Use sensitivity labels as conditions in DLP policies

You can use sensitivity labels as a condition in DLP policies for these locations:

- Exchange email messages
- SharePoint
- OneDrive
- Devices
- Instances
- On-premises repositories
- Microsoft 365 Copilot
- Fabric and Power BI workspaces
- Inline web traffic (Unmanaged cloud apps and adaptive app scopes)

Sensitivity labels appear as an option in the **Content contains** condition list.

Supported items, file types, scenarios, and policy tips

You can use sensitivity labels as conditions on these items and in the following scenarios.

Supported items

Expand table

Service	Item type	Available to policy tip	Enforceable	Notes
Exchange	email message	Yes	Yes	
Exchange	email attachment	Yes	Yes	
SharePoint	items in SharePoint	Yes	Yes	
OneDrive	items	Yes	Yes	
Teams	Teams and channel messages	Not applicable	Not applicable	
Teams	attachments	Yes	Yes	If SharePoint or OneDrive are included as locations in your DLP policy, you don't need to set Teams as a location. This is because attachments sent in Teams over 1:1 chat or channels are automatically uploaded to OneDrive and SharePoint and will be evaluated by DLP then.
Devices	items	Yes	Yes	
MCAS (preview)	items	Yes	Yes	
Inline web traffic	Uploaded and downloaded files	No	Yes	DLP policies don't support custom policy tips for inline web traffic.

> **Note**
>
> DLP's ability to detect sensitivity labels in SharePoint and OneDrive is limited. For more information, see Enable sensitivity labels for files in SharePoint and OneDrive.

Supported file types

Expand table

Workload	File types supported
Exchange emails	.docx, .xlsx, .pptx, .pdf, .pfile
SharePoint	.docx, .xlsx, .pptx, .pdf
OneDrive	.docx, .xlsx, .pptx, .pdf
endpoint devices	.docx, .xlsx, .pptx, .pdf, .pfile
Inline web traffic	.docx, .xlsx, .pptx, .pdf, .pfile, .eml - legacy Office file types, .doc, .xls, and .ppt, aren't supported.

Supported scenarios

- DLP Admin can see a list of all sensitivity labels in the tenant when they choose to include one or more sensitivity labels as a condition.
- All workloads support using sensitivity labels as a condition, as shown in the support matrix.
- DLP policy tips continue to show across workloads for DLP policies that contain one or more sensitivity labels as a condition.
- Sensitivity labels appear as part of the incident report email if a DLP policy with one or more sensitivity labels as a condition is matched.
- Sensitivity label details show in the DLP rule match audit log for DLP policy matches that contain a sensitivity label as a condition.
- For policies that apply to the Inline web traffic location, content that's encrypted can't be extracted for evaluation by DLP. The only conditions that work are metadata based ones, for example:
- **Content contains** > **Sensitivity label** returns the label name
- **File size** returns the size of the encrypted file
- **File extension is** returns the extension of the encrypted file Conditions that rely on the content being evaluated don't work, for example:
- **Content contains** > **Sensitive information type**
- **Content contains** > **Trainable classifiers**
- **File type is**

Support policy tips

Expand table

Workload	Policy tips supported/not supported
OWA	supported
Outlook for Windows	supported
SharePoint	supported
OneDrive	supported
endpoint devices	not supported
Inline web traffic	not supported

> **Note**
>
> If you use sensitivity labels as a condition and policy tips in a DLP policy for Exchange, and, at the same time, you have mandatory labeling for sensitivity labels configured, when a user selects a label through the Mandatory Labeling prompt, the client does not re-invoke the DLP Policy Tips evaluation gate with the newly applied label. In result, the policy tip is **not ** going to show, but the action configured in the DLP policy will be enforced.

Last updated on 08/17/2026

Data loss prevention Exchange conditions and actions reference

Conditions in Microsoft Purview Data Loss Prevention (DLP) policies identify sensitive items that the policy is applied to. Actions define what happens as a consequence of a condition being met.

- Conditions define what to include
- Actions define what happens as a consequence of condition being met

Most conditions have one property that supports one or more values. For example, if the DLP policy is being applied to Exchange emails, the **The sender is** condition requires the sender of the message. Some conditions have two properties. For example, the **A message header includes any of these words** condition requires one property to specify the message header field, and a second property to specify the text to look for in the header field. Some conditions or exceptions don't have any properties. For example, the **Attachment is password protected** condition simply looks for attachments in messages that are password protected.

Actions typically require additional properties. For example, when the DLP policy rule redirects a message, you need to specify where the message is redirected to.

Exchange conditions for DLP policies

The tables in the following sections describe the conditions and exceptions that are available in DLP.

- Senders
- Recipients
- Message subject or body
- Attachments
- Message headers
- Message properties

Senders

If you use the sender address as a condition the actual field where the value is looked for varies depending on the sender address location configured. By default, DLP rules use the Header address as the sender address.

At the tenant level, you can configure a sender address location to be used across all rules, unless overridden by a single rule. To set tenant DLP policy configuration to evaluate the sender address from the Envelope across all rules, you can run the following command:

PowerShell

```
Set-PolicyConfig -SenderAddressLocation Envelope
```

To configure the sender address location at a DLP rule level, the parameter is *SenderAddressLocation*. The available values are:

- **Header**: Only examine senders in the message headers (for example, the **From**, **Sender**, or **Reply-To** fields). This is the default value.
- **Envelope**: Only examine senders from the message envelope (the **MAIL FROM** value that was used in the SMTP transmission, which is typically stored in the **Return-Path** field).
- **Header or envelope** (`HeaderOrEnvelope`) Examine senders in the message header and the message envelope.

Expand table

Condition or Exception in DLP	Condition/Exception parameters in Security & Compliance PowerShell	Property type	Description
Sender is	Condition: *From* Exception: *ExceptIfFrom*	*Addresses*	Messages sent by the specified mailboxes, mail users, mail contacts.
The sender is a member of	Condition: *FromMemberOf* Exception: *ExceptIfFromMemberOf*	*Addresses*	Messages sent by a member of the specified distribution group whether assigned or dynamic, mail-enabled security group, or Microsoft 365 group whether assigned or dynamic.
Sender IP address is	Condition: *SenderIPRanges* Exception: *ExceptIfSenderIPRanges*	*IPAddressRanges*	Messages where the sender's IP address matches the specified IP address, or falls within the specified IP address range.

Condition or Exception in DLP	Condition/Exception parameters in Security & Compliance PowerShell	Property type	Description
Sender address contains words	Condition: *FromAddressContainsWords* Exception: *ExceptIfFromAddressContainsWords*	*Words*	Messages that contain the specified words in the sender's email address.
Sender address matches patterns	Condition: *FromAddressMatchesPatterns* Exception: *ExceptIfFromAddressMatchesPatterns*	*Patterns*	Messages where the sender's email address contains text patterns that match the specified regular expressions.
Sender domain is	Condition: *SenderDomainIs* Exception: *ExceptIfSenderDomainIs*	*DomainName*	Messages where the domain of the sender's email address matches the specified value. If you need to find sender domains that *contain* the specified domain (for example, any subdomain of a domain), use **The sender address matches pattern** (*FromAddressMatchesPatterns*) condition and specify the domain by using the syntax: `'\.domain\.com$'`.
Sender scope	Condition: *FromScope* Exception: *ExceptIfFromScope*	*UserScopeFrom*	Messages sent by either internal or external senders.
The sender's specified properties include any of these words	Condition: *SenderADAttributeContainsWords* Exception: *ExceptIfSenderADAttributeContainsWords*	First property: *ADAttribute* Second property: *Words*	Messages where the specified Microsoft Entra ID attribute of the sender contains any of the specified words.
The sender's specified properties match these text patterns	Condition: *SenderADAttributeMatchesPatterns* Exception: *ExceptIfSenderADAttributeMatchesPatterns*	First property: *ADAttribute* Second property: *Patterns*	Messages where the specified Microsoft Entra ID attribute of the sender contains text patterns that match the specified regular expressions.

Recipients

When an email is sent to multiple recipients and the DLP policy rules allow only some of those emails to be delivered, the email might get *bifurcated*. For example, say that your DLP policy rules

allow emails to be sent to email addresses within your organization and blocks emails from being sent to external email addresses.

There are several policy conditions that cause bifurcation; that allowing an email to be sent to some users but not to others. For more information about bifurcation and the details about how bifurcation works, see the article on Bifurcation.

Expand table

Condition or Exception in DLP	Condition/Exception parameters in Security & Compliance PowerShell	Property type	Description	Bifurcating?
Recipient is	Condition: *SentTo* Exception: *ExceptIfSentTo*	*Addresses*	Messages where one of the recipients is the specified mailbox, mail user, or mail contact in the organization. The recipients can be in the **To**, **Cc**, or **Bcc** fields of the message.	Yes
Recipient domain is	Condition: *RecipientDomainIs* Exception: *ExceptIfRecipientDomainIs*	*DomainName*	Messages where the domain of the recipient's email address matches the specified value.	Yes
Recipient address contains words	Condition: *AnyOfRecipientAddressContainsWords* Exception: *ExceptIfAnyOfRecipientAddressContainsWords*	*Words*	Messages that contain the specified words in the recipient's email address. **Note**: This condition doesn't consider messages that are sent	No

			to recipient proxy addresses. It only matches messages that are sent to the recipient's primary email address.	
Recipient address matches patterns	Condition: *AnyOfRecipientAddressMatchesPatterns* Exception: *ExceptIfAnyOfRecipientAddressMatchesPatterns*	*Patterns*	Messages where a recipient's email address contains text patterns that match the specified regular expressions. **Note**: This condition doesn't consider messages that are sent to recipient proxy addresses. It only matches messages that are sent to the recipient's primary email address.	No
Sent to member of	Condition: *SentToMemberOf* Exception: *ExceptIfSentToMemberOf*	*Addresses*	Messages that contain recipients who are members of the specified distribution group whether assigned or	Yes

Condition or Exception in DLP	Condition/Exception parameters in Security & Compliance PowerShell	Property type	Description	Bifurcating?
			dynamic, mail-enabled security group, or Microsoft 365 group whether assigned or dynamic. The group can be in the **To**, **Cc**, or **Bcc** fields of the message.	
The recipient's specified properties include any of these words	Condition: *RecipientADAttributeContainsWords* Exception: *ExceptIfRecipientADAttributeContainsWords*	First property: *ADAttribute* Second property: *Words*	Messages where the specified Microsoft Entra ID attribute of a recipient contains any of the specified words. Note that the **Country** attribute requires the two-letter country code value (for example, DE for Germany).	Yes
The recipient's specified properties match these text patterns	Condition: *RecipientADAttributeMatchesPatterns* *ExceptIfRecipientADAttributeMatchesPatterns*	First property: *ADAttribute* Second property: *Patterns*	Messages where the specified Entra ID attribute of a recipient contains text patterns that match the specified regular expressions.	Yes

Condition or Exception in DLP	Condition/Exception parameters in Security & Compliance PowerShell	Property type	Description	Bifurcating?
Recipient scope/Content is shared with	Condition: *AccessScope* Exception: *ExceptIfAccessScope*	*UserScopeFrom*	Messages that are received by either internal or external recipients.	Yes
Unique recipient count over	Condition: *RecipientCountOver*	*Number*	Messages where the count of recipients is greater than the specified value. Groups are expanded and final recipient count is compared.	No
Unique recipient domain over	Condition: *DomainCountOver*	*Number*	Messages where the count of recipients' domains is greater than the specified value.	No

> **Note**
>
> DLP supports only mail enabled security groups, distribution groups assigned, and dynamic, and Microsoft 365 Groups, both assigned and dynamic for sender and recipient based conditions that accept groups as input.

Message subject or body

			This condition has limited support for non-english multibyte characters.

Attachments

Expand table

Condition or Exception in DLP	Condition/Exception parameters in Security & Compliance PowerShell	Property type	Description
Attachment is password protected	Condition: *DocumentIsPasswordProtected* Exception: *ExceptIfDocumentIsPasswordProtected*	None	Messages where an attachment is password protected (and therefore can't be scanned). Password detection works for Office documents, compressed files (.zip, .7z), and .pdf files.
Attachment's file extension is	Condition: *ContentExtensionMatchesWords* Exception: *ExceptIfContentExtensionMatchesWords*	*Words*	Messages where an attachment's visible or the actual file extension matches any of the specified words. To detect renamed .7z files, you must configure configure the rule to protect files with the .7zip extension.
Any email attachment's content could not be scanned	Condition: *DocumentIsUnsupported* Exception: *ExceptIf DocumentIsUnsupported*	N/A	Messages where an attachment isn't recognized by Exchange Online.
Any email attachment's content didn't complete scanning	Condition: *ProcessingLimitExceeded* Exception: *ExceptIfProcessingLimitExceeded*	N/A	Messages where the rules engine couldn't complete the scanning of the attachments. You can use this condition to create rules that work together to identify and process messages where the content couldn't be fully scanned.
Document scan failures	Condition: *DocumentScanFailures*	N/A	Recommend using with **Document could not be scanned** or **Document didn't complete scanning** conditions to enforce actions on granular scanning error scenarios across

Condition or Exception in DLP	Condition/Exception parameters in Security & Compliance PowerShell	Property type	Description
			classification timeout, throttling or other failures.
Document name contains words	Condition: *DocumentNameMatchesWords* Exception: *ExceptIfDocumentNameMatchesWords*	*Words*	Messages where an attachment's file name matches any of the specified words that are delimited between the start of the name, any non-alphanumeric character that appears on the keyboard, or end of the name.
Document name matches patterns	Condition: *DocumentNameMatchesPatterns* Exception: *ExceptIfDocumentNameMatchesPatterns*	*Patterns*	Messages where an attachment's file name contains text patterns that match the specified regular expressions. This has been discontinued for SharePoint and OneDrive workloads. Existing rules can't be modified and new rules can't be created. Existing customers can continue to use this condition.
Document property is	Condition: *ContentPropertyContainsWords* Exception: *ExceptIfContentPropertyContainsWords*	*Words*	Messages with documents where an attachment's custom property matches the given value.
Document size equals or is greater than	Condition: *DocumentSizeOver* Exception: *ExceptIfDocumentSizeOver*	Size	Messages where any attachment is greater than or equal to the specified value.
Any attachment's content includes any of these words	Condition: *DocumentContainsWords* Exception: *ExceptIfDocumentContainsWords*	*Words*	Messages where an attachment contains the specified words.
Any attachments content matches these text patterns	Condition: *DocumentMatchesPatterns* Exception: *ExceptIfDocumentMatchesPatterns*	*Patterns*	Messages where an attachment contains text patterns that match the specified regular expressions.

Message Headers

Expand table

Condition or Exception in DLP	Condition/Exception parameters in Security & Compliance PowerShell	Property type	Description
Header contains words or phrases	Condition: *HeaderContainsWords* Exception: *ExceptIfHeaderContainsWords*	*Hash Table*	Messages that contain the specified header field, and the value of that header field contains the specified words.
Header matches patterns	Condition: *HeaderMatchesPatterns* Exception: *ExceptIfHeaderMatchesPatterns*	*Hash Table*	Messages that contain the specified header field, and the value of that header field contains the specified regular expressions.

Message properties

Expand table

Condition or Exception in DLP	Condition/Exception parameters in Security & Compliance PowerShell	Property type	Description
With importance	Condition: *WithImportance* Exception: *ExceptIfWithImportance*	*Importance*	Messages that are marked with the specified importance level.
Content character set contains words	Condition: *ContentCharacterSetContainsWords* Exception: *ExceptIfContentCharacterSetContainsWords*	*CharacterSets*	Messages that have any of the specified character set names.
Has sender override	Condition: *HasSenderOverride* Exception: *ExceptIfHasSenderOverride*	N/A	Messages where the sender has chosen to override a data loss prevention (DLP) policy. For more information, see Learn about data loss prevention
Message type matches	Condition: *MessageTypeMatches* Exception: *ExceptIfMessageTypeMatches*	*MessageType*	Messages of the specified type. **Note**: The available message types are Automatic reply, Auto-forward, Encrypted (S/MIME), Calendaring, Permission controlled (rights management), Voicemail, Signed, Read receipt, and Approval request.
The message size is greater than or equal to	Condition: *MessageSizeOver* Exception: *ExceptIfMessageSizeOver*	*Size*	Messages where the total size (message plus attachments) is greater than or equal to the specified value. **Note**: Message size limits on mailboxes are

Condition or Exception in DLP	Condition/Exception parameters in Security & Compliance PowerShell	Property type	Description
			evaluated before mail flow rules. A message that's too large for a mailbox will be rejected before a rule with this condition is able to act on the message.

Enhanced matched conditions in alerts and Activity Explorer (preview)

When an Exchange Online DLP policy matches a message, the DLP alert and the corresponding Activity Explorer event surface enhanced detail for every non-sensitive information type (SIT) condition that contributed to the match. This applies to all condition categories listed in the preceding sections: Senders, Recipients, Message subject or body, Attachments, Message headers, and Message properties. For the full list of supported conditions and detail levels, see Enhanced matched conditions for Exchange DLP events.

Actions for DLP policies

This table describes the actions that are available in DLP.

Expand table

Action in DLP	Action parameters in Security & Compliance PowerShell	Property type	Description
Restrict access or encrypt content in Microsoft 365 locations	BlockAccess	First property: *Boolean* Second property: *BlockAccessScope*	This allows you to block the access or encrypt the content to the specified users using RMS template
Set header	SetHeader	First property: *Header Name* Second property: *Header Value*	The `SetHeader` parameter specifies an action for th rule that adds or modifies a header field and value message header. This parameter uses the syntax `"HeaderName:HeaderValue"`. You can specify multipl header name and value pairs separated by comma
Remove header	RemoveHeader	First property: *MessageHeaderField* Second property: *String*	The `RemoveHeader` parameter specifies an action fo DLP rule that removes a header field from the mes header. This parameter uses the syntax `HeaderName` `"HeaderName:HeaderValue`. You can specify multiple

Action in DLP	Action parameters in Security & Compliance PowerShell	Property type	Description
			header names or header name and value pairs sep by commas
Redirect the message to specific users	RedirectMessageTo	*Addresses*	Redirects the message to the specified recipients. T message isn't delivered to the original recipients, a notification is sent to the sender or the original recipients.
Forward the message for approval to sender's manager	Moderate	First property: *ModerateMessageByManager* Second property: *Boolean* `$true`	The *Moderate* parameter specifies an action for the rule that sends the email message to a moderator user's manager or specified approvers). To forward message to the user's manager for approval, use th syntax: `@{ModerateMessageByManager = $true}`
Forward the message for approval to specific approvers	Moderate	First property: *ModerateMessageByManager* Second property: *Boolean* `$false` Third property: *ModerateMessageByUser* Fourth property: *Addresses*	The *Moderate* parameter specifies an action for the rule that sends the email message to a moderator user's manager or specified approvers). To forward message to specified recipients for approval, use th syntax: `@{ModerateMessageByManager = $false; ModerateMessageByUser = @("emailaddress1","emailaddress2",..."emailaddre`
Add recipient	AddRecipients	First property: *Field* Second property: *Addresses*	Adds one or more recipients to the **To/Cc/Bcc** fielc message. This parameter uses the syntax: `@{<AddToRecipients \<CopyTo | BlindCopyTo\> = "emailaddress"}`
Add the sender's manager as recipient	AddRecipients	First property: *AddedManagerAction* Second property: *Field*	Adds the sender's manager to the message as the specified recipient type (**To**, **Cc**, **Bcc**), or redirects th message to the sender's manager without notifyin sender or the recipient. This action only works if th sender's `Manager` attribute is defined in the Micros Entra ID. This parameter uses the syntax: `@{AddManagerAsRecipientType = "\<To | Cc | Bc`
Prepend subject	PrependSubject	*String*	Adds the specified text to the beginning of the **Sul** field of the message. Consider using a space or a c as the last character of the specified text to differer it from the original subject text. To prevent the same string from being added to messages that already contain the text in the subje example, replies), add the *The subject contains wor* (`ExceptIfSubjectContainsWords`) exception to the r

Action in DLP	Action parameters in Security & Compliance PowerShell	Property type	Description
Apply HTML disclaimer	ApplyHtmlDisclaimer	First property: *Text* Second property: *Location* Third property: *Fallback action*	Applies the specified HTML disclaimer to the requi location of the message. This parameter uses the syntax: `@{Text = " " ; Lo = \<Append | Prepend\>; FallbackAction = \<Wrap Ignore | Reject\>}`
Remove message encryption and rights protection	RemoveRMSTemplate	N/A	Removes message encryption applied on an email
Apply Branding to encrypted messages	ApplyBrandingTemplate	*String*	The `ApplyBrandingTemplate` parameter specifies an for the DLP rule that applies a custom branding ter for messages encrypted by Microsoft Purview Mes Encryption. You identify the custom branding temp name. If the name contains spaces, enclose the nar quotation marks (").
Make external recipients open mail in encrypted message portal	EnforcePortalAccess	*Boolean*	The `EnforcePortalAccess` parameter controls whet external users are required to use the encrypted m portal to view encrypted messages
Deliver the message to the hosted quarantine	*Quarantine*	n/a	Delivers the message to the quarantine in Microso For more information, see Quarantined email mess
Modify Subject	ModifySubject	*PswsHashTable*	Remove text from the subject line that matches a s pattern and replace it with different text. See the e below. You can: - **Replace** all matches in the subject with the replac text - **Append** to remove all matches in the subject anc inserts the replacement text at the end of the subje - **Prepend** to remove all matches and inserts the replacement text at the beginning of the subject. F more information, see the ModifySubject paramete description in the New-DlpComplianceRule referer article.

Data loss prevention policy tip reference for Outlook for Microsoft 365

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Mailboxes must be hosted in Exchange Online. For more information, see: Learn about data loss prevention.

Microsoft Purview Data Loss Prevention (DLP) will only process the first 4 MB on message content for policy tip in Outlook for Microsoft 365 and only classify up to 2 MB of attachments.

> **Important**
>
> Policy Tips won't be displayed in the classic Outlook client for DLP policies scoped to nonmail enabled security groups but rule actions are enforced.

Licensing

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

Conditions that support policy tips for Outlook perpetual users

Expand table

For Outlook perpetual versions and users	These conditions apply
-E3 users -E5 users	- For email and unencrypted Microsoft 365 files **Content contains built-in/custom sensitive information types** - **Content is shared from Microsoft 365**

Conditions that support policy tips for Outlook for Microsoft 365 users

Expand table

For Outlook for Microsoft versions and users	These conditions apply
- All E3 users - All offline E5 users - All E5 users with connected experience disabled - All online E5 users with production version builds lower than 2303 (Build 16.0.16216.10000) - All online E5 users with Semi-Annual Enterprise Channel version builds lower than 2302 (Build 16.0.16130.20478)	- Content contains built-in/custom sensitive information types - Content is shared from Microsoft 365
- All online E5 users with connected experience enabled in WW commercial and GCC/GCC-H/DoD clouds - production version 2303 & Build 16.0 16216.10000 or higher - Semi-Annual Enterprise Channel version 2302 & Build 16.0.16130.20478 or higher - Users without a Microsoft 365 E5 license must be assigned a license that includes the Information Protection for Office 365 - Premium service plan to support DLP Policy Tips in Outlook Classic.	- Content contains built-in/custom sensitive information types (works for email and unencrypted Microsoft 365 and PDF files) - Message (includes email subject) contains built-in/custom sensitive information types - Attachment contains built-in/custom sensitive information types - Content contains sensitivity labels (Works for email and Office & PDF file types) - Content is shared - Sender is - Sender is member of (Only Distribution lists, Azure-based Dynamic Distribution groups, and email-enabled Security groups are supported.) - Sender domain is - Recipient is - Recipient is a member of (Only Distribution lists, Azure-based Dynamic Distribution groups, and email-enabled Security groups are supported.) - Recipient domain is - Subject contains words - Content isn't labeled - Message isn't labeled - Attachment isn't labeled - File extension is

Actions that support policy tips

All Exchange actions support policy tips

- Restrict access or encrypt the content in Microsoft 365 locations
- Set headers
- Remove header
- Redirect the message to specific users
- Forward the message for approval to sender's manager
- Forward the message for approval to specific approvers
- Add recipient to the To box
- Add recipient to the Cc box
- Add recipient to the Bcc box
- Add the sender's manager as recipient
- Removed O365 Message Encryption and rights protection
- Prepend Email Subject
- Add HTML Disclaimer
- Modify Email Subject
- Deliver the message to the hosted quarantine

Sensitive information types that support policy tips for Outlook perpetual users

Exact Data Match sensitive information types that support policy tips Outlook for Microsoft 365

Applies to

- Online E5 users with connected experience enabled
- Production version 2303 (Build 16.0.16216.10000) or higher.
- Semi-Annual Enterprise Channel version 2302 (Build 16.0.16130.20478) or higher.

For more information on exact data match based SITs, see Learn about exact data match based sensitive information types.

Trainable classifiers support for Outlook for Microsoft 365

> **Important**
>
> Trainable classifiers aren't supported for the following conditions:
>
> - For **new** conditions:
> - `Message contains`
> - `Attachment contains`

- For the **existing** `Content contains` condition when used in combination with `Evaluate rule per component` condition. (Preview limitation)

Applies to:

For these Outlook versions and users:

- Online E5 users with connected experience enabled
- Production version 2303 (Build 16.0.16216.10000) or higher.
- Semi-Annual Enterprise Channel version 2302 (Build 16.0.16130.20478) or higher.

These trainable classifiers are supported:

- Adult, racy, and gory images
- Agreements
- Bank statement
- Budget
- Business plan
- Completion certificates
- Construction specifications
- Corporate sabotage
- Customer complaints
- Discrimination
- Employee disciplinary action
- Employee insurance
- Employment agreement
- Employee Pension Records
- Employee Stocks and Financial Bond Records
- Enterprise Risk Management
- Finance
- Financial audit
- Financial statement
- Freight Documents
- Gifts & entertainment
- Harassment
- Health/Medical forms
- Healthcare
- Human resources

- Invoice
- Intellectual property
- Information technology
- Legal affairs
- Legal Agreements
- License agreement
- Loan agreements and offer letters
- Merger and acquisition files
- Manufacturing batch records
- Meeting notes
- Money laundering
- Network design files
- Non-disclosure agreement
- Paystub
- Personal Financial Information
- Procurement
- Project documents
- Profanity
- Quotation
- Regulatory collusion
- Resume
- Safety records
- Sales and revenue
- Software product development files
- Source code
- Standard Operating Procedures and Manuals
- Statement of Accounts
- Statement of work
- Stock manipulation
- Tax documents
- Threat
- Unauthorized disclosure
- Wire Transfer
- Word count requirements

For more information on trainable classifiers, see Learn about trainable classifiers.

Sensitivity label support for Outlook for Microsoft 365

Applies to:

- Online E5 users with connected experience enabled
- Production version 2303 (Build 16.0.16216.10000) or higher.
- Semi-Annual Enterprise Channel version 2302 (Build 16.0.16130.20478) or higher.

For more information on sensitivity labels, see Learn about sensitivity labels.

Oversharing dialog for Outlook for Microsoft 365

The oversharing dialog is available in DLP for Outlook desktop for E5 users. When enabled in a DLP rule, this feature displays popups for warning, override, or block actions to end users who are sharing labeled or sensitive emails in Outlook desktop.

For information about legacy AIP Add-in, see admin guide for the AIP client.

There are multiple types of oversharing dialogs that can be presented to your users.

Default Oversharing Dialog

Applies to:

- Online E5 users with connected experience enabled
- Production version 2303 (Build 16.0.16216.10000) or higher.
- Semi-Annual Enterprise Channel version 2308 (Build 16.0.16731.20716) or higher.

This dialog uses the exact same text as the policy tip (default or custom) and when applicable, a noncustomizable set of justification options to override the policy.

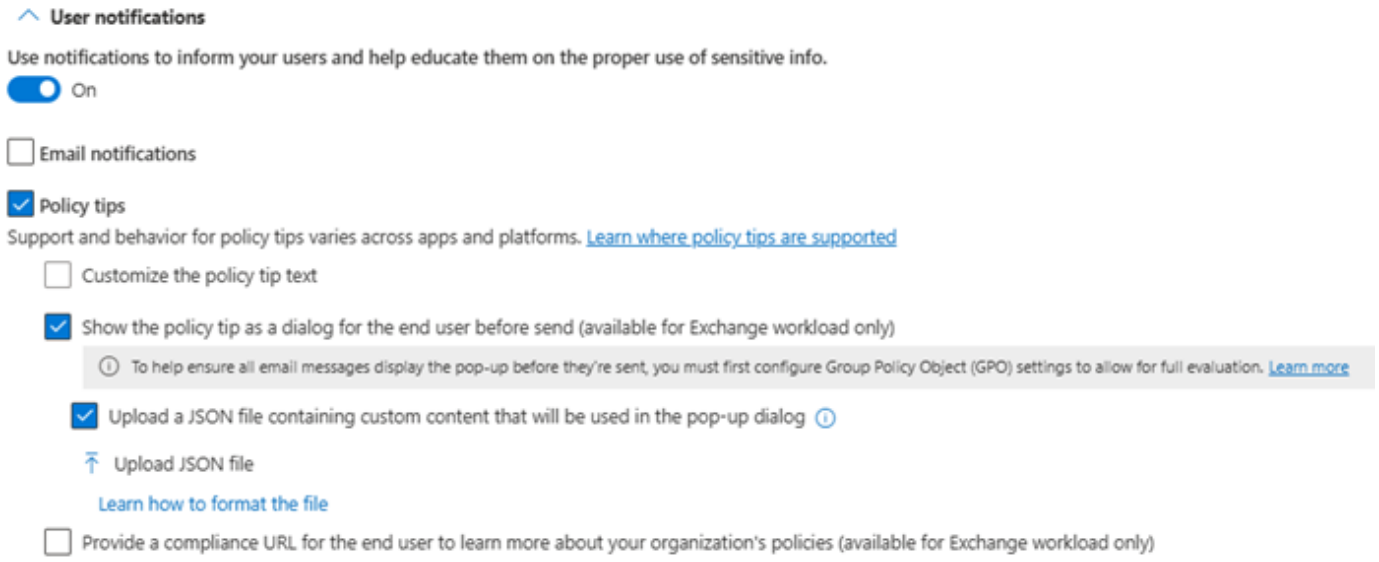
Customized Oversharing Dialog

Applies to:

- Online E5 users with connected experience enabled
- Production version 2404 (Build 16.0.17531.20000) or higher.
- Semi-Annual Enterprise Channel version 2408 (Build TBD) or higher.

You can choose to tailor your oversharing dialog with a customized title, body, and dynamic variables like %%MatchedRecipientsList%%, and justification options.

For customized dialog, create a JSON file like this and ensure the following:



- The file is UTF-8 encoded.
- The content is plain text.
- No comments are included.

JSON

```
{
    "LocalizationData": [
        {
            "Language": "en-us",
            "Title": "WARNING: A Sensitivity Label Not for External Use was
Detected.",
            "Body": "The following classification(s) have been detected on this email
or its attachments. <LineBreak /><LineBreak /><Bold>%%MatchedLabelName%%</Bold>
<LineBreak /><LineBreak />The email cannot be sent until either the following issues
are corrected or a justification is provided. <LineBreak /><LineBreak />Attachment(s)
needing attention (if applicable): <LineBreak />%%MatchedAttachmentName%% <LineBreak
/><LineBreak />List of external recipients: <LineBreak />%%MatchedRecipientsList%%
<LineBreak /><LineBreak />",
            "Options": [
                "The recipients have signed an NDA",
                "Manager has approved this email",
                "Organization required this content to be shared"
            ]
        },
{
            "Language": "es-es",
            "Title": "ADVERTENCIA: Etiqueta de sensibilidad no para uso externo
detectada.",
            "Body": "Se ha detectado la(s) siguiente(s) clasificación(es) en este
correo electrónico o sus archivos adjuntos. <LineBreak /><LineBreak />
<Bold>%%MatchedLabelName%%</Bold><LineBreak /><LineBreak />El correo electrónico no se
puede enviar hasta que se corrijan los siguientes problemas o se proporcione una
justificación. <LineBreak /><LineBreak />Archivos adjuntos que necesitan atención (si
corresponde): <LineBreak />%%MatchedAttachmentName%% <LineBreak /><LineBreak />Lista
de destinatarios externos: <LineBreak />%%MatchedRecipientsList%% <LineBreak />
<LineBreak />",
            "Options": [
                "Los destinatarios han firmado un NDA",
                "El gerente ha aprobado este correo electrónico",
                "La organización requirió que se compartiera este contenido"
            ]
        }
    ],
    "DefaultLanguage": "en-us"
}
```

The above JSON content can be uploaded in a DLP rule using below options:

UX instructions

PowerShell

PowerShell

```
$content = Get-Content "path to the JSON file" -Encoding utf8| Out-String
```

PowerShell

```
New-DlpComplianceRule -Name "<Rule_name>" -Policy "<Policy_name>" `-<Any_Condition>
<Condition_Value> `-NotifyPolicyTipCustomDialog $content `
-NotifyPolicyTipDisplayOption Dialog
```

PowerShell

```
  Set-DlpComplianceRule -Identity "<Rule_name>" `-NotifyPolicyTipCustomDialog
$content `-NotifyPolicyTipDisplayOption Dialog
```

When you run the cmdlet, validation checks are run on the content. The validation checks include, the JSON character limit, formatting and, mandatory presence of one default language validation. The administrator is notified of any errors so that they can be corrected

Features and limitations

The dialog title, body, and override justifications options can be customized using the JSON file. You can apply bold, underline, italic formatting, and line breaks. There can be up to three justifications options plus an option for free-text input.

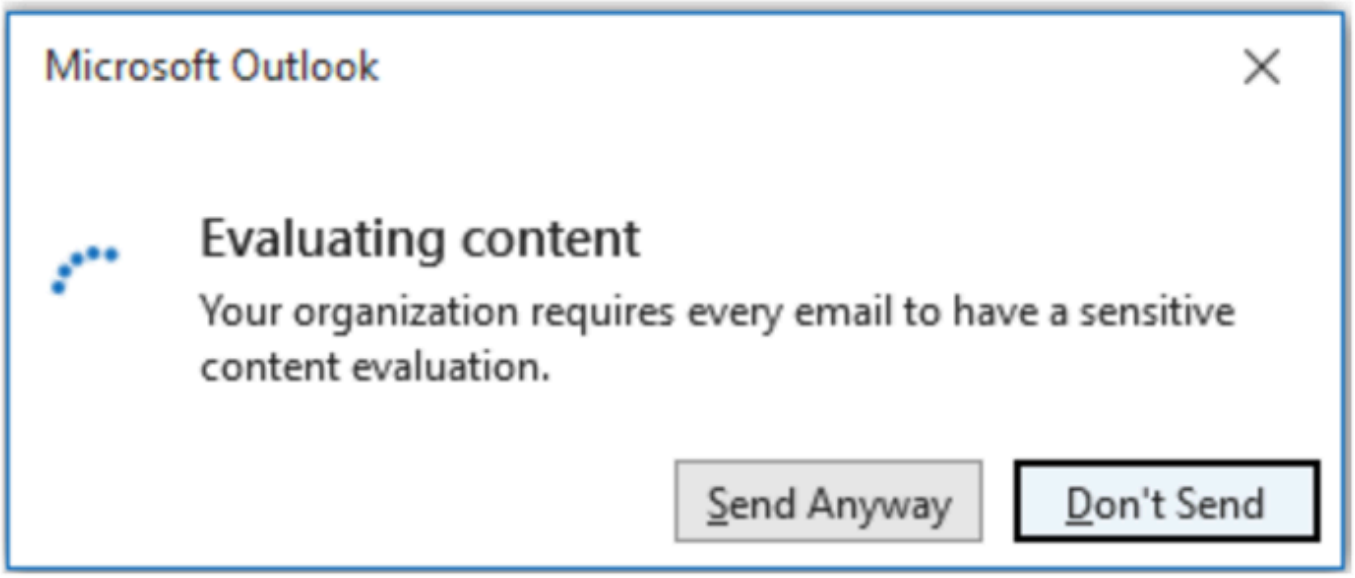
The text for **Acknowledgement** and **False positive overrides** isn't customizable.

Here's the required structure of the JSON files. You use this to customize the dialog for matched rules. The keys are **all case sensitive**. Formatting and dynamic tokens for matched conditions can only be used in the *Body* key.

Expand table

Keys	Mandatory?	Rules/Notes
{}	Y	Container
LocalizationData	Y	Array that contains all the language options.
Language	Y	Specify language code, limited to 10 languages.
Title	Y	Specify the title for the dialog. Limited to 75 characters.
Body	Y	Specify the body for the dialog. Limited to 800 characters. Dynamic tokens for matched conditions can be added in the body.
HasFreeTextOption	N	This can be set to true or false. True will display a text box as a last option in the dialog.
DefaultLanguage	Y	One of the languages must be defined as DefaultLanguage within the LocalizationData key.

Dynamic tokens and text formatting in custom Oversharing dialog



Expand table

Placeholder	Explanation
%%MatchedRecipientsList%%	Display the matched recipients for a given DLP rule for these conditions: - **Recipient is** - **Recipient domain is** - **Recipient is a member of** - **Content is shared from Microsoft 365**
%%MatchedLabelName%%	Display the matched labels for a given DLP rule for this condition: - **Content contains sensitivity label**
%%MatchedAttachmentName%%	Display the matched attachments for a given DLP rule for these conditions: - **Content contains sensitive information** - **Content contains sensitivity label** - **Attachment is not labeled** - **File extension is**
<Bold>lorem ipsum</Bold>	Bold format
<Italic>lorem ipsum</Italic>	Italic format
<Underline>lorem ipsum</Underline>	Underline

Placeholder	Explanation
<Linebreak /> or	Introduce a line break

Wait on Send dialog support for Oversharing for Outlook for Microsoft 365

After you've configured the Oversharing dialog, you can optionally enable the **Wait on send** dialog feature using the *dlpwaitonsendtimeout Registry key (DWORD value)*. Do this on all devices where you want to ensure sensitive emails are evaluated according to your DLP policies before they're sent. This registry key defines the maximum amount of time to hold an email when the user selects **Send**. It allows DLP policy evaluation to complete for labeled or sensitive content. The **Wait on send** dialog is noncustomizable.

Applies to:

- Online E5 users with connected experience enabled
- Production version 2303 (Build 16.0.16216.10000) or higher.
- Semi-Annual Enterprise Channel version 2302 (Build 16.0.16130.20478) or higher.

Configure Wait on send

To configure **Wait on send** see, Steps to configure Wait on send.

> **Important**
>
> Policy tips aren't supported for meeting invitations.

DLP policy tips supported

Yes.

Email notification supported for Outlook on the Web

Yes.

Conditions that support policy tips in Outlook on the Web

- Content contains (SITs, sensitivity labels)
- Content is shared from M365
- Sender is a member of
- Recipient Domain Is
- Recipient is
- Subject Contains Words or phrases
- Sender is
- Sender domain is
- File extension is
- Subject matches patterns
- Subject or Body contains words or phrases
- Doc or Attachment is password protected
- Document name contains words or phrases

- Sender address contains words
- Document size equals or is greater than
- Subject or Body matches patterns
- Recipient address contains words
- Sender address matches patterns
- Document name matches patterns
- Recipient address matches patterns
- Message importance is
- Document property is
- Content is not labeled

Actions that support policy tips in Outlook on the Web

- Restrict access or encrypt the content in Microsoft 365 locations
- Set headers
- Remove header
- Redirect the message to specific users
- Forward the message for approval to sender's manager
- Forward the message for approval to specific approvers
- Add recipient to the To box
- Add recipient to the Cc box
- Add recipient to the Bcc box
- Add the sender's manager as recipient
- Removed O365 Message Encryption and rights protection
- Prepend Email Subject
- Add HTML Disclaimer
- Modify Email Subject
- Deliver the message to the hosted quarantine

Sensitive information types that support policy tips in Outlook on the Web

These preconfigured sensitive information types (SITs) support policy tips in Outlook on the Web.

Exact data match sensitive information types support for policy tips in Outlook on the Web

Yes.

All exact data match sensitive information types are custom created. For more information, see Learn about exact data match based sensitive information types.

Custom sensitive information types support for policy tips in Outlook on the Web

Yes.

Custom sensitive information types that use REGEX, functions, keyword lists, and keyword dictionaries support policy tips in Outlook on the Web. For more information, see Create custom sensitive information types and Create a custom sensitive information type using PowerShell.

Sensitivity labels support for policy tips in Outlook on the Web

Yes.

Retention labels support for policy tips in Outlook on the Web

No.

Trainable classifiers support for policy tips in Outlook on the Web

No.

Important information

- When emails are encrypted with Microsoft Purview Message Encryption and the policy used to detect them uses the *detect encryption* condition, policy tips will not appear.
- Administrators can use the DlpViaDcsEnabled parameter to enable exact same features and conditions that New Outlook does, see: Learn about Organisation configuration.

Exact data match sensitive information types support for policy tips in SharePoint in Microsoft 365 and OneDrive for work or school web client

Yes.

All exact data match sensitive information types are custom created. For more details, see Learn about exact data match based sensitive information types.

Custom sensitive information types support for policy tips in SharePoint in Microsoft 365 and OneDrive for work or school web client

Yes.

Custom sensitive information types that use REGEX, functions, keyword lists and keyword dictionaries support policy tips in Outlook on the Web. For more details, see Create custom sensitive information types and Create a custom sensitive information type using PowerShell.

Sensitivity labels support for policy tips in SharePoint in Microsoft 365 and OneDrive for work or school web client

Yes.

Retention labels support for policy tips in SharePoint in Microsoft 365 and OneDrive for work or school web client

No.

Trainable classifiers support for policy tips in SharePoint in Microsoft 365 and OneDrive for work or school web client

No.

Last updated on 06/15/2026

Data loss prevention policy tip reference for new Outlook for Windows

New Outlook now supports data loss prevention (DLP) policy tips with commonly used predicates and exceptions, advanced classifiers, and override capabilities.

Licensing requirements

For information on licensing, see

- Microsoft 365 Enterprise Plans
- Microsoft 365 Service Descriptions

> **Note**
>
> Features are enabled based on Licenses and connected experience settings. Review license requirements in. For any of the following conditions to work, connected experience must be turned on.

Expand table

License	These conditions apply
E3 and equivalent licenses	- Content contains Microsoft built-in or custom sensitive information types - Content is shared from Microsoft 365
E5 and equivalent licenses	- Content contains built-in or custom sensitive information types - Content is shared - Content contains sensitivity labels (works for email and Office and PDF file types) - Sender is - Sender is member of (Only Distribution lists, Azure-based Dynamic Distribution groups, and email-enabled Security groups are supported) - Sender domain is - Recipient is - Recipient is a member of (Only Distribution lists, Azure-based Dynamic Distribution groups, and email-enabled Security groups are supported) - Recipient domain is - Subject contains words - Content isn't labeled - Message isn't labeled

License	These conditions apply
	- Attachment isn't labeled - File extension is

> **Note**
>
> Conditions related to attachments are supported, except for messages (.msg) and emails (.eml), and encrypted attachments, which can't be scanned for content. See the new Outlook roadmap for details on future updates.

Actions that support policy tips

Refer to the Exchange actions support policy tips for details on actions that support policy tips.

> **Note**
>
> Offline evaluation for data loss prevention isn't available for new Outlook.

Sensitive information types that support policy tips

Refer to the Sensitive information types for details on sensitive information types that support policy tips for Outlook perpetual users and Microsoft 365 users.

Oversharing dialog for New Outlook for Windows

The oversharing dialog is available in DLP for new Outlook for E5 users. When enabled in a DLP rule, this feature displays popups for warning, override, or block actions to end users who are sharing labeled or sensitive emails in Outlook desktop.

For information about legacy AIP Add-in, see admin guide for the AIP client.

Default Oversharing Dialog

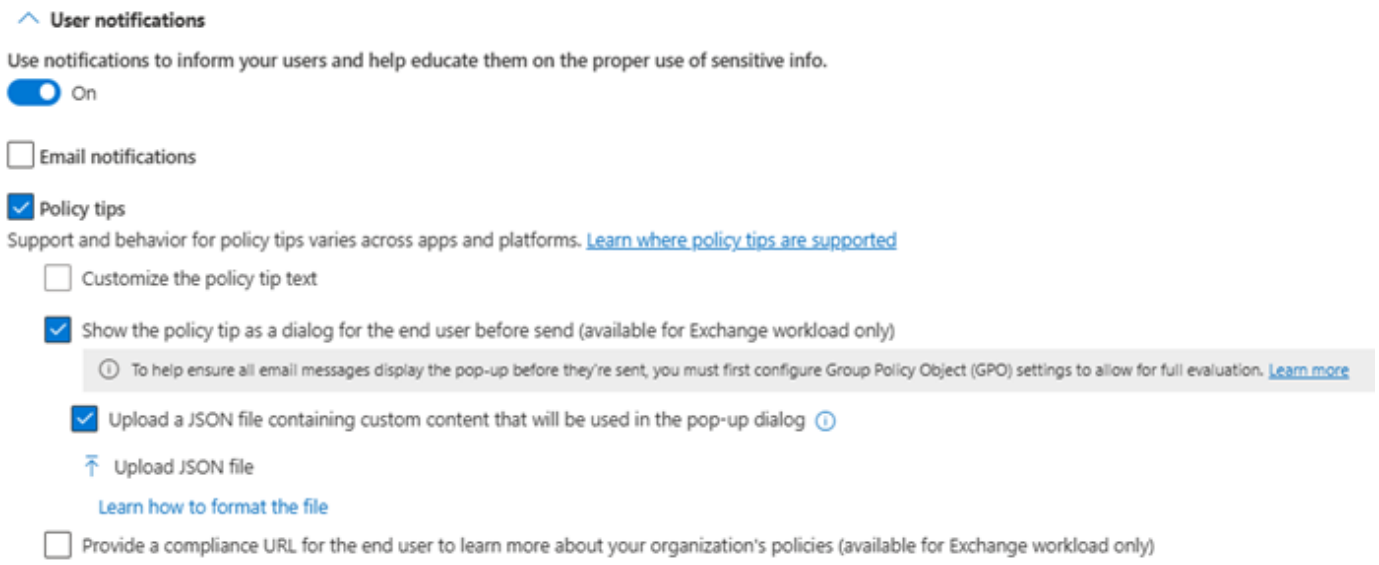
This dialog uses the exact same text as the policy tip (default or custom) and when applicable, a noncustomizable set of justification options to override the policy.

Customized Oversharing Dialog

You can choose to tailor your oversharing dialog with a customized title, body, and dynamic variables like %%MatchedRecipientsList%%, and justification options.

For customized dialog, create a JSON file like this and ensure the following:

- The file is UTF-8 encoded.
- The content is plain text.
- No comments are included.



JSON

```
{
    "LocalizationData": [
        {
            "Language": "en-us",
            "Title": "WARNING: A Sensitivity Label Not for External Use was
Detected.",
            "Body": "The following classification(s) have been detected on this email
or its attachments. <LineBreak /><LineBreak /><Bold>%%MatchedLabelName%%</Bold>
<LineBreak /><LineBreak />The email cannot be sent until either the following issues
are corrected or a justification is provided. <LineBreak /><LineBreak />Attachment(s)
needing attention (if applicable): <LineBreak />%%MatchedAttachmentName%% <LineBreak
/><LineBreak />List of external recipients: <LineBreak />%%MatchedRecipientsList%%
<LineBreak /><LineBreak />",
            "Options": [
                "The recipients have signed an NDA",
                "Manager has approved this email",
                "Organization required this content to be shared"
            ]
        },
{
            "Language": "es-es",
            "Title": "ADVERTENCIA: Etiqueta de sensibilidad no para uso externo
detectada.",
            "Body": "Se ha detectado la(s) siguiente(s) clasificación(es) en este
correo electrónico o sus archivos adjuntos. <LineBreak /><LineBreak />
<Bold>%%MatchedLabelName%%</Bold><LineBreak /><LineBreak />El correo electrónico no se
puede enviar hasta que se corrijan los siguientes problemas o se proporcione una
justificación. <LineBreak /><LineBreak />Archivos adjuntos que necesitan atención (si
corresponde): <LineBreak />%%MatchedAttachmentName%% <LineBreak /><LineBreak />Lista
de destinatarios externos: <LineBreak />%%MatchedRecipientsList%% <LineBreak />
<LineBreak />",
            "Options": [
                "Los destinatarios han firmado un NDA",
                "El gerente ha aprobado este correo electrónico",
                "La organización requirió que se compartiera este contenido"
            ]
        }
    ],
```

```
    "DefaultLanguage": "en-us"
}
```

The above JSON content can be uploaded in a DLP rule using below options:

UX instructions

PowerShell

PowerShell

```
$content = Get-Content "path to the JSON file" -Encoding utf8| Out-String
```

PowerShell

```
New-DlpComplianceRule -Name "<Rule_name>" -Policy "<Policy_name>" `-<Any_Condition>
<Condition_Value> `-NotifyPolicyTipCustomDialog $content `
-NotifyPolicyTipDisplayOption Dialog
```

PowerShell

```
  Set-DlpComplianceRule -Identity "<Rule_name>" `-NotifyPolicyTipCustomDialog
$content `-NotifyPolicyTipDisplayOption Dialog
```

When you run the cmdlet, validation checks are run on the content. The validation checks include, the JSON character limit, formatting and, mandatory presence of one default language validation. The administrator is notified of any errors so that they can be corrected

Features and limitations

The dialog title, body, and override justifications options can be customized using the JSON file. You can apply bold, underline, italic formatting, and line breaks. There can be up to three justifications options plus an option for free-text input.

The text for **Acknowledgement** and **False positive overrides** isn't customizable.

Here's the required structure of the JSON files. You use this to customize the dialog for matched rules. The keys are **all case sensitive**. Formatting and dynamic tokens for matched conditions can only be used in the *Body* key.

Expand table

Keys	Mandatory?	Rules/Notes
{}	Y	Container
LocalizationData	Y	Array that contains all the language options.
Language	Y	Specify language code, limited to 10 languages.
Title	Y	Specify the title for the dialog. Limited to 75 characters.
Body	Y	Specify the body for the dialog. Limited to 800 characters. Dynamic tokens for matched conditions can be added in the body.
HasFreeTextOption	N	This can be set to true or false. True will display a text box as a last option in the dialog.
DefaultLanguage	Y	One of the languages must be defined as DefaultLanguage within the LocalizationData key.

Dynamic tokens and text formatting in custom Oversharing dialog

Expand table

Placeholder	Explanation
%%MatchedRecipientsList%%	Display the matched recipients for a given DLP rule for these conditions: - **Recipient is** - **Recipient domain is** - **Recipient is a member of** - **Content is shared from Microsoft 365**
%%MatchedLabelName%%	Display the matched labels for a given DLP rule for this condition: - **Content contains sensitivity label**
%%MatchedAttachmentName%%	Display the matched attachments for a given DLP rule for these conditions: - **Content contains sensitive information** - **Content contains sensitivity label** - **Attachment is not labeled** - **File extension is**

Placeholder	Explanation
<Bold>lorem ipsum</Bold>	Bold format
<Italic>lorem ipsum</Italic>	Italic format
<Underline>lorem ipsum</Underline>	Underline
<Linebreak /> or	Introduce a line break

Wait on send dialog support for oversharing

New Outlook now supports *DLP Wait-to-Send* through centrally managed Exchange Online mailbox settings. The new experience allows for multi-tasking and doesn't block the user to use New Outlook even when mail is in evaluation.

During evaluation, a toast briefly notifies the user that Outlook hasn't sent the email yet and is evaluating the content. The toast gets autodismissed while evaluation continues in the background.

The wait-to-send experience is controlled solely through the following Exchange mailbox parameters:

- **DLPWaitOnSendEnabled** *boolean*: true or false.
  Default: false When true, it enables evaluation of the mail for Data loss prevention before mail is sent.

- **DLPWaitOnSendTimeout** *Integer*: range 0–10,000 seconds.
  Default:__ 9999 Specifies how long Outlook waits for DLP evaluation to complete before offering override. For Example – If the value is set to 25 seconds, Outlook waits to complete the evaluation for 25 seconds before it allows user to override and allow to send the mail without completing evaluation.

Note that this doesn't mean that evaluation is stopped after the set time, it just means that it allows for overriding the evaluation.

- When DLPWaitOnSendTimeout = 0, user will immediately see “Send Anyway” in the infobar of mail.

- When DLPWaitOnSendTimeout >= 9999, user will never be allowed to send the email without DLP evaluation getting completed.

Refer this page for Exchange mailbox parameters - Set-OrganizationConfig (ExchangePowerShell) | Microsoft Learn

Data loss prevention policy tip reference for Outlook for Android, iOS, and macOS

This feature is in ***preview***.

Outlook for Android, iOS, and macOS now supports data loss prevention (DLP) policy tips with commonly used predicates and exceptions, advanced classifiers, and override capabilities.

Licensing requirements

Policy tips supported in Outlook for Android, iOS, and macOS

Enable Policy Tips UI to Appear

Policy Tip UI is turned off by default in Outlook for Android, iOS, and macOS to allow for administrators to test and perform user training prior to deployment.

To enable Policy Tip UI to appear in Outlook for Android, iOS, and macOS, you must enable the policy listed in the following section in the Microsoft 365 Apps Admin Center. To access this policy setting, go to the Microsoft 365 Admin Center, expand "All Admin Centers" to find the "Microsoft 365 app" admin center.

You can access this policy under **Customization** and **Policy Management**. You can target policies to individuals or groups, so you can test and deploy policy tip UI as needed through your organization.

Expand table

Policy Name	Value
Enable Purview Data Loss Prevention (DLP) policy tips in Outlook	(default) **Disabled** policy tips aren't shown **Enabled** policy tips are shown

Supported conditions and actions

For details on actions that support policy tips, see Exchange actions support policy tips.

Supported SITs

For details on sensitive information types that support policy tips for Microsoft 365 users, see Sensitive information types.

Supported custom SITs

All custom SITs are supported.

Supported EDM SITs

All EDM SITs are supported.

Supported sensitivity labels

All sensitivity labels are supported.

Supported retention labels

All retention labels are supported.

Supported trainable classifiers

All trainable classifiers are supported.

Actions and information types that support policy tips

All actions and information types for email communications are supported.

For details on creating and using all policy tip types, see DLP Policy Reference.

Oversharing dialog for Outlook for Android and iOS

The oversharing dialog is available in DLP for Outlook for Android and iOS users when used with the necessary licenses and configuration. When you enable this feature in a DLP rule, it displays popups for warning, override, or block actions to end users who are sharing labeled or sensitive emails in Outlook for Android and iOS.

Default oversharing dialog

This dialog uses the exact same text as the policy tip (default or custom) and, when applicable, a noncustomizable set of justification options to override the policy.

Customized oversharing dialog

You can choose to tailor your oversharing dialog with a customized title, body, and dynamic variables like %%MatchedRecipientsList%%, and justification options. For more information, see Customized Oversharing Dialog.

Wait on send dialog support for oversharing

Outlook for Android and iOS doesn't yet support *DLP Wait-to-Send, which is* centrally managed Exchange Online mailbox settings. For future announcements, see the Microsoft 365 Roadmap, Microsoft 365 Roadmap.

For Exchange mailbox parameters, see Set-OrganizationConfig (ExchangePowerShell) | Microsoft Learn.

Learn about Data Security Investigations

Microsoft Purview Data Security Investigations helps cybersecurity teams in your organization use generative artificial intelligence (AI) to analyze and respond to data security incidents, risky insiders, and data breaches. Investigations help you quickly identify risks from sensitive data exposure and more effectively collaborate with your partner teams to remediate the issues. It simplifies tasks that traditionally are time consuming and complex.

https://learn-video.azurefd.net/vod/player?id=cf1d0239-cb00-4db6-a925-dfdb9e605dd2&locale=en-us&embedUrl=%2Fpurview%2Fdata-security-investigations

Analysts in your organization can use Data Security Investigations features to:

- Quickly and efficiently search, discover, and identify impacted data.
- Use deep content AI analysis to discover exact data risks hidden in data.
- Take action to reduce the impact of data security incidents and quickly mitigate ongoing risks.
- Collaborate with internal and external stakeholders on investigation details.
- Receive notifications through the Microsoft Purview Notification Center and email when setup completes and investigations are ready to use.

For more information about how Data Security Investigations can help you respond to data security incidents, watch the following videos:

- Data Security Investigations in Microsoft Purview
- Enhance data security investigations with Microsoft Purview
- Introducing Microsoft Purview Data Security Investigations
- Unlock the Power of Data Security Investigations with Microsoft Purview
- Microsoft Purview Data Security Investigations Ask Me Anything

AI integration

Data Security Investigations uses generative AI to conduct deep content analysis and uncover key security and sensitive data risks for data included in investigations. AI helps analysts quickly analyze large volumes of data with high accuracy, saving critical time for triage, review, and mitigation actions.

There are three main AI-related investigative capabilities:

- **Vector search**: Vector-based semantic search enables similarity-based information retrieval and understands user intent beyond literal words. Analysts query impacted data to find all assets related to a particular subject, even if keywords are missing.
- **Categorization**: To get an initial understanding of incident severity, analysts can use **Standard** or **Advanced** AI options to categorize impacted data, narrowing focus to high-risk assets. Data Security Investigations automatically sorts data into default, custom, or AI-suggested categories. Categorized items also include grouping by subject matter and risk level.
- **Examination**: Data Security Investigations enables analysts to easily address the number one priority for most data security incidents - finding security risks buried within impacted data. By examining impacted data for security risks, analysts can find compromised credentials, network risks, personal data exposure, or evidence of threat actor discussions associated with security incidents.

For more information about AI integration and these tools, see Learn about AI analysis in Data Security Investigations.

Common data breach actions

Most organizations are concerned with the increasing risks and impact related to internal and external data security breaches. Your cybersecurity team is responsible for identifying impacted data during a data breach scenario and reducing the time required to mitigate the risk associated with vulnerabilities exposed within a data breach scenario. When a data breach occurs, you must respond quickly and effectively to mitigate risks and protect sensitive information.

Your cybersecurity team needs to:

- **Assess the data breach**: Analysts must understand the scope and impact of the data breach. This understanding includes identifying all affected systems, the data impacted, and any external and internal users associated with the data breach.
- **Containment and communication**: Analysts must isolate affected systems to minimize and prevent further damage. Additionally, internal stakeholders and departments in your organization (IT, Legal, Executive Management) need notification and the details about the data breach.
- **Forensics and evidence preservation**: Analysts might need support when engaging with data forensics experts. System and status details must be retained (logs, system snapshots, network traffic) for potential legal and regulatory requirements.

- **Risk assessment and mitigation**: Analysts must evaluate potential risks and prioritize mitigation actions based on risk severity. This information helps with implementing configuration and policy updates, including implementing applicable security patches.
- **Data purge and protection**: Analysts might need to remove unnecessary or compromised data and delete redundant copies. Data Security Investigations supports soft purge and hard purge options to remove or permanently delete items from data sources. Other tasks might include strengthening access controls, data encryption, and monitoring.
- **Reporting and compliance**: Depending on the nature of the data involved and the jurisdictions affected, analysts might need to comply with regulatory requirements for breach notification. These requirements might include informing affected individuals, regulatory bodies, and other stakeholders about the nature of the breach and the steps taken to address it.

Common scenarios

Investigate a data breach

After a data security incident, it can be difficult to understand the impact of sensitive data exposure. As part of your mitigation strategy, you need to identify the intellectual property, personal data, and financial information that might be compromised. Additionally, some organizations build and maintain custom tools to investigate these issues.

When you use Microsoft Defender XDR to investigate data security incidents, you might discover a document containing unfiled patents. When you create an investigation from the incident in Data Security Investigations, further analysis shows which users downloaded the document and if it was accessed from a risky IP address. This information gives you critical context to take mitigation steps, such as protecting or purging the sensitive document from your organization.

Investigate a potential data leak from a risky insider

When you use Insider Risk Management to investigate data leak alerts for a risky user in your organization, you might learn that the user shared emails and files with an external storage solution. With built-in integration, you can create a new investigation in Data Security Investigations from the Insider Risk Management case to quickly review preliminary insights about the shared content. Before committing any additional compute resources or charges, you can decide if this content needs further analysis.

If you add the shared items to the scope of the investigation, processing automatically starts so you can dig further into the details of the content. When processing completes, all the data is

categorized and assessed for risk severity. Analysts can quickly review the highest severity items and identify the items needing a closer look. Details about usernames, passwords, documentation content, and source code are all available for review as applicable. Analysts can then work with other stakeholders in your organization to take action on the most critical items to mitigate ongoing risks from the data leak.

Confidential data leak

In scenarios where confidential, sensitive, or protected information is intentionally or unintentionally exposed outside its intended environment, you can use Data Security Investigations to further investigate a potential data leak, better understand incident impact, and take necessary next steps.

Proactive data security assessment

You can also use Data Security Investigations to proactively assess your data estate for data risk. You can analyze a sample of high-value data sources and users for data risk or run proactive scans of specific high-value data sources or a broader organization-wide scope. The assessment helps to identify opportunities for refining policies or organizational changes to strengthen security practices and potentially prevent or reduce the impact of future data security incidents.

When you enable proactive AI insights from Data Security Posture Management (preview), Data Security Investigations automatically analyzes recently exfiltrated sensitive data across five risk categories, providing continuous visibility into data exposure without manual investigation creation.

Integration with other Microsoft platforms and solutions

Data Security Investigations is a unified, purpose-built solution that's tightly integrated with other Microsoft security services. Integrated with the Microsoft Graph-enabled approach to security, Data Security Investigations draws correlations between impacted data, users, and activities. This integration helps you quickly identify impacted data, investigate incidents using generative AI, and securely collaborate with other members of your security team to mitigate risk.

Microsoft Defender XDR

Microsoft Defender XDR is a unified pre- and post-breach enterprise defense suite that natively coordinates detection, prevention, investigation, and response across endpoints, identities, email,

and applications to provide integrated protection against sophisticated attacks. With built-in integration with Data Security Investigations, you can extend the analysis of threat signals and dive deeper into data associated with attacks and security incidents.

Using the Microsoft Defender portal, you can assess alerts and quickly open an investigation in Data Security Investigations for deeper insights about the data and users associated with the incident. The investigation helps you analyze the alert details, understand what they mean, and collect and examine data for deeper review and mitigation efforts.

For more information about Microsoft Defender XDR features, see Get started with Microsoft Defender XDR.

Microsoft Purview Insider Risk Management

By combining the integration and investigative capabilities of Data Security Investigations with the proactive risk management features of Microsoft Purview Insider Risk Management, your organization has a holistic view of potential risks and the ability to take timely actions to protect sensitive data. Insider Risk Management investigators might not have important insights into the content contained in files associated with risky alerts. This gap might lead to the mishandling of alerts and ultimately hinder your effectiveness at mitigating insider threats.

The integration between Data Security Investigations and Insider Risk Management enables seamless collaboration between your cybersecurity and risk management teams. This collaboration allows for more efficient identification and a quicker mitigation of insider threats. For more information about Insider Risk Management features, see the following articles:

- Get started with Insider Risk Management
- Create and manage Insider Risk Management policies
- Investigate insider risk activities
- Take action on insider risk cases

Microsoft Purview Data Security Posture Management

If you're using Microsoft Purview Data Security Posture Management (DSPM), you can escalate potential data exfiltration findings to Data Security Investigations for deeper, AI-powered content analysis. You can manually create an investigation from a DSPM (preview) insight, or enable proactive AI insights that automatically create and refresh an investigation for your tenant every 24 hours. Investigations created from DSPM are automatically scoped to all sensitive data recently exfiltrated from your organization, allowing your team to quickly understand what was exposed, assess its sensitivity, and take informed remediation actions.

Unified audit log

Microsoft Purview auditing solutions provide an integrated solution to help organizations effectively respond to security events, forensic investigations, internal investigations, and compliance obligations. Your organization's unified audit log captures, records, and retains thousands of user and admin operations performed in dozens of Microsoft services and solutions.

Data Security Investigations integrates with the unified audit log in two ways:

- **Audit search**: Use audit search to identify and collect content based on user activities recorded in the unified audit log. Audit search queries the unified audit log for content-associated activities, such as file access, downloads, and sensitivity label changes, and adds the related content directly to your investigation scope.
- **Activity logging**: Data Security Investigations provides powerful investigation tools that might require the ability to audit activities taken to ensure secure and approved use of the solution. To meet these requirements, Data Security Investigations activities are automatically logged in the unified audit log.

For more information about these activities, see the Data Security Investigations activities section in the Audit log activities article.

Microsoft Purview Endpoint Data Loss Prevention

Microsoft Purview Endpoint Data Loss Prevention (DLP) monitors and protects sensitive items on onboarded Windows and macOS devices. For a general overview of DLP capabilities, see Learn about data loss prevention. When endpoint DLP policies are configured with evidence collection for file activities on devices, copies of files that match policies are captured and stored for review.

Data Security Investigations integrates with endpoint DLP evidence collection (preview), allowing investigators to query captured endpoint data and add it to an investigation scope for AI-powered analysis. Instead of triaging individual endpoint DLP alerts one by one, investigators can aggregate endpoint events and analyze them collectively to detect patterns such as mass exfiltration or coordinated data theft.

For more information about using endpoint DLP data in investigations, see Endpoint DLP evidence collection (preview).

Billing models

Data Security Investigations helps you identify data risks for breached content by using large language models (LLMs) and Microsoft Copilot for Security. Because Data Security Investigations provides on-demand AI analysis and integrates with other Microsoft Purview solutions, it uses pay-as-you-go and capacity billing models. This billing structure means you pay for the storage and AI capacity features you use in the solution. However, you don't need a dedicated enterprise plan or license to use Data Security Investigations.

If you enable proactive AI insights from DSPM, storage and AI capacity costs are incurred continuously while the toggle remains enabled, as the auto-created investigation refreshes every 24 hours.

For more information about billing, see Billing models in Data Security Investigations.

Learn about the Data Security Investigations workflow

The Data Security Investigations workflow helps you quickly identify, investigate, and take action on data associated with security and data breach incidents. This workflow isn't a linear process. It includes significant iteration requirements for several of the steps to fine tune searches, evidence gathering, classification, and investigation by using AI and activities.

Identifying and taking action on data and access uses the following workflow:

Step 1: Identify and escalate incidents

Identify a data security incident

Data breaches and other data security incidents require quick action to identify and contain potential risks to your organization. You need to quickly identify these incidents and streamline an integrated response. Investigating a data security incident can be daunting. It might include inefficient workflows across multiple tools, manual work, and extra complexity as the investigation grows in size. You might face labor-intensive reviews of impacted data and increased costs.

Data Security Investigations helps you investigate and mitigate data security incidents and accelerates the time to resolution. After you identify a data security incident, create a new investigation to enable your data security team to identify incident-related data, conduct deep content analysis, and mitigate risk within one unified solution.

Escalate a data security incident from Microsoft Defender XDR

If you're already using Microsoft Defender XDR in your organization, the integration with Data Security Investigations allows you to quickly and seamlessly create a new investigation. The investigation automatically includes all incident-related data items from the Defender XDR incident node.

Escalate a data security incident from Insider Risk Management

If you're already using Insider Risk Management in your organization, the integration with Data Security Investigations allows you to quickly create a new investigation for identified risky user activities.

Escalate from an insight in Data Security Posture Management

If you're already using Data Security Posture Management in your organization, the integration with Data Security Investigations allows you to quickly create a new investigation from potential data exfiltration findings and insights.

Step 2: Create an investigation and find impacted data

Creating an investigation in Data Security Investigations is quick and easy. Depending on your scenario, you can create investigations from:

- **Microsoft Defender XDR incidents**: Create an investigation from a Defender XDR incident.
- **Microsoft Purview Insider Risk Management cases**: Create an investigation from Insider Risk Management.
- **Data Security Posture Management insights**: Create an investigation from Data Security Posture Management exfiltration findings, or enable proactive AI insights that auto-create an investigation.
- **Manually by using full draft mode**: Create an investigation by using the full draft mode option to configure specific data sources and search conditions.

Step 3: Search, evaluate results, and review

After creating an investigation, you can review and update data sources. Use search tools to identify items related to the data security incident. This review includes items from the following Microsoft 365 services:

Expand table

Data source	Content type searched	Risky content examples
Endpoint Data Loss Prevention (DLP)	Files captured by endpoint DLP evidence collection	Files copied to USB, printed, uploaded to cloud, or accessed by unauthorized apps on onboarded devices.
Exchange Online	Emails and attachments in user mailboxes	Credentials or secrets sent in email, sensitive files shared externally.
Microsoft Copilot	AI prompts and responses	Sensitive data in Copilot or AI prompts.
Microsoft Teams	Chat messages (1:1 and group chats) and channel posts	Secrets included in chats, confidential information in Teams conversations.
OneDrive	User files	User files with secure access keys, export of databases, and more.
SharePoint	Documents and files in sites	Documents containing passwords, customer data, or confidential plans.

You can create and run different searches that are associated with an investigation. Use conditions such as keywords, file types, incidents, and more in the query builder to create custom search queries. These queries return results with the data most likely relevant to the data security incident. You can also use audit search to identify content based on user activities recorded in the unified audit log, such as files accessed, downloads, and sensitivity label changes. Additionally, you can use endpoint DLP evidence collection to query data captured by endpoint DLP policies on onboarded devices.

Step 4: Add data to the investigation scope

After you review and refine your search query, add all relevant data items to the investigation scope. In this step, you filter and review specific data items. You also identify any items you don't want to review by using AI tools in Data Security Investigations.

Step 5(a): Investigate items

After adding data items to the investigation scope, start refining and narrowing the data to the most relevant items for your investigation. Narrowing the items to the smallest amount of applicable data helps increase the speed and reduce costs associated with AI processing.

In this step, perform the following actions:

- Select specific items to add directly to your mitigation plan if applicable.
- Identify or exclude specific items from AI processing.

After data items are added to the investigation scope, the system automatically prepares all items. This automatic vectorization enables semantic searches and categorization of data.

Step 5(b): Investigate with AI

After Add to scope completes for the data items in the investigation, start using AI-related tools to help narrow the focus of your investigation to only the most impactful and critical items.

Use the following tools and actions in your review to identify and take action on specific data items:

- Use vector search for natural language queries to identify items for review.
- Use Search with AI (preview) with natural language queries and keywords to summarize search results for review.
- Define and configure AI-driven categories for the content.
- Use built-in and custom examination areas for selected items.
- Select items to add to the mitigation plan.

> **Important**
>
> Storage and AI capacity cost considerations are associated with the usage of each of the AI tools in Data Security Investigations. For more information, see **Billing models in Data Security Investigations** and **Use AI analysis in Data Security Investigations**.

Step 6: Take actions to mitigate

After you identify the most relevant and impactful items associated with the data security incident, take specific actions to help mitigate risks.

- **Review mitigation recommendations**: When you select items for examination and choose *Mitigation* as the focus area, the solution creates mitigation recommendations. Automated

AI processing identifies related threats and recommends mitigation steps.

- **Review credentials examinations**: When you select items for examination and choose *Credentials* as the focus area, the solution identifies credentials and other access asset examinations. AI analysis processing automatically identifies and generates credential details, type, and specific recommendations.
- **Review risk examinations**: When you select items for examination and choose *Risks* as the focus area, the solution automatically creates a security risk score and examination. The risk score helps you prioritize mitigation actions for the most impactful and risky data items.
- **Review personal data examinations**: When you select items for examination and choose *Personal Data* as the focus area, the solution identifies and extracts personal data from selected items. AI analysis processing automatically identifies PII types, extracts values, and provides surrounding context.
- **Use the mitigation plan**: After reviewing examinations and recommendations, add specific data items from the investigation scope to the mitigation plan. This plan helps you manage and track the mitigation status for each data item.
- **Purge items if needed**: Create a search query and save it as a purge query to help you identify and remove items in your organization. You can soft purge items to move them to the recoverable items folder or hard purge items to permanently delete them.

Best practices

- **Iterate and use AI analysis wisely**: Investigations rarely finish in one step. Use the AI suggestions in categorization and vector search to uncover hidden issues. Always validate any critical findings by using human judgment. The investigator's judgment is key in critical decision-making.
- **Keep the investigation scope focused**: It's easy to get overwhelmed as you discover more data. Use categorization to exclude irrelevant information and concentrate primarily on any risky items.
- **Engage the right teams in your organization early**: Data security incidents often span multiple areas. These areas might include security, IT, and compliance in your organization. Share with partner teams as soon as you identify areas needing action.
- **Use integrated Microsoft services**: Data Security Investigations is part of the broader Microsoft Purview and Defender ecosystem. If your investigation suggests an insider risk, open an Insider Risk Management case. If it started from a Microsoft Defender XDR alert, update that incident with your findings. The goal is an end-to-end view of the incident in your organization.

Email and portal notifications

Data Security Investigations sends notifications to inform investigators about setup status and keep them updated on investigation progress. Notifications are delivered through both the Microsoft Purview Notification Center (bell icon in the Microsoft Purview portal) and email. Email notifications include the investigation name as the header and a button that links directly to the relevant page in the Microsoft Purview portal.

The following table describes the notifications associated with setup and onboarding:

Expand table

Notification	Trigger	Recipients	Description
Setup complete	Initial setup is completed	All users with Data Security Investigations roles	Notifies all assigned users that Data Security Investigations is configured and ready for use.
Integration investigation ready	Initial setup is completed and user previously created investigations from Microsoft Defender XDR, Insider Risk Management, or Data Security Posture Management	Users who created investigations before setup completed	Directs users back to their pre-existing investigation to begin AI analysis.
Setup reminder	User created an investigation but initial setup isn't completed after 7 days	User who created the investigation	Reminds the user or their admin to complete setup so the investigation can proceed.
Permissions provisioning complete	1 hour after permissions assignment when final onboarding step isn't completed	User completing onboarding	Reminds the user to complete the final onboarding step after permissions are provisioned.

> **Note**
>
> Notification preference settings aren't currently available. All users with Data Security Investigations roles receive notifications for the scenarios listed in this section.

Learn about AI analysis in Data Security Investigations

> **Important**
>
> Data Security Investigations uses generative artificial intelligence (AI), large language models, and orchestration in the analysis of data in your organization. Results generated by AI might not always be accurate or complete. While we strive to provide reliable and helpful information, AI systems can produce incorrect or false results. It is important to verify the information and use it with caution. Microsoft makes no warranties, express, implied, or statutory, as to the information provided by AI systems.

Data Security Investigations uses AI services and tools to help you quickly review and take action on items associated with security incidents. AI-related services include the following tools:

- Vector search
- Categorization
- Examination

Vector search

Vector search in Data Security Investigations provides a way to contextually search through data that you add to the investigation scope by using advanced orchestration and embeddings. Vector search is a search engine technology that focuses on understanding the meaning and context behind words and phrases in a query, rather than just matching keywords.

Some key aspects of vector search are:

- **Contextual understanding**: Vector search interprets the context of your search terms, considering factors like your organization, search history, and the overall meaning of the query.
- **Intent recognition**: Vector search works to understand your intent, whether you're looking for information, trying to take an action, or seeking a specific type of content associated with a search.

- **Relevance and accuracy**: By focusing on the semantics (the meaning and intent of words in your query), vector search provides more accurate and relevant results and improves the overall search experience.

- **Suggested search (preview)**: Vector search also enables customized suggested search queries for you to select based on the investigation context or any previous searches in an investigation. If your investigation doesn't have a context defined and you don't have any previous searches, you can choose from the following default suggested searches:
  - Look for anything containing credentials or passwords
  - Find all content containing sensitive information
  - List all legal and financial documents

When investigators in your organization investigate compromised data sets, vector search in Data Security Investigations can significantly enhance your investigation by addressing several key challenges:

- **Identifying relevant information**: Vector search understands the context and intent behind your queries. This focus helps you quickly locate relevant documents, emails, or records, even if they don't contain the exact keywords you used.
- **Handling ambiguity**: Vector search disambiguates terms that have multiple meanings, ensuring that you get results that are contextually appropriate to your investigation.
- **Reducing noise**: Vector search filters out irrelevant information, so you can focus on the most pertinent data and reduce the time spent sifting through unrelated results.
- **Improving efficiency**: Vector search streamlines the search process, making your investigation more efficient and effective by quickly surfacing the most relevant information.

How it works

When you create an investigation and define the scope, the system automatically prepares data for AI. Starting June 2026, add to scope automatically encompasses the previous **Prepare for AI** action for all new investigations. You can then run vector searches over the data set. While previous steps of the process allow for simple keyword, metadata, and date range search, vector search uses AI embeddings to contextually search through data. This process allows investigators to find items without knowing their exact content.

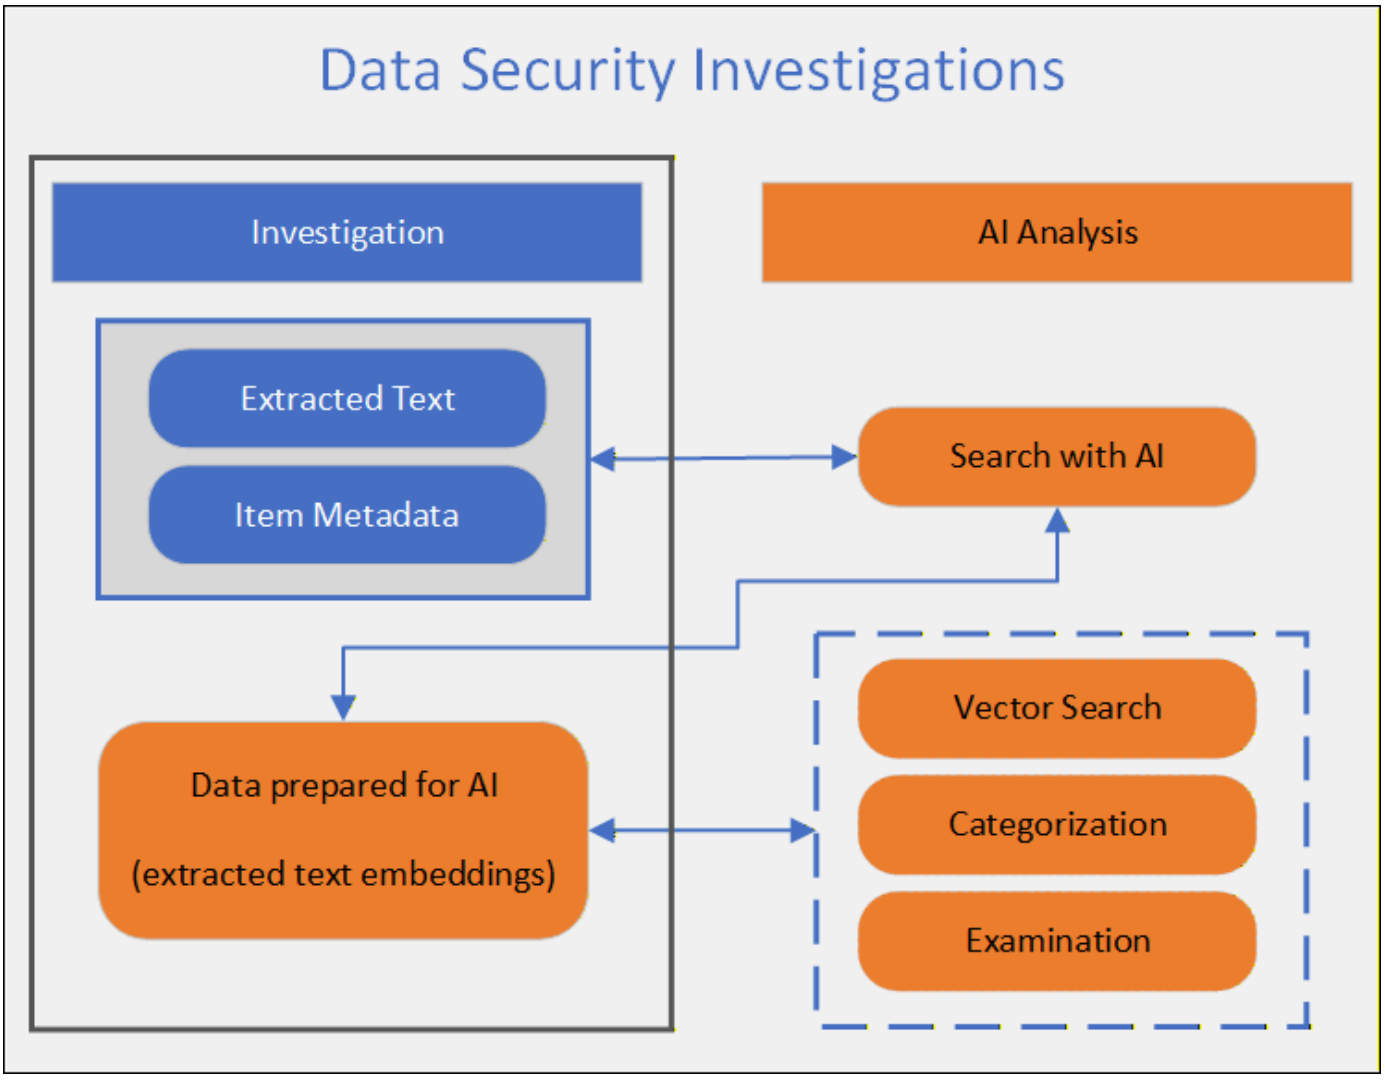
> **Important**
>
> Items are vectorized if they contain text or supported image content with extractable text. For JPEG, PNG, and scanned PDF files, Optical Character Recognition (OCR) automatically

extracts text from images before vectorization. Meeting invites and calendar notifications without text in the body are excluded from vectorization.

Vector search works by first running all scoped data in an investigation through an AI embeddings model. This model extracts semantic meaning from every item in your data set and breaks them into smaller parts. This process is called embedding and allows Data Security Investigations to use dimension values to understand your data contextually. A semantic search index is built from these values that you can query.

When you create a vector search query in an investigation, AI automatically expands and broadens your query and runs the query through the semantic search index. Data Security Investigations then matches the semantic meaning of your query with the semantic meaning of your content and returns all contextually relevant items.

For example, if you search for "Confidential data included in the Contoso Security project", the vector search engine understands that you're looking for confidential data in this specific project rather than simply matching keywords (*confidential*, *data*, *Contoso*, etc.) contained in the search query. Using vector search, you can query impacted data to find all data items related to a particular subject, even if keywords are missing.



Additionally, a search relevance score is automatically assigned to each item returned. The search relevance score helps you quickly determine the confidence level of the connection between your search and the items identified by vector search.

For more information about vector search concepts, see the concepts section in the Vectors in Azure AI Search article.

Search with AI (preview)

Building on vector search, Search with AI (preview) incorporates retrieval-augmented generation (RAG) capabilities and optimizes the search results model. This feature includes search relevant items based on item file types, sizes, versions, and more.

This capability expansion to vector search also includes a search summary based on individual items returned in the search, including citation links to specific search results samples, to help you quickly evaluate if the search meets your needs.

Categorization

When your organization is breached and you identify the impacted data, investigators need to prioritize data to start identifying security risks. Data Security Investigations categorization speeds up investigations by automatically grouping content around the data security risks you care about, so analysts can narrow thousands of files down to a small set of prioritized, meaningful clusters - without manual review.

You can use **Standard** or **Advanced** AI-powered categorization in Data Security Investigations to more quickly reason through and prioritize potentially impacted data. To categorize data, you can select all or some default category options, use AI-suggested categories based on their investigation, or create your own custom categories.

You can also add categories incrementally after an initial categorization run completes. When you add new categories, only the net new categories are processed and previously categorized data is preserved. You can also change existing categories between **Standard** and **Advanced** processing levels.

The AI-generated categories are enriched with additional information for subject-level content in scope:

- **Name**: The name of the category or area based on the content
- **Summary**: A short description of the underlying content

Within each category, you can use vector search and examination tools on any content.

How categorization processes data

Categorization is designed to prioritize the most relevant content for each selected category rather than analyze every item in the investigation scope. When you run categorization, the system uses AI to evaluate content against your selected categories, scores each content segment for relevance, and retains the highest-confidence results. Content that doesn't meet the relevance threshold for a category isn't included in the results for that category.

Because categorization is optimized for speed and cost efficiency, be aware of the following considerations:

- **Results represent prioritized content**: Categorization surfaces a prioritized subset of the most relevant content for each category, not an exhaustive analysis of all items in your data set.
- **Content volume can affect results**: In large datasets, documents with extensive content might be more strongly represented in results. Some relevant items might not appear if they score below the relevance threshold.
- **Categories are processed independently**: Each selected category is evaluated separately. The number of categories you select affects processing time and compute unit costs but doesn't change how relevance is determined for individual categories.

When you select **Standard** categorization, the system groups content into your selected categories based on relevance scoring. When you select **Advanced** categorization, the system performs additional processing to identify and organize content into specific topics within each category, providing more granular groupings for deeper analysis.

> **Tip**
>
> If your investigation requires comprehensive analysis of all content in scope, use examination tools instead of or in addition to categorization. Categorization is best for fast

prioritization and triage of large datasets, while examination provides targeted, item-level analysis for selected items.

Default categories

Data Security Investigations includes default categories to categorize items in your investigation scope. When you run categorization, you can select all default categories or only the default categories that apply to the scope of your review. The analysis ignores unselected default categories, and you can't review results for these categories.

AI processing determines the initial default categories for content items:

- **Business information**: General business information. This category typically contains a large number of items. Some example areas in this category might include digital engagement and analysis, user and human resources, routine administrative communication, customer engagement/experience, and more.
- **Communication records**: General communication information. This category also typically contains a large number of items. Use this category to see your investigations based on areas of communications. Some example areas in this category might include client complaints, holiday greetings, internal memos, project updates, and more.
- **Credentials and access information**: Information related to access assets in investigations. This information helps identify potentially risky data and communications in your organization. Some example areas in this category might include user credentials, unauthorized database access, data exposure, and more.
- **Customer information**: Information shared with customers. Use this category to understand what customer data might be at risk. Some example areas in this category might include payment confirmations, customer experience improvement, delivery information, and more.
- **User information**: Information related to users in your organization. This category also typically contains a large number of items. Some example areas in this category might include user employment information, user retention strategies, specialized group memberships, and more.
- **Financial information**: Financial information in an investigation. Some example areas in this category might include financial planning, grant opportunities, budgets, financial statements, and more.
- **Health information**: Health and medical-related items in an investigation. Some example areas in this category might include wellness and health records, COVID-19 safety protocol updates, health claims and incident reports, and more.

- **Incident and investigation information**: Items about incidents and investigations in an investigation. This category includes security incidents and investigations within your organization. Some example areas in this category might include data breach, health records incidents, high-risk client account monitoring, and more.
- **Intellectual property**: Intellectual property (IP) data in an investigation. Some example areas in this category might include future patent applications, research and development work, experiment result metrics, and more.
- **Marketing information**: Marketing data in an investigation. Some example areas in this category might include press releases, advertising campaigns, marketing and sales plans, or strategies and more.
- **Operational information**: Your organization's operational data. Some example areas in this category might include logistics, shipping, inventory, compliance, tax records, and more.
- **Personally identifiable information**: Group personal data and related items in an investigation. Some example areas in this category might include event guest lists, staff and training sessions, employee personal information, and more.
- **Regulated data**: Regulated data in an investigation. Some example areas in this category might include regulatory, data protection, regulatory records, and more.

> ⓘ Note
>
> Investigations auto-created by proactive AI insights from Data Security Posture Management (DSPM) use five fixed risk categories: Credentials and access information, Personally identifiable information, Financial information, Confidential information, and Intellectual property. These categories are separate from the 13 default categories listed here and aren't configurable in the current preview.

Suggested categories

Data Security Investigations also provides AI-generated suggested categories based on the content analyzed in your investigation scope. These suggested categories automatically help investigations review items grouped in unexpected or unknown areas. Depending on the type of content included, the suggested categories vary.

If the content analyzed primarily focuses on a specific subject area outside of the default category areas, the suggested categories customize to that specific content area. For example, if the analyzed content focuses on a highly confidential subject with terms and concepts specific solely to your organization, the suggested categories are automatically created for these areas. These categories are unique to your organization and the content analyzed.

Custom categories

Data Security Investigations enables you to manually create custom categories for the generative AI process to use when analyzing content. By defining categories that best fit your investigation needs, you can save time and let the AI process automatically categorize items based on these custom categories.

Custom categories can be specific words or phrases that capture the specific nature of content you're interested in during the investigation. For example, custom categories might include *Security vulnerability*, *Bug fix*, specific project code names, or custom intellectual property like R&D related to a specific medicine or drug candidates.

Some additional custom categories that might be helpful in your investigations:

- Access codes
- API access documentation
- API authentication keys
- API tokens
- Application configuration files
- Certificate Authority (CA) details
- Certificates
- Database credentials
- Digital certificates
- Disaster recovery plans
- Employee location data
- Encryption keys
- Environment configuration files
- Incident Management Logs
- Integration tokens
- JWT tokens
- Key management policies
- Multifactor authentication (MFA) backup codes
- Personal Identification Numbers (PINs)
- Privileged account details
- Secure strings
- Security logs
- Security policies
- Session

- SSH private keys
- Third-party API secrets
- User credentials
- Vulnerability assessments

Examination

As you identify items that require deeper analysis, Data Security Investigations provides AI-based examination capabilities to help you focus on key security and sensitive data risks.

- **Credentials**: Use this examination focus area to scan and extract credentials from all selected items in an investigation scope. This information provides investigators with a quick way to understand which accounts and credentials are associated with a security incident and that might be potentially exfiltrated.

- **Risk**: Use this examination focus area to score all the risk areas in selected files to help investigators focus and prioritize investigations. This tool provides the overall risk for each item, if the item is privileged content, and other specific risks for the item.

  Types of risk areas include:
  - Asset identifiers
  - Credentials and secrets
  - Evidence of threat actor and breach discussions
  - Urgent security incidents
  - Vulnerability and security hygiene
  - Personal and sensitive content
  - Network and access information
  - Policy compliance and data protection
  - Infrastructure information
  - Customer information
  - Government information
  - Privileged information
  - Trade secrets

- **Mitigation**: Use this examination focus area to score the risk for selected files and enable Data Security Investigations to provide you with mitigation instructions for what to do next. Selected files get a risk score, risk summary, and detailed mitigation recommendations to prevent more harm from a content breach.

- **Personal data**: Use this examination focus area to identify and extract personal data from selected items in an investigation scope. This information provides investigators with a quick way to understand what personal data types are present in data associated with a security incident, including names, email addresses, employee IDs, IP addresses, and other PII.

- **Custom**: Use this examination focus area to define a custom analysis using a natural language prompt. Describe what you want the AI to look for in selected items, up to 2,000 characters. Custom examinations produce the same structured results as built-in focus areas, with findings validated by safety guardrails. For more information about creating custom examinations, see Create a custom examination.

AI analysis recommendations

The following table outlines recommendations, example scenarios, and best practices when using the AI analysis tools in Data Security Investigations.

Expand table

Recommendations	Vector search	Categorization	Examination
When to use	Look for examples of specific items within a vectorized data set (invoices, bug fixes, and more) to confirm and further investigation hypotheses. Use vector search for quick interactive analysis, results are quickly populated.	Quickly prioritize large amounts of data into default, custom, or AI-generated categories by sensitivity and severity. Categorization surfaces the most relevant content for each category rather than analyzing every item. Depending on the size of the data set, categorization might take some time to complete.	Comprehensive, targeted analysis at the item level for all selected data items. Helps extract detailed insights from confirmed data assets for next steps. Use examination to identify items for mitigation.
Example scenario	Evaluation of potentially fraudulent activity.	Prioritization of items for analysis after large breach.	Extraction of credentials and personal data from a validated data set and recommended mitigation steps.
Analysis scope	All vectorized content in the investigation scope.	Prioritized subset of the most relevant content for each selected category.	All selected items in the investigation scope.

Recommendations	Vector search	Categorization	Examination
Best practices	Search across all vectorized content for items of interest to generate more meaningful AI suggested categories.	Select one or multiple categories and use vector search to search within the category. Review AI-generated areas within each category to understand specific content within the data set.	Use examination to drill into specific items with high sensitivity to get individual scores and results.

Last updated on 06/11/2026

Get started with Data Security Investigations

Use Data Security Investigations to identify, investigate, and mitigate data risk either reactively when an incident occurs or proactively to improve data security hygiene for your organization. Complete the following steps in the workflow to set up prerequisites and configure Data Security Investigations.

For more information about how Data Security Investigations can help you with security incidents in your organization, see Learn about Data Security Investigations.

Step 1: Read and agree to terms

The first time you access Data Security Investigations in the Microsoft Purview portal, you must read and agree to the terms of the Privacy Statement.

Confirm that you accept the terms and select **Get started**.

Step 2: Configure permissions

To allow users to access Data Security Investigations tools in the Microsoft Purview portal, assign the users the appropriate permissions. The easiest way to assign roles is to use the setup task or add the user the appropriate role group on the **Role groups** page in the Microsoft Purview portal.

Members of the *Compliance Administrator* and *Organization Management* role groups automatically have Data Security Investigations administrative and contributor access. Members of the *Data Security Management* and *Insider Risk Management* role groups automatically have contributor access. For more information about access levels, see Additional role groups with Data Security Investigations access.

> **Important**
>
> To configure the AI capacity for Data Security Investigations, you must be a member of the *Data Security Investigations Admins* role group.

For step-by-step guidance, see Assign permissions in Data Security Investigations.

Step 3: Configure billing and usage

To get started with Data Security Investigations, configure billing and usage settings for data storage and AI analysis features. Data Security Investigations uses a payment model based on how much data you add to investigations and how much AI capacity you use for analysis of that data.

For step-by-step guidance, see Billing models in Data Security Investigations.

If you plan to enable proactive AI insights from Data Security Posture Management (DSPM), configure billing before enabling the toggle because the auto-created investigation incurs storage and AI costs immediately.

> **Tip**
>
> After setup completes, all users with Data Security Investigations roles receive a notification through the Microsoft Purview Notification Center and email confirming the solution is ready. For more information, see **Email and portal notifications**.

Step 4: Create an investigation

To get started with Data Security Investigations, you must create an investigation and configure investigation settings.

You can create investigations in several ways. Choose from the following methods to create a new investigation:

- From a Microsoft Defender XDR incident.
- From an Insider Risk Management case.
- From Data Security Posture Management insights.
- Manually using the full draft mode.

The user who creates the investigation is automatically added as a member. Members of the investigation can access the investigation in the Microsoft Purview portal and perform Data Security Investigations tasks.

To configure user access and permissions for specific investigations, see Configure investigation access and permission settings in Data Security Investigations.

Step 5: Search and evaluate results

After creating an investigation, use search tools to identify content such as email, documents, and instant messaging conversations in your organization that are relevant to a data security incident.

> **Tip**
>
> Refining and narrowing searches to key areas of your investigation is an iterative process. Narrow the results as much as possible before adding data items to the investigation scope. Use filters to identify non-relevant items, select the items, and mark the items as excluded.

Search tools allow you to:

- Define custom data sources
- Create custom searches with the query builder
- View scope and sample dashboards for search result items

Step 6: Add items to an investigation scope

After you add data items from your search queries to the scope of the investigation, the system automatically vectorizes items for AI analysis.

You can group and view items in the investigation scope, including file detail views for each data item. After automatic vectorization completes, you can use AI-powered tools for advanced analysis.

Step 7: Investigate items

Use generative AI processing to help you quickly identify and review data items in the investigation scope. These tools help you decide which items need closer examination and if they should be added to the mitigation plan.

- Vector search
- Categorization
- Examination

Step 8: Take mitigation actions

Create detailed examinations and review risk examinations and recommendations for items in the investigation scope:

- Review mitigation recommendations

- Review credentials examinations
- Review risk examinations
- Review personal data examinations
- Use the mitigation plan

ⓘ**Note:** The author created this article with assistance from AI. Learn more

Last updated on 06/11/2026

Get started with the Data Security Posture agent (preview) in Data Security Investigations

> **Important**
>
> Data Security Investigations uses generative artificial intelligence (AI), large language models, and orchestration in the analysis of data in your organization. Results generated by AI might not always be accurate or complete. While we strive to provide reliable and helpful information, AI systems can produce incorrect or false results. It is important to verify the information and use it with caution. Microsoft makes no warranties, express, implied, or statutory, as to the information provided by AI systems.

The Data Security Posture agent (preview) in Data Security Investigations helps your organization proactively surface credentials buried in data across your organization at scale. Rather than manually investigating individual items, the Posture agent automates credential scanning across Microsoft 365 data locations, including SharePoint sites, OneDrive accounts, Exchange mailboxes, and Teams content. After the agent completes scanning, it produces AI-generated risk assessments with confidence scores and supporting reasoning to help your security team quickly prioritize and remediate credential exposure risks.

> **Important**
>
> The Posture agent in Data Security Investigations is currently in preview. Features and functionality might change before general availability.

How the Posture agent works

The Posture agent in Data Security Investigations uses the same agent as Data Security Posture Management (DSPM) (preview). When you enable the Posture agent, you make it available in both DSPM and Data Security Investigations. If you already enabled the Posture agent in DSPM, you don't need to onboard again to use it in Data Security Investigations.

By using the Posture agent in Data Security Investigations, you can:

- **Scan for credentials at scale**: Run tenant-wide or scoped credential scanning tasks to discover exposed credentials across your organization's Microsoft 365 data.

- **Track tasks on a task board**: Monitor the progress of scanning tasks through a Kanban-style task board with statuses like *In progress* and *Ready for review*.
- **Review AI-generated risk assessments**: Examine AI-produced risk scores, confidence levels, and reasoning for flagged items to help prioritize remediation efforts.
- **Explore data with KQL queries**: Use the Data Explorer to run Kusto Query Language (KQL) queries against credential findings for advanced analysis and investigation.
- **Download reports**: Generate and download reports of credential scan results for offline review and compliance reporting.

Prerequisites

Before you can use the Posture agent in Data Security Investigations, confirm the following prerequisites are in place:

- **Permissions**: You must be assigned to one of the role groups that includes Posture agent access. For more information, see Permissions for deploying, running and viewing results from the Posture Agent.
- **Agent enabled**: You must enable the Posture agent in the Microsoft Purview portal. For more information, see Enable the Posture agent.
- **Security Compute Units (SCUs)**: Your organization must have Security Copilot SCUs provisioned for the Posture agent to run.

> **Tip**
>
> You don't need to configure or enable Data Security Investigations to use the Posture agent. The Posture agent is independent of the Data Security Investigations solution and doesn't require Data Security Investigations billing, permissions, or setup to be completed. As long as the Posture agent is enabled and your organization has SCUs provisioned, the Posture agent experience is available in the Data Security Investigations navigation. Other Data Security Investigations features, such as creating investigations and AI analysis, still require separate Data Security Investigations configuration and billing.

Enable the Posture agent

If your organization hasn't already enabled the Posture agent, use the following steps to enable it:

1. Go to the Microsoft Purview portal and sign in by using the credentials for a user account assigned the appropriate permissions.
2. Select **Agents** in the left navigation.

3. Select **Explore agents**, and then select **View details** for the Posture agent in Data Security Investigations.
4. Select **Set up** to enable the agent for your organization.

After you enable the Posture agent, it appears in Agents, DSPM, and Data Security Investigations. In Data Security Investigations, you can access the agent by selecting **Posture agent** in the left navigation.

> **Note**
>
> If you already enabled the Posture agent in DSPM, you don't need to complete these steps. The agent is automatically available in Data Security Investigations.

Create a credential scanning task

Create a credential scanning task so the Posture agent can scan your organization's data for exposed credentials. You can scope the scan to your entire tenant or narrow it to specific users, sites, or groups.

Complete the following steps to create a credential scanning task:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in by using the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Posture agent** in the left navigation.
3. Select **Assign to agent** to create a credential scanning task.
4. For the **Credential Scanning Task**, enter a name for the task in the **Task name** field.
5. Configure the data sources for the scan. You can select a tenant-wide scan or narrow the scope to your organization, specific sites, users, mailboxes, or groups.
6. Select **Save**.
7. In the **Additional context for AI**, use natural language guidance to help AI scope the agents to applicable areas.
8. Select **Create** to start the task.

After you create the task, it appears in the **In progress** column on the task board.

> **Tip**
>
> If you realize you scoped a task incorrectly after it starts, you can stop the task and create a new one with the correct scope.

Monitor tasks on the task board

The Posture agent uses a Kanban-style task board to help you track the progress of credential scanning tasks. Each task appears in one of the following columns:

- **In progress**: The agent actively scans the specified data locations and analyzes content.
- **Ready for review**: The agent finished scanning and the results are ready for a human reviewer to examine.
- **Closed**: A human reviewer has marked a tasked as completed.

The task board displays key information for each task, including the scan scope, the number of locations scanned, and the number of items analyzed. You can also assign a security operations center (SOC) administrator to review the results for a specific task.

Review scan results

After a credential scanning task finishes and moves to the **Ready for review** column, you can review the results to identify and prioritize credential exposure risks.

Summary view

The summary view provides a high-level overview of the credential scan results. In the summary view, you can:

- **Sort by risk level**: View results sorted by *High*, *Medium*, or *Low* risk to prioritize the most critical findings.
- **Group by credential category**: Organize results by credential type to understand the distribution of exposed credentials.
- **Review AI reasoning**: For each flagged item, the AI provides its reasoning for the assigned risk level, helping you understand why a specific item is flagged as high, medium, or low risk.
- **Download reports**: Generate a report of the scan results for offline review, compliance reporting, or sharing with stakeholders.

Item details

Select a specific item in the scan results to view detailed information, including:

- The detected credential type.
- The data location where the credential was found.
- The AI-generated risk and confidence scores.

- The reasoning behind the risk classification.

Explore data with Data Explorer

Data Explorer provides advanced analysis capabilities by allowing you to run Kusto Query Language (KQL) queries against the credential findings from the Posture agent scans. This experience is similar to advanced hunting in Microsoft Defender XDR and provides a schema-based metadata framework for querying credential data.

To use Data Explorer, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal.
2. Select **Posture agent** in the left navigation.
3. Select a completed task, and then select the **Data Explorer** tab.
4. Write and run KQL queries against the credential findings schema.

> **Tip**
>
> If you're new to KQL, see **Kusto Query Language overview** to learn the basics of writing queries.

ⓘ **Note:** The author created this article with assistance from AI. Learn more

---

Last updated on 03/23/2026

Assign permissions in Data Security Investigations

To enable users to access Data Security Investigations capabilities and features in the Microsoft Purview portal, assign users the appropriate permissions.

This article describes the permissions required to perform specific Data Security Investigations tasks. For more information about Microsoft Purview role groups and permissions, see Permissions in the Microsoft Purview portal.

Roles and role groups

> **Important**
>
> After you configure your role groups, it might take up to 30 minutes for the role group permissions to apply to assigned users across your organization.

To quickly assign the *Admin* or *Investigator* roles to users, use the **Assign roles to your team members** setup task. Complete the following steps to assign these roles:

1. Go to Data Security Investigations in the Microsoft Purview portal with an account assigned the *Global Administrator* role.
2. Select **Overview** in the left navigation.
3. Select **Assign roles to your team members** in the **Setup tasks** section.
4. Select users in the **Admin** field on the **Role assignment** flyout pane.
5. Select users in the **Investigators** field.
6. Select **Confirm** to assign users these roles.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

You can also add users to the appropriate role group on the **Role groups** page in the Microsoft Purview portal. To continue with these configuration steps in the Microsoft Purview portal, you

must be assigned to the *Data Security Investigations Admins* role group.

Configure permissions

To manage Data Security Investigations workflow and investigations, assign users to specific role groups to manage different sets of Data Security Investigations features. You can assign users with different security responsibilities to specific role groups to manage different areas of Data Security Investigations features. Or, assign all user accounts for designated admins, investigators, and reviewers to the *Data Security Investigations Admins* role group. Use a single role group or multiple role groups to best fit your security management requirements.

> **Tip**
>
> Always have at least one user in the *Data Security Investigations Admins* role group so that your Data Security Investigations configuration doesn't get in to a 'zero administrator' scenario if specific users leave your organization.

Choose from these solution role group options when configuring and managing Data Security Investigations:

Expand table

Actions	Data Security Investigations Admins	Data Security Investigations Investigators	Data Security Investigations Reviewers
Add, delete, manage items for a mitigation plan	Yes	Yes	Yes
Create and manage all investigations	Yes	No	No
Create and manage assigned investigations	Yes	Yes	No
Create searches and add items to an investigation	Yes	Yes	No
Estimate and preview search results	Yes	Yes	No
Manage investigation scope	Yes	Yes	No

Actions	Data Security Investigations Admins	Data Security Investigations Investigators	Data Security Investigations Reviewers
Run categorization activities	Yes	Yes	Yes
Run examination activities	Yes	Yes	Yes
Run vector searches	Yes	Yes	Yes
Create and run purge queries	Yes	Yes	No
View data risk graphs	Yes	Yes	Yes
View the Pay-as-you-go usage dashboard	Yes	No	No

> **Important**
>
> Global admins must be assigned to one of the listed role groups for Data Security Investigations to create and access investigations.

Additional role groups with Data Security Investigations access

In addition to the dedicated Data Security Investigations role groups, the following Microsoft Purview role groups automatically include Data Security Investigations roles. Members of these role groups have Data Security Investigations access without needing explicit assignment to a Data Security Investigations-specific role group.

Expand table

Role group	Data Security Investigations role included	Access level
Compliance Administrator	Data Security Investigation Admin	Full administrative access
Organization Management	Data Security Investigation Admin, Data Security Investigation Contributor	Administrative and contributor access
Data Security Management	Data Security Investigation Contributor	Contributor access
Insider Risk Management	Data Security Investigation Contributor	Contributor access

Members with the *Data Security Investigation Contributor* role can create and manage investigations they own or are members of. This role doesn't include access to data storage, AI job execution, or the Pay-as-you-go usage dashboard.

For more information about these role groups and their complete role assignments, see Roles and role groups in Microsoft Defender for Office 365 and Microsoft Purview.

Option 1: Assign multiple users to the Data Security Investigations Admins role group

Complete these steps to give multiple users administrative access and responsibilities for Data Security Investigations in your organization.

1. Go to the Microsoft Purview portal with an admin account in your Microsoft 365 organization.
2. Select **Settings** in the upper-right corner of the page, select **Roles and groups**, then select **Role groups** in the left navigation.
3. Select the *Data Security Investigations Admins* role group, then select **Edit**.
4. Select **Choose users**, then select the checkboxes for all the users you want to add to the role group.
5. Select **Select**, then select **Next**.
6. Select **Save** to add the users to the role group, then select **Done**.

Option 2: Assign users to specific Data Security Investigations role groups

Complete these steps to assign users to specific role groups to segment Data Security Investigations access and responsibilities among different users in your organization.

1. Go to the Microsoft Purview portal with an admin account in your Microsoft 365 organization.
2. Select **Settings** in the upper-right corner of the page, then select **Role groups** in the left navigation.
3. Select one of the Data Security Investigations role groups, then select **Edit**.
4. Select **Choose users**, then select the checkboxes for all the users you want to add to the role group.
5. Select **Select**, then select **Next**.
6. Select **Save** to add the users to the role group.

7. Select the next Data Security Investigations role group, then repeat the previous steps for each required role group.
8. Select **Close** when you're done.

ⓘ **Note:** The author created this article with assistance from AI. Learn more

Last updated on 04/23/2026

Billing in Data Security Investigations

Billing in Data Security Investigations is based solely on the combination of the amount of stored data and the associated computing capacity needed for AI analysis. It isn't based on a dedicated enterprise plan or license.

This billing combination is based on the **storage meter** and **AI capacity** models. The Data Security Investigations non-AI processing and storage meter lets you store data related to an investigation. Data Security Investigations Compute Units (compute unit) measure the computational capacity needed to run the AI analysis within Data Security Investigations.

Storage meter

The storage meter for Data Security Investigations uses the pay-as-you-go billing model. You pay for storage on a gigabyte (GB) per month basis for stored data associated with all investigations in your organization.

For example, you have three investigations in your organization that have the following data associated with the items included in the investigation scopes for the current month:

Expand table

Investigation	Items	Total data
Data breach 02/12/2025	3,766	200 GB
Potential data theft 03/03/2025	1,982	10 GB
Risky user activity 04/06/2025	287	5 GB

For the current month, your total storage meter is 215 GB and you pay for that amount at the current per gigabyte rate. When you delete an investigation, you stop paying for the associated data storage amount. The charges are prorated to the number of days the data was stored in the billing cycle.

Some other important considerations for managing storage charges:

- If you create an investigation, use data storage, and then delete the investigation in a single 24-hour period, you pay for the storage amount.

- When you delete an investigation anytime after 00:00 UTC, you pay for storage for the full day (24 hours).
- Investigations auto-created by proactive AI insights from DSPM consume storage continuously while the toggle is enabled. Because the investigation refreshes every 24 hours, storage charges are ongoing.

For more data storage rates and pricing, see Data Security Investigations storage meter pricing.

AI capacity

> **Important**
>
> To configure the AI capacity for Data Security Investigations, you must be a member of the *Data Security Investigations Admins* role group.

Data Security Investigations uses the pay-as-you-go billing model for AI capacity. You need compute units for deep analysis and AI-related processing in your investigations. You can change the maximum limit of compute units ready to use at any time. You pay only for the compute units you use.

Proactive AI insights from DSPM also consume compute units. Each 24-hour refresh cycle uses compute units to generate AI insights across five fixed risk categories. For more information, see Enable proactive AI insights from DSPM.

For guidance on calculating the compute unit needs for your organization, see the Estimate and manage usage of Data Security Investigations Compute Units section in this article.

Locations for compute units and AI processing

Compute unit processing uses GPU resources in Azure datacenters protected by Azure security and privacy controls. You can choose where to use compute units from any of the following locations:

- Australia/New Zealand (ANZ)
- Europe (EU)
- United Kingdom (UK)
- United States (US)

You can opt in to having compute units provisioned and AI analysis processing done anywhere in the world to mitigate potential disruptions in case your primary location experiences high activity.

Microsoft recommends having compute units and AI processing done anywhere with available GPU capacity. This recommendation enables Data Security Investigations and Azure to determine the optimal location based on load, latency, and responsiveness.

Best practices for managing investigation costs

Planning and managing costs is an essential part of running effective Data Security Investigations. By estimating costs up front, applying safeguards during configuration, and continuously monitoring usage, you can control spending without limiting your ability to respond to security incidents.

The following best practices help ensure investigations remain cost-efficient while still providing the flexibility required for thorough and timely analysis.

1. **Use the in-product cost estimator before starting investigations**: Before launching an investigation, use the in-product cost estimator to anticipate costs based on investigation size and the analyses you plan to conduct. This process helps data security teams plan budgets with precision and prevent unforeseen expenses.

2. **Use built-in spending controls in Azure**: Use the powerful built-in spend controls included with your Azure subscription, including:

    - Create budgets for the Data Security Investigations resource group and meter level.
    - Configure alerts when spending approaches defined thresholds (for example, 50%, 75%, or 90%).
    - Use Azure Cost Analysis for drill-downs and anomaly detection.

3. **Scope investigations tightly**: Focus on the investigation scope to lower storage and compute costs. Start with targeted searches and expand only as needed based on initial findings.

4. **Delete completed investigations promptly**: When you delete an investigation, you no longer incur costs for using data storage. Charges are prorated to the number of days the data was stored in the billing cycle. Regularly review and remove investigations that you no longer need to minimize ongoing storage costs.

5. **Monitor usage with the usage dashboard**: Use the usage dashboard to track storage and compute unit spending within Data Security Investigations in real time. This granular visibility helps identify cost-saving opportunities and optimize resource allocation across investigations.

6. **Right-size your AI analysis**: Not every investigation requires the full suite of AI capabilities. Consider which analyses (categorization, vector search, examination) are truly necessary for each investigation to optimize compute unit consumption.

7. **Add categories incrementally**: When using categorization, start with a focused set of categories and add more as your investigation progresses. When you add new categories to an existing categorization, you're only charged for the compute units needed to process the net new categories. This approach helps you manage costs effectively while expanding your analysis over time.

8. **Budget for proactive AI costs from DSPM**: If you enable proactive AI insights from DSPM, the auto-created investigation refreshes every 24 hours, incurring ongoing storage and AI compute charges. Monitor usage regularly and factor these recurring costs into your monthly budget.

Estimate your investigation data storage and AI costs

Before configuring billing, use the estimate costs tool to calculate an estimate of potential monthly data storage and AI costs for investigations in Data Security Investigations. Use the estimator tool to plan your costs before setting up data storage and compute units for AI features.

Use the tool to estimate individual investigation costs to create an average investigation cost or use the tool to estimate the costs of all anticipated investigations. This estimate is based on current storage and AI usage billing meters for a 30-day period.

Use the guidelines in the Investigation size and complexity section in this article to help complete the fields in the estimator tool.

To estimate investigations costs, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with the credentials for a user account assigned Data Security Investigations permissions.
2. On the **Estimate storage and AI usage costs** card, select **Estimate costs**.
3. Complete the required and optional fields for a single investigation to calculate an estimated average cost or for the total number of investigations in your organization.
4. Select **Calculate**.
5. Review the estimated costs and recalculate as needed.

Configure billing

Before you can use Data Security Investigations in your organization, you must configure both billing models. Storage meter billing requires a link to an Azure subscription for pay-as-you-go billing. Capacity billing requires dedicated compute unit configuration.

Prerequisites

To configure the storage meter and capacity for Data Security Investigations, you must have:

- An Azure subscription in the same tenant as Microsoft Purview.
- An Azure resource group in that subscription.
- The *Global Administrator* role.
- The resource group *Owner* or *Contributor* role.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Configure storage meter

The Azure subscription you configure for Data Security Investigations manages all pay-as-you-go capabilities across Microsoft Purview solutions. If you previously configured an Azure subscription for other Microsoft Purview solutions, you don't need to configure an additional subscription.

To configure the storage meter for Data Security Investigations, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Setup pay-as-you-go-billing for data storage** in the **Setup tasks** section.
3. On the **Setup pay-as-you-go-billing for data storage** flyout pane, complete the following fields for the Azure subscription:
   a. **Azure subscription**: The Azure subscription you want to assign to the storage meter.
   b. **Resource group**: The resource group in your Azure subscription you want to assign to the storage meter.
4. Select **Enable**.

Configure AI capacity

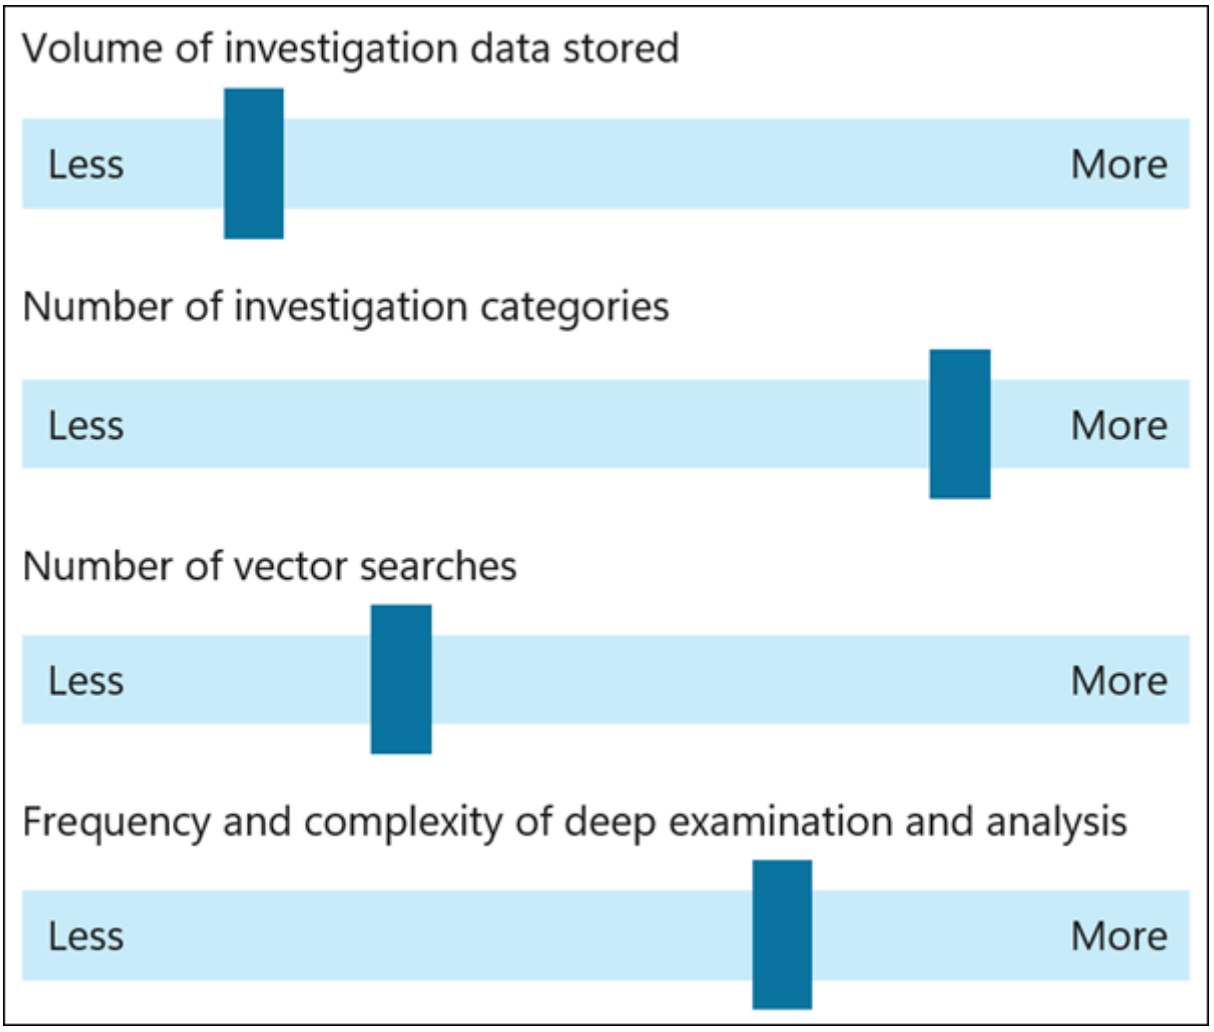
When you configure compute units, you enable the AI capacity for investigations in your organization. To configure AI capacity for Data Security Investigations, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Setup pay-as-you-go to use AI** in the **Setup tasks** section.
3. On the **Set up AI capacity** pane, complete the following fields:
   a. **AI analysis data processing location**: The primary country/region. Select from the available locations.
4. In the **Number of compute units** section, select one of the following options:
   a. **No limit**.
   b. **Set maximum limit**.
5. Select the check box to confirm that you read, understood, and agreed to the terms and conditions.
6. Select **Confirm**.

Estimate and manage usage of compute units

To manage the usage of compute units in Data Security Investigations, estimate your likely compute unit usage and the general size of the investigation. While it's challenging to estimate the exact amount of these variables, having a general sense of the investigation processing, size, and complexity helps you make informed decisions about provisioning and scaling compute unit usage.

Investigation processing



Data Security Investigations supports various processing tools to help you identify and take action on data security incidents. Each processing tool has different variables that you should consider when estimating support for each processing type:

Expand table

Process type example	Scale units or variables
Add to scope (including data preparation for AI analysis)	Size of data and extracted text
Vector searches	Size of data searched

Process type example	Scale units or variables
Categorization	Number of new categories selected. Adding categories to an existing categorization only processes net new categories.
Examination	Number of files analyzed

These variables primarily influence the cost for compute unit billing. They work together to determine the exact amount of compute unit usage per investigation. Each investigation might have a different combination of these cost influencers, so determining the exact compute unit billing estimation is challenging.

Investigation size and complexity

Each investigation uses different amounts of storage and processing power. To estimate the compute unit usage for an investigation, consider the overall size of the investigation. In general, investigations fall into one of the following sizes:

- **Small investigation**: A small investigation to test usage as a proof of concept in your organization.

- **Medium investigation**: A medium investigation, such as a data audit or responding to a minor data security incident.
- **Large investigation**: A large investigation for a significant data breach or leak incident.
- **Extra large investigation**: An extra large investigation for a major data security breach, leak, or incident.

To estimate the total compute units your organization needs for specific types of investigations, use the investigation processing, size, and complexity guidelines in this section. See the following sections during your planning and configuration:

- Add to scope
- Vector search and compute units
- Categorization and compute units
- Examination and compute units

> ⓘ **Important**
>
> You aren't billed for failed compute unit operations but are billed for partial completions. For example, you pay when you successfully vectorize partial data in an investigation scope. If you cancel an in-progress job (such as **Add to scope**, Categorization, or Examination), you still pay for any compute units consumed before the cancellation.

Pay-as-you-go usage dashboard

Use the **Pay-as-you-go usage dashboard** to quickly view and track data storage and compute unit usage for each investigation in your organization. The current data storage and compute unit totals for each investigation help you manage usage and cost per investigation. This information is helpful during reactive investigation surges associated with severe data breaches and ongoing data storage trends.

> ⓘ **Note**
>
> It might take up to 48 hours for the latest billing data to show up on the **Pay-as-you-go usage dashboard** for your organization. Only users assigned the *Data Security Investigations Admin* role can access the **Pay-as-you-go usage dashboard**.

To view the **Pay-as-you-go usage dashboard**, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with the credentials for a user account assigned to the Data Security Investigations Administrator role group.
2. Select **Usage dashboard** in the left-navigation.

From the **Pay-as-you-go usage dashboard**, you can review:

- The data storage usage for each investigation and the total for each process.
- The total amount of compute units used by Data Security Investigations processes.
- The compute units per day, for the last 7, 14, or 30 day timescale.
- The compute unit usage for each investigation and the total for each process.

Each investigation has the total data storage for each of the following processes:

- **Add to scope**: Storage and compute supporting processes when adding items to the investigation scope, including automatic vectorization.
- **Categorization**: Storage and compute supporting categorization processes for an investigation.
- **Examination**: Storage and compute supporting examination processes for an investigation.
- **Interactive AI**: Storage and compute supporting semantic search and AI suggested categories.

To export the data storage and compute information for all investigations, select **Export**. The export file lists the following information:

- **ID**: The ID of the investigation.
- **Date**: The date the report was created for each investigation.
- **Storage**: The total data storage for each process in the investigation.
- **InvestigationName**: The friendly name of the investigation.
- **JobType**: The type of process associated with the data storage or compute usage.
- **JobID**: The ID for the process.
- **ConsumedUnits**: The amount of compute units used for the process.

Stop billing

To stop billing for Data Security Investigations, disable both storage meter and AI capacity support. This action deletes all investigations in Data Security Investigations and deletes compute units for your resource group.

> ⊗ **Caution**

Deleting investigations and your compute unit resource group is irreversible. Make sure you export or preserve any investigation results or reports before stopping billing.

Stop storage meter billing

Data storage charges start when you add items to the scope of an investigation. To stop storage metering, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with the credentials for a user account assigned to the Data Security Investigations Administrators role group.
2. Delete all existing investigations in your organization.
3. Verify that no active or pending investigations remain in your organization.

When you delete all investigations, you remove the associated data and stop storage billing for Data Security Investigations.

Stop AI capacity billing

AI analysis is billed through compute units in Microsoft Azure. To stop compute unit billing, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with a user account that has either the **Owner** or **Contributor** role for the Azure subscription associated with the Data Security Investigations compute unit resource.
2. Go to the **Subscription** where you deployed your Data Security Investigations resource.
3. Select the associated **Resource group** for Data Security Investigations.
4. Select and delete the **DSI compute unit capacity resource** (for example, `DataSecurityInvestigation-GUID`).

When you delete the compute unit resource, all AI capacity and compute billing stops for Data Security Investigations.

ⓘ**Note:** The author created this article with assistance from AI. Learn more

Last updated on 06/11/2026

Create an investigation in Data Security Investigations

After configuring billing and usage options for Data Security Investigations and assigning permissions to analysts in your organization that manage investigations, create and manage an investigation for collection and analysis activities.

Investigations dashboard

Depending on your permissions, the **Investigations** dashboard in the Microsoft Purview portal displays investigations in your organization. If you're not assigned to the *Data Security Investigations Admins* role group, you can only view investigations you're assigned to as an investigator or reviewer.

The **Investigations** dashboard lets you quickly see the investigations in your organization that you have access to, the description of the investigations, and important information associated with each investigation.

- **Name**: The name of the investigation. The investigation name must be unique in your organization.
- **Description**: The description entered when the investigation was created.
- **Created on**: The date and time in Coordinated Universal Time (UTC) when the investigation was created.
- **Last modified**: The date and time in Coordinated Universal Time (UTC) when the investigation was last modified.

Select **Edit columns** to customize the displayed columns and the order of the columns in the **Investigations** dashboard. Choose the columns to display or drag and drop columns to reorder.

AI context for investigations

Additional context for AI helps focus AI-provided results in an investigation to specific areas, subjects, and issues to help eliminate noise and decrease the time it takes to discover and mitigate relevant items. Without additional context, AI analysis might return nonrelated categories and risk examinations results for data prepared for AI in your investigation. By providing detailed context for an investigation, categorization and risk examination results more accurately represent the areas you need to investigate.

For example, if you want an investigation to focus primarily on bribery issues, consider including *Find instances of bribery* in the **Additional context for AI** field on the **Create an investigation** dialog when creating new investigations in full-draft mode, from Defender XDR, or from Insider Risk Management. The more details that you provide as the context for the investigation, the more focused the AI analysis results are in the investigation.

> **Tip**
>
> Use natural language to provide the context and details you're looking for in the investigation. The context is automatically processed to remove typos, incorrect grammar or punctuation, symbols, and more to help improve clarity and readability for backend AI processing. This context review doesn't change the original intent of the provided context.

Any AI-related analysis for an investigation includes the context you provide for a new or existing investigation. Context-related categories are automatically included in AI-suggest categories and risk examinations for investigations including a custom context statement. You can add or edit context for an investigation at any time, but you must rerun categorization and risk examinations after any context changes. All changes to context statements are automatically recorded as extended properties for an investigation.

Create an investigation

Depending on your scenario, you can create investigations by using each of the following methods:

- **From Microsoft Defender XDR incidents**: Create an investigation from a Defender XDR incident.
- **From Microsoft Insider Risk Management cases**: Create an investigation from an Insider Risk Management case.
- **From Data Security Posture Management insights**: Create an investigation from exfiltration activities identified in Data Security Posture Management.
- **Manually by using full draft mode**: Create an investigation by using the *full draft mode* option to configure specific data sources and search conditions.

Create an investigation from Defender XDR

With the integration with the Microsoft Defender XDR solution, you can quickly open an investigation in Data Security Investigations as part of your response to data breach incidents.

You can create an investigation from Defender XDR incidents containing mailbox, email message, or file nodes. To create investigations in Data Security Investigations in the Microsoft Defender portal, you must have the following roles assigned:

- Security Administrator
- Security Operator

Create a new investigation from a Defender XDR incident by using one of the following methods:

- Select **Create investigation** from the Data Security Investigations banner at the top of any incident in Defender XDR. This banner automatically displays if the incident might contain sensitive information. The new investigation contains all nodes included in the Defender XDR incident.
- Select **Create Data Security Investigation** from the ellipsis control in the top right of an incident page. The new investigation contains all nodes included in the Defender XDR incident.
- Select any individual mailbox, email message, or file node in the Defender XDR incident to display the node menu and select **Create Data Security Incident**. The investigation contains only the selected node from the Defender XDR incident.

After you select one of the previous options, the **Create a data security investigation** dialog is displayed. Complete the following steps:

1. In the **Name** field, give the investigation a name (required). The investigation name must be unique in your organization. If the name you enter isn't unique, you're notified when you select **Create**.
2. In the **Description** field, add an optional description to help others understand this investigation.
3. In the **Scope** field, choose the items from the incident to include in the investigation.
4. In the **Additional context for AI** field, enter additional context to help AI focus your investigation on specific areas and issues.

> ⓘ **Important**
>
> You can't include mailboxes in the scope of an investigation and also include files or email messages. Investigations created from incidents including mailboxes must be standalone investigations. Select either mailboxes in the scope area OR email messages and files. Both email messages and files from an incident can be included in the same investigation.

1. Select **Create** to create the investigation.

The items included in the scope of the investigation are automatically included as data sources and you're ready to start reviewing and adding these items to the investigation scope in Data Security Investigations.

> **Note**
>
> Sometimes the data sources for SharePoint site or files might not autopopulate in an investigation. If this situation occurs, manually add the data sources and use the suggested query.

> **Important**
>
> Investigations created from Defender XDR incidents that contain more than approximately 3,000 items might not return complete results. The exact limit depends on the file names and paths of the returned items. For more information about limits, see Limits in Data Security Investigations.

Create an investigation from Insider Risk Management

With the integration of Microsoft Purview Insider Risk Management, you can quickly open an investigation in Data Security Investigations from a case and for potentially risky activities. To create investigations in Data Security Investigations in Insider Risk Management, you must have at least one of the following roles assigned:

- Insider Risk Management
- Insider Risk Management Investigator

To create a new investigation from an Insider Risk Management case, complete the following steps:

1. In the Microsoft Purview portal, go to **Insider Risk Management** > **Cases** and select a case.
2. On the **Cases** page, select **Case actions**.
3. Select **Investigate data security with AI**.
4. In the **Create a data security investigations** dialog box, complete the following fields:

a. In the **Name** field, enter a name for the investigation (required). The investigation name must be unique in your organization. If the name you enter isn't unique, you're notified when you select **Create investigation**.
b. In the **Description** field, add an optional description to help others understand this investigation.
c. In the **Investigation scope** field, choose the items from the case to include in the investigation.
d. In the **Additional context for AI** field, enter additional context to help AI focus your investigation on specific areas and issues.

5. Select **Create investigation** to create the investigation.

The items included in the case are automatically included as data sources. You're ready to start reviewing and adding these items to the investigation scope in Data Security Investigations.

> ⓘ **Important**
>
> Investigations created from Insider Risk Management cases that contain more than approximately 3,000 items might not return complete results. The exact limit depends on the file names and paths of the returned items. For more information about limits, see Limits in Data Security Investigations.

Create an investigation from Data Security Posture Management

By using the integration with the Microsoft Purview Data Security Posture Management (DSPM) solution, you can investigate data exposure insights surfaced by DSPM exfiltration objectives. The **Prevent exfiltration to risky destinations** objective card supports two investigation modes:

- **Manual investigation**: Create an investigation on demand from the exfiltration objective card to analyze specific data exposure insights.
- **Proactive AI insights (preview)**: Enable an opt-in toggle that automatically creates and refreshes a single investigation for your tenant every 24 hours. This investigation continuously analyzes recently exfiltrated sensitive data across five fixed risk categories: credentials and access information, personally identifiable information (PII), financial information, confidential information, and intellectual property (IP). The DSPM exfiltration objective card displays the count of items identified in each risk category.

Investigations created from DSPM automatically scope to all sensitive data exfiltrated from your organization in the last 30 days. These investigations enable deeper, AI-powered content analysis of recently exfiltrated data, giving security teams actionable insights without extra configuration.

For more information about the roles and permissions needed to create an investigation in Data Security Investigations from DSPM, see Permissions for Microsoft Purview Data Security Posture Management.

Create a manual investigation from DSPM

To manually create a new investigation from DSPM, complete the following steps:

1. In the Microsoft Purview portal, go to **DSPM**.
2. In **Objectives**, select the **Prevent exfiltration to risky destinations** card.
3. Select **View objective** to view exfiltration details and proactive insights.

   > **Note**
   >
   > It might take 24 hours or more for insights to display for the objective.

4. On the **Exfiltration risk patterns** card, select **Create investigation**.
5. In the **Create a data security investigation** dialog, complete the following fields:

   - **Name**: Enter a unique name for the investigation (required).
   - **Description**: Provide a description to help others understand the purpose of the investigation (optional).
   - **Add context for AI**: Provide context for the investigation (optional).

6. Select **Create investigation** to create the investigation in Data Security Investigations.

After the investigation is created, it automatically includes all scoped data items as data sources. You're ready to start reviewing, analyzing, and taking mitigation actions by using the full capabilities of Data Security Investigations. If you didn't configure Data Security Investigations before creating the investigation, the investigation is created but you need to configure Data Security Investigations before you can view the investigation.

The most recent manual investigation that you created from DSPM (preview) is always available for selection on the **Exfiltration risk patterns** card in the **Prevent exfiltration to risky destinations** objective.

Enable proactive AI insights from DSPM

To enable proactive AI insights, complete the following steps:

1. In the Microsoft Purview portal, go to **DSPM (preview)**.
2. In **Objectives**, select the **Prevent exfiltration to risky destinations** card.
3. Select **View objective** to view exfiltration details.
4. On the **Exfiltration risk patterns** card, turn on the **Proactive AI insights** toggle.

After you enable the toggle, the first investigation is created automatically. Insights might take up to 24 hours to appear after initial activation. The investigation refreshes automatically every 24 hours while the toggle remains enabled.

> **Important**
>
> Proactive AI insights consume Data Security Investigations storage and AI analysis meters while the toggle is enabled. In the current preview, proactive AI insights use five fixed risk categories. Custom category templates and per-item deletion within the auto-created investigation aren't supported. For more information about billing, see Data Security Investigations billing.

Create an investigation using full draft mode

In some scenarios, you might prefer to create a new investigation that isn't associated with a Microsoft Purview Insider Risk Management or Microsoft Defender XDR incident. By using full draft mode, create a new investigation that starts with new data sources and queries.

Manage investigation settings

Investigation settings include investigation information and access permissions. You can access settings for a specific investigation by selecting **Investigation settings** after selecting an investigation.

For more information about investigation settings, see:

- Investigation settings
- Access and permissions settings

Note: The author created this article with assistance from AI. Learn more

Last updated on 06/22/2026

Create an investigation using full draft mode in Data Security Investigations

When you create an investigation by using full draft mode in Data Security Investigations, you get the most flexibility and options for analyzing a data security incident. With this process, you can customize the data sources and query in your investigation.

Use full draft mode

Complete the following steps to create an investigation and configure the investigation scope by using the *full draft mode*. The user who creates the investigation is automatically added as a member. Members of the investigation can access the investigation in the Microsoft Purview portal and perform Data Security Investigations tasks.

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with the credentials for a user account assigned Data Security Investigations permissions. Members of the *Compliance Administrator*, *Organization Management*, *Data Security Management*, and *Insider Risk Management* role groups can also create investigations.

2. Select **Investigations** in the left navigation.

3. Select **Create investigation**.

4. On the **Create an investigation** dialog, complete the following fields:

    - **Title**: Enter a name for the investigation (required). The investigation name must be unique in your organization.
    - **Description**: Add an optional description to help others understand this investigation.
    - **Additional context for AI**: Enter additional context to help AI focus your investigation on specific areas and issues.

5. Select **Switch to full draft mode**.

6. Select **Add data sources**

7. On the **Manage data sources** flyout pane, search and add data sources for your investigation query. You can filter to scope data sources to help you choose one or more users or group sources to add to the investigation.

Use one or more of the following options in the **Search for people, groups, locations, or tenant locations** field to select from the following default filters:

- *All people and groups (default)*
- *All apps*
- *All public folders*

If needed, enter specific people, groups, locations, or tenant locations to reduce the scope of sources to specific resources in your organization.

8. Select **Save**.
9. Use the query builder to create a new search query for the investigation.
10. Select **Review scope** to review statistics about the results from the query
11. Select **Add to scope** to add data items to the investigation scope.

Next steps

After you create your investigation and add data items to the investigation scope, the system automatically vectorizes the items for AI analysis.

Investigation settings in Data Security Investigations

Investigation details let you view and update investigation information. You can take action on specific investigations.

Investigation details

The investigation settings display the following information for the selected investigation:

- **ID**: Shows the investigation ID number. You can review this ID but can't change it after the investigation is created.
- **Investigation name**: Shows the investigation name. This field is required. To change the investigation name, enter the new investigation name and select **Actions** > **Save**.
- **Investigation description**: Shows an optional description to help others understand this investigation. To change the investigation description, enter the new investigation description and select **Actions** > **Save**.
- **Investigation status**: Shows the current investigation status.
- **Investigation created**: Shows the date and time when the investigation was created.

Delete an investigation

Delete investigations when they're no longer needed for your organization. When you delete an investigation, you also delete all components associated with the investigation, such as searches, investigation scopes, and mitigation plans. You can't recover a deleted investigation.

To delete an investigation, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Investigations** in the left navigation.
3. Select an investigation, then select **Investigation settings**.
4. On the **Investigation settings** page, select **Actions**, then select **Delete investigations**.

Configure investigation access and permission settings in Data Security Investigations

Access and permission settings in Data Security Investigations allow you to add or remove users to an investigation, manage role group membership for an investigation, and add people outside your organization as guest users for an investigation.

Add or remove users from an investigation

You can add or remove users to manage who can access the investigation. However, before a user can access an investigation (and perform tasks in the investigation), you must add the user to the *Data Security Investigations Manager* role group in the Microsoft Purview portal. For more information, see Assign Data Security Investigations permissions.

Add users to an investigation

Complete the following steps to add users to an investigation:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in using the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Investigations** in the left nav.
3. Select an investigation, then select **Investigation settings**.
4. On the **Investigation settings** page, select **Permissions**.
5. Under **Users**, select **Add** to add users to the investigation. You can also choose to add a role group to the investigation by selecting **Add** under **Role groups**.
6. In the list of users or role groups that can be added to the investigation, select the check box next to the names of the users or role groups that you want to add.

> **Note**

When adding a role group to an investigation, you can only add the role groups that you're a member of.

7. After selecting the people or role groups to add as members of the investigation, select **Add**. The selected users are added to the investigation.

> **Important**
>
> If a role is added or removed from a role group that you added as a member of an investigation, then the role group is automatically removed as a member of the investigation (or any investigation the role group is a member of). The reason for this process is to protect your organization from inadvertently providing additional permissions to members of an investigation. If a role group is deleted, it's removed from all investigations it's a member of. For more information, see Assign Data Security Investigations permissions.

Remove users from an investigation

Only a Data Security Investigations Administrator can remove users from an investigation. Even if you're assigned to the *Data Security Investigations Manager* role group or initially created the investigation, you aren't able to remove yourself or other members from an investigation unless you're also a Data Security Investigations Administrator. To remove yourself or other members from an investigation, contact a Data Security Investigations Administrator in your organization.

Complete the following steps to remove users from an investigation:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in using the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Investigations** in the left nav.
3. Select an investigation, then select **Investigation settings**.
4. On the **Investigation settings** page, select **Permissions**.
5. Under **Users**, select **Remove** to remove users from the investigation. You can also remove users from a role group for the investigation by selecting **Remove** under **Role groups**.
6. In the list of users or role groups that can be removed from the investigation, select the check box next to the names of the users or role groups that you want to remove.
7. After selecting the people or role groups to add as members of the investigation, select **Remove**. The selected users are removed from the investigation.

Search, review, and refine results in Data Security Investigations

Use search in Data Security Investigations to find Microsoft 365 content such as email, documents, and instant messaging conversations in your organization that are relevant to a security incident. Use search to find content in these cloud-based Microsoft 365 data sources:

Expand table

Data source	Content type searched	Risky content examples
Endpoint Data Loss Prevention (DLP)	Files captured by endpoint DLP evidence collection	Files copied to USB, printed, uploaded to cloud, or accessed by unauthorized apps on onboarded devices.
Exchange Online	Emails and attachments in user mailboxes	Credentials or secrets sent in email, sensitive files shared externally.
Microsoft Copilot	AI prompts and responses	Sensitive data in Copilot or AI prompts.
Microsoft Teams	Chat messages (1:1 and group chats) and channel posts	Secrets included in chats, confidential information in Teams conversations.
OneDrive	User files	User files with secure access keys, export of databases, and more.
SharePoint	Documents and files in sites	Documents containing passwords, customer data, or confidential plans.

Create and run different searches that are associated with an investigation. Use conditions such as keywords, file types, incidents, and more to build search queries that return search results with the data most relevant to the investigation. You can also:

- View search statistics that help you refine a search query to narrow results.
- Preview the search results to quickly verify whether you're finding the relevant data.
- Revise a query and rerun the search.
- Use audit search to identify content based on user activities recorded in the unified audit log.
- Use endpoint DLP evidence collection (preview) to query data captured by endpoint DLP policies on onboarded devices.

Consider the activities that triggered the investigation. For example, reported password sharing or leak, a suspicious file, work with an external development team, or an alert about data exfiltration or specific individuals or teams who may be involved. Use this information to help develop your initial search query. For example, if an administrator reported that passwords might be stored in plain text in SharePoint, start by searching for known password keywords or file names across SharePoint and OneDrive, or specific SharePoint sites managed by engineering teams.

When you're satisfied with the results of a search and ready to review and analyze the results, add them to an investigation scope in the investigation. Adding copies of the original data to an investigation scope also facilitates the AI analysis and review process by providing you with advanced categorization, examination, and vector search tools.

Access search tools

Select **Summary** from the navigation options at the top of any page within a specific investigation to access search tools on the Identify page.

The Identify page is organized into the following tabs:

- **Search**: Create search queries to identify content relevant to the investigation. The **Search** tab includes three options:
  - **Query builder**: Search for content based on keywords, file types, dates, and other conditions.
  - **Audit**: Use audit search to identify content based on user activities recorded in the unified audit log.
  - **Endpoint DLP**: Use endpoint DLP evidence collection (preview) to query data captured by endpoint DLP policies on onboarded devices.
- **Review estimates**: Review scope and sample statistics for search results to refine your query before adding results to an investigation scope.

You can refine search query data sources and conditions at any time during the investigation and add the results to an investigation scope.

Data sources

In Microsoft 365, data is stored across three platforms: Exchange, Teams, and SharePoint. These platforms serve as the backbone for organizing and managing data within Microsoft 365 applications.

> **Important**
>
> If you set a site status to *Locked* and set the site to *NoAccess*, Data Security Investigations doesn't return search results. For more information about managing site lock statuses, see Lock and unlock sites. In addition, if you restrict a document in the content store, the Data Security Investigations investigator must be a site admin, site owner, or the owner or last modifier of the restricted document to access it in Data Security Investigations. For more information about restricted content, see Data Loss Prevention policy reference.

Most Microsoft 365 apps store data in one or more of the following containers:

- **Users**: Data associated with individual users, such as their mail, 1:1 Teams messages, and OneDrive files.
- **Groups**: Data owned by the organization or a group of users within an organization. These groups are often referred to as Unified Groups or Teams.

In Data Security Investigations, the concept of *data sources* streamlines the process of identifying and managing data across Microsoft 365 platforms. Analysts select a user or group and scope searches to those data sources. Analysts can refine the scope by selecting or excluding specific locations.

Analysts can also use organization-wide sources to perform search across your organization. Organization-wide sources include:

- **All people and groups**: Includes all users and all groups in your organization.
- **All public folders**: Includes all content in Exchange public folders mailboxes.

> **Important**
>
> If your organization has configured compliance boundaries using search permissions filters, Data Security Investigations searches respect those boundaries. Investigators whose accounts are scoped by a compliance boundary only see search results for content locations within their permitted boundary. For more information about how compliance boundaries and search permissions filters work, see Set up compliance boundaries in eDiscovery and Configure search permissions filtering in eDiscovery.

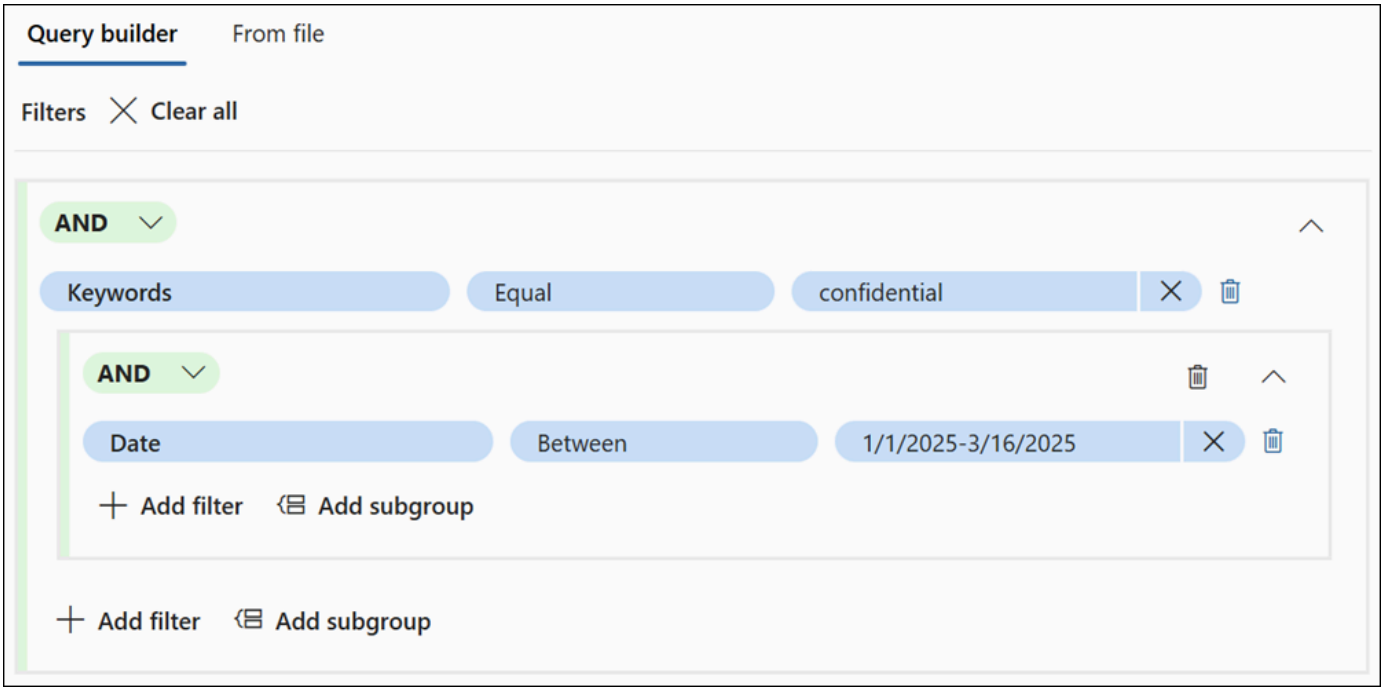
Query builder

The **Query builder** option on the **Search** tab provides a visual filtering experience when you build search queries in Data Security Investigations. Since you'll use AI analysis tools to quickly identify applicable data in items returned by your search, one strategy is to broaden your search scope to include more sources of data. This approach helps reduce the chance of excluding any relevant content for review.

Use the query builder to construct complex queries with additional functionality, including AND, OR, and grouping of conditions. These features in the query builder help you build queries more effectively, provide a visual interface for grouping subqueries, and provide additional space for complex keyword queries to be constructed and reviewed.

Use the query builder

To create a query and custom filtering for your search, use the following controls:



- **AND/OR**: These conditional logical operators help you choose the query condition that applies to specific filters and filter subgroups. Use these operators to include multiple filters or subgroups connected to a single filter in your query.
- **Select a filter**: Choose filters for the specific data sources and location content you select for the collection.
- **Add filter**: Add multiple filters to your query. This option becomes available after you define at least one query filter.
- **Select an operator**: Depending on the selected filter, choose from compatible operators. For example, if you select the *Date* filter, you can choose from *Before*, *After*, and *Between*. If you select the *Size (in bytes)* filter, you can choose from *Greater than*, *Greater or equal*, *Less than*, *Less or equal*, *Between*, and *Equal*.
- **Value**: Depending on the selected filter, enter compatible values. Some filters support multiple values, while others support a single specific value. For example, if you select the *Date* filter, enter date values. If you select the *Size (in bytes)* filter, enter a value for bytes.
- **Add subgroup**: After you define a filter, add a subgroup to refine the results returned by the filter. You can also add a subgroup to a subgroup for multilayered query refinement.
- **Remove a filter condition**: To remove an individual filter or subgroup, select the remove icon to the right of each filter line or subgroup.
- **Clear all**: To clear the entire query of all filters and subgroups, select **Clear all**.

Scenario example

A Data Security Investigations analyst needs to create a query for any item that includes the keyword *confidential* used between January 1, 2025, and March 16, 2025*. For this example, the

analyst creates the following query using the query builder:

1. For the first filter, the analyst selects *Keyword*, then selects the *Equal* operator, then enters *confidential* in the **Value** control.
2. Next, the analyst selects **Add subgroup** and the **AND** operator, then the **Add filter**.
3. The analyst selects the *Date* filter, the *Between* operator, and start and ending dates for the *Value*.
4. The analyst selects **Save** to save the query, then **Review scope** to run the search query.

Example search queries

You can use Keyword Query Language (KeyQL) syntax in the query builder to create targeted search queries for common investigation scenarios. Use these examples as starting points and adjust the date ranges, paths, and keywords to match your investigation.

> **Tip**
>
> Since you can use AI analysis tools to quickly identify applicable data in items returned by your search, consider broadening your search scope to include more sources of data. This helps reduce the chance of excluding any relevant content for review.

Exchange Online

Search for emails only

To search mailboxes for email messages only and exclude other items such as calendar invites, tasks, and to-do items, use the `Kind` property. This example returns emails sent after a specified date.

Data sources: All people and groups

```
(Kind=email) AND (Date>2025-01-01)
```

Microsoft Teams

Search all Teams content

To search for all Teams content, including chat messages, channel posts, meeting entries, and calls, use the `Kind=microsoftTeams` filter.

Data sources: All people and groups

```
(Kind=microsoftTeams) AND (Date>2025-01-01)
```

Search chat messages only

To narrow your search to Teams chat messages only and exclude meetings and channel posts, use `Kind=IM`.

Data sources: All people and groups

```
(Kind=IM)
```

SharePoint Online

Search a specific SharePoint site

To search all content in a specific SharePoint site, use the `Path` property.

```
(Path="https://contoso.sharepoint.com/sites/ProjectAlpha")
```

Search a site and exclude system-generated content

To search a SharePoint site for documents created after a specified date while excluding system-generated content, use the `Author` property with the NOT (`-`) operator.

text

```
((Date>2025-01-01) AND
(Path="https://contoso.sharepoint.com/sites/EngineeringTeam/Shared Documents") AND ((-
Author="System Account") AND (-Author="SHAREPOINT\System")))
```

Search multiple sites for specific file names

To search across multiple SharePoint sites for files with names that begin with a specific term, use the `OR` operator to combine paths and the `filename` property to filter by name.

text

```
(((Path="https://contoso.sharepoint.com/sites/ProjectAlpha") OR
(Path="https://contoso.sharepoint.com/sites/ProjectBeta")) AND (filename="proposal*"))
```

Search for specific files

To search for known files by their full path, use the `Identifier` property and the `OR` operator to combine multiple file paths.

text

```
((Identifier="https://contoso.sharepoint.com/sites/EngineeringTeam/Docs/SecurityReport
.docx") OR
(Identifier="https://contoso.sharepoint.com/sites/EngineeringTeam/Docs/IncidentLog.xls
x"))
```

Microsoft Copilot

Search Copilot prompts and responses

Copilot interactions are stored in users' Exchange Online mailboxes. To search for Copilot prompts and responses after a specified date, use the `ItemClass` property with the Copilot item class value.

Data sources: All people and groups

text

```
(ItemClass=IPM.SkypeTeams.Message.Copilot.*) AND (Date>2025-01-01)
```

For more information about Copilot item classes and searching for Copilot data, see Search for and delete Copilot and other AI data in eDiscovery.

Audit search

Use audit search in Data Security Investigations to identify and collect content based on user activities recorded in the Microsoft Purview unified audit log. While the query builder searches Microsoft 365 content directly, audit search queries the unified audit log for specific user activities, such as accessing, copying, or downloading files, and pulls the associated content into your investigation. You can also filter audit search results by keywords, specific users, and file or site locations.

Example scenario: Departing employee data exfiltration

A security team receives an alert that a departing employee might have exfiltrated sensitive files before their last day. Using audit search, the investigator queries for **Downloaded file** and **Sent email** activities scoped to that user over their final two weeks. Data Security Investigations pulls the associated content directly into the investigation scope - no manual file hunting required - so the team can quickly assess what data was accessed and whether anything was shared externally.

Get started with Audit search

When you create an audit search, Data Security Investigations queries the unified audit log for the specified activities and adds the associated content directly to your investigation scope. Audit search uses the permissions and role-based access control requirements from the unified audit log.

Audit search requires that your organization is configured for audit log and audit search. For more information about audit log requirements, see Search the audit log.

Supported activities

Audit search supports a curated set of content-associated activities from the unified audit log. You can only audit search activities that are associated with identifiable content items, such as files and emails. Audit search doesn't support activities that aren't associated with specific content, such as signing in to a solution.

The following activities are supported for audit search:

Expand table

Activity	Description
Accessed file	A user accessed a file in SharePoint or OneDrive.
Copied file	A user copied a file in SharePoint or OneDrive.
Deleted file	A user deleted a file from SharePoint or OneDrive.
Downloaded file	A user downloaded a file from SharePoint or OneDrive.
Moved file	A user moved a file between folders in SharePoint or OneDrive.
Renamed file	A user renamed a file in SharePoint or OneDrive.
Changed sensitivity label applied to file	A user changed the sensitivity label on a file.
Removed sensitivity label from file	A user removed a sensitivity label from a file.
Uploaded file	A user uploaded a file to SharePoint or OneDrive.
Sent email	A user sent an email message from Exchange Online.

Create an audit search

To create an audit search and add the associated content to your investigation scope, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal and open an investigation.
2. Select **Summary** from the navigation options at the top of the page.
3. On the **Search** tab, select **Audit**.
4. Configure the search parameters:
    - **Date and time range (UTC)** (required): Specify a **Start** and **End** date and hour for the activity search.
    - **Activities - friendly names**: Select one or more supported activities by their display name from the activities list.
    - **Activities - operation names**: Select one or more supported activities by their operation name.

- **Users**: Select users to search for activities performed by specific users.
- **ObjectID (file, folder, or site)**: Enter a file, folder, or site path to narrow the search to activities associated with a specific location.
- **Keyword search**: Enter keywords to search for in audit log entries.

5. Select **Search** to run the audit query. Data Security Investigations queries the unified audit log and displays the results in the results section at the bottom of the Audit page. Review the results to verify the query returns the expected data. To discard the search without adding results, select **Cancel**.

6. Select **Add to scope** to add the content associated with the search results to your investigation scope.

After you add to scope, Data Security Investigations starts processing the results. You can monitor the progress of audit search jobs on the Activities page for the investigation. Previously submitted audit searches are also listed in the audit search history at the bottom of the Audit page.

> ⓘ Note
>
> The **Review estimates** and **Save** buttons on the command bar are visible but unavailable when the **Audit** option is selected. These options are only available for the **query builder**. To preview audit search results before adding them to an investigation scope use the **Audit solution** to test your queries separately.

Audit search jobs and query chunking

Audit search uses *query chunking* to process results. This method creates multiple jobs to ingest data into the investigation scope. When you submit an audit search, the following jobs appear on the Activities page:

- **One audit search job**: The primary job that queries the unified audit log for the specified activities.
- **Multiple add-to-scope jobs**: Additional jobs that process and add the associated content to your investigation scope. The number of add-to-scope jobs depends on the volume of data returned by the search.

After all jobs complete, the system automatically vectorizes the data for AI analysis. You can continue investigating the data after Add to scope completes.

> **Tip**
>
> After submitting an audit search, you see an *Audit Search* activity and multiple *Add to scope* activities on the **Activities** page. This result indicates that query chunking is processing the results.

Audit search and the unified audit log

Audit searches you create in Data Security Investigations also appear in the search history of the Microsoft Purview unified audit log. This behavior is expected because Data Security Investigations queries the unified audit log directly as the data source for audit searches.

> **Important**
>
> Data Security Investigations supports up to 10 concurrent audit searches per user. Audit searches that return more than approximately 3,000 items might not return complete results. The exact limit depends on the file names and paths of the returned items. For more information about limits, see Limits in Data Security Investigations.

Endpoint DLP evidence collection (preview)

You can use endpoint DLP evidence collection (preview) in Data Security Investigations to query data captured by endpoint data loss prevention policies on onboarded devices and add the associated content to your investigation scope. Instead of triaging individual endpoint DLP alerts one by one, investigators can aggregate endpoint events and analyze them collectively using Data Security Investigations AI tools.

Endpoint DLP evidence collection queries the data stored by the evidence collection for file activities on devices feature. This data includes files that matched endpoint DLP policies when users attempted activities such as copying to USB, printing, uploading to cloud services, or accessing files with unauthorized apps.

Prerequisites

Before you can use endpoint DLP evidence collection (preview) in Data Security Investigations, ensure the following requirements are met:

- Devices are onboarded to Microsoft Purview.

- An endpoint DLP policy is configured and active in your organization.
- The endpoint DLP policy has evidence collection for file activities on devices enabled with the **Collect original file as evidence for all selected file activities on endpoint** option selected.
- Microsoft-managed storage is configured for evidence collection.

> **Note**
>
> In addition to the standard Data Security Investigations permissions, you must also be a member of the Insider Risk Management role group and View-Only DLP Compliance Management role to query from endpoint evidence collection.

Key considerations

Keep the following considerations in mind when using endpoint DLP evidence collection (preview) in Data Security Investigations:

- **Data availability depends on evidence collection retention**: If endpoint DLP evidence collection data is no longer available in the evidence store due to retention expiration, Data Security Investigations can't query it. The same query run at different times might yield different results based on the current state of the evidence store.
- **Data isn't immutable before ingestion**: Endpoint DLP evidence collection data can change in the evidence store before you add it to your investigation scope. After you add items to scope, the data is static within the investigation.
- **File content only**: Data Security Investigations ingests the file content associated with endpoint DLP events. Some contextual metadata from endpoint DLP, such as per-event device details, isn't preserved in the investigation scope. For detailed per-event context, use the DLP Alerts dashboard or Activity explorer.
- **Data availability latency**: Evidence collection data might not appear immediately after a policy match. Availability depends on device connectivity and upload timing.
- **Endpoint DLP only**: This feature queries data from endpoint DLP policies only. Browser DLP, network DLP, and non-endpoint DLP scenarios aren't supported for this search option.

Create an endpoint DLP search (preview)

To query endpoint DLP evidence collection data and add the associated content to your investigation scope, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal and open an investigation.
2. Select **Summary** from the navigation options at the top of the page.
3. On the **Search** tab, select **Endpoint DLP**.
4. Configure the search parameters:
    - **Date range** (required): Specify a start and end date for the endpoint DLP events to query.
    - **Users** (optional): Select one or more users to narrow the search to endpoint DLP events for specific users. If you don't select any users, the search returns results for all users in your organization.
5. Select **Search** to run the query. Data Security Investigations queries the endpoint DLP evidence collection data and displays the results.
6. Review the pre-ingestion estimate, which includes a summary of matched alerts, users, actions, and policies.
7. Select **Add to scope** to add the content associated with the search results to your investigation scope.

After you add items to scope, Data Security Investigations starts processing the results. You can monitor the progress on the Activities page for the investigation.

> **Important**
>
> Endpoint DLP evidence collection searches that return more than approximately 3,000 items might not return complete results. To ensure complete coverage, narrow your search by using a shorter date range or by selecting specific users. For more information about limits, see Limits in Data Security Investigations.

Work with large audit search results

When an investigation involves a large volume of user activity, audit searches might exceed the approximately 3,000-item limit. To work with large result sets, use the Audit solution to analyze the full scope of results. Then, split the data into smaller time-based slices that fit within the Data Security Investigations audit search limit.

Analyze audit results outside Data Security Investigations

The Audit solution doesn't have the same per-search item limit as Data Security Investigations audit search. Use the Audit solution to run the full query first and determine the total volume of results before splitting it into smaller searches.

To analyze audit results, complete the following steps:

1. Go to Audit in the Microsoft Purview portal.
2. Configure the same search parameters you plan to use in Data Security Investigations:
   - **Date and time range**: Specify the full date and time range for the investigation.
   - **Activities**: Select the same activities you need for the investigation.
   - **Users**: Specify the same users you plan to search.
3. Run the search and export the results to a CSV file.

Identify time slices for audit searches

After you export the audit results, use the CSV data to identify time periods that contain fewer than approximately 3,000 items each. These time periods become the individual audit searches you run in Data Security Investigations.

To identify time slices, complete the following steps:

1. Open the exported CSV file in Microsoft Excel.
2. Add helper columns to break the `CreationDate` timestamp into components for grouping:

Expand table

Column name	Formula	Description
Date	`=LEFT(B2,10)`	Extracts the date portion (YYYY-MM-DD).
Hour	`=MID(B2,12,2)`	Extracts the hour (HH).
Day-Hour	`=I2&" "&J2&":00"`	Combines date and hour for hourly grouping.
Day-Hour-Minute	`=I2&" "&J2&":"&MID(B2,15,2)`	Combines date, hour, and minute for finer grouping.

> **Note**

> Replace `B2` with the column reference for `CreationDate` in your export, and `I2`/`J2` with the column references for your Date and Hour helper columns. Adjust column references based on your export format.

3. Create a PivotTable to count records by user and time period:
    - Set **Rows** to the user column and the *Day-Hour* helper column.
    - Set **Values** to count of records.
    - Identify time groups that contain fewer than approximately 3,000 items.
4. For time groups that exceed approximately 3,000 items, apply finer grouping:
    - Break hourly groups into minute-level slices using the *Day-Hour-Minute* column.
    - Optionally, split by activity type if a single time period still exceeds the limit.

Run sliced audit searches in Data Security Investigations

After you identify the time slices, run separate audit searches in Data Security Investigations for each slice and add all results to the same investigation scope.

To run sliced audit searches, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal and open an investigation.
2. Select **Summary** from the navigation options at the top of the page.
3. On the **Search** tab, select **Audit**.
4. Configure the search parameters for the first time slice:
    - **Date and time range (UTC)**: Enter the start and end times for the slice.
    - **Activities**: Select the same activities as the original query.
    - **Users**: Select the same users as the original query.
5. Select **Search** to run the audit query.
6. Select **Add to scope** to add the results to your investigation scope.
7. Repeat for each remaining time slice until all data is ingested into the investigation.

> **Tip**

Data Security Investigations automatically deduplicates items across audit searches. If time slices overlap, duplicate items aren't added to the investigation scope more than once. You can also run up to 10 concurrent audit searches per user to speed up the ingestion process.

Scope dashboard

The **Review estimates** tab displays statistics and metrics for the data results included in the search query. This view helps you determine if the search query results are ready for adding to the investigation scope or if you need to refine your query for broader or narrower results.

The search results for the **Scope** dashboard are included in the following sections:

- **Summary**: Shows the number of search hits, locations, data sources, and the total file size of partially indexed items.
  - **Total matches**: Displays the total search hit count and volume from all items matching the query criteria from locations searched.
  - **Locations**: Displays the fraction of locations with hits out of all locations searched. The numerator shows the locations with hits and denominator shows the number of locations searched. Locations with errors appear in red. To view full details on all the locations and associated hits and errors, select **Download report** to download the full .csv report.
  - **Data sources**: Displays the fraction of data sources with hits out of all data sources searched. The numerator shows the data sources with hits and denominator shows the number of data sources included in the search. This data source is consistent with the data source in the search design flow and should match the number of people or groups included in the search. A tenant-wide data source of *All people and all groups* counts as a single data source.
  - **Partially indexed items** or "Advanced indexed items hits": Displays the count and volume of partially and unindexed items returned as part of the search. The advanced indexed hit count comes from a statistic sample on the partially indexed items, actual hits might be more and you can confirm by using the *Add to a review set* and *Export search results* actions.
  - **Top data sources**: Displays the top five data sources that make up the most search hits matching your query. The names of these data sources (names of users, groups, or organization-wide locations) are listed with the hit count. These data sources should match what you selected in the data sources workflow when building the search query.
  - **Indexing status**: Breakdown of unindexed (including partially indexed) and fully indexed data items.
  - **Top location type**: Hit count by location type (mailbox versus site).

Select **Regenerate view** to rerun the query and to review the most current results. Select **Download report** to combine all **Scope** results into a single .csv file. When viewing the top 100 results for any trend area, select **Download report** for a .csv file of the top 100 results of the selected hit trend.

Samples dashboard

Samples let you inspect a representative subset of individual items and details for each item returned for the search. The number of samples per location and the number of sample locations defined in the search determine the number of sample items and location representation in the sample items.

The search results for the **Samples** dashboard columns contain the following information for each item:

- **Subject/Title**: The subject or title of the items included in the sample.
- **Date**: The date the item was created or sent.
- **Sender/Author**: The sender or author of the item.

Select a sample item to view the Source information for the item. If available for the item, this view displays a rich view of a selected item so that you can evaluate the relevancy of the item as it relates to the defined search data source and conditions.

Select **Download reports** to combine all **Sample** results into a single .csv file. Select **View settings** to view the settings applied to the sample view generation.

Data risk graph in Data Security Investigations

> **Important**
>
> We are retiring Data risk graph (Explore insights) in Microsoft Purview Data Security Investigations (DSI). **Beginning September 30, 2026**, organizations will no longer be able to configure Data risk graph. The feature will be fully retired and no longer available after **November 30, 2026**.

Data risk graphs in Data Security Investigations provide a visual investigation experience that combines asset and activity data into a single view. Powered by Microsoft Sentinel integration, it summarizes the previous 30 days of activity for any file scoped in your investigation. It helps you identify risky user accounts that interacted with content of interest and analyze the sequence of events leading up to recent incidents. By enriching analysis with activity insights, data risk graphs can help you resolve your data security incidents faster and with greater confidence.

For more information about Microsoft Sentinel integration, see Learn about Microsoft Sentinel in Microsoft Purview.

> **Note**
>
> Admin units aren't supported in the data risk graph. If you're scoped to an admin unit, data doesn't appear in data risk graphs.

Supported activities in data risk graph

The data risk graph currently supports the following exfiltration activities:

- Anonymous links created in SharePoint or OneDrive
- Anonymous links used via SharePoint or OneDrive
- Company links created in SharePoint or OneDrive
- File downloads from SharePoint and OneDrive
- Files renamed in SharePoint and OneDrive

Before you begin

Before you can use data risk graphs in Data Security Investigations, complete the following steps:

- Learn about pay-as-you-go billing in Microsoft Sentinel for your organization.
- Configure the prerequisites for Microsoft Sentinel data lake and Microsoft Sentinel graph.
- Review the changes made when onboarding to Microsoft Sentinel data lake and Microsoft Sentinel graph.
- Create an investigation in Data Security Investigations.

Configure data risk graph

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview **roles and permissions**.

After you complete the prerequisites, complete the following steps to configure data risk graph in Data Security Investigations:

1. Go to Data Security Investigations in the Microsoft Purview portal with an account assigned the *Global Administrator* or *Security Administrator* role.

2. Select **Overview** in the left navigation.

3. In the **Setup tasks** section, select **Set up data lake and data risk graph**.

   If you don't have the correct permissions to set up the data lake, a notification appears to contact a global or billing administrator in your organization.

4. On the **Setup** tab on **Set up data lake & risk graph (preview)**, configure the following settings:
   a. **Subscription**: Enter the Azure subscription you want to use. Your selected subscription must be valid and accessible. You must be a subscription owner.
   b. **Resource group**: Enter the resource group you want to use. Your selected resource group must be valid and accessible.

   > **Important**

After the data lake is provisioned for a specific Azure subscription and resource group, you can't migrate it to a different subscription or resource group.

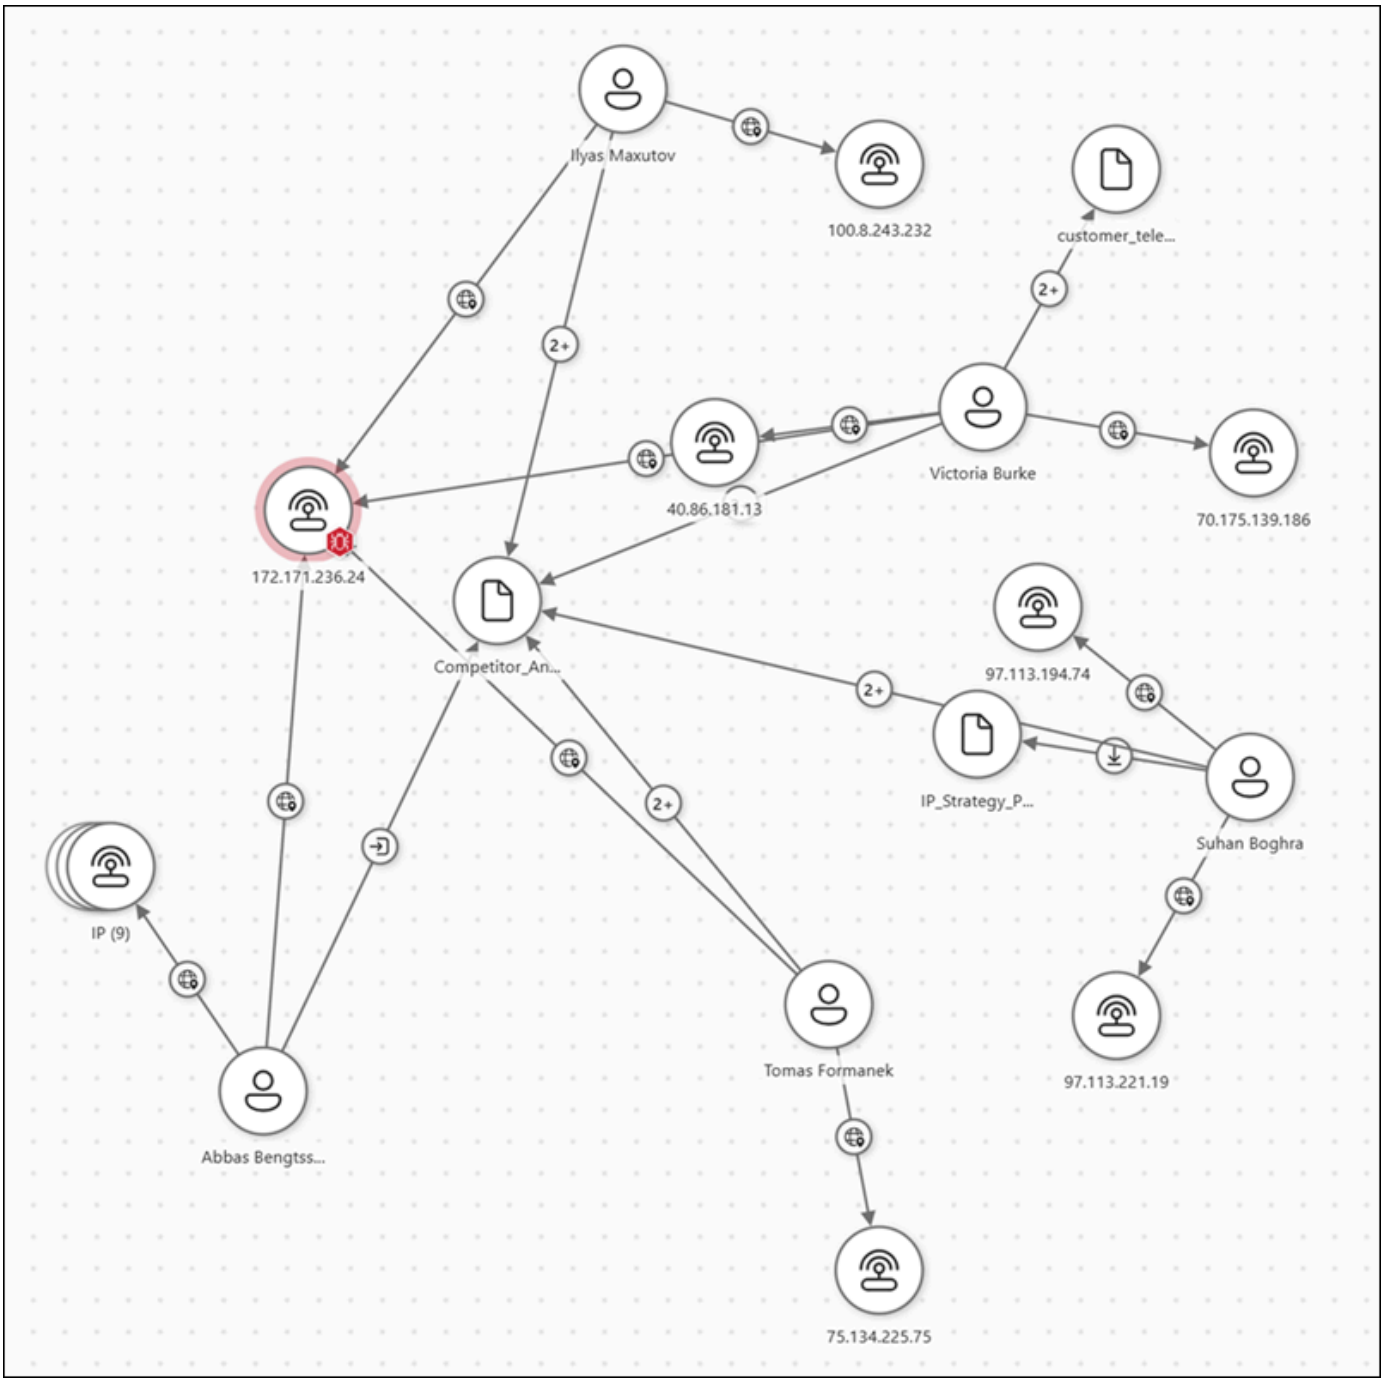
5. Select **Setup**.

> **Important**
>
> When the data risk graph is first created, it includes the most recent seven days of data. As the data risk graph refreshes over time, the look-back window expands up to a maximum of 30 days. It might take some time for the data risk graph to reach the full 30-day window, so expect gradual growth after initial setup.

The set up process begins and onboarding might take up to 60 minutes to complete. You can close the setup panel while the process is running. After the onboarding process completes, you see *Complete* on **Set up data lake & risk graph (preview)**. The data risk graph shows events that occur after your Microsoft Sentinel data lake was created or onboarded.

Initial processing of data and data risk graph availability for an investigation might take 24-48 hours.

> **Important**
>
> You always have one data lake. If you already onboarded to the data lake with another Microsoft service, your existing data lake is used. If you never onboarded to the data lake, onboarding in Data Security Investigations enables Microsoft Sentinel data lake and graph in the Defender portal.



Use data risk graph

Data risk graph in Data Security Investigations uniquely visualizes correlations between impacted data, users, and their activities. It provides critical context to guide mitigation and next steps. For example, upon uncovering a highly sensitive document, data risk graphs give you visibility into which users downloaded it or if they accessed it from a risky IP address. This visibility lets you uncover new nodes to a data security incident, like additional users or new content that requires investigation.

To view the data risk graph for an investigation, you must be assigned to at least one built-in Data Security Investigations role group:

- *Data Security Investigations Admins*
- *Data Security Investigations Investigators*
- *Data Security Investigations Reviewers*

For more information about role groups, see Assign permissions in Data Security Investigations.

To use the data risk graph in Data Security Investigations, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal with an account assigned to a Data Security Investigations role group.

2. Select **Investigations** in the left navigation.

3. Select an investigation to review, then select one of the following options:

a. On **Summary**, select **Manage scope** on the **Investigation scope** card.
b. Select the **Analysis** tab to list items included in the **Investigation scope**.

4. Select items (up to 100) included in the scope, and then select **Explore insights**.

> ⓘ Note
>
> **Explore insights** isn't available unless you configure Data Security Investigations for Microsoft Sentinel data lake and graph.

5. Filter the time as applicable and select individual data risk graph nodes for more information about each connection during triage.

6. Expand relationships in the graph by selecting the + icon on users or assets.

The data risk graph contains several nodes. Selecting a node shows details about the node:

- **User details**: Shows information about users associated with the investigation. This information includes organization information for each user, including User Principal Name (UPN), labels, location, job title, and more.
- **Relationships**: Shows information about starting and ending connections between nodes. This information includes starting and last connection dates, relationship types, and more.
- **IP addresses**: Shows information about each IP address node.
- **Data details**: Shows information about files and sites. This information includes the object location, type, labels, and more.

You can view data risk graph information for users based on the last 30 days of activity. This duration is fixed and can't be extended.

ⓘ**Note:** The author created this article with assistance from AI. Learn more

Manage investigation scopes in Data Security Investigations

After you add data items from your search queries to the scope of the investigation, you can start working with your data and validate items before preparing for AI analysis. You can add items to an investigation scope by using any of the following search tools:

- Query builder: Search by keywords, file types, and conditions.
- Audit search: Identify content based on user activities in the unified audit log.
- Endpoint DLP: Query data captured by endpoint data loss prevention policies.

An investigation scope contains all the data items from your search results that you want to analyze and review. Analysts in your organization can now access this data for AI preparation and further review.

Access the investigation scope

Select **Analysis** from the navigation options at the top of any page within a specific investigation to access the investigation scope. The investigation scope includes a dashboard of scoped items and includes filter and viewer tools to help with item review.

Investigation scope dashboard

The investigation scope dashboard lists all the scoped data items in an investigation. This dashboard allows you to review details about individual data items and displays information about each item.

The investigation scope dashboard contains the following information and controls:

- **Subject/Title**: The subject or title of the data item.
- **Exclude**: The exclude status of a data item. Values are *Yes* or blank.
- **Vectorized**: The vectorization status of a data item. Values are *Yes* or blank.
- **Date**: The date and time the data item was last modified.

To customize the columns display on the investigation scope dashboard, select **Customize columns** to choose the columns to display or drag and drop the columns in the list to reorder.

To download the list of data items and the column information, select **Download list** to create a .csv file containing this information.

Grouping data items

When you view a large list of data items in an investigation, it's often helpful to group the investigation scope by family or conversations and related items. Select **Group** to group data items by this criteria.

Review data items

To view detailed information about individual data items, select the item in the investigation scope dashboard or use **Filters** to narrow items based on specific attributes.

Filter items

Filters are automatically created based on the data items you add to the scope of the investigation. Typical filter options include attributes such as *Author*, *File class*, *Location name*, *Native file extension*, *Sender*, and many more.

Expand a filter area and select one or more filters to refine the data items included in the investigation scope dashboard view. Each filter attribute lists the total number of data items matching the attribute.

For example, to view only email and email attachments, expand the **File class** filter and select the **Email** and **Attachment** filters. The displayed data items are automatically filtered by the selected attributes.

View item details

Select a data item to display more information about the item. Use the investigation scope viewers to examine source, plain text, metadata, and audit details for the selected item.

Item actions

For each data item, you can choose to exclude the item from AI analysis, add the item to your mitigation plan, or purge the item from its source location. Select **Actions** on the command bar for these options. To purge items directly from the investigation scope, see Purge a single item. To purge items by using a search query, see Purge items with a search query. Review and exclude any redundant items for your investigation, such as system generated emails or meeting invites.

Reducing redundant data in your investigation helps reduce data preparation time and improves overall AI insight quality.

All data items in the investigation scope are prepared for AI analysis unless you explicitly exclude them. You can change the status of any excluded data item later if you want to have the data item processed for AI analysis.

Automatic vectorization

After you add data items to the investigation scope, the system automatically prepares all items for AI analysis. This automatic vectorization process runs in the background during each **Add to scope** action and enables you to use AI-based categorization and examination tools on these items. Automatic data preparation utilizes the latest Azure OpenAI embedding models to help improve the cost and performance of your AI results.

Automatic data preparation doesn't require many compute units, even for larger amounts of data included in an investigation scope. The system doesn't revectorize previously vectorized items. The system doesn't vectorize items that don't contain text. Some examples of these items include:

- Calendar notifications
- Meeting invites

You can see the Add to scope processing status of data items at the top of the investigation analysis page. Depending on the amount of scoped data, Add to scope can take some time to complete. If you need to cancel an in-progress **Add to scope** job, select **Cancel** on the **Analysis** tab. You still pay for any compute units consumed before the cancellation. For more information about billing, see Billing in Data Security Investigations.

Existing investigations with unvectorized data

Starting June 2026, all new investigations automatically vectorize data when items are added to the investigation scope. The **Prepare for AI** action is no longer needed or available for new investigations created after this date.

For investigations created before June 2026, the following transition applies:

- **June–August 2026**: Existing investigations that already have scoped data retain the **Prepare for AI** experience. You can continue to use **Prepare for AI** to vectorize data in these investigations during this transition period.

- **After August 2026**: The **Prepare for AI** action is removed from all investigations. All existing investigations will vectorize data automatically during the Add to scope process. If you have an existing investigation with data that was never prepared for AI, you must rerun **Add to scope** to trigger automatic vectorization for those items.

> **Important**
>
> Rerunning **Add to scope** on previously scoped data doesn't create duplicate copies or incur additional storage charges. The system recognizes data that is already stored and only initiates the vectorization process for items that haven't been prepared yet.

Next steps

After Add to scope is complete, you're ready to review and use AI analytics tools for the data in the investigation scope.

Last updated on 06/22/2026

Group and view items in an investigation scope in Data Security Investigations

Data Security Investigations investigation scopes display content by using different grouping options. They include specialized viewers that you can use to examine details about individual items.

Grouping

Use the **Group** control in the command bar of an investigation scope to view review content grouped by the following options:

- **Group by families**: All items related to a specific file are grouped together by using the same Group ID. For example, if you have a PowerPoint file in the investigation scope that includes embedded images or .zip files, these images and files are grouped with the PowerPoint file and shown as nested items with the file in the item list view. Microsoft 365 Copilot and Microsoft 365 Copilot Chat user prompts and responses are also grouped together by using the same Group ID when there are multiple prompts and responses associated with a file.
- **Group by conversations**: All email messages, Teams conversations, and Viva Engage conversations are grouped by using the same Thread ID and appear as nested items. Additionally, all associated content for these messages and conversations is also grouped together. For example, if you have an email conversation that includes several email messages, some of which include attachments and some that include embedded images, all of the email messages, attachments, and images are grouped together in the investigation scope list view under an applicable item.

Source view

The **Source** viewer displays the richest view of a selected document. It supports hundreds of file types and is meant to display the truest to native experience possible. For Microsoft Office files, the viewer uses the web version of Office apps to display content such as document comments, Microsoft Teams chats, Excel formulas, hidden rows and columns, and PowerPoint notes.

Plain text view

The **Plain text** viewer provides a view of the extracted text of a selected file. It ignores any embedded images and formatting but is useful if you're trying to understand the content quickly. A line counter makes it easier to reference specific portions of a document.

For image-based items, the evidence detail pane displays text extracted through Optical Character Recognition (OCR) alongside the original image. This view allows you to verify the accuracy of the text extraction and review content identified through OCR processing.

Metadata view

The panel in the **Metadata** view displays various metadata associated with the selected document. Search for specific metadata by using the **Search metadata name** field.

AI Summary view

> **Note**
>
> This viewer is only available for items returned as results when you use Search with AI (preview).

The AI Summary viewer provides information about the relevance categorization for an item and provides an AI summary and explanation for the reasoning behind the categorization.

Note: The author created this article with assistance from AI. Learn more

---

Last updated on 05/29/2026

Use AI analysis in Data Security Investigations

After automatic vectorization completes for your investigation scope, you're ready to review and use AI analytics tools for the data in the investigation. Generative AI processing conducts a deep content analysis of selected items and can uncover key security and sensitive data risks within impacted data.

To get started with AI analysis in an investigation, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Investigations** in the left navigation.
3. Select an investigation, then select **Analysis** on the navigation bar.

> **Tip**
>
> Consider increasing the default item display from 50 to 1,000 items for easier selection of multiple items to exclude from the investigation scope.

Use categorization

Categorization considerations

Keep the following considerations in mind when configuring categorization and reviewing the results:

- **Not all items may appear in results**: Categorization uses relevance scoring to prioritize content. Items that score below the relevance threshold for a category aren't included in the results for that category, even if the items exist in the investigation scope.
- **Results may change when categories are updated**: When you add new categories or change existing categories between Standard and Advanced processing, the system reprocesses those categories. Because relevance is evaluated per category, results may differ based on the categories you select.
- **Large documents may be more strongly represented**: Documents with extensive content may contribute more content segments to categorization results, which can affect the

distribution of results across documents.

- **Use examination for comprehensive analysis**: If your investigation requires analysis of all items in scope rather than a prioritized subset, use examination tools to perform item-level analysis on selected data items.

Configure categorization

When you first open the **Analysis** page, items aren't categorized. Configure categorization first because it's helpful to start your triage by grouping items by risk.

Categorization takes time to complete. The completion time depends on the data volume and consumes AI capacity (compute units). To get an initial understanding of incident severity, use AI to categorize impacted data and narrow the focus to high-risk assets. Data Security Investigations sorts data into default, custom, or AI-generated categories, including by subject matter and risk.

> **Note**
>
> Investigations auto-created by proactive AI insights from Data Security Posture Management (DSPM) arrive pre-categorized with five fixed risk categories. You can run additional categorization with default, suggested, or custom categories on these investigations.

To categorize data items in the investigation scope, complete the following steps.

> **Important**
>
> Add to scope must complete before you can configure categorization.

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Investigations** in the left navigation.
3. Select an investigation, then select **Analysis**.
4. Select **Categorize**.
5. Select the **Standard** or **Advanced** categorization option.

- **Standard**: AI groups your scope into the selected categories. This option can significantly reduce the time it takes to complete processing and the amount of Data Security Investigations Compute Units (compute unit) needed for categorization.
- **Advanced**: AI further groups your scope into various topics within each category. This grouping takes additional time and compute units to process.

> **Important**
>
> Categorization prioritizes the most relevant content for each selected category rather than analyzing every item in the investigation scope. Results represent the highest-confidence content segments for each category. If your investigation requires comprehensive analysis of all items, use **examination tools** instead of or in addition to categorization. For more information, see **How categorization processes data**.

6. In the **Categorize with AI** dialog, complete the following areas to customize your categories as applicable:

   - **Default categories**: Select one or more default categories.
   - **Suggested categories**: Select one or more AI suggested categories. Suggested categories are generated based on the most recent vector search. If searches aren't run, no categories are suggested.
   - **Custom categories**: Select **Create category** and enter a theme or area to include. Select **Save** for the custom category.

7. After configuring your categorization settings, select **Save**.

Categorization processing can take some time depending on data volume. If you need to cancel an in-progress categorization job, select **Cancel** on the **Analysis** tab. You still pay for any compute units consumed before the cancellation. For more information, see Billing in Data Security Investigations.

After categorization processing completes, select categorization areas or individual subject areas within a category to filter data items for review. Examining the categories helps you quickly identify incident severity and scope.

When you select a specific subject area, a summary for the subject area displays with the following information:

- **Topic name**: The name of the subject area in the category.
- **Topic description**: The description of the subject area generated from AI processing.

- **Topic impact score**: The impact score related to potential risk generated from AI processing.
- **Total documents in sample**: The total number of data items that match the subject area in the investigation scope.

Add or update categories

After the initial categorization run finishes, you can add new categories or update existing categories without reprocessing the entire categorization job. When you add categories, the system processes only the new categories, and you pay only for the compute units needed to process those newly added categories. The system preserves previously categorized data unless you select an existing category in a new categorization run. Selecting existing categories in a new run reprocesses the category.

You can also change existing categories from **Standard** to **Advanced** or from **Advanced** to **Standard**. When you change the categorization option for existing categories, the system reprocesses those categories with the new option.

To add or update categories for an existing categorization, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Investigations** in the left navigation.
3. Select an investigation, then select **Analysis**.
4. Select **Categorize**.
5. Add new categories or update existing categories as applicable:
    - To add new default, suggested, or custom categories, select the categories you want to add to the existing categorization.
    - To change the categorization option for existing categories, select **Standard** or **Advanced** to update the processing level.
6. Select **Save**.

> **Tip**

Adding categories incrementally helps you manage compute unit costs effectively. Start with a focused set of categories and expand as your investigation progresses, rather than selecting all categories upfront.

Categorization and compute units

For example, you might see the following categories in your investigation:

- **Credentials (712 items)**: This category identifies documents or emails containing passwords or API keys.
- **Operational Information (356 items)**: This category identifies items that contain app credentials in a SharePoint site used by a team in your organization.
- **Internal Communications (122 items)**: This category identifies chat logs or emails that include shared credentials.

From an incident response perspective in this example, exposed credentials are typically the highest risk and the priority to triage, then the other areas for follow-up investigation.

Using categorization in Data Security Investigations might require a significant number of compute units, even for smaller amounts of data included in an investigation scope. The compute unit requirements are directly proportional to the number of categories selected, not the size of the data. When you add new categories to an existing categorization, you pay only for the compute units needed to process the new categories. Previously processed categories don't incur additional compute unit costs.

For more information about compute unit capacity and billing, see Billing models in Data Security Investigations.

Use vector search

Use vector search to describe what you're looking for in the vectorized data items in the investigation scope. Vector-based semantic search enables similarity-based information retrieval and understands user intent beyond literal words. You can query your impacted data to find all assets related to a particular subject, even if keywords are missing. For example, a pharmaceutical company might use vector search to find all emails, documents, Copilot prompts and responses, and Microsoft Teams messages related to vaccine trials to identify relevant assets that don't mention the words *vaccine* or *trial* but remain pertinent to the investigation.

Vector search also includes content from image-based items that were processed through Optical Character Recognition (OCR). You can find text from screenshots and scanned documents alongside text-based content.

Additionally, Data Security Investigations supports searching and returning results across multiple languages. You can create a vector search in one language, and vector search can also identify items with the same terms in other languages. For example, if you search for *shared passwords* in English, vector search might identify content in French containing *mot de passe* or content in Spanish containing *contrasena*.

Use natural language to ask a question or enter phrases with specific focus to narrow down items for review. Vector search queries don't add any extra compute unit related capacity costs because the system already processes these scoped items.

To create a vector search, complete the following steps:

> **Important**
>
> Add to scope must complete before you can use vector search.

1. In an investigation, select the **Analyze** card or the **Analysis** tab.
2. Select **Standard** mode.
3. Describe what you're looking for in the search field or select one of the suggested searches.
4. Select the search arrow or press **Enter**.

The vector or suggested search starts and lists data items associated with your query in the items area. Each item includes a search relevance score. The results are listed from high to low by default, with the most relevant items listed first. The search relevance measures how closely each result matches the terms of the search that you provided. The search relevance score indicates the confidence level of the connection and helps give you a sense of confidence about how well each result fits your search. The score applies only to the current vector search, and item scores can change based on the search performed.

Search relevance scores are as follows:

- **High**: Strong connection signals, highly relevant vector search results.
- **Medium**: Moderate connection signals, likely relevant vector search results.
- **Low**: Weak connection signals, possibly less relevant vector search results.

> **Important**
>
> Search relevance scores show only when vector search items are returned.

Vector search and compute units

Using vector search in Data Security Investigations doesn't require many compute units, even for larger amounts of data included in an investigation scope.

For more information about compute unit capacity and billing, see Billing models in Data Security Investigations.

> **Tip**
>
> Consider adding **context to the investigation** to help focus categories on specific areas or issues.

Use Search with AI (preview)

Use Search with AI (preview) to ask natural language questions or enter keywords with a specific focus to narrow down items for review. Search with AI (preview) supplements vector search and extends AI capabilities when analyzing your data. Search with AI (preview) now includes metadata for data items, which helps you narrow down relevant items based on item file types, sizes, versions, and more.

In addition to relevant items, search results also include a high-level summary of all results. This summary helps you quickly determine if the search items are relevant to your search question or keywords. The summary includes citations to specific items returned by the search and relevance scores for each item.

To use Search with AI (preview), complete the following steps:

> **Important**
>
> Add to scope must complete before you can use Search with AI (preview).

1. In an investigation, select the **Analyze** card or the **Analysis** tab.
2. Select **Ask AI (preview)** mode.

3. In the **Search with AI (preview)** pane, enter your question about the data or enter keywords.
4. After the search completes, review the search summary, item results, and item AI search details.

The item detail pane displays all items matching the context related to your AI search. Use filters to help focus the results by document and sender or author. Select **Document** to view a list of cited items included in the results to automatically filter by relevant items. Use actions on the command bar to examine, categorize, or add one or more items to your mitigation plan.

Select an item in the results and select the **AI summary** view to review the relevance categorization score and a snippet with an extracted example that matches the intent of the search.

Use examination tools

> **Tip**
>
> Consider adding **context to the investigation** to help focus examination results on specific areas or issues.

Use examination to run deep content analysis with AI on selected data items. This examination helps you find security risks buried within impacted data. By examining impacted data for security risks, you can find credentials, network risks, or evidence of threat actor discussion. After you identify security risks, you can scan for sensitive data, like personal data, financial, or health information.

In addition to summarizing risks, Data Security Investigations provides mitigation steps and the thought process to explain the assessment. From here, you can add open issues to the mitigation plan, connecting analysis to mitigation. This analysis helps you identify data relevant to your investigation and quickly take action to minimize the impact.

You can choose examination processing for the following focus areas:

- **Credentials**: Credentials processing examines and extracts credentials and access assets included in selected data items.
- **Risks**: Risks processing analyzes and scores selected data items for active risks.
- **Mitigation**: Mitigation processing identifies specific threats and recommends mitigation steps for selected data items.

- **Personal data**: Personal data processing identifies and extracts personal data from selected data items, including names, email addresses, employee IDs, IP addresses, and other PII.
- **Custom**: Define a custom examination focus area using a natural language prompt to describe what you want AI to analyze. Custom examinations produce the same structured results as built-in focus areas. For more information about creating and using custom examinations, see Create a custom examination.

Examination processing can take some time depending on data volume and the focus area you select. If you need to cancel an in-progress examination job, select **Cancel** on the **Analysis** tab. You still pay for any compute units consumed before the cancellation. For more information, see Billing in Data Security Investigations.

When the examination process completes for a focus area, select **Probing history** from the command bar on the right side of the investigation scope page. In the **Probing history** pane, select **View details** for a specific examination process.

Create a custom examination

In addition to the built-in focus areas, you can create a custom examination to analyze data items for specific scenarios unique to your investigation. Custom examinations use a natural language prompt that you define to instruct the AI on what to look for.

Complete the following steps to create a custom examination:

1. On the investigation scope page, select one or more data items.
2. Select **Examine** from the command bar.
3. Select **Custom** as the examination type.
4. In the prompt field, enter a natural language description of what you want the AI to analyze. Prompts can be up to 2,000 characters.
5. Select **Verify prompt**.
6. Verify the prompt is understood with the same intent.
7. Select **Examine** to start the examination.

After the examination completes, results appear in **Probing history** with the same structured output as built-in focus areas, including findings, severity, surrounding snippets, and thought process explanations.

To edit and re-run a custom examination prompt, select the previously created custom examination type and select **Edit**.

Example prompts

The following examples illustrate custom examination prompts for common investigation scenarios:

- **Protected Health Information (PHI)**: "Identify any Protected Health Information (PHI) including patient names, medical record numbers, diagnosis codes, treatment information, and insurance identifiers."
- **Insider trading**: "Identify references to specific stock tickers, trade volumes, non-public earnings data, or language suggesting intent to trade on insider information."
- **IP exfiltration**: "Identify references to project codenames, patent application numbers, unreleased product specifications, or proprietary algorithms."

Examination and compute units

Using examination in Data Security Investigations might require a significant number of compute units, even for smaller amounts of data included in an investigation scope. The compute unit requirements are directly proportional to the size of the data categorized and each examination option you select.

For more information about compute unit capacity and billing, see Billing models in Data Security Investigations.

Examination process information

Select **Probing history** from the far-right command bar to display a list of the examination activities for the investigation scope.

The list shows the following summary information for each examination process:

- **Name**: The name of the examination.
- **Created by**: The user principal name (UPN) of the user that created the examination process.
- **Probe**: The probing area selected for the examination.
- **Scope**: The number of items selected for examination.
- **Date**: The creation date of the examination process.
- **Status**: The process status. Values include *In progress*, *Successful*, *Failed*, or *Cancelled*.

Select **View details** when the process finishes to view the examination report and recommendations.

Next steps

After the examination process finishes, review the recommendation summaries that you selected:

- Review credentials examinations.
- Review risk examinations.
- Review mitigation recommendations.
- Review personal data examinations.

Review mitigation recommendations in Data Security Investigations

Analyze data for mitigation information

Complete the following steps to identify risks in data items included in the investigation scope:

> **Important**
>
> Add to scope must complete before you can configure examinations.

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Investigations** in the left navigation.
3. Select an investigation, then select **Analysis** on the navigation bar.
4. Use vector search or categorization tools to identify data for credentials examination.
5. Select one or more items, then select **Examine** on the command bar.
6. In the **Examine** dialog, enter a name for your examination process in the **Name** field.
7. Enter a description for the examination process in the **Description** field.
8. Select *Mitigation: Identify threats and recommend mitigation steps in selected evidence* in the **Choose a focus area** field.
9. Select **Examine** to start the AI analysis.

> **Note**
>
> The time estimates for the process to complete are based on the amount and size of the selected data. To reduce processing time, filter and exclude data not applicable to the investigation.

Mitigation recommendation report

After the AI processing completes for the selected data items, you can review the mitigation plan to identify details and recommended mitigation steps for each item.

The mitigation recommendation reports include the following information for each item:

- **Subject/Title**: The subject or title of the data item.
- **Risk score**: The risk score of the data item. Values range from 0.00 to 0.10.
- **Risk summary**: A summary of the risks associated with an item. Includes information about content types, users, senders/recipients, details about communications, and more.
- **Mitigation steps**: Guidance for recommended steps to help mitigate the risk associated with the item. Includes audit log reviews, location tracing, access reviews, monitoring suggestions, and more.
- **Thought process**: A summary of the reasoning as to why the risks associated with the item are important. Includes security, legal, financial justifications, and more.
- **Risk implications**: A summary of the implications if the identified risks aren't addressed.
- **Errors**: A summary of any processing errors encountered when the AI process runs.

ⓘ**Note:** The author created this article with assistance from AI. Learn more

Review credentials examinations in Data Security Investigations

Understanding how credentials and other asset access information associate with a data security incident is an important part of identifying and mitigating risks.

For example, if you discover credentials within impacted data associated with the data security incident, a Microsoft Entra admin in your organization can join the investigation, securely view the extracted credentials, and take necessary next steps to reset the accounts. You can also use investigation learnings to refine existing account management policies to strengthen your organization's security practices.

Analyze data for credentials and asset access information

Complete the following steps to identify credentials and asset access data in items included in the investigation scope:

> **Important**
>
> Add to scope must complete before you can configure examinations.

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in by using the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Investigations** in the left navigation.
3. Select an investigation, then select **Analysis** on the navigation bar.
4. Use vector search or categorization tools to identify data for credentials examination.
5. Select one or more items, then select **Examine** on the command bar.
6. In the **Examine** dialog, enter a name for your examination process in the **Name** field.
7. Enter a description for the examination process in the **Description** field.
8. Select *Credentials: Extract the credentials and access assets in selected evidence* in the **Choose a focus area** field.
9. Select **Examine** to start the AI analysis.

> **Note**

The time estimates for the process to complete is based on the amount and size of the selected data. To reduce processing time, filter and exclude data not applicable to the investigation.

Credentials examinations

After the AI processing completes for the selected data items, you can review credentials examinations to identify credential and asset access details for each item.

The credentials examinations include the following information for each item:

- **Subject/Title**: The subject or title of the data item.
- **Extracted credentials**: The credential details included in the data item. This information includes user names, passwords, and more.
- **Credential type**: The credential type. Might include user credentials, API tokens, MFA backup codes, and more.
- **Surrounding snippet**: The text or string values surrounding the credential details. This information helps with determining the context in which the credential is used in the data item.
- **Thought process**: A summary of the reasoning as to why the credentials associated with the item are important.
- **Errors**: A summary of any processing errors encountered when the AI process runs.

Credentials examination example

The output of the examination might be a summary or annotation for each identified item. The examination highlights sentences or pieces of data in the content that are likely sensitive.

For example, the examination might return *In File X, the AI found what looks like 10 user passwords and 5 API keys* in a document. Or for an email, *Email Y contains a conversation about sharing database credentials*. This summary saves you from manually reading every line for each item and helps you triage risky content very quickly. Here's an example of a deep examination output for an item with Credential Risk:

Expand table

File	String	Type	Extracted Value	Analysis
EV-1.docx	T9!vX3p@7qLz	LoosePassword	T9!vX3p@7qLz	The string matches a typical password pattern, featuring uppercase, lowercase, numbers, and special characters. There are no other indicators, so it's classified as a `LoosePassword`.

An item with cleartext passwords might be tagged as `Critical risk: Credentials exposed` by the system. These examinations are important and they align with what a human analyst would consider severe and they also include explanations.

You should also take the following actions:

- **Manually verify critical details**: While the examination process does the heavy lifting, you should manually verify the most critical pieces. If a specific password is identified in a document, open the document to confirm the context. You should verify that it's an actual active password, and whose password it is. For instance, the string `P@ssw0rd123` might be identified and it's labeled as a password. But by opening the file, you verify it's in a table titled *VPN Credentials* and not in the content only as an example placeholder. This confirms it's actionable and gives you the information needed to act.
- **Expand the scope**: Sometimes examinations reveal new clues that require pulling in more data. For example, you discover references to a project name or a user account you didn't search for initially. You should consider another search for the project or user account to see if there are related items. A vector search for the project name might find related files that didn't explicitly mention passwords, but are related to the security incident.

Review risk examinations in Data Security Investigations

By examining impacted data for security risks, you can find network risks or data that presents continued security risks in your organization. Risk examinations provide reasoning for risk scores and recommended mitigation steps for each item so you can take the appropriate mitigation steps. Data Security Investigations summarizes scores and explanations for the risk focus areas.

Analyze data for risk information

Complete the following steps to identify risks in data items included in the investigation scope:

> **Important**
>
> Add to scope must complete before you can configure examinations.

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Investigations** in the left navigation.
3. Select an investigation, then select **Analysis** on the navigation bar.
4. Use vector search or categorization tools to identify data for credentials examination.
5. Select one or more items, then select **Examine** on the command bar.
6. In the **Examine** dialog, enter a name for your examination process in the **Name** field.
7. Enter a description for the examination process in the **Description** field.
8. Select *Risk: Analyze and score all active risks in selected evidence* in the **Choose a focus area** field.
9. Select **Examine** to start the AI analysis.

> **Note**
>
> The time estimates for the process to complete are based on the amount and size of the selected data. To reduce processing time, filter and exclude data not applicable to the investigation.

Risk examination scores range between 0 (low risk) to 4 (critical risk) and include the following information for each item:

- **Subject/Title**: The subject or title of the data item.
- **Privileged content**: Indication if the data item is privileged content. Values are *Yes* or *No*.
- **Overall security risk score**: The risk score of the data item. Values from 0 to 4, higher values indicate higher risk items.
- **Overall security risk explanation**: A summary of the reasoning as to why the risks associated with the item are important.
- **Errors**: A summary of any processing errors encountered when the AI process runs.

The following risk examination areas, with scores and explanations, are available for each item:

- **Asset identifiers score**: Score reflecting the presence and severity of information related to identities or internal assets within emails and files.
- **Credentials and secrets exposure score**: Score reflecting the discussion of credential exposure within emails and files.
- **Customer intel risk score**: Score capturing the risk associated with confidential information related to business deals, trade secrets, corporate strategy, and cybersecurity vulnerabilities.
- **Government intel risk score**: Score capturing the risk associated with confidential government information related to security of infrastructure and products, domestic and foreign security, and domestic and foreign affairs.
- **Infrastructure risk score**: Score assessing the risk related to infrastructure exploits, critical gaps related to infrastructure, and potential infrastructure related discussions.
- **Network and access risk score**: Score reflecting the risk associated with network security and access control, including exposed ports and anonymous connections.
- **Personal sensitive content score**: Score reflecting the level of personal or sensitive information within emails and files, such as medical details, financial information, or confidential topics.
- **Policy compliance and data protection risk score**: Score capturing the risk associated with policy deviations, compliance, and data protection practices.
- **Privileged information risk score**: Score capturing the risk associated with exposure of privileged and confidential information and/or attorney communication for business matters.
- **Threat actor or breach discussion score**: Score reflecting the discussion of threat actors or sensitive topics within emails and files, including past breaches, ongoing investigations, or internally reported risks.

- **Trade secret risk score**: Score capturing the risk associated with policy deviations, compliance, and data protection practices.
- **Urgent security incident score**: Score reflecting the discussion of any urgent, immediately actionable security incidents that threat actors might find valuable.
- **Vulnerability and security hygiene information score**: Score reflecting the discussion of vulnerabilities within emails and files, such as zero-day exploits, security hygiene practices, internet-exposed endpoints, and over-provisioned accounts.

Review personal data examinations in Data Security Investigations

Understanding what personal data is present in data associated with a security incident is a critical part of investigating and responding to data breaches. After a data security incident, one of the most time-consuming and high-stakes tasks for investigators is determining which personal data elements were exposed and whether regulatory notification obligations exist under frameworks such as the General Data Protection Regulation (GDPR), the Health Insurance Portability and Accountability Act (HIPAA), or state-level privacy laws.

For example, if you discover personal data within impacted data associated with a data security incident, you can quickly assess potential privacy exposure, support compliance reporting, and build defensible evidence chains from detection to action. You can also use investigation learnings to inform regulatory notification decisions and strengthen your organization's data protection practices.

Personal data examinations support common investigation scenarios, including:

- **Data breach privacy impact assessment**: Run personal data examinations on impacted files to quickly determine which personal data types were exposed and which individuals might be affected.
- **Regulatory compliance evidence**: Generate structured, auditable results showing what personal data was found, in which files, at what risk level, with AI-generated reasoning to support breach notification reporting.
- **Insider risk investigation**: Identify the types and risk levels of personal data present in data associated with risky user activities, helping prioritize which files require immediate attention and remediation.
- **Cross-functional incident response**: Provide security, legal, and privacy teams with a shared, actionable summary of personal data exposure that all teams can reference during incident response.
- **Post-incident audit**: Conduct a systematic review of past incidents to ensure personal data exposure was accounted for, validating or supplementing earlier manual review efforts.

Analyze data for personal data

Complete the following steps to identify personal data in items included in the investigation scope:

> **Important**
>
> Add to scope must complete before you can configure examinations.

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in by using the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Investigations** in the left navigation.
3. Select an investigation, and then select **Analysis** on the navigation bar.
4. Use vector search or categorization tools to identify data for personal data examination.
5. Select one or more items, and then select **Examine** on the command bar.
6. In the **Examine** dialog, enter a name for your examination process in the **Name** field.
7. Enter a description for the examination process in the **Description** field.
8. Select *Personal data: Identify and extract the personally identifiable information in selected evidence* in the **Choose a focus area** field.
9. Select **Examine** to start the AI analysis.

> **Note**
>
> The time estimates for the process to complete are based on the amount and size of the selected data. To reduce processing time, filter and exclude data that aren't applicable to the investigation.

Personal data examinations

After the AI finishes processing the selected data items, you can review the personal data examinations to identify personal data details for each item.

The personal data examinations include the following information for each item:

- **Subject/Title**: The subject or title of the data item.
- **Risk level**: The risk levels for all personal data found in the item. Values include *High*, *Medium*, and *Low*.
- **Contains Personal Data**: Indication if the data item contains personal data. Values are *Yes* or *No*.

- **Type of Personal Data**: A list of personal data types found in the data item. For more information, see Personal data types and risk level classification.
- **Personal Data Found**: A list of extracted personal data values from the data item.
- **Surrounding Snippet**: The text or string values surrounding the personal data details. This information helps with determining the context in which the personal data appears in the data item.
- **Thought Process**: A summary of the reasoning as to why the personal data associated with the item was classified and its risk level rationale.
- **Errors**: A summary of any processing errors encountered when the AI process runs.

Personal data types and risk level classification

Each personal data finding is assigned a risk level based on the type of personal data identified. The risk level helps you prioritize which findings require immediate attention and remediation. The following table includes examples of personal data types for each risk level. These examples aren't a comprehensive list of all personal data types detected by the examination.

Expand table

Risk level	Example personal data types	Description
High	SSN/National ID, bank account numbers, financial account numbers, routing numbers	Financial identifiers and government-issued identification numbers that pose the highest risk if exposed.
Medium	Email addresses, phone numbers, dates of birth, medical record numbers, insurance IDs	Contact information that can be used to identify or reach individuals.
Low	Full names, addresses, device identifiers	General identifying information that presents lower risk when exposed individually.

> **Note**
>
> A single data item might contain multiple personal data instances of different types and risk levels. The process captures and reports personal data instances individually.

Personal data examination example

The output of the examination might be a summary or annotation for each identified item. The examination highlights personal data elements in the content that are likely sensitive.

For example, the examination might return *In File X, what looks like 3 Social Security numbers and 5 email addresses were found* in a document. Or for an email, *Email Y contains a conversation where bank account details were shared*. This summary saves you from manually reading every line for each item and helps you triage risky content very quickly. Here's an example of a personal data examination output for an item:

Expand table

File	String	Type	Risk level	Analysis
EV-2.docx	555-12-3456	SSN/National ID	High	The string matches a Social Security number pattern (XXX-XX-XXXX) found in a table titled *User Records*. It's associated with a full name in the adjacent column, confirming it as identifiable PII.
EV-3.msg	user1@contoso.com	EmailAddress	Medium	The email address appears in the body of the message as a recipient of shared financial documents, making it contextually relevant to the investigation.

Take the following actions:

- **Manually verify critical details**: While the examination process does the heavy lifting, manually verify the most critical pieces. If the process identifies a specific personal data value in a document, open the document to confirm the context. For instance, the process might identify a Social Security number in a file, but by opening the file, you verify it's in a table titled *User Records* and not only in the content as an example placeholder. This verification confirms the finding is actionable and gives you the information needed to act.
- **Expand the scope**: Sometimes examinations reveal new clues that require pulling in more data. For example, you discover references to a user account or a department you didn't search for initially. Consider another search for the user account or department to see if there are related items. A vector search for the department name might find related files that didn't explicitly mention personal data but are related to the security incident.
- **Connect findings to the mitigation plan**: After reviewing personal data examination results, add specific data items to the mitigation plan to manage and track the mitigation status for each item. This approach creates an auditable chain from detection to remediation.

- **Consider regulatory implications**: Personal data exposure might trigger notification obligations under privacy regulations. Use the structured examination results, including risk levels, personal data types, and AI-generated reasoning, to support compliance reporting and regulatory notification decisions.

ⓘ**Note:** The author created this article with assistance from AI. Learn more

Last updated on 06/11/2026

Take mitigation actions in Data Security Investigations

Data Security Investigations provides several features to help you quickly mitigate the impact of data security incidents in your organization.

Mitigation plan

The mitigation plan helps you connect analysis to specific mitigation actions from examination tools and analyst reviews. Use the mitigation plan like a to-do list to manage and track data risk mitigation actions in your investigation. This plan helps analysts centralize all items that require attention or action to mitigate risks associated with the investigation and data security incident.

Using the mitigation plan, take the following actions:

- **Prioritize by risk level**: Immediately address anything that might lead to an active security breach if you don't fix it.
- **Mark items for follow-up**: Use the mitigation plan to track follow-up activities.
- **Consult or involve relevant stakeholders**: Make sure your plan addresses responsibilities for the following areas:
  - **Credentials**: Identify who resets credentials and by when.
  - **Data exposure**: Identify who removes external sharing links or moves files to a secure location.
  - **User education or enforcement**: Identify who follows up with training or disciplinary measures.
  - **Further investigation**: Identify who is responsible for any item that suggests a larger security issue in your organization.

Mitigation plan dashboard

The **Mitigation plan** displays all items you add to the mitigation plan in your investigation. By using this view, you can quickly see all the items that need action in your investigation, the status for each item, and other important information about each item in the plan.

- **Name**: The subject or title of the data item.
- **Type**: The file type of the data item.

- **Description**: The description of the data item.
- **Status**: The current status of the data item. Values include *In-progress* or *Complete*.
- **Last modified by**: The name of the analyst or investigator that last updated information about the data item.
- **Last updated (UTC)**: The date and time in Coordinated Universal Time (UTC) that the data item was last updated.

Select **Customize columns** to customize the displayed columns and the order of the columns in the mitigation plan. Choose the columns to display or hide. Select **Add filter** and choose an available filter to filter items in the mitigation plan.

Select **Download list** to create a .csv file containing the list of data items and the column information in the mitigation plan.

Item detailed view

Analysts can view details about each data item included in the mitigation plan as part of the review and evaluation process. After you select a data item, you see an item summary and viewers to view metadata, source, and other information.

Update item status

As you review data items and work to mitigate risks for each data item, manage the current status for each item. Update the status for individual items or bulk update the status for multiple data items.

To update the status for a data item, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with the credentials for a user account assigned Data Security Investigations permissions.
2. Select the **Data Security Investigations** solution card, then select **Investigations** in the left navigation.
3. Select an investigation, then select **Mitigation**.
4. Select one or more data items in the mitigation plan.
5. Select **Update status**, then select the applicable status.

You can also change the status of a data item from the item detail view. From the detailed view for an item, select **Complete** to change the status of the data item.

Implement the mitigation plan

To implement your mitigation plan, work through the following mitigation steps:

- **Revoke or change credentials immediately**: For each exposed password or secret, ensure the responsible owner resets it. This action might involve forcing password resets for user accounts, deleting or regenerating access keys, or changing service account credentials.
- **Contain data exposure**: If files were accessible publicly or to too many people, lock down permissions immediately. Remove external guest access on SharePoint sites if a sensitive file was shared. If an email with secrets was sent externally, reach out to the recipient to delete it (if appropriate) or use message recall if possible.
- **Remediate documents**: For files that shouldn't contain certain information, decide whether to delete them, redact them, or secure them. Often, removing the sensitive content from the source is advised (or encrypting it). Consider applying sensitivity labels or Data Loss Prevention policies to prevent files from being shared again.
- **Track activities and insights**: Use the activity timeline for items. This information might identify related user activities. Check if any risky user behavior is ongoing and if further investigation of that user might be warranted.
- **Document every action**: In the activity history, every search, analysis, and mitigation action is logged. This information is useful for audit and post-incident review. Ensure the log shows that all risky items are addressed.
- **Communicate and resolve the incident**: Update all stakeholders on the following information:
  - Confirm that critical holes (credentials, public links, and other vulnerabilities) are closed.
  - If necessary, prepare any external notifications. For example, informing customers of a data breach and informing applicable regulators.
  - Conduct a debrief with all stakeholders. The insights and lessons learned can be used to improve policies and prevent future incidents.

Purge

Data Security Investigations includes purge features to help you identify and remove Exchange mailbox and Microsoft Teams items in your organization. This need might include identifying items associated with highly confidential or sensitive information about financial, marketing, or sales projects, or other proprietary property. By using the built-in search capability for investigations, you can quickly create a new search query and save it as a purge query that you can review and run whenever needed.

> **Tip**
>
> Use soft purge as the default purge method for most investigation-driven workflows. Soft purge lets you quickly remove sensitive content from a user's view while preserving the ability to restore items if needed. Reserve hard purge for scenarios where you have high confidence that permanent deletion is required and items are correctly identified.

Data Security Investigations supports the following purge options:

- **Soft purge**: Items are moved to the recoverable items folder and retained based on your retention settings. Soft purge is only supported for Exchange mailbox items. Teams messages and OneDrive and SharePoint files aren't supported for soft purge.
- **Hard purge**: Items are permanently deleted from their data sources. This action can't be undone and search queries can't be edited after the purge is complete.

> **⚠ Warning**
>
> Hard purge permanently deletes items with no recovery path. Only use hard purge when you have high confidence that the items are correctly identified and permanent deletion is explicitly required.

Soft purge is useful for scenarios such as user terminations or active data-leak containment, where you need to quickly remove sensitive content from a user's view while preserving the ability to restore items if the investigation scope changes or the content is needed for further evidence review.

Both soft purge and hard purge respect litigation holds, eDiscovery holds, and retention policies. If items are subject to a hold or retention policy, purged items are preserved in the recoverable items folder and can't be permanently deleted until the hold is removed or the retention period expires. For more information, see The principles of retention, or what takes precedence?.

> **ⓘ Important**
>
> Purging removes items from their original source locations but doesn't remove items from the investigation scope in Data Security Investigations. To remove all items from Data Security Investigations, **delete the investigation**.

You pay for the processing needed to purge the volume of data resulting from your search query and uses the new Data Security Investigations compute unit. For more information about the compute unit, see Billing in Data Security Investigations.

Purge queue dashboard

The **Purge queue** displays all the saved purge queries in your investigation. By using this view, you can quickly see all the purge queries in your investigation, the status for each query, and other important information about each query in the queue.

- **Name**: The name of the purge query.
- **Status**: The current status of the purge query. Values include *Not started*, *In-progress*, *Failed*, or *Complete*.
- **Added by**: The name of the investigator that added the purge query.
- **Added date (UTC)**: The date and time in Coordinated Universal Time (UTC) that the purge query was added to the purge queue.

Select **Customize columns** to customize the displayed columns and the order of the columns in the purge queue. Choose the columns to display or hide. Select **Add filter** and choose an available filter to filter items in the purge queue.

Select **Download list** to create a .csv file containing the list of data items and the column information in the purge queue.

Choose a purge method

Use the following table to determine the best purge method for your scenario:

Expand table

Consideration	Soft purge	Hard purge
Action	Moves items to the recoverable items folder	Permanently deletes items from data sources
Recoverable	Yes, based on retention settings.	No, action can't be undone.
Supported data sources	Exchange mailbox items only.	Exchange mailbox items and Teams messages.
Risk level	Lower risk - items can be restored if needed.	High risk - irreversible, no recovery path.

Consideration	Soft purge	Hard purge
Recommended use	Default for most investigation-driven purges, bulk or search-based purges, and scenarios where query scope might be broad.	Only when you have high confidence that items are correctly identified and permanent deletion is required.
Example scenarios	User terminations, active data-leak containment, removing sensitive content while preserving evidence.	Confirmed malicious content, prohibited material with no compliance retention requirement.

Purge items with a search query

To purge specific items in your organization, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Investigations** in the left navigation.
3. Select an investigation or select **Create investigation** to create a new investigation.
4. On the **Search** tab, select the data sources that contain the items you want to purge.

   > **Important**
   >
   > Only items in Exchange mailboxes and Microsoft Teams currently support purge. Selecting SharePoint sites or OneDrive accounts disables purge actions. Soft purge is only supported for Exchange mailbox items. If the search query includes Teams messages or OneDrive and SharePoint files, the soft purge option isn't available.

5. Create a search to identify the items you want to purge, and then select **Review for purge**.

   > **Important**
   >
   > *FileID* isn't available for purged items not added to a review set or when exported. Use *ImmutableID* if needed.

6. On the **Review for purge** page, verify that the items returned in the estimates align with the items you want to purge. You can purge up to 10,000 items per search.

   If you need to edit the search, select **Search** and update the conditions of the search. To view details for search matches, select the ellipsis and **View samples** or select **Add to scope**.

> **ⓘ Important**
>
> If you add items to an investigation scope, a copy of the items is added to the Azure storage account associated with Data Security Investigations in your organization. Running the purge query in the **Purge queue** removes items from all their current source locations, but not from the investigation scope in Data Security Investigations. To remove all items from Data Security Investigations, delete the investigation.

7. Select **Save for purge** and enter a unique name for the purge query in the **Query name** field.

8. Select **Save** to save the query and add the query to the purge queue. This step only saves the query as a purge query and doesn't purge any items.

   > **⚠ Warning**
   >
   > The item count displayed during review for purge is an *estimate* based on the search results at the time of review. If you don't run the purge query immediately, the items matching the query can change significantly over time. Running a saved purge query at a later date could result in purging substantially more items than originally estimated, including items you didn't intend to delete. To avoid unintended data loss, always review for purge again immediately before running the purge query.

9. On the **Mitigation** tab for the investigation, you're automatically directed to the **Purge queue** dashboard.

10. Select the purge query you want to run.

11. On the purge query details page, review the query details and select **Run**.

12. On the purge confirmation dialog, select the purge method for the query:

    - **Soft purge**: Moves items to the recoverable items folder and retains them based on your retention settings. This option isn't supported for Teams messages and OneDrive and SharePoint files. If the search query includes unsupported items, the soft purge option isn't available.
    - **Hard purge**: Permanently deletes items from their data sources. This action can't be undone.

> ⓘ Note
>
> If items are under a litigation hold, eDiscovery hold, or retention policy, the purge process preserves the items and can't permanently delete them until the hold is removed or the retention period expires.

13. Select **Confirm purge**.
14. To view the status of the purge query, select the **Activities** tab.

After the purge is complete, you can download a report as a .zip file that includes item, location, settings, and summary information about the purged items.

Purge a single item

To purge a single item from an investigation, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Investigations** in the left navigation.
3. Select an investigation, then select **Analysis** to access the investigation scope.
4. Select the item you want to purge from the investigation scope.
5. Select **Add to mitigation**, and then select **Mitigation** to see the Mitigation list.
6. Select the item from the Mitigation list.
7. Select **Add to purge queue**, then select **Purge queue** to view the Purge queue.
8. Select the item from the Purge queue, then select **Purge**.
9. Select the purge method for the item:
    - **Soft purge**: Moves the item to the recoverable items folder and retains it based on your retention settings. This option is only available for Exchange mailbox items.
    - **Hard purge**: Permanently deletes the item from its data source. This action can't be undone.

> ⓘ Note

If items are under a litigation hold, eDiscovery hold, or retention policy, the purge process preserves the items and can't permanently delete them until the hold is removed or the retention period expires.

10. Select **Confirm purge**.

11. To view the status of the purge, select the **Activities** tab.

Use the Activity history in Data Security Investigations

The Activity history for Data Security Investigations shows information about activities you perform in each area of your investigation. It includes activities associated with searches, investigation scopes, AI analysis, and mitigation activities.

Each time you create or request an activity in a workflow area, the system automatically starts and logs specific activities in the Activity history. For example, if you search for data and select **Estimate scope** in an investigation, the **Generate statistics** and **Generate sample** activities appear in the Activity history list for the investigation.

To view and manage activities, complete the following steps:

1. Go to Data Security Investigations in the Microsoft Purview portal and sign in with the credentials for a user account assigned Data Security Investigations permissions.
2. Select **Investigations** in the left navigation.
3. Select an investigation, then select the **Activities** tab.

Activity history dashboard

The Activity history dashboard lists all the activities for an investigation and shows the following information for each activity:

- **Activity type**: The type of activity.
- **Status**: The status of the activity.
- **Export name**: The name of the export. For non-export activity types, this value is blank.
- **Created**: The date and time the activity was created.
- **Completed**: The date and time the activity was completed.
- **Duration**: The duration of the activity.
- **Created by**: The user that created the activity.

To customize the columns display for the Activity history, select **Customize columns** to choose the columns to display or drag and drop the columns in the list to reorder. To download the list of activities and the column information, select **Download list** to create a .csv file containing this information.

Group activities

When you view a large list of activities for an area, it's often helpful to group activities. Select **Group** to group review sets by the following parameters:

- **None**: Activities are ungrouped in the Activity history.
- **Activity type**: Activities grouped by the *Activity type* values.
- **Created by**: Activities grouped by the *Created by* values.

Activity details

Select an activity listed in the Activity history for more information in the following areas:

- **Overview** tab: Lists a summary of information for the activity. Includes a calculation for the time remaining to completion for in-progress activities. Select **Download report** to combine all **Overview** information into a single .zip file.
- **Settings** tab: Summarizes the **Statistics view** setting options selected for the investigation.

