\System32\GroupPolicy\Machine\Scripts\Startup`.
6. If you aren't implementing a single entry for each device, copy DeviceComplianceOnboardingScript.cmd.
7. If you're implementing a single entry for each device, copy both Onboard-NonPersistentMachine.ps1 and DeviceComplianceOnboardingScript.cmd.

   > ⓘ Note
   >
   > If you don't see the `C:\WINDOWS\System32\GroupPolicy\Machine\Scripts\Startup` folder, it might be hidden. You need to choose the **Show hidden files and folders** option from File Explorer.

8. Open a Local Group Policy Editor window and navigate to **Computer Configuration** > **Windows Settings** > **Scripts** > **Startup**.

   > ⓘ Note
   >
   > Domain Group Policy may also be used for onboarding non-persistent VDI devices.

9. Depending on the method you'd like to implement, follow the appropriate steps:

   For single entry for each device

   Select the **PowerShell Scripts** tab, then select **Add** (Windows Explorer opens directly in the path where you copied the onboarding script earlier). Navigate to onboarding PowerShell script `Onboard-NonPersistentMachine.ps1`.

For multiple entries for each device:

Select the **Scripts** tab, then select **Add** (Windows Explorer opens directly in the path where you copied the onboarding script earlier). Navigate to the onboarding bash script `DeviceComplianceOnboardingScript.cmd`.

10. Test your solution:
    a. Create a pool with one device.
    b. Sign in device.
    c. Sign out from device.
    d. Sign in device with another user.
    e. **For single entry for each device**: Check only one entry in Microsoft Defender Security Center. **For multiple entries for each device**: Check multiple entries in Microsoft Defender Security Center.
11. Select **Devices list** on the Navigation pane.
12. Use the search function by entering the device name and select **Device** as search type.

Updating non-persistent virtual desktop infrastructure (VDI) images

As a best practice, we recommend using offline servicing tools to patch golden images.

For example, you can use the below commands to install an update while the image remains offline:

Windows Command Prompt

```
DISM /Mount-image /ImageFile:"D:\Win10-1909.vhdx" /index:1
/MountDir:"C:\Temp\OfflineServicing"
DISM /Image:"C:\Temp\OfflineServicing" /Add-Package
/Packagepath:"C:\temp\patch\windows10.0-kb4541338-x64.msu"
DISM /Unmount-Image /MountDir:"C:\Temp\OfflineServicing" /commit
```

For more information on DISM commands and offline servicing, please refer to the articles below:

- Modify a Windows image using DISM
- DISM Image Management Command-Line Options
- Reduce the Size of the Component Store in an Offline Windows Image

If offline servicing isn't a viable option for your non-persistent VDI environment, the following steps should be taken to ensure consistency and sensor health:

1. After booting the golden image for online servicing or patching, run an offboarding script to turn off the Microsoft 365 device monitoring sensor. For more information, see Offboard devices using a local script.

2. Ensure the sensor is stopped by running the command below in a CMD window:

   Windows Command Prompt

   ```
   sc query sense
   ```

3. Service the image as needed.

4. Run the below commands using PsExec.exe (which can be downloaded from https://download.sysinternals.com/files/PSTools.zip) to clean up the cyber folder contents that the sensor may have accumulated since boot:

   Windows Command Prompt

   ```
   PsExec.exe -s cmd.exe
   cd "C:\ProgramData\Microsoft\Windows Defender Advanced Threat
   Protection\Cyber"
   del *.* /f /s /q
   REG DELETE "HKLM\SOFTWARE\Microsoft\Windows Advanced Threat Protection" /v
   senseGuid /f
   exit
   ```

5. Reseal the golden image as you normally would.

Onboard macOS devices into Microsoft 365 overview

MacOS devices can be onboarded into Microsoft Purview solutions using either Intune, JAMF Pro, or any other MDM solutions. The onboarding procedures differ depending on which management solution you use. If your macOS devices have already been onboarded into Microsoft Defender for Endpoint (MDE), there are fewer steps. See Next steps for links to the appropriate procedures for you.

Applies to:

- Endpoint data loss prevention (DLP)
- Insider risk management

Before you begin

Before you get started with Endpoint DLP on macOS devices (the three latest versions), familiarize yourself with these articles:

- Learn about Endpoint data loss prevention
- Get started with Endpoint data loss prevention

If you aren't familiar with DLP at all, you should familiarize yourself with these articles as well:

- Learn about data loss prevention
- Plan for data loss prevention (DLP)
- Data loss prevention policy reference

If you aren't familiar with Insider Risk, read these articles:

- Insider risk management
- Plan for insider risk management

Your macOS devices must already be managed through Intune, JAMF Pro or any other MDM solutions.

- To onboard into Intune, see Deployment guide: Manage macOS devices in Microsoft Intune and Enroll your Mac with Intune Company Portal.

- To onboard into JAMF Pro see, JAMF Pro administrators guide and JAMF Pro Installation and Configuration Guide for Mac
- To onboard into other MDM solution see,

To take advantage of the classification improvements on file read access on macOS devices, roadmap ID 476099, the device must have Microsoft Defender Antimalware client version 101.25012.008 or newer installed.

Supported processors

macOS devices with x64 and M1, M2 and M3 (ARM64) processors are supported.

Supported browsers

Endpoint DLP supports these browsers on macOS (three latest released versions):

- Microsoft Edge (latest version)
- Safari (latest version, macOS only)
- Chrome (latest version)
- Firefox (latest version)

Licensing guidance

See, Microsoft 365 licensing guidance for information protection.

Prerequisites for each feature

Here are the prerequisites for each feature.

Expand table

Feature	Prerequisite
Device and Device group-based policy scoping support for Endpoint DLP (Roadmap ID 526792)	101.25072 or newer build is required

Conditions supported on macOS

Once a macOS device is onboarded into Microsoft Purview solutions, you can use the following condition with data loss prevention (DLP) policies:

Content Contains – Applies to documents that contain sensitive information types and sensitivity labels.

Content is not labeled - Applies to documents that do not contain any sensitivity labels as defined by Microsoft Purview Data Loss Prevention (DLP) policies.

> ⓘ **Note**
>
> '**Content is not labeled**' condition only works for doc/docx, xls/xlsx, ppt/pptx, and pdf file for Endpoint DLP.

File type is - This condition allows you to specify which types of files you want to monitor, restrict, or apply certain rules to, based on their format.

File extension is - This condition allows you to create policies that target files based on their extensions such as pdf, docx etc.

Document name contains words - Detects documents where the file name contains specific words or phrases such as 'credit'.

Document could not be scanned - Applies to documents when their content wasn't scanned. Examples include password protected files, files for which text extraction failed, files that exceed file size limit (64 MB for non-archive, 256 MB for archive)

Document or Attachment is password protected - Detects documents that are password protected.

Document couldn't complete scanning - Applies to documents when their content was scanned, however the entire document was not scanned. Examples include files for which extracted text exceeded the limits/thresholds.

Document Size equals or is greater than - Detects documents with file sizes that are greater than or equal to the specified value.

Activities that can be audited and restricted on macOS

Once a macOS device is onboarded into Microsoft Purview solutions, you can monitor and restrict the following actions using data loss prevention (DLP) policies.

Copy to a USB removable media – When enforced, this action blocks, warns, or audits the copying or moving of protected files from an endpoint device to USB removable media.

Copy to network shares – When enforced, this action blocks, warns, or audits the copying or moving of protected files from an endpoint device to any network share.

Print – When enforced, this action blocks, warns, or audits when protected files are printed from an endpoint device.

Copy to clipboard – When enforced, this action blocks, warns, or audits data in protected file that is being copied to a clipboard on an endpoint device.

Upload to cloud – This action blocks, warns, or audits when protected files are uploaded or prevented from being uploaded to cloud services based on the allow/unallowed domains list in global settings. When this action is set to warn or block, other browsers (defined on the unallowed browsers list under Global settings) are blocked from accessing the file.

Accessed by unallowed apps – When enforced, this action prevents applications that are on the unallowed apps list (as defined in Global settings) from accessing protected files on an endpoint device.

Onboarding devices into device management

You must enable device monitoring and onboard your endpoints before you can monitor and protect sensitive items on a device. Both of these actions are done in the Microsoft Purview portal.

When you want to onboard devices that haven't been onboarded yet, download the appropriate script and deploy it to those devices.

1. Open the Microsoft Purview portal **Settings** page, expand **Device onboarding**, select **Devices**, and choose **Enable device monitoring**.

> **Note**
>
> While it usually takes about 60 seconds for device onboarding to be enabled, please allow up to 30 minutes before engaging with Microsoft support.

1. Once device Monitoring is enabled, choose **Turn on macOS device monitoring**.

Next steps

Getting devices onboarded into Microsoft Purview solutions is required in order to receive DLP sensor telemetry and to enforce data loss prevention policies. As mentioned, macOS devices can be onboarded into Microsoft Purview solutions using Intune, JAMF Pro or any other MDM solutions. Review the following articles for the procedures appropriate to your situation.

Expand table

Topic	Description
Intune	For macOS devices that are managed through Intune
Intune for Microsoft Defender for Endpoint customers	For macOS devices that are managed through Intune and that have Microsoft Defender for Endpoint (MDE) deployed to them
JAMF Pro	For macOS devices that are managed through JAMF Pro
JAMF Pro for Microsoft Defender for Endpoint	For macOS devices that are managed through JAMF Pro and that have Microsoft Defender for Endpoint (MDE) deployed to them
Any MDM	For macOS devices that are managed through Any MDM
Any MDM for Microsoft Defender for Endpoint	For macOS devices that are managed through any MDM that have Microsoft Defender for Endpoint (MDE) deployed to them

Device configuration and policy sync status

You can check the **Configuration status** and the **Policy sync status** of all your onboarded devices in the **Devices** list. For macOS devices, the Microsoft Defender for Endpoint (MDE) minimum version is 101.95.07. For more information on the configuration and policy status, select an onboarded device and then open the details pane.

Configuration status shows you whether the device is configured correctly, meets DLP configuration requirements, and the last time the configuration was validated. For macOS devices, configuration includes:

- If you use Intune, check the UPN configuration by making sure your devices are onboarded into Intune.
- If you use Intune, make sure that your devices are enrolled in the Company Portal
- If you use JAMF Pro, make sure your devices are onboarded before checking the UPN configuration.
- If you use other MDM solutions, make sure your devices are onboarded in your solution before checking the UPN configuration.

For more information see: https://learn.microsoft.com/en-us/entra/identity-platform/apple-sso-plugin

Policy sync status shows you whether the most current versions of the endpoint DLP policies have been synchronized to the device and the last time a policy sync occurred.

Expand table

Field value	Configuration status	Policy sync status
Updated	Device health parameters are enabled and correctly set.	Device has been updated with the current versions of policies.
Not updated	You need to enable the configuration settings for this device. Follow the procedures for your environment: - Onboard and offboard macOS devices into Microsoft Purview solutions using Intune - Onboard and offboard macOS devices into Purview solutions using Intune for Microsoft Defender for Endpoint customers - Onboard and offboard macOS devices into Microsoft Purview solutions using JAMF Pro - Onboard and offboard macOS devices into Purview solutions using JAMF Pro for Microsoft Defender for Endpoint customers	This device hasn't synced the latest policy updates. If the policy update was made within the last 2 hours, wait for the policy to reach your device.
Not available	Device properties aren't available in the device list. This could be because the device doesn't meet the minimum OS version or configuration, or because the device was just onboarded.	Device properties aren't available in the device list. This could be because the device doesn't meet the minimum OS version or configuration, or because the device was just onboarded.

Last updated on 06/26/2026

Onboard and offboard macOS devices into Microsoft Purview solutions using Intune

09/26/2025

You can use Microsoft Intune to onboard macOS devices into Microsoft Purview solutions.

> **Important**
>
> Use this procedure if you ***do not*** have Microsoft Defender for Endpoint (MDE) deployed to your macOS devices

Applies to:

- Endpoint data loss prevention (DLP)
- Insider risk management

Before you begin

- Make sure your macOS devices are onboarded into Intune and are enrolled in the Company Portal app.
- Make sure you have access to the Microsoft Intune admin center.
- Create the user groups that you're going to assign the configuration updates to.
- OPTIONAL: Install the v95+ Microsoft Edge browser on your macOS devices to have native Endpoint DLP support on Microsoft Edge.

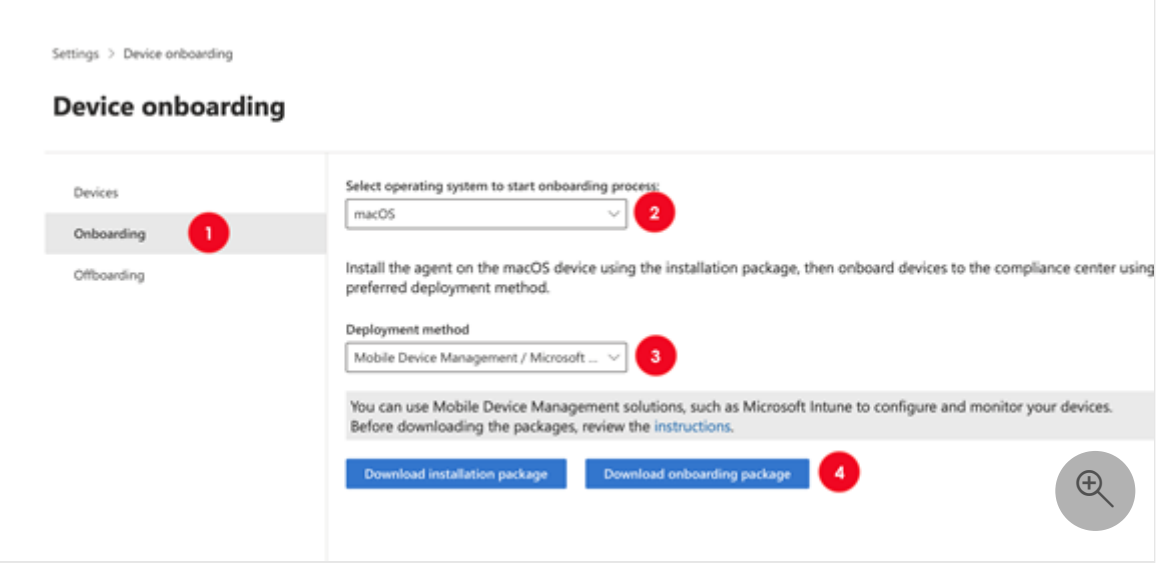
> **Note**
>
> The three most recent major releases of macOS are supported.

Onboard macOS devices into Microsoft Purview solutions using Microsoft Intune

Onboarding a macOS device into Purvoiew solutions is a multi-phase process.

1. Get the device onboarding package
2. Deploy the mobileconfig and onboarding packages
3. Publish the application

Prerequisites



Download the following files:

Expand table

File	Description
mdatp.mobileconfig	System mobile config file
com.microsoft.wdav.mobileconfig.	MDE preferences

> **Tip**
>
> We recommend downloading the bundled **mdatp.mobileconfig** file, rather than the **individual** *.mobileconfig* files. The bundled file includes the following required files:
>
> - accessibility.mobileconfig
> - fulldisk.mobileconfig
> - netfilter.mobileconfig
> - sysext.mobileconfig
>
> If any of these files are updated, you need to either download the updated bundle, or download each updated file individually.

Get the device onboarding package

1. In the **Microsoft Purview portal** open **Settings** > **Device Onboarding** and then choose **Onboarding**.

2. For the **Select operating system to start onboarding process** option, choose **macOS**.
3. For **Deployment method**, choose **Mobile Device Management/Microsoft Intune**.
4. Choose **Download onboarding package**.
5. Extract the .ZIP file and open the *Intune* folder. This contains the onboarding code in the *DeviceComplianceOnboarding.xml* file.

Deploy the mobileconfig and onboarding packages

1. Open the **Microsoft Intune admin center** and navigate to **Devices** > **macOS** > **Configuration**.
2. Choose: **+ Create** and then choose **New policy**.
3. Select the following values:
   a. **Platform** = macOS
   b. **Profile type** = Templates
   c. **Template name** = Custom
4. Choose **Create**.
5. On the **Basics** page, Enter a name for the profile, such as *Microsoft Purview System MobileConfig*, and then Choose **Next**.
6. On the **Configuration settings** page, Choose the `mdatp.mobileconfig` file that you downloaded in the pre-requisites section as the configuration profile file.
7. Choose **Next**.
8. On the **Assignments** tab, add the group you want to deploy these configurations to and then choose **Next**.
9. Review your settings and then choose **Create** to deploy the configuration.
10. Repeat steps 2-9 to create profiles for the:
    a. **DeviceComplianceOnboarding.xml** file. Name it *Microsoft Purview Device Onboarding Package*
    b. **com.microsoft.wdav.mobileconfig** file. Name it *Microsoft Endpoint Device Preferences*
11. In the macOS **Configuration policies** page, the policies you created now display. Select **Refresh** if your changes don't show up right away.
12. Choose the profile that you just created. Next, view the **Device and user check-in status** report of the configuration policy.

Publish the application

Microsoft Endpoint data loss protection is installed as a component of Microsoft Defender for Endpoint on macOS. This procedure applies to onboarding devices into Microsoft Purview solutions

1. In the Microsoft Intune admin center, open **Apps**.
2. Select **macOS**.
3. On the **macOS** > **macOS apps** page, select **Create**.
4. On the **Select app type** > **Create app** slider, select the App type drop-down and then **macOS** under **Microsoft Defender for Endpoint**.
5. Choose the **Select** button.
6. On the **App Information** tab, keep the default values and then choose **Next**.
7. On the **Assignments** tab, add assignments and then choose **Next**.
8. You can visit **Apps** > **macOS** to see the new application listed.

Offboard macOS devices using Intune

> **Note**
>
> Offboarding causes the device to stop sending sensor data to the portal. However, data from the device, including reference to any alerts it has had, will be retained for up to six months.

1. In the **Microsoft Intune admin center**, open **Devices** > **macOS** > **Configuration**. The policies you created are listed.
2. Select **Microsoft Endpoint Device Preferences** policy.
3. Under **Properties** > **Assignments,** choose **Edit**.
4. Remove the group from the assignment. This will uninstall the com.microsoft.wdav.mobileconfig configuration profile file and offboard the macOS device from Purview solutions.

Onboard and offboard macOS devices into Purview solutions using Intune for Microsoft Defender for Endpoint customers

Summarize this article for me

You can use Microsoft Intune to onboard macOS devices into Microsoft Purview solutions.

> **Important**
>
> Use this procedure ***if you have already deployed*** Microsoft Defender for Endpoint (MDE) to your macOS devices.

Applies to:

- Customers who have MDE deployed to their macOS devices.
- Endpoint data loss prevention (DLP)
- Insider risk management

Before you begin

- Make sure your macOS devices are onboarded to Intune and enrolled in the Company Portal app.
- Make sure you have access to the Microsoft Intune admin center.
- OPTIONAL: Install the v95+ Microsoft Edge browser on your macOS devices.

> **Note**
>
> The three most recent major releases of macOS are supported.

Onboard macOS devices into Microsoft Purview solutions using Microsoft Intune

Given that Microsoft Defender for Endpoints (MDE) has already been deployed to your macOS devices, you can still onboard the devices into Purview solutions by competing the following steps:

1. Validate existing FDA system configuration profile

2. Update MDE Preferences

Validate existing system configuration profile

1. A full disk access (FDA) configuration profile should have been created and deployed previously for MDE. (For details, see Intune-based deployment for Microsoft Defender for Endpoint on Mac).

2. Endpoint data loss prevention (DLP) *requires additional FDA permission* for the new application (`com.microsoft.dlp.daemon`). Validate that the `com.microsoft.dlp.daemon` is in the fulldisk.mobileconfig file

Update MDE Preferences

1. Find the existing **MDE Preferences** configuration profile. See Intune-based deployment for Microsoft Defender for Endpoint on Mac for details.

2. Add the following key to the `com.microsoft.wdav` configuration profile file, then save the file.

```xml
<key>features</key>
<dict>
  <key>dataLossPrevention</key>
  <string>enabled</string>
</dict>
```

Offboard macOS devices using Microsoft Intune

> **Important**
>
> Offboarding causes the device to stop sending sensor data to the portal. However, data received from the device, including references to any alerts it has had, will be retained for up to six months.

1. In the **Microsoft Intune admin center**, open **Devices** > **Configuration**. The policies you created display.

2. Choose the **MDE Preferences** policy.

3. Under **Properties** > **Configuration Settings**, choose **Edit**

4. Remove these settings:

```xml
<key>features</key>
<dict>
    <key>dataLossPrevention</key>
    <string>enabled</string>
</dict>
```

5. Choose **Review+**Save**. This will offboard the macOS devices from Purview solutions while not changing the macOS device enrollment in MDE.

Last updated on 02/17/2026

Onboard and offboard macOS devices into Microsoft Purview solutions using JAMF Pro

09/26/2025

You can use JAMF Pro to onboard macOS devices into Microsoft Purview solutions such as Endpoint data loss prevention (DLP).

> **Important**
>
> Use this procedure if you ***do not*** have Microsoft Defender for Endpoint (MDE) deployed to your macOS devices.

Applies to:

- Endpoint data loss prevention (DLP)
- Insider risk management

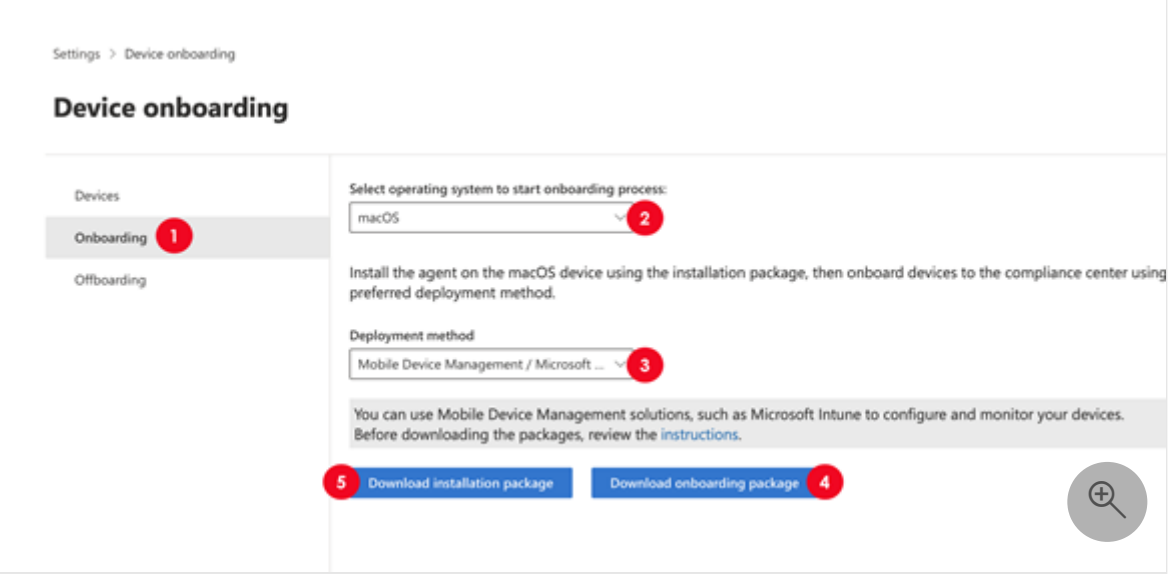
Before you begin

- Make sure your macOS devices are managed through JAMF pro and are associated with an identity (Microsoft Entra joined UPN) through JAMF Connect.
- OPTIONAL: Install the v95+ Microsoft Edge browser on your macOS devices for native Endpoint DLP support on Microsoft Edge.

> **Note**
>
> The three most recent major releases of macOS are supported.

Onboard devices into Microsoft Purview solutions using JAMF Pro

Prerequisites



Download the following files.

Expand table

File	Description
mdatp.mobileconfig	This is the bundled file.
schema.json	This is the MDE preference file.

> **Tip**
>
> We recommend downloading the bundled **mdatp.mobileconfig** file, rather than the **individual** *.mobileconfig* files. The bundled file includes the following required files:
>
> - accessibility.mobileconfig
> - fulldisk.mobileconfig
> - netfilter.mobileconfig
> - sysext.mobileconfig
>
> If any of these files are updated, you need to either download the updated bundle, or download each updated file individually.

Get the device onboarding and installation packages

1. In the Purview portal, open **Settings** > **Device Onboarding** and then choose **Onboarding**.
2. For the **Select operating system to start onboarding process** value, choose **macOS**.
3. For **Deployment method**, choose **Mobile Device Management/Microsoft Intune**.

4. Choose **Download onboarding package** and then extract the contents of the device onboarding package. the *DeviceComplianceOnboarding.plist* file is downloaded to the JAMF folder.

5. Choose **Download installation package**.

Deploy onboarding packages

Create a new configuration profile in JAMF Pro. Use the following values:

- **Name:** *MDATP onboarding for macOS*
- **Description:** **MDATP EDR onboarding for macOS*
- **Category:** *none*
- **Distribution method:** *`*install automatically*
- **Level:** *computer level*

For help with performing steps within the Jamf Pro console, refer to the JAMF Pro documentation, or contact Jamf Pro support.

Configure application preferences

> **Important**
>
> You must use *com.microsoft.wdav* as the **Preference Domain** value. Microsoft Defender for Endpoint uses this name and *com.microsoft.wdav.ext* to load the managed settings.

For information about how to create a new configuration profile in JAMF Pro, refer to the JAMF Pro documentation. Or contact Jamf Pro support.

Use these values:

- **Name:** *MDATP MDAV configuration settings*
- **Description:** *Leave this blank*
- **Category:** *none*
- **Distribution method:** *install automatically*
- **Level:** *computer level*

Deploy system configuration profiles

For information about how to deploy system configuration profiles in JAMF Pro, refer to the JAMF Pro documentation, or contact Jamf Pro support.

Offboard macOS devices using JAMF Pro

> **Important**
>
> Offboarding causes the device to stop sending sensor data to the portal. However, data from the device, including references to any alerts it has had, will be retained for up to six months.

1. If you aren't using MDE, uninstall the application. See the **Package Deployment** section in the JAMF Pro documentation.

2. Restart the macOS device. (Some applications may lose printing functionality until they're restarted.)

Onboard and offboard macOS devices into Purview solutions using Jamf Pro for Microsoft Defender for Endpoint customers

09/26/2025

You can use Jamf Pro to onboard macOS devices into Microsoft Purview solutions.

> **Important**
>
> Use this procedure ***if you have*** deployed Microsoft Defender for Endpoint (MDE) to your macOS devices

Applies to:

- Customers who have MDE deployed to their macOS devices.
- Endpoint data loss prevention (DLP)
- Insider risk management

Before you begin

- Make sure your macOS devices are managed through Jamf pro and are associated with an identity (Microsoft Entra joined UPN) through Jamf Connect.
- OPTIONAL: Install the v95+ Edge browser on your macOS devices to have native Endpoint DLP support on Edge.

> **Note**
>
> The three most recent major releases of macOS are supported.

Onboard devices into Microsoft Purview solutions using Jamf Pro

Onboarding a macOS device into Purview solutions is a multi-phase process.

1. Update the existing MDE Preference domain profile using the Jamf Pro console
2. Enable full-disk access
3. Enable accessibility access to Microsoft Purview data loss prevention

4. Check the macOS device

Prerequisites

Download the following files:

Expand table

File	Description
accessibility.mobileconfig	Accessibility
fulldisk.mobileconfig	Full disk access (FDA)
schema.json	MDE preference

If any of these individual files are updated, you must download the updated bundled file and redeploy as described.

> **Tip**
>
> We recommend downloading the bundled **mdatp.mobileconfig** file, rather than the **individual** *.mobileconfig* files. The bundled file includes the following required files:
>
> - accessibility.mobileconfig
> - fulldisk.mobileconfig
> - netfilter.mobileconfig
> - sysext.mobileconfig
>
> If any of these files are updated, you need to either download the updated bundle, or download each updated file individually.

Update the existing MDE Preference domain profile using the Jamf Pro console

For information about how to replace the *schema.json* file in the MDE deployment with the updated version, and configure the settings in the Jamf Pro console, refer to the Jamf Pro documentation, or contact Jamf Pro support.

Enable full-disk access

To update the existing full disk access profile with the `fulldisk.mobileconfig` file, upload `fulldisk.mobileconfig` to Jamf. For more information, refer to Set up the Microsoft Defender for Endpoint on macOS policies in Jamf Pro.

Enable accessibility access to Microsoft Purview data loss prevention

To grant accessibility access to DLP, upload the `accessibility.mobileconfig` file you downloaded previously to Jamf, as described in Deploy system configuration profiles.

Check the macOS device

1. Restart the macOS device.
2. Verify that the following profiles are listed under Profiles in System Settings:

    - Accessibility
    - MAU
    - MDATP Onboarding
    - MDE Preferences
    - Management profile
    - Network filter
    - Notifications
    - System extension profile

Offboard macOS devices using Jamf Pro

> **Important**
>
> Offboarding causes the device to stop sending sensor data to the portal. However, data from the device, including references to any alerts it has had, will be retained for up to six months.

For information about how to offboard a macOS device using Jamf Pro, refer to the Jamf Pro documentation, or contact Jamf Pro support.

Any mobile device management tool for customers without Microsoft Defender for Endpoint

09/26/2025

You can use any mobile device management (MDM) solution to onboard macOS devices into Microsoft Purview solutions such as Endpoint data loss prevention (DLP).

> **Important**
>
> Use this procedure if you ***do not*** have Microsoft Defender for Endpoint (MDE) deployed to your macOS devices.

Applies to:

- Endpoint data loss prevention (DLP)

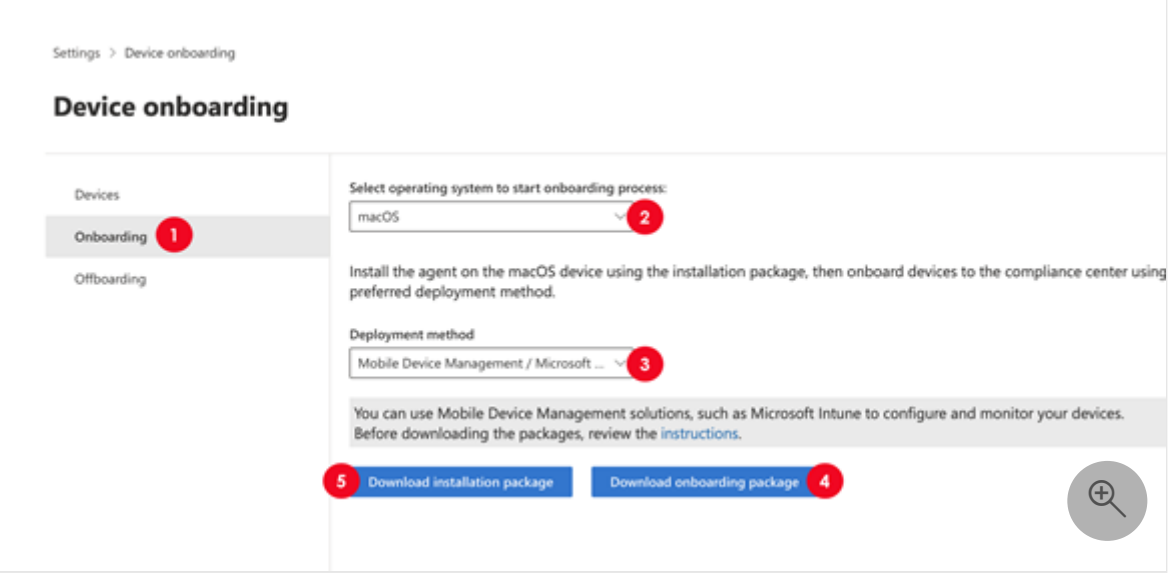
Before you begin

- OPTIONAL: Install the v95+ Microsoft Edge browser on your macOS devices for native Endpoint DLP support on Microsoft Edge.

> **Note**
>
> The three most recent major releases of macOS are supported.

Onboard devices into Microsoft Purview solutions using any MDM

Prerequisites



- You must have Microsoft Defender Antimalware client version 101.25012.0005 or newer installed on the device.
- Download the following files.

Expand table

File	Description
mdatp.mobileconfig	This is the bundled file.
schema.json	This is the MDE preference file.

> **Tip**
>
> We recommend downloading the bundled **mdatp.mobileconfig** file, rather than the **individual** *.mobileconfig* files. The bundled file includes the following required files:
>
> - accessibility.mobileconfig
> - fulldisk.mobileconfig
> - netfilter.mobileconfig
> - sysext.mobileconfig
>
> If any of these files are updated, you need to either download the updated bundle, or download each updated file individually.

Get the device onboarding and installation packages

1. In the Microsoft Purview portal, open **Settings** > **Device Onboarding** and then choose **Onboarding**.
2. For the **Select operating system to start onboarding process** value, choose **macOS**.
3. For **Deployment method**, choose **Mobile Device Management/Microsoft Intune**.
4. Choose **Download onboarding package** and then extract the contents of the device onboarding package. the *DeviceComplianceOnboarding.plist* file is downloaded to the

JAMF folder.

5. Choose **Download installation package**.

Deploy onboarding packages

1. Create a new configuration profile in your MDM. Use the following values (if applicable):

- **Name:** *MDATP onboarding for macOS*
- **Description:** **MDATP EDR onboarding for macOS*
- **Category:** *none*
- **Distribution method:** *`*install automatically*
- **Level:** *computer level*

1. Upload *DeviceComplianceOnboarding.plist* as a custom settings
2. Enter `com.microsoft.wdav.atp` as the **Preference Domain**,
3. Choose **Save**. Refer to your MDM documentation on creating configuration profile.

Configure application preferences

> **Important**
>
> You must use *com.microsoft.wdav* as the **Preference Domain** value. Microsoft Defender for Endpoint uses this name and *com.microsoft.wdav.ext* to load the managed settings.

For information about how to create a new configuration profile, refer to your MDM documentation.

1. Create a new configuration profile. Use these values (if applicable):

- **Name:** *MDATP MDAV configuration settings*
- **Description:** *Leave this blank*
- **Category:** *none*
- **Distribution method:** *install automatically*
- **Level:** *computer level*

2. Add the `schema.json` as a custom schema in the configuration profile.

3. Under **Preference Domain Properties**, locate **Data Loss Prevention** and select `enabled`.

4. Save the profile after adjusting other MDE settings (if necessary).

Deploy system configuration profiles

For information about how to deploy system configuration profiles, refer to your MDM documentation.

1. Create a new configuration profile by uploading the `mdatp.mobileconfig` file into your MDM.

Register Identity

Depending on your configuration, you register the Microsoft Entra identity of the using one of these two methods.

Method 1: Register without the Microsoft Intune Company Portal

1. Install any Microsoft application such as Microsoft Office, or Teams, or Microsoft Edge. When the user logs in using valid Microsoft Entra account, that account is registered as the UPN for DLP policy evaluation. Personal Microsoft accounts aren't considered as valid. The device may need to restart to complete the registration.

Method 2: Register with the Microsoft Intune Company Portal

This method is for users whose macOS devices don't use Microsoft apps.

You can Get the Microsoft Intune Company Portal if you don't already have it.

1. Deploy Microsoft Enterprise SSO plug-in for Apple devices to their managed macOS devices using your MDM solution. The Microsoft Intune Company Portal for macOS provides the SSO plugin for smooth user experience. So, the Microsoft Intune Company Portal must be installed on the macOS device, but the user doesn't need to be signed into the Intune Company portal. When the user signs-in to any non-Microsoft Authentication Library (MSAL) application, like Safari browser, the SSO plugin is enabled to register the UPN. The device may need to restart to complete the registration.

For information on troubleshooting the Microsoft Enterprise SSO Extension, go to Troubleshooting the Microsoft Enterprise SSO Extension plugin on Apple devices.

Offboard macOS devices using any MDM

> **Important**

Offboarding causes the device to stop sending sensor data to the portal. However, data from the device, including references to any alerts it has had, will be retained for up to six months.

1. If you aren't using MDE, uninstall the application. Refer to your MDM documentation for any MDM specific instructions for uninstallation.
2. Restart the macOS device. (Some applications may lose printing functionality until they're restarted.)

Any mobile device management tool for Microsoft Defender for Endpoint customers

09/26/2025

You can use any MDM to onboard macOS devices into Microsoft Purview solutions.

> **Important**
>
> Use this procedure ***if you have*** deployed Microsoft Defender for Endpoint (MDE) to your macOS devices

Applies to:

- Customers who have MDE deployed to their macOS devices.
- Endpoint data loss prevention (DLP)

Before you begin

- OPTIONAL: Install the v95+ Microsoft Edge browser on your macOS devices to have native Endpoint DLP support on Microsoft Edge.

> **Note**
>
> The three most recent major releases of macOS are supported.

Onboard devices into Microsoft Purview solutions using any MDM solution

Onboarding a macOS device into Purview solutions is a multi-phase process.

1. Update any existing MDE Preference domain profile by setting `com.microsoft.wdav` as Preference domain to enable Data Loss Prevention. Refer to update preference domain profile.
2. Enable full-disk access
3. Enable accessibility access to Microsoft Purview Data Loss Prevention
4. Register identity
5. Check the macOS device

Prerequisites

- Device must have Microsoft Defender Antimalware client version 101.25012.0005 or newer installed.
- Download the following files:

Expand table

File	Description
accessibility.mobileconfig	Accessibility
fulldisk.mobileconfig	Full disk access (FDA)
schema.json	MDE preference

If any of these individual files are updated, you must download the updated bundled file and redeploy as described.

> **Tip**
>
> We recommend downloading the bundled **mdatp.mobileconfig** file, rather than the **individual** *.mobileconfig* files. The bundled file includes the following required files:
>
> - accessibility.mobileconfig
> - fulldisk.mobileconfig
> - netfilter.mobileconfig
> - sysext.mobileconfig
>
> If any of these files are updated, you need to either download the updated bundle, or download each updated file individually.

Update the existing MDE Preference domain profile

1. Replace the *schema.json* file in the MDE deployment with the updated version that you just downloaded. For information about how to replace the *schema.json* file in the MDE deployment with the updated version, and configure the settings in your MDM solution, refer to your MDM solution documentation.

Enable full-disk access

To update the existing full disk access profile with the `fulldisk.mobileconfig` file, upload `fulldisk.mobileconfig` to your MDM solution to enable full disk access for Data Loss Prevention.

Enable accessibility access to Microsoft Purview Data Loss Prevention

To grant accessibility access to DLP, upload the `accessibility.mobileconfig` file you downloaded previously to your MDM solution. This should be similar to what is described in Deploy system configuration profiles.

Register Identity

Depending on your configuration, you'll register the Microsoft Entra identity of the using one of these two methods.

Method 1: Register without the Microsoft Intune Company Portal

1. Install any Microsoft application such as Microsoft Office, or Teams, or Microsoft Edge. When the user logs in using valid Microsoft Entra account, that account is registered as the UPN for DLP policy evaluation. Personal Microsoft accounts aren't considered as valid.

Method 2: Register with the Microsoft Intune Company Portal

This method is for users whose macOS devices don't use Microsoft apps.

You can Get the Microsoft Intune Company Portal if you don't already have it.

1. Deploy Microsoft Enterprise SSO plug-in for Apple devices to their managed macOS devices using your MDM solution. The Microsoft Intune Company Portal for macOS provides the SSO plugin for smooth user experience. So, the Microsoft Intune Company Portal must be installed on the macOS device, but the user doesn't need to be signed into the Intune Company portal. When the user signs-in to any non-Microsoft Authentication Library (MSAL) application, like Safari browser, the SSO plugin is enabled to register the UPN.

For information on troubleshooting the Microsoft Enterprise SSO Extension, go to Troubleshooting the Microsoft Enterprise SSO Extension plugin on Apple devices.

Check the macOS device

1. Restart the macOS device.
2. Verify that the following profiles are listed under Profiles in System Settings:

    - Accessibility
    - MAU
    - MDATP Onboarding
    - MDE Preferences
    - Management profile
    - Network filter
    - Notifications
    - System extension profile

Offboard macOS devices

> **ⓘ Important**
>
> Offboarding causes the device to stop sending sensor data to the portal. However, data from the device, including references to any alerts it has had, will be retained for up to six months.

For information about how to offboard a macOS using any MDM solution, refer to the documetentation of your MDM solution.

Security Copilot in Microsoft Purview Overview

Summarize this article for me

Microsoft Security Copilot is a cloud-based AI platform that can assist security and compliance professionals in protecting their organization's data. Security and compliance professionals can use Security Copilot to identify, summarize, triage, and remediate issues within the following Microsoft Purview solutions:

- Data Security Posture Agent (DSPM)
- Microsoft Purview Data Loss Prevention (DLP)
- Microsoft Purview Insider Risk Management
- Microsoft Purview Communication Compliance
- Microsoft Purview eDiscovery

For more information about what Security Copilot can do and the different scenarios it supports, read What is Microsoft Security Copilot?.

Know before you begin

If you're new to Security Copilot, you should familiarize yourself with it by reading these articles:

- What is Microsoft Security Copilot?
- Microsoft Security Copilot experiences
- Get started with Microsoft Security Copilot
- Understand authentication in Microsoft Security Copilot
- Prompting in Microsoft Security Copilot
- Configure Owner settings
- Learn about Security Copilot in Microsoft 365 E5

Security Copilot integration in Microsoft Purview

When you sign up for Security Copilot in the same tenant as Microsoft Purview, you can use both the Security Copilot embedded and standalone experiences. Security Copilot capabilities, like summarizing DLP or insider risk management alerts, are embedded into Microsoft Purview features.

Copilot in Microsoft Purview embedded experiences is a set of capabilities that are embedded in Microsoft Purview features. For more information, see standalone and embedded

experiences.

Copilot in Microsoft Purview standalone experience is a chat-like experience that you can use to ask questions and get answers about your data. For more information, see standalone and embedded experiences.

Key features in the embedded experience

You can open Security Copilot in Microsoft Purview by selecting the **Copilot** icon in the top navigation bar. It's available across all Microsoft Purview solutions.

The embedded experience in Purview can help you:

- *Get AI-generated summaries from Microsoft Purview product documentation*.
- *Use suggested or customized prompts in DSPM*. Learn more about the data security posture in your organization. For more information, see Use Microsoft Security Copilot with Data Security Posture Management.
- *Summarize alerts in DLP*. For more information on this and how to access Security Copilot in DLP, see Investigate a DLP alert.
- *Get insights into policies*. Security copilot can help you understand what your policies are doing in your organization, and where they're active. For more information, see Get Insights with Microsoft Security Copilot.
- *Summarize alerts in insider risk management*. For more information on this and how to access Security Copilot in Insider Risk Management, see Investigate insider risk management activities.
- *Summarize policy matches based on trainable classifiers for communication compliance*. Communication compliance also provides an interactive prompt experience to dig deeper into the summary. For more information on this and the steps to access Copilot in Communication Compliance, see Investigate and remediate communication compliance alerts.
- *Get contextual summary for eDiscovery cases*. For more information, see Group and view documents in a review set in eDiscovery (Premium).
- *Gain insights in activity explorer data and generate filters from natural language prompts (preview)*. For more information, see Microsoft Security Copilot in activity explorer (preview).

Key features in the standalone experience

The Security Copilot in Microsoft Purview standalone experience has many built in capabilities. You can use these capabilities to get insights from your Purview data and make connections between datapoints. This information can help you understand your information security and compliance posture and triage alerts.

- *DLP and Insider Risk Management data and user risk promptbook*. Security Copilot in Microsoft Purview analyzes data from DLP and insider risk management and, by running multiple, sequential prompts contained in a promptbook, presents you with integrated results. For more information, see Microsoft Copilot in Microsoft Purview prompts and promptbooks.

System capabilities of Security Copilot

In the standalone experience, there are built-in capabilities (prompts) that are available once the Microsoft Purview plugin is enabled.

Security Copilot in Microsoft Purview brings three types of capabilities:

- Summarize Microsoft Purview alerts.
- Triage Microsoft Purview alerts.
- Drill down into your Microsoft Purview data.

Enable the Microsoft Purview source in Microsoft Security Copilot

> **Important**
>
> Security Copilot in Purview must be enabled for both the standalone and embedded experiences to work.

Security Copilot in Purview is enabled by default. To enable or disable the Microsoft Purview source in Microsoft Security Copilot, follow these steps:

1. Ensure that you have permissions.
2. Open https://securitycopilot.microsoft.com/.
3. Open **Sources** in the prompt bar.

4. On the **Manage plugins** page, set the **Purview** toggle to **On** to enable or **Off** to disable.

Review the Microsoft Purview system capabilities

1. Select the capabilities control in the prompt bar.

2. Select **See all system capabilities** to see all the system capabilities that are available for Microsoft Purview. Here are a few:

    - Get Data Risk Summary
    - Get User Risk Summary
    - Summarize Purview Alert
    - Triage Purview Alerts
    - Zoom into Purview Data and User Risk

Sample prompts

For guidance on writing effective prompts, see Prompting in Microsoft Security Copilot. Here are some examples:

- *Show me the top five DLP alerts from the past 24 hours.*
- *Summarize the DLP alert with ID <12345>.*
- *What's the risk profile of the user that's associated with the DLP alert <12345>.*
- *Show me the Insider Risk Management alerts for <user> .*
- *What items did user <user> exfiltrate in the past 30 days.*

Provide feedback

Your feedback is vital to guide the current and planned development of the product. The best way to provide this feedback is directly in the product. Select **How's this response?** at the bottom of each completed prompt and choose any of the following options:

- **Looks right** - Select if the results are accurate, based on your assessment.
- **Needs improvement** - Select if any detail in the results is incorrect or incomplete, based on your assessment.
- **Inappropriate** - Select if the results contain questionable, ambiguous, or potentially harmful information.

For each feedback option, you can provide more information in the next dialog box that appears. Whenever possible, and especially when the result is **Needs improvement**, write a few words explaining what can be done to improve the outcome. If you entered prompts specific to Microsoft Purview and the results aren't related, then include that information.

Privacy and data security in Microsoft Security Copilot

To understand how Microsoft Security Copilot in Purview handles your prompts and the data that's retrieved from the service (prompt output), see the Privacy and data security in Microsoft Security Copilot.

Last updated on 02/24/2026

Microsoft Security Copilot in Microsoft Purview prompts and promptbooks

Summarize this article for me

Microsoft Security Copilot is a stand-alone chat-based experience that helps you get insights from your security data and make connections between datapoints. You interact with the stand-alone experience by entering prompts, and Security Copilot returns results. This article focuses on the stand-alone experience and how to use it to get insights from your Microsoft Purview data.

Know before you begin

If you're new to Microsoft Security Copilot, read these articles before you begin creating your own prompts and promptbooks:

- What is Microsoft Security Copilot?
- Microsoft Security Copilot experiences
- Get started with Microsoft Security Copilot
- Microsoft Security Copilot in Microsoft Purview
- Understand authentication in Microsoft Security Copilot
- Prompting in Microsoft Security Copilot

> **Important**
>
> You must enable the Security Copilot in Purview plugin to use the Microsoft Purview prompts and promptbooks. Use the steps in **Enable the Microsoft Purview source in Microsoft Security Copilot**

Prompting in Security Copilot in Microsoft Purview

You can use prompts in three different ways:

Open ended

Open ended prompts are ones that you write yourself without any suggestions from Security Copilot. You can use these prompts to ask questions about your data that are specific to your needs at a certain point in time or when you need a custom prompt that isn't covered by the

prompt suggestions or a promptbook. For more information on creating solid prompts, see Create effective prompts.

Prompt suggestions

Prompt suggestions are prewritten prompts that you can use as a starting point and customize to fit your needs. They're listed under all system capabilities. Once you enable the Purview add-in, these prompt suggestions are available to you.

Get Data Risk Summary fetches information from Microsoft Purview Information Protection and Microsoft Purview Data Loss Prevention (DLP), and summarizes the risk associated with data impacted by a security incident or a DLP alert.

Get User Risk Summary summarizes the risk associated with any user by using their risk profile from Microsoft Purview Insider Risk Management.

Summarize Purview Alert provides more details about a Purview alert, including a DLP alert and an insider risk management alert.

Triage Purview Alerts retrieves the top or most recent DLP alerts, organizing DLP alerts based on user preferences.

Zoom Into Purview Data Risk fetches the information from Microsoft Purview Information Protection and DLP and helps identify the risks and attributes related to the data.

Zoom Into Purview User Risk fetches information about the user's activities, including operations and actions done by the user, user activity over a time span, data leakage or exfiltration activities by the user, sequential activities by the user, or any signs of anomalous or unusual behavior by the user.

Promptbooks

A promptbook is a collection of prompts that are in sequence. The stand-alone experience can use the output from one prompt as the input for the next prompt, and it can run multiple prompts in a sequence. As you use Security Copilot with the Microsoft Purview add-in enabled, you may find that you keep using the same prompts over and over. You can save time by collecting all these prompts into a promptbook. Then, you can run the promptbook to get all the insights you need in one go. You can limit the use of a promptbook to yourself, or you can share it with others in your organization.

This article provides two sample sets of prompts you can use for investigating Microsoft Purview Data Loss Prevention (DLP) and Microsoft Purview Insider Risk Management data. You

can start with these prompts, then customize them to fit your specific needs. Once you have them tuned the way you want, you can create promptbooks from them.

Run a prompt

1. Go to Microsoft Security Copilot and sign in with your credentials.
2. By default, the **Purview** plugin should be enabled. To confirm, select **Sources**. In **Plugins**, confirm Microsoft Purview is on. Close **Sources**.
3. Navigate to the prompt bar.
4. Enter your prompt.

For example, enter:

- *Show me the five most recent high severity DLP alerts* or
- *Show me the risk associated with user user@contoso.com*.

For more information on creating solid prompts, see Create effective prompts

Promptbooks for Microsoft Purview features

Here are two sequences of prompts that you can use to investigate Microsoft Purview Data Loss Prevention (DLP) and Microsoft Purview Insider Risk Management data. Refer to Build your own promptbooks for the procedures on how to create, share, and edit a promptbook.

Sample prompt sequences

Microsoft Purview Data Loss Prevention

1. Show me the top five high severity DLP alerts.
2. Summarize the first alert in the list.
3. What actions were performed on the file in the alert?
4. Who is the user related to the alert?
5. What are the data risks related to the alert?
6. What is the risk summary of the user?

Microsoft Purview Insider Risk Management

1. Show me the risk associated with user *user@contoso.com*
2. Show me the exfiltration activities for this user.
3. Show me the sequential activities for this user.

4. Show me obfuscation activities for this user.
5. Show me all the activities that this user performed over the past 30 days.

Security Copilot agents in Microsoft Purview overview

Microsoft Security Copilot agents are AI-powered processes that help you with specific role-based tasks. Microsoft Purview offers:

- Microsoft Purview Data Loss Prevention (DLP) triage agent
- Microsoft Purview Insider Risk Management triage agent
- Data Security Posture Management posture agent in preview
- Data Security Investigations posture agent in preview

Data Security Triage Agent

The triage agent provides a managed alert queue where it identifies and prioritizes the highest risk activities. The agent analyzes the content and potential intent involved in the activity based on the organization's chosen parameters and level of risk tolerance. The agent offers a comprehensive explanation for the logic behind the categorization.

You can find these agents in the **Microsoft Purview embedded experiences**. For more information, see embedded experiences.

Triaging and assigning a priority to alerts can be complex and time consuming. When you set an agent to triage and prioritize alerts, it reduces the amount of time required to complete the task. The agent helps you focus on the most important alerts by sifting them out from the noise of lower risk alerts. This prioritization improves your response time and helps increase the efficiency and effectiveness of your team.

For information on deploying, configuring, and using the triage agents, see:

- Get started with the Microsoft Purview Triage Agent in Data Loss Prevention
- Get started with the Microsoft Purview Triage Agent in Insider Risk Management

Data Security Posture Agent

Searching for relevant data and identifying its protection is a time-consuming, tedious, and highly manual task. The agent's primary role is to help you discover sensitive data across your data estate by using a simple natural language-based search. Instead of relying on keyword- or filter-based search tools, it uses large language models (LLMs) to understand user intent. It searches scoped content across your Microsoft 365 ecosystem—including documents, emails, messages, and Copilot interactions—and returns results quickly. The experience includes a concise summary and an associated risk analysis generated by the LLM.

In Data Security Investigations, the Posture agent extends these capabilities to help you proactively discover exposed credentials at scale across your tenant. The agent automates credential scanning across Microsoft 365 data locations, produces AI-generated risk assessments, and tracks tasks on a Kanban-style task board for streamlined review and remediation. For more information, see Get started with the Data Security Investigations Posture Agent (preview).

For information on deploying, configuring, and using the posture agents, see:

- Get started with the Posture Agent in Data Security Posture Management
- Get started with the Posture agent (preview) in Data Security Investigations

Before you begin

If you're new to Security Copilot or Security Copilot agents, familiarize yourself with the information in these articles:

- Microsoft Security Copilot agents overview
- What is Microsoft Security Copilot?
- Microsoft Security Copilot experiences
- Get started with Microsoft Security Copilot
- Understand authentication in Microsoft Security Copilot
- Prompting in Microsoft Security Copilot
- Configure Owner settings
- Learn about Security Copilot in Microsoft 365 E5

Security Copilot agent concepts

Microsoft Purview agents run on Security Compute Units (SCU). Your organization must have SCUs provisioned for the agents to run. For more information, see:

- Get started with the Microsoft Purview Triage Agent in Data Loss Prevention
- Get started with the Microsoft Purview Triage Agent in Insider Risk Management
- Get started with the Microsoft Purview Posture Agent in Data Security Posture Management
- Get started with the Data Security Investigations Posture Agent (preview)

The following sections apply only to the Triage agent. They don't apply to the Posture Agent.

Triggers

Triggers are groupings of parameters whose values must be met for the agent to triage any given alert. Triggers include:

- Time frame: You can define the time scope that alerts are generated in for triaging. See, Select Alert timeframe.
- Custom Instructions: You can define certain instructions for the agent to learn and prioritize from.

Run automatically or manually

When you deploy an agent, and when you edit triggers, you can select whether the agent runs **automatically based on a set schedule** or **Agent runs manually on one alert at a time** . If you select **Run automatically based on a set schedule**, the agent triages the alerts that are included in the **Select Alert timeframe** setting.

Select alert timeframe

When you deploy an agent and edit an agent's triggers, you can pick the timeframe the agent uses to decide which alerts to triage. The options are:

- Only triage new alerts
- Last 24 hours
- Last 48 hours
- Last 72 hours
- Last 7 days
- Last 14 days
- Last 21 days
- Last 30 days

If you select **Only triage new alerts**, the agent only triages alerts that are generated after the agent is deployed. The agent doesn't triage any alerts that were generated before the agent was deployed, which means that all the *Last # hours or days* options are ignored.

If you select any of the *Last # hours or days* options, the agent triages alerts that were generated in the selected timeframe. The selection lets you triage all alerts generated before the agent was deployed. The agent also triages all newly generated alerts.

> **ⓘ Important**
>
> The timeframe scope for alerts to be triaged is anchored to the moment of successful agent enablement. Essentially, the clock starts ticking when you enable the agent. So, *Last*

number of hours or days refers to the time period before agent deployment. ***This timeframe isn't rolling***.

Agent identity

You can set up agents, including the Posture agent, by using two options:

- **Create and use agent identity (recommended):** Create a separate Microsoft Entra agent identity for the agent. Associate all agent activities with this agent identity. To learn more, see Microsoft Entra agent identity and Microsoft Entra agent identities for AI agents.
- **Assign and use my identity:** Set up the agent by using the identity of the user or admin who sets up the agent. Associate all activities with the user's identity.

> **Important**
>
> Agents aren't administrative unit aware. But if the agent runs in the context of an administrative-unit restricted admin, and there are policies that are administrative-unit scoped to that admin, the agent only sees alerts from the policies that scoped to the admin unit.

Custom instructions

During the agent configuration process, you can give the agent *custom instructions*. (Custom instructions only apply to the Triage agent in DLP). Microsoft Purview agents use these natural language instructions to enhance alert triage by:

- Translating your input into structured classification logic.
- Running this logic against the document content associated with each alert.
- Raising the alert's priority if the content matches your custom instruction.

For custom instructions, the agent only analyzes document content, not metadata or behavioral attributes. This means the agent supports content categories like:

- Tax, financial, or legal information.
- Named entities, like credit card numbers, Social Security numbers, and names.
- Logical conditions like *more than five SSNs, contains financial documents*.

If you're unsure whether the condition you want to use is supported, check whether the condition is marked as a content condition. If it is, the agent can use it in custom instructions.

For example, if you enter: *I want to focus on alerts with content that is tax or finance related and contains more than five credit card numbers or SSNs*. The agent interprets this condition as:

JSON

```
{
  "logic_expression": "MATCH(content, 'Tax') or MATCH(content, 'Finance') and
(COUNT(content, 'U.S. social security number') >= 5) or (COUNT(content, 'U.S.
credit card number') >= 5)"
}
```

Triaged alerts

The agent triages alerts generated in the timeframe and using policies you select. The agent doesn't triage all alerts.

The agent groups triaged alerts into four categories:

All: This category includes all the alerts that the agent triaged. The count indicated in the category might not accurately reflect the true number of alerts until you go into that view and scroll down to load all the alerts. If the conditions that caused the alert to be raised change, or if the alert isn't triaged yet, you can select the alert and then select **Run agent** to manually run the agent on the alert.

Needs attention: This category contains alerts that the agent evaluated and determined pose the greatest risk to your organization. When you select one of these alerts, the details flyout opens to show a summary of the alert and other details.

Less Urgent: This category contains alerts that the agent evaluated and determined to pose a lower risk to your organization. When you select one of these alerts, the details flyout opens to show a summary of the alert and other details.

Not categorized: This category contains alerts that the agent wasn't able to successfully triage. This condition can happen for many reasons, including:

- Server error
- In process of reviewing
- Other error
- Unsupported error for alerts that contain activities that the agent doesn't support.

Agents triage files up to 2 MB in size.

How agents prioritize

The Triage Agent in DLP prioritizes alerts based on these risk factors:

- Content Risk: This category is the primary risk factor used during agent triage. It covers sensitive content based on Microsoft provided sensitive information types (SIT), trainable classifiers, and default sensitivity labels. For more information, see default sensitivity labels.
- Exfiltration Risk: Exfiltration of sensitive data shared externally.
- Policy Risk: Policy mode and rules with actions affect the prioritization of alerts.
- Content Risk: Label removed or downgraded.

The Triage Agent in Insider Risk Management prioritizes alerts based on:

- Activity risk: The agent identifies activities with the highest risk of exfiltration and reports historical alert insights.
- User risk: Attributes of the user that can affect the prioritization of alerts such as priority user group configuration or number of currently active cases.

Alert triage details

> **Important**
>
> The Triage agent in DLP only supports alerts from policies that are in active mode. It doesn't triage alerts from DLP policies that are running in simulation mode.

Agents can review alerts that were generated up to 30 days before enablement if the tenant has sufficient SCUs. Alerts that were generated more than 30 days before agent enablement are out of scope.

The Triage agent in DLP triages alerts from Exchange, Devices, SharePoint, OneDrive, and Teams. To triage alerts from Devices, you must enable evidence collection for file activities on devices.

In DLP, the agent doesn't triage alerts by non-SITs or non-trainable classifier policy conditions only, such as `Email subject match`.

You should do manual analysis on alerts that the agent doesn't evaluate.

Partially triaged alerts

Here are some examples of situations where you might partially triage alerts.

- DLP rule contains some conditions that aren't supported, such as `The user accessed a sensitive site from Edge`.
- The DLP rule includes certain conditions, but the system can't retrieve the corresponding properties of the email or files, such as `Document couldn't be scanned`.
- User not found.
- During preview, the insider risk management agent analyzes only SharePoint file content. It doesn't analyze email and device activities with accompanying files. If an alert contains only email or device activities, the agent doesn't analyze it.
- An alert generated from a policy that looks only at endpoint or email activities for Insider Risk Management.

Content analysis

There are some situations where content analysis might be limited.

The content risk prioritization of an alert is based on Sensitive Information Types (SITs), trainable classifiers, and sensitivity labels in content. When an agent evaluates content risk, it only looks for SITs and trainable classifiers that are defined in the policy.

When a DLP alert is associated with fewer than 10 files, the agent scans all the files and uses them to generate the content summary. When an alert includes 10 or more files, the agent uses the potentially top 10 files to generate the file risk summary. In DLP, the triage agent selects the top 10 risky files based on the number of policy classifier hits, the file size, and the most recent file access time. Once this selection is done, the triage agent adds a note stating that the content summary doesn't include all the files in the alert.

Get started with the Microsoft Purview Triage Agent in Insider Risk Management

Use these steps to deploy the Microsoft Purview triage agent in Microsoft Purview Insider Risk Management. Before you begin, make sure you meet the licensing, permissions, and infrastructure prerequisites described in this article.

Before you begin

If you're new to Microsoft Purview triage agent in Insider Risk Management, you should read this article.

- Security Copilot Agents in Microsoft Purview Overview (preview)

SKU/subscriptions licensing

The Triage Agent in Insider Risk Management requires both the standard per-seat licensing model and the pay-as-you-go billing model. For more information, see Purview billing models. Your organization must be licensed for:

- Microsoft Purview Insider Risk Management to use the Insider Risk Management triage agent.

Microsoft Purview triage agents consume security compute units (SCUs) as they perform their tasks. You must have SCUs provisioned for the triage agents to work. The number of SCUs consumed depends on the number and type of alerts that are processed. For more information about SCUs, see Security compute units (SCUs). You can track your SCU consumption in the Security Copilot usage monitoring tool. For more information about onboarding into Microsoft Security Copilot, see Get started with Microsoft Security Copilot.

For information on Security Copilot licensing in E5 see, Learn about Security Copilot in Microsoft 365 E5

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions and roles

There are different permissions and roles needed to perform different functions. For more information, see Permissions in the Microsoft Purview portal, and Roles and role groups in the Microsoft Purview portals.

Assign these roles for setting up the agent using a recommended agent identity, actions like configuring or customizing, or deactivating and removing agents:

For admins (any one from each group):

Group A

Deployment and configuration roadmap

Deploying the Microsoft Purview Insider Risk Management triage agent involves these phases:

1. Infrastructure prerequisites
2. Enabling agents
3. Set up agents
4. Deactivate agents
5. Remove agents

Infrastructure prerequisites

Microsoft Purview triage agents run on Microsoft Security Copilot.

1. Your tenant must be onboarded to Microsoft Security Copilot. For more information on how to onboard, see Get started with Microsoft Security Copilot.
2. You must enable Microsoft 365 data sharing in Security Copilot. For more information, see Accessing data from Microsoft 365 services .
3. You must enable the Microsoft Purview plug-in in Microsoft Security Copilot. For more information, see Enable the Microsoft Purview source in Microsoft Security Copilot.

Enabling agents

This procedure is for organizations that haven't enabled any of the Microsoft Purview agents or have previously removed the agents and want to enable them again. Once you enable the agents, they're available for use in Microsoft Purview. There can be only one instance of each agent in a tenant. This procedure works for both the Purview DLP triage agent and the Insider Risk Management triage agent.

1. Sign in to the Microsoft Purview portal with an account that has the required Purview agent permissions.
2. In the left hand navigation pane, select **Agents**.
3. Select **Explore agents**.
4. Select the agent that you want to enable and select **Add**. This opens a page that shows the requirements to enable the agent.

5. Select **Setup**, this opens the **Deploy agent** global configuration page. You can:
    a. Choose to **Run automatically based on a set schedule**. If you don't choose this option, you must run the agent manually one at a time. The scheduled is set by Microsoft and isn't configurable by organizations. You can change this setting later when you edit the agent.
    b. **Select the alert timeframe**, which is how far back the agent looks for alerts to triage. Analysts can shorten the timeframe when they edit the agent but not lengthen it. For more information, see Select Alert timeframe.
6. Select **Deploy**. You see the *Alert Triage Agent in <solution> is deployed* message when the agent is successfully deployed.

Set up agents

Once an agent is enabled, you need to set specific triggers for the agent. The triggers are used to determine which alerts the agent triages. You can do this either in the **Agents** page or, for first run experience on the **Alerts** page for the solution. For this procedure, we'll use the first run experience **Alerts** page method. This procedure assumes that you still have the Microsoft Purview portal open to the **Explore agents** page from the Enabling agents procedure.

> **Important**
>
> The most recent agent configuration is always used.

1. Select **Go to <solution>**. This opens the **Alerts** page for the solution.
2. Because you are in the first run experience, you see dialog box that with a **Customize** button which, when selected, opens the **Customize Alert Triage Agent** flyout.
3. Here, choose either to accept the default global setting for **Select alert timeframe** or change it to be shorter than what was configured during agent deployment.
4. Enter custom instructions for the agent. The agent interprets your natural language input and uses it to better identifyw hich types of alerts matter most to you. This helps you identify and respond faster to the most relevant alerts.
5. Choose **Select policies** to select the policies whose alerts will be triaged by the agent. In preview, all policies are selected by default, you can change that here.
6. Select **Review**.
7. Select **Start agent**. Allow up to 2 hours for the agent to complete triaging the in scope alerts and enabled manual runs from this initial setup.

Deactivate agents

Use the following steps to deactivate an agent without removing it.

1. Sign in to the Microsoft Purview portal with an account that has the required Purview agent permissions.
2. In the left hand navigation pane, select **Agents**.
3. Select **Explore agents**.
4. Select **View agent** for the agent you want to deactivate. This opens the agent overview page.
5. On the far right upper right hand corner of the agent overview page, select the ellipses (three dots) that are located *next to* the **Edit agent** button.
6. Select **Deactivate agent**.

Deactivating the agent stops it from triaging alerts. It doesn't remove the agent and it doesn't reset the **Select alert timeframe** reference point in time.

Remove agents

Use the following steps to permanently remove an agent from Microsoft Purview.

1. Sign in to the Microsoft Purview portal with an account that has the required Purview agent permissions.
2. In the left hand navigation pane, select **Agents**.
3. Select **Explore agents**.
4. Select **View agent** for the agent you want to pause. This opens the agent overview page.
5. On the far right upper right hand corner of the agent overview page, select the ellipses (three dots) that are located *next to* the **Edit agent** button.
6. Select **Remove agent**.

> ⚠ **Warning**
>
> Removing the agent deletes it from Microsoft Purview and resets the **Select Alert timeframe** reference point in time. If you want to use the agent again, you must re-enable and set it up again.

Edit agents

Use the following steps to edit an existing agent's configuration and triggers.

1. Sign in to the Microsoft Purview portal with an account that has the required Purview agent permissions.
2. In the left hand navigation pane, select **Agents**.
3. Select **Explore agents**.
4. Select **View agent** for agent you want to edit. This opens the agent overview page.
5. Select **Edit agent**. This opens the **Edit agent** page.
6. Select **Triggers**.
7. Here you can change when the agent runs, either **Agent will run manually on one alert at a time** or **Agent will run automatically based on a set schedule**.
8. Select **Edit** to change the **Select alert timeframe** value and the policies that the agent will triage alerts from.
9. If you select **Agent will run manually on one alert at a time**, you can select a single alert in the **Alerts** page for the solution. Set the toggle to **Alert Triage Agent** and select **Run Agent**.
10. You can also change the **Intent** if you want.

Monitoring SCU usage

Use the following steps to view security compute unit (SCU) usage for an agent.

1. Sign in to the Microsoft Purview portal with an account that has the required Purview agent permissions.
2. In the left hand navigation pane, select **Agents**.
3. Select **Explore agents**.
4. Select **View agent** for agent you want to edit. This opens the agent overview page.
5. Select **Edit agent**. This opens the **Edit agent** page.
6. Select **Usage monitoring**.
7. You can track your SCU consumption in the Security Copilot usage monitoring tool.

Alerts page overview

Use the following steps to open the Alerts page and view alerts triaged by the agent.

1. Sign in to the Microsoft Purview portal with an account that has the required Purview agent permissions.
2. Open the solution you want to view the triaged alerts for.
3. Open the **Alerts** page for the solution.

4. In the top right hand area of the page, there's a new toggle that lets you choose between the **Standard** view of the alerts page and a **Triage Agent** view of the alerts page. Set the toggle to the **Triage Agent** view. This view shows the alerts that have been triaged by the agent. The alerts are grouped by the agent into four categories:

    - **All**
    - **Needs attention**
    - **Less Urgent**
    - **Not categorized**

Get started with the Microsoft Purview Triage Agent in Data Loss Prevention

Use these steps to deploy the Microsoft Purview triage agent in Data Loss Prevention (DLP) in both the Microsoft Purview and Microsoft Defender XDR portals.

The Microsoft Purview Triage Agent in DLP triages alerts from policies that are scoped to Exchange, Teams, OneDrive, SharePoint, and devices (Endpoint) locations, *only*. If you want to triage alerts from devices, Evidence collection for file activities on devices must be enabled.

Before you begin

If you're new to Microsoft Security Copilot Agent in Microsoft, read this article.

- Security Copilot agents in Microsoft Purview overview

Subscriptions and licensing

This agent requires both the standard per seat licensing model and the pay-as-you-go billing model. Your organization must be licensed for:

- Microsoft Data Loss Prevention (DLP) to use the DLP triage agent.

The agent consumes security compute units (SCUs) as it performs its tasks. You must have SCUs provisioned for the triage agent to work. The number of SCUs consumed depends on the number and type of alerts that are processed. For more information about SCUs, see Security compute units (SCUs). You can track your SCU consumption in the usage monitoring tool. For more information about onboarding into Microsoft Security Copilot, see Get started with Microsoft Security Copilot.

For information on Security Copilot licensing in E5 see, Learn about Security Copilot in Microsoft 365 E5.

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions and Roles

There are different permissions and roles needed to perform different functions with the agent. For more information, Permissions and roles needed are specific to the agent's various functions. For more information, see Permissions in the Microsoft Purview portal, and Roles and role groups in the Microsoft Purview portals.

> **Important**
>
> An agent now has its own agent identity (read more: https://learn.microsoft.com/en-us/entra/agent-id/identity-platform/what-is-agent-id-platform) or can be set up by assigning the user's identity who is setting the agent. These settings can be changed anytime by visiting the deployment configurations tab for the agent in Explore agents page. Regarding an agent that that was set up using a user's identity, migration to the agent identity in agent settings is recommended.

Permissions for enabling and configuring the Triage Agent in DLP from Microsoft Purview and Defender XDR portals

Assign these roles for setting up the agent using an recommended agent identity, actions like configuring or customizing, or deactivating and removing agents:

For admins (any one from each group):

Group A

See Microsoft Entra Agent ID documentation | Microsoft Learn for more on agent identity.

Wait for 30-min post setting the agent with agent identity for the roles based access to get reflected before initiating any manual run on an alert.

> **Important**
>
> After setup is complete, the agent starts running within 30–60 minutes and begins triaging DLP alerts. By default, the agent processes alerts from all DLP policies generated within the past 30 days. You can modify this behavior at any time by updating the agent's settings.

Roles assigned to the agent

These roles are assigned to the Triage agent in DLP when agent identity is used:

- Information Protection Analyst
- Purview content Analyst
- Data classification content viewer (needed to get the contextual summary)
- Data classification content downloader (needed for endpoint scenario)

- Purview Copilot Workspace Contributor
- Security Copilot Contributor

> **Important**
>
> The agent starts running within 30–60 minutes after setup is complete, and begins triaging DLP alerts. By default, the agent processes alerts from all DLP policies generated in the past 30 days. You can modify this behavior at any time by updating the agent's settings.

Permissions for viewing alert results in Purview and Defender XDR and managing Microsoft Purview Triage Agent for DLP

The account you use to view results along with update triggers, give feedback, or custom instruction for the Triage Agent in DLP must be assigned the roles (any one from each group):

Deployment and configuration roadmap

Implementing Microsoft Purview agents involves several phases:

1. Infrastructure prerequisites for agents
2. Enable agents
3. Edit agents
4. Deactivate agents
5. Remove agents

Infrastructure prerequisites

Microsoft Purview triage agent in DLP runs on Microsoft Security Copilot.

- Your tenant must be onboarded to Microsoft Security Copilot. For more information on how to onboard, see Get started with Microsoft Security Copilot.

- You must enable Microsoft 365 data sharing in Security Copilot. For more information, see Accessing data from Microsoft 365 services .
- You must enable the Microsoft Purview plug-in in Microsoft Security Copilot. For more information, see Enable the Microsoft Purview source in Microsoft Security Copilot.
- To use the Remediation Capability of the Triage Agent in Data Loss Prevention, you must configure the Microsoft Teams Admin Center to allow the Data Security Triage Agent app to send messages to users. For detailed configuration steps, see Configure Microsoft Teams for the Data Security Triage Agent remediation messages.

Enable the agent

This procedure is for organizations that didn't enable any of the Microsoft Purview agents or removed agents and want to enable them again. Once you enable the Microsoft Purview Triage Agent in Data Loss Prevention, they're available for use in Microsoft Purview and Microsoft Defender XDR.

> **Note**
>
> There can be only one instance of each agent in a tenant, regardless of the portal in which it was deployed.

This process works for the Triage Agent in Microsoft Purview.

1. Sign in to the Microsoft Purview portal with an account that has the required permissions.
2. In the left hand navigation pane, select **Agents**.
3. Select **Explore agents**.
4. On the card for the Triage agent in Data Loss Prevention, select **View Details** to open a page that shows the details about the agent.
5. Select **Setup** to open the **Deploy agent** global configuration page. You can:
    a. Choose to **Run automatically based on a set schedule**. If you don't choose this option, you must run the agent manually one at a time. Microsoft sets the schedule and it isn't configurable by organizations. You can change this setting later when you edit the agent.

b. Select the **alert timeframe**, which is how far back the agent looks for alerts to triage. Analysts can shorten the timeframe when they edit the agent but not lengthen it. For more information, see Select Alert timeframe.

c. Enable **Remediation reminders in Microsoft Teams**. For Sharepoint/OneDrive alerts triaged as Needs Attention, the agent sends a Microsoft Teams chat to the last modified user of the file, and ask them to remove the sensitive information found in the file related to the alert. (Preview)

d. Select **Reminder duration**, which is the number of days the agent sends the reminders on Microsoft Teams for a particular file requiring action from last modified user. (Preview)

6. The agent is assigned **Agent Identity**, which allows it to access data and take actions

7. Select **Start**. You see the *Triage Agent in <solution> is active* message when the agent is successfully deployed.

This process works for the Triage Agent in Defender XDR.

> **ⓘ Important**
>
> The Triage Agent can be deployed from both Microsoft Purview and Defender XDR portals, but can only be managed, edited, and disabled from the Microsoft Purview portal. After deployment from either portal, Agent summaries and outputs can be viewed in both the Microsoft Purview and Defender XDR portals.

1. Sign in to the Microsoft Defender XDR portal with an account that has the required permissions.

2. In the left hand navigation pane, select "Investigation & response" then select "Incidents & alerts" and then select "Alerts".

3. Click into any DLP alert the alert queue.

4. If you don't have the Triage Agent deployed, you will find a banner inside a DLP alert suggesting you deploy it.

   a. Click on "Get started" to start the agent with default settings.

   b. Click on "Learn more" to understand more about the configuration options available to you.

c. Finish deploying the Agent

Deploy from the Defender XDR Security Store

You can also deploy the Data Security Triage Agent from the Security Copilot Security Store in the Defender XDR portal.

> **Important**
>
> The Triage Agent can be deployed from both Microsoft Purview and Defender XDR portals, but can only be managed, edited, and disabled from the Microsoft Purview portal. After deployment from either portal, agent summaries and outputs can be viewed in both portals.

1. Sign in to the Microsoft Defender XDR portal with an account that has the required permissions.
2. Select **Security Copilot** > **Security Store**.
3. Search for or browse to the **Triage Agent in Data Loss Prevention** card.
4. Select the agent card, then select **Get agent** to begin deployment.
5. After purchase, select **Security Copilot** > **Agents**, find the agent in the **Ready for setup** section, and select **Set up**.
6. Choose whether to run automatically or manually, set the alert timeframe, and optionally enable remediation reminders in Microsoft Teams. For more information on these settings, see Triggers and settings.
7. Select **Start**. The agent begins triaging DLP alerts within 30–60 minutes.

'One-Click' deployment and enabling the agent

A quick setup flow with default triggers was introduced. Any admin or analyst for a tenant (with no agent deployed) sees a banner or card on alerts page for Triage agent setup. Select **Start agent** to deploy and enable the agent. The roles needed for this setup align with the roles mentioned previously for normal setup flow.

The default settings for 'One-Click' setup are:

- Identity: Create and use agent identity
- Trigger: Run automatically based on a set schedule
- Alert timeframe: Triage alerts from the last 30 days

- Remediation reminder: Turned OFF (Preview)
- Policy scope: All policies in scope for triage.

These settings can be customized during 'One-Click' setup by selecting the Customize option.

Edit agent

Once an agent is enabled, it's ready to triage alerts. Edit and set specific triggers for the agent to act upon. These triggers are used to determine which alerts the agent will triage.

Select which triggers are used on either the **Agents** page or, for first run experience, on the **Alerts** page for the solution. Select the **Agent details** button on the top right on alerts page or:

1. In the Microsoft Purview navigation pane (left hand side of the screen), select **Agents**.
2. Select **Explore agents**.
3. Select **Go to agent** for agent you want to edit.
4. Select **Edit agent**.
5. Select **Agent configuration** for editing and configuring settings like Trigger, alert timeframe, remediation reminders, reminder duration, and policy scope.
6. Go to **Agent Custom Instruction** for editing and configuring the customized instruction on how the agent should work in your tenant.
7. Select **Save**

> **Important**
>
> The most recent agent configuration is always used. Agent settings can only be edited from the Microsoft Purview portal even if it was deployed from the Defender XDR portal.

Allow up to 2 hours for the agent to complete triaging in-scope alerts and enabled manual runs after this initial setup.

Deactivate agents

1. Sign in to the Microsoft Purview portal with an account that has the required permissions.
2. In the left hand navigation pane, select **Agents**.
3. Select **Explore agents**.
4. Select **Go to agent** for the agent you want to deactivate.
5. On the far right upper right hand corner of the agent overview page, select the ellipses (three dots) that are located *next to* the **Edit agent** button.

6. Select **Deactivate agent**. Deactivating the agent stops the agent from triaging alerts. It doesn't remove the agent and it doesn't reset the **Select alert timeframe** reference point in time.

> **Important**
>
> Agent can only be deactivated from the Microsoft Purview portal even if it was deployed from the Defender XDR portal.

Remove agents

1. Sign in to the Microsoft Purview portal with an account that has the required permissions.
2. In the left hand navigation pane, select **Agents**.
3. Select **Explore agents**.
4. Select **Go to agent** for the agent you want to remove.
5. On the far right upper right hand corner of the agent overview page, select the ellipses (three dots) that are located *next to* the **Edit agent** button.
6. Select **Remove agent**. Removing the agent deletes it from Microsoft Purview. If you want to use it again you must go through the Enable the Agents, and Edit agents procedures again.

> **Important**
>
> Agent can only be removed from the Microsoft Purview portal even if it was deployed from the Defender XDR portal.

Triggers and settings

Triggers are groupings of parameters whose values must be met in order for the agent to triage any given alert. Triggers include:

Run automatically or manually

Once an agent is deployed, and triggers are edited, select whether the agent runs **automatically based on a set schedule** or the **Agent runs manually on one alert at a time** . If you select **Run automatically based on a set schedule**, the agent triages the alerts that are included in the **Select Alert timeframe** setting.

Select alert timeframe

Choose an alert timeframe. The options are:

- Only triage new alerts
- Last 24 hours
- Last 48 hours
- Last 72 hours
- Last 7 days
- Last 14 days
- Last 21 days
- Last 30 days

If **Only triage new alerts** is selected, the agent only triages alerts that are generated after the agent is deployed. The agent won't triage any alerts that were generated before the agent was deployed, which means that all the *Last # hours or days* options are ignored.

If any of the *Last # hours or days* options are selected, the agent triages alerts that were generated in the selected timeframe. This selection triages all alerts generated before the agent was deployed. All newly generated alerts are also triaged.

Remediation reminder (Preview)

The Remediation Capability extends the effectiveness of the Alert Triage Agent in Data Loss Prevention by reaching out to the user who violated DLP Policies--by including sensitive data in SharePoint and OneDrive files, for example--via Microsoft Teams. This is applicable only for the alerts categorized as "Needs Attention".

Enabling this setting also enables the bot in Microsoft Teams for the tenant. Reminders are sent once daily to the user who is last modifier of the file in context (combining up to 10 files if multiple files require remediation).

The remediation message includes the file name and a description of what sensitive information requires attention. Once the last person who modified, remediates the file, the file is removed from the remediation reminder for the next day. If no files are found, no reminder is sent.

> **ⓘ Important**
>
> If your organization's settings for Microsoft Teams do not allow the deployment of new Microsoft Teams apps, the Remediation reminders will not be sent to users in your

organization. For configuration steps, see [Configure Microsoft Teams for the Data Security Triage Agent remediation messages](#).

Reminder duration (Preview)

The reminder duration reports the number of days the Agent should follow up with the user on files that aren't remediated.

Policy Scope

A DLP policy must meet certain criteria for it to appear in the **Specify Policy Scope** list and be eligible to be included triage.

Specify the policy scope of the triage agent to control which DLP policy alerts and which policies are eligible for remediation reminders. Remediation reminders must be enabled, and eligible policies must be a subset of the policies defined for agent triage.

Full eligibility

A policy is fully *eligible* for inclusion if the DLP Alert Triage Agent supports all the conditions in the policy. All alerts from a fully eligible policy are triaged.

Limited eligibility

If a policy has some unsupported conditions--a state called *limited eligibility*--the Microsoft Purview DLP triage agent might not be able to triage all the alerts from that policy. Based on the criteria listed some alerts from the policy won't be triaged in limited eligibility. The reason for policy showing as *limited* can be seen by selecting **Limited** state in the **Specify Policy Scope** picker.

Here are some reasons why a policy can be in a limited eligibility state:

- Get started with collecting files that match data loss prevention policies from devices isn't enabled or the storage associated with it isn't Microsoft storage. Also the File collection setting in policy rule is turned OFF for policies targeting endpoint or devices workload.
- The policy doesn't include one of these workloads: SharePoint, OneDrive, Exchange, Teams, and devices (Endpoint).

The same eligibility status is shown on the DLP policy list page. The eligibility column appears when the DLP Triage Agent is enabled and set up. Once the policies are included in agent scope,

only future alerts are checked for scoped policies. Existing triaged alerts, or alerts that have already been generated, aren't impacted.

Custom instructions (Preview)

During the agent config process, you can give the agent *custom instructions*. Custom instructions only apply to the Triage agent in DLP. Microsoft Purview agents use these natural language instructions to enhance alert triage by:

- Translating your input into structured classification logic.
- Running this logic against the alert content associated with each alert.
- Raising or lowering the alert’s priority if the content matches your custom instruction.

For custom instructions, the agent now supports both content, and metadata-based instruction, such as:

- Focus on alerts related to tax, financial, or legal information from last seven days
- Don't focus on alerts containing credit card numbers, social security numbers, and names of users like Mary@contoso.com
- Deprioritize alerts where the related assets have .pdf or .jpg files

Users can also use provided templates when unsure how to provide instruction. These templates are:

- *Generic instruction*: Helps define the clear classifiers targeted, or prioritized conditions versus those classifiers that aren’t prioritized. Separate complex conditions to avoid agent generating complex inferences.
- *Focus on*: Helps define clear conditions to prioritize. Other conditions are marked as Less Urgent.
- *Reduce overload*: Helps define conditions to deprioritize.
- *Definitions*: Defines definitions for classifiers for the agent's understanding.

Edit custom instructions

- The user can add multiple templates to the instruction as required. In other words, they can select a generic instruction and add all needed details or remove whatever isn't required. However, they can also add these templates on demand and enter definitions, then add a couple of *Reduce overload conditions*.
- The user can add more than one condition by clicking on multiple templates, or add separate lines after single template select.

- They can also add conditions in any order and repeat conditions if necessary. For example, the user can add template for definition, then add a *Focus on*, a *Reduce overload*, a *Focus on*, and any needed *Definitions*. Compounding these conditions is like adding things to a cart by selecting and removing the items as required and in any sequence.
- The existing text in the input box isn't removed or replaced when a template is selected. The template-based text is always appended to existing text.
- Users can always edit the input box even with the template as required. They can remove the complete template-provided input or make changes.

On review, the agent combines all instances and presents agentic understanding for confirmation. The output is shown in three segments:

- *Classifiers identified from instructions*: Shows list of classifiers the agent identifies from the instruction.
- *Agent-inferred instructions*: Agent interpretation converts user-provided natural language instruction. Users can deselect any instruction they don't want.
- *Unsupported instructions*: Highlights the instruction if any part of the instruction isn't supported. Users can edit the custom instruction at any time and review it again to remove any unsupported conditions.

Once the instruction is saved, the agent uses it to triage all future alerts. If an alert matches the instruction, a separate summary is generated. The agent also highlights the custom-instruction–matched classifiers for each related document associated with the alert.

Monitor SCU usage

1. Sign in to the Microsoft Purview portal with an account that has the required permissions.
2. In the left hand navigation pane, select **Agents**.
3. Select **Explore agents**.
4. Select **View agent** for agent you want to edit.
5. Select **Edit agent**.
6. Select **Usage monitoring**.
7. You can track your SCU consumption in the usage monitoring tool.

Microsoft Purview Alerts page overview

1. Sign in to the Microsoft Purview portal with an account that has the required permissions.
2. Open the solution you want to view the triaged alerts for.
3. Open the **Alerts** page for the solution.

4. In the top right hand area of the page, there's a new toggle that lets you choose between the **Standard** view of the alerts page and a **Triage Agent** view of the alerts page. Set the toggle to the **Triage Agent** view. This view shows agent triaged alerts. The agent groups alerts into four categories:

- **All**
- **Needs attention**
- **Less urgent**
- **Not categorized**

Defender XDR Alert queue

1. Sign in to the Microsoft Defender XDR portal with an account that has the required permissions.
2. In the left hand navigation pane, select "Investigation & response" then select "Incidents & alerts" and then select "Alerts".
3. Agent-provided summaries and risk factors will be available on DLP alerts triaged by the Agent as they are in Microsoft Purview.

Triaged alerts

The agent triages alerts generated in the timeframe and using policies you selected. Not all alerts are triaged. Triaged alerts are available to review in both the Microsoft Purview and Defender XDR portals.

Triaged alerts in Microsoft Purview are grouped into four categories:

1. **All**: This category includes all the alerts that the agent triaged. The count indicated in the category might not accurately reflect the true number of alerts until you go into that view and scroll down to load all the alerts. If the conditions that caused the alert to be raised in the first place changed, or if the alert isn't triaged yet, you can select the alert and then select **Run agent** to manually run the agent on the alert.

2. **Needs attention**: This category contains alerts that the agent evaluated and determined pose the greatest risk to your organization. When you select one of these alerts, the details flyout opens to show a summary of the alert and other details.

3. **Less Urgent**: These less urgent results are the alerts the agent evaluated and determined to pose a lower risk to your organization. When you select one of these alerts, the details flyout opens to show a summary of the alert and other details.

4. **Not categorized**: Uncategorized results are the alerts that the agent wasn't able to successfully triage, which can happen for many reasons, including:

- Server error
- In process of reviewing
- other error
- Unsupported error for alerts that contain activities that the agent doesn't support.

Agents triage files up to 2 MB in size.

How agents prioritize

The Triage Agent in DLP prioritizes alerts based these risk factors:

- *Content Risk*: This category is the primary risk factor used during agent triage, it covers sensitive content based on Microsoft provided sensitive information types (SIT), trainable classifiers, and default sensitivity labels. For more information, see default sensitivity labels.
- *Exfiltration Risk*: Exfiltration of sensitive data shared externally.
- *Policy Risk*: Policy mode and rules with actions affect the prioritization of alerts.
- *Content Risk*: Label removed or downgraded.

Additionally, any custom instruction or feedback is applied for the final verdict categorization.

Alert Triage details

> **Important**
>
> The Triage agent in DLP only supports alerts from policies that are in active mode. It doesn't triage alerts from DLP policies that are running in simulation mode.

Agents can review alerts that were generated up to 30 days before enablement if the tenant has sufficient SCUs. Alerts that were generated more than 30 days before agent enablement are out of scope.

The Triage agent in DLP triages alerts from Exchange, Devices, SharePoint, OneDrive, Teams. To triage alerts from Devices, you must enable evidence collection for file activities on devices.

Do manual analysis on alerts not evaluated by an agent.

Content Analysis

There are some situations where content analysis can be limited.

The content risk prioritization of an alert is based on Sensitive Information Types (SITs), trainable classifiers, and sensitivity labels in content. When an agent evaluates content risk, it only looks for SITs, and trainable classifiers that are defined in the policy.

When a DLP alert is associated with fewer than 10 files, the agent scans all the files and uses them to generate the content summary. When an alert includes 10 or more files, the agent uses the potentially top 10 files to generate the file risk summary. In DLP, the triage agent selects the top 10 risky files based on the number of policy classifier hits, the file size, and the most recent file access time. Once this selection is done, the triage agent adds a note stating that the content summary doesn't include all the files in the alert.

Remediation capability within alert view (Preview)

There are two ways to view the agent's remediation progress.

You can view remediation status at the alert level on the Triage Agent alert queue in the DLP solution. This view lets a user see fully remediated alerts, meaning users remediated all files implicated in the alert. *In progress* means that the Agent reached out to the user, but the user didn't remediate all the files yet. *Error* indicates that the Teams message couldn't be sent.

Use the second view to see files in a DLP alert that are remediated. You can see the status inside each DLP alert in the *Related assets* section that lists all the files implicated in the alert and the respective remediation status. *Remediated* indicates that the user remediated all detected SITs in the file. If the user remediated some or none of the SITs, the status indicates *In progress*.

> **Note**
>
> The Remediation Capability doesn't cost anything extra. The only costs associated with using this capability are the SCUs needed to triage the DLP alert first.

Feedback for alerts triaged

> **Important**
>
> You can only provide feedback on alerts in that are in the **Needs attention** or **Less urgent** categories. If you disagree with the agent's initial categorization of an alert, you can use the feedback mechanism to revise the categorization. If the initial value is **Needs attention**, you

can change it to **Less urgent**. If the initial categorization is **Less urgent**, you can reprioritize it as **Needs attention**.

You can also add properties, such as a **Sensitive info type** or a **File path** that the agent should use in future evaluations to improve performance. These properties are supported in preview.

- **User email address**: the user who performed the activity that triggered the alert
- **External recipient email address**: to track alerts triggered by Exchange email or Teams interactions with external recipients
- **Sensitive information type**: shows all the SITs within the subscription, the SITs involved in the policy rule triggering the alert are preselected
- **Trainable classifier**: shows all trainable classifiers, the trainable classifiers that are involved in the policy rule triggering the alert are preselected
- **Sensitivity label**: The labels present in the subscription
- **File path**: in case the alert is related to a file and the file path is available. The file path isn't enabled for Endpoint DLP (device) alerts but Full file evidence wasn't enabled at the time of alert triaging
- **Target domain**: for endpoint devices DLP alerts where target domain is present

1. Select any **Needs attention**, or **Less urgent** alert. The selection opens a flyout with the agent provided summary and other settings.
2. Select **Agent feedback**.
3. The **Revise to** field shows the value of the recategorization.
4. Select **+ Add property** and add one or more properties. The added properties are used to improve triaging performance.
5. If you want to **Apply the feedback to all policies**, select that option. Otherwise, the feedback is applied only to the policy that triggered the alert.
6. Select **Review** to see a summary of the changes.
7. Select **Submit** to save the feedback.
8. The current alert doesn't change immediately. Admin has to manually run a triage pass on the alert to change the categorization based on the feedback provided.

Managing feedback

You can view and manage all the feedback given for a triaged alert, including exporting, editing, and deleting feedback.

1. In the solution for the alert, open the **Alerts** page.
2. Select the **Needs attention** or **Less urgent** category.

3. Select the alert that you want to manage the feedback for.
4. Select **Agent feedback**.
5. Select **View all feedback**.
6. Select the alert and feedback entry that you want to manage.
7. **Edit**, **Delete**, or **Export** the feedback as needed.

Feedback conflict resolution

Feedback conflict can occur when multiple admins provide conflicting feedback for the same user and policy combination on different alerts. Feedback conflict generates an error.

For example:

- Admin 1 provides feedback to change *all* alert's categorization to **Less urgent** if the alert is for User A and Policy P.
- Admin 2 provides feedback to change *an* alert's categorization to **Needs attention** if the alert is for User A and Policy P.

Other considerations

- For the alert count, only the alerts where single instance of match is enabled are counted. In case an alert is generated for a threshold scenario--for example, generate alert if there are 10 matches in last 24 hours--those alerts aren't counted.

Next steps

Configure Microsoft Teams for the Data Security Triage Agent remediation messages

The Data Security Triage Agent in Data Loss Prevention (DLP) can send remediation messages through Microsoft Teams to users who last modified files containing sensitive information. Before the agent can deliver these messages, you must configure two settings in the Microsoft Teams Admin Center.

This article covers the required Microsoft Teams configuration, how to control which users receive remediation messages, and how to troubleshoot common delivery failures.

> **Important**
>
> Remediation reminders for the Data Security Triage Agent are currently in **Preview**. Features and steps described in this article might change before general availability.

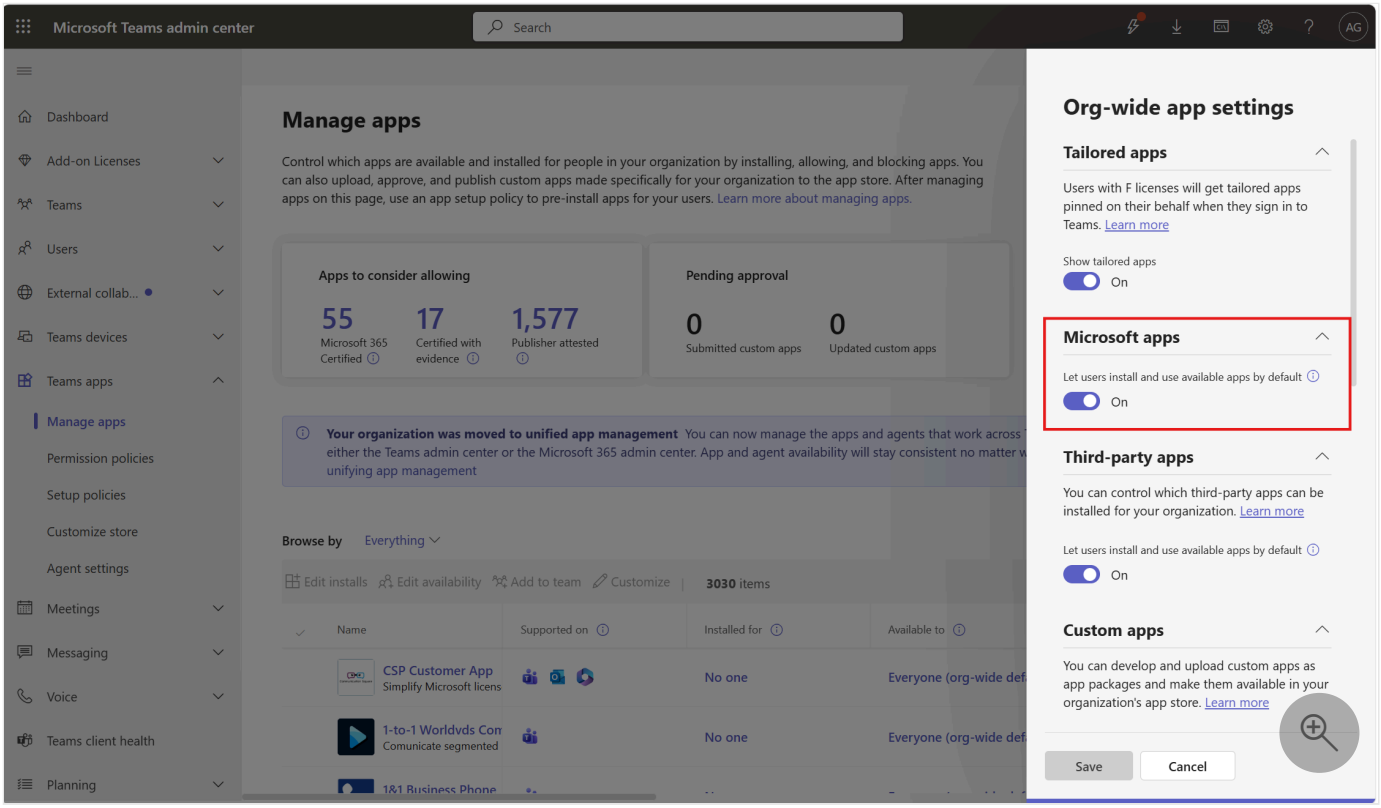
For information about deploying and configuring the triage agent itself, see Get started with the Microsoft Purview Triage Agent in Data Loss Prevention.

Prerequisites

Before configuring Teams for remediation messages, ensure these requirements are met:

- The Data Security Triage Agent in DLP must be deployed and configured.
- **Remediation reminders** must be enabled in the agent's settings. For more information, see Remediation reminder (Preview).
- You must have Teams admin permissions to configure the Microsoft Teams Admin Center settings described in this article.

> **Note**
>
> The Purview admin or analyst who configures the triage agent might not have permissions to access the Microsoft Teams Admin Center. If that's the case, coordinate with a user in your organization who has Teams admin permissions to configure these settings.



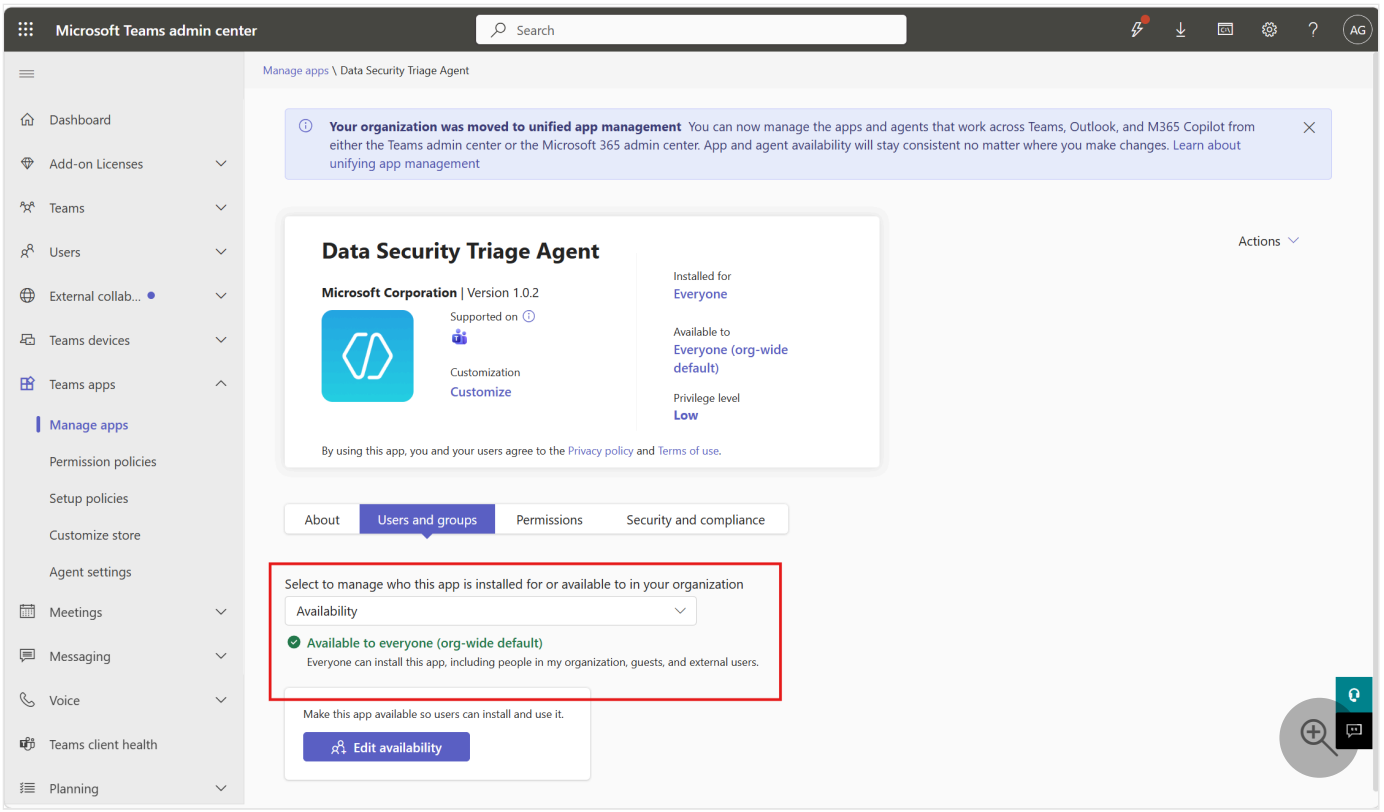
Required Teams Admin Center settings

Two settings must be correctly configured for the Data Security Triage Agent to send remediation messages through Microsoft Teams.

Enable org-wide Microsoft apps

The org-wide Microsoft apps setting controls whether Microsoft-published apps can be used across your organization. This toggle must be set to **On** for the Data Security Triage Agent to function.

1. Sign in to the Teams Admin Center.
2. Go to **Teams apps** > **Manage apps**.
3. Select **Actions** > **Org-wide app settings**.
4. In the **Org-wide app settings** panel, set the **Microsoft apps** toggle to **On**.
5. Select **Save**.



Make the Data Security Triage Agent app available

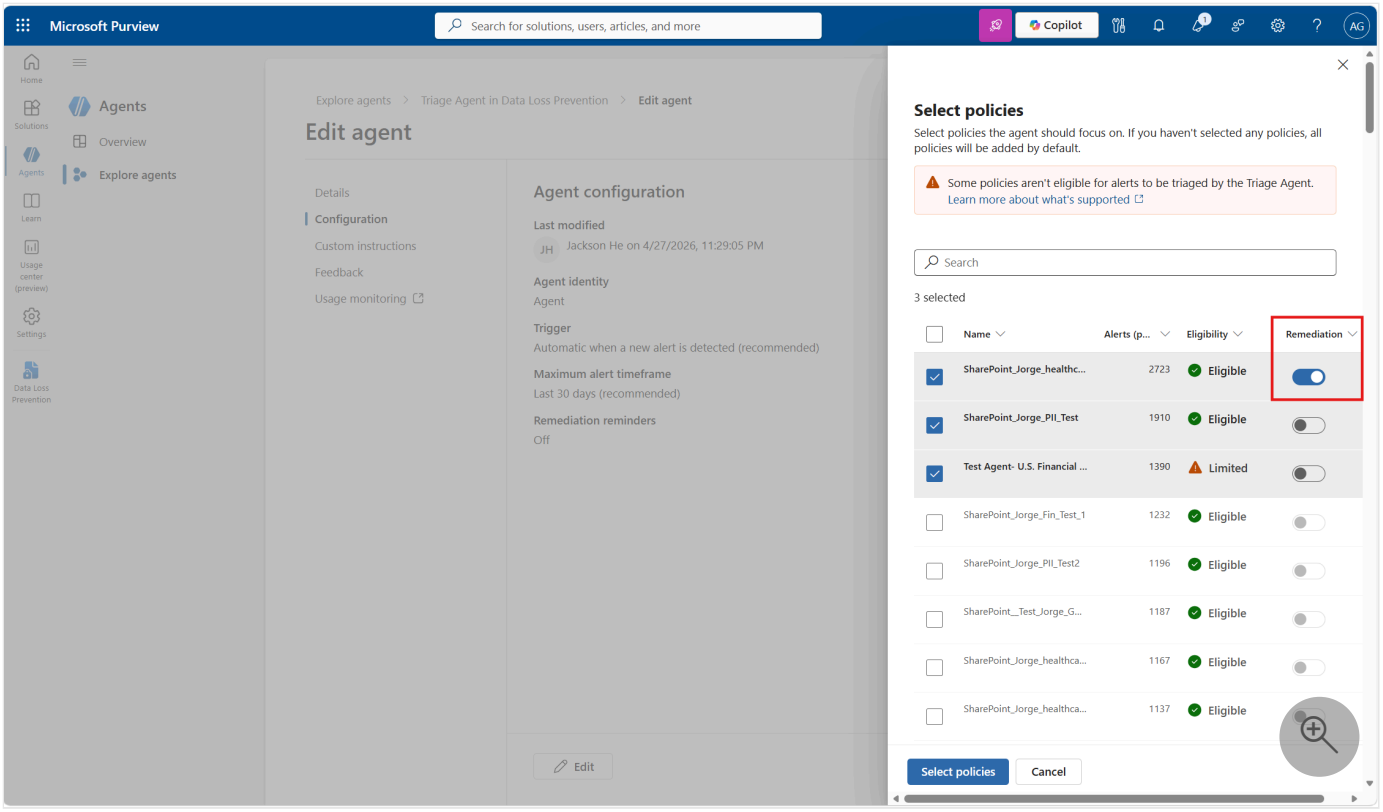
The Data Security Triage Agent app must not be blocked for users who should receive remediation messages.

1. Sign in to the Teams Admin Center.
2. Go to **Teams apps** > **Manage apps**.
3. Search for **Data Security Triage Agent** and select it.
4. Go to the **Users and groups** tab.

5. Verify that **Availability** is set to **Available to everyone (org-wide default)**.

> **Important**
>
> The Data Security Triage Agent app doesn't need to be preinstalled for users. Microsoft Purview automatically installs the app for a specific user at the time a remediation message is sent. The app only needs to be *available* (not blocked) in your organization.

Control who receives remediation messages



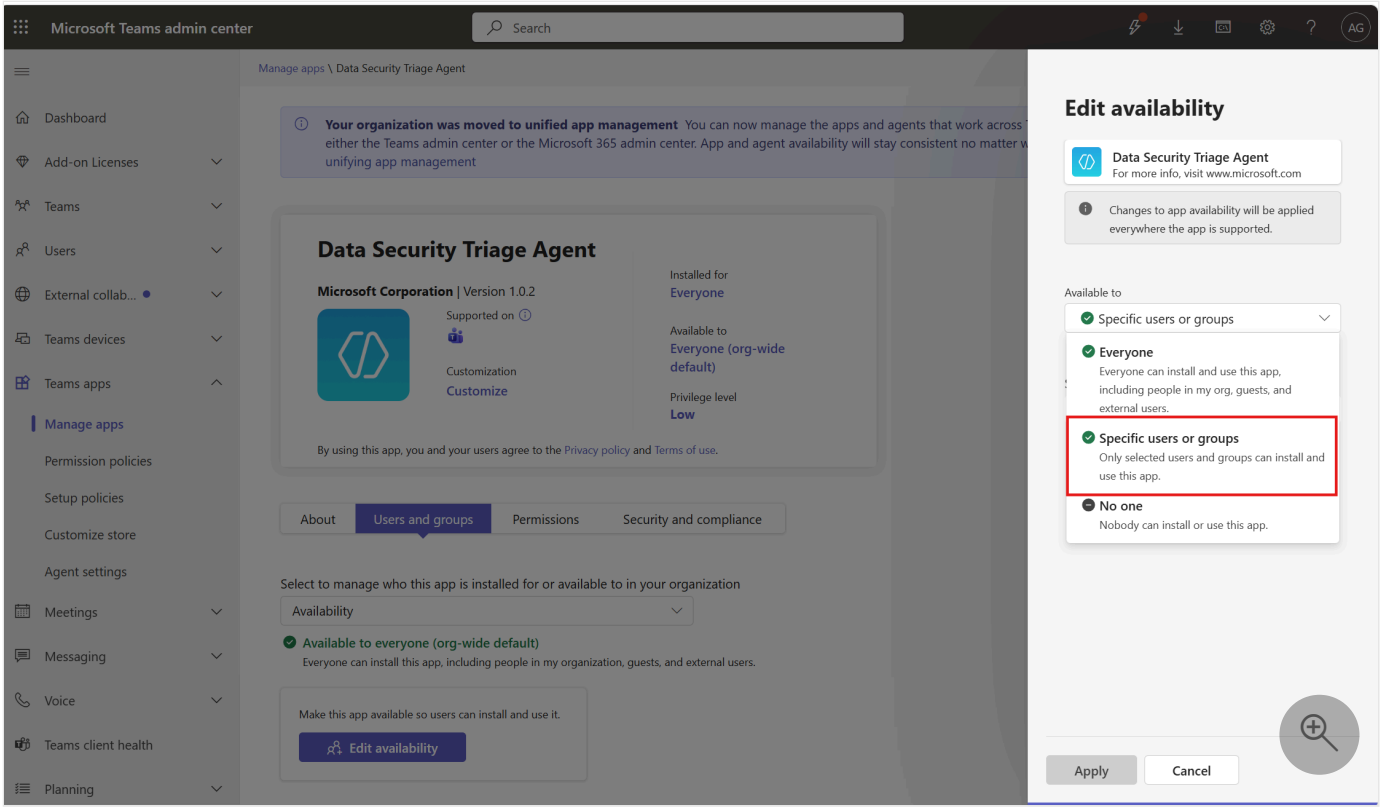
When remediation reminders are enabled, the Data Security Triage Agent sends Microsoft Teams messages to users who last modified files containing sensitive information. You can control which users receive these messages through two mechanisms.

Limit remediation to specific policies

To limit the scope of remediation to specific files or locations, edit the agent's policy scope to enable remediation on only a subset of triage-eligible policies. Policies enabled for remediation are always a subset of policies enabled for triage.

1. In the Microsoft Purview portal, go to **Agents** > **Explore agents**.
2. Select **Go to agent** for the Triage Agent in Data Loss Prevention.
3. Select **Edit agent** > **Agent configuration**.

4. Under **Set agent scope**, select **Edit**.
5. In the **Select policies** panel, enable the **Remediation** toggle only for the policies where you want remediation messages sent to users.
6. Select **Select policies** to save.



This approach limits remediation by controlling which DLP policies trigger remediation messages. Users who violate policies that aren't enabled for remediation don't receive Teams messages from the agent.

Block the app for specific users or groups

To prevent the agent from sending messages to specific users--such as executives, sensitive roles, or specific organizational groups--change the app's availability in the Microsoft Teams Admin Center.

1. Sign in to the Teams Admin Center.
2. Go to **Teams apps** > **Manage apps**.
3. Search for **Data Security Triage Agent** and select it.
4. Go to the **Users and groups** tab.
5. Select **Edit availability**.
6. Change the availability from **Everyone** to **Specific users or groups**, then add only the users or groups who should receive remediation messages.

> **Important**
>
> Blocking the app for a user is a hard block. Even if an alert is triaged and a remediation message is generated, the message *won't* be sent to users for whom the app is blocked. This result is a failsafe mechanism--if you need to *immediately* stop all remediation messages, set availability to **No one**.

> **Tip**
>
> Use policy scoping in Purview for routine control over what files and locations trigger remediation. Use Teams Admin Center blocking as another safeguard when you need to guarantee that specific users never receive messages from this agent, regardless of which policies are in scope.

Troubleshoot remediation message delivery

If remediation messages aren't being sent, check:

Expand table

Symptom	Likely cause	Resolution
No users receive messages	Org-wide Microsoft apps toggle is off	Enable org-wide Microsoft apps
No users receive messages	Data Security Triage Agent app is blocked	Make the app available
Some users don't receive messages	App is blocked for specific users or groups	Check the app's **Users and groups** settings in Teams Admin Center
Messages sent but not appearing	User hasn't opened Teams recently	Messages appear once the user signs in to Teams

> **Important**
>
> A common misconfiguration occurs when the org-wide Microsoft apps toggle is *enabled* but the Data Security Triage Agent app is *individually blocked*. Both settings must be correctly configured for remediation to work.

Get started with the Data Security Posture Agent

This feature is in preview.

The Microsoft Purview Posture Agent in Data Security Posture Management uses natural language prompts to help you find sensitive information across your organization. Follow these steps to deploy the Microsoft Purview Posture Agent in the following Microsoft Purview solutions:

- Data Security Investigations
- Data Security Posture Management

Before you begin

If you're new to Microsoft Security Copilot Agent in Microsoft Purview, read this article.

- Security Copilot Agents in Microsoft Purview Overview

SKU/subscriptions and licensing

This agent requires both the standard per seat licensing model and the pay-as-you-go billing model. Your organization must be licensed for:

- Microsoft 365 E5, with security compute units (SCUs) provisioned to use the Microsoft Purview posture agent in Data Security Posture Management.

The agent consumes security compute units (SCUs) as it performs its tasks. You must have SCUs provisioned for the agent to work. The agent consumes SCUs every time it runs based on the complexity of analysis it performs. For more information about SCUs, see Security compute units (SCUs). You can track your SCU consumption in the usage monitoring tool. For more information about onboarding into Microsoft Security Copilot, see Get started with Microsoft Security Copilot.