Progress bar

When you select an activity in the Activity history, a progress bar appears that shows details about the current state of the activity. For long-running activities, the progress bar has three phases:

- **Assessment phase**: In this phase, the progress bar submits the progress and backend services assess the scope of the activity. This activity includes examining the input conditions based on data sources, query, and relevant activity settings. The service analyzes the scope of the work and identifies the number of locations and number of items for activities. During this phase, a completion estimate isn't available and a flashing progress bar is displayed. The progress bar displays the status of the assessment while the scope is calculated. When all locations and items are identified, the activity transitions to the next phase.
- **In progress phase**: In this phase, the progress bar displays the current status, number of locations, and number of items for the activity. An estimated completion and current elapsed time are displayed in hours, minutes, and seconds.
- **Catch-up phase (optional)**: If there are locations or items with errors, activities are retried. The progress of any retries is displayed.

Download activity list

To download a .csv file of the activity items on the Activity history dashboard, select **Download list** on the dashboard command bar.

Activity types and descriptions

These activities start when users take actions to use and manage searches, investigation scopes, AI activities, and more.

Expand table

Activity type	Area	Description
Add to scope	Investigation scope	A user adds search results to an investigation scope. The process copies the items to an Azure Storage location and then reindexes those items in the Azure Storage location. This new index enables querying and analyzing items in the data set.
Audit search	Search	A user submits an audit search to query the unified audit log for content-associated activities. This activity queries the audit log and identifies content items associated with the specified activities.
Categorize	AI analysis	A user categorizes items in an investigation scope.
Examine	AI analysis	A user analyzes data in an investigation scope by running AI examination and recommendation tools, such as Credentials, Mitigation, Risks.
Generate sample	Search	After a user creates and runs a new search (or reruns an existing search), the search tool prepares a sample subset of items that match the search query for preview. Previewing search results helps you determine the effectiveness of the search.
Generate scope	Search	After a user creates and runs or reruns a search, the search tool searches the index for items that match the search query and prepares a scope estimate that includes the number and total size of all items by the search, the number of data sources searched, and other relevant pattern to the search hits like keywords, sensitive information types, and more.

> **Note**
>
> When an audit search is submitted, query chunking creates an *Add to scope* activity and multiple additional activities to process the results. Seeing multiple *Add to scope* activities after an audit search is expected behavior.

Activity status

The following table describes the different status states for activities:

Expand table

Status	Description
Abandoned	The system automatically stops the activity. This stoppage might occur due to excessive activities time or other reasons.
Canceled	The user cancels the activity.
Complete	The activity successfully completes.
Failed	The activity encounters an error and fails to complete. This error might be caused by a wrongly formatted query.
In progress	The activity is in progress. You can monitor the progress of the activity in the progress bar in the applicable area.

> **Note**
>
> In addition to tracking activities on this page, Data Security Investigations sends notifications through the Microsoft Purview Notification Center and email when setup completes and investigations are ready to use. For more information, see Email and portal notifications.

Application card: Microsoft Purview Data Security Investigations

What is an Application or Platform Card?

Microsoft's Application and Platform cards are intended to help you understand how our AI technology works, the choices application owners can make that influence application performance and behavior, and the importance of considering the whole application, including the technology, the people, and the environment. Application cards are created for AI applications and platform cards are created for AI platform services. These resources can support the development or deployment of your own applications and can be shared with users or stakeholders impacted by them.

As part of its commitment to responsible AI, Microsoft adheres to six core principles: fairness, reliability and safety, privacy and security, inclusiveness, transparency, and accountability. These principles are embedded in the Responsible AI Standard, which guides teams in designing, building, and testing AI applications. Application and Platform Cards play a key role in operationalizing these principles by offering transparency around capabilities, intended uses, and limitations. For further insight, readers are encouraged to explore Microsoft's Responsible AI Transparency Report and Code of Conduct, which outline how enterprise customers and individuals can engage with AI responsibly.

Overview

Microsoft Purview Data Security Investigations is an AI-enabled investigation application for cybersecurity and data security teams. It helps organizations analyze data associated with potential breaches, insider incidents, and exfiltration events by combining search, AI analysis, and mitigation planning in one workflow. The application uses generative AI to identify sensitive content risks, prioritize high-impact items, and produce recommendations that support containment and remediation.

The application is designed to reduce time and complexity in post-breach and high-risk investigations. Instead of manually reviewing very large sets of files, emails, and messages, analysts can use vector search, categorization, and examination tools to focus on the most relevant and risky content first. This improves triage efficiency, supports cross-team coordination,

and helps organizations take timely actions such as investigation-driven mitigation planning and purge operations.

Data Security Investigations is intended for enterprise customers and downstream users such as security analysts, incident responders, threat investigators, and data protection teams. Key documentation includes Learn about Data Security Investigations amd Learn about AI analysis in Data Security Investigations.

Key terms

The following list provides a glossary of key terms related to Microsoft Purview Data Security Investigations:

- **Categorization**: An AI capability that groups scoped investigation content into default, custom, or AI-suggested categories to speed prioritization. Standard and Advanced processing options help analysts move from broad triage to deeper topic-level clustering.
- **Examination**: An AI analysis mode that performs focused item-level review for areas such as credentials, risk, and mitigation guidance. Examination outputs help investigators understand severity and recommended next actions.
- **Investigation scope**: The set of content items selected for review and analysis in an investigation.
- **Mitigation plan**: A structured set of actions for items identified as high priority during investigation. It helps analysts track and execute remediation and risk-reduction tasks.
- **Purge (soft/hard)**: A mitigation action to remove risky items identified in an investigation. Soft purge moves items to recoverable locations, while hard purge permanently deletes items.
- **Risk score**: A score generated during examination that helps analysts prioritize content based on potential security impact. It supports triage and escalation decisions.
- **AI Search (preview)**: A retrieval-augmented search experience that combines semantic retrieval with AI-generated summaries and citations. It helps analysts assess whether search results match investigative intent.
- **Vector search**: A semantic search method that uses embeddings to retrieve contextually relevant content, even when exact keywords are missing. It supports intent-aware queries and relevance-based ranking.

Key features or capabilities

The key features and capabilities outlined here describe what Microsoft Purview Data Security Investigations is designed to do and how it performs across supported tasks.

- **Integrated incident-to-investigation workflow**: The application supports investigation creation from Microsoft Defender XDR incidents, Insider Risk Management cases, Data Security Posture Management (preview) insights, or manual draft mode. This helps security teams move from alerting to data-focused analysis without switching tools. It also improves collaboration between cybersecurity, compliance, and risk teams.
- **AI-powered semantic retrieval**: Vector search enables intent-aware retrieval across scoped, text-based content. Analysts can find relevant items even when content does not contain exact query terms. This improves recall and reduces manual keyword trial-and-error.
- **AI-assisted prioritization through categorization**: Categorization organizes data into default, custom, and AI-suggested categories so analysts can quickly focus on higher-risk areas. Advanced categorization provides additional topic-level organization for deeper review. This reduces review effort in large investigations by surfacing prioritized content instead of requiring full manual review first.
- **Targeted risk and credential examination**: Examination tools extract credentials, assess item risk, and generate mitigation-oriented outputs for selected content. Analysts get a faster understanding of what might be exposed and what to do next. This supports quicker containment and remediation in active incidents.
- **Mitigation and purge actions**: Investigators can convert findings into concrete actions through mitigation plans and purge workflows. This ties analysis outputs directly to risk-reduction execution. Teams can track progress and status of mitigation decisions within the investigation lifecycle.
- **Audit and ecosystem integration**: The solution integrates with Microsoft Purview audit workflows and Microsoft security solutions, helping teams preserve evidence context and align response actions. It also supports investigation activity logging in the unified audit log to strengthen operational accountability.

Intended uses

Microsoft Purview Data Security Investigations can be used in multiple scenarios. Some examples of use cases include:

- **Breach response from a Defender XDR incident**: An analyst can create new Data Security Investigation directly from a Defender XDR incident to assess the blast radius of a compromised user. AI-powered examination surfaces credentials, sensitive documents, and communications the attacker could have accessed, with regulated and customer-impacting

data prioritized first. Mitigation actions are taken within the same investigation, producing a documented response for audit and follow-up.

- **Tracing employee data exfiltration through the audit log**: When an employee is suspected of exfiltrating a large volume of data, an investigator queries the Unified Audit Log through Data Security Investigations to trace files downloaded and accessed. AI categorization separates routine activity from suspicious content and focuses attention on the highest-risk data. AI enriched findings are handed off to legal and privacy teams for further actions.
- **Hunting sensitive data in an overexposed SharePoint site**: After learning that a SharePoint site containing sensitive content is broadly overshared, an investigator scopes an investigation to that site and runs AI analysis to identify what is actually at risk. Vector search and categorization surface concentrations of sensitive content that would be impractical to review manually.
- **Reviewing risky AI interactions**: An investigator scopes a DSI investigation to AI prompts and responses involving sensitive data, whether from Microsoft Copilot or third-party AI tools. Examinations identify where regulated content, credentials, or PII appeared in interactions, and categorization highlights recurring patterns of risky use. Findings inform both immediate remediation on exposed content and broader follow-up with the users and tools involved.

Models and training data

Microsoft Purview Data Security Investigations leverages a variety of AI models to power the experience that users see. Some examples include Azure OpenAI Service models and Microsoft Security Copilot platform capabilities used for vector embeddings, categorization, and examination-related AI outputs. To learn more about the data used to train the foundation models behind Microsoft Purview Data Security Investigations, refer to the linked model cards to find the relevant data cards.

- Transparency note for Azure OpenAI
- Privacy and data security in Microsoft Security Copilot
- Responsible AI practices at Microsoft

Performance

Microsoft Purview Data Security Investigations is designed to perform reliably in enterprise post-breach and data risk investigation workflows where investigation scope is properly defined and users are assigned the required role groups. In these conditions, analysts can iteratively refine

search results, prioritize data through categorization, and run examination on selected items to support mitigation decisions.

The intended inputs are primarily enterprise content and investigator prompts. Inputs include files, emails, and messages scoped from supported Microsoft 365 data sources; metadata and audit-linked context; and natural language or keyword queries used in vector search and Search with AI (preview). The expected outputs include relevance-ranked search results, category groupings, risk and credential examination outputs, and mitigation-oriented recommendations.

The primary evaluated and documented AI interaction modality is text. Vectorization and semantic retrieval depend on text-bearing content. Some content types that do not include usable text are excluded from vectorization workflows, so investigators should account for this during scope planning.

Performance and usefulness are influenced by investigation setup quality, including scope precision, category selection, and iterative human review. In large datasets, categorization returns prioritized subsets rather than exhaustive coverage for each category. For comprehensive item-level analysis, teams should combine categorization with examination and investigator validation.

Limitations

Understanding Microsoft Purview Data Security Investigations's limitations is crucial to determine if it is used within safe and effective boundaries. While we encourage customers to leverage Microsoft Purview Data Security Investigations in their innovative solutions or applications, it's important to note that Microsoft Purview Data Security Investigations was not designed for every possible scenario. We encourage users to refer to either the Microsoft Enterprise AI Services Code of Conduct (for organizations) or the Code Conduct section in the Microsoft Services Agreement (for individuals) as well as the following considerations when choosing a use case:

- **AI output reliability constraints**: Results generated by generative AI might not always be fully accurate or complete. This limitation is important because investigators may otherwise overestimate confidence and miss context that changes incident severity. Users should validate critical findings, especially before legal, compliance, or irreversible technical actions. Human judgment remains required in final decisions.
- **Text-content dependency for semantic tooling**: Vector search and related semantic workflows require text-bearing content. Certain content types, such as image-only items or content without extractable text, may be excluded from vectorization and therefore from some AI-assisted retrieval workflows. Teams should evaluate whether key evidence might

require additional review methods outside semantic search. This helps avoid false assumptions about complete coverage.

- **Prioritized-not-exhaustive categorization behavior**: Categorization is optimized to surface high-relevance content for selected categories, not to guarantee full review of every item in scope per category. In large datasets, relevant lower-scoring items might not appear in category outputs. Users should use examination for comprehensive item-level analysis where complete coverage is required. This is especially important in high-impact investigations.
- **Operational limits and capacity boundaries**: Investigation and feature limits apply, including limits on total documents, total file size per investigation, and limits in audit search and purge workflows. These constraints can affect how teams segment work and sequence large investigations. Users should plan scope and processing strategy around published limits to avoid delays. Capacity-aware planning improves both cost control and investigative continuity.
- **Not intended for unsupported scenarios or prohibited use**: Data Security Investigations is intended for data security incident investigation and mitigation contexts. Using it as a sole decision-maker, outside governance and security workflows, or in ways prohibited by terms and code-of-conduct requirements can create safety and compliance risk. Organizations should keep the tool within intended operational boundaries and apply layered controls. This includes legal and policy review before high-consequence actions.

Evaluations

Performance and safety evaluations assess whether AI applications are operating reliably and securely by examining factors like groundedness, relevance, and coherence while identifying the risks of generating harmful content. The following evaluations were conducted with safety components already in place, which are also described in 9. Safety Components and Mitigations.

Performance and quality evaluations

Performance and quality evaluations for AI features in Microsoft Purview Data Security Investigations focus on practical investigation outcomes, including vector search relevance, categorization accuracy, and examination output usefulness. Based on product documentation, evaluation activities include pre-release testing and scenario-based validation to assess whether AI-assisted discovery, prioritization, and analysis features help investigators act on identified risks.

For current AI experiences, the primary evaluated modality is text. Ideal outcomes are accurate, relevant findings that help analysts quickly identify high-risk items and take informed

investigative actions. Suboptimal outcomes include results that are incomplete, irrelevant, or require substantial additional analysis and validation.

Risk and safety evaluations

Our evaluation data is custom-built to assess AI application performance across key areas of safety and quality, simulating real-world scenarios and risks. We begin by identifying relevant evaluation aspects of concern based on multi-disciplinary research and expert input. These concerns are translated into targeted evaluation objectives and guide formulation of evaluation metrics. For safety, we create adversarial prompts to elicit undesirable or edge-case responses, which are then scored using AI-assisted annotators trained to assess alignment with Microsoft's safety standards. For quality, we craft rubric-based prompts relevant to scenarios including evaluating retrieval-augmented generation (RAG) applications and agents. Datasets are curated from diverse sources including synthetic and public datasets to simulate real-world user scenarios. Using the curated datasets, both evaluations undergo iterative refinement and human alignment to improve metric efficacy and reliability. This methodology forms the foundation of repeatable, rigorous assessments that reflect how customers use evaluations to build better and safer AI.

Custom evaluations

Data Security Investigations was evaluated using multiple quality and reliability indicators, including AI accuracy, result relevance, and output clarity. Based on documented practices, evaluations use a combination of manual red teaming and human grading to test whether AI-assisted outputs are useful and dependable for incident investigation workflows. The primary evaluated modality for current AI experiences is text.

Evaluation scenarios include semantic retrieval, categorization relevance, and examination outputs used to prioritize and mitigate risk. Ideal results are contextually relevant findings that help analysts quickly identify high-risk items and take informed next actions. Suboptimal results include incomplete, unclear, or less relevant outputs that require additional iteration and validation by investigators.

Operational feedback is also used to improve performance over time. The product collects selected quality-focused metrics about AI inputs and outputs to help tune relevance and usefulness, while documented privacy controls describe what content is and is not collected. This continuous loop supports ongoing quality improvements after release.

Safety components & mitigations

- **Role-based access controls**: Data Security Investigations uses dedicated role groups (Admins, Investigators, Reviewers) to control feature access and responsibilities. This helps limit who can run sensitive activities such as purge and administrative configuration. Clear separation of duties reduces misuse risk and strengthens accountability in investigation workflows.
- **Human-in-the-loop decision making**: AI outputs are designed to assist analysts, not replace investigator judgment. Teams are expected to validate high-impact findings and mitigation recommendations before taking consequential action. This mitigates overreliance and reduces the chance of acting on incomplete AI output.
- **Scope refinement and exclusion controls**: Investigators can iteratively narrow investigation scope and exclude irrelevant items before advanced AI analysis. This improves relevance, reduces noise, and lowers exposure to unnecessary content processing. Focused scope management also supports cost control and faster incident response.
- **Audit logging and evidentiary traceability**: Investigation-related activities are logged through integrated auditing workflows. Logging supports forensic traceability, operational review, and compliance accountability. This is a key mitigation for governance and post-incident validation requirements.
- **Privacy and data handling safeguards**: Documented controls describe tenant-isolated investigation storage and privacy protections for AI processing. Data sharing, logging, and scanning controls in integrated processing paths are documented as off by default for specific Copilot processing contexts. These safeguards help reduce privacy risk and support enterprise compliance expectations.

Best practices for deploying and adopting Microsoft Purview Data Security Investigations

Responsible AI is a shared commitment between Microsoft and its customers. While Microsoft builds AI applications with safety, fairness, and transparency at the core, customers play a critical role in deploying and using these technologies responsibly within their own contexts. To support this partnership, we offer the following best practices for deployers and end users to help customers implement responsible AI effectively. Deployers and end-users (admins) should:

- Exercise caution and evaluate outcomes when using Microsoft Purview Data Security Investigations for consequential decisions or in sensitive domains: Consequential decisions are those that may have a legal or significant impact on a person's access to education, employment, financial platforms, government benefits, healthcare, housing, insurance, legal platforms, or that could result in physical, psychological, or financial harm. Sensitive

domains—such as financial platforms, healthcare, and housing—require particular care due to the potential for disproportionate impact on different groups of people. When using AI for decisions in these areas, make sure that impacted stakeholders can understand how decisions are made, appeal decisions, and update any relevant input data.

- Evaluate legal and regulatory considerations: Customers need to evaluate potential specific legal and regulatory obligations when using any AI platforms and solutions, which may not be appropriate for use in every industry or scenario. Additionally, AI platforms or solutions are not designed for and may not be used in ways prohibited in applicable terms of service and relevant codes of conduct.
- **Plan investigations for iterative analysis**: Data Security Investigations workflows are intentionally iterative, especially for search refinement, scope tuning, and AI-assisted triage. Teams should define repeatable checkpoints for when to run vector search, categorization, and examination. This improves consistency, reduces unnecessary compute use, and strengthens investigation quality.
- **Coordinate cross-functional response early**: Security incidents often involve security, IT, legal, compliance, and business owners. Bring these stakeholders into the investigation process as soon as high-risk findings are identified. Early coordination improves containment speed and reduces downstream remediation friction.

End-users should:

- **Use clear and focused investigation prompts**: For vector search and Search with AI (preview), prompts should include context, subject, and intent (for example, credentials in a named project or access-risk content for a specific incident). Clear prompts produce more relevant retrieval and reduce investigative noise. Users should iterate and compare outputs before drawing conclusions.
- **Validate AI findings with supporting evidence**: Review citations, item details, and activity context before escalating or mitigating. AI outputs can accelerate triage but may miss edge cases or include lower-confidence results. Cross-checking with search, scope views, and stakeholder input reduces error risk.
- Exercise human oversight when appropriate: Human oversight is an important safeguard when interacting with AI applications. While we continuously improve our AI applications, AI might still make mistakes. The outputs generated may be inaccurate, incomplete, biased, misaligned, or irrelevant to your intended goals. This could happen due to various reasons, such as ambiguity in the inputs or limitations of the underlying models. As such, users should review the responses generated by Microsoft Purview Data Security Investigations and verify that they match their expectations and requirements.

- Be aware of the risk of overreliance: Overreliance on AI happens when users accept incorrect or incomplete AI outputs, mainly because mistakes in AI outputs may be hard to detect. For the end-user, overreliance could result in decreased productivity, loss of trust, application abandonment, financial loss, psychological harm, physical harm, among others. (e.g. a doctor accepts an incorrect AI output).
- Exercise caution when designing agentic AI in sensitive domains: Users should exercise caution when designing and/or deploying agentic AI applications in sensitive domains where agent actions are irreversible or highly consequential.
- Additional precautions should also be taken when creating autonomous agentic AI as described further in either the Microsoft Enterprise AI Services Code of Conduct (for organizations) or the Code Conduct section in the Microsoft Services Agreement (for individuals).

Deployers should:

- **Configure permissions and ownership model upfront**: Assign Data Security Investigations role groups based on least privilege and operational responsibility before incidents occur. Include backup admins and clear role coverage to avoid response delays. This reduces risk from overbroad access and strengthens continuity during active incidents.
- **Design for limits, costs, and throughput**: Investigation, audit search, and purge limits should inform how teams segment large incidents. Teams should also monitor capacity usage and stage AI processing to align with urgency and budget. This avoids bottlenecks and supports predictable response performance.
- **Test mitigation workflows and escalation paths**: Run tabletop or pilot investigations using representative data to validate query patterns, categorization strategy, and mitigation handoffs. Pre-tested workflows reduce confusion during real incidents and improve time to action. Include checks for legal and compliance notification requirements as part of this testing.

Privacy FAQ for Data Security Investigations

How is my data stored in Microsoft Purview Data Security Investigations?

When you use Data Security Investigations, Microsoft copies user queried organization data from the Microsoft 365 application storage to tenant-isolated regional investigation storage. This data is stored until Data Security Investigations administrators or investigators delete the investigation. Only Data Security Investigations Administrators, Investigators, and Reviewers have access to this data in your organization.

How is my data processed for Data Security Investigations AI features?

Data Security Investigations partners closely with Microsoft Security Copilot platform to power Data Security Investigations AI features. This means that data leaves Data Security Investigations (Microsoft 365 compliance area) and travels to Microsoft Security Copilot (Microsoft Azure compliance area) for up to 48 hours and return with AI generated content and insights. This generates the vector embeddings for vector search, category and subject generation, and examination results.

To ensure user privacy, all data sharing, logging, and scanning is turned off by default for Microsoft Security Copilot processing of Data Security Investigations data. For more information on Microsoft Security Copilot, see Privacy and data security in Microsoft Security Copilot

What feedback information does Data Security Investigations collect?

Data Security Investigations collects customer feedback to enhance its AI features and improve user experience. This feedback is gathered during the public preview stage and includes specific metrics related to the AI features' inputs and outputs.

- **What we collect**: We collect metrics such as the number of files returned to a vector search query, the total number of vectorized files in the user's data set, category impact scores, AI generated risk and relevance scores of files, and the number of files selected for AI

examination. These metrics help us understand the effectiveness and relevance of our AI features.

- **What we don't collect**: We don't collect customer content or any personal data from the files themselves. Our focus is solely on collecting metrics and qualitative data about the inputs and outputs of our AI services to improve their performance and accuracy.

By collecting these metrics, Data Security Investigations aims to continuously improve its AI features and provide users with more accurate and relevant results. Your feedback is invaluable in helping us achieve this goal.

Limits in Data Security Investigations

This article describes the limits in Microsoft Purview Data Security Investigations.

Investigation limits

The following table lists the limits for investigations in Data Security Investigations.

Expand table

Description of limit	Data Security Investigations feature support
Total number of documents that you can add to an investigation.	40 million
Total file size per investigation.	1 TB

Purge limits

The following table lists the limits for purge in Data Security Investigations.

Expand table

Description of limit	Data Security Investigations feature support
Maximum number of items per purge search query.	10,000

Search and integration limits

The following table lists the search and integration limits for Data Security Investigations. These limits apply to searches and investigations created from the following solutions:

- Audit search
- Endpoint DLP evidence collection. For more information about endpoint DLP, see Learn about endpoint data loss prevention.
- Insider Risk Management
- Microsoft Defender XDR

Expand table

Description of limit	Data Security Investigations feature support
Maximum items returned per search or integration query.	Approximately 3,000
Maximum concurrent audit searches per user.	10

> **Tip**
>
> If your investigation involves more than approximately 3,000 audit items, you can split the data into smaller time-based slices. For more information, see Work with large audit search results.

Note: The author created this article with assistance from AI. Learn more

Partially indexed items in Data Security Investigations

Summarize this article for me

Data Security Investigations searches automatically include partially indexed items in the estimated search results. Partially indexed items are Exchange mailbox items and documents on SharePoint and OneDrive sites that aren't completely indexed for search. In Exchange, a partially indexed item typically contains a file (of a file type that can't be indexed) attached to an email message.

The following list describes other reasons why items can't be indexed for search and are returned as partially indexed items:

- The file type is unrecognized or unsupported for indexing.
- Messages have an attached file that can't be opened. This issue is the most common cause of partially indexed email items.
- The file type is supported for indexing but an indexing error occurred for a specific file.
- Too many files attached to an email message.
- A file attached to an email message is too large.
- A file is encrypted with non-Microsoft technologies.
- A file is password-protected.

> **Note**
>
> Most organizations have less than 1% of content by volume and less than 12% by size that is partially indexed. The reason for the difference between volume and size is that larger files have a higher probability of containing content that can't be fully indexed.

File types not indexed for search

Certain types of files, such as Bitmap (.bmp) or MP3 (.mp3) files, don't contain content that can be indexed. The search indexing servers in Exchange and SharePoint don't perform full-text indexing on these types of files and they're considered as unsupported file types. There are also file types for which full-text indexing is disabled, either by default or by an administrator. Unsupported and disabled file types are labeled as unindexed items in searches.

For a list of supported and disabled file formats, see the following articles:

- **Exchange**: File formats indexed by Exchange Search
- **Exchange**: Get-SearchDocumentFormat

- **SharePoint**: Default crawled file name extensions and parsed file types in SharePoint

Messages and documents with partially indexed file types returned in search results

Not every email message with a partially indexed file attachment or every partially indexed SharePoint document is automatically returned as a partially indexed item. That's because other message or document properties, such as the **Subject** property in email messages and the **Title** or **Author** properties for documents, are indexed and available to be searched. For example, a keyword search for *financial* returns items with a partially indexed file attachment if that keyword appears in the subject of an email message or in the file name or title of a document. However, if the keyword appears only in the body of the file, the message or document is returned as a partially indexed item.

Similarly, messages with partially indexed file attachments and documents of a partially indexed file type are included in search results when other message or document properties, which are indexed and searchable, match the search criteria. Message properties that are indexed for search include sent and received dates, sender and recipient, the file name of an attachment, and text in the message body. Document properties indexed for search include created and modified dates. So even though a message attachment might be a partially indexed item, the message is included in the regular search results if the value of other message or document properties matches the search criteria.

> **Note**
>
> If a mailbox item is moved from a folder that is indexed to a folder that isn't indexed, a flag is set to unindex the item and the item is removed from the index and isn't searchable. Later, if that same item is moved back to a folder that is indexed, the flag isn't reset. That means the item remains unindexed, and not searchable.

To perform a deeper analysis of partially indexed items, use Purview eDiscovery to export and review partially indexed items. For more information, see Partially indexed items in eDiscovery.

More information about partially indexed items

- Because message and document properties and their metadata are indexed, a keyword search might return results if that keyword appears in the indexed metadata. However, that same keyword search might not return the same item if the keyword only appears in the content of an item with an unsupported file type. In this case, the item is returned as a partially indexed item.

- Although a file type is supported for indexing and is indexed, indexing or search errors can cause a file to be returned as a partially indexed item. For example, searching a large Excel file might be partially successful (because the first 4 MB are indexed), but then fails because the file size limit is exceeded. In this case, it's possible that the same file is returned with the search results and as a partially indexed item.
- Files that are encrypted with Microsoft encryption technologies (and stored in SharePoint or OneDrive) are partially indexed.
- Email messages encrypted with S/MIME are partially indexed. This limitation includes encrypted messages with or without file attachments.
- Email messages protected using Azure Rights Management are indexed and are included in the search results if they match the search query.

Last updated on 02/18/2026

Supported file types in Data Security Investigations

Microsoft Purview Data Security Investigations supports Optical Character Recognition (OCR) text extraction for supported image file types. The following table lists the currently supported image file types and indicates if a file type is supported for file identification, metadata extraction, and OCR text extraction.

Image

Extraction of images is part of adding items to an investigation scope and automatic OCR processing isn't an additional charge for your organization.

Expand table

Mime type	File identification	Metadata extraction	OCR text extraction	Possible Extensions
image/bmp	Yes	Yes	Yes	.bmp
image/emf	Yes	Yes	Yes	.emf
image/gif	Yes	Yes	Yes	.gif
image/jpeg	Yes	Yes	Yes	.jpeg; .jpg
image/png	Yes	Yes	Yes	.png
image/svg+xml	Yes	Yes	Yes	.svg
image/tiff	Yes	Yes	Yes	.tif
image/vnd.dwg	Yes	Yes	Yes	.dwg; .dxf
image/wmf	Yes	Yes	Yes	.wmf

> **Note**
>
> The **OCR text extraction** column indicates that you can extract text from these image formats when data is automatically vectorized. OCR text extraction occurs automatically during data preparation and the extracted text is vectorized for use in AI-based analysis tools.

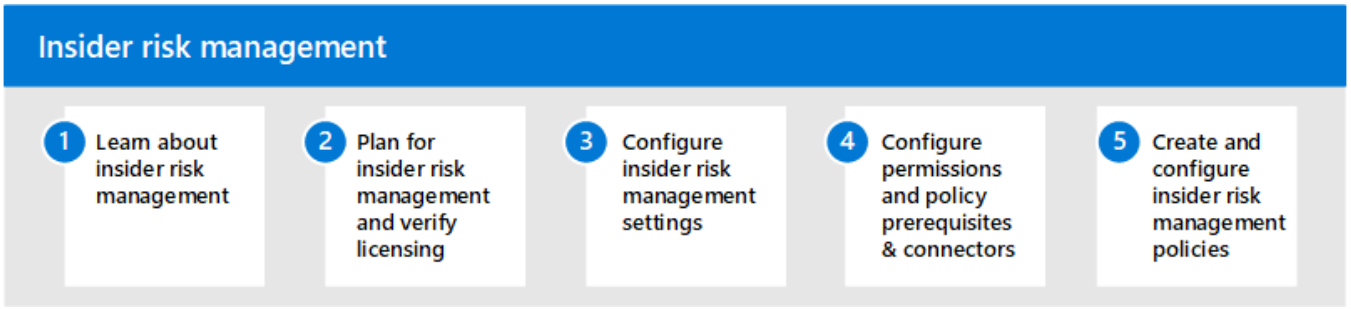
Insider Risk Management

09/26/2025

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Employees now have more access to create, manage, and share data across a broad spectrum of platforms and services. In most cases, organizations have limited resources and tools to identify and mitigate organization-wide risks while also meeting compliance requirements and employee privacy standards. These risks include potential data theft by departing employees and risk of data leaks of information outside your organization by accidental oversharing or malicious intent.

Microsoft Purview Insider Risk Management uses the full breadth of service and third-party indicators to help you quickly identify, triage, and act on potentially risky activity. By using logs from Microsoft 365 and Microsoft Graph, Insider Risk Management allows you to define specific policies to identify risk indicators. After identifying the risks, you can take action to mitigate these risks, and if necessary open investigation cases and take appropriate legal action.



Watch the following videos to learn how Insider Risk Management can help your organization prevent, detect, and contain risks:

Insider Risk Management solution & development:
https://learn-video.azurefd.net/vod/player?id=13a0ac77-ac1a-49e0-9b8b-4af3e6df6053&locale=en-us&embedUrl=%2Fpurview%2Finsider-risk-management-solution-overview

Insider Risk Management workflow:
https://learn-video.azurefd.net/vod/player?id=bf70614d-1ba7-4f60-978d-080ae514eb6f&locale=en-us&embedUrl=%2Fpurview%2Finsider-risk-management-solution-overview

Configure Insider Risk Management

Use the following steps to configure Insider Risk Management for your organization:

1. Learn about Insider Risk Management
2. Plan for Insider Risk Management and verify licensing
3. Configure Insider Risk Management settings
4. Configure permissions and policy prerequisites & connectors
5. Create and configure Insider Risk Management policies

More information about Insider Risk Management

- Manage insider risk policies
- Investigate insider risk activities
- Act on insider risk cases

Learn about Insider Risk Management

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Microsoft Purview Insider Risk Management is a compliance solution that helps minimize internal risks by enabling you to detect, investigate, and act on malicious and inadvertent activities in your organization. With insider risk policies, you can define the types of risks to identify and detect in your organization. You can also set up processes for acting on cases and escalating cases to Microsoft eDiscovery (Premium) if needed. Risk analysts in your organization can quickly take appropriate actions to make sure users are compliant with your organization's compliance standards.

For more information and an overview of the planning process to address potentially risky activities in your organization that might lead to a security incident, see Starting an Insider Risk Management program.

Watch the following videos to learn how Insider Risk Management can help your organization prevent, detect, and contain risks while prioritizing your organization values, culture, and user experience:

Check out the Microsoft Mechanics video on how Insider Risk Management and Communication Compliance work together to help minimize data risks from users in your organization.

> **Important**
>
> Insider Risk Management is currently available in tenants hosted in geographical regions and countries supported by Azure service dependencies. To verify that Insider Risk Management is supported for your organization, see Azure dependency availability by country/region.

Modern risk pain points

Managing and minimizing risk in your organization starts with understanding the types of risks found in the modern workplace. Some risks come from external events and factors that you can't directly control. Other risks come from internal events and user actions that you can minimize and avoid. Some examples are risks from illegal, inappropriate, unauthorized, or unethical behavior and actions by users in your organization. These behaviors include a broad range of internal risks from users:

- Leaks of sensitive data and data spillage
- Confidentiality violations
- Intellectual property (IP) theft
- Fraud
- Insider trading
- Regulatory compliance violations

Users in the modern workplace can create, manage, and share data across a broad spectrum of platforms and services. In most cases, organizations have limited resources and tools to identify and mitigate organization-wide risks while also meeting user privacy standards.

Insider Risk Management uses the full breadth of service and third-party indicators to help you quickly identify, triage, and act on risk activity. By using logs from Microsoft 365 and Microsoft Graph, Insider Risk Management enables you to define specific policies to identify risk indicators. These policies help you identify risky activities and act to mitigate these risks.

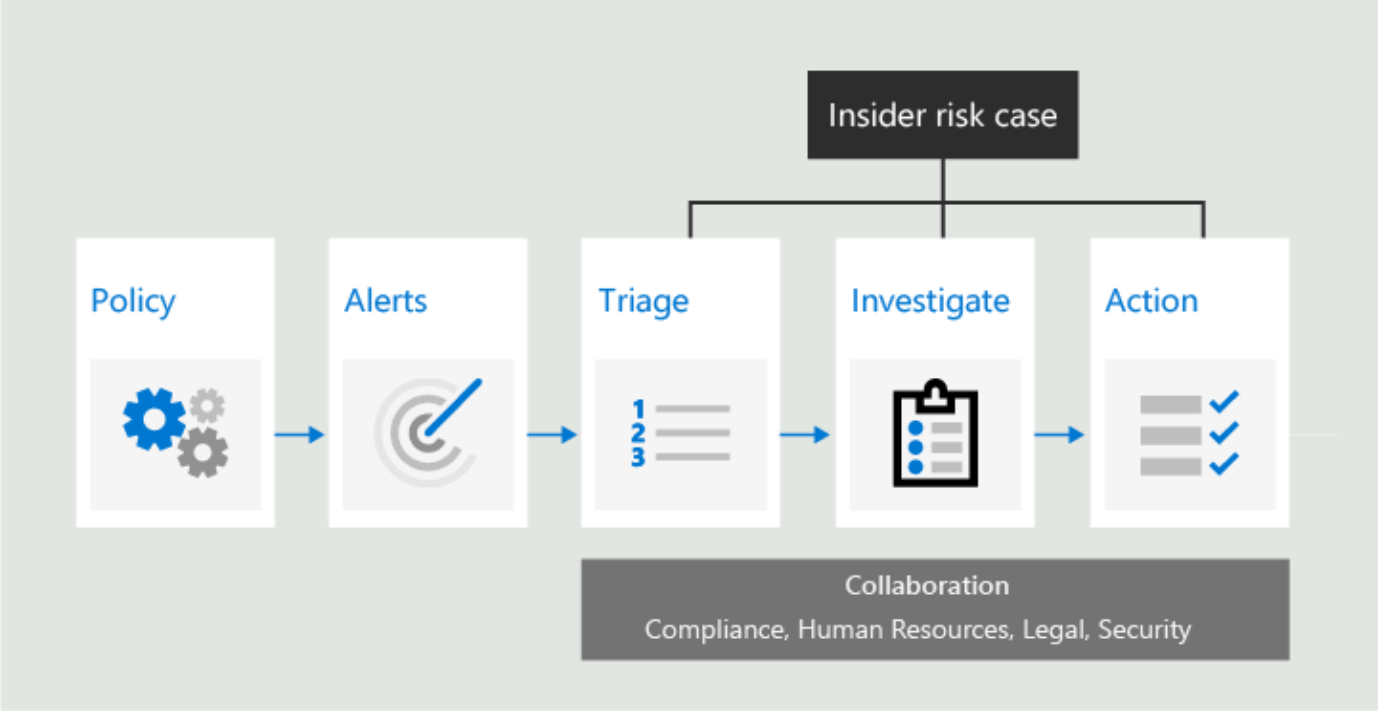
Insider Risk Management centers around the following principles:

- **Transparency**: Balance user privacy versus organization risk with privacy-by-design architecture.
- **Configurable**: Configurable policies based on industry, geographical, and business groups.
- **Integrated**: Integrated workflow across Microsoft Purview solutions.
- **Actionable**: Provides insights to enable reviewer notifications, data investigations, and user investigations.

Identifying potential risks with analytics

Insider risk analytics enables you to evaluate potential insider risks in your organization without configuring any insider risk policies. This evaluation can help your organization identify potential areas of higher user risk and help determine the type and scope of Insider Risk Management policies you might consider configuring. This evaluation can also help you determine needs for additional licensing or future optimization of existing insider risk policies.

For more information about insider risk analytics, see Insider Risk Management settings: Analytics.



Get started with recommended actions

Whether you're setting up Insider Risk Management for the first time or getting started with creating new policies, the new recommended actions experience can help you get the most out of Insider Risk Management capabilities. Recommended actions include setting up permissions, choosing policy indicators, creating a policy, and more.

Workflow

The Insider Risk Management workflow helps you identify, investigate, and take action to address internal risks in your organization. With focused policy templates, comprehensive activity signaling across the Microsoft 365 service, and alert and case management tools, you can use actionable insights to quickly identify and act on risky behavior.

Identifying and resolving internal risk activities and compliance issues with Insider Risk Management uses the following workflow:

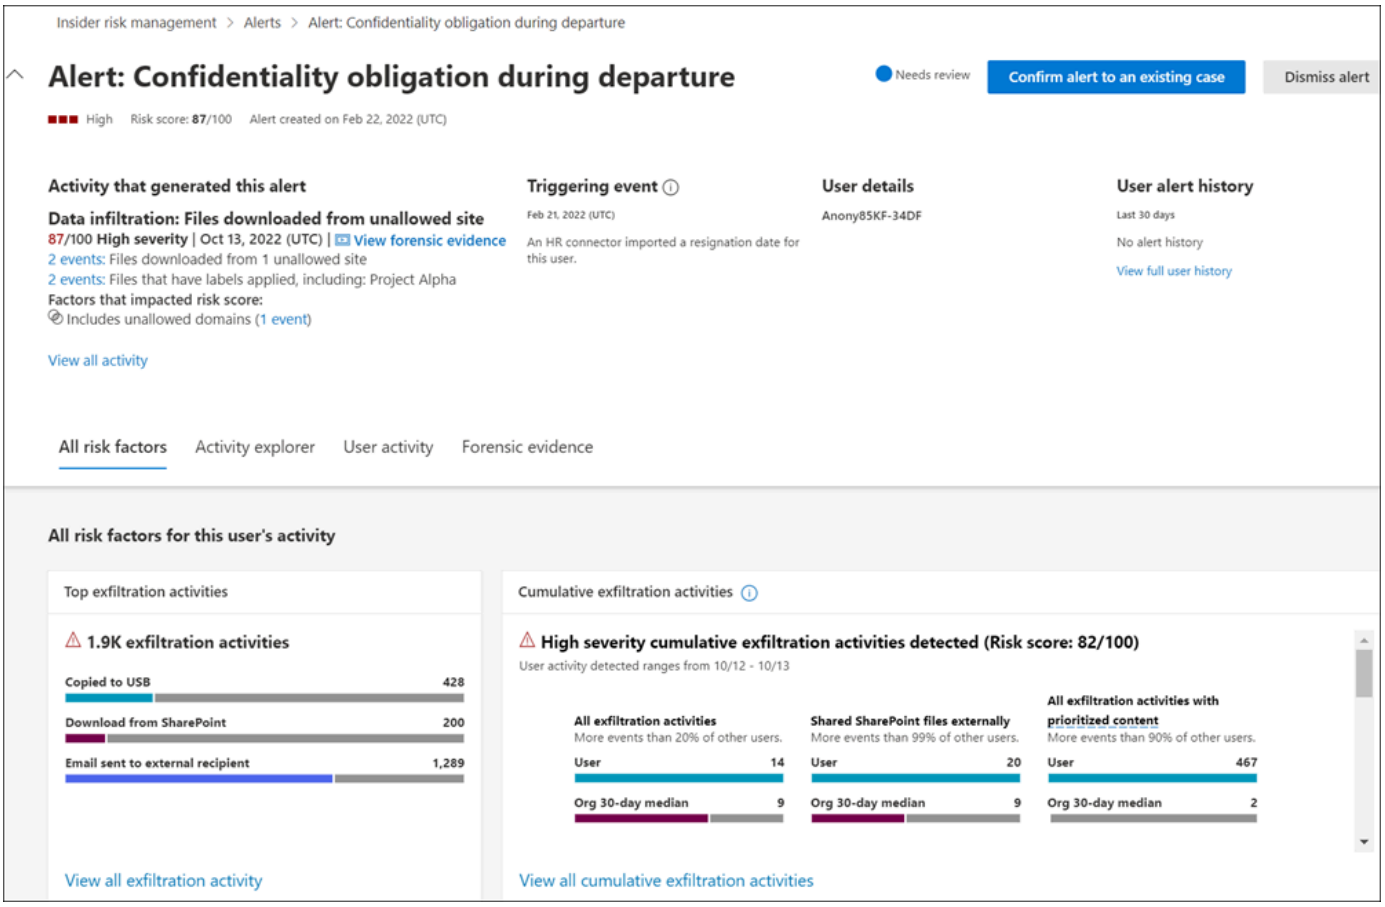
Policies

You create Insider Risk Management policies by using predefined templates and policy conditions that define which triggering events and risk indicators to examine in your organization. These conditions include how risk indicators are used for alerts, which users are included in the policy, which services are prioritized, and the detection time period.

To quickly get started with Insider Risk Management, select from the following policy templates:

- Data theft by departing users
- Data leaks
- Data leaks by priority users
- Data leaks by risky users
- Patient data misuse (preview)
- Risky Agents
- Risky AI usage
- Risky browser usage (preview)
- Security policy violations
- Security policy violations by departing users
- Security policy violations by risky users
- Security policy violations by priority users

Alerts



Risk indicators automatically generate alerts when they match policy conditions. You can see these alerts in the Alerts dashboard or the Triage Agent dashboard. These dashboards provide a quick view of all alerts that need review, open alerts over time, and alert statistics for your organization. All policy alerts display the following information to help you quickly identify the status of existing alerts and new alerts that need action:

- ID
- Users
- Alert
- Status
- Alert severity
- Time detected
- Case
- Case status
- Risk factors

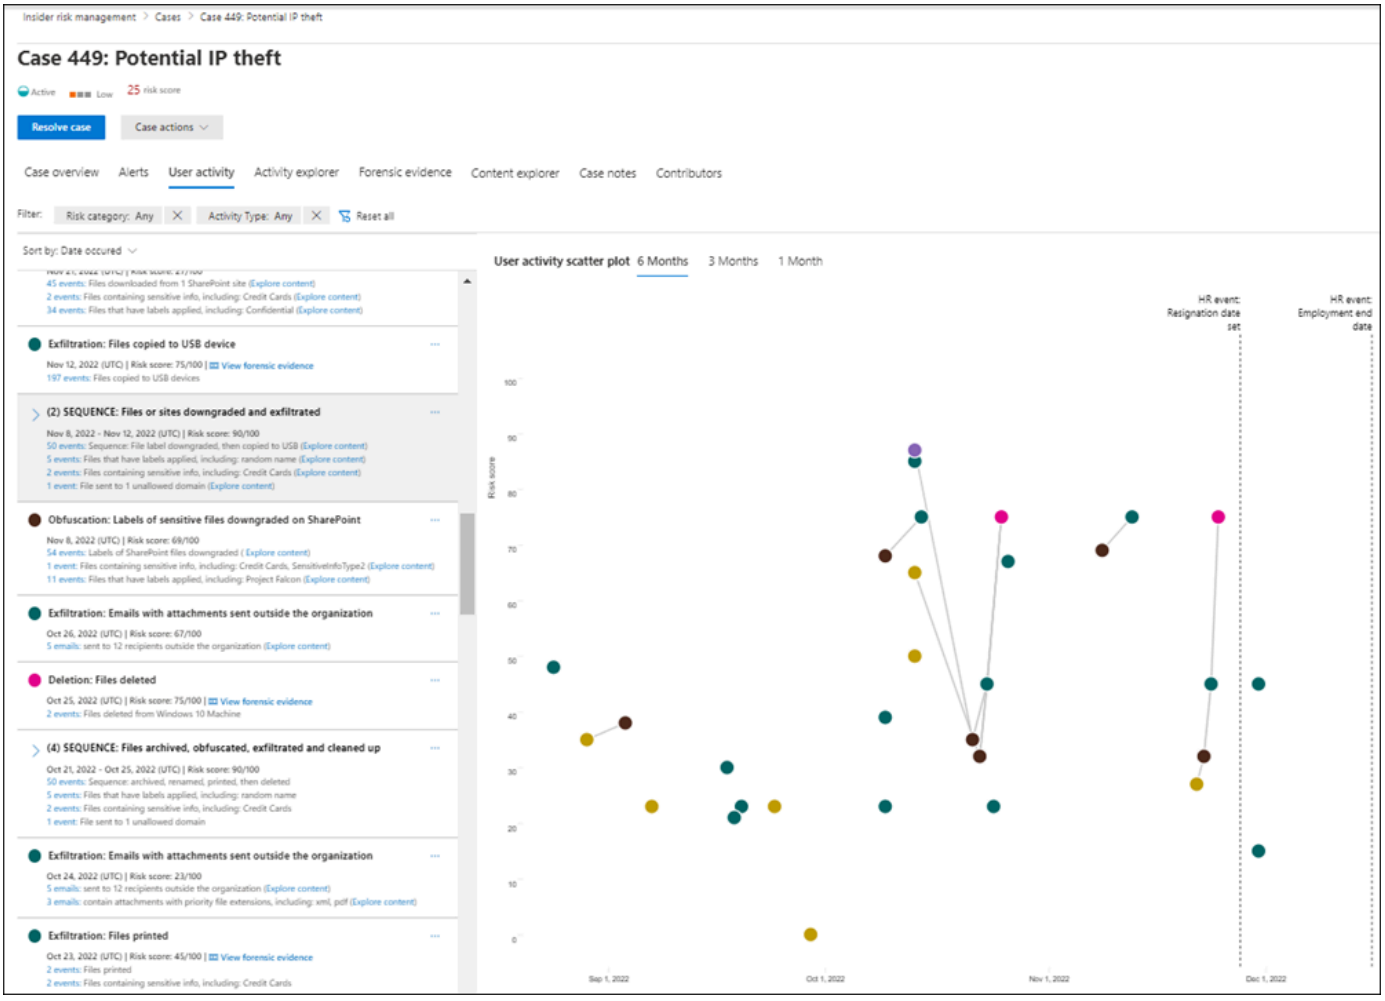
Triage

New user activities that need investigation automatically generate alerts and assign them a *Needs review* status. Reviewers can quickly identify, review, evaluate, and triage these alerts.

Resolve alerts by opening a new case, assigning the alert to an existing case, or dismissing the alert. With alert filters, you can quickly identify alerts by status, severity, or time detected. As part of the triage process, reviewers can view alert details for the activities identified by the policy, view user activity associated with the policy match, see the severity of the alert, and review user profile information.

Investigate

Quickly investigate all risky activities for a selected user with User activity reports (preview). These reports let investigators in your organization examine activities for specific users during a defined time period without temporarily or explicitly assigning them to an Insider Risk Management policy. After examining activities for a user, investigators can dismiss individual activities as benign, share or email a link to the report with other investigators, or choose to assign the user temporarily or explicitly to an Insider Risk Management policy.



Cases are created for alerts that require deeper review and investigation of the activity details and circumstances around the policy match. The **Case dashboard** provides an all-up view of all active cases, open cases over time, and case statistics for your organization. Reviewers can quickly filter cases by status, the date the case was opened, and the date the case was last updated.

Selecting a case on the case dashboard opens the case for investigation and review. This step is the heart of the Insider Risk Management workflow. This area synthesizes risk activities, policy conditions, alert details, and user details into an integrated view for reviewers. The primary investigation tools in this area are:

- **User activity**: An interactive chart automatically displays user risk activity. It plots activities over time and by risk level for current or past risk activities. Reviewers can quickly filter and

view the entire risk history for the user and drill into specific activities for more details.

- **Content explorer**: The Content explorer automatically captures and displays all data files and email messages associated with alert activities. Reviewers can filter and view files and messages by data source, file type, tags, conversation, and many more attributes.
- **Case notes**: Reviewers can provide notes for a case in the Case Notes section. This list consolidates all notes in a central view and includes reviewer and date submitted information.

Additionally, the new Audit log (preview) enables you to stay informed of the actions taken on Insider Risk Management features. This resource allows an independent review of the actions taken by users assigned to one or more Insider Risk Management role groups.

Action

After investigating cases, reviewers can quickly act to resolve the case or collaborate with other risk stakeholders in your organization. If users accidentally or inadvertently violate policy conditions, reviewers can send a simple reminder notice to the user from notice templates you can customize for your organization. These notices might serve as simple reminders or might

direct the user to refresher training or guidance to help prevent future risky behavior. For more information, see Insider Risk Management notice templates.

In more serious situations, you might need to share the Insider Risk Management case information with other reviewers or services in your organization. Insider Risk Management tightly integrates with other Microsoft Purview solutions to help you with end-to-end risk resolution.

- **eDiscovery (Premium)**: Escalating a case for investigation allows you to transfer data and management of the case to Microsoft Purview eDiscovery (Premium). eDiscovery (Premium) provides an end-to-end workflow to preserve, collect, review, analyze, and export content that's responsive to your organization's internal and external investigations. It allows legal teams to manage the entire legal hold notification workflow. To learn more about eDiscovery (Premium) cases, see Overview of Microsoft Purview eDiscovery (Premium).
- **Office 365 Management APIs integration (preview)**: Insider Risk Management supports exporting alert information to security information and event management (SIEM) services via the Office 365 Management APIs. Having access to alert information in the platform that best fits your organization's risk processes gives you more flexibility in how to act on risk activities. To learn more about exporting alert information with Office 365 Management APIs, see Export alerts.

Scenarios

Insider Risk Management can help you detect, investigate, and take action to mitigate internal risks in your organization in several common scenarios:

Data theft by departing users

When users leave an organization, either voluntarily or as the result of termination, legitimate concerns often arise that company, customer, and user data are at risk. Users might innocently assume that project data isn't proprietary, or they might be tempted to take company data for personal gain and in violation of company policy and legal standards. Insider Risk Management policies that use the Data theft by departing users policy template automatically detect activities typically associated with this type of theft. With this policy, you automatically receive alerts for suspicious activities associated with data theft by departing users so you can take appropriate investigative actions. You need to configure a Microsoft 365 HR connector for your organization for this policy template.

Intentional or unintentional leak of sensitive or confidential information

In most cases, users try their best to properly handle sensitive or confidential information. But occasionally users make mistakes and information is accidentally shared outside your organization or in violation of your information protection policies. In other circumstances, users might intentionally leak or share sensitive and confidential information with malicious intent and for potential personal gain. Insider Risk Management policies created using the following policy templates automatically detect activities typically associated with sharing sensitive or confidential information:

- Data leaks
- Data leaks by priority users
- Data leaks by risky users
- Risk AI usage

Intentional or unintentional security policy violations (preview)

Users typically have a large degree of control when managing their devices in the modern workplace. This control might include permissions to install or uninstall applications needed in the performance of their duties or the ability to temporarily disable device security features. Whether this risk activity is inadvertent, accidental, or malicious, this conduct can pose risk to your organization and is important to identify and act to minimize. To help identify these risky security activities, the following Insider Risk Management security policy violation templates scores security risk indicators and use Microsoft Defender for Endpoint alerts to provide insights for security-related activities:

- Security policy violations
- Security policy violations by departing users
- Security policy violations by priority users
- Security policy violations by risky users

Policies for users based on position, access level, or risk history

Users in your organization might have different levels of risk depending on their position, level of access to sensitive information, or risk history. This structure might include members of your organization's executive leadership team, IT administrators that have extensive data and network access privileges, or users with a past history of risky activities. In these circumstances, closer inspection and more aggressive risk scoring are important to help surface alerts for investigation

and quick action. To help identify risky activities for these types of users, you can create priority user groups and create policies from the following policy templates:

- Security policy violations by priority users
- Data leaks by priority users

Healthcare (preview)

For organizations in the healthcare industry, recent studies found a very high rate of insider-related data breaches. Detecting misuse of patient data and health record information is a critical component of safeguarding patient privacy and complying with compliance regulation such as the Health Insurance Portability and Accountability Act (HIPAA) and the Health Information Technology for Economic and Clinical Health (HITECH) Act. Patient data misuse can range from accessing privileged patient records to accessing records of patients from family or neighbors with malicious intent. To help identify these types of risky activities, the following Insider Risk Management policy template uses the Microsoft 365 HR connector and a healthcare-specific data connector to start scoring risk indicators relating to behaviors that can occur within your electronic heath record (EHR) systems:

- Patient data misuse (preview)

Actions and behaviors by risky users

Employment stressor events can impact user behavior in several ways that relate to insider risks. These stressors might be a poor performance review, a position demotion, or the user being placed on a performance review plan. Stressors might also result in potentially inappropriate behavior such as users sending potentially threatening, harassing, or discriminatory language in email and other messages. Though most users don't respond maliciously to these events, the stress of these actions can result in some users behaving in ways that they might not normally consider during normal circumstances. To help identify these types of potentially risky activities, the following Insider Risk Management policy templates can use the HR connector and/or integration with a dedicated Communication Compliance policy to bring users into scope for Insider Risk Management policies and start scoring risk indicators relating to behaviors that might occur:

- Data leaks by risky users
- Risk AI usage
- Risky browser usage (preview)
- Security policy violations by risky users

Visual context for potentially risky user activities with forensic evidence

Having visual context is crucial for security teams during forensic investigations to get better insights into potentially risky user activities that might lead to a security incident. This insight might include visual capturing of these activities to help evaluate if they're indeed risky or taken out of context and not potentially risky. For activities that are determined to be risky, having forensic evidence captures can help investigators and your organization better mitigate, understand, and respond to these activities. To help with this scenario, enable forensic evidence capturing for online and offline devices in your organization.

Ready to get started?

- See Plan for Insider Risk Management to prepare for enabling Insider Risk Management policies in your organization.
- See Get started with Insider Risk Management settings to configure global settings for insider risk policies.
- See Get started with Insider Risk Management to configure prerequisites, create policies, and start receiving alerts.

Plan for Insider Risk Management

08/20/2025

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Before you get started with Insider Risk Management in your organization, review important planning activities and considerations with your information technology and compliance management teams. Thoroughly understanding and planning for deployment in the following areas helps ensure that your implementation and use of Insider Risk Management features goes smoothly and aligns with best practices.

For more information and an overview of the planning process to address risky activities in your organization, see Starting an Insider Risk Management program.

To learn how the Insider Risk Management workflow can help your organization prevent, detect, and contain risks while prioritizing your organization values, culture, and user experience, watch the following video:
https://learn-video.azurefd.net/vod/player?id=bf70614d-1ba7-4f60-978d-080ae514eb6f&locale=en-us&embedUrl=%2Fpurview%2Finsider-risk-management-plan

Check out the Microsoft Mechanics video on how Insider Risk Management and Communication Compliance work together to help minimize data risks from users in your organization.

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the Microsoft Purview trials hub. Learn details about signing up and trial terms.

Work with stakeholders in your organization

Identify the appropriate stakeholders in your organization to collaborate for taking actions on Insider Risk Management alerts and cases. Consider including the following areas of your organization in initial planning and the end-to-end Insider Risk Management workflow:

- Information technology
- Compliance
- Privacy
- Security
- Human resources
- Legal

Determine regional compliance requirements

Different geographic and organizational areas might have compliance and privacy requirements that differ from other areas of your organization. Work with the stakeholders in these areas to ensure they understand the compliance and privacy controls in Insider Risk Management and how to use them across different areas of your organization. In some scenarios, compliance and privacy requirements might require policies that designate or restrict some stakeholders from investigations and cases based on the case for a user or regulatory or policy requirements for the area.

If you have requirements for specific stakeholders to be involved in case investigations that involve users in certain regions, roles, or divisions, consider implementing separate (even if identical) Insider Risk Management policies that target the different regions and populations. This configuration makes it easier for the right stakeholders to triage and manage cases that are relevant to their roles and regions. Consider creating processes and policies for regions where investigators and reviewers speak the same language as the users. This approach can help streamline the escalation process for Insider Risk Management alerts and cases.

Plan permissions to support the review and investigation workflow

Depending on how you want to manage Insider Risk Management policies and alerts, assign users to specific role groups to manage different sets of Insider Risk Management features. You can assign users with different compliance responsibilities to specific role groups to manage different areas of Insider Risk Management features. Or, assign all user accounts for designated administrators, analysts, investigators, and viewers to the *Insider Risk Management* role group. For more information, see Assign Insider Risk Management permissions.

Understand requirements and dependencies

Depending on how you plan to implement Insider Risk Management policies, you need the proper Microsoft 365 licensing subscriptions. You also need to understand and plan for some solution prerequisites.

Licensing: Microsoft offers Insider Risk Management as part of a wide selection of Microsoft 365 licensing subscriptions. For details, see the Getting started with Insider Risk Management article.

> **Important**
>
> Microsoft currently offers Insider Risk Management in tenants hosted in geographical country/regions supported by Azure service dependencies. To verify that Microsoft supports Insider Risk Management for your organization, see **Azure dependency availability by country/region**.

If you don't have an existing Microsoft 365 Enterprise E5 plan and want to try Insider Risk Management, you can add Microsoft 365 to your existing subscription or sign up for a trial of Microsoft 365 Enterprise E5.

Policy template requirements: Depending on the policy template you choose, understand the following requirements and plan accordingly prior to configuring Insider Risk Management in your organization:

- For the **Data theft by departing users** template, configure a Microsoft 365 HR connector to periodically import resignation and termination date information for users in your organization. For step-by-step guidance to configure the Microsoft 365 HR connector, see the Import data with the HR connector article.
- For the **Data leaks** template, configure at least one Microsoft Purview Data Loss Prevention (DLP) policy to define sensitive information in your organization and to receive insider risk alerts for High Severity DLP policy alerts. For step-by-step guidance to configure DLP policies, see the Create and Deploy data loss prevention policies article.
- For the **Security policy violation** template, enable Microsoft Defender for Endpoint for Insider Risk Management integration in the Defender Security Center to import security violation alerts. For step-by-step guidance to enable Defender for Endpoint integration with Insider Risk Management, see Configure advanced features in Microsoft Defender for Endpoint.
- For the **Risky user** template, configure a Microsoft 365 HR connector to periodically import performance or demotion status information for users in your organization. For

step-by-step guidance to configure the Microsoft 365 HR connector, see the Import data with the HR connector article.

Test with a small group of users in a production environment

Before enabling this solution broadly in your production environment, consider testing the policies with a small set of production users so you can complete the necessary compliance, privacy, and legal reviews in your organization. Evaluating Insider Risk Management in a test environment requires that you generate simulated user actions and other signals to create alerts for triage and cases for processing. This approach might not be practical for many organizations, so we recommend that you test Insider Risk Management with a small group of users in a production environment.

Keep the anonymization feature in policy settings enabled to anonymize user display names in the Insider Risk Management console during this testing to maintain privacy within the tool. This setting helps protect the privacy of users that have policy matches and can help promote objectivity in data investigation and analysis reviews for insider risk alerts.

If you don't see any alerts immediately after configuring an Insider Risk Management policy, it might mean the minimum risk threshold isn't met yet. Check the **Users** page to verify that the policy is triggered and working as expected and to see if users are in-scope for the policy.

Migrating between Microsoft 365 US Government Cloud and the commercial cloud

If you migrate your organization from the Microsoft 365 US Government Cloud to the worldwide commercial cloud or from the worldwide commercial cloud to the Government Cloud, active cases and alerts don't migrate. Close any alerts and cases before starting the migration.

Resources for stakeholders

Share Insider Risk Management documentation with the stakeholders in your organization that are included in your management and remediation workflow:

- Create and manage insider risk policies
- Investigate insider risk activities
- Take action on insider risk cases
- Review case data with the insider risk Content explorer

- Create insider risk notice templates

Ready to get started?

Ready to configure Insider Risk Management for your organization? We recommend that you review the following articles:

- Get started with Insider Risk Management settings to configure global policy settings.
- Get started with Insider Risk Management to configure prerequisites, create policies, and start receiving alerts.
- Get started with Insider Risk Management forensic evidence for step-by-step guidance to configure forensic evidence capturing in your organization.

Get started with Insider Risk Management

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Use Insider Risk Management policies to identify risky activities and management tools to act on risk alerts in your organization. Complete the following steps to set up prerequisites and configure an Insider Risk Management policy.

> **Important**
>
> The Insider Risk Management solution provides a tenant-level option to help customers facilitate internal governance at the user level. Tenant-level administrators can set up permissions to provide access to this solution for members of your organization and set up data connectors in the Microsoft Purview portal to import relevant data to support user-level identification of potentially risky activity. Customers acknowledge insights related to the individual user's behavior, character, or performance materially related to employment can be calculated by the administrator and made available to others in the organization. In addition, customers acknowledge that they must conduct their own full investigation related to the individual user's behavior, character, or performance materially related to employment, and not just rely on insights from the Insider Risk Management service. Customers are solely responsible for using the Insider Risk Management service, and any associated feature or service in compliance with all applicable laws, including laws relating to individual user identification and any remediation actions.

For more information about how insider risk policies can help you manage risk in your organization, see Learn about Insider Risk Management.

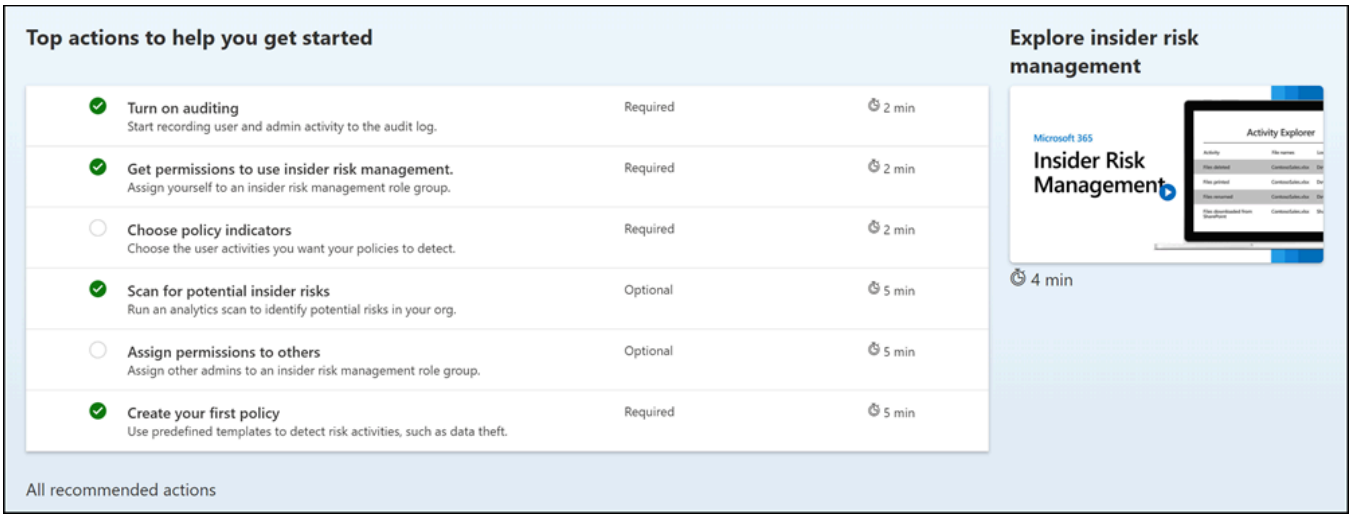
Subscriptions and licensing

Before getting started with Insider Risk Management, confirm your Microsoft 365 subscription and any add-ons. To access and use Insider Risk Management, administrators need to verify their organization has a supported subscription and assign the appropriate

licenses to users. For more information about subscriptions and licensing, see the subscription requirements for Insider Risk Management.

> **Important**
>
> Insider Risk Management is currently available in tenants hosted in geographical regions and countries supported by Azure service dependencies. To verify that Insider Risk Management is supported for your organization, see **Azure dependency availability by country/region**.

If you don't have an existing Microsoft 365 Enterprise E5 plan and want to try Insider Risk Management, you can add Microsoft 365 to your existing subscription or sign up for a trial of Microsoft 365 Enterprise E5.



Pay-as-you-go billing

Some indicators included in Insider Risk Management are only available if you enable the pay-as-you-go billing model for your organization. For more information, see Configure policy indicators in Insider Risk Management.

This feature uses pay-as-you-go billing or per-user licensing for Microsoft Purview capabilities or both. To help you understand and manage your usage, Microsoft Purview provides a **Usage center** in the Microsoft Purview portal. For more information, see Manage pay-as-you-go and per-user licensing usage.

Recommended actions

Recommended actions can help your organization quickly get started with Insider Risk Management. Recommended actions, which are included on the **Overview** page, help guide you through the steps to configure and deploy policies.

The following recommendations help you get started with or maximize your Insider Risk Management configuration:

- **Turn on auditing**: When turned on, Microsoft 365 records user and admin activity in your organization to the audit log. Insider risk policies and analytics scans use this log to detect risk activities.
- **Get permissions to use Insider Risk Management**: The level of access you have to Insider Risk Management features depends on which role group you're assigned. To access and configure recommended actions, users must be assigned to the *Insider Risk Management* or *Insider Risk Management Admins* role groups.
- **Choose policy indicators**: Indicators are essentially the risk management activities you want to detect and investigate. You can choose indicators to detect activity across several Microsoft 365 locations and services.
- **Scan for potential insider risks**: Run an analytics scan to discover potential insider risks occurring in your organization. After evaluating results, review recommended policies to set up.
- **Assign permissions to others**: If there are additional team members who are responsible for managing insider risk features, assign them to the appropriate role groups.
- **Create your first policy**: To receive alerts on potentially risky activities, set up policies based on predefined templates that define the user activities you want to detect and investigate.
- **Configure data risk graph**: Use data risk graph to view connections between assets, users, and their activities using an interactive graph experience.

Each recommended action included in this experience has four attributes:

- **Action**: Name and description of the recommended action.
- **Status**: Status of the recommended action. Values are *Not started*, *In progress*, *Saved for later*, or *Completed*.
- **Required or optional**: Whether the recommended action is required or optional for Insider Risk Management features to function as expected.

- **Estimated time to complete**: Estimated time to complete the recommended action in minutes.

Select a recommendation from the list to get started with configuring Insider Risk Management. Each recommended action guides you through the required action for the recommendation, including any requirements, what to expect, and the impact of configuring the feature in your organization. Each recommended action is automatically marked as complete when configured or you can manually select the action as complete when configured.

Step 1 (required): Assign permissions for Insider Risk Management

To use any of the Insider Risk Management-related tools in the Microsoft Purview portal, users need the appropriate permissions. The easiest way to assign roles is to add the user to the appropriate role group on the **Role groups** page in the Microsoft Purview portal.

For step-by-step guidance, see Assign permissions in Insider Risk Management.

Step 2 (required): Enable the Microsoft 365 audit log

Insider Risk Management uses Microsoft 365 audit logs for user insights and risk management activities identified in policies and analytics insights. The Microsoft 365 audit logs are a summary of all activities within your organization and Insider Risk Management policies might use these activities for generating policy insights.

Auditing is enabled for Microsoft 365 organizations by default. Some organizations might have disabled auditing for specific reasons. If auditing is disabled for your organization, it might be because another administrator has turned it off. We recommend confirming that it's OK to turn auditing back on when completing this step.

For step-by-step instructions to turn on auditing, see Turn audit log search on or off. After you turn on auditing, a message is displayed that says the audit log is being prepared and that you can run a search in a couple of hours after the preparation is complete. You only have to do this action once. For more information about the using the Microsoft 365 audit log, see Search the audit log.

Step 3 (optional): Enable and view insider risk analytics insights

If you enable Insider Risk Management analytics, you can:

- **Scan for potential insider risks before creating policies.** You can conduct an evaluation of potential insider risks in your organization without configuring any insider risk policies. This evaluation can help your organization identify potential areas of higher user risk and help determine the type and scope of Insider Risk Management policies you might want to configure. This evaluation might also help you determine needs for additional licensing or future optimization of existing policies. Analytics scan results might take up to 48 hours before insights are available as reports for review. To learn more about analytics insights, see Insider Risk Management settings: Analytics and check out the Insider Risk Management Analytics video to help understand how analytics can help accelerate the identification of potential insider risks and help you to quickly take action.
- **Receive real-time recommendations for indicator threshold settings.** Manually tuning policies to reduce "noise" can be a very time-consuming experience that requires you to do a lot of trial and error to determine the desired configuration for your policies. If analytics is turned on, Insider Risk Management can provide real-time recommendations for indicator thresholds. You can also manually adjust the provided recommendations and see in real time how many users are brought into scope of the policy based on the changes you make. Learn more about real-time indicator threshold recommendations

> **Note**
>
> To enable insider risk analytics, you must be a member of the *Insider Risk Management*, *Insider Risk Management Admins*, or Microsoft 365 *Global admin* role group.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Enable insider risk analytics

1. Sign in to the Microsoft Purview portal with an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.

3. On the **Overview** tab, on the **Scan for insider risks in your organization** card, select **Run scan**. This action turns on analytics scanning for your organization. You can also turn on scanning by going to **Insider risk settings** > **Analytics** and enabling **Scan your tenant's user activity to identify potential insider risks**.
4. On the **Analytics details** pane, select **Run scan to start the scan for your organization**. Analytics scan results might take up to 48 hours before insights are available as reports for review.

After reviewing the analytics insights, choose the insider risk policies and configure the associated prerequisites that best meet your organization's insider risk mitigation strategy.

Step 4 (recommended): Configure prerequisites for policies

Most Insider Risk Management policies have prerequisites that you must configure for policy indicators to generate relevant activity alerts. Configure the appropriate prerequisites depending on the policies you plan to configure for your organization.

Connect to cloud apps in Microsoft Defender

Insider Risk Management includes the following cloud indicators (preview):

- Cloud storage indicators, including Google Drive, Box, and Dropbox
- Cloud service indicators, including Amazon S3 and Azure (Storage and SQL Server)

Cloud storage indicators

Use cloud storage indicators to detect the following activities in Google Drive, Box, and Dropbox:

- **Discovery:** Techniques used to figure out the environment
- **Collection:** Techniques used to gather data of interest
- **Exfiltration:** Techniques used to steal data, such as sensitive documents
- **Deletion (impact):** Techniques used to disrupt the availability or compromise the integrity of a system

Cloud service indicators

Use cloud service indicators to detect the following activities in Amazon S3 and Azure:

- **Defense evasion:** Techniques used to avoid detection of risky activities by disabling trace logs or by updating or deleting SQL Server firewall rules
- **Exfiltration:** Techniques used to steal data, such as sensitive documents
- **Deletion (impact):** Techniques used to disrupt the availability or compromise the integrity of a system
- **Privilege escalation:** Techniques used to gain higher-level permissions to systems and data

Prerequisites for accessing cloud indicators

To select from cloud indicators in Insider Risk Management settings and policies, you must first connect to the relevant cloud apps in Microsoft Defender, if you didn't already.

After connecting to the apps, you can find the indicators on the Policy indicators settings page and from individual policies.

Configure Insider Risk Indicator (preview) connector

You can extend Insider Risk Management by importing detections for non-Microsoft (third-party) workloads. For example, you might want to extend your detections to include Salesforce and Dropbox activities and use them alongside the built-in detections provided by the Insider Risk Management solution, which focuses on Microsoft services like SharePoint Online and Exchange Online.

To bring your own detections to the Insider Risk Management solution, import preprocessed, aggregated detections from security information and event management (SIEM) solutions such as Microsoft Sentinel or Splunk. Import a sample file into the Insider Risk Indicators connector workflow. The connector workflow analyzes the sample file and configures the required schema.

> **Note**
>
> Currently, you can't import "raw" detection signals into Insider Risk Management. You can only import preprocessed aggregations as a file.

You can use a custom indicator as:

- A trigger to bring a user into the scope of a policy.
- A policy indicator to score the user for risk.

For step-by-step guidance to configure the Insider Risk Indicators connector for your organization, see the Insider Risk Indicators connector article. After you configure the

connector, return to these configuration steps.

Configure Microsoft 365 HR connector

Insider Risk Management supports importing user and log data imported from third-party risk management and human resources platforms. The Microsoft 365 Human Resources (HR) data connector allows you to pull in human resources data from CSV files, including user termination dates, last employment dates, performance improvement plan notifications, performance review actions, and job level change status. This data helps drive alert indicators in Insider Risk Management policies and is an important part of configuring full risk management coverage in your organization. If you configure more than one HR connector for your organization, Insider Risk Management automatically pulls indicators from all HR connectors.

The Microsoft 365 HR connector is required when using the following policy templates:

- Data leaks by risky users
- Departing user data theft
- Patient data misuse
- Security policy violations by departing users
- Security policy violations by risky users

For step-by-step guidance to configure the Microsoft 365 HR connector for your organization, see the Set up a connector to import HR data article. After you configure the HR connector, return to these configuration steps.

Configure a Microsoft Healthcare connector

Insider Risk Management supports importing user and log data from third-party electronic medical record (EMR) systems. The Microsoft Healthcare connector enables you to bring in activity data from your EMR system through CSV files, including improper patient record access, suspicious volume activities, and editing and exporting activities. This data helps drive alert indicators in Insider Risk Management policies and plays an important role in configuring full risk management coverage in your organization.

If you configure more than one Healthcare connector for your organization, Insider Risk Management automatically supports event and activity signals from all Healthcare connectors. The Microsoft 365 Healthcare connector is required when using the following policy template:

- Patient data misuse

For step-by-step guidance to configure a healthcare-specific connector for your organization, see Set up a connector to import healthcare data. After you configure a connector, return to

these configuration steps.

Configure data loss prevention (DLP) policies

Insider Risk Management supports using DLP policies to help identify the intentional or accidental exposure of sensitive information to unwanted parties for high severity level DLP alerts. When you configure an Insider Risk Management policy with any of the **Data leaks** templates, you can assign a specific DLP policy to the policy for these types of alerts.

> **Tip**
>
> You can also use Adaptive Protection in Insider Risk Management to dynamically apply DLP protection controls to high-risk users while maintaining productivity for lower-risk users. **Learn more about Adaptive Protection**.

Data loss policies help identify users to activate risk scoring in Insider Risk Management for high severity DLP alerts for sensitive information. They're an important part of configuring full risk management coverage in your organization. For more information about Insider Risk Management and DLP policy integration and planning considerations, see Insider Risk Management policies.

> **Important**
>
> Make sure you complete the following steps:
>
> - Understand and properly configure the in-scope users in both the DLP and Insider Risk Management policies to produce the policy coverage you expect.
> - Configure the **Incident reports** setting in the DLP policy for Insider Risk Management used with these templates for *High* severity level alerts. Insider Risk Management alerts aren't generated from DLP policies with the **Incident reports** field set at *Low* or *Medium*.

A DLP policy is optional when using the following policy templates:

- Data leaks
- Data leaks by priority users

For step-by-step guidance to configure DLP policies for your organization, see Create and Deploy data loss prevention policies. After you configure a DLP policy, return to these configuration steps.

> **Note**
>
> Endpoint DLP now supports virtualized environments, which means that the Insider Risk Management solution supports virtualized environments through endpoint DLP. Learn more about support for virtualized environments in endpoint DLP.

Configure sharing of insider risk levels with Microsoft Defender and DLP alerts

You can share insider risk levels from Insider Risk Management (preview) to bring unique user context to Microsoft Defender and DLP alerts. Insider Risk Management analyzes user activities over a period of 90-120 days and looks for anomalous behavior over that period. Adding this data to Microsoft Defender and DLP alerts enhances the data available in those solutions to help analysts prioritize alerts. Learn more about sharing user risk severity levels with Microsoft Defender and DLP alerts.

Sharing Insider Risk Management user risk severity levels also enhances the Microsoft Security Copilot. For example, in Security Copilot, you might want to start by asking Copilot to summarize a DLP alert, then ask Copilot to show the insider risk level associated with the user flagged in the alert. Or you might want to ask why the user is considered a high-risk user. The user risk information in this case comes from Insider Risk Management. Security Copilot seamlessly integrates Insider Risk Management with DLP to assist with investigations. Learn more about using the standalone version of Copilot for combined DLP/Insider Risk Management investigations.

Configure priority user groups

Insider Risk Management supports assigning priority user groups to policies to help identify unique risk activities for users with critical positions, high levels of data and network access, or a past history of risk behavior. Creating a priority user group and assigning users to the group helps scope policies to the unique circumstances presented by these users.

To enable the *priority user groups* risk score booster, go to the *Insider Risk Management settings* page, then select **Policy indicators** and **Risk score boosters**. Analysts and investigators can review and prioritize these users' risk severity to help triage alerts in accordance with your organization's risk policies and standards.

A priority user group is required when using the following policy templates:

- Security policy violations by priority users
- Data leaks by priority users

See the Getting started with Insider Risk Management settings article for step-by-step configuration guidance.

Configure Physical badging connector

Insider Risk Management supports importing user and log data from physical control and access platforms. The Physical badging connector lets you pull in access data from JSON files, including user IDs, access point IDs, access time and dates, and access status. This data helps drive alert indicators in Insider Risk Management policies and is an important part of configuring full risk management coverage in your organization. If you configure more than one Physical badging connector for your organization, Insider Risk Management automatically pulls indicators from all Physical badging connectors. Information from the Physical badging connector supplements other insider risk signals when using all insider risk policy templates.

> **Important**
>
> For Insider Risk Management policies to use and correlate signal data related to departing and terminated users with event data from your physical control and access platforms, you must also configure the Microsoft 365 HR connector. If you enable the Physical badging connector without enabling the Microsoft 365 HR connector, Insider Risk Management policies only process events for unauthorized physical access for users in your organization.

See the Set up a connector to import physical badging data article for step-by-step guidance to configure the Physical badging connector for your organization. After you configure the connector, return to these configuration steps.

Configure Microsoft Defender for Endpoint

Microsoft Defender for Endpoint is an enterprise endpoint security platform designed to help enterprise networks prevent, detect, investigate, and respond to advanced threats. To gain better visibility of security violations in your organization, you can import and filter Defender for Endpoint alerts for activities used in policies created from Insider Risk Management security violation policy templates.

If you create security violation policies, you need to configure Microsoft Defender for Endpoint in your organization and enable Defender for Endpoint for Insider Risk Management integration in the Defender Security Center to import security violation alerts. For more information about requirements, see the Minimum requirements for Microsoft Defender for Endpoint article.

For step-by-step guidance to configure Defender for Endpoint for Insider Risk Management integration, see the Configure advanced features in Defender for Endpoint article. After you configure Microsoft Defender for Endpoint, return to these configuration steps.

Configure forensic evidence

Having visual context is crucial for security teams during forensic investigations to get better insights into risky user activities that might lead to a security incident. With customizable event triggers and built-in user privacy protection controls, forensic evidence enables customizable capturing across devices to help your organization better mitigate, understand, and respond to potential data risks like unauthorized data exfiltration of sensitive data.

For step-by-step guidance to configure forensic evidence for your organization, see the Get started with Insider Risk Management forensic evidence article.

Configure optical character recognition

Microsoft Purview can scan for sensitive content in documents to help protect those documents from inappropriate exposure. When you enable optical character recognition (OCR) in Microsoft Purview, data classifiers, such as sensitive information types and trainable classifiers, can also detect characters in stand-alone images. After configuring OCR settings (preview), your existing insider risk policies apply to both images and documents.

For the OCR preview, Insider Risk Management supports scanning in the following locations: Windows endpoint devices, SharePoint Online, and Teams. Exchange Online and OneDrive aren't supported for the preview.

OCR settings don't apply to forensic evidence clips in Insider Risk Management.

Learn more about setting up OCR scanning and pay-as-you-go billing.

Step 5 (required): Configure insider risk settings

Insider risk settings apply to all Insider Risk Management policies, regardless of the template you choose when creating a policy. You configure settings by using **Settings** located at the top of Insider Risk Management pages. These settings control privacy, indicators, global exclusions, detection groups, intelligent detections, and more. Learn more about settings to consider before you creating a policy.

Step 6 (required): Create an Insider Risk Management policy

Insider Risk Management policies include assigned users and define which types of risk indicators are configured for alerts. Before potentially risky activities can trigger alerts, you must configure a policy. Use the policy workflow to create new Insider Risk Management policies.

> **Note**
>
> To create a custom trigger or indicator for a non-Microsoft workload, see Custom indicators.

Create policy

1. Sign in to the Microsoft Purview portal with an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Policies** in the left navigation.
4. Select **Create policy** to open the policy workflow.
5. On the **Policy template** page, choose a policy category and then select the template for the new policy. These templates consist of conditions and indicators that define the risk activities you want to detect and investigate. Review the template prerequisites, triggering events, and detected activities to confirm this policy template fits your needs.

   > **Important**
   >
   > Some policy templates have prerequisites that you must configure for the policy to generate relevant alerts. If you didn't configure the applicable policy prerequisites, see Step 4.

   Select **Next** to continue.
6. On the **Name and description** page, complete the following fields:

   - **Name (required)**: Enter a friendly name for the policy. You can't change this name after you create the policy.

- **Description (optional)**: Enter a description for the policy.

Select **Next** to continue.

7. If admin units exist for your tenant, you see the **Admin units** page. Otherwise, you see the **Users and groups** page and can skip to the next step.

   If you want to scope the policy to one or more admin units, select **Add admin units**, then select the admin units that you want to apply to the policy.

   > ⓘ Note
   >
   > You can only see the admin units that are scoped to your role. If you're an unrestricted administrator, you can see all admin units for the tenant. To view a summary of the role groups and admin units that you're assigned to, select **View my permissions**.

   Select **Next** to continue.

8. On the **Users and groups** page, select one of the following options:

   - **Include all users and groups**. When you select this option, Insider Risk Management looks for triggering events for all users and groups in your organization to start assigning risk scores for the policy.

     If your policy is scoped by one or more admin units, this option selects all users and groups within the administrative units.

     > ⓘ Note
     >
     > To take advantage of real-time analytics (preview) for indicator threshold settings, you must scope your policy to **Include all users and groups**. Real-time analytics enables you to see estimates of the number of users that could potentially match a given set of policy conditions in real time. This feature helps you efficiently adjust the selection of indicators and thresholds of activity occurrence so you don't have too few or too many policy alerts. Scoping your policy to **Include all users and groups** also provides better overall protection across your tenant. For more information on real-time analytics for indicator threshold settings, see Indicator level settings.

     > ⓘ Note

> Insider Risk Management supports selection of following types of groups in policies - Microsoft 365 groups, Distribution groups, and Security groups (both mail-enabled and non-mail-enabled types) with a limitation that non-mail-enabled Security groups cannot be selected if your policy is **scoped by one or more admin units**. For more information on different types of groups, see **Compare Groups**.

- **Include specific users and groups**. Select this option to define which users or groups are included in the policy.

  If your policy is scoped by one or more admin units, you can only choose users within the admin unit scope.

  > ⓘ **Note**
  >
  > Guest accounts aren't supported.

- **Adaptive scope**. This option appears if you select the **Include specific users and groups** option. Select **Add or edit adaptive scopes** to apply an adaptive scope to the policy. You must create the adaptive scope before you create or edit the policy. If the policy is also scoped by one or more admin units, the adaptive scopes available to you are limited by the admin units. Learn how adaptive scopes work together with admin units.

- **Add or edit priority user groups**. This option appears only if you choose the *Data leaks by priority users* template. Select this option, then add or edit priority user groups.

  > ⓘ **Note**
  >
  > If the policy template is based on priority user groups, you can't select an **admin unit** to scope the policy. Priority user groups aren't currently supported for use with admin units.

Select **Next** to continue.

9. Use the **Exclude users and groups (optional) (preview)** page if you want to exclude certain users or groups from the policy scope. For example, you might want to create a policy that detects potentially risky actions for people in the whole organization but excludes executive-level sales managers. Select **Add users to exclude** or **Add groups to exclude** to select the users or groups that you want to exclude. If your policy is scoped by

one or more admin units, you can only exclude users or groups that are within the admin unit scope.

Select **Next** to continue.

10. On the **Content to prioritize** page, assign the sources to prioritize, if needed. Prioritizing these sources increases the chance of generating a high severity alert for these sources. Select one of the following choices:

    - **I want to prioritize content**. Select this option to prioritize *SharePoint sites*, *Sensitivity labels*, *Sensitive info types*, and *File extensions* content types. If you choose this option, you must select at least one priority content type.
    - **I don't want to specify priority content right now**. Select this option to skip the priority content detail pages in the workflow.

    Select **Next** to continue.

11. If you select **I want to prioritize content** in the previous step, you see the detail pages for *SharePoint sites*, *sensitivity labels*, *sensitive info types*, *file extensions*, and *Scoring*. Use these detail pages to define the SharePoint, sensitive info types, sensitivity labels, trainable classifiers, and file extensions to prioritize in the policy. The *Scoring* detail page allows you to scope the policy to only assign risk scores and generate alerts for specified activities that include priority content.

    - **SharePoint sites**: Select **Add SharePoint site** and select the SharePoint sites you have access to and want to prioritize. For example, "*group1@contoso.sharepoint.com/sites/group1*".

      > ⓘ **Note**
      >
      > If your policy is scoped by one or more admin units, you still see all SharePoint sites, not just SharePoint sites scoped to your admin units since admin units don't support SharePoint sites.

    - **Sensitive info type**: Select **Add sensitive info type** and select the sensitivity types you want to prioritize. For example, "*U.S. Bank Account Number*" and "*Credit Card Number*".
    - **Sensitivity labels**: Select **Add sensitivity label** and select the labels you want to prioritize. For example, "*Confidential*" and "*Secret*".
    - **Trainable classifiers**: Select **Add trainable classifier** and select the trainable classifiers you want to prioritize. For example, *Source code*.

- **File extensions**: Add up to 50 file extensions. You can include or omit the '.' with the file extension. For example, *.py* or *py* would prioritize Python files.
- **Scoring**: Decide whether to assign risk scores to all risk management activities detected by this policy or only for activities that include priority content. Choose **Get alerts for all activity** or **Get alerts only for activity that includes priority content**.

Select **Next** to continue.

12. If you select the *Data leaks* or *Data leaks by priority users* templates, you see options on the **Triggers for this policy** page for custom-triggering events and policy indicators. You can select a DLP policy or indicators for triggering events that bring users assigned to the policy in-scope for activity scoring. If you select the **User matches a data loss prevention (DLP) policy triggering event** option, you must select a DLP policy from the DLP policy dropdown list to enable triggering indicators for the DLP Policy for this Insider Risk Management policy. If you select the **User performs an exfiltration activity triggering event** option, you must select one or more of the listed indicators for the policy triggering event.

    > ⓘ **Note**
    >
    > Priority user groups aren't currently supported for admin units. If you're creating a policy based on the *Data leaks by priority users* template or the *Security policy violations by priority users* template, you can't select admin units for scoping the policy. Unrestricted administrators can select priority user groups without selecting admin units, but restricted or scoped administrators can't create these policies at all.

    > ⓘ **Important**
    >
    > If you're unable to select a listed indicator or sequence, it's because they aren't currently enabled for your organization. To make them available to select and assign to the policy, select the **Turn on indicators** prompt.

    If you select other policy templates, custom triggering events aren't supported. The built-in policy triggering events apply. Skip to Step 15 without defining policy attributes.

13. If you select the *Data leaks by risky users* or *Security policy violations by risky users* templates, you see options on the **Triggers for this policy** page for integration with Communication Compliance and HR data connector events. You can assign risk scores when users send messages that contain potentially threatening, harassing, or discriminatory language or bring users into the policy scope after risky user events are

reported in your HR system. If you select the **Risk triggers from Communication Compliance (preview)** option, you can accept the default Communication Compliance policy (automatically created), choose a previously created policy scope for this trigger, or create another scoped policy. If you select **HR data connector events**, you must configure an HR data connector for your organization.

Select **Next** to continue.

14. If you select the *Data leaks* or *Data leaks by priority users* templates and select the **User performs an exfiltration activity and associated indicators**, you can choose custom or default thresholds for the indicator triggering events that you select. Choose either the **Use default thresholds (Recommended)** or **Use custom thresholds for the triggering events**.

    Select **Next** to continue.

15. If you select **Use custom thresholds for the triggering events**, for each triggering event indicator that you selected in Step 10, choose the appropriate level to generate the desired level of activity alerts. You can use the recommended thresholds, custom thresholds, or thresholds based on anomalous activities (for certain indicators) over the daily norm for users.

    Select **Next** to continue.

16. On the **Policy indicators** page, you see the indicators that you define as available on the **Insider risk settings** > **Indicators** page which include indicator variants if you have defined any. Select the indicators you want to apply to the policy.

    > **ⓘ Important**
    >
    > If indicators on this page can't be selected, select the indicators you want to enable for all policies. You can use **Turn on indicators** in the workflow or select indicators on the **Insider Risk Management** > **Settings** > **Policy indicators** page.

    If you select at least one *Office* or *Device* indicator, select the **Risk score boosters** as appropriate. Risk score boosters only apply for selected indicators. If you select a *Data theft* or *Data leaks* policy template, select one or more **Sequence detection** methods and a **Cumulative exfiltration detection** method to apply to the policy. If you select the *Risky browser usage* policy template, select one or more of the **Browsing indicators**.

    Select **Next** to continue.

17. On the **Decide whether to use default or custom indicator thresholds** page, choose custom or default thresholds for the policy indicators that you select. Choose either the **Use default thresholds for all indicators** or **Specify custom thresholds** for the selected policy indicators. If you select **Specify custom thresholds**, choose the appropriate level to generate the desired level of activity alerts for each policy indicator.

    > **Tip**
    >
    > To view a graph that helps you determine appropriate threshold settings, select the **View impact** link in the insight for each set of threshold settings. **Learn more about manually customizing thresholds**.

    Select **Next** to continue.

18. On the **Review** page, review the settings you chose for the policy and any suggestions or warnings for your selections. Select **Edit** to change any of the policy values or select **Submit** to create and activate the policy.

Next steps

After you complete these steps to create your first Insider Risk Management policy, you start receiving alerts from activity indicators after about 24 hours. Configure additional policies as needed by using the guidance in Step 4 of this article or the steps in Create a new insider risk policy.

To learn more about investigating insider risk alerts and the **Alerts dashboard** or the **Triage Agent dashboard**, see Insider Risk Management activities.

Assign permissions in Insider Risk Management

09/30/2025

Use six role groups to configure Insider Risk Management features. To make **Insider Risk Management** available as a menu option in Microsoft Purview and to continue with these configuration steps, you must be assigned to one of the following roles or role groups:

- Microsoft Entra ID *Global Administrator* role
- Microsoft Entra ID *Compliance Administrator* role
- Microsoft Purview *Organization Management* role group
- Microsoft Purview *Compliance Administrator* role group
- *Insider Risk Management* role group
- *Insider Risk Management Admins* role group

Depending on how you want to manage Insider Risk Management policies and alerts, assign users to specific role groups to manage different sets of Insider Risk Management features. You can assign users with different compliance responsibilities to specific role groups to manage different areas of Insider Risk Management features. Or you might decide to assign all user accounts for designated administrators, analysts, investigators, and viewers to the *Insider Risk Management* role group. Use a single role group or multiple role groups to best fit your compliance management requirements.

> **Important**
>
> After configuring your role groups, it might take up to 30 minutes for the role group permissions to apply to assigned users across your organization.

Choose from these role group options and solution actions when working with Insider Risk Management:

Expand table

Actions	Insider Risk Management	Insider Risk Management Admins	Insider Risk Management Analysts	Insider Risk Management Investigators	Insider Risk Management Auditors	Insider Risk Management Approvers
Access & investigate alerts	Yes	No	Yes	Yes	No	No

Actions	Insider Risk Management	Insider Risk Management Admins	Insider Risk Management Analysts	Insider Risk Management Investigators	Insider Risk Management Auditors	Insider Risk Management Approvers
Access & investigate cases	Yes	No	Yes	Yes	No	No
Access & view forensic evidence captures	Yes	No	No	Yes	No	No

View alert and case reports	Yes	Yes	Yes	Yes	No	No
View data risk graphs for alerts	Yes	No	Yes	Yes	No	No

> **Important**
>
> Make sure you always have at least one user in the built-in *Insider Risk Management* or *Insider Risk Management Admins* role groups (depending on the option you choose) so that your Insider Risk Management configuration doesn't get into a 'zero administrator' scenario if specific users leave your organization.

Members of the following roles can assign users to Insider Risk Management role groups and have the same solution permissions included with the *Insider Risk Management Admins* role group:

- Microsoft Entra ID *Global Administrator*
- Microsoft Entra ID *Compliance Administrator*
- Microsoft Purview *Organization Management*
- Microsoft Purview *Compliance Administrator*

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Add users to the Insider Risk Management role group

1. Sign in to the Microsoft Purview portal with an admin account in your Microsoft 365 organization.
2. Select **Settings** in the upper-right corner of the page, select **Roles and groups**, then select **Roles groups** in the left navigation pane.
3. Select the *Insider Risk Management* role group, then select **Edit**.
4. Select **Choose users**, then select the checkboxes for all the users you want to add to the role group.
5. Select **Select**, then select **Next**.
6. Select **Save** to add the users to the role group, then select **Done**.

Consider administrative units if you want to scope user permissions to a region or department

You can use administrative units in Insider Risk Management to scope user permissions to a particular geography or department. For example, a global company that has subsidiaries throughout the world might want to create an admin unit that provides a German scope for investigators so that they only see user activity for German users.

To use admin units in Insider Risk Management, you must first create the admin units if they aren't already created, then assign the admin units to members of role groups. After you assign admin units to members of role groups, those members become *restricted administrators* and have limited access to Insider Risk Management settings, policies, and user data in the organization. Members who aren't assigned administrative units are *unrestricted administrators* and have access to all settings, policies, and user data.

> **Important**
>
> Restricted administrators can't access alerts for the users assigned to them through security groups or distribution groups added in administrative units. Such user alerts are visible only to unrestricted administrators. Microsoft recommends adding users directly to administrative units to ensure their alerts are also visible to restricted administrators with administrative units assigned.

Effect of admin unit scoping on Insider Risk Management roles

The following table shows how admin units, when enforced, affect each combination of Insider Risk Management task and role.

> **Note**

Scoped in the following table means that the admin actions for that role are limited by their assigned admin unit.

Expand table

Task	Scoped Insider Risk Management	Scoped Insider Risk Management Admin	Scoped Insider Risk Management Analysts	Scoped Insider Risk Management Investigators	Scoped Insider Risk Management Approvers

> **Note**
>
> You can use adaptive scopes together with admin units. If one or more admin units scope role groups for your organization, the admin units limit the adaptive scopes that you can select when you create or edit a policy.

Microsoft Purview Insider Risk Management and Communication Compliance privacy guide

08/20/2025

Microsoft Purview insider risk solutions give organizations the tools to help detect and reduce potential risks and policy violations. The Microsoft Purview insider risk solutions include:

- **Microsoft Purview Insider Risk Management** uses different signals to find potential malicious or accidental insider risks, such as intellectual property theft, data leakage, and security violations. Insider risk management lets customers create policies to manage security and compliance.
- **Microsoft Purview Communication Compliance** provides tools to help organizations detect potential regulatory compliance issues (for example SEC or FINRA) and business conduct violations such as sensitive or confidential information, harassing or threatening language, and sharing of adult content.

Insider risk management and communication compliance are built with privacy by design and balance user privacy with tools that help detect and reduce organizational risks. We're committed to protecting user trust and maintaining user-level privacy through our core privacy principles:

- Pseudonymization
- Role-based access controls
- Admin explicit opt-in
- Audit logs

Pseudonymization

Pseudonymization helps protect end-user privacy by removing identifiable user details like user name or email address. Pseudonymization also helps prevent potential bias and conflicts of interest by removing identifiable user details (name, email) and personal data (title, department, or location) exposed in the solution. For example, a user named John Smith is pseudonymized into a nonpersonal identifier such as ANON2340. Pseudonyms are on by default for specific roles such as *Insider Risk Management Analysts* and *Insider Risk Management Investigators* (review alerts and take action respectively) and *Communication Compliance Analysts* (review policy alerts).

Role-based access controls

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

We recommend using stringent role-based access controls so only authorized insider risk management and communication compliance roles can use and access alerts and insights into potential policy violations. By default, global administrators don't have access to insider risk management and communication compliance features. This default setting helps ensure that only the appropriate stakeholders can access the solution and details specific to their role permissions. Organizations can assign users to specific role groups to manage different sets of features based on their responsibilities. For example, insider risk management and communication compliance admins can create, configure, and delete policies but can't access or investigate alerts or cases. On the other hand, insider risk management and communication compliance investigators can access and investigate alerts and cases but can't configure policies.

> **Note**
>
> Insider risk management admins can allow investigators and analysts to make edits to policy indicators and thresholds by using the inline alert customization setting.

Whether your organization chooses a single role group or multiple role groups to fit your organization's compliance and privacy requirements, both insider risk management and communication compliance allow admins to choose from predefined role group options within each solution.

Learn more about role group options for each solution:

- Get started with insider risk management
- Get started with communication compliance

Admin explicit opt-in

Insider risk management and communication compliance policies detect risky activities and communications and potential policy violations that could result in a security incident. An admin with the right permissions can explicitly scope employees into a policy.

Additionally, by default, insider risk management and communication compliance indicators that help detect risky activities and communications that might lead to potential data security incidents are disabled. For example, indicators like "downloading content from OneDrive", "sharing SharePoint files with people outside the organization", or "sending sensitive information or harassing messages" are off by default. Insider risk management and communication compliance don't detect those activities without an admin's explicit opt-in. Admins with the right permissions must explicitly select and opt in to one or more indicators in settings before a policy can detect those activities.

Admin explicit opt-in controls help safeguard end-user privacy by ensuring the solutions only flag alerts and policy violations for users and indicators specified in the policies.

Audit logs

Microsoft Purview insider risk solutions audit logs record all admin actions. With these logs, organizations can stay informed about all actions taken within Microsoft Purview insider risk solutions, including when an admin creates or edits a policy, adds a user, views user activity insights, or adds indicators.

Audit logs are enabled by default for all Microsoft 365 organizations. With these logs, organizations can audit privileged admins' actions and meet compliance and privacy requirements.

For more information about audit logs capabilities for each solution, see:

- Review activities with the insider risk management audit log
- Use communication compliance reports and audits

Protect user trust and build a holistic insider risk program

User privacy and trust are essential for organizations to establish a holistic insider risk program. The right set of tools can help you address risks in a way that meets security needs. Learn how to build a holistic insider risk management program with five elements that help companies have stronger data protection while ensuring user trust.

Monitoring agents in Insider Risk Management

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Microsoft Purview Insider Risk Management enables organizations to identify, investigate, and respond to potential insider risks across users and agents. As organizations increasingly adopt AI agents, Insider Risk Management provides built-in capabilities to help monitor agent activity and surface risky behaviors that could lead to data exposure, compliance violations, or security concerns.

Before you begin monitoring agents in your organization, you must complete the steps provided in Get started with Insider Risk Management. For information about subscriptions, licensing, and permissions, see Subscriptions and licensing and Permissions in Insider Risk Management.

Risky Agents policy

The Risky Agents (preview) policy provides out-of-the-box coverage for common risk scenarios associated with AI agents. The policy is designed to help surface behaviors that may indicate inappropriate or unsafe agent usage, including situations where agents interact with sensitive data, generate risky outputs, or share information outside organizational boundaries.

By default, the policy detects:

- Risky prompts
- Agents generating sensitive responses
- Agents accessing sensitive data
- Accessing risky websites

These detections help security, compliance, and risk teams gain visibility into how agents are being used and where potential risks may exist.

Supported agents

The Risky Agents (preview) policy supports the following agent types:

- Copilot Studio agents
- Microsoft Foundry agents
- Agents built using the P4AI SDK

Default policy availability and behavior

The Risky Agents (preview) policy is available by default to all organizations with supported licenses. When the service is set up, this policy is automatically present and ready to generate alerts based on observed agent activity.

This default configuration enables organizations to:

- Begin monitoring agent activity immediately.
- Gain early visibility into potential agent-related risks.
- Investigate agent behaviors using established Insider Risk Management workflows.

Customize agent risk monitoring

While the default Risky Agents (preview) policy provides broad coverage for common scenarios, some organizations may require more specific or tailored monitoring.

If the default policy doesn't meet your organizational requirements, you can create a custom Insider Risk Management policy to better align with your risk posture or investigation needs. For more information, see Create a new policy.

Investigate agent-related alerts

When the Risky Agents (preview) policy detects relevant activity, alerts are generated within Insider Risk Management. These alerts can be reviewed and investigated using the standard alert investigation workflow.

Through alert investigation, analysts can:

- Review details of the detected activity.
- Understand the context of agent behavior.
- Determine whether further action is required.

> **Note**
>
> When guest users are interacting with agents, the full prompt and response content isn't available for investigation. Instead, only indicators of sensitive information detected in those prompts and responses are shown.

> **Note**
>
> Admins units are currently not supported for agent alerts. If a scoped analyst is signing in, then they can't see agent related alerts.

For detailed guidance on reviewing and managing alerts, see Triaging alerts.

Share agent risk with other Microsoft solutions

Agent risk calculated in Microsoft Purview Insider Risk Management is shared with the following solutions:

- Data Security Posture Management for AI
- Microsoft 365 admin center

Learn about Insider Risk Management settings

08/20/2025

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Before you get started with Insider Risk Management policies, understand and choose the Insider Risk Management settings that best meet the compliance needs for your organization. Insider Risk Management settings apply to all Insider Risk Management policies, regardless of the template you choose when creating a policy.

> **Note**
>
> Use **Settings** at the top of any Insider Risk Management page to make settings changes.

The following table describes each Insider Risk Management setting and provides a link to learn more about the setting.

Expand table

Setting	Description
Admin notifications	Use the **Admin notifications** setting to automatically send an email notification to selectable Insider Risk Management role groups. You can: - Send a notification email when the first alert is generated for a new policy - Send a daily email when new high-severity alerts are generated - Send a weekly email summarizing policies that have unresolved warnings
Analytics	Insider risk analytics enables you to conduct an evaluation of potential insider risks in your organization without configuring any insider risk policies. This evaluation can help your organization identify potential areas of higher user risk and help determine the type and scope of Insider Risk Management policies you might consider configuring.
Data sharing	Use the **Data sharing** setting to do either of the following: 1) Export Insider Risk Management alert information to SIEM solutions by using the Office 365 Management

Setting	Description
	Activity API schema; 2) Share Insider Risk Management user risk levels with Microsoft Defender and DLP alerts.
Detection groups	Use the **Detection groups** setting to create variants of built-in indicators if you want to tailor detections for different sets of users. Creating detection groups helps to reduce false positives.
Export alerts	Insider Risk Management alert information is exportable to security information and event management (SIEM) and security orchestration automated response (SOAR) solutions by using the Office 365 Management Activity API schema. You can use the Office 365 Management Activity APIs to export alert information to other applications your organization might use to manage or aggregate insider risk information.
Global exclusions	Use the **Global exclusions** setting to specify global exclusions that won't be scored by your Insider Risk Management policies.
Inline alert customization	Inline alert customization allows you to quickly tune an Insider Risk Management policy directly from the **Alerts dashboard** while reviewing the alert. Alerts are generated when a risk management activity meets the thresholds configured in the related policy. To reduce the number of alerts you get from this type of activity, you can change the thresholds or remove the risk management activity from the policy altogether.
Intelligent detections	Use the **Intelligent detections** setting to boost the score for unusual download activity, control alert volume, import and filter Microsoft Defender for Endpoint alerts, and specify unallowed and third-party domains for risk scoring.
Microsoft Teams (preview)	You can enable Microsoft Teams support so that compliance analysts and investigators can use Teams to collaborate on Insider Risk Management cases. Use Teams to: - Coordinate and review response activities for cases in private Teams channels - Securely share and store files and evidence related to individual cases - Detect and review response activities by analysts and investigators
Policy indicators	Each Insider Risk Management policy template is based on specific indicators that correspond to specific triggers and risk activities. All global indicators are disabled by default; **you must select one or more indicators to configure an Insider Risk Management policy**. Indicator level settings help you control how the number of occurrences of risk events in your organization affect the risk score.
Policy timeframes	The **Policy timeframes** setting allows you to define past and future review periods that are triggered after policy matches based on events and activities for the Insider Risk Management policy templates.
Power Automate flows (preview)	Microsoft Power Automate is a workflow service that automates actions across applications and services. By using flows from templates or created manually, you can automate common tasks associated with these applications and services. When you enable Power Automate flows for Insider Risk Management, you can automate important tasks for cases and users. You can configure Power Automate flows to retrieve user, alert, and case information and share this information with stakeholders and other applications, as well as automate actions in Insider Risk Management, such

Setting	Description
	as posting to case notes. Power Automate flows are applicable for cases and any user in scope for a policy.
Priority physical assets (preview)	Identifying access to priority physical assets and correlating access activity to user events is an important component of your compliance infrastructure. These physical assets represent priority locations in your organization, such as company buildings, data centers, or server rooms. Insider risk activities might be associated with users working unusual hours, attempting to access these unauthorized sensitive or secure areas, and requests for access to high-level areas without legitimate needs.
Priority user groups	Users in your organization might have different levels of risk depending on their position, level of access to sensitive information, or risk history. Prioritizing the examination and scoring of the activities of these users can help alert you to potential risks that might have higher consequences for your organization. Use the **Priority user groups** setting to define the users in your organization that need closer inspection and more sensitive risk scoring.
Privacy	Choose whether to display usernames or anonymized versions of usernames for all current and past policy matches for alerts and cases.

Manage username privacy in Insider Risk Management

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Protecting the privacy of users that have policy matches in Microsoft Purview Insider Risk Management is important. It helps promote objectivity in data investigation and analysis reviews for insider risk alerts. For users with an insider risk policy match, choose one of the following settings:

> **Important**
>
> With the anonymized versions of usernames setting enabled, you cannot use data risk graph.

- **Show anonymized versions of usernames**: The solution anonymizes the names of users to prevent admins, data investigators, and reviewers from seeing who is associated with policy alerts. For example, a user 'Grace Taylor' appears with a randomized pseudonym such as 'AnonIS8-988' in all areas of the Insider Risk Management experience. Choosing this setting anonymizes all users with current and past policy matches and applies to all policies.

  > **Important**
  >
  > If you're using the Triage Agent for Insider Risk Management, user names in prioritized alerts aren't anonymized in the Triage Agent dashboard if **Show anonymized versions of usernames** is enabled.

  User profile information in the insider risk alert and case details won't be available when this option is chosen. However, names of users that appear in the metadata of an activity, in the

metadata of files in Content explorer, and within content of files in Content explorer **aren't anonymized**. Usernames are displayed when adding new users to existing policies or when assigning users to new policies. If you choose to turn off this setting, usernames are displayed for all users that have current or past policy matches.

> **Important**
>
> To maintain referential integrity for users who have insider risk alerts or cases in Microsoft 365 or other systems, anonymization of usernames isn't preserved for exported alerts when using the exporting API or when exporting to Microsoft Purview eDiscovery solutions. Exported alerts display usernames for each alert in this case. If you export to CSV files from alerts or cases, anonymization *is* preserved.

- **Do not show anonymized versions of usernames**: Usernames are displayed for all current and past policy matches for alerts and cases. User profile information (the name, title, alias, and organization or department) is displayed for the user for all Insider Risk Management alerts and cases.

Change the privacy setting

Perform the following steps to change the privacy setting for displayed usernames:

1. Sign in to the Microsoft Purview portal with an admin account in your Microsoft 365 organization.
2. Select **Settings** in the upper-right corner of the page.
3. Select **Insider Risk Management** to go to the Insider Risk Management settings.
4. Select **Privacy**.
5. Select the option you want, to show anonymized names or not.

Configure policy indicators in Insider Risk Management

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Insider risk policy templates in Microsoft Purview Insider Risk Management define the type of risk activities that you want to detect and investigate. Each policy template is based on specific indicators that correspond to specific triggers and risk activities. All global indicators are disabled by default; **you must select one or more indicators to configure an Insider Risk Management policy**.

Policies collect signals and trigger alerts when users perform activities related to the indicators.

Types of events and indicators

Insider Risk Management uses different types of events and indicators to collect signals and create alerts:

- **Triggering events**: Events that determine if a user is active in an Insider Risk Management policy. If you add a user to an Insider Risk Management policy that doesn't have a triggering event, the policy doesn't evaluate the user as a potential risk. For example, User A is added to a policy created from the *Data theft by departing users* policy template and the policy and Microsoft 365 HR connector are properly configured. Until User A has a termination date reported by the HR connector, the policy doesn't evaluate User A for potential risk. Another example of a triggering event is if a user has a *High* severity data loss prevention (DLP) policy alert when using *Data leaks* policies.
- **Global settings indicators**: Indicators enabled in global settings for Insider Risk Management define both the indicators available for configuration in policies and the types of events signals collected by Insider Risk Management. For example, if a user copies data

to personal cloud storage services or portable storage devices and you select these indicators only in global settings, you can review the user's potentially risky activity in the Activity explorer. If you don't define this user in an Insider Risk Management policy, the policy doesn't evaluate the user as a potential risk and therefore doesn't assign a risk score or generate an alert.

- **Policy indicators**: Indicators included in Insider Risk Management policies determine a risk score for an in-scope user. You enable policy indicators from indicators defined in global settings. The policy indicators activate only after a triggering event occurs for a user. Examples of policy indicators include:
  - A user copies data to personal cloud storage services or portable storage devices.
  - A user account is removed from Microsoft Entra ID.
  - A user shares internal files and folders with unauthorized external parties.

You can use certain policy indicators and sequences to customize triggering events for specific policy templates. When you configure these indicators or sequences in the policy workflow for the *General data leaks* or *Data leaks by priority users* templates, you get more flexibility and customization for your policies and when users are in-scope for a policy. You can also define risk management activity thresholds for these triggering indicators for more fine-grained control in a policy.

Define the insider risk policy indicators that are enabled in all insider risk policies

To enable policy indicators for all insider risk policies, complete the following steps:

1. Select **Settings**, then select **Policy indicators**.
2. Select one or more policy indicators. The indicators you select on the **Policy indicators** settings page can't be individually configured when creating or editing an insider risk policy in the policy workflow.

   > ⓘ **Note**
   >
   > It might take several hours for new manually added users to appear in the **Users dashboard**. Activities for the previous 90 days for these users might take up to 24 hours to display. To view activities for manually added users, select the user on the **Users dashboard** and open the **User activity** tab in the details pane.

Two types of policy indicators: built-in indicators and custom indicators

Indicators and pay-as-you-go billing

Some indicators included in Insider Risk Management require that you enable the pay-as-you-go billing model for your organization. Depending on your configured billing model, a notification might be displayed prompting you to configure pay-as-you-go billing to use these indicators.

Built-in indicators vs. custom indicators

Policy indicators are organized into two tabs:

- **Built-in indicators**: Insider Risk Management includes many built-in indicators for various scenarios that you can use right away in your policies. Choose the indicators that you want to activate, then customize indicator thresholds for each indicator level when you create an insider risk policy. This article describes the built-in indicators in more detail.
- **Custom indicators**: Use custom indicators together with the Insider Risk Indicators (preview) connector to bring non-Microsoft detections to Insider Risk Management. For example, you might want to extend your detections to include Salesforce and Dropbox and use them alongside the built-in detections provided by the Insider Risk Management solution, which is focused on Microsoft workloads (SharePoint Online and Exchange Online, for example). Create a custom indicator

Built-in indicators

Insider Risk Management includes the following built-in indicators.

Office indicators

These indicators include policy indicators for SharePoint sites, Microsoft Teams, and email messaging.

Cloud storage indicators

> ⓘ **Important**
>
> To use this indicator, enable pay-as-you-go billing in your organization.

These indicators include policy indicators for Google Drive, Box, and Dropbox that you can use to detect techniques used to determine the environment, gather and steal data, and disrupt the availability or compromise the integrity of a system. To select from cloud storage indicators, you must connect cloud storage apps in Microsoft Defender.

After configuring the cloud storage indicators, you can turn off indicators for the apps you don't want to use in settings. For example, you can select a content download indicator for Box and Google Drive, but not Dropbox.

Cloud service indicators

> **Important**
>
> To use this indicator, enable pay-as-you-go billing in your organization.

These indicators include policy indicators for Amazon S3 and Azure (SQL Server and Storage) that you can use to detect techniques used to avoid detection or risky activities. These techniques might include:

- Disabling trace logs
- Updating or deleting SQL Server firewall rules
- Techniques used to steal data, such as sensitive documents
- Techniques used to disrupt the availability or compromise the integrity of a system
- Techniques used to gain higher-level permissions to systems and data.

To select from cloud service indicators, you must connect source service apps in Microsoft Defender.

Network indicators

> **Important**
>
> To use this indicator, enable pay-as-you-go billing in your organization.

These indicators include HTTP and HTTPS network traffic from third party network security solutions. You can identify sensitive items that are being shared through these interactions. Detection of network traffic activities requires creation of a collection policy as a prerequisite. Learn more about network data security.

Microsoft Entra ID indicators

These indicators include risk detections from Microsoft Entra ID Protection. Risk detections are a powerful resource that can include any suspicious or anomalous activity related to a user account in the directory. Microsoft Entra ID Protection risk detections can be linked to an individual user or sign-in event.

User risk detections might flag a legitimate user account as at risk when a potential threat actor gains access to an account by compromising their credentials or when they detect some type of anomalous user activity. Sign-in risk detections represent the probability that a given authentication request isn't the authorized owner of the account.

To maintain relevance of the indicators to Insider Risk Management policies, only Microsoft Entra alerts in a *ConfirmedCompromised* or *Remediated* status state are evaluated. To learn more about the risk detections in Microsoft Entra ID Protection, see Risks detections in Microsoft Entra ID Protection.

Microsoft Fabric indicators

> **Important**
>
> To use the Microsoft Fabric indicators, enable pay-as-you-go billing in your organization.

These indicators include policy indicators for Microsoft Fabric workloads such as Power BI and Lakehouse. They help you detect techniques used to:

- Figure out the environment (for example, viewing Power BI reports and dashboards).
- Gather data of interest (for example, downloading Power BI reports).
- Obfuscate the data gathered or change protection (for example, downgrading or removing sensitivity labels of Power BI or Lakehouse assets).
- Exfiltrate the data (for example, sharing Lakehouse data with people outside the organization).

Generative AI apps indicators

These indicators include policy indicators for numerous generative AI applications. Use these indicators in policies to analyze interactions (prompts and responses) entered into these applications and help detect inappropriate or risky interactions or sharing of confidential information. These indicators include the following generative AI applications:

- **Microsoft Copilot experiences**: Support for user interactions in Copilot in Microsoft Fabric, Microsoft Security Copilot, Microsoft Copilot Studio, any connected or cloud AI application.

  > **ⓘ Important**
  >
  > To use the Microsoft Copilot experiences indicator for non-Microsoft 365 AI data, enable pay-as-you-go billing in your organization. Non-Microsoft 365 AI data includes information from other generative AI applications from Microsoft and other connected external AI applications. This data type includes Copilot in Microsoft Fabric, Microsoft Security Copilot, Microsoft Copilot Studio, and any connected or cloud AI application. There aren't any pay-as-you-go billing requirements or charges for Microsoft 365 detecting inappropriate or risky interaction for Microsoft 365 Copilot data.

- **Enterprise AI apps**: Non-Copilot AI applications connected using Microsoft Entra and Microsoft Purview Data Map connectors.

  > **ⓘ Important**
  >
  > To use the Enterprise AI apps indicator, enable pay-as-you-go billing in your organization.

- **Other AI applications**: AI applications that users in your organization discover from their browser activity.

  > **ⓘ Important**
  >
  > To use this indicator, enable pay-as-you-go billing in your organization.

- **Azure AI Content Safety indicators**: Support for Communication Compliance indicators to identify prompts and responses matching classifiers provided by Azure AI Content Safety like Prompt shields and Protected Materials.

  > **ⓘ Important**
  >
  > When you select the Azure AI Content Safety indicator, you create a Communication Compliance policy. If you modify this policy in Communication Compliance, you might need to pay for pay-as-you-go billing.

For Microsoft Copilot experiences and Enterprise AI apps, you can select which specific generative AI apps you want to monitor. By default, all available apps are selected. You can deselect apps that aren't relevant to your organization to reduce alert noise and avoid unnecessary pay-as-you-go billing charges. When an app is deselected, signals from that app aren't processed and no cost is incurred.

Select generative AI apps to monitor

> **Note**
>
> For **Microsoft Copilot experiences** and **Enterprise AI apps** only, you can review and deselect apps to optimize costs and reduce alert noise.

1. In the Microsoft Purview portal, go to **Insider Risk Management** > **Settings** > **Policy indicators**.
2. Expand **Generative AI apps indicators**.
3. For **Microsoft Copilot experiences** and **Enterprise AI apps**, select **Choose apps to monitor**.
4. From the side panel, you can select or clear the checkbox for each app to include or exclude it from monitoring.
5. Select **Save**.

Communication Compliance indicators

These indicators include policy indicators that detect employment stressor events, such as emotional outbursts, bullying, failure to take criticism, inability to work or communicate with a team or group, discrimination, violent threats, extremist behavior, and so on. Insider Risk Management works together with the Microsoft Purview Communication Compliance solution to detect these types of stressors that indicate an unhealthy workplace environment. Employment stressor events can impact user behavior for risky personas (whether initiators or targets of bad behavior) in several ways that relate to insider risks. Counterproductive work behavior can be a precursor to more serious violations, such as sabotaging company assets or leaking sensitive information.

Additionally, you can choose to detect messages matching specific sensitivity information types (SITs). Including sensitive information inadvertently or maliciously included in messages to user risk scores and their activity history provides investigators with more information to help quickly take actions to mitigate potential data leakage. You can select up to 30 SITs for a policy. Some scenarios might include helping to detect:

- Foreign recruitment
- State actor poaching
- Sharing sensitive information like secret formulas, financial reports, and other proprietary property
- Sharing passwords

> **Note**
>
> You can also use a Communication Compliance policy as a trigger.

How it works

You can choose from these Communication Compliance indicators:

- Sending inappropriate content
- Sending financial regulatory text that might be risky
- Sending inappropriate images

You can also choose to detect sensitive information types included in messages.

When you select **Create policy** from the **Communication Compliance indicators** section:

- A single policy is created in Communication Compliance that detects messages in Microsoft Exchange Online, Microsoft Teams, Microsoft Viva Engage, and Microsoft 365 Copilot and Microsoft 365 Copilot Chat. The Communication Compliance policy is based on the indicators and SITs you select. Each indicator is associated with specific trainable classifiers used by Communication Compliance. For more information, see Content safety classifiers based on large language models.

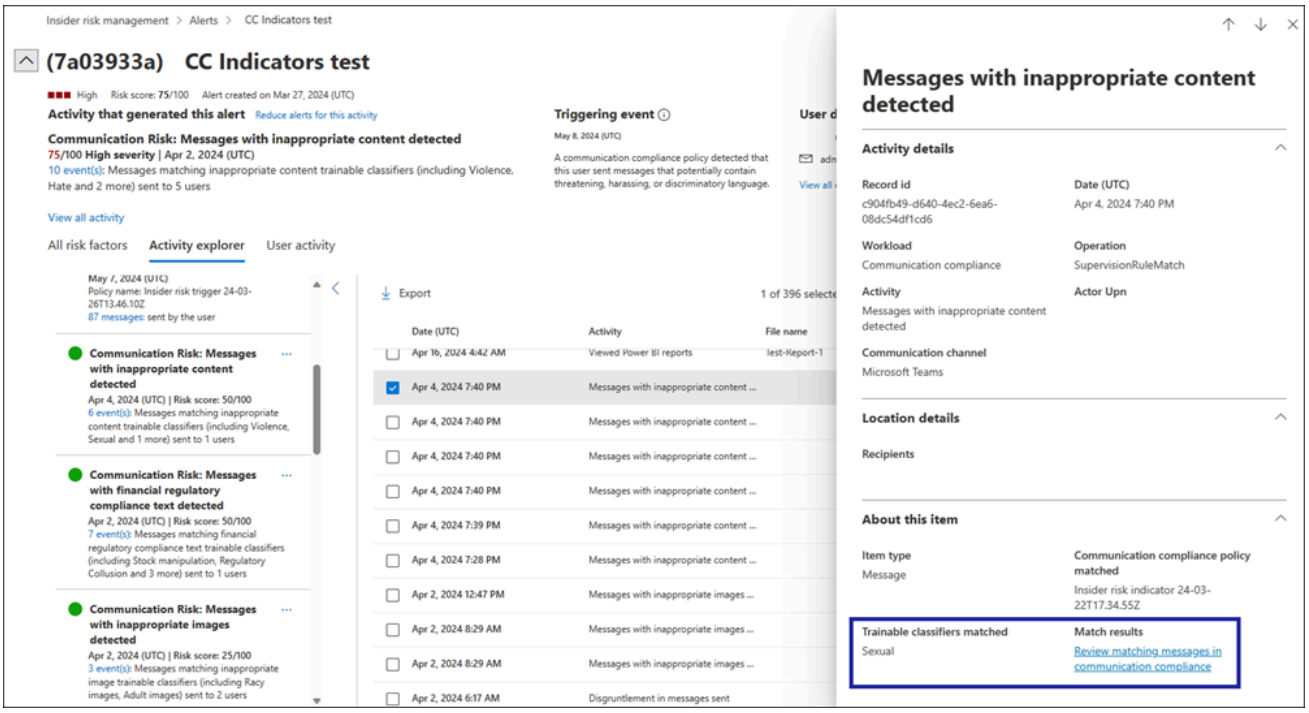
  > **Tip**
  >
  > Select the information icon next to each indicator to see the trainable classifiers that the indicator uses.

  In Communication Compliance, the trainable classifiers and SITs are listed as conditions for the policy.

- The Communication Compliance policy is named "Insider risk indicator" plus the timestamp, for example: "Insider risk indicator 24-05-01T09.27.17Z" or "Insider risk SIT indicator 24-05-01T09.27.17Z".

- Anyone with the *Insider Risk Investigators* role in Insider Risk Management is automatically added as a reviewer for the Communication Compliance policy.

  > ⓘ **Note**
  >
  > After creating the Communication Compliance policy, to add a reviewer to the policy, you must add the reviewer manually to the ***Communication Compliance Investigators* role group**.



- If you turn off all of the indicators in the **Policy indicators** setting, you pause the Communication Compliance policy. The policy is reenabled if you turn any of the indicators back on.

- You make the Communication Compliance indicators available for new and existing policies in Insider Risk Management that are based on the *Data theft* or *Data leaks* templates.

- If content sent in a message matches any of the trainable classifiers, it results in a policy match in Communication Compliance that can be remediated. For details, see Investigate and remediate Communication Compliance alerts.

- Indicators included in Insider Risk Management policies determine a risk score for an in-scope user. They activate only after a triggering event occurs for a user.

- *Communication Risk* insights appear in the **Activity explorer** and **User activity** tabs in Insider Risk Management. If you drill down into a policy match from the **Activity explorer** or **User activity** tab, you can learn more about the activity and access a link that opens the Communication Compliance policy. In the Communication Compliance policy, you can see the content of the messages that were sent.

> ⓘ Note
>
> You must have the *Communication Compliance* role or the *Communication Compliance Investigators* role to access the Communication Compliance link.

Enable Communication Compliance indicators in Insider Risk Management

To enable Communication Compliance indicators in Insider Risk Management, complete the following steps:

1. In Insider Risk Management, go to **Settings** > **Policy indicators**, then scroll to the **Communication Compliance indicators (preview)** section.

2. Under **Detect messages matching specific trainable classifiers (preview)**, select **Create policy**.

   The policy you create is in Communication Compliance, and the Communication Compliance indicators become available in the **Policy indicators** setting.

> ⓘ Note
>
> If you already created a Communication Compliance policy but paused it, selecting **Create policy** resumes the Communication Compliance policy. In this case, the **Status** column in the Communication Compliance **Policies** list shows "Resuming".

3. Select one or more of the Communication Compliance indicators in the **Policy indicators** setting.

   > **Note**
   >
   > If you already created a Communication Compliance policy and you select different indicators, the Communication Compliance policy changes to reflect the appropriate trainable classifiers. Turning off all indicators pauses the Communication Compliance policy.

4. Select **Save**.

5. To use the indicators, create an insider risk management policy or update an existing policy. The indicators appear on the **Indicators** page of the policy workflow. You can adjust thresholds for the indicators as you would for any other indicators in an Insider Risk Management policy.

   > **Note**
   >
   > At this time, real-time analytics for indicator threshold settings aren't available for the Communication Compliance indicators.

Data loss prevention alerts indicators

These indicators include policy indicators that integrate with data loss prevention (DLP) policies. By selecting DLP policies as indicators in Insider Risk Management policies, you can automatically detect if a user has existing alerts in connected DLP policies. DLP policies help protect sensitive information and reduce the risks of oversharing data with inappropriate users or organizations.

When an Insider Risk Management alert is generated for a user, you can quickly determine if the user has any high risk alerts associated with DLP policies in your organization without having to navigate to DLP solution in the Microsoft Purview portal. You can review and evaluate the Insider Risk Management activity and associated DLP alerts within Insider Risk Management in a unified view.

Supported DLP workloads

The High Severity DLP Alert indicator currently supports alerts generated by DLP policies scoped to the following workloads:

Expand table

Supported workload	Description
Exchange Online	DLP policy matches on email messages
SharePoint Online	DLP policy matches on documents stored in SharePoint sites
OneDrive for Business	DLP policy matches on documents stored in OneDrive accounts

> **Important**
>
> The following DLP workloads are **not** currently supported by the High Severity DLP Alert indicator. Alerts generated by DLP policies that apply exclusively to these workloads won't trigger the indicator and won't appear in Insider Risk Management alerts, cases, or activity views:
>
> - **Endpoint DLP**: DLP policy matches on Windows and macOS devices
> - **Microsoft Teams**: DLP policy matches in Teams chat and channel messages
> - **Microsoft 365 Copilot**: DLP policy matches in Copilot interactions
> - **On-premises repositories**: DLP policy matches on on-premises file shares and SharePoint Server
> - **Power BI**: DLP policy matches in Power BI datasets
>
> This is by design. Only DLP alerts written to the Microsoft 365 audit log by the supported workloads listed above are evaluated by Insider Risk Management. If your DLP policy spans multiple workloads (for example, Exchange + Endpoint), only the alerts from the supported workloads (Exchange Online, SharePoint Online, and OneDrive for Business) are processed.

Configure DLP alerts indicators

Step 1: To enable the DLP alerts as indicators, complete the following steps:

1. In Insider Risk Management settings, select **Policy indicators** and then select the **Built-in Indicators** tab.
2. Navigate to **Data loss prevention (DLP) indicators**
3. Select **Add DLP policies**
4. Select the DLP policies that you want to see alerts for in Insider Risk Management.

5. Select **Add**.

6. Select the **Generating alerts from selected DLP policies** checkbox.

7. Select **Save**.

Step 2: To assign DLP alerts indicators to a specific Insider Risk Management policy, complete the following steps:

1. Create a custom policy using one of the following templates:

    - Data theft by departing users
    - Data leaks
    - Data leaks by priority users
    - Data leaks by risky users
    - Risky AI usage

2. Configure the policy as applicable until you reach the **Indicators** page.

3. On the **Indicators** page, navigate to **Data loss prevention (DLP) indicators**.

4. Select the **Generating alerts from selected DLP policies** checkbox.

5. Complete the policy configuration workflow and save the new policy.

Device indicators

These policy indicators include activities such as sharing files over the network or with devices. Indicators include activities involving all file types, excluding executable (.exe) and dynamic link library (.dll) file activity. If you select *Device indicators*, the system processes activity for devices with Windows 10 Build 1809 or higher and macOS (three latest released versions) devices. For both Windows and macOS devices, you must onboard devices. Device indicators also include browser signal detection to help your organization detect and act on exfiltration signals for nonexecutable files viewed, copied, shared, or printed in Microsoft Edge and Google Chrome. For more information on configuring Windows devices for integration with insider risk, see Enable device indicators and onboard Windows devices. For more information on configuring macOS devices for integration with insider risk, see Enable device indicators and onboard macOS devices. For more information about browser signal detection, see Learn about and configure Insider Risk Management browser signal detection.

> **Important**

Device indicators are included in collection policy evaluations. When you configure and deploy a collection policy, if there's a mismatch between an Insider Risk Management policy that includes device indicators and a collection policy in your organization, the collection policy configuration takes precedence. This configuration means that if you configure an Insider Risk Management policy to monitor a specific activity for devices, but you configure the collection policy to filter out that device activity, the device activity isn't collected and isn't available for review in Insider Risk Management.

Microsoft Defender for Endpoint indicators (preview)

These indicators come from Microsoft Defender for Endpoint and relate to unapproved or malicious software installation or bypassing security controls. To receive alerts in Insider Risk Management, you must have an active Defender for Endpoint license and insider risk integration enabled. For more information on configuring Defender for Endpoint for Insider Risk Management integration, see Configure advanced features in Microsoft Defender for Endpoint.

Health record access indicators

These policy indicators cover patient medical record access. For example, attempted access to patient medical records in your electronic medical records (EMR) system logs can be shared with Insider Risk Management healthcare policies. To receive these types of alerts in Insider Risk Management, you must have a healthcare-specific data connector and the HR data connector configured.

Physical access indicators

These policy indicators cover physical access to sensitive assets. For example, attempted access to a restricted area in your physical badging system logs can be shared with Insider Risk Management policies. To receive these types of alerts in Insider Risk Management, you must have priority physical assets enabled in Insider Risk Management and the Physical badging data connector configured. To learn more about configuring physical access, see Configure priority physical assets.

Microsoft Defender for Cloud Apps indicators

These policy indicators come from shared alerts from Defender for Cloud Apps. Automatically enabled anomaly detection in Defender for Cloud Apps immediately starts detecting and collating results, targeting numerous behavioral anomalies across your users and the machines and devices connected to your network. To include these activities in Insider Risk Management

policy alerts, select one or more indicators in this section. To learn more about Defender for Cloud Apps analytics and anomaly detection, see Get behavioral analytics and anomaly detection.

Risky Agents indicators (preview)

These policy indicators cover agent interactions with users and sensitive or risky resources. Risky agent prompts, agent generated sensitive responses, accessing sensitive or priority SharePoint files, agents accessing risky websites, or agents using tools with sensitive information are included.

Risky AI usage indicators (preview)

These policy indicators cover Microsoft AI tools and applications. Risky prompt behavior from users and AI-generated responses that include sensitive information are both included in these indicators. For example, attempted sharing of sensitive information in an AI tool or application by a user is considered risky activity. Similarly, an AI tool or application returning a response that contains sensitive information is also considered risky behavior.

Risky browsing indicators (preview)

These policy indicators cover browsing activity related to websites that are considered malicious or risky and pose potential insider risk that might lead to a security or compliance incident. Risky browsing activity refers to users who visit potentially risky websites, such as those associated with malware, pornography, violence, and other unallowed activities. To include these risk management activities in policy alerts, select one or more indicators in this section. To learn about configuring browser exfiltration signals, see Insider Risk Management browser signal detection.

Cumulative exfiltration detection indicators

These indicators detect when a user's exfiltration activities across all exfiltration channels over the last 30 days exceed organization or peer group norms. For example, if a user is in a sales role and communicates regularly with customers and partners outside of the organization, their external email activity is likely higher than the organization's average. However, the user's activity might not be unusual compared to the user's teammates, or others with similar job titles. A risk score is assigned if the user's cumulative exfiltration activity is unusual and exceeds organization or peer group norms.

> **Note**

Peer groups are defined based on organization hierarchy, access to shared SharePoint resources, and job titles in Microsoft Entra ID. If you enable cumulative exfiltration detection, your organization agrees to share Microsoft Entra data with the Microsoft Purview portal, including organization hierarchy and job titles. If your organization doesn't use Microsoft Entra ID to maintain this information, detection might be less accurate.

Risk score boosters

These indicators raise the risk score for activity for the following reasons:

- *Activity that is above the user's usual activity for that day*: Scores are boosted if the detected activity deviates from the user's typical behavior.
- *User had a previous case resolved as a policy violation*: Scores are boosted if the user had a previous case in Insider Risk Management that was resolved as a policy violation.
- *User is a member of a priority user group*: Scores are boosted if the user is a member of a priority user group.
- *User is detected as a potential high impact user*: When you enable this indicator, users are automatically flagged as potential high-impact users based on the following criteria:
  - The user interacts with more sensitive content compared to others in the organization.
  - The user's level in the organization's Microsoft Entra hierarchy.
  - The total number of users reporting to the user based on the Microsoft Entra hierarchy.
  - The user is a member of a Microsoft Entra built-in role with elevated permissions.

  > **Note**
  >
  > When you enable the potential high impact user risk score booster, you agree to share Microsoft Entra data with the Microsoft Purview portal. If your organization doesn't use sensitivity labels or has not configured organization hierarchy in Microsoft Entra ID, this detection might be less accurate. If a user is detected as both a member of a priority user group and also a potential high-impact user, their risk score is only boosted once.

In some cases, you might want to limit the insider risk policy indicators that apply to insider risk policies in your organization. You can turn off the policy indicators for specific areas by disabling them from all insider risk policies in global settings. You can only modify triggering events for policies created from the *Data leaks* or *Data leaks by priority users* templates. Policies created from all other templates don't have customizable triggering indicators or events.

Custom indicators

Use the **Custom Indicators** tab to create a custom indicator to use as a trigger or as a policy indicator in your policies.

> ⓘ **Note**
>
> To create a custom indicator to import third-party indicator data, you must first create an Insider Risk Indicators connector (preview).

1. In Insider Risk Management settings, select **Policy indicators** and then select the **Custom Indicators** tab.
2. Select **Add custom indicator**.
3. Enter an indicator name and a description (optional).
4. In the **Data connector** list, select the Insider Risk Indicator connector that you created previously.

   When you select a data connector:

   - The name of the source column that you select when you create the connector appears in the **Source column from mapping file** field. If you don't select a source column when you create the connector, **None** appears in this field and you don't need to make a selection.
   - In the **Values in source column** list, select the value that you want to assign to the custom indicator. These values relate to the source column that you specified when you created the connector. For example, if you create a single connector that includes data for two indicators (Salesforce and Dropbox), you see those values in the list.
5. If you want to use a column to set threshold values, in the **Data from mapping file** list, select the column that you want to use for the threshold setting; otherwise, select the **Use only as a triggering event without any thresholds** option.

   > ⓘ **Note**

Only fields that have a *Number* data type appear in the **Data from mapping file** list, since a *Number* data type is required to set a threshold value. The data type is specified when you set up the connector.

6. Select **Add indicator**. The indicator is added to the **Custom Indicators** list.

Now you can add the custom indicator to an insider risk policy in any *Data theft* or *Data leaks* policies that you create or edit.

- If you use the custom indicator as a trigger, select your custom trigger on the **Triggers** page when you create or edit the policy.
- If you use the custom indicator as a policy indicator, select your custom indicator on the **Indicators** page when you create or edit the policy.

> **Note**
>
> After selecting your custom trigger or indicator, make sure to set a custom threshold (don't use the default thresholds). You can't set trigger thresholds on a custom indicator if you select the **Use only as a triggering event without any thresholds** option.

After adding the custom indicator to your policies, the triggers and insights generated based on the custom indicators appear in the **Alerts dashboard**, **Activity explorer**, and **User timeline**.

> **Important**
>
> Wait 24 hours before running the sample script to upload your data after you update the custom indicators and the associated policies. It can take several hours to sync all components. If you immediately upload the data while the updates are syncing, some data might not be scored for risk.

Create a variant of a built-in indicator

You can create detection groups and use them with variants of built-in indicators to tailor detections for different sets of users. For example, to reduce the number of false positives for email activities, you might want to create a variant of the *Sending email with attachments to recipients outside the organization* built-in indicator to only detect email sent to personal domains. A variant inherits all the properties of the built-in indicator. You can modify the variant with exclusions or inclusions.

1. In Insider Risk Management settings, select **Policy indicators**.
2. Select **New indicator variant (preview)**. This step opens the **New indicator variant (preview)** pane on the right side of the screen.
3. In the **Base indicator** list, select the indicator that you want to create a variant for.

   > ⓘ **Note**
   >
   > You can create up to ten variants for each built-in indicator and a total of 100 variants across all indicators. If you already created ten variants for a particular built-in indicator, the built-in indicator appears grayed out in the list. Some built-in indicators (Microsoft Defender for Endpoint indicators, for example) don't support variants.

4. Add a name for the variant (or accept the suggested name). A variant name can't be more than 110 characters.
5. Add a description for the variant (optional). The description appears in the policy to help you differentiate it from other indicators or indicator variants. A description for a variant can't be more than 256 characters.
6. Under **Detection group**, select one of the following options:

   - **Ignore activity involving items in selected groups**. Select this option if you want to capture everything except for a few *exclusions*. For example, you might want to use this option to capture all outgoing email except for email sent to specific domains.
   - **Only detect activity involving items in selected groups**. Select this option if you want to specify *inclusions* to capture. For example, select this option if you want to capture only email sent to certain domains.

   > ⓘ **Note**
   >
   > If you didn't already create a detection group, you can't select an option in the **Detection group** section.

7. In the **Select one or more detection groups** list, select the detection groups that you want to apply to the variant. Detection groups are listed under the appropriate detection type heading to help you find the appropriate group. For a single variant, you can add up to five

detection groups of a single type. For example, you can add up to five groups of domains, five groups of file types, and so on.

> **Note**
>
> Only detection groups that are applicable to the variant appear in the list. For example, a file type detection group won't appear for the *Sharing SharePoint folders with people outside the organization* indicator since it's not applicable.

8. Select **Save**.

9. In the **Next steps** dialog box, if you want to apply the new variant to a specific policy, select the **Policies page** link.

> **Tip**
>
> To make sure that a variant captures all the important activities that you want to detect, you can apply the built-in indicator and the variant of the built-in indicator in the same policy. You can then observe the activities that each indicator captures in alerts and then use only the variant indicator after making sure everything is detected.

Use a variant in a policy

To use an indicator variant in a policy, complete the following steps:

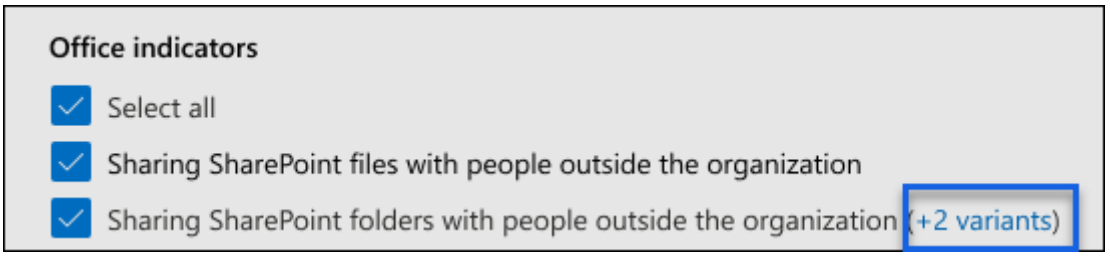
1. Go to the **Indicators** page of the policy workflow.

2. Find the built-in indicator that includes one or more variants. A small blue box in the variant checkbox marks built-in indicators that have variants. A list appears at the end of the indicator descriptor text to show the number of selected variants. Open the list to see the variants.

   > **Note**
   >
   > If you select one or more checkboxes in the variant list, the first-level checkbox for the built-in indicator becomes a solid blue checkbox. If you don't select any of the boxes in the variant list, the first-level checkbox is blank.

3. Select **Next**.

4. In the **Customize thresholds** page, you can customize threshold values for variants individually.



Investigate insights provided by variants

When you add variants to policies, the dashboard generates alerts. An investigator can view more details in the **Activity explorer** and **User activity** tabs.

Edit a variant

To edit an existing variant, complete the following steps:

1. Select the blue text at the end of the indicator description text. For example, select **+2** variants as shown in the following screenshot example.

2. In the **View/edit indicators** page, select **Edit**.

3. Make your changes.

Variant limitations

- You can create up to ten variants for each built-in indicator and a total of 100 variants across all indicators.
- You can add up to five detection groups of a single type for a single variant. For example, you can add a maximum of five groups of domains, five groups of file types, and so on.
- Variants don't support sequences, cumulative exfiltration activities, the risk score booster, or real-time analytics for the detections group preview.

How variants are prioritized against global exclusions and priority content

Insider Risk Management scopes activities in the following priority order:

1. Global exclusions
2. Variant scoping exclusion/inclusion

3. Priority content

Enable device indicators and onboard Windows devices

To enable the detection of risk activities on Windows devices and include policy indicators for these activities, your Windows devices must meet the following requirements, and you must complete the following onboarding steps. Learn more about device onboarding requirements

Step 1: Prepare your endpoints

Make sure that the Windows 10 devices you plan to report in Insider Risk Management meet these requirements.

1. The device must run Windows 10 x64 build 1809 or later and have the Windows 10 update (OS Build 17763.1075) from February 20, 2020 installed.
2. The user account used to sign in to the Windows 10 device must be an active Microsoft Entra account. The Windows 10 device might be Microsoft Entra ID, Microsoft Entra hybrid, joined, or registered.
3. Install the Microsoft Edge browser on the endpoint device to detect actions for the cloud upload activity. See Download the new Microsoft Edge based on Chromium.

> **Note**
>
> Endpoint DLP now supports virtualized environments, which means that the Insider Risk Management solution supports virtualized environments through endpoint DLP. **Learn more about support for virtualized environments in endpoint DLP**

Step 2: Onboard devices

To detect Insider Risk Management activities on a device, you must enable device checking and onboard your endpoints. You perform both actions in Microsoft Purview.

To enable devices that you didn't onboard yet, download the appropriate script and deploy it as outlined in this article.

If you already onboarded devices into Microsoft Defender for Endpoint, they appear in the managed devices list.

Onboard devices

Use this deployment scenario to enable devices that aren't onboarded yet when you want to detect insider risk activities on Windows devices.

1. Sign in to the Microsoft Purview portal with an admin account in your Microsoft 365 organization.
2. Select **Settings** in the upper-right corner of the page.
3. Under **Device onboarding**, select **Devices**. The list is empty until you onboard devices.
4. Select **Turn on device onboarding**.

   > **Note**
   >
   > While it usually takes about 60 seconds to enable device onboarding, allow up to 30 minutes before engaging with Microsoft Support.

5. Select how you want to deploy to these devices from the **Deployment method** list, then select **Download package**.
6. Follow the appropriate procedures in Onboarding tools and methods for Windows machines. This link takes you to a landing page where you can access Microsoft Defender for Endpoint procedures that match the deployment package you selected in step 5:

   - Onboard Windows machines using Group Policy
   - Onboard Windows machines using Microsoft Endpoint Configuration Manager
   - Onboard Windows machines using Mobile Device Management tools
   - Onboard Windows machines using a local script
   - Onboard non-persistent virtual desktop infrastructure (VDI) machines

When you finish and onboard the endpoint device, it appears in the devices list. The endpoint device starts reporting audit activity logs to Insider Risk Management.

> **Note**
>
> This experience is under license enforcement. Without the required license, data isn't visible or accessible.

If devices are already onboarded to Microsoft Defender for Endpoint

If you already deployed Microsoft Defender for Endpoint and endpoint devices are reporting in, the endpoint devices appear in the managed devices list. To expand coverage, onboard new devices into Insider Risk Management by going to Step 2: Onboarding devices.

Enable device indicators and onboard macOS devices

You can onboard macOS devices (Catalina 10.15 or later) into Microsoft 365 to support Insider Risk Management policies by using either Intune or JAMF Pro. For more information and configuration guidance, see Onboard macOS devices into Microsoft 365 overview (preview).

Indicator level settings

When you create a policy by using the policy workflow, you can configure how the daily number of risk events influences the risk score for insider risk alerts. These indicator settings help you control how the number of occurrences of risk events in your organization affect the risk score and the associated alert severity for these events.

For example, suppose you decide to enable SharePoint indicators in the insider risk policy settings and select custom thresholds for SharePoint events when configuring indicators for a new insider risk *Data leaks* policy. In the insider risk policy workflow, you configure three different daily event levels for each SharePoint indicator to influence the risk score for alerts associated with these events.

For the first daily event level, set the threshold to:

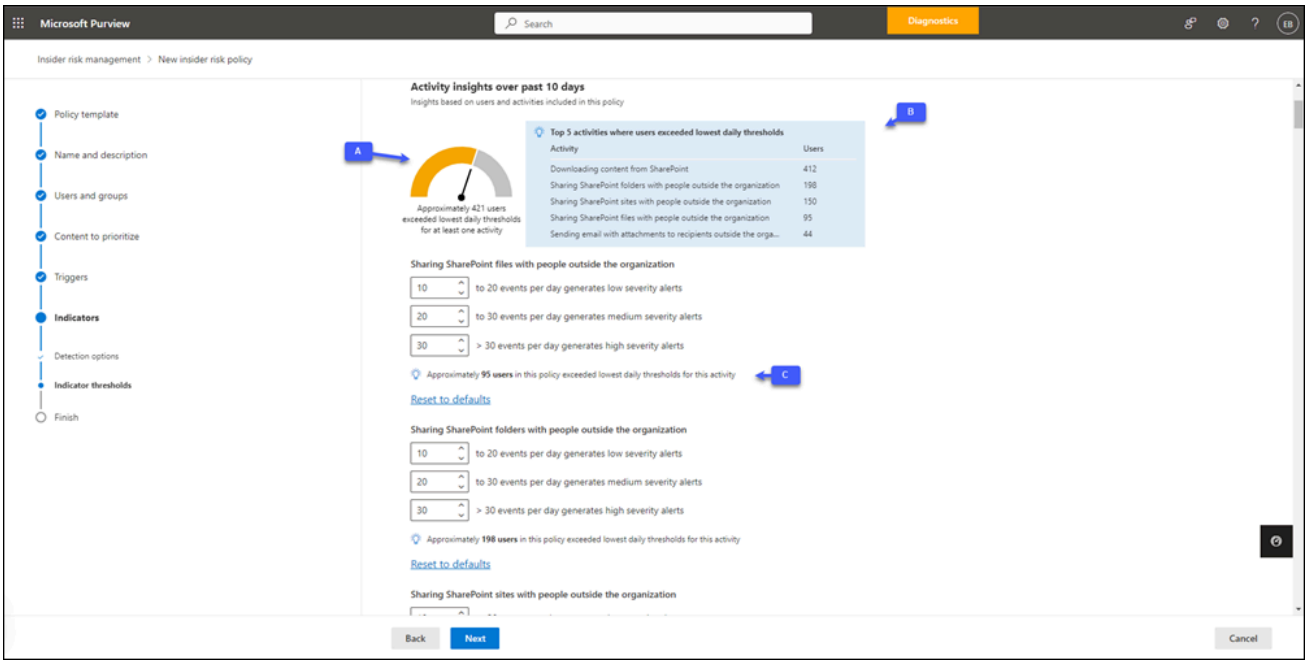
- *10 or more events per day* for a lower impact to the risk score for the events
- *20 or more events per day* for a medium impact to the risk score for the events
- *30 or more events per day* for a higher impact to the risk score for the events

These settings mean:

- If there are 1-9 SharePoint events that take place after the triggering event, risk scores are minimally impacted and tend not to generate an alert.
- If there are 10-19 SharePoint events that take place after a triggering event, the risk score is inherently lower and alert severity levels tend to be at a low level.
- If there are 20-29 SharePoint events that take place after a triggering event, the risk score is inherently higher and alert severity levels tend to be at a medium level.
- If there are 30 or more SharePoint events that take place after a triggering event, the risk score is inherently higher and alert severity levels tend to be at a high level.

Another option for policy thresholds is to assign the policy triggering event to risk management activity that is over the typical daily number of users. Instead of being defined by specific threshold settings, each threshold is dynamically customized for anomalous activities detected for in-scope policy users. If threshold activity for anomalous activities is supported for an individual indicator, you can select **Activity is above user's usual activity for the day** in the policy workflow for that indicator. If this option isn't listed, anomalous activity triggering isn't available for the indicator. If the **Activity is above user's usual activity for the day** option is listed for an indicator, but isn't selectable, you need to enable this option in **Insider risk settings** > **Policy indicators**.

Use real-time analytics recommendations to set thresholds



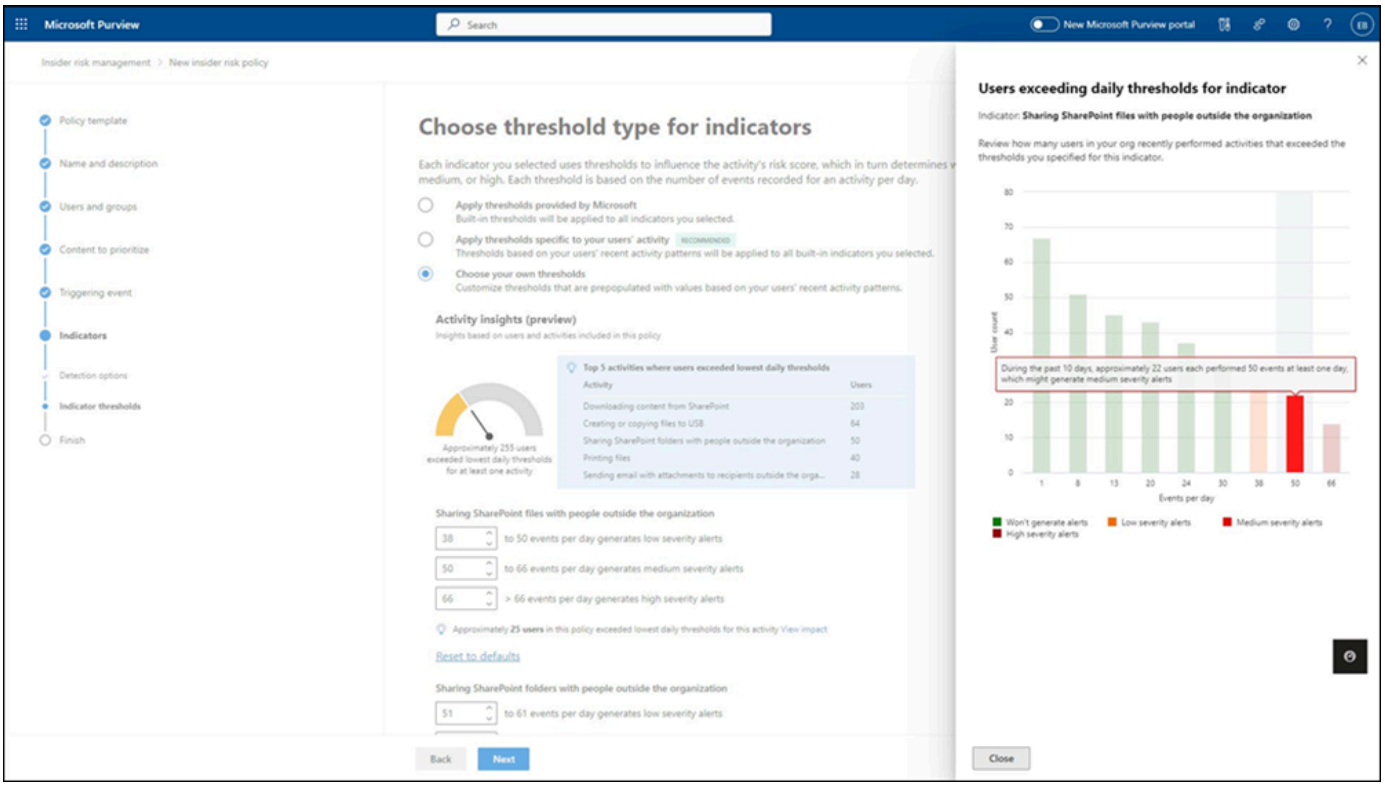
Use real-time analytics (preview) to get a guided, data-driven threshold configuration experience. With this experience, you can quickly select the right thresholds for policy indicators. The guided experience helps you efficiently adjust the selection of indicators and thresholds for activity occurrences so you don't have too few or too many policy alerts.

When you turn on analytics:

- The **Apply thresholds specific to your users' activity** option is enabled on the **Indicators** page of the policy workflow. Select this option if you want Insider Risk Management to provide indicator threshold recommendations based on the previous 10 days of user activity in your organization.

  > ⓘ **Note**
  >
  > To use this option, you must select at least one built-in policy indicator. Insider Risk Management doesn't provide recommended thresholds for custom indicators or variants of built-in indicators.

- If you select the **Choose your own thresholds** option on the **Indicators** page of the policy workflow, the defaults for the threshold settings are based on recommended threshold values (based on activity in your organization) instead of the built-in default values. You also see a gauge, a list of the top five indicators, and insights for each indicator.



- **A.** The gauge shows the approximate number of scoped users whose activities from the previous 10 days exceeded the *lowest daily thresholds* for at least one of the selected built-in indicators for the policy. This gauge helps you estimate the number of alerts that might be generated if all users included in the policy were assigned risk scores.
- **B.** The top five indicators list is sorted by the number of users exceeding the *lowest daily thresholds*. If your policies generate too many alerts, focus on these indicators to reduce "noise."
- **C.** Insights for each indicator are displayed for the set of threshold settings for that indicator. The insight shows the approximate number of users whose activities from the previous 10 days exceeded the specified *low thresholds* for the indicator. For example, if the low threshold setting for *Downloading content from SharePoint* is set to 100, the insight shows the number of users in the policy who performed more than 100 download activities on average in the previous 10 days.

> ⓘ Note
>
> Global exclusions (intelligent detections) are taken into account for real-time analytics.

Adjust threshold settings manually

If you select the **Choose your own thresholds** option and manually adjust a threshold setting for a specific indicator, the insight for the indicator updates in real time. This feature helps you configure the appropriate thresholds for each indicator to achieve the highest level of alert effectiveness before activating your policies.

To save time and make it easier to understand the impact of manual changes to threshold values, select the **View impact** link in the insight to display the **Users exceeding daily thresholds for indicator** graph. This graph provides sensitivity analysis for each policy indicator.

> **Important**
>
> This graph isn't available if you select the **Include specific users** option when you create the policy. You must select the **Include all users and groups** option.

Use this graph to analyze the activity patterns of users in your organization for the selected indicator. For example, in the preceding illustration, the threshold indicator for *Sharing SharePoint files with people outside the organization* is set to **38**. The graph shows how many users performed actions that exceeded that threshold value and the distribution of low, medium, and high severity alerts for those actions. Select a bar to see insights for each value. For example, in the previous illustration, the bar for the **50** value is selected and the insight shows that at that threshold value, approximately 22 users each performed at least 50 events on at least one day in the past 10 days.

Prerequisites for using real-time analytics

To use real-time analytics (preview), you must enable insider risk analytics insights. After you enable analytics, it can take 24 to 48 hours for insights and recommendations to appear.

Fine-tune exclusions in Insider Risk Management by creating detection groups (preview)

Overview

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

You can exclude items from being scored by Insider Risk Management policies by using the Global exclusions setting. These types of exclusions apply to every trigger and indicator for all policies that you create within a tenant. By using detection groups, you can modify a built-in global exclusion to make it specific for your organization's needs.

You can also use detection groups to modify the built-in insider risk indicators to tailor detections for different sets of users at the policy level. For example, to reduce the number of false positives for email activities, you might want to create a variant of the *Sending email with attachments to recipients outside the organization* built-in indicator to only detect email sent to personal domains.

Process for creating and using detection groups

To use a detection group as part of a global exclusion, create the detection group as described in this article, then select it in the Global exclusions settings.

Using a detection group to modify a built-in indicator includes the following steps:

1. Create the detection group as described in the Create a detection group section of this article. You select this detection group when you create the variant.
2. Create the variant.

3. Use the variant in a new or existing policy.
4. Review alerts related to the activities specified in the variant.

Create a detection group

A detection group helps you scope a built-in indicator or a global exclusion to focus on the high-value activities important to your organization.

Detection types for policy indicators

Every policy indicator includes certain detection types that are applicable to that indicator. For example, for the *Sharing SharePoint files with people outside the organization* indicator, one of the detection types is *domains*. When you share a SharePoint file, you choose a domain to share the file with. Not all indicators have the same detection types. For example, *domains* is a detection type of the *Sharing SharePoint files with people outside the organization* indicator, but it's not a detection type of the *Creating or copying files to USB* indicator since it's not applicable in that case.

Insider Risk Management currently supports seven detection types:

- Domains
- File paths
- File types
- Keywords
- Sensitive info types
- SharePoint sites
- Trainable classifiers

> **Tip**
>
> When you create a detection group, you can see all the applicable indicators for a particular detection by selecting the **View applicable indicators** link in the introductory text for the group type.

Use the procedures in this section to create a detection group for each supported group type: domains, file paths, file types, keywords, sensitive info types, SharePoint sites, and trainable classifiers.

Create a domains detection group

To create a domains detection group, complete these steps:

1. In Insider Risk Management settings, select **Detection groups (preview)**.
2. In the panel to the right, under **Type**, select **Domains**.
3. In the panel to the right, select **New domain group**.
4. In the **New domain group** pane, enter a name for the group (or accept the suggested name) and an optional description.
5. In the **Add domains** field, enter a domain, then press Enter. Continue adding more domains in the same way. To add a long list of domains, import them as a CSV file by selecting **Import domains from CSV file**. The domains you add appear at the bottom of the pane. You can create up to 10 domain detection groups, and each group can have up to 500 items.

   > **Note**
   >
   > To specify multi-level subdomains for a root domain, select the **Include multi-level subdomains** checkbox, add a domain, then press Enter to add the domain to the list. Any subdomains included within that domain are included. Repeat the same process to add more domains, then select **Add domains** when you're done.

   > **Tip**
   >
   > Use wildcards to help match variations of root domains or subdomains. For example, to specify `sales.wingtiptoys.com` and `support.wingtiptoys.com`, use the wildcard entry `*.wingtiptoys.com` to match these subdomains (and any other subdomain at the same level).

6. Select **Save**. You see a **Next steps** dialog box that advises you on the next step in the process, which includes using this detection group in a variant.

How the *Free public domains* domain group detects exfiltration of business data to personal email domains

The Domains detection group includes a special domain group called *Free public domains* that consists of a list of free email providers (such as `gmail.com` or `yahoo.com`) that users can use to create a personal email ID. This list automatically highlights exfiltration of business data to

personal email domains for the email insight on the **User activity** and **Activity explorer** tabs. The insight lists the number of emails sent to free public domains by an in-scope user. The list also supports the algorithm that identifies email sent to self (sent to the in-scope user's personal email account). The email insight lists the number of emails sent to self.

You can use this built-in domain group like any other domain group to create a variant of a built-in indicator for your policies. This domain group only applies to the *Sending email with attachments to recipients outside the organization* indicator. For more information, see Create a variant of a built-in indicator.

Create a file paths detection group

To create a file paths detection group, complete these steps:

1. In Insider Risk Management settings, select **Detection groups (preview)**.
2. In the panel to the right, under **Type**, select **File paths**.
3. In the panel to the right, select **New file path group**.
4. In the **New file path group** pane, add a name for the group or accept the suggested name, and add a description (optional).
5. Select **Add file paths**, select the file paths, then select **Add**. You can create up to 10 file path detection groups and each group can have up to 500 items.
6. Select **Save**. You see a **Next steps** dialog box that advises you on the next step in the process, which includes using this detection group in a variant.

Create a file types detection group

To create a file types detection group, complete these steps:

1. In Insider Risk Management settings, select **Detection groups (preview)**.
2. In the panel to the right, under **Type**, select **File types**.
3. In the panel to the right, select **New file type group**.
4. In the **New file type group** pane, add a name for the group or accept the suggested name, and add a description (optional).
5. In the **Add file type** field, enter a file extension, then press Enter. Continue adding more file extensions the same way. The extensions that you add are listed at the bottom of the pane. You can create up to 10 file types detection groups and each group can have up to 500 items.
6. Select **Save**. You see a **Next steps** dialog box that advises you on the next step in the process, which includes using this detection group in a variant.

Create a keywords detection group

To create a keywords detection group, complete these steps:

1. In Insider Risk Management settings, select **Detection groups (preview)**.
2. In the panel to the right, under **Type**, select **Keywords**.
3. In the panel to the right, select **New keywords group**.
4. In the **New keywords group** pane, add a name for the group or accept the suggested name, and add a description (optional).
5. In the **Add keywords** field, enter a keyword, then press Enter. Repeat this process for each keyword you want to add. The keywords that you add are listed at the bottom of the pane. You can create up to 10 keywords detection groups and each group can have up to 500 items.
6. Select **Save**. You see a **Next steps** dialog box that advises you on the next step in the process, which includes using this detection group in a variant.

Create a sensitive info types detection group

> ⓘ **Note**
>
> The exclusion list of sensitive info types takes precedence over the priority content list.

1. In Insider Risk Management settings, select **Detection groups (preview)**.
2. In the panel to the right, under **Type**, select **Sensitive info types**.

3. In the panel to the right, select **New sensitive info type group**.
4. In the **New sensitive info type group** pane, enter a name for the group or accept the suggested name. Optionally, add a description.
5. Select **Add sensitive info types**, select the sensitive info types, then select **Add**. Default SIT exclusions are not available for selection. You can create up to 10 sensitive info type groups, and each group can have up to 500 items.
6. Select **Save**. You see a **Next steps** dialog box that advises you on the next step in the process, which includes using this detection group in a variant.

Create a SharePoint sites detection group

To create a SharePoint sites detection group, complete these steps:

1. In Insider Risk Management settings, select **Detection groups (preview)**.
2. In the panel to the right, under **Type**, select **SharePoint sites**.
3. In the panel to the right, select **New SharePoint site group**.
4. In the **New SharePoint site group** pane, enter a name for the group or accept the suggested name. Optionally, add a description.
5. Select **Add sites**, select the SharePoint sites, then select **Add**. You can create up to 10 SharePoint sites detection groups, and each group can have up to 500 items.
6. Select **Save**. You see a **Next steps** dialog box that advises you on the next step in the process, which includes using this detection group in a variant.

Create a trainable classifier detection group

To create a trainable classifier detection group, complete these steps:

1. In Insider Risk Management settings, select **Detection groups (preview)**.
2. In the panel to the right, under **Type**, select **Trainable classifiers**.
3. In the panel to the right, select **New trainable classifiers group**.
4. In the **New trainable classifiers group** pane, enter a name for the group or accept the suggested name. Optionally, add a description.
5. Select **Add trainable classifiers**, select the trainable classifiers, then select **Add**. You can create up to 10 trainable classifier detection groups, and each group can have up to 500 items.
6. Select **Save**. You see a **Next steps** dialog box that advises you on the next step in the process, which includes using this detection group in a variant.

Set up global exclusions for Insider Risk Management policies

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Use the **Global exclusions** setting in Microsoft Purview Insider Risk Management to exclude items from being scored by Insider Risk Management policies. For example, to reduce "noise" in your policies, you might want to exclude certain file types or domains from being scored for risk if those file types or domains don't present risk to your organization.

When you set up global exclusions, consider using detection groups to tailor detections for different sets of users. Detection groups can help you reduce false positives for your policies.

Configure a domain exclusion

You can exclude specific domains related to user activities from being scored by your Insider Risk Management polices. These activities include:

- Email sent to external domains.
- Files, folders, and sites shared with external domains.
- Files uploaded to external domains (using the Microsoft Edge browser).

Allowed domains are ignored by your policies and don't generate alerts.

Set up a domain exclusion

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.

2. Select **Settings** in the upper-right corner of the page, then select **Insider Risk Management** to go to the Insider Risk Management settings.

3. Under **Insider risk settings**, select **Global exclusions**.

4. In the **Type** panel to the right, select **Domains**.

5. In the **Domains** panel to the right, select one of the following tabs:

   - **Individual domains**. To add domains one at a time:

     a. Select **Add domains**, then enter an exact domain in the **Domain** field or use a wildcard asterisk (*) to detect a subdomain (for example, *.contoso.com). Preceding the domain name with a wildcard detects a maximum of one subdomain (for example, support.contoso.com).

     b. To include all subdomains within the domain, select the **Include multi-level subdomains** checkbox.

     > **Note**
     >
     > You can use wildcards to help match variations of root domains or subdomains. For example, to specify sales.wingtiptoys.com and support.wingtiptoys.com, use the wildcard entry "*.wingtiptoys.com" to match these subdomains (and any other subdomain at the same level). To specify multi-level subdomains for a root domain, you must select the **Include multi-level subdomains** checkbox.

     c. Press Enter.

     d. Repeat this process for each domain that you want to add.

     Each domain that you enter is added to the **Domain** column and **Yes** or **No** is added to the **Multi-level subdomains included** list.

     > **Tip**
     >
     > If you don't want to add domains one at a time, you can import a list of domains from a CSV file by selecting **Import domains from CSV file** on the previous page.

     e. Select **Add domains**.

   - **Domain groups**. To select a domain detection group that you already created:

a. Select **Add domain group**.

b. Select the appropriate domain groups from the list. The number of domains included in each domain group is listed in the **Included domains** column.

c. Select **Save**.

Configure an email signature attachments exclusion

One of the main sources of noise in Insider Risk Management policies is images in email signatures. The system often detects these images as attachments in emails. If you select the *Sending email with attachments to recipients outside the organization* indicator, the system scores the attachment like any other email attachment sent outside the organization, even if the only thing in the attachment is the email signature. You can use the **Ignore email signature attachments (preview)** setting to exclude these attachments from scoring.

Turning on this setting significantly reduces noise from email signature attachments, but it doesn't completely eliminate all noise. This limitation exists because the system excludes from scoring only the email signature attachment of the email sender (the person who initiates the email or replies to the email). The system still scores a signature attachment for anyone on the To, CC, or BCC line. Also, if someone changes their email signature, the system needs to profile the new signature, which can cause alert noise for a short period of time.

Configure an email signature attachments exclusion

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Select **Settings** in the upper-right corner of the page, then select **Insider Risk Management** to go to the Insider Risk Management settings.
3. Under **Insider risk settings**, select **Global exclusions**.
4. In the **Type** panel to the right, select **Email signature attachments**.
5. In the **Ignore email signature attachments (preview)** panel to the right, turn the setting **On**.
6. Select **Save**.

Configure a file path exclusion

When you exclude file paths, user activities that map to specific indicators and that occur in those file path locations don't generate policy alerts. Examples include copying or moving files to a system folder or network share path. You can enter up to 500 file paths for exclusion.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.

2. Select **Settings** in the upper-right corner of the page, then select **Insider Risk Management** to go to the Insider Risk Management settings.

3. Under **Insider risk settings**, select **Global exclusions**.

4. In the **Type** panel to the right, select **File paths**.

5. In the **File paths** panel to the right, select one of the following tabs:

   - **Individual file paths**. To add an individual file path, select **Add file paths to exclude**, enter an exact network share or device file path, then select **Add file paths to exclude**. Repeat this process for each file path that you want to exclude. Examples:

     Expand table

Example	Description
\ms.temp\LocalFolder\ or C:\temp	Excludes files directly under the folder and all subfolders for every file path starting with the entered prefix.
\public\local	Excludes files from every file path containing the entered value. Matches with 'C:\Users\Public\local\', 'C:\Users\User1\Public\local', and '\ms.temp\Public\local'.
C:\Users*\Desktop	Matches with 'C:\Users\user1\Desktop' and 'C:\Users\user2\Desktop'.
C:\Users*(2)\Desktop	Wilcards with numbers are supported. Matches with 'C:\Users\user1\Desktop' and 'C:\Users\user2\Shared\Desktop'.

     Each file path that you enter is added to the **File path column** on the page.

     > **Note**
     >
     > See Default file paths for file paths that are automatically excluded from generating policy alerts.

   - **File path groups**. To select a file path detection group that you have already created, select **Add file path group**, then select the appropriate file path groups. The number of file paths included in each group is listed in the **Included file paths** column.

6. Select **Save**.

Default file paths

By default, the system automatically excludes several file paths from generating policy alerts. Activities in these file paths are typically benign and could potentially increase the volume of non-actionable alerts. If needed, you can cancel the selection for these default file path exclusions to enable risk scoring for activities in these locations.

The default file path exclusions are:

- \Users*\AppData
- \Users*\AppData\Local
- \Users*\AppData\Roaming
- \Users*\AppData\Local\Temp

The wildcards in these paths denote that all folder levels between the \Users and \AppData are included in the exclusion. For example, activities in *C:\Users\Test1\AppData\Local* and *C:\Users\Test2\AppData\Local*, *C:\Users\Test3\AppData\Local* (and so on) are all included and not scored for risk as part of the *\Users*\AppData\Local* exclusion selection.

Configure a file type exclusion

You can exclude specific file types from all Insider Risk Management policy matching. For example, you might want to exclude all .wav files. Files with that extension are ignored for risk scoring by all Insider Risk Management policies.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.

2. Select **Settings** in the upper-right corner of the page, then select **Insider Risk Management** to go to the Insider Risk Management settings.

3. Under **Insider risk settings**, select **Global exclusions**.

4. In the **Type** panel to the right, select **File types**.

5. In the **File types** panel to the right, select one of the following tabs:

    - **Individual file types**. To add file types one at a time, select **Add file type**, enter a file type, and then press Enter. Repeat this process for each file type that you want to add. Each file type that you enter is added to the page.

- **File type groups**. To select a file type detection group that you have already created, select **Add File type group**, then select the appropriate file type groups from the list.

6. Select **Save**.

Configure a keyword exclusion

You can configure exclusions for keywords that appear in file names, file paths, or email message subject lines. This configuration provides flexibility for organizations that need to reduce potential alert frequency due to flagging of benign terms. Your Insider Risk Management policies ignore activities related to files or email subjects containing the keyword and don't generate alerts. You can exclude up to 500 keywords.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.

2. Select **Settings** in the upper-right corner of the page, then select **Insider Risk Management** to go to the Insider Risk Management settings.

3. Under **Insider risk settings**, select **Global exclusions**.

4. In the **Type** panel to the right, select **Keywords**.

5. In the **Keywords** panel to the right, select one of the following tabs:

   - **Individual keywords**. To add keywords one at a time, enter a keyword in the **Exclude these keywords** field, then press Enter. Repeat this process for each keyword that you want to add. To delete a keyword that you added to the list, select the *X* next to the keyword.

     > **Tip**
     >
     > If you want to exclude a keyword from scoring, but you want to score that keyword when it's used in combination with other keywords or a phrase, enter the keyword you want to exclude in the **Exclude these keywords** field, then enter the word or words that are part of the phrase that you do want to score in the **Exclude the above keywords only if these terms aren't also present** field. For example, if you add the keyword "compliance" to the **Exclude these keywords** field, but enter the keyword "training" in the **Exclude the above keywords only if**

these terms aren't also present field, the word "compliance" by itself is excluded from scoring, but the phrase "compliance training" is scored.

- **Keyword groups**. To select a keyword detection group that you already created, select **Add keyword group**, then select the appropriate keyword groups from the list. The number of keywords included in each group displays under the **Included keywords** heading.

6. Select **Save**.

Configure a sensitive info type (preview) exclusion

Excluded sensitive info types map to indicators and triggers involving file-related activities for Endpoint, SharePoint, Teams, OneDrive, and Exchange. The system treats these excluded types as non-sensitive info types. If a file contains any sensitive info type you identify in this section, the system risk scores the file but doesn't show activities involving content related to sensitive info types. For a complete list of sensitive info types, see Sensitive information type entity definitions.

You can select sensitive info types to exclude from the list of all available (out-of-box and custom) types available in your organization. You can choose up to 500 sensitive info types.

> **Note**
>
> The exclusion list of sensitive info types takes precedence over the **priority content** list.

Configure a sensitive info type exclusion

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.

2. Select **Settings** in the upper-right corner of the page, then select **Insider Risk Management** to go to the Insider Risk Management settings.

3. Under **Insider risk settings**, select **Global exclusions**.

4. In the **Type** panel to the right, select **Sensitive info types**.

5. In the **Sensitive info types** panel to the right, select one of the following tabs:

- **Individual sensitive info types**. To add sensitive info types one at a time, select **Add or edit sensitive info types to exclude**, select the sensitive info types you want to exclude, and then select **Add**. You can also use the search box to search for a sensitive info type.
- **SIT groups**. To select a sensitive info type detection group that you already created, select **Add sensitive info type group**, then select the appropriate groups from the list. The number of sensitive info types included in a sensitive info type group displays under the **Included sensitive info types** heading. Select **Save** when you're done.

Configure a Sharepoint site exclusion

You can configure SharePoint site exclusions to prevent activities that occur in SharePoint (and SharePoint sites associated with Teams channel sites) from generating policy alerts. For example, you might want to exclude sites or channels that contain non-sensitive files and data that you can share with stakeholders or the public. You can enter up to 500 SharePoint site URL paths.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.

2. Select **Settings** in the upper-right corner of the page, then select **Insider Risk Management** to go to the Insider Risk Management settings.

3. Under **Insider risk settings**, select **Global exclusions**.

4. In the **Type** panel to the right, select **SharePoint sites**.

5. In the **SharePoint sites** panel to the right, select one of the following tabs:

   - **Individual sites**. To add SharePoint sites one at a time, select **Add or edit sites to exclude**, select the sites you want to exclude, then select **Edit**. You can also use the search box to search for a site.
   - **Site groups**. To select a SharePoint site detection group that you already created, select **Add SharePoint site group**, then select the appropriate groups from the list. The number of sites included in a site group displays under the **Included sites** heading. Select **Save** when you're done.

Set up a trainable classifier (preview) exclusion

Excluded trainable classifiers map to indicators and triggers that involve file-related activities for SharePoint, Teams, OneDrive, and Exchange. If any file contains a trainable classifier identified as

an exclusion, the file is risk scored but not shown as activity involving content related to trainable classifiers. For a complete list of pre-trained classifiers, see Trainable classifiers definitions.

You can select trainable classifiers to exclude from the list of all available (out-of-box and custom) types in your organization. Insider Risk Management excludes some trainable classifiers by default, including Threat, Profanity, Targeted harassment, Offensive language, and Discrimination. You can choose up to 500 trainable classifiers.

> **Note**
>
> Optionally, you can choose trainable classifiers to include in the priority content list.

Configure a trainable classifier exclusion

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Select **Settings** in the upper-right corner of the page, then select **Insider Risk Management** to go to the Insider Risk Management settings.
3. Under **Insider risk settings**, select **Global exclusions**.
4. In the **Type** panel to the right, select **Trainable classifiers**.
5. In the **Trainable classifiers** panel to the right, select one of the following tabs:
   - **Individual trainable classifier**. To select trainable classifiers one at a time, select **Add or edit trainable classifiers to exclude**, select the appropriate trainable classifiers from the list, and then select **Add**. You can use the search box to search for a trainable classifier.
   - **Trainable classifier groups**. To select a trainable classifier detection group that you already created, select **Add trainable classifier group**, then select the appropriate groups from the list. The number of trainable classifiers included in a trainable classifier group displays under the **Included trainable classifiers** heading. Select **Save** when you're done.

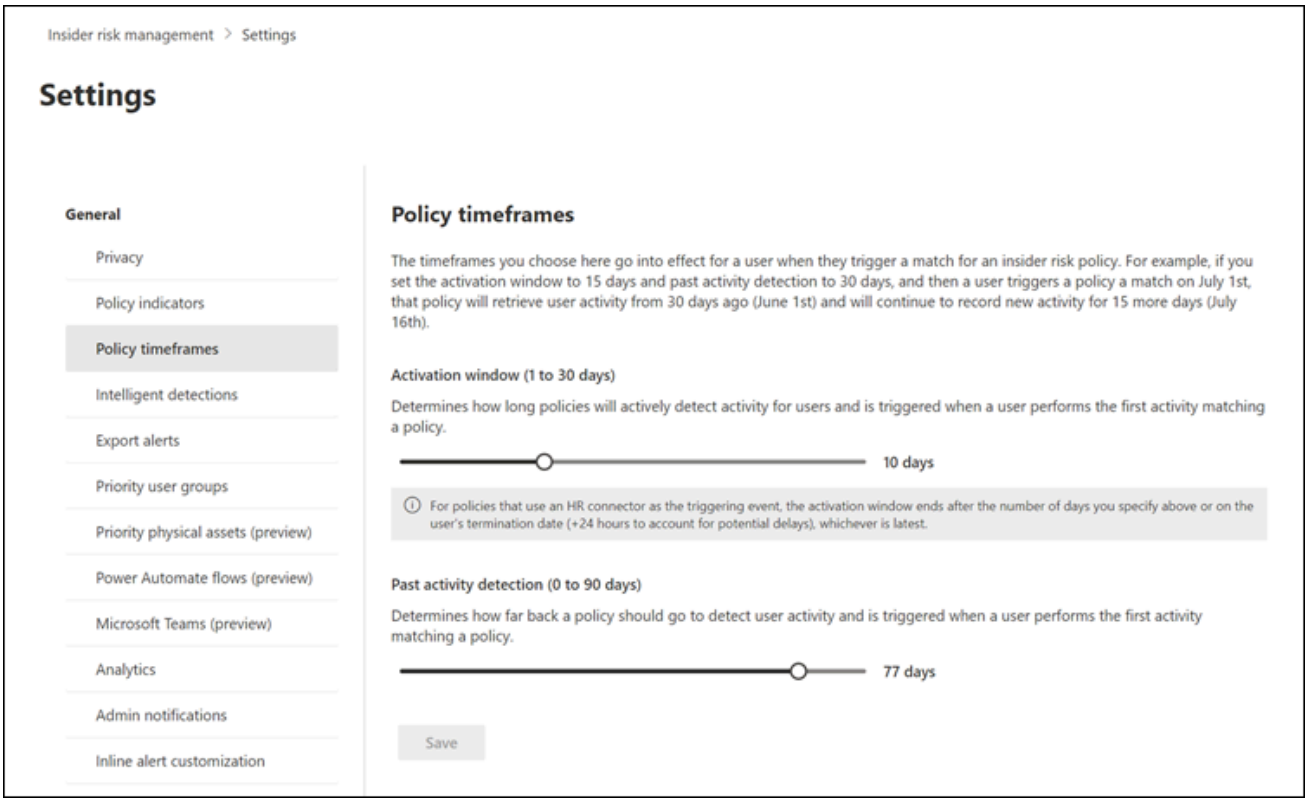
Set policy timeframes in Insider Risk Management

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Policy timeframes in Microsoft Purview Insider Risk Management let you set past and future review periods that start after policy matches events and activities for the Insider Risk Management policy templates. Depending on the policy template you choose, you can set the following policy timeframes:

- **Activation window**: Available for all policy templates, *Activation window* is the number of days that the window activates **after** a triggering event. The window activates for 1 to 30 days after a triggering event occurs for any user assigned to the policy. For example, you configure an Insider Risk Management policy and set *Activation window* to 30 days. Several months pass since you configured the policy, and a triggering event occurs for one of the users included in the policy. The triggering event activates *Activation window* and the policy is active for that user for 30 days after the triggering event occurred.



- **Past activity detection**: Available for all policy templates, *Past activity detection* is the number of days that the window activates **before** a triggering event. For activities in the audit log, the window activates for 0 to 90 days before a triggering event occurs for any user assigned to the policy. For example, you configure an Insider Risk Management policy and set *Past activity detection* to 90 days. Several months pass since you configured the policy, and a triggering event occurs for one of the users included in the policy. The triggering event activates *Past activity detection* and the policy gathers historic activities for that user for 90 days prior to the triggering event.

  > **Note**

For email activities, the past activity detection period is 10 days.

Configure policy timeframes

1. In Insider Risk Management settings, select **Policy timeframes**.
2. Move the slider for **Activation window** and **Past activity detection** to the number of days that you want.

Configure intelligent detections in Insider Risk Management

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

> **Note**
>
> Global exclusions settings that the **Intelligent detections** setting previously included now appear in the Global exclusions (preview) setting.

Use the **Intelligent detections** setting in Microsoft Purview Insider Risk Management to:

- Boost the score for unusual file download activities by entering a minimum number of daily events.
- Increase or decrease the volume and distribution of high, medium, and low alerts.
- Import and filter Defender for Endpoint alerts for activities used in policies created from Insider Risk Management templates.
- Specify unallowed domains to boost the risk score for potentially risky activity.
- Specify third-party domains to generate alerts for potentially risky download activity.

File activity detection

Use this section to specify the number of daily events required to boost the risk score for download activity that's unusual for a user. For example, if you enter "25", and a user downloads 10 files on average over the previous 30 days, but a policy detects that they downloaded 20 files on one day, the score for that activity doesn't get boosted even though it's unusual for that user because the number of files they downloaded that day is less than 25.

Configure alert volume levels

Insider risk policies assign a specific risk score to potentially risky activities they detect. This risk score determines the alert severity: low, medium, or high. By default, Insider Risk Management generates a certain number of low, medium, and high severity alerts. You can increase or decrease the volume of a specific level of alerts to suit your needs.

To adjust the volume of alerts for all Insider Risk Management policies, choose one of the following settings:

- **Fewer alerts**: You see all high-severity alerts, fewer medium-severity alerts, and no low-severity alerts. You might miss some true positives if you choose this setting.
- **Default volume**: You see all high-severity alerts and a balanced amount of medium-severity and low-severity alerts.
- **More alerts**: You see all medium-severity and high-severity alerts and most low-severity alerts. This setting might result in more false positives.

Microsoft Defender for Endpoint alert statuses

> **Important**
>
> To import security violation alerts, you must configure Microsoft Defender for Endpoint in your organization and enable Defender for Endpoint for Insider Risk Management integration in the Defender Security Center. For more information on configuring Defender for Endpoint for Insider Risk Management integration, see Configure advanced features in Defender for Endpoint.

Microsoft Defender for Endpoint is an enterprise endpoint security platform designed to help enterprise networks prevent, detect, investigate, and respond to advanced threats. To have better visibility of security violations in your organization, you can import and filter Defender for Endpoint alerts for activities used in policies created from Insider Risk Management security violation policy templates.

Depending on the types of signals you're interested in, you can choose to import alerts to Insider Risk Management based on the Defender for Endpoint alert triage status. You can define one or more of the following alert triage statuses in the global settings to import:

- Unknown
- New
- In progress
- Resolved

Alerts from Defender for Endpoint are imported daily. Depending on the triage status you choose, you might see multiple user activities for the same alert as the triage status changes in Defender for Endpoint.

For example, if you select *New*, *In progress*, and *Resolved* as the alert triage statuses to import, when a Microsoft Defender for Endpoint alert is generated and the status is *New*, an initial alert activity is imported for the user in Insider Risk Management. When the Defender for Endpoint triage status changes to *In progress*, a second activity for this alert is imported. When the final Defender for Endpoint triage status of *Resolved* is set, a third activity for this alert is imported. This functionality allows investigators to follow the progression of the Defender for Endpoint alerts and choose the level of visibility that their investigation requires.

Configure unallowed and third-party domains

To boost your detections, specify unallowed and third-party domains:

- **Unallowed domains:** When you specify an unallowed domain, risk management activity that takes place with that domain has a higher risk score. Optionally, use it as a setting in policy triggers. For example, you might want to specify activities that involve sharing content with someone (such as sending email to someone with a gmail.com address) or activities that involve users downloading content to a device from an unallowed domain. You can add up to 500 unallowed domains.
- **Third-party domains:** If your organization uses third-party domains for business purposes (such as cloud storage), include them in the **Third-party domains** section to receive alerts for potentially risky activity related to the device indicator *Use a browser to download content from a third-party site*. You can add up to 500 third-party domains.

> **Tip**
>
> You can also specify domains to exclude from being scored by Insider Risk Management policies.

Add an unallowed domain

To add an unallowed domain to the Intelligent detections settings, perform the following steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.

2. Select **Settings** in the upper-right corner of the page, and then select **Insider Risk Management** to go to the Insider Risk Management settings.
3. Under **Insider risk settings**, select **Intelligent detections**.
4. Scroll down to the **Unallowed domains** section, and then select **Add domains**.
5. Enter a domain.

   > **Tip**
   >
   > To add multiple domains at once, import them as a CSV file by selecting **Import domains from CSV file** on the previous page.

6. To include all subdomains within the domain you entered, select the **Include multi-level subdomains** checkbox.

   > **Note**
   >
   > Use wildcards to help match variations of root domains or subdomains. For example, to specify sales.wingtiptoys.com and support.wingtiptoys.com, use the wildcard entry "*.wingtiptoys.com" to match these subdomains (and any other subdomain at the same level). To specify multi-level subdomains for a root domain, select the **Include multi-level subdomains** checkbox.

7. Press Enter. Repeat steps 5 and 6 for each additional domain that you want to add.
8. Select **Add domains**.

Add a third-party domain

To add a third-party domain to the Intelligent detections settings, perform the following steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Select **Settings** in the upper-right corner of the page, and then select **Insider Risk Management** to go to the Insider Risk Management settings.
3. Under **Insider risk settings**, select **Intelligent detections**.

4. Scroll down to the **Third-party domains** section, and then select **Add domains**.

5. Enter a domain.

   > **Tip**
   >
   > To add multiple domains at once, import them as a CSV file by selecting **Import domains from CSV file** on the previous page.

6. To include all subdomains within the domain you entered, select the **Include multi-level subdomains** checkbox.

   > **Note**
   >
   > Use wildcards to help match variations of root domains or subdomains. For example, to specify sales.wingtiptoys.com and support.wingtiptoys.com, use the wildcard entry "*.wingtiptoys.com" to match these subdomains (and any other subdomain at the same level). To specify multi-level subdomains for a root domain, select the **Include multi-level subdomains** checkbox.

7. Press Enter. Repeat steps 5 and 6 for each additional domain that you want to add.

8. Select **Add domains**.

Share Insider Risk Management data with other solutions

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

You can share data from Insider Risk Management in the following ways:

- Export alert information to SIEM solutions.
- Share alerts and user risk severity levels with Microsoft Defender XDR.
- Share user risk severity levels with data loss prevention (DLP) alerts.

Export alert information to SIEM solutions

You can export Microsoft Purview Insider Risk Management alert information to security information and event management (SIEM) and security orchestration automated response (SOAR) solutions by using the Office 365 Management Activity API schema. Use the Office 365 Management Activity APIs to export alert information to other applications your organization uses to manage or aggregate insider risk information. Alert information is exported and available every 60 minutes through the Office 365 Management Activity APIs.

>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

If your organization uses Microsoft Sentinel, you can also use the out-of-the-box Insider Risk Management data connector to import insider risk alert information to Microsoft Sentinel. For more information, see Insider Risk Management in the Microsoft Sentinel article.

> **Important**
>
> To maintain referential integrity for users who have insider risk alerts or cases in Microsoft 365 or other systems, anonymization of usernames isn't preserved for exported alerts when using the exporting API or when exporting to Microsoft Purview eDiscovery solutions. Exported alerts display usernames for each alert in this case. If you export to CSV files from alerts or cases, anonymization *is* preserved.

Use the APIs to review insider risk alert information

Use the following steps to enable alert export by using the APIs:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Select **Settings** in the upper-right corner of the page.
3. Select **Insider Risk Management** to go to the Insider Risk Management settings.
4. Select **Export alerts**. By default, this setting is disabled for your Microsoft 365 organization.
5. Turn the setting **On**.
6. Filter the common Office 365 audit activities by *SecurityComplianceAlerts*.
7. Filter *SecurityComplianceAlerts* by the *InsiderRiskManagement* category.

Alert information contains information from the Office 365 Management Activity API Security and Compliance Alerts schema and common schema. The following fields and values are exported for Insider Risk Management alerts for the common schema:

- CreationTime
- ID
- Operation
- OrganizationId
- RecordType
- UserId
- UserKey
- UserType

Share alert severity levels with other Microsoft security solutions

You can share alert severity levels from Insider Risk Management to bring unique user context to alert investigation experiences in the following Microsoft security solutions:

- Microsoft Defender XDR
- Microsoft Purview Communication Compliance
- Microsoft Purview Data Loss Prevention (DLP)

Insider Risk Management analyzes user activities over a period of 90 to 120 days and looks for anomalous behavior over that period. Adding this data to other security solutions enhances the data available in those solutions to help analysts prioritize alerts.

> **Tip**
>
> *Alert severity levels* in Insider Risk Management are different from *insider risk levels* that are defined in Adaptive Protection.
>
> - Alert severity levels (Low, Medium, or High) are assigned to users based on activity detected in Insider Risk Management policies. The system calculates these levels from alert risk scores assigned to all active alerts associated with the user. These levels help insider risk analysts and investigators prioritize and respond to user activity accordingly.
> - Insider risk levels (Elevated, Moderate, or Minor) in Adaptive Protection measure risk determined by admin-defined conditions such as the number of exfiltration activities users perform in a day or whether their activity generated a high-severity insider risk alert.

Prerequisites

To share Insider Risk Management user risk levels with other Microsoft security solutions, the user must meet the following conditions:

- Be part of an Insider Risk Management policy.
- Perform exfiltration activities that bring the user into the scope of the policy.
- **For sharing with DLP**: Have DLP alert permissions. After the **Data sharing** setting is turned on, users with DLP alert permissions can access Insider Risk Management context for DLP alert investigation and for the Microsoft Defender XDR Users page. Users with Insider Risk Management permissions can also access this data.
- **For sharing with Communication Compliance**: Be assigned either the *Communication Compliance Analyst* or *Communication Compliance Investigator* roles to view user risk

severity levels and activity history in Communication Compliance.

> **Tip**
>
> If you have access to DLP alerts in Microsoft Purview and/or Microsoft Defender, you can view user context from Insider Risk Management shared with those solutions.

Share data with other Microsoft security solutions

You can share Insider Risk Management alert severity levels with other Microsoft security solutions by turning on a single setting.

1. In Insider Risk Management settings, select the **Data sharing** setting.
2. Under the **Sharing data with other Microsoft security solutions** section, turn on the setting.

> **Note**
>
> If you don't turn on this setting, the value displayed in the DLP alerts **Insider risk severity** column is "User data isn't available" and is displayed as "Insider Risk Activity not available" in Communication Compliance.

What happens when you share Insider Risk Management alert severity levels?

When you turn on data sharing, Insider Risk Management severity information becomes available in the following Microsoft security experiences:

In Microsoft Defender XDR

Sharing alert data in the Microsoft Defender portal is vital for protecting your organization's sensitive information and maintaining security. Security operations center (SOC) analysts can:

- Investigate Insider Risk Management alerts in the Microsoft Defender alert queue.
- Investigate Insider Risk Management alerts correlated with alerts from other detection sources such as Data Loss Prevention, Microsoft Defender for Identity, Microsoft Defender for Office, and more in the Microsoft Defender XDR incident queue.
- Run Advanced Hunting queries on two new tables containing Insider Risk Management alert data.
- Export rich Insider Risk Management alert data through Microsoft Graph API.

- View Insider Risk Management severity for a user during your alert triage. An **Insider risk severity** field is added to the **Users** page for users that have a **High**, **Medium**, or **Low** risk level in Insider Risk Management. This data is available for any users with an active Insider Risk Management alert. An insider risk activity summary and activity timeline for that user appears on the right side of the **Users** page.

Migrating from Office 365 management activity APIs to Microsoft Graph APIs

You can access Insider Risk Management alert metadata through Office 365 management activity API. However, Graph API provides richer metadata and bi-directional support. We recommend migrating to Graph API to integrate Insider Risk Management data with your enterprise systems.

The following table summarizes the most common Office 365 management activity API parameters and the equivalent Microsoft Graph API parameter:

Expand table

Office 365 management activity API parameter	Microsoft Graph API parameter
Alert parameter	No equivalent parameter
AlertId	ID
Category	ServiceSource
Comments	No equivalent parameter
Data	Evidence.useraccount.userPrincipalName(along with suffix)
Name	AlertPolicyName
PolicyId	AlertPolicyId
Severity	Severity
Source	DetectionSource
Status	Status
Version	No equivalent parameter

For detailed schema mapping, see the Defender XDR schema in the Office 365 management activity API and Microsoft Graph API.

Integrating Insider Risk Management with ServiceNow Security Operations

ServiceNow provides integrations to connect with Microsoft security technologies using Microsoft Graph. These solutions include Microsoft Sentinel, Microsoft Defender Advanced Threat Protection, and Azure Advanced Threat Protection. The ServiceNow Microsoft Graph integration allows you to access valuable insights from Microsoft products and helps you efficiently manage and respond to security incidents centrally using the ServiceNow platform. Insider Risk Management alert data is accessed outside the Microsoft Purview environment through the Microsoft Graph security API.

To share Insider Risk Management alert data with ServiceNow, complete the following steps:

1. Get the Microsoft Graph Security API Alert Ingestion Integration For Security Operations
2. Follow the ServiceNow documentation to set up or create a profile for the Microsoft Graph Security API alert ingestion integration.

For more information, see Investigate insider risk threats in the Microsoft Defender portal.

In Communication Compliance alerts

For every Communication Compliance policy match, you can view the user risk severity associated with the sender. View this information on the **User activity** tab in communication for the alert. This view provides risk profile, policy matches, and user activities captured by Insider Risk Management and Communication Compliance.

The severity levels are categorized as *High*, *Medium*, *Low*, or *None*.

For risk severity levels of *None*, the reason might be for any of the following scenarios:

- The user isn't included in an insider risk policy.
- The user's activities aren't assigned a risk score, meaning the user isn't in the active scope for the policy.
- The user is included in an Insider Risk Management policy, but didn't engage in any risky activity.
- The organization doesn't have an active Insider Risk Management policy.

If the user risk severity isn't available, data sharing isn't enabled from Insider Risk Management.

You can view insider risk activities for up to 120 days in the **View Details** section on the **User history** tab in Insider Risk Management. Currently, the user activity summary in Communication Compliance shows only data from exfiltration indicators.

In DLP alerts

In DLP alerts, shared Insider Risk Management data appears in the following ways:

- For the Insider Risk Management policy associated with the DLP alert, the DLP alerts queue includes an **Insider risk severity** column with values of *High*, *Medium*, *Low*, or *None*. If multiple users have activities that match the policy, the queue displays the user with the highest insider risk level.

  A value of **None** can mean either of the following:

  - The user isn't part of any Insider Risk Management policy.
  - The user is part of an Insider Risk Management policy, but they didn't perform risky activities that bring them into the scope of the policy (there's no exfiltration data).

- You can select the insider risk level in the DLP alerts queue to access the **User activity summary** tab, which shows a timeline of all exfiltration activities for that user for the past 90-120 days. Like the DLP alerts queue, the **User activity summary** tab shows the user with the highest insider risk level. This deep context into what a user did over the past 90 to 120 days provides a wider view of the risks presented by that user.

  Only data from exfiltration indicators appear in the user activity summary. Data from other sensitive indicators, such as HR, browsing, and so on, don't share with DLP alerts.

- An **Actor details** section is added to the DLP Alert details page. You can use this page to see *all* users involved in the specific DLP alert. For each user involved in the DLP alert, you can view all the exfiltration activities for the past 90 to 120 days.

- If you select **Get a summary from Security Copilot** in a DLP alert, the alert summary provided by Microsoft Security Copilot includes the Insider Risk Management severity level in addition to the DLP summary info, if the user is in scope of an Insider Risk Management policy.

  > **Tip**
  >
  > You can also use Security Copilot to investigate DLP alerts. If the Insider Risk Management **Data sharing** setting is turned on, you can then do a combined DLP/Insider Risk Management investigation. For example, you might want to start by asking Copilot to summarize a DLP alert, then ask Copilot to show the insider risk level associated with the user flagged in the alert. Or you might want to ask why the user is

considered a high-risk user. The user risk information in this case comes from Insider Risk Management. Security Copilot seamlessly integrates Insider Risk Management with DLP to assist with investigations. **Learn more about using the standalone version of Copilot for combined DLP/Insider Risk Management investigations**.

Prioritize user groups for Insider Risk Management policies

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Users in your organization might have different levels of risk depending on their position, level of access to sensitive information, or risk history. Prioritizing the examination and scoring of the activities of these users can help alert you to potential risks that might have higher consequences for your organization. Priority user groups in Microsoft Purview Insider Risk Management help define the users in your organization that need closer inspection and more sensitive risk scoring. Coupled with the *Security policy violations by priority users* and *Data leaks by priority users* policy templates, users you add to a priority user group have an increased likelihood of insider risk alerts and alerts with higher severity levels.

Instead of being open to review by all analysts and investigators, you might need to restrict review activities for priority user groups to specific users or insider risk role groups. You can assign individual users and role groups to review users, alerts, cases, and reports for each priority user group. You can assign review permissions for priority user groups to the built-in *Insider Risk Management*, *Insider Risk Management Analysts*, and *Insider Risk Management Investigators* role groups, one or more of these role groups, or to a custom selection of users.

For example, you need to protect against data leaks for a highly confidential project where users have access to sensitive information. You choose to create the *Confidential Project Users* priority user group for users in your organization that work on this project. Also, you don't want all the default Insider Risk Management admins, analysts, and investigators to see users, alerts, cases, and reports associated with this priority user group. In settings, you create the *Confidential Project Users* priority user group and assign two users as reviewers that can view data related to the group. Use the policy workflow and the *Data leaks by priority users* policy template to create a new policy and assign the *Confidential Project Users* priority users group to the policy. Activities examined by the policy for members of the *Confidential Project Users* priority user group are more sensitive to risk and activities by these users are more likely to generate alerts and have alerts with higher severity levels.

Create a priority user group

You must be a member of the *Insider Risk Management* or *Insider Risk Management Admins* role group to create a priority user group.

1. Sign in to the Microsoft Purview portal as a member of the *Insider Risk Management* or *Insider Risk Management Admins* role group.
2. Select **Settings** in the upper-right corner of the page.
3. Select **Insider Risk Management** to go to the Insider Risk Management settings.
4. Select **Priority user groups**.
5. On the **Priority user groups** page, select **Create priority user group** to start the group creation workflow.
6. On the **Name and describe the priority user group** page, complete the following fields:
   - **Name (required)**: Enter a friendly name for the priority user group. You can't change the name of the priority user group after you complete the workflow.
   - **Description (optional)**: Enter a description for the priority user group.
7. Select **Next** to continue.
8. On the **Choose members** page, select **Choose members** to search and select which mail-enabled user accounts are included in the group or select the **Select all** checkbox to add all users in your organization to the group. Select **Add** to continue.

   > **Note**
   >
   > You can add up to 10,000 users to a priority user group.

9. Select **Upload** to add members by uploading a CSV file if needed. The .csv file must have a column titled *user principal name* with the list of users you want to add.
10. Select **Next** to continue.
11. On the **Choose who can view this group** page, you must define who can review users, alerts, cases, and reports for the priority user group. Assign at least one user or Insider Risk Management role group. Select **Choose users and role groups**, and then select the users or Insider Risk Management role groups you want to assign to the priority user group. Select **Add** to assign the selected users or role groups to the group.

12. Select **Next** to continue.
13. On the **Review** page, review the settings you chose for the priority user group. Select the **Edit** links to change any of the group values or select **Submit** to create and activate the priority user group.
14. On the confirmation page, select **Done**.

Update a priority user group

To update a priority user group, you must be a member of the *Insider Risk Management* or *Insider Risk Management Admins* role group.

1. Sign in to the Microsoft Purview portal as a member of the *Insider Risk Management* or *Insider Risk Management Admins* role group.
2. Select **Settings** in the upper-right corner of the page.
3. Select **Insider Risk Management** to go to the Insider Risk Management settings.
4. Select **Priority user groups**.
5. Select the priority user group you want to edit, then select **Edit group**.
6. On the **Name and describe** page, update the **Description** field if needed. You can't update the name of the priority user group. Select **Next** to continue.
7. On the **Choose members** page, add new members to the group using the **Choose members** control. To remove a user from the group, select the 'X' next to the user you want to remove. Select **Next** to continue.
8. On the **Choose who can view this group** page, add or remove users or role groups that can review users, alerts, cases, and reports for the priority user group.
9. Select **Next** to continue.
10. On the **Review** page, review the update settings for the priority user group. Select the **Edit** links to change any of the group values or select **Submit** to update the priority user group.
11. On the confirmation page, select **Done**.

Delete a priority user group

> **Important**
>
> Deleting a priority user group removes it from any active policy to which it's assigned. If you delete a priority user group that an active policy uses, the policy has no included users. The policy is idle and doesn't create alerts.

To delete a priority user group, you must be a member of the *Insider Risk Management* or *Insider Risk Management Admin* role group.

1. Sign in to the Microsoft Purview portal as a member of the *Insider Risk Management* or *Insider Risk Management Admin* role group.
2. Select **Settings** in the upper-right corner of the page.
3. Select **Insider Risk Management** to go to the Insider Risk Management settings.
4. Select **Priority user groups**.
5. Select the priority user group you want to delete, then select **Delete**.
6. In the **Delete** dialog box, select **Yes**.

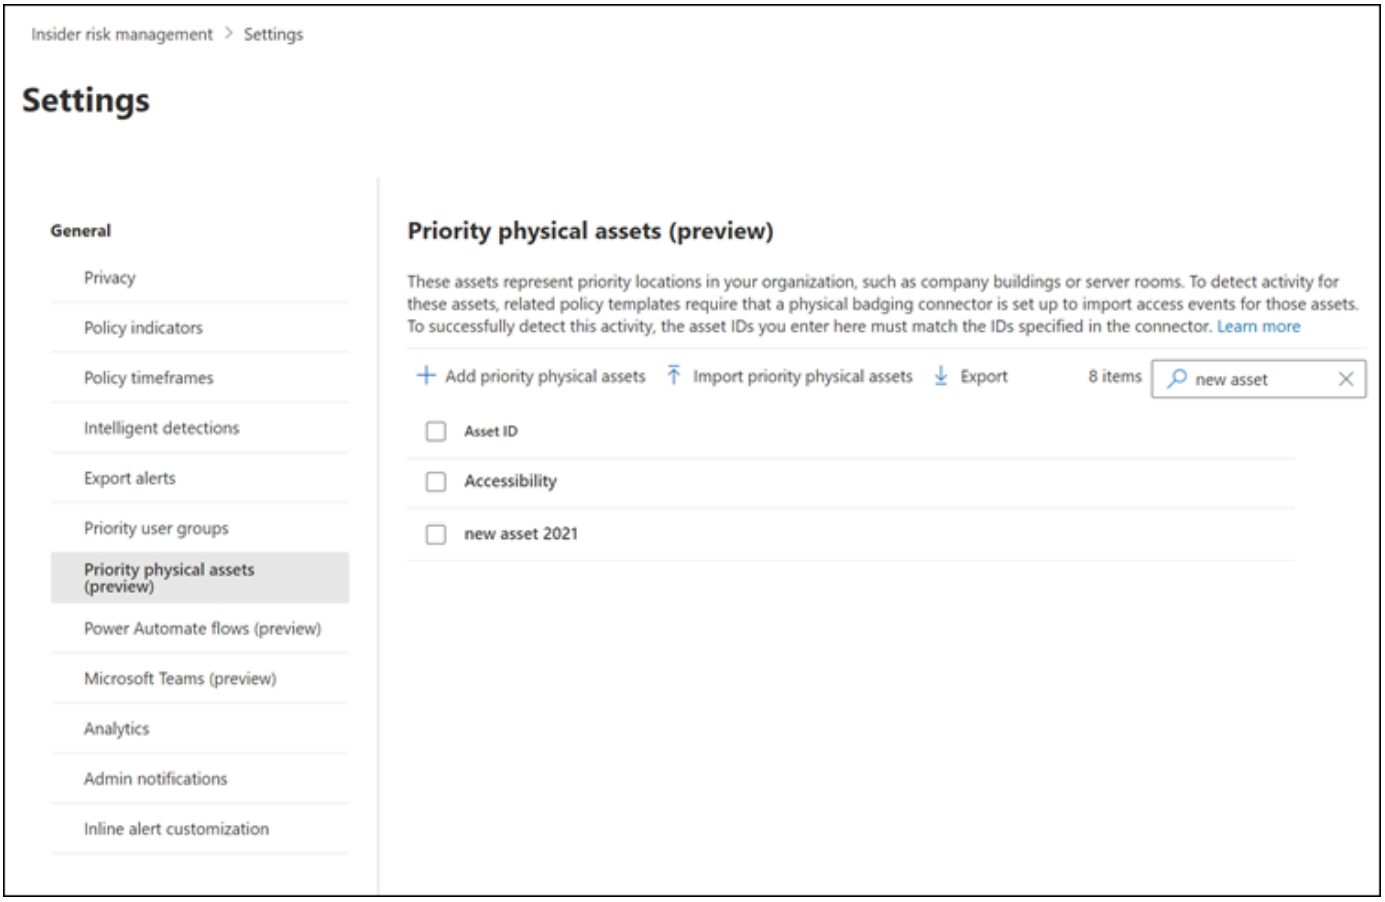
Identify priority physical assets for Insider Risk Management policies

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.



Identifying access to priority physical assets and correlating access activity to user events is an important component of your Microsoft Purview Insider Risk Management compliance infrastructure. These physical assets represent priority locations in your organization, such as company buildings, data centers, or server rooms. Insider risk activities might be associated with users working unusual hours, attempting to access unauthorized sensitive or secure areas, and requests for access to high-level areas without legitimate needs.

When you enable priority physical assets and configure the Physical badging data connector, Insider Risk Management integrates signals from your physical control and access systems with other user risk activities. By examining patterns of behavior across physical access systems and correlating these activities with other insider risk events, Insider Risk Management helps compliance investigators and analysts make more informed response decisions for alerts.

Insider Risk Management scores and identifies access to priority physical assets in insights differently from access to non-priority assets. For example, your organization has a badging system for users that governs and approves physical access to normal working and sensitive project areas. You have several users working on a sensitive project and these users return to other areas of your organization when the project is completed. As the sensitive project nears completion, you want to make sure that the project work remains confidential and that access to the project areas is tightly controlled.

You enable the Physical badging data connector in Microsoft 365 to import access information from your physical badging system and specify priority physical assets in Insider Risk Management. By importing information from your badging system and correlating physical access information with other risk activities identified in Insider Risk Management, you notice that

one of the users on the project is accessing the project offices after normal working hours and is also exporting large amounts of data to a personal cloud storage service from their normal work area. This physical access activity associated with the online activity might point to possible data theft and compliance investigators and analysts can take appropriate actions as dictated by the circumstances for this user.

Configure priority physical assets

To configure priority physical assets, configure the Physical badging connector and use setting controls in the Insider Risk Management solution. To configure priority physical assets, you must be a member of the *Insider Risk Management* or *Insider Risk Management Admin* role group.

> **Important**
>
> For Insider Risk Management policies to use and correlate signal data related to departing and terminated users with event data from your physical control and access platforms, also configure the Microsoft 365 HR connector. If you enable the Physical badging connector without enabling the Microsoft 365 HR connector, Insider Risk Management policies only process events for physical access activities for users in your organization.

1. Follow the configuration steps for Insider Risk Management in the Getting started with Insider Risk Management article. In Step 3, make sure to configure the Physical badging connector.

2. Sign in to the Microsoft Purview portal using credentials for an admin account in your Microsoft 365 organization, select **Settings** in the upper-right corner of the page, and select **Insider Risk Management** to open the Insider Risk Management settings. Select **Priority physical assets**.

3. On the **Priority physical assets** page, you can either manually add the physical asset IDs imported by the Physical badging connector or import a CSV file of all physical asset IDs imported by the Physical badging connector:
   a. To manually add physical asset IDs, choose **Add priority physical assets**, enter a physical asset ID, and then select **Add**. Enter other physical asset IDs, then select **Add priority physical assets** to save all the assets you entered.
   b. To add a list of physical asset IDs from a CSV file, choose **Import priority physical assets**. In the file explorer dialog box, select the CSV file you want to import, then select **Open**. The physical asset IDs from the CSV files are added to the list.

4. In settings, select **Policy indicators**.

5. On the **Policy indicators** page, go to the **Physical access indicators** section, then select the **Physical access after termination or failed access to sensitive asset** check box.

6. Select **Save**.

Delete a priority physical asset

To delete a priority physical asset, you must be a member of the *Insider Risk Management* or *Insider Risk Management Admins* role group.

> **Important**
>
> When you delete a priority physical asset, you remove it from examination by any active policy that includes it. However, alerts generated by activities associated with the priority physical asset aren't deleted.

1. Sign in to the Microsoft Purview portal as a member of the *Insider Risk Management* or *Insider Risk Management Admins* role group.
2. Select **Settings** in the upper-right corner of the page.

3. Select **Insider Risk Management** to go to the Insider Risk Management settings.
4. Select **Priority physical assets**.
5. On the **Priority physical assets** page, select the asset you want to delete.
6. Select **Delete**.

Automate Insider Risk Management actions with Microsoft Power Automate flows

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Microsoft Power Automate is a workflow service that automates actions across applications and services. By using flows from templates or created manually, you can automate common tasks associated with these applications and services. When you enable Power Automate flows for Microsoft Purview Insider Risk Management, you can automate important tasks for cases and users. You can configure Power Automate flows to retrieve user, alert, and case information and share this information with stakeholders and other applications, as well as automate actions in Insider Risk Management, such as posting to case notes. Power Automate flows are applicable for cases and any user in scope for a policy.

Customers with Microsoft 365 subscriptions that include Insider Risk Management don't need extra Power Automate licenses to use the recommended Insider Risk Management Power Automate templates. These templates can be customized to support your organization and cover core Insider Risk Management scenarios. If you choose to use premium Power Automate features in these templates, create a custom template by using the Microsoft Purview connector, or use Power Automate templates for other compliance areas in Microsoft 365, you might need more Power Automate licenses.

The following Power Automate templates support process automation for Microsoft Purview Insider Risk Management users and cases:

- **Notify users when they're added to an insider risk policy**: Use this template if your organization has internal policies, privacy requirements, or regulatory requirements that users must be notified when they're subject to Microsoft Purview Insider Risk Management policies. When you configure this flow and select it for a user, the user and their manager receive an email message when the user is added to a Microsoft Purview Insider Risk

Management policy. This template also supports updating a SharePoint list hosted on a SharePoint site to detect notification message details like date/time and the message recipient. If you choose to anonymize users through the **Privacy** setting, flows created from this template don't function as intended so that user privacy is maintained.

Power Automate flows using this template are available on the **Users dashboard**.

- **Request information from HR or business about a user in an insider risk case**: When acting on a case, insider risk analysts and investigators might need to consult with HR or other stakeholders to understand the context of the case activities. When you configure this flow and select it for a case, analysts and investigators send an email message to HR and business stakeholders configured for this flow. Each recipient receives a message with preconfigured or customizable response options. When recipients select a response option, the response is recorded as a case note and includes recipient and date/time information. If you choose to anonymize users through the **Privacy** setting, flows created from this template don't function as intended so that user privacy is maintained.

  Power Automate flows using this template are available on the **Cases dashboard**.

- **Notify manager when a user has an insider risk alert**: Some organizations might need to have immediate management notification when a user has a Microsoft Purview Insider Risk Management alert. When you configure and select this flow, the manager for the case user receives an email message with the following information about all case alerts:
  - Applicable policy for the alert
  - Date/time of the alert
  - Severity level of the alert

  The flow automatically updates the case notes that the message was sent and that the flow was activated. If you choose to anonymize users through the **Privacy** setting, flows created from this template don't function as intended so that user privacy is maintained.

  Power Automate flows using this template are available on the **Cases dashboard**.

- **Create record for insider risk case in ServiceNow**: Use this template if your organization wants to use their ServiceNow solution to keep track of Microsoft Purview Insider Risk Management cases. When in a case, insider risk analysts and investigators can create a record for the case in ServiceNow. You can customize this template to populate selected fields in ServiceNow based on your organization's requirements. For more information on available ServiceNow fields, see the ServiceNow Connector reference article.

Power Automate flows using this template are available on the **Cases dashboard**.

Create a Power Automate flow from an Insider Risk Management template

> **Important**
>
> Currently, only Power Automate flows that you create in the default environment work with Insider Risk Management.

To create a Power Automate flow in the settings area, you must be a member of the *Insider Risk Management* or *Insider Risk Management Admins* role group. To create a Power Automate flow with the **Manage Power Automate flows** option, you must be a member of at least one Insider Risk Management role group.

1. Perform one of the following actions:

   - Sign in to the Microsoft Purview portal, select **Settings** in the upper-right corner of the page, select **Insider Risk Management** to go to the Insider Risk Management settings, then select **Power Automate flows**.
   - In the **Cases dashboard** or the **Users dashboard**, select **Automate** > **Manage Power Automate flows**.

2. On the **Power Automate flows** page, select a recommended template from the **Insider Risk Management templates you may like** section.
3. Review the flow's embedded connections and check their statuses. If needed, update any connections that aren't displayed as available, then select **Continue**.
4. By default, the recommended flows come pre-configured with the recommended Insider Risk Management and Microsoft 365 service data fields required to complete the assigned task for the flow. If needed, customize the flow components by using the **Show advanced options** control and configuring the available properties for the flow component.
5. If needed, add any other steps to the flow by selecting **New step**. In most cases, you shouldn't need to add steps for the recommended default templates.
6. Select **Save draft** to save the flow for further configuration or select **Save** to complete the configuration for the flow.
7. Select **Close** to return to the **Power Automate flows** page. The new template appears as a flow on the **My flows** tabs and is automatically available from the **Automate** dropdown control when working with Insider Risk Management cases for the user creating the flow.

> **Important**
>
> To give other users in your organization access to the flow, you must share the flow.

Create a custom Power Automate flow for Insider Risk Management

> **Important**
>
> Currently, only Power Automate flows that you create in the default environment work with Insider Risk Management.

Some processes and workflows for your organization might be outside the recommended Insider Risk Management flow templates. In these cases, you might need to create custom Power Automate flows for Insider Risk Management areas. Power Automate flows are flexible and support extensive customization, but they have required steps to integrate with Insider Risk Management features.

To create a custom Power Automate template for Insider Risk Management:

1. **Check your Power Automate flow license**: To create customized Power Automate flows that use Insider Risk Management triggers, you need a Power Automate license. The recommended Insider Risk Management flow templates don't require extra licensing and are included as part of your Insider Risk Management license.
2. **Create an automated flow**: Create a flow that performs one or more tasks after it's triggered by an Insider Risk Management event. For details on how to create an automated flow, see Create a flow in Power Automate.
3. **Select the Microsoft Purview connector**: Search for and select the Microsoft Purview connector. This connector enables Insider Risk Management triggers and actions. For more information on connectors, see the Connector reference overview article.
4. **Choose Insider Risk Management triggers for your flow**: Insider Risk Management has two triggers available for custom Power Automate flows:

    - **For a selected Insider Risk Management case**: You can select flows with this trigger from the Insider Risk Management **Cases dashboard**.
    - **For a selected Insider Risk Management user**: You can select flows with this trigger from the Insider Risk Management **Users dashboard**.

5. **Choose Insider Risk Management actions for your flow:** You can choose from several actions for Insider Risk Management to include in your custom flow:

    - Get Insider Risk Management alert
    - Get Insider Risk Management case
    - Get Insider Risk Management user
    - Get Insider Risk Management alerts for a case
    - Add Insider Risk Management case note

Share a Power Automate flow with other users

By default, only the creator can access Power Automate flows they create. For other Insider Risk Management users to access and use a flow, the flow creator must share it. To share a flow, use the settings controls in the Insider Risk Management solution or the **Manage Power Automate flows** option from the **Automate** control when working directly in the **Cases dashboard** or **Users dashboard**. After you share a flow, everyone you share it with can access the flow in the **Automate** control dropdown in the **Cases dashboard** and **Users dashboard**.

To share a Power Automate flow in the settings area, you must be a member of the *Insider Risk Management* or *Insider Risk Management Admins* role group. To share a Power Automate flow with the **Manage Power Automate flows** option, you must be a member of at least one Insider Risk Management role group.

Share a Power Automate flow

1. Perform one of the following actions:

    - Sign in to the Microsoft Purview portal, select **Settings** in the upper-right corner of the page, select **Insider Risk Management** to go to the Insider Risk Management settings, then select **Power Automate flows**.
    - In the **Cases dashboard** or the **Users dashboard**, select **Automate** > **Manage Power Automate flows**.

2. On the **Power Automate flows** page, select the **My flows** or **Team flows** tab.
3. Select the flow to share, then select **Share** from the flow options menu.
4. On the flow sharing page, enter the name of the user or group you want to add as an owner for the flow.
5. In the **Connection Used** dialog box, select **OK** to acknowledge that the added user or group has full access to the flow.

Edit a Power Automate flow

To edit a Power Automate flow in the settings area, you must be a member of the *Insider Risk Management* or *Insider Risk Management Admins* role group. To edit a Power Automate flow with the **Manage Power Automate flows** option, you must be a member of at least one Insider Risk Management role group.

1. Perform one of the following actions:

    - Sign in to the Microsoft Purview portal, select **Settings** in the upper-right corner of the page, select **Insider Risk Management** to go to the Insider Risk Management settings, then select **Power Automate flows (preview)**.
    - In the **Cases dashboard** or the **Users dashboard**, select **Automate** > **Manage Power Automate flows**.

2. On the **Power Automate flows** page, select a flow to edit, then select **Edit** from the flow control menu.
3. Select **ellipsis** > **Settings** to change a flow component setting or **ellipsis** > **Delete** to delete a flow component.
4. Select **Save**, then select **Close** to complete editing the flow.

Delete a Power Automate flow

> **Note**
>
> When you delete a flow, you remove it as an option for all users.

To delete a Power Automate flow in the settings area, you must be a member of the *Insider Risk Management* or *Insider Risk Management Admins* role group. To delete a Power Automate flow with the **Manage Power Automate flows** option, you must be a member of at least one Insider Risk Management role group.

1. Perform one of the following actions:

    - Sign in to the Microsoft Purview portal, select **Settings** in the upper-right corner of the page, select **Insider Risk Management** to go to the Insider Risk Management settings, then select **Power Automate flows**.
    - In the **Cases dashboard** or the **Users dashboard**, select **Automate** > **Manage Power Automate flows**.

2. On the **Power Automate flows** page, select a flow to delete, then select **Delete** from the flow control menu.
3. In the deletion confirmation dialog box, select **Delete**.

Enable Microsoft Teams for collaborating on Insider Risk Management cases

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Compliance analysts and investigators can use Microsoft Teams to collaborate on Microsoft Purview Insider Risk Management cases. They can communicate with other stakeholders on Teams to:

- Coordinate and review response activities for cases in private Teams channels
- Securely share and store files and evidence related to individual cases
- Detect and review response activities by analysts and investigators

When you enable Teams for Insider Risk Management, the solution creates a dedicated team every time you confirm an alert and create a case. By default, the team automatically includes all members of the *Insider Risk Management*, *Insider Risk Management Analysts*, and *Insider Risk Management Investigators* role groups (up to 100 initial users). You can add additional organization contributors to the team after it's created and as appropriate.

For existing cases created before enabling Teams, analysts and investigators can choose to create a new team when working on a case, if needed. When you resolve the Insider Risk Management case linked to that team, the solution automatically archives the team (moves to hidden and read-only).

Learn more: Overview of teams and channels in Microsoft Teams.

Enable Teams support

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Select **Settings** in the upper-right corner of the page.

3. Select **Insider Risk Management** to go to the Insider Risk Management settings.
4. Select **Microsoft Teams (preview)**.
5. Turn the setting on.
6. Select **Save**.

Create a team for existing cases

If you enable Teams support for Insider Risk Management after you have existing cases, you need to manually create a team for each case, as needed. Users need permission to create Microsoft 365 Groups in your organization to create a team from a case. For more information about managing permissions for Microsoft 365 Groups, see Manage who can create Microsoft 365 Groups.

> **Note**
>
> After enabling Teams support in Insider Risk Management settings, when you create a new case, the system automatically creates a new team.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Cases** in the left navigation, then select an existing case.
4. On the case action menu, select **Create Microsoft Team**.
5. In the **Team name** field, enter a name for the new Microsoft Teams team.
6. Select **Create Microsoft team**, then select **Close**.

Depending on the number of users assigned to Insider Risk Management role groups, it might take 15 minutes for all investigators and analysts to be added to the newly created Microsoft Teams team for the case.

Enable analytics in Insider Risk Management

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

When you enable Microsoft Purview Insider Risk Management analytics, you get several important benefits. You can:

- Evaluate potential insider risks in your organization without configuring any insider risk policies.
- Get real-time guidance on configuring indicator threshold settings.
- Generate insider risk severity and user activity summary for the users not part of policies. Share this summary information with Data Loss Prevention, Communication Compliance, and Microsoft Defender.

Evaluate insider risks in your organization

Microsoft Purview Insider Risk Management analytics enables you to evaluate potential insider risks in your organization without configuring any insider risk policies. This evaluation can help your organization identify potential areas of higher user risk and help determine what types of Insider Risk Management policies to configure and how broadly to scope them. Analytics scans offer the following advantages for your organization:

- **Easy to configure**: Select **Run scan** when prompted by the analytics recommendation or go to **Insider risk settings** > **Analytics** and enable analytics.
- **Privacy by design**: Scanned results and insights are returned as aggregated and anonymized user activity. Reviewers can't identify individual usernames. Since Insider Risk Management doesn't classify any identity in the organization for analytics, the solution accounts for all the UPNs/identities that might be involved in data leaving the organization boundary. Accounting for all relevant identities might involve user accounts, system accounts, guest accounts, and non-person accounts.

- **Understand potential risks through consolidated insights**: Scan results help you quickly identify potential risk areas for your users and which policy best helps mitigate these risks.

To learn how analytics can help accelerate the identification of potential insider risks, see the Insider Risk Management Analytics video.

Areas scanned

Analytics scans several sources for risk management activity to help you identify insights into potential areas of risk. Depending on your current configuration, analytics looks for qualifying risk activities in the following areas:

- **Microsoft 365 audit logs**: Included in all scans, this primary source helps you identify most of the potentially risky activities.
- **Exchange Online**: Included in all scans, Exchange Online activity helps you identify activities where data in attachments are emailed to external contacts or services.
- **Microsoft Entra ID**: Included in all scans, Microsoft Entra history helps you identify risky activities associated with users with deleted user accounts.
- **Microsoft 365 HR data connector**: If configured, HR connector events help you identify risky activities associated with users that have resignation or upcoming termination dates.