For information on Security Copilot licensing in E5 see, Learn about Security Copilot in Microsoft 365 E5.

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Permissions and Roles

You can enable and deploy the Microsoft Purview Posture Agent in Data Security Posture Management or Data Security Investigations with either an organizational user account or an *agent identity*.

We recommend that you deploy the agent using an *agent identity*. The account used to deploy the agent with an agent identity must have the *Role Management* role. To get started with agent identities, see Governing Agent Identities (preview).

If you enable and deploy the agent with your organizational user account, see Permissions for deploying the Posture Agent.

There are different permissions and roles needed to perform different functions with the agent. For more information, see Permissions in the Microsoft Purview portal, and Roles and role groups in the Microsoft Purview portals.

Permissions for deploying the Posture Agent

Use an account that has **the following roles as described** in the table.

Expand table

One from Group A	OR Both from Group B	AND One from Group C
- Compliance Admin OR - Security Reader OR Data Security Viewer OR - Data Security AI Viewer OR - Data Security AI Admin	- Purview Content Analyst - Purview Agent Deployment	- Purview Copilot Workspace Contributor

Permissions for running and viewing results from the Posture Agent

Use an account that has **the following roles as described** in the table.

Expand table

Role Name	Can run Posture Agent and view summary	Can view content snippet that matched intent	Can view file matched intent	Can label file
Compliance Admin	Yes	No	No	No
Security Reader	Yes	No	No	No

Role Name	Can run Posture Agent and view summary	Can view content snippet that matched intent	Can view file matched intent	Can label file
Data Security Viewer	Yes	No	No	No
Data Security AI Viewer	Yes	No	No	No
Data Security AI Admin	Yes	No	No	No
Data Classification Content Viewer	Yes	Yes	Yes	Yes
Data Classification List Viewer	Yes	Yes	No	No
Data Security Investigation Reviewer	Yes	Yes	No	No
Data Security Investigation Investigator	Yes	Yes	Yes	Yes
Data Security Investigation Admin	Yes	Yes	Yes	Yes
Purview Content Analyst	Yes	Yes	Yes	Yes

Deployment and configuration roadmap

Implementing the Microsoft Purview agents involves several phases:

1. Infrastructure prerequisites
2. Enable the agent
3. Manage the agent configuration
4. Monitor SCU usage

Infrastructure prerequisites

- Your tenant must be onboarded to Microsoft Security Copilot. For more information on how to onboard, see Get started with Microsoft Security Copilot.
- You must enable Microsoft 365 data sharing in Security Copilot. For more information, see Accessing data from Microsoft 365 services.
- You must enable the Microsoft Purview plug-in in Microsoft Security Copilot. For more information, see Enable the Microsoft Purview source in Microsoft Security Copilot.

> **Important**
>
> You can only run two prompts concurrently.

Enabling the agent

This procedure is for organizations that without the Microsoft Purview Posture Agent for Data Security Posture Management enabled or organizations who removed it and want to enable it again. After you enable the agent, it's available in Microsoft Purview. There can be only one instance of each agent in a tenant.

1. Sign in to the Microsoft Purview portal with an account that has the required permissions.
2. In the left hand navigation pane, select **Agents**.
3. Select **Explore agents**.
4. Select the agent to enable, and then select **Add**. A page opens that shows the requirements to enable the agent.
5. Select **Setup**, this action opens the **Deploy agent** global configuration page. You can:
   a. Choose **Create and use agent identity (recommended)** or **Assign and use my identity**.
6. Select **Start**. You see the **Agent is now active** message when the agent is successfully deployed.

Managing the agent configuration

After the agent is deployed, make minor changes to the agent configuration as needed.

1. Sign in to the Microsoft Purview portal with an account that has the required permissions.
2. In the left hand navigation pane, select **Agents**.
3. Select **Explore agents**.
4. Select **Go to agent** for the agent you want to manage. This action opens the agent overview page.
5. Select the ellipses (three dots) on the upper right hand corner of the agent overview page, next to the **Edit agent** button. From here you can **Deactivate agent** which makes it inactive, but doesn't uninstall it. If you want to uninstall it, select **Remove agent**.
6. Select **Edit agent** to update **Agent identity** under **Deployment configuration**.

Deactivate agent

1. Sign in to the Microsoft Purview portal with an account that has the required permissions.

2. In the left hand navigation pane, select **Agents**.
3. Select **Explore agents**.
4. Select **View agent** for the agent you want to pause. This action opens the agent overview page.
5. In the upper-right corner of the agent overview page, select the ellipsis (three dots) next to the **Edit agent** button.
6. Select **Deactivate agent**. Deactivating the agent stops it from functioning. It doesn't remove the agent.

Remove agent

1. Sign in to the Microsoft Purview portal with an account that has the required permissions.
2. In the left hand navigation pane, select **Agents**.
3. Select **Explore agents**.
4. Select **View agent** for the agent you want to remove. This action opens the agent overview page.
5. On the far right upper right hand corner of the agent overview page, select the ellipses (three dots) that are located *next to* the **Edit agent** button.
6. Select **Remove agent**. Removing the agent deletes it from Microsoft Purview. To use it again, follow Enabling the agent.

Monitoring SCU usage

1. Sign in to the Microsoft Purview portal with an account that has the required permissions.
2. In the left hand navigation pane, select **Agents**.
3. Select **Explore agents**.
4. Select **View agent** for the agent you want to edit. This action opens the agent overview page.
5. Select the **Performance** tab.
6. Track your SCU consumption in the usage monitoring tool.

In some cases, the Agent downloads and scans max 5 GB or 10K items from the selected data sources. The Agent only returns the top 1,000 matched items.

Labeling files discovered by the Agent

You can apply sensitivity labels directly to discovered files. This application means the Data Security Posture Agent not only helps you identify sensitive content, but also helps you start protecting it faster without switching to a separate workflow.

The sensitivity labels available in this feature are the same labels that you define in the Information Protection solution. You can select up to 10 files at a time and apply the same label to all selected files. For supported file types, see File types supported - Microsoft Information Protection (MIP) SDK | Microsoft Learn.

Prerequisites:

1. To view the latest status for labels applied to files, make sure auditing is turned on: https://learn.microsoft.com/en-us/purview/audit-log-enable-disable
2. Users with the Data Classification Content Viewer or the Purview Content Analyst role can apply sensitivity labels.

Steps to apply the label

1. Select a discovery that includes items on the **Files** tab.
2. Review the items in the list, then select up to 10 files by using the checkboxes.
3. After you select the files, select **Label** to open the list of sensitivity labels available in your organization. you can apply sensitivity labels directly to discovered files.
4. Choose a label.
5. Refresh the page after 30 to 60 minutes to check the labeling status.

Run Agent on a schedule

Schedule prompts to run automatically on a recurring basis—daily, weekly, or monthly—so you can continuously monitor data risks without manual effort. Instead of rerunning the same investigations, the agent re-executes the prompt on the same prompt and data sources and surfaces updated results based on changes in your data estate. This scheduling helps you stay on top of new or evolving sensitive data over time while building a consistent monitoring workflow.

You can set a schedule for a prompt at the time of or after running a prompt, if the prompt is eligible to be scheduled.

Run prompts the Agent intelligently suggests

The Agent generates rich insights based on what the Agent observed in your environment. These insights may help you ask the right questions to the Agent and run more targeted prompts.

Instead of starting from scratch, you can build on what the agent already found, making investigations feel more relevant.

Each recommendation includes a **suggested prompt** and **pre-selected data source**, so you can launch a discovery directly from the card with a single click. The intent and sources are prefilled, but you can also edit them further.

Tips and Tricks to write better prompts and get sharper results

Help the Agent understand your intent better. The Agent particularly understands these five search parameters well:

Expand table

Search parameter	How it helps
Identifiers	Basic filters such as people, titles, file names, file characteristics, time ranges, and sharing status. Example: Emails from john@contoso.com; files modified last seven days; documents with attachments; externally shared items.
Sensitive information types (SITs)	Filters for regulated or business-sensitive content using named sensitive information types or their identifiers. Example: Documents containing credit card numbers; emails with passport numbers; files with at least five SSNs and confidence above 85%.
Sensitivity labels	Filters based on the sensitivity labels already applied to content. Example: Documents labeled Confidential; items with the Public label.
Keywords	Searches for specific words or phrases that appear in the body text of an item. Example: Emails containing the words "merger" and "acquisition".
Intent of the file/data asset	Meaning-based search for broader themes or concepts rather than exact keywords. Example: Documents discussing strategies for improving employee retention; communications about frustration with project delays.

Example of a prompt that may deliver sharp results

A single request can combine multiple filter types in one query for sharper results.

Example: "PDF documents larger than 1 MB, labeled Confidential, that explain data privacy policies, from the last 90 days."

This prompt contains search parameters Identifiers, Sensitivity labels, Keywords, and Intent of the file/data asset.

Examples of prompts that may not deliver sharp results

Sometimes a request is too vague, contradictory, or asks for something the search service doesn't support. In those cases, you see an invalid result with a reason explaining why the request couldn't be interpreted.

Expand table

Prompt	Why it may not deliver sharp results
"Find stuff", "Sensitive data", "Emails"	Too vague
"What's the weather today?"	Unrelated to search
"Files created in 2025 and modified in the last week"	Conflicting time ranges
"Emails from the legal team", "messages from the finance team"	Abstract groups instead of concrete people
A request that doesn't yield any keywords, conditions, or topic to search on	Asks for something with no actionable detail at all

Get started with the Data Security Posture agent (preview) in Data Security Investigations

> **Important**
>
> Data Security Investigations uses generative artificial intelligence (AI), large language models, and orchestration in the analysis of data in your organization. Results generated by AI might not always be accurate or complete. While we strive to provide reliable and helpful information, AI systems can produce incorrect or false results. It is important to verify the information and use it with caution. Microsoft makes no warranties, express, implied, or statutory, as to the information provided by AI systems.

The Data Security Posture agent (preview) in Data Security Investigations helps your organization proactively surface credentials buried in data across your organization at scale. Rather than manually investigating individual items, the Posture agent automates credential scanning across Microsoft 365 data locations, including SharePoint sites, OneDrive accounts, Exchange mailboxes, and Teams content. After the agent completes scanning, it produces AI-generated risk assessments with confidence scores and supporting reasoning to help your security team quickly prioritize and remediate credential exposure risks.

> **Important**
>
> The Posture agent in Data Security Investigations is currently in preview. Features and functionality might change before general availability.

How the Posture agent works

The Posture agent in Data Security Investigations uses the same agent as Data Security Posture Management (DSPM) (preview). When you enable the Posture agent, you make it available in both DSPM and Data Security Investigations. If you already enabled the Posture agent in DSPM, you don't need to onboard again to use it in Data Security Investigations.

By using the Posture agent in Data Security Investigations, you can:

- **Scan for credentials at scale**: Run tenant-wide or scoped credential scanning tasks to discover exposed credentials across your organization's Microsoft 365 data.

- **Track tasks on a task board**: Monitor the progress of scanning tasks through a Kanban-style task board with statuses like *In progress* and *Ready for review*.
- **Review AI-generated risk assessments**: Examine AI-produced risk scores, confidence levels, and reasoning for flagged items to help prioritize remediation efforts.
- **Explore data with KQL queries**: Use the Data Explorer to run Kusto Query Language (KQL) queries against credential findings for advanced analysis and investigation.
- **Download reports**: Generate and download reports of credential scan results for offline review and compliance reporting.

Prerequisites

Before you can use the Posture agent in Data Security Investigations, confirm the following prerequisites are in place:

- **Permissions**: You must be assigned to one of the role groups that includes Posture agent access. For more information, see Permissions for deploying, running and viewing results from the Posture Agent.
- **Agent enabled**: You must enable the Posture agent in the Microsoft Purview portal. For more information, see Enable the Posture agent.
- **Security Compute Units (SCUs)**: Your organization must have Security Copilot SCUs provisioned for the Posture agent to run.

> **Tip**
>
> You don't need to configure or enable Data Security Investigations to use the Posture agent. The Posture agent is independent of the Data Security Investigations solution and doesn't require Data Security Investigations billing, permissions, or setup to be completed. As long as the Posture agent is enabled and your organization has SCUs provisioned, the Posture agent experience is available in the Data Security Investigations navigation. Other Data Security Investigations features, such as creating investigations and AI analysis, still require separate Data Security Investigations configuration and billing.

Enable the Posture agent

If your organization hasn't already enabled the Posture agent, use the following steps to enable it:

1. Go to the Microsoft Purview portal and sign in by using the credentials for a user account assigned the appropriate permissions.
2. Select **Agents** in the left navigation.

3. Select **Explore agents**, and then select **View details** for the Posture agent in Data Security Investigations.
4. Select **Set up** to enable the agent for your organization.

After you enable the Posture agent, it appears in Agents, DSPM, and Data Security Investigations. In Data Security Investigations, you can access the agent by selecting **Posture agent** in the left navigation.

> **Note**
>
> If you already enabled the Posture agent in DSPM, you don't need to complete these steps. The agent is automatically available in Data Security Investigations.

Create a credential scanning task

Create a credential scanning task so the Posture agent can scan your organization's data for exposed credentials. You can scope the scan to your entire tenant or narrow it to specific users, sites, or groups.

Complete the following steps to create a credential scanning task:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in by using the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Posture agent** in the left navigation.
3. Select **Assign to agent** to create a credential scanning task.
4. For the **Credential Scanning Task**, enter a name for the task in the **Task name** field.
5. Configure the data sources for the scan. You can select a tenant-wide scan or narrow the scope to your organization, specific sites, users, mailboxes, or groups.
6. Select **Save**.
7. In the **Additional context for AI**, use natural language guidance to help AI scope the agents to applicable areas.
8. Select **Create** to start the task.

After you create the task, it appears in the **In progress** column on the task board.

> **Tip**
>
> If you realize you scoped a task incorrectly after it starts, you can stop the task and create a new one with the correct scope.

Monitor tasks on the task board

The Posture agent uses a Kanban-style task board to help you track the progress of credential scanning tasks. Each task appears in one of the following columns:

- **In progress**: The agent actively scans the specified data locations and analyzes content.
- **Ready for review**: The agent finished scanning and the results are ready for a human reviewer to examine.
- **Closed**: A human reviewer has marked a tasked as completed.

The task board displays key information for each task, including the scan scope, the number of locations scanned, and the number of items analyzed. You can also assign a security operations center (SOC) administrator to review the results for a specific task.

Review scan results

After a credential scanning task finishes and moves to the **Ready for review** column, you can review the results to identify and prioritize credential exposure risks.

Summary view

The summary view provides a high-level overview of the credential scan results. In the summary view, you can:

- **Sort by risk level**: View results sorted by *High*, *Medium*, or *Low* risk to prioritize the most critical findings.
- **Group by credential category**: Organize results by credential type to understand the distribution of exposed credentials.
- **Review AI reasoning**: For each flagged item, the AI provides its reasoning for the assigned risk level, helping you understand why a specific item is flagged as high, medium, or low risk.
- **Download reports**: Generate a report of the scan results for offline review, compliance reporting, or sharing with stakeholders.

Item details

Select a specific item in the scan results to view detailed information, including:

- The detected credential type.
- The data location where the credential was found.
- The AI-generated risk and confidence scores.

- The reasoning behind the risk classification.

Explore data with Data Explorer

Data Explorer provides advanced analysis capabilities by allowing you to run Kusto Query Language (KQL) queries against the credential findings from the Posture agent scans. This experience is similar to advanced hunting in Microsoft Defender XDR and provides a schema-based metadata framework for querying credential data.

To use Data Explorer, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal.
2. Select **Posture agent** in the left navigation.
3. Select a completed task, and then select the **Data Explorer** tab.
4. Write and run KQL queries against the credential findings schema.

> **Tip**
>
> If you're new to KQL, see **Kusto Query Language overview** to learn the basics of writing queries.

Learn about Microsoft Sentinel in Microsoft Purview

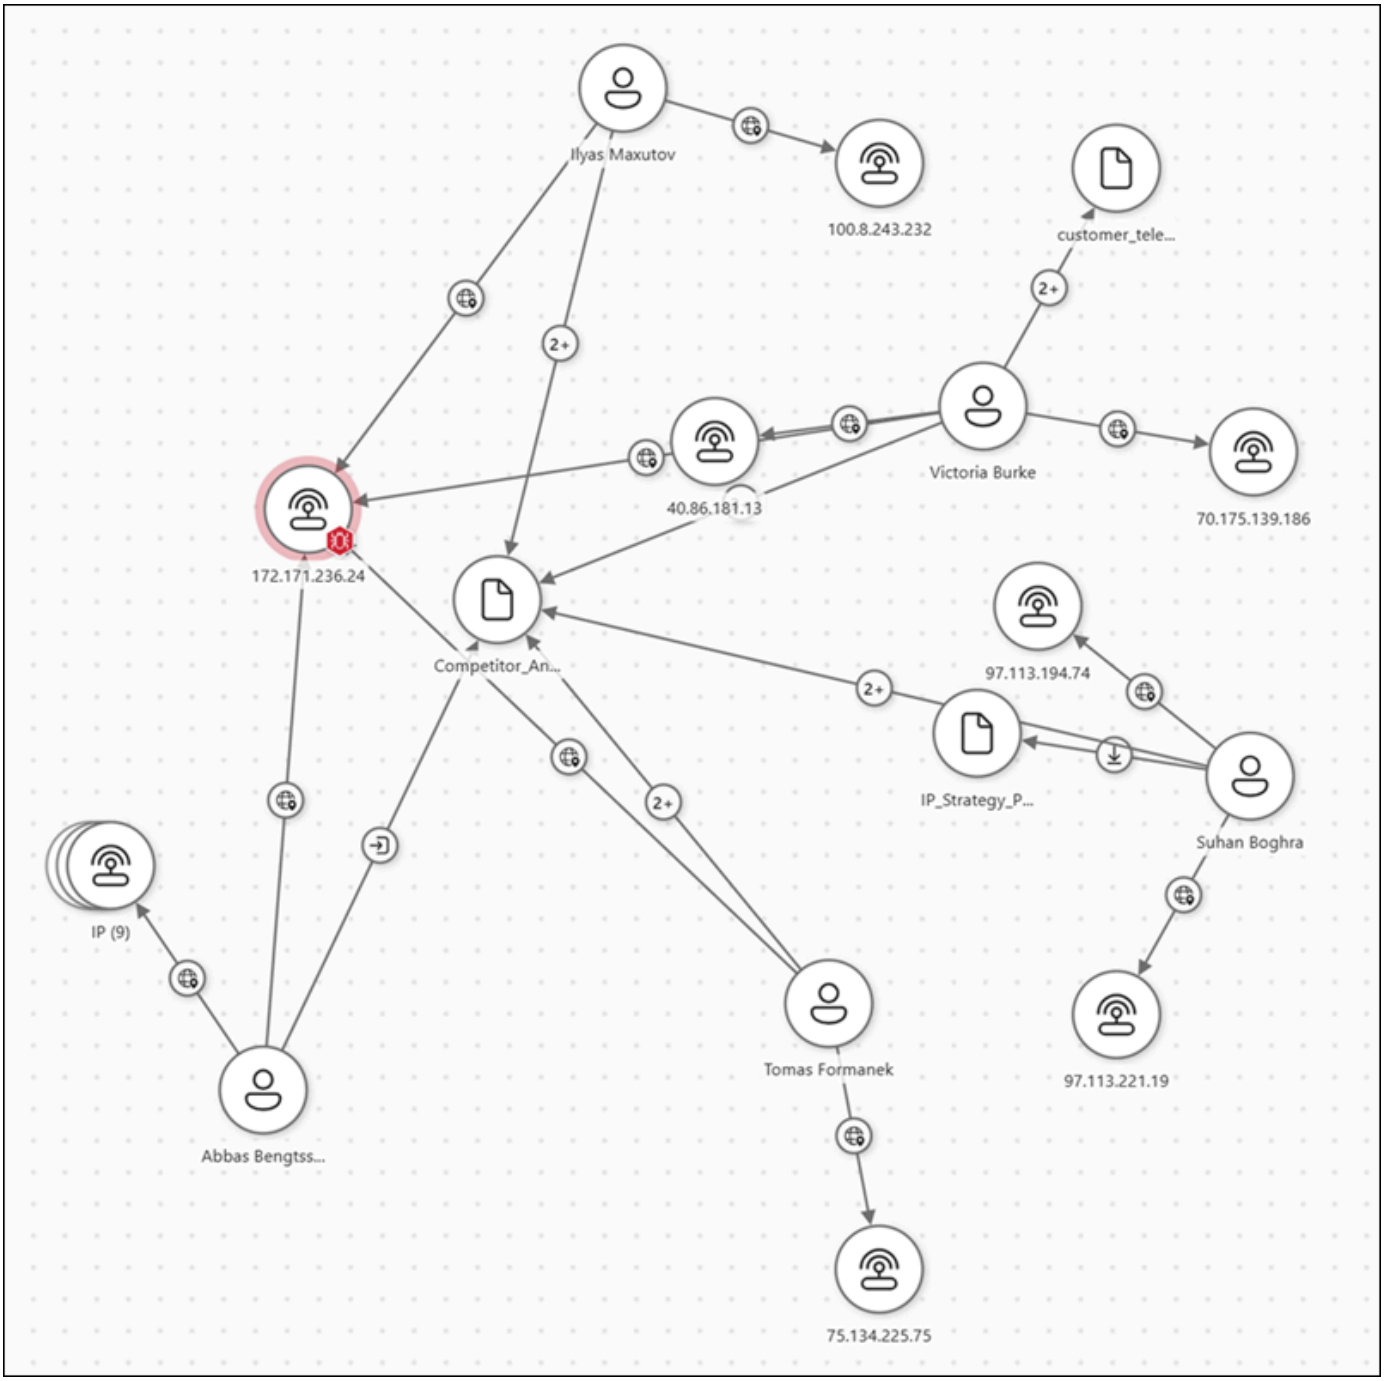
Microsoft Sentinel is a scalable, cloud-native security information and event management (SIEM) solution that delivers cost-efficient security across multicloud and multiplatform environments with built-in AI, automation, threat intelligence, and a modern data lake and graph architecture. The Microsoft Sentinel data lake and graph are tenant-wide repositories for collecting, storing, and managing large volumes of security-related data from various sources. These solutions integrate with Microsoft Purview solutions and support data risk graphs.

> ⓘ **Important**
>
> **Data risk graph is being deprecated.** The data risk graph in Microsoft Purview Insider Risk Management will be retired on **November 24, 2026**. After that date, the data risk graph experience will no longer be available.

Data risk graph capabilities are available in the following Microsoft Purview solutions:

- Microsoft Purview Data Security Investigations (preview)
- Microsoft Purview Insider Risk Management

Partner integrations are available in the following Microsoft Purview solution:



- Microsoft Purview Data Security Posture Management

Data risk graph

Powered by Microsoft Sentinel graph, data risk graphs in Microsoft Purview solutions allow you to view connections between impacted assets, users, and their activities in an interactive graph experience. Microsoft Sentinel graph is a unified graph analytics capability within Microsoft Sentinel that powers graph-based experiences across Microsoft Purview solutions. For more information about Microsoft Sentinel graph, see What is Microsoft Sentinel graph?

Data risk graphs natively represent the real-world web of users, devices, cloud resources, data flows, activities, and attacker actions associated with activities identified in Microsoft Purview solutions. By connecting activities to assets, analysts can:

- **Understand context**: View a user's role and file locations to assess whether behavior is typical or suspicious.
- **Assess impact**: Visualize which assets might be impacted by tracing activity paths within sensitive sites.
- **Collaborate effectively**: Use the data risk graph to communicate findings with stakeholders by showing connections between users, actions, and assets.

Data risk graph controls

Data risk graphs in Microsoft Purview solutions have the following controls to help you discover and work with information about item relationships and connected nodes:

- **Movable nodes**: Change the presentation of the graph by moving nodes to customize the view of nodes, relationships, and connections.
- **Layers**: The **Vulnerability** layer is presented as the default **Insights layer** in a data risk graph. To change layers, select the **Layers** control in the lower-left corner of a graph.
- **Maximize the graph view**: To quickly maximize a graph, select the **Zoom to fit** control in the lower-left corner of a graph.
- **Scale the graph to any size**: To enlarge or reduce the size of the graph, select the + or - controls in the lower-left corner of a graph. Select the **Settings** control in the lower-left corner of a graph to enable or disable the **Zoom slider** control.

Data risk graph features

Data risk graphs in Microsoft Purview solutions include the following features to help you discover and work with information about item relationships and connected nodes:

- **Nodes**: Nodes include users, sites, files, and IP addresses associated with each other.
- **Relationships**: Connections between nodes describing how they interact with each other. Badges on each relationship describe actions and meanings. For example, badges might include *Signed in from*, *Downloaded*, *Uploaded*, and more.

Prerequisites and onboarding changes

To use the data risk graph in supported Microsoft Purview solutions, you must onboard to the Microsoft Sentinel data lake and graph and meet specific requirements. Additionally, when you onboard to data lake and graph, the onboarding process makes changes in several areas and services in your organization. The onboarding process includes changes to your existing data lake, primary and other connected workspaces in Microsoft Defender, and more.

Data risk graphs use a pay-as-you-go billing model to ingest and store data, but data risk graph usage doesn't incur any extra charges. If data needed to populate the data risk graph is already enabled or stored, you don't incur any extra charges.

For step-by-step guidance for all prerequisites, billing information, and changes made in your onboarding process, see the following articles:

- Prerequisites for Microsoft Sentinel data lake and Microsoft Sentinel graph
- Changes made when onboarding to Microsoft Sentinel data lake and Microsoft Sentinel graph

Configure data risk graph

After you meet the prerequisites for Microsoft Sentinel data lake and Microsoft Sentinel graph and understand the changes made during the onboarding process, you're ready to configure data risk graph in Microsoft Purview solutions. The data lake for your organization stores all activity and asset data from Microsoft Purview data risk graphs.

To configure data risk graph in Microsoft Purview solutions, see the following articles:

- Configure data risk graph in Data Security Investigations (preview)
- Configure data risk graph in Insider Risk Management

Partner integrations

Set up Microsoft Sentinel data lake to integrate partner solutions and centralize security posture monitoring across all data sources. To see the available partner solutions and then select one from Data Security Posture Management, you must first connect to the Microsoft Sentinel content hub. The Microsoft Sentinel content hub is the centralized catalog where you discover and deploy partner solutions. Initial partners include Cyera (for Snowflake), BigID (for Databricks), OneTrust (for Google Cloud Platform), and Varonis (for Salesforce).

Data risk graph in Data Security Investigations

> **Important**
>
> We are retiring Data risk graph (Explore insights) in Microsoft Purview Data Security Investigations (DSI). **Beginning September 30, 2026**, organizations will no longer be able to configure Data risk graph. The feature will be fully retired and no longer available after **November 30, 2026**.

Data risk graphs in Data Security Investigations provide a visual investigation experience that combines asset and activity data into a single view. Powered by Microsoft Sentinel integration, it summarizes the previous 30 days of activity for any file scoped in your investigation. It helps you identify risky user accounts that interacted with content of interest and analyze the sequence of events leading up to recent incidents. By enriching analysis with activity insights, data risk graphs can help you resolve your data security incidents faster and with greater confidence.

For more information about Microsoft Sentinel integration, see Learn about Microsoft Sentinel in Microsoft Purview.

> **Note**
>
> Admin units aren't supported in the data risk graph. If you're scoped to an admin unit, data doesn't appear in data risk graphs.

Supported activities in data risk graph

The data risk graph currently supports the following exfiltration activities:

- Anonymous links created in SharePoint or OneDrive
- Anonymous links used via SharePoint or OneDrive
- Company links created in SharePoint or OneDrive
- File downloads from SharePoint and OneDrive
- Files renamed in SharePoint and OneDrive

Before you begin

Before you can use data risk graphs in Data Security Investigations, complete the following steps:

- Learn about pay-as-you-go billing in Microsoft Sentinel for your organization.
- Configure the prerequisites for Microsoft Sentinel data lake and Microsoft Sentinel graph.
- Review the changes made when onboarding to Microsoft Sentinel data lake and Microsoft Sentinel graph.
- Create an investigation in Data Security Investigations.

Configure data risk graph

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview **roles and permissions**.

After you complete the prerequisites, complete the following steps to configure data risk graph in Data Security Investigations:

1. Go to Data Security Investigations in the Microsoft Purview portal with an account assigned the *Global Administrator* or *Security Administrator* role.

2. Select **Overview** in the left navigation.

3. In the **Setup tasks** section, select **Set up data lake and data risk graph**.

   If you don't have the correct permissions to set up the data lake, a notification appears to contact a global or billing administrator in your organization.

4. On the **Setup** tab on **Set up data lake & risk graph (preview)**, configure the following settings:
   a. **Subscription**: Enter the Azure subscription you want to use. Your selected subscription must be valid and accessible. You must be a subscription owner.
   b. **Resource group**: Enter the resource group you want to use. Your selected resource group must be valid and accessible.

   > **Important**

After the data lake is provisioned for a specific Azure subscription and resource group, you can't migrate it to a different subscription or resource group.

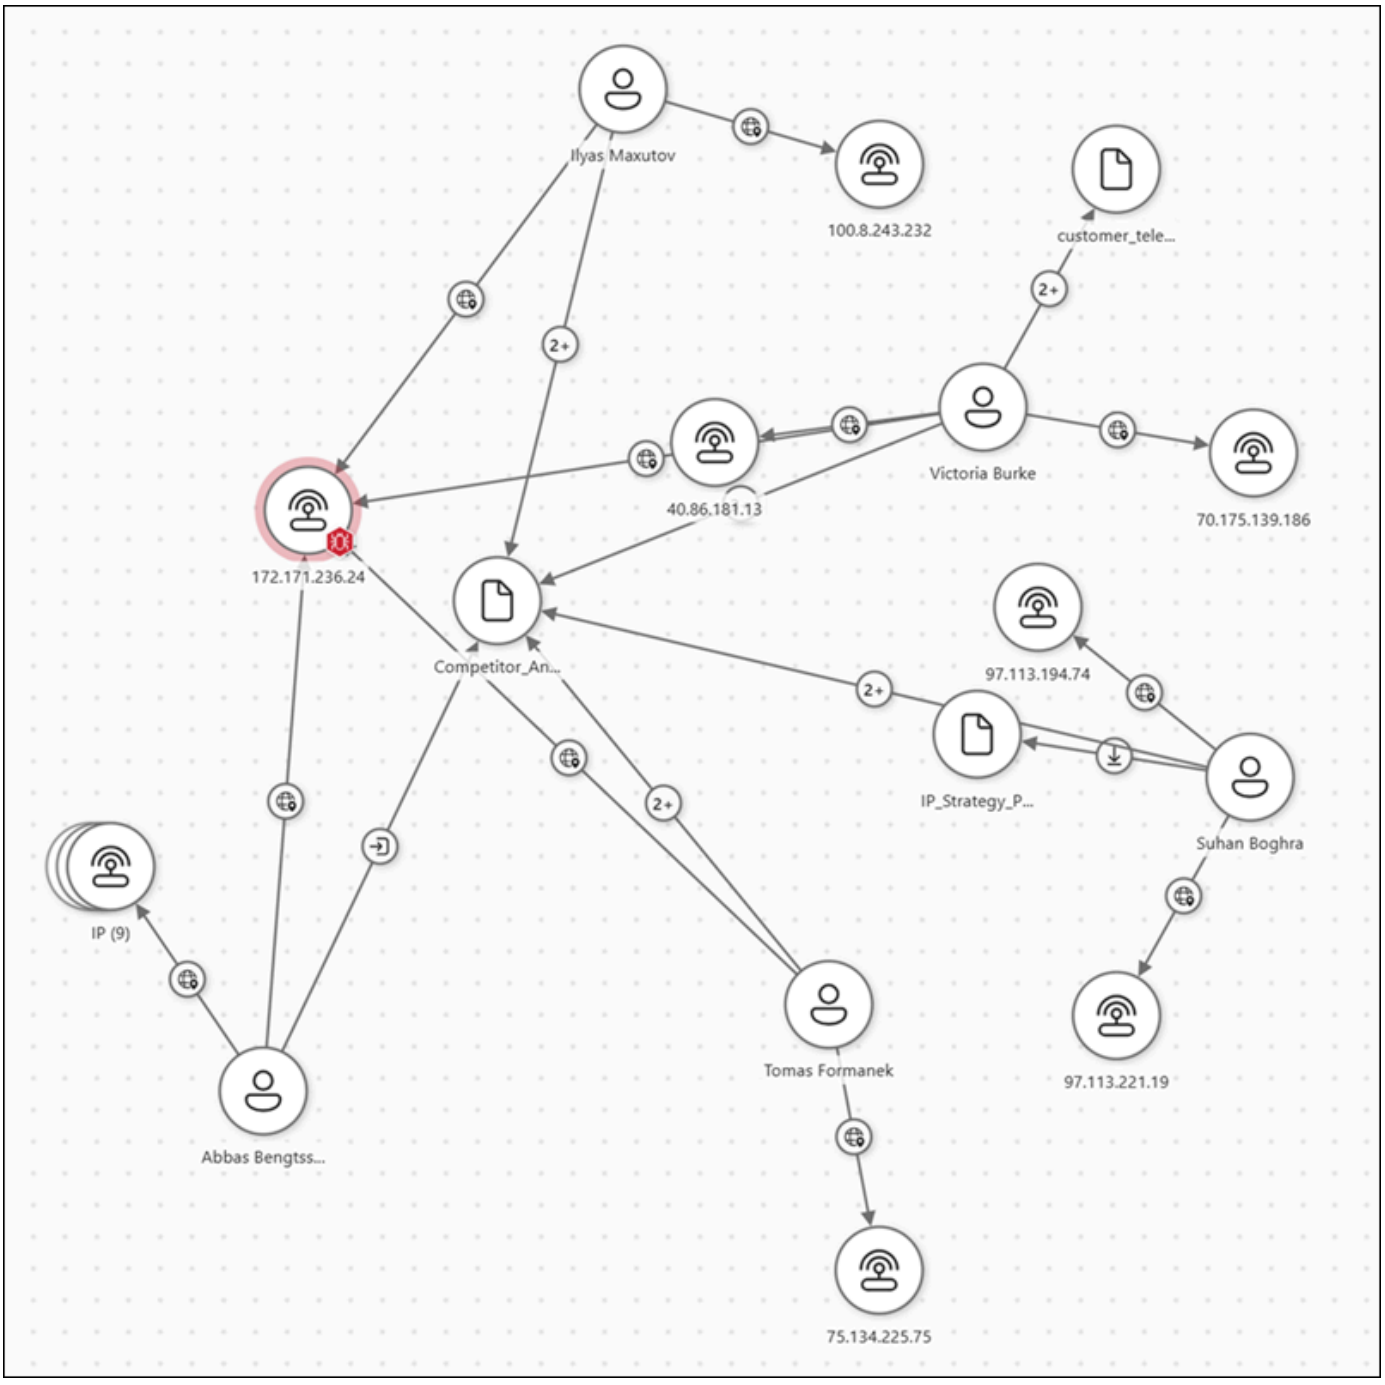
5. Select **Setup**.

> **Important**
>
> When the data risk graph is first created, it includes the most recent seven days of data. As the data risk graph refreshes over time, the look-back window expands up to a maximum of 30 days. It might take some time for the data risk graph to reach the full 30-day window, so expect gradual growth after initial setup.

The set up process begins and onboarding might take up to 60 minutes to complete. You can close the setup panel while the process is running. After the onboarding process completes, you see *Complete* on **Set up data lake & risk graph (preview)**. The data risk graph shows events that occur after your Microsoft Sentinel data lake was created or onboarded.

Initial processing of data and data risk graph availability for an investigation might take 24-48 hours.

> **Important**
>
> You always have one data lake. If you already onboarded to the data lake with another Microsoft service, your existing data lake is used. If you never onboarded to the data lake, onboarding in Data Security Investigations enables Microsoft Sentinel data lake and graph in the Defender portal.



Use data risk graph

Data risk graph in Data Security Investigations uniquely visualizes correlations between impacted data, users, and their activities. It provides critical context to guide mitigation and next steps. For example, upon uncovering a highly sensitive document, data risk graphs give you visibility into which users downloaded it or if they accessed it from a risky IP address. This visibility lets you uncover new nodes to a data security incident, like additional users or new content that requires investigation.

To view the data risk graph for an investigation, you must be assigned to at least one built-in Data Security Investigations role group:

- *Data Security Investigations Admins*
- *Data Security Investigations Investigators*
- *Data Security Investigations Reviewers*

For more information about role groups, see Assign permissions in Data Security Investigations.

To use the data risk graph in Data Security Investigations, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal with an account assigned to a Data Security Investigations role group.

2. Select **Investigations** in the left navigation.

3. Select an investigation to review, then select one of the following options:

a. On **Summary**, select **Manage scope** on the **Investigation scope** card.
b. Select the **Analysis** tab to list items included in the **Investigation scope**.

4. Select items (up to 100) included in the scope, and then select **Explore insights**.

> ⓘ Note
>
> **Explore insights** isn't available unless you configure Data Security Investigations for Microsoft Sentinel data lake and graph.

5. Filter the time as applicable and select individual data risk graph nodes for more information about each connection during triage.

6. Expand relationships in the graph by selecting the + icon on users or assets.

The data risk graph contains several nodes. Selecting a node shows details about the node:

- **User details**: Shows information about users associated with the investigation. This information includes organization information for each user, including User Principal Name (UPN), labels, location, job title, and more.
- **Relationships**: Shows information about starting and ending connections between nodes. This information includes starting and last connection dates, relationship types, and more.
- **IP addresses**: Shows information about each IP address node.
- **Data details**: Shows information about files and sites. This information includes the object location, type, labels, and more.

You can view data risk graph information for users based on the last 30 days of activity. This duration is fixed and can't be extended.

ⓘ**Note:** The author created this article with assistance from AI. Learn more

Last updated on 09/02/2026

Data risk graph in Insider Risk Management

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Data risk graphs in Insider Risk Management provide a visual investigation experience that combines asset and activity data into a single view. Powered by Microsoft Sentinel integration, it summarizes alert-related activity by a potential insider over the past 30 days, helping analysts triage alerts by revealing hidden contextual connections.

> **Important**
>
> **Data risk graph is being deprecated.** The data risk graph in Microsoft Purview Insider Risk Management will be retired on **November 24, 2026**. After that date, the data risk graph experience will no longer be available.

For more information about Microsoft Sentinel integration, see Learn about Microsoft Sentinel in Microsoft Purview.

> **Important**
>
> You cannot use this feature with the anonymized usernames privacy setting enabled. If you have anonymized user names, the graph will not load.

> **Note**
>
> Admin units aren't supported in the data risk graph. If you're scoped to an admin unit, data doesn't appear in data risk graphs.

Supported activities in data risk graph

The data risk graph currently supports the following exfiltration activities:

- Anonymous links created in SharePoint or OneDrive
- Anonymous links used via SharePoint or OneDrive
- Company links created in SharePoint or OneDrive
- File downloads from SharePoint and OneDrive
- Files renamed in SharePoint and OneDrive

For more information about exfiltration detection indicators, see Configure policy indicators in Insider Risk Management.

Before you begin

Before you can use data risk graphs in Insider Risk Management, complete the following steps:

- Learn about pay-as-you-go billing in Microsoft Sentinel for your organization.
- Configure the prerequisites for Microsoft Sentinel data lake and Microsoft Sentinel graph
- Review the changes made when onboarding to Microsoft Sentinel data lake and Microsoft Sentinel graph
- Configure at least one Insider Risk Management policy for supported data exfiltration activities.

Configure data risk graph

> **Important**
>
> You always have one data lake. If you already onboarded to the data lake with another Microsoft service, your existing data lake is used. If you never onboarded to the data lake, onboarding in Insider Risk Management enables Microsoft Sentinel data lake and graph in the Defender portal.

After you complete the prerequisites and understand the onboarding changes that Microsoft Sentinel data lake and graph make to your organization, complete the following steps to configure data risk graph in Insider Risk Management:

> **Important**

Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

1. Go to the Microsoft Purview portal with an account assigned the *Global Administrator* or *Security Administrator* role.
2. Select the **Insider Risk Management** solution card, then select **Recommended actions** in the left nav.
3. In the **Comprehensive protection** section, select **Set up data lake and data risk graph**.

   If you don't have the correct permissions to set up the data lake, a notification appears to contact a global or billing administrator in your organization.
4. On the **Setup** tab on **Set up data lake & risk graph**, configure the following settings:
   a. **Subscription**: Enter the Azure subscription you want to use. Your selected subscription must be valid and accessible and you must be the subscription owner.
   b. **Resource group**: Enter the resource group you want to use. Your selected resource group must be valid and accessible.

   > **Important**
   >
   > After the data lake is provisioned for a specific Azure subscription and resource group, you can't migrate it to a different subscription or resource group.
5. Select **Setup**.

The data lake and data risk graph setup process begins, and onboarding might take up to 60 minutes to complete. You can close the setup panel while the process is running. After the onboarding process completes, you see *Complete* on **Set up data lake & risk graph**. The data risk graph shows events that occur after your Microsoft Sentinel data lake was created or onboarded.

Initial processing of data and data risk graph availability for an investigation can take 24–48 hours.

> **Important**
>
> When the data risk graph is first created, it includes the most recent seven days of data. As the data risk graph refreshes over time, the look-back window expands up to a maximum of

30 days. It might take some time for the data risk graph to reach the full 30-day window, so expect gradual growth after initial setup.

Use data risk graph

Data risk graph in Insider Risk Management uniquely visualizes correlations between impacted data, users, and their activities. It provides critical context to guide mitigation and next steps. For example, when you uncover an alert related to a highly sensitive document, data risk graphs give you visibility into which users downloaded it or if they accessed it from an IP address flagged as risky by your organization's security signals. This visibility lets you uncover new nodes to a data security incident, like additional users or new content related to an alert.

To view the data risk graph for an alert, you must be assigned the *Insider Risk Management Graph Reader* role. This role is included by default in several Insider Risk Management built-in role groups. For more information, see Assign permissions in Insider Risk Management.

> **Important**
>
> All user names are visible in data risk graph, even if pseudonymization is enabled in Insider Risk Management privacy settings.

To use the data risk graph in Insider Risk Management, complete the following steps:

1. Go to the Microsoft Purview portal with an account assigned the *Insider Risk Management Graph Reader* role.
2. Select the **Insider Risk Management** solution card, then select **Alerts** in the left nav.
3. Select an alert to review, then select the **Data risk graph** tab.
4. Filter the time as applicable and select individual data risk graph nodes for more information about each connection during triage.
5. Expand relationships in the graph by selecting the + icon on users or assets.

The data risk graph contains several nodes. Selecting a node shows details about the node:

- **User details**: Shows information about users associated with the alert. This information includes organization information for each user, including User Principal Name (UPN), labels, location, job title, and more.
- **Data details**: Shows information about files and sites. This information includes the object location, type, labels, and more.

You can view data risk graph information for users based on the last 30 days of activity. This fixed duration isn't extendable.

Export policy configuration in Microsoft Purview

The **Export to zip** option on the policies page downloads a point-in-time snapshot of all your policy configurations as a ZIP file in XML format. The export captures the full configuration details for every policy in the current solution at the moment of export, including rules, conditions, actions, scoping, and priority settings where relevant. For example, Label policies include the labels in the export, but not rules or conditions as they don't have any. You can't select individual policies for export—the ZIP file always contains all policies.

> **Important**
>
> The exported ZIP file is a read-only, point-in-time snapshot of your policy configuration. It's intended for reference only. You can't import it back into your tenant to restore or create policies, and it doesn't automatically update to reflect subsequent configuration changes.

> **Note**
>
> The **Export to CSV** option exports only the summary information shown in the policies table, such as policy name, status, and last modified date.

Common scenarios

Common scenarios for using the ZIP export include:

- **Support requests** — Attach the ZIP file to a support ticket so that support engineers can review your complete policy configuration without a live troubleshooting session.
- **Configuration backup** — Save periodic snapshots of your policy configuration for version control and change tracking purposes.
- **Configuration analysis** — Extract the XML file and analyze your policies locally by using PowerShell or by uploading the file to Microsoft 365 Copilot.

Export your policy configuration

1. Sign in to the Microsoft Purview portal.

2. Navigate to the policies page for the solution whose policies you want to export. If exporting is supported for that solution, the **Export to zip** option will be available.
3. Select **Export to zip**.
4. Save the ZIP file when prompted. The file downloads to your default downloads folder.
5. Extract the ZIP file to access the XML configuration file.

View the exported configuration by using PowerShell

You can use the standard PowerShell `Import-Clixml` cmdlet to deserialize the exported XML file into PowerShell objects for local analysis. This cmdlet reads the file locally and doesn't connect to any service.

1. Open a PowerShell window.

2. Import the XML file into a variable by using the `Import-Clixml` cmdlet. Replace the path with the location of your extracted XML file.

   PowerShell

   ```
   $p = Import-Clixml -Path "<path to extracted XML file>"
   ```

3. List the available properties in the exported configuration.

   PowerShell

   ```
   $p | Get-Member -MemberType Properties
   ```

4. View the data for a specific property by using `Format-Table` for a readable summary.

   PowerShell

   ```
   $p.<PropertyName> | Format-Table
   ```

   For example, if the export contains DLP policies:

   PowerShell

   ```
   $p.DlpCompliancePolicies | Format-Table
   $p.DlpComplianceRules | Format-Table
   ```

> **Tip**

The property names in the exported XML vary by solution. Use `$p | Get-Member -MemberType Properties` to discover which properties are available in your export.

Microsoft Purview data security and compliance protections for generative AI apps

> *Microsoft Purview service description*

Use Microsoft Purview to mitigate and manage the risks associated with AI usage, and implement corresponding protection and governance controls.

The following sections on this page provide an overview of Data Security Posture Management for AI and the Microsoft Purview capabilities that provide additional data security and compliance controls to accelerate your organization's adoption of Copilots and agents, and other generative AI apps.

In some Microsoft Purview solutions, you might see the supported AI apps grouped by the following category names:

- **Copilot experiences and agents** or **Microsoft Copilot experiences** for supported Copilots and agents that include:
  - Microsoft 365 Copilot
  - Security Copilot
  - Copilot in Fabric
  - Copilot Studio

- **Enterprise AI apps** for non-Copilot AI apps and agents connected to your organization through Entra registration, data connectors, Microsoft Foundry, and other methods, and include:
  - Microsoft Foundry
  - Entra-registered AI apps
  - Anthropic Claude (Enterprise)
  - ChatGPT Enterprise

- **Other AI apps** that are detected through browser activity and categorized as "Generative AI" in the Defender for Cloud Apps catalog. This category can include AI apps and agents from the other two categories but also uniquely includes AI apps and agents from third-party LLMs, such as:

- ChatGPT
- Google Gemini
- Microsoft Copilot (consumer version)
- DeepSeek

For a breakdown of Microsoft Purview security and compliance supported capabilities for AI interactions by app, see the additional pages identified in the following table. Where these AI apps support agents, they inherit the same security and compliance capabilities as their parent AI app. However, for a quick summary, see Use Microsoft Purview to manage data security & compliance for AI agents.

Expand table

Copilot experiences and agents	Enterprise AI apps	Other AI apps
Microsoft 365 Copilot & Microsoft 365 Copilot Chat	Entra-registered AI apps	Other AI apps
Microsoft Security Copilot	Microsoft Foundry	
Copilot in Fabric	ChatGPT Enterprise	
Microsoft Copilot Studio	Anthropic Claude (Enterprise)	
Microsoft Facilitator		
Channel Agent in Teams		

For a list of supported Microsoft Purview security and compliance supported capabilities for Microsoft Agent 365, see Use Microsoft Purview to manage data security & compliance for Microsoft Agent 365.

If you're new to Microsoft Purview, you might also find an overview of the product helpful: Learn about Microsoft Purview.

DSPM and DSPM for AI (classic)

Use Data Security Posture Management or Data Security Posture Management for AI (classic) as your front door to discover, secure, and apply compliance controls for AI usage across your enterprise. Both DSPM versions use existing controls from Microsoft Purview information protection and compliance management with easy-to-use graphical tools and reports to quickly gain insights into AI use within your organization. With personalized recommendations, and one-click policies help you protect your data and comply with regulatory requirements.

Microsoft Purview strengthens information protection for AI apps

Because of the power and speed AI can proactively surface content, generative AI amplifies the problem and risk of oversharing or leaking data. Learn how information protection capabilities from Microsoft Purview can help to strengthen your existing data security solutions.

Sensitivity labels and AI interactions

AI apps that Microsoft Purview support use existing controls to ensure that data stored in your tenant is never returned to the user or used by a large language model (LLM) if the user doesn't have access to that data. When the data has sensitivity labels from your organization applied to the content, there's an extra layer of protection:

- When a file is open in Word, Excel, PowerPoint, or similarly an email or calendar event is open in Outlook, the sensitivity of the data is displayed to users in the app with the label name and content markings (such as header or footer text) that have been configured for the label. Loop components and pages also support the same sensitivity labels.
- When the sensitivity label applies encryption, users must have the EXTRACT usage right, as well as VIEW, for the AI apps to return the data.
- This protection extends to data stored outside your Microsoft 365 tenant when it's open in an Office app (data in use). For example, local storage, network shares, and cloud storage.

> **Tip**
>
> If you haven't already, we recommend you enable sensitivity labels for SharePoint and OneDrive and also familiarize yourself with the file types and label configurations that these services can process. When sensitivity labels aren't enabled for these services, the encrypted files that Copilot and agents can access are limited to data in use from Office apps on Windows.
>
> For instructions, see **Enable sensitivity labels for Office files in SharePoint and OneDrive**.

If you're not already using sensitivity labels, see Get started with sensitivity labels.

Encryption without sensitivity labels and AI interactions

Even if a sensitivity label isn't applied to content, services and products might use the encryption capabilities from the Azure Rights Management service. As a result, AI apps can still check for the VIEW and EXTRACT usage rights before returning data and links to a user, but there's no automatic inheritance of protection for new items.

> **Tip**
>
> You'll get the best user experience when you always use sensitivity labels to protect your data, and encryption is applied by a label.

Examples of products and services that can use the encryption capabilities from the Azure Rights Management service without sensitivity labels:

- Microsoft Purview Message Encryption
- Microsoft Information Rights Management (IRM)
- Microsoft Rights Management connector
- Microsoft Rights Management SDK

For other encryption methods that don't use the Azure Rights Management service:

- S/MIME protected emails won't be returned by Copilot, and Copilot isn't available in Outlook when an S/MIME protected email is open.
- Password-protected documents can't be accessed by AI apps unless they're already opened by the user in the same app (data in use). Passwords aren't inherited by a destination item.

As with other Microsoft 365 services, such as eDiscovery and search, items encrypted with Microsoft Purview Customer Key or your own root key (BYOK) are supported and eligible to be returned by Copilot.

Data loss prevention and AI interactions

Microsoft Purview Data Loss Prevention (DLP) helps you identify sensitive items across Microsoft 365 services and endpoints, monitor them, and helps protect against leakage of those items. It uses deep content inspection and contextual analysis to identify sensitive items and it enforces policies to protect sensitive data such as financial records, health information, or intellectual property.

Windows computers that are onboarded to Microsoft Purview can be configured for Endpoint data loss prevention (DLP) policies that warn or block users from sharing sensitive information

with third-party generative AI sites that are accessed via a browser. For example, a user is prevented from pasting credit card numbers into ChatGPT, or they see a warning that they can override. For more information about the supported DLP actions and which platforms support them, see the first two rows in the table from Endpoint activities you can monitor and take action on.

Insider Risk Management and AI interactions

Microsoft Purview Insider Risk Management helps you detect, investigate, and mitigate internal risks such as IP theft, data leakage, and security violations. It leverages machine learning models and various signals from Microsoft 365 and third-party indicators to identify potential malicious or inadvertent insider activities. The solution includes privacy controls like pseudonymization and role-based access, ensuring user-level privacy while enabling risk analysts to take appropriate actions.

Use the Risky AI usage policy template to detect risky usage that includes prompt injection attacks and accessing protected materials. Insights from these signals are integrated into Microsoft Defender XDR to provide a comprehensive view of AI-related risks.

Data classification and AI interactions

Microsoft Purview data classification provides a comprehensive framework for identifying and tagging sensitive data across various Microsoft services, including Office 365, Dynamics 365, and Azure. Classifying data is often the first step to ensure compliance with data protection regulations and safeguard against unauthorized access, alteration, or destruction. You can use built-in system classifications or create your own.

Sensitive information types and trainable classifiers can be used to find sensitive data in user prompts and responses when they use AI apps. The resulting information then surfaces in Microsoft Purview Reports overview and activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM.

Microsoft Purview supports compliance management for AI apps

Interactions using supported AI apps can be monitored for each user in your tenant. As such, together with data classification, you can use Microsoft Purview's auditing, communication compliance, eDiscovery with content search, and automatic retention and deletion capabilities from Data Lifecycle Management to manage this AI usage.

Auditing and AI interactions

Microsoft Purview Audit solutions provide comprehensive tools for searching and managing audit records of activities performed across various Microsoft services by users and admins, and help organizations to effectively respond to security events, forensic investigations, internal investigations, and compliance obligations.

Like other activities, prompts and responses are captured in the unified audit log. Events include how and when users interact with the AI app, and can include in which Microsoft 365 service the activity took place, and references to the files stored in Microsoft 365 that were accessed during the interaction. If these files have a sensitivity label applied, that's also captured.

These events flow into activity explorer in the **AI activities** tab in the current version of DSPM and in DSPM for AI, where the data from prompts and responses can be displayed. You can also use the **Audit** solution from the Microsoft Purview portal to search and find these auditing events.

For more information, see Audit logs for Copilot and AI activities.

Communication compliance and AI interactions

Microsoft Purview Communication Compliance provides tools to help you detect and manage regulatory compliance and business conduct violations across various communication channels, which include user prompts and responses for AI apps. It's designed with privacy by default, pseudonymizing usernames and incorporating role-based access controls. The solution helps identify and remediate inappropriate communications, such as sharing sensitive information, harassment, threats, and adult content.

To learn more about using communication compliance policies for AI apps, see Configure a communication compliance policy to detect for generative AI interactions.

eDiscovery with content search and AI interactions

Microsoft Purview eDiscovery lets you identify and deliver electronic information that can be used as evidence in legal cases. The eDiscovery tools in Microsoft Purview support searching for content in Exchange Online, OneDrive for Business, SharePoint Online, Microsoft Teams, Microsoft 365 Groups, and Viva Engage teams. You can then prevent the information from deletion and export the information.

Because user prompts and responses for AI apps are stored in a user's mailbox, you can create a case and use search when a user's mailbox is selected as the source for a search query. For

example, select and retrieve this data from the source mailbox by selecting from the query builder **Add condition** > **Type** > **Contains any of** > **Edit** > *Copilot activity*. This query condition includes all Copilot and other AI application activity.

After the search is refined, you can export the results or add to a review set. You can review and export information directly from the review set.

For more information about identifying and deleting user AI interaction data, see Search for and delete Copilot data in eDiscovery.

Data Lifecycle Management and AI interactions

Microsoft Purview Data Lifecycle Management provides tools and capabilities to manage the lifecycle of organizational data by retaining necessary content and deleting unnecessary content. These tools ensure compliance with business, legal, and regulatory requirements.

Use retention policies to automatically retain or delete user prompts and responses for AI apps. For detailed information about this retention works, see Learn about retention for Copilot & AI apps.

As with all retention policies and holds, if more than one policy for the same location applies to a user, the principles of retention resolve any conflicts. For example, the data is retained for the longest duration of all the applied retention policies or eDiscovery holds.

Compliance Manager and AI interactions

Microsoft Purview Compliance Manager is a solution that helps you automatically assess and manage compliance across your multicloud environment. Compliance Manager can help you throughout your compliance journey, from taking inventory of your data protection risks to managing the complexities of implementing controls, staying current with regulations and certifications, and reporting to auditors.

To help you keep compliant with AI regulations, Compliance Manager provides regulatory templates to help you assess, implement, and strengthen your compliance requirements for all generative AI apps. For example, monitoring AI interactions and preventing data loss in AI applications. For more information, see Assessments for AI regulations.

Use Microsoft Purview to manage data security & compliance for Microsoft 365 Copilot & Microsoft 365 Copilot Chat

> *Microsoft Purview service description*

Use the following sections to identify the Microsoft Purview capabilities that are supported for AI interactions with Microsoft 365 Copilot & Microsoft 365 Copilot Chat, and some get started recommendations for you to manage these AI interactions for security and compliance.

Capabilities supported

Use the following table to see at a glance the Microsoft Purview capabilities that are supported with Microsoft 365 Copilot & Microsoft 365 Copilot Chat.

Expand table

Capability or solution in Microsoft Purview	Supported for AI interactions
DSPM and DSPM for AI (classic)	✓
Auditing	✓
Data classification	✓
Sensitivity labels	✓
Encryption without sensitivity labels	✓
Data loss prevention	✓
Insider Risk Management	✓
Communication compliance	✓
eDiscovery	✓
Data Lifecycle Management	✓
Compliance Manager	✓

DSPM and DSPM for AI (classic)

Use Data Security Posture Management or Data Security Posture Management for AI (classic) as your front door to discover, secure, and apply compliance controls for AI usage across your enterprise. Both DSPM versions use existing controls from Microsoft Purview information protection and compliance management with easy-to-use graphical tools and reports to quickly gain insights into AI use within your organization. With personalized recommendations, and one-click policies help you protect your data and comply with regulatory requirements.

AI app-specific information:

- Data risk assessments help you identify and fix issues that could results in oversharing of data. From the recommendations:
  - **Protect your data from potential oversharing risks** for the default weekly data risk assessment.
  - **Protect sensitive data references in Copilot and agent responses** for a custom data risk assessment.
- Recommendation: **Get guided assistance to AI regulations**, which uses control-mapping regulatory templates from Compliance Manager.
- Additional guidance from **Overview** > **Microsoft 365 Copilot** view.
- One-click policies available:
  - **Sensitivity labels and policies** from the recommendation or remediation action **Protect your data with sensitivity labels**.
  - **DSPM for AI - Detect risky AI usage** from the recommendation or remediation action **Detect risky interactions in AI apps**.
  - **DSPM for AI - Unethical behavior in AI apps** from the recommendation or remediation action **Detect unethical behavior in AI**.
  - **DSPM for AI - Protect sensitive data from Copilot processing** from the recommendation or remediation action **Protect items with sensitivity labels from Microsoft 365 Copilot and agent processing**
  - **DSPM for AI - Detect sensitive info shared with AI via network** from the recommendation or remediation action **Extend insights into sensitive data in AI app interactions**.

Auditing and AI interactions

Microsoft Purview Audit solutions provide comprehensive tools for searching and managing audit records of activities performed across various Microsoft services by users and admins, and

help organizations to effectively respond to security events, forensic investigations, internal investigations, and compliance obligations.

Like other activities, prompts and responses are captured in the unified audit log. Events include how and when users interact with the AI app, and can include in which Microsoft 365 service the activity took place, and references to the files stored in Microsoft 365 that were accessed during the interaction. If these files have a sensitivity label applied, that's also captured.

These events flow into activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM, where the data from prompts and responses can be displayed. You can also use the **Audit** solution from the Microsoft Purview portal to search and find these auditing events.

For more information, see Audit logs for Copilot and AI activities.

Data classification and AI interactions

Microsoft Purview data classification provides a comprehensive framework for identifying and tagging sensitive data across various Microsoft services, including Office 365, Dynamics 365, and Azure. Classifying data is often the first step to ensure compliance with data protection regulations and safeguard against unauthorized access, alteration, or destruction. You can use built-in system classifications or create your own.

Sensitive information types and trainable classifiers can be used to find sensitive data in user prompts and responses when they use AI apps. The resulting information then surfaces in Microsoft Purview Reports overview and activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM.

Sensitivity labels and AI interactions

AI apps that Microsoft Purview support use existing controls to ensure that data stored in your tenant is never returned to the user or used by a large language model (LLM) if the user doesn't have access to that data. When the data has sensitivity labels from your organization applied to the content, there's an extra layer of protection:

- When a file is open in Word, Excel, PowerPoint, or similarly an email or calendar event is open in Outlook, the sensitivity of the data is displayed to users in the app with the label name and content markings (such as header or footer text) that have been configured for the label. Loop components and pages also support the same sensitivity labels.

- When the sensitivity label applies encryption, users must have the EXTRACT usage right, as well as VIEW, for the AI apps to return the data.
- This protection extends to data stored outside your Microsoft 365 tenant when it's open in an Office app (data in use). For example, local storage, network shares, and cloud storage.

> **Tip**
>
> If you haven't already, we recommend you enable sensitivity labels for SharePoint and OneDrive and also familiarize yourself with the file types and label configurations that these services can process. When sensitivity labels aren't enabled for these services, the encrypted files that Copilot and agents can access are limited to data in use from Office apps on Windows.
>
> For instructions, see **Enable sensitivity labels for Office files in SharePoint and OneDrive**.

If you're not already using sensitivity labels, see Get started with sensitivity labels.

AI app-specific information:

- Microsoft 365 Copilot Chat displays the sensitivity label for items listed in the response and citations. Using the sensitivity labels' priority number that's defined in the Microsoft Purview portal, the latest response in Microsoft 365 Copilot Chat and threaded summaries in Copilot in Teams chat and channels display the highest priority sensitivity label from the data used for that Copilot chat.

  Although compliance admins define a sensitivity label's priority, a higher priority number usually denotes higher sensitivity of the content, with more restrictive permissions. As a result, Copilot responses display the most restrictive sensitivity label to educate the user about the sensitivity of the data.

- Copilot in Word, Copilot in PowerPoint, and Copilot in Outlook support sensitivity label inheritance for newly created content. See the following section for more information.

Sensitivity label inheritance

If you use Copilot in Word, Copilot in PowerPoint, and Copilot in Outlook to create new content based on an item that has a sensitivity label applied, the sensitivity label from the source file is automatically inherited, with the label's protection settings.

For example, a user selects **Draft with Copilot** in Word and then **Reference a file**. Or a user selects **Create presentation from file** in PowerPoint, or **Edit in Pages** from Microsoft 365 Copilot Chat. The source content has the sensitivity label **Confidential\Anyone (unrestricted)** applied and that label is configured to apply a footer that displays "Confidential". The new content is automatically labeled **Confidential\Anyone (unrestricted)** with the same footer.

To see an example of this in action, watch the following demo from the Ignite 2023 session, "Getting your enterprise ready for Microsoft 365 Copilot". The demo shows how the default sensitivity label of **General** is replaced with a **Confidential** label when a user drafts with Copilot and references a labeled file. The information bar under the ribbon informs the user that content created by Copilot resulted in the new label being automatically applied:

https://learn-video.azurefd.net/vod/player?id=e24ee590-7684-49aa-ab7e-b0e5652171b6&locale=en-us&embedUrl=%2Fpurview%2Fai-m365-copilot

If multiple files are used to create new content, the sensitivity label with the highest priority is used for label inheritance.

As with all automatic labeling scenarios, the user can always override and replace an inherited label (or remove, if you're not using mandatory labeling).

Encryption without sensitivity labels and AI interactions

Even if a sensitivity label isn't applied to content, services and products might use the encryption capabilities from the Azure Rights Management service. As a result, AI apps can still check for the VIEW and EXTRACT usage rights before returning data and links to a user, but there's no automatic inheritance of protection for new items.

> **Tip**
>
> You'll get the best user experience when you always use sensitivity labels to protect your data, and encryption is applied by a label.

Examples of products and services that can use the encryption capabilities from the Azure Rights Management service without sensitivity labels:

- Microsoft Purview Message Encryption
- Microsoft Information Rights Management (IRM)
- Microsoft Rights Management connector

- Microsoft Rights Management SDK

For other encryption methods that don't use the Azure Rights Management service:

- S/MIME protected emails won't be returned by Copilot, and Copilot isn't available in Outlook when an S/MIME protected email is open.
- Password-protected documents can't be accessed by AI apps unless they're already opened by the user in the same app (data in use). Passwords aren't inherited by a destination item.

As with other Microsoft 365 services, such as eDiscovery and search, items encrypted with Microsoft Purview Customer Key or your own root key (BYOK) are supported and eligible to be returned by Copilot.

Data loss prevention and AI interactions

Microsoft Purview Data Loss Prevention (DLP) helps you identify sensitive items across Microsoft 365 services and endpoints, monitor them, and helps protect against leakage of those items. It uses deep content inspection and contextual analysis to identify sensitive items and it enforces policies to protect sensitive data such as financial records, health information, or intellectual property.

Windows computers that are onboarded to Microsoft Purview can be configured for Endpoint data loss prevention (DLP) policies that warn or block users from sharing sensitive information with third-party generative AI sites that are accessed via a browser. For example, a user is prevented from pasting credit card numbers into ChatGPT, or they see a warning that they can override. For more information about the supported DLP actions and which platforms support them, see the first two rows in the table from Endpoint activities you can monitor and take action on.

AI app-specific information:

- Use the **Microsoft 365 Copilot and Copilot Chat** policy location to restrict the processing of prompts that contain sensitive information types, or processing files and emails that have specific sensitivity labels applied. For more information, see Learn about using Microsoft Purview Data Loss Prevention to protect interactions with Microsoft 365 Copilot and Copilot Chat.
- Microsoft 365 Copilot Chat supports the following Endpoint DLP capabilities only:
  - Block paste of sensitive content
  - Block files based on a specified sensitivity label

Insider Risk Management and AI interactions

Microsoft Purview Insider Risk Management helps you detect, investigate, and mitigate internal risks such as IP theft, data leakage, and security violations. It leverages machine learning models and various signals from Microsoft 365 and third-party indicators to identify potential malicious or inadvertent insider activities. The solution includes privacy controls like pseudonymization and role-based access, ensuring user-level privacy while enabling risk analysts to take appropriate actions.

Use the Risky AI usage policy template to detect risky usage that includes prompt injection attacks and accessing protected materials. Insights from these signals are integrated into Microsoft Defender XDR to provide a comprehensive view of AI-related risks.

Communication compliance and AI interactions

Microsoft Purview Communication Compliance provides tools to help you detect and manage regulatory compliance and business conduct violations across various communication channels, which include user prompts and responses for AI apps. It's designed with privacy by default, pseudonymizing usernames and incorporating role-based access controls. The solution helps identify and remediate inappropriate communications, such as sharing sensitive information, harassment, threats, and adult content.

To learn more about using communication compliance policies for AI apps, see Configure a communication compliance policy to detect for generative AI interactions.

eDiscovery and AI interactions

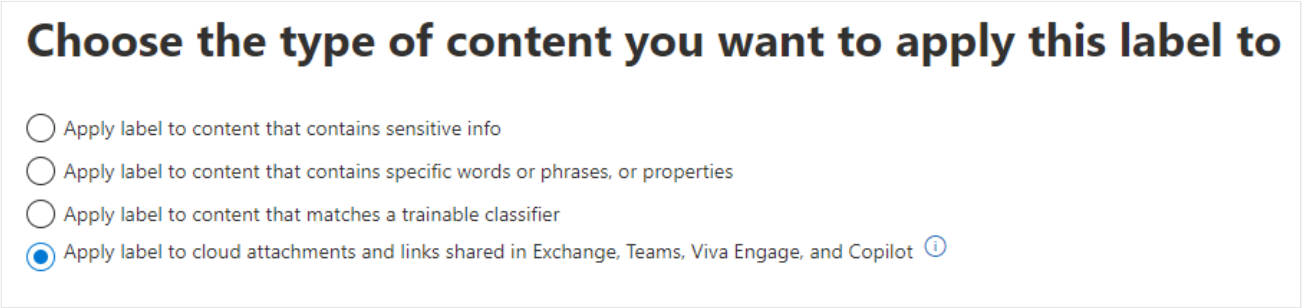
Microsoft Purview eDiscovery lets you identify and deliver electronic information that can be used as evidence in legal cases. The eDiscovery tools in Microsoft Purview support searching for content in Exchange Online, OneDrive for Business, SharePoint Online, Microsoft Teams, Microsoft 365 Groups, and Viva Engage teams. You can then prevent the information from deletion and export the information.

Because user prompts and responses for AI apps are stored in a user's mailbox, you can create a case and use search when a user's mailbox is selected as the source for a search query. For example, select and retrieve this data from the source mailbox by selecting from the query builder **Add condition** > **Type** > **Contains any of** > **Edit** > *Copilot activity*. This query condition includes all Copilot and other AI application activity.

After the search is refined, you can export the results or add to a review set. You can review and export information directly from the review set.

For more information about identifying and deleting user AI interaction data, see Search for and delete Copilot data in eDiscovery.

Data Lifecycle Management and AI interactions



Microsoft Purview Data Lifecycle Management provides tools and capabilities to manage the lifecycle of organizational data by retaining necessary content and deleting unnecessary content. These tools ensure compliance with business, legal, and regulatory requirements.

Use retention policies to automatically retain or delete user prompts and responses for AI apps. For detailed information about this retention works, see Learn about retention for Copilot & AI apps.

As with all retention policies and holds, if more than one policy for the same location applies to a user, the principles of retention resolve any conflicts. For example, the data is retained for the longest duration of all the applied retention policies or eDiscovery holds.

AI app-specific information:

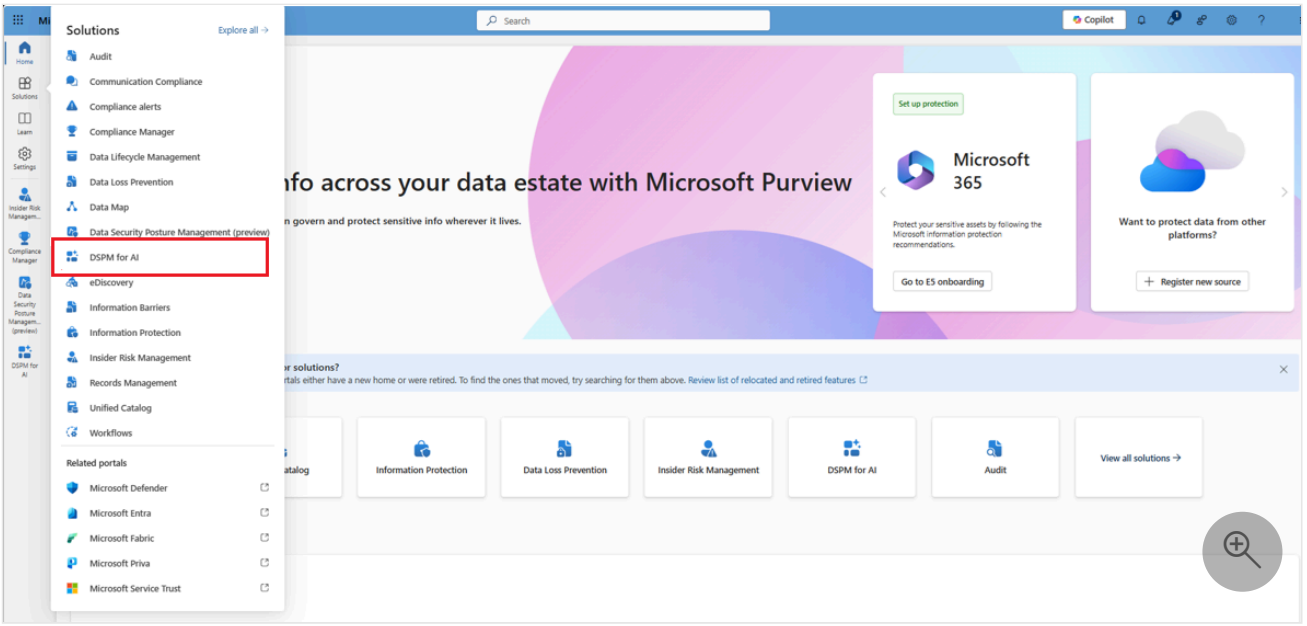
- For retention policies, select the option for **Microsoft Copilot Experiences**.
- Retention labels can automatically retain files referenced in Microsoft 365 Copilot when you select the option for cloud attachments with an auto-apply retention label policy: **Apply label to cloud attachments and links shared in Exchange, Teams, Viva Engage, and Copilot**. As with all retained cloud attachments, the file version at the time it's referenced is retained.

  For detailed information about how this retention works, see How retention works with cloud attachments.

Compliance Manager and AI interactions

Microsoft Purview Compliance Manager is a solution that helps you automatically assess and manage compliance across your multicloud environment. Compliance Manager can help you throughout your compliance journey, from taking inventory of your data protection risks to managing the complexities of implementing controls, staying current with regulations and certifications, and reporting to auditors.

To help you keep compliant with AI regulations, Compliance Manager provides regulatory templates to help you assess, implement, and strengthen your compliance requirements for all generative AI apps. For example, monitoring AI interactions and preventing data loss in AI applications. For more information, see Assessments for AI regulations.



Getting started recommended steps

Use the following steps to get started with managing data security & compliance for AI interactions from Microsoft 365 Copilot & Microsoft 365 Copilot Chat.

> **Note**
>
> These steps focus on managing a specific AI app or agent. For broader coverage that uses security objectives with guided workflows, use the current version of **Data Security Posture Management**.

Because Data Security Posture Management for AI is your front door for securing and managing AI interactions, most of the following instructions use that solution:

- Sign in to the Microsoft Purview portal > **Solutions** > **DSPM for AI (classic)** with an account that has appropriate permissions. For example, an account that's a member of the **Microsoft Entra Compliance Administrator** group role.

Confirm that auditing is turned on

From **DSPM for AI (classic)** > **Overview** > **All AI apps** view > **Get Started** section, look to see if auditing is on for your tenant. If not, select **Activate Microsoft Purview Audit**.

Use the Microsoft 365 Copilot view to discover, protect, and apply compliance controls

Change the view from **All AI apps** to **Microsoft 365 Copilot** and work your way through the sections:

- **Assess and prevent oversharing of sensitive data**
- **Secure your data in Microsoft 365 Copilot**
- **Discover Microsoft 365 Copilot activity**

These sections include recommendations that are specific to Microsoft 365 Copilot. Wait at least a day for data to display for the reports on this page.

> **Tip**
>
> **Secure your data in Microsoft 365 Copilot** includes the following recommendations with manual configuration instructions for their respective Microsoft Purview solutions: **Create sensitivity labels for your organization** and **Protect items with sensitivity labels from Copilot processing**

If you prefer, you can use DSPM for AI one-click policies for these recommendations, as described in the next section.

Use one-click policies to increase coverage

Select **Recommendations** from the navigation and use one-click policies to automatically create policies that help you discover, protect, and apply compliance controls. Specific to Microsoft 365 Copilot:

- **Protect your data with sensitivity labels**
- **Detect risky interactions in AI apps**
- **Detect unethical behavior in AI**
- **Protect items with sensitivity labels from Microsoft 365 Copilot and agent processing**

View data from your policies

1. Wait at least a day for data, and then navigate to the **Reports** page to view the results of your policies. Select **Copilot experiences & agents** and view information such as:

    - Total interactions over time (Microsoft Copilot and agents)
    - Sensitive interactions per AI app
    - Top unethical AI interactions
    - Top sensitivity labels references in Microsoft 365 Copilot and agents
    - Insider Risk severity
    - Insider risk severity per AI app
    - Potential risky AI usage

2. Select **View details** for each of the report graphs to view detailed activities in the activity explorer.

    From the filters, select the **AI app category** of **Copilot experiences & agents**, and then use the other filters if you need to further refine the displayed data. Then drill down to each activity to view details that include displaying the prompts and response when you're a member of the Microsoft Purview Content Explorer Content Viewer role group. For more information about this requirement, see Permissions for Data Security Posture Management for AI.

Apply additional compliance controls to Microsoft 365 Copilot interactions

1. If you need to retain the exact version of files referenced in Microsoft 365 Copilot interactions:

   In the Microsoft Purview portal, navigate to **Data Lifecycle Management** > **Retention labels** > and either locate or create a retention label with the required retention period. Then, navigate to **Label policies** to auto-apply that label, and select the option **Apply label to cloud attachments and links shared in Exchange, Teams, Viva Engage, and Copilot**. For more information, see Automatically apply a retention label to retain or delete content.

2. If you need to preserve, collect, analyze, review, or export Microsoft 365 Copilot interactions:

   In the Microsoft Purview portal, navigate to **eDiscovery** > **Cases** > **Create case**. In the case, create a search and use the *ItemClass* property and the `IPM.SkypeTeams.Message.Copilot.*` value to search for these interactions in your organization.

Routinely review the reports and data risk assessments in DSPM for AI to determine if you need to make changes, and use activity explorer and events for deeper analysis of how users are interacting with Microsoft 365 Copilot & Microsoft 365 Copilot Chat.

Other documentation to help you secure and manage generative AI apps

For more detailed information, see Considerations to manage Microsoft 365 Copilot for security and compliance.

Microsoft 365 Copilot documentation:

- Microsoft 365 Copilot documentation
- Microsoft 365 Copilot admin guide for E5 + SAM licenses
- Apply principles of Zero Trust to Microsoft 365 Copilot

Last updated on 05/01/2026

Use Microsoft Purview to manage data security & compliance for Microsoft 365 Copilot Cowork

> *Microsoft Purview service description*

Use the following sections to identify the Microsoft Purview capabilities that are supported for Microsoft 365 Copilot Cowork.

> **Note**
>
> Although Copilot Cowork is part of Microsoft 365 Copilot, Cowork introduces long-running, multi-step work across apps. Because this model can result in different behaviors and feature support, its capabilities are documented separately to provide accurate guidance for administrators to better understand security and compliance scenarios.

Capabilities supported

Use the following table to see at a glance the Microsoft Purview capabilities that are supported with Copilot Cowork.

Expand table

Capability or solution in Microsoft Purview	Supported for AI interactions
DSPM and DSPM for AI (classic)	✓
Auditing	✓
Data classification	✗
Sensitivity labels	✓
Encryption without sensitivity labels	✓
Data loss prevention	✓
Insider Risk Management	✓

Capability or solution in Microsoft Purview	Supported for AI interactions
Communication compliance	✓
eDiscovery	✓
Data Lifecycle Management	✓
Compliance Manager	✗

DSPM and DSPM for AI (classic)

Use Data Security Posture Management or Data Security Posture Management for AI (classic) as your front door to discover, secure, and apply compliance controls for AI usage across your enterprise. Both DSPM versions use existing controls from Microsoft Purview information protection and compliance management with easy-to-use graphical tools and reports to quickly gain insights into AI use within your organization. With personalized recommendations, and one-click policies help you protect your data and comply with regulatory requirements.

AI app-specific information:

- Data risk assessments help you identify and fix issues that could results in oversharing of data. From the recommendations:
  - **Protect your data from potential oversharing risks** for the default weekly data risk assessment.
  - **Protect sensitive data references in Copilot and agent responses** for a custom data risk assessment.

- One-click policies available:
  - **Sensitivity labels and policies** from the recommendation or remediation action **Protect your data with sensitivity labels**.
  - **DSPM for AI - Detect risky AI usage** from the recommendation or remediation action **Detect risky interactions in AI apps**.
  - **DSPM for AI - Unethical behavior in AI apps** from the recommendation or remediation action **Detect unethical behavior in AI**.

- Although interactions from Cowork display in activity explorer (**AI activities** tab), they don't display in the **Apps and agents** dashboard or the **AI observability** page.

Auditing and AI interactions

Microsoft Purview Audit solutions provide comprehensive tools for searching and managing audit records of activities performed across various Microsoft services by users and admins, and help organizations to effectively respond to security events, forensic investigations, internal investigations, and compliance obligations.

Like other activities, prompts and responses are captured in the unified audit log. Events include how and when users interact with the AI app, and can include in which Microsoft 365 service the activity took place, and references to the files stored in Microsoft 365 that were accessed during the interaction. If these files have a sensitivity label applied, that's also captured.

These events flow into activity explorer in the **AI activities** tab in the current version of DSPM and in DSPM for AI, where the data from prompts and responses can be displayed. You can also use the **Audit** solution from the Microsoft Purview portal to search and find these auditing events.

For more information, see Audit logs for Copilot and AI activities.

AI app-specific information:

Typical auditing events:

- A user starts a new Cowork conversation
- A user adds, removes, or shares a skill or plugin
- A user runs a scheduled prompt
- A user starts a browser task
- A user uploads a file to Cowork
- Cowork creates an artifact in OneDrive on behalf of a user

Sensitivity labels and AI interactions

AI apps that Microsoft Purview support use existing controls to ensure that data stored in your tenant is never returned to the user or used by a large language model (LLM) if the user doesn't have access to that data. When the data has sensitivity labels from your organization applied to the content, there's an extra layer of protection:

- When a file is open in Word, Excel, PowerPoint, or similarly an email or calendar event is open in Outlook, the sensitivity of the data is displayed to users in the app with the label name and content markings (such as header or footer text) that have been configured for the label. Loop components and pages also support the same sensitivity labels.

- When the sensitivity label applies encryption, users must have the EXTRACT usage right, as well as VIEW, for the AI apps to return the data.

- This protection extends to data stored outside your Microsoft 365 tenant when it's open in an Office app (data in use). For example, local storage, network shares, and cloud storage.

> **Tip**
>
> If you haven't already, we recommend you enable sensitivity labels for SharePoint and OneDrive and also familiarize yourself with the file types and label configurations that these services can process. When sensitivity labels aren't enabled for these services, the encrypted files that Copilot and agents can access are limited to data in use from Office apps on Windows.
>
> For instructions, see **Enable sensitivity labels for Office files in SharePoint and OneDrive**.

If you're not already using sensitivity labels, see Get started with sensitivity labels.

AI app-specific information:

- Microsoft 365 Copilot Cowork displays the sensitivity label for items listed in the response and citations. Using the sensitivity labels' priority number that's defined in the Microsoft Purview portal, the latest response displays the highest priority sensitivity label from the data used for that Copilot chat.

  Although compliance admins define a sensitivity label's priority, a higher priority number usually denotes higher sensitivity of the content, with more restrictive permissions. As a result, Copilot responses display the most restrictive sensitivity label to educate the user about the sensitivity of the data.

- Sensitivity label inheritance is supported for newly created content. See the following section for more information.

Sensitivity label inheritance

If you use Cowork to create new content in Word, PowerPoint, and Outlook based on an item that has a sensitivity label applied, the sensitivity label from the source file is automatically inherited, with the label's protection setting.

For example, Cowork creates a new Word document based on labeled data. The source content has the sensitivity label **Confidential\Anyone (unrestricted)** applied and that label is configured to apply a footer that displays "Confidential". The new content is automatically labeled **Confidential\Anyone (unrestricted)** with the same footer.

If multiple sources are used to create new content, the sensitivity label with the highest priority is used for label inheritance.

As with all automatic labeling scenarios, a user can always override and replace an inherited label (or remove, if you're not using mandatory labeling).

Encryption without sensitivity labels and AI interactions

Even if a sensitivity label isn't applied to content, services and products might use the encryption capabilities from the Azure Rights Management service. As a result, AI apps can still check for the VIEW and EXTRACT usage rights before returning data and links to a user, but there's no automatic inheritance of protection for new items.

> **Tip**
>
> You'll get the best user experience when you always use sensitivity labels to protect your data, and encryption is applied by a label.

Examples of products and services that can use the encryption capabilities from the Azure Rights Management service without sensitivity labels:

- Microsoft Purview Message Encryption
- Microsoft Information Rights Management (IRM)
- Microsoft Rights Management connector
- Microsoft Rights Management SDK

For other encryption methods that don't use the Azure Rights Management service:

- S/MIME protected emails won't be returned by Copilot, and Copilot isn't available in Outlook when an S/MIME protected email is open.
- Password-protected documents can't be accessed by AI apps unless they're already opened by the user in the same app (data in use). Passwords aren't inherited by a destination item.

As with other Microsoft 365 services, such as eDiscovery and search, items encrypted with Microsoft Purview Customer Key or your own root key (BYOK) are supported and eligible to be returned by Copilot.

Insider Risk Management and AI interactions

Microsoft Purview Insider Risk Management helps you detect, investigate, and mitigate internal risks such as IP theft, data leakage, and security violations. It leverages machine learning models and various signals from Microsoft 365 and third-party indicators to identify potential malicious or inadvertent insider activities. The solution includes privacy controls like pseudonymization and role-based access, ensuring user-level privacy while enabling risk analysts to take appropriate actions.

Use the Risky AI usage policy template to detect risky usage that includes prompt injection attacks and accessing protected materials. Insights from these signals are integrated into Microsoft Defender XDR to provide a comprehensive view of AI-related risks.

Communication compliance and AI interactions

Microsoft Purview Communication Compliance provides tools to help you detect and manage regulatory compliance and business conduct violations across various communication channels, which include user prompts and responses for AI apps. It's designed with privacy by default, pseudonymizing usernames and incorporating role-based access controls. The solution helps identify and remediate inappropriate communications, such as sharing sensitive information, harassment, threats, and adult content.

To learn more about using communication compliance policies for AI apps, see Configure a communication compliance policy to detect for generative AI interactions.

eDiscovery and AI interactions

Microsoft Purview eDiscovery lets you identify and deliver electronic information that can be used as evidence in legal cases. The eDiscovery tools in Microsoft Purview support searching for content in Exchange Online, OneDrive for Business, SharePoint Online, Microsoft Teams, Microsoft 365 Groups, and Viva Engage teams. You can then prevent the information from deletion and export the information.

Because user prompts and responses for AI apps are stored in a user's mailbox, you can create a case and use search when a user's mailbox is selected as the source for a search query. For example, select and retrieve this data from the source mailbox by selecting from the query builder **Add condition** > **Type** > **Contains any of** > **Edit** > *Copilot activity*. This query condition includes all Copilot and other AI application activity.

After the search is refined, you can export the results or add to a review set. You can review and export information directly from the review set.

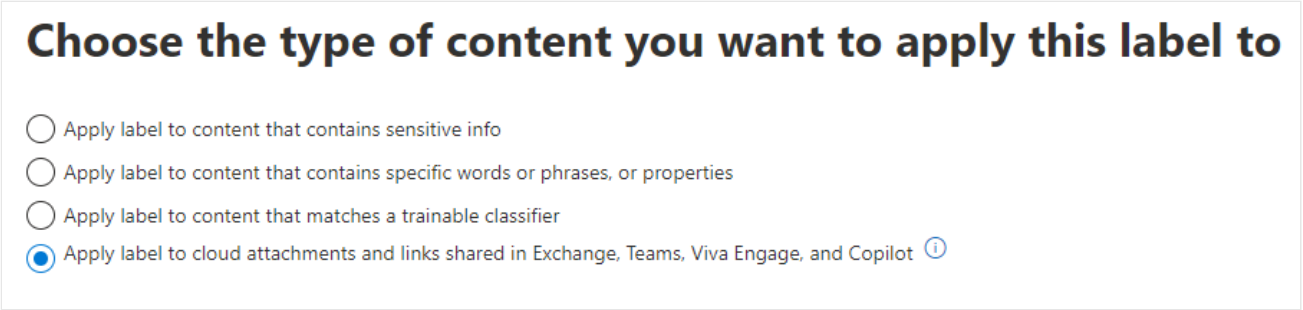
For more information about identifying and deleting user AI interaction data, see Search for and delete Copilot data in eDiscovery.

AI app-specific information:

In scope for eDiscovery:

- Conversation transcripts — The full text of a user's Cowork conversations, including prompts and responses.
- Files Cowork created — Documents, decks, PDFs, and images saved to the user's OneDrive.
- Scheduled prompts — The prompt text and the conversations created by each scheduled run.
- Uploaded files — Files a user uploaded to Cowork that are retained in the user's OneDrive or in the conversation.

Data Lifecycle Management and AI interactions



Microsoft Purview Data Lifecycle Management provides tools and capabilities to manage the lifecycle of organizational data by retaining necessary content and deleting unnecessary content. These tools ensure compliance with business, legal, and regulatory requirements.

Use retention policies to automatically retain or delete user prompts and responses for AI apps. For detailed information about this retention works, see Learn about retention for Copilot & AI apps.

As with all retention policies and holds, if more than one policy for the same location applies to a user, the principles of retention resolve any conflicts. For example, the data is retained for the longest duration of all the applied retention policies or eDiscovery holds.

AI app-specific information:

- For retention policies, select the option for **Microsoft Copilot Experiences**.
- Retention labels can automatically retain files referenced in Microsoft 365 Copilot Cowork when you select the option for cloud attachments with an auto-apply retention label policy: **Apply label to cloud attachments and links shared in Exchange, Teams, Viva Engage, and Copilot**. As with all retained cloud attachments, the file version at the time it's referenced is retained.

For detailed information about how this retention works, see How retention works with cloud attachments.

Use Microsoft Purview to manage data security & compliance for Microsoft Security Copilot

> *Microsoft Purview service description*

Use the following sections to identify the Microsoft Purview capabilities that are supported for AI interactions with Microsoft Security Copilot, and some get started recommendations for you to manage these AI interactions for security and compliance.

Before Microsoft Purview can manage these AI interactions, you must first turn on the Security Copilot option **Allow Microsoft Purview to access, process, copy, and store Customer Data from your Security Copilot Service**. For more information, see Enable Security Copilot for Purview Audit and DSPM Solutions.

Managing these AI interactions with Microsoft Purview requires you to enable pay-as-you-go billing in your organization.

Capabilities supported

Use the following table to see at a glance the Microsoft Purview capabilities that are supported with Microsoft Security Copilot.

Expand table

Capability or solution in Microsoft Purview	Supported for AI interactions
DSPM and DSPM for AI (classic)	✓
Auditing	✓
Data classification	✓
Sensitivity labels	✗
Encryption without sensitivity labels	✗
Data loss prevention	✗
Insider Risk Management	✓

Capability or solution in Microsoft Purview	Supported for AI interactions
Communication compliance	✓
eDiscovery	✓
Data Lifecycle Management	✓
Compliance Manager	✓

DSPM and DSPM for AI (classic)

Use Data Security Posture Management or Data Security Posture Management for AI (classic) as your front door to discover, secure, and apply compliance controls for AI usage across your enterprise. Both DSPM versions use existing controls from Microsoft Purview information protection and compliance management with easy-to-use graphical tools and reports to quickly gain insights into AI use within your organization. With personalized recommendations, and one-click policies help you protect your data and comply with regulatory requirements.

AI app-specific information:

- Recommendation **Get guided assistance to AI regulations**, which uses control-mapping regulatory templates from Compliance Manager.
- One-click policies available:
  - **DSPM for AI - Capture interactions for Copilot experiences** from the recommendation or remediation action **Secure interactions in Microsoft Copilot experiences**.
  - **DSPM for AI - Detect risky AI usage** from the recommendation or remediation action **Detect risky interactions in AI apps**.
  - **DSPM for AI - Unethical behavior in AI apps** from the recommendation or remediation action **Detect unethical behavior in AI apps**
  - **DSPM for AI - Detect sensitive info shared with AI via network** from the recommendation or remediation action **Extend insights into sensitive data in AI app interactions**.

Auditing and AI interactions

Microsoft Purview Audit solutions provide comprehensive tools for searching and managing audit records of activities performed across various Microsoft services by users and admins, and help organizations to effectively respond to security events, forensic investigations, internal investigations, and compliance obligations.

Like other activities, prompts and responses are captured in the unified audit log. Events include how and when users interact with the AI app, and can include in which Microsoft 365 service the activity took place, and references to the files stored in Microsoft 365 that were accessed during the interaction. If these files have a sensitivity label applied, that's also captured.

These events flow into activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM, where the data from prompts and responses can be displayed. You can also use the **Audit** solution from the Microsoft Purview portal to search and find these auditing events.

For more information, see Audit logs for Copilot and AI activities.

Data classification and AI interactions

Microsoft Purview data classification provides a comprehensive framework for identifying and tagging sensitive data across various Microsoft services, including Office 365, Dynamics 365, and Azure. Classifying data is often the first step to ensure compliance with data protection regulations and safeguard against unauthorized access, alteration, or destruction. You can use built-in system classifications or create your own.

Sensitive information types and trainable classifiers can be used to find sensitive data in user prompts and responses when they use AI apps. The resulting information then surfaces in Microsoft Purview Reports overview and activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM.

Insider Risk Management and AI interactions

Microsoft Purview Insider Risk Management helps you detect, investigate, and mitigate internal risks such as IP theft, data leakage, and security violations. It leverages machine learning models and various signals from Microsoft 365 and third-party indicators to identify potential malicious or inadvertent insider activities. The solution includes privacy controls like pseudonymization and role-based access, ensuring user-level privacy while enabling risk analysts to take appropriate actions.

Use the Risky AI usage policy template to detect risky usage that includes prompt injection attacks and accessing protected materials. Insights from these signals are integrated into Microsoft Defender XDR to provide a comprehensive view of AI-related risks.

AI app-specific information:

- For prompts and responses, requires a collection policy such as **DSPM for AI - Capture interactions for Copilot experiences** from the DSPM for AI recommendation **Secure interactions in Microsoft Copilot experiences**.

Communication compliance and AI interactions

Microsoft Purview Communication Compliance provides tools to help you detect and manage regulatory compliance and business conduct violations across various communication channels, which include user prompts and responses for AI apps. It's designed with privacy by default, pseudonymizing usernames and incorporating role-based access controls. The solution helps identify and remediate inappropriate communications, such as sharing sensitive information, harassment, threats, and adult content.

To learn more about using communication compliance policies for AI apps, see Configure a communication compliance policy to detect for generative AI interactions.

AI app-specific information:

- For prompts and responses, requires a collection policy such as **DSPM for AI - Capture interactions for Copilot experiences** from the DSPM for AI recommendation **Secure interactions in Microsoft Copilot experiences**.

eDiscovery and AI interactions

Microsoft Purview eDiscovery lets you identify and deliver electronic information that can be used as evidence in legal cases. The eDiscovery tools in Microsoft Purview support searching for content in Exchange Online, OneDrive for Business, SharePoint Online, Microsoft Teams, Microsoft 365 Groups, and Viva Engage teams. You can then prevent the information from deletion and export the information.

Because user prompts and responses for AI apps are stored in a user's mailbox, you can create a case and use search when a user's mailbox is selected as the source for a search query. For example, select and retrieve this data from the source mailbox by selecting from the query builder **Add condition** > **Type** > **Contains any of** > **Edit** > *Copilot activity*. This query condition includes all Copilot and other AI application activity.

After the search is refined, you can export the results or add to a review set. You can review and export information directly from the review set.

For more information about identifying and deleting user AI interaction data, see Search for and delete Copilot data in eDiscovery.

AI app-specific information:

- For prompts and responses, requires a collection policy such as **DSPM for AI - Capture interactions for Copilot experiences** from the DSPM for AI recommendation **Secure interactions in Microsoft Copilot experiences**.

Data Lifecycle Management and AI interactions

Microsoft Purview Data Lifecycle Management provides tools and capabilities to manage the lifecycle of organizational data by retaining necessary content and deleting unnecessary content. These tools ensure compliance with business, legal, and regulatory requirements.

Use retention policies to automatically retain or delete user prompts and responses for AI apps. For detailed information about this retention works, see Learn about retention for Copilot & AI apps.

As with all retention policies and holds, if more than one policy for the same location applies to a user, the principles of retention resolve any conflicts. For example, the data is retained for the longest duration of all the applied retention policies or eDiscovery holds.

AI app-specific information:

- For retention policies, select the option for **Microsoft Copilot Experiences**.
- For prompts and responses, requires a collection policy such as **DSPM for AI - Capture interactions for Copilot experiences** from the DSPM for AI recommendation **Secure interactions in Microsoft Copilot experiences**.

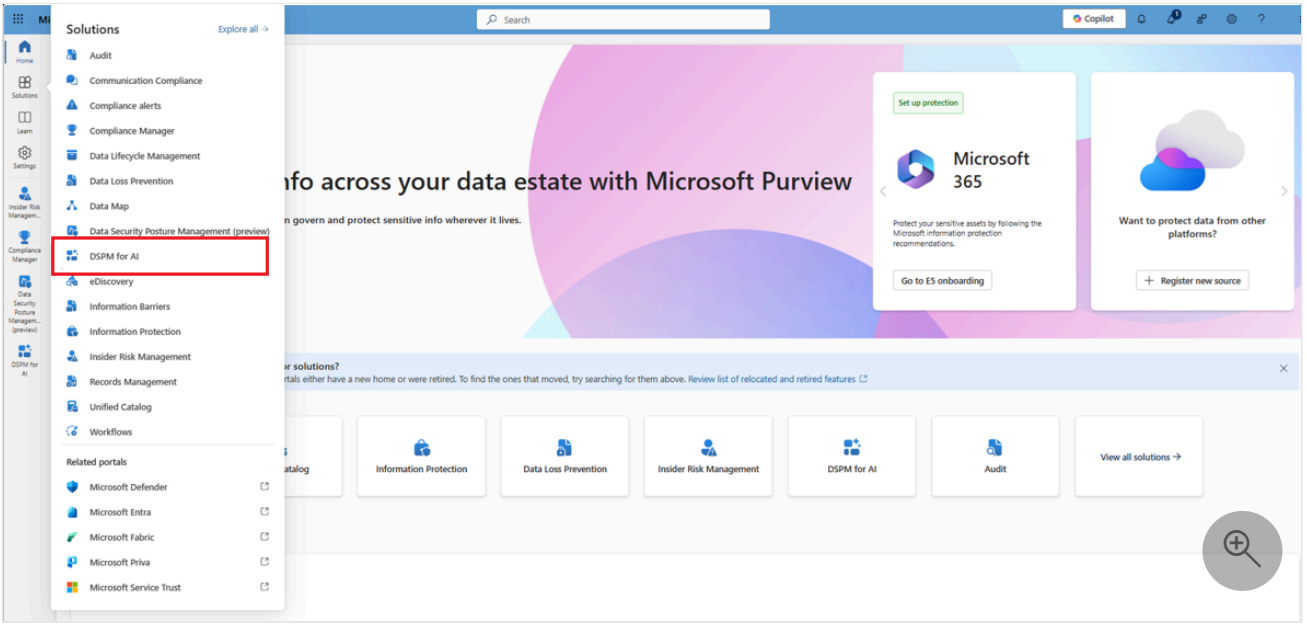
Compliance Manager and AI interactions

Microsoft Purview Compliance Manager is a solution that helps you automatically assess and manage compliance across your multicloud environment. Compliance Manager can help you throughout your compliance journey, from taking inventory of your data protection risks to managing the complexities of implementing controls, staying current with regulations and certifications, and reporting to auditors.

To help you keep compliant with AI regulations, Compliance Manager provides regulatory templates to help you assess, implement, and strengthen your compliance requirements for all

generative AI apps. For example, monitoring AI interactions and preventing data loss in AI applications. For more information, see Assessments for AI regulations.

Getting started recommended steps



Use the following steps to get started with managing data security & compliance for AI interactions from Microsoft Security Copilot.

> **Note**
>
> These steps focus on managing a specific AI app or agent. For broader coverage that uses security objectives with guided workflows, use the current version of Data Security Posture Management.

Managing data security & compliance for Copilot in Fabric requires the enterprise version of Microsoft Purview data governance, to support the required APIs.

Because Data Security Posture Management for AI is your front door for securing and managing AI interactions, most of the following instructions use that solution:

- Sign in to the Microsoft Purview portal > **Solutions** > **DSPM for AI (classic)** with an account that has appropriate permissions. For example, an account that's a member of the **Microsoft Entra Compliance Administrator** group role.

Discover potential security risks in Microsoft Security Copilot interactions

1. From **DSPM for AI (classic)** > **Overview**, in the **Get Started** section, look to see if auditing is on for your tenant. If not, select **Activate Microsoft Purview Audit**.

2. In the **Recommendations** section, select **View all recommendations** to take you to the **Recommendations** page. If they have a status of **Not Started**, take action on the following recommendations that create one-click policies:

   - **Secure interactions in Microsoft Copilot experiences**: This recommendation creates a policy to policy captures prompts and responses for data security posture and regulatory compliance from Copilot in Fabric, and Security Copilot.

   - **Detect risky interactions in AI apps**: This recommendation creates a policy to help calculate user risk by detecting risky prompts and responses in Microsoft 365 Copilot, agents, and other generative AI apps.

3. Wait at least a day for data, and then navigate to the **Reports** page to view the results of your policy. Select **Copilot experiences & agents** and view information such as:

   - Total interactions over time (Microsoft Copilot and agents)
   - Sensitive interactions per AI app
   - Top unethical AI interactions
   - Insider Risk severity
   - Insider risk severity per AI app
   - Potential risky AI usage

4. Select **View details** for each of the report graphs to view detailed activities in the activity explorer.

   From the filters, select the **AI app category** of **Copilot experiences & agents**, and then use the other filters if you need to further refine the displayed data. Then drill down to each activity to view details that include displaying the prompts and response when you're a member of the Microsoft Purview Content Explorer Content Viewer role group. For more information about this requirement, see Permissions for Data Security Posture Management for AI.

Apply compliance controls to Microsoft Security Copilot

1. From **DSPM for AI (classic)** > **Recommendations** page, under **Not Started**, locate, and select and take actions on the following recommendation:

- **Detect unethical behavior in AI**: This recommendation creates a policy to detect sensitive information in prompts and responses in Microsoft Security Copilot and agents, and other generative AI apps.

2. If you need to ensure that Microsoft Security Copilot interactions are retained for compliance reasons:

   In the Microsoft Purview portal, navigate to **Data Lifecycle Management** > **Policies** > **Retention Policies** and create a retention policy to retain Microsoft Security Copilot interactions by selecting the location **Microsoft Copilot Experiences** and specify the required retention period. For more information, see Create and configure retention policies.

3. If you need to preserve, collect, analyze, review, or export Microsoft Security Copilot interactions:

   In the Microsoft Purview portal, navigate to **eDiscovery** > **Cases** > **Create case**. In the case, create a search and use the *ItemClass* property and the `IPM.SkypeTeams.Message.Copilot.Security.SecurityCopilot` value to search for these interactions in your organization.

Routinely review the reports and data risk assessments in DSPM for AI to determine if you need to make changes, and use activity explorer and events for deeper analysis of how users are interacting with Microsoft Security Copilot.

Use Microsoft Purview to manage data security & compliance for Copilot in Fabric

> *Microsoft Purview service description*

Use the following sections to identify the Microsoft Purview capabilities that are supported for AI interactions with Copilot in Fabric, and some get started recommendations for you to manage these AI interactions for security and compliance.

The first Copilot in Fabric that's supported by Microsoft Purview is Copilot for Power BI. Current support extends to all prompts and all text-based responses.

> **Note**
>
> Microsoft Purview support for other Copilot experiences in Fabric and Fabric Data Agent is currently in preview.

As a prerequisite for Microsoft Purview to manage these AI interactions, the **Allow Microsoft Purview to secure AI interactions** option in the Microsoft Fabric admin portal must be **Enabled**, which is the default setting. For more information about this option, see Tenant settings index.

Managing these AI interactions with Microsoft Purview requires you to enable pay-as-you-go billing in your organization.

Capabilities supported

Use the following table to see at a glance the Microsoft Purview capabilities that are supported with Copilot in Fabric.

Expand table

  - **DSPM for AI - Unethical behavior in AI apps** from the recommendation or remediation action **Detect unethical behavior in AI apps**.
  - **DSPM for AI - Detect sensitive info shared with AI via network** from the recommendation or remediation action **Extend insights into sensitive data in AI app interactions**.

Auditing and AI interactions

Microsoft Purview Audit solutions provide comprehensive tools for searching and managing audit records of activities performed across various Microsoft services by users and admins, and help organizations to effectively respond to security events, forensic investigations, internal investigations, and compliance obligations.

Like other activities, prompts and responses are captured in the unified audit log. Events include how and when users interact with the AI app, and can include in which Microsoft 365 service the activity took place, and references to the files stored in Microsoft 365 that were accessed during the interaction. If these files have a sensitivity label applied, that's also captured.

These events flow into activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM, where the data from prompts and responses can be displayed. You can also use the **Audit** solution from the Microsoft Purview portal to search and find these auditing events.

For more information, see Audit logs for Copilot and AI activities.

Data classification and AI interactions

Microsoft Purview data classification provides a comprehensive framework for identifying and tagging sensitive data across various Microsoft services, including Office 365, Dynamics 365, and Azure. Classifying data is often the first step to ensure compliance with data protection regulations and safeguard against unauthorized access, alteration, or destruction. You can use built-in system classifications or create your own.

Sensitive information types and trainable classifiers can be used to find sensitive data in user prompts and responses when they use AI apps. The resulting information then surfaces in Microsoft Purview Reports overview and activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM.

Insider Risk Management and AI interactions

Microsoft Purview Insider Risk Management helps you detect, investigate, and mitigate internal risks such as IP theft, data leakage, and security violations. It leverages machine learning models and various signals from Microsoft 365 and third-party indicators to identify potential malicious or inadvertent insider activities. The solution includes privacy controls like pseudonymization and role-based access, ensuring user-level privacy while enabling risk analysts to take appropriate actions.

Use the Risky AI usage policy template to detect risky usage that includes prompt injection attacks and accessing protected materials. Insights from these signals are integrated into Microsoft Defender XDR to provide a comprehensive view of AI-related risks.

AI app-specific information:

- For prompts and responses, requires a collection policy such as **DSPM for AI - Capture interactions for Copilot experiences** from the DSPM for AI recommendation **Secure interactions in Microsoft Copilot experiences**.

Communication compliance and AI interactions

Microsoft Purview Communication Compliance provides tools to help you detect and manage regulatory compliance and business conduct violations across various communication channels, which include user prompts and responses for AI apps. It's designed with privacy by default, pseudonymizing usernames and incorporating role-based access controls. The solution helps identify and remediate inappropriate communications, such as sharing sensitive information, harassment, threats, and adult content.

To learn more about using communication compliance policies for AI apps, see Configure a communication compliance policy to detect for generative AI interactions.

AI app-specific information:

- For prompts and responses, requires a collection policy such as **DSPM for AI - Capture interactions for Copilot experiences** from the DSPM for AI recommendation **Secure interactions in Microsoft Copilot experiences**.

eDiscovery and AI interactions

Microsoft Purview eDiscovery lets you identify and deliver electronic information that can be used as evidence in legal cases. The eDiscovery tools in Microsoft Purview support searching for content in Exchange Online, OneDrive for Business, SharePoint Online, Microsoft Teams, Microsoft 365 Groups, and Viva Engage teams. You can then prevent the information from deletion and export the information.

Because user prompts and responses for AI apps are stored in a user's mailbox, you can create a case and use search when a user's mailbox is selected as the source for a search query. For example, select and retrieve this data from the source mailbox by selecting from the query

builder **Add condition** > **Type** > **Contains any of** > **Edit** > *Copilot activity*. This query condition includes all Copilot and other AI application activity.

After the search is refined, you can export the results or add to a review set. You can review and export information directly from the review set.

For more information about identifying and deleting user AI interaction data, see Search for and delete Copilot data in eDiscovery.

AI app-specific information:

- For prompts and responses, requires a collection policy such as **DSPM for AI - Capture interactions for Copilot experiences** from the DSPM for AI recommendation **Secure interactions in Microsoft Copilot experiences**.

Data Lifecycle Management and AI interactions

Microsoft Purview Data Lifecycle Management provides tools and capabilities to manage the lifecycle of organizational data by retaining necessary content and deleting unnecessary content. These tools ensure compliance with business, legal, and regulatory requirements.

Use retention policies to automatically retain or delete user prompts and responses for AI apps. For detailed information about this retention works, see Learn about retention for Copilot & AI apps.

As with all retention policies and holds, if more than one policy for the same location applies to a user, the principles of retention resolve any conflicts. For example, the data is retained for the longest duration of all the applied retention policies or eDiscovery holds.

AI app-specific information:

- For retention policies, select the option for **Microsoft Copilot Experiences**.
- For prompts and responses, requires a collection policy such as **DSPM for AI - Capture interactions for Copilot experiences** from the DSPM for AI recommendation **Secure interactions in Microsoft Copilot experiences**.

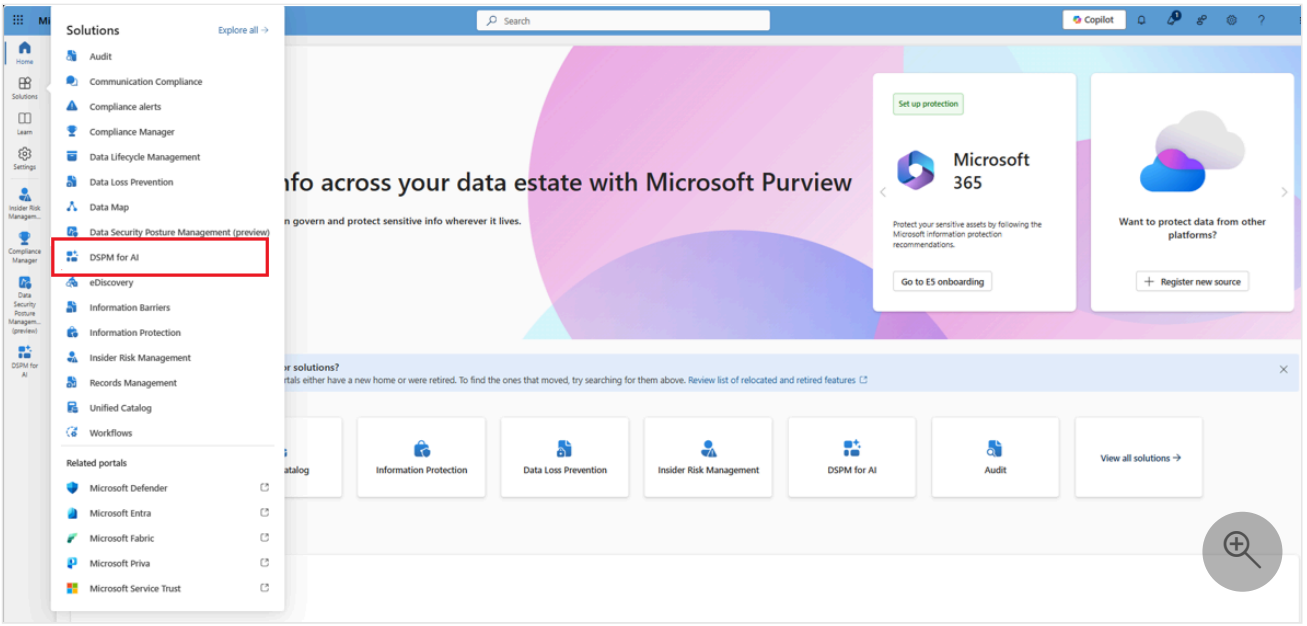
Compliance Manager and AI interactions

Microsoft Purview Compliance Manager is a solution that helps you automatically assess and manage compliance across your multicloud environment. Compliance Manager can help you throughout your compliance journey, from taking inventory of your data protection risks to

managing the complexities of implementing controls, staying current with regulations and certifications, and reporting to auditors.

To help you keep compliant with AI regulations, Compliance Manager provides regulatory templates to help you assess, implement, and strengthen your compliance requirements for all generative AI apps. For example, monitoring AI interactions and preventing data loss in AI applications. For more information, see Assessments for AI regulations.

Getting started recommended steps



Use the following steps to get started with managing data security & compliance for AI interactions from Copilot in Fabric.

> **Note**
>
> These steps focus on managing a specific AI app or agent. For broader coverage that uses security objectives with guided workflows, use the current version of Data Security Posture Management.

Managing data security & compliance for Copilot in Fabric requires the enterprise version of Microsoft Purview data governance, to support the required APIs.

Because Data Security Posture Management for AI is your front door for securing and managing AI interactions, most of the following instructions use that solution:

- Sign in to the Microsoft Purview portal > **Solutions** > **DSPM for AI (classic)** with an account that has appropriate permissions. For example, an account that's a member of the **Microsoft Entra Compliance Administrator** group role.

Discover potential security risks in Copilot in Fabric interactions

1. From **DSPM for AI (classic)** > **Overview**, in the **Get Started** section, look to see if auditing is on for your tenant. If not, select **Activate Microsoft Purview Audit**.

2. In the **Recommendations** section, select **View all recommendations** to take you to the **Recommendations** page. If they have a status of **Not Started**, take action on the following recommendations that create one-click policies:

    - **Secure interactions in Microsoft Copilot experiences**: This recommendation creates a policy to policy captures prompts and responses for data security posture and regulatory compliance from Copilot in Fabric, and Security Copilot.

    - **Detect risky interactions in AI apps**: This recommendation creates a policy to help calculate user risk by detecting risky prompts and responses in Microsoft 365 Copilot, agents, and other generative AI apps.

3. Wait at least a day for data, and then navigate to the **Reports** page to view the results of your policy. Select **Copilot experiences & agents** and view information such as:

    - Total interactions over time (Microsoft Copilot and agents)
    - Sensitive interactions per AI app
    - Top unethical AI interactions
    - Insider Risk severity
    - Insider risk severity per AI app
    - Potential risky AI usage

4. Select **View details** for each of the report graphs to view detailed activities in the activity explorer.

   From the filters, select the **AI app category** of **Copilot experiences & agents**, and then use the other filters if you need to further refine the displayed data. Then drill down to each activity to view details that include displaying the prompts and response when you're a member of the Microsoft Purview Content Explorer Content Viewer role group. For more information about this requirement, see Permissions for Data Security Posture Management for AI.

Apply compliance controls to Copilot in Fabric

1. From **DSPM for AI (classic)** > **Recommendations** page, under **Not Started**, locate, and select and take actions on the following recommendation:

   - **Detect unethical behavior in AI**: This recommendation creates a policy to detect sensitive information in prompts and responses in Copilot in Fabric and agents, and other generative AI apps.

2. If you need to ensure that Copilot in Fabric interactions are retained for compliance reasons:

   In the Microsoft Purview portal, navigate to **Data Lifecycle Management** > **Policies** > **Retention Policies** and create a retention policy to retain Microsoft Security Copilot interactions by selecting the location **Microsoft Copilot Experiences** and specify the required retention period. For more information, see Create and configure retention policies.

3. If you need to preserve, collect, analyze, review, or export Microsoft Fabric interactions:

   In the Microsoft Purview portal, navigate to **eDiscovery** > **Cases** > **Create case**. In the case, create a search and use the *ItemClass* property and the `IPM.SkypeTeams.Message.Copilot.Fabric.*` value to search for these interactions in your organization.

Routinely review the reports in DSPM for AI to determine if you need to make changes, and use activity explorer and events for deeper analysis of how users are interacting with Copilot in Fabric.

DSPM and DSPM for AI (classic)

Use Data Security Posture Management or Data Security Posture Management for AI (classic) as your front door to discover, secure, and apply compliance controls for AI usage across your enterprise. Both DSPM versions use existing controls from Microsoft Purview information protection and compliance management with easy-to-use graphical tools and reports to quickly gain insights into AI use within your organization. With personalized recommendations, and one-click policies help you protect your data and comply with regulatory requirements.

AI app-specific information:

- Recommendation **Get guided assistance to AI regulations**, which uses control-mapping regulatory templates from Compliance Manager.
- One-click policies available:
  - **DSPM for AI - Detect risky AI usage** from the recommendation or remediation action **Detect risky interactions in AI apps**.
  - **DSPM for AI - Unethical behavior in AI apps** from the recommendation or remediation action **Detect unethical behavior in AI apps**
  - **DSPM for AI - Detect sensitive info shared with AI via network** from the recommendation or remediation action **Extend insights into sensitive data in AI app interactions**.

Auditing and AI interactions

Microsoft Purview Audit solutions provide comprehensive tools for searching and managing audit records of activities performed across various Microsoft services by users and admins, and help organizations to effectively respond to security events, forensic investigations, internal investigations, and compliance obligations.

Like other activities, prompts and responses are captured in the unified audit log. Events include how and when users interact with the AI app, and can include in which Microsoft 365 service the activity took place, and references to the files stored in Microsoft 365 that were accessed during the interaction. If these files have a sensitivity label applied, that's also captured.

These events flow into activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM, where the data from prompts and responses can be displayed. You can also use the **Audit** solution from the Microsoft Purview portal to search and find these auditing events.

For more information, see Audit logs for Copilot and AI activities.

Data classification and AI interactions

Microsoft Purview data classification provides a comprehensive framework for identifying and tagging sensitive data across various Microsoft services, including Office 365, Dynamics 365, and Azure. Classifying data is often the first step to ensure compliance with data protection regulations and safeguard against unauthorized access, alteration, or destruction. You can use built-in system classifications or create your own.

Sensitive information types and trainable classifiers can be used to find sensitive data in user prompts and responses when they use AI apps. The resulting information then surfaces in Microsoft Purview Reports overview and activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM.

Sensitivity labels and AI interactions

AI apps that Microsoft Purview support use existing controls to ensure that data stored in your tenant is never returned to the user or used by a large language model (LLM) if the user doesn't have access to that data. When the data has sensitivity labels from your organization applied to the content, there's an extra layer of protection:

- When a file is open in Word, Excel, PowerPoint, or similarly an email or calendar event is open in Outlook, the sensitivity of the data is displayed to users in the app with the label name and content markings (such as header or footer text) that have been configured for the label. Loop components and pages also support the same sensitivity labels.
- When the sensitivity label applies encryption, users must have the EXTRACT usage right, as well as VIEW, for the AI apps to return the data.
- This protection extends to data stored outside your Microsoft 365 tenant when it's open in an Office app (data in use). For example, local storage, network shares, and cloud storage.

> **Tip**

If you haven't already, we recommend you enable sensitivity labels for SharePoint and OneDrive and also familiarize yourself with the file types and label configurations that these services can process. When sensitivity labels aren't enabled for these services, the encrypted files that Copilot and agents can access are limited to data in use from Office apps on Windows.

For instructions, see **Enable sensitivity labels for Office files in SharePoint and OneDrive**.

If you're not already using sensitivity labels, see Get started with sensitivity labels.

AI app-specific information:

- Supported when the knowledge source is SharePoint (includes OneDrive), and Dataverse with auto-labeling policies for the Data Map.
- Encryption is supported only with sensitivity labels, and only for the SharePoint knowledge source.
- Like sensitivity labels in Microsoft 365 Chat, agents built in Copilot Studio display the sensitivity label for items listed in the response and citations. Using the sensitivity labels' priority number that's defined in the Microsoft Purview portal, the latest response in Copilot displays the highest priority sensitivity label from the data used for that Copilot chat.
- Also like sensitivity label inheritance for Microsoft 365 Copilot, newly created content from Word and PowerPoint inherits the highest priority sensitivity label.

Data loss prevention and AI interactions

Microsoft Purview Data Loss Prevention (DLP) helps you identify sensitive items across Microsoft 365 services and endpoints, monitor them, and helps protect against leakage of those items. It uses deep content inspection and contextual analysis to identify sensitive items and it enforces policies to protect sensitive data such as financial records, health information, or intellectual property.

Windows computers that are onboarded to Microsoft Purview can be configured for Endpoint data loss prevention (DLP) policies that warn or block users from sharing sensitive information with third-party generative AI sites that are accessed via a browser. For example, a user is prevented from pasting credit card numbers into ChatGPT, or they see a warning that they can override. For more information about the supported DLP actions and which platforms support them, see the first two rows in the table from Endpoint activities you can monitor and take action on.

AI app-specific information:

- The following Endpoint DLP capability is supported only:
  - When the knowledge source is SharePoint, a DLP policy scoped to the Microsoft 365 Copilot location can restrict agents built in Copilot Studio for Microsoft Teams, SharePoint, and Microsoft 365 Copilot from processing sensitive content based on a specified sensitivity label.

Insider Risk Management and AI interactions

Microsoft Purview Insider Risk Management helps you detect, investigate, and mitigate internal risks such as IP theft, data leakage, and security violations. It leverages machine learning models and various signals from Microsoft 365 and third-party indicators to identify potential malicious or inadvertent insider activities. The solution includes privacy controls like pseudonymization and role-based access, ensuring user-level privacy while enabling risk analysts to take appropriate actions.

Use the Risky AI usage policy template to detect risky usage that includes prompt injection attacks and accessing protected materials. Insights from these signals are integrated into Microsoft Defender XDR to provide a comprehensive view of AI-related risks.

Communication compliance and AI interactions

Microsoft Purview Communication Compliance provides tools to help you detect and manage regulatory compliance and business conduct violations across various communication channels, which include user prompts and responses for AI apps. It's designed with privacy by default, pseudonymizing usernames and incorporating role-based access controls. The solution helps identify and remediate inappropriate communications, such as sharing sensitive information, harassment, threats, and adult content.

To learn more about using communication compliance policies for AI apps, see Configure a communication compliance policy to detect for generative AI interactions.

eDiscovery and AI interactions

Microsoft Purview eDiscovery lets you identify and deliver electronic information that can be used as evidence in legal cases. The eDiscovery tools in Microsoft Purview support searching for content in Exchange Online, OneDrive for Business, SharePoint Online, Microsoft Teams, Microsoft 365 Groups, and Viva Engage teams. You can then prevent the information from deletion and export the information.

Because user prompts and responses for AI apps are stored in a user's mailbox, you can create a case and use search when a user's mailbox is selected as the source for a search query. For example, select and retrieve this data from the source mailbox by selecting from the query builder **Add condition** > **Type** > **Contains any of** > **Edit** > *Copilot activity*. This query condition includes all Copilot and other AI application activity.

After the search is refined, you can export the results or add to a review set. You can review and export information directly from the review set.

For more information about identifying and deleting user AI interaction data, see Search for and delete Copilot data in eDiscovery.

Data Lifecycle Management and AI interactions

Microsoft Purview Data Lifecycle Management provides tools and capabilities to manage the lifecycle of organizational data by retaining necessary content and deleting unnecessary content. These tools ensure compliance with business, legal, and regulatory requirements.

Use retention policies to automatically retain or delete user prompts and responses for AI apps. For detailed information about this retention works, see Learn about retention for Copilot & AI apps.

As with all retention policies and holds, if more than one policy for the same location applies to a user, the principles of retention resolve any conflicts. For example, the data is retained for the longest duration of all the applied retention policies or eDiscovery holds.

AI app-specific information:

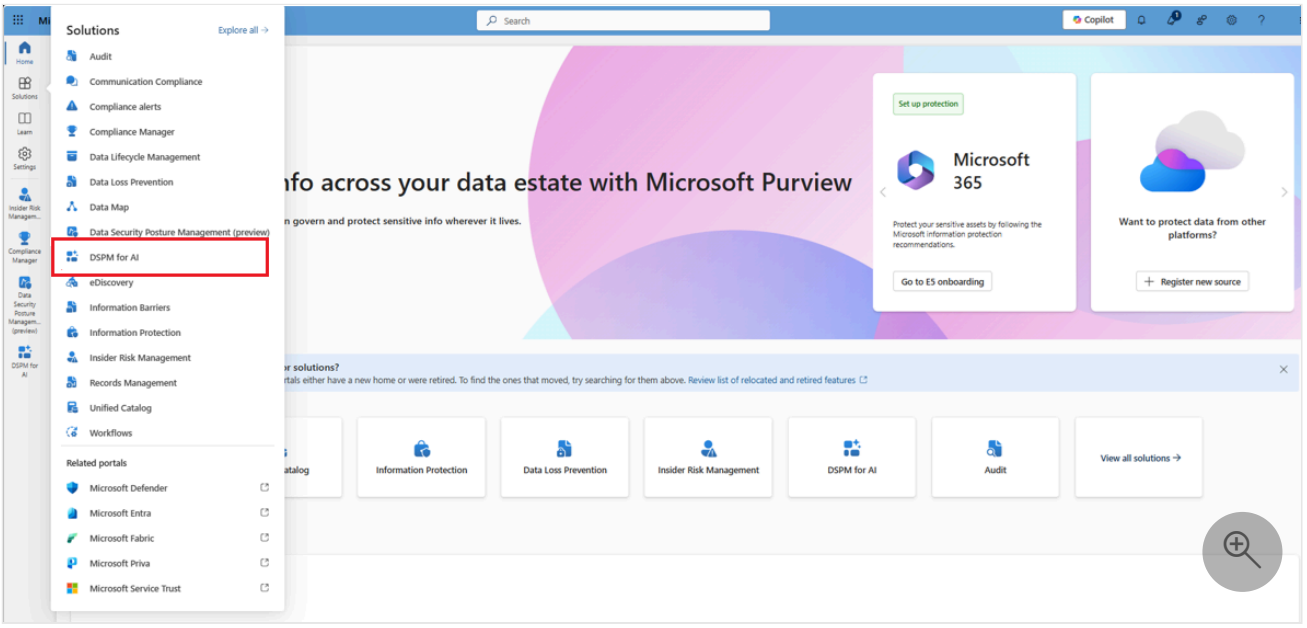
- For retention policies, select the option for **Microsoft Copilot Experiences**.

Compliance Manager and AI interactions

Microsoft Purview Compliance Manager is a solution that helps you automatically assess and manage compliance across your multicloud environment. Compliance Manager can help you throughout your compliance journey, from taking inventory of your data protection risks to managing the complexities of implementing controls, staying current with regulations and certifications, and reporting to auditors.

To help you keep compliant with AI regulations, Compliance Manager provides regulatory templates to help you assess, implement, and strengthen your compliance requirements for all

generative AI apps. For example, monitoring AI interactions and preventing data loss in AI applications. For more information, see Assessments for AI regulations.



Getting started recommended steps

Use the following steps to get started with managing data security & compliance for interactions from agents built in Microsoft Copilot Studio.

> **Note**
>
> These steps focus on managing a specific AI app or agent. For broader coverage that uses security objectives with guided workflows, use the current version of Data Security Posture Management.

Because Data Security Posture Management for AI is your front door for securing and managing AI interactions, most of the following instructions use that solution:

- Sign in to the Microsoft Purview portal > **Solutions** > **DSPM for AI (classic)** with an account that has appropriate permissions. For example, an account that's a member of the **Microsoft Entra Compliance Administrator** group role.

Discover potential security risks in Microsoft Copilot Studio interactions

1. From **DSPM for AI (classic)** > **Overview**, in the **Get Started** section, look to see if auditing is on for your tenant. If not, select **Activate Microsoft Purview Audit**.

2. In the **Recommendations** section, select **View all recommendations** to take you to the **Recommendations** page. If the following recommendation has a status of **Not Started**, take action on it to create a one-click policy:

    - **Detect risky interactions in AI apps**: This recommendation creates a policy to help calculate user risk by detecting risky prompts and responses in Microsoft 365 Copilot, agents, and other generative AI apps.

3. Wait at least a day for data, and then navigate to the **Reports** page to view the results of your policy. Select **Copilot experiences & agents** and view information such as:

    - Total interactions over time (Microsoft Copilot and agents)
    - Sensitive interactions per AI app
    - Top unethical AI interactions
    - Insider Risk severity
    - Insider risk severity per AI app
    - Potential risky AI usage

4. Select **View details** for each of the report graphs to view detailed activities in the activity explorer.

    From the filters, select the **AI app category** of **Copilot experiences & agents**, and then use the other filters if you need to further refine the displayed data. Then drill down to each activity to view details that include displaying the prompts and response when you're a member of the Microsoft Purview Content Explorer Content Viewer role group. For more information about this requirement, see Permissions for Data Security Posture Management for AI.

Apply compliance controls to Microsoft Copilot Studio

1. From **DSPM for AI (classic)** > **Recommendations** page, under **Not Started**, locate, and select and take actions on the following recommendation:

    - **Detect unethical behavior in AI**: This recommendation creates a policy to detect sensitive information in prompts and responses in agents built in Copilot Studio, and other generative AI apps.

2. If you need to ensure that interactions from agents built in Copilot Studio are retained for compliance reasons:

In the Microsoft Purview portal, navigate to **Data Lifecycle Management** > **Policies** > **Retention Policies** and create a retention policy to retain Microsoft Security Copilot interactions by selecting the location **Microsoft Copilot Experiences** and specify the required retention period. For more information, see Create and configure retention policies.

3. If you need to preserve, collect, analyze, review, or export Microsoft Copilot Studio interactions:

   In the Microsoft Purview portal, navigate to **eDiscovery** > **Cases** > **Create case**. In the case, create a search and use the *ItemClass* property and the `IPM.SkypeTeams.Message.Copilot.Studio.*` value to search for these interactions in your organization.

Routinely review the reports and data risk assessments in DSPM for AI to determine if you need to make changes, and use activity explorer and events for deeper analysis of how users are interacting with agents built in Copilot Studio.

Use Microsoft Purview to manage data security & compliance for Microsoft Facilitator

> *Microsoft Purview service description*

Use the following sections to identify the Microsoft Purview capabilities that are supported for AI interactions with Microsoft Facilitator, and some get started recommendations for you to manage these AI interactions for security and compliance.

For additional information, see Set up Facilitator in Microsoft Teams.

Capabilities supported

Use the following table to see at a glance the Microsoft Purview capabilities that are supported with Microsoft Facilitator.

Expand table

Capability or solution in Microsoft Purview	Supported for AI interactions
DSPM and DSPM for AI (classic)	✓
Auditing	✓
Data classification	✓
Sensitivity labels	✗
Encryption without sensitivity labels	✗
Data loss prevention	✗
Insider Risk Management	✗
Communication compliance	✓
eDiscovery	✓
Data Lifecycle Management	✓
Compliance Manager	✓

DSPM and DSPM for AI (classic)

Use Data Security Posture Management or Data Security Posture Management for AI (classic) as your front door to discover, secure, and apply compliance controls for AI usage across your enterprise. Both DSPM versions use existing controls from Microsoft Purview information protection and compliance management with easy-to-use graphical tools and reports to quickly gain insights into AI use within your organization. With personalized recommendations, and one-click policies help you protect your data and comply with regulatory requirements.

AI app-specific information:

- One-click policies available:
  - **DSPM for AI - Detect risky AI usage** from the recommendation or remediation action **Detect risky interactions in AI apps**.
  - **DSPM for AI - Unethical behavior in AI apps** from the recommendation or remediation action **Detect unethical behavior in AI**.
  - **DSPM for AI - Detect sensitive info shared with AI via network** from the recommendation or remediation action **Extend insights into sensitive data in AI app interactions**.

Auditing and AI interactions

Microsoft Purview Audit solutions provide comprehensive tools for searching and managing audit records of activities performed across various Microsoft services by users and admins, and help organizations to effectively respond to security events, forensic investigations, internal investigations, and compliance obligations.

Like other activities, prompts and responses are captured in the unified audit log. Events include how and when users interact with the AI app, and can include in which Microsoft 365 service the activity took place, and references to the files stored in Microsoft 365 that were accessed during the interaction. If these files have a sensitivity label applied, that's also captured.

These events flow into activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM, where the data from prompts and responses can be displayed. You can also use the **Audit** solution from the Microsoft Purview portal to search and find these auditing events.

For more information, see Audit logs for Copilot and AI activities.

AI app-specific information:

- Facilitator AI-generated notes, moderation, and questions and answers for meetings are supported.

Data classification and AI interactions

Microsoft Purview data classification provides a comprehensive framework for identifying and tagging sensitive data across various Microsoft services, including Office 365, Dynamics 365, and Azure. Classifying data is often the first step to ensure compliance with data protection regulations and safeguard against unauthorized access, alteration, or destruction. You can use built-in system classifications or create your own.

Sensitive information types and trainable classifiers can be used to find sensitive data in user prompts and responses when they use AI apps. The resulting information then surfaces in Microsoft Purview Reports overview and activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM.

Insider Risk Management and AI interactions

Microsoft Purview Insider Risk Management helps you detect, investigate, and mitigate internal risks such as IP theft, data leakage, and security violations. It leverages machine learning models and various signals from Microsoft 365 and third-party indicators to identify potential malicious or inadvertent insider activities. The solution includes privacy controls like pseudonymization and role-based access, ensuring user-level privacy while enabling risk analysts to take appropriate actions.

Use the Risky AI usage policy template to detect risky usage that includes prompt injection attacks and accessing protected materials. Insights from these signals are integrated into Microsoft Defender XDR to provide a comprehensive view of AI-related risks.

Communication compliance and AI interactions

Microsoft Purview Communication Compliance provides tools to help you detect and manage regulatory compliance and business conduct violations across various communication channels, which include user prompts and responses for AI apps. It's designed with privacy by default, pseudonymizing usernames and incorporating role-based access controls. The solution helps identify and remediate inappropriate communications, such as sharing sensitive information, harassment, threats, and adult content.

To learn more about using communication compliance policies for AI apps, see Configure a communication compliance policy to detect for generative AI interactions.

eDiscovery and AI interactions

Microsoft Purview eDiscovery lets you identify and deliver electronic information that can be used as evidence in legal cases. The eDiscovery tools in Microsoft Purview support searching for content in Exchange Online, OneDrive for Business, SharePoint Online, Microsoft Teams, Microsoft 365 Groups, and Viva Engage teams. You can then prevent the information from deletion and export the information.

Because user prompts and responses for AI apps are stored in a user's mailbox, you can create a case and use search when a user's mailbox is selected as the source for a search query. For example, select and retrieve this data from the source mailbox by selecting from the query builder **Add condition** > **Type** > **Contains any of** > **Edit** > *Copilot activity*. This query condition includes all Copilot and other AI application activity.

After the search is refined, you can export the results or add to a review set. You can review and export information directly from the review set.

For more information about identifying and deleting user AI interaction data, see Search for and delete Copilot data in eDiscovery.

AI app-specific information:

- Facilitator AI-generated notes, moderation, and questions and answers for meetings are supported with a KeyQL query.

Data Lifecycle Management and AI interactions

Microsoft Purview Data Lifecycle Management provides tools and capabilities to manage the lifecycle of organizational data by retaining necessary content and deleting unnecessary content. These tools ensure compliance with business, legal, and regulatory requirements.

Use retention policies to automatically retain or delete user prompts and responses for AI apps. For detailed information about this retention works, see Learn about retention for Copilot & AI apps.

As with all retention policies and holds, if more than one policy for the same location applies to a user, the principles of retention resolve any conflicts. For example, the data is retained for the longest duration of all the applied retention policies or eDiscovery holds.

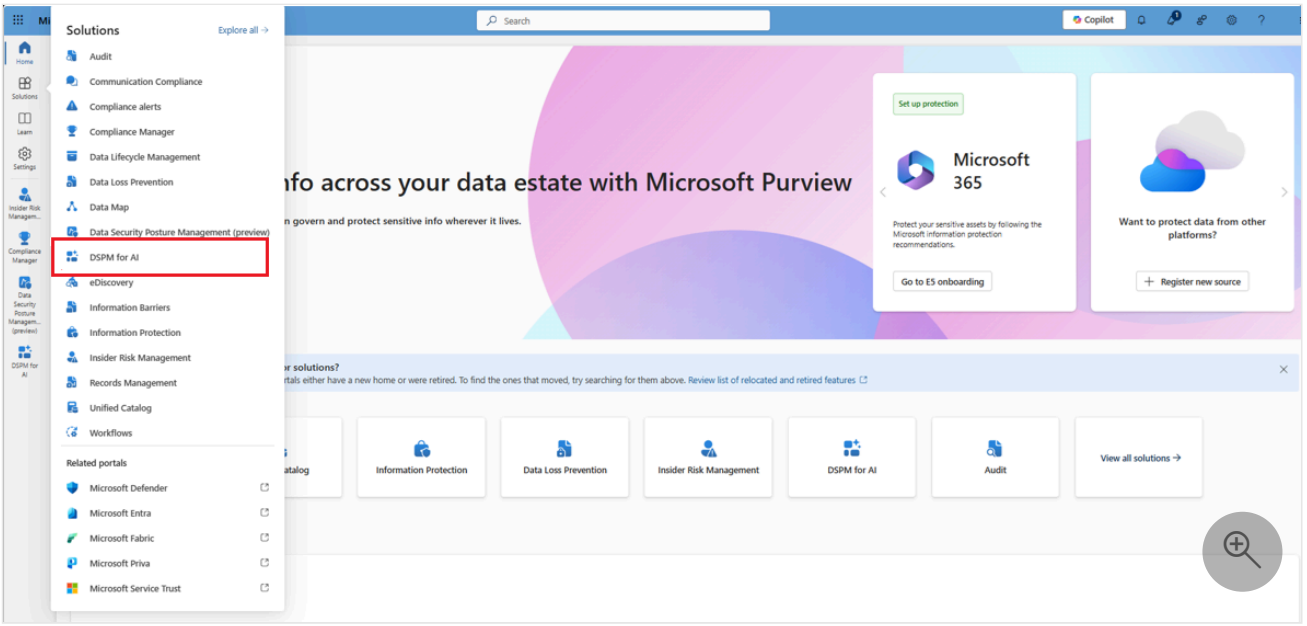
AI app-specific information:

- Configuration for retention and deletion:
  - For Facilitator AI interactions in meetings, use a retention policy with the **Teams chats** option.
  - For Facilitator AI-generated notes in meetings, use a retention policy or retention labels with the **OneDrive accounts** option.

Compliance Manager and AI interactions

Microsoft Purview Compliance Manager is a solution that helps you automatically assess and manage compliance across your multicloud environment. Compliance Manager can help you throughout your compliance journey, from taking inventory of your data protection risks to managing the complexities of implementing controls, staying current with regulations and certifications, and reporting to auditors.

To help you keep compliant with AI regulations, Compliance Manager provides regulatory templates to help you assess, implement, and strengthen your compliance requirements for all generative AI apps. For example, monitoring AI interactions and preventing data loss in AI applications. For more information, see Assessments for AI regulations.



Getting started recommended steps

Use the following steps to get started with managing data security & compliance for Microsoft Facilitator AI interactions.

> **Note**
>
> These steps focus on managing a specific AI app or agent. For broader coverage that uses security objectives with guided workflows, use the current version of Data Security Posture Management.

Because Data Security Posture Management for AI is your front door for securing and managing AI interactions, the following instructions use that solution:

- Sign in to the Microsoft Purview portal > **Solutions** > **DSPM for AI (classic)** with an account that has appropriate permissions. For example, an account that's a member of the **Microsoft Entra Compliance Administrator** group role.

Discover interactions from Microsoft Facilitator

1. From **DSPM for AI (classic)** > **Overview**, in the **Get Started** section, look to see if auditing is on for your tenant. If not, select **Activate Microsoft Purview Audit**.

2. In the **Recommendations** section, select **View all recommendations** to take you to the **Recommendations** page. If the following recommendation has a status of **Not Started**, select it to create a one-click policy:

   - **Detect risky interactions in AI apps**: This recommendation creates a policy to help calculate user risk by detecting risky prompts and responses in Microsoft 365 Copilot, agents, and other generative AI apps.

3. Wait at least a day for data, and then navigate to the **Reports** page. Select the AI app category of **Copilot experiences & agents** and view information such as:

   - Total interactions over time (Microsoft Copilot and agents)
   - Sensitive interactions per AI app
   - Insider Risk severity
   - Insider risk severity per AI app

4. Select **View details** for each of the report graphs to view detailed activities in the activity explorer.

   Select the available filters to see the results from **Copilot experiences & agents** based on the different **Activity type**, **AI app category**, **App**, and **Scope** for administrative units, and more. Then drill down to each activity to view details that include displaying the prompts and response when you're a member of the Microsoft Purview Content Explorer Content

Viewer role group. For more information about this requirement, see Permissions for Data Security Posture Management for AI.

Apply compliance controls to interactions with Microsoft Facilitator

1. If you need to ensure that interactions with Microsoft Facilitator are retained for compliance reasons:

   In the Microsoft Purview portal, navigate to **Data Lifecycle Management** > **Policies** > **Retention Policies** and create a retention policy with the following policy locations: - **Teams chats** for Facilitator interactions in meetings - **OneDrive accounts** for Facilitator AI-generated notes in meetings

2. If you need to preserve, collect, analyze, review, or export Microsoft Facilitator interactions:

   In the Microsoft Purview portal, navigate to **eDiscovery** > **Cases** > **Create case**. In the case, create a search and use the *ItemClass* property and the `IPM.SkypeTeams.Message` value to search for these interactions in your organization.

Use Microsoft Purview to manage data security & compliance for Channel Agent in Teams

> *Microsoft Purview service description*

Use the following sections to identify the Microsoft Purview capabilities that are supported for AI interactions with agents in Teams channels, and some get started recommendations for you to manage these AI interactions for security and compliance.

For additional information, see Get started with Channel Agent in Microsoft Teams.

Capabilities supported

Use the following table to see at a glance the Microsoft Purview capabilities that are supported with Channel Agent in Teams.

Expand table

Capability or solution in Microsoft Purview	Supported for AI interactions
DSPM and DSPM for AI (classic)	✓
Auditing	✓
Data classification	✓
Sensitivity labels	✓
Encryption without sensitivity labels	✗
Data loss prevention	✓
Insider Risk Management	✗
Communication compliance	✓
eDiscovery	✓
Data Lifecycle Management	✓

DSPM and DSPM for AI (classic)

Use Data Security Posture Management or Data Security Posture Management for AI (classic) as your front door to discover, secure, and apply compliance controls for AI usage across your enterprise. Both DSPM versions use existing controls from Microsoft Purview information protection and compliance management with easy-to-use graphical tools and reports to quickly gain insights into AI use within your organization. With personalized recommendations, and one-click policies help you protect your data and comply with regulatory requirements.

AI app-specific information:

- One-click policies available:
  - **DSPM for AI - Detect risky AI usage** from the recommendation or remediation action **Detect risky interactions in AI apps**.
  - **DSPM for AI - Unethical behavior in AI apps** from the recommendation or remediation action **Detect unethical behavior in AI**.
  - **DSPM for AI - Detect sensitive info shared with AI via network** from the recommendation or remediation action **Extend insights into sensitive data in AI app interactions**.

Auditing and AI interactions

Microsoft Purview Audit solutions provide comprehensive tools for searching and managing audit records of activities performed across various Microsoft services by users and admins, and help organizations to effectively respond to security events, forensic investigations, internal investigations, and compliance obligations.

Like other activities, prompts and responses are captured in the unified audit log. Events include how and when users interact with the AI app, and can include in which Microsoft 365 service the activity took place, and references to the files stored in Microsoft 365 that were accessed during the interaction. If these files have a sensitivity label applied, that's also captured.

These events flow into activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM, where the data from prompts and responses can be displayed. You can also use the **Audit** solution from the Microsoft Purview portal to search and find these auditing events.

For more information, see Audit logs for Copilot and AI activities.

Data classification and AI interactions

Microsoft Purview data classification provides a comprehensive framework for identifying and tagging sensitive data across various Microsoft services, including Office 365, Dynamics 365, and Azure. Classifying data is often the first step to ensure compliance with data protection regulations and safeguard against unauthorized access, alteration, or destruction. You can use built-in system classifications or create your own.

Sensitive information types and trainable classifiers can be used to find sensitive data in user prompts and responses when they use AI apps. The resulting information then surfaces in Microsoft Purview Reports overview and activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM.

Sensitivity labels and AI interactions

AI apps that Microsoft Purview support use existing controls to ensure that data stored in your tenant is never returned to the user or used by a large language model (LLM) if the user doesn't have access to that data. When the data has sensitivity labels from your organization applied to the content, there's an extra layer of protection:

- When a file is open in Word, Excel, PowerPoint, or similarly an email or calendar event is open in Outlook, the sensitivity of the data is displayed to users in the app with the label name and content markings (such as header or footer text) that have been configured for the label. Loop components and pages also support the same sensitivity labels.
- When the sensitivity label applies encryption, users must have the EXTRACT usage right, as well as VIEW, for the AI apps to return the data.
- This protection extends to data stored outside your Microsoft 365 tenant when it's open in an Office app (data in use). For example, local storage, network shares, and cloud storage.

> **Tip**
>
> If you haven't already, we recommend you enable sensitivity labels for SharePoint and OneDrive and also familiarize yourself with the file types and label configurations that these services can process. When sensitivity labels aren't enabled for these services, the encrypted files that Copilot and agents can access are limited to data in use from Office apps on Windows.
>
> For instructions, see **Enable sensitivity labels for Office files in SharePoint and OneDrive**.

If you're not already using sensitivity labels, see Get started with sensitivity labels.

AI app-specific information:

- Channel Agent in Teams responses display the sensitivity label for items listed in the response and citations. Using the sensitivity labels' priority number that's defined in the Microsoft Purview portal, the latest response from Channel Agent displays the highest priority sensitivity label from the data used for that channel chat.

  Although compliance admins define a sensitivity label's priority, a higher priority number usually denotes higher sensitivity of the content, with more restrictive permissions. As a result, the Channel Agent responses display the most restrictive sensitivity label to educate the user about the sensitivity of the data.

- When Channel Agent creates newly created content that supports sensitivity labels, that action supports sensitivity label inheritance. See the following section for more information.

- Currently, Channel Agent could summarize for an authorized user the content of encrypted items that one or more users in the channel don't have permissions to open. The requesting user is warned of this risk and administrators always have the ability to turn off Channel Agent in Teams. For additional information about this and other deployment considerations, see Information protection considerations for Channel Agent in Teams.

Sensitivity label inheritance

If you use Channel Agent in Teams to create new content based on an item that has a sensitivity label applied, the sensitivity label from the source item is automatically inherited, with the label's protection settings.

For example, you ask an agent to create a Loop component based on a file that's uploaded to the channel. The file has the sensitivity label **Confidential\Project Bluebird** applied and that label is configured to apply encryption that restricts access to people involved with the project. The new Loop component is automatically labeled **Confidential\Project Bluebird** and can't be opened by people who aren't involved with the project.

AI-generated items that currently support sensitivity label inheritance for Channel Agent in Teams: Loop components and pages, and files in OneDrive and SharePoint.

If multiple labeled sources are used to create new content, the sensitivity label with the highest priority is used for label inheritance.

As with all automatic labeling scenarios, a user can always override and replace an inherited label (or remove, if you're not using mandatory labeling).

Data loss prevention and AI interactions

Microsoft Purview Data Loss Prevention (DLP) helps you identify sensitive items across Microsoft 365 services and endpoints, monitor them, and helps protect against leakage of those items. It uses deep content inspection and contextual analysis to identify sensitive items and it enforces policies to protect sensitive data such as financial records, health information, or intellectual property.

Windows computers that are onboarded to Microsoft Purview can be configured for Endpoint data loss prevention (DLP) policies that warn or block users from sharing sensitive information with third-party generative AI sites that are accessed via a browser. For example, a user is prevented from pasting credit card numbers into ChatGPT, or they see a warning that they can override. For more information about the supported DLP actions and which platforms support them, see the first two rows in the table from Endpoint activities you can monitor and take action on.

AI app-specific information:

- The following DLP capability only is supported for Channel Agent in Teams:
  - When an agent interacts with a user in a Teams conversation, a DLP policy can scan the messages for sensitive data.

Insider Risk Management and AI interactions

Microsoft Purview Insider Risk Management helps you detect, investigate, and mitigate internal risks such as IP theft, data leakage, and security violations. It leverages machine learning models and various signals from Microsoft 365 and third-party indicators to identify potential malicious or inadvertent insider activities. The solution includes privacy controls like pseudonymization and role-based access, ensuring user-level privacy while enabling risk analysts to take appropriate actions.

Use the Risky AI usage policy template to detect risky usage that includes prompt injection attacks and accessing protected materials. Insights from these signals are integrated into Microsoft Defender XDR to provide a comprehensive view of AI-related risks.

Communication compliance and AI interactions

Microsoft Purview Communication Compliance provides tools to help you detect and manage regulatory compliance and business conduct violations across various communication channels, which include user prompts and responses for AI apps. It's designed with privacy by default,

pseudonymizing usernames and incorporating role-based access controls. The solution helps identify and remediate inappropriate communications, such as sharing sensitive information, harassment, threats, and adult content.

To learn more about using communication compliance policies for AI apps, see Configure a communication compliance policy to detect for generative AI interactions.

eDiscovery and AI interactions

Microsoft Purview eDiscovery lets you identify and deliver electronic information that can be used as evidence in legal cases. The eDiscovery tools in Microsoft Purview support searching for content in Exchange Online, OneDrive for Business, SharePoint Online, Microsoft Teams, Microsoft 365 Groups, and Viva Engage teams. You can then prevent the information from deletion and export the information.

Because user prompts and responses for AI apps are stored in a user's mailbox, you can create a case and use search when a user's mailbox is selected as the source for a search query. For example, select and retrieve this data from the source mailbox by selecting from the query builder **Add condition** > **Type** > **Contains any of** > **Edit** > *Copilot activity*. This query condition includes all Copilot and other AI application activity.

After the search is refined, you can export the results or add to a review set. You can review and export information directly from the review set.

For more information about identifying and deleting user AI interaction data, see Search for and delete Copilot data in eDiscovery.

Data Lifecycle Management and AI interactions

Microsoft Purview Data Lifecycle Management provides tools and capabilities to manage the lifecycle of organizational data by retaining necessary content and deleting unnecessary content. These tools ensure compliance with business, legal, and regulatory requirements.

Use retention policies to automatically retain or delete user prompts and responses for AI apps. For detailed information about this retention works, see Learn about retention for Copilot & AI apps.

As with all retention policies and holds, if more than one policy for the same location applies to a user, the principles of retention resolve any conflicts. For example, the data is retained for the longest duration of all the applied retention policies or eDiscovery holds.

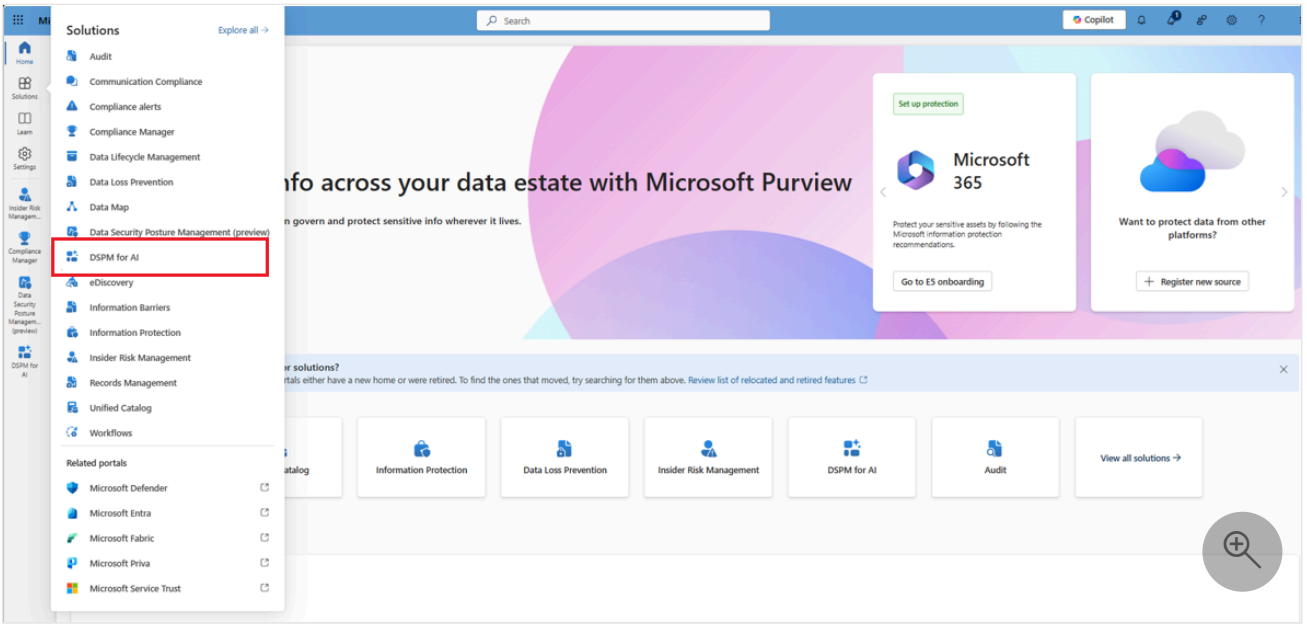
AI app-specific information:

- Configuration for retention and deletion:
  - For Channel Agent in Teams interactions, use a retention policy with the **Teams chats** option.

Compliance Manager and AI interactions

Microsoft Purview Compliance Manager is a solution that helps you automatically assess and manage compliance across your multicloud environment. Compliance Manager can help you throughout your compliance journey, from taking inventory of your data protection risks to managing the complexities of implementing controls, staying current with regulations and certifications, and reporting to auditors.

To help you keep compliant with AI regulations, Compliance Manager provides regulatory templates to help you assess, implement, and strengthen your compliance requirements for all generative AI apps. For example, monitoring AI interactions and preventing data loss in AI applications. For more information, see Assessments for AI regulations.



Getting started recommended steps

Use the following steps to get started with managing data security & compliance for AI interactions with Channel Agent in Teams.

> **Note**
>
> These steps focus on managing a specific AI app or agent. For broader coverage that uses security objectives with guided workflows, use the current version of Data Security Posture Management.

Because Data Security Posture Management for AI is your front door for securing and managing AI interactions, the following instructions use that solution:

- Sign in to the Microsoft Purview portal > **Solutions** > **DSPM for AI (classic)** with an account that has appropriate permissions. For example, an account that's a member of the **Microsoft Entra Compliance Administrator** group role.

Discover interactions from Channel Agent in Teams

1. From **DSPM for AI (classic)** > **Overview**, in the **Get Started** section, look to see if auditing is on for your tenant. If not, select **Activate Microsoft Purview Audit**.

2. In the **Recommendations** section, select **View all recommendations** to take you to the **Recommendations** page. If the following recommendation has a status of **Not Started**, select it to create a one-click policy:

   - **Detect risky interactions in AI apps**: This recommendation creates a policy to help calculate user risk by detecting risky prompts and responses in Microsoft 365 Copilot, agents, and other generative AI apps.

3. Wait at least a day for data, and then navigate to the **Reports** page. Select the AI app category of **Copilot experiences & agents** and view information such as:

   - Total interactions over time (Microsoft Copilot and agents)
   - Sensitive interactions per AI app
   - Insider Risk severity
   - Insider risk severity per AI app

4. Select **View details** for each of the report graphs to view detailed activities in the activity explorer.

   Select the available filters to see the results from **Copilot experiences & agents** based on the different **Activity type**, **AI app category**, **App**, and **Scope** for administrative units, and more. Then drill down to each activity to view details that include displaying the prompts and response when you're a member of the Microsoft Purview Content Explorer Content

Viewer role group. For more information about this requirement, see Permissions for Data Security Posture Management for AI.

Apply compliance controls to interactions with Channel Agent in Teams

1. If you need to ensure that interactions with Channel Agent in Teams are retained for compliance reasons:

   In the Microsoft Purview portal, navigate to **Data Lifecycle Management** > **Policies** > **Retention Policies** and create a retention policy with the following policy location: - **Teams chats** for interactions with a channel agent

2. If you need to preserve, collect, analyze, review, or export interactions for Channel Agent in Teams:

   In the Microsoft Purview portal, navigate to **eDiscovery** > **Cases** > **Create case**. In the case, create a search and use the *ItemClass* property and the `IPM.SkypeTeams.Message` value to search for these interactions in your organization.

Other documentation to help you secure and manage generative AI apps

Securing and managing AI interactions with Channel Agent in Teams has much in common with securing and managing AI interactions with Microsoft 365 Copilot. For more detailed information, see Considerations for Microsoft Purview to manage Microsoft 365 Copilot and Channel Agent in Teams for security and compliance.

Last updated on 05/01/2026

Use Microsoft Purview to manage data security & compliance for Microsoft Agent 365

> *Microsoft Purview service description*

Data lifecycle management	✓
Compliance manager	✓

When you create an agent instance for Agent 365, it's automatically enabled for audit, detection of sensitive data with data classification, and included with the Assessments for AI regulations from Compliance Manager. For other capabilities, include the agent instance in policies as you would a user.

DSPM and DSPM for AI (classic)

Use Data Security Posture Management or Data Security Posture Management for AI (classic) as your front door to discover, secure, and apply compliance controls for AI usage across your enterprise. Both DSPM versions use existing controls from Microsoft Purview information protection and compliance management with easy-to-use graphical tools and reports to quickly gain insights into AI use within your organization. With personalized recommendations, and one-click policies help you protect your data and comply with regulatory requirements.

AI app-specific information:

- Supported for Data Security Posture Management only, use the **AI observability** page to gain visibility into active agent instances to better understand potential risks and how to remediate them. For more information, see the Getting started recommended steps.

Auditing and AI interactions

Microsoft Purview Audit solutions provide comprehensive tools for searching and managing audit records of activities performed across various Microsoft services by users and admins, and help organizations to effectively respond to security events, forensic investigations, internal investigations, and compliance obligations.

Like other activities, prompts and responses are captured in the unified audit log. Events include how and when users interact with the AI app, and can include in which Microsoft 365 service the activity took place, and references to the files stored in Microsoft 365 that were accessed during the interaction. If these files have a sensitivity label applied, that's also captured.

These events flow into activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM, where the data from prompts and responses can be displayed. You can also use the **Audit** solution from the Microsoft Purview portal to search and find these auditing events.

For more information, see Audit logs for Copilot and AI activities.

AI app-specific information:

- Audit an agent instance as you would a user.
- Supported interactions: All agent-to-human, human-to-agent, agent-to-tools, and agent-to-agent interactions.
- In addition to displaying in activity explorer in DSPM, search the audit log for Agent 365 activities.

Data classification and AI interactions

Microsoft Purview data classification provides a comprehensive framework for identifying and tagging sensitive data across various Microsoft services, including Office 365, Dynamics 365, and Azure. Classifying data is often the first step to ensure compliance with data protection regulations and safeguard against unauthorized access, alteration, or destruction. You can use built-in system classifications or create your own.

Sensitive information types and trainable classifiers can be used to find sensitive data in user prompts and responses when they use AI apps. The resulting information then surfaces in Microsoft Purview Reports overview and activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM.

Sensitivity labels and AI interactions

AI apps that Microsoft Purview support use existing controls to ensure that data stored in your tenant is never returned to the user or used by a large language model (LLM) if the user doesn't have access to that data. When the data has sensitivity labels from your organization applied to the content, there's an extra layer of protection:

- When a file is open in Word, Excel, PowerPoint, or similarly an email or calendar event is open in Outlook, the sensitivity of the data is displayed to users in the app with the label name and content markings (such as header or footer text) that have been configured for the label. Loop components and pages also support the same sensitivity labels.
- When the sensitivity label applies encryption, users must have the EXTRACT usage right, as well as VIEW, for the AI apps to return the data.
- This protection extends to data stored outside your Microsoft 365 tenant when it's open in an Office app (data in use). For example, local storage, network shares, and cloud storage.

> **Tip**
>
> If you haven't already, we recommend you enable sensitivity labels for SharePoint and OneDrive and also familiarize yourself with the file types and label configurations that these services can process. When sensitivity labels aren't enabled for these services, the encrypted files that Copilot and agents can access are limited to data in use from Office apps on Windows.

For instructions, see **Enable sensitivity labels for Office files in SharePoint and OneDrive**.

If you're not already using sensitivity labels, see Get started with sensitivity labels.

AI app-specific information:

- For agent instances to access files, the files must be explicitly shared with them.
- If an applied sensitivity label is configured for encryption, that encryption must explicitly grant the agent instance VIEW and EXTRACT usage rights. For example, a sensitivity label that's configured for **Add all users and groups in your organization** or **Add any authenticated users** wouldn't be sufficient.
- Newly created content from Agent 365 doesn't inherit sensitivity labels from the source items. As a result, that content isn't automatically labeled or encrypted.

Data loss prevention and AI interactions

Microsoft Purview Data Loss Prevention (DLP) helps you identify sensitive items across Microsoft 365 services and endpoints, monitor them, and helps protect against leakage of those items. It uses deep content inspection and contextual analysis to identify sensitive items and it enforces policies to protect sensitive data such as financial records, health information, or intellectual property.

Windows computers that are onboarded to Microsoft Purview can be configured for Endpoint data loss prevention (DLP) policies that warn or block users from sharing sensitive information with third-party generative AI sites that are accessed via a browser. For example, a user is prevented from pasting credit card numbers into ChatGPT, or they see a warning that they can override. For more information about the supported DLP actions and which platforms support them, see the first two rows in the table from Endpoint activities you can monitor and take action on.

AI app-specific information:

- Supported by explicitly specifying agent instances in the DLP policy as you would a user, or by specifying a security group that includes agent instances.
- Supported interactions: Block or audit agent-to-human and human-to-agent for Microsoft Teams, OneDrive or SharePoint, and emails.
- Because an agent instance is unaware of the block action, the agent owner must actively monitor a DLP policy that uses this configuration and understand the impact to subsequent workflows.

Insider Risk Management and AI interactions

Microsoft Purview Insider Risk Management helps you detect, investigate, and mitigate internal risks such as IP theft, data leakage, and security violations. It leverages machine learning models and various signals from Microsoft 365 and third-party indicators to identify potential malicious or inadvertent insider activities. The solution includes privacy controls like pseudonymization and role-based access, ensuring user-level privacy while enabling risk analysts to take appropriate actions.

Use the Risky AI usage policy template to detect risky usage that includes prompt injection attacks and accessing protected materials. Insights from these signals are integrated into Microsoft Defender XDR to provide a comprehensive view of AI-related risks.

AI app-specific information:

- Supported by explicitly specifying agent instances in the Insider Risk Management policy as you would a user.
- Supports built-in trigger events, such as data exfiltration.

Communication compliance and AI interactions

Microsoft Purview Communication Compliance provides tools to help you detect and manage regulatory compliance and business conduct violations across various communication channels, which include user prompts and responses for AI apps. It's designed with privacy by default, pseudonymizing usernames and incorporating role-based access controls. The solution helps identify and remediate inappropriate communications, such as sharing sensitive information, harassment, threats, and adult content.

To learn more about using communication compliance policies for AI apps, see Configure a communication compliance policy to detect for generative AI interactions.

AI app-specific information:

- Supports detection of unethical communication for Microsoft Teams and emails, for agent-to-human and human-to-agent interactions.

eDiscovery and AI interactions

Microsoft Purview eDiscovery lets you identify and deliver electronic information that can be used as evidence in legal cases. The eDiscovery tools in Microsoft Purview support searching for content in Exchange Online, OneDrive for Business, SharePoint Online, Microsoft Teams,

Microsoft 365 Groups, and Viva Engage teams. You can then prevent the information from deletion and export the information.

Because user prompts and responses for AI apps are stored in a user's mailbox, you can create a case and use search when a user's mailbox is selected as the source for a search query. For example, select and retrieve this data from the source mailbox by selecting from the query builder **Add condition** > **Type** > **Contains any of** > **Edit** > *Copilot activity*. This query condition includes all Copilot and other AI application activity.

After the search is refined, you can export the results or add to a review set. You can review and export information directly from the review set.

For more information about identifying and deleting user AI interaction data, see Search for and delete Copilot data in eDiscovery.

AI app-specific information:

- Identify an agent instance as you would a user.
- Supports agent-to-human and human-to-agent interactions.

Data Lifecycle Management and AI interactions

Microsoft Purview Data Lifecycle Management provides tools and capabilities to manage the lifecycle of organizational data by retaining necessary content and deleting unnecessary content. These tools ensure compliance with business, legal, and regulatory requirements.

Use retention policies to automatically retain or delete user prompts and responses for AI apps. For detailed information about this retention works, see Learn about retention for Copilot & AI apps.

As with all retention policies and holds, if more than one policy for the same location applies to a user, the principles of retention resolve any conflicts. For example, the data is retained for the longest duration of all the applied retention policies or eDiscovery holds.

AI app-specific information:

- Supports locations that include Microsoft Teams, OneDrive and SharePoint, and emails.
- Supports agent-to-human and human-to-agent interactions.

Compliance Manager and AI interactions

Microsoft Purview Compliance Manager is a solution that helps you automatically assess and manage compliance across your multicloud environment. Compliance Manager can help you throughout your compliance journey, from taking inventory of your data protection risks to managing the complexities of implementing controls, staying current with regulations and certifications, and reporting to auditors.

To help you keep compliant with AI regulations, Compliance Manager provides regulatory templates to help you assess, implement, and strengthen your compliance requirements for all generative AI apps. For example, monitoring AI interactions and preventing data loss in AI applications. For more information, see Assessments for AI regulations.

Getting started recommended steps

To get started with managing data security & compliance for Agent 365. use the Microsoft Purview portal. You need an account that has appropriate permissions for security and compliance management, such as an account that's a member of the Entra **Compliance Administrator** role, or the **Microsoft Purview Compliance Administrator** role group.

Then navigate to Data Security Posture Management: **DSPM** > **AI observability**.

> ⓘ **Note**
>
> Don't confuse this current version with the older version, that's named **Data Security Posture Management (classic)**. The classic version doesn't support Agent 365.

From the **AI observability** page:

- Review the overview of all agents in your organization with activities in the last 30 days, prioritized with the highest risk level determined by Insider Risk Management.
- Analyze top risky activities: oversharing, exfiltration, and unethical behavior.
- Select a specific agent to see details:
  - Agent details that include Entra-enabled status, created date, owner, agent user ID, and which agent it's an instance of.
  - Agent activities that include the risk level determined by Insider Risk Management and any risky activities from agent interactions.
  - Recommendations for remediation that use Microsoft Purview solutions, based on the identified risks.

Last updated on 05/01/2026

Use Microsoft Purview to manage data security & compliance for Entra-registered AI apps

> *Microsoft Purview service description*

Use the following sections to identify the Microsoft Purview capabilities that are supported for AI interactions for custom AI apps that are registered with Entra for user authentication, and integrated with the Microsoft Purview SDK. Then refer to the get started recommendations for you to manage these AI interactions for security and compliance.

Managing these AI interactions with Microsoft Purview requires you to enable pay-as-you-go billing in your organization.

Capabilities supported

Use the following table to see at a glance the Microsoft Purview capabilities that are supported for Entra-registered AI apps.

Expand table

Capability or solution in Microsoft Purview	Supported for AI interactions
DSPM and DSPM for AI (classic)	✓
Auditing	✓
Data classification	✓

Communication compliance	✓
eDiscovery	✓
Data Lifecycle Management	✓

Capability or solution in Microsoft Purview	Supported for AI interactions
Compliance Manager	✓

DSPM and DSPM for AI (classic)

Use Data Security Posture Management or Data Security Posture Management for AI (classic) as your front door to discover, secure, and apply compliance controls for AI usage across your enterprise. Both DSPM versions use existing controls from Microsoft Purview information protection and compliance management with easy-to-use graphical tools and reports to quickly gain insights into AI use within your organization. With personalized recommendations, and one-click policies help you protect your data and comply with regulatory requirements.

AI app-specific information:

- Recommendation **Get guided assistance to AI regulations**, which uses control-mapping regulatory templates from Compliance Manager.
- One-click policies available:
  - **DSPM for AI - Capture interactions for enterprise AI apps** from the recommendation or remediation action **Secure interactions from enterprise apps**.
  - **DSPM for AI - Detect sensitive info shared with AI via network** from the recommendation or remediation action **Extend insights into sensitive data in AI app interactions**.

Auditing and AI interactions

Microsoft Purview Audit solutions provide comprehensive tools for searching and managing audit records of activities performed across various Microsoft services by users and admins, and help organizations to effectively respond to security events, forensic investigations, internal investigations, and compliance obligations.

Like other activities, prompts and responses are captured in the unified audit log. Events include how and when users interact with the AI app, and can include in which Microsoft 365 service the activity took place, and references to the files stored in Microsoft 365 that were accessed during the interaction. If these files have a sensitivity label applied, that's also captured.

These events flow into activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM, where the data from prompts and responses can be

displayed. You can also use the **Audit** solution from the Microsoft Purview portal to search and find these auditing events.

For more information, see Audit logs for Copilot and AI activities.

Data classification and AI interactions

Microsoft Purview data classification provides a comprehensive framework for identifying and tagging sensitive data across various Microsoft services, including Office 365, Dynamics 365, and Azure. Classifying data is often the first step to ensure compliance with data protection regulations and safeguard against unauthorized access, alteration, or destruction. You can use built-in system classifications or create your own.

Sensitive information types and trainable classifiers can be used to find sensitive data in user prompts and responses when they use AI apps. The resulting information then surfaces in Microsoft Purview Reports overview and activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM.

Sensitivity labels and AI interactions

AI apps that Microsoft Purview support use existing controls to ensure that data stored in your tenant is never returned to the user or used by a large language model (LLM) if the user doesn't have access to that data. When the data has sensitivity labels from your organization applied to the content, there's an extra layer of protection:

- When a file is open in Word, Excel, PowerPoint, or similarly an email or calendar event is open in Outlook, the sensitivity of the data is displayed to users in the app with the label name and content markings (such as header or footer text) that have been configured for the label. Loop components and pages also support the same sensitivity labels.
- When the sensitivity label applies encryption, users must have the EXTRACT usage right, as well as VIEW, for the AI apps to return the data.
- This protection extends to data stored outside your Microsoft 365 tenant when it's open in an Office app (data in use). For example, local storage, network shares, and cloud storage.

> **Tip**
>
> If you haven't already, we recommend you enable sensitivity labels for SharePoint and OneDrive and also familiarize yourself with the file types and label configurations that these

services can process. When sensitivity labels aren't enabled for these services, the encrypted files that Copilot and agents can access are limited to data in use from Office apps on Windows.

For instructions, see **Enable sensitivity labels for Office files in SharePoint and OneDrive**.

If you're not already using sensitivity labels, see Get started with sensitivity labels.

Encryption without sensitivity labels and AI interactions

Even if a sensitivity label isn't applied to content, services and products might use the encryption capabilities from the Azure Rights Management service. As a result, AI apps can still check for the VIEW and EXTRACT usage rights before returning data and links to a user, but there's no automatic inheritance of protection for new items.

> **Tip**
>
> You'll get the best user experience when you always use sensitivity labels to protect your data, and encryption is applied by a label.

Examples of products and services that can use the encryption capabilities from the Azure Rights Management service without sensitivity labels:

- Microsoft Purview Message Encryption
- Microsoft Information Rights Management (IRM)
- Microsoft Rights Management connector
- Microsoft Rights Management SDK

For other encryption methods that don't use the Azure Rights Management service:

- S/MIME protected emails won't be returned by Copilot, and Copilot isn't available in Outlook when an S/MIME protected email is open.
- Password-protected documents can't be accessed by AI apps unless they're already opened by the user in the same app (data in use). Passwords aren't inherited by a destination item.

As with other Microsoft 365 services, such as eDiscovery and search, items encrypted with Microsoft Purview Customer Key or your own root key (BYOK) are supported and eligible to be returned by Copilot.

Data loss prevention and AI interactions

Microsoft Purview Data Loss Prevention (DLP) helps you identify sensitive items across Microsoft 365 services and endpoints, monitor them, and helps protect against leakage of those items. It uses deep content inspection and contextual analysis to identify sensitive items and it enforces policies to protect sensitive data such as financial records, health information, or intellectual property.

Windows computers that are onboarded to Microsoft Purview can be configured for Endpoint data loss prevention (DLP) policies that warn or block users from sharing sensitive information with third-party generative AI sites that are accessed via a browser. For example, a user is prevented from pasting credit card numbers into ChatGPT, or they see a warning that they can override. For more information about the supported DLP actions and which platforms support them, see the first two rows in the table from Endpoint activities you can monitor and take action on.

AI app-specific information:

- Support today is only available for a DLP policy that blocks prompts based on sensitive information types. This requires the configuration of a PowerShell cmdlet that's scoped to a specific Entra-registered AI app. The AI app can honor this configuration by integration with the Microsoft Purview APIs. The AI app developer can use this GitHub sample to help achieve this integration.

Insider Risk Management and AI interactions

Microsoft Purview Insider Risk Management helps you detect, investigate, and mitigate internal risks such as IP theft, data leakage, and security violations. It leverages machine learning models and various signals from Microsoft 365 and third-party indicators to identify potential malicious or inadvertent insider activities. The solution includes privacy controls like pseudonymization and role-based access, ensuring user-level privacy while enabling risk analysts to take appropriate actions.

Use the Risky AI usage policy template to detect risky usage that includes prompt injection attacks and accessing protected materials. Insights from these signals are integrated into Microsoft Defender XDR to provide a comprehensive view of AI-related risks.

AI app-specific information:

- For prompts and responses, requires a collection policy such as **DSPM for AI - Capture interactions for enterprise AI apps** from the DSPM for AI recommendation **Secure interactions from enterprise apps**.

Communication compliance and AI interactions

Microsoft Purview Communication Compliance provides tools to help you detect and manage regulatory compliance and business conduct violations across various communication channels, which include user prompts and responses for AI apps. It's designed with privacy by default, pseudonymizing usernames and incorporating role-based access controls. The solution helps identify and remediate inappropriate communications, such as sharing sensitive information, harassment, threats, and adult content.

To learn more about using communication compliance policies for AI apps, see Configure a communication compliance policy to detect for generative AI interactions.

AI app-specific information:

- For prompts and responses, requires a collection policy such as **DSPM for AI - Capture interactions for enterprise AI apps** from the DSPM for AI recommendation **Secure interactions from enterprise apps**.

eDiscovery and AI interactions

Microsoft Purview eDiscovery lets you identify and deliver electronic information that can be used as evidence in legal cases. The eDiscovery tools in Microsoft Purview support searching for content in Exchange Online, OneDrive for Business, SharePoint Online, Microsoft Teams, Microsoft 365 Groups, and Viva Engage teams. You can then prevent the information from deletion and export the information.

Because user prompts and responses for AI apps are stored in a user's mailbox, you can create a case and use search when a user's mailbox is selected as the source for a search query. For example, select and retrieve this data from the source mailbox by selecting from the query builder **Add condition** > **Type** > **Contains any of** > **Edit** > *Copilot activity*. This query condition includes all Copilot and other AI application activity.

After the search is refined, you can export the results or add to a review set. You can review and export information directly from the review set.

For more information about identifying and deleting user AI interaction data, see Search for and delete Copilot data in eDiscovery.

AI app-specific information:

- For prompts and responses, requires a collection policy such as **DSPM for AI - Capture interactions for enterprise AI apps** from the DSPM for AI recommendation **Secure interactions from enterprise apps**.

Data Lifecycle Management and AI interactions

Microsoft Purview Data Lifecycle Management provides tools and capabilities to manage the lifecycle of organizational data by retaining necessary content and deleting unnecessary content. These tools ensure compliance with business, legal, and regulatory requirements.

Use retention policies to automatically retain or delete user prompts and responses for AI apps. For detailed information about this retention works, see Learn about retention for Copilot & AI apps.

As with all retention policies and holds, if more than one policy for the same location applies to a user, the principles of retention resolve any conflicts. For example, the data is retained for the longest duration of all the applied retention policies or eDiscovery holds.

AI app-specific information:

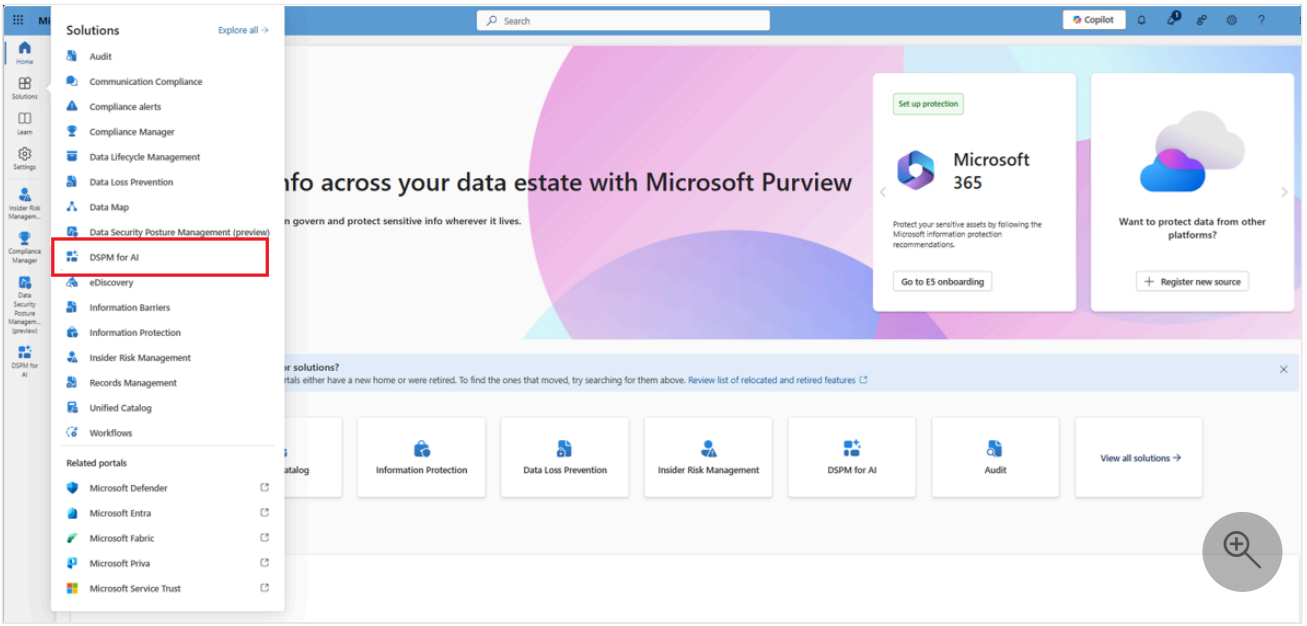
- For retention policies, select the option for **Enterprise AI apps**.
- For prompts and responses, requires a collection policy such as **DSPM for AI - Capture interactions for enterprise AI apps** from the DSPM for AI recommendation **Secure interactions from enterprise apps**.

Compliance Manager and AI interactions

Microsoft Purview Compliance Manager is a solution that helps you automatically assess and manage compliance across your multicloud environment. Compliance Manager can help you throughout your compliance journey, from taking inventory of your data protection risks to managing the complexities of implementing controls, staying current with regulations and certifications, and reporting to auditors.

To help you keep compliant with AI regulations, Compliance Manager provides regulatory templates to help you assess, implement, and strengthen your compliance requirements for all

generative AI apps. For example, monitoring AI interactions and preventing data loss in AI applications. For more information, see Assessments for AI regulations.



Getting started recommended steps

Use the following steps to get started with managing data security & compliance for AI interactions that use Entra-registered AI apps.

> **Note**
>
> These steps focus on managing a specific AI app or agent. For broader coverage that uses security objectives with guided workflows, use the current version of Data Security Posture Management.

Because Data Security Posture Management for AI is your front door for securing and managing AI interactions, most of the following instructions use that solution:

- Sign in to the Microsoft Purview portal > **Solutions** > **DSPM for AI (classic)** with an account that has appropriate permissions. For example, an account that's a member of the **Microsoft Entra Compliance Administrator** group role.

1. From **DSPM for AI (classic)** > **Recommendations** page, locate and select **Secure interactions from enterprise apps**, which creates a one-click policy to capture prompts and responses from enterprise AI apps.

2. Wait at least a day for data, and then navigate to the **Reports** page to view the results of your policy. Select the AI app category of **Enterprise AI apps** and view information such as:

- Total interactions over time (enterprise AI apps)
- Sensitive interactions per AI app
- Insider Risk severity
- Insider risk severity per AI app

3. Select **View details** for each of the report graphs to view detailed activities in the activity explorer.

   From the filters, select the **AI app category** of **Enterprise AI apps** with the **App** filter of **??**, and then use the other filters if you need to further refine the displayed data. Drill down to each activity to view details that include displaying the prompts and response when you're a member of the Microsoft Purview Content Explorer Content Viewer role group. For more information about this requirement, see Permissions for Data Security Posture Management for AI.

4. If you need to ensure that interactions from Entra-registered AI apps are retained for compliance reasons:

   In the Microsoft Purview portal, navigate to **Data Lifecycle Management** > **Policies** > **Retention Policies** and create a retention policy to retain interactions with Entra-registered AI apps by selecting the location **Enterprise AI apps** and specify the required retention period. For more information, see Create and configure retention policies.

5. If you need to preserve, collect, analyze, review, or export Entra-registered AI app interactions:

   In the Microsoft Purview portal, navigate to **eDiscovery** > **Cases** > **Create case**. In the case, create a search and use the *ItemClass* property and the `IPM.SkypeTeams.Message.ConnectedAIApp.Entra.<AppID>` value to search for these interactions in your organization.

Routinely review the reports in DSPM for AI to determine if you need to make changes, and use activity explorer and events for deeper analysis of how users are interacting with Entra-registered AI apps.

Last updated on 05/01/2026

Use Microsoft Purview to manage data security & compliance for Microsoft Foundry

> *Microsoft Purview service description*

Use the following sections to identify the Microsoft Purview capabilities that are supported for AI interactions that use Microsoft Foundry, and some get started recommendations for you to manage these AI interactions for security and compliance.

Before Microsoft Purview can manage these AI interactions, ensure you perform either of the following configuration steps:

1. Enable Microsoft Purview Data Security in the Microsoft Foundry Control Plane using the Microsoft Foundry portal. For more information, see Manage compliance and security in Microsoft Foundry.
2. Enable Microsoft Purview Data Security for Microsoft Foundry in Microsoft Defender for Cloud in your Microsoft Azure portal. For more information, see Enable Data Security for Azure AI with Microsoft Purview.

Managing policies for Microsoft Foundry AI interactions with Microsoft Purview requires you to enable pay-as-you-go billing in your organization. Note that Microsoft Purview Audit includes Microsoft Foundry data as part of the Microsoft Purview license.

Capabilities supported

Use the following table to see at a glance the Microsoft Purview capabilities that are supported for Microsoft Foundry.

Expand table

Capability or solution in Microsoft Purview	Supported for AI interactions
DSPM and DSPM for AI (classic)	✓
Auditing	✓
Data classification	✓
Sensitivity labels	✓

Capability or solution in Microsoft Purview	Supported for AI interactions
Encryption without sensitivity labels	✗
Data loss prevention	✓
Insider Risk Management	✓
Communication compliance	✓
eDiscovery	✓
Data Lifecycle Management	✓
Compliance Manager	✓

DSPM and DSPM for AI (classic)

Use Data Security Posture Management or Data Security Posture Management for AI (classic) as your front door to discover, secure, and apply compliance controls for AI usage across your enterprise. Both DSPM versions use existing controls from Microsoft Purview information protection and compliance management with easy-to-use graphical tools and reports to quickly gain insights into AI use within your organization. With personalized recommendations, and one-click policies help you protect your data and comply with regulatory requirements.

AI app-specific information:

- Recommendation **Secure data in Azure AI apps and agents**, which has set up instructions to capture prompts and responses for AI apps that use one or more Azure AI subscriptions.
- Recommendation **Get guided assistance to AI regulations**, which uses control-mapping regulatory templates from Compliance Manager.
- One-click policies available:
  - **DSPM for AI - Capture interactions for enterprise AI apps** from the recommendation or remediation action **Secure interactions from enterprise apps**
  - **DSPM for AI - Detect sensitive info shared with AI via network** from the recommendation or remediation action **Extend insights into sensitive data in AI app interactions**.

Auditing and AI interactions

Microsoft Purview Audit solutions provide comprehensive tools for searching and managing audit records of activities performed across various Microsoft services by users and admins, and

help organizations to effectively respond to security events, forensic investigations, internal investigations, and compliance obligations.

Like other activities, prompts and responses are captured in the unified audit log. Events include how and when users interact with the AI app, and can include in which Microsoft 365 service the activity took place, and references to the files stored in Microsoft 365 that were accessed during the interaction. If these files have a sensitivity label applied, that's also captured.

These events flow into activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM, where the data from prompts and responses can be displayed. You can also use the **Audit** solution from the Microsoft Purview portal to search and find these auditing events.

For more information, see Audit logs for Copilot and AI activities.

Data classification and AI interactions

Microsoft Purview data classification provides a comprehensive framework for identifying and tagging sensitive data across various Microsoft services, including Office 365, Dynamics 365, and Azure. Classifying data is often the first step to ensure compliance with data protection regulations and safeguard against unauthorized access, alteration, or destruction. You can use built-in system classifications or create your own.

Sensitive information types and trainable classifiers can be used to find sensitive data in user prompts and responses when they use AI apps. The resulting information then surfaces in Microsoft Purview Reports overview and activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM.

> **Note**
>
> Microsoft Purview Data Security Policies for Foundry Services interactions apply to API calls that use Microsoft Entra ID authentication with a user-context token, or for API calls that explicitly include user context. To learn more, see Gain end-user context for Azure AI API calls.
>
> For all other authentication scenarios, user interactions are displayed in Microsoft Purview Audit and AI Interactions with classifications in DSPM for AI Activity Explorer only.
>
> Ensure your AI application developers are aware of the above requirements.

Sensitivity labels and AI interactions

AI apps that Microsoft Purview support use existing controls to ensure that data stored in your tenant is never returned to the user or used by a large language model (LLM) if the user doesn't have access to that data. When the data has sensitivity labels from your organization applied to the content, there's an extra layer of protection:

- When a file is open in Word, Excel, PowerPoint, or similarly an email or calendar event is open in Outlook, the sensitivity of the data is displayed to users in the app with the label name and content markings (such as header or footer text) that have been configured for the label. Loop components and pages also support the same sensitivity labels.
- When the sensitivity label applies encryption, users must have the EXTRACT usage right, as well as VIEW, for the AI apps to return the data.
- This protection extends to data stored outside your Microsoft 365 tenant when it's open in an Office app (data in use). For example, local storage, network shares, and cloud storage.

> **Tip**
>
> If you haven't already, we recommend you enable sensitivity labels for SharePoint and OneDrive and also familiarize yourself with the file types and label configurations that these services can process. When sensitivity labels aren't enabled for these services, the encrypted files that Copilot and agents can access are limited to data in use from Office apps on Windows.
>
> For instructions, see **Enable sensitivity labels for Office files in SharePoint and OneDrive**.

If you're not already using sensitivity labels, see Get started with sensitivity labels.

AI app-specific information:

- RAG-based Foundry apps and agents built with AI search as the knowledge retrieval service can honor sensitivity labels the same way as Microsoft 365 Copilot does. For encrypted items, a user must have the EXTRACT usage right, as well as VIEW, for these items to be returned in search results. For more information, see Query-Time Microsoft Purview Sensitivity Label Enforcement in Azure AI Search.

Data loss prevention and AI interactions

Microsoft Purview Data Loss Prevention (DLP) helps you identify sensitive items across Microsoft 365 services and endpoints, monitor them, and helps protect against leakage of those items. It uses deep content inspection and contextual analysis to identify sensitive items and it enforces policies to protect sensitive data such as financial records, health information, or intellectual property.

Windows computers that are onboarded to Microsoft Purview can be configured for Endpoint data loss prevention (DLP) policies that warn or block users from sharing sensitive information with third-party generative AI sites that are accessed via a browser. For example, a user is prevented from pasting credit card numbers into ChatGPT, or they see a warning that they can override. For more information about the supported DLP actions and which platforms support them, see the first two rows in the table from Endpoint activities you can monitor and take action on.

AI app-specific information:

- Support today is only available for a DLP policy that blocks prompts based on sensitive information types. This requires the configuration of a PowerShell cmdlet that's scoped to a specific Entra-registered AI app. The AI app can honor this configuration by integration with the Microsoft Purview APIs. The AI app developer can use this GitHub sample to help achieve this integration.

Insider Risk Management and AI interactions

Microsoft Purview Insider Risk Management helps you detect, investigate, and mitigate internal risks such as IP theft, data leakage, and security violations. It leverages machine learning models and various signals from Microsoft 365 and third-party indicators to identify potential malicious or inadvertent insider activities. The solution includes privacy controls like pseudonymization and role-based access, ensuring user-level privacy while enabling risk analysts to take appropriate actions.

Use the Risky AI usage policy template to detect risky usage that includes prompt injection attacks and accessing protected materials. Insights from these signals are integrated into Microsoft Defender XDR to provide a comprehensive view of AI-related risks.

AI app-specific information:

- For prompts and responses, requires a collection policy such as **DSPM for AI - Detect sensitive info shared with AI via network** from the DSPM for AI recommendation **Extend insights into sensitive data in AI app interactions**.

Communication compliance and AI interactions

Microsoft Purview Communication Compliance provides tools to help you detect and manage regulatory compliance and business conduct violations across various communication channels, which include user prompts and responses for AI apps. It's designed with privacy by default, pseudonymizing usernames and incorporating role-based access controls. The solution helps identify and remediate inappropriate communications, such as sharing sensitive information, harassment, threats, and adult content.

To learn more about using communication compliance policies for AI apps, see Configure a communication compliance policy to detect for generative AI interactions.

AI app-specific information:

- For prompts and responses, requires a collection policy such as **DSPM for AI - Detect sensitive info shared with AI via network** from the DSPM for AI recommendation **Extend insights into sensitive data in AI app interactions**.

eDiscovery and AI interactions

Microsoft Purview eDiscovery lets you identify and deliver electronic information that can be used as evidence in legal cases. The eDiscovery tools in Microsoft Purview support searching for content in Exchange Online, OneDrive for Business, SharePoint Online, Microsoft Teams, Microsoft 365 Groups, and Viva Engage teams. You can then prevent the information from deletion and export the information.

Because user prompts and responses for AI apps are stored in a user's mailbox, you can create a case and use search when a user's mailbox is selected as the source for a search query. For example, select and retrieve this data from the source mailbox by selecting from the query builder **Add condition** > **Type** > **Contains any of** > **Edit** > *Copilot activity*. This query condition includes all Copilot and other AI application activity.

After the search is refined, you can export the results or add to a review set. You can review and export information directly from the review set.

For more information about identifying and deleting user AI interaction data, see Search for and delete Copilot data in eDiscovery.

AI app-specific information:

- For prompts and responses, requires a collection policy such as **DSPM for AI - Detect sensitive info shared with AI via network** from the DSPM for AI recommendation **Extend insights into sensitive data in AI app interactions**.

Data Lifecycle Management and AI interactions

Microsoft Purview Data Lifecycle Management provides tools and capabilities to manage the lifecycle of organizational data by retaining necessary content and deleting unnecessary content. These tools ensure compliance with business, legal, and regulatory requirements.

Use retention policies to automatically retain or delete user prompts and responses for AI apps. For detailed information about this retention works, see Learn about retention for Copilot & AI apps.

As with all retention policies and holds, if more than one policy for the same location applies to a user, the principles of retention resolve any conflicts. For example, the data is retained for the longest duration of all the applied retention policies or eDiscovery holds.

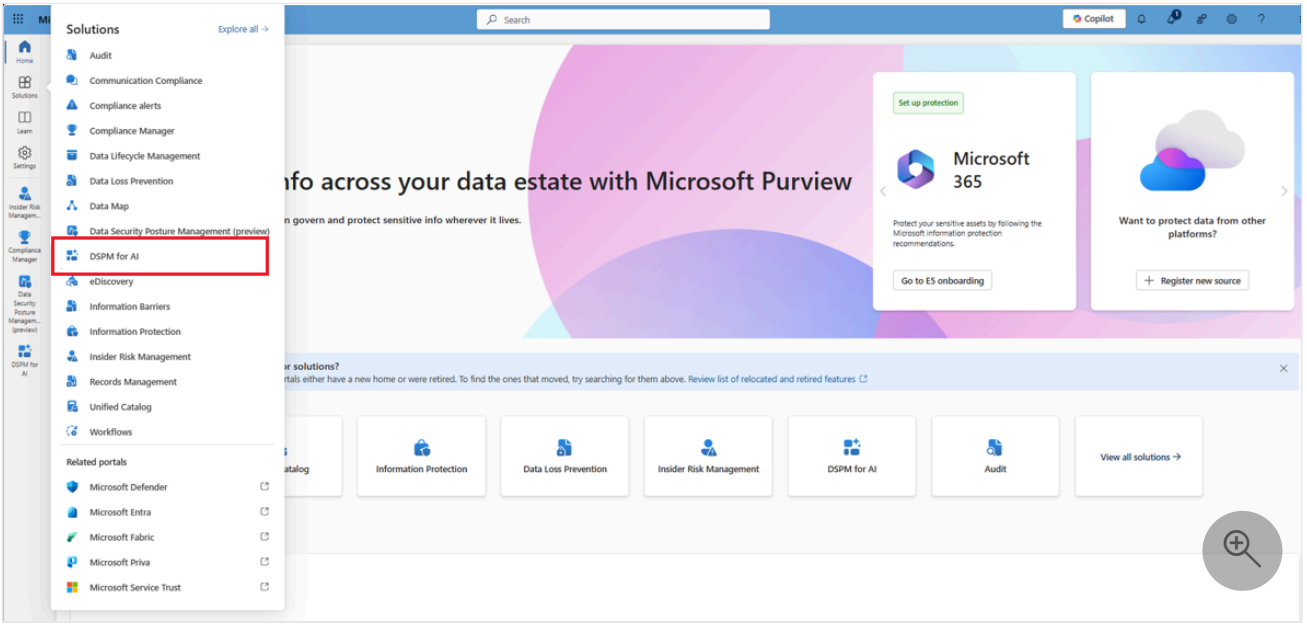
AI app-specific information:

- For retention policies, select the option for **Enterprise AI apps**.
- For prompts and responses, requires a collection policy such as **DSPM for AI - Detect sensitive info shared with AI via network** from the DSPM for AI recommendation **Extend insights into sensitive data in AI app interactions**.

Compliance Manager and AI interactions

Microsoft Purview Compliance Manager is a solution that helps you automatically assess and manage compliance across your multicloud environment. Compliance Manager can help you throughout your compliance journey, from taking inventory of your data protection risks to managing the complexities of implementing controls, staying current with regulations and certifications, and reporting to auditors.

To help you keep compliant with AI regulations, Compliance Manager provides regulatory templates to help you assess, implement, and strengthen your compliance requirements for all generative AI apps. For example, monitoring AI interactions and preventing data loss in AI applications. For more information, see Assessments for AI regulations.



Getting started recommended steps

Use the following steps to get started with managing data security & compliance for AI interactions that use Microsoft Foundry.

> **Note**
>
> These steps focus on managing a specific AI app or agent. For broader coverage that uses security objectives with guided workflows, use the current version of Data Security Posture Management.

Because Data Security Posture Management for AI is your front door for securing and managing AI interactions, most of the following instructions use that solution:

- Sign in to the Microsoft Purview portal > **Solutions** > **DSPM for AI (classic)** with an account that has appropriate permissions. For example, an account that's a member of the **Microsoft Entra Compliance Administrator** group role.

1. From **DSPM for AI (classic)** > **Recommendations** page, locate and select **Secure data in Azure AI apps and agents**, which has set up instructions to capture prompts and responses for AI apps that use one or more Azure AI subscriptions.

2. Also from the recommendations list, select **Secure interactions from enterprise apps**, which creates a one-click policy to capture prompts and responses from enterprise AI apps.

3. Wait at least a day for data, and then navigate to the **Reports** page to view the results of your policy. Select **Enterprise AI apps** and view information such as:

    - Total interactions over time (enterprise AI apps)

- Sensitive interactions per AI app
- Insider Risk severity
- Insider risk severity per AI app

4. Select **View details** for each of the report graphs to view detailed activities in the activity explorer.

   From the filters, select the **AI app category** of **Enterprise AI apps** with the **App** filter of **Azure AI**, and then use the other filters if you need to further refine the displayed data. Drill down to each activity to view details that include displaying the prompts and response when you're a member of the Microsoft Purview Content Explorer Content Viewer role group. For more information about this requirement, see Permissions for Data Security Posture Management for AI.

5. If you need to ensure that interactions from Microsoft Foundry are retained for compliance reasons:

   In the Microsoft Purview portal, navigate to **Data Lifecycle Management** > **Policies** > **Retention Policies** and create a retention policy to retain interactions with Microsoft Foundry by selecting the location **Enterprise AI apps** and specify the required retention period. For more information, see Create and configure retention policies.

6. If you need to preserve, collect, analyze, review, or export Azure AI service interactions:

   In the Microsoft Purview portal, navigate to **eDiscovery** > **Cases** > **Create case**. In the case, create a search and use the *ItemClass* property and the `IPM.SkypeTeams.Message.ConnectedAIApp.AzureAI.<AzureResourceName>` value to search for these interactions in your organization.

Routinely review the reports in DSPM for AI to determine if you need to make changes, and use activity explorer and events for deeper analysis of how users are interacting with Microsoft Foundry.

Use Microsoft Purview to manage data security & compliance for ChatGPT Enterprise

> *Microsoft Purview service description*

Use the following sections to identify the Microsoft Purview capabilities that are supported for AI interactions with ChatGPT Enterprise, and some get started recommendations for you to manage these AI interactions for security and compliance.

For setup information and prerequisites, see Connect to and manage ChatGPT Enterprise AI interactions in Microsoft Purview. You must run the connector scan before Microsoft Purview can manage the AI interactions for ChatGPT Enterprise.

Managing these AI interactions with Microsoft Purview requires you to enable pay-as-you-go billing in your organization.

Capabilities supported

Use the following table to see at a glance the Microsoft Purview capabilities that are supported for ChatGPT Enterprise.

Expand table

Capability or solution in Microsoft Purview	Supported for AI interactions
DSPM and DSPM for AI (classic)	✓
Auditing	✓
Data classification	✓
Sensitivity labels	✗
Encryption without sensitivity labels	✗
Data loss prevention	✗
Insider Risk Management	✓
Communication compliance	✓

Capability or solution in Microsoft Purview	Supported for AI interactions
eDiscovery	✓
Data Lifecycle Management	✓
Compliance Manager	✓

> **Note**
>
> These features only apply to the enterprise version of ChatGPT. For more information on the available Purview features for the consumer version, see Learn about Microsoft Purview Network Data Security and Learn about Data Loss Prevention for Cloud Apps in Edge for Business.

DSPM and DSPM for AI (classic)

Use Data Security Posture Management or Data Security Posture Management for AI (classic) as your front door to discover, secure, and apply compliance controls for AI usage across your enterprise. Both DSPM versions use existing controls from Microsoft Purview information protection and compliance management with easy-to-use graphical tools and reports to quickly gain insights into AI use within your organization. With personalized recommendations, and one-click policies help you protect your data and comply with regulatory requirements.

AI app-specific information:

- Recommendation **Get guided assistance to AI regulations**, which uses control-mapping regulatory templates from Compliance Manager.
- One-click policies available:
  - **DSPM for AI - Capture interactions for enterprise AI apps** from the recommendation or remediation action **Secure interactions from enterprise apps**.
  - **DSPM for AI - Detect sensitive info shared with AI via network** from the recommendation or remediation action **Extend insights into sensitive data in AI app interactions**.

Auditing and AI interactions

Microsoft Purview Audit solutions provide comprehensive tools for searching and managing audit records of activities performed across various Microsoft services by users and admins, and

help organizations to effectively respond to security events, forensic investigations, internal investigations, and compliance obligations.

Like other activities, prompts and responses are captured in the unified audit log. Events include how and when users interact with the AI app, and can include in which Microsoft 365 service the activity took place, and references to the files stored in Microsoft 365 that were accessed during the interaction. If these files have a sensitivity label applied, that's also captured.

These events flow into activity explorer in the **AI activities** tab in the current version of DSPM and in DSPM for AI, where the data from prompts and responses can be displayed. You can also use the **Audit** solution from the Microsoft Purview portal to search and find these auditing events.

For more information, see Audit logs for Copilot and AI activities.

Data classification and AI interactions

Microsoft Purview data classification provides a comprehensive framework for identifying and tagging sensitive data across various Microsoft services, including Office 365, Dynamics 365, and Azure. Classifying data is often the first step to ensure compliance with data protection regulations and safeguard against unauthorized access, alteration, or destruction. You can use built-in system classifications or create your own.

Sensitive information types and trainable classifiers can be used to find sensitive data in user prompts and responses when they use AI apps. The resulting information then surfaces in Microsoft Purview Reports overview and activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM.

Insider Risk Management and AI interactions

Microsoft Purview Insider Risk Management helps you detect, investigate, and mitigate internal risks such as IP theft, data leakage, and security violations. It leverages machine learning models and various signals from Microsoft 365 and third-party indicators to identify potential malicious or inadvertent insider activities. The solution includes privacy controls like pseudonymization and role-based access, ensuring user-level privacy while enabling risk analysts to take appropriate actions.

Use the Risky AI usage policy template to detect risky usage that includes prompt injection attacks and accessing protected materials. Insights from these signals are integrated into Microsoft Defender XDR to provide a comprehensive view of AI-related risks.

AI app-specific information:

- For prompts and responses, requires a collection policy such as **DSPM for AI - Capture interactions for enterprise AI apps** from the DSPM for AI recommendation **Secure interactions from enterprise apps**.

Communication compliance and AI interactions

Microsoft Purview Communication Compliance provides tools to help you detect and manage regulatory compliance and business conduct violations across various communication channels, which include user prompts and responses for AI apps. It's designed with privacy by default, pseudonymizing usernames and incorporating role-based access controls. The solution helps identify and remediate inappropriate communications, such as sharing sensitive information, harassment, threats, and adult content.

To learn more about using communication compliance policies for AI apps, see Configure a communication compliance policy to detect for generative AI interactions.

AI app-specific information:

- For prompts and responses, requires a collection policy such as **DSPM for AI - Capture interactions for enterprise AI apps** from the DSPM for AI recommendation **Secure interactions from enterprise apps**.

eDiscovery and AI interactions

Microsoft Purview eDiscovery lets you identify and deliver electronic information that can be used as evidence in legal cases. The eDiscovery tools in Microsoft Purview support searching for content in Exchange Online, OneDrive for Business, SharePoint Online, Microsoft Teams, Microsoft 365 Groups, and Viva Engage teams. You can then prevent the information from deletion and export the information.

Because user prompts and responses for AI apps are stored in a user's mailbox, you can create a case and use search when a user's mailbox is selected as the source for a search query. For example, select and retrieve this data from the source mailbox by selecting from the query builder **Add condition** > **Type** > **Contains any of** > **Edit** > *Copilot activity*. This query condition includes all Copilot and other AI application activity.

After the search is refined, you can export the results or add to a review set. You can review and export information directly from the review set.

For more information about identifying and deleting user AI interaction data, see Search for and delete Copilot data in eDiscovery.

AI app-specific information:

- For prompts and responses, requires a collection policy such as **DSPM for AI - Capture interactions for enterprise AI apps** from the DSPM for AI recommendation **Secure interactions from enterprise apps**.

Data Lifecycle Management and AI interactions

Microsoft Purview Data Lifecycle Management provides tools and capabilities to manage the lifecycle of organizational data by retaining necessary content and deleting unnecessary content. These tools ensure compliance with business, legal, and regulatory requirements.

Use retention policies to automatically retain or delete user prompts and responses for AI apps. For detailed information about this retention works, see Learn about retention for Copilot & AI apps.

As with all retention policies and holds, if more than one policy for the same location applies to a user, the principles of retention resolve any conflicts. For example, the data is retained for the longest duration of all the applied retention policies or eDiscovery holds.

AI app-specific information:

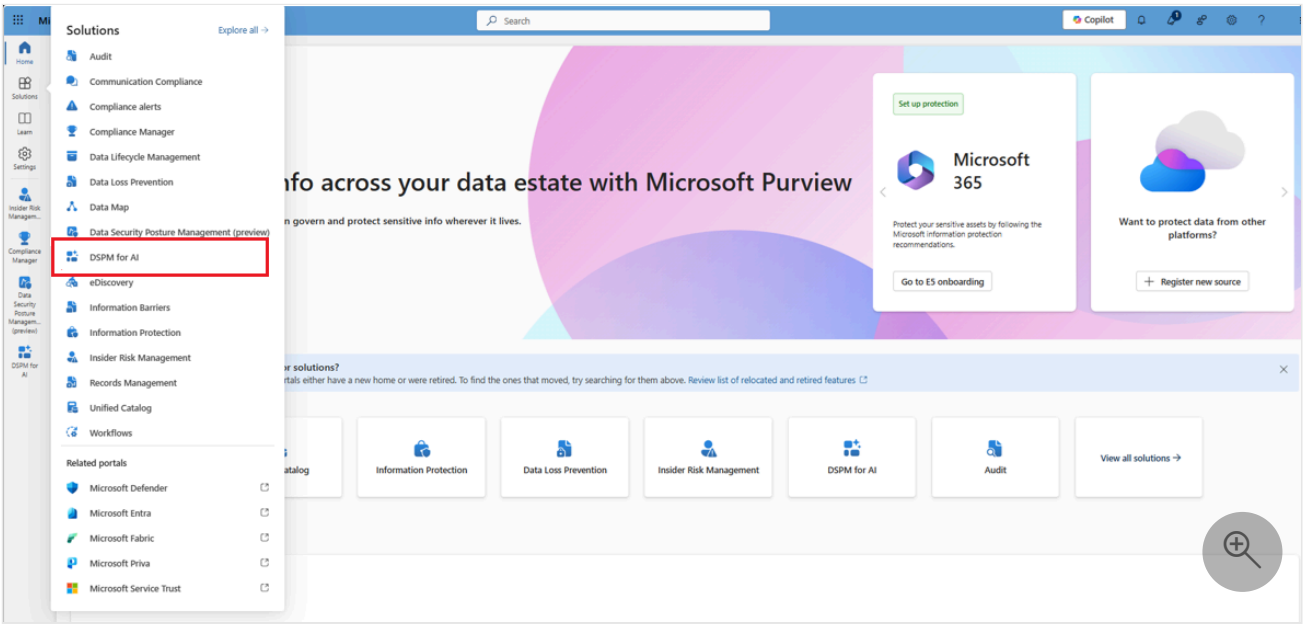
- For retention policies, select the option for **Enterprise AI apps**.
- For prompts and responses, requires a collection policy such as **DSPM for AI - Capture interactions for enterprise AI apps** from the DSPM for AI recommendation **Secure interactions from enterprise apps**.

Compliance Manager and AI interactions

Microsoft Purview Compliance Manager is a solution that helps you automatically assess and manage compliance across your multicloud environment. Compliance Manager can help you throughout your compliance journey, from taking inventory of your data protection risks to managing the complexities of implementing controls, staying current with regulations and certifications, and reporting to auditors.

To help you keep compliant with AI regulations, Compliance Manager provides regulatory templates to help you assess, implement, and strengthen your compliance requirements for all

generative AI apps. For example, monitoring AI interactions and preventing data loss in AI applications. For more information, see Assessments for AI regulations.



Getting started recommended steps

Use the following steps to get started with managing data security & compliance for AI interactions that use ChatGPT Enterprise.

> **Note**
>
> These steps focus on managing a specific AI app or agent. For broader coverage that uses security objectives with guided workflows, use the current version of Data Security Posture Management.

Because Data Security Posture Management for AI is your front door for securing and managing AI interactions, most of the following instructions use that solution:

- Sign in to the Microsoft Purview portal > **Solutions** > **DSPM for AI (classic)** with an account that has appropriate permissions. For example, an account that's a member of the **Microsoft Entra Compliance Administrator** group role.

1. From **DSPM for AI (classic)** > **Recommendations** page, locate and select **Discover and govern interactions with ChatGPT Enterprise AI**, which has set up instructions to capture prompts and responses for AI apps that use one or more Azure AI subscriptions.

2. Also from the recommendations list, select **Secure interactions from enterprise apps**, which creates a one-click policy to capture prompts and responses from enterprise AI apps.

3. Wait at least a day for data, and then navigate to the **Reports** page to view the results of your policy. Select the AI app category of **Enterprise AI apps** and view information such as:

    - Total interactions over time (enterprise AI apps)
    - Sensitive interactions per AI app
    - Insider Risk severity
    - Insider risk severity per AI app

4. Select **View details** for each of the report graphs to view detailed activities in the activity explorer.

    From the filters, select the **AI app category** of **Enterprise AI apps** with the **App** filter of **ChatGPT Enterprise**, and then use the other filters if you need to further refine the displayed data. Drill down to each activity to view details that include displaying the prompts and response when you're a member of the Microsoft Purview Content Explorer Content Viewer role group. For more information about this requirement, see Permissions for Data Security Posture Management for AI.

5. If you need to ensure that interactions from ChatGPT Enterprise are retained for compliance reasons:

    In the Microsoft Purview portal, navigate to **Data Lifecycle Management** > **Policies** > **Retention Policies** and create a retention policy to retain interactions with ChatGPT Enterprise by selecting the location **Enterprise AI apps** and specify the required retention period. For more information, see Create and configure retention policies.

6. If you need to preserve, collect, analyze, review, or export ChatGPT Enterprise interactions:

    In the Microsoft Purview portal, navigate to **eDiscovery** > **Cases** > **Create case**. In the case, create a search and use the *ItemClass* property and the `IPM.SkypeTeams.Message.ConnectedAIApp.Connector.<ChatGPTEnterprise>` value for local machine activities or the `IPM.SkypeTeams.Message.CloudAIApp.SaaS.<AppID>` value for browser-based activities to search for these interactions in your organization.

Routinely review the reports in DSPM for AI to determine if you need to make changes, and use activity explorer and events for deeper analysis of how users are interacting with ChatGPT Enterprise.

Use Microsoft Purview to manage data security & compliance for Anthropic Claude (Enterprise)

> *Microsoft Purview service description*

Use the following sections to identify the Microsoft Purview data security and compliance protections for generative AI apps with Anthropic Claude, and recommendations to get started to help you manage these AI interactions for security and compliance.

For setup information and prerequisites, see Set up a connector to manage Anthropic Claude data. You must set up and configure the connector before Microsoft Purview can manage the AI interactions for Anthropic Claude.

> **Important**
>
> Managing these AI interactions with Microsoft Purview requires you to enable pay-as-you-go billing in your organization, which is subject to the Microsoft Purview billing model. For more information, see Consent to use pay-as-you-go capabilities and Learn about Microsoft Purview billing models.

> **Note**
>
> The Anthropic Claude connector is currently in preview.

Capabilities supported

The following table lists the Microsoft Purview capabilities supported for Anthropic Claude.

Expand table

Capability or solution in Microsoft Purview	Supported for AI interactions
DSPM and DSPM for AI (classic)	✓
Auditing	✓

Capability or solution in Microsoft Purview	Supported for AI interactions
Data classification	✓
Sensitivity labels	✗
Encryption without sensitivity labels	✗
Data loss prevention	✗
Insider Risk Management	✓
Communication compliance	✓
eDiscovery	✓
Data Lifecycle Management	✓
Compliance Manager	✓

DSPM and DSPM for AI (classic)

Use Data Security Posture Management or Data Security Posture Management for AI (classic) as your front door to discover, secure, and apply compliance controls for AI usage across your enterprise. Both DSPM versions use existing controls from Microsoft Purview information protection and compliance management with easy-to-use graphical tools and reports to quickly gain insights into AI use within your organization. With personalized recommendations, and one-click policies help you protect your data and comply with regulatory requirements.

AI app-specific information:

- Currently, there are no recommendations or one-click policies applicable to Anthropic Claude, but you can view and monitor the AI interactions by using the **Reports** page, **activity explorer** (**AI activities** tab), and the **Apps and agents** dashboard.
- Because agents for Anthropic Claude aren't currently supported, they aren't displayed in **AI observability**.

Auditing and AI interactions

Microsoft Purview Audit solutions provide comprehensive tools for searching and managing audit records of activities performed across various Microsoft services by users and admins, and help organizations to effectively respond to security events, forensic investigations, internal investigations, and compliance obligations.

Like other activities, prompts and responses are captured in the unified audit log. Events include how and when users interact with the AI app, and can include in which Microsoft 365 service the activity took place, and references to the files stored in Microsoft 365 that were accessed during the interaction. If these files have a sensitivity label applied, that's also captured.

These events flow into activity explorer in the **AI activities** tab in the current version of DSPM and in DSPM for AI, where the data from prompts and responses can be displayed. You can also use the **Audit** solution from the Microsoft Purview portal to search and find these auditing events.

For more information, see Audit logs for Copilot and AI activities.

Recommended steps to get started

Use the following steps to get started with managing data security & compliance for AI interactions that use Anthropic Claude.

> **Note**
>
> These steps focus on managing a specific AI app or agent. For broader coverage that uses security objectives with guided workflows, use the current version of Data Security Posture Management.

Because Data Security Posture Management for AI is your front door for securing and managing AI interactions, most of the following instructions use that solution:

1. Sign in to the Microsoft Purview portal > **Solutions** > **DSPM for AI (classic)** with an account that has appropriate permissions. For example, an account that's a member of the **Microsoft Entra Compliance Administrator** group role. For more information, see Permissions for Data Security Posture Management for AI - (classic).

2. If you haven't already set up and configured the connector to manage AI interactions for Anthropic Claude, see Set up a connector to manage Anthropic Claude data.

3. After setting up the Anthropic Claude connector, wait at least a day for data to populate. Go to the **Reports** page to view information such as:

    - Total interactions over time.
    - Interaction trends by AI app.

4. Select **View details** for each of the report graphs to view detailed activities in activity explorer.

   From the filters, select the **AI app category** of **Enterprise AI apps** with the **App** filter of **Anthropic Claude**, and then use the other filters if you need to further refine the displayed data.

Regularly review the reports in DSPM for AI to determine whether you need to make changes, and use activity explorer for deeper analysis of how users are interacting with Anthropic Claude.

Use Microsoft Purview to manage data security & compliance for other AI apps

> *Microsoft Purview service description*

Use the following sections to identify the Microsoft Purview capabilities that are supported for AI interactions that use a browser to third-party AI sites, and some get started recommendations for you to manage these AI interactions for security and compliance.

Managing these AI interactions with Microsoft Purview requires you to enable pay-as-you-go billing in your organization.

Capabilities supported

Use the following table to see at a glance the Microsoft Purview capabilities that are supported for third-party AI sites, such as ChatGPT, Google Gemini, and DeepSeek.

Unless noted for specific solutions, the list of supported AI sites is the same as those supported for DSPM for AI: List of AI sites supported by Microsoft Purview Data Security Posture Management for AI.

Expand table

Capability or solution in Microsoft Purview	Supported for AI interactions
DSPM and DSPM for AI (classic)	✓
Auditing	✓
Data classification	✓
Sensitivity labels	✗
Encryption without sensitivity labels	✗
Data loss prevention	✓
Insider Risk Management	✓
Communication compliance	✓
eDiscovery	✓

Capability or solution in Microsoft Purview	Supported for AI interactions
Data Lifecycle Management	✓
Compliance Manager	✓

Most of the supported capabilities and solutions require the Microsoft Purview browser extension and devices onboarded to Microsoft Purview. The exceptions are, with their own prerequisites:

- Network data security to detect sensitive information types at the network layer, using a Secure Access Service Edge or Security Service Edge integration.
- Browser data security to detect sensitive information types at the Edge browser layer, using a direct integration from Purview into the Edge browser.

DSPM and DSPM for AI (classic)

Use Data Security Posture Management or Data Security Posture Management for AI (classic) as your front door to discover, secure, and apply compliance controls for AI usage across your enterprise. Both DSPM versions use existing controls from Microsoft Purview information protection and compliance management with easy-to-use graphical tools and reports to quickly gain insights into AI use within your organization. With personalized recommendations, and one-click policies help you protect your data and comply with regulatory requirements.

AI app-specific information:

- The **Getting started** section from the **Overview** page contains the required steps and information to install the Microsoft Purview browser extension and devices onboarding process.

- Recommendation **Get guided assistance to AI regulations**, which uses control-mapping regulatory templates from Compliance Manager.

- One-click policies available:
  - **DSPM for AI: Detect sensitive info added to AI sites** from the recommendation or remediation action **Extend your insights for data discovery**
  - **DSPM for AI - Detect when users visit AI sites** from the recommendation or remediation action **Extend your insights for data discovery**
  - **DSPM for AI - Detect sensitive info shared in AI prompts in Edge** from the recommendation or remediation action **Extend your insights for data discovery**
  - **DSPM for AI - Detect sensitive info shared with AI via network** from the recommendation or remediation action **Extend insights into sensitive data in AI app**

interactions.

Auditing and AI interactions

Microsoft Purview Audit solutions provide comprehensive tools for searching and managing audit records of activities performed across various Microsoft services by users and admins, and help organizations to effectively respond to security events, forensic investigations, internal investigations, and compliance obligations.

Like other activities, prompts and responses are captured in the unified audit log. Events include how and when users interact with the AI app, and can include in which Microsoft 365 service the activity took place, and references to the files stored in Microsoft 365 that were accessed during the interaction. If these files have a sensitivity label applied, that's also captured.

These events flow into activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM, where the data from prompts and responses can be displayed. You can also use the **Audit** solution from the Microsoft Purview portal to search and find these auditing events.

For more information, see Audit logs for Copilot and AI activities.

AI app-specific information:

- Use network data security to audit prompts and responses at the network layer, using a Secure Access Service Edge or Security Service Edge integration.

Data classification and AI interactions

Microsoft Purview data classification provides a comprehensive framework for identifying and tagging sensitive data across various Microsoft services, including Office 365, Dynamics 365, and Azure. Classifying data is often the first step to ensure compliance with data protection regulations and safeguard against unauthorized access, alteration, or destruction. You can use built-in system classifications or create your own.

Sensitive information types and trainable classifiers can be used to find sensitive data in user prompts and responses when they use AI apps. The resulting information then surfaces in Microsoft Purview Reports overview and activity explorer in DSPM for AI and the **AI activities** tab in activity explorer from the preview version of DSPM.

AI app-specific information:

- Use network data security to detect sensitive info types at the network layer, using a Secure Access Service Edge or Security Service Edge integration.
- Use browser data security to detect sensitive info types at the Edge browser layer, using a direct integration from Purview into the Edge browser.

Data loss prevention and AI interactions

Microsoft Purview Data Loss Prevention (DLP) helps you identify sensitive items across Microsoft 365 services and endpoints, monitor them, and helps protect against leakage of those items. It uses deep content inspection and contextual analysis to identify sensitive items and it enforces policies to protect sensitive data such as financial records, health information, or intellectual property.

Windows computers that are onboarded to Microsoft Purview can be configured for Endpoint data loss prevention (DLP) policies that warn or block users from sharing sensitive information with third-party generative AI sites that are accessed via a browser. For example, a user is prevented from pasting credit card numbers into ChatGPT, or they see a warning that they can override. For more information about the supported DLP actions and which platforms support them, see the first two rows in the table from Endpoint activities you can monitor and take action on.

AI app-specific information:

- Endpoint DLP supports an option to block the upload of files based on a specified sensitivity label.

Insider Risk Management and AI interactions

Microsoft Purview Insider Risk Management helps you detect, investigate, and mitigate internal risks such as IP theft, data leakage, and security violations. It leverages machine learning models and various signals from Microsoft 365 and third-party indicators to identify potential malicious or inadvertent insider activities. The solution includes privacy controls like pseudonymization and role-based access, ensuring user-level privacy while enabling risk analysts to take appropriate actions.

Use the Risky AI usage policy template to detect risky usage that includes prompt injection attacks and accessing protected materials. Insights from these signals are integrated into Microsoft Defender XDR to provide a comprehensive view of AI-related risks.

AI app-specific information:

- For prompts and responses, requires a collection policy that includes the setting to capture content. For more information, see Collection Policies solution overview.

Communication compliance and AI interactions

Microsoft Purview Communication Compliance provides tools to help you detect and manage regulatory compliance and business conduct violations across various communication channels, which include user prompts and responses for AI apps. It's designed with privacy by default, pseudonymizing usernames and incorporating role-based access controls. The solution helps identify and remediate inappropriate communications, such as sharing sensitive information, harassment, threats, and adult content.

To learn more about using communication compliance policies for AI apps, see Configure a communication compliance policy to detect for generative AI interactions.

AI app-specific information:

- Support restricted to the Edge browser, for ChatGPT, Microsoft Chat (consumer version), Google Gemini, and DeepSeek.
- For prompts and responses, requires a collection policy that includes the setting to capture content. For more information, see Collection Policies solution overview.
- Use network data security to analyze prompts and responses at the network layer, using a Secure Access Service Edge or Security Service Edge integration.

eDiscovery and AI interactions

Microsoft Purview eDiscovery lets you identify and deliver electronic information that can be used as evidence in legal cases. The eDiscovery tools in Microsoft Purview support searching for content in Exchange Online, OneDrive for Business, SharePoint Online, Microsoft Teams, Microsoft 365 Groups, and Viva Engage teams. You can then prevent the information from deletion and export the information.

Because user prompts and responses for AI apps are stored in a user's mailbox, you can create a case and use search when a user's mailbox is selected as the source for a search query. For example, select and retrieve this data from the source mailbox by selecting from the query builder **Add condition** > **Type** > **Contains any of** > **Edit** > *Copilot activity*. This query condition includes all Copilot and other AI application activity.

After the search is refined, you can export the results or add to a review set. You can review and export information directly from the review set.

For more information about identifying and deleting user AI interaction data, see Search for and delete Copilot data in eDiscovery.

AI app-specific information:

- Support restricted to the Edge browser, for ChatGPT, Microsoft Chat (consumer version), Google Gemini, and DeepSeek.
- For prompts and responses, requires a collection policy that includes the setting to capture content. For more information, see Collection Policies solution overview.
- Use network data security to analyze prompts and responses at the network layer.

Data Lifecycle Management and AI interactions

Microsoft Purview Data Lifecycle Management provides tools and capabilities to manage the lifecycle of organizational data by retaining necessary content and deleting unnecessary content. These tools ensure compliance with business, legal, and regulatory requirements.

Use retention policies to automatically retain or delete user prompts and responses for AI apps. For detailed information about this retention works, see Learn about retention for Copilot & AI apps.

As with all retention policies and holds, if more than one policy for the same location applies to a user, the principles of retention resolve any conflicts. For example, the data is retained for the longest duration of all the applied retention policies or eDiscovery holds.

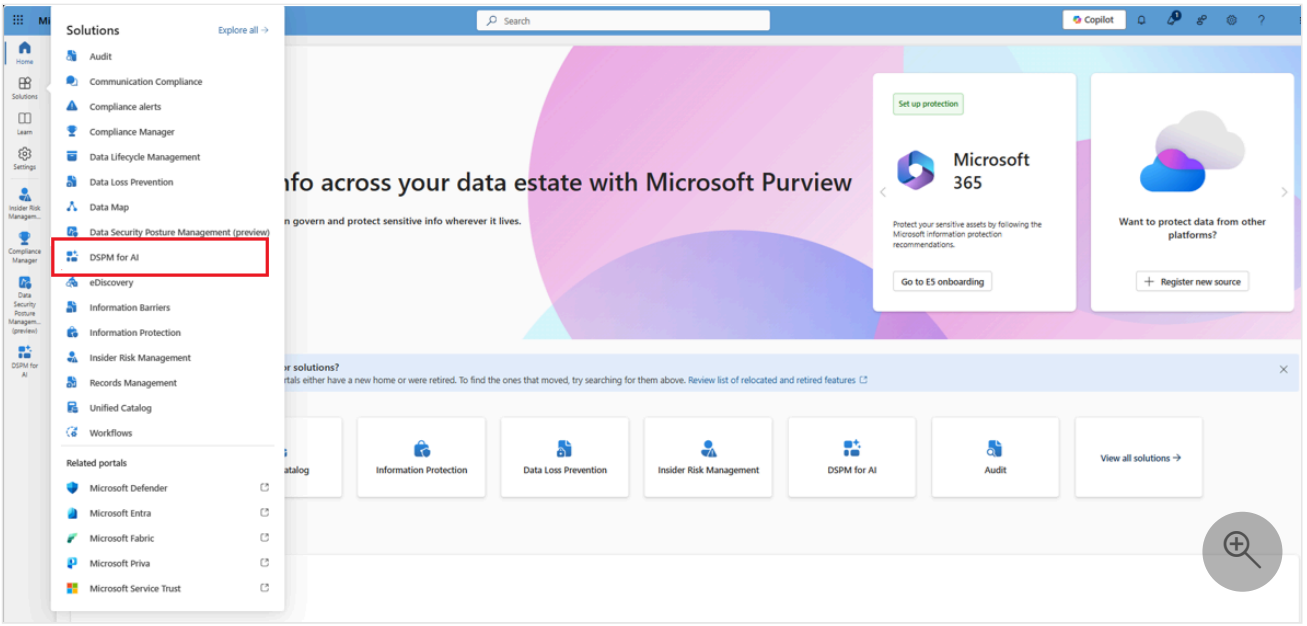
AI app-specific information:

- Support restricted to the Edge browser, for ChatGPT, Microsoft Chat (consumer version), Google Gemini, and DeepSeek.
- For retention policies, select the option for **Other AI apps**.
- For prompts and responses, requires a collection policy that includes the setting to capture content. For more information, see Collection Policies solution overview.
- Use network data security to retain prompts and responses at the network layer.
- Use browser data security to retain prompts and responses at the Edge browser layer.

Compliance Manager and AI interactions

Microsoft Purview Compliance Manager is a solution that helps you automatically assess and manage compliance across your multicloud environment. Compliance Manager can help you throughout your compliance journey, from taking inventory of your data protection risks to managing the complexities of implementing controls, staying current with regulations and certifications, and reporting to auditors.

To help you keep compliant with AI regulations, Compliance Manager provides regulatory templates to help you assess, implement, and strengthen your compliance requirements for all generative AI apps. For example, monitoring AI interactions and preventing data loss in AI applications. For more information, see Assessments for AI regulations.



Getting started recommended steps

Use the following steps to get started with managing data security & compliance for AI interactions that use a browser to third-party AI sites.

> **Note**
>
> These steps focus on managing a specific AI app or agent. For broader coverage that uses security objectives with guided workflows, use the current version of Data Security Posture Management.

Because Data Security Posture Management for AI is your front door for securing and managing AI interactions, the following instructions use that solution:

- Sign in to the Microsoft Purview portal > **Solutions** > **DSPM for AI (classic)** with an account that has appropriate permissions. For example, an account that's a member of the **Microsoft Entra Compliance Administrator** group role.

Discover potential security risks in interactions with other AI apps

1. From **DSPM for AI (classic)** > **Overview**, in the **Get Started** section, locate and take action on the following required steps:

   - **Install Microsoft Purview browser extension**
   - **Onboard devices to Microsoft Purview**
   - **Extend your insights for data discovery**

   If you need more information about the browser extension, or other onboarding requirements, see Prerequisites for Data Security Posture Management for AI.