Analytics insights from scans use the same risk management activity signals as Insider Risk Management policies. They report results based on both single and sequence user activities. However, the risk scoring for analytics uses up to 10 days of activity while insider risk policies use daily activity for insights. When you first enable and run analytics in your organization, you see the scan results for one day. If you leave analytics enabled, you see the results of each daily scan added to the insight reports for a maximum range of the previous 10 days of activity.

Receive real-time guidance on configuring indicator threshold settings

Manually tuning policies to reduce "noise" can be a time-consuming experience that requires a lot of trial and error testing to determine the desired configuration for your policies. If you turn on analytics, you can get real-time insights to help you efficiently adjust the selection of indicators and thresholds of activity occurrence so that you don't receive too few or too many policy alerts. Use real-time analytics recommendations to set thresholds.

Enable analytics and start a scan of potential insider risks in your organization

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

To enable insider risk analytics, you must be a member of the *Insider Risk Management*, *Insider Risk Management Admins*, or *Microsoft 365 Global admin* role group.

1. Sign in to the Microsoft Purview portal with an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. On the **Overview** tab, scroll down to the **Insider risk analytics** card. Selecting **Run scan** turns on analytics scanning for your organization, and scan results can take up to 48 hours before insights are available as reports for review. Under **Scan for insider risks in your organization**, select **Run scan**.

> **Tip**
>
> You can also turn on scanning in your organization through **Settings** at the top of any Insider Risk Management page. Select **Analytics**, then turn on the setting.

View analytics insights after the first analytics scan

To view the results of analytics scanning in your organization, go to **Insider Risk Management** > **Reports** > **Analytics**. For more information about reports, see Use reports in Insider Risk Management.

Turn off analytics

To turn off insider risk analytics, you must be a member of the *Insider Risk Management*, *Insider Risk Management Admins*, or Microsoft 365 *Global admin* role group.

> **Important**

Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview **roles and permissions**.

1. Sign in to the Microsoft Purview portal with an admin account in your Microsoft 365 organization.
2. Select **Settings** in the upper-right corner of the page.
3. Select **Insider Risk Management** to go to the Insider Risk Management settings.
4. Under **Insider risk settings**, select **Analytics**, and then turn off the setting.

When you disable analytics:

- Analytics insight reports stop updating and don't show new risks.
- You can't see real-time analytics when you customize indicator threshold settings for your policies.

Enable user-level analytics in your organization

Insider Risk Management generates user activity summaries and insider risk severity insights for potentially risky behaviors at a user level. You can view these insights in the following experiences:

- Data Loss Prevention (DLP) alerts
- Communication Compliance policies
- Microsoft Defender user entity pages and alerts

User analytics cover all eligible users in your organization, including users not in the scope of any Insider Risk Management policy. When investigating alerts in Microsoft Defender, DLP, or Communication Compliance, analysts automatically have access to user information that helps improve risk assessments. Analysts can also use insider risk severity to quickly identify the most egregious and time-sensitive alerts and prioritize these alerts for investigation and remediation.

To enable insider risk user-level analytics, you must be a member of the *Insider Risk Management*, *Insider Risk Management Admins*, or Microsoft 365 *Global admin* role group.

Important

Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview **roles and permissions**.

1. Sign in to the Microsoft Purview portal with an admin account in your Microsoft 365 organization.
2. Select **Settings** in the upper-right corner of the page.
3. Select **Insider Risk Management** to go to the Insider Risk Management settings.
4. Under **Insider Risk Management settings**, select **Analytics** and turn on the **Show insights at user level** setting.
5. Under **Insider Risk Management settings**, select **Data sharing** and turn on the **Share user risk details with other security solutions** setting.

Enable admin notifications in Insider Risk Management

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Admin notifications

When you turn on the **Admin notifications** setting in Microsoft Purview Insider Risk Management, the system automatically sends email notifications to selected role groups. You can send email notifications for the following scenarios:

- Send a notification email when the first alert is generated for a new policy. The system checks policies every 24 hours for first-time alerts and doesn't send notifications on subsequent alerts for the policy.
- Send a daily email when new high-severity alerts are generated. The system checks policies every 24 hours for high severity alerts.
- Send a weekly email summarizing policies that have unresolved warnings.

If you enable Insider Risk Management analytics for your organization, members of the *Insider Risk Management Admins* role group automatically receive an email notification for initial analytics insights for data leaks, theft, and exfiltration activities.

> **Note**
>
> Add individuals to the role group to receive notifications. Email notifications don't support Admin Units, Priority Users Groups, or Entra ID Security Groups.

Disable admin and analytics notifications

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Select **Settings** in the upper-right corner of the page, and then select **Insider Risk Management** to go to the Insider Risk Management settings.
3. Under **Insider risk settings**, select **Admin notifications**.
4. Clear the check boxes for the following options, as applicable:
    - **Send a notification email when the first alert is generated for a new policy**
    - **Send an email when an analytics scan detects an insight for the first time**
    - **Send an email when analytics is turned off for your organization**
5. Select **Save**.

ⓘ**Note:** The author created this article with assistance from AI. Learn more

Configure inline alert customization in Insider Risk Management

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Inline alert customization in Microsoft Purview Insider Risk Management enables you to quickly tune an Insider Risk Management policy directly from the **Alert dashboard** while reviewing the alert. Alerts are generated when a risk management activity meets the thresholds configured in the related policy. To reduce the number of alerts you get from the risk management activity associated with the alert, you can change the thresholds or remove the risk management activity from the policy altogether.

You can enable inline alert customization to allow users assigned to the *Insider Risk Management Analysts* and *Insider Risk Management Investigators* role groups to edit policy thresholds and to disable specific indicators. If you don't enable inline alert customization, only users assigned to the *Insider Risk Management Admins* or *Insider Risk Management* role groups can edit these policy conditions. Inline alert customization supports alerts regardless of the current alert status, so analysts and investigators can update policies for *Dismissed* and *Resolved* alerts if needed.

When enabled, analysts and investigators can select **Reduce alerts for this activity** for an alert on the **Alert dashboard** and view details about the risk management activity and indicators associated with the alert. The portal displays the current policy thresholds for the number of events used to create low, medium, and high severity alerts. If you select **Reduce alerts for this activity** and a previous policy edit changes the threshold or removes the associated indicator, you see a notification message detailing previous changes to the policy.

Analysts and investigators can choose from the following options on the **Reduce alerts for this activity** pane to quickly edit the policy that created the alert:

- **Reduce alerts using Microsoft's recommended thresholds**: This option automatically increases the thresholds in the policy for you. You can review the new recommended threshold settings before changing the policy.
- **Reduce alerts by choosing your own thresholds**: This option lets you manually increase the thresholds for the risk management activity associated with the alert for the current and future alerts. You can review the current threshold settings and configure the new threshold settings before changing the policy.
- **Stop getting alerts for this activity**: This option removes the indicator associated with the selected alert from the policy and the risk management activity is no longer detected by the policy. This option applies to all indicators, regardless of whether the indicator is threshold-based.

After choosing an option, analysts and investigators can choose two options to update the policy:

- **Save and dismiss alert**: Saves the changes to the policy and updates the alert status to *Resolved*.
- **Save only**: Saves the changes to the policy, but the alert status remains the same.

Enable inline alert customization

Perform the following steps to enable inline alert customization:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Select **Settings** in the upper-right corner of the page.
3. Select **Insider Risk Management** to go to the Insider Risk Management settings.
4. Under **Insider risk settings**, select **Inline alert customization**, and then turn on the setting.
5. Select **Save**.

> **Note**
>
> After turning on the **Inline alert customization** setting, it takes approximately one hour before inline alert customization is available in new and existing policy alerts.

Note: The author created this article with assistance from AI. Learn more

Last updated on 06/26/2026

Learn about Insider Risk Management policy templates

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Policy templates

Insider Risk Management templates are predefined policy conditions that define the types of risk indicators and risk scoring model used by the policy. Each policy must have an assigned template in the policy creation workflow before the policy is created. Insider Risk Management supports up to 100 policies for each policy template. When you create a new insider risk policy with the policy workflow, choose from one of the following policy templates:

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Data theft by departing users

When users leave your organization, there are specific risk indicators typically associated with potential data theft by departing users. This policy template uses exfiltration indicators for risk scoring and focuses on detection and alerts in this risk area. Data theft for departing users might include downloading files from SharePoint Online, printing files, and copying data to personal cloud messaging and storage services near their employment resignation and end dates. When you use either the Microsoft HR connector or the option to automatically check for user account deletion in Microsoft Entra for your organization, this template starts scoring for risk indicators relating to these activities and how they correlate with user employment status. This can include cloud indicators for services such as Box, Dropbox, Google Drive, Amazon S3, and Azure.

> **Important**
>
> When you use this template, you can configure a Microsoft 365 HR connector to periodically import resignation and termination date information for users in your organization. See the Import data with the HR connector article for step-by-step guidance to configure the Microsoft 365 HR connector. If you choose not to use the HR connector, select the User account deleted from Microsoft Entra option when configuring trigger events in the policy workflow.

Data leaks

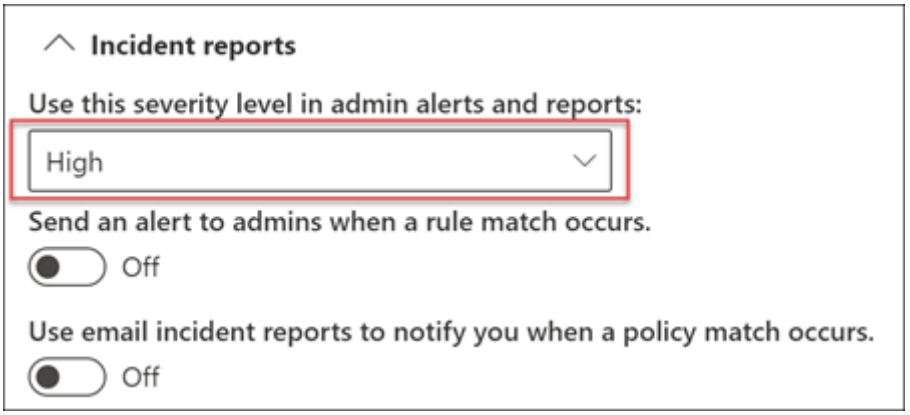
Protecting data and preventing data leaks is a constant challenge for most organizations, particularly with the rapid growth of new data created by users, devices, and services. Users can create, store, and share information across services and devices, which makes managing data leaks increasingly complex and difficult. Data leaks can include accidental oversharing of information outside your organization or data theft with malicious intent. This template scores real-time detections of suspicious SharePoint Online data downloads, file and folder sharing, printing files, and copying data to personal cloud messaging and storage services.

When you use a *Data leaks* template, you can assign a DLP policy to trigger indicators in the insider risk policy for high severity alerts in your organization. Whenever a high severity alert is generated by a DLP policy rule and added to the Office 365 audit log, insider risk policies created with this template automatically examine the high severity DLP alert. If the alert contains an in-scope user defined in the insider risk policy, the alert is processed by the insider risk policy as a new alert and assigned an insider risk severity and risk score. You can also choose to assign selected indicators as triggering events for a policy. This flexibility and customization helps scope the policy to only the activities covered by the indicators. This policy allows you to evaluate this alert in context with other activities included in the case.

This template can also include cloud indicators for services such as Box, Dropbox, Google Drive, Amazon S3, and Azure.

Data leaks policy guidelines

When creating or modifying data loss prevention policies for use with Insider Risk Management policies, consider the following guidelines:



- Prioritize data exfiltration events and be selective when assigning **Incident reports** settings to *High* when configuring rules in your DLP policies. For example, emailing sensitive documents to a known competitor should be a *High* alert level exfiltration event. Over-assigning the *High* level in the **Incident reports** settings in other DLP policy rules

can increase the noise in the Insider Risk Management alert workflow and make it more difficult for your data investigators and analysts to properly evaluate these alerts. For example, assigning *High* alert levels to access denial activities in DLP policies makes it more challenging to evaluate truly risky user behavior and activities.

- When using a DLP policy as the triggering event, make sure you understand and properly configure the in-scope users in both the DLP and Insider Risk Management policies. Only users defined as in-scope for Insider Risk Management policies using the **Data leaks** template have high severity DLP policy alerts processed. Additionally, only users defined as in-scope in a rule for a high severity DLP alert are analyzed by the Insider Risk Management policy for consideration. Don't unknowingly configure in-scope users in both your DLP and insider risk policies in a conflicting manner.

  For example, if your DLP policy rules are scoped to only users on the Sales Team and the insider risk policy created from the **Data leaks** template has defined all users as in-scope, the insider risk policy only processes high severity DLP alerts for the users on the Sales Team. The insider risk policy doesn't receive any high priority DLP alerts for users to process that aren't defined in the DLP rules in this example. Conversely, if your Insider Risk Management policy created from **Data leaks** templates is scoped to only users on the Sales Team and the assigned DLP policy is scoped to all users, the insider risk policy only processes high severity DLP alerts for members of the Sales Team. The Insider Risk Management policy ignores high severity DLP alerts for all users not on the Sales Team.

- Make sure the **Incident reports** rule setting in the DLP policy used for this Insider Risk Management template is configured for *High* severity level alerts. The *High* severity level is the triggering events and Insider Risk Management alerts aren't generated from rules in DLP policies with the **Incident reports** field set at *Low* or *Medium*.

> ⓘ **Note**

When creating a new DLP policy using the built-in templates, select the **Create or customize advanced DLP rules** option to configure the **Incident reports** setting for the *High* severity level.

Each Insider Risk Management policy created from the **Data leaks** template can only have one DLP policy assigned when using this triggering event option. Consider creating a dedicated DLP policy that combines the different activities you want to detect and act as triggering events for insider risk policies that use the **Data leaks** template.

For step-by-step guidance to configure DLP policies for your organization, see Create and Deploy data loss prevention policies.

Data leaks by priority users

Protecting data and preventing data leaks for users in your organization might depend on their position, level of access to sensitive information, or risk history. Data leaks can include accidental oversharing of highly sensitive information outside your organization or data theft with malicious intent. With an assigned data loss prevention (DLP) policy as a triggering event option, this template starts scoring real-time detections of suspicious activity and results in an increased likelihood of insider risk alerts and alerts with higher severity levels. Priority users are defined in priority user groups configured in the Insider Risk Management settings area.

As with the **Data leaks** template, you can choose a DLP policy to trigger indicators in the insider risk policy for high severity alerts in your organization. Follow the Data leaks policy guidelines for DLP policies when creating a policy with the DLP option when using this template. You can also choose to assign selected indicators as triggering events for a policy. This flexibility and customization help scope the policy to only the activities covered by the indicators. Additionally, you need to assign priority user groups created in **Insider Risk Management** > **Settings** > **Priority user groups** to the policy.

Data leaks by risky users

When users experience employment stressors, they might become risky users, which might increase the chances of insider risk activity. This template starts scoring user activity when an indicator associated with risky user is identified. Examples include performance improvement notifications, poor performance reviews, changes to job level status, or email and other messages that might signal risk activities. Data leaks for risky users might include downloading files from SharePoint Online and copying data to personal cloud messaging and storage services.

When using this template, you must either configure an HR connector, select the option to integrate Communication Compliance risk signals from user messages, or do both. The HR connector enables the periodic import of performance improvement notifications, poor performance review statuses, or job level change information for users in your organization. Communication Compliance risk integration imports signals for user messages that might contain potentially threatening, harassing, or discriminatory text content. Associated alerts generated in Communication Compliance don't need to be triaged, remediated, or changed in status to be integrated with the Insider Risk Management policy.

To configure an HR connector, see the Import data with the HR connector article. To configure integration with Communication Compliance, select this option in the workflow when you configure the policy.

Patient data misuse (preview)

Protecting healthcare record data and preventing the misuse of patient personal data is a significant concern for organizations in the healthcare industry. This misuse might include confidential data leaks to unauthorized persons, fraudulent modification of patient records, or the theft of patient healthcare records. Preventing this misuse of patient data helps meet the regulatory requirements of the Health Insurance Portability and Accountability Act (HIPAA) and the Health Information Technology for Economic and Clinical Health (HITECH) Act. Both of these acts establish the requirements for safeguarding patient protected health information (PHI).

This policy template enables risk scoring for internal users that detects suspicious activities associated with records hosted on existing electronic medical record (EMR) systems. Detection focuses on unauthorized access, viewing, modification, and export of patient data. You need to configure a connector the Microsoft Healthcare connector to support detection of access, exfiltration, or obfuscation activities in your EMR system.

When using this template, you must also configure a Microsoft HR connector to periodically import organization profile data for users in your organization. See the Set up a connector to import HR data article for step-by-step guidance to configure the Microsoft 365 HR connector.

Risky Agents (preview)

This template helps you detect activities of agents hosted on Microsoft Copilot Studio and Microsoft Foundry. The use of agents within your organization introduces new risk opportunities. Agents interact with other users, other agents, and tools. Misconfigured agents could send sensitive data externally, or sensitive data could be shared at a user's request.

This policy detects risky prompts, agents generating sensitive responses, agents accessing sensitive or priority SharePoint files, agents accessing risky websites, and agents sharing SharePoint files with people outside of the organization. It also tracks activity above the agent's baseline.

This policy template is applied by default for all organizations.

Risky AI usage

The use of AI tools and applications in many organizations presents new risk opportunities that might be difficult to identify and help mitigate. Users might inadvertently or purposefully create prompts in Microsoft AI tools that might contain sensitive information or risky intent. Additionally, AI tools might inappropriately use sensitive information to provide responses to user prompts that might expose your organization to increased risks.

To help protect against these risks, this policy can help detect and enable risk scoring for these types of prompts and responses across AI tools in your organization. Detection focuses on user browsing activities to generative AI websites, user prompts and AI responses containing sensitive information in Microsoft 365 Copilot, Microsoft Copilot, and agents. Detection of risky activity by this policy also contributes to the user risk scoring in Adaptive Protection.

When using this template, you must configure the Microsoft Insider risk extension (on Microsoft Edge browser) or Microsoft Purview extension (on Chrome browser) on the user devices. We also recommend optionally configuring a Microsoft HR connector to detect departing users and configuring a Communication Compliance policy to detect inappropriate content in messages for wider detection coverage. This policy can also be created as a one-click policy in Microsoft Purview Data Security Posture Management (DSPM) for AI when you take action on the recommendation **Detect risky interactions in AI apps**.

Risky browser usage (preview)

Identifying user visits to potentially inappropriate or unacceptable websites on organization devices and networks is an important part of minimizing security, legal, and regulatory risks. Users who inadvertently or purposefully visit these types of websites might expose the organization to legal actions from other users, violate regulatory requirements, elevate network security risks, or jeopardize current and future business operations and opportunities. This misuse is often defined in an organization's acceptable use policy for user devices and organization network resources but is often difficult to quickly identify and act on.

To help protect against these risks, this policy detects and enables risk scoring for web browsing that might violate your organization's acceptable use policy, such as visiting sites that pose a threat (phishing sites, for example) or that contain adult content. Several types of

categories are available for automatic categorization of web browsing activities by in-scope users.

This policy template has several prerequisites. For more information, see Learn about and configure Insider Risk Management browser signal detection.

Security policy violations

In many organizations, users have permission to install software on their devices or to modify device settings to help with their tasks. Either inadvertently or with malicious intent, users might install malware or disable important security features that help protect information on their device or on your network resources. This policy template uses security alerts from Microsoft Defender for Endpoint to start scoring these activities and focus detection and alerts to this risk area. Use this template to provide insights for security policy violations in scenarios when users might have a history of security policy violations that might be an indicator of insider risk.

You need to configure Microsoft Defender for Endpoint in your organization and enable Defender for Endpoint for Insider Risk Management integration in the Defender Security Center to import security violation alerts. For more information on configuring Defender for Endpoint for Insider Risk Management integration, see Configure advanced features in Defender for Endpoint.

Security policy violations by departing users

Departing users, whether they're leaving on positive or negative terms, might pose higher risks for security policy violations. To help protect against inadvertent or malicious security violations for departing users, this policy template uses Defender for Endpoint alerts to provide insights into security-related activities. These activities include the user installing malware or other potentially harmful applications and disabling security features on their devices. When you use the Microsoft HR connector or the option to automatically check for user account deletion in Microsoft Entra for your organization, this template starts scoring for risk indicators relating to these security activities and how they correlate with user employment status.

You need to configure Microsoft Defender for Endpoint in your organization and enable Defender for Endpoint for Insider Risk Management integration in the Defender Security Center to import security violation alerts. For more information on configuring Defender for Endpoint for Insider Risk Management integration, see Configure advanced features in Defender for Endpoint.

Security policy violations by priority users

Protecting against security violations for users in your organization might depend on their position, level of access to sensitive information, or risk history. Because security violations by priority users might have a significant impact on your organization's critical areas, this policy template starts scoring on these indicators, and uses Microsoft Defender for Endpoint alerts to provide insights into security-related activities for these users. These activities might include the priority users installing malware or other potentially harmful applications and disabling security features on their devices. Priority users are defined in priority user groups configured in the Insider Risk Management settings area.

You need to configure Microsoft Defender for Endpoint in your organization and enable Defender for Endpoint for Insider Risk Management integration in the Defender Security Center to import security violation alerts. For more information on configuring Defender for Endpoint for Insider Risk Management integration, see Configure advanced features in Defender for Endpoint. Additionally, you need to assign priority user groups created in **Insider Risk Management** > **Settings** > **Priority user groups** to the policy.

Security policy violations by risky users

Users who experience employment stressors might be at higher risk for inadvertent or malicious security policy violations. These stressors could include being placed on a performance improvement plan, receiving a poor performance review, or experiencing a demotion. This policy template starts risk scoring based on these indicators and activities associated with these types of events.

When you use this template, you must configure an HR connector, or select the option to integrate Communication Compliance risk signals from user messages, or both. The HR connector enables the periodic import of performance improvement notifications, poor performance review statuses, or job level change information for users in your organization. Communication Compliance risk integration imports signals for user messages that might contain potentially threatening, harassing, or discriminatory text content. Associated alerts generated in Communication Compliance don't need to be triaged, remediated, or changed in status to be integrated with the Insider Risk Management policy. To configure an HR connector, see the Import data with the HR connector article. To configure integration with Communication Compliance, select this option in the workflow when you configure the policy.

You also need to configure Microsoft Defender for Endpoint in your organization and enable Defender for Endpoint for Insider Risk Management integration in the Defender Security Center to import security violation alerts. For more information on configuring Defender for Endpoint for Insider Risk Management integration, see Configure advanced features in Defender for Endpoint.

Policy template prerequisites and triggering events

Depending on the template you choose for an Insider Risk Management policy, the triggering events and policy prerequisites vary. Triggering events are prerequisites that determine if a user is active for an Insider Risk Management policy. If you add a user to an Insider Risk Management policy but the user doesn't have a triggering event, the policy doesn't evaluate the user's activity unless you manually add the user in the Users dashboard. Policy prerequisites are required items so that the policy receives the signals or activities necessary to evaluate risk.

The following table lists the triggering events and prerequisites for policies created from each Insider Risk Management policy template:

Expand table

Policy template	Triggering events for policies	Prerequisites
Data leaks by priority users	Data leak policy activity that creates a *High severity* alert or built-in exfiltration event triggers	DLP policy configured for *High severity* alerts OR Customized triggering indicators Priority user groups configured in insider risk settings
Data leaks by risky users	- Performance improvement, poor performance, or job level change indicators from HR connector. - Messages containing potentially threatening, harassing, or discriminatory language	Microsoft 365 HR connector configured for disgruntlement indicators AND/OR Communication Compliance integration and dedicated disgruntlement policy
Data leaks	Data leak policy activity that creates a *High severity* alert or built-in exfiltration event triggers	DLP policy configured for *High severity* alerts OR Customized triggering indicators
Data theft by departing users	Resignation or termination date indicator from HR connector or Microsoft Entra account deletion	(optional) Microsoft 365 HR connector configured for termination and resignation date indicators
Patient data misuse	Defense evasion of security controls from EMR systems User and patient address matching indicators from HR systems	Healthcare access indicators selected in policy or insider risk settings Microsoft 365 HR connector configured for address matching

Policy template	Triggering events for policies	Prerequisites
		Microsoft Healthcare or Epic connector configured
Risky Agents	- Exposing agent to risky prompts - Agent generating sensitive responses - Accessing sensitive or priority SharePoint files - Accessing risky websites - Sharing SharePoint files with people outside the organization - Activity is above agent's usual activity for the day	Copilot Studio agents Microsoft Foundry agents
Risky AI usage		Microsoft Insider risk extension (on Microsoft Edge browser) or Microsoft Purview extension (on Chrome browser) must be installed on the user's devices At least one browsing indicator selected in the policy AND (optional) Microsoft 365 HR connector configured for termination and resignation date indicators (optional) A Communication Compliance policy detecting inappropriate content in messages
Risky browser usage	User browsing activity related to security that matches at least one selected *Browsing indicator*	See the complete list of prerequisites in the browser signal detection article
Security policy violations by departing users	Resignation or termination date indicators from HR connector or Microsoft Entra account deletion	(optional) Microsoft 365 HR connector configured for termination and resignation date indicators Active Microsoft Defender for Endpoint subscription Configuration of Microsoft Defender for Endpoint integration with Microsoft Purview portal
Security policy violations by	Defense evasion of security controls or unwanted software	Active Microsoft Defender for Endpoint subscription

Policy template	Triggering events for policies	Prerequisites
priority users	detected by Microsoft Defender for Endpoint	Configuration of Microsoft Defender for Endpoint integration with Microsoft Purview portal Priority user groups configured in insider risk settings
Security policy violations by risky users	- Performance improvement, poor performance, or job level change indicators from HR connector. - Messages containing potentially threatening, harassing, or discriminatory language	Microsoft 365 HR connector configured for risk indicators AND/OR Communication Compliance integration and dedicated risky user policy AND Active Microsoft Defender for Endpoint subscription Configuration of Microsoft Defender for Endpoint integration with Microsoft Purview portal
Security policy violations	Defense evasion of security controls or unwanted software detected by Microsoft Defender for Endpoint	Active Microsoft Defender for Endpoint subscription Configuration of Microsoft Defender for Endpoint integration with Microsoft Purview portal

Policy template limits

Insider Risk Management policy templates use limits to manage the volume and rate of processing for in-scope user risk activities and for integration with supporting Microsoft 365 services. Each policy template supports a maximum number of users who can actively receive risk scores for the policy. The policy can effectively process and report potentially risky activities. In-scope users are users with triggering events for the policy.

The limit for each policy calculates the total number of unique users receiving risk scores per policy template type. If the number of users for a policy template type nears or exceeds the user limit, the policy performance reduces. To view the current number of users for a policy, go to the Policy tab and the Users in scope column. These maximum limits apply to users across all policies using a given policy template.

For user scope limits for specific policy templates, see Limits in Insider Risk Management.

Integration with collection policies

Depending on your configuration, collection policies might impact Insider Risk Management policy behavior. When you configure and deploy a collection policy, the collection policy configuration takes precedence if there's a mismatch between an Insider Risk Managment policy that includes device indicators and a collection policy in your organization. This configuration means that if you configure an Insider Risk Management policy to monitor a specific activity for devices, but you configure the collection policy to filter out that device activity, the device activity isn't collected and isn't available for review in Insider Risk Management.

Last updated on 11/21/2025

Create and manage Insider Risk Management policies

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Insider Risk Management policies determine which users are in scope and which types of risk indicators are configured for alerts. You can quickly create a security policy that applies to all users in your organization or define individual users or groups for management in a policy. Policies support content priorities to focus policy conditions on multiple or specific Microsoft Teams, SharePoint sites, data sensitivity types, and data labels. By using templates, you can select specific risk indicators and customize event thresholds for policy indicators, effectively customizing risk scores, and level and frequency of alerts.

You can also configure quick data leak and data theft policies by departing user policies that automatically define policy conditions based on results from the latest analytics. Also, risk score boosters and anomaly detections help identify potentially risky user activity that is of higher importance or unusual. Policy windows allow you to define the time frame to apply the policy to alert activities and are used to determine the duration of the policy once activated.

For an overview of how policies created with built-in policy templates can help you quickly act on potential risks, see the Insider Risk Management Policies Configuration video.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Policy dashboard

The **Policy dashboard** lets you quickly see the user and agent policies in your organization, the health of each policy, manually add users to security policies, and view the status of alerts associated with each policy. Your policies are separated into two categories: **User policy** and **Agent policy**. Switch between the two to locate relevant policy details. **Agent policy** covers agents from Microsoft Copilot Studio and Microsoft Foundry.

- **Policy name**: Name assigned to the policy in the policy workflow.
- **Status**: Health status for each policy. Displays number of policy warnings and recommendations, or a status of *Healthy* for policies without issues. You can select the policy to see the health status details for any warnings or recommendations.
- **Active alerts**: Number of active alerts for each policy.
- **Confirmed alerts**: Total number of alerts that resulted in cases from the policy in the last 365 days.
- **Actions taken on alerts**: Total number of alerts that were confirmed or dismissed for the last 365 days.
- **Policy alert effectiveness**: Percentage determined by total confirmed alerts divided by total actions taken on alerts (which is the sum of alerts that were confirmed or dismissed over the past year).

Policy recommendations from analytics

Insider risk analytics gives you an aggregate view of anonymized user activities related to security and compliance. With this view, you can evaluate potential insider risks in your organization without configuring any insider risk policies. This evaluation helps your organization identify potential areas of higher risk and helps determine the type and scope of Insider Risk Management policies you might consider configuring. If you decide to act on analytics scan results for data leaks or data theft by departing users policies, you can even configure a quick policy based on these results.

For more information about insider risk analytics and policy recommendations, see Insider Risk Management settings: Analytics.

> **Note**
>
> You must be an unrestricted administrator to access analytics insights. Learn how administrative groups affect permissions.

Quick policies

For many organizations, getting started with an initial policy can be a challenge. If you're new to Insider Risk Management or are using the recommended actions to get started, use a quick policy to create and configure a new policy. Quick policy settings automatically populate from recommended best practices or on results from the latest analytics scan in your organization. For example, if the analytics check detected potential data leak activities in your organization, the *Date leaks* quick policy automatically includes the indicators used to detect those activities.

You can choose from the following quick policies:

- **Critical assets protection**: Detects activities involving your organization's most valuable assets. Loss of these assets could result in legal liability, financial loss, or reputational damage.
- **Data leaks**: Detect potential data leaks from all users in your organization, which can range from accidental oversharing of sensitive info to data theft with malicious intent.
- **Data theft from Microsoft 365 apps by users leaving your organization**: Detects potential data theft from Microsoft 365 cloud apps by users leaving your organization or whose account was deleted from Microsoft Entra ID.
- **Data theft from non-Microsoft 365 apps by users leaving your organization**: Detects potential data theft from non-Microsoft 365 cloud apps, including Microsoft Fabric, by users leaving your organization or whose account was deleted from Microsoft Entra ID.
- **Email exfiltration**: Detects when users email sensitive assets outside your organization. For example, users emailing sensitive assets to their personal email address.

To get started, go to **Insider Risk Management** > **Policies** and select **Create policy** > **Quick policy**. If you're reviewing analytics reports, select **View details** > **Get started** to get started with a quick policy for the applicable area.

When you start the quick policy workflow, review the policy settings and configure the policy with a single selection. If you need to customize a quick policy, change the conditions after the policy

is created. Stay up to date with the detection results for a quick policy by configuring email notifications each time you have a policy warning or each time the policy generates a high severity alert.

> **Note**
>
> You must be an unrestricted administrator to create quick policies. Learn how administrative groups affect permissions.

Prioritize content in policies

Insider Risk Management policies support specifying a higher priority for content depending on where you store it, the type of content, or how you classify it. You can also choose whether to assign risk scores to all activities detected by a policy or only activities that include priority content. Specifying content as a priority increases the risk score for any associated activity, which in turn increases the chance of generating a high severity alert. However, some activities don't generate an alert at all unless the related content contains built-in or custom sensitive info types or you specify it as a priority in the policy.

For example, your organization has a dedicated SharePoint site for a highly confidential project. Data leaks for information in this SharePoint site could compromise the project and would have a significant impact on its success. By prioritizing this SharePoint site in a Data leaks policy, you automatically increase risk scores for qualifying activities. This prioritization increases the likelihood that these activities generate an insider risk alert and raises the severity level for the alert.

Additionally, you can choose to focus this policy for SharePoint site activity that only includes priority content for this project. Risk scores are assigned and alerts are generated only when specified activities include priority content. Activities without priority content aren't scored, but you can still review them if an alert is generated.

> **Important**
>
> Cumulative exfiltration activity always receives a risk score, regardless of whether or not it contains prioritized content.

The following policy templates support priority content selection:

- Data leaks
- Data leaks by priority users
- Data leaks by risky users
- Data theft by departing users
- Risky AI usage

> **Note**
>
> If you configure a policy to generate alerts only for activity that includes priority content, no changes are applied to risk score boosters.

When you create an Insider Risk Management policy in the policy workflow, you can choose from the following priorities:

- **SharePoint sites**: Assign a higher risk score to any activity associated with all file types in defined SharePoint sites. Users configuring the policy and selecting priority SharePoint sites can select SharePoint sites that they have permission to access. If SharePoint sites aren't available for selection in the policy by the current user, another user with the required permissions can select the sites for the policy later, or the current user should be given access to the required sites.
- **Sensitive information types**: Assign a higher risk score to any activity associated with content that contains sensitive information types.
- **Sensitivity labels**: Assign a higher risk score to any activity associated with content that has specific sensitivity labels applied.
- **File extensions**: Assign a higher risk score to any activity associated with content that has specific file extensions. Users configuring a data theft/leak policy that selects **File extensions to prioritize** in the policy workflow can define up to 50 file extensions to prioritize in the policy. Entered extensions can include or omit a '.' as the first character of the prioritized extension.
- **Trainable classifiers**: Assign a higher risk score to any activity associated with content that is included in a trainable classifier. Users configuring a policy that selects Trainable classifiers in the policy workflow can select up to 5 trainable classifiers to apply to the policy. These classifiers can be existing classifiers that identify patterns of sensitive information like social security, credit card, or bank account numbers or custom classifiers created in your organization.

Sequence detection

Risk management activities might not occur as isolated events. These risks are frequently part of a larger sequence of events. A sequence is a group of two or more potentially risky activities performed one after the other that might suggest an elevated risk. Identifying these related user activities is an important part of evaluating overall risk. When you select sequence detection for data theft or data leaks policies, you see insights from sequence information activities on the **User activity** tab within an Insider Risk Management case. The following policy templates support sequence detection:

- Data leaks
- Data leaks by priority users
- Data leaks by risky users
- Data theft by departing users
- Risky AI usage

These Insider Risk Management policies can use specific indicators and the order that they occur to detect each step in a sequence of risk. Selected sequence detections only detect sequences of risk in the order displayed in policy setup workflow. For policies created from the *Data leaks* and *Data leaks by priority user* templates, you can also select which sequences trigger the policy. File names are used when mapping activities across a sequence. These risks are organized into four main categories of activity:

- **Collection**: Detects download activities by in-scope policy users. Example risk management activities include downloading files from SharePoint sites, third-party cloud services, unallowed domains, or moving files into a compressed folder.
- **Exfiltration**: Detects sharing or extraction activities to internal and external sources by in-scope policy users. An example risk management activity includes sending emails with attachments from your organization to external recipients.
- **Obfuscation**: Detects the masking of potentially risky activities by in-scope policy users. An example risk management activity includes renaming files on a device.
- **Clean-up**: Detects deletion activities by in-scope policy users. An example risk management activity includes deleting files from a device.

> ⓘ **Note**
>
> Sequence detection uses indicators that you enable in the global settings for Insider Risk Management. If you don't select appropriate indicators, you can turn on these indicators in the sequence detection step in the policy workflow.

You can customize individual threshold settings for each sequence detection type when you configure it in the policy. These threshold settings adjust alerts based on the volume of files associated with the sequence type.

> **Note**
>
> A **sequence** might contain one or more events that are excluded from risk scoring based on your settings configuration. For example, your organization might use the **Global exclusions setting** to exclude .png files from risk scoring since .png files aren't normally risky. But a .png file could be used to obfuscate a malicious activity. For this reason, if an event that's excluded from risk scoring is part of a sequence due to an obfuscation activity, the event is included in the sequence since it might be interesting in the context of the sequence. **Learn more about how exclusions that are part of a sequence are shown in the Activity explorer**.

To learn more about sequence detection management in the **User activity** view, see Insider Risk Management cases: User activity.

Cumulative exfiltration detection

With privacy on by default, insider risk indicators help identify unusual levels of risk activities when evaluated daily for users that are in-scope for insider risk policies. Cumulative exfiltration detection uses machine learning models to help you identify when exfiltration activities that a user performs over a certain time exceed the normal amount performed by users in your organization for the past 30 days over multiple exfiltration activity types. For example, if a user shared more files than most users over the past month, this activity is detected and classified as a cumulative exfiltration activity.

Insider Risk Management analysts and investigators might use cumulative exfiltration detection insights to help identify exfiltration activities that might not typically generate alerts but are more than what is typical for their organization. Some examples might be departing users slowly exfiltrate data across a range of days, or when users repeatedly share data across multiple channels more than usual for data sharing for your organization, or compared to their peer groups.

> **Note**
>
> By default, cumulative exfiltration detection generates risk scores based on a user's cumulative exfiltration activity compared to their organization norms. You can enable

Cumulative exfiltration detection options in the **Policy indicators** section of the Insider Risk Management settings page.

Higher risk scores are assigned to cumulative exfiltration activities for SharePoint sites, sensitive information types, and content with sensitivity labels configured as priority content in a policy or for activity involving labels configured as high priority in Microsoft Purview Information Protection.

Cumulative exfiltration detection is enabled by default when using the following policy templates:

- Data leaks
- Data leaks by priority users
- Data leaks by risky users
- Data theft by departing users

> **Important**
>
> The option to only score activities containing priority content doesn't apply to cumulative exfiltration activities. Cumulative exfiltration activity always receives a risk score, regardless of whether or not it contains prioritized content.

Peer groups for cumulative exfiltration detection

Insider Risk Management identifies three types of peer groups for analyzing exfiltration activity performed by users. It defines peer groups for users based on the following criteria:

SharePoint sites: Insider Risk Management identifies peer groups based on users who access similar SharePoint sites. **Similar organization**: Users with reports and team members based on organization hierarchy. This option requires that your organization uses Microsoft Entra ID to maintain organization hierarchy. **Similar job title**: Users with a combination of organizational distance and similar job titles. For example, a user with a Senior Sales Manager title with a similar role designation as a Lead Sales Manager in the same organization is identified as similar job title. This option requires that your organization uses Microsoft Entra ID to maintain organization hierarchy, role designations, and job titles. If you don't have Microsoft Entra ID configured for organization structure and job titles, then Insider Risk Management identifies peer groups based on common SharePoint sites.

When you enable cumulative exfiltration detection, your organization agrees to share Microsoft Entra data with the Microsoft Purview portal, including organization hierarchy and job titles. If

your organization doesn't use Microsoft Entra ID to maintain this information, detection might be less accurate.

> **Note**
>
> Cumulative exfiltration detection uses exfiltration indicators that you enable in the global settings for Insider Risk Management and exfiltration indicators that you select in a policy. As such, cumulative exfiltration detection only evaluates the necessary exfiltration indicators. Cumulative exfiltration activities for sensitivity labels configured in priority content generate higher risk scores.

When you enable cumulative exfiltration detection for data theft or data leak policies, insights from cumulative exfiltration activities appear on the **User activity** tab within an Insider Risk Management case. For more information about user activity management, see Insider Risk Management cases: User activities.

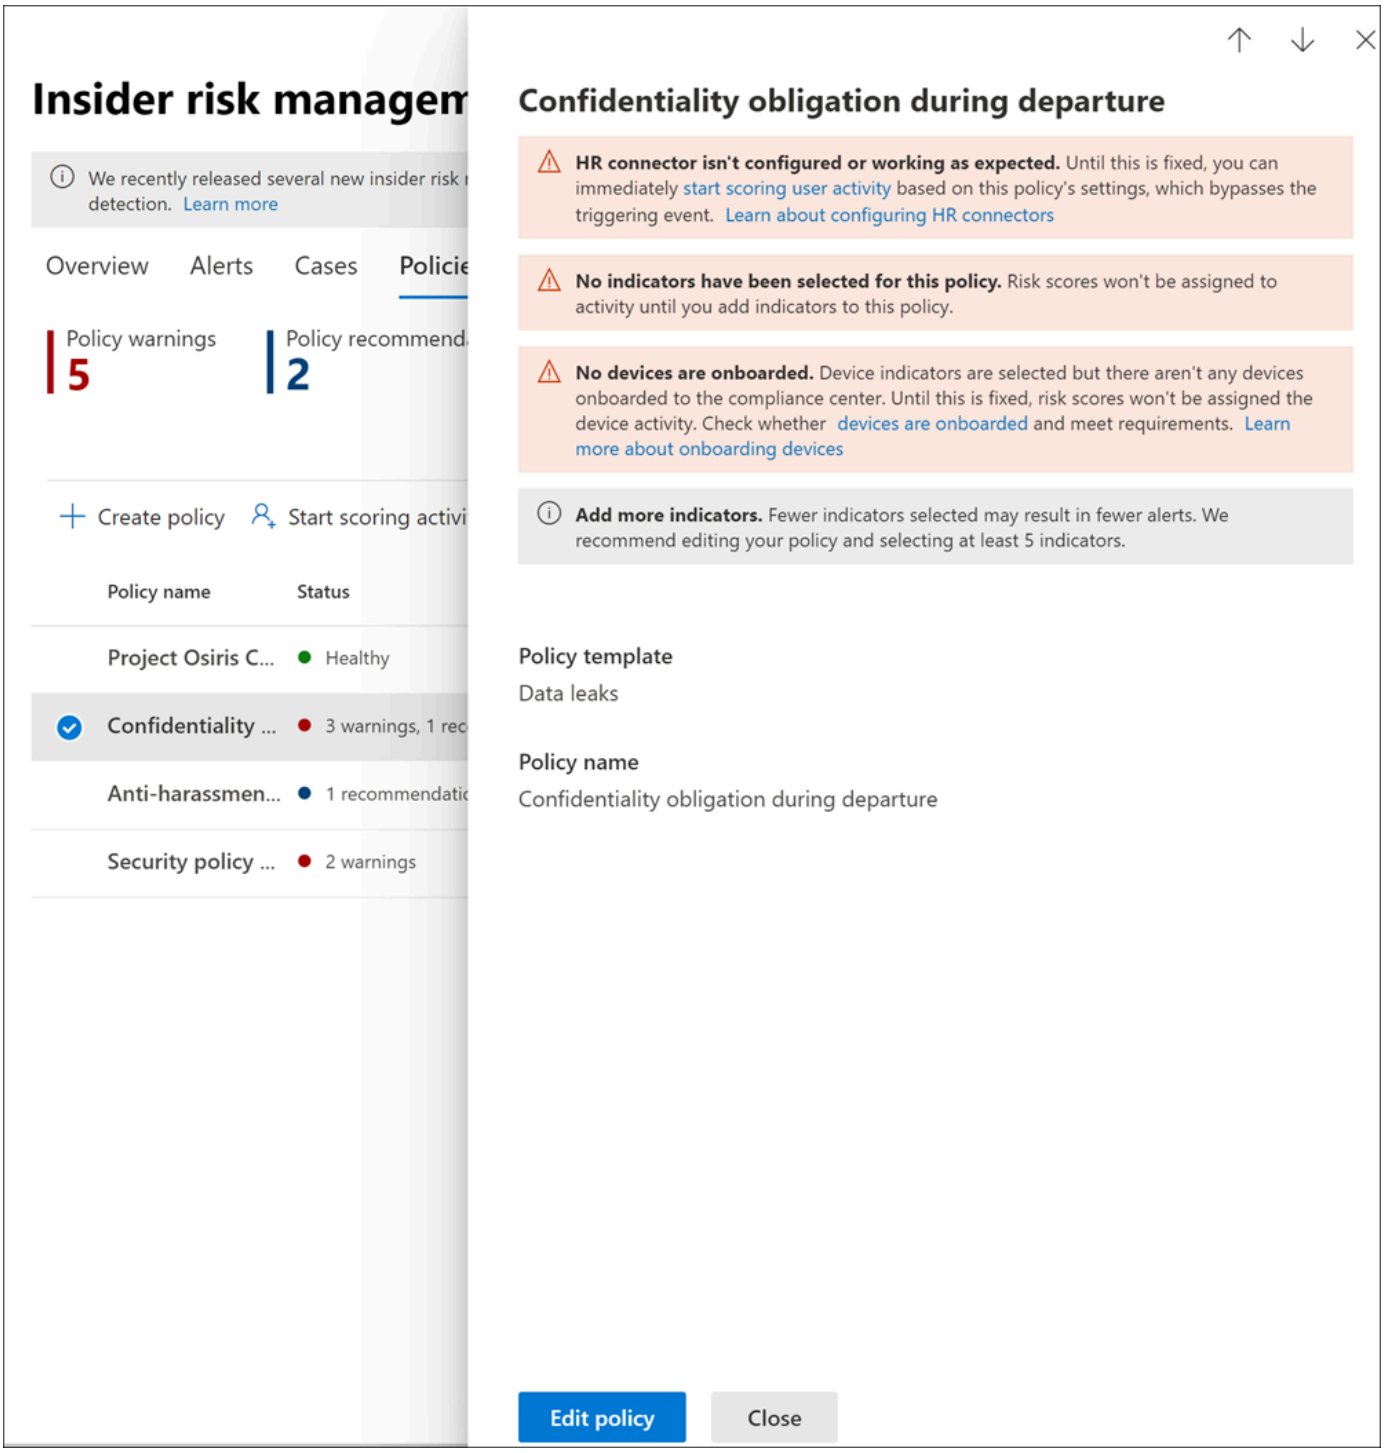
Policy health

> **Note**
>
> If your policy is scoped by one or more administrative units, you can only view policy health for the policies you're scoped for. If you're an unrestricted administrator, you can view policy health for all policies in the tenant.

The policy health status gives you insights into potential issues with your Insider Risk Management policies. The **Status** column on the **Policies** tab alerts you to policy issues that might prevent user activity from being reported or explain why the number of activity alerts is unusual. The policy health status also confirms that the policy is healthy and doesn't need attention or configuration changes.

> **Important**
>
> You must have the *Insider Risk Management* or the *Insider Risk Management Admins* role to access policy health.

If there are issues with a policy, the policy health status displays notification warnings and recommendations to help you take action to resolve policy issues. These notifications can help



you resolve the following issues:

- **Policies with incomplete configuration**. These issues might include missing users or groups in the policy or other incomplete policy configuration steps.
- **Policies with indicator configuration issues**. Indicators are an important part of each policy. If you don't configure indicators, or if you select too few indicators, the policy might not evaluate risky activities as expected.
- **Policy triggers aren't working, or policy trigger requirements aren't properly configured**. Policy functionality might depend on other services or configuration requirements to effectively detect triggering events to activate risk score assignment to users in the policy. These dependencies might include issues with connector configuration, Microsoft Defender for Endpoint alert sharing, or data loss prevention policy configuration settings.
- **Volume limits are nearing or over limits**. Insider Risk Management policies use numerous Microsoft 365 services and endpoints to aggregate risk activity signals. Depending on the number of users in your policies, volume limits might delay identification and reporting of risk activities. Learn more about these limits in the Policy template limits section.

To quickly view the health status for a policy, go to the **Policy** tab and check the **Status** column. You see the following policy health status options for each policy:

- *Healthy*: No issues are identified with the policy.
- *Recommendations*: An issue with the policy that might prevent the policy from operating as expected.
- *Warnings*: An issue with the policy that might prevent it from identifying potentially risky activities.

For more details about any recommendations or warnings, select a policy on the **Policy** tab to open the policy details card. The **Notifications** section of the details card displays more information about the recommendations and warnings, including guidance on how to address these issues.

Notification messages

Use the following table to learn more about recommendations and warning notifications and actions to take to resolve potential issues.

Expand table

Notification messages	Policy templates	Causes / Try this action to fix
DLP policy doesn't meet requirements	- Data leaks - Data leaks by priority users	DLP policies used as triggering events must be configured to generate high severity alerts.

Notification messages	Policy templates	Causes / Try this action to fix
		1. Edit your DLP policy to assign applicable alerts as *High severity*. OR 2. Edit this policy and select *User performs an exfiltration activity* as the triggering event.
DLP policy isn't selected as the triggering event	- Data leaks - Data leaks by priority users	A DLP policy wasn't selected as a triggering event or the selected DLP policy was deleted. Edit the policy and either select an active DLP policy or 'User performs an exfiltration activity' as the triggering event in the policy configuration.
DLP policy used in this policy is turned off	- Data leaks - Data leaks by priority users	DLP policy used in this policy is turned off. 1. Turn the DLP policy assigned to this policy on. OR 2. Edit this policy and either select a new DLP policy or 'User performs an exfiltration activity' as the triggering event in the policy configuration.
HR connector hasn't uploaded data recently	- Data theft by departing user - Security policy violations by departing user - Data leaks by risky users - Security policy violations by risky users	HR connector didn't import data in more than 7 days. Check that your HR connector is configured correctly and sending data.
HR connector isn't configured or working as expected	- Data theft by departing user - Security policy violations by departing user - Data leaks by risky users - Security policy violations by risky users	There's an issue with the HR connector. 1. If you're using an HR connector, check that your HR connector is sending correct data OR 2. Select the Microsoft Entra account deleted triggering event.
Microsoft Defender for Endpoint alerts aren't being	- Security policy violations	Microsoft Defender for Endpoint alerts aren't being shared with the Microsoft Purview portal.

Notification messages	Policy templates	Causes / Try this action to fix
shared with the Microsoft Purview portal	- Security policy violations by departing users - Security policy violations by risky users - Security policy violations by priority users	Configure sharing of Microsoft Defender for Endpoint alerts.
No devices are onboarded	- Data theft by departing users - Data leaks - Data leaks by risky users - Data Leaks by priority users	Device indicators are selected but there aren't any devices onboarded to the Microsoft Purview portal Check whether devices are onboarded and meet requirements.
No indicators have been selected for this policy	All policy templates	Indicators weren't selected for the policy Edit your policy and select appropriate policy indicators for the policy.
No priority user groups are included in this policy	- Data leaks by priority users - Security policy violations by priority users	Priority user groups aren't assigned to the policy. Configure priority user groups in Insider Risk Management settings and assign priority user groups to the policy.
No triggering event has been selected for this policy	All policy templates	A triggering event isn't configured for the policy Risk scores won't be assigned to user activities until you edit the policy and select a triggering event.
No users or groups are included in this policy	All policy templates	Users or groups aren't assigned to the policy. Edit your policy and select users or groups for the policy.
Policy hasn't generated any alerts	All policy templates	You might want to review your policy configuration so that you're analyzing the most relevant scoring activity. 1. Confirm that you selected indicators that you want to score. The more indicators selected, the more activities are assigned risk scores. 2. Review threshold customization for policy. If the thresholds selected don't align with your organization's risk tolerance, adjust the selections so

Notification messages	Policy templates	Causes / Try this action to fix
		that alerts are created based on your preferred thresholds. 3. Review the users and groups selected for the policy. Confirm you selected all of the applicable users and groups. 4. For security violation policies, confirm you selected the alert triage status that you want to score for Microsoft Defender for Endpoint alerts in Intelligent Detections in settings.
Policy isn't assigning risk scores to activity	All policy templates	You might want to review your policy scope and triggering event configuration so that the policy can assign risk scores to activities 1. Review the users that are selected for the policy. If you have few users selected, you might want to select additional users. 2. If you're using an HR connector, check that your HR connector is sending the correct data. 3. If you're using a DLP policy as your triggering event, check your DLP policy configuration to ensure it's configured to be used in this policy. 4. For security violation policies, review the Microsoft Defender for Endpoint alert triage status selected in Insider risk settings > Intelligent detections. Confirm that the alert filter isn't too narrow.
Triggering event is repeatedly occurring for over 15% of users in this policy	All policy templates	Adjust the triggering event to help reduce how often users are brought into the policy scope.
We're unable to check the status of your HR connector right now, please check again later	- Data theft by departing user - Security policy violations by departing user - Data leaks by risky users - Security policy violations by risky users	The Insider Risk Management solution is unable to check the status of your HR connector. Check that your HR connector is configured correctly and sending data, or come back and check the policy status.
You're approaching the maximum limit of users being actively scored for this policy template	All policy templates	Each policy template has a maximum number of included users. See the Policy template limits section for details. Review the users in the Users tab and remove any users who don't need to be scored anymore.

Notification messages	Policy templates	Causes / Try this action to fix
Your organization doesn't have a Microsoft Defender for Endpoint subscription	- Security policy violations - Security policy violations by departing users - Security policy violations by risky users - Security policy violations by priority users	An active Microsoft Defender for Endpoint subscription wasn't detected for your organization. Until a Microsoft Defender for Endpoint subscription is added, these policies won't assign risk scores to user activity.

Create a new policy

To create a new Insider Risk Management policy, generally use the policy workflow in the **Insider Risk Management** solution in the Microsoft Purview portal. You can also create quick policies for general data leaks and data theft by departing users from Analytics checks if applicable.

Complete Create an Insider Risk Management policy to configure new insider risk policies.

Update a policy

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Policies** in the left navigation.
4. On the policy dashboard, select the policy you want to update.
5. On the policy details page, select **Edit policy**.
6. On the **Name and description** page, update the description for the policy if you want.

   > **Note**
   >
   > You can't edit the **Policy template** or **Name** field.

7. Select **Next** to continue.
8. Follow the remaining steps to configure your Insider Risk Management policy.

Copy a policy

You might need to create a new policy that's similar to an existing policy but needs just a few configuration changes. Instead of creating a new policy from scratch, you can copy an existing policy and then modify the areas that need to be updated in the new policy.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Policies** in the left navigation.
4. On the policy dashboard, select the policy you want to copy.
5. On the policy details page, select **Copy**.
6. In the policy workflow, name the new policy, and then update the policy configuration as needed.

Immediately start scoring user activity

Some scenarios require assigning risk scores to users with insider risk policies outside of the Insider Risk Management triggering event workflow. Use **Start scoring activity for users** on the **Policies** tab to manually add one or more users to one or more insider risk policies for a specific amount of time. This action starts assigning risk scores to their activity and bypasses the requirement for a user to have a triggering indicator, like a DLP policy match or an Employment End Date from the HR Connector.

The value in the **Reason for scoring activity** field appears on the users' activity timeline. The **Users** dashboard displays users you manually add to policies, and alerts are created if the activity meets the policy alert thresholds. You can have up to 4,000 users in scope that you manually add by using the **Start scoring activity for users** feature.

Some scenarios where you might want to immediately start scoring user activities include:

- You identify users with risk concerns and want to immediately start assigning risk scores to their activity for one or more of your policies.
- There's an incident that might require you to immediately start assigning risk scores to involved users' activity for one or more of your policies.
- You haven't configured your HR connector yet, but you want to start assigning risk scores to user activities for HR events by uploading a .csv file.

> **Note**

It might take several hours for manually added users to appear in the **Users** dashboard. Activities for the previous 90 days for these users might take up to 24 hours to display. To view activities for manually added users, go to the **Users** tab, select the user on the **Users** dashboard, and then open the **User activity** tab on the details pane.

Manually start scoring activity for users in one or more Insider Risk Management policies

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Policies** in the left navigation.
4. On the policy dashboard, select the policies where you want to add users.
5. Select **Start scoring activity for users**.
6. In the **Add users to multiple policies** pane, enter a reason for adding the users in the **Reason** field.
7. Define the number of days to score the user's activity in the **This should last for (choose between 5 and 30 days)** field.
8. Enter the name of the user you want to add, or use the **Search user to add to policies** field to search for a user, then select the user name. Repeat this process to assign additional users. The list of users you select appears in the users section of the **Add users to multiple policies** pane.

   > **Note**
   >
   > If the policy is scoped by one or more administrative units, you can only see users that you're scoped for.

   Select **Import** to import a .csv (comma-separated values) file to import a list of users. The file must be in the following format and must list the user principal names:

   ```
   csv
   ```

```
user principal name
user1@domain.com
user2@domain.com
```

9. Select **Add users to policies** to accept the changes.

Stop scoring users in a policy

To stop scoring users in a policy, see the Insider Risk Management users: Remove users from in-scope assignment to policies article.

Delete a policy

> **Important**
>
> You can't undo a policy deletion.

When you delete a policy, you have two options. You can:

- Delete just the policy.
- Delete the policy and all associated alerts and users.

If you choose the second option:

- All alerts generated by that policy are deleted unless they're associated with a case. Associated cases are never deleted when you delete a policy.
- Any user associated with an alert from that policy is removed from the **Users** page.
- If a user is in scope of more than one policy, you remove the user only from the policy that you're deleting. You don't remove the user from other active policies.

For example, you might create a policy for test purposes before rolling it out to your organization. After you finish testing, you can quickly delete the policy and all associated test data so that you can start fresh when you're ready to push the policy live.

It can take up to 72 hours to complete a policy deletion.

> **Note**
>
> If you delete a policy associated with Insider Risk Management Adaptive Protection, you see a warning that Adaptive Protection stops assigning insider risk levels to users until you

choose a different policy in Adaptive Protection. This warning appears because Adaptive Protection must be associated with a policy to be in effect.

To delete a policy

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Policies** in the left navigation.
4. On the policy dashboard, select the policy you want to delete.
5. Select **Delete** on the dashboard toolbar.
6. Choose one of the following options:

   - Select **Delete only the policy**.
   - Select **Delete the policy and all associated alerts and users**.

   > **Important**
   >
   > You can't undo a policy deletion.

7. Select **Confirm**.

   You see a message in the upper part of the screen that tells you if the deletion was successful or whether it's pending.

Investigate Microsoft Purview Insider Risk Management activities

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

To minimize insider risks in your organization, investigate potentially risky user activities. These risks might be activities that generate alerts from Insider Risk Management policies. They can also be risks from compliance-related activities that the policies detect but don't immediately create Insider Risk Management alerts for users.

You can investigate these types of activities by using User activity reports or with the **Triage Agent in Insider Risk Management** and **Standard alert** dashboards.

Triaging alerts

Investigate and act on alerts in Insider Risk Management by following these steps:

1. **Review the dashboards for alerts**. On the Standard dashboard, filter alerts by alert *Status* to locate *Needs review* alerts. You can also use spotlighted alerts on the dashboard to quickly see prioritized alerts. On the Alert Triage Agent dashboard, select the **Needs attention** filter to view alerts with the highest prioritization.

2. **Start with the alerts with the highest severity**. Filter alerts by alert *Severity* if needed to help locate these types of alerts.

3. **Select an alert to discover more information and to review the alert details**. Review details and connections associated with the alert:
   a. View the agent summary tab to review intelligently distilled user activity and risk pattern narratives.
   b. Use the Activity explorer tab to review a timeline of the associated potentially risky behavior, and to identify all risk activities for the alert.
   c. Use the Data risk graph to review connections and details about users and files for the alert.

   > **Tip**
   >
   > If **Content preview (preview)** is available for the content within the alert, you can review relevant files from SharePoint, Exchange, and OneDrive for Business in Activity explorer to identify false positives, confirm that sensitive data is present, and quickly decide whether the alert warrants escalation.

4. **Act on the alert**. You can either confirm and create a case for an alert or dismiss and resolve the alert.

You can triage alerts by going to the **Alert details** page for an alert in either dashboard. On the **Alert details** page, you can review information about the alert. You can confirm the alert and create a new case, confirm the alert and add to an existing case, or dismiss the alert.

The **Alert details** page also includes the current status for the alert and the alert risk severity level, listed as *High*, *Medium*, or *Low*. The severity level might increase or decrease over time if you don't triage the alert. For false positives, you can select multiple alerts and dismiss them in bulk by selecting **Dismiss alerts**.

Use Copilot to summarize an alert

Select **Summarize with Copilot** or the Copilot icon to quickly summarize an alert and prioritize the alerts that need further investigation. You can summarize selected alerts without opening the alert or after viewing the details of the alert. When you summarize an alert with Microsoft Copilot in Microsoft Purview, a **Copilot** pane appears on the right side of the screen with an alert summary.

The alert summary includes all the essential details about the alert, such as the policy that triggered the alert, the activity that generated the alert, the triggering event, the user involved, their last working date (if applicable), any key user attributes, and the user's top risk factors. Copilot in Microsoft Purview consolidates information about the user from all their alerts and in-scope policies and emphasizes the user's top risk factors.

Suggested prompts automatically show to help further refine your summary and provide additional insights to the activities associated with the alert. Choose from the following suggested prompts:

- *List all the data exfiltration activities involving this user.*
- *List all the sequential activities involving this user.*
- *Did the user engage in any unusual behavior?*
- *Show key actions performed by the user in the last 10 days.*
- *Summarize user's last 30 days of activity.*

> **Tip**
>
> You can also use the standalone version of Microsoft Security Copilot to investigate Insider Risk Management, Microsoft Purview Data Loss Prevention (DLP), and Microsoft Defender XDR alerts.

Alerts (preview)

The new unified alert experience combines the Triage Agent and classic alert dashboards into a single alerts list page. This unified view lets you manage both classic and agent-triaged alerts from one location, making it easier to investigate and act on alerts without toggling between dashboards.

The unified alert experience includes the following capabilities:

- **Preview agent summaries, alert, and user details directly on the alerts list page** without opening the full alert details.

- **Filter by all classic and agent attributes on one page**, including a filter for agent-triaged alerts that need attention.
- **Manage the Triage Agent directly from the alerts list page**, including viewing agent categorization details.
- **New Agent Categorization column** added to the alerts list to quickly identify how the agent has categorized each alert.

> **Important**
>
> The following changes apply to the unified alert experience:
>
> - Alert **Spotlight** is no longer available in the unified experience. To prioritize agent-triaged alerts, use the **Needs Attention** filter instead.
> - The ability to toggle between the Triage Agent and classic alert dashboards is no longer available. Both alert types appear in a single unified view.
> - The classic and new alert experiences will both be available for at least 60 days. After August 31, only the unified experience will be supported.

To access the unified alert experience, select the **Alerts (preview)** tab in the left navigation of the Insider Risk Management solution.

System-generated notes for alerts (preview)

In the unified alert experience, system-generated notes are automatically added to alerts when there's a change in alert status, a change in the assigned user, or closure of an alert. These notes appear in the **Notes** tab within the alert details panel, helping analysts and investigators stay up to date with all activity on an alert without needing to manually track changes. Some system-generated notes might not appear for activity prior to July 1. For information about system-generated notes for cases, see Case notes.

Alert notes (preview)

Analysts and investigators can add and view notes directly on alerts within the Purview portal.

> **Important**
>
> - You can add up to 50 manual notes per alert or case (not including system-generated notes).

- Notes can't be edited or deleted at this time.
- There's no sync between alert notes in Insider Risk Management and Microsoft Defender.

User profile details (preview)

In the unified alert experience, you can view expanded user profile details directly from an alert. The expanded user profile aggregates all Insider Risk Management user signals into a unified view, making it easier to understand complete user risk at a glance.

To access expanded user profile details:

1. Select **Alerts (preview)** in the left navigation.
2. Select an alert.
3. Scroll down to **User details**.
4. Select **View user details**.

The expanded user profile includes the following additional signals from the user's Microsoft Entra profile:

- **Office location**
- **Employee type**
- **Department**
- **Last working date**
- **Entra account deletion date**

The profile also aggregates the following Insider Risk Management signals:

- **Past alert and case history**
- **Priority user group status**
- **Policy inclusion**
- **HR Connector last working date**

> ⓘ **Note**
>
> When pseudo-anonymization is enabled, the expanded user profile details aren't visible.

For more information about user profile details, see View user details.

Use Spotlight to prioritize alerts (preview)

> **Note**
>
> Alert Spotlight will be removed in the unified alert experience (preview) on August 31, 2026. To prioritize alerts in the new experience, use the **Needs Attention** filter for agent-triaged alerts instead.

The alert **Spotlight** on the **Alerts** dashboard helps you prioritize alerts to triage. Every generated alert has a risk score, a list of activities performed, tags, and triggers. Alert spotlighting uses this information to determine if an alert is spotlighted.

An alert is automatically spotlighted if it has a risk score of 85 or higher and if at least three of the following conditions are met:

- One insight from the following table matches the highest insight of the alert.
- The alert contains priority content or the user is detected as a potential high impact user.
- The user is manually brought into scope.
- Alert activity contains two or more high-confidence insights from the following table.

Expand table

Category	Indicator (high confidence insights)
Device indicator	- Creating or transferring files to a network share - Creating or copying files to USB - Using a browser to upload files to the web
Office indicator	- Sharing SharePoint files with people outside the organization - Sharing SharePoint folders with people outside the organization - Sharing file links with people outside organization in a Teams chat
Policy	- Content to prioritize - Start scoring activity for users
Risk score booster	- User is detected as a potential high impact user
Sequence detection	- Download from Microsoft 365 location then exfiltrate - Download from Microsoft 365 location, exfiltrate, then delete - Download from Microsoft 365 location, obfuscate, then exfiltrate

Triage Agent in Insider Risk Management dashboard

When you enable the Triage Agent in Insider Risk Management in your organization, the agent reviews alerts and displays them on the Triage Agent dashboard. This dashboard automatically includes prioritized alerts and filters to help Insider Risk Management analysts quickly investigate and resolve issues.

You can customize the dashboard columns and filter alerts triaged by the agent by priority, date, alert status, or alert scope. To view the Triage Agent dashboard, select **Triage Agent** at the top of the dashboard page.

Select an alert to display the Agent summary and overview details for the alert. Select **View details** to view details for the alert and for access to the details sections like the risk factors, risk pattern narratives (preview), the Activity explorer, and more.

If you disagree with the **Agent categorization**, select **Is this incorrect?** (preview) to provide feedback on why the categorization is incorrect.

> **Important**
>
> The file risk section of the Triage Agent is deprecated.

For an overview of how alerts provide details, context, and related content for risky activity and how to make your investigation process more effective, see the Insider Risk Management Alerts Triage Experience video.

Understand the Agent summary tab

The **Agent summary** section in the **Alert details** page is only available when selecting an alert from the Triage Agent in Insider Risk Management dashboard. Agent summary information includes details on the categorization for the alert and details about the associated risks used in the triage process. This view provides you with the following information:

- **Agent categorization**: Alerts are categorized as **Needs attention** or **Less urgent**.
- **User info**: Provides the **Alert history**, **Title**, **Organization** and **Last working date** for the user. Select the tile to view additional details (preview).
- **Risk patterns**: Provides a narrative summary of each risk associated with the alert (preview).

Select the narrative summary (preview) for each listed risk to review the following details:

- **Summary**: Each risk pattern includes a narrative summary detailing the risky activity, the sensitive data involved, and the affected files.

- **Actors**: The device involved in the alert and the client IP address, if available.
- **Timeframe**: Provides the start and end dates and times in UTC.
- **Sensitive data involved**: Lists the sensitive information types, classifiers, and file sensitivity labels involved in the alert.
- **Activity names**: The types of actions taken by the user.
- **Activity details**: Explains key aspects of the observed activity, such as the scope of events, sensitive data and files involved, and other contextual signals that contribute to the risk assessment.

Select **Filter activity** for a filtered view of the relevant information in the Activity explorer that contributed to the selected narrative.

> ⓘ **Note**
>
> The Triage Agent does the following:
>
> - Performs an in-depth analysis of the most recent 30,000 activity events associated with the user referenced in the alert.
> - Evaluates all recorded user activities to assess risk, rather than limiting the analysis to only the activities defined in the policy that triggered the alert.
> - Relies on underlying activity log details to determine risk, and when specific information isn't available, it clearly indicates this by marking the detail as "Not found by agent".

Standard alert dashboard

Insider Risk Management policies automatically generate alerts based on risk indicators you define, and display them on the Standard alert dashboard. These alerts give compliance analysts and investigators an all-up view of the current risk status and allow your organization to triage and take actions for discovered potential risks. By default, policies generate a certain number of low, medium, and high severity alerts, but you can increase or decrease the alert volume to suit your needs. Additionally, you can configure the alert threshold for policy indicators when creating a new policy with the policy creation tool. To view the Standard dashboard, select **Standard** at the top of the dashboard page.

> ⓘ **Note**

For any generated alerts, Insider Risk Management generates a single aggregated alert per user. The system adds any new insights for that user to the same alert.

Important

If you scope your policies by one or more administrative units, you can only see alerts for the users you're scoped for. For example, if an administrative scope applies to just users in Germany, you can only see alerts for users in Germany. Unrestricted administrators can see all alerts for all users in the organization.

Restricted administrators can't access alerts for the users assigned to them through security groups or distribution groups added in administrative units. Such user alerts are visible only to unrestricted administrators. Microsoft recommends adding users directly to administrative units to ensure their alerts are also visible to restricted administrators with administrative units assigned.

Filter alerts, save a view of a filter set, customize columns, or search for alerts

Depending on the number and type of active Insider Risk Management policies in your organization, reviewing a large queue of alerts can be challenging. To help you keep track of alerts, you can:

- Filter alerts by various attributes.
- Save a view of a filter set to reuse later.
- Display or hide columns.
- Search for an alert.
- View alert reports.

Filter alerts

To narrow the alerts shown on the dashboard, follow these steps:

1. Select **Add filter**.

2. Select one or more of the following attributes:

Expand table

Attribute	Description
Activity that generated the alert	Displays the top potentially risky activity and policy match during the activity evaluation period that leads to the alert. This value can update over time.
Alert dismissal reason	The reason for dismissing the alert.
Assigned to	The admin that the alert is assigned to for triaging (if assigned).
Policy	The name of the policy.
Risk factors	The risk factors that help determine how risky a user's activity might be. The possible values are *Cumulative exfiltration activities*, *Activities include priority content*, *Sequence activities*, *Activities include unallowed domains*, *Member of a priority user group*, and *Potential high impact user*.
Severity	The user's risk severity level. The options are *High*, *Medium*, and *Low*.
Status	Status of the alert. The options are *Confirmed*, *Dismissed*, *Needs review*, and *Resolved*.
Time detected (UTC)	The start and end dates for when the alert was created. The filter searches for alerts between UTC 00:00 on the start date and UTC 00:00 on the end date.
Triggering event	The event that brought the user into scope of the policy. The triggering event can change over time.

The attributes that you select are added to the filter bar.

3. Select an attribute in the filter bar, and then select a value to filter by. For example, select the **Time detected (UTC)** attribute, enter or select the dates in the **Start date** and **End date** fields, and then select **Apply**.

> **Tip**
>
> To start over at any point, select **Reset all** on the filter bar.

Save a view of a filter set to reuse later

To save the current filter set for later reuse, follow these steps:

1. After applying the filters as described in the preceding procedure, select **Save**, enter a name for the filter set, and then select **Save**.

The filter set is added as a card. It includes a number that shows the count of alerts that meet the criteria in the filter set.

> **Note**
>
> You can save up to five filter sets. To delete a filter set, select the ellipsis (three dots) in the upper-right corner of the card, and then select **Delete**.

2. To reapply a saved filter set, select the card for the filter set.

Display or hide columns

To customize which columns appear in the alerts view, follow these steps:

1. On the right side of the page, select **Customize columns**.
2. Select or clear the checkboxes for the columns you want to display or hide.

The column settings are saved across sessions and across browsers.

Search for alerts

Use the **Search** control to search for a user principal name (UPN), an assigned admin name, or an Alert ID.

View alert reports

Go to **Insider Risk Management** > **Reports** > **Alerts** to view Insider Risk Management alert reports for generated alerts, alerts by region, alerts by triggering event, and more.

Header/summary section of the Alert details page

The **Header/summary** section in the **Alert details** page is only available when selecting an alert from the Standard dashboard. It contains general information about the user and alert. Use this information for context while reviewing detailed information about the detected risk management activity included in the alert for the user:

- **Activity that generated this alert**: Displays the top potentially risky activity and policy match during the activity evaluation period that led to the alert being generated.
- **Triggering event**: Displays the most recent triggering event that prompted the policy to start assigning risk scores to the user's activity. If you configure integration with

Communication Compliance for *Data leaks by risky users* or *Security policy violations by risky users* policies, the triggering event for these alerts is scoped to Communication Compliance activity.

- **User details**: Displays general information about the user assigned to the alert. If anonymization is enabled, the username, email address, alias, and organization fields are anonymized.
- **User alert history**: Displays a list of alerts for the user for the last 30 days. Includes a link to view the complete alert history for the user.

> **Note**
>
> When a user is detected as a potential high impact user, this information is highlighted in the alert header in the **User details** page. The user details also include a summary with the reasons the user is detected as such. To learn more about setting policy indicators for potential high impact users, see Insider Risk Management settings.

Alerts generated from policies scoped to only activities that include priority content include the *Only activity with priority content was scored for this alert* notification in the **Header/summary** section.

> **Tip**
>
> To get a quick overview of an alert, select **Summarize** on the alert details page. When you select **Summarize**, a **Copilot** pane appears on the right side of the page with an alert summary. The alert summary includes all the essential details about the alert, such as the policy that was triggered, the activity that generated the alert, the triggering event, the user involved, their last working date (if applicable), any key user attributes, and the user's top risk factors. Copilot in Microsoft Purview consolidates information about the user from all their alerts and in-scope policies and emphasizes the user's top risk factors. You can also summarize the alert from the Alerts queue without having to open the alert by using Copilot. Or use the standalone version of Microsoft Security Copilot to investigate Insider Risk Management, Microsoft Purview Data Loss Prevention (DLP), and Microsoft Defender XDR alerts.

All risk factors tab

You can access this tab in **Alert details** for alerts in both dashboard views. It opens the summary of risk factors for the user's alert activity. Risk factors help you determine how risky the user's risk management activity is during your review. The risk factors include summaries for:

- **Cumulative exfiltration activities**: Events associated with cumulative exfiltration activities.
- **Health record access**: Potentially risky activities for events associated with accessing health records.
- **Priority content**: Potentially risky activities associated with priority content.
- **Risky browser usage**: Potentially risky activities for events associated with browsing to potentially inappropriate websites.
- **Sequences of activities**: Detected potentially risky activities associated with risk sequences.
- **Top exfiltration activities**: Exfiltration activities with the highest number of events for the alert.
- **Unallowed domains**: Potentially risky activities for events associated with unallowed domains.
- **Unusual activity for this user**: Specific activities for the user that are considered potentially risky, as they're unusual and a departure from their typical activities.

With these filters, you see only alerts with these risk factors, but the activity that generated an alert might not fall into any of these categories. For example, an alert containing sequence activities might be generated simply because the user copied a file to a USB device.

Content detected

The **Content detected** section on the **All risk factors** tab includes content associated with the risk activities for the alert and summarizes activity events by key areas. When you select an activity link, you open the Activity explorer and see more details about the activity.

Activity explorer tab

> ⓘ **Note**
>
> Users can access Activity explorer in the alert management area when their organization enables the feature and after the users trigger events.

The **Activity explorer** tab is available for alerts in both dashboard views. It provides risk investigators and analysts with a comprehensive analytics tool that provides detailed information about alerts. With the Activity explorer, reviewers can quickly review a timeline of detected potentially risky activity and identify and filter all risk activities associated with alerts.

Content preview (preview)

For supported activities, investigators can preview related content directly within Activity explorer to quickly validate risk without creating a case. Content preview (preview) enables early triage by helping investigators determine whether an activity contains sensitive data, represents a false positive, or requires escalation to a full investigation. Content preview is supported for activities that involve accessing or transmitting content.

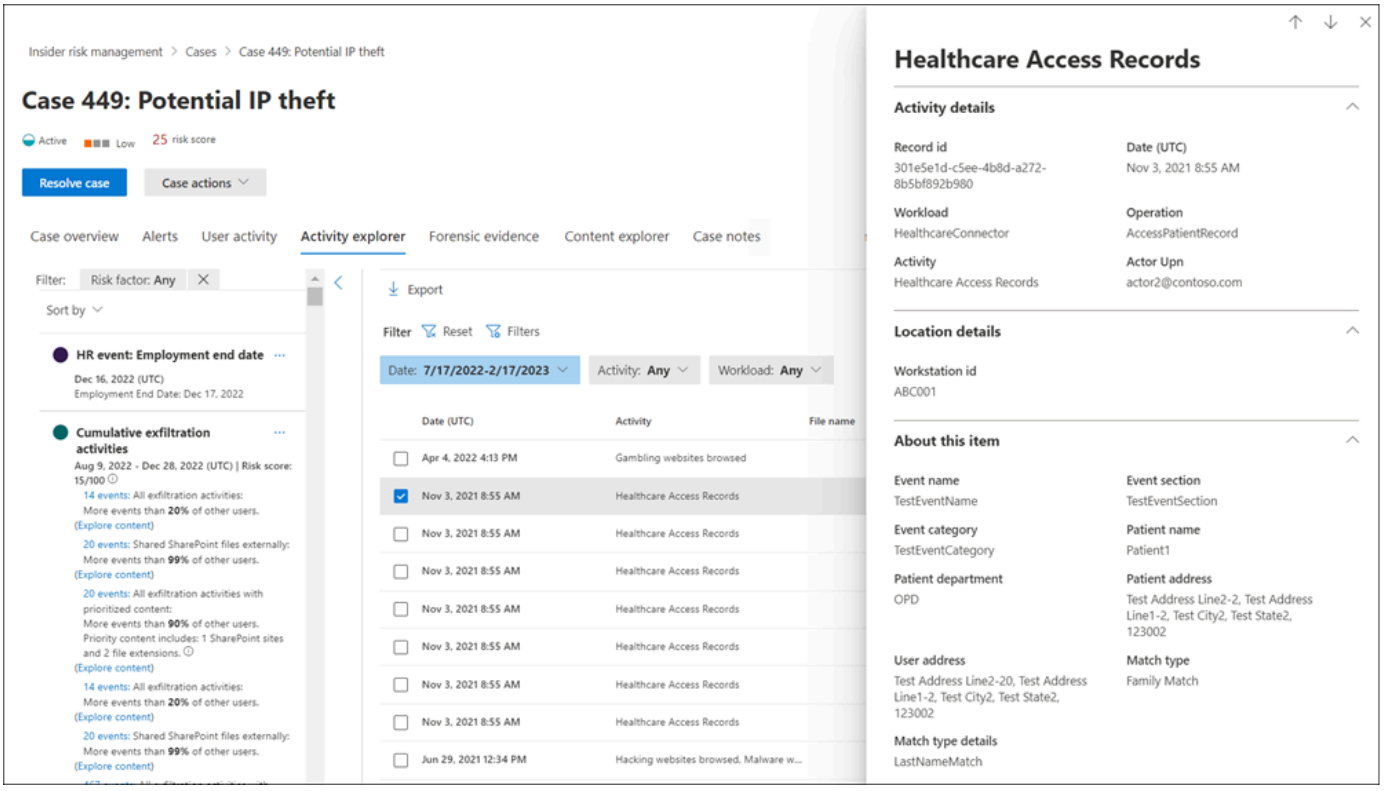
Supported Content preview (preview) activities

Content preview is supported for activities that involve accessing or transmitting content, including:

- **SharePoint**: File accessed, file download, full file sync download
- **Exchange**: Email sent (hygiene events), Data loss prevention rule matches
- **OneDrive for Business**: File accessed, file download, full file sync download

Limitations of Content preview (preview)

Content preview isn't supported for activities that represent state changes, permission changes, deletions, or signal-only events. Examples include:



- File or folder deletion and recycle bin events
- Endpoint activities (such as file deletion, copying, printing, or USB transfers)
- Browser or removable media events
- Metadata-only events (user or group changes, Power BI export or deletion events)
- Files that have been renamed

Use the Activity explorer

When reviewing activities in the Activity explorer, investigators and analysts can select a specific activity and open the activity details pane. The pane displays detailed information about the activity that investigators and analysts can use during the alert triage process. Detailed information might provide context for the alert and assist with identifying the full scope of the risk activity that triggered the alert.

When selecting an activity's events from the activity timeline, the number of activities displayed in the explorer might not match the number of activity events listed in the timeline. Examples of why this difference might occur include:

- **Cumulative exfiltration detection**: Cumulative exfiltration detection analyzes event logs but applies a model that includes deduplicating similar activities to compute cumulative exfiltration risk. Additionally, you might see a difference in the number of potentially risky activities displayed in the Activity explorer if you make changes to your existing policy or settings. For example, if you modify allowed/unallowed domains or add new file type exclusions after a policy is created and potentially risky activity matches occur, the cumulative exfiltration detection activities differ from the results before the policy or settings changes. Cumulative exfiltration detection activity totals are based on the policy and settings configuration at the time of computation and don't include activities prior to the policy and settings changes.
- **Emails to external recipients**: Potentially risky activity for emails sent to external recipients is assigned a risk score based on the number of emails sent, which might not match the activity event logs.

Sequences that contain events excluded from risk scoring

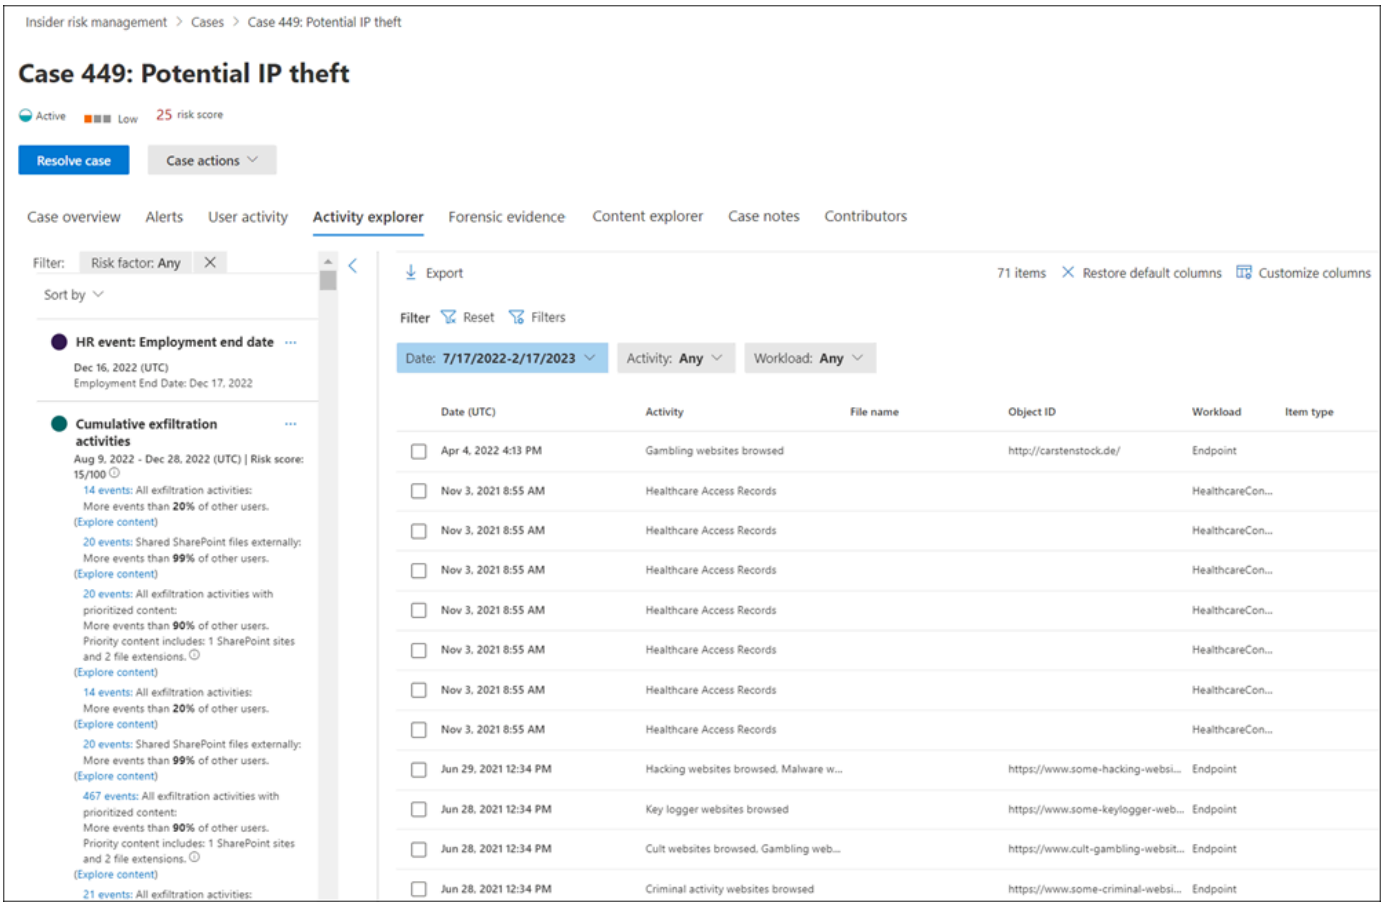
A sequence detection might contain one or more events that are excluded from risk scoring based on your settings configuration. For example, your organization might use the **Global exclusions** setting to exclude .png files from risk scoring since .png files aren't normally risky. But a .png file could be used to obfuscate a malicious activity. For this reason, if an event that's excluded from risk scoring is part of a sequence due to an obfuscation activity, the event is included in the sequence since it might be interesting in the context of the sequence.

The Activity explorer displays the following information for excluded events in sequences:

- If a sequence contains a step where *all* events are excluded, the insight includes just the activity name and date. Select the **View the excluded events** link to filter for the excluded events in the Activity explorer. The User activity scatter plot icon has a risk score of 0 if all events are excluded.
- If a sequence has an insight where *some* events are excluded, the event information for the nonexcluded events is displayed, but the event count doesn't include the excluded events. Select the **View the excluded events** link to filter for the excluded events in the Activity explorer.
- If you select a *sequence link* for an insight, you can drill down into the sequence of events in the activity details pane, including any events that were excluded from scoring. An event excluded from scoring is marked as **Excluded**.

Filter alerts in the Activity explorer

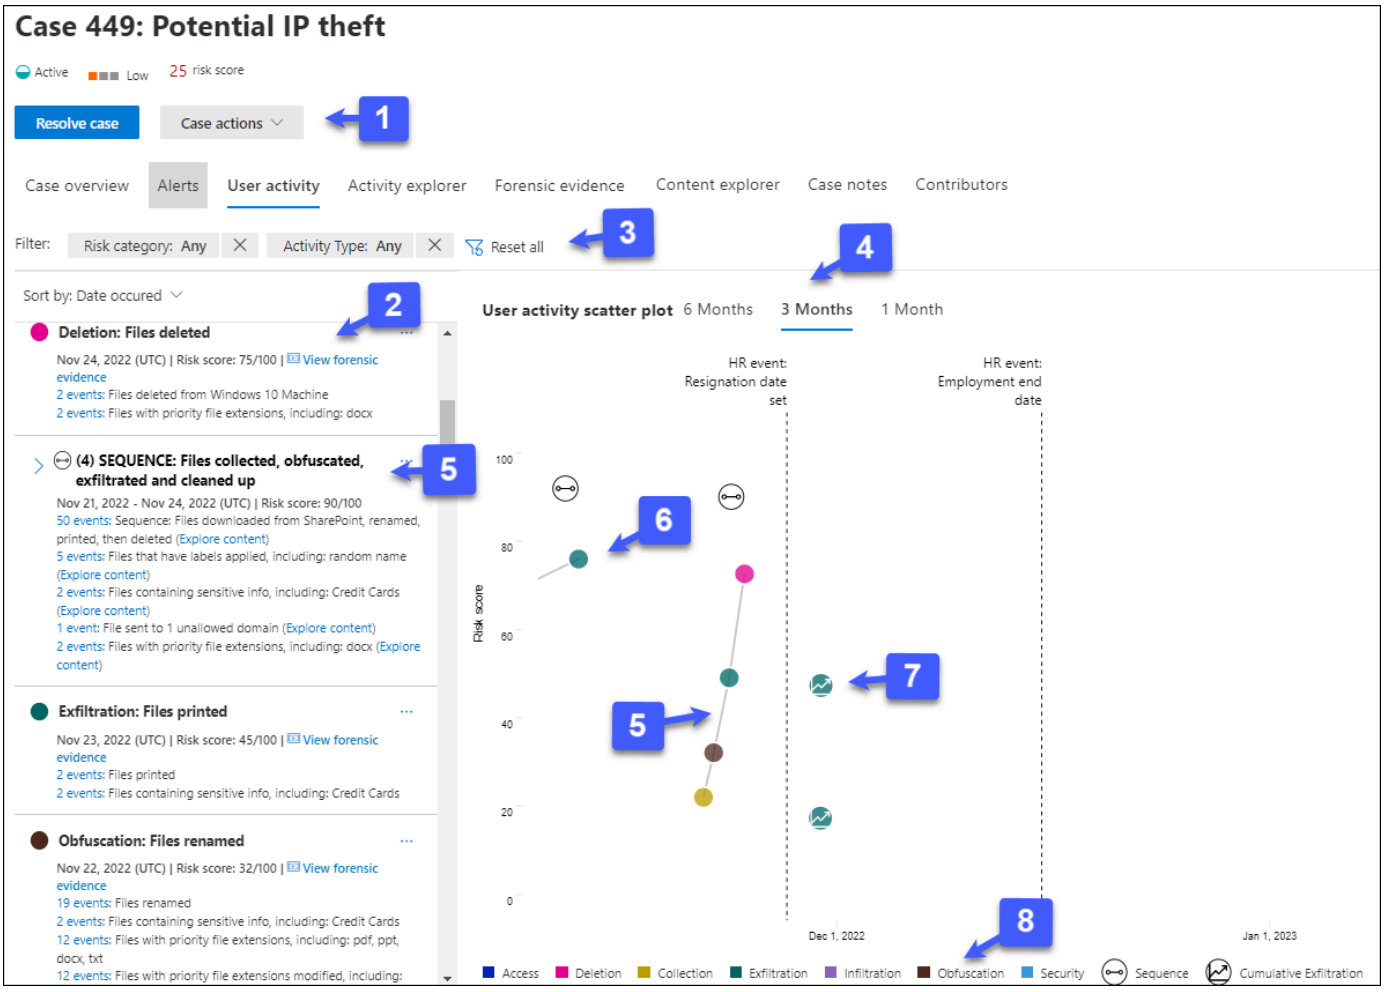
To filter alerts in the Activity explorer for column information, select **Filters**. You can filter alerts by one or more attributes listed in the details pane for the alert. Activity explorer also supports customizable columns to help investigators and analysts focus the dashboard on the information most important to them.



Use the *Activity scope*, *Risk factor*, and *Review status* filters to display and sort activities and insights for the following areas.

- **Activity scope**: Filters all scored activities for the user.
  - All scored activity for this user
  - Only scored activity in this alert

- **Risk factor**: Filters for risk factor activity applicable for all policies assigning risk scores. This filter includes all activity for all policies for included users.
  - Unusual activity
  - Includes events with priority content
  - Includes events with unallowed domain
  - Sequence activities
  - Cumulative exfiltration activities
  - Health record access activities
  - Risky browser usage



- **Review status**: Filters activity review status.
  - All

- Not yet reviewed (filters out any activity that was part of a dismissed or resolved alert)

Review the User activity tab

Both dashboard views provide the **User activity** tab for alerts. It's one of the most powerful tools for internal risk analysis and investigation for alerts and cases in the Insider Risk Management solution. You can quickly review all activities for a user, including a historical timeline of all alerts, alert details, the current risk score for the user, and the sequence of risk events.

1. **Case actions**: The case action toolbar provides options for resolving the case. When viewing a case, you can resolve the case, send an email notice to the user, or escalate the case for a data or user investigation.

2. **Risk activity chronology**: The full chronology of all risk alerts associated with the case, including all the details available in the corresponding alert bubble.

3. **Filters and sorting (preview)**:

    - **Risk category**: Filter activities by the following risk categories: *Activities with risk scores > 15 (unless in a sequence)* and *Sequence activities*.
    - **Activity Type**: Filter activities by the following types: *Access*, *Deletion*, *Collection*, *Exfiltration*, *Infiltration*, *Obfuscation*, *Security*, *Custom Indicator*, *Defense Evasion*, *Privilege Escalation*, *Communication Risk*, *User Compromise Risk*, and *AI Usage*.
    - **Sort by**: List the timeline of potentially risky activities by *Date occurred* or *Risk score*.

4. **Time filters**: By default, the User activity chart displays the last three months of potentially risky activities. You can easily filter the chart view by selecting the *6 Months*, *3 Months*, or *1 Month* tabs on the bubble chart.

5. **Risk sequence**: The chronological order of potentially risky activities is an important aspect of risk investigation. Identifying these related activities is an important part of evaluating overall risk for your organization. Alert activities that are related are displayed with connecting lines to highlight that these activities are associated with a larger risk area. An icon positioned over the sequence activities identifies sequences in this view relative to the risk score for the sequence. Hover over the icon to see the date and time of the risky activity associated with this sequence. This view of activities can help investigators 'connect the dots' for risk activities that could have been viewed as isolated or one-off events. Select the icon or any bubble in the sequence to display details for all the associated risk activities. Details include:

    - **Name** of the sequence.
    - **Date** or **Date range** of the sequence.
    - **Risk score** for the sequence. This score is the numerical score for the sequence of the combined alert risk severity levels for each related activity in the sequence.
    - **Number of events associated with each alert in the sequence**. Links to each file or email associated with each potentially risky activity are also available.
    - **Show activities in sequence**. Displays the sequence as a highlight line on the bubble chart and expands the alert details to display all related alerts in the sequence.

6. **Risk alert activity and details**: The User activity chart visually displays potentially risky activities as colored bubbles. The chart creates bubbles for different categories of risk. Select a bubble to display the details for each potentially risky activity. Details include:

    - **Date** of the risk activity.
    - The **risk activity category**. For example, *Email(s) with attachments sent outside the organization* or *File(s) downloaded from SharePoint Online*.
    - **Risk score** for the alert. This score is the numerical score for the alert risk severity level.
    - Number of events associated with the alert. Links to each file or email associated with the risk activity are also available.

7. **Cumulative exfiltration activities**: Select to view a visual chart of how activity is building over time for the user.

8. **Risk activity legend**: Across the bottom of the user activity chart, a color-coded legend helps you quickly determine risk category for each alert.

Use the Data risk graph tab

> **Important**
>
> **Data risk graph is being deprecated.** The data risk graph in Microsoft Purview Insider Risk Management will be retired on **November 24, 2026**. After that date, the data risk graph experience will no longer be available.
>
> You can't use this feature with the anonymized usernames privacy setting enabled.

Both dashboard views provide access to the **Data risk graph** tab for alerts. By integrating with Microsoft Sentinel, the data risk graph helps you view connections between impacted assets, users, and their activities in an interactive graph experience.

For more information about data risk graphs, see Data risk graph in Insider Risk Management.

Save a view of a filter to reuse later

If you create a filter and customize columns for the filter, you can save a view of your changes so that you or others can quickly filter for the same changes again later. When you save a view, you save both the filters and columns. When you load the view, it loads both saved filters and columns.

1. Create a filter and customize columns.

   > **Tip**
   >
   > To start over at any point, select **Reset**. To change columns that you customized, select **Reset columns**.

2. When you have the filter the way you want it, select **Save this view**, enter a name for the view, and then select **Save**.

   > **Note**
   >
   > The maximum length for a view name is 40 characters and you can't use any special characters.

3. To reuse the view of the filter later, select **Views**, and then select the view you want to open from the **Recommended views** tab (shows the most-used views) or the **Custom views** tab (displays the most frequently used filters).

When you select a view this way, it resets all the existing filters and replaces them with the view that you selected.

Alert status and severity

> **Note**
>
> Insider Risk Management throttles trigger processing to help protect and optimize your risk investigation and review experience. This throttling guards against issues that might result in an overload of policy alerts, such as misconfigured data connectors or data loss prevention policies. Insider Risk Management doesn't process signals received beyond the throttling limits. Learn more about limits in Insider Risk Management.

You can triage alerts into one of the following statuses:

- **Confirmed**: An alert you confirm and assign to a new or existing case.
- **Dismissed**: An alert you dismiss as benign in the triage process. You can provide a reason for the alert dismissal and include notes that are available in the user's alert history to provide additional context for future reference or for other reviewers. Reasons could range from expected activities, nonimpactful events, simply reducing the number of alert activities for the user, or a reason related to the alert notes. Reason classification choices include *Activity is expected for this user*, *Activity is impactful enough for me to investigate further*, and *Alerts for this user contain too much activity*.
- **Needs review**: A new alert where triage actions haven't yet been taken.
- **Resolved**: An alert that's part of a closed and resolved case.

The system automatically calculates alert risk scores from several risk activity indicators. These indicators include the type of risk activity, the number and frequency of the activity occurrence, the history of users' risk activity, and the addition of activity risks that might boost the seriousness of the potentially risky activity. The alert risk score drives the programmatic assignment of a risk severity level for each alert and can't be customized. If you don't triage alerts and risk activities continue to accrue to the alert, the risk severity level can increase. Risk analysts and investigators can use alert risk severity to help triage alerts in accordance with your organization's risk policies and standards.

Alert risk severity levels are:

- **High severity**: The potentially risky activities and indicators for the alert pose significant risk. The associated risk activities are serious, repetitive, and correlate strongly to other

significant risk factors.

- **Medium severity**: The potentially risky activities and indicators for the alert pose a moderate risk. The associated risk activities are moderate, frequent, and have some correlation to other risk factors.
- **Low severity**: The potentially risky activities and indicators for the alert pose a minor risk. The associated risk activities are minor, more infrequent, and don't correlate to other significant risk factors.

Dismiss multiple alerts (preview)

To save triage time, analysts and investigators can dismiss multiple alerts at once. With the **Dismiss alerts** command bar option, you can select one or more alerts with a *Needs review* status on the dashboard and quickly dismiss these alerts as benign. You can select up to 400 alerts to dismiss at one time.

Dismiss an insider risk alert

To dismiss alerts, you must be a member of the *Insider Risk Management*, *Insider Risk Management Analysts*, or *Insider Risk Management Investigators* role group.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Alerts** in the left navigation.
4. On the **Alerts dashboard**, select the alerts that have a *Needs review* status.
5. On the Alerts command bar, select **Dismiss alerts**.
6. On the **Dismiss alerts** detail pane, review the user and policy details associated with the selected alerts.
7. Select **Dismiss alerts** to resolve the alerts as benign.

Reports for alerts

To see reports for alerts, go to the **Reports** page. Each report widget on the **Reports** page displays information for the last 30 days:

- **Total alerts that need review**: The total number of alerts needing review and triage, including a breakdown by alert severity.
- **Open alerts over past 30 days**: The total number of alerts created by policy matches over the last 30 days, sorted by high, medium, and low alert severity levels.

- **Average time to resolve alerts**: A summary of useful alert statistics:
  - Average time to resolve high severity alerts, listed in hours, days, or months.
  - Average time to resolve medium severity alerts, listed in hours, days, or months.
  - Average time to resolve low severity alerts, listed in hours, days, or months.

Assign an alert

If you're an administrator and a member of the *Insider Risk Management*, *Insider Risk Management Analysts*, or *Insider Risk Management Investigators* role group, you can assign ownership of an alert to yourself or to an Insider Risk Management user with one of the same roles. After you assign an alert, you can reassign it to a user with any of the same roles. You can only assign an alert to one admin at a time.

> **Note**
>
> If you **scope your policies by one or more administrative units**, you can only give ownership of an alert to Insider Risk Management users with the appropriate role group permissions. The user highlighted in the alert must be in scope of the admin unit. For example, if an administrative scope applies to just users in Germany, the Insider Risk Management user can only see alerts for users in Germany. Unrestricted administrators can see all alerts for all users in the organization.

After you assign an admin, you can search by admin.

> **Note**
>
> Admins contained within a Microsoft Entra security group aren't supported for alert assignment. Admins must be directly assigned to one of the required roles.
>
> If you're using a custom group, make sure that the custom group contains the ***Case management* role**. The *Insider Risk Management Analysts* and the *Insider Risk Management Investigators* role groups both contain the *Case management* role. If you're using a custom group, you must explicitly add the *Case management* role to the group.

Assign an alert from the Alerts dashboard

To assign an alert from the Alerts dashboard, complete the following steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Alerts** in the left navigation.
4. On the **Alerts dashboard**, select the alerts that you want to assign.
5. In the command bar over the alerts queue, select **Assign**.
6. In the **Assign owner** pane on the right side of the screen, search for an admin with the appropriate permissions, and then select the checkbox for that admin.
7. Select **Assign**.

Assign an alert from the Alerts detail page

To assign an alert from the alert details page, follow these steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Alerts** in the left navigation.
4. Select an alert.
5. In the detail pane for the alert, in the upper-right corner of the page, select **Assign**.
6. In the **Suggested contacts** list, select the appropriate admin.

Create a case for an alert

Create a case for an alert to investigate potentially risky activity. You must be a member of the *Insider Risk Management* or *Insider Risk Management Investigators* role group to create a case.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Alerts** in the left navigation.
4. On the **Alerts dashboard**, select the alert you want to confirm and create a new case for.
5. On the **Alerts details pane**, select **Actions** > **Confirm alerts & create case**.
6. In the **Confirm alert and create insider risk case** dialog box, enter a name for the case, select users to add as contributors, and add comments as applicable. Comments automatically add to the case as a case note.
7. To download the content for the case, select **Create case with content download on** (preview). After you reach the content download limit, you can still create cases, but you

must leave the box unchecked. If you don't enable content download when you create the case, you can enable downloads when the case is active.

8. Select **Create case** to create a new case.

After you create the case, investigators and analysts can manage and act on the case. For more information, see the Insider Risk Management case article.

Retention and item limits

As Insider Risk Management alerts age, their value to minimize potentially risky activity diminishes for most organizations. Conversely, active cases and associated artifacts (alerts, insights, activities) always provide value and don't have an automatic expiration date. This retention policy includes all future alerts and artifacts in an active status for any user associated with an active case.

To minimize the number of older items that provide limited current value, the following retention and limits apply for Insider Risk Management alerts, cases, and user reports:

Expand table

Item	Retention/Limit
Active cases (and associated artifacts)	2,000 active cases, retained indefinitely and never expire
Alerts with Needs review status	120 days from alert creation, then automatically deleted
Maximum number of active cases	100
Resolved cases (and associated artifacts)	120 days from case resolution, then automatically deleted
User activities reports	120 days from report creation, then automatically deleted

Best practices for managing your alert volume

To minimize insider risks in your organization, regularly review, investigate, and act on potentially risky insider alerts. Quickly taking action to reduce these risks can potentially save your organization time, money, and potential regulatory or legal consequences. Learn about best practices for managing your Insider Risk Management alert queue.

Data risk graph in Insider Risk Management

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Data risk graphs in Insider Risk Management provide a visual investigation experience that combines asset and activity data into a single view. Powered by Microsoft Sentinel integration, it summarizes alert-related activity by a potential insider over the past 30 days, helping analysts triage alerts by revealing hidden contextual connections.

> **Important**
>
> **Data risk graph is being deprecated.** The data risk graph in Microsoft Purview Insider Risk Management will be retired on **November 24, 2026**. After that date, the data risk graph experience will no longer be available.

For more information about Microsoft Sentinel integration, see Learn about Microsoft Sentinel in Microsoft Purview.

> **Important**
>
> You cannot use this feature with the anonymized usernames privacy setting enabled. If you have anonymized user names, the graph will not load.

> **Note**
>
> Admin units aren't supported in the data risk graph. If you're scoped to an admin unit, data doesn't appear in data risk graphs.

Supported activities in data risk graph

The data risk graph currently supports the following exfiltration activities:

- Anonymous links created in SharePoint or OneDrive
- Anonymous links used via SharePoint or OneDrive
- Company links created in SharePoint or OneDrive
- File downloads from SharePoint and OneDrive
- Files renamed in SharePoint and OneDrive

For more information about exfiltration detection indicators, see Configure policy indicators in Insider Risk Management.

Before you begin

Before you can use data risk graphs in Insider Risk Management, complete the following steps:

- Learn about pay-as-you-go billing in Microsoft Sentinel for your organization.
- Configure the prerequisites for Microsoft Sentinel data lake and Microsoft Sentinel graph
- Review the changes made when onboarding to Microsoft Sentinel data lake and Microsoft Sentinel graph
- Configure at least one Insider Risk Management policy for supported data exfiltration activities.

Configure data risk graph

> **Important**
>
> You always have one data lake. If you already onboarded to the data lake with another Microsoft service, your existing data lake is used. If you never onboarded to the data lake, onboarding in Insider Risk Management enables Microsoft Sentinel data lake and graph in the Defender portal.

After you complete the prerequisites and understand the onboarding changes that Microsoft Sentinel data lake and graph make to your organization, complete the following steps to configure data risk graph in Insider Risk Management:

> **Important**

Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

1. Go to the Microsoft Purview portal with an account assigned the *Global Administrator* or *Security Administrator* role.
2. Select the **Insider Risk Management** solution card, then select **Recommended actions** in the left nav.
3. In the **Comprehensive protection** section, select **Set up data lake and data risk graph**.

   If you don't have the correct permissions to set up the data lake, a notification appears to contact a global or billing administrator in your organization.
4. On the **Setup** tab on **Set up data lake & risk graph**, configure the following settings:
   a. **Subscription**: Enter the Azure subscription you want to use. Your selected subscription must be valid and accessible and you must be the subscription owner.
   b. **Resource group**: Enter the resource group you want to use. Your selected resource group must be valid and accessible.

   > **Important**
   >
   > After the data lake is provisioned for a specific Azure subscription and resource group, you can't migrate it to a different subscription or resource group.
5. Select **Setup**.

The data lake and data risk graph setup process begins, and onboarding might take up to 60 minutes to complete. You can close the setup panel while the process is running. After the onboarding process completes, you see *Complete* on **Set up data lake & risk graph**. The data risk graph shows events that occur after your Microsoft Sentinel data lake was created or onboarded.

Initial processing of data and data risk graph availability for an investigation can take 24–48 hours.

> **Important**
>
> When the data risk graph is first created, it includes the most recent seven days of data. As the data risk graph refreshes over time, the look-back window expands up to a maximum of

30 days. It might take some time for the data risk graph to reach the full 30-day window, so expect gradual growth after initial setup.

Use data risk graph

Data risk graph in Insider Risk Management uniquely visualizes correlations between impacted data, users, and their activities. It provides critical context to guide mitigation and next steps. For example, when you uncover an alert related to a highly sensitive document, data risk graphs give you visibility into which users downloaded it or if they accessed it from an IP address flagged as risky by your organization's security signals. This visibility lets you uncover new nodes to a data security incident, like additional users or new content related to an alert.

To view the data risk graph for an alert, you must be assigned the *Insider Risk Management Graph Reader* role. This role is included by default in several Insider Risk Management built-in role groups. For more information, see Assign permissions in Insider Risk Management.

> **Important**
>
> All user names are visible in data risk graph, even if pseudonymization is enabled in Insider Risk Management privacy settings.

To use the data risk graph in Insider Risk Management, complete the following steps:

1. Go to the Microsoft Purview portal with an account assigned the *Insider Risk Management Graph Reader* role.
2. Select the **Insider Risk Management** solution card, then select **Alerts** in the left nav.
3. Select an alert to review, then select the **Data risk graph** tab.
4. Filter the time as applicable and select individual data risk graph nodes for more information about each connection during triage.
5. Expand relationships in the graph by selecting the + icon on users or assets.

The data risk graph contains several nodes. Selecting a node shows details about the node:

- **User details**: Shows information about users associated with the alert. This information includes organization information for each user, including User Principal Name (UPN), labels, location, job title, and more.
- **Data details**: Shows information about files and sites. This information includes the object location, type, labels, and more.

You can view data risk graph information for users based on the last 30 days of activity. This fixed duration isn't extendable.

Best practices for managing your alert volume in Insider Risk Management

08/20/2025

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Reviewing, investigating, and acting on potentially risky insider alerts are important parts of minimizing insider risks in your organization. When you quickly take action to minimize the impact of these risks, you can potentially save time, money, and regulatory or legal ramifications for your organization. In this remediation process, the first step of reviewing alerts can seem like the most difficult task for many analysts and investigators.

This article provides best practices for managing the volume of alerts in your organization so that you don't have too many or too few alerts. For a general discussion of how alerts are generated and the tools for managing alerts, see Investigate insider risk activities.

Too few alerts to review

If you're receiving too few Insider Risk Management alerts, try the following solutions:

- **Update your settings:** Changes that you make to settings apply globally across all of your policies.
  - **Enable more indicators:** When you select more indicators, your policies can detect a larger group of activities.

    How to: Go to **Settings** > **Policy indicators**, and then enable all available and relevant indicators.
  - **Adjust the Alert volume slider:** Use this slider to see all medium and high severity alerts, and most low severity alerts. **Note:** Adjusting the slider might result in more false positives.

How to: Go to **Settings** > **Intelligent detections** > **Alert volume**, and then move the slider to **More alerts**.

- **Modify the policy:** Find the policy that isn't generating enough alerts, and then consider the following actions:

  - **Increase the user coverage in the policy:** Policies with few users included in the scope are less likely to generate alerts. If applicable, consider increasing the number of users in scope for your policy.

    How to: Select a specific policy on the **Policies** page, select **Edit policy**, and then go to the **Users and groups** page to increase the number of in-scope users.

  - **Lower the trigger thresholds:** For policies based on the *Data leaks* and *Risky Browser Usage (preview)* templates, you can customize some trigger thresholds. These thresholds define when you start to detect user activities. If you lower trigger thresholds, you lower the criteria for a user to start being evaluated for risky activity. **Note:** If a user doesn't appear in the **Users and groups** page, it means that triggering event criteria isn't met yet.

    How to: Go to the specific policy on the **Policies** page, select **Edit policy**, go to the **Trigger thresholds** page, select the **Use custom thresholds** option, and then adjust your thresholds.

  - **Add more indicators:** Indicators are the activities a user must do to be considered risky. If you don't have many indicators (activities considered to be risky) selected in your policy, alerts are less likely to be generated.

    How to: Go to the specific policy on the **Policies** page, select **Edit policy**, go to the **Indicators** page, and then select more indicators.

  - **Lower indicator thresholds:** After your users begin getting evaluated (have a triggering event), an alert is generated only if they do activities over a certain threshold that might indicate that their activity is risky. When you lower the indicator thresholds, you lower the threshold that users must surpass to generate an alert.

    How to: Go to the specific policy on the **Policies** page, select **Edit policy**, go to the **Indicator thresholds** page, select the **Customize thresholds** option, and then set your thresholds. Learn about indicator threshold recommendations

Too many alerts to review

If you receive too many valid alerts or have too many stale low-risk alerts, consider taking the following actions:

- **Enable analytics:** When you enable analytics, you can quickly identify potential risk areas for your users. Analytics helps you determine the type and scope of Insider Risk Management policies that you might want to configure.

  How to: Go to **Settings** > **Analytics**.

- **Get real-time insights:** If you want to take advantage of threshold recommendations, get real-time insights from analytics. These insights can help you efficiently adjust the selection of indicators and thresholds of activity occurrence so that you don't receive too few or too many policy alerts.

  How to: See Use real-time analytics to help manage alert volume.

- **Adjust your policies:** The most basic method to address the type and volume of alerts is selecting and configuring the correct insider risk policy. Starting with the appropriate policy template helps you focus the types of risk activities and alerts you see. Other factors that might impact alert volume are the size of the in-scope user and groups and the content and channels that you prioritize. Consider adjusting policies to refine these areas to what is most important for your organization.

  How to: Select a specific policy on the **Policies** page, then select **Edit policy**.

- **Modify your insider risk settings:** Insider risk settings include a wide variety of configuration options that can impact the volume and types of alerts you receive. Review and understand the following settings to filter out alert noise:
  - Policy indicators and indicator thresholds
  - Global exclusions
  - Detection groups
  - Variants of built-in indicators
  - Intelligent detections
  - Policy timeframes

- **Enable inline alert customization:** When you enable inline alert customization, analysts and investigators can quickly edit policies when reviewing alerts. They can update thresholds for activity detection with Microsoft recommendations, configure custom thresholds, or choose to ignore the type of activity that created the alert. If you don't enable this setting, only users assigned to the *Insider Risk Management* role group can use inline alert customization.

  How to: Go to **Settings** > **Inline alert customization**.

- **Bulk delete alerts, where applicable:** To save triage time for your analysts and investigators, consider immediately dismissing multiple alerts in bulk. You can select up to 400 alerts to dismiss at one time.

Managing resource constraints in your organization

Modern workplace users often have a wide variety of responsibilities and demands on their time. To address resource constraints, take these actions:

- **Focus analyst and investigator efforts on the highest risk alerts first:** Depending on your policies, you might capture user activities and generate alerts with varying degrees of potential impact on your risk mitigation efforts. Filter alerts by severity and prioritize *High severity* alerts.
- **Use Microsoft Copilot**: You can use Microsoft Copilot in Microsoft Purview to summarize an alert without even opening it. This approach can speed up the triaging experience.
- **Assign users as analysts and investigators:** Having the right user assigned to the proper roles is an important part of the insider risk alert review process. Make sure you assign the appropriate users to the *Insider Risk Management Analysts* and *Insider Risk Management Investigators* role groups.
- **Use automated insider risk features to help discover the highest risk activities:**
  - Use Insider Risk Management sequence detection and cumulative exfiltration detection to quickly discover harder to find risks in your organization.
  - Consider fine-tuning your risk score boosters, and use global exclusions, detection groups, and variants.
  - Fine tune minimum indicator threshold settings for your policies.

Investigate Insider Risk Management activities

Take action on Insider Risk Management cases

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Cases are the core of Insider Risk Management. They let you investigate and act on issues that risk indicators in your policies generate. Create cases manually from alerts when you need to take extra steps to address a compliance-related issue for a user. Each case focuses on one user. You can add multiple alerts for that user to an existing case or start a new case.

After you investigate the details of a case, take action by:

- Sending the user a notice
- Resolving the case as benign
- Sharing the case with your ServiceNow instance or with an email recipient
- Escalating the case for an eDiscovery (Premium) investigation

For an overview of how you investigate and manage cases in Insider Risk Management, see the Insider Risk Management Investigation and Escalation video.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Use the Cases dashboard

> **Tip**

To see reports for cases, go to the **Reports** page. Each report widget on the **Reports** page displays information for the last 30 days:

- **Active cases**: The total number of active cases under investigation.
- **Cases over past 30 days**: The total number of cases created, sorted by *Active* and *Closed* status.
- **Statistics**: Average time of active cases, listed in hours, days, or months.

The Insider Risk Management **Cases dashboard** enables you to view and act on cases. The case queue lists all active and closed cases for your organization, along with the current status of the following case attributes:

- **Case ID**: The ID of the case.
- **Case name**: The name of the case, defined when you confirm an alert and create the case.
- **Status**: The status of the case, either *Active* or *Closed*.
- **User**: The user for the case. If you enable anonymization for usernames, the portal displays anonymized information.
- **Content download**: This field shows whether content download is on or off for the case.
- **Time case opened**: The time that passes since the case is opened.
- **Total policy alerts**: The number of policy matches included in the case. This number might increase if you add new alerts to the case.
- **Last activity date**: The time that passes since you add a case note or change the case state.
- **Last updated by**: The name of the Insider Risk Management analyst or investigator that last updated the case.

> ⓘ **Note**
>
> If you scope your policies by one or more administrative units, you can only give ownership of a case to Insider Risk Management users with the appropriate role group permissions. The user highlighted in the alert must be in scope of the admin unit. For example, if an administrative scope applies to just users in Germany, the Insider Risk Management user can only see alerts for users in Germany. Unrestricted administrators can see all cases for all users in the organization.

Use the **Search** control to search for a Case ID or to search for specific text in case names. Use the case filter to sort cases by the following attributes:

- Status

- Time case opened, start date, and end date
- Last updated, start date, and end date

Assign a case

If you're an administrator with the appropriate permissions, you can assign ownership of a case to yourself or to an Insider Risk Management user with the Insider Risk Management, Insider Risk Management Analyst, or Insider Risk Management Investigator role. After you assign a case, you can reassign it to a user with any of the same roles. You can only assign a case to one admin at a time.

If you assign an admin to a case, you can filter by admin.

Assign a case from the Cases dashboard

To assign a case from the Cases dashboard, complete the following steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Cases** in the left navigation.
4. On the **Cases dashboard**, select the cases that you want to assign.
5. In the command bar over the cases queue, select **Assign**.
6. On the **Assign owner** pane on the right side of the screen, search for an admin with the appropriate permissions, and then select the checkbox for that admin.
7. Select **Assign**.

Assign a case from the Cases detail page

To assign a case from the case detail page, complete the following steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Cases** in the left navigation.
4. Select a case.
5. In the detail pane for the case, select **Assign**.
6. In the **Suggested contacts** list, select the appropriate admin.

Filter cases

Depending on the number and type of active Insider Risk Management policies in your organization, reviewing a large queue of cases can be challenging. By using case filters, analysts and investigators can sort cases by several attributes. To filter alerts on the **Cases dashboard**, select the **Filter** control. You can filter cases by one or more attributes:

- **Status**: Select one or more status values to filter the case list. The options are *Active* and *Closed*.
- **Time case opened**: Select the start and end dates for when the case was opened.
- **Last updated**: Select the start and end dates for when the case was updated.

Filter cases, save views, customize columns, or search cases

Depending on the number and type of active Insider Risk Management policies in your organization, reviewing a large queue of cases can be challenging. To help you keep track of cases, you can:

- Filter cases by various attributes.
- Save a view of a filter set to reuse later.
- Display or hide columns.
- Search for an alert.

Filter cases

To filter cases on the Cases dashboard, complete the following steps:

1. Select **Add filter**.
2. Select one or more of the following attributes:

Expand table

Attribute	Description
Assigned to	The admin that the alert is assigned to for triaging (if assigned).
Last activity date	The start and end dates for when the case was last updated.
Status	Current status of the case. The options are *Active* and *Closed*.
Time case opened	The start and end dates for when the case was opened.

The filter bar shows the attributes that you select.

3. Select an attribute in the filter bar, and then select a value to filter by. For example, select the **Last activity date** attribute, enter or select the dates in the **Start date** and **End date** fields, and then select **Apply**.

   > **Tip**
   >
   > To start over at any point, select **Reset all** on the filter bar.

Save a view of a filter set to reuse later

To save a filter set for reuse, complete the following steps:

1. After applying the case filters described in Filter cases, select **Save** over the filter bar, enter a name for the filter set, and then select **Save**.

   The filter set appears as a card over the filter bar. It includes a number that shows the count of cases that meet the criteria in the filter set.

   > **Note**
   >
   > You can save up to five filter sets. To delete a filter set, select the ellipsis (three dots) in the upper-right corner of the card, and then select **Delete**.

2. To reapply a saved filter set, select the card for the filter set.

Display or hide columns

To display or hide columns on the Cases dashboard, complete the following steps:

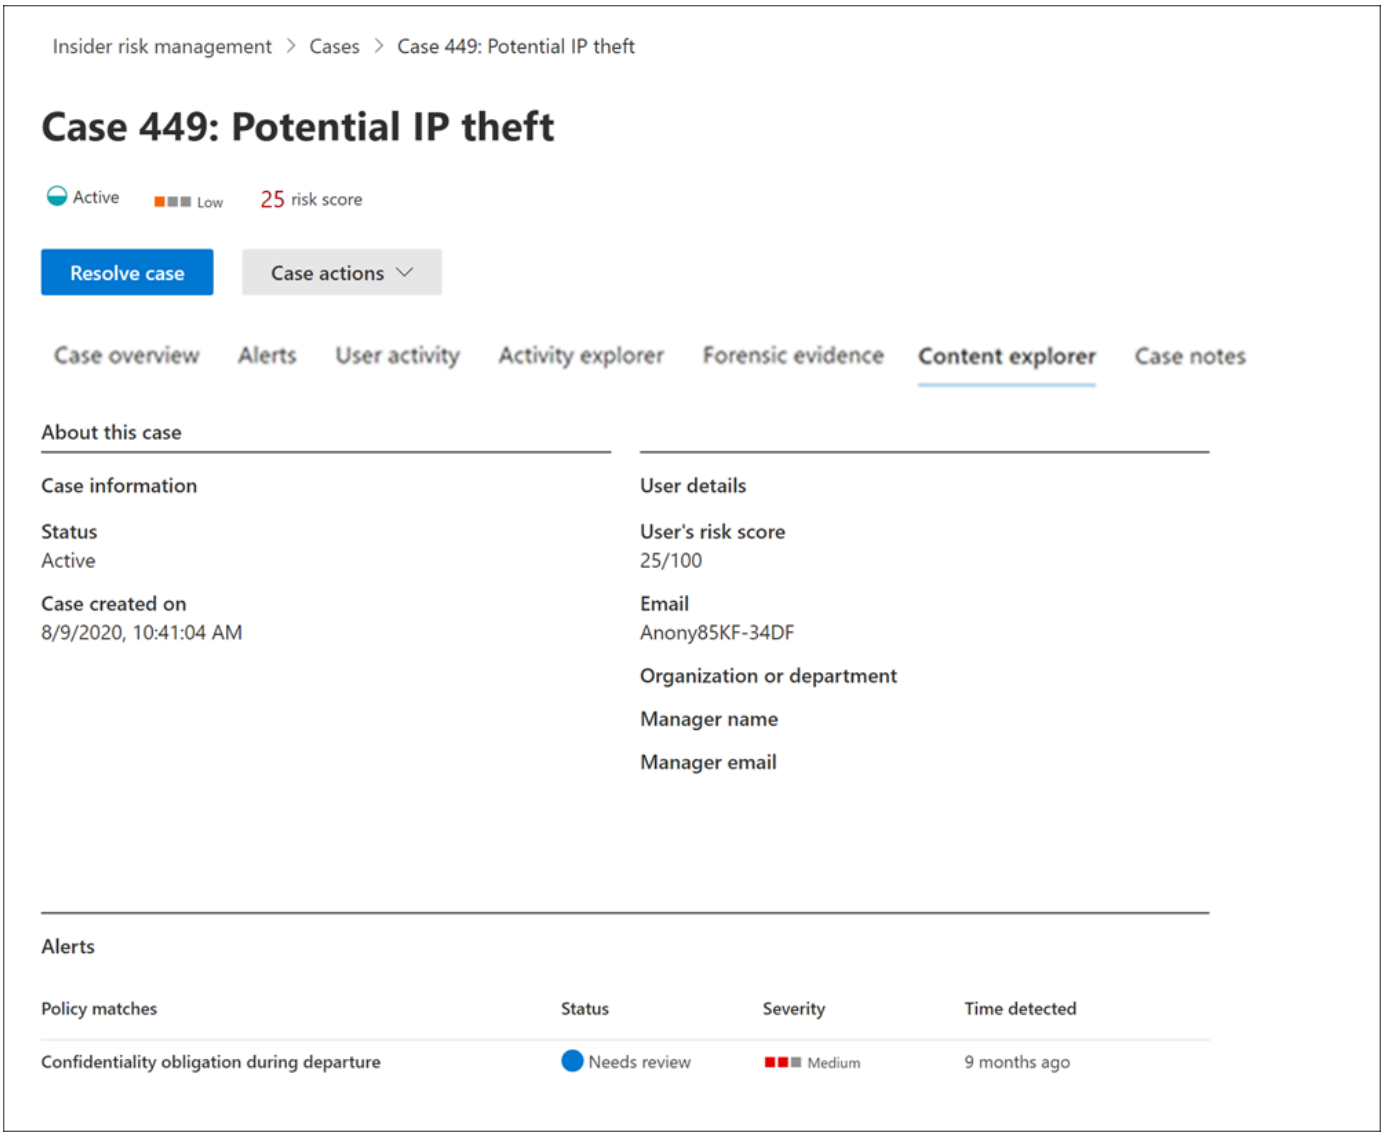
1. On the right side of the page, select **Customize columns**.
2. Select or clear the checkboxes for the columns you want to display or hide.

The portal saves the column settings across sessions and across browsers.

Search for cases

Use the **Search** control to search for a user principal name (UPN), an assigned admin name, or an Alert ID.

Investigate a case



Deeper investigation into Insider Risk Management alerts is critical to taking proper corrective actions. Insider Risk Management cases are the central management tool to dive deeper into user risk activity history, alert details, the sequence of risk events, and to explore the content and messages exposed to risks. Risk analysts and investigators also use cases to centralize review feedback and notes and to process case resolution.

Selecting a case opens the case management tools and allows analysts and investigators to dig into the details of cases.

Review the case overview

The **Case overview** tab summarizes the case details for risk analysts and investigators. It includes the following information in the **About this case** area:

- **Case ID**: The ID of the case.
- **Status**: The current status of the case, either Active or Closed.
- **Case created on**: The date and time the case was created.
- **User's risk score**: The current calculated risk level of the user for the case. The system calculates this score every 24 hours and uses alert risk scores from all active alerts associated to the user. When *User is detected as a potential high impact user* or *User is a member of a priority user group* risk booster is enabled as **Risk score boosters** in the **Policy indicators** section of the **Insider Risk Management settings** page, the **User details** page includes detailed information about the user's calculated risk level.
- **Email**: The email alias of the user for the case.
- **Organization or department**: The organization or department that the user is assigned to.
- **Manager name**: The name of the user's manager.
- **Manager email**: The email alias of the user's manager.

The **Case overview** tab also includes an **Alerts** section that includes the following information about policy match alerts associated with the case:

- **Policy matches**: The name of the Insider Risk Management policy associated with the match alerts for potentially risky user activity that might lead to a security incident.
- **Status**: Status of the alert.
- **Severity**: Severity of the alert.
- **Time detected**: The time that has passed since the alert was generated.

Review alerts in a case

The **Alerts** tab summarizes the current alerts included in the case. You can add new alerts to an existing case. When you assign new alerts, the **Alert** queue includes them. The queue lists the following alert attributes:

- Alert
- Alert ID

- Status
- Severity
- Time detected

Select an alert from the queue to display the **Alert detail** page.

Use the search control to search for an Alert ID or specific text in alert names. Use the alert filter to sort cases by the following attributes:

- Status
- Severity
- Time detected, start date, and end date

Use the filter control to filter alerts by several attributes, including:

- **Status**: Select one or more status values to filter the alert list. The options are *Confirmed*, *Dismissed*, *Needs review*, and *Resolved*.
- **Severity**: Select one or more alert risk severity levels to filter the alert list. The options are *High*, *Medium*, and *Low*.
- **Time detected**: Select the start and end dates for when the alert was created.
- **Policy**: Select one or more policies to filter the alerts generated by the selected policies.

Review user activity in a case

Risk analysts and investigators use the **User activity** tab to review user activity details. It provides a visual representation of all the potentially risky activities associated with risk alerts and cases. Use this information to determine whether those risky activities might lead to a security incident. For example, as part of the alert triage process, analysts might need to review all the risk activities associated with the case for more details. In cases, risk investigators can review user activity details and the bubble chart to help understand the overall scope of the risk activities associated with the case. For more information about the User activity chart, see the Insider Risk Management activities article.

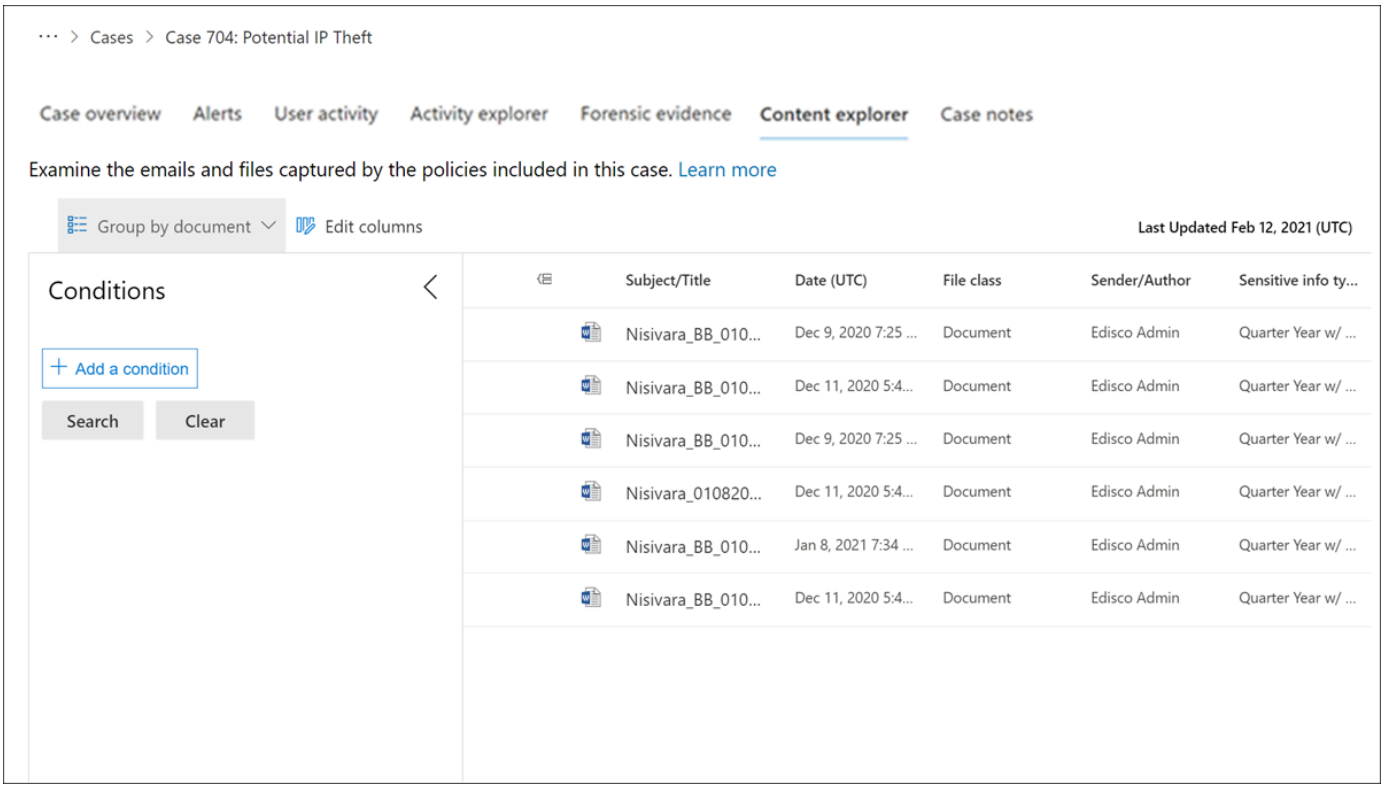
Activity explorer (preview)

The **Activity explorer** tab helps risk analysts and investigators review case activity details associated with risk alerts. For example, as part of the case management actions, investigators and analysts might need to review all the risk activities associated with the case for more details. By using the **Activity explorer**, reviewers can quickly examine a timeline of detected potentially risky activity and identify and filter all risk activities associated with alerts.

For more information about the Activity explorer, see the Insider Risk Management activities article.

Review forensic evidence

The **Forensic evidence** tab helps risk investigators review visual captures associated with risk activities included in cases. For example, as part of the case management actions, investigators might need to clarify the context of the user activity under review. Viewing the actual clips of the activity can help the investigator determine if the user activity is potentially risky and might lead to a security incident.



For more information about forensic evidence, see the Learn about Insider Risk Management forensic evidence article.

Use Content explorer for case evidence

The **Content explorer** tab helps risk investigators review copies of all individual files and email messages associated with risk alerts. For example, if an alert is created when a user downloads hundreds of files from SharePoint Online and the activity triggers a policy alert, the case captures and copies all the downloaded files for the alert to the Insider Risk Management case from original storage sources.

If content download is off for the case, select **Add content** from the Content explorer tab. If you've reached the maximum number cases with content downloaded limit, you must resolve cases to download additional content.

The Content explorer is a powerful tool with basic and advanced search and filtering features. To learn more about using the Content explorer, see Insider Risk Management Content explorer.

Manage case notes

Risk analysts and investigators use the **Case notes** tab in a case to share comments, feedback, and insights about their work for the case. Notes are permanent additions to a case. After saving a note, you can't edit or delete it. When you create a case from an alert, the comments you enter in the **Confirm alert and create insider risk case** dialog box automatically become a case note.

The case notes dashboard shows notes by the user who created the note and the time that passes since the note is saved. To search the case note text field for a specific keyword, use **Search** on the case dashboard and enter a specific keyword.

System-generated notes (preview)

System-generated notes are automatically added to cases when there's a change in status or assignment. The following changes trigger a system-generated note:

- A change in case status
- A change in the assigned user
- Closure of a case
- A case escalation

System-generated notes appear alongside analyst-created notes in the **Notes** tab within the case details panel, helping you stay up to date with all activity on a case.

Add a case note

To add a note to a case, complete the following steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Cases** in the left navigation.
4. Select a case, then select the **Case notes** tab.
5. Select **Add case note**.
6. In the **Add case note** dialog box, type the note.
7. Select **Save** to add the note to the case.

Manage case contributors

Risk analysts and investigators can add other reviewers to the case through the **Contributors** tab. Users must be assigned the **Role Management** role to add contributors to the case. By default, all users assigned the **Insider Risk Management Investigators** and the **Insider Risk Management** roles appear as contributors for each active and closed case.

You can grant temporary access to a case by adding a user as a contributor, but with the following restrictions:

- Analysts and investigators can add contributors.
- You can't add analysts as contributors.
- Contributors can't add contributors.

Contributors have all case management control on the specific case except for:

- Permission to confirm or dismiss alerts.
- Permission to edit the contributors for cases.

Add a contributor to a case

To add a contributor to a case, complete the following steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Cases** in the left navigation.
4. Select a case, and then select the **Contributors** tab.
5. Select **Add contributor**.

6. In the **Add contributor** dialog box, start typing the name of the user you want to add, and then select the user from the suggested user list. This list comes from the Microsoft Entra ID of your tenant subscription.
7. Select **Add** to add the user as a contributor.

Case actions

Risk investigators can take action on a case in one of several methods. The method depends on the severity of the case, the history of risk of the user, and the risk guidelines of your organization. In some situations, you might need to escalate a case to a user or data investigation to collaborate with other areas of your organization and to dive deeper into risk activities. Insider Risk Management is tightly integrated with other Microsoft Purview solutions to help you with end-to-end resolution management.

Send email notice

In most cases, user actions that create insider risk alerts are inadvertent or accidental. Sending a reminder notice to the user by email is an effective method for documenting case review and action. This method reminds users of corporate policies or points them to refresher training. You generate notices from notice templates that you create for your Insider Risk Management infrastructure.

Remember that sending an email notice to a user ***does not*** resolve the case as *Closed*. In some cases, you might want to leave a case open after sending a notice to a user to look for more risk activities without opening a new case. If you want to resolve a case after sending a notice, select **Resolve case** as a follow-on step after sending a notice.

Send a notice to the user assigned to a case

To send a notice to the user assigned to a case, complete the following steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Cases** in the left navigation.
4. Select a case, and then select **Send email notice** on the case action toolbar.
5. In the **Send e-mail notice** dialog box, select the **Choose a notice template** dropdown control to select the notice template for the notice. This selection pre-fills the other fields in the notice.

6. Review the notice fields and update as appropriate. The values you enter override the values in the template.
7. Select **Send** to send the notice to the user. All sent notices are added to the case notes queue on the **Case notes** dashboard.

Escalate for investigation

Escalate the case for user investigation when you need extra legal review for the user's risk activity. This escalation opens a new Microsoft Purview eDiscovery (Premium) case in your Microsoft 365 organization. eDiscovery (Premium) provides an end-to-end workflow to preserve, collect, review, analyze, and export content that's responsive to your organization's internal and external legal investigations. It also lets your legal team manage the entire legal hold notification workflow to communicate with custodians involved in a case. Escalating to an eDiscovery (Premium) case from an Insider Risk Management case helps your legal team take appropriate action and manage content preservation. For more information about eDiscovery (Premium) cases, see Overview of Microsoft Purview eDiscovery (Premium).

Escalate a case to a user investigation

To escalate a case to a user investigation, complete the following steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Cases** in the left navigation.
4. Select a case, and then select **Escalate for investigation** on the case action toolbar.
5. In the **Escalate for investigation** dialog box, enter a name for the new user investigation. If needed, enter notes about the case, and then select **Escalate**.
6. Review the notice fields and update as appropriate. The values you enter override the values on the template.
7. Select **Confirm** to create the user investigation case.

After you escalate the Insider Risk Management case to a new user investigation case, you can review the new case in the **eDiscovery** > **Advanced** area in the Microsoft Purview portal.

Run automated tasks by using Power Automate flows for the case

By using recommended Power Automate flows, risk investigators and analysts can quickly take action to:

- Request information from HR or business about a user in an insider risk case.
- Notify manager when a user has an insider risk alert.
- Create a record for an Insider Risk Management case in ServiceNow.
- Notify users when they're added to an insider risk policy.

To run, manage, or create Power Automate flows for an Insider Risk Management case:

1. Select **Automate** on the case action toolbar.
2. Choose the Power Automate flow to run, and then select **Run flow**.
3. After the flow completes, select **Done**.

For more information about Power Automate flows for Insider Risk Management, see Getting started with Insider Risk Management settings.

View or create a Microsoft Teams team for the case

When you enable Microsoft Teams integration for Insider Risk Management in settings, the solution automatically creates a Microsoft Teams team every time you confirm an alert and create a case. Risk investigators and analysts can quickly open Microsoft Teams and navigate directly to the team for a case by selecting **View Microsoft Teams team** on the case action toolbar.

For cases you open before enabling Microsoft Team integration, risk investigators and analysts can create a new Microsoft Teams team for a case by selecting **Create Microsoft Teams team** on the case action toolbar.

When you resolve a case, the solution automatically archives the associated Microsoft Team (hides it and turns it to read-only).

For more information about Microsoft Teams for Insider Risk Management, see Getting started with Insider Risk Management settings.

Resolve the case

After risk analysts and investigators complete their review and investigation, resolve a case to act on all the alerts currently included in the case. Resolving a case adds a resolution classification, changes the case status to *Closed*, and automatically adds the resolution action reasons to the case notes queue on the **Case notes** dashboard. Resolve cases as either:

- **Benign**: The classification for cases where policy match alerts are evaluated as low risk, non-serious, or false positive.
- **Confirmed policy violation**: The classification for cases where policy match alerts are evaluated as risky, serious, or the result of malicious intent.

> **Note**
>
> If you select the option to delete the case and associated content immediately when resolving the case, you permanently remove all related content, alerts, and insights.

Resolve a case

To resolve a case, complete the following steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Cases** in the left navigation.
4. Select a case, and then select **Resolve case** on the case action toolbar.
5. In the **Resolve case** dialog box, select the **Resolve as** dropdown control to select the resolution classification for the case. The options are **Benign** or **Confirmed policy violation**.
6. In the **Resolve case** dialog box, enter the reasons for the resolution classification in the **Action taken** text field.
7. Select **Resolve** to close the case.

Review activities with the Insider Risk Management audit log

08/20/2025

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

The Insider Risk Management audit log helps you stay informed about actions taken on Insider Risk Management features. This log makes it possible to independently review the actions of users assigned to one or more Insider Risk Management role groups. Your organization automatically enables the Insider Risk Management audit log and you can't disable it.

The audit log automatically and immediately updates whenever it detects identified risk activities. The audit log keeps information for 180 days (about six months). After 180 days, the log permanently deletes data.

Areas in identified risk activity detection include:

- Policies
- Cases
- Alerts
- Settings
- Users
- Notice templates

To view and export data from the audit log, assign users to the *Insider Risk Management* or *Insider Risk Management Auditors* role groups. For more information about Insider Risk Management role groups, see Assign Insider Risk Management permissions.

> **Note**
>
> The Insider Risk Management audit log isn't associated with the Microsoft 365 audit log, as they're independent auditing systems that capture information on separate areas. Disabling Microsoft 365 auditing doesn't impact activity auditing within Insider Risk Management.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

View activity in the insider risk audit log

To view feature activity detected for Insider Risk Management, go to the **Insider risk audit log** link in the top-right area of any Insider Risk Management tab. By default, you see the following information displayed for Insider Risk Management activities:

- **Activity:** A description of the identified risk activity taken within the Insider Risk Management solution by a user.
- **Category:** The area or item where the identified risk activity was performed. For example, you see *Policies* as the category when policy change activities were performed.
- **Activity performed by:** The user name of the user that performed the identified risk activity.
- **Date:** The date and time the identified risk activity was performed. The date and time are the local date and time for your organization.

For more information about a logged activity, select the activity to display the activity details pane. This pane includes additional information about the identified risk activity.

Columns and filtering

To make it easier for auditors to review audit logs, filtering is supported in the **Insider risk audit log**. For basic filtering, queue columns are available to add to the view to provide different pivots on the files and messages. You can filter identified risk activities by the **Category, Date range,** and **Activity performed by** fields.

To add or remove column headings for the queue, use the **Customize columns** control and select from the column options. These columns map to common conditions supported in the **Insider risk audit log** and are listed later in this article.

Audit log export

Users assigned to the *Insider Risk Management* or *Insider Risk Management Auditors* role groups can export audit log activity to a .csv (comma-separated values) file by selecting **Export** on the **Insider risk audit log** page. Depending on the audit log activity, some fields might not be included in the filtered queue, and those fields appear as blank in the exported file.

The file contains audit log activity information for the following fields:

- **Activity performed by:** Name of the user modifying an item value. Users listed here are assigned to one or more of the following Insider Risk Management role groups: *Insider Risk Management*, *Insider Risk Management Admins*, *Insider Risk Management Analysts*, *Insider Risk Management Investigators*. Each role group has different permission levels for managing insider risk features.
- **Activity:** Type of activity taken on an item. Values are *Viewed, Deleted, Added, Edited policy, Case, User, Alert,* and *Settings*.
- **Added**: Objects you add during the identified risk activity, such as users, file types, or domains.
- **Alert volume**: Level of alert volume defined in Insider Risk Management settings.
- **Amount**: Currently selected custom indicator amounts for a policy.
- **Asset ID**: Asset ID of the priority physical asset the activity was performed on.
- **Category:** Category of the item modified. Values are *Policies, Cases, Users, Alerts, Settings,* and *Notice templates*.
- **Date:** Date and time, listed in your organization's local date and time.
- **Description**: Description input by the user for the object being acted on (such as a policy or a priority user group).

- **DLP policy**: The Microsoft Purview Data Loss Prevention (DLP) policy selected to trigger inclusion in an Insider Risk Management policy.
- **Indicator**: Indicator in the within insider risk settings that the activity was performed on (such as adding or removing an indicator).
- **Notice template**: Notice template that the identified risk activity was performed on.
- **Number of days**: Policy activation window defined in insider risk settings.
- **Number of files**: File volume limit defined in Insider Risk Management settings.
- **Policy template**: Policy template that the indicators acted on belongs to.
- **Previous amount**: Previously selected custom indicator amounts for a policy.
- **Priority user group**: Priority user group the identified risk activity was performed on.
- **Removed**: Objects you remove during the identified risk activity, such as users, file types, or domains.
- **Sender**: Sender field of the notice template the identified risk activity was performed on.
- **Target policy**: The policy the identified risk activity was performed on (such as adding a user to or removing a user from).
- **Template message body**: The message body of the notice template the identified risk activity was performed on.
- **Template subject**: The subject field of the notice template the identified risk activity was performed on.
- **User:** User the identified risk activity was performed on.

Review data with the Insider Risk Management content explorer

10/01/2025

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

The Insider Risk Management **Content explorer** enables users assigned the *Insider Risk Management Investigators* role to examine the context and details of content associated with activity in alerts. The case data in Content explorer refreshes daily to include new risk activity. For all alerts that you confirm to a case, the solution archives copies of data and message files as a snapshot in time of the items, while maintaining the original files and messages in the storage sources. If needed, you can export case data files as a portable document file (PDF) or in the original file format.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Use the Content explorer to view details for a specific case

To examine the emails and files captured by the policies included in a specific case, go to the Insider Risk Management **Cases** page and select the row of the *Case name* in the list for the case you want to view details for. Then in the case details page, select the **Content explorer** tab to open the Content explorer.

> **Important**

After you confirm an alert to a case, Content explorer doesn't display any details for that case if the organization hasn't assigned a user to either the *Insider Risk Management Investigators* or *Insider Risk Management* role group.

Content explorer includes user activities related to Microsoft 365 service files, such as user activity on SharePoint, Exchange, and OneDrive for Business. For new cases, it usually takes about an hour for content to populate in Content explorer. For cases with large amounts of content, it might take longer to create a snapshot. If content is still loading in Content explorer, you see a progress indicator that displays the completion percentage.

In some cases, you might not be able to review data associated with a case as a snapshot in Content explorer. This situation might occur when you delete or move case data, or when a temporary error occurs when processing case data. If this situation occurs, select **View files** in the warning bar to view the file names, file path, and reason for the failure for each file. If needed, you can export this information to a .csv (comma-separated values) file.

If the content includes Information Rights Management permissions, these permissions are maintained for the copied content and users assigned the *Insider Risk Management Investigators* role need these permissions and rights if they need to open and view the files. Each file and message are automatically assigned a unique file ID in the Insider Risk Management case for management purposes. Documents associated with device indicator activities aren't included in Content explorer.

Note

After a case is active for over 30 days, Content explorer isn't updated to reflect new activities. To update content explorer with new activities for a user in this scenario, resolve the case and open a new case for the user.

View options

Source view

The **Source** viewer displays the richest view of a selected document. It supports hundreds of file types and is meant to display the truest to native experience possible. For Microsoft Office files, the viewer uses the web version of Office apps to display content such as document comments, Microsoft Teams chats, Excel formulas, hidden rows and columns, and PowerPoint notes.

Plain text view

The **Plain text** viewer (preview) provides a view of the extracted text of a selected file. It ignores any embedded images and formatting but is useful if you want to understand the content quickly. The text view also includes these features:

- Line counter makes it easier to reference specific portions of a document
- Search hit highlighting that highlights terms within the document and in the scrollbar

Annotate view

The **Annotate** view (preview) provides features that let you apply markup on a selected document, including the ability to:

- **Select annotations**: Select annotations on a document to delete
- **Select text**: Select text on the document to delete
- **Area redactions**: Draw a box on the document to hide sensitive content
- **Pencil**: Free-hand draw in selectable colors on a document to bring attention to certain portions of a document
- **Toggle annotation transparency**: Make annotations semi-transparent to view the content behind the annotation
- **Previous page**: Navigate to previous page
- **Next page**: Navigate to the next page
- **Go to page**: Enter a specific page number to navigate to
- **Zoom**: Set the zoom level for annotate view
- **Rotate**: Rotate the document clockwise

Metadata view

The panel in the **Metadata** view (preview) displays various metadata associated with the selected document. Search for specific metadata by using the **Search metadata name** field.

You can toggle the panel in the **Metadata** view on or off to display various metadata associated with the selected document. Although you can customize the search results grid to display specific metadata, there are instances where scrolling horizontally can be difficult while reviewing data. The File metadata panel allows you to toggle on a view within the viewer.

Group options

Use the **Group** control to view content grouped by the following options:

- **Group by families**: All items related to a specific file are grouped together using the same Group ID. For example, if you have a PowerPoint file in the alert that includes imbedded images or .zip files, these images and files are grouped with the PowerPoint file and shown as nested items with the file in the item list view. Microsoft 365 Copilot and Microsoft 365 Copilot Chat user prompts and responses are also grouped together using the same Group ID when there are multiple prompts and responses associated with a file.
- **Group by conversations and related items**: All email messages, Teams conversations, and Viva Engage conversations are grouped using the same Thread ID and appear as nested items. Additionally, all associated content for these messages and conversations is also grouped together. For example, if you have an email conversation that includes several email messages, some of which include attachments and some that include embedded images, all of the email messages, attachments, and images are grouped together in the alert list view under an applicable item.

Column options

To help risk analysts and investigators review captured data and messages, the Content explorer includes several filtering and sorting tools. For basic sorting, the **Date** and **File class** columns support sorting by using the column titles in the content queue pane. You can add other queue columns to the view to provide different pivots on the files and messages.

To add, remove, or reorder column headings for the content queue, use the **Customize columns** control and select from the following column options. These columns map to the common, email, and document property conditions supported in the Content explorer.

View results in UTC or your local time by toggling the **Time zone** option in the action bar.

Expand table

Column option	Description
Author	The author field from Office documents, which persists if a document is copied. For example, if a user creates a document and the emails it to someone else who then uploads it to SharePoint, the document still retains the original author.
Bcc	Available for email messages, the users in the Bcc message field.
Cc	Available for email messages, the users in the Cc message field.
Compound path	Human readable path that describes the source of the item.
Conversation ID	Conversation ID from the message.
Conversation index	Conversation index from the message.

Column option	Description
Created time	The time the file or email message was created.
Date (UTC)	For email, the date a message was received by a recipient or sent by the sender. For documents, the date a document was last modified. Date is in Coordinated Universal Time (UTC).
Dominant theme	Dominant theme as calculated for analytics.
Email set ID	Group ID for all messages in the same email set.
Family ID	Family ID groups together all items; for email, this column includes the message and all attachments; for documents, this column includes the document and any embedded items.
File class	For content from SharePoint and OneDrive: **Document**; for content from Exchange: **Email** or **Attachment**.
File ID	Document identifier unique within the case.
File type icon	The extension of a file; for example, docx, one, pptx, or xlsx. This field is the same property as the FileExtension site property.
ID	The GUID identifier for the file.
Immutable ID	Immutable ID as stored in Office 365.
Inclusive type	Inclusive type calculated for analytics: **0** - not inclusive; **1** - inclusive; **2** - inclusive minus; **3** - inclusive copy.
Last modified	The date that a document was last changed.
Marked as representative	One document from each set of exact duplicates is marked as representatives.
Message kind	The type of email message to search for. Possible values: contacts, docs, email, external data, faxes, im, journals, meetings, microsoft teams (returns items from chats, meetings, and calls in Microsoft Teams), notes, posts, RSS feeds, tasks, voicemail
Participants	List of all participants of a message; for example, Sender, To, Cc, Bcc.
Pivot ID	The ID of a pivot.
Received	The date that an email message was received by a recipient. This field is the same property as the Received email property.
Recipients	All recipient fields in an email message. These fields are To, Cc, and Bcc.
Representative ID	Numeric identifier of each set of exact duplicates.

Column option	Description
Sender	The sender of an email message.
Sender/Author	For email, the person who sent a message. For documents, the person cited in the author field from Office documents. You can type more than one name, separated by commas. Two or more values are logically connected by the OR operator.
Sensitive info types	The sensitive info types identified in content.
Sensitivity labels	The sensitivity labels applied to the content.
Sent	The date that an email message was sent by the sender. This field is the same property as the Sent email property.
Size	For both email and documents, the size of the item (in bytes).
Subject	The text in the subject line of an email message.
Subject/Title	For email, the text in the subject line of a message. For documents, the title of the document. As previously explained, the Title property is metadata specified in Microsoft Office documents. You can type the name of more than one subject/title, separated by commas. Two or more values are logically connected by the OR operator.
Themes list	Themes list as calculated for analytics.
Title	The title of the document. The Title property is metadata that's specified in Office documents. It's different than the file name of the document.
To	The recipient of an email message in the To field.

Filtering

Use one or more filters to narrow the scope of a search and return a more refined set of results. To set a filter, select **Query** (preview) at the top of the content queue. Many filters include additional conditions to help narrow the results returned by the filter. For example, the *Date* filter includes controls to configure a *Start date* and *Ending date* for the **Date** filter. Save queries for future use by selecting **Save filters** and following the prompts. Select one or more filter items from the following example categories:

Common filters

Expand table

Filter	Description
Date (UTC)	For email, the date a message was received by a recipient or sent by the sender. For documents, the date a document was last modified.
Sender/Author	For email, the person who sent a message. For documents, the person cited in the *Author* field from Office documents. Type more than one name, separated by commas.
Source	The location of the document in your organization. For example, a specific SharePoint site location.
Subject/Title	For email, the text in the subject line of a message. For documents, the title of the document. The Title property in documents is metadata specified in Microsoft Office documents. Type the name of more than one subject/title, separated by commas. Two or more values are logically connected by the OR operator.

Email filters

Expand table

Filter	Description
Bcc	The Bcc field of an email message.
Cc	The Cc field of an email message.
Has attachment	Indicates whether a message has an attachment. Values are listed as **true** or **false**.
Is email attachment	If the document is an attachment, the value is listed as **Yes**.
Is embedded document	If the document is embedded in the email message, the value is listed as **Yes**.
Is inline attachment	If the document is an inline attachment in the email message, the value is listed as **Yes**.
Participants	All the people fields in an email message. These fields are From, To, Cc, and Bcc.
Received	The date that an email message was received by a recipient.
Recipient domains	List of all domains of recipients of a message.
Recipients	The email message recipients.
Sender domain	Domain of the sender.
Sender	Sender (From) field for message types. Format is **DisplayName <SmtpAddress>**.

Filter	Description
To	The To field of an email message.
Unique in email set	False if there's a duplicate of the attachment in its email set.

Document filters

Expand table

Filters	Description
Compliance labels	Compliance labels applied in Microsoft 365.
Created time (UTC)	The date and time the file or email message was created. The date and time are in Coordinated Universal Time (UTC).
File extension	The extension type of the file.
Last modified date (UTC)	The date that a document was last changed. The date and time are in Coordinated Universal Time (UTC).
User activity events	Activity for items related to specific user activity in a case. For example, when you select a link to 'Explore Content' for an activity in the **User Activity** page of a case, this filter is used to display items related to that activity.
Work product	The type of work product for the document. For example, annotations or tags in the document.

Advanced filters

Advanced filters (preview) let you build more flexible and granular filters. This advanced filtering capability enables you to:

- Quickly search for filter conditions.
- Create complex filters using subgroups, *AND*, or *OR* conditions.
- Easily change your queries with **Clear all** and **Reset all** controls.
- Manage saved filters without having to navigate to another area.
- Use *Is empty* and *Is not empty* conditions for each filter.

Filter types

Every searchable field in an alert has a corresponding filter that you can use for filter items based on a specific field.

There are multiple types of filters:

- **Freetext**: A freetext filter is applied to text fields such as *Subject*. You can list multiple search terms by separating them with a comma.
- **Date**: A date filter is used for date fields such as *Last modified date*.
- **Search options**: A search options filter provides a list of possible values (each value is displayed with a checkbox that you can select) for particular fields in the review. This filter is used for fields, such as *Sender*, where there's a finite number of possible values in the alert.
- **Keyword**: A keyword condition is a specific instance of freetext condition that you can use to search for terms. You can also use Keyword Query language (KeyQL) in this type of filter. For more information, see the [Query language](#
) and [Advanced query builder](#
) sections in this article.

Advanced filter controls

To create and custom filtering for your search results, use the following controls:

- **AND/OR**: These conditional logical operators allow you to select the query condition that applies to specific filters and filter subgroups. These operators allow you to use multiple filters or subgroups connected to a single filter in your query.
- **Add conditions**: Allows you to add multiple filtering conditions to your query. Is available after you've defined at least one query filter.
- **Select an operator**: Depending on the selected filter, the operators compatible for the filter are available to select. For example, if the *Date* filter is selected, the available operators are *Before*, *After*, and *Between*. If the *Size (in bytes)* filter is selected, the available operators are *Greater than*, *Greater or equal*, *Less than*, *Less or equal*, *Between*, and *Equal*. If it's a file name, ID, or keyword, the available operators are *Equal any of*, *Equal none of*, *Contains all of*, *Contains any of*, *Contains none of*, *Is empty*, or *Is not empty*.
- **Value**: Depending on the selected filter, the values compatible for the filter are available. Additionally, some filters support multiple values and some filters support one specific value. For example, if the *Date* filter is selected, select date values. If the *Size (in bytes)* filter is selected, select a value for bytes.
- **Add subgroup**: After you've defined a filter, you can add a subgroup to refine the results returned by the filter. You can also add a subgroup to a subgroup for multi-layered query refinement.
- **Save**: Allows you to save the current set of filters, conditions, and operators for future use. These saved queries are user-specific.
- **Remove a filter condition**: To remove an individual filter or subgroup, select the remove icon to the right of each filter line or subgroup.

- **Clear all**: To clear the entire query of all filters and subgroups, select **Clear all**.

Help dynamically mitigate risks with Adaptive Protection

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Adaptive protection in Microsoft Purview uses machine learning to identify the most critical risks and proactively and dynamically apply protection controls from:

- Microsoft Purview Data Loss Prevention (DLP)
- Microsoft Purview Data Lifecycle Management (preview)
- Microsoft Entra Conditional Access (preview)

Integration with data loss prevention, data lifecycle management, and Conditional Access helps organizations automate their response to insider risks and reduces the time required to identify and remediate potential threats. By using the capabilities of all four solutions, organizations can create a more comprehensive security framework that addresses both internal and external threats.

> **Important**
>
> To learn about licensing requirements for using Adaptive Protection with data loss prevention, data lifecycle management, and Conditional Access, see Microsoft 365, Office 365, Enterprise Mobility + Security, and Windows 11 Subscriptions.

Adaptive protection helps mitigate potential risks by using:

- **Context-aware detection**. Helps identify the most critical risks with ML-driven analysis of both content and user activities.
- **Dynamic controls**. Helps enforce effective controls on high-risk users while others maintain productivity.

- **Automated mitigation**. Helps minimize the impact of potential data security incidents and reduce admin overhead.

Adaptive protection dynamically assigns appropriate data loss prevention, data lifecycle management, and Conditional Access policies to users based on the insider risk levels defined and analyzed by the machine learning models in Insider Risk Management. Policies become adaptive based on user context, ensuring that the most effective policy, such as blocking data sharing through data loss prevention or blocking application access through Conditional Access, is applied only to high-risk users while low-risk users maintain productivity. Data loss prevention and Conditional Access policy controls constantly adjust, so when a user's insider risk level changes, an appropriate policy dynamically applies to match the insider new risk level. In the case of data lifecycle management, Insider Risk Management detects *Elevated risk level* users and preserves their deleted data for 120 days by using an automatically created data lifecycle management retention label policy.

> **Important**
>
> Insider Risk Management is currently available in tenants hosted in geographical regions and countries supported by Azure service dependencies. To verify that the Insider Risk Management solution is supported for your organization, see Azure dependency availability by country/region. Insider Risk Management is available for commercial clouds but isn't available for US Government cloud programs at this time.

Watch the following video for a summary of how Adaptive Protection can help identify and mitigate the most critical risks in your organization:

Insider risk levels and preventive controls

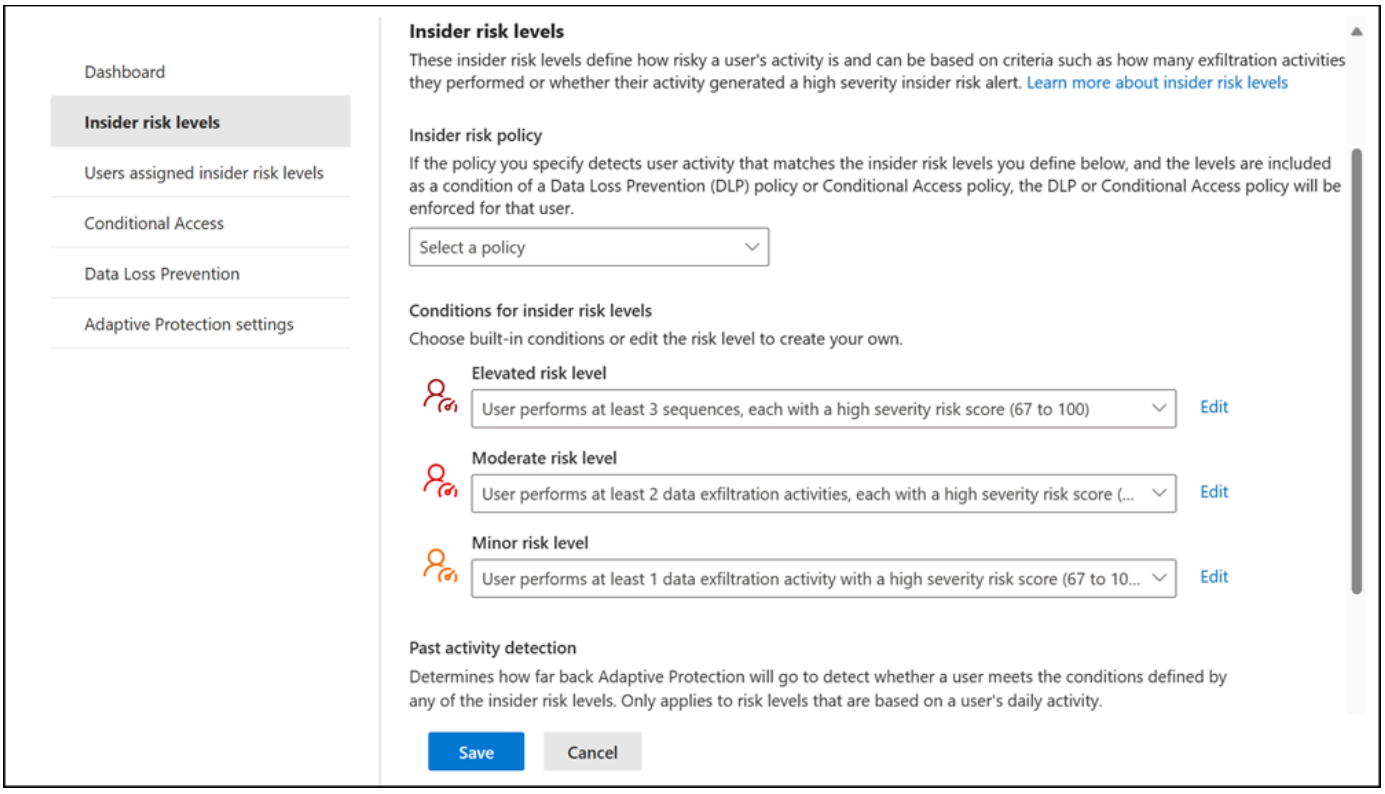
With Adaptive Protection, administrators can configure risk factors or activities for customizable insider risk levels based on your organization's needs. The insider risk levels for Adaptive Protection update continuously and automatically based on the users' risk factors and insights. When users' data security risks increase or decrease, their insider risk levels adjust accordingly. Based on the insider risk levels, data loss prevention policies and Conditional Access policies automatically apply the right level of preventative controls as configured by admins, such as *block*, *block with override*, or *warning*.

> **Tip**
>
> *Insider risk levels* in Adaptive Protection differ from *alert severity levels* that assign Insider Risk Management users based on activity detected in Insider Risk Management policies.
>
> - Insider risk levels (Elevated, Moderate, or Minor), as described in this article, measure risk determined by admin-defined conditions such as the number of exfiltration activities users perform in a day or whether their activity generated a high-severity insider risk alert.
> - Alert severity levels (Low, Medium, or High) assign to users based on activity detected in Insider Risk Management policies. These levels calculate based on alert risk scores assigned to all active alerts associated with the user. These levels help insider risk analysts and investigators prioritize and respond to user activity accordingly.

For data lifecycle management, the data lifecycle management policy monitors users that assign an *Elevated risk level* by Insider Risk Management Adaptive Protection. When a risky user deletes any content from SharePoint, OneDrive, or Exchange Online, the contents are automatically preserved for 120 days. Admins can contact Microsoft support to restore any preserved content.

Depending on the Insider Risk Management policy assigned in Adaptive Protection, different criteria (users, groups, indicators, thresholds, etc.) are used to determine applicable insider risk levels. Insider risk levels are based on user insights, not solely on the number of instances of specific user activities. Insights are a calculation of the aggregate number of activities and the severity level of these activities.

For example, insider risk levels for User A wouldn't be determined by User A performing a potentially risky activity more than three times. The insider risk levels for User A would be determined by an insight of the aggregate number of activities and risk scores would be assigned to the activity based on the thresholds configured in the selected policy.



Insider risk levels

Insider risk levels in Adaptive Protection define how risky a user's activity is and can base on criteria such as how many exfiltration activities they performed or whether their activity generated a high severity insider risk alert. These insider risk levels have built-in insider risk level definitions, but you can customize these definitions as needed:

- **Elevated risk level**: This risk level includes built-in definitions for users with high severity alerts, users with at least three sequence insights that each have a high severity alert for specific risk activities, or one or more confirmed high severity alerts.
- **Moderate risk level**: This risk level includes built-in definitions for users with medium severity alerts or users with at least two data exfiltration activities with high severity scores.
- **Minor risk level**: This risk level includes built-in definitions for users with low severity alerts or users with at least one data exfiltration activity with a high severity score.

For an insider risk level to assign to a user, the number of insights and the severity assigned to the activity need to match the definition for the insider risk level. The number of activities for an insight might be a single activity or multiple activities accruing to the single insight. The number of insights evaluates for the insider risk level definition, not the number of activities contained in an insight.

For example, suppose the conditions in the Insider Risk Management policy assigned to Adaptive Protection scope for identifying downloads from SharePoint sites in your organization. If the policy detects that a user downloaded 10 files from a SharePoint site in a single day that are determined to be high severity, this counts as a single insight that consists of 10 activity events. To qualify for assigning an *Elevated risk level* to the user, two additional insights (with high severity) require for the user. The additional insights might or might not contain one or more activities.

Customizing insider risk levels

Custom insider risk levels enable you to create insider risk levels that fit your organization's needs. You can customize the criteria for the insider risk level and define conditions for when to assign the insider risk level to users.

Consider the following examples for using Adaptive Protection together with data loss prevention, data lifecycle management, and Conditional Access policies.

- **Data loss prevention policies**:
  - Allow users with the *Minor risk level* or *Medium risk level* to receive policy tips and education on best practices for handling sensitive data. With this approach, you can influence positive behavior changes over time and reduce organizational data risks.
  - Block users with the *Elevated risk level* from saving or sharing sensitive data to minimize the impact of potential data incidents.
- **Data lifecycle management policy**:
  - Preserve any SharePoint, OneDrive, or Exchange Online content deleted by a risky user for 120 days. A risky user in this case is a user that Adaptive Protection assigns the *Elevated risk level*.
- **Conditional Access policies**:
  - Require *Minor risk level* users to acknowledge Terms of Use before using an application.
  - Block *Medium risk level* users from accessing certain applications.

- Completely block *Elevated risk level* users from using *any* applications. Learn more about commonly applied Conditional Access policies

Insider risk level criteria and conditions

You can customize insider risk level criteria and conditions based on the following areas:

- **Alerts generated or confirmed for a user**: Choose conditions based on the severity level for alerts that the selected Insider Risk Management policy generates or confirms for a user. Conditions for alerts aren't additive. The insider risk level is assigned to a user if one of the conditions is met.
- **Specific user activity**: Choose conditions for activity to detect, its severity, and the number of daily occurrences during the past activity detection window (optional). Conditions for user activity are additive. The insider risk level is assigned to a user only if all the conditions are met.

Past activity detection

The **Past activity detection** setting determines how many days back Adaptive Protection examines to detect whether a user meets the conditions defined by any of the insider risk levels. The default setting is 7 days, but you can choose between 5 and 30 days of previous activity to apply insider risk level conditions. This setting only applies to insider risk levels that are based on a user's daily activity and excludes insider risk levels based on alerts.

The following example illustrates how past activity detection settings and insider risk levels interact to determine if a user's past activity is in-scope:

- **Elevated risk level** setting: User performs at least three sequences, each with a high severity risk score (67 to 100)
- **Past activity detection** setting: 3 days

Expand table

User activity	Activity in-scope for insider risk level
User has 1 high severity sequence each day on Day T-3, T-2, T-1	Yes
User has 1 high severity sequence on Day T-4 and 2 high severity sequences on Day T-3	No
User has 3 high severity sequences on Day T-3	Yes

Insider risk level timeframe

The **Insider risk level timeframe** setting determines how long an insider risk level remains assigned to a user before it's automatically reset. The default setting is 7 days, but you can choose between 5 and 30 days before resetting the insider risk level for a user.

Insider risk levels also reset for a user when:

- The associated alert for the user is dismissed.
- The associated case for the user is resolved.
- The insider risk level end date is manually expired.

> **Note**
>
> If a user is currently assigned an insider risk level and that user meets the criteria again for that insider risk level, the insider risk level timeframe extends for the defined number of days for the user.

Risk level expiration options

When you enable the automatic expiration option (enabled by default), Adaptive Protection risk levels for a user automatically expire when the associated alert for a user is dismissed or the associated case for the user is closed. If you want to keep the Adaptive Protection risk level for a user even if the alert is dismissed or the case is closed, disable the option.

Permissions for Adaptive Protection

> **Important**
>
> To learn about licensing requirements for using Adaptive Protection with data loss prevention, data lifecycle management, and Conditional Access, see Microsoft 365, Office 365, Enterprise Mobility + Security, and Windows 11 Subscriptions.

Depending on how you use Insider Risk Management built-in role groups and role groups for data loss prevention or Conditional Access, you might need to update Insider Risk Management permissions for administrators, analysts, and investigators in your organization.

The following table describes the permissions required for specific Adaptive Protection tasks.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Expand table

Task	Required role group
Configure Adaptive Protection and update settings	*Insider Risk Management* or *Insider Risk Management Admins*
Create and manage Conditional Access policies with the Adaptive Protection condition	One of the following: *Global administrator*, *Conditional Access Administrator*, *Security Administrator*
Create and manage data loss prevention policies with the Adaptive Protection condition	One of the following: *Compliance Administrator*, *Compliance Data Administrator*, *DLP Compliance Management*, *Global Administrator*
View details on users' or agents' assigned insider risk levels	*Insider Risk Management*, *Insider Risk Management Analysts*, or *Insider Risk Management Investigators*

> **Important**
>
> The four categories of role groups correspond to the following tabs on the Adaptive Protection page: **Insider risk levels**, **Users assigned insider risk levels**, **Data Loss Prevention**, **Conditional Access**. If you're not assigned to the appropriate role group, the tab doesn't appear on the **Adaptive protection** page.

Learn more about role groups in Microsoft Defender for Office 365 and Microsoft Purview compliance

Configure Adaptive Protection

Depending on the needs of your organization or where you're currently configured with Insider Risk Management, data loss prevention, data lifecycle management, and Conditional Access, you have two options to get started with Adaptive Protection:

- Quick setup

- Custom setup

Quick setup

The quick setup option is the fastest way to get started with Adaptive Protection. With this option, you don't need any preexisting Insider Risk Management, data loss prevention, data lifecycle management, or Conditional Access policies. You also don't need to preconfigure any settings or features. If your organization doesn't have a current subscription or license that supports Insider Risk Management, data loss prevention, or data lifecycle management, sign up for a Microsoft Purview risk and compliance solutions trial before starting the quick setup process. You can also sign up for a Microsoft Entra trial for Conditional Access.

To get started, select **Turn on Adaptive Protection** from the Adaptive Protection cards on the Microsoft Purview portal home page or the data loss prevention Overview page. You can also start the quick setup process by going to **Insider Risk Management** > **Adaptive protection** > **Dashboard** > **Quick setup**.

> **Note**
>
> If you're already a scoped admin for Microsoft Purview, you can't turn on quick setup.

Here's what the quick setup process configures for Adaptive Protection:

Expand table

Area	Configuration
A new insider risk policy	- Policy template: Data leaks - Policy name: Adaptive Protection policy for Insider Risk Management - Policy scope for users and groups: All users and groups - Priority content: None - Triggering events: Selected exfiltration events (you can view in Insider Risk Management settings) - Policy indicators: A subset of Office indicators (you can view in Insider Risk Management settings) - Risk score boosters: Activity is over user's usual activity for that day
Adaptive protection insider risk levels	- *Elevated risk level*: Users must have at least three high severity exfiltration sequences - *Moderate risk level*: Users must have at least two high severity activities (excluding some types of downloads) - *Minor risk level*: Users must have at least one high severity activity (excluding some types of downloads)

Area	Configuration
Insider risk settings (if already configured)	- Policy indicators: Office indicators not already configured (you can view in Insider Risk Management settings) - All other settings previously configured aren't updated or changed. - Analytics: On (thresholds for triggering events in policies are the default settings determined by Analytics recommendations)
Insider risk settings (if not already configured)	- Privacy: Show anonymized versions of user names. **Note:** User names aren't anonymized in Conditional Access or data loss prevention. - Policy timeframes: Defaults - Policy indicators: A subset of Office indicators (you can view in Insider Risk Management settings) - Risk score boosters: All - Intelligent Detections: Alert Volume = Default volume - Analytics: On - Admin notifications: Send notification email when first alert is generated to all
New Conditional Access policy (created in Report-only mode so users won't be blocked)	**1-Block access for users with Insider Risk (Preview)** - Included users: All users - Excluded guest or external users: B2bDirectConnect User; OtherExternalUser; ServiceProvider - Cloud apps: Office 365 apps - Insider risk levels: *Elevated* - Block access: Selected
New data lifecycle management policy	An organization-wide autoapply label policy that monitors users assigned the *Elevated risk level*. Any SharePoint, OneDrive, or Exchange Online content deleted by a risky user is preserved for 120 days. If you haven't already turned on Adaptive Protection, the policy is automatically created and applied when you turn on Adaptive Protection. If you have already turned on Adaptive Protection, you need to explicitly opt in to the data lifecycle management policy that's created automatically.
Two new data loss prevention policies	Adaptive Protection policy for Endpoint DLP - *Elevated risk level* rule: Blocked - *Moderate/Minor risk level* rule: Audit - Policy starts in test mode (audit only) Adaptive Protection policy for Teams and Exchange DLP - *Elevated risk level* rule: Blocked - *Moderate/Minor risk level* rules: Audit - Policy starts in test mode (audit only)

After you start the quick setup process, it can take up to 72 hours before the following items are completed:

- Analytics
- Associated Insider Risk Management, data loss prevention, data lifecycle management, and Conditional Access policies
- Adaptive Protection insider risk levels, data loss prevention, data lifecycle management, and Conditional Access actions applied to applicable user activities.

> **Note**
>
> Once you enable Adaptive Protection, don't disable it before the setup process completes. Disabling Adaptive Protection before the setup process completes might lead to policy errors.

Administrators receive a notification email when the quick setup process completes.

Custom setup

The custom setup option lets you customize the Insider Risk Management policy, the insider risk levels, and the data loss prevention and Conditional Access policies configured for Adaptive Protection.

> **Note**
>
> For data lifecycle management, if you don't turn on Adaptive Protection, the policy isn't created and applied automatically. If you turn on Adaptive Protection for your organization, you need to **explicitly opt in to apply the data lifecycle management policy**.

The custom setup option also lets you configure these items before enabling the Adaptive Protection connections between Insider Risk Management and data loss prevention. In most cases, use this option if your organization already has Insider Risk Management and data loss prevention policies in place.

Complete the following steps to configure Adaptive Protection by using the custom setup.

Step 1: Create Insider Risk Management policy

Assign insider risk levels to users or agents when a policy assigned in Adaptive Protection either detects user or agent activity or generates alerts that match the insider risk level conditions you define in the next step. If you don't want to use an existing Insider Risk Management policy,

create a new Insider Risk Management policy. Your Insider Risk Management policy for Adaptive Protection should include:

- **Users whose activity you want to detect**. This group can include all users and groups in your organization or just a subset for specific risk mitigation scenarios or testing purposes.
- **Activities you consider risky and custom thresholds that influence an activity's risk score**. Risky activities might include emailing people outside your organization or copying files to USB devices.

Select **Create insider risk policy** to start the new policy workflow. The Data leaks policy template is automatically selected in the workflow, but you can select any policy template.

> **Important**
>
> Depending on the policy template you select, you might need to configure additional settings for the policy to properly detect potentially risky activities and to create applicable alerts.

Step 2: Configure insider risk level settings

Select the **Insider risk levels** tab. Start by selecting the Insider Risk Management policy you want to use for Adaptive Protection. This policy can be the new policy you created in Step 1 or an existing policy or policies that you already configured.

Next, accept the applicable built-in insider risk level conditions or create your own. Depending on the type of policy you select, the insider risk level conditions reflect the applicable conditions associated with indicators and activities you configure in the policy.

For example, if you choose a policy based on the Data leaks policy template, the built-in insider risk level condition choices apply to indicators and activities available in that policy. If you select a policy based on the Security policy violations policy template, the built-in insider risk level conditions automatically scope to indicators and activities available in that policy.

Customize an insider risk level for your policy

1. Sign in to the Microsoft Purview portal by using credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Adaptive protection** in the left navigation, then select **Insider risk levels**.

4. On the **Insider risk levels** page, select **Edit** for the insider risk level you want to customize (*Elevated*, *Moderate*, or *Minor*).

5. On the **Custom insider risk level** pane, select an option in the **Insider risk level based on** section:

   - **Alert generated or confirmed for a user**
   - **Specific user activity**

6. If you select the **Alert generated or confirmed for a user** option, choose the severity levels for alerts that are generated or confirmed for a user that should use this insider risk level. You can keep the *Severity for generated alerts* and the *Severity for confirmed alerts* conditions or remove one of these conditions if you only want to use one. If you need to add one of these conditions back, select **Add condition**, then select the condition. For each condition, choose the severity level that should be applied for the condition (*High*, *Medium*, or *Low*). If the **any** of the conditions are met, the insider risk level is assigned to a user.

7. If you select the **Specific user activity** option, choose the activity to detect, its severity, and number of daily occurrences during the past activity detection window. You must configure the *Activities*, *Activity severity*, and *Activity occurrences during detection window* conditions for this insider risk level.

   For the *Activities* condition, the options you can choose from automatically update for the types of activities you define with the indicators configured in the associated policy. If needed, select the **Assign this insider risk level to any user who has a future alert confirmed, even if conditions above aren't met** checkbox. If the **all** of the conditions are met, the insider risk level is assigned to a user.

   For the *Activity severity* condition, specify the severity level for the activities included in the daily activity insight. The options are *High*, *Medium*, and *Low*, and are based on risk score ranges.

   For the *Activity occurrences during detection window* condition, specify the number of times selected activities must be detected within the specified *Past activity detection* period. This number isn't related to the number of events that might occur for an activity. For example, if the policy detects that a user downloaded 20 files from SharePoint in one day, that count is one daily activity insight consisting of 20 events.

8. Select **Confirm** to apply the custom insider risk level conditions.

How insider risk level is assigned if a user is in scope for multiple policies

If a user is in scope for multiple policies and receives alerts of different severity levels, the user is assigned the highest severity level received. For example, consider a policy that assigns an *Elevated risk level* if users receive a high severity alert. If a user receives a low-severity alert from policy 1, a medium-severity alert from policy 2, and a high-severity alert from policy 3, the user is assigned an *Elevated risk level* - the level for the highest alert severity received.

Insider risk level conditions must be present in selected policies to be detected. For example, if you select the *Copy to USB* activity to assign a *Moderate risk level*, but the activity is selected in just one of three selected policies, then only activity from that one policy assigns a *Moderate risk level* for that activity.

Step 3: Create or edit a data loss prevention policy

Next, create a new data loss prevention policy or edit an existing policy to restrict actions for users who match your insider risk level conditions in Adaptive Protection. Use the following guidelines for your data loss prevention policy configuration:

- You must include the *User's insider risk level for Adaptive Protection is* condition in your data loss prevention policy. This data loss prevention policy can include other conditions as needed.
- Although you can include other locations in the data loss prevention policy, Adaptive Protection currently supports only Exchange, Microsoft Teams, and devices.

Select **Create policy** to start the data loss prevention policy workflow and create a new data loss prevention policy. If you have an existing data loss prevention policy that you'd like to configure for Adaptive Protection, go to **Data loss prevention** > **Policies** in the Microsoft Purview portal and select the data loss prevention policy you'd like to update for Adaptive Protection. For guidance on how to configure a new data loss prevention policy or update an existing data loss prevention policy for Adaptive Protection, see Learn about Adaptive Protection in data loss prevention: Manual configuration.

> **Tip**
>
> We recommend testing the data loss prevention policy (with policy tips) so you can review data loss prevention alerts to verify that the policy is working as expected before enabling Adaptive Protection.

Step 4: Create or edit a Conditional Access policy

Next, create a new Conditional Access policy or edit an existing policy to restrict actions for users who match your insider risk level conditions in Adaptive Protection. Use the following guidelines for your Conditional Access policy configuration:

- On the Conditional Access page where you control access based on signals from conditions, set the *Insider risk* condition to *Yes*, and then select an insider risk level (*Elevated*, *Moderate*, or *Minor*). This is the insider risk level that users must have in order for the policy to be enforced.

Select **Create policy** to start the Conditional Access policy workflow and create a new Conditional Access policy. If you have an existing Conditional Access policy that you'd like to configure for Adaptive Protection, go to **Protection** > **Conditional Access** in the Microsoft Entra admin center and select the Conditional Access policy you'd like to update for Adaptive Protection. For guidance on how to configure a new Conditional Access policy or update an existing Conditional Access policy for Adaptive Protection, see Common Conditional Access policy: Insider risk based policy.

Step 5: Turn on Adaptive Protection

After you complete the Insider Risk Management policy, insider risk level, DLP policy, and Conditional Access policy configuration steps, you're ready to enable Adaptive Protection. When you turn on Adaptive Protection:

- The Insider Risk Management policy starts looking for user activity matching your insider risk level conditions. If detected, the insider risk levels are assigned to users.
- Users who are assigned insider risk levels appear on the **Users assigned insider risk levels** tab in Adaptive Protection.
- The data loss prevention policy applies protection actions for any user assigned to insider risk levels included in the data loss prevention policy. The data loss prevention policy is added to the **Data Loss Prevention** tab in **Adaptive protection**. You can view details about the data loss prevention policy and edit policy conditions from the dashboard.
- The data lifecycle management policy, which is automatically created, applies protection actions for any user assigned to the *Elevated risk level*. The following message appears with a green background on the **Adaptive Protection** tab to let users know that proactive data preservation is being applied: "Your organization is also being dynamically protected from users who might potentially delete critical data." The message also provides a link to the

data lifecycle management setting where you can turn off the proactive data preservation feature, if desired.

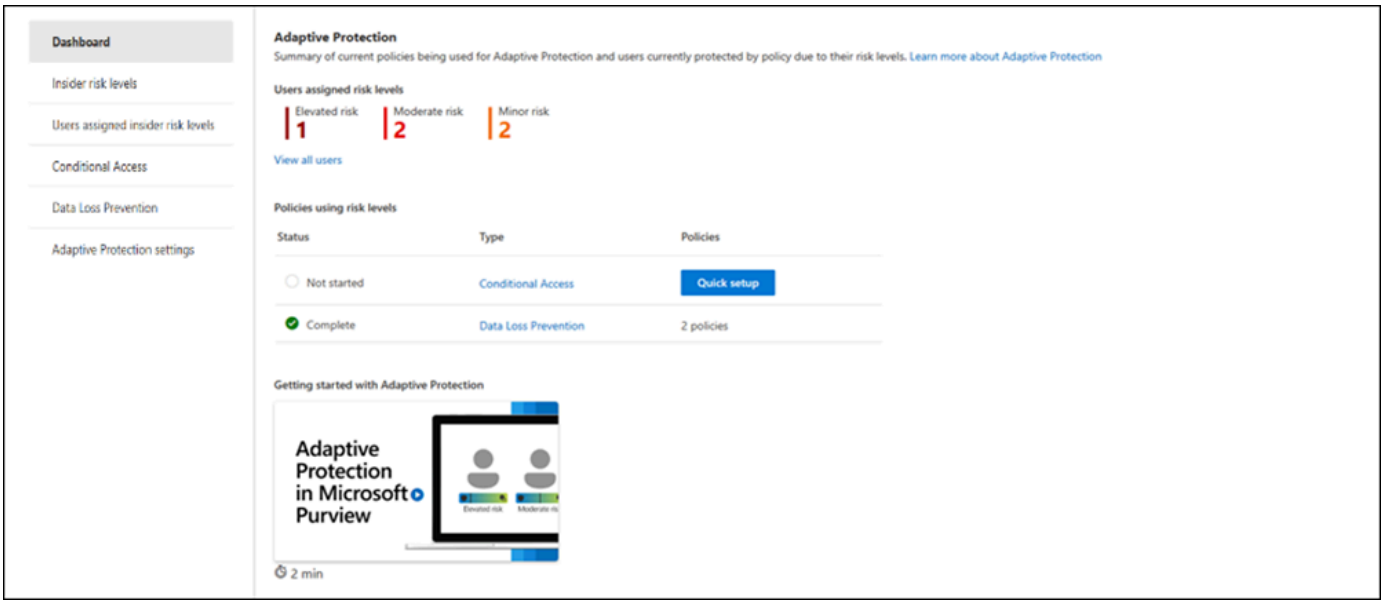
- The Conditional Access policy applies protection actions for any user assigned to insider risk levels included in the Conditional Access policy. The Conditional Access policy is added to the **Conditional Access policies** tab in **Adaptive protection**. You can view details about the Conditional Access policy and edit policy conditions from the dashboard.

To enable Adaptive Protection, select the **Adaptive Protection settings** tab, and then turn **Adaptive Protection** to *On*. It might take up to 36 hours before you can expect to see Adaptive Protection insider risk levels and data loss prevention, data lifecycle management, and Conditional Access actions applied to applicable user activities.

Watch the following video on the Microsoft Mechanics channel to see how Adaptive Protection can automatically adjust the strength of data protection based on calculated data security insider risk levels of users.

Manage Adaptive Protection

When you enable Adaptive Protection and configure your Insider Risk Management, data loss prevention, and Conditional Access policies, you can access information about policy metrics, users currently included, and insider risk levels currently in scope.



> **Note**
>
> Data lifecycle management metrics don't currently appear on the dashboard. However, if proactive data preservation is turned on, you see the following message on the **Adaptive Protection** tab: "Your organization is also being dynamically protected from users who might potentially delete critical data."

Use the Adaptive Protection dashboard

After you complete either the Quick setup or Custom setup process, the **Dashboard** tab in **Adaptive protection** displays widgets for summary information about user insider risk levels, Conditional Access policies, and data loss prevention policies.

- **Users assigned insider risk levels**: Shows the number of users for each insider risk level (*Elevated*, *Moderate*, and *Minor*).
- **Policies using insider risk levels**: Shows the status of policies (*Not started* or *Complete*), the type of policy (*Conditional Access* or *Data Loss Prevention*), and the number of configured

policies for each type of policy. If a policy type isn't configured, select **Quick setup** to configure the policy.

View users assigned insider risk levels

The **Users assigned insider risk levels** tab shows users assigned an insider risk level in Adaptive Protection. You can review the following information for each user:

- **Users**: Lists the user name. For data loss prevention policies, if the Show anonymized versions of usernames option is selected in Insider Risk Management settings, you see anonymized user names. For Conditional Access policies, user names aren't anonymized even if the **Show anonymized versions of usernames** setting is selected.

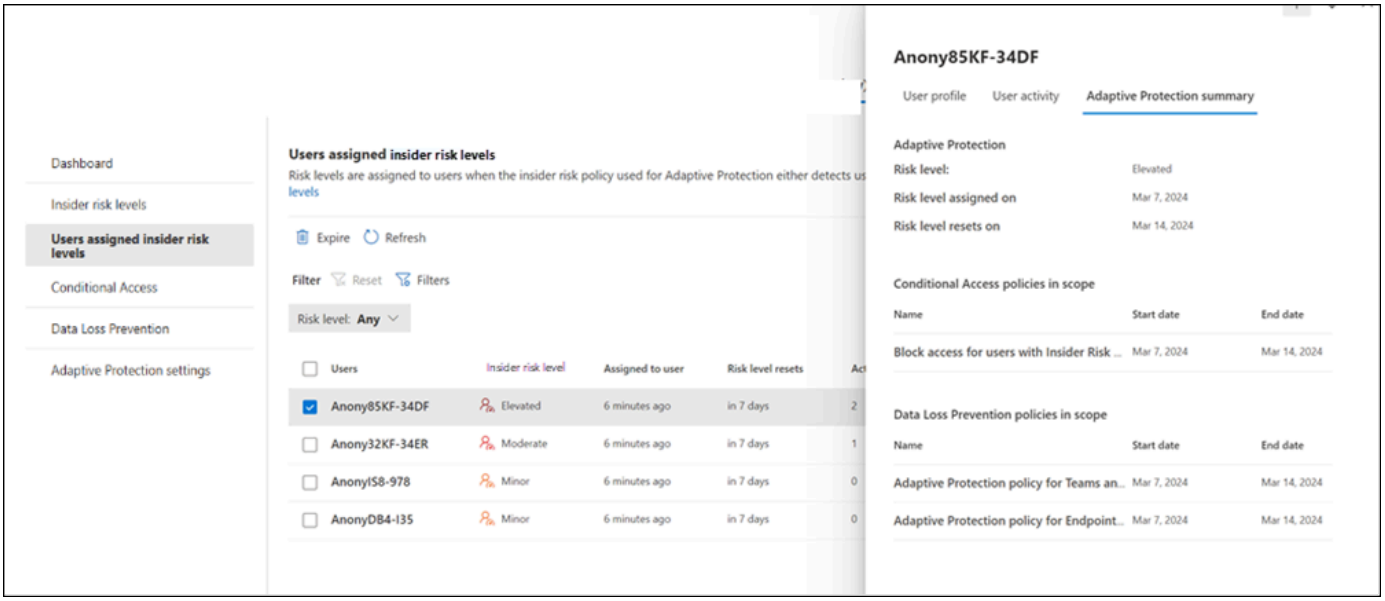
  > **Important**
  >
  > To maintain referential integrity, anonymization of usernames (if turned on) isn't preserved for users from Adaptive Protection who have alerts or activity that appear outside Insider Risk Management. Actual usernames appear in related data loss prevention alerts and the activity explorer.

- **Insider risk level**: The current insider risk level assigned to the user.
- **Assigned to user**: The number of days or months that pass since assigning an insider risk level to the user.
- **Insider risk level resets**: The number of days until the insider risk level automatically resets for the user.

To manually reset the insider risk level for a user, select the user, then select **Expire**. This user no longer has an assigned insider risk level. Existing alerts or cases for this user aren't removed. If this user is included in the selected Insider Risk Management policy, an insider risk level is assigned again if a triggering event is detected.

- **Active alerts**: The number of current Insider Risk Management alerts for the user.
- **Cases confirmed as violation**: The number of confirmed cases for the user.
- **Case**: The name of the case.

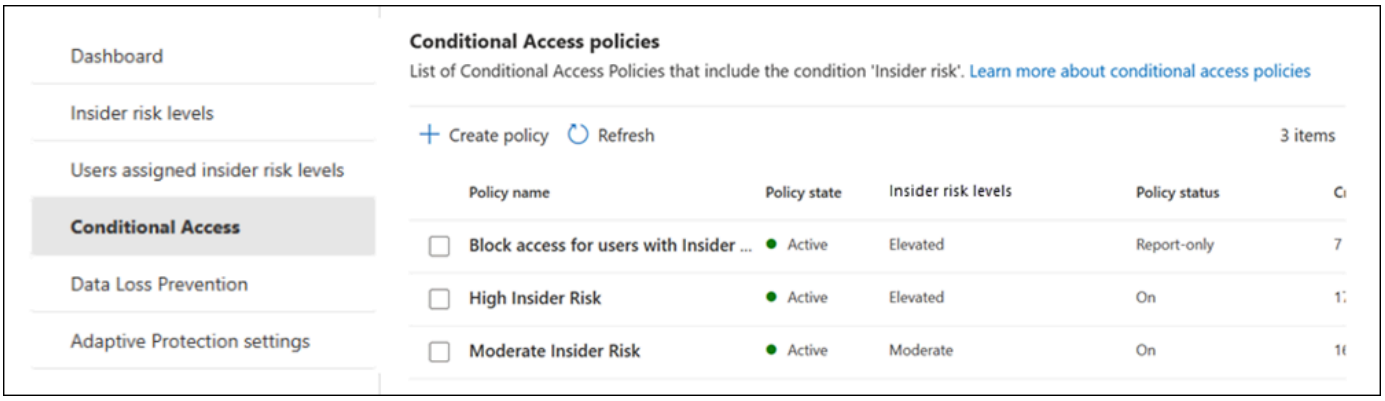
You can filter users by *Insider risk level*.



To view detailed insider risk and Adaptive Protection information for a specific user, select the user to open the user details pane. The details pane contains three tabs: **User profile**, **User activity**, and **Adaptive protection summary**. For information about the **User profile** and **User activity** tabs, see View user details.

The **Adaptive protection summary** tab aggregates information in four sections:

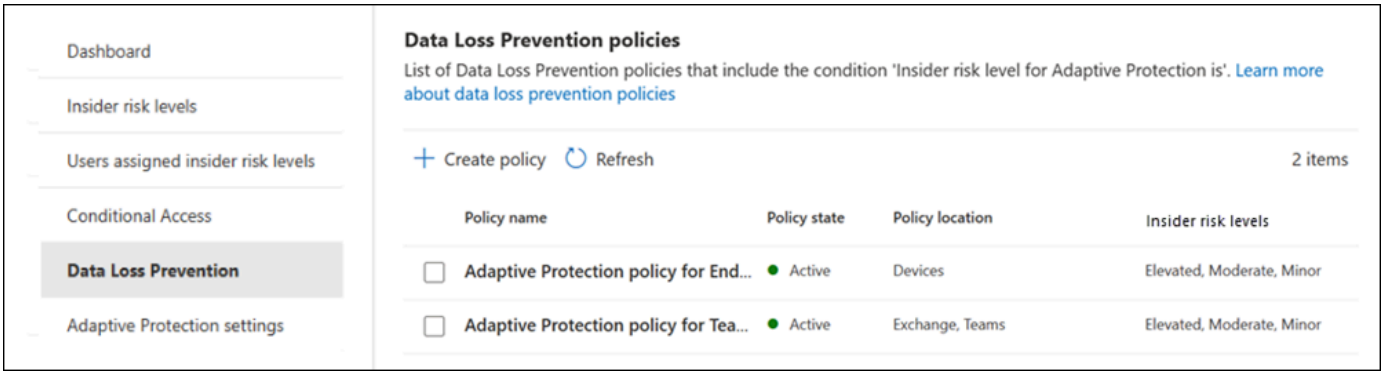
- **Adaptive protection**: Displays information about the current *Risk level*, *Risk level assigned on*, and *Risk level reset on* for the user.
- **Data Loss Prevention policies in scope (dynamic)**: Displays all the data loss prevention policies currently in scope for the user and the start and end date for the policy. This information is based on the insider risk level for the user and data loss prevention policy configuration for insider risk levels. For example, if a user has activities that are defined as *Elevated risk level* for Insider Risk Management policies, and two data loss prevention policies are configured with the *Elevated risk level* condition, these two data loss prevention policies are displayed here for the user.



- **Conditional Access policies in scope (dynamic)**: Displays all the Conditional Access policies currently in scope for the user and the start and end date for the policy. This information is based on the insider risk level for the user and Conditional Access policy configuration for insider risk levels. For example, if a user has activities that are defined as *Elevated risk level* for Insider Risk Management policies, and a Conditional Access policy is configured with the *Elevated risk level* condition, the Conditional Access policy is displayed here for the user.
- **Insider risk policy for Adaptive protection**: Displays any Insider Risk Management policy where the user is currently in-scope.

Manage Conditional Access policies for Adaptive Protection

The **Conditional Access policies** page shows all Conditional Access policies that use the **Insider risk** condition. You can review the following information for each policy:



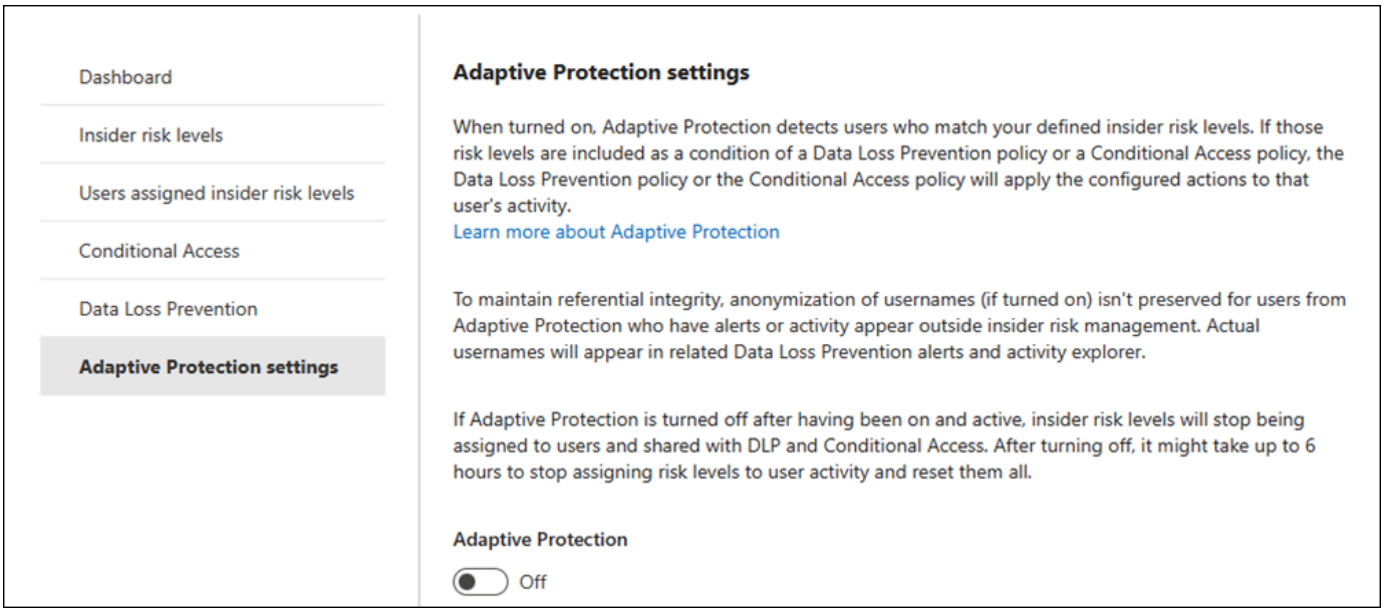
- **Policy name**: The name of the Conditional Access policy.
- **Policy state**: The current state of the policy. Values are *Active* or *Inactive*.
- **Insider risk levels**: The insider risk levels included in the Conditional Access policy by using the **Insider Risk** condition. The options are *Elevated*, *Moderate*, or *Minor*.
- **Policy status**: The current status of the Conditional Access policy. The options are *On* or *Test with notifications*.
- **Created on**: The date you created the Conditional Access policy.
- **Last modified**: The date you last edited the Conditional policy.

Manage Data Loss Prevention policies for Adaptive Protection

The **Data Loss Prevention policies** page shows all data loss prevention policies that use the **User's insider risk level for Adaptive Protection is** condition. You can review the following information for each policy:

- **Policy name**: The name of the data loss prevention policy.
- **Policy state**: The current state of the policy. Values are *Active* or *Inactive*.
- **Policy location**: The DLP policy locations included in the data loss prevention policy. Currently, Adaptive Protection supports Exchange, Teams, and Devices.
- **Insider risk levels**: The insider risk levels included in the data loss prevention policy by using the **Insider risk level for Adaptive Protection is** condition. The options are *Elevated*, *Moderate*, or *Minor*.
- **Policy status**: The current status of the data loss prevention policy. The options are *On* or *Test with notifications*.
- **Created**: The date you created the data loss prevention policy.
- **Last modified**: The date you last edited the data loss prevention policy.

Tune your insider risk level settings



After reviewing users with insider risk levels, you might find too many or too few users assigned an insider risk level. Use these two methods to tune your policy configurations and adjust the number of users assigned insider risk levels:

- Modify insider risk level settings. Adjust your thresholds to assign an insider risk level to a user:
  - Increase or decrease the severity of the activity required to assign an insider risk level. For example, reduce the activity or alert severity if you're seeing too few users with insider risk levels.
  - If the insider risk level is based on a specific user activity, increase or decrease the activity occurrences during the detection window. For example, reduce the activity occurrences if you're seeing too few users with insider risk levels.
  - Change what the insider risk level is based on. For example, assign an insider risk level only if the alert is confirmed to decrease the number of users if you're seeing too many users with insider risk levels.
- Modify policy thresholds. Since policy detections assign insider risk levels, modify your policy to change the requirements to assign an insider risk level. Modify a policy by increasing or decreasing the policy thresholds that lead to high, medium, or low severity activities and alerts.

Disable Adaptive Protection

In certain scenarios, you might need to temporarily disable Adaptive Protection. To disable Adaptive Protection, select the **Adaptive Protection settings** tab and turn **Adaptive Protection** *Off*.

If you turn off Adaptive Protection after it's been on and active, the system stops assigning insider risk levels to users and stops sharing them with data loss prevention, data lifecycle management, and Conditional Access. All existing insider risk levels for users are reset. After turning off Adaptive Protection, it might take up to six hours to stop assigning insider risk levels to user activity and reset them all. The Insider Risk Management, data loss prevention, data lifecycle management, and Conditional Access policies aren't automatically deleted.

> **Note**
>
> You can opt out of data lifecycle management protection without disabling Insider Risk Management Adaptive Protection by turning off the **Adaptive protection in Data Lifecycle Management** setting in data lifecycle management. If you turn off this setting, the data lifecycle management policy is deleted. The setting isn't enabled again unless you turn it back on. Learn more about the Adaptive protection in Data Lifecycle Management setting

Learn about Insider Risk Management forensic evidence

08/20/2025

> **Important**
>
> Forensic evidence is an opt-in add-on feature in Microsoft Purview Insider Risk Management that gives security teams visual insights into potential insider data security incidents, with user privacy built in. Forensic evidence includes customizable event triggers and built-in user privacy protection controls, enabling security teams to better investigate, understand and respond to potential insider data risks like unauthorized data exfiltration of sensitive data.
>
> Organizations set the right policies for themselves, including what risky events are highest priority for capturing forensic evidence and what data is most sensitive. Forensic evidence is off by default, policy creation requires dual authorization and usernames can be masked with pseudonymization (which is on by default for Insider Risk Management). Setting up policies and reviewing security alerts within Insider Risk Management leverages strong role-based access controls (RBAC), ensuring that the designated individuals in the organization are taking the right actions with additional auditing capabilities.

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Visual context is crucial for security teams during forensic investigations to get better insights into potentially risky security-related user activities. With customizable event triggers and built-in user privacy protection controls, forensic evidence enables customizable visual activity capturing across devices to help your organization better mitigate, understand, and respond to potential data risks like unauthorized data exfiltration of sensitive data. You set the right policies for your organization, including what risky events are the highest priority for capturing forensic evidence, what data is most sensitive, and whether users are notified when forensic

capturing is activated. Forensic evidence capturing is off by default and policy creation requires dual authorization.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Feature capabilities

- **Visual capturing** enables your organization to capture clips of key security-related user activities, so you can have more secure or compliant visibility that meets your organizational needs.
- **Include or exclude desktop applications and websites** to configure a recording policy that focuses on the applications and websites that present the most risk. This approach preserves storage space and user privacy. For example, you can exclude personal email and social media accounts.
- **Enhanced phishing protection (preview)** enables your organization to capture clips related to Enhanced Phishing Protection in Microsoft Defender SmartScreen. For example, you can capture when a user enters the Microsoft password they used to sign into their Windows 11 device on a phishing site or application connecting to a phishing site. Learn more about Enhanced Phishing Protection in Microsoft Defender SmartScreen
- **Protected user privacy** through multiple levels of approval for the activation of the capturing feature.
- **Customizable triggers and capturing options** mean that security teams can set up forensic evidence to meet their needs, whether it be based on incidents (for example, *Capture 5 min before and 10 min after a user has downloaded 'SecretResearchPlans.docx'*), or based on continuous capturing needs.
- **User-centric policy targeting** means that security and compliance teams can focus on activity by user, not device, for better contextual insights.
- **Strong role-based access controls (RBAC)** mean that the ability to set up and review forensic clips is tightly controlled and only available to individuals in the organization with the right permissions.
- **Deep integration with current Insider Risk Management features**, making for easier onboarding and more familiar workflows for Insider Risk Management administrators and a trusted single-platform approach.
- **Trial capacity (up to 20 GB)** for captured clips, with quick access to capacity utilization and the ability to purchase additional capacity.

Device and configuration requirements

The following tables include the supported minimum requirements for utilizing Insider Risk Management forensic evidence.

Supported platforms

Expand table

Operating system	SKU	Processor
Windows 10 (including Windows 365)	Enterprise	64-bit (Intel or AMD)
Windows 11 (including Windows 365)	Enterprise	64-bit (Intel or AMD)

Physical devices

Expand table

Hardware	Minimum requirement
RAM	Minimum of 8 GB (at least 2 GB should be available for client usage)
CPU processor	Intel i5 or higher and AMD Ryzen 5 or higher
Graphics card	Compatible with DirectX 11 or later, with a WDDM 1.0 driver or later (currently only integrated graphics cards supported)
Disk space	Minimum of 10 GB of disk storage
Display	Minimum screen resolution of 1920 x 1080

Hyper-V and virtual machines

Expand table

Hardware	Minimum requirement
RAM	Minimum of 16 GB (at least 2 GB should be available for client usage)
CPU processor	Minimum of eight vCPU processors or equivalent
Disk space	Minimum of 10 GB of disk storage

Hardware	Minimum requirement
Display	Minimum screen resolution of 1920 x 1080

> **Important**
>
> If you don't meet the minimum requirements, you might run into Microsoft Purview client issues and the quality of forensic captures might not be reliable.

Capturing options

Triggering events, global indicators, and policy indicators play an important role in all Insider Risk Management policies, including forensic evidence policies. Triggering events are user actions that determine if users are brought into scope for evaluation in Insider Risk Management policies. Global settings indicators determine what activities Insider Risk Management collects. Policy indicators determine a risk score for an in-scope user.

Depending on how your organization decides to configure forensic evidence, you can choose from two capturing options:

- **Specific activities**: This policy option captures activity only when a triggering event brings an approved user into scope for the forensic evidence policy and when the conditions for a policy indicator are detected for the user. For example, a user approved for forensic evidence capturing is brought in-scope to the forensic evidence policy and the user copies data to personal cloud storage services or portable storage devices. Capturing is scoped only to the configured time frame when the user is copying the data to the personal cloud storage service or portable storage device. You can review captures for this option on the **Forensic evidence** tab on the **Alerts** dashboard.
- **All activities**: This policy option captures any activity performed by users. For example, your organization has a time-sensitive need for capturing activities for an approved user that is actively involved in potentially risky activities that might lead to a security incident. Policy indicators might not have reached the threshold for an alert to be generated by the policy and the potentially risky activity might not be documented. Continuous capturing help prevents the potentially risky activity from being missed or going undetected. You can review captures for this option on the **Forensic evidence** tab on the **User activity reports (preview)** dashboard.

> **Important**

Forensic evidence clips are deleted 120 days after they're captured or at the end of the preview period, whichever is sooner. You can download or transfer forensic evidence clips before they're deleted.

Workflow

The overall workflow for detecting, investigating, and remediating alerts that contain clip capturing follows the same basic steps as other Insider Risk Management policies. However, some notable differences exist for forensic evidence when configured in your organization:

- **Users subject to capturing must have explicit capturing requests and approvals**: This extra process isn't included as a part of configuring other Insider Risk Management policies. Users assigned to the *Insider Risk Management* or *Insider Risk Management Admins* role groups must submit a request to users assigned to the *Insider Risk Management Approvers* role group before any user in your organization is eligible for any clip capturing options. For example, this requirement helps support organizational scenarios where your Insider Risk Management admins must get explicit approval from your designated legal or human resources personnel before capturing for any user is enabled.
- **Devices must be onboarded and have the Microsoft Purview client installed**: Before forensic evidence can collect and store clips captured for eligible users, their devices must be onboarded to the Microsoft Purview portal. Additionally, each device must have the Microsoft Purview Client installed. These prerequisites enable support for both online and offline device capturing.

Ready to get started?

- For step-by-step guidance to configure forensic evidence capturing in your organization, see Get started with Insider Risk Management forensic evidence.
- To configure prerequisites, create policies, and start receiving alerts, see Get started with Insider Risk Management.

Get started with Insider Risk Management forensic evidence

08/20/2025

> **Important**
>
> Forensic evidence is an opt-in add-on feature in Microsoft Purview Insider Risk Management that gives security teams visual insights into potential insider data security incidents, with user privacy built in. Forensic evidence includes customizable event triggers and built-in user privacy protection controls, enabling security teams to better investigate, understand and respond to potential insider data risks like unauthorized data exfiltration of sensitive data.
>
> Organizations set the right policies for themselves, including what risky events are highest priority for capturing forensic evidence and what data is most sensitive. Forensic evidence is off by default, policy creation requires dual authorization and usernames can be masked with pseudonymization (which is on by default for Insider Risk Management). Setting up policies and reviewing security alerts within Insider Risk Management leverages strong role-based access controls (RBAC), ensuring that the designated individuals in the organization are taking the right actions with additional auditing capabilities.

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Configuring forensic evidence in your organization is similar to configuring other policies from Insider Risk Management policy templates. In general, you follow the same basic configuration steps to set up forensic evidence, but a few areas require feature-specific configuration actions before you get started with the basic configuration steps.

> **Tip**

Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Step 1: Confirm your subscription and configure data storage access

Before you get started with forensic evidence, confirm your Insider Risk Management subscription and any add-ons.

Also, add the following domains to your firewall and proxy server allowlist to support forensic evidence capture storage for your organization:

Worldwide - Domain

```
- compliancedrive.microsoft.com
- *.events.data.microsoft.com
- officeclient.microsoft.com
- odc.officeapps.live.com
- hrd.svc.cloud.microsoft
```

GCC/GCC High - Domain

```
- *.compliancedrive.microsoft.us
- tb.events.data.microsoft.com
- officeclient.microsoft.com
- odc.officeapps.live.com
- hrd.svc.cloud.microsoft
```

DOD - Domain

```
- dod.compliancedrive.apps.mil
- pf.events.data.microsoft.com
- officeclient.microsoft.com
- odc.officeapps.live.com
- hrd.svc.cloud.microsoft
```

For more information on these endpoints, see Microsoft 365 endpoints.

> **Note**
>
> Captures and capture data are stored at these domains and are assigned only to your organization. No other Microsoft 365 organization has access to forensic evidence captures for your organization.
>
> Forensic evidence data is stored in one region where your Exchange Online region is set.

Step 2: Configure supported devices

To capture forensic evidence, eligible user devices must be onboarded to the Microsoft Purview portal and have the Microsoft Purview Client installed.

> **Important**
>
> The Microsoft Purview Client automatically collects general diagnostic data related to device configuration and performance metrics. This data includes information on critical errors, RAM consumption, process failures, and other data. This data helps us assess the client's health and identify any issues. For more details about how diagnostic data might be used, see the Use of Software with Online Services on the **Microsoft Product Terms**.

For a list of device and configuration requirements, see Learn about forensic evidence. To onboard supported devices, complete the steps outlined in the Onboard Windows 10 and Windows 11 devices into Microsoft 365 overview article.

Install the Microsoft Purview client

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Forensic Evidence** in the left navigation, then select **Client installation**.
4. Select **Download installer package (x64 version)** to download the installation package for Windows.
5. After downloading the installation package, use your preferred method to install the client on users' devices. These options might include manually installing the client on

devices or using tools to help automate the client installation:

- **Microsoft Intune**: Microsoft Intune is an integrated solution for managing all of your devices. Microsoft brings together Configuration Manager and Intune, without a complex migration, and with simplified licensing.
- **Third-party device management solutions**: If your organization uses third-party device management solutions, see the documentation for these tools to install the client.

Step 3: Configure settings

Forensic evidence has several configuration settings that provide flexibility for the types of security-related user activity captured, capturing parameters, bandwidth limits, and offline capturing options. By configuring forensic evidence capturing, you can create policies based on your requirements. Adding users to a policy requires dual authorization.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Forensic evidence** in the left navigation, then select **Forensic evidence settings**.
4. Select **Forensic evidence capturing** to enable capturing support in your forensic evidence policies. If you turn this setting off, it removes all previously added users for forensic evidence policies.

   > **Important**
   >
   > The Microsoft Purview Client used to capture activity on users' devices is licensed under the Use of Software with the Online Services on the Microsoft Product Terms. Customers are solely responsible for using the Insider Risk Management solution, including the Microsoft Purview Client, in compliance with all applicable laws.

5. In the **Capturing window** section, define when to start and stop activity capturing. Available values are *10 seconds*, *30 seconds*, *1 minute*, *3 minutes*, or *5 minutes*.
6. In the **Upload bandwidth limit** section, define the amount of capture data to upload into your data storage account per user, per day. Available values are *100 MB*, *250 MB*, *500 MB*, *1 GB*, or *2 GB*.

7. In the **Offline capturing cache limit** section, define the maximum cache size to store on users' devices when offline capturing is enabled. Available values are *100 MB*, *250 MB*, *500 MB*, *1 GB*, or *2 GB*.

8. Select **Save**.

Step 4: Create a policy

Forensic evidence policies define the scope of security-related user activity to capture for configured devices. You have two options for capturing forensic evidence:

- **Capture only specific activities (such as printing or exfiltrating files).** With this option, you choose the device activities to capture. You can also choose to capture activity for specific desktop apps and websites. This option lets you focus on just the activities, apps, and websites that present risk.
- **Capture all activities that approved users perform on their devices.** This option typically covers a specific period of time, such as when a particular user is potentially involved in risky activity that might lead to a security incident. All forensic evidence indicators are automatically included, such as device indicators and Enhanced Phishing Protection indicators. To preserve capacity and user privacy, you can choose to exclude specific desktop apps and websites from the capture.

After you create a policy, include it in forensic evidence requests to control what activity to capture for users whose requests are approved.

> **Note**
>
> Continuous forensic policies (capturing all activities) take precedence over selective forensic evidence policies (capturing only specific activities).

Capture only specific activities

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.

2. Go to the **Insider Risk Management** solution.

3. Select **Forensic evidence** in the left navigation, then select **Forensic evidence policies**.

4. Select **Create forensic evidence policy**.

5. On the **Scope** page, select **Specific activities**. This option only captures activities detected by policies that users are included in. These activities are defined by the indicators selected in forensic evidence policies. You can review captures for this option on the **Forensic evidence (preview)** tab on the **Alerts** or **Cases** dashboard.

6. Select **Next**.

7. On the **Name and description** page, complete the following fields:

   - **Name (required)**: Enter a friendly name for the forensic evidence policy. You can't change this name after the policy is created.
   - **Description (optional)**: Enter a description for the forensic evidence policy.

8. Select **Next**.

9. On the **Choose device activities to capture** page:
   a. Select any device activities that you want to capture. The policy only captures the selected activities.

   > ⓘ **Note**
   >
   > If the indicators aren't selectable, you're prompted to turn them on.

10. To capture activity for particular desktop apps and websites in your policy, select the **Opening a specific app or website** check box under **App and web browsing activities to capture**.

    > ⓘ **Important**
    >
    > To capture browsing activities (to include or exclude specific URLs in your forensic evidence policies), make sure to install the necessary browser extensions. You also need to turn on at least one browsing indicator. If you haven't already turned on one or more browsing indicators, you're prompted to do so if you choose to include or exclude desktop apps or websites. The triggering event for capturing browsing activities is a URL update in the URL bar that contains the specified URL.

    Select **Next**.

11. (Optional) If you chose to capture activity for particular desktop apps and websites, in the **Add apps and websites you want to capture activity for** page:
    a. To add a desktop app, select **Add desktop apps**, enter the name of an executable file (for example, teams.exe), then select **Add**. Repeat this process for each desktop app

that you want to add (up to 25 apps). To find the name of an executable file for the app, open the Task Manager, then view the properties for the app. Here's a list of exe names for some of the common applications: Microsoft Edge (msedge.exe), Microsoft Excel (Excel.exe), the Snipping tool (SnippingTool.exe), Microsoft Teams (Teams.exe), Microsoft Word (WinWord.exe), and Microsoft Remote Desktop Connection (mstsc.exe).

> **Note**
>
> Sometimes, the exe names for an app might differ based on the device and the permissions with which the app was opened. For example, on a Windows 11 enterprise device, when Windows PowerShell is opened without administrator permissions, the exe name is WindowsTerminal.exe but when opened with administrator permissions, the exe name changes to powershell.exe. Make sure to include/exclude both exe names in such scenarios.

a. To add a web app or website, select **Add web apps and websites**, enter a URL (for example, https://teams.microsoft.com), then select **Add**. Repeat this process for each web app or website that you want to add. You can add up to 25 URLs with a character length of 100 for each URL.

> **Tip**
>
> If an app has a desktop and web version, add both the desktop executable and the web URL to make sure you capture activity for both.

a. Select **Next**.

12. On the **Review settings and finish** page, review the settings you chose for the policy and any suggestions or warnings for your selections. Edit any of the policy values or select **Submit** to create and activate the policy.

13. After you complete the policy configuration steps, continue to Step 5.

Capture all activities

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.

2. Go to the **Insider Risk Management** solution.

3. Select **Forensic evidence** in the left navigation, then select **Forensic evidence policies**.

4. Select **Create forensic evidence policy**.
5. On the **Scope** page, select **All activities**. This option captures any activity performed by users. You can review captures for this option on the **Forensic evidence (preview)** tab on the **User activity reports (preview)** dashboard.
6. Select **Next**.
7. On the **Name and description** page, complete the following fields:
    - **Name (required)**: Enter a friendly name for the forensic evidence policy. You can't change this name after the policy is created.
    - **Description (optional)**: Enter a description for the forensic evidence policy.
8. Select **Next**.
9. On the **Choose device activities to capture** page, if you want to exclude certain desktop apps and/or web apps or websites from the capture, under **App and web browsing activities to capture**, select the **Exclude specific apps or websites** check box.
10. Select **Next**.
11. If you chose to exclude particular desktop apps and websites from the capture, in the **Exclude applications/URLs** page:
    - To exclude a desktop app from the capture, select **Exclude desktop apps**, enter the name of an executable file (for example, teams.exe), and then select **Add**. Repeat this process for each desktop app that you want to exclude (up to 25 apps). To find the name of an executable file for an app, open the Task Manager, and then view the properties for the app.
    - To exclude a web app or website, select **Exclude web apps and websites**, enter a URL (for example, https://teams.microsoft.com), and then select **Add**. Repeat this process for each web app or website that you want to exclude. You can exclude up to 25 URLs with a character length of 100 for each URL.

    > **Tip**
    >
    > If an app has a desktop and web version, add both the desktop executable and the web URL to make sure you exclude both.

12. On the **Review settings and finish** page, review the settings you chose for the policy and any suggestions or warnings for your selections. Edit any of the policy values or select **Submit** to create and activate the policy.

13. After you complete the policy configuration steps, continue to Step 5.

Step 5: Define and approve users for capturing

Before you can capture security-related user activities, admins must follow the dual authorization process in forensic evidence. This process requires that applicable people in your organization both define and approve the enabling of visual capturing for specific users.

You must request to enable forensic evidence capturing for specific users. When you submit a request, approvers in your organization receive an email notification and can approve or reject the request. If approved, the user appears on the **Approved users** tab and is eligible for capturing. For more information, see these links:

- Request approval for forensic evidence capturing.
- Approve (or reject) requests for forensic evidence capturing.

Next steps

After you configure your forensic evidence policy, it can take up to two hours for policy enforcement, given that the forensic evidence clients (installed at the endpoint devices) are online. When a client captures a clip, it can take up to one hour before the clip is available to review. For more information about managing forensic evidence and reviewing clip captures, see the Manage information risk management forensic evidence article.

Manage Insider Risk Management forensic evidence

> **Important**
>
> Forensic evidence is an opt-in add-on feature in Microsoft Purview Insider Risk Management that gives security teams visual insights into potential insider data security incidents, with user privacy built in. Forensic evidence includes customizable event triggers and built-in user privacy protection controls, enabling security teams to better investigate, understand and respond to potential insider data risks like unauthorized data exfiltration of sensitive data.
>
> Organizations set the right policies for themselves, including what risky events are highest priority for capturing forensic evidence and what data is most sensitive. Forensic evidence is off by default, policy creation requires dual authorization and usernames can be masked with pseudonymization (which is on by default for Insider Risk Management). Setting up policies and reviewing security alerts within Insider Risk Management leverages strong role-based access controls (RBAC), ensuring that the designated individuals in the organization are taking the right actions with additional auditing capabilities.

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

When you complete the configuration steps and create your forensic evidence policy, you start seeing alerts for potentially risky security-related user activities that meet the conditions for indicators defined in the policy.

> **Tip**

Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Use the forensic evidence dashboard

The forensic evidence dashboard provides a summary view of key areas of the forensic evidence configuration in your organization. For this preview release, the dashboard includes only a **Forensic evidence device health** section. Select **View device health report** to open the **Device health** tab and report.

Manage forensic evidence users and approvals

You must request and approve specific users before they're eligible for forensic evidence capturing. Simply adding users to a forensic evidence policy doesn't automatically make those users eligible for capturing. You can request and approve users before or after creating forensic evidence policies, but the clip captures associated with policy indicators are created and available for reviewing only after approving the users.

Users assigned to the *Insider Risk Management* or *Insider Risk Management Admins* role groups can submit approval requests to users assigned to the *Insider Risk Management Approvers* role group.

Request capturing approvals

Request turning on forensic evidence to capture information for specific users. When you submit a request, approvers in your organization receive an email notification and can approve or reject the request. If approved, the user appears on the **Approved users** tab and is eligible for capturing. If not addressed, the request expires six months from the day it was submitted.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Forensic evidence** in the left navigation, then select **User management**.
4. Select the **Manage forensic evidence requests** tab.
5. Select **Create request**.

6. On the **Users** page, select **Add users**.
7. Use **Search** to locate a specific user or select one or more users from the list. Select **Add**, then select **Next**.
8. On the **Forensic evidence policy** page, select a forensic evidence policy for the added users. The policy you choose determines the scope of activity to capture for users.
9. Select **Next**.
10. On the **Justification** page, explain why you're requesting that capturing be enabled for the users you added in the **Justification for turning on forensic evidence capturing** text box. This is a required field. When complete, select **Next**.
11. On the **Email notifications** page, use a notification template to send an email to users letting them know that forensic evidence capturing is turned on for their device in accordance with your organization's policies. The email is sent to users only if their request is approved.

    Select the **Send an email notification to approved users** check box. Choose an existing template or create a new one. To create a new template, select **Create a notification template** and complete the required fields in the **New email notification template** pane.
12. Select **Next**.
13. On the **Finish** page, review your settings before submitting the request. Select **Edit users** or **Edit justification** to change any of the request values or select **Submit** to create and send the request to reviewers.