   For more information about the one-click policies that are automatically created with the option to extend your insights for data discovery, see Default policies for data discovery using Data Security Posture Management for AI and the policies that have the source of **Extend your insights for data discovery**.

2. Wait at least a day for data, and then navigate to the **Reports** page to view the results of your policy. Select **Other AI apps** and view information such as:

   - Total interactions over time (other AI apps)
   - Total visits (other AI apps)
   - Sensitive interactions per AI app
   - Insider Risk severity
   - Insider risk severity per AI apps

3. Select **View details** for each of the report graphs to view detailed activities in the activity explorer.

   Select the available filters to see the results from **Copilot experiences & agents** based on the different **Activity type**, **AI app category**, **App**, and **Scope** for administrative units, and more. Then drill down to each activity to view details that include displaying the prompts and response when you're a member of the Microsoft Purview Content Explorer Content Viewer role group. For more information about this requirement, see Permissions for Data Security Posture Management for AI.

Protect sensitive data in interactions with other AI apps

1. From **DSPM for AI (classic)** > **Recommendations** page, under **Not Started**, select **Fortify your data security** to create the following one-click policies:

   - **Block elevated risk users from pasting or uploading sensitive info on AI sites**: This recommendation creates a policy that uses Adaptive Protection to give a block-with-override to elevated risky users attempting to paste or upload sensitive information to other AI apps in Edge, Chrome, and Firefox. This policy covers all users and groups in your org in test mode.

   - **Block elevated risk users from submitting prompts to AI apps in Microsoft Edge**: This recommendation guides you through the process of creating a Purview Data Loss Prevention (DLP) policy to block elevated, moderate, and minor risk users attempting to put information in AI apps while using Microsoft Edge.

   - **Block sensitive info sharing to AI apps in Edge**: This recommendation guides you through the process of creating a Purview Data Loss Prevention (DLP) policy to detect inline for a selection of common sensitive information types and blocks prompts from being sent in AI apps while using Microsoft Edge.

Apply compliance controls to interactions with other AI apps

If you need to ensure that interactions with supported other AI apps are retained for compliance reasons:

- In the Microsoft Purview portal, navigate to **Data Lifecycle Management** > **Policies** > **Retention Policies** and create a retention policy to retain interactions with other AI apps by selecting the location **Other AI apps** and specify the required retention period. For more information, see Create and configure retention policies.

> **Note**
>
> Retention is supported only for the Edge browser, and for ChatGPT, Microsoft Chat (consumer version), Google Gemini, and DeepSeek.

- In the Microsoft Purview portal, navigate to **eDiscovery** > **Cases** > **Create case**. In the case, create a search and use the *ItemClass* property and the `IPM.SkypeTeams.Message.ConnectedAIApp.Connector.<AppName>` value for local machine activities or the `IPM.SkypeTeams.Message.CloudAIApp.SaaS.<AppID>` value for browser-based activities to search for these interactions in your organization.

Routinely review the reports in DSPM for AI to determine if you need to make changes, and use activity explorer and events for deeper analysis of how users are interacting with other AI apps when they use a browser to third-party AI sites.

Use Microsoft Purview to manage data security & compliance for AI agents

> *Microsoft Purview service description*

Use the following table to see at a glance the Microsoft Purview capabilities that are supported for AI interactions for AI agents from Microsoft AI apps and supported enterprise AI apps.

Managing these AI interactions with Microsoft Purview might require you to enable pay-as-you-go billing in your organization.

Capabilities supported

AI agents typically have the same security and compliance protections for AI interactions as their parent AI app. Select the name of each app to learn the support details at the solution or capabilities level.

All the listed agents are supported by Data Security Posture Management and Data Security Posture Management for AI (classic), and have their own dedicated **Apps and agents** page. Only Data Security Posture Management has an additional **AI observability** page that includes more information and support for Agent 365. Use the dashboard from those pages to view how the agents and their apps are being used across your organization.

Expand table

AI app and agents	Information protection for AI interactions	Compliance management for AI interactions
Microsoft 365 Copilot agents	✓	✓
Microsoft Security Copilot agents	✓ [1]	✓
Copilot in Fabric agents	✓ [1]	✓
Microsoft Copilot Studio agents	✓ [2]	✓
Microsoft Facilitator agents	✓ [1]	✓

AI app and agents	Information protection for AI interactions	Compliance management for AI interactions
Channel Agent in Teams agents	✓ [3]	✓
Entra-registered agents	✓	✓
Microsoft Foundry agents	✓ [2]	✓
ChatGPT Enterprise agents	✓ [4]	✓
Anthropic Claude (Enterprise) agents	✗	✗

Footnotes

The following capabilities are supported:

[1] Data classification

[2] Data classification, sensitivity labels, data loss prevention, Insider Risk Management

[3] Data classification, sensitivity labels, data loss prevention

[4] Data classification, Insider Risk Management

Considerations to manage Microsoft 365 Copilot and Channel Agent in Teams for security and compliance

> *Microsoft Purview service description*

When you understand how you can use Microsoft Purview to manage data security and compliance protections for Microsoft 365 Copilot and Channel Agent in Teams, use the following detailed information for any prerequisites, considerations, and exemptions that might apply to your organization. Be sure to read these in conjunction with Microsoft 365 Copilot requirements and Enterprise data protection in Microsoft 365 Copilot and Microsoft Copilot 365 Chat.

For licensing information to use these capabilities for Copilot, see the licensing and service description links at the top of the page. For licensing information for Copilot, see the service description for Microsoft 365 Copilot.

Information protection considerations for Microsoft 365 Copilot

Microsoft 365 Copilot, Microsoft 365 Copilot Chat, and agents have the capability to access data stored within your Microsoft 365 tenant, including mailboxes in Exchange Online and documents in SharePoint or OneDrive.

In addition to accessing Microsoft 365 content, Copilot and agents can also use content from the specific file you're working on in the context of an Office app session, regardless of where that file is stored. For example, local storage, network shares, cloud storage, or a USB stick. When files are open by a user within an app, access is often referred to as *data in use*.

Before you deploy licenses for Copilot, make sure you're familiar with the following details that help you strengthen your data protection solutions:

- If content grants a user VIEW usage rights but not EXTRACT:
  - When a user has this content open in an app, they won't be able to use Copilot.
  - Copilot won't summarize this content but can reference it with a link so the user can then open and view the content outside Copilot.

- You can further prevent Copilot and agents from summarizing labeled files and emails (whether encrypted or not) that are identified by a Microsoft Purview Data Loss Protection policy. Copilot and agents won't summarize this content but can reference it with a link so the user can then open and view the content outside Copilot.
- Just like your Office apps, Copilot and agents can access sensitivity labels from your organization, but not other organizations. For more information about labeling support across organizations, see Support for external users and labeled content.
- An advanced PowerShell setting for sensitivity labels can prevent Office apps from sending content to connected experiences, which includes Microsoft 365 Copilot and agents.
- Copilot and agents can't access unopened documents in SharePoint and OneDrive when they're labeled and encrypted with user-defined permissions, unless the label is used as a default sensitivity label that extends SharePoint permissions to downloaded documents or they're directly referenced by typing "/" (and in both cases, the user has EXTRACT permissions). Copilot and agents can always access these documents for a user when they're open in the app (data in use).
- Sensitivity labels that are applied to containers (groups and sites) aren't inherited by items in those containers. As a result, the items won't display their container label in Copilot and can't support sensitivity label inheritance. For example, Teams channel chat messages that are summarized from a team that's labeled as Confidential won't display that label for sensitivity context in Microsoft 365 Copilot Chat. Similarly, content from SharePoint site pages and lists won't display the sensitivity label of their container label. Containers that support sensitivity labels include Teams, SharePoint sites, Micrsosoft 365 Groups, Loop workspaces, and Viva Engage.
- If you're using SharePoint information rights management (IRM) library settings that restrict users from copying text, be aware that usage rights are applied when files are downloaded, and not when they're created or uploaded to SharePoint. If you don't want Copilot and agents to summarize these files when they're at rest, use sensitivity labels that apply encryption without the EXTRACT usage right.
- Unlike other automatic labeling scenarios, an inherited label when you create new content will replace a lower priority label that was manually applied.
- When an inherited sensitivity label can't be applied, the text won't be added to the destination item. For example:
  - The destination item is read-only

    - The destination item is already encrypted and the user doesn't have permissions to change the label (requires EXPORT or FULL CONTROL usage rights)
    - The inherited sensitivity label isn't published to the user

- If a user asks Copilot or agents to create new content from labeled and encrypted items, label inheritance isn't supported when the encryption is configured for user-defined permissions or if the encryption was applied independently from the label. The user won't be able to send this data to the destination item.

- Because Double Key Encryption (DKE) is intended for your most sensitive data that's subject to the strictest protection requirements, Copilot and agents can't access this data. As a result, items protected by DKE won't be returned by Copilot, and if a DKE item is open (data in use), you won't be able to use Copilot in the app.

- Sensitivity labels that protect Teams meetings and chat aren't currently recognized by Copilot and agents. For example, data returned from a meeting chat or channel chat won't display an associated sensitivity label, copying chat data can't be prevented for a destination item, and the sensitivity label can't be inherited. This limitation doesn't apply to meeting invites, responses, and calendar events that are protected by sensitivity labels.

- For Microsoft 365 Copilot Chat (formerly known as Business Chat, Graph-grounded chat, and Microsoft 365 Chat):
    - When meeting invites have a sensitivity label applied, the label is applied to the body of the meeting invite but not to the metadata, such as date and time, or recipients. As a result, questions based just on the metadata return data without the label. For example, "What meetings do I have on Monday?" Questions that include the meeting body, such as the agenda, return the data as labeled.
    - If content is encrypted independently from its applied sensitivity label, and that encryption doesn't grant the user EXTRACT usage rights (but includes the VIEW usage right), the content can be returned by Copilot and therefore sent to a source item. An example of when this configuration can occur if a user has applied Office restrictions from Information Rights Management when a document is labeled "General" and that label doesn't apply encryption.
    - If you're using the extension capabilities that include plugins and the Microsoft Graph Connector, sensitivity labels and encryption that are applied to this data from external sources aren't recognized by Microsoft 365 Copilot Chat. Most of the time this limitation won't apply because the data is unlikely to support sensitivity labels and encryption, although one exception is Power BI data. You can always disconnect the external data

sources by using the Microsoft 365 admin center to turn off those plugins for users, and disconnect connections that use a Graph API connector.

App-specific exceptions:

- **Microsoft 365 Copilot in Outlook**: You must have a minimum version of Outlook to use Microsoft 365 Copilot for encrypted items in Outlook:
  - **Outlook (Classic) for Windows**: Starting with version 2408 in Current Channel and Monthly Enterprise Channel
  - **Outlook for Mac**: Version 16.86.609+
  - **Outlook for iOS**: Version 4.2420.0+
  - **Outlook for Android**: Version 4.2420.0+
  - **Outlook on the web**: Yes
  - **New Outlook for Windows**: Yes
- **Microsoft 365 Copilot in Edge**, **Microsoft 365 Copilot in Windows**: Unless data loss prevention (DLP) is used in Edge, Copilot can reference encrypted content from the active browser tab in Edge when that content doesn't grant the user EXTRACT usage rights. For example, the encrypted content is from Office for the web or Outlook for the web.

Will an existing label be overridden for sensitivity label inheritance?

Summary of outcomes when Microsoft 365 Copilot automatically applies protection with sensitivity label inheritance:

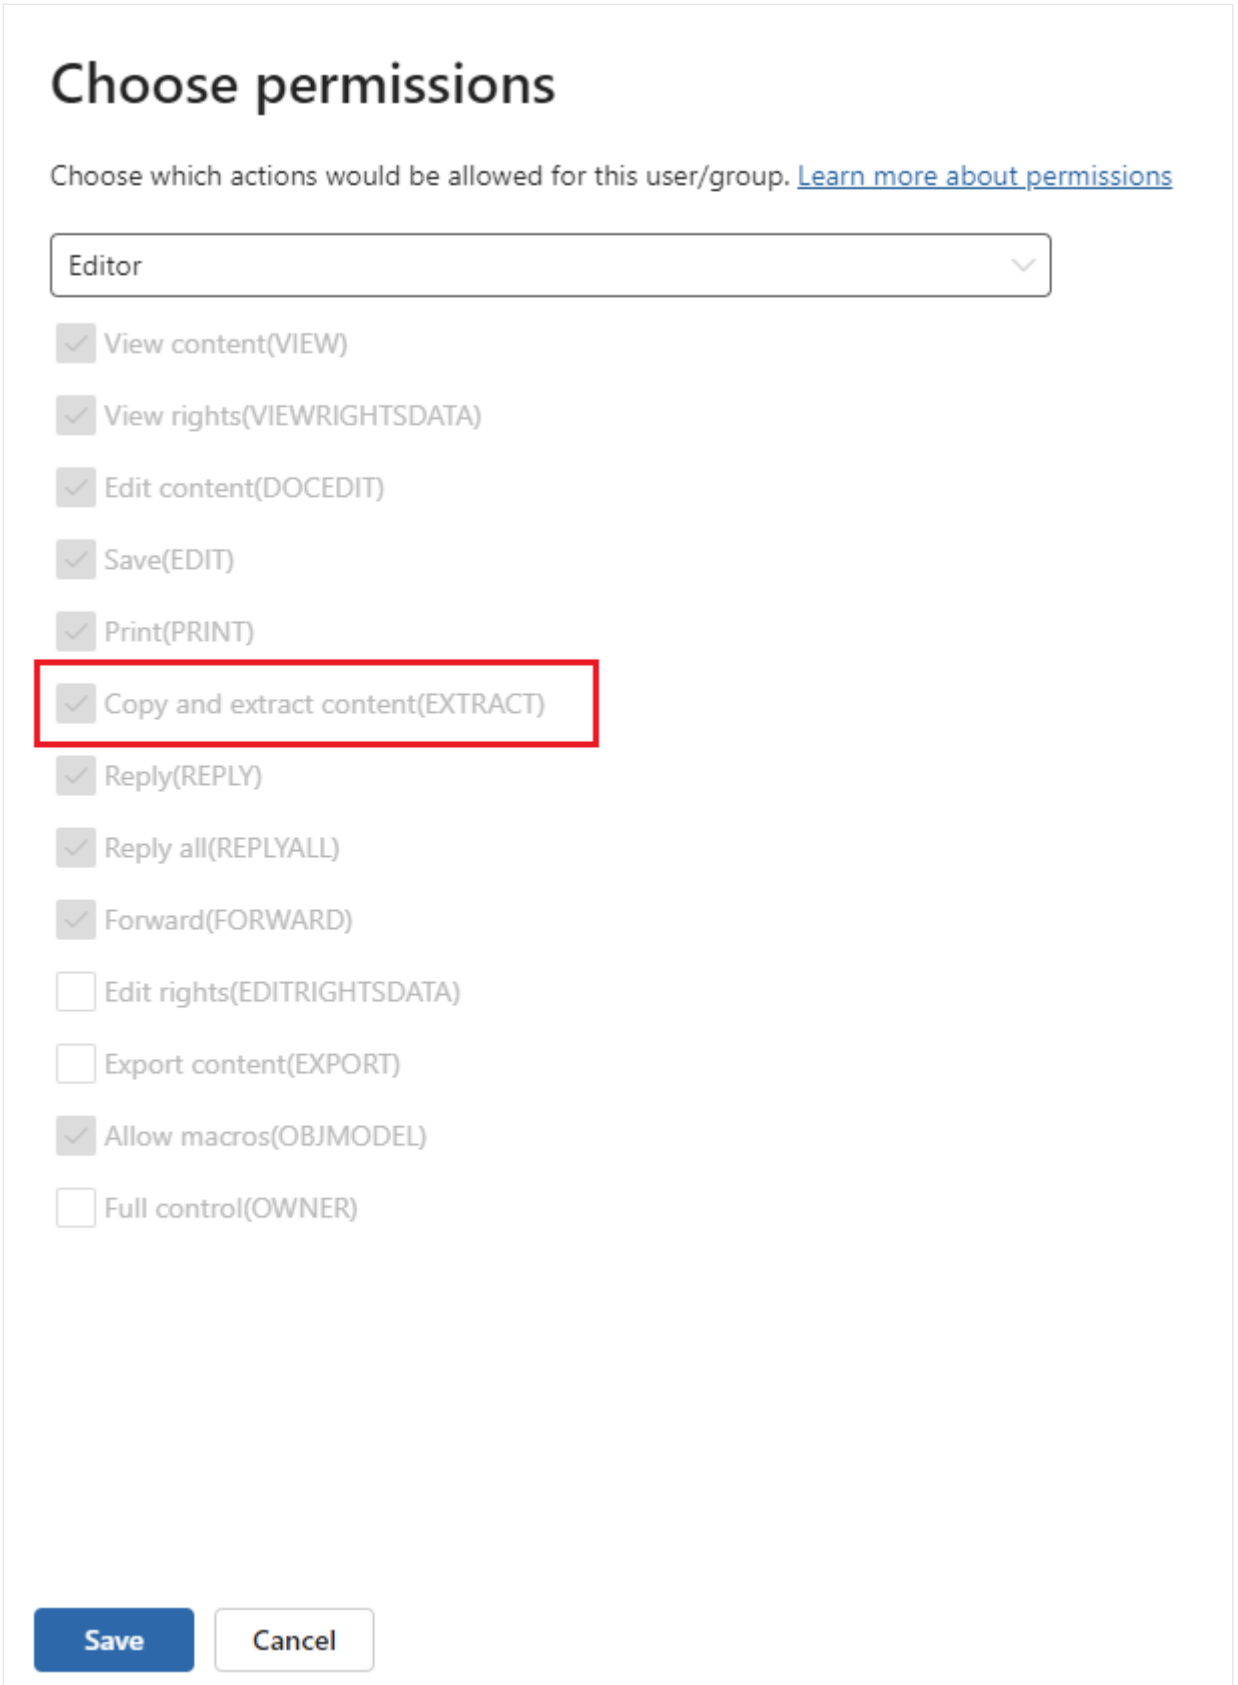
Expand table

Existing label	Override with sensitivity label inheritance
Manually applied, lower priority	Yes
Manually applied, higher priority	No
Automatically applied, lower priority	Yes
Automatically applied, higher priority	No
Default label from policy, lower priority	Yes
Default label from policy, higher priority	No
Default sensitivity label for a document library, lower priority	Yes

Existing label	Override with sensitivity label inheritance
Default sensitivity label for a document library, higher priority	No

Copilot honors existing protection with the EXTRACT usage right

Although you might not be very familiar with the individual usage rights for encrypted content, they've been around a long time. From Windows Server Rights Management, to Active Directory Rights Management, to the cloud version that became Azure Information Protection with the Azure Rights Management service.



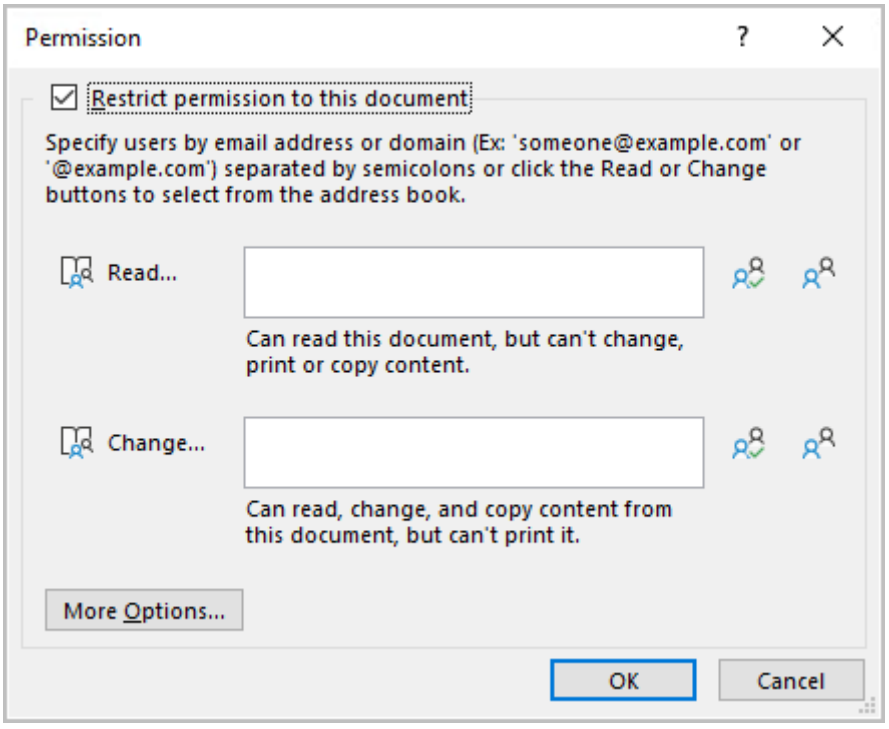
If you've ever received a "Do Not Forward" email, it's using usage rights to prevent you from forwarding the email after you've been authenticated. As with other bundled usage rights that map to common business scenarios, a Do Not Forward email grants the recipient usage rights that control what they can do with the content, and it doesn't include the FORWARD usage right. In addition to not forwarding, you can't print this Do Not Forward email, or copy text from it.

The usage right that grants permission to copy text is **EXTRACT**, with the more user-friendly, common name of **Copy**. It's this usage right that determines whether Copilot or agents can display text to the user from encrypted content.

> ⓘ **Note**
>
> Because the Full control (OWNER) usage right includes all the usage rights, EXTRACT is automatically included with Full control.

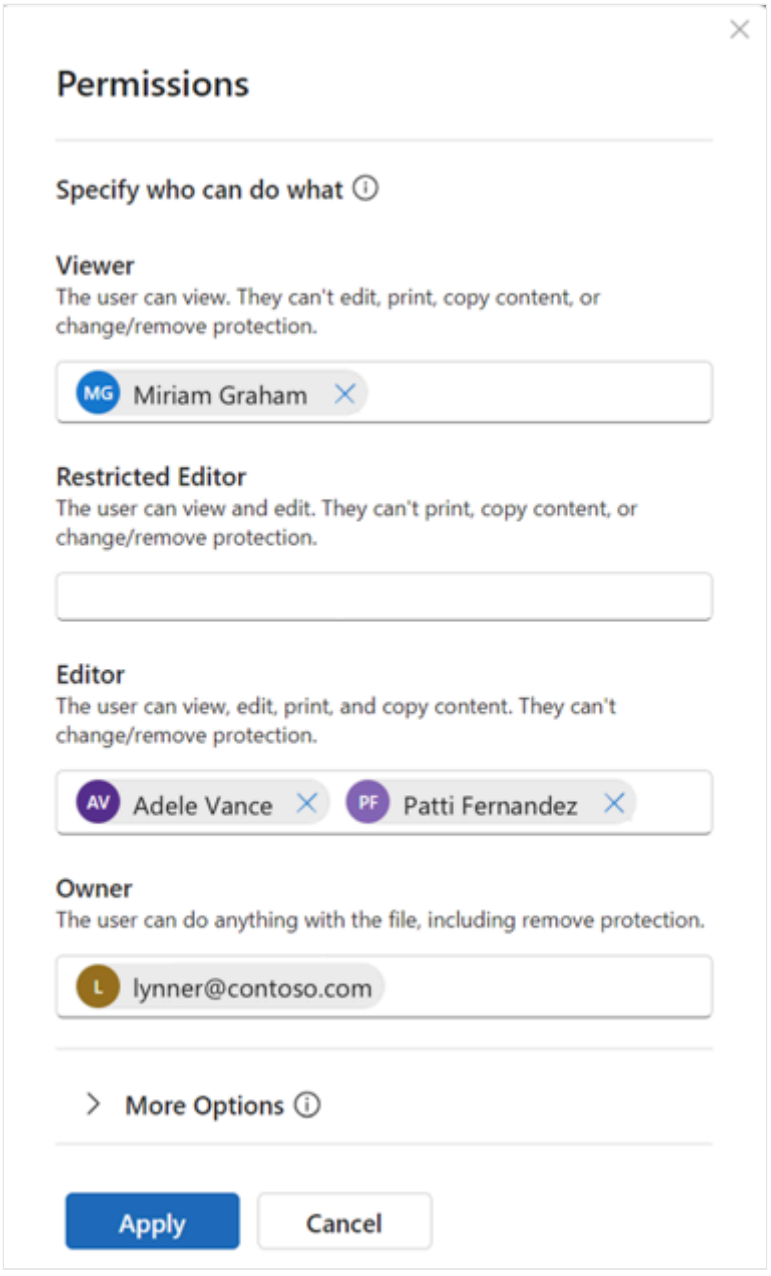
When you use the Microsoft Purview portal to configure a sensitivity label to apply encryption, the first choice is whether to assign the permissions now, or let users assign the permissions. If you assign now, you configure the permissions by either selecting a predefined permission level with a preset group of usage rights, such as Co-Author or Reviewer. Or, you can select custom permissions where you can individually select available usage rights.

In the Microsoft Purview portal, the EXTRACT usage right is displayed as **Copy and extract content(EXTRACT)**. For example, the default permission level selected is **Editor**, where you see **Copy and extract content(EXTRACT)** is included. As a result, content protected with this encryption configuration can be returned by Copilot and agents



If you select **Custom** from the dropdown box, and then **Full control(OWNER)** from the list, this configuration will also grant the EXTRACT usage right.

> ⓘ **Note**



The person applying the encryption always has the EXTRACT usage right, because they are the Rights Management owner. This special role automatically includes all usage rights and some other actions, which means that content a user has encrypted themselves is always eligible to be returned to them by Microsoft 365 Copilot, Microsoft 365 Copilot Chat, and agents. The configured usage restrictions apply to other people who are authorized to access the content.

Alternatively, if you select the encryption configuration to let users assign permissions, for Outlook, this configuration includes predefined permissions for Do Not Forward and Encrypt-Only. The Encrypt-Only option, unlike Do Not Forward, does include the EXTRACT usage right.

When you select custom permissions for Word, Excel, and PowerPoint, users select their own permissions in the Office app when they apply the sensitivity label. There are currently two versions of the dialog box. In the older version, they're informed that from the two selections, **Read** doesn't include the permission to copy content, but **Change** does. These references to copy refer to the EXTRACT usage right. If the user selects **More Options**, they can add the EXTRACT usage right to Read by selecting **Allow users with read access to copy content**.

In the latest version of the dialog box, **Read** and **Change** is replaced with permission levels where the descriptions that state copy isn't allowed won't include the EXTRACT usage right. The permission levels that do include EXTRACT are **Editor** and **Owner**. For example:

> **Tip**
>
> If you need to check whether a document you're authorized to view includes the EXTRACT usage right, open it in the Windows Office app and customize the status bar to show **Permissions**. Select the icon next to the sensitivity label name to display **My Permission**. View the value for **Copy**, which maps to the EXTRACT usage right, and confirm whether it displays **Yes** or **No**.
>
> For emails, if the permissions aren't displayed at the top of the message in Outlook for Windows, select the information banner with the label name, and then select **View Permission**.

Copilot and agents honor the EXTRACT usage right for a user, however it was applied to the content. Most times, when the content is labeled, the usage rights granted to the user match

those from the sensitivity label configuration. However, there are some situations that can result in the content's usage rights being different from the applied label configuration:

- The sensitivity label is applied after usage rights are already applied
- Usage rights are applied after a sensitivity label has been applied

For more information about configuring a sensitivity label for encryption, see Restrict access to content by using sensitivity labels to apply encryption.

For technical details about the usage rights, see Configure usage rights for the Azure Rights Management service.

Information protection considerations for Channel Agent in Teams

Channel Agent in Teams uses sensitivity labeled information to answer user questions that might be derived from its channel files in SharePoint, channel messages and meetings, and standard meetings. For these sensitivity labels, they have many of the same information protection considerations as those listed in the previous section for Microsoft 365 Copilot. For example:

- The highest priority label is displayed in the chat and is used for label inheritance when new AI-generated content is created.
- The content from items encrypted with user-defined permissions and Double Key Encryption isn't accessible.
- Sensitivity labels applied to the channel from the labels' groups and sites configuration aren't used by Channel Agent in Teams.

However, unlike sensitivity labels in Microsoft 365 Copilot:

- Although Channel Agent in Teams honors the EXTRACT permission like Copilot does for the requesting user, the permissions aren't checked for all users in the channel. As a result, Channel Agent could summarize the content of items that one or more users in the channel don't have permissions to open. The requesting user is warned of this risk and administrators have the ability to turn off Channel Agent in Teams.
- You can't prevent Channel Agent from summarizing labeled files that are identified by a Microsoft Purview Data Loss Protection policy.
- You can't prevent users from copying chat responses from Channel Agent or prevent these responses from being used by another channel agent in Teams channels.
- Information barriers aren't supported for Channel Agent and as a result, these it might return information that crosses barriers.

- Channel Agent in Teams isn't supported with Microsoft Purview Customer Key.

Compliance management considerations for Microsoft 365 Copilot

Compliance management for interactions with Microsoft 365 Copilot and agents extend across the following apps: Word, Excel, PowerPoint, Outlook, Teams, Loop and Copilot Pages, Whiteboard, OneNote, and Microsoft 365 Copilot Chat (formerly Business Chat, Graph-grounded chat, and Microsoft 365 Chat).

> ⓘ **Note**
>
> Compliance management for Microsoft 365 Copilot Chat includes prompts and responses to and from the public web when users are signed in and select the **Work** option rather than **Web**.

Compliance tools identify the source Microsoft 365 Copilot interactions by the name of the app. For example, **Copilot in Word**, **Copilot in Teams**, and **Microsoft 365 Chat** (for Microsoft 365 Copilot Chat).

Before your organization uses Microsoft 365 Copilot, make sure you're familiar with the following details to support your compliance management solutions:

- The audit data is designed for data security and compliance purposes, and provides comprehensive visibility into Microsoft 365 Copilot interactions for these use cases. For example, to discover data oversharing risks or to collect interactions for regulatory compliance or legal purposes. It's not intended to be used as the basis for Copilot usage reporting.

  > ⓘ **Note**
  >
  > Any aggregated metrics that you build on top of this audit data such as "prompt count" or "active user count" might not be consistent with the corresponding data points in the official Copilot usage reports provided by Microsoft. Microsoft can't provide guidance on how to use audit log data as the basis for usage reporting, nor can Microsoft guarantee that aggregated usage metrics built on top of audit log data will match similar usage metrics reported in other tools.

To access accurate information about Copilot usage, use one of the following reports: the **Microsoft 365 Copilot usage report** in the Microsoft 365 Admin Center or the **Copilot Dashboard** in Viva Insights.

- Auditing captures the Microsoft 365 Copilot activity of search, but not the actual user prompt or response. For this information, use eDiscovery. Or from Microsoft Purview Data Security Posture Management for AI, use **AI interaction** from the **Activity explorer** page.
- Admin-related changes for auditing Copilot aren't yet supported.
- Device identify information isn't currently included in the audit details.
- Retention policies for Copilot interactions don't inform users when messages are deleted as a result of a retention policy.

App-specific exceptions:

- **Microsoft 365 Copilot in Teams**:
  - If transcripts are turned off, the capabilities for auditing, eDiscovery, and retention aren't supported
  - If transcripts are referenced, this action isn't captured for auditing
  - For Microsoft 365 Copilot Chat, Copilot currently can't retain as cloud attachments, referenced files that it returns to users. Files referenced by users are supported to be retained as cloud attachments.

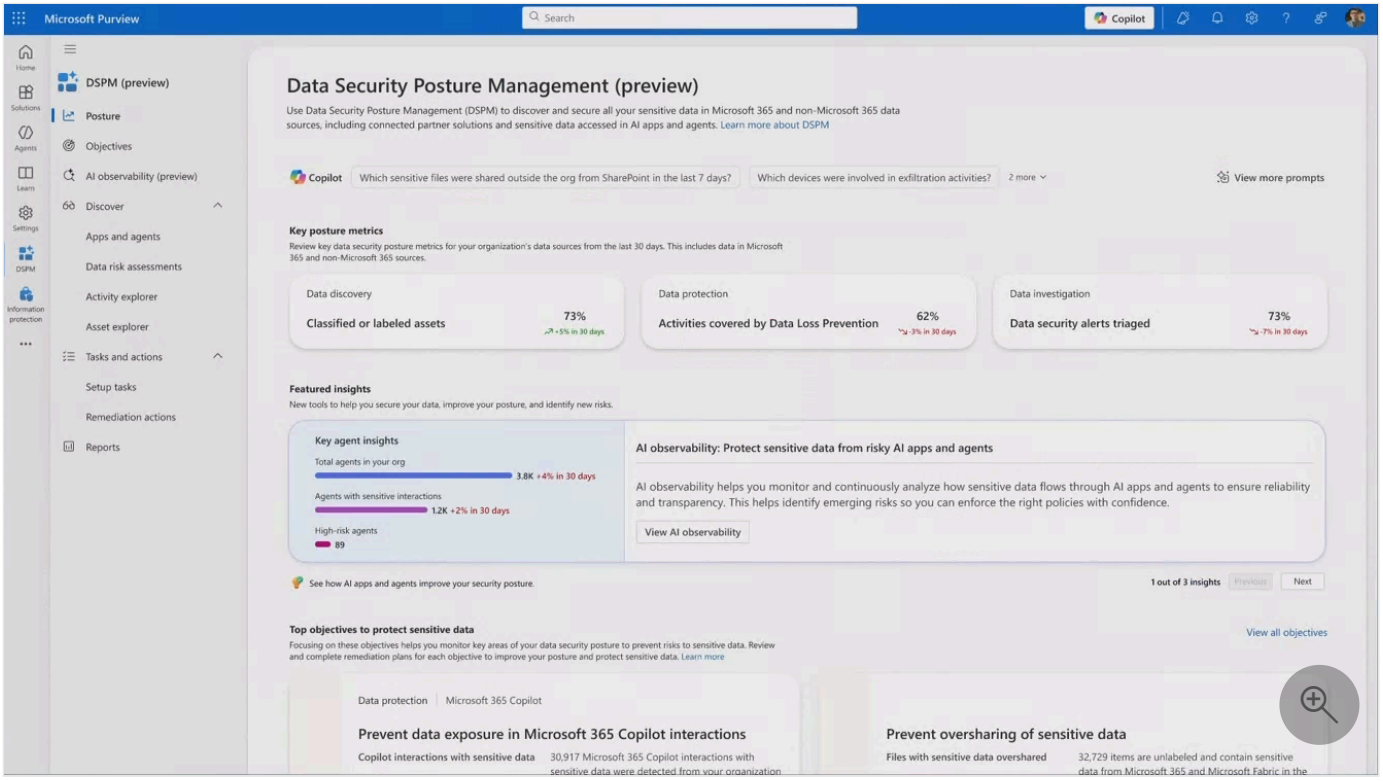
Learn about Data Security Posture Management

> *Microsoft Purview service description*

> **Note**
>
> This documentation is for the **current** version of Data Security Posture Management that expands coverage to more data sources, introduces guided workflows for proactive risk management, and streamlines data security operations so you can more confidently adopt AI across your digital estate.
>
> Most new features will be added to this version only but you can still access the previous versions and their documentation:
>
> - DSPM for AI (classic)
> - DSPM (classic)



Microsoft Purview Data Security Posture Management (DSPM) helps organizations discover, protect, and investigate sensitive data risks across their digital estate. This solution provides unified visibility and control for both traditional applications and AI apps and agents, supporting data governance across Microsoft 365, Azure, Fabric, and integrated third-party SaaS platforms. Monitor, assess, and remediate data risks, regardless of where sensitive data resides.

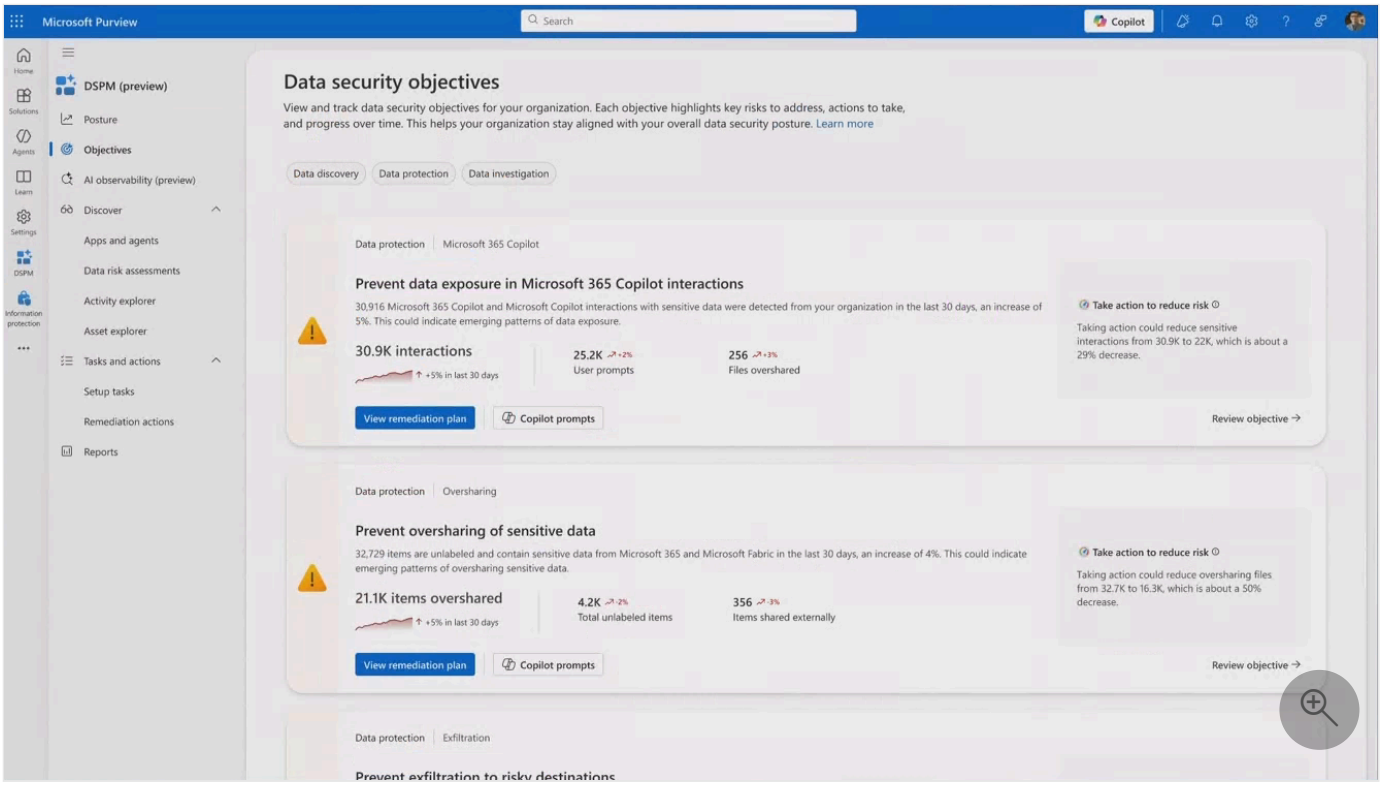
Instead of focusing on infrastructure or endpoints, Data Security Posture Management centers on the data itself—identifying where it resides, who can access it, how it's used, and whether it's adequately protected. This is especially important as data becomes more distributed and exposed in today's AI-driven workplaces where data is constantly moving and changing, making it harder to keep track of and control.

Data Security Posture Management continuously scans your environment to identify sensitive data, assess risk, and recommend actions to reduce exposure. It consolidates insights from the Microsoft Purview solutions data loss prevention (DLP), Insider Risk Management, information protection with sensitivity labels, and Data Security Investigations. These insights provide a single view for monitoring data risks, policy coverage, and posture trends. This version of Data Security Posture Management extends coverage to third-party SaaS and IaaS platforms, such as Google

Cloud Platform, Snowflake, and Databricks, and integrates with partner solutions such as Varonis, Cyera, BigID, and OneTrust for comprehensive risk insights.

Dedicated dashboards and metrics monitor risks associated with AI apps and agents. AI observability enables you to track agent-specific activities, such as oversharing, exfiltration, and unusual access patterns, across both Microsoft and third-party environments. Enhanced reporting provides advanced filtering and customizable views, supporting granular analysis of sensitive data usage, DLP activity, and posture trends. The dashboards and reports can be tailored to align with your organization's compliance requirements and operational priorities. Audit logs and activity explorer features help track interactions with AI apps and agents, supporting compliance investigations and incident response. Integrated investigation and forensics tools support rapid incident response and root cause analysis for data security events.

These insights help uncover shadow data, classify sensitive information, analyze access patterns, and highlight risks. The unified approach replaces the need for multiple solutions and manual audits, answering the four practical questions:



- What data do we have?
- Where is it stored?
- Who can access it?
- How is it protected?

When these questions are addressed, Data Security Posture Management can automate remediation steps, such as removing public sharing links or applying data loss prevention

policies, to help prevent incidents before they happen. Investigation, alerting, analytics, and reporting are all integrated, supporting a layered security approach. Key metrics are tracked over time, supporting continuous improvement of your organization's data security posture.

Data security objectives

New in this version of Data Security Posture Management, after the initial setup tasks, you see **Data security objectives** displayed as prominent, selectable cards or modules. They're also available in context from the initial **Posture** page. Each security objective represents a specific security goal, such as **Prevent data exposure in Microsoft 365 Copilot and Microsoft Copilot interactions**, **Prevent oversharing of sensitive data**, **Prevent exfiltration to risky locations**, and **Discover sensitive data in your organization**.

Selecting each one guides you through an end-to-end workflow by grouping together the most relevant Microsoft Purview solutions, such as information protection, data loss prevention (DLP), Insider Risk Management, and eDiscovery. As a result, you can focus on achieving specific data security outcomes rather than navigating separate solutions. Each **Outcome** card displays key metrics, such as the percentage of data covered by policies, number of risky sharing incidents, or improvements over time. This information lets you quickly see your current security posture and track progress as you remediate risks.

Within each outcome, you see suggested prioritized actions, such as applying sensitivity labels, configuring DLP policies, or investigating alerts, all tailored to your organzation's data. You can

take action directly from the workflow, such as remediating oversharing, configuring one-click policies, or launching investigations into suspicious activity. Reporting and analytics are also organized by outcome, making it easier to identify and report improvements, compliance, and risk reduction.

The **Prevent exfiltration to risky destinations** objective also supports proactive AI insights powered by Data Security Investigations. When enabled, Data Security Investigations automatically creates and refreshes an investigation that continuously analyzes recently exfiltrated sensitive data across five risk categories.

Operational insights are surfaced throughout Data Security Posture Management, including:

- Impact prediction visuals and progress tracking for remediation steps
- Role-based access controls to provide granular access to features and AI content for delegated administration and compliance

How AI helps achieve data security outcomes

This version of Data Security Posture Management not only secures and governs AI apps and agents, but also uses Microsoft Security Copilot and AI agents to help secure and govern your data. This AI integration helps you more quickly identify, protect, and investigate data that resides across cloud, SaaS, on-premises, and AI environments. Data security becomes more adaptive and less reliant on manual intervention. AI analyzes access patterns, sharing behaviors, and policy gaps to surface actionable risks. It can also detect unusual activity, such as excessive sharing or suspicious downloads, and prioritize incidents that seem to need immediate attention.

You're always in control of your data and under your guidance, AI agents can take direct action on detected risks, such as removing public sharing links, applying DLP policies, or revoking permissions. To streamline investigations, AI-driven triage agents review alerts from the DLP and insider risk management solutions, filtering out noise and highlighting the most critical threats. You review, approve, or customize automated actions taken by AI agents, and these actions are always audited. Use the **View agent activity** options throughout the data security objectives for easy access to the agents' activity.

For example, the proactive AI insights feature uses Data Security Investigations to automatically analyze exfiltrated data and surface risk counts by category on the exfiltration objective card, without requiring manual investigation creation.

These AI capabilities from Data Security Posture Management help ensure that sensitive data is governed, labeled, and monitored, with streamlined management. For more information:

- How AI is used within Data Security Posture Management, see Application card: Microsoft Purview Data Security Posture Management
- For the best experience using Security Copilot prompts, see Tips for custom Security Copilot prompts in Data Security Posture Management

How to use Data Security Posture Management

To get started with Data Security Posture Management, use the Microsoft Purview portal. You need an account that has appropriate permissions for security and compliance management, such as an account that's a member of the Entra **Compliance Administrator** role, or the **Microsoft Purview Compliance Administrator** role group. Some Data Security Posture Management activities need additional permissions, such as the Data Security Viewer role to use Security Copilot. For more information, see Permissions for Data Security Posture Management.

If you're new to Data Security Posture Management, the following steps provide a recommended walkthrough.

1. Sign in to the Microsoft Purview portal > **Solutions** > **DSPM**.

   Don't confuse this with the previous versions, that are now named **Data Security Posture Management (classic)** and **DSPM for AI (classic)**.

2. With the first-time use of DSPM, you're prompted to accept some initial setup tasks if they're not already turned on for your tenant. Allow a day or so before you start to see data from your tenant that you can take action on.

   In the meantime, watch the Microsoft Mechanics video, New Data Security Posture Management for an overview introduction with same sample data to see how you might use the following key pages from DSPM to discover, protect, and investigate sensitive data:

   - **Posture**: The dashboard that lets you immediate interact with Security Copilot with suggested prompts, or work your way down the key posture metrics, top objectives to address based on risk, a snapshot of data use across your data estate, and a 30-day trending graph for your organization's data security posture.

   - **Objectives**: Data security objectives to help you address data security risks that have been identified for your organization, each with a remediation plan that includes one-click policies and recommended actions.

   - **AI observability**: An inventory of all AI apps and agents (including recently released Microsoft Agent 365) with activity in the last 30 days, how many are high risk and the

total with sensitive interactions, with a breakdown of individual agents and policies to govern them.

- **Asset explorer**: Use the **Agent** tab for the Data Security Posture Agent, and the **Standard** tab to see a unified view across your organization of unlabeled or classified data by workload, filtered by Microsoft and non-Microsoft locations. Microsoft locations currently include Microsoft 365 only. Non-Microsoft locations are made possible by integration with partner solutions.

- **Reports**: To help you track sensitive data usage and labeling, policy usage, and risky behavior of users and AI agents.

- **Setup tasks**: To identify and complete configuration steps independently from the security objectives. They include, in preview, setting up Microsoft Sentinel data lake to integrate with partner solutions for non-Microsoft data sources, such as Google Cloud Platform and Snowflake.

3. Explore the following DSPM pages that aren't directly covered in the video:

   - **Discover** > **Apps and agents**: To view a dashboard of AI apps and their agents that have been used across your organization, although it doesn't include Agent 365 (use the **AI observability** page, instead). For the top 20 most recently used agents, view details about sensitive data that they accessed and how they're protected by policies from Microsoft Purview.

   - **Discover** > **Activity explorer**: To understand activity related to content that contains sensitive information or has sensitivity labels applied. Use the **AI activities** tab to see data specific to AI interactions, such as when a user browsed to a generative AI site, the prompts and responses and if they contained sensitive information, and when a data loss prevention rule was matched during one of these interactions. For more information about these events, see Activity explorer events in Data Security Posture Management.

   - **Discover** > **Data risk assessments**: To help prevent oversharing of sensitive data in your organization with the default or custom assessments that identify and fix potential data oversharing risks. For more information, see Prevent oversharing with data risk assessments from Data Security Posture Management.

   - **Tasks and actions** > **Remediation actions**: To identify and create automatic policies independently from the initial setup tasks and security objectives. Most of these

policies originate from the previous version, DSPM for AI. For more information about them, see:

- Default policies for data discovery using Data Security Posture Management for AI
- Default policies from data security to help you protect sensitive data used in generative AI

If you're familiar with the previous versions that are now named DSPM for AI (classic) and DSPM (classic), you might find it helpful to refer to Find familiar tasks that you did in DSPM for AI or in DSPM.

Find familiar tasks that you did in DSPM for AI or in DSPM

> *Microsoft Purview service description*

> **Note**
>
> This documentation is for the **current** version of Data Security Posture Management that expands coverage to more data sources, introduces guided workflows for proactive risk management, and streamlines data security operations so you can more confidently adopt AI across your digital estate.
>
> Most new features will be added to this version only but you can still access the previous versions and their documentation:
>
> - DSPM for AI (classic)
> - DSPM (classic)

Microsoft Purview Data Security Posture Management (DSPM) for AI, and Microsoft Purview Data Security Posture Management (DSPM), have converged into a single, central solution. This unified version helps you more easily discover, protect, and investigate your data by using security and governance solutions from Microsoft Purview.

Many of tasks that you used to do in previous versions are now embedded in the context of data security objectives, although they can still be accessed independently. Data security objectives are new in Data Security Posture Management, and you find them front and center with **DSPM** > **Objectives**.

Data security objectives focus on the business outcomes you want to achieve. Choose an objective and we recommend a combination of Microsoft Purview solutions and specific actions to help you meet that outcome, with as few clicks as possible to achieve it. For more information, see Objectives and outcomes.

To help you navigate the new Data Security Posture Management for the tasks you used to do in previous versions, use the following tables.

Tasks that you did in DSPM for AI

Expand table

Task in DSPM for AI	Navigation for the new Data Security Posture Management
Setup tasks that include auditing and extending your insights for data discovery	1. When you first open **DSPM** > **Getting Started** 2. **DSPM** > **Actions** > **Setup tasks**
Recommendations for AI apps	**DSPM** > **Actions** > **Remediation actions**
Microsoft 365 Copilot overview page	**DSPM** > **Reports** > **Microsoft 365 Copilot**
Reports to see results of one-click policies	**DSPM** > **Reports**
Policies for AI apps	**DSPM** > **Reports** > **Policies with AI workloads**
Apps and agents	**DSPM** > **Discover** > **Apps and agents** See also: **AI observability** that includes more information and support for Agent 365
Activity explorer	**DSPM** > **Discover** > **Activity explorer** > **AI activities** tab
Data risk assessments	**DSPM** > **Discover** > **Data risk assessments**

Tasks that you did in DSPM

Prevent oversharing with data risk assessments from Data Security Posture Management

> *Microsoft Purview service description*

> **Note**
>
> This documentation is for the **current** version of Data Security Posture Management that expands coverage to more data sources, introduces guided workflows for proactive risk management, and streamlines data security operations so you can more confidently adopt AI across your digital estate.
>
> Most new features will be added to this version only but you can still access the previous versions and their documentation:
>
> - DSPM for AI (classic)
> - DSPM (classic)

Data risk assessments from Data Security Posture Management help you identify and fix potential data oversharing risks in your organization. Because of the power and speed AI can proactively surface content that might be obsolete, over-permissioned, or lack governance controls, generative AI amplifies the problem of oversharing data. Use data risk assessments to both identify and remediate issues.

You can access data risk assessments from the Microsoft Purview portal > **DSPM** > **Discover** > **Data risk assessments**, and insights from these assessments are surfaced from the security objective **Prevent oversharing of sensitive data**.

Default data risk assessments

For oversharing insights in SharePoint and OneDrive, use the **Microsoft 365** tab, and the **Fabric** tab for items in Fabric workspaces.

Microsoft 365

A default data risk assessment automatically runs weekly for the top 100 SharePoint sites based on usage in your organization, and you might have already run a custom assessment as one of the recommendations. However, come back regularly to this option to check the latest weekly results of the default assessment and run custom assessments when you want to check for different users or specific sites. After a custom assessment has run, wait at least 48 hours to see the results that don't update again. You'll need a new assessment to see any changes in the results.

The **Default assessment** displays at the top of the page with a quick summary, such as the total number of items found, the number of sensitive data detected, and the number of links sharing data with anyone. The first time the default assessment is created there's a 4-day delay before results are displayed.

After you select **View details** for more in-depth information, from the list, select each site to access the flyout pane that has tabs for **Overview**, **Identify**, **Protect**, and **Monitor**. Use the information on each tab to learn more, and take recommended actions. For example:

Use the **Identify** tab to identify how much data has been scanned or not scanned for sensitive information types, with an option to initiate an on-demand classification scan as needed.

Use the **Protect** tab to select options to remediate oversharing, which include:

- **Restrict access by label**: Use Microsoft Purview Data Loss Prevention to create a DLP policy that prevents Microsoft 365 Copilot and agents from summarizing data when it has sensitivity labels that you select. For more information about how this works and supported scenarios, see Learn about using Microsoft Purview Data Loss Prevention to protect interactions with Microsoft 365 Copilot and Copilot Chat.
- **Restrict all items**: Use SharePoint Restricted Content Discovery to list the SharePoint sites to be exempt from Microsoft 365 Copilot. For more information, see Restrict discovery of SharePoint sites and content.
- **Create an auto-labeling policy**: When sensitive information is found for unlabeled files, use Microsoft Purview Information Protection to create an auto-labeling policy to automatically apply a sensitivity label for sensitive data. For more information about how to create this policy, see How to configure auto-labeling policies for SharePoint, OneDrive, and Exchange.
- **Create retention policies**: When content hasn't been accessed for at least 3 years, use Microsoft Purview Data Lifecycle Management to automatically delete it. For more

information about how to create the retention policy, see Create and configure retention policies.

Use the **Monitor** tab to view the number of items in the site shared with anyone, shared with everyone in the organization, shared with specific people, and shared externally. Select **Start a SharePoint site access review** for information how to use the SharePoint data access governance reports.

Custom data risk assessments

To create your own custom data risk assessment, select **Create custom assessment** to identify potential oversharing issues for all or selected users, the data sources to scan, and run the assessment.

> **Note**
>
> Microsoft 365 custom assessments optionally support item-level scanning with remediation actions when you complete a one-time authentication process. To specify the required settings, you must have a registered Entra application. For more information about the Entra application, see Prerequisites for Microsoft 365 item-level scanning for data risk assessments.
>
> Select **Item-level** on the **Scan level** page, and then **Authenticate** to specify the Entra application information.

This data risk assessment is created in the **Custom assessments** category. Wait for the status of your assessment to display **Completed**, and select it to view details. To rerun a custom data risk assessment, and to see results after the 30-day expiration, use the duplicate option to create a new assessment with the same selections.

Item-level scanning and remediation for items that are potentially overshared is applicable to Microsoft 365 only, and currently restricted to SharePoint sites. This scan identifies items as potentially overshared if they have a sharing link for external or anonymous users, and also shows any applied sensitivity label and the owner of each item.

When the scan is complete, open the custom assessment and view item-level insights from the **Potentially overshared items** tab or the **View items** button from the **Potentially overshared**

items banner. The following remediation actions can be taken on the identified potentially overshared items:

- **Resolve**, for example if you decide the item isn't at risk of oversharing.
- **Apply sensitivity label** for items that are identified as currently unlabeled or should have a different sensitivity label.
- **Notify** the site owner with an email notification (not customizable).
- **Remove sharing link** to remove the existing sharing link so it can no longer be used to access the item. This is an action to be used sparingly because it could prevent people from accessing the item legitimately. In this scenario, the site owner or item owner must then set a less permissive sharing link type for authorized users. If you haven't already, consider configuring sensitivity labels for a default sharing link.

The email notification contains information and instructions about the potentially overshared items in the site. It also contains options for them to go to the SharePoint site to manage access to the items from there, or to the Microsoft Purview portal for a read-only view of the item-level scan results that only show items and sites that they own.

> **Tip**
>
> Both the default and custom data risk assessments provide an **Export** option that let you save and customize the data into a choice of file formats (Excel, CSV, JSON, TSV).

Limits for Microsoft 365:

- A maximum of 200,000 items per location, which applies to both a custom data risk assessment and a default data risk assessment. The count of files reported might not be accurate when there are more than 100,000 files per location.
- OneDrive currently isn't supported for item-level scanning.
- A current maximum of 10 SharePoint sites for item-level scanning.

Setup tasks for Data Security Posture Management

> *Microsoft Purview service description*

> **Note**
>
> This documentation is for the **current** version of Data Security Posture Management that expands coverage to more data sources, introduces guided workflows for proactive risk management, and streamlines data security operations so you can more confidently adopt AI across your digital estate.
>
> Most new features will be added to this version only but you can still access the previous versions and their documentation:
>
> - DSPM for AI (classic)
> - DSPM (classic)

When you first access Data Security Posture Management (DSPM) for your tenant, you see an initial setup task for **Audting and analytics** that's required to see meaningful data that you can take action on. Optionally, create collection policies to capture AI interactions. Other setup tasks can be revealed in the context of data security objectives.

All setup tasks can found from **DSPM** > **Actions** > **Setup tasks**. They include step-by-step instructions, status, estimated time to complete, and other helpful information such as any impact to users and links to additional information.

Some of these setup tasks include creating preconfigured policies with just one click so you can more quickly gain insights and protect your data. These one-click policies originated from the previous version, and so have the prefix of **DSPM for AI**. For more information about these policies, see the DSPM for AI documentation, One-click policies from Data Security Posture Management for AI.

> **Note**

Although not listed as setup tasks, you might also want to check for **prerequisites**, such as permissions, and other requirements for specific tasks.

Activate Microsoft Purview Audit

This setup task is likely already complete because auditing is on by default for new tenants, and checked when you first run Data Security Posture Management. If you need more information, see Learn about auditing solutions in Microsoft Purview and Turn auditing on or off.

Extend insights into sensitive data in AI interactions

Create a one-click policy that helps you gain visibility into sensitive data shared wtih AI apps through network activity.

Extend insights for data discovery

Create one-click policies for collecting information about users visiting third-party generative AI sites and sending sensitive information to them.

Install Microsoft Purview browser extension

The Microsoft Purview browser extension must be deployed to Windows users to discover visits to third-party generative AI sites by using an Insider Risk Management policy. The browser extension is also required for endpoint DLP policies on Windows when you use Chrome.

Integrate with partner solutions

This options is in preview.

Set up Microsoft Sentinel data lake to integrate partner solutions and centralize security posture monitoring across all data sources. To see the available partner solutions and then select one from this task, you must first connect to the Microsoft Sentinel content hub. Initial partners include Varonis (for Salesforce), Cyera (for Snowflake), BigID (for Databricks), and OneTrust (for Google Cloud Platform).

Onboard devices to Microsoft Purview

Devices must be onboarded to Microsoft Purview for:

- Gaining visibility into sensitive information that's shared with third-party generative AI sites. For example, a user pastes credit card numbers into ChatGPT.
- Applying endpoint DLP policies to warn or block users from sharing sensitive information with third-party generative AI sites. For example, a user identified as elevated risk in Adaptive Protection is blocked with the option to override when they paste credit card numbers into ChatGPT.

Protect your data with sensitivity labels

Create default sensitivity labels and sensitivity label policies, if they don't already exist in your tenant.

Secure interactions from enterprise AI apps

Create a one-click policy that captures prompts and responses for regulatory compliance from enterprise AI apps, such as Chat GPT Enterprise and AI apps connected through Microsoft Entra or Azure AI Foundry, so they can be managed in Microsoft Purview solutions like eDiscovery, Data Lifecycle Management, and more.

Secure interactions in Microsoft Copilot experiences

Create a one-click policy that captures prompts and responses for data security posture and regulatory compliance from Copilot in Fabric and Security Copilot.

Set up pay-as-you-go billing for data storage

For some options you must set up pay-as-you-go billing for your organization. When this billing model is applicable for specific configurations, you'll see notifications and instructions in the UI.

You might find it helpful to use the **Usage center** to help you understand and manage your usage. For more information, see Manage pay-as-you-go and per-user licensing usage.

Last updated on 05/01/2026

Permissions for Data Security Posture Management

> *Microsoft Purview service description*

> **Note**
>
> This documentation is for the **current** version of Data Security Posture Management that expands coverage to more data sources, introduces guided workflows for proactive risk management, and streamlines data security operations so you can more confidently adopt AI across your digital estate.
>
> Most new features will be added to this version only but you can still access the previous versions and their documentation:
>
> - DSPM for AI (classic)
> - DSPM (classic)

Members of your security and compliance teams who are responsible for managing AI apps in Microsoft Purview Data Security Posture Management need appropriate permissions when they sign in to the Microsoft Purview portal.

Roles and role groups that can view, create, and edit in Data Security Posture Management:

- **Microsoft Entra Compliance Administrator** role
- **Microsoft Entra Global Administrator** role
- **Microsoft Purview Compliance Administrator** role group

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Roles and role groups that can view-only in Data Security Posture Management:

- **Microsoft Purview Security Reader** role group
- **Purview Data Security AI Viewer** role
- **Data Security Viewers** role group and **Data Security Viewer** role
- AI Administrator role from Entra
- **Purview Data Security AI Content Viewer** role for AI interactions only

To help you assign the right permissions to users, use the following guidance, depending on the portal you're using:

- Permissions in the Microsoft Purview portal
- Assign Microsoft Entra roles to users
- Permissions in Exchange Online

Use the following table to understand the detailed permissions for different activities in Data Security Posture Management.

Permissions by activities

✓: Supported. The role or role group have permissions to do the specified activities.

✕: Not supported. The role or role group don't have permissions to do the specified activities.

Expand table

[1] Includes Microsoft Purview Security Reader role group, Microsoft Purview Data Security AI Viewer role, the AI Administrator role from Entra, and the Data Security Viewers role group and Data Security Viewer role.

[2] The activities that display AI data security information, for view-only. For example, AI data from objectives such as exfiltration to AI apps and prevent oversharing, with their AI-related policies and metrics. Includes Microsoft Purview Data Security AI Viewer role and the AI Administrator role from Entra.

Custom role groups

Instead of granting access to Data Security Posture Management by using the built-in role groups, you can grant access by including the Microsoft Purview Compliance Administrator role in a custom role group. For read-only permissions, include the the Microsoft Purview Security Reader role, the Purview Data Security AI Viewer role, or the AI Administrator role from Entra.

If a custom role group includes the Microsoft Purview Compliance Administrator role, the user has the same access to Data Security Posture Management as the Microsoft Purview Compliance Administrator role group, except for the following:

- Create, view, update, and delete policies for insider risk management and communication compliance

If a custom role group includes the Microsoft Purview Security Reader role, the Purview Data Security AI Viewer role, or the AI Administrator role, the user has the same access to Data Security Posture Management the Microsoft Purview Security Reader role group, except for the following:

- View information protection policies

Considerations for Microsoft Purview Data Security Posture Management

> *Microsoft Purview service description*

> **Note**
>
> This documentation is for the **current** version of Data Security Posture Management that expands coverage to more data sources, introduces guided workflows for proactive risk management, and streamlines data security operations so you can more confidently adopt AI across your digital estate.
>
> Most new features will be added to this version only but you can still access the previous versions and their documentation:
>
> - DSPM for AI (classic)
> - DSPM (classic)

For the most part, Microsoft Purview Data Security Posture Management is easy to use and self-explanatory, guiding you through setup and configuration tasks to help secure and govern your data. Use this section to complement that information and provide additional details that you might need.

Prerequisites for Data Security Posture Management

Use this section to identify prerequisites that aren't included in setup tasks.

- You have a supporting license for this Microsoft Purview solution, and your region is supported. For more information, see the Microsoft Purview service description.
- You have the right permissions.
- For Microsoft 365 Copilot and agents, users are assigned a license for Microsoft 365 Copilot.
  - For Copilot in Fabric and Security Copilot:
    - The enterprise version of Microsoft Purview data governance, to support the required APIs.

    - A collection policy, such as the one created from the setup task **Secure interactions in Microsoft Copilot experiences**.

- For monitoring interactions and applying DLP policies to other AI apps in Edge:
    - An Edge configuration policy is required to activate the Microsoft Purview integration in Edge. For configuration information, see Activate your DLP policy in Microsoft Edge.

- For Fabric data risk assessments, shared with DSPM for AI (classic): Configuration in both Entra and the Fabric admin portal.

- For Microsoft 365 custom data risk assessments and item-level scanning, shared with DSPM for AI (classic): Configuration in the Entra admin portal.

- For Entra-registered AI apps, they are integrated with the Microsoft Purview SDK to support all the Microsoft Purview capabilities.

- For Security Copilot promptbooks and agents that support data discovery and remediation for sensitive data, Enable Security Copilot for Purview Audit and DSPM Solutions.

Support for administrative units in Data Security Posture Management

When your tenant is configured for administrative units, restricted administrators who view policies, reports, activity explorer or asset explorer see data for users in their assigned administrative units only.

Because the one-click policies apply to all users, restricted administrators can't create these policies. You must be an unrestricted administrator to create one-click policies.

Activity explorer events in Data Security Posture Management

Use the following information to help you understand the events you might see in the activity explorer from Data Security Posture Management and the **AI activities** tab. References to a generative AI site can include Microsoft 365 Copilot, Microsoft 365 Copilot Chat, agents, other Microsoft copilots, and third-party AI sites.

Expand table

Event	Description
AI interaction	User interacted with a generative AI site. Details include the prompts and responses, except for unmanaged AI apps in Edge where text prompts only are included. For Microsoft 365 Copilot and Microsoft 365 Copilot Chat, this event requires auditing to be turned on. For Copilot in Fabric and Security Copilot, and for non-Copilot AI apps, prompts and responses require a collection policy with content capture selected to capture these interactions.
AI website visit	User browsed to a generative AI site.
DLP rule match	A data loss prevention rule was matched when a user interacted with a generative AI site. Includes DLP for Microsoft 365 Copilot.
Sensitive info types	Sensitive information types were found while a user interacted with a generative AI site. For Microsoft 365 Copilot and Microsoft 365 Copilot Chat, this event requires auditing to be turned on but doesn't require any active policies.

Known issues:

- The **AI interaction** event doesn't always display text for the prompt and response. Sometimes, the prompt and response spans consecutive entries. Other scenarios can include:
  - Microsoft Facilitator AI-generated notes, no prompt or response is displayed
  - When a user doesn't have a mailbox hosted in Exchange Online, no prompt or response is displayed
- The **Sensitive info types detected** event doesn't display the user risk level.
- For Microsoft Facilitator AI-generated notes, **AI interaction** events can't be linked to **Sensitive info types detected** events.
- For collection policies, no prompt or response is displayed if the option to capture content isn't selected in the policy. For example, the one-click policy **DSPM for AI - Detect sensitive info shared with AI via network** doesn't select this option when the policy is automatically created, but you can manually edit the policy and select this option after the policy is created.

Data updates paused for inactive tenants

To optimize resources,Microsoft pauses the background processing that refreshes Microsoft 365 data in Data Security Posture Management when a tenant hasn't accessed the solution for more than 60 days. While paused, you won't see any information for Microsoft 365 data in places such as in asset explorer, the data snapshot, and the data scanned posture metric.

Processing automatically resumes when you or another admin for your tenant returns to Data Security Posture Management. Data begins displaying again, although you can expect an initial delay. You might see an in-product message to indicate that updates were paused due to inactivity. This message disappears after processing resumes and no action is required from you to restart the updates.

Using the Data Security Posture Agent

The Data Security Posture Agent is currently in preview.

This agent acts as a quick, intent-based search mechanism for sensitive data. It's designed for pre-investigation checks rather than formal cases that still require other Microsoft Purview solutions, such as eDiscovery, audit, and Data Security Investigations. It uses natural-language search and doesn't rely on keywords, sensitive information types, or classifiers to search across files in SharePoint and OneDrive, messages in Teams, emails in Exchange, and interactions with Copilot.

The Data Security Posture Agent is exclusive to the current version of Data Security Posture Management and isn't available in Data Security Posture Management (classic). Before you can use it, you must first activate and configure it. For more information, see Get started with the Microsoft Purview Posture Agent in Data Security Posture Management.

Run searches from **DSPM** > **Discover** > **Asset explorer** > **Agent** tab. As with all Security Copilot agents, you can use this agent with preconfigured prompts and custom prompts. Before you run a custom prompt, you must first select **Add data sources**. In the flyout pane, enter at least 3 characters to search for users, groups, or sites. If you specify a user or group, the agent automatically selects the related mailbox, OneDrive account, or Sharepoint site. Keep in mind the following:

- For more efficient and faster processing, use a restricted search rather than tenant-wide searches.
- If you don't specify a time period for your prompt, search results are returned for the last 7 days.
- Search supports content up to 1 GB of data, but not metadata. For example, the agent can search all files containing financial information but not all files containing financial information and shared externally by a specific user in the last 7 days.

When a prompt is processed, you see a count of items matched against each item with any applied sensitivity labels and its risk level. The risk level is based on how closely related the match

of the content is from the prompt provided to the agent.

The **View Insights** option provides a report that includes a summary, risk assessment, findings, labeled or unlabeled items, and the top unlabeled items. You can download this report as a Word document to share with others for further analysis.

For auditing events as a result of running this agent, see Data Security Posture Agent activities from the auditing documentation.

Tips for custom Security Copilot prompts in Data Security Posture Management

For an enhanced experience with Security Copilot in Data Security Posture Management, use the following tips for higher accuracy for your Copilot responses:

- Always include the user's UPN for questions involving a specific user.
- Always specify the complete name for the sensitive info type or label for questions that involve a specific type of sensitive info type or label.
- Clearly list the sorting criteria for questions for top users, activities, and alerts.
- Always specify the date period for questions for data in a specific date period. If you don't specify a date period, only data from the last 10 days from current date is included. The maximum lookback is 30 days from the current date.
- Put all items (classifiers or labels) in single quotes in your prompt.
- Use "/" as a separator for any path (for example, a file path) in a user prompt.
- Scope the prompt to a single intent for higher accuracy of responses. Break complex prompts into single intent questions and enter the prompts one by one.
- Make questions self-contained. Avoid referring to previous questions or responses.
- Avoid using generic terms.
- Support prompts for data security across Information Protection, DLP, Insider Risk Management, or from public documentation.

For more information about creating Security Copilot prompts, see Create effective prompts.

Application card: Microsoft Purview Data Security Posture Management

What is an Application or Platform Card?

Microsoft's Application and Platform cards are intended to help you understand how our AI technology works, the choices application owners can make that influence application performance and behavior, and the importance of considering the whole application, including the technology, the people, and the environment. Application cards are created for AI applications and platform cards are created for AI platform services. These resources can support the development or deployment of your own applications and can be shared with users or stakeholders impacted by them.

As part of its commitment to responsible AI, Microsoft adheres to six core principles: fairness, reliability and safety, privacy and security, inclusiveness, transparency, and accountability. These principles are embedded in the Responsible AI Standard, which guides teams in designing, building, and testing AI applications. Application and Platform Cards play a key role in operationalizing these principles by offering transparency around capabilities, intended uses, and limitations. For further insight, readers are encouraged to explore Microsoft's Responsible AI Transparency Report and Code of Conduct, which outline how enterprise customers and individuals can engage with AI responsibly.

Overview

Microsoft Purview Data Security Posture Management is a data security application within the Microsoft Purview portal that helps organizations discover, protect, and investigate sensitive data risks across their digital estate. Rather than focusing on infrastructure or endpoints, Data Security Posture Management centers on the data itself, identifying where it resides, who can access it, how it's used, and whether it's adequately protected. It uses AI to analyze access patterns, sharing behaviors, and policy gaps in order to surface actionable risks and recommend remediation steps.

Data Security Posture Management addresses a growing challenge in today's AI-driven workplaces: the increasing complexity and volume of data makes it difficult for security teams to maintain visibility and control. The application solves this problem by consolidating insights from multiple Microsoft Purview solutions, including data loss prevention (DLP), Insider Risk

Management, information protection with sensitivity labels, and Data Security Investigations, into a single view for monitoring data risks, policy coverage, and posture trends. This unified approach replaces the need for multiple tools and manual audits, helping administrators close data security gaps more efficiently.

Data Security Posture Management is designed to perform reliably in enterprise environments where organizations need to monitor and protect sensitive data across multiple locations. The application includes an embedded Microsoft Security Copilot experience that allows these users to ask natural language questions about their data security posture, as well as AI agents from Security Copilot that can take guided remediation actions on detected risks. For an overview introduction, see the Microsoft Mechanics video: New Data Security Posture Management.

Key terms

The following list provides a glossary of key terms related to Data Security Posture Management:

AI observability: A feature within Data Security Posture Management that provides an inventory of AI apps and agents with recent activity, showing how many are high risk and the total with sensitive interactions, along with a breakdown of individual agents and the policies governing them.

Collection policy: A policy that captures prompts and responses from AI interactions for Copilot in Fabric and Security Copilot, and for non-Copilot AI apps, so they can be managed in Microsoft Purview solutions.

Copilot interactions: Prompts and responses from Copilots and agents that Microsoft Purview supports for data security and compliance protections. Includes Microsoft 365 Copilot, Security Copilot, Copilot in Fabric, Copilot Studio.

Data loss prevention (DLP): A Microsoft Purview solution that helps prevent users from inappropriately sharing sensitive data by using content analysis techniques including keyword matching, expression evaluation, and machine learning algorithms.

Data risk assessment: An automated or custom scan that identifies and helps fix potential data oversharing risks, particularly for SharePoint sites and Fabric workspaces. Default assessments run weekly for the top 100 sites based on usage.

Data security objectives: Guided workflows within Data Security Posture Management that each represent a specific security goal, such as preventing data exposure in Copilot interactions or

preventing oversharing. Each objective groups together relevant Microsoft Purview solutions and prioritized actions.

Data Security Posture Agent: A Microsoft Security Copilot agent exclusive to the current version of Data Security Posture Management that uses natural language search across files in SharePoint, OneDrive, Teams, Exchange, and Copilot interactions. It is designed for pre-investigation checks rather than formal cases.

Insider Risk Management: A Microsoft Purview solution that uses built-in service and third-party indicators to help identify, triage, and act on potentially risky activity by users in an organization.

One-click policy: A preconfigured policy within Data Security Posture Management that can be activated with a single click to quickly gain insights and protect data, without requiring manual policy configuration.

Promptbook: A built-in sequence of prompts for Microsoft Security Copilot that helps users quickly investigate specific data security scenarios, such as risky user behavior or sensitive data protection.

Security Copilot: Microsoft Security Copilot and its agents is a generative AI-powered security solution that helps data security professionals investigate and respond to security incidents. Within Data Security Posture Management, it provides an open-ended prompt experience for asking natural language questions about data security.

Sensitivity label: A label from Microsoft Purview Information Protection that can be applied to content to define and enforce protection policies for sensitive data across clouds, apps, and devices.

Key features or capabilities

The key features and capabilities outlined here describe what Data Security Posture Management is designed to do and how it performs across supported tasks.

- **Data security posture dashboard**: The central landing page that provides immediate access to key posture metrics, top objectives to address based on risk, a snapshot of data usage across the data estate, and a 30-day trending graph of the organization's data security posture. Users can interact directly with Security Copilot through suggested prompts on this page.
- **Data security objectives with guided workflows**: Selectable cards that each represent a specific security goal, such as preventing data exposure in Copilot interactions, preventing

oversharing of sensitive data, preventing exfiltration to risky locations, and discovering sensitive data. Each objective provides an end-to-end workflow with prioritized actions, one-click policies, and progress tracking, so users can focus on achieving outcomes rather than navigating separate solutions.

- **AI observability**: An inventory of AI apps and agents with activity in the last 30 days, showing how many are high risk and the total with sensitive interactions. Provides a breakdown of individual agents, their activities, and the policies governing them, enabling administrators to monitor risks such as oversharing, exfiltration, and unusual access patterns.

- **Data risk assessments**: Automated and custom scans that identify potential data oversharing risks. Default assessments run weekly for the top 100 SharePoint sites based on usage. Custom assessments can target specific users, sites, or Fabric workspaces. Results include remediation options such as restricting access by label, creating auto-labeling policies, or creating retention policies.

- **Data security recommendations and remediation actions**: Insights and recommendations generated from processed data that help administrators create or refine DLP and Insider Risk Management policies. Includes one-click policies for quick deployment directly from the Data Security Posture Management workflow.

- **Reports and analytics**: Tracks the organization's data security posture over time with reports summarizing sensitivity label usage, DLP policy coverage, risky user behavior, and AI app activity. Enhanced reporting provides advanced filtering, customizable views, and export capabilities to support compliance requirements.

- **Activity explorer**: Provides detailed visibility into content-related activity, including AI interactions (prompts, responses, and sensitive information detected), DLP rule matches, AI website visits, and sensitive information type detections. Supports filtering by workload categories such as Copilot experiences, enterprise AI apps, and other AI apps.

- **Data Security Posture Agent**: An AI-powered agent from Microsoft Security Copilot and that uses natural language search to find sensitive data across SharePoint, OneDrive, Teams, Exchange, and Copilot interactions. It provides item counts, sensitivity label classifications, and risk-level assessments, along with exportable insight reports. This agent is designed for quick, pre-investigation checks.

- **Embedded Security Copilot experience**: An open-ended prompt experience where users can ask natural language questions about their data security posture. Includes built-in

promptbooks for risky user investigation and sensitive data protection, as well as a prompt gallery with categorized prompts for alerts, data at risk, risky users, suspicious activity, and sensitive data.

- **AI agent-driven remediation**: Under user guidance, AI agents can take direct action on detected risks, such as removing public sharing links, applying DLP policies, or revoking permissions. AI-driven triage agents review alerts from DLP and Insider Risk Management, filtering noise and highlighting critical threats. All agent actions are audited and subject to user review and approval.

Intended uses

Data Security Posture Management can be used in multiple scenarios across a variety of industries. Some examples of use cases include:

- **Monitoring data security posture across the enterprise**: A compliance officer at a financial services organization uses Data Security Posture Management to get a unified view of their sensitive data across different locations. The posture dashboard surfaces key metrics and trends, enabling the officer to quickly identify where unprotected sensitive data exists and track improvements over time. This eliminates the need to manually review multiple separate tools and dashboards.

- **Preventing oversharing before deploying Microsoft 365 Copilot**: An IT administrator preparing for a Microsoft 365 Copilot deployment runs data risk assessments to identify SharePoint sites with potentially overshared content. Data Security Posture Management surfaces sites where sensitive files have broad sharing links or lack sensitivity labels, and provides one-click remediation options such as restricting access or creating auto-labeling policies. This helps the organization reduce data exposure before AI tools begin processing that content.

- **Investigating risky user behavior with AI-assisted analysis**: A data security analyst receives an alert about a user performing unusual file-sharing activities. Using the embedded Security Copilot experience, the analyst runs the risky user investigation promptbook, which automatically analyzes the user's sensitive data activities, identifies potential exfiltration patterns, checks for anomalies, and suggests protective actions, all through a sequence of natural language prompts.

- **Governing AI app usage across the organization**: A security team at a healthcare organization uses AI observability to monitor which AI apps and agents employees are

interacting with, which of those interactions involve sensitive patient data, and whether appropriate DLP policies are in place. The team uses data security objectives to create targeted policies that prevent sensitive health information from being shared with unauthorized AI applications.

- **Responding to compliance requirements**: A compliance team at a government agency uses Data Security Posture Management reports and activity explorer to demonstrate that sensitive data is appropriately labeled, protected by DLP policies, and monitored for risky activity. The export capabilities and customizable views allow the team to generate audit-ready documentation aligned with their regulatory obligations.

- **Discovering unprotected sensitive data in new environments**: An organization just getting started with Microsoft Purview uses Data Security Posture Management to automatically scan data and user activities, gaining baseline insights and recommendations focused on unprotected data. This helps the organization quickly establish DLP, information protection, and Insider Risk Management policies without conducting deep manual analysis.

Data Security Posture Management is not intended for use as a general-purpose AI assistant, for scenarios unrelated to data security within Microsoft Purview, or for formal legal investigations (which require dedicated solutions such as eDiscovery and Data Security Investigations).

Models and training data

Data Security Posture Management leverages existing AI agents and AI functionality. As such, it's dependent on any external configuration that these provide. For example, model choice for Microsoft Security Copilot for the embedded natural language prompt experience. Data Security Posture Management also uses content analysis within Data Loss Prevention for detecting sensitive information through keyword matching, expression evaluation, and machine learning algorithms. To learn more, refer to the linked application cards and documentation.

Performance

Data Security Posture Management is designed to perform reliably in enterprise environments where organizations need to monitor and protect sensitive data across multiple locations. The application processes and correlates data from existing Microsoft Purview solutions, including DLP, Insider Risk Management, and information protection, to generate insights, recommendations, and posture metrics. Performance is optimized for organizations using supported Microsoft cloud services, and results improve as more Microsoft Purview solutions are configured and more data is available for analysis.

The application accepts text-based inputs across its features. Users interact with Data Security Posture Management through the Microsoft Purview portal interface, where they can navigate dashboards, configure policies, and run data risk assessments. The embedded Security Copilot experience accepts natural language text prompts and returns text-based responses, including data summaries, risk analysis, and recommended actions. The Data Security Posture Agent accepts natural language search queries and returns structured results, including item counts, sensitivity label classifications, and risk-level assessments, with an option to export reports as Word documents.

Data Security Posture Management supports the languages available in the Microsoft Purview portal interface. The Security Copilot experience is designed and evaluated primarily for English-language prompts and responses. Sensitive information type detection supports multiple languages as documented in the individual sensitive information type definitions. Users should be aware that performance of the natural language prompt and search features may vary when using languages other than English.

After initial setup, Data Security Posture Management requires time to process organizational data. Scanning times vary based on the size of the organization and the amount of data and activities to process, and it may take up to three days for initial processing to complete. New policies require at least 24 hours to collect data before results appear. Data risk assessments require at least 48 hours after completion before updated results are available. The Data Security Posture Agent can search up to 1 GB of content per query, and restricted searches targeting specific users or sites perform significantly faster than tenant-wide searches.

Limitations

Understanding Data Security Posture Management's limitations is crucial to determine it is used within safe and effective boundaries. While we encourage customers to leverage Data Security Posture Management in their innovative solutions or applications, it's important to note that Data Security Posture Management was not designed for every possible scenario. We encourage users to refer to either the Microsoft Enterprise AI Services Code of Conduct (for organizations) or the Code of Conduct section in the Microsoft Services Agreement (for individuals) as well as the following considerations when choosing a use case:

- **Data security scope**: The Security Copilot experience in Data Security Posture Management is designed to answer questions about data security associated with Insider Risk Management, Information Protection, and Data Loss Prevention in Microsoft Purview. All other Purview solutions are currently out of scope for Data Security Posture Management

insights. Users should direct questions outside of these areas to the appropriate solution-specific tools.

- **Data coverage**: The asset explorer Standard tab is filtered by Microsoft and non-Microsoft locations. Microsoft locations currently include Microsoft 365 only. Non-Microsoft locations are made possible by integration with partner solutions. Organizations with significant data in environments that aren't included should be aware that visibility through the asset explorer may be limited and should supplement with other tools as needed.

- **Data risk assessment volume limits**: A maximum of 200,000 items per location applies to both custom and default data risk assessments. The reported file count may not be accurate when there are more than 100,000 files per location. Organizations with very large SharePoint sites should consider running multiple targeted assessments. Additionally, OneDrive is not currently supported for item-level scanning, and custom assessments support a maximum of 10 SharePoint sites for item-level scanning.

- **Processing time requirements**: After a custom data risk assessment completes, results require at least 48 hours to become available and do not update after that point. A new assessment is needed to see changes. New policies require at least 24 hours before data appears. Users should plan ahead and avoid expecting real-time results from newly created assessments or policies.

- **Activity explorer data completeness**: The AI interaction event may not always display prompt and response text. In some cases, prompts and responses span consecutive entries. When a user does not have a mailbox hosted in Exchange Online, no prompt or response is displayed. Microsoft Facilitator AI-generated notes may not display prompts or responses. Users should be aware of these gaps when relying on activity explorer for compliance or investigative purposes.

- **Data Security Posture Agent constraints**: The agent supports content searches up to 1 GB of data but does not support metadata-based searches. If no time period is specified, results default to the last 7 days. The agent is designed for pre-investigation checks and is not a replacement for formal investigation tools such as eDiscovery, audit, or Data Security Investigations.

- **Language support**: The Security Copilot experience and the Data Security Posture Agent are designed and evaluated primarily for English-language prompts. Using other languages may result in reduced accuracy or incomplete responses. Users should exercise caution when operating outside the intended language scope.

- **Generative AI response accuracy**: As with all generative AI systems, Security Copilot responses in Data Security Posture Management may occasionally contain inaccurate or incomplete information. Users should verify AI-generated insights against actual data before taking consequential actions based on those responses.

Evaluations

Performance and safety evaluations assess whether AI applications are operating reliably and securely by examining factors like groundedness, relevance, and coherence while identifying the risks of generating harmful content. The following evaluations were conducted with safety components already in place, which are also described in Safety Components and Mitigations.

Data Security Posture Management was evaluated using custom evaluation methods developed by the product team. The evaluation focused on the accuracy of the embedded Security Copilot experience when responding to natural language questions about data security.

The evaluation data set consisted of relevant prompts identified by the product team and customers, including an expanded test set of prompts based on table schemas and descriptions. Microsoft evaluated performance using an accuracy rate metric: a response is considered accurate if the generated query provides the exact information asked in the prompt. The team tested across a range of data security scenarios covering DLP, information protection, and Insider Risk Management insights to verify that Security Copilot responses are factually supported by the underlying data and contextually appropriate to the user's question.

An ideal result is one where the Security Copilot response returns exactly the information requested, grounded in the organization's actual data, with no fabricated or misleading content. A suboptimal result would be a response that returns inaccurate data, misinterprets the user's question, or provides information outside the scope of the supported data security solutions. The evaluation process is iterative, with the product team refining the prompt sets and accuracy thresholds based on customer feedback and real-world usage patterns.

Safety components and mitigations

- **Role-based access control**: Data Security Posture Management enforces granular permissions through Microsoft Entra and Microsoft Purview role groups. Different activities require specific roles, such as Compliance Administrator for editing, Data Security Viewer for using Security Copilot, and Content Explorer Content Viewer for viewing AI interaction prompts and responses. This ensures that users can only access data and take actions appropriate to their role, reducing the risk of unauthorized access to sensitive information.

- **Comprehensive audit logging**: All automated actions taken by AI agents in Data Security Posture Management are recorded in audit logs. This includes actions such as removing sharing links, applying policies, and revoking permissions. Audit logs and activity explorer features provide a full trail of interactions with AI apps and agents, supporting compliance investigations, incident response, and accountability.

- **Human review and approval for agent actions**: Users always maintain control over AI agent behavior within Data Security Posture Management. AI-driven triage agents and the Data Security Posture Agent surface recommendations and findings, but users review, approve, or customize all automated actions before they take effect. The "View agent activity" options throughout the interface provide easy access to agent activity for oversight.

- **Opt-in analytics processing**: Data Security Posture Management requires explicit opt-in before processing organizational data. Analytics in both Insider Risk Management and DLP must be enabled before Data Security Posture Management can generate insights. This ensures that organizations make a deliberate decision to share data for analysis and are aware of the processing that takes place.

- **Scoped AI capabilities**: The Security Copilot experience in Data Security Posture Management is deliberately scoped to data security topics associated with Insider Risk Management, Information Protection, and Data Loss Prevention. Questions outside this scope are not answered, reducing the risk of the AI generating responses about topics where it lacks reliable data. The Data Security Posture Agent is similarly scoped to content searches within Microsoft 365 and limited to 1 GB of content per query.

- **Risk-level classification for search results**: The Data Security Posture Agent assigns a risk level to each search result based on how closely the content matches the user's prompt. Results are categorized to help users prioritize and focus on the most relevant findings. When the agent cannot determine the risk level, items are marked as "not categorized," providing transparency about the agent's confidence level.

- **Alert triage and noise reduction**: AI-driven triage agents review DLP and Insider Risk Management alerts and categorize them as "needs attention," "less urgent," or "not categorized." This filtering reduces alert fatigue and helps security analysts focus on genuine threats rather than false positives.

- **Privacy-preserving design**: Insider Risk Management, which feeds data into Data Security Posture Management, includes privacy controls such as pseudonymization and role-based access to ensure user-level privacy while enabling risk analysis. The Security Copilot

component follows the data privacy and security practices documented in the Microsoft Security Copilot privacy and data security documentation.

- **In-product feedback mechanism**: Users can provide feedback on each Security Copilot response by marking it as "looks right," "needs improvement," or "inappropriate." This feedback loop helps Microsoft continuously improve the quality and safety of AI-generated responses.

Best practices for deploying and adopting Data Security Posture Management

Responsible AI is a shared commitment between Microsoft and its customers. While Microsoft builds AI applications with safety, fairness, and transparency at the core, customers play a critical role in deploying and using these technologies responsibly within their own contexts. To support this partnership, we offer the following best practices for deployers and end users to help customers implement responsible AI effectively.

Deployers and end-users should:

- **Exercise caution and evaluate outcomes when using Data Security Posture Management for consequential decisions or in sensitive domains**: Consequential decisions are those that may have a legal or significant impact on a person's access to education, employment, financial platforms, government benefits, healthcare, housing, insurance, legal platforms, or that could result in physical, psychological, or financial harm. Sensitive domains—such as financial platforms, healthcare, and housing—require particular care due to the potential for disproportionate impact on different groups of people. When using AI for decisions in these areas, make sure that impacted stakeholders can understand how decisions are made, appeal decisions, and update any relevant input data.

- **Evaluate legal and regulatory considerations**: Customers need to evaluate potential specific legal and regulatory obligations when using any AI platforms and solutions, which may not be appropriate for use in every industry or scenario. Additionally, AI platforms or solutions are not designed for and may not be used in ways prohibited in applicable terms of service and relevant codes of conduct.

End-users should:

- **Exercise human oversight when appropriate**: Human oversight is an important safeguard when interacting with AI applications. While we continuously improve our AI applications, AI might still make mistakes. The outputs generated may be inaccurate, incomplete, biased,

misaligned, or irrelevant to your intended goals. This could happen due to various reasons, such as ambiguity in the inputs or limitations of the underlying models. As such, users should review the responses generated by Data Security Posture Management and verify that they match their expectations and requirements.

- **Be aware of the risk of overreliance**: Overreliance on AI happens when users accept incorrect or incomplete AI outputs, mainly because mistakes in AI outputs may be hard to detect. For the end-user, overreliance could result in decreased productivity, loss of trust, application abandonment, financial loss, psychological harm, physical harm, among others. In the context of Data Security Posture Management, overreliance could mean acting on an inaccurate Security Copilot insight without verifying it against actual data, potentially leading to misguided policy changes or missed security risks.

- **Scope Security Copilot questions to supported areas**: For the best results, ask questions about data security topics associated with Insider Risk Management, Information Protection, and Data Loss Prevention. Questions outside these areas may return incomplete or inaccurate responses because they fall outside the data Data Security Posture Management is designed to analyze.

- **Use specific and targeted prompts**: When using the Security Copilot experience or the Data Security Posture Agent, provide clear and specific prompts that include relevant details such as user names, time periods, and data locations. For example, instead of asking "show me security risks," ask "show all sensitive data activities performed by user@contoso.com in the last 30 days." More specific prompts produce more accurate and actionable results.

- **Provide feedback to improve quality**: Use the in-product feedback option to mark Security Copilot responses as "looks right," "needs improvement," or "inappropriate." This feedback helps Microsoft identify and address quality issues in AI-generated responses.

Deployers should:

- **Configure appropriate permissions before granting access**: Assign the minimum required roles to each user based on their responsibilities. Use the detailed permissions table in the Data Security Posture Management permissions documentation to determine which role groups are needed for each activity. Restricting access reduces the risk of unauthorized users viewing sensitive data or taking unintended actions.

- **Complete all setup tasks before relying on insights**: Ensure that auditing, analytics, and collection policies are properly configured before evaluating Data Security Posture Management insights. Incomplete setup can result in missing data and inaccurate posture

metrics. Allow sufficient processing time (up to three days for initial scans, at least 24 hours for new policies) before making decisions based on Data Security Posture Management data.

- **Use restricted searches for efficient processing**: When using the Data Security Posture Agent, configure searches to target specific users, groups, or sites rather than running tenant-wide scans. Restricted searches are significantly faster and more efficient, reducing processing time and producing more focused results.

- **Review and refine one-click policies after deployment**: One-click policies provide a useful starting point, but they should be reviewed and customized based on your organization's specific requirements. After initial deployment, monitor policy results through Data Security Posture Management reports and activity explorer, and adjust policy settings in the corresponding solution (DLP, Insider Risk Management, or Information Protection) to match your organization's risk tolerance and compliance needs.

- **Establish a regular review cadence**: Use Data Security Posture Management posture trends and reports to track your organization's data security posture over time. Establish a regular cadence for reviewing data risk assessments, policy coverage, and AI observability metrics. Regular reviews help identify emerging risks, policy gaps, and changes in user behavior before they become security incidents.

- **Plan for collection policy configuration**: If your organization needs to capture prompts and responses from Copilot in Fabric and Security Copilot, and for non-Copilot AI apps, configure collection policies with the content capture option selected. For apps that use these collection policies, AI interaction events in activity explorer will not display prompt and response text, limiting the usefulness of the data for compliance monitoring.

Learn more about Data Security Posture Management

For additional guidance or to learn more about the responsible use of Data Security Posture Management, we recommend reviewing the following documentation:

Learn about Data Security Posture Management for AI - (classic)

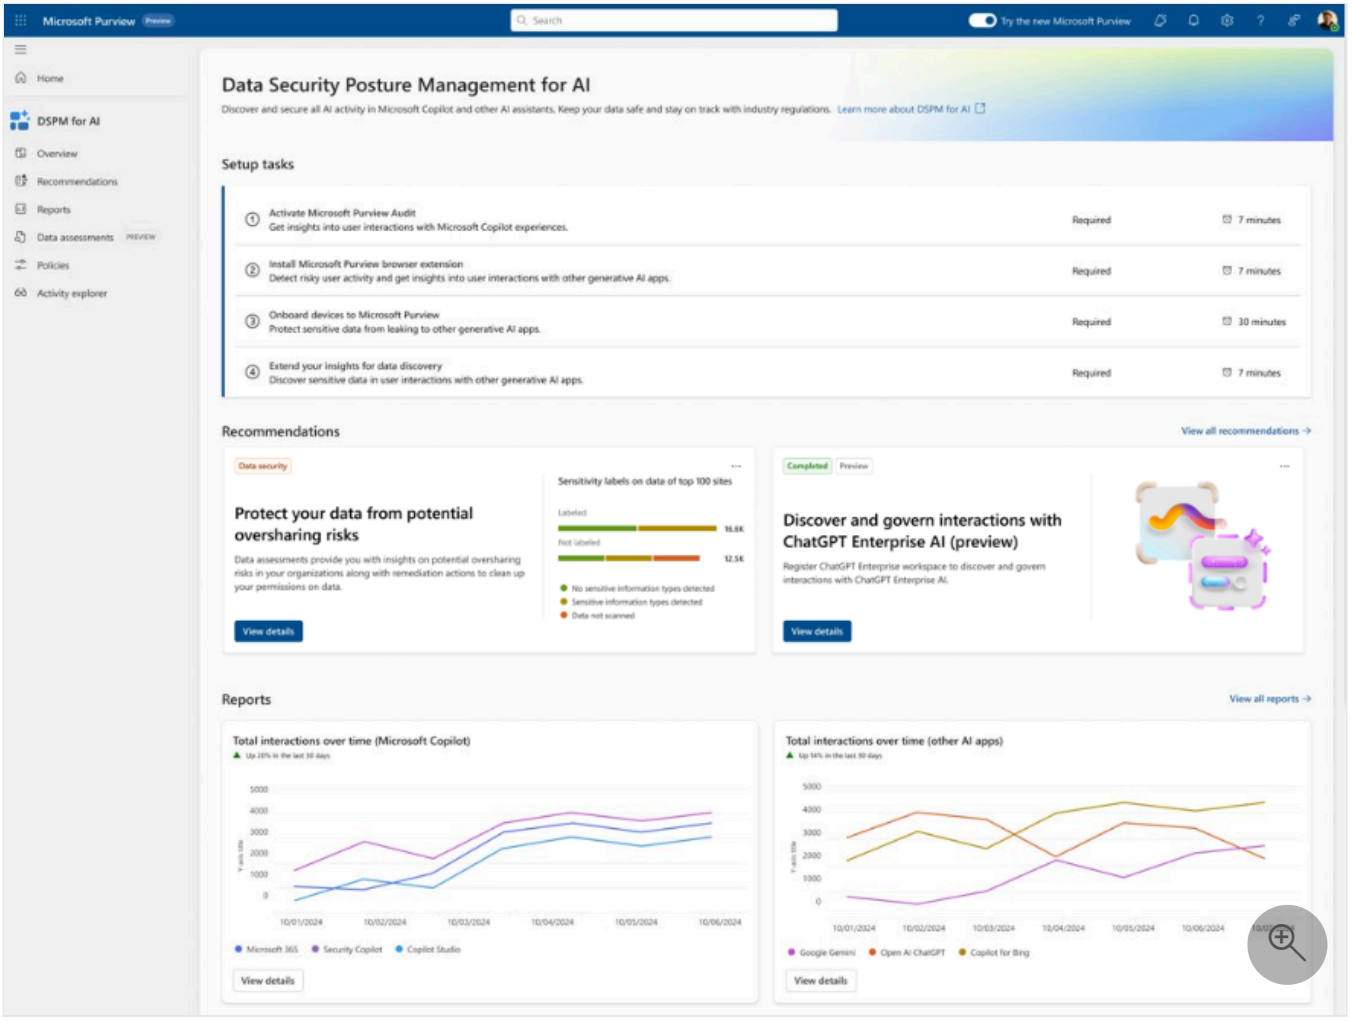
> *Microsoft 365 licensing guidance for security & compliance*

> **Note**
>
> This article is for the **classic** version of Data Security Posture Management that's being replaced with a new version that introduces guided workflows for proactive risk management, and streamlines data security operations so you can more confidently adopt AI across your digital estate.
>
> These improvements won't be added to this classic version so we invite you to try the new Data Security Posture Management, currently in preview.

Microsoft Purview Data Security Posture Management (DSPM) for AI from the Microsoft Purview portal provides a central management location to help you quickly secure data for AI apps and proactively monitor AI use. These apps include Copilots, agents, and other AI apps that use third-party large language modules (LLMs).

Data Security Posture Management for AI offers a set of capabilities so you can safely adopt AI without having to choose between productivity and protection:

- Insights and analytics into AI activity in your organization
- Ready-to-use policies to protect data and prevent data loss in AI prompts
- Data risk assessments to identify, remediate, and monitor potential oversharing of data.
- Compliance controls to apply optimal data handling and storing policies



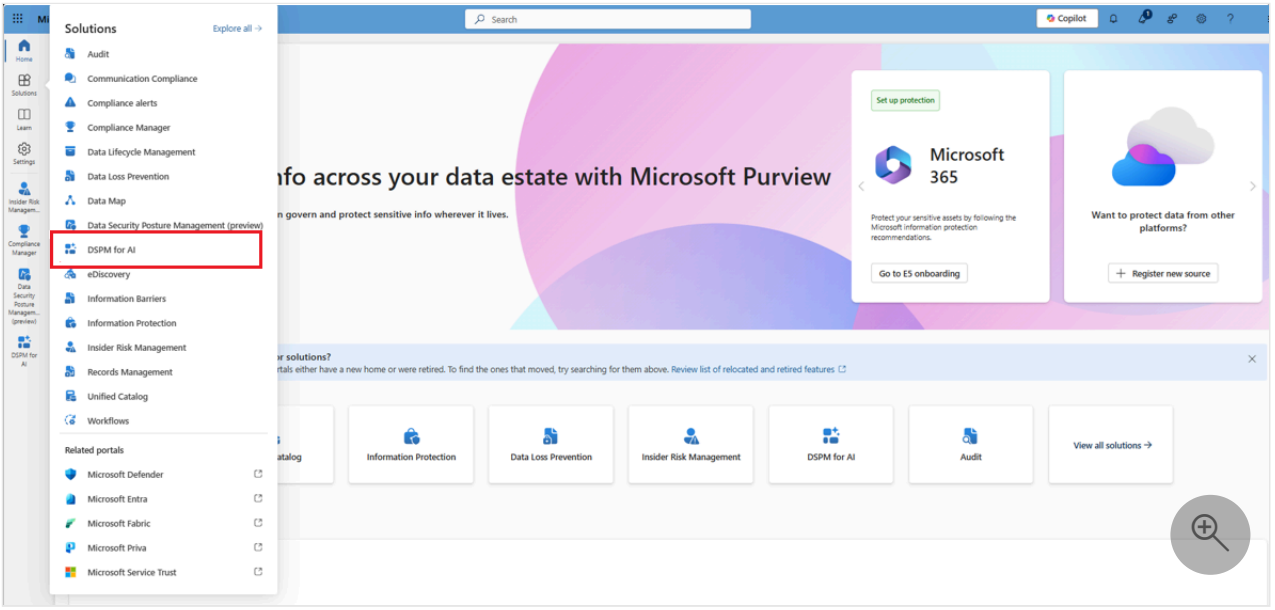
https://learn-video.azurefd.net/vod/player?id=e3504512-f69e-455e-847c-798d92839d8a&locale=en-us&embedUrl=%2Fpurview%2Fdspm-for-ai

For a list of supported third-party AI sites, such as those used for Gemini and ChatGPT, see Supported AI sites by Microsoft Purview for data security and compliance protections.

How to use Data Security Posture Management for AI

To help you more quickly gain insights into AI usage and protect your data, Data Security Posture Management for AI provides some recommended preconfigured policies that you can activate with a single click. If you're using administrative units, you must be an unrestricted administrator to create these policies that apply to all users in your organization.

Allow at least 24 hours for these new policies to collect data to display the results in Data Security Posture Management for AI, or reflect any changes that you make to the default settings.



No activation needed, Data Security Posture Management for AI automatically runs a weekly data risk assessment for the top 100 SharePoint sites based on usage in your organization. You can supplement this with your own custom data risk assessments, currently in preview. These assessments are designed specifically to help you identify, remediate, and monitor potential oversharing of data, so you can be more confident about your organization using Microsoft 365 Copilot and agents, and Microsoft 365 Copilot Chat.

https://learn-video.azurefd.net/vod/player?id=d68ad746-d47d-4e62-b5a5-de8dac5c940e&locale=en-us&embedUrl=%2Fpurview%2Fdspm-for-ai

To get started with Data Security Posture Management for AI, use the Microsoft Purview portal. You need an account that has appropriate permissions for compliance management, such as an account that's a member of the **Microsoft Entra Compliance Administrator** group role.

> **Tip**
>
> The following steps provide a recommended walkthrough to use all the available capabilities from DSPM for AI. If you're interested in using DSPM for AI just for a specific AI app, use the links in the **Next steps** section.

1. Sign in to the Microsoft Purview portal > **Solutions** > **DSPM for AI (classic)**.

2. From **Overview**, keep the **All AI apps** view selected. Review the **Get started** section to learn more about Data Security Posture Management for AI, and the immediate actions you can take. Select each one to display the flyout pane to learn more, take actions, and verify your current status.

Expand table

Action	More information
Turn on Microsoft Purview Audit	Auditing is on by default for new tenants, so you might already meet this prerequisite. If you do, and users are already assigned licenses for Microsoft 365 Copilot, you start to see insights about Copilot and agents activities from the **Reports** section further down the page.
Install Microsoft Purview browser extension	A prerequisite for third-party AI sites.

Action	More information
Onboard devices to Microsoft Purview	Also a prerequisite for third-party AI sites.
Extend your insights for data discovery	One-click policies for collecting information about users visiting third-party generative AI sites and sending sensitive information to them. The option is the same as the **Extend your insights** button in the AI data analytics section further down the page.

For more information about the prerequisites, see Prerequisites for Data Security Posture Management for AI.

For more information about the preconfigured policies that you can activate, see One-click policies from Data Security Posture Management for AI.

3. Then, review the **Recommendations** section and decide whether to implement any options that are relevant to your tenant. View each recommendation to understand how they're relevant to your data and learn more.

   These options include running a data risk assessment across SharePoint sites, creating sensitivity labels and policies to protect your data, and creating some default policies to immediately help you detect and protect sensitive data sent to generative AI sites. Examples of recommendations:

   - **Protect your data from potential oversharing risks** by viewing the results of your default data risk assessment to identify and fix issues to help you more confidently deploy Microsoft 365 Copilot.
   - **Protect your data with sensitivity labels** by creating a set of default sensitivity labels if you don't yet have sensitivity labels, and policies to publish them and automatically label documents and emails.
   - **Protect items with sensitivity labels from Microsoft 365 Copilot and agent processing** by prompting you to select one or more sensitivity labels that prevent Microsoft 365 Copilot and agents summarizing the labeled data. For more information about this capability, see Learn about using Microsoft Purview Data Loss Prevention to protect interactions with Microsoft 365 Copilot and Copilot Chat.
   - **Detect risky interactions in AI apps** to calculate user risk by detecting risky prompts and responses in Microsoft 365 Copilot, agents, and other generative AI apps. For more information, see Risky AI usage.
   - **Discover and govern interactions with ChatGPT Enterprise AI** by registering ChatGPT Enterprise workspaces, you can identify potential data exposure risks by detecting sensitive information that's shared with ChatGPT Enterprise.

- **Get guided assistance to AI regulations**, which uses control-mapping regulatory templates from Compliance Manager.
- **Secure interactions for Microsoft Copilot experiences**, which captures prompts and responses for Copilot in Fabric, and Security Copilot. Without a policy similar to the one that's created with this recommendation, auditing events are captured for Copilot in Fabric and Security Copilot, but not the prompts and responses.
- **Detect sensitive info shared with AI via network**, which uses network data security to detect sensitive info types shared with AI apps in browsers, applications, APIs, add-ins, and more, using a Secure Access Service Edge or Security Service Edge integration.
- **Secure interactions from enterprise apps**, which captures prompts and responses for regulatory compliance from Entra-registered AI apps, ChatGPT Enterprise Connector, and applications built on Microsoft Foundry.
- **Secure data in Azure AI apps and agents**, which has set up instructions to capture prompts and responses for AI apps that use one or more Azure AI subscriptions.

You can use the **View all recommendations** link, or **Recommendations** from the navigation pane to see all the available recommendations for your tenant, and their status. When a recommendation is complete or dismissed, you no longer see it on the **Overview** page.

4. Use the **Reports** section or the **Reports** page from the navigation pane to view the results of the default policies created. You need to wait at least a day for the reports to be populated. Select the categories of **Copilot experiences and agents**, **Enterprise AI apps**, and **Other AI apps** to help you identify the specific generative AI app.

5. Use the **Policies** page to monitor the status of the default one-click policies created and AI-related policies from other Microsoft Purview solutions. To edit the policies, use the corresponding management solution in the portal. For example, for **DSPM for AI - Unethical behavior in Copilot**, you can review and remediate the matches from the **Communication Compliance** solution.

   > ⓘ Note
   >
   > If you have the older retention policies for the location **Teams chats and Copilot interactions**, they aren't included on this page. Learn how to create separate retention policies for Microsoft Copilot Experiences that will be included on this **Policy** page.

6. Select **Apps and agents** to view a dashboard of AI apps and their agents used across your organization so you can identify and manage any potential data security risks. For each

agent, view details about sensitive data that they accessed and how they are protected by policies from Microsoft Purview.

7. Select **Activity explorer** to see details of the data collected from your policies.

   This more detailed information includes activity type and user, date and time, AI app category and app, app accessed in, any sensitive information types, files referenced, and sensitive files referenced.

   Examples of activities include **AI interaction**, **Sensitive info types**, and **AI website visit**. Prompts and responses are included in the **AI interaction** events when you have the right permisisons. You can use the **Web queries** filter in activity explorer to more easily identify which AI interactions have a web query, with the AI interaction flyout pane diplaying the search query text in the **Web references AI app used** section. For more information about the events, see Activity explorer events.

   Similar to the report categories, workloads include **Copilot experiences and agents**, **Enterprise AI apps**, and **Other AI Apps**. Examples of an app ID and app host for **Copilot experiences and agents** include **Microsoft 365 Copilots** and **Copilot Studio**. **Enterprise AI apps** includes **ChatGPT Enterprise**. **Other AI Apps** include the apps from the supported third-party AI sites, such as those used for Gemini and ChatGPT.

8. Select **Data risk assessments** to identify and fix potential data oversharing risks in your organization. Because of the power and speed AI can proactively surface content that might be obsolete, over-permissioned, or lacking governance controls, generative AI amplifies the problem of oversharing data. Use data risk assessements to both identify and remediate issues.

   For oversharing insights in SharePoint and OneDrive, use the **Microsoft 365** tab, and the **Fabric** tab for items in Fabric workspaces.

   Microsoft 365

   A default data risk assessment automatically runs weekly for the top 100 SharePoint sites based on usage in your organization, and you might have already run a custom assessment as one of the recommendations. However, come back regularly to this option to check the latest weekly results of the default assessment and run custom assessments when you want to check for different users or specific sites. After a custom assessment has run, wait at least 48 hours to see the results that don't update again. You'll need a new assessment to see any changes in the results.

   The **Default assessment** displays at the top of the page with a quick summary, such as the total number of items found, the number of sensitive data detected, and the

number of links sharing data with anyone. The first time the default assessment is created there's a 4-day delay before results are displayed.

After you select **View details** for more in-depth information, from the list, select each site to access the flyout pane that has tabs for **Overview**, **Identify**, **Protect**, and **Monitor**. Use the information on each tab to learn more, and take recommended actions. For example:

Use the **Identify** tab to identify how much data has been scanned or not scanned for sensitive information types, with an option to initiate an on-demand classification scan as needed.

Use the **Protect** tab to select options to remediate oversharing, which include:

- **Restrict access by label**: Use Microsoft Purview Data Loss Prevention to create a DLP policy that prevents Microsoft 365 Copilot and agents from summarizing data when it has sensitivity labels that you select. For more information about how this works and supported scenarios, see Learn about using Microsoft Purview Data Loss Prevention to protect interactions with Microsoft 365 Copilot and Copilot Chat.
- **Restrict all items**: Use SharePoint Restricted Content Discovery to list the SharePoint sites to be exempt from Microsoft 365 Copilot. For more information, see Restrict discovery of SharePoint sites and content.
- **Create an auto-labeling policy**: When sensitive information is found for unlabeled files, use Microsoft Purview Information Protection to create an auto-labeling policy to automatically apply a sensitivity label for sensitive data. For more information about how to create this policy, see How to configure auto-labeling policies for SharePoint, OneDrive, and Exchange.
- **Create retention policies**: When content hasn't been accessed for at least 3 years, use Microsoft Purview Data Lifecycle Management to automatically delete it. For more information about how to create the retention policy, see Create and configure retention policies.

Use the **Monitor** tab to view the number of items in the site shared with anyone, shared with everyone in the organization, shared with specific people, and shared externally. Select **Start a SharePoint site access review** for information how to use the SharePoint data access governance reports.

9. To create your own custom data risk assessment, select **Create custom assessment** to identify potential oversharing issues for all or selected users, the data sources to scan, and run the assessment.

> **Note**
>
> Microsoft 365 custom assessments optionally support item-level scanning with remediation actions when you complete a one-time authentication process. To specify the required settings, you must have a registered Entra application. For more information about the Entra application, see **Prerequisites for Microsoft 365 item-level scanning for data risk assessments**.
>
> Select **Item-level** on the **Scan level** page, and then **Authenticate** to specify the Entra application information.

This data risk assessment is created in the **Custom assessments** category. Wait for the status of your assessment to display **Completed**, and select it to view details. To rerun a custom data risk assessment, and to see results after the 30-day expiration, use the duplicate option to create a new assessment with the same selections.

Item-level scanning and remediation for items that are potentially overshared is applicable to Microsoft 365 only, and currently restricted to SharePoint sites. This scan identifies items as potentially overshared if they have a sharing link for external or anonymous users, and also shows any applied sensitivity label and the owner of each item.

When the scan is complete, open the custom assessment and view item-level insights from the **Potentially overshared items** tab or the **View items** button from the **Potentially overshared items** banner. The following remediation actions can be taken on the identified potentially overshared items:

- **Resolve**, for example if you decide the item isn't at risk of oversharing.
- **Apply sensitivity label** for items that are identified as currently unlabeled or should have a different sensitivity label.
- **Notify** the site owner with an email notification (not customizable).
- **Remove sharing link** to remove the existing sharing link so it can no longer be used to access the item. This is an action to be used sparingly because it could prevent people from accessing the item legitimately. In this scenario, the site owner or item owner must then set a less permissive sharing link type for authorized users. If you haven't already, consider configuring sensitivity labels for a default sharing link.

The email notification contains information and instructions about the potentially overshared items in the site. It also contains options for them to go to the SharePoint site to manage access to the items from there, or to the Microsoft Purview portal for a read-only view of the item-level scan results that only show items and sites that they own.

> **Tip**
>
> Both the default and custom data risk assessments provide an **Export** option that let you save and customize the data into a choice of file formats (Excel, CSV, JSON, TSV).

Limits for Microsoft 365:

- A maximum of 200,000 items per location, which applies to both a custom data risk assessment and a default data risk assessment. The count of files reported might not be accurate when there are more than 100,000 files per location.
- OneDrive currently isn't supported for item-level scanning.
- A current maximum of 10 SharePoint sites for item-level scanning.