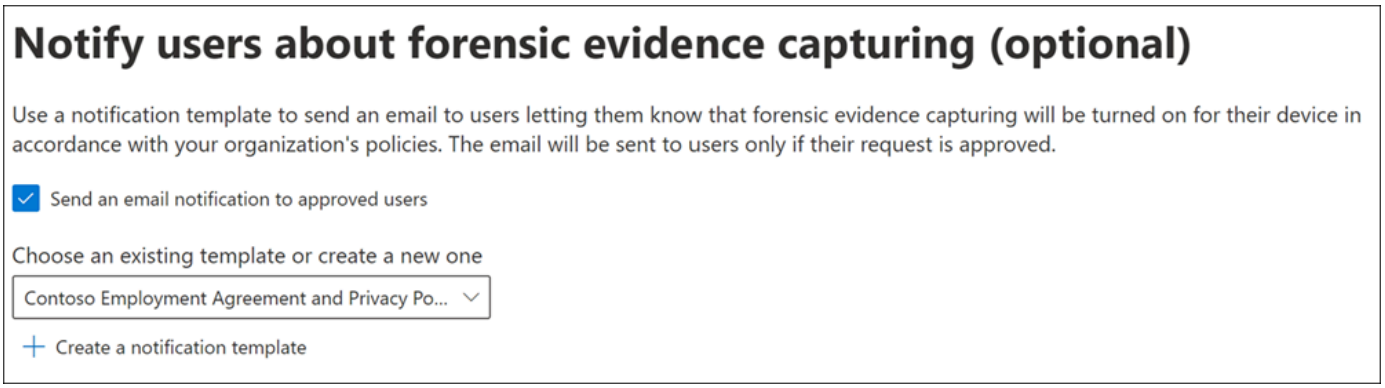
To view pending approval requests, go to **Insider Risk Management** > **Forensic evidence** > **Pending requests**. Here you see the users with pending requests, their email address, the request submission date, and who submitted the approval request. If no users are displayed, there aren't any pending approval requests for any users.

Users assigned to the *Insider Risk Management Approvers* role group can select a user on the **Forensic evidence request** tab and review the request. After reviewing the request, these users can approve or reject the forensic evidence capturing request. Approving or rejecting the capturing request removes the pending request for users from this view.

Approve or reject capturing requests

After a capturing approval request is submitted, users assigned to the *Insider Risk Management Approvers* role group receive an email notification for the approval request.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Forensic evidence** in the left navigation, then select **Pending requests**.
4. Select a user to review.
5. On the **Review forensic evidence request (preview)** pane, review the justification submitted by the requestor. Select **Approve** or **Reject** as applicable.
6. On the **Request approved** or **Request rejected** page, select **Close**.



Revoke capturing approvals

If needed, you can revoke approval for specific users and exclude them from forensic evidence capturing. Revoking approval doesn't delete or remove any existing captures for these users. It only disables future capturing of activity for these users.

1. Sign in to the Microsoft Purview portal as a member of the *Insider Risk Management Approvers* role group.
2. Go to the **Insider Risk Management** solution.
3. Select **Forensic evidence** in the left navigation, then select **User management**.
4. Select the **Approved users** tab.
5. Select a user, then select **Remove**.
6. On the removal confirmation page, select **Remove** to revoke capturing approval.

Create and manage forensic evidence notification templates

You can create and use a notification template to send an email to users, letting them know that forensic evidence capturing is turned on for their device in accordance with your organization's policies. The email is sent to users only if their request is approved.

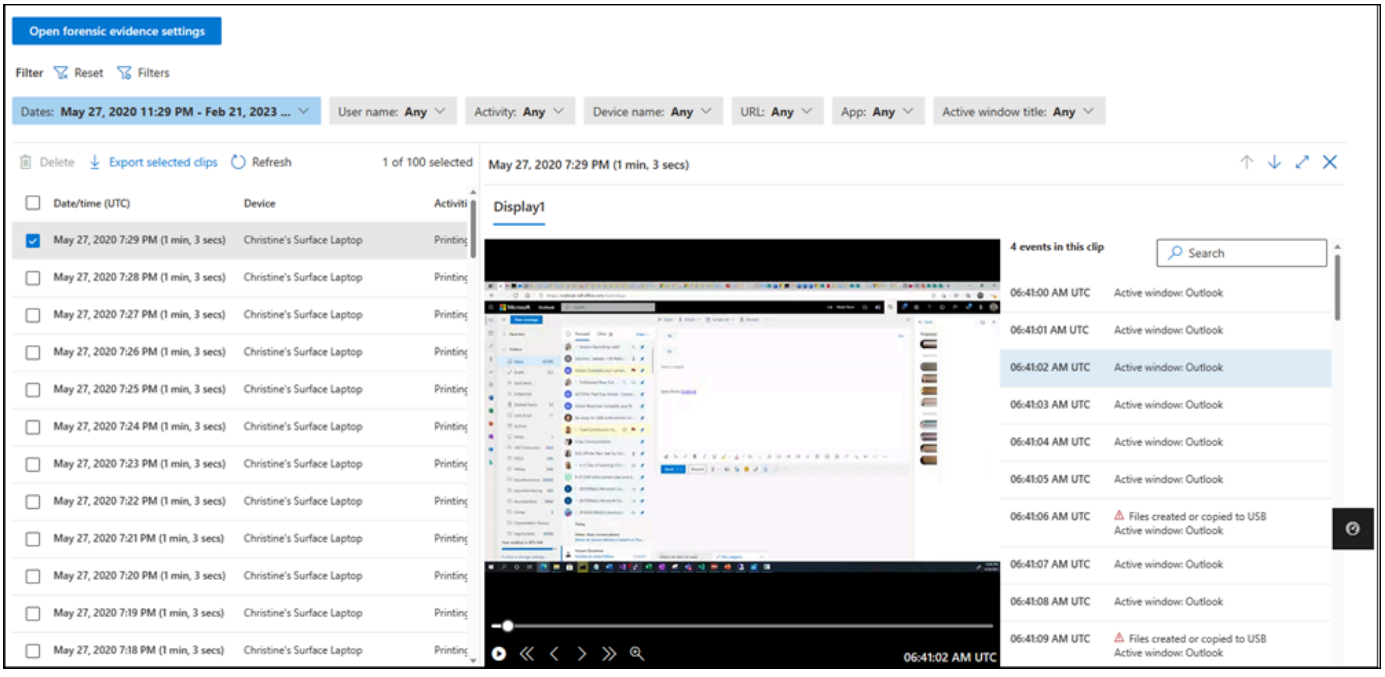
Create a new notification template

To create a notification template, complete the following steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Forensic evidence** in the left navigation, then select **Notification templates**.
4. Select **Create notification template**.
5. On the **New email notification template** pane, enter the following required fields:
    - Template name
    - Send from
    - Subject
    - Message body
6. Select **Save**.

> **Note**
>
> To delete an existing notification template, select the template, then select **Delete**.

View and manage captured clips



You can view and explore captured clips by selecting the **Forensics evidence** tab when you open Microsoft Purview Insider Risk Management. You can also select the **Forensics evidence** tab from other areas in the solution to view a list of captured clips in context:

- **Alerts dashboard**. Clips accessible from the **Alerts** dashboard correspond to the option to capture **specific user activities** when the forensic evidence policy is created. The captured clips are defined by indicators you select in the forensic evidence policy.

- **User activity reports**. Clips accessible from **User activity** reports correspond to the option to capture **any security-related activity** performed by users included in forensic evidence policies.
- **Cases dashboard**. Clips accessible from the **Cases** dashboard are alerts that you escalated to cases.

> **Note**
>
> If you're a member of both the *Insider Risk Management Investigators* role group and the *Insider Risk Management Admins* role group, you see **Review captured clips** when you open Microsoft Purview Insider Risk Management. If you select **Review captured clips**, it changes to **Open forensic evidence settings**. Selecting **Review captured clips** or **Open forensic evidence settings** lets you switch between the list of captured clips and settings if you have both roles. Learn more about role groups.

When you select the **Forensics evidence** tab, captured clips and associated information display in a list. If you select a captured clip in the list, a video player appears in the center of the screen, and a transcript of activities and events from the clip displays to the right of the video player.

Each captured clip includes the following information:

- **Date/time (UTC)**: The date, time (UTC), and duration of the capture. The duration of the capture is the total time spanned by the capture. The actual length of the capture might be shorter since Insider Risk Management automatically eliminates identical frames.
- **Device**: The name of the device in Windows 10/11.

- **Activities**: The Insider Risk Management activity type included in the capture. These activities are based on global and policy indicators assigned to the associated policy.
- **User**: The name of the user.
- **URL** (if applicable): The URL that the user was accessing when the activity took place.
- **Application** (if applicable): The application that the user was accessing when the activity took place.
- **Active window title**: The title of the window that the user was accessing when the activity took place.

To view a captured clip:

1. If needed, configure the filters at the top of the list.
2. Select a clip from the list.
3. Using the video player controls, select the *Play control* to review the entire clip from beginning to end.
4. To scope the review to a specific activity or event in the clip, select the activity or event in the transcript. You can also use the search box to search for specific activities or events.

   > **Note**
   >
   > A red triangle in the transcript denotes an activity.

Filtering the captured clips list

You can use the filters for the captured clips list to filter for specific activities and information. Each filter supports up to 10 unique IDs so, for example, you can filter on up to 10 users at one time. The following table describes the different filters.

Expand table

Filter name	Description
Active window title	Filter for the active window title. You can select **Contains any of** or **Contains all of** to filter in the same way as the **App** filter.
Activity	Select a specific activity to filter on, such as *Printing files* or *Password used to sign into the device has been reused*.

Filter name	Description
App	Filter by app name. You can select **Contains any of** or **Contains all of** with this filter. Example: if you select **Contains any of** and enter "Contoso.com,Contoso2.com", you could have one clip that captures Contoso.com and another that captures Contoso2.com. If you select **Contains all of** and enter "Contoso.com,Contoso2.com", any captures would have to contain both domains.
Device name	Filter on any device name.
URL	Filter for a domain name or search for any keyword after filtering for a domain name. Example: entering "SharePoint" as a keyword returns any URL that includes "SharePoint" anywhere in the URL.
User name	Filter on any user name.

Deleting clips

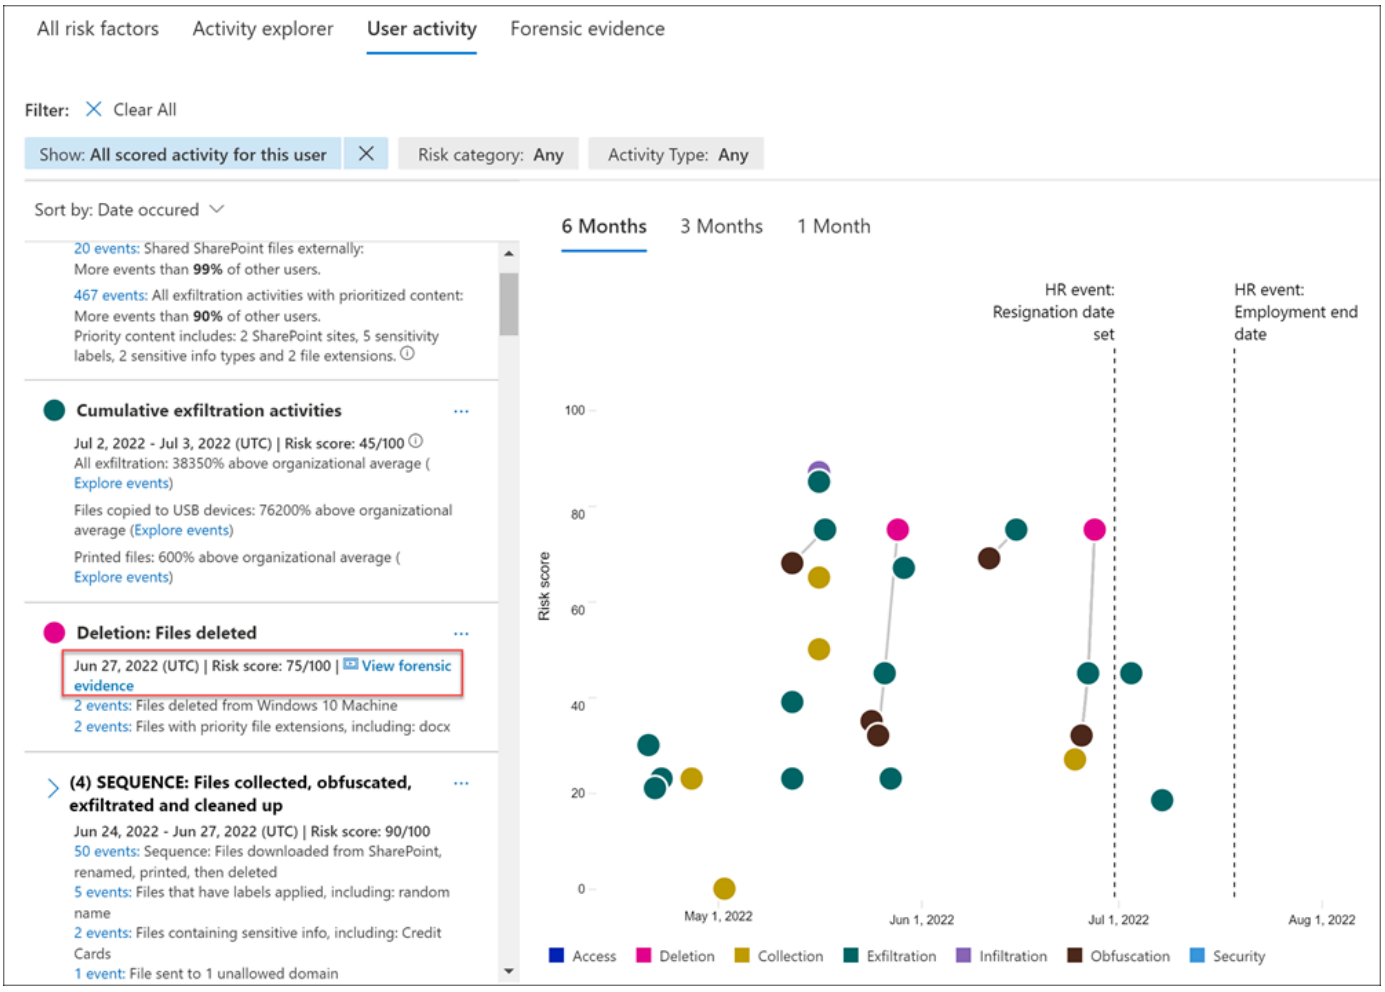
Users assigned to the *Insider Risk Management Investigators* role group can delete individual clips from the captured clips list. To do this:

1. Select the check box next to the capture.
2. Select **Delete**.

Users assigned to the *Insider Risk Management Admins* role group can do bulk deletions through settings.

Make a bulk deletion

To delete clips in bulk for a specific user, complete the following steps:



1. Sign in to the Microsoft Purview portal as a member of the *Insider Risk Management Admins* role group.
2. Go to the **Insider Risk Management** solution.
3. Select **Forensic evidence** in the left navigation, then select **Forensic evidence settings**.
4. Make sure that the **Allow deletion of forensic user data by an Administrator or Investigator** option is set to **On**.
5. Under **Delete a user's** data, choose **Select a user**, then select the user that you want to delete clips for.

> **Important**

Forensic evidence clips are deleted 120 days after they're captured. You can export or transfer forensic evidence clips before they're deleted.

View captured clips in the Alerts dashboard

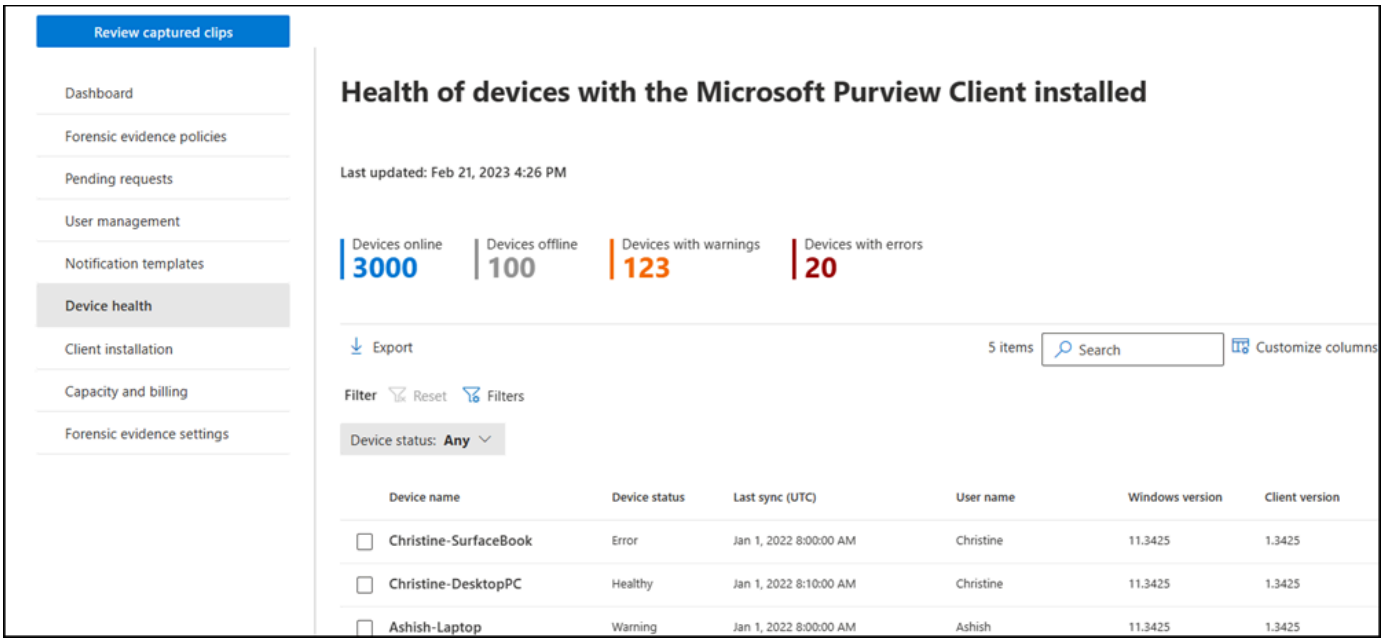
For alerts generated by policies, you can review forensic evidence captures on the **Forensic evidence** tab on the **Alerts** dashboard. If one or more captures are available for the alert, you also see a **View forensic evidence** notification link in the activity that generates an alert header section. You can select the notification link or the **Forensic evidence** tab to review a list of activity captures.

Reviewing an alert for potentially risky activity that might contain forensic evidence captures is essentially the same as reviewing an alert without forensic evidence captures. The significant difference is the inclusion of any applicable captures. The **Forensic evidence** tab provides access to all available captures associated with the alert.

View captured clips in the Cases dashboard

If you escalate alerts to cases, include all associated forensic evidence captures as part of the case. Reviewing forensic evidence captures for cases follows the same process as reviewing captures for alerts.

View captured clips in user activity reports



User activity reports allow you to examine activities for specific users for a defined time period without having to assign them temporarily or explicitly to an Insider Risk Management policy. If these user activities include activities supported by forensic evidence capturing, the report includes clips with the user activity.

If you configure forensic evidence to capture all security-related user activity, regardless of whether they're included in a forensic evidence policy, review these captures by following these steps:

1. Select **Insider Risk Management** > **Overview**.
2. At the bottom of the **Overview** screen, under **Investigate user activity**, select **Manage reports**.
3. Select a specific user, then select the **Forensic evidence** tab.
4. Select a clip from the list, then use the video player controls to review the clip. To scope the review to a specific activity or event, select the activity or event in the transcript.

Device health report (preview)

After you configure devices to support forensic evidence, you can review the Microsoft Purview Client health status for all devices in your organization by going to **Insider Risk Management** > **Forensic evidence** > **Device health**.

For a list of minimum device and configuration requirements, see Learn about forensic evidence. To onboard supported devices, follow the steps in the Onboard Windows 10 and Windows 11 devices into Microsoft 365 overview article.

The Device health report lets you view the status and health of all devices that have the forensic evidence agent installed. Each report widget on the report displays information for last 24 hours.

- **Devices online**: The total number of devices currently online.
- **Devices offline**: The total number of devices currently offline.
- **Devices with warnings**: The total number of devices with a warning.
- **Devices with errors**: The total number of devices with an error.

The device health queue lists all the devices configured for forensic evidence in your organization. In addition, the report lists the status of the following device attributes:

- **Device name**: The name of the device, defined by the *ComputerName* attribute of the device.
- **Device status**: The status of the Microsoft Purview Client on the device. Status values are as follows:
  - ***Healthy***: The client on the device is working properly and forensic evidence capture features are fully supported.
  - ***Warning***: The client on the device has a warning and forensic evidence capture features might not be fully supported.
  - ***Error***: The client on the device has an error and forensic evidence capture features are disabled or not fully supported.
- **Status details**: More information about the device status.
- **Last sync (UTC)**: Date and time of the last status sync for the device.

- **User name**: The user name for the user logged into the device when the status sync was performed.
- **Windows version**: The version of Microsoft Windows installed on the device.
- **Client version**: The version of the Microsoft Purview Client installed on the device.

The device health status gives you insights into potential issues with your devices and the Microsoft Purview Client. The **Device status** column on the **Device health** page can alert you to device issues that might prevent user activity from being captured or why the volume of forensic evidence capturing is unusual. The device health status can also confirm that the devices included in forensic evidence capturing are healthy and don't need attention or configuration changes. The following table lists potential status detail messages and recommended actions you can take to address warnings and errors:

Expand table

Status details	Status	Suggested action
An internal server error occurred. As a result, capture data might be missing.	Error	Create a support ticket with Microsoft for further investigation
CPU usage on the device has exceeded the maximum threshold.	Error	The capture process has been stopped and will restart in a few minutes.
Device is unable to access the directory that stores forensic evidence captures.	Error	Reinstall the client on this device
Encoder initialization failed.	Error	Reinstall the client on this device.
GPU usage on the device has exceeded the maximum threshold.	Error	The capture process has been stopped and will restart in a few minutes.
Memory usage on the device has exceeded the maximum threshold.	Error	The capture process has been stopped and will restart in a few minutes.
Offline storage has reached 90% of the configured limit on this device. Captures might be overwritten soon.	Warning	Increase the offline capturing cache limit on the Forensic evidence settings page.
The configured offline storage limit has been reached on this device. As a result, offline captures are being overwritten.	Error	Increase the offline capturing cache limit on the Forensic evidence settings page.
The configured upload bandwidth limit has been reached on this device. No more captures are uploaded	Error	Increase the upload bandwidth limit on the Forensic evidence settings

Status details	Status	Suggested action
for the day.		page.
The Microsoft Purview Client installed on the device hasn't synced with the forensic evidence policy in over 24 hours.	Error	Connect to network & reinstall client
The Microsoft Purview Client installed on the device in unable to sync with the forensic evidence policy.	Warning	Connect to network & reinstall client
The Microsoft Purview Client is unable to capture activity because display monitors on this device were turned off or disconnected.	Error	Connect/Turn on display monitors for the device
The Microsoft Purview Client is unable to capture activity because no display monitors are detected on this device.	Error	Add display monitors for this device
The Microsoft Purview Client is unable to capture activity because no graphics card is detected on this device.	Error	Add a graphics card or replace the device with one that has a graphics card
Upload bandwidth has reached 90% of the configured limit on this device. Captures might be overwritten soon.	Warning	Increase the upload bandwidth limit on the Forensic evidence settings page.

Contact Microsoft Support if the recommended actions don't resolve issues with the client.

Capacity and billing

When you configure forensic evidence, you can choose to purchase the forensic evidence add-on for Insider Risk Management for your captured clips. Organizations with any of the following licenses can get the add-on: Microsoft 365 E5, Microsoft Purview Suite (formerly known as Microsoft 365 E5 Compliance), or Microsoft 365 E5 Insider Risk Management.

Organizations can purchase the add-on in units of 100 GB per month. Purchased capacity applies to the ingestion of forensic evidence starting on the date of purchase and resets on the first of the month. Unused capacity doesn't carry over. We recommend purchasing the license at the beginning of the month to maximize the value of the license. One hundred gigabytes roughly equals around 1,100 hours of forensic evidence captures per tenant, at a video resolution of 1080p. You can download the Forensic evidence capacity calculator to help estimate the number of GBs needed per month.

Once you ingest the forensic evidence, the system retains it for 120 days. You can export forensic evidence if needed after the 120-day retention period.

Compare forensic evidence payment plans

When you purchase the add-on through the Microsoft 365 admin center, you have two payment plans available:

- **Pay yearly (available in all channels).** With the annual commitment option, you buy the number of licenses you specify each month for 12 months. This option is suitable for customers who want to ensure they have capacity available each month to ingest forensic evidence without interruption. This payment plan automatically replenishes the number of licenses purchased each month. Purchased capacity applies to the ingestion of forensic evidence starting on the date of purchase and resets on the first of the month. Unused capacity doesn't carry over. Customers can choose to be billed one time or split the bill into 12 monthly payments.
- **Pay monthly (only available in web direct).** If you don't want to make an annual commitment, you can buy the number of licenses needed each month. Purchased capacity applies to the ingestion of forensic evidence starting on the date of purchase and resets on the first of the month. Unused capacity doesn't carry over.

Can I try the forensic capability before purchasing it?

Each tenant with a Microsoft 365 E5, Microsoft Purview Suite (formerly known as Microsoft 365 E5 Compliance), or Microsoft 365 E5 Insider Risk Management license can sign up for a 20-GB trial license to try the forensic evidence capability.

> ⓘ **Note**
>
> The 20-GB trial license is only available for customers on the legacy commerce platform.

The trial license provides 20 GB of capacity until you use it up or until one year from the activation date, whichever comes first. If you purchase a forensic evidence add-on license before using all the trial capacity, you can use the remaining trial capacity before the system starts metering the purchased capacity.

If you use up the 20 GB of trial capacity without purchasing the forensic add-on for Insider Risk Management, you can view any ingested clips but can't ingest new clips.

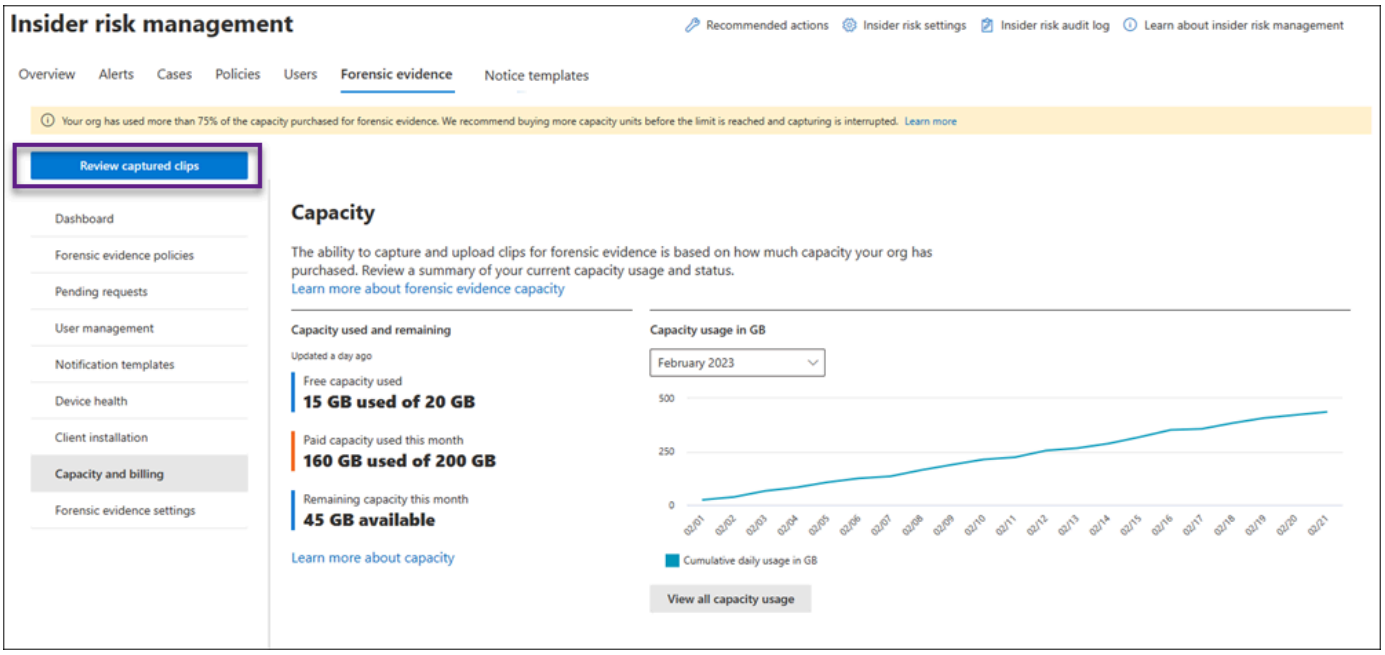
Sign up for the 20-GB trial license

To claim the 20-GB trial license, complete the following steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Forensic evidence** in the left navigation, then select **Capacity and billing**.

   > **Note**
   >
   > You can also sign up for the trial license from the **Insider Risk Management** > **Forensic evidence** > **Dashboard** tab.

4. Select **Claim 20 GB of capacity**.
5. Follow the prompts in the Microsoft 365 admin center.



Purchase the forensic add-on for Insider Risk Management

To purchase the forensic evidence add-on, complete the following steps:

1. Go to **Microsoft 365 admin center** > **Marketplace** > **All products**.
2. Search for "forensic evidence".

Analyze your capacity

After purchasing capacity or signing up for the 20-GB trial license, use the **Capacity** page to check how much capacity you used and how much capacity remains. You can also see how much capacity you use each month by selecting an option from the **Capacity usage in GB** list or by selecting **View all capacity usage**.

> **Note**
>
> The commerce platform has a legacy billing platform and a modern billing platform. Insider Risk Management billing works with the modern billing platform. Purchased capacity applies to the ingestion of forensic evidence each month, starting on the date of purchase and resetting on the first day of every month. Any purchased capacity can be fully used in that month and resets on the first day of the next month. You can use the capacity until the date the license expires. For more information, see New commerce experience for license-based services.

Use reports in Insider Risk Management

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Use reports in Microsoft Purview Insider Risk Management to understand the landscape of your insider risk program. Reports provide deeper insights and summary information for all areas relating to insider risk, including alerts, cases, user activity, and analytics generated from qualifying risk activities across Microsoft services to help identify insights into potential areas of risk.

The following reports are available by navigating to **Insider Risk Management** > **Reports** in the Microsoft Purview portal:

- **Alerts (preview)**: View alert report trends for generated alerts, actions taken on alerts over time, and alerts by policy.
- **Analytics**: View an analytics reports summary of anonymized user activities detected in your organization.
- **Cases (preview)**: View case report trends for created cases, actions taken on cases over time, and case status by policy and region.
- **User activity**: Review recent user activity reports, regardless if the user is included in a policy or alert.
- **Pay-as-you-go**: Review pay-as-you-go usage reports to identify cost-saving opportunities and fine-tune your policy configurations.

Work with reports

To get started and view Insider Risk Management reports, you must be a member of the applicable role or role group. Permission requirements differ for viewing reports for alerts and cases and the permissions required to view reports for analytics. If your organization uses administrative units, access might vary for these reports. For more information, see:

- Permissions for Insider Risk Management
- Permissions for Insider Risk Management and administrative units

Customize charts

For each report area, predefined report filter controls and a date selector help you quickly scope insights to specific criteria or date ranges. Select a filter at the top of the page for each area to quickly scope all the reports in the area to a filter setting. For reporting dates, select a specific month or select *Last 3 months* to view all data for the report area.

You might also want to pick and choose which reports to display by default in each report area. To customize the reports shown in each area, select **Customize view**. On the **Customize view** flyout pane, you can choose which reports to display and which reports to hide in each area.

Chart details

To explore the results in a report, select **View details** for the report. In the details view, you can filter the information and change your view by dates or policies. To export data in a report, select **Export** to download either an image of the report chart or a .csv file with the report values.

Alert reports (preview)

Investigating potentially risky user activities is an important step in minimizing insider risks for your organization. These risks might be activities that generate alerts from Insider Risk Management policies. Alert reports provide insights into alert volumes, progress of managing alerts, common alert sources, and time spent triaging. You can quickly filter all alert reports by *All alerts*, *Confirmed alerts*, and *Dismissed alerts*.

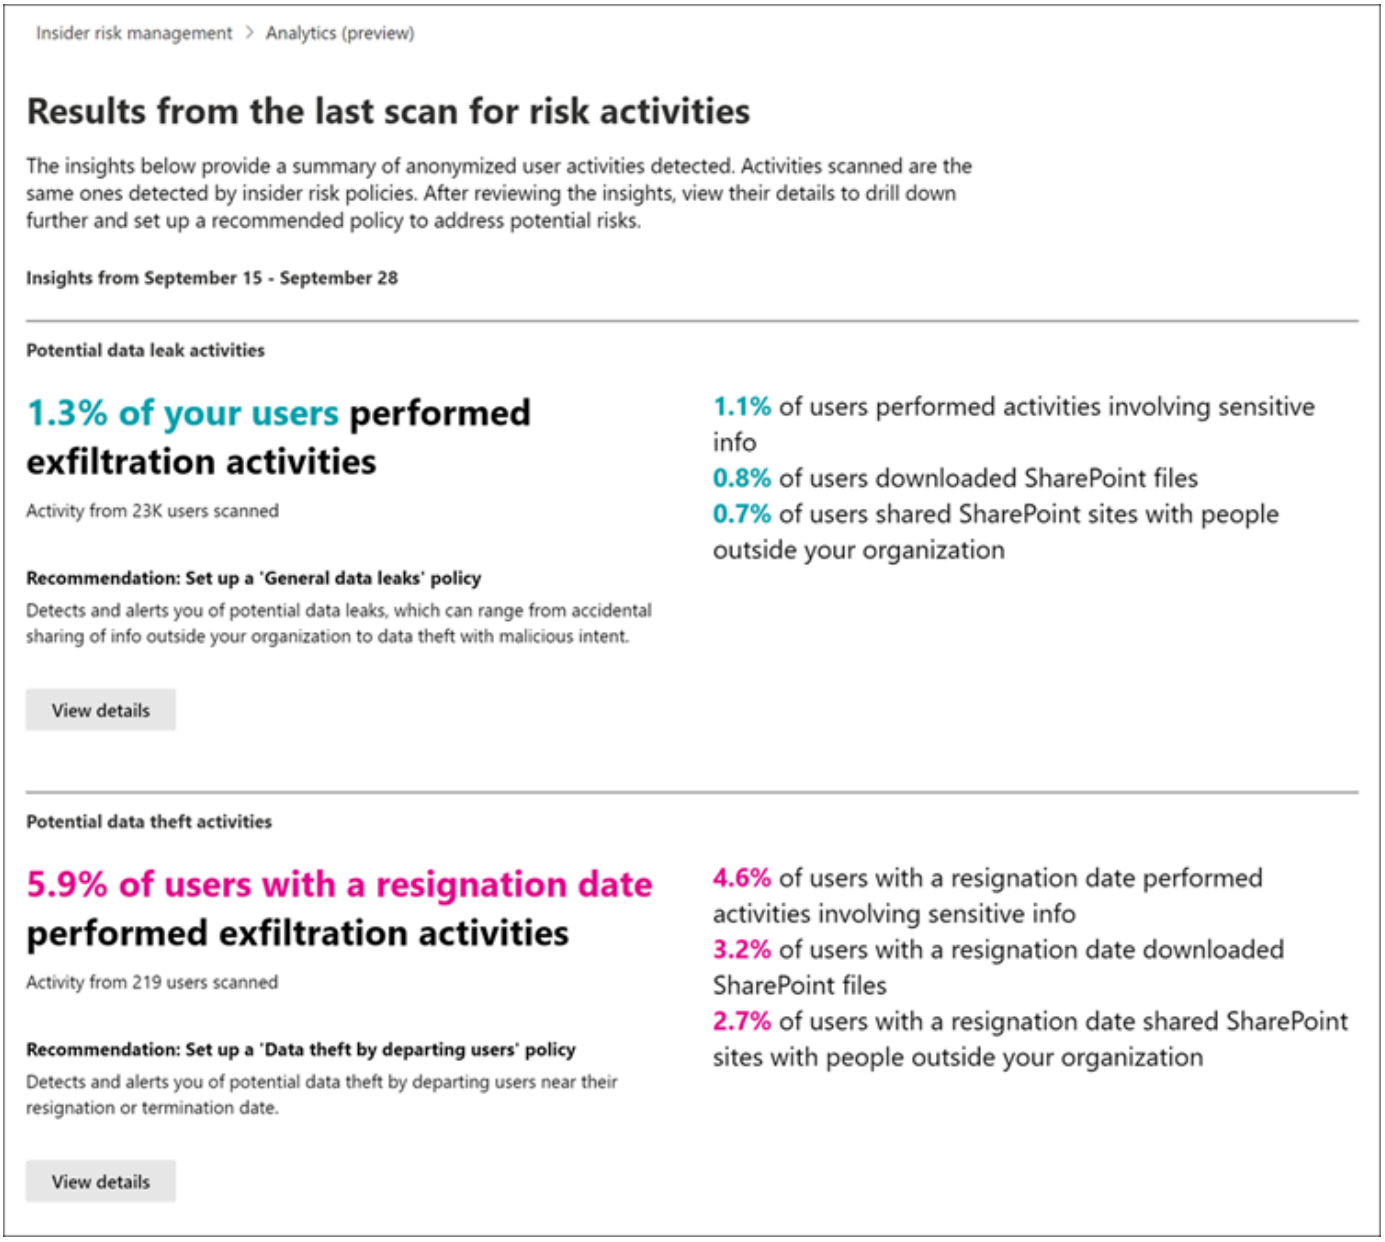
Expand table

Report type	Report	Description
Summary	Alerts generated	Shows the number of low, medium, and high severity alerts generated during the specified date range.
	Alerts acted on	Shows the number of alerts confirmed to a case or dismissed during the specified date range.
	Dismissal reasons	Shows...
Demographics	Top countries/regions with alerts	Shows the number of alerts generated for users based on what country or region they're in. *Not specified* means their country or region isn't specified in Microsoft Entra ID.

Report type	Report	Description
	Alerts generated by department	Shows the number of alerts generated for users based on what department they're in. *Not specified* means their department isn't specified in Microsoft Entra ID.
Insights	Alerts by top triggering event	Shows the number of alerts based on top triggering events detected during the specified date range.
	Alerts by top activity that generated the alert	Shows the number of alerts based on top activities detected during the specified date range.
Productivity	Alert status by assignment	Shows the number of alerts assigned to specific admins, broken down by alert status.
	Average days alerts are in *Needs Review*	Shows the average number of days that alerts remained in a *Needs review* status during the specified date range.

Analytics reports

After the first analytics scan completes for your organization, members of the *Insider Risk Management Admins* role group automatically receive an email notification. They can view the initial insights and recommendations for potentially risky activities by your users. Daily scans continue unless you turn off analytics for your organization. Admins receive email notifications for each of the three in-scope categories for analytics (data leaks, theft, and exfiltration) after the first instance of potentially risky activity in your organization. Admins don't receive email notifications for follow-up risk management activity detection resulting from the daily scans.



> ⓘ **Note**
>
> If you disable and then re-enable the **Analytics** setting, you reset automatic email notifications. Members of the *Insider Risk Management Admins* role group receive email notifications for new scanning insights.

To view potential risks for your organization, go to **Insider Risk Management** > **Reports** > **Analytics**.

> ⓘ **Note**
>
> If the scan for your organization isn't complete, you see a message that the scan is still active.

For completed analyses, you see the potential risks discovered in your organization and insights and recommendations to address these risks. Reports include identified risks and specific insights grouped by area, the total number of users (all types of Microsoft Entra accounts, including user, guest, system, and so on) with identified risks, the percentage of these users with potentially risky activities, and a recommended insider risk policy to help mitigate these risks. The reports include:

- **Data leaks insights**: For all users that might include accidental oversharing of information outside your organization or data leaks by users with malicious intent.
- **Data theft insights**: For departing users or users with deleted Microsoft Entra accounts that might include risky sharing of information outside your organization or data theft by users with malicious intent.
- **Top exfiltration insights**: For all users that might include sharing data outside of your organization.

To display more information for an insight, select **View details** to display the details pane for the insight. The details pane includes the complete insight results, an insider risk policy recommendation, and **Create policy** to quickly help you create the recommended policy. Selecting **Create policy** takes you to the policy workflow and automatically selects the recommended policy template related to the insight. For example, if the analytics insight is for *Data Theft* activity, the *Data Theft* policy template is pre-selected in the policy workflow for you.

Potential data theft activities

The exfiltration activities below might be related to data theft by departing users near their resignation or termination date. After reviewing them, consider setting up the recommended policy to help address potential risks.

What we detected

The following is recent activity based on a scan of 219 users who are leaving your organization.

5.9% of users with a resignation date performed exfiltration activities

4.6% of users with a resignation date performed activities involving sensitive info
3.2% of users with a resignation date downloaded SharePoint files
2.7% of users with a resignation date shared SharePoint sites with people outside your organization
2.3% of users with a resignation date shared SharePoint folders with people outside your organization
2.3% of users with a resignation date emailed people outside your organization
1.8% of users with a resignation date copied content to USB
1.8% of users with a resignation date printed a large number of files
1.4% of users with a resignation date shared SharePoint files with people outside your organization
1.4% of users with a resignation date copied sensitive content to personal cloud
0.9% of users with a resignation date shared files across network

Recommendation

Create a 'Data theft by departing users' policy that detects data theft by users near their resignation or termination date, which can range from accidental sharing of info outside your organization to data theft with malicious intent.

Case reports (preview)

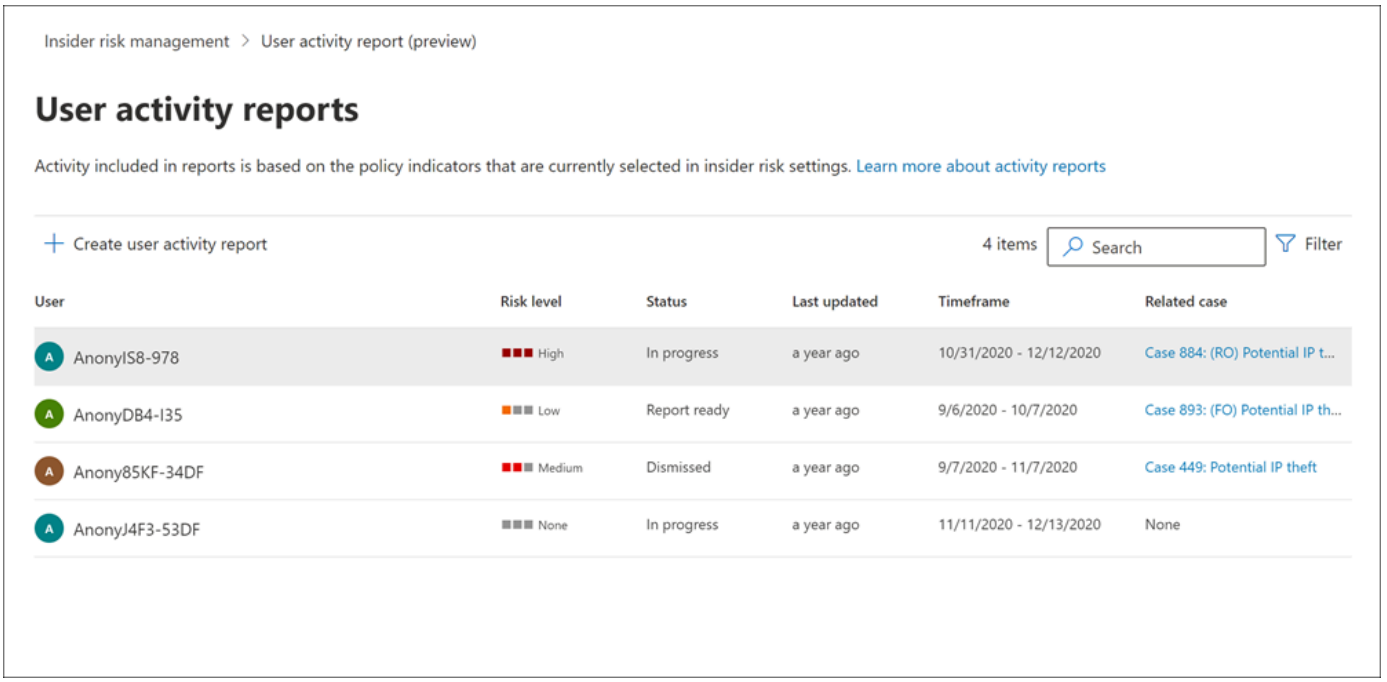
Cases help you investigate and act on issues generated by risk indicators defined in your policies. You manually create cases from alerts when you need to take further action to address a compliance-related issue for a user. Case reports provide trend information to help you track the type of cases, the current status of cases, cases by region or assignment, and more. You can quickly filter all case reports by *All cases*, *Confirmed cases*, and *Benign cases*.

Expand table

Report type	Report	Description
Summary	Cases created	Shows the number of cases created during the specified date range.
	Actioned cases	Shows the number of cases with activity during the specified date range.
Demographics	Top countries/regions with cases	Shows the number of cases created for users based on their country or region. *Not specified* means their country or region isn't specified in Microsoft Entra ID.
	Top departments with cases	Shows the number of cases created for users based on their department. *Not specified* means their country or region isn't specified in Microsoft Entra ID.
Productivity	Case status by assignment	Shows the number of cases assigned to specific admins, broken down by alert status.
	Average days with active status	Shows the average number of days that cases stayed in an *Active* status during the specified date range.

Pay-as-you-go usage reports

Pay-as-you-go usage reports provide transparency and enable more accurate budget planning and policy tuning. The reports let you explore granular breakdowns of billed processing usage across different data source categories and activity indicators over time. View your usage and trends, and understand activity patterns. This information empowers you to identify cost-saving opportunities and fine-tune your policy configurations.



This report is available in the **Reports** page by default. For prerequisites and billing details, see Pay-as-you-go billing model.

User activity reports

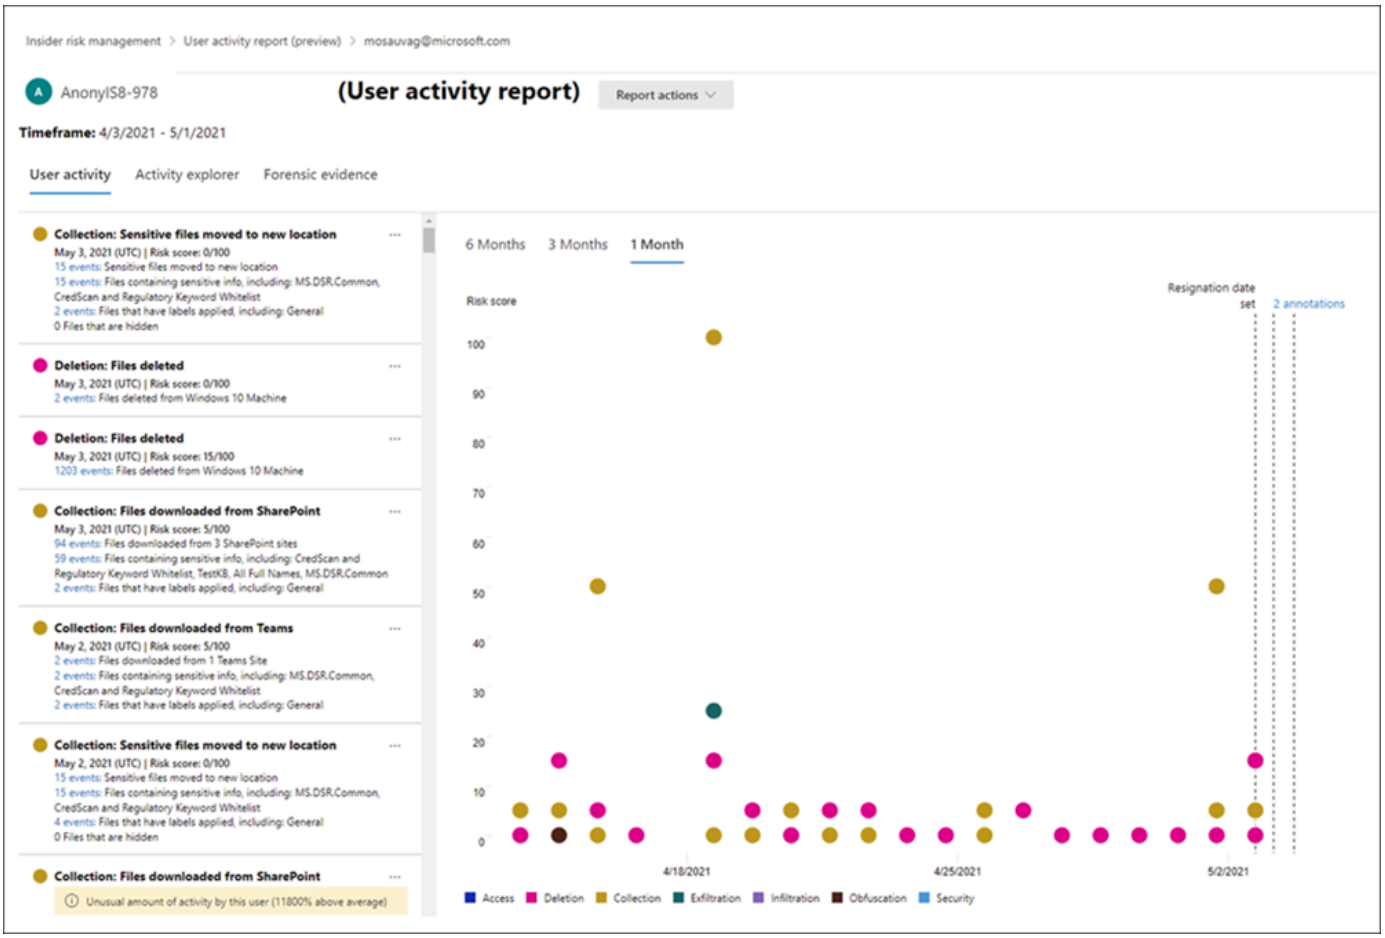
User activity reports let you examine potentially risky activities for specific users during a defined time period without assigning these activities, temporarily or explicitly, to an Insider Risk Management policy. In most Insider Risk Management scenarios, you explicitly define users in policies. These users might have policy alerts (depending on triggering events) and risk scores associated with the activities. But in some scenarios, you might want to examine the activities for users that you don't explicitly define in a policy. These activities might be for users that you receive a tip about the user and potentially risky activities, or users that typically don't need to be assigned to an Insider Risk Management policy.

After you configure indicators on the Insider Risk Management **Settings** page, the solution detects user activity for potentially risky activity associated with the selected indicators. This configuration makes all detected activity for users available for review, regardless if it has a triggering event or if it creates an alert. Reports are created on a per-user basis and can include all activities for a custom 90-day period. The solution doesn't support multiple reports for the same user.

After examining potentially risky activities, investigators can dismiss individual user's activities as benign. They can also share or email a link to the report with other investigators, or choose to assign users (temporarily or explicitly) to an Insider Risk Management policy. To view the **User activity reports** page, you must assign users to the *Insider Risk Management Investigators* role group.

Create a user activity report

To create a user activity report, complete the following steps:



1. Go to **Insider Risk Management** > **Reports** > **User activity**.
2. Select **Create user activity report**.
3. Select a date for the **Start date**.
4. Select a date for the **End date**.
5. In the **Users** field, search for one or more users by name or user principal name.
6. Select **Create report**.

User activity data becomes available for reporting about 48 hours after the activity occurs. For example, to review user activity data for December 1, you need to wait at least 48 hours before creating the report (you can create a report on December 3 at the earliest).

New reports typically take up to 10 hours before they're ready for review. When the report is ready, *Report ready* appears in the **Status** column on the User activity report page.

View a user activity report

Select the user to view the detailed report:

The **User activity report** for the selected user contains the **User activity**, **Activity explorer**, and **Forensic evidence** tabs:

- **User activity**: Use this chart view to investigate potentially risky activities and view potentially related activities that occur in sequences. This tab is structured to enable quick review of a case, including a historical timeline of all activities, activity details, the current risk score for the user in the case, the sequence of risk events, and filtering controls to help with investigative efforts. For more information, see User activity.
- **Activity explorer**: This tab provides risk investigators with a comprehensive analytics tool that provides detailed information about activities. With the Activity explorer, reviewers can quickly review a timeline of detected risky activity and identify and filter all potentially risky activities associated with alerts. For more information, see Activity explorer.
- **Forensic evidence**: This tab allows risk investigators to review visual captures associated with risk activities included in cases from forensic evidence detection.

Learn about and configure Insider Risk Management browser signal detection

08/20/2025

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

In Microsoft Purview Insider Risk Management, you can use browser signal detection with the following templates:

- Data theft by departing users
- Data leaks
- Forensic evidence
- Risky browser usage (preview)

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Browsers and templates

Users often use web browsers to access both sensitive and nonsensitive files within an organization. Insider Risk Management enables your organization to detect and act on browser exfiltration signals for all nonexecutable files viewed in Microsoft Edge and Google Chrome browsers. With these signals, analysts and investigators can quickly act when in-scope policy users perform any of the following risky activities while using these browsers:

- Copying files to personal cloud storage
- Printing files to local or network devices
- Transferring or copying files to a network share

- Copying files to USB devices
- Browsing potentially risky websites

Microsoft Edge detects signals for these events by using built-in browser capabilities and the *Microsoft Compliance Extension* add-on. In Google Chrome, customers use the *Microsoft Compliance Extension* for signal detection.

The following table summarizes identified risk activities and extension support for each browser:

Expand table

Detected activities	Microsoft Edge	Google Chrome
Browsing potentially risky websites	Extension	Extension
Files copied to personal cloud storage	Native	Extension
Files copied to USB devices	Extension	Extension
Files printed to local or network devices	Native	Extension
Files transferred or copied to a network share	Extension	Extension

The following table summarizes activities by template:

Expand table

Detected activities	Data theft by departing users	Data leaks	Risky browser usage
Browsing potentially risky websites	No	No	Yes
Files copied to personal cloud storage	Yes	Yes	No
Files copied to USB devices	Yes	Yes	No
Files printed to local or network devices	Yes	Yes	No
Files transferred or copied to a network share	Yes	Yes	No

Tip

If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and

compliance needs. Start now at the Microsoft Purview trials hub. Learn details about signing up and trial terms.

Forensic evidence

For forensic evidence, you can capture all types of browsing activities; you're not limited to the browsing indicators of the Risky browser usage template. You can specify the desktop apps and websites that you want to include or exclude. To capture browsing activity for forensic evidence, you must install the extensions described in this article, and you must also turn on at least one risky browsing indicator in the insider risk settings.

Common requirements

Before installing the Microsoft Edge add-on or Google Chrome extension, ensure that devices for in-scope policy users meet the following requirements:

- Latest Windows 10 x64 build is recommended, minimum Windows 10 x64 build 1809 for signal detection support. Browser signal detection isn't currently supported on non-Windows devices.
- Current Microsoft 365 subscription with Insider Risk Management support.
- Devices must be onboarded to the Microsoft Purview portal.

For specific browser configuration requirements, see the Microsoft Edge and Google Chrome sections later in this article.

Additional requirements

If you use policies based on the *Risky browser usage* template, select at least one *Browsing indicator* in **Insider Risk Management** > **Settings** > **Policy indicators**.

Configure browser signal detection for Microsoft Edge

Microsoft Edge browser requirements

- Meet the common requirements
- Latest Microsoft Edge x64, version 91.0.864.41 or higher
- Latest *Microsoft Compliance Extension* add-on, version 1.0.0.44 or higher

- Edge.exe isn't configured as an unallowed browser

Option 1: Basic setup (recommended for testing with Microsoft Edge)

Use this option to configure a single-machine self-host for each device in your organization when testing browser signal detection.

1. Go to Microsoft Compliance Extension.
2. Install the extension.

Option 2: Intune setup for Microsoft Edge

Use this option to configure the extension and requirements for your organization by using Intune.

1. Sign in to the Microsoft Intune admin center.
2. Go to **Devices** > **Configuration Profiles**.
3. Select **Create Profile**.
4. Select **Windows 10 and later** as the platform.
5. Select **Settings catalog** as the profile type.
6. Select **Create**.
7. Enter a name and optional description on the **Basics** tab, then select **Next**.
8. Select **Add settings** on the **Configuration settings** tab.
9. Select **Administrative Templates** > **Microsoft Edge** > **Extensions**.
10. Select **Control which extensions are installed silently**.
11. Change the toggle to **Enabled**.
12. Enter the following value for the extensions and app IDs and update URL: `lcmcgbabdcbngcbcfabdncmoppkajglo`.
13. Select **Next**.
14. Add or edit scope tags on the **Scope tags** tab as needed, then select **Next**.
15. Add the required deployment users, devices, and groups on the **Assignments** tab, then select **Next**.
16. Select **Create**.

Option 3: Group Policy setup for Microsoft Edge

Use this option to configure the extension and requirements organization-wide by using Group Policy.

Step 1: Import the latest Microsoft Edge Administrative Template (.admx) file.

Devices must be manageable by using Group Policies. Import all Microsoft Edge Administrative Templates into the Group Policy Central Store. For more information, see How to create and manage the Central Store for Group Policy Administrative Templates in Windows.

Step 2: Add the *Microsoft Compliance Extension* add-on to the *Force Install* list.

1. In the **Group Policy Management Editor**, go to your Organizational Unit (OU).
2. Expand the following path **Computer/User configuration** > **Policies** > **Administrative templates** > **Classic administrative templates** > **Microsoft Edge** > **Extensions**. This path might vary depending on the configuration of your organization.
3. Select **Configure which extensions are installed silently.**
4. Right-click and select **Edit**.
5. Check **Enabled**.
6. Select **Show**.
7. For **Value**, add the following entry:
   lcmcgbabdcbngcbcfabdncmoppkajglo;https://edge.microsoft.com/extensionwebstorebase/v1/crx
8. Select **OK**, then select **Apply**.

Configure browser signal detection for Google Chrome

Insider Risk Management browser signal detection support for Google Chrome is enabled through the *Microsoft Compliance Extension*. This extension also supports Endpoint DLP on Chrome. For more information about Endpoint DLP support, see Get started with the Microsoft Compliance Extension (preview).

Google Chrome browser requirements

- Meet common requirements
- Latest version of Google Chrome x64
- Latest *Microsoft Compliance Extension* version (2.0.0.183 or higher)
- Chrome.exe isn't configured as an unallowed browser

Option 1: Basic setup (recommended for testing with Chrome)

Use this option to configure a single-machine self-host for each device in your organization when testing browser signal detection.

1. Go to Microsoft Compliance Extension.
2. Install the extension.

Option 2: Intune setup for Chrome

Use this option to configure the extension and requirements for your organization by using Intune.

1. Sign in to the Microsoft Intune admin center.
2. Go to **Devices** > **Configuration Profiles**.
3. Select **Create Profile**.
4. Select **Windows 10 and later** as the platform.
5. Select **Settings catalog** as the profile type.
6. Select **Custom** as the template name.
7. Select **Create**.
8. Enter a name and optional description on the **Basics** tab, then select **Next**.
9. Select **Add settings** on the **Configuration settings** tab.
10. Select **Administrative Templates** > **Google** > **Google Chrome** > **Extensions**.
11. Select **Configure the list of force-installed apps and extensions**.
12. Change the toggle to **Enabled**.
13. Enter the following value for the extensions and app IDs and update URL:
    `echcggldkblhodogklpincgchnpgcdco;https://clients2.google.com/service/update2/crx`
14. Select **Next**.
15. Add or edit scope tags on the **Scope tags** tab as needed, then select **Next**.
16. Add the required deployment users, devices, and groups on the **Assignments** tab, then select **Next**.
17. Select **Create**.

Option 3: Group Policy setup for Chrome

Use this option to configure the extension and requirements organization-wide by using Group Policy.

Step 1: Import the Chrome Administrative Template file

Your devices must be manageable by using Group Policy. Import all Chrome Administrative Templates into the Group Policy Central Store. For more information, see How to create and manage the Central Store for Group Policy Administrative Templates in Windows.

Step 2: Add the Chrome extension to the Force Install list

1. In the **Group Policy Management Editor**, go to your organizational unit (OU).
2. Expand the following path **Computer/User configuration** > **Policies** > **Administrative templates** > **Classic administrative templates** > **Google** > **Google Chrome** > **Extensions**.

This path might vary depending on the configuration for your organization.

3. Select **Configure the list of force installed extensions**.
4. Right-click and select **Edit**.
5. Select **Enabled**.
6. Select **Show**.
7. For **Value**, add the following entry:
   echcggldkblhodogklpincgchnpgcdco;https://clients2.google.com/service/update2/crx
8. Select **OK**, then select **Apply**.

Test and verify Insider Risk Management browser signal detections

1. Create an Insider Risk Management policy with device indicators enabled.

2. To test signal detection for files copied to personal cloud storage, complete the following steps from a supported Windows device:

   - Open a file sharing website (Microsoft OneDrive, Google Drive, etc.) with the browser type that you configured for signal detection.
   - With the browser, upload a nonexecutable file to the website.

3. To test signal detection for files printed to local or network devices, files transferred or copied to a network share, and files copied to USB devices, complete the following steps from a supported Windows device:

   - Open a nonexecutable file directly in the browser. You must open the file directly through File Explorer or open it in a new browser tab for viewing rather than a webpage.
   - Print the file.
   - Save the file to a USB device.
   - Save the file to a network drive.

4. After you create your first Insider Risk Management policy, you start receiving alerts from activity indicators after about 24 hours. Check the Alerts dashboard for Insider Risk Management alerts for the tested activities.

Manage the workflow with the Insider Risk Management users dashboard

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

The **Users dashboard** is an important tool in the Insider Risk Management workflow. It helps investigators and analysts have a more complete understanding of risk activities. This dashboard offers views and management features to meet administrative needs between creating Insider Risk Management policies and managing Insider Risk Management cases.

After users are added to Insider Risk Management policies, background processes automatically evaluate user activities for triggering indicators. After the process identifies triggering indicators, it assigns risk scores to user activities. Some of these activities result in an insider risk alert, but some activities don't meet a minimum risk score level and an insider risk alert isn't created. The **Users dashboard** allows you to view users with these types of indicators and risk scores, as well as users that have active insider risk alerts.

Learn more about how the Users dashboard displays users in the following scenarios:

- Users with active insider risk policy alerts
- Users with triggering events
- Users identified as potential high impact users or in priority user groups
- Users added temporarily to policies

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Users with active insider risk policy alerts

The **Users dashboard** automatically displays all users with active insider risk policy alerts. These users with alerts have both a triggering indicator and an activity risk score that meets the requirements for creating an insider risk alert. You can view activities for these users by selecting the user in the **Users dashboard** and navigating to the **User activity** tab.

Users with triggering events

The **Users dashboard** automatically displays all users with triggering events, but that don't have an activity risk score that would create an insider risk alert. For example, a user with a reported resignation date is displayed because this activity is a triggering event but isn't an activity that has a risk score. You can view activities for these users by selecting the user in the **Users dashboard** and navigating to the **User activity** tab.

Users added temporarily to policies

The **Users dashboard** shows users you add to Insider Risk Management policies after an unusual event outside of the Insider Risk Management workflow. Temporarily adding users (from the Policies dashboard) is also a way to start scoring user activity for an Insider Risk Management policy for testing the policy, even if you don't configure a required connector.

When you manually add a user to a policy, the solution scores user activities for the previous 90 days and adds them to the **User activity** timeline. For example, you have a user not currently being assigned risk scores for an insider risk policy and the user has data leak activities reported to the legal department in your organization. The legal department recommends that you configure new short-term detection requirements for the user. You can temporarily assign the user to your *Data leaks* policy for a designated length of time (activation window). All users added temporarily are displayed in the **Users dashboard** because triggering event requirements are waived.

> **Note**
>
> It might take several hours for new manually added users to appear in the **Users dashboard**. Activities for the previous 90 days for these users might take up to 24 hours to display. To view activities for manually added users, select the user on the **Users dashboard** and open the **User activity** tab on the details pane.

The user is automatically removed from the **Users dashboard** and scoring stops when the time defined in the **Activation window** expires if:

- the user doesn't have any additional triggering events or insider risk policy alerts, and
- the manually defined **Activation window** duration is longer than the global policy **Activation window** duration.

The **Activation window** setting with the longest duration always overrides the **Activation window** setting with a shorter duration. For example, you configure the **Activation window** on the global **Policy timeframes** tab in the Insider Risk Management global settings for 15 days, which automatically applies to all your insider risk policies.

You temporarily add a user to your *Data leaks* insider risk policy and define 30 days as the **Activation window** for this user. The global **Activation window** setting of 15 days is overridden by defining the **Activation window** setting of 30 days for the temporarily added user. The temporarily added user remains in the **Users dashboard** and is in-scope for the policy for 30 days.

In the opposite scenario where the global **Activation window** setting is longer than the **Activation window** setting defined for a temporarily added user, the global **Activation window** setting overrides the **Activation window** setting for the temporarily added user. The temporarily added user remains in the **Users dashboard** and is in-scope for the policy for the number of days defined in the global **Activation window** settings.

View user information on the Users dashboard

Each user displayed in the **Users dashboard** shows the following information:

- **Users**: Username for a user. This field is anonymized if the global anonymization setting for Insider Risk Management is enabled.
- **Alert severity level**: Current calculated risk level of the user. The system calculates this score every 24 hours and uses the alert risk scores from all active alerts associated with the user. For users with only triggering indicators, the alert severity level is zero.
- **Active alerts**: Number of active alerts for all policies.
- **Confirmed violations**: Number of cases resolved as *confirmed policy violation* for the user.
- **Case**: Current active case for the user.

To quickly locate a specific user, use **Search** at the top right of the Users dashboard. When searching for users, you must use the user principal name (UPN). For example, when searching for

a user named 'Tiara Hidayah' that has a UPN of 'thidayah' in your organization, enter 'thidayah' or some part of the UPN in **Search**.

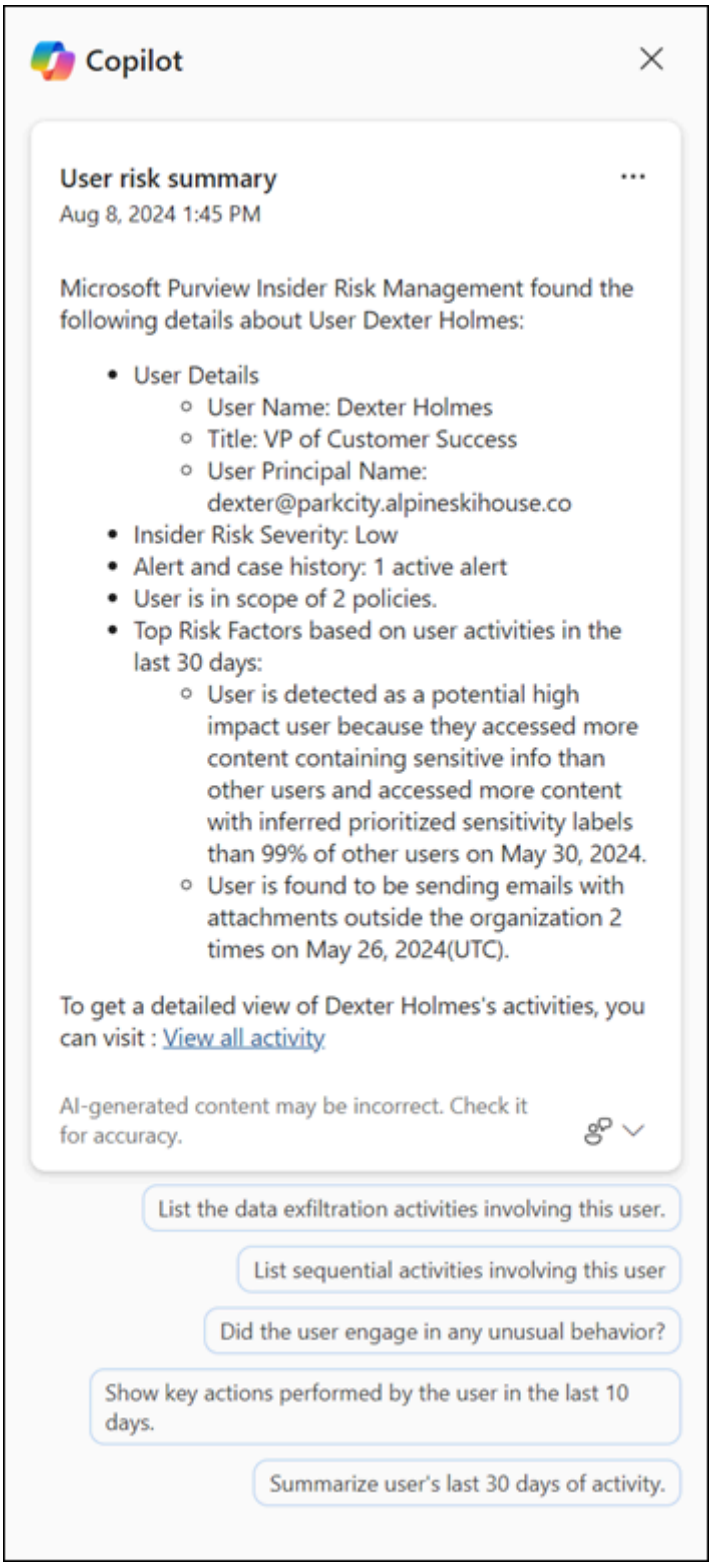
> **Note**
>
> The number of users displayed on the **Users dashboard** might be limited in some instances, depending on the volume of active alerts and matching policies. The **Users dashboard** displays users with active alerts as the system generates the alerts. In rare cases, the maximum number of displayed users is reached. If the maximum number of displayed users is reached, the **Users dashboard** adds users with active alerts who aren't displayed as existing user alerts are triaged.

View user details

To view more details about risk activity for a user, open the user details pane by double-clicking a user in the **Users dashboard**. On the details pane, you can view the following information:

- **User profile** tab
  - **Name and title**: Name and position title for the user from Microsoft Entra ID. These user fields are anonymized or empty if you enable the global anonymization setting for Insider Risk Management.
  - **User details**: Shows whether the user is a potential high impact user or if the user is in priority user groups.
  - **Alert and activity summary**: Shows active user alerts and open cases.
  - **User email**: Email address for the user.
  - **Alias**: Network alias for the user.
  - **Organization or department**: Organization or department for the user.
  - **In scope**: Shows in-scope assignment of the user to policies.

The following additional user profile signals are available in the unified alert experience (preview). To access, select an alert on the **Alerts (preview)** tab, scroll down to **User details**, and select **View user details**:



- **Office location**: The user's office location from their Entra profile.
- **Employee type**: The user's employee type from their Entra profile.
- **Department**: The user's department from their Entra profile.
- **Last working date**: The user's last scheduled date of work, if available.
- **Past alert and case history**: A summary of the user's previous alerts and cases across Insider Risk Management.
- **Priority user group status**: Shows whether the user belongs to any priority user groups.
- **Policy inclusion**: Lists the policies in which the user is currently in scope.

> ⓘ **Note**
>
> When pseudo-anonymization is enabled, the expanded user profile details aren't visible.

- **User activity** tab
  - **History of recent user activity**: Shows both triggering indicators and insider risk indicators for risk activities up to the last 90 days. All risk activities pertinent to insider risk indicators are also scored, though the activities might or might not have generated an insider risk alert. Triggering indicator examples might be a resignation date or the last scheduled date of work for the user. Insider risk indicators are activities determined to have an element of risk, which might potentially lead to a security incident, and are defined in policies that the user is included in. Event and risk activities are listed with the most recent item listed first.

Use Copilot to summarize user activities (preview)

Select **Summarize with Copilot** on the user details pane to quickly summarize the activities for users that might need further investigation. When you summarize user risk activities with Microsoft Copilot in Microsoft Purview, a **Copilot** pane appears on the right side of the screen with a user summary.

The user summary includes essential details such as the user's name, title, user principal name, alert and case history, and top risk factors. The top risk factors provide crucial insights into the user roles, permissions, involvement in exfiltration activities, sequential patterns, or any unusual behavior. This view helps you identify users who might pose the highest insider risk to your organization.

Suggested prompts are automatically listed to help further refine your summary and to help provide additional insights to the activities associated with the user. Choose from the following suggested prompts:

- *List all the data exfiltration activities involving this user.*
- *List all the sequential activities involving this user.*
- *Did the user engage in any unusual behavior?*
- *Show key actions performed by the user in the last 10 days.*
- *Summarize user's last 30 days of activity.*

> **Tip**
>
> You can also use the standalone version of Microsoft Security Copilot to investigate Insider Risk Management, Microsoft Purview data loss prevention (DLP), and Microsoft Defender XDR alerts.

Remove users from in-scope assignment to policies

You might need to stop assigning risk scores to a user in Insider Risk Management policies. Use **Stop scoring activity for users** on the **Users dashboard** to stop assigning risk scores for a user from all Insider Risk Management policies that they're currently in scope for. Stopping scoring activity doesn't remove the user from the overall policy assignment (when you add users or groups to a policy configuration), but simply removes the user from active processing by policies after current triggering events. If the user has another triggering event in the future, risk scores from policies automatically begin to be assigned to the user again. Any existing alerts or cases for this user don't remove.

Remove a user from in-scope status in all Insider Risk Management policies

To remove a user from in-scope status in all Insider Risk Management policies, complete the following steps:

1. Sign in to the Microsoft Purview portal with an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Users** in the left navigation.
4. On the **Users dashboard**, select the users you want to stop scoring activity for.
5. Select **Stop scoring activity for users**.

> **Note**

Removing a user from in-scope status might take several minutes. When the process completes, the user doesn't appear on the **Users dashboard**. If the removed user has active alerts or cases, the user remains on the **Users dashboard** and the user details show that they are no longer in-scope for a policy.

Run automated tasks with Power Automate flows for a user

Using recommended Power Automate flows, risk investigators and analysts can quickly take action to notify users when they're added to an insider risk policy.

To run, manage, and create Power Automate flows for Insider Risk Management users:

1. Select **Automate** on the user action toolbar.
2. Choose the Power Automate flow to run, then select **Run flow**.
3. After the flow completes, select **Done**.

For more information about Power Automate flows for Insider Risk Management, see Getting started with Insider Risk Management settings.

Create Insider Risk Management notice templates

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

Insider Risk Management notice templates enable you to automatically send email messages to users when you create a case for risk activities that generate a policy match and confirmed alert. For most alerts that generate cases, user actions result from mistakes or inadvertent actions without ill intent. Use notices as simple reminders for users to be more careful, to provide links to information for refresher training, or to corporate policy resources. Notices can be an important part of your internal compliance training program and can help create a documented audit trail for users with recurring risk activities.

Create notice templates if you want to send users an email reminder notice for policy matches as part of the case resolution process. You can only send notices to the user email address associated with the specific case being reviewed. When selecting a notice template to apply to a policy match, you can choose to accept the field values defined in the template or overwrite the fields as needed.

> **Tip**
>
> Get started with Microsoft Security Copilot to explore new ways to work smarter and faster using the power of AI. Learn more about Microsoft Security Copilot in Microsoft Purview.

Notice templates dashboard

The **Notices templates dashboard** displays a list of configured notice templates and lets you create new notice templates. The portal lists the notice templates in reverse date order with the most recent notice template listed first.

HTML for notices

If you want to create more than a simple text-based email message for notifications, you can create a more detailed message by using HTML in the message body field of a notice template. The following example provides the message body format for a basic HTML-based email notification template:

HTML

```
<!DOCTYPE html>
<html>
<body>
<h2>Action Required: Contoso User Code of Conduct Policy Training</h2>
<p>A recent activity you've performed has generated a risk alert prohibited by the
Contoso User <a href='https://www.contoso.com'>Code of Conduct Policy</a>.</p>
<p>You are required to attend the Contoso User Code of Conduct <a
href='https://www.contoso.com'>training</a> within the next 14 days. Please contact
<a href='mailto:hr@contoso.com'>Human Resources</a> with any questions about this
training request.</p>
<p>Thank you,</p>
<p><em>Human Resources</em></p>
</body>
</html>
```

> **Note**
>
> In Insider Risk Management notice templates, the HTML href attribute implementation currently supports only single quotation marks instead of double quotation marks for URL references.

Create a new notice template

To create a new Microsoft Purview Insider Risk Management notice template, use the notice creation tool in the **Insider Risk Management** solution in the Microsoft Purview portal.

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Notification templates** in the left navigation.
4. Select **Create notification template** to open the notice creation tool.
5. On the **New email notification template** page, complete the following fields:

    - **Template name**: Enter a friendly name for the notice. This name appears on the list of notices on the notice dashboard and in the notice selection list when sending notices from a case.
    - **Send from**: Enter the sender email address for the notice. This address appears in the **From:** field in all notices sent to users unless changed when sending a notice from a case.
    - **Subject**: Enter the information that appears in the subject line of the message. You can enter text values.
    - **Message body**: Enter the information that appears in the message body. You can enter text or HTML values.

6. Select **Create** to create and save the notice template.

Update a notice template

To update an existing notice template, complete the following steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Notification templates** in the left navigation.
4. In the **Email notification templates** list, select the notification template that you want to manage.
5. On the notice details page, select **Edit**.
6. On the **Edit** page, edit the following fields:

    - **Template name**: Enter a new friendly name for the notice. This name appears on the list of notices on the notice dashboard and in the notice selection list when sending notices from a case.
    - **Send from**: Update the sender email address for the notice. This address appears in the **From:** field in all notices sent to users unless changed when sending a notice from a case.

- **Subject**: Update the information that appears in the subject line of the message. You can enter text characters.
- **Message body**: Update the information that appears in the message body. You can enter text characters or HTML values.

7. Select **Save** to update and save the notice.

Delete a notice template

To delete a notice template that you no longer need, complete the following steps:

1. Sign in to the Microsoft Purview portal with credentials for an admin account in your Microsoft 365 organization.
2. Go to the **Insider Risk Management** solution.
3. Select **Notification templates** in the left navigation.
4. In the **Email notification templates** list, select the notification template that you want to delete.
5. Select the **Delete** icon on the toolbar.
6. Select **Yes**.

Limits in Insider Risk Management

08/20/2025

> **Important**
>
> Microsoft Purview Insider Risk Management correlates various signals to identify potential malicious or inadvertent insider risks, such as IP theft, data leakage, and security violations. Insider Risk Management enables customers to create policies to manage security and compliance. Built with privacy by design, users are pseudonymized by default, and role-based access controls and audit logs are in place to help ensure user-level privacy.

This article describes the limits in Microsoft Purview Insider Risk Management.

Global settings

Expand table

Item	Limit
Lookback period limits (Exchange Online).	10 days
Lookback period limits for all other signals.	90 days
Maximum number of custom indicators.	10
Maximum number of fields per custom indicator.	20
Maximum number of items in a detection group	200
Maximum number of items in each global exclusion list (Domains, SharePoint sites, File paths, Keywords, and File types).	500 for each list
Maximum number of users that you can add to a priority user group.	10,000
Maximum number of variants per indicator.	3

Triggers (per UTC calendar day)

Expand table

Item	Limit
Custom indicators	15,000
All other triggers	5,000
All signals collected through the HR connector	15,000
Maximum trigger volume for an organization	50,000
User account deleted from Microsoft Entra ID	15,000

> **Note**
>
> Limitations apply to each individual trigger type.

Maximum number of users in scope for a policy template

Expand table

Template name	Limit
Data leaks by priority users	1,000
Data leaks by risky users	7,500
Data leaks	15,000
Data theft by departing users	20,000
Forensic evidence	Unlimited
Patient data misuse (preview)	5,000
Risky AI usage	10,000
Risky browser usage (preview)	7,000
Security policy violations by departing users	15,000
Security policy violations by priority users	1,000
Security policy violations by risky users	7,500
Security policy violations	1,000

> **Note**
>
> You can add any number of users to a policy. The limit applies to users *in scope* of a policy template (users brought in scope after a triggering event).

Other policy limits

Expand table

Item	Limit
Maximum number of policies that you can create per template type.	100
Maximum number of priority file extensions.	50
Maximum number of priority sensitive info types.	50
Maximum number of priority sensitivity labels.	50
Maximum number of priority sites.	50
Maximum number of priority trainable classifiers.	5

> **Note**
>
> The **Users in scope** column on the **Policies** tab shows the number of in-scope users for a policy.

Adaptive protection

Expand table

Item	Limit
Maximum number of users that you can include in a Data Loss Prevention (DLP) policy for each risk level.	10,000

Manual user scoring

Expand table

Item	Limit
Maximum number of users that you can score manually.	4,000

Cases

Expand table

Item	Limit
Maximum number of active cases.	100

Exporting

Expand table

Item	Limit
Maximum number of alerts that you can export from the **Alerts** page.	1,000
Maximum number of logs that you can export to a CSV file from Activity explorer.	100,000
Maximum number of users that you can export from the **Users** page.	1,000

Retention limits for alerts, cases, and associated artifacts

As Insider Risk Management alerts age, their value to minimize potentially risky activity diminishes for most organizations. Conversely, active cases and associated artifacts (alerts, insights, activities) are always valuable to organizations and shouldn't have an automatic expiration date. This value includes all future alerts and artifacts in an active status for any user associated with an active case.

To help minimize the number of older items that provide limited current value, the following retention limits apply for Insider Risk Management alerts, cases, and user reports:

Expand table

Item	Retention period
Active cases (and associated artifacts)	Indefinite retention, never expire.

Item	Retention period
Alerts with Needs review or Dismissed status	120 days from alert creation, then automatically deleted.
Resolved cases (and associated artifacts)	120 days from case resolution, then automatically deleted.
User activities reports	120 days from report creation, then automatically deleted.

Connectors

Expand table

Item	Limit
Maximum number of records in the JSON file that the API processes	50,000

Learn about Information Barriers

Microsoft Purview Information Barriers (IB) is a compliance solution that restricts two-way communication and collaboration between groups and users in Microsoft Teams, SharePoint, and OneDrive. Often used in highly regulated industries, IB helps avoid conflicts of interest and safeguards internal information between users and organizational areas.

When you create IB policies, users who can't communicate or share files with other specific users can't find, select, chat, or call those users. IB policies automatically put checks in place to detect and prevent unauthorized communication and collaboration among defined groups and users. IB policies are independent from compliance boundaries for eDiscovery investigations that control user content locations that eDiscovery managers can search.

IB policies can allow or prevent communication and collaboration between groups and users for the following example scenarios:

- Users in the *Day Trader* group can't communicate or share files with the *Marketing Team*.
- Instructors in one school can't communicate or share files with students in another school in the same school district.
- Finance personnel working on confidential company information can't communicate or share files with certain groups within their organization.
- An internal team with trade secret material can't call or chat online with users in certain groups within their organization.
- A research team can only call or chat online with a product development team.
- A SharePoint site for *Day Trader* group can't be shared or accessed by anyone outside of the *Day Trader* group.
- A lawyer's data obtained from one client can't be accessed by a lawyer at the same firm who represents a different client.
- Government information access and control are limited across departments and groups.
- A group of people in a company can only chat with a client or a specific customer via guest access during a customer engagement.

> **Important**

Information Barriers **only supports** two-way communication and collaboration restrictions. For example, a scenario where Marketing can communicate and collaborate with Day Traders, but Day Traders can't communicate and collaborate with Marketing **isn't supported**.

> **Important**
>
> Information barrier (IB) policies can't restrict communication and collaboration between groups and users in email messages including Exchange Online. If your organization needs to define and control email communications, consider using Exchange mail flow rules.

Information Barriers and Microsoft Teams

In Microsoft Teams, IB policies determine and prevent the following kinds of unauthorized communication and collaboration:

- Searching for a user
- Adding a member to a team
- Starting a chat session with someone
- Starting a group chat
- Inviting someone to join a meeting
- Sharing a screen
- Placing a call
- Sharing a file with another user
- Accessing a file through a sharing link

If the users conducting these activities in Microsoft Teams are included in an IB policy to prevent the activity, they can't proceed. In addition, everyone included in an IB policy can be potentially blocked from communicating with other users in Microsoft Teams. When users affected by IB policies are part of the same team or group chat, they might be removed from those chat sessions and further communication with the group might not be allowed.

For more information, see Information Barriers in Microsoft Teams.

Information Barriers and SharePoint and OneDrive

In SharePoint and OneDrive, IB policies detect and prevent the following kinds of unauthorized collaboration:

- Adding a member to a site
- Accessing site or content by a user
- Sharing site or content with another user
- Searching a site

For more information, see Information Barriers in SharePoint and Information Barriers in OneDrive.

Information Barriers and Microsoft Planner

As a work management tool, Microsoft Planner enables users to collaborate on plans and tasks. If your compliance admin configures IB policies to restrict communication and collaboration between user segments, Microsoft Planner supports these restrictions.

IB policies allow administrators to enable or disable search restrictions in the people picker. By using IB support in Planner, when a user searches for others in the people picker to share a plan or to assign a task, they don't see users from segments they're restricted from communicating with. This restriction prevents users from one segment from sharing plans or assigning tasks to users in another segment.

IB support in Microsoft Planner is available only for basic plans in the following applications:

- Planner Web
- Planner in Teams web
- Planner in Teams desktop
- Planner in Teams mobile app

Policy behavior

When IB policy administrators create a new policy or modify an existing policy, users can still access existing plans shared with them or already assigned tasks. For any subsequent plan sharing or task assignment, an IB policy check is triggered and collaboration is permitted or restricted as defined by the policy.

Information Barriers and Exchange Online

Information barrier (IB) policies can't restrict communication and collaboration between groups and users in email messages. If your organization needs to define and control email communications, consider using Exchange mail flow rules. **Enabling Information Barriers in**

environments without configured ABPs can result in the loss of Address List visibility between all users.

The following table summarizes the key differences between IB modes for Exchange Online Address Book Policies (ABPs):

Expand table

Feature	Single and multi-segment modes	Legacy mode
ABP management	Automatic; no reliance on existing ABPs	Automatic; existing ABPs must be removed first
ABP for unsegmented users	System creates ABP with empty address lists	Not applicable
Custom ABP changes	Allowed; keep consistent with IB segments	Not supported; IB controls all ABPs
Hierarchical address book	Available for users not in an IB segment	Available for users not in an IB segment
Key prerequisite	None for ABPs	Remove all existing ABPs before enabling IB

Information Barriers and Exchange for single and multi-segment modes

If your organization uses *single* or multi-segment mode, Information Barriers no longer relies on Exchange Online Address Book Policies (ABPs). Information barrier (IB) policies can't restrict communication in email messages. If your organization needs to define and control email communications, consider using Exchange mail flow rules.

Enabling Information Barriers doesn't affect organizations that use ABPs. If users don't have an ABP defined with associated IB segments and policies, the system **automatically creates an ABP with empty address lists for these users**. You can change these ABPs as needed, they are not automatically adjusted based on your IB Segmentation. Keep your ABPs consistent with the segments you configure in Information Barriers to avoid losing proper Address List visibility. Avoid user visibility differences between your existing ABPs and your new Information Barriers configuration.

Information Barriers and Exchange for legacy mode

If your organization uses *legacy* mode, IB policies rely on Exchange Online Address Book Policies (ABPs). ABPs let organizations virtually assign users into specific groups to provide customized views of the organization's global address list (GAL). When you create IB policies, the system automatically creates ABPs for the policies. As you add IB policies in your organization, the structure and behavior of your GAL changes to comply with IB policies.

Before you define and apply IB policies, remove all existing Exchange address book policies in your organization. IB policies rely on address book policies, and existing ABPs aren't compatible with the ABPs that IB creates. To remove your existing address book policies, see Remove an address book policy in Exchange Online. When you enable IB policies and enable hierarchical address book, all users not included in an IB segment see the hierarchical address book in Exchange Online.

Ready to get started?

- Get started with Information Barriers: Define segments and create your first IB policies.
- Information Barriers attributes: Review the Microsoft Entra attributes available for defining user segments.
- Use multi-segment support in Information Barriers: Assign users to multiple segments for complex organizational scenarios.

Get started with Information Barriers

This article describes how to configure Information Barriers (IB) policies in your organization. Several steps are involved, so review the entire process before you begin configuring IB policies.

Use the Microsoft Purview portal or Security & Compliance PowerShell to configure IB in your organization. For organizations configuring IB for the first time, use the **Information Barriers** solution in the Microsoft Purview portal. If you're managing an existing IB configuration and you're comfortable using PowerShell, you can still use that option.

For more information about IB scenarios and features, see Learn about Information Barriers.

> **Tip**
>
> To help you prepare your plan, this article includes an **example scenario**.

Required subscriptions and permissions

Before you get started with IB, confirm your Microsoft 365 subscription and any add-ons. To access and use IB, your organization must have supporting subscriptions or add-ons. For more information, see the subscription requirements for Information Barriers.

To manage IB policies, you must be assigned one of the following roles:

- Microsoft 365 global administrator
- Office 365 global administrator
- Compliance administrator
- IB Compliance Management

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview **roles and permissions**.

Configuration concepts

When you configure IB, you work with several objects and concepts.

- **User account attributes**: Microsoft Entra ID (or Exchange Online) defines these attributes. These attributes can include department, job title, location, team name, and other job profile details. You assign users or groups to segments by using these attributes.
- **Segments**: You define these sets of groups or users in the Microsoft Purview portal or by using PowerShell. They use selected group or user account attributes.

  Your organization can have up to 5,000 segments, and users can be assigned to a maximum of 10 segments. See the list of IB supported attributes for details.

  > **ⓘ Important**
  >
  > Support for 5,000 segments and assigning users to multiple segments is only available when your organization isn't in *Legacy* mode. Assigning users to multiple segments requires extra steps to change the Information Barriers mode for your organization. For more information, see **Use multi-segment support in Information Barriers**.
  >
  > For organizations in *Legacy* mode, the maximum number of segments supported is 250, and users are restricted to being assigned to only one segment. Organizations in *Legacy* mode are eligible to upgrade to the newest version of Information Barriers in the future. For more information, see the **Information Barriers roadmap**.

- **IB policies**: These policies determine communication limits or restrictions. When you define IB policies, you choose from two kinds of policies:
  - *Block* policies prevent one segment from communicating with another segment.
  - *Allow* policies allow one segment to communicate with only certain other segments.

    > **ⓘ Note**
    >
    > **For organizations in *Legacy* mode**: Non-IB groups and users **aren't visible** to users included in IB segments and policies for *allow* policies. If you need non-IB groups and users to be visible to users included in IB segments and policies, you must use *block* policies.
    >
    > **For organizations in *SingleSegment* or *MultiSegment* mode**: Non-IB groups and users are visible to users included in IB segments and policies.

To verify your IB mode, see Check the IB mode for your organization.

- **Policy application**: You apply all IB policies after you define them.
- **Visibility of non-IB users and groups**: Non-IB users and groups are users and groups excluded from IB segments and policies. Depending on when you configure IB policies in your organization and the type of IB policies (block or allow), the behavior for these users and groups differs in Microsoft Teams, SharePoint, OneDrive, and in your global address list.
  - **For organizations in *Legacy* mode**: For users defined in *allow* policies, non-IB groups and users aren't visible to users included in IB segments and policies. For users defined in *block* policies, non-IB groups and users are visible to users included in IB segments and policies.
  - **For organizations in *SingleSegment* or *MultiSegment* mode**: Non-IB groups and users are visible to users included in IB segments and policies.
- **Group support**: IB currently supports only Microsoft 365 Groups. Distribution Lists and Security Groups are treated as non-IB groups.
- **Hidden or disabled user and guest accounts**: For hidden or disabled user and guest accounts in your organization, the *HiddenFromAddressListEnabled* parameter is automatically set to *True* when you hide or disable user accounts, or when you create a guest. When the organization mode is *Legacy* for IB-enabled organizations, IB policies aren't enforced for these accounts in Microsoft Teams. Administrators can change this behavior by manually setting the *HiddenFromAddressListEnabled* parameter to *False*, which allows IB policy enforcement for these users. When the organization is in *SingleSegment* or *MultiSegment* mode, IB policies are enforced for hidden users.

Configuration overview

- Step 1: Make sure prerequisites are met: Verify required subscriptions, permissions, directory data for segmenting users, audit logging, IB mode, and Exchange address book policy configuration.
- Step 2: Segment users in your organization: Determine what policies you need, identify attributes to use, and define segments in terms of policy filters.
- Step 3: Create Information Barriers policies: Create your policies (don't apply them yet) and select from two kinds (block or allow).

- **Step 4: Apply Information Barriers policies**: Set policies to active status, run the policy application, and view policy status.
- **Step 5: Configure Information Barriers on SharePoint and OneDrive (optional)**: Configure IB for SharePoint and OneDrive.
- **Step 6: Information Barriers modes (optional)**: Update IB modes if applicable.
- **Step 7: Configure user discoverability (optional)**: Enable or restrict user discoverability in the people picker if applicable.

Step 1: Make sure prerequisites are met

In addition to the required subscriptions and permissions, make sure that you meet the following requirements before configuring IB:

- **Directory data**: Make sure that your organization's structure is reflected in directory data. To take this action, make sure that user account attributes (such as group membership, department name, and other attributes) are populated correctly in Microsoft Entra ID or Exchange Online. For more information, see the following resources:
  - Attributes for Information Barriers policies
  - Add or update a user's profile information using Microsoft Entra ID
  - Configure user account properties with Office 365 PowerShell
- **Scoped directory search**: Before you define your organization's first IB policy, you must enable scoped directory search in Microsoft Teams. Wait at least 24 hours after enabling scoped directory search before you set up or define IB policies.
- **Verify audit logging is enabled**: To look up the status of an IB policy application, audit logging must be turned on. Auditing is enabled for Microsoft 365 organizations by default. Some organizations might disable auditing for specific reasons. If auditing is disabled for your organization, it might be because another administrator turned it off. Confirm that it's OK to turn auditing back on when completing this step. For more information, see Turn the audit log search on or off.
- **Check the IB mode for your organization**: Support for multiple segments, people discoverability options, Exchange ABPs, and other features is determined by the IB mode for your organization. To verify the IB mode for your organization, see Check the IB mode for your organization.
- **Remove existing Exchange Online address book policies (optional)**:

- **For organizations in *Legacy* mode**: Before you define and apply IB policies, remove all existing Exchange Online address book policies in your organization. IB policies are based on address book policies and existing ABPs aren't compatible with the ABPs created by IB. To remove your existing address book policies, see Remove an address book policy in Exchange Online. For more information about IB policies and Exchange Online, see Information Barriers and Exchange Online.
- **For organizations in *SingleSegment* or *MultiSegment* mode**: Information Barriers no longer uses Exchange Online Address Book Policies (ABPs). Enabling Information Barriers doesn't affect existing ABPs.

- **Manage using PowerShell (optional)**: You can define and manage IB segments and policies in the Microsoft Purview portal, or you can use Security & Compliance PowerShell if preferred or needed. Although several examples are provided in this article, you need to be familiar with PowerShell cmdlets and parameters if you choose to use PowerShell to configure and manage IB segments and policies. You also need the following modules depending on your configuration:

Expand table

Module	Used for	Installation
Security & Compliance PowerShell	Segments, policies, and organization settings	Connect to Security & Compliance PowerShell
Microsoft Graph PowerShell SDK	User and group management	Install the Microsoft Graph PowerShell SDK
SharePoint Online Management Shell	SharePoint and OneDrive IB configuration	Get started with SharePoint Online Management Shell

When you meet all the prerequisites, proceed to the next step.

Step 2: Segment users in your organization

In this step, you determine what IB policies you need, make a list of segments to define, and define your segments. Defining segments doesn't affect users; it just sets the stage for defining and applying IB policies.

Determine what policies you need

Consider the needs of your organization and determine the groups within your organization that need IB policies. Ask yourself the following questions:

- Are there internal, legal, or industry regulations that require the restriction of communication and collaboration between groups and users in your organization?
- Are there any groups or users you should prevent from communicating with another group of users?
- Are there any groups or users you should allow to communicate only with one or two other groups of users?

Think about the policies you need as belonging to one of two types:

- *Block* policies prevent one group from communicating with another group.
- *Allow* policies allow a group to communicate with only specific groups.

When you have your initial list of needed groups and policies, proceed to identify the segments you need for the IB policies.

Identify segments

In addition to your initial list of policies, make a list of segments for your organization. Users included in IB policies should belong to at least one segment. Users can be assigned to multiple segments if needed. You can have up to 5,000 segments in your organization, and each segment can have only one IB policy applied.

> **Important**
>
> For organizations in *Legacy* or *SingleSegment* modes, a user can belong to only one segment. To verify your IB mode, see **Check the IB mode for your organization**.

Determine which attributes in your organization's directory data you'll use to define segments. You can use *Department*, *MemberOf*, or any of the supported IB attributes. Make sure that you have values in the attribute you select for users. For more information, see the supported attributes for IB.

> **Important**
>
> **Before you proceed to the next section, make sure your directory data has values for attributes that you can use to define segments**. If your directory data doesn't have values for the attributes you want to use, update the user accounts to include that information before you proceed with configuring IB. For help, see the following resources:

- Configure user account properties with Office 365 PowerShell
- Add or update a user's profile information using Microsoft Entra ID

Enable multiple segment support for users (optional)

Support for assigning users to multiple segments is available only when your organization isn't in *Legacy* mode. To support assigning users to multiple segments, see Use multi-segment support in Information Barriers.

Users can be assigned to only one segment for organizations in *Legacy* mode. Organizations in *Legacy* mode are eligible to upgrade to the newest version of Information Barriers in the future. For more information, see the Information Barriers roadmap.

Define segments using the portals

Complete the following steps to define segments:

1. Go to the Microsoft Purview portal with credentials for an admin account in your organization.
2. Select the **Information Barriers** solution card. If you don't see the **Information Barriers** solution card, select **View all solutions** and then select **Information Barriers** from the **Risk & Compliance** section.
3. Select **Segments**.
4. On the **Segments** page, select **New segment** to create and configure a new segment.
5. On the **Name** page, enter a name for the segment. You can't rename a segment after you create it.
6. Select **Next**.
7. On the **User group filter** page, select **Add** to configure the group and user attributes for the segment. Choose an attribute for the segment from the list of available attributes.
8. For the selected attribute, select either *Equal* or *Not equal* and then enter the value for the attribute. For example, if you select *Department* as the attribute and *Equals*, you could enter *Marketing* as the defined *Department* for this segment condition. Select **Add condition** to add extra conditions for an attribute. To delete an attribute or attribute condition, select the delete icon for the attribute or condition.
9. Add extra attributes as needed on the **User group filter** page, then select **Next**.
10. On the **Review your settings** page, review the settings you chose for the segment and any suggestions or warnings for your selections. Select **Edit** to change any of the segment attributes and conditions or select **Submit** to create the segment.

Define segments using PowerShell

To define segments by using PowerShell, complete the following steps:

1. Use the **New-OrganizationSegment** cmdlet with the **UserGroupFilter** parameter that corresponds to the attribute you want to use.

   Syntax:

   ```
   PowerShell
   New-OrganizationSegment -Name "segmentname" -UserGroupFilter "attribute -eq 'attributevalue'"
   ```

   Example:

   ```
   PowerShell
   New-OrganizationSegment -Name "HR" -UserGroupFilter "Department -eq 'HR'"
   ```

   In this example, you define a segment named *HR* by using *HR*, a value in the *Department* attribute. The **-eq** operator refers to "equals." (Alternately, you can use **-ne** to mean "not equals". See PowerShell reference: "Equals" and "not equals" in segment definitions.)

   After you run each cmdlet, you see a list of details about the new segment. Details include the segment's type, who created or last modified it, and so on.

2. Repeat this process for each segment you want to define.

After you define your segments, go to Step 3: Create IB policies.

Step 3: Create IB policies

When you create your IB policies, decide whether to prevent communications between certain segments or limit communications to certain segments. Use the minimum number of IB policies to ensure your organization complies with internal, legal, and industry requirements. Use the Microsoft Purview portal or PowerShell to create and apply IB policies.

> **Tip**
>
> For user experience consistency, use *Block* policies for most scenarios.

With your list of user segments and the IB policies you want to define, select a scenario and follow the steps.

- Scenario 1: Block communications between segments
- Scenario 2: Allow a segment to communicate only with one other segment

> **Important**
>
> **Don't assign more than one policy to a segment**. For example, if you define one policy for a segment called *Sales*, don't define an additional policy for the *Sales* segment.
>
> As you define IB policies, set those policies to inactive status until you're ready to apply them. Defining (or editing) policies doesn't affect users until you set those policies to active status and then apply them.

Scenario 1: Block communications between segments

When you want to block segments from communicating with each other, define two policies: one for each direction. Each policy blocks communication in one direction only.

For example, suppose you want to block communications between Segment A and Segment B. Define two policies:

- One policy preventing Segment A from communicating with Segment B
- A second policy to prevent Segment B from communicating with Segment A

Create policies using the portals for Scenario 1

Complete the following steps to create policies:

1. Go to the Microsoft Purview portal with credentials for an admin account in your organization.
2. Select the **Information Barriers** solution card. If you don't see the **Information Barriers** solution card, select **View all solutions** and then select **Information Barriers** from the **Risk & Compliance** section.
3. Select **Policies**.
4. On **Policies**, select **Create policy** to create and configure a new IB policy.

5. On **Name**, enter a name for the policy, and then select **Next**.
6. On **Assigned segment**, select **Choose segment**. Use the search box to search for a segment by name or scroll to select the segment from the displayed list. Select **Add** to add the selected segment to the policy. You can only select one segment.
7. Select **Next**.
8. On **Communication and collaboration**, select the policy type in the **Communication and collaboration** field. The policy options are either *Allowed* or *Blocked*. In this example scenario, select *Blocked* for the first policy.

   > **Important**
   >
   > You can't change the Allowed and Blocked status for segments after creating a policy. To change the status, delete the policy and create a new one.

9. Select **Choose segment** to define the actions for the target segment. You can assign more than one segment in this step. For example, if you want to block users in a segment called *Sales* from communicating with users in a segment called *Research*, define the *Sales* segment in Step 5 and assign *Research* in the **Choose segment** option in this step.
10. Select **Next**.
11. On **Policy status**, toggle the active policy status to **On**. Select **Next** to continue.
12. On **Review your settings**, review the settings you choose for the policy and any suggestions or warnings for your selections. Select **Edit** to change any of the policy segments and status or select **Submit** to create the policy.

In this example, repeat the previous steps to create a second *Block* policy to restrict users in a segment called *Research* from communicating with users in a segment called *Sales*. Define the *Research* segment in Step 5 and assign *Sales* (or multiple segments) in the **Choose segment** option.

Create policies using PowerShell for Scenario 1

To define policies by using PowerShell, complete the following steps:

1. To define your first blocking policy, use the **New-InformationBarrierPolicy** cmdlet with the **SegmentsBlocked** parameter.

Syntax:

```
PowerShell
New-InformationBarrierPolicy -Name "policyname" -AssignedSegment "segmentAname" -
SegmentsBlocked "segmentBname"
```

Example:

```
PowerShell
New-InformationBarrierPolicy -Name "Sales-Research" -AssignedSegment "Sales" -
SegmentsBlocked "Research" -State Inactive
```

In this example, you define a policy called *Sales-Research* for a segment called *Sales*. When active and applied, this policy prevents users in *Sales* from communicating with users in a segment called *Research*.

2. To define your second blocking segment, use the **New-InformationBarrierPolicy** cmdlet with the **SegmentsBlocked** parameter again, this time with the segments reversed.

   Example:

```
PowerShell
New-InformationBarrierPolicy -Name "Research-Sales" -AssignedSegment "Research" -
SegmentsBlocked "Sales" -State Inactive
```

   In this example, you define a policy called *Research-Sales* to prevent *Research* from communicating with *Sales*.

3. Proceed to one of the following actions:

   - (If needed) Define a policy to allow a segment to communicate only with one other segment
   - (After all your policies are defined) Apply IB policies

Scenario 2: Allow a segment to communicate only with one other segment

When you want to allow a segment to communicate with only one other segment, define two policies: one for each direction. Each policy allows communication in one direction only.

In this example, define two policies:

- One policy that allows Segment A to communicate with Segment B
- A second policy that allows Segment B to communicate with Segment A

Create policies using the portals for Scenario 2

Complete the following steps to create policies:

1. Go to the Microsoft Purview portal with credentials for an admin account in your organization.

2. Select the **Information Barriers** solution card. If you don't see the **Information Barriers** solution card, select **View all solutions** and then select **Information Barriers** from the **Risk & Compliance** section.

3. On **Policies**, select **Create policy** to create and configure a new IB policy.

4. On **Name**, enter a name for the policy, and then select **Next**.

5. On **Assigned segment**, select **Choose segment**. Use the search box to search for a segment by name or scroll to select the segment from the displayed list. Select **Add** to add the selected segment to the policy. You can only select one segment.

6. Select **Next**.

7. On the **Communication and collaboration** page, select the policy type in the **Communication and collaboration** field. The policy options are either *Allowed* or *Blocked*. In this example scenario, select *Allowed* for the policy.

   > **Important**
   >
   > You can't change the Allowed and Blocked status for segments after creating a policy. To change the status, delete the policy and create a new one.

8. Select **Choose segment** to define the actions for the target segment. You can assign more than one segment in this step. For example, if you want to allow users in a segment called *Manufacturing* to communicate with users in a segment called *HR*, define the *Manufacturing* segment in Step 5 and assign *HR* in the **Choose segment** option in this step.

9. Select **Next**.

10. On **Policy status**, toggle the active policy status to **On**. Select **Next** to continue.

11. On **Review your settings**, review the settings you choose for the policy and any suggestions or warnings for your selections. Select **Edit** to change any of the policy segments and status or select **Submit** to create the policy.

12. Repeat the previous steps to create a second *Allow policy* to allow users in a segment called *Research* to communicate with users in a segment called *Sales*. Define the *Research* segment in **Step 5** and assign *Sales* (or multiple segments) in the **Choose segment** option.

Create a policy using PowerShell for Scenario 2

To define policies by using PowerShell, complete the following steps:

1. To allow one segment to communicate with the other segment, use the **New-InformationBarrierPolicy** cmdlet with the **SegmentsAllowed** parameter.

   Syntax:

   ```
   PowerShell
   New-InformationBarrierPolicy -Name "policyname" -AssignedSegment "segmentAname" -SegmentsAllowed "segmentBname","segmentAname"
   ```

   Example:

   ```
   PowerShell
   New-InformationBarrierPolicy -Name "Manufacturing-HR" -AssignedSegment "Manufacturing" -SegmentsAllowed "HR","Manufacturing" -State Inactive
   ```

   In this example, you define a policy called *Manufacturing-HR* for a segment called *Manufacturing*. When active and applied, this policy allows users in *Manufacturing* to communicate only with users in a segment called *HR*. In this case, *Manufacturing* can't communicate with users who aren't part of *HR*.

   If needed, you can specify multiple segments by using this cmdlet, as shown in the following example.

   Syntax:

   ```
   PowerShell
   ```

```
New-InformationBarrierPolicy -Name "policyname" -AssignedSegment "segmentAname" -
SegmentsAllowed "segmentBname","segmentCname","segmentDname"
```

Example:

PowerShell

```
New-InformationBarrierPolicy -Name "Research-HRManufacturing" -AssignedSegment
"Research" -SegmentsAllowed "HR","Manufacturing","Research" -State Inactive
```

In this example, you define a policy that allows the *Research* segment to communicate with only *HR* and *Manufacturing*.

Repeat this step for each policy you want to define to allow specific segments to communicate with only certain other specific segments.

2. To define your second allowing segment, use the **New-InformationBarrierPolicy** cmdlet with the **SegmentsAllowed** parameter again, this time with the segments reversed.

   Example:

   PowerShell

   ```
   New-InformationBarrierPolicy -Name "Research-Sales" -AssignedSegment "Research" -
   SegmentsAllowed "Sales" -State Inactive
   ```

   In this example, you define a policy called *Research-Sales* to allow *Research* to communicate with *Sales*.

3. Proceed to one of the following actions:

   - (If needed) Define a policy to block communications between segments
   - (After all your policies are defined) Apply IB policies

Step 4: Apply IB policies

IB policies take effect when you set them to active status and apply the policies.

Apply policies using the portals

Complete the following steps to apply policies:

1. Go to the Microsoft Purview portal with credentials for an admin account in your organization.
2. Select the **Information Barriers** solution card. If you don't see the **Information Barriers** solution card, select **View all solutions** and then select **Information Barriers** from the **Risk & Compliance** section.
3. Select **Policy application**.
4. On the **Policies application** page, select **Apply all policies** to apply all IB policies in your organization.

> **Note**
>
> Allow 30 minutes for the system to start applying the policies. The system applies policies user by user and processes about 5,000 user accounts per hour.

Apply policies using PowerShell

To apply policies by using PowerShell, complete the following steps:

1. Use the **Get-InformationBarrierPolicy** cmdlet to see a list of defined policies. Note the status and identity (GUID) of each policy.

   ```PowerShell
   Get-InformationBarrierPolicy
   ```

2. Use the **Set-InformationBarrierPolicy** cmdlet with the **Identity** parameter and the **State** parameter set to **Active** to set a policy to active status.

   Syntax:

   ```PowerShell
   Set-InformationBarrierPolicy -Identity GUID -State Active
   ```

   Example:

   ```PowerShell
   ```

```
Set-InformationBarrierPolicy -Identity 43c37853-ea10-4b90-a23d-ab8c93772471 -
State Active
```

In this example, you set an IB policy that has the GUID *43c37853-ea10-4b90-a23d-ab8c93772471* to active status.

Repeat this step for each policy.

3. When you finish setting your IB policies to active status, use the **Start-InformationBarrierPoliciesApplication** cmdlet in Security & Compliance PowerShell.

```
PowerShell
Start-InformationBarrierPoliciesApplication
```

After you run `Start-InformationBarrierPoliciesApplication`, allow 30 minutes for the system to start applying the policies. The system applies policies user by user and processes about 5,000 user accounts per hour.

View status of user accounts, segments, policies, or policy application

By using PowerShell, you can view the status of user accounts, segments, policies, and policy application.

View user account IB relationships

Use the Get-ExoInformationBarrierRelationship cmdlet with RecipientId parameters. You can use any value that uniquely identifies each user, such as name, alias, distinguished name, canonical domain name, email address, or GUID.

```
PowerShell
Get-ExoInformationBarrierRelationship -RecipientId1 meganb -RecipientId2 alexw
```

In this example, you refer to two user accounts: *meganb* for *Megan*, and *alexw* for *Alex*. This cmdlet returns information about users, such as attribute values and any IB policies that are applied.

View all segments

PowerShell

```
Get-OrganizationSegment
```

This cmdlet displays a list of all segments defined for your organization.

View all IB policies

PowerShell

```
Get-InformationBarrierPolicy
```

This cmdlet displays a list of IB policies that you defined, and their status.

View the most recent IB policy application

PowerShell

```
Get-InformationBarrierPoliciesApplicationStatus
```

This cmdlet displays information about whether policy application completed, failed, or is in progress.

View all IB policy applications

PowerShell

```
Get-InformationBarrierPoliciesApplicationStatus -All
```

This cmdlet displays information about whether policy application completed, failed, or is in progress.

What if I need to remove or change policies?

You can find resources to help you manage your IB policies.

- To edit, stop, or remove IB policies, see Manage Information Barriers policies.
- If something goes wrong with IB, see Resolve Information Barriers issues.

Step 5: Configure Information Barriers on SharePoint and OneDrive

If you configure IB for SharePoint and OneDrive, you need to enable IB on these services. You also need to enable IB on these services if you configure IB for Microsoft Teams. When you create a team in Microsoft Teams, you automatically create and associate a SharePoint site with Microsoft Teams for the files experience. By default, IB policies don't apply to this new SharePoint site and files.

To enable IB in SharePoint and OneDrive, follow the guidance and steps in the Use Information Barriers with SharePoint article.

Step 6: Information Barriers modes (optional)

Modes help strengthen access, sharing, and membership of a Microsoft 365 resource based on the resource's IB mode. Microsoft 365 Groups, Microsoft Teams, OneDrive, and SharePoint sites support modes. Your new or existing IB configuration automatically enables modes.

The following IB modes support Microsoft 365 resources:

Expand table

Mode	Description	Example
Open	The Microsoft 365 resource has no IB policies or segments associated with it. Anyone can be invited to be a member of the resource.	A team site created for a picnic event for your organization.
Owner Moderated	The resource owner's IB policy determines the IB policy of the Microsoft 365 resource. The resource owners can invite any user to the resource based on their IB policies. This mode is useful when your company wants to allow collaboration among incompatible segment users that the owner moderates. Only the resource owner can add new members per their IB policy.	The VP of HR wants to collaborate with the VPs of Sales and Research. A new SharePoint site that is set with IB mode *Owner Moderated* to add both Sales and Research segment users to the same site. It's the responsibility of the owner to ensure appropriate members are added to the resource.
Implicit	The resource members' IB policy determines the IB policy or segments of the Microsoft 365 resource. The owner can add members as long as they're compatible with the existing members of the resource. This mode is the default IB mode for Microsoft Teams.	The Sales segment user creates a Microsoft Teams team to collaborate with other compatible segments in the organization.
Explicit	The segments associated with the resource determine the IB policy of the Microsoft 365 resource. The resource owner or SharePoint	A site created only for Sales segment members to collaborate by associating the Sales segment with the site.

Mode	Description	Example
	administrator can manage the segments on the resource.	
Mixed	Only applicable to OneDrive. The segments associated with the OneDrive determine the IB policy of the OneDrive. The resource owner or OneDrive administrator can manage the segments on the resource.	A OneDrive created for Sales segment members to collaborate is allowed to be shared with unsegmented users.

Implicit mode updates

Depending on when you enabled IB in your organization, your organization is in either *Legacy*, *SingleSegment*, or *MultiSegment* organization mode. To verify your mode, see Check the IB mode for your organization.

If your organization is in *SingleSegment* or *MultiSegment* mode and the Information Barriers mode of the Teams group is *Implicit*, the Teams-connected groups and sites don't have any segments associated with them.

For more information about IB modes and how to configure them across services, see the following articles:

- Information Barriers modes and Microsoft Teams
- Information Barriers modes and OneDrive
- Information Barriers modes and SharePoint

Step 7: Configure user discoverability for Information Barriers (optional)

By using Information Barriers policies, administrators can enable or disable search restrictions in the people picker. By default, the people picker restriction is enabled for IB policies. For example, IB policies that block two specific users from communication can also restrict the users from seeing each other when using the people picker.

> **Important**
>
> Support for enabling or disabling search restrictions is only available when your organization isn't in *Legacy* mode. Organizations in *Legacy* mode can't enable or disable search restrictions. Enabling or disabling search restrictions requires additional actions to change the Information Barriers mode for your organization. For more information, see Use multi-

segment support in Information Barriers.

Organizations in *Legacy* mode are eligible to upgrade to the newest version of Information Barriers in the future. For more information, see the Information Barriers roadmap.

To disable the people picker search restriction by using PowerShell, complete the following steps:

1. Use the **Set-PolicyConfig** cmdlet to disable the people picker restriction:

```
PowerShell
Set-PolicyConfig -InformationBarrierPeopleSearchRestriction 'Disabled'
```

Example scenario: Contoso's departments, segments, and policies

To see how an organization might approach defining segments and block-based policies, consider the following example scenario.

> **Tip**
>
> For an example of allow-based policies with multi-segment support, see the North School District example in **Use multi-segment support in Information Barriers**.

Contoso's departments and plan

Contoso has five departments: *HR*, *Sales*, *Marketing*, *Research*, and *Manufacturing*. To comply with industry regulations, users in some departments can't communicate with other departments, as shown in the following table:

Expand table

Segment	Can communicate with	Can't communicate with
HR	Everyone	(no restrictions)
Sales	HR, Marketing, Manufacturing	Research
Marketing	Everyone	(no restrictions)
Research	HR, Marketing, Manufacturing	Sales

Segment	Can communicate with	Can't communicate with
Manufacturing	HR, Marketing	Anyone other than HR or Marketing

For this structure, Contoso's plan includes three IB policies:

1. An IB policy that prevents Sales from communicating with Research.
2. An IB policy that prevents Research from communicating with Sales.
3. An IB policy that allows Manufacturing to communicate with HR and Marketing only.

For this scenario, you don't need to define IB policies for *HR* or *Marketing*.

Contoso's defined segments

Contoso uses the Department attribute in Microsoft Entra ID to define segments, as follows:

HR segment:

```PowerShell
New-OrganizationSegment -Name "HR" -UserGroupFilter "Department -eq 'HR'"
```

Sales segment:

```PowerShell
New-OrganizationSegment -Name "Sales" -UserGroupFilter "Department -eq 'Sales'"
```

Marketing segment:

```PowerShell
New-OrganizationSegment -Name "Marketing" -UserGroupFilter "Department -eq
'Marketing'"
```

Research segment:

```PowerShell
New-OrganizationSegment -Name "Research" -UserGroupFilter "Department -eq 'Research'"
```

Manufacturing segment:

PowerShell

```
New-OrganizationSegment -Name "Manufacturing" -UserGroupFilter "Department -eq
'Manufacturing'"
```

After defining the segments, Contoso defines the IB policies.

Contoso's IB policies

Contoso defines three IB policies:

Policy 1: Prevent Sales from communicating with Research.

PowerShell

```
New-InformationBarrierPolicy -Name "Sales-Research" -AssignedSegment "Sales" -
SegmentsBlocked "Research" -State Inactive
```

In this example, the IB policy is called *Sales-Research*. When you activate and apply this policy, it prevents users in the Sales segment from communicating with users in the Research segment. This policy is a one-way policy; it doesn't prevent Research from communicating with Sales. For that, Policy 2 is needed.

Policy 2: Prevent Research from communicating with Sales.

PowerShell

```
New-InformationBarrierPolicy -Name "Research-Sales" -AssignedSegment "Research" -
SegmentsBlocked "Sales" -State Inactive
```

In this example, the IB policy is called *Research-Sales*. When you activate and apply this policy, it prevents users in the Research segment from communicating with users in the Sales segment.

Policy 3: Allow Manufacturing to communicate with HR and Marketing only.

PowerShell

```
New-InformationBarrierPolicy -Name "Manufacturing-HRMarketing" -AssignedSegment
"Manufacturing" -SegmentsAllowed "HR","Marketing","Manufacturing" -State Inactive
```

In this case, the IB policy is called *Manufacturing-HRMarketing*. When you activate and apply this policy, Manufacturing can communicate only with HR and Marketing. HR and Marketing aren't restricted from communicating with other segments.

After defining the segments and policies, Contoso applies the policies by running the **Start-InformationBarrierPoliciesApplication** cmdlet.

When the cmdlet finishes, Contoso complies with industry requirements.

PowerShell reference: "Equals" and "not equals" in segment definitions

When you define segments by using PowerShell, use "equals" (`-eq`) and "not equals" (`-ne`) parameters. Also, use logical *AND* and *OR* operators for complex group filters.

Basic "equals" example:

```
PowerShell
New-OrganizationSegment -Name "HR" -UserGroupFilter "Department -eq 'HR'"
```

Defines a segment named *HR* by using *HR*, a value in the *Department* attribute. The **-eq** portion of the cmdlet refers to "equals".

Basic "not equals" example:

```
PowerShell
New-OrganizationSegment -Name "NotSales" -UserGroupFilter "Department -ne 'Sales'"
```

Defines a segment called *NotSales* that includes everyone who isn't in *Sales*. The **-ne** portion of the cmdlet refers to "not equals".

Using "AND" operators:

```
PowerShell
New-OrganizationSegment -Name "LocalFTE" -UserGroupFilter "Location -eq 'Local'" -and "Position -ne 'Temporary'"
```

Defines a segment called *LocalFTE* that includes users who are located locally and whose positions aren't listed as *Temporary*.

Using "AND" with MemberOf:

```
PowerShell
```

```
New-OrganizationSegment -Name "Segment1" -UserGroupFilter "MemberOf -eq
'group1@contoso.com'' -and MemberOf -ne 'group3@contoso.com'"
```

Defines a segment called *Segment1* that includes users who are members of group1@contoso.com and not members of group3@contoso.com.

Using "OR" with MemberOf:

PowerShell

```
New-OrganizationSegment -Name "Segment2" -UserGroupFilter "MemberOf -eq
'group2@contoso.com' -or MemberOf -ne 'group3@contoso.com'"
```

Defines a segment called *Segment2* that includes users who are members of group2@contoso.com and not members of group3@contoso.com.

Combining "OR" and "AND" operators:

PowerShell

```
New-OrganizationSegment -Name "Segment1and2" -UserGroupFilter "(MemberOf -eq
'group1@contoso.com' -or MemberOf -eq 'group2@contoso.com') -and MemberOf -ne
'group3@contoso.com'"
```

Defines a segment called *Segment1and2* that includes users in group1@contoso.com and group2@contoso.com and not members of group3@contoso.com.

> **Tip**
>
> If possible, use segment definitions that include `-eq` or `-ne`. Avoid defining complex segment definitions.

PowerShell cmdlet quick reference

The following table lists the PowerShell cmdlets you can use to manage Information Barriers segments and policies.

Expand table

Cmdlet	Module	Purpose
New-OrganizationSegment	Security & Compliance PowerShell	Create a new segment
Get-OrganizationSegment	Security & Compliance PowerShell	View all defined segments
Set-OrganizationSegment	Security & Compliance PowerShell	Edit a segment definition
Remove-OrganizationSegment	Security & Compliance PowerShell	Remove a segment
New-InformationBarrierPolicy	Security & Compliance PowerShell	Create a new IB policy
Get-InformationBarrierPolicy	Security & Compliance PowerShell	View IB policies and their status
Set-InformationBarrierPolicy	Security & Compliance PowerShell	Edit or activate a policy
Remove-InformationBarrierPolicy	Security & Compliance PowerShell	Remove a policy
Start-InformationBarrierPoliciesApplication	Security & Compliance PowerShell	Apply all active IB policies
Stop-InformationBarrierPoliciesApplication	Security & Compliance PowerShell	Stop applying IB policies
Get-InformationBarrierPoliciesApplicationStatus	Security & Compliance PowerShell	View policy application status
Get-ExoInformationBarrierRelationship	Security & Compliance PowerShell	View IB relationship between users
Get-PolicyConfig	Security & Compliance PowerShell	View IB organization mode
Set-PolicyConfig	Security & Compliance PowerShell	Configure IB organization settings

For managing Information Barriers in SharePoint and OneDrive, see the SharePoint Online Management Shell cmdlets documented in Use Information Barriers with SharePoint and Use Information Barriers with OneDrive.

Next steps

- Manage Information Barriers policies: Edit or remove segments and policies after initial configuration.
- Use Information Barriers with SharePoint: Configure IB modes and segment associations for SharePoint sites.
- Use Information Barriers with OneDrive: Configure IB modes and segment associations for OneDrive accounts.
- Information Barriers in Microsoft Teams: Understand how IB policies affect Teams chats, meetings, and channels.

Last updated on 04/22/2026

Information Barriers attributes

You can use certain attributes in Microsoft Entra ID to segment users in Information Barriers (IB). After you define segments, use them as filters for IB policies. For example, you might use **Department** to define segments of users by department within your organization (assuming no single user works for two departments at the same time).

This article describes how to use attributes with Information Barriers and provides a list of attributes you can use. For more information about Information Barriers, see the following resources:

- Information Barriers
- Define policies for Information Barriers in Microsoft Teams
- Edit (or remove) IB policies

How to use attributes in IB policies

Use the attributes listed in this article to define or edit segments of users. Your defined segments serve as parameters (called *UserGroupFilter* values) in IB policies.

1. Decide which attribute you want to use to define segments. (See the Reference section in this article.)

2. Make sure the user accounts have values filled in for the attribute(s) you selected in Step 1. View user account details, and if necessary, edit user accounts to include attribute values.

    - To edit multiple accounts or use PowerShell to edit a single account, see Configure user account properties with Office 365 PowerShell.
    - To edit a single account, see Add or update a user's profile information using Microsoft Entra ID.

3. Define segments using PowerShell, similar to the following examples. Before running these cmdlets, connect to Security & Compliance PowerShell.

    > **Tip**

You can also define segments using the Microsoft Purview portal. For more information, see Define segments using the portals.

Define a segment using the Department attribute:

```
PowerShell
New-OrganizationSegment -Name "Segment1" -UserGroupFilter "Department -eq 'Department1'"
```

Define a segment using the MemberOf attribute (suppose this attribute contains group names, such as "BlueGroup"):

```
PowerShell
New-OrganizationSegment -Name "SegmentA" -UserGroupFilter "MemberOf -eq 'BlueGroup'"
```

Define a segment using ExtensionAttribute1 (suppose this attribute contains job titles, such as "DayTrader"):

```
PowerShell
New-OrganizationSegment -Name "DayTraders" -UserGroupFilter "ExtensionAttribute1 -eq 'DayTrader'"
```

Tip

When you define segments, use the same attribute for all your segments. For example, if you define some segments using *Department*, define all of the segments using *Department*. Don't define some segments using *Department* and others using *MemberOf*. Make sure your segments don't overlap; each user belongs to exactly one segment.

Reference

The following table lists the attributes that you can use with Information Barriers.

Tip

The most commonly used attributes for defining segments are **Department**, **MemberOf**, **Company**, and **ExtensionAttribute1–15**. For more information about defining segments, see Get started with Information Barriers.

Expand table

Microsoft Entra property name (LDAP display name)	Exchange property name
Co	Co
Company	Company
Department	Department
Description	Description
ExtensionAttribute1	CustomAttribute1
ExtensionAttribute2	CustomAttribute2
ExtensionAttribute3	CustomAttribute3
ExtensionAttribute4	CustomAttribute4
ExtensionAttribute5	CustomAttribute5
ExtensionAttribute6	CustomAttribute6
ExtensionAttribute7	CustomAttribute7
ExtensionAttribute8	CustomAttribute8
ExtensionAttribute9	CustomAttribute9
ExtensionAttribute10	CustomAttribute10
ExtensionAttribute11	CustomAttribute11
ExtensionAttribute12	CustomAttribute12
ExtensionAttribute13	CustomAttribute13
ExtensionAttribute14	CustomAttribute14
ExtensionAttribute15	CustomAttribute15
Mail	WindowsEmailAddress
MailNickname	Alias

Microsoft Entra property name (LDAP display name)	Exchange property name
MemberOf	MemberOfGroup
MSExchExtensionCustomAttribute1	ExtensionCustomAttribute1
MSExchExtensionCustomAttribute2	ExtensionCustomAttribute2
MSExchExtensionCustomAttribute3	ExtensionCustomAttribute3
MSExchExtensionCustomAttribute4	ExtensionCustomAttribute4
MSExchExtensionCustomAttribute5	ExtensionCustomAttribute5
PhysicalDeliveryOfficeName	Office
PostalCode	PostalCode
ProxyAddresses	EmailAddresses
StreetAddress	StreetAddress
TargetAddress	ExternalEmailAddress
UsageLocation	UsageLocation
UserPrincipalName	UserPrincipalName

Next steps

- Get started with Information Barriers: Use these attributes to define segments and create IB policies.
- Manage Information Barriers policies: Edit segments if you need to change the attributes used to define them.
- Use multi-segment support in Information Barriers: Assign users to multiple segments for complex organizational scenarios.

Last updated on 04/14/2026

Use multi-segment support in Information Barriers

> **Important**
>
> Support for 5,000 segments and assigning users to multiple segments is only available when your organization isn't in *Legacy* mode. Assigning users to multiple segments requires extra steps to change the Information Barriers mode for your organization. For more information, see Use multi-segment support in Information Barriers.
>
> For organizations in *Legacy* mode, the maximum number of segments supported is 250, and users are restricted to being assigned to only one segment. Organizations in *Legacy* mode are eligible to upgrade to the newest version of Information Barriers in the future. For more information, see the Information Barriers roadmap.

By using the multi-segment mode, you can assign users in your organization to up to 10 segments in Information Barriers instead of being limited to just one segment. This support for more diverse communication rules between individuals and groups supports more complex organizational and operational scenarios. For organizations using multi-segment support, define all Information Barriers policies with an allow list.

When you configure multi-segment support, user compatibility depends on each user's assignment to a shared segment. If users share assignment to the same segment, they're compatible. For example, the following table shows that User A and User B aren't compatible because they don't share an assigned segment. However, User A is compatible with User C and User B is compatible with User C because they each have an assigned segment in common.

Expand table

User	Assigned segments
User A	Segment 1, Segment 2
User B	Segment 3, Segment 4
User C	Segment 2, Segment 4

Multi-segment example: North School District's schools, segments, and policies

The North School District has two schools, School 1 and School 2. The district policy is to allow students and teachers to communicate with each other only if they're both in the same school. For example, a student and teacher that are both in School 1 can communicate, but a student in School 1 can't communicate with a teacher in School 2. For this scenario, configure multiple segments to support the following district policy scenarios:

North School District's schools and plan

North School District has two schools:

Expand table

Segment	Allowed communication	Prevented communication
School 1	Students and teachers in School 1	Students and teachers in School 2
School 2	Students and teachers in School 2	Students and teachers in School 1

For this structure, North School District's plan includes three IB policies:

1. An IB policy that enables students and teachers in School 1 to communicate with each other.
2. An IB policy that enables students and teachers in School 2 to communicate with each other.
3. An IB policy that allows teachers in School 1 and School 2 to communicate with each other.

North School District's defined segments

North School District uses the *Department* attribute in Microsoft Entra ID to define segments, as follows:

School1 segment:

PowerShell

```
New-OrganizationSegment -Name "School1" -UserGroupFilter "Department -eq 'School1'"
```

School2 segment:

PowerShell

```
New-OrganizationSegment -Name "School2" -UserGroupFilter "Department -eq 'School2'"
```

AllTeachers segment:

```
PowerShell
New-OrganizationSegment -Name "AllTeachers" -UserGroupFilter "MemberOfGroup -eq
'AllTeachersgroup@northschoolsdistrict.com'"
```

After defining the segments, North School District defines the IB policies.

North School District's IB policies

North School District defines three IB policies:

Policy 1: Students and teachers in School 1 can communicate with each other.

```
PowerShell
New-InformationBarrierPolicy -Name School1Policy -SegmentsAllowed 'School1' -
AssignedSegment 'School1' -State Active
```

When you activate and apply this policy, students and teachers in School 1 can communicate with each other. This policy is a one-way policy; it doesn't prevent students and teachers in School 1 from communicating with School 2. For that, Policy 2 is needed.

Policy 2: Students and teachers in School 2 can communicate with each other.

```
PowerShell
New-InformationBarrierPolicy -Name School2Policy -SegmentsAllowed 'School2' -
AssignedSegment 'School2' -State Active
```

When you activate and apply this policy, students and teachers in School 2 can communicate with each other.

Policy 3: Teachers in different schools can communicate with each other.

```
PowerShell
New-InformationBarrierPolicy -Name AllTeachersPolicy -SegmentsAllowed 'AllTeachers'
-AssignedSegment 'AllTeachers' -State Active
```

When you activate and apply this policy, teachers in School 1 and School 2 can communicate with each other.

After defining segments and policies, North School District runs the **Start-InformationBarrierPoliciesApplication** cmdlet to apply the policies. When the cmdlet finishes, North School District implements its communication policy for students and teachers.

Check the IB mode for your organization

To support assigning users to multiple segments, verify that your IB organization supports multiple segments. Run the following cmdlet to verify your IB mode in the Security & Compliance PowerShell:

PowerShell

```
Get-PolicyConfig
```

If the value of the `InformationBarrierMode` property is *SingleSegment*, enable multi-segment support by following the guidance in the Enable multiple segment support for users section in this article. If the value of the `InformationBarrierMode` property is *MultiSegment*, you can skip enabling support for multi-segment because it's already enabled for your organization.

If the value of the `InformationBarrierMode` property is *Legacy*, enabling multi-segment isn't supported for your organization. *Legacy* organizations are eligible to upgrade to the newest version of Information Barriers in the future. For more information, see the Information Barriers roadmap.

Enable multiple segment support for users

To enable multiple segment support for organizations in *SingleSegment* mode, make sure that you don't currently have any IB segments or policies defined for your organization. Run the following cmdlet to enable multiple segment support in your organization:

PowerShell

```
Set-PolicyConfig -InformationBarrierMode 'MultiSegment'
```

> **Important**
>
> If you enable multiple segments and configure IB in your organization, don't revert to single segment support.

Multi-segment support for users in OneDrive

When you configure OneDrive for Information Barriers to support multiple segments, the following behavior applies:

- A multi-segment user's OneDrive is automatically set to *Owner Moderated* mode.
- In *Explicit* or *Mixed* mode, a multi-segment user can access a OneDrive if they belong to at least one of its segments and have site access permission. All other modes use the same access experience as single segment support.
- Sharing behavior follows the IB mode set for OneDrive. In *Explicit* mode, users can share with others who have the same segment. In *Open* or *Owner Moderated* mode, users can share with compatible users per IB policies.

For more information, see Use Information Barriers with OneDrive.

Multi-segment support for users in SharePoint Online

When you configure SharePoint for Information Barriers to support multiple segments, the following behavior applies:

- A user with multiple segments who creates a SharePoint site (either a Microsoft 365 group connected site or a non-group site) automatically uses *Owner Moderated* mode.
- In *Explicit* mode, users get access if they have at least one segment that matches the site's segment and they have site access permission. All other modes use the same access experience as single segment support.
- Sharing behavior follows the IB mode of the site. In *Explicit* mode, users can share with others who match the site's segment. In *Implicit* or *Owner Moderated* mode, users can share with existing members of the connected Microsoft 365 group. In *Open* mode, users can share with compatible users per IB policy.

For more information, see Use Information Barriers with SharePoint.

Multi-segment support for users in Microsoft Teams

When you configure Teams for Information Barriers to support multiple segments, the following behavior applies:

- A user with multiple segments who creates a team automatically uses *Implicit* mode.
- All users in the team must have one segment that is compatible with all other users.

For more information, see Use Information Barriers with Microsoft Teams.

- Information Barriers in OneDrive

Last updated on 03/30/2026

Manage Information Barriers policies

After you define Information Barriers (IB) policies, you might need to change those policies or your user segments as part of troubleshooting or regular maintenance.

Manage segments and policies

- **Edit user account attributes**: Fill in attributes in Microsoft Entra ID that you can use to define segments. Edit user account attributes when users aren't included in segments they should be, to change which segments users are in, or to define segments by using different attributes.
- **Edit a segment**: Edit segments when you want to change how you define a segment. For example, you might have originally defined segments by using *Department* and now want to use another attribute, such as *MemberOf*.
- **Edit a policy**: Edit an Information Barriers policy when you want to change how a policy works. For example, instead of blocking communications between two segments, you might decide you want to allow communications to occur only between certain segments.
- **Set a policy to inactive status**: Set a policy to inactive status when you want to make changes to a policy, or when you don't want a policy to be in effect.
- **Remove a policy**: Remove an Information Barriers policy when you no longer need a particular policy in place.
- **Remove a segment**: Remove an Information Barriers segment when you no longer need a particular segment.
- **Remove a policy and a segment**: Remove an Information Barriers policy and a segment at the same time.
- **Stop a policy application**: Stop the process of applying Information Barriers policies. Stopping a policy application isn't instant, and it doesn't undo policies that are already applied to users.
- **Enable or disable user discoverability**: Enable or disable if users are displayed in the people picker.
- **Define policies for Information Barriers**: Define an Information Barriers policy when you don't already have such policies in place, and you must restrict or limit communications between specific groups of users.
- **Resolve Information Barriers issues**: Refer to this article when you run into unexpected issues with Information Barriers.

> **ⓘ Important**
>
> To perform the tasks described in this article, you must be assigned an appropriate role, such as one of the following roles:
>
> - Microsoft 365 Enterprise Global Administrator
> - Global Administrator
> - Compliance Administrator
> - IB Compliance Management
>
> For more information about prerequisites for Information Barriers, see Prerequisites (for Information Barriers policies).
>
> Make sure to connect to the Security & Compliance PowerShell.

> **ⓘ Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Edit user account attributes

Complete the following steps to edit attributes that segment users. For example, if you're using a Department attribute and one or more user accounts don't currently have any values listed for Department, edit those user accounts to include Department information. Use user account attributes to define segments so you can assign Information Barriers policies.

1. Use the **Get-ExoInformationBarrierRelationship** cmdlet to view details for a specific user account, such as attribute values and assigned segments. Use Identity parameters in Exchange Online PowerShell. You can use any value that uniquely identifies each user, such as name, alias, distinguished name, canonical domain name, email address, or GUID.

   Syntax:

   PowerShell

   ```
   Get-ExoInformationBarrierRelationship -RecipientId1 <value> -RecipientId2 <value>
   ```

Example:

```
PowerShell
Get-ExoInformationBarrierRelationship -Identity meganb -Identity2 alexw
```

In this example, two user accounts are referenced: *meganb* for *Megan*, and *alexw* for *Alex*.

2. Decide which attribute to edit for your user account profiles. For more information, see Attributes for Information Barriers policies.

3. Edit one or more user accounts to include values for the attribute you selected in the previous step. Use one of the following procedures:

   - To edit a single account, see Add or update a user's profile information using Microsoft Entra ID.
   - To edit multiple accounts (or use PowerShell to edit a single account), see Configure user account properties with Office 365 PowerShell.

Edit a segment

Complete the following steps to edit the definition of a user segment. For example, you might change the name of a segment or the filter that determines who is included in the segment.

1. Use the **Get-OrganizationSegment** cmdlet to view all existing segments.

```
PowerShell
Get-OrganizationSegment
```

You see a list of segments and details for each segment, such as the segment type, its UserGroupFilter value, who created or last modified it, GUID, and more.

> **Tip**
>
> Print or save your list of segments for reference. For example, if you want to edit a segment, you need to know its name or identifying value (used with the Identity parameter).

2. Use the **Set-OrganizationSegment** cmdlet with the **Identity** parameter and relevant details to edit a segment.

   Syntax:

   ```
   PowerShell
   Set-OrganizationSegment -Identity GUID -UserGroupFilter "attribute -eq 'attributevalue'"
   ```

   Example:

   ```
   PowerShell
   Set-OrganizationSegment -Identity c96e0837-c232-4a8a-841e-ef45787d8fcd -UserGroupFilter "Department -eq 'HRDept'"
   ```

   In this example, you update the department name to *HRDept* for the segment with GUID *c96e0837-c232-4a8a-841e-ef45787d8fcd*.

3. When you finish editing segments for your organization, you can either define or edit Information Barriers policies.

Edit a policy

1. Use the **Get-InformationBarrierPolicy** cmdlet to view a list of current Information Barriers policies.

   ```
   PowerShell
   Get-InformationBarrierPolicy
   ```

   In the list of results, find the policy that you want to change. Note the policy's GUID and name.

2. Use the **Set-InformationBarrierPolicy** cmdlet with an **Identity** parameter, and specify the changes you want to make.

   Example: Suppose you defined a policy to block the *Research* segment from communicating with the *Sales* and *Marketing* segments:

   ```
   PowerShell
   ```

```
New-InformationBarrierPolicy -Name "Research-SalesMarketing" -AssignedSegment
"Research" -SegmentsBlocked "Sales","Marketing"
```

Suppose you want to change it so that users in the *Research* segment can only communicate with users in the *HR* segment. To make this change:

PowerShell

```
Set-InformationBarrierPolicy -Identity 43c37853-ea10-4b90-a23d-ab8c93772471 -
SegmentsAllowed "HR"
```

In this example, you change *SegmentsBlocked* to *SegmentsAllowed* and specify the *HR* segment.

3. When you finish editing a policy, make sure to apply your changes. For more information, see Apply Information Barriers policies.

Set a policy to inactive status

1. Use the **Get-InformationBarrierPolicy** cmdlet to view a list of current Information Barriers policies.

PowerShell

```
Get-InformationBarrierPolicy
```

In the list of results, find the policy that you want to change or remove. Note the policy's GUID and name.

2. Use the **Set-InformationBarrierPolicy** cmdlet with the *Identity* parameter and the *State* parameter set to *Inactive* to set the policy's status to inactive.

Syntax:

PowerShell

```
Set-InformationBarrierPolicy -Identity GUID -State Inactive
```

Example:

PowerShell

```
Set-InformationBarrierPolicy -Identity 43c37853-ea10-4b90-a23d-ab8c9377247 -
State Inactive
```

In this example, the Information Barriers policy that has GUID *43c37853-ea10-4b90-a23d-ab8c9377247* is set to an inactive status.

3. Use the **Start-InformationBarrierPoliciesApplication** cmdlet to apply your changes.

PowerShell

```
Start-InformationBarrierPoliciesApplication
```

Changes are applied user-by-user for your organization. If your organization is large, it can take 24 hours or more for this process to complete. As a general guideline, it takes about an hour to process 5,000 user accounts.

4. One or more Information Barriers policies are set to inactive status. From here, you can take any of the following actions:

   - Keep it as is (a policy set to inactive status has no effect on users)
   - Edit a policy
   - Remove a policy

Remove a policy

1. Use the **Get-InformationBarrierPolicy** cmdlet to view a list of current Information Barriers policies.

PowerShell

```
Get-InformationBarrierPolicy
```

In the list of results, find the policy that you want to remove. Note the policy's GUID and name.

2. Make sure the policy is set to inactive status. To set the policy's status to inactive, use the **Set-InformationBarrierPolicy** cmdlet with an Identity parameter and the State parameter set to Inactive.

Syntax:

```
```

PowerShell

```
Set-InformationBarrierPolicy -Identity GUID -State Inactive
```

Example:

PowerShell

```
Set-InformationBarrierPolicy -Identity 43c37853-ea10-4b90-a23d-ab8c9377247 -
State Inactive
```

In this example, you set an Information Barriers policy that has GUID *43c37853-ea10-4b90-a23d-ab8c9377247* to an inactive status.

3. To apply your changes on the policy, use the **Start-InformationBarrierPoliciesApplication** cmdlet.

PowerShell

```
Start-InformationBarrierPoliciesApplication
```

Changes are applied user-by-user for your organization. If your organization is large, it can take 24 hours or more for this process to complete. As a general guideline, it takes about an hour to process 5,000 user accounts.

4. Use the **Remove-InformationBarrierPolicy** cmdlet with an Identity parameter.

Syntax:

PowerShell

```
Remove-InformationBarrierPolicy -Identity GUID
```

Example:

PowerShell

```
Remove-InformationBarrierPolicy -Identity 43c37853-ea10-4b90-a23d-ab8c93772471
```

In this example, you remove the policy that has GUID *43c37853-ea10-4b90-a23d-ab8c93772471*.

When prompted, confirm the change.

Remove a segment

1. Use the **Get-OrganizationSegment** cmdlet to view all existing segments.

   ```
   PowerShell
   Get-OrganizationSegment
   ```

   You see a list of segments and details for each segment, such as the segment type, its UserGroupFilter value, who created or last modified it, GUID, and more.

   > **Tip**
   >
   > Print or save your list of segments for reference later. For example, if you want to edit a segment, you need to know its name or identify value (this value works with the Identity parameter).

2. Identify the segment to remove and make sure you remove the IB policy associated with the segment. For more information, see the Remove a policy procedure.

3. Edit the segment to remove the relationship of users to that segment. This action updates the segment definition and removes all users from the segment. Use the UserGroupFilter parameter to disassociate users from the segment before removal.

   Use the **Set-OrganizationSegment** cmdlet with the *Identity* parameter and relevant details to edit a segment.

   Syntax:

   ```
   PowerShell
   Set-OrganizationSegment -Identity GUID -UserGroupFilter "attribute -eq
   'attributevalue'"
   ```

   Example:

   ```
   PowerShell
   Set-OrganizationSegment -Identity c96e0837-c232-4a8a-841e-ef45787d8fcd -
   UserGroupFilter "Department -eq 'FakeDept'"
   ```

In this example, for the segment that has the GUID c96e0837-c232-4a8a-841e-ef45787d8fcd, you define the department name as *FakeDept* to remove users from the segment. This example uses the *Department* attribute, but you can use other attributes as appropriate. The example uses *FakeDept* because this doesn't exist and is certain to not contain any users.

4. Use the **Start-InformationBarrierPoliciesApplication** cmdlet to apply your changes.

```
PowerShell
Start-InformationBarrierPoliciesApplication -CleanupGroupSegmentLink
```

> **Note**
>
> The *CleanupGroupSegmentLink* attribute removes group associations with the segment with no user associations.

Changes are applied user-by-user for your organization. If your organization is large, it can take 24 hours or more for this process to complete. As a general guideline, it takes about an hour to process 5,000 user accounts.

5. Use the **Remove-OrganizationSegment** cmdlet with the *Identity* parameter and relevant details to remove a segment.

Syntax:

```
PowerShell
Remove-OrganizationSegment -Identity GUID
```

Example:

```
PowerShell
Remove-OrganizationSegment -Identity c96e0837-c232-4a8a-841e-ef45787d8fcd
```

In this example, you remove the segment that has the GUID c96e0837-c232-4a8a-841e-ef45787d8fcd.

Remove a policy and segment

1. Use the **Get-InformationBarrierPolicy** cmdlet to view a list of current Information Barriers policies.

   ```PowerShell
   Get-InformationBarrierPolicy
   ```

   In the list of results, find the policy that you want to remove. Note the policy's GUID and name.

2. Use the **Get-OrganizationSegment** cmdlet to view all existing segments.

   ```PowerShell
   Get-OrganizationSegment
   ```

   You see a list of segments and details for each, such as segment type, its *UserGroupFilter* parameter value, who created or last modified it, GUID, and so on.

   > **Tip**
   >
   > Print or save your list of segments for reference later. For example, if you want to edit a segment, you need to know its name or identify value (this value works with the Identity parameter).

3. Set the policy to inactive status using the **Set-InformationBarrierPolicy** cmdlet.

   Syntax:

   ```PowerShell
   Set-InformationBarrierPolicy -Identity GUID -State Inactive
   ```

   Example:

   ```PowerShell
   Set-InformationBarrierPolicy -Identity 43c37853-ea10-4b90-a23d-ab8c93772471 -
   State Inactive
   ```

   In this example, this command sets an Information Barriers policy that has GUID 43c37853-ea10-4b90-a23d-ab8c93772471 to an inactive status.

4. Edit the segment that you want to remove to remove the relationship of users to that segment. This action updates the segment definition and removes all users from the segment. Use the *UserGroupFilter* parameter to disassociate users from the segment before removal.

   Syntax:

   ```PowerShell
   Set-OrganizationSegment -Identity GUID -UserGroupFilter "attribute -eq 'attributevalue'"
   ```

   Example:

   ```PowerShell
   Set-OrganizationSegment -Identity c96e0837-c232-4a8a-841e-ef45787d8fcd -UserGroupFilter "Department -eq 'FakeDept'"
   ```

   In this example, for the segment that has the GUID c96e0837-c232-4a8a-841e-ef45787d8fcd, the department name is updated to *FakeDept* to remove users from the segment. This example uses the *Department* attribute, but you can use other attributes as appropriate. The example uses *FakeDept* because this doesn't exist and is certain to contain no users.

5. Use the **Start-InformationBarrierPoliciesApplication** cmdlet to apply your changes.

   ```PowerShell
   Start-InformationBarrierPoliciesApplication -CleanupGroupSegmentLink
   ```

   > ⓘ **Note**
   >
   > The *CleanupGroupSegmentLink* attribute removes group associations with the segment with no user associations.

   Changes are applied user-by-user for your organization. If your organization is large, it can take 24 hours or more for this process to complete. As a general guideline, it takes about an hour to process 5,000 user accounts.

6. Remove the policy using the **Remove-InformationBarrierPolicy** cmdlet.

Syntax:

```
PowerShell
Remove-InformationBarrierPolicy -Identity GUID
```

Example:

```
PowerShell
Remove-InformationBarrierPolicy -Identity 43c37853-ea10-4b90-a23d-ab8c93772471
```

In this example, the policy that has GUID *43c37853-ea10-4b90-a23d-ab8c93772471* is removed.

When prompted, confirm the change.

7. Remove the segment using the **Remove-OrganizationSegment** cmdlet.

   Syntax:

   ```
   PowerShell
   Remove-OrganizationSegment -Identity GUID
   ```

   Example:

   ```
   PowerShell
   Remove-OrganizationSegment -Identity c96e0837-c232-4a8a-841e-ef45787d8fcd
   ```

   In this example, the segment with GUID c96e0837-c232-4a8a-841e-ef45787d8fcd was removed.

Stop applying a policy

If you started applying Information Barriers policies and want to stop applying those policies, complete the following steps. It takes about 30 to 35 minutes for the process to start.

1. Use the **Get-InformationBarrierPoliciesApplicationStatus** cmdlet to view the status of the most recent Information Barriers policy application.

   ```
   PowerShell
   ```

```
Get-InformationBarrierPoliciesApplicationStatus
```

Note the application's GUID.

2. Use the **Stop-InformationBarrierPoliciesApplication** cmdlet with an Identity parameter.

   Syntax:

   ```
   PowerShell
   Stop-InformationBarrierPoliciesApplication -Identity GUID
   ```

   Example:

   ```
   PowerShell
   Stop-InformationBarrierPoliciesApplication -Identity 46237888-12ca-42e3-a541-3fcb7b5231d1
   ```

   In this example, you're stopping the application of Information Barriers policies.

Enable or disable user discoverability

> **Important**
>
> Support for enabling or disabling search restrictions is only available when your organization isn't in *Legacy* mode. Organizations in *Legacy* mode can't enable or disable search restrictions. Enabling or disabling search restrictions requires additional actions to change the Information Barriers mode for your organization. For more information, see Use multi-segment support in Information Barriers.
>
> Organizations in *Legacy* mode are eligible to upgrade to the newest version of Information Barriers in the future. For more information, see the Information Barriers roadmap.

To enable the people picker search restriction by using PowerShell, complete the following steps:

1. Use the **Set-PolicyConfig** cmdlet to enable the people picker restriction:

PowerShell

```
Set-PolicyConfig -InformationBarrierPeopleSearchRestriction 'Enabled'
```

To disable the people picker search restriction by using PowerShell, complete the following steps:

1. Use the **Set-PolicyConfig** cmdlet to disable the people picker restriction:

PowerShell

```
Set-PolicyConfig -InformationBarrierPeopleSearchRestriction 'Disabled'
```

Next steps

- Get started with Information Barriers: Re-apply policies after editing segments or policies.
- Create an Information Barriers policy compliance report: Identify SharePoint and OneDrive sites that don't comply after policy changes.
- Information Barriers attributes: Review available attributes when redefining segment filters.

Change Information Barriers modes with a PowerShell script

Applies to: Microsoft Teams

Use this PowerShell script to update the Information Barriers (IB) mode for all Teams-connected groups in your tenant. You need to update the mode for these groups after you deploy Information Barriers. Groups created before you enable IB are assigned the *Open* mode. In *Open* mode, there aren't any applicable IB policies. After you enable IB, *Implicit* becomes the default mode for any new groups you create. However, existing groups still keep *Open* mode configuration. Run this script to change these existing groups to *Implicit* mode.

In this script, you use the Get-UnifiedGroup cmdlet, which is in the Exchange Online PowerShell module to update the mode. For more information about managing Teams using PowerShell, see Teams PowerShell overview.

Prerequisites

Before you run this script, make sure you have the following prerequisites:

- The Exchange Online PowerShell module installed.
- A work or school account that has the global administrator role for your tenant.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Run the script

Complete the following steps to update the IB mode for all existing Teams-connected groups:

1. Connect to Exchange Online PowerShell:

```
PowerShell
```

```
Connect-ExchangeOnline
```

2. Copy and run the following script. The script identifies all Teams-connected groups in *Open* mode and updates them to *Implicit* mode.

3. After the script finishes, review the output for the number of groups successfully updated. If any groups fail to update, check the `BackfillFailedTeams.csv` file generated in your current directory for details and retry the failed groups.

Sample script

PowerShell

```
<#
.SYNOPSIS
This script updates the IB mode for all Teams-connected groups in your tenant at
the same time.
.DESCRIPTION
Use this script to update the info barrier mode from open to implicit across the
groups in your tenant.
#>

$teams = Get-UnifiedGroup -Filter {ResourceProvisioningOptions -eq "Team"} -
ResultSize Unlimited

Write-Output ([string]::Format("Number of Teams = {0}", @($teams).Length))

$teamsToUpdate = New-Object System.Collections.ArrayList

foreach($team in $teams)
{
  if ($team.InformationBarrierMode -eq "Open")
  {
    $teamsToUpdate.Add($team.ExternalDirectoryObjectId) | out-null
  }
}

Write-Output ([string]::Format("Number of Teams to be backfilled = {0}",
@($teamsToUpdate).Length))

$outfile = "BackfillFailedTeams.csv"

if (!(Test-Path "$outfile"))
{
  $newcsv = {} | Select "ExternalDirectoryObjectId", "ExceptionDetails" | Export-
Csv $outfile -NoTypeInformation
}
else
{
  $dateTime = Get-Date
```

```
  $newEntry = "{0},{1}" -f "New session started", $dateTime
  $newEntry | add-content $outfile
}

$SuccessfullyBackfilledGroup = 0

for($i = 0; $i -lt @($teamsToUpdate).Length; $i++)
{
  Invoke-Command { Set-UnifiedGroup $teamsToUpdate[$i] -InformationBarrierMode
"Implicit" } -ErrorVariable ErrorOutput

  if ($ErrorOutput)
  {
    # saving the errors in a csv file
    $errorBody = $ErrorOutput[0].ToString() -replace "`n"," " -replace "`r"," " -
replace ",", " "
    $newEntry = "{0},{1}" -f $teamsToUpdate[$i].ToString(), '"' + $errorBody + '"'
    $newEntry | add-content $outfile
  }
  else
  {
    $SuccessfullyBackfilledGroup++
  }

  if (($i+1) % 100 -eq 0)
  {
    # print the number of teams backfilled after the batch of 100 updates
    Write-Output ([string]::Format("Number of Teams processed= {0}", $i+1))
  }
}

Write-Output ([string]::Format("Backfill completed. Groups backfilled: {0}, Groups
failed to backfill: {1}", $SuccessfullyBackfilledGroup, @($teamsToUpdate).Length -
$SuccessfullyBackfilledGroup))

if (!($SuccessfullyBackfilledGroup -eq @($teamsToUpdate).Length))
{
  Write-Output ([string]::Format("Check the failed teams in
BackfillFailedTeams.csv, retry to backfill the failed teams."))
}
```

Next steps

- Information Barriers in Microsoft Teams: Verify Teams IB behavior after updating group modes to Implicit.
- Use Information Barriers with SharePoint: Update IB modes for SharePoint sites connected to the updated Teams.
- Manage Information Barriers policies: Edit segments or policies if compliance issues arise after mode changes.

Information Barriers in Microsoft Teams

Applies to: Microsoft Teams

Microsoft Purview Information Barriers (IBs) are policies that prevent individuals or groups from communicating with each other. This article covers IB behavior in Microsoft Teams, including shared channels. For more information about shared channels and Information Barriers behavior, see Information Barriers and shared channels.

For Microsoft Teams, Information Barriers can determine and prevent the following kinds of unauthorized collaborations:

- Adding a user to a team or channel
- User access to team or channel content
- User access to 1:1 and group chats
- User access to meetings
- Prevents lookups and discovery, users aren't visible in the people picker.

> **Note**
>
> - You can't create IB groups across tenants.
> - Version 1 doesn't support using bots, Microsoft Entra apps, or APIs to send activity feed notifications, and it doesn't support some APIs to add users.
> - Private channels comply with Information Barriers policies that you configure.
> - For information about support for barriers for SharePoint sites that are connected to Teams, see Segments associated with Microsoft Teams sites.

Background

The primary driver for Information Barriers is the financial services industry, where the Financial Industry Regulatory Authority (FINRA) reviews IBs and conflicts of interest within member firms (Debt Research Regulatory Notice 15-31). However, IBs are useful across many industries including education, legal, government, and professional services. For more information about IB scenarios, see Learn about Information Barriers.

When to use Information Barriers

Use IBs in situations like these:

- You need to prevent a team from communicating or sharing data with a specific other team.
- You need to prevent a team from communicating or sharing data with anyone outside of the team.

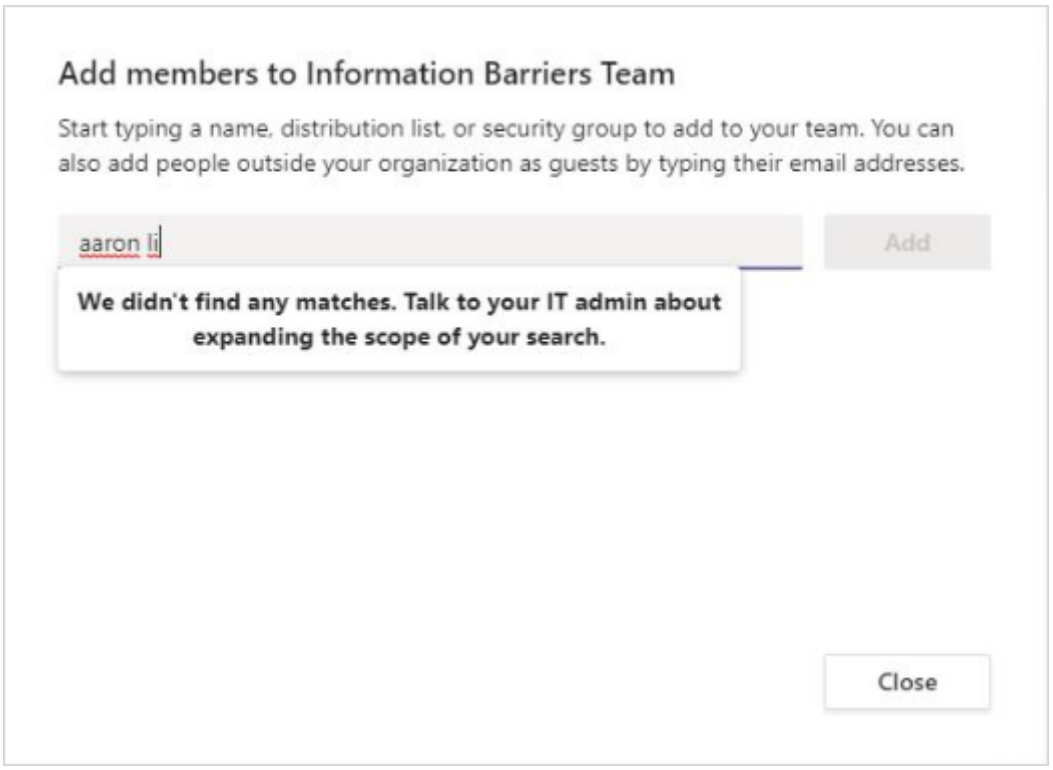
The Information Barrier Policy Evaluation Service determines whether a communication complies with IB policies.

Manage segments and policies

Manage IB segments and policies in the Microsoft Purview portal or by using PowerShell cmdlets. For full guidance, see Get started with Information Barriers and Manage Information Barriers policies.

> **Important**
>
> Support for 5,000 segments and assigning users to multiple segments is only available when your organization isn't in *Legacy* mode. Assigning users to multiple segments requires extra steps to change the Information Barriers mode for your organization. For more information, see **Use multi-segment support in Information Barriers**.
>
> For organizations in *Legacy* mode, the maximum number of segments supported is 250, and users are restricted to being assigned to only one segment. Organizations in *Legacy* mode are eligible to upgrade to the newest version of Information Barriers in the future. For more information, see the **Information Barriers roadmap** .

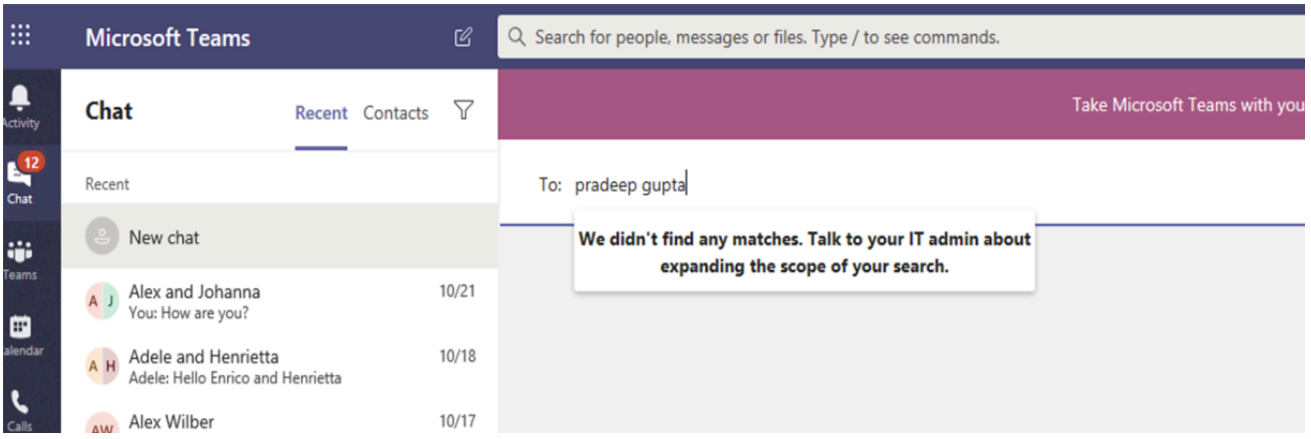
> **Important**
>
> Before you set up or define policies, you must enable scoped directory search in Microsoft Teams. Wait at least a few hours after enabling scoped directory search before you set up or define policies for IB. For more information, see **Define IB policies**.



Information Barriers administrator role

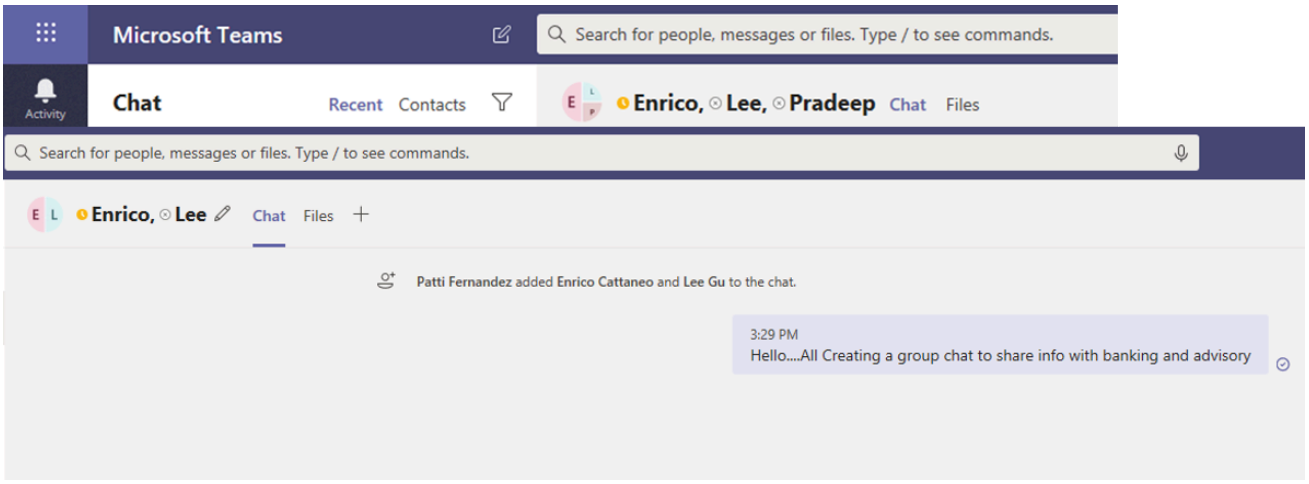
The IB Compliance Management role is responsible for managing IB policies. For more information about this role, see Permissions in the Microsoft Purview portal.

Information barrier triggers



IB policies activate when the following Teams events take place:

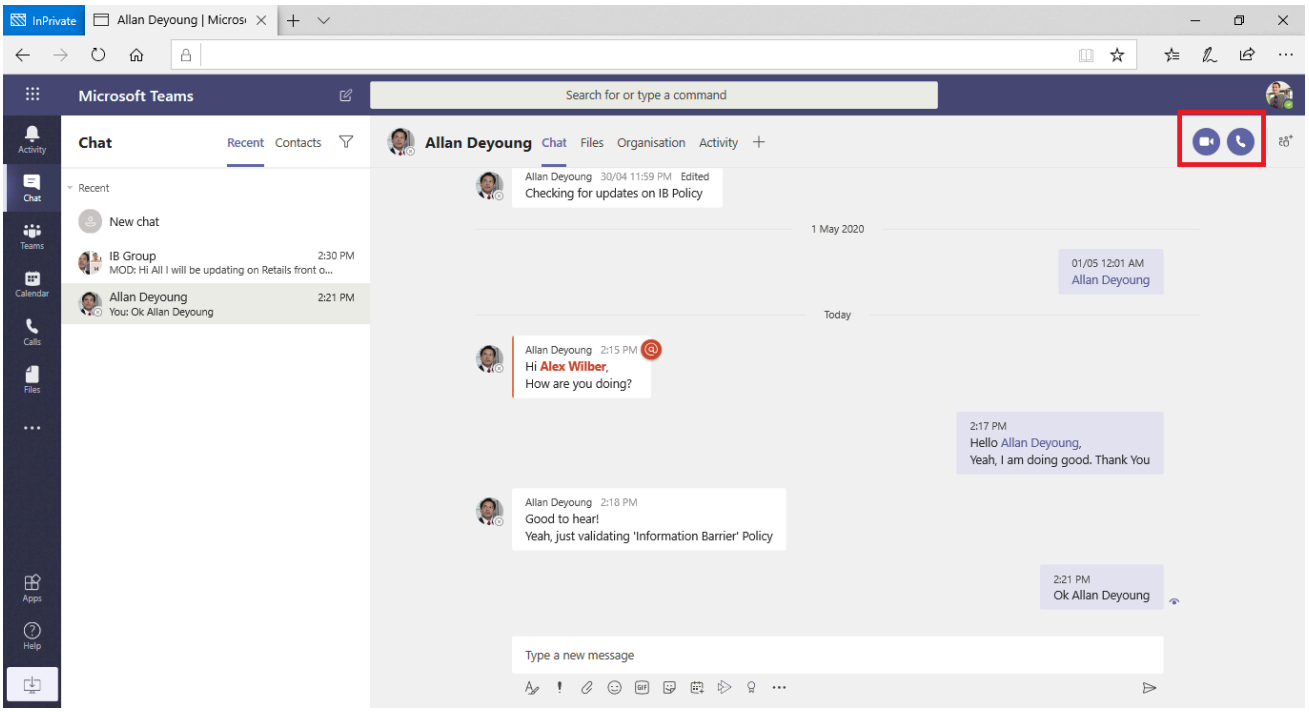
- **Add members to a team**: Whenever you add a user to a team, the system evaluates the user's policy against the IB policies of other team members. After the user is successfully added, the user can perform all functions in the team without further checks. If the user's policy blocks them from being added to the team, the user doesn't show up in search.



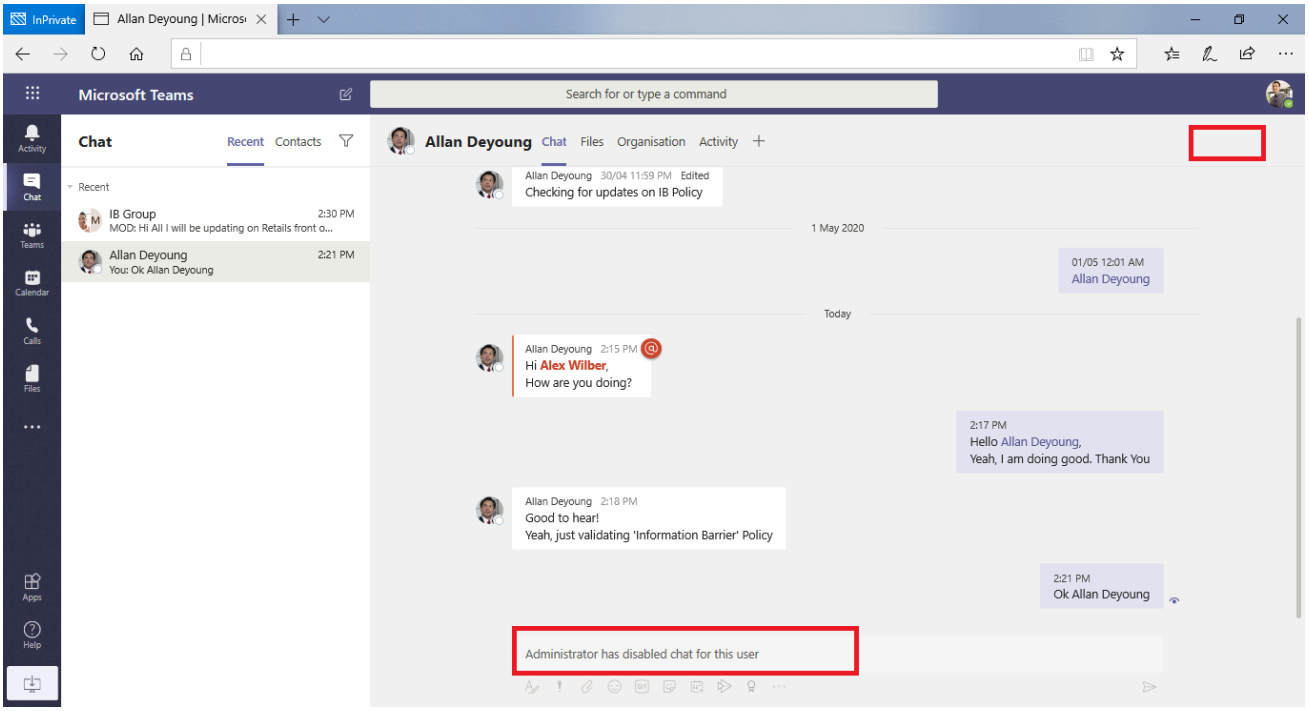
- **Request a new chat**: Each time that a user requests a new chat with one or more other users, the system evaluates the chat to make sure that it isn't violating any IB policies. If the conversation violates an IB policy, the conversation isn't started.

  Here's an example of a 1:1 chat.

  Here's an example of a group chat.



- **Invite a user to join a meeting**: When you invite a user to join a meeting, the system evaluates the IB policy that applies to the user against the IB policies that apply to the other team members. If there's a violation, the user isn't allowed to join the meeting.



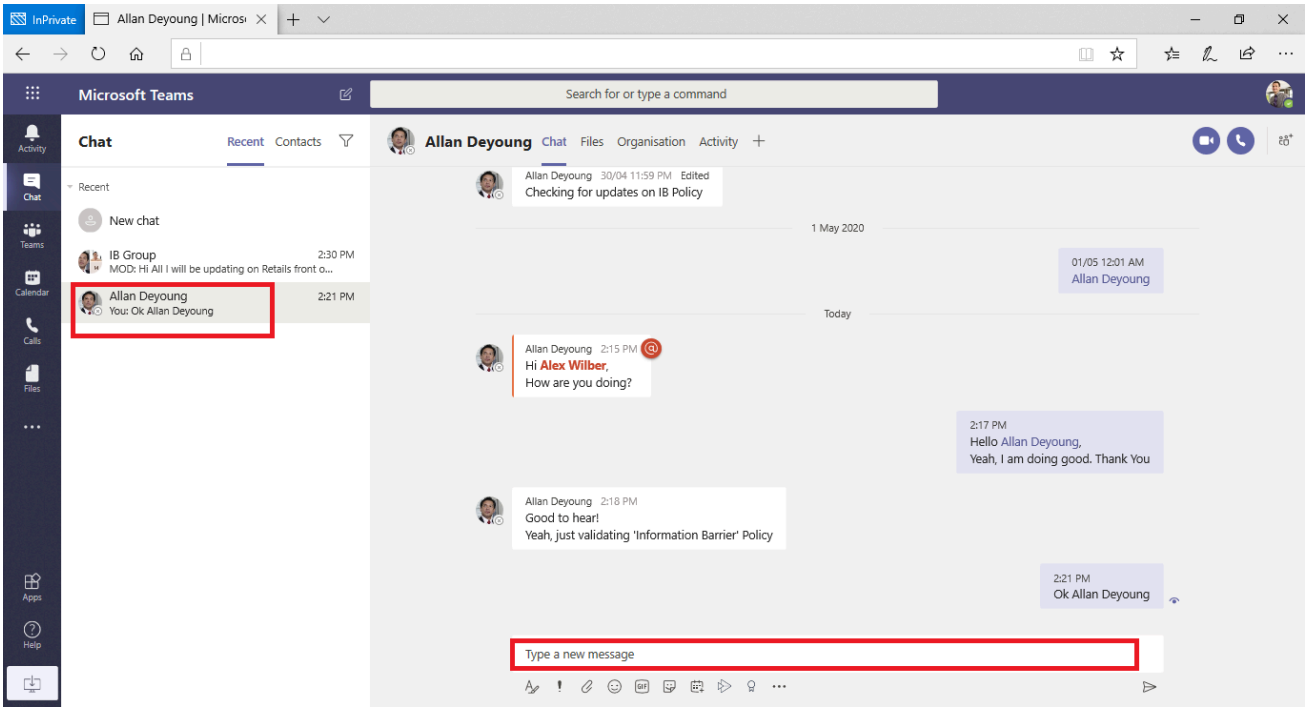
- **Share a screen between two or more users**: When a user shares a screen with other users, the system evaluates the sharing to make sure that it doesn't violate the IB policies of other users. If an IB policy is violated, the screen share isn't allowed.

  Here's an example of screen share before the policy is applied.

Here's an example of screen share after the policy is applied. The screen share and call icons aren't visible.

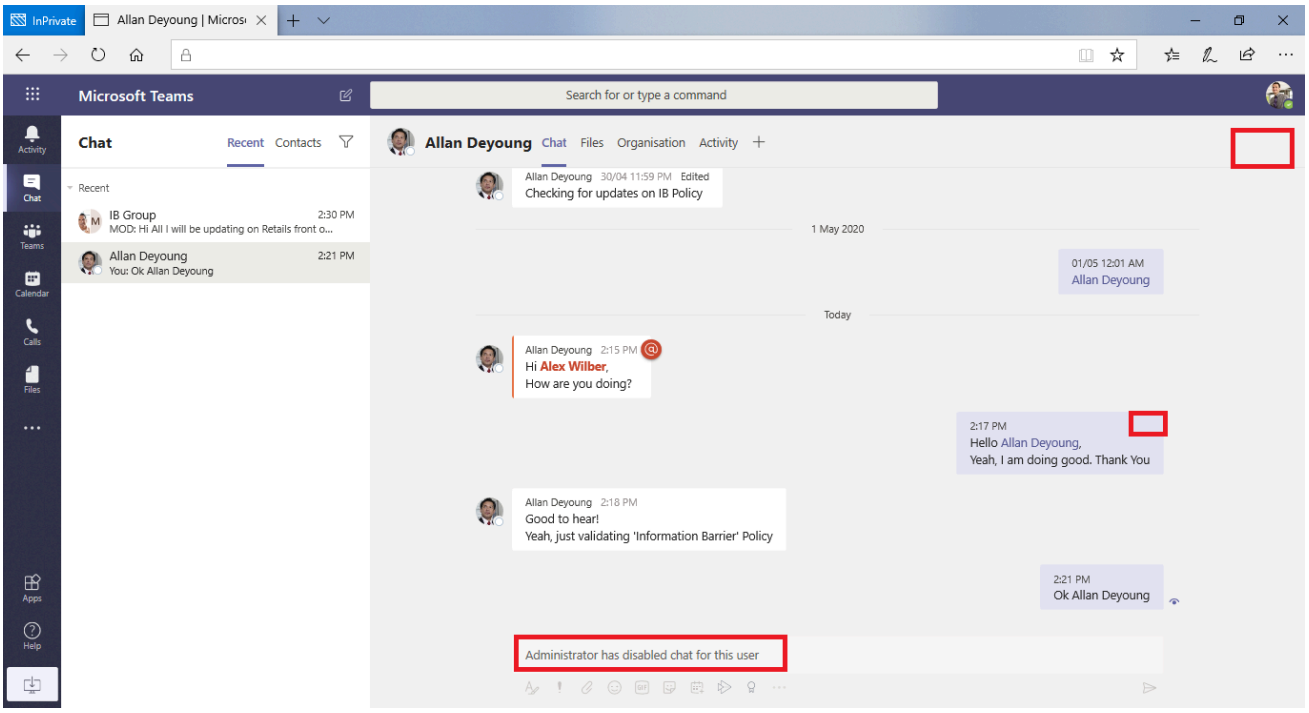
- **Place a phone call in Teams**: Whenever a user initiates a voice call (via VOIP) to another user or group of users, the system evaluates the call to make sure that it doesn't violate the IB policies of other team members. If there's any violation, the voice call is blocked.

- **Guests in Teams**: IB policies apply to guests in Teams, too. If guests need to be discoverable in your organization's global address list, see Manage guest access in Microsoft 365 Groups. After guests are discoverable, you can define IB policies.



How policy changes impact existing chats

When the IB policy administrator changes a policy or activates a policy change because of a change to a user's profile (such as for a job change), the Information Barrier Policy Evaluation Service automatically searches the members to ensure that their membership in the team doesn't violate any policies.

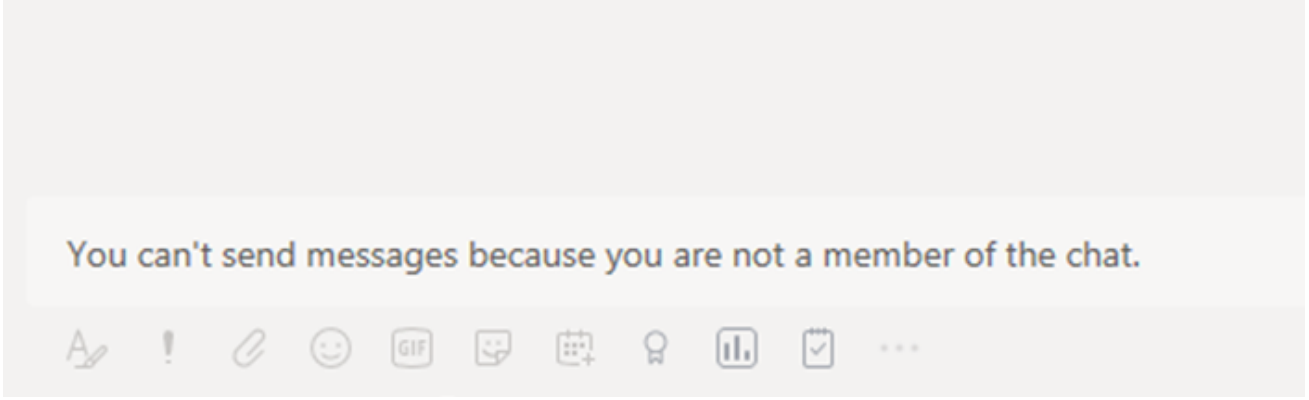


If users have an existing chat or other communication, and you set a new policy or change an existing policy, the service evaluates existing communications to make sure that the communications are still allowed.

- **1:1 chat**: If communication between two users is no longer allowed (because of application to one or both users of a policy that blocks communication), the service blocks further communication. Their existing chat conversations become read-only.

  Here's an example that shows the chat is visible.

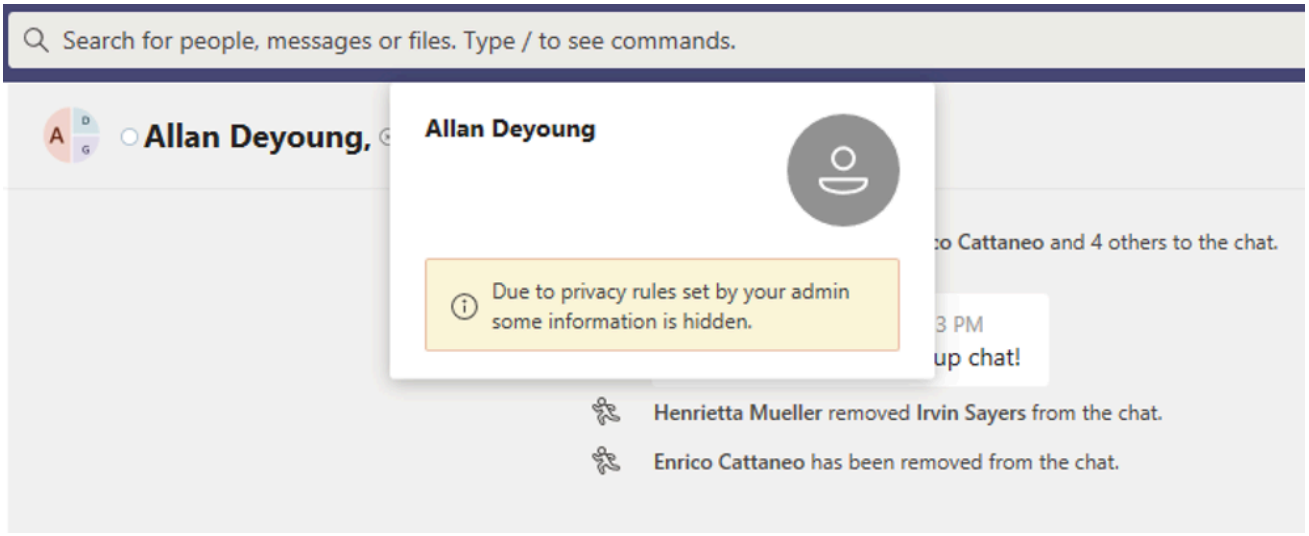
  Here's an example that shows the chat is disabled.



- **Group chat**: If communication from one user to a group is no longer allowed (for example, because a user changed jobs), the service removes the user, along with the other users whose participation violates the policy, from group chat, and blocks further communication with the group. The user can still see old conversations, but can't see or participate in any new conversations with the group. If the new or changed policy that prevents communication is applied to more than one user, the service removes the users who are affected by the policy from group chat. They can still see old conversations.

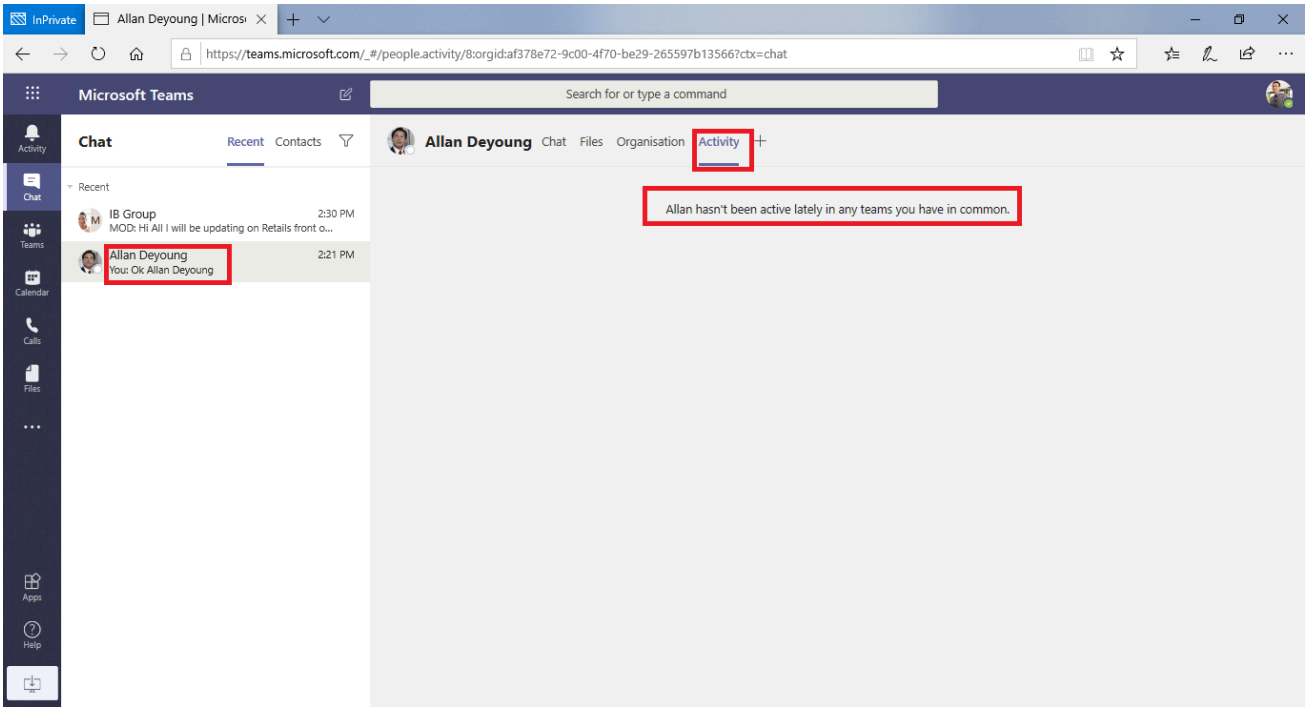
  In this example, Enrico moves to a different department within the organization and is removed from the group chat.

Enrico can no longer send messages to the group chat.



- **Team**: The service removes any users who are removed from the group from the team and they can't see or participate in existing or new conversations.

Scenario: A user in an existing chat becomes blocked



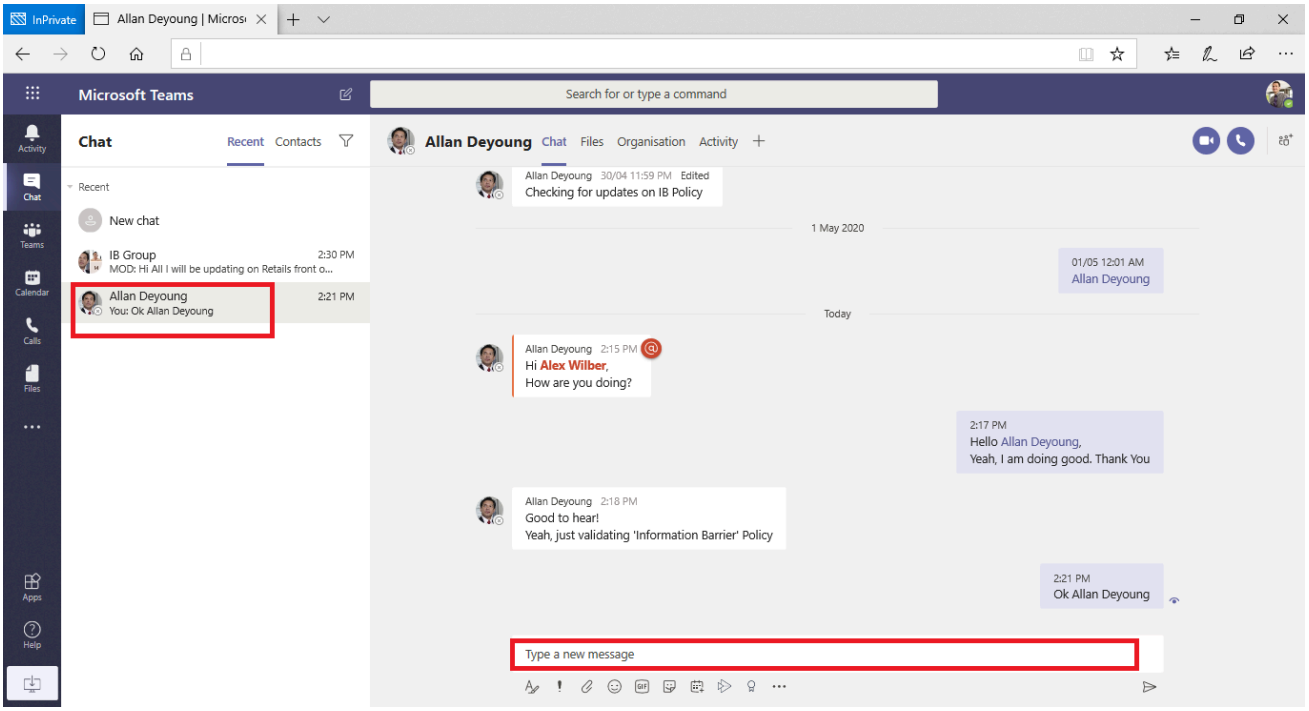
Currently, users experience the following scenarios if an IB policy blocks another user:

- **People tab**: A user can't see blocked users on the **People** tab.
- **People Picker**: Blocked users aren't visible in the people picker.

- **Activity tab**: If a user visits the **Activity** tab of a blocked user, no posts appear. (The **Activity** tab displays channel posts only, and there are no common channels between the two users.)

  Here's an example of the activity tab view that is blocked.

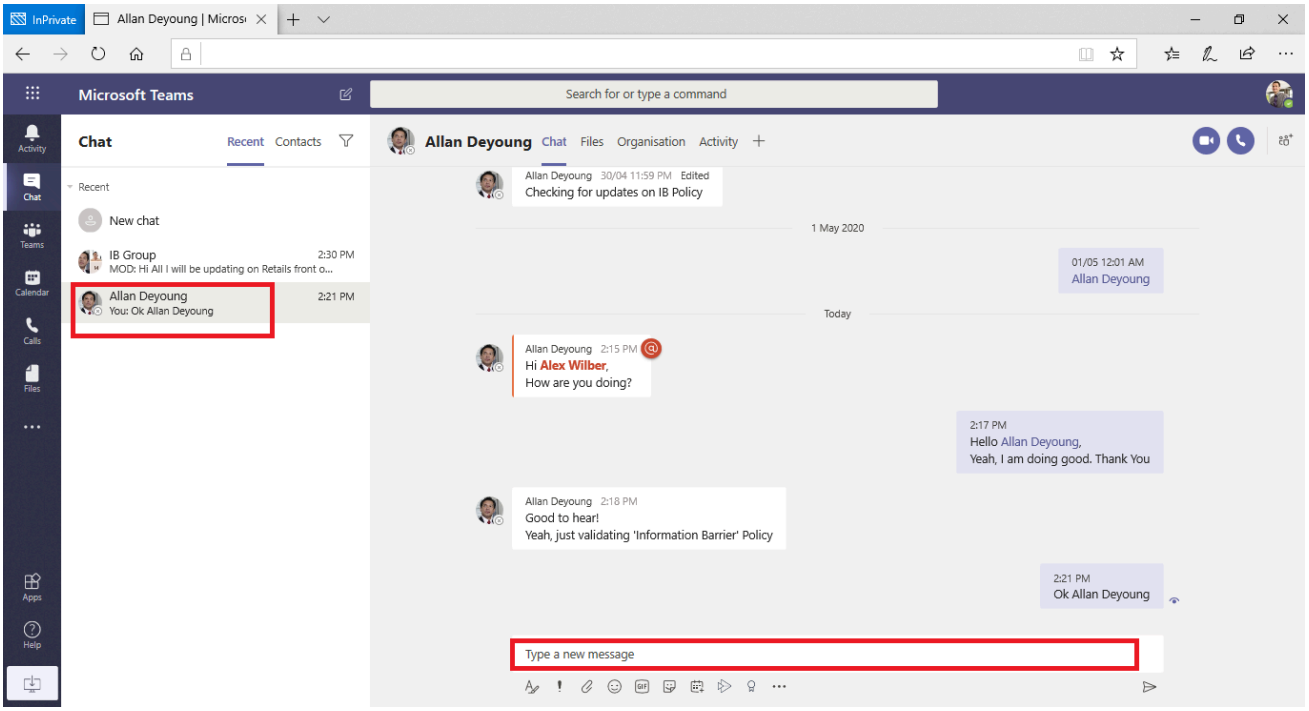
- **Org charts**: If a user accesses an org chart on which a blocked user appears, the blocked user doesn't appear on the org chart. Instead, an error message appears.



- **People card**: If a user participates in a conversation and the user is later blocked, other users see an error message instead of the people card when they hover over the blocked user's name. Actions listed on the card (such as calling and chat) are unavailable.

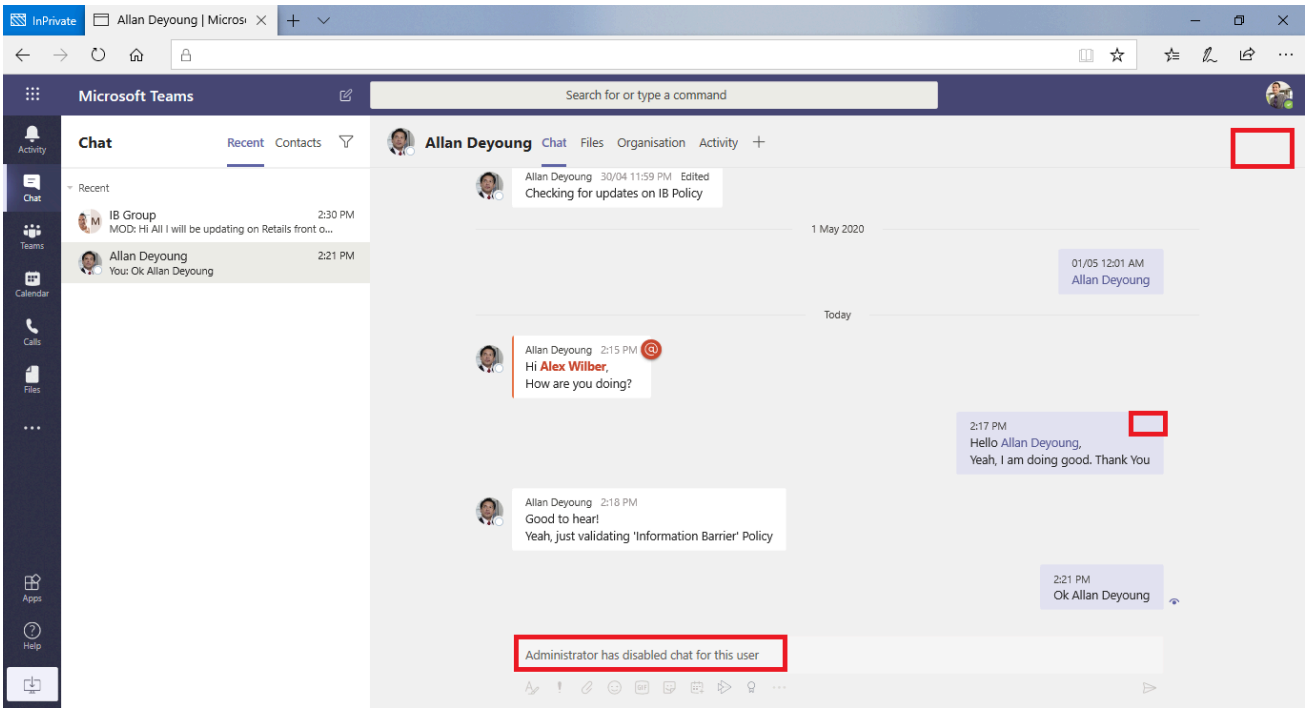
- **Suggested contacts**: Blocked users don't appear on the suggested contacts list (the initial contact list that appears for new users).

- **Chat contacts**: A user can see blocked users on the chats contact list, but the blocked users are identified. The only action that the user can perform on the blocked users is to delete them. The user can also select them to view their past conversation.



- **Calls contacts**: A user can see blocked users on the calls contact list, but the blocked users are identified. The only action that the user can perform on the blocked users is to delete them.

  Here's an example of a blocked user in the calls contact list.



- **Skype to Teams migration**: During a migration from Skype for Business to Teams, the migration process includes all users—even those users who are blocked by IB policies. The migration process handles those users as described previously.

  Here's an example of a blocked user in the calls contact list.

Here's an example of the chat being disabled for a user on the calls contact list.

Teams policies and SharePoint sites

When you create a team, you also create and associate a SharePoint site with Microsoft Teams for the files experience. Information barrier policies don't apply to this SharePoint site and its files by default. To enable Information Barriers in SharePoint and OneDrive, follow the guidance and steps in the Use Information Barriers with SharePoint article.

Information barrier modes and Teams

Information barrier modes help control who you can add to or remove from a Team. When you use Information Barriers with Teams, the following IB modes are supported:

- **Open**: This configuration is the default IB mode for all existing groups that were provisioned before Information Barriers were enabled. In this mode, no IB policies apply.
- **Implicit**: This configuration is the default IB mode when you provision a Team after enabling Information Barriers. *Implicit* mode allows you to add all compatible users in the group.
- **Owner Moderated**: This mode is set on a team when you want to allow collaboration between incompatible segment users that the owner moderates. The team owner can add new members per their IB policy.

Teams created before activating an IB policy in your tenant are automatically set to *Open* mode by default. When you activate IB policies on your tenant, you must update mode of your existing teams to *Implicit* to ensure that existing teams are IB-compliant. For more information about updating modes, see Change Information Barriers modes with a PowerShell script.

Use the Set-UnifiedGroup cmdlet with the *InformationBarrierMode* parameter that corresponds to the mode you want to use for your segments. The allowed values for the *InformationBarrierMode* parameter are *Open*, *Implicit*, and *Owner Moderated*.

For example, to configure *Implicit* mode for a Microsoft 365 Group, use the following PowerShell command:

```
PowerShell
Set-UnifiedGroup -InformationBarrierMode Implicit
```

To update the mode from *Open* to *Implicit* for all existing teams, use this PowerShell script.

If you change the *Open* mode configuration on existing Teams-connected groups to meet compliance requirements for your organization, you need to update the IB modes for associated SharePoint sites connected to the Teams team.

IB policy application in Teams

The IB policy application is a background IB processor for Teams that gets a notification when there are changes to either users (policy or segment changes) or groups (mode changes). The following steps outline the processing flow:

- The policy application receives a group change notification when mode is updated and retrieves the message thread and Group IDs applicable to the update.
- If the message thread exists, the application schedules processing and fetches all members from the team. It sends the underlying group and members to downstream Teams components for IB evaluation.
- The application evaluates the mode on the group and the IB policies per user and sends the results to the policy application.
- The policy application removes the non-compliant users from the group and team.

Required licenses and permissions

For more information about licenses and permissions, plans, and pricing, see the subscription requirements for Information Barriers.

Usage notes

- **Users can't join any scheduled meetings**: If you enable IB policies, users can't join meetings if the meeting chat roster reaches its current limit of 1,000 users. IB checks rely on whether a user can be added to the meeting chat roster - only users who can be added are allowed to join the meeting. Every meeting in an IB-enabled tenant performs IB checks at the point of entry, even if the meeting organizer isn't explicitly covered by IB policies.

  Teams also enforces a separate meeting limit of 1,000 users. If you enable overflow, additional participants can join as view-only attendees. View-only participants aren't subject to IB policy checks. If you invite a large audience (for example, more than 1,000 users), Teams pre-adds 750 users to the meeting chat before the meeting starts. This process reserves room for about 250 additional users who actually join the meeting. Because pre-added users count toward the chat roster limit even if they never join the meeting, the chat roster can reach capacity before the meeting attendance limit is met. For recurring meetings, the roster can fill quickly, as any user who joins once remains on the roster for future occurrences. After the 1,000-user chat roster limit is reached, you can't add more users to the meeting.

  A short-term solution is to remove inactive members from the meeting chat roster to make space for new users or keep the chat disabled until the meeting begins and enable it only when needed. This solution helps align the chat participant count more closely with the meeting participant count. Regular Teams meetings work best for audiences of fewer than 1,000 expected attendees. For larger audiences, use Teams Town hall for a smoother experience.

- **Users can't join channel meetings**: If you enable IB policies, users can't join channel meetings if they're not a member of the team. The root cause is that IB checks rely on whether users can be added to a meeting chat roster, and only when they can be added to the roster are they allowed to join the meeting. The chat thread in a channel meeting is available to Team/Channel members only, and non-members can't see or access the chat thread. If you enable IB for the organization and a non-team member attempts to join a channel meeting, that user isn't allowed to join the meeting. However, if you don't enable IB for the organization and a nonteam member attempts to join a channel meeting, the user is allowed to join the meeting but they don't see the chat option in the meeting.

- **IB policies are supported in federated communication**: If you allow federation with external organizations, the users of those organizations aren't restricted by IB policies. If users of your organization join a group chat, meeting chat, or a call organized by external federated users, IB policies continue to restrict communication between users of your organization.

Next steps

- Use Information Barriers with SharePoint: Enable IB on SharePoint sites connected to Teams.
- Information Barriers and shared channels: Understand how IB policies apply when sharing channels with other teams.
- Change Information Barriers modes with a PowerShell script: Update existing Teams groups from Open to Implicit mode after enabling IB.
- Manage Information Barriers policies: Edit or remove IB policies and segments.

Information Barriers and moderated meetings

Applies to: Microsoft Teams

Moderated meetings in Information Barriers (IB) enable controlled interactions between users who can't communicate because of IB policies. This feature ensures that meetings occur with the presence of a designated moderator, such as a compliance admin, who oversees the interaction and ensures compliance with IB policies.

Moderated meetings in IB provide the following benefits:

- **Granular control**: Selectively allow meetings with IB-incompatible users, such as town halls or new hire orientations.
- **Moderator role**: Designated moderators facilitate the meeting, ensuring that all interactions comply with IB policies.
- **Flexible user discovery**: Users can look up and invite participants on either side of the IB during scheduling.
- **Compliance and security**: Adheres to regulatory requirements and provides a secure environment for sensitive discussions.

> **Important**
>
> Your organization must use the IBv2 architecture to use moderated meetings in IB. The IBv2 architecture supports flexible people discovery and the creation of a separate moderator segment. This support is required for necessary compliance and security measures in moderated interactions.

Set up moderators, segments, and policies

Setting up moderators and associated segments and policies is crucial for conducting moderated meetings where attendees from segments blocked from communicating with each other attend a common meeting.

To configure these settings, you must be assigned one of the following roles in your organization:

- Microsoft 365 global administrator
- Office 365 global administrator
- Compliance administrator
- IB Compliance Management

> **ⓘ Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Additionally, all users included in Moderated Meeting must meet the following prerequisites:

- All users and the admin must have a Microsoft 365 E5 license
- All users scheduling a Moderated Meeting in Teams must have a Microsoft Teams Premium license.

Step 1: Define a moderators group in Microsoft Entra

Complete the following steps to define a moderators group in Microsoft Entra:

1. Go to the Microsoft Entra admin center, select **Expand groups**, select **Select all groups**, and then select **Add new group**.
2. For **Group type**, select *Microsoft 365*.
3. Enter a name for the group in the **Group name** field.
4. Enter *moderator* in the **Group email address** field. If you delete the moderators' group or this group name isn't available, use one of the following address names:

   - moderators1@<domain>.com
   - moderators2@<domain>.com

   > **ⓘ Important**
   >
   > The name of the group email ID must contain the keyword *moderator* and be in stated format.

5. Enter a description for the group in the **Group description** field.

6. Select **No** for **Microsoft Entra roles can be assigned to this group**.
7. Select *Assigned* for **Membership type**.
8. Add owners and moderators to this group.
9. Select **Create**.

You use the *Object ID* of the moderator group in the next step for the creation of a moderators segment in Microsoft Purview portal.

Step 2: Define the moderators segment

After you configure a Microsoft Entra group with all the needed moderators, use this group to configure a new moderator segment.

Complete the following steps to define a moderators group in the Microsoft Purview portal:

1. Go to the Microsoft Purview portal and navigate to **Information Barriers** > **Segments**.
2. Select **New segment**.
3. On the **Provide a segment name** page, enter a name for the segment and select **Next**.
4. On the **Add user group filter** page, select **Add**.
5. Select the *MemberOf* filter.
6. Copy the *Object ID* of the group you created in Step 1 in Microsoft Entra and paste it in the **Member of** condition field with the *Equal* operator. Select **Next**.
7. Review the segment details and select **Submit** to create the segment.

When you create the segment, add or remove owners and moderators by updating the Microsoft Entra group. This segment updates automatically if there are any membership changes in the Microsoft Entra group.

Step 3: Create a policy for the moderator segment

Create an *Allow* policy for the moderator segment. This policy enables moderators to facilitate meetings for participants from all segments, even if existing IB policies block those participants.

To create a policy for the moderator segment in the Microsoft Purview portal, complete the following steps:

1. Go to the Microsoft Purview portal and navigate to **Information Barriers** > **Policies** > **Policies**.
2. Select **Create policy**.

3. On the **Provide a policy name** page, enter a name for the policy and select **Next**.
4. On the **Add assigned segment details** page, select **Choose segment**.
5. Select the segment you created in Step 2, and then select **Add** and **Next**.
6. On the **Configure communication and collaboration details** page, select **Allowed**.
7. Select the **Allow moderation** checkbox.
8. Add all the segments in your organization that should participate in a moderated meeting. Add all segments in your organization, including the moderators segment you created in Step 2.
9. Select **Add** and **Next**.
10. On the **Policy status** page, enable **Set your policy to active status** and select **Next**.
11. Review the policy details and select **Submit** to create the policy.

To verify that the policy is applied in your organization, go to **Information Barriers** > **Policies** > **Policy applications** and select **Apply all policies**.

> ⓘ **Note**
>
> When you select **Apply all policies**, the system evaluates all existing and new policies. You might see some validation errors. Update policies to correct any errors as needed and rerun the evaluation. Applying all policies might take several hours, depending on the size of your organization.

Step 4: Setting policy configuration

> ⓘ **Important**
>
> Before you begin, make sure you have the following PowerShell modules installed:
>
> - Exchange Online Management module (`ExchangeOnlineManagement`)
> - Security & Compliance PowerShell (for `Connect-IPPSSession`)

Complete the following steps to change your IB mode to multi-segment and to disable the IB *InformationBarrierPeopleSearchRestriction* property.

1. Start PowerShell in admin mode and use the following command to change your IB mode to multi-segment:

```
PowerShell
```

```
Connect-IPPSSession -UserPrincipalName <compliance admin email id>
Import-Module ExchangeOnlineManagement
Get-PolicyConfig | fl "Information*"
Set-PolicyConfig -InformationBarrierMode 'MultiSegment'
```

> **Note**
>
> If you configure any Block policies in your organization, multi-segment doesn't work. For multi-segment IBv2 to work, configure your organization with Allow policies only. All segments that aren't set to allow are blocked.

2. Use the following cmdlet to disable the *InformationBarrierPeopleSearchRestriction* property:

PowerShell

```
Set-PolicyConfig -InformationBarrierPeopleSearchRestriction 'Disabled'
```

To verify that you configured multi-segment support and disabled the *InformationBarrierPeopleSearchRestriction* property, use the following cmdlet:

PowerShell

```
Get-PolicyConfig | fl "Information*"
```

Step 5: Apply policies

To apply the changes in Step 4, you must apply the policy changes again in your organization. To apply these changes in your organization, go to **Information Barriers** > **Policies** > **Policy applications** and select **Apply all policies**.

> **Note**
>
> When you select **Apply all policies**, the system evaluates all existing and new policies. You might see some validation errors. Update policies to correct any errors as needed and rerun the evaluation. Applying all policies might take several hours, depending on the size of your organization.

Next steps

- Information Barriers in Microsoft Teams: Understand how IB policies affect other Teams interactions beyond moderated meetings.
- Get started with Information Barriers: Apply updated policies after configuring moderator segments.
- Use multi-segment support in Information Barriers: Assign moderators to multiple segments for broader meeting facilitation.

Information Barriers and shared channels

Applies to: Microsoft Teams

Shared channels in Microsoft Teams create collaboration spaces where you can invite people who aren't in the team. You implement Microsoft Purview Information Barriers policies to restrict and prevent users and groups from communicating with each other within and outside of your organization.

Shared channels are enabled by default in Teams. You can decide if people can create shared channels, share them with people outside your organization, and participate in external shared channels by creating a channel policy. When you create Information Barriers policies in your organization, Teams performs checks when configuring shared channels to verify that none of the existing channel members and any new users added to the shared channel violate Information Barriers policy conditions.

Use the following table to understand how Information Barriers policies affect communications and result in specific behaviors when configuring shared channels:

Expand table

Scenario	Information Barriers behavior
Share a channel with a user in your organization	If an Information Barriers policy prevents the user from communicating with shared channel members, the user doesn't appear in the user search and the channel isn't shared with the team. If an Information Barriers policy prevents adding the user, you see the following message: *We didn't find any matches. Talk to your IT admin about expanding the scope of your search.*
Share a channel in your organization with another team that you own	If an Information Barriers policy prevents users in the other team from communicating with shared channel members, the channel isn't shared with the team. If an Information Barriers policy prevents communications, you see the following message: *The channel can't be shared with this team. Pick another team or contact your admin for more info.*
Share a channel in your organization with another team that you don't own	If an Information Barriers policy prevents the team owner or any users of the other team from communicating with shared channel members, the channel can't be shared with the team.

Scenario	Information Barriers behavior
	If an Information Barriers policy prevents communications, you see the following message: *The channel can't be shared with this team. Pick another team or contact your admin for more info.*
Add a new user to the team when the team has shared channels with other teams	If an Information Barriers policy prevents the new user from communicating with members of the shared channel team, the user can't be added to the team. When you add a user to a team with six or more shared channels, you immediately add the user to the channel and support sharing. Sharing for the team and the previously shared channels stops if an Information Barriers policy finds the new user to be non-compliant. If an Information Barriers policy prevents adding the user, you see the following message: *Unable to add user due to an Information Barriers policy.*
Share a channel with an external team	Information Barriers policies on internal and external organizations don't restrict communications between users from the different organizations. You can share shared channels with external guests.

Next steps

- Information Barriers in Microsoft Teams: Understand how IB policies affect chats, meetings, and standard channels.
- Manage Information Barriers policies: Edit policies if shared channel restrictions need adjustment.
- Use Information Barriers with SharePoint: Configure IB on SharePoint sites associated with shared channels.

Use Information Barriers with SharePoint

Microsoft Purview Information Barriers (IB) are policies that prevent users from communicating and collaborating with each other. This article covers IB behavior in SharePoint.

For SharePoint, Information Barriers can determine and prevent the following kinds of unauthorized collaborations:

- Adding a user to a site
- User access to a site or site content
- Sharing a site or site content with other users

Information Barriers modes and SharePoint sites

Information Barriers modes help strengthen access, sharing, and membership of a site based on its IB mode and segments associated with the site.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

When you use Information Barriers with SharePoint, the following IB modes apply:

- **Open**: The site has no segments. Anyone can be invited to be a member. This mode is the default when a SharePoint site doesn't have segments.
- **Owner Moderated**: The site owner moderates collaboration between incompatible segments. Only the resource owner can add new members per their IB policy.
- **Implicit**: Microsoft Teams sets the site's IB mode when it provisions the site. A SharePoint Administrator or Global Administrator can't manage segments with the *Implicit* mode configuration.
- **Explicit**: Segments are associated with the site, either through user site creation or by a SharePoint Administrator. Only users matching the site's segments can access and share content.

Open mode

Open mode sharing behavior

When a site has no segments and you set the site's IB mode to *Open*:

- Users can share the site and its contents based on the IB policy applied to them. For example, if a user in HR is allowed to communicate with users in Research, the user can share the site with those users.

> **Tip**
>
> If you want to allow sharing of *Open* mode sites with mail-enabled security groups, see the **Allow sharing of Open mode sites with mail-enabled security groups** section in this article.

Open mode access behavior

For a user to access a SharePoint site that has no segment and the site's Information Barriers mode is set to *Open*:

- The user has site access permissions.

Owner Moderated mode

Owner Moderated sharing behavior

When you set a site's Information Barriers mode to *Owner Moderated*:

- The option to share with *Anyone with the link* is disabled.
- The option to share with *Company-wide link* is disabled.
- (For group connected sites) The site and its content can be shared with existing members.
- (For non-group connected sites) Only the site owner can share the site and its content, according to their IB policy.

Owner moderated access behavior

For a user to access a SharePoint site with the site's Information Barriers mode set to *Owner Moderated*:

- (For non-group connected sites) The user has site access permissions.
- (For group connected sites) The user must be a member of the Microsoft 365 group connected to the site.

Implicit mode

Implicit mode sharing behavior

When you set a site's Information Barriers mode to *Implicit*:

- The option to share with *Anyone with the link* is disabled.
- The option to share with *Company-wide link* is disabled.
- The site and its content can be shared with existing members via a sharing link.
- You can't add new users to the site directly. The Team owner should add users to the Team's group by using Microsoft Teams.

> **Note**
>
> If you enabled Information Barriers for SharePoint in your organization before March 15, 2022, see the **Enable SharePoint and OneDrive Information Barriers** section in this article.

Implicit mode access behavior

To access SharePoint sites that use Information Barriers mode set to *Implicit*:

- You're a member of the Microsoft 365 group connected to the site.
- If you're not a member of the Microsoft 365 group connected to the site, you can't access the site.
- The Information Barriers compliance assistant ensures the group membership is IB compliant.

> **Note**
>
> If you enabled Information Barriers for SharePoint in your organization before March 15, 2022, see the **Enable SharePoint and OneDrive Information Barriers** section in this article.

Explicit mode

Explicit mode sharing behavior

When you associate a site with segments and set the site's Information Barriers mode to *Explicit*:

- The option to share with *Anyone with the link* is disabled.
- The option to share with *Company-wide link* is disabled.
- You can share the site and its content only with users whose segment matches that of the site. For example, if you associate a site with the HR segment, you can share the site with just HR users (even though HR is compatible with both Sales and Research segments).
- You can add new users as site members only if their segment matches the segment of the site.

Explicit mode access behavior

To access SharePoint sites that use segments and site's Information Barriers mode is *Explicit*:

- Your segment matches a segment that's associated with the site.

  AND

- You have access permission to the site.

Non-segment users can't access a site associated with segments. They see an error message.

Allow apps running in app-only mode to access IB sites

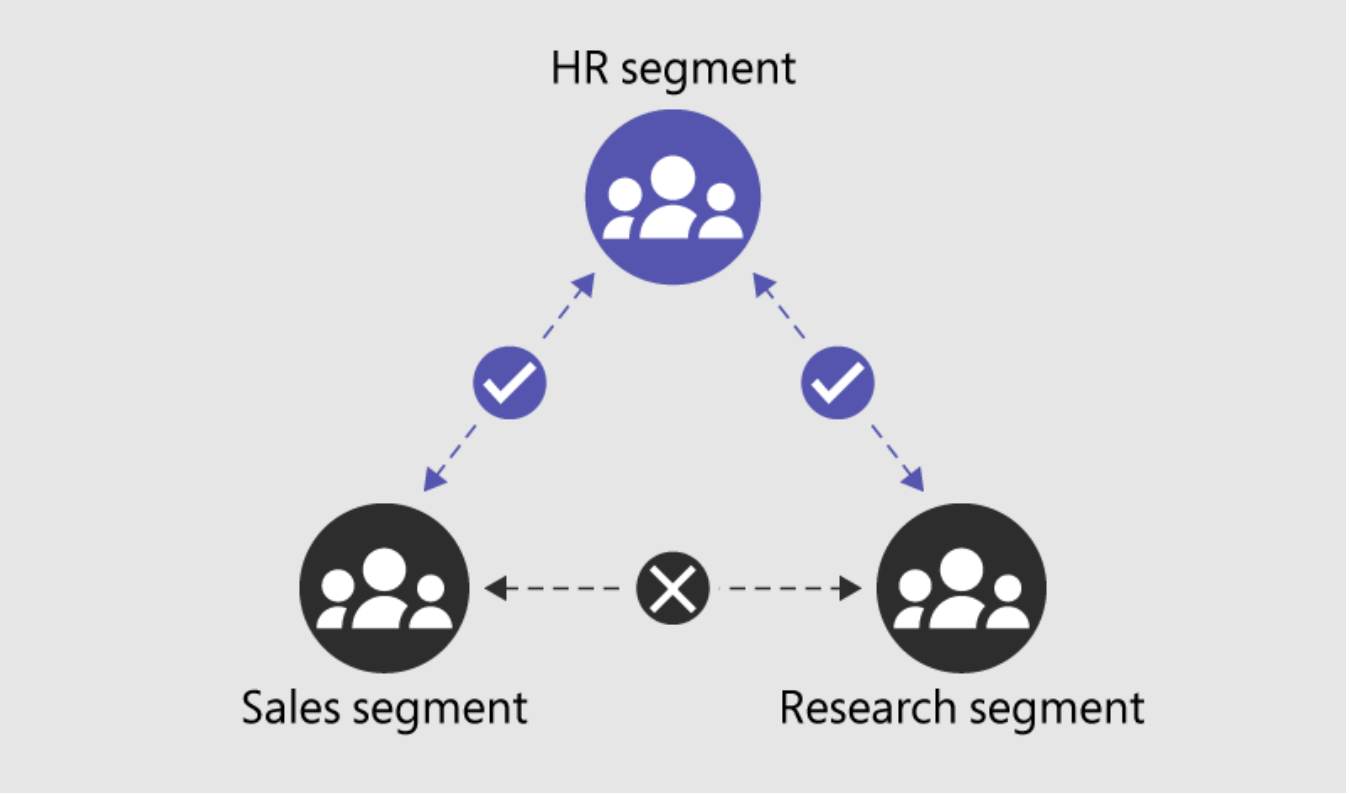
Many organizations use applications running in an app-only context in their organization. To allow these apps running in app-only mode to access IB protected sites, SharePoint admins can enable the opt-in capability.

> **ⓘ Important**
>
> Information Barriers policies might impact the applications accessing sites in app-only mode. We recommend that you enable the policy and then test the experience for the apps used in your organization.

To enable applications running in app-only mode to access IB sites, run the following command:

PowerShell

```
Set-SPOTenant -AppBypassInformationBarriers $true
```



If you enable Teams Meeting Recording or EDU Assignment application in your organization, run the following command to allow these applications to interact with IB protected sites:

PowerShell

```
Set-SPOTenant -AppOnlyBypassPeoplePickerPolicies $true
```

Example scenario

The following example illustrates three segments in an organization: HR, Sales, and Research. An IB policy blocks communication and collaboration between the Sales and Research segments. These segments are incompatible.

By using SharePoint Information Barriers, a SharePoint Administrator or Global Administrator can associate segments to a site to prevent the site from being shared with or accessed by users outside the segments. You can associate up to 100 compatible segments with a site. You associate the segments at the site level (previously called site collection level). The Microsoft 365 group connected to the site is also associated with the site's segment.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

In the previous example, the HR segment is compatible with both Sales and Research. However, because the Sales and Research segments are incompatible, you can't associate them with the same site.

Prerequisites

1. Make sure you meet the licensing requirements for Information Barriers.
2. Create IB policies that allow or block communication between the segments, and then set them to active. Create segments and define the users in each segment.
3. Wait 24 hours after configuring and activating your IB policies for the changes to propagate through your organization.
4. Complete the steps in the following sections to enable and manage SharePoint and OneDrive Information Barriers in your organization.

Enable SharePoint and OneDrive Information Barriers in your organization

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview **roles and permissions**.

SharePoint Administrators or Global Administrators can enable Information Barriers in SharePoint and OneDrive in your organization. Complete the following steps to enable Information Barriers for your organization:

1. You must use the latest version of the SharePoint Online Management Shell. If you installed a previous version of the SharePoint Online Management Shell, go to **Add or remove programs** and uninstall *SharePoint Online Management Shell*. Then, install the latest version. To learn more, see Get started with SharePoint Online Management Shell.

2. Connect to SharePoint Online as a Global Administrator or SharePoint Administrator in Microsoft 365. To learn how, see Getting started with SharePoint Online Management Shell.

3. Run the following command to enable Information Barriers in SharePoint and OneDrive:

   PowerShell

```
Set-SPOTenant -InformationBarriersSuspension $false
```

4. Wait for approximately 1 hour for the changes to take effect after you enable Information Barriers for SharePoint and OneDrive in your organization.

> **Note**
>
> If you enabled Information Barriers for SharePoint in your organization before March 15, 2022, the default access and sharing control for Implicit mode for Microsoft Teams-connected sites are based on the segments associated with the site.

To enable Microsoft 365 group-membership based access and sharing control for all Implicit mode Teams-connected sites in your tenant, run the following command:

PowerShell

```
Set-SPOTenant -IBImplicitGroupBased $true
```

> **Note**
>
> If you have Microsoft 365 Multi-Geo, run this command for each of your geolocations.

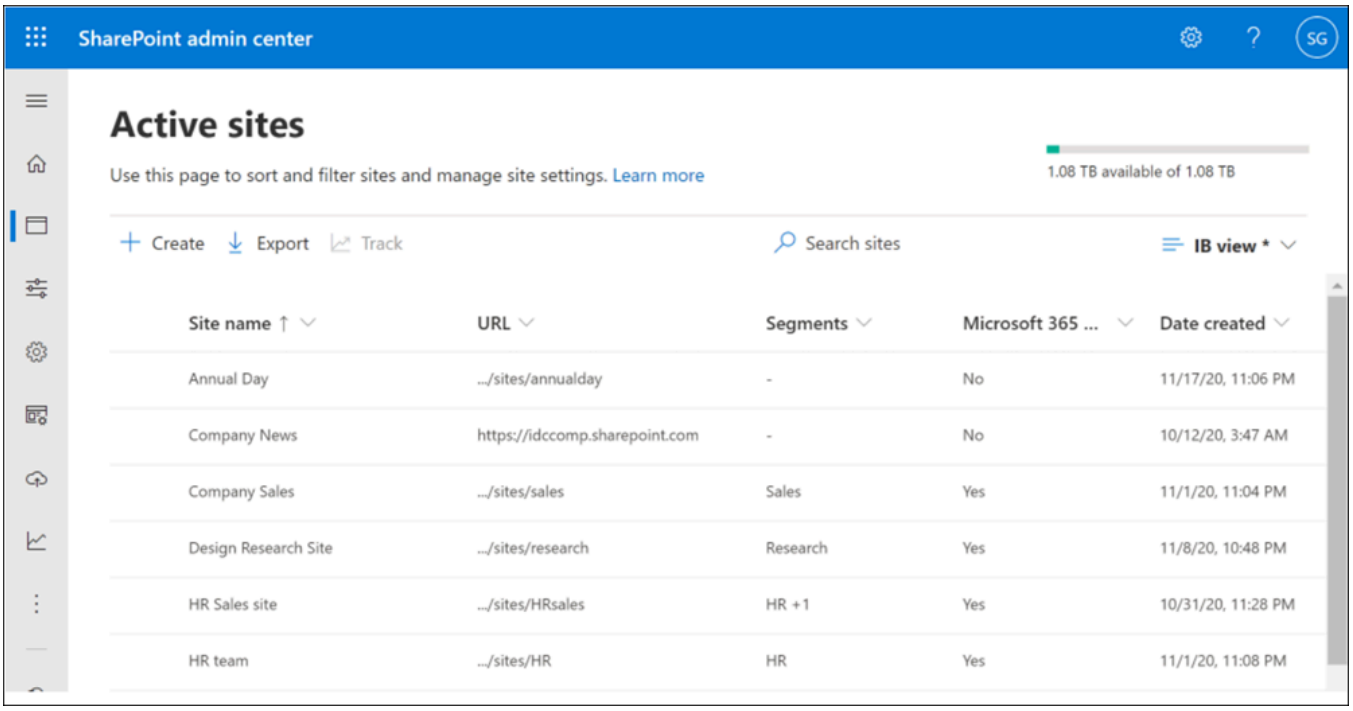
View and manage segments as an administrator

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

SharePoint Administrators or Global Administrators can view and manage segments on a SharePoint site. Your organization can have up to 5,000 segments, and users can be assigned to multiple segments.

> **Important**
>
> Support for 5,000 segments and assigning users to multiple segments is only available when your organization isn't in *Legacy* mode. Assigning users to multiple segments

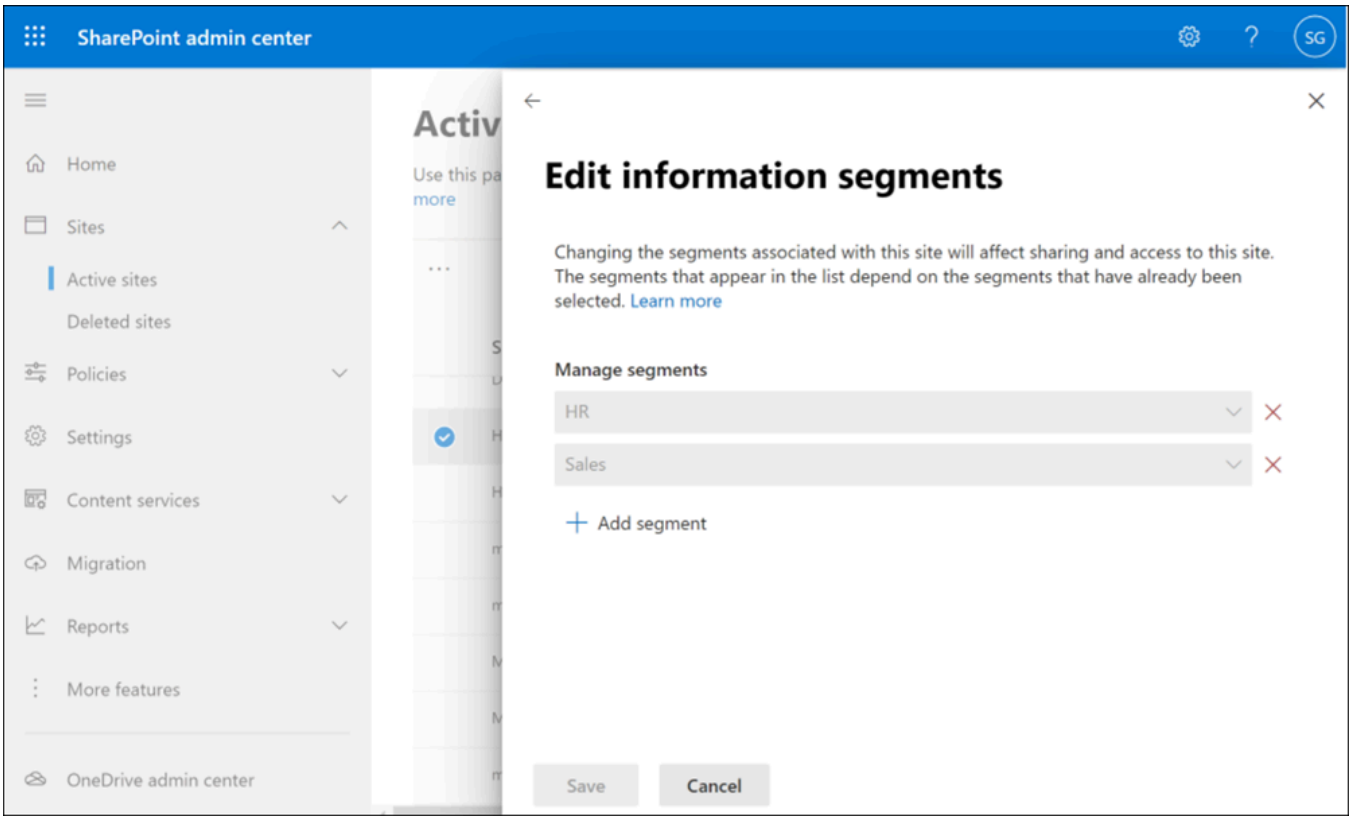
requires extra steps to change the Information Barriers mode for your organization. For more information, see Use multi-segment support in Information Barriers.



For organizations in *Legacy* mode, the maximum number of segments supported is 250, and users are restricted to being assigned to only one segment. Organizations in *Legacy* mode are eligible to upgrade to the newest version of Information Barriers in the future. For more information, see the Information Barriers roadmap.

View and manage Information Barriers segments as follows:

1. Use the SharePoint admin center to view and manage information segments



To view, edit, or remove information segments for a site, use **Active sites** in the SharePoint admin center.

The Segments column lists the first segment associated with the site and shows whether the site has other segments associated. Learn how to show or move this column.

To view the complete list of segments associated with a site, select the site name to open the details panel, and then select the **Settings** tab.

To edit the segments associated with the site, select **Edit**, add or remove segments, and then select **Save**.

2. Use SharePoint PowerShell to view and manage information segments on a site

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

1. Connect to Security & Compliance PowerShell as a Global Administrator.
2. Run the following command to get the list of segments and their GUIDs.

```
PowerShell
Get-OrganizationSegment | ft Name, EXOSegmentID
```

3. Save the list of segments.

Expand table

Name	EXOSegmentId
Sales	a9592060-c856-4301-b60f-bf9a04990d4d

Name	EXOSegmentId
Research	27d20a85-1c1b-4af2-bf45-a41093b5d111
HR	a17efb47-e3c9-4d85-a188-1cd59c83de32

4. You must use the latest version of the SharePoint Online Management Shell. If you installed a previous version of the SharePoint Online Management Shell, go to **Add or remove programs** and uninstall *SharePoint Online Management Shell*. Then, install the latest version. To learn more, see Get started with SharePoint Online Management Shell.

5. Connect to SharePoint Online as a Global Administrator or SharePoint Administrator in Microsoft 365. To learn how, see Getting started with SharePoint Online Management Shell.

6. Run the following command:

   PowerShell

   ```
   Set-SPOSite -Identity <site URL> -AddInformationSegment <segment GUID>
   ```

   For example:

   PowerShell

   ```
   Set-SPOSite -Identity https://contoso.sharepoint.com/sites/ResearchTeamSite -
   AddInformationSegment 27d20a85-1c1b-4af2-bf45-a41093b5d111
   ```

You see an error message if you attempt to associate a segment that isn't compatible with the site's existing segments.

> **Note**
>
> When you add a segment to a site, the site's IB mode is automatically updated to *Explicit*.

To remove a segment from a site, run the following command:

PowerShell

```
Set-SPOSite -Identity <site URL> -RemoveInformationSegment <segment GUID>
```

For example:

PowerShell

```
Set-SPOSite -Identity https://contoso.sharepoint.com/sites/ResearchTeamSite -
RemoveInformationSegment 27d20a85-1c1b-4af2-bf45-a41093b5d111
```

> **Note**
>
> When you remove all segments from a site, the site's IB mode is automatically updated to *Open*.

To view the segments of a site, run the following command to return the GUIDs of any segments associated with the site.

PowerShell

```
Get-SPOSite -Identity <site URL> | Select InformationSegment
```

3. Use the SharePoint REST API to view and manage information segments on a site

SharePoint includes a Representational State Transfer (REST) service that you can use to manage segments on a site. To access SharePoint resources and manage site segments by using REST, construct a RESTful HTTP request by using the OData standard. This request corresponds to the desired client object model application programming interface (API).

For more information about the SharePoint REST service, see Get to know the SharePoint REST service.

View and manage IB modes as an administrator with SharePoint PowerShell

To view the IB mode of a site, run the following command:

PowerShell

```
Get-SPOSite -Identity <site URL> | Select InformationBarriersMode
```

Owner Moderated mode scenario

You want to allow a Sales and Research user to collaborate on a SharePoint site in the presence of an HR user.

Owner Moderated is a mode applicable to sites (Teams-connected sites, non-group connected sites) that grants incompatible segment users access to the site. Only the site owner can invite incompatible segment users to the same site.

To update a site's mode to *Owner Moderated*, run the following PowerShell command:

PowerShell

```
Set-SPOSite -Identity <siteurl> -InformationBarriersMode OwnerModerated
```

You can't set the Owner Moderated IB mode on a site with segments. Remove the segments first before setting IB mode as Owner Moderated. Users who have site access permissions can access an Owner Moderated site. Only the site owner can share an Owner Moderated site and its contents according to their IB policy.

Auditing

You can view audit events in the Microsoft Purview portal to monitor IB activities. The system logs audit events for the following activities:

- Enabling Information Barriers for SharePoint and OneDrive
- Applying a segment to a site
- Changing the segment of a site
- Removing the segment of a site
- Applying Information Barriers mode to a site
- Changing Information Barriers mode of a site
- Disabling Information Barriers for SharePoint and OneDrive

For more information about SharePoint segment auditing in Microsoft 365, see Search the audit log in the Microsoft Purview portal.

Site creation and management by site owners

When a segmented user creates a SharePoint site, the site associates with the user's segment and the site's Information Barriers mode automatically sets to *Explicit*.

Site owners can add more segments to a SharePoint site that already has segments with the site's mode set as *Explicit*. Site owners can't remove added segments from sites. SharePoint Administrators need to remove added segments in your organization if needed.

When a non-segmented user creates a SharePoint site, the site doesn't associate with any segment and the site's Information Barriers mode automatically sets to *Open*.

When a SharePoint Administrator creates a SharePoint site from the SharePoint admin center, the site doesn't associate with any segment and the site's IB mode sets to *Open*.

To help site owners add a segment to a site, share the Associate information segments with SharePoint sites article with your SharePoint site owners.

Microsoft Teams sites

When you create a team in Microsoft Teams, you also automatically create a SharePoint site for the team's files. To protect the Microsoft Teams sites by using Information Barriers control, enable Information Barriers in SharePoint for your tenant.

Within 24 hours, the site's Information Barriers mode is automatically set to *Implicit* and segments associated with the team's members are associated with the site.

Microsoft Teams sites with the IB mode set to *Implicit* have site access and sharing based on Microsoft 365 group membership.

For example, users have access to the Microsoft Teams site if they're members of the Microsoft 365 group connected to the site. The Microsoft 365 group connected to the Team is IB compliant.

> **Note**
>
> If you enabled Information Barriers for SharePoint in your organization before March 15, 2022, the Teams-connected site's access and sharing is based on the segments of the site. For example:

- You can share the site and its content with users whose segment matches that of the site.
- Users can access the site and its content if they have the same segment as that of the site and have site access permissions.

To enable Microsoft 365 group membership-based access and sharing control for all *Implicit* mode sites in your organization, see Enable SharePoint and OneDrive Information Barriers in your organization.

Private channel and Information Barriers

When you enable SharePoint Information Barriers in your organization, any new private channel site automatically inherits its parent Microsoft Team's IB mode within 24 hours. The mode for a private channel is assigned as follows:

Expand table

Parent Team's IB mode	Private channel site's IB mode
Open	Open
Implicit or Owner Moderated	Implicit

The private channel site's IB mode governs access and sharing for the private channel site:

- Private channel site with *Open* Information Barriers mode
  - Access anyone with site access permissions
  - Sharing links are allowed per the site's existing sharing policy
  - People picker allows discoverability of user per the sharer's IB policy
- Private channel site with *Implicit* Information Barriers mode
  - Access only to users who are currently members of the private channel
  - Sharing by using **People with existing access link**

Private channel sites already configured in your organization have their Information Barriers mode set as *Open*. To configure existing private channel sites to *Implicit* mode, run the following cmdlet in the SharePoint PowerShell module:

PowerShell

```
Set-Sposite -Identity <site URL> -InformationBarriersMode Implicit
```

Learn more about managing Microsoft Teams connected teams sites.

Search

Users see search results from:

- **Segment associated sites**: When the site's segment matches the user's segment and the user has site access permission. For example, a site with *Explicit* mode.
- **Non-segmented sites**: When the user has existing access to the content or site. For example, sites with *Open*, *Owner Moderated*, or *Implicit* mode. When the user selects the search result to open the content in the site, the user is denied access if they don't match the site's IB policy.

Tenant wide search and Copilot experience

Users experience is as follows:

- **Segment associated sites**: When the site's segment matches the user's segment and the user has site access permission. For example, a site with *Explicit* mode.
- **Open mode sites:** When the user has existing access to the content or site.
- **Implicit and Owner moderated mode sites:**
  - When the user has existing access to the content or site.
  - If the user had access to the site and content prior to the policy application, they continue to see the site and its contents in search and Copilot results. However, when attempting to open the content, they're denied access if they don't comply with the site's IB policy.

Effects of changes to user segments

If a SharePoint site owner or site member's segment changes, they retain access to the site or content according to the site's IB mode:

- **Open mode**: User can access the site if they have existing site access permissions.
- **Owner Moderated**: User can access the site if they have existing site access permissions.
- **Implicit Mode**: If the user is a member of the Microsoft 365 group, they retain access to the site.
- **Explicit Mode**: If the user's new segment matches the site's segment and user has site access permissions, they retain access to the site.

Effects of changes to existing IB policies

If a compliance administrator changes an existing IB policy, the change might affect the compatibility of the segments associated with a site (in *Explicit* or *Implicit* mode*). For example, segments that were once compatible might no longer be compatible.

By using the Information Barriers policy compliance report, the SharePoint Administrator can view the list of sites where segments are no longer compatible. For more information, see Learn how to create an Information Barriers policy compliance report in PowerShell.

To manage out of compliance sites:

- In *Explicit* mode, a SharePoint Administrator must change the associated segments to bring them into IB compliance.
- In *Implicit* mode, a SharePoint Administrator can't manage segments directly. The Teams admin should manage the Team's membership to bring the Teams membership roster and segments into IB compliance.

How to suspend SharePoint and OneDrive Information Barriers in your organization

If your organization wants to temporarily suspend Information Barriers on SharePoint, use SharePoint Online Management Shell and the Set-Spotenant cmdlet.

To suspend Information Barriers, run the following command:

```
PowerShell
Set-SPOTenant -InformationBarriersSuspension $true
```

> **Note**
>
> If you have Microsoft 365 Multi-Geo, run this command for each of your geo-locations.

Allow sharing of Open mode sites with mail-enabled security groups

IB supports an opt-in capability available in the SharePoint PowerShell module for sites in *Open* mode to be shared with mail-enabled security groups for site permissions, sharing, and audience targeting. This capability is only supported in *Open* mode sites. SharePoint admins can enable this support in your organization. Ensure the security group membership is IB compliant.

Before enabling group support, verify that you meet the following prerequisites:

- Your organization has only IB *Block* policies.
- Your organization is enabled for SharePoint IB (see this section in this article).

To configure mail-enabled security group support in *Open* mode sites, run the following command:

```
PowerShell
Set-SPOTenant -ShowPeoplePickerGroupSuggestionsForIB $true
```

- Information Barriers in OneDrive

Last updated on 03/30/2026

Use Information Barriers with OneDrive

Microsoft Purview Information Barriers are policies that prevent users from communicating and collaborating with each other. This article covers IB behavior in OneDrive.

For OneDrive, Information Barriers can determine and prevent the following kinds of unauthorized collaborations:

- User access to OneDrive or stored content
- Sharing OneDrive or stored content with other users

Information Barriers modes and OneDrive

When you enable Information Barriers on SharePoint and OneDrive, you automatically protect the OneDrive of segmented users with IB policies. Information Barriers modes help strengthen access, sharing, and membership of a OneDrive site based on its IB mode and segments associated with the OneDrive.

When you use Information Barriers with OneDrive, the following IB modes apply:

- **Open**: The OneDrive has no segments. This mode is the default when a non-segmented user provisions their OneDrive.
- **Owner Moderated**: The OneDrive is used for collaboration with incompatible users in the presence of the site owner/moderator. See this section for details.
- **Explicit**: The user's segment and other compatible segments are associated with the OneDrive. This mode is the default when a segmented user provisions their OneDrive within 24 hours of enablement.
- **Mixed**: The segmented user's OneDrive is allowed to be shared with unsegmented users. This mode is an opt-in mode that the SharePoint admin can set on a OneDrive of a segmented user.

> ⓘ **Note**
>
> Starting July 12, 2022, *Inferred* mode changed to *Mixed* mode. The functionality for the mode remains the same.

Open mode

Open mode sharing behavior

When a OneDrive has no segments and IB mode as *Open*:

- The user can share files and folders based on the IB policy applied to the user and the sharing setting for the OneDrive.

Open mode access behavior

For a user to access content in a OneDrive with no segments and IB mode as *Open*:

- The files must be shared with the user.

Owner Moderated mode

Owner Moderated sharing behavior

When a OneDrive has Information Barriers mode set to *Owner Moderated*:

- The option to share with *Anyone with the link* is disabled.
- The option to share with *Company-wide link* is disabled.
- You can share the site and its content with existing members.
- Only the OneDrive owner can share the site and its content, following their IB policy.

Owner Moderated access behavior

For a user to access a OneDrive with Information Barriers mode set to *Owner Moderated*:

- The user has site access permissions.

Explicit mode

Explicit mode sharing behavior

When a OneDrive has Information Barriers segments and the mode is set to *Explicit*:

- The option to share with *Anyone with the link* is disabled.
- The option to share with *Company-wide link* is disabled.
- You can share files and folders only with users whose segment matches that of the OneDrive.

Explicit mode access behavior

For a user to access content in a OneDrive with segments and IB mode set to *Explicit*:

1. The user's segment matches a segment associated with the OneDrive.

   AND

2. The files are shared with the user.

> **Note**
>
> By default, non-segment users can access shared OneDrive files only from other non-segment users with IB modes set to *Open*. They can't access shared files from OneDrive that have segments applied and the IB mode is *Explicit*.

Mixed mode

Mixed mode sharing behavior

When a OneDrive uses Information Barriers segments and the mode is set to *Mixed*:

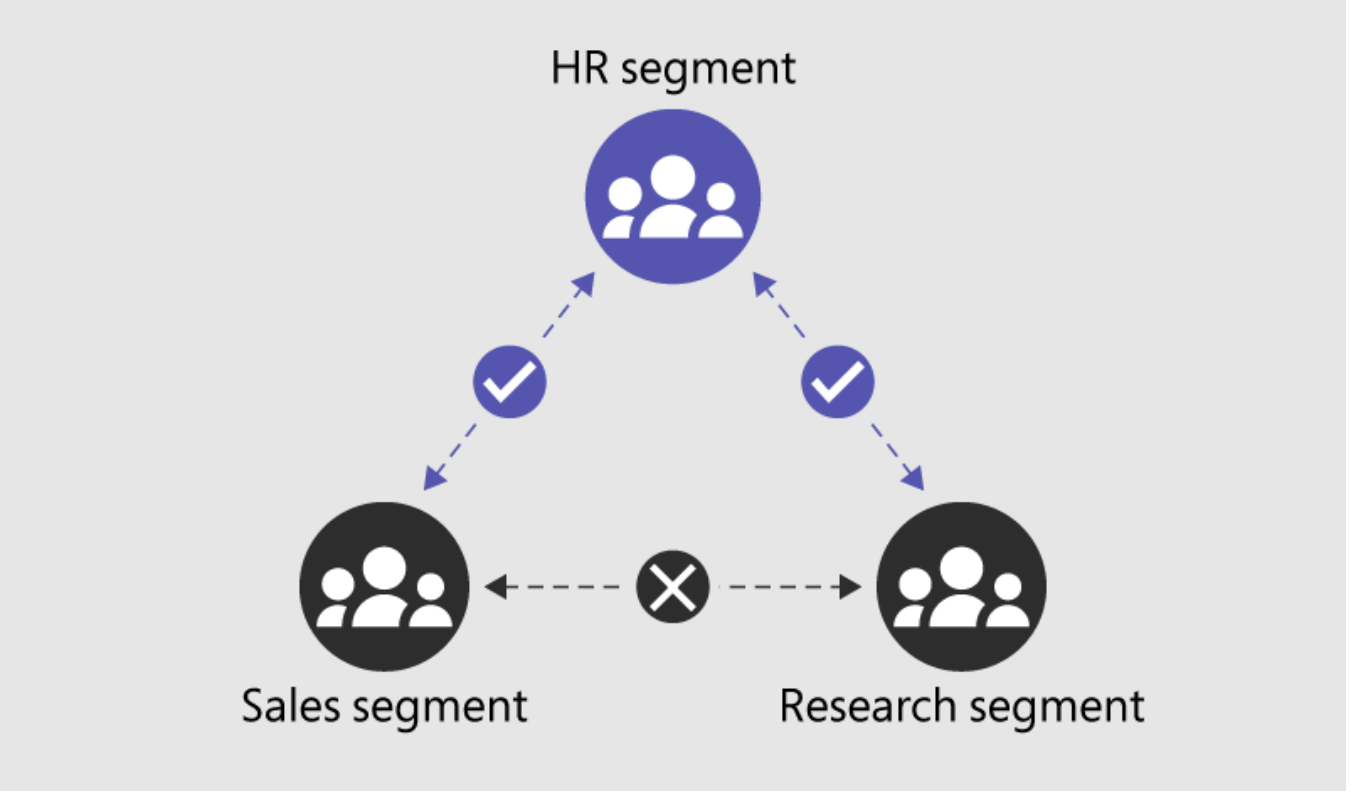
- The option to share with *Anyone with the link* is disabled.
- The option to share with *Company-wide link* is disabled.
- You can share files and folders with users whose segment matches that of the OneDrive and unsegmented users in the tenant.

Mixed mode access behavior

For a segmented user to access content in a OneDrive with segments and IB mode set to *Mixed*:

1. The user's segment matches a segment associated with the OneDrive.

   AND



2. The files are shared with the user.

For an unsegmented user to access content in a OneDrive with segments and IB mode set to *Mixed*:

- The user has site access permissions.

Example scenario

The following example illustrates three segments in an organization: HR, Sales, and Research. You define an IB policy that blocks communication and collaboration between the Sales and Research segments.

By using Information Barriers in OneDrive, when you apply a segment to a user, the segment automatically associates with the user's OneDrive within 24 hours. The OneDrive also associates with other segments that are compatible with the user's segment and with each other. A OneDrive can have up to 100 associated segments. A global or SharePoint admin can manage these segments by using PowerShell, as described later in the section Associate or remove additional segments on a user's OneDrive.

The following table shows the effects of this example configuration:

Expand table

Components	HR users	Sales users	Research users	Non-segment users
Segments associated with OneDrive	HR	Sales, HR	Research, HR	None
IB mode on OneDrive	Explicit	Explicit	Explicit	Open
OneDrive content can be shared with	HR only	Sales and HR	Research and HR	Anyone based on the sharing settings selected
OneDrive content can be accessed by	HR only	Sales and HR	Research and HR	Anyone with whom the content is shared

Enable SharePoint and OneDrive Information Barriers in your organization

You configure enabling Information Barriers for SharePoint and OneDrive in a single action. You can't enable Information Barriers for the services separately. For more information, see Enable SharePoint and OneDrive Information Barriers in your organization. After you enable Information Barriers for SharePoint and OneDrive, continue with the OneDrive guidance in this article.

Prerequisites

1. Make sure you meet the licensing requirements for Information Barriers.
2. Create IB policies that allow or block communication between the segments and activate the policies. Create segments and define the users in each.
3. After you configure and activate your IB policies, wait 24 hours for the changes to propagate through your organization.
4. Enable Information Barriers for OneDrive. You configure enabling Information Barriers for SharePoint and OneDrive in a single action. You can't enable these services separately. For more information, see the guidance and steps in the Use Information Barriers with SharePoint article.
5. Complete the steps in the following sections to customize and manage Information Barriers for OneDrive in your organization.

Use PowerShell to view the segments associated with a OneDrive

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

A global admin or SharePoint admin can view and change the segments associated with a user's OneDrive. Your organization can have up to 5,000 segments, and users can be assigned to multiple segments.

> **Important**

Support for 5,000 segments and assigning users to multiple segments is only available when your organization isn't in *Legacy* mode. Assigning users to multiple segments requires extra steps to change the Information Barriers mode for your organization. For more information, see Use multi-segment support in Information Barriers.

For organizations in *Legacy* mode, the maximum number of segments supported is 250, and users are restricted to being assigned to only one segment. Organizations in *Legacy* mode are eligible to upgrade to the newest version of Information Barriers in the future. For more information, see the Information Barriers roadmap.

1. Connect to Security & Compliance PowerShell as a global admin.
2. Run the following command to get the list of segments and their GUIDs.

```
PowerShell
Get-OrganizationSegment | ft Name, EXOSegmentID
```

3. Save the list of segments.

Expand table

Name	EXOSegmentId
Sales	a9592060-c856-4301-b60f-bf9a04990d4d
Research	27d20a85-1c1b-4af2-bf45-a41093b5d111
HR	a17efb47-e3c9-4d85-a188-1cd59c83de32

4. You must use the latest version of the SharePoint Online Management Shell. If you installed a previous version of the SharePoint Online Management Shell, go to **Add or remove programs** and uninstall *SharePoint Online Management Shell*. Then, install the latest version. To learn more, see Get started with SharePoint Online Management Shell.
5. Connect to SharePoint as a global admin or SharePoint admin in Microsoft 365. To learn how, see Getting started with SharePoint Online Management Shell.
6. Run the following command:

```
PowerShell
Get-SPOSite -Identity <site URL> | Select InformationSegment
```

For example:

PowerShell

```
Get-SPOSite -Identity https://contoso-
my.sharepoint.com/personal/John_contoso_onmicrosoft_com | Select
InformationSegment
```

Manage segments on a user's OneDrive

> ⚠ **Warning**
>
> If the segments associated with a user's OneDrive don't match the segment you apply to the user, the user can't access their OneDrive. Don't associate any segments with the OneDrive of a non-segment user.

> ⓘ **Note**
>
> Any changes you make are overwritten if the user's segment changes.

To associate a segment with a OneDrive, run the following command in the SharePoint Online Management Shell.

PowerShell

```
Set-SPOSite -Identity <site URL> -AddInformationSegment <segment GUID>
```

For example:

PowerShell

```
Set-SPOSite -Identity https://contoso-
my.sharepoint.com/personal/John_contoso_onmicrosoft_com -AddInformationSegment
27d20a85-1c1b-4af2-bf45-a41093b5d111
```

When you add segments to a OneDrive, the site's IB mode automatically updates to *Explicit*. An error appears if you attempt to associate a segment that isn't compatible with the existing segments on the OneDrive.

To remove a segment from a OneDrive, run the following command.

PowerShell

```
Set-SPOSite -Identity <site URL> -RemoveInformationSegment <segment GUID>
```

For example:

PowerShell

```
Set-SPOSite -Identity https://contoso-
my.sharepoint.com/personal/John_contoso_onmicrosoft_com -RemoveInformationSegment
27d20a85-1c1b-4af2-bf45-a41093b5d111
```

If you remove all the segments of a OneDrive site, the IB mode of the OneDrive automatically updates to *Open*.

Manage the IB mode of a user's OneDrive (preview)

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

To view the IB mode of a OneDrive site, run the following command in the SharePoint Online Management Shell as a SharePoint admin or global administrator:

PowerShell

```
Get-SPOSite -Identity <site URL> | Select InformationBarriersMode
```

For example:

PowerShell

```
Get-SPOSite -Identity https://contoso-
my.sharepoint.com/personal/John_contoso_onmicrosoft_com | Select
InformationBarriersMode
```

A SharePoint admin or global administrator can also manage the IB mode of a OneDrive site to meet the needs of your organization by using new IB modes:

Owner Moderated mode example

Allow an incompatible segment user access to a OneDrive. For example, you want to allow HR user's OneDrive to be accessed by both Sales and Research segment users in your tenant.

Owner Moderated is a mode applicable to OneDrive sites that allows incompatible segment users to access OneDrive in the presence of a moderator/owner. Only the site owner has the capability to invite incompatible segment users on the same site.

To update a OneDrive site IB mode to *Owner Moderated*, run the following PowerShell command:

PowerShell

```
Set-SPOSite -Identity <siteurl> -InformationBarriersMode OwnerModerated
```

You can't set the Owner Moderated IB mode on a site with segments. Remove the segments before setting the IB mode as Owner Moderated. Users with site access permissions can access an Owner Moderated site. Only the site owner can share an Owner Moderated OneDrive and its contents per their IB policy.

Mixed mode example

Allow unsegmented users to access OneDrive associated with segments. For example, you want to allow HR users' OneDrive to be accessed by HR segment and unsegmented users in your tenant. Mixed mode applies to OneDrive sites that allow segmented and unsegmented users to access OneDrive.

To update a OneDrive site's IB Mode to Mixed, run the following PowerShell command:

PowerShell

```
Set-SPOSite -Identity <siteurl> -InformationBarriersMode Mixed
```

You can't set mixed IB mode on a site without segments. Add segments before setting the IB mode as mixed.

Effects of changes to user segments

If a user's segment changes, the OneDrive segment and IB mode automatically update within 24 hours as described in the OneDrive Information Barriers section.

Example 1: User's segment updated from Research to Sales, the user's OneDrive updates as follows within 24 hours:

- Segment: Sales, HR
- IB mode: *Explicit*

Example 2: User's segment updated from HR to None

- Segment: None
- IB mode: *Open*

Effects of changes to IB policies

If a compliance administrator changes an existing policy, the change might affect the compatibility of the segments associated with the OneDrive.

For example, segments that were once compatible might no longer be compatible. A SharePoint admin must change the segments associated with an affected site. For more information, see create an Information Barriers policy compliance report in PowerShell.

If you change a policy after users share files, the sharing links work only if the user attempting to access the shared files has a segment applied that matches a segment associated with the OneDrive.

Auditing

Audit events are available in the Microsoft Purview portal to help you monitor IB activities. The system logs audit events for the following activities:

- Enabling Information Barriers for SharePoint and OneDrive
- Applying segment to site
- Changing segment of site
- Removing segment of site
- Applying Information Barriers mode to site
- Changing Information Barriers mode of site
- Disabling Information Barriers for SharePoint and OneDrive

For more information about OneDrive segment auditing in Microsoft 365, see Search the audit log.

SharePoint and OneDrive insights reports (preview)

The insights report in Information Barriers (IB) helps you identify and discover usage patterns across SharePoint sites and OneDrive accounts in your organization. As an administrator, you can use PowerShell to create and view reports that identify top sites and their modes, so you can apply suitable controls for the sites.

The insights report provides the following information for the top 100 most actively used SharePoint sites and OneDrive accounts in your organization:

Expand table

Report section	Description	Applies to
Explicit mode section	Top restrictive sites with highest collaboration between IB users	SharePoint sites and OneDrive accounts
Implicit mode section	Top sites with highest collaboration between compatible users	SharePoint sites only
Mixed mode section	Top accounts with collaboration between segmented and unsegmented users	OneDrive accounts only
Mode Distribution section	The number and percentage of modes across all sites and accounts	SharePoint sites and OneDrive accounts
Open mode section	Top least restrictive sites	SharePoint sites and OneDrive accounts
Owner Moderated mode section	Top sites with highest collaboration between IB users and non-IB users	SharePoint sites and OneDrive accounts

Prerequisites

- Your organization must have Information Barriers enabled for SharePoint and OneDrive to create the insights report. To enable IB in SharePoint and OneDrive for your organization, see Use Information Barriers with SharePoint.
- You must use the latest version of the SharePoint Online Management Shell. If you installed a previous version of the SharePoint Online Management Shell, go to **Add or remove programs** and uninstall *SharePoint Online Management Shell*. Then, install the latest version. To learn more, see Get started with SharePoint Online Management Shell.

Create the insights report

Before you can run specific queries for Information Barriers details, you must first create a report. After the report finishes successfully, you can run specific detail reports.

The system supports one insights report for every 24-hour period. When you create the next report, it overwrites the previous report. For example, if you create an insights report on April 25, 2023, at 4:10 PM, you can't create another insights report until after 4:10 PM on April 26, 2023.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

To create the insights report, complete the following steps:

1. Connect to SharePoint Online as a global administrator or SharePoint administrator in Microsoft 365.
2. Run the following PowerShell cmdlet and accept the confirmation prompt to create the insights report:

   ```PowerShell
   Start-SPOInformationBarriersInsightsReport
   ```

   > **Note**
   >
   > Depending on the number of SharePoint sites and OneDrive accounts in your organization, it might take up to one hour to create this report.

   You can automate acceptance of the confirmation prompt when creating the insights report by appending the *-Yes* parameter to the cmdlet. For example, `Start-SPOInformationBarriersInsightsReport -Yes`.

3. Run the following PowerShell cmdlet to view the status of the insights report:

   ```PowerShell
   Get-SPOInformationBarriersInsightsReport
   ```

The following example shows the information returned for the insights report:

```text
State: Completed
Id: ec65a1cf-9b1a-48c2-a1b4-f923ac4c0776
StartTimeInUtc: 4/25/2023 4:10:16 PM
CompleteTimeInUtc: 4/25/2023 4:10:25 PM
QueuedTimeInUtc: 4/25/2023 4:06:47 PM
```

The report is ready to view or download when the *State* value is *Completed*. Other *State* values include:

- *Not Started*: State when the insights report hasn't started.
- *In Progress*: State when the insights report is in progress.
- *Error*: State when the insights report failed.

Insights reports for SharePoint sites

View a summary of modes with results for SharePoint sites

To view a summary of the modes with results for SharePoint sites, use the following cmdlet syntax to view insights from the report:

```PowerShell
Get-SPOInformationBarriersInsightsReport -reportId <ID>
```

Example:

```PowerShell
Get-SPOInformationBarriersInsightsReport -reportId ec65a1cf-9b1a-48c2-a1b4-
f923ac4c0776
```

Example results:

```text
Content: Explicit, Implicit, Open, OwnerModerated, ModeDistribution
State: Completed
Id: ec65a1cf-9b1a-48c2-a1b4-f923ac4c0776
StartTimeInUtc: 4/25/2023 4:10:16 PM
```

```
CompleteTimeInUtc: 4/25/2023 4:10:25 PM
QueuedTimeInUtc: 4/25/2023 4:06:47 PM
```

In this example, the insights report results are displayed for SharePoint sites included in the organization with an ID of *ec65a1cf-9b1a-48c2-a1b4-f923ac4c0776*. The values in the *Content* line represent the modes that have results in the report. If a mode (applicable to SharePoint) isn't listed, there aren't any SharePoint sites in the organization with that mode.

View the details for a specific mode for SharePoint sites

To view details about a specific mode with results for SharePoint sites, use the following cmdlet syntax to view insights from the insights report:

PowerShell

```
Get-SPOInformationBarriersInsightsReport -reportId <ID> -section <Mode>
```

Example:

PowerShell

```
Get-SPOInformationBarriersInsightsReport -reportId ec65a1cf-9b1a-48c2-a1b4-
f923ac4c0776 -section Explicit
```

Example results:

text

```
SiteName: Contoso Budget Planning
SiteURL: https://contoso.sharepoint.com/sites/ContosoBudgetPlanning
Site Owner: User1
LastActivity: 4/25/2023 4:10:16 PM
IBMode: Explicit

SiteName: Contoso Training Budgets
SiteURL: https://contoso.sharepoint.com/sites/ContosoTrainingBudgets
Site Owner: User2
LastActivity: 4/25/2023 4:10:16 PM
IBMode: Explicit

SiteName: Contoso Viewpoint Project
SiteURL: https://contoso.sharepoint.com/sites/ContosoViewpointProject
Site Owner: User3
LastActivity: 4/25/2023 4:10:16 PM
IBMode: Explicit
```

View the details for the mode distribution for SharePoint sites

To view details about the mode distribution with results for SharePoint sites, use the following cmdlet syntax to view insights from the insights report:

```PowerShell
Get-SPOInformationBarriersInsightsReport -reportId <ID> -section <ModeDistribution>
```

Example:

```PowerShell
Get-SPOInformationBarriersInsightsReport -reportId ec65a1cf-9b1a-48c2-a1b4-f923ac4c0776 -section ModeDistribution
```

Example results:

```text
Total site count: 10000
Owner Moderated SiteCount: 500 SitePercentage: 5
Open SiteCount: 1682 SitePercentage: 16.82
Explicit SiteCount: 3628 SitePercentage: 36.82
Implicit SiteCount: 4190 SitePercentage: 41.9
```

Insights reports for OneDrive accounts

View a summary of modes with results for OneDrive accounts

To view a summary of the modes with results for OneDrive accounts, use the following cmdlet syntax to view insights from the insights report:

```PowerShell
Get-SPOInformationBarriersInsightsReport -reportId <ID> -service <OneDrive>
```

Example:

```PowerShell
Get-SPOInformationBarriersInsightsReport -reportId ec65a1cf-9b1a-48c2-a1b4-f923ac4c0776 -service OneDrive
```

Example results:

```text
Content: Explicit, Mixed, Open, OwnerModerated, ModeDistribution
State: Completed
Id: ec65a1cf-9b1a-48c2-a1b4-f923ac4c0776
StartTimeInUtc: 4/25/2023 4:10:16 PM
CompleteTimeInUtc: 4/25/2023 4:10:25 PM
QueuedTimeInUtc: 4/25/2023 4:06:47 PM
```

In this example, you see the insights report results for OneDrive accounts included in the organization with an ID of *ec65a1cf-9b1a-48c2-a1b4-f923ac4c0776*. The values in the *Content* line represent the modes that have results in the report. If a mode (applicable to OneDrive) isn't listed, there aren't any OneDrive accounts in the organization with that mode.

View the details for a specific mode for OneDrive accounts

To view details about a specific mode with results for OneDrive accounts, use the following cmdlet syntax to view insights from the insights report:

```PowerShell
Get-SPOInformationBarriersInsightsReport -reportId <ID> -service OneDrive -section
<Mode>
```

Example:

```PowerShell
Get-SPOInformationBarriersInsightsReport -reportId ec65a1cf-9b1a-48c2-a1b4-
f923ac4c0776 -service OneDrive -section Open
```

Example results:

```text
SiteName: User1
SiteURL: https://spdfcontoso-
my.sharepoint.com/personal/user1_spdfcontoso_onmicrosoft_com
Site Owner: user1@spdfcontoso.onmicrosoft.com
LastActivity: 4/25/2023 4:10:16 PM
IBMode: Open

SiteName: User2
SiteURL: https://spdfcontoso-
my.sharepoint.com/personal/user2_spdfcontoso_onmicrosoft_com
```

```
Site Owner: user2@spdfcontoso.onmicrosoft.com
LastActivity: 4/25/2023 4:10:16 PM
IBMode: Open

SiteName: User3
SiteURL: https://spdfcontoso-
my.sharepoint.com/personal/user3_spdfcontoso_onmicrosoft_com
Site Owner: user3@spdfcontoso.onmicrosoft.com
LastActivity: 4/25/2023 4:10:16 PM
IBMode: Open
```

View the details for the mode distribution for OneDrive accounts

To view details about the mode distribution with results for OneDrive accounts, use the following cmdlet syntax to view insights from the insights report:

PowerShell

```
Get-SPOInformationBarriersInsightsReport -reportId <ID> -service OneDrive -section
<ModeDistribution>
```

Example:

PowerShell

```
Get-SPOInformationBarriersInsightsReport -reportId ec65a1cf-9b1a-48c2-a1b4-
f923ac4c0776 -service OneDrive -section ModeDistribution
```

Example results:

text

```
Total site count: 19305
Owner Moderated SiteCount: 167 SitePercentage: 0.87
Mixed SiteCount: 4881 SitePercentage: 25.28
Explicit SiteCount: 4910 SitePercentage: 25.43
Open SiteCount: 9347 SitePercentage: 48.42
```

Download the results of the insights report

To download the full results of a specific insights report for SharePoint sites, use the following cmdlet syntax:

```
```

PowerShell

```
Get-SPOInformationBarriersInsightsReport -reportId <ID> -section <report you want to download> -action Download -FullDetails
```

The report automatically exports as a .csv file with a file name of *SharePoint_the name of the report type*. For example, if you download the *Explicit* report, the file name is *SharePoint_Explicit.csv*. The *-FullDetails* property supports downloading up to 1 million records for SharePoint sites.

To download the results of a specific insights report for OneDrive accounts, use the following cmdlet syntax:

PowerShell

```
Get-SPOInformationBarriersInsightsReport -reportId <ID> -service OneDrive -section <report you want to download> -action Download
```

The report automatically exports as a .csv file with a file name of *OneDrive_the name of the report type*. For example, if you download the *Explicit* report, the file name is *OneDrive_Explicit.csv*.

To rename the report or export to custom locations, use standard PowerShell parameters. For more information, see the PowerShell documentation.

Audit activities for the insights report

You can view audit events for the insights report in the Microsoft Purview portal. For more information about the activities logged, see Information Barriers activities.

Last updated on 03/30/2026

Create an Information Barriers policy compliance report

If a compliance administrator changes an existing Information Barriers policy, the change might affect the compatibility of segments already associated with a site.

For example, a policy might allow communication and collaboration between the Sales and Research segments. Later, the policy might not allow communication and collaboration between these segments. The segments are incompatible and shouldn't be associated with the same site.

By using the SharePoint Information Barriers policy compliance report, SharePoint administrators can view the list of sites that don't comply with existing policies. The report covers these sites:

- Microsoft 365 group-connected team sites that aren't connected to Microsoft Teams
- Communication sites
- Modern team sites that aren't connected to Microsoft 365 groups
- OneDrive
- User-owned SharePoint Embedded containers

The report displays the list of sites that don't comply with the existing policies that you recently updated. For each noncompliant site, it shows compatible segments, incompatible segments, and invalid segments (those segments that no longer exist).

If a OneDrive or user-owned SharePoint Embedded container doesn't comply, this report lets you update its segments to be compliant with the latest IB policies in your organization.

> **Note**
>
> You only need to run this report if you change Information Barriers policies. Depending on the number of sites in your organization, it can take a long time for this report to run.

Run the report

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your

organization. Learn more about Microsoft Purview roles and permissions.

1. You must use the latest version of the SharePoint Online Management Shell. If you installed a previous version of the SharePoint Online Management Shell, go to **Add or remove programs** and uninstall *SharePoint Online Management Shell*. Then, install the latest version. To learn more, see Get started with SharePoint Online Management Shell.

2. Connect to SharePoint Online as a Global Administrator or SharePoint Administrator in Microsoft 365. For more information, see Getting started with SharePoint Online Management Shell.

3. Run the following command to build the report:

   PowerShell

   ```
   Start-SPOInformationBarriersPolicyComplianceReport
   ```

   Or, to automatically update any noncompliant OneDrive accounts when you build the report, run:

   PowerShell

   ```
   Start-SPOInformationBarriersPolicyComplianceReport -UpdateOneDriveSegments
   ```

   Or, to automatically update any noncompliant user-owned SharePoint Embedded containers when you build the report, run:

   PowerShell

   ```
   Start-SPOInformationBarriersPolicyComplianceReport -
   UpdateUserOwnedContainerSegments
   ```

4. Run the following command to view the status of the task:

   PowerShell

   ```
   Get-SPOInformationBarriersPolicyComplianceReport
   ```

   The command returns the following set of information:

   text

```
State: Completed
Id: beedfc3e-850c-4ca2-9ae0-7eacbe529d77
StartTimeInUtc: 9/21/2026 1:11:32 AM
CompleteTimeInUtc: 9/21/2026 1:11:33 AM
QueuedTimeInUtc: 9/21/2026 1:07:11 AM
UpdateOneDriveSegments: False
UpdateUserOwnedContainerSegments: True
```

5. Run the following command to view the report:

PowerShell

```
Get-SPOInformationBarriersPolicyComplianceReport -reportid <ID>
```

(Where *ID* is the report's ID from the previous step.)

The command returns the following set of information for each site:

text

```
Content: {8d7c4a12-5f6e-4b8d-9a31-c7e2f4a9d6b5}
HasNonCompliantSites: True
State: Completed
Id: beedfc3e-850c-4ca2-9ae0-7eacbe529d77
StartTimeInUtc: 9/21/2026 1:11:32 AM
CompleteTimeInUtc: 9/21/2026 1:11:33 AM
QueuedTimeInUtc: 9/21/2026 1:07:11 AM
UpdateOneDriveSegments: False
UpdateUserOwnedContainerSegments: True
```

The **Content** row lists the sites that aren't compliant. If all sites are compliant, the **Content** row is empty and **HasNonCompliantSites** is `False`.

6. Run the following command to view details about the noncompliant segments associated with each site:

PowerShell

```
$report = Get-SPOInformationBarriersPolicyComplianceReport -reportid <ID>
$report.Content
```

(Where *ID* is the report's ID from the previous step.)

The command returns the following set of information for each site:

text

```
SiteId: 3ef21e8a-69d9-4bf0-a70f-0328e5a18087
SiteUrl: https://contoso.sharepoint.com/sites/Research
SiteType: Group
ComplianceState: NonCompliant
CurrentSegments: Sales, Research
OriginalSegments: Sales, Research
InvalidIBSegments:
IncompatibleSegmentsPairs: <Sales, Research>
FailedToBeProcessed: False
```

> **Note**
>
> For info about removing incompatible segments, see Use Information Barriers with SharePoint. When you finish with a report, delete it by using `Remove-SPOInformationBarriersPolicyComplianceReport -reportid <>`.

Next steps

- Use Information Barriers with SharePoint: Remove incompatible segments from noncompliant SharePoint sites identified in the report.
- Use Information Barriers with OneDrive: Update segments on noncompliant OneDrive accounts identified in the report.
- Manage Information Barriers policies: Edit policies to resolve widespread compliance issues across sites.

Information Barriers compliance assistant (preview)

This article explains how to enable the Information Barriers (IB) compliance assistant for group-connected SharePoint sites. These sites are sites that don't have an associated team in Microsoft Teams. When you enable the IB compliance assistant, it automatically removes users who don't match the segments specified on this site to ensure group membership honors configured IB policies. This configuration helps ensure your organization remains compliant with standards, policies, and compliance regulations.

Prerequisites

1. Make sure you define policies for Information Barriers.
2. Configure IB segments on a SharePoint Site.
3. Install the Azure PowerShell module.
4. Install the Microsoft Graph PowerShell SDK.
5. PowerShell account must have directory administrator access for the tenant.

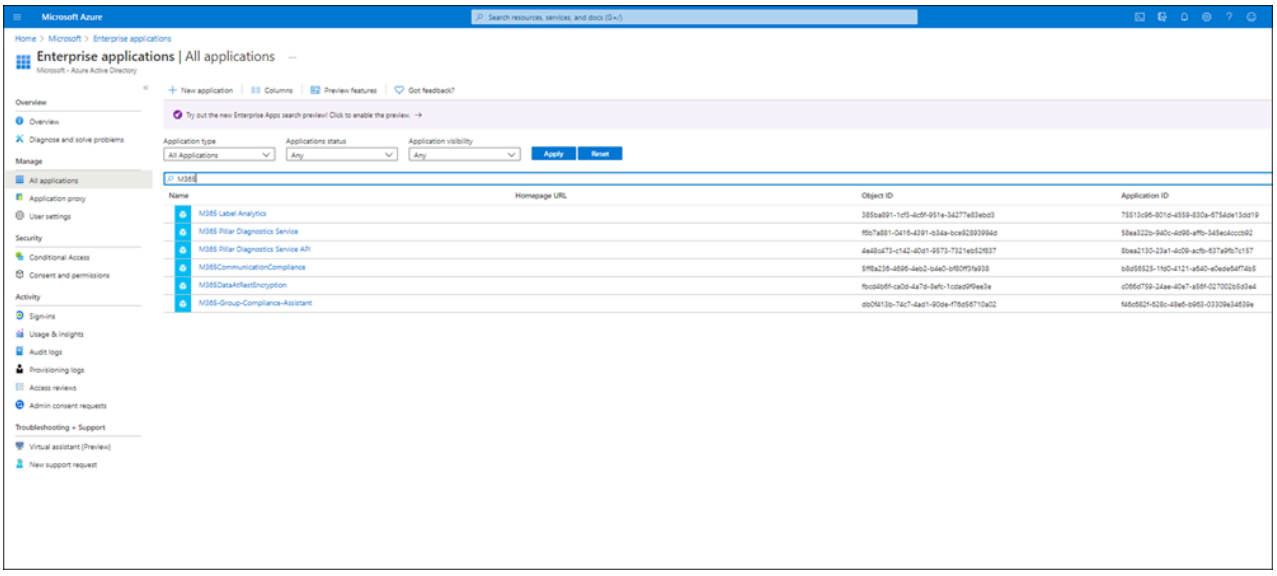
Enable the background compliance assistant

These steps create a new application in your organization's enterprise applications. For the compliance assistant to function properly, you must have explicitly added segments to a SharePoint site. Complete the following steps to enable the compliance assistant:

1. Run the following PowerShell cmdlets.

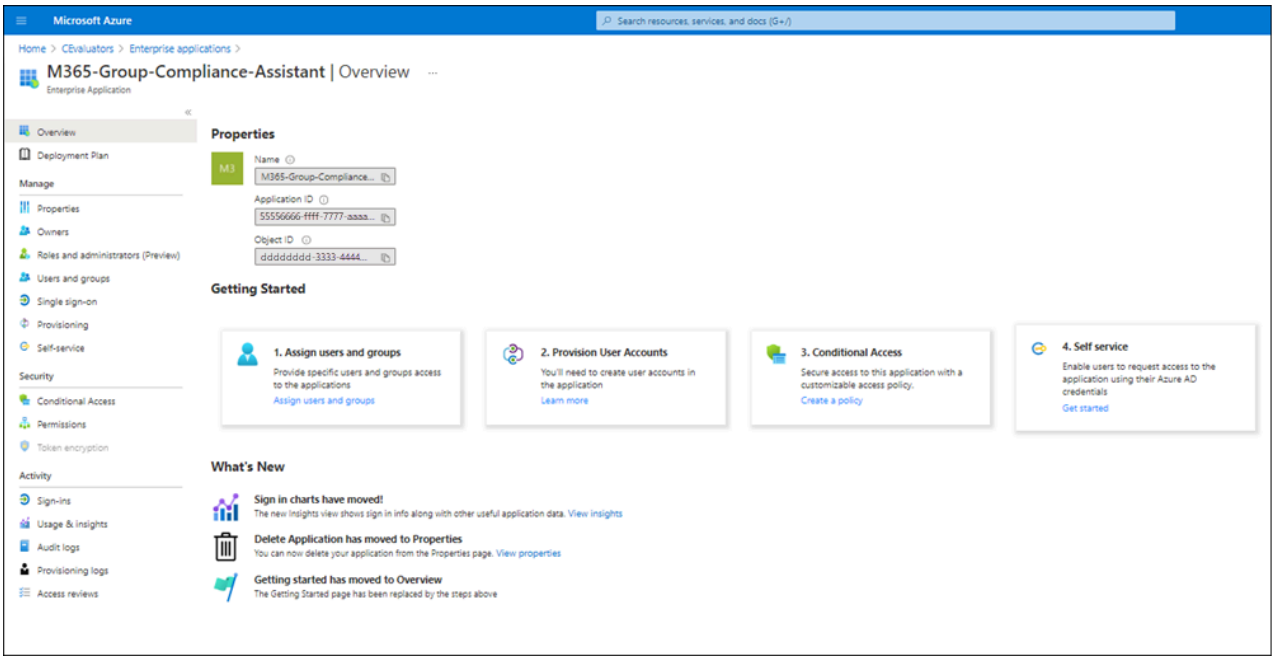
   PowerShell

   ```
   Connect-MgGraph
   Connect-AzAccount
   $appId="00001111-aaaa-2222-bbbb-3333cccc4444"
   $sp=Get-AzADServicePrincipal -ServicePrincipalName $appId
   if ($sp -eq $null) {New-AzADServicePrincipal -ApplicationId $appId}
   Start-Process "https://login.microsoftonline.com/common/adminconsent?
   client_id=$appId"
   ```



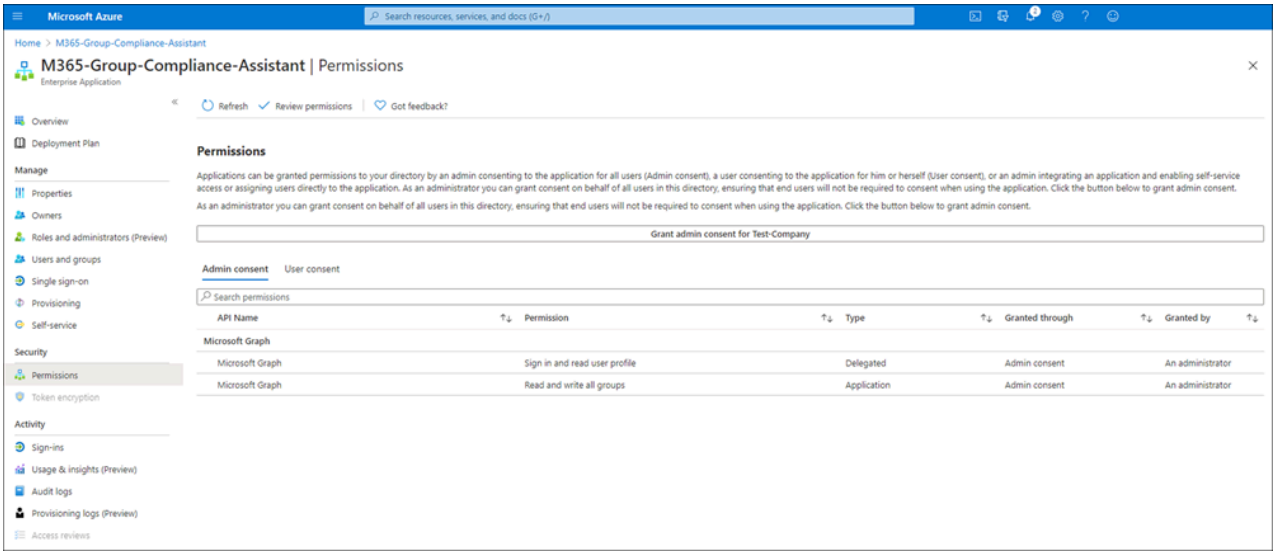
2. When prompted, sign in by using your Microsoft 365 work or school account.

3. In the **Permissions requested** dialog box, review the information, and select **Accept**. This action configures admin consent for the compliance assistant.



Verify you created a new application

To verify you created a new application in your organization's enterprise applications, complete the following steps:



1. Sign in to portal.azure.com with directory administrator credentials.
2. Select **Manage Microsoft Entra ID**.
3. Select **Enterprise Applications** in the left nav.
4. Search for the compliance assistant by using 'M365' as the search term.

5. Select **M365-Group-Compliance-Assistant** from the list of search results.
6. On the **M365-Group-Compliance-Assistant overview** page, review the application properties.

7. Select **Permissions** in the left nav to review the permissions that the application is authorized for.

8. In this example, the **M365-Group-Compliance-Assistant** is authorized to add or remove noncompliant IB users from your Microsoft 365 groups.

You can use audit log search in the Microsoft Purview portal to search, review, and track audit log events for the M365-Group-Compliance-Assistant application. The audit activities associated with the compliance assistant are:

- **IB assistant removed group member**: The IB noncompliant group member was removed from the group by the compliance assistant.
- **IB assistant removed group owner**: The IB noncompliant owner was removed from the group by the compliance assistant.

- **Identified as IB non-compliant group**: The segments on the group are non-IB compliant with each other.

To search the audit log for Microsoft 365 Groups activities, see Search the audit log.

> **Note**
>
> The compliance assistant runs periodically (every 24 hours). The assistant runs on group-connected SharePoint sites that don't have an associated team in Microsoft Teams. To enable the compliance assistant for SharePoint sites connected to Microsoft Teams, follow the instructions in the **Define IB policies** article.

Next steps

- Use Information Barriers with SharePoint: Manage IB segments and modes on the SharePoint sites the assistant monitors.
- Create an Information Barriers policy compliance report: Identify noncompliant sites that need manual remediation beyond the assistant.
- Manage Information Barriers policies: Update segments or policies to resolve recurring compliance issues.

Privileged access management

When users have standing access to sensitive information or critical network configuration settings in Microsoft Exchange Online, compromised accounts or internal threat activities can occur. Microsoft Purview Privileged Access Management helps protect your organization from breaches and helps you meet compliance best practices by limiting standing access to sensitive data or access to critical configuration settings. Instead of administrators having constant access, implement just-in-time access rules for tasks that need elevated permissions. When you enable privileged access management for Exchange Online in Microsoft 365, your organization operates with zero standing privileges and provides a layer of defense against standing administrative access vulnerabilities.

Configure privileged access management

Use the following steps to configure privileged access management for your organization:

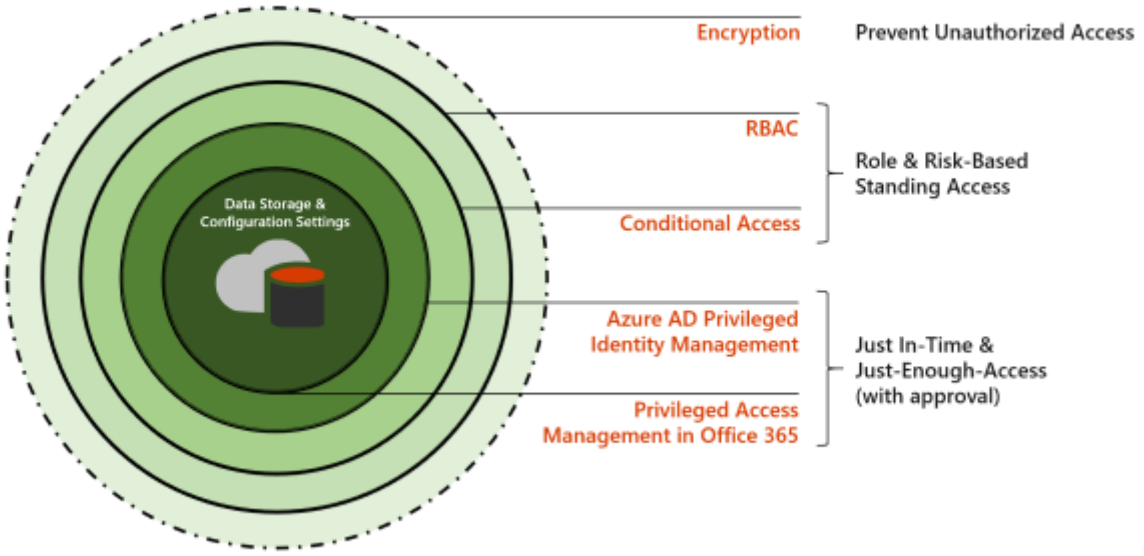
1. Learn about privileged access management
2. Create an approver's group
3. Enable privileged access management
4. Create an access policy
5. Submit/approve privileged access requests

More information about privileged access management

- Frequently asked questions about privileged access management

---

Last updated on 03/24/2026



Learn about privileged access management

Microsoft Purview Privileged Access Management provides granular access control over privileged admin tasks in Microsoft 365. It helps protect your organization from breaches that use existing privileged admin accounts with standing access to sensitive data or access to critical configuration settings. Privileged access management requires users to request just-in-time access to complete elevated and privileged tasks through a highly scoped and time-bounded approval workflow. This configuration gives users just enough access to perform the task at hand, without risking exposure of sensitive data or critical configuration settings. When you enable privileged access management, your organization operates with zero standing privileges and provides a layer of defense against standing administrative access vulnerabilities.

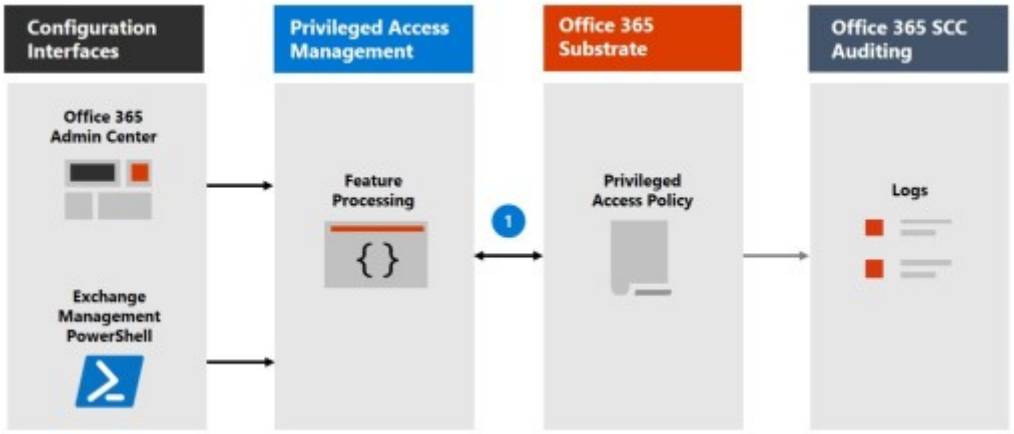
For a quick overview of the integrated Customer Lockbox and privileged access management workflow, see this Customer Lockbox and privileged access management video.

Layers of protection

Privileged access management complements other data and access feature protections within the Microsoft 365 security architecture. Including privileged access management as part of an integrated and layered approach to security provides a security model that maximizes protection of sensitive information and Microsoft 365 configuration settings. As shown in the diagram, privileged access management builds on the protection provided by native encryption of Microsoft 365 data and the role-based access control security model of Microsoft 365 services. When used with Microsoft Entra Privileged Identity Management, these two features provide access control with just-in-time access at different scopes.

Privileged access management is defined and scoped at the **task** level, while Microsoft Entra Privileged Identity Management applies protection at the **role** level with the ability to execute multiple tasks. Microsoft Entra Privileged Identity Management primarily manages accesses for AD roles and role groups, while Microsoft Purview Privileged Access Management applies only at the task level.

- **Enable privileged access management while already using Microsoft Entra Privileged Identity Management:** Adding privileged access management provides another granular layer of protection and audit capabilities for privileged access to Microsoft 365 data.
- **Enable Microsoft Entra Privileged Identity Management while already using Microsoft Purview Privileged Access Management:** Adding Microsoft Entra Privileged Identity Management to Microsoft Purview Privileged Access Management can extend privileged access to data outside of Microsoft 365 that's primarily defined by user roles or identity.



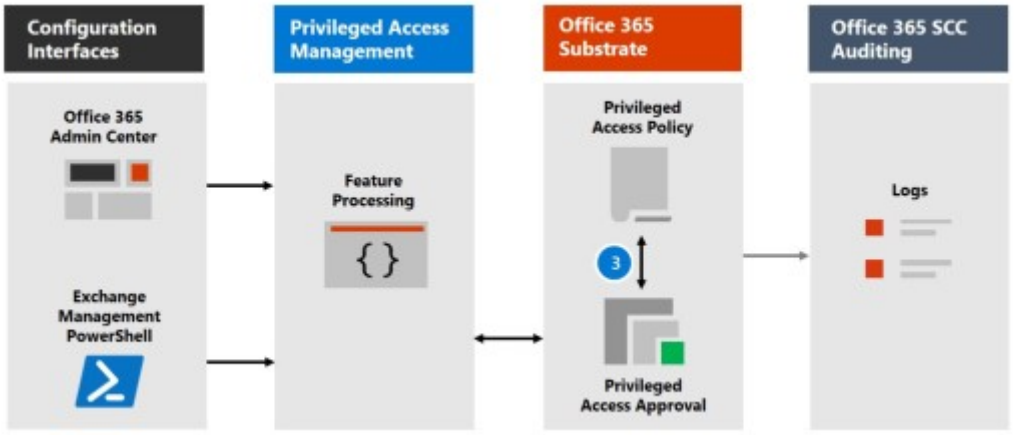
Privileged access management architecture and process flow

Each of the following process flows outlines the architecture of privileged access and how it interacts with the Microsoft 365 substrate, auditing, and the Exchange Management runspace.

Step 1: Configure a privileged access policy

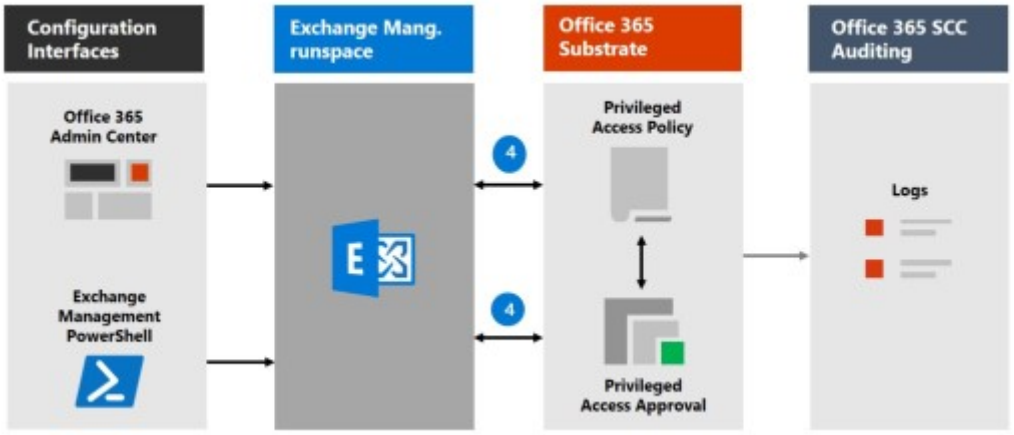
When you configure a privileged access policy with the Microsoft 365 admin center or the Exchange Management PowerShell, you define the policy and the privileged access feature processes and the policy attributes in the Microsoft 365 substrate. The system logs the

activities in the audit log. The policy is now enabled and ready to handle incoming requests for approvals.



Step 2: Access request

In the Microsoft 365 admin center or by using Exchange Management PowerShell, users can request access to elevated or privileged tasks. The privileged access feature sends the request to the Microsoft 365 substrate for processing against the configured privileged access policy and records the activity in the audit logs.



Step 3: Access approval

The privileged access feature generates an approval request and sends a pending request notification to approvers by email. If approvers grant approval, the privileged access feature processes the privileged access request as an approval and makes the task ready to complete. If approvers deny the request, the privileged access feature blocks the task and grants no access to the requestor. The requestor receives an email message that notifies them of the request approval or denial.

Step 4: Access processing

For an approved request, the Exchange Management runspace processes the task. The Microsoft 365 substrate checks the approval against the privileged access policy and processes it. The audit logs record all activity for the task.

Frequently asked questions

What SKUs can use privileged access in Microsoft 365?

You can use privileged access management with a wide selection of Microsoft 365 and Microsoft 365 subscriptions and add-ons. For details, see Get started with privileged access management.

When will privileged access management support Microsoft 365 workloads beyond Exchange?

For more information about the timeline for privileged access management support, see the Microsoft 365 Roadmap.

My organization needs more than 30 privileged access policies. Will this limit be increased?

Yes, Microsoft is working on increasing the current limit of 30 privileged access policies per organization.

Do I need to be a Global Admin to manage privileged access in Microsoft 365?

Yes, you need the *Global Admin* role assigned to accounts that manage privileged access in Microsoft 365. Users included in an approvers' group don't need to have the *Global Admin* or *Role Management* roles assigned to review and approve requests by using PowerShell. Users must have the *Exchange Administrator* role assigned to request, review, and approve privileged access requests in the Microsoft 365 admin center.

How is privileged access management related to Customer Lockbox?

Customer Lockbox provides access control for organizations when Microsoft accesses data. Privileged access management provides granular access control within an organization for all Microsoft 365 privileged tasks.

Ready to get started?

Start configuring your organization for privileged access management.

Learn more

Interactive guide: Monitor and control administrator tasks with privileged access management

ⓘ **Note:** The author created this article with assistance from AI. Learn more

---

Last updated on 04/14/2026

Get started with privileged access management

This article guides you through enabling and configuring privileged access management in your organization. You can use either the Microsoft 365 admin center or Exchange Management PowerShell to manage and use privileged access.

Before you begin

Before you get started with privileged access management, confirm your Microsoft 365 subscription and any add-ons.

To access and use privileged access management, your organization must have supporting subscriptions or add-ons. For more information, see the subscription requirements for privileged access management.

If you don't have an existing Microsoft 365 Enterprise E5 plan and want to try privileged access management, you can add Microsoft 365 to your existing Microsoft 365 subscription or sign up for a trial of Microsoft 365 Enterprise E5.

Enable and configure privileged access management

Complete the following steps to set up and use privileged access in your organization:

- Step 1: Create an approver's group

  Before you start using privileged access, determine who needs approval authority for incoming requests for access to elevated and privileged tasks. Any user who is part of the Approvers' group can approve access requests. Enable this group by creating a mail-enabled security group in Microsoft 365.

- Step 2: Enable privileged access

  Explicitly enable privileged access in Microsoft 365 with the default approver group, including a set of system accounts that you want to exclude from the privileged access management access control.

- Step 3: Create an access policy

Define specific approval requirements scoped at individual tasks by creating an approval policy. The approval type options are **Auto** or **Manual**.

- Step 4: Submit and approve privileged access requests

  Once enabled, privileged access requires approvals for any task that has an associated approval policy defined. For tasks included in an approval policy, users must request and be granted access approval to have permissions necessary to execute the task.

After approval is granted, the requesting user can execute the intended task. Privileged access authorizes and executes the task on behalf of the user. The approval remains valid for the requested duration (the default duration is four hours), during which the requester can execute the intended task multiple times. All such executions are logged and made available for security and compliance auditing.

> **Note**
>
> To use Exchange Management PowerShell to enable and configure privileged access, follow the steps in **Connect to Exchange Online PowerShell using Multi-Factor authentication** to connect to Exchange Online PowerShell with your Microsoft 365 credentials. You don't need to enable multi-factor authentication for your organization to use the steps to enable privileged access while connecting to Exchange Online PowerShell. Connecting with multi-factor authentication creates an auth token that privileged access uses for signing your requests.

Step 1: Create an approver's group

1. Sign in to the Microsoft 365 admin center with credentials for an admin account in your organization.
2. In the admin center, go to **Groups** > **Add a group**.
3. Select **mail-enabled security group** and then enter the **Name**, **Group email address**, and **Description** for the new group.
4. Save the group. It might take a few minutes for the group to be fully configured and to appear in the Microsoft 365 admin center.
5. Select the new approvers group and select **edit** to add users to the group.

6. Save the group.

Step 2: Enable privileged access

In the Microsoft 365 admin center

1. Sign in to the Microsoft 365 admin center with credentials for an admin account in your organization.
2. In the admin center, go to **Settings** > **Org Settings** > **Security & Privacy** > **Privileged access**.
3. Turn on **Require approvals for privileged tasks**.
4. Assign the approvers group you created in Step 1 as the **Default approvers group**.
5. **Save** and **Close**.

In Exchange Management PowerShell

To enable privileged access and assign the approver group, run the following command in Exchange Online PowerShell:

PowerShell

```
Enable-ElevatedAccessControl -AdminGroup '<default approver group>' -SystemAccounts @('<systemAccountUPN1>','<systemAccountUPN2>')
```

Example:

PowerShell

```
Enable-ElevatedAccessControl -AdminGroup 'pamapprovers@fabrikam.onmicrosoft.com' -SystemAccounts @('sys1@fabrikamorg.onmicrosoft.com', 'sys2@fabrikamorg.onmicrosoft.com')
```

> **Note**
>
> The system accounts feature ensures that certain automations within your organizations work without privileged access. However, make such exclusions exceptional and regularly approve and audit those allowed.

Step 3: Create an access policy

You can create and configure up to 30 privileged access policies for your organization.

In the Microsoft 365 admin center

1. Sign in to the Microsoft 365 admin center with credentials for an admin account in your organization.
2. In the Admin Center, go to **Settings** > **Org Settings** > **Security & Privacy** ** > **Privileged access**.
3. Select **Manage access policies and requests**.
4. Select **Configure policies** and select **Add a policy**.
5. From the drop-down fields, select the appropriate values for your organization:
    - **Policy type**: Task, Role, or Role Group
    - **Policy scope**: Exchange
    - **Policy name**: Select from the available policies
    - **Approval type**: Manual or Auto
    - **Approval group**: Select the approvers group created in Step 1
6. Select **Create** and then **Close**. It might take a few minutes for the policy to be fully configured and enabled.

In Exchange Management PowerShell

To create and define an approval policy, run the following command in Exchange Online PowerShell:

PowerShell

```
New-ElevatedAccessApprovalPolicy -Task 'Exchange\<exchange management cmdlet name>'
-ApprovalType <Manual, Auto> -ApproverGroup '<default/custom approver group>'
```

Example:

PowerShell

```
New-ElevatedAccessApprovalPolicy -Task 'Exchange\New-MoveRequest' -ApprovalType
Manual -ApproverGroup 'mbmanagers@fabrikamorg.onmicrosoft.com'
```

Step 4: Submit or approve privileged access requests

Request elevation authorization to execute privileged tasks

Requests for privileged access are valid for up to 24 hours after submission. If approvers don't approve or deny the request within 24 hours, the request expires and access isn't granted.

In the Microsoft 365 Admin Center

1. Sign in to the Microsoft 365 Admin Center with your credentials.
2. In the Admin Center, go to **Settings** > **Org Settings** > **Security & Privacy** ** > **Privileged access**.
3. Select **Manage access policies and requests**.
4. Select **New request**. From the drop-down fields, select the appropriate values for your organization:
   - **Request type**: Task, Role, or Role Group
   - **Request scope**: Exchange
   - **Request for**: Select from the available policies
   - **Duration (hours)**: Number of hours of requested access. You can request any number of hours.
   - **Comments**: Text field for comments related to your access request
5. Select **Save** and then **Close**. The system sends your request to the approver group by email.

In Exchange Management PowerShell

Run the following command in Exchange Online PowerShell to create and submit an approval request to the approver group:

PowerShell

```
New-ElevatedAccessRequest -Task 'Exchange\<exchange management cmdlet name>' -
Reason '<appropriate reason>' -DurationHours <duration in hours>
```

Example:

PowerShell

```
New-ElevatedAccessRequest -Task 'Exchange\New-MoveRequest' -Reason 'Attempting to
fix the user mailbox error' -DurationHours 4
```

View status of elevation requests

After you create an approval request, you can check the status of the elevation request in the admin center or in Exchange Management PowerShell by using the associated request ID.

In the Microsoft 365 admin center

1. Sign in to the Microsoft 365 admin center with your credentials.
2. In the admin center, go to **Settings** > **Org Settings** > **Security & Privacy** > **Privileged access**.
3. Select **Manage access policies and requests**.
4. Select **View** to filter submitted requests by **Pending**, **Approved**, **Denied**, or **Customer Lockbox** status.

In Exchange Management PowerShell

Run the following command in Exchange Online PowerShell to view an approval request status for a specific request ID:

PowerShell

```
Get-ElevatedAccessRequest -Identity <request ID> | select RequestStatus
```

Example:

PowerShell

```
Get-ElevatedAccessRequest -Identity 28560ed0-419d-4cc3-8f5b-603911cbd450 | select
RequestStatus
```

Approving an elevation authorization request

When you create an approval request, members of the relevant approver group receive an email notification. They can approve the request by using the request ID. The requestor receives an email notification when you approve or deny the request.

In the Microsoft 365 admin center

1. Sign in to the Microsoft 365 admin center with your credentials.
2. In the admin center, go to **Settings** > **Org Settings** > **Security & Privacy** > **Privileged access**.
3. Select **Manage access policies and requests**.
4. Select a listed request to view the details and take action on the request.
5. Select **Approve** to approve the request or select **Deny** to deny the request. You can revoke access for previously approved requests by selecting **Revoke**.

In Exchange Management PowerShell

To approve an elevation authorization request, run the following command in Exchange Online PowerShell:

```
PowerShell
Approve-ElevatedAccessRequest -RequestId <request id> -Comment '<approval comment>'
```

Example:

```
PowerShell
Approve-ElevatedAccessRequest -RequestId a4bc1bdf-00a1-42b4-be65-b6c63d6be279 -
Comment '<approval comment>'
```

To deny an elevation authorization request, run the following command in Exchange Online PowerShell:

```
PowerShell
Deny-ElevatedAccessRequest -RequestId <request id> -Comment '<denial comment>'
```

Example:

```
PowerShell
Deny-ElevatedAccessRequest -RequestId a4bc1bdf-00a1-42b4-be65-b6c63d6be279 -Comment
'<denial comment>'
```

Delete a privileged access policy in Microsoft 365

If your organization no longer needs a privileged access policy, you can delete it.

In the Microsoft 365 admin center

1. Sign in to the Microsoft 365 admin center with credentials for an admin account in your organization.
2. In the admin center, go to **Settings** > **Org Settings** > **Security & Privacy** > **Privileged access**.
3. Select **Manage access policies and requests**.
4. Select **Configure policies**.
5. Select the policy you want to delete, and then select **Remove Policy**.
6. Select **Close**.

In Exchange Management PowerShell

To delete a privileged access policy, run the following command in Exchange Online PowerShell:

```
PowerShell
Remove-ElevatedAccessApprovalPolicy -Identity <identity GUID of the policy you want
to delete>
```

Disable privileged access in Microsoft 365

If needed, you can disable privileged access management for your organization. Disabling privileged access doesn't delete any associated approval policies or approver groups.

In the Microsoft 365 admin center

1. Sign in to the Microsoft 365 admin center with credentials for an admin account in your organization.
2. In the Admin Center, go to **Settings** > **Org Settings** > **Security & Privacy** ** > **Privileged access**.
3. Turn on **Require approvals for privileged access**.

In Exchange Management PowerShell

To disable privileged access, run the following command in Exchange Online PowerShell:

PowerShell

```
Disable-ElevatedAccessControl
```

Encryption

09/26/2025

Encryption is an important part of your file protection and information protection strategy. This article provides an overview of encryption for Microsoft 365. Get help with encryption tasks like how to set up encryption for your organization and how to password-protect Microsoft 365 documents.

- For information about certificates and technologies like TLS, see Technical reference details about encryption in Microsoft 365.
- For an overview of how to configure or set up encryption for your organization, see Set up encryption in Microsoft 365 Enterprise.

What is encryption, and how does it work in Microsoft 365?

The encryption process encodes your data (referred to as plaintext) into ciphertext. Unlike plaintext, ciphertext can't be used by people or computers unless and until the ciphertext is decrypted. Decryption requires an encryption key that only authorized users have. Encryption helps ensure that only authorized recipients can decrypt your content. Content includes files, email messages, calendar entries, and so on.

Encryption by itself doesn't prevent content interception. Encryption is part of a larger information protection strategy for your organization. By using encryption, you help ensure that only authorized parties can use the encrypted data.

You can have multiple layers of encryption in place at the same time. For example, you can encrypt email messages and also the communication channels through which your email flows. With Microsoft 365, your data is encrypted at rest and in transit, using several strong encryption protocols, and technologies that include Transport Layer Security/Secure Sockets Layer (TLS/SSL), Internet Protocol Security (IPSec), and Advanced Encryption Standard (AES).

Encryption for data at rest and data in transit

Examples of data at rest include files that you uploaded to a SharePoint library, Project Online data, documents that you uploaded in a Skype for Business meeting, email messages and attachments that you stored in folders in your mailbox, and files you uploaded to OneDrive.

Examples of data in transit include mail messages that are in the process of being delivered, or conversations that are taking place in an online meeting. In Microsoft 365, data is in transit

whenever a user's device is communicating with a Microsoft server, or when a Microsoft server is communicating with another server.

With Microsoft 365, multiple layers and kinds of encryption work together to secure your data. The following table includes some examples, with links to additional information.

Expand table

Kinds of Content	Encryption Technologies	Resources to learn more
Files on a device. These files can include email messages saved in a folder, documents saved on a computer, tablet, or phone, or data saved to the Microsoft cloud. Chats, messages, and files in transit between recipients using Microsoft Teams.	Teams uses TLS and MTLS to encrypt instant messages. Media traffic is encrypted using Secure RTP (SRTP). Teams uses FIPS (Federal Information Processing Standard) compliant algorithms for encryption key exchanges.	Encryption for Teams

Microsoft 365 Crypto Update

In late August 2023, Microsoft Purview Information Protection began to use Advanced Encryption Standard (AES) with 256-bit key length in Cipher Block Chaining mode (AES256-CBC). By October 2023, AES256-CBC became the default for encryption of Microsoft 365 Apps documents and emails. You might need to take action to support this change in your organization. For more information, see Technical reference details about encryption.

What if I need more control over encryption to meet security and compliance requirements?

Microsoft 365 provides Microsoft-managed solutions for volume encryption, file encryption, and mailbox encryption in Microsoft 365. In addition, Microsoft provides encryption solutions that you can manage and control. These encryption solutions are built on Azure.

Learn about the Azure Rights Management encryption service

09/03/2025

Azure Rights Management, sometimes abbreviated to Azure RMS, is the main cloud-based encryption service from Microsoft Purview Information Protection.

Azure Rights Management helps to protect items such as files and emails across multiple devices that include phones, tablets, and PCs by using encryption, identity, and authorization policies.

For example, when employees email a document to a partner company, or save a document to their cloud drive, the persistent encryption from Azure Rights Management helps secure the data.

- **Encryption settings remain with your data**, even when it leaves your organization's boundaries, keeping your content protected both within and outside your organization.
- **Encryption may be legally required** for compliance, legal discovery requirements, or best practices for information management.
- **Use Azure Rights Management with Microsoft 365 subscriptions or subscriptions for Microsoft Purview Information Protection**. For more information, see the Microsoft 365 licensing guidance for security & compliance page.

Azure Rights Management ensures that authorized people and services, such as search and indexing, can continue to read and inspect the encrypted data.

Ensuring ongoing access for authorized people and services, also known as "reasoning over data", is a crucial element in maintaining control of your organization's data. This capability may not be easily accomplished with other information protection solutions that use peer-to-peer encryption.

Protection features

Expand table

Feature	Description
Encrypt multiple file types	In early implementations of Rights Management, only Office files could be encrypted, using built-in Rights Management protection.

Feature	Description
	Azure Rights Management provides support for additional file types. For more information, see Supported file types.
Protect files anywhere	When a file is encrypted, this protection stays with the file, even if it's saved or copied to storage that isn't under the control of IT, such as a cloud storage service.

Collaboration features

Expand table

Feature	Description
Safely share information	Encrypted files are safe to share with others, such as an attachment to an email or a link to a SharePoint site. If the sensitive information is within an email message, encrypt the email, or use the **Do Not Forward** option from Outlook.
Support for business-to-business collaboration	Because Azure Rights Management is a cloud service, there's usually no need to explicitly configure trusts with other organizations before you can share encrypted content with them. By default, collaboration with other organizations that already have a Microsoft 365 or a Microsoft Entra directory is automatically supported. Some additional configuration might be needed for advanced configurations or specialized scenarios. For organizations without Microsoft 365 or a Microsoft Entra directory, users can sign up for the free RMS for individuals subscription, or use a Microsoft account for supported applications.

Tip

Attaching encrypted files, rather than encrypting an entire email message, enables you to keep the email text unencrypted.

For example, you may want to include instructions for first-time use if the email is being sent outside your organization. If you attach an encrypted file, the basic instructions can be read by anyone, but only authorized users will be able to open the document, even if the email or document is forwarded to other people.

Platform support features

The Azure Rights Management service supports a broad range of platforms and applications, including:

Expand table

Feature	Description
Commonly used devices not just Windows computers	Client devices include: - Windows computers and phones - Mac computers - iOS tablets and phones - Android tablets and phones
On-premises services	In addition to working seamlessly with Microsoft 365, you can use Azure Rights Management with the following on-premises services when you deploy the Microsoft Rights Management connector: - Exchange Server - SharePoint Server - Windows Server running File Classification Infrastructure
Application extensibility	Azure Rights Management has tight integration with Microsoft 365 applications and services, and extends support for other applications by using the Microsoft Purview Information Protection client. The Microsoft Information Protection SDK provides your internal developers and software vendors with APIs to write custom applications that support the Azure Rights Management service.

Infrastructure features

The Azure Rights Management service provides the following features to support IT departments and infrastructure organizations:

- Create simple and flexible policies
- Easy activation
- Auditing and monitoring services
- Ability to scale across your organization
- Maintain IT control over data

> **Note**
>
> Organizations always have the choice to stop using the Azure Rights Management service without losing access to content that was previously protected by Azure Rights

Management.

For more information, see Decommission and deactivate the Azure Rights Management service.

Create simple and flexible policies

Encryption settings that are applied with sensitivity labels provide a quick and easy method for administrators to apply information protection policies, and for users to apply the correct level of protection for each item as needed.

For example, for a company-wide strategy paper to be shared with all employees, apply a read-only policy to all internal employees. For a more sensitive document, such as a financial report, restrict access to executives only.

For more information, see Restrict access to content by using sensitivity labels to apply encryption.

Easy activation

For new subscriptions, activation is automatic. For existing subscriptions, activating the Rights Management service requires just two PowerShell commands.

Auditing and monitoring services

Audit and monitor usage of your encrypted files, even after these files leave your organization's boundaries.

For example, if a Contoso, Ltd employee works on a joint project with three people from Fabrikam, Inc, they might send their Fabrikam partners a document that's encrypted and restricted to *read-only*.

Azure Rights Management auditing can provide the following information:

- Whether the Fabrikam partners opened the document, and when.
- Whether other people who weren't specified, attempted, and failed to open the document. This might happen if the email was forwarded on, or saved to a shared location.

Administrators can track document usage and revoke access for Office files. Users can revoke access for their labeled and encrypted documents as needed.

Ability to scale across your organization

Because Azure Rights Management runs as a cloud service with the Azure elasticity to scale up and out, you don't have to provision or deploy additional on-premises servers.

Maintain IT control over data

Organizations can benefit from IT control features, such as:

Expand table

Feature	Description
Tenant key management	Use tenant key management solutions, such as Bring Your Own Key (BYOK) or Double Key Encryption (DKE). For more information, see: - Planning and implementing your Azure Rights Management tenant key - What is Double Key Encryption (DKE)?
Auditing and usage logging	Use auditing and usage logging to analyze for business insights, monitor for abuse, and perform forensic analysis for information leaks.
Access delegation	Delegate access with the super user feature, ensuring that IT can always access encrypted content, even if a document was encrypted by an employee who then leaves the organization. In comparison, peer-to-peer encryption solutions risk losing access to company data.
Active Directory synchronization	Synchronize just the directory attributes that Azure RMS needs to support a common identity for your on-premises Active Directory accounts, by using a hybrid identity solution, such as Microsoft Entra Connect.
Single-sign on	Enable single-sign on without replicating passwords to the cloud, by using AD FS.
Migration from AD RMS	If you've deployed Active Directory Rights Management Services (AD RMS), migrate to the Azure Rights Management service without losing access to data that was previously encrypted by AD RMS.

Security, compliance, and regulatory requirements

Azure Rights Management supports the following security, compliance, and regulatory requirements:

- **Use of industry-standard cryptography and supports FIPS 140-2.** For more information, see the Cryptographic controls: Algorithms and key lengths information.

- **Support for nCipher nShield hardware security module (HSM)** to store your tenant key in Microsoft Azure data centers.

  Azure Rights Management uses separate security worlds for its data centers in North America, EMEA (Europe, Middle East and Africa), and Asia, so your keys can be used only in your region.

- **Certification for the following standards**:
  - ISO/IEC 27001:2013 (./includes ISO/IEC 27018)
  - SOC 2 SSAE 16/ISAE 3402 attestations
  - HIPAA BAA
  - EU Model Clause
  - FedRAMP as part of Microsoft Entra ID in Office 365 certification, issued FedRAMP Agency Authority to Operate by HHS
  - PCI DSS Level 1

For more information about these external certifications, see the Microsoft Trust Center.

Frequently asked questions

Some of our more frequently asked questions about the Azure Rights Management encryption service from Microsoft Purview Information Protection:

Do files have to be in the cloud to be encrypted by the Azure Rights Management service?

No, this is a common misconception. The Azure Rights Management service (and Microsoft) doesn't see or store your data as part of the encryption process. Information that you encrypt is never sent to or stored in Azure unless you explicitly store it in Azure or use another cloud service that stores it in Azure.

For more information, see How the Azure Rights Management service works: Technical details to understand how a secret formula that's created and stored on-premises is encrypted by the Azure Rights Management service but remains on-premises.

What's the difference between Azure Rights Management encryption and encryption in other Microsoft cloud services?

Microsoft provides multiple encryption technologies that enable you to protect your data for different, and often complementary scenarios. For example, while Microsoft 365 offers encryption at-rest for data stored in Microsoft 365, the Azure Rights Management service from

Microsoft Purview Information Protection independently encrypts your data so that it's protected regardless of where it's located or how it's transmitted.

These encryption technologies are complementary and using them requires enabling and configuring them independently. When you do so, you might have the option to bring your own key for the encryption, a scenario also known as "BYOK." Enabling BYOK for one of these technologies doesn't affect the others. For example, you can use BYOK for the Azure Rights Management service and not use BYOK for other encryption technologies, and vice versa. The keys used by these different technologies might be the same or different, depending on how you configure the encryption options for each service.

I see Microsoft Rights Management Services is listed as an available cloud app for conditional access—how does this work?

Yes, you can configure Microsoft Entra Conditional Access for the Azure Rights Management service.

When a user opens a document that's encrypted by the Azure Rights Management service, administrators can block or grant access to users in their tenant, based on the standard conditional access controls. Requiring multifactor authentication (MFA) is one of the most commonly requested conditions. Another one is that devices must be compliant with your Intune policies so that, for example, mobile devices meet your password requirements and a minimum operating system version, and computers must be domain-joined.

For more information, see Conditional Access policies and encrypted documents.

Additional information:

Expand table

Topic	Details
Evaluation frequency	For Windows computers, the conditional access policies for the Azure Rights Management service are evaluated when the user environment is initialized (this process is also known as bootstrapping), and then every 30 days. To fine-tune how often your conditional access policies get evaluated, configure the token lifetime.
Administrator accounts	We recommend that you don't add administrator accounts to your conditional access policies because these accounts won't be able to access the Azure Rights Management service when you configure encryption settings for sensitivity labels in the Microsoft Purview portal.

Topic	Details
MFA and B2B collaboration	If you use MFA in your conditional access policies for collaborating with other organizations (B2B), you must use Microsoft Entra B2B collaboration and create guest accounts for the users you want to share with in the other organization.
Terms of Use prompts	You can prompt users to accept a terms of use before they open an encrypted document for the first time.
Cloud apps	If you use many cloud apps for conditional access, you might not see **Microsoft Information Protection Sync Service** and **Microsoft Rights Management Service** displayed in the list to select. In this case, use the search box at the top of the list. Start typing "Microsoft Information Protection Sync Service" and "Microsoft Rights Management Service" to filter the available apps. Providing you have a supported subscription; you'll then see these options and will be able to select them.

I've encrypted a document and now want to change the usage rights or add users—do I need to re-encrypt the document?

If the document was encrypted by using a sensitivity label or rights management template, there's no need to re-encrypt the document. Modify the sensitivity label or rights management template by making your changes to the usage rights or add new groups (or users), and then save these changes:

- When a user hasn't accessed the document before you made the changes, the changes take effect as soon as the user opens the document.
- When a user has already accessed the document, these changes take effect when their use license expires. Re-encrypt the document only if you can't wait for the use license to expire. For example, remove the sensitivity label that applied the encryption, save, and apply the label again. Re-encrypting effectively creates a new version of the document, and therefore a new use license for the user.

Alternatively, if you have already configured a group for the required permissions, you can change the group membership to include or exclude users and there isn't a need to change the sensitivity label or rights management template. There might be a small delay before the changes take effect because group membership is cached by the Azure Rights Management service.

If the document was encrypted by using user-defined permissions, such as the Let users assign permissions encryption setting for sensitivity labels, you can't change the permissions for the

existing document. You must encrypt the document again and specify all the users and all the usage rights that are required for this new version of the document. To re-encrypt an encrypted document, you must have the Full Control usage right.

If I use this encryption solution for my production environment, is my company then locked into the solution?

No, you always remain in control of your data and can continue to access it, even if you decide to no longer use the Azure Rights Management service. For more information, see Decommission and deactivate the Azure Rights Management service.

Can I control which of my users can use the Azure Rights Management service to encrypt content?

Yes, when you use sensitivity labels to encrypt content, label publishing policies define which users see the labels in their apps. If you don't want some users to encrypt content, create a separate label publishing policy for them and in the policy, include only labels that don't apply encryption. For more information, see Create and configure sensitivity labels and their policies.

When I share an encrypted document with somebody outside my company, how does that user get authenticated?

By default, the Azure Rights Management service uses a Microsoft Entra account and an associated email address for user authentication, which makes business-to-business collaboration seamless for administrators. If the other organization uses Azure services, users already have accounts in Microsoft Entra ID, even if these accounts are created and managed on-premises and then synchronized to Azure. If the organization has Microsoft 365, this service also uses Microsoft Entra ID for the user accounts. If the user's organization doesn't have managed accounts in Azure, they can be authenticated with a guest account. For more information, see Sharing encrypted documents with external users.

The authentication method for these accounts can vary, depending on how the administrator in the other organization has configured the Microsoft Entra accounts. For example, they could use passwords that were created for these accounts, federation, or passwords that were created in Active Directory Domain Services and then synchronized to Microsoft Entra ID.

Other authentication methods:

- If you encrypt an email with an Office document attachment to a user who doesn't have an account in Microsoft Entra ID, the authentication method changes. The Azure Rights Management service is federated with some popular social identity providers, such as

Gmail. If the user's email provider is supported, the user can sign in to that service and their email provider is responsible for authenticating them. If the user's email provider isn't supported, or as a preference, the user can apply for a one-time passcode that authenticates them and displays the email with the encrypted document in a web browser.

- The Azure Rights Management service can use Microsoft accounts for supported applications. However, not all applications can open encrypted content when a Microsoft account is used for authentication.

What type of groups can I use with the Azure Rights Management service?

For most scenarios, you can use any group type in Microsoft Entra ID that has an email address. This rule of thumb always applies when you assign usage rights but there are some exceptions for administering the Azure Rights Management service. For more information, see Azure Rights Management service requirements for group accounts.

How do I send an encrypted email to a Gmail or Hotmail account?

When you use Exchange Online and the Azure Rights Management service, you just send the email to the user as an encrypted message. For example, you can select a sensitivity label that automatically applies Do Not Forward for you.

The recipient sees an option to sign in to their Gmail, Yahoo, or Microsoft account, and then they can read the encrypted email. Alternatively, they can choose the option for a one-time passcode to read the email in a browser.

To support this scenario, Exchange Online must be enabled for the Azure Rights Management service and Microsoft Purview Message Encryption.

For more information about the capabilities that include supporting all email accounts on all devices, see the following blog post: Announcing new capabilities available in Office 365 Message Encryption.

Which file types are supported by the Azure Rights Management service?

The Azure Rights Management service can support all file types. For text, image, Microsoft Office (Word, Excel, PowerPoint) files, PDF files, and some other application file types, the Azure

Rights Management service supports native encryption that includes the enforcement of usage rights (permissions). For all other applications and file types, generic encryption provides file encapsulation and authentication to verify if a user is authorized to open the file.

For a list of file types supported for Office apps and services, see Office file types supported from the sensitivity labeling documentation.

For a list of additional file types that are supported by the Microsoft Purview Information Protection client, see Supported file types from the information protection client documentation.

When I open an Office document that's encrypted by the Azure Rights Management service, does the associated temporary file become encrypted by this service as well?

No. In this scenario, the associated temporary file doesn't contain data from the original document but instead, only what the user enters while the file is open. Unlike the original file, the temporary file is obviously not designed for sharing and would remain on the device, protected by local security controls, such as BitLocker and EFS.

How do we regain access to files that were encrypted by an employee who has now left the organization?

Use the super user feature, which grants the Full Control usage rights to authorized users for all items that are encrypted by your tenant. Super users can always read this encrypted content, and if necessary, remove the encryption or re-encrypt the item for different users. This same feature lets authorized services index and inspect items, as needed.

If your content is stored in SharePoint or OneDrive, admins can run the Unlock-SensitivityLabelEncryptedFile cmdlet, to remove both the sensitivity label and the encryption. For more information, see Remove encryption for a labeled document.

Can Rights Management prevent screen captures?

By not granting the **Copy** usage right, Rights Management can prevent screen captures from many of the commonly used screen capture tools on Windows platforms. In Office for Mac, screen captures can similarly be prevented in Office for Mac, for Word, Excel, and PowerPoint, but not Outlook.

However, for other apps on iOS and for Android, these operating systems don't allow apps to prevent screen captures. In addition, browsers other than Edge can't prevent screen captures.

Browser use includes Outlook on the web and Office for the web.

Preventing screen captures can help to avoid accidental or negligent disclosure of confidential or sensitive information. But there are many ways that a user can share data that is displayed on a screen, and taking a screenshot is only one method. For example, a user intent on sharing displayed information can take a picture of it using their camera phone, retype the data, or simply verbally relay it to somebody.

As these examples demonstrate, even if all platforms and all software supported the Rights Management APIs to block screen captures, technology alone can't always prevent users from sharing data that they should not. Rights Management can help to safeguard your important data by using authorization and usage policies, but this enterprise rights management solution should be used with other controls. For example, implement physical security, carefully screen and monitor people who have authorized access to your organization's data, and invest in user education so users understand what data shouldn't be shared.

What's the difference between a user encrypting an email with Do Not Forward and usage rights that don't include the Forward right?

Despite its name, **Do Not Forward** isn't the opposite of the Forward usage right, or a template. It's actually a set of rights that include restricting copying, printing, and saving the email outside the mailbox, in addition to restricting the forwarding of emails. The rights are dynamically applied to users via the chosen recipients, and not statically assigned by the administrator. For more information, see the Do Not Forward option for emails section in Configure usage rights for the Azure Rights Management service.

Next steps

For more technical information about how the Azure Rights Management service works, see How the Azure Rights Management service works: Technical details.

If you're ready to make Azure Rights Management encryption an integrated part of your information protection solution, see Deploy an information protection solution with Microsoft Purview.

Requirements for the Azure Rights Management service

08/31/2025

Before you start to encrypt items by using the Azure Rights Management service from Microsoft Purview Information Protection, make sure you meet all the requirements.

Firewalls and network infrastructure

If you have firewalls or similar intervening network devices that are configured to allow specific connections, the network connectivity requirements are listed in the following Microsoft 365 article: Microsoft 365 Common and Office Online.

The Azure Rights Management service has the following additional requirements:

- **If you use the Microsoft Purview Information Protection client**: To download sensitivity labels and label policies, allow the following URL over HTTPS: ***.protection.outlook.com**

- **If you use web proxies**: If your web proxy requires authentication, you must configure the proxy to use integrated Windows authentication with the user's Active Directory sign in credentials.

  To support **Proxy.pac** files when using a proxy to acquire a token, add the following new registry key:
  - **Path**: `Computer\HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Microsoft\MSIP\`
  - **Key**: `UseDefaultCredentialsInProxy`
  - **Type**: `DWORD`
  - **Value**: `1`

- **TLS client-to-service connections**. Don't terminate any TLS client-to-service connections, for example to perform packet-level inspection, to the **aadrm.com** URL. Doing so breaks the certificate pinning that clients for the Azure Rights Management service use with Microsoft-managed Certificate Authorities (CAs) to help secure their communication with the Azure Rights Management service.

  To determine whether your client connection is terminated before it reaches the Azure Rights Management service, use the following PowerShell commands:

  PowerShell

  ```
  $request =
  [System.Net.HttpWebRequest]::Create("https://admin.na.aadrm.com/admin/admin.s
  ```

```
vc")
$request.GetResponse()
$request.ServicePoint.Certificate.Issuer
```

The result should show that the issuing CA is from a Microsoft CA, for example: `CN=Microsoft Secure Server CA 2011, O=Microsoft Corporation, L=Redmond, S=Washington, C=US`.

If you see an issuing CA name that isn't from Microsoft, it's likely that your secure client-to-service connection is being terminated and needs reconfiguration on your firewall.

- **Microsoft 365 Enhanced Configuration Service (ECS)**. The Azure Rights Management service must have access to the **config.edge.skype.com** URL, which is a Microsoft 365 Enhanced Configuration Service (ECS).

  ECS provides Microsoft the ability to reconfigure the Azure Rights Management service when it's necessary. For example, ECS is used to control the gradual rollout of features or updates, while the impact of the rollout is monitored from diagnostic data being collected.

  ECS is also used to mitigate security or performance issues with a feature or update. ECS also supports configuration changes related to diagnostic data, to help ensure that the appropriate events are being collected.

  Limiting the **config.edge.skype.com** URL may affect Microsoft's ability to mitigate errors and may affect your ability to test preview features.

  For more information, see Essential services for Office.

- **Audit logging URL network connectivity**. The Azure Rights Management service must be able to access the following URLs to support audit logs:
  - `https://*.events.data.microsoft.com`
  - `https://*.aria.microsoft.com` (Android device data only)

Coexistence with Active Directory Rights Management Services (AD RMS)

Using the on-premises version of Active Directory Rights Management Services (AD RMS) and the Azure Rights Management service side by side, in the same organization, to encrypt content by the same user in the same organization, isn't supported in AD RMS unless you're using the HYOK (hold your own key) configuration for the AD RMS root encryption key.

This scenario isn't supported for a migration to the Azure Rights Management Service. The supported migration paths are:

- From AD RMS to the Azure Rights Management service
- From the Azure Rights Management service to AD RMS

For other, non-migration scenarios, where both services are active in the same organization, both services must be configured so that only one of them allows any given user to encrypt content. Configure such scenarios as follows:

- Use redirections for an AD RMS to Azure Rights Management migration.
- If both services must be active for different users at the same time, use service-side configurations to enforce exclusivity. Use onboarding controls from the Azure Rights Management service, and an ACL on the Publish URL to set **Read-Only** mode for AD RMS.

Azure Network Security Groups and Service Tags

If you're using an Azure endpoint and an Azure Network Security Group (NSG), make sure to allow access to all ports for the following Service Tags:

- **AzureInformationProtection**
- **AzureActiveDirectory**
- **AzureFrontDoor.Frontend**

Additionally, in this case, the Azure Rights Management service also depends on the following IP addresses and ports:

- **13.107.9.198**
- **13.107.6.198**
- **2620:1ec:4::198**
- **2620:1ec:a92::198**
- **13.107.6.181**
- **13.107.9.181**
- **Port 443**, for HTTPS traffic

Make sure to create rules that allow outbound access to these specific IP addresses, and via this port.

Supported on-premises servers for the Azure Rights Management service

The following on-premises servers are supported with the Azure Rights Management service when you use the Microsoft Rights Management connector:

- Exchange Server
- SharePoint Server
- File servers that run Windows Server and use File Classification Infrastructure (FCI)

For supported versions, other requirements, and configuration steps for the connector, see Deploying the Microsoft Rights Management connector.

Supported operating systems

The following operating systems natively support the Azure Rights Management service. However, if you install an app that uses the Azure Rights Management service, such as Microsoft 365 Enterprise apps or the Microsoft Purview Information Protection client, check that app's requirements for supported operating systems.

Expand table

OS	Supported versions
Windows computers	- Windows 10 (x86, x64) - Windows 11 (x86, x64)
macOS	Minimum version of macOS 10.8 (Mountain Lion)
Android phones and tablets	Minimum version of Android 6.0
iPhone and iPad	Minimum version of iOS 11.0
Windows phones and tablets	Windows 10 Mobile

Microsoft Entra requirements

A Microsoft Entra directory is a requirement for using the Azure Rights Management service. Use an account from a Microsoft Entra directory to sign in to the Microsoft Purview portal.

If you have a subscription that includes Microsoft Purview Information Protection, your Microsoft Entra directory is automatically created for you if needed.

The following sections list additional Microsoft Entra requirements for specific scenarios.

Support for certificate-based authentication (CBA)

When iOS and Android apps support the Azure Rights Management service, they support certificate-based authentication.

For more information, see Get started with certificate-based authentication in Microsoft Entra ID with federation.

Multifactor authentication (MFA)

To use multifactor authentication (MFA) with the Azure Rights Management service, you must have at least one of the following installed:

- **Microsoft-managed tenants, with Microsoft Entra ID or Microsoft 365**. Configure Azure MFA to enforce MFA for users.

  For more information, see:
  - Plan a Microsoft Entra multifactor authentication deployment
  - How it works: Microsoft Entra multifactor authentication

- **Federated tenants, where federation servers operate on-premises**. Configure your federation servers for Microsoft Entra ID or Microsoft 365. For example, if you're using Active Directory Federation Services (AD FS), see Configure Additional Authentication Methods for AD FS.

Rights Management connector and MFA

The Rights Management connector and the Microsoft Purview Information Protection scanner don't support MFA.

If you deploy the connector or scanner, the following accounts mustn't require MFA:

- The account that installs and configures the connector.
- The service principal account in Microsoft Entra ID, **Aadrm_S-1-7-0**, that the connector creates.
- The service account that runs the scanner.

User UPN values don't match their email addresses

Configurations where users' UPN values don't match their email addresses isn't a recommended configuration, and doesn't support single-sign on for the Azure Rights Management service.

If you can't change the UPN value, configure alternate IDs for the relevant users, and instruct them how to sign in to their Office apps by using this alternate ID.

For more information, see Configuring Alternate Login ID.

> **Tip**
>
> If the domain name in the UPN value is a domain that is verified for your tenant, add the user's UPN value as another email address to the Microsoft Entra ID **proxyAddresses** attribute. This allows the user to be authorized for the Azure Rights Management service if their UPN value is specified at the time the usage rights are granted.

For more information, see Learn how user accounts and groups use the Azure Rights Management service.

Authenticating on-premises using another authentication provider

If you're using a mobile device or Mac computer that authenticates on-premises using a non-Microsoft authentication provider, it must support the OAuth 2.0 protocol.

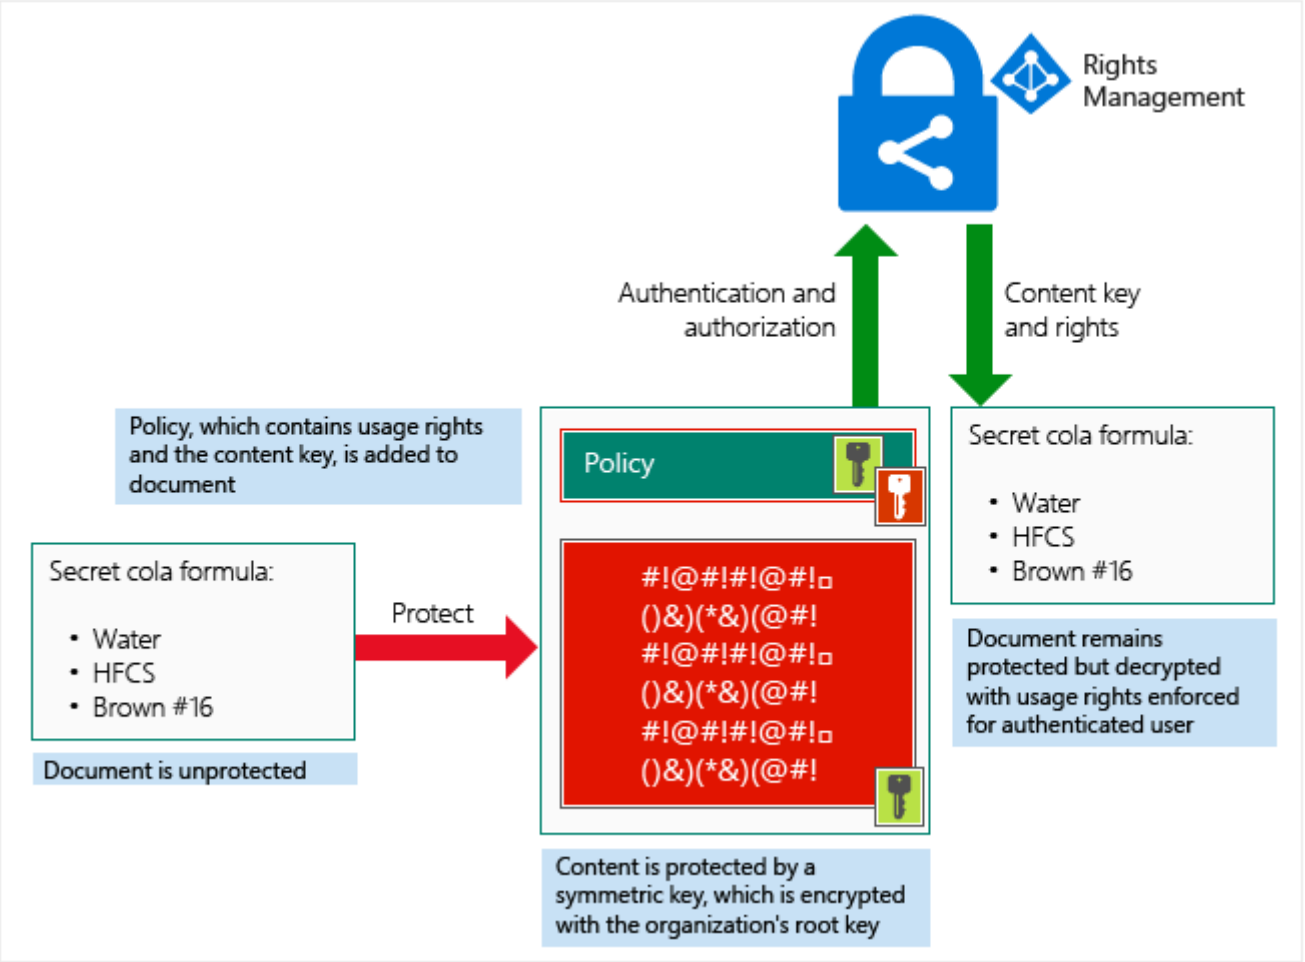
Advanced configurations for Entra ID

For dependent configurations in Entra that can prevent or allow access to the Azure Rights Management service, see Microsoft Entra configuration for encrypted content.

How the Azure Rights Management service works: Technical details

> *Microsoft Purview service description*

Use the following information if you want to understand, in-depth, how the Azure Rights Management service works. You don't need to know this level of information to configure or apply the encryption settings to protect your data.



> **Note**
>
> When the Azure Rights Management service was available as a standalone product rather than part of Microsoft Purview Information Protection, it was often abbreviated to *Azure RMS*. You see this abbreviation in the pictures in this article.

An important concept to understand about the Azure Rights Management service is that this service doesn't see or store your data as part of the encryption process. Information that you encrypt is never sent to or stored in Azure, unless you explicitly store it in Azure or use another cloud service that stores it in Azure. The Azure Rights Management service simply makes the data in an item unreadable to anyone other than authorized users and services:

- The data is encrypted at the application level and includes a policy that defines the authorized use for that item.
- When an encrypted item is used by a legitimate user or it's processed by an authorized service, the data in the item is decrypted and the rights that are defined in the policy are enforced.

At a high level, you can see how this process works in the following picture. A document containing the secret formula is encrypted, and then successfully opened by an authorized user or service. The document is encrypted by a content key (the green key in this picture). The content key is unique for each document and is placed in the file header where it's encrypted by your Azure Rights Management tenant root key (the red key in this picture). Your tenant key can be generated and managed by Microsoft, or you can generate and manage your own tenant key.

Throughout the encrypted process when the Azure Rights Management service is encrypting and decrypting, authorizing, and enforcing restrictions, the secret formula is never sent to Azure.

For a detailed description of what's happening, see the Walkthrough of how the service works: First use, content encryption, content consumption section in this article.

For details about the algorithms and key lengths that the service uses, see Cryptographic controls: Algorithms and key lengths.

Cryptographic controls: Algorithms and key lengths

Even if you don't need to know in detail how this technology works, you might be asked about the cryptographic controls that it uses. For example, to confirm that the encryption is industry-standard.

Expand table

Cryptographic controls	Use in the Azure Rights Management service
Algorithm: AES Key length: 128 bits and 256 bits [1]	Content encryption

Cryptographic controls	Use in the Azure Rights Management service
Algorithm: RSA Key length: 2048 bits [2]	Key encryption
SHA-256	Certificate signing

Footnote 1: 256 bits is used by the Microsoft Purview Information Protection client in the following scenarios:

- Generic encryption (.pfile).
- Native encryption for PDF documents when the document has been encrypted with the ISO standard for PDF encryption, or the resulting encrypted document has a .ppdf file name extension.
- Native encryption for text or image files (such as .ptxt or .pjpg).

Footnote 2: 2048 bits is the key length when the Azure Rights Management service is activated. 1024 bits is supported for the following optional scenarios:

- During a migration from on-premises if the Active Directory Rights Management Services (AD RMS) cluster is running in Cryptographic Mode 1.
- For archived keys that were created on-premises before the migration, so that content that was previously encrypted by AD RMS can continue to be opened by the Azure Rights Management service post migration.

How the cryptographic keys are stored and secured

For each document or email that is protected by the Azure Rights Management service, the service creates a single AES key (the "content key"), and that key is embedded to the document, and persists through editions of the document.

The content key is encrypted with the organization's RSA key (the "Azure Rights Management tenant key") as part of the policy in the document, and the policy is also signed by the author of the document. This tenant key is common to all documents and emails that are protected by the Azure Rights Management service for the organization and the tenant key can only be changed by an administrator for the service if the organization is using a tenant key that is customer-managed (known as "bring your own key", or BYOK).

This tenant key is protected in Microsoft's online services, in a highly controlled environment and under close monitoring. When you use a customer-managed tenant key (BYOK), this security is enhanced by the use of an array of high-end hardware security modules (HSMs) in each Azure region, without the ability for the keys to be extracted, exported, or shared under any circumstances. For more information about the tenant key and BYOK, see Managing the root key for your Azure Rights Management service.

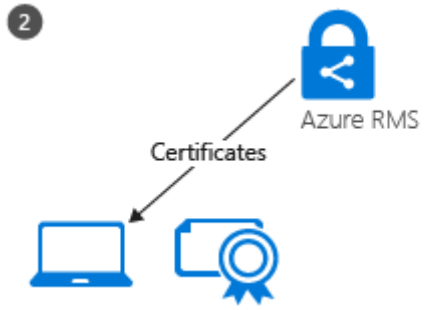
Licenses and certificates that are sent to a Windows device are encrypted with the client's device private key. This private key is created the first time a user on the device uses the Azure Rights Management service. This private key, in turn, is encrypted with DPAPI on the client, which protects these secrets by using a key derived from the user's password. On mobile devices, the keys are used only one time, so because they aren't stored on the clients, these keys don't need to be encrypted on the device.

Walkthrough of how the service works: First use, content encryption, content consumption

To understand in more detail how the Azure Rights Management service works, let's walk through a typical flow after the Azure Rights Management service is activated and when a user first uses the Rights Management service from their Windows computer (a process sometimes known as **initializing the user environment** or bootstrapping), **encrypts content** (a document or email), and then **consumes** (opens and uses) content that has been encrypted by somebody else.

After the user environment is initialized, that user can then encrypt documents or consume encrypted documents on that computer.

> **Note**
>
> If this user moves to another Windows computer, or another user uses this same Windows computer, the initialization process is repeated.



Initializing the user environment

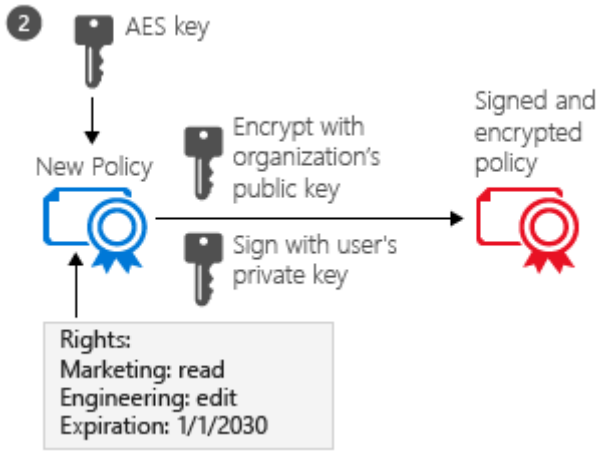
Before a user can encrypt content or consume encrypted content on a Windows computer, the user environment must be prepared on the device. This is a one-time process and happens automatically without user intervention when a user tries to encrypt or consume encrypted content:

What's happening in step 1: The client for the Azure Rights Management service that runs on the computer first connects to the service, and the service authenticates the user by using their Microsoft Entra account.

When the user's account is federated with Microsoft Entra ID, this authentication is automatic and the user isn't prompted for credentials.

What's happening in step 2: After the user is authenticated, the connection is automatically redirected to the organization's tenant, which issues certificates that let the user authenticate to the Azure Rights Management service in order to consume encrypted content and to encrypt content offline.

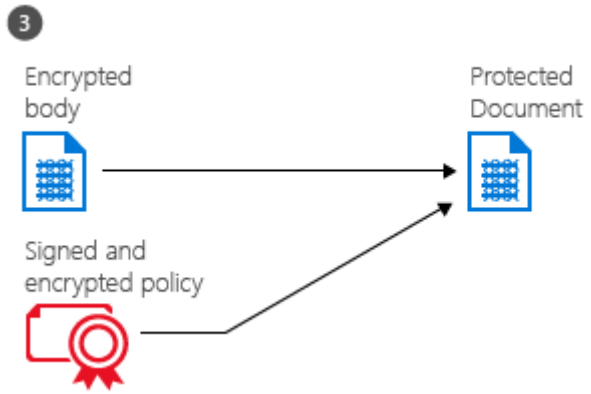
One of these certificates is the rights account certificate. This certificate, often abbreviated as RAC, authenticates the user to Microsoft Entra ID and is valid for 31 days. The certificate is automatically renewed by the client, providing the user account is still in Microsoft Entra ID and the account is enabled. This certificate isn't configurable by an administrator.



A copy of this certificate is stored in Azure so that if the user moves to another device, the certificates are created by using the same keys.

Content encryption

When a user encrypts a document, the client for the Azure Rights Management service takes the following actions on an unencrypted document:

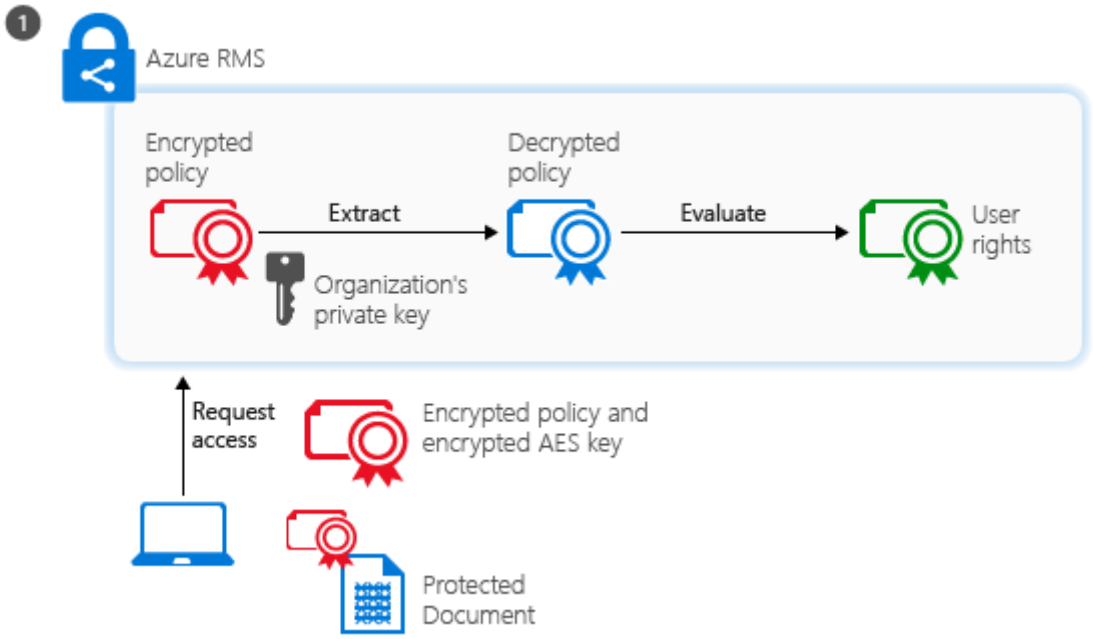


What's happening in step 1: The client creates a random key (the content key) and encrypts the document using this key with the AES symmetric encryption algorithm.

What's happening in step 2: The client then creates a certificate that includes a policy for the document that includes the usage rights for users or groups, and other restrictions, such as an expiration date. These settings can be defined with sensitivity label encryption settings that an administrator previously configured, or specified at the time the content is encrypted (sometimes referred to as "user-defined permissions" or an "ad hoc policy").

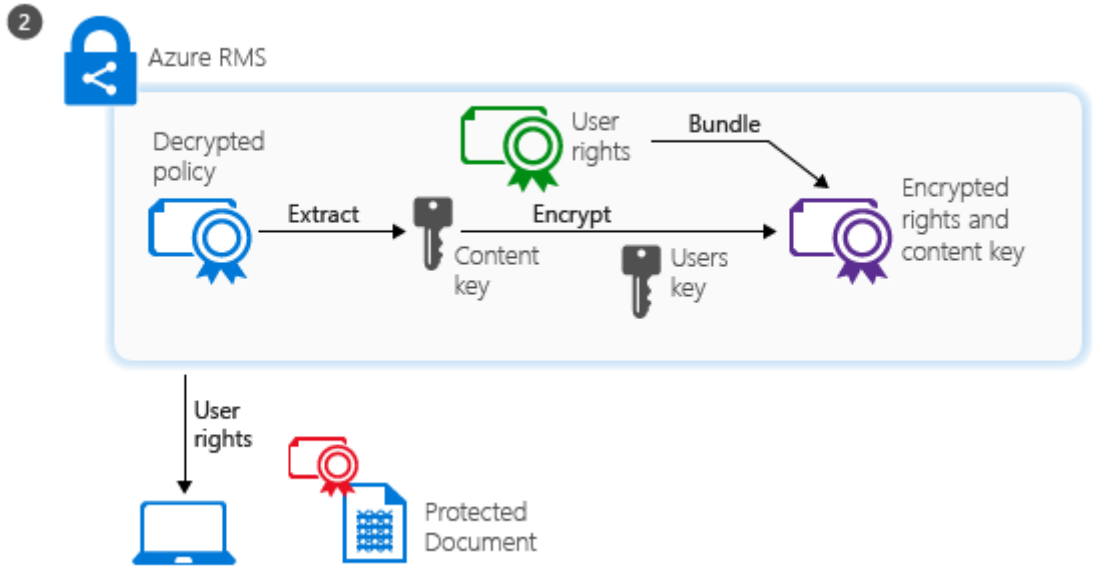
The main Microsoft Entra attribute used to identify the selected users and groups is the Microsoft Entra **ProxyAddresses** attribute, which stores all the email addresses for a user or group. However, if a user account doesn't have any values in the AD ProxyAddresses attribute, the user's **UserPrincipalName** value is used instead.

The client then uses the organization's key that was obtained when the user environment was initialized and uses this key to encrypt the policy and the symmetric content key. The client also signs the policy with the user's certificate that was obtained when the user environment was initialized.



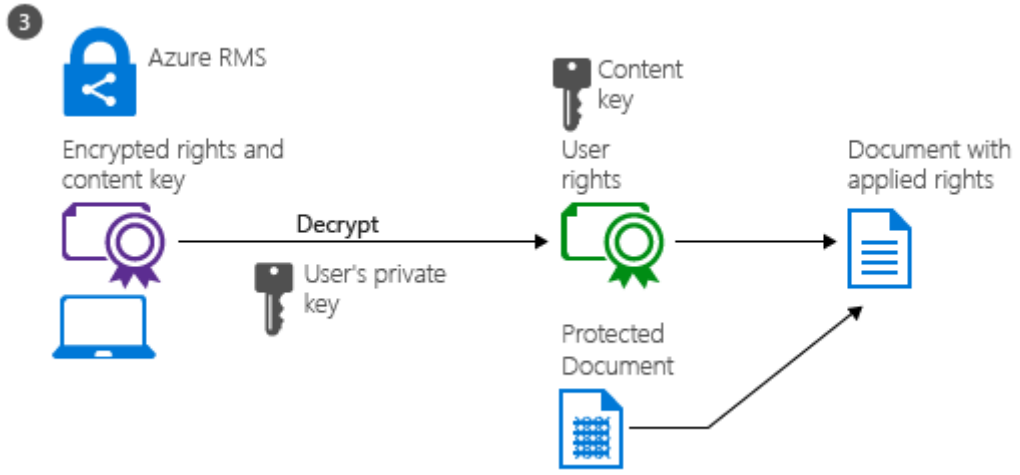
What's happening in step 3: Finally, the client embeds the policy into a file with the body of the document encrypted previously, which together comprise an encrypted document.

This document can be stored anywhere or shared by using any method, and the policy always stays with the encrypted document.



Content consumption

When a user wants to consume an encrypted document, the client starts by requesting access to the Azure Rights Management service:



What's happening in step 1: The authenticated user sends the document policy and the user's certificates to the Azure Rights Management service. The service decrypts and evaluates the policy, and builds a list of rights (if any) the user has for the document. To identify the user, the Microsoft Entra ProxyAddresses attribute is used for the user's account and groups to which the user is a member. For performance reasons, group membership is cached. If the user account

hasn't any values for the Microsoft Entra ProxyAddresses attribute, the value in the Microsoft Entra UserPrincipalName is used instead.

What's happening in step 2: The service then extracts the AES content key from the decrypted policy. This key is then encrypted with the user's public RSA key that was obtained with the request.

The re-encrypted content key is then embedded into an encrypted use license with the list of user rights, which is then returned to the client.

What's happening in step 3: Finally, the client takes the encrypted use license and decrypts it with its own user private key. This lets the client decrypt the document's body as it is needed and render it on the screen.

The client also decrypts the rights list and passes them to the application, which enforces those rights in the application's user interface.

> **Note**
>
> When users who are external to your organization consume content that you have encrypted, the consumption flow is the same. What changes for this scenario, is how the user is authenticated. For more information, see **When I share an encrypted document with somebody outside my company, how does that user get authenticated?**

Variations

The preceding walkthroughs cover the standard scenarios but there are some variations:

- **Email encryption**: When Exchange Online and Microsoft Purview Message Encryption is used to encrypt email messages, authentication for consumption can also use federation with a social identity provider or by using a one-time passcode. Then, the process flows are very similar, except that content consumption happens service-side in a web browser session over a temporarily cached copy of the outbound email.

- **Mobile devices**: When mobile devices encrypt or consume files with the Azure Rights Management service, the process flows are simpler. Mobile devices don't first go through the user initialization process because instead, each transaction (to encrypt or consume content) is independent. As with Windows computers, mobile devices connect to the Azure Rights Management service and authenticate. To encrypt content, mobile devices submit a policy and the Azure Rights Management service sends them a publishing license and symmetric key to encrypt the document. To consume encrypted content, when mobile devices connect to the Azure Rights Management service and authenticate, they send the document policy to the Azure Rights Management service and request a use license to consume the document. In response, the Azure Rights Management service sends the necessary keys and restrictions to the mobile devices. Both processes use TLS to protect the key exchange and other communications.

- **Rights Management connector**: When the Azure Rights Management service is used with the Rights Management connector, the process flows remain the same. The only difference is that the connector acts as a relay between the on-premises services (such as Exchange Server and SharePoint Server) and the Azure Rights Management service. The connector itself doesn't perform any operations, such as the initialization of the user environment, or encryption or decryption. It simply relays the communication that would usually go to an AD RMS server, handling the translation between the protocols that are used on each side. This scenario lets you use the Azure Rights Management service with on-premises services.

- **Generic encryption (.pfile)**: When the Azure Rights Management service generically encrypts a file, the flow is basically the same for content encryption except that the client creates a policy that grants all rights. When the file is consumed, it's decrypted before it's passed to the target application. This scenario lets you encrypt all files, even if they don't natively support the Azure Rights Management service.

- **Microsoft accounts**: The Azure Rights Management service can authorize email addresses for consumption when they're authenticated with a Microsoft account. However, not all applications can open encrypted content when a Microsoft account is used for authentication. Supported scenarios for opening protected documents.

Next steps

For a less technical overview of the Azure Rights Management service, see Learn about the Azure Rights Management service.

If you're ready for deployment recommended steps that include encryption to protect your data, see Deploy an information protection solution with Microsoft Purview.

Compliance and supporting information for the Azure Rights Management service

> *Microsoft Purview service description*

The Azure Rights Management service supports other services and also relies on other services. If you're looking for information that is related to this encryption service but not about how to use the service, check the following resources:

Suitability for different countries/regions

Given the variability between laws and regulations in different countries/regions, different use cases and scenarios, and the varying requirements between different business sectors, consult your legal adviser to help you answer whether the Azure Rights Management service is suitable for your country/region.

However, some relevant information that can help your legal adviser make a determination:

- The Azure Rights Management service uses AES 256 and AES 128 to encrypt documents. For more information, see Cryptographic controls, algorithms, and key lengths.
- All encryption keys used by the Azure Rights Management service are protected with a customer-specific root key that uses RSA 2048 bits. RSA 1024 bits is also supported for backwards compatibility. For more information, see Cryptographic controls, algorithms, and key lengths.
- Customer-specific root keys are either managed by Microsoft or provisioned by the customer in a nCipher HSM by using "bring your own key" (BYOK). The Azure Rights Management service also supports features for on-premises encryption, for content that cannot be encrypted with a cloud-based key. For more information, see Managing the root key for your Azure Rights Management service.
- The Azure Rights Management service is hosted in regional data centers across the globe. The Azure Rights Management service keys always remain within the region in which the service was originally deployed.

- The Azure Rights Management service doesn't transmit document contents from clients to the Azure Rights Management service. Content encryption and decryption operations are performed in-place in the client device. Or, for service-based rendering, these operations are performed within the service that's rendering the content. For more information, see How the Azure Rights Management service works.

Legal and privacy

- For Microsoft Azure agreement information: Microsoft Azure Agreement
- For Microsoft Azure privacy information: Microsoft Azure Privacy Statement

Security, compliance, and auditing

See the Security, compliance, and regulatory requirements section in the Learn about the Azure Rights Management service article, for information about specific certifications for the Azure Rights Management service. In addition:

- For external certifications for the Azure Rights Management service: Microsoft Azure Trust Center
- For FIPS 140 information: FIPS 140 Validation

For in-depth technical information about how the encryption technology works, see How the Azure Rights Management service works: Technical details.

Service level agreements (SLAs)

The following service level agreement resources apply to the Azure Rights Management service and its dependencies:

- SLA for the Azure Rights Management service
- SLA for Microsoft Entra ID
- SLA for Azure Key Vault

Documentation

For related product documentation, see the following resources:

- Microsoft Entra documentation: Microsoft Entra ID

- Microsoft 365 documentation: Microsoft 365 for enterprise documentation and resources

Microsoft Entra configuration for encrypted content

Service description

> *Microsoft Purview service description*

If you protect sensitive items such as emails and documents by using encryption from the Azure Rights Management service from Microsoft Purview Information Protection, there are some Microsoft Entra configurations that can prevent authorized access to this encrypted content.

Similarly, if your users receive encrypted email from another organization or collaborate with other organizations that encrypt documents by using the Azure Rights Management service, your users might not be able to open that email or document because of how their Microsoft Entra ID is configured.

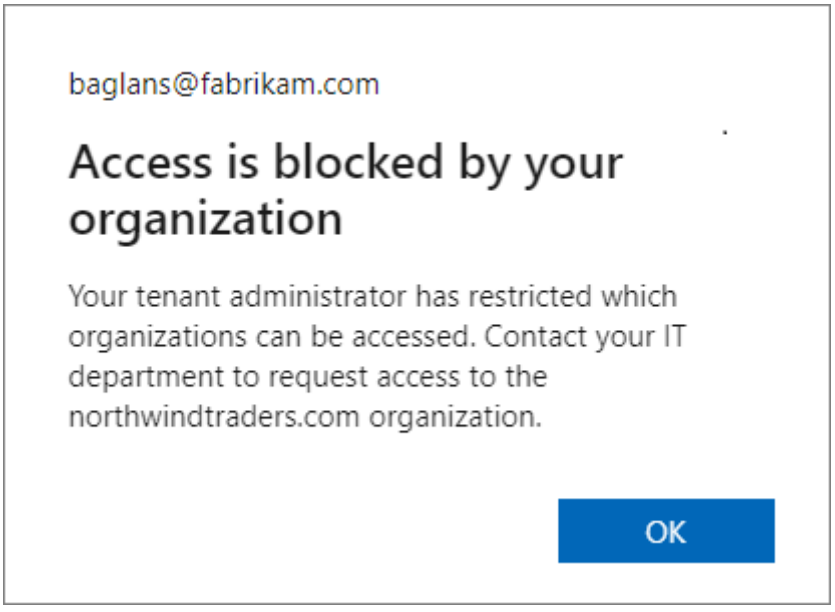
For example:

- A user can't open encrypted email sent from another organization. Or, a user reports that the recipients in another organization can't open an encrypted email that they sent them.
- Your organization collaborates with another organization on a joint project, and project documents are protected by encrypting them, granting access by using groups in Microsoft Entra ID. Users can't open the documents encrypted by users in the other organization.
- Users can successfully open an encrypted document when they are in the office, but can't when they try to access this document remotely and they're prompted for multifactor authentication (MFA).

To ensure access to the encryption service isn't inadvertently blocked, use the following sections to help configure your organization's Microsoft Entra ID, or relay the information to a Microsoft Entra administrator in another organization. Without access to the Azure Rights Management service, users can't be authenticated and aren't authorized to open encrypted content.

Cross-tenant access settings and encrypted content

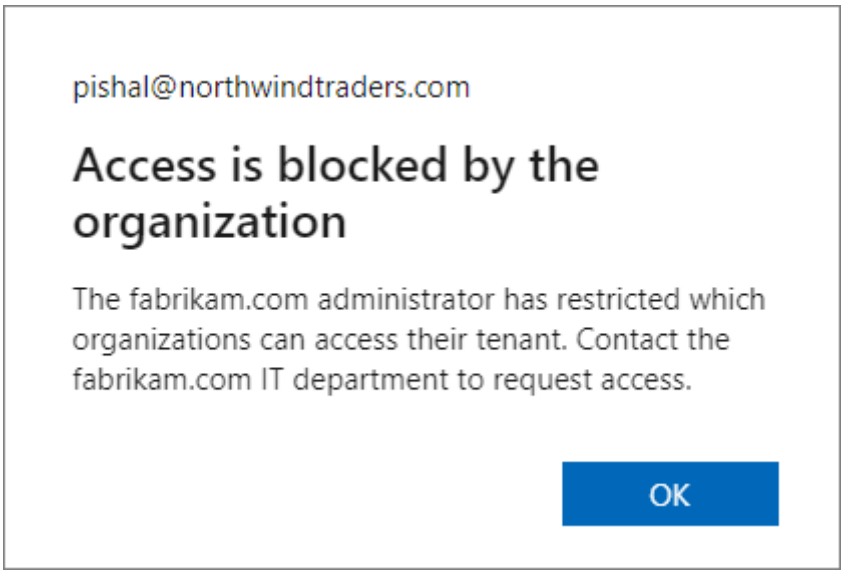
> **Important**



Another organization's cross-tenant access settings can be responsible for either their users being unable to open content that your users have encrypted, or your users being unable to open content encrypted by the other organization.

The message that users see indicates which organization blocked access. You might need to direct the Microsoft Entra admin from another organization to this Cross-tenant access settings and encrypted content section.

By default, there's nothing to configure for cross-tenant authentication to work when users protect content by using encryption from the Azure Rights Management service. However, your organization can restrict access by using Microsoft Entra External Identities cross-tenant access settings. Conversely, another organization can also configure these settings to restrict access with users in your organization. These settings affect opening any encrypted items, which include encrypted emails and encrypted documents.



For example, another organization might have settings configured that prevent their users from opening content encrypted by your organization. In this scenario, until their Microsoft Entra admin reconfigures their cross-tenant settings, an external user attempting to open that content sees a message that informs them **Access is blocked by your organization** with a reference to **Your tenant administrator**.

Example message for the signed in user from the Fabrikam, Inc organization, when their local Microsoft Entra ID blocks access:

Your users will see a similar message when it's your Microsoft Entra configuration that blocks access.

From the perspective of the signed in user, if it's another Microsoft Entra organization that's responsible for blocking access, the message changes to **Access is blocked by the organization** and displays the domain name of that other organization in the body of the message. For example:

Whenever cross-tenant access settings restrict access by applications, they must be configured to allow access to the rights management service, which has the following app ID:

```plaintext
00000012-0000-0000-c000-000000000000
```

If access to the rights management service isn't allowed, users can't be authenticated and authorized to open encrypted content. This configuration can be set as a default setting and as an organizational setting:

- To permit sharing of encrypted content with another organization, create an inbound setting that allows access to Microsoft Rights Management Service (ID: 00000012-0000-0000-c000-000000000000).
- To permit access to encrypted content that users receive from other organizations, create an outbound setting that allows access to Microsoft Rights Management Service (ID: 00000012-0000-0000-c000-000000000000)

When these settings are configured for the encryption service, the application displays **Microsoft Rights Management Services**.

For instructions to configure these cross-tenant access settings, see Configure cross-tenant access settings for B2B collaboration.

If you configured Microsoft Entra Conditional Access policies that require multifactor authentication (MFA) for users, see Conditional Access policies and encrypted documents.

Conditional Access policies and encrypted documents

If your organization has implemented Microsoft Entra Conditional Access policies that include **Microsoft Rights Management Services** and the policy extends to external users who need to open documents encrypted by your organization:

- For external users who have a Microsoft Entra account in their own tenant, we recommend you use External Identities cross-tenant access settings to configure trust settings for MFA claims from one, many, or all external Microsoft Entra organizations.
- For external users not covered by the previous entry, for example, users who don't have a Microsoft Entra account or you haven't configured cross-tenant access settings for trust settings, these external users must have a guest account in your tenant.

Without one of these configurations, external users can't open the encrypted content and see an error message. The message text might inform them that their account needs to be added as an external user in the tenant, with the incorrect instruction for this scenario to **Sign out and sign in again with a different Microsoft Entra user account**.

If you can't meet these configuration requirements for external users who need to open content encrypted by your organization, you must either remove Microsoft Rights Management Services from the Conditional Access policies, or exclude external users from the policies.

For more information, see the frequently asked question, I see Microsoft Rights Management Services is listed as an available cloud app for conditional access—how does this work?

Guest accounts for external users to open encrypted documents

You might need guest accounts in your Microsoft Entra tenant for external users to open documents encrypted by your organization. Options to create the guest accounts:

- Create these guest accounts yourself. You can specify any email address that these users already use. For example, their Gmail address.

  The advantage of this option is that you can restrict access and rights to specific users by specifying their email address in the encryption settings. The downside is the administration

overhead for the account creation and coordination with the label configuration.

- Use SharePoint and OneDrive integration with Microsoft Entra B2B so that guest accounts are automatically created when your users share links.

  The advantage of this option is minimum administrative overhead because the accounts are created automatically, and simpler label configuration. For this scenario, you must select the encryption option Add any authenticated user because you won't know the email addresses in advance. The downside is that this setting doesn't let you restrict access and usage rights to specific users.

External users can also use a Microsoft account to open encrypted documents when they use Windows and Microsoft 365 Apps (formerly Office 365 apps; see Microsoft 365 Apps name change) or the standalone edition of Office 2019. More recently supported for other platforms, Microsoft accounts are also supported for opening encrypted documents on macOS (Microsoft 365 Apps, version 16.42+), Android (version 16.0.13029+), and iOS (version 2.42+).

For example, a user in your organization shares an encrypted document with a user outside your organization, and the encryption settings specify a Gmail email address for the external user. This external user can create their own Microsoft account that uses their Gmail email address. Then, after signing in with this account, they can open the document and edit it, according to the usage restrictions specified for them. For a walkthrough example of this scenario, see Opening and editing the protected document.

> **Note**
>
> The email address for the Microsoft account must match the email address specified to restrict access for the encryption settings.

When a user with a Microsoft account opens an encrypted document in this way, it automatically creates a guest account for the tenant if a guest account with the same name doesn't already exist. When the guest account exists, it can then be used to open documents in SharePoint and OneDrive by using Office for the web, in addition to opening encrypted documents from the supported desktop and mobile Office apps.

However, the automatic guest account isn't created immediately in this scenario, because of replication latency. If you specify personal email addresses as part of your encryption settings, we recommend that you create corresponding guest accounts in Microsoft Entra ID. Then, let these

users know that they must use this account to open an encrypted document from your organization.

> **Tip**
>
> Because you can't be sure that external users will be using a supported Office client app, sharing links from SharePoint and OneDrive after creating guest accounts (for specific users) or when you use **SharePoint and OneDrive integration with Microsoft Entra B2B** (for any authenticated user) is a more reliable method to support secure collaboration with external users.

Cross-cloud access settings and encrypted content

Cross-tenant access settings enable cross-cloud access to encrypted documents. As a result, users who are part of an organization in another cloud environment can open Word, Excel, and PowerPoint files that are encrypted by your organization. For example, these users might be in Microsoft Azure Government, or Microsoft Azure China (operated by 21Vianet).

Supported scenarios

The following scenarios are supported for cross-cloud access to encrypted content:

- Organizations in the Microsoft Azure Commercial cloud can allow access to organizations in the Microsoft Azure Government cloud or Microsoft Azure China (operated by 21Vianet) cloud without contacting Microsoft.
- Organizations in the Microsoft Azure China (operated by 21Vianet) cloud can allow access to organizations in the Microsoft Azure Commercial cloud without contacting Microsoft.
- Encrypted Word, Excel, and PowerPoint files can be shared with users in another cloud environment and viewed on Windows, MacOS, and mobile devices. This scenario doesn't apply to files shared via SharePoint or OneDrive sharing links, but rather to methods like direct email attachments, USB drive, file share, or shared and downloaded from SharePoint.
- Encrypted PDFs and generically encrypted files (.pfile extension) can be shared with users in another cloud environment and viewed using the Microsoft Purview Information Protection Viewer on Windows.
- The user can be, but isn't required to be, a guest in your organization.
- External users and domains can be configured for sensitivity labels that apply encryption when you use admin-defined permissions, or specified by users when the labels are configured for user-defined permissions.

Unsupported scenarios

The following scenarios are currently unsupported for cross-cloud access to encrypted content:

- Email isn't supported, including all Outlook clients.
- PDF viewers such as Microsoft Edge or Adobe Acrobat are currently unsupported.

Requirements

Before you configure cross-cloud access, ensure the following requirements are met:

- Microsoft 365 Apps version 2402 or later or Microsoft Office 2024.
- Microsoft Purview Information Protection client 3.1.310.0 or later.
- Administrators on both sides must:
  - Configure cross-tenant access settings to enable cross-cloud access
  - Add the partner organization as a permitted organization
- Users opening encrypted files must have an email address assigned.

Cross-tenant access settings: Enable cross-cloud collaboration

There's a one-time step required to enable collaboration across different cloud environments:

1. In the Microsoft Entra admin center, navigate to **External identities** > **Cross-tenant access settings**.
2. Select **Microsoft cloud settings**.
3. Select the cloud environment you need to enable for collaboration:

   - Organizations in the Commercial Cloud see both **Microsoft Azure Government** and **Microsoft Azure China (operated by 21Vianet)**.
   - Organizations in a sovereign cloud see only **Microsoft Azure Commercial Cloud**.

4. Select the cloud environment where your partner organization is hosted, and select **Save**.

> **Note**
>
> Both organizations must complete this step, and select the partner cloud.

Cross-tenant access settings: Configure organizational settings

To configure organizational settings:

1. In the Microsoft Entra admin center, navigate to **External identities** > **Cross-tenant access settings**.
2. Select **Organizational settings**.
3. Select **Add organization**.
4. Enter the **Microsoft Entra tenant ID** for the partner organization.
5. Select **Add**.

The tenant ID is displayed in the **Overview** section of the Microsoft Entra admin center and should be provided by the partner organization.

Cross-tenant access settings: Trust external MFA claims

If external users aren't invited as guests, inbound trust settings should be configured to trust external MFA claims. If users are invited as guests and you trust external MFA claims, it's recommended to exclude external users from MFA registration in your organization.

Review Manage cross-tenant access settings for B2B collaboration for configuration details.

Cross-tenant access settings: Inbound and outbound access settings

The steps to enable the partner cloud and add the partner organization are sufficient to enable both organizations to consume protected content from the partner organization. If you'd like to restrict the cross-cloud collab to only permit document decryption, excluding other services, or to make the relationship one-way, review Cross-tenant access settings and encrypted content.

Changes to domain-based sharing

When the encryption scenario is confined to the same cloud environment, specifying a single domain for the label encryption settings results in authenticating and authorizing all users from the organization that owns the specified domain, regardless of the users' email domain. For more information about this domain-based access, see the note in Restrict access to content by using sensitivity labels to apply encryption.

However, the cross-cloud functionality relies on data embedded in Entra access tokens. The feature makes use of two optional claims: `verified_primary_email` and `verified_secondary_email`.

During authorization, these claims are extracted and evaluated against the permissions defined in the label. When the rights management service evaluates domain-based access, it can evaluate

only the email suffixes that were provided in the access token. This results in a scenario where the admin-defined permissions or user-defined permissions must contain a domain name that maps exactly to a user's email suffix.

Cross-cloud common issues

External users see "Access is blocked by your organization" when they try to open encrypted files

Cross-tenant access settings aren't configured correctly on one or both sides. Review the Cross-tenant access settings and encrypted content section and the Cross-tenant access settings: Inbound and outbound access settings section.

AADSTS90072: Nonguest users see "User account {user@contoso.com} from identity provider 'microsoftonline.com' does not exist in..."

This error indicates that external MFA claims aren't trusted. For configuration details, see Manage cross-tenant access settings for B2B collaboration.

Next steps

For addition configurations you might need to make, see Restrict access to a tenant. Specific to network infrastructure configuration for the Azure Rights Management service, see Firewalls and network infrastructure.

If you use sensitivity labels to encrypt documents and emails, you might be interested in Support for external users and labeled content to understand which label settings apply across tenants. For configuration guidance for the label encryption settings, see Restrict access to content by using sensitivity labels to apply encryption.

Interested to learn how and when the encryption service is accessed? See Walkthrough of how the service works: First use, content encryption, content consumption.

Learn how user accounts and groups use the Azure Rights Management service

08/26/2025

Before you use the Azure Rights Management service to encrypt content for your organization, understand how the service works with accounts for users and groups in Microsoft Entra ID.

There are different ways to create these accounts for users and groups, which include:

- You create the users in the Microsoft 365 admin center, and the groups in the Exchange Online admin center.
- You create the users and groups in the Azure portal.
- You create the users and group by using PowerShell cmdlets.
- You create the users and groups in your on-premises Active Directory and synchronize them to Microsoft Entra ID.
- You create the users and groups in another directory and synchronize them to Microsoft Entra ID.

When you create users and groups by using the first three methods from this list, with one exception, they're automatically created in Microsoft Entra ID, and the Azure Rights Management service can use these accounts directly. However, some enterprise networks use an on-premises directory to create and manage users and groups. The Azure Rights Management service can't use these accounts directly; you must synchronize them to Microsoft Entra ID.

The exception referred to in the previous paragraph is dynamic distribution lists that you can create for Exchange Online. Unlike static distribution lists, these groups aren't replicated to Microsoft Entra ID and so can't be used by the Azure Rights Management service.

How users and groups are used by the Azure Rights Management service

There are two scenarios for using users and groups with the Azure Rights Management service:

For encryption settings when you use the Azure Rights Management service to encrypt documents and emails. Administrators and users can select users and groups that can open the encrypted content, and additionally:

- Usage rights that determine how they can use the content. For example, whether they can only read it, or read and print it, or read and edit it.
- Access controls include an expiry date and whether a connection to the internet is required for access.

For configuring the Azure Rights Management service to support specific scenarios, and therefore only administrators select these groups. Examples include configuring the following:

- Super users, so that designated services or people can open encrypted content if required for eDiscovery or data recovery.
- Delegated administration of the Azure Rights Management service.
- Onboarding controls to support a phased deployment.

Azure Rights Management service requirements for user accounts

For encryption settings, and configuring the Azure Rights Management service:

- To authorize users, two attributes in Microsoft Entra ID are used: **proxyAddresses** and **userPrincipalName**.
- The **Microsoft Entra proxyAddresses** attribute stores all email addresses for an account and can be populated in different ways. For example, a user in Microsoft 365 that has an Exchange Online mailbox automatically has an email address that is stored in this attribute. If you assign an alternative email address for a Microsoft 365 user, it is also saved in this attribute. It can also be populated by the email addresses that are synchronized from on-premises accounts.

  The Azure Rights Management service can use any value in this Microsoft Entra proxyAddresses attribute, providing the domain has been added to your tenant (a "verified domain"). For more information about verifying domains:

  - For Microsoft Entra ID: Add a custom domain name to Microsoft Entra ID
  - For Microsoft 365: Add a domain to Microsoft 365
- The **Microsoft Entra userPrincipalName** attribute is used only when an account in your tenant doesn't have values in the Microsoft Entra proxyAddresses attribute. For example, you create a user in the Azure portal, or create a user for Microsoft 365 that doesn't have a mailbox.

Encryption settings for external users

In addition to using the Microsoft Entra proxyAddresses and Microsoft Entra userPrincipalName for users in your tenant, the Azure Rights Management service also uses these attributes in the same way to authorize users from another tenant.

Other authorization methods:

- For email addresses that aren't in Microsoft Entra ID, the Azure Rights Management service can authorize these when they're authenticated with a Microsoft account. However, not all applications can open encrypted content when a Microsoft account is used for authentication.
- When an email is sent by using Microsoft Purview Message Encryption to a user who doesn't have an account in Microsoft Entra ID, the user is first authenticated by using federation with a social identity provider or by using a one-time passcode. Then the email address specified in the protected email is used to authorize the user.

Azure Rights Management service requirements for group accounts

For assigning usage rights and access controls:

- You can use any type of group in Microsoft Entra ID that has an email address that contains a verified domain for the user's tenant. A group that has an email address is often referred to as a mail-enabled group.

For configuring the Azure Rights Management service:

- You can use any type of group in Microsoft Entra ID that has an email address from a verified domain in your tenant, with one exception. That exception is when you configure onboarding controls to use a group, which must be a security group in Microsoft Entra ID for your tenant.
- You can use any group in Microsoft Entra ID (with or without an email address) from a verified domain in your tenant for delegated administration of the Azure Rights Management service.

Encryption settings for external groups

In addition to using the Microsoft Entra proxyAddresses for groups in your tenant, the Azure Rights Management service also uses this attribute in the same way to authorize groups from

another tenant.

Using accounts from Active Directory on-premises

If you have accounts that are managed on-premises that you want to use with the Azure Rights Management service, you must synchronize these to Microsoft Entra ID. For ease of deployment, we recommend that you use Microsoft Entra Connect. However, you can use any directory synchronization method that achieves the same result.

When you synchronize your accounts, you don't need to synchronize all attributes. For a list of the attributes that must be synchronized, see the Azure RMS section from the Microsoft Entra documentation.

From the attributes list for Azure Rights Management, you see that for users, the on-premises AD attributes of **mail**, **proxyAddresses**, and **userPrincipalName** are required for synchronization. Values for **mail** and **proxyAddresses** are synchronized to the Microsoft Entra proxyAddresses attribute. For more information, see How the proxyAddresses attribute is populated in Microsoft Entra ID

Considerations if email addresses change

If you change the email address of a user or group, we recommend that you add the old email address as a second email address (also known as a proxy address, alias, or alternate email address) to the user or group. When you do this, the old email address is added to the Microsoft Entra proxyAddresses attribute. This account administration ensures business continuity for any usage rights or other configurations there were saved when the old email address was in use.

If you can't do this, the user or group with the new email address risks being denied access to documents and emails that were previously protected with the old email address. In this case, you must repeat the protection configuration to save the new email address. For example, if the user or group was granted usage rights in templates or labels, edit those templates or labels and specify the new email address with same usage rights as you granted to the old email address.

Note that it's rare for a group to change its email address and if you assign usage rights to a group rather to than individual users, it doesn't matter if the user's email address changes. In this scenario, the usage rights are assigned to the group email address and not individual user email addresses. This is the most likely (and recommended) method for an administrator to configure usage rights that protect documents and emails. However, users might more typically assign custom permissions for individual users. Because you can't always know

whether a user account or group has been used to grant access, it's safest to always add the old email address as a second email address.

Group membership caching

For performance reasons, the Azure Rights Management service caches group membership. This caching means that any changes to group membership in Microsoft Entra ID can take up to three hours to take effect when these groups are used by the Azure Rights Management service and this time period is subject to change.

Remember to factor this delay into any changes or testing that you do when you use groups for granting usage rights or configuring the Azure Rights Management service.

Next steps

When you have confirmed that your users and groups can be used with the Azure Rights Management service, check whether you need to activate the Azure Rights Management service:

- Beginning with February 2018: If your subscription that includes Azure Rights Management or Microsoft Purview Information Protection was obtained during or after this month, the service is automatically activated for you.
- If your subscription was obtained before February 2018: You must activate the service yourself.

For more information, which includes checking the activation status, see Activate the Azure Rights Management service.

Administering the Azure Rights Management service by using PowerShell

> *Microsoft Purview service description*

PowerShell is required to manually activate the Azure Rights Management encryption service, and you also need PowerShell for some advanced configurations. Some configurations can be done from the Microsoft Purview portal, however, you might prefer to use PowerShell for more efficient command-line control and scripting.

The following table lists some of the advanced configuration scenarios that use PowerShell. When the configuration can also be completed without using PowerShell, this information is also included in the table.

For a complete list of the available cmdlets for this module, with more information about each one, see AIPService.

To install this PowerShell module, see Install the AIPService PowerShell module for the Azure Right Management service.

> **Tip**
>
> In addition to this service-side PowerShell module, the Microsoft Purview Information Protection client installs a supplemental PowerShell module, **PurviewInformationProtection**.
>
> This client module supports labeling and encrypting multiple files so that, for example, you can bulk-protect all files in a folder. For more information, see **Set up the information protection client using PowerShell**.

Cmdlets grouped by administration task

The following table groups common administration tasks by the cmdlets used to complete them.

Expand table

If you need to...	...use the following cmdlets
Migrate from on-premises Rights Management (AD RMS or Windows RMS) to the Azure Rights Management service from Microsoft Purview Information Protection.	Import-AipServiceTpd Set-AipServiceKeyProperties
Connect to or disconnect from the Rights Management service for your organization.	Connect-AipService Disconnect-AipServiceService
Generate and manage your own root key for the Azure Rights Management service – the bring your own key (BYOK) scenario.	Set-AipServiceKeyProperties Use-AipServiceKeyVaultKey Get-AipServiceKeys
Activate or deactivate the Azure Rights Management service for your organization.	Enable-AipService Disable-AipService
Configure onboarding controls for a phased deployment of the Azure Rights Management service.	Get-AipServiceOnboardingControlPolicy Set-AipServiceOnboardingControlPolicy
Create and manage Rights Management templates for your organization.	Add-AipServiceTemplate Export-AipServiceTemplate Get-AipServiceTemplate Get-AipServiceTemplateProperty Import-AipServiceTemplate New-AipServiceRightsDefinition Remove-AipServiceTemplate Set-AipServiceTemplateProperty
Configure the maximum number of days that content that your organization encrypts can be accessed without an internet connection (the use license validity period).	Get-AipServiceMaxUseLicenseValidityTime Set-AipServiceMaxUseLicenseValidityTime
Manage the super user feature of the Azure Rights Management service for your organization.	Enable-AipServiceSuperUserFeature Disable-AipServiceSuperUserFeature

If you need to...	...use the following cmdlets
	Add-AipServiceSuperUser Get-AipServiceSuperUser Remove-AipServiceSuperUser Set-AAipServiceSuperUserGroup Get-AipServiceSuperUserGroup Clear-AipServiceSuperUserGroup
Manage users and groups who are authorized to administer the Azure Rights Management service for your organization.	Add-Aip-ServiceRoleBasedAdministrator Get-Aip-ServiceRoleBasedAdministrator Remove-Aip-ServiceRoleBasedAdministrator
Get a log of the Azure Rights Management service administrative tasks for your organization.	Get-AipServiceAdminLog
Log and analyze usage logging for the Azure Rights Management service.	Get-AipServiceUserLog
Display the current configuration of the Azure Rights Management service for your organization.	Get-AipServiceConfiguration
Migrate your organization from the Azure Rights Management service to an on-premises AD RMS deployment.	Set-AipServiceMigrationUrl Get-AipServiceMigrationUrl
Manage the legacy document tracking site for rights-protected documents	Disable-AipServiceDocumentTrackingFeature Enable-AipServiceDocumentTrackingFeature Get-AipServiceDocumentTrackingFeature Set-AipServiceDoNotTrackUserGroup Clear-AipServiceDoNotTrackUserGroup Get-AipServiceDoNotTrackUserGroup

If you need to...	...use the following cmdlets
	Get-AipServiceTrackingLog Get-AipServiceDocumentLog

Install the AIPService PowerShell module for the Azure Rights Management service

> *Microsoft Purview service description*

Use the following information to help you install the PowerShell module for the Azure Right Management encryption service from Microsoft Purview Information Protection. The name of this module is AIPService, and it replaces the previous version that was named AADRM.

You can use this PowerShell module to administer the Azure Rights Management encryption service from the command line by using any Windows computer that has an internet connection and that meets the prerequisites listed in the following table. PowerShell for the Azure Rights Management service supports scripting for automation or might be necessary for advanced configuration scenarios. For more information about the administration tasks and configurations that the AIPService module supports, see Administering the Azure Rights Management service by using PowerShell.

Prerequisites

This table lists the prerequisites to install and use the AIPService PowerShell module for the Azure Rights Management encryption service.

Expand table

Requirement	More information
Supported PowerShell versions	Windows PowerShell 5.1, or PowerShell 7.4 and later. You can confirm the version you're running by typing `$PSVersionTable` in a PowerShell session. The `PSEdition` property shows `Desktop` for Windows PowerShell and `Core` for PowerShell 7. To install PowerShell 7, see Installing PowerShell on Windows. PowerShell 7 requires AIPService version 3.1.0.0 or later. Earlier versions of the module support Windows PowerShell only.
Minimum .NET version	Windows PowerShell 5.1 requires Microsoft .NET Framework 4.8. This minimum version of the Microsoft .NET Framework is included with the later operating systems but if it's not already installed, you can download Microsoft .NET Framework 4.8. This minimum version of the Microsoft .NET Framework is required

Requirement	More information
	for some of the classes that the AIPService module uses. PowerShell 7.4 and later includes the .NET version that the module requires, so no separate installation is needed.
Required license	You must have a product license to use this feature. For more information, see Microsoft 365 licensing guidance for security & compliance - Service Descriptions.

PowerShell editions

AIPService version 3.1.0.0 supports both PowerShell editions on Windows from a single package:

Expand table

Edition	Host	Runtime
Desktop	Windows PowerShell 5.1	.NET Framework 4.8
Core	PowerShell 7.4 and later	.NET 8

The module selects the correct edition automatically when you import it, so the same `Install-Module` command works in both hosts. Cmdlet names, parameters, and output are the same in both editions.

Interactive sign-in differs between the two editions. Windows PowerShell 5.1 signs in through an embedded web view, while PowerShell 7 uses your default web browser and a local loopback address. On a computer with no default browser available, such as a Server Core installation, or in a remote session, use certificate-based or service principal authentication instead. For more information, see Connect-AipService.

To confirm which editions your installed version supports, run:

PowerShell

```
(Get-Module AIPService -ListAvailable).CompatiblePSEditions
```

If you have the AADRM module installed

The AIPService module replaces the older module, AADRM. If you have the older module installed, uninstall it and then install the AIPService module.

The AIPService module has aliases to the cmdlet names in the AADRM module so that any existing scripts will continue to work. The AADRM module fell out of support on July 15, 2020.

If you installed the AADRM module from the PowerShell Gallery, to uninstall it, start a PowerShell session with the **Run as Administrator** option, and type:

```
PowerShell
Uninstall-Module -Name AADRM
```

If you installed the AADRM module with the Azure Rights Management Administration Tool, use your Windows remove applications procedures to uninstall **Windows Azure AD Rights Management Administration**.

How to install the AIPService module

The AIPService module is on the PowerShell Gallery and is not available from the Microsoft Download Center.

To install the AIPService module from the PowerShell Gallery

If you're new to the PowerShell Gallery, see Get Started with the PowerShell Gallery. Follow the PowerShell Gallery setup instructions, including installing the PowerShellGet module and the NuGet provider.

To see details about the AIPService module on the PowerShell Gallery, visit the AIPService package in PowerShell Gallery.

To install the AIPService module, start a PowerShell session with the **Run as Administrator** option, and type:

```
PowerShell
Install-Module -Name AIPService
```

If you are warned about installing from an untrusted repository, you can press Y to confirm. Or, press N and configure the PowerShell Gallery as a trusted repository by using the command `Set-PSRepository -Name PSGallery -InstallationPolicy Trusted` and then rerun the command to install the AIPService module.

If you have a previous version of the AIPService module installed from the Gallery, update it to the latest by typing:

PowerShell

```
Update-Module -Name AIPService
```

> ⓘ Note
>
> To use the module in PowerShell 7, run `Install-Module -Name AIPService` from a PowerShell 7 session. Windows PowerShell and PowerShell 7 use separate per-user module folders, so a module that was installed for the current user in Windows PowerShell isn't available in PowerShell 7.

Next steps

In a PowerShell session, confirm the version of the installed module. This check is particularly important if you upgraded from an older version:

PowerShell

```
(Get-Module AIPService -ListAvailable).Version
```

> ⓘ Note
>
> If `(Get-Module AIPService -ListAvailable).Version` fails, first run **Import-Module AIPService**.

To see which cmdlets are available, type the following:

Powershell

```
Get-Command -Module AIPService
```

Use the `Get-Help <cmdlet_name>` command to see the Help for a specific cmdlet, and use the **-online** parameter to see the latest help on the Microsoft documentation site. For example:

PowerShell

```
Get-Help Connect-AipService -online
```

For more information:

- Full list of cmdlets available: AIPService Module
- List of main configuration scenarios that support PowerShell: Administering the Azure Rights Management service by using PowerShell

Before you can run any commands that configure the Azure Rights Management service, you must connect to the service by using the Connect-AipService cmdlet.

When you have finished running your configuration commands, as a best practice, disconnect from the service by using the Disconnect-AipService cmdlet. If you do not disconnect, the connection is automatically disconnected after a period of inactivity. Because of the automatic disconnection behavior, you might find that you need to occasionally reconnect in a PowerShell session.

> **Note**
>
> If the Azure Rights Management service is not yet activated, you can activate it after you have connected to the service by using the **Enable-AipService** cmdlet.

Managing the root key for your Azure Rights Management service

> *Microsoft Purview service description*

The Azure Rights Management tenant key is your organization's root key for the main encryption service for Microsoft Purview Information Protection. Other keys can be derived from this root key, including user keys, computer keys, or document encryption keys. Whenever the Azure Rights Management service uses these keys for your organization, they cryptographically chain to your tenant's root key for the Azure Rights Management service.

In addition to your tenant root key, your organization may require on-premises security for specific documents. On-premises key encryption is typically required only for a small amount of content, and therefore is configured together with a tenant root key.

Your Azure Rights Management tenant key can be Microsoft-managed (the default), customer-managed through Bring Your Own Key (BYOK), or supplemented with Double Key Encryption (DKE) for highly sensitive content. Each option provides different levels of control over key life-cycle operations such as rekeying, backup, export, and breach response. To understand your options, see Key types for the service and Operations for your tenant key.

If you're migrating across tenants, such as after a company merger, we recommend that you read our blog post on mergers and spin-offs for more information.

Key types for the service

The root key for your Azure Rights Management service can either be:

- Generated by Microsoft
- Generated by customers with Bring Your Own Key (BYOK)

If you have highly sensitive content that requires additional, on-premises protection, we recommend using Double Key Encryption (DKE).

Tenant root key generated by Microsoft

The default root key, automatically generated by Microsoft, is the default key used exclusively for the Azure Rights Management service to manage most aspects of your tenant key life cycle.

Continue using the default Microsoft key when you want to use the Azure Rights Management service quickly and without special hardware, software, or an Azure subscription. Examples include testing environments or organizations without regulatory requirements for key management.

For the default key, no configuration steps are required.

> **Note**
>
> The default root key generated by Microsoft is the simplest option with the lowest administrative overheads.
>
> In most cases, you may not even know that you have a tenant key, as you can configure encryption settings for Microsoft Purview Information Protection and the key management process is handled by Microsoft.

Bring Your Own Key (BYOK) option

BYOK uses keys that are created by customers, either in the Azure Key Vault or on-premises in the customer organization. These keys are then transferred to Azure Key Vault for further management.

Use BYOK when your organization has compliance regulations for key generation, including control over all life-cycle operations. For example, when your key must be protected by a hardware security module.

For more information, see Configure BYOK.

Double Key Encryption (DKE)

DKE provides additional security for your content by using two root keys that work together: one created and held by Microsoft in Azure, and another created and held on-premises by the customer.

DKE requires both keys to access encrypted content, which ensures that Microsoft and other third parties never have access to encrypted data on their own.

DKE can be deployed either in the cloud or on-premises, providing full flexibility for storage locations.

For more information, see Double key encryption.

Operations for your tenant key

Depending on your Azure Rights Management service key type, you have different levels of control and responsibility for your Azure Rights Management tenant key.

Terminology for key management operations:

- When you use a tenant key that's generated by Microsoft, the key is **Microsoft-managed**.
- When you use a key in Azure Key Vault that you generated with BYOK, the key is **customer-managed**.

Use the following table to identify the management operations that you can do, depending on whether your Azure Rights Management tenant key is Microsoft-managed or customer-managed:

Expand table

Life cycle operation	Microsoft-managed (default)	Customer-managed (BYOK)
Revoke your tenant key	✕ (automatic)	✓
Rekey your tenant key	✓	✓
Backup and recover your tenant key	✕	✓
Export your tenant key	✓	✕
Respond to a breach	✓	✓

For more information about revoke, rekey, backup, export, and breach response operations, see the **Microsoft-managed** or **Customer-managed (BYOK)** section for your tenant key type.

However, if you want to create an Azure Rights Management tenant key by importing a trusted publishing domain (TPD) from Active Directory Rights Management Services, this import operation is part of the migration from AD RMS to Azure Information Protection. As part of the design, an AD RMS TPD can only be imported to one tenant.

Microsoft-managed

The following sections describe key management operations when Microsoft manages your Azure Rights Management tenant key.

Revoke your tenant key

When you cancel the only or last subscription that includes the Azure Rights Management service, the service stops using your Azure Rights Management tenant key and no action is needed from you.

Rekey your tenant key

Rekeying is also known as rolling your key. When you rekey, the Azure Rights Management service stops using the existing tenant key to encrypt items, and starts to use a different key. Policies and rights management templates are immediately resigned but this changeover is gradual for existing clients and services using the Azure Rights Management service. So for some time, some new content continues to be encrypted with the old Azure Rights Management tenant key.

To rekey, you must configure the Azure Rights Management tenant key object and specify the alternative key to use. Then, the previously used key is automatically marked as archived for the Azure Rights Management service. Archiving the previously used key ensures that content encrypted with that key remains accessible.

Examples of when you might need to rekey for the Azure Rights Management service:

- You have migrated from Active Directory Rights Management Services (AD RMS) with a cryptographic mode 1 key. When the migration is complete, you want to change to using a key that uses cryptographic mode 2.
- Your company has split into two or more companies. When you rekey your Azure Rights Management tenant key, the new company won't have access to new content that your employees encrypt. They can access the old content if they have a copy of the old Azure Rights Management tenant key.
- You want to move from one key management topology to another.
- You believe the master copy of your Azure Rights Management tenant key is compromised.

To rekey, you can select a different Microsoft-managed key to become your Azure Rights Management tenant key, but you can't create a new Microsoft-managed key. To create a new key, you must change your key topology to be customer-managed (BYOK).

You have more than one Microsoft-managed key if you migrated from Active Directory Rights Management Services (AD RMS) and chose the Microsoft-managed key topology for the Azure Rights Management service. In this scenario, you have at least two Microsoft-

managed keys for your tenant. One key, or more, is the key or keys that you imported from AD RMS. You'll also have the default key that was automatically created for your Azure Rights Management tenant.

To select a different key to be your active tenant key for the Azure Rights Management service, use the Set-AipServiceKeyProperties cmdlet from the AIPService module. To help you identify which key to use, use the Get-AipServiceKeys cmdlet. You can identify the default key that was automatically created for your Azure Rights Management tenant by running the following command:

```PowerShell
(Get-AipServiceKeys) | Sort-Object CreationTime | Select-Object -First 1
```

To change your key topology to be customer-managed (BYOK), see Bring your own key for the Azure Rights Management service root key.

Backup and recover your tenant key

Microsoft is responsible for backing up your Azure Rights Management tenant key and no action is required from you.

Export your tenant key

You can export your Azure Rights Management service configuration and corresponding tenant key by following the instructions in the following three steps:

Step 1: Initiate export

Start the export process by opening a support case with Microsoft.

- Contact Microsoft Support to open an **Microsoft Purview Information Protection support case with a request for an Azure Rights Management key export**. You must prove you're a global administrator for your tenant, and understand that this process takes several days to confirm. Standard support charges apply; exporting your tenant key is not a free-of-charge support service.

Step 2: Wait for verification

After you submit the request, Microsoft reviews and verifies it.

- Microsoft verifies that your request to release your Azure Rights Management tenant key is legitimate. This process can take up to three weeks.

Step 3: Receive key instructions from CSS

After verification, Microsoft sends you the files and instructions needed to complete the export.

- Microsoft Customer Support Services sends you your Azure Rights Management service configuration and tenant key encrypted in a password-protected file. This file has a **.tpd** file name extension. To prepare the encrypted file, a Microsoft support engineer first sends you (as the person who initiated the export) a tool by email. You must run the tool from a command prompt as follows:

  PowerShell

  ```
  AadrmTpd.exe -createkey
  ```

  This generates an RSA key pair and saves the public and private halves as files in the current folder. For example: **PublicKey-FA29D0FE-5049-4C8E-931B-96C6152B0441.txt** and **PrivateKey-FA29D0FE-5049-4C8E-931B-96C6152B0441.txt**.

  Respond to the email from the support engineer, attaching the file that has a name that starts with **PublicKey**. Microsoft Support next sends you a TPD file as an .xml file that is encrypted with your RSA key. Copy this file to the same folder as you ran the AadrmTpd tool originally, and run the tool again, using your file that starts with **PrivateKey** and the file from Microsoft Support. For example:

  PowerShell

  ```
  AadrmTpd.exe -key PrivateKey-FA29D0FE-5049-4C8E-931B-96C6152B0441.txt -
  target TPD-77172C7B-8E21-48B7-9854-7A4CEAC474D0.xml
  ```

  The output of this command should be two files: a password text file containing the plain text password for the password-protected TPD, and an exported TPD XML file containing the password-protected TPD itself. The files have a new GUID, for example:

  - Password-5E4C2018-8C8C-4548-8705-E3218AA1544E.txt
  - ExportedTPD-5E4C2018-8C8C-4548-8705-E3218AA1544E.xml

Back up these files and store them safely to ensure that you can continue to decrypt content that is encrypted with this tenant key. In addition, if you're migrating to AD RMS, you can import this TPD file (the file that starts with **ExportedTDP**) to your AD RMS server.

Step 4: Ongoing: Protect your tenant key

After you receive your tenant key, keep it well-guarded, because if somebody gets access to it, they can decrypt all items that are encrypted by using that key.

If the reason to export your tenant key is because you no longer want to use the Azure Rights Management service, as a best practice, now deactivate the Azure Rights Management service in your tenant. Don't delay deactivating the Azure Rights Management service after you receive your tenant key, because deactivation helps to minimize the consequences if your tenant key is accessed by somebody who shouldn't have it. For instructions, see Decommission and deactivate the Azure Rights Management service.

Respond to a breach

No security system, no matter how strong, is complete without a breach response process. Your Azure Rights Management tenant key might be compromised or stolen. Even when it’s protected well, vulnerabilities might be found in current generation key technology or in current key lengths and algorithms.

Microsoft has a dedicated team to respond to security incidents in its products and services. As soon as there's a credible report of an incident, Microsoft's security incident response team engages to investigate the scope, root cause, and mitigations. If the investigated security incident affects your assets, Microsoft will notify the global administrators for your tenant by email.

If you have a breach, the best action that you or Microsoft can take depends on the scope of the breach; Microsoft works with you through this process. The following table shows some typical situations and the likely response, although the exact response depends on all the information that is revealed during the investigation.

Expand table

Incident description	Likely response
Your Azure Rights Management tenant key is leaked.	Rekey your tenant key. See the Rekey your tenant key section in this article.

Incident description	Likely response
An unauthorized individual or malware got rights to use your Azure Rights Management tenant key, but the key itself didn't leak.	Rekeying your tenant key doesn't help here and requires root-cause analysis. If a process or software bug was responsible for the unauthorized individual to get access, that situation must be resolved.
Vulnerability discovered in the RSA algorithm, or key length, or brute-force attacks become computationally feasible.	Microsoft must update the Azure Rights Management service to support new algorithms and longer key lengths that are resilient and instruct all customers to rekey their Azure Rights Management tenant key.

Bring your own key for the Azure Rights Management service root key

> *Microsoft Purview service description*

Use the information in this article if you've decided to configure your tenant to use your own root key for the Azure Rights Management service, instead of a default key generated by Microsoft. This configuration is often referred to as Bring Your Own Key (BYOK).

For more information about the root key options, see Key types for the service.

BYOK and usage logging work seamlessly with applications that integrate with the Azure Rights Management service used by Microsoft Purview Information Protection.

Supported applications include:

- **Cloud services**, such as Microsoft SharePoint or Microsoft 365
- **On-premises services** running Exchange and SharePoint applications that use the Azure Rights Management service by using the Rights Management connector
- **Client applications**, such as Office 2024 and Office 2021.

> **Tip**
>
> If needed, apply additional security to specific documents using an additional on-premises key. For more information, see **Double Key Encryption (DKE)**.

Azure Key Vault key storage

Customer-generated keys must be stored in the Azure Key Vault for BYOK.

> **Note**
>
> Using HSM-protected keys in the Azure Key Vault requires an Azure Key Vault Premium service tier, which incurs an additional monthly subscription fee.

Sharing key vaults and subscriptions

We recommend using a **dedicated key vault** for your Azure Rights Management tenant key. Dedicated key vaults help to ensure that calls by other services don't cause service limits to be exceeded. Exceeding service limits on the key vault where your tenant key is stored may cause response time throttling for the Azure Rights Management service.

Because different services have varying key management requirements, Microsoft also recommends using **a dedicated Azure subscription** for your key vault for the following reasons:

- Help safeguard against misconfigurations
- More secure when different services have different administrators

To share an Azure subscription with other services that use Azure Key Vault, make sure that the subscription shares a common set of administrators. Confirm that all administrators who use the subscription have a thorough understanding of every key they can manage. Administrators with this level of understanding are less likely to misconfigure your keys.

Example: Use a shared Azure subscription when the administrators for your Azure Rights Management tenant key are the same people that administer your keys for Microsoft Purview Customer Key and Dynamics 365 Online. If the key administrators for these services are different, we recommend using dedicated subscriptions.

Benefits of using Azure Key Vault

Azure Key Vault provides a centralized and consistent key management solution for many cloud-based and on-premises services that use encryption.

In addition to managing keys, Azure Key Vault offers your security administrators the same management experience to store, access, and manage certificates and secrets (such as passwords) for other services and applications that use encryption.

Storing your tenant key in the Azure Key Vault provides the following advantages:

Expand table

Advantage	Description
Built-in interfaces	Azure Key Vault supports a number of built-in interfaces for key management, including PowerShell, CLI, REST APIs, and the Azure portal. Other services and tools have integrated with Azure Key Vault for optimized capabilities

Advantage	Description
	for specific tasks, such as monitoring. For example, analyze your key usage logs with Azure Monitor Agent, set alerts when specified criteria are met, and so on.
Role separation	Azure Key Vault provides role separation as a recognized security best practice. Role separation ensures that administrators for the Azure Rights Management service can focus on their highest priorities, including managing data classification and protection, as well as encryption keys and policies for specific security or compliance requirements.
Master key location	Azure Key Vault is available in a variety of locations, and supports organizations with restrictions where master keys can live. For more information, see the Products available by region page on the Azure site.
Separated security domains	Azure Key Vault uses separate security domains for its data centers in regions such as North America, EMEA (Europe, Middle East and Africa), and Asia. Azure Key Vault also uses different instances of Azure, such as Microsoft Azure Germany, and Azure Government.
Unified experience	Azure Key Vault also enables security administrators to store, access, and manage certificates and secrets, such as passwords, for other services that use encryption. Using Azure Key Vault for your tenant keys provides a seamless user experience for administrators who manage all of these elements.

For the latest updates and to learn how other services use Azure Key Vault, visit the Azure Key Vault team blog.

Usage logging for BYOK

Usage logs are generated by every application that makes requests to the Azure Rights Management service.

Although usage logging is optional, we recommend using the near real-time usage logs for the Azure Rights Management service to see exactly how and when your Azure Rights Management tenant key is being used.

For more information about key usage logging for BYOK, see Usage logging for the Azure Rights Management service.

> **Tip**
>
> For additional assurance, this usage logging can be cross referenced with **Azure Key Vault logging**. Azure Key Vault logs provide a reliable method to independently monitor that your key is only used by the Azure Rights Management service.
>
> If necessary, immediately revoke access to your key by removing permissions on the key vault.

Options for creating and storing your key

> **Note**
>
> For general information about the Managed HSM offering, and how to set up a vault and a key, see the Azure Key Vault documentation.
>
> This section contains additional instructions about granting key authorization for the Azure Rights Management service.

BYOK supports keys that are created either in Azure Key Vault or on-premises.

If you create your key on-premises, you must then transfer or import it into your key vault and configure the Azure Rights Management service to use the key. Perform any additional key management from within Azure Key Vault.

Options to create and store your own key:

- **Created on-premises**. Create your key on-premises and transfer it to Azure Key Vault using one of the following options:
  - **HSM-protected key, transferred as an HSM-protected key**. The most typical method chosen.

    While this method has the most administrative overhead, it may be required for your organization to follow specific regulations. The HSMs used by Azure Key Vault have FIPS 140 validation.
  - **Software-protected key that is converted and transferred to Azure Key Vault as an HSM-protected key**. This method is supported only when migrating from Active Directory Rights Management Services (AD RMS).

- **Created on-premises as a software-protected key and transferred to Azure Key Vault as a software-protected key**. This method requires a .PFX certificate file.

For example, do the following to use a key created on-premises:

1. Generate your tenant key on your premises, in line with your organization's IT and security policies. This key is the master copy. It remains on-premises, and you're responsible for its backup.

2. Create a copy of the master key, and securely transfer it from your HSM to Azure Key Vault. Throughout this process, the master copy of the key never leaves the hardware protection boundary.

Once transferred, the copy of the key is protected by Azure Key Vault.

- **Created in Azure Key Vault**. Create and store your key in Azure Key Vault as an HSM-protected key or a software-protected key.

  > ⚠ **Warning**
  >
  > Keys that are generated directly in Azure Key Vault can't be exported for use outside Azure Key Vault. Most organizations that use BYOK have compliance requirements that mandate that they maintain their own copy of the key outside of Azure Key Vault. **Do not create the key directly in Azure Key Vault**; instead, create the key on-premises and transfer it to Azure Key Vault.
  >
  > If your organization requires that keys are exportable, and in your possession, you must create the key on-premises and import to Azure Key Vault and maintain your own backups of the key on-premises. Disaster recovery planning and testing should include measures to regularly test recovery of these keys. Keys can be backed up from Azure Key Vault but can only be imported to the original subscription.

Exporting your trusted publishing domain

If you ever decide to stop using the Azure Rights Management service, you'll need a trusted publishing domain (TPD) to decrypt content that was encrypted by the Azure Rights Management service.

However, exporting your TPD isn't supported if you're using BYOK for your Azure Rights Management tenant key.

To prepare for this scenario, make sure to create a suitable TPD ahead of time. For more information, see How to prepare an Azure Information Protection "Cloud Exit" plan.

Implementing BYOK for your Azure Rights Management tenant key

Use the following steps to implement BYOK:

1. Review BYOK prerequisites
2. Choose a key vault location
3. Create and configure your key

Prerequisites for BYOK

BYOK prerequisites vary, depending on your system configuration. Verify that your system complies with the following prerequisites as needed:

Expand table

Requirement	Description
Azure subscription	Required for all configurations. For more information, see Verifying that you have a BYOK-compatible Azure subscription.
AIPService PowerShell module for the Azure Rights Management service	Required for all configurations. For more information, see Install the AIPService PowerShell module for the Azure Rights Management service. **Note:** The AIPService module runs on Windows PowerShell 5.1, and on PowerShell 7.4 and later with module version 3.1.0.0 or later.
Azure Key Vault prerequisites for BYOK	If you're using an HSM-protected key that was created on-premises, ensure that you also comply with the prerequisites for BYOK listed in the Azure Key Vault documentation.
Thales firmware version 11.62	You must have a Thales firmware version of 11.62 if you're migrating from AD RMS to the Azure Rights Management service by using software key to hardware key and are using Thales firmware for your HSM.
Firewall bypass for trusted Microsoft services	If the key vault that contains your tenant key uses Virtual Network Service Endpoints for Azure Key Vault, you must allow trusted Microsoft services to bypass this firewall. For more information, see Virtual Network Service Endpoints for Azure Key Vault.

Verifying that you have a BYOK-compatible Azure subscription

Your Azure Rights Management tenant must have an Azure subscription. If you don't have one yet, you can sign up for a free account. However, to use an HSM-protected key, you must have the Azure Key Vault Premium service tier.

The free Azure subscription that provides access to Microsoft Entra configuration isn't sufficient for using Azure Key Vault.

To confirm whether you have an Azure subscription that is compatible with BYOK, do the following to verify, using Azure PowerShell cmdlets:

1. Start an Azure PowerShell session as an administrator.
2. Run `Connect-AzAccount` and sign in with a role that can access resources in Azure Key Vault.
3. Run `Get-AzSubscription` to confirm that the following values are displayed:

   - Your subscription name and ID
   - Your tenant ID for the Azure Rights Management service
   - Confirmation that the state is enabled

   If no values are displayed and you're returned to the prompt, you don't have an Azure subscription that can be used for BYOK.

4. Verify that you can use the Azure Key Vault Premium tier, which is required for HSM-protected keys. If you have an existing key vault, run the following command to check its SKU:

   PowerShell

   ```powershell
   Get-AzKeyVault -VaultName "YourVaultName" | Select-Object VaultName, Sku
   ```

   The **Sku** value must be **Premium** for HSM-protected keys. If you're creating a new key vault, ensure you select the Premium tier during creation. For pricing information, see Azure Key Vault pricing.

Choosing your key vault location

When you create a key vault to contain the key to be used as your tenant key for the Azure Rights Management service, you must specify a location. This location is an Azure region, or Azure instance.

Make your choice first for compliance, and then to minimize network latency:

- If you have chosen the BYOK key method for compliance reasons, those compliance requirements might also mandate which Azure region or instance can be used to store your Azure Rights Management tenant key.
- All cryptographic calls for protection chain to your Azure Rights Management key. Therefore, you may want to minimize the network latency these calls require by creating your key vault in the same Azure region or instance as your Azure Rights Management tenant.

To identify the location of your tenant that uses the Azure Rights Management service, use the Get-AipServiceConfiguration PowerShell cmdlet and identify the region from the URLs. For example:

PowerShell

```
LicensingIntranetDistributionPointUrl : https://5c6bb73b-1038-4eec-863d-
49bded473437.rms.na.aadrm.com/_wmcs/licensing
```

The region is identifiable from **rms.na.aadrm.com**, and for this example, it is in North America.

The following table lists recommended Azure regions and instances for minimizing network latency:

Expand table

Azure region or instance	Recommended location for your key vault
rms.**na**.aadrm.com	**North Central US** or **East US**
rms.**eu**.aadrm.com	**North Europe** or **West Europe**
rms.**ap**.aadrm.com	**East Asia** or **Southeast Asia**
rms.**sa**.aadrm.com	**West US** or **East US**
rms.**govus**.aadrm.com	**Central US** or **East US 2**
rms.**aadrm.us**	**US Gov Virginia** or **US Gov Arizona**
rms.**aadrm.cn**	**China East 2** or **China North 2**

Create and configure your key

> **Important**
>
> For information specific for Managed HSMs, see **Enabling key authorization for Managed HSM keys via Azure CLI**.

Create an Azure Key Vault and the key you want to use for the Azure Rights Management service. For more information, see the Azure Key Vault documentation.

> **Important**
>
> After creating the Azure Key Vault, immediately enable both soft delete and purge protection. This prevents accidental deletion of the vault and keys. Loss of the keys without sufficient backups results in complete data loss of encrypted files and emails. For details, see **Azure Key Vault: soft-delete overview**.

Note the following for configuring your Azure Key Vault and key for BYOK:

- Key length requirements
- Creating an HSM-protected key on-premises and transferring it to your key vault
- Configuring the Azure Rights Management service for your key ID
- Authorizing the Azure Rights Management service to use your key

Key length requirements

When you create your key, make sure that the key length is 2048 bits. Other key lengths aren't supported by the Azure Rights Management service.

Creating an HSM-protected key on-premises and transferring it to your key vault

To create an HSM-protected key on-premises and transfer it to your key vault as an HSM-protected key, follow the procedures in the Azure Key Vault documentation: How to generate and transfer HSM-protected keys for Azure Key Vault.

For the Azure Rights Management service to use the transferred key, the following Key Vault operations must be permitted for the key:

- get
- decrypt

- sign

To check the permitted operations for a specific key, run the following PowerShell command:

PowerShell

```
(Get-AzKeyVaultKey -VaultName <key vault name> -Name <key name>).Attributes.KeyOps
```

Configuring the Azure Rights Management service for your key ID

Keys stored in the Azure Key Vault each have a key ID.

The key ID is a URL that contains the name of the key vault, the keys container, the name of the key, and the key version. For example: `https://contosorms-kv.vault.azure.net/keys/contosorms-byok/aaaabbbbcccc111122223333`

Configure the Azure Rights Management service to use your key by specifying its key vault URL.

Authorizing the Azure Rights Management service to use your key

The Azure Rights Management service must be authorized to use your key through Azure RBAC. This requires creating a custom role with the necessary permissions and assigning it to the Rights Management service principal.

> **Note**
>
> This role, when assigned, allows the Azure Rights Management service to perform cryptographic operations with your key. Members assigned to this role can use all keys in the vault for these operations. Assign only to a vault dedicated to the Azure Rights Management service. Do not assign this role to other vaults or use the vault for other services.

Enabling key authorization using Azure CLI

1. Sign in to Azure CLI and get your key vault's subscription ID:

   Azure CLI

   ```
   az login
   az keyvault show --name <vault-name> --resource-group <resource-group-name> --
   query "id" -o tsv
   ```

The output contains the subscription ID in the format: `/subscriptions/<subscription-id>/resourceGroups/...`

2. Create a JSON file named `PurviewRMSCustomAKVRole.json` with the following content, replacing `<subscription-id>` with the subscription ID from the previous step:

JSON

```
{
  "Name": "Purview Rights Management key vault Encryption User",
  "IsCustom": true,
  "Description": "Grants access to use key vault keys for the Purview Rights
Management service.",
  "Actions": [],
  "NotActions": [],
  "DataActions": [
    "Microsoft.KeyVault/vaults/keys/read",
    "Microsoft.KeyVault/vaults/keys/sign/action",
    "Microsoft.KeyVault/vaults/keys/decrypt/action"
  ],
  "NotDataActions": [],
  "AssignableScopes": [
    "/subscriptions/<subscription-id>"
  ]
}
```

3. Create the custom role definition, changing the role definition file path if necessary:

Azure CLI

```
az role definition create --role-definition "./PurviewRMSCustomAKVRole.json"
```

> **Note**
>
> Run this command from the directory where you saved `PurviewRMSCustomAKVRole.json`, or replace `./PurviewRMSCustomAKVRole.json` with the full path to the file.

4. Get the key vault resource ID and assign the role to the Rights Management service principal in a single command:

Azure CLI

```
az role assignment create --role "Purview Rights Management key vault Encryption
User" --assignee "00000012-0000-0000-c000-000000000000" --scope $(az keyvault
```

```
show --name <vault-name> --resource-group <resource-group-name> --query "id" -o
tsv)
```

Enabling key authorization using Azure PowerShell

1. Sign in to Azure PowerShell and get your key vault's subscription ID:

PowerShell

```
Connect-AzAccount

# Define your key vault and resource group names
$vaultName = "<vault-name>"
$resourceGroupName = "<resource-group-name>"

# Get the key vault resource ID and subscription ID
$keyVault = Get-AzKeyVault -VaultName $vaultName -ResourceGroupName
$resourceGroupName
$resourceId = $keyVault.ResourceId
$subscriptionId = ($resourceId -split "/")[2]

# Create the custom role definition JSON file
$jsonRoleDefinition = @"
{
  "Name": "Purview Rights Management key vault Encryption User",
  "IsCustom": true,
  "Description": "Grants access to use key vault keys for the Purview Rights
Management service.",
  "Actions": [],
  "NotActions": [],
  "DataActions": [
    "Microsoft.KeyVault/vaults/keys/read",
    "Microsoft.KeyVault/vaults/keys/sign/action",
    "Microsoft.KeyVault/vaults/keys/decrypt/action"
  ],
  "NotDataActions": [],
  "AssignableScopes": [
    "/subscriptions/$($subscriptionId)"
  ]
}
"@

$jsonRoleDefinition | Out-File -FilePath "./PurviewRMSCustomAKVRole.json"

# Create the custom role definition
New-AzRoleDefinition -InputFile "./PurviewRMSCustomAKVRole.json"

# Assign the role to the Rights Management service principal
New-AzRoleAssignment -RoleDefinitionName "Purview Rights Management key vault
Encryption User" -ServicePrincipalName "00000012-0000-0000-c000-000000000000" -
Scope $resourceId
```

Enabling key authorization for Managed HSM keys via Azure CLI

To grant the Azure Rights Management service principal user permissions as a **Managed HSM Crypto** user, run the following command:

Azure CLI

```
az keyvault role assignment create --hsm-name "ContosoMHSM" --role "Managed HSM Crypto User" --assignee-principal-type ServicePrincipal --assignee https://aadrm.com/ --scope /keys/contosomhskey
```

Where:

- **ContosoMHSM** is a sample HSM name. When running this command, replace this value with your own HSM name.

The **Managed HSM Crypto User** user role allows the user to decrypt, sign, and get permissions to the key, which are all required for the Managed HSM functionality.

Configure the Azure Rights Management service to use your key

After you've completed the previous steps, you're ready to configure the Azure Rights Management service to use this key as your organization's tenant key.

First, copy the URL for your key from Azure Key Vault, including the key version. You can retrieve this using Azure CLI or PowerShell:

Azure CLI:

Azure CLI

```
az keyvault key show --vault-name <vault-name> --name <key-name> --query "key.kid" -o tsv
```

Azure PowerShell:

PowerShell

```
(Get-AzKeyVaultKey -VaultName "<vault-name>" -Name "<key-name>").Id
```

Configuring a new BYOK key

If this is a new key, use the following steps to configure the Azure Rights Management service:

1. Install and import the AIPService PowerShell module if you haven't already:

   > **Note**
   >
   > The AIPService module runs on Windows PowerShell 5.1, and on PowerShell 7.4 and later with module version 3.1.0.0 or later.

   PowerShell

   ```
   Install-Module -Name AIPService
   Import-Module -Name AIPService
   ```

2. Connect to the Azure Rights Management service:

   PowerShell

   ```
   Connect-AipService
   ```

3. Run the Use-AipServiceKeyVaultKey cmdlet, specifying the key URL:

   PowerShell

   ```
   Use-AipServiceKeyVaultKey -KeyVaultKeyUrl "https://contosorms-
   kv.vault.azure.net/keys/contosorms-byok/<key-version>"
   ```

   > **Important**
   >
   > In this example, `<key-version>` is the version of the key you want to use. You must specify the key version. If your key is later updated or renewed, the Azure Rights Management service will stop working for your tenant unless you update the configuration with the new key version.

4. List the keys configured for your tenant to get the key ID of the new key using `Get-AipServiceKeys`. Find the key with the matching KeyVaultKeyUrl. Copy the KeyIdentifier value:

   PowerShell

```
Get-AipServiceKeys | Select-Object KeyIdentifier, KeyVaultKeyUrl
```

5. Set the new key as the active tenant key using new key ID from the previous command:

PowerShell

```
Set-AipServiceKeyProperties -KeyIdentifier <key-id-from-previous-step> -Active $true
```

The Azure Rights Management service is now configured to use your key instead of the default Microsoft-created key that was automatically created for your tenant.

Migrating from Azure Key Vault hsmPlatform 1 to hsmPlatform 2

Azure Key Vault hsmPlatform 1 is being retired. For more information about this retirement, see Azure Key Vault hsmPlatform 1 retirement announcement.

If your Azure Rights Management tenant key is stored on a hsmPlatform 1 key vault, you must migrate to hsmPlatform 2 to continue using BYOK.

Determine if your key is on hsmPlatform 1

First, identify whether your existing Rights Management key is on hsmPlatform 1:

Using Azure CLI:

Azure CLI

```
az keyvault key show --vault-name <vault-name> --name <key-name> --query "attributes.hsmPlatform" -o tsv
```

Using Azure PowerShell:

PowerShell

```
(Get-AzKeyVaultKey -VaultName "<vault-name>" -Name "<key-name>").Attributes.HsmPlatform
```

- If the `hsmPlatform` value is `1`, your key is on hsmPlatform 1 and requires migration.
- If the `hsmPlatform` value is `2` or higher, your key is already on hsmPlatform 2 and no action is required.

Migration steps for keys on hsmPlatform 1

If your key is on hsmPlatform 1, follow these steps to migrate:

Step 1: Locate your on-premises HSM

You must have access to the on-premises HSM that was originally used to generate the key material, or a backup of that key that can be imported into a compatible HSM within your administrative boundary.

> **ⓘ Important**
>
> If you no longer have access to the original HSM or the key material, see **My organization has lost access to the original key material**.

Step 2: Re-import the key as a new version in the existing key vault

You don't need to create a new key vault for this migration. Package and re-import the same key material from your on-premises HSM into the existing Azure Key Vault as a **new key version**. For detailed instructions, see How to generate and transfer HSM-protected keys for Azure Key Vault.

Step 3: Validate that the new key version is on hsmPlatform 2

After the import completes, confirm that the new key version reports `hsmPlatform` `2` before you update the Rights Management service:

Using Azure CLI:

Azure CLI

```
az keyvault key show --vault-name <vault-name> --name <key-name> --version <new-key-version> --query "attributes.hsmPlatform" -o tsv
```

Using Azure PowerShell:

PowerShell

```
(Get-AzKeyVaultKey -VaultName "<vault-name>" -Name "<key-name>" -Version "<new-key-version>").Attributes.HsmPlatform
```

The returned value must be `2`. If it isn't, stop and verify that you imported the correct key material and that the import completed successfully.

Step 4: Verify that the public keys match

Before updating the Rights Management service configuration, verify that the public keys match across all locations:

1. **Get the public key from the new key version in Azure Key Vault:**

   Using Azure CLI:

   ```
   Azure CLI
   az keyvault key show --vault-name <vault-name> --name <key-name> --version <new-key-version> --query "key.n" -o tsv
   ```

   Using Azure PowerShell:

   ```
   PowerShell
   Get-AzKeyVaultKey -VaultName "<vault-name>" -Name "<key-name>" -Version "<new-key-version>" | Format-List Key
   ```

Review the **n** value from the output, which represents the public key modulus.

1. **Get the public key from the Rights Management service:**

   ```
   PowerShell
   Connect-AipService
   Get-AipServiceKeys | Select-Object KeyIdentifier, PublicKey
   ```

2. **Compare with your on-premises HSM copy** using your HSM vendor's tools to export or display the public key. Contact your HSM vendor for assistance if you're unable to locate the public key details. Microsoft Support can't assist with HSM-specific operations.

All three public keys must match exactly. If they don't match, verify you're importing the correct key from your HSM.

Step 5: Update the Azure Rights Management service to use the new key version

Run Convert-AipServiceKeyToKeyVault to update the key URL to the new key version:

PowerShell

```
Connect-AipService
Convert-AipServiceKeyToKeyVault -KeyIdentifier <existing-key-id> -KeyVaultKeyUrl
"https://<vault-name>.vault.azure.net/keys/<key-name>/<new-key-version>"
```

> ⓘ Note
>
> This command fails if the public keys don't match exactly between the existing BYOK key and the key in the new Azure Key Vault. Ensure you've completed the verification in Step 4 before running this command.

My organization has lost access to the original key material

If you no longer have access to the original on-premises HSM or the key material used to create your BYOK key, you must create a new key:

1. **Create a new key** following the steps in Create and configure your key.
2. **Configure access control** as described in Authorizing the Azure Rights Management service to use your key.
3. **Set the new key as active:**

   PowerShell

   ```
   Connect-AipService
   Use-AipServiceKeyVaultKey -KeyVaultKeyUrl "https://<vault-
   name>.vault.azure.net/keys/<key-name>/<key-version>"
   Set-AipServiceKeyProperties -KeyIdentifier <new-key-id> -Active $true
   ```

4. **Open a support case** with Microsoft Purview support to discuss next steps for content that was protected with the previous key. Go to Microsoft 365 admin center and open a service request, or contact your Microsoft support representative. For more information, see Get support for Microsoft 365 for business.

> ⚠ Warning
>
> If you aren't able to migrate the original key, **do not remove** the existing hsmPlatform 1 key after creating the new key. Content protected with the previous key will become inaccessible if the key is removed.

Next steps

If you haven't yet activated the Rights Management service, do this step now.

If the service was activated before you configured BYOK, users are gradually transitioned from the old key to the new key over the course of a few weeks. During this transition, documents and files that were encrypted with the old tenant key remain accessible to authorized users.

Use the Azure Rights Management usage logging to see every transaction that the Azure Rights Management service and your key performs. For example, from a log file displayed in Excel, the **KeyVaultDecryptRequest** and **KeyVaultSignRequest** request types show that the tenant key is being used.

date	time	row-id	request-type	user-id	result	correlation-id
7/18/2016	17:41:39	-	KeyVaultDecryptRequest	''	'Success'	b9e063ac-6208-4d2

Activate the Azure Rights Management service

> *Microsoft Purview service description*

This article describes how administrators can activate the Azure Rights Management encryption service for Microsoft Purview Information Protection. When this encryption service is activated for your organization, administrators and users can start to protect important data by using apps and services that support this encryption solution. Administrators can also manage and monitor encrypted items that your organization owns.

The configuration information in this article is for administrators who are responsible for a service that applies to all users in an organization. If you are looking for user help and information to use the Rights Management functionality for a specific application or how to open a file or email that is rights-protected, use the help and guidance that accompanies your application.

Automatic activation for the Azure Rights Management service

When you have a service plan that includes the Azure Rights Management service, you may not have to activate the service:

- **If your subscription that includes the Azure Rights Management service, Azure Information Protection (former name), or Microsoft Purview Information Protection was obtained towards the end of February 2018 or later**: The service is automatically activated for you. You do not have to activate the service unless you or another administrator for your organization deactivated the Azure Rights Management service.

- **If your subscription that includes the Azure Rights Management service, Azure Information Protection (former name), or Microsoft Purview Information Protection was obtained before or during February 2018**: Microsoft activates the Azure Rights Management service for these subscriptions if your tenant is using Exchange Online. For these subscriptions, the service will be activated for you unless you see that **AutomaticServiceUpdateEnabled** is set to **false** when you run Get-IRMConfiguration.

If neither of the listed scenarios apply to you, you must manually activate the Azure Rights Management service.

How to activate or confirm the status of the encryption service

> **Important**
>
> Do not activate the Azure Rights Management service if you have Active Directory Rights Management Services (AD RMS) deployed for your organization. **Prepare your environment for AD RMS**.

To activate the Azure Rights Management service, your organization must have a service plan that includes the Azure Rights Management service from Microsoft Purview Information Protection. For details about required service plans, see Microsoft 365 licensing guidance for security & compliance.

When the Azure Rights Management service is activated, all users in your organization can apply encryption to items such as documents and emails, and all users can open (consume) items that have been encrypted by this service. However, if you prefer, you can restrict who can apply this encryption, by using onboarding controls for a phased deployment. For more information, see the Configuring onboarding controls for a phased deployment section in this article.

Activate the Azure Rights Management service via PowerShell

You must use PowerShell to activate the Azure Rights Management service. You can no longer activate or deactivate this service from admin portals.

1. Install the AIPService module to configure and manage the Azure Rights Management service. For instructions, see Install the AIPService PowerShell module for the Azure Right Management service.

2. Use the Connect-AipService cmdlet to connect your PowerShell session to the Azure Rights Management service. Run `Connect-AipService` and sign in with a role that has permissions to activate the Azure Rights Management service for your tenant. For example, the compliance administrator role, or compliance data administrator role.

3. Run Get-AipService to confirm whether the Azure Rights Management service is activated. A status of **Enabled** confirms activation; **Disabled** indicates that the service is deactivated.

4. To activate the service, run Enable-AipService.

Configuring onboarding controls for a phased deployment

If you don't want all users to be able to encrypt documents and emails immediately by using the Azure Rights Management service, you can configure user onboarding controls by using the Set-AipServiceOnboardingControlPolicy PowerShell command. You can run this command before or after you activate the Azure Rights Management service.

For example, if you initially want only administrators in the "IT department" group (that has an object ID of aaaaaaaa-0000-1111-2222-bbbbbbbbbbbb) to be able to protect content for testing purposes, use the following command:

PowerShell

```
Set-AipServiceOnboardingControlPolicy -UseRmsUserLicense $False -SecurityGroupObjectId
"aaaaaaaa-0000-1111-2222-bbbbbbbbbbbb"
```

For this configuration option, you must specify a group; you can't specify individual users. To get the object ID for the group, you can use the Microsoft Graph PowerShell—for example, for version 1.0 of the module, use the Get-MgGroup command. Or, you can copy the **Object ID** value of the group from the Azure portal.

Alternatively, if you want to ensure that only users who are correctly licensed to use the Azure Rights Management service can protect content:

PowerShell

```
Set-AipServiceOnboardingControlPolicy -UseRmsUserLicense $True
```

When you no longer need to use onboarding controls, whether you used the group or licensing option, run:

PowerShell

```
Set-AipServiceOnboardingControlPolicy -UseRmsUserLicense $False
```

For more information about this cmdlet and additional examples, see the Set-AipServiceOnboardingControlPolicy help.

When you use these onboarding controls, all users in the organization can always consume encrypted content that has been protected by your subset of users, but they won't be able to apply encryption themselves from client applications. Server-side applications, such as Exchange, can implement their own per-user controls to achieve the same result. For example, to prevent users from protecting emails in Outlook on the web, use Set-OwaMailboxPolicy to set the *IRMEnabled* parameter to *$false*.

Next steps

Now that the Azure Rights Management service is activated for your organization, apps and services can apply encryption to help protect your data. The easiest, and recommended way to apply encryption, is by using sensitivity labels from Microsoft Purview Information Protection. If you're ready to do that, see Get started with sensitivity labels.

To verify the service is working, try a simple test. Use one account to apply a sensitivity label that encrypts a document or email. Then use a different account on another computer to open that item.

Configure usage rights for the Azure Rights Management service

08/28/2025

This article describes usage rights you can configure to be automatically applied when a sensitivity label from Microsoft Purview Information Protection is selected by users, administrators, or configured services.

Usage rights are selected when you configure sensitivity labels or rights management templates for encryption. For example, you can select roles that configure a logical grouping of usage rights, or configure the individual rights separately. Alternatively users might select and apply the usage rights themselves.

> **Important**
>
> Use this article to understand how usage rights are designed to be interpreted by applications.
>
> Applications may vary in how they implement usage rights, and we recommend you consult your application's documentation and do your own testing to check application behavior before you deploy in production.

Usage rights and descriptions

The following table lists and describes the usage rights that Rights Management supports, and how they're used and interpreted. They're listed by their **common name**, which is typically how you might see the usage right displayed or referenced, as a more friendly version of the single-word value that is used in the code (the **Encoding in policy** value).

In this table:

- The **API Constant or Value** is the SDK name for an MSIPC or Microsoft Information Protection SDK API call, used when you write an application that checks for a usage right, or adds a usage right to a policy.
- The names from **AD RMS templates** are included for customers on or migrating from the on-premises rights management solution, Active Rights Rights Management Services.

Expand table

Usage right	Description	Implementation
Common name: **Edit Content, Edit** Encoding in policy: **DOCEDIT**	Allows the user to modify, rearrange, format, or sort the content inside the application, which includes Office on the web. It doesn't grant the right to save the edited copy.	Office custom rights: As part of the **Change** and **Full Control** options. Name in the Microsoft Purview portal: **Edit Content, Edit (DOCEDIT)** Name in AD RMS templates: **Edit** API constant or value: **MSIPC:** Not applicable. **MIP SDK:** `DOCEDIT`
Common name: **Save** Encoding in policy: **EDIT**	Allows the user to save the item to the current location. In Office on the web, it also allows the user to edit the content. In Office applications, this right allows the user to save the contents of the file to a new location and with a new name if the selected file format has built-in support for Rights Management. The list of file formats available is restricted to those that support Rights Management. This restriction ensures that the original encryption can't be removed from the file.	Office custom rights: As part of the **Change** and **Full Control** options. Name in the Microsoft Purview portal: **Save (EDIT)** Name in AD RMS templates: **Save** API constant or value: **MSIPC:** `IPC_GENERIC_WRITE L"EDIT"` **MIP SDK:** `EDIT`
Common name: **Comment** Encoding in policy: **COMMENT**	Enables the option to add annotations or comments to the content. This right is available in the SDK, is available as an ad-hoc policy in the PurviewInformationProtection PowerShell module, and has been implemented in some software vendor applications. However, it isn't widely used and isn't supported by Office applications.	Office custom rights: Not implemented. Name in the Microsoft Purview portal: Not implemented. Name in AD RMS templates: Not implemented. API constant or value: **MSIPC:** `IPC_GENERIC_COMMENT L"COMMENT` **MIP SDK:** `COMMENT`

Usage right	Description	Implementation
Common name: **Save As, Export** Encoding in policy: **EXPORT**	Enables the option to save the content to a different file name (Save As). This right also allows the user to perform other export options in applications, such as **Send to OneNote**.	Office custom rights: As part of the **Full Control** option. Name in the Microsoft Purview portal: **Save As, Export (EXPORT)** Name in AD RMS templates: **Export (Save As)** API constant or value: **MSIPC:** `IPC_GENERIC_EXPORT L"EXPORT"` **MIP SDK:** `EXPORT`
Common name: **Forward** Encoding in policy: **FORWARD**	Enables the option to forward an email message and to add recipients to the **To** and **Cc** lines. This right does not apply to documents; only email messages. Does not allow the forwarder to grant rights to other users as part of the forward action. When you grant this right, also grant the **Edit Content, Edit** right (common name), and additionally grant the **Save** right (common name) to ensure that the encrypted email message isn't delivered as an attachment. Also specify these rights when you send an email to another organization that uses the Outlook client or Outlook web app. Or, for users in your organization that are exempt from using Rights Management encryption because you have implemented onboarding controls.	Office custom rights: Denied when using the **Do Not Forward** standard policy. Name in the Microsoft Purview portal: **Forward (FORWARD)** Name in AD RMS templates: **Forward** API constant or value: **MSIPC:** `IPC_EMAIL_FORWARD L"FORWARD"` **MIP SDK:** `FORWARD`
Common name: **Full Control** Encoding in policy: **OWNER**	Grants all rights to the item and all available actions can be performed. Includes the ability to remove encryption and re-encrypt a document. Note that this usage right isn't the same as the Rights Management owner.	Office custom rights: As the **Full Control** custom option. Name in the Microsoft Purview portal: **Full Control (OWNER)** Name in AD RMS templates: **Full Control** API constant or value:

Usage right	Description	Implementation
		MSIPC: `IPC_GENERIC_ALL L"OWNER"` **MIP SDK:** `OWNER`
Common name: **Print** Encoding in policy: **PRINT**	Enables the options to print the content.	Office custom rights: As the **Print Content** option in custom permissions. Not a per-recipient setting. Name in the Microsoft Purview portal: **Print (PRINT)** Name in AD RMS templates: **Print** API constant or value: **MSIPC:** `IPC_GENERIC_PRINT L"PRINT"` **MIP SDK:** `PRINT`
Common name: **Reply** Encoding in policy: **REPLY**	Enables the **Reply** option in an email client, without allowing changes in the **To** or **Cc** lines. When you grant this right, also grant the **Edit Content, Edit** right (common name), and additionally grant the **Save** right (common name) to ensure that the encrypted email message isn't delivered as an attachment. Also specify these rights when you send an email to another organization that uses the Outlook client or Outlook web app. Or, for users in your organization that are exempt from using Rights Management protection because you have implemented onboarding controls.	Office custom rights: Not applicable. Name in AD RMS templates: **Reply** API constant or value: **MSIPC:** `IPC_EMAIL_REPLY` **MIP SDK:** `REPLY`
Common name: **Reply All** Encoding in policy: **REPLYALL**	Enables the **Reply All** option in an email client, but doesn't allow the user to add recipients to the **To** or **Cc** lines. When you grant this right, also grant the **Edit Content, Edit** right (common name), and additionally grant the **Save** right (common name) to ensure that the encrypted email message isn't delivered as an attachment. Also specify these rights when you send an email to another organization that uses the Outlook client or Outlook web app. Or, for users in your organization that are exempt from using the Azure Rights Management service because you have implemented onboarding controls.	Office custom rights: Not applicable. Name in the Microsoft Purview portal: **Reply All (REPLY ALL)** Name in AD RMS templates: **Reply All** API constant or value: **MSIPC:** `IPC_EMAIL_REPLYALL`

Usage right	Description	Implementation
		`L"REPLYALL"` **MIP SDK:** `REPLYALL`
Common name: **View, Open, Read** Encoding in policy: **VIEW**	Allows the user to open the document and see the content. Additionally: - In Microsoft 365 Copilot and other AI apps, allows the LLM to reference the item with a link but without summarizing the content, so the user can then open and view the content outside the AI app. In Excel, this right isn't sufficient to sort data, which requires the following right: **Edit Content, Edit**. To filter data in Excel, you need the following two rights: **Edit Content, Edit** and **Copy**.	Office custom rights: As the **Read** custom policy, **View** option. Name in the Microsoft Purview portal: **View, Open, Read (VIEW)** Name in AD RMS templates: **Read** API constant or value: **MSIPC:** `IPC_GENERIC_READ` `L"VIEW"` **MIP SDK:** `VIEW`

Common name: **Copy**
 	
Encoding in policy: **EXTRACT**
	Enables options to copy data (including screen captures) from the item into the same or another item. Additionally:
	- In Microsoft 365 Copilot and other AI apps, allows the LLM to access and summarize the content for the requesting user.
	- In some applications, this right also allows the entire document to be saved unencrypted.
	
	In Microsoft Teams and similar screen-sharing applications, the presenter must have this right to successfully present an encrypted document. If the presenter doesn't have this right, the attendees can't view the document and it displays as blacked out to them.
		Office custom rights: As the **Allow users with Read access to copy content** custom policy option.
		
		Name in the Microsoft Purview portal: **Copy (EXTRACT)**
		
		Name in AD RMS templates: **Extract**
		
		API constant or value:
		MSIPC:
		`IPC_GENERIC_EXTRACT`
		`L"EXTRACT"`
		MIP SDK: `EXTRACT`

Common name: **View Rights** Encoding in policy: **VIEWRIGHTSDATA**	Allows the user to see the policy that is applied to the document. Not supported by Office apps or by the Microsoft Purview Information Protection client.	Office custom rights: Not implemented. Name in the Microsoft Purview portal: **View Rights (VIEWRIGHTSDATA)**. Name in AD RMS templates: **View Rights**

Usage right	Description	Implementation
		API constant or value: **MSIPC:** `IPC_READ_RIGHTSL"VIEWRIGHTSDATA"` **MIP SDK:** `VIEWRIGHTSDATA`
Common name: **Change Rights** Encoding in policy: **EDITRIGHTSDATA**	Allows the user to change the policy that is applied to the document. Includes removing encryption. Not supported by Office apps or the Microsoft Purview Information Protection client.	Office custom rights: Not implemented. Name in the Microsoft Purview portal: **Edit Rights (EDITRIGHTSDATA)**. Name in AD RMS templates: **Edit Rights** API constant or value: **MSIPC:** `PC_WRITE_RIGHTSL"EDITRIGHTSDATA"` **MIP SDK:** `EDITRIGHTSDATA`
Common name: **Allow Macros** Encoding in policy: **OBJMODEL**	Enables the option to run macros or perform other programmatic or remote access to the content in a document.	Office custom rights: As the **Allow Programmatic Access** custom policy option. Not a per-recipient setting. Name in the Microsoft Purview portal: **Allow Macros (OBJMODEL)** Name in AD RMS templates: **Allow Macros** API constant or value: **MSIPC:** Not implemented. **MIP SDK:** `OBJMODEL`

Rights included in permissions levels

Some applications group usage rights together into permissions levels, to make it easier to select usage rights that are typically used together. These permissions levels help to abstract a level of complexity from users, so they can choose options that are role-based. For example, **Viewer** and **Restricted Editor**. Although these options often show users a summary of the rights, they might not include every right that is listed in the previous table.

Use the following table for a list of these permissions levels and a complete list of the usage rights that they contain. The usage rights are listed by their common name.

Expand table

Permissions level	Applications	Usage rights included
Viewer	Microsoft Purview portal Microsoft Purview Information Protection client	View, Open, Read; View Rights; Reply [1]; Reply All [1]; Allow Macros [2] Note: For emails, use Reviewer rather than this permission level to ensure that an email reply is received as an email message rather than an attachment. Reviewer is also required when you send an email to another organization that uses the Outlook client or Outlook web app. Or, for users in your organization that are exempt from using the Azure Rights Management service because you have implemented onboarding controls.
Restricted Editor (Previously **Reviewer** [3])	Microsoft Purview portal Microsoft Purview Information Protection client	View, Open, Read; Save; Edit Content, Edit; View Rights; Reply: Reply All; Forward; Allow Macros [2]
Editor (Previously **Co-Author** [3])	Microsoft Purview portal Microsoft Purview Information Protection client	View, Open, Read; Save; Edit Content, Edit; Copy; View Rights; Allow Macros [2]; Save As, Export [4]; Print; Reply; Reply All; Forward
Owner (Previously **Co-Owner** [3])	Microsoft Purview portal Microsoft Purview Information Protection client	View, Open, Read; Save; Edit Content, Edit; Copy; View Rights; Change Rights; Allow Macros; Save As, Export; Print; Reply; Reply All; Forward; Full Control

Footnote 1

Not included in the Microsoft Purview portal.

Footnote 2

Not included in the custom permissions dialog in Word, Excel, and PowerPoint for Windows (version 2408+).

Footnote 3

The Microsoft Purview portal and the custom permissions dialog in Word, Excel, and PowerPoint for Windows (version 2411+) have updated permissions level naming. **Reviewer** is now called **Restricted Editor**, **Co-Author** is now called **Editor**, and **Co-Owner** is now called **Owner**. Other applications continue to use the original permissions level naming.

Footnote 4

Not included in the Microsoft Purview portal.

Do Not Forward option for emails

Exchange clients and services (for example, the Outlook client, Outlook on the web, Exchange mail flow rules, and DLP actions for Exchange) have an additional information rights protection option for emails: **Do Not Forward**.

Although this option appears to users (and Exchange administrators) as if it's a default Rights Management template that they can select, **Do Not Forward** isn't a template. Instead, the **Do Not Forward** option is a set of usage rights that is dynamically applied by users to their email recipients.

When the **Do Not Forward** option is applied to an email, the email is encrypted and recipients must be authenticated. Then, the recipients can't forward it, print it, or copy from it. For example, in the Outlook client, the Forward button isn't available, the **Save As** and **Print** menu options are not available, and you can't add or change recipients in the **To**, **Cc**, or **Bcc** boxes.

Unencrypted Office documents that are attached to the email automatically inherit the same restrictions. The usage rights applied to these documents are **Edit Content, Edit**; **Save**; **View, Open, Read**; and **Allow Macros**. If you want different usage rights for an attachment, or your attachment isn't an Office document that supports this inherited encryption, encrypt the file before you attach it to the email. You can then assign the specific usage rights that you need for the file.

Difference between Do Not Forward and not granting the Forward usage right

There's an important distinction between applying the **Do Not Forward** option and applying a rights management template that doesn't grant the **Forward** usage right to an email: The **Do Not Forward** option uses a dynamic list of authorized users that is based on the user's chosen recipients of the original email; whereas the rights in the template have a static list of authorized users that the administrator has previously specified. What's the difference? Let's take an example:

A user wants to email some information to specific people in the Marketing department that shouldn't be shared with anybody else. Should they protect the email with a rights management template that restricts rights (viewing, replying, and saving) to the Marketing department? Or should they choose the **Do Not Forward** option? Both choices would result in the recipients not able to forward the email.

- If they applied the template, the recipients could still share the information with others in the marketing department. For example, a recipient could use Explorer to drag and drop the email to a shared location or a USB drive. Now, anybody from the marketing department (and the email owner) who has access to this location can view the information in the email.
- If they applied the **Do Not Forward** option, the recipients will not be able to share the information with anybody else in the marketing department by moving the email to another location. In this scenario, only the original recipients (and the email owner) will be able to view the information in the email.

> ⓘ **Note**
>
> Use **Do Not Forward** when it's important that only the recipients that the sender chooses should see the information in the email. Use a template for emails to restrict rights to a group of people that the administrator specifies in advance, independently from the sender's chosen recipients.

Encrypt-only option for emails

When Exchange Online uses Microsoft Purview Message Encryption, a new **Encrypt** email option becomes available, to encrypt the data without additional restrictions.

This option is available to tenants who use Exchange Online and can be selected as follows:

- **In Outlook on the web** with the **Encrypt** option or a sensitivity label that's configured for **Let users assign permissions** and the **Encrypt-Only** option
- **As another rights protection option** for a mail flow rule

- **As Microsoft Purview DLP action**
- **From the Outlook app** for desktops and mobile devices:
  - With a sensitivity label that's configured for **Let users assign permissions** and the **Encrypt-Only** option, for Windows, macOS, iOS and Android when you use sensitivity labels with the minimum versions listed in the table for sensitivity label capabilities in Outlook.
  - With the **Encrypt** option on Windows and macOS, for the versions listed in the table of supported versions for Microsoft 365 Apps by update channel.

For more information about the encrypt-only option, see the following blog post when it was first announced from the Office team: Encrypt only rolling out in Office 365 Message Encryption.

When this option is selected, the email is encrypted and recipients must be authenticated. Then, the recipients have all usage rights except **Save As, Export** and **Full Control**. This combination of usage rights means that the recipients have no restrictions except that they can't remove the encryption. For example, a recipient can copy from the email, print it, and forward it.

Similarly, by default, unencrypted Office documents that are attached to the email inherit the same permissions. These documents are automatically encryption and when they're downloaded, they can be saved, edited, copied, and printed from Office applications by the recipients. When the document is saved by a recipient, it can be saved to a new name and even a different format. However, only file formats that support Rights Management encryption are available so that the document can't be saved without the original encryption. If you want different usage rights for an attachment, or your attachment isn't an Office document that supports this inherited encryption, encrypt the file before you attach it to the email. You can then assign the specific usage rights that you need for the file.

Alternatively, you can change this encryption inheritance of documents by specifying `Set-IRMConfiguration -DecryptAttachmentForEncryptOnly $true` with Exchange Online PowerShell. Use this configuration when you don't need to retain the original encryption for the document after the user is authenticated. When recipients open the email message, the document isn't encrypted.

> **Note**
>
> If you see references to **DecryptAttachmentFromPortal**, this parameter is now deprecated for Set-IRMConfiguration. Unless you have previously set this parameter, it's not available.

Automatically encrypt PDF documents with Exchange Online

When Exchange Online uses Microsoft Purview Message Encryption, you can automatically encrypt PDF documents when they're attached to an encrypted email. The document inherits the same permissions as those for the email message. To enable this configuration, set **EnablePdfEncryption $True** with Set-IRMConfiguration.

Recipients can use Microsoft Edge to view the encrypted PDF document. Alternatively, recipients can read the encrypted PDF document in the OME portal.

Rights Management issuer and Rights Management owner

When an item is encrypted by using the Azure Rights Management service, the account that encrypts that content automatically becomes the Rights Management issuer for that content. This account is logged as the **issuer** field in the usage logs.

The Rights Management issuer is always granted the Full Control usage right for the item, and in addition:

- If the encryption settings include an expiry date, the Rights Management issuer can still open and edit the document or email after that date.
- The Rights Management issuer can always access the document or email offline.
- The Rights Management issuer can still open a document after it's revoked.

By default, this account is also the **Rights Management owner** for that content, which is the case when a user who created the item initiates the encryption. But there are some scenarios where an administrator or service can encrypt content on behalf of users. For example:

- An administrator bulk-encrypts files on a file share: The administrator account in Microsoft Entra ID encrypts the documents for the users.
- The Rights Management connector encrypts Office documents on a Windows Server folder: The service principal account in Microsoft Entra ID that is created for the Rights Management connector encrypts the documents for the users.

In these scenarios, the Rights Management issuer can assign the Rights Management owner to another account by using the Microsoft Information Protection SDKs or PowerShell. For example, when you use the Set-LabelFile PowerShell cmdlet with the Microsoft Purview

Information Protection client, you can specify the *Owner* parameter to assign the Rights Management owner to another account.

When the Rights Management issuer encrypts on behalf of users, assigning the Rights Management owner ensures that the original item owner has the same level of control for their encrypted content as if they initiated the encryption themselves.

For example, the user who created the document can print it, even though it's now labeled with encryption settings that don't include the Print usage right. The same user can always access their document, regardless of the offline access setting or expiry date that might have been configured in the encryption settings. In addition, because the Rights Management owner has the Full Control usage right, this user can also re-encrypt the document to grant additional users access (at which point the user then becomes the Rights Management issuer as well as the Rights Management owner), and this user can even remove the encryption. However, only the Rights Management issuer can track and revoke a document.

The Rights Management owner for an item is logged as the **owner-email** field in the usage logs.

> **Note**
>
> The Rights Management owner is independent from the Windows file system Owner. They're often the same but can be different, even if you don't use the SDKs or PowerShell.

Rights Management use license

When a user opens an item that has been encrypted by the Azure Rights Management service, a Rights Management use license for that content is granted to the user. This use license is a certificate that contains the user's usage rights for item, and the encryption key that was used to encrypt the content. The use license also contains an expiry date if this has been set, and how long the use license is valid.

A user must have a valid use license to open the content in addition to their rights account certificate (RAC), which is a certificate that's granted when the user environment is initialized and then renewed every 31 days.

For the duration of the use license, the user isn't reauthenticated or reauthorized for the content. This lets the user continue to open the encrypted item without an internet connection. When the use license validity period expires, the next time the user accesses the encrypted item, the user must be reauthenticated and reauthorized.

When items are encrypted by using a sensitivity label that defines the encryption settings, you can change these settings in your sensitivity label without having to encrypt the content again. If the user has already accessed the content, the changes take effect after their use license has expired. However, when users apply permissions themselves (also known as user-defined permissions, custom permissions, or an ad-hoc rights policy) and these permissions need to change after the item is encrypted, that content must be encrypted again with the new permissions. User-defined permissions for an email message are implemented with the Do Not Forward option.