Next steps

Use the policies, tools, and insights from DSPM for AI in conjunction with additional protections and compliance capabilities from Microsoft Purview. If you're interested in a specific AI app, use the following links:

- Microsoft 365 Copilot & Microsoft 365 Copilot Chat
- Microsoft Security Copilot
- Copilot in Fabric
- Microsoft Copilot Studio
- Microsoft Facilitator
- Channel Agent in Microsoft Teams
- Entra-registered AI apps
- Microsoft Foundry
- ChatGPT Enterprise
- Other AI apps
- Agents

Considerations for DSPM for AI to manage data security and compliance protections for AI interactions - (classic)

> *Microsoft Purview service description*

> **Note**
>
> This article is for the **classic** version of Data Security Posture Management for AI that's now replaced with a new version that incorporates support for AI apps and agents, new features and broader reach, with simplified management.
>
> These improvements won't be added to this classic version so we invite you to try the new Data Security Posture Management.

For the most part, Data Security Posture Management for AI is easy to use and self-explanatory, guiding you through prerequisites and preconfigured reports and policies. Use this section to complement that information and provide additional details that you might need.

Prerequisites for Data Security Posture Management for AI

To use Data Security Posture Management for AI from the Microsoft Purview portal, you must have the following prerequisites:

- You have the right permissions.
- Required for monitoring interactions with Copilot and agents:
  - Microsoft Purview auditing is enabled for your organization. Although this is the default, you might want to check the instructions for Turn auditing on or off.
  - For Microsoft 365 Copilot and agents, users are assigned a license for Microsoft 365 Copilot.
  - For Copilot in Fabric and Security Copilot:

    - The enterprise version of Microsoft Purview data governance, to support the required APIs.
    - A collection policy, such as the one created from the recommendation or remediation action **Secure interactions for Microsoft Copilot experiences**.

- Required for monitoring interactions and applying DLP policies to other AI apps in Edge:
    - An Edge configuration policy is required to activate the Microsoft Purview integration in Edge. For configuration information, see Activate your DLP policy in Microsoft Edge.

- Required for monitoring interactions with third-party generative AI sites:

    - Devices are onboarded to Microsoft Purview, required for:
        - Gaining visibility into sensitive information that's shared with third-party generative AI sites. For example, a user pastes credit card numbers into ChatGPT.
        - Applying endpoint DLP policies to warn or block users from sharing sensitive information with third-party generative AI sites. For example, a user identified as elevated risk in Adaptive Protection is blocked with the option to override when they paste credit card numbers into ChatGPT.

    - The Microsoft Purview browser extension is deployed to Windows users and required to discover visits to third-party generative AI sites by using an Insider Risk Management policy. The browser extension is also required for Endpoint DLP policies on Windows when you use Chrome.

- For Entra-registered AI apps, they are integrated with the Microsoft Purview SDK to support all the Microsoft Purview capabilities.

- For AI apps other than Microsoft 365 Copilot and Microsoft Facilitator, you've set up pay-as-you-go billing for your organization. When this billing model is applicable for specific configurations, you'll see notifications and instructions in the UI.

You'll find more information about the prerequisites for auditing, device onboarding, and the browser extension in Data Security Posture Management for AI: Navigate to **Overview** > **Get started** section.

For a list of currently supported third-party AI apps, see Supported AI sites by Microsoft Purview for data security and compliance protections.

> ⓘ **Note**

If you're using **administrative units**, restricted administrators won't be able to create the one-click policies that apply to all users. You must be an unrestricted administrator to create these policies. Restricted administrators see the results only for users in their assigned administrative unit for the **Policies** page, and in the reports and activity explorer in Microsoft Purview Data Security Posture Management for AI.

Prerequisites for Fabric data risk assessments

Use the following instructions to meet the prerequisites to run data risk assessments for Fabric workspaces, and before you select **Set config** in DSPM for AI.

For steps 1 and 2, use one of the following Entra roles for the required permissions:

- Cloud Application Administrator
- Application Administrator
- Privileged Role Administrator

For step 3, you must be a Fabric administrator.

1. In the Microsoft Entra admin portal, create and configure a registered app to be the service principal authentication for Fabric. You will authenticate the app in one of two ways: With **Federated Credentials** (recommended) or **Client Secret**. The federated credentials option is more secure because it lets Kubernetes workloads authenticate to Azure services without hard-coding secrets, while ensuring each pod only has the permissions it needs. For more information about this authentication method, see Overview of federated identity credentials in Microsoft Entra ID.

   After you've created this registered app and still in the Entra admin portal, copy and store the **Application (client) ID**, which is always required to setup data risk assessments for Fabric. Then, to authenticate with federated credentials, work with your compliance administrator to identify and enter the **OIDC Issuer URL**, **Namespace**, and **Service Account Name** under **Edit connection**. Enter these values into the corresponding fields in **Your App name** > **Certificates & Secrets** > **Federated Credentials** > **Kubernetes accessing Azure resources**. Alternatively, to authenticate with a client secret, store the **Client Secret** value to then enter in the Microsoft Purview portal:

   - To locate the **Application (client) ID**: In the Microsoft Entra admin portal, **Identity** > **Applications** > **App registrations**, select the app you created for Fabric. The **Application (client) ID** is displayed on the **Overview** tab.

- Create a client secret for this app. Copy and securely save the value immediately. It will only be shown once.

2. Now navigate to **Groups** to add the registered app as a group member to a new or existing security group. Its type displays as **Enterprise application**.

3. In the Fabric admin portal, navigate to **Tenant settings** > **Admin API settings** and enable the options **Service principals can access read-only admin APIs** and **Service principals can access admin APIs used for updates**. For both of these, in the **Apply to:** sections, select **Specific security groups** and specify the security group that you configured in the previous step. Select **Apply** to save and apply these tenant settings.

For more information about steps 1-2, see Enable service principal authentication for admin APIs.

For more information about the tenant settings and support for information protection in Fabric, see Tenant settings index and Information protection in Microsoft Fabric.

Prerequisites for Microsoft 365 item-level scanning for data risk assessments

Use the following instructions to create an Entra application with the required permissions for Microsoft 365 item-level scanning in a custom data risk assessment.

You must have one of the following Entra roles to create and configure the required registered app:

- Cloud Application Administrator
- Application Administrator
- Privileged Role Administrator

In the Entra admin portal, create and configure a registered app with the following settings:

- **Supported account types**: **Accounts in this organizational directory only**

- **API permissions**: **Microsoft APIs** > **Microsoft Graph** > **Application permissions**
  - **Application: Application.Read.All**
  - **Directory: Directory.Read.All**
  - **Files: Files.ReadWrite.All**
  - **SensitivityLabels: SensitivityLabels.Read.All**
  - **Sites: Sites.ReadWrite.All**
  - **User: User.Read.All**

- Grant admin consent for your tenant

Now create a client secret for this app. Copy and securely save the value immediately. It will only be shown once.

You'll also need the registered application's ID, which is displayed as **Application (client) ID** in the **Overview** tab.

One-click policies from Data Security Posture Management for AI

After the default policies are created, you can view and edit them at any time from their respective solution areas in the portal. For example, you want to scope the policies to specific users during testing, or for business requirements. Or, you want to add or remove classifiers that are used to detect sensitive information. Use the **Policies** page to quickly navigate to the right place in the portal.

Some policies, such as **DSPM for AI - Capture interactions for Copilot experiences** and **DSPM for AI - Detect sensitive info shared with AI via network** are collection policies that you can edit, and if necessary, delete like any other collection policy. For more information, see Accessing collection policies.

If you delete any of the policies, their status on the **Policies** page displays **PendingDeletion** and continues to show as created in their respective recommendation cards until the deletion process is complete.

For sensitivity labels and their policies, view and edit these independently from Data Security Posture Management for AI, by navigating to **Information Protection** in the portal. For more information, use the configuration links in Default labels and policies to protect your data.

For more information about the supported DLP actions and which platforms support them, see the first two rows in the table from Endpoint activities you can monitor and take action on.

For the default policies that use Adaptive Protection, this capability is turned on if it's not already on, using default risk levels for all users and groups to dynamically enforce protection actions. For more information, see Quick setup

> ⓘ **Note**

Any default policies created while Data Security Posture Management for AI was in preview and named Microsoft Purview AI Hub won't be changed. For example, policy names will retain their **Microsoft AI Hub -** prefix.

Default policies for data discovery using Data Security Posture Management for AI

- DLP policy: **DSPM for AI: Detect sensitive info added to AI sites**

  Source: **Extend your insights for data discovery**

  This policy discovers sensitive content pasted or uploaded in Microsoft Edge, Chrome, and Firefox to AI sites. This policy covers all users and groups in your org in audit mode only.

- Insider risk management policy: **DSPM for AI - Detect when users visit AI sites**

  Source: **Extend your insights for data discovery**

  This policy detects when users use a browser to visit AI sites.

- Insider risk management policy: **DSPM for AI - Detect risky AI usage**

  Source: Recommendation **Detect risky interactions in AI apps**

  This policy helps calculate user risk by detecting risky prompts and responses in Microsoft 365 Copilot, agents, and other generative AI apps.

- Communication Compliance: **DSPM for AI - Unethical behavior in AI apps**

  Source: Recommendation **Detect unethical behavior in AI apps**

  This policy detects sensitive information in prompts and responses in Microsoft 365 Copilot, agents, and other generative AI apps. This policy covers all users and groups in your organization.

- Collection policy: **DSPM for AI - Capture interactions for Copilot experiences**

  Source: Recommendation **Secure interactions in Microsoft Copilot experiences**

  This policy captures prompts and responses for data security posture and regulatory compliance from Copilot in Fabric, and Security Copilot. Manage them in Microsoft Purview solutions like eDiscovery, Data Lifecycle Management, and more.

- Collection policy: **DSPM for AI - Detect sensitive info shared with AI via network**

  Source: Recommendation **Extend insights into sensitive data in AI app interactions**

  This policy detects sensitive information shared with AI apps in browsers, applications, APIs, add-ins, and more, using a Secure Access Service Edge (SASE) or Security Service Edge (SSE) integration.

  > **Important**
  >
  > This policy requires that you manually add one or more Secure Access Service Edge (SASE) or Security Service Edge (SSE) integrations in Data Loss Prevention settings. The detection of AI interactions is dependent on the network partner implementation.
  >
  > If you want to capture prompts and responses in addition to detecting sensitive information, you must edit the collection policy and select the option to capture content.

- Collection policy: **DSPM for AI - Capture interactions for enterprise AI apps**

  Source: Recommendation **Secure interactions from enterprise apps**

  This policy captures prompts and responses for regulatory compliance from enterprise AI apps, such as Chat GPT Enterprise and AI apps connected through Microsoft Entra or Microsoft Foundry, so they can be managed in Microsoft Purview solutions like eDiscovery, Data Lifecycle Management, and more.

- Collection policy: **DSPM for AI - Detect sensitive info shared in AI prompts in Edge**

  Source: **Extend your insights for data discovery**

  This policy detects prompts sent to generative AI apps in Microsoft Edge and discovers sensitive information shared in prompt contents. This policy covers all users and groups in your organization in audit mode only and doesn't capture content.

Default policies from data security to help you protect sensitive data used in generative AI

- DLP policy **DSPM for AI - Block sensitive info from AI sites**

  Source: Recommendation **Fortify your data security**

This policy uses Adaptive Protection to give a block-with-override to elevated risky users attempting to paste or upload sensitive information to other AI apps in Edge, Chrome, and Firefox. This policy covers all users and groups in your org in test mode.

- DLP policy **DSPM for AI - Block elevated risk users from submitting prompts to AI apps in Microsoft Edge**

  Source: Recommendation **Fortify your data security**

  Using Adaptive Protection, this policy blocks elevated, moderate, and minor risk users attempting to put information in AI apps while using Microsoft Edge. Users included in this policy will be blocked from using unprotected browsers because this policy includes unmanaged apps.

- DLP policy **DSPM for AI - Block sensitive info from AI apps in Edge**

  Source: Recommendation **Fortify your data security**

  This policy detects inline for a selection of common sensitive information types and blocks prompts from being sent to AI apps while using Microsoft Edge. Users included in this policy will be blocked from using unprotected browsers because this policy includes unmanaged apps.

- DLP policy **DSPM for AI - Protect sensitive data from Copilot processing**

  Source: Recommendation **Protect items with sensitivity labels from Microsoft 365 Copilot and agent processing**

  This policy blocks Microsoft 365 Copilot and agents from processing items with the sensitivity labels selected in this policy.

- Information Protection - **Sensitivity labels and policies**

  Source: Recommendation **Protect your data with sensitiivity labels**

  This recommendation creates default sensitivity labels and sensitivity label policies. If you've already configured sensitivity labels and their policies, this configuration is skipped.

Activity explorer events

Use the following information to help you understand the events you might see in the activity explorer from Data Security Posture Management for AI. References to a generative AI site can

include Microsoft 365 Copilot, Microsoft 365 Copilot Chat, agents, other Microsoft copilots, and third-party AI sites.

Expand table

Event	Description
AI interaction	User interacted with a generative AI site. Details include the prompts and responses, except for unmanaged AI apps in Edge where text prompts only are included. For Microsoft 365 Copilot and Microsoft 365 Copilot Chat, this event requires auditing to be turned on. For Copilot in Fabric and Security Copilot, and for non-Copilot AI apps, prompts and responses require a collection policy with content capture selected to capture these interactions.
AI website visit	User browsed to a generative AI site.
DLP rule match	A data loss prevention rule was matched when a user interacted with a generative AI site. Includes DLP for Microsoft 365 Copilot.
Sensitive info types	Sensitive information types were found while a user interacted with a generative AI site. For Microsoft 365 Copilot and Microsoft 365 Copilot Chat, this event requires auditing to be turned on but doesn't require any active policies.

Known issues:

- The **AI interaction** event doesn't always display text for the prompt and response. Sometimes, the prompt and response spans consecutive entries. Other scenarios can include:
  - Microsoft Facilitator AI-generated notes, no prompt or response is displayed
  - When a user doesn't have a mailbox hosted in Exchange Online, no prompt or response is displayed
- The **Sensitive info types detected** event doesn't display the user risk level.
- For Microsoft Facilitator AI-generated notes, **AI interaction** events can't be linked to **Sensitive info types detected** events.
- For collection policies, no prompt or response is displayed if the option to capture content isn't selected in the policy. For example, the one-click policy **DSPM for AI - Detect sensitive info shared with AI via network** doesn't select this option when the policy is automatically created, but you can manually edit the policy and select this option after the policy is created.

Last updated on 05/01/2026

Permissions for Data Security Posture Management for AI - (classic)

> *Microsoft Purview service description*

> **Note**
>
> This article is for the **classic** version of Data Security Posture Management that's being replaced with a new version that expands coverage to more data sources, introduces guided workflows for proactive risk management, and streamlines data security operations so you can more confidently adopt AI across your digital estate.
>
> These improvements won't be added to this classic version so we invite you to try the new Data Security Posture Management, currently in preview.

Members of your security and compliance teams who are responsible for managing AI apps in the Microsoft Purview Data Security Posture Management for AI need appropriate permissions when they sign in to the Microsoft Purview portal.

Roles and role groups that can view, create, and edit in Data Security Posture Management for AI:

- **Microsoft Entra Compliance Administrator** role
- **Microsoft Entra Global Administrator** role
- **Microsoft Purview Compliance Administrator** role group

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Roles and role groups that can view-only in Data Security Posture Management for AI:

- **Microsoft Purview Security Reader** role group
- **Purview Data Security AI Viewer** role

- **AI Administrator** role from Entra
- **Purview Data Security AI Content Viewer** role for AI interactions only

To help you assign the right permissions to users, use the following guidance, depending on the portal you're using:

- Permissions in the Microsoft Purview portal
- Assign Microsoft Entra roles to users
- Permissions in Exchange Online

Use the following table to understand the detailed permissions for different activities in Data Security Posture Management for AI.

Permissions by activities

✓: Supported. The role or role group have permissions to do the specified activities.

✕: Not supported. The role or role group don't have permissions to do the specified activities.

* Includes Microsoft Purview Security Reader role group, Microsoft Purview Data Security AI Viewer role, and the AI Administrator role from Entra

Custom role groups

Instead of granting access to Data Security Posture Management for AI by using the built-in role groups, you can grant access by including the Microsoft Purview Compliance Administrator role in a custom role group. For read-only permissions, include the the Microsoft Purview Security Reader role, the Purview Data Security AI Viewer role, or the AI Administrator role from Entra.

If a custom role group includes the Microsoft Purview Compliance Administrator role, the user has the same access to Data Security Posture Management for AI as the Microsoft Purview Compliance Administrator role group, except for the following:

- Create, view, update, and delete policies for insider risk management and communication compliance

If a custom role group includes the Microsoft Purview Security Reader role, the Purview Data Security AI Viewer role, or the AI Administrator role, the user has the same access to Data Security Posture Management for AI as the Microsoft Purview Security Reader role group, except for the following:

- View information protection policies

Last updated on 04/01/2026

List of AI sites supported by Microsoft Purview Data Security Posture Management (DSPM) and DSPM for AI (classic)

Summarize this article for me

> *Microsoft Purview service description*

This article lists the generative AI sites that are supported by Microsoft Purview Data Security Posture Management and Microsoft Purview Data Security Posture Management for AI (classic).

You can expect this list to increase over time.

Supported AI sites

Learn about Data Security Posture Management - (classic)

> **Note**
>
> This article is for the **classic** version of Data Security Posture Management that's being replaced with a new version that introduces guided workflows for proactive risk management, and streamlines data security operations so you can more confidently adopt AI across your digital estate.
>
> These improvements won't be added to this classic version so we invite you to try the new Data Security Posture Management, currently in preview.

Strengthening data security and minimizing exposure to data risks for sensitive information is often challenging for organizations in the modern workplace. The increasing complexity of data, the variety of data sources and platforms, limited visibility into sensitive data, and fragmented security solutions can pose significant challenges for administrators and data security professionals. Adding multicloud platforms and generative AI applications to these areas makes it even more difficult to assess data security coverage and to correlate insights from user data points. To help discover and mitigate data risks, organizations must address the following questions:

- What is my sensitive data?
- Where is it located?
- What data is currently unprotected?
- How is unprotected sensitive data being handled and accessed?
- How can I help lower the risk and help secure unprotected sensitive data?

Microsoft Purview Data Security Posture Management (DSPM) enables you to quickly and easily monitor cross-cloud data and user risk through dynamic reports and trend analysis. By processing and correlating data across other Microsoft Purview data security and risk and compliance solutions, DSPM helps you identify vulnerabilities with unprotected data and quickly take action to help you improve your data security posture and minimize risk. DSPM provides:

- **Data security recommendations**: Gain insights into your data security posture and get recommendations for creating Insider Risk Management and data loss prevention (DLP) policies to help protect sensitive data and to close data security gaps. For example, some recommendations might include creating policies to prevent users from printing sensitive files or to prevent users from copying sensitive files to other network locations.

- **Data security analytic trends and reports**: Track your organization's data security posture over time with reports summarizing sensitivity label usage, DLP policy coverage, changes in risky user behavior, and more.
- **Microsoft Security Copilot**: Use Security Copilot promptbooks and custom prompts to help you investigate alerts, identify risk patterns, and pinpoint the top data security risks in your organization.

Integration with Microsoft Purview solutions

DSPM processes and correlates data state, signals, and user activities based on the current configuration of other data security and risk and compliance solutions in Microsoft Purview. For optimal coverage and deeper insights, consider using the features and capabilities of the following solutions:

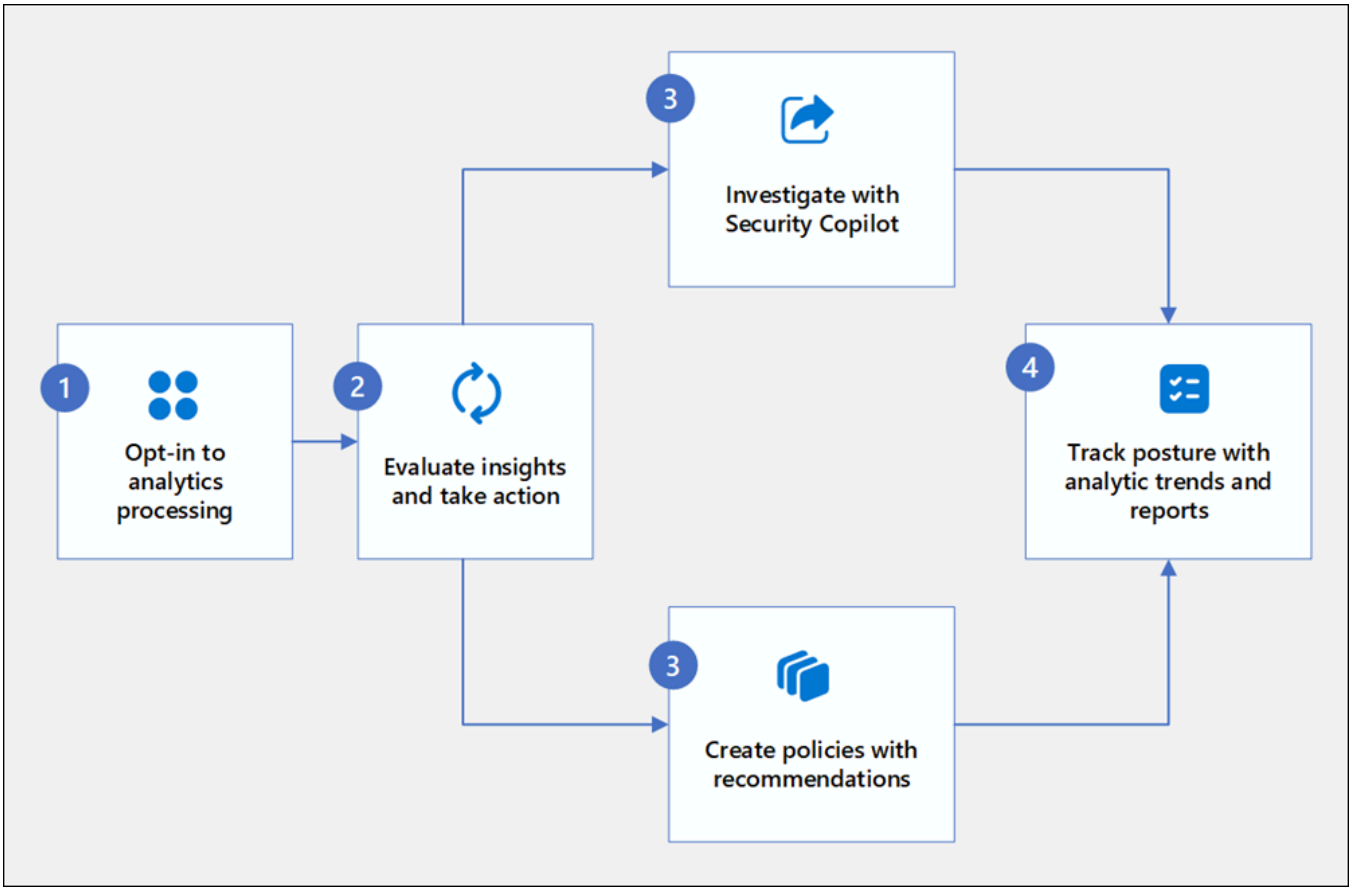
- **Data loss prevention (DLP)**: Microsoft Purview Data Loss Prevention policies help you prevent users from inappropriately sharing sensitive data. DLP detects sensitive information by using content analysis that includes keyword matching, evaluations of expressions, internal validation, machine learning algorithms, and more.

  Depending on the specific recommendations for the data, you can choose to quickly create an applicable DLP policy directly in the DSPM workflow.

- **Information protection**: Microsoft Purview Information Protection provides a framework, process, and capabilities you can use to protect sensitive data across clouds, apps, and devices. By using sensitivity labels, trainable classifiers, and sensitive information types, you can define and apply protection policies to sensitive data.

- **Insider risk management**: Microsoft Purview Insider Risk Management uses the full breadth of built-in service and third-party indicators to help you quickly identify, triage, and act on potentially risky activity by users in your organization. By using logs from Microsoft 365 and Microsoft Graph, Insider Risk Management allows you to define specific policies to identify risk indicators. After identifying the risks, you can take action to mitigate these risks, and if necessary open investigation cases and take appropriate legal action.

  Depending on the specific recommendations for the data, you can choose to quickly create an applicable Insider Risk Management policy directly in the DSPM workflow.



Working with Adaptive Protection

Adaptive protection in Microsoft Purview uses machine learning to identify the most critical risks and proactively and dynamically apply protection controls from data loss prevention, data

lifecycle management, and Microsoft Entra conditional access. If Adaptive Protection isn't currently enabled for unprotected sensitive data, you can create a new Adaptive Protection policy directly in the DSPM workflow.

Workflow

The DSPM workflow helps you investigate and take action to address potential security concerns with unprotected data across your organization.

1. **Opt in to analytics processing**: To get started with DSPM, enable and opt in to:
   a. Insider risk management analytics
   b. DLP analytics
   c. Analytics processing in DSPM to scan for unprotected data in your organization.
2. **Evaluate insights and take action**: After the automated analytics processing completes, evaluate the insights created by DSPM to help mitigate risks for unprotected data.
3. **Actions**:
   a. **Investigate with Security Copilot**: Use built-in promptbooks and custom prompts with Security Copilot to help identify specific areas of risk.
   b. **Create policies with recommendations**: Use recommendations to quickly create Insider Risk Management and DLP policies to help mitigate data security risks for unprotected data assets.

4. **Track posture with analytic trends and reports**: Use analytic trends and reports to view your posture over time and for data locations across your organization.

Using DSPM (classic) in new environments

For organizations just getting started with Microsoft Purview, DSPM helps provide easy configuration and new policy creation across several data security and risk and compliance solutions.

By automatically scanning data and activities across your organization, you quickly get baseline insights and recommendations focused on unprotected data that can help you quickly get started in DLP, information protection, and Insider Risk Management.

Using data security in existing environments

If your organization is already using DLP, information protection, and Insider Risk Management in Microsoft Purview, DSPM helps identify any gaps in your current policy coverage.

Without having to conduct deeper dives into your existing policies, DSPM can quickly determine and highlight any unprotected data at risk, saving you the time and effort associated with reviewing and testing numerous individual data security and risk and compliance policies.

Ready to get started?

- Get started with Data Security Posture Management - (classic)
- Take action with Data Security Posture Management recommendations - (classic)
- Use Microsoft Security Copilot with Data Security Posture Management - (classic)
- Use Data Security Posture Management analytics trends and reports - (classic)

Last updated on 12/15/2025

Get started with Data Security Posture Management - (classic)

> **Note**
>
> This article is for the **classic** version of Data Security Posture Management that's being replaced with a new version that introduces guided workflows for proactive risk management, and streamlines data security operations so you can more confidently adopt AI across your digital estate.
>
> These improvements won't be added to this classic version so we invite you to try the new Data Security Posture Management, currently in preview.

Use Data Security Posture Management (DSPM) to quickly identify unprotected sensitive data assets and potentially risky user activities in your organization. Complete the steps in this article to get started with the DSPM workflow.

Subscriptions and licensing

Before getting started with DSPM, confirm your Microsoft 365 subscription and any add-ons. Depending on the licensing and subscriptions for your organization, you can access other data security and risk and compliance solutions in the Microsoft Purview portal.

To access and use DSPM, you need a Microsoft 365 E5 or Microsoft Purview Suite (formerly known as Microsoft 365 E5 Compliance) license. Administrators need to verify that their organization has a supported subscription and assign the appropriate licenses to users. For more information about subscriptions and licensing, see the subscription requirements for DSPM.

Step 1: Assign permissions

> **Important**
>
> If your permissions are restricted in specific administrative units in your organization, you can't access DSPM.

To continue with these configuration steps, you must be assigned to one of the following roles or role groups:

- *Data Security Management* role group
- *Data Security Viewer* role. If the DSPM dashboard is opted in, this role grants permission to view all the insights. This role is required to use Security Copilot in DSPM.
- Insider Risk Management Admins role
- Microsoft Entra ID *Global Administrator* role
- Microsoft Entra *Compliance Administrator* role

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview **roles and permissions**.

Step 2: Opt in to analytics processing and scanning

To get started with DSPM, you need to enable analytics in Insider Risk Management and data loss prevention (DLP). When you opt into DSPM, the system automatically enables analytics in Insider Risk Management and analytics in DLP if they're not already active. If you enable analytics in Insider Risk Management and analytics in DLP, the system automatically enables DSPM.

For more information about analytics in these solutions, see:

- Enable analytics in Insider Risk Management
- Enable analytics in DLP

When you complete the opt-in process, the system starts an automated scan of data and user activities for your organization. Scanning times vary based on the size of your organization and the amount of data and activities that need processing. It might take up to three days for this processing to complete.

Step 3: Configure Security Copilot

To access Copilot in DSPM, you must configure your organization for Security Copilot. For step by step guidance, see Get started with Microsoft Copilot for Security.

Step 4: Evaluate insights and take action

Review and take action with recommendations

DSPM generates recommendations directly from the processed data, user activities, and current state of unprotected assets in your organization. Specific recommendations let you take action and quickly create data loss prevention (DLP) and Insider Risk Management policies to help you mitigate data security risks.

For more information about recommendations, see Take action with Data Security Posture Management recommendations - (classic).

Use Microsoft Security Copilot investigate data security details

Use Security Copilot promptbooks and custom prompts to quick dive into the details and get answers about unprotected sensitive data assets and potentially risky user activities in your organization. Data security insights are generated from scanned data across data loss prevention (DLP), information protection, and Insider Risk Management solutions.

For more information about using Security Copilot, see Use Microsoft Security Copilot with Data Security Posture Management - (classic).

Step 5: Review analytics and trends to track your data security posture

DSPM analytics trends and reports help you quickly see the unprotected and protected sensitive assets and potentially risky user activities in your organization.

For more information about using trends and reports, see Use Data Security Posture Management analytics trends and reports - (classic).

Last updated on 12/15/2025

Take action with Data Security Posture Management recommendations - (classic)

> **Note**
>
> This article is for the **classic** version of Data Security Posture Management that's being replaced with a new version that introduces guided workflows for proactive risk management, and streamlines data security operations so you can more confidently adopt AI across your digital estate.
>
> These improvements won't be added to this classic version so we invite you to try the new Data Security Posture Management, currently in preview.

Data Security Posture Management (DSPM) generates recommendations directly from the processed data, current state of unprotected sensitive assets in your organization, and user activities that put the unprotected sensitive assets at risk. Specific recommendations enable you to take action and quickly create data loss prevention (DLP) and Insider Risk Management policies to help mitigate data security risks. DSPM recommendations can also help you identify coverage gaps in existing Insider Risk Management and DLP policies.

Using recommendations

To display and review recommendations, go to **Data Security Posture Management (classic)** > **Overview** or **Data Security Posture Management (classic)** > **Recommendations**.

- From the **Overview** page, you can review the top two data security recommendations or select **View all recommendations** for a complete listing of all recommendations.
- From the **Recommendations** page, you can directly review a complete listing of all recommendations.

Recommendations come from the last 30 days of user activity and the state of unprotected sensitive assets. As processing continues, the list of recommendations automatically updates and removes recommendations older than 30 days.

Each recommendation provides a short description of the risky activity or state of the unprotected sensitive asset and includes a recommended policy to configure to help mitigate ongoing and future data security risks. The recommendation displays metrics for the number of activities, the associated type of protection, and the number of users involved.

Select **View recommendation** to take action and create a new policy to help mitigate the data security risks associated with the recommendation.

Creating policies from recommendations

After selecting **View recommendation** for a specific recommendation, you can create one or more policies in data loss prevention (DLP) and/or Insider Risk Management to help mitigate the data security risks associated with the recommendation.

For example, if you have a recommendation to prevent users from copying sensitive files to network shares, the recommendation might be to create both an Insider Risk Management policy to detect when certain users perform risky activities containing sensitive data and a DLP policy to prevent those same users from sharing the data with others.

To create policies from a recommendation, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned DSPM permissions.
2. Select the **Data Security Posture Management (classic)** solution card, then select **Recommendations** in the left nav.
3. Select a recommendation, then select **View recommendation**.
4. On the recommendation flyout pane, choose the option to create either one type of policy or multiple policies. By default, if more than one policy applies to the recommendation, the option to create multiple policies is selected by default.
5. Each policy type has a dedicated section for configuring the policy options:
6. For the **Insider Risk Management policy** section options, configure the following policy options:
   a. **Policy name**: Enter a unique policy name or accept the suggested policy name.
   b. **User scope**: Select **Include all users and groups (recommended for best coverage)** or **I want to choose specific users and groups**. If you choose to include specific users or groups, enter the user and group names in the picker field.
   c. **Settings we filled in for you**: The settings for the policy are automatically scoped to the type of activity and unprotected data asset insights associated to the recommendation. These settings include specific policy templates, triggering events, and indicators. If you need to change the suggested settings, select **Customize** > **Insider risk policy** to create the policy in the Insider Risk Management policy workflow.
7. For the **Data Loss Prevention policy** section options, configure the following policy options:
   a. **Policy name**: Enter a unique policy name.
   b. **Mode**: Select **Simulation** or **On**.
   c. **Settings we filled in for you**: The settings for the policy are automatically scoped to the type of activity and unprotected data asset insights associated to the recommendation. These settings include specific sensitive information types, enforcement actions, triggering events, and data locations. If you need to change the

suggested settings, select **Customize** > **DLP policy** to create the policy in the DLP policy workflow.

8. If the suggested policy options meet your needs, select **Create policy**. This step creates one or more policies in the applicable solutions.

It takes a few minutes to create each policy. The new policies appear on the **Policies** tab in the applicable solutions. Once the policy is active, it could take at least 24 hours for the triggering event to occur and score user activity, then the first alert is generated. If administrator notifications are turned on, you get an email when this alert occurs.

You can triage the alert and confirm it to a case for further investigation or dismiss it as normal behavior. After you review a few alerts, fine tune your policy to control how many alerts are generated, what activities are detected, and more. Additional recommendations might be generated for this type of activity that can help you with policy updates.

Updating policies in other solutions

To update policies you created from recommendations, use the policy management tools in each solution. The tools in the solutions let you fully customize policies beyond the quick policy settings included with recommendations.

- Manage Insider Risk Management policies
- Manage DLP policies

Verifying the configuration of existing policies

If your organization already has Insider Risk Management or DLP policies configured, recommendations in DSPM help you identify and correct any gaps in your current policy configurations. Instead of using the policy creation options directly in the recommendation, you might choose to use the insights associated with the recommendation to update or refine an existing Insider Risk Management or DLP policy.

Last updated on 12/15/2025

Use Data Security Posture Management analytics trends and reports - (classic)

> **Note**
>
> This article is for the **classic** version of Data Security Posture Management that's being replaced with a new version that introduces guided workflows for proactive risk management, and streamlines data security operations so you can more confidently adopt AI across your digital estate.
>
> These improvements won't be added to this classic version so we invite you to try the new Data Security Posture Management, currently in preview.

Data security posture management (DSPM) analytics trends and reports help you quickly view the unprotected and protected sensitive assets and potentially risky user activities in your organization.

Working with reports

For each report, use the following features to help filter, review, evaluate, and export DSPM insights:

- **Charts**: Hover on specific areas of report information for metrics and more details about insights.
- **Customize columns**: Select **Customize columns** to add or remove columns and associated information from a report.
- **Export**: Select **Export** to create a .csv file that contains the values included in a report.

Analytics reports

- **Unprotected sensitive assets across data sources**: This report displays the location of sensitive assets containing one or more classifiers (sensitive information types, exact data match classifiers, trainable classifiers) and:
  - Aren't protected by a data loss prevention (DLP) policy that restricts exfiltration activities.
  - Don't have a sensitivity label applied that controls access.

- **Users performing top risk-related activities on unprotected sensitive assets**: This report displays the number of users flagged by Insider Risk Management (departing users,

potentially disgruntled users, high risk users, potential high impact users, potentially risky users) who recently performed activities containing sensitive assets that:

- Contain any type of classifier (sensitive information types, exact data match classifiers, trainable classifiers) that aren't protected by a DLP policy that blocks access or don't have a sensitivity label applied that control access.

Trends

You can view trends on the **Overview** page. They help you see the recent history of sensitive data assets and user activities in your organization. Trends help you monitor your data security posture over time and track the status of protected assets. When you hover over specific points in the trends, you can view details about that point in time or area.

- **Sensitive assets labeled (automatically + manually)**: Percentage of assets per week that have sensitivity labels applied, either manually by users or automatically by auto-labeling policies.
- **Sensitive assets protected by at least one DLP policy**: Percentage of sensitive assets in your organization that contain any type of classifier (sensitive information types, exact data match classifiers, trainable classifiers) and are protected by at least one DLP policy.
- **Potentially risky users**: Number of users per week who are assigned insider risk severity levels (*Low*, *Medium*, *High*) based on activity detected by Insider Risk Management policies.

Last updated on 12/15/2025

Use Microsoft Security Copilot with Data Security Posture Management - (classic)

> **Note**
>
> This article is for the **classic** version of Data Security Posture Management that's being replaced with a new version that introduces guided workflows for proactive risk management, and streamlines data security operations so you can more confidently adopt AI across your digital estate.
>
> These improvements won't be added to this classic version so we invite you to try the new Data Security Posture Management, currently in preview.

Use Microsoft Security Copilot and Data Security Posture Management (DSPM) to quickly explore the details and get answers about unprotected sensitive data assets and potentially risky user activities in your organization. Data security insights come from scanned data across Data Loss Prevention (DLP), Information Protection, and Insider Risk Management solutions in Microsoft Purview.

Get started with Copilot

After you configure DSPM, onboard your organization to Security Copilot, and complete the automated scanning, use Security Copilot featured promptbooks and the new prompt gallery to help you get started. Promptbooks are a built-in sequence of prompts that help you quickly learn more about your data security posture. Choose from the following Security Copilot promptbooks or built-in prompts in the Copilot Prompt Gallery:

Risky user investigation promptbook

This promptbook is a six-prompt sequence that helps you investigate users handling sensitive data and shows their data activities, anomalies, and related alerts. By providing the User Principal Name (UPN) for a user and a duration (in days), this promptbook automatically runs the following prompts in order:

1. Show all sensitive data activities performed by <upn> in the last <duration> days
2. Was <upn> involved in any potential sensitive data exfiltration (for example, email forwarding, external file sharing, USB transfers, cloud uploads) in the last <duration> days?
3. Summarize <upn>'s sensitive data interactions over the last <duration> days, highlighting the most accessed classifiers, labels, SharePoint sites, common upload

domains, and primary email recipient domains and users.
4. Did <upn> exhibit unusual behavior or take uncommon actions like excessive access or downloads in the last <duration> days?
5. Are there any alerts associated with <upn> in the last <duration> days, and what is the user's current risk level?
6. What actions can be taken to prevent <upn> from leaking sensitive data? Include policies, data loss prevention controls, and access restriction strategies.

Sensitive data protection promptbook

This promptbook is a sequence of six prompts that helps you identify and protect sensitive data across your organization. It suggests recommended policy changes and data loss prevention rules. By using the full name of the trainable classifier, sensitivity label, or sensitive information type (SIT) and a duration in days, this promptbook automatically runs the following prompts in order:

1. Where is data labeled as <label_or_classifier_or_SIT> stored?
2. Provide an overview of activities involving <label_or_classifier_or_SIT> data in the last <duration> days.
3. Identify instances where <label_or_classifier_or_SIT> data was transferred outside of the organization in the last <duration> days.
4. Who are the top five users with the most <label_or_classifier_or_SIT> data exfiltration in the last <duration> days?
5. Are there any alerts for users who interacted with <label_or_classifier_or_SIT> data in the last <duration> days?
6. How can I prevent unauthorized transfers of <label_or_classifier_or_SIT> data?

To get started with Security Copilot promptbooks, complete the following steps:

1. Go to the Microsoft Purview portal and sign in with the credentials for a user account assigned DSPM permissions.

2. Select the **Data Security Posture Management (classic)** solution card, then select **Overview** in the left nav.

3. Select one of the suggested prompts for Security Copilot:

    - Risky user investigation promptbook
    - Sensitive data protection promptbook

4. Enter the requested inputs for the user, classifier, sensitivity label, or SIT and duration in days.

5. Select **Submit**.

The promptbook responses automatically scope insight data and provide quick answers in a separate flyout pane. You can select additional built-in prompts to automatically update and generate new responses in the flyout pane. Select **New chat** to clear previous responses to suggested prompts. Create additional custom prompts directly in Copilot to generate responses from AI-driven analytics based on the scanning results from your organization.

Copilot prompt gallery

Data Security Posture Management also offers built-in prompts to help you investigate sensitive areas, potentially risky users, potentially suspicious activity, and more in your organization. To view these built-in Copilot prompts, select **View more in prompt gallery** in the **Get started with Security Copilot featured promptbooks** section on the **Overview** page. You can customize the built-in prompt or immediately run the prompt directly in Copilot.

Select built-in Copilot prompts from the following categories:

- Alerts and policies
- Data at risk
- Potentially risky users
- Potentially suspicious activity
- Sensitive data

Tips for custom Copilot prompts in DSPM

For an enhanced experience with Security Copilot in Data Security Posture Management, use the following tips for higher accuracy for your Copilot responses:

- Always include the user's UPN for questions involving a specific user.
- Always specify the complete name for the sensitive info type or label for questions that involve a specific type of sensitive info type or label.
- Clearly list the sorting criteria for questions for top users, activities, and alerts.
- Always specify the date period for questions for data in a specific date period. If you don't specify a date period, only data from the last 10 days from current date is included. The maximum lookback is 30 days from the current date.
- Put all items (classifiers or labels) in single quotes in your prompt.
- Use "/" as a separator for any path (for example, a file path) in a user prompt.
- Scope the prompt to a single intent for higher accuracy of responses. Break complex prompts into single intent questions and enter the prompts one by one.
- Make questions self-contained. Avoid referring to previous questions or responses.
- Avoid using generic terms.

- Support prompts for data security across Information Protection, DLP, Insider Risk Management, or from public documentation.

For more information about creating Security Copilot prompts, see Create effective prompts.

Using Copilot in other solutions

Security Copilot is also available directly in other Purview solutions to help you quickly find answers for specific scenarios or to generate insights scoped to specific solution areas that aren't related to unprotected assets.

- Using Copilot to summarize an alert in Insider Risk Management
- Use Copilot to summarize user activities in Insider Risk Management

---

Application card: Microsoft Purview Data Security Posture Management

What is an Application or Platform Card?

Microsoft's Application and Platform cards are intended to help you understand how our AI technology works, the choices application owners can make that influence application performance and behavior, and the importance of considering the whole application, including the technology, the people, and the environment. Application cards are created for AI applications and platform cards are created for AI platform services. These resources can support the development or deployment of your own applications and can be shared with users or stakeholders impacted by them.

As part of its commitment to responsible AI, Microsoft adheres to six core principles: fairness, reliability and safety, privacy and security, inclusiveness, transparency, and accountability. These principles are embedded in the Responsible AI Standard, which guides teams in designing, building, and testing AI applications. Application and Platform Cards play a key role in operationalizing these principles by offering transparency around capabilities, intended uses, and limitations. For further insight, readers are encouraged to explore Microsoft's Responsible AI Transparency Report and Code of Conduct, which outline how enterprise customers and individuals can engage with AI responsibly.

Overview

Microsoft Purview Data Security Posture Management is a data security application within the Microsoft Purview portal that helps organizations discover, protect, and investigate sensitive data risks across their digital estate. Rather than focusing on infrastructure or endpoints, Data Security Posture Management centers on the data itself, identifying where it resides, who can access it, how it's used, and whether it's adequately protected. It uses AI to analyze access patterns, sharing behaviors, and policy gaps in order to surface actionable risks and recommend remediation steps.

Data Security Posture Management addresses a growing challenge in today's AI-driven workplaces: the increasing complexity and volume of data makes it difficult for security teams to maintain visibility and control. The application solves this problem by consolidating insights from multiple Microsoft Purview solutions, including data loss prevention (DLP), Insider Risk

Management, information protection with sensitivity labels, and Data Security Investigations, into a single view for monitoring data risks, policy coverage, and posture trends. This unified approach replaces the need for multiple tools and manual audits, helping administrators close data security gaps more efficiently.

Data Security Posture Management is designed to perform reliably in enterprise environments where organizations need to monitor and protect sensitive data across multiple locations. The application includes an embedded Microsoft Security Copilot experience that allows these users to ask natural language questions about their data security posture, as well as AI agents from Security Copilot that can take guided remediation actions on detected risks. For an overview introduction, see the Microsoft Mechanics video: New Data Security Posture Management.

Key terms

The following list provides a glossary of key terms related to Data Security Posture Management:

AI observability: A feature within Data Security Posture Management that provides an inventory of AI apps and agents with recent activity, showing how many are high risk and the total with sensitive interactions, along with a breakdown of individual agents and the policies governing them.

Collection policy: A policy that captures prompts and responses from AI interactions for Copilot in Fabric and Security Copilot, and for non-Copilot AI apps, so they can be managed in Microsoft Purview solutions.

Copilot interactions: Prompts and responses from Copilots and agents that Microsoft Purview supports for data security and compliance protections. Includes Microsoft 365 Copilot, Security Copilot, Copilot in Fabric, Copilot Studio.

Data loss prevention (DLP): A Microsoft Purview solution that helps prevent users from inappropriately sharing sensitive data by using content analysis techniques including keyword matching, expression evaluation, and machine learning algorithms.

Data risk assessment: An automated or custom scan that identifies and helps fix potential data oversharing risks, particularly for SharePoint sites and Fabric workspaces. Default assessments run weekly for the top 100 sites based on usage.

Data security objectives: Guided workflows within Data Security Posture Management that each represent a specific security goal, such as preventing data exposure in Copilot interactions or

preventing oversharing. Each objective groups together relevant Microsoft Purview solutions and prioritized actions.

Data Security Posture Agent: A Microsoft Security Copilot agent exclusive to the current version of Data Security Posture Management that uses natural language search across files in SharePoint, OneDrive, Teams, Exchange, and Copilot interactions. It is designed for pre-investigation checks rather than formal cases.

Insider Risk Management: A Microsoft Purview solution that uses built-in service and third-party indicators to help identify, triage, and act on potentially risky activity by users in an organization.

One-click policy: A preconfigured policy within Data Security Posture Management that can be activated with a single click to quickly gain insights and protect data, without requiring manual policy configuration.

Promptbook: A built-in sequence of prompts for Microsoft Security Copilot that helps users quickly investigate specific data security scenarios, such as risky user behavior or sensitive data protection.

Security Copilot: Microsoft Security Copilot and its agents is a generative AI-powered security solution that helps data security professionals investigate and respond to security incidents. Within Data Security Posture Management, it provides an open-ended prompt experience for asking natural language questions about data security.

Sensitivity label: A label from Microsoft Purview Information Protection that can be applied to content to define and enforce protection policies for sensitive data across clouds, apps, and devices.

Key features or capabilities

The key features and capabilities outlined here describe what Data Security Posture Management is designed to do and how it performs across supported tasks.

- **Data security posture dashboard**: The central landing page that provides immediate access to key posture metrics, top objectives to address based on risk, a snapshot of data usage across the data estate, and a 30-day trending graph of the organization's data security posture. Users can interact directly with Security Copilot through suggested prompts on this page.
- **Data security objectives with guided workflows**: Selectable cards that each represent a specific security goal, such as preventing data exposure in Copilot interactions, preventing

oversharing of sensitive data, preventing exfiltration to risky locations, and discovering sensitive data. Each objective provides an end-to-end workflow with prioritized actions, one-click policies, and progress tracking, so users can focus on achieving outcomes rather than navigating separate solutions.

- **AI observability**: An inventory of AI apps and agents with activity in the last 30 days, showing how many are high risk and the total with sensitive interactions. Provides a breakdown of individual agents, their activities, and the policies governing them, enabling administrators to monitor risks such as oversharing, exfiltration, and unusual access patterns.

- **Data risk assessments**: Automated and custom scans that identify potential data oversharing risks. Default assessments run weekly for the top 100 SharePoint sites based on usage. Custom assessments can target specific users, sites, or Fabric workspaces. Results include remediation options such as restricting access by label, creating auto-labeling policies, or creating retention policies.

- **Data security recommendations and remediation actions**: Insights and recommendations generated from processed data that help administrators create or refine DLP and Insider Risk Management policies. Includes one-click policies for quick deployment directly from the Data Security Posture Management workflow.

- **Reports and analytics**: Tracks the organization's data security posture over time with reports summarizing sensitivity label usage, DLP policy coverage, risky user behavior, and AI app activity. Enhanced reporting provides advanced filtering, customizable views, and export capabilities to support compliance requirements.

- **Activity explorer**: Provides detailed visibility into content-related activity, including AI interactions (prompts, responses, and sensitive information detected), DLP rule matches, AI website visits, and sensitive information type detections. Supports filtering by workload categories such as Copilot experiences, enterprise AI apps, and other AI apps.

- **Data Security Posture Agent**: An AI-powered agent from Microsoft Security Copilot and that uses natural language search to find sensitive data across SharePoint, OneDrive, Teams, Exchange, and Copilot interactions. It provides item counts, sensitivity label classifications, and risk-level assessments, along with exportable insight reports. This agent is designed for quick, pre-investigation checks.

- **Embedded Security Copilot experience**: An open-ended prompt experience where users can ask natural language questions about their data security posture. Includes built-in

promptbooks for risky user investigation and sensitive data protection, as well as a prompt gallery with categorized prompts for alerts, data at risk, risky users, suspicious activity, and sensitive data.

- **AI agent-driven remediation**: Under user guidance, AI agents can take direct action on detected risks, such as removing public sharing links, applying DLP policies, or revoking permissions. AI-driven triage agents review alerts from DLP and Insider Risk Management, filtering noise and highlighting critical threats. All agent actions are audited and subject to user review and approval.

Intended uses

Data Security Posture Management can be used in multiple scenarios across a variety of industries. Some examples of use cases include:

- **Monitoring data security posture across the enterprise**: A compliance officer at a financial services organization uses Data Security Posture Management to get a unified view of their sensitive data across different locations. The posture dashboard surfaces key metrics and trends, enabling the officer to quickly identify where unprotected sensitive data exists and track improvements over time. This eliminates the need to manually review multiple separate tools and dashboards.

- **Preventing oversharing before deploying Microsoft 365 Copilot**: An IT administrator preparing for a Microsoft 365 Copilot deployment runs data risk assessments to identify SharePoint sites with potentially overshared content. Data Security Posture Management surfaces sites where sensitive files have broad sharing links or lack sensitivity labels, and provides one-click remediation options such as restricting access or creating auto-labeling policies. This helps the organization reduce data exposure before AI tools begin processing that content.

- **Investigating risky user behavior with AI-assisted analysis**: A data security analyst receives an alert about a user performing unusual file-sharing activities. Using the embedded Security Copilot experience, the analyst runs the risky user investigation promptbook, which automatically analyzes the user's sensitive data activities, identifies potential exfiltration patterns, checks for anomalies, and suggests protective actions, all through a sequence of natural language prompts.

- **Governing AI app usage across the organization**: A security team at a healthcare organization uses AI observability to monitor which AI apps and agents employees are

interacting with, which of those interactions involve sensitive patient data, and whether appropriate DLP policies are in place. The team uses data security objectives to create targeted policies that prevent sensitive health information from being shared with unauthorized AI applications.

- **Responding to compliance requirements**: A compliance team at a government agency uses Data Security Posture Management reports and activity explorer to demonstrate that sensitive data is appropriately labeled, protected by DLP policies, and monitored for risky activity. The export capabilities and customizable views allow the team to generate audit-ready documentation aligned with their regulatory obligations.

- **Discovering unprotected sensitive data in new environments**: An organization just getting started with Microsoft Purview uses Data Security Posture Management to automatically scan data and user activities, gaining baseline insights and recommendations focused on unprotected data. This helps the organization quickly establish DLP, information protection, and Insider Risk Management policies without conducting deep manual analysis.

Data Security Posture Management is not intended for use as a general-purpose AI assistant, for scenarios unrelated to data security within Microsoft Purview, or for formal legal investigations (which require dedicated solutions such as eDiscovery and Data Security Investigations).

Models and training data

Data Security Posture Management leverages existing AI agents and AI functionality. As such, it's dependent on any external configuration that these provide. For example, model choice for Microsoft Security Copilot for the embedded natural language prompt experience. Data Security Posture Management also uses content analysis within Data Loss Prevention for detecting sensitive information through keyword matching, expression evaluation, and machine learning algorithms. To learn more, refer to the linked application cards and documentation.

Performance

Data Security Posture Management is designed to perform reliably in enterprise environments where organizations need to monitor and protect sensitive data across multiple locations. The application processes and correlates data from existing Microsoft Purview solutions, including DLP, Insider Risk Management, and information protection, to generate insights, recommendations, and posture metrics. Performance is optimized for organizations using supported Microsoft cloud services, and results improve as more Microsoft Purview solutions are configured and more data is available for analysis.

The application accepts text-based inputs across its features. Users interact with Data Security Posture Management through the Microsoft Purview portal interface, where they can navigate dashboards, configure policies, and run data risk assessments. The embedded Security Copilot experience accepts natural language text prompts and returns text-based responses, including data summaries, risk analysis, and recommended actions. The Data Security Posture Agent accepts natural language search queries and returns structured results, including item counts, sensitivity label classifications, and risk-level assessments, with an option to export reports as Word documents.

Data Security Posture Management supports the languages available in the Microsoft Purview portal interface. The Security Copilot experience is designed and evaluated primarily for English-language prompts and responses. Sensitive information type detection supports multiple languages as documented in the individual sensitive information type definitions. Users should be aware that performance of the natural language prompt and search features may vary when using languages other than English.

After initial setup, Data Security Posture Management requires time to process organizational data. Scanning times vary based on the size of the organization and the amount of data and activities to process, and it may take up to three days for initial processing to complete. New policies require at least 24 hours to collect data before results appear. Data risk assessments require at least 48 hours after completion before updated results are available. The Data Security Posture Agent can search up to 1 GB of content per query, and restricted searches targeting specific users or sites perform significantly faster than tenant-wide searches.

Limitations

Understanding Data Security Posture Management's limitations is crucial to determine it is used within safe and effective boundaries. While we encourage customers to leverage Data Security Posture Management in their innovative solutions or applications, it's important to note that Data Security Posture Management was not designed for every possible scenario. We encourage users to refer to either the Microsoft Enterprise AI Services Code of Conduct (for organizations) or the Code of Conduct section in the Microsoft Services Agreement (for individuals) as well as the following considerations when choosing a use case:

- **Data security scope**: The Security Copilot experience in Data Security Posture Management is designed to answer questions about data security associated with Insider Risk Management, Information Protection, and Data Loss Prevention in Microsoft Purview. All other Purview solutions are currently out of scope for Data Security Posture Management

insights. Users should direct questions outside of these areas to the appropriate solution-specific tools.

- **Data coverage**: The asset explorer Standard tab is filtered by Microsoft and non-Microsoft locations. Microsoft locations currently include Microsoft 365 only. Non-Microsoft locations are made possible by integration with partner solutions. Organizations with significant data in environments that aren't included should be aware that visibility through the asset explorer may be limited and should supplement with other tools as needed.

- **Data risk assessment volume limits**: A maximum of 200,000 items per location applies to both custom and default data risk assessments. The reported file count may not be accurate when there are more than 100,000 files per location. Organizations with very large SharePoint sites should consider running multiple targeted assessments. Additionally, OneDrive is not currently supported for item-level scanning, and custom assessments support a maximum of 10 SharePoint sites for item-level scanning.

- **Processing time requirements**: After a custom data risk assessment completes, results require at least 48 hours to become available and do not update after that point. A new assessment is needed to see changes. New policies require at least 24 hours before data appears. Users should plan ahead and avoid expecting real-time results from newly created assessments or policies.

- **Activity explorer data completeness**: The AI interaction event may not always display prompt and response text. In some cases, prompts and responses span consecutive entries. When a user does not have a mailbox hosted in Exchange Online, no prompt or response is displayed. Microsoft Facilitator AI-generated notes may not display prompts or responses. Users should be aware of these gaps when relying on activity explorer for compliance or investigative purposes.

- **Data Security Posture Agent constraints**: The agent supports content searches up to 1 GB of data but does not support metadata-based searches. If no time period is specified, results default to the last 7 days. The agent is designed for pre-investigation checks and is not a replacement for formal investigation tools such as eDiscovery, audit, or Data Security Investigations.

- **Language support**: The Security Copilot experience and the Data Security Posture Agent are designed and evaluated primarily for English-language prompts. Using other languages may result in reduced accuracy or incomplete responses. Users should exercise caution when operating outside the intended language scope.

- **Generative AI response accuracy**: As with all generative AI systems, Security Copilot responses in Data Security Posture Management may occasionally contain inaccurate or incomplete information. Users should verify AI-generated insights against actual data before taking consequential actions based on those responses.

Evaluations

Performance and safety evaluations assess whether AI applications are operating reliably and securely by examining factors like groundedness, relevance, and coherence while identifying the risks of generating harmful content. The following evaluations were conducted with safety components already in place, which are also described in Safety Components and Mitigations.

Data Security Posture Management was evaluated using custom evaluation methods developed by the product team. The evaluation focused on the accuracy of the embedded Security Copilot experience when responding to natural language questions about data security.

The evaluation data set consisted of relevant prompts identified by the product team and customers, including an expanded test set of prompts based on table schemas and descriptions. Microsoft evaluated performance using an accuracy rate metric: a response is considered accurate if the generated query provides the exact information asked in the prompt. The team tested across a range of data security scenarios covering DLP, information protection, and Insider Risk Management insights to verify that Security Copilot responses are factually supported by the underlying data and contextually appropriate to the user's question.

An ideal result is one where the Security Copilot response returns exactly the information requested, grounded in the organization's actual data, with no fabricated or misleading content. A suboptimal result would be a response that returns inaccurate data, misinterprets the user's question, or provides information outside the scope of the supported data security solutions. The evaluation process is iterative, with the product team refining the prompt sets and accuracy thresholds based on customer feedback and real-world usage patterns.

Safety components and mitigations

- **Role-based access control**: Data Security Posture Management enforces granular permissions through Microsoft Entra and Microsoft Purview role groups. Different activities require specific roles, such as Compliance Administrator for editing, Data Security Viewer for using Security Copilot, and Content Explorer Content Viewer for viewing AI interaction prompts and responses. This ensures that users can only access data and take actions appropriate to their role, reducing the risk of unauthorized access to sensitive information.

- **Comprehensive audit logging**: All automated actions taken by AI agents in Data Security Posture Management are recorded in audit logs. This includes actions such as removing sharing links, applying policies, and revoking permissions. Audit logs and activity explorer features provide a full trail of interactions with AI apps and agents, supporting compliance investigations, incident response, and accountability.

- **Human review and approval for agent actions**: Users always maintain control over AI agent behavior within Data Security Posture Management. AI-driven triage agents and the Data Security Posture Agent surface recommendations and findings, but users review, approve, or customize all automated actions before they take effect. The "View agent activity" options throughout the interface provide easy access to agent activity for oversight.

- **Opt-in analytics processing**: Data Security Posture Management requires explicit opt-in before processing organizational data. Analytics in both Insider Risk Management and DLP must be enabled before Data Security Posture Management can generate insights. This ensures that organizations make a deliberate decision to share data for analysis and are aware of the processing that takes place.

- **Scoped AI capabilities**: The Security Copilot experience in Data Security Posture Management is deliberately scoped to data security topics associated with Insider Risk Management, Information Protection, and Data Loss Prevention. Questions outside this scope are not answered, reducing the risk of the AI generating responses about topics where it lacks reliable data. The Data Security Posture Agent is similarly scoped to content searches within Microsoft 365 and limited to 1 GB of content per query.

- **Risk-level classification for search results**: The Data Security Posture Agent assigns a risk level to each search result based on how closely the content matches the user's prompt. Results are categorized to help users prioritize and focus on the most relevant findings. When the agent cannot determine the risk level, items are marked as "not categorized," providing transparency about the agent's confidence level.

- **Alert triage and noise reduction**: AI-driven triage agents review DLP and Insider Risk Management alerts and categorize them as "needs attention," "less urgent," or "not categorized." This filtering reduces alert fatigue and helps security analysts focus on genuine threats rather than false positives.

- **Privacy-preserving design**: Insider Risk Management, which feeds data into Data Security Posture Management, includes privacy controls such as pseudonymization and role-based access to ensure user-level privacy while enabling risk analysis. The Security Copilot

component follows the data privacy and security practices documented in the Microsoft Security Copilot privacy and data security documentation.

- **In-product feedback mechanism**: Users can provide feedback on each Security Copilot response by marking it as "looks right," "needs improvement," or "inappropriate." This feedback loop helps Microsoft continuously improve the quality and safety of AI-generated responses.

Best practices for deploying and adopting Data Security Posture Management

Responsible AI is a shared commitment between Microsoft and its customers. While Microsoft builds AI applications with safety, fairness, and transparency at the core, customers play a critical role in deploying and using these technologies responsibly within their own contexts. To support this partnership, we offer the following best practices for deployers and end users to help customers implement responsible AI effectively.

Deployers and end-users should:

- **Exercise caution and evaluate outcomes when using Data Security Posture Management for consequential decisions or in sensitive domains**: Consequential decisions are those that may have a legal or significant impact on a person's access to education, employment, financial platforms, government benefits, healthcare, housing, insurance, legal platforms, or that could result in physical, psychological, or financial harm. Sensitive domains—such as financial platforms, healthcare, and housing—require particular care due to the potential for disproportionate impact on different groups of people. When using AI for decisions in these areas, make sure that impacted stakeholders can understand how decisions are made, appeal decisions, and update any relevant input data.

- **Evaluate legal and regulatory considerations**: Customers need to evaluate potential specific legal and regulatory obligations when using any AI platforms and solutions, which may not be appropriate for use in every industry or scenario. Additionally, AI platforms or solutions are not designed for and may not be used in ways prohibited in applicable terms of service and relevant codes of conduct.

End-users should:

- **Exercise human oversight when appropriate**: Human oversight is an important safeguard when interacting with AI applications. While we continuously improve our AI applications, AI might still make mistakes. The outputs generated may be inaccurate, incomplete, biased,

misaligned, or irrelevant to your intended goals. This could happen due to various reasons, such as ambiguity in the inputs or limitations of the underlying models. As such, users should review the responses generated by Data Security Posture Management and verify that they match their expectations and requirements.

- **Be aware of the risk of overreliance**: Overreliance on AI happens when users accept incorrect or incomplete AI outputs, mainly because mistakes in AI outputs may be hard to detect. For the end-user, overreliance could result in decreased productivity, loss of trust, application abandonment, financial loss, psychological harm, physical harm, among others. In the context of Data Security Posture Management, overreliance could mean acting on an inaccurate Security Copilot insight without verifying it against actual data, potentially leading to misguided policy changes or missed security risks.

- **Scope Security Copilot questions to supported areas**: For the best results, ask questions about data security topics associated with Insider Risk Management, Information Protection, and Data Loss Prevention. Questions outside these areas may return incomplete or inaccurate responses because they fall outside the data Data Security Posture Management is designed to analyze.

- **Use specific and targeted prompts**: When using the Security Copilot experience or the Data Security Posture Agent, provide clear and specific prompts that include relevant details such as user names, time periods, and data locations. For example, instead of asking "show me security risks," ask "show all sensitive data activities performed by user@contoso.com in the last 30 days." More specific prompts produce more accurate and actionable results.

- **Provide feedback to improve quality**: Use the in-product feedback option to mark Security Copilot responses as "looks right," "needs improvement," or "inappropriate." This feedback helps Microsoft identify and address quality issues in AI-generated responses.

Deployers should:

- **Configure appropriate permissions before granting access**: Assign the minimum required roles to each user based on their responsibilities. Use the detailed permissions table in the Data Security Posture Management permissions documentation to determine which role groups are needed for each activity. Restricting access reduces the risk of unauthorized users viewing sensitive data or taking unintended actions.

- **Complete all setup tasks before relying on insights**: Ensure that auditing, analytics, and collection policies are properly configured before evaluating Data Security Posture Management insights. Incomplete setup can result in missing data and inaccurate posture

metrics. Allow sufficient processing time (up to three days for initial scans, at least 24 hours for new policies) before making decisions based on Data Security Posture Management data.

- **Use restricted searches for efficient processing**: When using the Data Security Posture Agent, configure searches to target specific users, groups, or sites rather than running tenant-wide scans. Restricted searches are significantly faster and more efficient, reducing processing time and producing more focused results.

- **Review and refine one-click policies after deployment**: One-click policies provide a useful starting point, but they should be reviewed and customized based on your organization's specific requirements. After initial deployment, monitor policy results through Data Security Posture Management reports and activity explorer, and adjust policy settings in the corresponding solution (DLP, Insider Risk Management, or Information Protection) to match your organization's risk tolerance and compliance needs.

- **Establish a regular review cadence**: Use Data Security Posture Management posture trends and reports to track your organization's data security posture over time. Establish a regular cadence for reviewing data risk assessments, policy coverage, and AI observability metrics. Regular reviews help identify emerging risks, policy gaps, and changes in user behavior before they become security incidents.

- **Plan for collection policy configuration**: If your organization needs to capture prompts and responses from Copilot in Fabric and Security Copilot, and for non-Copilot AI apps, configure collection policies with the content capture option selected. For apps that use these collection policies, AI interaction events in activity explorer will not display prompt and response text, limiting the usefulness of the data for compliance monitoring.

Learn more about Data Security Posture Management

For additional guidance or to learn more about the responsible use of Data Security Posture Management, we recommend reviewing the following documentation:

Data governance with Microsoft Purview

Article • 02/20/2025

Data governance is how you ensure that the data you use in your business operations, reports, and analysis is discoverable, accurate, trusted, and protected. With ever-evolving regulations combined with the proliferation of AI, and regulations for AI, data governance is as critical as data security.

Managing the quality of your data in the era of AI is essential. When your AI systems ingest trusted, high quality data, you have accurate insights for making sound business decisions. But managing data quality is time-consuming. Data professionals often spend most their time simply finding, cleaning, and organizing data, instead of using the data that's clean and trusted.

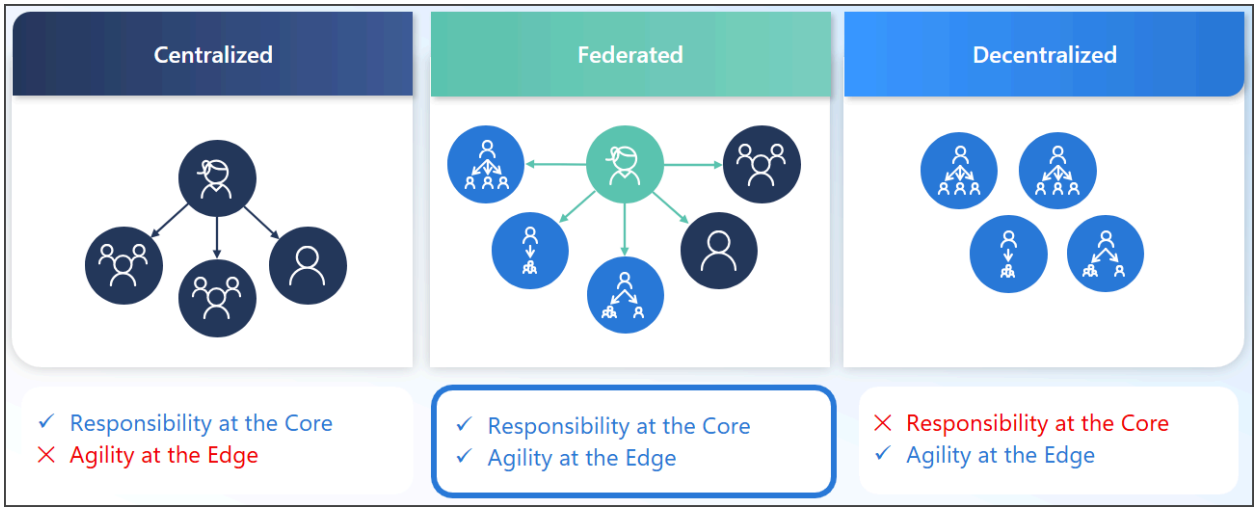
Microsoft Purview data governance solutions, Unified Catalog and Data Map, deliver a modern data governance experience to provide comprehensive visibility, data confidence, and responsible innovation by streamlining metadata from disparate catalogs and sources. With Unified Catalog at the center of your day-to-day operations, your organization can experience comprehensive visibility, data confidence, and responsible innovation to help you achieve greater business value in the era of AI.

Data governance solutions

Microsoft Purview data governance involves two primary solutions:

- Microsoft Purview Data Map
- Microsoft Purview Unified Catalog

Data Map is what you use to scan all your assets and multicloud sources to capture metadata. Unified Catalog is a searchable catalog of your scanned data where you curate, grant access to, and improve the health of your data. The catalog is a software as a service (SaaS) experience based on a single-tenant model, providing end-to-end capabilities for curating data, managing data quality and health, and granting users in your organization access to data. With a user-friendly and modern experience, Unified Catalog helps organizations achieve greater business value in the era of AI through high quality data.



To get an overview, check out this video explaining Microsoft Purview data governance capabilities, how to set up for success, and the day-to-day management

experience.

> **Important**
>
> As you work with Data Map and Unified Catalog, keep these points in mind:
>
> - All data in Data Map and Unified Catalog is **metadata**, not the underlying data itself.
> - None of the permissions or roles in Data Map or Unified Catalog provide access to underlying data itself.

Federated approach to data governance

A federated approach to data governance is a middle ground between a centralized and a decentralized approach. An organization's central data office sets the rules, while individuals in various roles and departments who use the data and understand its function are entrusted to govern that data appropriately. The federated model ensures that there's centralized oversight and helps unlock business innovation by facilitating how users request access to the data they need.

User-friendly tools for data professionals

An effective system of data governance empowers your organization's data professionals to easily manage, discover, and access data. Microsoft Purview data governance solutions are built for each role performed in your organization. Business domain experts can accelerate data value while your data office and stewards provide the standards for consistent operations and can maintain commonalities.

- **Central data office**: Establishes and ensures governance policies, active metadata, compliance, and insights into overall governance health.
- **Data consumers**: Quickly find and use relevant, trusted datasets through streamlined access request workflow.
- **Data owners**: Register data assets for use, manage classifications and access, and ensure high quality standards.
- **Data stewards**: Ensure data quality, seamless data discovery, glossary, consistency, and lineage. Work with central data office.

Key capabilities

Comprehensive visibility

Simplify visibility across disparate catalogs, data sources, data management, and data security with these capabilities:

- Unified Catalog, providing AI-enabled recommendations for data quality and data curation.
- Data products within the Unified Catalog, which are groups of assets with a use case that can be shard with data consumers.
- Actionable oversight that helps you analyze and track data health while ensuring users have access to the data they need.

Data confidence

Maintain confidence in your organization's data with built-in data quality and data lineage capabilities aligned to industry standards and policies:

- Governance domains of data products and business concepts for easier access and use. Use governance controls across your data estate to complement the domains set up in other technical catalogs. Establish accountability for the area of your data estate.
- Data lineage helps you easily see the relationship between the data products and any assets associated with them to identify the root cause of quality issues.
- Data quality experiences built-in to empower data owners to oversee the quality of their data ecosystem and facilitate actions for improvement.

Responsible innovation

Responsibly unlock business value with easier data discovery and actionable insights with these capabilities:

- Role-based access controls to ensure the right people have access to the right data through reader and owner level rights.
- Simplified access and discovery by searching on business context and natural language, with help from Security Copilot.
- Quick access to analytics with Purview Analytics in OneLake, so you can export data from Unified Catalog and import it into OneLake for business users running analytics in Microsoft Fabric.

> **Tip**
>
> Visit **Learn about Unified Catalog** for detailed information about features and how to get started using the catalog.

Workflow at a glance

There are different approaches your organization can take to start building a data governance practice. Listed below are the overarching steps involved in setting up data governance with Microsoft Purview:

1. Assign a user in your organization the Data Governance Administrator role, which grants permissions to assign roles to other users in your organization for key governance tasks and data curation.
2. Using Data Map, scan your data assets and multicloud sources in Data Map to capture metadata.
3. In Unified Catalog, build governance domains and curate data products.
4. Connect your data with business concepts, such as objectives and key results (OKRs) and glossary terms.
5. Improve data quality and remove data issues to improve data health.

> **Tip**
>
> We've mapped out suggested paths to help you get started depending on your situation at **Plan for data governance**.

Billing

Before you get started, review the pricing model for Microsoft Purview data governance solutions.

Getting started

If you're ready to begin, use these resources to get started:

- Learn how to plan for data governance.
- Visit Get started to view detailed instructions with links to deeper technical content.
- Review the roles and permissions needed for users in your organization who play a role in data governance.

Plan for data governance with Microsoft Purview

Article • 02/20/2025

Before you get started with data governance, there are important planning activities and considerations that should be reviewed by your information technology and data management teams. Thoroughly understanding and planning for deployment will help ensure that your implementation and use of features in Microsoft Purview Unified Catalog and Microsoft Purview Data Map go smoothly and align with the best practices.

> **Note**
>
> Check to see which regions are supported for Microsoft Purview data governance solutions.

Relationship between Unified Catalog and Data Map

The Data Map is the technical layer of Microsoft Purview that stores the data about the assets. Data sources are scanned to create the inventory of what assets are available in the different data sources across your organization's data estate.

The Unified Catalog is the business-friendly layer where data stewards curate data, and data consumers find the right data to use. The Unified Catalog is powered by the asset inventory in the Data Map to create a marketplace of data products, ensuring consumers can find the right data and use it responsibly.

> **Important**
>
> As you work with Data Map and Unified Catalog, keep these points in mind:
>
> - All data in Data Map and Unified Catalog is **metadata**, not the underlying data itself.
> - None of the permissions or roles in Data Map or Unified Catalog provide access to underlying data itself.

Who to involve in data governance

When you start your data governance planning with data owners, data stewards, and other business users with expertise, you'll ensure that the Unified Catalog has all of the information needed to build new value with data. IT teams are critical organizational partners in their data use, and help to ensure the right data sources are prioritized for onboarding to the Data Map.

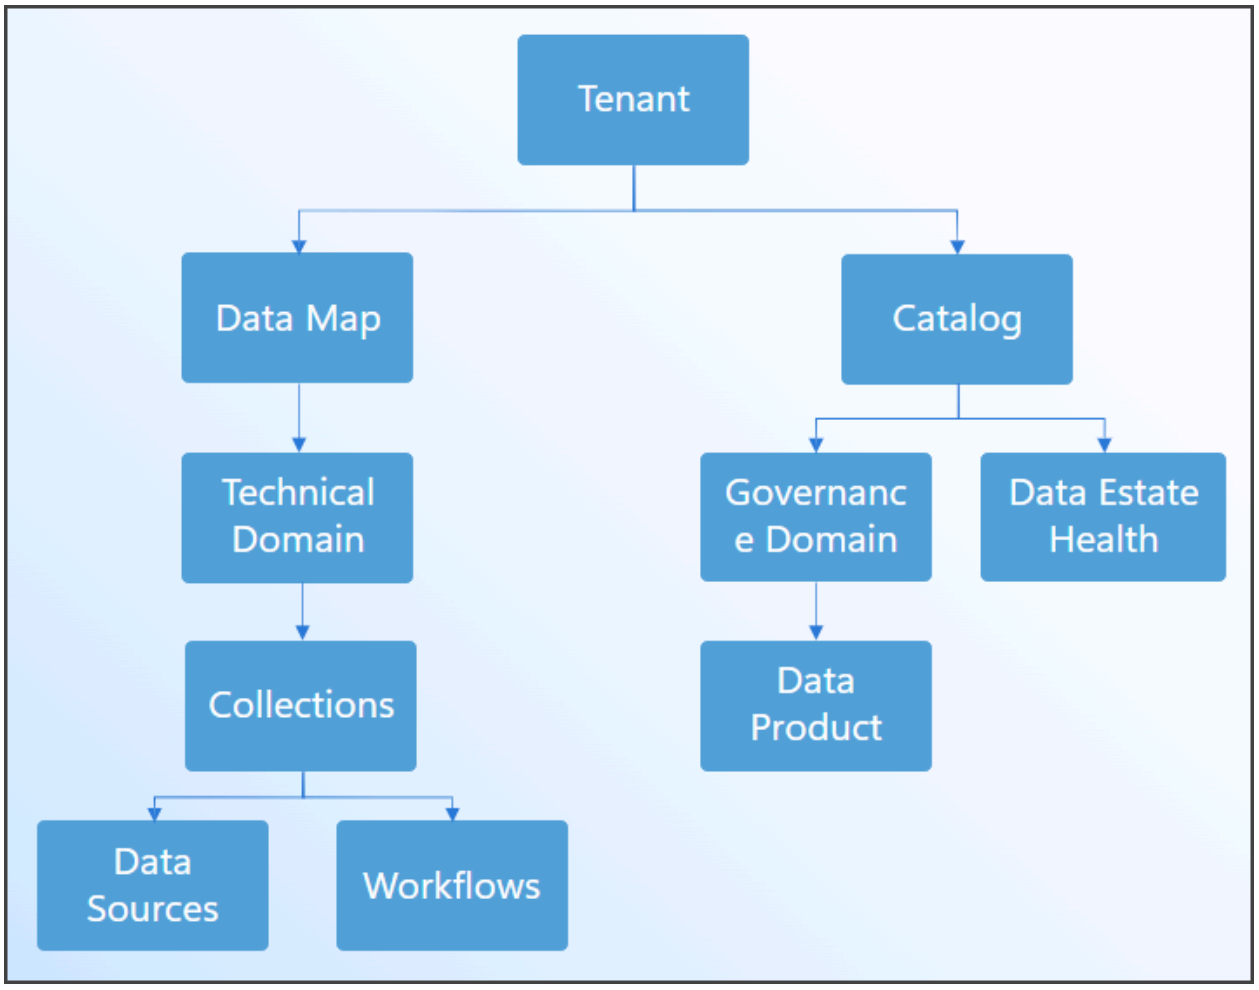
Your organization's data office will oversee the creation of the catalog with company-wide standards, and help build bridges between teams to provide the best governance framework. Having both the data publishing teams and the data consumers included in the process of building out the catalog will provide the most value from the data, and build the collaboration to include all of the experts across your organization.

> **Tip**
>
> For the best success, **it's critical to involve all parties early**. This is because the practice of data governance isn't done by a single person, and no one knows everything about the data, the business, and what it means to use that data responsibly.

Where to start

There's more than one way to start building your data governance practice with Microsoft Purview. How you start is up to you. The sequence in which you perform your initial setup tasks might depend on your business strategy and who's doing the work. Regardless of the order, the full value of Microsoft Purview for data governance isn't realized until all key tasks are completed. The tabs below provide guidance based on your situation or preferred approach.

New to Microsoft Purview or data governance



If you're new to data governance or to Microsoft Purview, we suggest starting with the stakeholders who are most passionate about data governance, or have the need to create a data catalog. Typically, business intelligence teams or data lake teams can be a good place to start because they have experts on the data and have invested in building data that others can use.

When you're ready to get started, we recommend doing the tasks outlined in Getting started with data governance in the following order:

1. Create a governance domain (Unified Catalog).
2. Add a domain owner who will be accountable for that domain (Unified Catalog).
3. Add the experts for that part of business to build business concepts (Unified Catalog).
4. Create a collection (Data Map).
5. Add a data source administrator from the data platform to onboard first (Microsoft Purview settings).
6. Register and scan the data source (Data Map).
7. Build out the data products for the most important and frequently used data in that source in the governance domain (Unified Catalog).

Permissions hierarchy

Before you start assigning roles and permissions to users in your organization, it's helpful to understand the relationship between the primary data governance solutions, Unified Catalog and Data Map, and the permissions granted by the roles for each solution.

- **Tenant, or organization**: Users who own the Microsoft Purview instance and need access to maintain its permissions and information.
- **Data Map**: Grants permissions to create and administrate technical domains and collections.
- **Unified Catalog**: Grants users permission to create governance domains or access data estate health.
- **Governance domain**: Grants permissions for objects within a governance domain, such as glossary terms or data products.

When you're ready to start assigning roles and permissions, Data governance roles and permissions gives detailed instructions. To guide you through the process, we recommend beginng with Getting started with data governance.

Next steps

- Ready to grant access and assign roles? Visit Roles and permissions.
- If you're ready to start setting up things, visit Get started with data governance.
- Want to follow an example? Review a walkthrough of a sample data governance setup.

Get started with Microsoft Purview data governance

This article takes you through technical steps to get started building your data governance solution in Microsoft Purview and integrating data governance with your day-to-day business operations.

You might find it helpful to review Plan for Unified Catalog as an orientation to the material below. For a step-by-step illustration of how to set up your environment, visit the sample setup walkthrough.

Prerequisites

1. You need a Microsoft Purview Enterprise instance, either by:
   a. Upgrading an existing account to the new experience
   b. Upgrading from the free version of Microsoft Purview to enterprise
2. Get your data sources registered and scanned in Microsoft Purview. View the list of supported data sources.

Data Governance Administrator role

The Data Governance Administrator role delegates the first level of access for Microsoft Purview Unified Catalog users. Granting this role to a user in your organization is your first step as you get started. Find details on how to assign roles for data governance.

Business concepts

Business concepts are elements in Unified Catalog that help you organize and understand your data in ways that make sense to the data consumers and curators in your organization. When we refer to business concepts in Unified Catalog, we're talking about these five elements:

1. Governance domains
2. Data products
3. Critical data elements (preview)
4. Glossary terms
5. Objectives and key results (OKRs)

The Plan for Unified Catalog article has detailed guidance to help you understand these concepts and how to start working with them. As a starting point, it's helpful to have a good understanding of **governance domains** and **data products**:

- **Governance domain**: A boundary that enables the common governance, ownership, and discovery of data products and other business concepts. The goal is to empower a governance domain owner to manage their data products, and establish rules for their access, usage, and distribution. Here are some examples of how you could set up your governance domains:
  - Corporate or business areas, such as human resources, sales, and finance.
  - Overarching subject areas, such as product or parties.
  - Regulatory domains, such as SOX, PCI, or anti-money laundering.
  - Boundaries based on organizational functions, such as customer experience, cloud supply chain, or business intelligence.

- **Data product**: A group of data assets, such as tables, files, or Microsoft Power BI reports, that are packaged together with a proper use case to be shared to data consumers in the organization. A governance domain can house many data products, but a data product is managed by a single governance domain and can be discovered across many governance domains.

Once you set up governance domains and data products, you can further curate your data by:

- Connecting to the other business concepts.
- Creating and applying attributes to your business concepts.

Basic setup steps

1. Assign users to the Data Governance Administrator role - Gives the admin permissions to grant users application-level-permissions like governance domain creation.
2. Build governance domains:
   a. Assign users the governance domain creator role
   b. Create at least one governance domain

      > **Tip**
      >
      > Use **our guide** to strategize your governance domain structure.

   c. Assign at least one governance domain owner on each governance domain. This user is the point of support and decision authority for data being consumed in this governance

domain.

3. Register your data sources in Microsoft Purview Data Map, and then scan the data sources to capture metadata.
4. Build data products:
   a. Assign data product owners to create data products in your governance domains. These should be business and data experts who can pair data with day-to-day scenarios in their governance domain.
   b. Create at least one data product in your governance domains.

   > **Tip**
   >
   > Use **our guide** for tips on how to build good data products.

5. Assign users catalog reader permissions in your governance domains so they can view and explore your data products in the Unified Catalog.

Connect your data with business concepts

Glossary terms provide vocabulary for business users. These terms let users discover and work with data in the vocabulary that's familiar to them, instead of using abstract technical terminology inherited from physical data sources.

Objectives and key results (OKRs) are the goals or desired outcomes of a governance domain; for example, 10% rise in sales or 3% reduction in support cases. Objectives should relate to everything an organization does and should define how they're achieving their outcomes.

Health management actions give you and your users steps to improve data health and governance across your data estate. These actions correspond to the checks made to calculate a data product's data governance health control score. Addressing these actions raises your health score and promotes an overall more usable and discoverable Unified Catalog. Understanding the value of your data products improves the trust others take in that data and helps with prioritizing which data to focus on improving first.

Connect action steps

1. Assign users data steward permission in your governance domains to create and manage glossary terms. These users should be data and business experts. They increase the value of data products by curating the information and attaching glossary terms to make the data understandable.

2. Create at least one OKR in your governance domain.
    a. Link your OKR to a data product to connect your data to your business goals.
3. Assign users data health reader permissions in Unified Catalog. These users monitor Unified Catalog use and current governance scores, and take actions to build trust in your data products.
4. Publish some glossary terms in your governance domain.
    a. Link a glossary term to a data product to improve discoverability.
5. Assign users data steward permission in your governance domains to create and manage OKRs. These users should be business strategy experts to ensure business leaders appreciate the value of their data, and the importance of data governance. They drive prioritization and strategize how teams build, maintain, and govern their data to create insights.
6. Review your health controls to get a baseline for your current health management.
7. Review health actions to start considering next steps for your data governance journey.
8. Create custom metadata and apply attributes to your business concepts.

Improve data quality and remove data issues

Data quality measures the quality of data in an organization. It uses data quality rules that you configure and define in Unified Catalog.

Data quality rules describe the state of the data with dimensions like accuracy, completeness, conformity, consistency, timeliness, and uniqueness. Each rule produces a score that describes how close the data is to its desired state.

Data profiling examines the data available in your data sources. It collects statistics and information, and assesses the quality level of the data according to a defined set of goals. If data is of poor quality or managed in structures that can't be integrated to meet the needs of the organization, it can affect business processes and decision-making.

Quality action steps

1. Assign users(s) data quality steward permissions to use all data quality features.
2. Set up a data source connection to prepare your source for data quality assessment.
3. Configure and run data profiling for an asset in your data source.
    a. When profiling is complete, browse the results for each column in the data asset to understand your data's current structure and state.
4. Set up data quality rules based on the profiling results, and apply them to your data asset.

5. Configure and run a data quality scan on a data product to assess the quality of all supported assets in the data product.
6. Review your scan results to evaluate your data product's current data quality.

Weekly planning

The following is a reference example to assist with planning the new Microsoft Purview data governance solution areas, scenarios, tasks, and personas with key stakeholders.

Week 1-2

Expand table

Area	Scenario	Task	Description/Outcomes	Persona
Data management	Catalog setup	Set up first governance domain	Identify governance domain scope, usage, and owners. Assign accountability to governance domain owner, define and create your first governance domain, description, and assign data owners. Capture feedback on establishing the governance domain.	Governance domain owner
	Catalog curation	Create data products in the governance domain	Identify scope of data to manage, publish, and owners. Create data products, descriptions, use cases, assign ownership, and create and assign glossary terms to help increase usability for data consumers. Map data assets to data products, create access policies for data consumers to attest to when requesting access – capture feedback (ease of use for business unit to manage, understand, and own curation)	Data product owner/data steward
	Publication	Publish the governance domain and data products	Publish the governance domain and associated data products to make available for discovery, understanding, and access through the Unified Catalog experience. Assign data consumers permissions to access and view the first governance domain by adding them to the Global Catalog reader role and capture feedback with publication.	Governance domain owner and data product owner
	Operations	Data governance and	Assess operational tasks, stakeholders, processes, and procedures to enable data governance and management. Evaluate	Data governance office

Area	Scenario	Task	Description/Outcomes	Persona
		management operations	against current state data governance policies, practice, and culture to identify potential areas for improvement or change.	

Week 2-3

Expand table

Area	Scenario	Task	Description/Outcomes	Persona
Data discovery, understanding, and access	Discover and access	Unified Catalog product search	Exercise the Unified Catalog product search experience to help data consumers and users discover and understand data products that are curated and developed for a specific business purpose. Assess data product metadata to determine proper usage, data quality, and applicability to data consumer business outcomes, and then request access. Assess ease of use to data products the user recently reviewed, and data products subscribed to – capture feedback on full data consumer experience.	Data consumer
Data management	Access management	Access request management	Review access requests for data products in the first governance domain and approve or reject. Engage with IT owners for approvals (as appropriate) to data assets.	Data product owner
	Catalog curation	Review data product discoverability	Review discoverability and usability of published data products along with data consumer feedback to inform semantic knowledge improvement opportunities (for example, glossary terms, attention to attention items in the action center, etc.).	Data product owner/data steward

Week 3-4

Expand table

Area	Scenario	Task	Description/Outcomes	Persona
Data management	Data quality	Improve data quality and reduce data issues	Assess top-level data quality by the first governance domain, and evaluate and set up data quality for associated data assets by data product (via connections). Use data quality profiling data to inform quality rules and dimensions to establish key data assets in the data product. Run data quality scans (ad-hoc or scheduled), monitor data quality activity and scans, and set up alerts to be informed of changes with data asset health (via target thresholds). Capture feedback on overall data quality experience.	Data quality steward
	Operations	Data governance and management operations	Assess operational tasks, stakeholders, processes, and procedures to enable data quality in the context of data governance and management. Evaluate against current state data governance policies, practice, and culture to identify potential areas for improvement or change.	Data governance office

Week 4-5

Expand table

Area	Scenario	Task	Description/Outcomes	Persona
Health management	Reports	Manage data governance	Review the controls with business data domain owners and set up regular review of reporting on those controls. The goal of the meeting is to review issues and prioritize solutions or data products that are needed to meet business needs.	Data governance office
	Health actions	Improve data governance	Take actions based on the controls to improve data governance and ensure standards are met.	Data stewards/data product owners

Unified Catalog overview page

The **Overview page** in Unified Catalog helps users in an organization get started with their data governance journey, understand, and navigate the different steps outlined in this document, using step by step instructions and video demos.

- Data governance roles and permissions

Last updated on 04/24/2026

Sample setup for data governance

10/13/2025

Microsoft Purview data governance, featuring Microsoft Purview Unified Catalog and Microsoft Purview Data Map, delivers comprehensive visibility, data confidence, and responsible innovation to help organizations achieve greater business value in the era of AI. Using an example of managing health data, follow the steps in this article to help you understand how to set up Unified Catalog and use its functionality to build a sound data governance practice for your organization.

Step 1: Set up your governance domains in Unified Catalog

Governance domains are the key to establishing accountability for your data and help to federate governance of that data across the company. When you create governance domains, start with the proper owner to ensure you can effectively identify and collaborate with experts for all of the data in the data estate. Governance domains can be many different types to align to the type of data boundary for the team that governs that data. For example: functional domains (finance, HR, sales), or data domains (product, customer, health).

Prerequisites

- You need the Data governance administrator role for the Unified Catalog.

Grant permissions and build the first governance domain

1. Open the Microsoft Purview portal.
2. Sign in to the Microsoft Purview portal using credentials for an admin account that has the *Role management* role (for example, a Purview administrator). Go to **Settings** > **Roles and scopes** to view and manage.
3. Select **Role groups**.
4. On the **Role groups for Microsoft Purview solutions** page, select the **Data Governance** role group.
5. On the **Edit member of the role group** page, select **Choose users** or **Choose groups**.
6. Select the check box for all users or groups you want to add to the role group.

7. Select **Select**.

8. In Unified Catalog, select **Catalog management**, then select **Governance domains**.

9. On the **Governance domains** page, you can set up the rest of your catalog to enable others to federate the ownership of data, empower teams to build out their knowledge, and establish business value of your data.
    a. Start by selecting **New governance domain**.
        i. You can update the name of your governance domain. For this tutorial, name it '(Tutorial) Personal Health' and give it a description of 'Personal health data refers to any information related to an individual's physical or mental health that is collected and used within the healthcare sector. This data can include a wide range of types, such as medical records, treatment histories, diagnostic images, and laboratory test results. It's often protected under various laws and regulations to ensure privacy and confidentiality.'
        ii. Select the type as a 'data domain'.
        iii. Leave the parent blank (if this is the first governance domain in the catalog, it doesn't have a parent).
        iv. Select **Create**.
        v. Now create two more domains on your own. These domains are key points of federation for collaboration and governance in your organization. Think about who might be the owners of your domains when you implement Unified Catalog.
            i. You can follow these examples:

                - A **Corporate** functional domain represents the highly controlled assets and terms that an entire company uses. - **Sales** is a functional domain that most organizations have as a child domain of Corporate.

10. Select the governance domain you created.

11. Select the **Roles** tab of the governance domain.

12. By default, when you create the governance domain, you're added to all roles in the governance domain. As a governance domain owner, you add the data stewards (business experts in your domain) and the data product owners (who know which data assets are best for others to consume).

13. Switch back to the **Details** tab.

14. Select **Manage policies** to apply a domain level policy. This policy applies to all data products in the domain. By enabling the automatic application of a policy, data experts don't have to be policy experts as well.

15. In the **Manage access policies** tab, select the checkbox next to **Permit data copies.** By selecting this policy option, it automatically applies an attestation requiring all users who request access to your data products to attest that they understand the data copy policy for your data.

16. Select **Save changes** to confirm the policy is set by the governance domain.

17. Select **Publish** on the governance domain, which publishes all other concepts within the domain.

Create glossary terms

Adding glossary terms to your governance domain helps others understand how the business uses and interprets the data. Glossary terms also ensure insights use common terms, and generally your knowledge across your governance domain.

1. On the page for your governance domain, find the **Glossary terms** card and select **View all**.

2. On the **Glossary terms** page, select **New term**.

3. Enter details: 1. Name: "Outbreak."
   a. Description: A disease that affects or has the potential to affect a large portion of the population.
   b. You can leave the rest blank for now but there are fields to collect: the term owner responsible for defining the term for your company, acronyms to share common also known as names of the term, lastly you can provide links to the resources that would have even more information about the term.

4. Select **Create**.

5. Select **Manage Policies**. Similar to the domain level policies, you can create term level policies that apply wherever the term is in use.

6. Check the box next to **Manager approval required**. This policy enforces a secondary approval from the user's manager in Microsoft Entra ID when access is requested to the data products.

7. Select **Publish** for the Outbreak term created. Published terms are filterable in Unified Catalog and ensure others that use the term to describe their data product can see that description in Unified Catalog while browsing the data product.

8. Now create two more terms. This time, select the "Outbreak" term as the parent term for the terms you created. Try building relationships between these child terms in the related

tab on either term to help build out the network of how these terms work together to explain the entirety of a topic.
   a. Pandemic: A global outbreak of a disease that affects a large number of people across multiple countries/regions or continents.
   b. Epidemic: A countrywide or regional outbreak of a disease that is highly contagious and affects a large portion of the population.

9. Try creating a couple of other terms in any other domains you created earlier. If you're not sure what to add, select **Get suggested terms** to have generative AI propose a few based on the description and name of the domain you already provided.

Add an OKR

Add an OKR (objective and key result) for your Personal Health domain to help others understand the business value of your data. This step builds a direct connection between your data and the business value it provides.

1. Select the **OKR** box from the governance domain page.

2. Select **New OKR**.

3. Enter the details of the objective first:
   a. Objective: Reduce pandemic risk by enabling effective patient vaccine uptake.
   b. Owner: Enter your name
   c. Target date: '2024-12-31'

4. Select **Create**.

5. Add key results to your objective to make the goals measurable and to monitor progress towards the goal. Select **Add key result**.

6. Enter the Key result details:
   a. Key result: Ensure 80% older age groups(>65 years) that are most likely to be affected by the pandemic receive full vaccination by end of the calendar year 2024.
   b. Progress status: On track
   c. Progress Amount: 70
   d. Goal amount: 80
   e. Maximum amount: 100

7. Select **Create**.

8. Select **Publish**.

Create critical data elements

Create a critical data element (CDE) in Personal Health to ensure the most important columns of data have a consistent definition and understanding. The CDE always meets business expectations for how that data is formed and stored.

1. From the governance domains page with the Personal Health domain selected, select the **Critical data elements** box.
2. Select **New critical data element**.
3. Enter the basic CDE metadata:
   a. Name: Age groups
   b. Description: Common grouping of person ages used to ensure needed analytical reports follow a reference that others can depend on and removing individual ages to improve anonymity of the data. The age group is divided into eight groups: <2 years, 2-4 years, 5-11 years, 12-17 years, 18-24 years, 25-49 years, 50-64 years, 65+ years.
   c. Owner: enter your name
   d. Expected Data Type: Text
   e. Select **Create**.

The real power of the CDE is that it maps directly to the physical data columns where this data is stored. This connection ensures common understanding and enables the evaluation of Data Quality rules and policies at scale.

1. From the CDE you just created, select **Add column**.
2. Search for the **Covid 19 Vaccine and Case Trends** data asset from the gold container of the data lake
3. Select the box, not the name, of the **Covid 19 Vaccine and Case Trends** asset.

   > **Tip**
   >
   > If you select the blue name of the asset, it opens a new window showing you the asset details.

4. Select the radio button next to the AgeGroupVacc column.
5. Select **Add**.
6. Select the **Data quality** tab at the top of the CDE you just created to apply data quality rules to the CDE. It's similar to how you added policies for glossary terms and governance domains.

7. Select **New rule**
8. Select **Data type match**
9. Enter Rule name: Confirm Age group formatting
10. Select **Create**.
11. Select **Publish** on the CDE

This CDE now automatically applies a data quality rule to every data product that uses the Covid 19 Vaccine and Case Trends asset, which you see in the next section.

1. Try creating a couple of other CDEs in your other domains. Here are some ideas:

    - Sales: Revenue and Seller Name
    - Corporate: Product ID

Step 2: Set up and register your data in Data Map

If you don't have data sources available for scanning, follow these steps to fully deploy an Azure Data Lake Storage (ADLS Gen2) example.

> **Tip**
>
> If you already have a data source in the same tenant as your Microsoft Purview account, move ahead the next part of this section to scan your assets.

In a real data estate, you find many different systems in use for different data applications. There are reporting environments like Fabric and Snowflake where teams use copies of data to build analytical solutions and power their reports and dashboards. There are operational data systems that power the applications teams or customers use to complete business processes that collect or add data based on decisions made during the process.

To create a more realistic data estate, show many sources of data in the catalog, which can cover the breadth of different data uses any company might have. The types of data required to power a use case can be vastly different with business users that need reports and dashboards, analysts need conformed dimensions and facts to build reports, data scientists or data engineers need raw source data that came directly from the system that collects the data. All of these and more enable different users to see the importance of finding, understanding, and accessing data in the same place.

For some other tutorials to add data to your estate, follow these guides:

- Fabric Lakehouse Tutorial – provides the base of a reporting environment
- Azure SQL Database (Sample) – provides a well structured example of an operational data store

Prerequisites

- Subscription in Azure: Create Your Azure Free Account Today
- Microsoft Entra ID for your tenant: Microsoft Entra ID Governance
- A Microsoft Purview account and administrator privileges (this is the default if you created the Microsoft Purview account).
- All resources; Microsoft Purview, your data source, and Microsoft Entra ID have to be in the same cloud tenant.

Set up your data estate

A. Create and populate a storage account

1. Follow this guide to create a storage account: Create a storage account for Azure Data Lake Storage Gen2
2. Create containers for your new data lake:
   a. Go to the **Overview** page of your Storage Account.
   b. Select the **Containers** tab under the Data storage section.
      i. Select **Container**.
      ii. Name the container "bronze" and select **Create**.
      iii. Repeat these steps to create a "gold" container.
3. Download some example CSV data from data.gov: Covid-19 Vaccination And Case Trends by Age Group, United States
4. Upload the CSV to the container named 'bronze' in the storage account you created.
5. Select the container named 'bronze' and select **Upload**.
6. Browse the location where you saved the CSV and select the **Covid-19_Vaccination_Case_Trends** file.
7. Select **Upload**.

B. Create an Azure Data Factory

This step demonstrates how data moves between layers of a medallion data lake and ensures the data is in a standardized format that consumers expect to use. This step is a prerequisite for running data quality.

1. Follow this guide to create an Azure Data Factory: Create an Azure Data Factory

2. Copy the data from the CSV in the 'bronze' container to the 'gold' container as a Delta format table using this Azure Data Factory guide: Transform data using a mapping data flow

3. Open the Azure Data Factory (ADF) experience from the Azure portal by selecting **Launch studio** on the **Overview** tab of the ADF resource created.

4. Select the **Author** tab in ADF studio.

5. Select the + command, then select **Data flow**.

6. Name the dataflow 'CSVtoDeltaC19VaxTrends'.

7. Select **Add Source** in the empty box.

8. Set Source settings to:
   a. Output stream name: 'C19csv'
   b. Description: leave blank
   c. Source type: Inline
   d. Inline dataset type: Delimited Text
   e. Linked Service: Select the data lake where you stored the csv

9. Set Source options to:
   a. File mode: File
   b. File path: /bronze/ Covid-19_Vaccination_Case _Trends
   c. Allow no files found: leave unchecked
   d. Change data capture: leave unchecked
   e. Compression type: None
   f. Encoding: Default(UTF-8)
   g. Column delimiter: Comma (,)
   h. Row delimiter: Default(\r, \n, or\r\n)
   i. Quote character: Double quote (")
   j. Escape character: Backslash ()
   k. First row as header: CHECKED
   l. Leave the rest as defaults

10. Select **Next** by the source created and select **Sink**.

11. Create the sink where the format and location of the data to be stored to move the data from a csv in 'bronze' to a delta table in 'gold'.
    a. Set the Sink values (leave all settings as default unless specified).
    b. Sink type: Inline.
    c. Inline dataset type: Delta.

d. Linked service: the same data lake as used in the source, because you are storing in a different container.

12. Set the Setting values (leave all settings as default unless specified)
    a. Folder path: gold/Covid19 Vaccine and Case Trends.
13. Enter the value because this name is how you want to store the data and it doesn't exist to select.
14. Select **Validate**. This action checks your data flow and provides instructions to fix any errors.
15. Select **Publish all**.
16. Select the + command, then select **Pipeline**.
17. Name your pipeline 'CSV to Delta C19 Vax Trends'.
18. Select the dataflow created in the previous steps CSV to Delta (C19VaxTrends) and drag and drop it on the open pipeline tab.
19. Select **Validate**.
20. Select **Publish**.
21. Select **Debug** (use activity runtime) to run the pipeline.

    > **Tip**
    >
    > If you get errors for spaces or inappropriate characters for delta format, open the downloaded CSV and make corrections. Then re-upload and overwrite the CSV in the bronze zone. Then rerun your pipeline.

22. Navigate to your gold container in the data lake and you should now see the new Delta table created during the pipeline.

Scan your assets

If you haven't scanned data assets into your Data Map, follow these steps to populate your data map.

Scanning sources in your data estate automatically collects the metadata of the data assets (tables, files, folders, reports, and more) in those sources. When you register a data source and create the scan, you establish the technical ownership over the sources and assets that appear

in the catalog. You also control who can access which metadata in Microsoft Purview. When you register and store sources and assets at the domain level, you store them at the highest level of access hierarchy. Typically, it's best to create some collections where you scan the asset metadata and establish the correct access hierarchy for that data.

- Provide reader access for Microsoft Purview Managed Identity (MSI) to your data lake or other data store.

  > **Tip**
  >
  > The MSI is the account name of the Microsoft Purview instance.

If you choose to use Fabric or SQL, use these guides to provide access:

- Microsoft Fabric
- Azure SQL Database

Register your data lake and scan your assets

1. In Data Map, under the domains tab, select the **Role assignments** for the domain (it's the name of Microsoft Purview account):
   a. Add yourself as the data source admin and the data curator to the domain.
      i. Select the person icon next to the role **Data source admin**. 1. Search your name as it is in Microsoft Entra ID (you might need to enter your full name spelled exactly as it is in Microsoft Entra ID).
      ii. Select **OK**.
      iii. Repeat these steps for data curator.

2. Register the data lake:
   a. Select the **Data sources** tab.
   b. Select **Register**.
   c. Select the Azure Data Lake Storage Gen2 storage type.

3. Provide the details to connect:
   a. Subscription (optional)
   b. Data Source Name (this is the name of the ADLS Gen2 source)
   c. Collection where asset metadata should be stored (optional)
   d. Select **Register**

4. Once registration of the data source is complete, you can configure the scan. Registration signifies that Microsoft Purview is connected to the data source and has placed it in the

correct collection for ownership. Scanning reads the metadata from the source and populates the assets in the data map.

5. Select the source you registered in data sources tab

6. Select new scan and provide details:
   a. Use the default integration runtime for this scan
   b. Credential should be Microsoft Purview MSI (system)
   c. Scan level is Auto Detect
   d. Select a collection or use the domain (collection must be the same collection or child collection of where the data source was registered)
   e. Select Continue

   > **Tip**
   >
   > At this point the connection is tested to validate a scan can be done. If you don't grant the Microsoft Purview MSI reader access on the data source, it fails. If you're not the data source owner or don't have user access contributor, the scan fails since it expects you have authorization to create the connection.

7. Now only select the container "gold" where you placed the delta table in the building data section of the tutorial. This selection prevents scanning any other data assets that are in your data store.
   a. Should have only one blue check next to gold, you can leave checks next to everything as it will scan the full source and still create the assets we'll use and more.
   b. Select **Continue**

8. In the select a scan rule set screen you should use the default scan rule set.

9. Select **Continue**

10. In set a scan trigger you'll set the frequency of the scanning so as you continue to add data assets to the gold container of the lake it will continue to populate the data map. Select **Once**.

11. Select **Continue**.

12. Select **Save and Run**. This action creates a scan that reads the metadata from the gold container of your data lake and populates the table we'll use in Unified Catalog in the next sections. If you only select save, it doesn't run the scan, and you don't see the assets. Once the scan is running, you see the scan you created with a **Last run** status of **Queued**. When the scan reads complete your assets are ready for the next section. This process

could take a few minutes or hours depending on how many assets you have in your source.

Step 3: Publish your data products

Creating data products is essential to ensure that your organization can discover the right data. Data products help prevent overgoverning data that has low or no value in your data estate because it has no use or limited value. When your data experts publish data products, you activate your most valuable data and build the right level of governance based on that value. Curating assets that technical teams don't know the business purpose of, or trying to govern everything in your complex and growing data estate, causes extra time and lost productivity chasing down the details of data that might never be used or could just be removed from the estate. Instead, focus on the pieces of data that have value and that people need to discover and build even more value. As teams use more data and gain a better understanding of what is needed, you can create more useful data products to meet those demands. Governance can adapt to ensure it always stays the right size based on the value and sensitivity of the data.

Prerequisites

- Be a data product owner for the governance domain you're using.
- Have data assets in the Data Map. If you don't, see section 2 of this tutorial to add some.
- Publish a governance domain to publish a data product. If you don't have one, see section 1 of this tutorial to create one.

Create and publish a data product

1. Open the Microsoft Purview portal.
2. Select **Unified Catalog**.
3. Select **Catalog management** and then **Governance domains**.
4. From the **Governance domains** page, select the Personal Health domain.
5. Select **Go to data products** under **Business concepts**.
6. Here's where the data experts called data product owners will identify the data assets that are intended to be consumed by others in your organization, and provide the necessary information to make them usable.
7. Select **New data product**.

8. Provide details about the data product: 1. Name: "Covid-19 Vaccination and Case Trending by Age" 1. Description: "This data comes from the CDC as a part of the U.S. Department of Health & Human Services. The data contains trends in vaccinations and cases by age group, at the US national level. Data is stratified by at least one dose and fully vaccinated. Data also represents all vaccine partners including jurisdictional partner clinics, retail pharmacies, long-term care facilities, dialysis centers, Federal Emergency Management Agency and Health Resources and Services Administration partner sites, and federal entity facilities."
    a. Type: Dataset
    b. Select **Next**.
    c. Use cases: `This data is provided for public use and is intended to help understand the trends of vaccination up take and new cases by different age groups. The ages are banded into two groups ranging from <2 years to 65+ years. Similarly the trends are provided in daily numbers that provide seven day average of new cases by age group.`
    d. Mark as **Endorsed** as checked.
    e. Select **Save**.

9. Now you have the base metadata of the data product built out. Next, add some properties and map the asset from Data Map.

10. Select **Add data assets**.

11. You see the assets you scanned into Data Map, including all folders and layers of the data source.

12. Search for the **Covid19 Vaccine and Case Trends** asset you added to the gold container of your data lake and select this resource set.

13. Select **Add**. You can select as many assets as needed for a data product but here only one is needed.

    > **Tip**
    >
    > Select **Get suggestions** to have generative AI help pick from the assets in your data map and select the Covid19 Vaccine and Case Trends from a reduced list of results.

14. You can now see the asset added to your data product.

15. Select **Add term** next to the glossary terms title.

16. Select the Outbreak term created earlier and select **Add**.

17. You should see the critical data element for age group from the asset mapped to the data product now.

18. Select **Add OKR** next to the OKR title.

19. Select the Reduce pandemic risk by enabling effective patient vaccine uptake. It's the objective you created in the first section.

Manage data product access request policies

At the top of the page, the last step before publishing the data product is to select **Manage policies**. Here, you configure the access policies and request access workflow by making selections and providing the names for approval. You can also use the **Inherited policies** tab to see the governance domain policy applied for data copies attestation you applied earlier. It's the same for the **Manager approval** required coming from the Outbreak glossary term.

1. Select the **Manage policies** tab.

2. Under **Access time limit**, provide details for how long the request for access is good before needing to be renewed. Set this value to grant access for up to one year.

3. In the box, enter 1.

4. Select years in the drop-down.

5. Under approval requirements, provide your name in the approvers box. (It requires the name registered in Microsoft Entra ID.)

   > ⓘ **Note**
   >
   > You don't need to check manager approval because that policy is inherited from the outbreak glossary term.

6. Select **Preview request form** to see what the catalog consumers view when requesting access. You see the data copy attestation and manager approval required because they were set by the governance domain and glossary term.

7. Select **Save changes**.

Once you map the data assets and configure the access policies, you're ready to publish your data product to the catalog.

1. Select **Publish** on the data product.

2. Try creating a Profit Report in other domains you created earlier
   a. Profit Report, Type: Dashboards/reports.
   b. Product Master, Type: Maser data and reference data.

> **Note**
>
> You can add many assets to these and see how a data product with many assets looks. Add the data products to the terms from any domain to see how the glossary is used to describe the data using a consistent set of terms.

Step 4: Run data quality

Now that you have a data product available in the catalog, running data quality rules tells everyone that the data is in good shape and ready to use. As you learn more about the data, add new data quality rules to make sure it's fit for all use cases. Ensuring data products are of the highest quality helps build trust in your data and shows others that you're monitoring and improving it. As the value of data increases, you need to more closely monitor and control the quality of that data. Poorly managed data quality issues can cause significant negative effects.

Prerequisites

- Data quality rules can only be run on delta format tables in ADLS Gen2 and Microsoft Fabric.
- The Managed Identity from Microsoft Purview must be enabled to read the data source as it is the only supported credential for data quality today.
- You must have the data quality steward role in the governance domain you're running data quality in.
- You must be the owner or have user access administrator access to the data source you're connecting data quality scanning to ensure proper security authorization to scan the data.
- You must have the data profile steward role to run profiles on your data.

Create and run data quality rules

1. Open the Microsoft Purview portal.
2. Select **Unified Catalog**.
3. Select the **Data quality** tab under **Data management**.
4. Select the Personal Health Domain created in section 1.

5. Select **Manage**, then select **Connections**. When you build this connection, you can run data quality scans on your data source in that governance domain. This step prevents teams from gaining access to knowledge of the data without proper authorization.

6. Select **New** on the connections screen to create a new connection: 1. Enter the display name "Personal Health ADLSg2 DQ".
   a. Select source type of Azure Data Lake Storage Gen2.
      i. Enter details of the data source created in section 2.

      > ⓘ **Note**
      >
      > Credential must be Microsoft Purview MSI (system) for a data quality connection.

      ii. Select **Test connection**.
      iii. Once the connection is tested, select **Submit**.

Once the connection is established, you're ready to run profiles and start building data quality rules. This step ensures that the experts who know the business rules and appropriate rules are running on the most important data products.

1. Go back to the **Data quality** page.
2. Select the Personal Health governance domain.
3. Select the **Covid-19 Vaccination and Case Trending by Age** data product built in section 3.
4. Select the asset that you added to the data product. (It must be in delta format from section 2 or data quality won't run).
5. Apply data quality rules to the columns of the data to measure if it meets your expectation of quality:
   a. Select **Rules** tab on the asset selected.
   b. Select **New rule**.
   c. Select Empty/blank fields rule.
   d. Enter details:

      - Select AgeGroupVacc column from the column drop-down
      - Rule Name: Confirm Vaccination Age Group Exists

   e. Select **Create**.
   f. Select **New rule**.
   g. Select **Data type match**.
   h. Enter details.
   i. Select DateAdministered column.
   j. Select **Create**.

6. Select **Run Data quality scan**.

Profile data

Create a profile for your data to see the high-level statistics of each column and discover any anomalies that could require a new rule.

1. In Unified Catalog, select **Health management**, then select **Data quality**.
2. Select **Profile data**.
3. Check the top box next to **Column name** to profile all columns. The system recommends which columns to profile, and you can select columns that you know are worth profiling to help prevent profiles on highly sensitive data or data you know is sparsely populated.
4. Select **Run profile**.

When the scan completes, you can review the data quality score and profile for your new data product. All users of the catalog can see the data quality score, so everyone knows the status of the data.

Create a schedule for your data quality scans to ensure you're continuously monitoring for data quality issues. Set alerts to make sure you're addressing data quality issues before consumers are affected.

1. Under **Health management**, select **Data quality**.
2. Select the Personal Health domain where you configured the data quality rules.
3. From the **Manage** dropdown list, select **Scheduled scans**.
4. On the **Scheduled scans** page, select **New**.
5. Add **Overview** details
    a. Name: Personal Health DQ Monthly Evaluation
    b. Description: Monthly scan of DQ rules for continuous improvement.
6. Select **Continue**
7. Select the scope of the scan
8. Check the box next to **Covid-19 Vaccination and Case Trending by Age** data product
9. Select **Continue**
10. Schedule the scan to ensure it runs on the last day of every month
    a. Select **Recurring**
    b. Recurrence: Every one Month
    c. Month days: Last
    d. Schedule scan time (UTC): 12:00:00
    e. Start recurrence at (UTC): leave as default
11. Select **Continue**
12. Review details of the scan to see if there are any changes you want to make before saving.

13. Select **Save**. Because you triggered a manual scan earlier, you don't need to trigger another scan now. If you need a new scan, select **Save and run**.

Configure alerts

After scheduling scans for data quality, you can set up alerts to notify stewards about issues or when data quality problems or scan failures need attention. Configure a data quality alert for failed scans and when the score decreases by more than 5%.

1. Return to the Personal Health domain on the **Data quality** page.
2. From the **Manage** dropdown list, select **Alerts**.
3. Select **New**.
4. Enter alert details
   a. Display Name: Personal Health DQ Monthly Scan
   b. Description: To ensure minimum DQ thresholds are meeting consumer expectations.
   c. Target: Score decreases by more than
   d. Threshold: 5
   e. Turn off notifications: leave unchecked
   f. Turn on notification for failed quality scans: leave checked
   g. Recipient: enter your name
5. Select **Continue**.

> **Tip**
>
> When implementing in Unified Catalog, send the alerts to the stewards who can notify consumers of the issue and work with the technical owner of the data to make corrections.

At the end of this section, you have a functioning Unified Catalog with operational data quality to manage the data you're offering to organizational data consumers. Everything is set up to get the most valuable data to the consumer and build trust in the data that they use. As the value of the data grows and new data strategies emerge, the next section shows how you can manage the entire catalog or go deeper into specific data management with master data.

Step 5: Master data management

Master data management (MDM) is the practice of conforming the most important data entities that must be accurate, unique, and consistently applied in all areas of the business because errors and issues in this data can impact the whole business. Through one of our MDM partners, you can integrate your choice of MDM solutions with Microsoft Purview to

enable data unification, standardization, and cleansing that enables golden record creation and the publication of master data as data products.

Follow the tutorials here for your solution of choice: Master data management in Microsoft Purview

Step 6: Manage data health

In the **Health management** area of Unified Catalog, the central data office and other data managers can evaluate the status of the data against their company standards and effectively manage progress towards their strategy. To make sure that everyone in the company knows what they can do to increase the value of their data, it's essential that the standards are understood and scalable to the whole organization without needing to make everyone a data governance expert. Starting from an industry standard set of controls that are available out of the box, each data office can customize the controls to meet their expectations and ensure it aligns with their data goals. Critical to the effectiveness of these controls isn't only the measurement of these standards but also ensuring those responsible for the data can take action on their own and be held accountable for making the improvements that affect the value of data. In Data Estate Health, you can set and manage all of these critical capabilities.

Prerequisites

- Data products, glossary terms, and other business concepts published in Unified Catalog. You can follow the previous sections to create these concepts:
  - Section 1 - Set up a governance domain
  - Section 3 - Publish your data products
- At least 24 hours since the curation of data products.
- You must have the Data Health Owner role in Unified Catalog.

Evaluate your data governance with data estate health

1. Open the Microsoft Purview portal.
2. Select **Unified Catalog**.
3. Under **Data Estate Health** in the left navigation, select **Health controls**.
4. Select the carrot > next to the **Value Creation** control group.
5. While hovering over a control title, select the pencil icon to edit the control. By editing the control, you change the threshold of the control to set expectations for what the score should be and set the color scoring to demonstrate the progress stages.

6. The details enable you to provide a description of the control and what it means to your organization and set an owner for a specific control.

7. Select the **Rules** tab of the control to change the threshold. This setting has a high target and if it isn't healthy it's critical to follow up on.
   a. Inherit from group: toggle to switch off (should turn grey).
   b. Target score: 90
   c. Select **New rule**.
   d. Set the box next to the score to GreaterThanOrEqual
   e. Set the percentage to 90
   f. Status = Health (green)
   g. Else Box Status = Critical (Purple)
   h. Select **Save**.

8. Under data estate health, select **Metadata quality**.

Here you can change or add rules that create the scores of the control. Here you want to change the severity of the actions for **Value Creation** to ensure all users know the importance of this action.

1. Select **Configure severity**
2. Select the **Value Creation** control group
3. Select the **Business OKRs alignment** control title
4. Change the Severity from Medium to High and select **Save**
5. Select the **Health actions** tab
6. Filter **Assigned to:** to your name
7. Select an action where you can see what the owner of the action needs to do to ensure governance expectations are met or they can assign a new owner to get the best expert to provide their input. There's also a status that lets others know what work is ongoing and where other actions could need prioritization.

Step 7: Data democratization

Data democratization enables users to find and access the data they need in a compliant manner. It ensures people can find the data they need to build business value. Unified Catalog provides a clean and easy experience to discover data. It empowers stewards to update and manage the data made available in the catalog at scale. In this section, you learn how users can find and request access to data and ensure that the appropriate approvers can track and provide inputs on those access requests.

Prerequisites

- Completed steps 1-4 at minimum:
  - Section 1 - Set up a governance domain
  - Section 2 - Set up your data estate
  - Section 3 - Publish your data products
- A catalog reader role in one governance domain

Discover data products

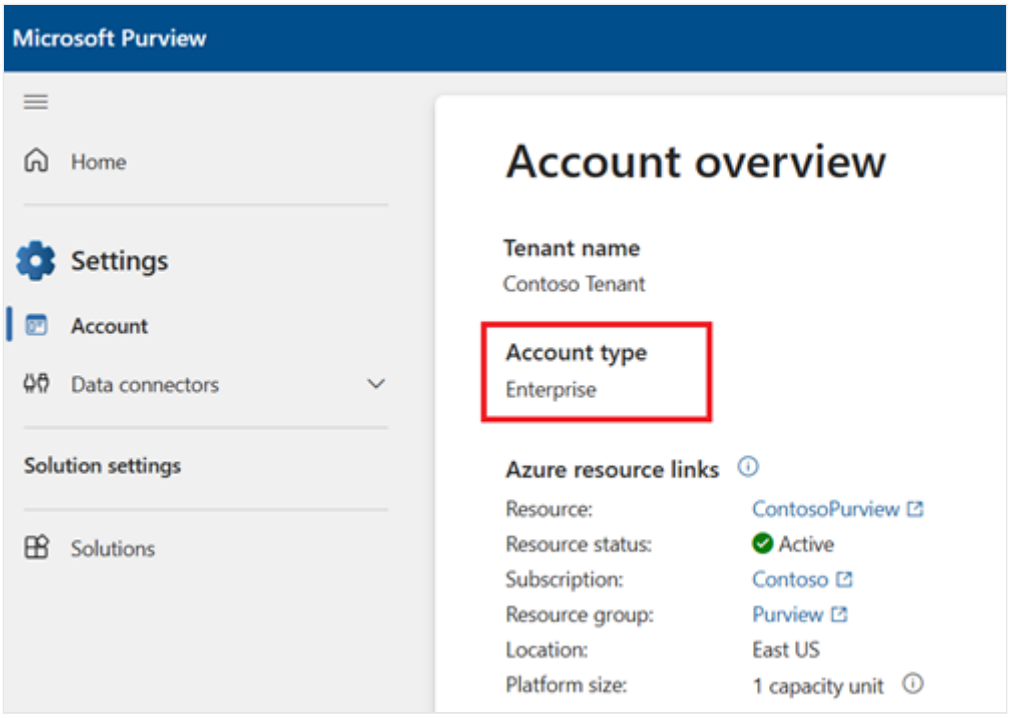
1. In Unified Catalog, select **Discovery**, then select **Data products**.
2. On the **Data products** page, use the search bar to search for vaccination rates by age.
3. Here you see the data products you published in section 2. This view shows how users only see the data intended for them and prevents users from having to navigate a highly technical data estate.
4. Select the **Covid-19 Vaccination and Case Trending by Age** data product
   a. Here, consumers can see the metadata you provided and any of the other properties that you configured during setup. The data quality score is here as well so consumers know the quality before they even get access to the data.
   b. Select the asset and the consumer can see all of the columns that are available in the data asset.
   c. Select the Outbreak glossary term and the consumer can see the description and other information about the term to gain a deeper understanding of the data.
5. Once the consumer is confident that they want to use that data, they need to get approved access to the data.
   a. Select **Request access**
   b. Fill in the form detail to submit a request.
   c. User: leave your name
   d. Manager Approval: automatically required and directed to the Microsoft Entra ID manager.
   e. Purpose: select a purpose
   f. Business justification: OKR monitoring
   g. Check the box next to the attestation to say you understand the expectations to use this data.
   h. Select *Send*.

The access request is now sent to the listed manager in Microsoft Entra ID. From here, the manager can access the requests by opening the email and selecting a link or coming into Microsoft Purview. Approving and managing access can be done directly in Microsoft Purview.

1. In Unified Catalog, select **Catalog management**, then select **Requests**.
2. Select the **Personal Health** domain.
3. Select the request you submitted.

4. Now the approvers are able to approve or decline by selecting **Respond** on the request.

Data governance roles and permissions in Microsoft Purview



> **Important**
>
> This article covers Microsoft Purview data governance permissions in the new Microsoft Purview portal using Microsoft Purview Unified Catalog.
>
> - If you're using the classic Data Catalog, see governance permissions for the classic Data Catalog.
> - For data governance permissions in the classic Microsoft Purview portal, see permissions in the classic Microsoft Purview governance portal.

Microsoft Purview data governance has two solutions in the Microsoft Purview Portal: Data Map and Unified Catalog. These solutions use tenant/organizational-level permissions, existing data access permissions, and domain/collection permissions to provide users access to governance tools and data assets.

The kind of permissions available to use depends on your Microsoft Purview account type.

Check your account type

Check whether your organization has the free or enterprise type of account. To check your account type, go to the Microsoft Purview portal, select the **Settings** card. Under **Account**, view your **Account type**.

> **Important**
>
> For users newly created in Microsoft Entra ID, it might take some time for permissions to propagate even after correct permissions are applied.

Permissions in the enterprise version

All users can view data assets for available sources where they have at least **Read** permissions. Users who are owners can manage the metadata for assets where they have at least **Owner/Write** permissions. Learn more about Microsoft Azure roles.

Permissions types

- Tenant/organization permissions: Assigned at the organizational level, these permissions provide general and administrative permissions.
- Unified Catalog permissions: These permissions allow users to browse Unified Catalog and build out their data governance solutions.
- Data Map domain and collection level permissions: Permissions in Data Map that grant access to data assets in Microsoft Purview.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your

organization. Learn more about Microsoft Purview **roles and permissions**.

Tenant level role groups

Assigned at the organizational level, tenant level role groups provide general and administrative permissions for both Microsoft Purview Data Map and Unified Catalog. If you're managing your Microsoft Purview account or your organization's data governance strategy, you probably need to belong to one or more of these role groups:

- Purview Administrators
- Data Source Administrators
- Data Governance

For more information, see descriptions of these roles.

For a full list of all available roles and role groups, not just for data governance, see roles, and role groups in the Microsoft Defender XDR and Microsoft Purview portals.

How to assign and manage role groups

A user must hold the *Role management* role in order to add users or groups to a Microsoft Purview role group. For instructions on assigning and managing roles in Microsoft Purview, see permissions in Microsoft Purview.

Unified Catalog permissions

Three levels of permissions grant users access to information in Unified Catalog:

1. Data governance tenant level: A tenant/organizational-level role group that has the Data Governance Admin role. That role delegates the first level of access for Governance Domain Creators. (This role isn't surfaced in Unified Catalog, but affects your ability to assign permissions in Unified Catalog.)

2. Catalog level permissions: Permissions that grant ownership to governance domains and access to health management.

3. Governance domain level permissions: Permissions to access and manage resources inside specific governance domains.

Permissions to search the full Unified Catalog

You don't need specific permissions in Unified Catalog to search the Unified Catalog. However, searching Unified Catalog only returns relevant data assets that you have permissions to view in Data Map. Users can find a data asset in Unified Catalog when:

- They search data products in a governance domain where they have catalog reader permissions.
- They have data reader permissions on a domain or collection in Data Map where the asset is stored.
- They have at least Read permissions on an available Azure or Microsoft Fabric resource.

> **Important**
>
> Users who already have **Read** permissions in Azure might have access to assets in Unified Catalog that you didn't intend for them to have. If you don't want them to have such access, you need to **remove their permissions**.

You manage permissions to these assets at the resource level and at the Data Map level.

If your catalog is well-curated, day-to-day business users shouldn't need to search the full catalog. They should be able to find the data they need in data products. For more information about setting up the Unified Catalog, see get started with data governance, and plan for Unified Catalog.

Catalog level permissions

Catalog level permissions provide high-level access within Unified Catalog and include these roles:

- Governance Domain Creator
- Global Catalog Reader
- Data Health Owner
- Data Health Reader

For more information, see descriptions of these roles.

How to assign catalog level roles

1. Sign in to the Microsoft Purview portal using credentials for an admin account that is assigned the *Data Governance* role.
2. Go to **Settings** and select **Unified Catalog**.

3. Select **Roles and permissions**.
4. Select **Governance Domain Creators** or another role, then select the add user icon.
5. Search for the user you want to add, then select the user.
6. Select **Save**.

Governance domain level permissions

Governance domain permissions provide access within a specific governance domain. Grant these permissions to data experts and business users so they can read and manage objects within the governance domain. Only a user with the **Governance domain owner** role can grant governance domain permissions.

See the list of these roles and descriptions.

> **Tip**
>
> A user in your organization who runs data governance or Unified Catalog should hold the **Governance domain owner** role. This role is essential for building entities such as governance domains, data products, and glossary terms. Assign at least two people as governance domain owners.

How to assign governance domain roles

A user needs to be a Governance Domain Owner in the governance domain to assign governance domain roles. Data Governance Administrators or Governance Domain Creators assign this role.

Assign governance domain roles under the **Roles** tab in a governance domain. For instructions on assigning roles, see how to manage governance domains.

Unified Catalog roles

> **Important**
>
> Be sure you understand the difference between the two Catalog Reader roles:
>
> **Global Catalog Reader** allows users to access published business concepts from published governance domains.
>
> **Local Catalog Reader** greatly reduces access to governance domains. When you assign users to this role within a governance domain:

- Only those users have reader access to published concepts within that governance domain.
- A user with this role can also hold other roles, such as Data Product Owner or Data Steward, that let them view published business concepts from other governance domains.

The **Local Catalog Reader** role is helpful when, for example, you need to limit access to a governance domain to meet regulatory or legal requirements. However, overuse of this role hinders a federated approach to data governance.

> **Note**
>
> Data observability uses the same roles as the rest of the Unified Catalog. Catalog Readers can't access the broader Data Observability explorer view in data estate health and they can only view published concepts. The Data Steward, Data Product Owners, Governance Domain Owners, and Governance Domain Creators have access to data observability views in both the concepts that they can view and the data health management view that enables broader exploration and view across the full data estate.

Expand table

Permission level	Role	Description
Tenant	Data Governance role group	Grants access to data governance roles within Microsoft Purview.
	Data Source Administrators role group	Manage data sources and data scans in the Microsoft Purview Data Map.
	Purview Administrators role group	Create, edit, and delete domains and perform role assignments.
Catalog	Data Governance Administrator	Delegates the first level of access for Governance Domain Creators and other catalog level permissions.
	Data Health Owner	Can create, update, and read artifacts in the **Health management** area of Unified Catalog.
	Data Health Reader	Can read artifacts in the **Health management** area of Unified Catalog.

Permission level	Role	Description
	Global Asset Curator	Can add published glossary terms to data assets and columns.
	Global Catalog Reader	Can read published artifacts across governance domains that don't have a Local Catalog Reader specified.
	Governance Domain Creator	Can create domains and delegate governance domain owner (or remains governance domain owner by default).
Governance domain	Data Product Owner*	Can create, update, and read data products only within their governance domain. Can read and build relationships with concepts in governance domains.
	Data Profile Reader	Has access to browse data profile insights and can drill down the profiling results to browse the statistics in column level. This is a sub-role that requires the user to also hold the **Governance Domain Reader** *and* either the **Global Catalog Reader** or **Local Catalog Reader** roles.
	Data Profile Steward	Can run data profiling jobs and access profiling insight details. This role can also browse through all data quality insights and can monitor profiling jobs. This role can't create rules and can't run data quality scanning. This is a sub-role that requires the user to also hold the **Governance Domain Reader** *and* **Data Product Owner** roles.
	Data Quality Metadata Reader	Can browse data quality insights (except profiling results column level insight), data quality rule definition, and rule level scores. This role can't access error records and can't run profiling and data quality scanning jobs. This is a sub-role that requires the user to also hold the **Governance Domain Reader** *and* either the **Global Catalog Reader** or **Local Catalog Reader** roles.
	Data Quality Reader	Can browse all data quality insights and data quality rules definitions. This role can't run data quality scanning and data profiling jobs, and can't access data profiling column level insight. This is a sub-role that requires the user to also hold the **Governance Domain Reader** *and* either the **Global Catalog Reader** or **Local Catalog Reader** roles.
	Data Quality Steward	Can use data quality features like data quality rule management, data quality scanning, browsing data quality insights, data quality scheduling, job monitoring, and configuring thresholds and alerts. This is a sub-role that requires the user to also hold the **Governance Domain Reader** *and* **Data Product Owner** roles.
	Data Steward*	Can create, update, and read artifacts and policies within their governance domain. Can also read artifacts from other governance domains.

Permission level	Role	Description
	Governance Domain Owner	Can delegate all other governance domain permissions, configure domain level data quality scan alerts, set up domain level schedule for data quality scanning job, and set domain level access policies.
	Governance Domain Reader	Can read governance domain metadata for published domains they're added to.
	Local Catalog Reader	Can read published concepts only in the governance domain they're granted access to. Because this role greatly limits the scope of who can access and manage data, it's recommended to limit use of this role so that you can better utilize a federated approach to data governance.

*To be able to add data assets to a data product, Data Product Owners and Data Stewards also need Data Map permissions to read those data assets in Data Map.

Data Map permissions

Data Map uses a set of predefined roles to control who can access what within the account. Domains and collections are tools used by Data Map to group assets, sources, and other artifacts into a hierarchy for discoverability, and to manage access control within Data Map.

Find a description of each role and learn how to add roles and restrict access through collections.

For more detailed information about the roles available in collections, see who should be assigned what roles or the collections example.

> **Tip**
>
> If you're a data steward or data product owner for Unified Catalog, it's a good idea to have Data Map permissions as well.

Data asset lifecycle example

To understand how permissions work between Data Map and Unified Catalog, review the table below on the full lifecycle of an Azure SQL table in the environment:

Expand table

Step	Role	Permission level
1. The Azure SQL Database is registered in Data Map	Data Source Administrator	Data Map
2. The Azure SQL Database is scanned in Data Map	Data Curator or Data Source Administrator	Data Map
3. The Azure SQL table is curated and certified	Data Curator	Data Map
4. A governance domain is created in the Microsoft Purview Account	Governance Domain Creator	Catalog
5. A data product is created in the governance domain	Governance Domain Owner and/or Data Product Owner	Governance domain
6. The Azure SQL table is added as an asset to the data product	Data Product Owner and/or Steward	Governance domain
7. An access policy is added to the data product	Data Product Owner and/or Steward	Governance domain
8. A user searches Unified Catalog, looking for data assets that match their needs	Asset permissions or data reader permission	Asset permissions or Data Map permissions
9. A user searches data products, looking for a product that matches their needs	Global Catalog Reader	Catalog
10. A user requests access to the resources in the data product	Global Catalog Reader	Catalog
11. A user views Data Health Insights to track the health of their Data Catalog	Data Health Reader	Catalog
12. A user wants to develop a new report to track data health progress in their catalog	Data Health Owner	Catalog

Learn about data governance in the Microsoft Purview portal

09/18/2025

The modern governance experience is available in the Microsoft Purview portal for anyone who didn't create a Microsoft Purview account in the Azure portal before, and for existing customers. This article explains how to use this new experience.

The new governance experience

The Microsoft Purview portal, https://purview.microsoft.com, is a single, organization-wide instance of Microsoft Purview that's the next step towards unifying your organization's governance, policy, compliance, risk, and security. It's a prerequisite to a single platform used to manage and govern any data, both structured and unstructured, across your data estate. Including Azure, Microsoft 365, Azure, on-premises, or multicloud and SaaS applications in future.

- If you're a new Microsoft Purview customer, read about the new governance experience for new customers.
- If you're an existing Microsoft Purview customer, read about the new governance experience for existing customers.

Learn more about all the governance, data security, and risk and compliance features available in the Microsoft Purview portal.

How to use the new experience

If you're a new Microsoft Purview governance customer (if your organization doesn't have any Microsoft Purview accounts in any Azure subscriptions under your Microsoft Entra tenant), you can start using the Microsoft Purview portal right now for your governance journey.

If your organization already has Microsoft Purview accounts in Azure, after your organization is enabled, getting started with the new experience depends on your organization's current structure:

- You only have one Microsoft Purview account:
  - Your account region matches your tenant region
  - Your account region doesn't match your tenant region
  - Your account has disabled all public access
- You have multiple Microsoft Purview accounts

For more information, visit the new experience FAQ.

One Microsoft Purview account

Your account has disabled all public network access

If your Microsoft Purview account had disabled all public network access and is using private endpoints, you need to make some changes before you upgrade it. You can continue to use *ingestion* private endpoints, but not *account* or *portal* private endpoints. The new experience uses a new private endpoint called a *platform* private endpoint.

To check your current public network settings:

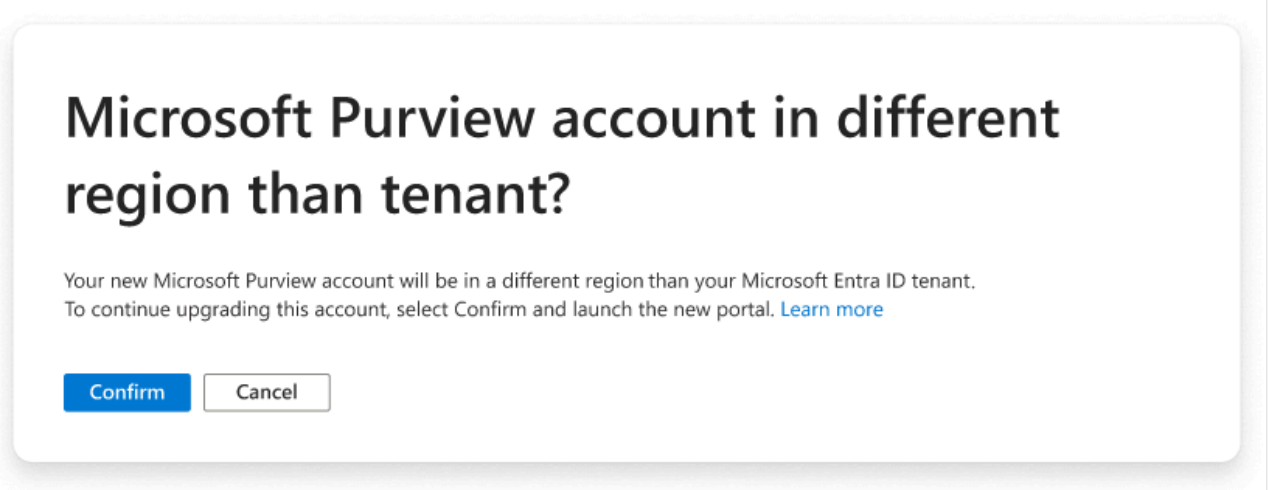
1. Go to the Azure portal.
2. Search for your Microsoft Purview account.
3. Select **Networking** under the **Settings** menu.
4. If your firewall is set to **Disabled from all networks**, you need to follow the next steps to upgrade. If your firewall is set to **Enabled from all networks** or **Disabled for ingestion only**, you should be able to upgrade without these steps.

To upgrade an account using private endpoints, you need to:

1. Confirm that your firewall allows these global and tenant-specific endpoints (replacing the `accountname` and `tenantid` with your values):
   a. `api.purview-service.microsoft.com`
   b. `accountname.purview.azure.com`
   c. `tenantid-api.purview-service.microsoft.com`
2. After upgrading to the new experience, you can follow this guide to set up private endpoints for governance solutions in the Microsoft Purview portal.

> **Important**
>
> 1. Currently, Azure Data Factory, Azure Machine Learning, and Azure Synapse lineage connections are not supported with the platform private endpoint, and might not work after switching. If your production replies on these lineage connections, wait until these connections are supported. (Azure Synapse is supported as a data source using a managed Virtual Network Integration Runtime and platform private endpoint.)
> 2. Scans that run after upgrading but before you set up the platform private endpoints might fail and need to be re-run after private endpoint set up.

Your region matches your tenant region



If your Microsoft Purview account's region matches your Microsoft Entra tenant region, and your networking settings are either **enabled from all networks** or **disabled for ingestion only**, you can use the new experience; no upgrade is required.

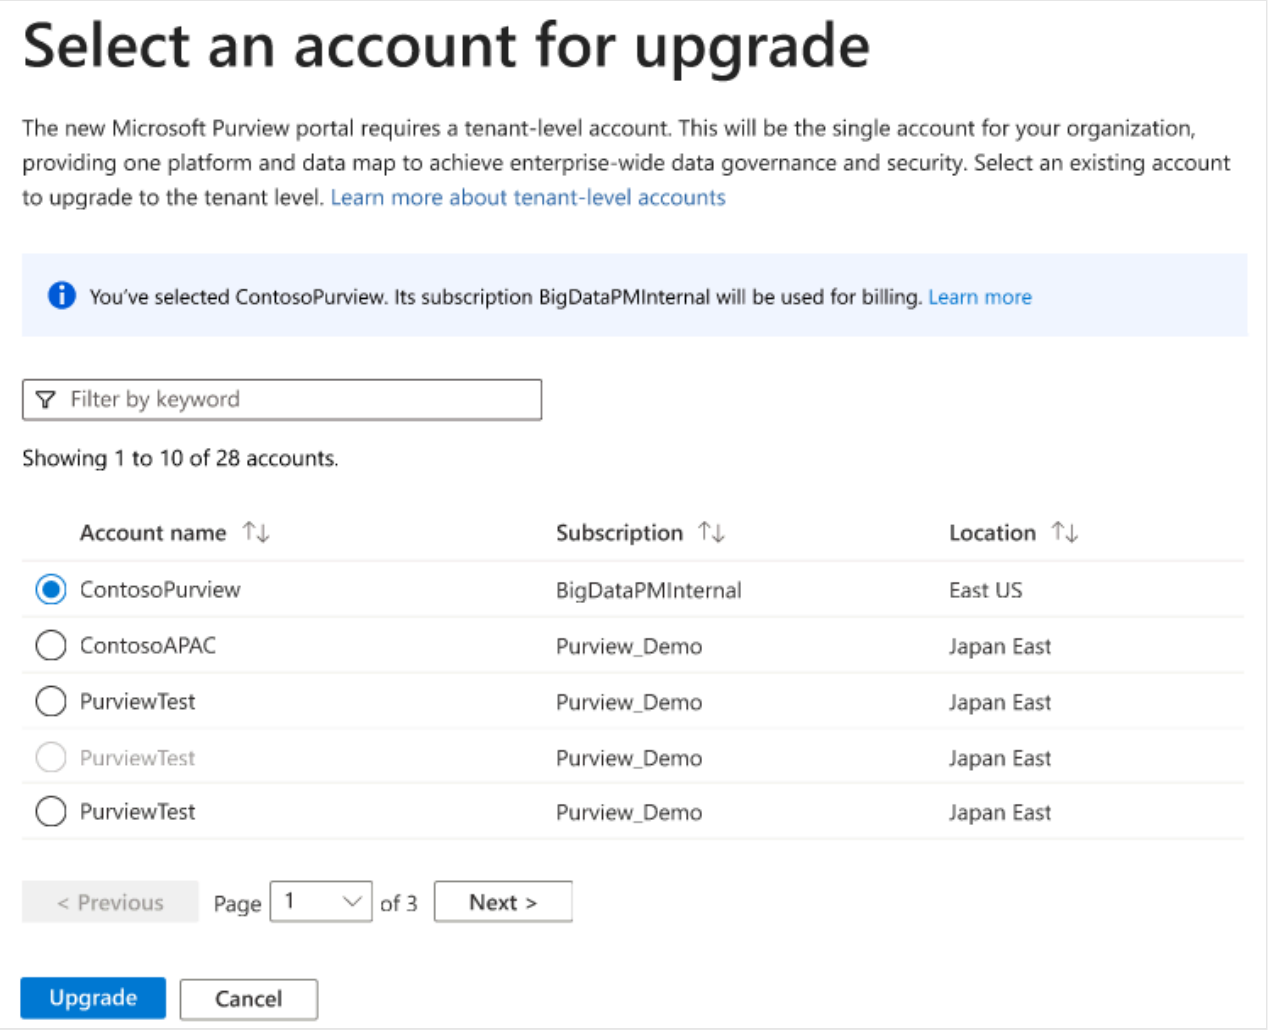
Your region doesn't map to your tenant region

1. A Microsoft Purview Admin selects the **Upgrade** button in the Azure portal, Microsoft Purview portal, or upgrade email.

   > **Note**
   >
   > If you don't have access to the Microsoft 365 role groups to assign users to the Microsoft Purview Admin role, contact support.

2. If your account is in a different region than your tenant, an admin **confirms** setup, as seen in this image:

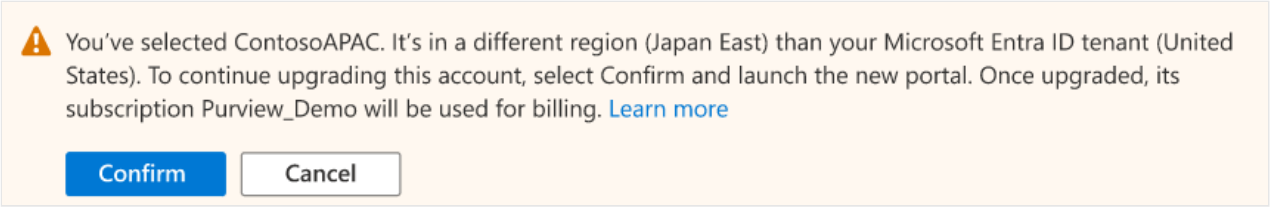
3. After confirmation, the new portal launches.



Multiple Microsoft Purview accounts

The new experience requires a single, tenant-level/organization-wide account that's the primary account for your organization. If you have multiple Microsoft Purview accounts in your tenant, you can upgrade one to the new experience and merge up to four other accounts into your primary account as domains.

1. If your Microsoft Purview account has disabled public network access and is using account or portal private endpoints, follow the steps at Disabled all public network access to upgrade.



2. A Microsoft Purview Admin selects the **Upgrade** button in the Azure portal, Microsoft Purview portal, or upgrade email.

3. Select an existing account to upgrade it to be your organization-wide account. See How to choosing a primary account.

> **Note**
>
> Upgrading one account doesn't affect your other Microsoft Purview accounts or their data. After upgrading, you can merge your secondary accounts into your primary account as domains.
>
> If you don't have access to the Microsoft 365 role groups to assign users to the Microsoft Purview Admin role, contact support.

4. If the account you select is in a different region than your tenant, an admin needs to confirm setup.

5. After confirmation, the new portal launches.
6. You can take the tour and begin exploring the new Microsoft Purview experience!
7. Merge your secondary accounts into your primary account as domains.

Disabled all public network access

If your Microsoft Purview account had disabled all public network access and is using private endpoints, you need to make some changes before you upgrade it. You can continue to use *ingestion* private endpoints, but not *account* or *portal* private endpoints. The new experience uses a new private endpoint called a *platform* private endpoint.

To check your current public network settings:

1. Go to the Azure portal.
2. Search for your Microsoft Purview account.
3. Select **Networking** under the **Settings** menu.
4. If your firewall is set to **Disabled from all networks**, you need to follow the next steps to upgrade. If your firewall is set to **Enabled from all networks** or **Disabled for ingestion only**, you should be able to upgrade without these steps.

To upgrade an account using private endpoints, you need to:

1. Confirm that your firewall allows these global and tenant-specific endpoints (replacing the `accountname` and `tenantid` with your values):
   a. `api.purview-service.microsoft.com`
   b. `accountname.purview.azure.com`
   c. `tenantid-api.purview-service.microsoft.com`
2. After upgrading to the new experience, you can follow this guide to set up private endpoints for governance solutions in the Microsoft Purview portal.

> **Important**
>
> 1. Currently, Azure Data Factory, Azure Machine Learning, and Azure Synapse lineage connections are not supported with the platform private endpoint, and might not work after switching. If your production replies on these lineage connections, wait

until these connections are supported. (Azure Synapse is supported as a data source using a managed Virtual Network Integration Runtime and platform private endpoint.)
2. Scans that run after upgrading but before you set up the platform private endpoints might fail and need to be re-run after private endpoint set up.

Why upgrade to the new experience

If you're already using the classic Microsoft Purview governance portal, upgrading your Microsoft Purview account to the new experience offers several benefits, including:

- **Prerequisites for unified experience**: The upgrade is a prerequisite and one step to bring your environment closer to use data governance, security, risk, and compliance capabilities under the same platform.
- **Improved user experience**: The new experience provides a more streamlined and intuitive user interface, making it easier for users to access and manage their data assets in the new Microsoft Purview portal.
- **Enhanced features**: Upgrading unlocks new features and capabilities, such as live view, preset scans, and more.
- **Consolidated management**: The enhanced experience offers a centralized management interface for all your Microsoft Purview resources, simplifying administration tasks.
- **Access to new capabilities**: All new Microsoft Purview features are only available in the upgraded tenant level account.

After upgrading an existing account to the new experience, here's what to expect:

- **Account consolidation**: You access all other Microsoft Purview accounts in your tenant through the classic portal. Be prepared to merge those accounts with the primary account when the feature becomes available. Microsoft notifies customers who need to perform other steps to merge these accounts.
- **Roles and permissions**: Fine grained access control via roles and permissions at collection scopes continues to function as-is after your accounts are upgraded. In addition, there are new tenant-level roles that you can manage in the new portal. For more information, see our tenant-level permissions documentation.
- **Adapting to new features:** Educate users within your organization on the new features and capabilities introduced in the upgraded account, enabling them to maximize the

benefits of these enhancements. This education includes understanding and using the following features:
    - Live view
    - Tenant-level permissions

Accessing support

With the free version of Microsoft Purview governance solutions, you can't open support tickets for Microsoft Purview. You need to upgrade to enterprise access for support.

How to choose a primary account

If you have a single Microsoft Purview account, your account is likely automatically upgraded. When you have multiple Microsoft Purview accounts under the same Microsoft Entra tenant, consider the following factors while selecting an account for the upgrade. Select an account as primary tenant-level account by following guidelines below:

- **Data assets**: Choose the account with the most valuable or frequently used data assets, as this account becomes the primary data map after the upgrade.
- **Account usage**: Evaluate how each account is currently being used and its role within your organization. Accounts that are considered "production" are most viable to select for this purpose.
- **Permissions and access controls**: Consider the existing permissions and access controls for each account, as they're carried over to the upgraded environment (as an isolated Domain).
- **System Assigned Managed Identity (SAMI) and User Assigned Managed Identity (UAMI)**: The existing system and user assigned managed identities for the primary upgraded account can be used across all domains in the Microsoft Purview instance.

Other considerations

- You can access the upgraded account through current endpoints and new endpoints, so there's no immediate effect if you use Microsoft Purview APIs. Any updates you perform in the upgraded account also reflect in the classic portal for the same Microsoft Purview account.
- New Microsoft Purview features are only available for the upgraded account.

- For other accounts in your tenant, you can continue to access through the classic governance portal.

Regions

> **Note**
>
> The regions listed here are for the single, organization-wide instance of Microsoft Purview that uses the Microsoft Purview portal.
>
> Regions available for Microsoft Purview Unified Catalog are different. Visit Supported regions for Unified Catalog.

This table lists the regions that are currently available to use Microsoft Purview in the new portal:

New Microsoft Purview portal experience for data governance FAQ

Where is the new portal?

The new Microsoft Purview portal is located at https://purview.microsoft.com. The classic data governance portal is located at https://web.purview.azure.com.

How can I use the new portal experience?

The new portal experience is available to all organizations. If you're using Microsoft Purview for the first time and you use Power BI or Microsoft Fabric, you'll automatically have access. If not, create a new account and you're automatically upgraded to the enterprise version of Microsoft Purview within a few weeks. For existing Microsoft Purview users, learn more about using the new experience if you have one Microsoft Purview account or if you have multiple Microsoft Purview accounts.

Is there a cost to use the enterprise version of Microsoft Purview?

Yes. Learn more about pricing at Microsoft Purview pricing.

Can I create new Microsoft Purview accounts in my subscription?

It depends:

- If your organization created an account after August 1, 2023, you can't create more accounts.
- If your organization hasn't created a Microsoft Purview account before, if you create an account it will automatically be reconciled to the new experience, and you can't create more accounts after.
- If your organization has a single Microsoft Purview account that has already been reconciled to the new experience, you can't create more accounts.
- If you're using the free version of Microsoft Purview governance solutions and haven't created a Microsoft Purview account, if you upgrade to the enterprise version, you can't create more

accounts.

- If you're using the free version of Microsoft Purview governance solutions and create an account, the newly created account will be automatically reconciled to the new experience and you can't create more accounts after that.
- If your organization already has multiple Microsoft Purview accounts, you can create Microsoft Purview accounts up to the preexisting quota, even if you have already reconciled an account to the new experience.

We already had a Microsoft Purview account, and are using the new portal experience. Is our account the free or enterprise version of Microsoft Purview?

If you're already using a Microsoft Purview account that's upgraded to use the new portal experience, your organization is using the enterprise version of Microsoft Purview. You can check your organization's account type in the Microsoft Purview portal by going to **Settings** > **View all settings**.

When I start using the new Microsoft Purview experience, does it create an account for my organization or just for me?

The new Microsoft Purview experience uses a single, organization-wide instance of Microsoft Purview.

What does this mean for my existing Microsoft Purview governance portal accounts?

One of your Microsoft Purview governance portal accounts are elevated to be the primary tenant/organization level account with all its current metadata and information. If you have other Microsoft Purview accounts, in the future their information will also be made available in the primary account.

Can multiple accounts in the same tenant have access to the new experience?

Not currently. The new experience uses a single, primary Microsoft Purview account. If you have multiple accounts, you select a primary account when you upgrade to the new experience. In the future, the information in your other accounts will also be made available in this environment.

What is the impact of upgrading the production account to the enhanced experience?

There's no impact on upgrading the account to the enhanced experience. Users can navigate the capabilities in the new Microsoft Purview portal and classic governance portal in Azure. If users browse Microsoft Purview portal from the Azure portal, the upgraded account provides two links to browse the portals.

How long does the upgrade take?

If your account is eligible, upgrading to the new experience only takes a few minutes.

What if my organization blocked the new portal endpoints on the firewall?

You can still access Microsoft Purview through the classic portal by launching the old endpoints through https://web.purview.azure.com.

What should I do if my organization can't use preview features?

Upgrading to enhanced experience doesn't change the status of generally available (GA) features.

My primary Microsoft Purview instance has private endpoints enabled. Can I upgrade it to enhanced experience?

If your Microsoft Purview account had disabled all public network access and is using private endpoints, you can still upgrade to the new experience. You can continue to use your *ingestion* private endpoints as is, but the new experience also uses a *platform* private endpoint. After upgrading to the new experience, you can follow this guide to set up platform the private endpoint for governance solutions in the Microsoft Purview portal. For more information, see what to do if your account has disabled all public network access.

How is access to the Microsoft Purview portal granted if you're a Dynamics 365, Microsoft 365 Enterprise, Microsoft Fabric, Power Apps, or Power BI user?

If your organization uses Dynamics 365, Microsoft 365 Enterprise, Microsoft Fabric, Power Apps, or Power BI, your tenant has the Microsoft Purview Discovery Plan added. Administrators can find this plan under **Your products** in the admin center. This plan has no cost and grants access to the new experience.

What if I'm not an Azure Enterprise, Dynamics 365, Microsoft 365 Enterprise, Microsoft Fabric, Power Apps, or Power BI customer?

If you're an existing Microsoft Purview customer (your Microsoft Entra tenant already has a Microsoft Purview account), a user holding a Purview Administrator role can upgrade your instance to the new experience. When that happens, you're prompted to confirm the upgrade. When you confirm, your tenant is added to the Microsoft Purview Discovery Plan. Administrators can find this plan under **Your products** in the admin center. This plan has no cost and grants access to the new experience. If a global or billing admin attempts this upgrade, they receive an error. If you don't have access to the Microsoft 365 role groups to assign Purview Admins, contact support.

My organization wants to continue using the classic portal. What link can we use to access it?

Access the classic portal at https://web.purview.azure.com.

If I continue to scan or curate assets in the existing classic portal, will the new or updated assets show up in the new portal?

Yes. The upgraded account is accessible via both portals, and changes in metadata and configurations are visible in the classic and new portals.

Can I opt out of migration to the new experience?

Existing Microsoft Purview accounts stay the same and remain operational in parallel with the new experience for a time. Eventually users are encouraged to transition to the new experience.

Should I start the upgrade now?

We recommend all Microsoft Purview customers to start the upgrade as soon as possible. New features and capabilities are only available on the new portal.

What do I need to prepare before the upgrade and what are some areas of considerations to include in my plan?

1. Prepare your change request. Before the upgrade, Microsoft Purview users can navigate to the classic Microsoft Purview governance portal only through legacy endpoints:

Portal: `web.purview.azure.com`
Endpoint: `https://[accountname].purview.azure.com/`

After the upgrade, the upgraded account is accessible via legacy experience and the new experience. To use the new experience, make sure your corporate firewalls allow outbound traffic to new endpoints.

Access to classic portal and endpoints:

Portal: `web.purview.azure.com`
Endpoint - `https://[accountname].purview.azure.com/`

Access to new portal and endpoints:
Portal: `purview.microsoft.com`
Endpoint: `api.purview-service.microsoft.com`

2. Add new endpoints to your corporate firewalls. Even though the classic portal and endpoints are still available, as part of retiring these endpoints, Microsoft suggests planning to include new URLs and endpoints to your firewall. These updates make sure your users' access and applications aren't impacted when the legacy endpoints are retired.

3. Adjust permissions. The upgraded account can be accessed by users through Microsoft Purview roles. New roles are also added to your Microsoft Purview account at the tenant level. You can manage these roles in new portal. Learn more about data governance roles and permissions.

What if my organization has multiple Microsoft Purview accounts?

You can upgrade your primary account. All other Microsoft Purview accounts in your tenant can still be accessed through the classic portal. Be prepared to merge those accounts with the primary account when the feature becomes available. Microsoft will notify customers who require to perform more steps to merge these accounts.

We have multiple Microsoft Purview accounts and want to upgrade to use the new portal. Which account should we select as the "primary"?

We suggest you select the production account, the account that is used by most of your end users, or the account that's the most critical to your daily operations. See our guide to choosing your primary account.

If I can't create a new account, what are my other options?

Use collections and assign role-based access on those collections to provide granular access control.

What can I access in the free version of Microsoft Purview governance solutions?

The free version allows users to explore their Azure and Microsoft Fabric resources. See what's available in the free version.

What region is Microsoft Purview in if we use the free version?

The free version of Microsoft Purview governance solutions uses the same location mappings as Microsoft 365, and maps to a location based on your Microsoft Entra ID home region.

How does Microsoft Purview choose the region for the enterprise version of Microsoft Purview?

If your tenant has no Microsoft Purview account: The free version of Microsoft Purview governance solutions is mapped to the same location as your Microsoft 365 instance. If that's unavailable, then it falls back to using the location geographically closest to your Microsoft Entra ID region. When you upgrade from free to enterprise, the enterprise version uses the same location.

If your tenant has a Microsoft Purview account: If your Microsoft Purview account is already upgraded to the new experience, it's using the region it was created in or the region that was selected during upgrade. If you haven't upgraded a Microsoft Purview account to the new experience, if you upgrade an existing account or create a new account to upgrade then the enterprise version will use that account's region.

The Microsoft Purview region is incidental; it doesn't affect your configurations or how you use your data, even if your sources are in another region. Microsoft Purview does all data processing

local to your data sources, and doesn't move your data to its own region or store your data. Your data remains securely in its own location, and ingress and egress charges that other Azure products sometimes incur aren't applicable. Regardless of where your data sources are housed, you don't need to change the region your Microsoft Purview account is using to interact with your sources.

If you're trying to upgrade from the free version to enterprise and can't upgrade due to security policy or data residency constraints around Microsoft Purview's mapped region, contact support. Also contact support if you're trying to create a first Microsoft Purview account in the Azure portal and can't create the account in the selected region due to security policy or data residency constraints.

If you're moving because of a security policy, you can only move to another region in your tenant's current Azure Geography. If you need to move to a region outside your tenant's current geography, you need to create a tenant in that geography.

How can I get more governance capabilities?

All governance features and capabilities are available by upgrading to the enterprise version of Microsoft Purview.

Last updated on 10/10/2025

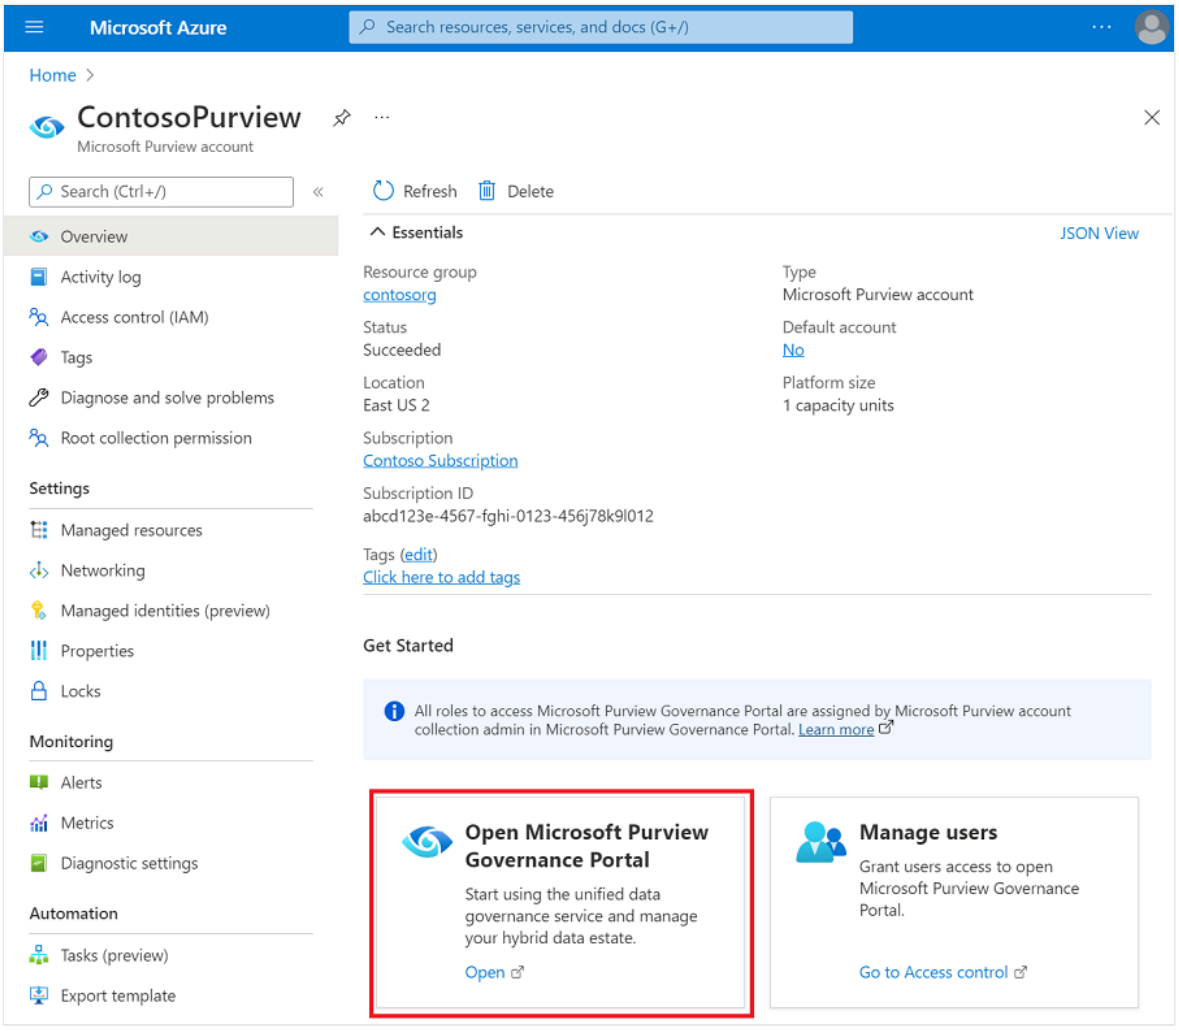
Classic Microsoft Purview governance portal

Article • 01/28/2025

> **Note**
>
> Microsoft Purview Data Catalog (classic) and Data Health Insights (classic) are no longer taking on new customers and these services, previously Azure Purview, are now in customer support mode.

This article gives an overview of some of the features in the classic Microsoft Purview governance portal.

> **Tip**
>
> Microsoft Purview has a new experience! If you're a new Microsoft Purview customer, or if you want more information, see our **article on the new portal** or the article about our new **data governance experience**.

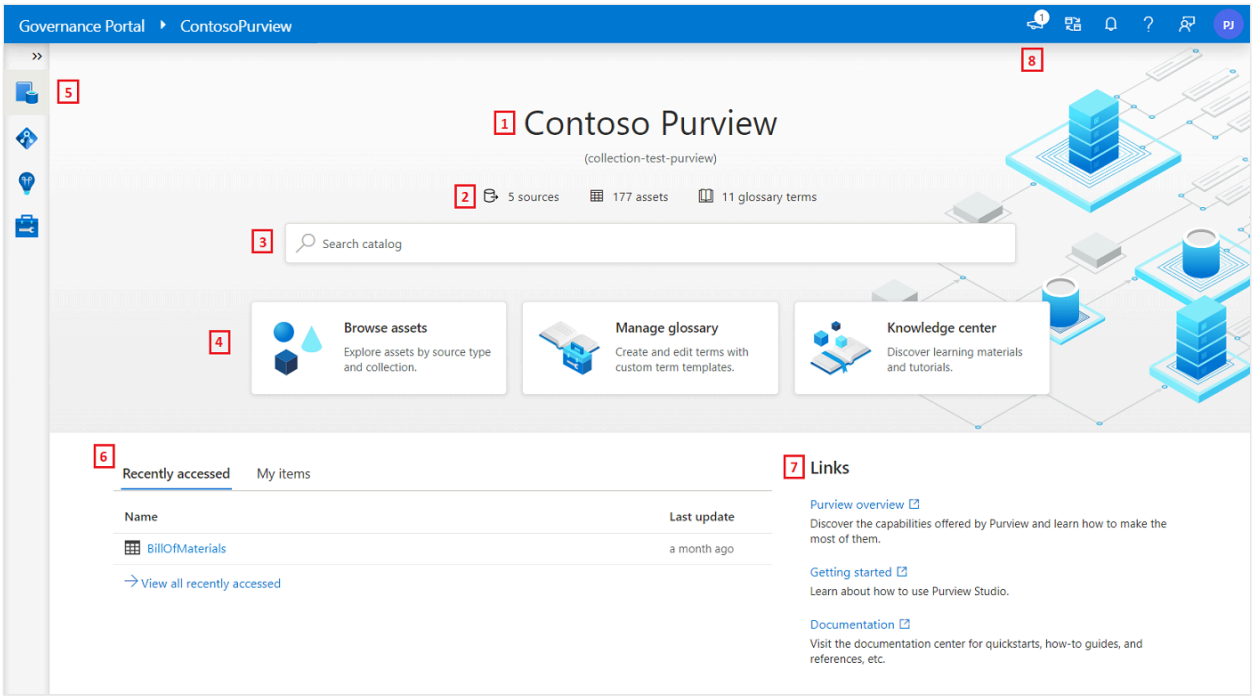


Prerequisites

- An Active Microsoft Purview account is already created in Azure portal
- The user has permissions to access the classic Microsoft Purview governance portal.

Launch Microsoft Purview account

- You can launch the Microsoft Purview account directly by going to `https://web.purview.azure.com`, selecting **Microsoft Entra ID** and the account name. Or by going to `https://web.purview.azure.com/resource/yourpurviewaccountname`



- To launch your Microsoft Purview account from the Azure portal, go to Microsoft Purview accounts in Azure portal, select the account you want to launch and launch the account.

> **Tip**
>
> If you can't access the portal, confirm you have the necessary permissions.

Home page

Home is the starting page for the Microsoft Purview governance portal.

The following list summarizes the main features of **Home page**. Each number in the list corresponds to a highlighted number in the preceding screenshot.

1. Friendly name of the catalog. You can set catalog name in **Management** > **Account information**.

2. Catalog analytics shows the number of:

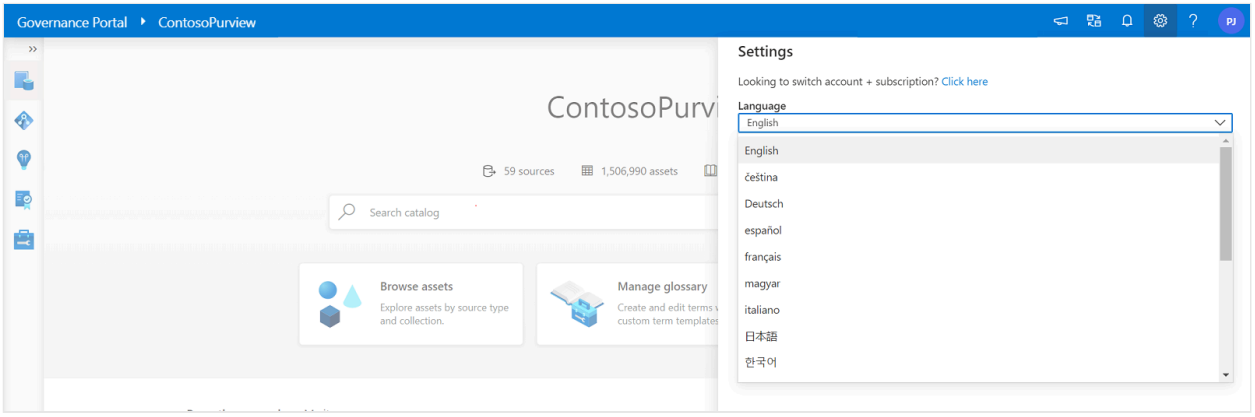
    - Data sources
    - Assets
    - Glossary terms

3. The search box allows you to search for data assets across the data catalog.

4. The quick access buttons give access to frequently used functions of the application. The buttons that are presented, depend on the role assigned to your user account at the root collection.

    - For *collection admin*, the available button is **Knowledge center**.
    - For *data curator*, the buttons are **Browse assets**, **Manage glossary**, and **Knowledge center**.
    - For *data reader*, the buttons are **Browse assets**, **View glossary**, and **Knowledge center**.
    - For *data source admin* + *data curator*, the buttons are **Browse assets**, **Manage glossary**, and **Knowledge center**.
    - For *data source admin* + *data reader*, the buttons are **Browse assets**, **View glossary**, and **Knowledge center**.

> **Note**
>
> For more information about Microsoft Purview roles, see Access control in Microsoft Purview.

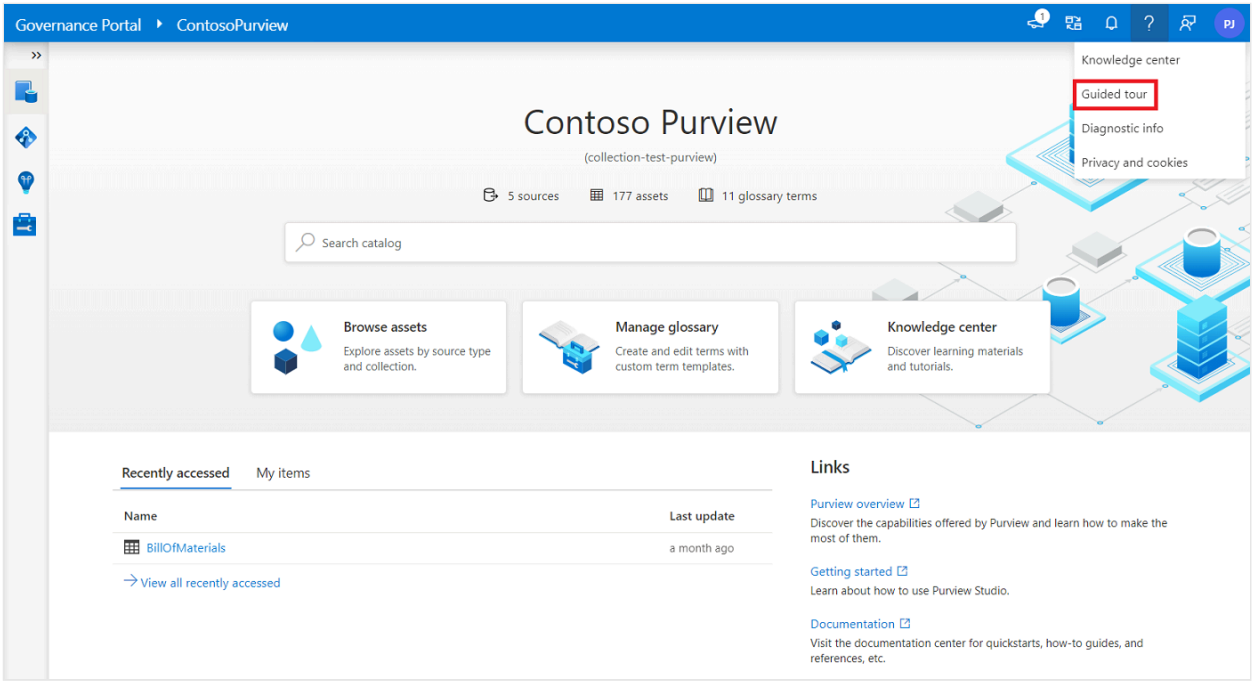


5. The left navigation bar helps you locate the main pages of the application.
6. The **Recently accessed** tab shows a list of recently accessed data assets. For information about accessing assets, see Search the Data Catalog and Browse by asset type. **My items** tab is a list of data assets owned by the logged-on user.
7. **Links** contains links to region status, documentation, pricing, overview, and Microsoft Purview status
8. The top navigation bar contains information about release notes/updates, change purview account, notifications, help, and feedback sections.

Knowledge center

The knowledge center is where you can find all the videos and tutorials related to Microsoft Purview.

Localization



Microsoft Purview is localized in 18 languages. To change the language used, go to the **Settings** from the top bar and select the desired language from the dropdown.

> **Note**
>
> Only generally available features are localized. Features still in preview are in English regardless of which language is selected.

Guided tours

Each UX in the Microsoft Purview governance portal will have guided tours to give overview of the page. To start the guided tour, select **help** on the top bar and select **guided tours**.

Learn about data governance billing

Microsoft Purview data governance solutions include Microsoft Purview Unified Catalog and Microsoft Purview Data Map. For Unified Catalog, you pay for governed assets and data health management capabilities. The billing for these components operates on a pay-as-you-go model. There's no cost to scan assets into Microsoft Purview Data Map when certain billing conditions are met. This article explains how to prepare for billing and how data governance capabilities are charged.

For complete pricing information, with pricing calculators, see the Microsoft Purview pricing site.

To learn more about the pay-as-you-go billing model for Microsoft Purview, including the consent experience, see Microsoft Purview billing models.

Prerequisites

To use Microsoft Purview pay-as-you go, you need:

- An Azure subscription in the same tenant as Microsoft Purview.
- An Azure resource group in that subscription.

If you already have these resources for other purposes, you can also use them with Microsoft Purview.

Billing setup

To use the data governance experience in the Microsoft Purview portal, you need to be set up for Microsoft Purview pay-as-you-go billing. Pay-as-you-go took effect for Microsoft Purview on January 6, 2025. For details about required roles and the setup experience, visit one of the resources below based on your situation:

- If you're a new data governance customer using Unified Catalog in the Microsoft Purview portal, see Enable Microsoft Purview pay-as-you-go features for new customers.
- If you're an existing Azure Purview customer using the classic data governance pricing model, see Consent to use pay-as-you-go capabilities.

If you don't consent to the pay-as-you-go pricing model, you can still use the classic Data Catalog in the classic data Microsoft Purview portal.

Your Data Map assets remain intact regardless of whether you consent to the new billing experience for Unified Catalog.

Pricing components

Two pricing components support data governance in Microsoft Purview. Unified Catalog has two meters that run based on:

1. Number of unique governed assets per day; see Unified Catalog billing.
2. Data governance processing units per run; see Data health management.

Unified Catalog billing

A single meter starts for an organization when users begin to govern unique data assets. A unique data asset can be a table or a view linked to a governance concept, such as a data product or a critical data element.

Assets that are collected in Data Map but aren't linked to a governance concept don't count as governed assets.

> **Tip**
>
> - To view specific pricing information and a calculator for your region, see the **Data Governance** tab on the Microsoft Purview pricing site.
> - For an admin view into your organization's consumption across governance domains, see Usage monitoring (preview).

What are governed assets and how are you billed

In Unified Catalog, when you actively manage and curate data assets, you turn them into **governed assets**. A governed asset is a data asset that you attach or associate to governance concepts, such as data products, critical data elements, glossary terms, and data quality. If you don't associate a technical asset to a governance concept, it isn't a governed asset.

For example, if you have a Microsoft SQL Server with 200 tables, and only 20 tables are in the gold tier of the medallion structure, you created 20 data products with each data product linked to a table. Every day, the Unified Catalog billing system counts the tables that are associated to the data product. Since only 20 tables link to data products, only 20 tables are governed assets, instead of the full 200 tables.

Over time, you might want to attach a glossary term and a policy to the data product, which then also apply to the governed assets. In each case, a governed asset is still a single governed asset regardless of how many concepts you attach to the asset.

- **Example 1:** A SQL table is referenced within a data product. You use the same SQL table in five other data products. The SQL table is counted one time only, once a day.
- **Example 2:** You create 50 governance domains and data products, but don't attach any tables, files, reports, or dashboards. In this case, you aren't charged for any governed assets.
- **Example 3:** You accidentally attach a server to the data product. Microsoft Purview counts just the server as a single asset, not all the children tables within the server.

View pricing information on the **Data Governance** tab on the Microsoft Purview pricing site.

Data health management usage

The Microsoft Purview Data Governance Enterprise Data Management meter starts when you run data quality and health management actions on your governed data estate. You pay for data management usage based on the data governance processing unit (DGPU) pay-as-you-go meters. A DGPU is the amount of service performance consumed for 60 minutes and comes in three different performance options: Basic, Standard, and Advanced. The Basic SKU option is the default performance option until you select a higher option.

View pricing information at each performance level on the **Data Governance** tab on the Microsoft Purview pricing site.

Data governance processing units explained

A DGPU is a fully managed compute unit that runs compute-heavy capabilities such as data quality and data health management. Each DGPU provides 60 minutes of compute time, running across varying sets of nodes based on the workload need.

The number of DGPUs you consume depends on:

1. Data quality or health (metadata quality) rule type: Out of the box or custom.
2. The volume of data.
3. Source type: The same volume of data might generate different DGPUs across two different source types.

Some ranges of DGPU generation are as follows:

Expand table

Data Source	Row count	SKU type	Rule type	DGPU per rule per run
Azure SQL DB	1 Million	Basic	Empty/blank check	0.02
Azure SQL DB	1 Million	Basic	StringFormat=Regex/Like check	0.02
Azure SQL DB	1 Million	Basic	Table lookup (1 mill row reference table)	0.03
Azure SQL DB	1 Million	Basic	Unique check	0.02
Azure SQL DB	1 Million	Basic	Duplicate check = 3 column-combo	0.02

Data health controls pricing

Data health controls, self-serve analytics, and reports within **Health management** use the Basic SKU, as these capabilities don't require higher processing capacity.

The total DGPU consumption depends on the data volume, the calculation of control scores, and report generation. The control job is scheduled to run daily when you initially provision it and triggers only if at least one business domain exists. If you remove all business domains, the job doesn't run.

You can adjust the schedule as needed; the job always runs based on your configured schedule. If you don't want to refresh a specific control, you can edit the control and toggle it to deactivate.

This flexibility lets you fully manage schedules and selectively inactivate controls to optimize costs and manage DGPU consumption.

> **Tip**
>
> - Default control refreshes daily. Scheduled controls run based on the schedule you configure.
> - To stop using data health controls, manually disable them from the schedule page. You can activate or deactivate individual controls separately, so you can focus on the most relevant controls.

Data quality pricing

Data quality usage is billed based on DGPU pay-as-you-go meters. For example, if you run 100 data quality jobs in a single day, and each run produces 0.02 DGPU, then the total DGPU for that day is two DGPUs. Data quality for on-premises data sources uses the Basic SKU for DGPU consumption. To calculate the cost based on performance option and region, visit the Microsoft Purview pricing site.

You can also use a data quality and data health control pricing calculator on the Microsoft Azure Pricing calculator page to calculate pricing for governed assets, DGPU consumption price for data quality, and data health controls. Use the calculator to budget the investment for the data governance program of your organization. On the calculator page, search for Microsoft Purview to calculate price and budget the data governance investment.

Here's example of consumed processing units for basic to complex rules for different data volumes, based on the standard performance option.

Expand table

Rule complexity	10,000 records	-	100,000 records	-	1,000,000 records	-	10,000,000 records	-	100,000,000 records	-	1,000,000,00 records
	Duration	PU	Duration	PU	Duration	PU	Duration	PU	Duration	PU	Duration
Simple	Elapsed time: 1m	0.02	Elapsed time: 1m	0.02	Elapsed time: 1m	0.02	Elapsed time: 1m	0.02	Elapsed time: 1m	0.02	Elapsed time 1m 31s

Rule complexity	10,000 records	-	100,000 records	-	1,000,000 records	-	10,000,000 records	-	100,000,000 records	-	1,000,000,00 records
	1s		1s		1s		16s		16s		
Medium	Elapsed time: 1m 1s	0.02	Elapsed time: 1m 1s	0.02	Elapsed time: 1m 1s	0.02	Elapsed time: 1m 16s	0.02	Elapsed time: 1m 31s	0.03	Elapsed time 2m 1s
High	Elapsed time: 1m 1s	0.02	Elapsed time: 1m 1s	0.02	Elapsed time: 1m 31s	0.03	Elapsed time: 1m 32s	0.03	Elapsed time: 2m 1s	0.03	Elapsed time 2m 51s

Tip

- Increase data volume: For testing, you can use the same data asset by adding more data, or you can create multiple data assets with different data volumes; see the example above.
- Example of rule complexity
  - Simple rule: Blank or empty value check.
  - Medium complex rule: Uniqueness rule, data type, or format check rule.
  - High complex rule: Duplicate check with multiple selected columns; credit card, national ID, table lookup, and SSN validation are in the category of complex rule.

Data Map and scanning charges

Unified Catalog currently runs on the existing Data Map. Data Map and scan charges don't apply to Unified Catalog customers once they either consent to the Microsoft Purview billing model or upgrade from free to enterprise tier. The new Unified Catalog is rolling out in multiple regions; check the supported regions for Unified Catalog.

Customers using the classic Data Catalog can check pricing on the **Data Map (Classic)** tab of the Microsoft Purview pricing site.

Last updated on 04/24/2026

Data governance billing frequently asked questions

When did the new pricing model go into effect?

The new pricing model took effect on January 6, 2025.

Is the asset counting done at a monthly level or daily level?

Assets are counted on a daily basis. Each day, unique governed assets are counted. If you ungovern any assets mid-month, the right asset count is picked for the day and multiplied by unique governed assets per day.

I have a single data product with three data assets attached. Am I charged for each data asset for 30 days?

Yes. When attaching three data assets to a data product, you're charged for each data asset each day.

I have the same data asset attached to both a data product and a critical data element. How am I charged?

You aren't charged for a data asset attached to both a data product and a critical data element. You're charged for a data asset once.

How am I charged if I scanned 10 data assets and only three are attached to data products?

You're charged for the three data assets attached to the data product. You aren't charged for the remaining seven data assets in Data Map.

If I use the classic glossary in Data Map and attach classic glossary terms to a data asset, am I charged?

No. Assets with classic glossary terms attached to them aren't charged.

If I attach a SQL server with 200 tables in it to a data product, how many governed assets am I charged for?

You're charged for a single asset as governed asset for a SQL server with many tables. Children won't be counted since the intent is to govern the server as a whole. We recommend putting an individual table or a selected group of tables in a data product, so the experience is more curated and meaningful. If the data product is data consumer facing, then limited data consumers would want access to a data product with 200 tables.

If I attach a Power BI semantic model into a data product that has 200 tables, and then I intentionally hand-pick 10 tables to be part of the data product, how many assets do I get charged for?

If the semantic model is still attached to the data product, we charge it as a single asset. If you have picked five tables to be attached to the data product, removing the semantic model we charge for the five tables only.

Can I run data quality rules on a database or its individual tables and columns?

Data quality runs are set on columns of tables. Running data quality on a data asset's columns or tables turns that data asset into a governed asset.

What type of billing transparency will I be able to see?

Usage monitoring (preview) in Unified Catalog settings provides Data Governance Administrators with a view of governed assets and data governance processing unit (DGPU) consumption across governance domains. Based on the processing units, you can decide if you're over-using, under-using, or if there are opportunities to optimize data quality rules. You can also charge back costs to the different governance domains using the consumption details.

Are there tools and guidance to help estimate costs with new pricing model?

Yes. You can find complete pricing information and a pricing calculator on the Microsoft Purview pricing site.

Is there a volume discount?

No, but based on usage at scale, we can work on volume-based pricing for future releases.

What cost reporting will be available, and where can I view this?

Costs can be viewed from January 6, 2025, in the Cost management section of the subscription tied to your Microsoft Purview tenant (in the Microsoft Purview portal, go to **Settings** > **Account** > **Account overview**). Data Governance Admininisrators can also view the usage monitoring (preview) report.

What meters are zeroed out from classic to Microsoft Purview Unified Catalog?

The following meters are zeroed out from classic to Microsoft Purview Unified Catalog in the following areas:

- Data Map population - Scanning including SHIR
- Data Map enrichment - Insights Generation, Data Map capacity units
- Data Map consumption - including insights consumption

Does the advanced resource set meter zero out for me?

The advanced resource set isn't offered as part of Microsoft Purview, so the meter is ineffective.

Last updated on 02/13/2026

Microsoft Purview data governance glossary

This glossary provides a brief description of important terms and concepts for the Microsoft Purview data governance experience.

A

Expand table

Term	Description
Advanced resource sets	A set of features activated at the Microsoft Purview instance level that, when enabled, enrich resource set assets by computing extra aggregations on the metadata to provide information such as partition counts, total size, and schema counts. Resource set pattern rules are also included.
Annotation	Information that is associated with data assets in the Microsoft Purview Data Map, for example, glossary terms and classifications. After they're applied, annotations can be used within Search to aid in the discovery of the data assets.
Approved	The state given to any request that has been accepted as satisfactory by the designated individual or group who has authority to change the state of the request.
Asset	Any single object that is stored within a Microsoft Purview Unified Catalog. Note: A single object in the catalog could potentially represent many objects in storage, for example, a resource set is an asset but it's made up of many partition files in storage.

C

Expand table

Term	Description
Capacity unit	A measure of data map usage. All Microsoft Purview Data Maps include one capacity unit by default, which provides up to 10 GB of metadata storage and has a throughput of 25 data map operations per second.
Classification report	A report that shows key classification details about the scanned data.
Classification rule	A set of conditions that determine how scanned data should be classified when content matches the specified pattern.

Term	Description
Classified asset	An asset where Microsoft Purview extracts schema and applies classifications during an automated scan. The scan rule set determines which assets get classified. If the asset is considered a candidate for classification and no classifications are applied during scan time, an asset is still considered a classified asset.
Classifier	The technology used to identify, categorize, classify, and label data. Microsoft Purview offers several classifiers, including sensitive info types, trainable classifiers, and exact data match (EDM) classifiers.
Collection	An organization-defined grouping of assets, terms, annotations, and sources. Collections allow for easier fine-grained access control and discoverability of assets within a Unified Catalog.
Collection admin	A role that can assign roles in the Microsoft Purview governance portal. Collection admins can add users to roles on collections where they're admins. They can also edit collections, their details, and add subcollections.
Column pattern	A regular expression included in a classification rule that represents the column names that you want to match.
Contact	An individual who is associated with an entity in Unified Catalog.
Control plane operation	An operation that manages resources in your subscription, such as role-based access control and Azure policy that are sent to the Azure Resource Manager end point. Control plane operations can also apply to resources outside of Azure across on-premises, multicloud, and SaaS sources.
Credential	A verification of identity or tool used in an access control system. Credentials can be used to authenticate an individual or group to grant access to a data asset.

D

Expand table

Term	Description
Data curator	A role that provides access to Unified Catalog to manage assets, configure custom classifications, set up glossary terms, and view insights. Data curators can create, read, modify, move, and delete assets. They can also apply annotations to assets.
Data dictionary	A list of canonical names of database columns and their corresponding data types. Often used to describe the format and structure of a database, and the relationship between its elements.
Data Estate Insights	An area of the Microsoft Purview governance portal that provides up-to-date reports and actionable insights about the data estate.

Term	Description
Data Map	A metadata repository that is the foundation of the Microsoft Purview governance portal. The data map is a graph that describes assets across a data estate and is populated through scans and other data ingestion processes. This graph helps organizations understand and govern their data by providing rich descriptions of assets, representing data lineage, classifying assets, storing relationships between assets, and housing information at both the technical and semantic layers. The data map is an open platform that can be interacted with and accessed through Apache Atlas APIs or the Microsoft Purview governance portal.
Data Map operation	A create, read, update, or delete action performed on an entity in the data map. For example, creating an asset in the data map is considered a data map operation.
Data owner	An individual or group responsible for managing a data asset.
Data pattern	A regular expression that represents the data that is stored in a data field. For example, a data pattern for employee ID could be Employee{GUID}.
Data plane operation	An operation within a specific Microsoft Purview instance, such as editing an asset or creating a glossary term. Each instance has predefined roles, such as "data reader" and "data curator" that control which data plane operations a user can perform.
Data reader	A role that provides read-only access to data assets, classifications, classification rules, collections, glossary terms, and insights.
Data Share contributor	A role that can share data within an organization and with other organizations using data share capabilities in Microsoft Purview. Data share contributors can view, create, update, and delete sent and received shares.
Data Sharing	Microsoft Purview Data Sharing is a set of features in Microsoft Purview that enables you to securely share data across organizations.
Data source admin	A role that can manage data sources and scans. A user in the Data source admin role doesn't have access to Microsoft Purview governance portal. Combining this role with the Data reader or Data curator roles at any collection scope provides Microsoft Purview governance portal access.
Data steward	An individual or group responsible for maintaining nomenclature, data quality standards, security controls, compliance requirements, and rules for the associated object.
Discovered asset	An asset that the Microsoft Purview Data Map identifies in a data source during the scanning process. The number of discovered assets includes all files or tables before resource set grouping.
Distinct match threshold	The total number of distinct data values that need to be found in a column before the scanner runs the data pattern on it. For example, a distinct match threshold of eight for employee ID requires that there are at least eight unique data values among the sampled values in the column that match the data pattern set for employee ID.

E

Expand table

Term	Description
Expert	An individual within an organization who understands the full context of a data asset or glossary term.

F

Expand table

Term	Description
Full scan	A scan that processes all assets within a selected scope of a data source.
Fully Qualified Name (FQN)	A path that defines the location of an asset within its data source.

G

Expand table

Term	Description
Glossary	A searchable list of specialized terms that an organization uses to describe key business words and their definitions. Using a business glossary can provide consistent data usage across the organization.
Glossary term	An entry in the glossary that defines a concept specific to an organization. Glossary terms can contain information on synonyms, acronyms, and related terms.

I

Expand table

Term	Description
Incremental scan	A scan that detects and processes assets that have been created, modified, or deleted since the previous successful scan. To run an incremental scan, at least one full scan must be completed on the source.

Term	Description
Ingested asset	An asset that has been scanned, classified (when applicable), and added to the Microsoft Purview Data Map. Ingested assets are discoverable and consumable within Unified Catalog through automated scanning or external connections, such as Azure Data Factory and Azure Synapse.
Insight reader	A role that provides read-only access to Data Estate Insights reports. Insight readers must have at least data reader role access to a collection to view reports about that specific collection.
Integration runtime	The compute infrastructure used to scan in a data source.
Item	Any single object that's stored within the Microsoft Purview Data Map.

L

Expand table

Term	Description
Lineage	How data transforms and flows as it moves from its origin to its destination. Understanding this flow across the data estate helps organizations see the history of their data, and aid in troubleshooting or impact analysis.

M

Expand table

Term	Description
Management	An area within the Microsoft Purview Governance Portal where you can manage connections, users, roles, and credentials. Also referred to as "Management center."
Microsoft Fabric	Microsoft's unified analytics solution that delivers an integrated and simplified experience for all analytics workloads and users on an enterprise grade data foundation with pervasive data governance.
Microsoft Purview instance	A single Microsoft Purview (formerly Azure Purview) account.
Minimum match threshold	The minimum percentage of matches among the distinct data values in a column that must be found by the scanner for a classification to be applied. For example, a minimum match threshold of 60% for employee ID requires that 60% of all distinct

Term	Description
	values among the sampled data in a column match the data pattern set for employee ID. If the scanner samples 128 values in a column and finds 60 distinct values in that column, then at least 36 of the distinct values (60%) must match the employee ID data pattern for the classification to be applied.

O

Expand table

Term	Description
Object type	A categorization of assets based upon common data structures. For example, an Azure SQL Server table and Oracle database table both have an object type of table.
On-premises data	Data that is in a data center controlled by a customer, for example, not in the cloud or software as a service (SaaS).
Owner	An individual or group in charge of managing a data asset.

P

Expand table

Term	Description
Pattern rule	A configuration that overrides how the Microsoft Purview Data Map groups assets as resource sets and displays them within the catalog.
Physical asset	An asset that represents a physical data object. Physical assets are different from business assets because they represent real data. For example, a database is a physical asset.
Policy	A statement or collection of statements that controls how access to data and data sources should be authorized.

R

Expand table

Term	Description
Registered source	A source that has been added to a Microsoft Purview instance and is now managed as a part of Unified Catalog.

Term	Description
Related terms	Glossary terms that are linked to other terms within the organization.
Resource set	A single asset that represents many partitioned files or objects in storage. For example, the Microsoft Purview Data Map stores partitioned Apache Spark output as a single resource set instead of unique assets for each individual file.
Role	Permissions assigned to a user within a Microsoft Purview instance. Roles, such as Microsoft Purview Data Curator or Microsoft Purview Data Reader, determine what can be done within the product.
Root collection	A system-generated collection that has the same friendly name as the Microsoft Purview account. All assets belong to the root collection by default.

S

Expand table

Term	Description
Scan	A Microsoft Purview Data Map process that discovers and examines metadata in a source or set of sources to populate the data map. A scan automatically connects to a source, extracts metadata, captures lineage, and applies classifications. Scans can be run manually or on a schedule.
Scan rule set	A set of rules that define which data types and classifications a scan ingests into a catalog.
Scan trigger	A schedule that determines the recurrence of when a scan runs.
Schema classification	A classification applied to one of the columns in an asset schema.
Search	A feature that allows users to find items in Unified Catalog by entering in a set of keywords.
Search relevance	The scoring of data assets that determine the order search results are returned. Multiple factors determine an asset's relevance score.
Self-hosted integration runtime	An integration runtime installed on an on-premises machine or virtual machine inside a private network that is used to connect to data on-premises or in a private network.
Sensitive info type (SIT)	A pattern-based classifier that helps detect sensitive information, such as credit card numbers, in items.

Term	Description
Sensitivity label	A label managed in the Microsoft Purview portal that defines how confidential an item is. Sensitivity labels can be configured to apply associated protection settings, helping users to remain compliant with organizational information protection policies.
Sensitivity label report	A summary that describes which sensitivity labels are applied across the data estate.
Service	A product that provides standalone functionality and is available to customers by subscription or license.
Share	A group of assets that are shared as a single entity.
Source	A system where data is stored. Sources can be hosted in various places such as a cloud or on-premises. You register and scan sources so that you can manage them in the Microsoft Purview governance portal.
Source type	A categorization of the registered sources used in Microsoft Purview; for example, Microsoft 365, Azure SQL Database, Azure Blob Storage, Amazon S3, Google Cloud, or SAP ECC.
Steward	An individual who defines the standards for a glossary term. They're responsible for maintaining quality standards, nomenclature, and rules for the assigned entity.

T

Expand table

Term	Description
Term template	A definition of attributes included in a glossary term. Users can either use the system-defined term template or create their own to include custom attributes.
Trainable classifier	A type of classifier that helps identify and categorize content that isn't easily identified by manual or automated pattern-matching methods. Unlike a sensitive info type, this method of categorization identifies an item based on what the item is (for example, a resume), not solely by elements included in the item (pattern matching). Trainable classifiers can be included in several Microsoft Purview solutions to detect, protect, and govern sensitive data.

U

Expand table

Term	Description
Unified Catalog	A searchable inventory of assets and their associated metadata that allows users to find and curate data across a data estate. Unified Catalog also includes a business glossary where subject matter experts can provide terms and definitions to add a business context to an item.

W

Expand table

Term	Description
Workflow	An automated process that coordinates the creation and modification of catalog entities, including validation and approval. Workflows define repeatable business processes to achieve high quality data, policy compliance, and user collaboration across an organization.

Learn about Microsoft Purview Unified Catalog

10/14/2025

> **Tip**
>
> The new Unified Catalog experience is rolling out across environments. If you don't see it yet, check the schedule for your region. Make sure you've upgraded to the enterprise version of the new Microsoft Purview experience in order to access the new experience when it's available in your region.

The goal of Microsoft Purview Unified Catalog is to not only provide a platform for data governance but also to drive business value creation in your organization.

Historically, data governance was a defense mechanism, a way to make sure your data is secure and compliant. But good data governance makes your data more visible to your users and provides many opportunities to reunite your business with the data that fuels it.

Most importantly, all of these new features are available in a single, integrated SaaS framework. Users shouldn't need to switch between applications to practice good data governance. We're working toward a solution where everything is in one place with experiences for data consumers, data stewards, and data owners.

Data governance for the era of AI

This era of artificial intelligence means that you have more data than ever, more ways to use it, and even more motivation to make sure you properly use and secure it. It's a task many organizations already struggle with, without the added complexity of using AI tools.

Governing data for an entire organization requires both rigor and flexibility. Clean, secure data requires consistency, but your teams' needs are unique for access and management. Because of this, use a federated governance approach: provide a centralized place to develop data safety, quality, and standards, but provide tools to create self-service access control, discoverability, and maintenance. Federated data governance spreads ownership across your business, reducing bottlenecks and encouraging participation in the life cycle of managing, governing, consuming, and applying data.

Data governance isn't just a gatekeeping function. When practiced well, it also accelerates data value creation. Your data users, stakeholders, and subject matter experts have crucial insights to the data-to day operations of your organization. Good data governance can apply that

expertise to reasonably scale the practice of data governance across your entire organization, including your nontechnical functions and business users. Said another way, good data governance utilizes your whole team and matches your data with your data-to-day business functions.

The point is both to reveal your data's business value and simplify its management even as your organization and data estate grow. Here's how it can help each sector of your business:

- For organization-wide data consumers:
  - Data discovery - help you easily find the data you need
  - Secure access - facilitates safe access to your data
  - Data understanding - providing what you need to know about the data before and while you use it

- For data owners and stewards:
  - Data curation and management - helps you deliver high quality data that's easy to understand and safely access for organization-wide applications
  - Responsible data use - helps you ensure that your data is used by intended users for intended purposes
  - Impact analysis - understand action anomaly states impacting your data

- For data officers and CxO stakeholders:
  - Data value creation - maximize value creation from your data while reducing operations spend
  - Data estate standardization - create common controls across your data estate with federated accountability so your data is healthy and safe.

Governance with the Unified Catalog

The new Unified Catalog experience lets you explore and understand your data categorized by governance domains. You can search through an AI-powered copilot and subscribe to data products that come equipped with all the data you need and the tools to safely access it. Over the last couple of years, we invested in a strong platform that has an inventory of all your data assets, their metadata, and their lineage so you can understand the topography of your data estate. Now we're providing better tools to manage it as it grows, and more points to surface that data to your business, to make use of it in the day-to-day.

Here are the tools that Unified Catalog provides to meet these data governance basics:

Expand table

Data governance principle	Catalog solution	Description
Data access - quickly provide right access and enforce right use to balance safety and innovation.	Unified Catalog access policies	Provides tools to manage self-service access requests that pairs data with compliance standards and right-use requirements.
	Critical data elements	Establish access policies on critical types of information to be applied across your data estate.
	Glossary terms	Attach access policies with your business vocabulary to promote right-use.
Data curation - organizing, annotating, and publishing your data so that it's safely accessible, reusable, and protected.	Governance domains	Organize data by business concepts, to make data more accessible and distribute ownership.
	Data products	Group related data assets so users can easily find the full data picture.
	Health actions	Take action to bring your data up to good governance standards.
Data discovery - users can find the data they need for day-to-day business and innovation.	Search & browse Unified Catalog	Search by governance domain, by data product, by keyword, or use the AI powered copilot to find what you need.
	Self-service access requests	Get access to all the data you need with a single request from inside Unified Catalog.
Data health - data quality standards are maintained across your estate, and there's an active data lifecycle keeping your data fresh and secure.	Health management	Ready-made reports provide the status of your data estate, and your data governance progress, at a glance.
	Critical data elements	Track important information to standardize and govern use.
	Data quality	Set quality rules from the top down to simplify distribution and provide snapshot progress tracking.
	Health controls	See how your data estate measures up to governance standards.
	OKRs	Map data health and governance goals to your business objectives.

Data governance principle	Catalog solution	Description
Data understanding - data has quality descriptors that help users understand what the data is and how it should be used.	Data products	Provide business context for a set of data assets.
	Glossary terms	Attach your day-to-day business vocabulary to your data assets.
	OKRs	Link data usage directly to your business objectives.

Get started

Ready to get started making your information clean, valuable, and accessible to your business users? We've created a guide to take you from zero to a fully integrated Unified Catalog in Get started with data governance.

Unified Catalog features

Now that you understand how Unified Catalog supports good data governance practice, and how the features promote data governance principals, explore the features in more detail:

- Governance domains: An organizational object that provides context for your data assets and makes it easier to scale data governance practices.
  - Unified Catalog access policies: Provide secure, self-service access to data products.
  - Critical data elements: Logically describe your key business data to govern them.
  - Glossary terms: Active values that provide context but also apply policies that determine how your data should be managed, governed, and made discoverable for use.
- Data products: A kit of data assets (tables, files, Microsoft Power BI reports, and more) that provides assets with a use case for ease of discovery and understanding.
- OKRs: Drive business value from your data and directly promote data governance objectives.
- Data estate health updates: Expanded features to provide new insights and encourage governance ownership.
  - Health controls: Track your governance progress with a health score.
  - Health actions: Follow these actions in your data estate to improve your governance score.
- Data quality: Set rules and get scores to get insight across your data estate.

Governance domains

Governance domains let you explore data through business concepts, like Marketing or Finance. This approach makes data more accessible to everyone.

Governance domains offer a new way to organize your data estate. You want and need to access your entire data estate, but a single, uncategorized list is overwhelming. A governance domain is a boundary that aligns your data estate to your organization. Think of it as a mini catalog inside Unified Catalog.

Inside your governance domain are the terms that define users' day-to-day work. There are objectives and key results (OKRs) to align your organization's goals with your data. There are data products that make data discovery more straightforward for your users.

The goal of the governance domain is to organize your Unified Catalog so that it not only drives healthy data governance but also ties your data directly to its business value and your objectives.

For more information, see the overview of governance domains.

Access policies

Unified Catalog access policies let you manage access to your data products and set up a system to provide access to users who request it. Promote innovation and flexibility in your data estate by creating self-service access opportunities, while upholding security and right-use standards. All in the Unified Catalog.

For more information, see how to create and manage Unified Catalog access policies.

Critical data elements

Critical data elements are a logical grouping of important pieces of information across your data estate. For example, a "Customer ID" critical data element can map "CustID" from one table and "CID" from another table into the same logical container. These groupings can make data easier to understand and promote standardization. You can attach data quality rules and access policies to these elements to further secure sensitive information across your data estate.

For more information, see how to create and manage critical data elements.

Glossary terms

If you use Microsoft Purview, you're familiar with glossary terms and how they provide critical business context to your data assets. We've taken them from static objects to active objects that help define how you should manage, govern, and make your data assets discoverable.

Policies within these terms allow data stewards to scale governance across your entire data estate. Terms applied to data products trickle down to the data assets and automatically secure those resources with their attached policies.

For more information, see the overview of glossary terms.

Data products

Data products improve catalog organization by grouping data assets together, such as tables, files, and reports, so users can easily discover them. You no longer need to request access to 15 different tables to build a data model. When one user researches and creates a viable data product, all other users benefit from that work. They can find and request access to the data in that product and have everything they need in one place.

For more information, see the overview of data products.

OKRs

Objectives and key results (OKRs) link data products directly to your objectives. They bridge the gap between your business and Unified Catalog. Use data to discover and track objectives in your business. Unified Catalog makes it easy to see those connections and track your goals.

For more information, see the overview of OKRs.

New data estate health features

Health management has a few new features for you to implement to enhance your data governance strategy and management.

Health controls

Track your journey to complete data governance by monitoring health controls. Health controls measure your current governance practices against standards and give your data estate a score.

Learn more about data health controls.

Health actions

Health actions are concrete steps you can take to improve data governance across your data estate. The actions are provided in a single list that can focus your data governance journey

and democratize ownership. Completing these actions improves data quality and discoverability across your data estate.

Learn more about viewing data health management actions.

Data quality

Data quality enables your organization to set rules through your governance domains, data products, and the data assets themselves. These rules trickle down across your environment so you can better evaluate your data across your data estate. You get data quality scores at the asset, data product, and governance domain levels, so you have full insight into your data estate.

Get an overview of data quality.

Plan for Unified Catalog with best practices

07/16/2025

In this article, we review the data governance strategies you can implement to maintain healthy, valuable, discoverable data. For a list of technical steps to set up Microsoft Purview Unified Catalog, see the get started guide.

Know your data with business concepts

Business concepts in Unified Catalog are the tools used to unite your data with your day-to-day business practices. This not only makes it easier for your data consumers to understand the data they're using, but it allows you to democratize the data governance of those resources. Use your existing experts and data champions to build Unified Catalog into a rich resource.

When we refer to business concepts in Unified Catalog, we're talking about these five elements:

1. Governance domains
2. Data products
3. Critical data elements (preview)
4. Glossary terms
5. Objectives and key results (OKRs)

Jump to a section below for best practices and scenario-based guidance on:

- ✓ Governance domain structure models and development planning
- ✓ Planning for and creating data products
- ✓ Glossary term development planning and defining
- ✓ Creating and using custom metadata

Create governance domains

Governance domains are used to both distribute ownership and maintenance tasks, and make it easier for users to find the data that they need. Distributing information by governance domains allows your users to reach the right level of information they need, without needing to traverse the entirety of your data estate.

When creating governance domains, or reviewing your governance domain structure, here are some things to consider:

1. Governance domain structure model
2. Development planning

Governance domain structure models

- **Central domain** (good): Using a single domain can be efficient for small organizations, but might not scale well and is prone to bottlenecks during growth.
- **Department-based domains** (good): Departments don't make decisions consistently, and if departments regularly shift, you might need to shift your Unified Catalog structure.
- **Functional/line-of-governance domains** (better): Grants flexibility to teams, and aligns with the existing business model. This can be difficult to manage at scale, and might need many sub domains to empower data decision makers. It can also create data use silos, which is the antithesis of the Unified Catalog's governance approach.
- **Domain mix** (best): Having a combination of domains across subject areas/data domains, functional domains, regulatory domains, and project domains align your data to its experts. In Unified Catalog, your data experts are your most powerful resource; they know what policies need to be applied and what others need to know to make the most use of the data. This structure will also be the most durable to organizational updates, since it's based on how the data is used in the day-to-day, instead of on business structures.

Governance domain development planning

> **Tip**
>
> It's not recommended to align your governance domains with your platform domains. IT is typically aligned with a technology structure or service/application, and isn't aligned with how data is used by business teams. Platform domains in Data Map likely align to these technology teams, instead of your business teams. The goal of governance domains is to align business users with the information that's most useful to them. Focus on data use, instead of data structure, to develop your governance domains.

1. When you begin creating your governance domains, start with a few domains aligned to teams that already have strong data stewardship:
   a. Assign data stewards and data product owners to your governance domains, and have them begin development on a glossary and data products that align with their current practices.
   b. If needed, scan data into the data map in parallel to supplement your data products.
   c. Leave your governance domain in a *draft* state until a few data products have been developed and are ready for users.
2. Publish your governance domain, and assign Global Catalog Reader permissions to your first users to let them start exploring.
3. With the feedback from your first batch of users, iterate on existing data products, or expand to your next data products or governance domains.

4. Starting with a few governance domains that have mostly complete coverage with data products ensures data consumers that the Unified Catalog has what they need and that they can continue to come back.

> **Tip**
>
> Learn more about governance domains.

Create data products

Much of the data that is stored today has little to no known value and can take time and manual effort to evaluate and understand before it can be removed or improved. Focusing on the data with known value and use will enable more teams to build consistent value and show the benefits to having well understood and highly utilized data. This drives further adoption of data governance practices and makes the effort to clean up data estates easier as the value of each data asset becomes clearer.

Focus on data resources that already exist in your organization. Adding these as data products in Unified Catalog makes it easier for your users to discover them. It will also make access more scalable, and improve trustworthiness with lineage, data quality, and accountability. Some examples of existing data resources are:

1. Gold zone data lakes, highly curated SQL stores, curated data warehouses/data lakehouses that teams use to support their day-to-day practices.
2. Reports that are used to make decisions.
3. Data tables that are used in reporting environments.
4. Master and reference data.

Data product development planning

1. Planning data products should be part of your intake process when data sources are added to the Microsoft Purview Data Map. Data Product Owners should know which data stores are being registered and scanned, and which have data assets ready to be added to Unified Catalog.
2. Build your first data products from core data assets that have been scanned into the data map.
3. Publish your first data products when your users are ready to consume data with that domain.

> **Tip**

Learn more about **data products**.

Define glossary terms

When you're building terms, start with what you already know and continue to build value from your data to show where effort is the most impactful. Here are some tips you can follow when creating and managing glossary terms to create the most value.

1. Giving data to the most passionate users demonstrates the ability to continue growing value and provides prioritization for more governance.
2. Many business teams already have a glossary to help new employees to orient themselves to the business. Use these as some of your first term candidates to describe a governance domain and its data.
3. If you aren't sure if a term represents another concept (like an entity or business process) adding a term is a good place to start so the most basic metadata is collected. If needed, th term can be expired, and a new concept can be used to collect more metadata and drive the intended end-to-end experience.
4. Once glossary terms are added, linking these terms to data products improves the discoverability of data products and enhance the consumers knowledge of the data.
5. Periodically checking the data products that are mapped to a term to enable data stewards to better understand their use across the data estate.
6. Term definitions can always be improved and edited. Waiting to publish a term until it's fully aligned will delay teams use of the term and prevent new value creation or escalation of potential improvements.

Term development planning

1. Data stewards should learn the framework of the governance domain, and then begin to add known terms and start to develop new ones.
2. Term definitions should be developed and contain valuable information for consumers to understand their context and use.
3. The first set of terms and data products should be published together for consumers to start their data use cases and discovery of data in the catalog.
4. Building semantic knowledge never stops, so make a plan on how you can enable your team to continue to contribute terms throughout your governance lifecycle.

> **Tip**
>
> Learn more about **glossary terms**.

Create and apply custom metadata

Custom metadata plays a crucial role in empowering organizations to govern their data effectively. By enabling users to define attributes tailored to their specific needs, custom metadata fosters better organization, accessibility, and utilization of data assets. In an era where data is the backbone of decision-making, custom metadata allows organizations to streamline processes, ensure compliance, and unlock the full potential of their data resources.

Unified Catalog > **Catalog management** > **Custom metadata** is where you create and manage business concept attributes and data asset attributes. Currently you can manage your custom attributes for business concept types and data asset types.

> **Tip**
>
> Learn more about **custom metadata**.

Unlock business value by making data accessible

Now that your basic Unified Catalog structures are in place, it's time to start unlocking the value of your data by making it accessible to your users, and tying it directly to your business goals. Creating value from data comes from using that data, but using data means every person in the company needs to find the right data at the right time and in the right format to provide the needed insights or functionality. Data consumers are the key to making new business value from data.

Jump to a section below for best practices and scenario-based guidance on:

- ✓ Helping your users search governance domains and data products
- ✓ Building out objectives and key results (OKRs)
- ✓ Establishing compliant data access
- ✓ Building logical data models with critica data elements (preview)

Let users search and browse your governance domains and data products

You've taken the time to build out governance domains and data products, so give your data consumers access to use them and see how they do. Business users might be looking for strategic reports that are already available with the insights they need to make business decisions in a timely and well informed manner.

Here's how you can think about granting access to your users strategically:

- **Do not start by granting access to Unified Catalog to everyone at your company.** Enable the teams that need the data you have in your catalog first. If your data products aren't available in the format data scientists need or the data isn't in predefined reports for business users, they'll lose trust in your catalog. Enabling the right roles to use the catalog first to build the pathway to success.
- **Do start with the teams that need the data you have in your catalog first.** Who did you build your data products for? Which teams helped develop your glossary terms? Those are good initial candidates.
- **Do start with analysts and data experts that can tell you where gaps exist in the catalog.** They can help point to experts and business owners that can contribute to Unified Catalog. Over time the completeness of Unified Catalog will be great enough everyone in the company will be able to find most of their data needs.

> **Tip**
>
> Learn more about managing access to data in Unified Catalog.

Create OKRs

Demonstrate the business value of your data by building objectives and key results (OKRs) and tying them to the data products that help to drive or measure that value. Ensuring business leaders appreciate the value of their data and the importance of governance will drive prioritization and new synergies in how teams build, maintain and govern their data to create insights.

Building out an objective provides immediate recognition of the importance of the data to the users and the business it drives. This greatly enhances the understanding of the role certain data plays in business processes or in the ability to achieve their goals.

1. Consider OKRs for process improvements, quality issues, major strategic goals, and anything else that you would measure with data to demonstrate business value and change.
2. Make sure to create key result for each objective to show how the objective is being measured and evaluated, and create accountability to meet that goal.
3. There can complex objectives that have many key results required to be able to accomplish. Key results might progress independently of the other key results that the measurement can show the areas that need prioritization or help to get back on track.

> **Tip**

Learn more about **OKRs**.

Compliant data access

Providing access to data can introduce risk to your company. Following known standards and policies is essential for ensuring access is granted appropriately and that there's responsible use of data. Users in Unified Catalog can complete a form for data access at the time of discovery or data use. Keeping this form and process as a part of the catalog makes access, secure, quick, and consistent for a highly variable and technical data estate. Here are some ways you can successfully set up access in your catalog:

- Ensure the appropriate approvers are in place on data products and that they understand the processing needs of the data products.
- Some data products might have hundreds or thousands of access requests, so having a team in distributed time zones could be required to ensure timely access approval and provisioning.
- Prepare groups or back up approvers in case there are vacations or unplanned time off.
- Governance domain owners should check on the access requests summary periodically to validate expectations and see if changes to controls monitoring the access request process are driving the desired response times.

Build logical data models with critical data elements (preview)

Improving deep technical understanding and expectations of data entities and elements will include new controls to assert if the data is meeting those expectations. Creating data dictionaries and logical models of data provides the structure and deep business expectations of the data to ensure that the data is fit for its purpose. By incorporating this knowledge into the Unified Catalog teams will immediately gain an understanding of how data is structured and why, and how what is available in the physical data estate might differ.

- Focus on the data elements that are most important for your domain. Critical data elements show the deep expertise and importance that data has on your business.
- **Don't** focus on the completeness of the elements across an entire domain. Not every column needs this level of control and many data elements might be self-explanatory for users.
- Evaluating critical data elements across different teams ensures that business teams have a common understanding of their data and how what one team creates is impacting many other areas of the business.
- Aligning access policies with critical data elements ensures proper access controls are in place for critical data across your whole data estate.

- Building data quality rules for critical data elements ensures that data meets expectations no matter where or how it's being used.

> **Tip**
>
> Learn more about critical data elements (preview).

Enhance data maturity

Improve your data estate and governance to fill gaps and remove bottlenecks to value creation:

- Monitor your health actions to improve governance incrementally across your entire Unified Catalog.
- Optimize for new uses of the data and eliminate data issues by improving data quality.
- Create best-in-class data products for single sources of truth with master data management.
- Evaluate your data health and prioritize for the greatest value impact.

Investing deeply in the core data that runs your company ensures this data is usable across the entire business consistently eliminating data issues and providing a stable base for insights creation. Having evidence of data issues helps to ensure actionability of data governance, and drives improvements that will immediately unlock new value without investing in data areas that have low value aren't fully understood yet. Continuously improving data maturity helps teams share learnings with each other and show the proof of the improvement as changes take place.

Jump to a section below for best practices and scenario-based guidance on:

- ✓ Improving data products with governance-focused actions
- ✓ Using data quality to improve the trustworthiness of your data
- ✓ Creating source of truth data products with master data management
- ✓ Using data health controls to measure governance maturity
- ✓ Building domain-specific standards

> **Tip**
>
> Start exploring how to manage data health and data quality.

Improve data products with governance-focused actions

Building trust in data requires continuous improvement and support. While consumers take time to find and apply data, bringing attention to issues or support needs there are easy actions that can be taken ahead of time based on best practices. Health actions in health management provide a complete list of these useful actions for Unified Catalog, to help you focus on what you can do next to improve your governance. Here are some best practices for using health actions to get the most value:

- Check the actions of your data products while they're still in a draft state. This ensures that when you do publish it has the basics covered and provide comfort to consumers that this data was published with care.
- Not all actions have to be taken at the same time. Some actions could take time to resolve as you learn more about the data or work with stewards to create more clarity. Keep checking on actions to see where new improvements are ready to be made.
- If actions begin to seem overwhelming, unnecessary, or distracting, consider making changes to your health controls. Optimizing the number of actions any person takes ensures that the right level of governance is being applied to data.

Improve the trustworthiness of your data with data quality

Too often data quality is a one-off project to fix a particular problem in the data. These improvements but don't last. Good data quality requires continuous evaluation and improvement to ensure problems won't return or new problems aren't created.

- Once a baseline of data quality expectations has been defined, building a plan to remediate issues in a timely manner is essential to keeping the business functioning with data fit for use.
- Scheduling your data quality scans to run regularly will help to ensure consumers that data is continuously being improved and is highly supported.
- Setting alerts on the critical rules and score changes enables data providers to correct issues before a consumer finds or experiences an issue. Alerting can also be used to share transparently with consumers issues before they find it in an experience or by making a decision based on poor quality data.

Create source of truth data products with master data management

Some data is so critical to nearly every process and the entire business that it deserves exceptional levels of management and governance. These data entities are usually cross-cutting entities like customer lists or employee profiles and they can require deep business expertise and experience in many business processes. Some data is highly usable but low scale, and still benefits from the deeper level of control and management; like reference data

attributes of country or region, currency, or industry segments. Each of these data types would benefit from master data management solutions to build a source of truth that is fit for use across your entire business.

- Practicing master data management with data quality is crucial to ensure that this vital data is clean and consistent.
- This level of data management is high effort, so choose valuable data elements or high-risk data elements to ensure your effort produces high value.
- Creating a critical data element and a data product for master data. These partner objects help to elevate your master data in the Unified Catalog and increase its use and understanding.
- Build new health controls for master data to continuously evaluate its use at scale and prevent new unmastered data from gaining use and causing confusion in a quickly evolving data estate.

> **Tip**
>
> Learn more about **master data management**.

Measure governance maturity with data health controls

Evaluating the maturity of data governance at scale across the entire business is required to ensure governance is effective and creating business value. By applying the built-in measurement of controls, health management enables the central data office or an individual governance domain to see where there's more that can be done. Collecting this evidence at scale quickly elevates the most critical data issues impacting the business and where one issue maybe impacting many areas of the business. This evidence helps to resolve prioritization issues with making data management changes and quickly demonstrates the value of having the right level of governance in place.

1. Establish a rhythm of business to review health management practices:
    a. Have a monthly review with governance domain leaders and the central data office to discuss priorities and needs for new governance or technical solutions.
    b. Empower teams to dig deep into their health management reports to make sure they can make the best decisions to create the value they need in their business.
    c. Bring health management to all levels of the business from the SLT to the individual steward to ensure that governance is right leveled and consistently actionable.
    d. Where data has larger issues requiring cross-business collaboration or deeper governance, consider creating a new governance domain and defining ownership for driving the governance of that data.

2. Don't expect all governance domains to have the same level of maturity or be focused on the same aspects of governance:
    a. Enabling governance at the right level empowers business owners to make the most valuable decisions about what to do with their data.
    b. Not all parts of the business have the same needs of their data and forcing deeper levels of governance might not help to create business value when the focus is elsewhere.
    c. Some data is less valuable or emergent in the data estate and the value isn't yet fully known. Enabling teams to move fast and adapt to their needs they can mature their governance with the value of the data.
3. Consistently evaluate health management to look for large changes that can indicate large issues or new learnings that need attention.
4. Share your health management scores. Sharing can bring teams together to learn what works for them or how they're finding new controls to build new value within a domain. Seeing what 'good' health looks like can motivate other teams to improve and ensure they're also delivering valuable data to their consumers.

Build domain-specific standards

Ensuring data governance is right sized for the level of value and control required is best handled by the business owners of the data. These business teams already have dependencies on the data and are in the best position to define their expectations and needs to make sure data is valuable.

- Empower governance domains to create new controls for their data regardless of where the data is used.
- Don't expect all governance domains to need the same level of controls or to adopt all controls. Data that is confined for use to a single part of the business by design might not benefit from a high level of control. Creating more control over data that doesn't have the appropriate value might prevent teams from collecting or keeping data that isn't fully utilized.
- Use the right level of control to help prioritize where low value data can be removed from the governance domain to eliminate risk and increase the value of the data estate.

Ready to get started?

To build a data governance practice in your organization using Unified Catalog and Data Map, see Get started with data governance or check out the sample setup walkthrough for more of a scenario-based example of how to perform key functions in Unified Catalog.

Manage Unified Catalog with the data governance admin role

In the data governance admin experience, you can manage the data governance settings that apply to Microsoft Purview Unified Catalog in one place. Users who hold the Data Governance Administrator role can set Unified Catalog roles and permissions, configure self-service analytics (preview), and manage other settings described in this article.

Prerequisites

To use the data governance admin experience, you need to be in the tenant-level data governance admin role.

Where to find Unified Catalog solution settings

To use the Data Governance Administrator experience in the Microsoft Purview portal:

1. In the Microsoft Purview portal, select **Settings**.
2. Under **Solution settings**, select **Unified Catalog**.
3. Select a setting name from the navigation. Each setting is explained in more detail in the following sections.

Roles and permissions

The roles and permissions item moved from the Unified Catalog solution to the solution settings, but the steps for applying those permissions are still the same. For more information about setting up roles and permissions for your users, see the data governance permissions documentation.

Solution integrations for self-serve analytics and insights

The **Solution integrations (preview)** page is where you set up self-service analytics and insights. These insights are data, tools, and platforms that enable business users to access, analyze, and generate insights from data independently by bringing their own tools and compute. For details, see Self-serve analytics and insights.

Usage settings (preview)

Data Governance Administrators can understand and adjust the usage settings available for Unified Catalog in this experience. The Data Health Management SKU can be changed for data quality jobs, and data quality monitoring can be used to monitor and understand the effect on processing. In the rare event of capacity not being available for a higher SKU, a basic SKU is defaulted to. Learn more about data governance billing.

Usage monitoring (preview)

> **Note**
>
> Usage monitoring is rolling out across regions. If you don't see it yet in your tenant, it will appear in the coming weeks.

The **Usage monitoring** experience is the Data Governance Administrator's view of governed assets and data governance processing unit (DGPU) consumption across different governance domains. This view lets the admin take the overall bill and use the consumption breakdown by governance domains to create a chargeback model in their organization across governed assets and DGPU meters.

The data reported in the charts reflects daily totals. The counts are by each governance domain and aren't aggregated to the parent.

Consumption data is split across governance domains as follows:

- **Governed asset**: Asset used in more than one governance domain split evenly across each domain that uses the asset. This count can show decimals in asset count.
- **Data quality**: Each data quality job maps to a governance domain, not split.
- **Data health management**: Split evenly across all governance domains.

You can use any other advanced split logic through self-serve analytics, when all DGPU data is available in self-serve analytics.

Other points to know:

- Cumulative governed assets are the cumulative governed assets for the time period you choose that is used to calculate your bill, not a unique count. For more information, see how governed assets are billed.
- The **Usage monitoring** settings don't show the actual bill; you can find your bill in the Microsoft Azure portal.
- If you rename a governance domain, the previous name shows on the chart for the date on which it changed. The new name shows on the date after the name change.

- When you delete a governance domain, only the GUID shows, not the domain name and owner name.

> **Tip**
>
> Find detailed information about **data governance billing** and a **billing FAQ**.

Data observability (preview)

Data observability (preview) provides a single view of your data estate to help you understand lineage and data health, and identify improvements in metadata, ownership, data quality, or data architecture. In this area of Unified Catalog settings, admins handle initial setup steps to generate data visualizations. For more information, see Set up data observability.

Virtual network

Data Governance Administrators can provision a virtual network compute location in supported Microsoft Azure regions. Get details at Manage virtual network provisioning

Governance domains in Unified Catalog

10/03/2025

A governance domain in Microsoft Purview Unified Catalog provides context for your data assets and makes it easier to scale data governance practices.

Data ownership is a central aspect of data governance. Controlling access and data use are core tenets of any successful governance program. Often, IT teams store and maintain data assets even though business teams own and use the data. That creates a gap between how data should be discovered and maintained and the teams that actually use it. Unified Catalog helps bridge that gap, but business owners still need clear context about their data assets and repeatable ways to scale governance across a growing data estate.

To address these needs, Unified Catalog introduces governance domains.

Overview and elements

At its simplest, a governance domain is a boundary that enables the common governance, ownership, and discovery of data products and business concepts like glossary terms, objectives and key results (OKRs), or critical data. The goal is to empower a governance domain owner to manage their data products and concepts, and establish rules for their access, use, and distribution. With this goal in mind, you could establish many kinds of governance domains:

- Fundamental business areas, such as human resources, sales, finance, and supply chain.
- Overarching subject areas, such as product and parties.
- Boundaries based on organizational functions, such as customer experience, cloud supply chain, and business intelligence.

In Microsoft Purview, governance domains are flexible so your organization can build the boundaries that make the most sense for your data. But once you've created them, how do they provide context or assist with data governance?

The parts of a governance domain: business concepts

A governance domain has a name and description, which helps users quickly understand what parts of your organization the governance domain represents. The domain also has owners who govern and maintain the domain and its assets.

Governance domains also contain the following business concepts:

- Data products: Packaged sets of data assets (tables, files, Power BI reports) grouped for discovery and reuse.
- Glossary terms: Business terms that provide context and can carry access and data-handling policies that determine how data should be managed and discovered.
- Objectives and key results (OKRs): Metrics that describe the value of your data with measurable values and goals.
- Critical data elements (preview): Logical groupings of important columns (for example, mapping "CustID" and "CID" to a single "Customer ID" concept) that require elevated governance.