The default use license validity period for a tenant is 30 days and you can configure this value by using the PowerShell cmdlet, Set-AipServiceMaxUseLicenseValidityTime. You can configure a more restrictive setting for when encryption is applied by using a sensitivity label that's configured to assign permissions now, or a rights management template:

- When you configure a sensitivity label, the use license validity period takes its value from the **Allow offline access** setting.

  For more information and guidance to configure this setting for a sensitivity label, see the recommendations table from the instructions how to configure permissions now for a sensitivity label.

- When you configure a rights management template by using PowerShell, the use license validity period takes its value from the *LicenseValidityDuration* parameter in the Set-AipServiceTemplateProperty and Add-AipServiceTemplate cmdlets.

  For more information and guidance to configure this setting by using PowerShell, see the help for each cmdlet.

Manage personal data for the Azure Rights Management encryption service

> *Microsoft Purview service description*

When you configure and use the Azure Rights Management encryption service from Microsoft Purview Information Protection, email addresses and IP addresses are stored and used by this service. The personal data can be found in the following items:

- Super users and delegated administrators for the Azure Rights Management service
- Administration logs for the Azure Rights Management service
- Usage logs for the Azure Rights Management service
- Usage logs for the Microsoft Purview Information Protection client and RMS client

> **Note**
>
> This article provides steps for how to delete personal data from the device or service and can be used to support your obligations under the GDPR. If you're looking for general info about GDPR, see the GDPR section of the Service Trust portal.

Viewing personal data that the Azure Rights Management service uses

- **Microsoft Purview Information Protection client**:

  For the Microsoft Purview Information Protection client, sensitivity labels and label policies are configured in the Microsoft Purview portal. For more information, see Create and configure sensitivity labels and their policies.

> **Note**
>
> When the Microsoft Purview Information Protection client is used to encrypt documents and emails, email addresses and the users' IP addresses might be saved in log files.

Super users and delegated administrators for the Azure Rights Management service

Run the Get-AipServiceSuperUser cmdlet and get-aipservicerolebasedadministrator cmdlet to see which users have been assigned the super user role or global administrator role for the Azure Rights Management service. For users who have been assigned either of these roles, their email addresses are displayed.

Administration logs for the Azure Rights Management service

Run the Get-AipServiceAdminLog cmdlet to get a log of admin actions for the Azure Rights Management service. This log includes personal data in the form of email addresses and IP addresses. The log is in plaintext and after it is downloaded, the details of a specific administrator can be searched offline.

For example:

PowerShell

```
PS C:\Users> Get-AipServiceAdminLog -Path '.\Desktop\admin.log' -FromTime 4/1/2018 -
ToTime 4/30/2018 -Verbose
The Rights Management administration log was successfully generated and can be found
at .\Desktop\admin.log.
```

Usage logs for the Azure Rights Management service

Run the Get-AipServiceUserLog cmdlet to retrieve a log of end-user actions that use the Azure Rights Management service. The log could include personal data in the form of email addresses and IP addresses. The log is in plaintext and after it is downloaded, the details of a specific administrator can be searched offline.

For example:

PowerShell

```
PS C:\Users> Get-AipServiceUserLog -Path '.\Desktop\' -FromDate 4/1/2018 -ToDate
4/30/2018 -NumberOfThreads 10

Usage logs for the Microsoft Purview Information Protection client and RMS client

When labels and encryption are applied to documents and emails, email addresses and IP addresses can be stored in log files on a user's computer in the following locations:

- For the Microsoft Purview Information Protection client: **%localappdata%\Microsoft\MSIP\Logs**
- For the RMS client: **%localappdata%\Microsoft\MSIPC\msip\Logs**

In addition, the Microsoft Purview Information Protection client logs this personal data to the local Windows event log **Applications and Services Logs** > **Microsoft Purview Information Protection**.

When the Microsoft Purview Information Protection client runs the scanner, personal data is saved to **%localappdata%\Microsoft\MSIP\Scanner\Reports** on the Windows Server computer that runs the scanner.

You can turn off logging information for the Microsoft Purview Information Protection client and the scanner by using the following configurations:

- For the Microsoft Purview Information Protection client: Edit the registry to change the local logging level for the Information Protection client to **Off**.
- For the Microsoft Purview Information Protection scanner: Use the Set-ScannerConfiguration cmdlet to set the *ReportLevel* parameter to **Off**.

> **Note**
>
> If you're interested in viewing or deleting personal data, please review Microsoft's guidance in the Microsoft Purview Compliance Manager and in the GDPR section of the Microsoft 365 Enterprise Compliance site. If you're looking for general information about GDPR, see the GDPR section of the Service Trust portal.

Document tracking logs

Relevant for: The Azure Rights Management service with the legacy tracking portal

Run the Get-AipServiceDocumentLog cmdlet to retrieve information from the document tracking site about a specific user. To get tracking information associated with the document logs, use the Get-AipServiceTrackingLog cmdlet.

For example:

PowerShell

```
PS C:\Users> Get-AipServiceDocumentLog -UserEmail "admin@aip500.onmicrosoft.com"

ContentId             : 6326fcb2-c465-4c24-a7f6-1cace7a9cb6f

IsHiddenInfo          : False
```

There is no search by ObjectID. However, you are not restricted by the `-UserEmail` parameter and the email address you provide doesn't need to be part of your tenant. If the email address provided is stored anywhere in the document tracking logs, the document tracking entry is returned in the cmdlet output.

Securing and controlling access to personal information

Personal data that you view and specify in the Microsoft Purview portal is accessible only to users who have been assigned one of the following Microsoft Entra ID built-in administrator roles:

- **Azure Information Protection administrator**
- **Compliance administrator**
- **Compliance data administrator**

- **Security administrator**
- **Security reader**
- **Global administrator**
- **Global reader**

Personal data that you view and specify by using the AIPService module is accessible only to users who have been assigned the **Azure Information Protection administrator**, **Compliance administrator**, **Compliance data administrator**, or **Global Administrator** roles from Microsoft Entra ID, or the global administrator role for the Azure Rights Management service.

Updating personal data

Sensitivity labels and label policies are configured in the Microsoft Purview. For more information, see the Create and configure sensitivity labels and their policies.

For the encryption settings, you can update the related personal data by using PowerShell cmdlets from the AIPService module.

You cannot update email addresses for the super users and delegated administrators. Instead, remove the specified user account, and add the user account with the updated email address.

Super users and delegated administrators for the Azure Rights Management service

When you need update an email address for a super user:

1. Use Remove-AipServiceSuperUser to remove the user and old email address.
2. Use Add-AipServiceSuperUser to add the user and new email address.

When you need update an email address for a delegated administrator:

1. Use Remove-AipServiceRoleBasedAdministrator to remove the user and old email address.
2. Use Add-AipServiceRoleBasedAdministrator to add the user and new email address.

Deleting personal data

Sensitivity labels and label policies are configured in the Microsoft Purview portal. For more information, see Create and configure sensitivity labels and their policies.

For the encryption settings, you can delete the related personal data by using PowerShell cmdlets from the AIPService module.

To delete email addresses for super users and delegated administrators, remove these users by using the Remove-AipServiceSuperUser cmdlet and Remove-AipServiceRoleBasedAdministrator.

To delete personal data in document tracking logs, administration logs, or usage logs for the Azure Rights Management service, raise a request with Microsoft Support by using the procedure in To delete personal data with Microsoft Support.

To delete personal data in the client log files and scanner logs that are stored on computers, use any standard Windows tools to delete the files or personal data within the files.

To delete personal data with Microsoft Support

Use the following three steps to request that Microsoft deletes personal data in document tracking logs, administration logs, or usage logs for the Azure Rights Management service.

Before you submit a delete request, make sure you can prove that you are an administrator for your tenant. Also be aware that this process takes several days to confirm.

Step 1: Initiate delete request Contact Microsoft Support to open Microsoft Purview Information Protection support case with a request for deleting data from your tenant. When you submit your request, you need to provide additional information, depending on the data that needs to be deleted.

- To delete the administration log, provide the **end date**. All admin logs until that end date will be deleted.
- To delete the usage logs, provide the **end date**. All usage logs until that end date will be deleted.
- To delete the document tracking logs, provide the **end date** and **UserEmail**. All document tracking information relating to the UserEmail until that end date will be deleted. Regular expression (Perl format) for UserEmail is supported.

Deleting this data is a permanent action. There is no means to recover the data after a delete request has been processed. It's recommended that administrators export the required data before submitting a delete request.

Step 2: Wait for verification Microsoft will verify that your request to delete one or more logs is legitimate. This process can take up to five working days.

Step 3: Get confirmation of the deletion Microsoft Customer Support Services (CSS) will send you a confirmation email that the data has been deleted.

Exporting personal data

When you use the AIPService cmdlets, the personal data is made available for search and export as a PowerShell object. The PowerShell object can be converted into JSON and saved by using the `ConvertTo-Json` cmdlet.

Restricting the use of personal data for profiling or marketing without consent

The Azure Rights Management service follows Microsoft's Microsoft Privacy Statement for profiling or marketing based on personal data.

Auditing and reporting

Only users who have been assigned the required administrator roles for accessing personal information can use the AIPService for search and export of personal data. These operations are recorded in the administration log that can be downloaded.

For delete actions, the support request acts as the auditing and reporting trail for the actions performed by Microsoft. After deletion, the deleted data will not be available for search and export, and the administrator can verify this using the Get cmdlets from the AIPService module.

Track and revoke document access

> *Microsoft Purview service description*

Document tracking provides information for administrators about when a protected document was accessed. If necessary, both admins and users can revoke document access for tracked documents.

A document must be registered for tracking before an admin can track access details, including successful access events and denied attempts, and revoke access if needed. For minimum versions of Office apps that support file registration the next time they're opened, see Requirements.

> **Note**
>
> Track and revoke features are supported for Office file types only.

Requirements

Use the capabilities table and the row **Document tracking and revocation** to identify the minimum versions of Word, Excel, and PowerPoint that automatically register label-protected local Office documents (if not already registered) the next time they're opened.

PowerShell cmdlets in this article use the AIPService PowerShell module, which you can install from the PowerShell Gallery. You must run Connect-AipService to connect to your tenant before you run any of the documented cmdlets.

Limitations

The following limitations apply to track and revoke features:

- Password-protected documents aren't supported by track and revoke features.
- If you attach multiple documents to an email, and then protect the email and send it, each of the attachments gets the same ContentID value. This ContentID value will be returned only with the first file that had been opened. Searching for the other attachments won't return the ContentID value required to get tracking data.

Additionally, revoking access for one of the attachments also revokes access for the other attachments in the same protected email.

- Documents protected with admin-defined permissions that are uploaded to SharePoint or OneDrive lose their **ContentID** value, and access can't be tracked or revoked.

- If a user downloads a file protected with admin-defined permissions from SharePoint or OneDrive, a new **ContentID** is applied to the document. Using the original **ContentID** value to track data won't include any access performed for the user's downloaded file. Additionally, revoking access based on the original **ContentID** value won't revoke access for any of the downloaded files.

  If administrators have access to the downloaded files, they can use PowerShell to identify a document's **ContentID** for track and revoke actions.

Track document access

Admins can track access for protected documents via PowerShell using the **ContentID** generated for the protected document during registration.

To view document access details:

Use the following cmdlets to find details for the document you want to track:

1. Find the **ContentID** value for the document you want to track.

   Use the Get-AipServiceDocumentLog cmdlet to search for a document using the filename or the email address of the user who applied protection.

   For example;

   PowerShell

   ```
   Get-AipServiceDocumentLog -ContentName "test.docx" -Owner "alice@contoso.com" -
   FromTime "12/01/2020 00:00:00" -ToTime "12/31/2020 23:59:59"
   ```

   This command returns the **ContentID** for all matching, protected documents that are registered for tracking.

   > ⓘ Note

Protected documents are registered for tracking when they're first opened in an Office app that supports file registration. If this command does not return the ContentID for your protected file, open it in a supported Office app. For minimum supported versions, see Office apps that support file registration.

2. Use the Get-AipServiceTrackingLog cmdlet with your document's **ContentID** to return your tracking data.

   For example:

   ```
   PowerShell
   Get-AipServiceTrackingLog -ContentId c03bf90c-6e40-4f3f-9ba0-2bcd77524b87
   ```

   Tracking data is returned, including emails of users who attempted access, whether access was granted or denied, the time and date of the attempt, and the domain and location where the access attempt originated.

Revoke document access from PowerShell

Admins can revoke access for any protected document stored in their local content shares, using the Set-AIPServiceDocumentRevoked cmdlet.

> **Note**
>
> If offline access is allowed, users will continue to be able to access the documents that have been revoked until the offline policy period expires.

1. Find the **ContentID** value for the document you want to revoke access for.

   Use the Get-AipServiceDocumentLog cmdlet to search for a document using the filename or the email address of the user who applied protection.

   For example:

   ```
   PowerShell
   Get-AipServiceDocumentLog -ContentName "test.docx" -Owner "alice@contoso.com" -
   FromTime "12/01/2020 00:00:00" -ToTime "12/31/2020 23:59:59"
   ```

   The data returned includes the ContentID value for your document.

> **Tip**
>
> Only documents that have been protected and registered for tracking have a **ContentID** value. If your document has no **ContentID**, open it in a supported Office app. For minimum supported versions, see **Office apps that support file registration**.

2. Use the Set-AIPServiceDocumentRevoked with your document's ContentID to revoke access.

   For example:

   ```
   PowerShell
   Set-AipServiceDocumentRevoked -ContentId 0e421e6d-ea17-4fdb-8f01-93a3e71333b8 -
   IssuerName testIssuer
   ```

By using the **Sensitivity** menu in their Office apps, users can also revoke access for any documents that they protected.

Restore access

If you've accidentally revoked access to a specific document, use the same **ContentID** value with the Clear-AipServiceDocumentRevoked cmdlet to remove the revoked status so that authorized users can access the document again. Specify the same **IssuerName** value that was used when the document was revoked.

For example:

```
PowerShell
Clear-AipServiceDocumentRevoked -ContentId   0e421e6d-ea17-4fdb-8f01-93a3e71333b8 -
IssuerName testIssuer
```

Document access is granted to the user you defined in the **IssuerName** parameter.

Turn off track and revoke features for your tenant

If you need to turn off track and revoke features for your tenant, such as for privacy requirements in your organization or region, run the Disable-AipServiceDocumentTrackingFeature cmdlet.

Document tracking and options to revoke access are turned off for your tenant:

- Opening protected documents no longer registers the documents for track and revoke.
- Access logs aren't stored when protected documents that are already registered are opened. Access logs that were stored before turning off these features are still available.
- Admins won't be able to track or revoke access via PowerShell, and although end-users still see the **Revoke** menu option in their Office apps, the site displays a message that tracking and revocation has been disabled by their administrator.

If you need to turn track and revoke back on, run the Enable-AipServiceDocumentTrackingFeature cmdlet.

Remove the track and revoke options from the Sensitivity menu

If you need to remove the Track & Revoke button from the Sensitivity menu on Office clients, use PowerShell advanced settings with the Set-LabelPolicy cmdlet.

The following example disables revoke support in the client UI by setting the `EnableRevokeGuiSupport` advanced setting to `False` in the global label policy:

PowerShell

```
Set-LabelPolicy -Identity Global -AdvancedSettings @{EnableRevokeGuiSupport="False"}
```

End user instructions for Office apps

See Track and revoke access to your files.

Usage logging for the Azure Rights Management service

The Azure Rights Management service is a cloud-based encryption technology used by Microsoft Purview Information Protection. It helps protect files and emails across devices by applying usage rights and encryption policies.

Use this information to help you understand how you can use usage logging for the encryption service, Azure Rights Management from Microsoft Purview Information Protection. This encryption service provides additional data protection for your organization's items such as documents and emails, and it can log every request. These requests include:

- When users encrypt items to protect them, and decrypt to read them or remove encryption.
- Actions performed by your administrators to manage the Azure Rights Management service, and actions performed by Microsoft operators to support the service.

You can then use these usage logs to support the following business scenarios:

- **Analyze for business insights**

  The logs generated by Azure Rights Management can be imported into a repository of your choice (such as a database, an online analytical processing (OLAP) system, or a map-reduce system) to analyze the information and produce reports. As an example, you could identify who is accessing your encrypted data. You can determine what encrypted data people are accessing, and from what devices and from where. You can find out whether people can successfully read encrypted content. You can also identify which people have read an important document that was encrypted.

- **Monitor for abuse**

  Logging information about how the Azure Rights Management service is used is available to you in near-real time, so that you can continuously monitor your company's use of the service. 99.9% of logs are available within 15 minutes of an initiated action to the service.

  For example, you might want to be alerted if there's a sudden increase of people reading encrypted data outside standard working hours, which could indicate that a malicious user is collecting information to sell to competitors. Or, if the same user apparently accesses data from two different IP addresses within a short time frame, which could indicate that a user account has been compromised.

- **Perform forensic analysis**

  If you have an information leak, you're likely to be asked who recently accessed specific documents and what information did a suspected person access recently. You can answer these types of questions when you use Azure Rights Management usage logging because people who use encrypted content must always get a Rights Management use license to open items that are encrypted by Azure Rights Management, even if these items are moved by email or copied to USB drives or other storage devices. This means that you can use these logs as a definitive source of information for forensic analysis when you protect your data by using the Azure Rights Management service.

Additional logging options for the Azure Rights Management service:

Expand table

Logging option	Description
Admin log	Logs administrative tasks for the Azure Rights Management service. For example, if the service is deactivated, when the super user feature is enabled, and when users are

Logging option	Description
	delegated admin permissions to the service. For more information, see the PowerShell cmdlet, Get-AipServiceAdminLog.
Document tracking	Lets users track and revoke their documents that they have encrypted with the Microsoft Purview Information Protection client. The Compliance Data Administrator role can also track these documents on behalf of users. For more information, see Track and revoke document access.

The remainder of this article explains how to download and interpret Azure Rights Management usage logs, including log format details and a PowerShell reference.

How to access and use your Azure Rights Management usage logs

Azure Rights Management usage logging is enabled by default for all customers. There's no extra cost for the log storage or for the logging feature functionality.

The Azure Rights Management service writes logs as a series of blobs to an Azure storage account that it automatically creates for your tenant. Each blob contains one or more log records, in W3C extended log format. The blob names are numbers, in the order in which they were created. For more information about log contents and their creation, see How to interpret your Azure Rights Management usage logs.

It can take a while for logs to appear in your storage account after an Azure Rights Management action. Most logs appear within 15 minutes. Usage logs are only available when the "date" field name contains a value of a previous date (in UTC time). Usage logs from the current date aren't available. We recommend that you download the logs to local storage, such as a local folder, a database, or a big-data processing system.

To download your usage logs, you use the AIPService PowerShell module for Microsoft Purview Information Protection. For installation instructions, see Install the AIPService PowerShell module for the Azure Right Management service.

To download your usage logs by using PowerShell

Use the following steps to connect to the Azure Rights Management service and download your usage logs by using PowerShell.

1. Start PowerShell with the **Run as administrator** option and use the Connect-AipService cmdlet to connect to the Azure Rights Management service:

   ```PowerShell
   Connect-AipService
   ```

2. Run the following command to download the logs for a specific date:

   ```PowerShell
   Get-AipServiceUserLog -Path <location> -fordate <date>
   ```

   For example, after creating a folder called Logs on your E: drive:

   - To download logs for a specific date (such as 2/1/2025), run the following command: `Get-AipServiceUserLog -Path E:\Logs -fordate 2/1/2025`
   - To download logs for a date range (such as from 2/1/2025 through 2/14/2025), run the following command: `Get-AipServiceUserLog -Path E:\Logs -fromdate 2/1/2025 –`

`todate 2/14/2025`

When you specify the day only, as in our examples, the time is assumed to be 00:00:00 in your local time, and then converted to UTC. When you specify a time with your -fromdate or -todate parameters (for example, -fordate "2/1/2025 15:00:00"), that date and time is converted to UTC. The Get-AipServiceUserLog command then gets the logs for that UTC time period.

You can't specify less than a whole day to download.

By default, this cmdlet uses three threads to download the logs. If you have sufficient network bandwidth and want to decrease the time required to download the logs, use the -NumberOfThreads parameter, which supports a value from 1 through 32. For example, if you run the following command, the cmdlet spawns 10 threads to download the logs: `Get-AipServiceUserLog -Path E:\Logs -fromdate 2/1/2025 –todate 2/14/2025 -numberofthreads 10`

> **Tip**
>
> You can aggregate all your downloaded log files into a CSV format by using Microsoft's Log Parser, which is a tool to convert between various well-known log formats. You can also use this tool to convert data to SYSLOG format, or import it into a database. After you have installed the tool, run `LogParser.exe /?` for help and information to use this tool.
>
> For example, you might run the following command to import all information into a .log file format: `logparser –i:w3c –o:csv "SELECT * INTO AllLogs.csv FROM *.log"`

How to interpret your usage logs

This section explains the Azure Rights Management log sequence, blob format, log record fields, and common request types so you can parse and analyze your usage logs.

The log sequence

The Azure Rights Management service writes the logs as a series of blobs.

Each entry in the log has a UTC timestamp. Because the service runs on multiple servers across multiple data centers, sometimes the logs might seem to be out of sequence, even when they're sorted by their timestamp. However, the difference is small and usually within a minute. In most cases, this isn't an issue that would be a problem for log analysis.

The blob format

Each blob is in W3C extended log format. It starts with the following two lines:

#Software: RMS

#Version: 1.1

The first line identifies that these are usage logs from Azure Rights Management. The second line identifies that the rest of the blob follows the version 1.1 specification. We recommend that any applications that parse these logs verify these two lines before continuing to parse the rest of the blob.

The third line enumerates a list of field names that are separated by tabs:

#Fields: date time row-id request-type user-id result correlation-id content-id owner-email issuer template-id file-name date-published c-info c-ip admin-action acting-as-user

Each of the subsequent lines is a log record. The values of the fields are in the same order as the preceding line, and are separated by tabs. Use the following table to interpret the fields.

Expand table

Field name	W3C data type	Description	Example value
date	Date	UTC date when the request was served. The source is the local clock on the server that served the request.	2013-06-25
time	Time	UTC time in 24-hour format when the request was served. The source is the local clock on the server that served the request.	21:59:28
row-id	Text	Unique GUID for this log record. If a value isn't present, use the correlation-id value to identify the entry. This value is useful when you aggregate logs or copy logs into another format.	aaaa0000-bb11-2222-33cc-444444dddddd
request-type	Name	Name of the RMS API that was requested.	AcquireLicense
user-id	String	The user who made the request. The value is enclosed in single quotation marks. Calls from an Azure Rights Management tenant key that is managed by you (BYOK) have a value of '', which also applies when the request types are anonymous.	'joe@contoso.com'

Field name	W3C data type	Description	Example value
result	String	'Success' if the request was served successful. The error type in single quotation marks if the request failed.	'Success'
correlation-id	Text	GUID that is common between the corresponding client log and server log for a given request. This value can be useful to help troubleshoot client issues.	bbbb1111-cc22-3333-44dd-555555eeeeee
content-id	Text	GUID, enclosed in curly braces that identifies the encrypted content (for example, a document). This field has a value only if request-type is AcquireLicense and is blank for all other request types.	{bb4af47b-cfed-4719-831d-71b98191a4f2}
owner-email	String	Email address of the owner of the document. This field is blank if the request type is RevokeAccess.	alice@contoso.com
issuer	String	Email address of the document issuer. This field is blank if the request type is RevokeAccess.	alice@contoso.com (or) FederatedEmail.4c1f4d-93bf-00a95fa1e042@contoso.onmicrosoft.com'
template-id	String	ID of the rights management template used to encrypt the document. This field is	{6d9371a6-4e2d-4e97-9a38-202233fed26e}

Field name	W3C data type	Description	Example value
		blank if the request type is RevokeAccess.	
file-name	String	File name of an encrypted document that is tracked by using the Microsoft Purview Information Protection client. Currently, some files (such as Office documents) display as GUIDs rather than the actual file name. This field is blank if the request type is RevokeAccess.	TopSecretDocument.docx
date-published	Date	Date when the document was encrypted. This field is blank if the request type is RevokeAccess.	2015-10-15T21:37:00
c-info	String	Information about the client platform that is making the request. The specific string varies, depending on the application (for example, the operating system or the browser).	'MSIPC;version=1.0.623.47;AppName=WINWORD.EXE;AppVersion=15.0.4753.1000;AppArch=x86;O
c-ip	Address	IP address of the client that makes the request.	64.51.202.144
admin-action	Bool	Whether an administrator has accessed the document tracking site in Administrator mode.	True
acting-as-user	String	The email address of the user for whom an administrator is accessing	'joe@contoso.com'

Field name	W3C data type	Description	Example value
		the document tracking site.	

Exceptions for the user-id field

Although the user-id field usually indicates the user who made the request, there are two exceptions where the value doesn't map to a real user:

- The value '**microsoftrmsonline@<YourTenantID>.rms.<region>.aadrm.com**'.

  This indicates a Microsoft 365 service, such as Exchange or SharePoint, is making the request. In the string, *<YourTenantID>* is the GUID for your tenant and *<region>* is the region where your tenant is registered. For example, **na** represents North America, **eu** represents Europe, and **ap** represents Asia.

- If you're using the Rights Management connector.

  Requests from this connector are logged with the service principal name of **Aadrm_S-1-7-0**, which is automatically generated when you install the Rights Management connector.

Typical request types

There are many request types for the Azure Rights Management service but the following table identifies some of the most typically used request types.

Expand table

Request type	Description
AcquireLicense	A client from a Windows-based computer is requesting a use license for encrypted content.
AcquirePreLicense	A client, on behalf of the user, is requesting a use license for encrypted content.
AcquireTemplates	A call was made to acquire rights management templates based on template IDs
AcquireTemplateInformation	A call was made to get the IDs of the rights management template from the service.
AddTemplate	A call is made from an admin portal to add a rights management template.
AllDocsCsv	A call is made from the document tracking site to download the CSV file from the **All Documents** page.
BECreateEndUserLicenseV1	A call is made from a mobile device to create an end-user license.
BEGetAllTemplatesV1	A call is made from a mobile device (back-end) to get all the rights management templates.
Certify	The client is certifying the user for the consumption and creation of encrypted content.
FECreateEndUserLicenseV1	Similar to the AcquireLicense request but from mobile devices.
FECreatePublishingLicenseV1	The same as Certify and GetClientLicensorCert combined, from mobile clients.
FEGetAllTemplates	A call is made, from a mobile device (front-end) to get the rights management templates.
FindServiceLocationsForUser	A call is made to query for URLs, which is used to call Certify or AcquireLicense.
GetClientLicensorCert	The client is requesting a publishing certificate (that is later used to encrypt content) from a Windows-based computer.

Request type	Description
GetConfiguration	A PowerShell cmdlet is called to get the configuration of the tenant for the Azure Rights Management service.
GetConnectorAuthorizations	A call is made from the Rights Management connectors to get their configuration from the cloud.
GetRecipients	A call is made from the document tracking site to navigate to the list view for a single document.
GetTenantFunctionalState	An admin portal is checking whether the Azure Rights Management service is activated.
KeyVaultDecryptRequest	The client is attempting to decrypt the Rights Management encrypted content. Applicable only for a customer-managed tenant key (BYOK) in Azure Key Vault.
KeyVaultGetKeyInfoRequest	A call is made to verify that the key specified to be used in Azure Key Vault for the Azure Rights Management tenant key is accessible and not already used.
KeyVaultSignDigest	A call is made when a customer-managed key (BYOK) in Azure Key Vault is used for signing purposes. This is called typically once per AcquireLicence (or FECreateEndUserLicenseV1), Certify, and GetClientLicensorCert (or FECreatePublishingLicenseV1).
KMSPDecrypt	The client is attempting to decrypt the Rights Management encrypted content. Applicable only for a legacy customer-managed tenant key (BYOK).
KMSPSignDigest	A call is made when a legacy customer-managed key (BYOK) is used for signing purposes. This is called typically once per AcquireLicence (or FECreateEndUserLicenseV1), Certify, and GetClientLicensorCert (or FECreatePublishingLicenseV1).
ServerCertify	A call is made from a Rights Management-enabled client (such as SharePoint) to certify the server.
SetUsageLogFeatureState	A call is made to enable usage logging.
SetUsageLogStorageAccount	A call is made to specify the location of the Azure Rights Management service logs.
UpdateTemplate	A call is made from an admin portal to update an existing rights management template.

Azure Rights Management usage logs and Microsoft Purview auditing

File access and denied events don't include the file name and aren't accessible in the Microsoft Purview unified audit log.

PowerShell reference

After you connect to the Azure Rights Management service, the only PowerShell cmdlet that you need to access your Azure Rights Management usage logging is Get-AipServiceUserLog.

For more information about using PowerShell for the Azure Rights Management service, see Administering the Azure Rights Management service by using PowerShell.

Configure Azure Rights Management super users for discovery services or data recovery

> *Microsoft Purview service description*

The super user feature of the Azure Rights Management service from Microsoft Purview Information Protection ensures that authorized people and services can always read and inspect the data that Azure Rights Management encrypts for your organization. If necessary, the encryption protection can then be removed or changed.

A super user always has the Rights Management Full Control usage right for documents and emails that have been encrypted by your organization's tenant. This ability is sometimes referred to as "reasoning over data" and is a crucial element in maintaining control of your organization's data. For example, you would use this feature for any of the following scenarios:

- An employee leaves the organization and you need to read the files that they encrypted.
- An IT administrator needs to remove the current encryption settings that were configured for files and apply new encryption settings.
- Exchange Server needs to index mailboxes for search operations.
- You have existing IT services for data loss prevention (DLP) solutions, content encryption gateways (CEG), and anti-malware products that need to inspect files that are already encrypted.
- You need to bulk decrypt files for auditing, legal, or other compliance reasons.

Configuration for the super user feature

By default, the super user feature isn't enabled, and no users are assigned to this role. It's enabled for you automatically if you configure the Rights Management connector for Exchange, and it's not required for standard services that run Exchange Online, Microsoft SharePoint Server, or SharePoint in Microsoft 365.

If you need to manually enable the super user feature, use the PowerShell cmdlet Enable-AipServiceSuperUserFeature, and then assign users (or service accounts) as needed by using the

Add-AipServiceSuperUser cmdlet or the Set-AipServiceSuperUserGroup cmdlet and add users (or other groups) as needed to this group.

Although using a group for your super users is easier to manage, for performance reasons, the Azure Rights Management service caches the group membership. So if you need to assign a new user to be a super user to decrypt content immediately, add that user by using Add-AipServiceSuperUser, rather than adding the user to an existing group that you configured by using Set-AipServiceSuperUserGroup.

> **Note**
>
> - When adding a user with the Add-AipServiceSuperUser cmdlet, you must also add the primary mail address or user principal name to the group. Email aliases aren't evaluated.
> - If you haven't yet installed the PowerShell module for the Azure Rights Management service, see Install the AIPService PowerShell module for the Azure Right Management service.

It doesn't matter when you enable the super user feature or when you add users as super users. For example, if you enable the feature on Thursday and then add a user on Friday, that user can immediately open content that was protected at the very beginning of the week.

Security best practices for the super user feature

Follow these security best practices when using the super user feature:

- Restrict and monitor the administrators who are assigned a global administrator for your tenant, or who are assigned the GlobalAdministrator role by using the Add-AipServiceRoleBasedAdministrator cmdlet. These users can enable the super user feature and assign users (and themselves) as super users, and potentially decrypt all files that your organization encrypts.
- To see which users and service accounts are individually assigned as super users, use the Get-AipServiceSuperUser cmdlet.
- To see whether a super user group is configured, use the Get-AipServiceSuperUserGroup cmdlet and your standard user management tools to check which users are a member of this group.

- Like all administration actions, enabling or disabling the super feature, and adding or removing super users are logged and can be audited by using the Get-AipServiceAdminLog command. For example, see Example auditing for the super user feature.
- When super users decrypt files, file decryption is logged and can be audited with usage logging.

  > **Note**
  >
  > While the logs include details about the decryption, including the user who decrypted the file, they don't detail when the user is a super user.
  >
  > Use the logs together with Get-AipServiceSuperUser and Get-AipServiceSuperUserGroup to first collect a list of super users that you can identify in the logs.

- If you don't need the super user feature for everyday services, enable the feature only when you need it, and disable it again by using the Disable-AipServiceSuperUserFeature cmdlet.

Example auditing for the super user feature

The following log extract shows some example entries from using the Get-AipServiceAdminLog cmdlet.

In this example, the administrator for Contoso Ltd confirms that the super user feature is disabled, adds Richard Simone as a super user, checks that Richard is the only super user configured for the Azure Rights Management service, and then enables the super user feature so that Richard can now decrypt some files that were protected by an employee who has now left the company.

```
2015-08-01T18:58:20 admin@contoso.com GetSuperUserFeatureState Passed Disabled
```

```
2015-08-01T18:59:44 admin@contoso.com AddSuperUser -id rsimone@contoso.com Passed True
```

```
2015-08-01T19:00:51 admin@contoso.com GetSuperUser Passed rsimone@contoso.com
```

```
2015-08-01T19:01:45 admin@contoso.com SetSuperUserFeatureState -state Enabled Passed True
```

Scripting options for super users

Often, somebody who is assigned a super user for the Azure Rights Management service needs to remove encryption from multiple files, in multiple locations. While it's possible to do this task manually, it's more efficient (and often more reliable) to script this using the Set-FileLabel cmdlet.

You can also use this cmdlet to apply a new label that doesn't apply encryption, or remove the label that applied encryption.

For more information about these cmdlets, see Use PowerShell with the Microsoft Purview Information Protection client from the PurviewInformationProtection PowerShell documentation.

> ⓘ **Note**
>
> The PurviewInformationProtection module is different from and supplements the **AIPService PowerShell module** that manages the Azure Rights Management service for Microsoft Purview Information Protection.

Removing encryption from PST files

To remove encryption from PST files, we recommend that you use eDiscovery from Microsoft Purview to search and extract encrypted emails and encrypted attachments in emails.

The super user ability is automatically integrated with Exchange Online so that eDiscovery in the Microsoft Purview portal can search for encrypted items prior to export, or decrypt encrypted email on export.

If you can't use Microsoft Purview eDiscovery, you might have another eDiscovery solution that integrates with the Azure Rights Management service to similarly reason over data.

Or, if your eDiscovery solution can't automatically read and decrypt protected content, you can still use this solution in a multi-step process together with the Set-FileLabel cmdlet:

1. Export the email in question to a PST file from Exchange Online or Exchange Server, or from the workstation where the user stored their email.

2. Import the PST file into your eDiscovery tool. Because the tool can't read encrypted content, expect these items to generate errors.

3. From all the items that the tool couldn't open, generate a new PST file that this time, contains just encrypted items. This second PST file will likely be much smaller than the original PST file.

4. Run Set-FileLabel on this second PST file to decrypt the contents of this much smaller file. From the output, import the now-decrypted PST file into your discovery tool.

For more detailed information and guidance for performing eDiscovery across mailboxes and PST files, see the following blog post: Azure Information Protection and eDiscovery Processes.

Decommission and deactivate the Azure Rights Management service

> *Microsoft Purview service description*

You're always in control of whether your organization protects content by using the Azure Rights Management encryption service from Microsoft Purview Information Protection. If you decide you no longer want to use this encryption service, you have the assurance that you won't be locked out of content that was previously encrypted.

If you don't need continued access to previously encrypted content, deactivate the Azure Rights Management encryption services and let your supporting subscription for this service expire. For example, this would be appropriate for when you have completed testing Microsoft Purview Information Protection before you deploy it in a production environment.

However, if you have deployed Microsoft Purview Information Protection in production and encrypted items by using the Azure Rights Management service, make sure that you have a copy of your Azure Rights Management service root key and suitable trusted publishing domain (TPD) before you deactivate the Azure Rights Management service. Make sure that you have a copy of your key and the TPD before your subscription expires to ensure that you can retain access to content that was encrypted by Azure Rights Management after the service is deactivated.

If you used the bring your own key solution (BYOK) where you generate and manage your own key in an HSM, you already have your Azure Rights Management root key. You'll also have a suitable TPD if you followed the instructions that prepare for a future cloud exit. However, if your Azure Rights Management root key was managed by Microsoft (the default), see the instructions for exporting your root key in the Manage the root key for your tenant's Azure Rights Management service article.

> **Tip**
>
> Even after your subscription expires, your tenant remains available for consuming encrypted content for an extended period. However, you will no longer be able to export your root key from the Azure Rights Management service.

When you have your Azure Rights Management service root key and the TPD, you can deploy Rights Management on premises (AD RMS) and import your Azure Rights Management root key as a trusted publishing domain (TPD). You then have the following options for decommissioning your Microsoft Purview Information Protection deployment:

Expand table

If this applies to you ...	... do this:
You want all users to continue using Rights Management, but use an on-premises solution rather than using the Azure Rights Management service →	Redirect your clients to the on-premises deployment by using the **LicensingRedirection** registry key for Office apps. For instructions, see Configure service discovery in the RMS client deployment notes.
You want to stop using Rights Management technologies completely →	Grant a designated administrator super user rights for Microsoft Purview encryption and install the Microsoft Purview Information Protection client for this user. This administrator can then use the PowerShell module from this client to bulk-decrypt files in folders that were encrypted by the Azure Rights Management service. Files revert to being unencrypted and can therefore be read without a Rights Management technology such as Microsoft Purview Information Protection or AD RMS. Because this PowerShell module can be used with both Microsoft Purview Information Protection and AD RMS, you have the choice of decrypting files before or after you deactivate the Azure Rights Management service, or a combination.
You can't identify all the files that were encrypted by the Azure Rights Management service. Or, you want all users to be able to automatically read any encrypted items that were missed →	Deploy a registry setting on all client computers by using the **LicensingRedirection** registry key for Office apps, as described in Configure service discovery in the RMS client deployment notes.
You want a controlled, manual recovery service for any files that were missed →	Grant designated users in a data recovery group super user rights for Microsoft Purview encryption and install the Microsoft Purview Information Protection client for these users so that they can decrypt files when this action is requested by standard users. On all computers, deploy the registry setting to prevent users from encrypting new files by setting **DisableCreation** to **1**, as described in Office registry settings for the DisableCreation policy.

For more information about the decommissioning options for your Microsoft Purview Information Protection deployment, see the following resources:

- For information about AD RMS and deployment references, see Active Directory Rights Management Services Overview.
- For instructions to import your Azure Rights Management service root key as a TPD file, see Add a Trusted Publishing Domain.
- To use PowerShell with the Microsoft Purview Information Protection client, see Set up the information protection client using PowerShell.

When you're ready to deactivate the Azure Rights Management encryption service, use the following instructions.

Deactivate the Azure Rights Management service

You must use PowerShell to deactivate the Azure Rights Management service from Microsoft Purview Information Protection. You can no longer activate or deactivate this encryption service from admin portals.

Before you begin, ensure you have an account with permissions to manage the Azure Rights Management service, such as a Compliance Administrator or Compliance Data Administrator for your tenant.

1. Install the AIPService module, to configure and manage the Azure Rights Management service. For instructions, see Install the AIPService PowerShell module for the Azure Right Management service.
2. From a PowerShell session, run Connect-AipService, and when prompted, provide the credentials for an account that has permissions to manage the Azure Rights Management service, such as a Compliance Administrator or Compliance Data Administrator for your tenant.
3. Run Get-AipService to confirm the current status of the Azure Rights Management service. A status of **Enabled** confirms activation; **Disabled** indicates that the service is deactivated.
4. To deactivate the service, run Disable-AipService.
5. Run Get-AipService again to confirm the encryption service is now deactivated. This time, the status should display **Disabled**.
6. Run Disconnect-AipService to disconnect from the service, and close your PowerShell session.

Email encryption

This article compares encryption options in Microsoft 365 including Microsoft Purview Message Encryption, S/MIME, Information Rights Management (IRM), and introduces Transport Layer Security (TLS).

Microsoft 365 delivers multiple encryption options to help you meet your business needs for email security. This article presents three ways to encrypt email in Office 365. If you want to learn more about all security features in Office 365, visit the Office 365 Trust Center. This article introduces the three types of encryption available for Microsoft 365 administrators to help secure email in Office 365:

- Microsoft Purview Message Encryption.
- Secure/Multipurpose Internet Mail Extensions (S/MIME).
- Information Rights Management (IRM).

How Microsoft 365 uses email encryption

Encryption is the process by which information is encoded so that only an authorized recipient can decode and consume the information. Microsoft 365 uses encryption in two ways: in the service, and as a customer control. In the service, encryption is used in Microsoft 365 by default; you don't have to configure anything. For example, Microsoft 365 uses Transport Layer Security (TLS) to encrypt the connection, or session, between two servers.

Here's how email encryption typically works:

- A message is encrypted, or transformed from plain text into unreadable ciphertext, either on the sender's machine, or by a central server while the message is in transit.
- The message remains in ciphertext while it's in transit in order to protect it from being read in case the message is intercepted.
- Once the message is received by the recipient, the message is transformed back into readable plain text in one of two ways:
    - The recipient's machine uses a key to decrypt the message, or

- A central server decrypts the message on behalf of the recipient, after validating the recipient's identity.

For more information on how Microsoft 365 secures communication between servers, such as between organizations within Microsoft 365 or between Microsoft 365 and a trusted business partner outside of Microsoft 365, see How Exchange Online uses TLS to secure email connections in Office 365.

Comparing email encryption options available in Office 365

Expand table

Email encryption technology			
What is it?	Message encryption is a service built on the Azure Rights Management service that lets you send encrypted email to people inside or outside your organization, regardless of the destination email address (Gmail, Yahoo! Mail, Outlook.com, etc.). As an admin, you can set up transport rules that define the conditions for encryption. When a user sends a message that matches a rule, encryption is applied automatically. To view encrypted messages, recipients can either get a one-time passcode, sign in with a Microsoft account, or sign in with a work or school account associated with Office 365. Recipients can also send encrypted replies. They don't need a Microsoft 365 subscription to view	IRM is an encryption solution that also applies usage restrictions to email messages. It helps prevent sensitive information from being printed, forwarded, or copied by unauthorized people. IRM capabilities in Microsoft 365 use the Azure Rights Management service.	S/MIME is a certificate-based encryption solution that allows you to both encrypt and digitally sign a message. The message encryption helps ensure that only the intended recipient can open and read the message. A digital signature helps the recipient validate the identity of the sender. Both digital signatures and message encryption are made possible through the use of unique digital certificates that contain the keys for verifying digital signatures and encrypting or decrypting messages. To use S/MIME, you must have public keys on file for each recipient. Recipients have to maintain their own private keys, which must remain secure. If a recipient's private keys are compromised, the recipient

Email encryption technology	OME 	IRM 	S/MIME 
	encrypted messages or send encrypted replies.		needs to get a new private key and redistribute public keys to all potential senders.
What does it do?	OME: Encrypts messages sent to internal or external recipients. Allows users to send encrypted messages to any email address, including Outlook.com, Yahoo! Mail, and Gmail. Allows you, as an admin, to customize the email viewing portal to reflect your organization's brand. Microsoft securely manages and stores the keys, so you don't have to. No special client side software is needed as long as the encrypted message (sent as an HTML attachment) can be opened in a browser.	IRM: Uses encryption and usage restrictions to provide online and offline protection for email messages and attachments. Gives you, as an admin, the ability to set up transport rules or Outlook protection rules to automatically apply IRM to select messages. Lets users manually apply templates in Outlook or Outlook on the web (formerly known as Outlook Web App).	S/MIME addresses sender authentication with digital signatures, and message confidentiality with encryption.
What does it not do?	OME doesn't let you apply usage restrictions to messages. For example, you can't use it to stop a recipient from forwarding or printing an encrypted message.	Some applications may not support IRM emails on all devices.	S/MIME doesn't allow encrypted messages to be scanned for malware, spam, or policies.
Recommendations and example scenarios	We recommend using OME when you want to send sensitive business information to people outside your organization, whether they're consumers or other businesses. For example: A bank employee sending	We recommend using IRM when you want to apply usage restrictions as well as encryption. For example: A manager sending confidential details to her team about a new	We recommend using S/MIME when either your organization or the recipient's organization requires true peer-to-peer encryption. S/MIME is most commonly used in the following scenarios:

Email encryption technology	OME 	IRM 	S/MIME 
	credit card statements to customers A doctor's office sending medical records to a patient An attorney sending confidential legal information to another attorney	product applies the "Do Not Forward" option. An executive needs to share a bid proposal with another company, which includes an attachment from a partner who is using Office 365, and require both the email and the attachment to be protected.	Government agencies communicating with other government agencies A business communicating with a government agency

Don't apply multiple email encryption technologies to the same email message. Some email clients, such as Outlook for Mac, Outlook for iOS, and Outlook for Android, aren't able to open messages with multiple email encryption technologies applied.

What encryption options are available for my Microsoft 365 subscription?

For information about email encryption options for your Microsoft 365 subscription see the Exchange Online service description. Here, you can find information about the following encryption features:

- The Azure Rights Management service, including both IRM capabilities and Microsoft Purview Message Encryption
- S/MIME
- TLS
- Encryption of data at rest (through BitLocker, service encryption, and DKM)

You can also use third-party encryption tools with Microsoft 365, for example, PGP (Pretty Good Privacy). Microsoft 365 does not support PGP/MIME and you can only use PGP/Inline to send and receive PGP-encrypted emails.

What about encryption for data at rest?

"Data at rest" refers to data that isn't actively in transit. In Microsoft 365, email data at rest is encrypted using BitLocker Drive Encryption. BitLocker encrypts the hard drives in Microsoft data centers to provide enhanced protection against unauthorized access. To learn more, see BitLocker Overview.

Message encryption

Article • 01/10/2025

People often use email to exchange sensitive information, such as financial data, legal contracts, confidential product information, sales reports and projections, patient health information, or customer and employee information. As a result, mailboxes can become repositories for large amounts of potentially sensitive information and information leakage can become a serious threat to your organization.

With Message encryption, your organization can send and receive encrypted email messages between people inside and outside your organization. Message encryption works with Outlook.com, Yahoo!, Gmail, and other email services. Email message encryption helps ensure that only intended recipients can view message content.

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the **Microsoft Purview trials hub**. Learn details about **signing up and trial terms**.

How Message Encryption works

The rest of this article applies to Microsoft Purview Message Encryption. Office 365 Message Encryption (OME) was deprecated.

Microsoft Purview Message Encryption is an online service that's built on Azure Rights Management (Azure RMS) which is part of Microsoft Purview Information Protection. This service includes encryption, identity, and authorization policies to help secure your email. You can encrypt messages by using rights management templates, the Do Not Forward option, and the encrypt-only option.

Users can then encrypt email messages and various attachments by using these options. For a full list of supported attachment types, see "File types covered by IRM policies when they're attached to messages" in Introduction to IRM for email messages.

As an administrator, you can also define mail flow rules to apply this protection. For example, you can create a rule that requires the encryption of all messages addressed to a specific recipient, or that contains specific words in the subject line, and also specify that recipients can't copy or print the contents of the message.

Message encryption provides a unified sender experience whether you're sending mail inside your organization or to recipients outside of Microsoft 365. In addition, recipients who receive a protected email message sent to a Microsoft 365 account in Outlook 2016 or Outlook on the web, don't have to take any other action to view the message. It works seamlessly. Recipients using other email clients and email service providers also have an improved experience. For information, see Learn about protected messages in Microsoft 365 and How do I open a protected message.

For a detailed list of the differences between the previous version of OME and Microsoft Purview Message Encryption, see Compare versions of message encryption.

When someone sends an email message that matches an encryption mail flow rule, the message is encrypted before it's sent. All Microsoft 365 end users that use Outlook clients to read mail receive native, first-class reading experiences for encrypted and rights-protected mail even if they're not in the same organization as the sender. Supported Outlook clients include Outlook desktop, Outlook Mac, Outlook mobile on iOS and Android, and Outlook on the web (formerly known as Outlook Web App).

Recipients of encrypted messages who receive encrypted or rights-protected mail sent to their Gmail and Yahoo accounts receive a wrapper mail that directs them to the encrypted message portal where they can easily authenticate using a Microsoft account, Gmail, or Yahoo credentials.

End users that read encrypted or rights-protected mail on clients other than Outlook also use the encrypted message portal to view encrypted and rights-protected messages that they receive.

If the sender of the protected mail is in GCC High and the recipient is outside of GCC High, including commercial users, Outlook.com users, and users of other email providers such as Gmail, the recipient receives a wrapper mail. The wrapper mail directs the recipient to the encrypted message portal where the recipient is able to read and reply to the message. Otherwise, if the sender and recipient are both in the GCC High environment, even if they're not in the same organization, then recipients that use Outlook clients to read mail receive native, first-class reading experiences for encrypted and rights-protected mail. For more information about the different experience in GCC High, see Compare versions of OME.

For more information about size limits for messages and attachments that you can encrypt using OME, see Exchange Online Limits.

How Microsoft Purview Advanced Message Encryption works on top of Microsoft Purview

Message Encryption

Microsoft Purview Advanced Message Encryption lets you create multiple branding templates so you can fine-tune control over recipient mail and create custom branding experiences to support a diverse organizational structure.

Advanced Message Encryption in Microsoft 365 helps you meet compliance obligations that require more flexible control over external recipient's access to encrypted emails. With Advanced Message Encryption, as an administrator, you can control sensitive emails shared outside the organization with automatic policies that detect sensitive information types (for example, personal data, Financial or Health IDs) or keywords to enhance protection by expiring access through a secure web portal to encrypted emails. As an admin you can further control encrypted emails accessed through a web portal by revoking access to an email anytime.

Message revocation and expiration only work for emails that your users send to recipients outside your organization. In addition, the recipients must access the email through the web portal. To ensure the recipient uses the portal to receive email, you set up a custom branding template that applies the wrapper. Then, you apply the branding template in a mail flow rule. For more information about Advanced Message Encryption, see Advanced Message Encryption.

Defining rules for Microsoft Purview Message Encryption

One way to enable Microsoft Purview Message Encryption is for Exchange Online and Exchange Online Protection administrators to define mail flow rules. These rules determine under what conditions email messages should be encrypted. When an encryption action is set for a rule, any messages that match the rule conditions are encrypted before they're sent.

Mail flow rules are flexible, letting you combine conditions so you can meet specific security requirements in a single rule. For example, you can create a rule to encrypt all messages that contain specified keywords and are addressed to external recipients. Microsoft Purview Message Encryption also encrypts replies from recipients of encrypted email.

For more information about how to create mail flow rules to take advantage of Microsoft Purview Message Encryption, see Define mail flow rules to encrypt email messages.

Get started with the Microsoft Purview Message Encryption

If you're ready to get started using Microsoft Purview Message Encryption within your organization, see Set up Microsoft Purview Message Encryption.

Sending, viewing, and replying to encrypted email messages

With Microsoft Purview Message Encryption, users can send encrypted email from Outlook and Outlook on the web. Additionally, admins can set up mail flow rules in Microsoft 365 to automatically encrypt emails based on keyword matching or other conditions.

Recipients of encrypted messages who are in organizations will be able to read those messages seamlessly in any version Outlook, including Outlook for PC, Outlook for Mac, Outlook on the web, Outlook for iOS, and Outlook for Android. Users that receive encrypted messages on other email clients can view the messages in the encrypted message portal.

For detailed guidance about how to send and view encrypted messages, take a look at these articles.

Set up Message Encryption

Microsoft Purview Message Encryption allows organizations to share encrypted email with anyone on any device. Users can exchange encrypted messages with other Microsoft 365 organizations, as well as third-parties using Outlook.com, Gmail, and other email services.

Follow the steps below to ensure that Microsoft Purview Message Encryption is available in your organization.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Verify that Azure Rights Management is active

Microsoft Purview Message Encryption uses the protection features from the Azure Rights Management service, the encrytion technology used by Microsoft Purview Information Protection to protect emails and documents by using encryption and access controls.

The only prerequisite for using Microsoft Purview Message Encryption is that the Azure Rights Management service must be activated in your organization's tenant. If it is, Microsoft 365 activates message encryption automatically and you don't need to do anything.

The Azure Rights Management service is also activated automatically for most eligible plans, so you probably don't have to do anything in this regard either. For more information, see Activate the Azure Rights Management service.

> **Important**
>
> If you use Active Directory Rights Management service (AD RMS) with Exchange Online, you need to migrate to the Azure Rights Management service before you can use message encryption. Microsoft Purview Message Encryption is not compatible with AD RMS.

For more information, see:

- Message Encryption FAQ to check whether your subscription plan includes Microsoft Purview Information Protection (which includes the Azure Rights Management encryption service).
- Microsoft Purview Information Protection for information about purchasing an eligible subscription.

Manually activating Azure Rights Management

If you disabled the Azure Rights Management service, or if it was not automatically activated for any reason, you can activate it manually.

For instructions, see How to activate or confirm the status of the encryption service.

Configure management of your Azure Rights Management tenant key

This is an optional step. Allowing Microsoft to manage the root key for the Azure Rights Management service is the default setting and recommended best practice for most organizations. If this is the case, you don't need to do anything.

There are many reasons, for example compliance requirements, that may necessitate you generating and managing your own root key, also known as "bring your own key" (BYOK). If this is the case, we recommend that you complete the required steps before setting up Microsoft Purview Message Encryption. See Bring your own key for the Azure Rights Management service root key for more.

Verify Microsoft Purview Message Encryption configuration in Exchange Online PowerShell

You can verify that your Microsoft 365 tenant is properly configured to use Microsoft Purview Message Encryption in Exchange Online PowerShell.

1. Using a work or school account that has sufficient permissions in your organization, such as Compliance Administrator, start a Windows PowerShell session and connect to Exchange Online. For instructions, see Connect to Exchange Online PowerShell.

2. Run the Get-IRMConfiguration cmdlet.

   You should see a value of `$True` for the AzureRMSLicensingEnabled parameter, which indicates that Microsoft Purview Message Encryption is configured in your tenant. If it is not,

use Set-IRMConfiguration to set the value of AzureRMSLicensingEnabled to `$True` to enable Microsoft Purview Message Encryption.

3. Run the Test-IRMConfiguration cmdlet using the following syntax:

```
PowerShell
Test-IRMConfiguration [-Sender <email address> -Recipient <email address>]
```

Example:

```
PowerShell
Test-IRMConfiguration -Sender securityadmin@contoso.com -Recipient
securityadmin@contoso.com
```

- For sender and recipient, use the email address of any user in your Microsoft 365 tenant.

  Your results should be similar to:

  ```
  Console
  Results : Acquiring RMS Templates ...
            - PASS: RMS Templates acquired.  Templates available: Contoso  -
  Confidential View Only, Contoso  - Confidential, Do Not
         Forward.
         Verifying encryption ...
             - PASS: Encryption verified successfully.
         Verifying decryption ...
             - PASS: Decryption verified successfully.
         Verifying IRM is enabled ...
             - PASS: IRM verified successfully.

         OVERALL RESULT: PASS
  ```

- Your organization name will replace *Contoso*.
- The default template names may be different from those displayed above.

4. If the test fails with an error message **Failed to acquire RMS templates**, execute the following commands and run the Test-IRMConfiguration cmdlet to verify that it passes. Connect to the AIPService module to run the cmdlet.

```
PowerShell
```

```
$RMSConfig = Get-AipServiceConfiguration
$LicenseUri = $RMSConfig.LicensingIntranetDistributionPointUrl
Set-IRMConfiguration -LicensingLocation $LicenseUri
Set-IRMConfiguration -InternalLicensingEnabled $true
```

5. Run the Remove-PSSession cmdlet to disconnect from the Rights Management service.

PowerShell

```
Remove-PSSession $session
```

Next steps: Define mail flow rules to use Microsoft Purview Message Encryption

If there are previously configured mail flow rules to encrypt email in your organization, you need to update the existing rules to use Microsoft Purview Message Encryption. For new deployments, you need to create new mail flow rules.

> **Important**
>
> If you do not update existing mail flow rules, your users will continue to receive encrypted mail that uses the previous HTML attachment format, instead of the new seamless experience.

Mail flow rules determine under what conditions email messages should be encrypted, as well as conditions for removing that encryption. When you set an action for a rule, any messages that match the rule conditions are encrypted when they're sent.

For steps on creating mail flow rules for message encryption, see Define mail flow rules to encrypt email messages.

To update existing rules to use Microsoft Purview Message Encryption:

1. In the Microsoft 365 admin center, go to **Admin centers** > **Exchange**.
2. In the Exchange admin center, go to **Mail flow** > **Rules**.
3. For each rule, in **Do the following**:

   - Select **Modify the message security**.
   - Select **Apply Office 365 Message Encryption and rights protection**.
   - Select **Encrypt** from the RMS template list.

- Select **Save**.
- Select **OK**.

Last updated on 05/04/2026

Define mail flow rules to encrypt email messages

> *Microsoft Purview service description*

As an administrator that manages Exchange Online, you can create mail flow rules (also known as transport rules) to help protect email messages you send and receive. You can set up rules to encrypt any outgoing email messages and remove encryption from encrypted messages coming from inside your organization or from replies to encrypted messages sent from your organization. You can use the Exchange admin center (EAC) or Exchange Online PowerShell to create these rules. In addition to overall encryption rules, you can also choose to enable or disable individual message encryption options for end users.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

You can't encrypt inbound mail from senders outside of your Exchange Online organization. If a mail flow rule is set up to encrypt mail from outside the organization, the inbound mail will be delivered without encryption.

If you recently migrated from Active Directory RMS to the Azure Rights Management service, you'll need to review your existing mail flow rules to ensure that they continue to work in your new environment. Also, to use Microsoft Purview Message Encryption with the Azure Rights Management service, you need to update your existing mail flow rules. Otherwise, your users will continue to receive encrypted mail that uses the previous HTML attachment format instead of the new, seamless experience. If you haven't set up message encryption yet, see Set up Microsoft Purview Message Encryption for information.

For information about the components that make up mail flow rules and how mail flow rules work, see Mail flow rules (transport rules) in Exchange Online.

> **Important**

For hybrid Exchange environments, on-premises users can send and receive encrypted mail using message encryption only if email is routed through Exchange Online. To configure message encryption in a hybrid Exchange environment, you need to first configure hybrid using the Hybrid Configuration wizard and then configure mail to flow from Office 365 to your email server and configure mail to flow from your email server to Office 365. Once you've configured mail to flow through Office 365, then you can configure mail flow rules for message encryption by using the procedures in this article.

Create mail flow rules to encrypt email messages with Microsoft Purview Message Encryption

You can define mail flow rules for triggering message encryption with by using the EAC.

Use the EAC to create a rule for encrypting email messages with Microsoft Purview Message Encryption

Perform the following steps to create a mail flow rule that encrypts email messages using Microsoft Purview Message Encryption.

1. In a web browser, using a work or school account that has been granted sufficient permissions, such as Compliance Administrator, sign in to Microsoft 365.
2. Choose the **Admin** tile.
3. In the Microsoft 365 admin center, choose **Admin centers** > **Exchange**.
4. In the EAC, go to **Mail flow** > **Rules** and select **New** + > **Create a new rule**. For more information about using the EAC, see Exchange admin center in Exchange Online.
5. In **Name**, type a name for the rule, such as Encrypt mail for DrToniRamos@hotmail.com.
6. In **Apply this rule if**, select where the mail originates from inside the Exchange Online organization. Add **The sender is located** > **Inside the organization** for sending mail.
7. In **Apply this rule if**, select a condition, and enter a value if necessary. For example, to encrypt messages going to DrToniRamos@hotmail.com:
    a. In **Apply this rule if**, select **the recipient is**.
    b. Select an existing name from the contact list or type a new email address in the **check names** box.

- To select an existing name, select it from the list and then click **OK**.
- To enter a new name, type an email address in the **check names** box and then select **check names** > **OK**.

8. To add more conditions, choose **More options** and then choose **add condition** and select from the list.

   For example, to apply the rule only if the recipient is outside your organization, select **add condition** and then select **The recipient is external/internal** > **Outside the organization** > **OK**.

9. To enable message encryption, from **Do the following**, select **Modify the message security** and then choose **Apply Office 365 Message Encryption and rights protection**. Select an RMS template from the list, choose **Save**, and then choose **OK**.

The list of templates includes all default templates and options as well as any custom templates you've created for use by Microsoft 365. If the list is empty, ensure that you have set up Microsoft Purview Message Encryption as described in Set up Microsoft Purview Message Encryption. For information about the **Do Not Forward** option, see Do Not Forward option for emails. For information about the **encrypt-only** option, see Encrypt-only option for emails.

You can choose **add action** if you want to specify another action.

Use the EAC to update an existing mail flow rule to use Microsoft Purview Message Encryption

Perform the following steps to update an existing mail flow rule to use Microsoft Purview Message Encryption.

1. In a web browser, using a work or school account that has been granted sufficient administrator permissions, such as Compliance Administrator, sign in to Microsoft 365.
2. Choose the **Admin** tile.
3. In the Microsoft 365 admin center, choose **Admin centers** > **Exchange**.
4. In the EAC, go to **Mail flow** > **Rules**.
5. In the list of mail flow rules, select the rule you want to modify to use with Microsoft Purview Message Encryption and then choose **Edit**.

6. To enable encryption using Microsoft Purview Message Encryption, from **Do the following**, choose **Modify the message security** and then choose **Apply Office 365 Message Encryption and rights protection**. Select an RMS template from the list, choose **Save** and then choose **OK**.

   The list of templates includes all default templates and options as well as any custom templates you've created for use by Microsoft 365. If the list is empty, ensure that you have set up Microsoft Purview Message Encryption as described in Set up Microsoft Purview Message Encryption. For information about the Do Not Forward option, see Do Not Forward option for emails. For information about the encrypt-only option, see Encrypt Only option for emails.

   You can choose **add action** if you want to specify another action.

7. From the **Do the following** list, remove any actions that are assigned to **Modify the message security** > **Apply the previous version of OME**.

8. Choose **Save**.

Create mail flow rules to remove encryption for email messages with Microsoft Purview Message Encryption

You can define mail flow rules to remove message encryption with Microsoft Purview Message Encryption by using the EAC.

Use the EAC to create a rule to remove encryption from email messages with Microsoft Purview Message Encryption

You can remove encryption from messages that was applied by your organization. You can also remove encryption from any encrypted attachments to ensure the whole email message is without any protection.

1. In a web browser, using a work or school account that has been granted sufficient permissions, such as Compliance Administrator, sign in to Microsoft 365.

2. Choose the **Admin** tile.

3. In the Microsoft 365 admin center, choose **Admin centers** > **Exchange**.

4. In the EAC, go to **Mail flow** > **Rules** and select **New +** > **Create a new rule**. For more information about using the EAC, see Exchange admin center in Exchange Online.

5. In **Name**, type a name for the rule, such as `Remove encryption from outgoing mail`.

6. In **Apply this rule if**, select the conditions where encryption should be removed from messages. Add **The sender is located** > **Inside the organization** for sending mail out to any recipients *or* add **The recipient is located** > **Inside the organization** for receiving mail replies from outside the organization.

7. In **Do the following**, select **Modify the message security** > **Remove Office 365 Message Encryption and rights protection applied by the organization**.

8. (Optional) In **Do the following**, select **Modify the message security** > **Remove attachment rights protection protection applied by the organization**.

9. Save the rule.

Create mail flow rules for Office 365 Message Encryption without Microsoft Purview Message Encryption

Office 365 Message Encryption is deprecated as of July 1, 2023. If you haven't yet moved your organization to Microsoft Purview Message Encryption, Microsoft recommends that you make a plan to move as soon as it is reasonable for your organization. For instructions, see Set up Microsoft Purview Message Encryption.

Last updated on 06/22/2026

Add your organization's brand to your Microsoft Purview Message Encryption encrypted messages

> *Microsoft Purview service description*

Apply your company branding to customize the look of your organization's email messages and the encryption portal. You need to apply sufficient permissions to your work or school account before you can get started, for example Compliance Administrator. You customize branding in one of two ways, using Exchange Online PowerShell or Microsoft Purview Data Loss Prevention (DLP) policies.

For more information about using Microsoft Purview Data Loss Prevention (DLP) policies to add customized branding to encrypted messages, see these resources.

- Supported action: Exchange for details on this action.
- Design a data loss prevention policy if you're new to DLP and want to learn more about what goes into preparing to create a DLP policy.
- Create and Deploy data loss prevention policies for examples on how to create and deploy a DLP policy.

The following sections describe how to use Exchange Online PowerShell to customize branding.

Use the Get-OMEConfiguration and Set-OMEConfiguration cmdlets in Exchange Online PowerShell to customize these parts of encrypted email messages:

- Introductory text
- Disclaimer text
- URL for Your organization's privacy statement
- Text in the encrypted message portal
- Logo that appears in the email message and encrypted message portal, or whether to use a logo at all
- Background color in the email message and encrypted message portal

You can also revert back to the default look and feel at any time.

If you'd like more control, use Microsoft Purview Advanced Message Encryption to create multiple templates for encrypted emails originating from your organization. Use these templates to control parts of the end-user experience. For example, specify whether recipients can use Google, Yahoo, and Microsoft Accounts to sign in to the encryption portal. Use templates to fulfill several use cases, such as:

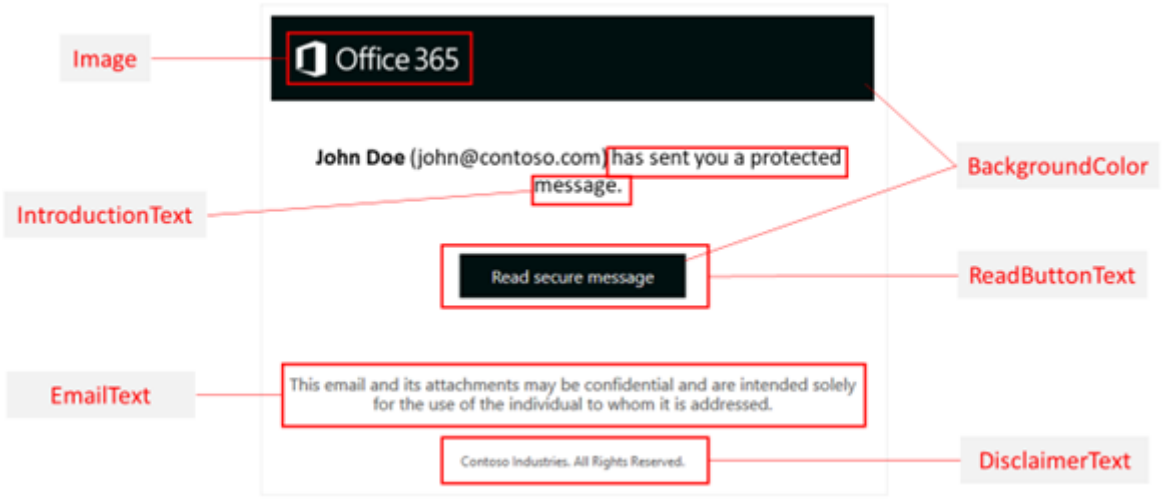
- Individual departments, such as Finance, Sales, and so on.
- Different products
- Different geographical regions or countries
- Whether you want to allow emails to be revoked
- Whether you want emails sent to external recipients to expire after a specified number of days.

Once you've created the templates, apply them to encrypted emails sent from your online mailbox by using Exchange mail flow rules. If you have Microsoft Purview Advanced Message Encryption, you can revoke any email that you have branded.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Work with branding templates

You can modify several features within a branding template, and modify, but not remove, the default template. If you have Advanced Message Encryption, you can also create, modify, and remove custom templates. Use Exchange Online PowerShell to work with one branding template at a time.



- Set-OMEConfiguration - Modify the default branding template or a custom branding template that you created.
- New-OMEConfiguration - Create a new branding template, Advanced Message Encryption only.
- Remove-OMEConfiguration - Remove a custom branding template, Advanced Message Encryption only. You can't delete the default branding template.

Modify a branding template

Use Exchange Online PowerShell to modify one branding template at a time. If you have Advanced Message Encryption, you can also create, modify, and remove custom templates.

1. Use a work or school account that has sufficient administrator permissions in your organization, such as Compliance Administrator, and connect to Exchange Online PowerShell. For instructions, see Connect to Exchange Online PowerShell.

2. Use the Set-OMEConfiguration cmdlet as described in Set-OMEConfiguration or use the following graphic and table for guidance.

Expand table

To customize this feature of the encryption experience	Use these commands

Background color	`Set-OMEConfiguration -Identity "<ConfigurationName>" -BackgroundColor "<#RRGGBB hexadecimal color code or name value>"`
	
	Example:
	
	`Set-OMEConfiguration -Identity "Branding Template 1" -BackgroundColor "#ffffff"`
	
	For more information about background colors, see Background colors.

Logo	`Set-OMEConfiguration -Identity "<ConfigurationName>" -Image <Byte[]>`
	
	Example:
	
	`Set-OMEConfiguration -Identity "Branding Template 1" -Image ([System.IO.File]::ReadAllBytes('C:\Temp\contosologo.png'))`
	
	Supported file formats: .png, .jpg, .bmp, or .tiff

To customize this feature of the encryption experience	Use these commands
	Optimal size of logo file: less than 40 KB Optimal size of logo image: 170x70 pixels. If your image exceeds these dimensions, the service resizes your logo for display in the portal. The service doesn't modify the graphic file itself. For best results, use the optimal size.

Text next to the sender's name and email address	`Set-OMEConfiguration -Identity "<ConfigurationName>" -IntroductionText "<String up to 1024 characters>"`
	
	Example:
	
	`Set-OMEConfiguration -Identity "Branding Template 1" -IntroductionText "has sent you a secure message."`

Text that appears on the "Read Message" button	`Set-OMEConfiguration -Identity "<ConfigurationName>" -ReadButtonText "<String up to 1024 characters>"`
	
	Example:
	
	`Set-OMEConfiguration -Identity "Message encryption configuration" -ReadButtonText "Read Secure Message."`

Text that appears below the "Read Message" button	`Set-OMEConfiguration -Identity "<ConfigurationName>" -EmailText "<String up to 1024 characters>"`
	
	Example:
	
	`Set-OMEConfiguration -Identity "Message encryption configuration" -EmailText "Encrypted message from ContosoPharma secure messaging system."`

URL for the Privacy Statement link	`Set-OMEConfiguration -Identity "<ConfigurationName>" -PrivacyStatementURL "<URL>"`
	
	Example:
	
	`Set-OMEConfiguration -Identity "Branding Template 1" -PrivacyStatementURL "https://contoso.com/privacystatement.html"`

Disclaimer statement in the email that contains the encrypted message	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -DisclaimerText "<Disclaimer statement. String of up to 1024 characters.>"`
	
	Example:
	
	`Set-OMEConfiguration -Identity "Branding Template 1" -DisclaimerText "This message is confidential for the use of the addressee only."`

Text that appears at the top of the encrypted	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -PortalText "<Text for your portal. String of up to 128 characters.>"`

To customize this feature of the encryption experience	Use these commands
mail viewing portal	**Example:** `Set-OMEConfiguration -Identity "Message encryption cfonfiguration" -PortalText "ContosoPharma secure email portal."`

To enable or disable authentication with a one-time pass code for this custom template	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -OTPEnabled <$true\|$false>`
	
	Examples:
	To enable one-time passcodes for this custom template
	
	`Set-OMEConfiguration -Identity "Branding Template 1" -OTPEnabled $true`
	
	To disable one-time passcodes for this custom template
	
	`Set-OMEConfiguration -Identity "Branding Template 1" -OTPEnabled $false`

To enable or disable authentication with Microsoft, Google, or Yahoo identities for this custom template	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -SocialIdSignIn <$true\|$false>`
	
	Examples:
	To enable social IDs for this custom template
	
	`Set-OMEConfiguration -Identity "Branding Template 1" -SocialIdSignIn $true`
	
	To disable social IDs for this custom template
	
	`Set-OMEConfiguration -Identity "Branding Template 1" -SocialIdSignIn $false`

Create an encrypted message branding template (Advanced Message Encryption)

If you have Microsoft Purview Advanced Message Encryption, you can create custom branding templates for your organization by using the New-OMEConfiguration cmdlet. Once you've created the template, you modify the template by using the Set-OMEConfiguration cmdlet as described in Modify a branding template. You can create multiple templates.

To create a new custom branding template:

1. Use a work or school account that has sufficient administrator permissions in your organization, such as Compliance Administrator, and connect to Exchange Online PowerShell. For instructions, see Connect to Exchange Online PowerShell.

2. Use the New-OMEConfiguration cmdlet to create a new template.

PowerShell

```
New-OMEConfiguration -Identity "<OMEConfigurationName>"
```

For example,

PowerShell

```
New-OMEConfiguration -Identity "Custom branding template"
```

Return the default branding template to its original values

To remove all modifications from the default template, including brand customizations, and so on, complete these steps:

1. Use a work or school account that has sufficient administrator permissions in your organization, such as Compliance Administrator, and connect to Exchange Online PowerShell. For instructions, see Connect to Exchange Online PowerShell.

2. Use the **Set-OMEConfiguration** cmdlet as described in Set-OMEConfiguration. To remove your organization's branded customizations from the DisclaimerText, EmailText, and PortalText values, set the value to an empty string, `""`. For all image values, such as Logo, set the value to `"$null"`.

   The following table describes the encryption customization option defaults.

Expand table

To revert this feature of the encryption experience back to the default text and image	Use these commands

Default text that comes with encrypted email messages. The default text appears above the instructions for viewing encrypted messages	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -EmailText "<empty string>"`
	
	Example:
	
	`Set-OMEConfiguration -Identity "Message encryption configuration" -EmailText ""`

Disclaimer statement in the email that contains the encrypted message	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" DisclaimerText "<empty string>"`

To revert this feature of the encryption experience back to the default text and image	Use these commands
	Example: `Set-OMEConfiguration -Identity "Message encryption configuration" -DisclaimerText ""`

Text that appears at the top of the encrypted mail viewing portal	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -PortalText "<empty string>"`
	
	Example reverting back to default:
	
	`Set-OMEConfiguration -Identity "Message encryption configuration" -PortalText ""`

Logo	`Set-OMEConfiguration -Identity "<OMEConfigurationName>" -Image <"$null">`
	
	Example reverting back to default:
	
	`Set-OMEConfiguration -Identity "Message encryption configuration" -Image $null`

Background color	`Set-OMEConfiguration -Identity "<ConfigurationName>" -BackgroundColor "$null">`
	
	Example reverting back to default:
	
	`Set-OMEConfiguration -Identity "Message encryption configuration" -BackgroundColor $null`

Remove a custom branding template (Advanced Message Encryption)

You can only remove or delete branding templates that you've made. You can't remove the default branding template.

To remove a custom branding template:

1. Use a work or school account that has sufficient administrator permissions in your organization, such as Compliance Administrator, and connect to Exchange Online PowerShell. For instructions, see Connect to Exchange Online PowerShell.

2. Use the **Remove-OMEConfiguration** cmdlet as follows:

> ⚠ **Warning**
>
> The following command permanently removes the specified custom branding template. This action can't be undone, and you can't remove the default branding template.

PowerShell

```
Remove-OMEConfiguration -Identity "<OMEConfigurationName>"
```

For example,

PowerShell

```
Remove-OMEConfiguration -Identity "Branding template 1"
```

For more information, see Remove-OMEConfiguration.

Create an Exchange mail flow rule that applies your custom branding to encrypted emails sent from your online organization to external recipients

> ⓘ **Important**
>
> Third-party applications that scan and modify mail can prevent branding from being applied correctly.

After you've either modified the default template or created new branding templates, you can create Exchange mail flow rules to apply your custom branding based on certain conditions. Most importantly, the email must be encrypted. Such a rule applies custom branding to mail sent from your online mailbox in the following scenarios:

- If the email was manually encrypted by the end user using Outlook or Outlook on the web, formerly Outlook Web App
- If the email was automatically encrypted by an Exchange mail flow rule or Microsoft Purview Data Loss Prevention policy

To ensure Microsoft Purview Message Encryption applies your custom branding, set up a mail flow rule to encrypt your messages. The priority of the encryption rule should be higher than the branding rule so that the encryption rule is processed first. By default, if you create the encryption rule before the branding rule, then the encryption rule has a higher priority. For information, see Define mail flow rules to encrypt email messages. For information on setting the priority of a mail flow rule, see Manage mail flow rules.

1. In a web browser, using a work or school account that has sufficient permissions in your organization, such as Compliance Administrator, sign in to Microsoft 365.

2. Choose the **Admin** tile.

3. In the Microsoft 365 admin center, choose **Admin centers** > **Exchange**.

4. In the EAC, go to **Mail flow** > **Rules** and select **New +** > **Create a new rule**. For more information about using the EAC, see Exchange admin center in Exchange Online.

5. In **Name**, type a name for the rule, such as **Branding for sales department**.

6. In **Apply this rule if**, select the condition **The sender is located inside the organization** and other conditions you want from the list of available conditions. For example, you might want to apply a particular branding template to:

   - All encrypted emails sent from members of the finance department
   - Encrypted emails sent with a certain keyword such as "External" or "Partner"
   - Encrypted emails sent to a particular domain

7. If you've already defined a mail flow rule to apply encryption, skip this step. Otherwise, to configure the mail flow rule to apply encryption, from **Do the following**, select **Modify the message security**, and then select **Apply Office 365 Message Encryption and rights protection**. Select a Rights Management Service (RMS) template from the list and then select **add action**.

   The list of templates includes default templates and options and any custom templates you create. If the list is empty, ensure that you have set up Microsoft Purview Message Encryption. For instructions, see Set up Microsoft Purview Message Encryption. For information about the **Do Not Forward** option, see the Do Not Forward option for emails. For information about the **Encrypt Only** option, see Encrypt Only option for emails.

8. From **Do the following**, select **Modify the message security** > **Apply custom branding to OME messages**. Next, from the drop-down, select a branding template.

Select **add action** if you want to specify another action, or select **Save**, and then select **OK**.

Background color reference

The color names that you can use for the background color are limited. Instead of a color name, you can use a hex code value (`#RRGGBB`). You can use a hex code value that corresponds to a color name, or you can use a custom hex code value. Be sure to enclose the hex code value in quotation marks (for example, `"#f0f8ff"`).

The available background color names and their corresponding hex code values are described in the following table.

Expand table

Color name	Color code
`aliceblue`	#f0f8ff

Create a sensitive information type policy for your organization using Microsoft Purview Message Encryption

> *Microsoft Purview service description*

You can use either Exchange mail flow rules or Microsoft Purview Data Loss Prevention (DLP) to create a sensitive information type policy with Microsoft Purview Message Encryption. To create an Exchange mail flow rule, you can use either the Exchange admin center (EAC) or Exchange PowerShell.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview **roles and permissions**.

To create the policy by using mail flow rules in the EAC

Sign in to the Exchange admin center and go to **Mail flow** > **Rules**. On the Rules page, create a rule that applies Message Encryption. You can create a rule based on conditions such as the presence of certain keywords or sensitive information types in the message or attachment.

To create the policy by using mail flow rules in Exchange PowerShell

Use a work or school account that has sufficient permissions in your organization, such as Compliance Administrator, connect to Exchange Online PowerShell. For instructions, see Connect to Exchange Online PowerShell. Use the `Set-IRMConfiguration` and `New-TransportRule` cmdlets to create the policy.

Example mail flow rule created with Exchange PowerShell

Run the following commands in PowerShell to create an Exchange mail flow rule that automatically encrypts emails sent outside your organization with the encrypt-only option if the emails or their attachments contain the following sensitive information types:

- ABA routing number
- Credit card number
- Drug Enforcement Agency (DEA) number
- U.S. or U.K. passport number
- U.S. bank account number
- U.S. Individual Taxpayer Identification Number (ITIN)
- U.S. Social Security Number (SSN)

PowerShell

```
Set-IRMConfiguration -DecryptAttachmentForEncryptOnly $true
New-TransportRule -Name "Encrypt outbound sensitive emails (out of box rule)" -
SentToScope  NotInOrganization  -ApplyRightsProtectionTemplate "Encrypt" -
MessageContainsDataClassifications @(@{Name="ABA Routing Number";
minCount="1"},@{Name="Credit Card Number"; minCount="1"},@{Name="Drug Enforcement
Agency (DEA) Number"; minCount="1"},@{Name="U.S. / U.K. Passport Number";
minCount="1"},@{Name="U.S. Bank Account Number"; minCount="1"},@{Name="U.S. Individual
Taxpayer Identification Number (ITIN)"; minCount="1"},@{Name="U.S. Social Security
Number (SSN)"; minCount="1"}) -SenderNotificationType "NotifyOnly"
```

For cmdlet syntax and parameter details, see Set-IRMConfiguration and New-TransportRule.

How recipients access attachments

After Microsoft encrypts a message, recipients have unrestricted access to attachments when they access and open their encrypted email.

To prepare for automatic encryption of outbound sensitive emails

You may want to update any applicable end-user documentation and training materials to prepare people in your organization for the automatic encryption of outbound messages containing sensitive information. Share these message encryption resources with your users as appropriate:

- Send, view, and reply to encrypted messages in Outlook for PC
- Microsoft 365 Essentials Video: Message Encryption

View these changes in the audit log

Microsoft 365 audits the creation of the mail flow rule and makes the audit record available to administrators. The operation is 'New-TransportRule' and a snippet of a sample audit entry from the Audit Log Search in the Microsoft Purview portal is as follows:

text

```
*{"CreationTime":"2018-11-28T23:35:01","Id":"a1b2c3d4-daa0-4c4f-a019-
03a1234a1b0c","Operation":"New-TransportRule","OrganizationId":"123456-221d-12345
","RecordType":1,"ResultStatus":"True","UserKey":"Microsoft
Operator","UserType":3,"Version":1,"Workload":"Exchange","ClientIP":"123.456.147.68:17
584","ObjectId":"","UserId":"Microsoft
Operator","ExternalAccess":true,"OrganizationName":"contoso.onmicrosoft.com","Originat
ingServer":"CY4PR13MBXXXX (15.20.1382.008)","Parameters":
{"Name":"Organization","Value":"123456-221d-12346"
{"Name":"ApplyRightsProtectionTemplate","Value":"Encrypt"},
{"Name":"Name","Value":"Encrypt outbound sensitive emails (out of box rule)"},
{"Name":"MessageContainsDataClassifications"...etc.*
```

To disable or customize the sensitive information types policy

Once you've created the Exchange mail flow rule, you can disable or edit the rule by going to **Mail flow** > **Rules** in the Exchange admin center and disabling the rule "*Encrypt outbound sensitive emails (out of box rule)*".

Manage message encryption

> *Microsoft Purview service description*

Once you've finished setting up Purview Message Encryption, you can customize the configuration of your deployment in several ways. For example, you can configure whether to enable one-time pass codes, display the **Encrypt** button in Outlook on the web, and more. The tasks in this article describe how.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Manage whether Google, Yahoo, and Microsoft Account recipients can use these accounts to sign in to the encrypted message portal

When you set up the message encryption, users in your organization can send messages to recipients that are outside of your organization. If the recipient uses a *social ID* such as a Google account, Yahoo account, or Microsoft account, the recipient can sign in to the encrypted message portal with a social ID. If you want, you can choose not to allow recipients to use social IDs to sign in to the encrypted message portal.

To manage whether recipients can use social IDs to sign in to the encrypted message portal

1. Connect to Exchange Online PowerShell.
2. Run the Set-OMEConfiguration cmdlet with the SocialIdSignIn parameter as follows:

```
PowerShell
Set-OMEConfiguration -Identity <"OMEConfigurationIdParameter"> -SocialIdSignIn
<$true|$false>
```

For example, to disable social IDs:

```
PowerShell
Set-OMEConfiguration -Identity "OME Configuration" -SocialIdSignIn $false
```

To enable social IDs:

```
PowerShell
Set-OMEConfiguration -Identity "OME Configuration" -SocialIdSignIn $true
```

Manage the use of one-time pass codes for the encrypted message portal

If the recipient of a message encrypted by message encryption doesn't use Outlook, regardless of the account used by the recipient, the recipient receives a limited-time web-view link that lets them read the message. This link includes a one-time pass code. As an administrator, you can decide if recipients can use one-time pass codes to sign in to the encrypted message portal.

To manage whether OME generates one-time pass codes

Perform the following steps to manage whether OME generates one-time pass codes.

1. Use a work or school account that has sufficient administrator permissions in your organization, such as Compliance Administrator, and connect to Exchange Online PowerShell. For instructions, see Connect to Exchange Online PowerShell.

2. Run the Set-OMEConfiguration cmdlet with the OTPEnabled parameter:

```
PowerShell
Set-OMEConfiguration -Identity <"OMEConfigurationIdParameter"> -OTPEnabled
<$true|$false>
```

For example, to disable one-time pass codes:

```
PowerShell
Set-OMEConfiguration -Identity "OME Configuration" -OTPEnabled $false
```

To enable one-time pass codes:

PowerShell

```
Set-OMEConfiguration -Identity "OME Configuration" -OTPEnabled $true
```

Manage the display of the Encrypt button in Outlook on the web

As an administrator, you can manage whether to display the **Encrypt** button in Outlook on the web to end users.

To manage whether the Encrypt button appears in Outlook on the web

Perform the following steps to manage whether the **Encrypt** button appears in Outlook on the web.

1. Use a work or school account that has sufficient permissions in your organization, such as Compliance Administrator, and connect to Exchange Online PowerShell. For instructions, see Connect to Exchange Online PowerShell.

2. Run the Set-IRMConfiguration cmdlet with the -SimplifiedClientAccessEnabled parameter:

   PowerShell

   ```
   Set-IRMConfiguration -SimplifiedClientAccessEnabled <$true|$false>
   ```

   For example, to disable the **Encrypt** button:

   PowerShell

   ```
   Set-IRMConfiguration -SimplifiedClientAccessEnabled $false
   ```

   To enable the **Encrypt** button:

   PowerShell

   ```
   Set-IRMConfiguration -SimplifiedClientAccessEnabled $true
   ```

Enable service-side decryption of email messages for iOS mail app users

The iOS mail app can't decrypt messages protected with message encryption. As a Microsoft 365 administrator, you can apply service-side decryption for messages delivered to the iOS mail app. When you choose to do use service-side decryption, the service sends a decrypted copy of the message to the iOS device. The client device stores a decrypted copy of the message. The message also retains information about usage rights even though the iOS mail app doesn't apply client-side usage rights to the user. The user can copy or print the message even if they didn't originally have the rights to do so. However, if the user attempts to complete an action that requires the Microsoft 365 mail server, such as forwarding the message, the server won't permit the action if the user didn't originally have the usage right to do so. However, end users can work around "Do Not Forward" usage restriction by forwarding the message from a different account within the iOS mail app. Regardless of whether you set up service-side decryption of mail, attachments to encrypted and rights protected mail can't be viewed in the iOS mail app.

If you choose not to allow decrypted messages to be sent to iOS mail app users, users receive a message that states that they don't have the rights to view the message. By default, service-side decryption of email messages isn't enabled.

For more information, and for a view of the client experience, see View encrypted messages on your iPhone or iPad.

To manage whether iOS mail app users can view messages protected by message encryption

Perform the following steps to manage whether iOS mail app users can view messages protected by message encryption.

1. Use a work or school account that has sufficient permissions in your organization, such as Compliance Administrator, and connect to Exchange Online PowerShell. For instructions, see Connect to Exchange Online PowerShell.

2. Run the Set-ActiveSyncOrganizations cmdlet with the AllowRMSSupportForUnenlightenedApps parameter:

   PowerShell

   ```
   Set-ActiveSyncOrganizationSettings -AllowRMSSupportForUnenlightenedApps
   <$true|$false>
   ```

   For example, to configure the service to decrypt messages before they're sent to unenlightened apps like the iOS mail app:

PowerShell

```
Set-ActiveSyncOrganizationSettings -AllowRMSSupportForUnenlightenedApps $true
```

Or, to configure the service not to send decrypted messages to unenlightened apps:

PowerShell

```
Set-ActiveSyncOrganizationSettings -AllowRMSSupportForUnenlightenedApps $false
```

> **Note**
>
> Individual mailbox policies (OWA/ActiveSync) override the AllowRMSSupportForUnenlightenedApps setting (i.e. if -IRMEnabled is set to False within the respective OWA Mailbox policy or ActiveSync Mailbox policy, then the AllowRMSSupportForUnenlightenedApps setting doesn't apply).

Enable service-side decryption of email attachments for web browser mail clients

Normally, when you use message encryption, attachments are automatically encrypted. As an administrator, you can apply service-side decryption for email attachments that users download from a web browser.

When you use service-side decryption, the service sends a decrypted copy of the file to the device. The message is still encrypted. The email attachment also keeps information about usage rights even though the browser doesn't apply client-side usage rights to the user. The user can copy or print the email attachment even if they didn't originally have the rights to do so. However, if the user tries to complete an action that requires the Microsoft 365 mail server, such as forwarding the attachment, the server won't permit the action if the user didn't originally have the usage right to do so.

Regardless of whether you set up service-side decryption of attachments, users can't view any attachments to encrypted and rights protected mail in the iOS mail app.

If you choose not to allow decrypted email attachments, which is the default, users receive a message that states that they don't have the rights to view the attachment.

For more information about how Microsoft 365 implements encryption for emails and email attachments with the Encrypt-Only option, see Encrypt-Only option for emails.

To manage whether email attachments are decrypted on download from a web browser

Perform the following steps to manage whether email attachments are decrypted when downloaded from a web browser.

1. Use a work or school account that has sufficient permissions in your organization, such as Compliance Administrator, and connect to Exchange Online PowerShell. For instructions, see Connect to Exchange Online PowerShell.

2. Run the Set-IRMConfiguration cmdlet with the DecryptAttachmentForEncryptOnly parameter:

   PowerShell

   ```
   Set-IRMConfiguration -DecryptAttachmentForEncryptOnly <$true|$false>
   ```

   For example, to configure the service to decrypt email attachments when a user downloads them from a web browser:

   PowerShell

   ```
   Set-IRMConfiguration -DecryptAttachmentForEncryptOnly $true
   ```

   To configure the service to leave encrypted email attachments as they are upon download:

   PowerShell

   ```
   Set-IRMConfiguration -DecryptAttachmentForEncryptOnly $false
   ```

Ensure all external recipients use the encrypted message portal to read encrypted mail

You can use custom branding templates to force recipients to receive a wrapper mail that directs them to read encrypted email in the encrypted message portal instead of using Outlook or Outlook on the web. You might want to do force this experience if you use want greater control over how recipients use the mail they receive. For example, if external recipients view email in the web portal, you can set an expiration date for the email, and you can revoke the email. These features are only supported through the encrypted message portal. You can use the Encrypt option and the Do Not Forward option when creating the mail flow rules.

Use a custom template to force all external recipients to use the encrypted message portal and for encrypted email

Perform the following steps to create a custom template that forces all external recipients to use the encrypted message portal for encrypted email.

1. Use a work or school account that has sufficient permissions in your organization, such as Compliance Administrator, and connect to Exchange Online PowerShell. For instructions, see Connect to Exchange Online PowerShell.

2. Run the New-TransportRule cmdlet:

   PowerShell

   ```
   New-TransportRule -name "<mail flow rule name>" -FromScope "InOrganization" -
   ApplyRightsProtectionTemplate "<option name>" -
   ApplyRightsProtectionCustomizationTemplate "<template name>"
   ```

   where:

   - `mail flow rule name` is the name you want to use for the new mail flow rule.
   - `option name` is either `Encrypt` or `Do Not Forward`.
   - `template name` is the name you gave the custom branding template, for example `OME Configuration`.

   To encrypt all external email with the "OME Configuration" template and apply the Encrypt-Only option:

   PowerShell

   ```
   New-TransportRule -name "<All outgoing mail>" -FromScope "InOrganization" -
   ApplyRightsProtectionTemplate "Encrypt" -
   ApplyRightsProtectionCustomizationTemplate "OME Configuration"
   ```

   To encrypt all external email with the "OME Configuration" template and apply the Do Not Forward option:

   PowerShell

   ```
   New-TransportRule -name "<All outgoing mail>" -FromScope "InOrganization" -
   ApplyRightsProtectionTemplate "Do Not Forward" -
   ApplyRightsProtectionCustomizationTemplate "OME Configuration"
   ```

Customize the appearance of email messages and the encrypted message portal

For detailed information about how you can customize Microsoft Purview Message Encryption for your organization, see Add your organization's brand to your encrypted messages. To track and revoke encrypted messages, you must add your custom branding to the encrypted message portal.

Disable Microsoft Purview Message Encryption

We hope it doesn't come to it, but if you need to, disabling Microsoft Purview Message Encryption is straightforward. First, remove any mail flow rules you've created that use Microsoft Purview Message Encryption. For information about removing mail flow rules, see Manage mail flow rules. Then, complete these steps in Exchange Online PowerShell.

To disable Microsoft Purview Message Encryption

Perform the following steps to disable Microsoft Purview Message Encryption.

1. Using a work or school account that has sufficient permissions in your organization, such as Compliance Administrator, connect to Exchange Online PowerShell. For instructions, see Connect to Exchange Online PowerShell.

2. If you enabled the **Encrypt** button in Outlook on the web, disable it by running the Set-IRMConfiguration cmdlet with the SimplifiedClientAccessEnabled parameter. Otherwise, skip this step.

   PowerShell

   ```
   Set-IRMConfiguration -SimplifiedClientAccessEnabled $false
   ```

3. Disable the Microsoft Purview Message Encryption by running the Set-IRMConfiguration cmdlet with the AzureRMSLicensingEnabled parameter set to false:

   PowerShell

   ```
   Set-IRMConfiguration -AzureRMSLicensingEnabled $false
   ```

Advanced Message Encryption

> *Microsoft Purview service description*

Advanced Message Encryption helps customers meet compliance obligations that require more flexible controls over external recipients and their access to encrypted emails. With Advanced Message Encryption in Office 365, you can control sensitive emails shared outside the organization with automatic policies and track those activities through the encrypted message portal access logs. You configure these policies to identify sensitive information types such as PII, Financial, or Health IDs, or you can use keywords to enhance protection. Once you've configured the policies, you pair policies with custom branded email templates and then add an expiration date for extra control of emails that fit the policy. Also, admins can further control encrypted emails accessed externally through a secure web portal by revoking access to the mail at any time.

You can only revoke and set an expiration date for emails sent to external recipients.

Get started with Microsoft Purview Advanced Message Encryption

The following articles describe how you set up and use Advanced Message Encryption.

If you do not have Office 365 Message Encryption set up already, see Set up new Office 365 Message Encryption capabilities.

With Advanced Message Encryption, you're not limited to a single branding template. Instead, you can create and use multiple branding templates. Adding custom branding also lets you enable tracking a revocation of encrypted messages. For information, see Add your organization's brand to your encrypted messages. When you use custom branding, external recipients receive a notification email that contains a link to the OME portal. The mail flow rule determines which branding template the notification email and OME Portal use. This way, your secure content isn't sent outside your organization.

You can only revoke messages and apply expiration dates to messages that users receive through the portal. In other words, email that has a custom branding template applied. For more information and an example, see the guidance in Ensure all external recipients use the encrypted message portal to read encrypted mail.

Set an expiration date for email encrypted by Microsoft Purview Advanced Message Encryption. Control sensitive emails shared outside the organization with automatic policies that enhance protection by expiring access through a secure web portal to encrypted emails.

Revoke email encrypted by Microsoft Purview Advanced Message Encryption. Control sensitive emails shared outside the organization and enhance protection by revoking access through a secure web portal to encrypted emails.

Encrypted message portal activity log by Microsoft Purview Advanced Message Encryption. Monitor sensitive emails shared outside the organization in the encrypted message portal.

Last updated on 05/14/2026

Encrypted message portal activity log by Microsoft Purview Advanced Message Encryption

You can access logs for encrypted messages through the encrypted message portal. With these logs, your organization can determine when external recipients read and forward messages. To ensure availability of logs for external recipients, apply a custom branding template to protected emails that your organization sends to external recipients. This template enforces a portal experience. For more information, see Add your organization's brand to your encrypted messages.

Enable message access audit logs in PowerShell

You can enable the access log by using Exchange Online PowerShell. The *EnablePortalTrackingLogs* parameter of the **Set-IrmConfiguration** cmdlet specifies whether to enable audit logs for accessing the encrypted message portal. Valid values are:

- $true: Turns on the audit feature.
- $false: Turns off the audit feature.

Example:

PowerShell

```
Set-IrmConfiguration -EnablePortalTrackingLogs $true
```

For more information, see Set-IRMConfiguration (ExchangePowerShell).

Message access audit information

The access log contains entries for messages sent through the encrypted message portal for the following types of activity:

- External user sign-in timestamp and authentication method
- External user reading messages or attachments
- Attachment download
- Mail replies and forwards

For more information on the message access log schema, see Audit log activities.

Search for events in the message access logs

Complete the following steps to get started with search:

1. Sign in to the Microsoft Purview portal.
2. Select the **Audit** solution card. If the **Audit** solution card isn't displayed, select **View all solutions** and then select **Audit** from the **Core** section.
3. Under **Search**, select the drop-down for **Activities** and type encrypted message portal activities.
4. Under encrypted message portal activities, select the event types to use in the search. Set the date range for the search (default is the previous week), you can also optionally add a particular user in your organization for the search. When ready, select **Search**.
5. Select an event from the list to view the audit properties.

Next steps

- Search the audit log: Search for broader activity related to the senders or recipients identified in encrypted message logs.
- Export, configure, and view audit log records: Export your encrypted message activity results for compliance reporting.

Set an expiration date for email encrypted by Microsoft Purview Advanced Message Encryption

> *Microsoft Purview service description*

You can use message expiration on emails that your users send to external recipients who use the OME Portal to access encrypted emails. You force recipients to use the OME portal to view and reply to encrypted emails sent by your organization by using a custom branded template that specifies an expiration date in PowerShell.

When you apply your company brand to customize the look of your organization's email messages, you can also specify an expiration for these email messages. With Microsoft Purview Advanced Message Encryption, you can create multiple templates for encrypted emails that originate from your organization. Using a template, you can control how long recipients have access to mail sent by your users.

When an end user receives mail that has an expiration date set, the user sees the expiration date in the wrapper email. If a user tries to open an expired mail, an error appears in the OME portal.

You can only set expiration dates for emails to external recipients.

With Microsoft Purview Advanced Message Encryption, anytime you apply custom branding, Microsoft 365 applies the wrapper to email that fits the mail flow rule to which you apply the template. You can only use expiration if you use custom branding.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Create a custom branding template to force mail expiration by using PowerShell

To create a custom branding template that forces mail expiration, complete the following steps.

1. Using a work or school account that has sufficient permissions in your organization, such as Compliance Administrator, start a Windows PowerShell session and connect to Exchange Online. For instructions, see Connect to Exchange Online PowerShell.

2. Run the New-OMEConfiguration cmdlet.

   PowerShell

   ```
   New-OMEConfiguration -Identity "Expire in 7 days" -ExternalMailExpiryInDays 7
   ```

Where:

- `Identity` is the name of the custom template.
- `ExternalMailExpiryInDays` identifies the number of days that recipients can keep mail before it expires. You can use any value between 1–730 days.

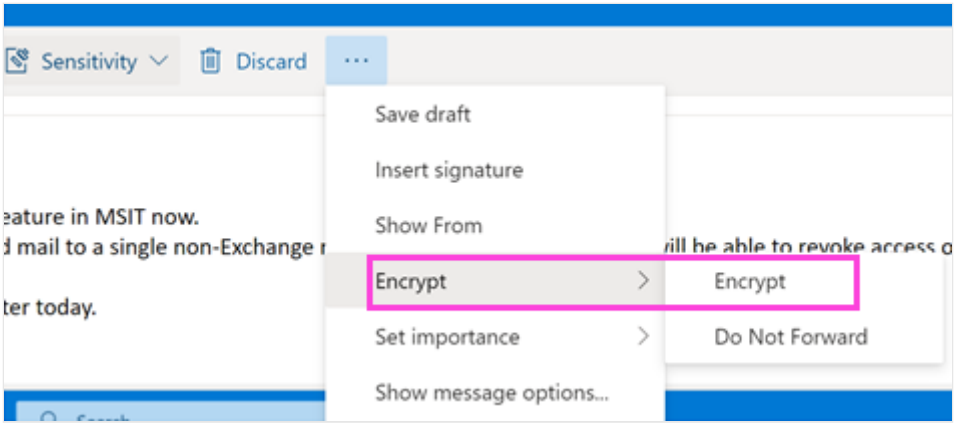
Revoke email encrypted by Advanced Message Encryption

> *Microsoft Purview service description*

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

This article is part of a larger series of articles about Microsoft Purview Message Encryption.

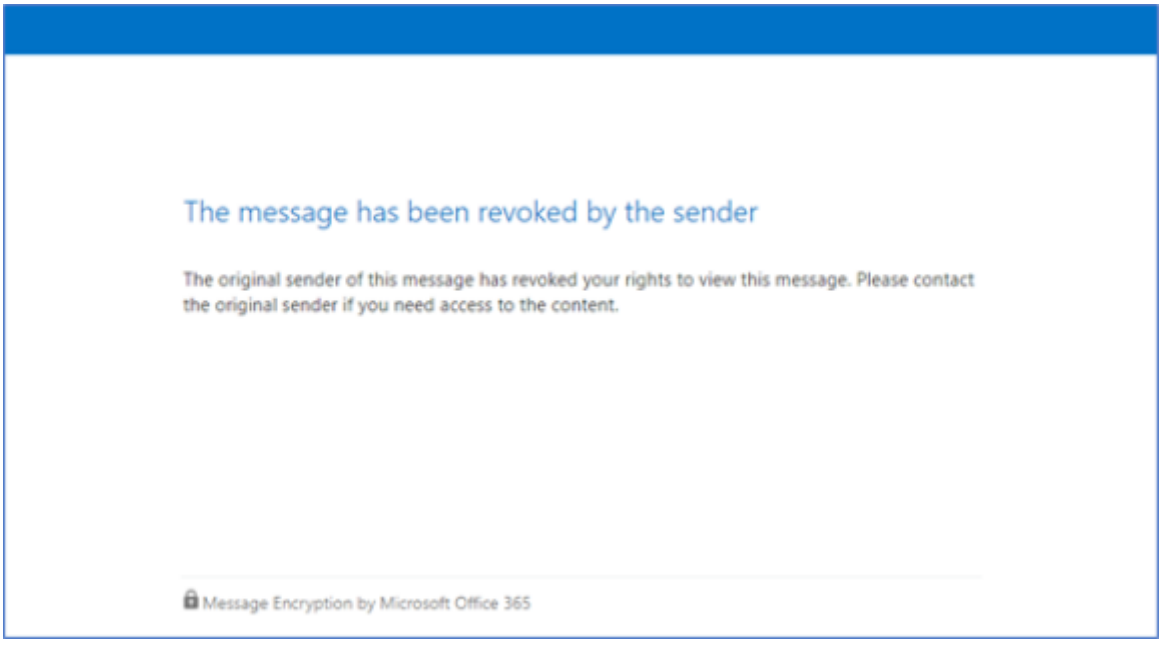
If a message was encrypted using Microsoft Purview Advanced Message Encryption, and you are a Microsoft 365 admin or you are the sender of the message, you can revoke the message under certain conditions. Admins revoke messages using PowerShell. As a sender, you revoke a message that you sent directly from Outlook on the web. This article describes the circumstances under which revocation is possible and how to do it.



> **Note**
>
> To guarantee that the ability to track and revoke encrypted messages is available, you must add a custom branding template. See Add your organization's brand to your encrypted messages

Encrypted emails that you can revoke

Admins and message senders can revoke encrypted emails if the recipient received a link-based, branded encrypted email. If the recipient received a native inline experience in a supported Outlook client, then you can't revoke the message.



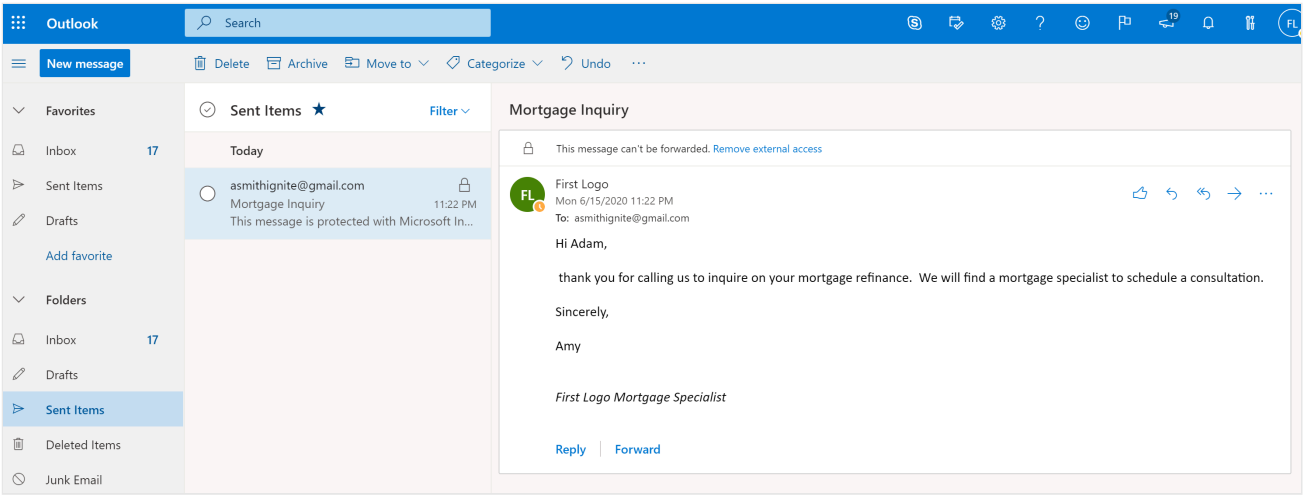
Whether a recipient receives a link-based experience or an inline experience depends on the recipient identity type: Microsoft 365 and Microsoft account recipients (for example, outlook.com users) get an inline experience in supported Outlook clients. All other recipient types, such as Gmail and Yahoo recipients, get a link-based experience.

Admins and message senders can revoke messages that are encrypted using encryption applied directly from Outlook on the web. For example, messages encrypted with the Encrypt Only option.

Recipient experience for revoked encrypted emails

Once an email has been revoked, the recipient receives an error when they access the encrypted email through the encryption portal: "The message has been revoked by the sender".

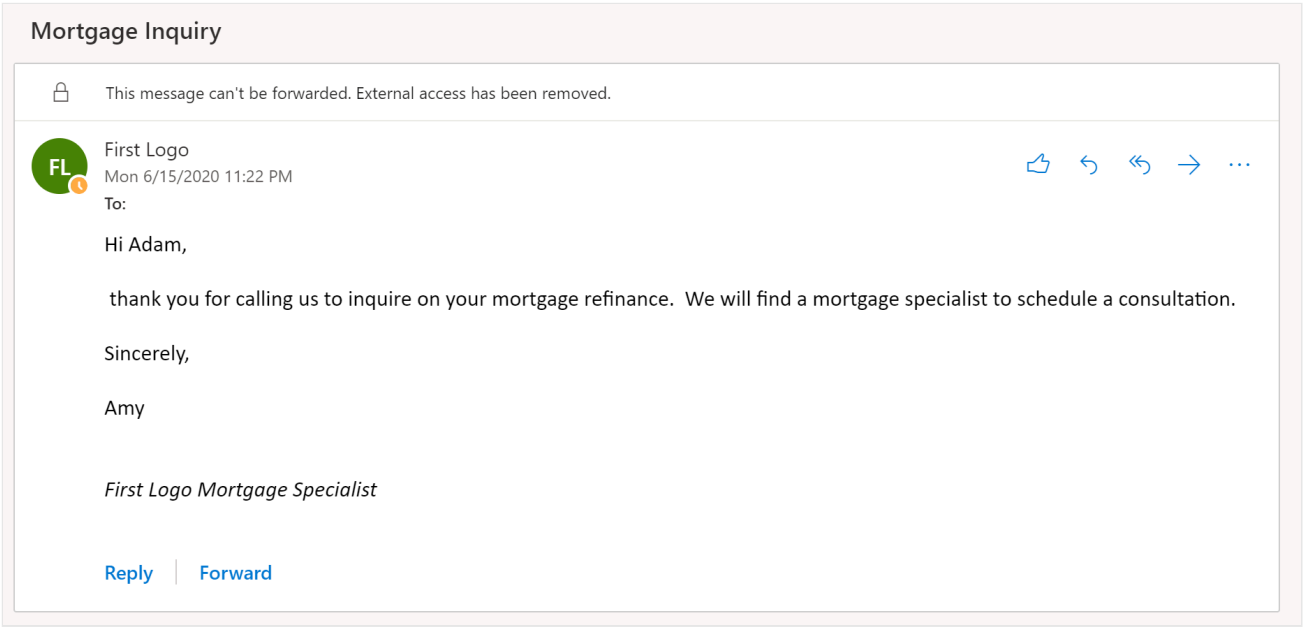
How to revoke an encrypted message that you sent



You can revoke a mail that you sent to a single recipient that uses a social account such as gmail.com or yahoo.com. In other words, you can revoke an email sent to a single recipient that received the link-based experience.

You cannot revoke a mail that you sent to a recipient that uses a work or school account from Microsoft 365 or a user that uses a Microsoft account, for example, an outlook.com account.

To revoke an encrypted message that you sent, complete these steps



1. In Outlook on the web, in your **Sent** folder, browse to the message you want to revoke.

   If the mail is revocable, you'll see the "Remove external access" link at the top of the message.

2. Click **Remove external access** to revoke the message.

   The message shows that its status is revoked.

How to revoke an encrypted message as an administrator

Microsoft 365 administrators follow these general steps to revoke an eligible encrypted email:

- Get the Message ID of the email.
- Verify that you can revoke the message.

- Revoke the mail.

Step 1: Obtain the Message ID of the email

Before you can revoke an encrypted mail, gather the Message ID of the mail. The MessageId is usually of the format:

`<xxxxxxxxxxxxxxxxxxxxxxx@xxxxxx.xxxx.prod.outlook.com>`

There are multiple ways to find the Message ID of the email that you want to revoke. The following procedures describe two options, but you can use any method that provides the ID.

To identify the Message ID of the email you want to revoke by using Message Trace in the Microsoft Purview portal

Use Message Trace in the Microsoft Purview portal to find the Message ID for the encrypted email.

1. Search for the email by sender or recipient using New Message Trace in Microsoft Purview portal.
2. Once you've located the email, select it to bring up the **Message trace details** pane. Expand **More Information** to locate the Message ID.

To identify the Message ID of the email you want to revoke by using Message Encryption reports in the Microsoft Purview portal

You can also use Message Encryption reports in the Microsoft Purview portal to locate the Message ID.

1. In the Microsoft Purview portal, navigate to the **Message encryption report**. For information on this report, see View email security reports in the Security & Compliance Center.
2. Choose the **View details** table and identify the message that you want to revoke.
3. Double-click the message to view details that include the Message ID.

Step 2: Verify that the mail is revocable

To verify whether you can revoke a message, check whether the Revocation Status field is visible in the Encryption report, in the **Details** table in the Microsoft Purview portal.

To verify whether you can revoke a particular email message by using Windows PowerShell, complete these steps.

1. Using a work or school account that has sufficient permissions in your organization, such as Compliance Administrator, start a Windows PowerShell session and connect to Exchange Online. For instructions, see Connect to Exchange Online PowerShell.

2. Run the Get-OMEMessageStatus cmdlet as follows:

   PowerShell

   ```
   Get-OMEMessageStatus -MessageId "<message id>" | ft -a  Subject, IsRevocable
   ```

   This command returns the subject of the message and whether the message is revocable. For example,

   Console

   ```
   Subject        IsRevocable
   -------        -----------
   "Test message" True
   ```

Step 3: Revoke the mail

Once you know the Message ID of the email you want to revoke, and you have verified that the message is revocable, you can revoke the email using the Microsoft Purview portal or Windows PowerShell.

To revoke the message using the Microsoft Purview portal

1. Using a work or school account that has compliance administrator permissions in your organization, connect to the Microsoft Purview portal.

2. In the **Encryption report**, in the **Details** table for the message, choose **Revoke message**.

To revoke an email by using Windows PowerShell, use the Set-OMEMessageRevocation cmdlet.

1. Using a work or school account that has compliance administrator, or Exchange administrator permissions in your organization, connect to Exchange Online PowerShell.

2. Run the Set-OMEMessageRevocation cmdlet as follows:

   PowerShell

```
Set-OMEMessageRevocation -Revoke $true -MessageId "<messageId>"
```

3. To check whether the email was revoked, run the Get-OMEMessageStatus cmdlet as follows:

PowerShell

```
Get-OMEMessageStatus -MessageId "<messageId>" | ft -a  Subject, Revoked
```

If revocation was successful, the cmdlet returns the following result:

Console

```
Revoked: True
```

Compare versions of message encryption

Article • 03/31/2025

> **Important**
>
> On February 28, 2021, Microsoft deprecated support for AD RMS in Exchange Online. If you've deployed a hybrid environment where your Exchange mailboxes are online and you're using IRM with Active Directory RMS on-premises, you'll need to migrate to Azure. Organizations that have deployed into the GCC Moderate environment are also affected. See "Overview of AD RMS deprecation in Exchange Online" in this article for information.

The rest of this article compares legacy Office 365 Message Encryption (OME) to Microsoft Purview Message Encryption and Microsoft Purview Advanced Message Encryption. Microsoft Purview Message Encryption is merger and newer version of both OME and Information Rights Management (IRM). Unique characteristics of deploying into GCC High are also outlined. The two can coexist in your organization. For information on how the new capabilities work, see Office 365 Message Encryption (OME).

This article is part of a larger series of articles about message encryption. This article is intended for administrators and ITPros. If you're just looking for information on sending or receiving an encrypted message, see the list of articles in Message encryption and locate the article that best fits your needs.

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the **Microsoft Purview trials hub**. Learn details about **signing up and trial terms**.

Overview of AD RMS deprecation in Exchange Online

Exchange Online includes Information Rights Management (IRM) functionality that provides online and offline protection of email messages and attachments. By default, Exchange Online uses Azure Information Protection. However, your organization may have configured Exchange Online IRM to use on-premises Active Directory Rights Management Service (AD RMS). AD RMS support in Exchange Online is retiring. Instead, Azure Information Protection will replace AD RMS entirely.

To assess whether this deprecation impacts your organization, see How to migrate AD RMS to Azure RMS in Exchange Online. This article provides recommendations on migration options.

Side-by-side comparison of message encryption features and capabilities

Expand table

Situation	Legacy OME	IRM in AD RMS	Microsoft Purview Message Encryption
Sending an encrypted mail	Through Exchange mail flow rules	End-user initiated from Outlook desktop or Outlook on the Web; or through Exchange mail flow rules	End-user initiated from Outlook desktop, Outlook for Mac, or Outlook on the Web; through Exchange mail flow rules (also known as transport rules) and data loss prevention (DLP)
Rights management template	N/A	Do Not Forward option and custom templates	Do Not Forward option, encrypt-only option, and custom templates
Recipient type	Internal and external recipients	Internal recipients only	Internal and external recipients
Experience for internal recipient	Recipients receive an HTML message that they download and open in a web browser or mobile app	Native inline experience in Outlook clients	Native inline experience for recipients in the same organization using Outlook clients. Recipients can read message from encrypted message portal using clients other than Outlook (no download or app required).
Experience for external recipient	Recipients receive an HTML message that they download and open in a web	N/A	Native inline experience for Microsoft 365 recipients. All other recipients can read

Situation	Legacy OME	IRM in AD RMS	Microsoft Purview Message Encryption
	browser or mobile app		message from OME portal (no download or app required).
Attachment permissions	No restrictions on attachments	Attachments are protected	Attachments are protected for the Do Not Forward option and custom templates. Admins can choose whether attachments for the encrypt-only option are protected or not.
Bring your own key (BYOK) support	None	None	BYOK supported

Advantages of Microsoft Purview Message Encryption over legacy OME

The new capabilities provide the following advantages:

- Ability to use the encrypt-only option (which enables secure collaboration), Do Not Forward option, and custom restrictions.
- Senders can send mail encrypted with the new capabilities manually from Outlook Desktop, Outlook for Mac and Outlook on the web clients.
- Microsoft 365 recipients get to use an inline experience in supported Outlook clients. Alternatively, admins can choose to show Microsoft 365 recipients a branded experience.
- Accounts outside of Microsoft 365, such as Gmail, Yahoo, and Microsoft accounts, are federated with the OME portal, which provides a better user experience for these recipients. All other identities use a one-time pass code to access encrypted messages.
- Admins can customize branding, and create multiple branding templates.
- Admins can revoke emails encrypted with the new capabilities.
- The new capabilities provide detailed usage reports through the Microsoft Purview portal.

Microsoft Purview Advanced Message Encryption capabilities

Microsoft Purview Advanced Message Encryption offers more capabilities on top of Microsoft Purview Message Encryption. You must have Microsoft Purview Message Encryption set up in your organization in order to use Advanced Message Encryption. Also, in order to use these capabilities, recipients must view and reply to secure mail through the Microsoft Purview Message Encryption Portal. The advanced capabilities include:

- Message revocation
- Message expiration
- Multiple branding templates
- Encrypted message portal activity logs

For information on using Advanced Message Encryption, see Microsoft Purview Advanced Message Encryption.

Unique characteristics of Microsoft Purview Message Encryption in a GCC High deployment

If you plan to use Microsoft Purview Message Encryption in a GCC High environment, there are some unique characteristics regarding the recipient experience.

Encrypted email between GCC High and GCC High recipients

Senders can manually encrypt emails in Outlook for PC and Mac and Outlook on the web, or organizations can set up a policy to encrypt emails using Exchange mail flow rules.

Recipients inside GCC High receive the same inline reading experience in Outlook for PC and Mac and Outlook on the web as all other users.

Encrypted email between GCC High and Non-GCC High recipients

Senders inside GCC High can send encrypted email outside of the GCC High boundary and vice versa.

All recipients outside GCC High, including commercial Microsoft 365 users, Outlook.com users, and other users of other email providers such as Gmail and Yahoo, receive a

wrapper mail. This wrapper mail redirects the recipient to the Microsoft Purview Message Encryption Portal where the recipient can read and reply to the message. This is also true for senders outside GCC High sending OME encrypted mail to GCC High.

Coexistence of legacy OME and Microsoft Purview Message Encryption in the same tenant

You can use both legacy OME and Microsoft Purview Message Encryption in the same tenant. As an administrator, you do this by choosing which version of message encryption you want to use when you create your mail flow rules.

- To specify the legacy version of OME, use the Exchange mail flow rule action **Apply the previous version of OME**.
- To specify Microsoft Purview Message Encryption, use the Exchange mail flow rule action **Apply Office 365 Message Encryption and rights protection**.

Users can manually send mail that is encrypted with Microsoft Purview Message Encryption from Outlook Desktop, Outlook for Mac, and Outlook on the web.

Migrate from legacy OME to Microsoft Purview Message Encryption

Even though both versions can coexist, we highly recommend that you edit your old mail flow rules that use the rule action **Apply the previous version of OME** to use Microsoft Purview Message Encryption. Update these rules to use the mail flow rule action **Apply Office 365 Message Encryption and rights protection**, select "Encrypt" in the RMS template list. For instructions, see Define mail flow rules to encrypt email messages.

Get started with OME

Typically, Microsoft Purview Message Encryption is automatically enabled for your organization. For more information about Microsoft Purview Message Encryption within your organization, see Set up Microsoft Purview Message Encryption.

The legacy version of OME is automatically enabled for your organization if you have enabled Azure Information Protection. In the past, legacy OME worked even if Azure Information Protection wasn't enabled. This is no longer the case.

To start using legacy OME, if you have enabled Azure Information Protection, configure mail flow rules that use the rule action **Apply the previous version of OME**. For instructions, see Define mail flow rules to encrypt email messages.

Was this page helpful? Yes No

Message encryption FAQ

Have a question about how the new message protection capabilities work? Check for an answer here. Also, look at [Frequently asked questions]](azure-rights-management-learn-about.md#frequently-asked-questions) for answers to questions about the Azure Rights Management encryption service from Microsoft Purview Information Protection.

What is Microsoft Purview Message Encryption?

Microsoft Purview Message Encryption combines email encryption and rights management capabilities. Rights management capabilities are powered by Microsoft Purview Information Protection.

Who can use Microsoft Purview Message Encryption?

You can use Microsoft Purview Message Encryption under the following conditions:

- If you haven't set up Office 365 Message Encryption (OME) or Information Rights Management (IRM) for Exchange.
- If you set up OME and IRM, you can use these steps if you're also using the Azure Rights Management service from Microsoft Purview Information Protection.
- If you're using Exchange with Active Directory Rights Management service (AD RMS), you can't enable these new capabilities right away. Instead, you need to migrate AD RMS to Azure Information Protection first. When you finish the migration, you can successfully set up Microsoft Purview Message Encryption.

  If you choose to continue to use on-premises AD RMS with Exchange instead of migrating to the Azure Rights Management service, you can't use Microsoft Purview Message Encryption.

What subscriptions do I need to use Microsoft Purview Message Encryption?

To use Microsoft Purview Message Encryption, you need one of the following plans:

- Microsoft Purview Message Encryption is offered as part of Office 365 Enterprise E3 and E5, Microsoft 365 Enterprise E3 and E5, Microsoft 365 Business Premium, Office 365 A1, A3, and A5, and Office 365 Government G3 and G5. You don't need extra licenses to receive the new protection capabilities powered by Microsoft Purview Information Protection.
- You can also add Azure Information Protection Plan 1 to the following plans to receive Microsoft Purview Message Encryption: Exchange Plan 1, Exchange Plan 2, Office 365 F3, Microsoft 365 Business Basic, Microsoft 365 Business Standard, or Office 365 Enterprise E1.
- Each user benefiting from Microsoft Purview Message Encryption needs a license to use message encryption.
- For the full list, see the Exchange service descriptions for Microsoft Purview Message Encryption.

Can I use Exchange with bring your own key (BYOK) for the Azure Rights Management service?

Yes! Microsoft recommends that you complete the steps to set up BYOK before you set up Microsoft Purview Message Encryption.

For more information about BYOK, see Planning and implementing your Azure Information Protection tenant key.

Do Microsoft Purview Message Encryption and BYOK with the Azure Rights Management service change Microsoft's approach to non-Microsoft data requests such as subpoenas?

No. Microsoft Purview Message Encryption and the option to provide and control your own encryption keys, called BYOK for the Azure Rights Management service, weren't designed to respond to law enforcement subpoenas. OME, with BYOK for the Azure Rights Managment service, was designed for compliance-focused organizations. Microsoft takes requests for customer data seriously. As a cloud service provider, we always advocate for the privacy of your

data. In the event we get a subpoena, we always attempt to redirect the request directly to you to obtain the information. (Read Brad Smith's blog: Protecting customer data from government snooping). We periodically publish detailed information of the request we receive. For more information regarding non-Microsoft data requests, see Responding to government and law enforcement requests to access customer data on the Microsoft Trust Center. Also, see "Disclosure of Customer Data" in the Online Services Terms (OST) .

How is this feature related to legacy Office 365 Message Encryption (OME) and Information Rights Management (IRM) features?

Microsoft Purview Message Encryption is an evolution of the existing IRM and legacy OME solutions. The following table provides more details.

Comparison of legacy OME, IRM, and Microsoft Purview Message Encryption

Expand table

Capability	Previous versions of OME	IRM	Microsoft Purview Message Encryption
Sending an encrypted email	Only through Exchange mail flow rules	End-user initiated from Outlook for Windows, Outlook for Mac, or Outlook on the web; or through Exchange mail flow rules	End-user initiated from Outlook for Windows, Outlook for Mac, or Outlook on the web; or through mail flow rules
Rights management	-	Do Not Forward option and custom templates	Do Not Forward option, encrypt-only option, default and custom templates
Supported recipient type	External recipients only	Internal recipients only	Internal and external recipients

Capability	Previous versions of OME	IRM	Microsoft Purview Message Encryption
Experience for recipient	External recipients received an HTML message that they downloaded and opened in a browser or downloaded mobile app.	Internal recipients only received encrypted email in Outlook for Windows, Outlook for Mac, and Outlook on the web.	Internal and external recipients receive email in Outlook for Windows, Outlook for Mac, Outlook on the web, Outlook for Android, and Outlook for iOS, or through a web portal, regardless of whether they are in the same organization or in any organization. The encrypted message portal requires no separate download.
Bring Your Own Key support	Not available	Not available	BYOK supported

How do I enable Microsoft Purview Message Encryption for my organization?

See Set up Microsoft Purview Message Encryption.

Is Office 365 Message Encryption deprecated?

Office 365 Message Encryption (OME) was deprecated on July 1, 2023. It's being automatically replaced with Microsoft Purview Message Encryption. If you have an active sender mailbox, you can still view mail from OME.

My organization uses Active Directory Rights Management, can I use this functionality?

No. If you're using Exchange Online with Active Directory Rights Management service (AD RMS), you can't enable these new capabilities right away. Instead, you need to migrate AD RMS to Azure Information Protection first.

My organization has an Exchange Hybrid deployment. Can I use this feature?

On-premises users can send encrypted mail using Exchange Online mail flow rules. You need to route email through Exchange. For more information, see Part 2: Configure mail to flow from your email server to Microsoft 365.

What email client do I need to use to create an encrypted message? What applications are supported for sending protected messages?

You can create protected messages from Outlook 2016, Outlook 2013 for Windows and Mac, and from Outlook on the web. For more information on sending encrypted messages, see Send, view, and reply to encrypted messages in Outlook for PC.

What email clients are supported to read and reply to protected emails?

Microsoft 365 users can read and respond from Outlook for Windows and Mac (2013 and 2016), Outlook on the web, and Outlook mobile (Android and iOS). You can also use the iOS native mail client if your organization allows it. If you aren't a Microsoft 365 user, you can read and reply to encrypted messages on the web through your web browser.

What email clients support the encrypt-only protected emails?

Microsoft 365 users can use Outlook for PC versions 2019 and Microsoft 365 to create mail protected with the encrypt-only policy. Messages that have the encrypt-only policy applied can be read directly in Outlook on the web, in Outlook for iOS and Android, and Outlook for PC versions 2019 and Microsoft 365.

Is there a size limit for messages you can send with OME?

Yes. The maximum message size you can send with Microsoft Purview Message Encryption, including attachments, is 25 MB. For more information, see Message limits.

Is there a limit to the number of recipients you can send OME-encrypted messages to?

Yes. In some cases that have connectors configured such as an Exchange Hybrid deployment, when you include recipients on the **BCC** line, the BCC recipients are removed before mail gets encrypted. Best practice is to move to an Exchange Online, or put all recipients in the **To:** or **CC** fields.

What type of messages does the encrypted message portal support?

The encrypted message portal only supports mail. The portal doesn't support other message types such as calendar or voice mail.

What file types are supported as attachments in protected emails? Do attachments inherit the protection policies and permissions associated with protected emails? What about PDF?

You can attach any file type to a protected mail. Protection policies are applied only to a subset of the file formats mentioned in Supported file types. By default, Microsoft Purview Message Encryption encrypts the following Office files extensions:

- docx
- docm
- dotx
- dotm
- pptx
- pptm
- potx
- potm

- ppsx
- ppsm
- thmx
- xlsx
- xlsm
- xlsb
- xltx
- xltm
- xlam
- xps

Microsoft Purview Message Encryption doesn't support the 97-2003 versions of the following Office programs: Word (.doc), Excel (.xls), and PowerPoint (.ppt).

If enabled in Exchange Online, PDF encryption allows you to protect sensitive PDF documents attached to emails. When you send an email, the Office 365 service encrypts PDF file attachments for the newest versions of Outlook, including:

- Outlook (new) Desktop
- Outlook on the web
- Outlook for Mac
- Outlook for iOS
- Outlook for Android

To enable encryption for PDF attachments, using a work or school account that has the Information Rights Management role at a minimum in your tenant, run the following command in Exchange Online PowerShell:

PowerShell

```
Set-IRMConfiguration -EnablePdfEncryption $true
```

Protection is inherited from mail to unencrypted attachments only. If a file format is supported, such as a Word, Excel, or PowerPoint file, the file is always protected, even after the recipient downloads the attachment.

For example, say an attachment is protected by Do Not Forward. The original recipient downloads the file, creates a message to a new recipient, and attaches the file. When the new recipient receives the file, they can't open it.

Can I use mail flow rules to encrypt or decrypt meeting invites and their responses?

No, you must use sensitivity labels to apply or remove encryption for meeting invites and their responses. For more information, see Use sensitivity labels to protect calendar items, Teams meetings, and chat.

Are SharePoint or OneDrive attachments supported?

Not yet. SharePoint or OneDrive attachments aren't supported. You can encrypt a mail message, but not the cloud attachments.

What email clients support preview of encrypted attachments in protected emails?

When attachments are protected with a protected mail, you can preview documents directly using Outlook clients. Outlook supports preview of Office documents (docx, xlsx, pptx, doc, xls, ppt). Outlook on the web supports preview of Office documents (docx, xlsx, pptx) and PDF.

What email clients support revocation of protected emails?

Outlook on the web supports revocation of protected mail. See How to revoke an encrypted message that you sent for details.

Does the encrypted message portal support preview of encrypted attachments in protected emails?

The encrypted message portal supports preview of any encrypted attachment copies added to the encrypted mail. The support file types include Word, Excel, PowerPoint, and PDF files.

Can I automatically encrypt messages by setting up policies?

Yes. Use mail flow rules in Exchange Online to automatically encrypt a message based on certain conditions. For example, you can create policies that are based on recipient ID, recipient domain, or on the content in the body or subject of the message. See Define mail flow rules to encrypt email messages in Office 365.

Can I automatically remove encryption on incoming and outgoing mail?

Admins can set up a mail flow rule to remove encryption for outgoing mail. You can only set up a rule to remove encryption for incoming mail that originates from your Exchange Online organization.

Can I automatically remove encryption on journal mail?

For an Exchange Online mailbox, admins must enable journal decryption and set up an Exchange Online journaling rule to generate a decrypted copy of the mail into the journaling mailbox. The journaling rule takes any mail or attachment that has encryption and send the original plus a decrypted copy into the journaling mailbox. You can only set up a journaling rule that can decrypt mail or attachments when the encrypted item originates from your organization.
To enable Exchange Online journaling:

PowerShell

```
Set-IRMConfiguration -JournalReportDecryptionEnabled $true
```

Can I automatically encrypt messages by setting up policies in Data Loss Prevention (DLP) through the Microsoft Purview portal?

Yes! You can set up mail flow rules in Exchange Online or by using DLP in the Microsoft Purview portal.

Can I customize encrypted messages with my company branding?

Yes, for mail sent from an Exchange Online mailbox in your organization! For information on customizing email messages and the encrypted message portal, see Add your organization's brand to your encrypted messages.

On what types of recipients do the encrypted message portal activity logs work?

The encrypted message portal activity logs only capture events for external recipients by accessing the encrypted message portals. Any activities in email clients triggered by external recipients aren't recorded. For internal recipients, see the *MailItemsAccessed* mailbox-auditing action in Purview Audit (Premium) - Mail items accessed logs.

Are there any reporting capabilities or insights for encrypted emails?

There's an Encryption report in the Microsoft Purview portal. See Microsoft Purview Reports overview.

Can I use message encryption with compliance features such as eDiscovery?

Yes, most messages protected by Microsoft Purview Message Encryption are discoverable. Microsoft Purview Message Encryption protected mail that you receive from another Microsoft 365 organization that has custom branding applied through a mail flow rule is undiscoverable by your eDiscovery service. In other words, if the mail isn't accessible through the user's mailbox, but rather, surfaced only through a link to the encrypted message portal, the mail isn't searchable. See eDiscovery activities that support encrypted items for details.

Can I send as a shared mailbox and encrypt emails?

When an email message matches an encryption mail flow rule, Exchange encrypts the message sending it.

Can I open encrypted messages sent to a shared mailbox?

Yes! You can open encrypted messages for a shared mailbox. When the mail is sent from the same organization, you can open the mail when you're signed in to a supported Outlook client. If the mail is sent from an external organization, you need to use Outlook on the web.

- Users can open protected mails in a shared mailbox where the shared mailbox received a protected mail as part of a distribution group.
- Users can view attachments that inherit protection from email when they use Outlook for Windows, Outlook for Mac, Outlook for Android, Outlook for iOS, and Outlook on the web.

The following table lists the supported clients for shared mailboxes.

Expand table

Platform	Read mail	View email attachments
Outlook on the web	Yes	Yes
Outlook for Windows	Yes	Yes*
Outlook for Mac	Yes	Yes
Outlook for Android	Yes	Yes*
Outlook for iOS	Yes	Yes*

> **Note**
>
> Android and iOS use the Office mobile app to display encrypted attachments, and don't display attachments directly in Outlook mobile. Outlook for Windows can display encrypted

attachments when user is directly assigned to a shared mailbox. (See below on user assignment.)

There are currently two known limitations:

- You can't open attachments to emails that you receive on mobile devices by using Outlook mobile.
- There are two ways to allow a user to view the encrypted mail directly in Outlook for Windows:

    1. Directly assign a user to the shared mailbox, with full access permissions and automapping enabled. For Outlook 64-bit, users don't need to be directly assigned to the mailbox. Automapping is enabled by default for Exchange.
    2. Assign a mail-enabled security group to a shared mailbox. This method requires Outlook version 2402 and only supports mail generated after June 2024.

To assign a user to a shared mailbox

1. Connect to Exchange Online PowerShell.
2. Run the `Add-MailboxPermission` cmdlet with the `Automapping` parameter. This example gives Ayla full access permission to a support mailbox.

    PowerShell

    ```
    Add-MailboxPermission -Identity support@contoso.onmicrosoft.com -User
    ayla@contoso.com -AccessRights FullAccess -AutoMapping $true
    ```

To assign a mail enabled security group to the shared mailbox

To use this method, you must encrypt mail with the **Do Not Forward** or **Encrypt-only** protection options. Only mail initiated by the shared mailbox or mail sent within an organization can be opened.

1. Connect to Exchange Online PowerShell.
2. Run the `Add-MailboxPermission` cmdlet to assign the security group. The following example gives the Contoso front desk security group full access permission to a support mailbox.

    PowerShell

```
Add-MailboxPermission -Identity support@contoso.onmicrosoft.com -User
frontdesk@contoso.com -AccessRights FullAccess
```

Is delegated access supported with opening encrypted messages? Even if a delegate has full access to another user's mailbox?

When delegates are given full access permission to a user's mailbox, delegated access of encrypted mail is supported in Outlook on the web, Outlook for Mac, Outlook for iOS, and Outlook for Android. Outlook for Windows doesn't support delegated access.

How long do I have access to the mail in the encrypted message portal?

You can sign in to the encrypted message portal to retrieve mail as long as the sender's organization is active and the mail isn't configured to expire.

What do I do if I don't receive the one-time pass code after I requested it?

First, check the junk or spam folder in your email client. DKIM and DMARC settings for your organization might cause these emails to end up filtered as spam.

Next, check quarantine in the Microsoft Purview portal. Often, messages containing a one-time pass code, especially the first ones your organization receives, end up in quarantine.

How Exchange Online secures your email secrets

> *Microsoft Purview service description*

This article describes how Microsoft secures your email secrets in its data centers.

How we secure secret information provided by you

In addition to the Office 365 Trust Center that provides Security, Privacy, and Compliance Information for Office 365, we use a technology called Distributed Key Manager (DKM).

Distributed Key Manager (DKM) is a client-side technology that uses a set of secret keys to encrypt and decrypt information. Only members of a specific security group in Active Directory Domain Services can access those keys in order to decrypt the data that is encrypted by DKM. In Exchange Online, only certain service accounts under which the Exchange processes run are part of that security group. No human is given credentials that are part of this security group and therefore no human has access to the keys that can decrypt these secrets.

For debugging, troubleshooting, or auditing purposes, a data center administrator must request elevated access to gain temporary credentials that are part of the security group. This process requires multiple levels of legal approval. If access is granted, all activity is logged and audited. Access is only granted for a set interval of time after which it automatically expires.

For extra protection, DKM technology includes automated key rollover and archiving. Automated rollover and archiving ensure that you can continue to access your older content without having to rely on the same key indefinitely.

Where Exchange Online uses DKM

Microsoft uses Distributed Key Manager to encrypt your secrets in Exchange Online data centers. For example:

- Email account credentials for connected accounts. Connected accounts are third-party accounts such as Hotmail, Gmail, and Yahoo! mail accounts.

- Customer Key. If you're using Customer Key, you'll use Azure Key Vault to safeguard your secrets.

How Exchange Online uses TLS to secure email connections

Article • 11/27/2023

Learn how Exchange Online and Microsoft 365 use Transport Layer Security (TLS) and Forward Secrecy (FS) to secure email communications.

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the **Microsoft Purview trials hub**. Learn details about **signing up and trial terms**.

TLS basics for Microsoft 365 and Exchange Online

Transport Layer Security (TLS), and Secure Sockets Layer (SSL) that came before TLS, are cryptographic protocols. These protocols secure communication over a network by using security certificates to encrypt a connection between computers. TLS supersedes SSL and is often referred to as SSL 3.1. Exchange Online uses TLS to encrypt the connections between Exchange servers and the connections between Exchange servers and other servers. For example, TLS is used to encrypt the connection between Exchange Online and your on-premises Exchange servers or your recipients' mail servers. Once the connection is encrypted, all data sent through that connection is sent through the encrypted channel.

TLS doesn't encrypt the message, just the connection. So, if you forward a message that was sent through a TLS-encrypted connection to a recipient organization that doesn't support TLS encryption, that message isn't necessarily encrypted.

If you want to encrypt the message, use an encryption technology that encrypts the message contents. For example, you can use Microsoft Purview Message Encryption or S/MIME. See Email encryption in Office 365 and Message encryption for information on message encryption in Office 365.

Use TLS in situations where you want to set up a secure channel of correspondence between Microsoft and your on-premises organization or another organization, such as a partner. Exchange Online always attempts to use TLS first to secure your email but

can't if the other party doesn't offer TLS security. Keep reading to find out how you can secure all mail to your on-premises servers or important partners by using *connectors*.

To provide the best-in-class encryption to our customers, Microsoft deprecated Transport Layer Security (TLS) versions 1.0 and 1.1 in Office 365 and Office 365 GCC. However, you can continue to use an unencrypted SMTP connection without any TLS. We don't recommend email transmission without any encryption.

How Exchange Online uses TLS between Exchange Online customers

Exchange Online servers always encrypt connections to other Exchange Online servers in our data centers with TLS 1.2. When you send a message to a recipient that is within your organization, Exchange Online automatically sends the message over an encrypted connection using TLS. Exchange Online also sends email that you send to other customers over encrypted connections using TLS that are secured using Forward Secrecy.

How Microsoft 365 uses TLS between Microsoft 365 and external, trusted partners

By default, Exchange Online always uses *opportunistic TLS*. Opportunistic TLS means Exchange Online always tries to encrypt connections with the most secure version of TLS first, then works its way down the list of TLS ciphers until it finds one on which both parties can agree. Unless you configure Exchange Online to ensure that messages to that recipient must use a secure connection, then by default Exchange sends the message without encryption if the recipient's organization doesn't support TLS encryption. Opportunistic TLS is sufficient for most businesses. However, for businesses that have compliance requirements such as medical, banking, or government organizations, you can configure Exchange Online to require, or force, TLS. For instructions, see Configure mail flow using connectors in Office 365.

If you decide to configure TLS between your organization and a trusted partner organization, Exchange Online can use *forced TLS* to create trusted channels of communication. Forced TLS requires your partner organization to authenticate to Exchange Online with a security certificate to send mail to you. Your partner needs to manage their own certificates. Exchange Online uses connectors to protect messages that you send from unauthorized access before they arrive at the recipient's email provider. For information on using connectors to configure mail flow, see Configure mail flow using connectors in Office 365.

TLS and hybrid Exchange Server deployments

If you're managing a hybrid Exchange deployment, your on-premises Exchange server needs to authenticate to Microsoft 365 using a security certificate to send mail to recipients whose mailboxes are only in Office 365. As a result, you need to manage your own security certificates for your on-premises Exchange servers. You must also securely store and maintain these server certificates. For more information about managing certificates in hybrid deployments, see Certificate requirements for hybrid deployments.

How to set up forced TLS for Exchange Online in Office 365

For Exchange Online customers, in order for forced TLS to work to secure all of your sent and received email, you need to set up more than one connector that requires TLS. You need one connector for messages sent to user mailboxes and another connector for messages sent from user mailboxes. Create these connectors in the Exchange admin center in Office 365. For instructions, see Configure mail flow using connectors in Office 365.

TLS certificate information for Exchange Online

The certificate information used by Exchange Online is described in the following table. If your business partner is setting up forced TLS on their email server, you need to provide this information to them. For security reasons, our certificates do change from time to time. The current certificate is valid from September 24, 2020.

Current certificate information valid from September 24, 2020

Expand table

What is Microsoft 365 service encryption?

09/26/2025

In addition to using volume-level encryption, Exchange Online, Microsoft Teams, SharePoint Online, OneDrive for Business, and Windows 365 Cloud PCs also use service encryption to encrypt customer data.

Service encryption allows for two key management options, Microsoft-managed keys and customer-managed keys.

Service encryption provides multiple benefits:

- Provides a layer of protection for all Microsoft 365 services and Windows 365 Cloud PCs. For Microsoft 365 services, service encryption is an extra layer of protection is on top of BitLocker.
- Provides separation of Windows operating system administrators from access to application data stored or processed by the operating system.
- Includes a Customer Key option that enables multitenant services to provide per-tenant key management.
- Enhances the ability of Microsoft 365 and Windows 365 to meet your specific compliance requirements regarding encryption.

What are Microsoft-managed keys?

By default, Microsoft manages all cryptographic keys including the root keys for service encryption. This option, called *Microsoft-managed keys*, is enabled by default for Exchange Online, SharePoint Online, OneDrive for Business, and Windows 365 Cloud PCs. Microsoft-managed keys provide default service encryption unless you decide to onboard using Customer Key. If, at a later date, you decide to stop using Customer Key without following the data purge path, then your data stays encrypted using the Microsoft-managed keys. Your data is always encrypted at this default level at a minimum.

What is Customer Key?

Customer Key is a customer-managed key solution. With Customer Key, you supply root keys used with service encryption and you manage these keys using Azure Key Vault while Microsoft manages all other keys. Customer Key is available for Exchange, SharePoint and OneDrive for Business, and Windows 365 Cloud PCs (Enterprise and Frontline modes).

Windows 365 support for Microsoft Purview Customer Key is generally available, including Windows 365 Frontline (Dedicated and Shared).

Using Customer Key, you generate your own cryptographic keys. You can use an on-premises Hardware Service Module (HSM) or Azure Key Vault (AKV) to generate your keys. AKV lets you control and manage the cryptographic keys used by Microsoft 365. Customer Key uses the keys stored in the AKV as the root of one of the key chains that encrypts your mailbox data or files.

Customer Key provides you with more control over how Microsoft processes your data. For example, You can use Customer Key as a technical control if you want to terminate service with Microsoft or remove a portion of your data stored in the cloud. Removing data ensures no one, including Microsoft, can access or process the data. Customer Key is in addition and complementary to Customer Lockbox that you use to control access to your data by Microsoft personnel.

To learn how to set up Customer Key for Exchange Online, Microsoft Teams, SharePoint Online, including Team Sites, and OneDrive for Business, see these articles:

- Overview of Customer Key
- Set up Customer Key
- Manage Customer Key
- Roll or rotate a Customer Key or an availability key
- Understand the availability key

BitLocker and Distributed Key Manager (DKM) for Encryption

Article • 09/08/2023

Microsoft servers use BitLocker to encrypt the disk drives containing customer data at rest at the volume-level. BitLocker encryption is a data protection feature that is built into Windows. BitLocker is one of the technologies used to safeguard against threats in case there are lapses in other processes or controls (e.g., access control or recycling of hardware) that could lead to someone gaining physical access to disks containing customer data. In this case, BitLocker eliminates the potential for data theft or exposure because of lost, stolen, or inappropriately decommissioned computers and disks.

BitLocker is deployed with Advanced Encryption Standard (AES) 256-bit encryption on disks containing customer data in Exchange Online, SharePoint Online, and Skype for Business. Disk sectors are encrypted with a Full Volume Encryption Key (FVEK), which is encrypted with the Volume Master Key (VMK), which in turn is bound to the Trusted Platform Module (TPM) in the server. The VMK directly protects the FVEK and therefore, protecting the VMK becomes critical. The following figure illustrates an example of the BitLocker key protection chain for a given server (in this case, using an Exchange Online server).

The following table describes the BitLocker key protection chain for a given server (in this case, an Exchange Online server).

Expand table

KEY PROTECTOR	GRANULARITY	HOW GENERATED?	WHERE IS IT STORED?	PROTECTION
AES 256-bit External Key	Per Server	BitLocker APIs	TPM or Secret Safe	Lockbox / Access Control
			Mailbox Server Registry	TPM encrypted
48-digit Numerical Password	Per Disk	BitLocker APIs	Active Directory	Lockbox / Access Control

KEY PROTECTOR	GRANULARITY	HOW GENERATED?	WHERE IS IT STORED?	PROTECTION
X.509 Certificate as Data Recovery Agent (DRA) also called Public Key Protector	Environment (for example, Exchange Online multitenant)	Microsoft CA	Build System	No one user has the full password to the private key. The password is under physical protection.

BitLocker key management involves the management of recovery keys that are used to unlock/recover encrypted disks in a Microsoft data center. Microsoft 365 stores the master keys in a secured share, only accessible by individuals who have been screened and approved. The credentials for the keys are stored in a secured repository for access control data (what we call a "secret store"), which requires a high level of elevation and management approvals to access using a just-in-time access elevation tool.

BitLocker supports keys which fall into two management categories:

- BitLocker-managed keys, which are short-lived and tied to the lifetime of an operating system instance installed on a server or to a given disk. These keys are deleted and reset during server reinstallation or disk formatting.
- BitLocker recovery keys, which are managed outside of BitLocker but used for disk decryption. BitLocker uses recovery keys for the scenario in which an operating system is reinstalled, and encrypted data disks already exist. Recovery keys are also used by Managed Availability monitoring probes in Exchange Online where a responder may need to unlock a disk.

BitLocker-protected volumes are encrypted with a full volume encryption key, which in turn is encrypted with a volume master key. BitLocker uses FIPS-compliant algorithms to ensure that encryption keys are never stored or sent over the wire in the clear. The Microsoft 365 implementation of customer data-at-rest-protection doesn't deviate from the default BitLocker implementation.

Overview of Service encryption with Microsoft Purview Customer Key

Microsoft 365 provides baseline, volume-level encryption through BitLocker and Distributed Key Manager (DKM). Windows 365 Enterprise and Business Cloud PC disks are encrypted using Azure Storage server-side encryption (SSE).

To give you more control, Microsoft 365 also offers an added layer of encryption for your content through Customer Key. This content includes data from Microsoft Exchange, SharePoint, OneDrive, Teams, and Windows 365 Cloud PCs (Enterprise), including Windows 365 Frontline Dedicated and Shared modes.

BitLocker isn't supported as an encryption option for Windows 365 Cloud PCs. For details, see Using Windows 10 virtual machines in Intune.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

How service encryption, BitLocker, SSE, and Customer Key work together

Your Microsoft 365 data is always encrypted at rest using BitLocker and Distributed Key Manager (DKM). For details, see How Exchange secures your email secrets.

Customer Key adds extra protection against unauthorized access to your data. It complements BitLocker disk encryption and server-side encryption (SSE) in Microsoft data centers. Customer Key helps you meet compliance or regulatory requirements by letting you control the root encryption keys at the application level.

You explicitly authorize Microsoft 365 to use your encryption keys to deliver value-added services like eDiscovery, anti-malware, anti-spam, and search indexing. Microsoft 365 uses these keys to encrypt your data at rest, as described in the Online Services Terms (OST).

Customer Key with hybrid deployments

Customer Key encrypts only data at rest in the cloud. It doesn't protect on-premises mailboxes or files. To protect on-premises data, use a separate method like BitLocker.

Learn about data encryption policies

A data encryption policy (DEP) defines the encryption hierarchy. Services use this hierarchy to encrypt data with both the keys you manage and the availability key that Microsoft protects. You create a DEP using PowerShell cmdlets, then assign it to encrypt application data.

Customer Key supports three types of DEPs. Each type uses different cmdlets and protects a different kind of data:

DEP for Multiple Microsoft 365 workloads

These DEPs encrypt data across several Microsoft 365 workloads for all users in the tenant:

- **Windows 365 Cloud PCs** (Enterprise), including Frontline Dedicated and Shared modes (details)
- **Teams**: Chat messages, media messages, calls/meeting recordings (in Teams storage), notifications, Cortana suggestions, status messages
- **Microsoft 365 Copilot** interactions
- **Exchange**: User/signal information and mailboxes not covered by a mailbox DEP
- **Microsoft Purview Information Protection**: EDM data (schemas, rule packages, salts), sensitivity label configurations

> ⓘ **Note**
>
> For EDM and Teams, the DEP encrypts new data from assignment. For Exchange, it encrypts all existing and new data.

Not encrypted by multi-workload DEPs (protected by other methods):

- SharePoint and OneDrive data (use SharePoint DEP)
- Teams files and recordings saved in SharePoint/OneDrive
- Teams Live Events, Viva Engage, Planner

You can create multiple DEPs per tenant but assign only one at a time. Encryption begins automatically after assignment.

DEPs for Exchange mailboxes

Mailbox DEPs give you more control over individual Exchange Online mailboxes. You can use them to encrypt data in UserMailbox, MailUser, Group, PublicFolder, and Shared mailboxes.

You can have up to 50 active mailbox DEPs per tenant. You can assign one DEP to multiple mailboxes, but only one DEP per mailbox.

By default, Exchange mailboxes are encrypted using Microsoft-managed keys. When you assign a Customer Key DEP, the service rewraps existing encrypted mailboxes on next access. Unencrypted mailboxes are marked for a move, with encryption occurring after the move completes. For details on move priorities, see Move requests in the Microsoft 365 service.

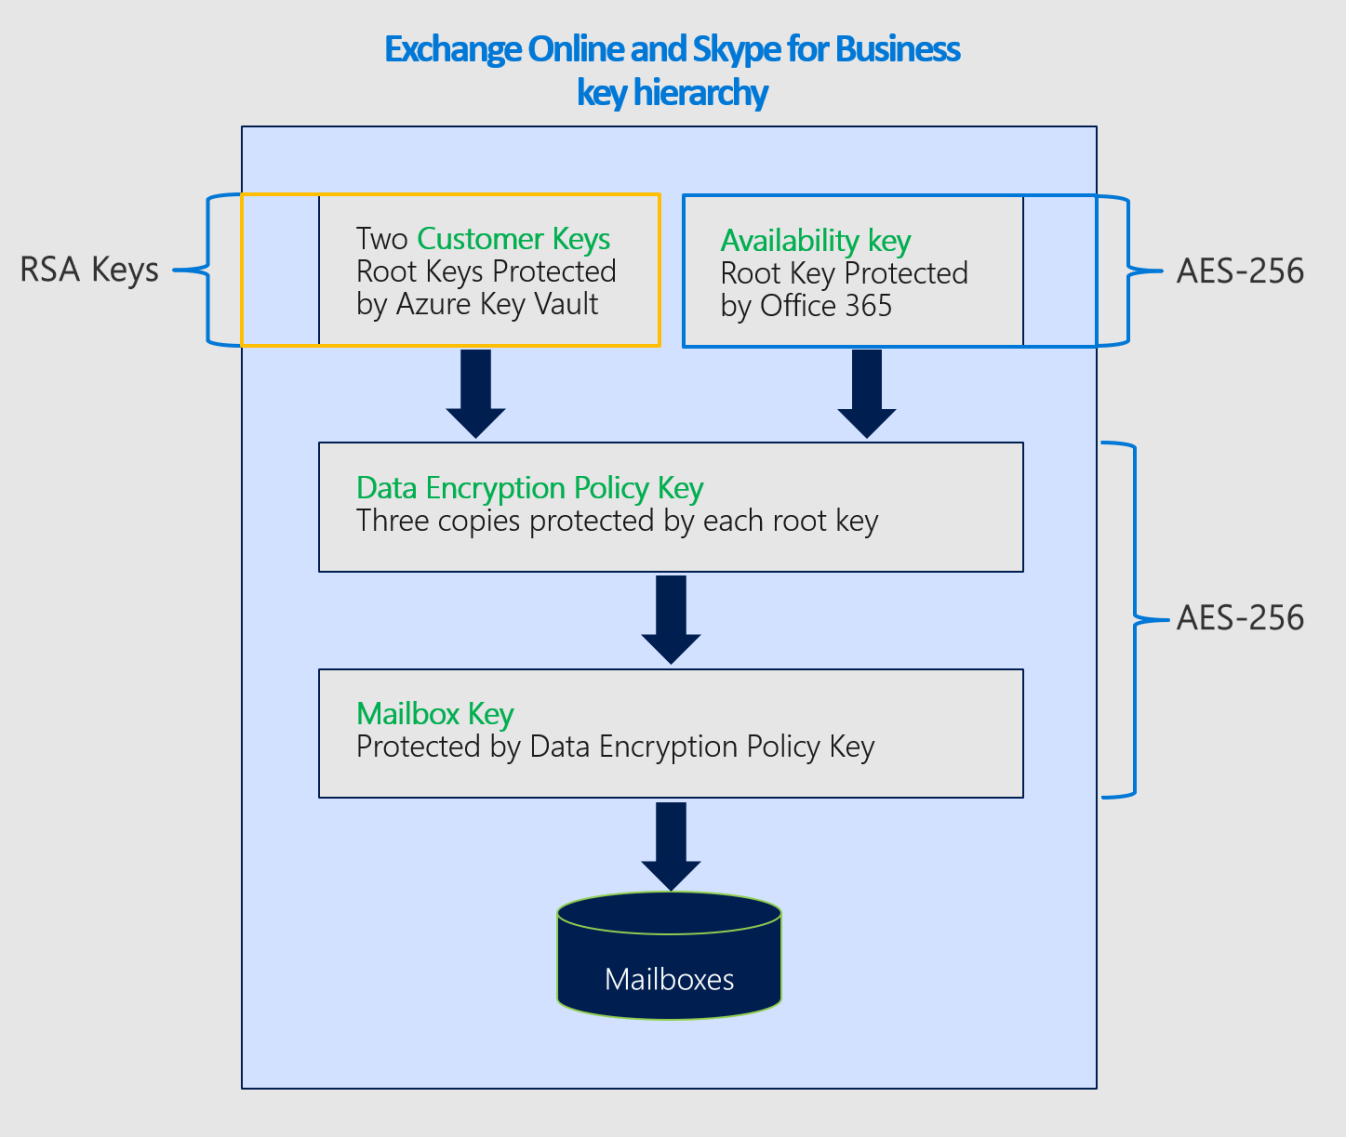
You can later refresh the DEP or assign a different one as described in Manage Customer Key for Office 365.

Each mailbox must meet licensing requirements to use Customer Key. For more info, see Prerequisites.

You can assign DEPs to shared, public folder, and group mailboxes as long as your tenant meets the licensing requirements for user mailboxes. You don't need separate licenses for non-user-specific mailboxes.

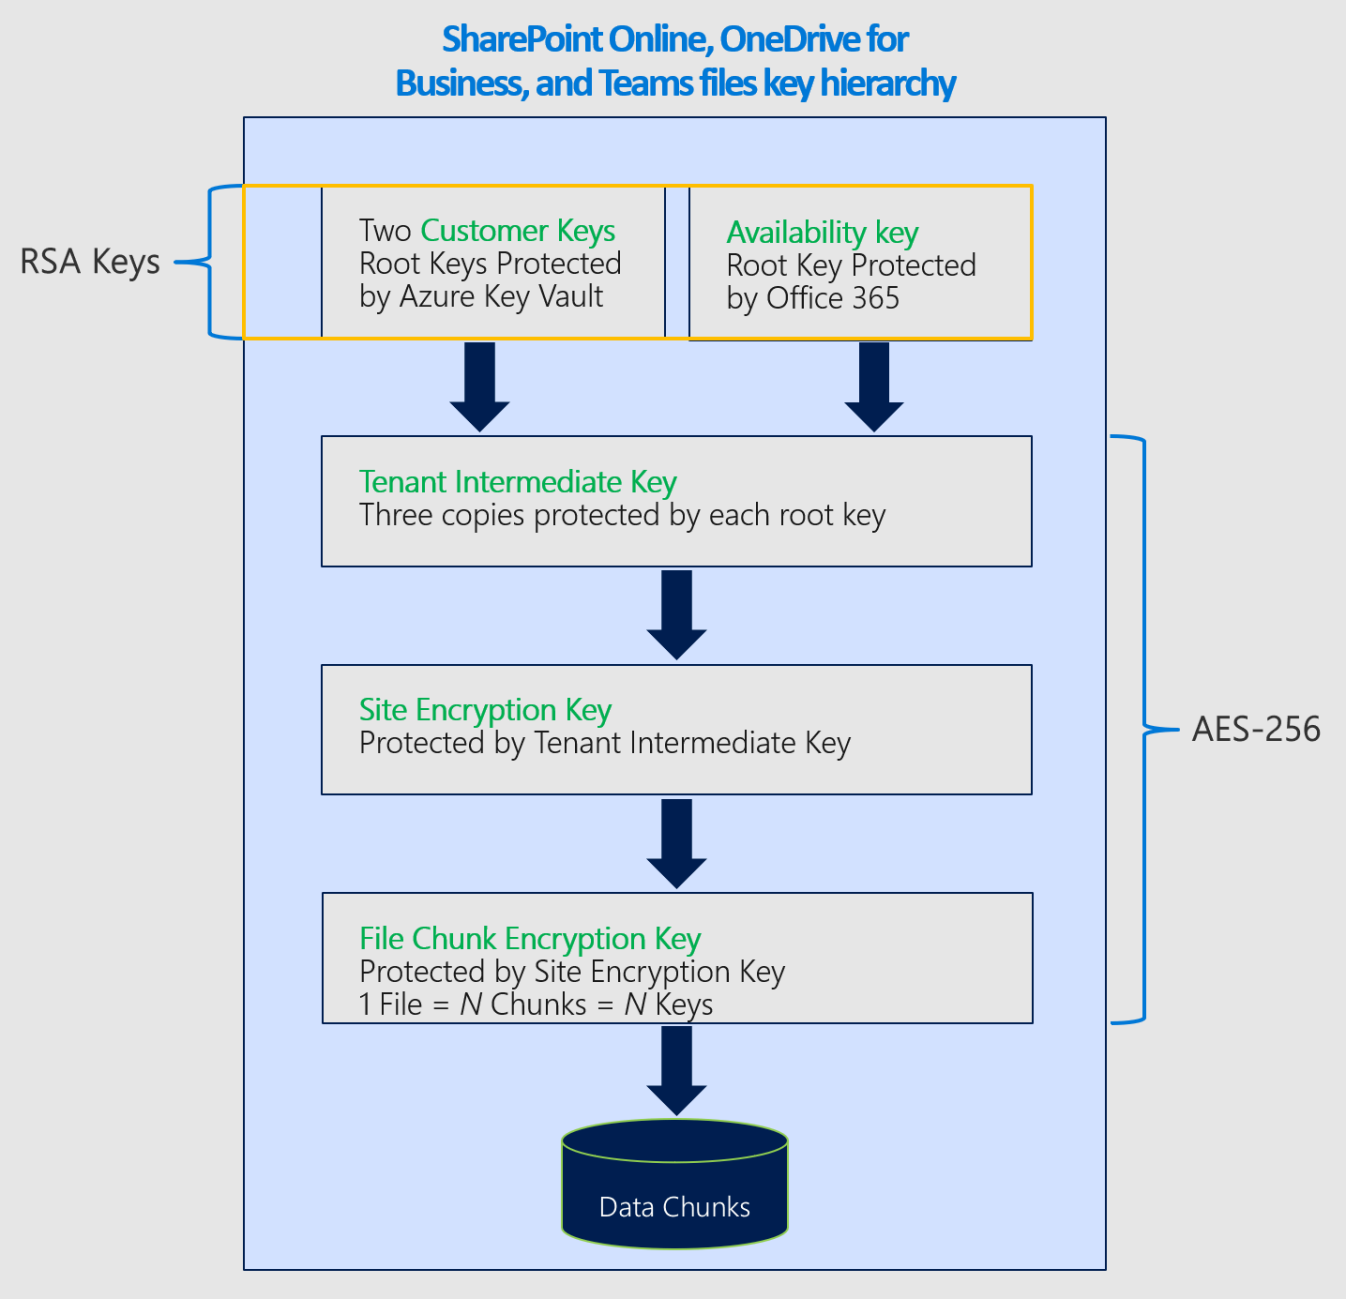
You can also request that Microsoft purge specific DEPs when leaving the service. Revoking access to your keys triggers deletion of the availability key, resulting in cryptographic deletion of your data. For details, see Revoke your keys and start the data purge path process.

DEP for SharePoint and OneDrive



This DEP encrypts content stored in SharePoint and OneDrive, including Teams files stored in SharePoint. Multi-geo tenants can create one DEP per geo; single-geo tenants can create one DEP. For setup instructions, see Set up Customer Key.

Encryption ciphers used by Customer Key



Customer Key uses different encryption ciphers to protect keys, as shown in the following diagrams.

The key hierarchy used for DEPs that encrypt data across multiple Microsoft 365 workloads is similar to the one used for individual Exchange mailboxes. The corresponding Microsoft 365 Workload Key replaces the Mailbox Key.

Encryption ciphers used to encrypt keys for Exchange

Encryption ciphers used to encrypt keys for SharePoint and OneDrive

Set up Customer Key

Customer Key lets you control your organization's encryption keys and configure Microsoft 365 to use those keys to encrypt your data at rest in Microsoft's datacenters.

This article walks you through creating and configuring the required Azure resources, then enabling Customer Key. After setup, you assign policies that determine which keys encrypt data across Microsoft 365 workloads.

For a general overview and more information, see Overview of Customer Key.

> ⓘ **Important**
>
> Be sure to follow the best practices in this article marked as **TIP**, **IMPORTANT**, and **NOTE**. Customer Key gives you control over root encryption keys that can affect your entire organization. Mistakes with these keys can lead to service interruptions or permanent data loss.

Prerequisites

Before setting up Customer Key, ensure you have:

- **Licensing**: One of the following:
  - Office 365 E5
  - Microsoft 365 E5
  - Microsoft Purview Suite (formerly Microsoft 365 E5 Compliance)
  - Microsoft 365 E5 Information Protection & Governance
  - Microsoft 365 Security and Compliance for FLW
  - Existing Office 365 Advanced Compliance licenses are also supported
- **Azure subscriptions**: Two paid Azure subscriptions (Free, Trial, Sponsorship, MSDN, or Legacy Support aren't eligible)
- **Permissions**: Exchange admin permissions (all Customer Key operations run through Exchange Online PowerShell)
- **PowerShell modules**:
  - Azure PowerShell (v4.4.0 or higher recommended) for Key Vault/HSM operations
  - Exchange Online PowerShell for DEP operations
- **Azure knowledge**: Familiarity with Azure Key Vault and Microsoft Entra tenant concepts

> ⓘ **Important**

Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview **roles and permissions**.

If you need help beyond the documentation, contact Microsoft Support. To share feedback or suggestions about Customer Key or this documentation, visit the Microsoft 365 Community.

Overview of steps to set up Customer Key

To set up Customer Key, complete the following tasks in order. The rest of this article provides detailed instructions for each task, or links out to more information for each step in the process.

> **Important**
>
> The setup process differs depending on whether you're using **Azure Key Vault** or **Managed HSM**. The shared prerequisites appear first, followed by configuration-specific instructions.

Prerequisites for all configurations

- Create two new Azure subscriptions
- Register the required Service Principals

Configuration-specific setup

- Set up using Azure Key Vault
- Set up using Managed HSM

Onboarding options

Choose the onboarding method that applies to your scenario:

- Onboard using the Customer Key Onboarding Service (recommended for most tenants)
- Onboard to Customer Key for SharePoint and OneDrive
- Onboard to Customer Key for special cloud environments

Quick reference: Key setup commands

Use the following tables to quickly find the commands you need during setup.

Service principal registration

Expand table

Task	Command
Check if Customer Key Onboarding app is registered	`Get-AzADServicePrincipal -ServicePrincipalName 19f7f505-34aa-44a4-9dcc-6a768854d2ea`
Register Customer Key Onboarding app	`New-AzADServicePrincipal -ApplicationId 19f7f505-34aa-44a4-9dcc-6a768854d2ea`
Check if M365DataAtRestEncryption app is registered	`Get-AzADServicePrincipal -ServicePrincipalName c066d759-24ae-40e7-a56f-027002b5d3e4`
Register M365DataAtRestEncryption app	`New-AzADServicePrincipal -ApplicationId c066d759-24ae-40e7-a56f-027002b5d3e4`
Check if Exchange Online app is registered	`Get-AzADServicePrincipal -ServicePrincipalName 00000002-0000-0ff1-ce00-000000000000`
Register Exchange Online app	`New-AzADServicePrincipal -ApplicationId 00000002-0000-0ff1-ce00-000000000000`

Azure Key Vault operations

Expand table

Task	Command
Create a key	`Add-AzKeyVaultKey -VaultName <VaultName> -Name <KeyName> -Destination HSM`
Get key URI	`(Get-AzKeyVaultKey -VaultName <VaultName>).Id`
Check key expiration	`Get-AzKeyVaultKey -VaultName <VaultName>`
Update key expiration	`Update-AzKeyVaultKey -VaultName <VaultName> -Name <KeyName> -Expires (Get-Date -Date "12/31/9999")`
Back up a key	`Backup-AzKeyVaultKey -VaultName <VaultName> -Name <KeyName> -OutputFile <BackupFile>`

Managed HSM operations

Expand table

Task	Command
Create a key	`Add-AzKeyVaultKey -HsmName <HSMName> -Name <KeyName> -Destination HSM`
Get key URI	`(Get-AzKeyVaultKey -HsmName <HSMName>).Id`
Check key expiration	`Get-AzKeyVaultKey -HsmName <HSMName>`
Update key expiration	`Update-AzKeyVaultKey -HsmName <HSMName> -Name <KeyName> -Expires (Get-Date -Date "12/31/9999")`
Back up a key	`Backup-AzKeyVaultKey -HsmName <HSMName> -Name <KeyName> -OutputFile <BackupFile>`

Customer Key onboarding

Expand table

Task	Command
Install onboarding module	`Install-Module -Name M365CustomerKeyOnboarding`
Create onboarding request	`New-CustomerKeyOnboardingRequest -Organization <TenantID> -Scenario <MDEP|EXO> -Subscription1 <SubID1> -KeyIdentifier1 <KeyURI1> -Subscription2 <SubID2> -KeyIdentifier2 <KeyURI2> -OnboardingMode <Validate|Enable>`
View onboarding requests	`Get-CustomerKeyOnboardingRequest -OrganizationID <TenantID>`
View failed validations	`$request.FailedValidations`
View passed validations	`$request.PassedValidations`

Create two new Azure subscriptions

Customer Key requires two Azure subscriptions. As a best practice, Microsoft recommends creating new Azure subscriptions specifically for use with Customer Key.

Azure Key Vault keys can only be authorized for applications in the same Microsoft Entra tenant. To assign data encryption policies (DEPs), make sure to create both subscriptions under the same Microsoft Entra tenant used by your organization. For example, use your work or school account that has proper administrator privileges in your organization. For step-by-step guidance, see Sign up for Azure as an organization.

> **Important**
>
> Customer Key requires two keys for each DEP. To support this requirement, you must create two separate Azure subscriptions. As a best practice, have different members of your organization manage one key in each subscription. These subscriptions should be used only to administer encryption keys for Microsoft 365. This configuration helps protect your organization in case someone accidentally, intentionally, or maliciously deletes or mismanages a key they control.

Following these best practices reduces the risk of human error and simplifies Customer Key management.

Register the required Service Principals

To use the Customer Key, your tenant must have the required service principals registered. The following sections show you how to check whether the service principals are already registered in your tenant. If they aren't, run the *'New-AzADServicePrincipal'* cmdlet.

Register the Service Principal for the Customer Key Onboarding Application

To check if the Customer Key Onboarding application is already registered with the correct permissions, run the following command:

PowerShell

```
Get-AzADServicePrincipal -ServicePrincipalName 19f7f505-34aa-44a4-9dcc-6a768854d2ea
```

If it isn't registered, run:

PowerShell

```
New-AzADServicePrincipal -ApplicationId 19f7f505-34aa-44a4-9dcc-6a768854d2ea
```

Register the Service Principal for the M365DataAtRestEncryption Application

To check if the M365DataAtRestEncryption application is already registered with the correct permissions, run the following command:

```
PowerShell
Get-AzADServicePrincipal -ServicePrincipalName c066d759-24ae-40e7-a56f-027002b5d3e4
```

If it isn't registered, run:

```
PowerShell
New-AzADServicePrincipal -ApplicationId c066d759-24ae-40e7-a56f-027002b5d3e4
```

Register the Service Principal for the Office 365 Exchange Online Application

To check if the Office 365 Exchange Online application is already registered with the correct permissions, run the following command:

```
PowerShell
Get-AzADServicePrincipal -ServicePrincipalName 00000002-0000-0ff1-ce00-000000000000
```

If it isn't registered, run:

```
PowerShell
New-AzADServicePrincipal -ApplicationId 00000002-0000-0ff1-ce00-000000000000
```

Configuration-specific setup steps

> **Important**
>
> The following steps differ depending on whether you're using **Azure Key Vault** or **Managed HSM**. Use the tabs below to select your configuration.

Azure Key Vault

Create a premium Azure Key Vault in each subscription

Prior to creating a key vault, perform the steps in Getting Started with Azure Key Vault. These steps guide you through installing and launching Azure PowerShell, and connecting to your subscription. Next, create a resource group and a key vault.

> **Important**
>
> When creating your key vaults, you **must** enable both **soft delete** and **purge protection** during the initial vault creation process. Customer Key requires all vaults to have both features enabled with a retention period of **90** days. These settings can't be disabled once enabled, so it's critical to configure them correctly from the start. If you plan to enable firewall on your key vaults, ensure you select the option for **Allow Trusted Microsoft Services**.

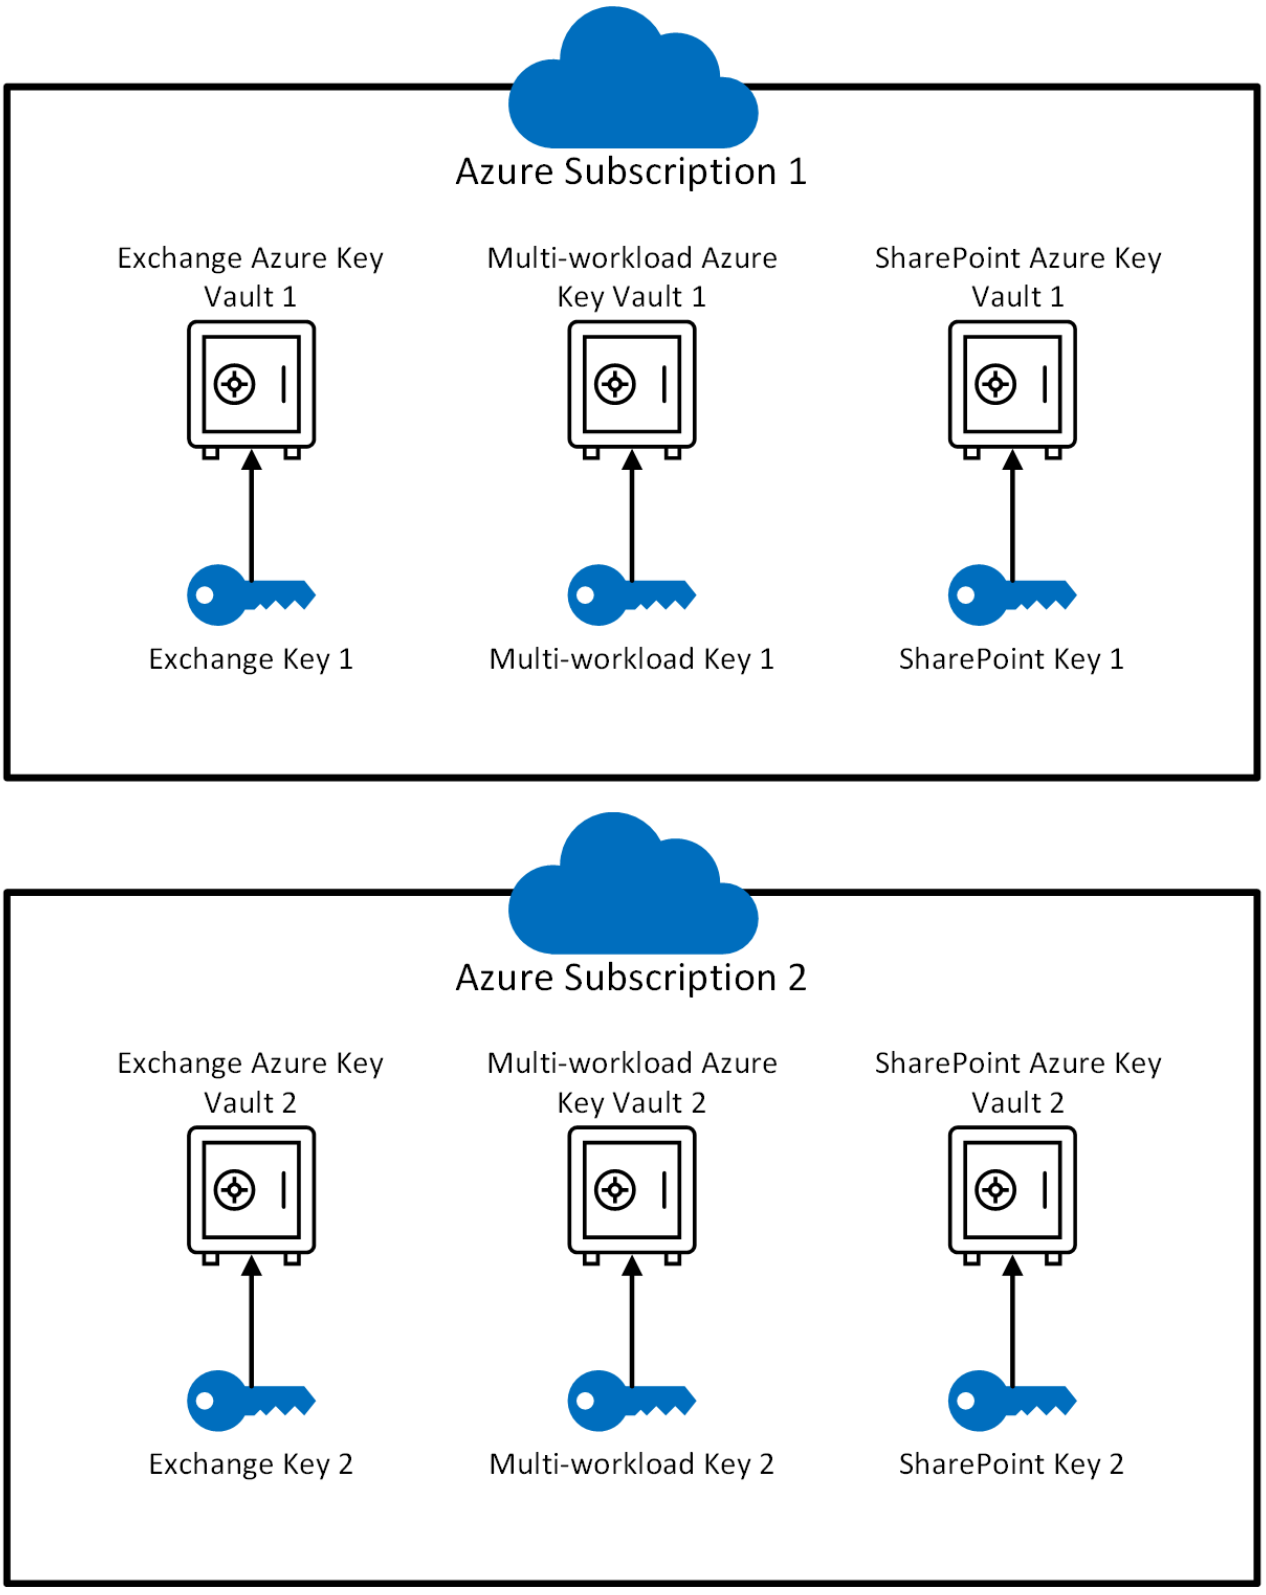
When you create a key vault, you must choose an SKU: either Standard or Premium. The Standard SKU uses software-protected keys without a Hardware Security Module (HSM), while the premium SKU allows the use of HSMs to protect keys. Customer Key supports key vaults with either of the two SKUs, but Microsoft strongly recommends using the Premium SKU. The cost of operations is the same for both; so, the only price difference comes from the monthly cost of each HSM-protected key. For pricing details, see Key Vault pricing.

> **Important**
>
> Use the Premium SKU key vaults and HSM-protected keys for production data. Use Standard SKU key vaults and keys only for testing and validation.

Enabling soft delete and purge protection

Soft delete allows you to recover deleted keys or vaults within 90 days. Purge protection prevents permanent deletion until the retention period passes. Customer Key requires both features with a **90-day** retention period. Soft delete is enabled by default for new vaults; enable it manually for existing vaults.

To enable these features, see Azure Key Vault recovery management with soft delete and purge protection.



For each Microsoft 365 workload for which you use Customer Key, create a key vault in each of the two Azure subscriptions you set up earlier.

Key Vault configuration

For example, if you're using Customer Key for Multiple Workloads, Exchange and SharePoint scenarios, you need **three pairs** of key vaults, for a total of **six**. Use a clear naming convention that reflects the intended use of the DEP with which you associate the vaults. The following table shows how to map each Azure Key Vault to each workload.

Expand table

Key Vault Name	Permissions for Multiple Microsoft 365 Workloads (M365DataAtRestEncryption)	Permissions for Exchange	Permissions for SharePoint and OneDrive
ContosoM365AKV01	**Yes**	No	No
ContosoM365AKV02	**Yes**	No	No
ContosoEXOAKV01	No	**Yes**	No
ContosoEXOAKV02	No	**Yes**	No
ContosoSPOAKV01	No	No	**Yes**
ContosoSPOAKV02	No	No	**Yes**

Creating key vaults also requires setting up Azure resource groups. Key vaults require a small amount of storage, and logging (if enabled) also stores data. As a best practice, Microsoft recommends assigning different administrators to manage each resource group. These roles should align with the admins responsible for managing the associated Customer Key resources.

For Exchange, a DEP is scoped at the mailbox level. Each mailbox can have only one policy assigned, and you can create up to 50 policies. A SharePoint policy covers all data in an

organization's geographic location (or geo), while a multi-workload policy covers supported workloads across all users in the organization.

> **ⓘ Important**
>
> If you're using Customer Key for Multiple Workloads, Exchange, and SharePoint and OneDrive, make sure to create two Azure Key Vaults for each workload. This means you need a total of six key vaults.

Assign permissions to each Azure Key Vault

Assign the required permissions to each key vault using Azure role-based access control (Azure RBAC) in the Azure portal. This section explains how to apply the correct permissions using RBAC.

Assigning permissions using RBAC method

To assign (`wrapKey`, `unwrapKey`, and `get`) on your **Azure Key Vault**, assign the **Key Vault Crypto Service Encryption User** role to the appropriate Microsoft 365 app. See Grant permission to applications to access an Azure Key Vault using Azure RBAC.

When assigning the role, search for the following app names in your tenant:

- **Multiple Workloads**: `M365DataAtRestEncryption`
- **Exchange**: `Office 365 Exchange Online`
- **SharePoint and OneDrive**: `Office 365 SharePoint Online`

If you don't see the app you're looking for, make sure you register the app in the tenant.

For more information about assigning roles and permissions, see Use role-based access control to manage access to your Azure subscription resources.

Assigning user roles

Customer Key requires both **Key Vault Administrators** (for daily key management tasks) and **Key Vault Contributors** (for permission and role assignment). By design, Administrators can't delete keys to prevent data loss.

For detailed steps, see Azure built-in roles for Key Vault data plane operations.

Add a key to each Key Vault either by creating or importing a key

There are two ways to add keys to an Azure Key Vault: you can create a key directly in the vault or import an existing key. Creating a key in Azure is simpler, but importing a key gives you full control over how the key is generated. Use RSA keys. Customer Key supports RSA key lengths up to 4,096 bits. Azure Key Vault doesn't support wrapping and unwrapping with elliptical curve (EC) keys.

To add a key to each vault, see Add-AzKeyVaultKey.

If you prefer to generate a key on-premises and then import it into Azure, perform the steps in How to generate and transfer HSM-protected keys for Azure Key Vault. Use the Azure instructions to add a key to each Key Vault.

Verify expiration date of your keys

To check that your keys don't have an expiration date, run the Get-AzKeyVaultKey cmdlet.

For Azure Key Vault:

PowerShell

```
Get-AzKeyVaultKey -VaultName <vault name>
```

Customer Key can't use expired keys. Any operation using an expired key fails and can cause service outages.

Once set, an expiration date can't be removed, but you can change it. If you must use a key with an expiration date, update it to `12/31/9999` and use the legacy onboarding method.

> **⊗ Caution**
>
> Don't set expiration dates on encryption keys used with Customer Key. The Customer Key Onboarding Service only accepts keys without an expiration date.

To change the expiration date, use the Update-AzKeyVaultKey cmdlet:

PowerShell

```
Update-AzKeyVaultKey -VaultName <vault name> -Name <key name> -Expires (Get-Date
-Date "12/31/9999")
```

Back up Azure Key Vault Key

After you create or modify a key, make sure to immediately back it up. Store backup copies in both online and offline locations to help prevent data loss.

To back up a key in Azure Key Vault, use the Backup-AzKeyVaultKey cmdlet.

> **Important**
>
> If a key is deleted without a backup, it can't be recovered. Always create a backup after any key change or creation.

Obtain the URI for each Azure Key Vault key

After you set up your Key Vaults and add your keys, run the following command to get the URI for each key. You need these URIs when creating and assigning DEPs; so, be sure to save them somewhere secure.

Run the following command in Azure PowerShell—once for each Key Vault:

PowerShell

```
(Get-AzKeyVaultKey -VaultName <vault name>).Id
```

Onboard using the Customer Key Onboarding Service

The Microsoft 365 Customer Key Onboarding Service allows you to enable Customer Key in your tenant. This service automatically validates the required Customer Key resources. If you'd prefer, you can validate your resources separately before proceeding with enablement.

> **Important**
>
> This service isn't currently available for the following scenarios:
>
> - **Special clouds tenant**: See Onboard to Customer Key for special cloud environments.
> - **SharePoint and OneDrive**: See Onboard to Customer Key for SharePoint and OneDrive.

The account used for onboarding **must** have the following permissions:

1. Service principal registration permissions: To register the required service principals.
2. Reader role: On each Azure Key Vault used in the onboarding cmdlet.

Install the `M365CustomerKeyOnboarding` PowerShell module

1. Sign in to your Azure subscription with Azure PowerShell. For guidance, see Sign in with Azure PowerShell.

2. Install the **latest version** of the `M365CustomerKeyOnboarding` module from the PowerShell Gallery.

- To confirm you're using the latest version, check the **Version History** tab at the bottom of the module page.
- Copy and paste the install command into your session and run it.
- If you're prompted, select **Yes to All** to continue.

Using the two different onboarding modes

There are two different onboarding modes available when using the Customer Key Onboarding Service: **Validate**, and **Enable**. Each mode serves a different purpose in the onboarding process.

When running the cmdlet (as guided in Create an Onboarding request), specify the mode using the `-OnboardingMode` parameter.

Validate

Use the `Validate` mode to confirm that your Customer Key resource configuration is correct. This mode doesn't make any changes to your environment.

> **Important**
>
> You can run this mode as many times as needed, especially after making changes to your configuration.

Enable

Use the `Enable` mode when you're ready to onboard your tenant to Customer Key. This mode enables Customer Key for the workload you specify using the `-Scenario` parameter.

If you want to enable Customer Key for both **Multiple Workloads** and **Exchange**, run the cmdlet twice, once for each workload.

Before running in Enable mode, make sure your validation results show **Passed** under `ValidationResult`.

> ⓘ **Important**
>
> Your resources must pass all checks in `Validate` mode for the onboarding process to succeed in Enable mode.

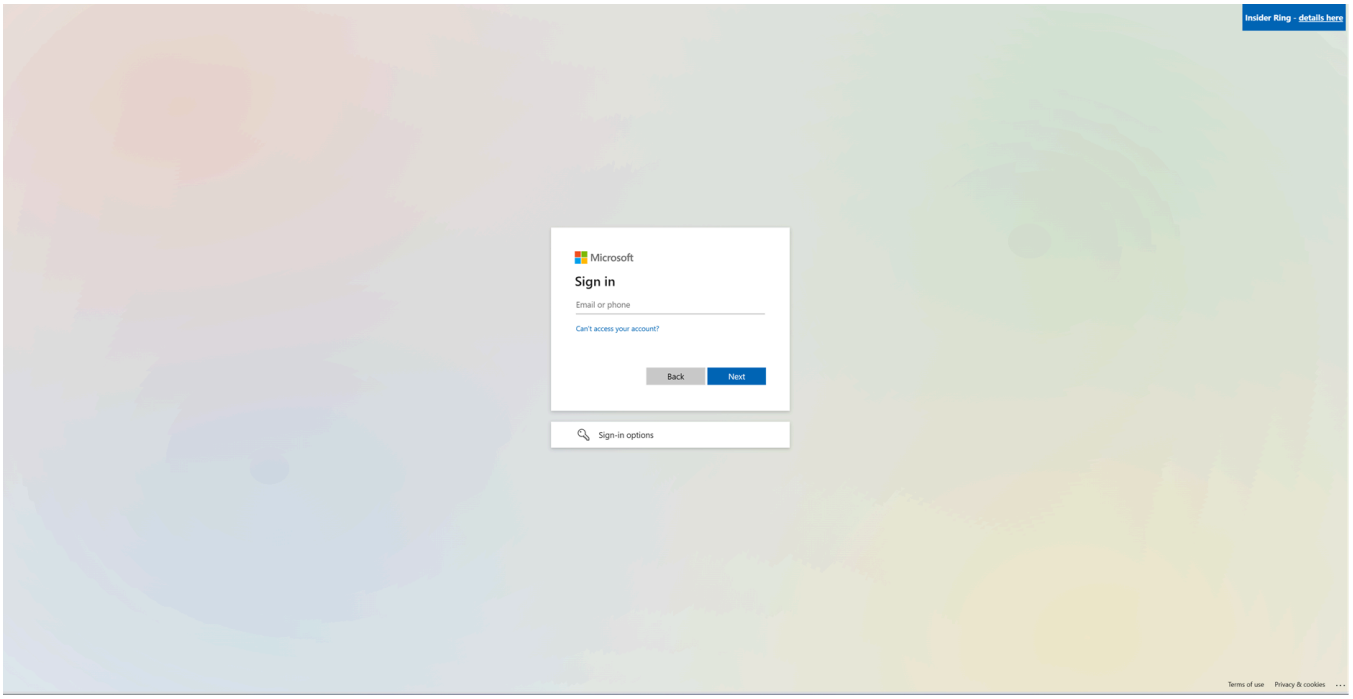
Creating an onboarding request

The first step in the onboarding process is to create a new request. In PowerShell, you can store the results of a cmdlet in a variable using the `$` symbol followed by the variable name.

In this example, the onboarding request is stored in a variable named `$request`:

PowerShell

```
$request = New-CustomerKeyOnboardingRequest -Organization <tenantID> -Scenario
<Scenario> -Subscription1 <subscriptionID1> -KeyIdentifier1 <KeyURI1> -Subscription2
<subscriptionID2> -KeyIdentifier2 <KeyURI2> -OnboardingMode <OnboardingMode>
```



Expand table

Parameter	Description	Example
`-Organization`	Your tenant ID (GUID format)	`abcd1234-abcd-efgh-hijk-abcdef123456`
`-Scenario`	Workload: `MDEP` (Multiple Workloads) or `EXO` (Exchange)	`MDEP` or `EXO`
`-Subscription1`	First Azure subscription ID	`p121d534-1234-5678-9876-g3def67j9k12`
`-KeyIdentifier1`	Key URI for first AKV/HSM key	`https://exampleVault1.vault.azure.net/keys/customerKey1`
`-Subscription2`	Second Azure subscription ID	`21k9j76f-ed3g-6789-8765-43215dl21pbd`

Parameter	Description	Example
`-KeyIdentifier2`	Key URI for second AKV/HSM key	`https://exampleVault2.vault.azure.net/keys/customerKey2`
`-OnboardingMode`	`Validate` (test only) or `Enable` (test and enable)	`Validate` or `Enable`

Sign in with your tenant admin credentials

When prompted, a browser window opens. Sign in using your tenant admin account with the necessary privileges to complete onboarding.

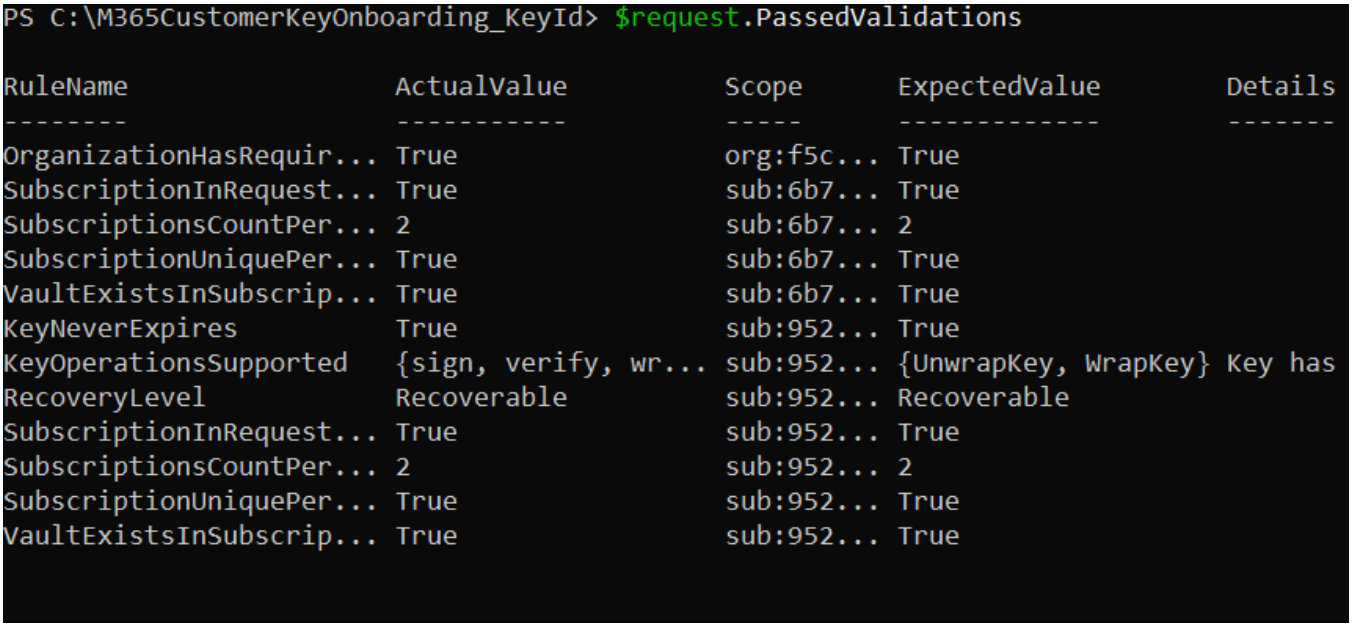
View validation and enablement details

After successfully signing in, return to your PowerShell window. Run the variable you used when creating the onboarding request to view its output:

PowerShell

```
$request
```

```
PS C:\Windows\System32> $request



Id                                   CreatedDate           ValidationResult EnablementResult
--                                   -----------           ---------------- ----------------
94a83419-edb8-4bf1-8037-cc54ceb71594 11/22/2023 12:07:22 AM Passed           NotAttempted
```

You receive an output that includes `ID`, `CreatedDate`, `ValidationResult`, and `EnablementResult`.

Expand table

Output	Description
`ID`	ID associated with the created onboarding request.
`CreatedDate`	Date on which the request was created.
`ValidationResult`	Indicator of successful/unsuccessful validation.
`EnablementResult`	Indicator of successful/unsuccessful enablement.

A tenant that's ready to use Customer Key shows **Success** for both `ValidationResult` and `EnablementResult` as shown in the following screenshot:

If both values show **Success**, proceed to Next Steps.

Troubleshooting failed validations details

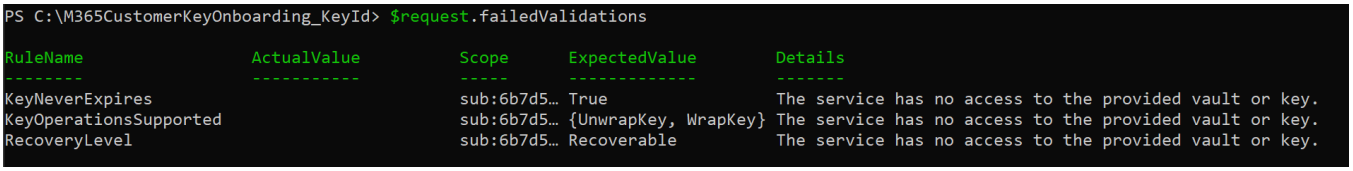
If validation fails during onboarding, perform the following steps to investigate the cause. This process helps identify which Customer Key resources are misconfigured.

1. List all onboarding requests for your tenant to find the `RequestID` of the one you want to investigate:

PowerShell

```
Get-CustomerKeyOnboardingRequest -OrganizationID <OrganizationID>
```

2. Store the specific onboarding request into a variable:



PowerShell

```
$request = Get-CustomerKeyOnboardingRequest -OrganizationID <OrganizationID> -
RequestID <RequestID>
```

3. View the failed validation details:

PowerShell

```
$request.FailedValidations
```

Each validation rule includes the following fields:

- **ExpectedValue**: What the resource configuration should be.
- **ActualValue**: What was detected in your environment.
- **Scope**: The first five characters of the subscription ID that helps you identify which subscription (and its associated Key Vault) has the issue.
- **Details**: Describes the root cause and offers guidance to resolve the problem.

The following table summarizes common validation rules and how to resolve failures:

Expand table

RuleName	Description	Solution
`OrganizationHasRequiredServicePlan`	Verifies whether your organization has the required licenses.	See Prerequisites.
`KeyNeverExpires`	Ensures that the key has no expiration date.	See the key expiration verification steps in Configuration-specific setup
`KeyOperationsSupported`	Verifies whether the key supports required operations for the workload.	See the permissions assignment steps in Configuration-specific setup
`RecoveryLevel`	Checks if the key recovery level is `Recoverable`.	Ensure both soft delete and purge protection are enabled. See Enabling Soft Delete and Purge Protection for Azure Key Vault or Create a resource group

RuleName	Description	Solution
		provision, and activate a Managed HSM for Managed HSM.
`SubscriptionInRequestOrganization`	Confirms that your Azure subscription belongs to your organization.	Make sure the subscription was created within the specified tenant.
`SubscriptionsCountPerScenario`	Confirms that two subscriptions were provided.	Make sure your onboarding request includes **two** subscriptions.
`SubscriptionUniquePerScenario`	Ensures you're using two unique subscriptions per scenario.	Double-check that both subscription IDs are different.
`VaultExistsinSubscription`	Confirms that the AKV/Managed HSM is part of the given subscription.	Verify whether the Key Vault/HSM was created in the correct subscription.

Checking passed validations

To view which validations were successful during the onboarding process, perform the following steps:

1. Store the specific onboarding request into the variable '$request'

PowerShell

```
$request = Get-CustomerKeyOnboardingRequest -OrganizationID <OrganizationID> -
RequestID <RequestID>
```

2. Run the following command to display all passed validations:

PowerShell

```
$request.PassedValidations
```

This command returns a list of all the validations that passed successfully for the selected onboarding request.

```
PS C:\M365CustomerKeyOnboarding_KeyId> $request.PassedValidations

RuleName                 ActualValue          Scope      ExpectedValue        Details

```

Onboard to Customer Key for special cloud environments

If your tenant is located in **GCC-H**, **DoD**, or **M365 operated by 21Vianet**, complete all required Customer Key setup steps first.

- For **GCC-H** and **DoD** tenants, contact Microsoft Support and request onboarding for government tenants.
- For customers in Microsoft 365 operated by 21Vianet (China), configure your Customer Key resources using Azure operated by 21Vianet portal. Then, contact Microsoft Support and request onboarding for your tenant.

Onboard to Customer Key for SharePoint and OneDrive

To onboard to Customer Key for SharePoint and OneDrive, your Azure Key Vaults must meet the following prerequisites:

1. Enable both soft delete and purge protection during the initial vault creation process. See Enabling Soft Delete and Purge Protection for Azure Key Vault.

If this prerequisite is satisfied, perform the steps in Create a DEP for use with SharePoint and OneDrive.

Next steps

After completing the setup steps in this article, you're ready to create and assign DEPs. For detailed instructions, see Manage Customer Key.

Manage Customer Key encryption policies

> *Microsoft Purview service description*

After setting up Customer Key, create and assign one or more **data encryption policies (DEPs)** to control how Microsoft 365 encrypts your organization's data at rest. After you assign them, you can manage your encryption keys and policies. For example, you can verify encryption status, view DEP details, disable a DEP, restore keys, or roll back to Microsoft-managed keys.

Microsoft Purview Customer Key also supports **Windows 365 Cloud PCs**. For more information, see Microsoft Purview Customer Key for Windows 365 Cloud PCs.

Prerequisites

Before managing Customer Key, make sure you have:

- **Completed setup**: Finish all steps in Set up Customer Key
- **Key Vault URIs**: Get the URIs for your Azure Key Vault keys. See Obtain the URI for each Azure Key Vault key
- **Permissions**: Exchange admin permissions (all DEP operations run through Exchange Online PowerShell)
- **PowerShell modules**:
  - Exchange Online PowerShell for DEP operations
  - Azure PowerShell for Key Vault operations

> **ⓘ Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Quick reference: Commands by task

Use the following tables to quickly find the command you need.

Create and assign DEPs

Expand table

Task	Workload	Command
Create a DEP	Multi-workload	`New-M365DataAtRestEncryptionPolicy -Name <Name> -AzureKeyIDs <KeyURI1>,<KeyURI2>`
Create a DEP	Exchange	`New-DataEncryptionPolicy -Name <Name> -AzureKeyIDs <KeyURI1>, <KeyURI2>`
Create a DEP	SharePoint/OneDrive	`Register-SPODataEncryptionPolicy -PrimaryKeyVaultName <Name> -PrimaryKeyName <Name> -PrimaryKeyVersion <Version> -SecondaryKeyVaultName <Name> -SecondaryKeyName <Name> -SecondaryKeyVersion <Version>`
Assign a DEP	Multi-workload	`Set-M365DataAtRestEncryptionPolicyAssignment -DataEncryptionPolicy <PolicyName>`
Assign a DEP	Exchange mailbox	`Set-Mailbox -Identity <Mailbox> -DataEncryptionPolicy <PolicyName>`
Assign a DEP	Hybrid mailbox	`Set-MailUser -Identity <MailUser> -DataEncryptionPolicy <PolicyName>`

View and verify DEPs

Expand table

Task	Workload	Command
List all DEPs	Multi-workload	`Get-M365DataAtRestEncryptionPolicy`
List all DEPs	Exchange	`Get-DataEncryptionPolicy`
View DEP assignment	Multi-workload	`Get-M365DataAtRestEncryptionPolicyAssignment`
View mailbox DEP	Exchange	`Get-MailboxStatistics -Identity <Mailbox> | fl DataEncryptionPolicyID`
View encryption status	SharePoint/OneDrive	`Get-SPODataEncryptionPolicy`
Check mailbox encryption	Exchange	`Get-MailboxStatistics -Identity <Mailbox> | fl IsEncrypted`

Manage and disable DEPs

Expand table

Task	Workload	Command
Disable a DEP	Multi-workload	`Set-M365DataAtRestEncryptionPolicy -Identity <Policy> -Enabled $false`
Unassign a DEP	Exchange	`Set-Mailbox -Identity <Mailbox> -DataEncryptionPolicy $null`

Key Vault operations

Expand table

Task	Command
View Key Vault permissions	`Get-AzKeyVault -VaultName <VaultName>`
Remove user access	`Remove-AzKeyVaultAccessPolicy -VaultName <VaultName> -UserPrincipalName <UPN>`
Restore a key	`Restore-AzKeyVaultKey -VaultName <VaultName> -InputFile <BackupFile>`

Create a multi-workload DEP

To create a multi-workload DEP, follow these steps:

1. On your local computer, sign in using a **work or school account** with **Compliance Administrator** permissions, and connect to Exchange Online PowerShell.

2. Run the following cmdlet to create a multi-workload data encryption policy:

   PowerShell

   ```
   New-M365DataAtRestEncryptionPolicy -Name <PolicyName> -AzureKeyIDs <KeyVaultURI1, KeyVaultURI2> [-Description <String>]
   ```

   Parameter definitions:

   - `-Name`: The name you want to use for the policy. No spaces allowed.
   - `-AzureKeyIDs`: URIs of the two Azure Key Vault keys used in the policy, separated by commas.

Example: `"https://contosoCentralUSvault1.vault.azure.net/keys/Key_02"` `"https://contosoWestUSvault1.vault.azure.net/keys/Key_01"`

- `Description` *(optional)*: A human-readable description of the policy.

  Example: `"Policy for multiple workloads for all users in the tenant."`

PowerShell

```
New-M365DataAtRestEncryptionPolicy -Name "Contoso_Global" -AzureKeyIDs "https://contosoWestUSvault1.vault.azure.net/keys/Key_01","https://contosoCentralUSvault1.vault.azure.net/keys/Key_02" -Description "Policy for multiple workloads for all users in the tenant."
```

Assign multi-workload policy

After creating a multi-workload data encryption policy (DEP), assign it using the `Set-M365DataAtRestEncryptionPolicyAssignment` cmdlet. After assignment, Microsoft 365 encrypts your organization's data using the keys specified in the DEP.

PowerShell

```
Set-M365DataAtRestEncryptionPolicyAssignment -DataEncryptionPolicy <PolicyName or ID>
```

Replace `<PolicyName or ID>` with the name or GUID of the policy.

Example:

PowerShell

```
Set-M365DataAtRestEncryptionPolicyAssignment -DataEncryptionPolicy "Contoso_Global"
```

Windows 365 Cloud PCs:

After assigning the policy, allow 3–4 hours for the Intune admin center to reflect the update. After the update, follow the steps in the admin center to encrypt existing Cloud PCs.

For more information, see Set up Customer Keys for your Windows 365 Cloud PCs.

Create a DEP for Exchange mailboxes

Before you begin, complete the required setup steps. For details, see Set up Customer Key. To create the DEP, you'll need the Azure Key Vault URIs obtained during setup. For more

information, see Obtain the URI for each Azure Key Vault key.

To create a DEP for Exchange mailboxes, follow these steps:

1. On your local computer, using a work or school account that has Exchange admin permissions, connect to Exchange Online PowerShell.

2. Create a DEP using the `New-DataEncryptionPolicy` cmdlet:

PowerShell

```
New-DataEncryptionPolicy -Name <PolicyName> -Description "Policy Description" -
AzureKeyIDs <KeyVaultURI1>, <KeyVaultURI2>
```

Expand table

Parameter	Description	Example
`-Name`	Enter a name for the policy. Names can't contain spaces.	`USA_mailboxes`
`-AzureKeyIDs`	Enter the URIs for two keys in separate Azure Key Vaults. Separate them with a comma and a space.	`https://contosoEastUSvault01.vault.azure.net/keys/USA_key_01`, `https://contosoEastUS2vault01.vault.azure.net/keys/USA_key_02`
`-Description`	A user-friendly description that helps identify the policy's purpose.	`"Root key for mailboxes in USA and its territories"`

Example:

PowerShell

```
New-DataEncryptionPolicy -Name USA_mailboxes -Description "Root key for mailboxes
in USA and its territories" -AzureKeyIDs
https://contoso_EastUSvault02.vault.azure.net/keys/USA_key_01,
https://contoso_CentralUSvault02.vault.azure.net/keys/USA_Key_02
```

For syntax and parameter information, see New-DataEncryptionPolicy.

Assign a DEP to a mailbox

Assign the DEP with the `Set-Mailbox` cmdlet. Once assigned, Microsoft 365 encrypts the mailbox with the keys in the DEP.

PowerShell

```
Set-Mailbox -Identity <MailboxIdParameter> -DataEncryptionPolicy <PolicyName>
```

For more information, see Set-Mailbox.

Assign a DEP to hybrid mailboxes

In hybrid environments, assign a DEP to synchronized on-premises mailbox data using `Set-MailUser`:

PowerShell

```
Set-MailUser -Identity <MailUserIdParameter> -DataEncryptionPolicy <PolicyName>
```

For more information, see Set-MailUser and on-premises mailboxes using Outlook for iOS and Android with hybrid Modern Authentication.

Assign a DEP before you migrate a mailbox to the cloud

Assigning a DEP before migration encrypts your mailbox contents during the move, which is more efficient than assigning a DEP after migration.

1. Connect to Exchange Online PowerShell using a work or school account with Exchange Online cmdlet permissions.

2. Run the following command:

   PowerShell

   ```
   Set-MailUser -Identity <GeneralMailboxOrMailUserIdParameter> -
   DataEncryptionPolicy <DataEncryptionPolicyIdParameter>
   ```

View the DEPs you created for Exchange mailboxes

To list all DEPs in your organization, connect to Exchange Online PowerShell and run:

PowerShell

```
Get-DataEncryptionPolicy
```

For detailed cmdlet information, see Get-DataEncryptionPolicy.

Determine the DEP assigned to a mailbox

To find the DEP assigned to a mailbox, connect to Exchange Online PowerShell and run:

PowerShell

```
Get-Mailbox -Identity <MailboxIdParameter> | fl DataEncryptionPolicy
```

To get the friendly name from the returned GUID:

PowerShell

```
Get-DataEncryptionPolicy <GUID>
```

For more information, see Get-MailboxStatistics.

Create a DEP for use with SharePoint and OneDrive

Before you begin, make sure you complete the required setup steps. For more information, see Set up Customer Key.

To configure Customer Key for SharePoint and OneDrive, use SharePoint PowerShell.

A DEP uses two keys from separate Azure Key Vaults in different regions. Single-geo tenants need one DEP; multi-geo tenants need one DEP per geo with different keys. You need the Key Vault URIs for both keys (see Obtain the URI for each Azure Key Vault key).

1. On your local computer, using a work or school account that has Exchange Online cmdlet permissions in your organization, connect to SharePoint PowerShell.

2. Use the `Register-SPODataEncryptionPolicy` cmdlet to register the DEP.

   PowerShell

   ```
   Register-SPODataEncryptionPolicy -PrimaryKeyVaultName <PrimaryKeyVaultName> -
   PrimaryKeyName <PrimaryKeyName> -PrimaryKeyVersion <PrimaryKeyVersion> -
   ```

```
SecondaryKeyVaultName <SecondaryKeyVaultName> -SecondaryKeyName
<SecondaryKeyName> -SecondaryKeyVersion <SecondaryKeyVersion>
```

Example:

PowerShell

```
Register-SPODataEncryptionPolicy -PrimaryKeyVaultName 'stageRG3vault' -
PrimaryKeyName 'SPKey3' -PrimaryKeyVersion 'f635a23bd4a44b9996ff6aadd88d42ba' -
SecondaryKeyVaultName 'stageRG5vault' -SecondaryKeyName 'SPKey5' -
SecondaryKeyVersion '2b3e8f1d754f438dacdec1f0945f251a'
```

If using Managed HSM: Use the full URL of the key **including version** for each vault.

PowerShell

```
Register-SPODataEncryptionPolicy -PrimaryKeyVaultUri <PrimaryKeyVaultURL> -
SecondaryKeyVaultUri <SecondaryKeyVaultURL>
```

Example:

PowerShell

```
Register-SPODataEncryptionPolicy -PrimaryKeyVaultURL https://M365-
Test.managedhsm.azure.net/keys/Sharepoint-01/aaaa5513974f4780ea67b2f5d8c3dd -
SecondaryKeyVaultURL https://M365-Test-02.managedhsm.azure.net/keys/Sharepoint-
02/7d8f30343bed4e44a57225bae2012388
```

> ⓘ **Note**
>
> After the DEP is registered, encryption of the geo's data begins. This process might take some time.

For full cmdlet reference, see Register-SPODataEncryptionPolicy.

Verify Customer Key encryption status

After rolling a Customer Key, assigning a new data encryption policy (DEP), or migrating a mailbox, follow the steps in this section to confirm that encryption is complete.

Verify encryption completes for Exchange mailboxes

Encrypting a mailbox with Customer Key can take time. To verify that encryption is complete, determine the DEP assigned to the mailbox and confirm that the returned data encryption policy ID matches the policy you assigned.

Verify encryption completes for SharePoint and OneDrive

Check on the status of encryption by running the Get-SPODataEncryptionPolicy cmdlet as follows:

PowerShell

```
Get-SPODataEncryptionPolicy
```

The output includes primary/secondary key URIs, encryption status, and percentage of sites onboarded. Status values:

Expand table

Status	Description
Unregistered	Customer Key encryption not applied
Registering	Encryption in progress (shows percentage complete)
Registered	Encryption complete
Rolling	Key roll in progress (shows percentage complete)

Get details about DEPs you use with multiple workloads

To view multi-workload DEPs, connect to Exchange Online PowerShell with Compliance Administrator permissions and run:

PowerShell

```
Get-M365DataAtRestEncryptionPolicy
```

For details about a specific DEP:

PowerShell

```
Get-M365DataAtRestEncryptionPolicy -Identity "Contoso_Global"
```

Get multi-workload DEP assignment information

To identify which DEP is assigned to your tenant, connect to Exchange Online PowerShell and run:

PowerShell

```
Get-M365DataAtRestEncryptionPolicyAssignment
```

Disable a multi-workload DEP

Before disabling, unassign the DEP from workloads in your tenant. Then connect to Exchange Online PowerShell and run:

PowerShell

```
Set-M365DataAtRestEncryptionPolicy -Identity "PolicyName" -Enabled $false
```

Restore Azure Key Vault keys

Before restoring, try using soft delete to recover keys (available for up to 90 days). Full restoration is only needed if a key or vault is permanently lost.

To restore a key using Azure PowerShell, run the following command:

PowerShell

```
Restore-AzKeyVaultKey -VaultName <vault name> -InputFile <filename>
```

Example:

PowerShell

```
Restore-AzKeyVaultKey -VaultName Contoso-O365EX-NA-VaultA1 -InputFile Contoso-O365EX-NA-VaultA1-Key001-Backup-20170802.backup
```

> **Important**
>
> If the key vault already contains a key with the same name, the restore operation fails. The `Restore-AzKeyVaultKey` cmdlet restores all versions of the key, including its metadata and name.

Manage key vault permissions

Use Azure PowerShell to view or remove key vault permissions (for example, when a user leaves the team).

To view permissions:

```
PowerShell
Get-AzKeyVault -VaultName <vault name>
```

Example:

```
PowerShell
Get-AzKeyVault -VaultName Contoso-O365EX-NA-VaultA1
```

To remove a user's access:

```
PowerShell
Remove-AzKeyVaultAccessPolicy -VaultName <vault name> -UserPrincipalName <UPN of user>
```

Roll back from Customer Key to Microsoft-managed keys

You can revert to Microsoft-managed keys, which re-encrypts your data using the default encryption method for each workload.

> ⓘ **Important**
>
> Rolling back reverts encryption but doesn't delete data. A **data purge** permanently crypto-deletes data and can't be performed on multi-workload policies.

Roll back from Customer Key for multiple workloads

> ⓘ **Important**
>
> Rolling back from Customer Key for multiple workloads is **not** supported in Gallatin.

If you no longer want to use Customer Key with multi-workload data encryption policies (DEPs), submit a support request through Microsoft Support. Include the following information in your request:

- Tenant fully qualified domain name (FQDN)
- Tenant contact for the rollback request
- Reason for discontinuing Customer Key
- Incident number

> **Important**
>
> You must retain your Azure Key Vaults (AKVs) and encryption keys with the appropriate permissions. This action is required so that data can be rewrapped using Microsoft-managed keys.

Roll back from Customer Key for Exchange

> **Important**
>
> Rolling back from Customer Key for Exchange is **not** supported in Gallatin.

If you no longer want to encrypt individual mailboxes using mailbox-level data encryption policies (DEPs), you can unassign those DEPs from all mailboxes.

To unassign a mailbox-level DEP, follow these steps:

1. Use a work or school account that has the necessary Exchange Online PowerShell permissions, and connect to Exchange Online PowerShell.
2. Run the following cmdlet.

```
PowerShell
Set-Mailbox -Identity <mailbox> -DataEncryptionPolicy $null
```

This command unassigns the current DEP and re-encrypts the mailbox using the default Microsoft-managed keys.

> **Note**

You can't unassign the DEP associated with Microsoft-managed keys. If you don't want to use Microsoft-managed keys, assign a different DEP to the mailbox instead.

Roll back from Customer Key for SharePoint and OneDrive

> **Note**
>
> Roll back for Customer Key for SharePoint and OneDrive is currently in preview and is not available to tenants in GCC High, DoD, or M365 operated by 21Vianet.

If you no longer want to use Customer Key for SharePoint and OneDrive, submit a support request through Microsoft Support. Include the following information in your request:

- Tenant fully qualified domain name (FQDN)
- Tenant contact for the rollback request
- Reason for discontinuing Customer Key
- Incident number

> **Important**
>
> You must retain your Azure Key Vaults (AKVs) and encryption keys with the appropriate permissions. This action is required so that data can be rewrapped using Microsoft-managed keys.

Revoke your keys and start the data purge path

You control revocation of all root keys, including the availability key. When you revoke keys to purge data and exit the service, the availability key is deleted after the purge completes. This functionality is only supported for DEPs assigned to individual mailboxes.

Microsoft 365 audits and validates the data purge process. For more information, see the SSAE 18 SOC 2 Report, Risk Assessment and Compliance Guide for Financial Institutions, and Microsoft 365 Exit Planning Considerations.

> **Important**
>
> Purging a multi-workload DEP isn't supported. These policies encrypt data across multiple workloads and users within your tenant. Purging such a DEP would make data across all

workloads inaccessible.

If you're exiting Microsoft 365 services entirely, see how to delete a tenant in Microsoft Entra ID.

Revoke your Customer Keys and the availability key for Exchange

When you initiate the data purge path for Exchange, you place a permanent data purge request on a data encryption policy (DEP). This action permanently deletes encrypted data in all mailboxes assigned to that DEP.

Because the PowerShell cmdlet works on only one DEP at a time, consider reassigning a single DEP to all mailboxes before starting the data purge process.

> ⚠ **Warning**
>
> Don't use the data purge path to delete a subset of mailboxes. This process is intended only for organizations that are fully exiting the service.

> ⓘ **Important**
>
> Rolling back from Customer Key for Exchange, is **not** supported in Gallatin.

To initiate the data purge path, follow these steps:

1. Remove wrap and unwrap permissions for **O365 Exchange Online** from your Azure Key Vaults.
2. Use a work or school account with the appropriate Exchange Online PowerShell permissions, and connect to Exchange Online PowerShell.
3. For each DEP that includes mailboxes you want to purge, run the Set-DataEncryptionPolicy cmdlet:

   PowerShell

   ```
   Set-DataEncryptionPolicy <Policy ID> -PermanentDataPurgeRequested -
   PermanentDataPurgeReason <Reason> -PermanentDataPurgeContact <ContactName>
   ```

If the command fails, confirm that Exchange Online permissions were removed from both keys in the Azure Key Vault, as described in step 1. After you run the `Set-DataEncryptionPolicy` cmdlet with the `-PermanentDataPurgeRequested` switch, the DEP can't be assigned to mailboxes anymore.

4. Contact Microsoft Support and request the Data Purge eDocument.

   Microsoft sends a legal document to confirm and authorize the data purge. The person who signs this is usually an executive or other legally authorized representative.

5. After your representative signs the document, return it to Microsoft (usually via electronic signature).

   After Microsoft receives the signed eDocument, it verifies the authenticity of the signature and signee. After verification, they run the necessary cmdlets to complete the data purge. This process deletes the DEP, marks affected mailboxes for permanent deletion, and removes the availability key. After the process finishes, the data is purged, inaccessible to Exchange, and can't be recovered.

Revoke your Customer Keys and the availability key for SharePoint and OneDrive

Purging DEPs for SharePoint and OneDrive isn't supported in Customer Key. If you're exiting Microsoft 365 services entirely, you can follow the documented process to delete your tenant.

For details, see how to delete a tenant in Microsoft Entra ID.

Migrate your Key Vaults from the legacy access policy model to RBAC

If you onboarded to Customer Key using the legacy access policy model, follow these steps to migrate all Azure Key Vaults to use role-based access control (RBAC). To compare the two models and understand why Microsoft recommends RBAC, see Azure role-based access control (Azure RBAC) vs. access policies (legacy).

Remove legacy access policies

To remove the existing access policies from your Key Vaults, use the `Remove-AzKeyVaultAccessPolicy` cmdlet.

1. Sign in to your Azure subscription with Azure PowerShell. For guidance, see Sign in with Azure PowerShell.

2. Run the following command to remove access for the **Microsoft 365 Service** principal:

```
PowerShell

Remove-AzKeyVaultAccessPolicy -VaultName <VaultName> -ServicePrincipalName
c066d759-24ae-40e7-a56f-027002b5d3e4
```

3. Run the following command to remove access for the **Exchange Online** principal:

```
PowerShell

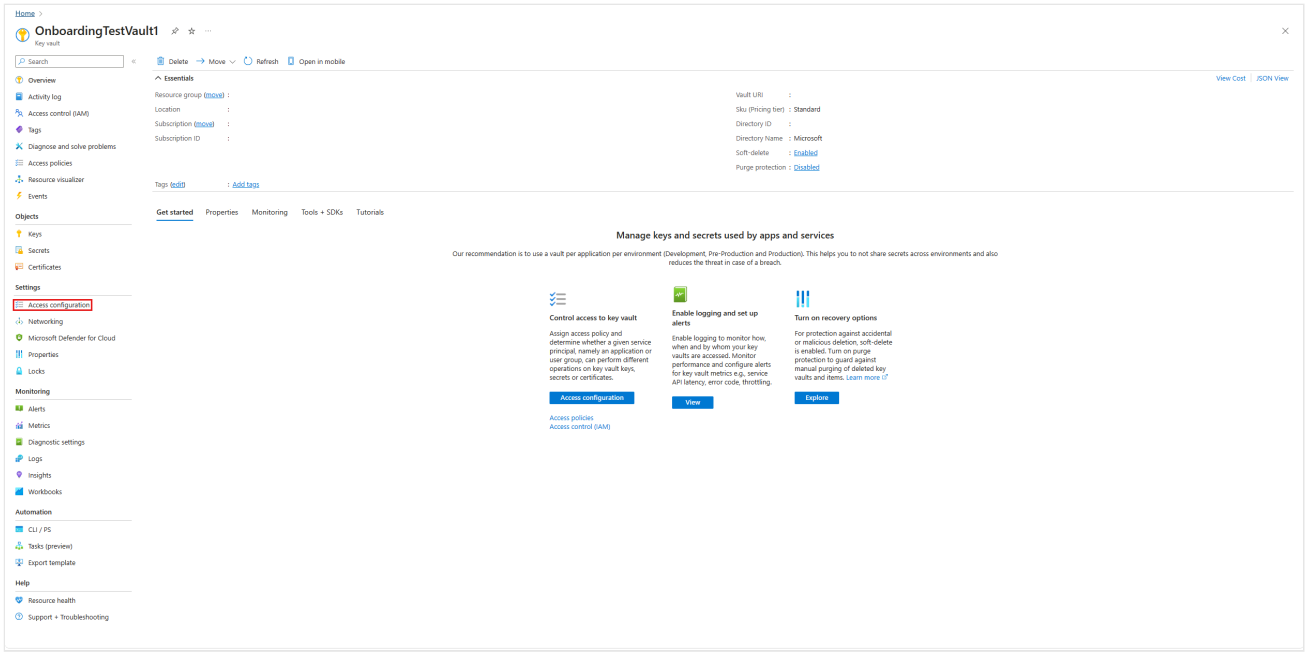
Remove-AzKeyVaultAccessPolicy -VaultName <VaultName> -ServicePrincipalName
00000002-0000-0ff1-ce00-000000000000
```

4. Run the following command to remove access for the **SharePoint and OneDrive for work or school service principal**:

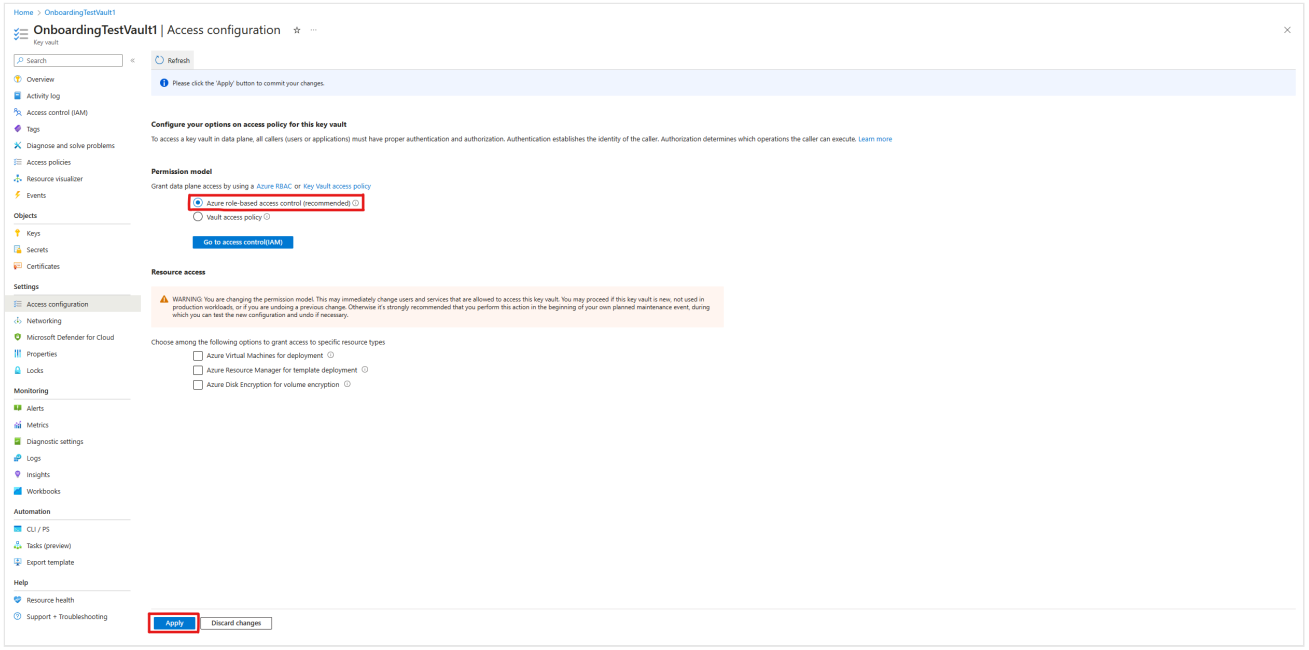
```
PowerShell

Remove-AzKeyVaultAccessPolicy -VaultName <VaultName> -ServicePrincipalName
00000003-0000-0ff1-ce00-000000000000
```

Change the access configuration permission model



After removing the access policies, update the permission model for each Key Vault in the Azure portal:



1. In the Azure portal, navigate to your Key Vault.

2. In the left-hand menu, under **Settings**, select **Access configuration**.

3. Under **Permission model**, choose **Azure role-based access control**.

4. Select **Apply** at the bottom of the screen.

Assign RBAC permissions

After you switch the permission model, follow the steps in Assign permissions to each Key Vault to grant the necessary roles.

Troubleshooting

The following table lists common Customer Key issues, possible causes, and recommended resolutions.

Expand table

Issue	Possible cause	Resolution
DEP creation fails	Invalid Key Vault URI	Verify the URI format and that the key exists in the vault
DEP assignment fails	Insufficient permissions	Ensure you have Exchange admin permissions
Mailbox not encrypted after one week	Database move not complete	Contact Microsoft Support
`Get-MailboxStatistics` returns no `DataEncryptionPolicyID`	DEP not assigned	Assign a DEP using `Set-Mailbox`
SharePoint encryption stuck at "Registering"	Large tenant or key access issue	Verify key permissions; for large tenants, encryption can take time
Key restore fails	Key with same name exists	Use a different vault or remove the existing key first
Can't connect to Exchange Online PowerShell	Module not installed or outdated	Install or update the Exchange Online PowerShell module

Roll or rotate a Customer Key or an availability key

> *Microsoft Purview service description*

> **⊗ Caution**
>
> Roll an encryption key used with Customer Key **only** if required by your organization's security or compliance policies.
>
> **Do not delete or disable any keys**, including older versions, that are or were associated with **Exchange**, **Multi-workload**, or **SharePoint** encryption policies.
>
> For example:
>
> - SharePoint retains backup content for restore and recovery, which might also rely on older keys.

Prerequisites

Before you roll or rotate keys, ensure you have:

- **Permissions**: Global Administrator or appropriate Exchange permissions
- **PowerShell modules installed**:
  - Azure PowerShell for Azure Key Vault operations
  - Exchange Online PowerShell to run the given cmdlets
- **Access to Azure Key Vault**: You must have permissions to create new key versions in your key vaults

> **ⓘ Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Quick reference: Commands by workload

Use the following table to quickly find the command you need based on your workload and scenario.

Expand table

Workload	Scenario	Command
Multi-workload	Refresh DEP with new key version	`Set-M365DataAtRestEncryptionPolicy -Identity <Policy> -Refresh`
Multi-workload	Replace keys in DEP	`Set-M365DataAtRestEncryptionPolicy -Identity <Policy> -Replace -AzureKeyIDs <KeyURI1>,<KeyURI2>`
Exchange	Refresh DEP with new key version	`Set-DataEncryptionPolicy -Identity <Policy> -Refresh`
Exchange	Replace keys in DEP	`Set-DataEncryptionPolicy -Identity <Policy> -Replace -AzureKeyIDs <KeyURI1>,<KeyURI2>`
SharePoint/OneDrive	Roll/Rotate a key	`Update-SPODataEncryptionPolicy <SPOAdminSiteUrl> -KeyVaultName <Name> -KeyName <Name> -KeyVersion <Version> -KeyType <Primary | Secondary>`
SharePoint/OneDrive	Check roll progress	`Get-SPODataEncryptionPolicy <SPOAdminSiteUrl>`
Azure Key Vault	Create new key version	`Add-AzKeyVaultKey -VaultName <VaultName> -Name <KeyName> -Destination HSM -KeyOps @('wrapKey','unwrapKey')`

> **Note**
>
> For SharePoint and OneDrive, the same cmdlet, `Update-SPODataEncryptionPolicy`, is used to roll (or rotate) and replace keys.

Choose your key rolling method

There are two ways to roll customer-managed root keys. Use the following table to determine which method is right for your scenario.

Expand table

Method	When to use	What happens
Update existing key (create new version)	Routine key rotation; maintaining the same key name	Creates a new version of the existing key. The DEP references the same key name but uses the new version after refresh.
Replace with new key	Compromised key; changing key vault; organizational restructuring	Creates an entirely new key with a new name. The DEP is updated to reference the new key URIs.

About rolling the availability key

You can't directly roll the availability key. You can only roll keys you manage in Azure Key Vault.

Microsoft 365 rolls availability keys automatically on an internal schedule with no customer-facing SLA. Administrators don't have direct access to the key store. For more information, see Understand the availability key.

> **Important**
>
> For Exchange, creating a new DEP effectively rolls the availability key since each new data encryption policy (DEP) generates a unique availability key.
>
> For SharePoint and OneDrive, availability keys are created at the forest level and shared across DEPs. These keys roll only on Microsoft's internal schedule, but SharePoint, OneDrive, and Teams roll the tenant intermediate key (TIK) with each new DEP to mitigate this.

Roll customer-managed root keys

Use one of the following methods to roll customer-managed root keys stored in Azure Key Vault. Choose the method that matches your scenario based on the guidance in Choose your key rolling method.

Method 1: Update an existing key (create a new version)

Use this method to create a new version of an existing key. This approach is recommended for routine key rotations.

Step 1: Create a new key version in Azure Key Vault

To request a new version of an existing key, use the `Add-AzKeyVaultKey` cmdlet with the same key name you used when creating the original key.

1. Sign in to your Azure subscription with Azure PowerShell. For instructions, see Sign in with Azure PowerShell.

2. Run the `Add-AzKeyVaultKey` cmdlet:

   PowerShell

   ```
   Add-AzKeyVaultKey -VaultName <VaultName> -Name <KeyName> -Destination HSM -KeyOps @('wrapKey','unwrapKey') -NotBefore (Get-Date)
   ```

   Example:

   PowerShell

   ```
   Add-AzKeyVaultKey -VaultName Contoso-CK-EX-NA-VaultA1 -Name Contoso-CK-EX-NA-VaultA1-Key001 -Destination HSM -KeyOps @('wrapKey','unwrapKey') -NotBefore (Get-Date -Date "12/27/2016 12:01 AM")
   ```

   In this example, a key named Contoso-CK-EX-NA-VaultA1-Key001 already exists in the Contoso-CK-EX-NA-VaultA1 vault. The cmdlet creates a new version of the key. Previous versions are retained in the key's version history.

3. Repeat this step in each Azure Key Vault that contains keys you want to roll.

Step 2: Refresh the DEP to use the new key version

After creating a new key version, refresh the DEP to use it. Connect to Exchange Online PowerShell with appropriate Exchange cmdlet permissions, then run the appropriate cmdlet:

For Multi-workload DEPs:

PowerShell

```
Set-M365DataAtRestEncryptionPolicy -Identity <Policy> -Refresh
```

For Exchange DEPs:

PowerShell

```
Set-DataEncryptionPolicy -Identity <Policy> -Refresh
```

> ⓘ Note
>
> The `DataEncryptionPolicyID` property remains the same when refreshing with a new version of the same key. Refreshing the DEP with a new version of the same key doesn't rotate the availability key.

For SharePoint and OneDrive DEPs:

SharePoint supports rolling only one key at a time. Wait for the first operation to finish before rolling a second key.

PowerShell

```
Update-SPODataEncryptionPolicy <SPOAdminSiteUrl> -KeyVaultName <Name> -KeyName <Name>
-KeyVersion <Version> -KeyType <Primary | Secondary>
```

For Managed HSM keys, use `-KeyVaultURL` instead of `-KeyVaultName`.

To check progress: `Get-SPODataEncryptionPolicy <SPOAdminSiteUrl>`

Method 2: Replace keys with newly generated keys

Use this method to replace existing keys entirely with new keys.

> ⓘ Important
>
> Keep old keys enabled and accessible until the replacement process is fully completed.

Connect to Exchange Online PowerShell with the appropriate Exchange cmdlet permissions, then run the appropriate cmdlet:

For Exchange DEPs:

PowerShell

```
Set-DataEncryptionPolicy -Identity <Policy> -Replace -AzureKeyIDs <KeyURI1>,<KeyURI2>
```

For Multi-workload DEPs:

PowerShell

```
Set-M365DataAtRestEncryptionPolicy -Identity <Policy> -Replace -AzureKeyIDs <KeyURI1>,
<KeyURI2>
```

> **Note**
>
> The order of key URIs doesn't matter. To replace only one key, you must still provide both URIs. Wait **24 hours** before disabling old keys, and then an **additional 24-48 hours** before purging.

Verify key roll status

Use the following commands to verify the status of your key roll operations.

Expand table

Workload	Verification command
SharePoint/OneDrive	`Get-SPODataEncryptionPolicy <SPOAdminSiteUrl>`
Exchange	`Get-DataEncryptionPolicy -Identity <Policy>`
Multi-workload	`Get-M365DataAtRestEncryptionPolicy -Identity <Policy>`

Troubleshooting

The following table lists common issues you might encounter when rolling keys and how to resolve them.

Expand table

Issue	Possible cause	Resolution
Key roll fails with permission error	Insufficient Azure Key Vault permissions	Verify your account has `wrapKey` and `unwrapKey` permissions on the key vault
DEP refresh fails	New key version not yet propagated	Wait a few minutes and retry the refresh command
SharePoint roll shows "In Progress" for extended time	Large tenant with significant data	SharePoint key rolls can take time for large tenants. Continue monitoring with `Get-SPODataEncryptionPolicy`
Can't access encrypted	Old key was disabled	Re-enable the old key and wait 24-48 hours before

Issue	Possible cause	Resolution
content after key roll	too soon	disabling again

Learn about the availability key for Customer Key

The availability key is a root key automatically generated when you create a data encryption policy (DEP). Microsoft 365 stores and protects this key. Unlike the keys you manage in Azure Key Vault, you can't directly access it. Only Microsoft 365 service code can use it programmatically.

Its primary purpose is recovery from unexpected loss of your root keys. If you lose control of your keys, contact Microsoft Support to recover data using the availability key and migrate to a new DEP.

The availability key differs from Azure Key Vault keys in three ways:

- **Recovery**: Provides a break-glass option if both Azure Key Vault keys are lost
- **Defense in depth**: Logical separation of control and storage prevents total loss from a single failure
- **High availability**: Supports temporary Azure Key Vault outages for Exchange/Multi-Workload (SharePoint/OneDrive only uses it during explicit recovery requests)

You have sole authority to disable or destroy the availability key when leaving the service. For more information, see the Microsoft Trust Center.

Availability key uses

The availability key supports recovery if an attacker gains control of your key vault or mismanagement causes key loss. All services share these behaviors:

- **Recovery**: Decrypts data so you can re-encrypt with a new DEP
- **Programmatic only**: No direct admin access; only service code can use it
- **Not a substitute**: Your two Customer Keys remain the primary encryption roots

Service-specific behavior:

Exchange and Multi-workload

In addition to supporting recovery, the availability key ensures continued access during short Azure Key Vault outages for background operations such as anti-malware scans, eDiscovery, DLP, mailbox migrations, and indexing.

Fallback logic: If unwrap fails with one Customer Key, the service tries the second. If both fail with system errors, it falls back to the availability key. Access denied errors don't

trigger fallback for user actions.

Availability key security

Microsoft protects availability keys in access-controlled internal secret stores. Customers can't directly access the availability key. You can only roll keys you manage in Azure Key Vault. All operations occur through automated service code. For more information, see Roll or rotate a Customer Key or an availability key.

Availability key secret stores

Management operations require privilege escalation through Lockbox with justification, manager approval, and automatic time-bound revocation.

Expand table

Workload	Storage location
Exchange and Multi-workload	Exchange Active Directory secret store in tenant-specific containers
SharePoint and OneDrive	Internal secret store with SQL Database back end; keys wrapped with AES-256/HMAC and RSA-2048 certificates

Defense-in-depth

Microsoft uses defense-in-depth to protect availability keys:

- **Application isolation**: Only Microsoft 365 service code can use keys for encryption/decryption
- **Logical separation**: Customer Keys, availability keys, and customer data are stored in isolated locations
- **Access controls**: Engineers have no direct access to secret stores (see Administrative Access Controls)
- **Technical controls**: Block interactive sign-in to privileged service accounts
- **Monitoring**: Continuous intrusion detection, centralized logging, and alerts for unauthorized access attempts or baseline deviations

Use the availability key to recover from key loss

If you lose control of your Customer Keys, the availability key lets you decrypt affected data and re-encrypt it under a new DEP with new Customer Keys.

Exchange and Multi-workload

1. Create two new Customer Keys in separate Azure subscriptions.
2. Create a new DEP (Exchange or Multi-workload).
3. Assign the DEP to impacted mailboxes or tenant.
4. Allow background re-encryption (up to 72 hours). The availability key protects data during transition.

How the availability key is used

Exchange and Multi-workload

When you create a DEP, Microsoft 365 generates a DEP Key encrypted three times: once with each Customer Key and once with the availability key. Only encrypted versions are stored.

Decryption flow:

1. Decrypt the DEP Key using a Customer Key.
2. Use the DEP Key to decrypt the Mailbox/Workload Key.
3. Use that key to decrypt and access the data.

Availability key triggers

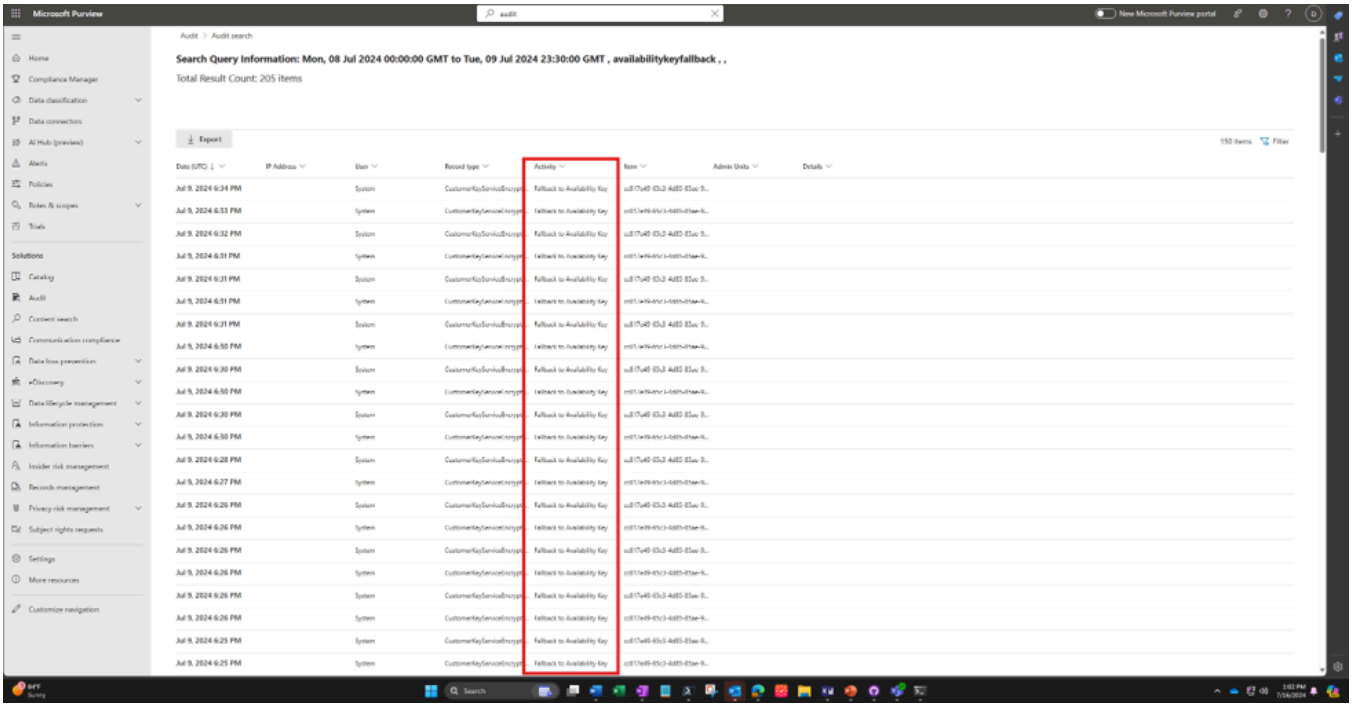
Exchange and Multi-workload

When Microsoft 365 needs a DEP Key:

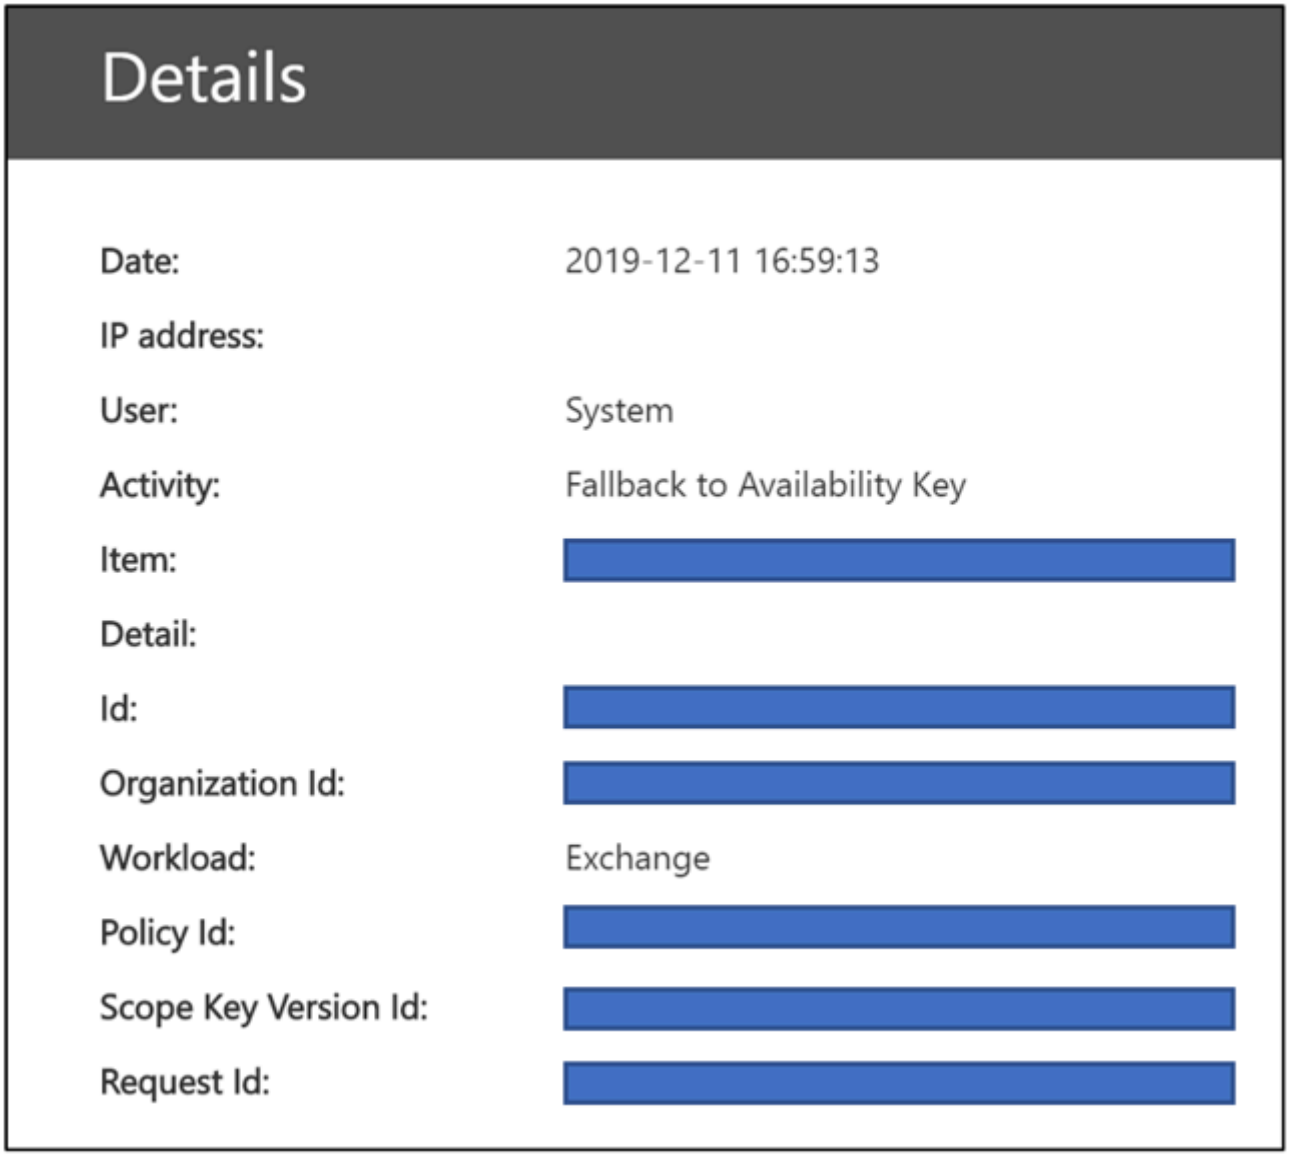
1. Reads the DEP to identify both Customer Keys.
2. Randomly selects one key and requests Azure Key Vault to unwrap the DEP Key.
3. If that fails, tries the alternate key.
4. If both fail, evaluates failure type:

    - **System errors** (Key Vault unavailable, timeouts, network faults): Falls back to availability key.

- **Access denied** (key deleted, permissions removed): User request fails with error (no fallback).



> **ⓘ Important**
>
> Internal operations (mailbox moves, indexing, anti-virus, eDiscovery, DLP) can still fall back to the availability key when both Customer Keys are unreachable, regardless of error type, until you delete the availability key.



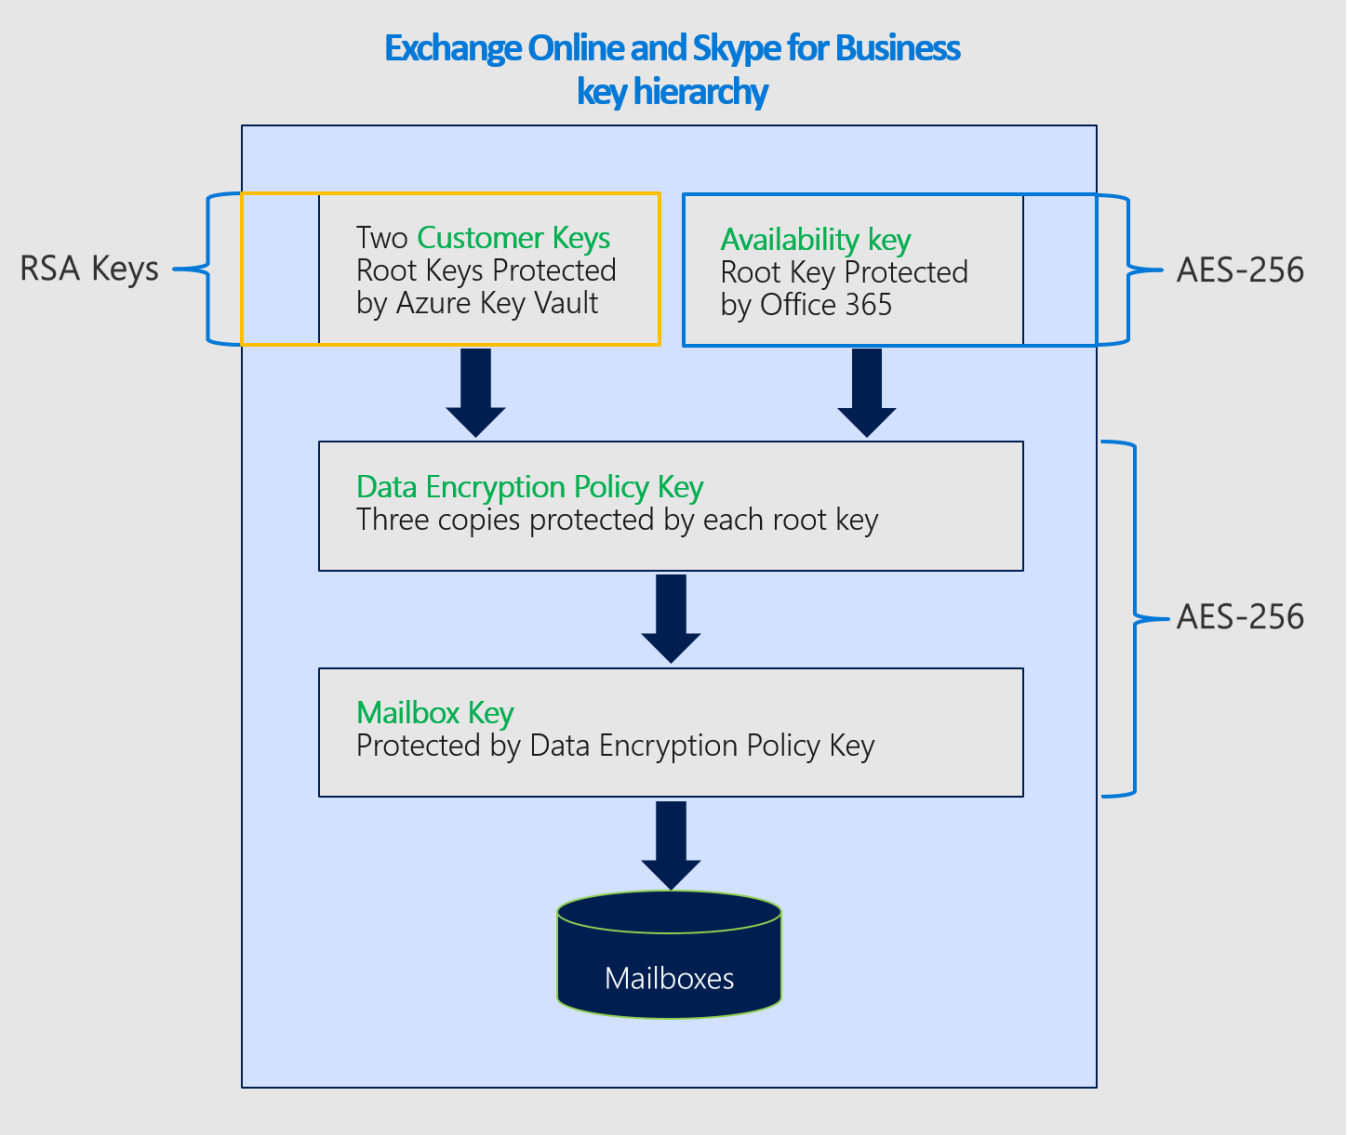
Audit logs and the availability key

Automated background processing doesn't generate customer-visible logs. When the availability key is used, fallback events create Unified Audit Log entries in the Microsoft Purview portal:

- **Record type**: CustomerKeyServiceEncryption
- **Activity**: Fallback to availability key
- **Workload field**: `Exchange` or `M365DataAtRestEncryption`

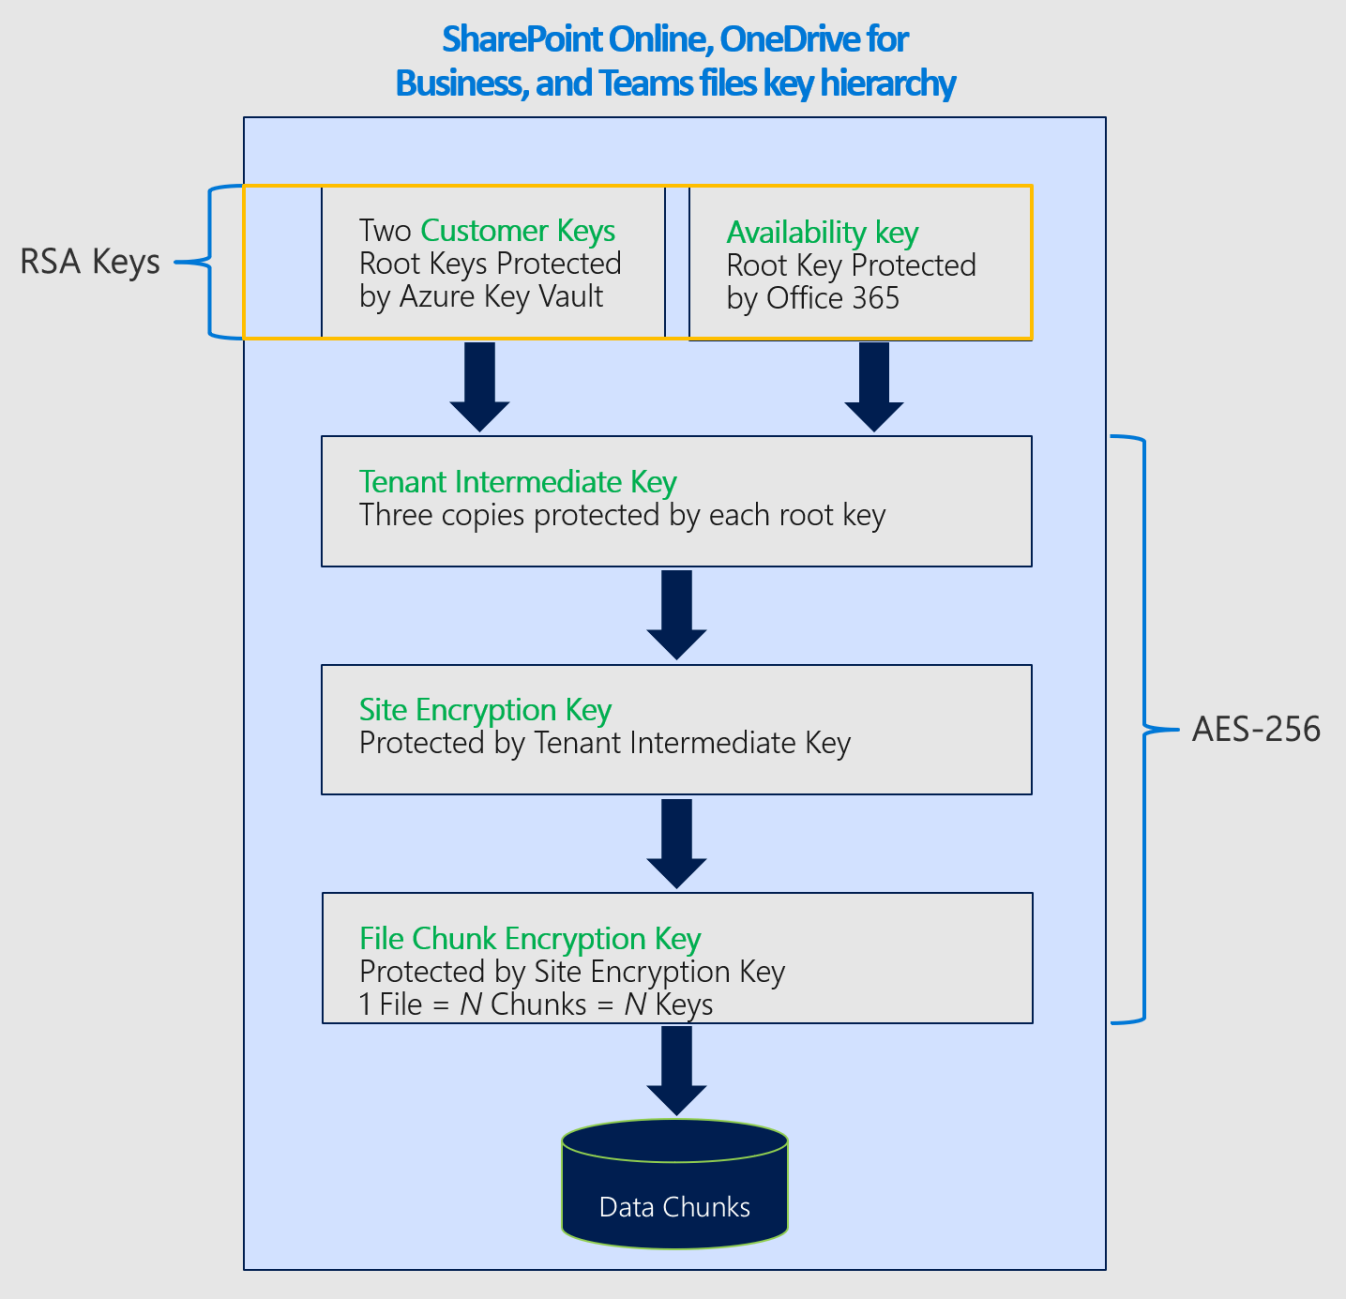
Fields include date, time, organization ID, DEP ID, Policy ID, and Request ID (schema details).

> **Note**
>
> SharePoint availability key usage isn't logged until the customer provides Lockbox approval.



Availability key in the Customer Key hierarchy

The availability key wraps the tier of keys below it in the encryption hierarchy. Algorithms by service:



Expand table

Service	Algorithm
Exchange and Multi-workload	AES-256
SharePoint and OneDrive	RSA-2048

Encryption ciphers for Exchange

Encryption ciphers for SharePoint

Microsoft Purview Customer Lockbox

Article • 02/03/2025

This article provides deployment and configuration guidance for Customer Lockbox. Customer Lockbox supports requests to access data in Exchange Online, SharePoint, OneDrive, Teams, and Windows 365. Additionally, all Microsoft 365 Copilot interactions are covered by Customer Lockbox through the support available for Exchange Online. To recommend support for other services, submit a request at Feedback Portal.

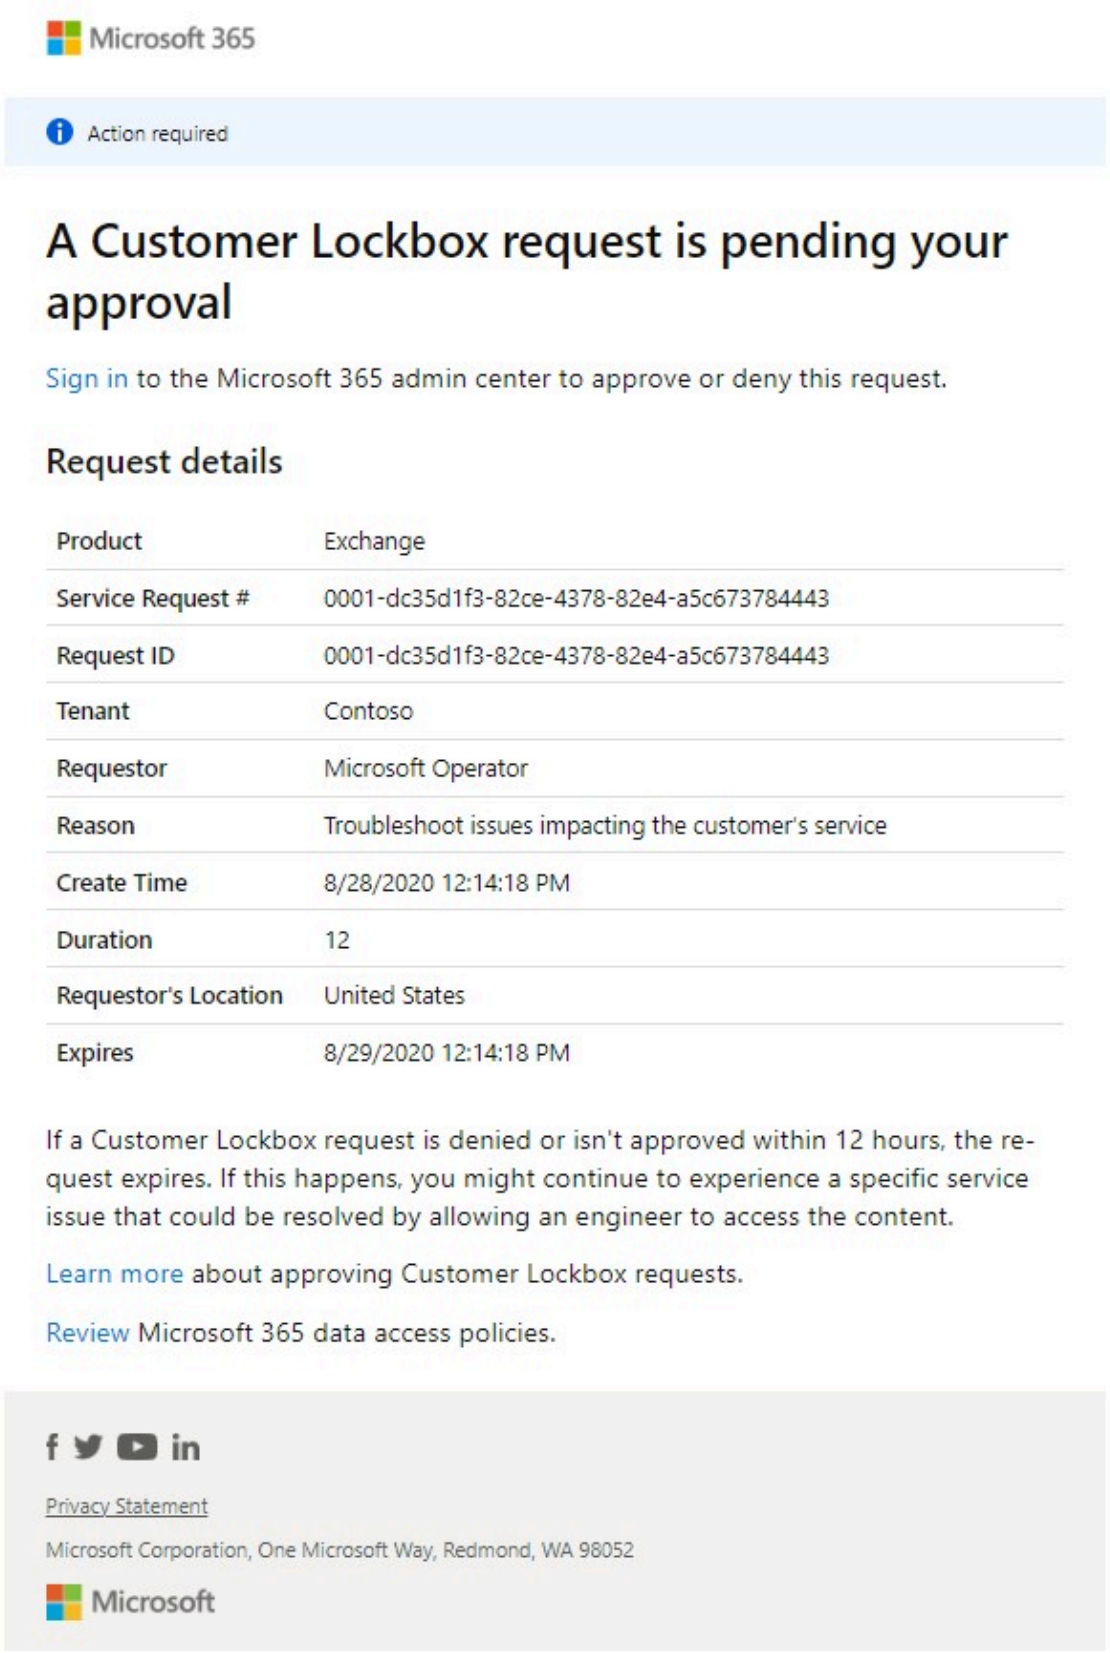
To see the options for licensing your users to benefit from Microsoft Purview offerings, see the Microsoft 365 licensing guidance for security & compliance.

Customer Lockbox ensures that Microsoft can't access your content to do service operations without your explicit approval. Customer Lockbox brings you into the approval workflow process that Microsoft uses to ensure only authorized requests allow access to your content. To learn more about Microsoft's workflow process, see Privileged access management.

Occasionally, Microsoft engineers help troubleshoot and fix issues that arise with the service. Usually, engineers fix issues using extensive telemetry and debugging tools Microsoft has in place for its services. However, some cases require a Microsoft engineer to access your content to determine the root cause and fix the issue. Customer Lockbox requires the engineer to request access from you as a final step in the approval workflow. This gives you the option to approve or deny the request for your organization, and provide direct-access control to your content.

> **Tip**
>
> If you're not an E5 customer, use the 90-day Microsoft Purview solutions trial to explore how additional Purview capabilities can help your organization manage data security and compliance needs. Start now at the **Microsoft Purview trials hub**. Learn details about **signing up and trial terms**.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview **roles and permissions**.



Customer Lockbox overview video

https://learn-video.azurefd.net/vod/player?id=016276d0-7e5d-43b5-8dee-8d4c6c542e23&locale=en-us&embedUrl=%2Fpurview%2Fcustomer-lockbox-requests

Customer Lockbox workflow

These steps outline the typical workflow when a Microsoft engineer starts a Customer Lockbox request:

1. Someone at an organization experiences an issue with their Microsoft 365 mailbox.
2. After the user troubleshoots the issue, but can't fix it, they open a support request with Microsoft Support.
3. A Microsoft support engineer reviews the service request and determines a need to access the organization's tenant to repair the issue.
4. The Microsoft support engineer logs into the Customer Lockbox request tool and makes a data access request that includes the organization's tenant name, service request number, expected start time of access (starts immediately post-approval if not specified), the estimated amount of time the engineer needs access to the data, and the service the request is for.
5. After a Microsoft Support manager approves the request, Customer Lockbox sends the designated approver at the organization an email notification about the pending access request from Microsoft.

Anyone who is assigned the Customer Lockbox access approver admin role in Microsoft 365 admin center can approve Customer Lockbox requests.

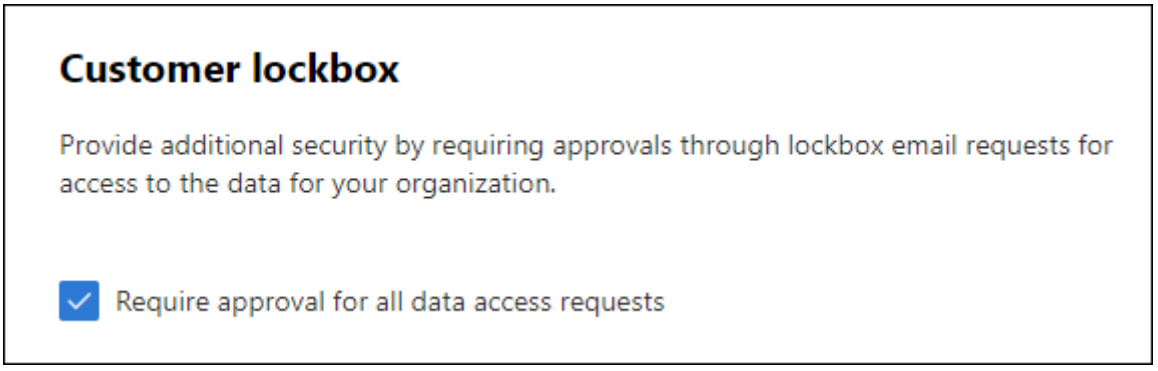
6. The approver signs in to the Microsoft 365 admin center and approves the request. This step triggers the creation of an audit record available by searching the audit log. For more information, see Auditing Customer Lockbox requests.

If the customer rejects the request or doesn't approve the request within 12 hours, the request expires and no access is granted to the Microsoft engineer.

> **Important**
>
> Microsoft does not include any links in Customer Lockbox email notifications requiring you to sign in to Office 365.

7. After the approver from the organization approves the request, the Microsoft engineer receives the approval message, logs into the tenant, and fixes the customer's issue. Microsoft engineers have the requested duration to fix the issue after which the access is automatically revoked.

> **Note**
>
> All actions performed by a Microsoft engineer are logged in the audit log. You can search for and review these audit records.

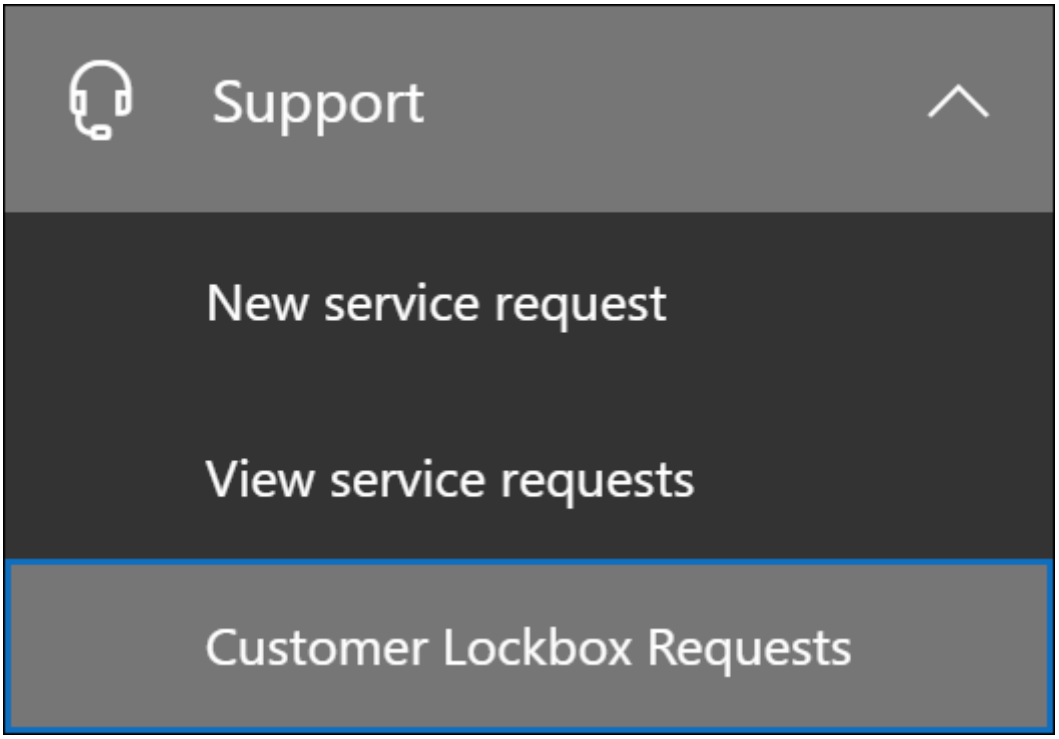


Turn Customer Lockbox requests on or off

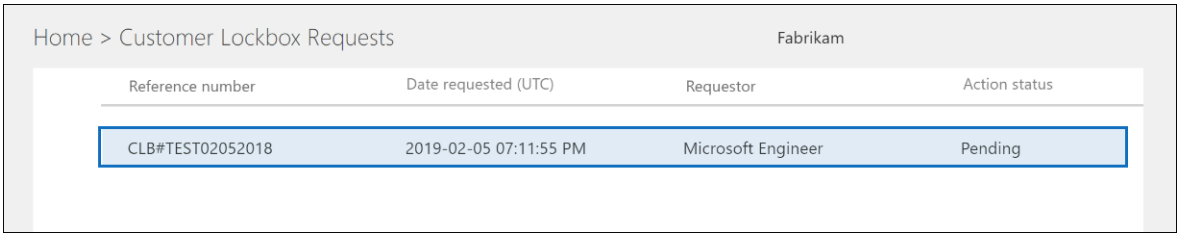
You can turn on Customer Lockbox controls in the Microsoft 365 admin center. When you turn on Customer Lockbox, Microsoft must obtain your organization's approval before accessing any of your tenant's content.

1. Using a work or school account that has either the global administrator or the **Customer Lockbox access approver** role assigned, go to https://admin.microsoft.com and sign in.

2. Choose **Settings** > **Org Settings** > **Security & Privacy**.

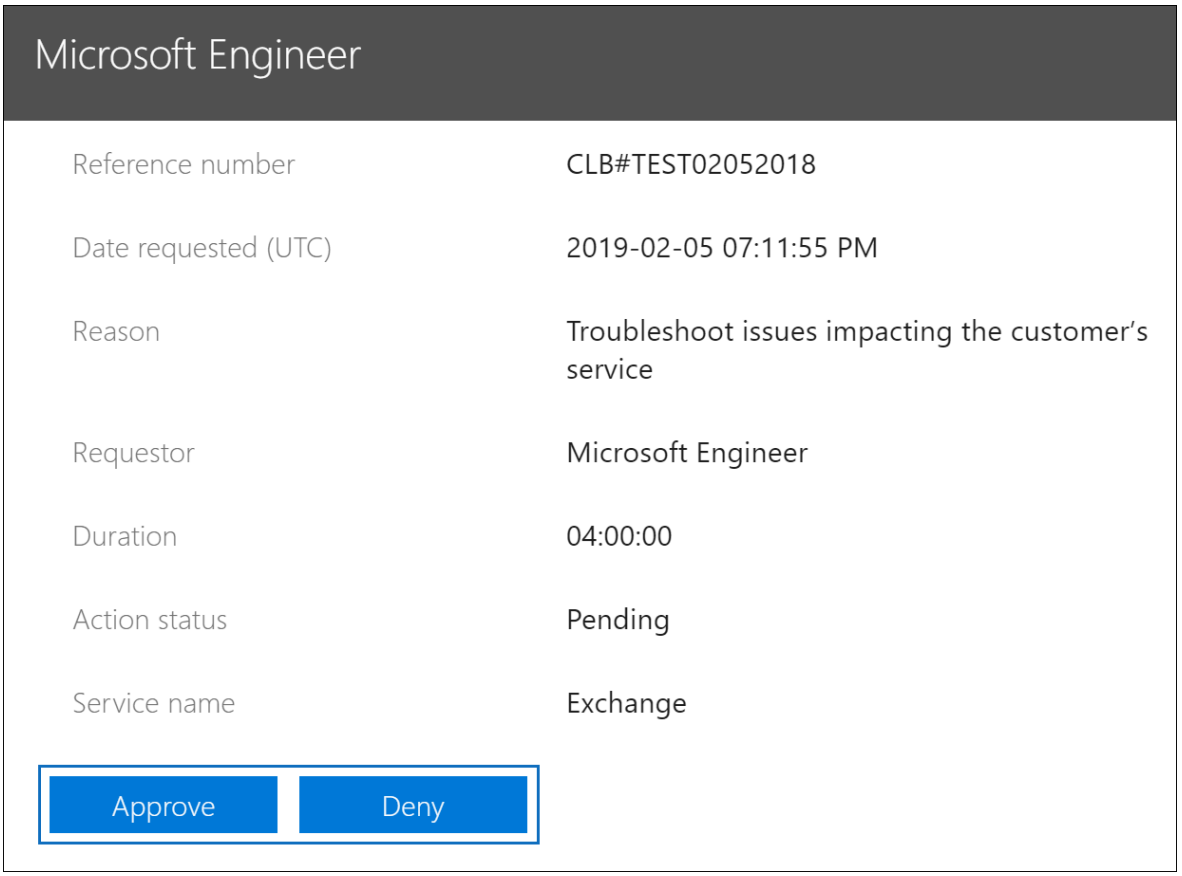


3. Select **Security & Privacy**, then select **Customer Lockbox** in the left column. Check the **Require approval for all data access requests** checkbox and save the changes to turn on the feature.



Approve or deny a Customer Lockbox request

1. Using a work or school account that has either the global administrator or the **Customer Lockbox access approver** role assigned, go to https://admin.microsoft.com and sign in.



2. Choose **Support** > **Customer Lockbox Requests**.

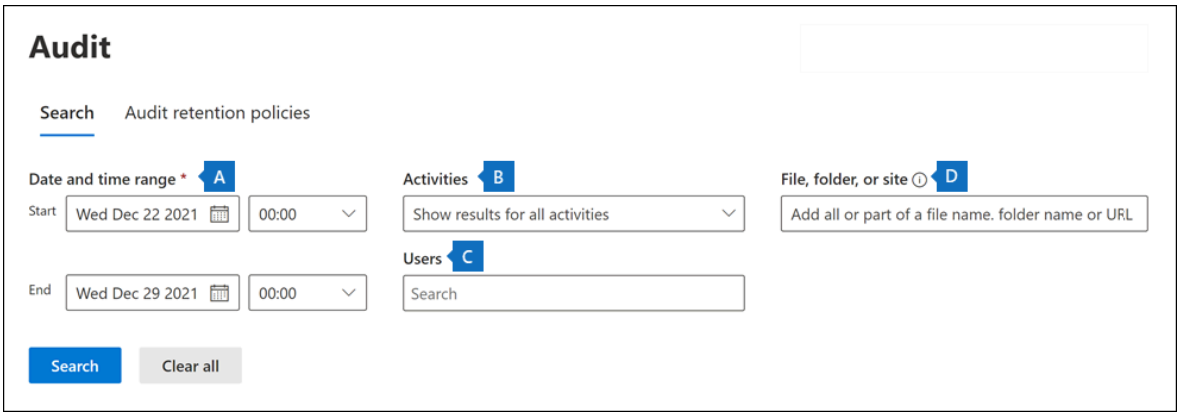
   A list of Customer Lockbox requests displays.

3. Select a Customer Lockbox request, and then choose **Approve** or **Deny**.

A confirmation message about the approval of the Customer Lockbox request displays.

> **Note**
>
> Use the Set-AccessToCustomerDataRequest cmdlet to approve, deny, or cancel Microsoft Purview Customer Lockbox requests that control access to your data by Microsoft support engineers. For more information, see Set-AccessToCustomerDataRequest.

Auditing Customer Lockbox requests



Audit records that correspond to Customer Lockbox requests are logged in the Microsoft 365 audit log. You can access these logs by using the audit log search tool in the Microsoft Purview portal. Actions related to accepting or denying a Customer Lockbox request and actions performed by Microsoft engineers (when access requests are approved) are also logged in the audit log. You can search for and review these audit records.

Search the audit log for activity related to Customer Lockbox requests

Before you can use the audit log to track requests for Customer Lockbox, there are some steps you need to take to set up audit logging, including assigning permissions to search the audit log. For more information, see Get started with auditing solutions. Once you've completed the setup, use these steps to create an audit log search query to return audit records related to Customer Lockbox:

1. Go to https://compliance.microsoft.com.
2. Sign in using an account that has been assigned the appropriate permissions to search the audit log.
3. In the left pane of the compliance center, choose **Audit**.

   The **Search** tab on the **Audit** page is displayed.

4. Configure the following search criteria:

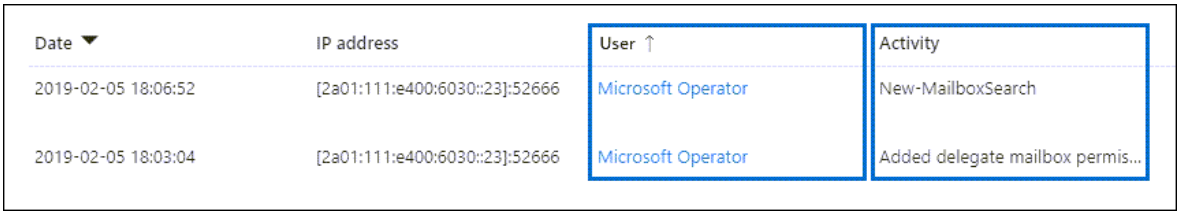
   a. **Start date** and **End date**. Select a date and time range to display the events that occurred within that period.

   b. **Activities**. Leave this field blank so that the search returns audit records for all activities. This is necessary to return any audit records related to Customer

Lockbox requests and corresponding activity performed by Microsoft engineers.

c. **Users**. Leave this field blank.

d. **File, folder, or site**. Leave this field blank.



5. Click **Search** to run the search using your search criteria.

   The search results are displayed after a few moments. More search results will be added to the page until the search is complete.

6. Click the header in the **Activity** column to sort the results alphabetically based on the values in the **Activity** column.

7. Scroll down and look for audit records with an activity of **Set-AccessToCustomerDataRequest**. Records with this activity are related to an approver in your organization approving or denying a Customer Lockbox request.

8. Alternatively, click the header in the **User** column to sort the results alphabetically using the values in the **User** column. Look for the value of **Microsoft Operator**, which indicates activities performed by a Microsoft engineer in response to an approved Customer Lockbox request. The **Activity** column displays the action performed by the engineer.

9. In the list of results, click an audit record to display it.

Export the audit log search results

You can also export the audit log search results to a CSV file and then open the file in Excel to use the filtering and sorting capabilities to make it easier to find and view audit records related to a Customer Lockbox access request.

To export audit records, use the previous steps to search the audit log. When the search is complete, select **Export** > **Download all results** at the top of the search results page. When the export process is complete, you can download the CSV file to your local computer. For more detailed instructions, see Export, configure, and view audit log records.

After you download the file, you can open it in Excel and then filter on the **Operations** column to display audit records for **Set-AccessToCustomerDataRequest** activities. You can also filter on the **UserIds** column (using the value **Microsoft Operator**) to display audit records for activities performed by Microsoft engineers.

> **Note**
>
> When viewing audit records in the CSV file, additional information is contained in the **AuditData** column. The information in this column is contained in a JSON object, which contains multiple properties that are configured as *property:value* pairs separated by commas. You can use the JSON transform feature in the Power Query Editor in Excel to split each property in the JSON object in the **AuditData** column into multiple columns so that each property has its own column. This makes it easier to interpret this information. For detail instructions, see **Format the exported audit log using the Power Query Editor**.

Use PowerShell to search and export audit records

An alternative to using the audit search tool in the Microsoft Purview portal is to run the Search-UnifiedAuditLog cmdlet in Exchange Online PowerShell. One advantage of using PowerShell is that you can specifically search for **Set-AccessToCustomerDataRequest** activities or activities performed by Microsoft engineers related to a Customer Lockbox request.

After you connect to Exchange Online PowerShell, run one of the following commands. Replace the placeholders with a specific date range.

Search for `Set-AccessToCustomerDataRequest` activities

PowerShell

```
Search-UnifiedAuditLog -StartDate xx/xx/xxxx -EndDate xx/xx/xxxx -Operations
Set-AccessToCustomerDataRequest
```

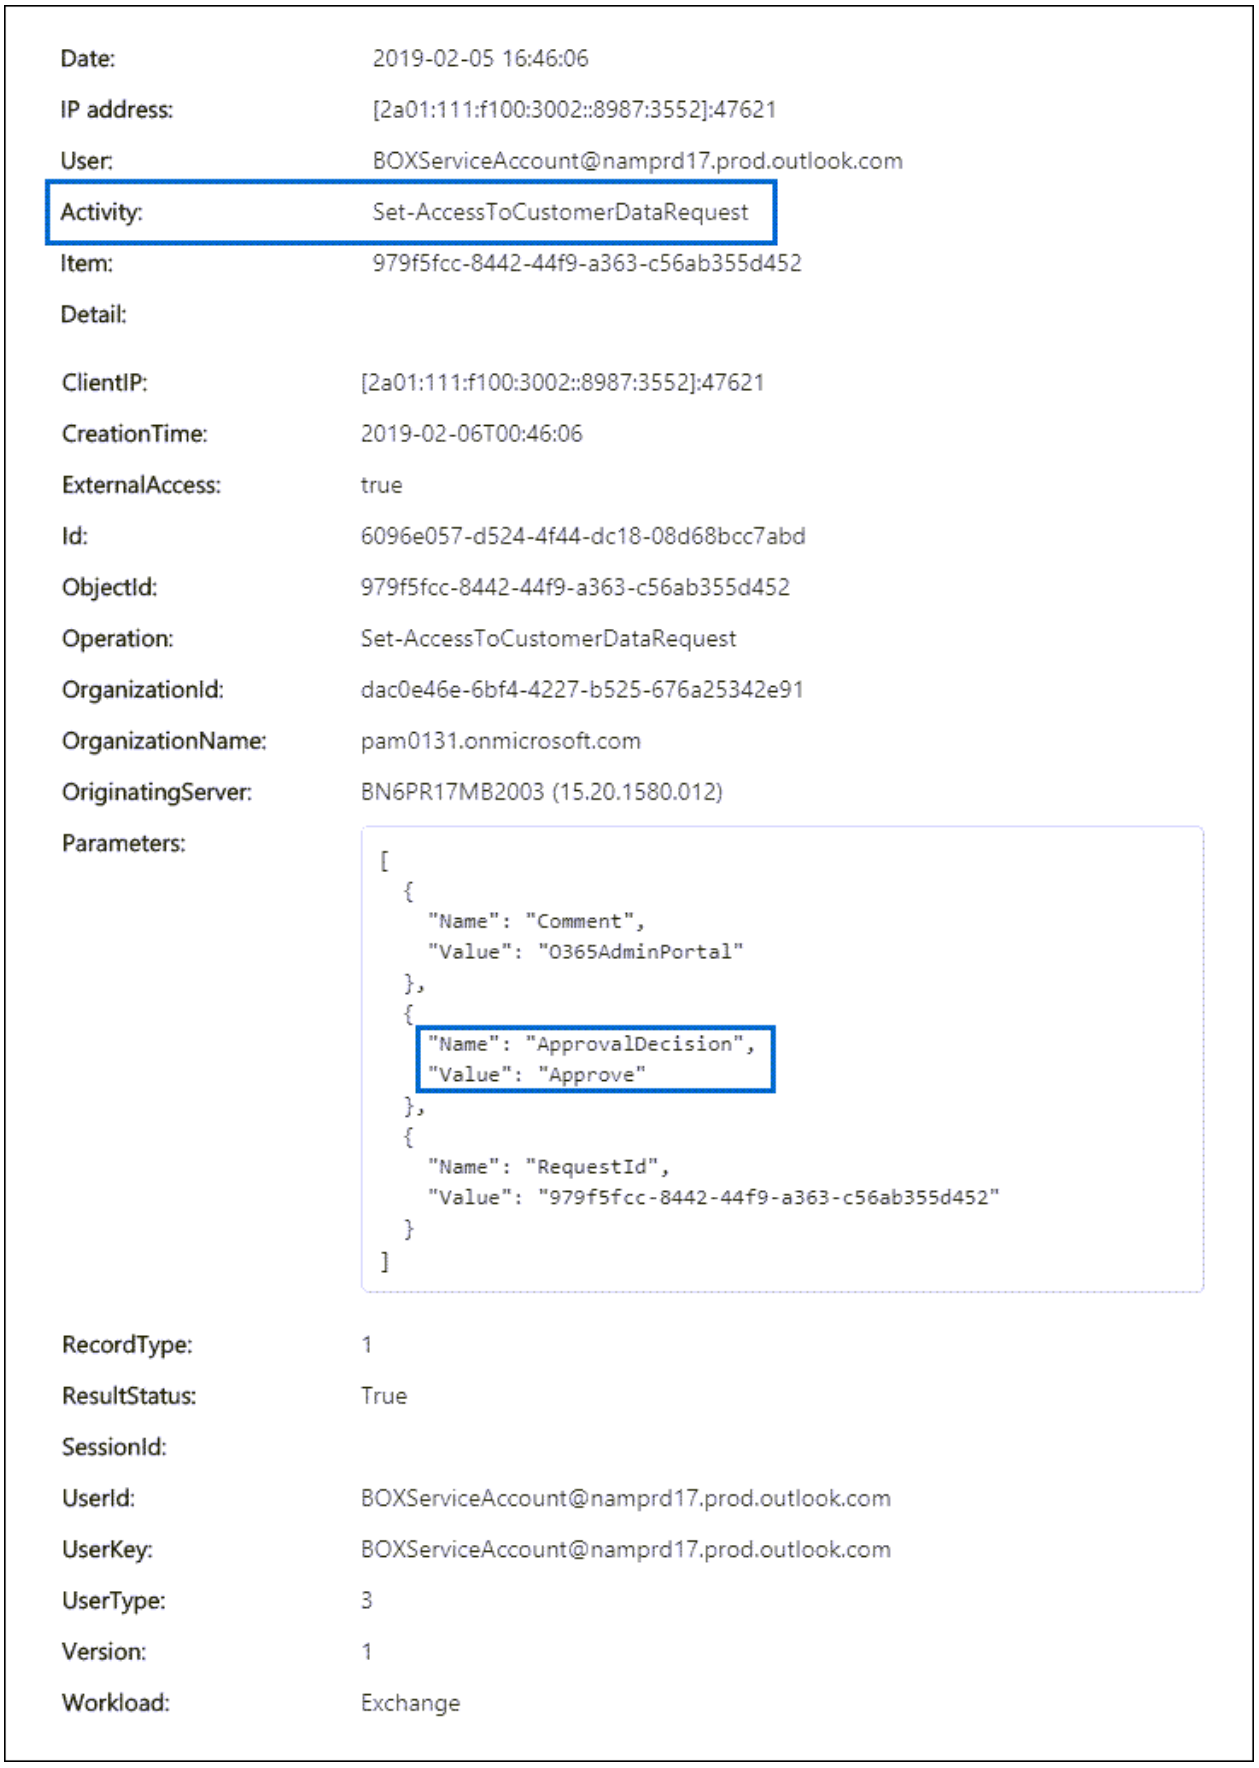
Search for activities performed by Microsoft engineers

PowerShell

```
Search-UnifiedAuditLog -StartDate xx/xx/xxxx -EndDate xx/xx/xxxx -UserIds
"Microsoft Operator"
```

For more information and examples, see Use PowerShell to search and export audit log records.

We've also provided a PowerShell script that you can use to search the audit log and export the results to a CSV file. For more information, see Use a PowerShell script to search the audit log.



Audit record for a Customer Lockbox request

When a person in your organization approves or denies a Customer Lockbox request, the audit record is logged in the audit log contains the following information.

Expand table

Audit record property	Description
Date	The date and time when the Customer Lockbox request was approved or denied.
IP address	The IP address of the machine the approver used to approve or deny a request.
User	The service account BOXServiceAccount@[customerforest].prod.outlook.com.
Activity	Set-AccessToCustomerDataRequest; this is the auditing activity that is logged when you approve or deny a Customer Lockbox request.
Item	The Guid of the Customer Lockbox request

The following screenshot shows an example of an audit record that corresponds to an approved Customer Lockbox request. If a Customer Lockbox request was denied, then the value of `ApprovalDecision` parameter would be `Deny`.

Audit record for an action performed by a Microsoft engineer

The actions performed by a Microsoft engineer after a Customer Lockbox request is approved (and that may result in accessing customer content) are logged in the audit

log. These records contain the following information.

Expand table

Audit record property	Description
Date	Date time when the action was performed. The time that this action was performed will be within 4 hours of when the Customer Lockbox request was approved.
IP address	The IP Address of the machine Microsoft engineer used.
User	Microsoft Operator; this value indicates the record is related to a Customer Lockbox request.
Activity	Name of the activity performed by the Microsoft engineer.
Item	<empty>

Frequently asked questions

Which Microsoft 365 services does Customer Lockbox apply to?

Customer Lockbox is currently supported in Exchange Online, SharePoint Online, OneDrive for Business, Teams, and Windows 365.

Is Customer Lockbox available to all customers?

Customer Lockbox is included with the Microsoft 365 or Office 365 E5 subscriptions and can be added to other plans with an Information Protection and Compliance or an Advanced Compliance add-on subscription. For Government customers, Customer Lockbox is included with Microsoft 365 or Office 365 G5 subscription. See Plans and pricing for more information.

What is customer content?

Customer content is the data created by users of Microsoft 365 services and applications. Examples of customer content include:

- Email body or email attachments

- SharePoint site contents
- Information in the body of a SharePoint file
- Skype for Business presentation file body
- Instant messages (IM) or voice conversations
- Text entered in Teams chats and Teams channels, for example, 1:1 chats, group chats, shared channels, private channels, and meeting chat
- Other data pasted into Teams chat threads, such as code snippets, images, audio and video messages, and links
- App and bot data in Teams chats and Teams channels
- Teams activity feed
- Teams meeting recordings and transcripts
- Voicemail
- Files posted to Teams chats and Teams channels
- Microsoft 365 Copilot interactions
- Customer-generated blob or structured storage data (for example, SQL Containers)
- Customer-owned security information (for example, certificates, encryption keys, and passwords)
- Inferences, and all subsequent inferences, if customer content remains

For more information about customer content in Office 365, see the Office 365 Trust Center.

Who is notified when there is a request to access my content?

Global administrators and anyone assigned the Customer Lockbox access approver admin role are notified. These are also the same users who can approve for Customer Lockbox requests.

Who can approve or reject these requests in my organization?

Global administrators and anyone assigned the Customer Lockbox access approver admin role can approve Customer Lockbox requests. Customers control these role assignments in their organizations.

How do I opt in to Customer Lockbox?

A global administrator can enable and configure Customer Lockbox in the Microsoft 365 admin center.

If I approve a Customer Lockbox request, what can the engineer do and how will I know what the Microsoft engineer did?

After you approve a Customer Lockbox request, the Microsoft engineer granted these necessary privileges to access customer content by using pre-approved cmdlets. Actions taken by Microsoft engineers in response to Customer Lockbox requests are logged and accessible in the audit log in the Security & Compliance Center.

How do I know that Microsoft follows the approval process?

You can cross-reference the email approval notifications sent to admins and approvers in your organization with the Customer Lockbox request history in the Microsoft 365 admin center.

Customer Lockbox is included in the latest SOC 1 SSAE 16 audit report. For more details, you can find the latest reports in the Microsoft Service Trust Portal.

Can Microsoft modify the list of approvers for my tenant? If not, how is it prevented?

Only a global administrator in your organization can specify who can approve Customer Lockbox requests. That means only the members of the Global administrator group in Microsoft Entra ID can specify who can approve request. Membership of the Global administrator group in Microsoft Entra ID is managed only by your organization.

What if I need more information about a content access request to approve it?

Each Customer Lockbox request contains a Microsoft 365 service request number. You can contact Microsoft Support and reference this service number to get more information about the request.

When a Customer Lockbox request is approved, how long are the permissions valid?

Currently, the maximum period for the access permissions granted to the Microsoft engineer is 4 hours. The Microsoft engineer can also request a shorter period.

How can I get a history of all Customer Lockbox requests?

All Customer Lockbox requests are viewed in the Microsoft 365 admin center.

How do I correlate the content access requests with the related audit logs?

The Compliance Center Activity Feed contains log activities of Customer Lockbox. Customers can cross-reference the Customer Lockbox log activities from the activity feed against the email request they receive.

What happens when a customer doesn't respond to a Customer Lockbox request?

Customer Lockbox requests have a default duration of 12 hours. If you don't respond to a request within 12 hour, the request expires.

What does Microsoft do when a customer rejects a Customer Lockbox request?

If a customer rejects a Customer Lockbox request, no access to customer content occurs. If a user in your organization continues to experience a service issue requiring Microsoft to access customer content to resolve the issue, then the service issue might persist and Microsoft will inform the user about this.

How do I set up alerts whenever a request has been approved?

There is no built-in option to alert administrators. However, administrators can set up alerts using Microsoft Defender for Cloud Apps.

Does Customer Lockbox protect against data requests from law enforcement agencies or other third parties?

No. Microsoft takes third-party requests for customer data seriously. As a cloud service provider, Microsoft always advocates for the privacy of customer data. In the event we get a subpoena, Microsoft always attempts to redirect the third party to the customer to obtain the information. (Read Brad Smith's blog: Protecting customer data from government snooping). We periodically publish detailed information about the law enforcement requests that Microsoft receives.

See the Microsoft Trust Center regarding third-party data requests and the "Disclosure of Customer Data" section in the Online Services Terms for more information.

How does Microsoft ensure that a member of its staff doesn't have standing access to customer content in Office 365 applications?

Microsoft implements extensive preventive measures through access control systems, and detective measures to identify and address attempts to circumvent these access control systems. Microsoft 365 operates with the principles of least privilege and just-in-time access. Therefore, no Microsoft personnel have permission to access customer content on an ongoing basis. If permission is granted, it is for a limited duration.

Microsoft 365 uses an access control system called *Lockbox* to process requests for permissions that grant the ability to perform operational and administrative functions within the service. An operator must request access to customer content using Lockbox, which then requires a second person to take action on the request (for example, approve it) before access is granted. That second person can't be the requestor and must be designated to approve access to customer content. Only if the request is approved does the operator acquire temporary access to customer content. After the elevation period expires, Lockbox revokes access.

Refer to the Online Services Terms for more details about Microsoft general security practices.

Under what circumstances do Microsoft engineers need access to my content?

The most common scenario where Microsoft engineers need access customer content is when the customer makes a support request that requires access for troubleshooting. A foundational principle of Microsoft 365 is that the service operates without Microsoft access to customer content. Nearly all service operations performed by Microsoft are fully automated and human involvement is highly controlled and abstracted away from customer content. The goal for Microsoft 365 is access to customer content to support the service isn't needed until the customer approves a specific request for Microsoft access.

I already thought my data was secure with the Microsoft cloud, so why do I need Customer Lockbox?

Customer Lockbox provides an extra layer of control by offering customers the ability to give explicit access authorization for service operations. By demonstrating that procedures are in place for explicit data access authorization, Customer Lockbox also helps customers meet certain compliance obligations such as HIPAA and FEDRAMP.

What is Double Key Encryption (DKE)?

> *Microsoft Purview service description*

> *Applies to: Microsoft Purview Double Key Encryption, Microsoft Purview , Microsoft Purview Information Protection*
>
> *Service description for: Microsoft Purview*

Double Key Encryption (DKE) enables you to protect your highly sensitive data to meet specialized requirements. DKE lets you maintain control of your encryption keys. It uses two keys to protect data; one key in your control and a second key you store securely in Microsoft Azure. You maintain control of one of your keys using the Double Key Encryption service. Viewing data protected with Double Key Encryption requires access to both keys.

DKE helps you meet regulatory requirements across several regulations and standards such as the General Data Protection Regulation (GDPR), the Health Insurance Portability and Accountability Act (HIPAA), the Gramm-Leach-Bliley Act (GLBA), Russia's data localization law – Federal Law No. 242-FZ, Australia's Federal Privacy Act 1988, and New Zealand's Privacy Act 1993.

After you set up the DKE service and your keys, you apply protection to your highly sensitive content by using sensitivity labels.

Supported deployment scenarios

DKE supports several different configurations including both cloud and on-premises deployments. These deployments help to ensure that encrypted data remains opaque wherever you store it.

You can host the Double Key Encryption service used to request your key in a location of your choice (on-premises key management server or in the cloud). You maintain the service as you would any other application. Double Key Encryption lets you control access to the Double Key Encryption service. You can store your highly sensitive data on-premises or move it to the cloud. Double Key Encryption gives you the control to store your data and key in the same geographical location.

For more information about the default, cloud-based tenant root keys, see Managing the root key for your Azure Rights Management service.

When your organization should adopt DKE

DKE isn't for every organization, nor for all of your data. Let's say a typical organizational data landscape has the following structure:

- Nonsensitive data (about 80% of data): Most of an organization's data falls into this category. There are no issues or concerns with moving this data to the cloud today. Moving such data to the cloud can be beneficial and the organization can use the security built into the cloud.

- Sensitive (about 15% of data): Sensitive data needs to be protected. The organization expects the cloud service provider to provide security while enhancing productivity for this category of data so that they can meet compliance regulations. You want to ensure this data is labeled correctly using Microsoft Purview Information Protection and is protected with access control and retention and audit policies.

- Highly sensitive (about 5% of data): This set is the organization's crown jewels and needs to be heavily guarded. The organization doesn't want anyone to have access to such data. This category of data can also have regulatory requirements to have the keys in the same geographical region as the data. The keys might also need to be under the organization's strict custody. This content has the highest classification in your organization ("Top Secret") and access is restricted to just a few people. Highly sensitive data is what malicious users are after. Loss of this data can damage the organization's reputation and break trust with their customers.

As mentioned, Double Key Encryption is intended for your most sensitive data that is subject to the strictest protection requirements. You should do due diligence in identifying the right data to cover with this solution before you deploy. In some cases, you might need to narrow your scope and use other solutions. For example, for most of your data, consider Microsoft Purview Information Protection with Microsoft-managed keys or bring your own key (BYOK). These solutions are sufficient for documents that aren't subject to enhanced protections and regulatory requirements. Also, these solutions enable you to use the most powerful Microsoft 365 services; services that you can't use with DKE encrypted content. For example:

- Mail flow rules including anti-malware and spam that require visibility into the attachment
- Microsoft Delve

- eDiscovery
- Content search and indexing
- Office Web Apps including coauthoring functionality
- Copilot

DKE encrypted data isn't accessible at rest to Microsoft 365 services including Copilot. While you're using your DKE encrypted data in Office, the data still isn't accessible to Copilot, and you can't use Copilot in apps while you're using DKE encrypted data.

External applications or services that aren't integrated with DKE through the Microsoft Information Protection SDK are unable to perform actions on the encrypted data. The Microsoft Information Protection SDK 1.7+ supports Double Key Encryption. Applications that integrate with our SDK can reason over this data with sufficient permissions and integrations in place.

When your DKE encrypted data is in use in an Office app, it might be accessible to other Microsoft 365 services, depending on your Office version:

- In the latest versions of Office, DKE encrypted data in use is also not accessible to Microsoft 365 services. Because this change rolled out at the same time as the separate privacy control for sensitivity labels that prevents sending labeled content to connected experiences for analysis, you can identify the minimum Office versions by using the capabilities table and the row **Prevent connected experiences that analyze content**.

- In previous versions of Office, DKE encrypted data in use is accessible to Microsoft 365 services unless you use a policy setting to turn off connected experiences that analyze content. For more information, see Use policy settings to manage privacy controls for Microsoft 365 Apps for enterprise.

Use Microsoft Purview Information Protection capabilities (classification and labeling) to protect most of your sensitive data and only use DKE for your mission-critical data. Double Key Encryption is relevant for sensitive data in highly regulated industries such as financial services and healthcare.

Sensitivity label features that don't support DKE

Because DKE doesn't use a cloud-based key managed by the Azure Rights Management service, several sensitivity label features can't work with DKE-encrypted content:

- **Co-authoring and AutoSave**

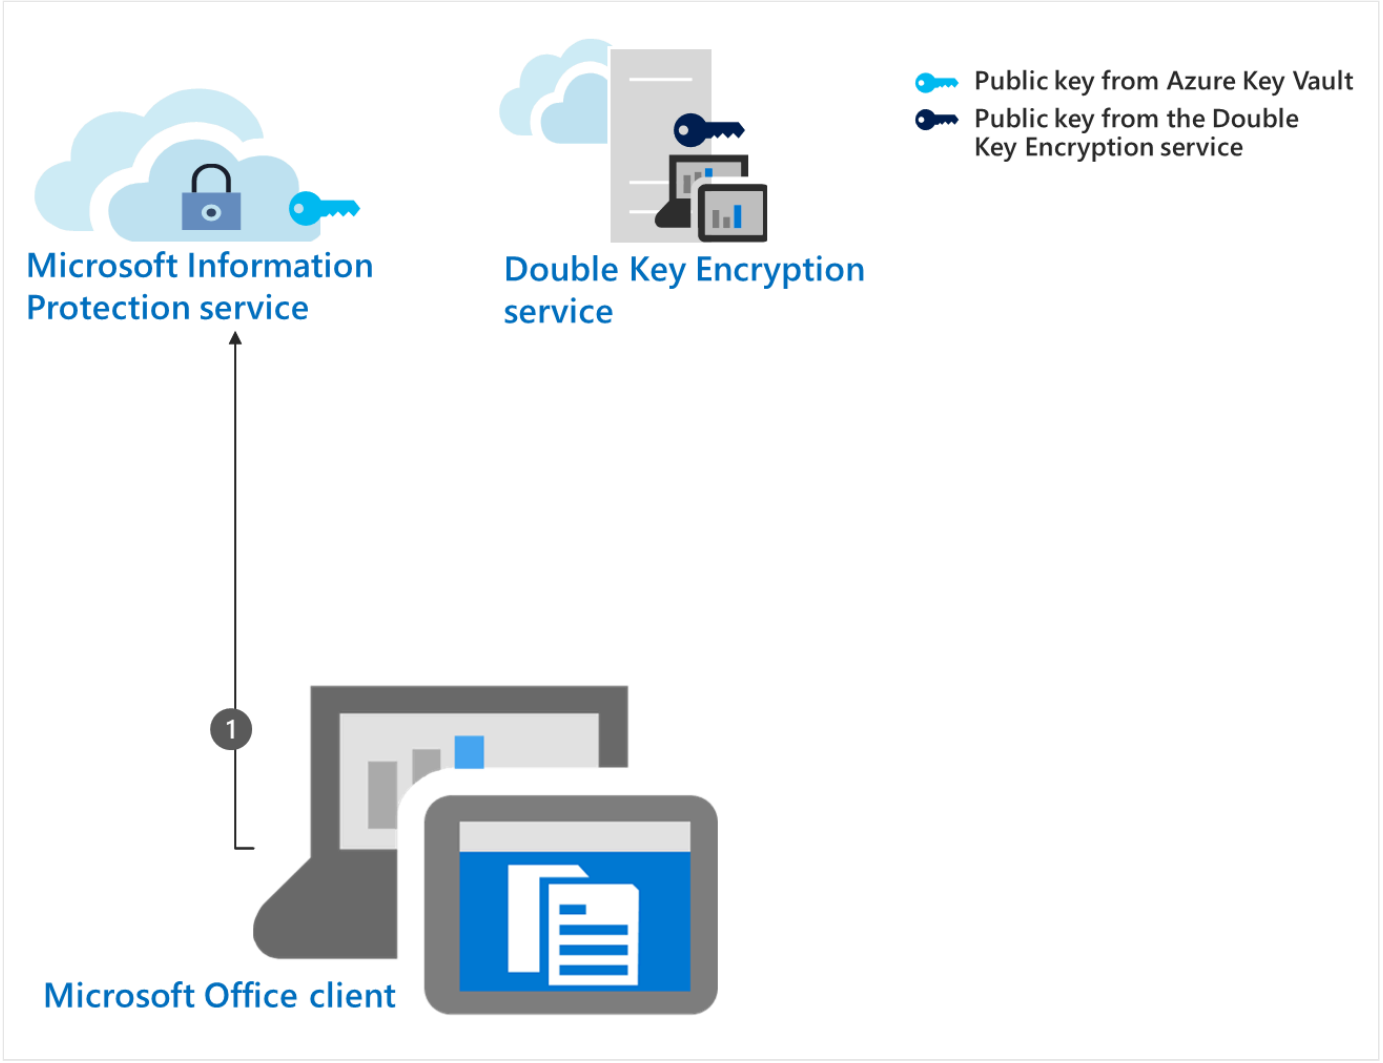
    - Coauthoring and AutoSave aren't supported for Office documents encrypted with DKE. Labels with DKE still display in Office apps, but coauthoring and AutoSave are disabled when the label is applied. For more information, see Coauthoring for files encrypted with sensitivity labels.

- **Files in SharePoint and OneDrive**
    - SharePoint and OneDrive can't process DKE-encrypted files. These files can't be opened in Office for the web, and collaborative features such as coauthoring, eDiscovery, data loss prevention, and search don't work for DKE-encrypted files in these locations. For more information, see Enable sensitivity labels for files in SharePoint and OneDrive.

- **Default label for a SharePoint document library**
    - A sensitivity label that uses DKE can't be set as the default sensitivity label for a SharePoint document library. For more information, see Configure a default sensitivity label for a SharePoint document library.

- **Loop components and pages**
    - Sensitivity labels configured with DKE aren't supported for Loop components and pages. For more information, see Sensitivity labels for Loop components and pages.

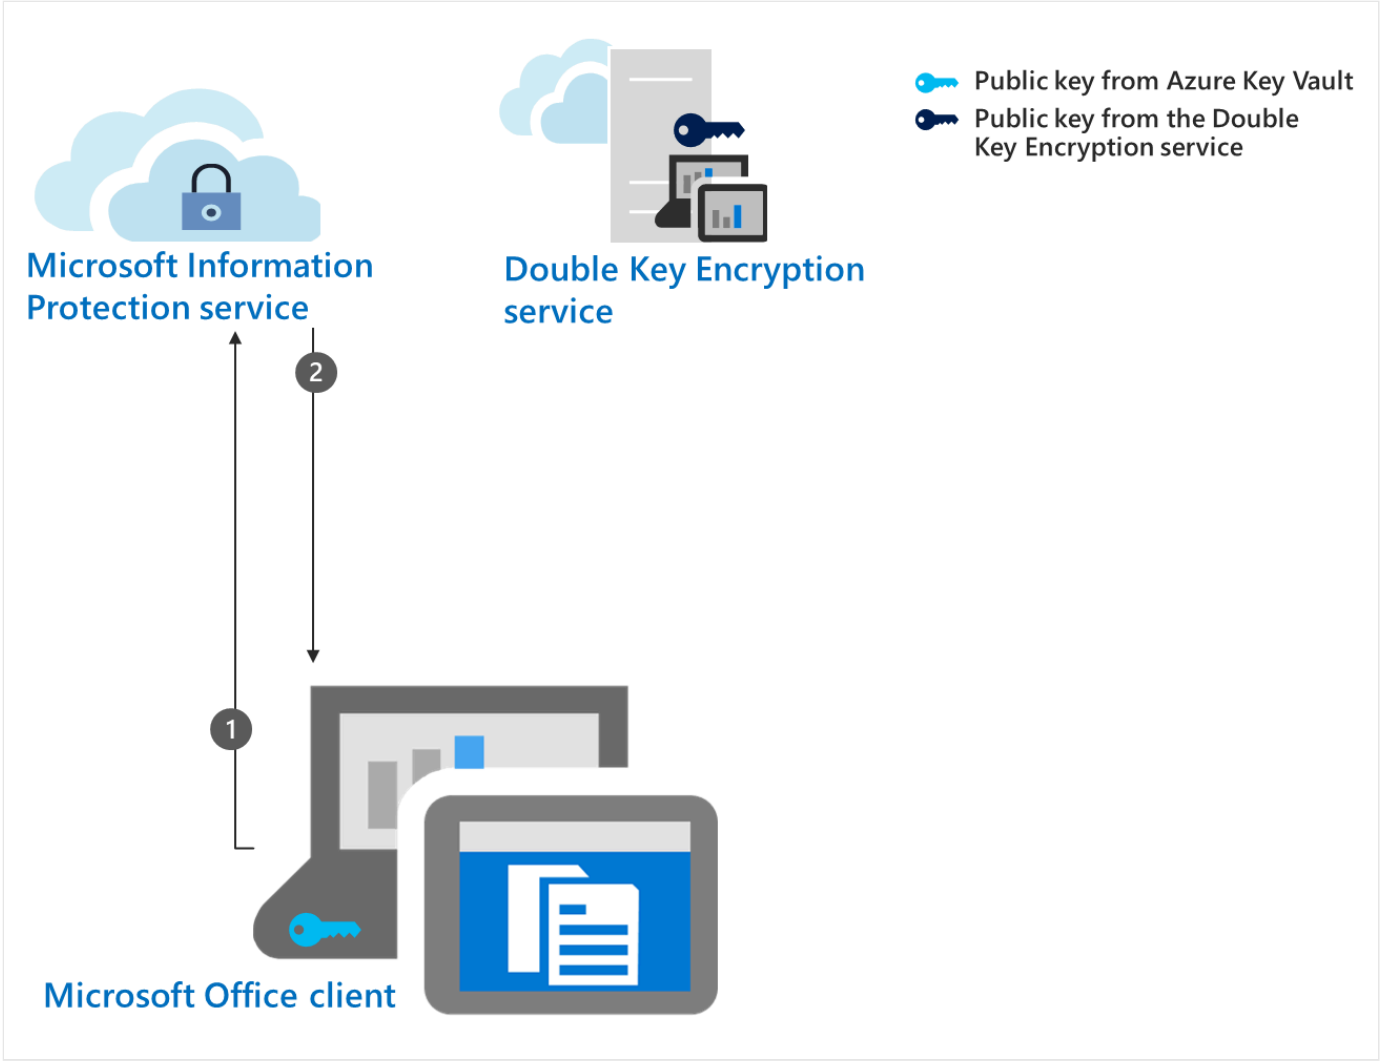
- **Teams meetings and chat**
    - DKE labels can't be used to protect calendar items, Teams meetings, and chat. Meetings and chat require encryption that uses the Azure Rights Management service. For more information, see Use sensitivity labels to protect calendar items, Teams meetings, and chat.



If your organizations have any of the following requirements, you can use DKE to help secure your content:

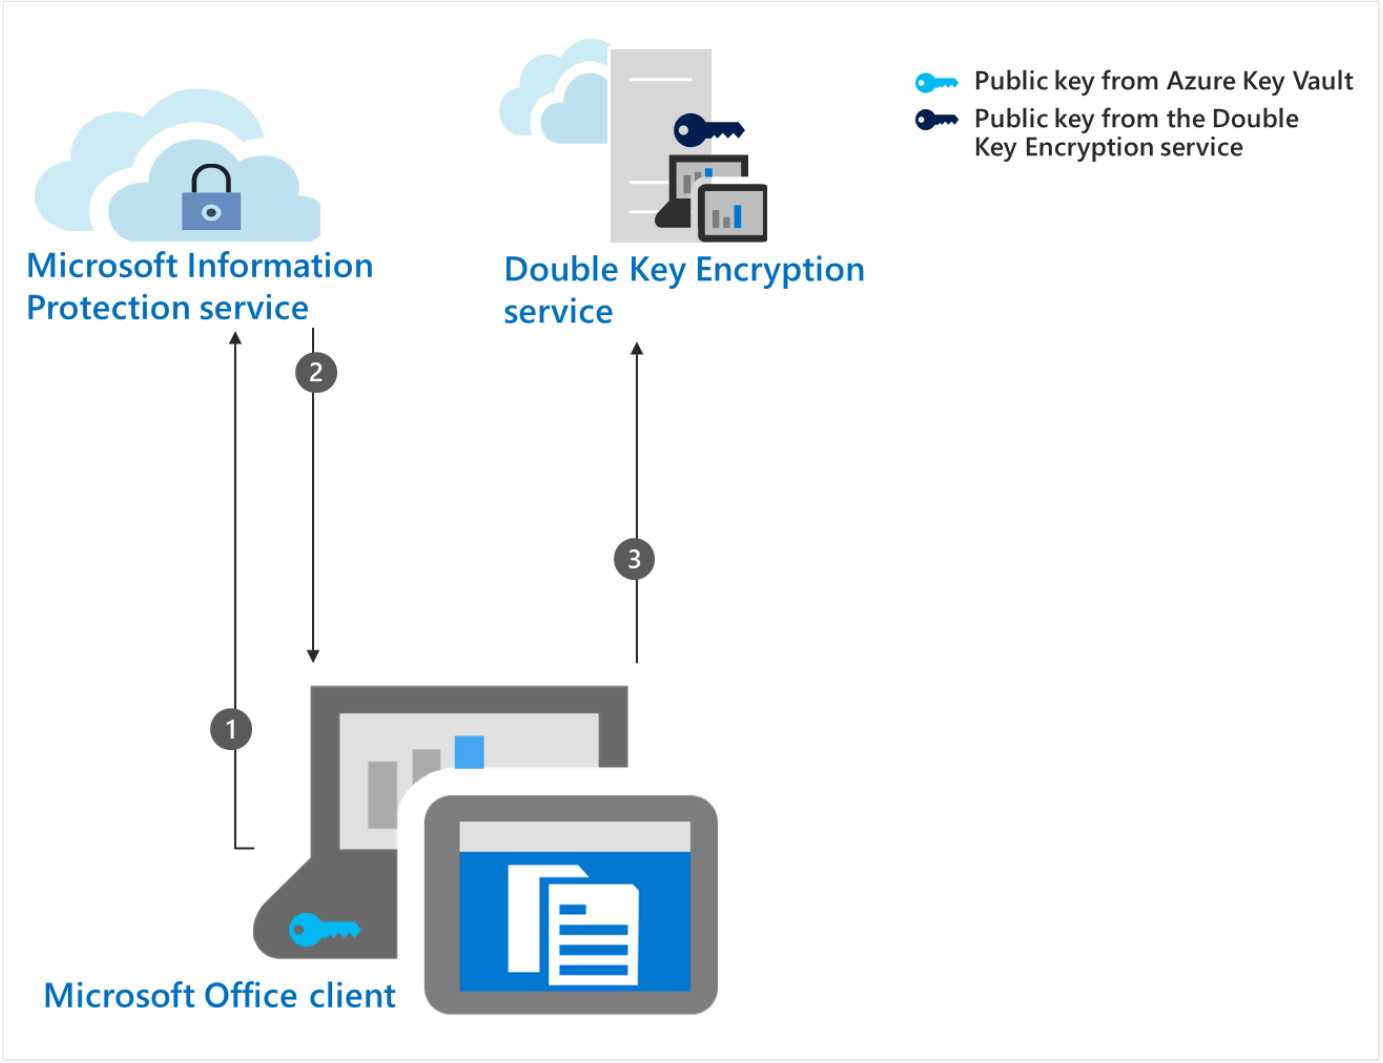
- You have regulatory requirements to hold keys within a geographical boundary.
- All of the keys that you hold for data encryption and decryption are maintained in your data center.

DKE encryption workflow



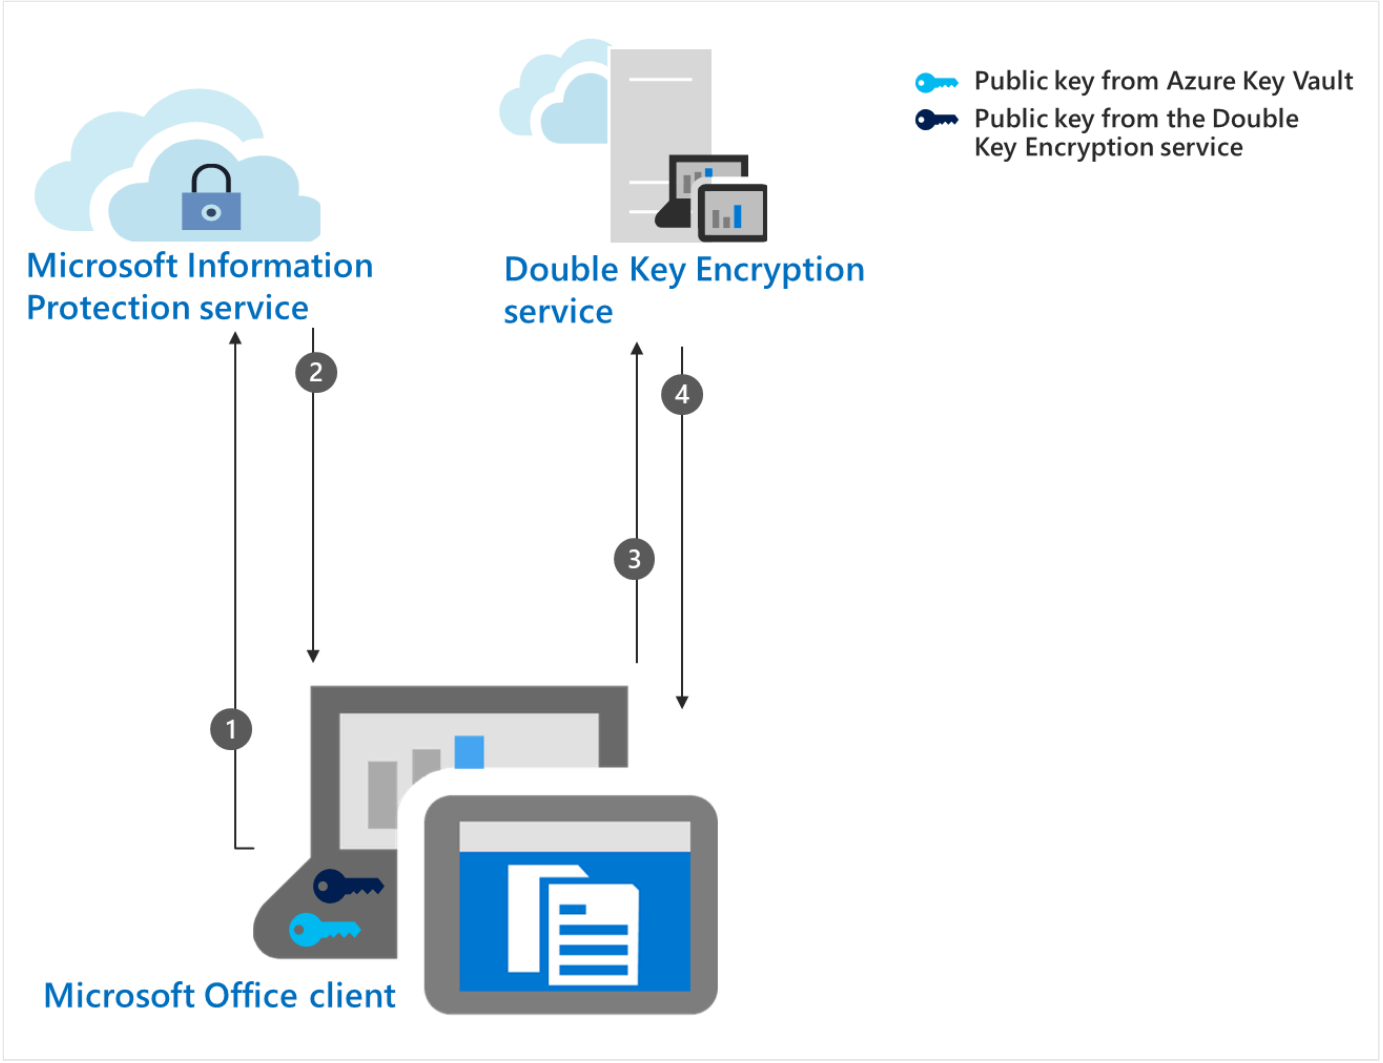
This section breaks apart the workflow into separate steps to illustrate how two keys are used to protect an Office document.

Step 1: Bootstrapping



The Microsoft Office client performs startup configuration tasks and sends requests and information to the Azure Rights Management encryption service. This process is also called *bootstrapping*. Tasks include authorizing the user using Microsoft Entra ID, downloading certificates and templates, and so on. Bootstrapping tasks are first-time connection and startup tasks that give the user access to the Azure Rights Management encryption policies.

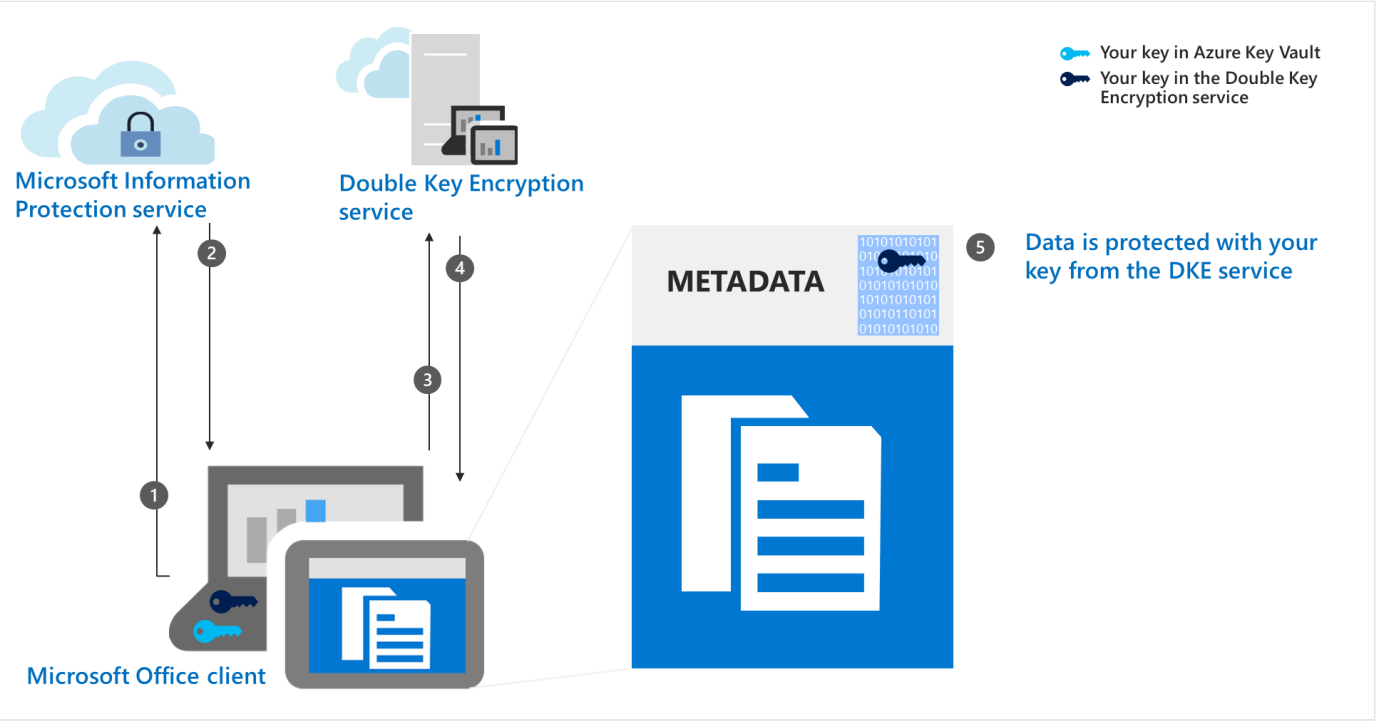
Step 2: Collect and cache the public key for the Azure Rights Management service



The Office app retrieves the public key from the Azure Key Vault in the encryption service based on the authorized user using Microsoft Entra ID. Once collected, the client caches the key for 30 days by default. Once cached, the client doesn't have to bootstrap to the Azure Rights Management service again until the key expires. As an administrator, you can configure a different caching period for the Azure Rights Management service. You need to set a cache period for this key or accept the 30 day default. Without a cache period, offline publishing doesn't work.

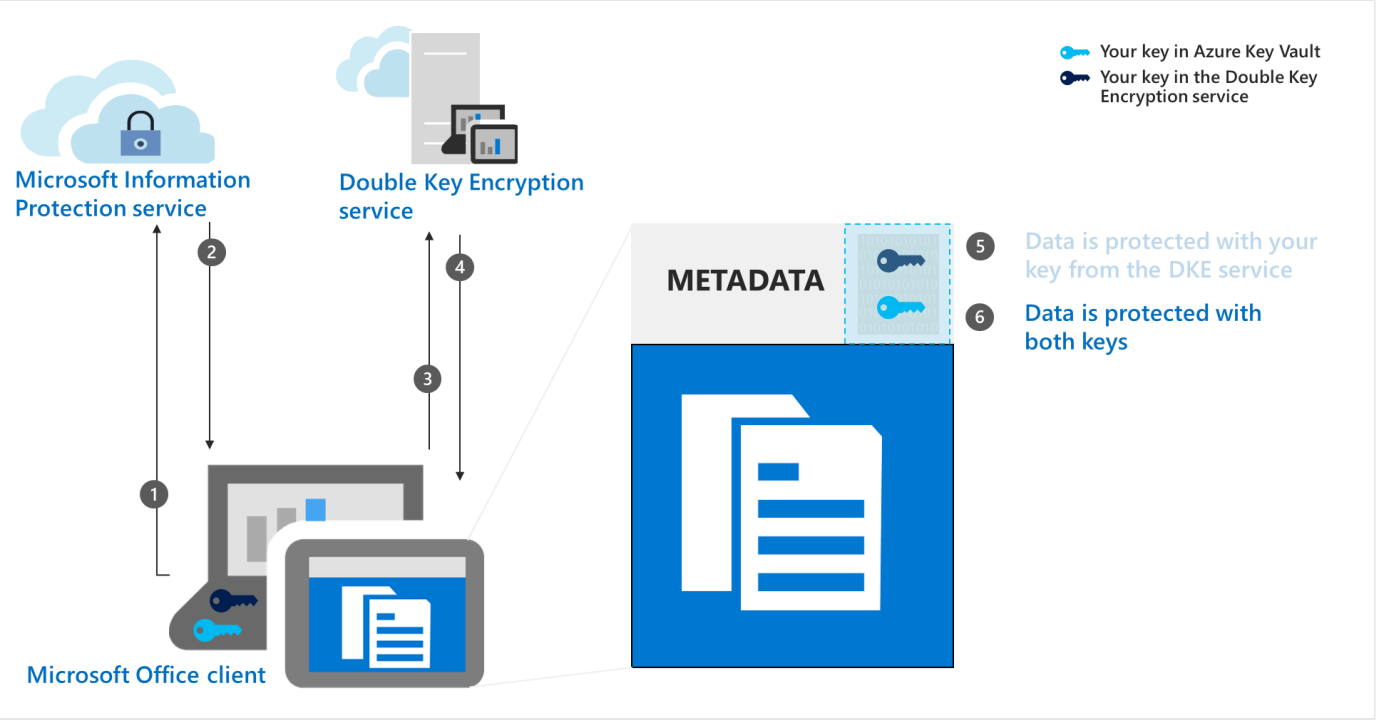
Step 3: Request the DKE public key

The Office client requests your other public key from the Double Key Encryption service based on the authorized user using Microsoft Entra ID.



Step 4: Collect and cache the DKE key

The Double Key Encryption service sends this public key to the Office client. The client caches the key in the device for as long you configured it to. Unlike the key from Azure,



- You don't have to set up a cache period for the key hosted by the Double Key Encryption service.
- If you do want to set up a cache period, you can set it up when you deploy the Double Key Encryption service, or after you deploy.

Step 5: Protect the document with the DKE key

The Microsoft Office client encrypts the part of the metadata **that controls access to the content** using your public key that was retrieved from the Double Key Encryption service.

Step 6: Protect the document with the Azure key

The Microsoft Office client encrypts **the already encrypted part of the document metadata** with your public key from Azure.

The data is now protected with both keys.

System and licensing requirements for DKE

This section details server and client system and configuration requirements that must be met before you can successfully deploy DKE in your environment.

licensing requirements for DKE

Double Key Encryption comes with Microsoft 365 E5. If you don't have a Microsoft 365 E5 license, you can sign up for a trial. For more information about these licenses, see Microsoft 365 licensing guidance for security & compliance.

The Azure Rights Management service is required for DKE

DKE works with sensitivity labels and requires encryption with rights management from Microsoft Purview Information Protection.

DKE labeling requirements for Office apps

Use sensitivity labels built in to Office apps to support DKE in Word, Excel, PowerPoint, and Outlook. For supported versions, see the capabilities tables and the row **Double Key Encryption (DKE)**.

DKE on client computers

Users apply DKE sensitivity labels through these interfaces.

- Sensitivity labeling in Windows Office apps
- Microsoft Purview Information Protection file labeler in Windows File Explorer
- Microsoft Purview Information Protection PowerShell
- Microsoft Purview Information Protection scanner

Install prerequisites on each client computer where you want to protect and consume protected documents.

Supported environments for storing and viewing DKE-protected content

Supported applications. Microsoft 365 Apps for enterprise clients on Windows, including Word, Excel, PowerPoint, and Outlook.

Online content support. You can store documents and files that are protected with Double Key Encryption online in both SharePoint and OneDrive. You must label and protect documents and files with DKE by supported applications before you upload to these locations. You can share encrypted content by email, but you can't view encrypted documents and files online. Instead, you must view protected content using the supported desktop applications and clients on your local computer.

Labeling scenarios outside of Office apps. Apply DKE labels outside of Office apps using the Microsoft Purview Information Protection file labeler in File Explorer right-click options, Microsoft Purview Information Protection PowerShell labeling cmdlets, or the Microsoft Purview Information Protection scanner.

Viewing DKE-protected content outside of Office apps. You can use the Microsoft Purview Information Protection Viewer to consume DKE-protected emails and documents such as PDF.

Encrypt Only and Do Not Forward scenarios. Encrypt Only and Do Not Forward aren't supported with DKE in Outlook. All other Office applications support user-defined permission labels with DKE.

Set up Double Key Encryption

07/23/2025

> *Applies to: Microsoft Purview Double Key Encryption, Microsoft Purview, Azure Information Protection*

> *Service description for: Microsoft Purview*

Follow these general steps to set up DKE. Once you complete these steps, your end users can protect your highly sensitive data with Double Key Encryption.

1. Deploy the DKE service as described in this article. Ensure your environment meets the minimum system and licensing requirements. For more information, see System and licensing requirements for DKE.

2. Create a label with Double Key Encryption. In the Microsoft Purview portal, navigate to **Information protection** and create a new label with Double Key Encryption. See Restrict access to content by using sensitivity labels to apply encryption.

3. Configure the registry on client devices so you can use Double Key Encryption labels. Next, protect your data by selecting the Double Key Encrypted label from the Sensitivity ribbon in Microsoft Office.

There are several ways you can complete some of the steps to deploy Double Key Encryption. This article provides detailed instructions so that less experienced admins successfully deploy the service. If you're comfortable doing so, you can choose to use your own methods.

Deploy DKE

This article and the deployment video use Azure as the deployment destination for the DKE service. If you're deploying to another location, you need to provide your own values.

Follow these general steps to set up Double Key Encryption for your organization.

1. Install software prerequisites for the DKE service
2. Clone the Double Key Encryption GitHub repository
3. Modify application settings
4. Generate test keys
5. Build the project
6. Deploy the DKE service and publish the key store
7. Validate your deployment

8. Register your key store
9. Create sensitivity labels using DKE
10. Migrate protected files from HYOK labels to DKE labels

When you're done, you can encrypt documents and files using DKE. For information, see Apply sensitivity labels to your files and email in Office.

Install software prerequisites for the DKE service

Install these prerequisites on the computer where you want to install the DKE service.

.NET 8.0 SDK. Download and install the SDK from Download .NET 8.0.

Visual Studio Code. Download Visual Studio Code from https://code.visualstudio.com/. Once installed, run Visual Studio Code and select **View** > **Extensions**. Install these extensions.

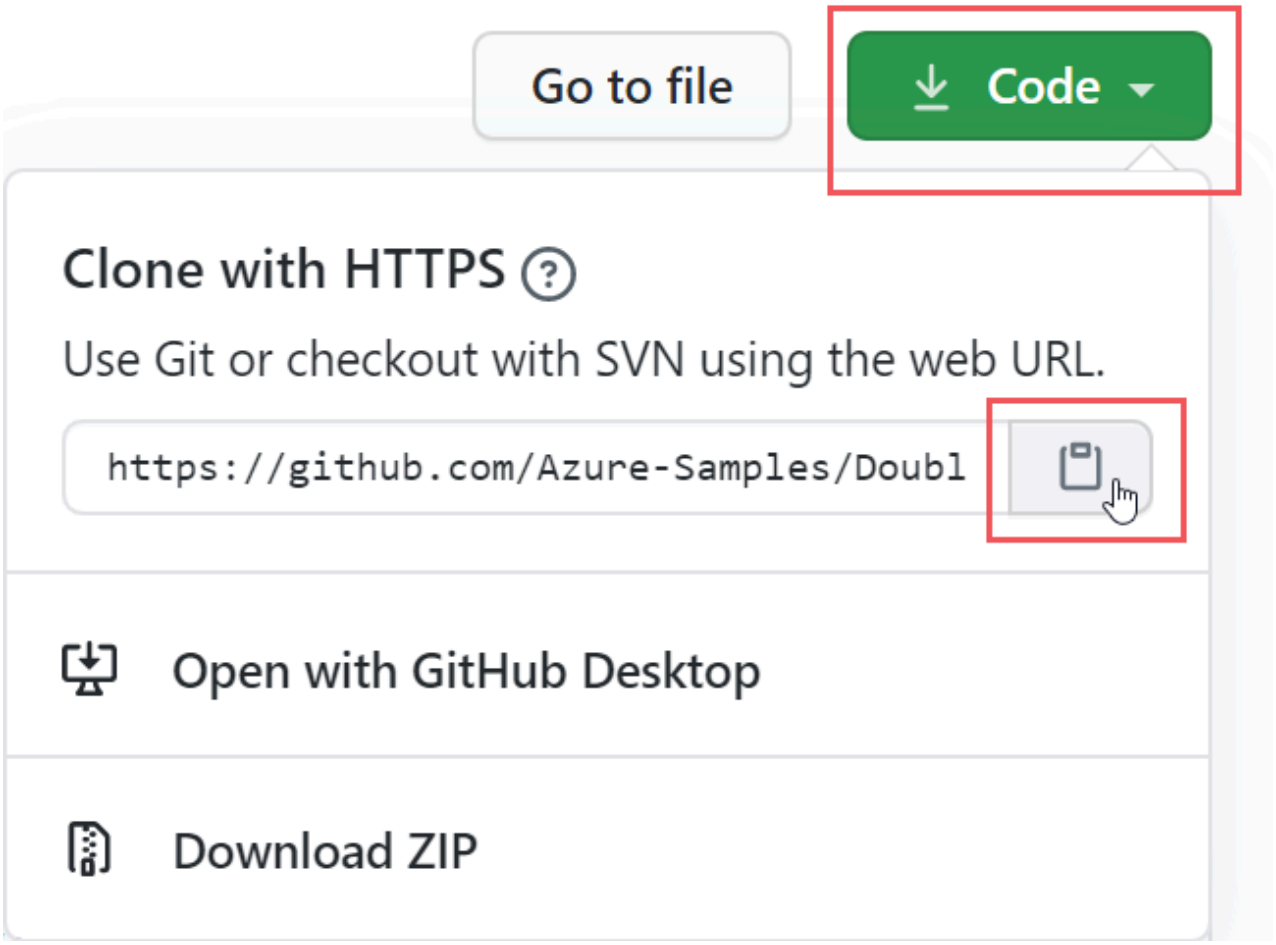
- C# for Visual Studio Code
- NuGet Package Manager

Git resources. Download and install one of the following.

- Git
- GitHub Desktop
- GitHub Enterprise

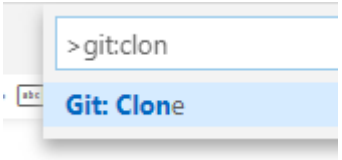
OpenSSL. You must have OpenSSL installed to generate test keys after you deploy DKE. Make sure you're invoking it correctly from your environment variables path. For example, see "Add the installation directory to PATH" at https://www.osradar.com/install-openssl-windows/ for details.

Clone the DKE GitHub repository



Microsoft supplies the DKE source files in a GitHub repository. You clone the repository to build the project locally for your organization's use. The DKE GitHub repository is located at https://github.com/Azure-Samples/DoubleKeyEncryptionService.

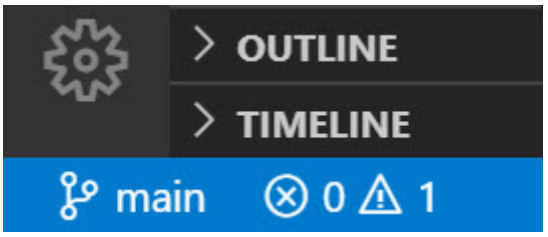
The following instructions are intended for inexperienced git or Visual Studio Code users:



1. In your browser, go to: https://github.com/Azure-Samples/DoubleKeyEncryptionService.

2. Towards the right side of the screen, select **Code**. Your version of the UI might show a **Clone or download** button. Then, in the dropdown that appears, select the copy icon to copy the URL to your clipboard.

   For example:



3. In Visual Studio Code, select **View** > **Command Palette** and select **Git: Clone**. To jump to the option in the list, start typing `git: clone` to filter the entries, and then select it from the drop-down. For example:

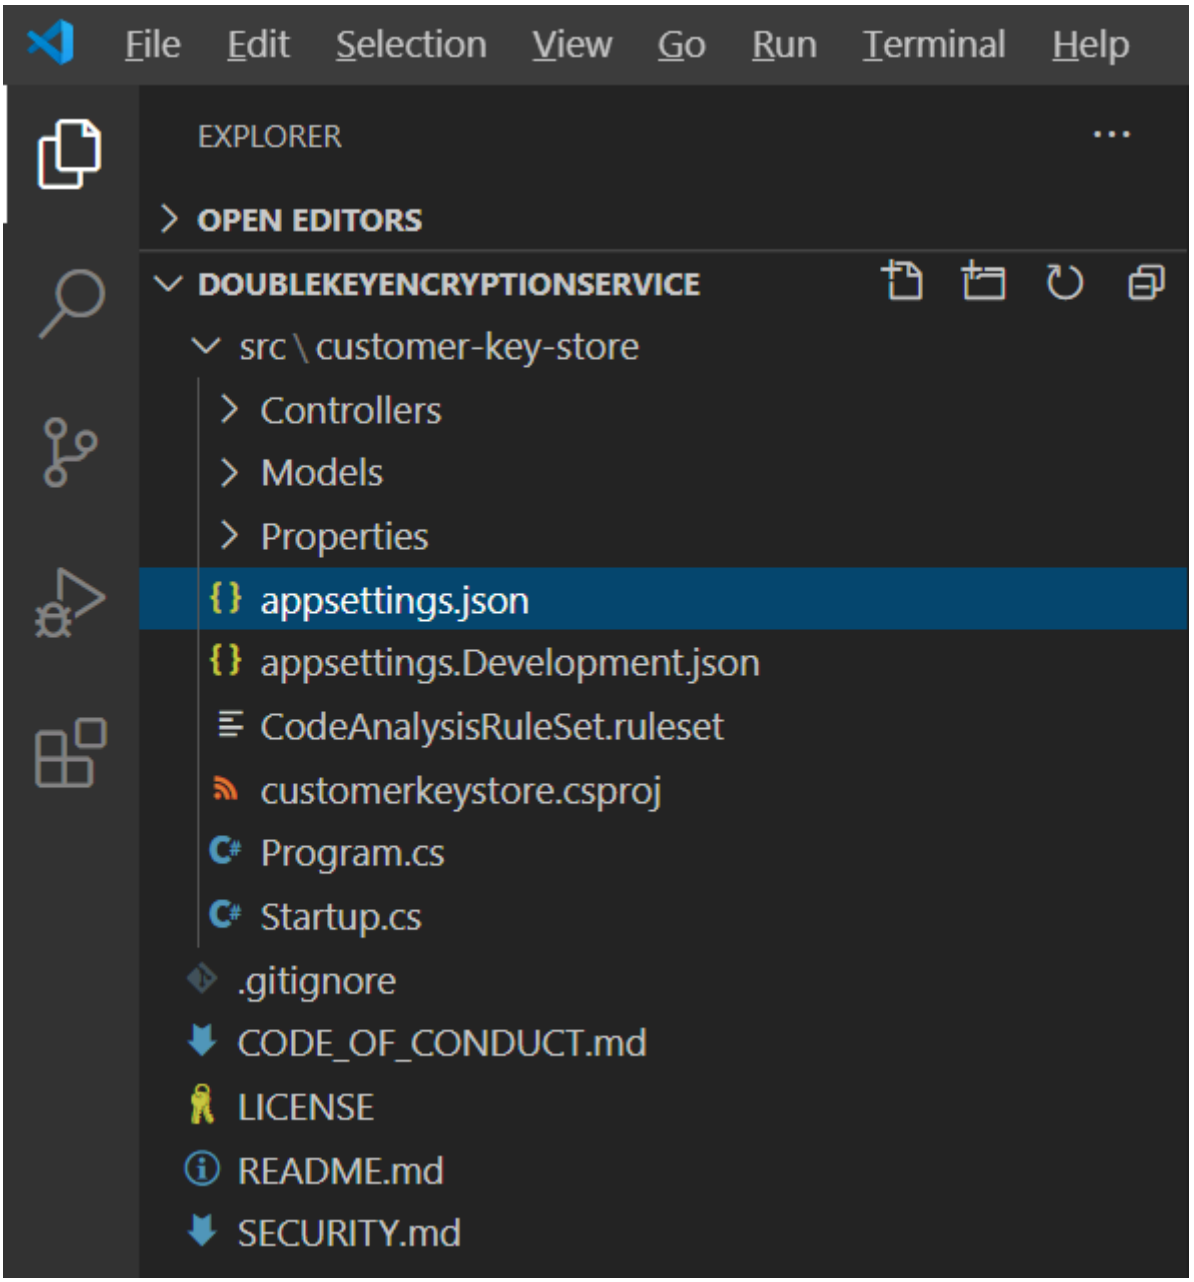
4. In the text box, paste the URL that you copied from Git and select **Clone from GitHub**.

5. In the **Select Folder** dialog that appears, browse to and select a location to store the repository. Select **Open**.

   The repository opens in Visual Studio Code, and displays the current Git branch at the bottom left. The branch should be **main**. For example:

6. If you're not on the main branch, select it. In Visual Studio Code, select the branch and choose **main** from the list of branches that displays.

   > **Important**
   >
   > Selecting the main branch ensures that you have the correct files to build the project. If you don't choose the correct branch your deployment will fail.



You now have your DKE source repository set up locally. Next, modify application settings for your organization.

Modify application settings

To deploy the DKE service, you must modify the following types of application settings:

- Key access settings
- Tenant and key settings

You modify application settings in the appsettings.json file. This file is located in the DoubleKeyEncryptionService repo you cloned locally under DoubleKeyEncryptionService\src\customer-key-store. For example, in Visual Studio Code, you can browse to the file as shown in the following picture.

Key access settings

Choose whether to use email or role authorization. DKE supports only one of these authentication methods at a time.

- **Email authorization**. Allows your organization to authorize access to keys based on email addresses only.
- **Role authorization**. Allows your organization to authorize access to keys based on Active Directory groups, and requires that the web service can query LDAP.

To set key access settings for DKE using email authorization

1. Open the **appsettings.json** file and locate the `AuthorizedEmailAddress` setting.

2. Add the email address or addresses that you want to authorize. Separate multiple email addresses with double quotes and commas. For example:

```
JSON

"AuthorizedEmailAddress": ["email1@company.com", "email2@company.com ",
"email3@company.com"]
```

3. Locate the `LDAPPath` setting and remove the text `If you use role authorization (AuthorizedRoles) then this is the LDAP path.` between the double quotes. Leave the double quotes in place. When you're finished, the setting should look like this.

```
JSON

"LDAPPath": ""
```

4. Locate the `AuthorizedRoles` setting and delete the entire line.

This image shows the **appsettings.json** file correctly formatted for email authorization.

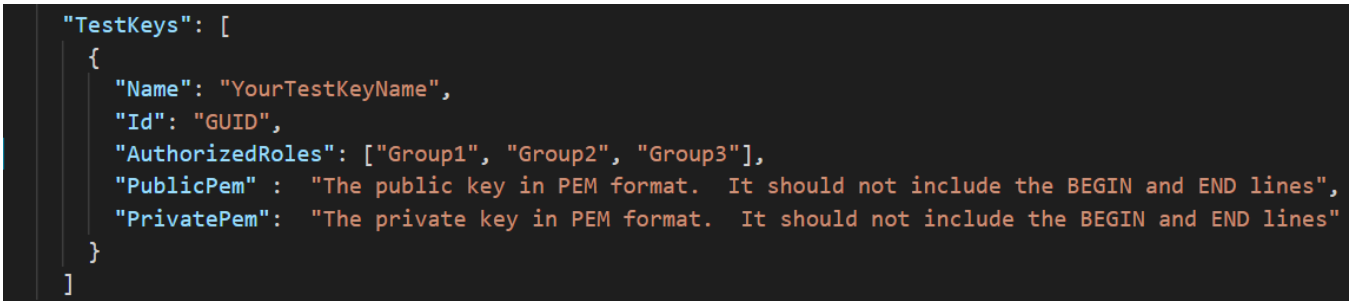
To set key access settings for DKE using role authorization

1. Open the **appsettings.json** file and locate the `AuthorizedRoles` setting.

2. Add the Active Directory group names you want to authorize. Separate multiple group names with double quotes and commas. For example:

```
JSON

"AuthorizedRoles": ["group1", "group2", "group3"]
```



3. Locate the `LDAPPath` setting and add the Active Directory domain. For example:

```
JSON

"LDAPPath": "contoso.com"
```

4. Locate the `AuthorizedEmailAddress` setting and delete the entire line.

This image shows the **appsettings.json** file correctly formatted for role authorization.

```
"TestKeys": [
  {
    "Name": "YourTestKeyName",
    "Id": "GUID",
    "AuthorizedRoles": ["Group1", "Group2", "Group3"],
    "PublicPem" :  "The public key in PEM format.  It should not include the BEGIN and END lines",
    "PrivatePem":  "The private key in PEM format.  It should not include the BEGIN and END lines"
  }
]
```

Tenant and key settings

DKE tenant and key settings are located in the **appsettings.json** file.

To configure tenant and key settings for DKE

1. Open the **appsettings.json** file.
2. Locate the `ValidIssuers` setting and replace `<tenantid>` with your tenant ID, making sure you keep the slash at the end of the tenant ID. You can locate your tenant ID by going to the Azure portal and viewing the tenant properties. For example:

   JSON

   ```
   "ValidIssuers": [
   "https://sts.windows.net/9c99431e-b513-44be-a7d9-e7b500002d4b/"
   ]
   ```

> **Note**
>
> If you want to enable external B2B access to your key store, you will also need to include these external tenants as part of the valid issuers' list.

Locate the `JwtAudience`. Replace the placeholder value, `"https://dkeservice.contoso.com"` in the json with the hostname of the machine where you want to run the DKE service.

> **Important**
>
> The value for `JwtAudience` must match the name of your host *exactly*.

- `TestKeys:Name`. Enter a name for your key. For example: `TestKey1`
- `TestKeys:Id`. Create a GUID and enter it as the `TestKeys:ID` value. For example, `DCE1CC21-FF9B-4424-8FF4-9914BD19A1BE`. You can use a site like Online GUID Generator to randomly generate a GUID.
- `JwtAuthorization`. Replace `{tenant-id}` with your tenant id.

The following json shows the correct format for tenant and keys settings in **appsettings.json**. `LDAPPath` is configured for role authorization.

JSON

```
{
  "TokenValidationParameters": {
    "ValidIssuers": [
      "https://sts.windows.net/9c99431e-b513-44be-a7d9-e7b50002d4b/"
    ]
  },
  "Logging": {
    "LogLevel": {
      "Default": "Warning"
    }
  },
  "AllowedHosts": "*",
  "JwtAudience": "https://dkeservice.contoso.com/",
  "JwtAuthorization": "https://login.microsoftonline.com/{tenant-
id}/oauth2/v2.0/authorize",
  "RoleAuthorizer": {
    "LDAPPath": ""
  },
  "TestKeys": [
    {
      "Name": "TestKey1",
      "Id": "DCE1CC21-FF98-4424-8FF4-9914BD19A1BE"
    }
  ]
}
```

Generate test keys

Once you have your application settings defined, you're ready to generate public and private test keys.

To generate keys:

1. From the Windows Start menu, run the OpenSSL Command Prompt.

2. Change to the folder where you want to save the test keys. The files you create by completing the steps in this task are stored in the same folder.

3. Generate the new test key.

```
Console

openssl req -x509 -newkey rsa:2048 -keyout key.pem -out cert.pem -days 365
```

4. Generate the private key.

   If you installed OpenSSL version 3 or later, run the following command:

```
Console

openssl rsa -in key.pem -out privkeynopass.pem -outform PEM -traditional
```

   Otherwise, run the following command:

```
Console

openssl rsa -in key.pem -out privkeynopass.pem -outform PEM
```

5. Generate the public key.

```
Console

openssl rsa -in key.pem -pubout > pubkeyonly.pem
```

6. In a text editor, open **pubkeyonly.pem**. Copy all of the content in the **pubkeyonly.pem** file, except the first and last lines, into the `PublicPem` section of the **appsettings.json** file.

7. In a text editor, open **privkeynopass.pem**. Copy all of the content in the **privkeynopass.pem** file, except the first and last lines, into the `PrivatePem` section of the **appsettings.json** file.

8. Remove all blank spaces and newlines in both the `PublicPem` and `PrivatePem` sections.

   > **ⓘ Important**
   >
   > When you copy this content, do not delete any of the PEM data.

9. In Visual Studio Code, browse to the **Startup.cs** file. This file is located in the DoubleKeyEncryptionService repo you cloned locally under DoubleKeyEncryptionService\src\customer-key-store.

10. Locate the following lines:

```
C#

#if USE_TEST_KEYS
#error !!!!!!!!!!!!!!!!!!!! Use of test keys is only supported for testing,
DO NOT USE FOR PRODUCTION !!!!!!!!!!!!!!!!!!!!!!!!!!!!
services.AddSingleton<ippw.IKeyStore, ippw.TestKeyStore>();
#endif
```

11. Replace these lines with the following text:

```
C#

services.AddSingleton<ippw.IKeyStore, ippw.TestKeyStore>();
```

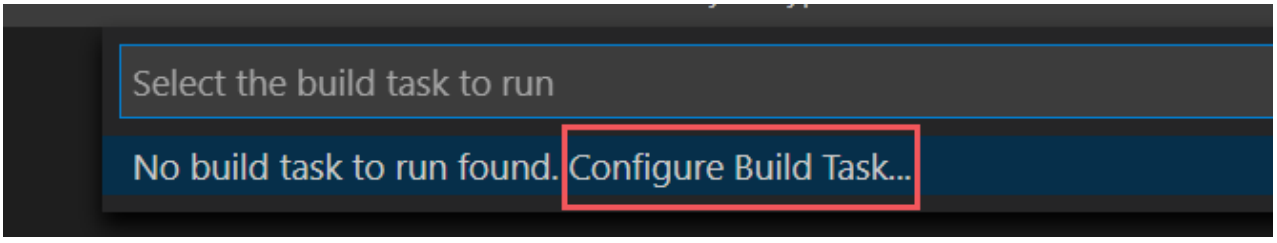
    The end results should look similar to the following.

```
services.AddSingleton<ippw.IKeyStore, ippw.TestKeyStore>();

services.AddTransient<ippw.KeyManager, ippw.KeyManager>();

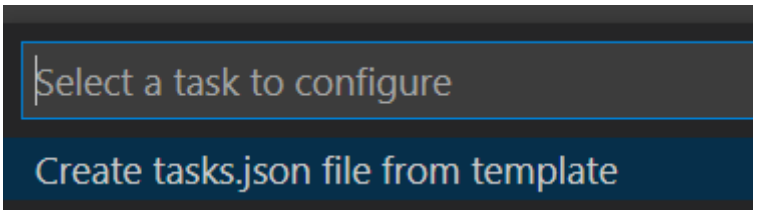
services.AddMvc().SetCompatibilityVersion(CompatibilityVersion.Version_2_1);
```

Now you're ready to build your DKE project.



Build the project

Use the following instructions to build the DKE project locally:



1. In Visual Studio Code, in the DKE service repository, select **View** > **Command Palette** and then type **build** at the prompt.

2. From the list, choose **Tasks: Run build task**.

    If there are no build tasks found, select **Configure Build Task** and create one for .NET core as follows.

    a. Choose **Create tasks.json from template**.

b. From the list of template types, select **.NET Core**.

c. In the build section, locate the path to the **customerkeystore.csproj** file. If it's not there, add the following line:

```JSON
"${workspaceFolder}/src/customer-key-store/customerkeystore.csproj",
```

d. Run the build again.

3. Verify that there are no red errors in the output window.

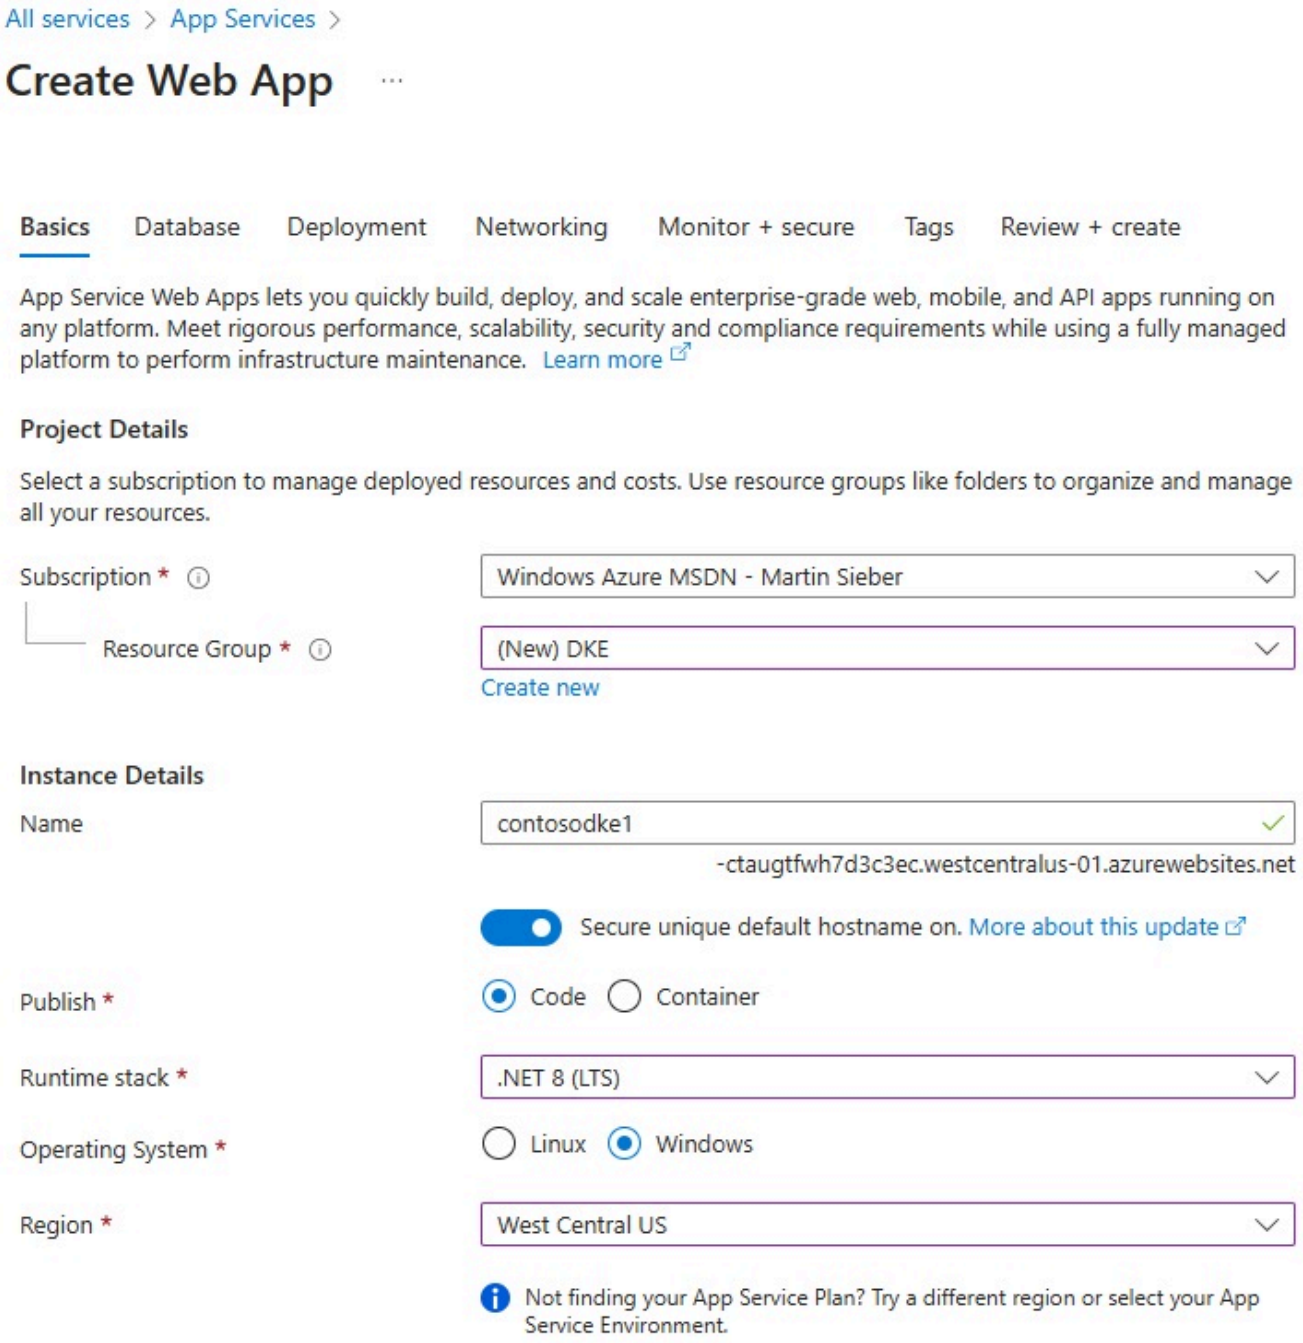
   If there are red errors, check the console output. Ensure that you completed all the previous steps correctly and the correct build versions are present.

Your setup is now complete. Before you publish the keystore, in appsettings.json, for the JwtAudience setting, ensure the value for hostname exactly matches your App Service host name.

Deploy the DKE service and publish the key store

For production deployments, deploy the service either in a third-party cloud or publish to an on-premises system.

You may prefer other methods to deploy your keys. Select the method that works best for your organization.



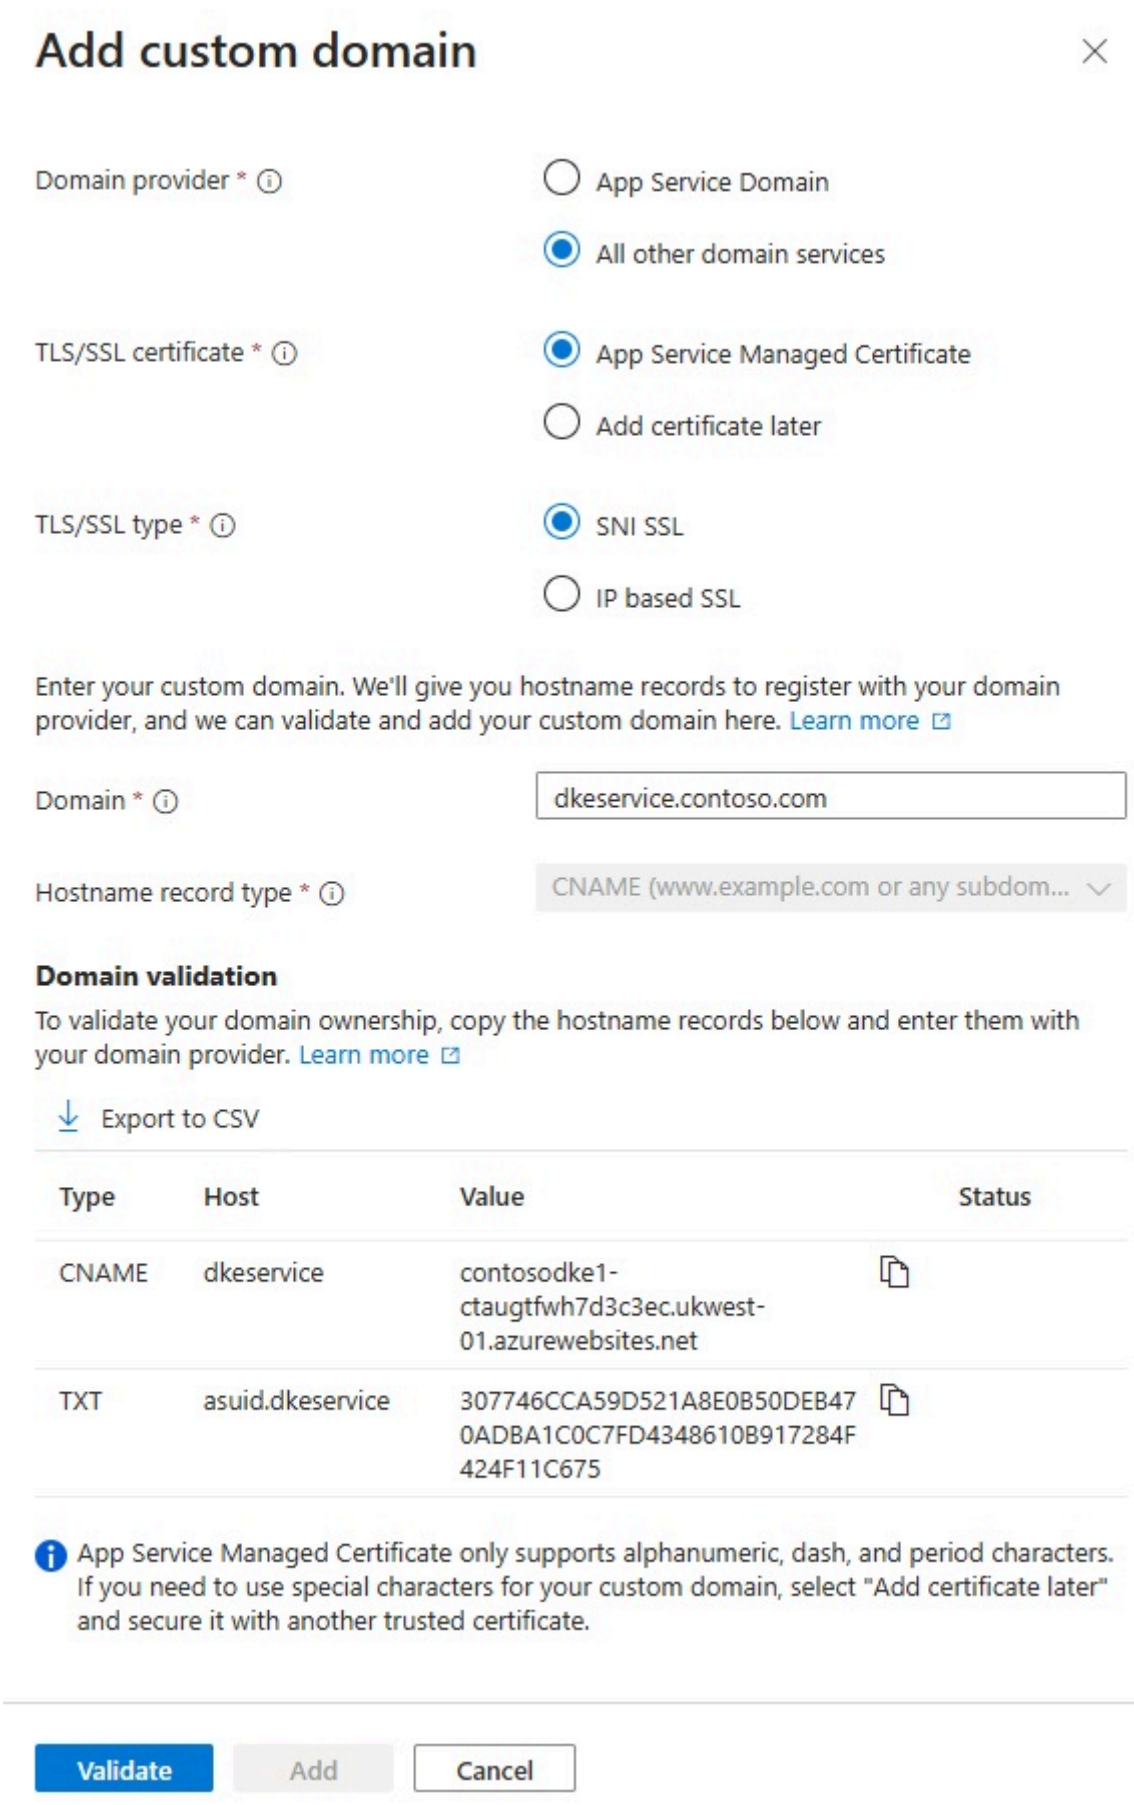
For pilot deployments, you can deploy in Azure and get started right away.

To create an Azure Web App instance to host your DKE deployment

To publish the key store, create an Azure App Service instance to host your DKE deployment. Next, publish your generated keys to Azure.

1. In your browser, sign in to the Microsoft Azure portal, and go to **App Services** > **Create** > **Web App**.
2. Create a new or select an existing resource group.
3. Provide a name for the instance, e.g. contosodke1. This name does not match the name in the config file. The value you provide for the name is also the WebAppInstanceName.
4. In pricing plan, select a size that allows custom domains, e.g. Basic B1.
5. For **Publish**, select **code**, and for **Runtime stack**, select **.NET 8 (LTS)**.
6. Select **Review + create**

For example:



1. In the newly created web app, go to “Settings”, “Custom domains”, select **Add custom domain**
2. In **Domain provider,** select **All other domain services**
3. In **Domain**, enter the hostname of the computer where you want to install the DKE service.

> **ⓘ Important**
>
> Make sure the hostname is the same name as the one defined for the JwtAudience setting in the appsettings.json file.

10. In the public DNS, perform the suggested changes as indicated in the Domain validation section and select **Validate**.

For example:

1. Do the following to publish your generated keys:

    - Publish via ZipDeployUI
    - You can use other methods to upload your binaries to that app, such as FTP.

for example, ftp

Publish via ZipDeployUI

1. Go to `https://<WebAppInstanceName>.scm.<location>.azurewebsites.net/ZipDeployUI`.

    For example: `https://dkeservice-ctaugtfwh7d3c3c.scm.westcentralus-01.azurewebsites.net/ZipDeployUI`

2. Launch a PowerShell prompt.

3. In the codebase for the key store, go to the **customer-key-store\src\customer-key-store** folder, and verify that this folder contains the **customerkeystore.csproj** file.

4. Run: **dotnet publish**

    The output window displays the directory where the publish was deployed.

    For example: `customer-key-store\src\customer-key-store\bin\Debug\net8.0\publish\`

5. Send all files in the publish directory to a .zip file. When creating the .zip file, make sure that all files in the directory are at the root level of the .zip file.

6. Drag and drop the .zip file you created to the ZipDeployUI site you opened before.

DKE is deployed and you can browse to the test keys you created. Continue to Validate your deployment in this article.

Validate your deployment

After deploying DKE using one of the methods described in this article, validate the deployment and the key store settings.

Run:

```PowerShell
src\customer-key-store\scripts\key_store_tester.ps1 dkeserviceurl/mykey
```

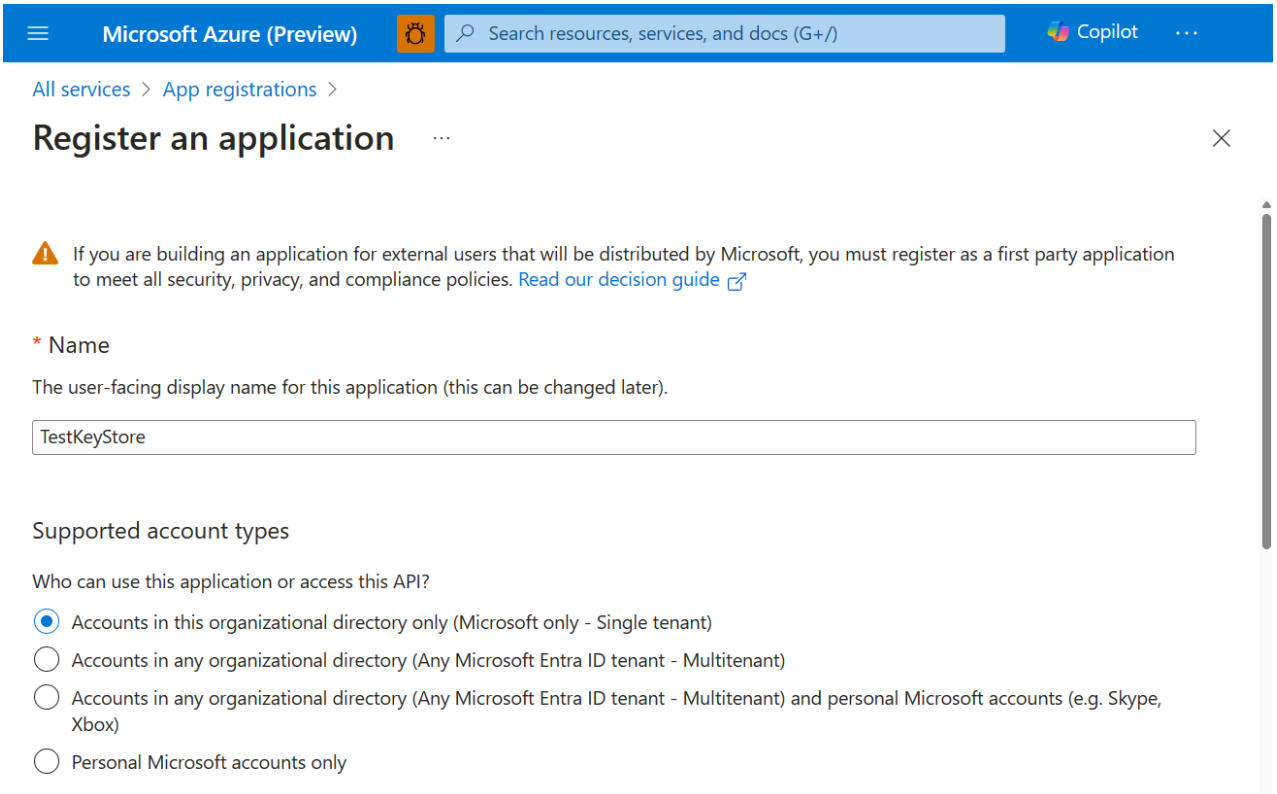
For example:

PowerShell

```
key_store_tester.ps1 https://dkeservice.contoso.com/TestKey1
```

Ensure that no errors appear in the output. When you're ready, register your key store.

The key name is case-sensitive. Enter the key name as it appears in the appsettings.json file.



Register your key store

The following steps enable you to register your DKE service. Registering your DKE service is the last step in deploying DKE before you can start creating labels.

To register the DKE service:

1. In your browser, open the Microsoft Azure portal, and go to **All Services** > **Identity** > **App Registrations**.
2. Select **New registration**, and enter a meaningful name.
3. Select an account type from the options displayed.

   For example:

4. At the bottom of the page, select **Register** to create the new App Registration.
5. In your new App Registration, in the left pane, under **Manage**, select **Authentication**.

6. Select **Add a platform**.

7. On the **Configure platforms** popup, select **Web**.

8. Under **Redirect URIs**, enter the URI of your double key encryption service. Enter the App Service URL, including both the hostname and domain.

   For example: `https://mydkeservicetest.com`

   - The URL you enter must match the hostname where your DKE service is deployed.
   - The domain must be a verified domain.
   - In all cases, the scheme must be **https**.

   Ensure the hostname exactly matches your App Service hostname.

9. Under **Implicit grant**, select the **ID tokens** checkbox.

10. Select **Save** to save your changes.

11. On the left pane, select **Expose an API**, next to Application ID URI, enter your App Service URL, including both hostname and domain, and then select **Set**.

12. Still on the **Expose an API** page, in the **Scopes defined by this API** area, select **Add a scope**. In the new scope:

    a. Define the scope name as **user_impersonation**.

    b. Select the administrators and users who can consent.

    c. Define any remaining values required.

    d. Select **Add scope**.

    e. Select **Save** at the top to save your changes.

13. Still on the **Expose an API** page, in the **Authorized client applications** area, select **Add a client application**.

    In the new client application:

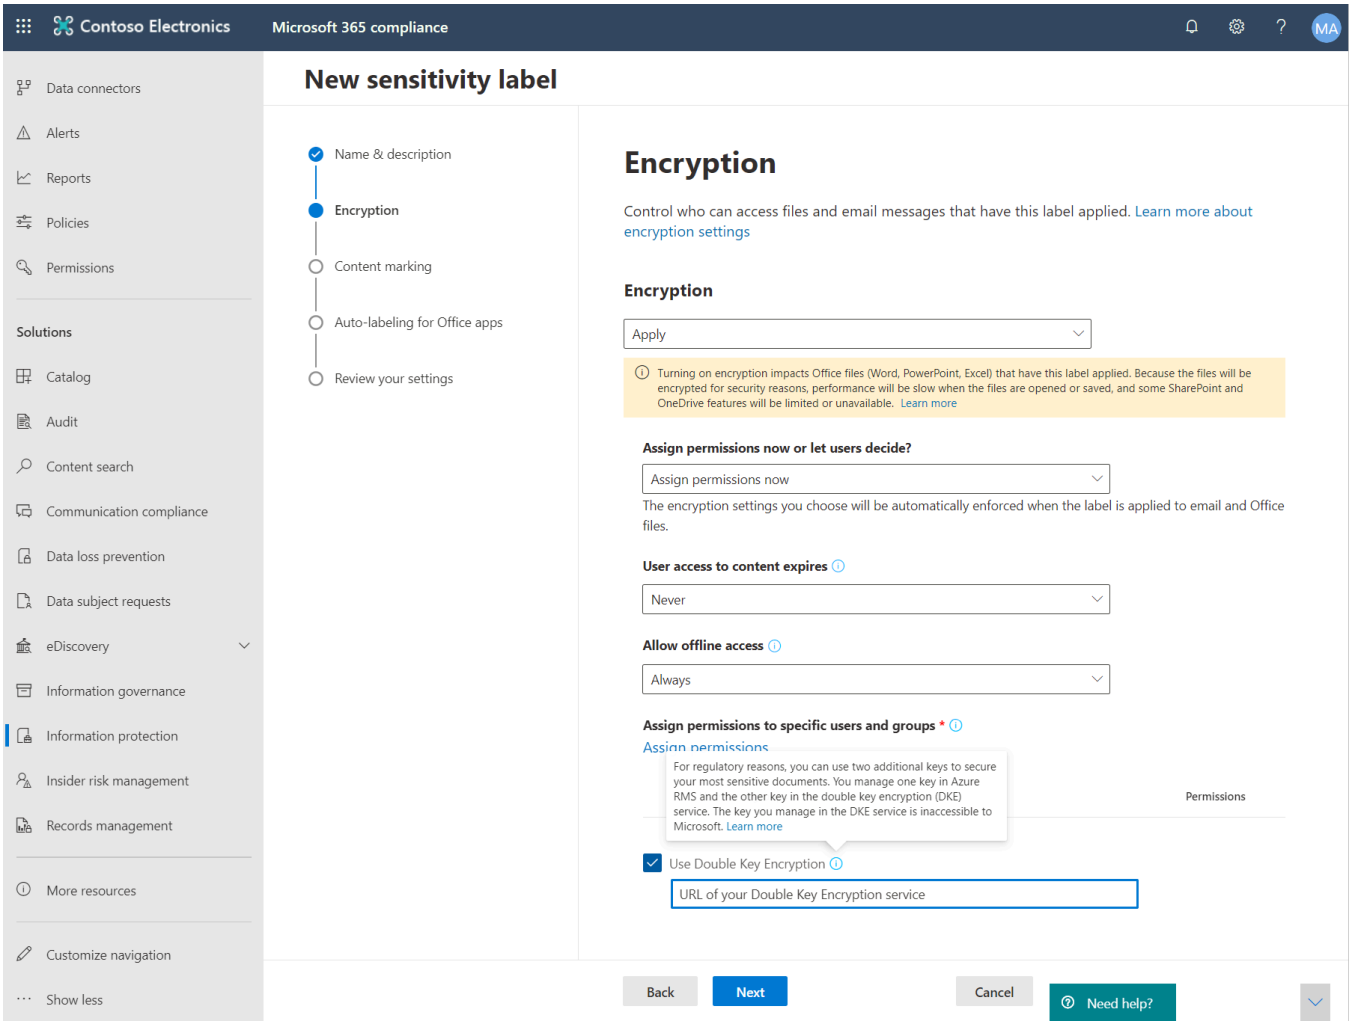
    a. Define the Client ID as `d3590ed6-52b3-4102-aeff-aad2292ab01c`. This value is the Microsoft Office client ID, and enables Office to obtain an access token for your key store.

    b. Under **Authorized scopes**, select the **user_impersonation** scope.

    c. Select **Add application**.

d. Select **Save** at the top to save your changes.

e. Repeat these steps, but this time, if you still use Azure Information Protection client, define the client ID as `c00e9d32-3c8d-4a7d-832b-029040e7db99`.



f. Repeat these steps, but this time, define the client ID as `0e25d998-b19a-4080-811c-d74d60d65e42`. This value is the Purview Information Protection client ID.

Your DKE service is now registered. Continue by creating labels using DKE.

Create sensitivity labels using DKE

In the Microsoft Purview portal, create a new sensitivity label and apply encryption as you would otherwise. Select **Use Double Key Encryption** and enter the endpoint URL for your key. You need to include the key name you provided in the "TestKeys" section of the appsettings.json file in the URL.

For example: `https://testingdke1.azurewebsites.net/KEYNAME`

Any DKE labels you add appear for users in the latest versions of Microsoft 365 Apps for enterprise.

> **Note**
>
> It may take up to 24 hours for the clients to refresh with the new labels.

Migrate protected files from HYOK labels to DKE labels

If you want, once you finish setting up DKE, you can migrate content that you protected using HYOK labels to DKE labels. To migrate, use the Microsoft Purview Information Protection scanner. To get started using the scanner, see Understand the information protection scanner.

If you don't migrate content, your HYOK protected content remains unaffected.

Other deployment options

We realize that for some customers in highly regulated industries, this standard reference implementation using software-based keys might not be sufficient to meet their enhanced compliance obligations and needs. We partner with third-party hardware security module (HSM) vendors to support enhanced key management options in the DKE service, including:

- Entrust
- Thales
- Utimaco

Reach out directly to these vendors for more information and guidance on their in-market DKE HSM solutions.

Set up clients to apply DKE sensitivity labels

On each client device, complete this task.

1. Ensure the following registry values are defined on each client. Create registry keys that aren't already there:

   Console

   ```
   [HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Microsoft\MSIPC\flighting]
   "DoubleKeyProtection"=dword:00000001
   ```

```
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSIPC\flighting]
"DoubleKeyProtection"=dword:00000001
```

Double Key Encryption FAQ

"Have questions about how Double Key Encryption works that we didn't cover elsewhere? Check for an answer here."

What Microsoft 365 Apps can I use with DKE?

You can use DKE labels to protect documents using the desktop versions of Word, Excel, PowerPoint, and Outlook on Windows. To ensure that you're using a supported version of Office apps, see the capabilities tables and the row **Double Key Encryption (DKE)**.

Can I use Double Key Encryption with Microsoft Office built-in sensitivity labeling?

Yes! Use can use built-in sensitivity labeling with Office apps. For information, see the capabilities tables and the row **Double Key Encryption (DKE)**. While you can use the information protection client to protect documents with Double Key Encryption for now, this method will be deprecated in the future.

How is Double Key Encryption different from the existing hold your own key (HYOK) solution?

Double Key Encryption encrypts your data with two keys. Your encryption key is in your control and the second key is stored in Microsoft Azure, allowing you to move your encrypted data to the cloud. HYOK protects your content with only one key and the key is always on premises.

Can Double Key Encrypted documents be shared externally?

You can share Double Key Encrypted documents with users on a separate tenant as long as those users:

- Have the required permission to access your key in your Double Key Encryption service.

- Have the required permission to access your key in Microsoft Azure.

What happens to documents that are protected with HYOK?

Deploying Double Key Encryption doesn't affect your existing HYOK setup. However, we recommend that you start using Double Key Encryption in parallel with HYOK.

Can I run Double Key Encryption in my non-Microsoft air-gapped environment?

DKE doesn't support these environments because the service requires access to Microsoft Azure.

Where can I store Double Key Encrypted documents?

You can store Double Key Encrypted documents on-premises or in the cloud. In the cloud, you can move encrypted content to SharePoint Online and OneDrive for Business. You can't view the encrypted documents online in Office Web Apps.

What regions and languages is Double Key Encryption available in? Is Double Key Encryption available worldwide?

DKE labels are localized to the same languages as other sensitivity labels in Microsoft Purview Information Protection. Double Key Encryption is available worldwide.

Can I convert a non-DKE label to a DKE label?

No. You can’t add DKE to a label after you create it. Instead, you must choose **Use Double Key Encryption** and provide the URL of your Double Key Encryption service when you create the label.

How do I roll my DKE keys?

For instructions on rolling (also called rotating or rekeying) the key you store in Azure, see Operations for your tenant key. See Tenant and key settings for information on creating a new key for the DKE service. When you create a key, you set up a name and a GUID. Then, if you rotate a key, you keep the old record with the name and GUID but add a new record with the same name but different GUID. The new key gets set as active so that the public key API starts returning it for new encryption. Both keys are available for decryption so that new content and old content can be decrypted.

Why can't I access Double Key Encrypted documents?

The right to view DKE-protected content requires users to authenticate to endpoints managed by your organization. If users in your organization can't view DKE-protected content, review the key access settings configuration.

What kind of mutual transport layer security (mTLS) is supported with the DKE service on Office Desktop Apps on Windows?

- Before 2402: No mTLS support.
- After 2402: The apps don’t support sending the client certification. Instead the desktop apps send the request with `WINHTTP_NO_CLIENT_CERT_CONTEXT`. For more information, see SSL in WinHTTP - Win32 apps.

Set up Information Rights Management (IRM) in SharePoint admin center

> *Microsoft Purview service description*

Within SharePoint in Microsoft 365, IRM protection is applied to files at the list and library level. Before your organization can use IRM protection, you must first set up Rights Management. IRM relies on the Azure Rights Management service from Azure Information Protection to encrypt and assign usage restrictions. Some Microsoft 365 plans include Azure Rights Management, but not all.

> **Important**
>
> Microsoft recommends that you use roles with the fewest permissions. Minimizing the number of users with the Global Administrator role helps improve security for your organization. Learn more about Microsoft Purview roles and permissions.

Turn on IRM service using SharePoint admin center

Before your organization can IRM-protect SharePoint lists and libraries, you must first activate the Rights Management service for your organization. To learn how, see Activating Azure Rights Management.

After you activate the Rights Management service, sign in to the SharePoint admin center to turn on IRM.

1. Sign in to SharePoint using a work or school account that has site owner or SharePoint administrator permissions.
2. Select the app launcher icon and choose **Admin** to open the Microsoft 365 admin center. (If you don't see the Admin tile, your work or school account doesn't have administrator permissions in your organization.)
3. In the left pane, choose **Admin centers** > SharePoint admin center.
4. In the left pane, choose **settings**, and then choose **classic settings page**.

5. In the **Information Rights Management (IRM)** section, choose **Use the IRM service specified in your configuration**, and then choose **Refresh IRM Settings**. After you refresh IRM settings, people in your organization can begin using IRM in their SharePoint lists and document libraries. However, the options to do so might take up to an hour to appear in Library Settings and List Settings.

IRM-enable SharePoint document libraries and lists

After IRM settings refresh, site owners can IRM-protect their SharePoint lists and document libraries. For more information, see Apply Information Rights Management to a list or library.

When site owners enable IRM for a list or library, they can protect any supported file types in that list or library. When IRM is enabled for a library, rights management applies to all of the files in that library. When you enable IRM for a list, rights management applies only to files that are attached to list items, not the actual list items.

When people download files in an IRM-enabled list or library, the files are encrypted so that only authorized people can view them. Each rights-managed file also contains an issuance license that imposes restrictions on the people who view the file. Typical restrictions include:

- Making a file read-only
- Disabling the copying of text
- Preventing people from saving a local copy
- Preventing people from printing the file

Client programs that can read IRM-supported file types use the issuance license within the rights-managed file to enforce these restrictions. So, a rights-managed file retains its protection even after download. To enable IRM on a list or library, see Apply Information Rights Management to a list or library.

You can't create or edit documents in an IRM-enabled library using Office in a browser. Instead, one person at a time can download and edit IRM-encrypted files. Use check-in and check-out to manage *coauthor*, or authoring across multiple users.

When you download a PDF file from an IRM-protected library, Microsoft 365 creates a protected PDF file. The file's extension doesn't change, but the file is protected. To view this file, you need the information protection viewer, the full information protection client, or another application that supports viewing protected PDF files.

SharePoint supports encryption of the following file types:

- PDF
- The 97-2003 file formats for the following Microsoft Office programs: Word, Excel, and PowerPoint
- The Office Open XML formats for the following Microsoft Office programs: Word, Excel, and PowerPoint
- The XML Paper Specification (XPS) format

> **Note**
>
> IRM protection can't be applied to protected documents (like digitally signed PDF files) as SharePoint needs to open the document on upload.

Next steps

Once you enabled IRM for SharePoint, you can start applying rights management to lists and libraries. For information, see Apply Information Rights Management to a list or library.

The OneDrive sync client for Windows supports synchronizing IRM-protected SharePoint document libraries and OneDrive locations (as long as the IRM setting for the library isn't set to expire document access rights). For more information, or to get started deploying the sync client, see Deploy the new OneDrive sync client for Windows.

Technical reference details about encryption

09/26/2025

Refer to this article for information about certificates, technologies, and TLS cipher suites used for encryption in Microsoft 365. This article also provides details about planned deprecations.

- If you're looking for overview information, see Encryption in Microsoft 365.
- If you're looking for setup information, see Set up encryption in Microsoft 365 Enterprise.
- For specific information about TLS 1.1 and 1.0 deprecation, see Disabling TLS 1.0 and 1.1 for Microsoft 365.
- For information about cipher suites supported by specific versions of Windows, see Cipher Suites in TLS/SSL (Schannel SSP).
- For certificate chains, see Microsoft 365 encryption chains and Microsoft 365 encryption chains - DOD and GCC High.

Microsoft Office 365 certificate ownership and management

You don't need to purchase or maintain certificates for Office 365. Instead, Office 365 uses its own certificates.

Current encryption standards and planned deprecations

To provide best-in-class encryption, Office 365 regularly reviews supported encryption standards. Sometimes, old standards are deprecated as they become out of date and less secure. This article describes currently supported cipher suites and other standards and details about planned deprecations.

FIPS compliance for Microsoft 365

All cipher suites supported by Office 365 use algorithms acceptable under FIPS 140-2. Office 365 inherits FIPS validations from Windows (through Schannel). For information about Schannel, see Cipher Suites in TLS/SSL (Schannel SSP).

AES256-CBC support for Microsoft 365

In late August 2023, Microsoft Purview Information Protection will begin to use Advanced Encryption Standard (AES) with 256-bit key length in Cipher Block Chaining mode (AES256-CBC). By October 2023, AES256-CBC will be the default for encryption of Microsoft 365 Apps documents and emails. You may need to take action to support this change in your organization.

Who is impacted and what do I need to do?

Use this table to figure out if you have to take action:

Expand table

Client applications	Service applications	Action required?	What do I need to do?
Microsoft 365 Apps	Exchange Online, SharePoint Online	No	N/A
Office 2013, 2016, 2019, or 2021	Exchange Online, SharePoint Online	Yes (Optional)	See Set up Office 2013, 2016, 2019, or 2021 for AES256-CBC mode.
Microsoft 365 Apps	Exchange Server or hybrid	Yes (Mandatory)	See Set up Exchange Server for AES256-CBC support.
Office 2013, 2016, 2019, or 2021	Exchange Server or hybrid	Yes (Mandatory)	Complete Option 1 (required), and then see Set up Office 2013, 2016, 2019, or 2021 for AES256-CBC mode.
Microsoft 365 Apps	MIP SDK	Yes (Optional)	See Set up MIP SDK for AES256-CBC support.
Any	SharePoint Server	No	N/A

Set up Office 2013, 2016, 2019, or 2021 for AES256-CBC mode

You need to configure Office 2013, 2016, 2019, or 2021 to use AES256-CBC mode using Group Policy, or by using the Cloud Policy service for Microsoft 365. Starting with version 16.0.16227 of Microsoft 365 Apps, CBC mode is used by default. Use the `Encryption mode for Information Rights Management (IRM)` setting under `User Configuration/Administrative Templates/Microsoft Office 2016/Security Settings`.

For example, to force CBC mode, select the group policy setting as follows:

Encryption mode for Information Rights Management (IRM): [1, Cipher Block Chaining (CBC)]

Set up Exchange Server for AES256-CBC support

Exchange Server doesn't support decrypting content that uses AES256-CBC. To work around this problem, you have two options.

Option 1

Customers using Exchange Online with the Azure Rights Management Connector service deployed will be opted out of the AES256-CBC publishing change in both Exchange Online and SharePoint Online.

To move to AES256-CBC mode, complete these steps:

1. Install the hotfix on your Exchange Servers when it becomes available. For the most recent information about ship dates, see the Microsoft 365 product roadmap.
2. If you're using Exchange Server with the Azure Rights Management Connector Service, you'll need to run the GenConnectorConfig.ps1 script on each Exchange server. For more information, see Configure servers for the Rights Management connector.

Once your organization has installed the patch across all of your Exchange Servers, open a support case and request these services to be enabled for AES256-CBC publishing.

Option 2

This option gives you some extra time before you need to patch all of your Exchange servers. Use this option if you're unable to complete the steps in option 1 when the hotfix becomes available. Instead, deploy group policy or client settings that force Microsoft 365 clients to keep using AES128-ECB mode. Deploy this setting using Group Policy, or by using the Cloud Policy service for Microsoft 365. You can configure Office and Microsoft 365 Apps for Windows to use ECB or CBC mode with the `Encryption mode for Information Rights Management (IRM)` setting under `User Configuration/Administrative Templates/Microsoft Office 2016/Security Settings`. Starting with version 16.0.16327 of Microsoft 365 Apps, CBC mode is used by default.

For example, to force EBC mode for Windows clients, set the group policy setting as follows:

Encryption mode for Information Rights Management (IRM): [2, Electronic Codebook (ECB)]

To configure settings for Office for Mac clients, see Set suite-wide preferences for Office for Mac.

As soon as you can, complete the steps in option 1.

Set up MIP SDK for AES256-CBC support

Update to MIP SDK 1.13 or later. If you choose to update to MIP SDK 1.13, you'll need to configure a setting to force AES256-CBC. For more information, see the MIP SDK Version 1.13.158 Critical Update. Later versions of the MIP SDK will protect Microsoft 365 files and email with AES256-CBC by default.

Versions of TLS supported by Microsoft 365

TLS, and SSL that came before TLS, are cryptographic protocols that secure communication over a network by using security certificates to encrypt a connection between computers. All Microsoft 365 support TLS version 1.2 (TLS 1.2). Support for TLS version 1.3 (TLS 1.3) is being rolled out throughout the service by the various applications and services. Exchange Online now supports TLS 1.3 for all email submissions and server communications with third-parties on the internet for worldwide customers. There is no timeline for TLS 1.3 for Exchange Online operated by 21Vianet.

> **Important**
>
> Be aware that TLS versions deprecate, and that deprecated versions *should not be used* where newer versions are available. If your legacy services do not require TLS 1.0 or 1.1 you should disable them.

Deprecations

- Cipher suites: We are constantly reviewing our supported cipher suite list. We have stop supporting weak SHA1 message authentication, and the non-forward-secrecy RSA key exchange algorithm in the past. The current list of supported ciphers can be seen here: TLS cipher suites supported by Microsoft 365.
- TLS 1.0 and TLS 1.1 versions: Support for these TLS versions ended on October 31, 2018 with their removal from the service completed since 2022. All connections with Microsoft 365 now use at least TLS 1.2 to communicate. One exception is the SMTP AUTH client submission protocol in Exchange Online which offers an opt-in endpoint for customers with legacy devices that still need TLS 1.0 or TLS 1.1.
- 3DES algorithm: Support for this encryption algorithm ended on October 31, 2018. Microsoft 365 removed the cipher suite using it, TLS_RSA_WITH_3DES_EDE_CBC_SHA cipher suite, from the service from February 28, 2019. For a list of supported ciphers, see TLS cipher suites supported by Microsoft 365.
- SHA-1 certificates: Support in Microsoft 365 for communications where the other third-party provides SHA-1 certificates ended from June 2016. SHA-2 (Secure Hash Algorithm

2) or stronger hashing algorithms are now needed in the certificate chain.

TLS cipher suites supported by Microsoft 365

TLS uses *cipher suites*, collections of encryption algorithms, to establish secure connections. Microsoft 365 supports the cipher suites listed in the following table. The table lists the cipher suites in order of strength, with the strongest cipher suite listed first.

Microsoft 365 responds to a connection request by first attempting to connect using the most secure cipher suite. If the connection doesn't work, Microsoft 365 tries the second most secure cipher suite in the list, and so on. The service continues down the list until the connection is accepted. Likewise, when Microsoft 365 requests a connection, the receiving service chooses whether to use TLS and which cipher suite to use.

Expand table

Cipher suite name	TLS protocol version
TLS_AES_256_GCM_SHA384	1.3
TLS_AES_128_GCM_SHA256	1.3
TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384	1.2
TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256	1.2
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384	1.2
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256	1.2

Azure Certificate Authority details

This article outlines the specific root and subordinate Certificate Authorities (CAs) that Azure service endpoints use. This CA list is distinct from the trust anchors on Azure VMs and hosted services, which use the trust anchors provided by the operating systems. The scope includes government and national clouds. The sections after the CA details tables provide the minimum requirements for public key encryption and signature algorithms, links to certificate downloads and revocation lists, and information about key concepts. These sections also provide the host names for the URIs that you should add to your firewall allow lists.

Certificate Authority details

Any entity trying to access Microsoft Entra identity services through the TLS/SSL protocols receives certificates from the CAs listed in this article. Different services might use different root or intermediate CAs. The following root and subordinate CAs are relevant to entities that use certificate pinning.

How to read the certificate details:

- The Serial Number (top string in the table) contains the hexadecimal value of the certificate serial number.
- The Thumbprint (bottom string in the table) is the SHA1 thumbprint.
- For CAs that you must download over HTTP instead of HTTPS, copy the link and paste it into the URL field in a new tab.

How to find certificate validity (expiry) dates:

To determine when a certificate expires, download the certificate file and view its properties. On Windows, double-click the downloaded `.crt` file and check the **Valid from** and **Valid to** fields under the **General** tab. On Linux or macOS, use `openssl x509 -in <certificate-file> -noout -dates` to display the validity period. Root CAs typically have validity periods of 15 to 25 years, while subordinate CAs have shorter validity periods of 3 to 10 years.

Microsoft TLS RSA Root G2	`http://caissuers.microsoft.com/pkiops/certs/Microsoft%20TLS%20RSA%20Root%20G2%20-%20xsign.crt`	0x0b0c6b2c466917b047 B5EE89E77326AB2BF177

Client compatibility for public PKIs

The CAs used by Azure are compatible with the following OS versions:

Expand table

Windows	Firefox	iOS	macOS	Android	Java
Windows XP SP3+	Firefox 32+	iOS 7+	OS X Mavericks (10.9)+	Android SDK 5.x+	Java JRE 1.8.0_101+

Review the following action steps when CAs expire or change:

- Update to a supported version of the required OS.
- If you can't change the OS version, you might need to manually update the trusted root store to include the new CAs. See the documentation provided by the manufacturer.
- If your scenario includes disabling the trusted root store or running the Windows client in disconnected environments, ensure that all root CAs are included in the Trusted Root CA store and all sub CAs listed in this article are included in the Intermediate CA store.
- Many distributions of **Linux** require you to add CAs to `/etc/ssl/certs`. See the distribution documentation.
- Ensure that the **Java** key store contains the CAs listed in this article. For more information, see the Java applications section of this article.
- If your application explicitly specifies a list of acceptable CAs, check whether you need to update the pinned certificates when CAs change or expire. For more information, see Certificate pinning.

Public key encryption and signature algorithms

Support for the following algorithms, elliptical curves, and key sizes are required:

Signature algorithms:

- ES256
- ES384
- ES512
- RS256
- RS384
- RS512

Elliptical curves:

- P256
- P384
- P521

Key sizes:

- ECDSA 256
- ECDSA 384
- ECDSA 521
- RSA 2048

- RSA 3072
- RSA 4096

Certificate downloads and revocation lists

To optimize connectivity, add the following domains (HTTP on port 80) to your firewall allow list. These domains serve Authority Information Access (AIA), certificate revocation list (CRL), and Online Certificate Status Protocol (OCSP) requests. The certificate revocation and chain-building standards define these requests as HTTP rather than HTTPS, so port 80 is expected.

This article is the authoritative list of these domains. When Azure adds or removes a certificate authority, it updates the corresponding AIA, CRL, and OCSP domains here and records the change in the Article change log. If your environment restricts outbound connectivity by fully qualified domain name (FQDN), monitor this article and the change log so that you can update your firewall allow list.

AIA:

- `cacerts.digicert.com`
- `cacerts.digicert.cn`
- `cacerts.geotrust.com`
- `caissuers.microsoft.com`
- `www.microsoft.com`

CRL:

- `crl3.digicert.com`
- `crl4.digicert.com`
- `crl.digicert.cn`
- `www.microsoft.com`

OCSP:

- `ocsp.digicert.com`
- `ocsp.digicert.cn`
- `oneocsp.microsoft.com`

Certificate pinning

Certificate pinning is a security technique where you accept only authorized, or *pinned*, certificates when establishing a secure session. The process rejects any attempt to establish a secure session using a different certificate. For more information, including guidance on static pinning of publicly trusted certificates, see Certificate pinning.

How to address certificate pinning

If your application explicitly specifies a list of acceptable CAs, you might need to periodically update pinned certificates when Certificate Authorities change or expire.

To detect certificate pinning, take the following steps:

- If you're an application developer, search your source code for references to certificate thumbprints, Subject Distinguished Names, Common Names, serial numbers, public keys, and other certificate properties of any of the Sub CAs involved in this change.
  - If there's a match, update the application to include the missing CAs.
- If you have an application that integrates with Azure APIs or other Azure services and you're unsure whether it uses certificate pinning, check with the application vendor.

Java applications

To determine if your Java application trusts the **Microsoft ECC Root Certificate Authority 2017** and **Microsoft RSA Root Certificate Authority 2017** root certificates, check the list of trusted root certificates that the Java Virtual Machine (JVM) uses.

1. Open a terminal window on your system.
2. Run the following command:

   Bash

   ```
   keytool -list -keystore $JAVA_HOME/jre/lib/security/cacerts
   ```

   - `$JAVA_HOME` refers to the path to the Java home directory.
   - If you're unsure of the path, find it by running the following command:

   Bash

   ```
   readlink -f $(which java) | xargs dirname | xargs dirname
   ```

3. Look for the **Microsoft RSA Root Certificate Authority 2017** in the output. The output should look similar to the following sample:

   - If the **Microsoft ECC Root Certificate Authority 2017** and **Microsoft RSA Root Certificate Authority 2017** root certificates are trusted, they should appear in the list of trusted root certificates used by the JVM.
   - If the certificate isn't in the list, add it.

   Bash

   ```
   ...
   Microsoft ECC Root Certificate Authority 2017, 20-Aug-2022, Root CA,
   Microsoft RSA Root Certificate Authority 2017, 20-Aug-2022, Root CA,
   ...
   ```

4. To add a root certificate to the trusted root certificate store in Java, use the `keytool` utility. The following example adds the **Microsoft ECC Root Certificate Authority 2017** and **Microsoft RSA Root Certificate Authority 2017** root certificates:

   Bash

   ```
   keytool -import -file microsoft-ecc-root-ca.crt -alias microsoft-ecc-root-ca -
   keystore $JAVA_HOME/jre/lib/security/cacerts
   keytool -import -file microsoft-rsa-root-ca.crt -alias microsoft-rsa-root-ca -
   keystore $JAVA_HOME/jre/lib/security/cacerts
   ```

   > ⓘ Note
   >
   > In this example, `microsoft-ecc-root-ca.crt` and `microsoft-rsa-root-ca.crt` are the names of the files that contain the **Microsoft ECC Root Certificate Authority 2017** and **Microsoft RSA Root Certificate Authority 2017** root certificates, respectively.

Past changes

The CA/Browser Forum updated the Baseline Requirements to require all publicly trusted public key infrastructures (PKIs) to stop using the SHA-1 hash algorithms for Online Certificate Status Protocol (OCSP) on May 31, 2022. Microsoft updated all remaining OCSP responders that used the SHA-1 hash algorithm to use the SHA-256 hash algorithm.

Microsoft updated Azure services to use TLS certificates from a different set of Root Certificate Authorities (CAs) on February 15, 2021, to comply with changes set forth by the CA/Browser Forum Baseline Requirements. Some services finalized these updates in 2022. For the latest information regarding managed TLS and Azure, see Managed TLS changes.

Disabling TLS 1.0 and 1.1 for Microsoft 365

09/26/2025

Applies to: Microsoft 365 Apps for enterprise, Office 365 Business, Office 365 Personal, Office Online Server, Office Web Apps

> **Important**
>
> We have already disabled TLS 1.0 and 1.1 for most Microsoft 365 services in the world wide environment. For Microsoft 365 operated by 21 Vianet, TLS 1.0/1.1 was disabled on June 30, 2023.

As of October 31, 2018, the Transport Layer Security (TLS) 1.0 and 1.1 protocols are deprecated for the Microsoft 365 service. The effect for end-users is minimal. This change has been publicized for over two years, with the first public announcement made in December 2017. This article is only intended to cover the Office 365 local client in relation to the Office 365 service but can also apply to on-premises TLS issues with Office and Office Online Server/Office Web Apps.

For SharePoint and OneDrive, you'll need to update and configure .NET to support TLS 1.2. For information, see How to enable TLS 1.2 on clients.

Office 365 and TLS overview

The Office client relies on the Windows web service (WINHTTP) to send and receive traffic over TLS protocols. The Office client can use TLS 1.2 if the web service of the local computer can use TLS 1.2. All Office clients can use TLS protocols, as TLS and SSL protocols are part of the operating system and not specific to the Office client.

On Windows 8 and later versions

By default, the TLS 1.2 and 1.1 protocols are available if no network devices are configured to reject TLS 1.2 traffic.

On Windows 7

TLS 1.1 and 1.2 protocols are not available without the KB 3140245 update. The update addresses this issue and adds the following registry sub key:

```
Console
```

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Internet
Settings\WinHttp
```

> **Note**
>
> Windows 7 users who do not have this update are affected as of October 31, 2018. KB 3140245 has details about how to change WINHTTP settings to enable TLS protocols.

More information

The value of the **DefaultSecureProtocols** registry key that the KB article describes determines which network protocols can be used:

Expand table

DefaultSecureProtocols Value	Protocol enabled
0x00000008	Enable SSL 2.0 by default
0x00000020	Enable SSL 3.0 by default
0x00000080	Enable TLS 1.0 by default
0x00000200	Enable TLS 1.1 by default
0x00000800	Enable TLS 1.2 by default
0x00002000	Enable TLS 1.3 by default

Office clients and TLS registry keys

You can refer to KB 4057306 Preparing for the mandatory use of TLS 1.2 in Office 365. This is a general article for IT administrators, and it's official documentation about the TLS 1.2 change.

The following table shows the appropriate registry key values in Office 365 clients after October 31, 2018.

Expand table

Enabled protocols for Office 365 service after October 31, 2018	Hexadecimal value
TLS 1.0 + 1.1 + 1.2	0x00000A80

Enabled protocols for Office 365 service after October 31, 2018	Hexadecimal value
TLS 1.1 + 1.2	0x00000A00
TLS 1.0 + 1.2	0x00000880
TLS 1.2	0x00000800

> **Important**
>
> Don't use the SSL 2.0 and 3.0 protocols, which can also be set by using the **DefaultSecureProtocols** key. SSL 2.0 and 3.0 are considered outdated and insecure protocols. The best practice is to end the use of SSL 2.0 and SSL 3.0, although the decision to do this ultimately depends on what best meets your product needs. For more information about SSL 3.0 vulnerabilities, refer to **KB 3009008**.

You can use the default Windows Calculator in Programmer mode to set up the same reference registry key values. For more information, see KB 3140245 Update to enable TLS 1.1 and TLS 1.2 as a default secure protocols in WinHTTP in Windows.

Regardless if the Windows 7 update (KB 3140245) is installed or not, the DefaultSecureProtocols registry sub key isn't present and must be added manually or through a group policy object (GPO). That is, unless you have to customize what secure protocols are enabled or restricted, this key is not required. You only need the Windows 7 SP1 (KB 3140245) update.

Update and configure the .NET Framework to support TLS 1.2

You'll need to update applications that call Microsoft 365 APIs over TLS 1.0 or TLS 1.1 to use TLS 1.2. .NET 4.5 defaults to TLS 1.1. To update your .NET configuration, see How to enable Transport Layer Security (TLS) 1.2 on clients.

More information

For more information, see Preparing for the mandatory use of TLS 1.2 in Office 365.

References

The following resources provide guidance to help make sure that your clients are using TLS 1.2 or a later version and to disable TLS 1.0 and 1.1:

- For Windows 7 clients that connect to Office 365, make sure that TLS 1.2 is the default secure protocol in WinHTTP in Windows. For more information, see KB 3140245 - Update to enable TLS 1.1 and TLS 1.2 as default secure protocols in WinHTTP in Windows.
- To address weak TLS usage by removing TLS 1.0 and 1.1 dependencies, see TLS 1.2 support at Microsoft.
- New IIS functionality makes it easier to find clients on Windows Server 2012 R2 and Windows Server 2016 that connect to the service by using weak security protocols.
- Get more information about how to solve the TLS 1.0 problem.
- For general information about our approach to security, go to the Office 365 Trust Center.
- Preparing for TLS 1.0/1.1 Deprecation - Office 365 Skype for Business
- Exchange Server TLS guidance, part 1: Getting Ready for TLS 1.2

Disabling TLS 1.0 and 1.1 in Microsoft 365 GCC High and DoD

09/26/2025Applies to: Office 365 Business

Summary

In order to comply with the latest compliance standards for the Federal Risk and Authorization Management Program (FedRAMP), we are disabling Transport Layer Security (TLS) versions 1.1 and 1.0 in Microsoft 365 for GCC High and DoD environments. This change was previously announced through Microsoft Support in Preparing for the mandatory use of TLS 1.2 in Office 365.

The security of your data is important, and we are committed to transparency about changes that could affect your use of the service.

Although the Microsoft TLS 1.0 implementation has no known security vulnerabilities, we remain committed to the FedRAMP compliance standards. Therefore, we disabled TLS 1.1 and 1.0 in Microsoft 365 in GCC High and DoD environments on January 15, 2020.

More information

Starting on January 15, 2020, Microsoft 365 in the GCC High and DoD environments will disable TLS 1.1 and 1.0.

By January 15, 2020, all combinations of client servers and browser servers should use TLS version 1.2 (or a later version) to make sure that all connections can be made without issues to Microsoft 365. This may require updates to certain combinations of client servers and browser servers.

For SharePoint and OneDrive, you'll need to update and configure .NET to support TLS 1.2. For information, see How to enable TLS 1.2 on clients.

You must update your client computers to make sure that you maintain uninterrupted access to Office 365 GCC High and DoD.

You'll need to update applications that call Microsoft 365 APIs over TLS 1.0 or TLS 1.1 to use TLS 1.2. .NET 4.5 defaults to TLS 1.1. To update your .NET configuration, see How to enable Transport Layer Security (TLS) 1.2 on clients. For more information, see Preparing for the mandatory use of TLS 1.2 in Office 365.

We know that the following client applications cannot use TLS 1.2:

- Android 4.3 and earlier versions
- Firefox version 5.0 and earlier versions
- Internet Explorer 8-10 on Windows 7 and earlier versions
- Internet Explorer 10 on Windows Phone 8.0
- Safari 6.0.4/OS X 10.8.4 and earlier versions

Although current analysis of connections to Microsoft Online services shows that most services and endpoints see little TLS 1.1 and 1.0 usage, we're providing notice of this change so that you can update any affected clients or servers as necessary before support for TLS 1.1 and 1.0 ends. If you are using any on-premises infrastructure for hybrid scenarios or Active Directory Federation Services (AD FS), make sure that the infrastructure can support both inbound and outbound connections that use TLS 1.2 (or a later version).

In addition to the outages that you might experience if you use the listed clients that cannot use TLS 1.2, removing TLS 1.1 and 1.0 will prevent you from being able to use the following Microsoft product:

- Lync phone

References

For guidance and references to help make sure that your clients are using TLS 1.2, see Preparing for the mandatory use of TLS 1.2 in Office 365.

Preparing for TLS 1.2 in Office 365 and Office 365 GCC

09/26/2025Applies to: Office 365 Business

Summary

To provide the best-in-class encryption to our customers, Microsoft has deprecated Transport Layer Security (TLS) versions 1.0 and 1.1 in Office 365 and Office 365 GCC. We understand that the security of your data is important, and we're committed to transparency about changes that may affect your use of the TLS service.

The Microsoft TLS 1.0 implementation has no known security vulnerabilities. But because of the potential for future protocol downgrade attacks and other TLS vulnerabilities, we discontinued support for TLS 1.0 and 1.1 in Microsoft Office 365 and Office 365 GCC.

For information about how to remove TLS 1.0 and 1.1 dependencies, see the following white paper: Solving the TLS 1.0 problem.

After you upgrade to TLS 1.2, make sure that the cipher suites you're using are supported by Azure Front Door. Microsoft 365 and Azure Front Door have slight differences in cipher suite support. For details, see What are the current cipher suites supported by Azure Front Door?.

More information

We began deprecation of TLS 1.0 and 1.1 as of January 2020. Any clients, devices, or services that connect to Office 365 through TLS 1.0 or 1.1 in our DoD or GCC High instances are unsupported. For our commercial customers of Office 365, deprecation of TLS 1.0 and 1.1 began October 15, 2020 and rollout continued over the following weeks and months.

We recommend that all client-server and browser-server combinations use TLS 1.2 (or a later version) in order to maintain connection to Office 365 services. You might have to update certain client-server and browser-server combinations.

> **Note**
>
> For SMTP Inbound mail flow, after deprecation of TLS 1.0 and 1.1, we will accept only TLS 1.2 connection. However, we will continue accepting SMTP Connection which is unencrypted without any TLS. We do not recommend email transmission without any encryption.

You'll need to update applications that call Microsoft 365 APIs over TLS 1.0 or TLS 1.1 to use TLS 1.2. .NET 4.5 defaults to TLS 1.1. To update your .NET configuration, see How to enable Transport Layer Security (TLS) 1.2 on clients.

The following clients are known to be unable to use TLS 1.2. Update these clients to ensure uninterrupted access to the service.

- Android 4.3 and earlier versions
- Firefox version 5.0 and earlier versions
- Internet Explorer 8-10 on Windows 7 and earlier versions
- Internet Explorer 10 on Windows Phone 8
- Safari 6.0.4/OS X10.8.4 and earlier versions

TLS 1.2 for Microsoft Teams Rooms and Surface Hub

Microsoft Teams Rooms (previously known as Skype Room System V2 SRS V2) have supported TLS 1.2 since December 2018. We recommend that Rooms devices have Microsoft Teams Rooms app version 4.0.64.0 or later installed. For more information, see the Release notes. The changes are backward and forward compatible.

Surface Hub released TLS 1.2 support in May 2019.

TLS 1.2 support for Microsoft Teams Rooms and Surface Hub products also requires the following server-side code changes:

- Skype for Business Online server changes were made live in April 2019. Now, Skype for Business Online supports connecting Microsoft Teams Rooms and Surface Hub devices by using TLS 1.2.

- Skype for Business Server customers must install a cumulative update (CU) to use TLS 1.2 for Teams Rooms Systems and Surface Hub.
  - For Skype for Business Server 2015, CU9 is already released in May 2019.
  - For Skype for Business Server 2019, CU1 was previously planned for April 2019 but is delayed to June 2019.

  > ⓘ **Note**
  >
  > Skype for Business on-premises customers should not disable TLS 1.0/1.1 before installing specific CUs for Skype for Business Server.

If you are using any on-premises infrastructure for hybrid scenarios or Active Directory Federation Services, make sure that the infrastructure can support both inbound and outbound

connections that use TLS 1.2.

Microsoft Purview data compliance solutions

Microsoft Purview data compliance solutions help you manage and monitor your data, protect information, minimize compliance risks, and meet regulatory requirements. This article helps you learn about Microsoft Purview data compliance solutions and quickly get started with deploying these solutions to meet specific compliance needs for your organization.

If you're new to Microsoft Purview, consider starting with the Microsoft Purview Suite trial to explore compliance capabilities at the E5 level for free.

Data compliance solutions

Microsoft Purview offers the following data compliance solutions to help your organization manage data risk, meet regulatory requirements, and respond to legal obligations:

- Monitor organizational activity with Microsoft Purview Audit
- Detect inappropriate messages with Microsoft Purview Communication Compliance
- Manage regulatory requirements with Microsoft Purview Compliance Manager
- Retain and delete content with Microsoft Purview Data Lifecycle Management
- Identify and collect data for legal cases with Microsoft Purview eDiscovery
- Meet record-keeping requirements with Microsoft Purview Records Management

Monitor organizational activity with Audit

Microsoft Purview auditing solutions provide an integrated solution to help organizations effectively respond to security events, forensic investigations, internal investigations, and compliance obligations. Your organization's unified audit log captures, records, and retains thousands of user and admin operations performed in dozens of Microsoft 365 services and solutions.

Use Audit when your organization needs to:

- Investigate possible security breaches and determine the scope of compromise.
- Support internal investigations by tracking user and admin activities across Microsoft 365 services.
- Meet compliance obligations through long-term audit record retention.

- Conduct forensic investigations by reviewing when mail items were accessed, forwarded, or replied to.

To get started with Audit or learn more, see the following articles:

- Get started with auditing solutions
- Search the audit log
- Audit logs for Copilot and AI applications
- Manage audit log retention policies

Detect inappropriate messages with Communication Compliance

Microsoft Purview Communication Compliance helps minimize risks by helping you quickly detect, capture, and take remediation actions for email and Microsoft Teams communications. These actions include inappropriate communications containing profanity, threats, and harassment and communications that share sensitive information inside and outside of your organization.

Use Communication Compliance when your organization needs to:

- Detect and act on workplace harassment, threats, or profanity in user communications.
- Monitor for inappropriate sharing of sensitive information inside and outside your organization.
- Meet regulatory requirements for messaging oversight in financial services, such as FINRA Rule 3110.
- Identify potential insider trading, collusion, or unauthorized communications about confidential projects.

To get started with Communication Compliance or learn more, see the following articles:

- Learn about communication compliance
- Plan for communication compliance
- Create and manage policies
- Investigate and remediate alerts

Manage regulatory requirements with Compliance Manager

Microsoft Purview Compliance Manager helps you manage your organization's compliance requirements with greater ease and convenience. Compliance Manager can help you throughout

your compliance journey, from taking inventory of your data protection risks to managing the complexities of implementing controls, staying current with regulations and certifications, and reporting to auditors. Microsoft also offers a comprehensive set of compliance offerings to help your organization comply with national, regional, and industry-specific requirements governing the collection and use of data.

Use Compliance Manager when your organization needs to:

- Assess and manage compliance posture across multicloud environments.
- Prepare for audits by tracking improvement actions and compliance scores.
- Stay current with evolving regulations by using prebuilt assessments for more than 360 industry and regional standards.
- Prioritize which actions to take first based on risk-based compliance scoring.

To get started with Compliance Manager or learn more, see the following articles:

- Get started with Compliance Manager
- Build and manage assessments
- Learn about regulations
- Working with improvement actions

Retain and delete content with Data Lifecycle Management

Microsoft Purview Data Lifecycle Management provides tools and capabilities to retain and delete content across Exchange, SharePoint, OneDrive, Microsoft 365 Groups, Teams, and Viva Engage. Retaining and deleting emails, documents, and messages often meets compliance and regulatory requirements. However, deleting content that no longer has business value also reduces your exposure to cyberattacks.

Use Data Lifecycle Management when your organization needs to:

- Retain content for a specified period to meet compliance and regulatory requirements.
- Delete content that no longer has business value to reduce your exposure to cyberattacks.
- Archive mailbox data for users who need more than 100 GB of storage.
- Retain mailbox content after users leave your organization through inactive mailboxes.

To get started with Data Lifecycle Management or learn more, see the following articles:

- Get started with data lifecycle management
- Learn about retention policies and retention labels
- Create retention policies

- Learn about archive mailboxes

Identify and collect data for legal cases with eDiscovery

Microsoft Purview eDiscovery is the process of identifying, collecting, and auditing electronic information for legal, regulatory, or business reasons. Use eDiscovery to search for data and content in Exchange Online, OneDrive, SharePoint, Microsoft Teams, Microsoft 365 Groups, and Viva Engage teams. You can search mailboxes and sites in the same eDiscovery search, and then export the search results for analysis and review.

Use eDiscovery when your organization needs to:

- Identify and collect electronically stored information as evidence for legal cases.
- Respond to regulatory investigation and litigation requests.
- Preserve content in place to prevent deletion during an investigation.
- Reduce review costs by using analytics like near-duplicate detection and email threading.

To get started with eDiscovery or learn more, see the following articles:

- Learn about the eDiscovery workflow
- Get started with eDiscovery
- Create and manage cases
- Search for content
- Manage review sets

Meet record-keeping requirements with Records Management

Microsoft Purview Records Management helps your organization manage its legal obligations, provides the ability to demonstrate compliance with regulations, and increases efficiency by regularly disposing of items that are no longer required to be retained, no longer of value, or no longer required for business purposes.

Use Records Management when your organization needs to:

- Declare items as records or regulatory records to ensure content remains immutable.
- Start retention periods based on specific events, such as contract expiration or employee termination.
- Conduct disposition reviews with proof of deletion for compliance auditing.
- Manage the lifecycle of business-critical content with strict control and audit trails.

To get started with Records Management or learn more, see the following articles:

- Get started with records management
- Declare records by using retention labels
- Create and manage retention labels with file plan
- Manage disposition of data

Related Microsoft Purview solutions

Microsoft Purview data compliance solutions work alongside other Microsoft Purview solution areas:

- Microsoft Purview data security solutions
- Microsoft Purview data governance solutions

To deploy integrated compliance solutions, see Deploy a data governance solution.

Learn about auditing solutions in Microsoft Purview

Microsoft Purview auditing solutions provide an integrated solution to help organizations effectively respond to security events, forensic investigations, internal investigations, and compliance obligations. Your organization's unified audit log captures, records, and retains thousands of user and admin operations performed in dozens of Microsoft services and solutions. Security ops, IT admins, insider risk teams, and compliance and legal investigators in your organization can search audit records for these events. This capability provides visibility into the activities performed across your organization.

Comparison of key capabilities

The following table compares the key capabilities available in Audit (Standard) and Audit (Premium). Audit (Premium) includes all Audit (Standard) functionality.

Expand table

Capability	Audit (Standard)	Audit (Premium)
Enabled by default	✔	✔
Thousands of searchable audit events	✔	✔
Audit search tool in the Microsoft Purview portal	✔	✔
Audit Search Graph API	✔	✔
Search-UnifiedAuditLog cmdlet	✔	✔
Export audit records to CSV file	✔	✔
Access to audit logs via Office 365 Management Activity API [1]	✔	✔
180-day audit log retention	✔	✔
Up to 1-year audit log retention		✔

Capability	Audit (Standard)	Audit (Premium)
10-year audit log retention [2]		✔
Audit log retention policies		✔
Intelligent insights		✔

> **Note**
>
> [1] Audit (Premium) includes higher bandwidth access to the Office 365 Management Activity API, which provides faster access to audit data.
>
> [2] In addition to the required licensing for Audit (Premium) (described in the next section), a user must be assigned a 10-Year Audit Log Retention add-on license to retain their audit records for 10 years. Audit records generated by non-user entities (such as service principal actions, system events, and application activities) are retained for a fixed period of one year. This retention period isn't configurable and custom audit log retention policies don't apply to these records.

Audit (Standard)

Microsoft Purview Audit (Standard) enables you to log and search for audited activities to support your forensic, IT, compliance, and legal investigations.

- **Enabled by default**. Audit (Standard) is enabled by default for all organizations with the appropriate subscription. That configuration captures and makes searchable records for audited activities. You only need to assign the necessary permissions to access the audit log search tool (and the corresponding cmdlet) and ensure that users have the right license for Microsoft Purview Audit (Premium) features.
- **Thousands of searchable audit events**. You can search for a wide range of audited activities that occur in most of the Microsoft services in your organization. For a list of the activities you can search for, see Audit log activities. For a list of the services and features that support audited activities, see Audit log record type.
- **Audit search tool in the Microsoft Purview portal**. Use the Audit log search tool in the portal to search for audit records. You can search for specific activities, for activities performed by specific users, and activities that occurred within a date range.

- **Audit Search Graph API**. Microsoft Graph offers a unified API endpoint for accessing data from multiple Microsoft cloud services in a single response. The Audit Search Graph API allows you to programmatically access the audit search experience through Microsoft Graph.

- **Search-UnifiedAuditLog cmdlet**. You can also use the **Search-UnifiedAuditLog** cmdlet in Exchange Online PowerShell (the underlying cmdlet for the search tool) to search for audit events or to use in a script. For more information, see:
  - Search-UnifiedAuditLog cmdlet reference
  - Use a PowerShell script to search the audit log

- **Export audit records to a CSV file**. After running the Audit log search tool in the Microsoft Purview portal, you can export the audit records returned by the search to a CSV file. This process lets you use Microsoft Excel to sort and filter on different audit record properties. You can also use Excel Power Query transform functionality to split each property in the AuditData JSON object into its own column. This process lets you effectively view and compare similar data for different events. For more information, see Export, configure, and view audit log records.

- **Access to audit logs via Office 365 Management Activity API**. A third method for accessing and retrieving audit records is to use the Office 365 Management Activity API. This method lets organizations retain auditing data for longer periods than the default 180 days and lets them import their auditing data to a SIEM solution. For more information, see Office 365 Management Activity API reference.

- **180-day audit log retention**. When a user or admin performs an audited activity, the system generates an audit record and stores it in the audit log for your organization. In Audit (Standard), the system retains records for 180 days, which means you can search for activities that occurred within the past six months.

> **Important**
>
> The default retention period for Audit (Standard) changed from 90 days to 180 days. Audit (Standard) logs generated before October 17, 2023, are retained for 90 days. Audit (Standard) logs generated on or after October 17, 2023, follow the new default retention of 180 days.

Audit (Premium)

> **Important**
>
> Classic Search retired on November 30, 2023. New Search includes enhancements such as faster search times, additional search options, ability to save searches, and more.

Audit (Premium) builds on the capabilities of Audit (Standard) by providing audit log retention policies, longer retention of audit records, high-value intelligent insights, and higher bandwidth access to the Office 365 Management Activity API.

- **Audit log retention policies**. Create customized audit log retention policies to retain audit records for longer periods, up to one year (and up to 10 years for users with the required add-on license). Create a policy to retain audit records based on the service where the audited activities occur, specific audited activities, or the user who performs an audited activity.
- **Longer retention of audit records**. Microsoft Entra ID, Exchange, OneDrive, and SharePoint audit records are retained for one year by default. Audit records for all other activities are retained for 180 days by default, or you can use audit log retention policies to configure longer retention periods.
- **Audit (Premium) intelligent insights**. Audit records for intelligent insights can help your organization conduct forensic and compliance investigations by providing visibility to events such as when mail items were accessed, or when mail items were replied to and forwarded, or when and what a user searched for in Exchange Online and SharePoint Online. These intelligent insights can help you investigate possible breaches and determine the scope of compromise.
- **Higher bandwidth to the Office 365 Management Activity API**. Audit (Premium) provides organizations with more bandwidth to access auditing logs through the Office 365 Management Activity API. Although all organizations (that have Audit (Standard) or Audit (Premium)) initially receive a baseline of 2,000 requests per minute, this limit dynamically increases depending on an organization's seat count and their licensing subscription. This change results in organizations with Audit (Premium) getting about twice the bandwidth as organizations with Audit (Standard).

Long-term retention of audit logs

Audit (Premium) retains all Exchange, SharePoint, and Microsoft Entra audit records for one year. This retention happens through a default audit log retention policy that retains any audit record that contains the value of **AzureActiveDirectory**, **Exchange**, **OneDrive**, or **SharePoint**, for the **Workload** property (which indicates the service in which the activity occurred) for one year.

Retaining audit records for longer periods can help with ongoing forensic or compliance investigations. For more information, see the "Default audit log retention policy" section in Manage audit log retention policies.

In addition to the one-year retention capabilities of Audit (Premium), Microsoft also released the capability to retain audit logs for 10 years. The 10-year retention of audit logs helps support long running investigations and respond to regulatory, legal, and internal obligations.

> **Note**
>
> Retaining audit logs for 10 years requires an additional per-user add-on license. After you assign this license to a user and set an appropriate 10-year audit log retention policy for that user, audit logs covered by that policy start to be retained for the 10-year period. This policy isn't retroactive and can't retain audit logs that were generated before the 10-year audit log retention policy was created.

Audit log retention policies

All audit records that other services generate and that the default audit log retention policy doesn't cover are retained for 180 days. You can create customized audit log retention policies to retain other audit records for longer periods, up to 10 years. You can create a policy to retain audit records based on one or more of the following criteria:

- The Microsoft service where the audited activities occur.
- Specific audited activities.
- The user who performs an audited activity.

> **Important**
>
> The default retention period for Audit (Standard) changed from 90 days to 180 days. Audit (Standard) logs generated before October 17, 2023, are retained for 90 days. Audit (Standard) logs generated on or after October 17, 2023, follow the new default retention of 180 days. You can also specify how long to retain audit records that match the policy and a priority level so that specific policies take priority over other policies. Any custom audit log retention policy takes precedence over the default audit retention policy if you need to retain Exchange, SharePoint, or Microsoft Entra ID audit records for less than a year or for 10

years for some or all users in your organization. For more information, see Manage audit log retention policies.

> **Important**
>
> The audit item lifetime for data is determined when the auditing pipeline adds the data and is based on the licensing defaults or applicable retention policies. Any changes to licensing or applicable retention policies change the expiration time of the audit data after updating. These changes don't affect any previously committed items.

Audit (Premium) activity properties

Audit (Premium) helps organizations conduct forensic and compliance investigations by providing access to important events, such as when users access mail items, reply to and forward mail items, and search in Exchange Online and SharePoint Online. These events can help you investigate possible breaches and determine the scope of compromise. In addition to these events in Exchange and SharePoint, other Microsoft services include important events that require assigning users the appropriate Audit (Premium) license. Assign an Audit (Premium) license to users so the system generates audit logs when they perform these events.

These activities require that you assign users the appropriate Audit (Premium) license. Assign an Audit (Premium) license to users so the system generates audit logs when they perform these activities and properties.

Audit (Premium) provides access to the following activity properties:

Exchange Online

High-bandwidth access to the Office 365 Management Activity API

Organizations that access auditing logs through the Office 365 Management Activity API faced throttling limits at the publisher level. This throttling limit meant that if a publisher pulled data for multiple customers, all those customers shared the same limit.

With Audit (Premium), this limit changed from a publisher-level limit to a tenant-level limit. Each organization now gets its own fully allocated bandwidth quota to access its auditing data. The bandwidth isn't a static, predefined limit. Instead, it's modeled on a combination of factors, including the number of seats in the organization. E5, A5, and G5 organizations get more bandwidth than non-E5, non-A5, and non-G5 organizations.

All organizations initially get a baseline of 2,000 requests per minute. This limit dynamically increases based on an organization's seat count and licensing subscription. E5, A5, and G5 organizations get about twice as much bandwidth as non-E5, non-A5, and non-G5 organizations. A cap on the maximum bandwidth protects the health of the service.

For more information, see the **API throttling** section in Office 365 Management Activity API reference.

Licensing requirements

Before you get started, review the subscription requirements for Audit (Standard) and Audit (Premium).

Next steps

> **Tip**
>
> Training your security operations team, IT administrators, and compliance investigators in Audit (Standard) and Audit (Premium) can help your organization get started more quickly. For more information, see **Describe the eDiscovery and audit capabilities of Microsoft Purview**.

- Get started with auditing solutions: Walk through the setup steps to enable Audit (Standard) or Audit (Premium) in your organization.
- Search the audit log: Run your first audit log search to find user and admin activities.
- Manage audit log retention policies: Create custom retention policies to keep audit records beyond the default period.

Get started with auditing solutions

Microsoft Purview Audit (Standard) and Audit (Premium) enable you to search for audit records of activities that users and admins perform in different Microsoft services. Because Audit (Standard) is enabled by default for most Microsoft 365 organizations, you only need to complete a few steps before you and others in your organization can search the audit log. To use features available only in Audit (Premium), you need to complete a few more configuration steps.

For more information about Audit (Standard) and Audit (Premium) capabilities, see Microsoft Purview auditing solutions.

Step 1: Verify organization subscription and billing

Licensing for Audit (Standard) and Audit (Premium) requires the appropriate organization subscription that provides access to the audit log search tool and per-user licensing that's required to log and retain audit records.

When a user or admin performs an audited activity, the system generates an audit record and stores it in the audit log for your organization. In Audit (Standard) and Audit (Premium), you can retain and search audit records in the audit log for 180 days.

> **Important**
>
> The default retention period for Audit (Standard) changed from 90 days to 180 days. Audit (Standard) logs that were generated before October 17, 2023, are retained for 90 days. Audit (Standard) logs that are generated on or after October 17, 2023, follow the new default retention of 180 days.

For a list of subscription and licensing requirements for these auditing solutions, see the subscription requirements for Audit (Standard) and Audit (Premium).

To audit user interactions with non-Microsoft 365 AI data, which includes information from other generative AI applications from Microsoft and connected external AI applications, you must enable pay-as-you-go billing for your organization. This data type includes Copilot in Microsoft Fabric, Microsoft Security Copilot, Microsoft Copilot Studio, and any connected or cloud AI application.

Step 2: Assign permissions to search the audit log

Admins and members of investigation teams must be assigned the *View-Only Audit Logs* or *Audit Logs* role in the Microsoft Purview portal to search or export the audit log. By default, the

Microsoft Purview portal **Role groups** page assigns these roles to the *Audit Reader* and *Audit Manager* role groups.

> ⓘ **Note**
>
> Currently, Exchange admin center permissions are required to enable or disable auditing and to access audit cmdlets. Use the existing *Audit Logs* and *View-Only Audit Logs* roles in Exchange admin center to grant access to audit cmdlets. Use the existing *Audit Logs* role in Exchange admin center to grant access to enable or disable auditing.

You can also create custom role groups with the ability to search the audit log by adding the *View-Only Audit Logs* or *Audit Logs* roles to a custom role group. For more information, see Permissions in the Microsoft Purview portal.

> ⓘ **Note**
>
> Access to the **Audit Search Graph API** requires additional permissions to be configured in Microsoft Graph. For more information, see **Permissions in Audit Search Graph API**.

Assign permissions to scope audit logs

To search or export the audit log, administrators or members of investigation teams must be assigned to at least one of the following audit-related role groups in the Microsoft Purview portal:

- **Audit Manager**: A user assigned to the *Audit Manager* role group can search and export the audit log and manage audit settings for the tenant (like enabling or disabling audit logging). This role group grants the *View-Only Audit Logs* and *Audit Logs* roles to the user.
- **Audit Reader**: A user assigned to the **Audit Reader** role group can only search and export the audit log. They can't enable or disable audit logging. This role group grants the *View-Only Audit Logs* role to the user.

Step 3: Enable/Disable SearchQueryInitiatedExchange/SearchQueryInitiatedShare events

SearchQueryInitiatedExchange must be enabled explicitly for logging when users perform searches in Exchange Online.

SearchQueryInitiatedSharePoint is by default enabled for logging when users perform searches in SharePoint.

To enable Exchange Online and SharePoint events to be audited for users, run the following cmdlet (for each user) in Exchange Online PowerShell:

PowerShell

```
Set-Mailbox <user> -AuditOwner @{Add="SearchQueryInitiated"} // For Exchange Online

Set-Mailbox <user> -AuditOwner @{Add="SharepointSearchQueryInitiated"} // For
SharePoint. Enabled by default.
```

In a multi-geo environment, you must run the **Set-Mailbox** command in the forest where the user's mailbox is located. To identify the user's mailbox location, run the following cmdlet:

PowerShell

```
Get-Mailbox <user identity> | FL MailboxLocations
```

If you previously ran the cmdlet to enable auditing of search queries in a forest that's different than the forest where the user's mailbox is located, remove the *SearchQueryInitiated/SharepointSearchQueryInitiated* value from the user's mailbox. To remove the value, run `Set-Mailbox -AuditOwner @{Remove="SearchQueryInitiated"} for Exchange Online and Set-Mailbox -AuditOwner @{Remove="SharepointSearchQueryInitiated"}`. Then, add it to the user's mailbox in the forest where the user's mailbox is located.

> **Note**
>
> These PowerShell cmdlets are valid only for SearchQueryInitiated and SharepointSearchQueryInitiated events and don't apply to other events within the audit log.

Step 4: Set up Audit (Premium) for users

> **Tip**
>
> Organizations using Audit (Standard) can skip this step.

Audit (Premium) features, such as the ability to log intelligent insights, require an appropriate E5 license assigned to users. Additionally, you must enable the Advanced Auditing app/service plan for those users.

To enable the Advanced Auditing service plan for users, complete the following steps for each user:

1. In the Microsoft 365 admin center, go to **Users** > **Active users**, and select a user.
2. On the user properties flyout page, select **Licenses and apps**.

3. In the **Licenses** section, verify that the user is assigned an E5 license or is assigned an appropriate add-on license. For a list of licenses that support Audit (Premium), see Audit licensing requirements.
4. Expand the **Apps** section and select the **Microsoft 365 Advanced Auditing** checkbox.
5. Select **Save changes**. The logging of Audit (Premium) insights begins within 24 hours.

If you customize the mailbox actions that are logged on user mailboxes or shared mailboxes, new Audit (Premium) events released by Microsoft aren't automatically audited on those mailboxes. For information about changing the mailbox actions that are audited for each sign-in type, see the "Change or restore mailbox actions logged by default" section in Manage mailbox auditing.

Step 5: Set up audit retention policies in Audit (Premium)

> **Tip**
>
> Organizations using Audit (Standard) can skip this step.

In addition to the default policy that retains Microsoft Entra ID, Exchange, OneDrive, and SharePoint audit records for one year, organizations using Audit (Premium) can create audit log retention policies to meet the requirements of your organization's security operations, IT, and compliance teams.

For more information, see Manage audit log retention policies.

Step 6: Search for audited events

Now that you have Audit (Standard) or Audit (Premium) configured for your organization, you're ready to search the audit log in the Microsoft Purview portal. For detailed guidance, see Search the audit log.

Next steps

- Search the audit log: Run your first audit log search now that auditing is configured.
- Manage audit log retention policies: Create custom retention policies to keep audit records longer than the default period.
- Export, configure, and view audit log records: Export search results to CSV for offline analysis.

ⓘ**Note:** The author created this article with assistance from AI. Learn more

---

Last updated on 09/08/2026

Turn auditing on or off

Audit logging is on by default for Microsoft 365 organizations. However, when you set up a new Microsoft 365 organization, verify the auditing status for your organization. For instructions, see Verify the auditing status for your organization.

When you turn on auditing in the Microsoft Purview portal, the audit log records user and admin activity from your organization and automatically retains it for 180 days. The retention (lifetime) for audit data starts when it's added to the auditing log and is retained based on audit log retention policies and the license assigned to users.

> **Important**
>
> Auditing isn't enabled by default for Small and Medium Business (SMB) licenses, including Microsoft 365 Business Basic, Business Standard, and Business Premium. Additionally, unmanaged tenants that use free trials of enterprise licenses don't have auditing enabled by default. In both these cases, you must manually enable auditing for your organization.

Changes to the user licensing or retention policies also change the expiration date of audit data.

Your organization might have reasons for not wanting to record and retain audit log data. In these cases, a global admin can turn off auditing in Microsoft 365 for your organization. For instructions, see Turn off auditing.

> **Important**
>
> If you turn off auditing in Microsoft 365, you can't use the Office 365 Management Activity API or Microsoft Sentinel to access auditing data or logs for your organization. When you turn off auditing, searches of the audit log in Microsoft Purview return no results. Running the **Search-UnifiedAuditLog** cmdlet in Exchange Online PowerShell also returns no results.

Before you turn auditing on or off

You must be assigned the *Audit Logs* role in Exchange Online to turn auditing on or off. By default, the *Compliance Management* and *Organization Management* role groups on the

Permissions page in the Exchange admin center have this role.

- For step-by-step instructions on searching the audit log, see Search the audit log.
- For more information about the Microsoft 365 Management Activity API, see Get started with Microsoft 365 Management APIs.

Verify the auditing status for your organization

To verify that auditing is turned on for your organization, run the following command in Exchange Online PowerShell:

```
PowerShell
Get-AdminAuditLogConfig | Format-List UnifiedAuditLogIngestionEnabled
```

A value of `True` for the *UnifiedAuditLogIngestionEnabled* property indicates that auditing is turned on. A value of `False` indicates that auditing isn't turned on.

> **Important**
>
> Be sure to run the previous command in Exchange Online PowerShell. Although the **Get-AdminAuditLogConfig** cmdlet is also available in Security & Compliance PowerShell, the *UnifiedAuditLogIngestionEnabled* property is always `False`, even when auditing is turned on.

Turn on auditing

If auditing isn't turned on for your organization, turn it on in the Microsoft Purview portal or by using Exchange Online PowerShell. Audit events might take several hours after you turn on auditing before they become searchable in the audit log.

Complete the following steps to turn on auditing:

1. Sign in to the Microsoft Purview portal.
2. Select the **Audit** solution card. If the **Audit** solution card isn't displayed, select **View all solutions** and then select **Audit** from the **Core** section.
3. If auditing isn't turned on for your organization, a banner is displayed prompting you to start recording user and admin activity.
4. Select the **Start recording user and admin activity** banner.

Enabling auditing might take up to 60 minutes to take effect.

Use PowerShell to turn on auditing

Complete the following steps to turn on auditing by using Exchange Online PowerShell:

1. Connect to Exchange Online PowerShell.
2. Run the following PowerShell command to turn on auditing.

   PowerShell

   ```
   Set-AdminAuditLogConfig -UnifiedAuditLogIngestionEnabled $true
   ```

   A message is displayed saying that enabling auditing might take up to 60 minutes to take effect.

Turn off auditing

Use Exchange Online PowerShell to turn off auditing.

1. Connect to Exchange Online PowerShell.
2. Run the following PowerShell command to turn off auditing.

   PowerShell

   ```
   Set-AdminAuditLogConfig -UnifiedAuditLogIngestionEnabled $false
   ```

3. After a while, verify that auditing is turned off (disabled). You can do this in two ways:

   - In Exchange Online PowerShell, run the following command:

     PowerShell

     ```
     Get-AdminAuditLogConfig | FL UnifiedAuditLogIngestionEnabled
     ```

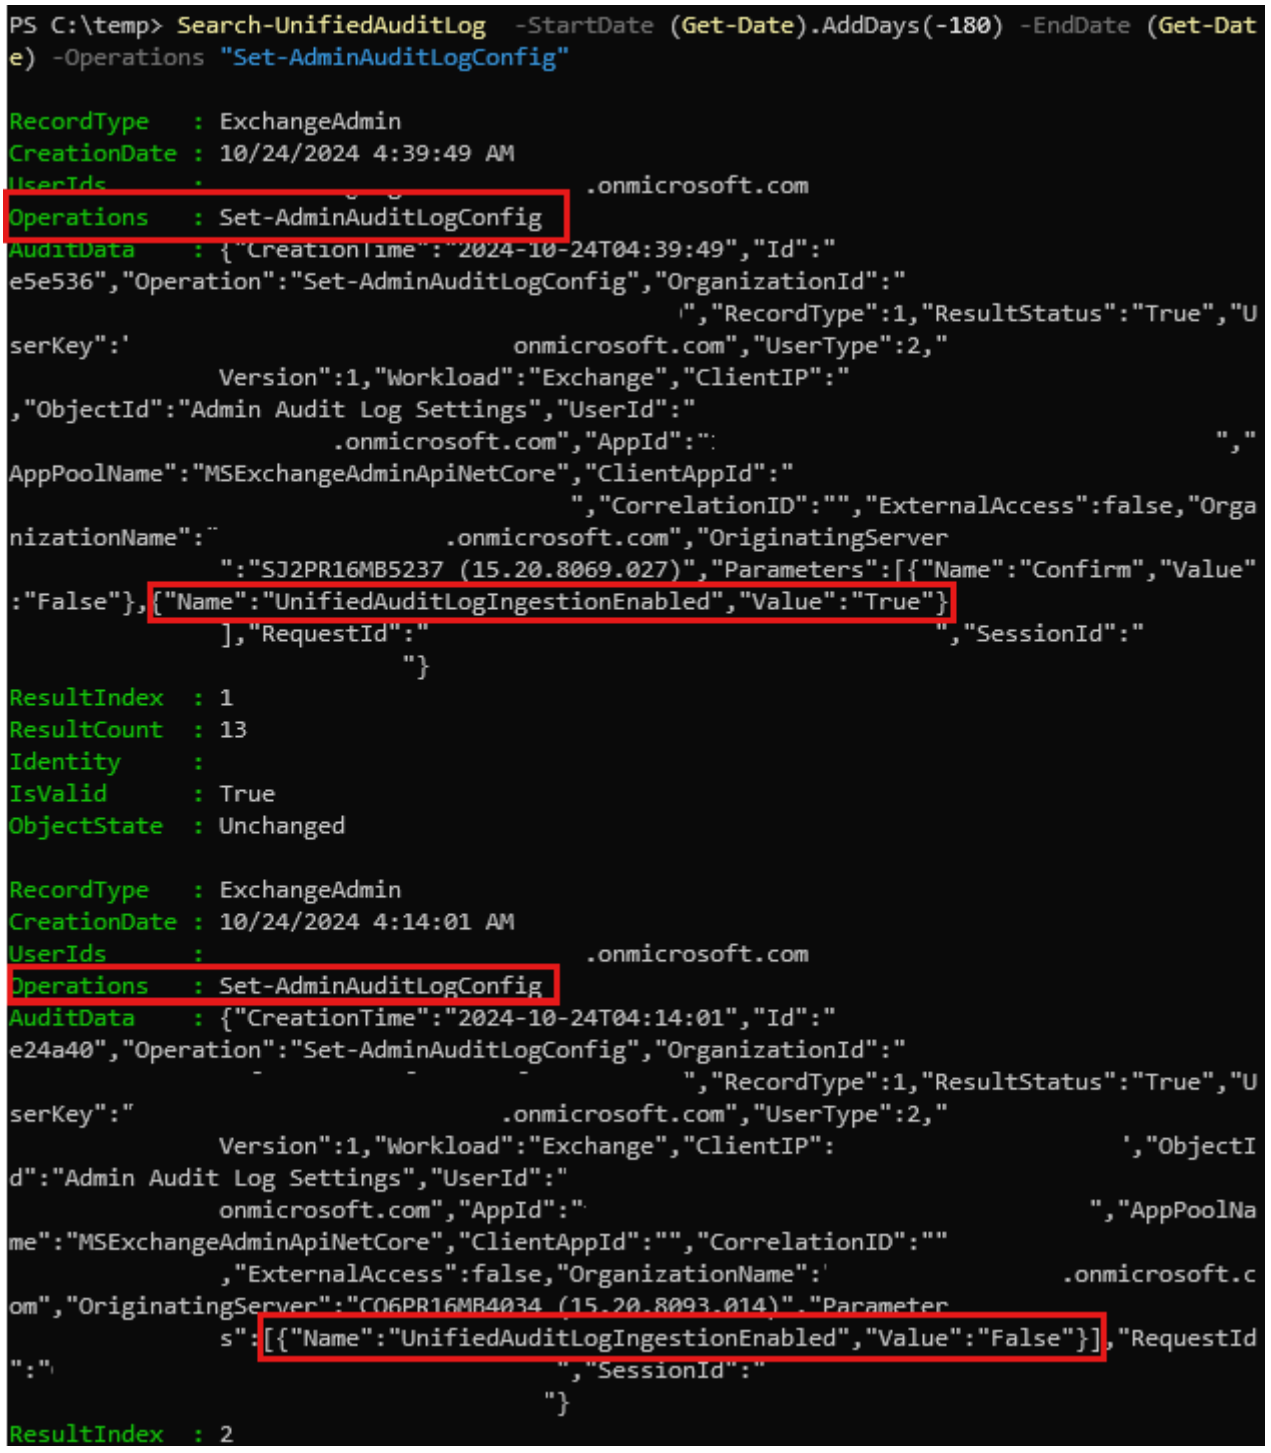
     The value of `False` for the *UnifiedAuditLogIngestionEnabled* property indicates that auditing is turned off.

   - Go to the **Audit** page in the Microsoft Purview portal.

     If auditing isn't turned on for your organization, a banner prompts you to start recording user and admin activity.

Audit records when auditing status is changed

Your organization audits changes to the auditing status. Audit records are logged when auditing is turned on or turned off. You can search the Exchange admin audit log for these audit records.



To search the Exchange admin audit log for audit records that are generated when turning auditing on or off, run the following command in Exchange Online PowerShell:

PowerShell

```
Search-UnifiedAuditLog -Operations Set-AdminAuditLogConfig
```

Audit records for turning auditing on or off contain information about when the auditing status was changed, the admin who changed it, and the IP address of the computer that was used to make the change. The following screenshots show audit records that correspond to changing the auditing status in your organization.

Audit record for Set-AdminAuditLogConfig

Look for the result value of `UnifiedAuditLogIngestionEnabled` in the *AuditData* property. The `UnifiedAuditLogIngestionEnabled` value indicates whether unified audit logging was turned on or off in the Microsoft Purview portal or by running the **Set-AdminAuditLogConfig -UnifiedAuditLogIngestionEnabled $true/false** cmdlet.

For more information about searching the Exchange admin audit log, see Search-UnifiedAuditLog.

Next steps

- Get started with auditing solutions: Complete the remaining setup steps after enabling auditing, including permissions and retention policies.
- Search the audit log: Start searching for user and admin activities now that auditing is turned on.
- Manage mailbox auditing: Verify and customize which mailbox actions are audited in your organization.

Search the audit log

Search in Microsoft Purview Audit (Standard) and Audit (Premium) gives your organization access to critical audit log event data so you can gain insight and further investigate user activities.

- Search jobs that you start through the Microsoft Purview portal don't need the web browser window to stay open to finish. These jobs keep running even after you close the browser window.
- The system now keeps completed search jobs for 30 days, so you can look back at past audit searches.
- Each admin Audit account user can have up to 10 search jobs running at the same time, with a limit of one unfiltered search job.

Before you search the audit log

Review the following items before you start searching the audit log.

- Audit log search is turned on by default for Microsoft 365 and Office 365 enterprise organizations. Verify the current unified audit log ingestion setting for your organization by running the following command in **Exchange Online PowerShell**:

  ```
  PowerShell
  Get-AdminAuditLogConfig | Format-List UnifiedAuditLogIngestionEnabled
  ```

  The value of `True` for the *UnifiedAuditLogIngestionEnabled* property indicates that audit log search is turned on. For more information, see Turn audit log search on or off.

  > **Important**
  >
  > Be sure to run the previous command in Exchange Online PowerShell. Although the **Get-AdminAuditLogConfig** cmdlet is also available in Security & Compliance PowerShell, the *UnifiedAuditLogIngestionEnabled* property is always `False`, even when audit log search is turned on.

- You must be assigned the *Audit Logs* or *View-Only Audit Logs* roles in the Microsoft Purview portal to search the audit log. For more information, see Get started with auditing solutions. To access audit cmdlets, you must be assigned the *Audit Logs* or *View-Only Audit Logs* roles

in the Exchange admin center. You can also create custom role groups with the ability to search the audit log by adding the *View-Only Audit Logs* or *Audit Logs* roles to a custom role group. For more information, see Permissions in the Microsoft Purview portal.

- When a user or admin performs an audited activity, the system generates an audit record and stores it in the audit log for your organization. The length of time that an audit record is retained (and searchable in the audit log) depends on your Office 365 or Microsoft 365 Enterprise subscription, and specifically the type of the license that is assigned to specific users.

  - For users assigned an Office 365 E5 or Microsoft 365 E5 license (or users with a Microsoft Purview Suite (formerly known as Microsoft 365 E5 Compliance) or Microsoft 365 E5 eDiscovery and Audit add-on license), the system retains audit records for Microsoft Entra ID, Exchange, and SharePoint activity for one year by default. Organizations can also create audit log retention policies to retain audit records for activities in other services for up to one year. For more information, see Manage audit log retention policies.

    > **Note**
    >
    > If your organization participated in the private preview program for the one-year retention of audit records, the retention duration for audit records that were generated before the general availability rollout date won't be reset.

  - For users assigned any other (non-E5) Office 365 or Microsoft 365 license, the system retains audit records for 180 days. For a list of Office 365 and Microsoft 365 subscriptions that support unified audit logging, see the subscription requirements for Audit (Standard) and Audit (Premium).

    > **Important**
    >
    > The default retention period for Audit (Standard) changed from 90 days to 180 days. Audit (Standard) logs generated before October 17, 2023 are retained for 90 days. Audit (Standard) logs generated on or after October 17, 2023 follow the new default retention of 180 days.

    > **Note**

> Even when mailbox auditing on by default is turned on, you might notice that mailbox audit events for some users aren't found in audit log searches in the Microsoft Purview portal or via the Office 365 Management Activity API. For more information, see **Mailbox audit logging**.

- To turn off audit log search for your organization, use the following command to disable unified audit log ingestion in Exchange Online PowerShell:

  ```
  PowerShell
  Set-AdminAuditLogConfig -UnifiedAuditLogIngestionEnabled $false
  ```

  To turn unified audit log ingestion back on for your organization, run the following command in Exchange Online PowerShell:

  ```
  PowerShell
  Set-AdminAuditLogConfig -UnifiedAuditLogIngestionEnabled $true
  ```

  For more information, see Turn off audit log search.

- The underlying cmdlet used to search the audit log is an Exchange Online cmdlet, which is **Search-UnifiedAuditLog**. That means you can use this cmdlet to search the audit log instead of using the search tool on the **Audit** page in the Microsoft Purview portal. You have to run this cmdlet in Exchange Online PowerShell. For more information, see Search-UnifiedAuditLog.

  For information about exporting the search results returned by the **Search-UnifiedAuditLog** cmdlet to a CSV file, see Tips for exporting and viewing the audit log.

- To programmatically download data from the audit log, use the Office 365 Management Activity API instead of a PowerShell script. The Office 365 Management Activity API is a REST web service that you can use to develop operations, security, and compliance monitoring solutions for your organization. For more information, see Office 365 Management Activity API reference.

- Microsoft Entra ID is the directory service for Microsoft 365. The unified audit log contains user, group, application, domain, and directory activities performed in the Microsoft 365 admin center or in the Azure management portal. For a complete list of Microsoft Entra events, see Microsoft Entra audit Report Events.

- Microsoft doesn't guarantee a specific time after an event occurs for the corresponding audit record to be returned in the results of an audit log search. For core services (such as Exchange, SharePoint, OneDrive, and Teams), audit record availability is typically 60 to 90 minutes after an event occurs. For other services, audit record availability might be longer. However, some issues that are unavoidable (such as a server outage) might occur outside of the audit service that delays the availability of audit records. For this reason, Microsoft doesn't commit to a specific time.
- To search for Power BI activities in the audit log, you have to enable auditing in the Power BI admin portal. For instructions, see the "Audit logs" section in Power BI admin portal.

Get started with search

> **Important**
>
> The execution time (search time) of a Search job depends on several factors, including the selected date range, the number of users included, the volume of activities, and overall tenant size. In large tenants with a high number of users, broadly-scoped Search jobs may take up to 48 hours to complete.

Complete the following steps to get started with search:

1. Sign in to the Microsoft Purview portal.
2. Select the **Audit** solution card. If the **Audit** solution card isn't displayed, select **View all solutions** and then select **Audit** from the **Core** section.
3. On the **Search** page, configure the following search criteria as applicable:
    a. **Date and time range (UTC)**: The last seven days are selected by default. Select a date and time range to display the events that occurred within that period. The date and time are presented in Coordinated Universal Time (UTC). The maximum date range that you can specify is 180 days. An error is displayed if the selected date range is greater than 180 days.

    > **Tip**
    >
    > If you use the maximum date range of 180 days, select the current time for the **Start date**. Otherwise, you receive an error saying that the start date is earlier than the

end date. If you turn on auditing within the last 180 days, the maximum date range can't start before the date that auditing was turned on.

b. **Keyword Search**: Enter a keyword or phrase to search for in the audit log. The keyword or phrase is searched for in the audit log or in the file, folder, or sites (if specified) for the search. To search for text that contains special characters, replace the special characters with an asterisk(*) in your keyword search. For example, to search for *test_search_document*, use *test*search*document*.

> **Important**
>
> Terms entered in the **Keyword Search** field are only searched within indexed content (content within the Audit *common schema*). Audit *data content* in the audit log isn't searched for these keywords.

c. **Admin Units**: Select the drop-down list to display the administrative units you want the audited activities scoped to for your search. You can select one or more administrative units to scope your search to. Leave this box blank to return entries for all administrative units in your organization.

d. **Activities - friendly names**: Select the drop-down list to display the friendly names for audited activities that you can search for. Friendly names for user and admin activities are organized into groups of related activities. Using friendly names, you can select specific audited activities or you can select the activity group name to select all activities in the group. You can also select a selected activity to clear the selection. To search for a friendly name in the **Activities - friendly names** drop-down list, use the search box above that list.

e. **Activities - operations names**: Enter the exact operation names to search for audited activities to include in your search results. You can enter one or more operation names, separated by commas. The **Activities - operations names** search criterion is similar to previous searches only available in PowerShell and provides greater flexibility helping you find the data that you need.

> **Important**

> Operation names must be entered exactly as they are named. If operation names are entered incorrectly, no results are returned.

For example, to search for all activities related to enabling and disabling information barriers for a SharePoint site in your organization, you would:

- Review the audit activities article to find the exact operation name for the information barriers activities you want to search for. In this information barriers activities example, the operation names are *SPOIBIsEnabled* and *SPOIBIsDisabled*.
- Enter *SPOIBIsEnabled,SPOIBIsDisabled* in the **Activities - operations names** field. Copy and paste the operation names directly from audit activities to the **Activities - operations names** field to ensure that they're entered correctly and without typos.

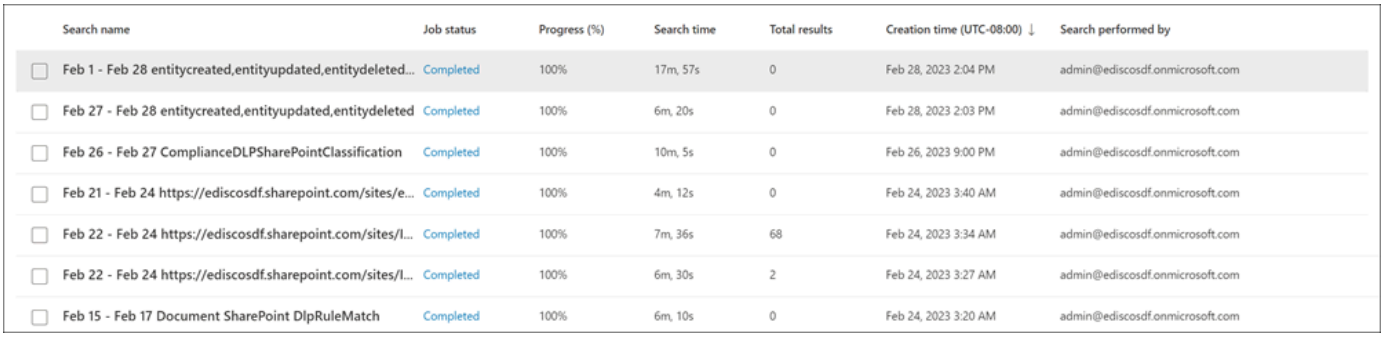
f. **Record types**: Select the drop-down list to display the record types for audited activities that you can search for. You can select one or more record types to search for. To search for a record type in the list, use the search box over the list.

   Specific record types are associated with specific Microsoft services and applications. For example, if you want to scope your search for specific record types associated with sensitivity labels in Microsoft Purview Information Protection (MIP), you could select the *MIPLabel*, *MipAutoLabelExchangeItem*, *MipAutoLabelSharePointItem*, and *MipAutoLabelSharePointPolicyLocation* record types from the list.

g. **Search name**: Enter in a custom name for your search job. This name is used to identify your search job in the search job history. If you don't enter a name, the search job is automatically named using a combination of the date and time defined for the search and other defined search criteria values.

h. **Users**: Select this field and select the names one or more users to display search results for. The audit log entries for the selected activity performed by the users you select in this box are displayed in the list of results. Leave this box blank to return entries for all users (and service accounts) in your organization.

i. **File, folder, or site**: Enter part or all of a file or folder name to find related activity. This returns results for matching files, folders, and sites. You can also enter a full URL or part of one, just avoid special characters or spaces. You can use * as a wildcard at the end of the URL. For example, `https://<tenantname>.sharepoint.com/sites/site123*`. Leave the field blank to see activity for all files and folders in your organization.



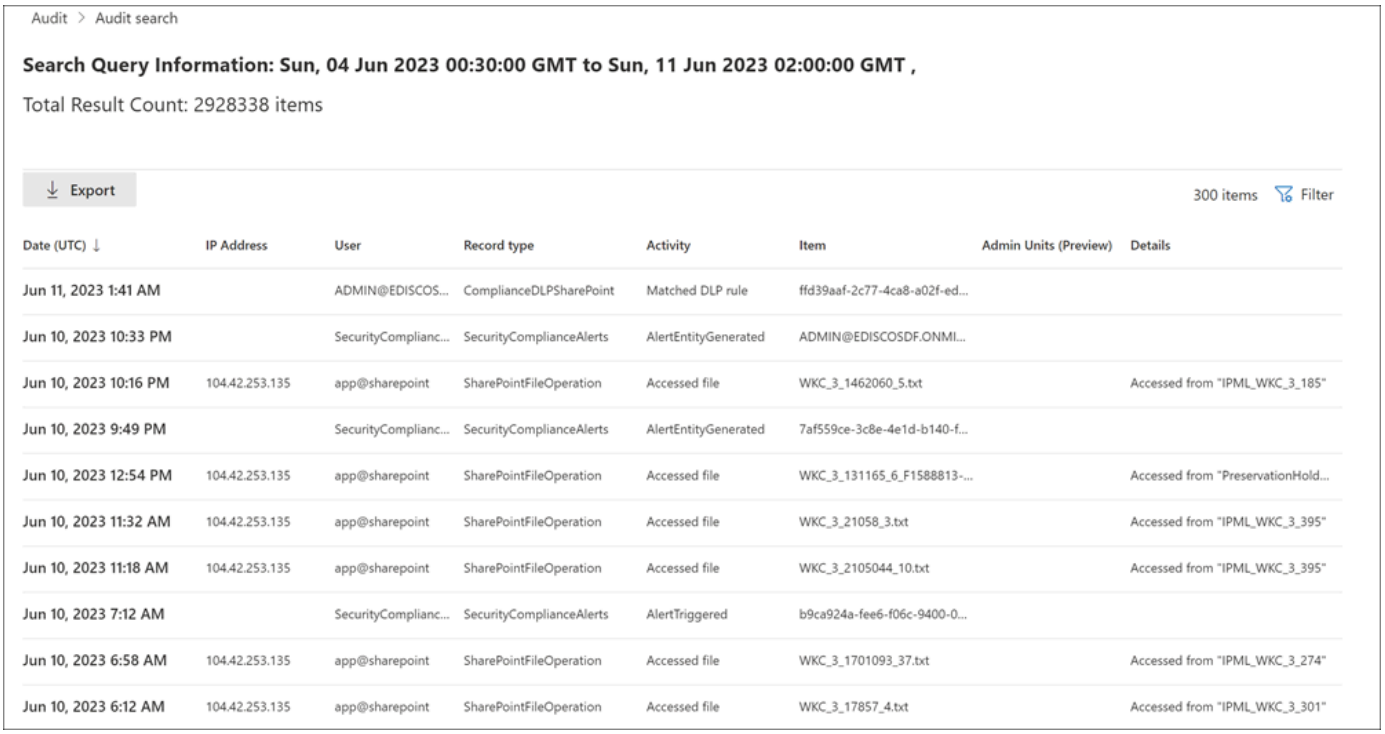
j. **Workloads**: Enter or search for workload services to search for activity related to the selected workloads. Enter the name of a workload to jump to the workload in the list or scroll to the workloads you'd like to select.

4. Select **Search** to start your search job. A maximum of 10 search jobs can be run in parallel for one user account. If a user requires more than 10 search jobs, they must wait for an *In progress* job to finish or delete a search job.

Search job dashboard

The search job dashboard displays active and completed search jobs. For each search job, the dashboard shows the following information:

- **Search name**: The name of the search job. You can see the full search name for a job by hovering the cursor over the search job name.
- **Job status**: The status of the search job. The status can be *Queued*, *In Progress*, or *Completed*.
- **Progress (%)**: The percentage of the search job that the job completes.
- **Search time**: The total running time that elapses to complete the search job.
- **Total results**: The total number of results the search job returns.
- **Creation time**: The date and time the search job created in UTC.
- **Search performed by**: The user account that creates the search job.



Search name	Job status	Progress (%)	Search time	Total results	Creation time (UTC-08:00) ↓	Search performed by
Feb 1 - Feb 28 entitycreated,entityupdated,entitydeleted...	Completed	100%	17m, 57s	0	Feb 28, 2023 2:04 PM	admin@ediscosdf.onmicrosoft.com
Feb 27 - Feb 28 entitycreated,entityupdated,entitydeleted	Completed	100%	6m, 20s	0	Feb 28, 2023 2:03 PM	admin@ediscosdf.onmicrosoft.com
Feb 26 - Feb 27 ComplianceDLPSharePointClassification	Completed	100%	10m, 5s	0	Feb 26, 2023 9:00 PM	admin@ediscosdf.onmicrosoft.com
Feb 21 - Feb 24 https://ediscosdf.sharepoint.com/sites/e...	Completed	100%	4m, 12s	0	Feb 24, 2023 3:40 AM	admin@ediscosdf.onmicrosoft.com
Feb 22 - Feb 24 https://ediscosdf.sharepoint.com/sites/l...	Completed	100%	7m, 36s	68	Feb 24, 2023 3:34 AM	admin@ediscosdf.onmicrosoft.com
Feb 22 - Feb 24 https://ediscosdf.sharepoint.com/sites/l...	Completed	100%	6m, 30s	2	Feb 24, 2023 3:27 AM	admin@ediscosdf.onmicrosoft.com
Feb 15 - Feb 17 Document SharePoint DlpRuleMatch	Completed	100%	6m, 10s	0	Feb 24, 2023 3:20 AM	admin@ediscosdf.onmicrosoft.com

Deleting a search job removes only the search job definition and the associated search result, not the backend data associated with search. To delete a search job, select the search job in the dashboard and then select **Delete** on the command bar.

To copy the search criteria for an existing search job, select the search job you want to copy and then select **Copy this search** on the command bar. The search criteria are copied to the search page and you can modify the search criteria as needed for a new search.

Search job details dashboard

To view details about a search job, select the search job in the dashboard. The dashboard shows the total number of items in the job at the top. The total result number removes duplicates, so it might be less than the number of items in the search job dashboard.

The search job details dashboard displays the following information about the individual items gathered in the search job results:

- **Date (UTC)**: The date and time the activity occurred.
- **IP Address**: The IP address of the device that was used to perform the activity.
- **User**: The user account that performed the activity.
- **Record type**: The record type associated with the activity.
- **Activity**: The friendly name of the activity that was performed.
- **Item**: The name of the file, folder, or site that the activity was acted on.
- **Admin Units**: The admin unit that the user account that performed the activity belongs to.
- **Details**: Additional details about the activity.

You can sort the search job items by using the column headers or create a custom filter by using the filter pane. Use the filter to filter the search job items for specific values for any of the dashboard column criteria. To export all search job items to a .csv file, select **Export** on the command bar. Export supports results up to 50,000 rows for Audit (Standard) and up to 1,000,000 rows for Audit (Premium).

Select a specific activity to see more details about the activity in a fly-out window. The fly-out window displays the additional information about the activity.

Scoping access to audit logs using administrative units

Access to search the audit log is based on the administrative units assigned to the user in the Microsoft Purview portal. A restricted admin can only search and export user-generated audit logs within the scope of their assigned administrative units. An unrestricted admin has access to all audit logs, including logs generated by non-user and system accounts. To access scoped activity logs from any Microsoft service, including Exchange mailbox activity logs, use the Search-UnifiedAuditLog cmdlet.

Expand table

Admin units assigned to admins	Admin units available to perform scoped search on	Access to search and export audit logs
None (Default): Unrestricted admin	All administrative units are available	Access to all activity logs from any user, nonuser, or system account.
One or more administrative units: Restricted admin	Only those administrative units assigned to the admin are available	Access to activity logs from users with a matching administrative unit assignment.

Only unrestricted admins can access the following audit activities through search queries. These logs are not yet accessible when queried by a restricted admin. To view a complete list of audit logs for these activities, submit a search request by using an unrestricted admin account.

Expand table

Service	Operation
Azure Information Protection	Discover
Dynamics 365	CrmDefaultActivity
Endpoint data loss prevention	FileCreated FileCreatedOnNetworkShare FileCreatedOnRemovableMedia FileDeleted
Exchange	Set-Mailbox Set-MailboxPlan SupervisionBulkEmailExclusion
Microsoft Forms	ViewRuntimeForm

For more information about administrative units, see Permissions in the Microsoft Purview portal.

Next steps

- Export, configure, and view audit log records: Export your search results to CSV and format them in Excel for analysis.
- Use a PowerShell script to search the audit log: Automate large or recurring audit log searches using PowerShell.
- Search the audit log to investigate common support issues: Apply your search skills to common investigation scenarios like compromised accounts and email forwarding.

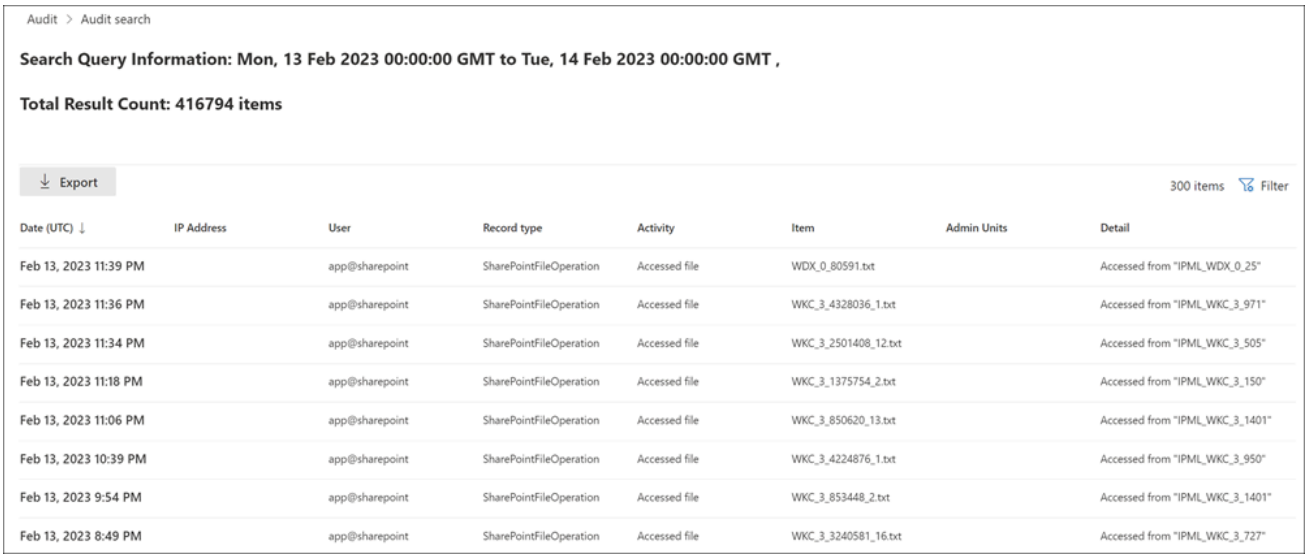
Export, configure, and view audit log records

When you search the audit log and download the search results to a comma-separated value (.csv) file, the file contains a column named **AuditData**. This column holds extra information about each event. The data in this column is formatted as a JSON object. This object contains multiple properties that appear as *property:value* pairs separated by commas. You can use the JSON transform feature in the Power Query Editor in Excel to split each property in the JSON object in the **AuditData** column into multiple columns so that each property has its own column. This feature lets you sort and filter on one or more of these properties, which can help you quickly locate the specific auditing data you're looking for.

Step 1: Export audit log search results

> **Important**
>
> For export processes to work correctly, make sure that your network firewall doesn't block the Azure Front Door domain (azurefd.net).

When you use Audit (Standard), you can export up to **50,000 records** to a .csv file from a single audit search query. For Audit (Premium), the export limit increases to **1,000,000 records**. If the number of results returned by your audit search query exceeds these limits, the exported .csv file doesn't include all results and might omit some audit logs. To ensure complete data export, consider the following recommendations:



1. **Refine the scope of your search query** by narrowing the date range or applying other filters like UserId, Operation, and more.
2. **Perform multiple searches** with smaller, segmented date ranges to capture all relevant audit logs.

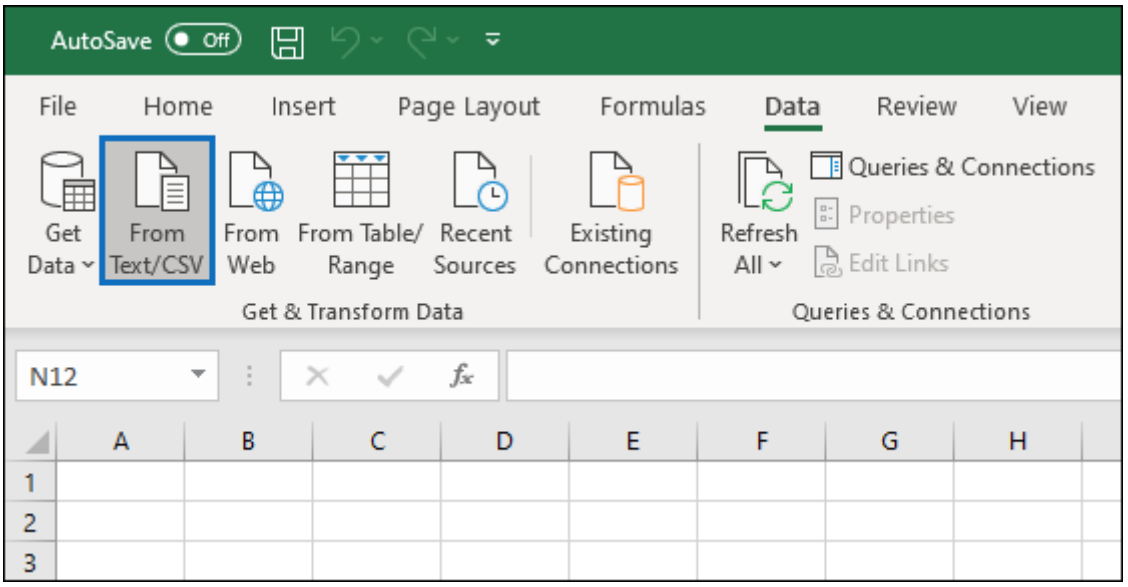
Narrowing the search scope and splitting large date ranges into smaller segments helps ensure comprehensive coverage of audit data within the export limits.

To search the audit log and export the results in a .csv file to your local computer, complete the following steps:

1. Run an audit log search and revise the search criteria if necessary until you have the desired results.

2. On the search results page, select **Export**.

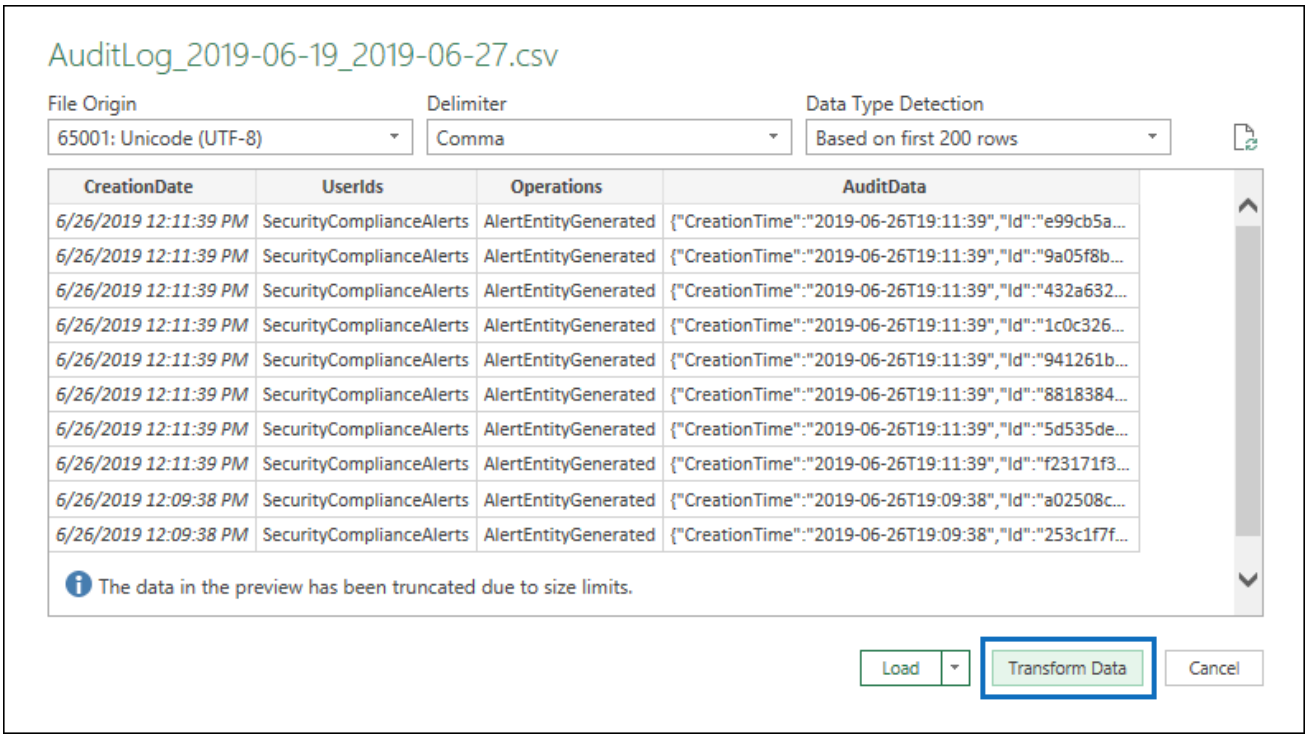
   This option exports all the audit records from the audit log search you ran in step 1. It adds the raw data from the audit log to a .csv file. It takes a while to prepare the download file for a large search. Large files result when searching for all activities or using a wide date range.



3. When the export process completes, a message appears at the top of the window that prompts you to open the .csv file and save it to your local computer. You might need to refresh the page to see this message. You can also access the .csv file in the **Downloads** folder.

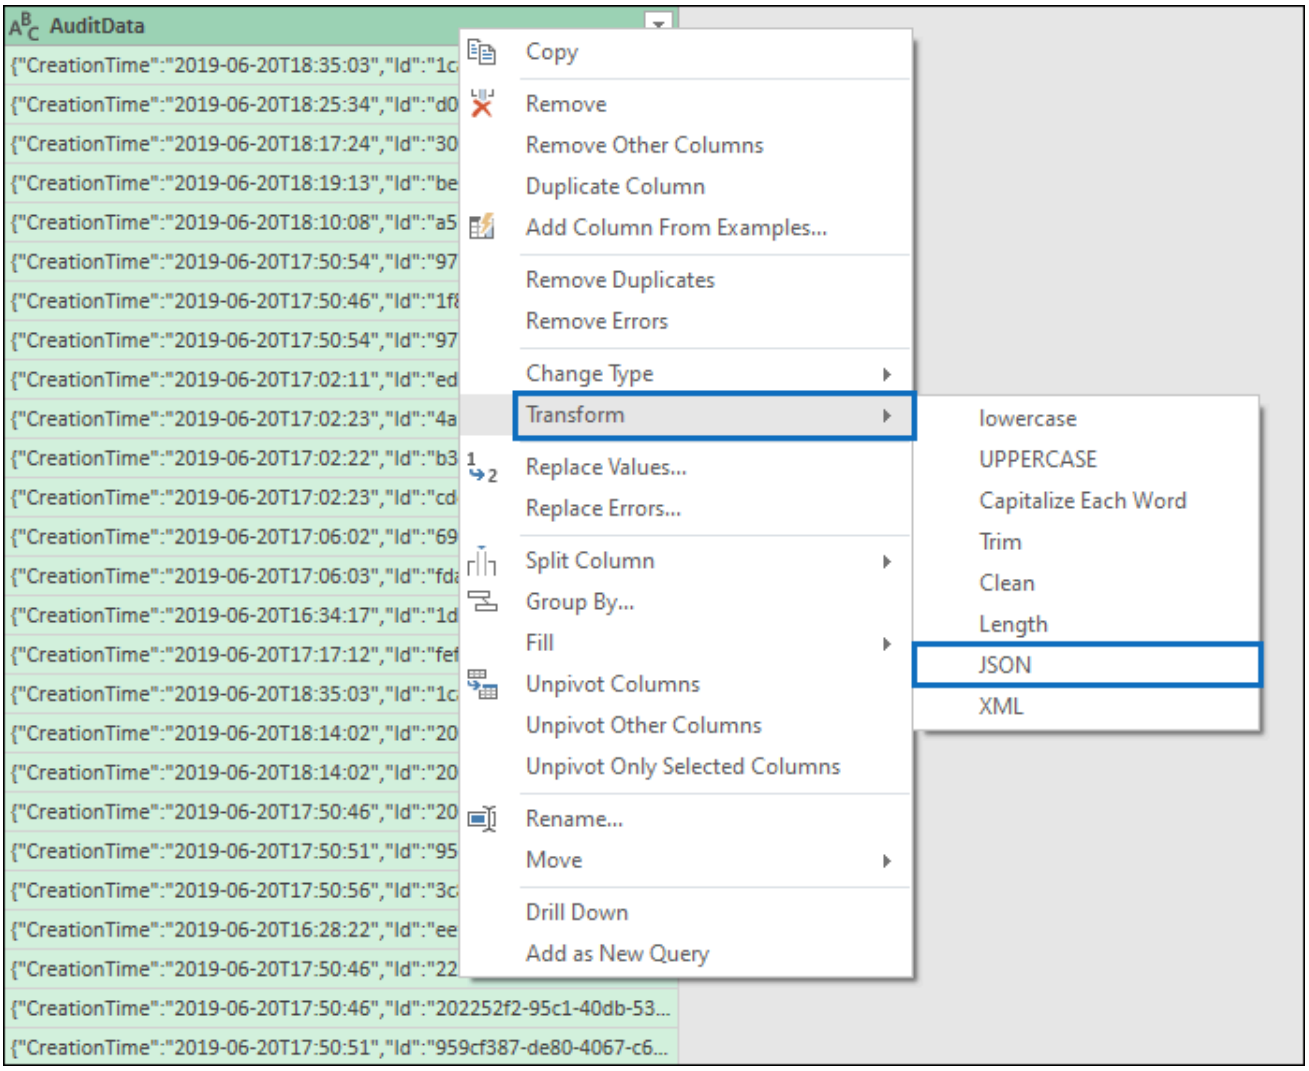
Step 2: Format the exported audit log using the Power Query Editor

In this step, you use the JSON transform feature in the Power Query Editor in Excel to split each property in the JSON object in the **AuditData** column into its own column. Then, you filter columns to view records based on the values of specific properties. This process helps you quickly locate the specific auditing data you're looking for.



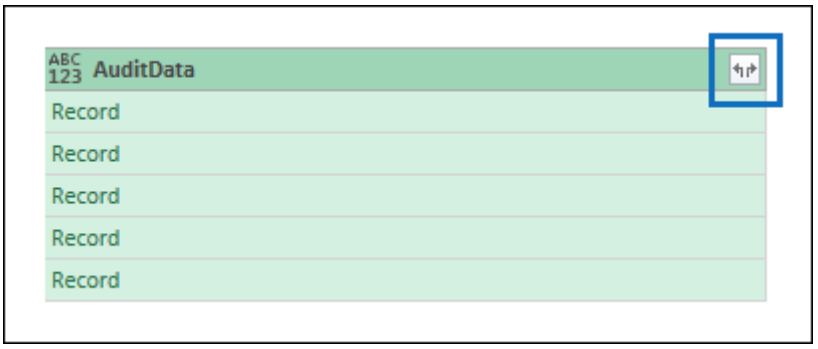
1. Open a blank workbook in Excel for Microsoft 365, Excel 2019, or Excel 2016.

2. On the **Data** tab, in the **Get & Transform Data** ribbon group, select **From Text/CSV**.



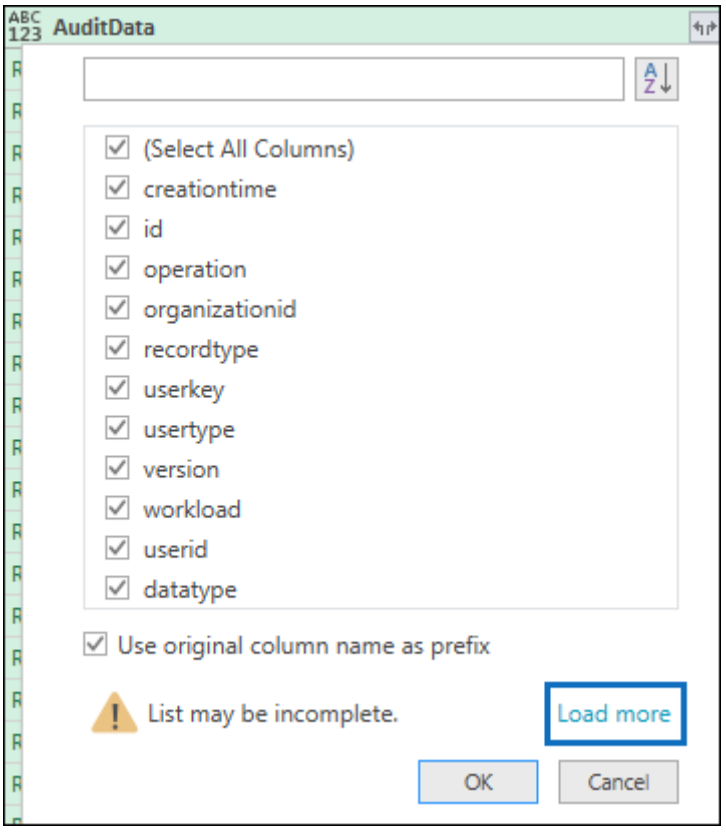
3. Open the .csv file that you downloaded in Step 1.

4. Select **Transform Data** in the window that's displayed.



The **Query Editor** opens the .csv file. You see four columns: **CreationDate**, **UserIds**, **Operations**, and **AuditData**. The **AuditData** column is a JSON object that contains multiple properties. You need to create a column for each property in the JSON object.

5. Right-click the title in the **AuditData** column, select **Transform**, and then select **JSON**.



6. Select the expand icon in the upper-right corner of the **AuditData** column.

You see a partial list of the properties in the JSON objects in the **AuditData** column.

7. Select **Load more** to display all properties in the JSON objects in the **AuditData** column.

You can clear the check box next to any property that you don't want to include. Eliminating columns that aren't useful for your investigation is a good way to reduce the amount of data displayed in the audit log.

> **Note**
>
> The JSON properties displayed in the previous screenshot (after you select **Load more**) are based on the properties found in the **AuditData** column from the first 1,000 rows in the .csv file. If different JSON properties exist in records after the first 1,000 rows, these properties (and a corresponding column) don't appear when you split the **AuditData** column into multiple columns. To help prevent this issue, consider rerunning the audit log search and narrow the search criteria so that fewer records return. Another workaround is to filter items in the **Operations** column to reduce the number of rows (before you perform step 5) before transforming the JSON object in the **AuditData** column.

> **Tip**
>
> To view an attribute within a list such as AuditData.AffectedItems, select the **Expand** icon in the upper right corner of the column you want to pull an attribute from, and then select **Expand to New Row**. From there it's a record and you can select the

Expand icon in the upper right corner of the column, view the attributes, and select the one you want to view or extract.

8. Do one of the following things to format the title of the columns that you add for each JSON property that you select.

   - Clear the **Use original column name as prefix** check box to use the name of the JSON property as the column names; for example, **RecordType** or **SourceFileName**.
   - Leave the **Use original column name as prefix** check box selected to add the AuditData prefix to the column names; for example, **AuditData.RecordType** or **AuditData.SourceFileName**.

9. Select **OK**.

   You split the **AuditData** column into multiple columns. Each new column corresponds to a property in the AuditData JSON object. Each row in the column contains the value for the property. If the property doesn't contain a value, the *null* value appears. In Excel, cells with null values are empty.

10. On the **Home** tab, select **Close & Load** to close the Power Query Editor and open the transformed .csv file in an Excel workbook.

Use PowerShell to search and export audit log records

Instead of using the audit log search tool in the Microsoft Purview portal, you can use the Search-UnifiedAuditLog cmdlet in Exchange Online PowerShell to export the results of an audit log search to a .csv file. Then you can follow the same procedure described in Step 2 to format the audit log using the Power Query editor. One advantage of using the PowerShell cmdlet is that you can search for events from a specific service by using the *RecordType* parameter. The following examples show how to use PowerShell to export audit records to a .csv file so you can use the Power Query editor to transform the JSON object in the **AuditData** column as described in Step 2.

In the following example, run the commands to return all records related to SharePoint sharing operations.

PowerShell

```
$auditlog = Search-UnifiedAuditLog -StartDate 06/01/2019 -EndDate 06/30/2019 -
RecordType SharePointSharingOperation
```

PowerShell

```
$auditlog | Select-Object -Property CreationDate,UserIds,RecordType,AuditData |
Export-Csv -Path c:\AuditLogs\PowerShellAuditlog.csv -NoTypeInformation
```

The search results are exported to a .csv file named *PowerShellAuditlog* that contains four columns: CreationDate, UserIds, RecordType, AuditData.

You can use the name or enum value for the record type. For a list of record type names and their corresponding enum values, see the *AuditLogRecordType* table in Office 365 Management Activity API schema.

You can only include a single value for the *RecordType* parameter. To search for audit records for other record types, run the two previous commands again to specify a different record type and append those results to the original .csv file. For example, run the following two commands to add SharePoint file activities from the same date range to the PowerShellAuditlog.csv file.

PowerShell

```
$auditlog = Search-UnifiedAuditLog -StartDate 06/01/2019 -EndDate 06/30/2019 -
RecordType SharePointFileOperation
```

PowerShell

```
$auditlog | Select-Object -Property CreationDate,UserIds,RecordType,AuditData |
Export-Csv -Append -Path c:\AuditLogs\PowerShellAuditlog.csv -NoTypeInformation
```

Tips for exporting and viewing the audit log

Here are some tips and examples of exporting and viewing the audit log before and after you use the JSON transform feature to split the **AuditData** column into multiple columns.

- Filter the **RecordType** column to display only the records from a specific service or functional area. For example, to show events related to SharePoint sharing, select **14** (the enum value for records triggered by SharePoint sharing activities). For a list of the services that correspond to the enum values displayed in the **RecordType** column, see Detailed properties in the audit log.
- Filter the **Operations** column to display the records for specific activities. For a list of most operations that correspond to a searchable activity in the audit log search tool in the Microsoft Purview portal, see the "Audited activities" section in Search the audit log.

Run the diagnostic for audit log configuration check

> **Note**
>
> You must be a Microsoft 365 global administrator to run the diagnostic.

To run the diagnostic for audit log configuration check, complete the following steps:

1. Select the diagnostic in the Microsoft 365 admin center.
2. Enter the User principal name (UPN) or email address of the user missing Audit entries.

> **Note**
>
> If you don't enter user details, the diagnostic performs general audit configuration validation checks.

1. Select **Run Tests**.
2. Review the key findings from the diagnostic to check the user and audit configuration for your organization.

Next steps

- Use a PowerShell script to search the audit log: Automate recurring searches and export large result sets using PowerShell.
- Detailed activity properties in the audit log: Understand the properties in your exported data to interpret results accurately.
- Search the audit log to investigate common support issues: Use exported data to investigate scenarios like compromised accounts or unauthorized access.

Use a PowerShell script to search the audit log

Security, compliance, and auditing are top priorities for IT administrators. Microsoft 365 has several built-in capabilities to help organizations manage security, compliance, and auditing. In particular, unified audit logging can help you investigate security incidents and compliance issues. You can retrieve audit logs by using the following methods:

- The Office 365 Management Activity API
- The audit log search tool in the Microsoft Purview portal
- The Search-UnifiedAuditLog cmdlet in Exchange Online PowerShell

If you need to regularly retrieve audit logs, consider a solution that uses the Office 365 Management Activity API. It provides large organizations with the scalability and performance to retrieve millions of audit records on an ongoing basis. Using the audit log search tool in Microsoft Purview portal is a good way to quickly find audit records for specific operations that occur in shorter time range. Using longer time ranges in the audit log search tool, especially for large organizations, might return too many records to easily manage or export.

When you need to manually retrieve auditing data for a specific investigation or incident, particularly for longer date ranges in larger organizations, using the **Search-UnifiedAuditLog** cmdlet might be the best option. This article includes a PowerShell script that uses the cmdlet. The script can retrieve 50,000 audit records each time you run the cmdlet and then export them to a CSV file. You can format the file by using Power Query in Excel to help with your review. Using the script in this article also minimizes the chance that large audit log searches time out in the service.

Before you run the script

- Audit logging must be enabled for your organization to successfully use the script to return audit records. Audit logging is turned on by default for Microsoft 365 and Office 365 enterprise organizations. To verify that unified audit log ingestion is enabled for your organization, run the following command in Exchange Online PowerShell. This check confirms that audit records are being collected and available for search:

  ```
  PowerShell
  ```

```
Get-AdminAuditLogConfig | FL UnifiedAuditLogIngestionEnabled
```

The value of `True` for the **UnifiedAuditLogIngestionEnabled** property indicates that audit log search is turned on.

- You must be assigned the *View-Only Audit Logs* or *Audit Logs* role in Exchange Online to successfully run the script. By default, these roles are assigned to the *Compliance Management* and *Organization Management* role groups on the **Permissions** page in the Exchange admin center.

- It might take a long time for the script to complete. How long it takes to run depends on the date range and the size of the interval that you configure the script to retrieve audit records for. Larger date ranges and smaller intervals result in a long running time. See the variable description table later in this article for more information about the date range and intervals.

- The sample script provided in this article isn't supported under any Microsoft standard support program or service. The sample script is provided **as-is** without warranty of any kind. Microsoft further disclaims all implied warranties including, without limitation, any implied warranties of merchantability or of fitness for a particular purpose. The entire risk arising out of the use or performance of the sample script and documentation remains with you. In no event shall Microsoft, its authors, or anyone else involved in the creation, production, or delivery of the script be liable for any damages whatsoever (including, without limitation, damages for loss of business profits, business interruption, loss of business information, or other pecuniary loss) arising out of the use of or inability to use the sample script or documentation, even if Microsoft has been advised of the possibility of such damages.

Step 1: Connect to Exchange Online PowerShell

First, connect to Exchange Online PowerShell. You can connect by using modern authentication or multifactor authentication (MFA). For step-by-step instructions, see Connect to Exchange Online PowerShell.

Step 2: Modify and run the script to retrieve audit records

After you connect to Exchange Online PowerShell, create, modify, and run the script to retrieve the auditing data. The first seven lines in the audit log search script contain the following

variables that you can modify to configure your search. See the following variable description table for details about these variables.

1. Save the following text to a Windows PowerShell script by using a filename suffix of .ps1. For example, SearchAuditLog.ps1.

PowerShell

```
#Modify the values for the following variables to configure the audit log search.
$logFile = "d:\AuditLogSearch\AuditLogSearchLog.txt"
$outputFile = "d:\AuditLogSearch\AuditLogRecords.csv"
[DateTime]$start = [DateTime]::UtcNow.AddDays(-1)
[DateTime]$end = [DateTime]::UtcNow
$record = "AzureActiveDirectory"
$resultSize = 5000
$intervalMinutes = 60

#Start script
[DateTime]$currentStart = $start
[DateTime]$currentEnd = $end

Function Write-LogFile ([String]$Message)
{
    $final = [DateTime]::Now.ToUniversalTime().ToString("s") + ":" + $Message
    $final | Out-File $logFile -Append
}

Write-LogFile "BEGIN: Retrieving audit records between $($start) and $($end),
RecordType=$record, PageSize=$resultSize."
Write-Host "Retrieving audit records for the date range between $($start) and
$($end), RecordType=$record, ResultsSize=$resultSize"

$totalCount = 0
while ($true)
{
    $currentEnd = $currentStart.AddMinutes($intervalMinutes)
    if ($currentEnd -gt $end)
    {
        $currentEnd = $end
    }

    if ($currentStart -eq $currentEnd)
    {
        break
    }

    $sessionID = [Guid]::NewGuid().ToString() + "_" +  "ExtractLogs" + (Get-
Date).ToString("yyyyMMddHHmmssfff")
    Write-LogFile "INFO: Retrieving audit records for activities performed
between $($currentStart) and $($currentEnd)"
    Write-Host "Retrieving audit records for activities performed between
$($currentStart) and $($currentEnd)"
```

```
    $currentCount = 0

    $sw = [Diagnostics.StopWatch]::StartNew()
    do
    {
        $results = Search-UnifiedAuditLog -StartDate $currentStart -EndDate
$currentEnd -RecordType $record -SessionId $sessionID -SessionCommand
ReturnLargeSet -ResultSize $resultSize

        if (($results | Measure-Object).Count -ne 0)
        {
            $results | export-csv -Path $outputFile -Append -NoTypeInformation

            $currentTotal = $results[0].ResultCount
            $totalCount += $results.Count
            $currentCount += $results.Count
            Write-LogFile "INFO: Retrieved $($currentCount) audit records out of
the total $($currentTotal)"

            if ($currentTotal -eq $results[$results.Count - 1].ResultIndex)
            {
                $message = "INFO: Successfully retrieved $($currentTotal) audit
records for the current time range. Moving on!"
                Write-LogFile $message
                Write-Host "Successfully retrieved $($currentTotal) audit records
for the current time range. Moving on to the next interval." -foregroundColor
Yellow
                ""
                break
            }
        }
    }
    while (($results | Measure-Object).Count -ne 0)

    $currentStart = $currentEnd
}

Write-LogFile "END: Retrieving audit records between $($start) and $($end),
RecordType=$record, PageSize=$resultSize, total count: $totalCount."
Write-Host "Script complete! Finished retrieving audit records for the date range
between $($start) and $($end). Total count: $totalCount" -foregroundColor Green
```

Alternatively, you can use the moreRecordsAvailable parameter, as shown in the following example.

PowerShell

```
#Modify the values for the following variables to configure the audit log search.
$logFile = "d:\AuditLogSearch\AuditLogSearchLog.txt"
$outputFile = "d:\AuditLogSearch\AuditLogRecords.csv"
[DateTime]$start = [DateTime]::UtcNow.AddDays(-1)
[DateTime]$end = [DateTime]::UtcNow
$record = "AzureActiveDirectory"
```

```
$resultSize = 5000
$intervalMinutes = 60

#Start script
[DateTime]$currentStart = $start
[DateTime]$currentEnd = $end

Function Write-LogFile ([String]$Message)
{
    $final = [DateTime]::Now.ToUniversalTime().ToString("s") + ":" + $Message
    $final | Out-File $logFile -Append
}

Write-LogFile "BEGIN: Retrieving audit records between $($start) and $($end),
RecordType=$record, PageSize=$resultSize."
Write-Host "Retrieving audit records for the date range between $($start) and
$($end), RecordType=$record, ResultsSize=$resultSize"

$totalCount = 0
while ($true)
{
    $currentEnd = $currentStart.AddMinutes($intervalMinutes)
    if ($currentEnd -gt $end)
    {
        $currentEnd = $end
    }

    if ($currentStart -eq $currentEnd)
    {
        break
    }

    $sessionID = [Guid]::NewGuid().ToString() + "_" +  "ExtractLogs" + (Get-
Date).ToString("yyyyMMddHHmmssfff")
    Write-LogFile "INFO: Retrieving audit records for activities performed
between $($currentStart) and $($currentEnd)"
    Write-Host "Retrieving audit records for activities performed between
$($currentStart) and $($currentEnd)"
    $currentCount = 0

    $sw = [Diagnostics.StopWatch]::StartNew()
    do
    {
        $results = Search-UnifiedAuditLog -StartDate $currentStart -EndDate
$currentEnd -RecordType $record -SessionId $sessionID -SessionCommand
ReturnLargeSet -ResultSize $resultSize

        if (($results | Measure-Object).Count -ne 0)
        {
            $results | export-csv -Path $outputFile -Append -NoTypeInformation

            $totalCount += $results.Count
            $currentCount += $results.Count
            Write-LogFile "INFO: Retrieved $($currentCount) audit records so far
for the current time range (running ResultCount: $($results[$results.Count -
```

```
1].ResultCount))"

            if (-not $results[$results.Count -
1].AuditSearchRequestMetadata.moreRecordsAvailable)
            {
                $message = "INFO: Successfully retrieved $($currentCount) audit
records for the current time range. Moving on!"
                Write-LogFile $message
                Write-Host "Successfully retrieved $($currentCount) audit records
for the current time range. Moving on to the next interval." -foregroundColor
Yellow
                ""
                break
            }
    }
    while (($results | Measure-Object).Count -ne 0)

    $currentStart = $currentEnd
}

Write-LogFile "END: Retrieving audit records between $($start) and $($end),
RecordType=$record, PageSize=$resultSize, total count: $totalCount."
Write-Host "Script complete! Finished retrieving audit records for the date range
between $($start) and $($end). Total count: $totalCount" -foregroundColor Green
```

2. Modify the variables listed in the following table to configure the search criteria. The script includes sample values for these variables, but change them (unless stated otherwise) to meet your specific requirements.

Expand table

Variable	Sample value	Description
`$logFile`	"d:\temp\AuditSearchLog.txt"	Specifies the name and location for the log file that contains information about the progress of the audit log search performed by the script. The script writes UTC timestamps to the log file.
`$outputFile`	"d:\temp\AuditRecords.csv"	Specifies the name and location of the CSV file that contains the audit records returned by the script.
`[DateTime]$start` and `[DateTime]$end`	[DateTime]::UtcNow.AddDays(-1) [DateTime]::UtcNow	Specifies the date range for the audit log search. The script returns records for audit activities that occurred within the specified date range. For example, to return activities performed in January 2021, you can use a start date of `"2021-01-01"` and an end date of `"2021-01-31"` (be sure to surround the values in double-quotation marks) The sample

Variable	Sample value	Description
		value in the script returns records for activities performed in the previous 24 hours. If you don't include a timestamp in the value, the default timestamp is 12:00 AM (midnight) on the specified date.
`$record`	"AzureActiveDirectory"	Specifies the record type of the audit activities (also called *operations*) to search for. This property indicates the service or feature that an activity was triggered in. For a list of record types that you can use for this variable, see Audit log record type. You can use the record type name or ENUM value. **Tip:** To return audit records for all record types, use the value `$null` (without double-quotations marks).
`$resultSize`	5000	Specifies the number of results returned each time the **Search-UnifiedAuditLog** cmdlet is called by the script (called a *result set*). The value of 5,000 is the maximum value supported by the cmdlet. Leave this value as-is.
`$intervalMinutes`	60	To help overcome the limit of 5,000 records returned, this variable takes the data range you specified and slices it up into smaller time intervals. Now each interval, not the entire date range, is subject to the 5000 record output limit of the command. The default value of 5,000 records per 60-minute interval within the date range should be sufficient for most organizations. But, if the script returns an error that says, `maximum results limitation reached`, decrease the time interval (for example, to 30 minutes or even 15 minutes) and rerun the script.

Most of the variables listed in the previous table correspond to parameters for the **Search-UnifiedAuditLog** cmdlet. For more information about these parameters, see Search-UnifiedAuditLog.

1. On your local computer, open Windows PowerShell and go to the folder where you saved the modified script.

2. After saving and configuring the script, run it from the directory where the script file is stored to start the audit log search:

PowerShell

```
.\SearchAuditLog.ps1
```

The script displays progress messages while it's running. After the script finishes running, it creates the log file and the .csv file that contains the audit records and saves them to the folders defined by the `$logFile` and `$outputFile` variables.

> **Important**
>
> There's a 50,000 limit for the maximum number of audit records returned each time you run the cmdlet in the script. If you run this script and it returns 50,000 results, audit records for activities that occurred within the date range likely weren't included. If this happens, divide the date range into smaller durations and then rerun the script for each date range. For example, if a date range of 90 days returns 50,000 results then you can rerun the script twice, once for the first 45 days in the date range and then again for the next 45 days.

Step 3: Format and view the audit records

After running the script and exporting the audit records to a .csv file, you might want to format the .csv to make it easier to review and analyze the audit records. One way to do this is to use the Power Query JSON transform feature in Excel to split each property in the JSON object in the **AuditData** column into its own column. For step-by-step instructions, see "Step 2: Format the exported audit log using the Power Query Editor" in Export, configure, and view audit log records.

Next steps

- Export, configure, and view audit log records: Format and view your exported audit records using Power Query in Excel.
- Detailed activity properties in the audit log: Interpret the properties in your exported results to understand activity details.
- Manage audit log retention policies: Ensure the audit data your scripts query is retained for the required period.

Manage mailbox auditing

Mailbox audit logging is turned on by default in all organizations. This setting automatically logs certain actions that mailbox owners, delegates, and admins perform. Admins can search the mailbox audit log for the corresponding mailbox audit records.

Some benefits of mailbox auditing on by default include:

- Auditing is automatically turned on when you create a new mailbox. You don't need to manually enable mailbox auditing for new users.
- You don't need to manage the mailbox actions that are audited. A predefined set of mailbox actions are audited by default for each sign-in type (Admin, Delegate, and Owner).
- When Microsoft releases a new mailbox action, the action might be automatically added to the list of mailbox actions that are audited by default, subject to the user having the appropriate license. Because new actions are added automatically, you don't need to add new actions on mailboxes as they're released.
- You have a consistent mailbox auditing policy across your organization because you're auditing the same actions for all mailboxes.

Verify mailbox auditing on by default is turned on

To verify that mailbox auditing on by default is turned on for your organization, run the following command in Exchange Online PowerShell:

PowerShell

```
Get-OrganizationConfig | Format-List AuditDisabled
```

The value **False** indicates that mailbox auditing on by default is turned on for the organization. Mailbox auditing on by default in the organization overrides whether auditing is enabled or disabled on individual mailboxes. It doesn't override mailbox-level audit operation settings.

How organization-level and mailbox-level auditing work together:

- **If organization-level auditing is ON and mailbox-level auditing is OFF**: Organization-level auditing overrides the mailbox setting and enables auditing. The mailbox's configured audit operations apply.

- **If organization-level auditing is ON and mailbox-level auditing is ON**: Mailbox-level auditing remains enabled, and the mailbox's configured audit operations apply.

For example, if mailbox auditing on by default is turned on for the organization, the *AuditEnabled* property returned by the `Get-Mailbox` cmdlet always displays **True**. The mailbox audits mailbox activity by using the mailbox's configured mailbox actions.

To keep mailbox auditing disabled for specific mailboxes, configure *mailbox auditing bypass* for the mailbox owner and other users with delegated access to the mailbox. For more information, see Bypass mailbox audit logging.

Supported mailbox types

The following table describes mailbox types that mailbox auditing supports by default:

Expand table

Mailbox type	Auditing supported	On by default supported
Microsoft 365 Group mailboxes	✓	✓
Public folder mailboxes		
Resource mailboxes		
Shared mailboxes	✓	✓
User mailboxes	✓	✓

> **Important**
>
> In a multigeo environment, cross-geo mailbox auditing isn't supported. If you assign a user permissions to access a shared mailbox in a different geo location, mailbox actions that the user performs aren't logged in the mailbox audit log of the shared mailbox. Exchange admin audit events are available for all locations via Microsoft Purview Audit and the Search-UnifiedAuditLog cmdlet.

Sign-in types and mailbox actions

Sign-in types classify who's responsible for the audited actions on the mailbox. The following list describes the sign-in types that mailbox audit logging uses:

- **Owner**: The mailbox owner (the account associated with the mailbox).
- **Delegate**:
  - A user assigned the SendAs, SendOnBehalf, or FullAccess permission to another mailbox.
  - An admin assigned the FullAccess permission to a user's mailbox.
- **Admin**:
  - The mailbox is searched by using one of the following Microsoft eDiscovery tools:
    - eDiscovery in the Microsoft Purview portal.
    - In-Place eDiscovery in Exchange Online.
  - The mailbox is accessed by using the Microsoft Exchange Server MAPI Editor.
  - The mailbox is accessed by an account impersonating another user. This access happens when the *ApplicationImpersonation* role is assigned to an account, such as an application, which is now actively accessing the data. For more information, see Configure impersonation.

Mailbox actions for user mailboxes and shared mailboxes

The following table describes the mailbox actions that you can use in mailbox audit logging for user mailboxes and shared mailboxes.

- A check mark (✓) indicates the mailbox action you can log for the sign-in type (not all actions are available for all sign-in types).
- An asterisk (*) after the check mark indicates the mailbox action is logged by default for the sign-in type.
- An admin with Full Access permission to a mailbox is considered a delegate.

Expand table

Mailbox action	Description	Admin	Delegate	Owner
AddFolderPermissions	Although this value is accepted as a mailbox action, it's already included in the **UpdateFolderPermissions** action and isn't audited separately. In other words, don't use this value.			
ApplyRecord	An item is labeled as a record.	✓*	✓*	✓*
AttachmentAccess	A mail message attachment was accessed through the Microsoft Graph API. This operation is enabled by default and can't be configured with the other mailbox actions.	✓*	✓*	✓*
Copy	A message was copied to another folder.	✓		

Mailbox action	Description	Admin	Delegate	Owner
Create	An item was created in the Calendar, Contacts, Draft, Notes, or Tasks folder in the mailbox (for example, a new meeting request is created). Creating, sending, or receiving a message isn't audited. Also, creating a mailbox folder isn't audited.	✓*	✓*	✓
FolderBind	A mailbox folder was accessed. This action is also logged when the admin or delegate opens the mailbox. **Note**: Audit records for folder bind actions performed by delegates are consolidated. One audit record is generated for individual folder access within a 24-hour period.	✓	✓	
HardDelete	A message purged from the Recoverable Items folder.	✓*	✓*	✓*
MailboxLogin	The user signed into their mailbox.			✓
MailItemsAccessed	Occurs when mail data is accessed by mail protocols and clients.	✓*	✓*	✓*
MessageBind	**Note**: This value is available only for users *without* E5/A5/G5 licenses. A message was viewed in the preview pane or opened by an admin.	✓		
ModifyFolderPermissions	Although this value is accepted as a mailbox action, it's already included in the **UpdateFolderPermissions** action and isn't audited separately. In other words, don't use this value.			
Move	A message was moved to another folder.	✓	✓	✓
MoveToDeletedItems	A message deleted and moved to the Deleted Items folder.	✓*	✓*	✓*
RecordDelete	An item that's labeled as a record was soft-deleted (moved to the Recoverable Items folder). Items labeled as records can't be permanently deleted (purged from the Recoverable Items folder).	✓	✓	✓
RemoveFolderPermissions	Although this value is accepted as a mailbox action, it's already included in the			

Mailbox action	Description	Admin	Delegate	Owner
	UpdateFolderPermissions action and isn't audited separately. In other words, don't use this value.			
SearchQueryInitiated	A person uses Outlook (Windows, Mac, iOS, Android, or Outlook on the web) or the Mail app for Windows 10 to search for items in a mailbox.			✓
Send	The user sends an email message, replies to an email message, or forwards an email message.	✓*		✓*
SendAs	A message was sent using the SendAs permission. This permission allows another user to send the message as though it came from the mailbox owner.	✓*	✓*	
SendOnBehalf	A message was sent using the SendOnBehalf permission. This permission allows another user to send the message on behalf of the mailbox owner. The message indicates to the recipient who the message was sent on behalf of and who actually sent the message.	✓*	✓*	
SoftDelete	A message permanently deleted or deleted from the Deleted Items folder. Soft-deleted items are moved to the Recoverable Items folder.	✓*	✓*	✓*
Update	A message or any of its properties changed.	✓*	✓*	✓*
UpdateCalendarDelegation	A calendar delegation was assigned to a mailbox. Calendar delegation gives someone else in the same organization permissions to manage the mailbox owner's calendar.	✓*		✓*
UpdateFolderPermissions	A folder permission was changed. Folder permissions control which users in your organization can access folders in a mailbox and the messages located in those folders.	✓*	✓*	✓*
UpdateInboxRules	An inbox rule was added, removed, or changed. Inbox rules process messages in the user's Inbox based on conditions. Actions specify what to do to messages that match the conditions of the rule. For example, move the message to a specified folder or delete the message.	✓*	✓*	✓*

> **Important**
>
> If you customize the mailbox actions to audit *before* mailbox auditing is turned on by default in your organization, the customized mailbox auditing settings are preserved on the mailbox and aren't overwritten by the default mailbox actions described in this section. To revert the audit mailbox actions to their default values (which you can do at any time), see Restore the default mailbox actions.

Mailbox actions for Microsoft 365 Group mailboxes

When you turn on mailbox auditing, Microsoft 365 Group mailboxes start logging mailbox audit data. However, you can't customize the logged data or add or remove mailbox actions for any sign-in type.

The following table describes the mailbox actions that Microsoft 365 Group mailboxes log by default for each sign-in type.

An admin with Full Access permission to a Microsoft 365 Group mailbox is a delegate.

Expand table

Mailbox action	Description	Admin	Delegate	Owner
Create	Creation of a calendar item. Creating, sending, or receiving a message isn't audited.	✓*	✓*	
HardDelete	A message purged from the Recoverable Items folder.	✓*	✓*	✓*
MoveToDeletedItems	A message deleted and moved to the Deleted Items folder.	✓*	✓*	✓*
SendAs	A message sent by using the SendAs permission.	✓*	✓*	
SendOnBehalf	A message sent by using the SendOnBehalf permission.	✓*	✓*	
SoftDelete	A message permanently deleted or deleted from the Deleted Items folder. Soft-deleted items are moved to the Recoverable Items folder.	✓*	✓*	✓*
Update	A message or any of its properties changed.	✓*	✓*	✓*

Verify that default mailbox actions are logged for each sign-in type

The *DefaultAuditSet* property's value shows whether the default mailbox actions (managed by Microsoft) are audited on the mailbox.

To see which default audit action sets are currently applied to a user mailbox or shared mailbox, replace `<MailboxIdentity>` with the name, alias, email address, or user principal name (username) of the mailbox and run the following command in Exchange Online PowerShell:

PowerShell

```
Get-Mailbox -Identity <MailboxIdentity> | Format-List DefaultAuditSet
```

To view the default audit set for a Microsoft 365 Group mailbox, replace `<MailboxIdentity>` with the name, alias, or email address of the group mailbox and run the following command in Exchange Online PowerShell:

PowerShell

```
Get-Mailbox -Identity <MailboxIdentity> -GroupMailbox | Format-List DefaultAuditSet
```

The value `Admin, Delegate, Owner` means:

- The system audits the default mailbox actions for all three sign-in types. You see this value on Microsoft 365 Group mailboxes.
- An admin didn't change the audited mailbox actions for any sign-in type on a user mailbox or a shared mailbox.

If an admin changes the mailbox actions that the system audits for a sign-in type (by using the *AuditAdmin*, *AuditDelegate*, or *AuditOwner* parameters on the **Set-Mailbox** cmdlet), the property value is different.

For example, the value `Owner` for the *DefaultAuditSet* property on a user mailbox or shared mailbox means:

- The system audits the default mailbox actions for the mailbox owner.
- The audited mailbox actions for the `Delegate` and `Admin` sign-in types are changed from the default actions.

A blank value for the *DefaultAuditSet* property means the mailbox actions for all three sign-in types are changed on the user mailbox or a shared mailbox.

For more information, see Change or restore mailbox actions logged by default.

Display the mailbox actions that are logged on mailboxes

To see the mailbox actions that are currently logged on user mailboxes or shared mailboxes, replace `<MailboxIdentity>` with the name, alias, email address, or user principal name (username) of the mailbox. Then run one or more of the following commands in Exchange Online PowerShell.

> **Note**
>
> Although you can add the `-GroupMailbox` switch to the following **Get-Mailbox** commands for Microsoft 365 Group mailboxes, don't trust the values that are returned. The default and static mailbox actions that are audited for Microsoft 365 Group mailboxes are described in Mailbox actions for Microsoft 365 Group mailboxes.

Owner actions

To view the mailbox actions currently audited for the Owner sign-in type, run the following command:

PowerShell

```
Get-Mailbox -Identity <MailboxIdentity> | Select-Object -ExpandProperty AuditOwner
```

Delegate actions

To review the delegate actions currently being audited on the mailbox, run the following command:

PowerShell

```
Get-Mailbox -Identity <MailboxIdentity> | Select-Object -ExpandProperty AuditDelegate
```

Admin actions

To verify the admin actions currently being audited on the mailbox, run the following command:

PowerShell

```
Get-Mailbox -Identity <MailboxIdentity> | Select-Object -ExpandProperty AuditAdmin
```

Change or restore mailbox actions logged by default

One of the key benefits of using the default mailbox actions is that you don't need to manage the mailbox actions that are audited. Microsoft manages the actions for you and automatically adds new mailbox actions to audit by default as they're released.

However, your organization might be required to audit a different set of mailbox actions for user mailboxes and shared mailboxes. The procedures in this section show you how to change the mailbox actions that are audited for each sign-in type, and how to revert back to the Microsoft-managed default actions.

> **Important**
>
> If you use the following procedures to customize the mailbox actions that are logged on user mailboxes or shared mailboxes, new default mailbox actions released by Microsoft aren't automatically audited on those mailboxes. You need to manually add any new mailbox actions to your customized list.

Change the mailbox actions to audit

To change the mailbox actions that Microsoft audits for user mailboxes and shared mailboxes, use the *AuditAdmin*, *AuditDelegate*, or *AuditOwner* parameters on the **Set-Mailbox** cmdlet. You can't customize audited actions for Microsoft 365 group mailboxes.

Use two different methods to specify the mailbox actions:

- *Replace* (overwrite) the existing mailbox actions by using this syntax: `action1,action2,...actionN`.
- *Add or remove* mailbox actions without affecting other existing values by using this syntax: `@{Add="action1","action2",..."actionN"}` or `@{Remove="action1","action2",..."actionN"}`.

The following example changes the admin mailbox actions for the mailbox named "Gabriela Laureano" by overwriting the default actions with SoftDelete and HardDelete.

PowerShell

```
Set-Mailbox -Identity "Gabriela Laureano" -AuditAdmin HardDelete,SoftDelete
```

The following example adds the MailboxLogin action to the audited owner actions for the mailbox laura@contoso.onmicrosoft.com.

PowerShell

```
Set-Mailbox -Identity laura@contoso.onmicrosoft.com -AuditOwner @{Add="MailboxLogin"}
```

The following example removes the MoveToDeletedItems action from the audited delegate actions for the Team Discussion mailbox.

PowerShell

```
Set-Mailbox -Identity "Team Discussion" -AuditDelegate @{Remove="MoveToDeletedItems"}
```

Regardless of the method you use, customizing the audited mailbox actions on user mailboxes or shared mailboxes has the following results:

- Microsoft no longer manages the audited mailbox actions for the sign-in type that you customized.
- The sign-in type that you customized is removed from the *DefaultAuditSet* property value for the mailbox, indicating that Microsoft no longer manages the default actions for that sign-in type. For details on how to verify this value, see Verify that default mailbox actions are logged for each sign-in type.

Restore the default mailbox actions

> **Note**
>
> The following procedures don't apply to Microsoft 365 Group mailboxes. Those mailboxes are limited to the default actions described in Mailbox actions for Microsoft 365 Group mailboxes.

If you customize the mailbox actions that the system audits on a user mailbox or a shared mailbox, you can restore the default mailbox actions for one or all sign-in types by using this syntax:

PowerShell

```
Set-Mailbox -Identity <MailboxIdentity> -DefaultAuditSet <Admin | Delegate | Owner>
```

You can specify multiple *DefaultAuditSet* values separated by commas.

This example restores the default audited mailbox actions for all sign-in types on the mailbox **mark@contoso.onmicrosoft.com**.

PowerShell

```
Set-Mailbox -Identity mark@contoso.onmicrosoft.com -DefaultAuditSet
Admin,Delegate,Owner
```

This example restores the default audited mailbox actions for the Admin sign-in type on the mailbox **chris@contoso.onmicrosoft.com**, but keeps the customized audited mailbox actions for the Delegate and Owner sign-in types.

PowerShell

```
Set-Mailbox -Identity chris@contoso.onmicrosoft.com -DefaultAuditSet Admin
```

When you restore the default audited mailbox actions for a sign-in type, you get the following outcomes:

- The current list of mailbox actions is replaced with the default mailbox actions for the sign-in type.
- Any new mailbox actions that Microsoft releases are automatically added to the list of audited actions for the sign-in type.
- The *DefaultAuditSet* property value for the mailbox is updated to include the restored sign-in type.

Turn off mailbox auditing on by default for your organization

To turn off mailbox auditing on by default for your entire organization, run the following command in Exchange Online PowerShell:

PowerShell

```
Set-OrganizationConfig -AuditDisabled $true
```

When you turn off mailbox auditing on by default, you make the following changes:

- Mailbox auditing is turned off for your organization.
- From the time you turn off mailbox auditing on by default, no mailbox actions are audited, even if mailbox auditing is enabled on a mailbox (the *AuditEnabled* property on the mailbox is **True**).
- Mailbox auditing isn't turned on for new mailboxes and setting the *AuditEnabled* property on a new or existing mailbox to **True** is ignored.
- Any mailbox audit bypass association settings (configured by using the **Set-MailboxAuditBypassAssociation** cmdlet) are ignored.
- Existing mailbox audit records are retained until the audit log age limit for the record expires.

Turn on mailbox auditing on by default

To turn mailbox auditing back on for your organization, run the following command in Exchange Online PowerShell:

PowerShell

```
Set-OrganizationConfig -AuditDisabled $false
```

Bypass mailbox audit logging

Currently, you can't disable mailbox auditing for specific mailboxes when mailbox auditing on by default is turned on in your organization. For example, the system ignores setting the *AuditEnabled* mailbox property to **False**.

However, you can use the **Set-MailboxAuditBypassAssociation** cmdlet in Exchange Online PowerShell to prevent *all* mailbox actions by the specified users from being logged, regardless of where the actions occur. For example:

- Mailbox owner actions that the bypassed users perform aren't logged.
- Delegate actions that the bypassed users perform on other users' mailboxes (including shared mailboxes) aren't logged.
- Admin actions that the bypassed users perform aren't logged.

To bypass mailbox audit logging for a specific user, replace `<MailboxIdentity>` with the name, email address, alias, or user principal name (username) of the user and run the following command:

PowerShell

```
Set-MailboxAuditBypassAssociation -Identity <MailboxIdentity> -AuditByPassEnabled $true
```

To verify that auditing is bypassed for the specified user, run the following command:

PowerShell

```
Get-MailboxAuditBypassAssociation -Identity <MailboxIdentity> | Format-List AuditByPassEnabled
```

The value **True** indicates that mailbox audit logging is bypassed for the user.

> **Note**
>
> The `AuditLogAgeLimit` property is no longer applicable for managing mailbox audit log retention. Audit log retention is now configured and managed through Microsoft Purview. For more information, see Manage audit log retention policies.

Next steps

- Search the audit log for mailbox activities in specific mailboxes: Search for audited mailbox actions using the filters you configured.
- Use MailItemsAccessed to investigate compromised accounts: Use the MailItemsAccessed action to investigate potential email breaches.
- Investigate shared mailbox activities using audit logs: Monitor activity in shared mailboxes for unauthorized access or changes.

Manage audit log retention policies

You can create and manage audit log retention policies in the Microsoft Purview portal. Audit log retention policies are part of the new Microsoft Purview Audit (Premium) capabilities. An audit log retention policy lets you specify how long to retain audit logs in your organization. You can retain audit logs for up to 10 years. You can create policies based on the following criteria:

- All activities in one or more Microsoft services
- Specific activities in a Microsoft service performed by all users or by specific users
- A priority level that specifies which policy takes precedence if you have multiple policies in your organization

Default audit log retention policy in Audit (Premium)

Audit (Premium) in Microsoft Purview provides a default audit log retention policy for all organizations. You can't modify this policy. It retains all Exchange Online, SharePoint, OneDrive, and Microsoft Entra audit records for one year. This default policy retains audit records that contain the value of **AzureActiveDirectory**, **Exchange**, **OneDrive**, and **SharePoint** for the **Workload** property (which is the service in which the activity occurred). Audit records for all other activities are retained for 180 days by default or you can change the retention to a different duration using a custom retention policy.

> **Note**
>
> The default audit log retention policy only applies to audit records for activity performed by users who are assigned an Office 365 or Microsoft 365 E5 license or have a Microsoft Purview Suite (formerly known as Microsoft 365 E5 Compliance) or E5 eDiscovery and Audit add-on license. If you have non-E5 users or guest users in your organization, their corresponding audit records are retained for 180 days.

The default retention period for audit records varies by license type and when the records were generated.

> **Important**

The default retention period for Audit (Standard) changed from 90 days to 180 days. Audit (Standard) logs generated before October 17, 2023 are retained for 90 days. Audit (Standard) logs generated on or after October 17, 2023 follow the new default retention of 180 days.

Before you create an audit log retention policy

- You need the *Organization Configuration* role in the Microsoft Purview portal to create or modify an audit retention policy.
- Your organization can have up to 50 audit log retention policies.
- To retain an audit log for longer than 180 days (and up to 1 year), the user who generates the audit log (by performing an audited activity) must have an Office 365 E5 or Microsoft 365 E5 license or a Microsoft Purview Suite (formerly known as Microsoft 365 E5 Compliance) or E5 eDiscovery and Audit add-on license. To retain audit logs for 10 years, the user who generates the audit log must also have a 10-year audit log retention add-on license in addition to an E5 license.

  > **Note**
  >
  > If the user generating the audit log doesn't have the licenses required for the selected retention duration, data is retained according to the highest priority retention policy. This retention might be either the default retention policy for the user's license or the highest priority policy that matches the user and its record type.

- All custom audit log retention policies (created by your organization) take priority over the default retention policy. For example, if you create an audit log retention policy for Exchange mailbox activity that has a retention period that's shorter than one year, audit records for Exchange mailbox activities are retained for the shorter duration specified by the custom policy.
- The audit item lifetime for data is determined when you add it to the auditing pipeline and is based on the licensing defaults or applicable retention policies. Any changes to licensing or applicable retention policies change the expiration time of the audit data after updating. These changes don't update any previously committed items.

Create an audit log retention policy

Complete the following steps to create an audit retention policy:

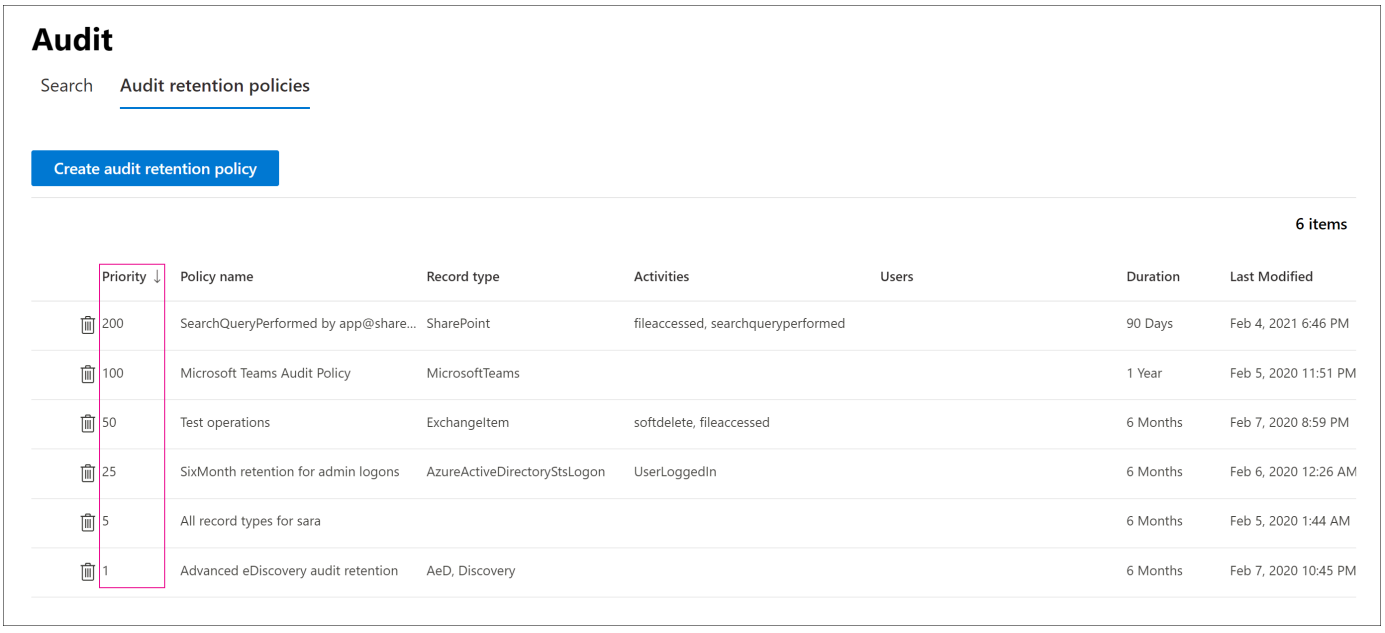
1. Sign in to the Microsoft Purview portal with a user account assigned the *Organization Configuration* role on the **Roles & scopes** page in the Microsoft Purview portal.
2. Select the **Audit** solution card. If the **Audit** solution card isn't displayed, select **View all solutions** and then select **Audit** from the **Core** section.
3. Select **Create audit retention policy**, and then complete the following fields on the flyout page:

- **Policy name**: The name of the audit log retention policy. This name must be unique in your organization, and you can't change it after creating the policy.
- **Description**: Optional, but helpful to provide information about the policy, such as the record type or workload, users specified in the policy, and the duration.
- **Users:** Select one or more users to apply the policy to. If you leave this box blank, the policy applies to all users.
- **Record type**: The audit record type the policy applies to. If you leave this property blank, the policy applies to all record types. You can select a single record type or multiple record types:
- If you select a single record type, the **Activities** field is dynamically displayed. Use the drop-down list to select activities from the selected record type to apply the policy to. If you don't select specific activities, the policy applies to all activities of the selected record type.
  - If you select multiple record types, you don't have the ability to select activities. The policy applies to all activities of the selected record types.
  - **Duration:** The amount of time to retain the audit logs that meet the criteria of the policy. The available options are *7 Days*, *30 Days*, *6 Months*, *9 Months*, *1 Year*, *3 Years*, *5 Years*, and *7 Years*. Users with the 10-year Audit Log Retention add-on license can select a *10 Years* option.

> **ⓘ Important**
>
> To retain audit logs for the 7 and 30 days duration options, you must have a Microsoft 365 Enterprise E5 subscription. To retain audit logs for the 3, 5, and 7 years duration options, you must be assigned to a 10-Year Audit Log Retention add-on license in addition to your Microsoft 365 Enterprise E5 subscription. For more information about Audit subscriptions and add-ons, see Auditing solutions in Microsoft Purview

- **Priority**: This value determines the order in which audit log retention policies in your organization are processed. A lower value indicates a higher priority. Valid priorities are numerical values between **1** and **10000**. A value of **1** is the highest priority, and a value of **10000** is the lowest priority. For example, a policy with a value of **5** takes priority over a policy with a value of **10**. Any custom audit log retention policy takes priority over the default policy for your organization.

4. Select **Save** to create the new audit log retention policy.



The new policy appears in the list on the **Policies** page.

Manage audit log retention policies in the Microsoft Purview portal

The **Audit retention policies** tab (also called the *dashboard*) lists audit log retention policies. You can use the dashboard to view, edit, and delete audit retention policies.

View policies in the dashboard

The dashboard lists audit log retention policies. One advantage of viewing policies in the dashboard is that you can select the **Priority** column to list the policies in the priority order in which they're applied. A lower value indicates a higher priority.

You can also select a policy to display its settings on the flyout page.

> **Note**
>
> The dashboard doesn't display the default audit log retention policy for your organization.

Edit policies in the dashboard

To edit a policy, select it to display the flyout page. You can modify one or more settings and then save your changes.

> **Important**
>
> If you use the *New-UnifiedAuditLogRetentionPolicy* cmdlet, you might create an audit log retention policy for record types or activities that aren't available in the **Create audit retention policy** tool in the dashboard. If the policy includes record types or activities that aren't available in the **Create audit retention policy** tool, you can't edit the policy (for example, change the retention duration or add and remove activities) from the **Audit retention policies** dashboard. You can only view and delete the policy in the Microsoft Purview portal. To edit the policy, you need to use the Set-UnifiedAuditLogRetentionPolicy cmdlet in Security & Compliance PowerShell. A message is displayed at the top of the flyout page for policies that you need to edit by using PowerShell.

Delete policies in the dashboard

To delete a policy, select the **Delete** icon and then confirm that you want to delete the policy. The policy is removed from the dashboard, but it might take up to 30 minutes for the policy to be removed from your organization.

Create and manage audit log retention policies in PowerShell

You can also use Security & Compliance PowerShell to create and manage audit log retention policies. One reason to use PowerShell is to create a policy for a record type or activity that isn't available in the UI.

Create an audit log retention policy in PowerShell

Complete the following steps to create an audit log retention policy in PowerShell:

1. Connect to Security & Compliance PowerShell.

2. Run the following command to create an audit log retention policy:

```
PowerShell
New-UnifiedAuditLogRetentionPolicy -Name "Microsoft Teams Audit Policy" -
Description "One year retention policy for all Microsoft Teams activities" -
RecordTypes MicrosoftTeams -RetentionDuration TenYears -Priority 100
```

This example creates an audit log retention policy named "Microsoft Teams Audit Policy" with these settings:

- A description of the policy.
- Retains all Microsoft Teams activities (as defined by the *RecordType* parameter).
- Retains Microsoft Teams audit logs for 10 years.
- A priority of 100.

The following example creates an audit log retention policy that retains audit logs for the "User logged in" activity for six months for the user admin@contoso.onmicrosoft.com.

PowerShell

```
New-UnifiedAuditLogRetentionPolicy -Name "SixMonth retention for admin logons" -
RecordTypes AzureActiveDirectoryStsLogon -Operations UserLoggedIn -UserIds
admin@contoso.onmicrosoft.com -RetentionDuration SixMonths -Priority 25
```

For more information, see New-UnifiedAuditLogRetentionPolicy.

View policies in PowerShell

Use the Get-UnifiedAuditLogRetentionPolicy cmdlet in Security & Compliance PowerShell to view audit log retention policies.

The following command displays the settings for all audit log retention policies in your organization. This command sorts the policies from the highest to lowest priority.

PowerShell

```
Get-UnifiedAuditLogRetentionPolicy | Sort-Object -Property Priority -Descending | FL
Priority,Name,Description,RecordTypes,Operations,UserIds,RetentionDuration
```

> ⓘ **Note**
>
> The *Get-UnifiedAuditLogRetentionPolicy* cmdlet doesn't return the default audit log retention policy for your organization.

Edit policies in PowerShell

Use the Set-UnifiedAuditLogRetentionPolicy cmdlet in Security & Compliance PowerShell to edit an existing audit log retention policy.

Delete policies in PowerShell

Use the Remove-UnifiedAuditLogRetentionPolicy cmdlet in Security & Compliance PowerShell to delete an audit log retention policy. It might take up to 30 minutes for the policy to be removed from your organization.

Next steps

- Search the audit log: Search for activities that are retained by your custom retention policies.
- Use a PowerShell script to search the audit log: Automate searches against your retained audit data for ongoing monitoring.
- Microsoft services that support auditing: Review which services generate the audit records your retention policies cover.

Audit logs for Copilot and AI applications

This article provides an overview of audit logs generated for user interactions and admin activities related to Microsoft Copilot and AI applications. The system automatically logs these activities as part of Audit (Standard). If your organization enables auditing, you don't need to take extra steps to configure auditing support for Copilot and AI applications.

Billing for auditing non-Microsoft AI applications

Audit logs for non-Microsoft AI applications use pay-as-you-go billing. This billing model provides user and admin interaction audit logs that the system retains for 180 days. These audit logs cover interactions with non-Microsoft AI applications.

Your enterprise subscription doesn't include audit logs for this type of user interaction. Instead, it falls under pay-as-you-go billing. The system logs these interactions under the *AIAppInteraction* recordType or *AIApp* workload. Some scenarios logged under the *ConnectedAiAppInteraction* recordType are also part of this pay-as-you-go billing model. You need to enable pay-as-you-go features to turn on these logs. When you enable them, the system retains these audit logs for 180 days. Consumption is charged based on the number of audit records ingested for user interactions with these non-Microsoft AI applications.

Pay-as-you-go billing doesn't apply to Microsoft applications. All Microsoft applications, including Microsoft Copilots like Microsoft Security Copilot, Copilot in Microsoft Fabric, and custom applications built using Microsoft Copilot Studio and Microsoft Foundry are included in Audit Standard.

Admin activities with Copilot and AI applications

The system generates audit logs when an administrator performs activities related to Copilot settings, plugins, promptbooks, or workspaces. For more information, see Microsoft 365 Copilot activities.

User activities with Copilot, Cowork, and AI applications

The system automatically generates audit logs when a user interacts with Copilot, Cowork, or an AI application. These audit records contain details about which user interacted with Copilot, when the interaction took place, and where it occurred. Audit records also include references to files, sites, or other resources Copilot, Cowork, and AI applications accessed to generate responses to user prompts.

Common properties in Copilot audit logs

The following table outlines some of the common properties included in audit logs.

Expand table

Attribute	Definition	Examples
AccessedResources	References to all resources (files, documents, emails, etc.) which Copilot accessed in response to the	For example: "AccessedResources": [{"Action":"Read","ID":"AAAAAEYE2GAACp1FlnN_CHXStUkHAGWJYgtgc 8706-4188-bd11-

Attribute	Definition	Examples
	user's request. - *ID* is the unique identifier for the resource. This could be a fileId on OneDrive, or a messageId in Teams, or email ID in Outlook, etc. - *SiteUrl* is the URL of the resource that was accessed. This could be the URL of a SharePoint site, full file path of a file, etc. - *ListItemUniqueId* is a unique identifier for an item in SharePoint. - *Type* refers to the type of resource that was accessed. It can contain values like the filetype extension (pptx, docx, etc.) or describe the type of resource (for non-SharePoint resources). - *Name* is the user-friendly readable name of the resource (for example, fileName). - *SensitivityLabelId* is the ID of the sensitivity label assigned to the resource. This is helpful in identifying whether Copilot accessed any sensitive information while generating its response. - *Action* refers to the nature of access which Copilot performed on the resource. Common values include *read*, *create*, *modify*. - *PolicyDetails* is used in scenarios where Copilot's access to a particular resource was blocked or restricted based on some policy. This property can include details like *PolicyId*, *PolicyName*, list of rules, etc. - *Status* is used to specify whether Copilot's action on a specific resource was a *success* or *failure*. - *XPIADetected* is a boolean that denotes whether there was an XPIA (Cross Prompt Injection Attack) detected from a particular resource which Copilot accessed.	ebb85995028c","SiteUrl":"`https://microsoft.sharepoint.com/teams/Off` `web=1`","Type":"docx","listItemUniqueId":"AAAAAEYE2GAACp1FlnN_CH)

	Microsoft 365 Copilot scenarios. - *ModelVersion* is the version of the model used. Not available in Microsoft 365 Copilot scenarios.	
Operation	Specifies the name of the activity that was audited.	For user interactions with Copilot or Cowork, this property contains *Co* as described in the RecordType row. Also includes Copilot admin operations like *UpdateTenantSettings*, *Crec*
RecordType	Identifies the category of Copilot or AI application that the user interacted with.	*CopilotInteraction* refers to scenarios where a user interacted with a Mi *ConnectedAIAppInteraction* refers to scenarios where a user interacted *AIAppInteraction* refers to interactions with third-party AI applications t
Workload	Identifies the app category, similar to RecordType.	*Copilot*, *ConnectedAIApp*, *AIApp*

Common AppHost scenarios in Copilot

The following table lists some of the commonly used values for AppHost and describes the scenarios in which they're used.

Expand table

AppHost	Copilot Scenario	Copilot product
Bing	**Business Chat via Bing/Windows interface.** Refers to Microsoft 365 Copilot's cross-app **Business Chat** access through the Bing Chat experience (for instance, in the Microsoft Edge browser sidebar, Windows Copilot, or the copilot.cloud.microsoft.com web portal). This scenario occurs when a user engages the Copilot in a general-purpose chat outside any specific Office app.	Microsoft 365 Copilot Chat
Bookings	Copilot in Microsoft Bookings.	Microsoft 365 Copilot
Copilot in Azure	**Copilot in Microsoft Azure (Cloud Management).** This refers to Copilot usage in the context of **Microsoft Azure**. Though labeled under Microsoft 365 Copilot, the scenario is a cloud admin or developer using Copilot to manage Azure resources. For example, in the Azure portal, ad admin might ask, "How do I set up an alert for CPU usage on my VMs?" and Copilot would generate an ARM template or Azure CLI steps. Or "list untagged resources and suggest a tagging scheme". Essentially, Copilot in Azure is an AI cloud assistant to query and control Azure services via natural language.	Microsoft 365 Copilot
Copilot in Defender	**Security Copilot in Microsoft Defender.** The user is using Copilot within the **Microsoft Defender** security portal. This assists security operations (SecOps) tasks. For example, an analyst could ask, "Investigate alert ID 23455 and summarize what happened," and Copilot analyzes Defender alerts and incidents to produce an explanation or even recommend next steps. It can also cross-reference threat intelligence. This scenario specifically focuses on **Defender for Endpoint/Office/Cloud, etc.** data via the Security Copilot interface.	Security Copilot
Copilot in Intune	**Security Copilot in Microsoft Intune (Endpoint Management).** Copilot is used in the **Microsoft Intune** admin center. It helps IT admins with device management and security posture. For instance, an admin might ask, "How many devices are noncompliant this week and why?". Copilot retrieves Intune data on device compliance and summarize reasons. It can also assist with troubleshooting by comparing device configuration or retrieving app deployment status. This is essentially Security Copilot tapping into Intune's information to answer questions and provide insights for IT and security teams.	Security Copilot

AppHost	Copilot Scenario	Copilot product
Designer	Copilot in Microsoft Designer.	Microsoft 365 Copilot
Edge	**Business Chat in Edge sidebar.** Represents Microsoft 365 Copilot chat accessed through the **Edge browser's Copilot (Bing Chat Enterprise) sidebar**. In this scenario, the user is likely using the Microsoft Edge sidebar Copilot to query organizational data (a BizChat experience within Microsoft Edge).	Microsoft 365 Copilot Chat
Excel	**Copilot in Microsoft Excel.** The user is using Copilot inside an Excel spreadsheet. For example, Copilot might be asked to analyze data, create formulas, or generate a summary of a table. It's the Excel-integrated Copilot helping with computations or insights in workbooks.	Microsoft 365 Copilot
Forms	**Copilot in Microsoft Forms.** Represents Copilot being used in the context of Forms. For example, Copilot could help create survey questions, quizzes, or analyze form responses. This would be the AI assistant helping content creation or summarization in Forms.	Microsoft 365 Copilot
Logic App	Copilot in Azure Logic Apps.	Microsoft 365 Copilot
Loop	**Copilot in Microsoft Loop.** This refers to Copilot assisting within the Microsoft Loop application or Loop components. The user might have Copilot generate or summarize content in a Loop workspace. For example, Copilot could help brainstorm in a Loop page, given Loop's collaborative canvas. This integration brings Copilot to the Loop app context.	Microsoft 365 Copilot
M365AdminCenter	**Copilot in Microsoft 365 Admin Center.** This refers to an AI assistant for IT administrators. In this scenario, Copilot could help an admin with tasks in the Microsoft 365 admin center. For example, answering questions about settings, generating PowerShell scripts, or summarizing user reports.	Microsoft 365 Copilot
M365App	**Business Chat via Microsoft 365 app (desktop or mobile).** Similar to the Office apphost, this denotes Business Chat launched from the **Microsoft 365 unified app** on Windows or mobile. It covers the scenario where a user uses the Office/Microsoft 365 app itself (outside a specific product like Word) to chat with Copilot across their data.	Microsoft 365 Copilot Chat
Microsoft Purview	**Security Copilot in Purview (Compliance).** The user is interacting with Copilot in the **Microsoft Purview** compliance portal. Copilot helps compliance officers and security teams triage and summarize issues related to data protection and governance. For example, Copilot can summarize a batch of Data Loss Prevention (DLP) alerts, highlight inside risk activities, or answer questions like "Have we had any policy violations in email this week?". It can work in both an embedded way (inside Microsoft Purview UI, summarizing whatever section you're on) and in a standalone Q&A way for Microsoft Purview data. This scenario brings AI to compliance workflows, making it faster to grasp risks and decide on actions.	Security Copilot
Office	**Business Chat via Office.com or Microsoft 365 app.** Indicates the Copilot Business Chat accessed through the Office.com or Microsoft 365 home app (web, desktop, or mobile). For example, when a user opens the "Copilot" chat on Office.com (microsoft365.com) or the Microsoft 365 mobile app to ask cross-domain questions.	Microsoft 365 Copilot Chat
OfficeCopilotNotebook	**Copilot Notebook (Microsoft 365).** Refers to the **Copilot Notebooks** feature in Microsoft 365 Copilot (a central AI-powered notebook). This scenario is when Copilot compiles or interacts with a **cross-application notebook** of content. Copilot Notebooks allow users to gather and generate information across multiple sources in a notebook interface. This AppHost appears when that notebook is used on the Office.com/Microsoft 365 side (outside of OneNote).	Microsoft 365 Copilot Chat

AppHost	Copilot Scenario	Copilot product
OfficeCopilotSearchAnswer	**Copilot answer in Microsoft 365 Search.** This value refers to Copilot generating an **AI-powered answer in the Office/Microsoft 365 search experience**. For instance, when a user searches on Office.com or SharePoint and Copilot provides a natural language answer (drawing from workplace data) instead of just search results. This is a Business Chat-like Q&A feature within the search context.	Microsoft 365 Copilot Chat
OneDrive	Also refers to the **Copilot in SharePoint** scenario, as described previously.	Microsoft 365 Copilot
OneNote	**Copilot in Microsoft OneNote.** The user is using Copilot inside OneNote notebooks. This in-app OneNote Copilot can summarize notes, generate plans or lists, or answer questions based on NoteNote content. Copilot "*supercharges your note-taking*" in OneNote, helping to create, recall, and organize information.	Microsoft 365 Copilot
OneNoteCopilotNotebook	**Copilot Notebook in OneNote.** Similar to the OfficeCopilotNotebook scenario, but specifically when the Copilot Notebook is accessed within OneNote. Microsoft introduced Copilot Notebooks integrated into OneNote, so this AppHost logs when a user uses the **AI-powered notebook inside OneNote** (bringing cross-data Copilot functionality into OneNote).	Microsoft 365 Copilot Chat
Outlook	**Copilot in Microsoft Outlook.** The user in engaging Copilot while using Outlook (desktop, web, or mobile). This typically means the Copilot is helping with email tasks. For example, drafting an email reply, summarizing a long email thread, or organizing an inbox.	Microsoft 365 Copilot Chat
OutlookOnCanvas	**Copilot inline in Outlook compose.** This refers to Copilot's assistance directly in the email canvas. For example, when composing an email, Copilot might autogenerate text right in the draft. It's the on-canvas helper in Outlook's compose window (as opposed to using a separate Copilot pane).	Microsoft 365 Copilot
OutlookSidepane	**Copilot in Outlook side pane.** Denotes the classic Outlook Copilot experience via the Copilot pane in Outlook. For example, a user opens the Copilot sidebar in Outlook to draft or summarize messages. This value explicitly captures that side pane interaction.	Microsoft 365 Copilot
Planner	**Copilot in Microsoft Planner.** Indicates a Copilot scenario in Planner, likely assisting with project plans or tasks. A user might ask Copilot to draft a plan, generate task checklists, or update task descriptions.	Microsoft 365 Copilot
Power BI	Copilot in Microsoft Power BI.	Microsoft 365 Copilot
PowerPoint	**Copilot in Microsoft PowerPoint.** Copilot is being used within a PowerPoint presentation. In this scenario, a user could ask Copilot to create slides, generate speaker notes, or redesign content in PowerPoint.	Microsoft 365 Copilot
PowerPointOnCanvas	**Copilot on PowerPoint slides.** Indicates an on-canvas Copilot experience in PowerPoint, where Copilot inserts or modifies content directly on slides. This could be the scenario of Copilot generating layouts or bulleted points straight into the presentation (without solely relying on the chat pane). It's a more embedded form of the PowerPoint Copilot.	Microsoft 365 Copilot
Security Copilot Standalone	**Security Copilot standalone experience.** The user is interacting with Security Copilot through the standalone experience, as opposed to interacting with Copilot through an embedded experience within Defender, Purview, etc.	Security Copilot
SharePoint	**Copilot in SharePoint.** Copilot is used within SharePoint (likely on a SharePoint site or page). For instance, a user might ask Copilot to summarize a SharePoint news post or draft content for a	Microsoft 365 Copilot

AppHost	Copilot Scenario	Copilot product
	SharePoint page. This scenario corresponds to a SharePoint-integrated Copilot helping with intranet content.	
Stream	Copilot in Microsoft Stream.	Microsoft 365 Copilot
Teams	**Copilot in Microsoft Teams.** Represents Copilot usage inside the Microsoft Teams app (Web/Desktop/Mobile). This covers interactions with Copilot in Teams chats or channels. For example, asking Copilot to summarize a Teams chat, answer a question in a channel, or assist in a meeting context. This is essentially the Copilot experience within Teams' interface. For example, the "Chat Copilot" in a Teams chat thread.	Microsoft 365 Copilot
TeamsAdminPortal	**Copilot in Microsoft Teams Admin Center.** Similar to the M365AdminCenter scenario, this indicated a Copilot scenario in the Teams Admin Portal. An admin might use Copilot to configure Teams settings or generate reports.	Microsoft 365 Copilot
VivaEngage	**Copilot in Viva Engage (Viva Engage).** The user is interaction with Copilot within Viva Engage. For example, drafting a post or summarizing conversation threads in a Viva Engage community. This scenario covers any AI assistance inside Viva Engage, such as helping craft announcements or answers.	Microsoft 365 Copilot
VivaGoals	**Copilot in Viva Goals.** Viva Goals manages OKRs (objectives and key results). A Copilot here could draft OKRs, update progress, or analyze goal attainment.	Microsoft 365 Copilot
VivaPulse	**Copilot in Viva Pulse.** Viva Pulse is a feedback survey tool; Copilot here might draft survey questions or summarize sentiment from responses.	Microsoft 365 Copilot
Whiteboard	**Copilot in Microsoft Whiteboard.** The user is using Copilot on a digital whiteboard. Copilot in Whiteboard helps brainstorm and organize ideas on the whiteboard canvas. For example, suggesting ideas, clustering sticky notes, or summarizing the board's content. This scenario covers using Copilot during a Whiteboard session (in Teams or the Whiteboard app) to enhance creativity and structure.	Microsoft 365 Copilot
Word	**Copilot in Microsoft Word.** The user is interacting with Copilot within Word. For example, asking it to draft or edit portions of a Word document. This is the in-app **Word Copilot** (side-pane chat and commands in Word). Copilot can generate content, summarize text, or adjust formatting the document context.	Microsoft 365 Copilot
WordOnCanvas	**Copilot inline in Word's document.** This refers to Copilot assistance directly *on the canvas* in Word. Instead of the side pane, Copilot acts within the document editing area. For example, the feature where Copilot writes directly into the document or provides inline suggestions. It's essentially Word Copilot's capabilities applies within the document body, rather than via the chat pane.	Microsoft 365 Copilot

Example Copilot scenarios for user activities

The following tables list some example scenarios and how they appear in the audit log. These example audit logs come from Copilot activities.

Microsoft Copilot

A user interacts with Microsoft Copilot through the Microsoft 365 Copilot Chat client.

Expand table

Operation	RecordType	AppIdentity	AppHost
CopilotInteraction	CopilotInteraction	Copilot.MicrosoftCopilot.BizChat	BizChat

Security Copilot

A user interacts with Security Copilot within Microsoft Defender.

TeamCopilotMsgInteraction	TeamCopilotInteraction	Copilot.TeamCopilot.Message	Teams

Identifying if Copilot accessed the web

When you enable web search, Microsoft 365 Copilot and Microsoft 365 Copilot Chat parse user prompts and determine whether web search would improve the quality of the response. To identify if Copilot referenced the public web in a user interaction, review the *AISystemPlugin.Id* property in the *CopilotInteraction* audit record. *AISystemPlugin.Id* contains the value *BingWebSearch* when user Copilot requests use the public web via Microsoft Bing for additional data.

Accessing Copilot audit logs

Access Copilot audit logs by using the Microsoft Purview portal and selecting **Audit**.

To search for specific Copilot or AI application scenarios, use the **Activities – operation names** field in the Microsoft Purview portal to filter audit logs by properties like *Operation*, *RecordType*, and *Workload*.

If you need to search for audit logs containing a specific *AppIdentity* value or set of values, first search and export all relevant Copilot audit logs by filtering by operation name. From the exported search results, apply a filter on the *AppIdentity* property offline.

Audit logs for Microsoft Copilot and Microsoft Copilot Chat include the model provider and model name when a request is processed. This information can help support auditing, compliance, and governance requirements in organizations that enable multiple model providers.

For example, if a user selects a specific model instead of **Auto**, audit records might include entries similar to:

- `ModelProvider: OpenAI, ModelName: gpt-55-high`
- `ModelProvider: Anthropic, ModelName: claude-sonnet-4-6` And, if a user selects **Auto**, the model provider and model name might not be available for every request, such as when an internal model is used.

Currently, Cowork doesn't show provider details.

Next steps

- Search the audit log: Run targeted searches for Copilot and AI application activities in the audit log.
- Manage audit log retention policies: Create retention policies to preserve Copilot audit records for your required period.
- Export, configure, and view audit log records: Export Copilot activity records for detailed analysis or compliance reporting.

Search the audit log to investigate common support issues

This article describes how to use the audit log search tool to help you investigate common support issues. This guidance includes using the audit log to:

- Find the IP address of the computer used to access a compromised account
- Determine who set up email forwarding for a mailbox
- Determine if a user deleted email items in their mailbox
- Determine if a user created an inbox rule
- Investigate why there was a successful sign-in by a user outside your organization
- Search for mailbox activities performed by users with non-E5 licenses
- Search for mailbox activities performed by delegate users

Use the audit log search tool

Each investigation scenario described in this article is based on using the audit log search tool in the Microsoft Purview portal. This section lists the permissions required to search the audit log and describes the steps to access and run audit log searches. Each scenario section explains how to configure an audit log search query and what to look for in the detailed information in the audit records that match the search criteria.

Permissions required to use the audit log search tool

To search the audit log, you must be assigned the *Audit Logs* or *View-Only Audit Logs* roles in Purview. By default, the *Audit Reader* and *Audit Manager* role groups on the **Role groups** page in the Microsoft Purview portal have these roles assigned.

To access audit cmdlets, you must be assigned the *Audit Logs* and *View-Only Audit Logs* roles in the Exchange admin center. By default, the *Compliance Management* and *Organization Management* role groups on the **Permissions page** in the Exchange admin center have these roles assigned.

For more information, see Get started with auditing solutions.

Running audit log searches

For detailed guidance on how to run a search of the audit log, see Search the audit log.

Find the IP address of the computer used to access a compromised account

Most audit records include the IP address for any user activity. The audit record also includes information about the client used.

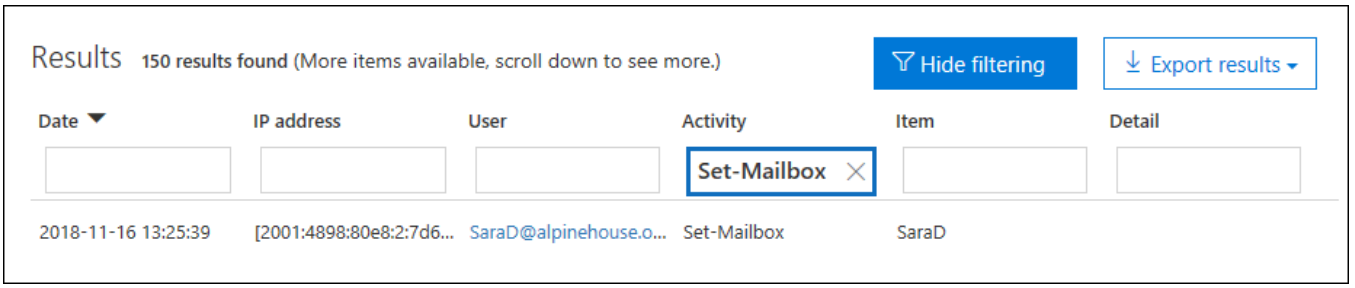
To configure an audit log search query for this scenario, use the following settings:

- **Activities:** If relevant to your case, select a specific activity to search for. For investigating compromised accounts, consider selecting the **User signed in to mailbox** activity under **Exchange mailbox activities**. This selection returns auditing records that show the IP address used when signing in to the mailbox. Otherwise, leave this field blank to return audit records for all activities.

> **Tip**
>
> If you leave this field blank, the search returns **UserLoggedIn** activities, which is a Microsoft Entra activity that indicates that someone signed in to a user account. Use filtering in the search results to display the **UserLoggedIn** audit records.

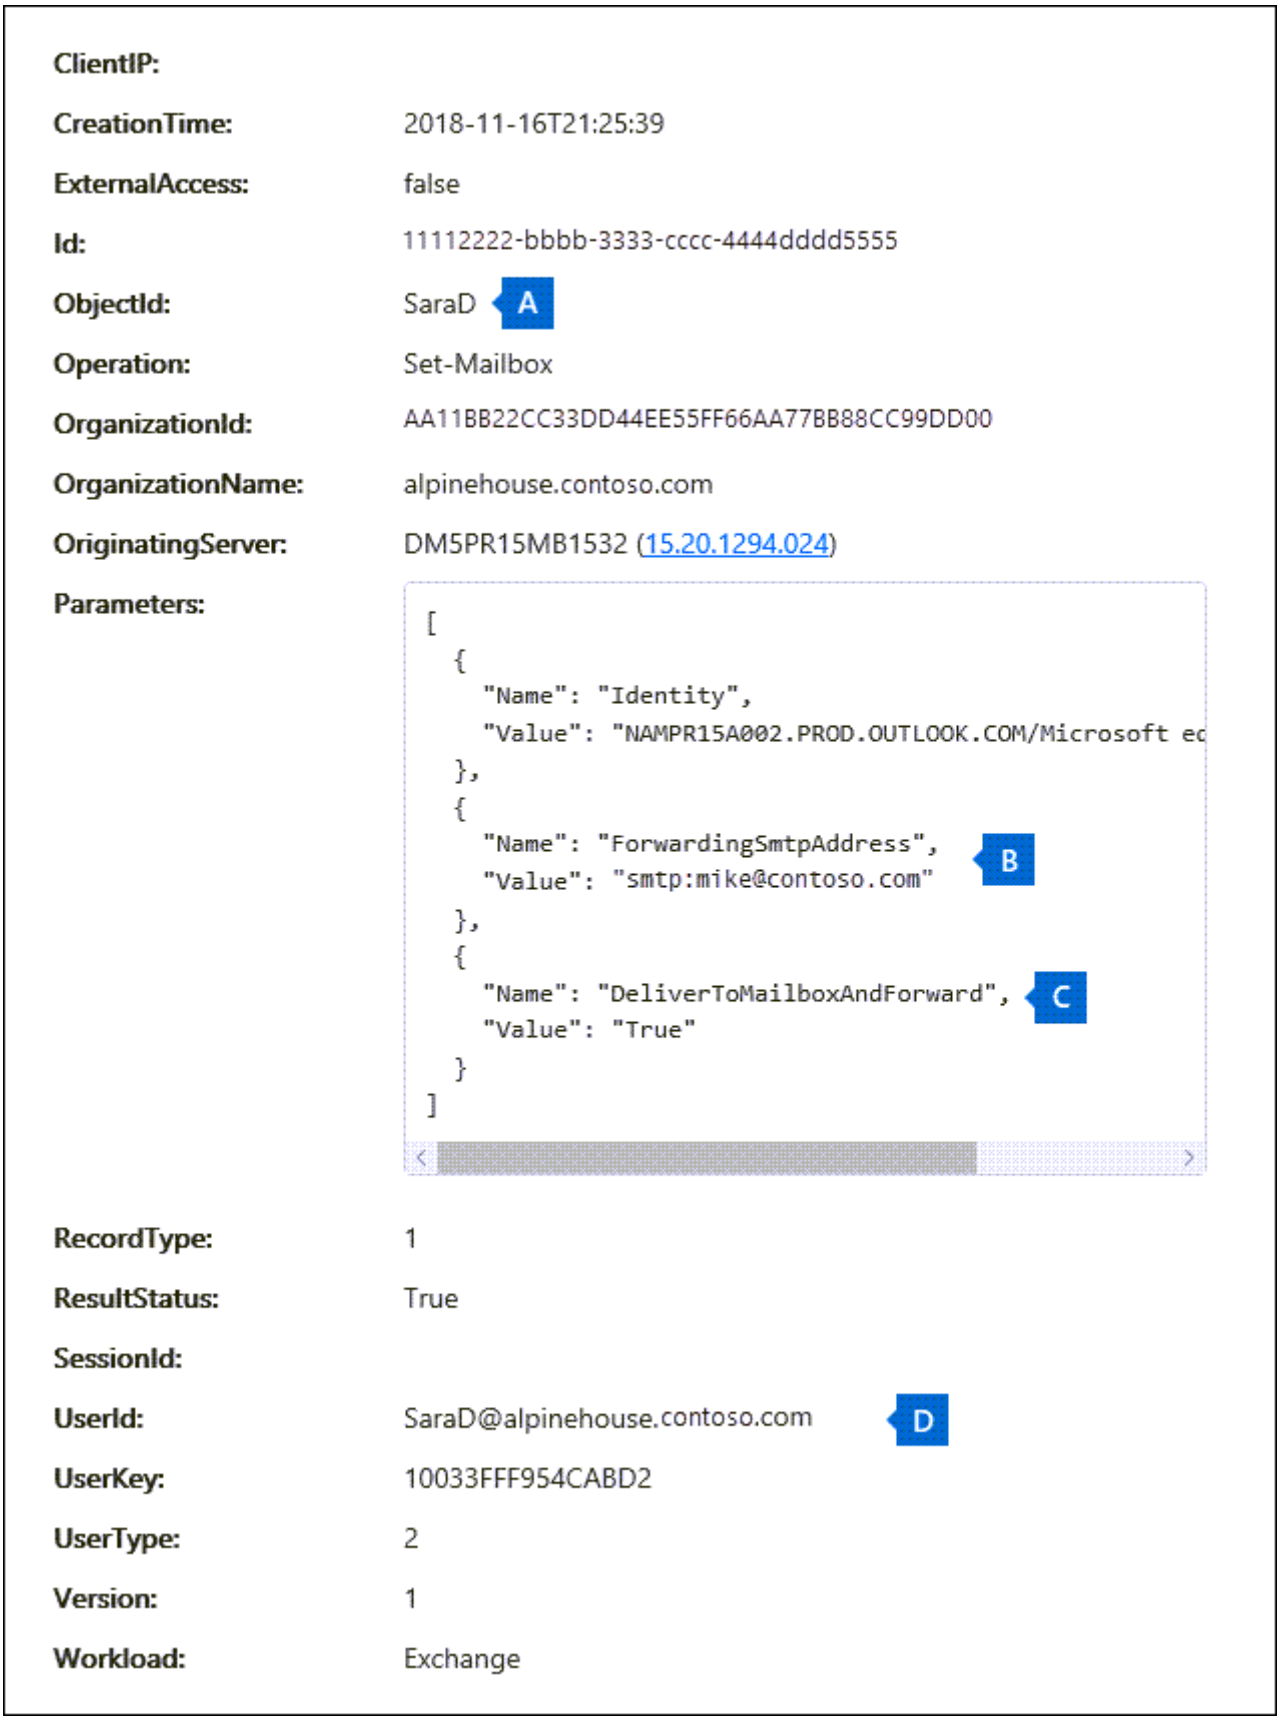
- **Start date** and **End date:** Select a date range that's applicable to your investigation.
- **Users:** If you're investigating a compromised account, select the user whose account was compromised. This selection returns audit records for activities performed by that user account.
- **File, folder, or site:** Leave this field blank.

After you run the search, the IP address for each activity appears in the **IP address** column in the search results. Select the record in the search results to view more detailed information on the detail page.



Determine who set up email forwarding for a mailbox

When you configure email forwarding for a mailbox, you forward email messages sent to that mailbox to another mailbox. You can forward messages to users inside or outside of your organization. When you set up email forwarding on a mailbox, use the underlying Exchange Online cmdlet **Set-Mailbox**.



To configure an audit log search query for this scenario, use the following settings:

- **Activities:** Leave this field blank so the search returns audit records for all activities. This setting is necessary to return any audit records related to the **Set-Mailbox** cmdlet.
- **Start date** and **End date:** Select a date range that's applicable to your investigation.
- **Users:** Unless you're investigating an email forwarding issue for a specific user, leave this field blank. This setting helps you identify if email forwarding was set up for any user.
- **File, folder, or site:** Leave this field blank.

After you run the search, select **Filter results** on the search results page. In the box under the **Activity** column header, type **Set-Mailbox** so only audit records related to the **Set-Mailbox** cmdlet are displayed.

You need to look at the details of each audit record to determine if the activity is related to email forwarding. Select the audit record to display the **Details** flyout page, and then select **More information**. The following screenshot and descriptions highlight the information that indicates email forwarding was set on the mailbox.

a. In the **ObjectId** field, the alias of the mailbox that email forwarding was set on is displayed. This mailbox also appears in the **Item** column in the search results page.

b. In the **Parameters** field, the value *ForwardingSmtpAddress* indicates that email forwarding was set on the mailbox. In this example, mail is being forwarded to the email address mike@contoso.com, which is outside of the alpinehouse.onmicrosoft.com organization.

c. The *True* value for the *DeliverToMailboxAndForward* parameter indicates that a copy of the message is delivered to sarad@alpinehouse.onmicrosoft.com *and* is forwarded to the email address specified by the *ForwardingSmtpAddress* parameter, which in this example is mike@contoso.com. If the value for the *DeliverToMailboxAndForward* parameter is set to *False*, then email is only forwarded to the address specified by the *ForwardingSmtpAddress* parameter. It's not delivered to the mailbox specified in the **ObjectId** field.

d. The **UserId** field indicates the user who set email forwarding on the mailbox specified in the **ObjectId** field. This user also appears in the **User** column on the search results page. In this case, it seems that the owner of the mailbox set email forwarding on the mailbox.

If you determine that email forwarding shouldn't be set on the mailbox, remove it by running the following command in Exchange Online PowerShell:

PowerShell

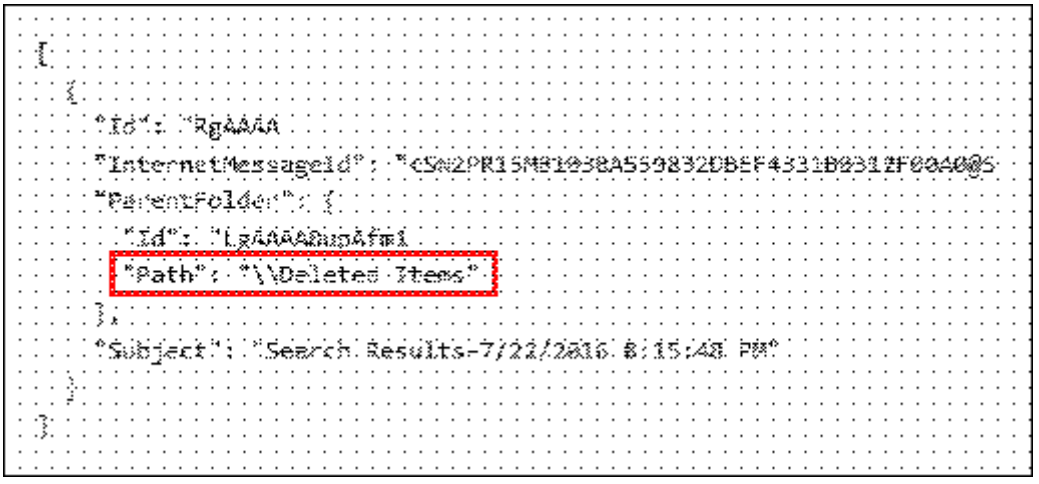
```
Set-Mailbox <mailbox alias> -ForwardingSmtpAddress $null
```

For more information about the parameters related to email forwarding, see the Set-Mailbox article.

Determine if a user deleted email items

Starting in January 2019, Microsoft turned on mailbox audit logging by default for all Office 365 and Microsoft 365 organizations. This change means that the system automatically logs certain actions that mailbox owners perform, and you can access the corresponding mailbox audit records when you search the mailbox audit log. Before this change, you had to manually enable mailbox audit logging for every user mailbox in your organization.

By default, the system logs mailbox actions that include the SoftDelete and HardDelete mailbox actions that mailbox owners perform. By using this audit logging, you can search the audit log for events related to deleted email items. For more information about mailbox auditing by default, see Manage mailbox auditing.



To configure an audit log search query for this scenario, use the following settings:

- **Activities:** Under **Exchange mailbox activities**, select one or both of the following activities:
- **Deleted messages from Deleted Items folder:** This activity corresponds to the **SoftDelete** mailbox auditing action. The audit log records this activity when a user deletes a message from the **Deleted Items** folder. It also records this activity when a user permanently deletes an item by selecting it and pressing **Shift+Delete**. After an item is permanently deleted, the user can recover it until the deleted item retention period expires.

- **Purged messages from mailbox:** This activity corresponds to the **HardDelete** mailbox auditing action. The audit log records this activity when a user purges an item from the **Recoverable Items** folder. Admins can use the search tool in the Microsoft Purview portal to search for and recover purged items until the deleted item retention period expires or longer if the user's mailbox is on hold.
- **Start date** and **End date:** Select a date range that's applicable to your investigation.
- **Users:** If you select a user in this field, the audit log search tool returns audit records for email items that the specified user deleted (SoftDeleted or HardDeleted). Sometimes the user who deletes an email isn't the mailbox owner.
- **File, folder, or site:** Leave this field blank.

After you run the search, you can filter the search results to display the audit records for soft-deleted items or for hard-deleted items. Select the audit record to display the **Details** flyout page, and then select **More information**. Additional information about the deleted item, such as the subject line and the location of the item when it was deleted, appears in the **AffectedItems** field. The following screenshots show an example of the **AffectedItems** field from a soft-deleted item and a hard-deleted item.

Example of AffectedItems field for soft-deleted item

Example of AffectedItems field for hard-deleted item

Recover deleted email items

Users can recover soft-deleted items if the deleted items retention period hasn't expired. In Exchange Online, the default deleted items retention period is 14 days, but admins can increase this setting to a maximum of 30 days. For instructions on recovering deleted items, see Recover deleted items or email in Outlook on the web.

As previously explained, admins might be able to recover hard-deleted items if the deleted item retention period hasn't expired or if the mailbox is on hold. In this case, items are kept until the hold duration expires. When you run a content search, soft-deleted and hard-deleted items in the Recoverable Items folder appear in the search results if they match the search query. For more information about running content searches, see Content Search in Office 365.

> **Tip**
>
> To search for deleted email items, search for all or part of the subject line that's displayed in the **AffectedItems** field in the audit record.

Determine if a user created an inbox rule

When users create an inbox rule for their Exchange Online mailbox, the system saves a corresponding audit record to the audit log. For more information about inbox rules, see:

- Use inbox rules in Outlook on the web
- Manage email messages in Outlook by using rules

To configure an audit log search query for this scenario, use the following settings:

- **Activities:** Under **Exchange mailbox activities**, select one or both of the following activities:
- **New-InboxRule Create new inbox rule from Outlook Web App**. This activity returns audit records when users create inbox rules by using Outlook web app or Exchange Online PowerShell.
- **Updated inbox rules from Outlook client**. This activity returns audit records when users create, modify, or remove inbox rules by using the Outlook desktop client.
- **Start date** and **End date:** Select a date range that's applicable to your investigation.
- **Users:** Unless you're investigating a specific user, leave this field blank. This approach helps you identify new inbox rules set up by any user.
- **File, folder, or site:** Leave this field blank.

After you run the search, the search results display any audit records for this activity. Select an audit record to display the **Details** flyout page, and then select **More information**. The

Parameters field displays information about the inbox rule settings. The following screenshot and descriptions highlight the information about inbox rules.

ClientIP:

SessionId:

UserId: SaraD@alpinehouse.onmicrosoft.com D

UserKey: 10033FFF954CABD2

UserType: 2

Version: 1

Workload: Exchange

a. In the **ObjectId** field, the audit record displays the full name of the inbox rule. This name includes the alias of the user's mailbox (for example, SaraD) and the name of the inbox rule (for example, "Move messages from admin").

b. In the **Parameters** field, the audit record displays the condition of the inbox rule. In this example, the condition is specified by the *From* parameter. The value defined for the *From* parameter indicates that the inbox rule acts on email sent by admin@alpinehouse.onmicrosoft.com. For a complete list of the parameters that you can use to define conditions of inbox rules, see the New-InboxRule article.

c. The *MoveToFolder* parameter specifies the action for the inbox rule. In this example, messages received from admin@alpinehouse.onmicrosoft.com are moved to the folder named *AdminSearch*. For a complete list of parameters that you can use to define the action of an inbox rule, see the New-InboxRule article.

d. The **UserId** field indicates the user who created the inbox rule specified in the **ObjectId** field. The **User** column on the search results page also displays this user.

Investigate why a user outside your organization successfully signed in

When you review audit records in the audit log, you might see records that show Microsoft Entra ID authenticated an external user who successfully signed in to your organization. For example, an admin in contoso.onmicrosoft.com might see an audit record showing that a user from a different organization (for example, fabrikam.onmicrosoft.com) successfully signed in to contoso.onmicrosoft.com. Similarly, you might see audit records that show users with a Microsoft Account (MSA), such as an Outlook.com or Live.com, successfully signed in to your organization. In these situations, the audited activity is **User logged In**.

This behavior is by design. Microsoft Entra ID, the directory service, supports *pass-through authentication* when an external user tries to access a SharePoint site or a OneDrive location in your organization. When the external user tries to access the resource, they're prompted to enter their credentials. Microsoft Entra ID uses the credentials to authenticate the user, so only Microsoft Entra ID verifies that the user is who they say they are. The indication of the successful sign-in in the audit record comes from Microsoft Entra authenticating the user. The successful sign-in doesn't mean that the user accessed any resources or performed any other actions in your organization. It only shows that Microsoft Entra ID authenticated the user. For a pass-through user to access SharePoint or OneDrive resources, a user in your organization must explicitly share a resource with the external user by sending them a sharing invitation or anonymous sharing link.

> **Note**
>
> Microsoft Entra ID supports pass-through authentication only for *first-party applications*, such as SharePoint Online and OneDrive for Business. It doesn't support pass-through authentication for other third-party applications.

Here's an example and descriptions of relevant properties in an audit record for a **User logged In** event that results from pass-through authentication. Select the audit record to display the **Details** flyout page, and then select **More information**.

D

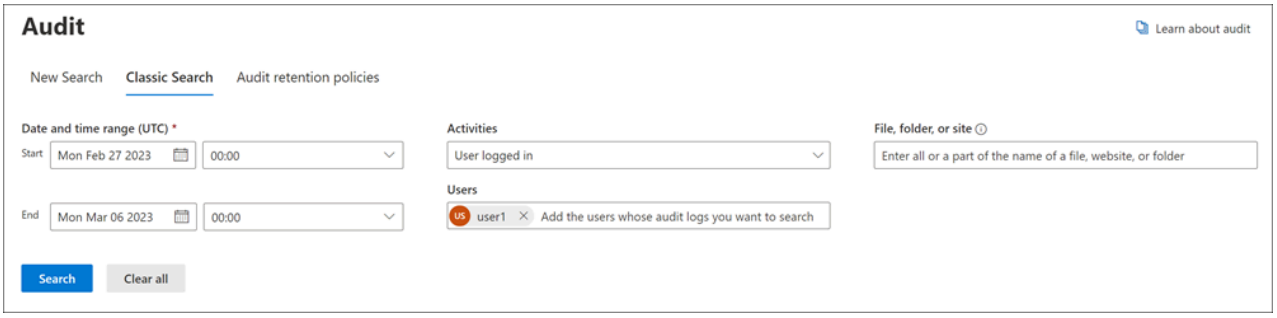
a. This field shows that the user who tried to access a resource in your organization isn't found in your organization's Microsoft Entra ID.

b. This field shows the UPN of the external user that tried to access a resource in your organization. This user ID also appears in the **User** and **UserId** properties in the audit record.

c. The **ApplicationId** property shows the application that triggered the sign-in request. The value of `00000003-0000-0ff1-ce00-000000000000` displayed in the **ApplicationId** property in this audit record indicates SharePoint Online. OneDrive for Business also has this same **ApplicationId**.

d. This field shows that the pass-through authentication succeeded. In other words, Microsoft Entra ID successfully authenticated the user.

e. The **RecordType** value of **15** shows that the audited activity (UserLoggedIn) is a Secure Token Service (STS) sign-in event in Microsoft Entra ID.



For more information about the other properties displayed in a UserLoggedIn audit record, see the Microsoft Entra related schema information in Office 365 Management Activity API schema.

Here are two example scenarios that result in a successful **User logged in** audit activity because of pass-through authentication:

- A user with a Microsoft Account (such as SaraD@outlook.com) tries to access a document in a OneDrive for Business account in fourthcoffee.onmicrosoft.com and there's no corresponding guest user account for SaraD@outlook.com in fourthcoffee.onmicrosoft.com.
- A user with a Work or School account in an organization (such as pilarp@fabrikam.onmicrosoft.com) tries to access a SharePoint site in contoso.onmicrosoft.com and there's no corresponding guest user account for pilarp@fabrikam.com in contoso.onmicrosoft.com.

Tips for investigating successful sign-ins resulting from pass-through authentication

- Search the audit log for activities performed by the external user identified in the **User logged in** audit record. Type the UPN for the external user in the **Users** box and use a date range if relevant to your scenario. For example, you can create a search using the following search criteria:

  In addition to the **User logged in** activities, you might see other audit records, such as records that indicate a user in your organization shared resources with the external user and whether the external user accessed, modified, or downloaded a document that was shared with them.

- Search for SharePoint sharing activities that indicate a file was shared with the external user identified by a **User logged in** audit record. For more information, see Use sharing auditing in the audit log.

- Export the audit log search results that contain records relevant to your investigation so that you can use Excel to search for other activities related to the external user. For more information, see Export, configure, and view audit log records.

Search for mailbox activities performed by users with non-E5 licenses

Even when mailbox auditing on by default is turned on for your organization, you might notice that mailbox audit events for some users don't appear in audit log searches by using the Microsoft Purview portal, the **Search-UnifiedAuditLog** cmdlet, or the Office 365 Management Activity API. The reason for this behavior is that mailbox audit events return only for users with E5 licenses when you use one of the previous methods to search the unified audit log.

To retrieve mailbox audit log records for non-E5 users, use one of the following workarounds:

- Manually enable mailbox auditing on individual mailboxes (run the `Set-Mailbox -Identity <MailboxIdentity> -AuditEnabled $true` command in Exchange Online PowerShell). After you enable mailbox auditing, search for mailbox audit activities by using the Microsoft Purview portal, the **Search-UnifiedAuditLog** cmdlet, or the Office 365 Management Activity API.

  > ⓘ **Note**
  >
  > If mailbox auditing already appears to be enabled on the mailbox, but your searches return no results, change the value of the *AuditEnabled* parameter to `$false` and then back to `$true`.

Search for mailbox activities performed in a specific mailbox (including shared mailboxes)

When you use the **Users** dropdown list in the audit log search tool in the Microsoft Purview portal or the **Search-UnifiedAuditLog -UserIds** command in Exchange Online PowerShell, you can search for activities performed by a specific user. For mailbox audit activities, this type of search finds activities performed by the specified user. It doesn't guarantee that the search results include all activities performed in the same mailbox. For example, an audit log search doesn't return audit records for activities performed by a delegate user because searching for mailbox activities performed by a specific user doesn't return activities performed by a delegate user who has been assigned permissions to access another user's mailbox. A delegate user is someone who is assigned the SendAs, SendOnBehalf, or FullAccess mailbox permission to another user's mailbox.

Also, using the **User** dropdown list in the audit log search tool or the **Search-UnifiedAuditLog -UserIds** doesn't return results for activities performed in a shared mailbox.

To search for the activities performed in a specific mailbox or to search for activities performed in a shared mailbox, use the following syntax when running the **Search-UnifiedAuditLog** cmdlet:

PowerShell

```
Search-UnifiedAuditLog -StartDate <date> -EndDate <date> -FreeText (Get-Mailbox <mailbox identity).ExchangeGuid
```

For example, the following command returns audit records for activities performed in the Contoso Compliance Team shared mailbox between August 2020 and October 2020:

PowerShell

```
Search-UnifiedAuditLog -StartDate 08/01/2020 -EndDate 10/31/2020 -FreeText (Get-Mailbox complianceteam@contoso.onmicrosoft.com).ExchangeGuid
```

Last updated on 03/30/2026

Use MailItemsAccessed to investigate compromised accounts

A compromised user account (also called an *account takeover*) is a type of cyberattack where an attacker gains access to a user account and operates as the user. When investigating compromised email accounts, assume that more mail data is compromised than might be indicated by tracing the attacker's actual presence. Depending on the type of data in email messages, you might face regulatory fines unless you can prove that sensitive information wasn't exposed. For example, HIPAA-regulated organizations face significant fines if there's evidence that patient health information (PHI) was exposed.

Use the *MailItemsAccessed* mailbox-auditing action to investigate compromised email accounts by auditing accesses of mail data by mail protocols and clients. This auditing action helps you better understand email data breaches and identify the scope of compromises to specific mail items. When a cyberattacker gains access to a specific piece of mail, Exchange Online audits the event even though there's no indication that the mail item was read.

The MailItemsAccessed mailbox-auditing action

The MailItemsAccessed action is part of Audit (Standard) functionality. It's part of Exchange mailbox auditing and is enabled by default for users that are assigned an Office 365 E3/E5 or Microsoft 365 E3/E5 license.

The MailItemsAccessed mailbox-auditing action covers all mail protocols: POP, IMAP, MAPI, EWS, Exchange ActiveSync, and REST. It also covers both types of accessing mail: *sync*, where clients download sets of messages from the server, and *bind*, where a user or client accesses an individual message.

Auditing sync access

Sync operations are only recorded when a mailbox is accessed by a desktop version of the Outlook client for Windows or Mac. During the sync operation, these clients typically download a large set of mail items from the cloud to a local computer. The audit volume for sync operations is huge. So, instead of generating an audit record for each mail item that's synced, the system generates an audit event for the mail folder containing items that were synced. All mail items in

the synced folder are assumed to be compromised. The access type is recorded in the OperationProperties field of the audit record.

For an example of displaying the sync access type in an audit record, see Use MailItemsAccessed audit records for forensic investigations, specifically the procedure for checking sync activities to determine context.

Auditing bind access

A bind operation is an individual access to an email message. For bind access, the InternetMessageId of individual messages is recorded in the audit record. The MailItemsAccessed audit action records bind operations and then aggregates them into a single audit record. All bind operations that occur within a 2-minute interval are aggregated in a single audit record in the Folders field within the AuditData property. Each message that was accessed is identified by its InternetMessageId. The number of bind operations that were aggregated in the record is displayed in the OperationCount field in the AuditData property.

For an example of displaying the bind access type in an audit record, see the "Check for bind activities" procedure in Use MailItemsAccessed audit records for forensic investigations.

Use MailItemsAccessed audit records for forensic investigations

Mailbox auditing generates audit records for access to email messages so that you can be confident that email messages aren't compromised. In circumstances where data access is uncertain, assume that the data is compromised by recording all mail access activity.

Use MailItemsAccessed audit records for forensic purposes after a data breach is resolved and the bad actor is evicted. Complete the following steps to begin your investigation:

1. Identify the set of mailboxes that the bad actor compromised.
2. Determine the time frame when the bad actor had access to mailboxes in your organization.
3. Use the **Search-UnifiedAuditLog** cmdlet in Exchange Online PowerShell to search audit records that correspond to the data breach.

Run one of the following commands to search for MailItemsAccessed audit records:

Unified audit log:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -UserIds
<user1,user2> -Operations MailItemsAccessed -ResultSize 1000
```

Complete the following steps to use MailItemsAccessed audit records to investigate a compromised user account. Each step includes the command syntax for the **Search-UnifiedAuditLog** cmdlet.

1. Check for sync activities. If a bad actor uses an email client to download messages in a mailbox, they can disconnect the computer from the Internet and access the messages locally without interacting with the server. In this case, mailbox auditing can't audit these activities.

   To search for MailItemsAccessed records where the mail items are accessed by a sync operation, run the following command:

   Unified audit log:

   PowerShell

   ```
   Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 02/20/2020 -UserIds
   <user1,user2> -Operations MailItemsAccessed -ResultSize 1000 | Where
   {$_.AuditData -like '*"MailAccessType","Value":"Sync"*'} | FL
   ```

2. Check sync activities to determine if any of them happen in the same context as the one used by the bad actor to access the mailbox. Context is identified and differentiated by the IP address of the client computer used to access the mailbox and the mail protocol.

   Use the properties listed in the following table to investigate. These properties are located in the **AuditData** or **OperationProperties** property. If any of the syncs occur in the same context as the bad actor activity, assume the bad actor synced all mail items to their client, which means the entire mailbox is compromised.

   Expand table

Property	Description
ClientInfoString	Describes protocol, client (includes version)
ClientIPAddress	IP address of the client machine.
SessionId	Session ID helps to differentiate bad actor actions vs day-to-day user activities on the same account (useful for compromised accounts)
UserId	UPN of the user reading the message.

3. Check for bind activities. After checking for sync activities and comparing their context to bad actor activity, you can be confident that all other access to email messages by the bad actor is captured in the MailItemsAccessed audit records that have a MailAccessType property with a value of "Bind".

   To search for MailItemsAccessed records where the mail items are accessed by a Bind operation, run the following command.

   Unified audit log:

   ```
   PowerShell
   Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -UserIds
   <user1,user2> -Operations MailItemsAccessed -ResultSize 1000 | Where
   {$_.AuditData -like '*"MailAccessType","Value":"Bind"*'} | FL
   ```

   Email messages that are accessed are identified by their internet message ID. You can also check to see if any audit records have the same context as the ones for other bad actor activity.

   You can use the audit data for bind operations in two different ways:

   - Access or collect all email messages the bad actor accessed by using the InternetMessageId to find them and then checking to see if any of those messages contains sensitive information.
   - Use the InternetMessageId to search audit records related to a set of potentially sensitive email messages. This is useful if you're concerned only about a few messages.

Filter duplicate audit records

To remove auditing noise, the system filters out duplicate audit records for the same bind operations that occur within an hour of each other. The system also filters out sync operations at one-hour intervals. An exception to this deduplication process occurs if, for the same InternetMessageId, any of the properties described in the following table are different. If one of these properties is different in a duplicate operation, the system generates a new audit record. The following table describes each property in more detail.

Expand table

Property	Description
ClientIPAddress	IP address of the client computer.

Property	Description
ClientInfoString	The client protocol, client used to access the mailbox.
ParentFolder	The full folder path of the mail item that was accessed.
Logon_type	The logon type of the user who performed the action. The logon types (and their corresponding Enum value) are Owner (0), Admin (1), or Delegate (2).
MailAccessType	Whether the access is a bind or a sync operation.
MailboxUPN	The UPN of the mailbox where the message being read is located.
User	The UPN of the user reading the message.
SessionId	The Session ID helps to differentiate attacker actions and day-to-day user activities in the same mailbox (if an account is compromised). For more information about sessions, see Contextualizing attacker activity within sessions in Exchange Online.

Next steps

Learn more about related audit tasks:

- Identify who deleted an email message or why an email is missing: Check for deleted or moved messages.
- Identify who modified mailbox rules: Check for forwarding or auto-delete rules.
- Export, configure, and view audit log records: Export audit data for your report.

Identify who deleted an email message or why an email is missing

Use this article to investigate missing email messages in Exchange Online and identify who deleted them. It guides administrators through using the Microsoft Purview audit log and Exchange Online PowerShell to locate deletion events, analyze mailbox configurations, check retention and migration activity, and determine whether mailbox rules or shared-mailbox access caused the loss.

Use these methods to investigate:

- Emails deleted by users or administrators
- Missing emails after migration or sync issues
- Emails removed by mailbox rules or retention policies
- Deleted emails from shared mailboxes
- Emails not appearing in expected folders

Before you begin

To investigate deleted emails and missing messages, you need:

- The *Audit Logs* role assigned in Microsoft Purview
- To connect to Exchange Online PowerShell by using Connect-ExchangeOnline

How to identify deleted emails

Use the following methods to investigate missing emails and identify deletion activities. Choose the method based on the type of deletion you're investigating.

Search for deleted emails by operation type

Use this method to search for the following operations:

- **SoftDelete**: Items moved to Deleted Items folder.
- **HardDelete**: Items permanently removed from mailbox.
- **MoveToDeletedItems**: Items moved to Deleted Items folder by user action.

To search for audit records of email deletions by using specific deletion operations, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -UserIds
<user1,user2> -Operations SoftDelete,HardDelete,MoveToDeletedItems -ResultSize 1000
```

Replace `<user1,user2>` with user email addresses. Specify multiple users by separating user names with commas.

Search for shared mailbox deletions

To investigate deletions from shared mailboxes, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -UserIds
<user1,user2> -FreeText <sharedmailbox@domain.com> -Operations
SoftDelete,HardDelete,MoveToDeletedItems -ResultSize 1000
```

> ⓘ Note
>
> Shared mailbox auditing might not be enabled by default. If this search returns no results, see Shared mailbox auditing not configured to enable auditing.

Search for missing emails by using keywords

This method helps identify deletion records for emails with specific subjects or content.

To search for audit records related to specific missing emails, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -FreeText "<email
subject or keyword>" -Operations SoftDelete,HardDelete,MoveToDeletedItems -ResultSize
1000
```

Search for comprehensive email activities

This broader search includes moves and updates that might explain missing emails.

To search for all activities that affect email visibility, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -UserIds
<user1,user2> -Operations SoftDelete,HardDelete,MoveToDeletedItems,Move,Update,Create
-ResultSize 1000
```

Understanding search results

Getting no results from audit searches can provide important insights about what didn't cause the missing emails:

- **Deletion operations not found**: Rules out user-initiated deletions during the timeframe.
- **No retention policy actions**: Indicates automated policies didn't delete the emails.
- **No migration activities**: Shows migration processes didn't remove the emails.
- **No administrator actions**: Confirms admins didn't perform bulk operations.

> ⓘ Note
>
> Document which searches return no results. This information helps narrow down the root cause by eliminating potential causes.

Missing search results

If your audit log searches don't find deletion records for missing emails, try the following steps.

Missing emails with no deletion audit records

Use the following steps to investigate when emails are missing but no deletion audit records are found.

1. Check if auditing was enabled when the deletion occurred.

   PowerShell

   ```
   Get-Mailbox <mailbox> | Select AuditEnabled,AuditOwner,AuditDelegate,WhenCreated
   ```

2. Enable comprehensive auditing for future monitoring.

   PowerShell

```
Set-Mailbox <mailbox> -AuditEnabled $true -AuditOwner
@{Add="SoftDelete","HardDelete","MoveToDeletedItems","Move","Create","Update"}
```

3. Search for retention policy actions that might remove emails.

```
PowerShell
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -UserIds
<user1,user2> -Operations TaggedAsRecord,ApplyRetentionTag -ResultSize 1000
```

If this command returns no results, it indicates that retention policies didn't automatically delete emails during the specified timeframe. This information helps you rule out automated policy-based deletions as the cause of missing emails.

Shared mailbox auditing not configured

Use the following steps to enable auditing for shared mailboxes when deletion records aren't found.

1. Check the current auditing configuration for the shared mailbox.

```
PowerShell
Get-Mailbox <sharedmailbox> | Select
AuditEnabled,AuditOwner,AuditDelegate,AuditAdmin
```

2. Enable comprehensive auditing for the shared mailbox.

```
PowerShell
Set-Mailbox <sharedmailbox> -AuditEnabled $true -AuditOwner
@{Add="SoftDelete","HardDelete","MoveToDeletedItems"} -AuditDelegate
@{Add="SoftDelete","HardDelete","MoveToDeletedItems","SendAs","Move"}
```

3. Search for activities by users with shared mailbox access.

```
PowerShell
Get-MailboxPermission <sharedmailbox> | Where {$_.User -ne "NT AUTHORITY\SELF"} |
ForEach {
    Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -UserIds
$_.User -Operations SoftDelete,HardDelete -ResultSize 100 }
```

Migration-related email loss investigation

The following steps show how to investigate emails lost during migration processes.

1. Search for migration-related activities during the migration timeframe.

```
PowerShell
Search-UnifiedAuditLog -StartDate <migration_start_date> -EndDate
<migration_end_date> -UserIds <user1,user2> -FreeText "<migration subject or
keyword>" -ResultSize 1000
```

Advanced investigation procedures

The following procedures show how to perform detailed analysis when standard searches don't reveal the cause of missing emails.

Analyze mailbox rules that might delete emails

If you suspect that mailbox rules are causing emails to be deleted or moved to unexpected folders, use the following dedicated mailbox rule investigation procedures.

> **Tip**
>
> For comprehensive mailbox rule investigation, see **Identify who modified mailbox rules** for detailed guidance on identifying who created, modified, or deleted mailbox rules that might affect email delivery.

Investigate retention and compliance policies

To check if compliance policies are causing email deletion, run the following commands:

1. Check retention policies applied to the mailbox.

```
PowerShell
Get-Mailbox <mailbox> | Select
RetentionPolicy,LitigationHoldEnabled,RetainDeletedItemsFor
```

2. Search for compliance-related deletions.

```
PowerShell
```

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -UserIds
<user1,user2> -Operations ComplianceSettingChanged,RetentionPolicyApplied -
ResultSize 1000
```

Check for administrator actions

To check if administrators performed actions that affected emails, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -UserIds
<user1,user2> -Operations Remove-MailboxFolderPermission,Set-Mailbox,New-
MailboxExportRequest,New-MailboxImportRequest -ResultSize 1000
```

Quick reference

Key operations for investigating deletions

The following table lists the key audit operations to use when investigating deleted or missing emails.

Expand table

Operation	Description	Use Case
ApplyRetentionTag	Retention policy applied to items	Automated policy actions
HardDelete	Items permanently removed from mailbox	Permanent deletions, second-level investigation
Move	Items moved between folders	Investigate folder changes
MoveToDeletedItems	Items moved to Deleted Items by user action	User-initiated moves to deleted items
SoftDelete	Items moved to Deleted Items folder	User deletions, first-level investigation
TaggedAsRecord	Items marked for retention	Compliance-related actions

Search parameters for investigating deletions

The following table describes the main `Search-UnifiedAuditLog` parameters used in these investigations.

Expand table

Parameter	Description	Example
-FreeText	Search for specific email identifiers	`<email subject or unique identifier>`
-Operations	Filter by deletion activity types	SoftDelete,HardDelete,MoveToDeletedItems
-ResultSize	Number of results to return	1,000 (standard), 5,000 (comprehensive)
-StartDate/-EndDate	Define investigation timeframe	Based on when emails went missing
-UserIds	Filter by who performed the action	`<user1@domain.com,user2@domain.com>`

Next steps

- Use MailItemsAccessed to investigate compromised accounts: Investigate whether deletions are part of a broader account compromise.
- Identify who modified mailbox rules: Check whether mailbox rules are auto-deleting or forwarding messages.
- Export, configure, and view audit log records: Export your investigation results for reporting or evidence preservation.

Search the audit log for specific email messages

Use this article to search the Microsoft Purview audit log for specific email messages that are missing, moved, or need investigation. It shows practical Exchange Online PowerShell searches and investigation steps you can use when standard audit searches don't return the records you expect.

Use these methods to investigate:

- Email migration issues
- Messages moved between folders
- Email access patterns
- Missing email items

Before you begin

To search audit logs for specific email items, you need:

- The *Audit Logs* role assigned in Microsoft Purview
- To connect to Exchange Online PowerShell by using Connect-ExchangeOnline

Search for specific email messages

Use these methods to find audit records for specific email messages. Select the method based on what information you have about the email you're looking for.

Search by email subject or keywords

Use the FreeText parameter to search for:

- Email subject lines
- Keywords from email content
- Sender names
- Any identifying text from the email

To search for audit records by using email subjects, keywords, or other identifying information, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -FreeText "<subject
or keyword>" -ResultSize 1000
```

Search for moved emails

To search for Move and MoveToDeletedItems operations in a mailbox, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -
UserIds <user1,user2> -Operations Move,MoveToDeletedItems -ResultSize 1000
```

> **Important**
>
> The audit feature for move operations isn't enabled by default.

Search all email activities

To search for all email-related activities in a mailbox, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -
UserIds <user1,user2> -
Operations Send,Create,Move,SoftDelete,HardDelete,MailItemsAccessed -ResultSize 1000
```

What to do when searches return no result

If your audit log searches don't find the email records you're looking for, try these investigation steps.

Missing emails after migration

Use the following steps to investigate missing emails after migration when searches return no results.

1. Check if auditing was enabled before the migration occurred.

PowerShell

```
Get-Mailbox <mailbox> | Select AuditEnabled,WhenCreated
```

1. Expand the search date range to cover a broader timeframe.

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/01/2020 -EndDate 03/31/2020 -
ObjectIds <mailbox> -ResultSize 1000
```

Emails moved but no audit records found

Use the following steps to investigate when users move emails but you can't find audit records.

1. Check if auditing is configured for move operations.

PowerShell

```
Get-Mailbox <mailbox> | Select AuditOwner
```

1. Enable auditing for move operations if it's not configured.

PowerShell

```
Set-Mailbox <mailbox> -
AuditOwner @{Add="Move","MoveToDeletedItems","SoftDelete","HardDelete"}
```

1. Search using additional operation types that might capture the activity.

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -
ObjectIds <mailbox> -Operations Move,MoveToDeletedItems,Update -ResultSize 1000
```

Locating specific email messages

The following steps help you investigate when you can't find audit records for specific email messages.

1. Search by subject or keywords

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -FreeText "<subject or keyword>" -ResultSize 1000 | FL
```

1. Search by user

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -UserIds <sender> -ResultSize 1000 | FL
```

Advanced investigation procedures

The following procedures help you resolve issues when standard investigation steps don't resolve the issue.

Enable comprehensive mailbox auditing

To enable all relevant audit actions and ensure future activities are captured, run the following command:

PowerShell

```
Set-Mailbox <mailbox> -AuditEnabled $true -AuditOwner @{Add="Move","MoveToDeletedItems","SoftDelete","HardDelete","Create"} -AuditDelegate @{Add="SendAs","Move"}
```

Verify organization-wide audit configuration

To ensure that auditing is enabled at the organization level, run the following command:

PowerShell

```
Set-OrganizationConfig -AuditDisabled $false
```

Quick reference

Search parameters

Use these key parameters to search audit logs for specific email items:

Expand table

Parameter	Description	Example
-FreeText	Search for specific email identifiers	`<email subject or unique identifier>`
-Operations	Filter by deletion activity types	SoftDelete,HardDelete,MoveToDeletedItems
-ResultSize	Number of results to return	1,000 (standard), 5,000 (comprehensive)
-StartDate/-EndDate	Define investigation timeframe	Based on when emails went missing
-UserIds	Filter by who performed the action	`<user1@domain.com,user2@domain.com>`

Next steps

- Identify who deleted an email message or why an email is missing: Investigate deletion causes if your search reveals missing or deleted messages.
- Search the audit log for deleted mailbox items: Narrow your search to deleted items using deletion-specific operations and filters.
- Export, configure, and view audit log records: Export your email search results for detailed review or reporting.

Identify who modified mailbox rules

This guide explains how to investigate changes to mailbox rules in Exchange Online, including how to view a mailbox's current inbox and forwarding rules and how to search the Microsoft Purview audit log to identify who created, modified, or deleted those rules.

Use these methods to investigate:

- Changes to email forwarding rules
- Rules that cause emails to not appear in expected folders
- Unauthorized rule modifications

Before you begin

To investigate mailbox rule modifications, you need:

- The *Audit Logs* role assigned in Microsoft Purview
- To connect to Exchange Online PowerShell by using Connect-ExchangeOnline

How to identify mailbox rule modifications

Use Get-InboxRule to check current mailbox rules and Search-UnifiedAuditLog to find mailbox rule modifications.

Check current mailbox rules

The Get-InboxRule output shows:

- **Current rule configuration**: Rule configuration
- **Rule actions**: Move, delete, or forward
- **Rule status**: Enabled or disabled

To see what rules currently exist in a mailbox, run the following command:

PowerShell

```
Get-InboxRule -Mailbox <mailbox> | FL
Name,Description,DeleteMessage,MoveToFolder,Enabled
```

Search for rule modification audit records

The Search-UnifiedAuditLog command looks for:

- **New-InboxRule**: New rules created
- **Set-InboxRule**: Existing rules modified
- **Remove-InboxRule**: Rules deleted

To find out who created, modified, or deleted mailbox rules, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -UserIds
<user1,user2> -Operations New-InboxRule,Set-InboxRule,Remove-InboxRule -ResultSize
1000
```

What to do when searches return no results

If your audit searches don't find rule modification records:

1. **Expand the date range** to capture older changes:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/01/2020 -EndDate 03/31/2020 -UserIds
<user1,user2> -Operations New-InboxRule,Set-InboxRule,Remove-InboxRule -ResultSize
1000
```

1. **Enable auditing** for future rule changes:

PowerShell

```
Set-Mailbox <mailbox> -AuditEnabled $true -AuditOwner @{Add="Create","Update"}
```

Quick reference

Key operations for rule investigation

The following table lists the mailbox rule operations that appear in audit results.

Expand table

Operation	Description
New-InboxRule	New mailbox rule created.

Operation	Description
Remove-InboxRule	Mailbox rule deleted.
Set-InboxRule	Existing mailbox rule modified.

Essential commands

The following commands are the primary tools for investigating mailbox rule changes.

Expand table

Command	Purpose
`Get-InboxRule -Mailbox <mailbox>`	Check current rule configuration.
`Search-UnifiedAuditLog -Operations New-InboxRule,Set-InboxRule,Remove-InboxRule`	Find who made rule changes.

Next steps

- Use MailItemsAccessed to investigate compromised accounts: Determine whether unauthorized rule changes indicate a compromised account.
- Identify who deleted an email message or why an email is missing: Investigate whether modified rules caused email deletions or missing messages.
- Export, configure, and view audit log records: Export your rule modification findings for compliance documentation.

ⓘ**Note:** The author created this article with assistance from AI. Learn more

Use the audit log to identify Exchange transport rule activities

This article explains how to determine whether a user created, modified, or removed a transport rule in Exchange Online. Transport rules, also known as mail flow rules, can significantly impact email delivery and processing, so understanding their origin is important for security and compliance investigations.

Before you begin

Before you begin, make sure you have the following information:

- The email address of the sender or recipient targeted by the transport rule.
- The license type assigned to the affected user.
- The exact date and time when the transport rule change occurred.
- The date and time when the audit search was run. If you perform the search shortly after the transport rule update, the logs might not yet reflect the change.
- An Extended Message Trace (EMT) from the Exchange Online admin center for sample emails sent before and after the transport rule change.

You must sign in to Exchange Online PowerShell and Microsoft Purview portal to complete the audit investigation procedure.

Check mailbox auditing status

> **Note**
>
> Before searching for audit activity, verify that mailbox auditing is enabled for the affected user.

Complete the following steps to confirm that mailbox auditing is enabled:

1. In Exchange Online PowerShell, run the following command to check the organization-level audit configuration:

   PowerShell

```
Get-AdminAuditLogConfig | FL UnifiedAudit*
```

> **Note**
>
> Run this command in Exchange Online PowerShell. In Security & Compliance PowerShell, the `UnifiedAuditLogIngestionEnabled` property always returns `False`, even when auditing is enabled.

2. Check if mailbox audit logs are disabled at the tenant level:

PowerShell

```
Get-OrganizationConfig | FL AuditDisabled
```

3. At the mailbox level, `AuditEnabled` always returns `True`, even if auditing is disabled for a specific mailbox. To verify, use:

PowerShell

```
Get-Mailbox -Filter {AuditEnabled -eq "True"}
```

If you receive an error that the mailbox can't be found, auditing is disabled for that mailbox. For more information, see Verify the auditing status for your organization.

Verify administrator permissions

Ensure that you have the required permissions to search or export audit logs:

1. In the Microsoft Purview portal, go to **Settings** > **Roles and scopes** > **Role groups**.
2. Verify that your account is assigned to the **View-Only Audit Logs** or **Audit Logs** role.
3. In the Exchange admin center, use the **Audit Logs** role to enable or disable auditing and access audit cmdlets. Use the **View-Only Audit Logs** role to grant read-only access to audit logs.

For more information, see Assign permissions to search the audit log.

Check audit log retention policies

Audit log retention policies determine whether older activities are still available:

1. Determine when the activity occurred.
2. By default, audit logs are retained for 180 days.
3. If the affected user doesn't have an Audit (Premium) license and no audit retention policy is configured, audit logs older than 180 days aren't available.

For more information, see Get-UnifiedAuditLogRetentionPolicy.

Search the audit log for rule activities

When searching in Microsoft Purview Audit, use filters to narrow your results.

Recommended audit filters:

- **Date and time range (UTC)**: Specify the exact range when the activity occurred. Audit timestamps are always in UTC.
- **Activities – operation names**:
  - New-TransportRule: Logged when you create a new transport rule.
  - Set-TransportRule: Logged when you modify an existing transport rule.
  - Disable-TransportRule: Logged when you disable a transport rule.
  - Enable-TransportRule: Logged when you enable a transport rule.
  - Remove-TransportRule: Logged when you remove a transport rule.
- **User**: Enter the email address of the person who performed the operation. This field is optional if the user identity is unknown.

By applying these filters, you can identify whether a transport rule was created, modified, enabled, disabled, or removed, and by whom.

Next steps

Use the following resources to continue your investigation:

- Identify who modified mailbox rules: Investigate specific rule changes and determine who created, modified, or deleted mailbox rules.
- Use MailItemsAccessed to investigate compromised accounts: Investigate whether suspicious rule changes are linked to a compromised account.
- Export, configure, and view audit log records: Export your rule activity results for evidence collection or compliance review.

Investigate shared mailbox activities using audit logs

This article explains how to investigate shared mailbox activity by using the Microsoft Purview audit log and Exchange Online PowerShell. It describes practical search patterns and remediation steps to find deletions, sent-as activity, folder browsing, mailbox rule and forwarding changes, and other delegate actions.

Use these methods to investigate:

- Email deletions from shared mailboxes
- Who sent emails from shared mailboxes
- Delegate access activities
- Email moves between folders
- Forwarding and rule configurations
- Missing emails in shared mailboxes

Before you begin

To investigate shared mailbox activities, you need:

- The *Audit Logs* role assigned in Microsoft Purview
- To connect to Exchange Online PowerShell by using Connect-ExchangeOnline

How to investigate shared mailbox activities

Use these methods to investigate activities in shared mailboxes. Choose the method based on the type of activity you're investigating.

Search for deleted emails in shared mailboxes

To search for audit records of email deletions from a shared mailbox, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -FreeText <shared-mailbox@domain.com> -Operations SoftDelete,HardDelete,MoveToDeletedItems -ResultSize 500
```

This command searches for:

- **SoftDelete**: Items moved to Deleted Items folder.
- **HardDelete**: Items permanently removed from mailbox.
- **MoveToDeletedItems**: Items moved to Deleted Items by user action.

Search for emails sent from shared mailboxes

To identify who sent emails from a shared mailbox using delegate permissions, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -UserIds
<user1,user2> -FreeText <shared-mailbox@domain.com> -Operations SendAs -ResultSize
500
```

Search for email moves between folders

To search for move operations in a shared mailbox, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -UserIds
<user1,user2> -FreeText <shared-mailbox@domain.com> -Operations
Move,MoveToDeletedItems -ResultSize 300
```

Monitor delegate folder access (FolderBind)

To track when delegates browse specific folders in shared mailboxes, use the following steps:

Check FolderBind configuration:

PowerShell

```
Get-Mailbox <shared-mailbox@domain.com> | Select AuditDelegate | Where-Object
{$_.AuditDelegate -contains "FolderBind"}
```

Enable FolderBind auditing:

PowerShell

```
Set-Mailbox <shared-mailbox@domain.com> -AuditDelegate @{Add="FolderBind"}
```

Search for folder browsing activities:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -FreeText <shared-mailbox@domain.com> -Operations FolderBind -ResultSize 500
```

> **Important**
>
> FolderBind tracks delegate and admin folder access only. It doesn't log shared mailbox owners browsing folders. Enable it proactively for compliance and security monitoring.

Common use cases:

- Monitor access to confidential folders in executive shared mailboxes
- Compliance audit trails for regulatory requirements
- Security investigations of unauthorized folder browsing
- Delegate behavior analysis for governance

Investigate delegate access activities

To identify users with delegate permissions to a shared mailbox, run the following command:

PowerShell

```
Get-MailboxPermission <shared-mailbox@domain.com> | Where-Object {$_.AccessRights -eq "FullAccess"}
```

To search for activities performed by a specific delegate, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -UserIds <delegate@domain.com> -ResultSize 500
```

> **Important**
>
> Use `-UserIds` to find activities performed **BY** a specific delegate user. Don't use `-UserIds` with the shared mailbox address, as this action doesn't return delegate activities performed **IN** the

shared mailbox. For activities performed in the shared mailbox by any user (including delegates), use the `-FreeText` parameter as shown in other sections.

Monitor email access activities

> **Note**
>
> This command requires Microsoft 365 E5 licensing to capture `MailItemsAccessed` operations.

To search for email access activities in shared mailboxes, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -UserIds
<user1,user2> -FreeText <shared-mailbox@domain.com> -Operations MailItemsAccessed -
ResultSize 200
```

Search for email forwarding configuration

To find who configured email forwarding on a shared mailbox, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -UserIds
<user1,user2> -FreeText <shared-mailbox@domain.com> -Operations Set-Mailbox -
ResultSize 200
```

Search for mailbox rule modifications

To search for inbox rule creation or modification activities, run the following command:

PowerShell

```
Search-UnifiedAuditLog -StartDate 01/06/2020 -EndDate 01/20/2020 -FreeText <shared-
mailbox@domain.com> -Operations New-InboxRule,Set-InboxRule -ResultSize 100
```

> **Tip**

For comprehensive mailbox rule investigation, see **Identify who modified mailbox rules** for detailed guidance on identifying who created, modified, or deleted mailbox rules that might be affecting email delivery.

What to do when searches return no results

If your audit log searches don't find shared mailbox activity records, try these steps to verify the auditing configuration.

Verify and enable mailbox auditing

1. Check if auditing is enabled at the organization level.

PowerShell

```
Get-OrganizationConfig | Select AuditDisabled
```

1. Check if auditing is enabled for the specific shared mailbox.

PowerShell

```
Get-Mailbox <shared-mailbox@domain.com> | Select AuditEnabled
```

1. Enable auditing if it's disabled.

PowerShell

```
Set-OrganizationConfig -AuditDisabled $false
Set-Mailbox <shared-mailbox@domain.com> -AuditEnabled $true
```

Advanced procedures

The following commands apply common shared mailbox fixes:

To enable sent items copying to shared mailbox (so sent emails appear in shared mailbox Sent Items), run the following command:

PowerShell

```
Set-Mailbox <shared-mailbox@domain.com> -MessageCopyForSentAsEnabled $true
```

To remove email forwarding from a shared mailbox, run the following command:

```
PowerShell
Set-Mailbox <shared-mailbox@domain.com> -ForwardingSmtpAddress $null
```

Quick reference

The following tables summarize common audit operations and key search parameters for shared mailbox investigations.

Common audit operations for shared mailboxes

The following table lists common audit operations you can use when investigating shared mailbox activity.

Expand table

Operation	Description	Investigation Focus
Create	Emails created or sent	Email creation activities
FolderBind	**Delegate folder access/browsing**	**Monitor who accessed specific folders**
HardDelete	Items permanently deleted	Permanent deletions from shared mailbox
MailItemsAccessed	Mailbox items accessed	Email access tracking (E5 required)
Move	Items moved between folders	Folder organization changes
New-InboxRule	Inbox rules created	Rule creation investigation
SendAs	Emails sent using delegate permissions	Identify who sent from shared mailbox
Set-Mailbox	Mailbox settings modified	Forwarding and configuration changes
SoftDelete	Items moved to Deleted Items folder	User deletions from shared mailbox

Key search parameters

The following table describes the main parameters used in the shared mailbox audit log search examples.

Expand table

Parameter	Description	Example
-FreeText	Activities performed in a specific mailbox	`<shared-mailbox@domain.com>`
-Operations	Filter by operation type	SoftDelete,HardDelete,SendAs
-ResultSize	Limit results (max 5000)	500 (standard), 1000 (comprehensive)
-StartDate/-EndDate	Define investigation timeframe	01/06/2020, 01/20/2020
-UserIds	Activities performed by a specific user	`<delegate@domain.com>`

> **Important**
>
> Replace `<shared-mailbox@domain.com>` and `<delegate@domain.com>` with actual email addresses before running commands.

Next steps

- Manage mailbox auditing: Adjust which shared mailbox actions are audited to capture the activities you need.
- Identify who deleted an email message or why an email is missing: Investigate specific email deletions discovered in shared mailbox activity.
- Export, configure, and view audit log records: Export your shared mailbox investigation results for evidence preservation.

Search the audit log for mailbox activities in specific mailboxes

This article explains how to search for mailbox activities in Microsoft Purview Audit for a specific mailbox, including shared mailboxes. It covers common investigation scenarios, such as when mailbox audit logs are missing or can't be found. It provides step-by-step instructions to verify auditing configuration, permissions, retention policies, and search methods.

Before you begin

To complete the steps in this article, you need:

- The email address of the affected mailbox.
- The license type assigned to the affected mailbox.
- Details about the operation you're searching for and the date and time it occurred.
- An understanding of how audit log searches are performed in Microsoft Purview Audit.

Check mailbox auditing status

> ⓘ **Note**
>
> Before searching for audit activity, verify that mailbox auditing is enabled for the affected user.

Complete the following steps to confirm that mailbox auditing is enabled:

1. In Exchange Online PowerShell, run the following command to check the organization-level audit configuration:

   PowerShell

   ```
   Get-AdminAuditLogConfig | FL UnifiedAudit*
   ```

   > ⓘ **Note**
   >
   > Run this command in Exchange Online PowerShell. In Security & Compliance PowerShell, the `UnifiedAuditLogIngestionEnabled` property always returns `False`,

even when auditing is enabled.

2. Check if mailbox audit logs are disabled at the tenant level:

```
PowerShell

Get-OrganizationConfig | FL AuditDisabled
```

3. At the mailbox level, `AuditEnabled` always returns `True`, even if auditing is disabled for a specific mailbox. To verify, use:

```
PowerShell

Get-Mailbox -Filter {AuditEnabled -eq "True"}
```

If you receive an error that the mailbox can't be found, auditing is disabled for that mailbox. For more information, see Verify the auditing status for your organization.

Verify administrator permissions

Ensure that you have the required permissions to search or export audit logs:

1. In the Microsoft Purview portal, go to **Settings** > **Roles and scopes** > **Role groups**.
2. Verify that your account is assigned to the **View-Only Audit Logs** or **Audit Logs** role.
3. In the Exchange admin center, use the **Audit Logs** role to enable or disable auditing and access audit cmdlets. Use the **View-Only Audit Logs** role to grant read-only access to audit logs.

For more information, see Assign permissions to search the audit log.

Check audit log retention policies

Audit log retention policies determine whether older activities are still available:

1. Determine when the activity occurred.
2. By default, audit logs are retained for 180 days.
3. If the affected user doesn't have an Audit (Premium) license and no audit retention policy is configured, audit logs older than 180 days aren't available.

For more information, see Get-UnifiedAuditLogRetentionPolicy.

Search for mailbox activities in Microsoft Purview Audit

When searching for activities, use the correct filters based on mailbox type.

User mailbox – recommended audit filters

- **Date and time range (UTC)**: Specify when the activity occurred. Audit timestamps are always in UTC.
- **Users**: Enter the affected mailbox.
- **Activities – operation names**: Select the specific operation you're looking for.
- **Activities – friendly names**: Alternatively, use the friendly activity names from the dropdown list.

Shared mailbox – recommended audit filters

- **Date and time range (UTC)**: Specify when the activity occurred.
- **Keywords**: Enter the primary SMTP address or Exchange GUID of the shared mailbox.

> ⓘ Note
>
> When searching for shared mailbox activities, enter the SMTP address under the **Keywords** field, not the **Users** field.

Shared mailbox auditing specifics

By default, the system doesn't audit all actions for shared mailboxes. The audited actions depend on the role of the person accessing the mailbox:

- **Owner**: The account associated with the mailbox.
- **Delegate**: A user with SendAs, SendOnBehalf, or FullAccess permissions to another mailbox. This role can include admins assigned FullAccess to a user's mailbox.
- **Admin**: Access via Microsoft eDiscovery tools in Microsoft Purview or Exchange Online, use of the Microsoft Exchange Server MAPI Editor, or access by an account impersonating another user (with the ApplicationImpersonation role).

Before searching, check the official documentation to confirm whether the action you're investigating is audited for the specific sign-in type. See Mailbox actions for user mailboxes and shared mailboxes.

Next steps

- Identify who deleted an email message or why an email is missing: Investigate specific email deletions found in your mailbox search results.
- Investigate shared mailbox activities using audit logs: Dig deeper into shared mailbox activities including delegate access and forwarding.
- Export, configure, and view audit log records: Export your mailbox activity results to CSV for offline analysis.

Search the audit log for events in Microsoft Teams

Applies to: Microsoft Teams

> **Important**
>
> The Microsoft Teams admin center is gradually replacing the Skype for Business admin center, and we're migrating Teams settings to it from the Microsoft 365 admin center. If a setting has been migrated, you'll see a notification and then be directed to the setting's location in the Teams admin center. For more information, see Manage Teams during the transition to the Teams admin center.

The audit log helps you investigate specific activities across Microsoft services. For Microsoft Teams, the audit log tracks activities such as:

- Team creation
- Team deletion
- Added channel
- Deleted channel
- Changed channel setting

For a complete list of Teams activities that are audited, see Teams activities in the audit log.

> **Note**
>
> Audit events from private channels are also logged as they are for teams and standard channels.

Turn on auditing in Teams

Before you can view audit data, you need to turn on auditing in the Microsoft Purview portal. For more information, see Turn auditing on or off.

> **Important**

Audit data is only available from the point at which you turn on auditing.

Retrieve Teams data from the audit log

To retrieve audit logs for Teams activities, use the Microsoft Purview portal. For step-by-step instructions, see Search the audit log.

> **Important**
>
> Audit data is only visible in the audit log if auditing is turned on.

The length of time that an audit record is retained and searchable in the audit log depends on your Microsoft 365 or Office 365 subscription, and specifically the type of license assigned to users. For more information, see the Security & Compliance Center service description.

Search the audit log effectively

Use the following tips when searching for Teams activities in the audit log.

- Select specific activities to search for by selecting the checkbox next to one or more activities. To cancel the selection, select the activity. Use the search box to display the activities that contain the keyword that you type.
- Select **Show results for all activities** in the **Activities** list to display events for activities run using cmdlets. If you know the name of the operation for these activities, type it in the search box to display the activity, then select it.
- Select **Clear all** to clear the current search criteria. The date range returns to the default of the last seven days.
- If 5,000 results are found, you can probably assume that there are more than 5,000 events that met the search criteria. Refine the search criteria and rerun the search to return fewer results, or export all the search results by selecting **Export** > **Download all results**. For step-by-step instructions to export audit logs, see Search the audit log.

For more information about using audit log search, see How to do an audit log search for Teams.

Teams activities

For a list of all events that are logged for user and admin activities in Teams in the Microsoft 365 audit log, see:

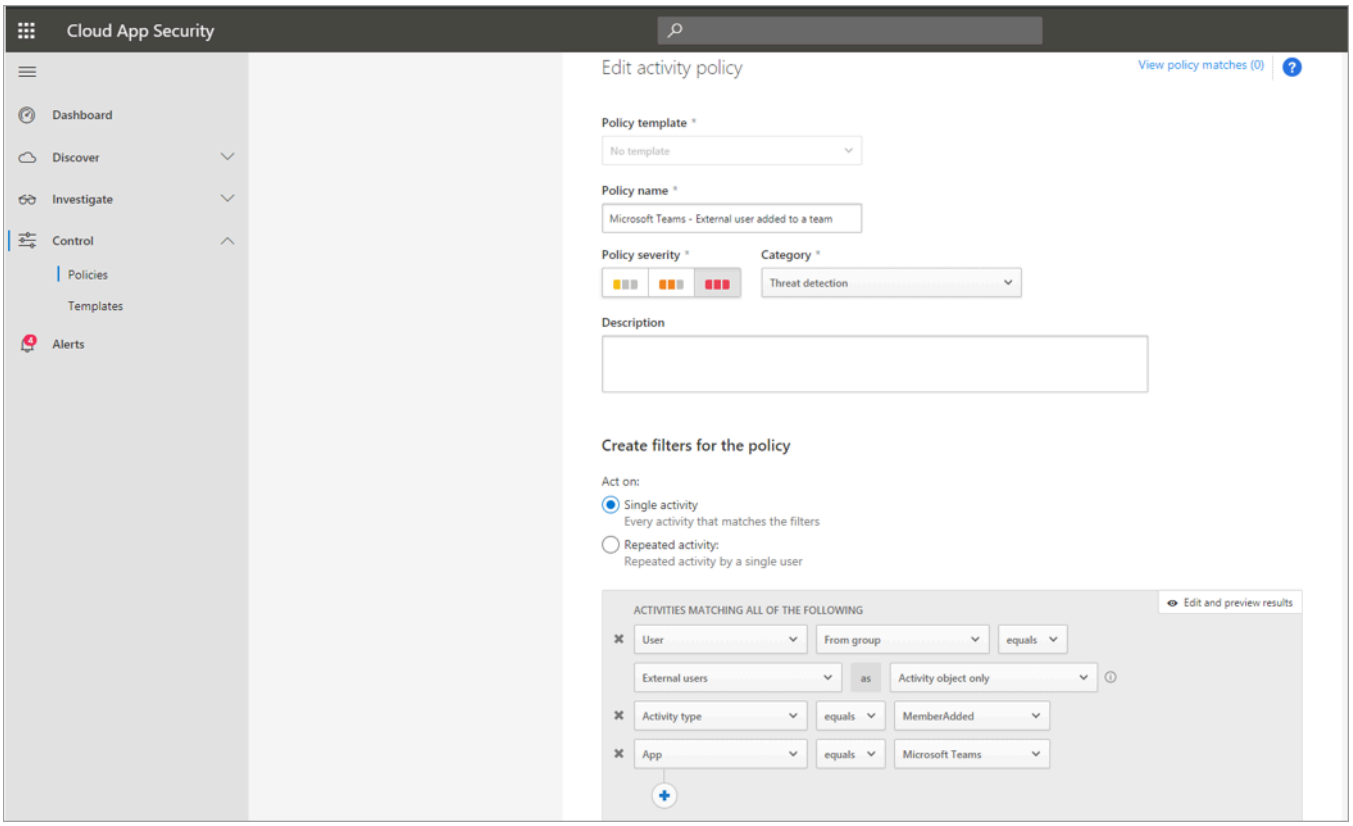
- Teams activities in the audit log
- Shifts app in Teams activities in the audit log
- Updates app in Teams activities in the audit log

Office 365 Management Activity API

You can use the Office 365 Management Activity API to get information about Teams events. For more information about the Management Activity API schema for Teams, see Teams schema.

Attribution in Teams audit logs

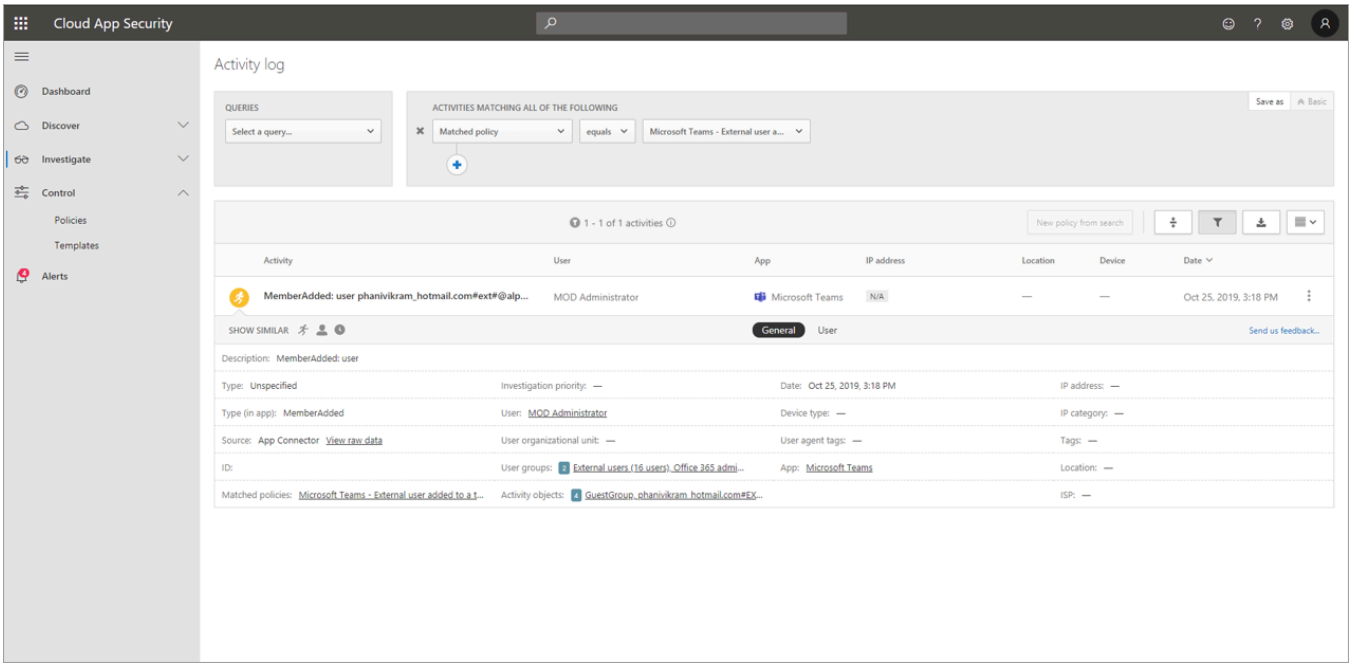
When you change membership in Teams (such as adding or deleting users) through Microsoft Entra ID, Microsoft 365 admin portal, or Microsoft 365 Groups Graph API, Teams audit messages and the General channel show an existing owner of the team as the initiator, not the actual initiator of the action. In these scenarios, check Microsoft Entra ID or Microsoft 365 Group audit logs to see the relevant information.



Use Defender for Cloud Apps to set activity policies

By using Microsoft Defender for Cloud Apps integration, you can set activity policies to enforce a wide range of automated processes by using the app provider's APIs. With these policies, you can monitor specific activities carried out by various users or follow unexpectedly high rates of one certain type of activity.

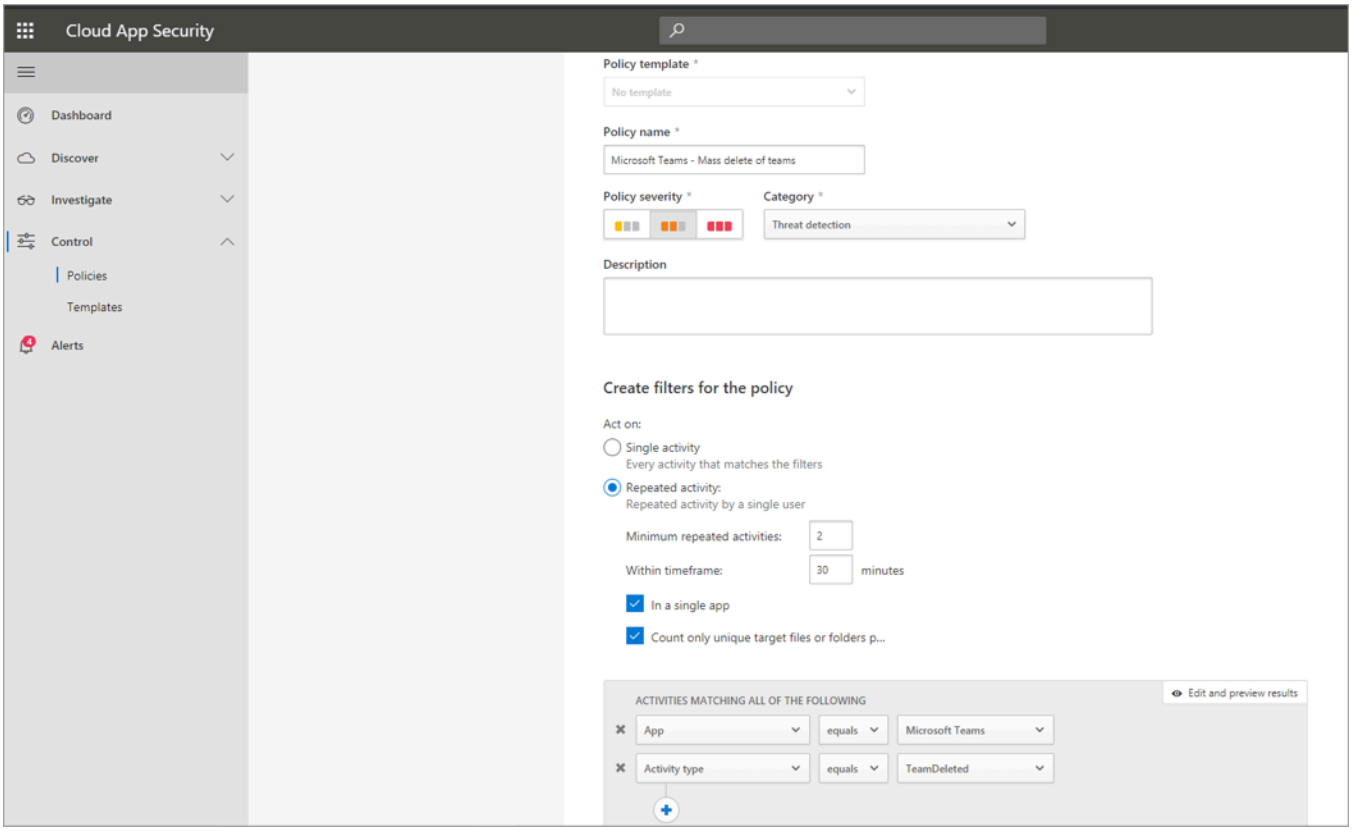
After you set an activity detection policy, it starts to generate alerts. Alerts only happen for activities that occur after you create the policy. Here are some example scenarios for how you can use activity policies in Defender for Cloud Apps to monitor Teams activities.



External user scenario

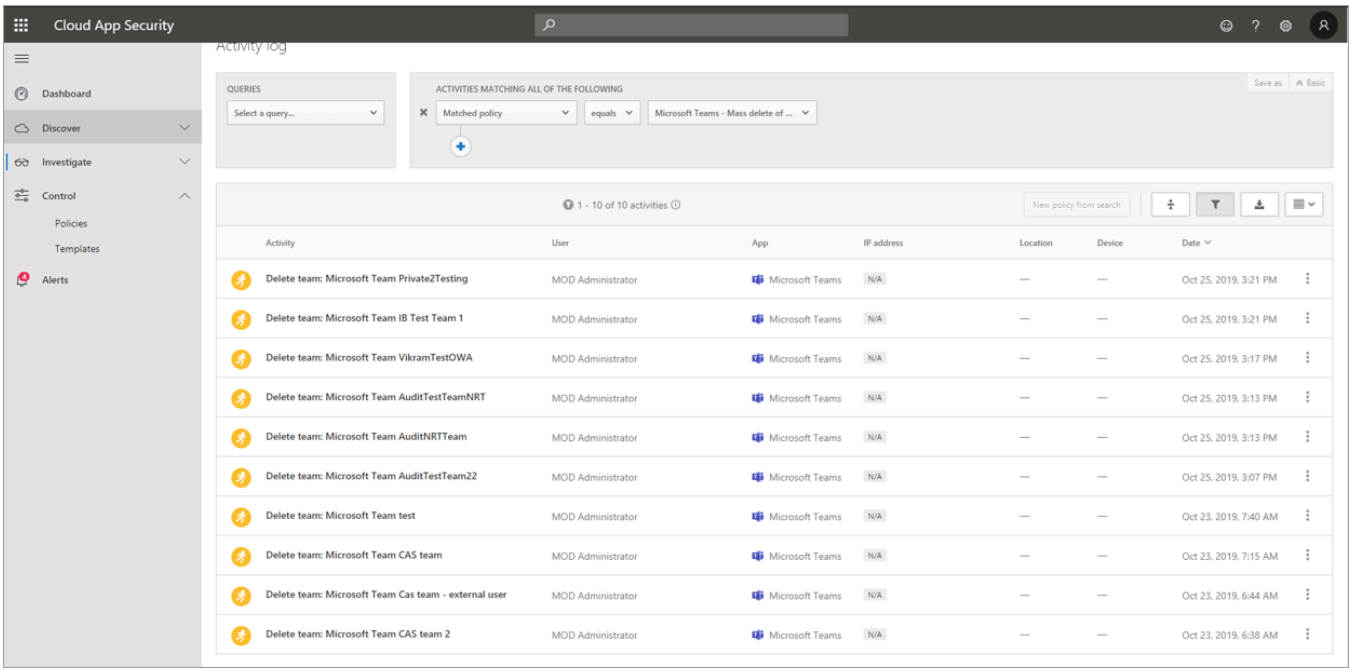
From a business perspective, you might want to keep an eye on the addition of external users to your Teams environment. If you enable external users, monitoring their presence is a good idea. You can use Defender for Cloud Apps to identify potential threats.

The screenshot of this policy to monitor adding external users shows you how to name the policy, set the severity according to your business needs, set it as (in this case) a single activity, and then establish the parameters that specifically monitor only the addition of noninternal users and limit this activity to Teams.



You can view the results from this policy in the activity log:

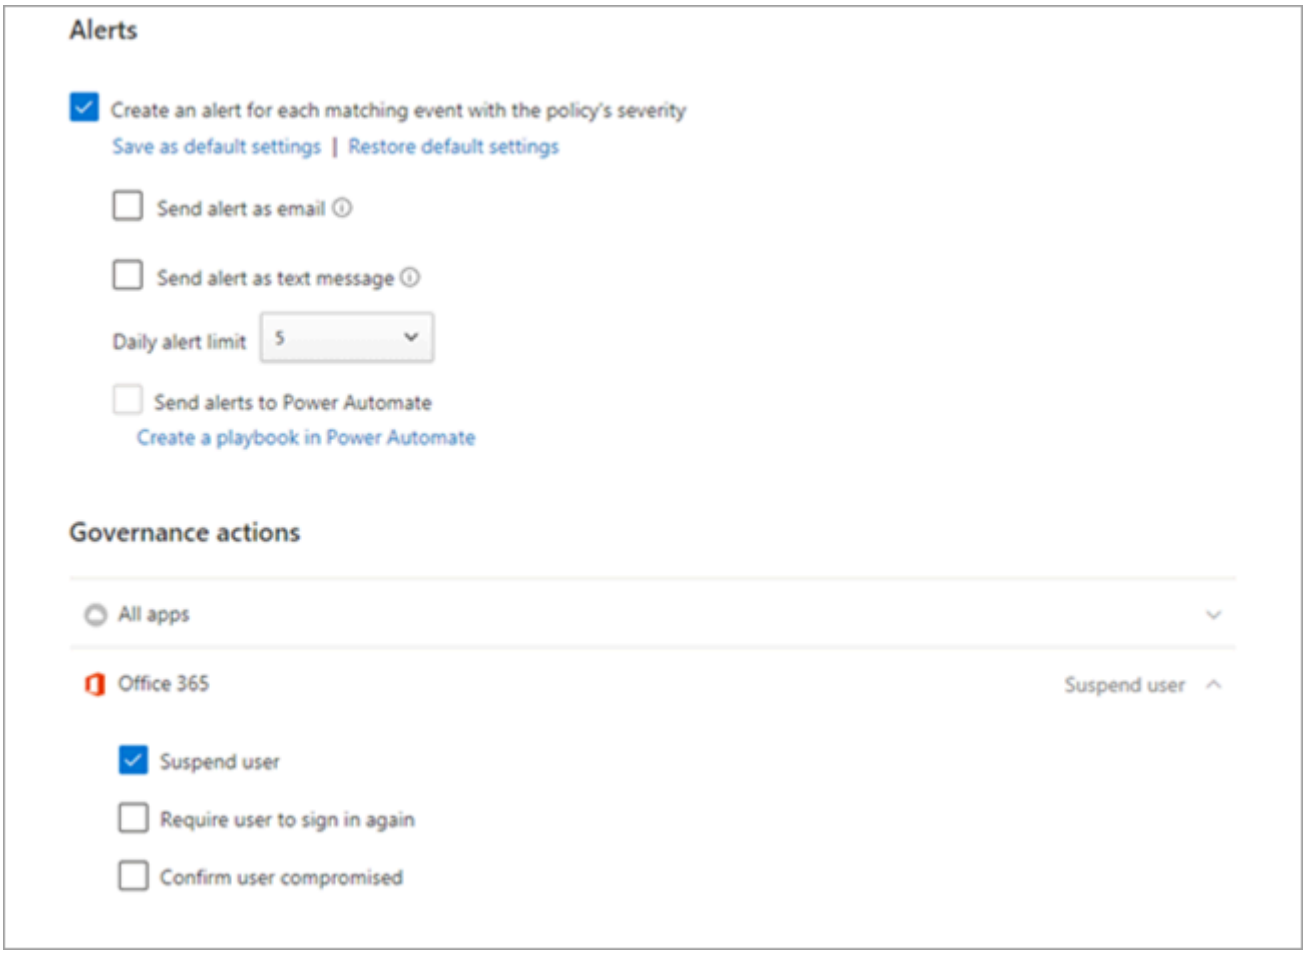
Here you can review matches to the policy you set, make any adjustments as needed, or export the results to use elsewhere.



Mass delete scenario

As mentioned earlier, you can monitor deletion scenarios. You can create a policy that monitors mass deletion of Teams sites. In this example, you set up an alert-based policy to detect mass deletion of teams within 30 minutes.

As the screenshot shows, you can set many different parameters for this policy to monitor Teams deletions, including severity, single or repeated action, and parameters limiting this to Teams and site deletion. You can set these parameters independently of a template, or you can use a template, depending on your organizational needs.



After you create a policy that works for your business, you can review the results in the activity log as events are triggered:

You can filter down to the policy you set to see the results. If the results you get in the activity log aren't satisfactory (maybe you see lots of results, or nothing at all), you can fine-tune the query to make it more relevant to what you need.

Alert and governance scenario

You can set alerts and send emails to admins and other users when an activity policy is triggered. You can set automated governance actions such as suspending a user or requiring a user to sign in again. This example shows how a user account can be suspended when an activity policy is triggered and determines a user deleted two or more teams in 30 minutes.

Use Defender for Cloud Apps to set anomaly detection policies

Anomaly detection policies in Defender for Cloud Apps provide out-of-the-box user and entity behavioral analytics (UEBA) and machine learning (ML) so that you can immediately run advanced threat detection across your cloud environment. Because they're automatically enabled, the new anomaly detection policies provide immediate results by providing immediate detections, targeting numerous behavioral anomalies across your users and the machines and devices connected to your network. Additionally, the new policies expose more data from the Defender for Cloud Apps detection engine, to help you speed up the investigation process and contain ongoing threats.

Teams events integration into anomaly detection policies is currently in development. You can set up anomaly detection policies for other Microsoft 365 products and take action on users who match those policies.

Next steps

- Export, configure, and view audit log records: Export your Teams audit results for analysis or compliance documentation.

- Use a PowerShell script to search the audit log: Automate recurring Teams activity searches using PowerShell.
- Manage audit log retention policies: Create retention policies to preserve Teams audit records beyond the default period.

ⓘ **Note:** The author created this article with assistance from AI. Learn more

Use sharing auditing in the audit log

Sharing is a key activity in SharePoint Online and OneDrive for Business, and organizations widely use it. Administrators can use sharing auditing in the audit log to determine how sharing is used in their organization.

SharePoint sharing schema reference

Sharing events (not including events related to sharing policy and sharing links) differ from file- and folder-related events in one primary way: one user performs an action that affects another user. For example, when a resource User A gives User B access to a file. In this example, User A is the *acting user* and User B is the *target user*. In the SharePoint File schema, the acting user's action only affects the file itself. When User A opens a file, the only information needed in the **FileAccessed** event is the acting user. To address this difference, there's a separate schema, called the *SharePoint Sharing schema* that captures more information about sharing events. This schema ensures that administrators have visibility into who shared a resource and the user the resource was shared with.

The Sharing schema provides two additional fields in an audit record related to sharing events:

- **TargetUserOrGroupType:** Identifies whether the target user or group is a Member, Guest, SharePointGroup, SecurityGroup, or Partner.
- **TargetUserOrGroupName:** Stores the UPN or name of the target user or group that a resource was shared with (User B in the previous example).

These two fields, in addition to other properties from the audit log schema such as User, Operation, and Date tell the full story about *which* user shared *what* resource with *whom* and *when*.

Another schema property is important to the sharing story. When you export audit log search results, the **AuditData** column in the exported CSV file stores information about sharing events. For example, when a user shares a site with another user, sharing the site adds the target user to a SharePoint group. The **AuditData** column captures this information to provide context for administrators. To parse the **AuditData** column into individual properties, use the JSON transform feature in the Power Query Editor in Excel as described in Use the PowerQuery Editor to format the exported audit log.

SharePoint sharing events

Sharing occurs when a user (the *acting* user) shares a resource with another user (the *target* user). Audit records related to sharing a resource with an external user (a user who is outside of your organization and doesn't have a guest account in your organization's Microsoft Entra ID) are identified by the following events, which the audit log records:

- **SharingInvitationCreated:** A user in your organization tries to share a resource (likely a site) with an external user. This event results in an external sharing invitation sent to the target user. The invitation grants no access to the resource at this point.
- **SharingInvitationAccepted:** The external user accepts the sharing invitation sent by the acting user and now has access to the resource.
- **AnonymousLinkCreated:** An anonymous link (also called an "Anyone" link) is created for a resource. Because an anonymous link can be created and then copied, it's reasonable to assume that any document that has an anonymous link is shared with a target user.
- **AnonymousLinkUsed:** This event is logged when an anonymous link is used to access a resource.
- **SecureLinkCreated:** A user creates a "specific people link" to share a resource with a specific person. This target user might be someone who is external to your organization. The person that the resource is shared with is identified in the audit record for the **AddedToSecureLink** event. The time stamps for these two events are nearly identical.
- **AddedToSecureLink:** A user is added to a specific people link. Use the **TargetUserOrGroupName** field in this event to identify the user added to the corresponding specific people link. This target user might be someone who is external to your organization.

How sharing auditing works

When a user (the acting user) wants to share a resource with another user (the target user), SharePoint (or OneDrive for Business) first checks if the email address of the target user is already associated with a user account in the organization's directory. If the target user is in the directory (and has a corresponding guest user account), SharePoint takes the following actions:

- Immediately assigns the target user permissions to access the resource by adding the target user to the appropriate SharePoint group, and logs an **AddedToGroup** event.
- Sends a sharing notification to the email address of the target user.
- Logs a **SharingSet** event. This event has a friendly name of "Shared file, folder, or site" and appears under **Sharing and access request activities** in the activities picker of the audit log

search tool.

If a user account for the target user isn't in the directory, SharePoint takes the following actions:

- Logs one of the following events, based on how the resource is shared:
  - **AnonymousLinkCreated**
  - **SecureLinkCreated**
  - **AddedToSecureLink**
  - **SharingInvitationCreated** (this event is logged only when the shared resource is a site)
- When the target user accepts the sharing invitation (by clicking the link in the invitation), SharePoint logs a **SharingInvitationAccepted** event and assigns the target user permissions to access the resource. If the target user is sent an anonymous link, the **AnonymousLinkUsed** event is logged after the target user uses the link to access the resource. For secure links, a **FileAccessed** event is logged when an external user uses the link to access the resource.

Additional information about the target user is also logged, such as the identity of the user the invitation is to and the user who accepts the invitation. In some cases, these users (or email addresses) can be different.

How to identify resources shared with external users

A common requirement for administrators is creating a list of all resources that administrators shared with users outside of the organization. By using sharing auditing in Office 365, administrators can generate this list. Complete the following steps.

Step 1: Search for sharing events and export the results to a CSV file

To search the audit log for sharing events, complete the following steps. For more information including the required permissions, see Search the audit log.

1. Sign in to the Microsoft Purview portal.
2. Select the **Audit** solution card. If the **Audit** solution card isn't displayed, select **View all solutions** and then select **Audit** from the **Core** section.
3. On the **Search** page and under **Activities - friendly names**, select **Sharing and access request activities** to search for sharing-related events.

4. Select a date and time range to find the sharing events that occurred within that period.
5. Select **Search** to run the search.
6. When the search finishes and displays the results, select **Export results** > **Download all results**.

   After you select the export option, a message at the bottom of the window prompts you to open or save the CSV file.
7. Select **Save** > **Save as** and save the CSV file to a folder on your local computer.

Step 2: Use the PowerQuery Editor to format the exported audit log

Use the JSON transform feature in the Power Query Editor in Excel to split each property in the **AuditData** column (which consists of a multi-property JSON object) into its own column. This feature lets you filter columns to view records related to sharing.

For step-by-step instructions, see "Step 2: Format the exported audit log using the Power Query Editor" in Export, configure, and view audit log records.

Step 3: Filter the CSV file for resources shared with external users

In this step, you filter the CSV file for the different sharing-related events that the SharePoint sharing events section describes. Alternatively, you can filter the **TargetUserOrGroupType** column to display all records where the value of this property is **Guest**.

After formatting the exported audit log with Power Query Editor in Excel so that each **AuditData** property has its own column, complete the following steps:

1. Open the formatted Excel file that contains the exported audit log with **AuditData** properties split into individual columns by the Power Query transformation.
2. On the **Home** tab, select **Sort & Filter**, then select **Filter**.
3. In the **Sort & Filter** dropdown list on the **Operations** column, clear all selections, then select one or more of the following sharing-related events and select **Ok**.

   - **SharingInvitationCreated**
   - **AnonymousLinkCreated**

- **SecureLinkCreated**
- **AddedToSecureLink**

Excel displays the rows for the events you selected.

4. Go to the column named **TargetUserOrGroupType** and select it.

5. In the **Sort & Filter** dropdown list, clear all selections, then select **TargetUserOrGroupType:Guest**, and select **Ok**.

   Now Excel displays the rows for sharing events **and** where the target user is outside of your organization, because external users are identified by the value **TargetUserOrGroupType:Guest**.

> **Tip**
>
> For the audit records that are displayed, the **ObjectId** column identifies the resource that you shared with the target user. For example, `ObjectId:https:\/\/contoso-my.sharepoint.com\/personal\/sarad_contoso_com\/Documents\/Southwater Proposal.docx`.

Next steps

- Export, configure, and view audit log records: Format and analyze your sharing audit exports using Power Query in Excel.
- Search the audit log: Broaden your investigation to search for other activity types related to the shared resources.
- Use a PowerShell script to search the audit log: Automate recurring sharing audits using PowerShell for ongoing monitoring.

Search the audit log for deleted mailbox items

Use this article to investigate whether a user deleted email items from a mailbox in Exchange Online. It provides step-by-step guidance on checking audit settings, verifying permissions, reviewing retention policies, and searching audit logs in Microsoft Purview. By following the procedure in this article, you can determine if deletion activity occurred and confirm whether the audit data is still available.

Before you start, review the prerequisites to ensure you have the required permissions, information, and access.

Before you begin

To complete this procedure, you need:

- The email address of the affected mailbox.
- The license type assigned to the affected mailbox.
- The approximate date and time when the operation occurred.

You must also have access to Exchange Online PowerShell and the Microsoft Purview portal with your administrator credentials.

Check mailbox auditing status

> **Note**
>
> Before searching for audit activity, verify that mailbox auditing is enabled for the affected user.

Complete the following steps to confirm that mailbox auditing is enabled:

1. In Exchange Online PowerShell, run the following command to check the organization-level audit configuration:

   ```
   PowerShell
   ```

```
Get-AdminAuditLogConfig | FL UnifiedAudit*
```

> **Note**
>
> Run this command in Exchange Online PowerShell. In Security & Compliance PowerShell, the `UnifiedAuditLogIngestionEnabled` property always returns `False`, even when auditing is enabled.

2. Check if mailbox audit logs are disabled at the tenant level:

PowerShell

```
Get-OrganizationConfig | FL AuditDisabled
```

3. At the mailbox level, `AuditEnabled` always returns `True`, even if auditing is disabled for a specific mailbox. To verify, use:

PowerShell

```
Get-Mailbox -Filter {AuditEnabled -eq "True"}
```

If you receive an error that the mailbox can't be found, auditing is disabled for that mailbox. For more information, see Verify the auditing status for your organization.

Verify administrator permissions

Ensure that you have the required permissions to search or export audit logs:

1. In the Microsoft Purview portal, go to **Settings** > **Roles and scopes** > **Role groups**.
2. Verify that your account is assigned to the **View-Only Audit Logs** or **Audit Logs** role.
3. In the Exchange admin center, use the **Audit Logs** role to enable or disable auditing and access audit cmdlets. Use the **View-Only Audit Logs** role to grant read-only access to audit logs.

For more information, see Assign permissions to search the audit log.

Check audit log retention policies

Audit log retention policies determine whether older activities are still available:

1. Determine when the activity occurred.
2. By default, audit logs are retained for 180 days.
3. If the affected user doesn't have an Audit (Premium) license and no audit retention policy is configured, audit logs older than 180 days aren't available.

For more information, see Get-UnifiedAuditLogRetentionPolicy.

Search for deletion activity in Microsoft Purview Audit

When searching for audit data, use filters that match the suspected deletion time and the mailbox deletion activity being investigated.

Option 1: Search by user and activities

Use this option to search for deletion activity by specifying the mailbox user and relevant audit operations.

- **Date and time range (UTC)**: Specify when the deletion occurred. Audit timestamps are always in UTC.
- **Users**: Enter the affected mailbox.
- **Activities – operation names**: Select Move, MoveToDeletedItems, Create, SoftDelete, and HardDelete.
- **Activities – friendly names**: If available, use the friendly names in the dropdown list.

Option 2: Search by activities and keywords

Use this option when you want to search by audit activity and identify the mailbox with a keyword such as its SMTP address or ExchangeGUID.

- **Date and time range (UTC)**: Specify when the deletion occurred.
- **Activities – operation names**: Select Move, MoveToDeletedItems, Create, SoftDelete, and HardDelete.
- **Keywords**: Enter the primary SMTP address or ExchangeGUID of the mailbox.

Option 3: Search by message ID prefix

Use this option if you know the message ID prefix and want to narrow the audit search to a specific message.

- **Date and time range (UTC)**: Specify when the deletion occurred.

- **Keywords**: Enter the prefix of the email messageID.

Next steps

After you complete your audit log search, use these resources to continue your investigation:

- Identify who deleted an email message or why an email is missing: Determine the root cause of deletions, including retention policies, rules, and admin actions.
- Export, configure, and view audit log records: Export your deletion search results for evidence collection or reporting.
- Use the MailItemsAccessed audit event to investigate compromised accounts: Check whether email deletions are linked to a compromised account.

Encrypted message portal activity log by Microsoft Purview Advanced Message Encryption

You can access logs for encrypted messages through the encrypted message portal. With these logs, your organization can determine when external recipients read and forward messages. To ensure availability of logs for external recipients, apply a custom branding template to protected emails that your organization sends to external recipients. This template enforces a portal experience. For more information, see Add your organization's brand to your encrypted messages.

Enable message access audit logs in PowerShell

You can enable the access log by using Exchange Online PowerShell. The *EnablePortalTrackingLogs* parameter of the **Set-IrmConfiguration** cmdlet specifies whether to enable audit logs for accessing the encrypted message portal. Valid values are:

- $true: Turns on the audit feature.
- $false: Turns off the audit feature.

Example:

PowerShell

```
Set-IrmConfiguration -EnablePortalTrackingLogs $true
```

For more information, see Set-IRMConfiguration (ExchangePowerShell).

Message access audit information

The access log contains entries for messages sent through the encrypted message portal for the following types of activity:

- External user sign-in timestamp and authentication method
- External user reading messages or attachments
- Attachment download
- Mail replies and forwards

For more information on the message access log schema, see Audit log activities.

Search for events in the message access logs

Complete the following steps to get started with search:

1. Sign in to the Microsoft Purview portal.
2. Select the **Audit** solution card. If the **Audit** solution card isn't displayed, select **View all solutions** and then select **Audit** from the **Core** section.
3. Under **Search**, select the drop-down for **Activities** and type encrypted message portal activities.
4. Under encrypted message portal activities, select the event types to use in the search. Set the date range for the search (default is the previous week), you can also optionally add a particular user in your organization for the search. When ready, select **Search**.
5. Select an event from the list to view the audit properties.

Next steps

- Search the audit log: Search for broader activity related to the senders or recipients identified in encrypted message logs.
- Export, configure, and view audit log records: Export your encrypted message activity results for compliance reporting.

Audit log activities

The tables in this article describe the activities recorded in the Microsoft 365 audit log. You can search for these activities by searching the audit log in the Microsoft Purview portal.

> **Tip**
>
> Select one of the links in the **In this article** list at the top of this article to go directly to a specific product table.

Audit logging is turned on by default for Microsoft 365 organizations. If auditing isn't turned on for your organization, a banner appears that prompts you to start recording user and admin activity. For instructions, see Turn on auditing.

These tables group related activities or the activities from a specific service. The tables include the friendly name that's displayed in the **Activities** drop-down list (or that are available in PowerShell) and the name of the corresponding operation that appears in the detailed information of an audit record and in the CSV file when you export the search results. For descriptions of the detailed information, see Audit log detailed properties.

> **Important**
>
> Some operation names listed in the **Operation** column in the following tables contain a period (`.`). You must include the period in the operation name if you specify the operation in a PowerShell command when searching the audit log, creating audit retention policies, creating alert policies, or creating activity alerts. Also be sure to use double quotation marks (`" "`) to contain the operation name.

Agent 365 activities

The following table lists Agent 365 activities that are logged when an agent is invoked or performs any actions or tool calls.

Expand table

Friendly name	Operation	Description
Executed AI tool	AIExecuteTool	Agent executed a tool call.
Invoked AI agent	AIInvokeAgent	AI agent is invoked by a user, agent, or event.
Made AI inference call	AIInferenceCall	AI agent leveraged an AI model to produce an answer or determine next steps.
Applied AI guardrail	AIGuardrail	A guardrail was applied to an AI agent's request or response to enforce safety or compliance policies.

Application administration activities

The following table lists application admin activities that Microsoft 365 audit logs when an admin adds or changes an application registered in Microsoft Entra ID. You must register any application that relies on Microsoft Entra ID for authentication in the directory.

Expand table

Friendly name	Operation	Description
Added credentials to a service principal	Add service principal credentials.	Credentials were added to a service principal in Microsoft Entra ID. A service principal represents an application in the directory.
Added delegation entry	Add delegation entry.	An authentication permission was created or granted to an application in Microsoft Entra ID.
Added service principal	Add service principal.	An application was registered in Microsoft Entra ID. A service principal represents an application in the directory.
Removed a service principal from the directory	Remove service principal.	An application was deleted or unregistered from Microsoft Entra ID. A service principal represents an application in the directory.
Removed credentials from a service principal	Remove service principal credentials.	Credentials were removed from a service principal in Microsoft Entra ID. A service principal represents an application in the directory.
Removed delegation entry	Remove delegation entry.	An authentication permission was removed from an application in Microsoft Entra ID.
Set delegation entry	Set delegation entry.	An authentication permission was updated for an application in Microsoft Entra ID.

Briefing email activities

The following table lists the activities in Briefing email that the Microsoft 365 audit log records. For more information about Briefing email, see:

- Overview of Briefing email
- Configure Briefing email

Expand table

Friendly name	Operation	Description
Updated organization privacy settings	UpdatedOrganizationBriefingSettings	Admin updates the organization privacy settings for Briefing email.
Updated user privacy settings	UpdatedUserBriefingSettings	Admin updates the user privacy settings for Briefing email.

Communication compliance activities

The following table lists communication compliance activities that the Microsoft 365 audit log records. For more information, see Learn about Microsoft Purview Communication Compliance.

> **Note**
>
> You can see these activities when you use the Search-UnifiedAuditLog PowerShell cmdlet. You can't see these activities in the **Activities** drop-down list.

Expand table

Friendly name	Operation	Description
Policy match	SupervisionRuleMatch	A user sent a message that matches a policy's condition.
Policy update	SupervisionPolicyCreated, SupervisionPolicyUpdated, SupervisionPolicyDeleted	A communication compliance administrator performed a policy update.
Tag applied to messages	SupervisoryReviewTag	Tags are applied to messages or messages are resolved.

Compliance Manager activities

The following table lists the operations and activities that the audit log records when an admin manages settings in Compliance Manager. For more information, see Learn about Compliance Manager.

Expand table

Friendly name	Operation	Description
Roles change	ComplianceManagerRolesChange	An admin changed the roles for users.
Tenant automation level change	ComplianceManagerAutomationLevelChange	An admin changed the automation level for the organization across all actions.
Testing source automation change	ComplianceManagerAutomationChange	An admin changed the testing source automation settings.

Content explorer activities

The following table lists the activities in Content explorer recorded in the Microsoft 365 audit log. You access content explorer on the Data classifications tool in the Microsoft Purview portal. For more information, see Using data classification content explorer.

Expand table

Friendly name	Operation	Description
Accessed item	LabelContentExplorerAccessedItem	An admin (or a user who's a member of the Content Explorer Content Viewer role group) used content explorer to view an email message or SharePoint and OneDrive document.
AccessedAggregates	AccessedAggregates	An admin used content explorer to navigate between different aggregates.
AccessedContentList	AccessedContentList	When admin Clicked on any site/user in Content Explorer to get list of items.
AccessedItemDownload	AccessedItemDownload	An admin used content explorer to download an item.
AccessedItemPreview	AccessedItemPreview	An admin used content explorer to preview an item.

Friendly name	Operation	Description
AccessedSiteList	AccessedSiteList	An admin used content explorer to navigate to SharePoint and OneDrive to get the site list.
AccessedUserList	AccessedUserList	An admin used content explorer to navigate to Exchange/Teams workload to get the user list.
SearchedContentList	SearchedContentList	When admin Searched for a file in Content Explorer.
SearchedSiteList	SearchedSiteList	An admin used content explorer to search for a site.
SearchedUserList	SearchedUserList	An admin used content explorer to search for a user.

Data Security Investigations activities

Data Security Investigations provides powerful investigation tools that might require the ability to audit activities to ensure secure and approved use of the solution. To meet these requirements, the unified audit log records Data Security Investigations activities.

The following table lists Data Security Investigations activities that the Microsoft 365 audit log records. For more information, see Learn about Microsoft Purview Data Security Investigations.

Expand table

Friendly name	Operation	Description
Canceled DSI sample view	DSISampleViewCancelled	A user canceled a samples view.
Canceled DSI statistics view	DSIStatisticsViewCancelled	A user canceled a statistics job.
Created DSI Investigation	CreatedDSIInvestigation	A user created an investigation.
Deleted Data Security Investigations capacity	DSICapacityDeleted	A user deleted the Data Security Investigation capacity.
Deleted DSI Investigation	DeletedDSIInvestigation	A user deleted an investigation.

Friendly name	Operation	Description
DSI AI feedback provided	DSIAIFeedbackProvided	A user provided AI feedback.
DSI investigation list viewed	DSIInvestigationListViewed	A user viewed the list of investigations.
DSI search added	DSIPurviewSearchAdded	A user added a search.
DSI search updated	DSIPurviewSearchUpdated	A user updated a search.
DSIProbeJobResultsViewed	DSIProbeJobResultsViewed	A user viewed the results of examination.
Get DSI Investigation	GetDSIInvestigation	A user viewed an investigation.
Get DSI search	GetSearchDSIInvestigation	A user viewed a search.
Investigation created from Defender XDR	DSIInvestigationCreatedFromXDR	A user created an investigation from Defender XDR.
Investigation created from Purview IRM	DSIInvestigationCreatedFromIRM	A user created an investigation from Microsoft Purview Insider Risk Management.
Item added to mitigation	DSIItemAddedToMitigation	A user added an item to an investigation's mitigation plan.
Item removed from mitigation	DSIItemRemovedFromMitigation	A user removed an item from an investigation's mitigation plan.
Mitigation plan list viewed	DSIMitigationPlanListViewed	A user viewed the mitigation plan list.
Started categorization job	DSIInvestigationCategorizationJobSubmitted	A user started a categorization job.
Started probing job	DSIProbeJobSubmitted	A user started an examination job.
Started purge job	DSIPurgeStarted	A user started a purge job.

Friendly name	Operation	Description
Started vectorization job	DSIInvestigationVectorizationJobSubmitted	A user stated a vectorization job.
Submitted DSI search add to evidence set job	DSIPurviewSearchAddToEvidenceSetJobSubmitted	A user added searched data to an investigation scope.
Submitted DSI search sample job	DSIPurviewSearchSampleJobSubmitted	A user started a samples job.
Submitted DSI search statistics job	DSIPurviewSearchStatisticsJobSubmitted	A user started a statistics job.
Updated Data Security Investigations capacity	DSICapacityUpdated	A user updated the Data Security Investigation capacity.
Updated DSI Investigation	UpdatedDSIInvestigation	A user updated an investigation.
Updated DSI Investigation members	DSIInvestigationMembersUpdated	A user updated an investigation's members.
Updated status on item from mitigation plan	DSIMitigationItemStatusUpdated	A user updated the status of an item on an investigation's mitigation plan.
Uploaded file for DSI search	DSIPurviewSearchUploadFile	A user uploaded a file to search.
Vector search started	DSIVectorSearchStarted	A user ran a vector search.
Viewed data processing errors for a DSI evidence set	DSIInvestigationSettingsUpdated	A user updated investigation settings.
Viewed Data Security Investigations capacity	DSICapacityViewed	A user viewed the Data Security Investigation capacity.
Viewed default DSI investigation settings	DSIInvestigationSettingsDefaultViewed	A user viewed investigation settings.
Viewed DSI evidence set document	DSIEvidenceSetDocumentViewed	A user viewed a document in an investigation.

Friendly name	Operation	Description
Viewed DSI investigation settings	DSIInvestigationSettingsViewed	A user viewed investigation settings.
Viewed DSI sample results	DSISampleResultsViewed	A user viewed sample results.
Viewed DSI sample status	DSISampleStatusViewed	A user viewed the status of a samples job.
Viewed DSI statistics results	DSIStatisticsResultsViewed	A user viewed search statistics.
Viewed individual activity	DSISingleActivityViewed	A user viewed an activity in an investigation.
Viewed investigation activities list	DSIActivitiesViewed	A user viewed the investigation activities.
Viewed investigation evidence set	DSIEvidenceSetViewed	A user viewed the list of items in the investigation.
Viewed item from mitigation plan	DSIItemViewedFromMitigation	A user viewed an item from an investigation's mitigation plan.

Data Security Posture Agent activities

The following table lists the activities for the Data Security Posture Agent in the Microsoft 365 audit log.

Expand table

Friendly name	Operation	Description
Agent Ran	AgentRan	User ran the Data Security Posture Agent.
Agent re-ran	Agent Reran	User reran the Data Security Posture Agent.
Agent result viewed	AgentResultViewed	User viewed the results of a Data Security Posture Agent run.
Agent run cancelled	AgentRunCancelled	User canceled a run for Data Security Posture Agent.
Agent run deleted	AgentRunDeleted	User deleted a run for Data Security Posture Agent.

Directory administration activities

The following table lists Microsoft Entra directory and domain-related activities that are logged when an administrator manages their organization in the Microsoft 365 admin center or in the Azure management portal.

Expand table

Friendly name	Operation	Description
Added a partner to the directory	Add partner to company.	Added a partner (delegated administrator) to your organization.
Added domain to company	Add domain to company.	Added a domain to your organization.
Removed a partner from the directory	Remove partner from company.	Removed a partner (delegated administrator) from your organization.
Removed domain from company	Remove domain from company.	Removed a domain from your organization.
Set company information	Set company information.	Updated the company information for your organization. Includes email addresses for subscription-related email that Microsoft 365 sends, and technical notifications about Microsoft 365 services.
Set domain authentication	Set domain authentication.	Changed the domain authentication setting for your organization.
Set password policy	Set password policy.	Changed the length and character constraints for user passwords in your organization.
Turned on Microsoft Entra ID Sync	Set DirSyncEnabled flag.	Set the property that enables a directory for Microsoft Entra ID Sync.
Updated domain	Update domain.	Updated the settings of a domain in your organization.
Updated the federation settings for a domain	Set federation settings on domain.	Changed the federation (external sharing) settings for your organization.
Verified domain	Verify domain.	Verified that your organization was the owner of a domain.
Verified email verified domain	Verify email verified domain.	Used email verification to verify that your organization is the owner of a domain.

Disposition review activities

The following table lists the activities a disposition reviewer took when an item reached the end of its configured retention period, or when an item automatically moved to the next disposition stage or was permanently deleted as a result of autoapproval.

Expand table

Friendly name	Operation	Description
Added reviewers	AddReviewer	A disposition reviewer added one or more other users to the current disposition review stage.
Approved disposal	ApproveDisposal	For manual approval: A disposition reviewer approved the disposition of the item to move it to the next disposition stage. If the item was in the only or final stage of disposition review, the disposition approval marked the item as eligible for permanent deletion. For autoapproval: No manual action was taken within the configured autoapproval time period so the item automatically moved to the next disposition stage. If the item was in the only or final stage of disposition review, the item automatically became eligible for permanent deletion.
Extended retention period	ExtendRetention	A disposition reviewer extended the retention period of the item.
Relabeled item	RelabelItem	A disposition reviewer relabeled the retention label.

Dragon Copilot admin activities

The following table lists administrative activities for Dragon Copilot recorded in the Microsoft 365 audit log. These events are logged when an administrator changes Dragon Copilot configuration. These events include changes in environments, products, Electronic Health Record (EHR) connectors, billing plans, groups, role assignments, settings, and extensions. If your organization uses Dragon Copilot, you can search the audit log for these activities by using the **Activities** picker list. For more information about Dragon Copilot, see the Dragon Copilot documentation.

You can also search for Dragon Copilot admin activities by running the `Search-UnifiedAuditLog -RecordType DragonCopilotAdmin` command in Exchange Online PowerShell.

Expand table

Friendly name	Operation	Description
Accepted terms	AcceptedTerms	Terms of service were accepted.
Activated subscription	ActivatedSubscription	A subscription was activated.
Added group member	AddedGroupMember	A user was added to a group.
Canceled deprovision	CanceledDeprovision	A previously queued deprovision was cancelled.
Created billing plan	CreatedBillingPlan	A billing plan was created.
Created child organization	CreatedChildOrganization	A child organization was created.
Created data export configuration	CreatedDataExportConfig	A data export configuration was created.
Created EHR connector	CreatedEhrConnector	An EHR connector was created.
Created EHR instance	CreatedEhrInstance	An EHR integration instance was created.
Created EHR user	CreatedEhrUser	An EHR user mapping was created.
Created environment	CreatedEnvironment	A new Dragon Copilot environment was created.
Created extension	CreatedExtension	An extension was installed.
Created group	CreatedGroup	A user group was created.
Created organization role assignment	CreatedOrganizationRoleAssignment	An organization role assignment was created.
Created role assignment	CreatedRoleAssignment	A role was assigned to a user.
Deleted billing plan	DeletedBillingPlan	A billing plan was deleted.
Deleted data export configuration	DeletedDataExportConfig	A data export configuration was deleted.
Deleted device connector	DeletedDeviceConnector	A device connector under an EHR connector was deleted.
Deleted EHR instance	DeletedEhrInstance	An EHR integration instance was removed.

Friendly name	Operation	Description
Deleted EHR user	DeletedEhrUser	An EHR user mapping was deleted.

Dragon Copilot Web activities

The following table lists user and application activities for Dragon Copilot Web recorded in the Microsoft 365 audit log. These events capture user access, clinical workflow actions, AI-assisted operations, and session lifecycle events performed within Dragon Copilot Web. Dragon Copilot Web supports clinical documentation workflows including ambient recording, transcript review, AI-assisted note generation, clinical chat, and EHR-integrated experiences.

If your organization uses Dragon Copilot Web, you can search for these activities in Microsoft Purview Audit by selecting the appropriate activity name or by filtering on the Dragon Copilot record types. Audit records are emitted under the following record types:

- DragonCopilotAccess
- DragonCopilotClinicalData
- DragonCopilotSession

You can also search for Dragon Copilot Web audit events by using `Search-UnifiedAuditLog` and filtering on the corresponding record type.

Dragon Copilot access activities

The following table lists user access and interaction activities for Dragon Copilot recorded in the Microsoft 365 audit log. These events are logged when users access Dragon Copilot or interact with its features and underlying services. These activities include launching Dragon Copilot from an EHR system, accessing Dragon Copilot, and updating patient session data. Events also capture failures related to these operations. If your organization uses Dragon Copilot, you can search the

audit log for these activities by using the **Activities** picker list. For more information about Dragon Copilot, see the Dragon Copilot documentation.

Expand table

Friendly name	Operation	Description
Application accessed	AppAccessed	A user opened the Dragon Copilot web application.
EHR launch completed	EhrLaunchCompleted	Dragon Copilot launch from EHR completed.
EHR launch failed	EhrLaunchFailed	Dragon Copilot launch from EHR failed.
Encounter accessed	EncounterAccessed	A user opened a patient encounter in Dragon Copilot.
License check failed	LicenseCheckFailed	User doesn't have Dragon Copilot license.
Session data updated	SessionDataUpdated	Session data updated.
Session data update failed	SessionDataUpdateFailed	Session data update failed.

Dragon Copilot clinical data activities

Expand table

Friendly name	Operation	Description