Types of governance domains

These are the supported out-of-the-box governance domain types:

- Functional unit: Organizations or business units, such as sales, marketing, or finance.
- Line of business: Products or services being sold, such as Xbox, Office, or Azure, and different markets or subsidiaries.
- Data domain: Key organization-wide entities, such as customers or employees.
- Regulatory: Compliance-related domains such as GDPR, SOX, or HIPAA.
- Project: Collaborative programs across the organization.

How governance domains provide business context

Governance domains provide context for your data products, which are combinations of files, tables, reports, and other assets, by defining an overarching category for them. For example, someone who needs supply delivery schedules can limit their search to the Supply Chain domain instead of scanning the entire catalog.

Each governance domain can define OKRs to describe the business value of its data products and set measurable goals. Domain owners can prioritize data products based on those goals so users understand how data supports organizational strategy.

This structure provides familiar landmarks for business users and lets domain owners tailor and scale governance as the data estate grows.

How governance domains scale data governance

In a flat catalog, governing each asset individually is costly and unsustainable. Governance domains provide boundaries where policies can be applied broadly to data products.

The key to propagating governance policies is the use of glossary terms. Glossary terms provide business-context labels that improve discovery. Glossary terms are defined within a governance domain and can be applied to any data product in that governance domain

Data owners and data stewards don't have to traverse an entire data estate to maintain governance. They can apply terms across a governance domain they understand and know that when these terms are attached to a data product, the right policies will automatically fall into place. As an example: In the Human Resources governance domain, the "Feedback Results" term denotes returned company-wide feedback queries that are considered sensitive. A designated review team evaluates access requests. A data access policy on the Feedback Results term is applied automatically to any data product labeled with that term when users request access.

Governance domain owners and data stewards define policies once and rely on terms to propagate those practices across the data estate, ensuring consistent enforcement even as new assets are added.

Governance domains use existing business context to make data more discoverable and consistently governed as it grows.

- How to create and manage governance domains.

Create and manage governance domains

Ownership of data is an important aspect of data governance. However, today IT infrastructure maintains and supports data without always having the full context for how data can and should be used in an organization. The use of governance domains brings users and data together with a data-use driven structure. This article covers how to create and manage governance domains in Microsoft Purview Unified Catalog.

Prerequisites

- To create a governance domain, you must have the governance domain creator role.
- To assign data stewards or data product owners, you must have governance domain owner permissions.
- To curate data, such as adding glossary terms or objectives and key results (OKRs) to a governance domain, you must have Data Steward permissions.
- To add data products to a governance domain, you must have Data Product Owner permissions.

Access governance domains

To see governance domains, you need the Global Catalog Reader role or the Local Catalog Reader role, which is a more restrictive role. For details about each role, see Catalog level permissions and Governance domain level permissions.

1. In the Microsoft Purview portal, open **Unified Catalog**.
2. Under **Catalog management**, select **Governance domains**. You see a list of all the governance domains in your organization. You can filter the governance domains by keyword.
3. Select a governance domain to see its details, roles, aggregate data quality score, health actions, associated data products, glossary terms, OKRs, and critical data.

Details

The **Details** tab shows key information about the domain and displays all associated business concepts.

Custom attributes

Under **Custom attributes**, you can see any custom attribute groups and attributes within groups, and the values set for each attribute. Only attributes with values are shown by default, but you can toggle **Show attributes without a value** on to view all attributes.

Roles

The **Roles** tab displays the users in your organization (grouped by role) who are associated to the domain. For details, see edit roles for governance domains.

Data estate mappings

Use the **Data estate mappings** tab to map your domain to a specific Data Map collection. For more information, see setting up data estate mappings.

Data observability (preview)

The **Observability** (preview) tab provides a detailed view of data health and lineage. This view requires a brief setup process. For more information, see the observability view for governance domains.

Monitoring

Select **Monitoring** on the **Details** page of a governance domain to view the status of bulk import jobs. The **Monitoring** page displays the status of bulk imports of glossary terms, data products, and critical data elements. The page will also list any upload errors and how to fix them.

Edit roles

To edit the users, groups, or service principals assigned to a role:

1. Go to the governance domain where you want to edit the roles.
2. On the **Roles** tab, select the + button next to the role name where you want to add the user.
3. Search for users, groups, or service principals to add to the role and select them.
4. To remove users from the list, select the **X** next to their name.
5. When you're done, select **Save**.

For more information, see roles assigned at the governance domain level.

View your business concepts

Your governance domain has many business concepts associated with it: data products, glossary terms, OKRs, and critical data.

You can find and view each of these concepts in your governance domain in the **Business concepts** area on the governance domain's **Details** tab. Select the card for each concept to view its details.

To add any of these concepts to your governance domain, see:

- Add data products.
- Add glossary terms.
- Add OKRs.
- Add critical data.

Filter your view by custom attribute

You can use business concept attributes as a filter when exploring business concepts in a governance domain.

1. On a governance domain details page, select **View all** on a business concept card.
2. Select **Add filter**.
3. At **Filter**, select an attribute name from the dropdown list.
4. At **Operator**, select a condition, such as **Equals** or **Starts with**, which varies based on the kinds of values allowed by the attribute.
5. At **Value**, enter your value.
6. Select **Apply**.

Create governance domains

> **Note**
>
> To create a governance domain, you need the governance domain creator role.

1. In Unified Catalog, select **Catalog management**, then select **Governance domains**.
2. Select **New Governance domain**.
3. On the **Basic details** page, enter a unique name for your governance domain and a description.

4. Select the governance domain **Type**: Functional unit, line of business, data domain, regulatory, or project. **Type** is an extra descriptor to indicate your governance domain's purpose. There aren't any behavioral differences between types.
5. Select an existing domain as a parent domain (optional). Parent/child relationships appear in a tree-like hierarchy.

   > **Note**
   >
   > Governance domain hierarchies in Unified Catalog can support as many as 200 domains, including a maximum of five levels of depth.

6. Select **Next**.
7. On the **Custom attributes** page, you can set values for all custom attributes defined by your admin in the **Custom attributes** section of the catalog. If the attribute is marked as required, you need to fill out all values on this page before you can complete the process.
8. Select **Create**.

You see your governance domain in the list of domains. Other users can't see this governance domain until you set its status to **Published**. You must also publish your domain before you can publish business concepts, like glossary terms or data products, within it.

> **Tip**
>
> Find guidance on what governance domains to create in your organization.

Manage governance domains

> **Note**
>
> To edit a governance domain, you need the governance domain owner role.

1. On the governance domain's details page, select **Edit**.
2. You can edit the domain's name, description, owner, and status.
3. When you're done, select **Save**.

To add data products to a governance domain, see Create and manage data products.

> **Note**

If a governance domain becomes uneditable because the owner leaves the organization, Data Governance admins can add new governance domain owners in the **Roles** tab.

Configure data estate mappings

You can map your governance domains to collections in your Data Map to direct your data stewards and data product owners to build business concepts from data assets belonging to specific collections. This mapping is meant to be recommended guidance, as these Data Governance roles require Data Map permissions to access the data assets.

To map your governance domain to a specific Data Map collection:

1. Go to the **Data estate mappings** tab in a governance domain.
2. Use the **Select a mapping** dropdown menu to select the collection you want to associate your governance domain with.

   > ⓘ **Note**
   >
   > You can only see the collections that you have access to in Data Map.

3. Select **Save**.

Delete governance domains

To delete a governance domain, unpublish it and delete all business concepts within it, including any subdomains. Then select the **Delete** button to delete the governance domain.

Manage domain policies

To manage domain policies, you need data owner or data steward permissions.

1. On your governance domain's page, select **Configure access**.
2. From the policy configuration window, you can create and manage your access policies. For more information, see how to manage access policies.

Access classic experiences in the governance domain

You can access classic glossaries, business assets, or managed attributes by going to **Catalog management**, then selecting **Classic types**.

Select a tab to access your classic experiences: **Glossaries**, **Business assets**, **Asset types**, or **Managed attributes**.

Data products in Unified Catalog

10/06/2025

A data product is a group of data assets, such as tables, files, and Power BI reports, with a defined use case that you can share with other users.

In Microsoft Purview, data governance isn't only a way to make sure your data is secure and compliant, but it's also a tool to accelerate your data's business value. Cataloging data in your estate makes it possible to better manage data for right use, but it also provides a complete picture of your data landscape. Now that there's a list of every available data asset, users no longer have to rely on networking or team knowledge to find what they need; they can search the catalog themselves. But giving every user a raw list of all available data is overwhelming and not inherently useful. Even with good descriptions, tagging, and glossary terms, it can be hard to know what you're looking for. And for a complete data visualization you probably need several data assets, and not just one. As Microsoft Purview Unified Catalog grows, context needs to grow alongside it to make it easier for your users to find and request access to the data they need.

To provide scalable data context and access management, Microsoft Purview is introducing the data product.

What's a data product?

A data product is a business concept with a name, description, owners, and most importantly a list of associated data assets. The data product provides context for these assets, grouping them under a use case for data consumers. A governance domain can house many data products but a data product is managed by a single governance domain and can be discovered across many domains.

A successful data product makes it easy for data consumers to recognize valuable data using their day-to-day language, and at the same time streamlines ownership responsibilities for those data assets. Let's explore what that looks like.

Scalable data context

As an example, a data scientist creates a set of data assets for their data model to consume and they want others to be able to use the same dataset.

Without data products, the data scientist can use Unified Catalog to add a glossary term to all the relevant data assets. A user might not know which glossary term to search, so it might be best to add a description to each data asset to make it more relevant in searches for similar

information. But both additions don't guarantee that other users see all the associated data assets. They might group in other assets that aren't as relevant, or miss a critical data piece, and spend time repeating research the original data scientist already performed.

With a data product, a data scientist can create a data product that lists all the assets used to create their data model. The description provides a full use case, with examples or suggestions on how to use the data. The data scientist is now a data product owner and they've improved their data consumer's search experience by helping them get everything they need in this one data product.

Scalable data governance

Data products streamline governance for data assets. Using the same example of a data scientist who creates a set of data assets:

Without data products, if a user wants access to the data assets for the data set, they must request access to each data asset individually. A data owner might know that these assets are used for machine learning models, but if they make any changes to policies around their security and use cases, they must update each asset individually.

With data products, a user finds the data product and requests access to the data product. After approval, they get access to all the associated data assets. If a data owner puts more approval or data use policies in place around datasets for machine learning, they only need to apply the new policies to the data product. The policies automatically trickle down to the assets.

Data products are also associated with business health controls and OKRs. These controls allow data owners to assess data health and prioritize assets that need attention. They also help assess which data assets provide business value. This support not only helps progress towards complete data governance in your estate but also encourages developing business value from your data. Assets are no longer abstract but tied to real use cases and business objectives that your team can focus on.

Data access policies

Data security and access is the core tenant of successful data governance. But to implement data governance and successfully drive data use (and therefore value), the data access process needs to be secure, convenient, and customizable to all scenarios across your data estate. Some data should be widely useable and accessible, and some needs to be under rigorous approval and monitoring to ensure right use.

Each data product has an access policy that determines how users request access, the terms of use for the data, and who should approve access to the data. Each of these access policies is customizable for appropriate use and will evolve to cover more use cases in the future. All users need to do is select **Request Access** inside a data product. They automatically go through the process to agree to terms of use and get approval from correct parties.

For more information about access for data products, see the article on managing Unified Catalog access policies in Microsoft Purview.

Next steps

- Create and manage data products
- Set up access to data products
- Request access to a data product

Create and manage data products

A data product in Microsoft Purview Unified Catalog is a set of information with a defined use case that you share with other users. For example, a data product can be a sales report, an ML model, or a data model and its associated tables. A data product is a logical grouping of related physical assets that you create for a specific purpose.

It can be hard to find the value of data presented by itself, but data already associated with a purpose is easier to find and use. Data products in Unified Catalog provide practical context for your users and for intelligence systems, to help users identify what data is useful to them.

To create data products for your organization and ensure those products have enough definition to be useful to your user base, follow these instructions.

Prerequisites

- To view data products, users need catalog reader permissions.
- To manage or edit data products, users need data product owner permissions.

View data products

1. In the Microsoft Purview portal, open **Unified Catalog**.
2. Under **Catalog management**, select **Data product**. You see a list of all the data products you have access to based on your permissions. You can scroll, sort, filter, and search through these data products to find the ones you're looking for.
3. Select a **Data product name** from the list to view more details on the data project's details page.

Filter your view by custom attribute

You can use business concept attributes as a filter when exploring data products.

1. Under **Catalog management**, select **Data products**.
2. Select **Add filter**.
3. At **Filter**, select an attribute name from the dropdown list.
4. At **Operator**, select a condition, such as **Equals** or **Starts with**, which varies based on the kinds of values allowed by the attribute.
5. At **Value**, enter your value.

6. Select **Apply**.

Details

The **Details** tab on the data product detail page provides a description and use cases. Here you find the governance domain, update frequency, status, owner, subscribers, terms of use, aggregate data quality score, health actions, and documentation.

1. You see a list of all the data products you have access to based on your permissions.
2. You can scroll, sort, filter, and search through these data products to find the ones you're looking for.
3. For more details about a specific data product, select that data product.
4. On the data product's detail page, you can view the governance domain, update frequency, status, owner, subscribers, terms of use, aggregate data quality score, health actions, and documentation.

Custom attributes

Under **Custom attributes**, you can see any custom attribute groups and attributes within groups, and the values set for each attribute. Only attributes with values are shown by default, but you can toggle **Show attributes without a value** on to view all attributes.

Data observability

The **Data observability** (preview) tab provides a more detailed view into data health and lineage. This view requires a brief setup process. Get details about the observability view for governance domains.

Create data products

> **Note**
>
> To create, edit, and manage data products, users need the Data Product Owner role. You can only create data products in governance domains where you have data product owner access.

There are two ways you can create data products:

1. Individually, by creating one term at a time.

2. In bulk, by importing a formatted CSV file (preview).

Create a single data product

1. In Unified Catalog, select **Catalog management**, select **Data products**, and then select **New data product**.

2. On **Basic details**, enter a **Name** and **Description**. If you use a name that already exists, you'll see a warning during the creation process. While duplicating names isn't recommended, you won't be blocked from using a duplicate name. The description should be a business narrative about the data, where it came from, and why you captured it. The goal is for a new user to understand the basics of when, what, why, and how the data came into existence. Provide clarity about the meaning of the specific data to the business. The description is limited to 10,000 characters.

3. Select a **Type** from the dropdown menu. Get details about data product types.

4. Make an optional selection from the **Audience** dropdown list.

5. Enter the **Owner** and any other owners for the data product.

6. Select **Next**.

7. On **Business details**, select the governance domain your data product should be associated with.

8. Enter a **Use case**. The use case describes what the data is used for today and how a user can effectively apply it to their own scenario. Add information about what filters or dimensions are available, which asset contains the view that's easiest to parse, or any other details that can accelerate the usage of the data. If the data is only appropriate for specific purposes, include these details so users don't request access for data that they won't be approved for or won't help them to achieve their goals.

9. If you decide to mark the data product as **Endorsed**, select the **Mark as Endorsed** box. Learn more about endorsing a data product.

10. Select **Next**.

11. On the **Custom attributes** page, you can set values for all custom attributes defined by your admin in the **Custom attributes** section of the catalog. If the attribute is marked as required, you need to fill out all values on this page before you can complete the process.

12. Select **Create**.

You arrive at the new data product's details page. This is where you can make other edits to the data product, which is currently in a **draft** state.

> **Important**
>
> Other users can't see the data product yet. To make it visible to other users, you need to add data assets, create an access policy, and then publish the data product.

Bulk import data products (preview)

You can create many data products at once and import them into a governance domain by uploading a formatted CSV file. During the bulk import process, you download a sample CSV file containing a header row. You fill out the file according to the instructions in this article, and then reupload it. The data products appear in the governance domain in a draft state.

You can't use the bulk import process to edit or update data products.

> **Note**
>
> - You must download the sample CSV (.csv) file and reupload it according to the following instructions. The file must have at least one row of data, not including the header row.
> - The CSV file can only include 1,000 rows. More rows cause an upload error. If you need to import more data products, fill out and upload a separate CSV file.
> - Special characters are allowed in all fields.
> - Each data product name must be unique. Duplicate names aren't supported for import.

To import data products in bulk to a governance domain, follow these steps:

1. In Unified Catalog, select **Catalog management**, then select **Governance domains**.
2. Select the name of the governance domain where you want to add data products.
3. On the **Details** tab of the governance domain's details page, find the **Data products** card and select **View all**.
4. On the **Data products** page, select **Import**.

5. On the **Import** flyout pane, select **Download a sample CSV file**.

6. Open the downloaded file. Fill out the worksheet as described in this article to avoid upload errors.

    - **Column A - name** (required): Enter the data product name. Every name must be unique; you can't have multiple rows with the same name. Maximum length is 256 characters.

    - **Column B - owners** (required): Enter a valid email address that belongs to the same tenant that you're importing from. You can add multiple email addresses separated by a semicolon. For example: `owner1@contoso.com;owner2@econtoso.com`. Groups without email aren't supported.

    - **Column C - type** (required): Enter a data product type; see list of types.

    - **Column D - audience**: Enter one of these allowed values to describe the intended audience for the data product:
        - BI engineer
        - Business analyst
        - Business user
        - Data analyst
        - Data engineer
        - Data scientist
        - Executive
        - Software engineer

    - **Column E - endorsed**: Enter **True** or **False**. Endorsed is a signal of confidence to data consumers that the data product meets the organization's quality and governance expectations. It shows as a label on the data product for data consumers.

    - **Column F - description** (required): Enter a description for the data product. Maximum length is 500,000 characters.

    - **Column G - business use** (required): This entry shows in the **Use case** area of the data product. Enter a description of what the data is used for today and how a user can effectively apply it to their own scenario.

    - **Column H and onward**: These columns are for custom attributes, which differ by governance domain based on how they're defined and scoped. Note these formatting requirements for specific entry types:

    - **Multiselect options**: Enter the objects inside square brackets and in quotes. For example, `["a"]`, or `["a", "b"]`.
    - **Single select options**: Enter the raw value. For example, `a1`, `b2`.
    - **Booleans**: Enter `true` or `false`. You can use upper or lowercase.
    - **String or rich text**: Use regular text; don't add quotes unless you want quotes reflected in the attribute.
    - **Numeric - short, int, long, double, float, bit, byte**: Don't add quotes. Just enter the number.

7. After formatting your CSV file, save it locally. Return to the **Import** flyout pane, select **Browse**, and then find and select your CSV file to upload it.

8. On the **Import** flyout pane, select **OK** to start the import process.

If there's a problem with the CSV file, an error message appears on the **Import** pane explaining the error so you can fix the CSV file and reupload it.

If there are no problems with the file, the import process begins. Depending on the size of the CSV file, it might take some time to complete the import process. If the file is small, the import happens immediately and you see a success message. Larger files take longer for the import process to complete.

Check the status by returning to the governance domain details page. On the **Details** tab, select **Monitoring** to view the status of your bulk import jobs, including any errors, on the **Monitoring** page.

Data product types

When you create a data product, you can optionally identify it as one of the following types. These types help identify the kinds of users that might want to use the data product, and you can use them to filter data products in a search.

- **Analytics model**: Data that's transformed from raw data to help build analytics from, and might be distinct fact and dimension tables.

- **Business system/Application**: A common set of consumable tables from a specific source, or available in a certain application that you consume together.

- **Dashboards/Reports**: Data visualizations that you use to make decisions and view common metrics. They might or might not include the data used to power the visualization.

- **Dataset**: An individual asset or group of assets used as a common data product type to make data discoverable for specific use cases.
- **Master and reference data**: Highly reusable data that you should consistently reference and highly control due to its common use and greater importance to the health of the data estate.
- **ML training data**: Data approved for use as training a new model. It's typically not production data and is desensitized to prevent potential risks.
- **ML testing data**: Data built to specifically test ML models for edge cases, fairness, and potential harms.
- **Model types**: Typically used for AI models and analytical or semantic models used with AI.
- **Operational**: A data product that you use for data quality, or to operate a portion of the data estate but not planned for high consumption or governance. It could be an investigatory data product of transitory data assets or data used to run a process, but isn't modeled or consolidated for analytical purposes.
- **Semantic model**: A group of related data tables and their relationships and meanings for interpretation and reuse.
- **Transactional data**: Data from an originating source that might have limited use cases, but is required for engineering scenarios or system-to-system integrations. It's not typically used for most business data consumption, but it could be important for governance and control scenarios.

Managing data products

Data product owners can view and modify the properties of a data product by following these steps:

1. In Unified Catalog, select **Catalog management**, and then select **Data products**.
2. Select the data product to open its details page.
3. Select **Edit**.

From the data product page, you can:

- Edit details about the data product.
- Update frequency.
- Change the data product's status.

- Manage data product access policies.
- Add or remove associated data assets.
- Remove data assets that are deleted from Data Map (preview).
- Manage associated terms or OKRs.
- Manage terms of use.
- Manage associated documentation.
- Endorse a data product.
- Edit values for custom attributes.

Edit data product

To edit a data product, you need data product owner permissions. You can only edit a data product when it's in **Draft** status.

1. On your data product page, select the **Edit** button.
2. On the **Basic details** page, update the name, description, type, and owners. If you change the name to one that already exists, you'll see a warning about the duplication but you can proceed to use the duplicate name.
3. Select **Save**.
4. On the **Business details** page, update use cases and endorsement status.
5. Select **Save**.
6. On the **Custom attributes** page, you can set values for all custom attributes defined by your admin in the **Custom attributes** section of the catalog. If the attribute is marked as required, you need to fill out all values on this page before you can complete the process.
7. To save your changes, select **Save**.

Update contacts

When you add owners to data products during the creation or editing process, the owners automatically appear in the **Contacts** section. You can customize the label by selecting the pencil icon in each contact card.

Update frequency

Use the update frequency to show how regularly you manage a data product. This indicator isn't currently automated.

1. To edit the update frequency, select the **Update frequency** attribute on the right side of the page.

2. Select the update frequency you expect for your data product.
3. Select **Done**.

Publish, draft, and expire

To publish a drafted data product, select **Publish** on the data product's details page. Before you can publish, you need to add data assets to your data product and set up a data access policy so users can request access to your data product.

> ⓘ **Note**
>
> Ensure your governance domain is published before you publish your data products.

After completing the requirements, you can publish your data product, which makes the data product available for users in Unified Catalog.

You can also set a previously published data product to a draft by **unpublishing** it:

1. Select the **Unpublish** button in the data product.
2. Select **Set to draft** which allows only stewards, governance domain owners, and data product owners to view and manage it.

You can also set your data product to **Expired**:

1. Select the **Unpublish** button in the data product.
2. Select **Set to expired** which makes it visible only to stewards, governance domain owners, and data product owners.

Manage data product access policies

To manage access policies, you need data product owner or data steward permissions.

1. If your data product is published, first unpublish it to manage policies.

2. On your data product page, select **Manage policies**.

3. From the policy configuration window, you can create and manage your data product's access policy. Learn how to set up data product access policies.

Add and remove data assets

A data product groups together data assets. Grouping assets in this way makes it easier to discover them. To add or remove data assets from a data product, see the following sections.

Add data assets

> **Note**
>
> When you add data assets, the search only shows assets that the governance domain is scoped for, or that the user has access to in Microsoft Purview Data Map.

To add data assets to a data product:

1. In Unified Catalog, select **Catalog management**, and then select **Data products**.
2. Select the data product you want to add assets to.
3. Select **Add data assets** under the description and use cases.
4. Search for your data assets by using keywords or filters. To add filters, select **Add filter**.
5. Select any assets you want to add to the data product.
6. Select **Selected assets** to edit your selected asset list.
7. When you're done selecting assets, select **Add**.

You see your newly added assets in your data product.

Remove data assets

> **Tip**
>
> Collaborate with your data quality team to perform necessary cleanup work, as described in the following section, before removing data assets and deleting data products.

Before you can remove a data asset from a data product, you must remove all data quality rules and previous data quality scans from the asset. For more information, see deleting data quality history.

Although data quality stewards might not be involved in creating data products, they're the subject matter experts in data quality rules and scans. Only users holding the Data Quality

Steward role can remove data quality rules and scans, so data product owners should work with data quality stewards to get rules and scans removed before the asset in question can be removed from the data product.

Follow these steps to remove a data asset:

1. In Unified Catalog, select **Catalog management**, and then select **Data products**.
2. Select the data product you want to remove assets from.
3. If the assets you want to remove are on the front page, select the ellipsis (...) on the data asset's card, and then select **Remove**.
4. If you don't see the assets on the main product page, select **View all data assets**. There you can search and filter the assets. To remove them, select their ellipsis button and select **Remove**.

   > **Note**
   >
   > The remove action is unavailable if the data asset has data quality rules running on it or failed data quality run history. You need the Data Quality Steward role to resolve these issues before the asset can be removed.

Remove assets that are deleted from Data Map and metadata sync from Data Map (preview)

If you delete a data asset in a data product in Data Map, a banner appears in the data product to inform you of the asset deletion. However, the asset still appears in the data product until you remove it.

Open the data product and select **View all data assets** to view the list of assets. Assets with a caution symbol on its row are deleted from Data Map. To remove the deleted asset from your data product, select ellipsis (...) in the row, and then select **Remove**.

When you open the asset detail page from assets in a data product, the metadata is retrieved from the Data map. Metadata changes in Data Map are now reflected in Unified Catalog after they're updated in Data Map or initiated by selecting the refresh button.

For metadata represented within parent assets, such as columns within tables and views, the changes may not appear immediately. However, in all cases, metadata changes are reflected in

Unified Catalog within 24 hours.

Manage linked resources

Link glossary terms and OKRs directly to your data products to improve understanding, apply policies, and associate your data products with your business goals.

When you map assets in your data product to critical data elements, the system automatically adds critical data elements.

Add linked resources

1. On the data products page, select the data product you want to add terms or OKRs to.
2. Under **Glossary terms** or **OKRs**, select the + button next to the listing of those items.
3. Search for your terms or OKRs by using keywords, governance domain, or filters by selecting **Filter**.
4. Select any terms or OKRs you want to add to the data product.
5. Select the **Add** button.
6. You can now see the term or OKR in the list for your data products.

Remove linked resources

1. On the data products page, select the data product you want to remove terms or OKRs from.
2. Under **Glossary terms** or **OKRs**, find the item you want to remove, and select its ellipsis button.
3. Select **Remove**.

> **Note**
>
> The system automatically adds critical data elements based on the assets in your data product. For more information, see managing critical data elements.

Terms of use

1. On the data products page, select the data product you want to manage terms of use for.
2. Select the **Terms of use** attribute, on the right side of the page.
3. To add more terms of use:
   a. Select + **Add link**.

b. Choose a particular data asset to link the use to (optional).
c. Enter a friendly name for the terms.
d. Enter the link to the terms of use.
e. Select **Create**.
f. Select **Done**.

4. To remove any terms of use:
   a. Hover over the term you want to remove.
   b. Select the trashcan **remove** button.
5. When you're finished, select **Done**.

Documentation

1. On the data products page, select the data product you want to manage documentation for.
2. Select the **Documentation** attribute on the right side of the page.
3. To add documentation:
   a. Select **Add link**.
   b. Choose a particular data asset to link the documentation to (optional).
   c. Enter a friendly name for the documentation.
   d. Enter the link to the documentation.
   e. Select **Create**.
   f. Select **Done**.
4. To remove documentation:
   a. Hover over the documentation you want to remove.
   b. Select the trashcan **Remove** button.
5. When you're finished, select **Done**.

Endorse a data product

As a Unified Catalog grows in size, it's important for data consumers to understand what data they can trust. Data consumers need to know if a data product meets their organization's quality standards and can be regarded as reliable.

Data product owners can now set the **Endorsed** flag for their data products to indicate that they certified their data products, and build confidence in the quality of their data product.

To endorse a data product, you need data product owner permissions.

1. On your data product page, select **Edit**.

2. Select **Details**.
3. Select the **Mark as 'Endorsed'** checkbox.
4. Select **Save**.

Delete data products

Plan carefully before deleting a data product, as the process requires several steps.

1. First, unpublish the data product.
   a. Also, remove links to all related business concepts and remove any data assets within the data product.
   b. If any assets have data quality rules running on them or failed data quality run history, delete the data quality history.

2. Then, inform subscribers of the data product about the upcoming deletion and delete their access request to the data product.

3. When you complete all tasks, select **Delete** on the data product's page to delete the data product.

Next steps

- Set up access to data products
- Request access to a data product
- Learn about glossary terms

Critical data elements (preview)

Not all data elements have the same importance or sensitivity. Dedicating resources to manage the quality of all data indiscriminately can be impractical and costly. Critical data elements are a logical grouping of important columns across tables in your data sources that you can use to focus your efforts.

These columns should be critical pieces of information that are necessary for decision making and so need to be governed with the highest care. For example, a "Customer ID" critical data element can map "CustID" from one table and "CID" from another table into the same logical container. Users can match this value across data assets to make connections, and when data producers create a new asset, they can use this element as a blueprint to provide quality information in the correct format.

Critical data elements (preview) in Microsoft Purview Unified Catalog are created within governance domains and can have policies set to manage these important pieces of information. When you create a critical data element, your organization can allocate resources strategically, focusing governance effort on areas that have the most significant effect on the business.

Prerequisites

- You must be using Microsoft Purview Unified Catalog.
- To create critical data elements and add columns to them, you must have data steward and data product owner permissions. For more information, see governance roles and permissions.
- To access data assets in the data map, you need at least data reader permissions on the collection where the asset is housed. For more information about data map permissions, see Data Map permissions.

Access critical data

Critical data is defined in governance domains. To see critical data in Unified Catalog:

1. In Unified Catalog, select **Catalog management**, then select **Governance domains**. You see a list of all the governance domains you have access to based on your permissions.
2. Select the governance domain where you want to see your critical data.
3. On the **Details** tab, find the **Critical data elements** card and select **View all**.

4. The **Critical data elements (preview)** page lists all of your critical data elements. Select a name to view its details.

You can also view a list of all critical data elements:

1. In Unified Catalog, under **Discovery**, select **Enterprise glossary**.
2. Select the **Critical data elements** tab.
3. Select the name of a critical data element to open its details page.

Filter your view by custom attribute

Use business concept attributes as a filter when exploring critical data elements.

1. On the **Critical data elements (preview)** page, select **Add filter**.
2. At **Filter**, select an attribute name from the dropdown list.
3. At **Operator**, select a condition, such as **Equals** or **Starts with**, which varies based on the kinds of values allowed by the attribute.
4. At **Value**, enter your value.
5. Select **Apply**.

Critical data element details

Select the name of a critical data element to view its details page. You can create and manage access policies for the critical data element by selecting **Manage policies**.

Overview

On the **Overview** tab, you see a description and:

- **Columns**: All data columns mapped from your assets to this critical data element. You can add columns.
- **Associated data products**: An automatically generated list of data products that have assets associated with your critical data element.

> **Note**
>
> The list of associated data products only refreshes when you add or remove columns.

Custom attributes

Under **Custom attributes**, you can see any custom attribute groups and attributes within groups, and the values set for each attribute. Only attributes with values are shown by default, but you can toggle **Show attributes without a value** on to view all attributes.

Create critical data

> ⓘ Note
>
> To create and upload critical data elements, you need the Data Steward role.

There are two ways you can create critical data elements:

1. Individually
2. In bulk, by importing a formatted CSV file (preview)

Create a single critical data element

1. In Unified Catalog, select **Catalog management**, then select **Governance domains**.
2. You see a list of all the governance domains you have access to based on your permissions. Select the governance domain where you want to add critical data.
3. On the **Details** tab, find the **Critical data elements** card and select **View all**.
4. Select **New critical data element**.
5. On the **Basic details** page, enter a name for your critical data. If you use a name that already exists, you'll see a warning during the creation process. While duplicating names isn't recommended, you won't be blocked from using a duplicate name.
6. Add a description, owner, and select an expected data type. Then select **Next**.
7. On the **Custom attributes** page, you can set values for all custom attributes defined by your admin in the **Custom attributes** section of the catalog. If the attribute is marked as required, you need to fill out all values on this page before you can complete the process.
8. When done, select **Create**.

You see your critical data in the list of critical data elements.

> ⓘ Note
>
> - Ensure your governance domain is published before you publish your critical data element.

- Other users can't see this critical data as a filter in the data product search until its status is set to **Published**.

Bulk import critical data elements (preview)

You can import multiple critical data elements at once into a governance domain by uploading a formatted CSV file. During the bulk import process, you download a sample CSV file containing a header row. You fill out the file according to the instructions below, then reupload it. The critical data elements then appear in the governance domain in a draft state.

The bulk import process can't be used to edit or update critical data elements.

> ⓘ **Note**
>
> - You must download the sample CSV (.csv) file and reupload it according to the following instructions. The file must have at least one row of data, not including the header row.
> - The CSV file can only include 1,000 rows; more rows cause an upload error. If you need to import more critical data elements, fill out and upload a separate CSV file.
> - Special characters are allowed in all fields.
> - Each critical data element name must be unique; duplicate names aren't supported for import.

Follow these steps to import critical data elements in bulk to a governance domain:

1. In Unified Catalog, select **Catalog management**, then select **Governance domains**.
2. Select the name of the governance domain you want to add critical data elements to.
3. On the **Details** tab of the governance domain's details page, find the **Critical data elements (preview)** card and select **View all**.
4. On the **Critical data elements (preview)** page, select **Import**.
5. On the **Import** flyout pane, select **Download a sample CSV file**.
6. Open the downloaded file. Fill out the worksheet as described below to avoid upload errors.
    - **Column A - name** (required): Enter the critical data element name. Every name must be unique; there can't be multiple rows with the same name. Maximum length is 256

characters.

- **Column B - description** (required): Enter a description for the critical data element. Maximum length is 10,000 characters.
- **Column C - owners** (required): Enter a valid email address that belongs to the same tenant that you're importing from. You can add multiple email addresses separated with a semicolon; for example: `owner1@contoso.com;owner2@econtoso.com`. Groups without email aren't supported.
- **Column D - data type** (required): Enter one of the possible values: number, text, date/time, Boolean.

7. **Column E and onward**: These are custom attributes, which differ by governance domain based on how they're defined and scoped. Note these formatting requirements for specific entry types: - **Multiselect options**: Enter the objects inside square brackets and in quotes; for example, `["a"]`, or `["a", "b"]`. - **Single select options**: Enter the raw value; for example, `a1`, `b2`. - **Booleans**: Enter `true` or `false`; can be upper or lowercase. - **String or rich text**: Use regular text; don't add quotes unless you want quotes reflected in the attribute. - **Numeric - short, int, long, double, float, bit, byte**: Don't add quotes, just enter the number.

8. After formatting your CSV file, save it locally. Return to the **Import** flyout pane, select **Browse**, then find and select your CSV file to upload it.

9. On the **Import** flyout pane, select **OK** to start the import process.

If there's a problem with the CSV file, an error message appears on the **Import** pane explaining the error so you can fix the CSV file and reupload it.

If there are no problems with the file, the import process begins. Depending on the size of the CSV file, it might take some time to complete the import process. If the file is small, the import happens immediately and you see a success message. Larger files take longer for the import process to complete.

Check the status by returning to the governance domain details page. On the **Details** tab, select **Monitoring** to view the status of your bulk import jobs, including any errors, on the **Monitoring** page.

Add columns

After you create your critical data, you can add data columns to map critical columns from your assets to this logical concept.

1. Select your critical data element from the list of critical data elements in your governance domain.
2. Select the + **Add column** button.
3. Search for your data sources by using keywords and filters, and select a data source.
4. In that data source, select any relevant column.
5. Select **Add**.
6. You should now see all your columns mapped to your critical data element.
7. Repeat for any number of data sources and columns.

   Below the columns you add, you also see the list of data products that are associated with the assets you add to your critical data element.

Remove column

To remove a column from a critical data element, select the ellipsis **...** button in the row where the column is listed, and select **Remove**.

If you can't find the column you want to remove, select the **View all columns** button to see the full list of columns.

Update and edit critical data

> ⓘ **Note**
>
> To edit a critical data element, you need the data steward role.

1. On the critical data's details page, select **Edit**.
2. On the **Basic details** page, you can edit the name, description, owner, and expected data type. If you change the name to one that already exists, you'll see a warning about the duplication but you can proceed to use the duplicate name.
3. On the **Custom attributes** page, you can set values for all custom attributes defined by your admin in the **Custom attributes** section of the catalog. If the attribute is marked as required, you need to fill out all values on this page before you can complete the process.
4. Select **Save** to save your changes.

To update the status of your critical data element, select the **Status** button to change between: **Draft**, **Published**, and **Expired**.

Manage related terms

You can link your critical data elements to related glossary terms.

1. Select the governance domain where your critical data element resides.
2. Select the **Critical data elements** button.
3. Search or browse for the critical data element and select it.
4. To link your critical data element to a glossary term, select the **+ Add term** button.
5. Search for the term, or terms, you want to link and select them.
6. To add your selected terms, select **Add**.
7. To remove a related term, select the term, then select the **...** ellipsis button, and then the **Remove** button.

Delete critical data

To delete a critical data element, you need to unpublish it and delete all columns within it, and any links to glossary terms. You can then select the **Delete** button and proceed with deleting the critical data element.

Remove data that's deleted from Data Map (preview)

If the parent data asset of a column in a critical data element is deleted in Data Map, a banner appears in the critical data element to inform you of the asset deletion. However, the column still appears in the critical data element until you remove it.

Open the critical data element to view the list of columns. Columns with a caution symbol on its row have been deleted from Data Map due to their parent data asset deletion. To remove the deleted column from your critical data element, select ellipsis (...) in the row, then select **Remove**.

Manage access policies

To manage access policies for critical data, you need data steward permissions.

1. On your governance domain's page, select your critical data elements.

2. Select a critical data element.

3. Select **Manage policies**.
4. From the policy configuration window, you're able to create and manage access policies for your critical data elements.
5. For more information about setting up access policies, see the documentation about managing access policies.

   These policies apply to all associated data products in your critical data element.

Glossary terms in Unified Catalog

Glossary terms in Microsoft Purview Unified Catalog are active values that provide context. They also apply policies that determine how you manage, govern, and make your data discoverable for use.

If you already use Microsoft Purview, you're familiar with the business glossary in general. It provides a vocabulary for business users. It consists of business terms that can be related to each other and allows them to be categorized so that they can be understood in different contexts. This structure helps abstract the technical jargon associated with the data repositories and allows the business user to discover and work with data in the vocabulary that is more familiar to them. Microsoft Purview takes these terms a step further by allowing them to play an active role in data governance. Now data stewards can use terms to apply policies and scale data governance as their data estate grows.

> **Note**
>
> You can now bring classic glossary terms into Unified Catalog and link all of your terms to data assets and columns. Follow the instructions to migrate glossary terms from the classic data governance experience and enable the curation of data assets (preview).

What is a glossary term?

Terms are individual concepts that define the business, processes, and systems used in an organization. You can apply them across a data estate, relating to data assets and data products to provide business context to your users. A technically named SQL table becomes less mysterious once it's linked to your "Account" business term, since users can immediately see what aspect of the business it's related to.

Create glossary terms under governance domains to impart context specific to each part of your organization. Both sales and marketing might use the same term to mean different things, and your governance domains help your team differentiate between those meanings.

After you create glossary terms, you can link them to data products, data assets, columns, and critical data elements to provide context and to provide specific data governance based on business context. It's easy to understand how a term and its definition provide business context

to a data product or asset, but how do terms provide data governance? Terms are an active part of Microsoft Purview that provide data governance by now containing policies.

Policies in a business term apply specific business health goals, data governance requirements, and terms of use to any data product or asset that you apply the term to.

How does this scale data governance?

Glossary terms were previously static terms that you applied to define a concept. But now they can be activated as objects that attach to policies that determine how you manage, govern, and make your data discoverable for use. Terms for data access and data health controls can trickle down to data products. Today, data stewards apply policies on single data objects. That's not scalable. Now a data steward can create a single term and create its policies. They might not know where to apply that term, but any time they apply the term to a data product or asset, all the associated policies are automatically applied. Active terms allow your data estate to naturally scale, and maintain security and discoverability without overburdening your data stewards.

Next steps

- Create and manage glossary terms

Last updated on 04/24/2026

Create and manage glossary terms

Glossary terms in Microsoft Purview Unified Catalog provide a vocabulary for business users. These terms allow users to discover and work with data in the vocabulary that is more familiar to them, rather than using abstract technical jargon inherited from data sources.

Use business terms to define a shared vocabulary for your organization. By creating terms, identifying their synonyms, acronyms, related terms, and more, you can create a flexible controlled taxonomy organized in a hierarchical way. Glossaries of terms help bridge the communication gap between various departments in your company by providing consistent definitions for concepts, metrics, and other important elements across the organization.

This article describes how to manage glossary terms in Microsoft Purview. It explains how to create a glossary term in a governance domain, and how to link glossary terms to data products, data assets, columns, and critical data elements.

Prerequisites

- Any user can read published glossary terms.
- To create, edit, and manage glossary terms, you need the Data Steward role in the governance domain where the terms reside.
- To link glossary terms to data assets and columns, in addition to needing the Data Steward role, you also need the Data Reader role in the assets' collections.

Access glossary terms

1. In the Microsoft Purview portal, open **Unified Catalog**.
2. Under **Catalog management**, select **Governance domains**.
3. Select the governance domain you want to see glossary terms for.
4. On the **Glossary terms** card, select **View all**.

You see a list of all the glossary terms for that governance domain. You can search or sort through these glossary terms, filter them, or change the view between a list, a compact list, or a tree.

> **Note**

There might be multiple pages of terms. Use the arrow buttons and the page selector to toggle between these pages.

You can also view a list of all glossary terms:

1. In Unified Catalog, under **Discovery**, select **Enterprise glossary**.
2. Select the **Glossary terms** tab.
3. Select the name of a glossary term to open its details page.

Filter your view by custom attribute

You can use business concept attributes as a filter when exploring glossary terms.

1. In Unified Catalog, go to **Discovery** > **Enterprise glossary**.
2. On the **Glossary terms** tab, select **Add filter**.
3. At **Filter**, select an attribute name from the dropdown list.
4. At **Operator**, select a condition, such as **Equals** or **Starts with**, which varies based on the kinds of values allowed by the attribute.
5. At **Value**, enter your value.
6. Select **Apply**.

Glossary term details

Select a term from the list to view its details page. To create and manage access policies for the critical data element, select **Manage policies**.

Overview

The **Overview** tab contains a description of the term.

Custom attributes

Under **Custom attributes**, you can see any custom attribute groups and attributes within groups, and the values set for each attribute. Only attributes with values are shown by default, but you can toggle **Show attributes without a value** on to view all attributes.

Related

The **Related** tab displays any related elements, such as acronyms, synonyms, and resources. It also shows you which data products, data assets, and columns the term is linked to.

Observability

If you set up data observability (preview), the **Data observability** tab is where you see its visualizations.

Create glossary terms

> **Note**
>
> To create and upload glossary terms, you need the Data Steward role.

There are two ways you can create glossary terms:

1. Individually, by creating one term at a time.
2. In bulk, by importing a formatted CSV file (preview).

Create a single glossary term

1. In Unified Catalog, select **Catalog management**, and then select **Governance domains**.
2. Select the name of the governance domain where you want to add a term.
3. On the **Details** tab for the domain, find the **Glossary terms** card and select **View all**.
4. Select **New term** to create a single new term.
5. On **Basic details**, enter a name and a definition for your term. If you use a name that already exists, you'll see a warning during the creation process. While duplicating names isn't recommended, you won't be blocked from using a duplicate name.. The description is limited to 10,000 characters.
6. Select an owner or several owners for the term.
7. For **Parent term**, select an existing term within the same domain as a parent term. Then select **Next**.

   > **Note**
   >
   > You can visualize parent and child relationships in a tree-like hierarchy within the terms list page by selecting **Tree** in the views drop-down.
8. On **Acronyms**, add any related acronyms or leave it blank, and then select **Next**.
9. On **Resources**, add any related resources, such as links to documentation or other sources that provide context for your term, or leave it blank. Then select **Next**.

10. On the **Custom attributes** page, you can set values for all custom attributes defined by your admin in the **Custom attributes** section of the catalog. If the attribute is marked as required, you need to fill out all values on this page before you can complete the process.
11. When done, select **Create**.

Your term is created in a draft state, where only stewards and domain owners can see it. To make it visible to all users, you need to publish the term.

You arrive at the details page for your new glossary term, where you can edit or manage your term, publish your term, or link the term to data products, data assets, columns, and critical data elements.

Bulk import glossary terms (preview)

You can create many glossary terms at once and import them into a governance domain by uploading a formatted CSV file. During the bulk import process, you download a sample CSV file containing a header row. You fill out the file according to the instructions below, then reupload it. The terms then appear in the governance domain in a draft state.

The bulk import process can't be used to edit or update glossary terms.

> **Note**
>
> - You must download the sample CSV (.csv) file and reupload it according to the following instructions. The file must have at least one row of data, not including the header row.
> - The CSV file can only include 1,000 rows; more rows cause an upload error. If you need to import more terms, fill out and upload a separate CSV file.
> - Special characters are allowed in all fields.
> - Each term name must be unique; duplicate names aren't supported for import.

Follow these steps to import glossary terms in bulk to a governance domain:

1. In Unified Catalog, select **Catalog management**, then select **Governance domains**.
2. Select the name of the governance domain you want to add glossary terms to.
3. On the **Details** tab of the governance domain's details page, find the **Glossary terms** card and select **View all**.

4. On the **Glossary terms** page, select **Import**.

5. On the **Import terms** flyout pane, select **Download a sample CSV file**.

6. Open the downloaded file. Fill out the worksheet as described below to avoid upload errors.

   - **Column A - name** (required): Enter the glossary term name. Every term name must be unique; there can't be multiple rows with the same name. Maximum length is 256 characters.

   - **Column B - description** (required): Enter a description for the term. Maximum length is 500,000 characters.

   - **Column C - owners** (required): Enter a valid email address that belongs to the same tenant that you're importing from. You can add multiple email addresses separated with a semicolon; for example: `owner1@contoso.com;owner2@econtoso.com`. Groups without email aren't supported.

   - **Column D - experts**: Enter the email address of one or more users who are considered experts of the term.

   - **Column E - acronyms**: Enter any common abbreviations or shortened versions of the term.

   - **Column F - resources**: Enter related resources, such as links to documentation or other sources that provide context for the term. Resource links must be a valid URL in this format: `https://www.contoso.com`; both `http://` and `https://` are acceptable. List multiple resources by following this example: `resourcename1|value1;resourcename2|value2`.

   - **Column G and onward**: These are custom attributes, which differ by governance domain based on how they're defined and scoped. Note these formatting requirements for specific entry types:
     - **Multiselect options**: Enter the objects inside square brackets and in quotes; for example, `["a"]`, or `["a", "b"]`.
     - **Single select options**: Enter the raw value; for example, `a1`, `b2`.
     - **Booleans**: Enter `true` or `false`; can be upper or lowercase.
     - **String or rich text**: Use regular text; don't add quotes unless you want quotes reflected in the attribute.
     - **Numeric - short, int, long, double, float, bit, byte**: Don't add quotes, just enter the number.

7. After formatting your CSV file, save it locally. Return to the **Import terms** flyout pane, select **Browse**, then find and select your CSV file to upload it.

8. On the **Import terms** flyout pane, select **OK** to start the import process.

If there's a problem with the CSV file, an error message appears on the **Import terms** pane explaining the error so you can fix the CSV file and reupload it.

If there are no problems with the file, the import process begins. Depending on the size of the CSV file, it might take some time to complete the import process. If the file is small, the import happens immediately and you see a success message. Larger files take longer for the import process to complete.

Check the status by returning to the governance domain details page. On the **Details** tab, select **Monitoring** to view the status of your bulk import jobs, including any errors, on the **Monitoring** page.

Publish terms

When your term is ready to use in your governance domain, publish it by following these steps:

1. Select the domain where your term resides.
2. On the **Glossary terms** card, select **View all**.
3. Search or browse for the glossary term and select it.
4. On the glossary term's details page, select **Publish**.

> **Note**
>
> Ensure your governance domain is published before you publish your glossary terms.

Manage term policies

To manage term policies, you need data steward permissions.

1. On your glossary term page, select **Manage policies**.
2. From the policy configuration window, create and manage your term policies. For more information, see the documentation about managing access policies.

Link terms to data products, assets, and critical data elements (preview)

You can link glossary terms to data products, data assets, columns, and critical data elements to add business context to your data. Glossary terms must be in **Draft** state in order to add links; if the term is published, select **Unpublish** on the term's page to put it in **Draft** state.

> **Note**
>
> - When working with data assets and columns, *in addition to* needing the **Data Steward** role, you need the **Data Reader** role in the collection to which the asset or column belongs. All users with the **Catalog Reader** role can see published glossary terms associated to data assets and columns.
> - You need to enable asset curation before you can attach terms to assets and columns.

1. Select the governance domain where the term you want to link resides.
2. On the **Glossary terms** card, select **View all**.
3. Search or browse for the glossary term and select it.
4. Select **Related**.
5. Depending on what you want to link it to, select any of the following options: **Add data product**, **Add data assets**, **Add column**, **Add critical data element**.
6. In the flyout pane, search for and select the items you want to link to, then select **Add**.

> **Tip**
>
> Your search results might span multiple pages. Check the page selector to view all pages.

You can view all your linked data products, data assets, and columns from within your glossary term. The **Related** tab lists the first 10 linked items of each type. Select **View all** to see and search the entire list.

To remove a link, select the element on the **Related** tab of the glossary term, then select **...**, then **Remove**.

Manage links to terms from data products and data assets

There are two other pathways through which you can manage links to glossary terms:

- Within a data product: Data Stewards can add or remove links to published and unpublished glossary terms from a data product's details page.

- Within a data asset: Data Stewards can add or remove links to published and unpublished glossary terms residing in their governance domains. Users with the Global Asset Curator role can add published glossary terms to data assets.

Manage related terms

Add related glossary terms from across all your governance domains to connect similar terms.

1. Select the governance domain where your term resides.
2. On the **Glossary terms** card, select **View all**.
3. Search or browse for the glossary term and select it.
4. On the glossary term's details page, select the **Related** tab.
5. To add a term, select **Add term** and choose whether to add the term as a synonym or a related term.

   > ⓘ **Note**
   >
   > You can link terms from different governance domains.

6. To remove a related term, select the **X** next to the term.

Update contacts

When you add owners to glossary terms during the creation or editing process, you automatically add them to the **Contacts** section on the glossary term's details page. You can add experts to glossary terms as a contact type. To update contacts, edit the glossary term and at **Basic details**, enter a user name at **Owner** to add them as a contact.

Edit glossary terms

1. Select the governance domain where you want to edit one of the terms.
2. On the **Glossary terms** card, select **View all**.
3. Search or browse for the glossary term and select it.
4. If the term is published, select **Unpublish**, and then select **Edit** to edit the name, definition, owners, or custom attributes. If you change the name to one that already exists, you'll see a

warning about the duplication but you can proceed to use the duplicate name. When you're done, select **Save**.

5. To edit an owner's description, select the pencil icon on the card with the owner's name, edit the text, and then select the check mark to save.
6. To update status, select **...**, and then select the new desired status.
7. When done editing, publish the term.

Bulk edit glossary terms (preview)

Use the bulk edit process to edit up to 50 glossary terms at one time. You can edit **Attributes**, such as owners and descriptions, and **Term relationships** by adding and removing synonyms and related terms. All glossary terms must be in **Draft** state for bulk editing.

1. Select the governance domain where you want to bulk edit terms.
2. On the **Glossary terms** card, select **View all**.
3. On the **Glossary terms** page, select **Bulk edit.**
4. Check the boxes next to the name of the **Draft** terms you want to edit, and then select **Edit items**.
5. On the **Editing terms** flyout pane, select **Select a new attribute**.
6. From the **Attribute** dropdown menu, select the attribute you want to edit:
   a. Description (required)
   b. Acronyms
   c. Owner (required)
   d. Expert
   e. Resources
   f. Parent term
7. For **Operation**, select one of these options:
   a. **Replace with**: Replace the value of the existing attribute.
   b. **Add**: Add a value to the attribute. This option isn't available for required attributes or for parent terms.
   c. **Remove**: Delete the attribute. This option isn't available for required attributes.
8. For **Replace with** and **Add** operations, enter a value at **New value**.
9. To edit more attributes, select **Select a new attribute**.
10. Expand **Term relationships** if you want to edit synonyms or related terms.
    a. Under **Synonyms** or **Related terms**, select **Select terms for operation**.
    b. Select **Add** or **Remove**.
    c. On the **Search and select** pane, check the box next to the synonyms and related terms you want to add or remove, and then select **Select**.

11. When you finish making edits, select **Save**.

Your changes are applied to all the terms you selected to edit.

> **Tip**
>
> You can also select **Publish** and **Unpublish** to publish draft glossary terms or unpublish published glossary terms in bulk.

Move terms between governance domains (preview)

You can move multiple glossary terms at once from one governance domain to another domain. To move terms, you need to be a Data Steward in both the domain you're moving terms from, and in the domain you're moving the terms to. You can only move terms in a **Draft** state. If you select a parent term to move, the term's associated child terms move with it.

Use these steps to move glossary terms in bulk:

1. Select the governance domain that contains the terms you want to move out.
2. On the **Glossary terms** card, select **View all**.
3. On the **Glossary terms** page, select **Move to**.
4. Select the checkbox next to the **Draft** terms that you want to move, then select **Move items**.
5. In the **Move to** window, select the governance domain from the dropdown that you want to move the terms into.
6. Select **Move**.

The glossary terms appear in their new governance domain and are removed from their previous domain.

Expire glossary terms

When you expire a glossary term, only Data Stewards and Governance Domain Owners can see it.

1. Select the governance domain where you want to remove or retire a term.
2. On the **Glossary terms** card, select **View all**.
3. Search or browse for the glossary term and select it.
4. Select **...**, and then select **Set to Expired**.
5. Select **Save**.

Delete glossary terms

To delete a glossary term, first unpublish it and remove any links to related business concepts such as glossary terms, data products, data assets, columns, and critical data elements. Then select **Delete** to delete the term.

Accessing the classic business glossary

You can still access the classic business glossary by following these steps:

1. In the Microsoft Purview portal, open **Unified Catalog**.
2. Select the **Catalog management** drop-down.
3. Select **Classic types**.
4. Select the **Glossaries** tab.

Last updated on 05/20/2026

Migrate classic glossary terms and enable asset curation (preview)

Microsoft Purview Unified Catalog provides a centralized place for creating and managing glossary terms for both business concepts and data assets. If you created glossary terms for data assets and columns in the classic data governance glossary experience, you can start migrating them into the unified glossary experience in Unified Catalog.

This article explains the one-time migration process and the benefits of managing all your glossary terms for business concepts and data assets in one centralized place.

> **Note**
>
> The process outlined in this article enables you to curate data assets with glossary terms. Therefore, even if you don't plan to migrate classic terms, you still need to complete the workflow described in the steps below to enable asset curation.

Overview

You can bring classic glossary terms into the Unified Catalog for centralized creation and management of all glossary terms. This migration process is also what enables curation of data assets. After your terms are migrated to the **.StagingDomain** domain (a system domain automatically created for migration), you can move them into the governance domain that manages them going forward.

With the new unified glossary experience, any glossary term can apply to a business concept and data asset and column. The **Related** tab on each glossary term page shows its relationship to other glossary terms, data products, critical data elements, data assets, and columns.

When you migrate your glossary terms, you can:

- Use Unified Catalog as your single entry point for glossary terms within governance domains.
- Connect your terms to logical business concepts and physical concepts, or data assets (tables and columns).
- Invoke Copilots to enhance your glossary term creation and management experience.

Who needs to complete this process

This process is a required step in order to curate, or attach glossary terms to, data assets.

If your organization has glossary terms in the classic data governance experience, the migration process brings those terms into the updated experience, Unified Catalog.

If you're new to Unified Catalog in the Microsoft Purview portal, or never created glossary terms in the classic data governance experience, you still need to follow the steps of the enablement process by confirming use of current terms in Unified Catalog.

Plan for the migration and enablement process

> **Important**
>
> **Review this section closely and plan early.** The migration and enablement process is a one-time action that you can't reverse. When the process finishes, terms in the classic governance experience become read-only, and term templates convert to custom attributes that you can't edit or delete. Use this information to help you develop a thorough migration plan that involves the right people and ensures the most efficient outcomes for your organization.

What gets migrated and what doesn't

Glossaries and terms

The migration process moves glossaries and glossary terms that you created in the classic data governance experience. You can find these classic terms in the new Purview portal in **Unified Catalog**, under **Catalog management**, on the **Classic types** page.

When you migrate terms, this metadata is migrated into Unified Catalog:

- Glossaries and terms within, including all out-of-the-box metadata such as acronyms and parent information.
- All existing relationships to assets and columns in Microsoft Purview Data Map.

Term templates

The migration process moves all term templates when you migrate terms. During this process, term templates convert to business concept attributes. The attributes have the **.StagingDomain**

domain scope, which you can extend to more domains.

You can't edit or delete business concept attributes, so be sure to review term templates and delete unwanted ones before you migrate them.

Workflows

Any workflows you have on classic terms are **not** migrated.

Cleanup work to do before migration

- **Review and delete unwanted terms.** Delete any classic terms that you don't want to migrate *before* beginning the migration process, so that unwanted terms don't clutter the **.StagingDomain** domain. This step greatly facilitates and speeds up your process of relocating terms once they're brought over into Unified Catalog.
- **Review and delete unwanted term templates.** Term templates convert to business concept attributes after migration. These attributes can't be edited or deleted, so be sure not to migrate anything you don't want to appear or manage in Unified Catalog.

What happens during migration

The migration process creates a system-generated **.StagingDomain** governance domain and adds the migrated terms to it. Depending on the number of terms, it can take up to 48 hours for all migrated terms to appear in the staging domain. All glossary terms are added to the staging domain as drafts.

Only users who have both the Governance Domain Creator and Data Curator roles can see the **.StagingDomain** domain. You can't edit or publish this domain.

What happens after migration

When migration finishes, all terms are added to the **.StagingDomain** domain. The classic terms no longer appear on the **Classic types** page in Unified Catalog.

The **.StagingDomain** domain stays in your list of governance domains, even after you reassign the terms to the appropriate governance domains. You can't delete it.

The classic glossary experience becomes read-only, and you can't create any new terms there. Classic glossary terms don't appear when you search for them in data assets in Data Map.

Classic term APIs become read-only after migration finishes.

Plan who moves and manages the migrated terms

Identify a user in your organization to conduct the migration. This user needs both the **Governance Domain Creator** and **Data Curator** roles. This user also needs access to the **.StagingDomain** domain.

Identify the Data Stewards in your organization who move the terms into the correct governance domains. Add each of those Data Stewards as owners of the **.StagingDomain** domain.

Required user roles

Expand table

Role	Necessary for	Description
Governance Domain Creator and **Data Curator** (both are required)	Performing the migration and accessing the **.StagingDomain** domain.	Only users with this role can start the migration process. The user who starts the migration process becomes the owner of the **.StagingDomain** domain. Users with this role can access the **.StagingDomain** domain to view and move migrated terms.
Data Steward	Adding glossary terms to a governance domain.	Data Stewards must be assigned to the governance domain that they're moving migrated glossary terms into. Data Stewards must also be added to the **.StagingDomain** domain so they can move terms from that domain to the appropriate governance domain.

Learn how to assign data governance roles and permissions.

Steps for migrating glossary terms and enabling asset curation

This process enables your organization to add glossary terms to data assets and columns. During this process, you choose whether to migrate your existing glossary terms in the classic experience into Unified Catalog, or to use the glossary terms you already have in the Unified Catalog without migrating classic terms.

Step 1: Assign the necessary roles

See the required roles for the migration process.

Step 2: Choose how to enable asset curation

1. In the Microsoft Purview portal, go to **Unified Catalog** > **Catalog management** > **Classic types**.
2. Select **Enable asset curation**.
3. On the **Enable asset curation** flyout pane, select one of the following options, then select **Enable**:

    - **Migrate classic terms to Unified Catalog**: Select this option to migrate classic terms into Unified Catalog. After migration, classic terms are deactivated and placed in a read-only state for reference. When full migration is complete, you can curate data assets and columns with Unified Catalog terms.
    - **Switch directly to terms in Unified Catalog**: Select this option if you don't have any classic terms, or you intend to no longer use your classic terms and don't want to migrate them. If you have classic terms and select this option, your classic terms are deactivated and placed in a read-only state.

If you select **Migrate classic terms to Unified Catalog**, you see a summary of what will be migrated on the **Migrate glossary terms** flyout pane. Migration is a one-time process that can't be reversed, so you have an option of migrating a small sample of terms to see how the process goes, or to do the full migration all at once. At **Mode**, select how you want to proceed:

- **Sample migration**: This option migrates up to five glossaries so you can see how the migration works. Select this option, and then select **Start sample migration** to start the sample migration.

- **Full migration**: This option moves all glossaries and terms at once. Select this option, and then select **Start full migration** to start the migration process. This process can't be stopped or reversed after you start it.

    > ⓘ **Note**
    >
    > After you start the full migration process, access to terms in the classic governance experience is restricted to read-only. Any classic terms added by using APIs going forward are automatically added to the **.StagingDomain** domain.

Step 3: View terms in the staging domain and add more users to roles

After you select **Start full migration**, the glossary terms gradually appear in the **.StagingDomain** domain on the governance domains page. Depending on the number of terms migrated, the

migration process can take up to 48 hours.

To locate the **.StagingDomain** domain:

1. In Unified Catalog, go to **Catalog management** > **Governance domains**.
2. At the top of the list, find the domain named **.StagingDomain**.

When you begin migration, assign the necessary **Data Stewards** to the **.StagingDomain** domain so they can move terms to governance domains. On the staging domain's page, go to the **Roles** tab. Select the icon next to the **Data Steward** header to add users to this role for the domain. You might also want to add more users as owners of the **.StagingDomain** domain to help manage the domain.

Step 4: Move terms from the staging domain to owning domains

> **Important**
>
> A single term can only have 100 relationships in Unified Catalog. Review the relationships and clean up before migrating.

When migration is complete, reassign the glossary terms from the **.StagingDomain** domain to the appropriate governance domains for ongoing ownership. To assign migrated terms to a governance domain:

1. In **Unified Catalog**, under **Catalog management**, select **Governance domains**.
2. Select **.StagingDomain**, at the top of the list of governance domains.
3. On the **Details** tab, find the **Glossary terms** card and select **View all**.
4. Select **Move to**, and then select the box next to the terms you want to move. Selected terms are moved into one governance domain. To move terms into separate domains, select the terms going into one domain at a time.
5. After selecting the terms to move, select **Move item**.
6. In the **Move to** window, select the governance domain from the dropdown list that you want to move the terms into.
7. Select **Move**.

The terms are moved into their new governance domain. You can now add glossary terms to data assets and columns. Data Stewards see a notice at the top of the glossary terms list page that new terms were added to their governance domain.

> **Note**
>
> - Term hierarchies always move as a unit. If you select a parent term, all of its children move with the parent. If you don't want the hierarchy to be moved, remove the parent terms first.
> - The migration process doesn't automatically move any terms with duplicate names in the destination governance domain.

Next steps

Get started linking glossary terms to your data assets and columns:

- Start from a glossary term and link it to an asset or column
- Start from a data asset and attach glossary terms

Objectives and key results (OKRs) in Unified Catalog

10/09/2025

Objectives and key results (OKRs) (preview) in Microsoft Purview Unified Catalog are trackable business objectives tied to governance domains and data products to emphasize the value of business data.

Data governance is an important practice that organizations often overlook unless they have strict compliance requirements. While organizations seem to understand the value of data, they don't always recognize the role data governance plays in promoting healthy, useful data. As data estates become overgrown with ungoverned information, valuable data gets neglected.

OKRs link data products directly to real business objectives to bridge the gap between the business and the data estate. Data governance isn't just an IT task or engineering best practice, it's a critical part of value generation. To make use of your data, you need to maintain your data estate, and you can share the work among the experts who know the data best.

What is an OKR

An OKR is the goal or desired outcome of a governance domain; for example, a 10% raise in sales or a 3% reduction in support cases. Objectives should relate to everything an organization does and should define how they achieve their outcomes.

Parts of an OKR

Unified Catalog OKRs have several parts:

- Owners: The users responsible for maintaining the objective.
- Definition: An overarching description of your objective, which can be as broad as “Increase sales,” or as specific as "Use marketing campaigns to increase sales in the first quarter."
- Target date: When you expect to achieve your goal.
- Key results: The measurable, time-bound goals associated with your objective. These should be how you track progress toward your objective.

Owner

These users are responsible for maintaining a business objective. They could be the leaders of the business and should have knowledge of how the business functions and where it's headed. Multiple owners are encouraged to provide a complete perspective on the business and to support each other in owning the objective.

Definition

Good objectives are specific and achievable in a time frame. The definition is a high-level text description of the mission or current goal of the team or process, and why it matters. The description itself should be succinct, but it isn't enough on its own. It requires a way to measure the goal's achievement and progress, which are the key results.

Target date

The target date is when you expect to meet the goal. This date helps drive progress toward the goal and encourages achievable goals, since you must complete them within a specific time frame.

Key results

Key results show how you measure progress toward your objective. Your objective might have several key results that roll up to your overall goals.

A good metric for goals and objectives uses the SMART acronym:

- **S**pecific
- **M**easurable
- **A**chievable
- **R**ealistic
- **T**ime-bound

To tie your objectives to real results, key results have several features:

- Result: A statement that encompasses the specific, measurable result you expect.
- Progress status: Is your progress on track, behind, or at risk? This status helps your business identify and prioritize issues.
- Progress amount: Where do you stand in relation to your goal? You need to use specific numbers or percentages to represent this amount.
- Goal amount: What's your goal? You need to use specific numbers or percentages to represent this amount.
- Maximum amount: What's the maximum achievable?

You can edit these values so business users and owners can update their goals and results over time. These values are also converted to graphics, so business owners can see at a glance how their organization is progressing toward their goals and where there might be blockages.

Related data products

You can connect an OKR to all data products that are relevant to that objective. It can be the data used to measure that OKR, or the data used to investigate new business opportunities. Data consumers can use this connection to see all data related directly to their business objectives, and business owners can track the health of the data directly associated with their goals.

How OKRs generate business value

Data governance directly supports these business objectives. After all, data helps you both track and achieve these objectives. You can also use data to uncover new areas for improvement and to guide which objectives need prioritization. OKRs help to directly tie data to its business value.

For example: Your marketing team develops an email campaign results data product that they use to track the effectiveness of their email marketing campaigns. Your marketing governance domain has a "Customer Response" OKR, with the goal of at least 20% customer response to email, telephone, and mail campaigns sent out. A business owner connects the "Customer Response" OKR to the email campaign results data product and creates an "Email Campaign Response" key result to measure the current percentage of customer response. When the marketing team tracks their quarterly progress, their objectives directly tie to the data they use to track that information. They're directly aware of the health and value of the data associated with their OKRs and naturally encouraged to invest in the health of the data.

This approach not only encourages your users to focus on their objectives but also promotes health, security, right use, and data discovery directly related to your business objectives. Your business and your data estate grow together naturally to support your goals.

Create and manage OKRs in Unified Catalog

10/09/2025

Objectives and key results (OKRs) in Microsoft Purview Unified Catalog are trackable business objectives tied to governance domains and data products to emphasize the value of business data.

This article describes how to manage OKRs in Microsoft Purview. It provides steps to create OKRs in a governance domain, create key results, and connect them to your data products.

Prerequisites

- Any user can read published OKRs.
- To create and edit OKRs, you need the steward role.

Access OKRs

1. In Unified Catalog, select **Catalog management**, then select **Governance domains**.
2. Select the governance domain you'd like to see OKRs for.
3. On the **Details** tab, find the **OKRs** card and select **View all**.

The full list of OKRs for that governance domain is displayed. Select an OKR to see its detailed view, and get more information about its key results.

You can also view a list of all OKRs:

1. In Unified Catalog, under **Discovery**, select **Enterprise glossary**.
2. Select the **OKRs** tab.
3. Select the name of an OKR to open its details page.

Filter your view by custom attribute

Use business concept attributes as a filter when exploring OKRs.

1. In Unified Catalog, go to **Discovery** > **Enterprise glossary**.
2. On the **OKRs** tab, select **Add filter**.
3. At **Filter**, select an attribute name from the dropdown list.
4. At **Operator**, select a condition, such as **Equals** or **Starts with**, which varies based on the kinds of values allowed by the attribute.

5. At **Value**, enter your value.
6. Select **Apply**.

Overview

The **Overview** tab shows key results, associated data products, target date, and current overall progress.

Custom attributes

Under **Custom attributes**, you can see any custom attribute groups and attributes within groups, and the values set for each attribute. Only attributes with values are shown by default, but you can toggle **Show attributes without a value** on to view all attributes.

Create OKRs

You can create OKRs directly in the Microsoft Purview portal.

1. In Unified Catalog, select **Catalog management**, then select **Governance domains**.
2. Select the governance domain you want to add an OKR to.
3. On the **Details** tab, find the **OKRs** card and select **View all**.
4. On the **OKRs** page, select **New OKR**.
5. On the **Basic details** page, at **Objective**, enter a statement describing the action you'll take and why it matters. For example: Revamp customer service to improve satisfaction and retention rates. If you use a name that already exists, you'll see a warning during the creation process. While duplicating names isn't recommended, you won't be blocked from using a duplicate name.
6. Select an owner or owners for your OKR.
7. Select a target date to meet the OKR.
8. Select **Next**.
9. On the **Custom attributes** page, you can set values for all custom attributes defined by your admin in the **Custom attributes** section of the catalog. If the attribute is marked as required, you need to fill out all values on this page before you can complete the process.
10. Select **Create**.

You see the details page for your new OKR, where you can edit or manage your OKR, view key results, and view linked data products.

> ⓘ **Note**

Only stewards and governance domain owners can see your OKR until you **publish it**.

Key results

Key results are how you track the overall progress of an OKR. They should be specific, measurable outcomes so you and your team can accurately gauge progress or completion.

The top key results are listed on the details page. To view any others, select **View all key results**.

Select a specific key result to see its details.

Create key result

To create a new key result for an OKR:

1. In your OKR's details page, select **Add key result**.
2. Add your key result statement - it should be a specific, measurable outcome that uses metrics. For example: Increase customer retention rate by 25%.
3. Select current progress status - on track, behind, or at risk.
4. Set progress amount as a percentage or a value.
5. Set goal amount as a percentage or a value.
6. Set the maximum allowed amount as a percentage or value.
7. Select **Create**.

Your newly created key result is now listed under key results in your OKR.

Update key result

1. In your OKR's details page, select the key result you want to update, or select **View all key results** to see a full list of key results.
2. Select the key result you want to edit, and select the **Edit** button.
3. Edit the result, progress status, progress amount, goal amount, or maximum amount.
4. Select **Save** to save your updates.

Data products

Add, remove, and view data product links all from within your business OKR.

View linked data products

You can view all your linked data products from within your OKR. The details page lists the first 10 linked data products. Select **View all data products** to see and search the entire list.

Add data product link

1. In your OKR's details page, select the **+ Link data product** button.
2. Search for the data products you want to link.
3. Select the data products you want to link.
4. Remove any selected products from the **Selected** list by selecting the **X** button next to their name.
5. To add your selected data products, select **Save**.

Remove linked data products

To remove a linked data product:

1. Open the OKR where the data product is linked.
2. Find the data product on the details page or select **View all data products** to search for it.
3. Select the ellipsis button (**...**) next to the data product and select **Remove link**.

Edit and manage OKRs

1. On the OKR's details page, select **Edit**.
2. On the **Basic details** page, update the objective, owner, and target date. If you change the name to one that already exists, you'll see a warning about the duplication but you can proceed to use the duplicate name.
3. Select **Save**.
4. On the **Custom attributes** page, you can set values for all custom attributes defined by your admin in the **Custom attributes** section of the catalog. If the attribute is marked as required, you need to fill out all values on this page before you can complete the process.
5. Select **Save**.

Draft, publish, or close

You can publish a drafted OKR, or unpublish a previously published OKR and set it to draft or closed. Closing an OKR limits its visibility to stewards and governance domain owners.

To publish or unpublish an OKR:

Closing an OKR limits its visibility to stewards and governance domain owners. Deleted OKRs are removed from the governance domain.

1. Select the governance domain you'd like to publish or unpublish an OKR from.
2. Select the **OKRs** card.
3. Search or browse for the OKR and select it.
4. Select **Publish** if in draft state and **Unpublish** if already published.
5. You can either **Set to draft** for further edits or **Set to closed** if you don't wish to use it any longer.

> **Note**
>
> Ensure your governance domain is published before you publish your OKRs.

Delete OKRs

To delete an OKR, first unpublish it and delete any key results and links to related data products. Then select **Delete** to delete the OKR.

Custom metadata (preview) in Unified Catalog

10/09/2025

Custom metadata plays a crucial role in data governance by providing you with the flexibility to add user-defined context to describe and organize your data. In Microsoft Purview Unified Catalog, you can define and apply organization specific business attributes to your data assets and business concepts that foster better organization, accessibility, and utilization of your data. The benefits of using custom metadata include:

- **Enhanced data discovery**: Custom metadata simplifies the search and retrieval of data by allowing users to apply specific tags, which are **attributes** in Unified Catalog, that make datasets easier to locate.
- **Help with compliance**: Organizations can use custom attributes to track regulatory requirements or flag sensitive data to help ensure adherence to legal and industry standards.
- **Streamlined communication**: Custom metadata facilitates better collaboration among teams by providing clear descriptions and classifications of data assets.
- **Optimized data utilization**: By categorizing data assets effectively, organizations can prioritize the use of high-value data for analytics and decision-making.

Custom metadata usage scenarios

Here are some examples of how you can use custom metadata to help achieve better data governance and compliance:

Example 1: Healthcare industry

A hospital's data catalog includes patient records, medical research, and operational data. By implementing custom metadata, administrators add attributes such as "Patient Age Group," "Disease Category," and "Research Priority Level" to the datasets. This approach enables the hospital to segment data effectively for clinical studies, prioritize urgent cases, and comply with healthcare regulations like HIPAA.

Example 2: Financial services

A financial institution uses custom metadata to govern its risk assessment data. Attributes like "Risk Rating," "Investment Sector," and "Regulatory Compliance Status" help ensure that

analysts can quickly identify high-risk investments, provide insights into sector-specific trends, and maintain legal compliance with financial regulations.

Example 3: Academic institutions

Universities use custom metadata to manage their research databases. Attributes like "Research Field," "Funding Source," and "Publication Status" enable academic departments to track progress, allocate resources effectively, and collaborate across institutions.

Example 4: AI and compliance

Organizations can include AI and compliance related attributes to define various data product types. AI-related attributes might cover aspects such as algorithm transparency, explainability, and model performance metrics, while compliance attributes might address regulatory requirements, data privacy, and ethical considerations. By incorporating these factors, organizations can ensure their data products are robust, compliant with laws and standards, and aligned with responsible AI practices.

Example 5: Tracking translations

Language can be a pivotal attribute to describe and discover glossary terms in different languages. By incorporating multilingual capabilities into metadata attributes, organizations can ensure seamless communication and understanding across diverse linguistic groups. This approach not only facilitates global collaboration but also enhances accessibility, enabling users to interact with data in their preferred language while maintaining consistency and clarity in terminology usage.

Types of custom metadata: attributes

Currently, you can use two types of custom metadata:

1. Business concept attributes: Attributes you create and apply to business concepts, such as governance domains, data products, critical data elements, glossary terms, and objectives and key results.
2. Data asset attributes: Attributes you create and apply to data assets.

You can find, create, and manage your custom metadata at **Unified Catalog** > **Catalog management** > **Custom metadata (preview)**.

Each type of attribute appears on its own tab on the **Custom metadata (preview)** page. The attribute list on each tab is organized by attribute group, and each attribute is nested within its group.

Get started

- Create business concept attributes
- Create data asset attributes

Create and manage business concept attributes (preview)

07/16/2025

Business concept attributes are a type of user-defined custom metadata in Microsoft Purview Unified Catalog that you can create and apply to your organization's business concepts for better organization, governance, and discovery.

The **Custom metadata (preview)** area in **Unified Catalog** > **Catalog management** is where you create and manage business concept attributes.

Workflow and tasks by role

Creating and managing business concept attributes involves three basic steps, each involving certain user roles and functions in your organization:

1. Admins create and maintain the attributes and attribute group definitions.
2. Data stewards and data product owners update the values for business concept attributes defined by their admins.
3. Data consumers or catalog readers can use business concept attributes to filter their view of published business concepts.

Use this table to guide you to relevant tasks depending on your role in the organization. See Data governance roles and permissions for role descriptions and how to assign roles.

Expand table

Role	Task
Admins - Governance Domain Creators and Data Curators	Create attribute groups Create attributes Set the scope for an attribute group Edit groups to add attributes Require values for attributes Expire attributes and attribute groups
Data Stewards Data Product Owners	Edit attributes Add values to attributes Use attributes as filters for viewing business concepts Delete attribute values
Catalog readers (local and global)	Use attributes as filters for viewing business

Role	Task
	concepts

Know before you start

Before you start creating attributes, we recommend reviewing these sections:

- Understand attributes and groups
- Field types for attribute values
- Scope settings for attribute groups

> **Note**
>
> As you start planning your attribute strategy, keep in mind that after you create a business concept attribute, **edits** are limited. Also, attributes and attribute groups can't be deleted; they can only be **expired**.

Understand attributes and groups

- **Business concept attributes**: Business concepts, such as governance domains and glossary terms, help you organize and understand your data in ways that make sense for your organization. An attribute is user-defined metadata that you can apply to your business concepts to better describe your organization's unique needs.
- **Attribute groups**: A category by which you group attributes, allowing for easier organization and consumption.

Field types for attribute values

Business concept attributes can include several types of values, such as text-based descriptions, numerical identifiers, or date-based identifiers. During the attribute creation process, the field type options are:

- Text
- Single choice: When you select this type, a **Choices** field appears, where you enter a name for the choice and can add more choices.
- Multiple choice: When you select this type, a **Choices** field appears, where you enter a name for the choice and can add more choices.
- Date
- Boolean

- Byte
- Double
- Float
- Integer
- Long
- Rich text
- Short

See Add values to attributes for more details.

Scope setting for attribute groups

The **Scope** setting for attribute groups allows you to apply attributes to a broad array of governance domains and business concepts in Unified Catalog at once.

When you create an attribute group, the **Scope** settings allow you to select all or some governance domains, business concepts, and data product types. Setting a scope means that every attribute in that group will apply to the governance domains, business concepts, and data products that you selected for that group.

Scope defaults to all governance domains and business concepts during the attribute group creation process. If scope needs to be narrowed, select each dropdown within **Scope** and set it to the desired scope.

When creating or editing an attribute, you can accept the **Inherit Group Scope** setting, which applies the group scope to the attribute, or you can override the inherited setting and select individual governance domains and business concepts as the scope for that particular attribute within the group.

Create and edit attribute groups

All business concept attributes must be connected to an attribute group. You might want to develop a grouping strategy ahead of time, then create one or more attribute groups before creating the attributes you'll assign to the groups. Alternatively, you can create an attribute group at the point in the attribute creation process where you assign a group to the attribute.

> **Note**
>
> When you apply an attribute group to a business concept, all attributes in that group are added to the concept.

Create an attribute group

1. Sign in to the Microsoft Purview portal > **Solutions** > **Unified Catalog** with an account that has a role in a tenant level role group.
2. Under **Catalog management**, select **Custom metadata**.
3. On the **Business concept attributes** tab, select **New**, then select **New attribute group**.
4. On the **New attribute group** flyout pane, enter an **Attribute group name** and an optional description.
5. You can create a new business concept attribute at this stage by selecting **New attribute**. This is the **only** stage at which you can mark an attribute as required.
6. Under **Scope**, select the **Governance Domains**, **Business Concepts**, and **Data product types** that will apply to the group and all attributes assigned to the group. All values are checked by default, so be sure to uncheck any values you don't want. Get more details on scope settings.
7. When done, select **Create**.

The group is now listed on the **Business concept attributes** tab of the **Custom metadata (preview)** page.

View and edit an attribute group

Find the name of an attribute group on the **Business concept attributes** tab, hover over its row and select the **Edit** pencil icon. A flyout pane appears, which contains all the details of the attribute group, including a list of all attributes in the group.

Add a new attribute to the group by selecting **New attribute**.

To change the scope of an attribute in the group or edit any details of the attribute, select the attribute name, make edits on the **Edit attribute** flyout pane, then select **Apply**.

Mark an attribute as required

When you create a business concept attribute as part of a business concept attribute group, you can make the attribute required by selecting **Mark as required**. Marking as required means that a value must be provided for the attribute. When a business concept is created or edited, the value for the required attribute must be filled out before you can complete the creation or editing process.

> **Important**
>
> - You can only select **Mark as required** when you create an attribute during the process of creating an attribute group. You can't mark the attribute required when creating just an attribute on its own.
> - If an existing attribute isn't marked as required, you can't mark it as required during the editing process.
> - Once you select **Mark as required** and create the attribute, you can't unselect it during the editing process.

Create attributes

1. Sign in to the Microsoft Purview portal > **Solutions** > **Unified Catalog** with an account that has the Data Steward role.
2. Under **Catalog management**, select **Custom metadata**.
3. On the **Business concept attributes** tab, select **New**, then select **New attribute**.
4. On the **New attribute** flyout pane, enter an **Attribute name** and an optional description.

   > **Note**
   >
   > You can create more than one attribute with the same name and link them to different attribute groups. Providing a detailed description for identically named attributes can help avoid confusion or the misapplication of attributes.

5. Select **Mark as required** if you want to require a value be provided for the attribute. This option is only available when creating an attribute during the process of creating an attribute group (learn more).
6. At **Attribute group**, select a group name from the dropdown list.

   - You can create a new attribute group at this step by selecting **New**, then follow the steps to create an attribute group.
   - If you're creating the attribute at the same time as you're creating the group, the **Attribute group** selector doesn't show; the attribute is automatically associated to the group you're creating.

7. At **Field type**, select an attribute field type.

8. The **Inherit Group Scope** toggle is on by default, which means that the attribute will have the same scope as the group to which you assign it. To override scope inheritance, toggle off the switch. Then select the individual governance domains, business concepts, and data product types that you want the attribute to apply to. Get details on scope settings.
9. When done, select **Create**.

Your attribute now appears on the list of attributes on the **Business concept attributes** tab, nested under its group.

Edit attributes

An admin can make edits to attribute groups and attributes. You can update the description, the scope, or set an attribute or group as expired. When you edit an attribute group, you can add attributes to it.

Follow these steps to make edits:

1. Find the attribute or group from the list on the **Custom metadata** page.
2. Hover over the name and select the **Edit** pencil icon.
3. Make your edits, then select **Update**.

Add values to attributes

Data stewards and data product owners can set and update values for attributes that are defined by their admins. The values don't have to be filled in at the time of business concept creation. However, if an attribute is marked as required, then whenever a user creates or edits an attribute, the values must be filled in before the attribute editing process can be completed.

Delete attribute values

Attributes that are expired display a trash can icon next to them when viewed on a business concept's **Custom attributes** page. To delete an attribute value:

- Open the business concept details page and select **Edit**.
- On the **Custom attributes** page, find the attribute you want to delete (expired attributes appear as grayed out).
- Select the trash can icon next to the attribute. The attribute is removed from the view.
- Select **Save**.

Expire an attribute or attribute group

A business concept attribute can't be deleted, and a business concept attribute group can't be deleted. They can only be expired. When an attribute or attribute group is expired, you can't apply them to other business concepts, and they can't be reactivated.

- **When you expire an attribute**: Any business concepts that had the attribute applied will continue to show that attribute.
- **When you expire an attribute group**: All the attributes within the group are also expired. Any business concepts that had an attribute within this group applied to it will continue to show that attribute.

To expire an attribute or attribute group:

1. On the **Business concept attributes** tab of the **Custom metadata (preview)** page, find the attribute or attribute group you want to expire and select the **Edit** pencil icon.
2. On the **Edit attribute** or **Edit attribute group** pane, select the **Mark as expired** checkbox.
3. Select **Update**.

View attributes and use as filters

Attributes are viewable, and can be used as filters, in various ways:

- List view of all attributes on the Custom metadata (preview) page.
- Displayed on a business concept's details page
- As a filter when exploring business concepts.
- As a filter for exploring data products.

On the Custom metadata (preview) page

Business concept attributes are listed in **Unified Catalog** > **Catalog management** > **Custom metadata** on the **Business concept attributes** tab. The list is organized by group name. Use the arrow next to the group name to expand or collapse the list of attributes underneath a group.

On a business concept details page

You can view details about attributes on the details pages for all business concepts and data products:

- Governance domains
- Data products
- Critical data elements
- Glossary terms

- Objectives and key results (OKRs)

Filters for viewing business concepts

You can use business concept attributes as a filter when browsing and searching for business concepts.

1. Go to **Unified Catalog** > **Discovery** > **Enterprise glossary**.
2. Select the tab of the business concept you want to search in. If you're searching in a governance domain, select **View all** on a business concept card.
3. Select **Add filter**.
4. At **Filter**, select an attribute name from the dropdown list.
5. At **Operator**, select a condition, such as **Equals** or **Starts with**, which will vary based on the kinds of values allowed by the attribute.
6. At **Value**, enter your value.
7. Select **Apply**.

Filter for exploring data products

When you explore data products by governance domains, you can filter your view by data asset attributes.

1. In Unified Catalog, go to **Discovery** > **Data products**.
2. Select **Explore all**. You arrive at the **Explore data products by governance domain** page.
3. Select **Add filter**.
4. At **Filter**, select an attribute name from the dropdown list.
5. At **Operator**, select a condition, such as **Equals** or **Starts with**, which will vary based on the kinds of values allowed by the attribute.
6. At **Value**, enter your value.
7. Select **Apply**.

Create and manage data asset attributes

10/09/2025

Data asset attributes are a type of custom metadata in Microsoft Purview Unified Catalog that you can create and apply to your organization's data assets. These user-defined attributes provide a business or organization level context to an asset, helping data consumers understand the role an asset plays in the organization.

Prerequisites

To create a **data asset attribute**, you must hold the Data Curator role in the Data Map.

Manage attributes on the Custom metadata (preview) page

> **Note**
>
> Data asset attributes were previously called "managed attributes" and were located under **Catalog management** > **Classic types**.

The **Custom metadata (preview)** area under **Unified Catalog** > **Catalog management** is where you create and manage two types of attributes:

1. Data asset attributes
2. Business concept attributes

The **Data asset attributes** tab is where you find all of your data asset attributes nested within each attribute group.

The **Business concept attributes** tab lists all of your attributes nested within each attribute group. Learn how to work with business concept attributes.

Know before you start

Before you start creating attributes, review these sections:

- Understand attributes and groups
- Attribute field types
- Learn when you can mark an attribute as required

Understand attributes and groups

- **Data asset attributes:** A set of user-defined attributes that provide a business or organization level context to a data asset. Each attribute has a name and a value. For example, "Department" is an attribute name and "Finance" is its value.
- **Attribute group:** A grouping of data asset attributes that makes it easier to organize and consume them.

Attribute field types

Data asset attributes can include several types of values, such as text-based descriptions, numerical identifiers, or date-based identifiers.

During the attribute creation process, you can choose from the following field type options:

- Text
- Single choice: When you select this type, a **Choices** field appears, where you enter a name for the choice and can add more choices.
- Multiple choice: When you select this type, a **Choices** field appears, where you enter a name for the choice and can add more choices.
- Date
- Boolean
- Byte
- Double
- Float
- Integer
- Long
- Short

Create and edit attribute groups

You must connect all data asset attributes to an attribute group. You might want to develop a grouping strategy ahead of time, then create one or more attribute groups before creating the attributes you assign to the groups. Alternatively, you can create an attribute group at the point in the attribute creation process where you assign a group to the attribute.

As you develop a grouping strategy, consider which attributes in a group you want to mark as required. **You can only set attributes to be required when you create an attribute group first, and then add assets *while you're in the process of creating the group*.**

Create an attribute group

1. Sign in to the Microsoft Purview portal > **Solutions** > **Unified Catalog**.
2. Under **Catalog management**, select **Custom metadata**.
3. On the **Data asset attributes** tab, select **New**, then select **New attribute group**.
4. On the **New attribute group** flyout pane, enter an **Attribute group name** and an optional description. You can't change a group name after you create the group.
5. You can create a new data asset attribute at this stage by selecting **New attribute**. This is the **only** stage at which you can mark an attribute as required.
6. When done, select **Create**.

The group is now listed on the **Data asset attributes** tab of the **Custom metadata (preview)** page.

View and edit an attribute group

Find the name of an attribute group on the **Data asset attributes** tab, hover over its row, and select the **Edit** pencil icon. A flyout pane appears, which contains all the details of the attribute group, including a list of all attributes in the group.

Add a new attribute to the group by selecting **New attribute**.

You can't edit an attribute group name after you create the group.

Mark an attribute as required

When you create a data asset attribute as part of a data asset attribute group, you can make it required by selecting **Mark as required**. Marking an attribute as required means that a value must be provided for this attribute. When you edit a data asset, you must fill out the required attribute before you can close the editor.

> **Important**
>
> - You can only select **Mark as required** when you create an attribute during the process of creating an attribute group. You can't mark the attribute as required when creating just an attribute on its own.
> - If an existing attribute isn't marked as required, you can't mark it as required during the editing process.

- Once you select **Mark as required** and create the attribute, you can't unselect it during the editing process.

1. Sign in to the Microsoft Purview portal > **Solutions** > **Unified Catalog**.
2. Under **Catalog management**, select **Custom metadata**.
3. On the **Data asset attributes** tab, select **New**, then select **New attribute group**.
4. Select **New** and select **New attribute**.
5. Fill out your attribute details, and select **Mark as required**.
6. Select **Apply** and finish adding other attributes to complete your attribute group.

Create data asset attributes

1. In the Microsoft Purview portal, under **Solutions**, select **Unified Catalog**.
2. Under **Catalog management**, select **Custom metadata**, then select the **Data asset attributes** tab.
3. Select **New**, then select **New attribute**.
4. On the **New attribute** flyout pane, enter an **Attribute name** and an optional description.

   > **Note**
   >
   > You can create more than one attribute with the same name and link them to different attribute groups. Providing a detailed description for identically named attributes can help avoid confusion or the misapplication of attributes.

5. Select **Mark as required** if you want to require a value for the attribute. This option is only available when creating an attribute during the process of creating an attribute group (learn more).
6. At **Attribute group**, select a group name from the dropdown list.

   - You can create a new attribute group at this step by selecting **New**, then follow the steps to create an attribute group.
   - If you're creating the attribute at the same time as you're creating the group, the **Attribute group** selector doesn't show; the attribute is automatically associated to the group you're creating.

7. At **Field type**, select an attribute field type.
8. At **Applicable asset types**, select one or more data asset types that the attribute can be applied to. For example, if you select "Azure SQL Table" for an attribute, it applies to Azure SQL Table assets, but not Azure Synapse Analytics Dedicated Table assets. When done, select **Apply**.
9. Select **Create**.

These attributes are automatically applied to the specified resources without a value. You need to apply a value for each asset.

Edit a data asset attribute

After you create a data asset attribute, you can't change its name, the attribute group it belongs to, or the field type. To edit other details, such as the description or to mark the attribute as expired, follow these steps:

- On the **Data asset attributes** tab of the **Custom metadata (preview)** page, hover over the attribute name and select the **Edit** pencil icon.
- Make your edits, then select **Update**.

Add a value to a data asset attribute

After you create a data asset attribute, you need to add a value for each of your assets. To add values to your assets, follow these steps:

1. Search for your data asset.
2. On the **Overview** tab of the asset's details page, see the **Data asset attributes** section with all attributes that have values. (You can see attributes without values by using the **Show attributes without a value** toggle.)
3. Select **Edit**.
4. Under **Data asset attributes**, add values for each of your attributes.
5. If any attributes are **Required**, you can't save until you add a value for that attribute.

Expire a data asset attribute or attribute group

You can't delete a data asset attribute or a data asset attribute group. You can only expire them. When you expire an attribute or attribute group, you can't apply them to other data assets, and you can't reactivate them.

- **When you expire an attribute**: Any data assets that had the attribute applied continue to show that attribute.
- **When you expire an attribute group**: All the attributes within the group are also expired. Any data assets that had an attribute within this group applied to it continue to show that attribute.

To expire an attribute or attribute group:

1. On the **Data assets attributes** tab of the **Custom metadata (preview)** page, find the attribute or attribute group you want to expire and select the **Edit** pencil icon.
2. On the **Edit attribute** or **Edit attribute group** pane, select the **Mark as expired** checkbox.
3. Select **Update**.

Create data asset attributes using APIs

You can programmatically create and apply data asset attributes by using the business metadata APIs in Apache Atlas 2.2. For more information, see the Use Atlas 2.2 APIs tutorial.

Best practices for using data asset attributes

Use data asset attributes to extend the fields available for an asset in the Microsoft Purview Unified Catalog. Data asset attributes are key-value pairs that add structured metadata to your catalog. When Microsoft Purview scans data, it adds technical information about the data, such as data type and classification. If you want to add more fields, you need to define data asset attributes.

For example, a data asset attribute lets a user tag tables with the department that publishes them. Use data asset attributes when you want to make sure assets are always tagged in exactly the same way with this information. The user also wants to filter by the publisher field when they search for data.

The data asset attribute in this example helps users quickly find all data published by a team, but it doesn't help someone understand the definition of a publisher or what it means if the team is the publisher of the data. For any information that needs a business explanation, use glossary terms.

Search for data products in Unified Catalog

This article outlines how to search and browse Microsoft Purview Unified Catalog to find data products.

Prerequisites

To search for data products, you need a Catalog Reader role.

How to search

You can search for data products by using keywords or natural language (preview). To find data products that best fit your business needs, use **Search with natural language (preview)**. Searching with natural language supports data products created in English, French, and Spanish languages, and search terms in the corresponding languages.

The data product search is based on these attributes:

- Data product name, description, and business use.
- Name and description of associated governance domain, glossary terms, CDEs, and OKRs.
- Name and description of contained data assets.

To search for data products in Unified Catalog, select **Discovery**, then select **Data products**.

In the search bar, search by keywords, partial keywords, or natural language search:

- **Partial keyword match**: Enter a partial keyword, and the search returns results that match the partial term. For example, entering *cust* returns results that match *customer*.
- **Exact match with double quotes**: Use double quotes to search for an exact phrase. For example, "*customer profile*" searches for the phrase as a single unit, rather than matching *customer* and *profile* separately.
- **Natural language (preview)**: Select the magnifying glass icon at the end of the search bar, then enter a description of the data you need to find, then press **Enter**. Examples:
  - *I need three years of North American revenue data from finance department to analyze sales trends.*
  - *Find certified master data for customer accounts, which includes customer ID, name, and address.*

- *I'm working on improving customer satisfaction. Show me Power BI reports of customer rating and feedback.*

A list of search results appears. Select a data product to view its details page. Hover over a search result to see why it was returned. The highlight shows which attributes matched your search query, such as name, description, or term.

You can filter search results by governance domain, data product type, owner, glossary terms, or critical data elements.

> **Note**
>
> Search isn't case sensitive, but spaces within search terms matter. Underscores and other non-space characters are treated as part of the keyword.

Explore data products by governance domain

You can browse data products in Unified Catalog by governance domain.

1. In the Microsoft Purview portal, go to **Discovery** > **Data products**.
2. Select a governed domain under **Explore data products by governance domain**, or select **Explore all** to navigate to a governance domain.
3. When you select a governance domain, a list of its data products appears. Select a data product name from the list to view that product's details page.

Explore data products by filtering on custom attributes

When you explore data products by governance domains, you can filter your view by business concept attributes.

1. In Unified Catalog, go to **Discovery** > **Data products**.
2. Select **Explore all**. You arrive at the **Explore data products by governance domain** page.
3. Select **Add filter**.
4. At **Filter**, select an attribute name from the dropdown list.
5. At **Operator**, select a condition, such as **Equals** or **Starts with**, which varies based on the kinds of values allowed by the attribute.
6. At **Value**, enter your value.
7. Select **Apply**.

View data product details

A data product details page contains a description, use case, terms of use, and contacts. The page lists the glossary terms, critical data elements (CDE), and data assets that are associated to the data product. Select an asset, term, or CDE to display a flyout with a **View details** button for further details.

View data asset details

Select a data asset from the data product details page to view a flyout pane with more information. Select **View details** on the flyout pane to open the details page for the data asset.

The data asset details page includes a description and owner, lists the data asset columns, and displays lineage information. The page also lists other data products that contain the data asset.

Next steps

- Request access to data product
- Manage Unified Catalog access policies

Search for data assets

After data is scanned and ingested into the Microsoft Purview Data Map, data consumers need to easily find the data they need for their analytics or governance workloads. Data discovery can be time consuming because you might not know where to find the data that you want. Even after finding the data, you might have doubts about whether you can trust the data and take a dependency on it.

This article outlines how to search Microsoft Purview Unified Catalog to quickly find the data you're looking for. You can search across all data assets, or focus on governed assets that have been curated with governance metadata such as glossary terms, data products, critical data elements, or data quality scores.

Permissions to search the Unified Catalog

Searching Unified Catalog only returns relevant data assets that you have permissions to view.

You can find a data asset in Unified Catalog when:

- You have at least read permissions on an available Azure or Microsoft Fabric resource.
- You have at least data reader permissions on a domain or collection in the Microsoft Purview Data Map where the asset is stored.

Manage permissions to these assets at the resource level and at the Microsoft Purview Data Map level, respectively. For more information on providing this access, see the links above.

To search for curated, ready-to-use data assets, search for data products your organization has developed.

> **Tip**
>
> If your Unified Catalog is well-curated, day-to-day business users shouldn't need to search the full catalog. They should be able to find data they need in data products, or by using the governed assets search to find curated data. For more information about setting up Unified Catalog, see Get started with data governance, and plan for Unified Catalog.

Permissions to search governed assets

Governed assets are visible to users with the Global Catalog Reader role. Local Catalog Readers can view governed assets in the governance domain they have access to. Published governance concepts, such as glossary terms, data products, and critical data elements, are also visible to catalog readers. Draft concepts are visible only to Data Product Owners and Data Stewards.

Existing Data Map reader and curator roles aren't changed by the governed assets search experience.

Searching the catalog

To search for data assets in Unified Catalog:

1. In the Microsoft Purview portal, open **Unified Catalog**.
2. Under **Discovery**, select **Data assets**.
3. In the search bar, enter keywords to narrow your search, such as name, data type, classifications, and glossary terms. Search suggestions appear as you enter keywords. Your search history is also presented so you can resume a previous data exploration.
4. To complete your search, select **View search results** or select **Enter**. For full search syntax information, see keyword search syntax.

The search results page shows a list of data assets and glossary terms that match the search terms. The keyword is highlighted in the return results, so you can see where the term was found in the asset. The **Governed assets** tab displays only governed assets search results, and the **All assets** tab displays the search results in all assets in your data estate, whether they're governed or not.

> **Note**
>
> Search only returns items in collections where you're a data reader or curator. For more information, see roles and permissions in collections.

The Microsoft Purview relevance engine sorts through all the matches and ranks them based on what it believes is useful to a user. For example, a data consumer is likely more interested in a table curated by a data steward that matches on multiple keywords than an unannotated folder. Many factors determine an asset's relevance score. The Microsoft Purview search team constantly tunes the relevance engine to ensure the top search results have value to you.

Keywords and keyword search syntax

Search queries consist of keywords and operators such as `AND`, `OR`, `NOT`, exact phrase quotes, field-scoped search, and parentheses for grouping. You can combine these operators to build precise queries that return exactly the assets you need.

For the full list of supported operators, field names, and detailed syntax guidance, see Keyword search syntax.

Filter results

If the top results don't include the assets you're looking for, you can filter your results by using the filter pane to the left of the search results.

On the search results page, select **Filter** to open and close the filter pane. With the filter pane open, select a filter category, then select the checkbox next to the values you want to filter on. For some filters, you can select the ellipsis to choose **Or** or **And**.

Available filters

You can add filters by selecting **Add filter** on the filter pane and selecting one of the following options:

- **Activity**: Refine your search to attributes created or updated within a certain timeframe.
- **Asset type**: Refine your search to specified asset types. For example: dashboards, files, glossary terms, or metamodel assets.
- **Assigned term**: Refine your search to assets with the selected terms applied.
- **Classification**: Refine your search to assets with certain classifications.
- **Collection**: Refine your search by assets in a specific collection.
- **Contact**: Refine your search to assets that have selected users listed as a contact.
- **Data source type**: Refine your search to assets from specified source types. For example: Azure Blob Storage or Power BI.
- **Endorsement**: Refine your search to assets with specified endorsements, like **Certified** or **Promoted**.
- **Label**: Refine your search to assets with specific security labels.
- **Data asset attributes**: Refine your search to assets with specified data asset attributes. Attributes are listed under their attribute group, and use operators to help search for specific values. For example: Equals or Doesn't equal.
- **Rating**: Refine your search to only data assets with a specified rating.
- **Tags**: Refine your search to assets with selected tags.

Search for governed assets (preview)

The governed assets search provides a focused view of data assets that are actively governed in Unified Catalog. Instead of searching across all assets, you can search only for assets that have governance metadata, such as glossary terms, data products, critical data elements, or data quality scores. Learn more about governed assets.

The governed assets search is helpful because organizations have large data estates but only a small percentage of assets are curated and ready for consumption. Data consumers can use this search to find meaningful, governed data without navigating the entire data estate.

To search for governed assets:

1. In the Microsoft Purview portal, open **Unified Catalog**.
2. Under **Discovery**, select **Data assets**.
3. Enter keywords in the search bar and select **Enter** or **View search results**.
4. On the search results page, select the **Governed assets** tab.

The search results show only assets that are governed in Unified Catalog. Each asset has a **Governed** label next to its name. Governed assets search supports semantic search, so you can use natural language queries to find assets.

Search capabilities

Governed assets search includes the following capabilities:

- **Partial keyword match**: Enter a partial keyword, and the search returns results that match the partial term. For example, entering *cust* returns results that match *customer*.
- **Exact match with double quotes**: Use double quotes to search for an exact phrase. For example, "*customer profile*" searches for the phrase as a single unit, rather than matching *customer* and *profile* separately.
- **Search highlights**: Hover over a search result to see why it was returned. The highlight shows which attributes matched your search query, such as name, description, or term.

> **Note**
>
> Search isn't case sensitive, but spaces within search terms matter. Underscores and other non-space characters are treated as part of the keyword.

Filter governed asset results

You can filter governed asset search results by using the following filters (see filter definitions):

- Asset type
- Data source type
- Classification
- Contact
- Glossary term
- Data product
- Critical data element

> **Note**
>
> The **Terms** filter in governed assets search uses Unified Catalog terms. After you migrate glossary terms and enable data asset curation, the **Assigned term** filter is no longer available in the all data assets search, and classic terms no longer appear on asset details pages.

View governed asset details

Select a governed asset from the search results to view its details. On the asset details page, select the **Governance** tab to see how the asset is governed. The **Governance** tab shows:

- Data products the asset is part of.
- Glossary terms linked to the asset.
- Critical data elements associated with columns in the asset.
- The latest data quality score, if a data quality run was performed on the asset.

The **Governance** tab follows existing permission models. If you have a Catalog Reader role, you see only published governance concepts. Draft concepts, such as draft glossary terms, are visible only to Data Product Owners and Data Stewards.

If an asset is deleted from Data Map, a warning icon appears next to the asset in search results. The asset continues to appear until the Data Product Owner removes it.

> **Note**

If an asset is ungoverned (all links to data products, glossary terms, and critical data elements are removed), the asset currently still appears in governed assets search results.

Bulk edit search results

If you want to make changes to multiple assets returned by search, you can modify glossary terms, classifications, and contacts in bulk. For more information, see How to bulk edit assets.

View assets

From the search results page, select an asset to view details, such as description, attributes, schema, lineage, and classifications.

Browse the Unified Catalog

Unified Catalog offers a browse experience that enables users to explore what data is available to them either by collection or by exploring the hierarchy of each data source in the catalog.

In Unified Catalog, go to **Discovery** > **Data assets**. Under **Explore your data**, select a card for how you want to explore your data: in Azure, in Microsoft Fabric, by source type, or by collection.

You can only see the data sources you have permission to view.

Searching Microsoft Purview in connected services

After you register your Microsoft Purview instance to an Azure Data Factory or an Azure Synapse Analytics workspace, you can search Unified Catalog directly from those services. For more information, see Discover data in ADF using Microsoft Purview and Discover data in Synapse using Microsoft Purview.

Link glossary terms to assets and columns (preview)

You can add business context to your data by linking glossary terms to data assets and columns.

Users need two roles in order to attach terms to assets and columns:

1. **Data Curator**: All users need to hold this role in the collection where the asset belongs. Only Data Curators can edit data assets. Learn more about this role and collections permissions in Data Map.

2. In addition, users need either one of these roles:
    a. **Data Steward**: Users can be a Data Steward in any governance domian. These users can see published and unpublished glossary terms, and can attach both kinds of terms to assets and columns.
    b. **Global Asset Curator**: This role allows users to attach published glossary terms to assets and columns. Users with this role can only see published terms and attach published terms to assets and columns.

See Data governance roles and permissions for role descriptions and how to assign roles.

Link terms to a data asset:

1. Search for an asset or column in Unified Catalog.
2. Select the data asset to open its details page.
3. Select **Edit**.
4. On the **Overview** page, at **Glossary terms**, select **Add term**.
5. Search for a term by entering keywords, or select the checkbox next to a term listed on the page. You can select multiple terms.
6. Select **Add**.
7. Select **Save**.

The terms are attached to the asset.

Link terms to a column within an asset:

1. Search for an asset or column in Unified Catalog.
2. Select the data asset to open its details page.
3. Select **Edit**.
4. On the **Schema** page, find the row for the column you want to add a term to, and select **Add term**.
5. Search for a term by entering keywords, or select the checkbox next to a term listed on the page. You can select multiple terms.
6. Select **Add**.
7. Select **Save**.

The terms are attached to the column.

Keyword search syntax

When you search for data assets, you can use keywords, operators, and field-scoped queries to find exactly the data you need. This article describes the supported query syntax so you can build precise, effective searches.

For a general overview of searching and browsing for data assets, see Search for data assets in Unified Catalog.

> **Note**
>
> The syntax described in this article applies to the **Unified Catalog** > **Discovery** > **Data assets** search experience in the Microsoft Purview portal. Search results are filtered based on your permissions, so you only see assets you have access to. For more information about permissions, see Search for data assets in Unified Catalog.

Quick reference

The following table summarizes the query syntax options available in Unified Catalog search.

Expand table

Syntax	Example	Description
Keyword	`customer`	Search all fields for the keyword.
Multiple keywords	`customer sales`	Search for assets matching either word. Assets matching both words are ranked higher.
AND	`customer AND sales`	Both terms must be present.
OR	`customer OR sales`	Either term can be present.
NOT	`customer NOT draft`	Must contain first term, must not contain second.
Exact phrase	`"sales report"`	Match the exact phrase in order.
Grouping	`(A OR B) AND C`	Control evaluation order.

Syntax	Example	Description
Field search	`name:customer`	Search only within a specific field.
Match all	`*` or empty	Return all assets.

Simple keyword search

A single keyword searches across all searchable fields in the catalog, including asset name, description, qualified name, schema columns, glossary terms, contacts, classifications, custom attributes, collections, domains, and sensitivity labels.

The following example returns any asset where `customer` appears in any searchable field:

```
customer
```

Results are ranked by relevance. An exact match on the asset name scores higher than a partial match in the description.

Multiple keywords

When you enter multiple words separated by spaces without an explicit operator, the search returns assets that contain *any* of the words. Assets that contain more of the keywords are ranked higher in the results.

The following example finds assets that contain `customer`, `sales`, or both:

```
customer sales
```

> **Important**
>
> A space-separated keyword search is **not** the same as an AND search. Consider the following differences:
>
> Expand table

Query	Behavior	Example result
`customer sales`	Matches `customer` OR `sales`. Assets with both score higher.	An asset named "Sales Dashboard" matches even without "customer."
`customer AND sales`	**Both** `customer` AND `sales` must be present.	"Sales Dashboard" doesn't match unless it also contains "customer."
`"customer sales"`	The exact phrase `customer sales` must appear in that order.	Only matches if `customer` is immediately followed by `sales`.

Boolean operators

Boolean operators let you combine search terms with explicit logic. Operators must be written in uppercase (`AND`, `OR`, `NOT`).

AND operator

Use the AND operator when all terms must be present in the matching assets. The terms don't need to be adjacent or in the same field.

```
customer AND sales
azure AND sql AND database
```

OR operator

Use the OR operator when any of the terms can be present.

```
customer OR client
sales OR marketing OR operations
```

NOT operator

Use the NOT operator to exclude assets that contain a specific term.

```
customer NOT draft
```

```
sales NOT internal NOT test
```

The following example returns assets that contain `customer` but don't contain `draft`:

```
customer NOT draft
```

Combine operators

You can chain operators in a single query:

```
customer AND sales NOT draft
```

This query returns assets that contain `customer` and `sales`, but don't contain `draft`.

Exact phrase search

Wrap your query in double quotes to search for an exact phrase. The words must appear in the specified order and adjacent to each other.

```
"sales report"
"customer data analysis"
```

The following table shows how phrase search differs from a keyword search:

Expand table

Query	Matches	Doesn't match
`"sales report"`	"Q1 **sales report** summary"	"report on sales" (wrong order)
`"sales report"`	"Annual **sales report**"	"sales quarterly report" (words not adjacent)

Use `sales report` (no quotes) when you want any asset that mentions `sales` or `report`. Use `"sales report"` (with quotes) when you want only assets that contain the exact phrase.

Grouping with parentheses

Parentheses control the order of evaluation, just like in math expressions.

```
(customer OR client) AND sales
```

Without parentheses, operator precedence can produce unexpected results. The following examples show how parentheses change the query interpretation:

Expand table

Query	Interpretation
`(customer OR client) AND sales`	Assets that contain `customer` or `client`, and also contain `sales`.
`customer OR (client AND sales)`	Assets that contain `customer`, or assets that contain both `client` and `sales`.

You can nest parentheses for more complex queries:

```
(A AND B) OR (C AND D) NOT E
((alpha OR beta) AND gamma) NOT delta
```

Field-scoped search

By default, a keyword is searched across all fields. Field-scoped search lets you restrict the search to a specific field.

Use the syntax `fieldName:value` or `fieldName:"phrase value"`:

```
name:customer
classification:Confidential
entityType:azure_sql_table
contact:alice@company.com
name:"sales report"
```

Supported fields

The following fields can be used with the `field:value` syntax:

Expand table

Field name	Description	Example
`name`	Asset name	`name:customer`
`qualifiedName`	Fully qualified name	`qualifiedName:sales_db.customers`
`description`	Asset description	`description:quarterly`
`userDescription`	User-provided description	`userDescription:important`
`displayText`	Display text	`displayText:customer`
`entityType`	Entity type	`entityType:azure_sql_table`
`assetType`	Asset category	`assetType:Tables`
`classification`	Sensitivity labels or tags	`classification:Confidential`
`endorsement`	Endorsement status	`endorsement:Certified`
`glossaryType`	Glossary type	`glossaryType:AtlasGlossaryTerm`
`termStatus`	Term status	`termStatus:Approved`
`termTemplate`	Term template	`termTemplate:BusinessTerm`
`glossary`	Glossary name	`glossary:Finance`
`fileExtension`	File extension	`fileExtension:csv`
`term`	Assigned glossary terms	`term:Revenue`
`contact`	Owner or expert contact	`contact:john@company.com`
`abbreviation`	Term abbreviation	`abbreviation:ROI`
`objectType`	Object type	`objectType:Tables`
`tag`	Tags	`tag:important`

Field names are case-insensitive. For example, `Name:customer` and `name:customer` produce the same results.

If you use a field name that isn't in the Supported fields table, the search engine doesn't return an error. Instead, it treats the entire expression as an unscoped keyword. For example, `alice AND report:myreport` searches for `alice` AND the literal text `report:myreport` across all fields, rather than restricting `myreport` to a field called `report`.

> **Important**
>
> Only one value token is captured after the colon. To search for a multiword value, use quotes:
>
> Expand table
>
> | Query | Behavior |
> | --- | --- |
> | `name:sales report` | Searches `name` for `sales`, then separately searches all fields for `report`. |
> | `name:"sales report"` | Searches `name` for the exact phrase `sales report`. |

Nested fields

Some supported fields, such as `contact` and `term`, represent composite data with multiple properties. For example, a contact has a display name, an email address, and an ID.

You can't use dot notation to target a specific property. The system only recognizes the top-level field names listed in the Supported fields table.

Expand table

Query	Supported	Behavior
`contact:Alice`	Yes	Searches across all contact properties (display name, email, ID).
`contact.displayName:Alice`	No	Not recognized as a field-scoped search.
`term:Revenue`	Yes	Searches across all term properties (name, glossary).
`term.name:Revenue`	No	Not recognized as a field-scoped search.

Use the top-level field name. For example, `contact:Alice` searches across all contact properties and returns assets where any property matches.

Combine keywords with field-scoped search

When you mix a plain keyword with a field-scoped search, a space doesn't imply AND. Space-separated clauses are treated as OR.

Expand table

Query	Behavior
`alice contact:bob`	`alice` OR contact contains `bob`.
`alice AND contact:bob`	`alice` AND contact contains `bob`.

> **Tip**
>
> Always use explicit `AND` or `OR` operators when combining keyword search with field-scoped search.

Match all results

An empty query or `*` returns all assets, subject to your permissions and any applied filters.

```
*
```

This option is useful as a starting point when you want to browse assets by using only filters and facets.

Case sensitivity

Search is generally case-insensitive. Searching for `Customer`, `customer`, or `CUSTOMER` returns the same results.

However, the casing and special characters in your search query can affect the number of results returned. Certain fields are processed by the search engine, which splits terms at specific boundaries before matching.

Token-splitting delimiters

The following boundaries cause a term to be split into separate tokens during both indexing and searching:

Expand table

Delimiter	Example input	Tokens produced
Case change (lowercase to uppercase)	`CustomerOrder`	`customer`, `order`, `customerorder`

Delimiter	Example input	Tokens produced
Underscore (`_`)	`customer_order`	`customer`, `order`, `customer_order`
Hyphen (`-`)	`customer-order`	`customer`, `order`, `customer-order`
Dot (`.`)	`customer.order`	`customer`, `order`, `customer.order`
Comma (`,`)	`item1,item2`	`item1`, `item2`
Colon (`:`)	`db:schema`	`db`, `schema`
Whitespace	`customer order`	`customer`, `order`
Letter-to-number transition	`version2release`	`version`, `2`, `release`
Number-to-letter transition	`2ndEdition`	`2`, `nd`, `edition`

> **Note**
>
> Splitting is cumulative. A name like `Customer_Order_Details` is split at every underscore and at every case-change boundary within each segment, producing tokens such as `customer`, `order`, `details`, `customer_order`, and `order_details`.

How casing affects results

When your search query contains mixed case (such as PascalCase or camelCase), the search engine splits it at case-change boundaries, producing multiple tokens. Each token is independently matched, which broadens the result set.

When your query is all lowercase, there are no case-change boundaries to split on, so it stays as a single token and must match as a contiguous string.

The following example illustrates the difference:

Expand table

Search query	Behavior	Effect on results
`CustomerOrder`	Split into tokens: `customer`, `order`, `customerorder`	Matches assets containing `customer` or `order` or `customerorder`. Broader results.
`customerorder`	Stays as one token: `customerorder`	Matches only assets containing the contiguous string `customerorder`. Narrower results.

Phrase search and casing

Quoted phrase search also interacts with casing. With `"CustomerOrder"` in quotes, the query tokens are still `customer`, `order`, `customerorder`, but because it's a phrase search, the tokens must appear adjacent and in order.

Expand table

Phrase query	Matches	Doesn't match
`"CustomerOrder"`	`CustomerOrder`, `FAC_Customer_OrderLine` (where `customer` and `order` are adjacent tokens)	`legacy customer database` (no adjacent `order` token)
`"customerorder"`	`CustomerOrder` (indexed as contiguous `customerorder`)	`FAC_Customer_OrderLine` (no contiguous `customerorder` token)

Recommendations for casing

- For the broadest results, use the natural casing of the term (for example, `CustomerOrder` or `SalesReport`). The case-change splitting finds partial matches.
- For the most precise results, use all lowercase (for example, `customerorder`) or use an exact phrase search with quotes.
- When in doubt, search for both forms or use explicit Boolean operators: `CustomerOrder OR customerorder`.

Result ranking

When a search returns multiple results, they're ordered by a relevance score. The following factors influence ranking, from highest to lowest impact. The exact ranking logic is subject to change as the relevance engine is continually tuned.

Where the match occurs

Not all fields carry equal weight. A match in the asset name is considered more relevant than a match in the description or other fields:

Expand table

Priority	Match type	Example
Highest	Exact match on asset name	Searching `customers` when the asset is named exactly `customers`.

Priority	Match type	Example
High	Case-insensitive exact match on name	Searching `Customers` when the asset is named `customers`.
Medium	Partial match on name or qualified name	Searching `customer` when the asset is named `CustomerOrderTable`.
Standard	Match in description, display text, classification, entity type, or other fields	Searching `customer` when the word appears in the asset description.
Lower	Match in schema columns, glossary terms, contacts, or custom attributes	Searching `customer` when a column named `customer_id` exists on the asset.

Within each level, assets matching more of the search tokens score higher than assets matching fewer.

Asset type

Leaf-level assets, such as individual tables, files, and glossary terms, receive a ranking boost over container assets like databases or storage accounts. When you search for `sales`, a table named `sales_data` typically ranks above the database that contains it.

Data completeness

Assets that are more fully curated receive a ranking boost. Each of the following signals independently contributes to a higher score:

- Has a description
- Has one or more classifications (sensitivity labels)
- Has one or more glossary terms assigned
- Has owners or experts defined
- Has schema or column information
- Has custom attributes populated
- Has sensitivity labels applied

Endorsement status

Endorsed assets rank higher than nonendorsed ones. **Promoted** assets receive a moderate boost, and **Certified** assets receive a boost that stacks with Promoted when both apply.

Freshness

Recently updated assets receive a slight ranking boost over stale ones. The boost decays gradually.

Popularity signals

Usage-based signals contribute to ranking, including modification frequency, data quality score, and user rating.

Personalization

When you perform a search, assets where you're listed as an owner or expert receive a small boost, making your own assets easier to find.

Smart keyword detection

The search system recognizes certain keywords and adjusts ranking:

- `my`: Boosts assets where you're an owner, expert, or recent editor.
- **Object type keywords**: Searching for a recognized asset category (such as `Tables`, `Files`, or `Folders`) boosts assets of that type.
- **Classification keywords**: Searching for a term that matches a known classification name (such as `PII` or `Confidential`) boosts assets with that classification.

> **Note**
>
> When an explicit sort order is applied (for example, sort by name or update time), relevance scoring is only used as a tiebreaker when two assets have the same sort value.

Query limits

Expand table

Limit	Value
Maximum keyword length	1,024 characters. Longer queries are truncated.

Known limitations

Grouping isn't supported within a field search. For example, `name:(alice AND bob)` is invalid syntax. Use `name:alice AND name:bob` instead.

Enterprise glossary (preview)

10/10/2025

This article helps you understand the Enterprise glossary (preview) area of Microsoft Purview Unified Catalog, where you can browse and search for published business concepts, such as governance domains, glossary terms, critical data elements, and objectives and key results (OKRs).

As a consumer of the catalog, you can discover data products through the search experience and through the enterprise glossary experience that links different business concepts to data products. This experience has three tabs for glossary terms, critical data elements, and OKRs, and gives you a consolidated view of all the published concepts within. Once you find the concept you're looking for, you can view the related data products and request access to the ones you need.

Prerequisites

To browse the enterprise glossary, you need a catalog reader role.

Search for business concepts in the catalog

You can browse and search for published business concepts within Unified Catalog.

1. In the Microsoft Purview portal, open **Unified Catalog**.
2. Under **Discovery**, select **Enterprise glossary**.
3. Select the **Governance domains**, **Glossary terms**, **Critical data elements**, or **OKRs** tab to learn more about published concepts under each concept.

> **Note**
>
> - You can visualize any parent/child relationships in a tree-like hierarchy within the **Glossary terms** tab by selecting **Tree** in the views drop-down.
> - The list view displays all published glossary terms but the tree visualization doesn't display terms with unpublished parents.

Search for any concept by name in the search bar. You can sort the results in ascending or descending alphabetical order, and filter results by governance domain, owner, or any other available filter.

Select a published concept to view its related concepts, such as data products.

Filter your view by custom attributes

Use business concept attributes as a filter when browsing and searching for business concepts.

1. In the Enterprise glossary, select the tab for the concept you want to search. If you're searching in a governance domain, select **View all** on a business concept card.
2. Select **Add filter**.
3. At **Filter**, select an attribute name from the dropdown list.
4. At **Operator**, select a condition, such as **Equals** or **Starts with**, which varies based on the kinds of values allowed by the attribute.
5. At **Value**, enter your value.
6. Select **Apply**.

Request access to linked data products

Manage data product access policies

> **Note**
>
> This article explains how to set access policies on business concepts including governance domains, data products, critical data elements, and glossary terms, and how to manage access requests. If you need to request access for yourself, see Request access to data products.

Access to a data product in Microsoft Purview Unified Catalog grants users permissions to the data product and permissions to the data assets within the data product. This article explains how you can manage access to your data products and set up a system to provide access to users who request it.

This article explains:

- How to set up a data product access policy.
- How to manage and approve access to data products.

Permissions

- To view and manage policies at the governance domain level, you need governance domain owner permissions.
- To view and manage policies at the data product level, you need data product owner permissions.
- To view and manage policies in critical data elements or glossary terms, you need data steward permissions.
- Unified Catalog readers can view and request access to data products.
- Managers and privacy approvers of access requests also need to have a minimum of a catalog reader to be able to use the Unified Catalog and approve requests as part of the tiered approval.

Considerations

In this experience, request approvers must provide access to the individual data assets manually as part of the approval process, or specify an access provider to do so.

The product doesn't enforce policies such as attestations (including the no copy attestation). The data consumer attests that they'll follow these policies while requesting access.

Skip the access policies and workflow setup

If you use an external solution for access management or don't want to have access requests on a data product, you can disable this feature during data product curation. When you disable access management on the data product, no access policies from business concepts, workflows, or the request access button apply to that data product.

To disable the access process on a data product:

1. Select the data product in a draft state.
2. Select the **Manage policies** tab.
3. Scroll down to the workflows section of the tab to the checkbox **Disable Access Management** and make sure it's checked.

Set up data product access policies

To build access policies, you usually need data product owner or data steward permissions.

> **Tip**
>
> Your data product needs to be in an unpublished state to manage access policies.

1. In the Microsoft Purview portal, open Unified Catalog.
2. Under **Catalog management**, select **Data products**, then select a data product.
3. On the data product's details page, select **Manage policies**. Here you can view and edit the default values assigned to the default set of data product access policies. The selected values affect what the data consumers see on their access request form and actions they need to take.
4. Under **Permitted access**, add your usage purposes, which are the authorized purposes for accessing and using the data product. Three purposes are provided by default. You can add more purposes and their descriptions, which the consumer can select in the request access form.
5. At **Approval requirements**, determine if manager approval or a privacy and compliance review is required.

   > **Note**

If you select these options, the access request form shows that a manager approver or a privacy and compliance review is required. The consumer's manager in Microsoft Entra ID is notified for the first tier of approval. The privacy reviewer named by the consumer in the request form is notified for their approval. The request is first reviewed by manager, followed by the privacy reviewer, and then by the access request approvers for approval and granting of access. The optional access provider tier is last, if selected. The request status is final only when all configured levels of approval are complete.

6. Under the **Approval requirements** dropdown, in **Access request approvers**, select the users that need to approve the access request. The first approver to take action approves the request and proceeds to grant access to the data assets manually, records the status of access provisioned at each asset, and specifies data access instructions or comments to the data consumer. By default, data product owners are populated and you can add more approvers. You can also add Microsoft Entra ID groups or security groups as approvers. Approvers can see detailed status in the request view.

7. An optional tier called **Access provider** can be set explicitly to grant access to the data assets manually, record the status of access provisioned at each asset, and specify data access instructions or comments to the data consumer. This practice ensures the data consumer is aware of the next steps they can take to access and use the data.

   > ⓘ **Note**
   >
   > You can select a role group to grant approver status to all the users in a group at once. However, users who belong to nested groups within the role group aren't supported at this time.

8. Under **Attestations**, determine if copies of the data are permitted. The attestations are reflected on the access request form for the consumer to attest to.

9. If terms of use are present on a data product, those terms are also reflected on the access request form for the consumer to attest to.

10. Add any more attestations by selecting **Add attestation** and adding a display name and the file location. These attestations are reflected on the request access form for the consumer to attest to.

11. If there are policies inherited from the governance domain, critical data element, or glossary term, you can see them in the **Inherited policies** tab. See the following section in this document for details: Policies on governance domains and glossary terms (inherited policies).

12. Select **Preview request form** to see what users see when they request access.

13. Select **Save changes** to save the access policy for the governance domain.

Policies on governance domains, glossary terms, and critical data elements (inherited policies)

You can set policies on governance domains, glossary terms, and critical data elements. Data products in the governance domain, or data products that have glossary terms or critical data elements applied, inherit and aggregate these policies.

You can see the inherited policies in the data product manage policies view, in a separate tab called **Inherited policies**. You can see the aggregated view by selecting the **Preview** button. Your data consumers see this aggregated view when they request access.

For example, if you set a manager approval policy on a glossary term applied to the data product, the data product also requires manager approval. Any attestation set on a business concept (governance domain, data product, glossary term, or critical data element) is aggregated on the data product, and the data consumer attests to all required attestations when requesting access.

To build access policies on governance domains, glossary terms, or critical data elements, you need governance domain owner or data steward permissions.

1. In the Microsoft Purview portal, open Unified Catalog.
2. Select the **Catalog management** dropdown and select **Governance domains**.
3. Select a governance domain.
4. On the governance domain page, select **Manage policies**.
5. Alternately on a glossary term or critical data element page, select **Manage policies**.
6. From the Policy configuration window, you're able to create and manage relevant access policies.

Configure inherited policies

In the **Manage policies** window, you can view and manage the default set of access policies on each business concept. The selected values affect what the data consumers see on their access request form and actions they need to take.

1. Determine if manager approval is required. The data consumer's manager, configured in Microsoft Entra ID, is notified as first tier of approval. If the request is approved, the request proceeds to the next tier.

2. Determine if copies of the data are permitted. This selection is reflected on the access request form for the consumer to attest to.

3. Add any more attestations you want by selecting **Add attestation** and adding a display name and the file location. These attestations are reflected on the request access form for the consumer to attest to.

View and manage access requests

> **Important**
>
> The **Requests** page in **Catalog management** shows only the access requests from the existing published data products before the new workflow feature became available on 11/12/2025. All access requests and other approvals moving forward are in the **Requests and approvals** tab under the **Waiting for my response** screen. The process and approvals are the same.

To view access requests in Unified Catalog, follow these steps. When you select an access request, the **Access Request** flyout pane opens. It contains details about the request and its status. You see only requests for which you're an approver.

1. In Unified Catalog, select **Catalog management**, then select **Requests**.

2. In the status column of the governance domain table, sort by any domains that have open access requests.

3. Select the governance domain that you want to manage access requests for.

4. On the access requests tab, you see a list of the most recent access requests.

5. Select the access request you want to respond to.

6. View the details submitted by the consumer.

7. Select **Approve** or **Deny**.

8. If you're the last approver in the sequence of approvers (a data product access request approver or an explicit access provider), record the status of access provisioned at each asset and specify data access instructions or comments to the data consumer. This practice ensures the data consumer is aware of the next steps they can take to access and use the data.

9. The data consumer is notified once you respond to the request.

10. The requestor is notified via email and can also view the status on the Microsoft Purview Unified Catalog **Discovery** drop-down, **Data products** page, in the **My data access tab**.

Request statuses

- **Pending**: The request is sent to an approver for review.
- **Declined**: The request is denied by the approver.
- **Approved**: The request is approved, but provisioning work isn't yet completed to grant access to the requestor.
- **Completed**: The data asset is provisioned to grant access for the requestor. This request is now fully complete.

Respond to access requests through email notification

1. In the email you receive as a request to approve an access request, select the **Approval** request link.

2. You're brought to the request detail view in **Requests** page in **Catalog management** .

3. View the details submitted by the consumer.

4. Select **Approve** or **Deny**.

5. If you're the last approver in the sequence of approvers, a data product access request approver, or an explicit access provider, record the status of access provisioned at each asset and specify data access instructions or comments to the data consumer. This step ensures the data consumer is aware of the next steps they can take to access and use the data.

6. If you're the last approver in the sequence of approvers, and there are multiple data assets in the data product, you can record the status and save intermittently and mark the request as complete only when you're done with all the data assets.

7. The data consumer is notified once the request is responded to and in its final state.

8. The requestor is notified via email and can also view the status on the Microsoft Purview Unified Catalog **Data product search** page, in the **My data access** tab.

Sequential or tiered approvals and request statuses

As noted in the section to manage policies on data product, depending on the approver selections you make, a sequential or tiered approval is in effect. The following sequence is maintained for data product access request approvals.

1. If you select manager approval, the consumer's manager in Microsoft Entra is notified for the first tier of approval.
2. Only after the manager approves the request, the privacy reviewer if selected is notified for their approval or can take action.
3. Once approved by the privacy reviewer, the access request approver is notified for approval and provisioning of access to the data assets in the data product. This tier approves and completes the request if there's no access provider specified, else they only approve.
4. If there's a last tier of access provider specified, then that tier provisions access to the data assets and records the status and instructions for data consumer. They complete the request. Complete is the final status.
5. The workflow proceeds until the last approval and completion occurs or the first denial occurs.
6. The data consumer is only notified after all approvers take their respective actions.
7. At any point the data consumer can see the status of the request in the Microsoft Purview Unified Catalog **Discovery** drop-down, **Data products** page, in the **My data access** tab.
8. A request status can go from pending to declined or pending to approved and then to completed.

Delete access requests

To revoke a user's access to a data product and the data assets within the data product, the request approver needs to complete both of the steps listed below.

> **Note**
>
> The only request approver who can remove access to a data product and delete an access request is the owner of that same data product. This data owner must also hold the Data Product Owner role.

1. Return to the individual data asset (such as in Azure Data Lake, Microsoft Fabric, or SQL) and manually remove the provisioning for the user.

2. Delete the request in Unified Catalog by following these steps:
    a. In Unified Catalog, select **Catalog management**, then select **Requests**.
    b. Select a governance domain, then select the name of the request you want to delete.
    c. On the **Access Request** flyout pane, select **Delete**.

If you remove the provisioning on the asset but don't delete the access request in Unified Catalog, the data product shows that the user's access is removed, but the user still has access to the underlying data assets.

Last updated on 11/19/2025

Request access to data products

10/10/2025

> **Note**
>
> This article explains how to request access to a data product. To manage access to data products, see Manage data products access policies.

Follow the steps in this article to request access to a data product and its assets in Microsoft Purview Unified Catalog.

Considerations

In this experience, the approvers of the request must provide access to the individual data assets manually as part of the approval process or specify an access provider to do so and record the status of access provisioned.

When you receive confirmation that your request is approved or see the status change on the Unified Catalog **Data product search** page in the **My data access** tab, you can view the details on how to access and use the data. Learn how to access and use data products.

How to request access to a data product

If you discover a data product in the catalog that you want to access, you can request access directly through Microsoft Purview. The request triggers a workflow that asks the owners of the data resource to grant you access to the data product.

This article outlines how to make an access request.

1. In Unified Catalog, select **Discovery**, then select **Data products**.
2. To find a data product, search or browse for it by entering a keyword or natural language in the search bar.
3. Select the data product to open the data product details page.
4. Select **Request access**.
5. Fill in the form. The form is different depending on your organization and the data product, but provide all information.
6. When you're finished, select **Send**.

Approval requests are sent to all involved parties. When your request is approved or rejected, you get an email notification.

How to view data product access requests

You can see all your requests in Unified Catalog by selecting **Discovery**, then **Data products**, and selecting the **My data access** tab.

Select a data product name to open the **Access Request** flyout pane. This detailed request view helps you understand the approvals or actions taken, and view the asset level access provisioning status and any instructions, if provided.

Request statuses

- **Pending**: The approver receives the request for review.
- **Declined**: The approver denies the request.
- **Approved**: The approver grants the request but hasn't finished provisioning access for the requestor.
- **Completed**: The data asset is provisioned, and the request is fully complete.

How to cancel an access request

You can cancel an access request if it isn't in the **Completed** status. To cancel an access request:

1. In Unified Catalog, select **Discovery**, then **Data products**, then the **My data access** tab.
2. On the **Access Request** flyout pane, select **Delete**.

If your request is approved and completed, only the data product owner can delete it. The data owner must manually deprovision access to individual assets before deleting a request.

Create workflows to automate processes in Unified Catalog

Workflows in Microsoft Purview Unified Catalog provide a centralized, automated way to manage approval scenarios, such as granting access to data products and publishing data products and glossary terms.

Workflows are automated, repeatable sets of actions or business processes that users can establish to streamline operations in their organization. The available workflows can automate the approval processes for requesting access to, and publishing, data products. Governance teams can use the workflows to automate their desired approval processes.

Workflow types

You can set up customizable workflows in Unified Catalog for these processes:

- Granting access to data products
- Publishing data products and glossary terms

You set up these workflows directly within Unified Catalog. The setup process follows a similar process as the existing data product access request, but gives more options to customize. The new workflows go through a new requests and approvals tab, but with the same out-of-the-box options available for configuration.

> **Note**
>
> Access workflows can be applied to a governance domain or a single data product. Publication workflows can only apply to governance domains.

Prerequisites

To create and manage workflows, users need to hold the **Governance Domain Creator** role for publication workflows, and the **Data Product Owner** role for data product access workflows. Learn more about Unified Catalog roles.

Data product access workflow

A data product access workflow allows you to manage data product access requests and generate approvals. A data product owner can only create a workflow for the data products in their governance domain.

If you previously created workflows in the classic catalog experience, you should update your workflow to the new experience by creating a new workflow for data access at the data product level. If you don't create a new workflow, your existing workflow continues to work.

For any new data products you create, you can only use the new workflow experience described in this article.

Steps to create workflow

You can create workflows from either a data product's details page or from the **Workflows** page.

1. In Unified Catalog, start from either of these locations:

    - **From a data product**:
        a. Under **Catalog management**, select **Data products**, then select the data product you want to create a workflow for.
        b. On the data product's details page, select **Manage policies**.
        c. On the **Manage access policies** flyout pane, under **Approval requirements**, either add your approvers like you're used to **or** select **New Workflow** to edit the approver process. If you choose to use the approvers list in the flyout page, the workflow is automatically generated for you when you select **Save**.

    - **From the Workflows page**:
        a. Under **Process automation**, select **Workflows**.

2. Starting from either location in step 1, you arrive at the **Workflows** page. Select **New**.

3. In the **New workflow** flyout pane, enter a **Name** and an optional description.

4. At **Workflow category**, select **Data product access** from the list.

5. Select **Create**. A base template for the workflow opens, which is where you build your workflow.

6. At **Start and wait for an approval**:

    - Select an **Approval type**:

    - **Pending on all**: If there are multiple approvers for the access request, all approvers must approve the request.
    - **Pending on any**: Only one approver needs to approve the request.
  - The **Title** is automatically filled in as **Approval for data access request**.
  - At **Assigned to**, enter the user name.

7. At **Condition**, select the condition you want to apply, such as **and** or **or**, and set the approval outcome.

8. The **Condition** leads to **If yes** and **If no** outcomes. **If yes** results in the approval of the access request. **If no** results in the rejection of the access request. Within the **Yes** and **No** outcomes, you can add more actions to create extra layers based on conditions.

9. When you're done setting conditions, select **Set scope** at the top right of the page.

10. On the **Set scope** flyout pane, expand the list under the governance domains listed to view its data products. Select one data product or an entire domain of data products. Then select **Save**.

Limitations

1. The current version doesn't support variables for contacts, metadata during the workflow, or email templates.
2. This set of workflows doesn't include external connectors.
3. You can only configure data product access workflows for a single data product or the whole governance domain of data products for the same list of approvers. You can't use these workflows for multiple data products or many domains.
4. If requests exist for a user on a data product in either workflow experience, the user can't create a new request. When you switch to the new workflow, remove all previously approved requests and have users recreate their requests if needed.
5. If the privacy approver is hard coded in a workflow, it won't prepopulate in the request form when filled in by the data consumer.
6. Security groups can be added for approvals, but someone from that group needs to manually approve the access request. This requirement applies for both the privacy approver and data product approver.
7. A security group added to be any approver must be email enabled to receive emails notification during workflow runs.
8. A group can be added to the access request if there are **zero** attestations on that data product. If attestations are required for a data product, only users and service principal

requests are supported.
9. Data access workflows experience and APIs only support user principals. Service principals won't work in the workflow roles.

Data product and glossary term publish workflow

A **Catalog curation** publish workflow lets you automate the publishing of data products and glossary terms for a specific governance domain. It enables governance domain data product owners and data stewards to collaborate more broadly during the drafting process but ensures a final review before publication to the catalog.

If you previously created workflows in the classic catalog experience, you can update your workflow to the new experience by creating a new workflow. If you don't create a new workflow, your existing workflow continues to work.

For any new data products and glossary terms you create, you can only use the new workflow experience described in this article.

Steps to create workflow

1. In Unified Catalog, under **Process automation**, select **Workflows**. You arrive at the **Workflows** page.

2. Select **New**.

3. In the **New workflow** flyout pane, enter a **Name** and an optional description.

4. At **Workflow category**, select **Catalog curation** from the list.

5. At **Workflow type**, select **Data product publish** or **Term publish**.

6. Select **Create**. A base template for the workflow opens, which is where you build your workflow.

7. At **Start and wait for an approval**:

    - Select an **Approval type**:
        - **Pending on all**: If there are multiple approvers for publishing, all approvers must approve the publish.
        - **Pending on any**: Only one approver needs to approve the publish.
    - The **Title** is automatically filled in as **Approval for data product publish**.
    - At **Assigned to**, enter the user name XYZ.

8. At **Condition**, select the condition you want to apply, such as **and** or **or**, and set the approval outcome.

9. The **Condition** leads to **If yes** and **If no** outcomes. **If yes** results in publishing the data product. **If no** results in the data product remaining in a draft state. Within the **Yes** and **No** outcomes, you can add more actions to create extra layers based on conditions.

10. When you're done setting conditions, select **Set scope** at the top right of the page.

11. On the **Set scope** flyout pane, expand the list under the governance domains listed. Select one governance domain for the publication workflow. Then select **Save**.

Adding actions

At the **If yes** and **If no** outcomes, add other actions to the workflow to build multiple levels and tiers based on the conditions. The available actions are:

- Start and wait for approval
- Condition
- Approve data subscription
- Complete data subscription
- Reject data subscription
- Send email notifications

Manage data health in Microsoft Purview Unified Catalog

08/20/2025

Health management refers to the ongoing processes and practices that ensure an organization's data remains accurate, complete, consistent, secure, and accessible throughout its lifecycle. It's a critical aspect of data governance, focusing on maintaining the overall "health" of data, much like how healthcare practices aim to maintain the health of individuals.

Importance of health management:

- **Informed decision-making:** High-quality, reliable data is essential for making informed business decisions.
- **Operational efficiency:** Healthy data reduces the time and resources spent on correcting errors and reconciling inconsistencies.
- **Risk management:** Proper data health management helps mitigate risks associated with data breaches, regulatory noncompliance, and inaccurate reporting.
- **Competitive advantage:** Organizations with healthy data are better positioned to leverage analytics, AI, and machine learning, leading to better insights and innovations.
- **Customer trust:** Ensuring data privacy and accuracy builds trust with customers and partners.

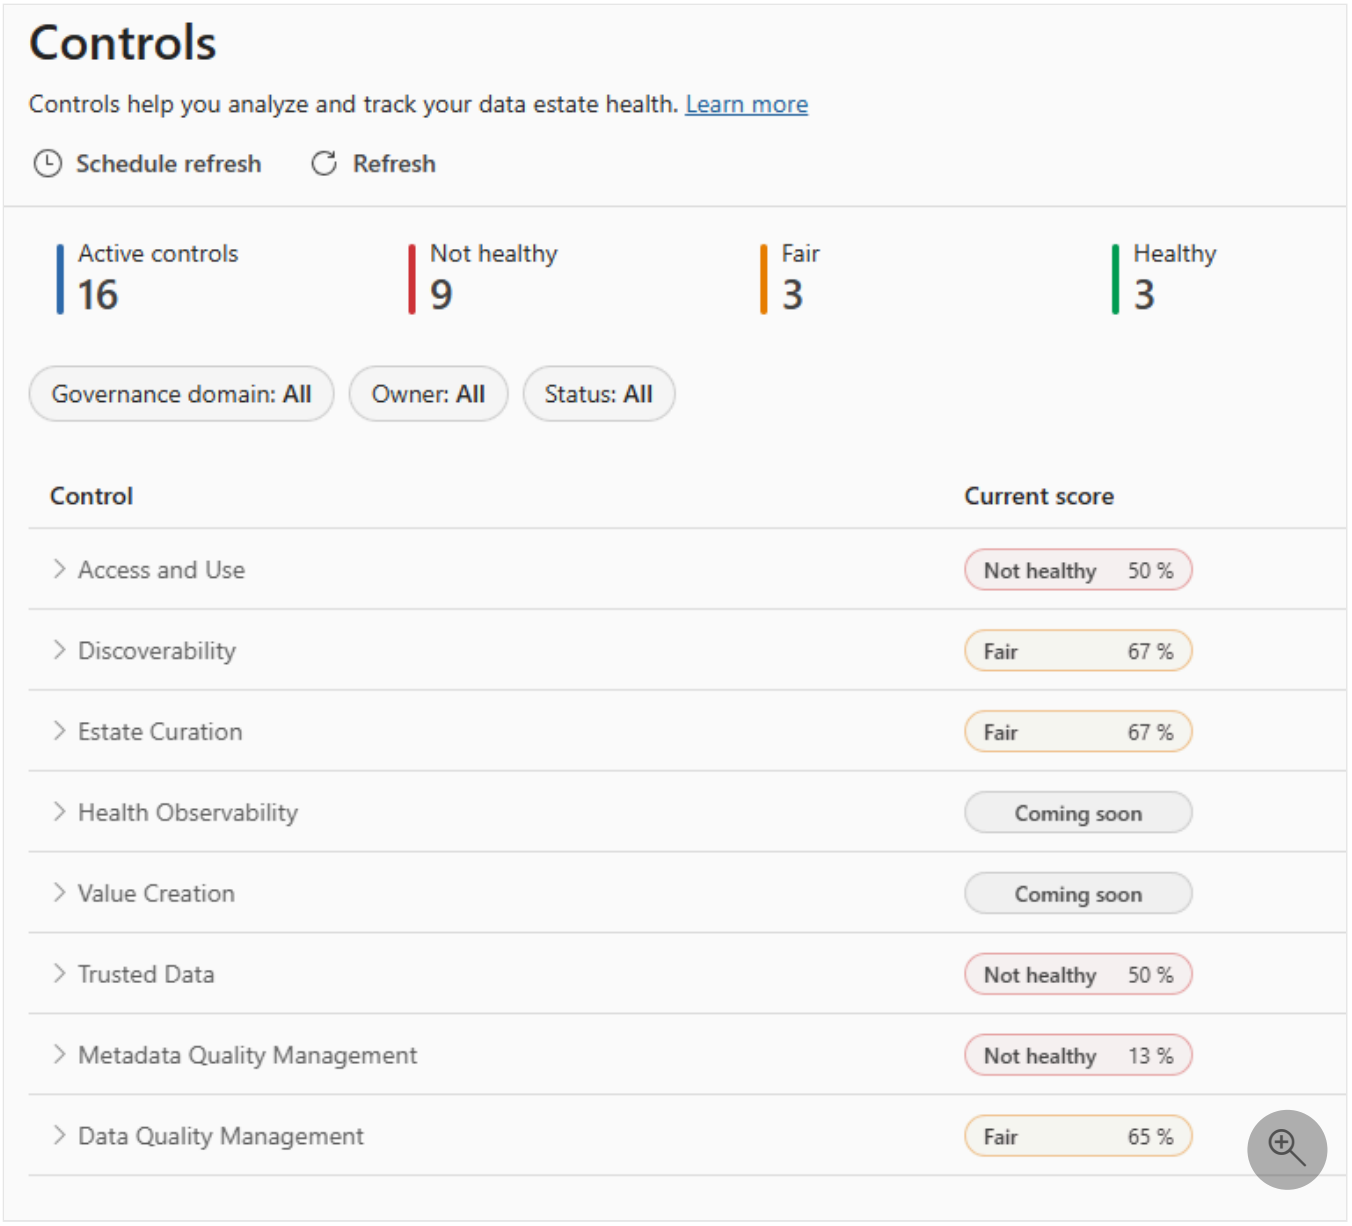
In summary, health management is about maintaining the integrity, reliability, and security of data throughout its lifecycle, ensuring that it remains a valuable asset to the organization.

Unified Catalog health management provides four key components and tools to help you understand your data and develop your data governance strategies:

- Controls
- Data quality
- Actions
- Reports

You can find these tools by opening **Unified Catalog** in the Microsoft Purview portal and selecting **Health management**.

This article provides a brief overview of each tool, its scope, and how you can use it to understand your data and develop your data governance strategies. Users need the **Data health owner** and **Data health reader** roles to access and configure rules for controls and to browse built-in reports.

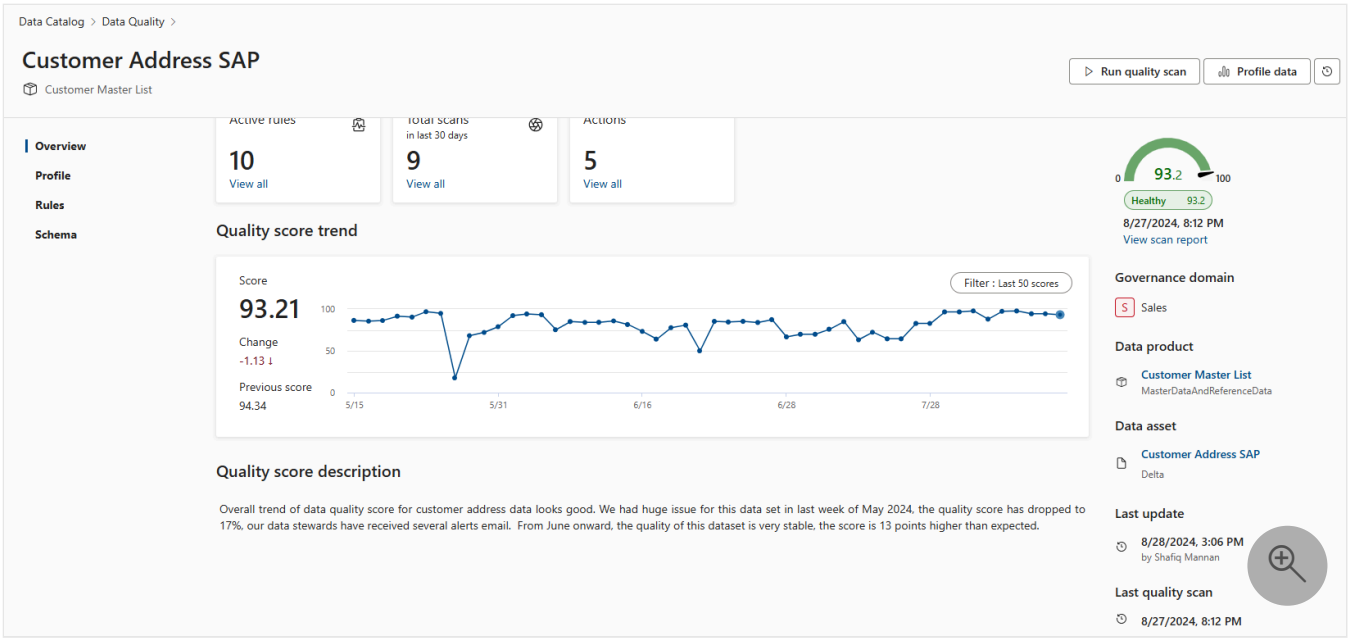


Expand table

Role	Description	Application
Data health owner	Create, update, and read artifacts in health management.	Health management
Data health reader	Can read artifacts in health management.	Health management

Controls

Controls help data stewards and chief data officers evaluate the health of their data estate through industry-recognized standards and controls. Set control rules at a global level but leave execution to individual governance domains. This approach lets you set broad standards while meeting the needs of individual groups in your organization.

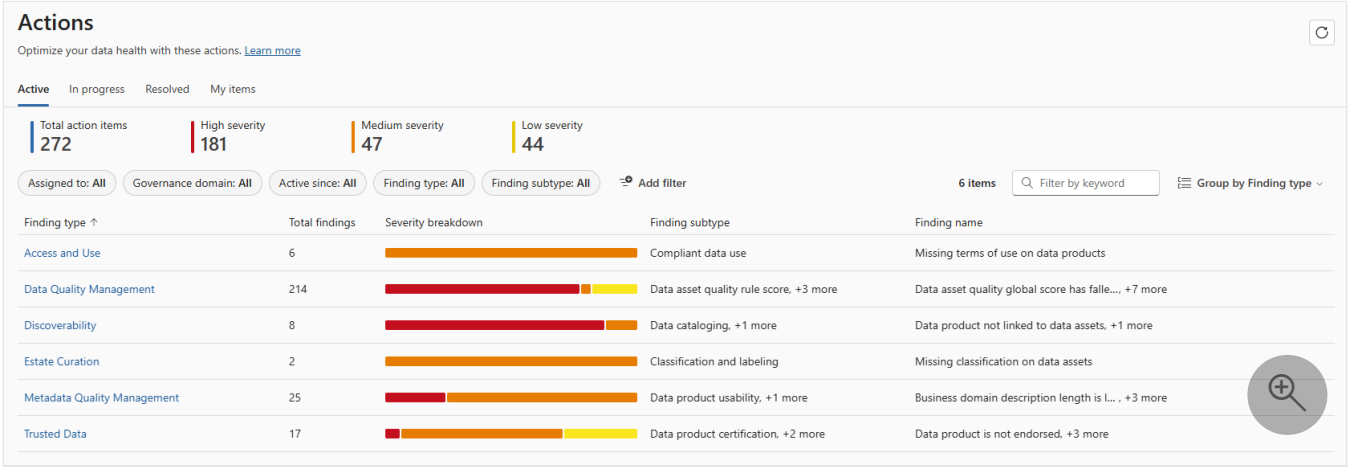


If you're a data health owner, you can edit controls and change the preset health ranges and thresholds to customize how you measure the success of your data estate. You can also edit the schedule for the overall data refresh rate for all active controls. For more information, see the Health management controls article.

Data quality

Microsoft Purview Data Quality is a comprehensive solution that empowers governance domain and data owners to assess and oversee the quality of their data ecosystem, facilitating targeted actions for improvement. In today's AI-driven landscape, the reliability of data directly impacts the accuracy of AI-driven insights and recommendations. Without trustworthy data, there's a risk of eroding trust in AI systems and hindering their adoption.

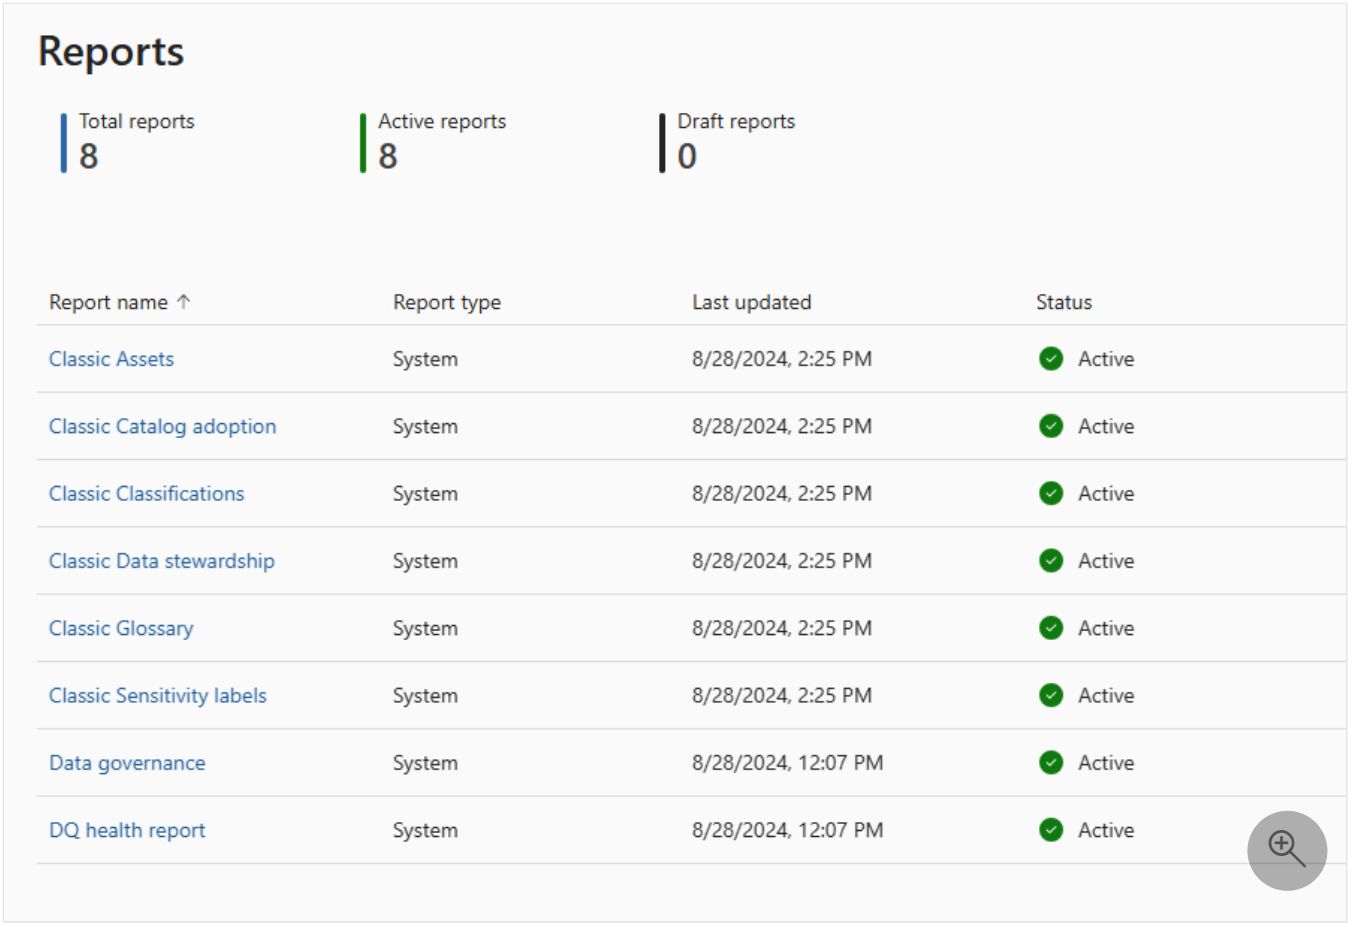
Microsoft Purview Data Quality also incorporates AI-powered data profiling capabilities, recommending columns for profiling while allowing human intervention to refine these recommendations. This iterative process not only enhances the accuracy of data profiling but also contributes to the continuous improvement of the underlying AI models.



Actions (preview)

Health actions give data governance practitioners truly actionable insights. All the anomalies that health controls note become actions, alerts with owners, and recommendations that you can track and address from within Unified Catalog.

As a data steward, you can review actions and filter the list by finding type, finding subtype, and finding name. You can assign a task to anyone in your organization, and that user sees the action in their list. These actions update on the same schedule as the health controls, since actions come from the controls themselves.



Get details about viewing all actions on the Actions (preview) page.

Reports

Data analysts and stewards in the federated data governance office can view built-in reports for deeper analysis of the data estate. These reports give summaries of individual business

concepts like governance domains or data products. They also address data governance goals, catalog adoption, and asset information like classification. For more information, see the health management reports article.

View all data health management actions on the Actions (preview) page

10/15/2025

The **Actions (preview)** page in Microsoft Purview Unified Catalog displays all health management actions related to catalog metadata, controls, and data quality. Health management actions give you and your users steps to take to improve data health and governance across your data estate. These actions correspond to the checks made to calculate a data product's data governance health control score. Addressing these actions raises your health score and promotes a more useful and discoverable Unified Catalog.

Prerequisites

- You need data health reader permissions to view data health information.
- You need data health owner permissions to update and assign health actions.

View health management actions

To view health management actions, go to **Unified Catalog** > **Health Management** > **Actions**. The **Actions (preview)** page shows a list of actions, how long they're active, the target for each action, and the owner.

You can search by keyword or filter these actions by many values, including: assigned to, governance domains, active since, action types, and more.

You can also group actions by selecting **Group by** to view actions by:

- Severity
  - High
  - Medium
  - Low
- Finding types and subtypes
- Finding subtype
- Finding name

> **Tip**
>
> - If you don't see the actions you expect, check the applied filters and group.

- You need the **Data Quality Metadata Reader** role to see the **Target entity** related to the action. The target entity provides a deep link to browse for remediation action.
- You won't see the **Target entity** if it's deleted from the governance domain or data product, or if you don't have the **Data Quality Metadata Reader** role.

Available actions

The actions available are determined by control rules or data quality rules. Learn more about data quality actions.

Here's a list of actions that are available from metadata quality:

Expand table

Finding type	Finding subtype	Finding Name	Severity
Access and use	Compliant data use	Missing terms of use on data products	Medium
	Self-serve access enablement	Missing access policy on data products	Medium
Discoverability	Data cataloging	Data product not linked to data assets	High
		Missing description on data products	High
		Missing published glossary terms on data products	High
		Missing use case on data products	High
	Data products connection	Data product not linked to data assets	Medium
Estate curation	Classification and labeling	Missing classification on data assets	Medium
Health observability	Health management monitoring, alerting, and insights		
Metadata quality management	Data product usability	Governance domain description length is fewer than 100 characters	Medium
		Data product description length is fewer than 100 characters	Medium

Finding type	Finding subtype	Finding Name	Severity
		Published glossary term's description length is fewer than 25 characters	Medium
	Linked assets	Data product description length is fewer than 100 characters	Medium
		Missing published glossary terms on data product	High
Trusted data	Data product certification	Data product isn't endorsed	Low
	Data product ownership	Missing owners on data assets	High
		Missing owners on data products	High
	Data quality enablement	Missing data quality scores on data assets	Medium
Value creation	Business OKRs alignment	Missing OKRs on data products	Medium

> **Tip**
>
> If the actions you see don't match up with these values and severities, check metadata quality. Your organization might have implemented custom checks and severities.

Action details

To see an action's details, select it. You see the action owners, the associated data product and governance domain, as well as its reason and any potential recommendations for resolving it.

Resolve an action

To resolve an action:

1. Assign owners who take steps to resolve the recommendations.
2. The owners investigate the issue based on the provided information and recommendation.
3. The owners update the status to reflect their current progress.
4. When they make the suggested updates, they update the action's status to **Resolved** and save the action.

As the entire health management refreshes in the next scheduled run, it reconciles all resolved actions from the catalog. If you artificially mark an action as resolved but the issue in the catalog remains, the action status changes and is added back to the health actions queue.

Next steps

- Metadata quality
- Health actions best practices

Data health controls in Unified Catalog

10/15/2025

Data health controls help your team analyze and track your health management. Track your journey to complete data governance by monitoring your governance health, and use the provided health controls to track your progress. Data health controls are specific measures, processes, and tools that you implement to monitor, maintain, and improve the quality, security, and overall health of your organization's data. These controls are part of a broader data governance framework and are essential for ensuring that data remains accurate, consistent, and usable across the organization.

Data health controls are essential components of a comprehensive data governance strategy. They help organizations maintain the integrity, security, and usability of their data assets. Some benefits include:

- **Improved data quality:** Ensures that data remains accurate, consistent, and reliable for decision-making.
- **Enhanced security:** Protects sensitive data from breaches, unauthorized access, and corruption.
- **Regulatory compliance:** Helps organizations adhere to legal and industry standards for data management.
- **Operational efficiency:** Reduces the time and resources spent on correcting data issues and ensures that data is readily available and usable.
- **Risk mitigation:** Prevents costly errors and data-related risks that can arise from poor data management.

Prerequisites

- You need data health reader permissions to view data estate health information.
- You need data health owner permissions to update or edit any health controls.

Limitations

- Currently, you can't create custom controls.

Access data health controls

To view controls, go to **Unified Catalog** > **Health management** > **Controls**. The **Controls** page shows your governance scores at the domain level, so you can understand your organization's progress at a glance.

Health controls are grouped into several categories that you can open to view their parts. Category scores are an aggregate of the controls underneath them. They show their current score and their target, so you can see areas for growth.

Select any category or individual health control for a detailed view.

Available health controls

The currently available health controls are:

Expand table

Control grouping	Control	Description
Access and use	Self-serve access enablement	Percentage of data products that have self-serve policies and workflows enabled.
	Compliant data use	Percentage of data subscriptions with a provided data use purpose.
Discoverability	Data cataloging	Percentage of data products that a data product owner publishes in the governance domain.
	Data products connection	Percentage of data products that have data assets mapped.
Estate Curation	Classification and labeling	Percentage of data products and governance domains that are classified and labeled.
	Critical data identification	Percentage of business domains with at least one critical data element.
Value creation	Business OKRs alignment	Percentage of data products aligned with one or more business objectives and key results (OKRs).
Trusted data	Data product ownership	Percentage of data products that have owners assigned.
	Data quality enablement	Percentage of data products with a data quality score.
	Data product certification	Percentage of data products certified by an authorized data product owner in the governance domain.
Metadata quality management	Data product useability	Percentage of data products that have: a description greater than 100 characters, a parent domain with a description of over 100 characters, and a glossary term with at least a 25 character description.

Control grouping	Control	Description
	Linked assets	Percentage of data products with at least one linked asset and published glossary term.

Edit health controls

If you're a data health owner, you can edit your health controls to:

- Edit control details, such as owners, description, and governance domains.
- Activate or deactivate a control to manage scores.
- Configure thresholds to reflect your business goals.

Edit control details

1. On the **Controls** page, expand a control group name to view individual controls.
2. Hover over the name of the control you want to edit and select the **Edit** pencil button. You arrive at the **Details** tab of the **Edit control** page.
3. At **Owner**, add or remove owner names.
4. At **Description**, edit the control's description.
5. At **Domains**, select all governance domains you want to include in the score, and deselect any domains you don't want to include.
6. Select **Save** at the top right of the page to save your changes.

Activate or deactivate a control

You can deactivate any control so that new scores no longer roll up to a control group.

1. On the **Controls** page, expand a control group name to view individual controls.
2. Hover over the name of the control you want to edit and select the **Edit** pencil button. You arrive at the **Details** tab of the **Edit control** page.
3. Select the **Active** toggle to switch the control to the active or inactive state.
4. Select **Save** at the top right of the page to save your changes.

Configure control thresholds

Adjust your health control's target score status, or threshold, to reflect your business goals.

1. On the **Controls** page, expand a control group name to view individual controls.
2. Hover over the name of the control you want to edit and select the **Edit** pencil button.

3. On the **Edit control** page, select **Thresholds**.

4. Make the following adjustments:
   a. Set the overall target score to reflect your goals.
   b. Adjust existing threshold conditions to show any of these statuses:

      - Undefined
      - Healthy
      - Fair
      - Not healthy
      - Critical

   c. Add and remove conditions on existing rules to calculate status based on score.
   d. Add or remove thresholds to calculate your status based on target score.

   > **Tip**
   >
   > To return to the saved calculation before your edits, select the **Reset** command at the top right of the page.

5. Select **Save** at the top right of the page to save your changes.

Configure control rules

Add rules to controls to measure their performance.

1. On the **Controls** page, expand a control group name to view individual controls.
2. Hover over the name of the control you want to edit and select the **Edit** pencil button.
3. On the **Edit control** page, select **Rules**.
4. Select **Add rule**. The **Add rule** flyout pane opens.
5. Search for a rule from the **Data product rules** list and select the rule to add it.
6. Select **OK**.
7. Add the needed parameter and accept it by selecting the check symbol.
8. Select **Save changes**.

Configure rules severity

1. On the **Controls** page, expand a control group name to view individual controls.
2. Hover over the name of the control you want to edit and select the **Edit** pencil button.
3. On the **Edit control** page, select **Rules**.
4. Select **Configure severity**.

5. Select a control name, and update the severity for the **Finding name**. Finding names are the rule names, and you see these finding names as action name if the defined rule fails for the applied severity.

Schedule control refresh

The schedule for the control refresh affects your health management actions and reports, as the controls provide the basis for many of these values. Consider how often you want to evaluate your overall data estate health, and schedule the controls refresh accordingly.

1. On the **Controls** page, select **Schedule refresh**.
2. At **Start**, enter a date, time, and time zone.
3. Set the frequency by selecting a number and choosing between **Days**, **Weeks**, or **Months**.
4. At **Until**, set an end date for the schedule, or leave blank if you want it to continue on the schedule indefinitely.
5. Save the configured schedule.

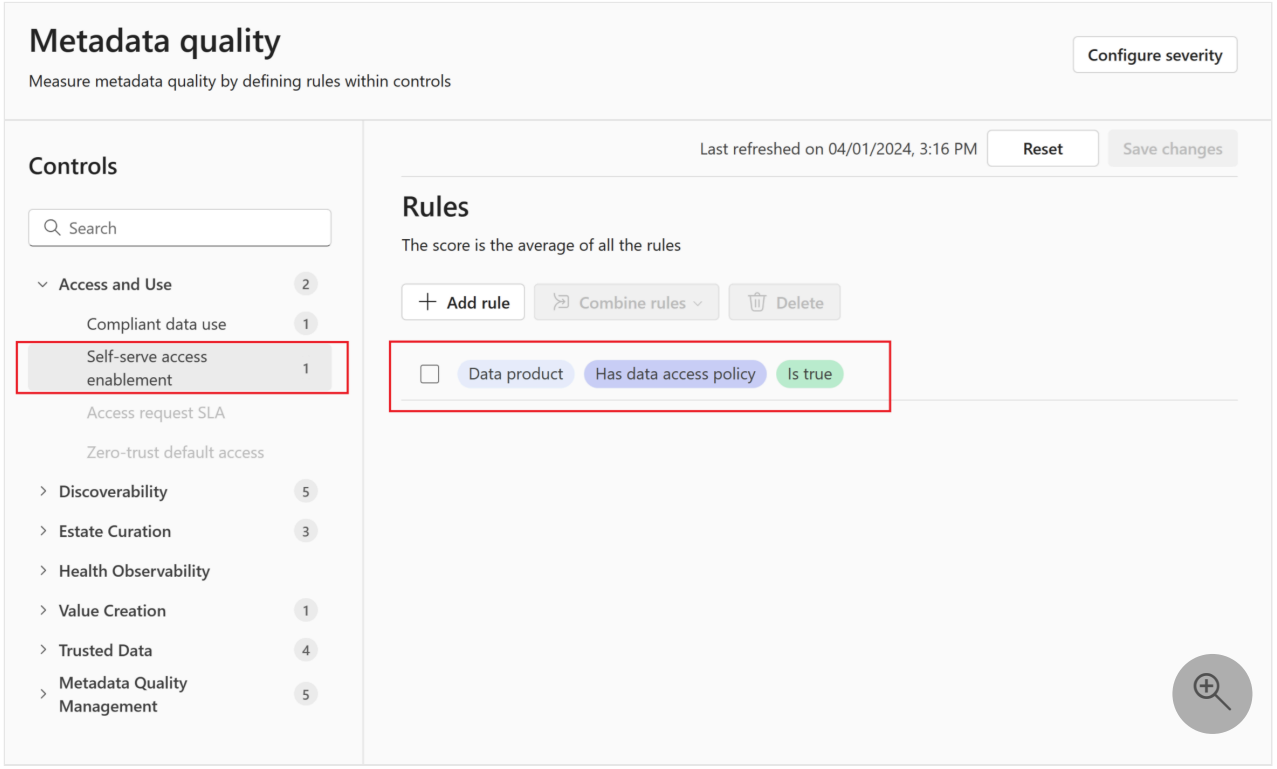
Data health controls pricing

Data health controls usage is billed based on the Data Governance Processing Unit (DGPU) pay-as-you-go meters. The Basic SKU is used for compute of data health controls. Find details on how pricing is computed for data health controls.

Metadata quality in Unified Catalog

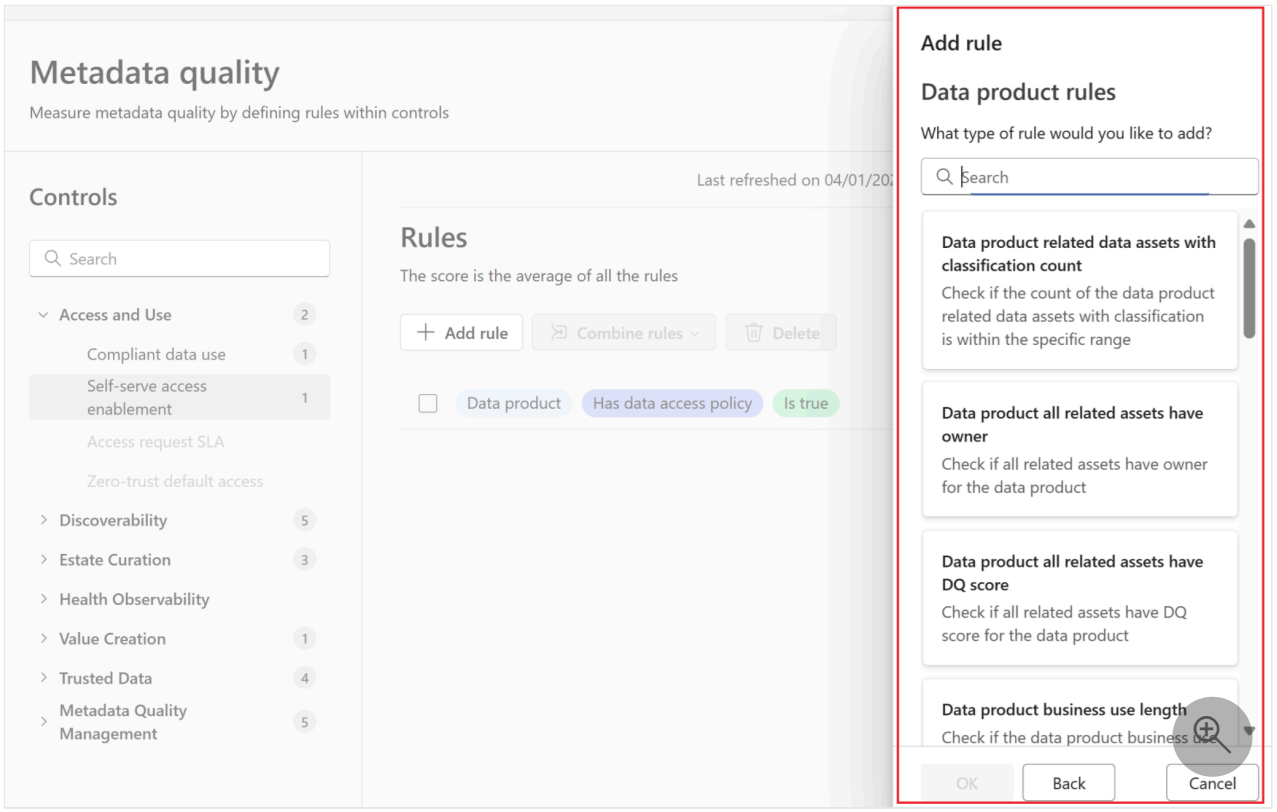
Metadata quality is a low-code or no-code experience for data stewards and members of the Chief Data Officer's office, to write any logic to test the metadata health and quality. Data stewards can write complex logic without worrying about coding, and immediately see results in Microsoft Purview Unified Catalog. Metadata quality comes with a set of predefined logic for each control, that you can read about in the health controls article. As a data steward, you can add more rules to the existing logic, and at the next refresh of the health controls, the new metadata quality logic applies to the metadata based on the scope, such as data product, governance domain, or other entity.

Prerequisites



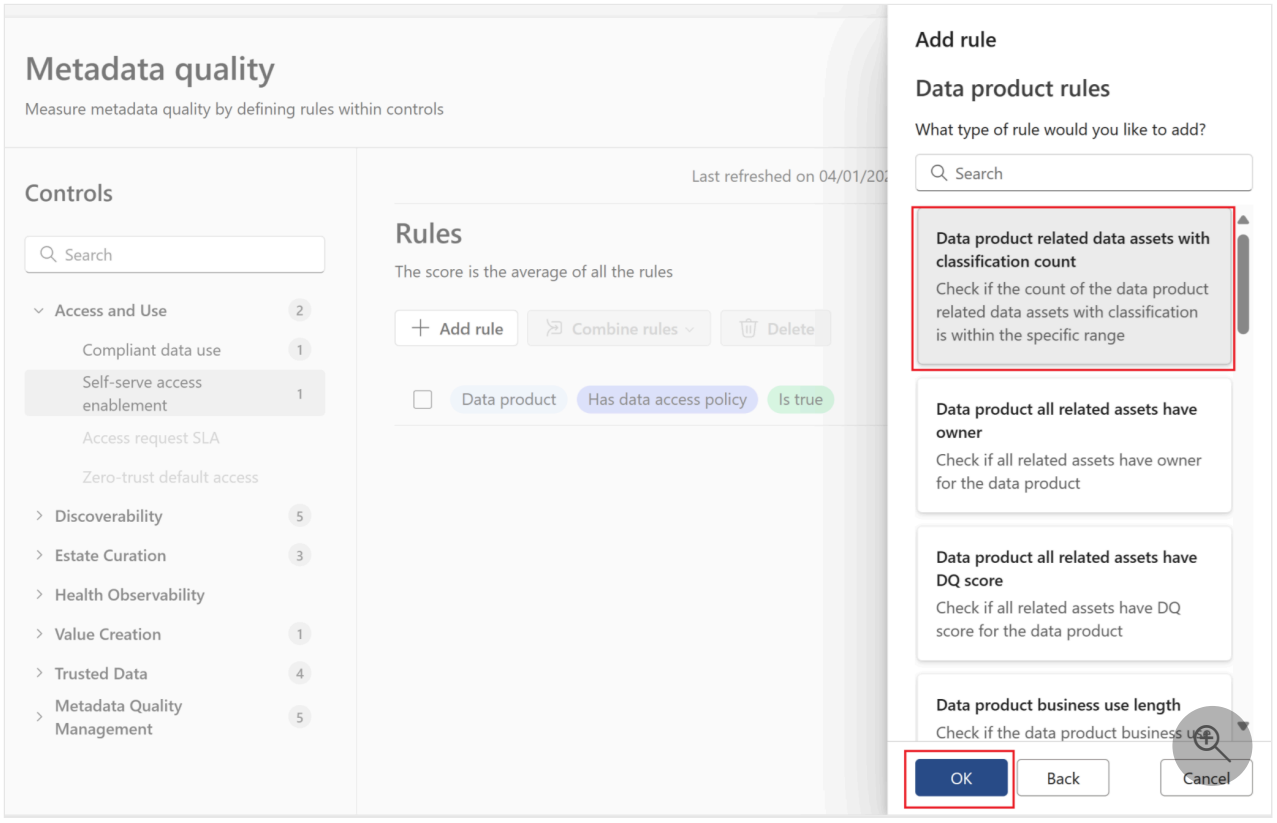
Users need the data health owner role to update and manage metadata quality.

Access metadata quality

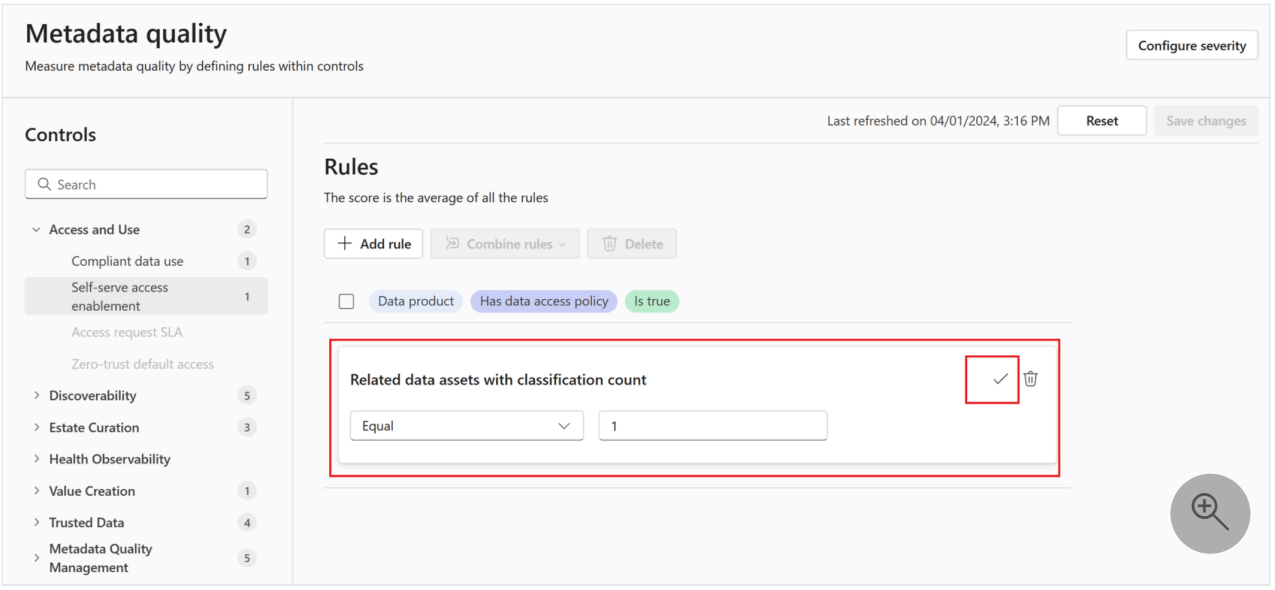


1. In **Unified Catalog**, select **Health management**, then select **Controls**.
2. On the **Controls** page, expand **Metadata Quality Management**.

Add a metadata quality control rule

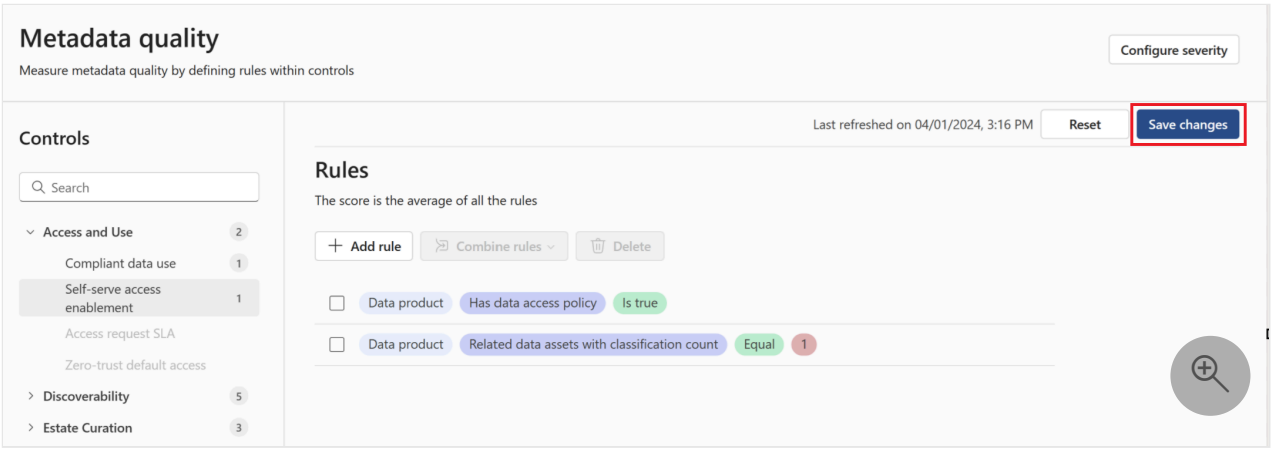


1. On the metadata quality page, select any control to see its list of controls.



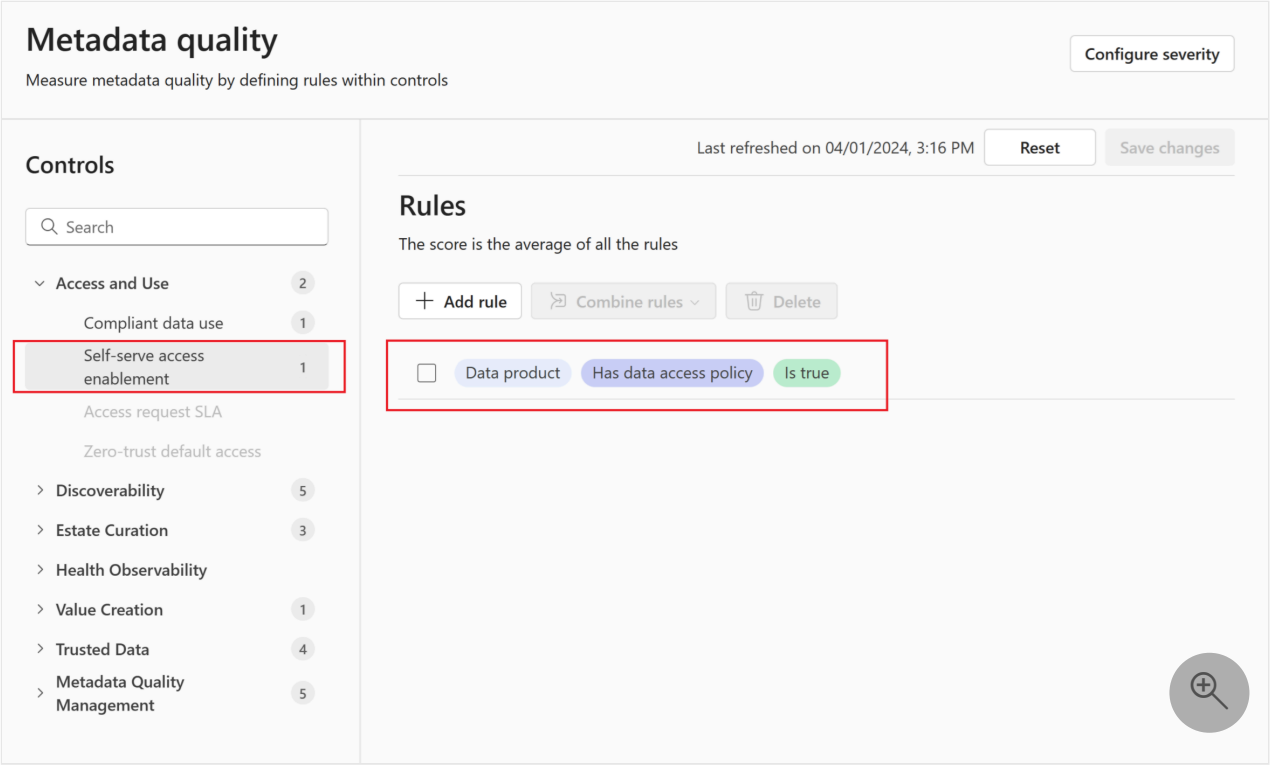
2. Add a new rule by selecting **Add rule**. The **Add rule** flyout pane opens with a list of all available rules for your current scope. (Example scope: Data product)

3. Select a rule, and select **OK**.



4. Select any more parameters required to complete the logic (For example, select the number of data assets with a classification count)

5. Select the checkmark button.



6. Select **Save changes** to save your updates.

> **Note**
>
> As the metadata quality rules run, all pass checks contribute to health control scores, and all failed checks contribute to health control actions.

Edit a metadata quality control rule

1. On the metadata quality page, select any control to see its list of controls.

2. Hover over any existing rule and select the pencil icon to edit, or the trash can icon to delete.

3. If you edit, update any rule logic and select the check mark button.

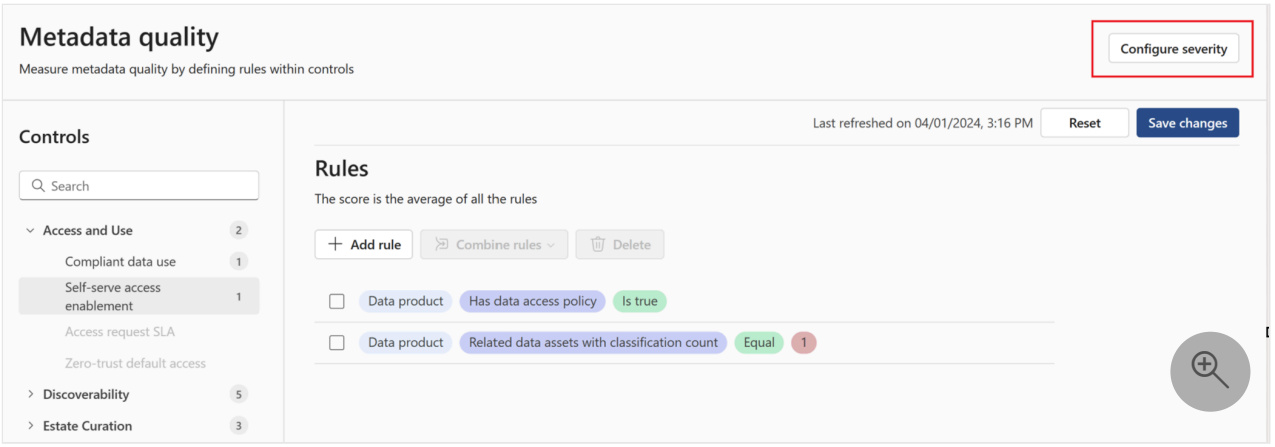
4. Select **Save changes** to save your changes.

Combine rules

1. Select the checkbox next to more than one rule, then select the **Combine rules** button.
2. Select whether you want to combine the rules with the OR or AND operator.
3. Select **Save changes** to save your updates.

Reset all rules

At any time, you can reset all rules back to their default using the **Reset** button. If you do, you lose any customizations you made.



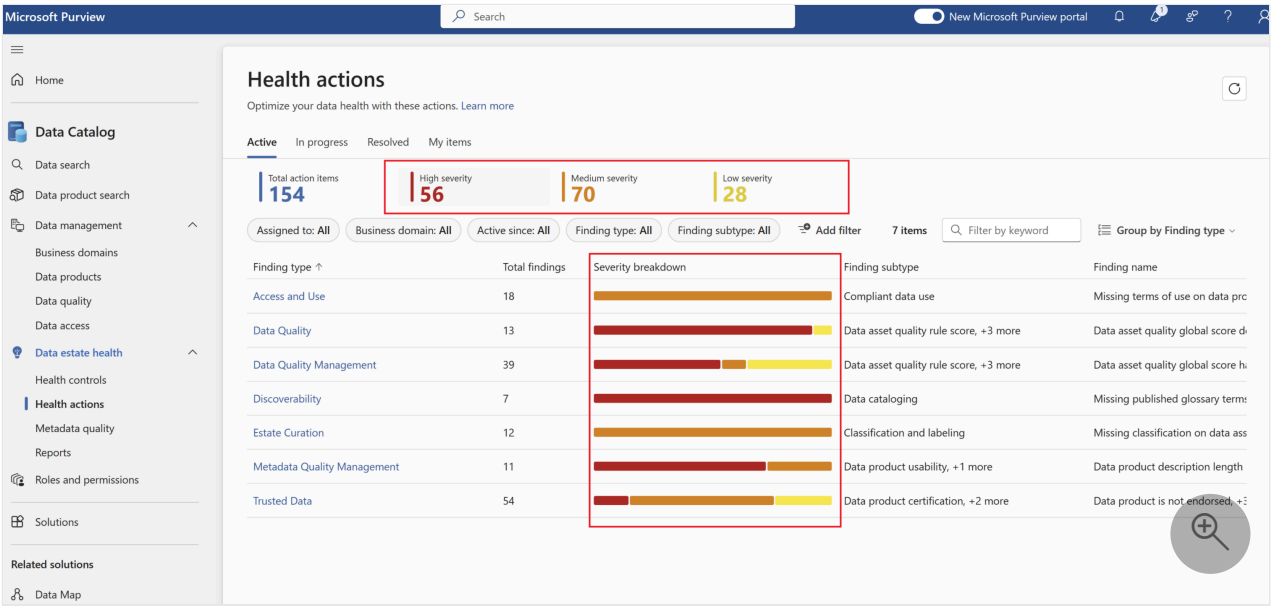
Set severity

Set the severity of your controls to change how they appear in the health actions when rule failures occur.

1. In **Unified Catalog**, select **Health management**.

2. Select **Metadata quality**.

3. Select **Configure severity**.



4. Select a control category, then select your control.

5. For each control, set the severity to one of these options: Low, Medium, High.

6. Select **Save** to save your changes.

7. When metadata quality rules run, your health actions update according to your new settings.

Default actions

Here's a list of the default actions that are available out of the box:

Expand table

Finding type	Finding subtype	Finding Name	Severity
Access and use	Compliant data use	Missing terms of use on data	Medium

Finding type	Finding subtype	Finding Name	Severity
		products	
	Self-serve access enablement	Missing access policy on data products	Medium
Discoverability	Data cataloging	Data product not linked to data assets	High
		Missing description on data products	High
		Missing published glossary terms on data products	High
		Missing use case on data products	High
	Data products connection	Data product not linked to data assets	Medium
Estate curation	Classification and labeling	Missing classification on data assets	Medium
Health observability	Health management monitoring, alerting, and insights		
Metadata quality management	Data product usability	Governance domain description length is fewer than 100 characters	Medium
		Data product description length is fewer than 100 characters	Medium
		Published glossary term's description length is fewer than 25 characters	Medium
	Linked assets	Data product description length is fewer than 100 characters	Medium
		Missing published glossary terms on data product	High
Trusted data	Data product certification	Data product isn't endorsed	Low
	Data product ownership	Missing owners on data assets	High
		Missing owners on data products	High
	Data quality enablement	Missing data quality scores on data assets	Medium
Value creation	Business OKRs alignment	Missing OKRs on data products	Medium

Limitations

Currently, you can edit and manage existing health control metadata quality, but you can't create new controls.

Next steps

- Health actions

Learn about data observability in Unified Catalog (preview)

Data observability in Microsoft Purview Unified Catalog provides a bird's eye view into the health of the data estate as data flows between sources. Data stewards, experts, and those accountable for data health can view their data estate in a single screen, providing the ability to view the lineage of data assets all the way up to the structure of the governance domains. This single view helps users understand where data starts and ends, what the issues are, and where there's an effect on reporting obligations.

How data observability works

The visualizations in data observability bring together all of the metadata from Microsoft Purview Unfiied Catalog for things like technical data lineage and data quality. Data observability provides contextual views and on-demand custom views in a single diagram.

Having the right view of the metadata in a single place allows you to dig into questions about how data quality is changing across your data estate, and how your data's being used and by whom. Viewing the entire data estate at one time enables the central data team or federated data teams to quickly identify improvements in metadata, ownership, data quality, or data architecture.

> **Note**
>
> Data observability doesn't create any of the lineage or metadata used in the visualization. If you haven't added lineage, or haven't yet created governance domains and business concepts, the screen shows a limited amount of the data estate to view.

Where observability shows up in Unified Catalog

You see an **Observability** tab when you look at a details page for a governance domain, a data product, and a glossary term. Also, the **Data observability (preview)** page under **Health management** in the left navigation provides a custom view of your entire data estate. See Observability views for details.

> **Note**

You need certain roles to see and work with data observability. See Unified Catalog roles for details.

Next steps

- Get set up for observability
- Understand observability views

Set up data observability in Unified Catalog (preview)

To start generating visualizations in Microsoft Purview Unified Catalog, complete the following setup steps. This setup enables two snapshot jobs that collect metadata needed to render the diagrams.

Prerequisites

1. Assign the Data Governance Administrator role in the Data Governance role group.
2. Create assets in Microsoft Purview Data Map, and create governance domains and concepts in the Unified Catalog.

Setup steps

1. Sign in to the Microsoft Purview portal using credentials for a *Data Governance Administrator* role.
2. Go to **Settings**, then select **Unified Catalog**.
3. Select **Data Observability**.
4. Select **Enable** next to the **Catalog Snapshot Job** heading.
5. Select **Enable** next to the **Data Quality Snapshot Job** heading.

The snapshot jobs take a few minutes to run before the visualizations are enabled. The catalog snapshot job refreshes the view of metadata and lineage every 1440 minutes. The data quality snapshot job refreshes the view of data quality scores every 10 minutes.

> **Important**
>
> There's a known limitation in browser performance that prevents rendering a large snapshot of more than 500 MB.

> **Tip**
>
> You don't have to enable the data quality snapshot job if you're not working on data quality. You can turn on this job later.

Last updated on 06/25/2026

Observability views (preview)

Data observability in Microsoft Purview Unified Catalog provides specific views focused on a business concept, such as a governance domain or data product, and the user who views that concept. Each view is scoped to a specific concept and provides alternate views in a dropdown menu to help give different perspectives of the data. You can also create your own view by using saved views in the data observability experience under **Health management**.

Saved views

When you create a saved view, you create a diagram that you can reference later or share with others. After building a diagram by providing minimal details and deciding on sharability, you can reuse the same view at any time.

To create a saved view:

1. In Unified Catalog, go to **Health management** > **Data observability**.
2. Create a diagram by searching, filtering, or selecting the items you want to focus on.
3. Select **Save this view** at the top right of the screen.
4. In the **Save view** window, provide details about the view:
   a. Enter a **View name**.
   b. Enter a **Description**.
   c. At **Owner**, you can add more users. Only the view owners can manage the view.
   d. Select **Visible to everyone** if you want other users to see the view.
5. Select **Save**.

To delete saved views:

1. In **Data observability**, select **Manage saved views** from the **Save this view** dropdown.
2. On the flyout pane, select the trash can icon next to the view you want to remove.
3. Select **OK**.

Known limitations:

- Only 25 shared views can exist at one time.
- Views aren't a point in time picture; they're based on what is in the most current snapshot for the view.
- Views are either personal or shared to all users of **Data observability**. Views don't impact the permissions the user has or what they can see in the catalog.
- You can't edit views. If you need to edit a view, start from the previous saved view, make the needed changes, create a new saved view, and delete the previous view.

Governance domains data observability

At the highest level of business concepts, the governance domain provides the structure and accountability for a portion of the data estate.

1. In Unified Catalog, under **Catalog management**, select **Governance domains**.
2. Select a governance domain that you have access to, then select the **Observability** tab.
3. Select a view from the **Current view** dropdown menu:
   a. **Data Products/Assets** displays all of the data products in the domain with all of the assets mapped to each product.
   b. **Data Products** displays only the data products of the domain.
   c. **Assets** displays only the assets that are mapped to data products of that domain.
   d. **Data Product Lineage** displays the inferred lineage between data products of that domain.
   e. **Data Asset Linage** displays the lineage between the assets used in the data products of the domain.
   f. **Data Assets with Data Quality issues** displays the assets that have at least one data quality dimension that isn't healthy.
   g. **Data Products with Data Quality issues** displays the data products that have at least one data quality dimension that isn't healthy.

Data product data observability

For data product owners, the **Observability** tab on a product's details page provides a quick view of everything within a single data product.

1. In Unified Catalog, select a data product by going to **Catalog management** > **Data products**.

2. On the data product's details page, select the **Observability** tab.

3. Select a view from the **Current View** dropdown menu:
   a. **Assets** displays the assets contained within the data product.
   b. **Data Assets with Data Quality issues** displays the assets with data quality issues that are in the data product.

Glossary term data observability

Glossary terms can link to data and give better context to where certain topics have data available in the governance domains across the data estate.

1. On the glossary term's page, select **Observability**.

2. The default view displays the glossary term and the connections to the data products from any domain using links to that glossary term.

Data observability in Health management

To view your entire data estate in Unified Catalog, go to **Health management**, then select **Data observability (preview)** for a custom view of data observability. This view provides a view of the entire data estate by governance domain by default, called the **Data Estate** view.

Two other views let you focus on either data assets or data products with data quality issues. The difference is that you can search for specific assets, columns, or business concepts, then add them to the diagram or add them to the diagram with lineage. Adding anything with lineage to the diagram includes all of the lineage connections from end to end for that specific asset, column, or business concept.

Other functions available for custom view:

- **Undo**: Go back a change in the diagram to the previous view.
- **Redo**: Go forward a change in the diagram to the view before a user clicked undo.
- **Scope to selection**: Focus the diagram to the single item selected on the screen.
- **Show Lineage**: Include all related items that are connected to the focus item at the same level of grain. If you're focused on a column, the diagram includes the column level lineage. If you're focused on an asset, the diagram includes asset level lineage.
- **Show non-governed assets**: Include all assets included in the lineage of an item even if they're not included in the governed assets of any domain.
- **Save Screenshot**: Download a picture of the current view for use offline.
- **Hierarchy Filter**: Select which levels of hierarchy in the concepts are shown. The hierarchy filter enables you to include deeper level of details in any currently scoped view. If the diagram is focused on data products, the hierarchy can be set to include data assets. If it has data assets, the asset schema can be added.

Overview of data quality in Microsoft Purview Unified Catalog

Data quality in Microsoft Purview Unified Catalog empowers governance domain and data owners to assess and oversee the quality of their data ecosystem, facilitating targeted actions for improvement. In today's AI-driven landscape, the reliability of data directly impacts the accuracy of AI-driven insights and recommendations. Without trustworthy data, there's a risk of eroding trust in AI systems and hindering their adoption.

Poor data quality or incompatible data structures can hamper business processes and decision-making capabilities. Data quality in Unified Catalog addresses these challenges by offering users the ability to evaluate data quality using no-code or low-code rules, including out-of-the-box (OOB) rules and AI-generated rules. These rules are applied at the column level and aggregated to provide scores at the levels of data assets, data products, and governance domains, ensuring end-to-end visibility of data quality within each domain.

Data quality in Microsoft Purview also incorporates AI-powered data profiling capabilities, recommending columns for profiling while allowing human intervention to refine these recommendations. This iterative process not only enhances the accuracy of data profiling but also contributes to the continuous improvement of the underlying AI models.

By applying data quality, organizations can effectively measure, monitor, and enhance the quality of their data assets, bolstering the reliability of AI-driven insights and fostering confidence in AI-based decision-making processes.

Data quality life cycle

1. Assign users(s) data quality steward permissions in Unified Catalog to use all data quality features.
2. Register and scan a data source in Microsoft Purview Data Map.
3. Add your data asset to a data product
4. Set up a data source connection to prepare your source for data quality assessment.
5. Configure and run data profiling for an asset in your data source.
    a. When profiling is complete, browse the results for each column in the data asset to understand your data's current structure and state.
6. Set up data quality rules based on the profiling results, and apply them to your data asset.

7. Configure and run a data quality scan on a data product to assess the quality of all supported assets in the data product.
8. Review your scan results to evaluate your data product's current data quality.
9. Repeat steps 5-8 periodically over your data asset's life cycle to ensure it's maintaining quality.
10. Continually monitor your data quality
    a. Review data quality actions to identify and resolve problems.
    b. Set data quality notifications to alert you to quality issues.

Supported data quality regions

Data quality is currently supported in the following regions.

> ⓘ **Important**
>
> Data Quality capability is supported only when the accounts and the data sources are in the Purview supported regions. Data sources and purview account need to be in the same azure region. Concurrent DQ job execution limits are:
>
> - **Manual scans**: Max 10 concurrent jobs.
> - **Scheduled scans**: Max 25 concurrent jobs.
> - **Manual profile**: Max 10 concurrent profiling jobs.
> - **DQ Rule suggestion**: Max 10 concurrent jobs.

Supported multicloud data sources

View the list of supported data sources.

> ⓘ **Important**
>
> Data quality for Parquet files is designed to support:
>
> 1. A directory with Parquet Part File. For example: **./Sales/{Parquet Part Files}**. The fully qualified name must follow `https://(storage account).dfs.core.windows.net/(container)/path/path2/{SparkPartitions}`. Make sure the directory and subdirectory structure doesn't include {n} patterns. Instead, use a direct FQN leading to {SparkPartitions}.

2. A directory with partitioned Parquet files, partitioned by columns within the dataset like sales data partitioned by year and month. For example: **./Sales/{Year=2018}/{Month=Dec}/{Parquet Part Files}.**

Both of these essential scenarios, which present a consistent Parquet dataset schema, are supported. **Limitation:** Data quality isn't designed to support arbitrary hierarchies of directories with Parquet files. **We recommend presenting data in the (1) or (2) constructed structure.**

Currently, Microsoft Purview can only run data quality scans by using Managed Identity as an authentication option. Data quality services run on **Apache Spark 3.5** and **Delta Lake 3.2.1**.

Data quality features

- **Data source connection configuration**
  - Configure connection to allow Microsoft Purview data quality SaaS application to have read access to data for quality scanning and profiling.
  - Microsoft Purview uses Managed Identity as an authentication option.
- **Data profiling**
  - AI-enabled data profiling experience.
  - Industry standard statistical snapshot (distribution, min, max, standard deviation, uniqueness, completeness, duplicate, and more).
  - Drill down column level profiling measures.
- **Data quality rules**
  - Out of box rules to measure six industry standards data quality dimensions (completeness, consistency, conformity, accuracy, freshness, and uniqueness).
  - Custom rules creation features include number of out of the box functions and expression values.
  - Auto generated rules with AI integrated experience.
- **Data quality scanning**
  - Select and assign rules to columns for data quality scan.
  - Apply data freshness rule in the entity or table level to measure the data freshness SLA.
  - Scheduling data quality scanning job for time period (hourly, daily, weekly, monthly, and more).
- **Data quality job monitoring**
  - Enable monitoring data quality job status (active, completed, failed, and more).
  - Enable browsing the data quality scanning history.

- **Data quality scoring**
  - Data quality score in rule level (what is the quality score for a rule that applied to a column).
  - Data quality score for data assets, data products, and governance domains (one governance domain can have many data products, one data product can have many data assets, one data asset can have many data columns).
- **Data quality alerts**
  - Configure alerts to notify data owners and data stewards if data quality threshold missed the expectation.
  - Configure email alias or distribution group to send the notification about data quality issues.
- **Data quality actions**
  - Actions center for data quality with actions to address data quality anomaly states, including diagnostic queries for data quality steward to zero in on the specific data to fix for each anomaly state.
- **Data quality managed virtual network**
  - A virtual network managed by data quality that connects with private endpoints to your Microsoft Azure data sources.

Data residency and encryption

Microsoft Managed Storage account stores data quality metadata and profiling summary. It stores them in the same region as the data source, so data residency remains intact. All data is encrypted. The Purview Resource Provider regional user data store is used for metadata. It handles all the encryption and is common across all Purview services. If you want more control over your data encryption with a customer-managed encryption key (CMK), use a separate process. Learn more about Microsoft Purview Customer Key.

Data quality compute pricing

Data quality usage is billed based on the Data Governance Processing Unit (DGPU) pay-as-you-go meters. Find details on how pricing is computed for data quality.

Limitations

- Virtual network isn't supported for Google Big Query yet.
- You can apply a maximum of 200 data quality rules per data asset for a data quality scan. Get details about this limit and workarounds.

Related content

- Data quality for Fabric data estate
- Data quality for Fabric mirrored data sources
- Data quality for Fabric shortcut data sources
- Data quality for Azure Synapse serverless and data warehouses
- Data quality for Azure Databricks Unity Catalog
- Data quality for Snowflake data sources
- Data quality for Google BigQuery
- Data quality native support for Iceberg data
- Data quality for on-premises data sources (preview)

Next steps

1. Assign users data quality steward permissions in Unified Catalog so they can use all data quality features.
2. Set up a data source connection to prepare your source for a data quality assessment.
3. Configure and run data profiling for an asset in your data source.

Data sources and file formats supported for data quality in Unified Catalog

Supported sources

Expand table

Data source	Data profiling	Data quality scan	Virtual network support	Note
Azure Data Lake Storage Gen2	Yes	Yes	Yes	
Azure Databricks Unity Catalog	Yes	Yes	Yes	
Azure Synapse serverless	Yes	Yes	Yes	
Azure Synapse Data Warehouse	Yes	Yes	Yes	
Azure SQL Database	Yes	Yes	Yes	
Azure SQL Managed Instance	Yes	Yes	Yes	
Azure Dedicated SQL Pool (formarly SQL DW)	Yes	Yes	No	
Google BigQuery	Yes	Yes	No	
Snowflake	Yes	Yes	Yes	
Fabric	Yes	Yes	Yes	Lakehouse, Shortcut to other filesystem, and mirroring with other database
Amazon S3	Yes	Yes	No	Supported via Fabric shortcut
Dataverse	Yes	Yes	No	Supported via Fabric shortcut
Google Cloud Storage	Yes	Yes	No	Supported via Fabric shortcut
Oracle	No	Yes	NA	On-premises infrastructure

Data source	Data profiling	Data quality scan	Virtual network support	Note
SQL Server	No	Yes	NA	On-premises infrastructure

Supported file formats

Expand table

File format	Data profiling	Data quality scan	vNet support
Delta	Yes	Yes	NA
Parquet	Yes	Yes	NA
Iceberg Avro	Yes	Yes	NA
Iceberg Orc	Yes	Yes	NA

Supported resource set pattern

Expand table

Pattern Name	Details
SparkPartitions	All patterns ending with {SparkPartitions} are supported provided that they do not contain any other mixed non-column patterns in their folder path.
Column partitions	All column partition patterns for parquet, delta and iceberg datasets are supported.

- **Example 1 (supported)**: Standard resource-set folder path: `https://myblob.blob.core.windows.net/sample-data/name-of-folder-output/{SparkPartitions}`
- **Example 2 (supported)**: Column partitioned resource-set folder path: `https://myblob.blob.core.windows.net/my-partitioned-data/Year={Year}/Month={Month}/Day={Day}/{SparkPartitions}`
- **Example 3 (not supported)**: Mixed resource-set path: `https://myblob.blob.core.windows.net/sample-data/data{N}.parquet`

For more information on Microsoft Data Map resource sets, see Understanding resource set.

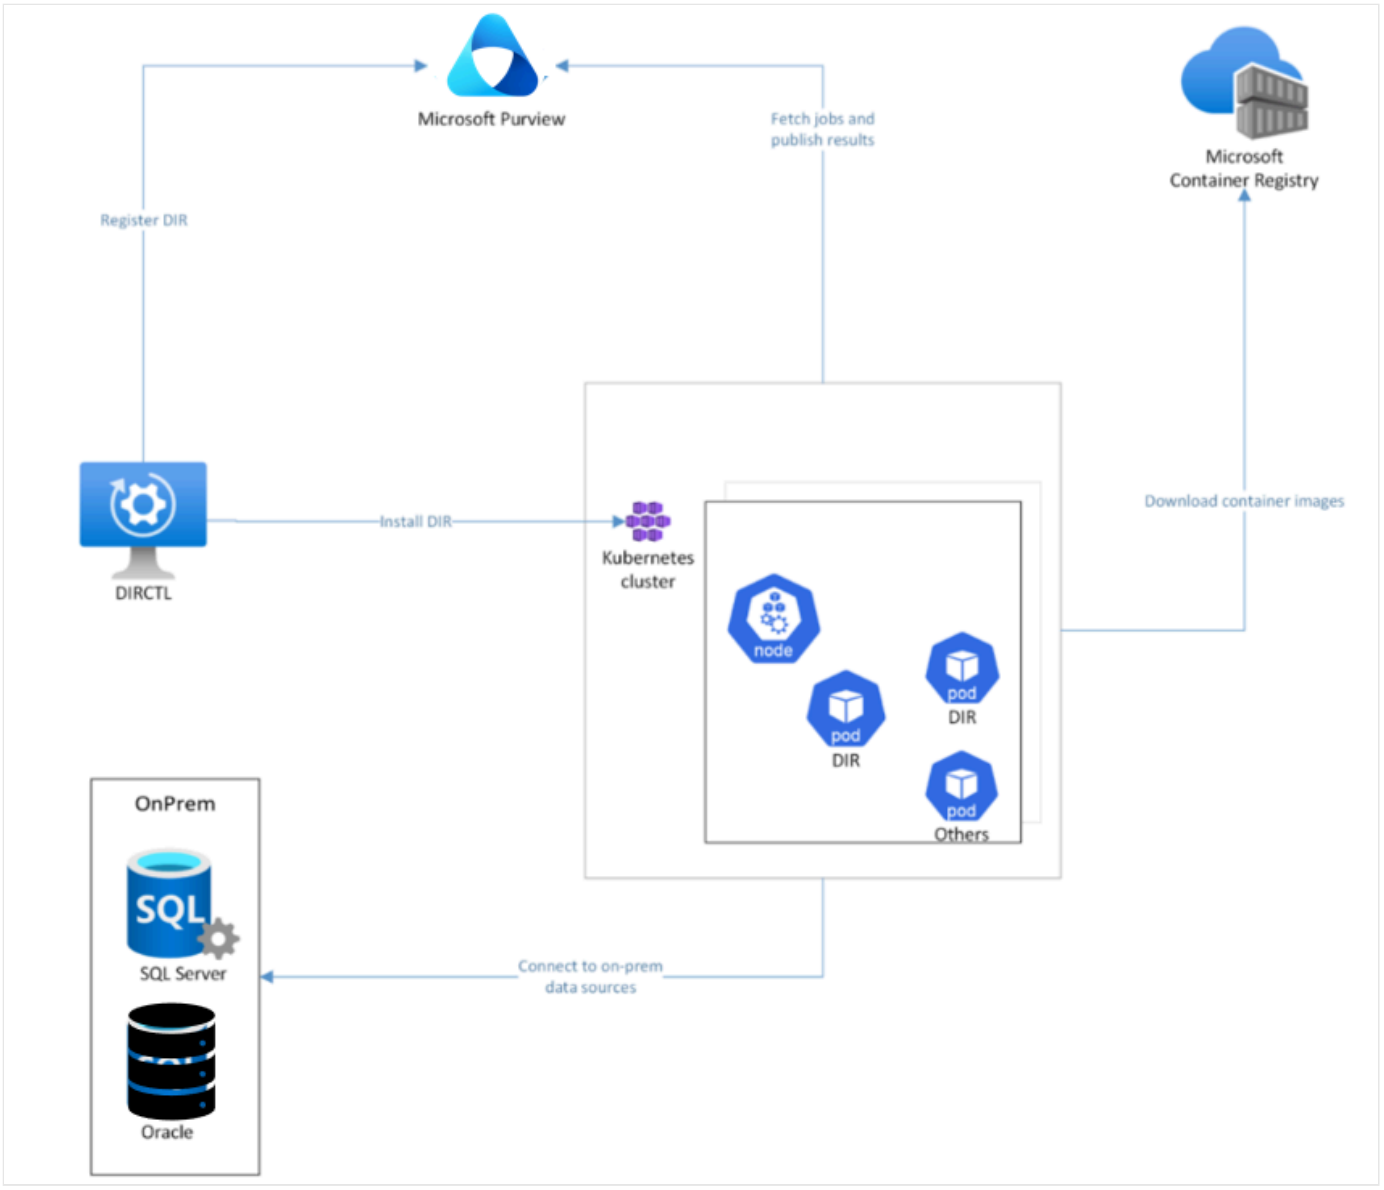
Kubernetes supported self-hosted data integration runtime for on-premises data sources (preview)

Microsoft Purview Data Quality for on-premises data sources enables organizations to assess, monitor, and improve the quality of data stored within internal systems such as databases and legacy platforms. It supports rule-based validation, error detection, and remediation workflows, while ensuring compliance with organizational policies. By integrating with existing infrastructure, it delivers consistent data quality insights and governance across both on-premises and cloud environments.

By using a self-hosted data integration runtime, you can scale data quality processes by securely connecting on-premises data sources to Purview. This article covers the Kubernetes-based, Linux self-hosted data integration runtime, which enhances the underlying infrastructure and provides several key benefits:

- Scalability: Ability to scale to hundreds of machines.
- Performance: Improved performance for scanning workloads.
- Security (containerized): Enables containerized deployment on a Kubernetes cluster, eliminating the need to host the data integration runtime directly on a Windows machine.

Supported data sources



- Oracle
- SQL Server

Architecture

At a high-level architectural view, when you install a Kubernetes-based data integration runtime, several pods are autocreated on the nodes of your Kubernetes cluster. A command line tool named DIRCTL triggers this installation. DIRCTL connects to the Microsoft Purview Service to register the data integration runtime and connect to the Kubernetes cluster to install the self-hosted data integration runtime.

During the installation, the process downloads data integration runtime images from MCR (Microsoft Container Registries) to the data integration runtime pods. After installation is done,

the pods in your cluster connect to the Purview service to pull scan jobs. As a scan job is pulled, it can connect your on-premises data source for Data Quality scanning.

Prerequisites

Data Integration Runtime Command Line tool (DIRCTL)

You need the Data Integration Runtime Command Line tool (DIRCTL) to set up data integration runtime. For download and installation instructions, see Set up DIRCTL tool for self-hosted integration runtime (preview).

Roles

To set up a self-hosted integrated runtime in Purview, you need the Data Governance Administrator role.

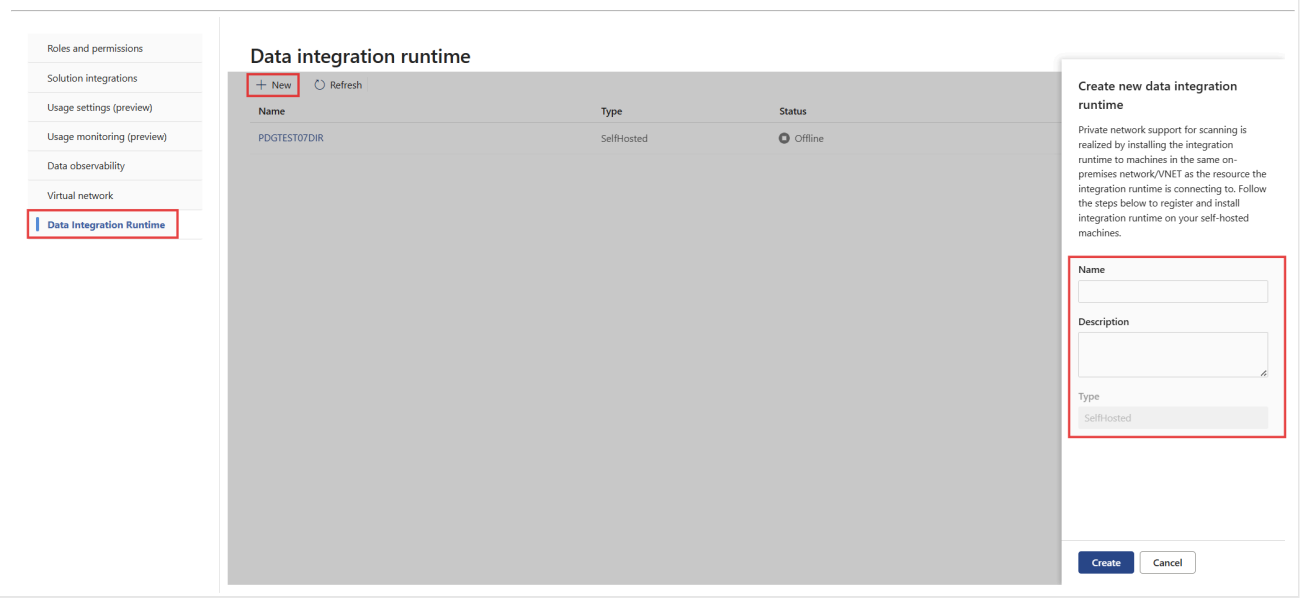
Kubernetes cluster

You need an existing Linux-based Kubernetes cluster, or you need to prepare one. Identify the nodes by using a node selector, which follows the definition of Kubernetes node selector. Minimum configuration:

- Container type: Linux
- Kubernetes version: 1.24.9 or later
- Node OS: Linux based OS running on x86 architecture
- Node spec: minimal eight cores CPU, 32-GB memory, and at least 80 GB of available hard disk space
- Node count: 1 or more (fixed, not enabled cluster auto scaler)
- Pod number per Node: 20 or more (max Pod number – count of other Pods not belonging to Self-Hosted IR)

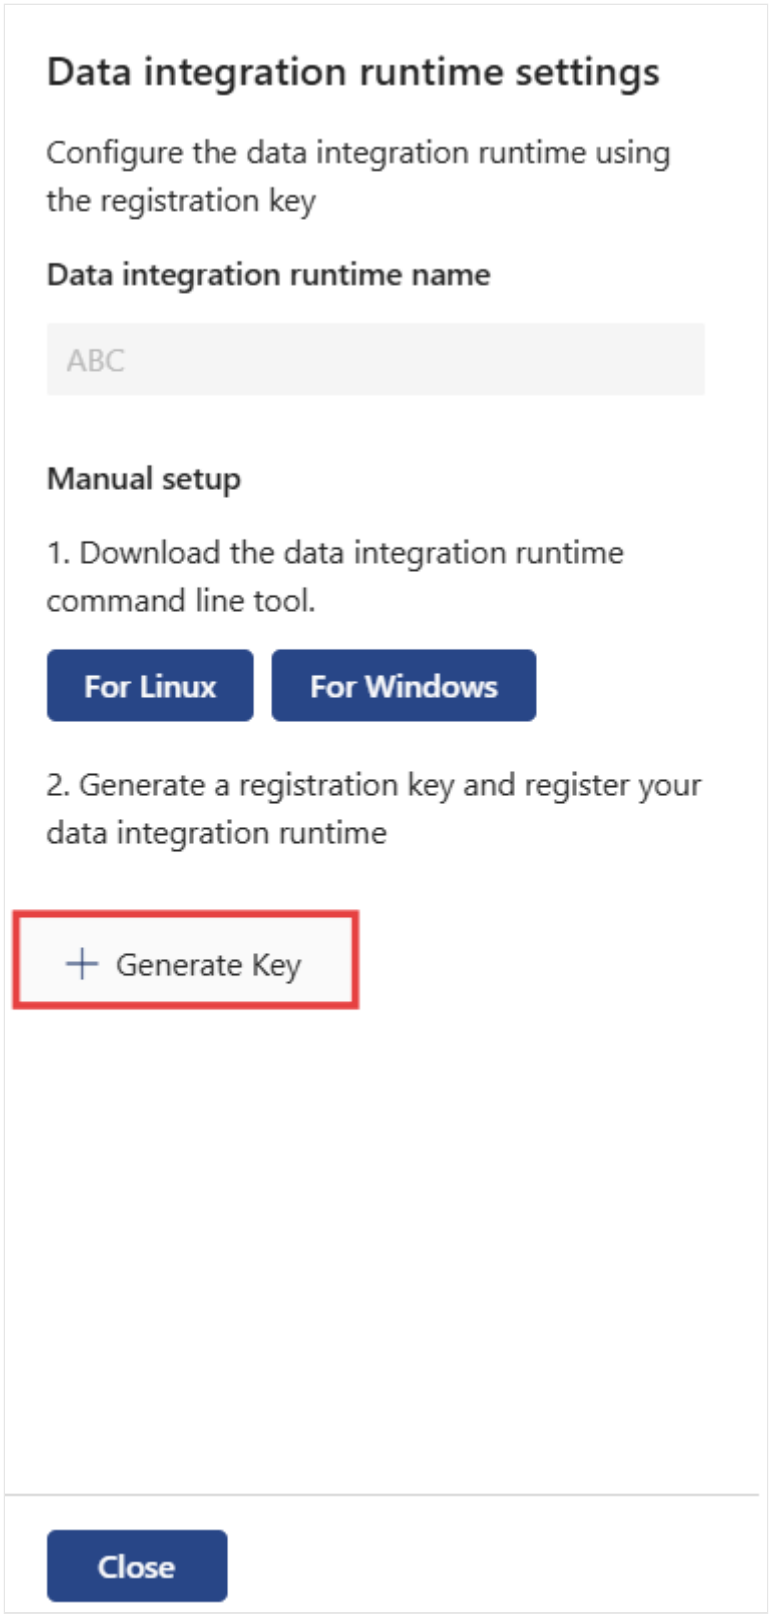
> **Note**
>
> The folder `/var/irstorage/` of each node is reserved for self-hosted integrated runtime. It's readable and writable to data integration runtime. You can get logs from this folder or upload external drivers to this folder. Data integration runtime creates the folder if it doesn't exist, and it doesn't delete the folder after data integration runtime is deleted. The container images used by data integration runtime are managed by Kubernetes Garbage Collection, which isn't cleaned up by data integration runtime. Configure the proper threshold for your Kubernetes cluster.
>
> Outbound connectivity is required to pull in container images as well as for further operation, which includes activities such as pulling data quality jobs and pushing generated stats.

Kubernetes context



Kubernetes context, which contains Kubernetes cluster information and user's permissions and credential for this cluster, is needed to talk to your Kubernetes cluster. To ease the configuration for the user's permissions for DIR management, you can start with Kubernetes Admin role. This context is generated with the setup of your Kubernetes cluster and saved in a config file. Where and how you can get this file depends on your setting up the Kubernetes cluster.

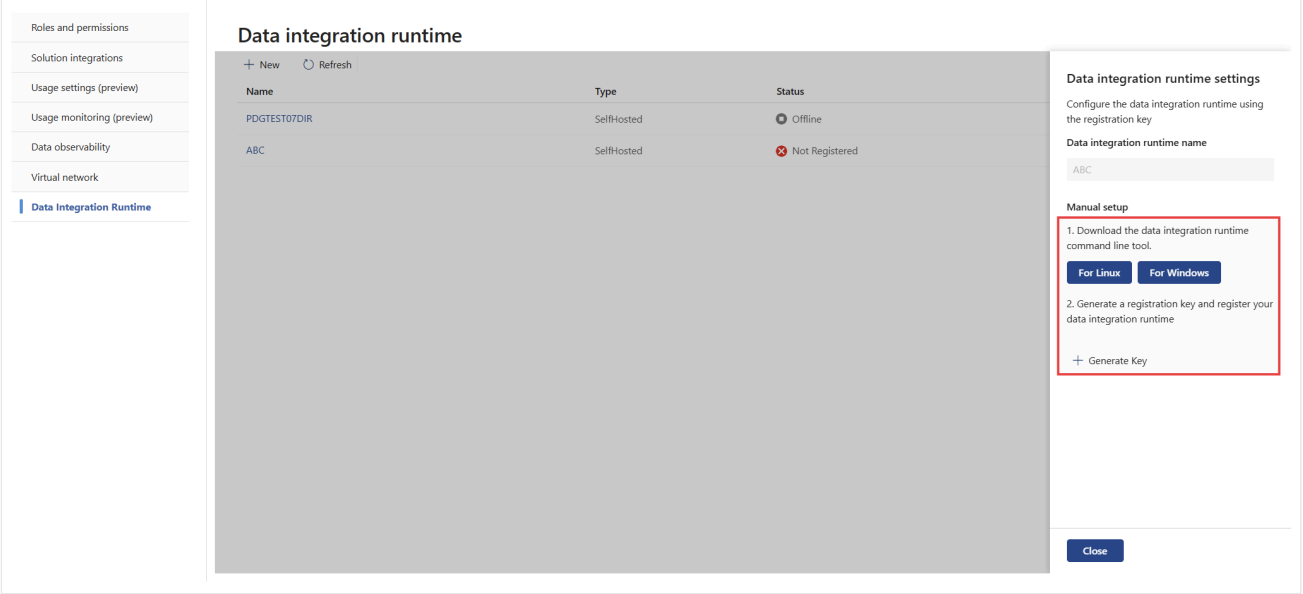
- If you use kubeadm init to set up the Kubernetes cluster, you can find the config file under `/etc/Kubernetes/admin.conf`.



- If you use AKS, you can follow the guidance of AKS to use Az PowerShell module command to get credentials of this cluster to your local machine. You can merge the context to the config file under `$HOME/.kube/config` directly.
- If you're using other tools setting up a Kubernetes cluster, refer to the Kubernetes documentation.
- After you get the config file for the Kubernetes context, merge it into the config file `$HOME/.kube/config` on the machine where you want to run the IRCTL command. Or, you can set the config file of the Kubernetes context in an environment variable named `KUBECONFIG`. For more information about the Kubernetes context, see how to configure access to multiple clusters.

Set up a self-hosted data integration runtime

1. Go to **Settings** > **Microsoft Purview Unified Catalog** > **Data Integration Runtime**, and then select **New** to create a data integration runtime.
2. Enter a **Name** and **Description** for the self-hosted integrated runtime, and then select **Create**.



3. Select **Generate key** to generate a registration key and register your data integration runtime.

4. Copy the key value and select **Done**.

> **Tip**
>
> If needed, you can regenerate a key or revoke a generated key.

5. Select **For Linux** to download the Data Integration Runtime Command Line (DIRCTL) tool. Get details on how to install and manage DIRCTL.

6. On the machine where you want to run the DIRCTL command line, install DIRCTL from the download. DIRCTL connects to your Kubernetes cluster by context of the Kube config. If you don't specify a context, DIRCTL uses the current context. You can set the context in one of two ways:
