  The driver writes the data to the VF PCI configuration space and returns the status of the request when it completes the OID request. This status is returned to the VF miniport driver after the call to **NdisMSetBusData** completes.

The VF miniport driver may also communicate with the PF miniport driver. This communication path is over a backchannel interface. For more information, see SR-IOV PF/VF Backchannel Communication.

Note The VF miniport driver must be aware that it is running in a virtualized environment so that it can communicate with the PF miniport driver for certain operations. For more information on how the driver does this, see Initializing a VF Miniport Driver.

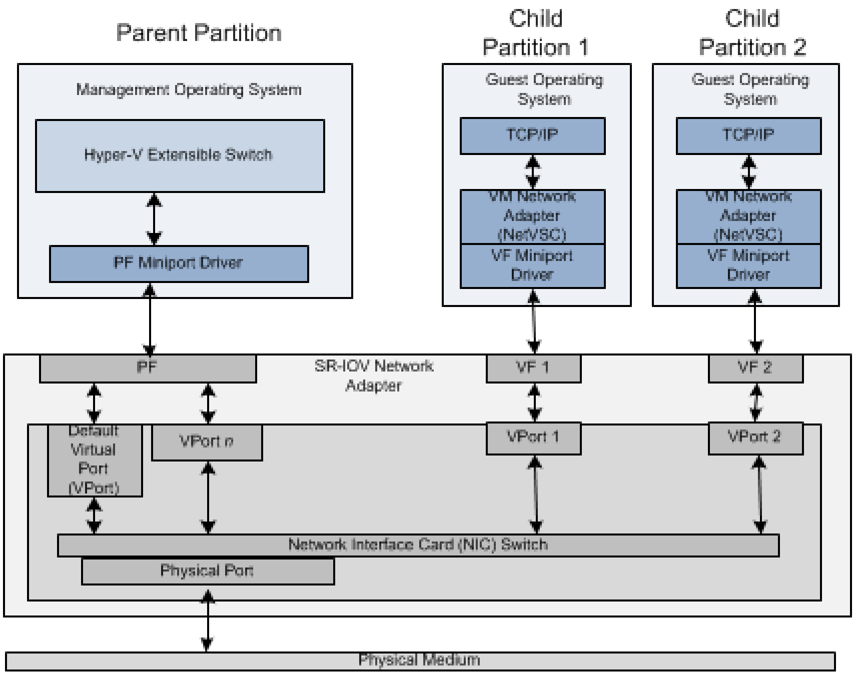
NIC Switches

Article • 12/15/2021

A network adapter that supports single root I/O virtualization (SR-IOV) must implement a hardware bridge that forwards network traffic between the physical port on the adapter and internal virtual ports (VPorts). This bridge is known as the *NIC switch* and is shown in the following figure.



Each NIC switch contains the following components:

- One external, or *physical*, port that provides network connectivity to the external physical network.

- One internal port that provides the PCI Express (PCIe) Physical Function (PF) on the network adapter with access to the external physical network. An internal port is known as a *virtual port (VPort)*.

  The PF always has a VPort that is created and assigned to it. This VPort is known as the *default VPort*, and is referenced by the DEFAULT_VPORT_ID identifier.

  For more information about VPorts, see Virtual Ports (VPorts).

- One or more VPorts that provide a PCIe Virtual Function (VF) on the network adapter with access to the external physical network.

  Note Additional VPorts can be created and allocated to the PF for network access.

Note Starting with NDIS 6.30 in Windows Server 2012, the SR-IOV interface supports only one NIC switch on the network adapter. This switch is known as the *default NIC* *switch*, and is referenced by the NDIS_DEFAULT_SWITCH_ID identifier.

The hardware resources for the NIC switch are managed by the PF miniport driver for the SR-IOV network adapter. The driver creates and configures the NIC switch through one of the following methods:

- Static creation based on standardized SR-IOV and NIC switch INF keywords. For more information on these keywords, see Standardized INF Keywords for SR-IOV.

- Dynamic creation based on object identifier (OID) method requests of OID_NIC_SWITCH_CREATE_SWITCH. NDIS or the Hyper-V extensible switch module issues these OID requests to create NIC switches on the SR-IOV network adapter.

For more information on how NIC switches are created, configured, and managed, see Managing NIC Switches.

Virtual Ports (VPorts)

Article • 03/09/2022

A virtual port (VPort) is a data object that represents an internal port on the NIC switch of a network adapter that supports single root I/O virtualization (SR-IOV). Each NIC switch has the following ports for network connectivity:

- One external physical port for connectivity to the external physical network.

- One or more internal VPorts which are connected to the PCI Express Physical Function (PF) or virtual functions (VFs).

  The PF is attached to the Hyper-V parent partition and is exposed as a virtual network adapter in the management operating system that runs in that partition.

  A VF is attached to the Hyper-V child partition and is exposed as a virtual network adapter in the guest operating system that runs in that partition.

The NIC switch bridges network traffic from the physical port to one or more VPorts. This provides virtualized access to the underlying physical network interface.

Each VPort has a unique identifier (*VPortId*) that is unique for the NIC switch on the network adapter. A default VPort always exists on the default NIC switch and can never be deleted. The default VPort has the VPortId of NDIS_DEFAULT_VPORT_ID.

When the PF miniport driver handles an object identifier (OID) method request of OID_NIC_SWITCH_CREATE_SWITCH, it creates the NIC switch and the default VPort for that switch. The default VPort is always attached to the PF and is always in an operational state.

Nondefault VPorts are created through OID method requests of OID_NIC_SWITCH_CREATE_VPORT. Only one nondefault VPort can be attached to a VF. Once attached, the default is in an operational state. One or more nondefault VPorts can also be created and attached to the PF. These VPorts are nonoperational when created and can become operational through an OID set request of OID_NIC_SWITCH_VPORT_PARAMETERS.

> ⓘ **Note**
>
> After a VPort becomes operational, it can only become nonoperational when it is deleted through an OID request of **OID_NIC_SWITCH_DELETE_VPORT**.

Each VPort has one or more hardware queue pairs associated with it for receiving and transmitting packets. The default queue pair on the network adapter is reserved for use by the default VPort. Queue pairs for nondefault VPorts are allocated and assigned when the VPort is created through the OID_NIC_SWITCH_CREATE_VPORT request.

Nondefault VPorts are created and configured through OID method requests of OID_NIC_SWITCH_CREATE_VPORT. The default VPort and nondefault VPorts are reconfigured through OID set requests of OID_NIC_SWITCH_VPORT_PARAMETERS. Each OID request contains an **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure that specifies the following configuration parameters:

- The PCIe function to which the VPort is attached.

  Each VPort can be either attached to the PF or with a VF at any time. After the VPort is created and attached to a PCIe function, the attachment cannot be dynamically changed to another PCIe function.

  > ⓘ **Note**
  >
  > The default VPort is always attached to the PF on the network adapter.

Starting with NDIS 6.30 in Windows Server 2012, only one nondefault VPort can be attached to a VF. However, multiple nondefault VPorts along with the default VPort can be attached to the PF.

- The number of hardware queue pairs that are assigned to a VPort.

  Each VPort has a set of hardware queue pairs that are available to it. Each queue pair consists of a separate transmit and receive queue on the network adapter.

  Queue pairs are limited resources on the network adapter. The total number of queue pairs reserved for use by the default and nondefault VPorts is specified when the NIC switch is created. This allows the number of queue pairs that are assigned to the default VPort to differ from the nondefault VPorts.

  Each nondefault VPort can be configured to have a different number of queue pairs. This is known as *asymmetric allocation* of queue pairs. If the NIC does not allow for such an asymmetric allocation, each nondefault VPort is configured to have equal number of queue pairs. This is known as *symmetric allocation* of queue pairs. For more information, see Symmetric and Asymmetric Assignment of Queue Pairs.

  > ⓘ **Note**

The PF miniport driver reports on whether it supports asymmetric allocation of queue pairs during ***MiniportInitializeEx***. For more information, see **Initializing a PF Miniport Driver**.

The number of queue pairs assigned to each VPort is not changed dynamically. The number of queue pairs assigned to a VPort cannot be changed after the VPort has been created.

ⓘ **Note**

One or more queue pairs assigned to the nondefault VPorts can be used for receive side scaling (RSS) by the VF miniport driver that runs in the guest operating system.

- Interrupt moderation parameters for the VPort.

  Different interrupt moderation types can be specified for different VPorts. This allows the virtualization stack to control the number of interrupts generated by a particular VPort.

In addition to configuration parameters, overlying drivers can configure receive filters for each VPort by issuing OID method requests of OID_RECEIVE_FILTER_SET_FILTER. The NIC switch performs the specified receive filtering on a VPort basis.

Receive filters parameters for VPorts include packet filtering conditions, such as a list of media access control (MAC) addresses and the virtual LAN (VLAN) identifiers. Filters for MAC addresses and VLAN identifiers are always specified together in the **NDIS_RECEIVE_FILTER_PARAMETERS** associated with the OID_RECEIVE_FILTER_SET_FILTER request. The NIC switch must filter incoming packets to the switch whose destination MAC address and VLAN identifier matches any receive filter condition that was set on the VPort. The NIC switch filters packets received from either another VPort or from the external physical port. If the packet matches a filter, the NIC switch must forward it to the VPort.

Multiple MAC address and VLAN identifier pairs may be set on the VPort. If only a MAC address is set, the receive filter specifies that the VPort should receive packets that match the following condition:

- The packet's destination MAC address matches the filter's MAC address.

- The packet has a VLAN tag or (if a VLAN tag is present) a VLAN identifier of zero.

Nondefault VPorts are deleted through OID set requests of OID_NIC_SWITCH_DELETE_VPORT. The default VPort is only deleted when the NIC switch is deleted through an OID set request of OID_NIC_SWITCH_DELETE_SWITCH.

SR-IOV Data Paths

Article • 12/15/2021

This section describes the possible data paths between a network adapter that supports single root I/O virtualization (SR-IOV) and the Hyper-V parent and child partitions.

This section includes the following topics:

Overview of SR-IOV Data Paths

Article • 12/15/2021

When a Hyper-V child partition is started and the guest operating system is running, the virtualization stack starts the Network Virtual Service Client (NetVSC). NetVSC exposes a virtual machine (VM) network adapter by providing a miniport driver edge to the protocol stacks that run in the guest operating system. In addition, NetVSC provides a protocol driver edge that allows it to bind to the underlying miniport drivers.

NetVSC also communicates with the Hyper-V extensible switch that runs in the management operating system of the Hyper-V parent partition. The extensible switch component operates as a Network Virtual Service Provider (NetVSP). The interface between the NetVSC and NetVSP provides a software data path that is known as the *synthetic data path*. For more information about this data path, see SR-IOV Synthetic Data Path.

If the physical network adapter supports the single root I/O virtualization (SR-IOV) interface, it can enable one or more PCI Express (PCIe) Virtual Functions (VFs). Each VF can be attached to a Hyper-V child partition. When this happens, the virtualization stack performs the following steps:

1. The virtualization stack exposes a network adapter for the VF in the guest operating system. This causes the PCI driver that runs in the guest operating system to start the VF miniport driver. This driver is provided by the independent hardware vendor (IHV) for the SR-IOV network adapter.

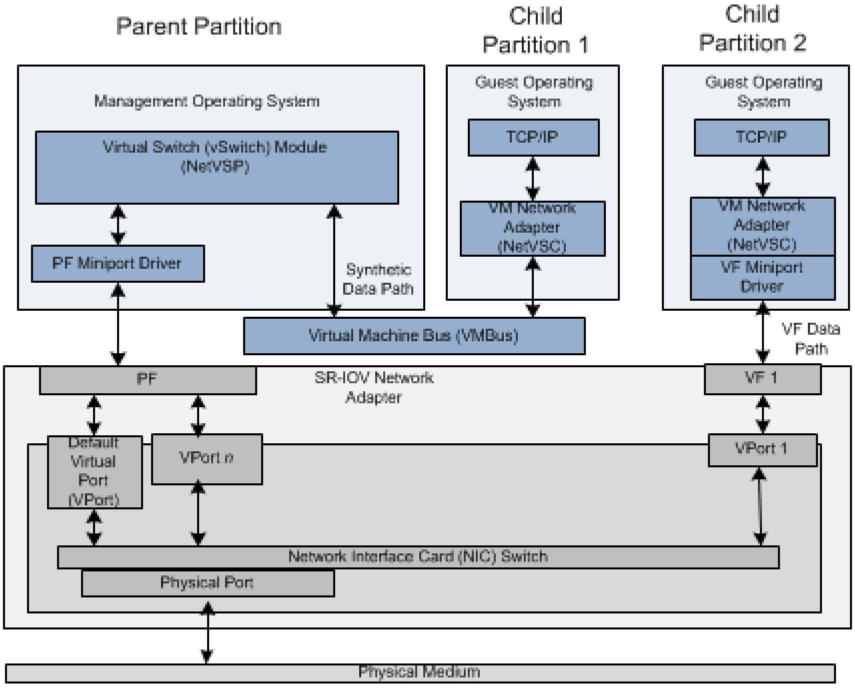
2. After the VF miniport driver is loaded and initialized, NDIS binds the protocol edge of the NetVSC in the guest operating system to the driver.

   Note NetVSC only binds to the VF miniport driver. No other protocol stacks in the guest operating system can bind to the VF miniport driver.

After the NetVSC successfully binds to the driver, network traffic in the guest operating system occurs over the *VF data path*. Packets are sent or received over the underlying VF of the network adapter instead of the synthetic data path.

For more information about the VF data path, see SR-IOV VF Data Path.

The following figure shows the various data paths that are supported over an SR-IOV network adapter.



After the Hyper-V child partition is started and before the VF data path is established, network traffic flows over the synthetic data path. After the VF data path is established, network traffic can revert to the synthetic data path if the following conditions are true:

- The VF becomes unattached to the Hyper-V child partition. For example, the virtualization stack could detach a VF from one child partition and attach it to another child partition. This might occur when there are more Hyper-V child partitions that are running than there are VF resources on the underlying SR-IOV network adapter.

  The process of failing over to the synthetic data path from the VF data path is known as *VF failover*.

- The Hyper-V child partition is being live migrated to a different host.

For more information about VF failover and live migration, see SR-IOV VF Failover and Live Migration.

SR-IOV VF Data Path

Article • 12/15/2021

If the physical network adapter supports the single root I/O virtualization (SR-IOV) interface, it can enable one or more PCI Express (PCIe) Virtual Functions (VFs). Each VF can be attached to a Hyper-V child partition. When this happens, the virtualization stack performs the following steps:

1. Once resources for the VF are allocated, the virtualization stack exposes a network adapter for the VF in the guest operating system. This causes the PCI driver that runs in the guest operating system to start the VF miniport driver. This driver is provided by the independent hardware vendor (IHV) for the SR-IOV network adapter.

   Note Resources for the VF must be allocated by the miniport driver for the PCIe Physical Function (PF) before the VF can be attached to the Hyper-V child partition. VF resources include assigning a virtual port (VPort) on the NIC switch to the VF. For more information, see SR-IOV Virtual Functions.

2. After the VF miniport driver is loaded and initialized, NDIS binds the protocol edge of the Network Virtual Service Client (NetVSC) in the guest operating system to the driver.

   Note NetVSC only binds to the VF miniport driver. No other protocol stacks in the guest operating system can bind to the VF miniport driver.

After the NetVSC successfully binds to the driver, network traffic in the guest operating system occurs over the *VF data path*. Packets are sent or received over the underlying VF of the network adapter instead of the software-based synthetic data path. For more information about the synthetic data path, see SR-IOV Synthetic Data Path.

The following diagram shows the components of the VF data path over an SR-IOV network adapter.

The use of the VF data path provides the following benefits:

- All data packets flow directly between the networking components in the guest operating system and the VF. This eliminates the overhead of the synthetic data path in which data packets flow between the Hyper-V child and parent partitions.

  For more information about the synthetic data path, see SR-IOV Synthetic Data Path.

- The VF data path bypasses any involvement by the management operating system in packet traffic from a Hyper-V child partition. The VF provides independent memory space, interrupts, and DMA streams for the child partition to which it is attached. This achieves networking performance that is almost compatible with nonvirtualized environments.

- The routing of packets over the VF data path is performed by the NIC switch on the SR-IOV network adapter. Packets are sent or received over the external network through the physical port of the adapter. Packets are also forwarded to or from other child partitions to which a VF is attached.

  Note Packets to or from child partitions to which no VF is attached are forwarded by the NIC switch to the Hyper-V extensible switch module. This module runs in the Hyper-V parent partition and delivers these packets to the child partition by using the synthetic data path.

SR-IOV Synthetic Data Path

Article • 12/15/2021

When a Hyper-V child partition is started and the guest operating system is running, the virtualization stack starts the Network Virtual Service Client (NetVSC). NetVSC exposes a virtual machine (VM) network adapter that provides a miniport driver edge to the protocol stacks that run in the guest operating system.

NetVSC also communicates with the Hyper-V extensible switch that runs in the management operating system of the Hyper-V parent partition. The extensible switch component operates as a Network Virtual Service Provider (NetVSP). The interface between the NetVSC and NetVSP provides a software data path that is known as the *synthetic data path*.

The following diagram shows the components of the synthetic data path over an SR-IOV network adapter.

Physical Medium

If the underlying SR-IOV network adapter allocates resources for PCI Express (PCIe) Virtual Functions (VFs), the virtualization stack will attach a VF to a Hyper-V child partition. Once attached, packet traffic within the child partition will occur over the hardware-optimized VF data path instead of the synthesized data path. For more information on the VF data path, see SR-IOV Data Path.

The virtualization stack may still enable the synthetic data path for a Hyper-V child partition if one of the following conditions is true:

- The SR-IOV network adapter has insufficient VF resources to accommodate all of the Hyper-V child partitions that were started. After all VFs on the network adapter are attached to child partitions, the remaining partitions use the synthetic data path.

  The process of failing over to the synthetic data path from the VF data path is known as *VF failover*.

- A VF was attached to a Hyper-V child partition but becomes detached. For example, the virtualization stack could detach a VF from one child partition and attach it to another child partition. This might occur when there are more Hyper-V child partitions that are running than there are VF resources on the underlying SR-IOV network adapter.

- The Hyper-V child partition is being live migrated to a different host.

Although the synthetic data path over an SR-IOV network adapter is not as efficient as the VF data path, it can still be hardware optimized. For example, if one or more virtual ports (VPorts) are configured and attached to the PCIe Physical Function (PF), the data path can provide the offload capabilities that resemble the virtual machine queue (VMQ) interface. For more information, see Nondefault Virtual Ports and VMQ.

SR-IOV VF Failover and Live Migration Support

Article • 12/15/2021

After the Hyper-V child partition is started, network traffic flows over the synthetic data path. If the physical network adapter supports the Single Root I/O Virtualization (SR-IOV) interface, it can enable one or more PCI Express (PCIe) Virtual Functions (VFs). Each VF can be attached to a Hyper-V child partition. When this happens, network traffic flows over the hardware-optimized SR-IOV VF Data Path.

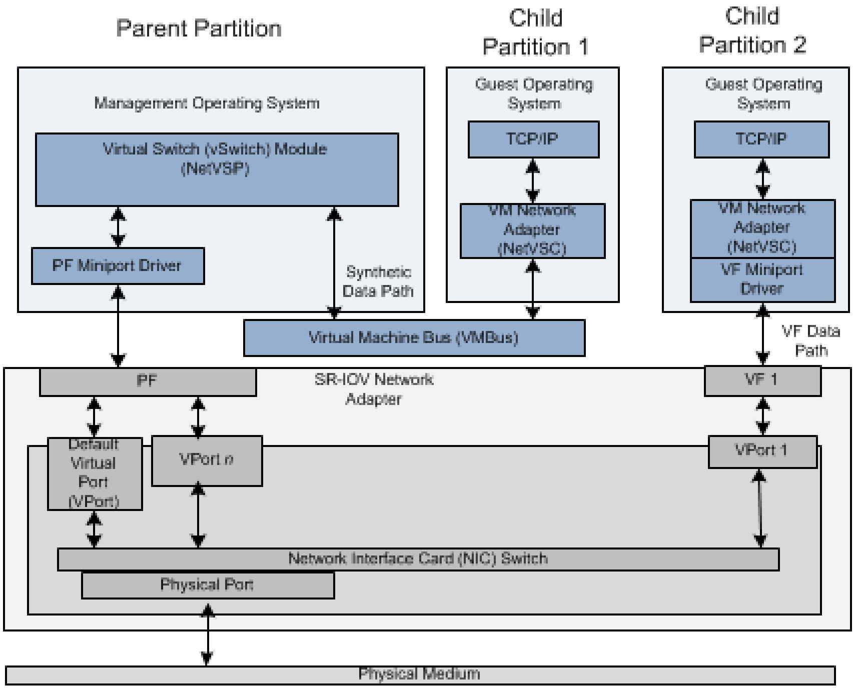
After the VF data path is established, network traffic can revert to the synthetic data path if any of the following conditions is true:

- A VF was attached to a Hyper-V child partition but becomes detached. For example, the virtualization stack could detach a VF from one child partition and attach it to another child partition. This might occur when there are more Hyper-V child partitions that are running than there are VF resources on the underlying SR-IOV network adapter.

  The process of failing over to the synthetic data path from the VF data path is known as *VF failover*.

- The Hyper-V child partition is being live migrated to a different host.

The following figure shows the various data paths that are supported over an SR-IOV network adapter.



The NetVSC exposes a Virtual Machine (VM) network adapter which is bound to the VF miniport driver to support the VF data path. During the transition to the synthetic data path, the VF network adapter is gracefully removed if possible from the guest operating system. If the VF cannot be removed gracefully and times out, it will be surprise removed. Then the VF miniport driver is halted, and the Network Virtual Service Client (NetVSC) is unbound from the VF miniport driver.

The transition between the VF and synthetic data paths occurs with minimum loss of packets and prevents the loss of TCP connections. Before the transition to the synthetic data path is complete, the virtualization stacks follows these steps:

1. The virtualization stack moves the Media Access Control (MAC) and Virtual LAN (VLAN) filters for the VM network adapter to the default Virtual Port (VPort) that is attached to the PCIe Physical Function (PF). The VM network adapter is exposed in the guest operating system of the child partition.

   After the filters are moved to the default VPort, the synthetic data path is fully operational for network traffic to and from the networking components that run in the guest operating system. The PF miniport driver indicates received packets on the default PF VPort which uses the synthetic data path to indicate the packets to the guest operating system. Similarly, all transmitted packets from the guest operating system are routed through the synthetic data path and transmitted through the default PF VPort.

   For more information about VPorts, see Virtual Ports (VPorts).

2. The virtualization stack deletes the VPort that is attached to the VF by issuing an Object Identifier (OID) set request of OID_NIC_SWITCH_DELETE_VPORT to the PF miniport driver. The miniport driver frees any hardware and software resources associated with the VPort and completes the OID request.

   For more information, see Deleting a Virtual Port.

3. The virtualization stack requests a PCIe Function Level Reset (FLR) of the VF before its resources are deallocated. The stack does this by issuing an OID set request of OID_SRIOV_RESET_VFto the PF miniport driver. The FLR brings the VF on the SR-IOV network adapter into a quiescent state and clears any pending interrupt events for the VF.

4. After the VF has been reset, the virtualization stack requests a deallocation of the VF resources by issuing an OID set request of OID_NIC_SWITCH_FREE_VF to the PF miniport driver. This causes the miniport driver to free the hardware resources associated with the VF.

For more information about this process, see Virtual Function Teardown Sequence.

Writing SR-IOV PF Miniport Drivers Overview

Article • 12/15/2021

This section discusses the requirements and guidelines for writing an NDIS miniport driver for the PCI Express (PCIe) Physical Function (PF) of a single root I/O virtualization (SR-IOV) network adapter.

This section includes the following topics:

Initializing a PF Miniport Driver

Managing NIC Switches

Managing Virtual Ports

Managing Virtual Functions

Halting a PF Miniport Driver

INF Requirements for PF Miniport Drivers

Note For information on how to write a miniport driver for a PCIe Virtual Function (VF) of the SR-IOV network adapter, see Writing SR-IOV VF Miniport Drivers.

Initializing a PF Miniport Driver Topics

Article • 12/15/2021

This section discusses the requirements and guidelines for initializing an NDIS miniport driver for the PCI Express (PCIe) Physical Function (PF) of a single root I/O virtualization (SR-IOV) network adapter.

This section includes the following topics:

Determining SR-IOV Capabilities

Determining NIC Switch Capabilities

Determining Receive Filtering Capabilities

Initialization Sequence for PF Miniport Drivers

Determining SR-IOV Capabilities

Article • 12/15/2021

This topic describes how NDIS and overlying drivers determine the single root I/O virtualization (SR-IOV) capabilities of a network adapter. This topic contains the following information:

Reporting SR-IOV Capabilities during *MiniportInitializeEx*

Querying SR-IOV Capabilities by Overlying Drivers

Reporting SR-IOV Capabilities during *MiniportInitializeEx*

When NDIS calls the miniport driver's *MiniportInitializeEx* function, the driver provides the following SR-IOV capabilities:

- The complete set of SR-IOV hardware capabilities that the network adapter can support.
- The SR-IOV capabilities that are currently enabled on the network adapter.
- Whether the miniport driver is managing the PCI Express (PCIe) Physical Function (PF) or Virtual Function (VF) on the network adapter.

The miniport driver reports the SR-IOV hardware capabilities of the underlying network adapter through an **NDIS_SRIOV_CAPABILITIES** structure that is initialized in the following way:

1. The miniport driver initializes the **Header** member. The driver sets the **Type** member of **Header** to NDIS_OBJECT_TYPE_DEFAULT.

   Starting with NDIS 6.30, the miniport driver sets the **Revision** member of **Header** to NDIS_SRIOV_CAPABILITIES _REVISION_1 and the **Size** member to NDIS_SIZEOF_SRIOV_CAPABILITIES_REVISION_1.

2. The miniport driver sets the appropriate flags in the **SriovCapabilities** member to report SR-IOV capabilities.

   If the network adapter supports SR-IOV, the miniport driver for the PCI Express (PCIe) Physical Function of the adapter must set the following flags:

   - NDIS_SRIOV_CAPS_SRIOV_SUPPORTED

- NDIS_SRIOV_CAPS_PF_MINIPORT

> ⓘ **Note**
>
> The miniport driver for a PCIe Virtual Function (VF) of the network adapter must set both the NDIS_SRIOV_CAPS_VF_MINIPORT flag and the NDIS_SRIOV_CAPS_SRIOV_SUPPORTED flag.

When NDIS calls the miniport driver's *MiniportInitializeEx* function, the driver registers the SR-IOV capabilities of the network adapter by following these steps:

1. The miniport driver initializes an **NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES** structure.

   The miniport driver sets the **HardwareSriovCapabilities** member to a pointer to the previously initialized **NDIS_SRIOV_CAPABILITIES** structure.

   If the registry setting for the ***SRIOV** INF keyword has a value of one, the SR-IOV capabilities are currently enabled on the network adapter. The miniport driver sets the **CurrentSriovCapabilities** members to a pointer to the same **NDIS_SRIOV_CAPABILITIES** structure.

   If the registry setting for the ***SRIOV** INF keyword has a value of zero, the SR-IOV capabilities are currently disabled on the network adapter. The miniport driver must set the **CurrentSriovCapabilities** member to NULL.

   For more information about the ***SRIOV** INF keyword, see Standardized INF Keywords for SR-IOV.

2. The driver calls **NdisMSetMiniportAttributes** and sets the *MiniportAttributes* parameter to a pointer to the **NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES** structure.

For more information about the adapter initialization process, see Initializing a Miniport Adapter.

Querying SR-IOV Capabilities by Overlying Drivers

NDIS passes the network adapter's currently enabled SR-IOV capabilities to overlying drivers that bind to the network adapter in the following way:

- When NDIS calls an overlying filter driver's *FilterAttach* function, NDIS passes the network adapter's SR-IOV capabilities through the *AttachParameters* parameter. This parameter contains a pointer to an **NDIS_FILTER_ATTACH_PARAMETERS** structure. The **SriovCapabilities** member of this structure contains a pointer to an **NDIS_SRIOV_CAPABILITIES** structure.

- When NDIS calls an overlying protocol driver's *ProtocolBindAdapterEx* function, NDIS passes the network adapter's SR-IOV capabilities through the *BindParameters* parameter. This parameter contains a pointer to an **NDIS_FILTER_ATTACH_PARAMETERS** structure. The **SriovCapabilities** member of this structure contains a pointer to an **NDIS_SRIOV_CAPABILITIES** structure.

NDIS also returns the **NDIS_SRIOV_CAPABILITIES** structure when it handles object identifier (OID) query requests of OID_SRIOV_HARDWARE_CAPABILITIES and OID_SRIOV_CURRENT_CAPABILITIES that are issued by overlying protocol or filter drivers.

Determining NIC Switch Capabilities

Article • 12/15/2021

This topic describes how NDIS and overlying drivers determine the NIC switch capabilities of a network adapter that supports single root I/O virtualization (SR-IOV). This topic contains the following information:

Reporting NIC Switch Capabilities during *MiniportInitializeEx*

Querying NIC Switch Capabilities by Overlying Drivers

Note Only the miniport driver for the PCI Express (PCIe) Physical Function (PF) of an SR-IOV network adapter can report NIC switch capabilities. Miniport drivers for PCIe Virtual Functions (VFs) must not report the NIC switch capabilities of the SR-IOV adapter.

For more information on NIC switches, see NIC Switches.

Reporting NIC Switch Capabilities during *MiniportInitializeEx*

When NDIS calls the miniport driver's *MiniportInitializeEx* function, the driver provides the following NIC switch capabilities:

- The complete set of hardware capabilities for a NIC switch that the network adapter can support.

  Note Starting with NDIS 6.30, only one NIC switch is created on the network adapter. This switch is known as the *default NIC switch*.

- The NIC switch capabilities that are currently enabled on the network adapter.

The miniport driver reports the NIC switch hardware capabilities of the underlying network adapter through an **NDIS_NIC_SWITCH_CAPABILITIES** structure that is initialized in the following way:

1. The miniport driver initializes the **Header** member. The driver sets the **Type** member of **Header** to NDIS_OBJECT_TYPE_DEFAULT.

   Starting with NDIS 6.30, the miniport driver sets the **Revision** member of **Header** to NDIS_NIC_SWITCH_CAPABILITIES_REVISION_2 and the **Size** member to NDIS_SIZEOF_NIC_SWITCH_CAPABILITIES_REVISION_2.

2. The miniport driver sets appropriate flags in the **NicSwitchCapabilities** member of the **NDIS_NIC_SWITCH_CAPABILITIES** structure to the NIC switch capabilities of the SR-IOV network adapter. For example, the miniport driver sets the NDIS_NIC_SWITCH_CAPS_PER_VPORT_INTERRUPT_MODERATION_SUPPORTED flag if the NIC switch supports interrupt moderation on each virtual port (VPort) that is created on the switch.

3. The miniport driver sets the other members of the **NDIS_NIC_SWITCH_CAPABILITIES** structure to the range of values for the NIC switch capabilities of the SR-IOV network adapter. For example, the miniport driver sets the **MaxNumVFs** and **MaxNumVPorts** members to the maximum number of VFs and VPorts that the adapter can support.

   Note Depending on the available hardware resources on the network adapter, the miniport driver can set the **MaxNumVFs** member to a value that is less than its ***NumVFs** keyword. For more information about this keyword, see Standardized INF Keywords for SR-IOV.

When NDIS calls the miniport driver's *MiniportInitializeEx* function, the driver registers the NIC switch capabilities of the network adapter by following these steps:

1. The miniport driver initializes an **NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES** structure.

   The miniport driver sets the **HardwareNicSwitchCapabilities** member to a pointer to a previously initialized **NDIS_NIC_SWITCH_CAPABILITIES** structure.

   If the registry setting for the ***SRIOV** INF keyword has a value of one, the network adapter is currently enabled for NIC switch creation and configuration. The miniport driver sets the **CurrentNicSwitchCapabilities** members to a pointer to the same **NDIS_NIC_SWITCH_CAPABILITIES** structure.

   If the registry setting for the ***SRIOV** INF keyword has a value of zero, the network adapter is not currently enabled for NIC switch creation and configuration. The miniport driver must set the **CurrentNicSwitchCapabilities** member to NULL.

   For more information about the ***SRIOV** INF keyword, see Standardized INF Keywords for SR-IOV.

2. The driver calls **NdisMSetMiniportAttributes** and sets the *MiniportAttributes* parameter to a pointer to the **NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES** structure.

For more information about the adapter initialization process, see Initializing a Miniport Adapter.

Creating a NIC switch without SR-IOV

Miniport drivers in NDIS 6.60 and later must adhere to the following requirements for the coexistence of a NIC switch and VMQ capabilities when SR-IOV is not enabled. When SR-IOV is enabled, the miniport driver should adhere to the existing requirements in the previous section.

- The miniport driver advertises both NIC switch and VMQ capabilities.
- The NIC can toggle between NIC switch and VMQ mode without a NIC restart.
  - When the NIC starts initially, it is ready to be in either mode (either creating a NIC switch or creating VMQ queues).
    - If a NIC switch is created, the miniport fails any subsequent VMQ queue allocation callbacks.
    - If a VMQ queue is created first, the miniport driver succeeds the VMQ queue allocation and fails any NIC switch allocation calls.
  - When the NIC switch is deleted or all VMQ queues are deleted, the miniport driver returns to the initial state and is ready to go into either of these modes again.

To advertise that a NIC switch can be created without the use of SR-IOV, the miniport driver sets the **NDIS_NIC_SWITCH_CAPS_NIC_SWITCH_WITHOUT_IOV_SUPPORTED** flag in the **NicSwitchCapabilities** member of the NDIS_NIC_SWITCH_CAPABILITIES structure.

Querying NIC Switch Capabilities by Overlying Drivers

NDIS passes the network adapter's currently enabled NIC switch capabilities to overlying drivers that bind to the network adapter in the following way:

- When NDIS calls an overlying filter driver's *FilterAttach* function, NDIS passes the network adapter's NIC switch capabilities through the *AttachParameters* parameter. This parameter contains a pointer to an NDIS_FILTER_ATTACH_PARAMETERS structure. The **NicSwitchCapabilities** member of this structure contains a pointer to an NDIS_NIC_SWITCH_CAPABILITIES structure.

- When NDIS calls an overlying protocol driver's *ProtocolBindAdapterEx* function, NDIS passes the network adapter's NIC switch capabilities through the *BindParameters* parameter. This parameter contains a pointer to an

NDIS_FILTER_ATTACH_PARAMETERS structure. The **NicSwitchCapabilities** member of this structure contains a pointer to an **NDIS_NIC_SWITCH_CAPABILITIES** structure.

NDIS also returns the **NDIS_NIC_SWITCH_CAPABILITIES** structure when it handles object identifier (OID) query requests of OID_NIC_SWITCH_HARDWARE_CAPABILITIES and OID_NIC_SWITCH_CURRENT_CAPABILITIES that are issued by overlying protocol or filter drivers.

Determining Receive Filtering Capabilities

Article • 12/15/2021

This topic describes how NDIS and overlying drivers determine the receive filtering capabilities of a network adapter that supports single root I/O virtualization (SR-IOV). This topic contains the following information:

Reporting Receive Filtering Capabilities during *MiniportInitializeEx*

Querying Receive Filtering Capabilities by Overlying Drivers

Note Only the miniport driver for the PCI Express (PCIe) Physical Function (PF) of an SR-IOV network adapter can report receive filtering capabilities. Miniport drivers for PCIe Virtual Functions (VFs) must not report the receive filtering capabilities of the SR-IOV adapter.

Reporting Receive Filtering Capabilities during *MiniportInitializeEx*

When NDIS calls the PF miniport driver's *MiniportInitializeEx* function, the driver provides the following receive filtering capabilities:

- The complete hardware receive filtering capabilities that the network adapter can support.
- The receive filtering capabilities for the interfaces that are currently enabled on the network adapter.

The miniport driver reports the complete hardware receive filtering capabilities of the underlying network adapter through an **NDIS_RECEIVE_FILTER_CAPABILITIES** structure that is initialized in the following way:

1. The miniport driver initializes the **Header** member. The driver sets the **Type** member of **Header** to NDIS_OBJECT_TYPE_DEFAULT.

   Starting with NDIS 6.30, the miniport driver sets the **Revision** member of **Header** to NDIS_RECEIVE_FILTER_CAPABILITIES_REVISION_2 and the **Size** member to NDIS_SIZEOF_RECEIVE_FILTER_CAPABILITIES_REVISION_2.

2. The miniport driver sets the other members of the **NDIS_RECEIVE_FILTER_CAPABILITIES** structure to the range of values for the receive filtering capabilities of the SR-IOV network adapter. For example, the miniport driver sets the appropriate flags in the **SupportedFilterTests** to specify filter test operations that the miniport driver supports.

3. Besides SR-IOV, receive filtering is also used in the following interfaces:

   - NDIS Packet Coalescing. For more information about how to use receive filters in this interface, see Managing Packet Coalescing Receive Filters.

   - Virtual Machine Queue (VMQ). For more information about how to use receive filters in this interface, see Setting and Clearing VMQ Filters.

   If the miniport driver supports any of these interfaces, it must also set the members of the **NDIS_RECEIVE_FILTER_CAPABILITIES** structure to the range of receive filtering capability values that are specific to the interface. For example, if the driver supports NDIS packet coalescing and SR-IOV, it must set the NDIS_RECEIVE_FILTER_PACKET_COALESCING_SUPPORTED_ON_DEFAULT_QUEUE flag in the **SupportedQueueProperties** member.

The miniport driver reports the currently-enabled receive filtering capabilities of the underlying network adapter through an **NDIS_RECEIVE_FILTER_CAPABILITIES** structure that is initialized in the following way:

1. The miniport driver initializes the **Header** member. The driver sets the **Type** member of **Header** to NDIS_OBJECT_TYPE_DEFAULT.

   Starting with NDIS 6.30, the miniport driver sets the **Revision** member of **Header** to NDIS_RECEIVE_FILTER_CAPABILITIES_REVISION_2 and the **Size** member to NDIS_SIZEOF_RECEIVE_FILTER_CAPABILITIES_REVISION_2.

2. The miniport driver sets the other members of the **NDIS_RECEIVE_FILTER_CAPABILITIES** structure to the range of values for the receive filtering capabilities of the interfaces that are currently enabled. For example, if NDIS packet coalescing is enabled, the driver must only set the members that are specific to this technology.

   Interfaces that use receive filtering are enabled or disabled through standardized INF keywords. For more information on how NDIS packet coalescing is enabled, see Standardized INF Keywords for Packet Coalescing. For more information on how SR-IOV and VMQ are enabled, see Handling SR-IOV, VMQ, and RSS Standardized INF Keywords.

When NDIS calls the miniport driver's *MiniportInitializeEx* function, the driver registers the receive filtering capabilities of the network adapter by following these steps:

1. The miniport driver initializes an NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES structure.

   The miniport driver sets the **HardwareReceiveFilterCapabilities** member to the address of an NDIS_RECEIVE_FILTER_CAPABILITIES structure. This structure was previously-initialized with the complete hardware receive filtering capabilities of the network adapter.

2. If the VMQ, SR-IOV, and NDIS packet coalescing are all currently disabled on the network adapter, the miniport driver sets the **CurrentReceiveFilterCapabilities** member to NULL.

3. If either VMQ, SR-IOV, or NDIS packet coalescing are currently enabled on the network adapter, the miniport driver must do the following:

   - The miniport driver must initialize another NDIS_RECEIVE_FILTER_CAPABILITIES structure with the current receive filtering capabilities for the interfaces that are currently enabled on the network adapter.

     If the SR-IOV interface is enabled, there are situations in which the miniport driver must set the members of the NDIS_RECEIVE_FILTER_CAPABILITIES structure to the same or different values. This is because the SR-IOV interface provides a similar queuing mechanism to VMQ, but uses virtual ports (VPorts) instead of VM receive queues.

     For example, the miniport driver must set the NDIS_RECEIVE_FILTER_VMQ_FILTERS_ENABLED flag in the **EnabledFilterTypes** member if either the VMQ or SR-IOV interface is enabled. However, the miniport driver must set the **NumQueues** member to zero if the SR-IOV interface is enabled and a nonzero value if the VMQ interface is enabled.

   - The miniport driver sets the **CurrentReceiveFilterCapabilities** member to the address of the NDIS_RECEIVE_FILTER_CAPABILITIES structure that contains the current receive filtering capabilities for the currently-enabled interface.

4. If either VMQ, SR-IOV, or NDIS packet coalescing are currently enabled on the network adapter, the miniport driver sets the **HardwareReceiveFilterCapabilities** member to the address of an NDIS_RECEIVE_FILTER_CAPABILITIES structure. This structure was previously-initialized with the currently-enabled receive filtering capabilities of the network adapter.

5. The driver calls **NdisMSetMiniportAttributes** and sets the *MiniportAttributes* parameter to a pointer to the **NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES** structure.

For more information about the adapter initialization process, see Initializing a Miniport Adapter.

Querying Receive Filtering Capabilities by Overlying Drivers

NDIS passes the network adapter's currently-enabled receive filtering capabilities to overlying drivers that bind to the network adapter in the following way:

- When NDIS calls an overlying filter driver's *FilterAttach* function, NDIS passes the network adapter's NIC switch capabilities through the *AttachParameters* parameter. This parameter contains a pointer to an **NDIS_FILTER_ATTACH_PARAMETERS** structure. The **ReceiveFilterCapabilities** member of this structure contains a pointer to an **NDIS_RECEIVE_FILTER_CAPABILITIES** structure.

- When NDIS calls an overlying protocol driver's *ProtocolBindAdapterEx* function, NDIS passes the network adapter's NIC switch capabilities through the *BindParameters* parameter. This parameter contains a pointer to an **NDIS_FILTER_ATTACH_PARAMETERS** structure. The **ReceiveFilterCapabilities** member of this structure contains a pointer to an **NDIS_RECEIVE_FILTER_CAPABILITIES** structure.

NDIS also returns the **NDIS_RECEIVE_FILTER_CAPABILITIES** structure when it handles object identifier (OID) query requests of OID_RECEIVE_FILTER_CURRENT_CAPABILITIES and OID_RECEIVE_FILTER_HARDWARE_CAPABILITIES that are issued by overlying protocol or filter drivers.

Initialization Sequence for PF Miniport Drivers

Article • 12/15/2021

This section describes the requirements and guidelines for the initialization sequence of a miniport driver for the PCI Express (PCIe) Physical Function (PF). The PF is a component of a network adapter that supports single root I/O virtualization (SR-IOV).

This section includes the following topics:

DriverEntry Guidelines for PF Miniport Drivers

MiniportAddDevice Guidelines for PF Miniport Drivers

MiniportInitializeEx Guidelines for PF Miniport Drivers

Note For information on initializing miniport drivers for a PCIe Virtual Function (VF) on the SR-IOV network adapter, see Initializing a VF Miniport Driver.

DriverEntry Guidelines for PF Miniport Drivers

Article • 12/15/2021

This topic describes the guidelines for writing a **DriverEntry** function for the miniport driver of the PCI Express (PCIe) Physical Function (PF). The PF is a component of a network adapter that supports single root I/O virtualization (SR-IOV).

Note These guidelines only apply to PF miniport drivers. For initialization guidelines for the miniport driver of a PCIe Virtual Function (VF) of the adapter, see Initializing a VF Miniport Driver.

The SR-IOV network adapter must implement a hardware bridge that forwards network traffic over the physical port on the adapter and internal virtual ports (VPorts). This bridge is known as the *NIC switch*. For more information, see NIC Switches.

If the PF miniport driver supports the static creation of the NIC switch on the SR-IOV network adapter, it may need to allocate switch resources when the functional device object (FDO) is created for the network adapter in the device stack. In this case, the driver must allocate those resources before NDIS calls *MiniportInitializeEx*. To do this, the driver must register optional Plug-and-Play (PnP) handlers so that it can participate in the process when the adapter's FDO is added or removed from the device stack.

The miniport driver must provide a *MiniportSetOptions* function to register these PnP handler functions. To do this, the driver follows these steps from the context of the call to its **DriverEntry** function:

1. The miniport driver initializes an **NDIS_MINIPORT_DRIVER_CHARACTERISTICS** structure with the entry points of the *MiniportXxx* functions. In particular, the driver sets the **SetOptionsHandler** member to the entry point of the driver's *MiniportSetOptions* function.

2. The miniport driver calls the **NdisMRegisterMiniportDriver** function to register its entry points. From the context of this call, NDIS calls the driver's *MiniportSetOptions* function

3. When NDIS calls *MiniportSetOptions*, the miniport driver calls the **NdisSetOptionalHandlers** function and specifies an **NDIS_MINIPORT_PNP_CHARACTERISTICS** structure. This structure defines the entry points for the *MiniportAddDevice*, *MiniportRemoveDevice*, *MiniportStartDevice*, and *MiniportFilterResourceRequirements* functions. NDIS calls

these handler functions when it handles PnP I/O request packets (IRPs) issued by the PCI bus driver.

If the PF miniport driver must allocate additional software resources for the NIC switch before NDIS calls the driver's *MiniportInitializeEx* function, the driver must register a *MiniportAddDevice* function. When NDIS calls the *MiniportAddDevice* function, the PF miniport driver can call **NdisReadConfiguration** to read the NIC switch configuration keyword settings from the registry. For more information about these keywords, see Standardized INF Keywords for SR-IOV.

For more information about guidelines for the *MiniportAddDevice* function, see *MiniportAddDevice* Guidelines for PF Miniport Drivers.

For more information on how NIC switches are created, see Creating a NIC Switch.

MiniportAddDevice Guidelines for PF Miniport Drivers

Article • 12/15/2021

This topic describes the guidelines for writing a *MiniportAddDevice* function for the miniport driver of the PCI Express (PCIe) Physical Function (PF). The PF is a component of a network adapter that supports single root I/O virtualization (SR-IOV).

Note These guidelines only apply to PF miniport drivers. For initialization guidelines for the miniport driver of a PCIe Virtual Function (VF) of the adapter, see Initializing a VF Miniport Driver.

The Plug and Play (PnP) Manager calls the NDIS *AddDevice* function to create the functional device object (FDO) for the network adapter. If the PF miniport driver registered a *MiniportAddDevice* entry point when it called **NdisMRegisterMiniportDriver**, NDIS calls the driver's *MiniportAddDevice* function.

When *MiniportAddDevice* is called, the PF miniport driver can allocate additional software resources for the SR-IOV and the network interface card (NIC) switch. Typically, these are resources that must be allocated before NDIS calls the driver's *MiniportInitializeEx* function.

The driver can do the following within the context of the call to *MiniportAddDevice*:

- The PF miniport driver can call **NdisReadConfiguration** to read the SR-IOV and NIC switch configuration settings from the registry. These configuration settings are defined through the standardized SR-IOV keywords. For more information about these keywords, see Standardized INF Keywords for SR-IOV.

- Based on these configuration settings, the PF miniport driver allocates the additional software resources for the SR-IOV network adapter.

Note The actual allocation of hardware resources and the enabling of SR-IOV in the PCI configuration space must only be done within the context of the call to *MiniportInitializeEx*. Because the network adapter's memory-mapped I/O (MMIO) space is uninitialized when *MiniportAddDevice* is called, the miniport driver must not read or write to the adapter until *MiniportInitializeEx* is called.

MiniportInitializeEx Guidelines for PF Miniport Drivers

Article • 12/15/2021

This topic describes the guidelines for writing a *MiniportInitializeEx* function for the miniport driver of the PCI Express (PCIe) Physical Function (PF). The PF is a component of a network adapter that supports single root I/O virtualization (SR-IOV).

Note These guidelines only apply to PF miniport drivers. For initialization guidelines for the miniport driver of a PCIe Virtual Function (VF) of the adapter, see Initializing a VF Miniport Driver.

The PF miniport driver follows the same steps as any NDIS miniport driver when its *MiniportInitializeEx* function. For more information about these steps, see Initializing a Miniport Driver.

In addition to these steps, the PF miniport driver must follow these additional steps when NDIS calls the driver's *MiniportInitializeEx* function:

1. The PF miniport driver calls the **NdisGetHypervisorInfo** function to verify that it is running in the Hyper-V parent partition. This function returns an **NDIS_HYPERVISOR_INFO** structure that defines the partition type. If the partition type is reported as **NdisHypervisorPartitionMsHvParent**, the miniport driver is running in the Hyper-V parent partition that is attached to the PF on the adapter.

   Note If the partition type is reported as **NdisHypervisorPartitionMsHvChild**, the miniport driver is running in the Hyper-V child partition that is attached to a VF on the adapter. In this case, the miniport driver must not initialize as a PF driver. If possible, the driver must initialize as a VF driver as described in Initializing a VF Miniport Driver.

2. The PF miniport driver must read the SR-IOV standardized keywords to determine whether SR-IOV is enabled and obtain the NIC switch configuration settings. For more information about these keywords, see Standardized INF Keywords for SR-IOV.

   Note If the PF miniport driver registered an entry point to a *MiniportSetOptions* function, the driver may have previously obtained these settings from the registry when NDIS called *MiniportSetOptions*.

3. If the network adapter supports SR-IOV, virtual machine queue (VMQ), or RSS, the miniport driver must determine which feature to enable on the network adapter.

For more information on how to determine this, see Handling SR-IOV, VMQ, and RSS Standardized INF Keywords.

4. Along with RSS and VMQ hardware capabilities (if supported), the miniport driver must report its full set of hardware SR-IOV capabilities. These capabilities must be advertised regardless of the SR-IOV standardized keyword settings in the registry.

   If SR-IOV is enabled on the network adapter, the miniport driver must also report the currentlyenabled SR-IOV settings on the adapter.

   For more information on reporting the SR-IOV capabilities, see Determining SR-IOV Capabilities.

5. The miniport driver must report its full set of hardware NIC switch capabilities. These capabilities must be advertised regardless of the SR-IOV standardized keyword settings in the registry.

   If SR-IOV is enabled on the network adapter, the miniport driver must also report the currentlyenabled NIC switch settings on the adapter.

   For more information on reporting the NIC switch capabilities, see Determining NIC Switch Capabilities.

6. The miniport driver must report its full set of hardware receive filtering capabilities. These capabilities must be advertised regardless of the SR-IOV standardized keyword settings in the registry.

   If SR-IOV is enabled on the network adapter, the miniport driver must also report the currentlyenabled receive filtering settings on the adapter.

   For more information on reporting the receive filtering capabilities, see Determining Receive Filtering Capabilities.

7. If the miniport driver supports static NIC switch creation, it must do the following in the context of the call to *MiniportInitializeEx*.

   - The driver configures the adapter hardware based on the NIC switch standardized keyword settings. Based on these settings, the driver allocates the necessary hardware and software resources for the NIC switch.

   - The miniport driver calls **NdisMEnableVirtualization** to enable SR-IOV and set the number of VFs on the network adapter. This function configures the SR-IOV Extended Capability in the adapter's PCI configuration space. If this function returns NDIS_STATUS_SUCCESS, SR-IOV is enabled and the VFs are exposed over the PCIe interface.

For more information, see Static Creation of a NIC Switch.

Note If the miniport driver supports dynamic NIC switch creation, it creates the switch and enables virtualization when it handles an object identifier (OID) method request of OID_NIC_SWITCH_CREATE_SWITCH. For more information, see Dynamic Creation of a NIC Switch.

Managing NIC Switches

Article • 12/15/2021

This section describes the requirements and guidelines for managing the NIC switch of a network adapter that supports single root I/O virtualization (SR-IOV). The miniport driver for the PCI Express (PCIe) Physical Function (PF) of the SR-IOV network adapter manages the NIC switch on the adapter.

This section includes the following topics:

Creating a NIC Switch

Deleting a NIC Switch

Enumerating NIC Switches on a Network Adapter

Querying the Parameters of a NIC Switch

Setting the Parameters of a NIC Switch

For more information on NIC switches for SR-IOV network adapters, see NIC Switches.

Note Only the PF miniport driver can configure the network adapter's hardware resources, such as the NIC switch. The miniport driver for a PCIe Virtual Function (VF) on the SR-IOV network adapter cannot directly access most of the adapter's hardware resources. For more information, see Writing SR-IOV VF Miniport Drivers.

Creating a NIC Switch

Article • 12/15/2021

This section describes the requirements and guidelines for creating the NIC switch of a network adapter that supports single root I/O virtualization (SR-IOV). The miniport driver for the PCI Express (PCIe) Physical Function (PF) of the SR-IOV network adapter creates and configures the NIC switch on the adapter.

A NIC switch can be created through one of the following methods:

Static Creation
The NIC switch is statically created on the SR-IOV network adapter by using a set of switch parameters defined by registry settings. After the NIC switch is created, its parameters cannot be changed while the driver is running.

The PF miniport driver statically creates the NIC switch within the context of the call to the driver's *MiniportInitializeEx* function. However, the NIC switch cannot be used until NDIS issues an object identifier (OID) method request of OID_NIC_SWITCH_CREATE_SWITCH. Even though the NIC switch was previously created, the PF miniport driver enabled the NIC switch for use when it handled this OID request.

For more information about this method, see Static Creation of a NIC Switch.

Dynamic Creation
The NIC switch is dynamically created on the SR-IOV network adapter through the OID method request of OID_NIC_SWITCH_CREATE_SWITCH. This OID request defines the NIC switch parameters through the **NDIS_NIC_SWITCH_PARAMETERS** structure. These parameters are also based on the staticallydefined registry settings but could change dynamically while the miniport driver is running.

For more information about this method, see Dynamic Creation of a NIC Switch.

For more information on how to handle the OID_NIC_SWITCH_CREATE_SWITCH request, see Handling the OID_NIC_SWITCH_CREATE_SWITCH Request.

For more information on NIC switches for SR-IOV network adapters, see NIC Switches.

Note The miniport driver for a PCIe Virtual Function (VF) on the SR-IOV network adapter does not create or configure the network adapter's hardware resources, such as the NIC switch. For more information, see Writing SR-IOV VF Miniport Drivers.

Static Creation of a NIC Switch

Article • 12/15/2021

A network adapter that supports single root I/O virtualization (SR-IOV) must be able to create a NIC switch. For some adapters, the NIC switch can be created statically within the context of the call to *MiniportInitializeEx*.

Only the miniport driver for the PCI Express (PCIe) Physical Function (PF) of the SR-IOV adapter can create a NIC switch on the adapter.

Note Starting with Windows Server 2012, the SR-IOV interface supports only one NIC switch on the network adapter. This switch is known as the *default NIC switch*, and is referenced by the NDIS_DEFAULT_SWITCH_ID identifier.

The parameters for the default NIC switch are defined through standardized keyword settings in the registry. For more information on these keywords, see Standardized INF Keywords for SR-IOV.

The PF miniport driver statically creates the NIC switch when NDIS calls the driver's *MiniportInitializeEx* function. Typically, the driver creates and configures the NIC switch as part of its initialization sequence before it enables SR-IOV on the network adapter.

The PF miniport driver follows these steps when it statically creates the NIC switch and enables SR-IOV on the network adapter in the context of the call to *MiniportInitializeEx*:

1. The PF miniport driver must read the SR-IOV standardized keywords to determine whether SR-IOV is enabled and obtain the NIC switch configuration parameters.

   Note If the PF miniport driver registered an entry point to a *MiniportSetOptions* function, the driver may have previously obtained these parameters from the registry when NDIS called *MiniportSetOptions*.

2. If SR-IOV is enabled, the PF miniport driver configures the network adapter with the NIC switch parameters from the registry. The driver must verify that the parameters are valid before it configures the network adapter. For example, the miniport driver must verify that the maximum number of PCIe Virtual Functions (VFs) assigned to the NIC switch does not exceed the number of VFs supported by the network adapter.

3. The miniport driver calls **NdisMEnableVirtualization** to enable SR-IOV and set the number of VFs on the network adapter. This function configures the SR-IOV Extended Capability in adapter's PCI configuration space. If this function returns

NDIS_STATUS_SUCCESS, SR-IOV is enabled and the VFs are exposed over the PCIe interface.

Note If the PF miniport driver statically creates the NIC switch, the switch cannot be used until NDIS issues an object identifier (OID) method request of OID_NIC_SWITCH_CREATE_SWITCH. If the PF miniport driver statically created the NIC switch, it must verify that the switch parameters are specified in the OID request. These parameters, as contained within the **NDIS_NIC_SWITCH_PARAMETERS** structure associated with the OID request, must be identical to the parameters the driver used to create the switch.

For more information on how to handle the OID_NIC_SWITCH_CREATE_SWITCH request, see Handling the OID_NIC_SWITCH_CREATE_SWITCH Request.

For more information on the initialization sequence and requirements for PF miniport drivers, see Initializing a PF Miniport Driver.

Dynamic Creation of a NIC Switch

Article • 12/15/2021

A network adapter that supports single root I/O virtualization (SR-IOV) must be able to create a NIC switch. For some adapters, the NIC switch can be created dynamically after the miniport driver has returned from the call to *MiniportInitializeEx*.

Only the miniport driver for the PCI Express (PCIe) Physical Function (PF) of the SR-IOV adapter can create a NIC switch on the adapter.

Note Starting with Windows Server 2012, the SR-IOV interface supports only one NIC switch on the network adapter. This switch is known as the *default NIC switch*, and is referenced by the NDIS_DEFAULT_SWITCH_ID identifier.

NDIS issues an object identifier (OID) method request of OID_NIC_SWITCH_CREATE_SWITCH to create a NIC switch on the SR-IOV network adapter. The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to the **NDIS_NIC_SWITCH_PARAMETERS** structure that contains the parameters for the switch.

If the PF miniport driver supports dynamic NIC switch creation, it must follow these steps when it handles this OID request:

1. The PF miniport driver allocates the necessary hardware and software resources for the NIC switch based on these parameters. The driver also configures the network adapter with these parameters.

   Note PF miniport drivers that support dynamic NIC switch creation do not have to read the switch parameters through the standardized SR-IOV keyword settings in the registry. NDIS reads these keywords to initialize the **NDIS_NIC_SWITCH_PARAMETERS** structure before it issues the OID_NIC_SWITCH_CREATE_SWITCH request. For more information on these keywords, see Standardized INF Keywords for SR-IOV.

2. The miniport driver calls **NdisMEnableVirtualization** to enable SR-IOV and set the number of VFs on the network adapter. This function configures the SR-IOV Extended Capability in adapter's PCI configuration space. If this function returns NDIS_STATUS_SUCCESS, SR-IOV is enabled and the VFs are exposed over the PCIe interface.

For more information on how to handle the OID_NIC_SWITCH_CREATE_SWITCH request, see Handling the OID_NIC_SWITCH_CREATE_SWITCH Request.

Handling the OID_NIC_SWITCH_CREATE_SWITCH Request

Article • 12/15/2021

NDIS issues an object identifier (OID) method request of OID_NIC_SWITCH_CREATE_SWITCH to do the following:

- Enable a NIC switch on a network adapter that was statically created by the miniport driver for the PCI Express (PCIe) Physical Function (PF). The PF is a hardware component of the network adapter that supports single root I/O virtualization (SR-IOV).

  A NIC switch is statically created by the PF miniport driver from within the context to the call to *MiniportInitializeEx*. The driver allocates the resources and creates the switch based on parameters read from registry settings.

- Dynamically create a NIC switch on a network adapter.

  If the PF miniport driver does not support static NIC switch creation, the miniport driver allocates the resources and creates the switch based on parameters that are specified in the OID request.

The PF miniport driver advertises its support of the SR-IOV interface when NDIS calls the driver's *MiniportInitializeEx* function. If the PF miniport driver supports SR-IOV, NDIS reads the NIC switch configuration from the registry. Before NDIS issues an OID method request of OID_NIC_SWITCH_CREATE_SWITCH to the PF miniport driver, NDIS formats an **NDIS_NIC_SWITCH_PARAMETERS** structure with the registry information in the following way:

- NDIS sets the **SwitchType** member to the type of the NIC switch.

  Starting with Windows Server 2012, Windows only supports a switch type of **NdisNicSwitchTypeExternal**. An external switch specifies that the virtual ports (VPorts) that are connected to this type of switch can access the external network through the physical port on the network adapter.

  For more information about the NIC switch, see SR-IOV Architecture.

- NDIS sets the **SwitchId** member to an identifier value for the NIC switch. The switch identifier is an integer between zero and the number of switches that the network adapter supports. An NDIS_DEFAULT_SWITCH_ID value indicates the default NIC switch.

Note Starting with Windows Server 2012, the SR-IOV interface only supports the default NIC switch on the network adapter.

- NDIS sets the **NumVFs** member that specifies the number of PCIe Virtual Function (VFs) that can be allocated on the NIC switch.

When it receives the OID method request of OID_NIC_SWITCH_CREATE_SWITCH, the PF miniport driver must do the following:

1. If the PF miniport driver supports static switch creation and configuration, it creates the NIC switch when NDIS calls *MiniportInitializeEx*. When the driver handles this OID request, it must verify the configuration parameters in the **NDIS_NIC_SWITCH_PARAMETERS** structure. The parameters must be the same as those used by the driver to create the switch during the call to *MiniportInitializeEx*. If this is not true, the driver must fail the OID request.

   For more information, see Static Creation of a NIC Switch.

2. If the PF miniport driver supports dynamic switch creation and configuration, the driver must validate the configuration values of the **NDIS_NIC_SWITCH_PARAMETERS** structure and create the NIC switch based on these values.

   For more information, see Dynamic Creation of a NIC Switch.

3. The PF miniport driver must allocate the necessary hardware and software resources for the default VPort on the NIC switch.

   Note The default VPort is always created through an OID request of OID_NIC_SWITCH_CREATE_SWITCH and deleted through an OID request of OID_NIC_SWITCH_DELETE_SWITCH. OID requests of OID_NIC_SWITCH_CREATE_VPORT and OID_NIC_SWITCH_DELETE_VPORT are used for the creation and deletion of nondefault VPorts on the NIC switch.

4. The PF miniport driver that supports dynamic switch creation and configuration must enable SR-IOV virtualization on the switch by calling **NdisMEnableVirtualization**. This call configures the **NumVFs** member and the **VF Enable** bit in the SR-IOV Extended Capability structure of the adapter's PCI Express (PCIe) configuration space.

   For more information about the SR-IOV configuration space, see the PCI-SIG Single Root I/O Virtualization and Sharing 1.1 ↗ specification.

Note If the PF miniport driver supports static switch creation, it enables SR-IOV virtualization after it creates the switch when *MiniportInitializeEx* is called.

If the PF miniport driver successfully completesthe OID method request of OID_NIC_SWITCH_CREATE_SWITCH, it allows the following to occur:

- VFs can be allocated on the NIC switch through OID method requests of OID_NIC_SWITCH_ALLOCATE_VF.
- Nondefault VPorts can be created on the NIC switch through OID method requests of OID_NIC_SWITCH_CREATE_VPORT.

  The miniport driver is responsible for managing its pool of nondefault VPorts. The driver specifies the number of nondefault VPorts in its pool through the **NumVPorts** member of the **NDIS_NIC_SWITCH_INFO** structure. The driver returns this structure through an OID query request of OID_NIC_SWITCH_ENUM_SWITCHES.

  Note The network adapter must always create a default VPort from its pool for the PF.

Deleting a NIC Switch

Article • 12/15/2021

A network adapter that supports single root I/O virtualization (SR-IOV) must be able to delete a NIC switch. Only the miniport driver for the PCI Express (PCIe) Physical Function (PF) of the SR-IOV adapter can delete a NIC switch on the adapter.

Note Starting with NDIS 6.30 in Windows Server 2012, the SR-IOV interface supports only one NIC switch on the network adapter. This switch is known as the *default NIC switch*, and is referenced by the NDIS_DEFAULT_SWITCH_ID identifier.

Prior to halting the PF miniport driver, NDIS deletes the NIC switch by issuing an object identifier (OID) set request of OID_NIC_SWITCH_DELETE_SWITCH. The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_NIC_SWITCH_DELETE_SWITCH_PARAMETERS** structure that specifies the identifier of the switch being deleted.

NDIS enforces the following policies before issuing the OID set request of OID_NIC_SWITCH_DELETE_SWITCH to the PF miniport driver:

- NDIS guarantees that all receive filters have been cleared from the default and nondefault virtual ports (VPorts) on the NIC switch. Receive filters are cleared through an OID set request of OID_RECEIVE_FILTER_CLEAR_FILTER.

- NDIS guarantees that all nondefault virtual ports (VPorts) created on the switch have been previously deleted. VPorts are deleted through an OID set request of OID_NIC_SWITCH_DELETE_VPORT.

- NDIS guarantees that all the resources for PCIe Virtual Functions (VFs) attached to the NIC switch have been previously freed. VFs are freed through an OID set request of OID_NIC_SWITCH_FREE_VF.

When it receives the OID method request of OID_NIC_SWITCH_DELETE_SWITCH, the PF miniport driver must do the following:

1. If the PF miniport driver supports static creation and configuration of NIC switches, it must free the software resources associated with the specified NIC switch. However, the driver can only free the hardware resources for the NIC switch when *MiniportHaltEx* is called.

   For more information about static NIC switch creation, see Static Creation of a NIC Switch.

2. If the PF miniport driver supports the dynamic creation and configuration of NIC switches, it must free the hardware and software resources associated with the specified NIC switch.

   For more information about dynamic NIC switch creation, see Dynamic Creation of a NIC Switch.

3. If the PF miniport driver supports the dynamic creation of NIC switches and all the NIC switches have been deleted on the network adapter, the driver must disable virtualization on the adapter by calling **NdisMEnableVirtualization**. To disable virtualization, the network adapter must set the *EnableVirtualization* parameter to FALSE and the *NumVFs* parameter to zero.

   NdisMEnableVirtualization clears the **NumVFs** member and the **VF Enable** bit in the SR-IOV Extended Capability structure in the PCIe configuration space of the network adapter's PF.

   Note If the PF miniport driver supports static creation and configuration of NIC switches, it must only call **NdisMEnableVirtualization** when *MiniportHaltEx* is called.

Enumerating NIC Switches on a Network Adapter

Article • 12/15/2021

An overlying driver or user application can obtain a list of all NIC switches that have been created on a network adapter that supports single root I/O virtualization (SR-IOV). The driver or application issues an object identifier (OID) query request of OID_NIC_SWITCH_ENUM_SWITCHES to obtain this list.

After a successful return from this OID request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to a buffer that contains the following:

- An **NDIS_NIC_SWITCH_INFO_ARRAY** structure that defines the number of elements within the array.

- An array of **NDIS_NIC_SWITCH_INFO** structures. Each of these structures contains the information about a single NIC switch created on the network adapter.

  Note If the network adapter has no NIC switches, the driver sets the **NumElements** member of the **NDIS_NIC_SWITCH_INFO_ARRAY** structure to zero and no **NDIS_NIC_SWITCH_INFO** structures are returned.

Note Starting with Windows Server 2012, the SR-IOV interface supports only one NIC switch on the network adapter. This switch is known as the *default NIC switch*, and is referenced by the NDIS_DEFAULT_SWITCH_ID identifier.

NDIS handles the OID_NIC_SWITCH_ENUM_SWITCHES request for miniport drivers. NDIS returns the information from an internal cache of the data that it maintains from the following sources:

- The standardized SR-IOV keyword settings in the registry. For more information on these keywords, see Standardized INF Keywords for SR-IOV.

- OID requests of OID_NIC_SWITCH_CREATE_SWITCH and OID_NIC_SWITCH_PARAMETERS.

Note NDIS also provides the enumeration of the switches in the **NicSwitchArray** member in the **NDIS_BIND_PARAMETERS** and **NDIS_FILTER_ATTACH_PARAMETERS** structures. Therefore, the overlying protocol and filter drivers do not have to issue OID_NIC_SWITCH_ENUM_SWITCHES requests to obtain this information.

Querying the Parameters of a NIC Switch

Article • 12/15/2021

An overlying driver or user application can obtain the parameters for a NIC switch that has been created on a network adapter that supports single root I/O virtualization (SR-IOV). The driver or application issues an object identifier (OID) method request of OID_NIC_SWITCH_PARAMETERS to obtain these parameters.

Before the overlying driver or user application issues this OID method request, it must initialize an **NDIS_NIC_SWITCH_PARAMETERS** structure. The driver or application must set the **SwitchId** member to the identifier of the NIC switch for which parameters are to be returned.

Note Starting with Windows Server 2012, the SR-IOV interface supports only one NIC switch on the network adapter. This switch is known as the *default NIC switch*, and is referenced by the NDIS_DEFAULT_SWITCH_ID identifier.

After a successful return from this OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_NIC_SWITCH_PARAMETERS** structure. This structure contains the parameters for the specified switch.

NDIS handles the OID_NIC_SWITCH_PARAMETERS request for miniport drivers. NDIS returns the information from an internal cache of the data that it maintains from the following sources:

- The standardized SR-IOV keyword settings in the registry. For more information on these keywords, see Standardized INF Keywords for SR-IOV.

- OID requests of OID_NIC_SWITCH_CREATE_SWITCH and OID_NIC_SWITCH_PARAMETERS.

Setting the Parameters of a NIC Switch

Article • 12/15/2021

An overlying driver can change the parameters for a NIC switch that has been created on a network adapter that supports single root I/O virtualization (SR-IOV). The driver issues an object identifier (OID) set request of OID_NIC_SWITCH_PARAMETERS to change these parameters. Only the miniport driver for the PCI Express (PCIe) Physical Function (PF) of the SR-IOV adapter handles this OID set request.

Before the overlying driver issues this OID set request, it must initialize an **NDIS_NIC_SWITCH_PARAMETERS** structure with the parameters to be changed on the NIC switch. The driver then initializes an **NDIS_OID_REQUEST** structure for the OID request, and sets the **InformationBuffer** member to a pointer of the **NDIS_NIC_SWITCH_PARAMETERS** structure.

Only a limited subset of configuration parameters for a NIC switch can be changed. The overlying driver specifies the parameter to change by setting the following members of the **NDIS_NIC_SWITCH_PARAMETERS** structure:

- The **SwitchId** member is set to the identifier of the NIC switch whose parameters will be changed.

  Note Starting with Windows Server 2012, the SR-IOV interface supports only one NIC switch on the network adapter. This switch is known as the *default NIC switch*. The **SwitchId** member must be set to NDIS_DEFAULT_SWITCH_ID.

- The appropriate NDIS_NIC_SWITCH_PARAMETERS_*Xxx*_CHANGED flags are set in the **Flags** member. Members of the **NDIS_NIC_SWITCH_PARAMETERS** structure can only be changed if a corresponding NDIS_NIC_SWITCH_PARAMETERS_*Xxx*_CHANGED flag is defined in Ntddndis.h.

- The members of the **NDIS_NIC_SWITCH_PARAMETERS** structure, which correspond to the NDIS_NIC_SWITCH_PARAMETERS_*Xxx*_CHANGED flags set in the **Flags** member, are set with the NIC switch configuration parameters that are to be changed.

  Note Starting with Windows Server 2012, only the **SwitchName** member of the **NDIS_NIC_SWITCH_PARAMETERS** structure can be changed through an OID set request of OID_NIC_SWITCH_PARAMETERS.

The PF miniport driver must follow these guidelines when it receives the OID set request of OID_NIC_SWITCH_PARAMETERS

- If the PF miniport driver can apply the changes without requiring a reinitialization of the network adapter, the driver applies the changes to the hardware and completes the OID request with NDIS_STATUS_SUCCESS.

  If this status code is returned, NDIS updates the NIC switch configuration information in the registry.

- If the PF miniport driver requires a reinitialization of the network adapter to apply the changes, the driver completes the OID request with NDIS_STATUS_REINIT_REQUIRED.

  If this status code is returned, NDIS also updates the NIC switch configuration information in the registry. However, the overlying driver that issued the OID set request must reinitialize the network adapter so that the changes can take effect.

  Note PF miniport drivers that support static NIC creation and configuration can return NDIS_STATUS_REINIT_REQUIRED to make sure that the adapter is reinitialized for the new parameters to take effect.

- If the PF miniport driver cannot apply the changes requested in the OID, it must fail the OID and return the appropriate NDIS_STATUS_*Xxx* code.

  In this case, NDIS does not update the NIC switch configuration information in the registry.

Managing Virtual Ports

Article • 12/15/2021

This section describes the requirements and guidelines for managing the virtual ports (VPorts) on a NIC switch. This switch is provided by a network adapter that supports single root I/O virtualization (SR-IOV).

This section includes the following topics:

Creating a Virtual Port

Deleting a Virtual Port

Enumerating Virtual Ports on a Network Adapter

Querying the Parameters of a Virtual Port

Setting the Parameters of a Virtual Port

Managing the Receive Filters for a Virtual Port

Symmetric and Asymmetric Assignment of Queue Pairs

Packet Flow over a Virtual Port

Nondefault Virtual Ports and VMQ

For more information on VPorts, see Virtual Ports (VPorts).

For more information on NIC switches, see NIC Switches.

Note Only the miniport driver for the PCI Express (PCIe) Physical Function (PF) can configure the network adapter's hardware resources, such as the VPorts. The miniport driver for the PCIe Virtual Function (VF) cannot directly access most of the SR-IOV adapter's hardware resources. For more information, see Writing SR-IOV VF Miniport Drivers.

Creating a Virtual Port

Article • 12/15/2021

A virtual port (VPort) is a data object that represents an internal port on the NIC switch of a network adapter that supports single root I/O virtualization (SR-IOV). Each NIC switch has the following ports for network connectivity:

- One external physical port for connectivity to the external physical network.
- One or more internal VPorts which are connected to the PCI Express (PCIe) Physical Function (PF) or Virtual Functions (VFs).

  The PF is attached to the Hyper-V parent partition and is exposed as a virtual network adapter in the management operating system that runs in that partition.

  A VF is attached to the Hyper-V child partition and is exposed as a virtual network adapter in the guest operating system that runs in that partition.

There are two types of VPorts:

Default VPort
The default VPort provides network connectivity to the networking components that run in the management operating system. The default VPort has an identifier of NDIS_DEFAULT_VPORT_ID.

When the PF miniport driver creates and configures the default NIC switch, the driver implicitly creates the default VPort and attaches it to the PF. The default VPort cannot be attached to a VF.

The default VPort is always in an activated state and cannot be explicitly deleted. The PF miniport driver implicitly deletes the default VPort only when it deletes the default NIC switch.

For more information on how to create a NIC switch and the default VPort on the switch, see Creating a NIC Switch.

Nondefault VPort
Nondefault VPorts are not created implicitly when the NIC switch is created. An overlying driver, such as the virtualization stack, explicitly creates these ports by issuing OID method requests of OID_NIC_SWITCH_CREATE_VPORT. Nondefault VPorts may be attached to the PF or to a VF, and can only be created after the NIC switch has been created.

A nondefault VPort that is attached to a VF provides network connectivity to the networking components that run in the guest operating system. After it is created and attached to the VF, the nondefault VPort is in an activated state.

A nondefault VPort that is attached to the PF provides additional network offload capabilities to the networking components that run in the management operating system. For example, nondefault VPorts on the PF could be used to provide offload capabilities similar to the virtual machine queue (VMQ) interface.

Note Nondefault VPorts can only be created after the NIC switch has been created.

An overlying driver issues an object identifier (OID) method request of OID_NIC_SWITCH_CREATE_VPORT to create a nondefault VPort on a specified NIC switch. This OID request also attaches the created VPort to the network adapter's PF or a previously allocated VF.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to the**NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure. After a successful return from the OID_NIC_SWITCH_CREATE_VPORT request, the **VPortId** member of the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure has a VPort identifier that is unique across the VPorts on the NIC switch.

The overlying driver initializes the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure with the configuration information about the nondefault VPort to be created. The configuration information includes the PCIe function to which the nondefault VPort is attached and the number of queue pairs for the nondefault VPort.

When it initializes the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure, the overlying driver must do the following:

- The **SwitchId** member must be set to the identifier of a NIC switch that was previously created on the network adapter through an OID method request of OID_NIC_SWITCH_CREATE_SWITCH.

  Note Starting with Windows Server 2012, the SR-IOV interface supports only one NIC switch on the network adapter. This switch is known as the *default NIC switch*. When creating a nondefault VPort, the overlying driver must set the **SwitchId** member to the NDIS_DEFAULT_SWITCH_ID identifier.

- The **VPortId** member must be set to NDIS_DEFAULT_VPORT_ID.

- The **AttachedFunctionId** member must be set to the identifier of the VF or PF on which the nondefault VPort is to be attached.

A value of NDIS_PF_FUNCTION_ID specifies the PF. Otherwise, the value must be set to the identifier of a VF whose resources were previously allocated through an OID method request of OID_NIC_SWITCH_ALLOCATE_VF.

Note The attachment of a nondefault VPort to a VF or PF cannot be changed after the nondefault VPort has been created.

The overlying driver can also specify the number of queue pairs assigned to the VPort. A queue pair is a transmit and receive queue on the network adapter that is assigned to the VPort. If the network adapter supports asymmetric queue pairs for nondefault VPorts, the overlying driver may specify a different number of queue pairs for each VPort that the driver creates. For more information, see Symmetric and Asymmetric Assignment of Queue Pairs.

The overlying driver calls **NdisOidRequest** to issue the OID_NIC_SWITCH_CREATE_VPORT request to the underlying PF miniport driver. Before NDIS forwards the OID method request to the miniport driver, it does the following:

1. NDIS validates the parameters within the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure. If the parameters are in error, NDIS fails the OID method request and does not pass the request to the PF miniport driver.

2. NDIS assigns an identifier for the nondefault VPort within the range from one to (**NumVPorts**– 1), where **NumVPorts** is the number of VPorts that the miniport driver has configured on the network adapter. The driver specifies this number in the **NumVPorts** member of the **NDIS_NIC_SWITCH_INFO** structure. The driver returns this structure through an OID query request of OID_NIC_SWITCH_ENUM_SWITCHES.

   Note A VPort identifier of NDIS_DEFAULT_VPORT_ID is reserved for the default VPort that is attached to the PF on the default NIC switch.

The assigned VPort identifier uniquely identifies the nondefault VPort on the NIC switch of the network adapter.

3. NDIS sets the **VPortId** member of the NDIS_NIC_SWITCH_VPORT_PARAMETERS structure with the assigned VPort identifier.

When the PF miniport driver is issued the OID request, the driver allocates the hardware and software resources associated with the specified nondefault VPort. After all of the resources are successfully allocated, the PF miniport driver completes the OID successfully by returning NDIS_STATUS_SUCCESS from *MiniportOidRequest*.

If the OID_NIC_SWITCH_CREATE_VPORT request is completed successfully, the PF miniport driver and the overlying driver must retain the **VPortId** value of the nondefault VPort for successive operations. The **VPortId** value is used during these operations:

- NDIS and the overlying drivers use the **VPortId** value to identify the nondefault VPort in successive OID requests related to this VPort, such as OID_NIC_SWITCH_VPORT_PARAMETERS and OID_NIC_SWITCH_DELETE_VPORT.

- During send operations, NDIS specifies the **VPortId** value to identify the VPort from which a packet was sent. This value is specified within the out-of-band (OOB) **NDIS_NET_BUFFER_LIST_FILTERING_INFO** data of the NET_BUFFER_LIST structure.

- During receive operations, the PF miniport driver specifies the **VPortId** value to which a packet is to be forwarded. This value is also specified in the OOB **NDIS_NET_BUFFER_LIST_FILTERING_INFO** data of the NET_BUFFER_LIST structure.

The following points apply to the creation of nondefault VPorts:

- Receive filters for media access control (MAC) and virtual LAN (VLAN) identifiers are configured on the VPort after it has been created. Overlying drivers dynamically set these receive filters by issuing OID method requests of OID_RECEIVE_FILTER_SET_FILTER. Receive filters can also be moved from one VPort to another through OID set requests of OID_RECEIVE_FILTER_MOVE_FILTER.

- A nondefault VPort attached to the VF is in an activated state when it is created. The VPort cannot be deactivated if it is attached to the VF.

  A nondefault VPort attached to the PF is in a deactivated state when it is created. An overlying driver, such as the Hyper-V extensible switch module, explicitly activates the nondefault VPort attached to the PF after the VPort has been created successfully. This is done by issuing an OID method request of OID_NIC_SWITCH_VPORT_PARAMETERS to the PF miniport driver.

  When the overlying driver issues this OID request, it passes an **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure with the **VPortState** member set to **NdisNicSwitchVPortStateActivated**.

  After a nondefault VPort is in an activated state, the PF miniport driver can allocate shared memory for the VPort by calling **NdisAllocateSharedMemory**. The driver must set the **VPortId** member in the **NDIS_SHARED_MEMORY_PARAMETERS** structure to the VPort's identifier value.

Note When a nondefault VPort is in an activated state, it is only set to a deactivated state when it is deleted through an OID set request of OID_NIC_SWITCH_DELETE_VPORT.

Deleting a Virtual Port

Article • 12/15/2021

An overlying driver issues an object identifier (OID) set request of OID_NIC_SWITCH_DELETE_VPORT to delete a nondefault virtual port (VPort) on a network adapter's NIC switch. The overlying driver can only delete a VPort that it has previously created by issuing an OID method request of OID_NIC_SWITCH_CREATE_VPORT.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to the **NDIS_NIC_SWITCH_DELETE_VPORT_PARAMETERS** structure.

An overlying driver, such as the virtualization stack, can delete a nondefault VPort that it has previously created. The overlying driver creates a VPort by issuing an OID method request of OID_NIC_SWITCH_CREATE_VPORT.

Before it issues the OID set request of OID_NIC_SWITCH_DELETE_VPORT, the overlying driver must do the following:

- The overlying drivers must clear or move all receive filters that the driver previously set on the VPort before deleting the VPort. Receive filters are set through OID requests of OID_RECEIVE_FILTER_SET_FILTER and are moved through OID requests of OID_RECEIVE_FILTER_MOVE_FILTER.

- The overlying driver sets the **VPortId** member of the **NDIS_NIC_SWITCH_DELETE_VPORT_PARAMETERS** structure to the identifier of the nondefault VPort to be deleted.

  Note The overlying driver must not set the **VPortId** member to **NDIS_DEFAULT_PORT_NUMBER**. This VPort identifier is reserved for the default VPort that is attached to the PCI Express (PCIe) Physical Function (PF) on the network adapter. The default VPort always exists and is not deleted explicitly though an OID set request of OID_NIC_SWITCH_DELETE_VPORT.

The overlying driver calls **NdisOidRequest** to issue the OID_NIC_SWITCH_DELETE_VPORT request to the underlying PF miniport driver. When the miniport driver receives the OID_NIC_SWITCH_DELETE_VPORT request, the driver must do the following:

- The driver must free the hardware and software resources that were allocated for the specified VPort.

- The driver must detach the specified VPort from the PF or a PCIe Virtual Function (VF).

If the VPort is attached to a VF, the virtualization stack ensures that the VF miniport driver that runs in the guest operating system has been previously paused and halted. As a result, all previouslyindicated receive packets from the VPort should have been returned to the VF miniport driver.

If the VPort is attached to the PF, the PF miniport driver must stop any additional DMA to the shared memory associated with the VPort. The PF miniport driver must make sure that all previouslyindicated receive packets from the VPort are returned to the miniport. The PF miniport driver must not make any additional receive indications to NDIS that specify the VPort's identifier in the packet's **NET_BUFFER_LIST** structure. After all of the indicated receive packets from the VPort are returned to the PF miniport driver, it must free the shared memory associated with the VPort by calling **NdisFreeSharedMemory**.

The following points apply to the deletion of VPorts:

- The overlying protocol driver must delete all nondefault VPorts that it created before it calls **NdisCloseAdapterEx**.

- The overlying filter driver must delete all nondefault VPorts that it created within its *FilterDetach* function.

- Before NDIS issues a set request of OID_NIC_SWITCH_DELETE_SWITCH to delete a NIC switch on the network adapter, it guarantees that all nondefault VPorts are deleted from that switch.

- Only nondefault VPorts can be explicitly deleted through OID requests of OID_NIC_SWITCH_DELETE_SWITCH. The default VPort is implicitly deleted when the PF miniport driver deletes the default NIC switch. For more information, see Deleting a NIC Switch.

Enumerating Virtual Ports on a Network Adapter

Article • 12/15/2021

An overlying driver or user application can obtain a list of all virtual ports (VPorts) on a NIC switch of a network adapter that supports single root I/O virtualization (SR-IOV). The driver or application issues an object identifier (OID) method request of OID_NIC_SWITCH_ENUM_VPORTS to obtain this list.

After a successful return from this OID query request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to a buffer that contains the following:

- An **NDIS_NIC_SWITCH_VPORT_INFO_ARRAY** structure that defines the number of elements within the array.

- An array of **NDIS_NIC_SWITCH_VPORT_INFO** structures. Each of these structures contains information about a VPort on the network adapter's NIC switch.

  Note If no VPorts have been created on the network adapter, the driver sets the **NumElements** member of the **NDIS_NIC_SWITCH_VPORT_INFO_ARRAY** structure to zero and no **NDIS_NIC_SWITCH_VPORT_INFO** structures are returned.

Before the overlying driver or user application issues the OID_NIC_SWITCH_ENUM_VPORTS request, it must initialize an **NDIS_NIC_SWITCH_VPORT_INFO_ARRAY** structure that is passed along with the request. The driver or application must follow these guidelines when initializing the **NDIS_NIC_SWITCH_VPORT_INFO_ARRAY** structure:

- If the NDIS_NIC_SWITCH_VPORT_INFO_ARRAY_ENUM_ON_SPECIFIC_SWITCH flag is set in the **Flags** member, information is returned for all VPorts created on a specified NIC switch. The NIC switch is specified by the **SwitchId** member of that structure.

  Note Starting with Windows Server 2012, the SR-IOV interface supports only one NIC switch on the network adapter. This switch is known as the *default NIC switch*, and is referenced by the NDIS_DEFAULT_SWITCH_ID identifier. Regardless of the flags that are set in the **Flags** member, the **SwitchId** member must be set to NDIS_DEFAULT_SWITCH_ID.

- If the NDIS_NIC_SWITCH_VPORT_INFO_ARRAY_ENUM_ON_SPECIFIC_FUNCTION flag is set in the **Flags** member, information is returned for all VPorts attached to a specified PCI Express (PCIe) Physical Function (PF) or Virtual Function (VF) on the network adapter. The PF or VF is specified by the **AttachedFunctionId** member of that structure.

  If the **AttachedFunctionId** member is set to NDIS_PF_FUNCTION_ID, information is returned for all VPorts. This includes the default VPort that is attached to the PF. If the **AttachedFunctionId** member is set to a valid VF identifier, information is returned for all VPorts attached to the specified VF.

  Note Starting with Windows Server 2012, only one nondefault VPort can be attached to a VF. However, multiple VPorts (including the default VPort) can be attached to the PF.

- If the **Flags** member is set to zero, information is returned for all VPorts attached to the PF or VF on the network adapter. In this case, the values of the **SwitchId** and **AttachedFunctionId** are ignored.

NDIS handles the OID_NIC_SWITCH_ENUM_VPORTS request for miniport drivers. NDIS returns the information from an internal cache of the data that it maintains from inspecting the following sources:

- OID method requests of OID_NIC_SWITCH_CREATE_VPORT.

- OID set requests of OID_NIC_SWITCH_VPORT_PARAMETERS.

Querying the Parameters of a Virtual Port

Article • 12/15/2021

An overlying driver can obtain the parameters for a virtual port (VPort) on a NIC switch on a network adapter that supports single root I/O virtualization (SR-IOV). The driver issues an object identifier (OID) method request of OID_NIC_SWITCH_VPORT_PARAMETERS to obtain these parameters.

Before the overlying driver issues this OID method request, it must initialize an **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure. The driver must set the members of this structure in the following way:

- The **SwitchId** member must be set to the identifier of the NIC switch for which parameters are to be returned.

  Note Starting with Windows Server 2012, the SR-IOV interface supports only one NIC switch on the network adapter. This switch is known as the *default NIC switch*. The **SwitchId** member must be set to NDIS_DEFAULT_SWITCH_ID.

- The **VPortId** member must be set to the identifier associated with the VPort. The overlying driver obtains the VPort identifier through one of the following ways:

  - From a previous OID method request of OID_NIC_SWITCH_CREATE_VPORT.

  - From a previous OID method request of OID_NIC_SWITCH_ENUM_VPORTS.

After a successful return from this OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure. This structure contains the parameters for the specified VPort.

NDIS handles the OID_NIC_SWITCH_VPORT_PARAMETERS request for miniport drivers. NDIS returns the information from an internal cache of the data that it maintains from inspecting the following sources:

- OID method requests of OID_NIC_SWITCH_CREATE_VPORT.

- OID set requests of OID_NIC_SWITCH_VPORT_PARAMETERS.

Setting the Parameters of a Virtual Port

Article • 12/15/2021

An overlying driver can change the parameters for a virtual port (VPort) on a NIC switch on a network adapter that supports single root I/O virtualization (SR-IOV). The driver issues an object identifier (OID) set request of OID_NIC_SWITCH_VPORT_PARAMETERS to change these parameters.

Before the overlying driver issues this OID set request, it must initialize an **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure with the parameters to be changed on the VPort. The driver then initializes an **NDIS_OID_REQUEST** structure for the OID request, and sets the **InformationBuffer** member to a pointer to the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure.

Only a limited subset of configuration parameters for a VPort can be changed. The overlying driver specifies the parameter to change by setting the following members of the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure:

- The **SwitchId** member must be set to the identifier of the NIC switch for which parameters are to be returned.

  Note Starting with Windows Server 2012, the SR-IOV interface supports only one NIC switch on the network adapter. This switch is known as the *default NIC switch*. The **SwitchId** member must be set to NDIS_DEFAULT_SWITCH_ID.

- The **VPortId** member must be set to the identifier associated with the VPort. The overlying driver obtains the VPort identifier through one of the following ways:

  - From a previous OID method request of OID_NIC_SWITCH_CREATE_VPORT.

  - From a previous OID method request of OID_NIC_SWITCH_ENUM_VPORTS.

- The appropriate NDIS_NIC_SWITCH_VPORT_PARAMS_*Xxx*_CHANGED flags must be set in the **Flags** member. Members of the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure can only be changed if a corresponding NDIS_NIC_SWITCH_VPORT_PARAMS_*Xxx*_CHANGED flag is defined in Ntddndis.h.

- The members of the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure, which correspond to the NDIS_NIC_SWITCH_VPORT_PARAMS_*Xxx*_CHANGED flags set in the **Flags** member, are set with the VPort configuration parameters that are to be changed.

Starting with Windows Server 2012, only the following members of the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure can be changed through an OID set request of OID_NIC_SWITCH_VPORT_PARAMETERS:

PortName
This member contains a user-friendly description of the VPort.

InterruptModeration
This member specifies the interrupt moderation setting of the VPort.

ProcessorAffinity
This member specifies the group number and a bitmap of the CPUs that this VPort can be associated with.

The overlying driver must follow these guidelines for changing the **ProcessorAffinity** member for a VPort:

- This member is valid only for the VPorts attached to the PF. This field is not valid for nondefault VPorts that are attached to a VF.

- For nondefault VPorts that are attached to the PF, at least one processor must be specified when the VPort is created. The processor affinity associated with the nondefault VPort can be changed after VPort creation.

  Note Nondefault VPorts are created through OID method requests of OID_NIC_SWITCH_CREATE_VPORT.

VPortState
This member specifies the current state of the VPort.

The overlying driver must follow these guidelines for changing the **VPortState** member for a VPort:

- For a nondefault VPort that is attached to a VF, the **VPortState** member must always be set to **NdisNicSwitchVPortStateActivated**.

- For a nondefault VPort that is attached to the PF, the **VPortState** member must be set to **NdisNicSwitchVPortStateDeactivated** when the VPort is created. The PF VPort is activated only after an OID set request of OID_NIC_SWITCH_VPORT_PARAMETERS is issued by the overlying drivers to change the VPortState to an activated state.

  When the nondefault VPort is activated, the PF miniport driver can allocate resources for the VPort, such as shared memory that is allocated through **NdisAllocateSharedMemory**. The PF miniport driver may allocate resources for

VPort any time after it is activated until the driver deletes the VPort through an OID set request of OID_NIC_SWITCH_DELETE_VPORT.

- The default VPort is always in an activated state. The value of the **VPortState** member must always be set to **NdisNicSwitchVPortStateActivated** for the default VPort.

- When a VPort is in an activated state, it cannot be deactivated. A PF miniport driver can receive and transmit packets from a VPort only if it is in an activated state and the corresponding MAC filters are set on the VPort. However, after the VPort is deleted through an OID set request of OID_NIC_SWITCH_DELETE_VPORT, the driver must free the resources that were allocated for the VPort. The driver must also cancel all pending transmit or receive operations for packets on the VPort.

After the PF miniport driver receives the OID set request of OID_NIC_SWITCH_VPORT_PARAMETERS, the driver configures the hardware with the configuration parameters. The driver can only change those configuration parameters identified by NDIS_NIC_SWITCH_VPORT_PARAMETERS_*Xxx*_CHANGED flags in the **Flags** member of the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure.

Managing the Receive Filters for a Virtual Port

Article • 12/15/2021

Receive filters can be set, cleared, moved, and enumerated on a virtual port (VPort) after the VPort has been created on the NIC switch.

This section includes the following topics:

Setting a Receive Filter on a Virtual Port

Clearing a Receive Filter on a Virtual Port

Moving a Receive Filter to a Virtual Port

Enumerating Receive Filters on a Virtual Port

For information about how to create VPorts, see Creating a Virtual Port.

Setting a Receive Filter on a Virtual Port

Article • 12/15/2021

After a virtual port (VPort) is created on the NIC switch of the network adapter, overlying drivers can set receive filters on the VPort. Only the driver that created the VPort can set a receive filter on that VPort

This topic contains the following information:

Setting a Receive Filter on a VPort

Using the NDIS_RECEIVE_FILTER_FIELD_MAC_HEADER_VLAN_UNTAGGED_OR_ZERO Flag

Using the Filter Identifier

Handling Receive Filters on a VPort

For more information on how to create a VPort, see Creating a Virtual Port.

Note Because the default VPort always exists and is never explicitly created, any overlying driver can set a receive filter on the default VPort. Overlying drivers do not own the default VPort. Therefore, all protocol drivers that are bound to a network adapter can use the default VPort. The default VPort has an identifier value of NDIS_DEFAULT_VPORT_ID.

Setting a Receive Filter on a VPort

To set and configure a filter on a VPort, an overlying driver issues an object identifier (OID) method request of OID_RECEIVE_FILTER_SET_FILTER. The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure initially contains a pointer to an **NDIS_RECEIVE_FILTER_PARAMETERS** structure.

Before the overlying driver issues this OID method request, it must initialize an **NDIS_RECEIVE_FILTER_PARAMETERS** structure. The driver must set the members of this structure in the following way:

- The **FilterType** member must be set to an **NDIS_RECEIVE_FILTER_TYPE** enumeration value.

  Note Starting with NDIS 6.30, only **NdisReceiveFilterTypeVMQueue** filter types are supported for the single root I/O virtualization (SR-IOV) interface.

- The **QueueId** member must be set to NDIS_DEFAULT_RECEIVE_QUEUE_ID.

- The **VPortId** member must be set to the identifier associated with the VPort. The overlying driver obtains the VPort identifier through one of the following ways:

  - From a previous OID method request of OID_NIC_SWITCH_CREATE_VPORT.

  - From a previous OID method request of OID_NIC_SWITCH_ENUM_VPORTS.

- The **FilterId** member must be set to NDIS_DEFAULT_RECEIVE_FILTER_ID.

  Note NDIS assigns a unique filter identifier in this member before it forwards the OID request to the miniport driver for processing.

- The **FieldParametersArrayOffset**, **FieldParametersArrayNumElements**, and **FieldParametersArrayElementSize** members of the **NDIS_RECEIVE_FILTER_PARAMETERS** structure must be set appropriately to define an array of **NDIS_RECEIVE_FILTER_FIELD_PARAMETERS** structures. Each **NDIS_RECEIVE_FILTER_FIELD_PARAMETERS** structure in the array sets the filter test criterion for one field in a network header.

  For the SR-IOV interface, the following field test parameters are defined:

  - The destination media access control (MAC) address in the packet equals the specified MAC address.

  - The virtual LAN (VLAN) identifier in the packet equals the specified VLAN identifier.

After a successful return from the OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_FILTER_PARAMETERS** structure with a new filter identifier.

Using the NDIS_RECEIVE_FILTER_FIELD_MAC_HEADER_VLAN_UNTAGGED_OR_ZERO Flag

The **Flags** member of the NDIS_RECEIVE_FILTER_FIELD_PARAMETERS structure specify actions to be performed for the receive filter. The following points apply to the **NDIS_RECEIVE_FILTER_FIELD_MAC_HEADER_VLAN_UNTAGGED_OR_ZERO** flag:

- If the **NDIS_RECEIVE_FILTER_FIELD_MAC_HEADER_VLAN_UNTAGGED_OR_ZERO** flag is set in the **Flags** member, the network adapter must indicate only received packets that match all of the following test criteria:

  - A packet with a matching MAC address.

  - A packet that has no VLAN tag or has a VLAN identifier of zero.

  If the **NDIS_RECEIVE_FILTER_FIELD_MAC_HEADER_VLAN_UNTAGGED_OR_ZERO** flag is set, the network adapter must not indicate packets that have a matching MAC address and a nonzero VLAN identifier.

  Note If the virtualization stack sets the MAC address filter and no VLAN identifier filter is configured by the OID_RECEIVE_FILTER_SET_FILTER set request, the switch also sets the **NDIS_RECEIVE_FILTER_FIELD_MAC_HEADER_VLAN_UNTAGGED_OR_ZERO** flag.

- Starting with NDIS 6.30, if the **NDIS_RECEIVE_FILTER_FIELD_MAC_HEADER_VLAN_UNTAGGED_OR_ZERO** flag is not set and there is no VLAN identifier filter configured by the OID_RECEIVE_FILTER_SET_FILTER method request, the miniport driver must do either one of the following:

  - The miniport driver must return a failed status for the OID_RECEIVE_FILTER_SET_FILTER method request.

  - The miniport driver must configure the network adapter to inspect and filter the specified MAC address fields. If a VLAN tag is present in the received packet, the network adapter must remove it from the packet data. The miniport driver must put the VLAN tag in an **NDIS_NET_BUFFER_LIST_8021Q_INFO** that is associated with the packet's **NET_BUFFER_LIST** structure.

- If a protocol driver sets a MAC address filter and a VLAN identifier filter with the OID_RECEIVE_FILTER_SET_FILTER method request, it does not set the **NDIS_RECEIVE_FILTER_FIELD_MAC_HEADER_VLAN_UNTAGGED_OR_ZERO** flag in either of the filter fields. In this case, the miniport driver should indicate packets that match both the specified MAC address and the VLAN identifier. That is, the miniport driver should not indicate packets with a matching MAC address that have a zero VLAN identifier or are untagged packets.

Using the Filter Identifier

NDIS assigns a filter identifier in the **FilterId** member of the **NDIS_RECEIVE_FILTER_PARAMETERS** structure and passes the OID method request of OID_RECEIVE_FILTER_SET_FILTER to the underlying miniport driver. Each filter that is set on a VPort has a unique filter identifier for a network adapter. That is, the filter identifiers are not duplicated on different queues that the network adapter manages.

The overlying driver must use the filter identifier that NDIS provides in later OID requests to change the filter parameters or to free a filter.

When NDIS receives an OID request to set a filter on a VPort, it verifies the filter parameters. After NDIS allocates the necessary resources and the filter identifier, it submits the OID request to the underlying network adapter. If the network adapter can successfully allocate the necessary software and hardware resources for the filter, it completes the OID request with **NDIS_STATUS_SUCCESS**.

The miniport driver must retain the filter identifiers for the allocated receive filters. NDIS uses the filter identifier of a filter with later OID requests to change the receive filter parameters or clear the receive filter. For more information about how to change parameters and clear filters, see Obtaining and Updating VM Queue Parameters and Clearing a VMQ Filter.

Handling Receive Filters on a VPort

The miniport driver programs the network adapter based on the filters in the following way:

- All field test parameters for a particular filter must match to assign a packet to the VPort.
- Multiple filters can be set on a VPort.
- Packets must be assigned to the VPort if any of the filters pass.

The network adapter combines the results from all the field tests with a logical **AND** operation. That is, if any field test that is included in the array of **NDIS_RECEIVE_FILTER_FIELD_PARAMETERS** structures fails, the network packet does not meet the specified filter criterion.

When a network adapter tests a received packet against these filter criteria, it must ignore all fields in the packet that have no test criteria that were specified.

Clearing a Receive Filter on a Virtual Port

Article • 12/15/2021

To clear a receive filter from a virtual port (VPort) on the NIC switch, an overlying driver issues an object identifier (OID) set request of OID_RECEIVE_FILTER_CLEAR_FILTER. The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_FILTER_CLEAR_PARAMETERS** structure.

Before the overlying driver issues the OID_RECEIVE_FILTER_CLEAR_FILTER request, it must initialize the **NDIS_RECEIVE_FILTER_CLEAR_PARAMETERS** structure and set the members in the following way:

- The **QueueId** member must be set to NDIS_DEFAULT_RECEIVE_QUEUE_ID.
- The **FilterId** member must be set to the filter identifier value that the driver obtained from an earlier OID_RECEIVE_FILTER_SET_FILTER method OID request. For more information about how to set receive filters, see Setting a Receive Filter on a Virtual Port.

An overlying driver must clear all of the filters that it set on a VPort before it frees the VPort. An overlying driver must also clear all of the filters that it set on the default VPort before it closes its binding to or detached from the network adapter.

Moving a Receive Filter to a Virtual Port

Article • 12/15/2021

The overlying driver issues an object identifier (OID) set request of OID_RECEIVE_FILTER_MOVE_FILTER to move a receive filter from a virtual port (VPort) to another VPort on the NIC switch. Typically, the overlying driver, such as the virtualization stack, issues this OID request if any of the following conditions are true:

- The virtualization stack sets a receive filter on the default VPort. This filter contains the media access control (MAC) address and virtual LAN (VLAN) parameters for the virtual machine (VM) network adapter that is exposed in the Hyper-V child partition. This allows packets to be forwarded between the VM network adapter and the underlying network adapter over the software-based synthetic data path.

  After resources for a PCI Express (PCIe) Virtual Function (VF) are allocated and the VF is attached to a child partition, the virtualization stack creates a nondefault VPort on the VF. The virtualization stack then moves the receive filter for the VM network adapter from the default VPort to the nondefault VPort attached to the VF. This allows packets to be forwarded between the VM network adapter and the underlying network adapter over the hardware-based VF data path.

  For more information about these data paths, see SR-IOV Data Paths.

- A VF has been detached from a Hyper-V child partition in which the guest operating system is still running. In this case, the overlying driver issues the OID set request to move the receive filter for the VM network adapter from the nondefault VPort to the default VPort attached to the PF. When this happens, packet traffic reverts to the synthetic data path.

To move a receive filter from one VPort to another VPort, an overlying driver issues an OID set request of OID_RECEIVE_FILTER_MOVE_FILTER. The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_FILTER_MOVE_FILTER_PARAMETERS** structure.

Before the overlying driver issues the OID_RECEIVE_FILTER_MOVE_FILTER request, it must initialize an **NDIS_RECEIVE_FILTER_MOVE_FILTER_PARAMETERS** structure in the following way:

- The driver sets the **FilterId** member to the identifier of the identifier of the previously allocated receive filter.

  Note The overlying driver obtained the filter identifier from an earlier OID method request of OID_RECEIVE_FILTER_SET_FILTER or OID_RECEIVE_FILTER_ENUM_FILTERS.

- The driver sets the **SourceQueueId** member to NDIS_DEFAULT_RECEIVE_QUEUE_ID.
- The driver sets the **SourceVPortId** member to the identifier of the VPort on which this filter was previously set.
- The driver sets the **DestQueueId** member to NDIS_DEFAULT_RECEIVE_QUEUE_ID.
- The driver sets the **DestVPortId** member to the identifier of the VPort on which this filter is to be moved.

NDIS validates the members of the NDIS_RECEIVE_FILTER_MOVE_FILTER_PARAMETERS before it forwards the OID set request to the PF miniport driver.

When the PF miniport driver handles this OID set request, it must move the receive filter in an atomic operation. The driver must be able to configure the network adapter to simultaneously remove the filter from a receive queue and VPort and set it on a different receive queue and VPort.

Enumerating Receive Filters on a Virtual Port

Article • 12/15/2021

After a virtual port (VPort) is created on the NIC switch of the network adapter, overlying drivers and user applications can do the following:

- Enumerate the parameters for receive filters on a VPort.

  For more information, see Enumerating Receive Filters.

- Query the parameters for a specific receive filter.

  For more information, see Querying a Specific Receive Filter.

For more information on how to create a VPort, see Creating a Virtual Port.

Enumerating Receive Filters

To obtain a list of all receive filters that are set on a virtual port (VPort) of a NIC switch, overlying drivers and applications can issue object identifier (OID) method requests of OID_RECEIVE_FILTER_ENUM_FILTERS.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure initially contains a pointer to an **NDIS_RECEIVE_FILTER_INFO_ARRAY** structure.

Before the overlying driver or user application issues this OID method request, it must initialize an **NDIS_RECEIVE_FILTER_INFO_ARRAY** structure and set the members of this structure in the following way:

- The **QueueId** member must be set to NDIS_DEFAULT_RECEIVE_QUEUE_ID.

- The **VPortId** member must be set to the identifier associated with the VPort. The overlying driver obtains the VPort identifier through one of the following ways:

  - From a previous OID method request of OID_NIC_SWITCH_CREATE_VPORT.

  - From a previous OID method request of OID_NIC_SWITCH_ENUM_VPORTS.

  Note This member is only valid if the driver or application sets the NDIS_RECEIVE_FILTER_INFO_ARRAY_VPORT_ID_SPECIFIED flag in the **Flags** member. If this flag is not set, receive filters are returned that were set on every VPort on the NIC switch.

After a successful return from the OID method request of OID_RECEIVE_FILTER_ENUM_FILTERS, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an updated **NDIS_RECEIVE_FILTER_INFO_ARRAY** structure that is followed by one or more **NDIS_RECEIVE_FILTER_INFO** structures. Each **NDIS_RECEIVE_FILTER_INFO** structure specifies the unique identifier for the receive filter that is set on the specified VPort.

Querying a Specific Receive Filter

Overlying drivers or applications can issue an OID method request of OID_RECEIVE_FILTER_PARAMETERS to obtain the parameters of a specific filter on a VPort.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure initially contains a pointer to an **NDIS_RECEIVE_FILTER_PARAMETERS** structure.

Before the overlying driver or user application issues this OID method request, it must initialize an **NDIS_RECEIVE_FILTER_PARAMETERS** structure and set the members of this structure in the following way:

- The **FilterId** member must be set to the nonzero identifier value of the filter whose parameters are to be returned.

  Note The overlying driver obtained the filter identifier from an earlier OID method request of OID_RECEIVE_FILTER_SET_FILTER or OID_RECEIVE_FILTER_ENUM_FILTERS. The application can obtain the filter identifier only from an earlier OID method request of OID_RECEIVE_FILTER_ENUM_FILTERS.

- The **QueueId** member must be set to NDIS_DEFAULT_RECEIVE_QUEUE_ID.

- The **VPortId** member must be set to the identifier associated with the VPort. The overlying driver obtains the VPort identifier through one of the following ways:

  - From a previous OID method request of OID_NIC_SWITCH_CREATE_VPORT.

  - From a previous OID method request of OID_NIC_SWITCH_ENUM_VPORTS.

NDIS handles the OID_RECEIVE_FILTER_ENUM_FILTERS and OID_RECEIVE_FILTER_PARAMETERS method OID requests for miniport drivers. NDIS obtained the information from an internal cache of the data that it received from the OID_RECEIVE_FILTER_SET_FILTER OID request.

Symmetric and Asymmetric Assignment of Queue Pairs

Article • 12/15/2021

A queue pair consists of a separate transmit and receive queue on the network adapter. Queue pairs are configured on a virtual port (VPort) when the VPort is created. Queue pairs associated with the default VPort are configured at the time of switch creation through an OID method request of OID_NIC_SWITCH_CREATE_SWITCH. One or more queue pairs are configured on a nondefault VPort through an OID method request of OID_NIC_SWITCH_CREATE_VPORT.

Each nondefault VPort can be configured to have a different number of queue pairs. This is known as *asymmetric allocation* of queue pairs. If the miniport driver does not support asymmetric allocations, each nondefault VPort is configured to have an equal number of queue pairs. This is known as *symmetric allocation* of queue pairs.

The miniport driver advertises its VPort and queue pair capabilities during *MiniportInitializeEx* by using an **NDIS_NIC_SWITCH_CAPABILITIES** structure. The driver advertises its support for asymmetric allocation of queue pairs by setting the NDIS_NIC_SWITCH_CAPS_ASYMMETRIC_QUEUE_PAIRS_FOR_NONDEFAULT_VPORT_SUPPORTED flag in the **NicSwitchCapabilities** member of this structure.

If the miniport driver supports asymmetric queue pair allocation, the virtualization stack configures each nondefault VPort with a different number of queue pairs. If the miniport driver supports symmetric queue pair allocation, the virtualization stack configures each VPort with the same number of queue pairs.

Note A miniport driver that supports either symmetric or asymmetric queue pair allocation on nondefault VPorts must support a different number of queue pairs to be allocated on the default VPort. The default VPort is always attached to the network adapter's PF.

The queue pair configuration is specified when the nondefault VPort is created or updated through OID requests of OID_NIC_SWITCH_CREATE_VPORT and OID_NIC_SWITCH_VPORT_PARAMETERS. The configuration parameters are specified in an **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure that is associated with both OID requests.

For example, assume that the miniport driver advertises the configuration for VPorts and queue pairs on the NIC switch by setting the following members of the **NDIS_NIC_SWITCH_CAPABILITIES** structure:

- **MaxNumQueuePairs** is set to 128.
- **MaxNumVPorts** is set to 64.
- **MaxNumQueuePairsPerNonDefaultPort** is set to 4.

If the miniport driver does not support asymmetric configuration of queue pairs on nondefault VPorts, the virtualization stack can specify the following queue pair configuration when VPorts are created:

- 63 nondefault VF VPorts with two queue pairs each, together with the default PF VPort with one queue pair.
- 31 nondefault VF VPorts with four queue pairs each, together with the default PF VPort with one queue pair.

Note Starting with Windows Server 2012, only one default VPort is supported and is always attached to the network adapter's PF.

Packet Flow over a Virtual Port

Article • 12/15/2021

The default NIC switch is a component of a network adapter that supports the single root I/O virtualization (SR-IOV) interface. The switch always attaches the default virtual port (VPort) to the PCI Express (PCIe) Physical Function (PF). The switch can attach one or more nondefault VPorts to the PF. For more information, see Creating a Virtual Port.

The following points apply to packets that are sent or received on a VPort that is attached to the PF:

- Packets sent or received over the default VPort are specified with a VPort identifier value of **DEFAULT_VPORT_ID**.

  Packets sent or received over nondefault VPorts are specified with the VPort identifier that was returned when the VPort was created through an OID method request of OID_NIC_SWITCH_CREATE_VPORT. When the driver handles this OID request, it obtains the VPort identifier from the **VPortId** member of the **NDIS_NIC_SWITCH_VPORT_PARAMETERS** structure that is associated with the OID request.

  Note When a VPort is deleted, it is possible for the miniport driver to receive an NBL that contains an invalid **VPortId** value. If this happens, the miniport should ignore the invalid VPort ID and use **DEFAULT_VPORT_ID** instead. The **VPortId** is found in the **NetBufferListFilteringInfo** portion of the NBL's OOB data, and is retrieved by using the **NET_BUFFER_LIST_RECEIVE_FILTER_VPORT_ID** macro.

- The PF miniport driver calls **NdisMIndicateReceiveNetBufferLists** to indicate packets received from a VPort. Before the PF miniport driver calls **NdisMIndicateReceiveNetBufferLists**, it must set the VPort identifier in the out-of-band (OOB) data in the **NET_BUFFER_LIST** structure for the packet. The driver does this by using the **NET_BUFFER_LIST_RECEIVE_FILTER_VPORT_ID** macro.

- The virtualization stack calls **NdisSendNetBufferLists** to transmit packets to a VPort. Before the virtualization stack calls **NdisSendNetBufferLists**, it sets the VPort identifier in the OOB data in the **NET_BUFFER_LIST** structure for the packet.

  The miniport driver obtains the VPort identifier by using the **NET_BUFFER_LIST_RECEIVE_FILTER_VPORT_ID** macro.

  The miniport driver must queue the transmit packet on the hardware transmit queue of the specified VPort.

Note The miniport driver for the PCIe Virtual Function (VF) does not set or query the VPort identifier in the OOB data of the **NET_BUFFER_LIST** structure for a packet. When the VF miniport driver sends a packet, it queues the packet on the hardware transmit queue for the single nondefault VPort that is attached to the VF.

Nondefault Virtual Ports and VMQ

Article • 07/07/2022

The default NIC switch is a component of a network adapter that supports the single root I/O virtualization (SR-IOV) interface. The switch always attaches the default virtual port (VPort) to the PCI Express (PCIe) Physical Function (PF). The switch can attach one or more nondefault VPorts to the PF. For more information, see Creating a Virtual Port.

The virtualization stack runs in the management operating system of the Hyper-V parent partition. This stack creates VPorts by issuing object identifier (OID) method requests of OID_NIC_SWITCH_CREATE_VPORT. However, the stack can create more VPorts than the number of active PCIe Virtual Functions (VFs) for which resources have been allocated through OID method requests of OID_NIC_SWITCH_ALLOCATE_VF.

If SR-IOV is enabled on a network adapter, full VMQ functionality must be disabled. However, nondefault VPorts that are attached to the PF and not attached to a VF can provide the same functionality as the virtual machine queue (VMQ) interface. The following points discuss how VPorts can provide hardware-accelerated data paths for packet transfer that is similar to VMQ:

- VMQ determines the target VM by media access control (MAC) filtering in hardware. This avoids the overhead of a determining the target VM in the virtualization stack.

  Starting with Windows Server 2012, the virtualization stack configures the receive filters on the VPort by issuing OID method requests of OID_RECEIVE_FILTER_SET_FILTER. For this OID request, the virtualization stack passes an **NDIS_RECEIVE_FILTER_PARAMETERS** structure that specifies the MAC address and virtual LAN (VLAN) identifier that is associated with the virtual network adapter. Similar to VMQ, it can configure multiple MAC address and VLAN ID pairs on the VPort. The virtualization stack also specifies the target VPort to which the receive filter will be set.

  The SR-IOV network adapter performs similar hardware filtering based on the filtering criteria that is specified through the OID_RECEIVE_FILTER_SET_FILTER request. When a packet is received on the hardware receive queue of a VPort, the miniport driver specifies the source VPort identifier in the out-of-band (OOB) data of a **NET_BUFFER_LIST** structure for the packet. Based on the VPort identifier, the virtualization stack determines the target VM and indicates the packets to the network stack that runs in the VM.

Similarly, the virtualization stack specifies the target VPort identifier in the OOB data of a **NET_BUFFER_LIST** structure for a transmit packet. When the driver handles the send request for the packet, it places the packet in the hardware transmit queue of the specified VPort.

The VPort identifier can be obtained from the packet's OOB data by using the **NET_BUFFER_LIST_RECEIVE_FILTER_VPORT_ID** macro.

For more information about this process, see Packet Flow over a Virtual Port.

For more information about the receive filtering requirements for an SR-IOV network adapter, see Determining Receive Filtering Capabilities.

- VMQ provides interrupt and DPC concurrency.

  Starting with NDIS 6.30 and Windows Server 2012, a VPort attached to the PF can be configured to have a specific CPU affinity. The virtualization stack configures the CPU affinity and interrupt moderation parameters for a VPort by using OID method requests of OID_NIC_SWITCH_CREATE_VPORT or OID_NIC_SWITCH_VPORT_PARAMETERS. By doing this, the virtualization stack configures interrupt-based parameters similar to VMQ for interrupt and DPC concurrency.

  For example, when the SR-IOV network adapter receives packets on a VPort that is configured to have a specific CPU affinity, the adapter generates the interrupts on the specified CPU. The miniport driver indicates the received packets to NDIS and the virtualization stack for that CPU.

The PF miniport driver advertises its SR-IOV capabilities within the context of the call to *MiniportInitializeEx*. The driver initializes an **NDIS_SRIOV_CAPABILITIES** structure with its capabilities and calls **NdisMSetMiniportAttributes** to register its capabilities. For more information, see Determining SR-IOV Capabilities.

The following members of the **NDIS_NIC_SWITCH_CAPABILITIES** structure affect the way that VPorts are allocated:

- **MaxNumVPorts**, which specifies the maximum number of VPorts that can be created on the network adapter.

- **MaxNumVFs**, which specifies the maximum number of VFs that can be allocated on the network adapter.

Starting with NDIS 6.30, when the miniport driver initializes the **NDIS_NIC_SWITCH_CAPABILITIES** structure, it can set the NDIS_NIC_SWITCH_CAPS_SINGLE_VPORT_POOL flag in the **NicSwitchCapabilities** member. This flag specifies that the nondefault VPorts can be created in a nonreserved manner from the VPort pool on the network adapter. This allows available nondefault VPorts to be created and assigned on an as-needed basis to the PF and allocated VFs. If the network adapter supports the VMQ interface, nondefault VPorts that are assigned to the PF can also be used for VM receive queues.

If the NDIS_NIC_SWITCH_CAPS_SINGLE_VPORT_POOL flag is set, available nondefault VPorts are created and assigned to the PF and allocated VFs. The maximum number of VPorts that can be created and assigned to the PF is the same value that the driver reports in the **MaxNumVPorts** member. The miniport driver must reserve one VPort to be used as the default VPort that is assigned to the PF. As a result, the maximum number of nondefault VPorts that can be assigned to the PF and used for VM receive queues is (**MaxNumVPorts**– 1).

> ⓘ Note
>
> If this flag is set, the creation and assignment of nondefault VPorts are not reserved for VF allocation. As a result, situations may occur where a VF may not be assigned a VPort if the pool has been exhausted of available VPorts.

If the NDIS_NIC_SWITCH_CAPS_SINGLE_VPORT_POOL flag is not set, the creation and assignment of nondefault VPorts is reserved for VF assignment. The maximum number of additional nondefault VPorts that can be created and assigned to the PF and used for VM receive queues is (**MaxNumVPorts**–**MaxNumVFs**).

For more information about VMQ, see Virtual Machine Queue (VMQ).

Managing Virtual Functions

Article • 12/15/2021

This section describes the requirements and guidelines for managing the PCI Express (PCIe) Virtual Functions (VFs) on a network adapter that supports single root I/O virtualization (SR-IOV).

This section includes the following topics:

Overview of Virtual Function Initialization and Teardown

Allocating Resources for a Virtual Function

Freeing Resources for a Virtual Function

Enumerating Virtual Functions on a Network Adapter

Querying the Parameters of a Virtual Function

Accessing the PCI Configuration Space of a Virtual Function

Setting the Power State of a Virtual Function

Resetting a Virtual Function

For more information on VFs for SR-IOV network adapters, see SR-IOV Virtual Functions (VFs).

Note Only the PF miniport driver can configure the network adapter's hardware resources, such as the VFs. The VF miniport driver cannot directly access most of the SR-IOV adapter's hardware resources. For more information, see Writing SR-IOV VF Miniport Drivers.

Overview of Virtual Function Initialization and Teardown

Article • 12/15/2021

This section provides an overview of the initialization and teardown sequence for PCI Express (PCIe) Virtual Functions (VFs). VFs are provided by a network adapter that supports single root I/O virtualization (SR-IOV).

This section includes the following topics:

Virtual Function Initialization Sequence

Virtual Function Teardown Sequence

For more information on VFs for SR-IOV network adapters, see SR-IOV Virtual Functions (VFs).

Note Only the PF miniport driver can configure the network adapter's hardware resources, such as the VFs. The VF miniport driver cannot directly access most of the SR-IOV adapter's hardware resources. For more information, see Writing SR-IOV VF Miniport Drivers.

Virtual Function Initialization Sequence

Article • 12/15/2021

A network adapter that supports single root I/O virtualization (SR-IOV) must be able to support the following hardware components:

- One PCI Express (PCIe) Physical Function (PF). The PF always exists on the network adapter and is attached to the Hyper-V parent partition.

  For more information on this hardware component, see SR-IOV Physical Function (PF).

- One or more PCIe Virtual Functions (VF). Each VF must be initialized and attached to a Hyper-V child partition before the networking components of the guest operating system can send or receive packets over the VF.

  For more information on this hardware component, see SR-IOV Virtual Functions (VFs).

The PF miniport driver, which runs in the management operating system of the Hyper-V parent partition, initializes and allocates resources for a VF on the SR-IOV network adapter. After NDIS calls the PF miniport driver's *MiniportInitializeEx* function, NDIS and the virtualization stack can issue object identifier (OID) requests to the PF miniport driver to do the following:

- Create a NIC switch on the network adapter. The NIC switch bridges network traffic between the VFs, PF, and the physical network port.

  For more information, see NIC Switches.

  Note Starting with Windows Server 2012, the SR-IOV interface supports only one NIC switch on the network adapter. This switch is known as the *default NIC switch*, and is referenced by the NDIS_DEFAULT_SWITCH_ID identifier.

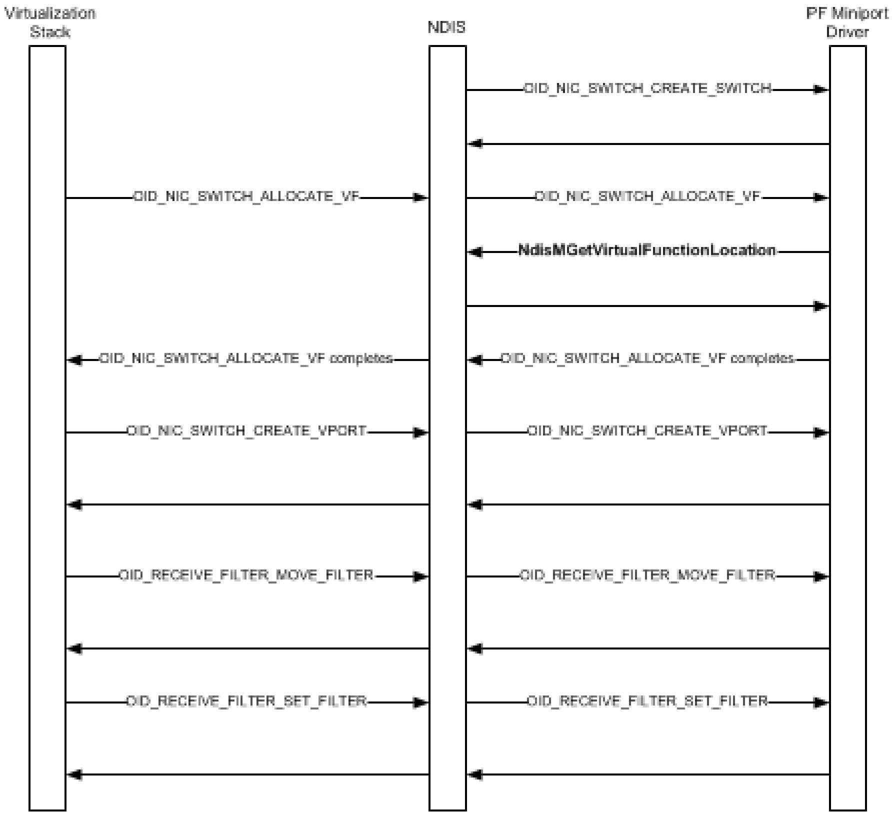
- Request the PF miniport driver to initialize and allocate resources for a VF on the network adapter.

  For more information, see SR-IOV Virtual Functions (VFs).

- Create a virtual port (VPort) on the NIC switch and attach it to the VF.

  For more information, see Virtual Ports (VPorts).

The following diagram shows the steps that are involved with VF initialization.



Virtualization Stack
NDIS
PF Miniport Driver
OID_NIC_SWITCH_CREATE_SWITCH
OID_NIC_SWITCH_ALLOCATE_VF
OID_NIC_SWITCH_ALLOCATE_VF
NdisMGetVirtualFunctionLocation
OID_NIC_SWITCH_ALLOCATE_VF completes
OID_NIC_SWITCH_ALLOCATE_VF completes
OID_NIC_SWITCH_CREATE_VPORT
OID_NIC_SWITCH_CREATE_VPORT
OID_RECEIVE_FILTER_MOVE_FILTER
OID_RECEIVE_FILTER_MOVE_FILTER
OID_RECEIVE_FILTER_SET_FILTER
OID_RECEIVE_FILTER_SET_FILTER

NDIS, the virtualization stack, and the PF miniport driver follow these steps during the VF initialization sequence:

1. NDIS reads the default switch configuration from the registry and issues an OID method request of OID_NIC_SWITCH_CREATE_SWITCH to provision the switch in the network adapter. The parameters that are passed in this OID request include information on how to configure important hardware resources such as VFs and VPorts. It also includes information on how to distribute the resources among the nondefault VPorts and the default VPort that are attached to the PF.

   After the OID has been successfully completed by the PF miniport driver, the NIC switch is ready to be used to create VPorts and allocate VFs on it.

   For more information on how to create a NIC switch, see Creating a NIC Switch.

2. A VF is treated as an offload mechanism for the virtual machine (VM) network adapter. This adapter is exposed in the guest operating system that runs in the Hyper-V child partition. By default, the networking components in the guest operating system send and receive packets over the software-based synthetic data path. However, if a child partition is enabled for VF offload, the virtualization stack issues OID requests to the PF miniport driver for the resource allocation and initialization of a VF. After the VF is attached to the child partition and a VPort on the NIC switch, the networking components send and receive packets over the VF data path. For more information about these data paths, see SR-IOV Data Paths.

If a Hyper-V child partition has been enabled for VF offload, the virtualization stack issues an OID method request of OID_NIC_SWITCH_ALLOCATE_VF to the PF miniport driver. The parameters that are passed in this OID request include the identifier of the NIC switch on which the VF is allocated. Other parameters include identifiers for the child partition to which the VF will be attached.

The PF miniport driver allocates the necessary hardware and software resources for the VF. The PF miniport driver also determines the PCIe Requestor Identifier (RID) for the VF by calling **NdisMGetVirtualFunctionLocation**. The RID is used for DMA and interrupt remapping when DMA requests and interrupts are generated by the VF.

The RID along with the VF identifier are returned by the PF miniport driver when it successfully completes the OID_NIC_SWITCH_ALLOCATE_VF request.

For more information about resource allocation for a VF, see Allocating Resources for a Virtual Function.

3. The virtualization stack creates a VPort on the NIC switch by issuing an OID method request of OID_NIC_SWITCH_CREATE_VPORT to the PF miniport driver. The parameters that are passed in this OID request include the identifier of the NIC switch on which the VPort is to be created. Other parameters include the identifier of the VF to which the VPort will be attached.

   Note The default VPort on the NIC switch always exists and is attached to the PF. Only a single nondefault VPort can be created and attached to a VF.

   Before NDIS forwards the OID request to the PF miniport driver, it allocates a valid VPort identifier that is unique over the network adapter.

   When the PF miniport driver handles the OID request, it allocates the hardware resources required for the VPort and retains the identifier for the VPort. This identifier is used in later OID requests and SR-IOV function calls.

   For more information about how to create a VPort, see Creating a Virtual Port.

4. The Hyper-V child partition may be started long before a VF and VPort are allocated. During this time, the networking components in the guest operating system send and receive packets over the synthetic data path. This involves packet traffic over the default VPort that is attached to the PF. To bridge traffic to the child partition, the virtualization stack configures the default VPort with the media access control (MAC) and virtual LAN (VLAN) filters for the VM network adapter of the child partition.

After resources for the VF and VPort are allocated, the virtualization stack issues an OID method request of OID_RECEIVE_FILTER_MOVE_FILTER to the PF miniport driver. This OID request moves the MAC and VLAN filters for the VM network adapter from the default VPort to the VPort that is attached to the VF. This causes packets that match these filters to be forwarded to the VF VPort over the VF data path.

Note Existing receive filters may be moved from the default VPort to the VF VPort by using OID_RECEIVE_FILTER_MOVE_FILTER. Also, new filters may be set on the VF VPort by using OID_RECEIVE_FILTER_SET_FILTER.

After the VF and the VPort are created successfully and the MAC filters have been set on the VPort, the virtualization stack notifies the Virtual PCI (VPCI) virtual service provider (VSP). This VSP runs in the management operating system of the Hyper-V parent partition. The notification informs the VPCI VSP that the VF that has been successfully allocated and attached to a child partition. The VPCI VSP sends messages over the virtual machine bus (VMBus) to the VPCI virtual service client (VSC) that runs in the guest operating system of the child partition. The VPCI VSC is a bus driver that exposes a PCI device for the VF network adapter.

After the VF network adapter is exposed, the PnP subsystem that runs in the guest operating system detects the adapter and loads the VF miniport driver. This driver registers with NDIS. After the VF miniport driver has been initialized and the appropriate packet filters are configured on the VF network adapter, the VF data path is fully operational. As a result, packet traffic in the guest operating system switched to this data path from the synthetic data path.

Virtual Function Teardown Sequence

Article • 12/15/2021

A network adapter that supports single root I/O virtualization (SR-IOV) must be able to support the following hardware components:

- One PCI Express (PCIe) Physical Function (PF). The PF always exists on the network adapter and is attached to the Hyper-V parent partition.

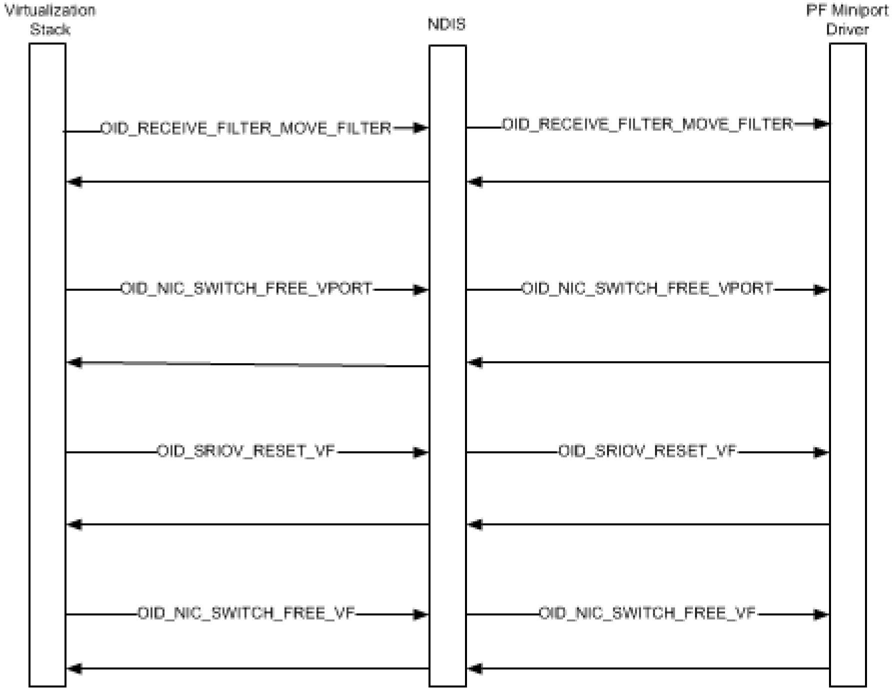
  For more information on this hardware component, see SR-IOV Physical Function (PF).

- One or more PCIe Virtual Functions (VF). Each VF must be initialized and attached to a Hyper-V child partition before the networking components of the guest operating system can send or receive packets over the VF.

  For more information on this hardware component, see SR-IOV Virtual Functions (VFs).

Before the VF is torn down and its resources freed, the virtualization stack notifies the Virtual PCI (VPCI) virtual service provider (VSP). This VSP runs in the management operating system of the Hyper-V parent partition. The notification informs the VPCI VSP that the VF will be torn down and detached from the child partition. The VPCI VSP sends messages over the virtual machine bus (VMBus) to the VPCI virtual service client (VSC) that runs in the guest operating system of the child partition. These messages request the VPCI VSC to gracefully remove the VF network adapter that was exposed when the VF was attached to the child partition. This causes the NetVSC to unbind from the VF miniport driver and the driver to be halted. At this point, packet traffic in the child partition migrates from the VF data path to the software-based synthetic data path. For more information about these data paths, see SR-IOV Data Paths.

After the failover to the synthetic data path is complete, the VF is torn down and its resources freed. The following diagram shows the steps that are involved with VF teardown.



NDIS, the virtualization stack, and the PF miniport driver follow these steps during the VF teardown sequence:

1. The virtualization stack moves the media access control (MAC) and virtual LAN (VLAN) filters for the virtual machine (VM) network adapter to the default virtual port (VPort) that is attached to the PF. The VM network adapter is exposed in the guest operating system of the child partition.

   Aftet the filters are moved to the default VPort, the synthetic data path is fully operational for network traffic to and from the networking components that run in the guest operating system. The PF miniport driver indicates received packets on the default PF VPort which uses the synthetic data path to indicate the packets to the guest operating system. Similarly, all transmitted packets from the guest operating system are routed through the synthetic data path and transmitted through the default PF VPort.

2. The virtualization stack deletes the VPort that is attached to the VF by issuing an object identifier (OID) set request of OID_NIC_SWITCH_DELETE_VPORT to the PF miniport driver. The miniport driver frees any hardware or software resources associated with the VPort and completes the OID request.

   For more information, see Deleting a Virtual Port.

3. The virtualization stack requests a PCIe function level reset (FLR) of the VF before its resources are deallocated. The stack does this by issuing an OID set request of OID_SRIOV_RESET_VFto the PF miniport driver. The FLR brings the VF on the SR-IOV network adapter into a quiescent state and clears any pending interrupt events for the VF.

4. After the VF has been reset, the virtualization stack requests a deallocation of the VF resources by issuing an OID set request of OID_NIC_SWITCH_FREE_VF to the PF miniport driver. This causes the miniport driver to free the hardware resources associated with the VF.

Allocating Resources for a Virtual Function

Article • 12/15/2021

A network adapter that supports single root I/O virtualization (SR-IOV) must be able to support the following hardware components:

- One PCI Express (PCIe) Physical Function (PF). The PF always exists on the network adapter and is attached to the Hyper-V parent partition.

  For more information on this hardware component, see SR-IOV Physical Function (PF).

- One or more PCIe Virtual Functions (VF). Each VF must be initialized and attached to a Hyper-V child partition before the networking components of the guest operating system can send or receive packets over the VF.

  For more information on this hardware component, see SR-IOV Virtual Functions (VFs).

The PF miniport driver, which runs in the management operating system of the Hyper-V parent partition, allocates resources for the PF and each VF on the SR-IOV network adapter. This driver allocates resources for the PF as it would for any network adapter. However, the driver allocates resources for each VF in the following way:

- The PF miniport driver allocates hardware resources for each VF when the driver creates the network interface card (NIC) on the network adapter. The driver completes the hardware resource allocation for the VFs by calling **NdisMEnableVirtualization**. For more information on this process, see Creating a NIC Switch.

- The PF miniport driver allocates software resources for a VF when the driver handles an object identifier (OID) method request of OID_NIC_SWITCH_ALLOCATE_VF. Even though the hardware resources have been allocated for a VF, it is considered nonoperational until the PF miniport driver successfully completes the OID_NIC_SWITCH_ALLOCATE_VF.

The overlying driver can request the allocation of software resources for a VF by issuing an OID method request of OID_NIC_SWITCH_ALLOCATE_VF. The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure for the OID request contains a pointer to an **NDIS_NIC_SWITCH_VF_PARAMETERS** structure.

After a successful return from the OID request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_NIC_SWITCH_VF_PARAMETERS** structure. This structure has an adapter-unique VF identifier and PCI Requestor Identifier (RID). These identifiers are used in the following ways:

- The overlying driver uses the VF identifier in actions related to the VF, such as the following:
    - Obtaining the current VF parameters through an OID method request of OID_NIC_SWITCH_VF_PARAMETERS.
    - Freeing previously allocated resources for the VF through an OID set request of OID_NIC_SWITCH_FREE_VF.
    - Issuing a PCI reset to the VF through an OID set request of OID_SRIOV_RESET_VF.
- The RID is used by the virtualization stack for remapping DMA and interrupts between the PF and VF. The RID also enables the hardware input/output memory management unit (IOMMU) to convert guest physical addresses to host physical addresses.

For more information on how the overlying driver issues OID_NIC_SWITCH_ALLOCATE_VF method requests, see Issuing OID_NIC_SWITCH_ALLOCATE_VF Requests.

For more information on how the PF miniport driver handles OID_NIC_SWITCH_ALLOCATE_VF method requests, see Handling OID_NIC_SWITCH_ALLOCATE_VF Requests.

Note After resources for a VF have been allocated through an OID method request of OID_NIC_SWITCH_ALLOCATE_VF, the resource parameters for the VF cannot be changed dynamically.

Issuing OID_NIC_SWITCH_ALLOCATE_VF Requests

Article • 12/15/2021

Before it issues the object identifier (OID) method request of OID_NIC_SWITCH_ALLOCATE_VF to the miniport driver for the PCI Express (PCIe) Physical Function (PF), the overlying driver formats an **NDIS_NIC_SWITCH_VF_PARAMETERS** structure. This structure contains the configuration parameters for the resources to be allocated for a PCIe Virtual Function (VF) on the network adapter. The overlying driver must set the members of this structure in the following way:

- The **SwitchId** member must be set to the identifier of a NIC switch that was previously created on the network adapter. A NIC switch is created through an OID method request of OID_NIC_SWITCH_CREATE_SWITCH.

  When it handles the OID method request of OID_NIC_SWITCH_ALLOCATE_VF, the miniport driver for the PCIe Physical Function (PF) allocates resources for the VF. If resources are allocated successfully, the PF miniport driver assigns the VF to the specified NIC switch.

  Note Starting with NDIS 6.30 in Windows Server 2012, the SR-IOV interface only supports the default NIC switch on the network adapter. The value of the **SwitchId** member must be set to NDIS_DEFAULT_SWITCH_ID.

  For more information on a NIC switch, see NIC Switches.

- The **VFId** member must be set to NDIS_INVALID_VF_FUNCTION_ID.

- The **RequestorId** member must be set to NDIS_INVALID_RID.

- The **VMFriendlyName** and **VMName** members must be set to the parameters of a Hyper-V child partition. The PF miniport driver uses these members only for informational purposes.

  Note The Hyper-V child partition is also known as a *virtual machine (VM)*.

  The VF is associated with the specified VM before the overlying driver issues the OID_NIC_SWITCH_CREATE_SWITCH request.

- The **NicName** member must be set to the identifier of the virtual machine (VM) network adapter. This virtual adapter is exposed in the guest operating system that runs in the VM. The PF miniport driver uses this member only for informational purposes.

When resources are allocated for the VF and it is attached to the child partition, a VF network adapter is exposed in the guest operating system. The VM network adapter teams with the VF network adapter for packet transfer over the hardware-based VF data path.

However, the VF could be detached from the child partition, such as during Live Migration. When this happens, the packet transfer occurs over the software-based synthetic data path. For more information on these data paths, see SR-IOV Data Paths.

- The **PermanentMacAddress** and **CurrentMacAddress** members must be set to the media access control (MAC) addresses for the virtual network adapter of the VF. These addresses are exposed to the network stack that runs in the guest operating system of the Hyper-V child partition.

The overlying driver issues the OID method request of OID_NIC_SWITCH_ALLOCATE_VF by following these steps:

1. The overlying driver initializes an **NDIS_OID_REQUEST** structure for the OID method request. The driver sets the **InformationBuffer** member to a pointer to an initialized **NDIS_NIC_SWITCH_VF_PARAMETERS** structure.

2. The overlying driver calls **NdisOidRequest** to issue the OID request to the underlying PF miniport driver.

   Note When the overlying driver calls **NdisOidRequest**, NDIS intercepts the OID request and verifies the VF parameters specified in the **NDIS_NIC_SWITCH_VF_PARAMETERS** structure. If the parameters are verified successfully, NDIS forwards the OID to the PF miniport driver. Otherwise, NDIS fails the OID request with NDIS_STATUS_INVALID_PARAMETER.

After an overlying driver requests resource allocation for a VF, that driver is the only component that can request the freeing of the resources for the same VF. The overlying driver must issue an OID set request of OID_NIC_SWITCH_FREE_VF to free the VF resources. Before the overlying driver can be halted, it must free the resources for each VF that was allocated by the driver's OID_NIC_SWITCH_ALLOCATE_VF request.

Handling OID_NIC_SWITCH_ALLOCATE_VF Requests

Article • 12/15/2021

When the miniport driver for the PCI Express (PCIe) Physical Function (PF) on the network adapter handles the object identifier (OID) method request of OID_NIC_SWITCH_ALLOCATE_VF, it does the following:

- The PF miniport driver allocates the software resources for a PCIe Virtual Function (VF) on the network adapter. These resources are configured based on the parameters that are specified in the **NDIS_NIC_SWITCH_VF_PARAMETERS** structure.

- The PF miniport driver assigns the VF to a NIC switch on the network adapter. The NIC switch is identified by the **SwitchId** member of the **NDIS_NIC_SWITCH_VF_PARAMETERS** structure.

  For more information on a NIC switch, see NIC Switches.

- The PF miniport driver updates the **VFId** member with a VF identifier. This identifier is a zero-based index and must be unique across all VFs that are allocated on the NIC switch by the PF miniport driver.

  The overlying driver uses the value of the **VFId** member in successive OID requests of OID_NIC_SWITCH_FREE_VF or OID_NIC_SWITCH_VF_PARAMETERS.

- The PF miniport driver updates the **RequestorId** member with a PCIe Requestor Identifier (RID) for the VF.

  The miniport driver calls **NdisMGetVirtualFunctionLocation** to get the RID information that corresponds to the VF. The driver then creates the RID by using the **NDIS_MAKE_RID** macro based on the information returned by the call to **NdisMGetVirtualFunctionLocation**.

  The RID is used by the virtualization stack for remapping DMA and interrupts between the PF and VF. The RID also enables the hardware input/output memory management unit (IOMMU) to convert guest physical addresses to host physical addresses.

- The PF miniport driver initializes and exposes the VF. This makes the VF ready for use by the virtualization stack.

If the PF miniport driver can successfully allocate the necessary software resources and initialize the VF, the driver completes the OID request with NDIS_STATUS_SUCCESS. The PF miniport driver must keep the VF IDs for each allocated VF. NDIS and the overlying drivers use the VF identifier in successive OID requests to the PF miniport driver for various actions, such as resetting or freeing the VF.

Note When resources for the VF are allocated, the VF is in an unattached state because a virtual port (VPort) is not attached to the VF. The overlying driver can issue an OID request of OID_NIC_SWITCH_CREATE_VPORT to create and attach a VPort to the VF. For more information, see Creating a Virtual Port.

Freeing Resources for a Virtual Function

Article • 12/15/2021

The overlying driver requests resource allocation for a PCI Express (PCIe) Virtual Function (VF) through object identifier (OID) method requests of OID_NIC_SWITCH_ALLOCATE_VF. After the VF resources are successfully allocated, the overlying driver frees the resources through an OID set request of OID_NIC_SWITCH_FREE_VF.

This section includes the following topics:

Issuing OID_NIC_SWITCH_FREE_VF Requests

Handling OID_NIC_SWITCH_FREE_VF Requests

Issuing OID_NIC_SWITCH_FREE_VF Requests

Article • 12/15/2021

An overlying driver issues an object identifier (OID) set request of OID_NIC_SWITCH_FREE_VF to free resources for a PCI Express (PCIe) Virtual Function (VF). These resources were previously allocated through an OID method request of OID_NIC_SWITCH_ALLOCATE_VF.

The overlying driver issues the OID_NIC_SWITCH_FREE_VF set request to the miniport driver for the PCIe Physical Function (PF). Before it issues this OID request, the overlying driver must do the following:

1. The overlying driver must make sure that the VF is not attached to any virtual port (VPort) on the NIC switch of the network adapter. The overlying driver must issue OID set requests of OID_NIC_SWITCH_DELETE_VPORT to delete all VPorts that are attached to the VF. For more information, see Deleting a Virtual Port.

2. The overlying driver initializes an **NDIS_NIC_SWITCH_FREE_VF_PARAMETERS** structure. The driver must set the **VFId** member to the VF identifier that was returned in the OID method request of OID_NIC_SWITCH_ALLOCATE_VF.

The overlying driver issues the OID set request of OID_NIC_SWITCH_FREE_VF by following these steps:

1. The overlying driver initializes an **NDIS_OID_REQUEST** structure for the OID method request. The driver sets the **InformationBuffer** member to a pointer to an initialized **NDIS_NIC_SWITCH_FREE_VF_PARAMETERS** structure.

2. The overlying driver calls **NdisOidRequest** to issue the OID request to the underlying PF miniport driver.

After an overlying driver requests resource allocation for a VF, that driver is the only component that can request the freeing of the resources for the same VF. The overlying driver must issue an OID set request of OID_NIC_SWITCH_FREE_VF to free the VF resources. Before the overlying driver can be halted, it must free the resources for each VF that was allocated by the driver's OID_NIC_SWITCH_ALLOCATE_VF request.

Note If an overlying driver issues an OID method request of OID_NIC_SWITCH_ALLOCATE_VF to allocate resources for a VF, that driver is the only component that can request the freeing of the resources for the same VF. The overlying driver must issue an OID set request of OID_NIC_SWITCH_FREE_VF to free the VF resources. Before the overlying driver can be halted, it must free the resources for each VF that was allocated by the driver's OID_NIC_SWITCH_ALLOCATE_VF request.

Handling OID_NIC_SWITCH_FREE_VF Requests

Article • 12/15/2021

When the miniport driver for the PCI Express (PCIe) Physical Function (PF) on the network adapter handles the object identifier (OID) set request of OID_NIC_SWITCH_FREE_VF, it does the following:

- The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure for the OID request contains a pointer to an **NDIS_NIC_SWITCH_FREE_VF_PARAMETERS** structure. The PF miniport driver must verify that the identifier of the PCIe Virtual Function (VF), which is specified by the **VFId** member, is valid. If this is not true, the driver must fail the OID set request by returning NDIS_STATUS_INVALID_PARAMETER.

- The PF miniport driver must verify that resources for the VF have been previously allocated through an OID method request of OID_NIC_SWITCH_ALLOCATE_VF. If this is not true, the driver must fail the OID set request by returning NDIS_STATUS_INVALID_PARAMETER.

- The PF miniport driver must verify that no virtual ports (VPorts) are currently attached to the VF. If this is not true, the driver must fail the set request by returning NDIS_STATUS_INVALID_PARAMETER.

- The PF miniport driver must free all software resources that were allocated for the specified VF.

- The PF miniport driver must detach the VF from the NIC switch on the network adapter.

If the PF miniport driver can successfully free the allocated software resources and detach the VF from the NIC switch, the driver completes the OID request with NDIS_STATUS_SUCCESS.

Note NDIS guarantees that all the VFs allocated on the miniport are freed before NDIS issues an OID set request of OID_NIC_SWITCH_DELETE_SWITCH to the PF miniport driver. When it handles this OID, the driver deletes a NIC switch on the network adapter.

Enumerating Virtual Functions on a Network Adapter

Article • 12/15/2021

An overlying driver or user application can obtain a list of all PCI Express (PCIe) Virtual Functions (VFs) on a network adapter that supports single root I/O virtualization (SR-IOV). The driver or application issues an object identifier (OID) method request of OID_NIC_SWITCH_ENUM_VFS to obtain this list.

Before the driver or application issues the OID request, it must initialize an **NDIS_NIC_SWITCH_VF_INFO_ARRAY** structure that is passed along with the request. The driver or application must follow these guidelines when initializing the **NDIS_NIC_SWITCH_VF_INFO_ARRAY** structure:

- If the NDIS_NIC_SWITCH_VF_INFO_ARRAY_ENUM_ON_SPECIFIC_SWITCH flag is set in the **Flags** member, the overlying driver or application must set the **SwitchId** member to the identifier of a NIC switch on the SR-IOV network adapter. By setting these members in this manner, VF information is returned only for the specified NIC switch on the SR-IOV network adapter.

  Note The overlying driver and user-mode application can obtain the NIC switch identifiers by issuing an OID query request of OID_NIC_SWITCH_ENUM_SWITCHES.

- If the **Flags** member is set to zero, the driver or application must set the **SwitchId** member to zero. By setting these members in this manner, VF information is returned for all NIC switches on the SR-IOV network adapter.

  Note Starting with Windows Server 2012, Windows supports only the default NIC switch on the network adapter. Regardless of the flags set in the **Flags** member, the **SwitchId** member must be set to NDIS_DEFAULT_SWITCH_ID.

After a successful return from this OID query request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to a buffer that contains the following:

- An **NDIS_NIC_SWITCH_VF_INFO_ARRAY** structure that defines the number of elements within the array.
- An array of **NDIS_NIC_SWITCH_VF_INFO** structures. Each of these structures contains information about a single VF on a NIC switch of the network adapter. A VF is attached to a NIC switch through OID method requests of OID_NIC_SWITCH_ALLOCATE_VF.

> **Note** If no VFs are attached to a NIC switch on the network adapter, the **NumElements** member of the **NDIS_NIC_SWITCH_VF_INFO_ARRAY** structure is set to zero and no **NDIS_NIC_SWITCH_VF_INFO** structures are returned.
>
> For more information on NIC switches, see NIC Switches.

NDIS handles the OID_NIC_SWITCH_ENUM_VFS request for miniport drivers. NDIS returns the information from an internal cache of the data that it maintains from inspecting the following sources:

- OID method requests of OID_NIC_SWITCH_ALLOCATE_VF.
- OID set requests of OID_NIC_SWITCH_VF_PARAMETERS.

Querying the Parameters of a Virtual Function

Article • 12/15/2021

An overlying driver or a user-mode application can obtain the current parameters for a PCI Express (PCIe) Virtual Function (VF) on a network adapter that supports single root I/O virtualization (SR-IOV). The driver or application issues an object identifier (OID) method request of OID_NIC_SWITCH_VF_PARAMETERS to obtain these parameters.

Before the overlying driver issues this OID method request, it must initialize an **NDIS_NIC_SWITCH_VF_PARAMETERS** structure. The driver or application must set the **VFId** member to the identifier of the VF for which parameters are to be returned. The VF identifier can be obtained in the following ways:

- By issuing an OID method request of OID_NIC_SWITCH_ENUM_VFS.

  If this OID request is completed successfully, the overlying driver or user-mode application receives a list of all VFs allocated on the network adapter. Each element within the list is an **NDIS_NIC_SWITCH_VF_INFO** structure, with the VF identifier specified by the **VFId** member.

- By issuing an OID method request of OID_NIC_SWITCH_ALLOCATE_VF.

  If this OID request is completed successfully, the overlying driver receives the identifier of the newly created VF in the **VFId** member of the returned **NDIS_NIC_SWITCH_VF_PARAMETERS** structure.

  Note Only overlying drivers can obtain the VF identifier in this manner.

After a successful return from the OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_NIC_SWITCH_VF_PARAMETERS** structure. This structure contains the configuration parameters for the specified VF.

NDIS handles the OID_NIC_SWITCH_VF_PARAMETERS request for miniport drivers. NDIS returns the information from an internal cache of the data that it maintains from inspecting the following sources:

- OID method requests of OID_NIC_SWITCH_ALLOCATE_VF.

- OID set requests of OID_NIC_SWITCH_VF_PARAMETERS.

Accessing the PCI Configuration Space of a Virtual Function

Article • 12/15/2021

This section describes guidelines for accessing the data from the PCI configuration space of PCI Express (PCIe) Virtual Functions (VFs). VFs are a hardware function of a network adapter that supports single root I/O virtualization (SR-IOV).

This section includes the following topics:

Querying the PCI Configuration Data of a Virtual Function

Setting the PCI Configuration Data of a Virtual Function

For more information on VFs for SR-IOV network adapters, see SR-IOV Virtual Functions (VFs).

Note Only the PF miniport driver can configure the PCI configuration space for a VF. The VF miniport driver cannot directly access most of the SR-IOV adapter's hardware resources, such as the PCI configuration space. For more information, see Writing SR-IOV VF Miniport Drivers.

Querying the PCI Configuration Space for a Virtual Function

Article • 12/15/2021

Note This method can only be used by overlying drivers that run in the management operating system of the Hyper-V parent partition.

The miniport driver for a PCI Express (PCIe) Virtual Function (VF) runs in the guest operating system of a Hyper-V child partition. Because of this, the VF miniport driver cannot directly access hardware resources, such as the VF's PCIe configuration space. Only the miniport driver for the PCIe Physical Function (PF) can access the PCIe configuration space for a VF. The PF miniport driver runs in the management operating system of a Hyper-V parent partition and has privileged access to the VF resources.

An overlying driver that runs in the management operating system issues an object identifier (OID) method request of OID_SRIOV_READ_VF_CONFIG_SPACE to read data from the PCIe configuration space for a specified VF on the network adapter.

For example, the virtualization stack that runs in the management operating system issues the OID method request of OID_SRIOV_READ_VF_CONFIG_SPACE when the VF miniport driver calls **NdisMGetBusData** to read from its VF PCIe configuration space.

Before it issues this OID method request, the overlying driver must set the members of the **NDIS_SRIOV_READ_VF_CONFIG_SPACE_PARAMETERS** structure in the following way:

- The **VFId** member must be set to the identifier of the VF from which the information is to be read.

- The **Offset** member must be set to the offset within the PCIe configuration space of the VF in which data will be read.

- The **Length** member must be set to the number of bytes to read from the VF's PCIe configuration space.

- The **BufferOffset** member must be set to the offset within the buffer (referenced by the **InformationBuffer** member) that will contain the data that is read from the specified VF's PCI configuration space. This offset is specified in units of bytes from the beginning of the **NDIS_SRIOV_READ_VF_CONFIG_SPACE_PARAMETERS** structure.

When it handles the OID method request of OID_SRIOV_READ_VF_CONFIG_SPACE, the PF miniport driver must follow these guidelines:

- The miniport driver must verify that the VF, specified by the **VFId** member of the **NDIS_SRIOV_READ_VF_CONFIG_SPACE_PARAMETERS** structure, has resources that have been previously allocated. The miniport driver allocates resources for a VF through an OID method request of OID_NIC_SWITCH_ALLOCATE_VF. If resources for the specified VF have not been allocated, the driver must fail the OID request.

- The miniport driver must verify that the buffer (referenced by the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure) is large enough to return the requested PCIe configuration space data. If this is not true, the driver must fail the OID request.

- The miniport driver typically calls **NdisMGetVirtualFunctionBusData** to query the requested PCIe configuration space. However, the miniport driver can also return PCIe configuration space data for the VF that the driver has cached from previous read or write operations of the PCIe configuration space.

  Note If an independent hardware vendor (IHV) provides a virtual bus driver (VBD) as part of its SR-IOV driver package, its miniport driver must not call **NdisMGetVirtualFunctionBusData**. Instead, the driver must interface with the VBD through a private communication channel, and request that the VBD call *ReadVfConfigBlock*. This function is exposed from the GUID_VPCI_INTERFACE_STANDARD interface that is supported by the underlying virtual PCI (VPCI) bus driver.

After a successful return from this OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to a caller-allocated buffer. This buffer is formatted to contain the following:

- An **NDIS_SRIOV_READ_VF_CONFIG_SPACE_PARAMETERS** structure that contains the parameters for a read operation of the PCIe configuration space of a VF.

- Additional buffer space for the data to be read from the PCIe configuration space. The driver copies the data to the buffer at the offset specified by the**BufferOffset** member of the **NDIS_SRIOV_READ_VF_CONFIG_SPACE_PARAMETERS** structure.

Querying the PCI Vendor and Device Identifiers for a Virtual Function

Article • 12/15/2021

Note This method can only be used by overlying drivers that run in the management operating system of the Hyper-V parent partition.

An overlying driver issues an object identifier (OID) method request of OID_SRIOV_VF_VENDOR_DEVICE_ID to query the PCI Express (PCIe) vendor identifier (*VendorID*) and device identifier (*DeviceID*). This data is read from the PCIe configuration space for the PCIe Virtual Function (VF) on the physical network adapter.

Overlying drivers issue this OID method request to the miniport driver of the PCI Express (PCIe) Physical Function (PF) of the network adapter. This OID method request is required for PF miniport drivers that support the single root I/O virtualization (SR-IOV) interface.

The guest operating system, which runs in a Hyper-V child partition, uses the VendorID and the DeviceID of the VF for generic Plug and Play (PnP) IDs for device enumeration. Starting with Windows Server 2012, the PF miniport driver can provide the following set of identifiers for the VF network adapter that is exposed in the child partition:

- The VendorID and DeviceID of the physical network adapter. This allows compatible drivers to be loaded in the guest operating system, which runs in the Hyper-V child partition, and the management operating system, which runs in the Hyper-V parent partition.

- A VendorID and DeviceID that differ from the identifiers of the physical network adapter. This allows a driver to be loaded in the guest operating system that is more appropriate for its use. For example, the PF miniport driver may return a VendorID and DeviceID for a VF network adapter so that a driver is loaded that disables certain feature sets, such as power management or protocol task offloads.

Before it issues this OID method request, the overlying driver must initialize an **NDIS_SRIOV_VF_VENDOR_DEVICE_ID_INFO** structure. The driver must set the **VFId** member to the identifier of the VF from which the information is to be read.

When it handles this OID request, the PF miniport driver must verify that the specified VF has resources that have been previously allocated. The PF miniport driver allocates resources for a VF during an OID method request of OID_NIC_SWITCH_ALLOCATE_VF. If resources for the specified VF have not been allocated, the driver must fail the OID request.

Querying the PCI Base Address Registers of a Virtual Function

Article • 12/15/2021

Note This method can only be used by overlying drivers that run in the management operating system of the Hyper-V parent partition.

The PCI bus driver, which runs in the management operating system of the Hyper-V parent partition, queries the memory or I/O address space requirements of each PCI Base Address Register (BAR) of the network adapter. The PCI bus driver performs this query when it first detects the adapter on the bus.

Through this PCI BAR query, the PCI bus driver determines the following:

- Whether a PCI BAR is supported by the network adapter.
- If a BAR is supported, how much memory or I/O address space is required for the BAR.

The PCI driver performs this PCI BAR query in following way:

1. The PCI driver first writes all ones to a BAR.
2. The PCI driver then reads the BAR to determine the required memory or address space that is required by the BAR. A value of zero indicates that the BAR is not supported by the network adapter.

The virtual PCI (VPCI) bus driver runs in the guest operating system of a Hyper-V child partition. When a PCI Express (PCIe) Virtual Function (VF) is attached to the child partition, the VPCI bus driver exposes a virtual network adapter for the VF (*VF network adapter*). Before it does this, the VPCI bus driver must perform a PCI BAR query to determine the required memory or address space that is required by the VF network adapter.

Because access to the PCI configuration space is a privileged operation, it can only be performed by components that run in the management operating system of a Hyper-V parent partition. When the VPCI bus driver queries the PCI BARs, NDIS issues an object identifier (OID) query request of OID_SRIOV_PROBED_BARS to the PF miniport driver. The results returned by this OID query request are forwarded to the VPCI bus driver so that it can determine how much memory address space would be needed by the VF network adapter.

Note OID requests of OID_SRIOV_BAR_RESOURCES can only be issued by NDIS. The OID request must not be issued by overlying drivers, such as protocol or filter drivers.

The OID_SRIOV_PROBED_BARS query request contains an NDIS_SRIOV_PROBED_BARS_INFO structure. When the PF miniport driver handles this OID, the driver must return the PCI BAR values within the array referenced by the **BaseRegisterValuesOffset** member of the **NDIS_SRIOV_PROBED_BARS_INFO** structure. For each offset within the array, the PF miniport driver must set the array element to the ULONG value of the BAR at the same offset within the physical network adapter's PCI configuration space.

Each BAR value returned by the driver must be the same value that would follow a PCI BAR query as performed by the PCI driver that runs in the management operating system. The PF miniport driver can call NdisMQueryProbedBars to determine this information.

For more information about the base address registers of a PCI device, see the *PCI Local Bus Specification*.

Setting the PCI Configuration Data of a Virtual Function

Article • 12/15/2021

The miniport driver for a PCI Express (PCIe) Virtual Function (VF) runs in the guest operating system of a Hyper-V child partition. Because of this, the VF miniport driver cannot directly access hardware resources, such as the VF's PCI configuration space. Only the miniport driver for the PCIe Physical Function (PF) can access the PCI configuration space for a VF. The PF miniport driver runs in the management operating system of a Hyper-V parent partition and has privileged access to the VF resources.

The overlying driver, such as the virtualization stack, issues the OID set request of OID_SRIOV_WRITE_VF_CONFIG_SPACE when the VF miniport driver calls **NdisMSetBusData** to write to its PCI configuration space.

Before it issues this OID set request, the overlying driver must set the members of the**NDIS_SRIOV_WRITE_VF_CONFIG_SPACE_PARAMETERS** structure in the following way:

- Set the **VFId** member to the identifier of the VF for which the information is to be written.

- Set the **Offset** member to the offset within the PCI configuration space of the VF in which data will be written.

- Set the **Length** member to the number of bytes to write to the VF's PCI configuration space.

- Set the **BufferOffset** member to the offset within the buffer (referenced by the**InformationBuffer** member) that will contain the data that is written to the specified VF's PCI configuration space. This offset is specified in units of bytes from the beginning of the **NDIS_SRIOV_WRITE_VF_CONFIG_SPACE_PARAMETERS** structure.

When it handles the OID method request of OID_SRIOV_WRITE_VF_CONFIG_SPACE, the PF miniport driver must follow these guidelines:

- The PF miniport driver must verify that the VF, specified by the **VFId** member of the **NDIS_SRIOV_WRITE_VF_CONFIG_SPACE_PARAMETERS** structure, has resources that have been previously allocated. The PF miniport driver allocates resources for a VF through an OID method request of OID_NIC_SWITCH_ALLOCATE_VF.

If resources for the specified VF have not been allocated, the driver must fail the OID request.

- The PF miniport driver calls **NdisMSetVirtualFunctionBusData** to write to the requested PCI configuration space. However, the PF miniport driver can also return PCI configuration space data for the VF that the driver has cached from previous read or write operations of the PCI configuration space.

  Note If an independent hardware vendor (IHV) provides a virtual bus driver (VBD) as part of its SR-IOV driver package, its PF miniport driver must not call **NdisMSetVirtualFunctionBusData**. Instead, the driver must interface with the VBD through a private communication channel, and request that the VBD call *SetVirtualFunctionData*. This function is exposed from the GUID_VPCI_INTERFACE_STANDARD interface that is supported by the underlying virtual PCI (VPCI) bus driver.

If the PF miniport driver can successfully complete the OID request, the driver must copy the requested PCI configuration space data to the buffer referenced by the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure. The driver copies the data to the buffer at the offset specified by the**BufferOffset** member of the **NDIS_SRIOV_READ_VF_CONFIG_SPACE_PARAMETERS** structure.

Setting the Power State of a Virtual Function

Article • 12/15/2021

An overlying driver issues an object identifier (OID) set request of OID_SRIOV_SET_VF_POWER_STATE to change the power state of a specified PCI Express (PCIe) Virtual Function (VF) on the network adapter. Because changing the power state is a privileged operation, overlying drivers issue this OID set request to the miniport driver of the PCIe Physical Function (PF) on the network adapter. The PF miniport driver then sets the specified power state on the VF.

For example, the virtualization stack manages the power state of the Hyper-V child partition that is attached to the VF. The stack changes the power state by issuing the OID_SRIOV_SET_VF_POWER_STATE to the PF miniport driver.

Before it issues the OID set request of OID_SRIOV_SET_VF_POWER_STATE, the overlying driver must set the members of **NDIS_SRIOV_SET_VF_POWER_STATE_PARAMETERS** structure in the following way:

- The **VFId** member must be set to the identifier of the VF from which the information is to be read.
- The **PowerState** member must be set to the power state that the VF should transition to.
- If the network adapter must have its WAKE# signal (on the PCI Express bus) or PME# signal (on the PCI bus) asserted as it goes into the low-power state, the **WakeEnable** member must be set to TRUE. Otherwise, this member must be set to FALSE.

When the PF miniport driver is issued this OID set request, it must follow these guidelines:

- The PF miniport driver must verify that the VF, specified by the **VFId** member of the **NDIS_SRIOV_SET_VF_POWER_STATE_PARAMETERS** structure, has resources that have been previously allocated. The PF miniport driver allocates resources for a VF during an OID method request of OID_NIC_SWITCH_ALLOCATE_VF. If the specified VF is not in an allocated state, the driver must fail the OID request.
- The power state operation must only affect the specified VF. The operation must not affect other VFs or the PF on the same network adapter.

Resetting a Virtual Function

Article • 12/15/2021

An overlying driver issues an object identifier (OID) set request of OID_SRIOV_RESET_VF to reset a specified PCI Express (PCIe) Virtual Function (VF). The VF is a hardware component of a network adapter that supports single root I/O virtualization. Overlying drivers issue this OID set request to the miniport driver of the PCI Express (PCIe) Physical Function (PF).

For example, the virtualization stack runs in the management operating system of the Hyper-V parent partition. Before the stack detaches a VF from a Hyper-V child partition, it requests a Function Level Reset (FLR) on the VF. Because the FLR is a privileged operation, it can be performed only by the PF miniport driver that also runs in the management operating system. To request an FLR of a specified VF, the virtualization stack issues the OID_SRIOV_RESET_VFrequest to the PF miniport driver.

Before it issues this OID set request, the overlying driver must initialize an **NDIS_SRIOV_RESET_VF_PARAMETERS** structure. The driver must set the **VFId** member to the identifier of the VF to be reset.

When it handles this OID request, the PF miniport driver must follow these guidelines:

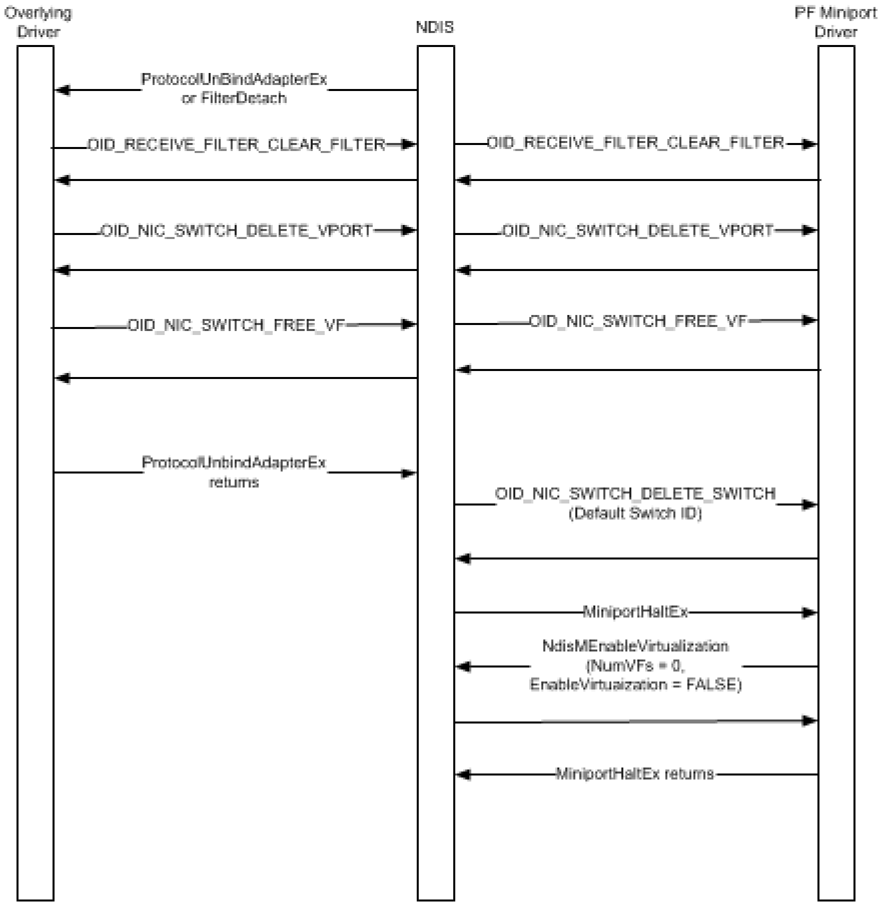
- The PF miniport driver must verify that the VF, specified by the **VFId** member of the **NDIS_SRIOV_RESET_VF_PARAMETERS** structure, has resources that have been previously allocated. The PF miniport driver allocates resources for a VF during an OID method request of OID_NIC_SWITCH_ALLOCATE_VF. If resources for the specified VF have not been allocated, the driver must fail the OID request.

- The reset operation must only affect the specified VF. The operation must not affect other VFs or the PF on the same network adapter.

Halting a PF Miniport Driver

Article • 12/15/2021

This topic discusses the steps that are involved with halting the miniport driver for a PCI Express (PCIe) Physical Function (PF) on an adapter that supports single root I/O virtualization (SR-IOV). These steps are shown in the following figure.



Overlying Driver
NDIS
PF Miniport Driver
ProtocolUnBindAdapterEx or FilterDetach
OID_RECEIVE_FILTER_CLEAR_FILTER
OID_RECEIVE_FILTER_CLEAR_FILTER
OID_NIC_SWITCH_DELETE_VPORT
OID_NIC_SWITCH_DELETE_VPORT
OID_NIC_SWITCH_FREE_VF
OID_NIC_SWITCH_FREE_VF
ProtocolUnbindAdapterEx returns
OID_NIC_SWITCH_DELETE_SWITCH (Default Switch ID)
MiniportHaltEx
NdisMEnableVirtualization (NumVFs = 0, EnableVirtuaization = FALSE)
MiniportHaltEx returns

This topic contains the following information:

- Actions Performed by NDIS and Overlying Drivers Before *MiniportHaltEx* is Called
- Actions Performed by the PF Miniport Driver When *MiniportHaltEx* is Called

Actions Performed by NDIS and Overlying Drivers Before *MiniportHaltEx* is Called

Before NDIS calls the PF miniport driver's *MiniportHaltEx* function, it first does the following:

- NDIS unbinds all protocol drivers that have previously bound to the underlying PF miniport driver. NDIS does this by calling the protocol driver's *ProtocolUnbindAdapterEx* function.

- NDIS detaches all filter drivers that have previously bound to the underlying PF miniport driver. NDIS does this by calling the filter driver's *FilterDetach* function.

When an overlying protocol or filter driver is being unbound or detached from the PF miniport driver, it must follow these steps:

1. The driver must issue an object identifier (OID) set request of OID_RECEIVE_FILTER_CLEAR_FILTER to clear any receive filters that it previously set. The driver sets these filters on the default virtual port (VPort) or any nondefault VPorts of the NIC switch on the network adapter. The driver sets these filters by issuing OID method requests of OID_RECEIVE_FILTER_SET_FILTER to the PF miniport driver.

2. The driver must issue an OID set request of OID_NIC_SWITCH_DELETE_VPORT to delete any nondefault VPorts that it previously created on the NIC switch. The driver sets these VPorts by issuing OID method requests of OID_NIC_SWITCH_CREATE_VPORT to the PF miniport driver.

3. The driver must issue an OID set request of OID_NIC_SWITCH_FREE_VF to free the resources for any PCIe Virtual Functions (VFs) that it previously allocated on the NIC switch. The driver allocates resources for the VF by issuing OID method requests of OID_NIC_SWITCH_ALLOCATE_VF to the PF miniport driver.

   For more information, see Freeing Resources for a Virtual Function.

   Note When resources for the VF are freed, NDIS calls the *MiniportHaltEx* function of the VF miniport driver. For more information, see Halting a VF Miniport Driver.

After all receive filters, nondefault VPorts, and VFs have been deleted from the NIC switch, NDIS follows these steps:

- NDIS deletes all NIC switches by issuing OID set requests of OID_NIC_SWITCH_DELETE_SWITCH to the PF miniport driver. For more information on how a NIC switch is deleted, see Deleting a NIC Switch.

  Note Starting with Windows Server 2012, the SR-IOV interface only supports the default NIC switch on the network adapter.

- After all NIC switches have been successfully deleted, NDIS calls the *MiniportHaltEx* function of the PF miniport driver.

Actions Performed by the PF Miniport Driver When *MiniportHaltEx* is Called

When NDIS calls *MiniportHaltEx*, the PF miniport driver must follow these steps:

1. If the PF miniport driver supports the static creation of NIC switches and all the NIC switches have been deleted, the driver must disable the virtualization on the adapter by calling **NdisMEnableVirtualization** with *EnableVirtualization* parameter set to FALSE and the *NumVFs* parameter set to zero.

   NdisMEnableVirtualization clears the **NumVFs** member and the **VF Enable** bit in the SR-IOV Extended Capability structure in the PCIe configuration space of the network adapter's PF.

   Note If the PF miniport driver supports dynamic creation and configuration of NIC switches, it must call **NdisMEnableVirtualization** when the driver handles the OID set request of OID_NIC_SWITCH_DELETE_SWITCH. This OID request is issued before *MiniportHaltEx* is called.

2. The PF miniport driver performs the other tasks associated with a miniport halt operation. For more information, see Halting a Miniport Adapter.

INF Requirements for PF Miniport Drivers

Article • 12/15/2021

This section describes the INF requirements for the miniport driver of a network adapter that supports the single root I/O virtualization (SR-IOV) interface. These are only requirements for the miniport driver of the adapter's PCI Express (PCIe) Physical Function (PF).

This section includes the following topics:

Standardized INF Keywords for SR-IOV

INF *DDInstall*.HW Section for PF Miniport Drivers

Handling SR-IOV, VMQ, and RSS Standardized INF Keywords

Standardized INF Keywords for SR-IOV

Article • 12/15/2021

This topic describes the standardized INF keywords for the single root I/O virtualization (SR-IOV) interface. These keywords apply to the INF file for the miniport driver of the PCI Express (PCIe) Physical Function (PF) of an SR-IOV network adapter.

The SR-IOV INF keywords are described in the following sections:

Standardized INF Keywords for the Enabling or Disabling SR-IOV Support

Standardized INF Keywords for Configuration of the Default NIC Switch

Standardized INF Keywords for Enabling or Disabling SR-IOV Support

Standardized INF keywords are defined to enable or disable support for the SR-IOV features of a network adapter.

***SRIOV**
A value that describes whether the device has enabled or disabled the SR-IOV feature.

After the driver is installed, administrators can update the ***SRIOV** keyword value in the **Advanced** property page for the network adapter. For more information about advanced properties, see Specifying Configuration Parameters for the Advanced Properties Page.

Note The miniport driver is automatically restarted after a change is made in the **Advanced** property page for the adapter.

***SriovPreferred**
A value that defines whether SR-IOV capabilities should be enabled instead of virtual machine queue (VMQ) or receive side scaling (RSS) capabilities.

This is a hidden keyword value that must not be specified in the INF file and is not displayed in **Advanced** property page for the network adapter.

For more information about how to interpret SR-IOV, VMQ, and RSS keywords, see Handling SR-IOV, VMQ, and RSS Standardized INF Keywords.

The SR-IOV standardized INF keywords are enumeration keywords and are described in the following table. The columns in this table describe the following attributes for an enumeration keyword:

SubkeyName
The name of the keyword that you must specify in the INF file. This name also appears in the registry under the **NDI\params\** key for the network adapter.

ParamDesc
The display text that is associated with the **SubkeyName** keyword.

Note The independent hardware vendor (IHV) can define any descriptive text for the SubkeyName.

Value
The enumeration integer value that is associated with each **SubkeyName** keyword in the list.

EnumDesc
The display text that is associated with each value that appears in the menu.

SubkeyName	ParamDesc	Value	EnumDesc
***SRIOV**	SR-IOV	0	Disabled
		1 (Default)	Enabled
***SriovPreferred**	The ParamDesc and EnumDesc entries for this subkey cannot be used in either INF files or a user interface.	0 (Default)	Report RSS or VMQ capabilities based on the ***VmqOrRssPreferrence** keyword. Do not report SR-IOV capabilities. For more information about the ***VmqOrRssPreferrence** keyword, see Standardized INF Keywords for VMQ.
		1	Report SR-IOV capabilities.

For more information about standardized INF keywords, see Standardized INF Keywords for Network Devices.

Standardized INF Keywords for Configuration of the Default NIC Switch

Starting with Windows Server 2012, the SR-IOV interface supports only one NIC switch on the network adapter. This switch is known as the *default NIC switch*, and is referenced by the NDIS_DEFAULT_SWITCH_ID identifier.

The INF file for the PF miniport driver must specify the configuration of the default NIC switch on the SR-IOV network adapter. This allows the network installer to copy the default switch configuration information from the INF to the miniport registry configuration under the subkey for the default switch (**NDI\params\NicSwitches\0**).

These keywords are not displayed in the **Advanced** property page for the network adapter and cannot be configured by the user. These keywords are specified by using the **AddReg** directive in the **DDInstall** section of the INF file. Each keyword is specified by a separate **AddReg** directive.

The following table describes the INF keywords for the default NIC switch configuration of the SR-IOV network adapter. The columns in this table describe the following attributes for these keywords:

SubkeyName
The name of the keyword that you must specify in the INF file. This name also appears in the registry under the **NDI\params\NicSwitches\0** key for the network adapter.

Data value
The value that is associated with the **SubkeyName** keyword.

Data type
The type of the data value.

SubkeyName	Data value	Data type	Notes
***Flags**	0	REG_DWORD	The keyword must be assigned this value.
***SwitchType**	1	REG_DWORD	The keyword must be assigned this value.
***SwitchId**	0	REG_DWORD	The keyword must be assigned this value.
***SwitchName**	“Default Switch”	REG_SZ	The keyword must be assigned this value.
***NumVFs**	(0-*n*),	REG_DWORD	*n* is the maximum number of PCIe Virtual Functions (VFs) that are supported by the SR-IOV network adapter. **Note** This registry key defines the maximum number of VFs that the network adapter supports. When the miniport driver calls NdisMSetMiniportAttributes, it can advertise less than this value depending on the available hardware resources on the network adapter. For more information, see Determining NIC Switch Capabilities.

The following is an example of **AddReg** directives for the default NIC switch configuration of an SR-IOV network adapter:

syntax

```
HKR, NicSwitches\0, *SwitchId,   0x00010001, 0
HKR, NicSwitches\0, *SwitchName, 0x00000000, “Default Switch”
```

For more information about the syntax of the **AddReg** directive, see **INF AddReg Directive**.

For more information about the default NIC switch, see NIC Switches.

INF DDInstall.HW Section for PF Miniport Drivers

Article • 12/15/2021

INF *DDInstall*.**HW** sections are typically used for setting up any device-specific information in the registry, whether with explicit **AddReg** directives or with **Include** and **Needs** entries.

The INF file for the miniport driver of the PCI Express (PCIe) Physical Function (PF) network adapter must have a *DDInstall*.**HW** section that contains the following INF entries:

- An **Include** entry that specifies the pci.inf file that is included with the Windows operating system.

- A **Needs** entry that specifies the **PciSriovSupported.HW** section to include from the pci.inf file. This section defines standard INF settings that apply to all PF miniport drivers for network adapters that support the single root I/O virtualization (SR-IOV) interface.

The following is an example of a *DDInstall*.**HW** section for a PF miniport driver:

```syntax
[Device_Inst.NT.HW]

Include=pci.inf
Needs=PciSriovSupported.HW
```

For more information about the *DDInstall* section, see DDInstall Section in a Network INF File.

For more information about the *DDInstall*.HW section, see **INF DDInstall.HW Section**.

Handling SR-IOV, VMQ, and RSS Standardized INF Keywords

Article • 12/15/2021

Network adapters that support single root I/O virtualization (SR-IOV), virtual machine queue (VMQ), and receive side scaling (RSS) can enable the use of these interfaces in the following way:

- SR-IOV and VMQ can be enabled individually or at the same time.
- RSS cannot be enabled on the network adapter when SR-IOV or VMQ is enabled.

The operating system enables the use of the SR-IOV, VMQ, or RSS interfaces in the following way:

- When the network adapter is bound to the TCP/IP stack, the operating enables the use of the RSS feature.
- When the network adapter is bound to the Hyper-V extensible switch driver stack, the operating system enables the use of either the SR-IOV or VMQ feature.

  For more information about the Hyper-V extensible switch, see Hyper-V Extensible Switch.

When the network adapter is unbound from the TCP/IP stack and the Hyper-V extensible switch driver stack, the miniport driver is halted and then reinitialized. Because of this, it is not possible for such network adapters to switch between RSS, VMQ, and SR-IOV automatically.

When NDIS calls the *MiniportInitializeEx* function, the miniport driver follows these steps before it reports its currently enabled SR-IOV, VMQ, or RSS capabilities to NDIS:

1. The miniport driver reads the ***SriovPreferred** keyword before reporting its currently enabled capabilities to NDIS.

   If the value of the ***SriovPreferred** keyword is one, the miniport driver is configured for SR-IOV preference.

2. The miniport driver reads the ***RssOrVmqPreference** keyword before reporting its currently enabled capabilities to NDIS.

   If the value of the ***RssOrVmqPreference** keyword is one, the miniport driver is configured for VMQ preference.

If the value of the ***RssOrVmqPreference** keyword is zero or the keyword is not present, the miniport driver is configured for RSS preference.

3. If the miniport driver is configured for SR-IOV preference, it must read the ***SRIOV** keyword to determine whether SR-IOV is enabled on the network adapter. If the keyword is set to one, the driver reports the currently enabled SR-IOV settings.

   For more information on how the miniport driver reports SR-IOV settings, see Determining SR-IOV Capabilities.

   For more information about the SR-IOV keywords, see Standardized INF Keywords for SR-IOV.

   Note If the miniport driver is configured for SR-IOV preference, it must not read any of the RSS standardized keywords. However, the driver must read the VMQ ***VMQVlanFiltering** standardized keyword. This keyword specifies whether the miniport driver is enabled to filter network packets by using the virtual VLAN (VLAN) identifier in the media access control (MAC) header. The miniport driver reports this capability by setting the NDIS_RECEIVE_FILTER_MAC_HEADER_VLAN_ID_SUPPORTED flag in the **SupportedMacHeaderFields** member of the **NDIS_RECEIVE_FILTER_CAPABILITIES** structure. For more information on the ***VMQVlanFiltering** standardized keyword, see Standardized INF Keywords for VMQ.

4. If the miniport driver is configured for VMQ preference, it must read the ***VMQ** keyword to determine whether VMQ is enabled on the network adapter. If the keyword is set to one, the driver reports the currently enabled VMQ settings. For more information on how the miniport driver reports VMQ settings, see Determining the VMQ Capabilities of a Network Adapter.

   For more information about VMQ keywords, see Standardized INF Keywords for VMQ.

   Note If the miniport driver is configured for VMQ preference, it must not read any of the RSS or SR-IOV standardized keywords.

5. If the miniport driver is configured for RSS preference, it must read the ***RSS** keyword to determine whether RSS is enabled on the network adapter. If the keyword is set to one, the driver reports the currently enabled RSS settings. For more information on how the miniport driver reports RSS settings, see RSS Configuration.

   For more information about the RSS keywords, see Standardized INF Keywords for RSS.

> **Note** If the miniport driver is configured for RSS preference, it must not read any of the VMQ or SR-IOV standardized keywords.

The following table describes how the miniport driver determines SR-IOV, VMQ, or RSS preference in order to enable the correct interface in the network adapter.

SriovPreferred	RssOrVmqPreference	*SRIOV*	VMQ	*RSS	Enabled interface
1	1	1	1	N/A	SR-IOV and VMQ
1	1	0	1	N/A	VMQ
1	1, 0, or not present in registry	0	0	N/A	None
0, or not present in registry	1	N/A	1	N/A	VMQ
0, or not present in registry	1	N/A	0	N/A	None
0, or not present in registry	0, or not present in registry	N/A	N/A	1	RSS
0, or not present in registry	0, or not present in registry	N/A	N/A	0	None

Note When the SR-IOV and VMQ interfaces are both enabled, SR-IOV nondefault virtual ports (VPorts) that are attached to the PCI Express (PCIe) Physical Function (PF) are used instead of VM queues for the VMQ interface. For more information, see Nondefault Virtual Ports and VMQ.

The miniport driver must advertise the capabilities of the currently enabled interface. For example, if SR-IOV is enabled, the miniport driver must advertise the SR-IOV capabilities but not the capabilities for VMQ or RSS. However, the miniport driver must always report the complete RSS, VMQ, and SR-IOV hardware capabilities regardless of which interface is enabled on the network adapter.

Note The VMQ and SR-IOV interfaces use receive filtering over VM queues or SR-IOV virtual ports (VPorts). As a result, some receive filtering capabilities require the same or different settings when either of these interfaces are enabled. For more information on how to report the receive filtering capabilities for the SR-IOV interface, see Determining Receive Filtering Capabilities. For more information on how to report the receive filtering capabilities for the VMQ interface, see Determining the VMQ Capabilities of a Network Adapter.

Writing SR-IOV VF Miniport Drivers Overview

Article • 12/15/2021

This section discusses the requirements and guidelines for writing an NDIS miniport driver for the PCI Express (PCIe) Virtual Function (VF) of a single root I/O virtualization (SR-IOV) network adapter.

This section includes the following topics:

Initializing a VF Miniport Driver

Halting a VF Miniport Driver

INF Requirements for VF Miniport Drivers

Note For information on how to write a miniport driver for a PCIe Physical Function (PF) of the SR-IOV network adapter, see Writing SR-IOV PF Miniport Drivers.

Initializing a VF Miniport Driver

Article • 12/15/2021

This topic describes the guidelines for writing a *MiniportInitializeEx* function for the miniport driver for a PCI Express (PCIe) Virtual Function (VF). The VF is exposed by a network adapter that supports single root I/O virtualization (SR-IOV).

> ⓘ Note
>
> These guidelines only apply to VF miniport drivers of the SR-IOV network adapter. For initialization guidelines for the miniport driver of a PCIe Physical Function (PF) of the adapter, see **Initializing a PF Miniport Driver**.

The VF miniport driver follows the same steps as any NDIS miniport driver when its *MiniportInitializeEx* function is called. For more information about these steps, see Initializing a Miniport Driver.

In addition to these steps, the VF miniport driver must follow these additional steps when NDIS calls the driver's *MiniportInitializeEx* function:

- The VF miniport driver calls the **NdisGetHypervisorInfo** function to verify that it is running in the Hyper-V child partition. This function returns an **NDIS_HYPERVISOR_INFO** structure which defines the partition type. If the partition type is reported as **NdisHypervisorPartitionMsHvChild**, the miniport driver is running in a Hyper-V child partition that is attached to the PF on the adapter.

  > ⓘ Note
  >
  > If the partition type is reported as **NdisHypervisorPartitionMsHvParent**, the miniport driver is running in the Hyper-V parent partition that is attached to the PF on the adapter. In this case, the miniport driver must not initialize as a VF driver. If possible, the driver must initialize as a PF driver as described in **Initialization Sequence for PF Miniport Drivers**.

- Unlike the PF miniport driver, the VF miniport driver must not be installed with the SR-IOV standardized keywords and must not attempt to read these keywords. For more information about these keywords, see Standardized INF Keywords for SR-IOV.

- The VF miniport driver reports the SR-IOV hardware capabilities of the underlying virtual network adapter through an NDIS_SRIOV_CAPABILITIES structure that is initialized in the following way:

  1. The miniport driver initializes the **Header** member. The driver sets the **Type** member of **Header** to NDIS_OBJECT_TYPE_DEFAULT.

     Starting with NDIS 6.30, the miniport driver sets the **Revision** member of **Header** to NDIS_SRIOV_CAPABILITIES _REVISION_1 and the **Size** member to NDIS_SIZEOF_SRIOV_CAPABILITIES_REVISION_1.

  2. The miniport driver sets the NDIS_SRIOV_CAPS_PF_MINIPORT flag in the **SriovCapabilities** member to report SR-IOV capabilities.

     > ⓘ Note
     >
     > The VF miniport driver must set both the NDIS_SRIOV_CAPS_VF_MINIPORT flag and the NDIS_SRIOV_CAPS_SRIOV_SUPPORTED flag.

  The VF miniport driver registers the SR-IOV capabilities of the network adapter by following these steps:

  1. The miniport driver initializes an NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES structure.

     The miniport driver sets the **HardwareSriovCapabilities** and **CurrentSriovCapabilities** members to a pointer to the previouslyinitialized NDIS_SRIOV_CAPABILITIES structure.

  2. The driver calls NdisMSetMiniportAttributes and sets the *MiniportAttributes* parameter to a pointer to the NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES structure.

- The VF miniport driver must not advertise virtual machine queue (VMQ) capabilities. However, the driver can advertise support for other NDIS technologies, such as power management and receive side scaling (RSS).

  For more information about RSS, see Receive Side Scaling.

Halting a VF Miniport Driver

Article • 12/15/2021

The VF miniport driver follows the same steps as any NDIS miniport driver when its *MiniportHaltEx* function is called. For more information about these steps, see Halting a Miniport Adapter.

INF Requirements for VF Miniport Drivers

Article • 12/15/2021

The INF file for the miniport driver of a PCI Express (PCIe) Virtual Function (VF) does not specify any standardized INF keywords for single root I/O virtualization (SR-IOV). Only the INF file of a PCIe Physical Function (PF) specifies standardized SR-IOV keywords. For more information about these keywords, see INF Requirements for PF Miniport Drivers.

The INF for a VF miniport driver follows (with one exception) the same requirements as other INF files for network adapters. For more information, see Standardized INF Keywords for Network Devices.

The only exception is that the INF file for the VF miniport driver must define the binding relationships to the services that manage the SR-IOV data paths. This is needed to ensure that network access can fail over to the synthetic data path if the VF data path is torn down for any reason. For more information about these data paths, see SR-IOV Data Paths.

To bind to the services that manage these data paths, the INF file for the VF miniport driver must specify the following settings for the **UpperRange** and **LowerRange** entries:

syntax

```
HKR, Ndi\Interfaces, UpperRange, 0, "ndisvf"
HKR, Ndi\Interfaces, LowerRange, 0, "iovvf"
```

SR-IOV PF/VF Backchannel Communication Overview

Article • 12/15/2021

The single root I/O virtualization (SR-IOV) interface provides a communication channel, or *backchannel*, between the miniport drivers of a PCI Express (PCIe) Virtual Function (VF) and the PCIe Physical Function (PF). Each VF miniport driver can issue requests over the backchannel to the PF miniport driver. The PF miniport driver can issue status notifications over the backchannel to individual VF miniport drivers.

Data exchanged between the PF and VF miniport drivers over the backchannel interface involves the use of a *VF configuration block*. Each VF configuration block is similar in concept to an interprocess communication (IPC) message, in which each block has a proprietary format, length, and block identifier. The independent hardware vendor (IHV) can define one or more VF configuration blocks for the PF and VF miniport drivers.

This section includes the following topics:

Backchannel Communication from a VF Miniport Driver

Backchannel Communication from the PF Miniport Driver

Backchannel Communication from a VF Miniport Driver

Article • 12/15/2021

A miniport driver of a PCI Express (PCIe) Virtual Function (VF) communicates with the miniport driver of the PCIe Physical Function (PF) to read or write data from a VF configuration block.

A VF configuration block is used for backchannel communication between the PF and VF miniport drivers. The independent hardware vendor (IHV) can define one or more VF configuration blocks for the device. Each VF configuration block has an IHV-defined format, length, and block ID. For example, the IHV can define a VF configuration block that can be used for the media access control (MAC) address of the VF miniport driver. Another VF configuration block can be used for the current VF and virtual port (VPort) configuration.

Note Data from each VF configuration block is used only by the PF and VF miniport drivers. The format and content of this data is opaque to components of the Windows operating system.

Each VF configuration block is assigned a unique identifier by the IHV. This allows the VF miniport driver to query or set information on specific VF configuration blocks.

VF miniport drivers initiate the read or write operation on a specified VF configuration block through the following functions:

- **NdisMReadConfigBlock**, which reads data from a specified VF configuration block. When the VF miniport driver calls this function, it specifies the block identifier and length of the data to be read. The driver also passes a pointer to the buffer that will contain the requested data.

- **NdisMWriteConfigBlock**, which writes data to a specified VF configuration block. When the VF miniport driver calls this function, it specifies the block identifier and length of the data to be written. The driver also passes a pointer to the buffer from which the data is to be written.

The PF miniport driver manages access to the specified VF configuration block in the following ways:

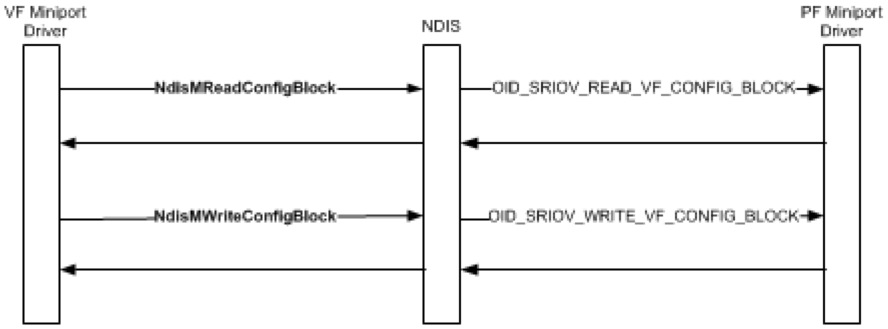
- When the VF miniport driver calls **NdisMReadConfigBlock**, NDIS issues an object identifier (OID) method request of OID_SRIOV_READ_VF_CONFIG_BLOCK to the PF miniport driver. This OID request contains the parameter data that was passed by the VF miniport driver in the function call.

The PF miniport driver performs the read operation and returns the requested data when the driver completes the OID request. After the OID request is completed, NDIS returns from the call to **NdisMReadConfigBlock**.

- When the VF miniport driver calls **NdisMWriteConfigBlock**, NDIS issues an OID method request of OID_SRIOV_WRITE_VF_CONFIG_BLOCK to the PF miniport driver. This OID request contains the parameter data that was passed by the VF miniport driver in the function call.

  The PF miniport driver performs the write operation and completes the OID request. After the OID request is completed, NDIS returns from the call to **NdisMWriteConfigBlock**.

The following figure shows the process involved in reading and writing VF configuration blocks over the SR-IOV backchannel interface.



Backchannel Communication from the PF Miniport Driver

Article • 12/15/2021

A miniport driver of the PCI Express (PCIe) Physical Function (PF) communicates with a miniport driver of the PCIe Virtual Function (VF) to issue notifications about changes in the data of a VF configuration block. The PF miniport driver issues these notifications to *invalidate* the data in the VF configuration block. In response to this notification, the VF miniport driver can issue a backchannel request to the PF miniport driver to read the data from an invalidated VF configuration block.

A VF configuration block is used for backchannel communication between the PF and VF miniport drivers. The IHV can define one or more VF configuration blocks for the device. Each VF configuration block has an IHV-defined format, length, and block ID.

Note Data from each VF configuration block is used only by the PF and VF miniport drivers. The format and content of this data is opaque to components of the Windows operating system.

The following steps occur when issuing and handling notifications of invalid VF configuration data:

1. In the guest operating system, NDIS issues an I/O control request of IOCTL_VPCI_INVALIDATE_BLOCK. When this IOCTL is completed, NDIS is notified that VF configuration data has changed.

2. In the management operating system that runs in the Hyper-V parent partition, the following steps occur:

   a. The PF miniport driver calls the NdisMInvalidateConfigBlock function to notify NDIS that VF configuration data has changed and is no longer valid. The driver sets the *BlockMask* parameter to a ULONGLONG bitmask that specifies which VF configuration blocks have changed. Each bit in the bitmask corresponds to a VF configuration block. If the bit is set to one, the data in the corresponding VF configuration block has changed.

   b. NDIS signals the virtualization stack, which runs in the management operating system, about the change to VF configuration block data. The virtualization stack caches the *BlockMask* parameter data.

      Note Each time that the PF miniport driver calls NdisMInvalidateConfigBlock, the virtualization stack ORs the *BlockMask* parameter data with the current value in its cache.

   c. The virtualization stack notifies the virtual PCI (VPCI) driver, which runs in the guest operating system, about the invalidation of VF configuration data. The virtualization stack sends the cached *BlockMask* parameter data to the VPCI driver.

3. In the guest operating system that runs in a Hyper-V child partition, the following steps occur:

   a. The VPCI driver saves the cached *BlockMask* parameter data in the **BlockMask** member of the **VPCI_INVALIDATE_BLOCK_OUTPUT** structure that is associated with the **IOCTL_VPCI_INVALIDATE_BLOCK** request.

   b. The VPCI driver successfully completes the **IOCTL_VPCI_INVALIDATE_BLOCK** request. When this happens, NDIS issues an object identifier (OID) method request of OID_SRIOV_VF_INVALIDATE_CONFIG_BLOCK to the VF miniport driver. An **NDIS_SRIOV_VF_INVALIDATE_CONFIG_BLOCK_INFO** is passed along in the OID request. This structure contains the cached *BlockMask* parameter data.

      NDIS also issues another **IOCTL_VPCI_INVALIDATE_BLOCK** request to handle successive notifications of changes to VF configuration data.

   c. When the VF driver handles the OID_SRIOV_VF_INVALIDATE_CONFIG_BLOCK request, it can read data from the specified VF configuration blocks by calling **NdisMReadConfigBlock**. For more information about this process, see Backchannel Communication from a VF Miniport Driver.

SR-IOV OIDs

Article • 12/15/2021

The single root I/O virtualization (SR-IOV) object identifiers (OIDs) apply to miniport and overlying drivers that support the SR-IOV interface. This interface is supported in NDIS version 6.30 and later versions.

The following table defines the characteristics of the SR-IOV OIDs. The following abbreviations are used to specify the OIDs' characteristics in the table.

- Q
  The OID is used only in query requests.
- S
  The OID is used only in set requests.
- M
  The OID is used only in method requests. These requests could be issued for set or query operations.
- N
  The OID request is handled directly by NDIS and not by the miniport driver. The driver will not be issued these OIDs.
- P
  The OID request is issued only to the miniport driver of the network adapter's physical function (PF).
  The PF driver must support these OIDs. The driver must also list these OIDs in the **SupportedOidList** member of the NDIS_MINIPORT_ADAPTER_GENERAL_ATTRIBUTES structure that the driver passes in the *MiniportAttributes* parameter of the call to NdisMSetMiniportAttributes.
- V
  The OID request is issued only to the miniport driver of one of the network's virtual functions (VFs).
  The VF driver must support these OIDs. The driver must also list these OIDs in the **SupportedOidList** member of the NDIS_MINIPORT_ADAPTER_GENERAL_ATTRIBUTES structure that the driver passes in the *MiniportAttributes* parameter of the call to NdisMSetMiniportAttributes.

NDIS_STATUS_NIC_SWITCH_CURRENT_CAPABILITIES

Article • 03/14/2023

The **NDIS_STATUS_NIC_SWITCH_CURRENT_CAPABILITIES** status indicates to NDIS and overlying drivers that the currently enabled hardware capabilities of the NIC switch in a network adapter have changed.

The status indication is made by the miniport driver of the network adapter's PCI Express (PCIe) Physical Function (PF). The PF miniport driver runs in the management operating system of the Hyper-V parent partition.

Remarks

The PF miniport driver must issue an **NDIS_STATUS_NIC_SWITCH_CURRENT_CAPABILITIES** status indication whenever it detects a change to the currently enabled hardware capabilities of the NIC switch on the network adapter. These capabilities could change when one of the following conditions is true:

- The currently enabled NIC switch hardware capabilities are changed through a management application developed by the independent hardware vendor (IHV).
- The currently enabled NIC switch hardware capabilities change for one or more network adapters that belong to a load balancing failover (LBFO) team managed by a MUX intermediate driver. For more information, see NDIS MUX Intermediate Drivers.

When the PF miniport driver issues the **NDIS_STATUS_NIC_SWITCH_CURRENT_CAPABILITIES** status indication, it must follow these steps:

1. The miniport driver initializes an NDIS_NIC_SWITCH_CAPABILITIES structure with the currently enabled hardware capabilities of the network adapter's NIC switch.
2. The miniport driver initializes an NDIS_STATUS_INDICATION structure in the following way:
    - The **StatusCode** member must be set to **NDIS_STATUS_NIC_SWITCH_CURRENT_CAPABILITIES**.

- The **StatusBuffer** member must be set to the pointer to a NDIS_NIC_SWITCH_CAPABILITIES structure. This structure contains the currently enabled hardware capabilities of the NIC switch.

- The **StatusBufferSize** member must be set to sizeof(NDIS_NIC_SWITCH_CAPABILITIES).

3. The PF miniport driver issues the status notification by calling NdisMIndicateStatusEx. The driver must pass a pointer to the NDIS_STATUS_INDICATION structure to the *StatusIndication* parameter.

Overlying drivers can use the **NDIS_STATUS_NIC_SWITCH_CURRENT_CAPABILITIES** status indication to determine the currently enabled NIC switch capabilities on the network adapter. Alternatively, these drivers can also issue OID query requests of OID_NIC_SWITCH_CURRENT_CAPABILITIES to obtain these capabilities at any time.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ndis.h

NDIS_STATUS_NIC_SWITCH_HARDWARE_CAPABILITIES

Article • 03/14/2023

The **NDIS_STATUS_NIC_SWITCH_HARDWARE_CAPABILITIES** status indicates to NDIS and overlying drivers that the hardware capabilities of the NIC switch in a network adapter have changed. These capabilities include the hardware capabilities that are currently disabled by INF file settings or through the **Advanced** properties page.

The status indication is made by the miniport driver of the network adapter's PCI Express (PCIe) Physical Function (PF). The PF miniport driver runs in the management operating system of the Hyper-V parent partition.

Remarks

The PF miniport driver must issue an **NDIS_STATUS_NIC_SWITCH_HARDWARE_CAPABILITIES** status indication whenever it detects a change to the hardware capabilities of the NIC switch on the network adapter. These capabilities could change when one of the following conditions is true:

- The NIC switch hardware capabilities are enabled or disabled through a management application developed by the independent hardware vendor (IHV).
- The NIC switch hardware capabilities change for one or more network adapters that belong to a load balancing failover (LBFO) team managed by a MUX intermediate driver. For more information, see NDIS MUX Intermediate Drivers.

When the PF miniport driver issues the **NDIS_STATUS_NIC_SWITCH_HARDWARE_CAPABILITIES** status indication, it must follow these steps:

1. The miniport driver initializes an **NDIS_NIC_SWITCH_CAPABILITIES** structure with the hardware capabilities of the network adapter's NIC switch.
2. The miniport driver initializes an **NDIS_STATUS_INDICATION** structure in the following way:
    - The **StatusCode** member must be set to **NDIS_STATUS_NIC_SWITCH_HARDWARE_CAPABILITIES**.

- The **StatusBuffer** member must be set to the pointer to a NDIS_NIC_SWITCH_CAPABILITIES structure. This structure contains the hardware capabilities of the NIC switch.

- The **StatusBufferSize** member must be set to sizeof(NDIS_NIC_SWITCH_CAPABILITIES).

3. The PF miniport driver issues the status notification by calling NdisMIndicateStatusEx. The driver must pass a pointer to the NDIS_STATUS_INDICATION structure to the *StatusIndication* parameter.

Overlying drivers can use the **NDIS_STATUS_NIC_SWITCH_HARDWARE_CAPABILITIES** status indication to determine the currently enabled NIC switch capabilities on the network adapter. Alternatively, these drivers can also issue OID query requests of OID_NIC_SWITCH_HARDWARE_CAPABILITIES to obtain these capabilities at any time.

Virtual Machine Queue (VMQ) Overview

Article • 09/12/2022

The NDIS Virtual Machine Queue (VMQ) interface supports Microsoft Hyper-V network performance improvements in NDIS 6.20 and later in Windows Server 2008 R2 and later versions of Windows Server.

The VMQ interface supports:

- Classification of received packets in network adapter hardware by using the destination media access control (MAC) address to route the packets to different receive queues.
- Shared memory; For more information see NDIS Memory Management Interface.
- Scaling to multiple processors by processing packets for different virtual machines on different processors.

The NDIS VMQ architecture provides advantages for virtualization such as:

- Virtualization impacts performance and VMQ helps overcome those effects.
- VMQ supports live migration.
- VMQ coexists with NDIS task offloads and other optimizations.

This section provides high-level information about the NDIS VMQ interface. You should read this section before writing an NDIS driver that supports VMQ.

For information about writing VMQ drivers, see Writing VMQ Drivers.

> **Note**
>
> Be sure to study the **NDIS Virtual Miniport Driver sample**, especially the vmq.c and vmq.h source files.

This section includes the following topics:

NDIS VMQ Live Migration Support

NDIS VM Queue States

Introduction to NDIS Virtual Machine Queue (VMQ)

Article • 03/14/2023

Many network adapters can support more than one unicast media access control (MAC) address for a network server. Therefore, the network adapter can receive network data frames with a destination MAC address that matches any of the unicast MAC addresses that are set on the network adapter hardware without being in promiscuous mode. Such hardware can allocate a receive queue for each MAC address and route incoming frames with a matching MAC address to the queue. This feature, coupled with the ability to allocate receive buffers for each queue from the memory address space that is assigned to each virtual machine, are the primary capabilities that are required for VMQ support.

A VMQ-capable network adapter can use DMA to transfer all incoming frames that should be routed to a receive queue to the receive buffers that are allocated for that queue. The miniport driver can indicate all of the frames that are in a receive queue in one receive indication call.

VMQ provides the following features:

- Improves network throughput by distributing processing of network traffic for multiple virtual machines (VMs) among multiple processors.

  Note In Hyper-V, a child partition is also known as a VM.

- Reduces CPU utilization by offloading receive packet filtering to network adapter hardware.

- Prevents network data copy by using DMA to transfer data directly to VM memory.

- Splits network data to provide a secure environment. For more information about security issues, see Security Issues with NDIS Virtual Machine (VM) Shared Memory.

  Note Starting with NDIS 6.30 and Windows Server 2012, splitting network data into separate lookahead buffers is no longer supported.

- Supports live migration. For more information about live migration, see NDIS VMQ Live Migration Support.

To introduce high-level VMQ concepts, this section includes the following additional topics:

VMQ Components

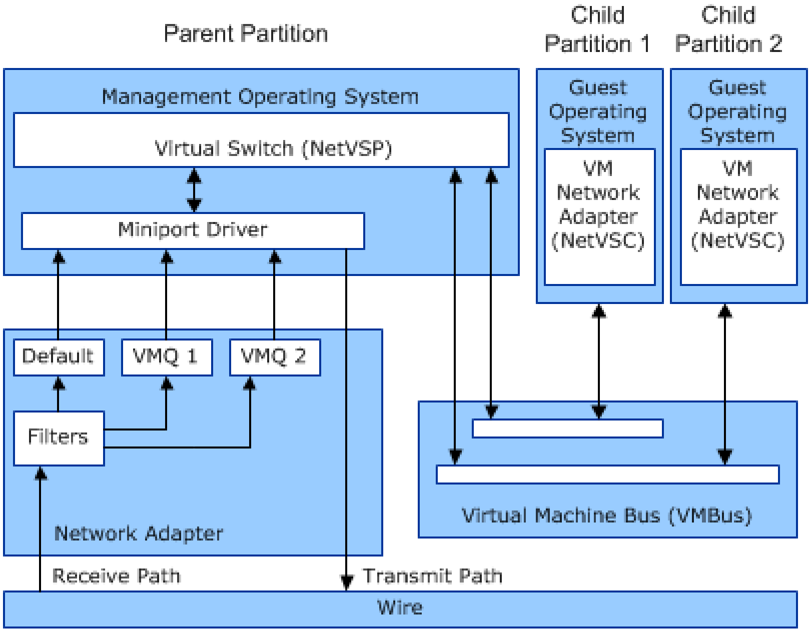
VMQ Receive Queues

VMQ Receive Filters

VMQ Components

Article • 12/15/2021

The following illustration shows the relationships among the various components in a virtual machine queue (VMQ) operating environment.



The preceding figure illustrates the following VMQ components:

Network Virtual Service Provider (NetVSP)
An NDIS driver that runs in the management operating system of the Hyper-V parent partition. This driver provides services to support networking access by the Hyper-V child partitions.

Note Starting with Windows Server 2008, the Hyper-V extensible switch component provides NetVSP support to the NetVSC components that run in the guest operating system. For more information about this component, see Hyper-V Extensible Switch.

Network Virtual Service Client (NetVSC)
An NDIS driver that runs in the guest operating system of a Hyper-V child partition. NetVSC exposes a virtualized view of the physical network adapter on the host computer. This virtualized device is known as the *VM network adapter*.

The NetVSC provides the following functionality:

- Supports networking device functionality in Hyper-V child partitions.
- Accesses the physical network adapter by passing messages over the virtual machine bus (VMBus) to the associated NetVSP driver. This driver runs in the management operating system of the Hyper-V parent partition.

Virtual Machine Bus (VMBus)
A virtual communications bus that passes control and data messages between the Hyper-V parent and child partitions.

Note In Hyper-V, a child partition is also known as a virtual machine (VM).

VM Bus Channel
A communications channel on the VMBus between a NetVSC in a Hyper-V child partition and the NetVSP in the Hyper-V parent partition.

VM Queue
A queue for received data. A network adapter that supports VMQ has hardware to route data to a VM queue.

VMQ Filter
A filter to test incoming data. A network adapter that supports VMQ uses filters to test packet data in order to assign the packet to a queue.

VMQ Receive Queues

Article • 12/15/2021

A virtual machine queue (VMQ) service provider allocates VMQ receive queues. The network adapter hardware assigns an incoming network data packet to a queue if the packet passes the filter tests that are set on the queue.

A VMQ receive queue has the following properties:

- A queue identifier that is unique to the associated network adapter.
- Processor affinity for interrupts.
- Filters that are set on the queue.
- Receive buffers that are assigned to the queue.

There is also a default queue that has the following properties:

- The default queue always exists. Other queues must be allocated.
- The default queue receives packets that do not pass the filter tests for the other queues.

Miniport drivers allocate shared memory for the receive buffers that are associated with a VMQ. Depending on the Windows Server version, miniport drivers must follow guidelines for buffer allocation that are described in the following sections:

- Allocating Shared Memory for VMQ Receive Buffers (Windows Server 2008 R2)
- Allocating Shared Memory for VMQ Receive Buffers (Windows Server 2012 and Later Versions)

VMQ shared memory requirements are designed to address potential security issues for virtual machines (VMs). For more information about VMQ security issues, see Security Issues with NDIS Virtual Machine (VM) Shared Memory.

Allocating Shared Memory for VMQ Receive Buffers (Windows Server 2008 R2)

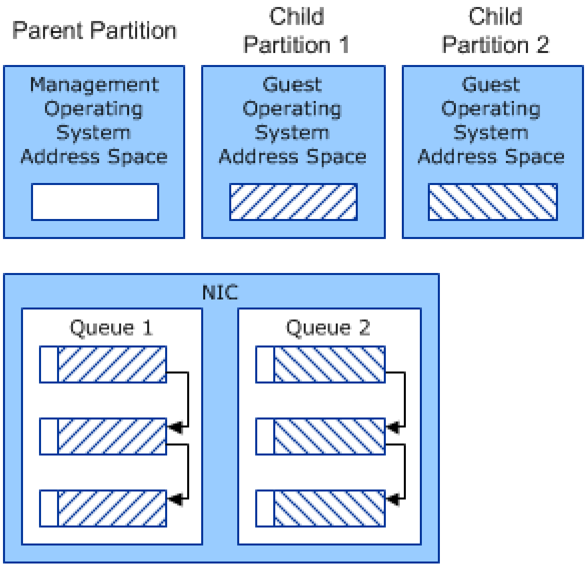
For NDIS 6.20 in Windows Server 2008 R2, if the miniport driver supports splitting packet data into separate lookahead buffers, it can allocate shared memory in the following way:

- The miniport driver allocates the shared memory for the pre-lookahead buffer from the address space of the management operating system that runs in a Hyper-V parent partition. The pre-lookahead buffer is the part of the packet that is inspected by the management operating system.

- The miniport driver allocates the shared memory for the post-lookahead buffer from the address space of the guest operating system that runs in a Hyper-V child partition. The post-lookahead buffer is the part of the packet that is inspected by the guest operating system.

  Note The Hyper-V child partition is also known as a VM.

The following figure shows the shared memory in the queues, the management operating system, and the guest operating systems.



Parent Partition
Child Partition 1
Child Partition 2
Management Operating System Address Space
Guest Operating System Address Space
Guest Operating System Address Space
NIC
Queue 1
Queue 2

In the figure, each packet in a queue is shown with header information that was allocated from the management operating system address space and data that was allocated from the guest operating system address space.

Allocating Shared Memory for VMQ Receive Buffers (Windows Server 2012 and Later Versions)

Starting with NDIS 6.30, splitting VMQ receive buffers into separate lookahead buffers is no longer supported. The miniport driver must allocate memory for each receive buffer from the address space of the management operating system.

VMQ Receive Filters

Article • 12/15/2021

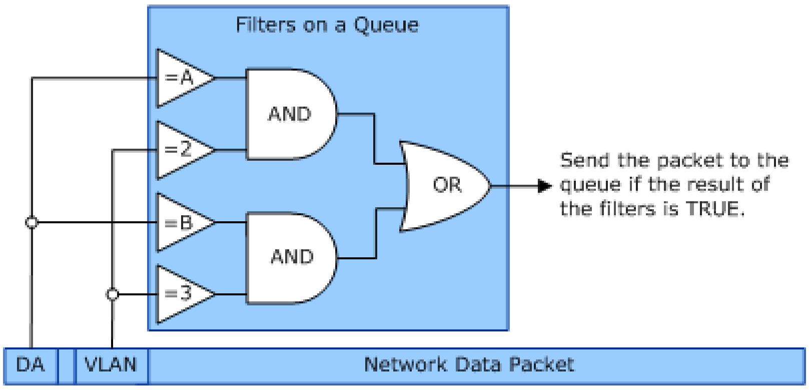
A network virtual service provider (VSP) sets VMQ receive filters on VMQ receive queues. Such a filter includes a set of network header field tests. The network adapter hardware performs these tests on header fields in incoming packets to determine the receive queue assignments for the packets. Each filter that is set on a queue has a unique filter identifier for a network adapter. That is, the filter identifiers are not duplicated on different queues that the network adapter manages.

The VMQ interface uses fields in the media access control (MAC) header in filter tests. Within the MAC header, VMQ filter tests use the virtual local area network (VLAN) identifier and the destination MAC address fields.

Multiple field tests can be specified in a receive filter. All of the tests must pass to match the criterion for the filter and assign a packet to a receive queue. VMQ filters test for fields that are equal to a specified value. For example, the destination MAC address is equal to a specified address.

Multiple filters can be set on a receive queue. If any of the filters on a queue match (that is, all of the tests for that filter were passed), the network adapter assigns the packet to that receive queue.

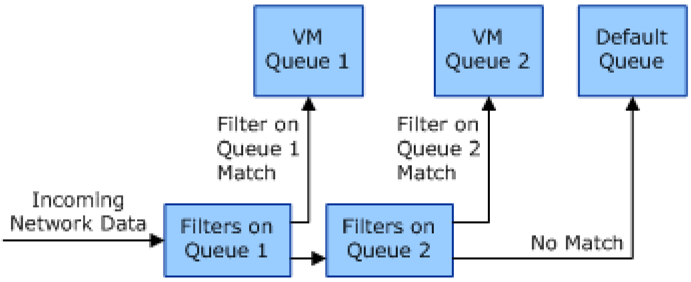
This following figure shows how filter tests are performed and how filters determine a queue assignment.



Filters on a Queue
=A
=2
=B
=3
AND
AND
OR
Send the packet to the queue if the result of the filters is TRUE.
DA
VLAN
Network Data Packet

In the preceding figure, the destination address (DA) is tested (compared to A and B). Also, the VLAN identifier is tested (compared to 2 and 3). The AND operation illustrates that both the DA and VLAN identifier must be equal to the specified values to have a filter match. The OR operation illustrates that any filter on the queue that matches results in the assignment of the network data packet to that queue.

This following figure shows how filters and queues affect the receive data flow.



If an incoming packet matches a filter on a queue, it is assigned to that queue. Otherwise, the packet is tested against the filters on the next queue and so on. If there is no filter match on any of the queues, the network adapter assigns the packet to the default queue.

Security Issues with NDIS Virtual Machine (VM) Shared Memory

Article • 03/14/2023

This topic discusses the potential security issues involved with allocating shared memory from a virtual machine (VM) for virtual machine queue (VMQ) receive buffers. The topic includes the following sections:

- Overview of the Security Issues with VM Shared Memory
- How Windows Server 2008 R2 Addresses the Security Issue
- How Windows Server 2012 and Later Versions Address the Security Issue

Note In Hyper-V, a child partition is also known as a VM.

Overview of the Security Issues with VM Shared Memory

VMs are not trusted software entities. That is, a malicious VM must not be able to interfere with other VMs or the management operating system that runs in the Hyper-V parent partition. This section provides background information and requirements to ensure that driver writers understand VMQ security issues and requirements for shared memory. For more information about shared memory, see the Shared Memory Resource Allocation topic in the Writing VMQ Drivers section.

In the virtualized environment, VM shared memory can be viewed or modified by the VM. However, viewing or modifying data that is associated with other VMs is not allowed. VMs are also not allowed to access the management operating address space.

The header portion of the received packets must be protected. A VM is not allowed to affect the behavior of the Hyper-V extensible switch in a network virtual service provider (VSP). Therefore, VLAN (virtual LAN) filtering must happen before the network adapter uses DMA to transfer the data to VM shared memory. Also, the media access control (MAC) address learning of the switch cannot be affected.

If the Hyper-V extensible switch port that is connected to a VM has an associated VLAN identifier, the host computer must ensure that the destination MAC address and the VLAN identifier of the incoming frame match those respective attributes of the port before the host forwards the packet to the VM's virtual network adapter. If the VLAN identifier of the frame does not match the VLAN identifier of the port, the packet is dropped. When the receive buffers for a virtual network adapter are allocated from host memory, the host can check the VLAN identifier and drop the frame if necessary before making the contents of the frame visible to the target VM. If the frame is not copied to a VM's address space, it cannot be accessed by that VM.

However, when VMQ is configured to use shared memory, the network adapter uses DMA to transfer incoming frames directly to the VM address space. This transfer introduces a security issue in which a VM can examine the contents of the received frames without waiting for the extensible switch to apply the required VLAN filtering.

How Windows Server 2008 R2 Addresses the Security Issue

In Windows Server 2008 R2, before the VSP configures a VM queue to use shared memory that is allocated from the VM address space, it uses the following filtering test for the queue.

syntax

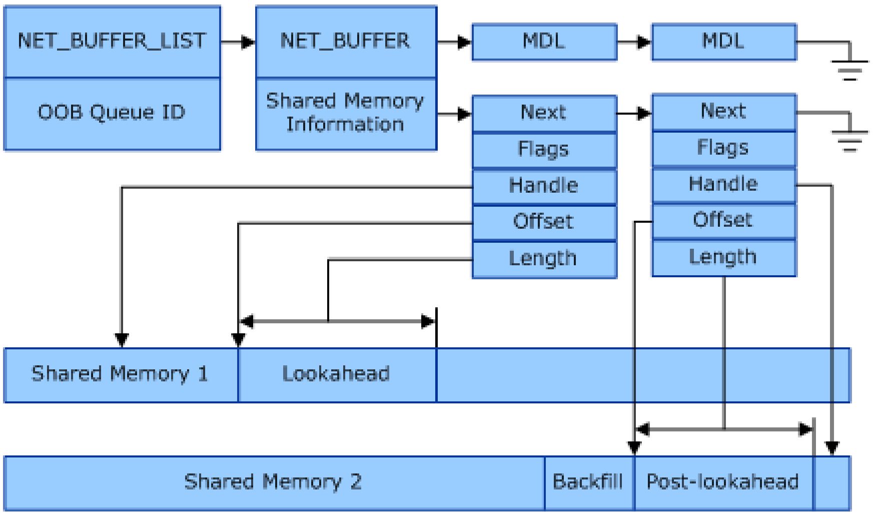
```
(MAC address == x) && (VLAN identifier == n)
```

If the network adapter hardware can support this test before the DMA transfer to the receive buffers, the network adapter can either drop frames with invalid VLAN identifiers or send them to the default queue so that they can be filtered out by the extensible switch. If the miniport driver succeeds in a request to set a filter with this test on a queue, the extensible switch can use VM shared memory for that queue. However, if the network adapter hardware is not capable of filtering the frames based on both destination MAC address and VLAN identifier, the extensible switch uses host shared memory for that queue.

The extensible switch inspects the source MAC address of received frames to configure the routing information for transmit frames—that is, it is similar to a physical learning switch. It is possible to install firewall filter drivers in the host stack; for example, above the miniport driver for the network adapter hardware and below the extensible switch driver. Firewall filter drivers can access data in a received frame before the extensible switch. If the entire receive buffer for each frame is allocated from VM address space, a malicious VM could access parts of the frame that would be examined by either a filter driver or the extensible switch that runs in the host.

To address this security issue, when using VM shared memory for a VM queue, the network adapter must split the packet at a byte offset that is at least the lookahead size, which is a predetermined fixed value. Any lookahead data— meaning data that is ahead of the byte offset for the lookahead size—must be transferred with DMA to shared memory that was allocated for lookahead data. The post-lookahead data—the rest of the frame payload—should be transferred with DMA to shared memory that was allocated for the post-lookahead data.

The following illustration shows the relationships for the network data structures when the incoming data is split into lookahead and post-lookahead shared memory buffers.



The summary requirements for VMQ shared memory are as follows:

- A network adapter can split a received frame at a network-header boundary that is larger than the lookahead size. However, when requested by NDIS, and without exception, all of the frames that are received and assigned to a VMQ must be split at or beyond the lookahead size boundary that NDIS requests.

- The lookahead data must be transferred with DMA to shared memory that is allocated by the miniport driver. The miniport driver must specify in the allocation call that the memory will be used for lookahead data.

- The post-lookahead data must be transferred with DMA to shared memory that is allocated by the miniport driver. The miniport driver must specify in the allocation call that the memory will be used for post-lookahead data.

- Miniport drivers must not be dependent upon which address space NDIS will use to complete the shared memory allocation request. That is, the shared memory address space for lookahead or post-lookahead data is implementation specific. In many cases, NDIS or the extensible switch might satisfy all the requests, including those for post-lookahead use, from host memory address space.

- The order in which frames are received on a VMQ receive queue must be preserved when the frames in that queue are indicated up the driver stack.

- The network adapter must allocate enough backfill memory space in each post-lookahead buffer. This allocation allows the lookahead data to be copied to the backfill portion of the post-lookahead buffer, and allows the frame to be delivered to the VM in a contiguous buffer.

If there is no mechanism in hardware to meet these requirements for VMQ shared memory, the hardware that supports scatter-gather DMA on the receive side might achieve the same results by allocating two receive buffers for each received frame. In this case, the size of the first buffer is limited to the requested lookahead size.

If the network adapter cannot meet these requirements for VMQ shared memory by any method, the VSP will allocate memory for the VMQ receive buffers from the host address space and will copy the received packets from the network adapter receive buffers to VM address space.

How Windows Server 2012 and Later Versions Address the Security Issue

Starting with Windows Server 2012, the VSP does not allocate shared memory from the VM for the VMQ receive buffers. Instead, the VSP allocates memory for the VMQ receive buffers from the host address space and then copies the received packets from the network adapter receive buffers to VM address space.

The following points apply to VMQ miniport drivers that run on Windows Server 2012 and later versions of Windows:

- For NDIS 6.20 VMQ miniport drivers, no change is required. However, when the VSP allocates a VM queue by issuing an OID (object identifier) method request of OID_RECEIVE_FILTER_ALLOCATE_QUEUE, it will set the **LookaheadSize** member of the **NDIS_RECEIVE_QUEUE_PARAMETERS** structure to zero. This will force a miniport driver to not split the packet into pre-lookahead and post-lookahead buffers.

- Starting with NDIS 6.30, VMQ miniport drivers must not advertise support for splitting packet data into pre-lookahead and post-lookahead buffers. When a miniport driver registers its VMQ capabilities, it must follow these rules when it initializes the **NDIS_RECEIVE_FILTER_CAPABILITIES** structure:

  - The miniport driver must not set the **NDIS_RECEIVE_FILTER_LOOKAHEAD_SPLIT_SUPPORTED** flag in the **Flags** member.

  - The miniport driver must set the **MinLookaheadSplitSize** and **MaxLookaheadSplitSize** members to zero.

For more information about how to register VMQ capabilities, see Determining the VMQ Capabilities of a Network Adapter.

NDIS VMQ Live Migration Support

Article • 03/14/2023

To support live migration, a virtual machine (VM) can be paused at any instruction or pending I/O boundary. That is, the VM might not finish pending receive requests. So, the network virtual service provider (VSP) returns all of the received packets to the underlying network adapter that the VM did not return.

Note In Hyper-V, a child partition is also known as a VM.

When the VM is restarted on another host, the network VSP on the new host handles the receive packets that the resumed VM returns and does not pass them down to the new underlying in miniport driver. After the migration is complete, the receive queue that was associated with the VM is freed and it can be reused for another VM.

Note The new network adapter might not support VMQ.

When NDIS requests a miniport driver to free a VMQ receive queue, it follows these steps:

1. The network adapter stops the DMA transfer of data to receive buffers that are associated with the receive queue, after which the queue must enter the DMA Stopped state. The network adapter probably stopped the DMA activity when it received the OID_RECEIVE_FILTER_CLEAR_FILTER OID request to clear the last set filter on the receive queue.

2. The miniport driver generates an **NDIS_STATUS_RECEIVE_QUEUE_STATE** status indication with the **QueueState** member of the **NDIS_RECEIVE_QUEUE_STATE** structure set to **NdisReceiveQueueOperationalStateDmaStopped** to notify NDIS that the DMA transfer has been stopped.

3. The miniport driver waits for all the indicated receive packets for that queue to be returned to the miniport driver.

4. The miniport driver frees all the shared memory that it allocated for the network adapter's receive buffers that are associated with the queue by calling **NdisFreeSharedMemory**.

5. The miniport driver completes the OID_RECEIVE_FILTER_FREE_QUEUE OID request to free the receive queue.

For more information about queue states, see NDIS VM Queue States.

NDIS Virtual Machine Queue States

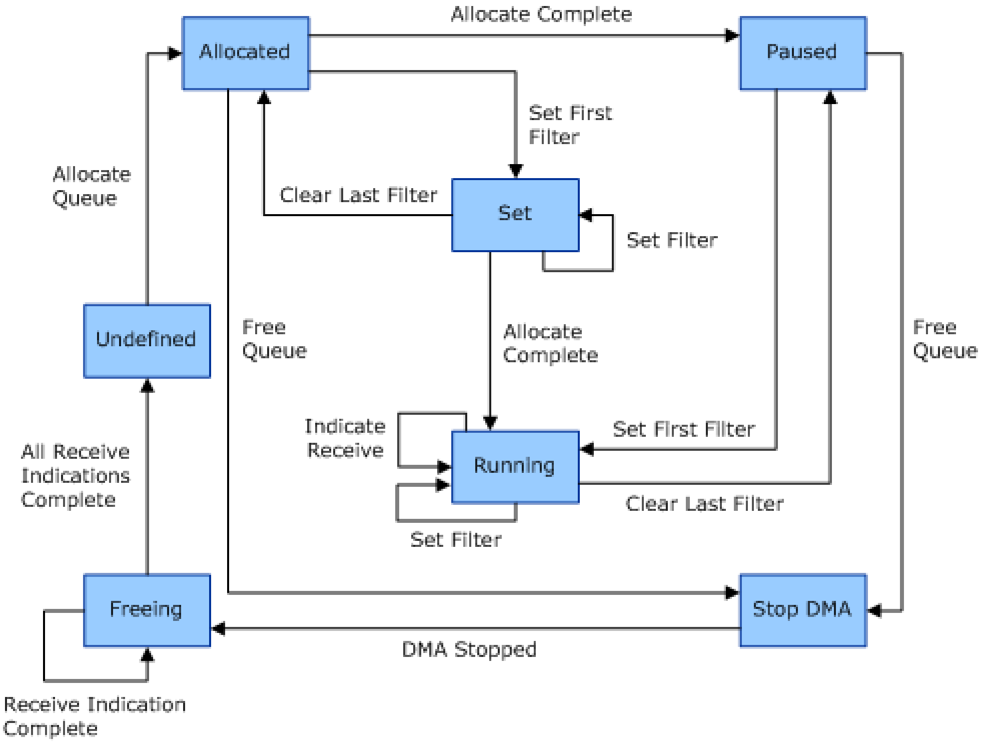
Article • 03/14/2023

This topic provides an overview of the operational states of NDIS virtual machine queues (VMQs). For more information about queue states, see the Queue States and Operations topic in the Writing VMQ Drivers section.

For each queue, a network adapter must support the following set of operational states:

- Undefined
- Allocated
- Set
- Paused
- Running
- Stop DMA
- Freeing

The following figure shows the relationships between these states.



The following defines the adapter states:

Undefined

Undefined is the initial state of a queue. In this state, the queue is not allocated. A queue (except the default queue which always exists) is undefined until the miniport driver receives a queue allocation request. Also, it is undefined after the free operation is complete and any receive indications that had been started are complete.

Allocated

A queue is in the *Allocated* state after an allocation request and before there are any filters set on the queue. The filter can also enter the Allocated state if the queue is in the Set state and the last filter is cleared on the queue. The queue enters the Paused state if the miniport driver receives an allocation complete request while the miniport driver is in the Allocated state. The queue enters the Stop DMA state if the miniport driver receives a free queue request.

Set

In the *Set* state, a queue is allocated and a least one filter is set on the queue but the miniport driver did not receive an allocation complete OID yet. The queue enters the Running state if it receives an allocation complete request. The queue enters the Allocated state if the last filter on the queue is cleared. Note that the queue cannot be freed while there are filters set on the queue.

Paused

In the *Paused* state, the queue is allocated but its miniport driver does not indicate received packets because there are no filters set on the queue. The miniport driver can enter the Paused state either from the Allocated state or from the Running state. The queue enters the Running state when it receives a filter set request. The queue enters the Stop DMA state when it receives a free queue request.

Running

In the *Running* state, a queue has filters set, the queue allocation is complete, and the network adapter indicates receive packets. The queue enters the Paused state if the last filter on the queue is cleared. Note that the queue cannot be freed while there are filters set on the queue. Also, the miniport driver can stop the DMA if the last filter is cleared. However, the miniport driver should not send the DMA stopped state indication in this case.

Stop DMA

In the *Stop DMA* state, the miniport driver received a free queue request and the DMA activity must be stopped. The miniport driver must send a DMA stopped state indication. After the miniport driver sends the status indication, the queue is in the Freeing state. Note that the DMA was probably already stopped when the last filter was cleared. However, the miniport driver should only send the status indication when it receives the free queue request.

Freeing
In the *Freeing* state, a miniport driver is waiting for all of the outstanding receive indications on a queue to complete and freeing the resources that are associated with the queue. After all of the resources are freed, the queue enters the Undefined state.

Getting Started Writing VMQ Drivers

Article • 12/15/2021

This section provides information about writing NDIS virtual machine queue (VMQ) drivers. You should already understand the Virtual Machine Queue Architecture before you read this section.

Note Be sure to study the NDIS Virtual Miniport Driver sample, especially the vmq.c and vmq.h source files.

A miniport driver that supports VMQ manages NICs that provide the VMQ hardware support. Such a NIC provides hardware services to filter incoming network data, and assign it to VM receive queues.

This section describes how overlying drivers obtain information about the underlying network adapter and set the VMQ configuration. Overlying drivers and user applications can obtain the current configuration and enable or disable VMQ features.

This section includes the following topics:

- VMQ Driver Configuration
- Queue States and Operations
- VMQ Interrupt Requirements
- Allocating and Freeing VM Queues
- Setting and Clearing VMQ Filters
- Obtaining and Updating VM Queue Parameters
- VMQ Send and Receive Operations
- Obtaining VMQ Information

VMQ Driver Configuration

Article • 12/15/2021

This section describes the features that NDIS provides to determine the virtual machine queue (VMQ) capabilities of network adapters.

A miniport driver reports its VMQ capabilities to NDIS and overlying drivers during network adapter initialization.

Standardized INF file entries can enable or disable VMQ features when a driver is installed.

This section includes the following topics:

Determining the VMQ Capabilities of a Network Adapter

Standardized INF Keywords for VMQ

Determining the VMQ Capabilities of a Network Adapter

Article • 12/15/2021

NDIS provides the interface to determine the VMQ capabilities of a network adapter, such as:

- The generic filtering capabilities of a network adapter.
- Supported VM queue capabilities.
- Lookahead support to allow splitting of the networking data memory into two separate buffers.

  Note Starting with NDIS 6.30, splitting packet data into separate lookahead buffers is no longer supported.

Miniport drivers provide the following information to NDIS during network adapter initialization:

- The VMQ hardware capabilities that the network adapter can support.
- The VMQ capabilities that are currently enabled.
- The global receive filtering features that are enabled or disabled on a network adapter.

Overlying drivers and applications can use the following OID query requests to obtain the network adapter capabilities.

OID_RECEIVE_FILTER_HARDWARE_CAPABILITIES

OID_RECEIVE_FILTER_CURRENT_CAPABILITIES

OID_RECEIVE_FILTER_GLOBAL_PARAMETERS

NDIS handles these OID query requests for miniport drivers. Therefore, the query is not requested for miniport drivers. NDIS reports the currently enabled receive VMQ capabilities of a network adapter during initialization. Therefore, overlying drivers do not have to query these OIDs.

The **NDIS_RECEIVE_FILTER_CAPABILITIES** structure specifies the filtering capabilities of a network adapter. This structure is used in the following ways:

- When NDIS calls the *MiniportInitializeEx* function, the miniport driver registers its filtering capabilities by initializing an **NDIS_RECEIVE_FILTER_CAPABILITIES** structure. The driver then sets the **HardwareReceiveFilterCapabilities** member of the **NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES** structure to point to the **NDIS_RECEIVE_FILTER_CAPABILITIES** structure. The driver next calls the **NdisMSetMiniportAttributes** function and then sets the *MiniportAttributes* parameter to a pointer to the **NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES** structure.

- An overlying protocol driver receives the **NDIS_RECEIVE_FILTER_CAPABILITIES** structure in the **NDIS_BIND_PARAMETERS** structure when NDIS calls the driver's *ProtocolBindAdapterEx* function.

- An overlying filter driver receives the **NDIS_RECEIVE_FILTER_CAPABILITIES** structure in the **NDIS_FILTER_ATTACH_PARAMETERS** structure when NDIS calls the driver's *FilterAttach* function.

- Overlying drivers receive the **NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES** structure by issuing an OID query request of OID_RECEIVE_FILTER_CURRENT_CAPABILITIES or OID_RECEIVE_FILTER_HARDWARE_CAPABILITIES. The **HardwareReceiveFilterCapabilities** and **CurrentReceiveFilterCapabilities** members point to an **NDIS_RECEIVE_FILTER_CAPABILITIES** structure.

The **NDIS_RECEIVE_FILTER_CAPABILITIES** structure includes the following information:

EnabledFilterTypes
The types of the supported receive filters. The NDIS_RECEIVE_FILTER_VMQ_FILTERS_ENABLED flag specifies that virtual machine queue (VMQ) filters are enabled.

EnabledQueueTypes
The types of supported receive queues. The NDIS_RECEIVE_FILTER_VM_QUEUES_ENABLED flag specifies that virtual machine (VM) queues are enabled.

NumQueues
The number of receive queues that the network adapter supports. To support VMQ, this number must be equal to or less than the number of unicast MAC addresses that the NIC supports. This number must not include the default queue.

Note The number of unicast MAC addresses or VM queues that a network adapter supports does not include the MAC address of the associated NIC.

SupportedQueueProperties

The queue properties that the network adapter supports. The NDIS_RECEIVE_FILTER_VM_QUEUE_SUPPORTED flag specifies that the network adapter provides the minimum requirements to support VMQ filtering. A VMQ-capable NIC must provide an MSI-X table entry for each receive queue. Therefore, a VMQ miniport driver must set the NDIS_RECEIVE_FILTER_MSI_X_SUPPORTED flag.

SupportedFilterTests

The filter test operations that a miniport driver supports. For example, the network adapter supports testing the selected header field to determine whether it is equal to a given value. A VMQ miniport driver must set the NDIS_RECEIVE_FILTER_TEST_HEADER_FIELD_EQUAL_SUPPORTED flag.

SupportedHeaders

The types of network packet headers that a miniport driver can inspect. For example, the network adapter can inspect the MAC header of a network packet. The MAC header includes the packet type, destination and source MAC addresses, the VLAN identifier, and the priority tag fields. A VMQ miniport driver must set the NDIS_RECEIVE_FILTER_MAC_HEADER_SUPPORTED flag.

SupportedMacHeaderFields

The types of MAC header fields that a miniport driver can inspect. A VMQ miniport driver must set the NDIS_RECEIVE_FILTER_MAC_HEADER_DEST_ADDR_SUPPORTED flag.

MaxMacHeaderFilters

The maximum number of MAC header filters that the miniport driver supports. There should be at least as many header filters as there are VM queues.

MaxQueueGroups

This member is reserved for NDIS.

MaxQueuesPerQueueGroup

This member is reserved for NDIS.

MinLookaheadSplitSize

The minimum size, in bytes, that the network adapter supports for lookahead packet segments.

Note Starting with NDIS 6.30, splitting packet data into separate lookahead buffers is no longer supported. Miniport drivers that support NDIS 6.30 or later versions must set this member to zero.

MaxLookaheadSplitSize

The maximum size, in bytes, that the network adapter supports for lookahead packet segments.

Note Starting with NDIS 6.30, splitting packet data into separate lookahead buffers is no longer supported. Miniport drivers that support NDIS 6.30 or later versions must set this member to zero.

After a successful return from the OID_RECEIVE_FILTER_HARDWARE_CAPABILITIES OID query, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an NDIS_RECEIVE_FILTER_CAPABILITIES structure. These capabilities can include VMQ hardware capabilities that are currently disabled by INF file settings or through the **Advanced** properties page. For more information about VMQ INF files settings, see VMQ Standard INF Entries.

NDIS miniport drivers supply the receive-filtering hardware capabilities during initialization in the **HardwareReceiveFilterCapabilities** member of the **NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES** structure.

After a successful return from the OID_RECEIVE_FILTER_CURRENT_CAPABILITIES OID query, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_FILTER_CAPABILITIES** structure. These capabilities include the currently enabled VMQ capabilities.

NDIS miniport drivers supply the currently enabled receive filtering capabilities during initialization in the **CurrentReceiveFilterCapabilities** member of the **NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES** structure.

NDIS reports the currently enabled receive filtering capabilities of an underlying network adapter to overlying protocol drivers in the **ReceiveFilterCapabilities** member of the **NDIS_BIND_PARAMETERS** structure during the bind operation.

The **NDIS_RECEIVE_FILTER_GLOBAL_PARAMETERS** structure is used in the OID_RECEIVE_FILTER_GLOBAL_PARAMETERS query OID to obtain the current global receive filter settings.

NDIS_RECEIVE_FILTER_GLOBAL_PARAMETERS includes the following information:

EnabledFilterTypes
The types of enabled receive filters. The NDIS_RECEIVE_FILTER_VMQ_FILTERS_ENABLED flag specifies that virtual machine queue (VMQ) filters are enabled.

EnabledQueueTypes
The types of enabled receive queues. The NDIS_RECEIVE_FILTER_VM_QUEUES_ENABLED flag specifies that virtual machine (VM) queues are enabled.

After a successful return from the OID_RECEIVE_FILTER_GLOBAL_PARAMETERS OID query, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_FILTER_GLOBAL_PARAMETERS** structure. The NDIS_RECEIVE_FILTER_GLOBAL_PARAMETERS structure specifies the receive-filtering features that are enabled or disabled on a network adapter.

NDIS protocol drivers use OID_RECEIVE_FILTER_GLOBAL_PARAMETERS to query the current global configuration parameters for receive filtering on a network adapter. For example, protocol drivers can use this OID to determine whether types of receive filters or receive queues are enabled or disabled.

Standardized INF Keywords for VMQ

Article • 12/15/2021

The following standardized INF keywords are defined to enable or disable support for the virtual machine queue (VMQ) features of network adapters.

***VMQ**
A value that describes whether the device has enabled or disabled the VMQ feature.

***VMQLookaheadSplit**
A value that describes whether the device has enabled or disabled the ability to split receive buffers into lookahead and post-lookahead buffers. The miniport driver reports this capability with the NDIS_RECEIVE_FILTER_LOOKAHEAD_SPLIT_SUPPORTED flag in the **SupportedQueueProperties** member of the NDIS_RECEIVE_FILTER_CAPABILITIES structure. For more information about this feature, see Shared Memory in Receive Buffers.

Note Starting with NDIS 6.30, splitting packet data into separate lookahead buffers is no longer supported. Starting with Windows Server 2012, this INF keyword is obsolete.

***VMQVlanFiltering**
A value that describes whether the device has enabled or disabled the ability to filter network packets by using the VLAN identifier in the media access control (MAC) header. The miniport driver reports this capability with the NDIS_RECEIVE_FILTER_MAC_HEADER_VLAN_ID_SUPPORTED flag in **SupportedMacHeaderFields** member of the NDIS_RECEIVE_FILTER_CAPABILITIES structure.

***RssOrVmqPreference**
A value that defines whether VMQ capabilities should be enabled instead of receive side scaling (RSS) capabilities.

This is a hidden keyword value that must not be specified in the INF file and is not displayed in **Advanced** property page for the network adapter. For more information, see Handling VMQ and RSS INF Keywords.

VMQ standardized INF keywords are enumeration keywords. The following table describes the possible INF entries for the VMQ standardized INF keywords.

SubkeyName	ParamDesc	Value	EnumDesc
***VMQ**	Virtual Machine Queues	0	Disabled

SubkeyName	ParamDesc	Value	EnumDesc
		1 (Default)	Enabled
***VMQLookaheadSplit**	VMQ Lookahead Split	0	Disabled **Note** Starting with NDIS 6.30, this keyword is no longer supported.
		1 (Default)	Enabled
***VMQVlanFiltering**	VMQ VLAN Filtering	0	Disabled
		1 (Default)	Enabled
***RssOrVmqPreference**	Note: The ParamDesc and EnumDesc entries for this subkey cannot be used in either INF files or a user interface. For more information, see Handling VMQ and RSS INF Keywords.	0 (Default)	**Note** Report RSS capabilities
		1	**Note** Report VMQ capabilities

The columns in this table describe the following attributes for an enumeration keyword:

SubkeyName
The name of the keyword that you must specify in the INF file. This name also appears in the registry under the **NDI\params** key for the network adapter.

ParamDesc
The display text that is associated with the SubkeyName INF entry.

Note The independent hardware vendor (IHV) can define any descriptive text for the SubkeyName.

Value
The enumeration integer value that is associated with each SubkeyName in the list.

EnumDesc
The display text that is associated with each value that appears in the **Advanced**

property page.

For more information about standardized INF keywords, see Standardized INF Keywords for Network Devices.

Handling VMQ and RSS INF Keywords

Network adapters that support VMQ and receive side scaling (RSS) cannot use these features simultaneously. The operating system enables the use of the RSS or VMQ features in the following way:

- When the network adapter is bound to the TCP/IP stack, the operating enables the use of the RSS feature.
- When the network adapter is bound to the Hyper-V extensible switch driver stack, the operating system enables the use of the VMQ feature.

  For more information, see Hyper-V Extensible Switch.

Because the network adapter is not disabled and then re-enabled when it is unbound from the TCP/IP stack and bound to the Hyper-V driver stack (or the reverse), it is not possible for such network adapters to switch between VMQ and RSS automatically.

When NDIS calls the *MiniportInitializeEx* function, the miniport driver follows these steps before it reports its currently-enabled VMQ or RSS capabilities to NDIS:

1. The miniport driver reads the ***RssOrVmqPreference** keyword before reporting its currently-enabled capabilities to NDIS.

   If the value of the ***RssOrVmqPreference** keyword is 1, the miniport driver is configured for VMQ preference.

   If the value of the ***RssOrVmqPreference** keyword is zero or the keyword is not present, the miniport driver is configured for RSS preference.

2. If the miniport driver is configured for VMQ preference, it must read the ***VMQ** keyword to determine if VMQ is enabled on the network adapter. If the keyword is set to 1, the driver reports the currently-enabled VMQ settings. For more information on how the miniport driver reports VMQ settings, see Determining the VMQ Capabilities of a Network Adapter.

   For more information about the VMQ keywords, see Standardized INF Keywords for VMQ.

Note If the miniport driver is configured for VMQ preference, it must not read any of the RSS standardized keywords.

3. If the miniport driver is configured for RSS preference, it must read the ***RSS** keyword to determine if RSS is enabled on the network adapter. If the keyword is set to 1, the driver reports the currently-enabled RSS settings. For more information on how the miniport driver reports RSS settings, see RSS Configuration.

   For more information about the RSS keywords, see Standardized INF Keywords for RSS.

   Note If the miniport driver is configured for RSS preference, it must not read any of the VMQ standardized keywords.

The following table describes how the miniport driver determines RSS or VMQ preference and advertises capabilities based on registry keywords:

*RssOrVmqPreference	*VMQ	*RSS	VMQ or RSS capabilities advertised
1	1	N/A	VMQ
1	0	N/A	None
0, or not present in registry	N/A	1	RSS
0, or not present in registry	N/A	0	None

Note The miniport driver must always report the complete RSS and VMQ hardware capabilities regardless of the values of these keywords. These keyword settings only affect how the driver reports the currently-enabled RSS and VMQ capabilities.

Reserved Registry Keywords

If the miniport driver supports VMQ and the VMQ interface is enabled on the network adapter, the driver must not read the following RSS INF entries:

SubkeyName	ParamDesc	Value
*RssMaxProcNumber	The maximum processor number of the RSS interface.	0 through (MAXIMUM_PROC_PER_GROUP-1),
*MaxRssProcessors	The maximum number of RSS processors.	1 through MAXIMUM_PROC_PER_SYSTEM.

The miniport driver that supports VMQ must not read the following subkeys under the **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\VMSMP\Parameters** registry key.

SubkeyName	ParamDesc	Value
***TenGigVmqEnabled**	Enable or disable VMQ on all 10 gigabits per second (Gbps) network adapters.	0=System default (disabled for Windows Server 2008 R2).
		1=Enabled.
		2=Explicitly disabled.
***BelowTenGigVmqEnabled**	Enable or disable VMQ on all network adapters that support less than 10 Gbps.	0=System default (disabled for Windows Server 2008 R2).
		1=Enabled.
		2=Explicitly disabled.
***RssMaxProcNumber**	The maximum processor number of the RSS interface.	0 through (MAXIMUM_PROC_PER_GROUP-1),
***MaxRssProcessors**	The maximum number of RSS processors.	1 through MAXIMUM_PROC_PER_SYSTEM.

Queue States and Operations

Article • 12/15/2021

For each queue, a network adapter must support the following set of operational states:

Undefined
The queue is not allocated. To allocate a queue, an overlying driver sends an OID_RECEIVE_FILTER_ALLOCATE_QUEUE OID request.

Allocated
The *Allocated* state is the initial state for a queue. When a queue is in the Allocated state, the overlying driver usually sets filters on the queue with the OID_RECEIVE_FILTER_SET_FILTER OID or completes the queue allocation with the OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE OID request.

Set
In the *Set* state, a queue has at least one filter allocated but the overlying driver has not sent the OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE OID.

Running
In the *Running* state, the queue has filters set, the queue allocation is complete and the miniport adapter is indicating receive packets for the queue.

Paused
In the *Paused* state, the network adapter does not indicate received network data for the queue. Either there were no filters set on the queue before the OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE OID request or all of the filters that were set on the queue were cleared with the OID_RECEIVE_FILTER_CLEAR_FILTER OID request.

DMA Stopped
In the *DMA Stopped* state, a miniport driver received an OID_RECEIVE_FILTER_FREE_QUEUE OID request. When the DMA is stopped and the driver has issued the DMA-stopped status indication (with **NDIS_STATUS_RECEIVE_QUEUE_STATE**), the driver enters the Freeing state.

Freeing
In the *Freeing* state, a miniport driver completes the operations that are required to stop send and receive operations for the queue, and releases the associated resources. After all of the outstanding receive indications are complete, the queue is deleted and the queue is Undefined.

In the following table, the headings are the queue states. Major events are listed in the first column. The rest of the entries in the table specify the next state that the queue enters after an event occurs within a state. The blank entries represent invalid event/state combinations.

Event \ State	Undefined	Allocated	Set	Running	Paused	Stop DMA	Freeing
OID_RECEIVE_FILTER_ALLOCATE_QUEUE - method (set)	Allocated						
OID_RECEIVE_FILTER_QUEUE_PARAMETERS - method (query) request		Allocated	Set	Running	Paused		
OID_RECEIVE_FILTER_QUEUE_PARAMETERS - set request		Allocated	Set	Running	Paused		
OID_RECEIVE_FILTER_SET_FILTER - method (set) request		Set	Set	Running	Running		
OID_RECEIVE_FILTER_CLEAR_FILTER - set request (last filter)			Allocated	Paused			

Event \ State	**Undefined**	**Allocated**	**Set**	**Running**	**Paused**	**Stop DMA**	**Freeing**
OID_RECEIVE_FILTER_CLEAR_FILTER - set request (not last filter)			Set	Running			
OID_RECEIVE_FILTER_ENUM_FILTERS - method (query request)		Allocated	Set	Running	Paused		
OID_RECEIVE_FILTER_PARAMETERS - method (query) request			Set	Running			
OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE - method (set) request		Paused	Running				
Receive packet				Running			
OID_RECEIVE_FILTER_FREE_QUEUE set request		Stop DMA			Stop DMA		
DMA is stopped and NDIS_STATUS_RECEIVE_QUEUE_STATE status indication was sent (Note: DMA was probably already stopped in Allocated or Paused state)						Freeing	
All receive indications are complete and the queue resources are freed							Undefined

Note The events listed in the preceding table include some secondary events that do not result in a state change. These secondary events are included in the table to specify the states where these events are valid.

The primary queue events are defined as follows:

OID_RECEIVE_FILTER_ALLOCATE_QUEUE - method (set) request
An overlying driver allocated a queue. For more information about allocating queues, see Allocating and Freeing VM Queues.

OID_RECEIVE_FILTER_SET_FILTER - method (set) request
An overlying driver set a filter on a queue. If the overlying driver has not sent the OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE OID, the queue is in the Set state. Otherwise, the queue is in the Running state. For more information about setting filters on queues, see Setting and Clearing VMQ Filters.

OID_RECEIVE_FILTER_CLEAR_FILTER - set request
An overlying driver cleared a filter on a queue. If the last filter was cleared on a running queue, the DMA can be stopped; receive indications are stopped and the queue should be cleared of received data, if any. For more information about clearing filters on queues, see Setting and Clearing VMQ Filters.

OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE - method (set) request
An overlying driver completed the queue allocation. If there are filters set on the queue, it is in the Running state and receive indications can start. For more information about completing queue allocation, see Allocating and Freeing VM Queues.

Receive packet
A miniport driver can only indicate receive packets for a queue that is in the Running state. For more information about indicating received data for queues, see VMQ Send and Receive Operations.

OID_RECEIVE_FILTER_FREE_QUEUE set request.
An overlying driver freed a queue. The driver issues the DMA-stopped status indication (with **NDIS_STATUS_RECEIVE_QUEUE_STATE**), the driver enters the Freeing state. When all of the outstanding receive indications are complete and the queue resources are freed, the queue is undefined.

VMQ Interrupt Requirements

Article • 12/15/2021

A miniport driver that supports the virtual machine queue (VMQ) functionality must also support the following interrupt allocation requirements:

- The miniport driver must support MSI-X. The driver must set the **NDIS_RECEIVE_FILTER_MSI_X_SUPPORTED** flag in the **SupportedQueueProperties** member of the NDIS_RECEIVE_FILTER_CAPABILITIES structure.

  The driver returns this structure in the NDIS_MINIPORT_ADAPTER_HARDWARE_ASSIST_ATTRIBUTES structure that the driver uses in its call to the NdisMSetMiniportAttributes function.

- The miniport driver must call the NdisGetRssProcessorInformation function to obtain processor information for allocating interrupt vectors. It must not rely on registry keys or information obtained from other sources for interrupt allocation.

  NdisGetRssProcessorInformation returns information about the set of processors that a miniport driver can use for RSS and VMQ. This information is contained in an NDIS_RSS_PROCESSOR_INFO structure.

- The miniport driver should allocate only one interrupt vector for each processor that is specified in the NDIS_RSS_PROCESSOR_INFO structure.

  The miniport driver should allocate no more than two interrupt vectors for other events that are not related to send or receive packet operations. For example, the driver could allocate an IDT for link status events.

- The miniport driver must support the minimum number of MSI-X interrupt vectors as defined in the following table:

Number of queues	Minimum number of required MSI-X interrupt vectors
1–16	1–16

Allocating and Freeing VM Queues

Article • 12/15/2021

This section includes the following topics:

Allocating a VM Queue

Article • 12/15/2021

To allocate a queue with an initial set of configuration parameters, an overlying driver issues an OID_RECEIVE_FILTER_ALLOCATE_QUEUE method OID request. The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure initially contains a pointer to an **NDIS_RECEIVE_QUEUE_PARAMETERS** structure. After a successful return from the OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_QUEUE_PARAMETERS** structure that has a new queue identifier and an MSI-X table entry.

The **NDIS_RECEIVE_QUEUE_PARAMETERS** structure is used in the OID_RECEIVE_FILTER_ALLOCATE_QUEUE OID and the OID_RECEIVE_FILTER_QUEUE_PARAMETERS OID. For more information about VM queue parameters, see Obtaining and Updating VM Queue Parameters.

The overlying driver initializes the **NDIS_RECEIVE_QUEUE_PARAMETERS** structure with the following queue configuration parameters:

- The queue type (**NdisReceiveQueueTypeVMQueue** from the **NDIS_RECEIVE_QUEUE_TYPE** enumeration.)

- The processor affinity for the queue.

- The queue name and the virtual machine name.

- The lookahead-split parameters.

  Note Starting with NDIS 6.30, splitting packet data into separate lookahead buffers is no longer supported.

Note The overlying driver can set the NDIS_RECEIVE_QUEUE_PARAMETERS_PER_QUEUE_RECEIVE_INDICATION and NDIS_RECEIVE_QUEUE_PARAMETERS_LOOKAHEAD_SPLIT_REQUIRED flags in the **Flags** member of the **NDIS_RECEIVE_QUEUE_PARAMETERS** structure. The other flags are not used for queue allocation.

When NDIS receives an OID request to allocate a receive queue, it verifies the queue parameters. After NDIS allocates the necessary resources and the queue identifier, it submits the OID request to the underlying miniport driver. The queue identifier is unique to the associated network adapter.

If the miniport driver can successfully allocate the necessary software and hardware resources for the receive queue, it completes the OID request with a success status.

Before NDIS sends the OID request to the miniport driver, NDIS assigns a queue identifier in the **QueueId** member of the **NDIS_RECEIVE_QUEUE_PARAMETERS** structure and passes the method request to the miniport driver. The miniport driver provides the MSI-X table entry in the **MSIXTableEntry** member.

The miniport driver must retain the queue identifiers for the allocated receive queues. NDIS uses the queue identifier of a receive queue for subsequent calls to the miniport driver to set a receive filter on the receive queue, change the receive queue parameters, or free the receive queue.

Note The default queue (queue identifier zero) is always allocated and cannot be freed.

The overlying driver must use the queue identifier that NDIS provides in subsequent OID requests, for example, to modify the queue parameters or free the queue. The queue identifier is also included in the OOB data on all **NET_BUFFER_LIST** structures that are associated with the queue. Drivers use the **NET_BUFFER_LIST_RECEIVE_QUEUE_ID** macro to retrieve the queue identifier in a NET_BUFFER_LIST structure.

Note A protocol driver can set VMQ filters at any time after it successfully allocates a queue and before the queue is deleted.

The protocol driver issues an OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE method OID request to complete the queue allocation. The miniport driver can allocate shared memory and other resources when the allocation is complete. For more information about allocating shared memory resources, see Shared Memory Resource Allocation.

After a miniport driver receives an OID_RECEIVE_FILTER_QUEUE_ALLOCATION OID request and handles it successfully, the queue is in the *Allocated* state. For more information about queue states, see Queue States and Operations.

After an overlying driver allocates one or more receive queues (and optionally sets the initial filters), it must issue OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE set OID requests to notify the miniport driver that the allocation is complete for the current batch of receive queues.

The miniport driver must not retain any packets in a receive queue if there are no filters set on that queue. If a queue never had any filters set or all the filters were cleared, the queue should be empty and any packets should be discarded. That is, they are not indicated up the driver stack or retained in the queue.

Overlying drivers use the OID_RECEIVE_FILTER_FREE_QUEUE OID to free queues that they allocate. For more information about freeing queues, see Freeing a VM Queue.

Freeing a VM Queue

Article • 12/15/2021

To free a receive queue, an overlying driver issues an OID_RECEIVE_FILTER_FREE_QUEUE set OID request. The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_QUEUE_FREE_PARAMETERS** structure with a queue identifier of type **NDIS_RECEIVE_QUEUE_ID**.

OID_RECEIVE_FILTER_FREE_QUEUE frees a receive queue that an overlying driver allocated by using the OID_RECEIVE_FILTER_ALLOCATE_QUEUE OID. For more information about allocating a receive queue, see Allocating a VM Queue.

Note The default queue, which has a queue identifier of **NDIS_DEFAULT_RECEIVE_QUEUE_ID**, is always allocated and cannot be freed.

An overlying driver must free all the filters that it sets on a queue before it frees the queue. Also, an overlying driver must free all the receive queues that it allocated on a network adapter before it calls the **NdisCloseAdapterEx** function to close a binding to the network adapter. NDIS frees all the queues that are allocated on a network adapter before it calls the miniport driver's *MiniportHaltEx* function.

When a miniport driver receives a request to free a queue, it does the following:

- Must immediately stop DMA to shared memory resources that are associated with the queue.
- Generates a status indication to indicate that the DMA is stopped.
- Waits for all outstanding **NET_BUFFER_LIST** structures, which are associated with the queue, to be returned.
- Frees the associated shared memory and hardware resources.

When a miniport driver receives an OID_RECEIVE_FILTER_FREE_QUEUE set request, the queue must enter the Stop DMA state, it stops the DMA on a queue and the miniport driver must indicate the status change by using the **NDIS_STATUS_RECEIVE_QUEUE_STATE** status indication. For more information about queue states, see Queue States and Operations.

After the miniport driver issues the **NDIS_STATUS_RECEIVE_QUEUE_STATE** status indication, it must wait for all the pending receive indications to complete before it can free the associated shared memory. For more information about freeing shared memory, see Shared Memory Resource Allocation.

Shared Memory Resource Allocation

Article • 12/15/2021

To allocate shared memory resources for a VM queue, a miniport driver calls the **NdisAllocateSharedMemory** function. For example, the miniport driver allocates shared memory when it receives the OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE OID. Also, a miniport driver can allocate shared memory for the default queue during network adapter initialization. For more information about allocating queues, see Allocating a VM Queue.

The miniport driver can allocate more memory for the queue until the queue is freed. For more information about freeing a queue, see Freeing a VM Queue.

The **NDIS_SHARED_MEMORY_PARAMETERS** structure specifies the shared memory parameters for a shared memory allocation request. Miniport drivers pass this structure to the **NdisAllocateSharedMemory** function. NDIS passes this structure to the **NetAllocateSharedMemory** function (that is, the ALLOCATE_SHARED_MEMORY_HANDLER entry point).

When a miniport driver allocates shared memory, it specifies the following:

- Queue identifier.
- Shared memory length.
- How the shared memory is used. For example, the miniport driver specifies **NdisSharedMemoryUsageReceive** if the shared memory is to be used for receive buffers.

If the NDIS_SHARED_MEM_PARAMETERS_CONTIGOUS flag is not set in the **Flags** member, shared memory can be specified in a scatter-gather list that is contained in non-contiguous memory.

The **NDIS_SHARED_MEMORY_USAGE** enumeration specifies how shared memory is used. The NDIS_SHARED_MEMORY_USAGE enumeration is used in the **NDIS_SHARED_MEMORY_PARAMETERS** and **NDIS_SCATTER_GATHER_LIST_PARAMETERS** structures. For information about shared memory parameters in VMQ receive data buffers, see Shared Memory in Receive Buffers.

The **NdisAllocateSharedMemory** function provides the following to the caller:

- Virtual address of the allocated memory.
- Scatter-gather list.

- Shared memory handle - for receive indications.

- Allocation handle - used to identify the memory later.

Miniport drivers call the **NdisFreeSharedMemory** function to free shared memory for a queue. If the miniport driver allocated the shared memory for a nondefault queue, it frees the shared memory in the context of the OID_RECEIVE_FILTER_FREE_QUEUE OID while it is freeing the queue. Miniport drivers free shared memory that they allocated for the default queue in the context of the *MiniportHaltEx* function.

Enumerating the Allocated Queues

Article • 12/15/2021

To get a list of all the receive queues that are allocated on a network adapter, an overlying driver issues an OID_RECEIVE_FILTER_ENUM_QUEUES query OID request. After a successful return from the OID query request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_QUEUE_INFO_ARRAY** structure that is followed by an **NDIS_RECEIVE_QUEUE_INFO** structure for each queue.

NDIS handles the OID_RECEIVE_FILTER_ENUM_QUEUES query OID request for miniport drivers. NDIS obtained the information from an internal cache of the data that it received from the OID_RECEIVE_FILTER_ALLOCATE_QUEUE and OID_RECEIVE_FILTER_QUEUE_PARAMETERS OID requests.

Overlying drivers and user-mode applications can use the OID_RECEIVE_FILTER_ENUM_QUEUES OID query request to enumerate the receive queues on a network adapter.

If a protocol driver issues the request, the request type in the **NDIS_OID_REQUEST** structure is set to **NdisRequestQueryInformation** and this OID returns an array of all the receive queues that the protocol driver allocated on the network adapter. If a user-mode application issued the request, the request type in the NDIS_OID_REQUEST is set to **NdisRequestQueryStatistics**, and this OID returns an array of information for all the receive queues on the miniport adapter.

Setting and Clearing VMQ Filters

Article • 12/15/2021

Filters can be set and cleared any time after the queue has been allocated. For information about allocating and freeing queues, see Allocating and Freeing VM Queues.

This section includes the following topics:

Setting a VMQ Filter

Clearing a VMQ Filter

Enumerating Filters on a VMQ

Setting a VMQ Filter

Article • 12/15/2021

After a receive queue is allocated, overlying drivers can set filters on the receive queue. Only the driver that allocated a receive queue can set a filter on that queue.

Note Because the default receive queue (**NDIS_DEFAULT_RECEIVE_QUEUE_ID**) always exists, overlying drivers can always set a receive filter on the default queue. Overlying drivers do not own the default queue. Therefore, all protocol drivers that are bound to a network adapter can use the default queue.

Setting a Filter on a Receive Queue

To set a filter on a receive queue with an initial set of configuration parameters, an overlying driver issues an OID_RECEIVE_FILTER_SET_FILTER method object identifier (OID) request. The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure initially contains a pointer to an **NDIS_RECEIVE_FILTER_PARAMETERS** structure. After a successful return from the OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_FILTER_PARAMETERS** structure with a new filter identifier.

The overlying driver initializes the **NDIS_RECEIVE_FILTER_PARAMETERS** structure with the following filter configuration parameters for the receive queue:

- The filter type that is specified through an **NDIS_RECEIVE_FILTER_TYPE** enumeration value.

  Note Starting with NDIS 6.20, only **NdisReceiveFilterTypeVMQueue** filter types are supported for the virtual machine queue (VMQ) interface.

- The queue identifier.

- One or more field test parameters that are formatted as **NDIS_RECEIVE_FILTER_FIELD_PARAMETERS** structures. For VMQ, the following field test parameters are defined.

  - The destination media access control (MAC) address in the packet equals the specified MAC address.

  - The virtual LAN (VLAN) identifier in the packet equals the specified VLAN identifier.

The **NDIS_RECEIVE_FILTER_PARAMETERS** structure is used with the OID_RECEIVE_FILTER_PARAMETERS OID and the OID_RECEIVE_FILTER_SET_FILTER OID to specify the configuration parameters of a filter.

The **FieldParametersArrayOffset**, **FieldParametersArrayNumElements**, and **FieldParametersArrayElementSize** members of the **NDIS_RECEIVE_FILTER_PARAMETERS** structure define an array of **NDIS_RECEIVE_FILTER_FIELD_PARAMETERS** structures. Each **NDIS_RECEIVE_FILTER_FIELD_PARAMETERS** structure in the array sets the filter test criterion for one field in a network header.

The **Flags** member of the **NDIS_RECEIVE_FILTER_FIELD_PARAMETERS** structure specifies actions to be performed for the receive filter. The following points apply to the **NDIS_RECEIVE_FILTER_FIELD_MAC_HEADER_VLAN_UNTAGGED_OR_ZERO** flag:

- If the **NDIS_RECEIVE_FILTER_FIELD_MAC_HEADER_VLAN_UNTAGGED_OR_ZERO** flag is set in the **Flags** member of the **NDIS_RECEIVE_FILTER_FIELD_PARAMETERS** structure, the network adapter must indicate only received packets that match all of the following test criteria:

    - A packet with a matching MAC address.

    - A packet that has no VLAN tag or has a VLAN identifier of zero.

  If the **NDIS_RECEIVE_FILTER_FIELD_MAC_HEADER_VLAN_UNTAGGED_OR_ZERO** flag is set, the network adapter must not indicate packets that have a matching MAC address and a nonzero VLAN identifier.

  Note If the Hyper-V extensible switch sets the MAC address filter and no VLAN identifier filter is configured in OID_RECEIVE_FILTER_SET_FILTER, the switch also sets the **NDIS_RECEIVE_FILTER_FIELD_MAC_HEADER_VLAN_UNTAGGED_OR_ZERO** flag.

- If the **NDIS_RECEIVE_FILTER_FIELD_MAC_HEADER_VLAN_UNTAGGED_OR_ZERO** flag is not set and there is no VLAN identifier filter configured by an OID set request of OID_RECEIVE_FILTER_SET_FILTER, the miniport driver must do one of the following:

    - If the miniport driver supports NDIS 6.20, it must return a failed status for the OID request of OID_RECEIVE_FILTER_SET_FILTER.

    - If the miniport driver supports NDIS 6.30 or later versions of NDIS, it must configure the network adapter to inspect and filter the specified MAC address fields. If a VLAN tag is present in the received packet, the network adapter must remove it from the packet data. The miniport driver must put the VLAN tag in an **NDIS_NET_BUFFER_LIST_8021Q_INFO** that is associated with the packet's **NET_BUFFER_LIST** structure.

- If a protocol driver sets a MAC address filter and a VLAN identifier filter with the OID_RECEIVE_FILTER_SET_FILTER OID, it does not set the **NDIS_RECEIVE_FILTER_FIELD_MAC_HEADER_VLAN_UNTAGGED_OR_ZERO** flag in either of the filter fields. In this case, the miniport driver should indicate packets that match both the specified MAC address and the VLAN identifier. That is, the miniport driver should not indicate packets with a matching MAC address that have a zero VLAN identifier or are untagged packets.

Using the Filter Identifier

NDIS assigns a filter identifier in the **FilterId** member of the **NDIS_RECEIVE_FILTER_PARAMETERS** structure and passes the OID method request of OID_RECEIVE_FILTER_SET_FILTER to the underlying miniport driver. Each filter that is set on a receive queue has a unique filter identifier for a network adapter. That is, the filter identifiers are not duplicated on different queues that the network adapter manages.

The overlying driver must use the filter identifier that NDIS provides in later OID requests; for example, to modify the filter parameters or to free a filter.

When NDIS receives an OID request to set a filter on a receive queue, it verifies the filter parameters. After NDIS allocates the necessary resources and the filter identifier, it submits the OID request to the underlying network adapter. If the network adapter can successfully allocate the necessary software and hardware resources for the filter, it completes the OID request with **NDIS_STATUS_SUCCESS**.

The miniport driver must retain the filter identifiers for the allocated receive filters. NDIS uses the filter identifier of a filter with later OID requests in order to change the receive filter parameters or clear the receive filter. For more information about how to change parameters and clear filters, see Obtaining and Updating VM Queue Parameters and Clearing a VMQ Filter.

Handling the Filter on a Receive Queue

The miniport driver programs the network adapter based on the filters in the following way:

- All field test parameters for a particular filter must match in order to assign a packet to the queue.

- Multiple filters can be set on a queue.
- Packets must be assigned to the receive queue if any of the filters pass.

The network adapter combines the results from all the field tests with a logical **AND** operation. That is, if any field test that is included in the array of **NDIS_RECEIVE_FILTER_FIELD_PARAMETERS** structures fails, the network packet does not meet the specified filter criterion.

When a network adapter tests a received packet against these filter criteria, it must ignore all fields in the packet that have no test criteria specified.

Receiving Packets from a Receive Queue

After a miniport driver receives an OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE request and has filters that are set on the queue, the queue is in the *Running* state. While the queue is in this state, the miniport driver can indicate packets on the queue. For more information about queue states, see Queue States and Operations.

If the miniport driver has received an OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE OID request for a queue but there are no filters set on the queue, the miniport driver must not indicate any receive packets on that queue. In this case, when the miniport driver receives an OID_RECEIVE_FILTER_SET_FILTER OID request for the queue, and possibly before it completes the OID request, it can indicate packets on that queue. If the miniport driver indicates packets on a queue while it is processing an OID_RECEIVE_FILTER_SET_FILTER OID request, the miniport driver must complete the OID_RECEIVE_FILTER_SET_FILTER request that has an **NDIS_STATUS_SUCCESS** return code.

Clearing a VMQ Filter

Article • 12/15/2021

To free a filter on a receive queue, an overlying driver issues an OID_RECEIVE_FILTER_CLEAR_FILTER set OID request. The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_RECEIVE_FILTER_CLEAR_PARAMETERS** structure.

The protocol driver obtained the filter identifier from an earlier OID_RECEIVE_FILTER_SET_FILTER method OID request. For more information about setting filters, see Setting a VMQ Filter.

A protocol driver must clear all the filters that it set on a queue before it frees the queue. A protocol driver must also clear all the filters that it set on the default queue before it closes its binding to the network adapter.

A miniport driver must not indicate packets on a nondefault queue if it has completed the OID_RECEIVE_FILTER_CLEAR_FILTER OID request to clear the last filter on the queue or if it has completed an OID_RECEIVE_FILTER_FREE_QUEUE OID request to free the queue.

Enumerating Filters on a VMQ

Article • 12/15/2021

To obtain a list of all the filters that are set on a receive queue, overlying drivers and applications can use the OID_RECEIVE_FILTER_ENUM_FILTERS method object identifier (OID) request.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure initially contains a pointer to an **NDIS_RECEIVE_FILTER_INFO_ARRAY** structure. When it formats the **NDIS_RECEIVE_FILTER_INFO_ARRAY** structure, the overlying driver or application must set the **QueueId** member to the identifier (ID) of the receive queue. The receive queue ID is obtained in the following ways:

- The overlying driver obtained the receive queue ID value from earlier OID method requests of OID_RECEIVE_FILTER_ALLOCATE_QUEUE or OID_RECEIVE_FILTER_ENUM_QUEUES. The driver can also specify **NDIS_DEFAULT_RECEIVE_QUEUE_ID** for the default receive queue.

- An application obtained the receive queue ID value from an earlier OID method request of OID_RECEIVE_FILTER_ENUM_QUEUES. The application can also specify **NDIS_DEFAULT_RECEIVE_QUEUE_ID** for the default receive queue.

After a successful return from the OID method request of OID_RECEIVE_FILTER_ENUM_FILTERS, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to an updated **NDIS_RECEIVE_FILTER_INFO_ARRAY** structure that is followed by one or more **NDIS_RECEIVE_FILTER_INFO** structures. Each **NDIS_RECEIVE_FILTER_INFO** structure specifies the ID for a filter that is set on the specified receive queue.

Overlying drivers or applications can use the OID_RECEIVE_FILTER_PARAMETERS OID method request to obtain the parameters of a specific filter on a receive queue.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure initially contains a pointer to an **NDIS_RECEIVE_FILTER_PARAMETERS** structure. The overlying driver or application formats the **NDIS_RECEIVE_FILTER_PARAMETERS** structure by setting the **FilterId** member to the nonzero ID value of the filter whose parameters are to be returned.

Note The overlying driver obtained the filter ID from an earlier OID method request of OID_RECEIVE_FILTER_SET_FILTER or OID_RECEIVE_FILTER_ENUM_FILTERS. The application can obtain the filter ID only from an earlier OID method request of OID_RECEIVE_FILTER_ENUM_FILTERS.

NDIS handles the OID_RECEIVE_FILTER_ENUM_FILTERS and OID_RECEIVE_FILTER_PARAMETERS method OID requests for miniport drivers. NDIS obtained the information from an internal cache of the data that it received from the OID_RECEIVE_FILTER_SET_FILTER OID request.

Obtaining and Updating VM Queue Parameters

Article • 12/15/2021

An overlying driver can set the configuration parameters of a VM queue after it is allocated. Also, an overlying driver or application can obtain the current parameters for a queue and parameters for the filters that are set on a queue.

To change the current configuration parameters of a queue, overlying drivers can use the OID_RECEIVE_FILTER_QUEUE_PARAMETERS set OID request. The overlying driver provides a pointer to an **NDIS_RECEIVE_QUEUE_PARAMETERS** structure in the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure.

The NDIS_RECEIVE_QUEUE_PARAMETERS structure is used in the OID_RECEIVE_FILTER_ALLOCATE_QUEUE OID and the OID_RECEIVE_FILTER_QUEUE_PARAMETERS OID. For more information about allocating queues, see Allocating a VM Queue.

To get the current configuration parameters of a queue, overlying drivers can use the OID_RECEIVE_FILTER_QUEUE_PARAMETERS method OID request. The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure initially contains a pointer to an **NDIS_RECEIVE_QUEUE_PARAMETERS** structure with a queue identifier of type NDIS_RECEIVE_QUEUE_ID. After a successful return from the OID method request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an **NDIS_RECEIVE_QUEUE_PARAMETERS** structure.

NDIS handles the method request for miniport drivers. Therefore, the OID_RECEIVE_FILTER_QUEUE_PARAMETERS method OID request is not requested for miniport drivers. NDIS obtained the information from an internal cache of the data that it received from the OID_RECEIVE_FILTER_ALLOCATE_QUEUE and OID_RECEIVE_FILTER_QUEUE_PARAMETERS OID requests.

To get the current configuration parameters of a filter on a receive queue, overlying drivers can use the OID_RECEIVE_FILTER_PARAMETERS method OID request. The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure initially contains a pointer to an **NDIS_RECEIVE_FILTER_PARAMETERS** structure. NDIS uses the **FilterId** member in the input structure to identify the filter. After a successful return from the method request, the **InformationBuffer** member of the NDIS_OID_REQUEST structure contains a pointer to an updated NDIS_RECEIVE_FILTER_PARAMETERS structure.

NDIS handles the OID_RECEIVE_FILTER_PARAMETERS method OID request for miniport drivers. NDIS obtained the information from an internal cache of the data that it received from the OID_RECEIVE_FILTER_SET_FILTER OID request.

Overlying drivers can use the OID_RECEIVE_FILTER_PARAMETERS method OID request to get the configuration parameters for a filter on a receive queue.

The overlying driver obtained the filter identifier from an earlier OID_RECEIVE_FILTER_SET_FILTER method OID request or from the OID_RECEIVE_FILTER_ENUM_FILTERS OID request. Only drivers can use the OID_RECEIVE_FILTER_SET_FILTER request.

An application obtained the filter identifier from the OID_RECEIVE_FILTER_ENUM_FILTERS OID request.

VMQ Send and Receive Operations

Article • 12/15/2021

This section provides information about implementing send and receive operations in NDIS drivers that support VMQ.

To support VMQ send and receive operations, the VMQ interface requires network adapter hardware that supports the VMQ filter operations. These filters determine the assignment of packets to receive queues.

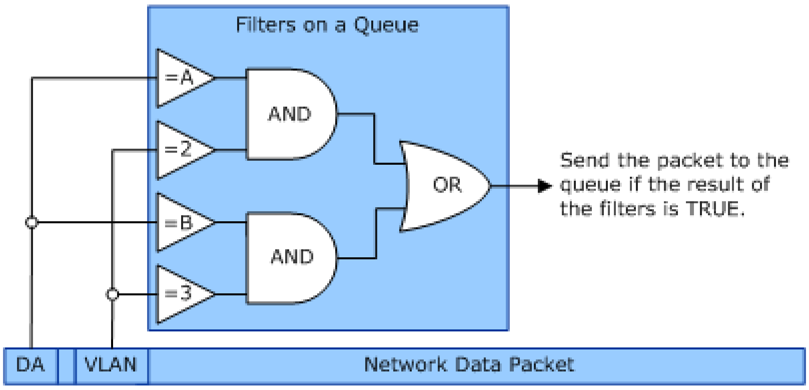
This section includes the following topics:

VMQ Filter Operations

Article • 12/15/2021

Multiple receive filters and can be set on a receive queue. Also, the current VMQ implementation supports filters on the destination media access control (MAC) address of the incoming packets and optional filters that inspect the virtual local area network (VLAN) identifier.

The following illustration shows the relationship between the VLAN identifier and MAC address tests, filters, and queues.



Filters on a Queue
=A
=2
=B
=3
AND
AND
OR
Send the packet to the queue if the result of the filters is TRUE.
DA
VLAN
Network Data Packet

In the preceding illustration, the network data packet includes a destination address (DA) and VLAN identifier field. The network adapter hardware implements the filters on the queue based on the settings that the miniport driver received and set in the network adapter hardware. For more information about setting filters on a receive queue, see Setting and Clearing VMQ Filters.

In this illustration, there are two filters; each filter compares a destination address and a VLAN identifier to the fields in the incoming packet. If both the VLAN and DA tests match, then the criterion for that filter is met and the incoming packet is assigned to the queue. If there is more than one filter on the queue and then a match for any filter, then the network adapter assigns the packet to the queue.

Shared Memory in Receive Buffers

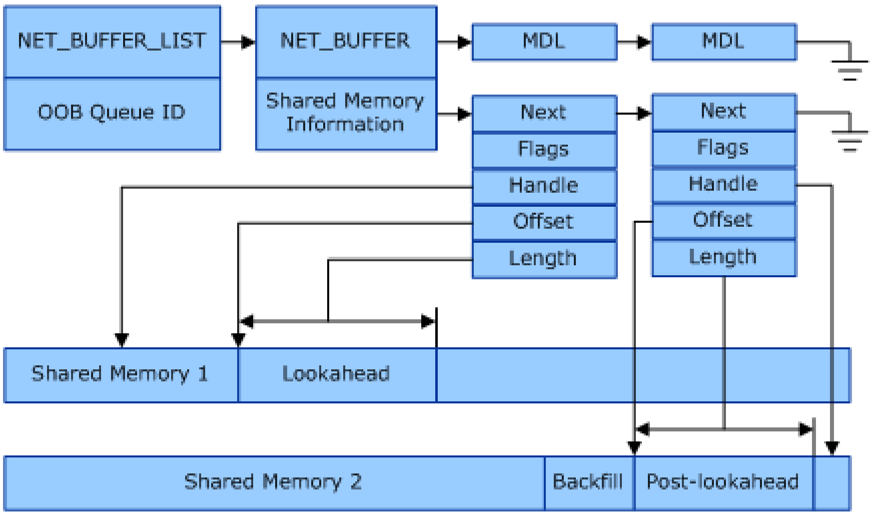
Article • 12/15/2021

This section describes the layout of the shared memory in VMQ receive buffers.For more information about using the buffers in receive indications, see VMQ Receive Path.

If the overlying protocol driver set the NDIS_RECEIVE_QUEUE_PARAMETERS_LOOKAHEAD_SPLIT_REQUIRED flag in the **Flags** member of the NDIS_RECEIVE_QUEUE_PARAMETERS structure, the network adapter should split a received packet at an offset equal to or greater than the requested lookahead size and use DMA to transfer the lookahead data and the post-lookahead data to separate shared memory segments.

Miniport drivers specify the settings for the lookahead type (**NdisSharedMemoryUsageReceiveLookahead**) or other shared memory types when the shared memory is allocated. For example, the miniport driver calls the NdisAllocateSharedMemory function and sets the **Usage** member in the NDIS_SHARED_MEMORY_PARAMETERS structure to **NdisSharedMemoryUsageReceiveLookahead**. Miniport drivers should allocated shared memory for a queue when the queue allocation is complete. For information about allocating and freeing shared memory resources for queues, see Shared Memory Resource Allocation.

The following illustration shows the relationships for the network data when the incoming data is split into two shared memory buffers.



The NET_BUFFER_SHARED_MEMORY structure specifies shared memory information. There can be a linked list of such shared memory buffers that are associated with a NET_BUFFER structure.

Use the NET_BUFFER_SHARED_MEM_NEXT_SEGMENT, NET_BUFFER_SHARED_MEM_FLAGS, NET_BUFFER_SHARED_MEM_HANDLE, NET_BUFFER_SHARED_MEM_OFFSET, and NET_BUFFER_SHARED_MEM_LENGTH macros to access the NET_BUFFER_SHARED_MEMORY in a NET_BUFFER structure. The **SharedMemoryInfo** member of the NET_BUFFER structure contains the first NET_BUFFER_SHARED_MEMORY structure in the linked list.

Note Starting with NDIS 6.30, splitting packet data into separate lookahead buffers is no longer supported. Starting with Windows Server 2012, the overlying protocol driver will not set the **NDIS_RECEIVE_QUEUE_PARAMETERS_LOOKAHEAD_SPLIT_REQUIRED** flag in the **Flags** member of the NDIS_RECEIVE_QUEUE_PARAMETERS structure.

VMQ Receive Path

Article • 12/15/2021

A network adapter indicates a received packet on a queue only if it passes all the filter field tests for a filter that is set on that queue. For more information about filter tests, see VMQ Filter Operations.

If the overlying protocol driver set the **NDIS_RECEIVE_QUEUE_PARAMETERS_PER_QUEUE_RECEIVE_INDICATION** flag in the **Flags** member of the NDIS_RECEIVE_QUEUE_PARAMETERS structure, the miniport driver must not mix NET_BUFFER_LIST structures for other receive queues with the **NET_BUFFER_LIST** structures for this queue in a single call to the NdisMIndicateReceiveNetBufferLists function. Also, the driver must set the **NDIS_RECEIVE_FLAGS_SINGLE_QUEUE** flag in the *ReceiveFlags* parameter of the **NdisMIndicateReceiveNetBufferLists** function.

If **NDIS_RECEIVE_QUEUE_PARAMETERS_PER_QUEUE_RECEIVE_INDICATION** was not set, miniport drivers can link NET_BUFFER_LIST structures for frames from different VM queues and indicate them in a single call to NdisMIndicateReceiveNetBufferLists. In this case, the indicated linked list of **NET_BUFFER_LIST** structures is not required to be sorted by queue number. **NET_BUFFER_LIST** structures for different queues are not required to be grouped together.

When a protocol driver sets **NDIS_RETURN_FLAGS_SINGLE_QUEUE** and it returns receive buffers, all of the NET_BUFFER_LIST structures in the *NetBufferLists* parameter of the NdisReturnNetBufferLists function must belong to the same VM queue. However, protocol drivers are not required to return all the **NET_BUFFER_LIST** structures that were indicated in a single call to the ProtocolReceiveNetBufferLists function in a single call to **NdisReturnNetBufferLists**. Also, the returned list can include **NET_BUFFER_LIST** structures from multiple receive indications if they belong to the same VM queue.

Protocol drivers set the **NDIS_RETURN_FLAGS_SINGLE_QUEUE** bit on the *ReturnFlags* parameter of NdisReturnNetBufferLists to indicate that all of the returned NET_BUFFER_LIST structures belong to the same VM queue.

VMQ receive indications must include the following out of band (OOB) information in the **NetBufferListInfo** member of the NET_BUFFER_LIST structures.

- Specify the queue identifier in the **NetBufferListFilteringInfo** information.
- Set the filter identifier in the **NetBufferListFilteringInfo** information to zero.

The **NetBufferListFilteringInfo** information is specified in an NDIS_NET_BUFFER_LIST_FILTERING_INFO structure. To access the NDIS_NET_BUFFER_LIST_FILTERING_INFO structure in the NET_BUFFER_LIST OOB data, an NDIS driver calls the NET_BUFFER_LIST_INFO macro and specifies the **NetBufferListFilteringInfo** information type.

To access the filter identifier and queue identifier directly, use the NET_BUFFER_LIST_RECEIVE_FILTER_ID and NET_BUFFER_LIST_RECEIVE_QUEUE_ID macros.

VMQ receive indications must define shared memory information at the **SharedMemoryInfo** member of the NET_BUFFER structure.

Note When a VMQ is deleted (for example, during VM live migration), it is possible for the miniport driver to receive an NBL that contains an invalid **QueueId** value. If this happens, the miniport should ignore the invalid queue ID and use 0 (the default queue) instead. The **QueueId** is found in the **NetBufferListFilteringInfo** portion of the NBL's OOB data, and is retrieved by using the NET_BUFFER_LIST_RECEIVE_QUEUE_ID macro.

To indicate that the NET_BUFFER_SHARED_MEMORY pointer at **SharedMemoryInfo** is valid, the miniport driver must set the NDIS_RECEIVE_FLAGS_SHARED_MEMORY_INFO_VALID flag in the *ReceiveFlags* parameter of the NdisMIndicateReceiveNetBufferLists function. For more information about the layout of shared memory buffers in VMQ receive buffers, see Shared Memory in Receive Buffers.

The receive indication must include the following information in the NET_BUFFER_SHARED_MEMORY structure.

NextSharedMemorySegment
A pointer to the next NET_BUFFER_SHARED_MEMORY structure in a **NULL**-terminated linked list of such structures.

SharedMemoryHandle
An NDIS shared memory handle that NdisAllocateSharedMemory returned.

SharedMemoryOffset
An offset, in bytes, to the start of the data from the beginning of the shared memory buffer.

SharedMemoryLength
The length, in bytes, of the shared memory segment.

If the overlying protocol driver set the **NDIS_RECEIVE_QUEUE_PARAMETERS_LOOKAHEAD_SPLIT_REQUIRED** flag in the **Flags** member of the NDIS_RECEIVE_QUEUE_PARAMETERS structure, each NET_BUFFER includes:

- Two MDLs and corresponding **SharedMemoryInfo** structures.
- A post-lookahead buffer with backfill space.

If necessary, the protocol driver copies the contents of the lookahead buffer to the backfill area. However, backfill space must exist even if the packet is entirely in the lookahead buffer.

If the overlying driver does not set the **NDIS_RECEIVE_QUEUE_PARAMETERS_LOOKAHEAD_SPLIT_REQUIRED** flag, each NET_BUFFER structure includes a single MDL and a single **SharedMemoryInfo** structure.

The byte count and byte offset in the MDL and the **DataLength** and **DataOffset** members in the NET_BUFFER_DATA structure are set in the same way as they are set for drivers that do not use VMQ. The **SharedMemoryLength** and **SharedMemoryOffset** members in the **SharedMemoryInfo** structure can be set once during initialization. The miniport driver is not required to update the **SharedMemoryLength** and **SharedMemoryOffset** members for every packet that is received because the overlying drivers and NDIS can use the NET_BUFFER **DataLength** member and the MDL byte count to determine the packet start and size.

Note Starting with NDIS 6.30 and Windows Server 2012, splitting packet data into separate lookahead buffers is no longer supported. The overlying protocol driver will not set the **NDIS_RECEIVE_QUEUE_PARAMETERS_LOOKAHEAD_SPLIT_REQUIRED** flag.

VMQ Transmit Path

Article • 12/15/2021

For transmit requests, the overlying driver uses the NET_BUFFER_LIST_RECEIVE_QUEUE_ID macro to set the queue identifier of the outgoing queue in the outgoing data with the **NetBufferListFilteringInfo** OOB information. The **NetBufferListFilteringInfo** information is specified in an NDIS_NET_BUFFER_LIST_FILTERING_INFO structure.

NDIS drivers can use the NET_BUFFER_LIST_RECEIVE_QUEUE_ID macro to set or get the queue identifier of a NET_BUFFER_LIST structure. If a queue group contains more than one VM queue, the queue identifier of the transmit packet might be set to the queue identifier of any of the VM queues in the group.

Protocol drivers set the NDIS_SEND_FLAGS_SINGLE_QUEUE bit on the *SendFlags* parameter of the NdisSendNetBufferLists function to indicate that all of the transmit NET_BUFFER_LIST structures in the call are for the same transmit queue.

Miniport drivers set the NDIS_SEND_COMPLETE_FLAGS_SINGLE_QUEUE bit on the *SendCompleteFlags* parameter of the NdisMSendNetBufferListsComplete function to indicate that all NET_BUFFER_LISTs in the call were sent on the same transmit queue.

For more information about filter tests, see VMQ Filter Operations.

Note When a VMQ is deleted (for example, during VM live migration), it is possible for the miniport driver to receive an NBL that contains an invalid **QueueId** value. If this happens, the miniport should ignore the invalid queue ID and use 0 (the default queue) instead. The **QueueId** is found in the **NetBufferListFilteringInfo** portion of the NBL's OOB data, and is retrieved by using the NET_BUFFER_LIST_RECEIVE_QUEUE_ID macro.

Obtaining VMQ Information

Article • 12/15/2021

The VMQ interface includes OID requests and WMI GUIDs that allow overlying drivers and applications to obtain information about the underlying VMQ configuration.

OID_RECEIVE_FILTER_ENUM_QUEUES enumerates the queues allocated on a network adapter. For more information about enumerating queues, see Enumerating the Allocated Queues.

As a method OID request, overlying drivers can use the OID_RECEIVE_FILTER_QUEUE_PARAMETERS OID to obtain the parameter settings of a particular queue. For more information about obtaining queue parameter settings, see Obtaining and Updating VM Queue Parameters.

OID_RECEIVE_FILTER_ENUM_FILTERS enumerates the filters that are allocated on a particular queue. For more information about enumerating the filters that are set on a queue, see Enumerating Filters on a VMQ.

As a method OID request, overlying drivers can use the OID_RECEIVE_FILTER_PARAMETERS OID to obtain the parameter settings of a filter. For more information about obtaining filter parameter settings, see Obtaining and Updating VM Queue Parameters.

Overlying drivers and applications can issue the following OID query requests to obtain the VMQ capabilities.

OID_RECEIVE_FILTER_HARDWARE_CAPABILITIES

OID_RECEIVE_FILTER_CURRENT_CAPABILITIES

OID_RECEIVE_FILTER_GLOBAL_PARAMETERS

For more information about obtaining VMQ capabilities, see Determining the VMQ Capabilities of a Network Adapter.

Introduction to Hyper-V Extensible Switch

Article • 12/15/2021

The Hyper-V extensible switch supports an interface that allows instances of NDIS filter drivers (known as *extensible switch extensions*) to bind within the extensible switch driver stack. After they are bound and enabled, extensions can monitor, modify, and forward packets to extensible switch ports. This also allows extensions to reject, redirect, or originate packets to ports that are used by the Hyper-V partitions.

The Hyper-V extensible switch is supported starting with NDIS 6.30 in Windows Server 2012.

This section includes the following topics that describe the Hyper-V extensible switch and its interface:

Getting Started Writing a Hyper-V Extensible Switch Extension

Article • 07/08/2024

A Hyper-V Extensible Switch extension is an NDIS filter or Windows Filtering Platform (WFP) filter that runs inside the Hyper-V Extensible Switch (also called the "Hyper-V virtual switch").

There are 3 classes of extensions: capture, filtering, and forwarding. All of them can be implemented as NDIS filter drivers. Filtering extensions can also be implemented as WFP filter drivers.

For an architectural overview for driver developers, see Overview of the Hyper-V Extensible Switch.

To create a Hyper-V Extensible Switch extension, follow these steps:

1. Learn the extension architecture and programming model.

   - Read the online documentation for NDIS-based extensions, beginning with Hyper-V Extensible Switch. Capture, filtering, and forwarding extensions use the standard NDIS filtering API. The NDIS interfaces have been enhanced to provide configuration, notifications, and identification of virtual switches and virtual machines.
     - Hyper-V Extensible Switch Functions
     - Hyper-V Extensible Switch Enumerations
     - Hyper-V Extensible Switch Structures and Unions
     - Hyper-V Extensible Switch OIDs
     - Hyper-V Extensible Switch Status Indications
     - Hyper-V Extensible Switch Macros
   - Read the online documentation for WFP-based extensions, beginning with Using Virtual Switch Filtering.
   - There are several PowerShell commands that can be used to manage extensions. These are listed in Managing Installed Hyper-V Extensible Switch Extensions.

2. Set up your development environment.

   - Install Microsoft Visual Studio Professional.
   - Download and install Windows Driver Kit.

3. Study the sample extensions.

- Download the NDIS forwarding extension sample.
- Download the WFP sample. This is a functioning prototype that includes vSwitch capability.

4. Write your extension.

    - You can use one of the samples as a starting point, port existing filter code, or write your extension from scratch.
    - If you're developing an NDIS extension, you can use the standard NDIS INF with a few changes as outlined in INF Requirements for Hyper-V Extensible Switch Extensions.

5. Build your extension and unit-test it.

    - You must use Visual Studio to build your extension.
    - You can familiarize yourself with the extension build process by using Visual Studio to compile and run the sample extensions.

6. Learn about the Windows certification (logo) process for getting an extension signed.

    - An extension must pass the tests in the Windows Hardware Lab Kit (HLK).
    - The requirements for an extension are listed under the Filter.Driver.vSwitchExtension.ExtensionRequirements in the Windows Hardware Certification Requirements - Filter Driver .

7. Set up your Windows Hardware Lab Kit environment.

    - Download and install the Windows Hardware Lab Kit (HLK).

8. Run the WHCK tests for extensions:

    - Filter.Driver.Fundamentals
    - Filter.Driver.Security
    - Filter.Driver.vSwitchExtension

9. After your final extension passes WHCK certification, submit it to Microsoft.

    - Your extension must be submitted as an MSI install package with a specific format to ensure that it can be tracked and deployed by management packages, such as System Center Virtual Machine Manager (SCVMM) 2012. The MSI format is defined in Extension Driver MSI Packaging Requirements.

10. List your extension on WindowsServerCatalog.com.

    - List a brief description of your extension on WindowsServerCatalog.com.

- Information on listing a certified extension on WindowsServerCatalog.com will be available soon.

Overview of the Hyper-V Extensible Switch

Article • 09/27/2024

Windows Server 2012 introduces the Hyper-V Extensible Switch (also called the Hyper-V Virtual Switch), which is a virtual Ethernet switch that runs in the management operating system of the Hyper-V parent partition. This page covers the following subjects:

- Background Reading
- Types of Hyper-V extensible switches and network adapters
- Types of extensible switch extensions
- Hyper-V extensible switch architectural diagrams

Background Reading

For high-level technical overviews of this technology and its underpinnings, see the following TechNet documentation:

- Hyper-V Virtual Switch Overview
- Hyper-V Network Virtualization Overview
- Hyper-V Overview

Types of Hyper-V extensible switches and network adapters

The Hyper-V Virtual Network Manager can be used to create, configure, or delete one or more extensible switches of the following types:

- An external extensible switch that supports ports that connect to a single external network adapter as well as one or more virtual machine (VM) network adapters. This type of switch allows packets to be sent or received between all Hyper-V partitions and the physical network interface on the host.

  Also, applications and drivers that run in the management operating system can send or receive packets through this type of switch.

- An internal extensible switch that supports ports that connect to one or more internal network adapters as well as one or more VM network adapters. This type of switch allows packets to be sent or received between the Hyper-V parent partition and one or more Hyper-V child partitions on the host.

Also, applications and drivers that run in the management operating system can send or receive packets through this type of switch.

- A private extensible switch that supports ports that connect to one or more VM network adapters. This type of switch allows packets to be sent or received only between Hyper-V child partitions.

  Note Applications and drivers that run in the management operating system cannot send or receive packets through this type of switch.

Each extensible switch module routes incoming and outgoing packets over the network adapters that are used by the Hyper-V child and parent partitions. These network adapters include the following:

- External network adapters that provide the connection to the physical network interface that is available on the host.

  For more information about this type of network adapter, see External Network Adapters.

  Note Only external extensible switches provide access to an external network adapter.

- Internal network adapters that provide access to an extensible switch for processes that run in the management operating system of the Hyper-V parent partition. This allows these processes to send or receive packets over the extensible switch.

  For more information about this type of network adapter, see Internal Network Adapters.

  Note Only external and internal extensible switches provide access to an internal network adapter.

- VM network adapters that are exposed within the guest operating system that runs in a Hyper-V child partition. VM network adapters provide a connection to the extensible switch for packets to be sent or received by processes that run in the guest operating system of the child partition.

  For more information about this type of network adapter, see Virtual Machine Network Adapters.

Each Hyper-V child partition can be configured to have one or more VM network adapters. Each VM network adapter is configured to be associated with an instance of an extensible switch. This allows a child partition to be configured in the following way:

- The child partition can be configured to have a single VM network adapter that is associated with one instance of an extensible switch.
- The child partition can be configured to have multiple VM network adapters, with each VM network adapter associated with an instance of an extensible switch.
- The child partition can be configured to have multiple VM network adapters, with one or more VM network adapters associated with the same instance of an extensible switch.

Types of extensible switch extensions

The Hyper-V extensible switch supports an interface in which independent software vendors (ISVs) can extend the switch functionality in the following ways:

- The Hyper-V extensible switch supports an interface that allows NDIS filter drivers, known as *extensions*, to bind within the extensible switch driver stack. This allows extensions to capture, filter, and forward packets to extensible switch ports. This also allows extensions to inject, drop, or redirect packets to ports that are connected to the network adapters exposed in the Hyper-V partitions.

  After extensions are installed, they can be enabled or disabled on separate instances of a Hyper-V extensible switch. For more information, see Installing Hyper-V Extensible Switch Extensions.

- The Windows Filtering Platform (WFP) provides an in-box filtering extension (Wfplwfs.sys) that allows WFP filters or callout drivers to intercept packets along the Hyper-V extensible switch data path. This allows the WFP filters or callout drivers to perform packet inspection or modification by using the WFP management and system functions.

  For an overview of WFP, see Windows Filtering Platform.

  For an overview of WFP callout drivers, see Windows Filtering Platform Callout Drivers.

  Note To perform WFP-based filtering of extensible switch packet traffic, ISVs only need to extend their WFP filters and callout drivers to use extended WFP calls and data types. ISVs do not need to develop their own extensions.

The extensible switch interface supports the following types of extensions:

Capturing Extensions
Extensions that capture and monitor packet traffic. This type of extension cannot modify

or drop packets, or exclude packets from being delivered to extensible switch ports. However, capturing extensions can originate packet traffic, such as packets that contain traffic statistics that the extension sends to a host application.

Multiple capturing extensions can be bound and enabled in each instance of an extensible switch.

For more information on this type of extension, see Capturing Extensions.

Filtering Extensions
These extensions have the same capabilities as capturing extensions. However, based on port or switch policy settings, this type of extension can inspect and drop packets, or exclude packet delivery to extensible switch ports. Filtering extensions can also originate, duplicate, or clone packets and inject them into the extensible switch data path.

Multiple filtering extensions can be bound and enabled in each instance of an extensible switch.

For more information on this type of extension, see Filtering Extensions.

Forwarding Extensions
These extensions have the same capabilities as filtering extensions, but are responsible for performing the core packet forwarding and filtering tasks of extensible switches. These tasks include the following:

- Determining the destination ports for a packet, unless the packet is an NVGRE packet. For more information, see Hybrid Forwarding.
- Filtering packets by enforcing standard port policies, such as security, profile, or virtual LAN (VLAN) policies.

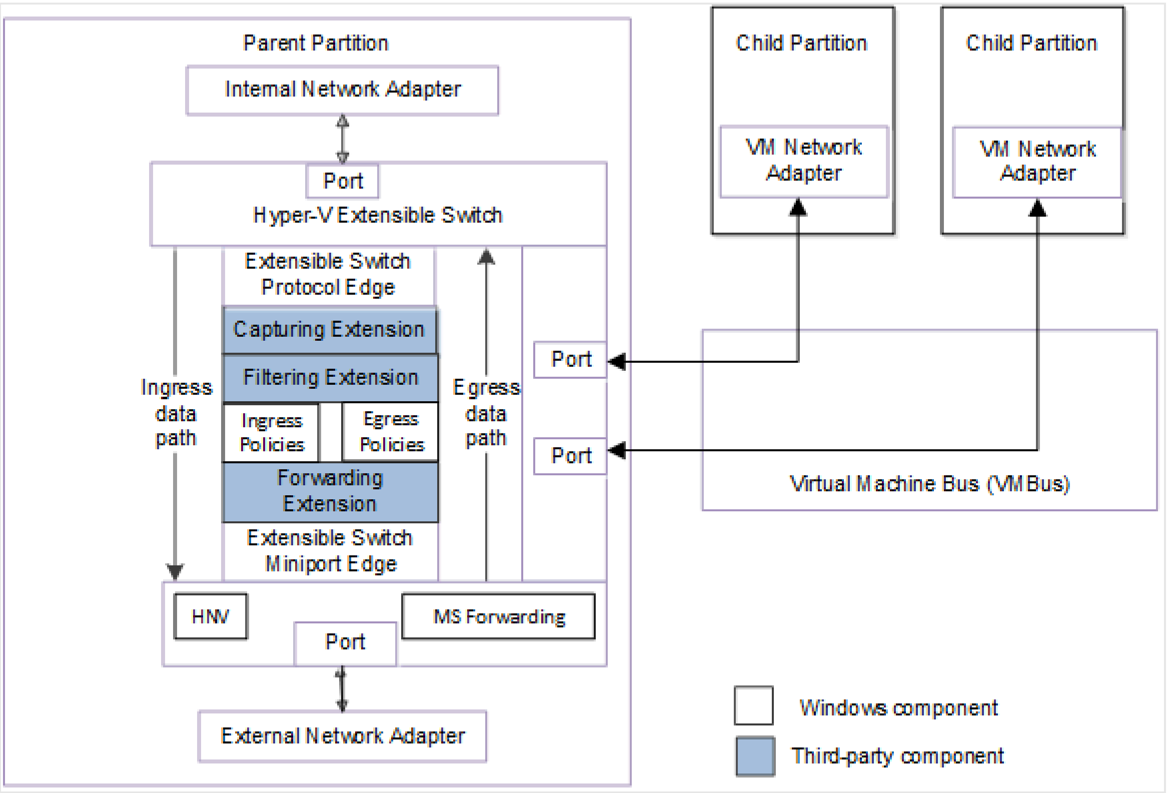
Note If a forwarding extension is not installed and enabled in the extensible switch, the switch determines a packet's destination ports as well as filters packets based on standard port settings.

Only one forwarding extension can be bound and enabled in each instance of an extensible switch.

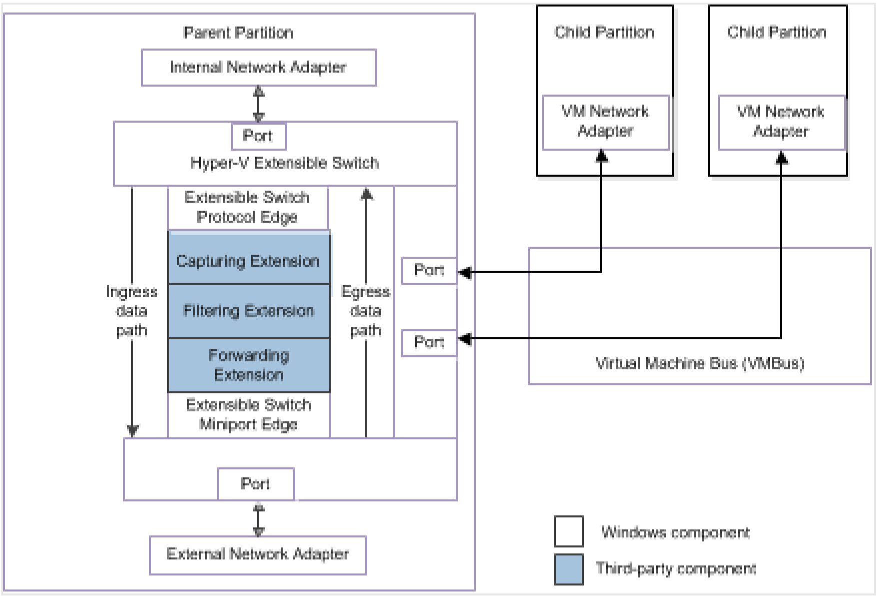
For more information on this type of extension, see Forwarding Extensions.

Hyper-V extensible switch architectural diagrams

The following figure shows the components of the extensible switch interface for NDIS 6.40 (Windows Server 2012 R2) and later.



The following figure shows the components of the extensible switch interface for NDIS 6.30 (Windows Server 2012).



For more information about the components for the extensible switch interface, see Hyper-V Extensible Switch Architecture.

Hyper-V Extensible Switch Architecture Topics

Article • 12/15/2021

This section describes the architecture of the Microsoft Hyper-V extensible switch interface. This section includes the following topics:

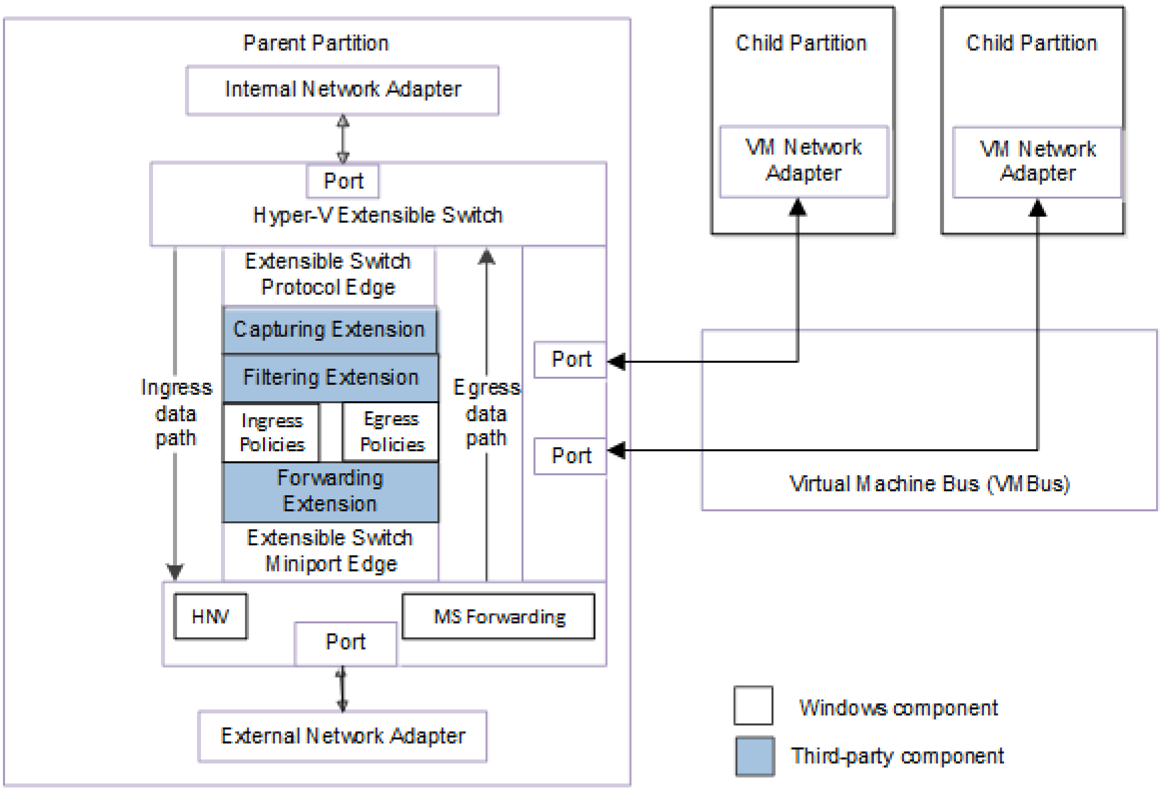
Hyper-V Extensible Switch Components Overview

Article • 12/15/2021

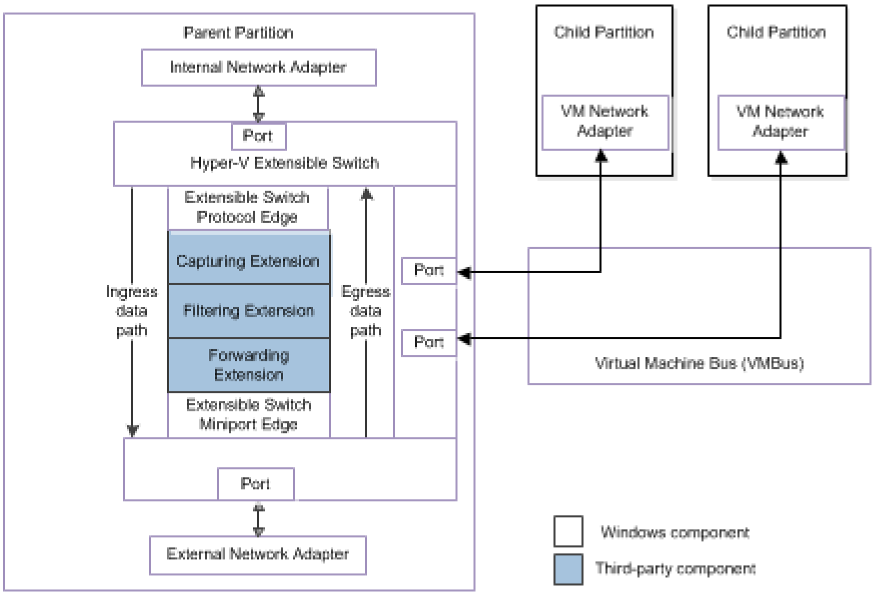
Starting with Windows Server 2012, the Hyper-V extensible switch supports an interface that allows NDIS filter drivers (known as *Hyper-V extensible switch extensions*) to bind within the extensible switch driver stack. This allows extensions to monitor, modify, and forward packets to extensible switch ports. This also allows extensions to drop, redirect, or originate packets to ports that are used by the Hyper-V partitions.

Extensions can be provisioned with policies that apply to packet traffic over an individual extensible switch port or the switch itself. This allows the extension to allow a packet to be sent or deny a packet from being sent.

The following figure shows the components of the extensible switch interface for NDIS 6.40 (Windows Server 2012 R2) and later.



The following figure shows the components of the extensible switch interface for NDIS 6.30 (Windows Server 2012).



This section includes the following topics that describe the extensible switch components:

Hyper-V Extensible Switch Extensions

Hyper-V Extensible Switch Ports

Hyper-V Extensible Switch Network Adapters

Hyper-V Extensible Switch Port and Network Adapter States

Hyper-V Extensible Switch Extensions

Article • 12/15/2021

This section describes the type of NDIS filter drivers that are supported in the extensible switch interface. These filter drivers are known as *extensible switch extensions*.

This section includes the following topics:

Capturing Extensions

Filtering Extensions

Forwarding Extensions

Note If multiple extensions of the same type are bound to an extensible switch instance, the order in which they are layered within the extensible switch driver stack can be modified. For more information, see Reordering Hyper-V Extensible Switch Extensions.

Capturing Extensions

Article • 12/15/2021

A Hyper-V extensible switch capturing extension inspects packet traffic, object identifier (OID) requests, and NDIS status indications. This type of extension cannot modify or drop packets, or exclude packets from being delivered to extensible switch ports. However, capturing extensions can originate packet traffic, such as packets that contain traffic statistics that the extension sends to a host application.

Capturing extensions are invoked at the start of the ingress data path and at the end of the egress data path. For more information about these data paths, see Hyper-V Extensible Switch Data Path.

A capturing extension has the following requirements and restrictions:

- A capturing extension must be developed as an NDIS filter driver that supports the extensible switch interface.

  For more information about filter drivers, see NDIS Filter Drivers.

  For more information on how to write a capturing extension, see Writing Hyper-V Extensible Switch Extensions.

- A capturing extension provides the same functionality as a standard NDIS monitoring filter driver. However, the INF file for a capturing extension must install it as a modifying filter driver.

  For more information about modifying filter drivers, see Types of Filter Drivers.

  For more information about the INF requirements for modifying filter drivers, see Configuring an INF File for a Modifying Filter Driver.

- A capturing extension can monitor packets over the ingress and egress extensible switch data path. However, this type of extension must always call **NdisFSendNetBufferLists** to forward the packets to underlying drivers in the extensible switch driver stack and not complete them.

- A capturing extension must not modify the data within the packets nor add port destinations to the out-of-band (OOB) data of the packet. The extension must not exempt the delivery of the packet to any extensible switch port.

- A capturing extension can originate packets. For example, the extension may originate packets in order to report traffic conditions to a remote monitoring application.

For more information on originating packets by an extension, see Originating Packet Traffic.

Note As with other extensions, the capturing extension can only originate packet traffic in the extensible switch ingress data path.

- A capturing extension can monitor packets, OID requests, and NDIS status indications that are issued over the extensible switch driver stack. However, this type of extension must forward packets, OID requests, and NDIS status indications through the extensible switch driver stack. The extension must not modify the data within the packets, OID requests, or NDIS status indications that it monitors.

- The **FilterClass** value in the INF file for the extension must be set to **ms_switch_capture**. For more information, see INF Requirements for Hyper-V Extensible Switch Extensions.

- Any number of capturing extensions can be bound to an extensible switch instance. By default, multiple capturing extensions are ordered based on when they were installed. For example, multiple capturing extensions are layered in the extensible switch driver stack with the most recently installed extension layered above other capturing extensions in the stack.

  Once bound to an extensible switch instance, the layering of capturing extensions in the extensible switch driver stack can be reordered. For more information, see Reordering Hyper-V Extensible Switch Extensions.

Filtering Extensions

Article • 12/15/2021

A Hyper-V extensible switch filtering extension can inspect, modify, and insert packets into the extensible switch data path. Based on extensible switch port and switch policy settings, the extension can drop a packet or exclude its delivery to one or more destination ports.

Filtering extensions are invoked after capturing extensions in the ingress data path and after the forwarding extensions in the egress data path. For more information about these data paths, see Hyper-V Extensible Switch Data Path.

A filtering extension can do the following with packets that were obtained on the ingress data path:

- Filter packet traffic and enforce custom port or switch policies for packet delivery through the extensible switch. When the filtering extension filters packets in the ingress data path, it can apply filtering rules based only on the source port and network adapter connection from which the packet originated. This information is stored in the out-of-band (OOB) data of a packet's **NET_BUFFER_LIST** structure and can be obtained by using the **NET_BUFFER_LIST_SWITCH_FORWARDING_DETAIL** macro.

  Note Packets obtained on the ingress data path do not contain destination ports. Filtering packets based on destination ports can be done only on packets obtained on the egress data path.

  Custom policies are defined by the independent software vendor (ISV). Property settings for this policy type are managed through the Hyper-V WMI management layer. The filtering extension is configured with these property settings through an object identifier (OID) request of OID_SWITCH_PORT_PROPERTY_UPDATE and OID_SWITCH_PROPERTY_UPDATE.

  For more information on custom extensible port or switch policies, see Managing Hyper-V Extensible Switch Policies.

  Note Only forwarding extensions can enforce standard port policies for packet delivery through the extensible switch.

- Inject new, modified, or cloned packets into the ingress data path.

  For more information, see Hyper-V Extensible Switch Send and Receive Operations.

A filtering extension can do the following with packets that were obtained on the egress data path:

- Filter packet traffic and enforce custom port or switch policies for packet delivery through the extensible switch. When the filtering extension filters packets in the egress data path, it can apply filtering rules based on the source or destination ports for a packet. Destination port data is stored in the OOB data of a packet's **NET_BUFFER_LIST** structure. Extensions obtain this information by calling the *GetNetBufferListDestinations* function.

- Exclude the delivery of the packet to one or more extensible switch destination ports. This allows the filtering extension to exclude the delivery of a packet to extensible switch ports.

  For more information on how to exclude packet delivery to extensible switch ports, see Excluding Packet Delivery to Extensible Switch Destination Ports.

- Manage the traffic flow to one or more destination ports by postponing the forwarding of packets up the egress data path.

  For example, a filtering extension that supports quality of service (QoS) functionality may want to immediately call **NdisFSendNetBufferLists** to forward packets that are specified with a higher priority value. Depending on the traffic flow, the extension may want to forward packets with a lower priority value at a later time.

- Modify the packet data. If the filtering extension needs to modify the data in a packet, it must first clone the packet without preserving port destinations. Then, the extension must inject the modified packet into the ingress data path. This allows the underlying extensions to enforce policies on the modified packet and the forwarding extension can add port destinations.

  For more information, see Cloning Packet Traffic.

Besides inspecting OID requests and NDIS status indications, a filtering extension can do the following:

- Veto the creation of an extensible switch port or network adapter connection by returning STATUS_DATA_NOT_ACCEPTED for the applicable extensible switch OIDs. For example, the filtering extension can veto a port creation request by returning STATUS_DATA_NOT_ACCEPTED when the driver receives an OID set request of OID_SWITCH_PORT_CREATE.

Note Filtering extensions do not create or delete ports or network adapter connections. The protocol edge of the extensible switch issues OIDs to notify the underlying filter drivers about the creation or deletion of ports or network adapter connections. For more information, see Hyper-V Extensible Switch Port and Network Adapter States.

- Veto the addition or update of an extensible switch or port policy by returning STATUS_DATA_NOT_ACCEPTED for the applicable extensible switch OIDs. For example, the filtering extension can veto the addition of a port policy by returning STATUS_DATA_NOT_ACCEPTED when the extension receives an OID set request of OID_SWITCH_PORT_PROPERTY_ADD.

  For more information about extensible switch policies, see Managing Hyper-V Extensible Switch Policies.

A filtering extension has the following requirements:

- A filtering extension must be developed as an NDIS filter driver that supports the extensible switch interface.

  For more information about filter drivers, see NDIS Filter Drivers.

  For more information on how to write a filtering extension, see Writing Hyper-V Extensible Switch Extensions.

  Note The Windows Filtering Platform (WFP) provides an in-box extensible switch filtering extension (Wfplwfs.sys). This extension allows WFP filters or callout drivers to intercept packets along the Hyper-V extensible switch data path. This allows the filters or callout drivers to perform packet inspection or modification by using the WFP management and system functions. For an overview of WFP, see Windows Filtering Platform.

- The INF file for a filtering extension must install the driver as a modifying filter driver. NDIS-monitoring filter drivers cannot be installed in the extensible switch driver stack.

  For more information about modifying filter drivers, see Types of Filter Drivers.

  For more information about the INF requirements for modifying filter drivers, see Configuring an INF File for a Modifying Filter Driver.

- The **FilterClass** value in the INF file for the filter driver must be set to **ms_switch_filter**. For more information, see INF Requirements for Hyper-V Extensible Switch Extensions.

- Any number of filtering extensions can be bound and enabled in the driver stack for each instance of an extensible switch. By default, multiple filtering extensions are ordered based on when they were installed. For example, multiple filtering extensions are layered in the extensible switch driver stack with the most recently installed extension layered above other filtering extensions in the stack.

  After they are bound and enabled in an extensible switch instance, the layering of filtering extensions in the extensible switch driver stack can be reordered. For more information, see Reordering Hyper-V Extensible Switch Extensions.

Forwarding Extensions

Article • 12/15/2021

A forwarding extension has the same capabilities as a filtering extension, but is responsible for performing the core packet forwarding and filtering tasks of the extensible switch. These tasks include the following:

- Determining the destination ports for a packet.

  Note If the packet is an NVGRE packet, the Hyper-V Network Virtualization (HNV) component of the extensible switch determines the destination ports and forwards the packet. For more information, see Hybrid Forwarding.

- Filtering packets by enforcing standard port policies, such as security, profile, or virtual LAN (VLAN) policies.

  Note The extensible switch still performs filtering based on built-in policies. These policies include access control lists (ACLs) and quality of service (QoS).

Note If a forwarding extension is not installed and enabled in the extensible switch, the switch determines a packet's destination ports as well as filters packets based on standard port settings.

Forwarding extensions are layered immediately above the extensible switch extension miniport driver in the egress and ingress data path. For more information about these data paths, see Hyper-V Extensible Switch Data Path.

A forwarding extension can do the following with packets that were obtained on the ingress data path:

- It can filter packet traffic and enforce custom and standard port or switch policies for packet delivery through the extensible switch. When the forwarding extension filters packets in the ingress data path, it applies filtering rules based on the source port as well as the destination ports that the extension assigns to the packet.

  Custom policies are defined by the independent software vendor (ISV). Standard policies are defined by the extensible switch interface. Property settings for these types of policies are managed through the Hyper-V WMI management layer. The forwarding extension is configured with these property settings through an object identifier (OID) request of OID_SWITCH_PORT_PROPERTY_UPDATE and OID_SWITCH_PROPERTY_UPDATE.

For more information on extensible switch policies, see Managing Hyper-V Extensible Switch Policies.

- It can inject new, modified, or cloned packets into the ingress data path.

  For more information, see Hyper-V Extensible Switch Send and Receive Operations.

- It can determine the delivery of the packet to one or more extensible switch destination ports. This allows the forwarding extension to add destination ports for the delivery of a packet to extensible switch ports.

  For more information on how to add destination ports, see Adding Extensible Switch Destination Port Data to a Packet.

A forwarding extension can do the following with packets that were obtained on the egress data path:

- It can filter packet traffic and enforce custom and standard port or switch policies for packet delivery through the extensible switch. When the forwarding extension filters packets in the egress data path, it can apply filtering rules based on the source or destination ports for a packet.

- It can exclude the delivery of the packet to one or more extensible switch destination ports. This allows the forwarding extension to exclude the delivery of a packet to extensible switch ports.

  For more information on how to exclude packet delivery to extensible switch ports, see Excluding Packet Delivery to Extensible Switch Destination Ports.

  Note The forwarding extension can only exclude packet delivery when it handles the packet on the egress data path. The extension can only add or modify destination ports for the packet on the ingress data path.

- It can modify the packet data. If the forwarding extension needs to modify the data in a packet, it must first clone the packet before it assigns port destinations. After the packet has been modified and port destinations assigned, the extension must inject the modified packet into the egress data path.

  For more information, see Cloning Packet Traffic.

Besides inspecting OID requests and NDIS status indications, a forwarding extension can do the following:

- It can inject OIDs or NDIS status indications into the extensible switch control path. This allows the forwarding extension to create or modify OIDs and status indications and forward them to or from underlying physical network adapters.

For example, the extensible switch external network adapter can be bound to the virtual miniport edge of an NDIS multiplexer (MUX) intermediate driver. The MUX intermediate driver itself can be bound to a team of one or more physical networks on the host. This configuration is known as an *extensible switch team*.

In this configuration, the extensible switch extensions are exposed to every network adapter in the extensible switch team. This allows the forwarding extension in the extensible switch driver stack to manage the configuration and use of individual network adapters in the team. For example, the extension can provide support for a load balancing failover (LBFO) solution over the team by forwarding outgoing packets to individual adapters. Such an extension is known as a *teaming provider*.

By acting as a teaming provider, the forwarding extension can create or modify OID requests to enable or disable hardware capabilities on an adapter in the team. The teaming provider can also create or modify NDIS status indications based on changes to one or more adapters in the team.

For more information about teaming providers, see Teaming Provider Extensions.

- It can veto the creation of an extensible switch port or network adapter connection by returning STATUS_DATA_NOT_ACCEPTED for the applicable extensible switch OIDs. For example, the forwarding extension can veto a port creation request by returning STATUS_DATA_NOT_ACCEPTED when the driver receives an OID set request of OID_SWITCH_PORT_CREATE.

  Note Forwarding extensions do not create or delete ports or network adapter connections. The protocol edge of the extensible switch issues OIDs to notify the underlying extensions about the creation or deletion of ports or network adapter connections. For more information, see Hyper-V Extensible Switch Port and Network Adapter States.

- It can veto the addition or update of an extensible switch or port policy by returning STATUS_DATA_NOT_ACCEPTED for the applicable extensible switch OIDs. For example, the forwarding extension can veto the addition of a port policy by returning STATUS_DATA_NOT_ACCEPTED when the driver receives an OID set request of OID_SWITCH_PORT_PROPERTY_ADD.

  For more information about extensible switch policies, see Managing Hyper-V Extensible Switch Policies.

A forwarding extension has the following requirements:

- A forwarding extension must be developed as an NDIS filter driver that supports the extensible switch interface.

  For more information about filter drivers, see NDIS Filter Drivers.

  For more information on how to write a forwarding extension, see Writing Hyper-V Extensible Switch Extensions.

- The INF file for a forwarding extension must install the extension as a modifying filter driver. NDIS-monitoring filter drivers cannot be installed in the extensible switch driver stack.

  For more information about modifying filter drivers, see Types of Filter Drivers.

  For more information about the INF requirements for modifying filter drivers, see Configuring an INF File for a Modifying Filter Driver.

- The **FilterClass** value in the INF file for the extension must be set to **ms_switch_forward**. For more information, see INF Requirements for Hyper-V Extensible Switch Extensions.

- Only one forwarding extension can be enabled in the driver stack for each instance of an extensible switch.

For more information about extensible switch teams, see Types of Physical Network Adapter Configurations.

For more information about forwarding extensions, see the following pages:

- Teaming Provider Extensions
- Hybrid Forwarding

Overview of the Hyper-V Extensible Switch

Teaming Provider Extensions

Article • 12/15/2021

The extensible switch external network adapter can be bound to the virtual miniport edge of an NDIS multiplexer (MUX) intermediate driver. The MUX intermediate driver itself can be bound to a team of one or more physical networks on the host. This configuration is known as an *extensible switch team*. For more information about extensible switch teams, see Types of Physical Network Adapter Configurations.

In this configuration, the extensible switch extensions are exposed to every network adapter in the extensible switch team. This allows the forwarding extension in the extensible switch driver stack to manage the configuration and use of individual network adapters in the team. For example, the extension can provide support for a load balancing failover (LBFO) solution over the team by forwarding outgoing packets to individual adapters. Such an extension is known as a *teaming provider*.

The following figure shows the data path for packet traffic to or from the underlying extensible switch team that is bound to the external network adapter for NDIS 6.40 (Windows Server 2012 R2) and later.

Teaming providers can do everything that a forwarding extension can. In addition, teaming providers can do the following.

- Forward outgoing packets to an individual physical adapter in the extensible switch team. This ability is especially useful for LBFO functionality.

- Forward standard NDIS object identifier (OID) requests to an individual physical adapter in the extensible switch team. This ability is especially useful for configuring the adapters in the team for hardware offloads.

  For example, the MUX driver advertises the common capabilities of the entire extensible switch team. However, the teaming provider can issue OID requests to query the individual capabilities of adapters within the team. Then, the teaming provider can issue OID requests to the extensible switch external network adapter to set the capabilities that apply to the entire team.

- Forward private OID requests to an individual physical adapter in the extensible switch team. These private OID requests are defined by the independent hardware vendor (IHV) for the physical network adapters. This allows a teaming provider that was also developed by the IHV to enable or disable proprietary attributes on individual physical adapters in the team.

- Modify NDIS status indications from the extensible switch team. This ability is especially useful for managing the extensible switch team for hardware offloads.

For example, the MUX driver issues NDIS status indications with settings that are common for the entire extensible switch team. If the status indication was for a hardware offload that the teaming provider enabled for a network adapter in the extensible switch team, the teaming provider can first issue an OID request to query the current capabilities on that adapter. Then, the teaming provider can modify the indication data to set those attributes that may have changed on the adapter.

Teaming providers must follow these guidelines when managing an extensible switch team:

- The teaming provider must maintain state for every physical network adapter for which an extensible switch network connection had been established.

  For every physical network adapter that is bound to the external network adapter, the protocol edge of the extensible switch issues a separate OID set request of OID_SWITCH_NIC_CREATE. This OID request notifies the extension about the creation of a network connection to an underlying physical adapter.

- When the network connection to the physical network adapter is created, it is assigned a nonzero index value that is unique for the port to which the external network adapter is connected.

  The teaming provider must specify the network adapter index value when it issues or forwards packets or OID requests to an underlying physical network adapter.

  For more information, see Network Adapter Index Values.

- If the teaming provider issues or forwards packets to a physical adapter, it must specify the nonzero network adapter index value of the physical adapter connection.

  When the provider receives packets, it can determine the source network adapter index value from the packet's out-of-band forwarding context in the **NET_BUFFER_LIST** structure. For more information about the forwarding context, see Hyper-V Extensible Switch Forwarding Context.

  For more information, see Hyper-V Extensible Switch Data Path.

- To issue forward OID requests to a physical adapter, the teaming provider must encapsulate the OID request within an **NDIS_SWITCH_NIC_OID_REQUEST** structure. The provider must set the **DestinationNicIndex** member to the nonzero network adapter index value of the physical adapter connection. The provider then issues an OID set request of OID_SWITCH_NIC_REQUEST to deliver the encapsulated OID request to the target physical adapter.

For more information, see Managing OID Requests to Physical Network Adapters.

- The teaming provider can issue NDIS status indications on behalf of an underlying physical adapter. To do this, the provider must encapsulate the indication within an **NDIS_SWITCH_NIC_STATUS_INDICATION** structure. The provider must set the **SourceNicIndex** member to the nonzero network adapter index value of the physical adapter connection. The provider then issues an NDIS status indication of **NDIS_STATUS_SWITCH_NIC_STATUS** to deliver the encapsulated status indication to overlying drivers in the extensible switch driver stack.

  For more information, see Managing NDIS Status Indications from Physical Network Adapters.

For more information about forwarding extensions, see Forwarding Extensions.

For more information on MUX drivers, see NDIS MUX Intermediate Drivers.

Hybrid Forwarding

Article • 12/15/2021

Starting with NDIS 6.40 (Windows Server 2012 R2, the Hyper-V extensible switch architecture supports hybrid forwarding by the Hyper-V Network Virtualization (HNV) component of the extensible switch and by forwarding extensions.

Note This page assumes that you are familiar with Network Virtualization using Generic Routing Encapsulation (NVGRE) Task Offload and Overview of the Hyper-V Extensible Switch.

NVGRE and non-NVGRE packets

In a hybrid forwarding environment, there are two types of packets that enter and leave the Hyper-V extensible switch: NVGRE packets and non-NVGRE packets:

- NVGRE packets have the encapsulated format that is specified in the NVGRE: Network Virtualization using Generic Routing Encapsulation Internet Draft. NVGRE packets are forwarded by the HNV component of the Hyper-V extensible switch.
- Non-NVGRE packets are just normal network packets. Non-NVGRE packets are forwarded by the forwarding extension (or, in the absence of a forwarding extension, the extensible switch itself).

Flow of NVGRE and non-NVGRE packets through the switch

In the ingress data path, after the capturing and filtering extensions but before the forwarding extension, if a packet is an NVGRE packet, the extensible switch sets the **NativeForwardingRequired** flag in the NDIS_SWITCH_FORWARDING_DETAIL_NET_BUFFER_LIST_INFO structure for the packet. This structure is contained in the **NetBufferListInfo** member of the packet's NET_BUFFER_LIST structure.

Note The **NetBufferListInfo** member of the NET_BUFFER_LIST is often referred to as the packet's "out-of-band (OOB) data."

If the **NativeForwardingRequired** flag is set in the packet's OOB data, the packet is an NVGRE packet. If it is not set, the packet is a non-NVGRE packet.

Extensions should use the NET_BUFFER_LIST_SWITCH_FORWARDING_DETAIL macro to check the value of the **NativeForwardingRequired** flag.

NVGRE and non-NVGRE packets are treated as follows:

- The HNV component of the Hyper-V extensible switch forwards (i.e., determines the destination table for) all NVGRE packets
- The HNV component performs NVGRE encapsulation and decapsulation as needed.
- The forwarding extension forwards all non-NVGRE packets.
- The forwarding extension cannot forward NVGRE packets, but it can perform the same filtering actions as a filtering extension, including adding or excluding destination ports or even dropping packets.
- If there is no forwarding extension, the Hyper-V extensible switch forwards all packets.

For more information, see Packet Flow through the Extensible Switch Data Path.

Support for third-party network virtualization

A **VirtualSubnetId** can be configured on a VM network adapter port as an external virtual subnet. This feature was added to enable forwarding extensions to provide third-party network virtualization solutions. On ingress, the Hyper-V extensible switch will not set the **NativeForwardingRequired** flag in the NET_BUFFER_LIST structures for these packets. A forwarding extension may then modify the packet headers, as required, during forwarding. Packets that are being modified must be cloned and their **ParentNetBufferList** pointers set to the original **NET_BUFFER_LIST**. (See Cloning Packet Traffic.)

Hyper-V Extensible Switch Ports Topics

Article • 12/15/2021

This section includes the following topics that describe the characteristics of Hyper-V extensible switch ports:

Overview of Hyper-V Extensible Switch Ports

Validation Ports

Operational Ports

Note NDIS ports and extensible switch ports are different objects. Packets that move through the extensible switch data path are always assigned to the NDIS port number of **NDIS_DEFAULT_PORT_NUMBER**. However, the packet's source and destination extensible switch port number can be a value of **NDIS_SWITCH_DEFAULT_PORT_ID** or greater. For more information, see Hyper-V Extensible Switch Data Path.

Overview of Hyper-V Extensible Switch Ports

Article • 12/15/2021

Each network connection to the Hyper-V extensible switch is represented by a port. The extensible switch interface creates and configures a port before a network connection is made. After the network connection is torn down, the interface may delete the port or reuse it for another network connection.

Every Hyper-V child partition that is configured with a network interface is assigned a port on the extensible switch. When a Hyper-V child partition is started, the extensible switch interface creates a port before the virtual machine (VM) network adapter is exposed within the guest operating system. After the VM network adapter is exposed and initialized, the extensible switch interface creates a network connection between the VM network adapter and the extensible switch port. If the child partition is stopped, the extensible switch interface first deletes the network connection and then deletes the extensible switch port.

When an extensible switch port is created, it is configured with a unique identifier and name. After it is created, the extensible switch port can be provisioned with policies that define various attributes for the management of packet traffic over the port. For example, standard port policies can be defined for virtual LAN (VLAN) attributes and access restrictions for port traffic. In addition, independent software vendors (ISVs) can define custom policies that individual ports can be provisioned with. For more information, see Port Policies.

Extensible switch ports consist of the following types:

Validation ports
Validation ports are used to validate and verify port settings. These ports are temporary and are created under certain conditions.

For example, when a Hyper-V child partition is created or reconfigured for network access, the extensible switch interface creates a validation port. The interface uses this port to verify the settings for the network connection to the virtual machine (VM) network adapter of the partition. After the verification is completed, the validation port is deleted and an operational port is created.

For more information, see Validation Ports.

Operational ports
Operational ports are created to host an extensible switch network adapter connection. When an operational port is created, it is assigned a port type. This port type is in effect after the port is created and before it is torn down. For ports assigned to Hyper-V child partitions, the operational port type stays in effect while the partition is running and operational.

For more information, see Operational Ports.

Extensible switch extensions are notified of port creation, update and deletion through the following extensible switch object identifier (OID) requests:

OID_SWITCH_PORT_CREATE
The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_PORT_CREATE to notify extensible switch extensions about the creation of an extensible switch port.

The extension can veto the creation notification by returning STATUS_DATA_NOT_ACCEPTED for the OID request. For example, if an extension cannot allocate resources to enforce its configured policies on the port, the extension vetoes the creation notification.

If the extension accepts the creation notification, it must forward the OID request down the extensible switch driver stack. The extension monitors the completion status of this OID request to determine whether underlying extensions have vetoed the port creation notification.

Extensions cannot forward packets to the newly created port until a network connection is created. For more information on this process, see Hyper-V Extensible Switch Network Adapters.

OID_SWITCH_PORT_UPDATED
The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_PORT_UPDATED to notify extensible switch extensions that an extensible switch port's parameters are being updated. The OID will only be issued for ports that have already been created, and have not yet begun the teardown/delete process. Currently only the *PortFriendlyName* field is subject to update after creation.

The protocol edge of the extensible switch issues this OID request when the previous network connection to the port has been torn down and all OID requests to the port have been completed.

Note This OID request could be issued if a network adapter connection was not previously made to the port.

The extension must always forward this OID set request down the extensible switch driver stack. The extension must not fail the request.

OID_SWITCH_PORT_TEARDOWN
The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_PORT_TEARDOWN to notify extensible switch extensions that an extensible switch port is being deleted. The protocol edge of the extensible switch issues this OID request when the previous network connection to the port has been torn down and all OID requests to the port have been completed.

Note This OID request could be issued if a network adapter connection was not previously made to the port.

The extension must always forward this OID set request down the extensible switch driver stack. The extension must not fail the request.

After the extension forwards this OID request, it can no longer issue OID requests for the port being deleted.

OID_SWITCH_PORT_DELETE
The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_PORT_DELETE to notify extensible switch extensions that an extensible switch port has been deleted. The protocol edge of the extensible switch issues this OID request after it issues the OID_SWITCH_PORT_TEARDOWN request and OID requests that target the port have been completed.

The extension must always forward this OID set request down the extensible switch driver stack. The extension must not fail the request.

All extensible switch ports that are created for network connections are assigned an identifier greater than **NDIS_SWITCH_DEFAULT_PORT_ID**. The **NDIS_SWITCH_DEFAULT_PORT_ID** identifier is reserved and used in the following ways:

- The source port identifier for a packet is stored in the packet's out-of-band (OOB) forwarding context that is associated with its **NET_BUFFER_LIST** structure. A source port identifier of **NDIS_SWITCH_DEFAULT_PORT_ID** specifies that the packet originated from the extensible switch extension and not from an extensible switch port. A packet with a source port identifier of **NDIS_SWITCH_DEFAULT_PORT_ID** is trusted and bypasses the extensible switch port policies, such as access control lists (ACLs) and quality of service (QoS).

  The extension may want the packet to be treated as if it originated from a particular port. This allows the policies for that port to be applied to the packet. The extension calls *SetNetBufferListSource* to change the source port for the packet.

However, there may be situations where the extension may want to assign the packet's source port identifier to **NDIS_SWITCH_DEFAULT_PORT_ID**. For example, the extension may want to set the source port identifier to **NDIS_SWITCH_DEFAULT_PORT_ID** for proprietary control packets that are sent to a device on the external network.

For more information about the forwarding context, see Hyper-V Extensible Switch Forwarding Context.

- Object identifier (OID) requests of OID_SWITCH_NIC_REQUEST are issued by the extensible switch interface to encapsulate OID requests that are issued to the extensible switch external network adapter. For example, hardware offload OID requests are encapsulated by the interface before they are issued down the extensible switch driver stack.

  An extension can also issue encapsulated OID requests in order to forward requests down the extensible switch control path. This allows extensions to query or configure the capabilities of an underlying physical network adapter.

  The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure for this OID request contains a pointer to an **NDIS_SWITCH_NIC_OID_REQUEST** structure. If the **SourcePortId** member is set to **NDIS_SWITCH_DEFAULT_PORT_ID**, this specifies that the OID request was originated by the extensible switch interface. If the **DestinationPortId** is set to **NDIS_SWITCH_DEFAULT_PORT_ID**, this specifies that the OID request is targeted for processing by an extension in the extensible switch driver stack.

  For more information about the control path for OID requests, see Hyper-V Extensible Switch Control Path for OID Requests.

- NDIS status indications of **NDIS_STATUS_SWITCH_NIC_STATUS** are issued by the miniport edge of the extensible switch to encapsulate a status indication from the extensible switch external network adapter.

  An extension can also issue encapsulated NDIS status indications in order to forward indications up the extensible switch control path. This allows extensions to change the reported capabilities of an underlying physical network adapter.

  The **StatusBuffer** member of the **NDIS_STATUS_INDICATION** structure for this indication contains a pointer to an **NDIS_SWITCH_NIC_STATUS_INDICATION** structure. If the **SourcePortId** member is set to **NDIS_SWITCH_DEFAULT_PORT_ID**, this specifies that the status indication was originated by the extensible switch interface. If the **DestinationPortId** is set to **NDIS_SWITCH_DEFAULT_PORT_ID**, this specifies that the OID request is targeted for processing by an extension in the extensible switch driver stack.

For more information about the control path for NDIS status indications, see Hyper-V Extensible Switch Control Path for NDIS Status Indications.

The extensible switch interface maintains a reference counter for each port that has been created. A port will not be deleted if its reference counter has a nonzero value. The interface provides the following handler functions for incrementing or decrementing an extensible switch port's reference counters:

ReferenceSwitchPort
The extensible switch extension calls this function to increment a port's reference counter. While the reference counter has a nonzero value, the protocol edge of the extensible switch will not issue an object identifier (OID) set request of OID_SWITCH_PORT_DELETE to delete the extensible switch port.

The extension must call *ReferenceSwitchPort* before it performs any operation that requires the port to be in an active state. For example, the extension must call *ReferenceSwitchPort* before it issues an OID method request of OID_SWITCH_PORT_PROPERTY_ENUM.

Note The extension must not call *ReferenceSwitchPort* for a port after it receives an OID set request of OID_SWITCH_PORT_TEARDOWN for that port.

DereferenceSwitchPort
The extensible switch extension calls this function to decrement a port's reference counter.

The extension must call *DereferenceSwitchPort* after the operation being performed on the port has completed. For example, if the extension called *ReferenceSwitchPort* before if issued an OID_SWITCH_PORT_PROPERTY_ENUM request, the extension must call *DereferenceSwitchPort* after the OID request has completed.

Note NDIS ports and extensible switch ports are different objects. Packets that move through the extensible switch data path are always assigned to the NDIS port number of **NDIS_DEFAULT_PORT_NUMBER**. However, the packet's source and destination extensible switch port number can be a value of **NDIS_SWITCH_DEFAULT_PORT_ID** or greater. For more information, see Hyper-V Extensible Switch Data Path.

Validation Ports

Article • 12/15/2021

Starting with NDIS 6.30 in Windows Server 2012, the extensible switch interface creates an operational port to host an extensible switch network adapter connection. Under certain conditions, the extensible switch interface creates a validation port before it creates the operational port for a Hyper-V child partition. The validation port is used to validate and verify settings for the operational port that will be connected to the extensible switch virtual machine (VM) network adapter of the child partition.

Note In Hyper-V, a child partition is also known as a VM.

This validation port is created under the following conditions:

- The VM is first created. Once the VM is powered on, the validation port is deleted and the operational port is created in its place.

- The VM enters a saved state. When the VM is restored and powered on, the validation port is deleted and the operational port is created in its place.

  For more information, see Hyper-V Extensible Switch Save and Restore Operations.

- The VM is stopped and powered down. Once the VM is powered on, the validation port is deleted and the operational port is created in its place.

- The VM is being live migrated to another host computer. Once the VM is created and powered on in the new host computer, the validation port is deleted and the operational port is created in its place.

After the validation port is created, the extensible switch interface issues OID requests to download port policies for the port. Because these ports are created for policy validation and verification, such as when a VM is first configured, it is important that the validation that occurs is appropriate for configuration time rather than run time. Extensions should perform the following types of policy validation for these ports:

- Syntax validation. This validation fails if the values are not properly formatted.

- Range validation. This validation fails if the settings do not conform to the expected range of minimum and maximum values.

- Applicability validation. This validation fails if the settings do not apply to the extensible switch. For example, a policy profile that defines an external network service-level agreement (SLA) would not apply to an extensible switch that does not have access to the external networking interface.

- Conflict detection. The validation fails if the settings conflict with other settings that are already set on the same port.

When the extensible switch extension validates port and policy settings for a validation port, it must follow these guidelines:

- Because the validation port is temporal, the extension must not validate and fail policy and configuration settings that cannot be currently satisfied by the extensible switch.

  For example, an extensible switch, which supports a maximum of 10 gigabits of bandwidth, may currently only have 1 gigabit of bandwidth available for reservation. The extension does not fail the validation of a port property that is reserving more than 1 gigabit of bandwidth. This kind of validation should instead occur when the operational port is created. This is because the settings that are being validated may still be applied to an operational port in which the bandwidth is available. This allows system administrators to initially configure VMs without being restricted by run-time constraints.

- The extension must not allocate or reserve resources for the validation port. For example, bandwidth reservation settings on a validation port should not deduct from the available bandwidth of the extensible switch. Reservation should occur only when the operational port is created.

For more information on extensible switch operational ports, see Operational Ports.

Operational Ports

Article • 12/15/2021

Starting with NDIS 6.30 in Windows Server 2012, the extensible switch interface creates an operational port to host an extensible switch network adapter connection. When an extensible switch port is created, it is assigned a port type. This port type is in effect after the port is created and before it is torn down. For ports assigned to Hyper-V child partitions, the operational port type stays in effect while the partition is running and operational.

Operational port types define the type of extensible switch network adapter that can connect to it. The extensible switch interface defines the following operational port types:

NdisSwitchPortTypeExternal
This is a port that is configured to be connected to the external network adapter of the extensible switch. This adapter is exposed in the management operating system that runs in the Hyper-V parent partition.

The external network adapter provides a connection to the physical network interface that is available on the host. The external network adapter can be accessed by the Hyper-V parent partition and all child partitions.

Note An extensible switch supports only one external network adapter connection.

NdisSwitchPortTypeInternal
This is a port that is configured to be connected to the internal network adapter of the extensible switch. This adapter is exposed in the management operating system that runs in the Hyper-V parent partition.

The internal network adapter provides access to an extensible switch for processes that run in the management operating system. This allows these processes to send or receive packets over the extensible switch.

Note An extensible switch supports only one internal network adapter.

NdisSwitchPortTypeSynthetic
This is a port that is configured to be connected to a synthetic network adapter. This adapter is exposed in a guest operating system that runs in a Hyper-V child partition.

Note A synthetic network adapter is a type of virtual machine (VM) network adapter. This adapter is exposed in a guest operating system that is running Windows Vista or a later version of Windows.

NdisSwitchPortTypeEmulated
This value specifies a port that is configured to be connected to an emulated network adapter. This adapter is exposed in a guest operating system.

Note An emulated network adapter is a type of VM network adapter. This adapter can be exposed in a guest operating system that is running Windows XP or a non-Windows operating system.

Overview of Hyper-V Extensible Switch Network Adapters

Article • 12/15/2021

The Hyper-V extensible switch supports connections from various types of virtual or physical network adapters. The connection to these types of network adapters is made through an extensible switch port. Ports are created before a virtual network adapter connection is made, and are deleted after the network adapter connection is torn down.

For example, when a Hyper-V child partition is started, the extensible switch interface creates a port before the virtual machine (VM) network adapter is exposed within the guest operating system. After the VM network adapter is exposed and enumerated, the extensible switch interface creates a network connection between the VM network adapter and the extensible switch port. If the child partition is stopped, the extensible switch interface first deletes the network connection and then deletes the extensible switch port.

The Hyper-V extensible switch supports connections from the following types of virtual network adapters:

External network adapters
This is an extensible switch network adapter that is exposed in the management operating system that runs in the Hyper-V parent partition. Each extensible switch supports only one external network adapter connection.

The external network adapter provides a connection to the physical network interface that is available on the host. The external network adapter can be accessed by the Hyper-V parent partition and all child partitions.

For more information about this type of network adapter, see External Network Adapters.

Internal network adapters
This is an extensible switch network adapter that is exposed in the management operating system that runs in the Hyper-V parent partition. Each extensible switch supports only one internal network adapter connection.

The internal network adapter provides access to an extensible switch for processes that run in the management operating system. This allows these processes to send or receive packets over the extensible switch.

For more information about this type of network adapter, see Internal Network Adapters.

Virtual machine (VM) network adapters
This is an extensible switch network adapter that is exposed in the guest operating system that runs in the Hyper-V child partition.

Note In Hyper-V, a child partition is also known as a VM.

The VM network adapter supports the following virtualization types:

- The VM network adapter could be a synthetic virtualization of a network adapter (*synthetic network adapter*). In this case, the network virtual service client (NetVSC) that runs in the VM exposes this virtual network adapter. NetVSC forwards packets to and from the extensible switch port over the VM bus (VMBus).

- The VM network adapter could be an emulated virtualization of a physical network adapter (*emulated network adapter*). In this case, the VM network adapter mimics an Intel network adapter and uses hardware emulation to forward packets to and from the extensible switch port.

For more information about this type of network adapter, see Virtual Machine Network Adapters.

Extensible switch network adapter connections are created, updated, and deleted through the following extensible switch OID requests:

OID_SWITCH_NIC_CREATE
The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_CREATE to notify extensible switch extensions about the creation of a network adapter connection to an extensible switch port. The port must have been previously created through an OID set request of OID_SWITCH_PORT_CREATE.

The OID_SWITCH_NIC_CREATE request only notifies the extension that a new extensible switch network adapter connection is being brought up and that packet traffic may soon begin to occur over the specified port.

The extension can veto the creation notification by returning STATUS_DATA_NOT_ACCEPTED for the OID request. For example, if an extension cannot satisfy its configured policies on the port that is used for the network adapter connection, the extension should veto the creation notification.

If the extension accepts the creation notification, it must forward the OID request down the extensible switch driver stack. The extension monitors the completion status of this

OID request to determine whether underlying extensions have vetoed the creation notification.

When the network adapter connection is created, it is assigned an NDIS_SWITCH_NIC_INDEX value. This index value identifies the network adapter connection on an extensible switch port. Connections to the external, internal, and VM network adapters are assigned an NDIS_SWITCH_NIC_INDEX value of **NDIS_SWITCH_DEFAULT_NIC_INDEX**. Each physical or virtual network adapter that is bound to the external network adapter is assigned an NDIS_SWITCH_NIC_INDEX value in the following way:

- If the physical or virtual network adapter is directly bound to the external network adapter, it is assigned an NDIS_SWITCH_NIC_INDEX value of one.

- If the physical network adapter is part of an extensible switch team, it is assigned an NDIS_SWITCH_NIC_INDEX value that is greater than or equal to one. An extensible switch team is a configuration in which a team of one or more physical network adapters are bound to the extensible switch external network adapter.

For more information about the different configurations in which physical network adapters can be bound to the external network adapter, see Types of Physical Network Adapter Configurations.

For more information on NDIS_SWITCH_NIC_INDEX values, see Network Adapter Index Values.

Note The extension cannot generate or forward packets over the network adapter connection until the protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_CONNECT.

OID_SWITCH_NIC_CONNECT
The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_CONNECT to notify extensible switch extensions that an extensible switch network adapter connection is fully operational.

The extension must always forward this OID set request down the extensible switch driver stack. The extension must not fail the request.

After the OID request has completed with NDIS_STATUS_SUCCESS, the network adapter connection and extensible switch port are fully operational. When the network adapter connection is in this state, the extension can do the following:

- Generate or forward packet traffic to the port's network adapter connection.

- Issue extensible switch OIDs or status indications that use the port as the source port.
- Call *ReferenceSwitchNic* to increment a reference counter for the network adapter connection. The extensible switch interface will not tear down a network adapter connection while the reference counter has a nonzero value.

OID_SWITCH_NIC_UPDATED
The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_UPDATED to notify extensible switch extensions that the parameters for an extensible switch network adapter have been updated. The OID will only be issued for NICs that have already been connected, and have not yet begun the disconnect process. These run-time configuration changes can include *NicFriendlyName*, *MTU*, *NetCfgInstanceId*, *PermanentMacAddress*, *VMMacAddress*, *CurrentMacAddress*, and *VFAssigned*.

The extension must always forward this OID set request down the extensible switch driver stack. The extension must not fail the request.

OID_SWITCH_NIC_DISCONNECT
The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_DISCONNECT to notify extensible switch extensions that an extensible switch network adapter connection is being torn down. After the connection has been completely torn down, the protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_DELETE.

The extension must always forward this OID set request down the extensible switch driver stack. The extension must not fail the request.

After the extension forwards this OID request, it can no longer generate or forward packets to the port on which the network adapter connection is being torn down. Also, the extension can no longer call *ReferenceSwitchNic* for the network adapter connection.

OID_SWITCH_NIC_DELETE
The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_DELETE to notify extensible switch extensions that an extensible switch network adapter connection has been torn down and deleted. This OID request is only issued for network connections for which an OID set request of OID_SWITCH_NIC_DISCONNECT was previously issued.

Note The extension must always forward this OID set request down the extensible switch driver stack. The extension must not fail the request.

After this OID request is completed, the protocol edge of the extensible switch issues an OID set request of OID_SWITCH_PORT_TEARDOWN to start the deletion process for the port that was used for the network adapter connection.

The extension must always forward this OID set request down the extensible switch driver stack. The extension must not fail the request.

The extensible switch interface maintains a reference counter for each network adapter connection that has been created. A network adapter connection will not be deleted if its reference counter has a nonzero value. The interface provides the following handler functions for incrementing or decrementing the reference counter of an extensible switch network adapter connection:

ReferenceSwitchNic
The extensible switch extension calls this function to increment a network adapter connection's reference counter. Although the reference counter has a nonzero value, the extensible switch interface does not delete the network adapter connection.

The extension should call *ReferenceSwitchNic* before it performs the following operations:

- Forwards an OID_SWITCH_NIC_REQUEST request down the extensible switch driver stack to an underlying external adapter.

- Forwards an **NDIS_STATUS_SWITCH_NIC_STATUS** status indication up the extensible switch driver stack from an underlying external adapter.

Note The extension must not call *ReferenceSwitchNic* for a network adapter connection after it receives an OID set request of OID_SWITCH_NIC_DISCONNECT for that connection.

DereferenceSwitchNic
The extensible switch extension calls this function to decrement a port's reference counter.

If the extension calls *ReferenceSwitchNic*, it must call *DereferenceSwitchNic* after the OID_SWITCH_NIC_REQUEST or **NDIS_STATUS_SWITCH_NIC_STATUS** indication have completed.

External Network Adapters

Article • 12/15/2021

The external network adapter is exposed in the management operating system that runs in the Hyper-V parent partition. The external network adapter provides the connection to a Hyper-V external network. This network forwards packet traffic over the physical network interface of the host.

The external network is accessed by the Hyper-V parent partition and all child partitions that are connected to the extensible switch. Each instance of the extensible switch supports no more than one external network adapter connection.

The external network adapter is a virtual representation of the underlying physical network adapter on the host. The external network adapter forwards packets, object identifier (OIDs) requests, and NDIS status indications to and from one or more underlying physical network adapters.

Internally, the external network adapter binds to various configurations of underlying physical network adapters. Each of these configurations provides access to the external network interface through one or more physical network adapters. For more information about these physical adapter configurations, see Types of Physical Network Adapter Configurations.

If the extensible switch is configured to provide an external network adapter connection, the following steps occur when the switch is started:

1. The protocol edge of the extensible switch issues an object identifier (OID) set request of OID_SWITCH_PORT_CREATE down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that a port is being created for the external network adapter.

2. The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_CREATE down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that a network connection for the external network adapter is being created for the port that was previously created.

3. The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_CONNECT down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that a network connection for the external network adapter is connected and operational. At this

point, the extension can inspect, inject, and forward packets to the port that is connected to the external network adapter.

The following steps occur when the extensible switch with an external network adapter connection is stopped:

1. The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_DISCONNECT down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that the connection to the external network adapter is being torn down.

2. After all packet traffic and OID requests that target the network connection are completed, the protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_DELETE down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that the connection to the external network adapter has been gracefully torn down and deleted.

3. The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_PORT_TEARDOWN down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that the port that was used for the external network adapter connection is being torn down.

4. The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_PORT_DELETE down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that the port that was used for the external network adapter connection has been torn down and deleted.

Types of Physical Network Adapter Configurations

Article • 12/15/2021

The Hyper-V extensible switch architecture supports the connection to a single external network adapter for access to the underlying physical medium. The external network adapter can be bound to one of the following physical network adapter configurations:

- The external network adapter can be bound to a single underlying physical network adapter. In this configuration, an extensible switch extension is exposed to and manages only one underlying network adapter on the host.

  The following figure shows the extensible switch configuration in which the external network adapter is bound to a single physical network adapter for NDIS 6.40 (Windows Server 2012 R2) and later.

  The following figure shows the extensible switch configuration in which the external network adapter is bound to a single physical network adapter for NDIS 6.30 (Windows Server 2012).

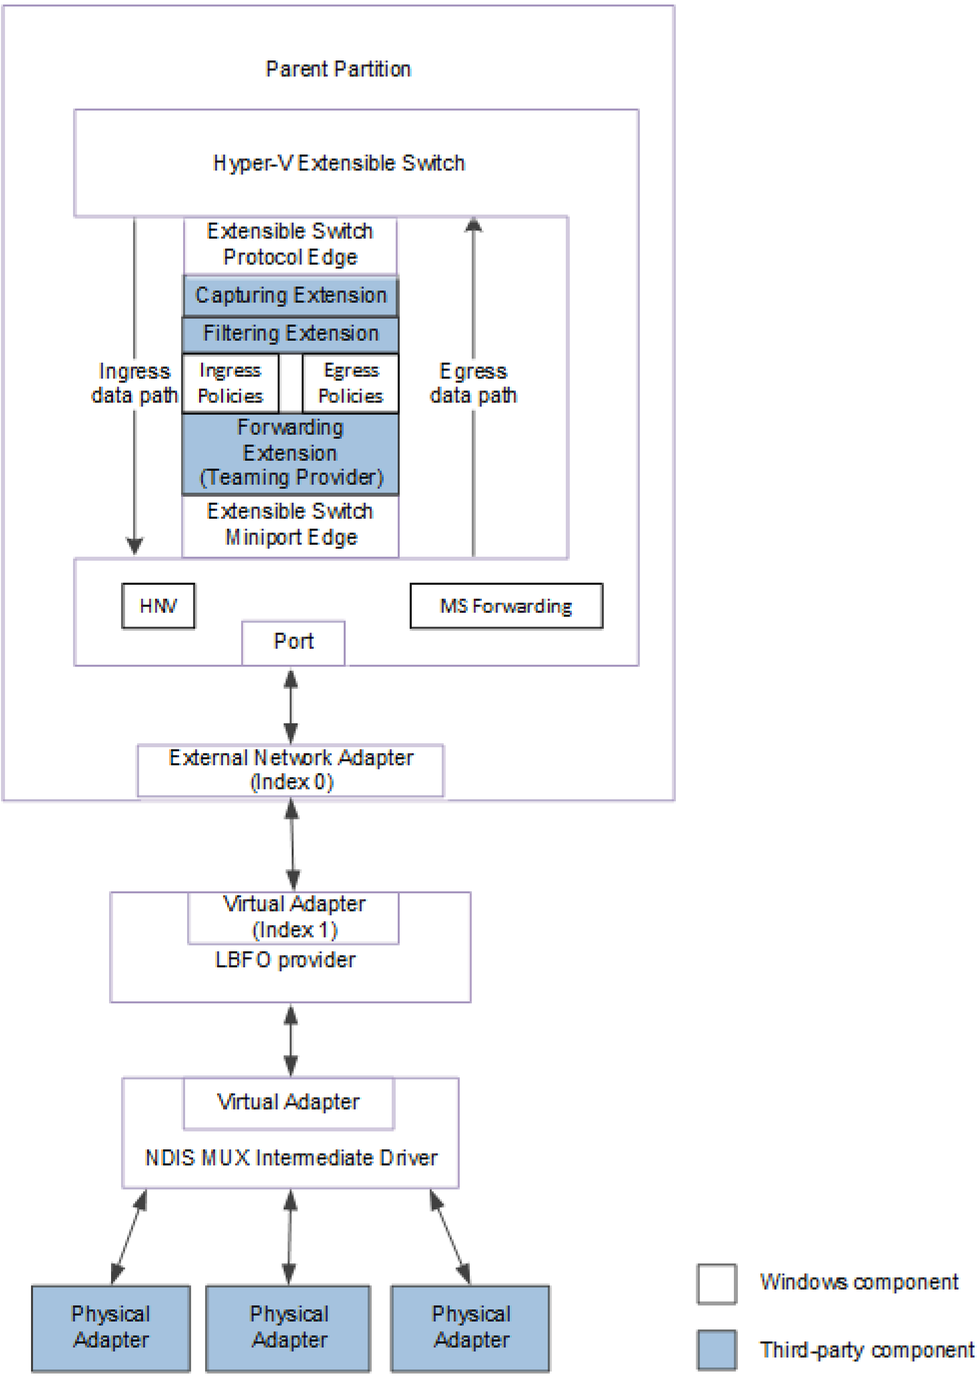
- The external network adapter can be bound to the virtual miniport edge of a load balancing failover (LBFO) provider. This is an NDIS filter driver that is layered above an NDIS multiplexer (MUX) driver, which may be bound to a team of one or more physical networks on the host. This configuration is known as an *LBFO team*.

  In this configuration, the extensible switch extensions are exposed to only the underlying virtual miniport edge as a network adapter. This allows the provider to support an LBFO solution by binding to multiple physical network adapters. These physical network adapters are not managed by a forwarding extension that runs in the extensible switch driver stack.

  The following figure shows an example of an LBFO team configuration for NDIS 6.40 (Windows Server 2012 R2) and later.



The following figure shows an example of an LBFO team configuration for NDIS 6.30 (Windows Server 2012).

Note To extensible switch extensions, an underlying LBFO team appears as a single virtual network adapter that is bound to the external network adapter.

- The external network adapter can be bound to the virtual miniport edge of an NDIS MUX intermediate driver. The MUX driver is bound to a team of one or more physical networks on the host. This configuration is known as an *extensible switch team*.

  In this configuration, an extensible switch extension is exposed to every network adapter in the team. This allows the extension to manage the configuration and use of individual network adapters in the team. For example, the extension can provide support for a load balancing failover (LBFO) solution over the team by forwarding outgoing packets to individual adapters.

  The following figure shows an example of an extensible switch team for NDIS 6.40 (Windows Server 2012 R2) and later.

Internal Network Adapters

Article • 12/15/2021

The internal network adapter is exposed in the management operating system that runs in the Hyper-V parent partition. This type of network adapter provides access to an extensible switch for processes that run in the management operating system. This allows these processes to send or receive packets over the extensible switch.

If the extensible switch is configured to provide an internal network adapter connection, the following steps occur when the switch is started:

1. The protocol edge of the extensible switch issues an object identifier (OID) set request of OID_SWITCH_PORT_CREATE down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that a port is being created for the internal network adapter

2. The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_CREATE down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that a network connection for the internal network adapter is being created for the port that was previously created.

3. The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_CONNECT down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that a network connection for the internal network adapter is connected and operational. At this point, the extension can inspect, inject, and forward packets to the port that is connected to the internal network adapter.

The following steps occur when the extensible switch with an internal network adapter connection is stopped:

1. The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_DISCONNECT down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that the connection to the internal network adapter is being torn down.

2. After all packet traffic and OID requests that target the network connection are completed, the protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_DELETE down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that the connection to the internal network adapter has been gracefully torn down and deleted.

3. The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_PORT_TEARDOWN down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that the port that was used for the internal network adapter connection is being torn down.

4. The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_PORT_DELETE down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that the port that was used for the internal network adapter connection has been torn down and deleted.

Virtual Machine Network Adapters

Article • 12/15/2021

The virtual machine (VM) network adapter is exposed in the guest operating system that runs in the Hyper-V child partition.

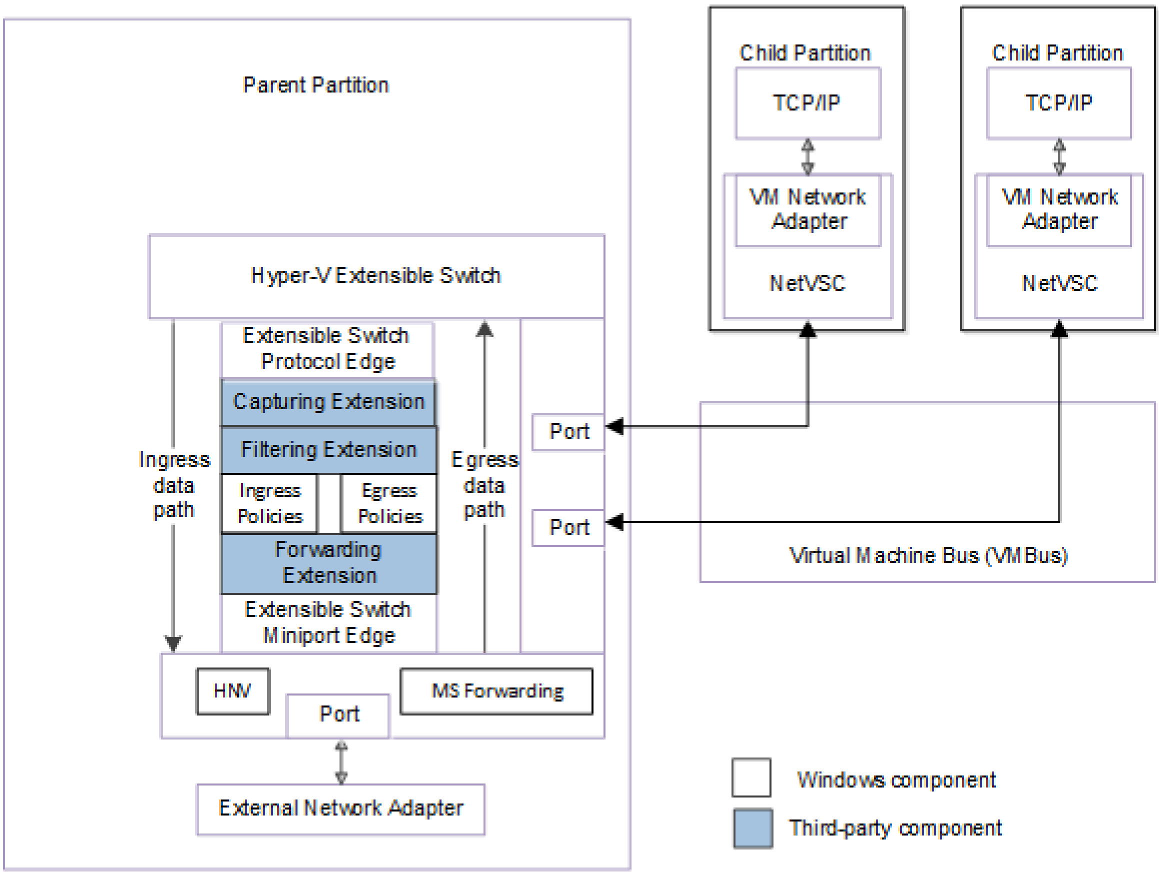
Note In Hyper-V, a child partition is also known as a VM.

The VM network adapter supports the following virtualization types:

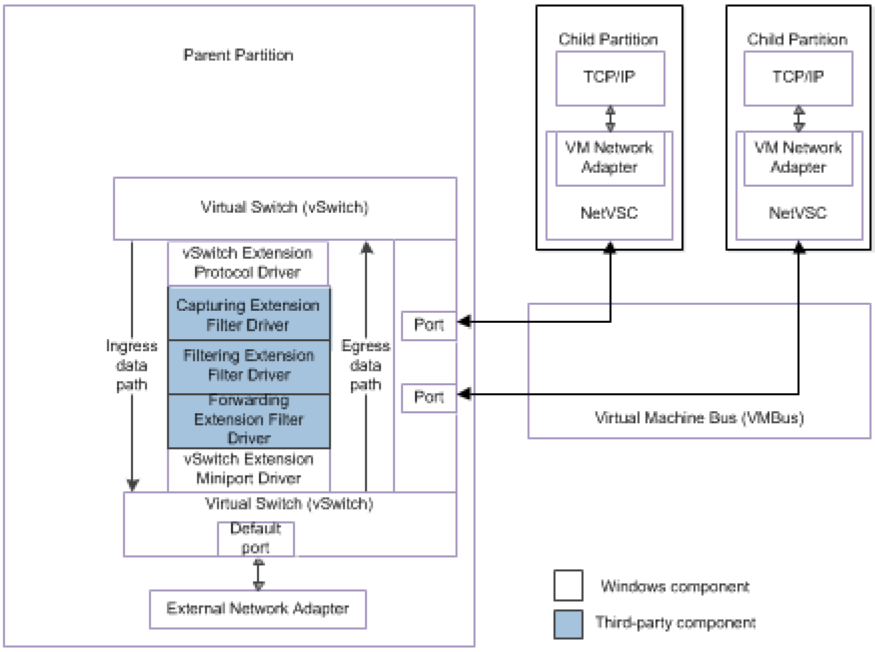
- The VM network adapter could be a synthetic virtualization of a network adapter (*synthetic network adapter*). In this case, the network virtual service client (NetVSC) that runs in the VM exposes this virtual network adapter. NetVSC forwards packets to and from the extensible switch port over the VM bus (VMBus).

- The VM network adapter could be an emulated virtualization of a physical network adapter (*emulated network adapter*). In this case, the VM network adapter mimics an Intel network adapter and uses hardware emulation to forward packets to and from the extensible switch port.

The following figure shows the interface between VM network adapters and the extensible switch NDIS 6.40 (Windows Server 2012 R2) and later.



The following figure shows the interface between VM network adapters and the extensible switch for NDIS 6.30 (Windows Server 2012).



The following steps occur when the user starts a Hyper-V VM:

1. The protocol edge of the extensible switch issues an object identifier (OID) set request of OID_SWITCH_PORT_CREATE down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that a port is being created for the VM.

2. The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_CREATE down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that a network connection for the VM network adapter is being created for the VM port that was previously created.

3. When the networking stacks are operational and have bound to the VM network adapter, the protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_CONNECT down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that a network connection for the VM network adapter is connected and operational. At this point, the extension can inspect, inject, and forward packets to the port that is connected to the VM network adapter.

The following steps occur when the user stops a Hyper-V VM:

1. The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_DISCONNECT down the extensible switch driver stack. This OID

request notifies the underlying extensible switch extensions that the connection to the VM network adapter is being torn down.

2. After all packet traffic and OID requests that target the network connection are completed, the protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_DELETE down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that the connection to the VM network adapter has been gracefully torn down and deleted.

3. The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_PORT_TEARDOWN down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that the port that was used for the VM network adapter connection is being torn down.

4. The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_PORT_DELETE down the extensible switch driver stack. This OID request notifies the underlying extensible switch extensions that the VM port has been torn down and deleted.

Network Adapter Index Values

Article • 12/15/2021

In the Hyper-V extensible switch interface, each network adapter that is connected to a port is assigned an NDIS_SWITCH_NIC_INDEX value. This index value identifies the network connection on an extensible switch port.

The index value is unique for each network adapter connection to a port. Although most network adapters require only one index value, the port connection to the external network adapter may be assigned multiple index values. For example, if the external network adapter is bound to a team of physical network adapters, the external network adapter and each physical network adapter is assigned a unique index value.

The connections to network adapters in the extensible switch are identified through the following NDIS_SWITCH_NIC_INDEX values:

NDIS_SWITCH_DEFAULT_NIC_INDEX
This index value specifies the index for the network adapter that is connected to an extensible switch port. This index value applies to any network adapter that is directly connected to an extensible switch port, such as an external network adapter, internal network adapter, or virtual machine (VM) network adapter.

Note NDIS_SWITCH_DEFAULT_NIC_INDEX is defined to be zero.

1-32
This index value specifies the index for an underlying physical network adapter that is bound to the extensible switch external network adapter. Index values are assigned based on the following configurations:

- If the external network adapter is bound to a single physical network adapter, it is assigned an index value of one.

- If the external network adapter is bound to a load balancing fail over (LBFO) team of physical network adapters, the entire team is assigned an index value of one. An LBFO team is a configuration in which the external network adapter is bound to the virtual miniport edge of an LBFO provider. The LBFO provider itself can bind to a team of one or more physical network adapters.

  Note To extensible switch extensions, an underlying LBFO team appears as a single network adapter that is bound to the external network adapter.

- If the external network adapter is bound to an extensible switch team of physical network adapters, each adapter in the team is assigned a unique index value that is greater than or equal to one. An extensible switch team is a configuration in which a team of one or more physical network adapters is bound to the external network adapter.

For more information about the different configurations in which physical network adapters can be bound to the external network adapter, see Types of Physical Network Adapter Configurations.

Hyper-V Extensible Switch Port and Network Adapter States

Article • 12/15/2021

The Hyper-V extensible switch interface manages the lifetime of the following components:

Hyper-V Extensible Switch Ports
Each network adapter connection to the extensible switch is represented by a port. Ports are created when a Hyper-V child partition is configured to connect to an instance of an extensible switch. Depending on the switch type, ports are also created for the external and internal network adapter connections. For more information about switch types, see Overview of the Hyper-V Extensible Switch.

Each port is used to hold the configuration for the network interface connection. If the configuration for the network interface connection is removed or the child partition is stopped, the port is torn down and deleted.

For more information about this component, see Hyper-V Extensible Switch Ports.

Hyper-V Extensible Switch Network Adapters
These are virtual network adapters that connect to the extensible switch port. These virtual network adapters are exposed within the Hyper-V child and parent partitions. This includes the virtual machine (VM) network adapter exposed in a child partition and the external network adapter that is teamed with the underlying physical network adapter.

Each network adapter connection requires a corresponding extensible switch port. The port must have been created before the network adapter connection is brought up. Similarly, the network adapter connection must be deleted before the port can be torn down and deleted.

Note In some situations, extensible switch ports could be created and deleted without ever having a network adapter connection.

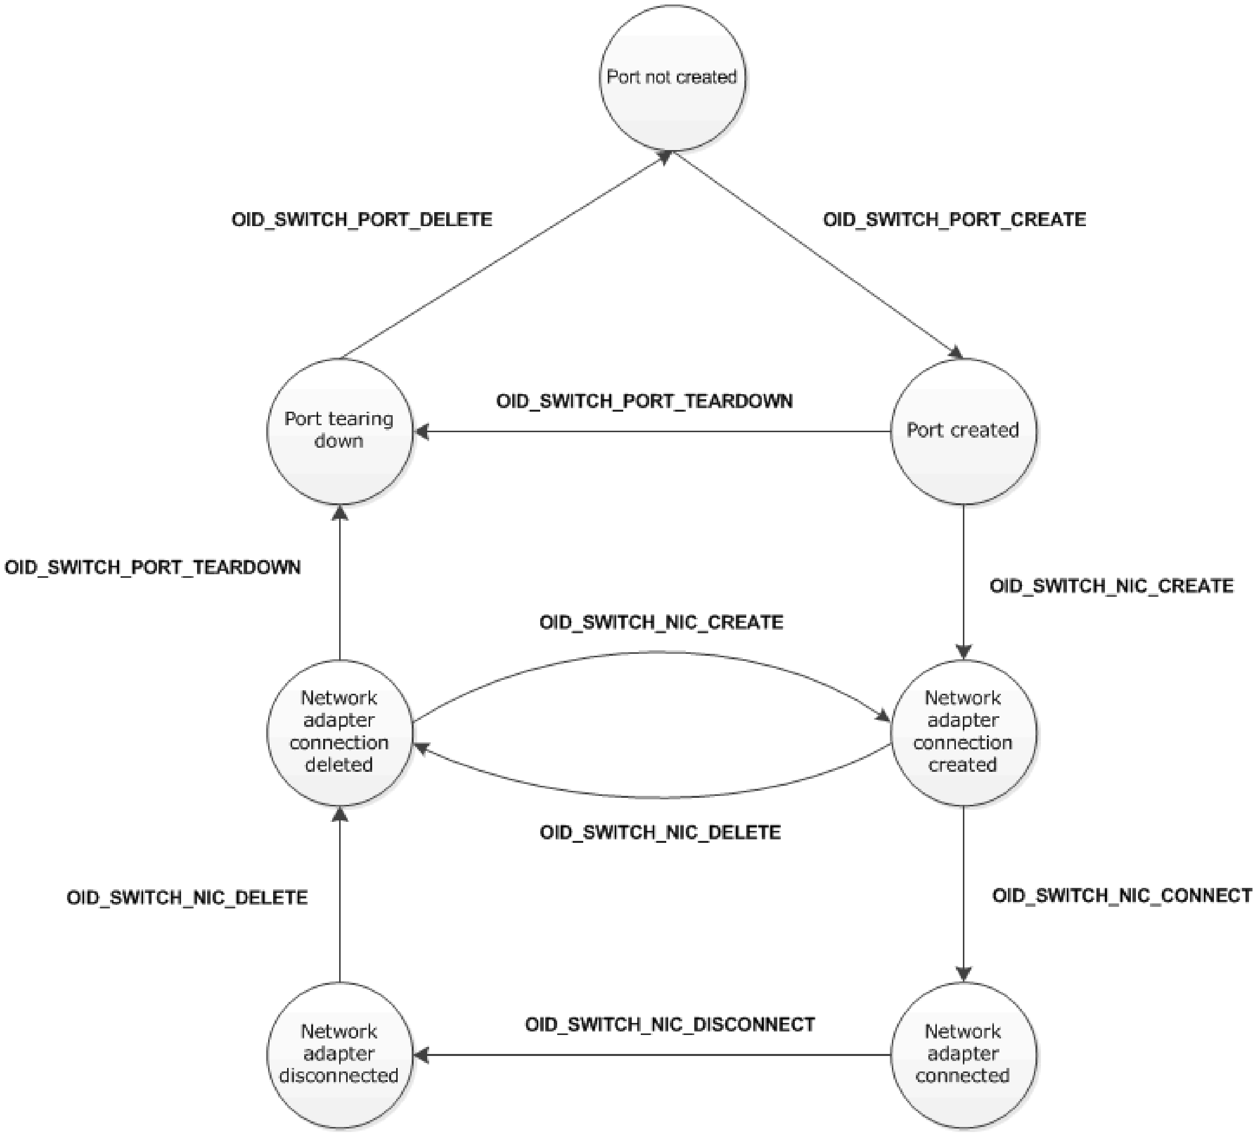
For example, when a Hyper-V child partition is started, the extensible switch interface creates a port before the VM network adapter is exposed within the guest operating system. After the VM network adapter is exposed and enumerated, the extensible switch interface creates a network connection between the VM network adapter and the extensible switch port. If the child partition is stopped, the extensible switch interface first deletes the network connection and then deletes the extensible switch port.

For more information about this component, see Hyper-V Extensible Switch Network Adapters.

When the extensible switch interface creates, deletes, or changes the configuration of these components, it issues object identifier (OID) set requests down the extensible switch driver stack. This operation is performed so that underlying extensible switch extensions can be notified about the state of the component and its configuration. Each OID set request results in a state transition for these components.

When an extension is bound and enabled on an extensible switch instance, it can issue OIDs to discover the existing port and network adapter connection configuration of the switch.

The following diagram shows the various states for the extensible switch port and network adapter connection components. The diagram also shows the OID set requests that cause the state transition for the component.



The following list describes the various states of the extensible switch port and network adapter connection components:

Port not created
In this state, an extensible switch port does not exist on the extensible switch. OID requests that target a previously created port cannot be issued after the port has entered this state.

Port created
When the extensible switch interface issues an OID set request of OID_SWITCH_PORT_CREATE, the port is created on the extensible switch. In this state, the extensible switch interface and extension can issue OID requests that target the port.

For more information about OID traffic through the extensible switch driver stack, see Hyper-V Extensible Switch Control Path.

Note An underlying extension can fail the OID set request and veto the port creation. The extension does this by completing the OID request with STATUS_DATA_NOT_ACCEPTED. If this is done, the port is not created on the extensible switch. For more information on this procedure, see Hyper-V Extensible Switch Ports.

Network adapter connection created
When the extensible switch interface issues an OID set request of OID_SWITCH_NIC_CREATE, the network adapter connection to the port is created on the extensible switch. In this state, the extensible switch interface can do the following:

- Issue OID requests that target the network adapter connection.
- Forward packet traffic to or from the network adapter connection.

It is also possible for a new adapter to connect to an existing port without going through a port teardown and create sequence.

In this state, the extension must forward these packets and OID requests through the extensible switch extension stack. However, the extension cannot originate or redirect packets or OID requests to other network adapter connections on the extensible switch.

Note In this state, the extension must not issue OID requests or originate packet traffic to the network adapter connection.

For more information about OID traffic through the extensible switch driver stack, see Hyper-V Extensible Switch Control Path.

For more information about packet traffic through the extensible switch driver stack, see Hyper-V Extensible Switch Data Path.

Note An underlying extension can fail the OID set request and veto the creation of the network adapter connection. If so, the connection is not created on the extensible switch port. For more information on this procedure, see Hyper-V Extensible Switch Network Adapters.

Network adapter connected
When the extensible switch interface issues an OID set request of OID_SWITCH_NIC_CONNECT, the network adapter is fully connected to the extensible switch port. In this state, the extension can now do the following:

- Issue OID requests that target the network adapter connection.
- Originate packet traffic to the network adapter connection.
- Redirect packet traffic to the network adapter connection. For example, the extension can redirect packets from one network adapter connection to another connection on the extensible switch.

  Note Only forwarding extensions can perform this operation. For more information, see Forwarding Extensions.

Network adapter disconnected
When the extensible switch interface issues an OID set request of OID_SWITCH_NIC_DISCONNECT, the network adapter is being disconnected from the extensible switch port. For example, this OID request is issued when the child partition, which exposed a VM network adapter, is stopped or the external network adapter is disabled.

In this state, the extensible switch extension can no longer originate packets or OID requests that target the connection. Also, forwarding extensions can no longer redirect packets to the connection.

Note Pending packets and OID requests that were issued by the extensible switch interface before the connection became disconnected may still be delivered to the extension. However, the extension must forward the packets and OID requests without making any modifications.

Network adapter connection deleted
After all packet traffic and OID requests that target the network adapter connection are completed, the extensible switch interface issues an OID set request of OID_SWITCH_NIC_DELETE to delete the connection from the extensible switch.

In this state, the extensible switch interface will no longer issue packets or OID requests that target the connection.

Port tearing down
When the extensible switch interface issues an OID set request of

OID_SWITCH_PORT_TEARDOWN, the extensible switch port is being torn down in preparation to being deleted.

In this state, the extensible switch extension can no longer originate OID requests that target the port.

Note Pending OID requests that were issued by the extensible switch interface before the port started its tear down process may still be delivered to the extension. However, the extension must forward the OID requests without making any modifications.

After all pending OID requests that target the port are completed, the extensible switch interface issues an OID set request of OID_SWITCH_PORT_DELETE. This causes the port to transition to a *Port not created* state.

The extension can call an extensible switch handler function to increment or decrement a reference counter on a port or network adapter connection component. While a component's reference counter is nonzero, the extensible switch interface cannot delete the component.

The extension can call *ReferenceSwitchPort* or *DereferenceSwitchPort* to increment or decrement a reference counter for an extensible switch port. These calls can be made after the port has reached the *Port created* state. These calls must not be made after the port has reached the *Port tearing down* or *Port not created* states.

The extension can call *ReferenceSwitchNic* or *DereferenceSwitchNic* to increment or decrement a reference counter for an extensible switch network adapter connection. These calls can be made after the connection has reached the *Network adapter connected* state. These calls must not be made after the connection has reached the *Network adapter disconnected* or *Network adapter deleted* states.

The following table describes the operations that are allowed based on the state of the extensible switch port or network adapter connection components.

Component state	Calls to *ReferenceSwitchPort* or *DereferenceSwitchPort* allowed?	Calls to *ReferenceSwitchNic* or *DereferenceSwitchNic* allowed?
Port not created	No	No
Port created	Yes	No
Network adapter connection created	Yes	No
Network adapter connected	Yes	Yes

Component state	Calls to *ReferenceSwitchPort* or *DereferenceSwitchPort* allowed?	Calls to *ReferenceSwitchNic* or *DereferenceSwitchNic* allowed?
Network adapter disconnected	Yes	No
Network adapter connection deleted	Yes	No
Port tearing down	No	No

Component state	OID requests from extensible switch allowed for port?	OID requests from extensions allowed for port?	OID requests from extensible switch allowed for network adapter connection?	OID requests from extensions allowed for network adapter connection?	Packet traffic from extensible switch allowed over network adapter connection?	Packet traffic from extensions allowed over network adapter connection?
Port not created	No	No	No	No	No	No
Port created	Yes	Yes	No	No	No	No
Network adapter connection created	Yes	Yes	Yes	No	Yes	No
Network adapter connected	Yes	Yes	Yes	Yes	Yes	Yes
Network adapter disconnected	Yes	Yes	Yes	No	Yes	No
Network adapter connection deleted	Yes	Yes	No	No	No	No
Port tearing down	Yes	No	No	No	No	No

Hyper-V Extensible Switch Data Path Topics

Article • 12/15/2021

This section discusses the Hyper-V extensible switch data path that packets move across. This section includes the following topics:

Overview of the Hyper-V Extensible Switch Data Path

Hyper-V Extensible Switch Forwarding Context

Hyper-V Extensible Switch Send and Receive Flags

Overview of the Hyper-V Extensible Switch Data Path

Article • 12/15/2021

This section describes the Hyper-V extensible switch data path over which packets move to or from extensible switch ports. It includes the following topics:

Packet Flow through the Extensible Switch Data Path

Packet Management Guidelines for the Extensible Switch Data Path

Packet Flow through the Extensible Switch Data Path

Article • 12/15/2021

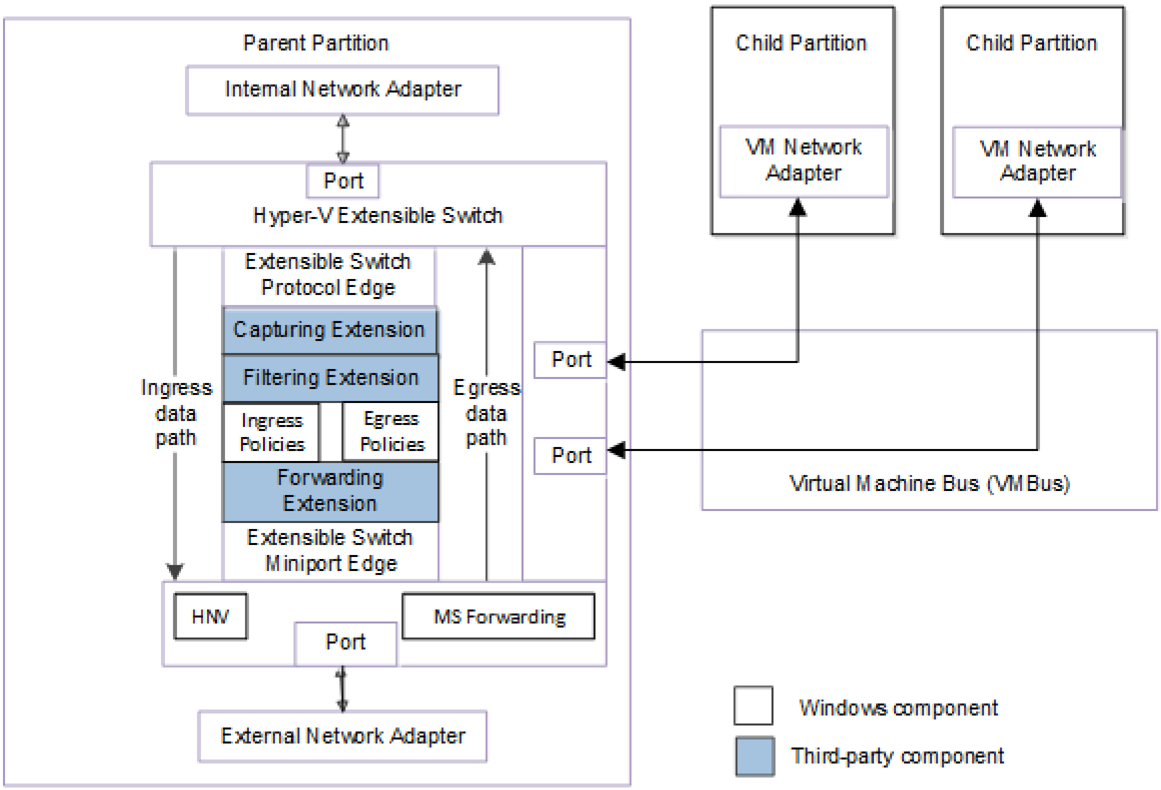
This topic describes how packets move to or from extensible switch ports through the Hyper-V extensible switch data path.

Note In the extensible switch interface, NDIS filter drivers are known as *extensible switch extensions* and the driver stack is known as the *extensible switch driver stack*. For more information about the extensions, see Hyper-V Extensible Switch Extensions.

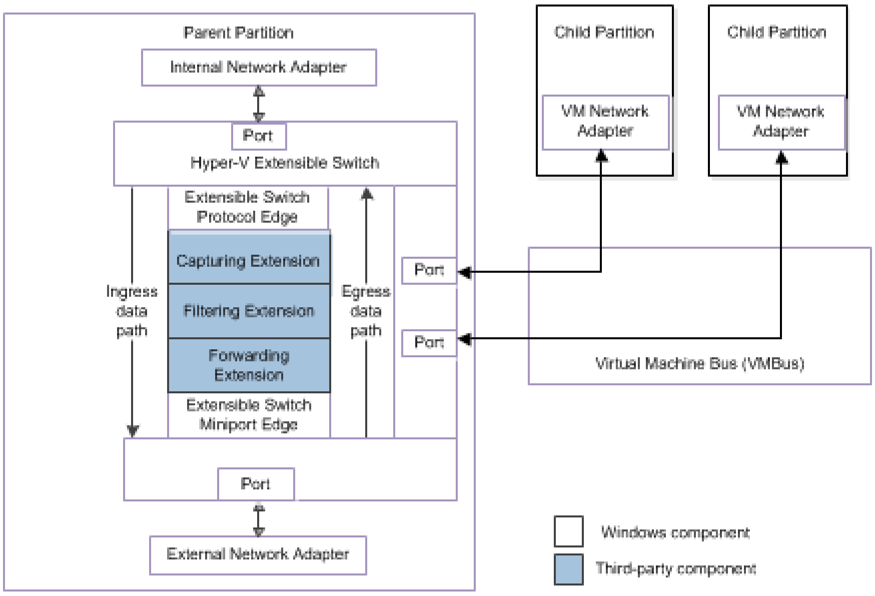
Note This page assumes that you are familiar with the information in Overview of the Hyper-V Extensible Switch and Hybrid Forwarding.

All packet traffic that arrives at the extensible switch from its ports follows the same path through the extensible switch driver stack. For example, packet traffic received from the external network adapter connection or sent from a virtual machine (VM) network adapter connection moves through the same data path.

The following figure shows the extensible switch data path for NDIS 6.40 (Windows Server 2012 R2) and later.



The following figure shows the extensible switch data path for NDIS 6.30 (Windows Server 2012).



For more information about the components for the extensible switch interface, see Hyper-V Extensible Switch Architecture.

The extensible switch data path has the following parts, listed in the order that packets flow through them:

- Overlying protocol edge
- Ingress data path
- Underlying miniport edge
- Egress data path

Overlying protocol edge

1. Packets arrive at the extensible switch from network adapters that are connected to the switch ports. These packets are first issued as send requests from the protocol edge of the extensible switch down the extensible switch ingress data path.

   The protocol edge of the extensible switch prepares the packets for the ingress data path. The protocol edge allocates a context area for these packets that contains the out-of-band (OOB) extensible switch forwarding context. It populates the OOB data with information about the source port and network adapter connection from which the packet was delivered to the extensible switch.

   For more information about the forwarding context, see Hyper-V Extensible Switch Forwarding Context.

2. In NDIS 6.40 (Windows Server 2012 R2) and later, if the packet is an NVGRE packet from an external network adapter, the extensible switch sets the

NativeForwardingRequired flag in the packet's out-of-band (OOB) information. For more information, see Hybrid Forwarding.

3. If the packet arrived on a port where the traffic has a virtual subnet, the extensible switch sets the **VirtualSubnetId** member of the **NDIS_NET_BUFFER_LIST_VIRTUAL_SUBNET_INFO** structure for the packet.

   Note The virtual subnet could be an HNV subnet or a third-party virtual subnet.

Ingress data path

1. An extension obtains a packet from the ingress data path when its *FilterSendNetBufferLists* function is called. The extension forwards the packet to underlying extensions on the ingress data path by calling **NdisFSendNetBufferLists**. Filtering and forwarding extensions can also drop the packet from the ingress data path by calling **NdisFSendNetBufferListsComplete**.

2. When capturing extensions obtain packets on the ingress data path, they can inspect the packet data. However, capturing extensions must not complete the send requests for packets on the ingress data path. These extensions must always forward the packets to underlying extensions in the extensible switch driver stack.

   A capturing extension can also originate packets on the ingress data path. For example, the extension may originate packets in order to report traffic conditions to a remote monitoring application.

   For more information on originating packets by an extension, see Originating Packet Traffic.

3. When filtering extensions obtain packets on the ingress data path, they can do the following:

   - Drop packets based on custom extensible switch or port policies.

     For more information about these policies, see Hyper-V Extensible Switch Policies.

     Note Packets obtained on the ingress data path do not have destination ports defined in the packet's OOB data. As a result, filtering extensions must only enforce custom policies based on the packet data or the packet's source port or network adapter connection.

- Clone or modify packets obtained from the ingress data path.

- Inject new packets into the ingress data path.

4. In NDIS 6.40 and later, after the capturing and filtering extensions but before the forwarding extension on the ingress data path, the extensible switch does the following:

    - If the packet is an NVGRE packet from an external network adapter, the address in the packet header is a provider address (PA) space address. The extensible switch indicates this by setting the **NativeForwardingRequired** flag in the packet's out-of-band (OOB) information. For more information, see Hybrid Forwarding.

    - The extensible switch applies the built-in ingress policies to the packet. These policies may include ingress access control lists (ACLs), DHCP Guard, and Router Guard.

5. If a forwarding extension is not enabled in the extensible switch driver stack, the destination port array for a packet is determined by the extensible switch.

6. If a forwarding extension is enabled, it must do the following when it obtains packets on the ingress data path:

    - In NDIS 6.40 and later, if the packet is an NVGRE packet (see Hybrid Forwarding), the forwarding extension cannot modify the destination port array in the OOB data of the packet in the ingress data path. However, it can drop the packet.

    - If the packet is not an NVGRE packet, the forwarding extension must add destination ports to the destination port array in the OOB data of the packet.

    - The forwarding extension must drop packets based on standard or custom extensible switch or port policies. Standard switch or port policies include security and virtual LAN (VLAN) properties. If a forwarding extension is not enabled in the extensible switch driver stack, these policies are enforced by the extensible switch.

      Note When the forwarding extension filters packets in the ingress data path, it applies filtering rules based on the source port as well as the destination ports that the extension assigns to the packet.

In addition, the forwarding extension can do the following:

- Clone or modify packets obtained from the ingress data path.

- Inject new packets into the ingress data path.

Underlying miniport edge

1. When the packet arrives at the underlying miniport edge of the extensible switch, the extensible switch applies its built-in policies to the packet. These policies include access control lists (ACLs) and quality of service (QoS) properties. If the packet is not dropped because of these policies, the extensible switch originates a receive indication for the packet and forwards the packet up the egress data path.

   Note If port mirroring is enabled on a port that the packet is to be delivered to, the miniport edge adds a destination port to the packet's OOB data for the mirror port. The miniport edge does this regardless of whether a forwarding extension is installed and enabled in the extensible switch driver stack. The miniport edge only adds the mirror port if it is not already specified in the array of destination ports for the packet.

2. If a forwarding extension is not enabled, the extensible switch determines the destination ports for the packet and add these destination ports to the packet's OOB data before it forwards the packet up the egress data path.

3. In NDIS 6.40 and later, the HNV component performs any needed NVGRE encapsulation or decapsulation after ingress and before egress, so that the forwarding extension can see the packet in encapsulated and decapsulated form. For example, if the packet arrived from an external network adapter and is destined for an internal VM, the forwarding extension obtains the encapsulated packet on ingress and the decapsulated packet on egress.

   Note In the encapsulated packet, the address in the packet header is a provider address (PA) space address. In the decapsulated packet, it is a customer address (CA) space address.

   a. If the packet is an NVGRE packet that arrived from an external network adapter, the Hyper-V Network Virtualization (HNV) component of the extensible switch performs NVGRE decapsulation on the packet. The HNV component determines the destinations for the packet according to HNV policies, and then the extensible switch forwards the packet up the egress data path.

   b. If the packet arrived from an internal VM, the HNV component will perform NVGRE encapsulation on the packet if HNV policies are set for the packet. The HNV component determines the destinations for the packet according to HNV policies, and then the extensible switch forwards the packet up the egress data path.

   c. Otherwise, the forwarding extension forwards the packet up the egress data path.

4. In NDIS 6.30, if a forwarding extension is enabled, it must forward the packet up the egress data path.

Egress data path

1. An extension obtains a packet from the egress data path when its *FilterReceiveNetBufferLists* function is called. The extension forwards the packet to overlying extensions on the egress data path by calling **NdisFIndicateReceiveNetBufferLists**. Filtering and forwarding extensions can also drop the packet from the egress data path by calling **NdisFReturnNetBufferLists**.

2. When the forwarding extension obtains a packet on the egress data path, it can inspect the packet's destination port information in the OOB data.

   Note The extension obtains this information from the OOB data by calling *GetNetBufferListDestinations*.

Based on standard or custom switch or port policies, the extension can exclude the delivery of the packet to one or more destination ports that are contained within the OOB data.

3. In NDIS 6.40 (Windows Server 2012 R2) and later, after the forwarding extension but before the filtering and capturing extensions on the egress data path, the extensible switch applies the built-in egress policies to the packet. These policies may include trunk mode, monitoring mode, egress ACLs, and quality of service (QoS) properties.

4. When filtering extensions obtain a packet on the egress data path, they can inspect the packet's destination port information in the OOB data. Based on custom switch or port policies, the extension can exclude the delivery of the packet to one or more destination ports that are contained within the OOB data.

   If the filtering extension needs to modify the data in a packet, it must first clone the packet without preserving port destinations. Then, the extension must inject the modified packet into the ingress data path. This allows the underlying extensions to enforce policies on the modified packet and the forwarding extension can add port destinations.

   For more information, see Cloning or Packet Traffic.

5. When capturing extensions obtain packets on the egress data path, they can inspect the packet data. However, if the capturing extension needs to originate packets in order to report traffic conditions to a remote monitoring application, it must originate this packet traffic by calling **NdisFSendNetBufferLists** to initiate a send operation on the ingress data path.

6. When the packet arrives at the overlying protocol edge of the extensible switch, the extensible switch interface forwards the packet to all specified destination ports.

7. Once the packet has been forwarded, the interface completes the packet through the same path in reverse. First, the interface calls the extension's *FilterReturnNetBufferLists* function to complete packets forwarded on the egress data path. Then, the interface calls the extension's *FilterSendNetBufferListsComplete* function to complete packets forwarded on the ingress data path.

   When the packet is completed on both the egress and ingress data path, the extension performs any necessary packet cleanup and post-processing that may be required.

Packet Management Guidelines for the Extensible Switch Data Path

Article • 12/15/2021

This topic describes the guidelines that Hyper-V extensible switch extensions must follow for managing packets obtained on the extensible switch data path.

Note In the extensible switch interface, NDIS filter drivers are known as *extensible switch extensions* and the driver stack is known as the *extensible switch driver stack*. For more information about the extensions, see Hyper-V Extensible Switch Extensions.

Note This page assumes that you are familiar with the information and diagrams in Overview of the Hyper-V Extensible Switch and Hybrid Forwarding.

Extensions must follow these guidelines for packet management in the extensible switch data path:

- Extensions that originate packets must call **NdisFSendNetBufferLists** to initiate a send request on the ingress data path. This must be done in this way to allow for proper forwarding of the packet through the extensible switch.

- A capturing extension can monitor packets on the extensible switch ingress and egress data path. However, this type of extension must always forward packets and must not drop the packets. Also, the capturing extension must not modify the packet data before it forwards the packet.

- On the extensible switch ingress data path, filtering and forwarding extensions can do the following:

  - Filtering extensions can filter packet traffic and enforce only custom port or switch policies for packet delivery through the extensible switch. When the extension filters packets in the ingress data path, it can only apply filtering rules based only on the source port and network adapter connection from which the packet originated. This information is stored in the OOB data of a packet's NET_BUFFER_LIST structure and can be obtained by using the NET_BUFFER_LIST_SWITCH_FORWARDING_DETAIL macro.

    Note Packets obtained on the ingress data path do not contain destination ports. Filtering packets based on destination ports can only be done on packets obtained on the egress data path.

  - Forwarding extensions can filter packet traffic and enforce custom and standard port or switch policies for packet delivery through the extensible switch. When the forwarding extension filters packets in the ingress data path, it applies filtering rules based on the source port as well as the destination ports that the forwarding extension assigns to the packet.

- On the extensible switch egress data path, filtering and forwarding extensions can do the following:

  - Filtering extensions can filter packet traffic and enforce only custom port or switch policies for packet delivery through the extensible switch. When the filtering extension filters packets in the egress data path, it can apply filtering rules based only on the destination ports for a packet.

    Destination port data is stored in the OOB data of a packet's **NET_BUFFER_LIST** structure. Extensions obtain this information by calling the *GetNetBufferListDestinations* function.

  - Forwarding extensions can filter packet traffic and enforce custom and standard port or switch policies for packet delivery through the extensible switch. When the forwarding extension filters packets in the egress data path, it can apply filtering rules based on the source or destination ports for a packet.

  - Based on the policies enforced on a packet, the filtering or forwarding extension can exclude the delivery of the packet to one or more destinations. For more information on this procedure, see Excluding Packet Delivery to Extensible Switch Destination Ports.

    Based on the policies enforced on a packet, the forwarding extension can exclude the delivery of the packet to one or more destinations. For more information, see Hybrid Forwarding.

- On the extensible switch egress data path, filtering and forwarding extensions must not do the following:

  - Modify the packet data before forwarding the packet on the egress data path.

    If a filtering extension needs to modify the data in a packet, it must first clone the packet without preserving port destinations. Then, the extension must inject the modified packet into the ingress data path. This allows the underlying extensions to enforce policies on the modified packet and the forwarding extension can add port destinations.

If the forwarding extension needs to modify the data in a packet, it must first clone the packet before it assigns port destinations. After the packet has been modified and port destinations assigned, the extension must inject the modified packet into the ingress data path.

For more information, see Cloning Packet Traffic.

Note If the extension clones a packet that was obtained on the egress data path, it can inject the new packet into the egress data path only if it has not changed the packet data and has preserved the original destination port data.

  - Add destination ports to the packet before forwarding the packet.

    Note Forwarding extensions are allowed to add destination ports to packets obtained on the ingress data path.

  - Inject new or cloned data packets into the egress data path.

- In the standard NDIS data path, non-extensible switch OOB data often has different formats depending on whether the packet is being indicated as a send or a receive. For example, the **NDIS_IPSEC_OFFLOAD_V2_HEADER_NET_BUFFER_LIST_INFO** OOB data is a union of send-and receive–specific structures.

  In the extensible switch data path, all packets move through the extension driver stack as both sends and receives. Because of this, the non-extensible switch OOB data within the packet's **NET_BUFFER_LIST** structure will be in either a send or receive format through the duration of the flow through the driver stack.

  The format of this OOB data depends upon the source extensible switch port from which the packet arrived at the extensible switch. If the source port is connected to the external network adapter, the non-extensible switch OOB data will be in a receive format. For other ports, this OOB data will be in a send format.

  Note If the extension clones a packet's **NET_BUFFER_LIST** structure, it must take the non-extensible switch OOB data into consideration if it adds or modifies the OOB data. The extension must call *CopyNetBufferListInfo* to copy the OOB data associated with the extensible switch data path from a source packet to a cloned packet. This function will maintain the OOB send or receive format when the data is copied to the cloned packet.

- If an extension drops a packet from either the ingress of egress data path, it must call *ReportFilteredNetBufferLists*. When this function is called, the extensible switch interface increments counters and logs events for the dropped or excluded packets.

Hyper-V Extensible Switch Forwarding Context Overview

Article • 12/15/2021

The **NET_BUFFER_LIST** structure for each packet that traverses the Hyper-V extensible switch data path contains out-of-band (OOB) data. This data specifies the source port from where the packet originated, as well as one or more destination ports for packet delivery. This OOB data is known as the *extensible switch forwarding context*.

This section includes the following topics about the extensible switch forwarding context:

Hyper-V Extensible Switch Forwarding Context Data Types

Managing the Hyper-V Extensible Switch Forwarding Context

Hyper-V Extensible Switch Forwarding Context Data Types

Article • 12/15/2021

The NET_BUFFER_LIST structure for each packet that traverses the Hyper-V extensible switch data path contains out-of-band (OOB) data. This data specifies the source port from where the packet originated, as well as one or more destination ports for packet delivery. This OOB data is known as the *extensible switch forwarding context*.

The following data types have been declared to access the extensible switch forwarding context within a packet's NET_BUFFER_LIST structure:

NDIS_SWITCH_FORWARDING_DETAIL_NET_BUFFER_LIST_INFO
This is a 64-bit union that contains the forwarding characteristics of a packet. This data includes the identifiers for the source port and network adapter connection from which the packet originated. This data also includes the number of unused elements that are available in the destination port array.

The extensible switch extension can access this data by using the NET_BUFFER_LIST_SWITCH_FORWARDING_DETAIL macro.

NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY
This structure defines the destination port array for the packet. Each element in this array is formatted as an NDIS_SWITCH_PORT_DESTINATION structure.

The NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY structure contains members that specify the current number of the total number of elements as well as the number of used elements in the array.

The extensible switch extension can obtain this array by calling the *GetNetBufferListDestinations* function. If the driver adds or modifies elements in the array for a packet with multiple destination ports, it must call the *UpdateNetBufferListDestinations* function. This function commits those changes to the destination port array in the packet's forwarding context.

Note To commit changes to a packet with only one destination port, it is more efficient for the driver to call the *AddNetBufferListDestination* function.

NDIS_SWITCH_PORT_DESTINATION
This structure defines a destination port for the packet. For packets with a single destination port, there is only one NDIS_SWITCH_PORT_DESTINATION element in the

destination port array. For packets with multiple destination ports, there are one or more of these elements in the array.

After the extensible switch extension has called *GetNetBufferListDestinations* to obtain the packet's destination port array, it can access individual elements in the array by using the **NDIS_SWITCH_PORT_DESTINATION_AT_ARRAY_INDEX** macro.

Managing the Hyper-V Extensible Switch Forwarding Context

Article • 12/15/2021

Note This page assumes that you are familiar with the information and diagrams in Overview of the Hyper-V Extensible Switch and Hybrid Forwarding.

The **NET_BUFFER_LIST** structure for each packet that traverses the Hyper-V extensible switch data path contains out-of-band (OOB) data. This data specifies the source port from where the packet originated, as well as one or more destination ports for packet delivery. This OOB data is known as the *extensible switch forwarding context*.

Note The extensible switch forwarding context is different from the **NET_BUFFER_LIST_CONTEXT** structure. This allows extensions to allocate their own context structures without affecting the forwarding context.

The extensible switch forwarding context is allocated and freed in the following way:

- When a packet arrives at the extensible switch from a network adapter, the extensible switch interface allocates the forwarding context and associates it with the packet's **NET_BUFFER_LIST** structure.

  When the packet is delivered to its destination ports, the interface frees the forwarding context from the packet's **NET_BUFFER_LIST** structure.

- If an extensible switch extension injects a new or cloned packet into the extensible switch data path, it must allocate the forwarding context before it calls **NdisFSendNetBufferLists**.

  After the extension allocates a **NET_BUFFER_LIST** structure for a new or cloned packet, it must call the *AllocateNetBufferListForwardingContext* function to allocate the forwarding context for the packet. When the send packet request is completed, the extension must call *FreeNetBufferListForwardingContext* before it frees or reuses the **NET_BUFFER_LIST** structure.

  Note When the extension calls *AllocateNetBufferListForwardingContext*, the source port for the packet is set to **NDIS_SWITCH_DEFAULT_PORT_ID**. This specifies that the packet originated from an extension instead of arriving at an extensible switch port. Under certain conditions, the extension may want to change the source port for the packet. For more information, see Modifying a Packet's Extensible Switch Source Port Data.

For more information, see Hyper-V Extensible Switch Send and Receive Operations.

All extensible switch extensions can call the following extensible switch handler functions to access the data within the packet's forwarding context:

AllocateNetBufferListForwardingContext
Allocates the extensible switch forwarding context and prepares a **NET_BUFFER_LIST** structure for send or receive operations within the extensible switch.

CopyNetBufferListInfo
Copies the forwarding context from a source packet's **NET_BUFFER_LIST** structure to a destination packet's **NET_BUFFER_LIST** structure. This data includes the extensible switch source port and network adapter information. The extensible switch destination port information can also be copied to the destination packet.

FreeNetBufferListForwardingContext
Frees the resources in the extensible switch forwarding context of a **NET_BUFFER_LIST** structure. This data was used for send or receive operations in a Hyper-V extensible switch, and was previously allocated by calling the *AllocateNetBufferListForwardingContext* function.

GetNetBufferListDestinations
Returns the destination ports from the forwarding context of a packet's **NET_BUFFER_LIST** structure.

A forwarding extension is responsible for adding destination ports for a packet, unless the packet is an NVGRE packet. (For more information, see Hybrid Forwarding.) The extension calls the following extensible switch handler functions to add or update the destination ports within the packet's forwarding context:

AddNetBufferListDestination
Adds a single destination to the extensible switch forwarding context area for a packet that is specified by a **NET_BUFFER_LIST** structure.

Note This call commits the change to the forwarding context area. In this case, the forwarding extension does not need to call *UpdateNetBufferListDestinations*.

GrowNetBufferListDestinations
Increases the size of the destination port array in the forwarding context area of a packet's **NET_BUFFER_LIST** structure.

UpdateNetBufferListDestinations
Commits modifications that the extension made to one or more extensible switch

destination ports of a packet. This function updates the forwarding context of a packet's **NET_BUFFER_LIST** structure with these changes.

Note After the forwarding extension commits the changes for destination ports to the forwarding context, destination ports cannot be removed and only the **IsExcluded** member of a destination port's **NDIS_SWITCH_PORT_DESTINATION** structure can be changed. For more information, see Excluding Packet Delivery to Extensible Switch Destination Ports.

Hyper-V Extensible Switch Forwarding Context

Hyper-V Extensible Switch Forwarding Context Data Types

Hyper-V Extensible Switch Send and Receive Flags

Article • 12/15/2021

Note This page assumes that you are familiar with the information and diagrams in Overview of the Hyper-V Extensible Switch and Hybrid Forwarding.

Packet traffic that moves over the Hyper-V extensible switch data path is obtained by extensions in the following way:

- An extension obtains a packet from the ingress data path when its *FilterSendNetBufferLists* function is called. The extension forwards the packet to underlying extensions on the ingress data path by calling **NdisFSendNetBufferLists**. Filtering and forwarding extensions can also drop the packet from the ingress data path by calling **NdisFSendNetBufferListsComplete**.

- An extension obtains a packet from the egress data path when its *FilterReceiveNetBufferLists* function is called. The extension forwards the packet to overlying extensions on the egress data path by calling **NdisFIndicateReceiveNetBufferLists**. Filtering and forwarding extensions can also drop the packet from the egress data path by calling **NdisFReturnNetBufferLists**.

The following flags may be set in the *SendFlags* parameter of *FilterSendNetBufferLists* or **NdisFSendNetBufferLists**:

NDIS_SEND_FLAGS_SWITCH_SINGLE_SOURCE
If this flag is set, all packets in a linked list of **NET_BUFFER_LIST** structures originated from the same Hyper-V extensible switch source port.

When NDIS calls *FilterSendNetBufferLists*, it will set this flag if the extensible switch extensible interface has grouped multiple packets from the same source port. For the best performance, the extensions should keep this grouping in place and set this flag when it calls **NdisFSendNetBufferLists**. The extension can also add any originated or cloned packets to the linked list of **NET_BUFFER_LIST** structures if the extension uses the same source port as the other packets in the list.

Note If each packet in the linked list of **NET_BUFFER_LIST** structures uses the same source port, the extension should set the **NDIS_SEND_COMPLETE_FLAGS_SWITCH_SINGLE_SOURCE** flag in the *SendCompleteFlags* parameter of **NdisFSendNetBufferListsComplete** when it completes the send request.

NDIS_SEND_FLAGS_SWITCH_DESTINATION_GROUP
If this flag is set, all packets in a linked list of **NET_BUFFER_LIST** structures are to be forwarded to the same extensible switch destination port.

A forwarding extension can use this flag for a linked list of **NET_BUFFER_LIST** structures that it forwards on the ingress data path after it determines each packet's destination ports. This flag is consumed and removed by the underlying miniport edge of the extensible switch before it forwards the packets up the egress data path.

Capturing and filtering extensions cannot use this flag.

Note The forwarding extension only determines the packet's destination ports for non-NVGRE packets. If the packet is an NVGRE packet, the Hyper-V Network Virtualization (HNV) component determines the packet's destination ports and forwards the packet. For more information, see Hybrid Forwarding.

For the best performance, forwarding extensions should set this flag if all packets in the linked list are to be forwarded to the same destination port. By setting this flag, the extension is acknowledging that all packets in the linked list have the same destination port elements in the extensible switch forwarding context.

Note The forwarding extension must not set this flag for a linked list of packets that have multiple destination ports.

The following flags may be set in the *ReceiveFlags* parameter of *FilterReceiveNetBufferLists* or **NdisFIndicateReceiveNetBufferLists**:

NDIS_RECEIVE_FLAGS_SWITCH_SINGLE_SOURCE
If this flag is set, all packets in a linked list of **NET_BUFFER_LIST** structures originated from the same Hyper-V extensible switch source port.

When NDIS calls *FilterReceiveNetBufferLists*, it will set this flag if the extensible switch has grouped multiple packets from the same source port. For the best performance, the extensions should keep this grouping in place and set this flag when it calls **NdisMIndicateReceiveNetBufferLists**. The extensions should also add any originated or cloned packets to the linked list of **NET_BUFFER_LIST** structures if the packet has the same source port as the other packets in the list.

Note If each packet in the linked list of **NET_BUFFER_LIST** structures use the same source port, the extension should set the **NDIS_RETURN_FLAGS_SWITCH_SINGLE_SOURCE** flag in the *ReturnFlags* parameter of *FilterReturnNetBufferLists* when the receive request completes. The extension must set this flag in the *ReturnFlags* parameter if it calls **NdisFReturnNetBufferLists** to return packets that it did not originate or clone.

NDIS_RECEIVE_FLAGS_SWITCH_DESTINATION_GROUP
If this flag is set, all packets in a linked list of **NET_BUFFER_LIST** structures are to be forwarded to the same extensible switch destination port.

When NDIS calls *FilterReceiveNetBufferLists*, it will set this flag if the extensible switch has grouped multiple packets that have the same destination ports. For the best performance, the extensions should keep this grouping in place and set this flag when it calls **NdisMIndicateReceiveNetBufferLists**. The extensions should also add any originated or cloned packets to the linked list of **NET_BUFFER_LIST** structures if the packet has the same destination ports as the other packets in the list.

Note When an extension calls **NdisFIndicateReceiveNetBufferLists**, it must not set the **NDIS_RECEIVE_FLAGS_RESOURCES** flag in the *ReceiveFlags* parameter. The extensible switch interface ignores this flag and will complete the receive indication by calling *FilterReturnNetBufferLists*.

Hyper-V Extensible Switch Control Path Topics

Article • 12/15/2021

This section discusses the control path that Hyper-V extensible switch object identifier (OID) requests and NDIS status indications move across.

This section includes the following topics:

Hyper-V Extensible Switch Control Path for OID Requests

Hyper-V Extensible Switch Control Path for NDIS Status Indications

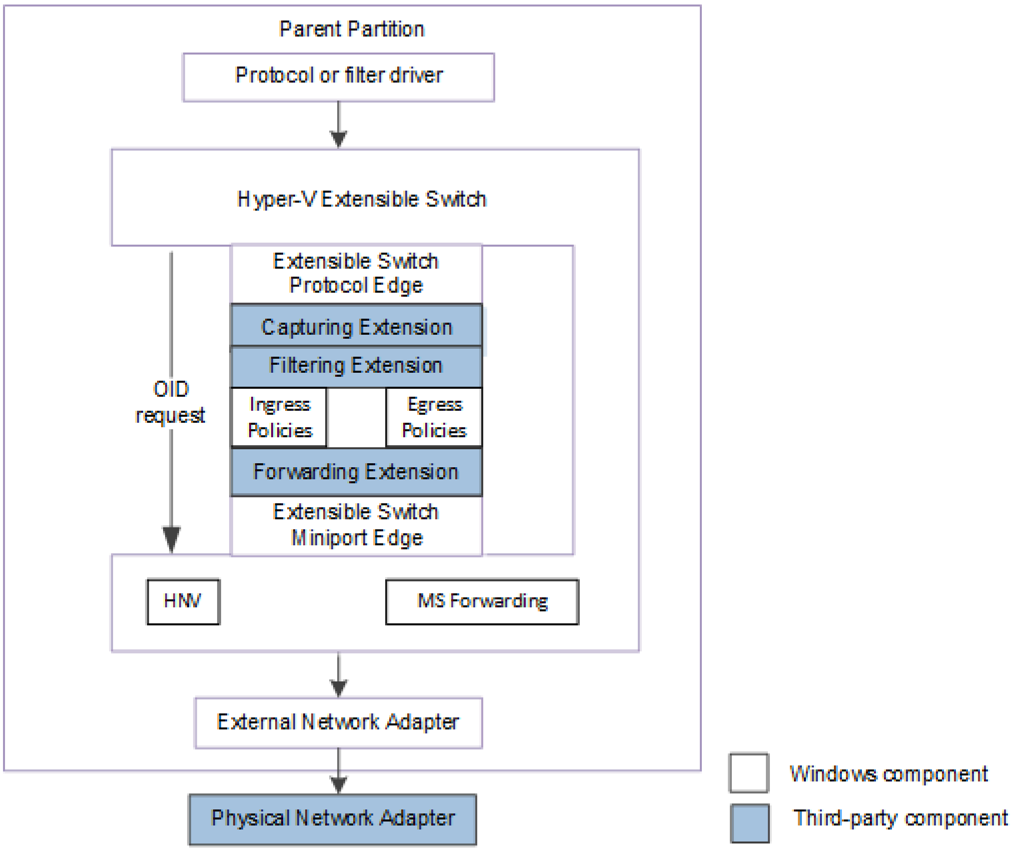
Note In the extensible switch interface, NDIS filter drivers are known as *extensible switch extensions* and the driver stack is known as the *extensible switch driver stack*.

Hyper-V Extensible Switch Control Path for OID Requests

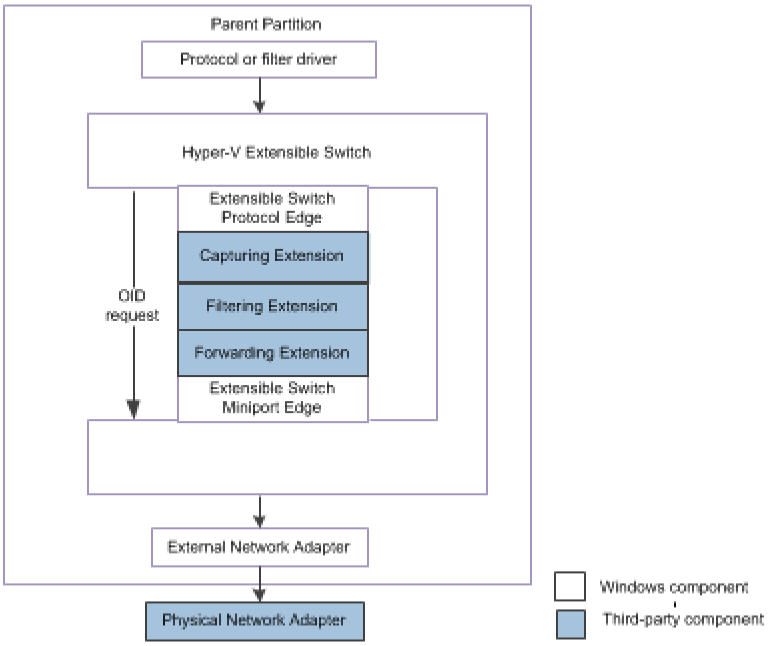
Article • 12/15/2021

This topic discusses the control path that Hyper-V extensible switch object identifier (OID) requests move across.

The following figure shows the extensible switch control path for OID requests for NDIS 6.40 (Windows Server 2012 R2) and later.



The following figure shows the extensible switch control path for OID requests for NDIS 6.30 (Windows Server 2012).



Note In the extensible switch interface, NDIS filter drivers are known as *extensible switch extensions* and the driver stack is known as the *extensible switch driver stack*.

Extensible switch extensions, such as filtering and forwarding extensions, are responsible for allowing or rejecting packet traffic based on port or switch policies. In order for these extensions to apply policy decisions, these extensions must be able to do the following:

- Receive the necessary information from the extensible switch interface about the new or updated configuration and state of the extensible switch, its ports, and its network adapter connections.
- Receive the necessary information from the extensible switch interface about the new or updated properties for a switch or port policy.
- Issue OID requests to the extensible switch interface to obtain the current configuration of the extensible switch, its ports, and its network adapter connections.

The extensible switch interface notifies underlying extensions about changes to its component configuration and policy parameters by issuing extensible switch OID set requests. These requests are issued by the protocol edge of the extensible switch to notify underlying extension about these changes. These OID requests move through the extensible switch driver stack to the underlying miniport edge of the extensible switch.

The miniport edge of the extensible switch is responsible for completing the OID requests. However, with some extensible switch OID requests, an underlying extension can fail an OID request in order to veto a notification. For example, when the protocol edge of the extensible switch notifies the extensions about a new port that will be created, it issues an OID set request of OID_SWITCH_PORT_CREATE. An underlying filtering or forwarding extension can veto the port creation by completing the OID request with STATUS_DATA_NOT_ACCEPTED. For more information on this procedure, see Receiving OID Requests about Hyper-V Extensible Switch Configuration Changes.

Note If the extension does not veto an extensible switch OID request, it should monitor the status when the request is completed. The extension should do this to determine whether the OID request was vetoed by underlying extensions in the extensible switch control path or by the extensible switch interface.

Note Stack restart requests using **NdisFRestartFilter** will not complete while an extensible switch OID request is pending. For this reason, an extension that is waiting for a stack restart must complete any ongoing OID requests.

Most of the extensible switch OID requests can only be issued by the extensible switch interface. However, some extensible switch OID requests can be issued by an extension to obtain information about the configuration of the extensible switch, its ports, and its network adapter connections. For more information, see Querying the Hyper-V Extensible Switch Configuration.

Hyper-V Extensible Switch Control Path for NDIS Status Indications

Article • 03/14/2023

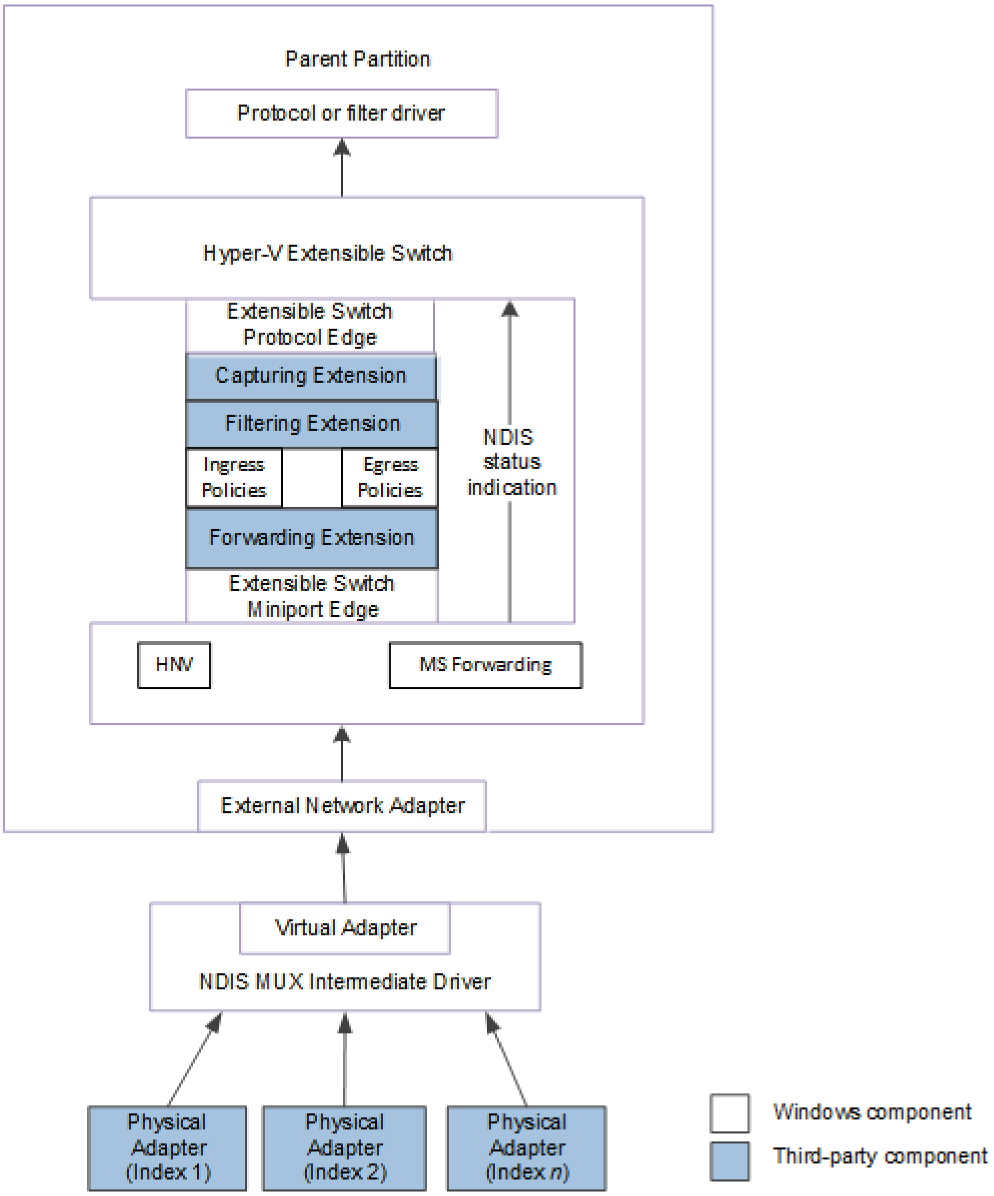
This topic discusses the control path that NDIS status indications from an underlying physical adapter move across. One or more underlying physical adapters can be teamed with the Hyper-V extensible switch external network adapter.

For example, the extensible switch external network adapter can be bound to the virtual miniport edge of an NDIS multiplexer (MUX) intermediate driver. The MUX intermediate driver itself can be bound to a team of one or more physical networks on the host. This configuration is known as an *extensible switch team*. For more information about extensible switch teams, see Types of Physical Network Adapter Configurations.

In this configuration, the extensible switch extensions are exposed to every network adapter in the extensible switch team. This allows the forwarding extension in the extensible switch driver stack to manage the configuration and use of individual network adapters in the team. For example, the extension can provide support for a load balancing failover (LBFO) solution over the team by forwarding outgoing packets to individual adapters. Such an extension is known as a *teaming provider*. For more information about teaming providers, see Teaming Provider Extensions.

Note Operations of this sort can only be performed by a forwarding extension. For more information about this type of driver, see Forwarding Extensions.

The following figure shows the extensible switch control path for NDIS status indications issued by an underlying extensible switch team for NDIS 6.40 (Windows Server 2012 R2) and later.



The following figure shows the extensible switch control path for NDIS status indications issued by an underlying extensible switch team for NDIS 6.30 (Windows Server 2012).

Windows component
Third-party component

Note In the extensible switch interface, NDIS filter drivers are known as *extensible switch extensions* and the driver stack is known as the *extensible switch driver stack*.

The extensible switch supports NDIS status indications from the underlying physical adapter or extensible switch team in the following ways:

- When an NDIS status indication arrives at the extensible switch interface, it encapsulates the indication inside an NDIS_SWITCH_NIC_STATUS_INDICATION structure. Then, the miniport edge of the extensible switch issues an NDIS_STATUS_SWITCH_NIC_STATUS indication that contains this structure.

  When a forwarding extension receives this indication, it can duplicate the indication to change the encapsulated data. This allows the forwarding extension to change the indicated status or capabilities of the underlying extensible switch team.

- A forwarding extension that operates as a teaming provider can participate in the configuration of the adapter team for hardware offloads by initiating NDIS_STATUS_SWITCH_NIC_STATUS indications that are related to the offload technology.

  For example, the provider can initiate an NDIS_STATUS_SWITCH_NIC_STATUS indication with an encapsulated

NDIS_STATUS_RECEIVE_FILTER_CURRENT_CAPABILITIES indication to modify the offload capabilities for the virtual machine queue (VMQ) on the adapter team.

- Teaming providers can also initiate an NDIS_STATUS_SWITCH_NIC_STATUS indication to modify other network adapter configurations other than an extensible switch team.

  For example, the extension can initiate an NDIS_STATUS_SWITCH_NIC_STATUS with an encapsulated NDIS_STATUS_SWITCH_PORT_REMOVE_VF indication. This indication removes the binding between a virtual machine (VM) network adapter and a PCI Express (PCIe) virtual function (VF). The VF is exposed by an underlying physical network adapter that supports the single root I/O virtualization (SR-IOV) interface.

  After this binding is removed, packets are delivered through an extensible switch port instead of directly between the VM network adapter and the VF of the underlying SR-IOV physical adapter. This allows the extensible switch port policies to be applied to packets that are received or sent over the extensible switch port.

Note The extensible switch extension must follow the same guidelines for filtering NDIS status indications that applies to all NDIS filter drivers. For more information, see Filter Module Status Indications.

For more information on how forwarding extensions can initiate NDIS_STATUS_SWITCH_NIC_STATUS indications, see Managing NDIS Status Indications from Physical Network Adapters.

Hyper-V Extensible Switch Policies Topics

Article • 12/15/2021

The Hyper-V platform and the extensible switch interface provide an infrastructure to manage switch and port policies for an extensible switch through PowerShell cmdlets and WMI. Hyper-V also provides the infrastructure to store and migrate policies.

This section includes the following topics that describe the various extensible switch policies:

Overview of Hyper-V Extensible Switch Policies

Port Policies

Switch Policies

Overview of Hyper-V Extensible Switch Policies

Article • 12/15/2021

The Hyper-V platform and the extensible switch interface provide an infrastructure to manage switch and port policies for an extensible switch. These policies are managed through PowerShell cmdlets and WMI-based application programs. This infrastructure also provides support for the storage and migration of policies.

Independent software vendors (ISVs) can use this infrastructure to register their own custom policies. After they are registered, these policies can be discovered and managed through the built-in Hyper-V policy interfaces. Properties of policies can be configured either on a per-port level or a per-switch level.

In addition to custom policy properties, the Hyper-V extensible switch interface provides the infrastructure to obtain status information for custom policy properties on a per-port or a per-switch basis. This status information is known as *feature status* information.

Extensible switch custom policy data is registered with the WMI management layer by using managed object format (MOF) class definitions. The following shows an example of a MOF class for a custom port policy property.

C++

   InterfaceRevision("0")]
  uint32 IntValue32 = 0;

  [WmiDataId(4),
   InterfaceVersion("1"),
   InterfaceRevision("0")]
  uint64 IntValue64 = 0;

  [WmiDataId(5),
   InterfaceVersion("1"),
   InterfaceRevision("0"),
   MaxLen(255)]
  string FixedLengthString = "";

  [WmiDataId(6),
   InterfaceVersion("1"),
   InterfaceRevision("0")]
  string VariableLengthString = "";

  [WmiDataId(7),
   InterfaceVersion("1"),
   InterfaceRevision("0"),
   Max(8)]
  uint32 FixedLengthArray[] = {};

  [WmiDataId(8),
   InterfaceVersion("1"),
   InterfaceRevision("0")]
  uint32 VariableLengthArray[] = {};

};
```

The WMI management layer serializes the MOF data when it is transferred to an underlying extensible switch extension. The MOF class is serialized to a corresponding C structure that can be processed by the Hyper-V extensible switch extension. The following shows an example of the C structure that was serialized for the MOF class from the previous example.

C++

```
#pragma pack(8)

typedef struct _VARIABLE_LENGTH_ARRAY
{
    UINT32 Buffer[1];
} VARIABLE_LENGTH_ARRAY;

typedef struct _SAMPLE_FEATURE_SETTINGS
```

```
{
    UINT8  IntValue8;
    UINT32 IntValue16;
    UINT32 IntValue32;
    UINT64 IntValue64;
    UINT16 FixedLengthStringByteCount;
    WCHAR  FixedLengthString[256];
    UINT32 VariableLengthStringOffset;    // offset to
VARIABLE_LENGTH_STRING structure
    UINT32 FixedLengthArrayElementCount;
    UINT32 FixedLengthArray[8];
    UINT32 VariableLengthArrayElementCount;
    UINT32 VariableLengthArrayOffset;   // offset to VARIABLE_LENGTH_ARRAY
} SAMPLE_FEATURE_SETTINGS;

typedef struct _VARIABLE_LENGTH_STRING
{
    USHORT StringLength;
    WCHAR  StringBuffer[1];
} VARIABLE_LENGTH_STRING;
```

This example highlights the following points that occur when a MOF class is serialized to a corresponding C structure for an extensible switch policy property:

- The version definition in MOF files is converted into a USHORT value, where the high-order bits contain the major version and the low-order bits contain the minor version. The version is serialized by using the following code:

  `(((MajorVersion) << 8) + (MinorVersion))`

  For example, Version("1") above would be serialized to a value of 0x0100 through `(((1) << 8) + (0))`. Version ("1.1") would be serialized to a value of 0x0101 through `(((1) << 8) + (1))`.

  When a custom policy property is issued to an underlying extension, the **PropertyVersion** member of the structures that define policy properties contains the serialized version value.

  For example, when the extensible switch interface issues an object identifier (OID) request of OID_SWITCH_PORT_PROPERTY_ADD, the OID is associated with an **NDIS_SWITCH_PORT_PROPERTY_PARAMETERS** structure. The **PropertyVersion** member of that structure contains the serialized version value.

- All variable-length strings are serialized into offsets within the buffer that contains the serialized C structure. Each variable-length string is formatted as a **VARIABLE_LENGTH_STRING** structure within this buffer offset.

Port Policies

Article • 12/15/2021

This section includes the following topics that describe custom properties for Hyper-V extensible switch port policies:

Overview of Port Policies

Custom Port Property Definition and Registration

Overview of Port Policies

Article • 12/15/2021

Starting with NDIS 6.30, the following types of policies are supported for Hyper-V extensible switch ports:

Built-in Port Policies
Built-in port policies specify properties that are enforced by the extensible switch interface. Extensions in the extensible switch driver stack are not provisioned with the properties of these policies.

Built-in port policies include access control lists (ACLs) and quality of service (QoS) properties. When a packet arrives at the miniport edge of the extensible switch on the ingress data path, the switch filters the packet and enforces these policies. If the packet passes the filtering, the switch forwards the packet up the egress data path for additional handling and filtering by overlying extensions.

For more information about the extensible switch data path, see Hyper-V Extensible Switch Data Path.

Standard Port Policies
Standard port policies specify security, profile, or virtual LAN (VLAN) properties. These properties are provisioned by object identifier (OID) requests issued by the protocol edge of the extensible switch. If a forwarding extension is not installed and enabled in the extensible switch data path, these policies are enforced by the underlying extensible switch's miniport edge. Otherwise, the forwarding extension enforces these policies if it allows the policy to be provisioned.

Standard port properties are specified by an **NDIS_SWITCH_PORT_PROPERTY_TYPE** enumeration value of **NdisSwitchPortPropertyTypeSecurity**, **NdisSwitchPortPropertyTypeVlan**, and **NdisSwitchPortPropertyTypeProfile**.

Note If a forwarding extension does not manage or enforce VLAN port properties, it must return STATUS_DATA_NOT_ACCEPTED for the OID_SWITCH_PORT_PROPERTY_ADD and OID_SWITCH_PORT_PROPERTY_UPDATE requests that add or update the property. VLAN port properties have a property type of **NdisSwitchPortPropertyTypeVlan**.

Custom Port Policies
Custom port policies specify proprietary properties that are defined by an independent software vendor (ISV). These properties are provisioned by OID requests issued by the extensible switch's protocol edge of the extensible switch and enforced by the underlying extension that manages the custom port policy.

Custom port properties are defined through managed object format (MOF) class definitions. The ISV defines the format of the custom port properties through the MOF class definition. After the MOF file is registered with the WMI management layer, the underlying extensions are provisioned with the custom port policy.

A custom port property is specified by **NDIS_SWITCH_PORT_PROPERTY_TYPE** enumeration value of **NdisSwitchPortPropertyTypeCustom**. Each custom port property is uniquely defined through a GUID value. The extension manages those custom port properties for which it has been configured with the property's GUID value.

Note The method by which the extension is configured with the property's GUID value is proprietary to the ISV.

Standard and custom port policies are provisioned through the following OID requests:

- The protocol edge issues OID set requests of OID_SWITCH_PORT_PROPERTY_ADD to notify underlying extensions of the addition of a standard or custom port property.
- The protocol edge issues OID set requests of OID_SWITCH_PORT_PROPERTY_UPDATE to notify underlying extensions of the update to a standard or custom port property.
- The protocol edge issues OID set requests of OID_SWITCH_PORT_PROPERTY_DELETE to notify underlying extensions of the deletion of a standard or custom port property.

A forwarding extension can block the provisioning of the new or updated port policy by vetoing the OID request. The extension does this by completing the OID request with STATUS_DATA_NOT_ACCEPTED. If the extension does not veto the OID request, it must call **NdisFOidRequest** to forward the OID request down the extensible switch control path.

Note If the extension does not veto the OID request, it monitors the status when the request is completed. The extension does this to determine whether the OID request was vetoed by underlying extensions in the extensible switch control path or by the extensible switch interface.

For more information on how to manage port policies and properties, see Managing Port Policies.

Custom Port Property Definition and Registration

Article • 12/15/2021

Custom property definitions for a Hyper-V extensible switch port policy are registered with the WMI management layer by using managed object format (MOF) class definitions. In addition to the structure members that define the attributes of the custom port property, the MOF class must also contain the following:

- A UUID that uniquely identifies the custom port property.
- A GUID that uniquely identifies the extensible switch extension. This GUID is declared as the **ExtensionId** qualifier of the MOF class and must match the value of the **NetCfgInstanceId** entry that is declared in the extension's INF file.
- A descriptive class name string. The name of the vendor must be included in the string.

The following shows an example of a MOF class for a custom property of an extensible switch port policy.

```C++
#pragma namespace("\\\\.\\root\\virtualization\\v2")

[ Dynamic,
 UUID("EB29F0F2-F5DC-45C6-81BB-3CD9F219BBBB"),
 ExtensionId("5CBF81BE-5055-47CD-9055-A76B2B4E369E"),
 Provider("VmmsWmiInstanceAndMethodProvider"),
 Locale(0x409),
 InterfaceVersion("1"),
 InterfaceRevison("0"),
DisplayName("Fabrikam, Inc. Port Settings Friendly Name") : Amended,
Description("Fabrikam, Inc. Port Settings detailed description.") : Amended]
class Fabrikam_PortCustomSettingData :
Msvm_EthernetSwitchPortFeatureSettingData {

    [ Read,
      Write,
      WmiDataId(1),
      InterfaceVersion("1"),
      InterfaceRevision("0"),
      Description (
         "int32 setting.") : Amended]
    uint32 SettingIntA = 0;

    [ Read,
      Write,
      WmiDataId(2),
      InterfaceVersion("1"),
      InterfaceRevision("0"),
      Description (
         "int64 setting.") : Amended]
    uint64 SettingIntB = 0;
};
```

The MOF classes for custom properties of a port policy are registered in the common information model (CIM) repository by using the MOF compiler (Mofcomp.exe). Once registered, the MOF class can be configured through PowerShell cmdlets and WMI-based application programs.

The following example shows the commands that must be entered to register a file (Fabrikam_PortCustomSettingData.mof) that contains the MOF class for a custom port property.

PowerShell

```
net stop vmms
mofcomp -N:root\virtualization\v2 Fabrikam_PortCustomSettingData.mof
net start vmms
```

For more information about how to use the MOF compiler, see Compiling a Driver's MOF File.

The following example shows how you can configure the sample feature. In this example, the Fabrikam_PortCustomSettingData MOF class is used to configure a port from a Hyper-V partition named "TestVm".

PowerShell

```
# Retrieve the template object for the custom configuration. We know the ID
already so
# we can retrieve it directly, otherwise Get-
VmSystemSwitchExtensionPortFeature can list all available
# properties.
PS C:\> $feature = Get-VMSystemSwitchExtensionPortFeature -FeatureId
EB29F0F2-F5DC-45C6-81BB-3CD9F219BBBB

# Output the values

Switch Policies

Article • 12/15/2021

This section includes the following topics that describe custom properties for Hyper-V extensible switch policies:

Overview of Switch Policies

Custom Switch Property Definition and Registration

Overview of Switch Policies

Article • 12/15/2021

Starting with NDIS 6.30, the following types of policies are supported for Hyper-V extensible switches:

Built-in Switch Policies
Built-in switch policies specify properties that are enforced by the extensible switch interface. Extensions in the extensible switch driver stack are not provisioned with the properties of these policies.

Built-in switch policies include properties that affect the switch configuration in general but do not affect traffic flow over individual switch ports. For example, one such built-in policy configures the switch to allow hardware offloads to physical adapters that support the single root I/O virtualization (SR-IOV) interface. For more information about this interface, see Single Root I/O Virtualization (SR-IOV).

Custom Switch Policies
Custom switch policies specify proprietary properties that are defined by an independent software vendor (ISV). These properties are provisioned by the protocol edge of the extensible switch and enforced by the underlying extension that manages the custom switch policy.

The ISV defines the format for the custom switch properties. The format of the custom switch property is proprietary to the ISV.

Custom switch properties are defined through managed object format (MOF) class definitions. After the MOF file is registered with the WMI management layer, the underlying extensions are provisioned with the custom switch policy.

A custom switch property is specified by the **NDIS_SWITCH_PROPERTY_TYPE** enumeration value of **NdisSwitchPropertyTypeCustom**. Each custom switch property is uniquely defined through a GUID value. The extension manages those custom switch properties for which it has been configured with the property's GUID value.

Note The method by which the extension is configured with the property's GUID value is proprietary to the ISV.

Custom switch policies are provisioned through the following OID requests:

- The protocol edge issues OID set requests of OID_SWITCH_PROPERTY_ADD to notify underlying extensions of the addition of a custom switch property.

- The protocol edge issues OID set requests of OID_SWITCH_PROPERTY_UPDATE to notify underlying extensions of the update to a custom switch property.
- The protocol edge issues OID set requests of OID_SWITCH_PROPERTY_DELETE to notify underlying extensions of the deletion of a custom switch property.

A forwarding extension can block the provisioning of the new or updated switch policy by vetoing the OID request. The extension does this by completing the OID request with STATUS_DATA_NOT_ACCEPTED. If the extension does not veto the OID request, it must call **NdisFOidRequest** to forward the OID request down the extensible switch control path.

Note If the extension does not veto the OID request, it monitors the status when the request is completed. The extension does this to determine whether the OID request was vetoed by underlying extensions in the extensible switch control path or by the extensible switch interface.

For more information on how to manage switch policies and properties, see Managing Switch Policies.

Custom Switch Property Definition and Registration

Article • 12/15/2021

Custom property definitions for a Hyper-V extensible switch policy are registered with the WMI management layer by using managed object format (MOF) class definitions. In addition to the structure members that define the attributes of the custom switch property, the MOF class must also contain the following:

- A UUID that uniquely identifies the custom switch property.
- A GUID that uniquely identifies the extensible switch extension. This GUID is declared as the **ExtensionId** qualifier of the MOF class and must match the value of the **NetCfgInstanceId** entry that is declared in the extension's INF file.
- A descriptive class name string. The name of the vendor must be included in the string.

The following shows an example of a MOF class for a custom property of an extensible switch policy.

```C++
#pragma namespace("\\\\.\\root\\virtualization\\v2")

[ Dynamic,
 UUID("FF36C3A6-D2F1-46ed-A376-32B43D6B8390"),
 ExtensionId("5CBF81BE-5055-47CD-9055-A76B2B4E369E"),
 Provider("VmmsWmiInstanceAndMethodProvider"),
  Locale(0x409),
 InterfaceVersion("1"),
 InterfaceRevison("0"),
DisplayName("Fabrikam, Inc.  Switch Settings Friendly Name") : Amended,
Description("Fabrikam, Inc.  Switch Settings detailed description.") :
Amended]
class Fabrikam_SwitchCustomSettingData :
Msvm_EthernetSwitchFeatureSettingData {

    [ Read,
      Write,
      WmiDataId(1),
      InterfaceVersion("1"),
      InterfaceRevision("0"),
      Description (
         "int32 setting.") : Amended]
    uint32 SwitchSettingIntA = 0;
    [ Read,
      Write,
      WmiDataId(2),
      InterfaceVersion("1"),
      InterfaceRevision("0"),
      Description (
         "int64 setting.") : Amended]
    uint64 SwitchSettingIntB = 0;
};
```

The MOF classes for custom properties of a switch policy are registered in the common information model (CIM) repository by using the MOF compiler (Mofcomp.exe). Once registered, the MOF class can be configured through PowerShell cmdlets and WMI-based application programs.

The following example shows the commands that must be entered to register a file (Fabrikam_SwitchCustomSettingData.mof) that contains the MOF class for a custom port property.

PowerShell

```
net stop vmms
mofcomp -N:root\virtualization\v2 Fabrikam_SwitchCustomSettingData.mof
net start vmms
```

For more information about how to use the MOF compiler, see Compiling a Driver's MOF File.

The following example shows how you can configure the sample feature. In this example, the Fabrikam_SwitchCustomSettingData MOF class is used to configure a switch named “TestSwitch”.

PowerShell

```
# Retrieve the template object for the custom configuration. We know the ID
already so
# we can retrieve it directly, otherwise Get-
VMSystemSwitchExtensionSwitchFeature can list all available
# properties.
PS C:\> $feature = Get-VMSystemSwitchExtensionSwitchFeature -FeatureId
FF36C3A6-D2F1-46ed-A376-32B43D6B8390

# Output the values
PS C:\temp> $feature

Hyper-V Extensible Switch Feature Status Information Overview

Article • 12/15/2021

The Hyper-V extensible switch interface supports the ability to obtain custom status information for an extensible switch or one of its ports. This status information is known as *feature status* information.

This section includes the following topics that describe the support for feature status information:

Custom Port Feature Status

Custom Switch Feature Status

Custom Port Feature Status

Article • 12/15/2021

The Hyper-V platform and Hyper-V extensible switch interface provide the infrastructure to obtain custom status information for an extensible switch port. This information is known as *port feature status* information.

Custom feature status definitions for a Hyper-V extensible switch port property are registered with the WMI management layer by using managed object format (MOF) class definitions. In addition to the structure members that define the attributes of the custom port feature status definition, the MOF class must also contain the following:

- A UUID that uniquely identifies the custom port feature status definition.
- A GUID that uniquely identifies the extensible switch extension. This GUID is declared as the **ExtensionId** qualifier of the MOF class and must match the value of the **NetCfgInstanceId** entry that is declared in the extension's INF file.
- A descriptive class name string. The name of the vendor must be included in the string.

The following shows an example of a MOF class for a custom feature status definition of an extensible switch port.

C++

```
#pragma namespace("\\\\.\\root\\virtualization\\v2")

[ Dynamic,
  UUID("DAA0B7CC-74DB-41ef-8354-7002F9FA463E"),
  ExtensionId("5CBF81BE-5055-47CD-9055-A76B2B4E369E"),
  Provider("VmmsWmiInstanceAndMethodProvider"),
  InterfaceVersion("1"),
  InterfaceRevison("0"),
  Locale(0x409),
  Description("Fabricam, Inc. port custom feature status description.") :
Amended,
  DisplayName("Fabricam, Inc.port custom feature status friendly name.") :
Amended]
class Fabrikam_CustomPortData  : Msvm_EthernetPortData {
    [ Read,
       Write,
       WmiDataId(1),
      InterfaceVersion("1"),
      InterfaceRevision("0"),
       Description(
         "The current status of custom feature on this port.") : Amended]
    uint32 CurrentStatus = 0 ;
};
```

The MOF classes for custom feature status definition of a port are registered in the common information model (CIM) repository by using the MOF compiler (Mofcomp.exe). After it is registered, the MOF class can be configured through PowerShell cmdlets and WMI-based application programs.

The following example shows the commands that must be entered to register a file (Fabrikam_CustomPortData.mof) that contains the MOF class for a custom port feature status definition.

PowerShell

```
net stop vmms
mofcomp -N:root\virtualization\v2 Fabrikam_CustomPortData.mof
net start vmms
```

For more information about how to use the MOF compiler, see Compiling a Driver's MOF File.

The following example shows how you can use the custom port feature status definition to obtain port data. In this example, the Fabrikam_CustomPortData MOF class is used to obtain port status from a Hyper-V partition named "TestVm". The Fabrikam, Inc. extension is enabled on the vSwitch “TestSwitch”, and is returning 123 for the status.

PowerShell

```
PS C:\> $portData = Get-VMSwitchExtensionPortData -VmName TestVm -FeatureId
DAA0B7CC-74DB-41ef-8354-7002F9FA463E
# Output the current value
PS C:\> $portData.Data.CurrentStatus
123
```

For more information on how extensible switch extensions manage port feature status information, see Managing Custom Port Feature Status Information.

Custom Switch Feature Status

Article • 12/15/2021

The Hyper-V platform and Hyper-V extensible switch interface provide the infrastructure to obtain custom status information for an extensible switch. This information is known as *switch feature status* information.

Custom switch feature status definitions are registered with the WMI management layer by using managed object format (MOF) class definitions. In addition to the structure members that define the attributes of the custom switch feature status definition, the MOF class must also contain the following:

- A UUID that uniquely identifies the custom switch feature status definition.
- A GUID that uniquely identifies the extensible switch extension. This GUID is declared as the **ExtensionId** qualifier of the MOF class and must match the value of the **NetCfgInstanceId** entry that is declared in the extension's INF file.
- A descriptive class name string. The name of the vendor must be included in the string.

The following shows an example of a MOF class for a custom feature status definition of an extensible switch.

C++

```
#pragma namespace("\\\\.\\root\\virtualization\\v2")

[ Dynamic,
  UUID("B3E57D77-8E95-4977-97DE-524F8DAF03E4"),
  ExtensionId("5CBF81BE-5055-47CD-9055-A76B2B4E369E"),
  Provider("VmmsWmiInstanceAndMethodProvider"),
  InterfaceVersion("1"),
  InterfaceRevison("0"),
  Locale(0x409),
  Description(
   "Fabricam, Inc. Switch custom feature status description.") : Amended,
  DisplayName("Fabricam, Inc. Switch custom feature status friendly name.")
: Amended]
class Fabrikam_CustomSwitchData  : Msvm_EthernetSwitchFeatureSettingData{
    [ Read,
       Write,
       WmiDataId(1),
       InterfaceVersion("1"),
       InterfaceRevision("0"),
       Description(
         "The current status of custom feature on this switch.") : Amended]
```

```
      uint32 CurrentStatus = 0 ;
  };
```

The MOF classes for custom feature status definition of an extensible switch are registered in the common information model (CIM) repository by using the MOF compiler (Mofcomp.exe). After it is registered, the MOF class can be configured through PowerShell cmdlets and WMI-based application programs.

The following example shows the commands that must be entered to register a file (Fabrikam_CustomSwitchData.mof) that contains the MOF class for a custom switch feature status definition.

PowerShell

```
net stop vmms
mofcomp -N:root\virtualization\v2 Fabrikam_CustomSwitchData.mof
net start vmms
```

For more information about how to use the MOF compiler, see Compiling a Driver's MOF File.

The following example shows how you can use the custom switch feature status definition to obtain switch data. In this example, the Fabrikam_CustomSwitchData MOF class is used to obtain switch status from a switch named “TestSwitch”. The Fabrikam, Inc. extension is enabled on the vSwitch “TestSwitch”, and is returning 123 for the status.

PowerShell

```
PS C:\> $switchData = Get-VMSwitchExtensionSwitchData -SwitchName TestSwitch
-FeatureId B3E57D77-8E95-4977-97DE-524F8DAF03E4
# Output the current value
PS C:\> $switchData$customSwitchData.Data.CurrentStatus
123
```

For more information on how extensible switch extensions manage switch feature status information, see Managing Custom Switch Feature Status Information.

Hyper-V Extensible Switch Save and Restore Operations Overview

Article • 12/15/2021

When a Hyper-V child partition is stopped, saved, or live migrated, the run-time state of the partition is saved. When the partition is restarted or has completed the live migration to another host computer, the run-time state is restored. During the transition between saved and restored states, the settings of the network interfaces for the child partition are unchanged and network connections to the Hyper-V extensible switch are not torn down.

The extensible switch interface notifies underlying extensions of save and restore operations for the child partition. During the save operation, the extension can return run-time data for each extensible switch network adapter (NIC). During the restore operation, the interface returns the run-time data to the extension so that it can restore the state of the NIC.

This section includes the following topics:

Hyper-V Extensible Switch Save Operations

Hyper-V Extensible Switch Restore Operations

Hyper-V Extensible Switch Live Migration Support

Hyper-V Extensible Switch Save Operations

Article • 12/15/2021

When a Hyper-V child partition is stopped, saved, or live migrated, the run-time state of the partition is saved. During the save operation, a Hyper-V extensible switch extension can save run-time data about an extensible switch network adapter (NIC).

When a save operation is being performed on a Hyper-V child partition, the extensible switch interface notifies the extension about the operation. The extension is notified through the following object identifier (OID) requests:

OID_SWITCH_NIC_SAVE
The extensible switch interface signals the protocol edge of the extensible switch to issue this OID during the save operation for an extensible switch NIC. When it handles this OID request, the extension returns run-time data for the NIC. After the run-time data is saved, it is restored through OID set requests of OID_SWITCH_NIC_RESTORE.

When it receives the OID_SWITCH_NIC_SAVE method request, the extension can do one of the following:

- If the extension has run-time data to save, it initializes an **NDIS_SWITCH_NIC_SAVE_STATE** structure and sets the various members, such as the **ExtensionId** member, to identify itself and the data that it is saving. The extension also saves the data within the **NDIS_SWITCH_NIC_SAVE_STATE** structure starting SaveDataOffset bytes from the start of the structure, and then completes the OID method request with NDIS_STATUS_SUCCESS.

- If the **NDIS_SWITCH_NIC_SAVE_STATE** structure does not provide a sufficient buffer size, enumerated in the NDIS_OBJECT_HEADER **Size** member to hold the run-time state, the extension sets the method structure's *BytesNeeded* field to NDIS_SIZEOF_NDIS_SWITCH_NIC_SAVE_STATE_REVISION_1 plus the amount of buffer necessary to hold the save data, and completes the OID with NDIS_STATUS_BUFFER_TOO_SHORT. The OID will be reissued with the required size.

- If the extension does not have run-time data to save, it must call **NdisFOidRequest**. This forwards the OID method request to underlying extensions in the extensible switch driver stack. For more information about this procedure, see Filtering OID Requests in an NDIS Filter Driver.

For more information about this OID request, see Handling the OID_SWITCH_NIC_SAVE Request.

OID_SWITCH_NIC_SAVE_COMPLETE
The extensible switch interface signals the protocol edge of the extensible switch to issue this OID at the completion of the save operation of run-time data for an extensible switch NIC.

This OID request notifies the extension that the save operation has completed only for a specified extensible switch NIC.

For more information about this OID request, see Handling the OID_SWITCH_NIC_SAVE_COMPLETE Request.

During the save operation for run-time data, the protocol edge of the extensible switch issues OID requests of OID_SWITCH_NIC_SAVE and OID_SWITCH_NIC_SAVE_COMPLETE for the network interface of a Hyper-V child partition is connected. If multiple Hyper-V child partitions are stopped or live migrated, the protocol edge issues separate sets of OID_SWITCH_NIC_SAVE and OID_SWITCH_NIC_SAVE_COMPLETE requests for each network interface connection.

Note The protocol edge of the extensible switch will not interleave save operations for run-time data for the same NIC. The protocol edge will start a run-time data save operation for a NIC only after a previous save operation has completed on the same NIC. However, the protocol edge may start a save operation for a NIC while another save operation is in progress for another NIC. Because of this, we highly recommend that extensions perform save operations in a non-interleaved fashion. For example, extensions should not assume that a new save operation cannot start on another NIC before an ongoing save operation has completed for a different NIC.

Hyper-V Extensible Switch Restore Operations

Article • 12/15/2021

When a Hyper-V child partition is restarted after it was stopped or live migrated, the run-time state of the partition is restored. During the restore operation, a Hyper-V extensible switch extension driver can restore run-time data about an extensible switch network adapter (NIC).

When a restore operation is being performed on a Hyper-V child partition, the extensible switch interface signals the protocol edge of the extensible switch to issue an OID set request of OID_SWITCH_NIC_RESTORE. The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure for the OID_SWITCH_NIC_RESTORE request contains a pointer to an **NDIS_SWITCH_NIC_SAVE_STATE** structure.

When it handles this OID request, the extension restores the run-time data for the network adapter. This run-time data was previously saved through OID requests of OID_SWITCH_NIC_SAVE and OID_SWITCH_NIC_SAVE_COMPLETE.

When it receives the OID_SWITCH_NIC_RESTORE request, the extensible switch extension must first determine whether it owns the run-time data. The driver does this by comparing the value of the **ExtensionId** member of the **NDIS_SWITCH_NIC_SAVE_STATE** structure to the GUID value that the driver uses to identify itself.

If the extension owns the run-time data, it restores this data in the following way:

1. The extension copies the run-time data in the **SaveData** member to driver-allocated storage.

   Note The value of the **PortId** member of the **NDIS_SWITCH_NIC_SAVE_STATE** structure may be different from the **PortId** value at the time that the run-time data was saved. This can occur if run-time data was saved during a Live Migration from one host to another. However, the configuration of the extensible switch NIC is retained during the Live Migration. This enables the extension to restore the run-time data to the extensible switch NIC by using the new **PortId** value.

2. The extension completes the OID set request with NDIS_STATUS_SUCCESS.

If the extension does not own the run-time data, it must call **NdisFOidRequest**. This forwards the OID method request to underlying extensions in the extensible switch driver stack. For more information about this procedure, see Filtering OID Requests in an NDIS Filter Driver.

OID_SWITCH_NIC_RESTORE_COMPLETE
The extensible switch interface signals the protocol edge of the extensible switch to issue this OID at the completion of the restore operation of run-time data for an extensible switch NIC.

This OID request notifies the extension that the restore operation has completed only for a specified extensible switch NIC.

For more information about this OID request, see OID_SWITCH_NIC_RESTORE_COMPLETE.

During the restore operation for run-time data, the protocol edge of the extensible switch issues OID requests of OID_SWITCH_NIC_RESTORE and OID_SWITCH_NIC_RESTORE_COMPLETE for the network interface of a Hyper-V child partition is connected. If multiple Hyper-V child partitions are restored, the protocol edge issues separate sets of OID_SWITCH_NIC_RESTORE and OID_SWITCH_NIC_RESTORE_COMPLETE requests for each network interface connection.

Note The protocol edge of the extensible switch will not interleave restore operations for run-time data for the same NIC. The protocol edge will start a run-time data restore operation for a NIC only after a previous restore operation has completed on the same NIC. However, the protocol edge may start a restore operation for a NIC while another restore operation is in progress for another NIC. Because of this, we highly recommend that extensions perform restore operations in a non-interleaved fashion. For example, extensions should not assume that a new restore operation cannot start on another NIC before an ongoing restore operation has completed for a different NIC.

For more information about this OID request, see Restoring Hyper-V Extensible Switch Run-Time Data.

Hyper-V Extensible Switch Live Migration Support

Article • 12/15/2021

During a Hyper-V live migration, a child partition, or *virtual machine (VM)*, is stopped on one host computer (*source host*) and migrated to another host computer (*destination host*). During live migration, the following operations occur:

- When the live migration starts on the source host, the extensible switch interface requests underlying extensions to save run-time data for each port and its associated network adapter connection.

  For more information about this operation, see Hyper-V Extensible Switch Save Operations.

- Before the live migration completes on the destination host, the extensible switch interface requests underlying extensions to restore run-time data for each port and its associated network adapter connection.

  For more information about this operation, see Hyper-V Extensible Switch Restore Operations.

During the live migration setup stage, the source host creates a TCP connection with the destination physical host. Hyper-V transfers the source VM's configuration data over this connection to the destination physical host. A skeleton VM is set up on the destination host and memory is allocated to the destination VM. At this point, Hyper-V transfers the source VM's state, including its memory pages, to the destination VM.

The extensible switch interface also uses the TCP connection to synchronize steps and results during the live migration. For example, the interface that runs on the destination host requests the transfer of run-time data from the source host for the port and network adapter connection associated with the migrated VM.

Before the destination VM is brought online on the destination host, the extensible switch interface performs these steps:

1. A validation port is created on the destination host through an object identifier (OID) set request of OID_SWITCH_PORT_CREATE. If the port is created successfully, the extensible switch interface issues other OID requests to verify the properties of port policies by underlying extensions.

If the extension fails the port creation or invalidates any of the policy properties, the live migration does not continue for that destination node and switch.

For more information about the validation port and its usages, see Validation Ports.

2. After the verification of policy properties is completed successfully, the validation port is deleted on the destination host through an OID set request of OID_SWITCH_PORT_DELETE. After this port is deleted, an operational port is created on the destination host and an operational port is created in its place. The **NDIS_SWITCH_PORT_PARAMETERS** structure that is associated with the OID_SWITCH_PORT_CREATE request for the operational port contains the same data that was used to create the port on the source host.

   If the operational port is created successfully, port policies are added to the operational port.

3. If the settings are successfully applied to the operational port on the destination host, a save operation is issued for the operational port on the source host.

4. If the save operation is completed successfully, the operational port and its network adapter connection are deleted on the source host in the following way:

   a. The network connection is first disconnected through an OID set request of OID_SWITCH_NIC_DISCONNECT. After this OID request is completed, the network adapter connection on the source host is deleted through an OID set request of OID_SWITCH_NIC_DELETE.

   b. After the network adapter connection is deleted, the operational port is torn down through an OID set request of OID_SWITCH_PORT_TEARDOWN. After this OID request is completed, the operational port is deleted through an OID set request of OID_SWITCH_PORT_DELETE.

5. A network adapter connection is created for the operational port on the destination host through an OID set request of OID_SWITCH_NIC_CREATE. If this OID request completes successfully, the network adapter connection is established on the associated operation port through an OID set request of OID_SWITCH_NIC_CONNECT.

   If the network adapter connection is established successfully, the run-time data for the operational port and network adapter connection is restored on the target host.

   At this point, the underlying extensions can perform resource reservation and validation on the network adapter connection.

Writing Hyper-V Extensible Switch Extensions Topics

Article • 12/15/2021

The following topics provide information about how to write Hyper-V extensible switch extensions:

Hyper-V Extensible Switch Send and Receive Operations

Hyper-V Extensible Switch OID Requests

Managing Hyper-V Extensible Switch Source and Destination Port Data

Managing Hyper-V Extensible Switch Policies

Managing Hyper-V Extensible Switch Feature Status Information

Managing Hyper-V Extensible Switch Run-Time Data

Managing Physical Network Adapters

Note Extensible switch extensions are based on the NDIS filter driver architecture. For more information, see NDIS Filter Drivers.

Hyper-V Extensible Switch Send and Receive Operations

Article • 12/15/2021

This section describes the send and receive operations for Hyper-V extensible switch extensions. The following table describes the operations that an extension can perform on packets that are sent or received over the extensible switch data path.

Operation	Capturing Extensions	Filtering Extensions	Forwarding Extensions
Originating packets	X	X	X
Cloning packets		X	X
Forwarding packets			X

This section includes the following topics:

Originating Packet Traffic

Cloning Packet Traffic

Forwarding Packets to Hyper-V Extensible Switch Ports

For more information about the extensible switch data path, see Hyper-V Extensible Switch Data Path.

Originating Packet Traffic

Article • 12/15/2021

This topic describes how Hyper-V extensions originate new packets and inject them into the extensible switch data path.

Note This page assumes that you are familiar with the information and diagrams in Overview of the Hyper-V Extensible Switch and Hybrid Forwarding.

Note In the extensible switch interface, NDIS filter drivers are known as *extensible switch extensions* and the driver stack is known as the *extensible switch driver stack*. For more information about the extensions, see Hyper-V Extensible Switch Extensions.

Extensible switch extensions can only inject new packets into the extensible switch ingress data path. This ensures that the extensible switch interface can filter and forward these packets correctly. Extensions must follow these guidelines for injecting new packets into the ingress data path:

- The extension must first allocate a **NET_BUFFER_LIST** structure for a new packet.

- After the extension allocates a **NET_BUFFER_LIST** structure for a new packet, it must call the *AllocateNetBufferListForwardingContext* handler function to allocate the extensible switch forwarding context for the packet.

  The forwarding context resides in the out-of-band (OOB) data of the packet. It contains forwarding information for the packet, such as its source port and an array of one or more destination ports.

  For more information about the forwarding context, see Hyper-V Extensible Switch Forwarding Context.

- After the extension calls *AllocateNetBufferListForwardingContext*, the source port for the packet will be set to **NDIS_SWITCH_DEFAULT_PORT_ID**. A packet with a source port identifier of **NDIS_SWITCH_DEFAULT_PORT_ID** is trusted and bypasses the extensible switch port policies, such as access control lists (ACLs) and quality of service (QoS).

  The extension may want the packet to be treated as if it originated from a particular port. This allows the policies for that port to be applied to the packet. The extension calls *SetNetBufferListSource* to change the source port for the packet.

  However, there may be situations where the extension may want to assign the packet's source port identifier to **NDIS_SWITCH_DEFAULT_PORT_ID**. For example, the extension may want to set the source port identifier to **NDIS_SWITCH_DEFAULT_PORT_ID** for proprietary control packets that are sent to a device on the external network.

- If the forwarding extension is sending a new packet on the ingress data path, it must determine the destination ports for the packet. For more information on this procedure, see Adding Extensible Switch Destination Port Data to a Packet.

  Note A capturing or filtering extension cannot add new destination ports to the new packet.

- When the extension creates a new packet, the packet data is located in local, or *trusted*, memory in the parent operating system of the Hyper-V parent partition. This memory is not accessible by the child partition. Therefore, it is considered "safe" from unsynchronized updates by the guest operating system that runs in that partition.

  The extension must obtain the **NDIS_SWITCH_FORWARDING_DETAIL_NET_BUFFER_LIST_INFO** union for the new packet by using the **NET_BUFFER_LIST_SWITCH_FORWARDING_DETAIL** macro. The extension must set the **IsPacketDataSafe** member to TRUE. This specifies that all of the packet data is located in trusted memory.

- When the extension calls **NdisFSendNetBufferLists** to inject the packet into the ingress data path, it must set the *Flags* parameter with the appropriate extensible switch flag settings. For more information about these flag settings, see Hyper-V Extensible Switch Send and Receive Flags.

- When NDIS calls the extension's *FilterSendNetBufferListsComplete* function to complete the send request of the new packet, the extension must call *FreeNetBufferListForwardingContext* to free the allocated forwarding context. The extension must do this before it frees or reuses the **NET_BUFFER_LIST** structure for the packet.

For more information about the extensible switch ingress and egress data paths, see Hyper-V Extensible Switch Data Path.

Cloning Packet Traffic

Article • 12/15/2021

This topic describes how Hyper-V extensible switch extensions clone, or duplicate, packets and inject them into the extensible switch data path. For more information on cloning packets, see Cloned NET_BUFFER_LIST Structures.

Note This page assumes that you are familiar with the information and diagrams in Overview of the Hyper-V Extensible Switch and Hybrid Forwarding.

Note In the extensible switch interface, NDIS filter drivers are known as *extensible switch extensions* and the driver stack is known as the *extensible switch driver stack*. For more information about the extensions, see Hyper-V Extensible Switch Extensions.

Extensible switch filtering and forwarding extensions can inject cloned packets into the extensible switch ingress or egress data path by following these guidelines:

- The extension must first allocate a **NET_BUFFER_LIST** structure for the cloned packet. The extension must then copy the packet data from the original packet to the cloned packet. For more information on how to clone packets, see Derived NET_BUFFER_LIST Structures.

- After the extension allocates a **NET_BUFFER_LIST** structure, it must call the *AllocateNetBufferListForwardingContext* handler function to allocate the extensible switch forwarding context for the packet.

  The forwarding context resides in the out-of-band (OOB) data of the packet. It contains forwarding information for the packet, such as its source port and an array of one or more destination ports.

  For more information about the forwarding context, see Hyper-V Extensible Switch Forwarding Context.

- The extension must copy the OOB data, including the existing source port, from the original packet to the cloned packet by calling *CopyNetBufferListInfo*. If the extension plans to inject the packet into the ingress data path, it must also copy the destination ports from the OOB data of the original packet.

  When it copies the OOB data, the extension must follow these guidelines:

  - If the filtering extension plans to inject the packet into the ingress data path, it must call *CopyNetBufferListInfo* with the NDIS_SWITCH_COPY_NBL_INFO_FLAGS_PRESERVE_DESTINATIONS flag unspecified. This causes the original packet's destination ports to not be copied to the cloned packets. When the filtering extension injects this packet into the ingress data path, destination ports will be added to the packet by either an underlying forwarding extension (if enabled in the driver stack) or the miniport edge of the extensible switch.

  - If the filtering extension plans to inject the packet into the egress data path, it must call *CopyNetBufferListInfo* with the NDIS_SWITCH_COPY_NBL_INFO_FLAGS_PRESERVE_DESTINATIONS flag specified. This causes the original packet's destination ports to be copied to the cloned packets.

- If the filtering extension is cloning or duplicating a packet that was obtained from the egress data path, it can change the destination ports for the packet after it calls *CopyNetBufferListInfo* with the NDIS_SWITCH_COPY_NBL_INFO_FLAGS_PRESERVE_DESTINATIONS flag specified. For more information on this procedure, see Modifying a Packet's Extensible Switch Source Port Data.

- If the forwarding extension is cloning or duplicating a packet that was obtained from the ingress data path, it must add new destination ports for the packet before it injects the packet into the ingress data path. For more information on this procedure, see Adding Extensible Switch Destination Port Data to a Packet.

- After the extension calls *CopyNetBufferListInfo*, the packet will be assigned the same source port information that was contained in the original packet.

  The extension can call *SetNetBufferListSource* to change the source port information in the packet's out-of-band (OOB) data.

  The extension may want the packet to be treated as if it originated from a particular port. This allows the policies for that port to be applied to the packet. The extension calls *SetNetBufferListSource* to change the source port for the packet.

  However, there may be situations where the extension may want to assign the packet's source port identifier to **NDIS_SWITCH_DEFAULT_PORT_ID**. For example, the extension may want to set the source port identifier to **NDIS_SWITCH_DEFAULT_PORT_ID** for proprietary control packets that are sent to a device on the external network.

- In the standard NDIS data path, non-extensible switch OOB data often has different values depending on whether the packet is being indicated as a send or a receive. For example, the

NDIS_IPSEC_OFFLOAD_V2_HEADER_NET_BUFFER_LIST_INFO OOB data is a union of send-and-receive–specific structures

In the extensible switch data path, all packets move through the extension driver stack as both sends and receives. Because of this, the non-extensible switch OOB data within the packet's NET_BUFFER_LIST structure will be in either a send or receive format through the duration of the flow through the driver stack.

The format of this OOB data depends on the source extensible switch port from which the packet arrived at the extensible switch. If the source port is connected to the external network adapter, the non-extensible switch OOB data will be in a receive format. For other ports, this OOB data will be in a send format.

The source port information is stored in the NDIS_SWITCH_FORWARDING_DETAIL_NET_BUFFER_LIST_INFO union in the OOB data of the packet's NET_BUFFER_LIST structure. The extension obtains the data by using the NET_BUFFER_LIST_SWITCH_FORWARDING_DETAIL macro.

Note If the extension clones a packet's NET_BUFFER_LIST structure, it must take the non-extensible switch OOB data into consideration if it adds or modifies the OOB data. The extension can call *CopyNetBufferListInfo* to copy all OOB data from a source packet to a cloned packet. This function will maintain the OOB send or receive format when the data is copied to the packet.

- When the extension clones a packet, the cloned packet data is located in local, or *trusted*, memory in the parent operating system of the Hyper-V parent partition. This memory cannot be accessed by the child partition. Therefore, it is considered "safe" from unsynchronized updates by the guest operating system that runs in that partition.

  After the original packet has been cloned, the extension must obtain the NDIS_SWITCH_FORWARDING_DETAIL_NET_BUFFER_LIST_INFO union in the cloned packet by using the NET_BUFFER_LIST_SWITCH_FORWARDING_DETAIL macro. The extension must set the **IsPacketDataSafe** member to TRUE. This specifies that all of the packet data is located in trusted memory.

Filtering and forwarding extensions must follow these guidelines for injecting cloned packets into the ingress or egress data path:

- The extension must call NdisFSendNetBufferLists to inject the cloned packet into the ingress data path. The extension must set the *SendFlags* parameter with the appropriate extensible switch flag settings. For more information about these flag settings, see Hyper-V Extensible Switch Send and Receive Flags.

When NDIS calls the extension's *FilterSendNetBufferListsComplete* function to complete the send request of the cloned packet, the extension must call *FreeNetBufferListForwardingContext* to free the allocated forwarding context. The extension must do this before it frees or reuses the **NET_BUFFER_LIST** structure for the packet.

Note The extension must inject the cloned packet into the ingress data path if it modifies the packet data or source port for a packet that it obtained from the egress data path. It must also inject the cloned packet into the ingress data path if the packet's destination ports are not preserved.

- The extension must call **NdisFIndicateReceiveNetBufferLists** to inject the cloned packet into the egress data path. The extension must set the *ReceiveFlags* parameter with the appropriate extensible switch flag settings.

  When NDIS calls the extension's *FilterReturnNetBufferLists* function to complete the receive request of the cloned packet, the extension must call *FreeNetBufferListForwardingContext* before it frees or reuses the **NET_BUFFER_LIST** structure for the packet.

  Note Before the forwarding extension calls **NdisFIndicateReceiveNetBufferLists**, it must have determined the cloned packet's destination ports and added this data to the packet's OOB data.

- If the extension clones a packet's **NET_BUFFER_LIST** structure, it must retain ownership of the original packet's **NET_BUFFER_LIST** structure until the cloned packet's send or receive request has completed. The extension must use the **ParentNetBufferList** member of the cloned packet's **NET_BUFFER_LIST** structure to link to the original packet's **NET_BUFFER_LIST** structure.

  Note In NDIS 6.30 (Windows Server 2012), the extension can use the **ParentNetBufferList** member to link to the original packet, but it is not required to do so. In NDIS 6.40 (Windows Server 2012 R2) and later, the extension is required to use the **ParentNetBufferList** member to link to the original packet.

  Once the cloned packet's send or receive request has completed, the extension must complete the send or receive request of the original packet.

  Note If the extension has cloned a packet's **NET_BUFFER_LIST** structure, it can complete the send or receive request of the original packet after it has been cloned.

- If the extension clones a packet, it can complete the send or receive request of the original packet as soon as it is cloned.

If the forwarding or filtering extension obtains a packet in the egress data path, it cannot inject a cloned version of the packet in this data path if the extension modified the packet data or changed the source port. However, the extension can inject these packets into the ingress data path. This allows the packet to be forwarded and filtered properly through the extensible switch data path.

Note Filtering extensions can only inject cloned packets into the ingress data path if the packet's destination ports are not preserved.

For example, assume that a packet with multiple destination ports was obtained in the extensible switch egress data path. If one destination port requires special handling, such as data encapsulation, the forwarding or filtering extension handles this by following these steps:

1. Exclude packet delivery to the port that requires special handling. The extension does this by setting the **IsExcluded** member of the destination port's **NDIS_SWITCH_PORT_DESTINATION** structure to a value of one. For more information on this procedure, see Excluding Packet Delivery to Extensible Switch Destination Ports.

2. Clone the original packet and perform the required handling of the packet data.

   Note The filtering extension must not add a destination port for the cloned packet. This data will be added later by the forwarding extension or the miniport edge of the extensible switch.

3. Forward the original packet on the egress data path by calling **NdisMIndicateReceiveNetBufferLists**.

4. Inject the cloned packet on the ingress data path by calling **NdisFSendNetBufferLists**.

For more information about the extensible switch ingress and egress data paths, see Hyper-V Extensible Switch Data Path.

Note Capturing extensions cannot clone packet traffic. However, they can originate packet traffic. For more information, see Originating Packet Traffic.

Forwarding Packets to Hyper-V Extensible Switch Ports

Article • 12/15/2021

This page describes how a Hyper-V extensible switch forwarding extension can forward packets to one or more ports. This type of extension can also forward packets to individual network adapters that are connected to the extensible switch external network adapter.

Note Only the extensible switch forwarding extension or the extensible switch itself can forward packets to extensible switch ports.

Note This page assumes that you are familiar with the information and diagrams in Overview of the Hyper-V Extensible Switch and Hybrid Forwarding.

Note In the extensible switch interface, NDIS filter drivers are known as *extensible switch extensions* and the driver stack is known as the *extensible switch driver stack*. For more information about extensions, see Hyper-V Extensible Switch Extensions.

If a forwarding extension is installed and enabled in the extensible switch driver stack, it is responsible for making forwarding decisions for each packet that it obtains on the extensible switch ingress data path. Based on these forwarding decisions, the extension adds destination ports into the destination port array in the out-of-band (OOB) data of the packet's **NET_BUFFER_LIST** structure. After the packet has completed its traversal of the extensible switch data path, the extensible switch interface delivers the packet to the specified destination ports.

Note If a forwarding extension is not installed or enabled, the extensible switch makes the forwarding decisions for packets it obtains from the ingress data path. The switch adds the destination ports to the OOB data of the packet's **NET_BUFFER_LIST** structure before it forwards the packet up the extensible switch egress data path.

Note If the packet is an NVGRE packet, the forwarding extension can add destination ports to the destination port array. However, the Hyper-V Network Virtualization (HNV) component of the extensible switch is responsible for determining the destination ports and forwarding the packet. For more information, see Hybrid Forwarding.

The forwarding extension can add port destinations only to packets obtained from the ingress data path. After the packet is forwarded up the egress data path, filtering and forwarding extensions can exclude packet delivery to extensible switch ports. For more information, see Excluding Packet Delivery to Extensible Switch Destination Ports.

Within the OOB data of a packet's NET_BUFFER_LIST structure, the data for destination ports are contained in an NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY structure. Each element in the array defines a destination port and is formatted as an NDIS_SWITCH_PORT_DESTINATION structure.

The forwarding extension can call the following Hyper-V Extensible Switch handler functions to manage the NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY structure and its NDIS_SWITCH_PORT_DESTINATION elements:

AddNetBufferListDestination
This function adds a single destination port to the NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY structure in the packet's OOB data.

GetNetBufferListDestinations
This function returns a pointer to the NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY structure in a packet's OOB data.

GrowNetBufferListDestinations
This function adds more destination port elements to the NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY structure of a packet's OOB data.

UpdateNetBufferListDestinations
This function commits the modifications that the extension made to add or exclude one or more destination ports for a packet. These changes are committed to the NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY structure in the packet's OOB data.

When the forwarding extension's *FilterSendNetBufferLists* function is called, the *NetBufferList* parameter contains a pointer to a linked list of NET_BUFFER_LIST structures. Each of these structures specifies a packet obtained from the ingress data path.

For each NET_BUFFER_LIST structure in this list, the forwarding extension adds destination ports for the packet by following these steps:

1. The extension makes forwarding decisions for the packet based on various types of criteria. These criteria include the following:

    - Policy criteria based on the packet's source port and network adapter connection. The forwarding extension obtains this information by using the NET_BUFFER_LIST_SWITCH_FORWARDING_DETAIL macro.

- Policy criteria for an extensible switch port based on the packet's payload data. For example, a policy for an extensible switch port may include a filter to allow delivery of only IP version 4 (IPv4) packets.

Note If the packet is an NVGRE packet, the HNV component of the extensible switch is responsible for forwarding the packet. However, the forwarding extension can apply its own policy criteria in the ingress and egress paths. For more information, see Hybrid Forwarding.

2. If the extension determines that the packet can be forwarded to one or more extensible switch ports, it must add destination ports to the packet's OOB data. For more information about this procedure, see Adding Extensible Switch Destination Port Data to a Packet.

   Note If the packet is an NVGRE packet, the forwarding extension is not required to add destination ports. For more information, see Hybrid Forwarding.

3. If the extension determines that the packet cannot be forwarded to any extensible switch port, it must drop the packet.

   Note This is not true if the packet is an NVGRE packet. For more information, see Hybrid Forwarding.

4. If the extension has added one or more destination ports for the packet, it must call **NdisFSendNetBufferLists** to forward the packet on the egress data path.

   Note If the packet is an NVGRE packet, the HNV component of the extensible switch is responsible for forwarding the packet. For more information, see Hybrid Forwarding.

For more information about the extensible switch ingress and egress data paths, see Hyper-V Extensible Switch Data Path.

Hyper-V Extensible Switch OID Requests

Article • 12/15/2021

The Hyper-V extensible switch interface includes object identifier (OID) requests that are used in the following ways:

- OID requests that are issued by an extensible switch extension to query the current configuration of the extensible switch. For example, the filter driver (also known as a *Hyper-V extensible switch extension*) can issue an OID query request of OID_SWITCH_NIC_ARRAY to obtain an array. Each element in the array specifies the configuration parameters of a network adapter that is associated with an extensible switch port.

  For more information, see Querying the Hyper-V Extensible Switch Configuration.

- OID requests that are issued by the extensible switch interface to notify underlying extensions about changes to the extensible switch configuration. For example, the protocol edge of the extensible switch issues an OID set request of OID_SWITCH_PORT_CREATE to notify extensions about the creation of an extensible switch port.

  For more information, see Receiving OID Requests about Hyper-V Extensible Switch Configuration Changes.

- OID requests from a Hyper-V child partition that are forwarded by the extensible switch interface to extensions over the extensible switch control path. This allows the extensions to obtain configuration information about the network interface that is used in the partition.

  For example, the protocol edge of the extensible switch in the extensibility interface forwards an OID set request of OID_802_3_ADD_MULTICAST_ADDRESS from a child partition down the extensible switch control path. This allows extensions to obtain the multicast address configuration that is used by the networking interface in that partition.

  For more information, see Forwarding OID Requests from a Hyper-V Child Partition.

For more information on how extensions and NDIS filter drivers handle OID requests, see Filter Module OID Requests.

Querying the Hyper-V Extensible Switch Configuration

Article • 12/15/2021

The Hyper-V extensible switch interface includes object identifier (OID) requests that are issued by an extensible switch extension to query the current configuration of the extensible switch, its ports, and its network adapter connections. These requests include the following OIDs:

OID_SWITCH_NIC_ARRAY
This OID query request returns an array. Each element in the array specifies the configuration parameters of a network adapter that is associated with an extensible switch port.

OID_SWITCH_PARAMETERS
This OID query request returns the current configuration of the extensible switch.

OID_SWITCH_PORT_ARRAY
This OID query request returns an array. Each element in the array specifies the configuration parameters for an extensible switch port.

OID_SWITCH_PORT_PROPERTY_ENUM
This OID method request returns an array. Each element in the array specifies the properties of a policy for a specified extensible switch port.

OID_SWITCH_PROPERTY_ENUM
This OID method request returns an array. Each element in the array specifies the properties of an extensible switch policy.

Note When a switch extension binds for a Hyper-v Extensible Switch, it must first issue the OID_SWITCH_PARAMETERS OID to obtain the basic switch information. If the **IsActive** member of the **NDIS_SWITCH_PARAMETERS** structure is FALSE, the extension must not issue the other query OIDs until the switch has finished activation. In this case, the **NetEventSwitchActivate** **NET_PNP_EVENT** notification specifies the switch activation event. If the **IsActive** member is TRUE at bind, the extension can safely issue the other query OIDs. Querying for the configuration while the Hyper-v Extensible Switch has not completed activation will result in the extension having an incomplete initial view of the switch configuration.

Note When an extension generates its own OID requests, it does this in the same way as any NDIS filter driver. For more information on how this is done, see Generating OID

Requests from an NDIS Filter Driver.

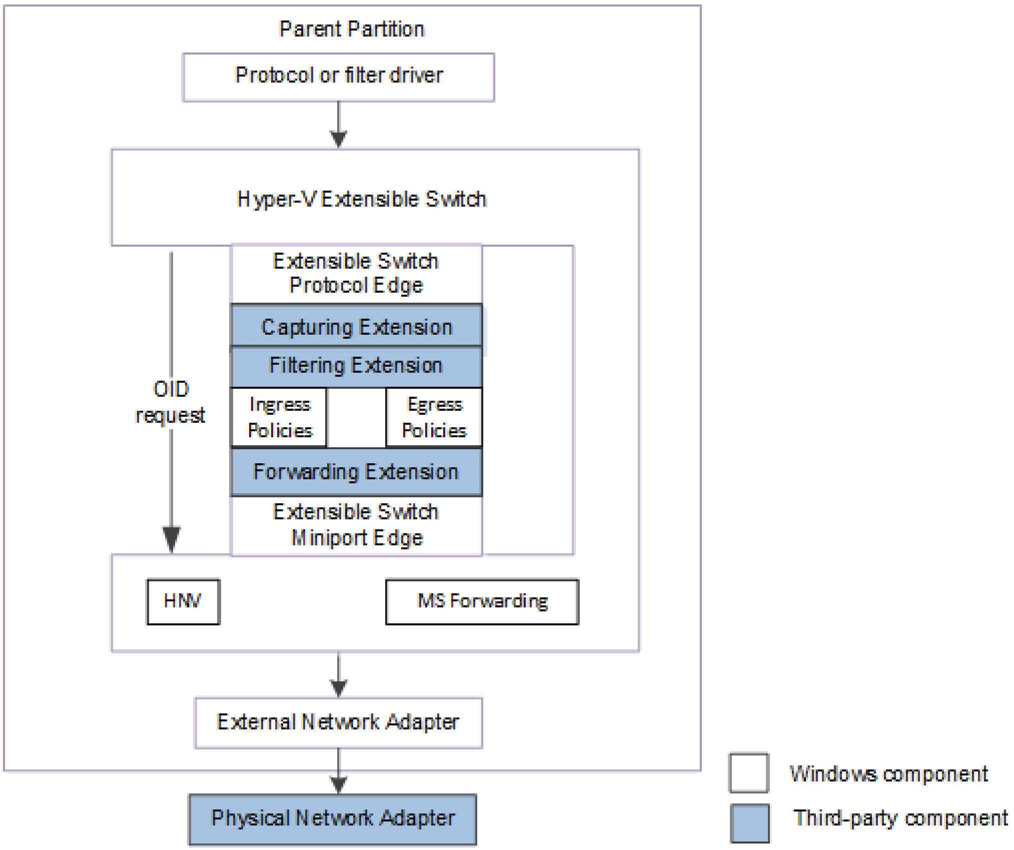
For more information on the control path for extensible switch OID requests, see Hyper-V Extensible Switch Control Path for OID Requests.

Receiving OID Requests about Hyper-V Extensible Switch Configuration Changes

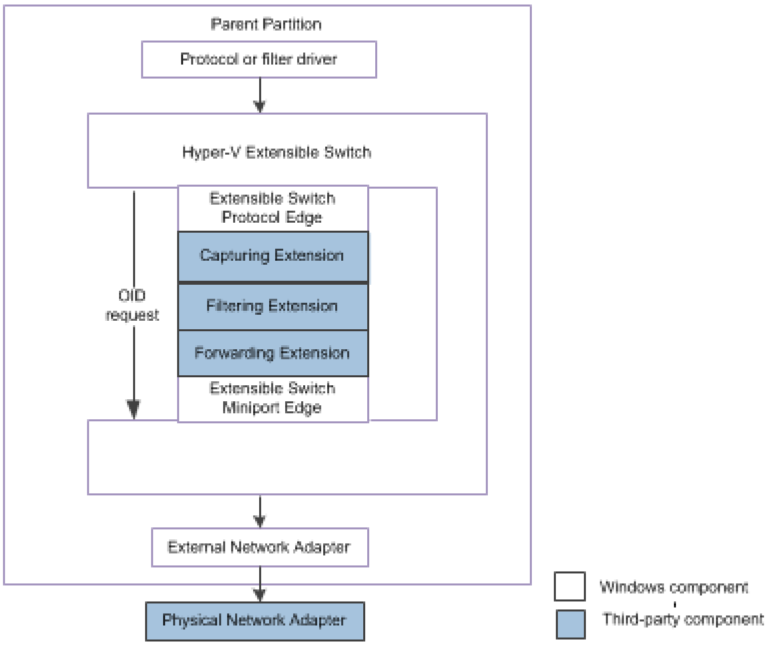
Article • 12/15/2021

The extensible switch interface notifies underlying extensions about changes to the extensible switch component configuration and policy parameters by issuing extensible switch object identifier (OID) set requests. These requests are issued by the protocol edge of the extensible switch to notify underlying extensions about changes to the extensible switch component configuration and policy parameters. These OID requests move through the extensible switch driver stack to the underlying miniport edge of the extensible switch.

The following figure shows the extensible switch control path for OID requests for NDIS 6.40 (Windows Server 2012 R2) and later.



The following figure shows the extensible switch control path for OID requests for NDIS 6.30 (Windows Server 2012).



Note In the extensible switch interface, NDIS filter drivers are known as *extensible switch extensions* and the driver stack is known as the *extensible switch driver stack*.

The protocol edge of the extensible switch issues OID set requests for the following types of notifications:

- Changes to the port configuration on the extensible switch.

  For example, the protocol driver issues OID_SWITCH_PORT_CREATE to notify underlying extensions about the creation of a port on the extensible switch. Similarly, the protocol driver issues OID_SWITCH_PORT_DELETE to notify extensions about the deletion of a port.

  For more information about this type of OID notification, see Hyper-V Extensible Switch Ports.

- Changes to the network adapter connection to a port on the extensible switch.

  For example, the protocol driver issues OID_SWITCH_NIC_CONNECT to notify underlying extensions about the connection of a network adapter to a port on the extensible switch. Similarly, the protocol driver issues OID_SWITCH_NIC_DISCONNECT to notify extensions that the network adapter has been disconnected from the port.

  For more information about this type of OID notification, see Hyper-V Extensible Switch Network Adapters.

- Changes to the extensible switch port or switch policies.

  For example, the protocol driver issues OID_SWITCH_PROPERTY_ADD to notify underlying extensions about the addition of an extensible switch property.

Similarly, the protocol driver issues OID_SWITCH_PORT_PROPERTY_DELETE to notify extensions about the deletion of a port property.

For more information about this type of OID notification, see Managing Hyper-V Extensible Switch Policies.

Note The extension is not notified of changes to the default port or switch policies that are managed by the underlying miniport edge of the extensible switch.

- Save or restore run-time port data.

  For example, the protocol driver issues OID_SWITCH_NIC_SAVE to notify underlying extensions to save run-time data for a specified port on the extensible switch. These OIDs are issued when the Hyper-V state is being saved or migrated to another host. Similarly, the protocol driver issues OID_SWITCH_NIC_RESTORE to notify extensions that run-time port data is being restored on the extensible switch.

  For more information about this type of OID notification, see Managing Hyper-V Extensible Switch Run-Time Data.

The extensible switch extension miniport driver is responsible for completing these OID requests. However, with some extensible switch OID requests, an underlying extension can fail an OID request to veto a notification. For example, when the extensible switch protocol driver notifies the filter drivers about a new port that will be created on the extensible switch, it issues an OID set request of OID_SWITCH_PORT_CREATE. An underlying filtering or forwarding extension can veto the port creation by completing the OID request with STATUS_DATA_NOT_ACCEPTED.

The extensible switch extension must follow these guidelines when its *FilterOidRequest* function is called for an extensible switch OID request:

- The extension must not modify any data that is pointed to by the *OidRequest* parameter.

- For some extensible switch OID requests, the extension can complete the OID request with STATUS_DATA_NOT_ACCEPTED. This vetoes the operation on an extensible switch component for which the OID request was issued.

  For example, the extension can complete the OID_SWITCH_NIC_CREATE request with STATUS_DATA_NOT_ACCEPTED. The driver may need to do this if it cannot satisfy its configured policies on the specified port to which the network connection is being created.

  The extension can complete requests in this manner for the following OIDs:

  - OID_SWITCH_NIC_CREATE
  - OID_SWITCH_PORT_CREATE
  - OID_SWITCH_PORT_PROPERTY_ADD
  - OID_SWITCH_PORT_PROPERTY_DELETE
  - OID_SWITCH_PORT_PROPERTY_UPDATE
  - OID_SWITCH_PROPERTY_ADD
  - OID_SWITCH_PROPERTY_DELETE
  - OID_SWITCH_PROPERTY_UPDATE

- If the extension does not complete the OID request, it must call **NdisFOidRequest** to forward the request down the extensible switch driver stack.

  Note Before the driver calls **NdisFOidRequest**, the driver must call **NdisAllocateCloneOidRequest** to allocate an **NDIS_OID_REQUEST** structure and transfer the request information to the new structure.

  The extension should monitor the completion result of the OID request when its *FilterOidRequestComplete* function is called. This allows the extension to determine whether the operation on an extensible switch component completed successfully or was vetoed by an underlying extension.

  For more information on how to filter and forward an OID request, see Filtering OID Requests in an NDIS Filter Driver.

- NDIS and overlying protocol and filter drivers can issue OID requests for hardware offload technologies to the underlying physical network adapter. This includes OID requests for offload technologies, such as virtual machine queue (VMQ), Internet Protocol security (IPsec), and single root I/O virtualization (SR-IOV).

  When these OID requests arrive at the extensible switch interface, it encapsulates the OID request inside an **NDIS_SWITCH_NIC_OID_REQUEST**. Then, the protocol edge of the extensible switch issues an OID request of OID_SWITCH_NIC_REQUEST that contains this structure.

- An extensible switch forwarding extension can provide support for an NDIS hardware offload technology on one or more physical adapters that are bound to the external network adapter. In this configuration, the extensible switch external network adapter is bound to the virtual miniport edge of an NDIS multiplexer (MUX) intermediate driver. The MUX intermediate driver is bound to a team of one or more physical networks on the host. This configuration is known as an *extensible switch team*. For more information about extensible switch teams, see Types of Physical Network Adapter Configurations.

In this configuration, the extensible switch extensions are exposed to every network adapter in the team. This allows the forwarding extension in the extensible switch driver stack to manage the configuration and use of individual network adapters in the team. For example, the extension can provide support for a load balancing failover (LBFO) solution over the team by forwarding outgoing packets to individual adapters. Such an extension is known as a *teaming provider*. For more information about teaming providers, see Teaming Provider Extensions.

By handling the OID request of OID_SWITCH_NIC_REQUEST, teaming providers can participate in the configuration of the adapter team for hardware offloads. For example, the extension can generate its own OID request of OID_SWITCH_NIC_REQUEST to configure a physical adapter with parameters for the hardware offload.

For more information on how to handle the OID_SWITCH_NIC_REQUEST OID request, see Forwarding OID Requests to Physical Network Adapters.

Note Extension filter drivers can generate OID requests of OID_SWITCH_NIC_REQUEST to issue private OIDs to any physical adapter that is bound to the extensible switch external network adapter.

Note Stack restart requests using **NdisFRestartFilter** will not complete while an extensible switch OID request is pending. For this reason, an extension that is waiting for a stack restart must complete any ongoing OID requests.

For more information on the control path for extensible switch OID requests, see Hyper-V Extensible Switch Control Path for OID Requests.

Forwarding OID Requests from a Hyper-V Child Partition

Article • 12/15/2021

Multicast object identifier (OID) requests, including OID_802_3_ADD_MULTICAST_ADDRESS and OID_802_3_DELETE_MULTICAST_ADDRESS, are issued by overlying protocol and filter drivers that run in the following:

- The management operating system that runs in the Hyper-V parent partition.
- The guest operating system that runs Windows Vista or a later version of the Windows operating system in the Hyper-V child partition.

The extensible switch interface forwards these OID requests down the extensible switch control path. This allows the extensions to obtain configuration information about the network interface that is used in the partition.

For example, the protocol edge of the extensible switch forwards an OID set request of OID_802_3_ADD_MULTICAST_ADDRESS from a child partition down the extensible switch control path. This allows extensions to obtain the multicast address configuration that is used by the networking interface in that partition.

When these multicast OID requests arrive at the extensible switch interface, the protocol edge of the extensible switch encapsulates the OID request within an **NDIS_SWITCH_NIC_OID_REQUEST** structure. The protocol edge also sets the members of this structure in the following way:

- The **SourcePortId** and **SourceNicIndex** members are set to the corresponding values for the port and network adapter used by the partition from which the OID request originated.

  Note If the multicast OID request was originated from the management operating system, the protocol edge sets these members to the values for the extensible switch internal network adapter.

- The **DestinationPortId** and **DestinationNicIndex** members are set to zero. This specifies that the encapsulated OID request is to be delivered to extensions in the control path.
- The **OidRequest** member is set to the address of an **NDIS_OID_REQUEST** structure for the encapsulated OID request.

The protocol edge then issues the OID_SWITCH_NIC_REQUEST request to forward the encapsulated OID request down the extensible switch control path. Underlying forwarding extensions can inspect these encapsulated OID requests and retain the multicast address information that they specify. For example, the extension may need this information if it originates multicast packets that it forwards to an extensible switch port.

For more information about the extensible switch control path, see Hyper-V Extensible Switch Control Path.

Managing Hyper-V Extensible Switch Source and Destination Port Data

Article • 12/15/2021

This section describes how a Hyper-V extensible switch extension manages the source and destination extensible switch port data within a packet's out-of-band (OOB) data. This section includes the following topics:

Managing Hyper-V Extensible Switch Source Port Data

Managing Hyper-V Extensible Switch Destination Port Data

Managing Hyper-V Extensible Switch Source Port Data

Article • 12/15/2021

This section describes how a Hyper-V extensible switch extension manages the source extensible switch port data within a packet's out-of-band (OOB) data. This section includes the following topics:

Querying a Packet's Extensible Switch Source Port Data

Modifying a Packet's Extensible Switch Source Port Data

Querying a Packet's Extensible Switch Source Port Data

Article • 12/15/2021

The Hyper-V extensible switch source port is specified by the **SourcePortId** member in the NDIS_SWITCH_FORWARDING_DETAIL_NET_BUFFER_LIST_INFO structure. This structure is contained in the out-of-band (OOB) forwarding context of the packet's NET_BUFFER_LIST structure. For more information on this context, see Hyper-V Extensible Switch Forwarding Context.

The extensible switch extension accesses the NDIS_SWITCH_FORWARDING_DETAIL_NET_BUFFER_LIST_INFO structure by using the NET_BUFFER_LIST_SWITCH_FORWARDING_DETAIL macro. The following example shows how the driver can obtain the source port identifier from the packet's **NDIS_SWITCH_FORWARDING_DETAIL_NET_BUFFER_LIST_INFO** structure.

```C++
PNDIS_SWITCH_FORWARDING_DETAIL_NET_BUFFER_LIST_INFO fwdDetail;
NDIS_SWITCH_PORT_ID sourcePortId;

fwdDetail = NET_BUFFER_LIST_SWITCH_FORWARDING_DETAIL(NetBufferList);
sourcePortId = fwdDetail->SourcePortId;
```

Modifying a Packet's Extensible Switch Source Port Data

Article • 12/15/2021

The Hyper-V extensible switch source port is specified by the **SourcePortId** member in the **NDIS_SWITCH_FORWARDING_DETAIL_NET_BUFFER_LIST_INFO** structure. This structure is contained in the out-of-band (OOB) forwarding context of the packet's **NET_BUFFER_LIST** structure. For more information about this context, see Hyper-V Extensible Switch Forwarding Context.

The extensible switch extension must follow these guidelines for modifying a packet's source port identifier:

- The extensible switch extension must call *SetNetBufferListSource* to modify the source port for a packet. The extension must not directly modify the **SourcePortId** member of the **NDIS_SWITCH_FORWARDING_DETAIL_NET_BUFFER_LIST_INFO** structure.

- If the extension is creating or cloning a packet, it must call the *AllocateNetBufferListForwardingContext* function after it calls **NdisAllocateNetBufferList**. This function allocates an extensible switch context area for the OOB data that is used for forwarding information for the packet.

  When the extension calls *AllocateNetBufferListForwardingContext*, the **SourcePortId** member is set to **NDIS_SWITCH_DEFAULT_PORT_ID**. This specifies that the packet originated from an extension instead of arriving at an extensible switch port.

  Packets with a source port of **NDIS_SWITCH_DEFAULT_PORT_ID** are treated by the extensible switch extension data path as privileged and trusted. Such traffic should not be subjected to the policies that are applied to packets from other source ports. For example, packets with a source port identifier of **NDIS_SWITCH_DEFAULT_PORT_ID** bypass the built-in extensible switch policies that are applied by the underlying miniport edge of the extensible switch. These policies include access control lists (ACLs) and quality of service (QoS).

  When the extension is originating packet traffic, it should use the source port of **NDIS_SWITCH_DEFAULT_PORT_ID** sparingly and carefully. In most cases, the extension should modify the source port identifier to an active port on the extensible switch. This allows the policies of that port to be applied to the packet.

However, there may be situations where the extension has to use the source port of **NDIS_SWITCH_DEFAULT_PORT_ID** for packets that it originates. For example, if the extension originates a control packet that has to be sent to its destination on the physical or virtual network, it should use **NDIS_SWITCH_DEFAULT_PORT_ID** for the source port identifier. This ensures that the packet will not be filtered and rejected by underlying extensions in the extensible switch driver stack.

Managing Hyper-V Extensible Switch Destination Port Data

Article • 12/15/2021

This section describes how a Hyper-V extensible switch extension manages the destination extensible switch port data within a packet's out-of-band (OOB) data. This section includes the following topics:

Querying a Packet's Extensible Switch Destination Port Data

Adding Extensible Switch Destination Port Data to a Packet

Excluding Packet Delivery to Extensible Switch Destination Ports

Querying a Packet's Extensible Switch Destination Port Data

Article • 12/15/2021

Each Hyper-V extensible switch destination port is specified by an **NDIS_SWITCH_PORT_DESTINATION** element within the **NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY** structure. This array is contained in the out-of-band (OOB) forwarding context of the packet's **NET_BUFFER_LIST** structure. For more information on this context, see Hyper-V Extensible Switch Forwarding Context.

The extensible switch extension calls the *GetNetBufferListDestinations* function to obtain a pointer to the **NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY** structure within a packet's **NET_BUFFER_LIST** structure. Individual **NDIS_SWITCH_PORT_DESTINATION** elements within this structure can be accessed by using the **NDIS_SWITCH_PORT_DESTINATION_AT_ARRAY_INDEX** macro.

To improve performance, a forwarding extension can call the *GrowNetBufferListDestinations* function instead of *GetNetBufferListDestinations* to obtain a pointer to the **NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY** structure. The extension does this if it determines that it needs additional array elements in the packet's OOB data for destination ports. For more information, see Adding Extensible Switch Destination Port Data to a Packet.

Note Only packets obtained from the extensible switch egress data path will contain destination port information. For more information, see Hyper-V Extensible Switch Data Path.

Adding Extensible Switch Destination Port Data to a Packet

Article • 12/15/2021

This topic describes how Hyper-V extensible switch forwarding extensions can specify the delivery of packets to one or more destination ports. These extensions can also forward packets to individual physical network adapters that are bound to the extensible switch external network adapter.

Note Only a forwarding extension or the switch itself can forward packets to extensible switch ports or individual network adapters.

The following figure shows the data path for packet traffic through the extensible switch driver stack for NDIS 6.40 (Windows Server 2012 R2) and later. Both figures also show the data path for packet traffic to or from the network adapters that are connected to extensible switch ports.

Each extensible switch destination port is specified by an **NDIS_SWITCH_PORT_DESTINATION** element within the **NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY** structure. This array is contained in the out-of-band (OOB) forwarding context of the packet's **NET_BUFFER_LIST** structure. For more information on this context, see Hyper-V Extensible Switch Forwarding Context.

If a forwarding extension is bound and enabled in the extensible switch driver stack, it is responsible for determining the destination ports for every packet obtained from the extensible switch ingress data path, unless the packet is an NVGRE packet. For more information about this data path, see Overview of the Hyper-V Extensible Switch Data Path. For more information about NVGRE packets, see Hybrid Forwarding.

Note If a forwarding extension is not bound or enabled in the driver stack, the extensible switch determines the destination ports for packets it obtains from the ingress data path.

The forwarding extension must follow these guidelines when it determines destination ports for a packet obtained on the ingress data path:

- The extension must initialize an **NDIS_SWITCH_PORT_DESTINATION** structure within the **NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY** structure with the destination port information.

If the destination port is not connected to the external network adapter, the extension must set the **NicIndex** member of the **NDIS_SWITCH_PORT_DESTINATION** structure to **NDIS_SWITCH_DEFAULT_NIC_INDEX**.

If the destination port is connected to the extensible switch external network adapter, the extension can specify the index of an underlying physical network adapter to forward the send request to. The extension does this by setting the **NicIndex** member to the nonzero NDIS_SWITCH_NIC_INDEX value of the destination network adapter that is bound to the external network adapter.

For more information, see Forwarding Packets to Physical Network Adapters.

- The extension must add destination ports to a packet's OOB data only for those ports that have active network adapter connections. If the extension had forwarded an OID_SWITCH_NIC_DISCONNECT request, it must not add a destination port that is associated with the disconnected network adapter.

- To improve performance, the extension must only add port destinations that are valid for packet delivery. In this case, the extension must set the **IsExcluded** member of the destination port's **NDIS_SWITCH_PORT_DESTINATION** structure to FALSE.

- To retain the 802.1Q virtual local area network (VLAN) data in a packet before it is delivered to a port, the extension sets the **PreserveVLAN** member to TRUE.

  To remove the 802.1Q virtual local area network (VLAN) data in a packet before it is delivered to a port, the extension sets the **PreserveVLAN** member to FALSE.

- To retain the 802.1Q priority data in a packet before it is delivered to a port, the extension sets the **PreservePriority** member to TRUE.

  To remove the 802.1Q priority data in a packet before it is delivered to a port, the extension sets the **PreservePriority** member to FALSE.

- If the forwarding extension adds multiple destination ports for a packet, it must follow these steps:

  1. The extension first accesses the packet's **NDIS_SWITCH_FORWARDING_DETAIL_NET_BUFFER_LIST_INFO** structure by using the **NET_BUFFER_LIST_SWITCH_FORWARDING_DETAIL** macro. The extension then reads the **NumAvailableDestinations** member to determine how many unused destination port elements are available in the destination port array. If the extension requires more destination ports than are available

in the array, it must call the *GrowNetBufferListDestinations* function to allocate space for additional destination ports in the array.

    When the extension calls *GrowNetBufferListDestinations*, it sets the *NumberOfNewDestinations* parameter to the number of new destination ports to be added to the packet.

    The extension also sets the *NetBufferLists* parameter to a pointer to the packet's **NET_BUFFER_LIST** structure.

    Note If there are available destination ports in the array, the extension should not call *GrowNetBufferListDestinations*.

  2. If the *GrowNetBufferListDestinations* function returns successfully, it has added the additional destination ports to the end of the destination array in the **NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY** structure. A pointer to this structure is returned in the *Destinations* parameter.

     Note If the *GrowNetBufferListDestinations* function cannot allocate the requested number of destination ports, it returns NDIS_STATUS_RESOURCES.

  3. The extension specifies new destination port elements in the **NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY** structure. The extension initializes each new destination port as an **NDIS_SWITCH_PORT_DESTINATION** structure.

     The extension initializes new destination ports to the array starting at the **NumDestinations** offset. **NumDestinations** is a member of the **NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY** structure.

  4. After the extension has finished adding or modifying destination port elements, it must call *UpdateNetBufferListDestinations* to commit those changes.

- If the extension adds a single destination port for a packet, it must follow these steps:

  1. The extension initializes the destination port information for the packet in an extension-allocated **NDIS_SWITCH_PORT_DESTINATION** structure.

  2. The extension calls *AddNetBufferListDestination* to commit the changes to the **NET_BUFFER_LIST** structure for the packet. The extension passes the address of the **NDIS_SWITCH_PORT_DESTINATION** structure in the *Destination* parameter.

Note The extension should not call the *UpdateNetBufferListDestinations* function to commit the changes to a packet with only one destination port.

- When the forwarding extension calls *AddNetBufferListDestination* or *UpdateNetBufferListDestinations* to commit the changes for destination ports, the extensible switch interface will not delete the extensible switch ports that are specified in the elements of the **NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY** structure. After the packet send or receive operation is complete, the interface is free to delete the port if it is necessary.

  Note After the forwarding extension commits the changes for destination ports to the forwarding context, destination ports cannot be removed and only the **IsExcluded** member of a destination port's **NDIS_SWITCH_PORT_DESTINATION** structure can be changed. For more information, see Excluding Packet Delivery to Extensible Switch Destination Ports.

- The forwarding extension must synchronize its handling of object identifier (OID) set requests of OID_SWITCH_NIC_DISCONNECT with its code that adds destination ports for the disconnected network adapter.

  If the forwarding extension's *FilterOidRequest* is called for an OID_SWITCH_NIC_DISCONNECT request, the extension can do one of the following:

  - If the extension called **NdisFOidRequest** to forward this OID request, it must not specify the port with the disconnected network adapter as a destination port for the packet.

    Note If the only destination port for the packet is the one with the disconnected network adapter, the extension must drop the packet.

  - The extension can return NDIS_STATUS_PENDING to complete the request asynchronously. This allows the extension to add the port with the disconnected network adapter as a destination port for the packet. This also allows the extension to call *AddNetBufferListDestination* or *UpdateNetBufferListDestinations* and complete the addition of destination ports to a packet.

    The extension may want to do this for packets that it has to forward to a port before it is torn down.

    Note If the extension returns NDIS_STATUS_PENDING, it can also call *ReferenceSwitchPort* to increment the reference counter for the port with the disconnected network adapter. However, the extension cannot forward the OID request until after it calls *DereferenceSwitchPort* to decrement the reference counter for the port.

- If the number of destination ports is zero, the forwarding extension must call **NdisMSendNetBufferListsComplete** to drop the packet. The extension must also call *ReportFilteredNetBufferLists* to notify the extensible switch interface about the dropped packet.

  Note If the forwarding extension obtained a linked list of **NET_BUFFER_LIST** structures for multiple packets from the ingress data path, it should create a separate list of dropped packets. By doing this, the extension can call **NdisMSendNetBufferListsComplete** and *ReportFilteredNetBufferLists* just once.

- If the number of destination ports is greater than zero, the forwarding extension must call **NdisFSendNetBufferLists** to forward the packet over the ingress data path to the miniport edge of the extensible switch.

  Note If the forwarding extension obtained a linked list of **NET_BUFFER_LIST** structures for multiple packets from the ingress data path, it should create a separate list of forwarded packets. By doing this, the extension can call **NdisFSendNetBufferLists** just once to forward the list of packets. In addition, the extension should maintain separate lists to forward packets that have the same destination ports. For more information, see Hyper-V Extensible Switch Send and Receive Flags.

Excluding Packet Delivery to Extensible Switch Destination Ports

Article • 12/15/2021

This topic describes how Hyper-V extensible switch extensions can exclude the delivery of packets to extensible switch ports. The destination ports for a packet are specified within the out-of-band (OOB) forwarding context within the packet's **NET_BUFFER_LIST** structure. For more information on this context, see Hyper-V Extensible Switch Forwarding Context.

Note This page assumes that you are familiar with the information and diagrams in Overview of the Hyper-V Extensible Switch and Hybrid Forwarding.

Note In the extensible switch interface, NDIS filter drivers are known as *extensible switch extensions* and the driver stack is known as the *extensible switch driver stack*. For more information about the extensions, see Hyper-V Extensible Switch Extensions.

Filtering and forwarding extensions can exclude the delivery of packets obtained on the extensible switch ingress or egress data paths. Excluding packet delivery can be done in the following ways:

- The extension can drop the packet by completing the packet request or indication. This excludes the delivery of a packet to any extensible switch port. This method can be used on packets that have one or more destination ports.

  For packets obtained on the extensible switch ingress data path, the extension completes the packet send request by calling **NdisFSendNetBufferListsComplete**.

  For packets obtained on the extensible switch egress data path, the extension completes the packet receive indication by calling **NdisFReturnNetBufferLists**.

- For packets obtained on the egress data path with multiple destination ports, the extension can exclude packet delivery by modifying the data for one or more destination ports. The extension does this by setting the **IsExcluded** member of the destination port's **NDIS_SWITCH_PORT_DESTINATION** structure to a value of one. This method allows the packet to be delivered to those ports whose **IsExcluded** value is set to zero.

  Note Packets obtained on the ingress data path do not contain destination ports. This data is only available after the extensible switch forwards the packet up the egress data path.

After the extension has modified the destination port's **IsExcluded** value, it must forward the packet in the egress data path to overlying extensions. However, if the **IsExcluded** data for all the packet's destination ports is set to one, the extension should drop the packet by completing the packet receive indication instead of forwarding it.

Note After an extension has set the destination port's **IsExcluded** value to one, overlying extensions on the egress data path cannot change this value to zero.

Note Capturing extensions cannot exclude the delivery of packets to extensible switch ports.

Filtering and forwarding extensions must follow these guidelines for excluding packet delivery to extensible switch ports:

- On the extensible switch ingress data path, filtering and forwarding extensions can exclude packet delivery based on a policy criteria for a packet's source port or data.

  The source port information is stored in the **NDIS_SWITCH_FORWARDING_DETAIL_NET_BUFFER_LIST_INFO** union in the OOB data of the packet's **NET_BUFFER_LIST** structure. The extension obtains the data by using the **NET_BUFFER_LIST_SWITCH_FORWARDING_DETAIL** macro.

  If the extension excludes the delivery of a packet obtained from the ingress data path, it must drop the packet by completing the packet send request.

- On the extensible switch ingress data path, forwarding extensions determine a packet's destination ports and add this information to the packet's OOB data. Based on policy criteria enforced by the extension, it can exclude packet delivery to a port by not adding its destination port information to the OOB data.

  For more information about this procedure, see Adding Extensible Switch Destination Port Data to a Packet.

- On the extensible switch egress data path, filtering and forwarding extensions can exclude the delivery of the packet based on policy criteria. For example, filtering extensions can exclude packet delivery based on policy criteria for a packet's source port or destination ports.

  Extensions exclude the delivery of a packet to destination ports by following these steps:

  1. The extension obtains the packet's destination ports by calling *GetNetBufferListDestinations*. If the call returns NDIS_STATUS_SUCCESS, the *Destinations* parameter contains a pointer to an

NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY structure. This structure specifies the extensible switch destination ports of the packet. Each destination port is formatted as an NDIS_SWITCH_PORT_DESTINATION structure.

Note If the **NumDestinations** member of the NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY structure contains a value of zero, the packet has no data for destination ports.

2. The extension excludes the packet delivery to an extensible switch port by setting the **IsExcluded** member of the destination port's NDIS_SWITCH_PORT_DESTINATION structure to a value of one.

   Note If the extension excludes delivery of the packet to all of its destination ports, the extension must drop the packet by completing the packet's receive indication.

3. If the extension excludes delivery to one or all destination ports in a packet, it must do the following:

   - The extension must call *UpdateNetBufferListDestinations* to commit these changes to the packet's OOB data.

   - The extension must call *ReportFilteredNetBufferLists*. When this function is called, the extensible switch interface increments counters and logs events for the excluded packet. The extension must make this call before it forwards the packet in the extensible switch data path from which it obtained the packet.

   Similarly, if the extension completes the packet send request or indication to exclude delivery to all ports for the packet, it must also call *ReportFilteredNetBufferLists*.

   Note The extension can create a linked list of NET_BUFFER_LIST structures for packets that the extension is excluding. When the extension calls *ReportFilteredNetBufferLists*, it sets the *NetBufferLists* parameter to a pointer to the linked list.

For more information about the extensible switch ingress and egress data paths, see Hyper-V Extensible Switch Data Path.

Managing Hyper-V Extensible Switch Policies

Article • 12/15/2021

This section describes how a Hyper-V extensible switch extension manages port and switch policies. This section includes the following topics:

Managing Port Policies

Managing Switch Policies

For more information on extensible switch policies, see Overview of Hyper-V Extensible Switch Policies.

Managing Port Policies

Article • 12/15/2021

Hyper-V extensible switch filtering and forwarding extensions can be provisioned with the properties of standard and custom port properties. Once provisioned, these extensions enforce the policies when they filter packets obtained on the extensible switch ingress data path. For more information about these policies, see Port Policies.

The Hyper-V extensible switch interface uses the following object identifiers (OIDs) to provision filtering and forwarding extensions with the properties of standard and custom port policies:

OID_SWITCH_PORT_PROPERTY_ADD
This OID set request is issued by the protocol edge of the extensible switch to notify underlying extensions of the addition of a property at the WMI management layer. The **InformationBuffer** of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SWITCH_PORT_PROPERTY_PARAMETERS** structure.

Note Custom port properties are specified by an **NDIS_SWITCH_PORT_PROPERTY_TYPE** enumeration value of **NdisSwitchPortPropertyTypeCustom**. Standard port properties are specified by an **NDIS_SWITCH_PORT_PROPERTY_TYPE** enumeration value of **NdisSwitchPortPropertyTypeSecurity**, **NdisSwitchPortPropertyTypeVlan**, and **NdisSwitchPortPropertyTypeProfile**.

OID_SWITCH_PORT_PROPERTY_UPDATE
This OID set request is issued by the protocol edge of the extensible switch to inform underlying extensions of the update of a property at the WMI management layer. The **InformationBuffer** of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SWITCH_PORT_PROPERTY_PARAMETERS** structure.

OID_SWITCH_PORT_PROPERTY_DELETE
This OID set request is issued by the protocol edge of the extensible switch to inform underlying extensions of the deletion of a property at the WMI management layer. The **InformationBuffer** of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SWITCH_PORT_PROPERTY_DELETE_PARAMETERS** structure.

OID_SWITCH_PORT_PROPERTY_ENUM
This OID method request is sent by the extension to query the underlying miniport edge of the extensible switch about the currently configured properties for a specified port on the extensible switch. The **InformationBuffer** of the **NDIS_OID_REQUEST** structure contains a pointer to a buffer. This buffer contains the following data:

- An NDIS_SWITCH_PORT_PROPERTY_ENUM_PARAMETERS structure that specifies the parameters for the policy enumeration of a specified port.

- An array of NDIS_SWITCH_PORT_PROPERTY_ENUM_INFO structures. Each of these structures contains information about the properties of an extensible switch port policy.

  Note If the **NumProperties** member of the NDIS_SWITCH_PORT_PROPERTY_ENUM_PARAMETERS structure is set to zero, no NDIS_SWITCH_PORT_PROPERTY_ENUM_INFO structures are returned.

Note The extension must not originate OID set requests of OID_SWITCH_PORT_PROPERTY_ADD. OID_SWITCH_PORT_PROPERTY_UPDATE, or OID_SWITCH_PORT_PROPERTY_DELETE.

The extensible switch extension must follow these guidelines when it handles an OID set request of OID_SWITCH_PORT_PROPERTY_ADD, OID_SWITCH_PORT_PROPERTY_UPDATE, or OID_SWITCH_PORT_PROPERTY_DELETE:

- The extension must not modify the NDIS_SWITCH_PORT_PROPERTY_PARAMETERS or NDIS_SWITCH_PORT_PROPERTY_DELETE_PARAMETERS structure that is associated with the OID request.

- The extension must handle these OID requests if the extension manages the property. Depending on the OID request, the extension must inspect the following members of the NDIS_SWITCH_PORT_PROPERTY_PARAMETERS or NDIS_SWITCH_PORT_PROPERTY_DELETE_PARAMETERS structures to determine whether it manages the port property:

  - The **PropertyType** member. This member specifies the type of the port property. Custom port properties have a **PropertyType** member value of **NdisSwitchPortPropertyTypeCustom**. Standard port properties have other property type values. For example, standard VLAN port policies have a property type value of **NdisSwitchPortPropertyTypeVlan**.

  - The **PropertyId** member. This member specifies a proprietary GUID value for a custom port property. This GUID value is created by the independent software vendor (ISV) who also defines the format of the custom extensible switch property.

    Note The extension must ignore this member for standard port policies.

- The extension must handle an OID_SWITCH_PORT_PROPERTY_UPDATE set request if the extension was previously provisioned with a port property that matches the following members of the **NDIS_SWITCH_PROPERTY_PARAMETERS** structure:

  - The **PropertyType** member.

  - The **PropertyId** member.

    Note The extension must ignore this member for standard port policies.

  - The **PropertyVersion** member. This member specifies the version of the port property that the extension was provisioned with.

  - The **PropertyInstanceId** member. This member specifies the instance of the port property that the extension was provisioned with.

- The filtering or forwarding extension can veto the addition or update of a port policy that it manages. The extension does this by completing the OID request with STATUS_DATA_NOT_ACCEPTED.

  Note Capturing extensions must not veto the addition or update of a port policy. Instead, it must forward the OID request down the extensible switch control path.

- A forwarding extension can fail the OID request for standard port properties that it does not support or if the property conflicts with its own policy configuration. In this case, the extension must complete the OID request and return the appropriate NDIS status code to report the failure.

- If the extension successfully handles the OID set request for a standard port policy, it must not complete the OID request and must forward it down the extensible switch control path.

- If the capturing or filtering extension successfully handles the OID set request for a custom port policy, it must not complete the OID request and must forward it down the extensible switch control path.

  If the forwarding extension successfully handles the OID set request for a custom port policy, it must complete the OID request and return the appropriate NDIS_STATUS_*Xxx* value.

- If the extension does not complete the OID set request, it must call **NdisFOidRequest** to forward the OID request down the extensible switch driver stack. In this case, the extensions should monitor the completion status of the OID to detect whether an underlying extension has failed the OID request.

Managing Switch Policies

Article • 12/15/2021

Hyper-V extensible switch filtering and forwarding extensions can be provisioned with the properties of custom switch properties. Once provisioned, these extensions enforce the policies when they filter packets obtained on the extensible switch ingress data path. For more information about these policies, see Switch Policies.

The Hyper-V extensible switch interface uses the following object identifiers (OIDs) to provision filtering and forwarding extensions with the properties of custom switch policies:

OID_SWITCH_PROPERTY_ADD
This OID set request is issued by the protocol edge of the extensible switch to notify underlying extensions of the addition of a property at the WMI management layer. The **InformationBuffer** of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SWITCH_PROPERTY_PARAMETERS** structure.

Note Custom switch properties are specified by an **NDIS_SWITCH_PROPERTY_TYPE** enumeration value of **NdisSwitchPropertyTypeCustom**.

OID_SWITCH_PROPERTY_UPDATE
This OID set request is issued by the protocol edge of the extensible switch to notify underlying extensions of the update of a property at the WMI management layer. The **InformationBuffer** of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SWITCH_PROPERTY_PARAMETERS** structure.

OID_SWITCH_PROPERTY_DELETE
This OID set request is issued by the protocol edge of the extensible switch to notify underlying extensions of the deletion of a property at the WMI management layer. The **InformationBuffer** of the **NDIS_OID_REQUEST** structure contains a pointer to an **NDIS_SWITCH_PROPERTY_DELETE_PARAMETERS** structure.

OID_SWITCH_PROPERTY_ENUM
This OID method request is sent by the extension to query the underlying miniport edge of the extensible switch about the currently configured switch properties on the extensible switch. The **InformationBuffer** of the **NDIS_OID_REQUEST** structure contains a pointer to a buffer. This buffer contains the following data:

- An **NDIS_SWITCH_PROPERTY_ENUM_PARAMETERS** structure that specifies the parameters for the property enumeration of a switch policy.

- An array of **NDIS_SWITCH_PROPERTY_ENUM_INFO** structures. Each of these structures contains information about the properties of a switch policy.

  Note If the **NumProperties** member of the **NDIS_SWITCH_PROPERTY_ENUM_PARAMETERS** structure is set to zero, no **NDIS_SWITCH_PROPERTY_ENUM_INFO** structures are returned.

Note The extension must not originate OID set requests of OID_SWITCH_PROPERTY_ADD. OID_SWITCH_PROPERTY_UPDATE, or OID_SWITCH_PROPERTY_DELETE.

The extensible switch extension must follow these guidelines when it handles an OID set request of OID_SWITCH_PROPERTY_ADD, OID_SWITCH_PROPERTY_UPDATE, or OID_SWITCH_PROPERTY_DELETE:

- The extension must not modify the **NDIS_SWITCH_PROPERTY_PARAMETERS** or **NDIS_SWITCH_PROPERTY_DELETE_PARAMETERS** structure that is associated with the OID request.

- The extension must handle an OID_SWITCH_PROPERTY_UPDATE or OID_SWITCH_PROPERTY_DELETE set request if the extension has been previously provisioned with a switch property that matches the following members of the **NDIS_SWITCH_PROPERTY_PARAMETERS** or **NDIS_SWITCH_PROPERTY_DELETE_PARAMETERS** structure:

  - The **PropertyType** member that specifies the type of switch property.

    Note Starting with NDIS 6.30, only switch properties of **NdisSwitchPropertyTypeCustom** are specified by the **NDIS_SWITCH_PROPERTY_PARAMETERS** or **NDIS_SWITCH_PROPERTY_DELETE_PARAMETERS** structures.

  - The **PropertyId** member that specifies a proprietary GUID value that the extension recognizes. This GUID value is created by the independent software vendor (ISV) who also defines the format of the custom extensible switch policy property.

    Note A custom extensible switch policy property is contained within an **NDIS_SWITCH_PROPERTY_CUSTOM** structure.

- If the extension handles these OID set requests, the extension must update or delete the switch policy that matches the following members of the **NDIS_SWITCH_PROPERTY_PARAMETERS** structure:

  - The **PropertyVersion** member that specifies the version of the extensible switch policy.

  - The **PropertyInstanceId** member that specifies the instance of the extensible switch policy.

  If the values of these members do not match a switch policy property for which the extension has been previously provisioned, the extension must fail the OID set request with NDIS_STATUS_INVALID_PARAMETER. Otherwise, the extension must complete the OID set request and return NDIS_STATUS_SUCCESS.

- The filtering or forwarding extension can veto the addition, deletion, or update of a switch policy. The extension does this by completing the OID request with STATUS_DATA_NOT_ACCEPTED.

  Note Capturing extensions must not veto the addition or update of a switch policy. Instead, it must forward the OID request down the extensible switch control path.

- If the capturing or filtering extension successfully handles the OID set request for a custom switch policy, it must not complete the OID request and must forward it down the extensible switch control path.

  If the forwarding extension successfully handles the OID set request for a custom switch policy, it must complete the OID request and return the appropriate NDIS_STATUS_*Xxx* value.

- If the extension does not complete the OID set request, it must call **NdisFOidRequest** to forward the OID request down the extensible switch driver stack. In this case, the extensions should monitor the completion status of the OID to detect whether an underlying extension has failed the OID request.

Managing Hyper-V Extensible Switch Feature Status Information

Article • 12/15/2021

The Hyper-V extensible switch interface supports the ability to obtain custom status information for an extensible switch or one of its ports. This status information is known as a feature status information.

This section includes the following topics:

Managing Custom Port Feature Status Information

Managing Custom Switch Feature Status Information

For more information on feature status information, see Hyper-V Extensible Switch Feature Status Information.

Managing Custom Port Feature Status Information

Article • 12/15/2021

The Hyper-V extensible switch interface uses the following object identifier (OID) to query custom status information for an extensible switch port. This status information is known as *port feature status* information:

OID_SWITCH_PORT_FEATURE_STATUS_QUERY
This OID method request is issued by the protocol edge of the extensible switch to obtain the custom feature status information for a specified port property.

After a successful return from this OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to a buffer. This buffer contains the following data:

- An **NDIS_SWITCH_PORT_FEATURE_STATUS_PARAMETERS** structure that specifies the custom feature status information that is to be returned.

  Note For a custom feature status, the **FeatureStatusType** member is set to **NdisSwitchPortPropertyTypeCustom**.

- An **NDIS_SWITCH_PORT_FEATURE_STATUS_CUSTOM** structure that contains the status information about a custom property assigned to an extensible switch port.

  When the protocol edge of the extensible switch issues the OID_SWITCH_PORT_FEATURE_STATUS_QUERY request, it sets the **FeatureStatusCustomBufferLength** and **FeatureStatusCustomBufferOffset** members to a location in the **InformationBuffer** member that the extension can use to return the feature status information.

The extensible switch extension must follow these guidelines when it receives an OID method request of OID_SWITCH_PORT_FEATURE_STATUS_QUERY:

- The extension must handle the OID request if it manages a custom extensible switch port property that matches the **FeatureStatusId** member of the **NDIS_SWITCH_PORT_FEATURE_STATUS_PARAMETERS** structure.

- If the extension handles the OID method request, it must return the feature status information that matches the parameters specified by the **NDIS_SWITCH_PORT_FEATURE_STATUS_PARAMETERS** structure.

  If the feature status buffer is too small, the extension must fail the OID request with NDIS_STATUS_INVALID_LENGTH. The extension must set the **DATA.SET_INFORMATION.BytesNeeded** member in the **NDIS_OID_REQUEST** structure to the minimum buffer size that is required.

  Otherwise, the extension must return the feature status information and complete the OID request with NDIS_STATUS_SUCCESS.

- If the extension does not manage the custom extensible switch property, it must call **NdisFOidRequest** to forward the OID request down the extensible switch driver stack.

  For more information about how to forward OID requests, see Filtering OID Requests in an NDIS Filter Driver.

For more information about how to define and register port feature status information, see Custom Port Feature Status.

Managing Custom Switch Feature Status Information

Article • 12/15/2021

The Hyper-V extensible switch interface uses the following object identifier (OID) to query custom status information for the extensible switch. This status information is known as *switch feature status* information:

OID_SWITCH_FEATURE_STATUS_QUERY
This OID method request is issued by the protocol edge of the extensible switch to obtain the custom feature status information for a specified switch property.

After a successful return from this OID method request, the **InformationBuffer** member of the **NDIS_OID_REQUEST** structure contains a pointer to a buffer. This buffer contains the following data:

- An **NDIS_SWITCH_FEATURE_STATUS_PARAMETERS** structure that specifies the custom feature status information that is to be returned.

  Note For a custom feature status, the **FeatureStatusType** member is set to **NdisSwitchPropertyTypeCustom**.

- An **NDIS_SWITCH_FEATURE_STATUS_CUSTOM** structure that contains the status information about a custom property assigned to an extensible switch port.

  When the protocol edge of the extensible switch issues the OID_SWITCH_FEATURE_STATUS_QUERY request, it sets the **FeatureStatusCustomBufferLength** and **FeatureStatusCustomBufferOffset** members to a location in the **InformationBuffer** member that the extension can use to return the feature status information.

The extensible switch extension must follow these guidelines when it receives an OID method request of OID_SWITCH_FEATURE_STATUS_QUERY:

- The extension must handle the OID request if it manages a custom extensible switch feature status that matches the **FeatureStatusId** member of the **NDIS_SWITCH_FEATURE_STATUS_PARAMETERS** structure.

- If the extension handles the OID method request, it must return the feature status information that matches the parameters specified by the **NDIS_SWITCH_FEATURE_STATUS_PARAMETERS** structure.

If the feature status buffer is too small, the extension must fail the OID request with NDIS_STATUS_INVALID_LENGTH. The extension must set the **DATA.SET_INFORMATION.BytesNeeded** member in the **NDIS_OID_REQUEST** structure to the minimum buffer size that is required.

Otherwise, the extension must return the feature status information and complete the OID request with NDIS_STATUS_SUCCESS.

- If the extension does not manage the custom extensible switch feature status, it must call **NdisFOidRequest** to forward the OID request down the extensible switch driver stack.

  For more information about how to forward OID requests, see Filtering OID Requests in an NDIS Filter Driver.

For more information about how to define and register switch feature status information, see Custom Switch Feature Status.

Managing Hyper-V Extensible Switch Run-Time Data

Article • 12/15/2021

This topic describes save and restore operations for Hyper-V extensible switch extensions. These operations allow an extension to save and restore run-time data for individual extensible switch network adapters(NICs). These operations are performed when a Hyper-V child partition that has a network adapter connection to an extensible switch port is being stopped or started.

Saving Hyper-V Extensible Switch Run-Time Data

This section describes the operation by which a Hyper-V Extensible Switch extension can save run-time data for individual network adapters (NICs). This operation is performed when a Hyper-V child partition with a network adapter connection to an extensible switch port is being stopped or its state is being saved.

Handling the OID_SWITCH_NIC_SAVE Request

When a Hyper-V child partition with a network adapter connection to an extensible switch port is stopped or its state is saved, the Hyper-V extensible switch interface is notified. This causes the protocol edge of the extensible switch to issue an object identifier (OID) method request of OID_SWITCH_NIC_SAVE down the extensible switch driver stack. When an extensible switch extension receives this OID request, it can save its run-time data for the specified network adapter connection that is attached to the child partition.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure for the OID_SWITCH_NIC_SAVE request contains a pointer to an **NDIS_SWITCH_NIC_SAVE_STATE** structure. This structure is allocated by the protocol edge of the extensible switch and initialized in the following way:

- The **Header** member is initialized to contain the current type, revisionof the **NDIS_SWITCH_NIC_SAVE_STATE** structure. Size is set to the full buffer size.
- The **PortId** member contains the unique identifier of the extensible switch port for which the save operation is being performed.

When it receives the OID_SWITCH_NIC_SAVE method request, the extension does the following:

1. The extension reads the **PortId** member of the **NDIS_SWITCH_NIC_SAVE_STATE** structure.

2. If the extension has run-time data to save for the specified NIC, it saves its data within the **NDIS_SWITCH_NIC_SAVE_STATE** structure starting with *SaveDataOffset* bytes from the start of the structure. The extension then completes the OID method request with NDIS_STATUS_SUCCESS.

3. If the **NDIS_SWITCH_NIC_SAVE_STATE** structure does not provide a sufficient buffer to hold the runtime state, the extension the extension sets the method structure's *BytesNeeded* field to **NDIS_SIZEOF_NDIS_SWITCH_NIC_SAVE_STATE_REVISION_1** plus the amount of buffer necessary to hold the save data, and completes the OID with **NDIS_STATUS_BUFFER_TOO_SHORT**. The OID will be re-issued with the required size.

4. If the extension does not have run-time data to save for the specified NIC, it must call **NdisFOidRequest**. This forwards the OID method request to underlying drivers in the extensible switch driver stack. For more information about this procedure, see Filtering OID Requests in an NDIS Filter Driver.

If the extension has run-time port data to save, it must follow these guidelines when it saves run-time port data within the **NDIS_SWITCH_NIC_SAVE_STATE** structure:

1. The extension sets the **ExtensionId** member to the GUID value that uniquely identifies the driver.

2. The extension sets the **ExtensionFriendlyName** member to the name of the driver.

   Note The NDIS_SWITCH_EXTENSION_FRIENDLYNAME data type is type-defined by the **IF_COUNTED_STRING** structure. A string that is defined by this structure does not have to be null-terminated. However, the length of the string must be set in the **Length** member of this structure. If the string is NULL-terminated, the **Length** member must not include the terminating NULL character.

3. If a feature class is associated with the saved run-time data, the extension sets the **FeatureClassId** with the GUID that uniquely identifies the class.

   Note If a feature class is not associated with the saved run-time data, the extension sets the **FeatureClassId** to zero.

4. The extension copies the run-time data to the **SaveData** member and sets the **SaveDataSize** member to the size, in bytes, of the run-time data.

Note The extension must not change the **Header** or **PortId** members of the **NDIS_SWITCH_NIC_SAVE_STATE** structure.

OID method requests of OID_SWITCH_NIC_SAVE are ultimately handled by the underlying miniport edge of the extensible switch. Once this OID method request has been forwarded to the miniport driver through the extensible switch driver stack, the miniport driver completes the OID request with NDIS_STATUS_SUCCESS. This notifies the protocol edge of the extensible switch that all extensions in the extensible switch driver stack have been queried for run-time port data. The protocol edge of the extensible switch then issues an OID set request of OID_SWITCH_NIC_SAVE_COMPLETE to complete the save operation.

Handling the OID_SWITCH_NIC_SAVE_COMPLETE Request

When a Hyper-V child partition that has a network adapter connection to an extensible switch port is paused or its state is being saved, the Hyper-V extensible switch interface is notified. This causes the protocol edge of the extensible switch to issue an object identifier (OID) method request of OID_SWITCH_NIC_SAVE down the extensible switch driver stack.

When every Hyper-V extensible switch extension has saved its run-time data, the protocol edge of the extensible switch notifies underlying extensions that the save operation has completed. The protocol edge does this by issuing an OID set request of OID_SWITCH_NIC_SAVE_COMPLETE down the extensible switch driver stack.

Note When a run-time save operation is started for an extensible switch network adapter connection, another save operation for the same network adapter connection will not be performed until the OID_SWITCH_NIC_SAVE_COMPLETE request is issued. However, save operations for other network adapter connections could occur during this time.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure for the OID_SWITCH_NIC_SAVE_COMPLETE request contains a pointer to an **NDIS_SWITCH_NIC_SAVE_STATE** structure. This structure is allocated by the protocol edge of the extensible switch.

When it receives the OID set request of OID_SWITCH_NIC_SAVE_COMPLETE, the extension must follow these guidelines:

- The extension must not modify the **NDIS_SWITCH_NIC_SAVE_STATE** structure that is associated with the OID request.

- The extension must call **NdisFOidRequest** to forward this OID request through the extensible switch extension stack. The extension must not fail the OID request.

  Note The extension should monitor the completion status of this OID request. The extension does this to detect whether the save operation has completed successfully.

OID method requests of OID_SWITCH_NIC_SAVE_COMPLETE are ultimately handled by the underlying miniport edge of the extensible switch. Once this OID method request has been received by the miniport edge, it completes the OID request with NDIS_STATUS_SUCCESS. This notifies the protocol edge of the extensible switch that all extensions in the extensible switch driver stack have completed the save operation.

Restoring Hyper-V Extensible Switch Run-Time Data

When a Hyper-V child partition that has a network adapter connection to an extensible switch port is resumed from a pause, the Hyper-V extensible switch interface is notified. This causes the protocol edge of the extensible switch to issue an object identifier (OID) set request of OID_SWITCH_NIC_RESTORE down the extensible switch driver stack. When an extension receives this OID request, it can restore its run-time data for the extensible switch port that is used by the child partition.

The **InformationBuffer** member of the **NDIS_OID_REQUEST** structure for the OID_SWITCH_NIC_RESTORE request contains a pointer to an **NDIS_SWITCH_NIC_SAVE_STATE** structure. This structure is allocated by the protocol edge of the extensible switch.

When it receives the OID set request of OID_SWITCH_NIC_RESTORE, the extensible switch extension must first determine whether it owns the run-time data. The extension does this by comparing the value of the **ExtensionId** member of the **NDIS_SWITCH_NIC_SAVE_STATE** structure to the GUID value that the extension uses to identify itself.

If the extension owns the run-time data for an extensible switch NIC, it restores this data in the following way:

1. The extension copies the run-time data in the **SaveData** member to driver-allocated storage.

> **Note** The value of the **PortId** member of the **NDIS_SWITCH_NIC_SAVE_STATE** structure may be different from the **PortId** value at the time that the run-time data was saved. This can occur if run-time data was saved during a Live Migration from one host to another. However, the configuration of the extensible switch NIC is retained during the Live Migration. This enables the extension to restore the run-time data to the extensible switch NIC by using the new **PortId** value.

2. The extension completes the OID set request with NDIS_STATUS_SUCCESS.

If the extension does not own the specified run-time data to save, the extension calls **NdisFOidRequest**. This forwards the OID set request to underlying drivers in the extensible switch driver stack. In this case, the extension must not modify the **NDIS_SWITCH_NIC_SAVE_STATE** structure that is associated with the OID request. For more information on how to forward OID requests, see Filtering OID Requests in an NDIS Filter Driver.

If the OID set request of OID_SWITCH_NIC_RESTORE is completed with NDIS_STATUS_SUCCESS, the protocol edge of the extensible switch issues another OID set request. When it receives this new OID set request, the extension can do one of the following:

- If it owns the run-time data in the new OID request, the extension restores the additional run-time data within the **NDIS_SWITCH_NIC_SAVE_STATE** structure. The extension then completes the OID request with NDIS_STATUS_SUCCESS.

- If it does not own the run-time data in the new OID request, the extension calls **NdisFOidRequest** to forward this OID set request to underlying drivers.

OID_SWITCH_NIC_RESTORE_COMPLETE
The extensible switch interface signals the protocol edge of the extensible switch to issue this OID at the completion of the restore operation of run-time data for an extensible switchnetwork adapter.

This OID request notifies the extension that the restore operation has completed only for a specified extensible switch NIC.

For more information about this OID request, see OID_SWITCH_NIC_RESTORE_COMPLETE.

Note If the OID_SWITCH_NIC_RESTORE set request is received by the miniport edge of the extensible switch, it completes the OID request with NDIS_STATUS_SUCCESS. This notifies the protocol edge of the extensible switch that no extension owns the run-time data. If this happens, the extensible switch interface logs an event that documents the

ExtensionId and **PortId** member values for the extension that originally saved the run-time port data.

Managing Physical Network Adapters

Article • 12/15/2021

This section describes the operations that a Hyper-V extensible switch extension can perform on underlying physical adapters that are bound to the extensible switch external network adapter.

These operations allow an extension to forward or originate object identifier (OID) requests to an underlying physical network adapter. The extension can also forward or originate NDIS status indications from a physical network adapter up the extensible switch driver stack.

Note Operations of this sort can only be performed by an extensible switch forwarding extension. For more information about this type of extension, see Forwarding Extensions.

This section includes the following topics:

Managing Physical Network Adapter Connection Status

Forwarding Packets to Physical Network Adapters

Managing OID Requests to Physical Network Adapters

Managing NDIS Status Indications from Physical Network Adapters

Managing Physical Network Adapter Connection Status

Article • 12/15/2021

The Hyper-V extensible switch architecture supports the connection to a single external network adapter for access to the underlying physical medium. The external network adapter can be bound to one or more underlying physical network adapters in a variety of configurations. For more information about these configurations, see Types of Physical Network Adapter Configurations.

The extensible switch interface notifies extensions of each physical network adapter connection status through the following steps:

1. The protocol edge of the extensible switch issues an object identifier (OID) set request of OID_SWITCH_NIC_CREATE. This OID request notifies underlying extensible switch extensions about the creation of network connection to the extensible switch external network adapter.

   When the network connection is created, it is assigned an NDIS_SWITCH_NIC_INDEX value. This index value identifies the network connection of the adapter on an extensible switch port. The network connection to the external network adapter is assigned an NDIS_SWITCH_NIC_INDEX value of **NDIS_SWITCH_DEFAULT_NIC_INDEX**.

2. For every network adapter that is bound directly or indirectly to the external network adapter, the protocol edge of the extensible switch issues a separate OID set request of OID_SWITCH_NIC_CREATE. This OID request notifies the extension about the creation of a network connection to an underlying network adapter.

   Each physical or virtual network adapter that is bound to the external network adapter is assigned an identifier in the following way:

   - If a single physical adapter is bound to the external network adapter, it is assigned a NDIS_SWITCH_NIC_INDEX value of one.

   - If an load balancing fail over (LBFO) team of network adapters is bound to the external network adapter, it is assigned a NDIS_SWITCH_NIC_INDEX value of one.

     Note In the LBFO team configuration, only the virtual miniport edge of the LBFO provider that supports the LBFO team is considered to be bound to the external network adapter.

- If an extensible switch team of network adapters is bound to the external network adapter, each physical network adapter in the team is assigned a unique NDIS_SWITCH_NIC_INDEX value that is greater than or equal to one.

  Note In the extensible switch team configuration, every physical network adapter in the team is considered to be bound to the external network adapter.

3. The protocol edge of the extensible switch issues an OID set request of OID_SWITCH_NIC_CONNECT for the external network adapter.

   Note At this point, the connection to the external network is not operational and cannot be used for packet traffic.

4. For every network adapter that is bound to the external network adapter, the protocol edge of the extensible switch issues a separate OID set request of OID_SWITCH_NIC_CONNECT. This OID request is issued after the OID set request of OID_SWITCH_NIC_CREATE is completed successfully.

   The OID_SWITCH_NIC_CONNECT OID request notifies the extension that the extensible switch network connection is now operational. If the external network adapter is bound to the virtual miniport edge of the MUX driver, the protocol edge issues a separate OID_SWITCH_NIC_CONNECT request.

   Note As soon as an OID_SWITCH_NIC_CONNECT request is issued for a physical network adapter with a NDIS_SWITCH_NIC_INDEX value greater than or equal to one, the connection to the external network is operational. At this point, packet traffic can be sent or received over the external network.

5. If the external network connection is being torn down, the protocol edge of the extensible switch first issues a separate OID set request of OID_SWITCH_NIC_DISCONNECT for every network adapter that is bound to the external network adapter. Once these OID requests are completed, the protocol edge of the extensible switch then issues separate OID set request of OID_SWITCH_NIC_DELETE for every physical network adapter that is bound to the external network adapter,

   Once all network connections to the underlying physical adapters have been disconnected and deleted, the protocol edge of the extensible switch issues OID_SWITCH_NIC_DISCONNECT and OID_SWITCH_NIC_DELETE requests to disconnect and delete the external network adapter connection.

For more information on NDIS_SWITCH_NIC_INDEX values, see Network Adapter Index Values.

Forwarding Packets to Physical Network Adapters

Article • 12/15/2021

Note This page assumes that you are familiar with the information and diagrams in the following pages:

- Forwarding Extensions
- Hybrid Forwarding
- Hyper-V Extensible Switch Extensions
- Overview of the Hyper-V Extensible Switch
- Teaming Provider Extensions

This page describes how Hyper-V extensible switch forwarding extensions can forward send requests of packets to underlying physical adapters. One or more physical network adapters can be bound to the extensible switch external network adapter.

For example, the extensible switch external network adapter can be bound to the virtual miniport edge of an NDIS multiplexer (MUX) intermediate driver. The MUX intermediate driver itself can be bound to a team of one or more physical networks on the host. This configuration is known as an *extensible switch team*. For more information about extensible switch teams, see Types of Physical Network Adapter Configurations.

In this configuration, the extensible switch extensions are exposed to every network adapter in the extensible switch team. This allows a forwarding extension in the extensible switch driver stack to manage the configuration and use of individual network adapters in the team. For example, the extension can provide support for a load balancing failover (LBFO) solution over the team by forwarding outgoing packets to individual adapters. Such as extension is known as a *teaming provider*. For more information about teaming providers, see Teaming Provider Extensions.

If a forwarding extension is installed and enabled in the extensible switch driver stack, it is responsible for making forwarding decisions for each packet that it obtains on the extensible switch ingress data path, unless the packet is an NVGRE packet. (For more information about NVGRE packets, see Hybrid Forwarding.) Based on these forwarding decisions, the extension can add destination ports into the out-of-band (OOB) data of the packet's **NET_BUFFER_LIST** structure. After the packet has completed its traversal of the extensible switch data path, the extensible switch interface delivers the packet to the specified destination ports.

Note If a forwarding extension is not installed or enabled, the extensible switch itself makes the forwarding decisions for packets it obtains from ingress data path. The switch adds the destination ports to the OOB data of the packet's **NET_BUFFER_LIST** structure before it forwards the packet up the extensible switch egress data path.

When the forwarding extension's *FilterSendNetBufferLists* function is called, the *NetBufferList* parameter contains a pointer to a linked list of **NET_BUFFER_LIST** structures. Each of these structures specifies a packet obtained from the ingress data path. Within the OOB data of each packet's **NET_BUFFER_LIST** structure, the data for destination ports are contained in an **NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY** structure. The extension obtains the **NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY** structure and its elements by calling *GetNetBufferListDestinations*.

Note To improve performance, a forwarding extension can call the *GrowNetBufferListDestinations* function instead of *GetNetBufferListDestinations* to obtain a pointer to the **NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY** structure. The extension does this if it determines that it needs additional array elements in the packet's OOB data for destination ports. For more information, see Adding Extensible Switch Destination Port Data to a Packet.

Each element in the **NDIS_SWITCH_FORWARDING_DESTINATION_ARRAY** array defines a destination port and is formatted as an **NDIS_SWITCH_PORT_DESTINATION** structure. This structure contains the following members:

- The **PortId** member contains a value that specifies the destination port on the extensible switch.

- The **NicIndex** member specifies the index of the network adapter that is connected to the extensible switch port specified by the **PortId** member.

  For more information on these index values, see Network Adapter Index Values.

If the forwarding extension adds a destination port that is connected to the external network adapter, the extension can specify the index of an underlying physical network adapter. For example, the extension could operate as a teaming provider for LBFO support over an extensible switch team. This allows the extension to balance the traffic overhead by forwarding send requests to different adapters of the team.

The forwarding extension must follow these guidelines when it adds or modifies an **NDIS_SWITCH_PORT_DESTINATION** structure to forward send requests to an underlying physical network adapter:

- If the **PortId** member specifies the extensible switch port to which the external network adapter is connected, the extension must set the **NicIndex** member to one of the following index values:
  - If only one physical network adapter is bound to the external network adapter, the extension must set the **NicIndex** member to **NDIS_SWITCH_DEFAULT_NIC_INDEX** or one.
  - If multiple physical network adapters are bound to the external network adapter, the extension must set the **NicIndex** member to the nonzero index value of the destination network adapter in the extensible switch team.

  Note If the **PortId** member does not specify the extensible switch port to which the external network adapter is connected, the extension must set the **NicIndex** member to **NDIS_SWITCH_DEFAULT_NIC_INDEX**.

- After the extension has added all of the destination ports for the packet, it must call **NdisFSendNetBufferLists** to forward the packet on the ingress data path.

For more information on how to add destination ports to a packet, see Forwarding Packets to Hyper-V Extensible Switch Ports.

For more information on the egress data path, see Hyper-V Extensible Switch Data Path.

Managing OID Requests to Physical Network Adapters

Article • 12/15/2021

This section discusses how Hyper-V extensible switch extensions manage object identifier (OID) requests for underlying physical network adapters over the extensible switch control path.

This section includes the following topics:

Forwarding OID Requests to Physical Network Adapters

Managing Hardware Offload OID Requests to Physical Network Adapters

For more information on how to manage OID requests over the Hyper-V extensible switch control path, see Hyper-V Extensible Switch Control Path for OID Requests.

Forwarding OID Requests to Physical Network Adapters

Article • 12/15/2021

This topic discusses how Hyper-V extensible switch extensions forward object identifier (OID) requests for underlying physical adapters over the Hyper-V extensible switch control path. The extension can also originate OID requests to underlying physical network adapters by following the methods described in this topic.

For example, the external network adapter can be bound to the virtual miniport edge of an NDIS multiplexer (MUX) intermediate driver. The MUX driver is bound to a team of one or more physical networks on the host. This configuration is known as an *extensible switch team*.

In this configuration, an extensible switch extension is exposed to every network adapter in the team. This allows the extension to manage the configuration and use of individual network adapters in the team. For example, a forwarding extension can provide support for a load balancing failover (LBFO) solution over the team by forwarding outgoing packets to individual adapters. A forwarding extension that manages an extensible switch team is known as a *teaming provider*. For more information about teaming providers, see Teaming Provider Extensions.

Note In the Hyper-V extensible switch interface, NDIS filter drivers are known as *extensible switch extensions* and the driver stack is known as the *extensible switch driver stack*.

OID requests must be encapsulated to forward the request to an underlying physical network adapter. OID requests are first encapsulated inside an **NDIS_SWITCH_NIC_OID_REQUEST** structure. Then, the OID requests are forwarded through the extensible switch control path by an OID set request of OID_SWITCH_NIC_REQUEST.

OID requests to the underlying physical adapters are issued by the following:

The extensible switch interface.
OID requests, such as requests for hardware offloads, are issued by overlying protocol or filter drivers that run in one of the following:

- The management operating system that runs in the Hyper-V parent partition.
- The guest operating system that runs in the Hyper-V child partition.

When these OID requests are received by the extensible switch, they are encapsulated and forwarded over the extensible switch control path. When a forwarding extension receives the encapsulated OID request, it can forward the request to an underlying physical adapter. This ability is especially useful for configuring the extensible switch team for hardware offloads.

For example, the MUX driver advertises the common capabilities of the entire extensible switch team. However, the forwarding extension can issue OID requests to query or set the individual capabilities of adapters within the team. Then, the forwarding extension can originate an NDIS status indication from the external network adapter to notify overlying drivers about the capabilities that apply to the entire team. For more information on this procedure, see Originating NDIS Status Indications from Physical Network Adapters.

When the forwarding extension forwards the OID request over the control path, it is received by the external network adapter. At this point, the OID request is decapsulated and forwarded to the specified physical network adapter.

Note Starting with Windows Server 2012, only hardware offload OID requests are encapsulated and forwarded in this manner. For example, offload OID requests for virtual machine queue (VMQ) or Internet Protocol security (IPsec) are encapsulated and forwarded over the extensible switch control path. For more information, see Managing Hardware Offload OID Requests to Physical Network Adapters.

A forwarding extension.
The forwarding extension can originate its own encapsulated OID requests and forward them to an underlying physical network adapter. The forwarding extension can encapsulate standard NDIS OID requests. The forwarding extension can also encapsulate private OID requests that are defined by the independent hardware vendor (IHV) for the physical network adapters. This allows a forwarding extension that was also developed by the IHV to enable or disable proprietary attributes on individual physical adapters in the team.

In addition, the forwarding extension can originate encapsulated hardware offload OID requests to allocate resources for a specified Hyper-V child partition. For example, the forwarding extension can originate encapsulated OID requests of OID_RECEIVE_FILTER_ALLOCATE_QUEUE to allocate a VMQ for a specified child partition. In this case, the extension encapsulates the request as originating from the extensible switch port and network adapter connection associated with the partition.

Note The forwarding extension can only originate its own encapsulated hardware offload OID request if it is filtering the same OID request that was issued by overlying drivers. In this case, the extension must not forward the original OID request. Instead, the extension must call **NdisFOidRequestComplete** to complete this request when NDIS calls its *FilterOidRequestComplete* to complete the originated OID request.

Filtering or capturing extensions
A filtering or capturing extension can originate its own encapsulated OID query requests and forward them to an underlying physical network adapter. These extensions can

encapsulate standard NDIS OID query requests or private OID query requests that are defined by the independent hardware vendor (IHV) for the physical network adapters.

Note Only forwarding extensions can originate encapsulated OID set requests to underlying physical adapters.

The forwarding extension must follow these steps when it forwards, redirects, or originates an encapsulated OID request for an underlying physical adapter:

1. If the forwarding extension is originating an OID request, it must initialize an extension-allocated **NDIS_OID_REQUEST** structure with the information related to the request.

   If the extension is forwarding an OID request, it must not change the existing **NDIS_OID_REQUEST** structure referenced by the *OidRequest* parameter of the *FilterOidRequest* function. Instead, the extension must call **NdisAllocateCloneOidRequest** to allocate memory for a new **NDIS_OID_REQUEST** structure and copy all the information from the existing **NDIS_OID_REQUEST** structure.

2. The extension sets the members of an extension-allocated **NDIS_SWITCH_NIC_OID_REQUEST** structure to the following values:

   - The **DestinationPortId** member must be set to the identifier of the extensible switch port to which the external network adapter is connected.

   - The **DestinationNicIndex** member must be set to the nonzero index value of the underlying physical network adapter.

     For more information on these index values, see Network Adapter Index Values.

   - If the forwarding extension is originating a hardware offload OID request for a Hyper-V child partition, the **SourcePortId** member must be set to the identifier of the port that is used by the partition. Also, the **SourceNicIndex** member must be set to the network adapter index for the network connection to that port.

     If the forwarding extension is originating a standard or private OID request for its own purposes, the **SourcePortId** and **SourceNicIndex** members must be set to zero.

     If the forwarding extension is forwarding or redirecting a hardware offload OID request, it must retain the values of the **SourcePortId** and **SourceNicIndex** members that were set by the extensible switch interface.

- The **OidRequest** member must be set to a pointer to an initialized NDIS_OID_REQUEST structure for the encapsulated OID request. The forwarding extension either allocates and initializes this structure or uses the cloned copy of the structure.

3. The extension sets the members of an extension-allocated NDIS_OID_REQUEST structure to the following values:

   - The **Oid** member must be set to OID_SWITCH_NIC_REQUEST.

   - The **InformationBuffer** member must contain a pointer to a buffer that contains the generated or filtered OID request data.

   - The **InformationBufferLength** member must contain the length, in bytes, of the buffer that contains the generated or filtered OID request data.

   The extension sets the other members to values that are valid for the NDIS_OID_REQUEST structure.

4. The extension calls *ReferenceSwitchNic* to increment a reference counter for the index of the destination physical network adapter. This guarantees that the extensible switch interface will not delete the physical network adapter connection while its reference counter is nonzero.

   When the extension calls *ReferenceSwitchNic*, it sets the *SwitchPortId* parameter to the value specified for the **DestinationPortId** member. The extension also sets the *SwitchNicIndex* parameter to the value specified for the **DestinationNicIndex** member.

   Note If *ReferenceSwitchNic* does not return NDIS_STATUS_SUCCESS, the OID request cannot be forwarded to the destination physical network adapter.

5. If the forwarding extension is originating a hardware offload OID request for a Hyper-V child partition, it also calls *ReferenceSwitchNic* to increment a reference counter for the index of the source network adapter connection that is associated with the partition. This guarantees that the extensible switch interface will not delete the physical network adapter connection while its reference counter is nonzero.

   When the extension calls *ReferenceSwitchNic*, it sets the *SwitchPortId* parameter to the value specified for the **SourcePortId** member. The extension also sets the *SwitchNicIndex* parameter to the value specified for the **SourceNicIndex** member.

   Note If *ReferenceSwitchNic* does not return NDIS_STATUS_SUCCESS, the OID request cannot be forwarded to the destination physical network adapter.

6. The extension calls **NdisFOidRequest** to forward the encapsulated OID request to the specified destination extensible switch port and network adapter.

   Note If the extension is forwarding a filtered OID request, it must call **NdisFOidRequest** within the context of the call to its *FilterOidRequest* function. If the extension is forwarding OID requests that it has generated, it calls **NdisFIndicateStatus** while it is in the *Running*, *Restarting*, *Paused*, and *Pausing* states. For more information on these states, see Filter Module States and Operations.

7. When NDIS calls the *FilterOidRequestComplete* function, the extension calls *DereferenceSwitchNic* to clear the reference counter for the index of the destination physical network adapter.

   If the forwarding extension originated a hardware offload OID request for a Hyper-V child partition, it also calls *DereferenceSwitchNic* to clear the reference counter for the index of the source network adapter connection for the adapter.

   In both cases, the extension sets the *SwitchPortId* and *SwitchNicIndex* parameters to the same values that it used in the call to *ReferenceSwitchNic*.

For more information on how the extension issues OID requests, see Generating OID Requests from an NDIS Filter Driver.

For more information on MUX drivers, see NDIS MUX Intermediate Drivers.

Managing Hardware Offload OID Requests to Physical Network Adapters

Article • 07/07/2022

This topic discusses how a Hyper-V extensible switch forwarding extension manages object identifier (OID) requests for hardware offload technologies on underlying physical adapters over the extensible switch control path.

For example, the external network adapter can be bound to the virtual miniport edge of an NDIS multiplexer (MUX) intermediate driver. The MUX driver is bound to a team of one or more physical networks on the host. This configuration is known as an *extensible switch team*.

In this configuration, an extensible switch extension is exposed to every network adapter in the team. This allows the extension to manage the configuration and use of individual network adapters in the team. For example, a forwarding extension can provide support for a load balancing failover (LBFO) solution over the team by forwarding outgoing packets to individual adapters. A forwarding extension that manages an extensible switch team is known as a *teaming provider*. For more information about teaming providers, see Teaming Provider Extensions.

The following figure shows an example of an extensible switch team for NDIS 6.40 (Windows Server 2012 R2) and later.

Note In the extensible switch interface, NDIS filter drivers are known as *extensible switch extensions* and the driver stack is known as the *extensible switch driver stack*.

By handling the OID request of OID_SWITCH_NIC_REQUEST, a forwarding extension can participate in the configuration of the extensible switch team for hardware offloads. For example, if the extension manages the physical network adapters of an extensible switch team, it can forward the OID_SWITCH_NIC_REQUEST request to a physical adapter that supports the hardware offload.

NDIS and overlying protocol and filter drivers can issue OID requests for hardware offload technologies to the underlying physical network adapter. When these OID requests arrive at the extensible switch interface, it encapsulates the OID request inside an **NDIS_SWITCH_NIC_OID_REQUEST**. Then, the protocol edge of the extensible switch issues an OID request of OID_SWITCH_NIC_REQUEST that contains this structure.

The extensible switch interface encapsulates OIDs for the following hardware offload technologies:

Internet Protocol security (IPsec) offload (version 2)
The following IPsec OID requests are encapsulated:

- OID_TCP_TASK_IPSEC_OFFLOAD_V2_ADD_SA
- OID_TCP_TASK_IPSEC_OFFLOAD_V2_ADD_SA_EX
- OID_TCP_TASK_IPSEC_OFFLOAD_V2_DELETE_SA

- OID_TCP_TASK_IPSEC_OFFLOAD_V2_UPDATE_SA

The forwarding extension must not fail, or *veto*, these OID requests.

For more information about version 2 of the IPsec hardware offload technology, see IPsec Offload Version 2.

Single root I/O virtualization (SR-IOV)
The following SR-IOV OID requests are encapsulated:

- OID_NIC_SWITCH_ALLOCATE_VF
- OID_NIC_SWITCH_CREATE_VPORT
- OID_NIC_SWITCH_DELETE_VPORT
- OID_NIC_SWITCH_FREE_VF
- OID_RECEIVE_FILTER_CLEAR_FILTER
- OID_RECEIVE_FILTER_MOVE_FILTER

The forwarding extension can veto OID requests of OID_NIC_SWITCH_ALLOCATE_VF and OID_NIC_SWITCH_CREATE_VPORT by completing the request with a status code other than NDIS_STATUS_SUCCESS. However, the extension must not veto the other SR-IOV OID requests.

For more information about the SR-IOV hardware offload technology, see Single Root I/O Virtualization (SR-IOV).

Virtualized machine queue (VMQ)
The following VMQ OID requests are encapsulated:

- OID_RECEIVE_FILTER_ALLOCATE_QUEUE
- OID_RECEIVE_FILTER_CLEAR_FILTER
- OID_RECEIVE_FILTER_FREE_QUEUE
- OID_RECEIVE_FILTER_QUEUE_ALLOCATION_COMPLETE
- OID_RECEIVE_FILTER_SET_FILTER

The forwarding extension can veto OID requests of OID_RECEIVE_FILTER_ALLOCATE_QUEUE and OID_RECEIVE_FILTER_SET_FILTER by completing the request with a status code other than NDIS_STATUS_SUCCESS. However, the extension must not veto the other VMQ OID requests.

For more information about the VMQ hardware offload technology, see Virtual Machine Queue (VMQ).

The forwarding extension must follow these guidelines for handling hardware offload OID requests:

- The Microsoft IM platform advertises only the common offload capabilities for the overall team. However, the extension can generate OID requests to query the capabilities of each adapter in the team.

  Once the extension has determined the hardware capabilities of the physical adapters in the team, it can forward OID set requests for hardware offloads to an adapter that is best suited for the offload.

- All hardware offload OID requests that are originated by overlying protocol or filter drivers will be encapsulated within a **NDIS_SWITCH_NIC_OID_REQUEST** structure. All hardware offload OID requests that are originated by the forwarding extension must also be encapsulated in an **NDIS_SWITCH_NIC_OID_REQUEST** structure.

  The extension forwards the encapsulated OID request to an underlying physical network adapter through an OID set request of OID_SWITCH_NIC_REQUEST. For more information on this procedure, see Forwarding OID Requests to Physical Network Adapters.

- The extension must not modify or fail hardware offload OID requests to clear, free, or complete the allocation of offload resources. For example, the extension must not fail OID requests of OID_RECEIVE_FILTER_CLEAR_FILTER or OID_NIC_SWITCH_DELETE_VPORT. The extensible switch interface must handle these OID requests to clean up state information for these resources.

  The extension can modify or fail hardware offload OID requests to allocate, move, or set offload resources. For example, the extension can fail or modify OID requests of OID_NIC_SWITCH_ALLOCATE_VF or OID_TCP_TASK_IPSEC_OFFLOAD_V2_ADD_SA.

- The extension can originate any hardware offload OIDs to an underlying physical network adapter. However, the extension must not originate a hardware offload OID that clears or frees offload resources that the extension did not allocate.

  For example, the extension must not originate a hardware offload OID request of OID_RECEIVE_FILTER_FREE_QUEUE if it did not originate an OID_RECEIVE_FILTER_ALLOCATE_QUEUE request for the same queue.

Note The extension can only originate its own encapsulated hardware offload OID request if it is filtering the same OID request that was issued by overlying drivers. In this case, the extension must not forward the original OID request. Instead, the extension must call **NdisFOidRequestComplete** to complete this request when NDIS calls its *FilterOidRequestComplete* to complete the originated OID request.

- If the extension is forwarding a hardware offload OID request to an underlying physical network adapter, the **DestinationNicIndex** member of the **NDIS_SWITCH_NIC_OID_REQUEST** structure must be set to the nonzero index value of the adapter. For more information on these index values, see Network Adapter Index Values.

  Also, the **DestinationPortId** member must be set to the identifier of the extensible switch port to which the external network adapter is connected.

- If the extension is originating a hardware offload OID request to allocate resources for a Hyper-V child partition, the **SourcePortId** member of the **NDIS_SWITCH_NIC_OID_REQUEST** structure must be set to the identifier of the extensible switch port to which the partition is connected.

  The **SourceNicIndex** member must be set to **NDIS_SWITCH_DEFAULT_NIC_INDEX**.

- When the extension calls **NdisFOidRequest** to forward the OID request, it must set the *OidRequest* parameter to a pointer to an **NDIS_OID_REQUEST** structure for an OID_SWITCH_NIC_REQUEST OID request.

For more information on how the extension filters OID requests, see Filtering OID Requests in an NDIS Filter Driver.

For more information on MUX drivers, see NDIS MUX Intermediate Drivers.

Managing NDIS Status Indications from Physical Network Adapters

Article • 03/14/2023

This section discusses how Hyper-V extensible switch extensions manage NDIS status indications from underlying physical network adapters over the extensible switch control path.

This section includes the following topics:

Forwarding NDIS Status Indications from Physical Network Adapters

Originating NDIS Status Indications from Physical Network Adapters

For more information on how to manage NDIS status indications over the Hyper-V extensible switch control path, see Hyper-V Extensible Switch Control Path for NDIS Status Indications.

Forwarding NDIS Status Indications from Physical Network Adapters

Article • 03/14/2023

This topic discusses the method that is used by extensible switch forwarding extensions to forward NDIS status indications from an underlying physical adapter. One or more underlying physical adapters can be bound to the external network adapter of the Hyper-V extensible switch.

For example, the external network adapter can be bound to the virtual miniport edge of an NDIS multiplexer (MUX) intermediate driver. The MUX driver is bound to a team of one or more physical networks on the host. This configuration is known as an *extensible switch team*.

In this configuration, an extensible switch extension is exposed to every network adapter in the team. This allows the extension to manage the configuration and use of individual network adapters in the team. For example, a forwarding extension can provide support for a load balancing failover (LBFO) solution over the team by forwarding outgoing packets to individual adapters. A forwarding extension that manages an extensible switch team is known as a *teaming provider*. For more information about teaming providers, see Teaming Provider Extensions.

The following figure shows the Hyper-V extensible switch control path for NDIS status indications from underlying physical network adapters for NDIS 6.40 (Windows Server 2012 R2) and later.

Note In the extensible switch interface, NDIS filter drivers are known as *extensible switch extensions* and the driver stack is known as the *extensible switch driver stack*.

The extensible switch interface forwards NDIS status indications that were generated by the underlying physical adapters. If an external network adapter is bound to an extensible switch team, the NDIS status indication is originated by the virtual adapter edge of a MUX driver. Otherwise, the status indication is originated by the single physical network adapter that is bound to the external network adapter.

When an NDIS status indication arrives at the extensible switch interface, it encapsulates the indication inside an NDIS_SWITCH_NIC_STATUS_INDICATION structure. Then, the miniport edge of the extensible switch issues an NDIS_STATUS_SWITCH_NIC_STATUS indication that contains this structure.

Once the forwarding extension receives the NDIS status indication, it can forward the original indication data or modify the data before it forwards the indication.

Note Only forwarding extensions can modify the data before forwarding the status indication. For more information about this type of extension, see Forwarding Extension.

A forwarding extension can modify and forward status indications from any underlying physical adapter that is bound to the external network adapter of the extensible switch. Typically, the extension issues these status indications to change the advertised hardware offload capabilities of the underlying physical adapter. For example, the extension can modify and forward status indications for the following types of hardware offloads:

- Internet Protocol security (IPsec)
- Virtualized machine queue (VMQ)
- Single root I/O virtualization (SR-IOV)

If the forwarding extension is forwarding an NDIS status indication, it must set the members of the NDIS_SWITCH_NIC_STATUS_INDICATION structure in the following way:

- The **SourcePortId** member must be set to the identifier of the port to which the external network adapter is connected. The external network adapter is bound to one or more physical adapters. For more information, see External Network Adapters.
- The **SourceNicIndex** member must be set to NDIS_SWITCH_DEFAULT_NIC_INDEX. This allows the status indication to be interpreted as originating from the entire extensible switch team that is bound to the external network adapter.
- The **DestinationPortId** member must be set to **NDIS_SWITCH_DEFAULT_PORT_ID**.
- The **DestinationNicIndex** member must be set to **NDIS_SWITCH_DEFAULT_NIC_INDEX**.
- The **StatusIndication** member must be set to a pointer to an NDIS_STATUS_INDICATION structure. This structure contains the data for the encapsulated NDIS status indication.

When a forwarding extension issues the encapsulated NDIS status indication, it must follow these steps:

1. The extension calls *ReferenceSwitchNic* to increment a reference counter for the external network adapter. This guarantees that the extensible switch interface will not delete the network adapter connection while its reference counter is nonzero.

   When the extension calls *ReferenceSwitchNic*, it sets the *SwitchPortId* parameter to the value specified for the **SourcePortId** member. The extension also sets the *SwitchNicIndex* parameter to the value specified for the **SourceNicIndex** member.

   Note If *ReferenceSwitchNic* does not return NDIS_STATUS_SUCCESS, the encapsulated NDIS status indication cannot be issued.

2. The extension calls **NdisFIndicateStatus** to forward the encapsulated status notification.

   Note If the extension is forwarding an encapsulated NDIS status indication, it must call **NdisFIndicateStatus** within the context of the call to its *FilterStatus* function.

3. After **NdisFIndicateStatus** returns, the extension calls *DereferenceSwitchNic* to clear the reference counter for the source or destination network adapter connection. The extension sets the *SwitchPortId* and *SwitchNicIndex* parameters to the same values that it used in the call to *ReferenceSwitchNic*.

For more information on MUX drivers, see NDIS MUX Intermediate Drivers.

Originating NDIS Status Indications from Physical Network Adapters

Article • 03/14/2023

This topic discusses the method that is used by an extensible switch forwarding extension to originate NDIS status indications for a network adapter that is connected to the switch. The extension can originate an NDIS status indication for the following types of adapters:

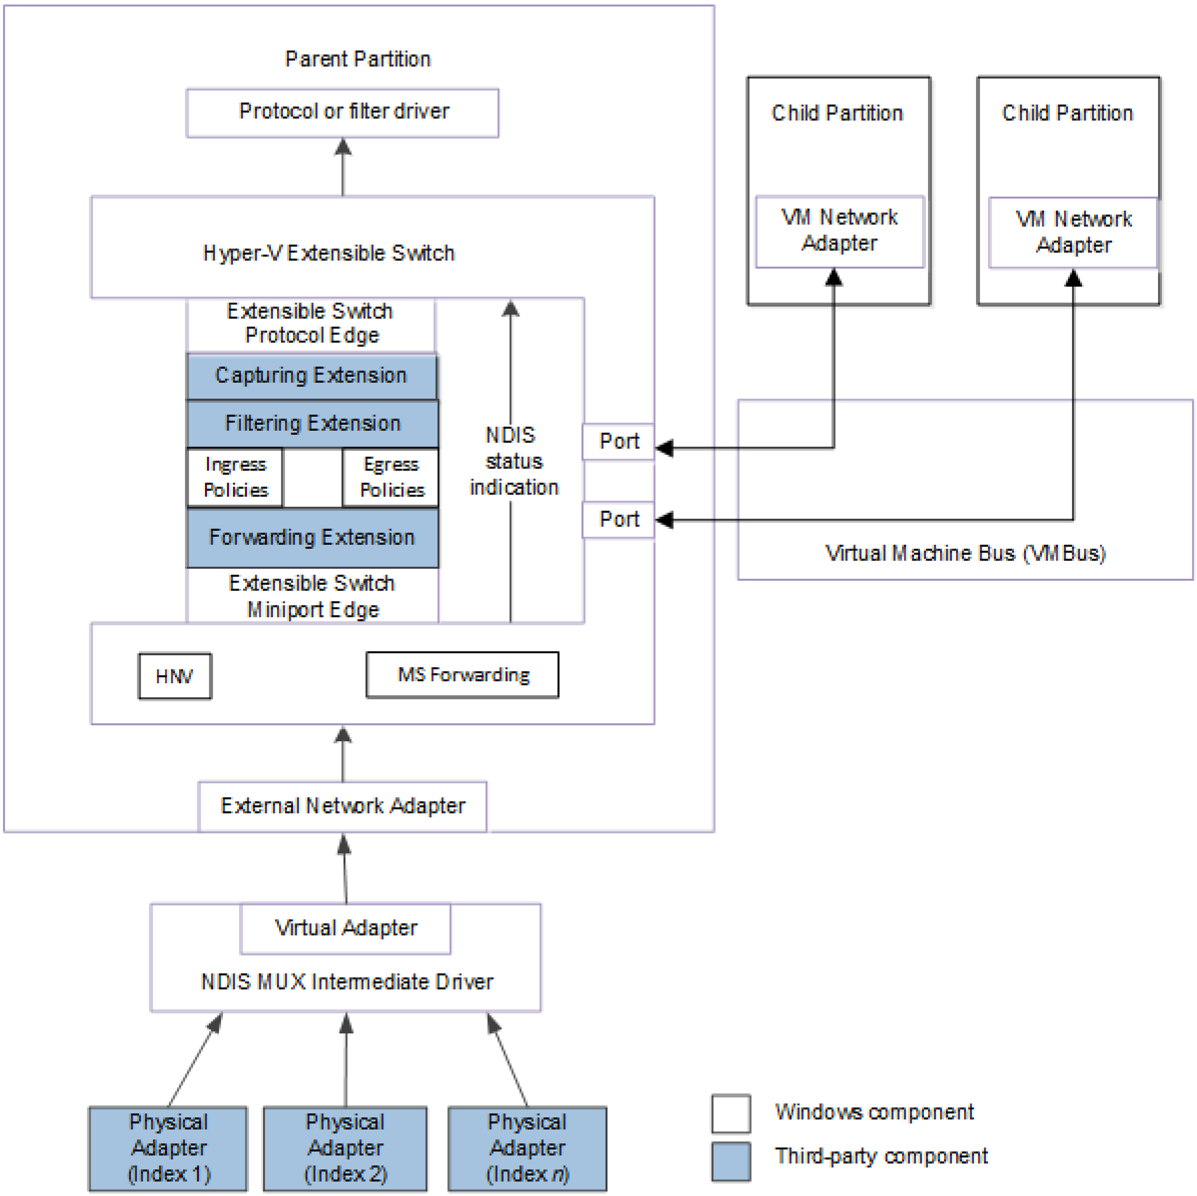
- One or more underlying physical adapters that are bound to the external network adapter of the extensible switch.

  For example, the external network adapter can be bound to the virtual miniport edge of an NDIS multiplexer (MUX) intermediate driver. The MUX driver is bound to a team of one or more physical networks on the host. This configuration is known as an *extensible switch team*.

  In this configuration, an extensible switch extension is exposed to every network adapter in the team. This allows the extension to manage the configuration and use of individual network adapters in the team. For example, a forwarding extension can provide support for a load balancing failover (LBFO) solution over the team by forwarding outgoing packets to individual adapters. A forwarding extension that manages an extensible switch team is known as a *teaming provider*. For more information about teaming providers, see Teaming Provider Extensions.

- A virtual machine (VM) network adapter that is exposed within a Hyper-V child partition and connected to an extensible switch port.

The following figure shows the Hyper-V extensible switch control path for NDIS status indications from physical and VM network adapters for NDIS 6.40 (Windows Server 2012 R2) and later.



The following figure shows the Hyper-V extensible switch control path for NDIS status indications from physical and VM network adapters for NDIS 6.30 (Windows Server 2012).

▨ Third-party component

Note In the extensible switch interface, NDIS filter drivers are known as *extensions* and the driver stack is known as the *extensible switch driver stack*.

A forwarding extension can originate encapsulated hardware offload status indications to overlying drivers in the extensible switch driver stack. This also allows the extension to change the current offload capabilities of the underlying team of physical adapters that are bound to the external network adapter of the extensible switch. When a team of adapters are bound to the external network adapter, only the common capabilities of the team are advertised to NDIS or overlying protocol and filter drivers. The extension can extend the advertised capabilities by originating encapsulated status indications to advertise capabilities that are supported by some adapters in the team. For example, the extension can issue an encapsulated NDIS_STATUS_RECEIVE_FILTER_CURRENT_CAPABILITIES indication to change the currently enabled receive filter capabilities for the entire team.

Note Only forwarding extensions can originate encapsulated status indications. For more information about this type of extension, see Forwarding Extension.

Typically, the forwarding extension originates encapsulated NDIS status indications to change the advertised hardware offload capabilities of the underlying physical adapter. For example, the extension can originate status indications for the following types of hardware offloads:

- Internet Protocol security (IPsec).

- Virtualized machine queue (VMQ).
- Single root I/O virtualization (SR-IOV).

The forwarding extension can also originate encapsulated NDIS status indications to change the hardware offload resources that are allocated for a Hyper-V child partition. Starting with NDIS 6.30, the extension can issue an encapsulated NDIS_STATUS_SWITCH_PORT_REMOVE_VF indication to remove the binding between a VM network adapter and a PCI Express (PCIe) virtual function (VF). The VF is exposed and supported by an underlying physical network adapter that supports the single root I/O virtualization (SR-IOV) interface.

If the forwarding extension originates an encapsulated NDIS status indication for the hardware offload resources of an underlying physical adapter, it must set the members of the NDIS_SWITCH_NIC_STATUS_INDICATION structure in the following way:

- The **DestinationPortId** member must be set to **NDIS_SWITCH_DEFAULT_PORT_ID**.
- The **DestinationNicIndex** member must be set to **NDIS_SWITCH_DEFAULT_NIC_INDEX**
- The **SourcePortId** member must be set to the identifier of the extensible switch port to which the external network adapter is connected.
- The **SourceNicIndex** member must be set to **NDIS_SWITCH_DEFAULT_NIC_INDEX**. This allows the status indication to be interpreted as originating from the entire extensible switch team that is bound to the external network adapter.

  Note The forwarding extension must also set this member to **NDIS_SWITCH_DEFAULT_NIC_INDEX** if only a single physical network adapter is bound to the external network adapter.

- The **StatusIndication** member must be set to a pointer to an NDIS_STATUS_INDICATION structure. This structure contains the data for the encapsulated NDIS status indication.

If the forwarding extension is originating an NDIS status indication for the hardware offload resources of a Hyper-V child partition, it must set the members of the NDIS_SWITCH_NIC_STATUS_INDICATION structure in the following way:

- The **DestinationPortId** and **DestinationNicIndex** members must be set to the corresponding values of the port and network adapter index for the network connection that is used by the partition.
- The **SourcePortId** member must be set to **NDIS_SWITCH_DEFAULT_PORT_ID**.

- The **SourceNicIndex** member must be set to **NDIS_SWITCH_DEFAULT_NIC_INDEX**.

- The **StatusIndication** member must be set to a pointer to an **NDIS_STATUS_INDICATION** structure. This structure contains the data for the encapsulated NDIS status indication.

When the extension issues the encapsulated NDIS status indication, it must follow these steps:

1. The extension calls *ReferenceSwitchNic* to increment a reference counter for the source or destination network adapter connection. This guarantees that the extensible switch interface will not delete the network adapter connection while its reference counter is nonzero.

   When the extension calls *ReferenceSwitchNic*, it sets the parameters in the following ways:

   - If the forwarding extension is originating an encapsulated NDIS status indication for an underlying physical adapter, it sets the *SwitchPortId* parameter to the value specified for the **SourcePortId** member. The extension also sets the *SwitchNicIndex* parameter to the value specified for the **SourceNicIndex** member.

   - If the forwarding extension is originating an NDIS status indication for a Hyper-V child partition, it sets the *SwitchPortId* parameter to the value specified for the **DestinationPortId** member. The extension also sets the *SwitchNicIndex* parameter to the value specified for the **DestinationNicIndex** member.

   Note If *ReferenceSwitchNic* does not return NDIS_STATUS_SUCCESS, the encapsulated NDIS status indication cannot be issued.

2. The extension calls **NdisFIndicateStatus** to forward the encapsulated status notification.

   Note If the extension is forwarding a filtered OID request, it must call **NdisFIndicateStatus** within the context of the call to its *FilterStatus* function.

3. After **NdisFIndicateStatus** returns, the extension calls *DereferenceSwitchNic* to clear the reference counter for the source or destination network adapter connection. The extension sets the *SwitchPortId* and *SwitchNicIndex* parameters to the same values that it used in the call to *ReferenceSwitchNic*.

Installing Hyper-V Extensible Switch Extensions

Article • 12/15/2021

This section describes the installation of Hyper-V extensible switch extensions and includes the following topics:

INF Requirements for Hyper-V Extensible Switch Extensions

Extension Driver MSI Packaging Requirements

Managing Installed Hyper-V Extensible Switch Extensions

INF Requirements for Hyper-V Extensible Switch Extensions

Article • 12/15/2021

Hyper-V extensible switch extensions are developed as NDIS filter drivers. As a result, the INF requirements for extensions are based on the INF requirements for all NDIS filter drivers. When you create an INF file for an extensible switch extension, you should use the INF settings for a modifying or monitoring filter driver. For more information on these settings, see INF File Settings for Filter Drivers.

In addition, you must follow these guidelines for INF files for extensible switch extensions:

- An extensible switch extension must be installed as a modifying filter driver.

  For more information on the INF requirements for a modifying filter driver, see Configuring an INF File for a Modifying Filter Driver.

  Note An extension with a filter class of **ms_switch_capture** can perform the same tasks as a monitoring filter driver. For more information, see Types of Filter Drivers.

- The **FilterMediaTypes** entry in the filter INF file defines the driver's bindings to other drivers and interfaces. The **FilterMediaTypes** entry for an extensible switch extension must include the **vmnetextension** value. This value specifies a binding to the extensible switch extension miniport adapter.

  The **FilterMediaTypes** entry allows a comma-delimited list of media types to be specified. This allows the extension to be bound to a physical interface or to the extensible switch interface.

  The following example shows a **FilterMediaTypes** entry that allows an extension to be bound to either the physical Ethernet network adapter or an extensible switch virtual network adapter.

  INF

  ```
  HKR, Ndi\Interfaces, FilterMediaTypes, , "ethernet, vmnetextension"
  ```

  If the **FilterMediaTypes** entry only specifies the **vmnetextension** value, the extension will only bind to the driver stacks for all extensible switches on the system.

If the **FilterMediaTypes** entry specifies **vmnetextension** as well as other media types, the extension can determine whether it is bound within an extensible switch driver stack by calling **NdisFGetOptionalSwitchHandlers**. If the function returns NDIS_STATUS_SUCCESS, the extension is bound within the extension driver stack. If the function returns NDIS_STATUS_NOT_SUPPORTED, the extension is bound within the driver stack for a different physical network interface.

For more information about the **FilterMediaTypes** entry, see Intermediate Driver UpperRange And LowerRange INF File Entries.

- The **FilterClass** value in the INF file for an extension determines its order in a stack of filters. The **FilterClass** entry must contain one of the values from the following table.

FilterClass value	Description
ms_switch_capture	An extension of this class monitors packet traffic. However, this class of extension cannot apply port policies or alter destination ports for a packet. For more information about this class of extension, see Capturing Extensions.
ms_switch_filter	An extension of this class filters packet traffic and enforces port or switch policy for packet delivery through the extensible switch. This class of driver can also inspect and remove destination ports for each packet based on policy settings. For more information about this class of extension, see Filtering Extensions.

FilterClass value	Description
ms_switch_forward	An extension of this class has the same capabilities as the **ms_switch_filter** class. This class of extension can also forward packets to other extensible switch ports, as well as inject packet traffic to any extensible switch port. On the ingress data path, this class of extension is invoked after the **ms_switch_filter** class of extension. On the egress data path, this class of extension is invoked before the **ms_switch_filter** class of extension. For more information about this class of extension, see Forwarding Extensions. **Note** Only one extension of this class is allowed in the extensible switch driver stack.

When the extension is installed with these INF settings, it will be configured to bind to every extensible switch instance. However, the binding will be disabled and must be explicitly enabled through a PowerShell cmdlet. For more information on this procedure, see Enabling Hyper-V Extensible Switch Extensions.

Extension Driver MSI Packaging Requirements

Article • 12/15/2021

Switch extensions must be packaged in a silently installable MSI file. This file can then be deployed to the computer where the extensions are used by management applications automatically.

The MSI file must meet the following requirements:

- Drivers must be packaged and distributed in the standard MSI package format.
- The MSI package must be silently uninstallable.
- The MSI package can contain only one extension.
- The MSI package must contain the required table fields described in the MSI table fields listed below. In addition, the MSI file must be able to silently install the driver .sys, .inf and any supplemental files required for the driver to operate using the parameters described in the *DriverInstallParams* field of the MSI Properties table fields list below.

Field	Required	Type	Details
Description	Required	**String**	Description for the extension that is displayed.
Manufacturer	Required	**String**	Name of the company publishing the extension driver. Localized strings can be stored.
ProductVersion	Required	**String**	The version of the this MSI package. Example: 1.0.0.0
ProductName	Required	**String**	Name of the driver.
DriverID	Required	**String**	Must match the Msvm_InstalledEthernetSwitchExtension.Name field that is available after the driver is installed and the driver ID in the driver's INF file.
DriverVersion	Required	**String**	The version of the driver contained in this package. Example: 1.0.0.0
ExtensionType	Required	**String**	Type of the extension. Values: Forwarding, Capture, Monitoring, Filter

Field	Required	Type	Details
DriverInstallParams	Required	**String**	Parameters used to install this driver silently. Example: /q
IsManagedByExtensionManager	Optional	**String**	Present and non-zero = Yes, 0 or not present = No
MinApplicableOSVersion	Required	**String**	The minimum version of the Windows operating system that this extension will run on. See Operating System Version for operating system version numbers. Note that the Hyper-V Extensible Switch feature was added in Windows Server 2012, so the lowest valid value for this field is "6.2".
MaxApplicableOSVersion	Optional	**String**	The maximum version of the Windows operating system that this extension will run on. See Operating System Version for operating system version numbers. Note that the Hyper-V Extensible Switch feature was added in Windows Server 2012, so the lowest valid value for this field is "6.2" or the value of **MinApplicableOSVersion**, whichever is higher. This field is optional. If no value is specified, the extension will run on **MinApplicableOSVersion** and later.

Managing Installed Hyper-V Extensible Switch Extensions

Article • 12/15/2021

Starting with Windows Server 2012, Hyper-V extensible switch extensions within each extensible switch instance can be managed through PowerShell cmdlets. Through these cmdlets, extensions can be enabled or disabled, and the order of extensions within the same class can be changed in the extensible switch driver stack. This allows each extensible switch instance to have a different set of enabled extensions and a unique ordering of extensions of the same class.

This section includes the following topics that describe how you use PowerShell cmdlets to manage Hyper-V extensible switch extensions:

- Enumerating Hyper-V Extensible Switch Instances
- Enumerating Hyper-V Extensible Switch Extensions
- Enabling Hyper-V Extensible Switch Extensions
- Disabling Hyper-V Extensible Switch Extensions
- Reordering Hyper-V Extensible Switch Extensions

Enumerating Hyper-V Extensible Switch Instances

Article • 12/15/2021

The Get-VMSwitch PowerShell cmdlet enumerates the Hyper-V virtual networks that have been created. One or more Hyper-V child partitions can be assigned to each virtual network. The Hyper-V virtualization stack creates an instance of a Hyper-V extensible switch for a virtual network when the first Hyper-V child partition that is assigned to the network is started.

The Get-VMSwitch cmdlet uses the following syntax:

syntax

```
Get-VMSwitch [[-Name] <string>] [-SwitchType <VMSwitchType[]>] [[-
ResourcePoolName] <string[]>] [-ComputerName
    <string[]>] [<CommonParameters>]

Get-VMSwitch [[-Id] <Guid[]>] [-SwitchType <VMSwitchType[]>] [[-
ResourcePoolName] <string[]>] [-ComputerName
    <string[]>] [<CommonParameters>]
```

The following example shows the output from the Get-VMSwitch cmdlet.

syntax

```
PS C:\Windows\system32> Get-VMSwitch

Name                           Learnable Status
                               Addresses
----                           --------- ------
Virtual Network - 1            2048      {OK}
Virtual Network - 2            2048      {OK}
```

Enumerating Hyper-V Extensible Switch Extensions

Article • 12/15/2021

The Get-VMSwitchExtension PowerShell cmdlet enumerates the Hyper-V extensible switch extensions that are currently bound to an instance of an extensible switch. This cmdlet also reports whether the extension is enabled in the extensible switch instance.

The Get-VMSwitchExtension cmdlet uses the following syntax:

syntax

```
Get-VMSwitchExtension [[-VMSwitchName] <string[]>] [[-Name] <string[]>] [-
ComputerName <string[]>]
    [<CommonParameters>]

Get-VMSwitchExtension [[-VMSwitch] <VMSwitch[]>] [-ComputerName <string[]>]
[<CommonParameters>]
```

The following example shows the output from the Get-VMSwitchExtension cmdlet.

syntax

```
PS C:\Windows\system32> Get-VMSwitchExtension PrivateNetwork | fl -property
@("Name","ExtensionType", "SwitchName","Enabled")

Name          : NDIS Capture LightWeight Filter
ExtensionType : Capture
SwitchName    : PrivateNetwork
Enabled       : False

Name          : Switch Extensibility Test Extension 2
ExtensionType : Filter
SwitchName    : PrivateNetwork
Enabled       : False

Name          : Switch Extensibility Test Extension 1
ExtensionType : Filter
SwitchName    : PrivateNetwork
Enabled       : False

Name          : WFP extensible switch Layers LightWeight Filter
ExtensionType : Filter
SwitchName    : PrivateNetwork
Enabled       : True
```

Note In order to minimize the amount of information, the example pipes the returned extension objects through the filter command "fl". This causes a subset of information to be displayed that matches the attributes of the **-property** switch.

Enabling Hyper-V Extensible Switch Extensions

Article • 12/15/2021

When Hyper-V extensible switch extensions are installed, they are bound to each instance of an extensible switch. However, the extensions are disabled by default and must be explicitly enabled on each extensible switch instance.

The Enable-VMSwitchExtension PowerShell cmdlet enables an extension on a specific instance of an extensible switch. This cmdlet uses the following syntax:

syntax

```
Enable-VMSwitchExtension [-Name] <string[]> [-ComputerName <string[]>]
[<CommonParameters>]

Enable-VMSwitchExtension [-Name] <string[]> [-VMSwitchName] <string[]> [-
ComputerName <string[]>]
    [<CommonParameters>]

Enable-VMSwitchExtension [-Name] <string[]> [-VMSwitch] <VMSwitch[]> [-
ComputerName <string[]>]
    [<CommonParameters>]

Enable-VMSwitchExtension [-VMSwitchExtension] <VMSwitchExtension[]> [-
ComputerName <string[]>] [<CommonParameters>]
```

The following shows an example of how to use the Enable-VMSwitchExtension cmdlet.

syntax

```
PS C:\Windows\system32> Enable-VMSwitchExtension "Switch Extensibility Test
Extension 1" PrivateNetwork

PS C:\Windows\system32> Get-VMSwitchExtension PrivateNetwork "Switch
Extensibility Test Extension 1" | fl -property @("Name","ExtensionType",
"SwitchName","Enabled")

Name          : Switch Extensibility Test Extension 1
ExtensionType : Filter
SwitchName    : PrivateNetwork
Enabled       : True
```

Note The Windows Filtering Platform (WFP) in-box filtering extension (Wfplwfs.sys) is enabled by default on each extensible switch instance.

Disabling Hyper-V Extensible Switch Extensions

Article • 12/15/2021

The Disable-VMSwitchExtension PowerShell cmdlet disables an extension on a specific instance of an extensible switch.

The Disable-VMSwitchExtension cmdlet uses the following syntax:

syntax

```
Disable-VMSwitchExtension [-VMSwitchExtensionName] <string[]> [-ComputerName
<string[]>] [<CommonParameters>]

Disable-VMSwitchExtension [-VMSwitchExtensionName] <string[]> [-
VMSwitchName] <string[]> [-ComputerName
    <string[]>] [<CommonParameters>]

Disable-VMSwitchExtension [-VMSwitchExtensionName] <string[]> [-VMSwitch]
<VMSwitch[]> [-ComputerName <string[]>]
    [<CommonParameters>]

Disable-VMSwitchExtension [-VMSwitchExtension] <VMSwitchExtension[]> [-
ComputerName <string[]>]
    [<CommonParameters>]
```

The following shows an example of how to use the Disable-VMSwitchExtension cmdlet.

syntax

```
PS C:\Windows\system32> Disable-VMSwitchExtension "Switch Extensibility Test
Extension 1" PrivateNetwork

PS C:\Windows\system32> Get-VMSwitchExtension PrivateNetwork "Switch
Extensibility Test Extension 1" | fl -property @("Name","ExtensionType",
"SwitchName","Enabled")

Name          : Switch Extensibility Test Extension 1
ExtensionType : Filter
SwitchName    : PrivateNetwork
Enabled       : False
```

Reordering Hyper-V Extensible Switch Extensions

Article • 12/15/2021

Multiple Hyper-V extensible switch capturing or filtering extensions can be enabled in each instance of an extensible switch.

Note Only one forwarding extension can be enabled in each instance of an extensible switch.

By default, multiple capturing or filtering extensions are ordered based on their type and when they were installed. For example, multiple capturing extensions are layered in the extensible switch driver stack with the most recently installed extension closest to the protocol edge of the switch.

When multiple capturing or filtering extensions are installed, you can use PowerShell cmdlets to reorder the drivers in the extensible switch driver stack. The following example shows the commands that you enter from a PowerShell window to do this.

syntax

```
# Show the current order. The ExtensionOrder field contains paths to WMI
extension instances.
# The [wmi] operator can be used to convert the paths to full WMI objects.
PS C:\Windows\system32> $privateNetwork = Get-VMSwitch PrivateNetwork
PS C:\Windows\system32> $extensionOrder = $privateNetwork.ExtensionOrder
PS C:\Windows\system32> $extensionOrder | ForEach-Object { Write-Host
"Name:" ([wmi]$_).ElementName }
Name: NDIS Capture LightWeight Filter
Name: Switch Extensibility Test Extension 2
Name: Switch Extensibility Test Extension 1
Name: WFP extensible switch Layers LightWeight Filter

Hyper-V Extensible Switch OIDs

Article • 12/15/2021

This section describes the Hyper-V extensible switch object identifiers (OIDs). These OIDs may be issued by either the extensible switch extension or a Hyper-V extensible switch extension.

The following table defines the characteristics of the extensible switch OIDs. The following abbreviations are used to specify the OIDs' characteristics in the table.

- Q
  The OID is used only in query requests.
- S
  The OID is used only in set requests.
- M
  The OID is used only in method requests. These requests could be issued for set or query operations.
- P
  The OID request is issued by the protocol edge of the extensible switch. The extension can inspect the results of the OID request to obtain information about the extensible switch, its ports, or virtual network adapters connected to the ports.
- E
  The OID request is issued by an extension.

Name	**Q**	**S**	**M**	**P**	**E**

Hyper-V Extensible Switch Status Indications

Article • 12/15/2021

This section describes the following NDIS status indications that can be issued or handled by a Hyper-V extensible switch extension:

- **NDIS_STATUS_SWITCH_NIC_STATUS**
- **NDIS_STATUS_SWITCH_PORT_REMOVE_VF**

For more information on how extensions issue or handle extensible switch extension status indications, see Hyper-V Extensible Switch Control Path for NDIS Status Indications.

NDIS_STATUS_SWITCH_NIC_STATUS

Article • 03/14/2023

The **NDIS_STATUS_SWITCH_NIC_STATUS** status indication is used to encapsulate a status indication from a physical network adapter that is bound to the external network adapter of the Hyper-V extensible switch. Through this encapsulation, the status indication is forwarded up the extensible switch driver stack.

The **StatusBuffer** member of the NDIS_STATUS_INDICATION structure for this indication contains a pointer to an NDIS_SWITCH_NIC_STATUS_INDICATION structure.

Remarks

When an underlying physical network adapter issues an NDIS status indication, it is received by the external network adapter. When this happens, the extensible switch interface performs these steps:

1. The interface encapsulates the status indication inside an NDIS_SWITCH_NIC_STATUS_INDICATION structure.

2. The interface issues an **NDIS_STATUS_SWITCH_NIC_STATUS** status indication to forward the encapsulated status indication up the extensible switch driver stack. This allows extensible switch extensions to modify the encapsulated status indication.

   Typically, the extension modifies an encapsulated status indication to change the current offload capabilities of the underlying team of physical adapters that are bound to the external network adapter.

   For more information about the different configurations in which physical network adapters can be bound to the external network adapter, see Types of Physical Network Adapter Configurations.

3. When the **NDIS_STATUS_SWITCH_NIC_STATUS** status indication is received by the overlying extensible switch protocol driver in the stack, the interface forwards the decapsulated status indication to overlying protocol or filter drivers.

An extension can also originate encapsulated hardware offload status indications to overlying drivers in the extensible switch driver stack. This also allows the driver to change the current offload capabilities of the underlying team of physical adapters that are attached to the external network adapter. When a team of adapters are bound to the external network adapter, only the common capabilities of the team are advertised to NDIS or the overlying protocol and filter drivers. The extension can extend the advertised capabilities by originating encapsulated status indications to advertise capabilities that are supported by some adapters in the team.

For example, the extension can issue an encapsulated NDIS_STATUS_RECEIVE_FILTER_CURRENT_CAPABILITIES indication to change the currently-enabled receive filter capabilities for the entire team.

For more information on how to forward or originate **NDIS_STATUS_SWITCH_NIC_STATUS** indications, see Managing NDIS Status Indications from Physical Network Adapters.

Requirements

Version	Supported in NDIS 6.30 and later.
Header	Ndis.h (include Ndis.h)

NDIS_STATUS_RECEIVE_FILTER_CURRENT_CAPABILITIES

NDIS_STATUS_SWITCH_PORT_REMOVE_VF

Article • 03/14/2023

The **NDIS_STATUS_SWITCH_PORT_REMOVE_VF** status indication is issued by a Hyper-V extensible switch forwarding extension to remove the binding between a virtual machine (VM) network adapter and a PCI Express (PCIe) virtual function (VF). The VF is exposed and supported by an underlying physical network adapter that supports the single root I/O virtualization (SR-IOV) interface.

In order to issue the **NDIS_STATUS_SWITCH_PORT_REMOVE_VF** status indication, the forwarding extension must encapsulate the indication in an **NDIS_SWITCH_NIC_STATUS_INDICATION** structure and issue an **NDIS_STATUS_SWITCH_NIC_STATUS** status indication.

For more information on this process, see Guidelines for Issuing an **NDIS_STATUS_SWITCH_PORT_REMOVE_VF** Status Indication.

Remarks

A PCIe VF is created and allocated by an underlying physical adapter that supports the SR-IOV interface. Once created, the virtualization stack attaches, or *assigns*, the VF to a Hyper-V child partition. The guest operating system that runs in this partition exposes a virtual machine (VM) network adapter that is bound to the VF of the underlying SR-IOV physical adapter.

After the virtual and physical network adapters are assigned, packets are routed directly between the VF and the VM network adapter. However, because the extensible switch is not involved in packet delivery, extensible switch port policies are not applied to these packets. This includes port policies for access control lists (ACLs) and quality of service (QoS).

An extensible switch forwarding extension can remove the assignment of the VF to the child partition by issuing an **NDIS_STATUS_SWITCH_PORT_REMOVE_VF** status indication. This indication causes the packets to be delivered through an extensible switch port instead of directly between the VM network adapter and the VF of the underlying SR-IOV physical adapter. This allows the extensible switch port policies to be applied to packets that are received or sent over the extensible switch port.

When the forwarding extension makes the **NDIS_STATUS_SWITCH_PORT_REMOVE_VF** status indication, it specifies the extensible switch port to which the VM network adapter is connected.

For more information about extensible switch forwarding extensions, see Forwarding Extensions.

Guidelines for Issuing an NDIS_STATUS_SWITCH_PORT_REMOVE_VF Status Indication

In order to issue the **NDIS_STATUS_SWITCH_PORT_REMOVE_VF** status indication, the forwarding extension must follow these steps:

1. The forwarding extension initializes an NDIS_STATUS_INDICATION structure for the **NDIS_STATUS_SWITCH_PORT_REMOVE_VF** indication. For this indication, the forwarding extensions sets the following members of the **NDIS_STATUS_INDICATION** structure:

   - The **StatusCode** member must be set to **NDIS_STATUS_SWITCH_PORT_REMOVE_VF**.

   - The **StatusBuffer** member must be set to **NULL**.

   - The **StatusBufferSize** must be set to zero.

2. The forwarding extension initializes an NDIS_SWITCH_NIC_STATUS_INDICATION structure. In order to remove a VF assignment, the forwarding extension must set the members in the following way:

   - The **DestinationPortId** member must be set to the identifier of an extensible switch port to which the VM network adapter is connected.

   - The **DestinationNicIndex** member must be set to the index value of the VM network adapter that is connected to the specified port.

   - The **SourcePortId** member must be set to **NDIS_SWITCH_DEFAULT_PORT_ID**.

   - The **SourceNicIndex** member must be set to **NDIS_SWITCH_DEFAULT_NIC_INDEX**.

   - The **StatusIndication** member must be set to the address of the NDIS_STATUS_INDICATION structure for the **NDIS_STATUS_SWITCH_PORT_REMOVE_VF** indication.

3. The forwarding extension initializes an NDIS_STATUS_INDICATION structure for the NDIS_SWITCH_NIC_STATUS_INDICATION indication. For this indication, the forwarding extension sets the following members of the **NDIS_STATUS_INDICATION** structure:

   - The **StatusCode** member must be set to NDIS_STATUS_SWITCH_NIC_STATUS.

   - The **StatusBuffer** member must be set to the address of the NDIS_SWITCH_NIC_STATUS_INDICATION structure.

   - The **StatusBufferSize** must be set to the length, in bytes, of the NDIS_SWITCH_NIC_STATUS_INDICATION structure and the NDIS_STATUS_INDICATION structure for the **NDIS_STATUS_SWITCH_PORT_REMOVE_VF** indication.

4. The forwarding extension must call *ReferenceSwitchNic* to increment a reference counter for the VM network adapter. If *ReferenceSwitchNic* does not complete with NDIS_STATUS_SUCCESS, the forwarding extension must not forward the status indication.

   Note If the forwarding extension has received an OID_SWITCH_NIC_DISCONNECT set request for the VM adapter, it must not call *ReferenceSwitchNic* nor forward the status indication.

5. The forwarding extension calls **NdisFIndicateStatus** to forward the **NDIS_STATUS_INDICATION** to overlying extensions in the extensible switch driver stack. When the forwarding extension calls this function, it sets the *StatusIndication* parameter to a pointer to the **NDIS_STATUS_INDICATION** structure for the **NDIS_STATUS_SWITCH_NIC_STATUS** indication.

6. After **NdisFIndicateStatus** returns, the forwarding extension must call *DereferenceSwitchNic* to decrement the reference counter for the VM network adapter.

Note The forwarding extension must follow the previous steps for each VF assignment that the forwarding extension is removing.

For more information on how a forwarding extension forwards status indications, see Filter Module Status Indications.

Guidelines for Determining VF Assignments

The forwarding extension can enumerate the current VF assignments for virtual network adapters by issuing an OID query request of OID_SWITCH_NIC_ARRAY. This request returns an **NDIS_SWITCH_NIC_ARRAY** structure that contains an array of **NDIS_SWITCH_NIC_PARAMETERS** structures. Each **NDIS_SWITCH_NIC_PARAMETERS** structure specifies the parameters of a network adapter that is exposed in one of the following environments:

- The management operating system that runs in the Hyper-V parent partition.

  Network adapters that are exposed in this operating system are specified with an **NDIS_SWITCH_NIC_TYPE** enumeration value of **NdisSwitchNicTypeExternal** or **NdisSwitchNicTypeInternal**.

- The guest operating system that runs in a Hyper-V child partition.

  Network adapters that are exposed in this operating system are specified with an **NDIS_SWITCH_NIC_TYPE** enumeration value of **NdisSwitchNicTypeSynthetic** or **NdisSwitchNicTypeEmulated**.

If the OID query request of OID_SWITCH_NIC_ARRAY completes with a status of NDIS_STATUS_SUCCESS, the forwarding extension can determine VF assignments by inspecting each **NDIS_SWITCH_NIC_PARAMETERS** structure in the returned array. If the **VFAssigned** member of the **NDIS_SWITCH_NIC_PARAMETERS** structure is set to **TRUE**, the network adapter that corresponds to the **NDIS_SWITCH_NIC_PARAMETERS** structure is assigned to a VF.

The forwarding extension can remove the assignment by issuing an **NDIS_STATUS_SWITCH_PORT_REMOVE_VF** status indication. In this case, the forwarding extension must set the **DestinationPortId** member of the **NDIS_SWITCH_NIC_STATUS_INDICATION** to the value of the **PortId** member of the **NDIS_SWITCH_NIC_PARAMETERS** structure.

For more information on how to issue an **NDIS_STATUS_SWITCH_PORT_REMOVE_VF** status indication, see Guidelines for Issuing an NDIS_STATUS_SWITCH_PORT_REMOVE_VF Status Indication.

Requirements

NDIS_STATUS_ISOLATION_PARAMETERS_CHANGE

Article • 03/14/2023

A VM network adapter miniport driver generates an **NDIS_STATUS_ISOLATION_PARAMETERS_CHANGE** status indication whenever the routing domain configuration is updated on the network adapter's port. This triggers the TCP layer to re-query the multi-tenancy configuration by issuing an OID_GEN_ISOLATION_PARAMETERS OID. This status indication does not have a status buffer.

Requirements

Version	Supported in NDIS 6.40 and later.
Header	Ndis.h

NDIS_STATUS_INDICATION

OID_GEN_ISOLATION_PARAMETERS

NDIS_STATUS_RECEIVE_FILTER_QUEUE_PARAMETERS

Article • 03/14/2023

The **NDIS_STATUS_RECEIVE_FILTER_QUEUE_PARAMETERS** status indicates to NDIS and overlying drivers that the current virtual machine (VM) queue parameters have changed on the network adapter.

Remarks

The miniport driver must issue an **NDIS_STATUS_RECEIVE_FILTER_QUEUE_PARAMETERS** status indication when the current VM queue parameters have changed on the network adapter. The VM queue parameters could change when one of the following conditions is true:

- The VM queue parameters are changed through a management application developed by the independent hardware vendor (IHV).
- The VM queue parameters change for one or more network adapters that belong to a load balancing failover (LBFO) team managed by a MUX intermediate driver. For more information, see NDIS MUX Intermediate Drivers.

When the miniport driver issues the **NDIS_STATUS_RECEIVE_FILTER_QUEUE_PARAMETERS** status indication, it must follow these steps:

1. The miniport driver initializes an **NDIS_RECEIVE_QUEUE_PARAMETERS** structure with the current VM queue parameters on the network adapter. The driver must also set the **Flags** member of this structure with the appropriate NDIS_RECEIVE_QUEUE_PARAMETERS_*Xxx*_CHANGED flags to report on **NDIS_RECEIVE_QUEUE_PARAMETERS** member values that have changed.

   Note Starting with NDIS 6.30, the miniport driver can only issue an **NDIS_STATUS_RECEIVE_FILTER_QUEUE_PARAMETERS** status indication to report on changes to the **InterruptCoalescingDomainId** member.

When the miniport driver initializes the **Header** member of this structure, it sets the **Type** member of **Header** to NDIS_OBJECT_TYPE_DEFAULT. The miniport driver sets the **Revision** member of **Header** to NDIS_RECEIVE_QUEUE_PARAMETERS_REVISION_2 and the **Size** member to NDIS_SIZEOF_RECEIVE_QUEUE_PARAMETERS_REVISION_2.

2. The miniport driver initializes an NDIS_STATUS_INDICATION structure in the following way:

   - The **StatusCode** member must be set to **NDIS_STATUS_RECEIVE_FILTER_QUEUE_PARAMETERS**.

   - The **StatusBuffer** member must be set to the pointer to a NDIS_RECEIVE_QUEUE_PARAMETERS structure. This structure contains the currently enabled hardware capabilities of the NIC switch.

   - The **StatusBufferSize** member must be set to sizeof(NDIS_RECEIVE_QUEUE_PARAMETERS).

3. The miniport driver issues the status notification by calling NdisMIndicateStatusEx. The driver must pass a pointer to the NDIS_STATUS_INDICATION structure to the *StatusIndication* parameter.

Overlying drivers can use the **NDIS_STATUS_RECEIVE_FILTER_QUEUE_PARAMETERS** status indication to determine the current VM queue parameters on the network adapter. Alternatively, these drivers can also issue object identifier (OID) query requests of OID_RECEIVE_FILTER_QUEUE_PARAMETERS to obtain these parameters at any time.

Requirements

Version	Supported in NDIS 6.30 and later.

NDIS_RECEIVE_QUEUE_PARAMETERS

NDIS_STATUS_INDICATION

OID_RECEIVE_FILTER_QUEUE_PARAMETERS

NDIS_STATUS_RECEIVE_QUEUE_STATE

Article • 03/14/2023

The NDIS_STATUS_RECEIVE_QUEUE_STATE status indicates to overlying drivers that the queue state of a virtual machine queue (VMQ) receive queue has changed.

Remarks

NDIS 6.20 and later miniport drivers that support the virtual machine queue interface generate this status indication.

The miniport driver supplies an **NDIS_RECEIVE_QUEUE_STATE** structure in the **StatusBuffer** member of the **NDIS_STATUS_INDICATION** structure.

The change to the *DMA Stopped* state is the only queue state change indication that is required. A miniport driver must indicate this state after it receives an OID_RECEIVE_FILTER_FREE_QUEUE set request and stops the DMA. In this case, the miniport driver sets the **QueueState** member of the **NDIS_RECEIVE_QUEUE_STATE** structure to **NdisReceiveQueueOperationalStateDmaStopped**.

After the miniport driver receives the OID_RECEIVE_FILTER_FREE_QUEUE set request, it must stop DMA to any shared memory that was allocated for the specified queue.

If the miniport driver stopped the DMA for some other reason (for example, it freed the last filter on a queue), the queue should not enter the *DMA Stopped* state. However, the DMA can be stopped in the *Paused* or *Running* states if there are no filters set on the queue.

Requirements

Version	Supported in NDIS 6.20 and later.
Header	Ndis.h

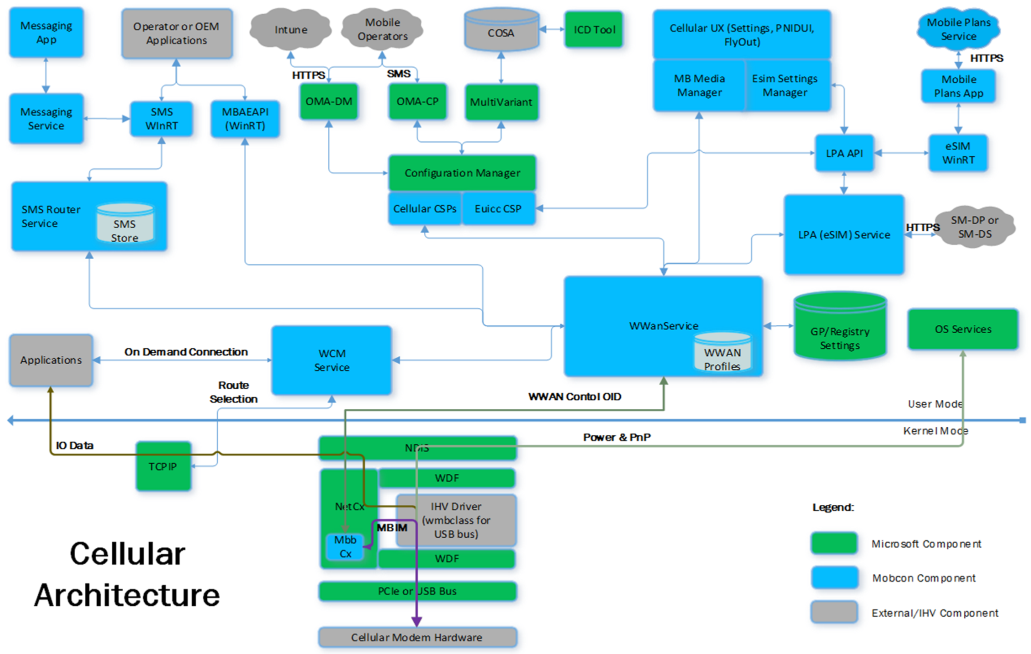
Cellular architecture

Article • 03/14/2023

This section describes the elements of the cellular architecture for Windows 10 and how they interact. It also includes the implementation requirements for making cellular modem hardware compatible with Windows 10.

Windows 10 cellular architecture



The following describes the elements shown in the Windows 10 cellular architecture:

User Mode

WWAN Service and MBAE WinRT API

The Wireless Wide Area Network Service (WwanSvc) is responsible for handling modem initialization, registration, power state changes, and automatic and manual connection for default and on-demand cellular connection. WWAN Service also handles the modem access interface for SAR, PCO, Scan, SMS, USSD, LTE configuration, SIM File, SIM PIN, and low level SIM card access. The Mobile Broadband Account Experience Windows Runtime (MBAE WinRT) API allows programmatic access to these interfaces for original equipment manufacturer (OEM)/Mobile Operator (MO) applications.

WCM Service

The Windows Connection Manager (WCM) Service controls L3 connectivity and dynamically selects which specific L2 media (Ethernet, Wi-Fi, or Cellular) should be connected or disconnected at any given time.

SMS Router Service and SMS WinRT API

The SMS Router Service is responsible for decoding the SMS Packet Data Unit (PDU) and routing SMS messages to associated applications. The SMS WinRT API allows applications to subscribe to SMS messages and launch when the matching messages are received. Apps can also send SMS messages. The SMS messages are temporarily stored for concatenation while decoding the messages and for reliable delivery to services and applications.

Messaging Service and Messaging App

The messaging service stores user text messages for persistent access and the application displays the messages to users.

LPA (eSIM) Service and eSIM WinRT API

The Local Profile Assistant (LPA) Service implements GSMA specification for remote SIM profile management by interacting with the Subscription Manager – Device Provisioning server (SM-DP+) to download eSIM profiles for the user. The WinRT API allows accessing eSIM profiles, enabling, disabling, and deleting profiles, and sending low level Application Protocol Data Unit (APDU) for firmware update via smartcard interface.

Cellular CSPs

Cellular Configuration Service Providers (CSPs) allow configuration management through Intune (Enterprise), Multivariant, and Open Mobile Alliance – Device Management and Client Provisioning (OMA-DM/CP). Enterprise uses EnterpriseAPN, eUICC, and MultiSIM CSPs to override the APN connectivity settings, download and activate eSIM profiles, and switch to preferred SIM slot. CM CellularEntries CSP is used to configure the default connectivity for the modem. Cellular Settings CSP is used to control roaming and automatic connection configurations. CSPLte is used for Verizon-specific configurations.

Mobile Plans Service and Mobile Plans App

The mobile plans service and application offers users a simplified mechanism to purchase and install eSIM profiles.

Cellular UX

Cellular UX is a settings application and VANUI network flyout that allows users to view and control the cellular settings, control connectivity, and change radio state. PNIDUI shows the default network connection and signal bars for the network. Quick actions and airplane mode controls allow radio state control.

COSA/MultiVariant Service

Country & Operator Settings Asset (COSA) is an OEM configurable database with settings that are applied through the MultiVariant service that are specific to the SIM inserted by the user.

Kernel Mode

NDIS

Network Driver Interface Specification (NDIS) is a driver model that abstracts network hardware from network drivers and specifies a standard interface between layered network drivers.

NetCx

Network Adapter WDF Class Extension (NetAdapterCx) is a driver model that enables you to write a KMDF-based client driver for a Network Interface Controller (NIC). NetAdapterCx gives you the power and flexibility of WDF and the networking performance of NDIS, and makes it easy to write a NIC driver.

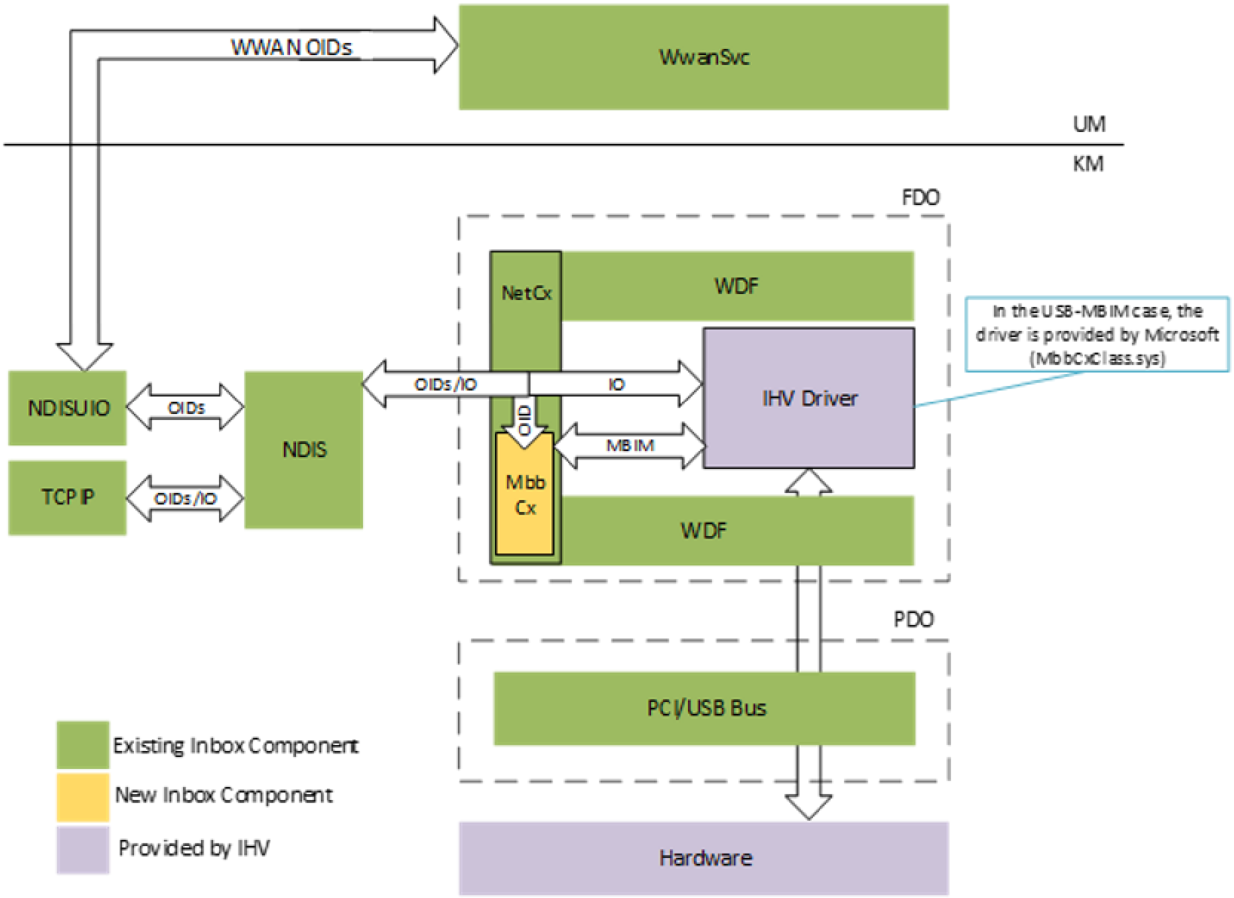
MBBCx

Mobile Broadband WDF Class Extension (MBBCx) extends the NetAdatperCx Driver Framework with cellular-specific functionalities, and implementing the "upper edge" which is common across different modems. MbbCx handles the control OIDs from NDIS and converts them to MBIM commands for the IHV driver.

IHV Driver (wmbclass)

The IHV-implemented "lower edge" cellular device driver implements all of the adapter-specific cellular driver functionalities that are specified by MBIM. For USB based modems, the interfaces are standardized and handled by the inbox wmbclass driver. For PCIe cellular modem devices, the IHV vendors are expected to provide an IHV client driver that translates the MBIM commands to be transmitted over the PCIe bus.

MBB and MBIM Driver Interactions



Windows 10 cellular implementation requirements

For Windows 10, the following is required.

- Implement the MBIM protocol interface in your modem hardware.
- Implement a USB interface to the modem hardware. This can be a removable USB dongle or another interface that presents itself as a USB host controller.

Roadmap to Develop MB Miniport Drivers

Article • 03/14/2023

To create an MB miniport driver, follow these steps:

- **Step 1**: Learn about Windows architecture and miniport drivers.

  You must understand the fundamentals of how drivers work in Windows operating systems. Knowing the fundamentals will help you make appropriate design decisions and let you streamline your development process. For more information about driver fundamentals, see Concepts for all driver developers.

- **Step 2**: Learn the fundamentals of MB miniport drivers.

  MB miniport drivers are supported in Windows 7 and later versions of Windows and conform to the *NDIS 6.20 Specification*. To understand the miniport driver design decisions you must make, see Introduction to NDIS 6.20.

- **Step 3**: Determine additional Windows driver design decisions.

  For information about how to make additional Windows design decisions, see Creating Reliable Kernel-Mode Drivers, Programming Issues for 64-Bit Drivers, and Creating International INF Files.

- **Step 4**: Learn about the Windows driver build, test, and debug processes and tools.

  Building a driver differs from building a user mode application. For information about Windows driver build, debug, and test processes, driver signing, and Windows Hardware Lab Kit (HLK) testing, see Building, Debugging, and Testing Drivers. For information about building, testing, verifying, and debugging tools, see Driver Development Tools.

- **Step 5**: Make design decisions about your MB miniport driver.

  For more information, see MB Interface Overview.

- **Step 6**: Develop, build, test, and debug your MB miniport driver.

  For information about iterative building, testing, and debugging, see Overview of Build, Debug, and Test Process. This process will help ensure that you build a miniport driver that works.

- **Step 7**: Create a driver package for your MB miniport driver.

For more information, see Providing a Driver Package.

- **Step 8**: Sign and distribute your MB miniport driver.

  The final step is to sign (optional) and distribute the miniport driver. If your miniport driver meets the quality standards that are defined for the Windows Hardware Lab Kit (HLK), you can distribute it through the Microsoft Windows Update program. For more information about how to distribute a driver, see Get started with the hardware submission process.

These are the basic steps. Additional steps might be necessary based on the needs of your individual miniport driver.

MB Interface Model Overview

Article • 03/14/2023

This section provides information for mobile broadband devices that are implemented based on the Mobile Broadband Interface Model (MBIM) specification.

Starting with Windows 8, Microsoft provides an inbox class driver, referred to as MBCD, for MBIM functions. Microsoft already provides an inbox driver, USBCCGP, for composite devices. This section describes the requirements for mobile broadband devices to load USBCCGP and MBCD in Windows 8.

Mobile broadband composite devices that use WMC UFD for grouping interfaces into functions should implement Microsoft OS descriptors to load USBCCGP on Windows 8 and instruct USBCCGP to parse WMC UFD to create functions. Mobile broadband composite devices that use Interface Association Descriptors (IADs) for grouping interfaces into functions do not need to implement Microsoft OS descriptors to load USBCCGP.

MBIM functions that are backward compatible should implement Microsoft OS descriptors to load MBCD. MBIM functions that are not backward compatible do not need to implement Microsoft OS descriptors to load MBCD.

Mobile broadband devices that exhibit identity morphing should also implement Microsoft OS descriptors.

These scenarios are discussed in more detail throughout the MB Interface Model topics. The following table summarizes all of the Microsoft OS compatible IDs mentioned in these subtopics. For more information see Microsoft OS Descriptors.

Microsoft OS compatible IDs

Microsoft OS Compatible ID	Microsoft OS Sub Compatible ID	Required for Scenario
"CDC_WMC"		Loading USBCCGP on composite devices that use WMC UFD for grouping interfaces into functions
"MBIM"		Loading MBCD on MBIM backward-compatible function
"ALTRCFG"	Configuration number in ASCII	Identity morphing with IADs

Microsoft OS Compatible ID	Microsoft OS Sub Compatible ID	Required for Scenario
"WMCALTR"	Configuration number in ASCII	Identity morphing with WMC UFD

The MB Interface Model in described further in the following subtopics:

MB Interface Terms MB Union Function Descriptors MB Identity Morphing MB Interface Model Supplement

MB Interface Terms

Article • 03/14/2023

The following terminology is used throughout the Mobile Broadband (MB)documentation:

Term	Description
MBIM	Mobile Broadband Interface Model, a USB Device Working Group (DWG) specification for mobile broadband devices.
MBIM function	A USB function within a USB device that is compliant with the MBIM specification.
Mobile broadband device	A USB device that is either single function or multi-functional. In the single function case, the function should be an MBIM function. In the multi-function case, one of the functions is the MBIM function. This may also be a multi-configuration device in which at least one of the configurations contains the MBIM function.
NCM2	The earlier name for the MBIM specification. Some diagrams still refer to the MBIM functions as NCM2 functions.
Virtual CD-ROM	A CD-ROM function that does not have a physical CD-ROM drive.
IAD	Interface association descriptors (IADs) used to group interfaces into functions.
WMC UFD	Union function descriptors (UFDs) described in the Wireless Mobile Communication (WMC) specifications. UFDs are used to group interfaces into functions. This is an alternative to using IADs.
Morphing	The ability of a USB device to expose a different set of USB functions than what is currently exposed.
Driver	Software required by Windows to work with a USB function.
Inbox driver	A driver supplied by Microsoft for USB functions. These drivers are present in Windows.
IHV driver	A driver supplied by the independent hardware vendor (IHV) for USB functions that do not have inbox drivers.
IHV driver package	A collection of all IHV drivers supplied by the IHV.
USBHUB	A Microsoft USB hub driver.
USBCCGP	A Microsoft driver for USB composite devices.

Term	Description
MBCD	Mobile Broadband Class Driver, the inbox driver in Windows 8 for USB functions that conform to the MBIM specification.

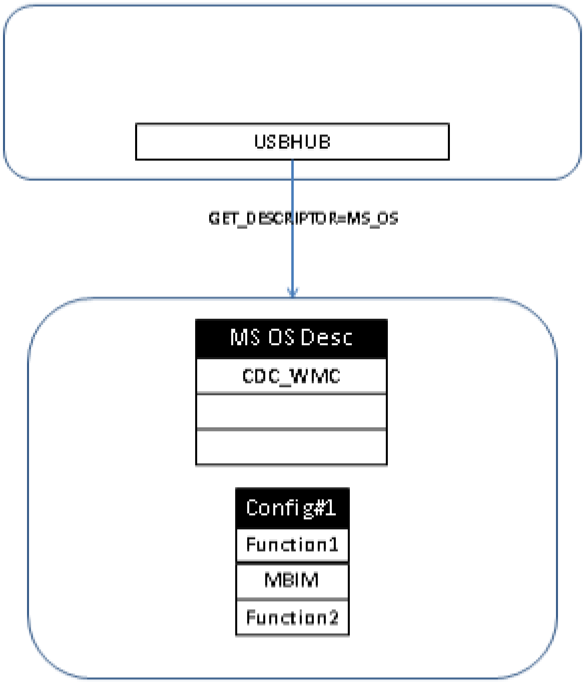
MB Union Function Descriptors

Article • 03/14/2023

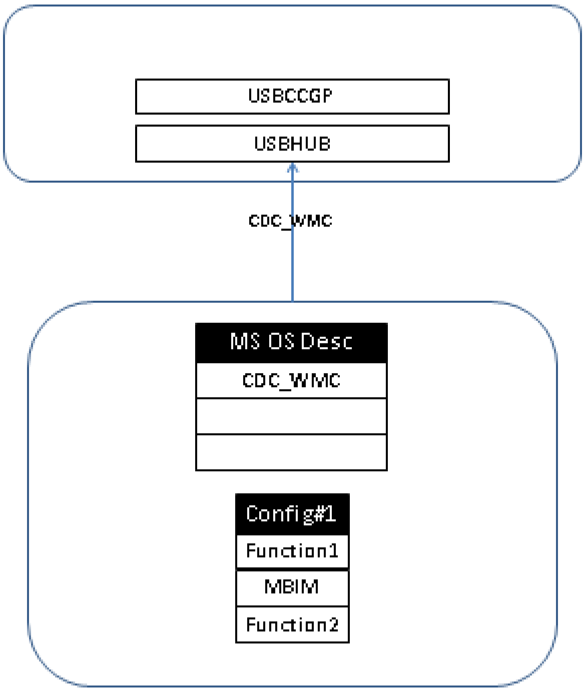
Union Function Descriptors

Mobile broadband devices that implement UFDs have Device Class / Subclass / Protocol of 2 / 0 / 0 as required for CDC devices. This prevents Windows from loading USBCCGP on the device. For information on how Windows loads USBCCGP on composite devices, see USB Generic Parent Driver (Usbccgp.sys).

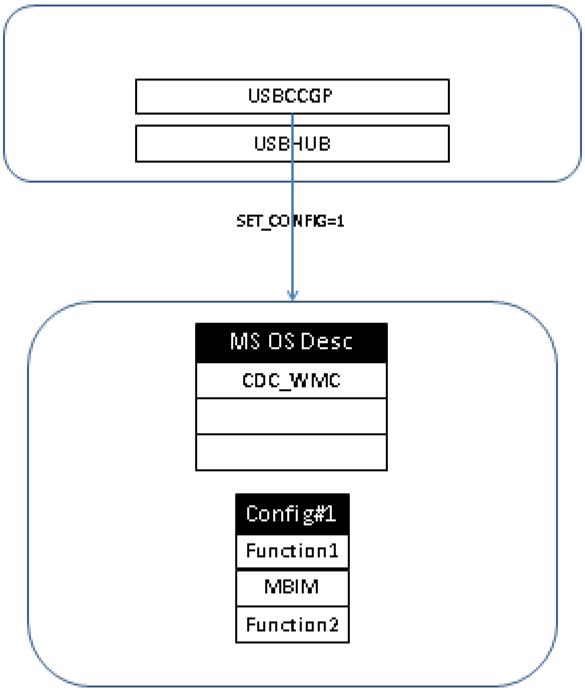
To allow Windows to load USBCCGP, the device needs to report a Microsoft OS compatible ID of "CDC_WMC" when the device is not configured. After detecting the compatible ID of "CDC_WMC", Windows loads USBCCGP, and USBCCGP sets the configuration on the device to 1. USBCCGP will then query again for the Microsoft OS compatible IDs. This time, however, the device should not report the Microsoft OS compatible ID of "CDC_WMC". The device may report Microsoft OS compatible IDs for functions in the selected configuration.



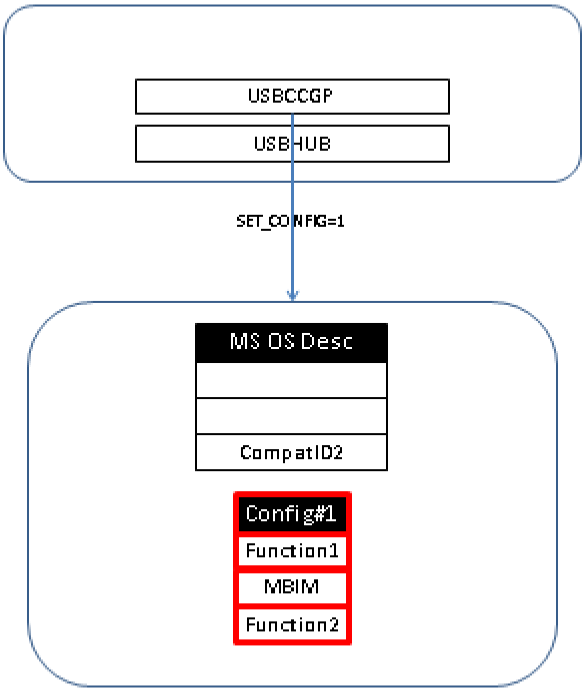
USBHUB queries for the Microsoft OS descriptor when the device is not configured



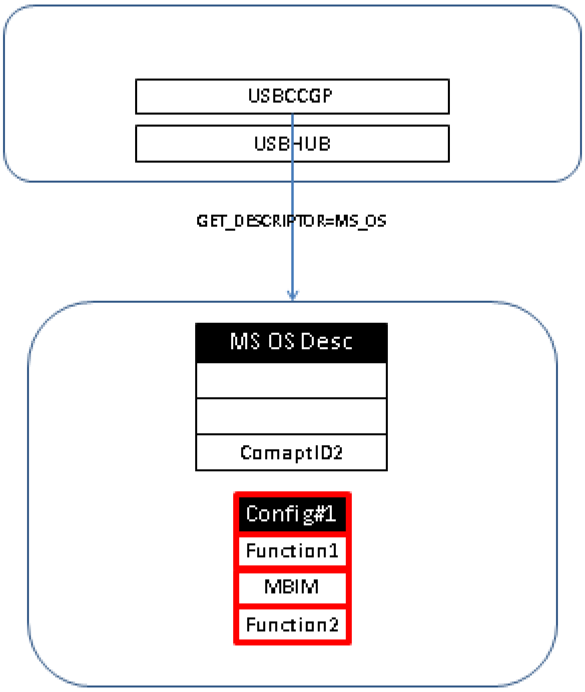
The device responds with "CDC_WMC", which causes Windows to load USBCCGP



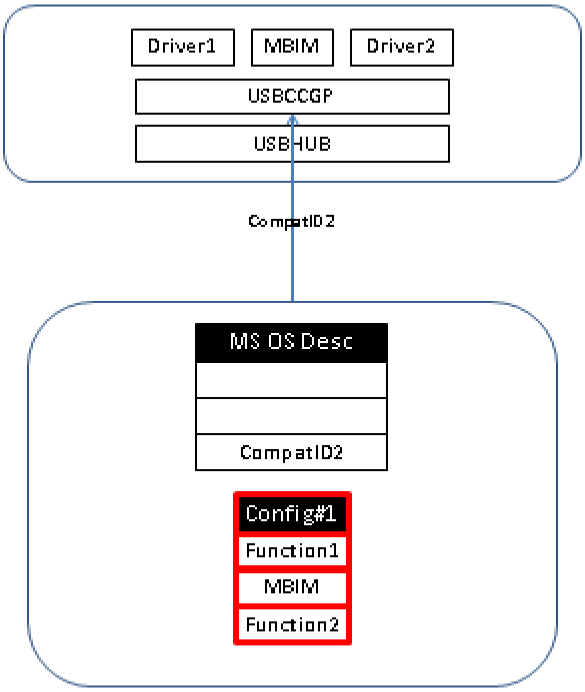
USBCCGP selects Configuration #1 on the device.



The device selects the configuration and morphs the list of compatible IDs. The device may include CompatID2, which is necessary for Function2.



After loading, USBCCGP queries for Microsoft OS compatible IDs again.



The device reports any compatible ID that it has for its function. USBCCGP then creates child device nodes for each function in the device.

MBIM Backward-Compatible Functions

MBIM functions that are backward compatible with the NCM 1.0 specification will come up as NCM 1.0 functions by default. Mobile broadband devices that consist of an MBIM backward-compatible function should report a Microsoft OS compatible ID of "MBIM" for the MBIM function. This allows Windows 8 to detect the NCM 1.0 function as the MBIM function and load MBCD as the function driver.

Introduction to MB Identity Morphing

Article • 03/14/2023

Identity Morphing

Mobile broadband USB dongle solutions eliminate the need for distributing the driver package for mobile broadband and other IHV functions through separate media (such as CD-ROM) by having a storage function in the USB device itself that contains the driver package.

Upon first time insertion of such a device in Windows, the device presents itself as mass storage, which results in the Windows AutoPlay dialog displayed to the user. At this point, the device exposes no other functions to the host except the mass storage function to prevent the other functions appearing to the user as non-functional due to missing driver software. The user can run the IHV-supplied software that installs the driver package. In addition to installing the driver package, the IHV-supplied software also morphs the device to expose the other functions to the user.

Mobile broadband devices that use the previously described mechanism when inserted in Windows 8 would come up as mass storage. Because Windows 8 has native support for mobile broadband functions that conform to the MBIM specification, installation of the driver package is not necessary for the user to use the mobile broadband function. The subtopics in this section provide guidance to IHVs on how to implement this solution for Windows 8 to allow the user to use the mobile broadband device without the need to install the driver package.

Mobile broadband devices that exhibit morphing behavior are referred to as morphing devices throughout the subtopics in this section.

MB Identity Morphing Solution Overview MB Identity Morphing Solution Details

MB Identity Morphing Solution Overview

Article • 03/14/2023

The solution maps the morphing device’s USB configuration to a set of USB functions. At any point in time, a single set of functions (by way of a configuration) are exposed to the host. The solution achieves morphing by switching between these configurations.

Logical configurations

The functions present in the device are grouped into the following logical sets.

Logical Set of Functions

Logical Set of Functions	Description
Windows-7-Configuration	Configuration selected by Windows 7 and older versions of Windows when the morphing device is inserted into the host for the first time.
Windows-8-Configuration	Configuration selected by Windows 8 when the morphing device is inserted into the host.
IHV-NCM-1.0-Configuration	Configuration selected by the IHV software installed on Windows 7 and older versions of Windows after the user installs the driver package.
IHV-NCM-2.0-Configuration	Configuration selected by the IHV software installed on Windows 8 after the user installs the driver package.

The following table shows the USB configurations listed in the previous table along with possible interfaces and functions. Additional requirements for each configuration are described in the remaining subtopics.

USB Configurations

Configuration 1 (Windows-7-Configuration)	Configuration 2(IHV–NCM-10-Configuration)	Configuration 3(Windows-8-Configuration)	Configuration 4(IHV–NCM-20-Configuration)

Configuration 1 (Windows-7-Configuration)	Configuration 2(IHV–NCM-10-Configuration)	Configuration 3(Windows-8-Configuration)	Configuration 4(IHV–NCM-20-Configuration)
Mass CD-ROM	Mass CD-ROM	Mass CD-ROM	Mass CD-ROM
Mass SD	Mass SD	Mass SD	Mass SD
	NCM1.0	MBIM	NCM2.0
	Modem		Modem
	TV		TV
	GPS		GPS
	FP		FP
	PC/SC smart card		PC/SC smart card
	Voice		Voice
	Diag		Diag

Goals of the solution

- In Windows 7, users need to perform the extra step of installing driver packages before being able to use the mobile broadband function on morphing devices.
- In Windows 8, users should not have to perform extra steps for installing driver packages to use the mobile broadband function on morphing devices that conform to the MBIM specification.
- In Windows 8, users need to perform the extra step of installing driver packages before being able to use IHV functions on morphing devices that do not have inbox drivers.

Assumptions

MBIM also includes backward compatibility for NCM 1.0.

Supported Transitions

For Windows 8

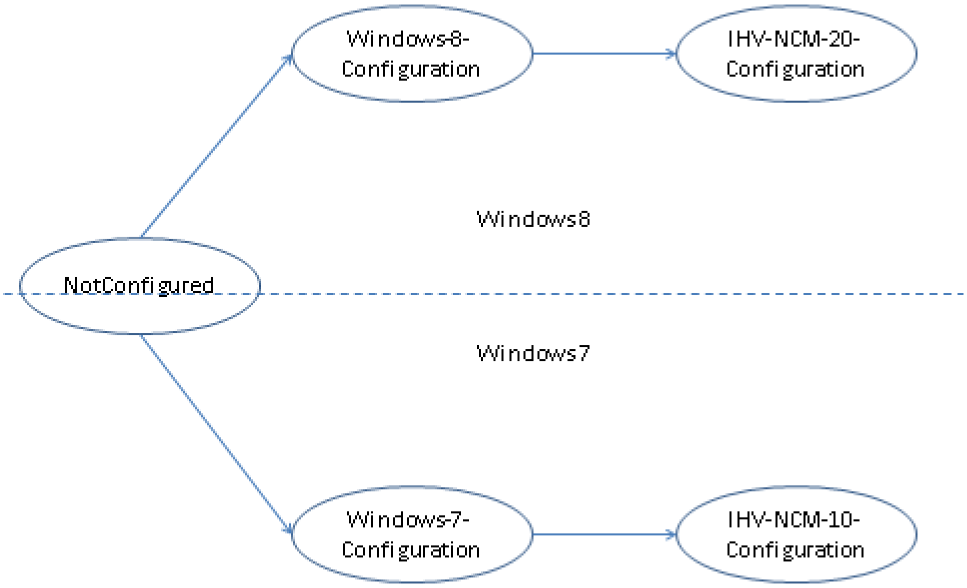
Not-Configured -> Windows-8-Configuration

Windows-8-Configuration -> IHV-NCM-2.0-Configuration

For Windows 7

Not-Configured -> Windows-7-Configuration

Windows-7-Configuration -> IHV–NCM-1.0-Configuration

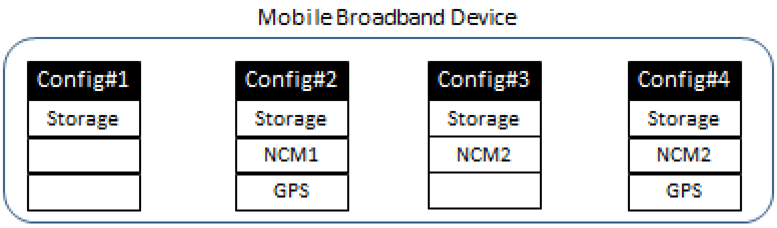


The configuration transition paths for Windows 7 and Windows 8

Note that any transition not shown previously is not supported.

Transition Details

Consider a sample USB morphing device with the following functions in its configurations.



Mobile Broadband Device

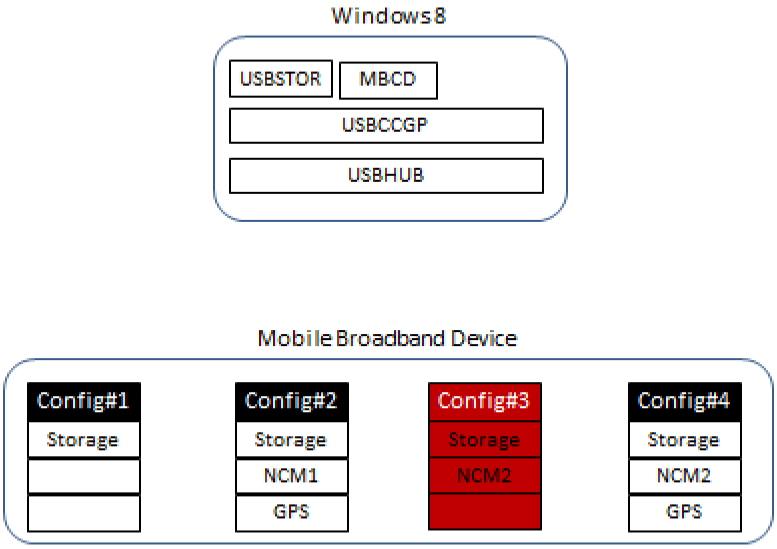
Config#1	Config#2	Config#3	Config#4
Storage	Storage	Storage	Storage
	NCM1	NCM2	NCM2
	GPS		GPS

USB device with multiple functions

Windows 8

Windows-8-Configuration

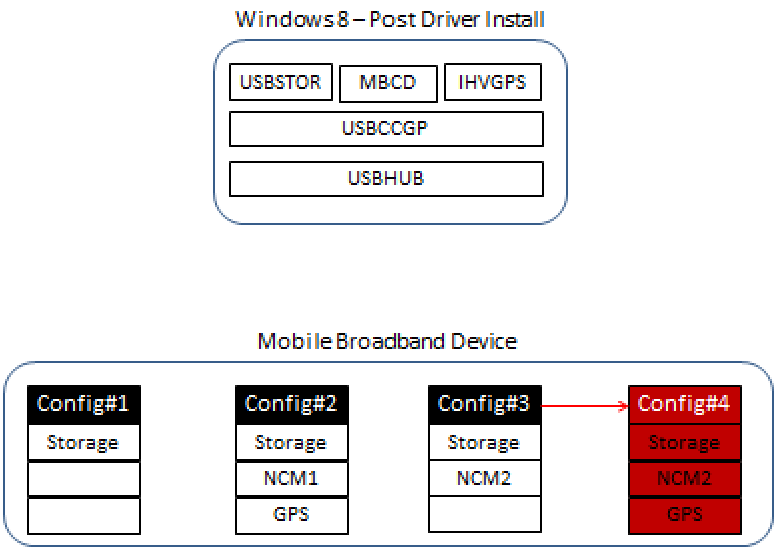
When the morphing device is plugged into a computer running Windows 8, the Windows-8-Configuration would be selected, which exposes the MBIM function. The Windows 8 Mobile Broadband Class Driver (MBCD) will be loaded on the MBIM function. In the following example, Configuration 3 is the Windows-8-Configuration containing the MBIM function.



Driver stack and device configuration on Windows 8 after device is plugged in

IHV-NCM-2.0-Configuration

In the Windows-8-Configuration, the morphing device also has a mass storage function that will allow the user to install the IHV driver package. After installation of the driver package from the mass storage function, the device will morph to expose the functions in the IHV-NCM-2.0-Configuration. This configuration has an additional IHV function such as GPS, diagnostics, and so on. Configuration 4 in the following diagram represents the IHV-NCM-2.0-Configuration.



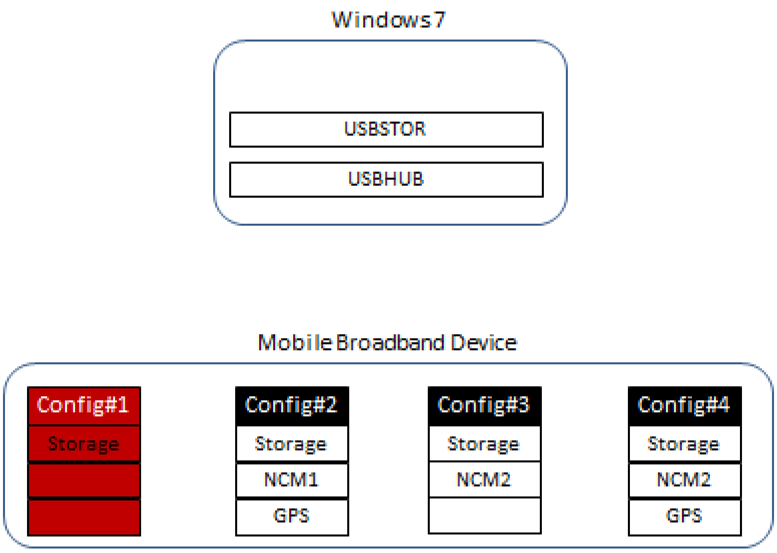
Driver stack and device configuration on Windows 8 after user installs IHV driver package

Windows 7

Windows-7-Configuration

When the morphing device is plugged into a computer running Windows 7 or an earlier version of Windows, the Windows-7-Configuration would be selected, which exposes the mass storage function. This will allow the user to install the IHV driver package from the mass storage function.

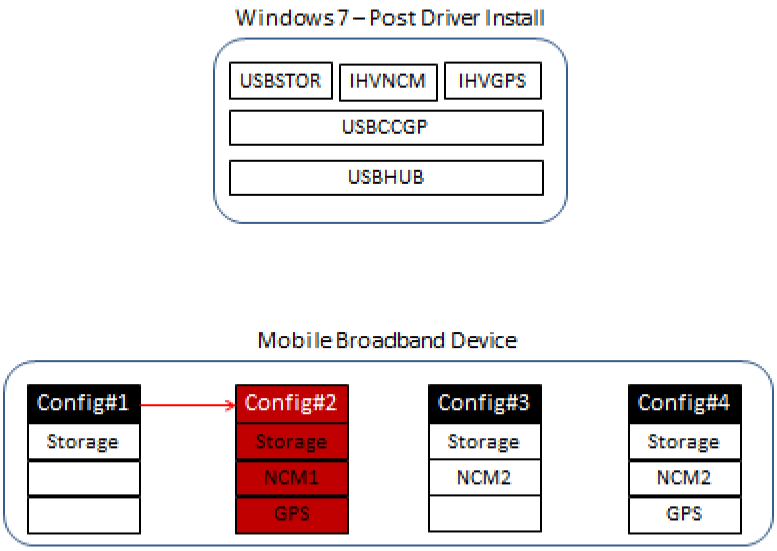
In the following example, Configuration 1 is the Windows-7-Configuration



Driver stack and device configuration on Windows 7 when the user has not installed the IHV driver package

IHV-NCM-1.0-Configuration

In Windows 7, the user can install the driver package from the mass storage function. Along with installing the driver software, the IHV software will also morph the device from the Windows-7-Configuration to the IHV-NCM-1.0-Configuration.



Driver stack and device configuration in Windows 7 after user installs IHV driver package

MB Identity Morphing Solution Details

Article • 03/14/2023

Configuration requirements

The order of the functions across transitions in Windows 8 needs to be maintained. For example, if MBIM is the third function in the Windows-8-Configuration, it should also be the third function in the IHV-NCM-2.0-Configuration.

Windows-7-Configuration

The Windows-7-Configuration should be the first configuration in the morphing device. This configuration should have the mass storage function as one of the functions. Windows 8 will not select this configuration. In Windows 7 and earlier versions of Windows, the Windows-7-Configuration is the default configuration selected. This configuration is used to expose a USB mass storage function where IHVs put their driver package, which allows users to install the IHV’s driver.

Windows-8-Configuration

The Windows-7-Configuration exposes the MBIM function as one of the functions on which MBCD is loaded. In Windows 8, the value of this configuration is used in the subCompatibleID value returned to USBCCGP. USBCCGP selects this configuration when it is loaded. The Windows-8-Configuration should be either Configuration 2, 3, or 4. No other configuration is supported as the Windows-8-Configuration. This configuration also exposes the mass storage function as the first function to allow a user to install the IHV’s driver package.

IHV-NCM-2.0-Configuration

The IHV-NCM-2.0-Configuration exposes IHV-specific functions along with MBIM and mass storage functions. This configuration is not set or used by Windows. The IHV software, after installation by the user, can morph to this configuration. Note that the order of the functions in this configuration should be the same as in the Windows-8-Configuration. Although extra functions can be added to the Windows-8-Configuration, the existing functions should be retained in the same order.

IHV-NCM-1.0-Configuration

The IHV-NCM-1.0-Configuration exposes IHV-specific functions along with NCM 1.0 and mass storage functions. This configuration is not set or used by Windows 8. This configuration is used only in Windows 7 and earlier versions of Windows after the IHV software is installed by the user. The IHV software morphs the morphing device from the Windows-7-Configuration to this configuration.

Compatible IDs

Compatible IDs are 8-character or smaller strings used by the device to indicate the driver loading preference to Windows. Devices can define compatible IDs by using Microsoft OS descriptors. Compatible and subcompatible IDs apply to individual functions. Each configuration can have a separate set of compatible IDs, which map to the set of functions within that configuration. Although compatible and subcompatible IDs apply to individual functions, the morphing device can have a single compatible ID when no configuration is selected. This compatible and subcompatible ID logically applies to the whole morphing device.

Loading USBCCGP

In Windows 8, a USBCCGP driver is required to automatically select the Windows-8-Configuration on the morphing device.

To load the USBCCGP driver, the morphing device needs to report the following compatible and subcompatible IDs when no configuration is selected on the morphing device:

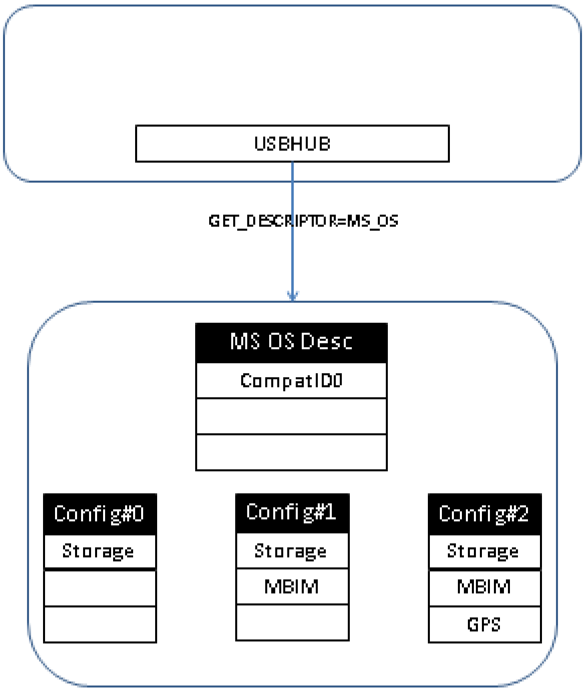
- If the morphing device uses IADs for grouping interfaces into functions, the compatible ID should be reported as "ALTRCFG" and the subcompatible ID as the number of the Windows-8-Configuration.
- If the morphing device uses WCM UFDs for grouping interfaces into functions, the compatible ID should be reported as "WMCALTR" and the subcompatible ID as the number of the Windows-8-Configuration.

For example, if the Windows-8-Configuration is Configuration 3, the subcompatible ID would be "3" in both of these cases.

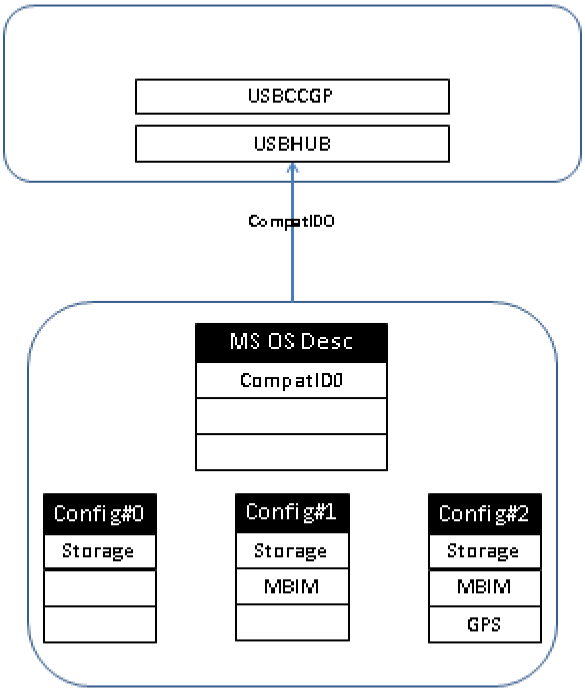
Morphing compatible IDs

During USB device enumeration, USBHUB queries the morphing device for the compatible ID when no configuration is selected on the morphing device. The morphing device should return the compatible and subcompatible ID used to load USBCCGP, as described in MB Identity Morphing Solution Overview.

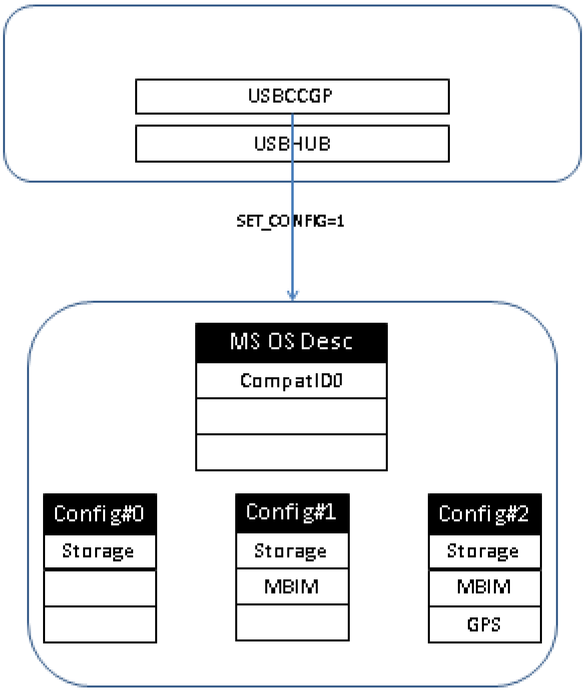
After USBHUB loads USBCCGP, USBCCGP selects the configuration indicated by the subcompatible ID reported earlier. USBCCGP then queries the compatible and subcompatible ID a second time. At this point, the morphing device should return the compatible and subcompatible IDs for the configuration that is currently selected. Therefore, after USBCCGP loads and selects a particular configuration, the morphing device needs to morph the compatible and subcompatible IDs that are reported. The morphing device must not report the compatible and subcompatible IDs that are used to load USBCCGP after a configuration is selected.



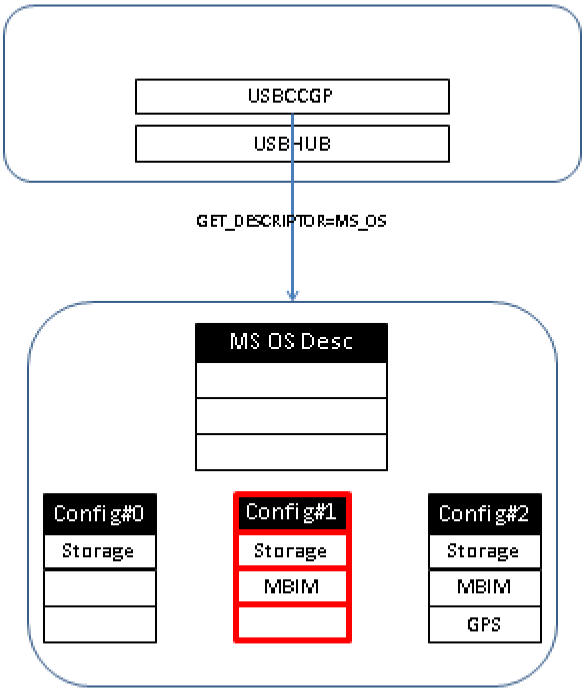
USBHUB querying the Microsoft OS descriptor from the device during enumeration.



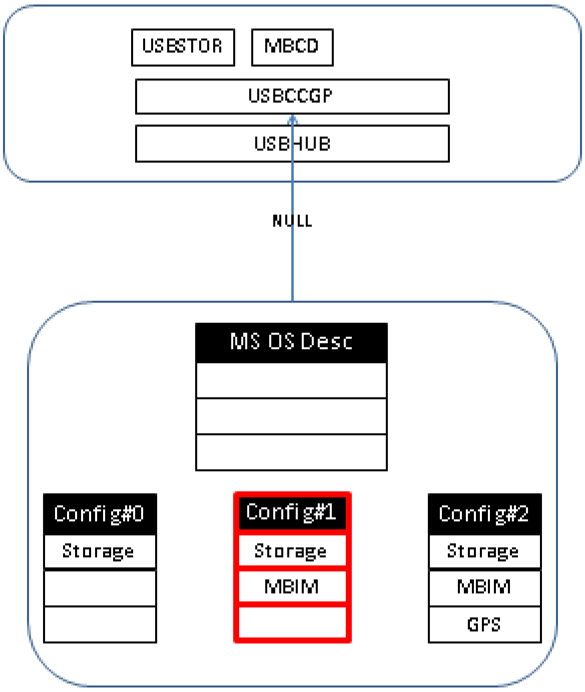
Device returns CompatId in the not-configured state. This CompatId is used to load USBCCGP.



USBCCGP selects the configuration reported in the subcompatible ID.



Device morphs its Microsoft OS descriptor based on the new configuration. USBCCGP queries for the Microsoft OS descriptor.



Device does not return any CompatID. Based on the Class / Subclass / Protocol, USBCCGP loads USBSTOR and MBCD.

MB Interface Model Supplement

Article • 03/14/2023

The Microsoft OS descriptor is broken up into the following segments:

- One Microsoft OS string descriptor
- One or more Microsoft OS feature descriptors

To support the OS descriptor, the device must implement the string descriptor. **String Descriptor**

The Microsoft OS string descriptor is a string that is stored at string index 0xEE. The format of this string is well defined.

The Microsoft OS String Descriptor is used to achieve the following objectives

- The presence of the Microsoft OS string descriptor indicates to the operating system that the device has information embedded in it, in the form of Microsoft OS feature descriptors.
- The Microsoft OS string descriptor has an embedded signature field that is used to differentiate it from random strings that might happen to be on a device at string index 0xEE.
- The Microsoft OS string descriptor also has an embedded version number that allows for future revisions of the Microsoft OS descriptor.

Only one Microsoft OS string descriptor is stored on a device. The following sections describe the structure of the Microsoft OS string descriptor and its retrieval procedure. **Structure of the OS string**

Here is the structure of the string descriptor:

String Descriptor Structure

Field	Length (Bytes)	Value	Description
bLength	1	0x12	Length of the descriptor
bDescriptorType	1	0x03	String descriptor
qwSignature	14	"MSFT100"	Signature field (4D00530046005400310030003000)
bMS_VendorCode	1	Vendor Code	Vendor code to fetch other OS feature descriptors

Field	Length (Bytes)	Value	Description
bPad	1	0x00	Pad field

The structure of the Microsoft OS string descriptor is fixed for version 1.00 and has an overall length of 18 bytes. The version number of the Microsoft OS string descriptor is listed in the **qwSignature** field. The information stored in the **bMS_VendorCode** field must be a single byte value. It will be used to retrieve Microsoft OS feature descriptors, and this byte value is used in the **bmRequestType** field described as follows:

Retrieving the OS string descriptor

To retrieve the information stored in the string, a standard GET_DESCRIPTOR request must be issued to the device. Here is the format of the request:

Standard Get_Descriptor String Request

bmRequestType	bRequest	wValue	wIndex	wLength	Data
1000 0000b	GET_DESCRIPTOR	0x03EE	0x0000	0x12	Returns the string

The **bmRequestType** field is a bitmap composed of three parts—direction of data transfer, descriptor type, and recipient. According to the USB specification, the value of **bmRequestType** is set to 1000 0000b (0x80).

For a GET_DESCRIPTOR request, the **wValue** field is split into two parts. The high byte stores the descriptor type and the low byte stores the descriptor index. To retrieve the Microsoft OS string descriptor, the high byte should be set to retrieve a string descriptor—0x03. Because the Microsoft OS string descriptor is always stored at index 0xEE, this string index should be stored in the lower byte of the **wValue** field.

The **wIndex** is used to store the language ID, but it must be set to zero for a Microsoft OS string descriptor.

The **wLength** field is used to indicate the length of the string descriptor to be retrieved. The device should respond to any valid range from 0x02–0xFF.

If a device does not have a valid descriptor at the corresponding address (0xEE), it will respond with a request error or stall. When devices do not respond with a stall, a single-ended zero reset will be issued to the device (to recover it, if it should go into an unknown state).

Verifying the integrity of the OS descriptor

Because vendors are allowed to use any string ID to store information, the operating system must verify that the string stored in index 0xEE is indeed the Microsoft OS string descriptor. To verify this, the following tests will be conducted. Failure of either will inhibit retrieval of the Microsoft OS feature descriptors.

- If a vendor stores a string in index location 0xEE, the operating system will retrieve the string and query it to see if it is the Microsoft OS string. This can be verified by comparing the signature field in the string to the signature field entry specified previously. A mismatch would prevent further parsing of the string.
- The second test will include a verification of the length of the string based on the version number specified in the signature field. The version number specified (in the string "MSFT100") is 1.00. This corresponds to an 18-byte string descriptor.

Microsoft OS string descriptor constraints

The following constraints apply to Microsoft OS string descriptors and their retrieval:

- To store information in compliance with the Microsoft OS descriptor specification, the device must have one and only Microsoft OS string descriptor that is in compliance with the information outlined in Microsoft OS Descriptors.
- A device vendor is free to use any value in the **bMS_VendorCode** field in the Microsoft OS string descriptor

Feature Descriptor

A feature descriptor is a fixed-format descriptor that has been defined for a specific purpose.

Retrieving an OS feature descriptor

To retrieve a Microsoft OS feature descriptor, a special GET_MS_DESCRIPTOR request needs to be issued to the device. Here is the format of the request:

Standard device request format

bmRequestType	bRequest	wValue	wIndex	wLength	Data
1100 0000b	GET_MS_DESCRIPTOR	X	Feature Index	Length	Returns descriptor

The **bmRequestType** field is a bitmap composed of three parts—direction of data transfer, descriptor type, and recipient—and is in accordance with the USB specification. The Microsoft OS feature descriptor is a vendor-specific descriptor and the direction of data transfer is from the device to the host. Therefore, the value of **bmRequestType** is set to 1100 0000b (0xC0).

The **bRequest** field is used to indicate the format of the request. To retrieve a Microsoft OS feature descriptor, the **bRequest** field should be populated with a special GET_MS_DESCRIPTOR byte. The value of this byte is indicated by the **bMS_VendorCode**, which is retrieved from the Microsoft string descriptor. For more information about the retrieval of the Microsoft OS string descriptor, see **Retrieving the OS string descriptor**.

The **wValue** field is put to special use and is broken up into a high byte and a low byte. The high byte is used to store the interface number. This is essential for storing feature descriptors on a per interface basis, especially for composite devices, or devices with multiple interfaces. In most cases, interface 0 will be used. The low byte is used to store a page number. This feature prevents descriptors from having a size boundary of 64 KB (a limit set by the size of the **wLength** field). A descriptor will be fetched with the page value initially set to zero. If a full descriptor (size is 64 KB) is received, the page value will be incremented by one and the request for the descriptor will be sent again (this time with the incremented page value). This process will repeat until a descriptor with a size less than 64 KB is received. Note that the maximum number of pages is 255, which places a limit of 16 MB on the descriptor size.

The **wIndex** field stores the feature index number for the Microsoft OS feature descriptor being retrieved. Microsoft will maintain this list of Microsoft OS feature descriptors and indexes. To learn more about Microsoft OS feature descriptors, see Microsoft OS Descriptors.

The **wLength** field specifies the length of the descriptor to be fetched. If the descriptor is longer than the number of bytes stated in the **wLength** field, only the initial bytes of the descriptor are returned. If it is shorter than the value specified in the **wLength** field, a short packet is returned.

If a particular OS descriptor is not present, the device will issue a request error or stall.

Microsoft OS feature descriptor constraints

The following constraints apply to Microsoft OS feature descriptors and their retrieval.

- All Microsoft OS feature descriptors are defined and standardized. Vendors are not allowed to modify, append, or create Microsoft OS feature descriptors without direct consent from Microsoft.
- All Microsoft OS feature descriptors will have a size and version number embedded in them. These values should always report correct information to the operating system.
- A device can have more than one Microsoft OS feature descriptor embedded in its firmware.

- Some Microsoft OS feature descriptors are stored on a per-interface level, while others are unique to the device. Device-level Microsoft OS feature descriptors should set the high byte of the wValue field as zero.

Structure of the feature descriptor

To identify itself as capable of supporting MBIM, a device must also support the extended configuration descriptor, which is one of the defined feature descriptors. The structure of this descriptor is as follows.

Header section

The header section stores information about the rest of the extended configuration descriptor. The **dwLength** field contains the length of the entire extended configuration descriptor. The header section also contains a version number, which will be initially set to 1.00 (0100H). Future revisions of this descriptor may be released at a later stage. Note that future versions of the extended configuration descriptor might also need to increase the number of entries in the header section, so please verify that this number is accurately stored in the device and read by the operating system.

Extended configuration descriptor header section

Offset	Field	Size	Value	Description
0	dwLength	4	Unsigned DWORD	The length field describes the length of the extended configuration descriptor, in bytes.
4	bcdVersion	2	BCD	Extended configuration descriptor release number in Binary Coded Decimal (for example, version 1.00 is 0100H).
6	wIndex	2	WORD	Fixed = 0x0004

Offset	Field	Size	Value	Description
8	bCount	1	BYTE	Total number of function sections that follow the header section = 0x01
9	RESERVED	7		RESERVED

Function section

The function section provides two important pieces of information. It groups consecutive interfaces that serve a similar purpose into function groups, and provides compatible and subcompatible IDs for each function.

Here is the format of the function section, including values that should be used by an MBIM device:

Extended configuration descriptor function section

Offset[1]	Field	Size	Value	Description
0	bFirstInterfaceNumber	1	Byte	Starting interface number for this function = 0x00
1	bInterfaceCount	1	Byte	Total number of Interfaces that must be included to from this function = 0x01
2	compatibleID	8	Bytes	Compatible ID
10	subCompatibleID	8	Bytes	Subcompatible ID
18	RESERVED	6		RESERVED = 0

[1]Offset of the custom property section has been reset to zero. To calculate the offset of a field from the beginning of the extended configuration descriptor, add the length of the sections that precede it.

Compatible and Subcompatible IDs based on the configuration exposing the MBIM function

bConfiguration	compatibleID	subCompatibleID

bConfiguration	compatibleID	subCompatibleID
2	ALTRCFG (0x41 0x4C 0x54 0x52 0x43 0x46 0x47 0x00)	20000000 (0x32 0x00 0x00 0x00 0x00 0x00 0x00 0x00)
3	ALTRCFG (0x41 0x4C 0x54 0x52 0x43 0x46 0x47 0x00)	30000000 (0x33 0x00 0x00 0x00 0x00 0x00 0x00 0x00)
4	ALTRCFG (0x41 0x4C 0x54 0x52 0x43 0x46 0x47 0x00)	40000000 (0x34 0x00 0x00 0x00 0x00 0x00 0x00 0x00)

- **bConfiguration** refers to the **bConfiguration** value within the USB configuration descriptor of the configuration that exposes the MBIM function. **bConfiguration** cannot be 1 because that is the default configuration exposing only the CDROM function. **bConfiguration** cannot be greater than 4; that is, the MBIM function should be exposed within the first four configurations.
- compatibleID remains the same for all configurations. The subcompatibleID changes based on the configuration

Example

This table shows a sample multi-configuration scenario. The table lists the functions available in each configuration and the actions that different versions of the operating system takes for each of these configurations:

Example of a multi-configuration mobile broadband device

bConfiguration	1 (Windows-7-Configuration)	2 (IHV-NCM-1.0-Configuration)	3 (Windows-8-Configuration)	3 (IHV-NCM-2.0-Configuration)

bConfiguration	1 (Windows-7-Configuration)	2 (IHV-NCM-1.0-Configuration)	3 (Windows-8-Configuration)	3 (IHV-NCM-2.0-Configuration)
Functions exposed	CDROM SD	CD-ROM SD NCM1.0 Modem TV GPS FP PC/SC smart card Voice Diag	CD-ROM SD MBIM	CD-ROM SD NCM2.0 Modem TV GPS FP PC/SC smart card Voice Diag

The following tables show the values used by the Microsoft OS string descriptor and the Microsoft OS extended configuration feature descriptor for the previous sample’s multi-configuration scenario.

Example of a multi-configuration mobile broadband device

Field	Length (Bytes)	Value
bLength	1	0x12
bDescriptorType	1	0x03
qwSignature	14	‘MSFT100’ 0x4D 0x00 0x53 0x00 0x46 0x00 0x54 0x00 0x31 0x00 0x30 0x00 0x30 0x00
bMS_VendorCode	1	0xA5
bPad	1	0x00

Example Microsoft OS extended configuration feature descriptor header

Offset	Field	Size	Value
0	dwLength	4	16

Offset	Field	Size	Value
4	bcdVersion	2	0100H
6	wIndex	2	0x0004
8	bCount	1	1
9	RESERVED	7	

Example Microsoft OS extended configuration feature descriptor function

Offset[2]	Field	Size	Value
0	bFirstInterfaceNumber	1	
1	bInterfaceCount	1	
2	compatibleID	8	
10	subCompatibleID	8	
18	RESERVED	6	

[2] Offset of the custom property section has been reset to zero. To calculate the offset of a field from the beginning of the extended configuration descriptor, add the length of the sections that precede it.

MB Interface Overview

Article • 03/14/2023

This documentation describes the Mobile Broadband (MB) driver model. The MB driver model is a software architecture provided with Windows 7 and later versions of Windows. It provides a framework for an integrated set of networking features based on CDMA-based (1xRTT/1xEV-DO/1xEV-DO RevA/1xEvDO RevB) and GSM-based (GPRS/EDGE/UMTS/HSDPA/TD-SCDMA) cellular technologies.

Windows 8 MB miniport drivers are based on the NDIS 6.30 interface. Windows 7 MB miniport drivers are based on the NDIS 6.20 interface. MB miniport drivers must follow the appropriate "NDIS 6.x Specification" in addition to the device driver interfaces (DDIs) described throughout this documentation.

The following diagram represents the architecture of the MB driver model.

Terminology

Be aware that the terms *Wireless Wide Area Network* (WWAN) and *Mobile Broadband* (MB) are used interchangeably throughout this documentation to represent the Mobile Broadband technology.

The terms *activate* and *activation* have two different meanings in this documentation. The term *activate* is related to service activation, such as when a network provider must explicitly enable the MB subscription before the provider's services can be used. The term *activation* is specific to setting up a connection in GSM-based (GPRS/EDGE/UMTS/HSDPA/TD-SCDMA) technologies. For example, *PDP context activation* refers to setting up an MB connection according to the parameters specified in the PDP context.

SIM access refers to accessing the Subscriber Identity Module (SIM, also known as the R-UIM). If the MB device does not have a SIM/R-UIM as a physical entity but instead has a logical equivalent embedded in the device, this term is applicable to that logical circuit equivalent as well. When SIM access is not required, the miniport driver is not expected to retrieve the information from the SIM in order to complete the request.

Semantics

The MB Service component in user mode cannot directly exchange data with MB miniport drivers in kernel mode. Intermediaries such as WMI or NDIS filter drivers are required. For simplicity, these intermediaries are not explicitly discussed in this documentation. However, this omission does not mean that the MB Service and MB miniport drivers can engage in direct data exchanges.

The following topics provide a summary of NDIS 6.20 and MB OID semantics, the procedures that miniport drivers must follow to perform synchronous and asynchronous operations, and an overview of the operations supported by the Mobile Broadband driver model:

MB / NDIS 6.20 Interfacing Overview

Article • 03/14/2023

This topic is designed to provide enough background about the *NDIS 6.20 Specification* to put the MB driver model into perspective. It is not intended to be a reference for NDIS 6.20. In the case of discrepancies between this content and the *NDIS 6.20 Specification*, see the NDIS 6.20 documentation for complete information.

In NDIS 6.20, the MB Service calls **NdisOidRequest** to issue OID requests to the miniport driver. Then, miniport drivers call **NdisMIndicateStatusEx** to return data back to the MB Service.

NDIS 6.20 supports the following types of OID operations:

- *Set* operations that send data from the service to a miniport driver.
- *Query* operations that request miniport drivers to return data to the service.
- *Method* operations, equivalent to a function call, that have both input parameters and output parameters.

Finally, miniport drivers may send *indications* that contain data to notify the service about state changes in the MB device.

Receiving *Set* and *Query* Requests

MB miniport drivers implement the *MiniportOidRequest* NDIS handler to respond to both *set* and *query* requests.

Sending Status Indications

Miniport drivers provide status indications to the MB Service by calling **NdisMIndicateStatusEx**. See the **NDIS_STATUS_INDICATION** structure for more details about status indications.

Connection State Indications

NDIS 6.20 miniport drivers must use the **NDIS_STATUS_LINK_STATE** status indication to notify NDIS and overlying drivers that there has been a change in the physical characteristics of a transmission medium.

The **StatusBuffer** member of the NDIS_STATUS_INDICATION structure is an NDIS_LINK_STATE structure, which specifies the physical state of the transmission medium.

MB miniport drivers should avoid sending the NDIS_STATUS_LINK_STATUS status indication if there have been no changes in the physical state of the medium. However, miniport drivers are not necessarily required to avoid sending this status indication.

MB miniport drivers must report the maximum data rate of the currently connected data-class. A change in data-class while connected must result in a Connection State Indication with the corresponding data rate reported. The following is a recommended implementation of this rule:

1. MB miniport drivers that conform to this specification must use NDIS_STATUS_LINK_STATE to indicate connection status changes instead of NDIS_STATUS_MEDIA_CONNECT, NDIS_STATUS_MEDIA_DISCONNECT, or NDIS_STATUS_LINK_SPEED_CHANGE (as in NDIS 5.1) for connection status indications.

2. The **XmitLinkSpeed** and **RcvLinkSpeed** members of the NDIS_LINK_STATE structure must not report NDIS_LINK_SPEED_UNKNOWN. Miniport drivers must report the speed by using the information in the following tables.

For GSM-based MB device speed links

Data class	XmitLinkSpeed	RcvLinkSpeed
GPRS	8 to 48 kbps	8 to 48 kbps
EDGE	8 to 220 kbps	8 to 220 kbps
UMTS	64 to 384 kbps	64 to 384 kbps
HSDPA	64 to 5.76 mbps	1.8 to 14.4 mbps
HSUPA	1.4 to 5.76 mbps	64 kbps to 7.2 mbps

For CDMA-based MB device speed links

Data Class	XmitLinkSpeed	RcvLinkSpeed
1xRTT	115.2 kbps to 307.2 kbps	153.6 kbps to 3 mbps
3xRTT	614 kbps to 1.04 mbps	307.2 kbps to 1.04 mbps
1xEV-DO	153.6 kbps	2.4 mbps

Data Class	XmitLinkSpeed	RcvLinkSpeed
1xEvDO Rev. A.	1.8 mbps	3.1 mbps
1xEV-DV	1.8 mbps	3.1 mbps
1xEvDO Rev. B.	27 mbps	3.1 mbps to 73.5 mbps

Note MB devices should report the speed in the range of speed shown in the previous tables.

Unlike NDIS 5.1, different link state change indications are consolidated into a single NDIS_STATUS_LINK_STATE indication by using the NDIS_LINK_STATE data structure. NDIS 5.1 indications can be mapped to this structure according to the information in the following table. In the case of link speed change, the consumer of the indication should compare the transmitting and receiving speed values with the ones it recorded for a previous indication to decide whether the link speed change has occurred or not.

MB Data Model

Article • 03/14/2023

The MB driver model uses a data model that consists of a set of objects defined as abstractions of MB device features. Each object is identified by a unique object identifier (OID) and is defined by a set of corresponding attributes. The set of attributes is organized into a data structure. To manage the device, the MB Service and the MB miniport driver exchange OIDs and their associated data structures based on OID requests and indications provided by the Network Driver Interface Specification (NDIS).

In the MB driver model, only *set* and *query* operations are used for OID requests. The MB driver model does not use *method* operations. For indications, the MB driver model uses both event and transactional notifications to indicate state changes in the objects of the MB device. Transactional notifications also signal completion of an asynchronous transaction.

The following tables list the OIDs and status indications defined for MB miniport drivers, as well as the associated data structures. MB miniport drivers must implement all mandatory general OIDs that the NDIS 6.20 Specification requires. For a list of general OIDs for NDIS 6.x, see General Operational OIDs.

In addition, MB miniport drivers must implement OID_GEN_PHYSICAL_MEDIUM even though the NDIS Specification describes it as optional to implement.

The syntax and semantics of the MB OIDs listed in the following table are described in MB Operational Semantics.

WWAN-Specific OIDs

OID and Corresponding Data Structure	Set, Windows 7	Set, Windows 8	Query, Windows 7	Query, Windows 8	GSM/CDMA
OID_WWAN_DRIVER_CAPS uses **NDIS_WWAN_DRIVER_CAPS**	Not supported	Not supported	S	S	GSM, CDMA
OID_WWAN_DEVICE_CAPS has no corresponding structure	Not supported	Not supported	A	A	GSM, CDMA
OID_WWAN_READY_INFO has no corresponding structure	Not supported Not supported	A	A	GSM, CDMA	
OID_WWAN_SERVICE_ACTIVATION† uses **NDIS_WWAN_SERVICE_ACTIVATION**	A	A	Not supported	Not supported	GSM, CDMA
OID_WWAN_RADIO_STATE uses **NDIS_WWAN_SET_RADIO_STATE**	A	A	A	A	GSM, CDMA
OID_WWAN_PIN uses **NDIS_WWAN_SET_PIN**	A	Not supported	A	Not supported	GSM, CDMA
OID_WWAN_PIN_LIST has no corresponding structure	Not supported	Not supported	A	A	GSM, CDMA
OID_WWAN_PIN_EX uses **NDIS_WWAN_SET_PIN_EX**	Not supported	A	Not supported	A	GSM, CDMA
OID_WWAN_HOME_PROVIDER has no corresponding structure	Not supported	Not supported	A	A	GSM, CDMA

OID and Corresponding Data Structure	Set, Windows 7	Set, Windows 8	Query, Windows 7	Query, Windows 8	GSM/CDMA
OID_WWAN_PREFERRED_PROVIDERS† uses **NDIS_WWAN_SET_PREFERRED_PROVIDERS**	A	A	A	A	GSM only
OID_WWAN_VISIBLE_PROVIDERS has no corresponding structure	Not supported	Not supported	A	A	GSM
OID_WWAN_REGISTER_STATE uses **NDIS_WWAN_SET_REGISTER_STATE**	A	A	A	A	CDMA
OID_WWAN_SIGNAL_STATE uses **NDIS_WWAN_SET_SIGNAL_INDICATION**	A	A	A	A	GSM, CDMA
OID_WWAN_PACKET_SERVICE uses **NDIS_WWAN_SET_PACKET_SERVICE**	A	A	A	A	GSM, CDMA
OID_WWAN_PROVISIONED_CONTEXTS†† uses **NDIS_WWAN_SET_PROVISIONED_CONTEXT**	A	A	A	A	GSM, CDMA
OID_WWAN_CONNECT uses **NDIS_WWAN_SET_CONTEXT_STATE**	A	A	A	A	GSM, CDMA
OID_WWAN_SMS_CONFIGURATION uses **NDIS_WWAN_SET_SMS_CONFIGURATION**	A	A	A	A	GSM, CDMA
OID_WWAN_SMS_READ uses **NDIS_WWAN_SMS_READ**	Not supported	A	A	A	GSM, CDMA
OID_WWAN_SMS_SEND uses **NDIS_WWAN_SMS_SEND**	A	A	Not supported	Not supported	GSM, CDMA
OID_WWAN_SMS_DELETE uses **NDIS_WWAN_SMS_DELETE**	A	A	Not supported	Not supported	GSM, CDMA
OID_WWAN_SMS_STATUS uses **NDIS_WWAN_SMS_STATUS**	Not supported	Not supported	A	A	GSM, CDMA
OID_WWAN_VENDOR_SPECIFIC† uses a vendor-defined structure	A	A	Not supported	Not supported	GSM, CDMA
OID_WWAN_DEVICE_SERVICES has no corresponding structure	Not supported	Not supported	Not supported	A	GSM, CDMA
OID_WWAN_SUBSCRIBE_DEVICE_SERVICE_EVENTS uses **NDIS_WWAN_SUBSCRIBE_DEVICE_SERVICE_EVENTS**	Not supported	A	Not supported	Not supported	GSM, CDMA
OID_WWAN_AUTH_CHALLENGE uses **NDIS_WWAN_AUTH_CHALLENGE**	Not supported	Not supported	Not supported	A	GSM, CDMA
OID_WWAN_USSD uses **NDIS_WWAN_USSD_REQUEST**	Not supported	A	Not supported	Not supported	GSM
OID_WWAN_DEVICE_SERVICE_COMMAND uses **NDIS_WWAN_DEVICE_SERVICE_COMMAND**	Not supported	A	Not supported	A	GSM, CDMA

ⓘ Note

The following notes apply to the preceding table: † represents optional OIDs that miniport drivers may support. Miniport drivers that do not support the optional OIDs must not return them in OID_GEN_SUPPORTED_LIST.

†† represents miniport drivers that support GSM-based devices which can optionally support OID_WWAN_PROVISIONED_CONTEXTS set and query operations. Miniport drivers that support CDMA-based devices can optionally support OID_WWAN_PROVISIONED_CONTEXTS query operations for CDMA-based devices that report Simple IP (WWAN_CTRL_CAPS_CDMA_SIMPLE_IP).

Miniport drivers must support all non-optional OIDs. The MB Service may ignore any miniport driver that does not report all of the mandatory OIDs.

"A" and "S" in the Set and Query operation columns in the preceding table reflect the nature of the transaction for completing the OID request: "A" stands for an asynchronous transaction and "S" for a synchronous transaction.

The data structures in the preceding table correspond to set operation OIDs and to return data for synchronous query operation OIDs.

The following OIDs share a common variable length list data structure called **WWAN_LIST_HEADER** in their corresponding data structures:

- OID_WWAN_READY_INFO
- OID_WWAN_PREFERRED_PROVIDERS
- OID_WWAN_VISIBLE_PROVIDERS
- OID_WWAN_PROVISIONED_CONTEXTS
- OID_WWAN_SMS_READ

MB Operational Semantics

Article • 03/14/2023

Asynchronous Transactions

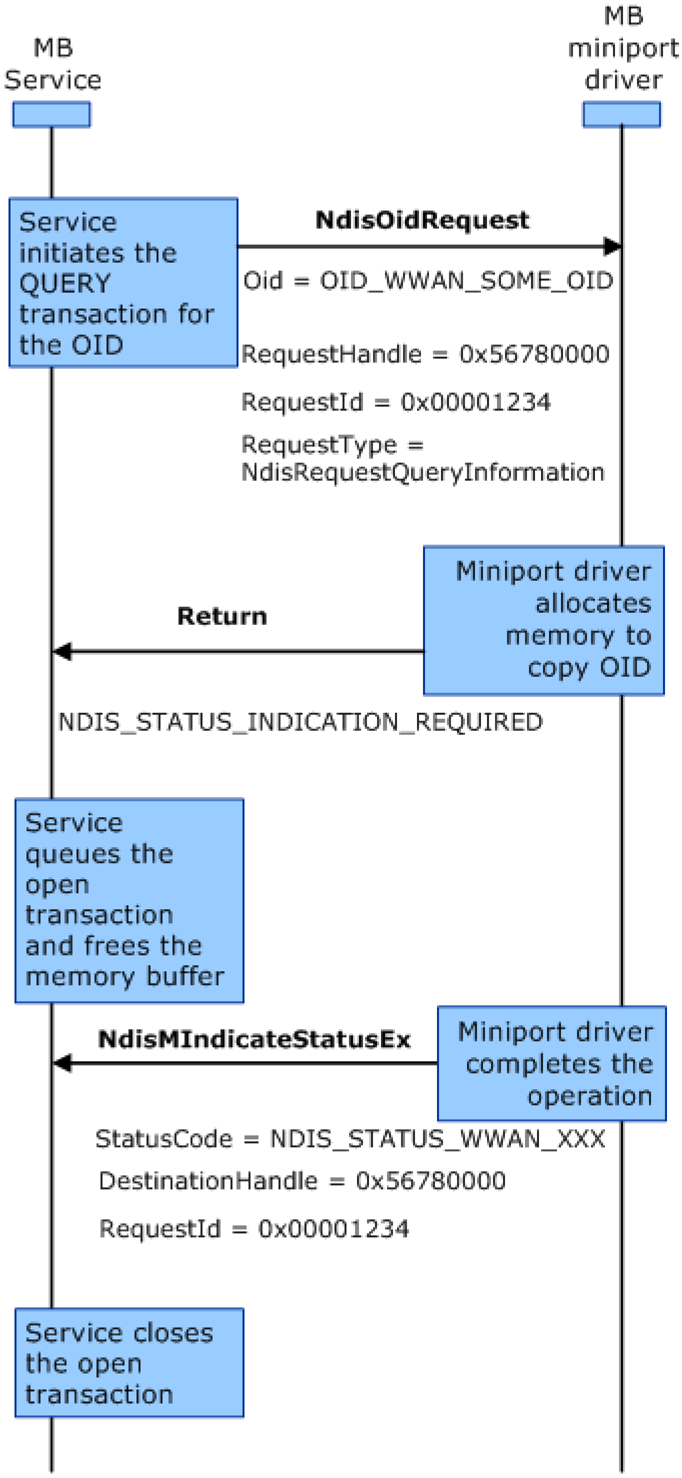
The MB driver model assumes non-blocking operational semantics between the MB Service and miniport drivers by using the asynchronous notification mechanism provided in NDIS 6.x. This mechanism allows the MB Service to continue to send OID requests to the miniport driver for processing without waiting for the current operation to complete.

An asynchronous transaction is a three-way handshake that starts with the initial request, followed by a request status response, and then completed by a final transactional indication. The request status response is provisional in that it only acknowledges that the miniport driver has received the request. The follow-up asynchronous indication is transactional in that it signals the completion of the transaction. The miniport driver returns the status code as well as the resulting data in the transactional indication.

Asynchronous *Set* and *Query* Requests

Many of the *set* and *query* OID requests that are used by the MB Service are processed asynchronously. For more information about *set* and *query* OID requests, see **NDIS_OID_REQUEST**. The "WWAN-specific OIDs" table in the MB Data Model topic identifies which OIDs are processed asynchronously.

The following diagram represents the interaction sequence for an asynchronous *query* transaction between the MB Service and the miniport driver. The labels in bold represent OID identifiers, or transactional flow control, and the labels in regular text represent the important flags within the OID structure.



MB Service
MB miniport driver
Service initiates the QUERY transaction for the OID
NdisOidRequest
Oid = OID_WWAN_SOME_OID
RequestHandle = 0x56780000
RequestId = 0x00001234
RequestType = NdisRequestQueryInformation
Miniport driver allocates memory to copy OID
Return
NDIS_STATUS_INDICATION_REQUIRED
Service queues the open transaction and frees the memory buffer
NdisMIndicateStatusEx
Miniport driver completes the operation
StatusCode = NDIS_STATUS_WWAN_XXX
DestinationHandle = 0x56780000
RequestId = 0x00001234
Service closes the open transaction

The three-way handshake is the same for both *query* and *set* requests.

Except for OID_WWAN_DRIVER_CAPS, all other MB-specific OID requests follow the asynchronous transaction mechanism for information exchange between miniport drivers and the MB Service, with the following additional notes:

- Miniport drivers should immediately fail an OID request on any error condition, such as an invalid OID request.
- Miniport drivers must return any WWAN-specific error conditions with the correct error code (for example, WWAN_STATUS_XXX) specified in the **uStatus** member of the event notification structure. Miniport drivers should also appropriately fill in

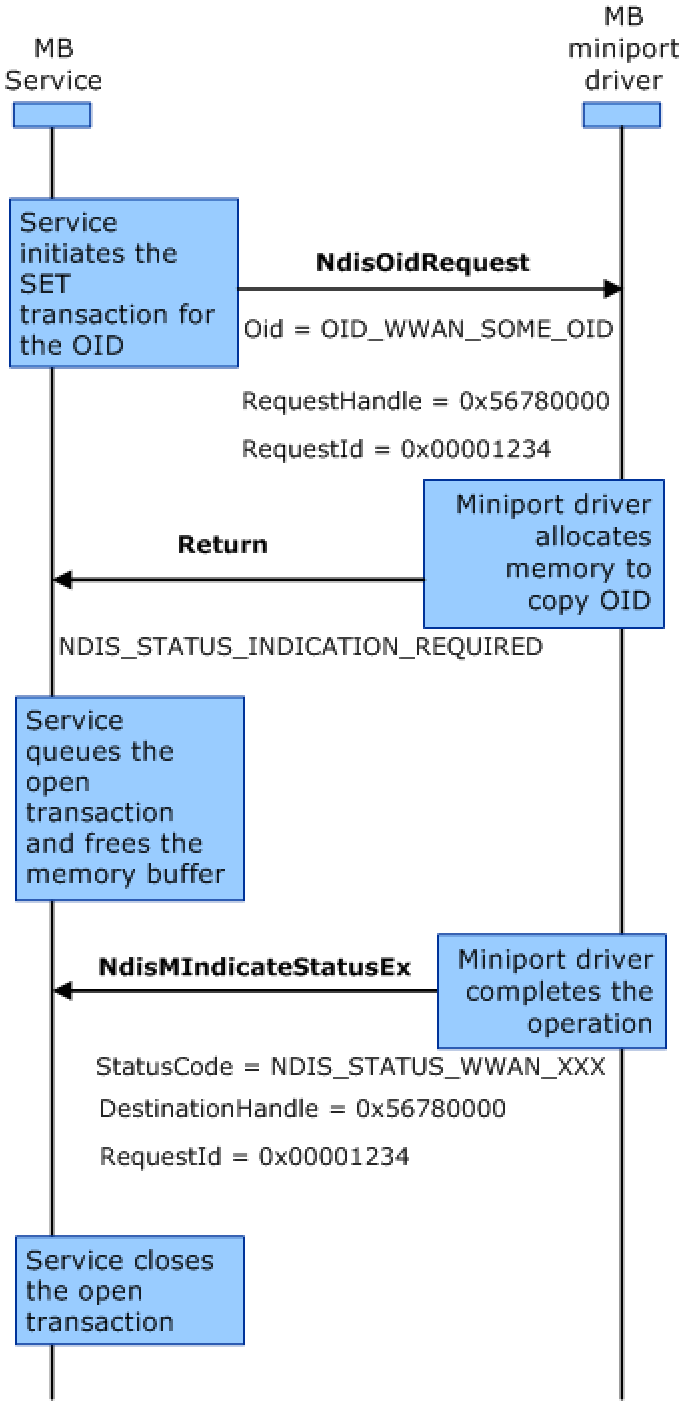
the members that follow the **uStatus** member, as needed. For example, miniport drivers should fill in the **ContextState.uNwError** member of the NDIS_WWAN_CONTEXT_STATE structure, if available. However, in the case of a failure when processing OIDs related to PINs, miniport drivers may not necessarily have the current PIN state information to specify in the **PinInfo.PinState** member of NDIS_WWAN_PIN_INFO.

- Miniport drivers should return NDIS_STATUS_INDICATION_REQUIRED as a provisional response for all asynchronous OID requests.

- Miniport drivers should be able to distinguish device state changes caused by an OID request from other causes. Miniport drivers should send transactional notifications for state changes resulting from OID requests, and they should send unsolicited event notifications for state changes from other causes.

- Miniport drivers are responsible for managing kernel-mode memory, although the MB Service initially allocates the memory for requests. After the MB Service receives a response from a miniport driver, the service may release the user-mode memory that it allocated for the OID request.

The following diagram represents the interaction sequence for an asynchronous *set* transaction between the MB Service and the miniport driver. The labels in bold represent OID identifiers, or transactional flow control, and the labels in regular text represent the important flags within the OID structure.



MB Service
MB miniport driver
Service initiates the SET transaction for the OID
NdisOidRequest
Oid = OID_WWAN_SOME_OID
RequestHandle = 0x56780000
RequestId = 0x00001234
Miniport driver allocates memory to copy OID
Return
NDIS_STATUS_INDICATION_REQUIRED
Service queues the open transaction and frees the memory buffer
NdisMIndicateStatusEx
Miniport driver completes the operation
StatusCode = NDIS_STATUS_WWAN_XXX
DestinationHandle = 0x56780000
RequestId = 0x00001234
Service closes the open transaction

Asynchronous Response

The *NDIS 6.0 Specification* (released with Windows Vista) introduced a new status code, NDIS_STATUS_INDICATION_REQUIRED, for miniport drivers to convey the asynchronous nature of a transaction to the MB Service in a miniport driver's provisional response to an OID request.

As mentioned in MB Interface Overview, the MB Service does not have direct access to kernel-mode memory that is allocated by an MB miniport driver. The execution result stored in the kernel-mode memory is assumed to be copied and made available to the MB Service by some intermediary, such as WMI or an NDIS filter driver. Hence, miniport drivers can release the allocated kernel-mode memory after the NdisMIndicateStatusEx function call returns in the transactional indication.

The handshake procedures that miniport drivers and the MB Service must follow are described in the following procedure.

MB miniport driver procedure

Upon receiving an OID request, miniport drivers should perform the following steps:

1. Allocate memory in kernel mode to copy the contents of the NDIS_OID_REQUEST data structure associated with the OID request.

2. Among the request's parameters, ensure that the **RequestId** and **RequestHandle** members of the OID request structure are also copied. These members will be used later in the transactional *indication*.

3. Return a provisional NDIS_STATUS_INDICATION_REQUIRED status response to inform the MB Service that the miniport driver will complete the request asynchronously.

4. Upon completion of the operation, store the result in local or driver-allocated memory, as appropriate.

5. Call the NdisMIndicateStatusEx function to notify the MB Service that the outstanding operation has been completed. Miniport drivers should fill in the members of the NDIS_STATUS_INDICATION structure as follows:
   a. Set the **StatusCode** member to the type of status notification. For example, NDIS_STATUS_WWAN_XXX.
   b. Set the **DestinationHandle** member to the **RequestHandle** member that was received in the NDIS_OID_REQUEST data structure when the miniport driver received the corresponding OID request.
   c. Set the **RequestId** member to match the **RequestId** member of the NDIS_OID_REQUEST status structure when the miniport driver received the corresponding OID request.
   d. Set the **StatusBuffer** and **StatusBufferSize** members to point to the miniport driver-allocated memory and the size of the memory buffer, respectively. This memory buffer contains the result of the completed operation.
   e. If the operation completes successfully, set the **uStatus** member to WWAN_STATUS_SUCCESS. Otherwise, set the **uStatus** member to the appropriate WWAN_STATUS_XXX value to indicate the type of failure.

6. When the function call returns, the miniport driver should release the memory it allocated for the OID request.

MB Service procedure

The MB Service processes asynchronous transactions by using the following procedure:

1. Allocate buffer memory for the request based on the OID data structure. Fill in the data structure members with appropriate values.

2. Call the NdisOidRequest function with the **InformationBuffer** member pointing to the OID data structure for the OID request and wait for the miniport driver to respond.

3. Upon receipt of an NDIS_STATUS_INDICATION_REQUIRED provisional response from the miniport driver, the MB Service saves the **RequestId**, releases the allocated memory, and marks the transaction as open. At this point, the MB Service is free to process subsequent OID requests and notifications.

4. Upon receipt of a notification with NDIS_STATUS_WWAN_XXX as the **StatusCode** value, check whether the **RequestId** matches that of any transaction marked as open. If there is a match, the service closes the transaction. If no match is found, treat the notification as an unsolicited event notification.

5. Process the data returned in the **StatusBuffer** member and make state changes to the MB Service as appropriate.

Indications

There are two types of WWAN-specific *indications* that miniport drivers can generate:

- Event notifications that result from an object state change in the MB device.

- Transactional notifications that signal the completion of an asynchronous operation.

In both cases, miniport drivers should call the NdisMIndicateStatusEx function.

Event Notification

Event notification is unsolicited in the sense that the miniport driver proactively sends the indication to the MB Service as a state change event. The state change is caused by an action from some entity other than the MB Service. The MB Service assumes miniport drivers are able to detect the cause of the change.

For any WWAN-specific event notification, miniport drivers must set the **RequestId** member of the NDIS_STATUS_INDICATION structure to zero. The **StatusCode** member specifies which object in the MB device has changed. The miniport driver can set this object to any of the following values:

NDIS_STATUS_WWAN_DEVICE_CAPS

NDIS_STATUS_WWAN_READY_INFO

NDIS_STATUS_WWAN_RADIO_STATE

NDIS_STATUS_WWAN_PIN_INFO

NDIS_STATUS_WWAN_PIN_LIST

NDIS_STATUS_WWAN_HOME_PROVIDER

NDIS_STATUS_WWAN_PREFERRED_PROVIDERS

NDIS_STATUS_WWAN_VISIBLE_PROVIDERS

NDIS_STATUS_WWAN_REGISTER_STATE

NDIS_STATUS_WWAN_PACKET_SERVICE

NDIS_STATUS_WWAN_SIGNAL_STATE

NDIS_STATUS_WWAN_CONTEXT_STATE

NDIS_STATUS_WWAN_PROVISIONED_CONTEXTS

NDIS_STATUS_WWAN_SERVICE_ACTIVATION

NDIS_STATUS_WWAN_SMS_CONFIGURATION

NDIS_STATUS_WWAN_SMS_RECEIVE

NDIS_STATUS_WWAN_SMS_SEND

NDIS_STATUS_WWAN_SMS_DELETE

NDIS_STATUS_WWAN_SMS_STATUS

NDIS_STATUS_WWAN_VENDOR_SPECIFIC

The MB Service may also process other event notifications from NDIS. These non-MB event notifications are not necessarily subject to the requirement that their **RequestId** values be set to zero.

Transactional Notifications

Miniport drivers use transactional notifications to inform the MB Service that an asynchronous transaction has completed, and the MB Service uses transactional notifications to close open transactions and to update its state machine.

The MB Service expects transactional notifications so that it can close open transactions. It is the final exchange of the three-way handshake between the MB Service and the miniport driver in an asynchronous transaction. The value of **RequestId** member of the NDIS_STATUS_INDICATION in any transactional notification must be nonzero, which is copied from the corresponding request in the same transaction.

You must set the **RequestId** member of the NDIS_STATUS_INDICATION structure correctly for the asynchronous mechanism to function properly. The MB Service ensures that the **RequestId** value is unique and nonzero among all outstanding requests. Miniport drivers must return the same **RequestId** value in the corresponding *indication* in order for the MB Service to correlate the indication with an open transaction.

Status Indication Structure

Both the asynchronous response for a given OID request and the unsolicited event notification structures share the following structure members that are pointed to by **StatusBuffer** member of the *StatusIndication* parameter to NdisMIndicateStatusEx:

C++

```cpp
typedef struct _NDIS_WWAN_XXX {
  NDIS_OBJECT_HEADER Header;
  WWAN_STATUS uStatus;
  ULONG uNwError;//Optional. Only used for network operations.
  WWAN_XXX XxxStruct;
} NDIS_WWAN_XXX, *PNDIS_WWAN_XXX;
```

A value of zero in the **RequestId** member of the NDIS_STATUS_INDICATION structure means it is an unsolicited event notification and can occur any time.

If the **uStatus** member in the returned indication of any *set* or *query* OID request does not equal WWAN_STATUS_SUCCESS the members of the associated NDIS_WWAN_XXX structure do not need to be valid.

In the case of unsolicited event notifications based on network events, miniport drivers must fill in the **uNwError** member as appropriate, if applicable.

The following table shows registration, packet-attach, and packet-detach cause code failure values that are defined in the *3GPP TS 24.008 Specification* for GSM-based networks:

3GPP 24.008 Cause code	Interpretation of cause code
2 - International Mobile Subscriber Identity (IMSI) unknown in HLR	Either the SIM or the device is not activated, or the subscription has expired, which caused a network deactivation.
4 - IMSI unknown in VLR	Roaming feature is not subscribed to.
6 - Illegal ME	MS blocked by network due to stolen report.
7 - GPRS services not allowed	User does not have a GPRS subscription. User has only a voice connection subscription.
8 - GPRS and non-GPRS services not allowed	GPRS and non-GPRS services are not allowed.
11 - PLMN not allowed	Service is blocked by the network due to an expired subscription or another cause.
12 - Location area not allowed	User subscription does not allow access in the present location area.
13 - Roaming not allowed in this location area	The subscription permits roaming, but roaming is not allowed in the present location area.
14 - GPRS services not allowed in this PLMN	Selected network provider does not provide GPRS service to the MS.
15 - No suitable cells in location area	No subscription for the service.
17 - Network failure	Registration failed.
22 - Congestion	Registration failed due to network congestion.

For example, if the network initiates a deactivate context event because roaming is not allowed in the location area, miniport drivers should set the **uNwError** member to 13 as per the 3GPP TS 24.008 Cause codes for GSM-based networks.

Similar logic should be applied to CDMA-based networks as well. However, there is no standard for CDMA-based network error codes. CDMA-based devices should use the network -specific or device-specific error codes.

In the case of a miniport driver's asynchronous response to OID requests, the **RequestId** member of the NDIS_STATUS_INDICATION structure is a non-zero number that was passed to the miniport driver as part of a *set* or *query* request. The miniport driver must fill the **uStatus** member as appropriate. For example, WWAN_STATUS_SUCCESS, or any of the appropriate error values listed in the following section. In addition to this, the miniport driver must fill in the **uNwError** member where appropriate and available.

Event Notification Status

The following table lists the WWAN_STATUS codes that MB miniport drivers can specify in the **uStatus** member of the NDIS_WWAN_XXX event notification structures.

Value	Meaning
WWAN_STATUS_SUCCESS	The operation succeeded.
WWAN_STATUS_FAILURE	The operation failed (a generic failure).
WWAN_STATUS_BUSY	The operation failed because the device is busy.
WWAN_STATUS_SIM_NOT_INSERTED	The operation failed because the SIM card was not inserted fully into the device.
WWAN_STATUS_BAD_SIM	The operation failed because the SIM card is bad and cannot be used any further.
WWAN_STATUS_PIN_REQUIRED	The operation failed because a PIN must be entered to proceed.
WWAN_STATUS_PIN_DISABLED	The operation failed because the PIN is disabled.
WWAN_STATUS_NOT_REGISTERED	The operation failed because the device is not registered with any network.
WWAN_STATUS_PROVIDERS_NOT_FOUND	The operation failed because no network providers could be found.
WWAN_STATUS_NO_DEVICE_SUPPORT	The operation failed because the device does not support the operation.
WWAN_STATUS_PROVIDER_NOT_VISIBLE	The operation failed because the service provider is not currently visible.
WWAN_STATUS_DATA_CLASS_NOT_AVAILABLE	The operation failed because the requested data-class was not available.
WWAN_STATUS_PACKET_SVC_DETACHED	The operation failed because packet service is detached.

Value	Meaning
WWAN_STATUS_MAX_ACTIVATED_CONTEXTS	The operation failed because the maximum number of activated contexts has been reached.
WWAN_STATUS_NOT_INITIALIZED	The operation failed because the device is in the process of initializing. Retry the operation after the ready-state of the device changes to **WwanReadyStateInitialized**.
WWAN_STATUS_VOICE_CALL_IN_PROGRESS	The operation failed because a voice call is in progress.
WWAN_STATUS_CONTEXT_NOT_ACTIVATED	The operation failed because the context is not activated.
WWAN_STATUS_SERVICE_NOT_ACTIVATED	The operation failed because service is not activated.
WWAN_STATUS_INVALID_ACCESS_STRING	The operation failed because the access string is invalid.
WWAN_STATUS_INVALID_USER_NAME_PWD	The operation failed because the user name and/or password supplied are invalid.
WWAN_STATUS_RADIO_POWER_OFF	The operation failed because the radio is currently powered off.
WWAN_STATUS_INVALID_PARAMETERS	The operation failed because of invalid parameters.
WWAN_STATUS_READ_FAILURE	The operation failed because of a read failure.
WWAN_STATUS_WRITE_FAILURE	The operation failed because of a write failure.

The following table shows SMS specific status values.

Value	Meaning
WWAN_STATUS_SMS_OPERATION_NOT_ALLOWED	The SMS operation failed because the operation is not allowed.
WWAN_STATUS_SMS_MEMORY_FAILURE	The SMS operation failed because of a memory failure.
WWAN_STATUS_SMS_INVALID_MEMORY_INDEX	The SMS operation failed because of an invalid memory index-- *WwanSmsFlagIndex* for OID_WWAN_SMS_READ.

Value	Meaning
WWAN_STATUS_SMS_UNKNOWN_SMSC_ADDRESS	The SMS operation failed because the service center number is either invalid or unknown.
WWAN_STATUS_SMS_NETWORK_TIMEOUT	The SMS operation failed because of a network timeout.
WWAN_STATUS_SMS_MEMORY_FULL	The SMS operation failed because the SMS message store is full.
WWAN_STATUS_SMS_UNKNOWN_ERROR	The SMS operation failed because of an unknown error (a generic error).
WWAN_STATUS_SMS_FILTER_NOT_SUPPORTED	The SMS operation failed because the filter type requested is not supported.
WWAN_STATUS_SMS_MORE_DATA	This transaction is not yet complete. Some data has been returned and there is more data to be returned.
WWAN_STATUS_SMS_LANG_NOT_SUPPORTED	The SMS operation failed because the SMS language is not supported. This applies to CDMA-based devices only.
WWAN_STATUS_SMS_ENCODING_NOT_SUPPORTED	The SMS operation failed because the SMS encoding is not supported. This applies to CDMA-based devices only.
WWAN_STATUS_SMS_FORMAT_NOT_SUPPORTED	The SMS operation failed because the SMS format is not supported.

Note These WWAN-specific status codes are used only for asynchronous transactions in the **uStatus** member of the NDIS_WWAN_XXX structures.

Miniport drivers use event notifications to inform the MB Service about an object state change in their MB device without first having received an OID request. The MB Service uses event notifications to update its state machine only.

Be aware that while NDIS serializes all requests that are sent to miniport drivers, miniport drivers might not return the responses in the same order. This is because the queued requests in the miniport driver might be processed in parallel. Hence the MB Service ensures that if two requests are dependent upon each other, it will not send the second request until the miniport driver completes the first request.

State Change Notification

In general, miniport drivers should always notify the MB Service about the updated state of their MB device either through transactional notifications or through unsolicited event notifications. The following scenarios are some exceptions where miniport drivers are not supposed to respond with updated state information. The MB Service can determine the updated state from the completion status of other operations:

1. Miniport drivers do not need to send an NDIS_STATUS_WWAN_PIN_LIST event indication when PIN state changes occur because the MB Service requested to enable or disable the PIN.

2. Miniport drivers do not need to return the updated list of the provisioned contexts in transactional responses to OID_WWAN_PROVISIONED_CONTEXT *set* operations.

3. Miniport drivers do not need to respond with the updated list of the preferred providers in transactional responses to OID_WWAN_PREFERRED_PROVIDERS *set* operations. The MB Service can determine this information based on the initial list and success status of the *set* operation.

4. Miniport drivers do not need to respond with the current WWAN_SMS_CONFIGURATION value for OID_WWAN_SMS_CONFIGURATION *set* operations.

MB Driver Model Versioning

Article • 03/14/2023

MB driver model versioning is accomplished by having the driver model version and individual OID data structure revisions. This is consistent with the versioning paradigm used in NDIS 6.x.

The driver model version defines the interface evolution between the MB Service and the MB miniport driver. The individual OID revisions keep track of the changes made to OIDs in different MB driver model versions. That is, the driver model version defines a set of OIDs whose data structures are identified by specific revision numbers.

Consistent with the *NDIS Specification*, the MB driver model evolution is *additive*. That is, new OIDs and new members can only be added to existing OID data structures. This ensures that the MB Service can support backward compatibility for miniport drivers.

Important Only under extremely rare circumstances will existing OIDs be deprecated or members of existing OID data structures not be used in the next version. If that happens, these changes and their impacts on backward compatibility shall be clearly documented in subsequent documentation about newer versions of the MB driver model specification.

This documentation covers the Windows 8 release of the MB driver model. The driver model version has been incremented to version 2.0. Some OID revisions continue to be revision number 1, while some have been updated to revision 2. For more information about which revisions to use with respective OIDs, see MB Data Model.

This documentation covers the initial release of the MB driver model, so both the driver model version and individual OID revisions start with revision number 1.

When the driver model moves to the next version, its version number is increased by 1. Any new OIDs added to the driver model will start at revision 1; any existing OIDs whose data structures have changed will increase their corresponding revision by 1, and any existing OIDs that do not change will keep their respective revision numbers.

The driver model version is conveyed by OID_WWAN_DRIVER_CAPS. The MB Service sends an OID_WWAN_DRIVER_CAPS query request to the miniport driver during MB Miniport Driver Initialization. Individual OID revisions are described by the **Revision** member of the **NDIS_OBJECT_HEADER** structure that is included as part of the data structure for each individual OID.

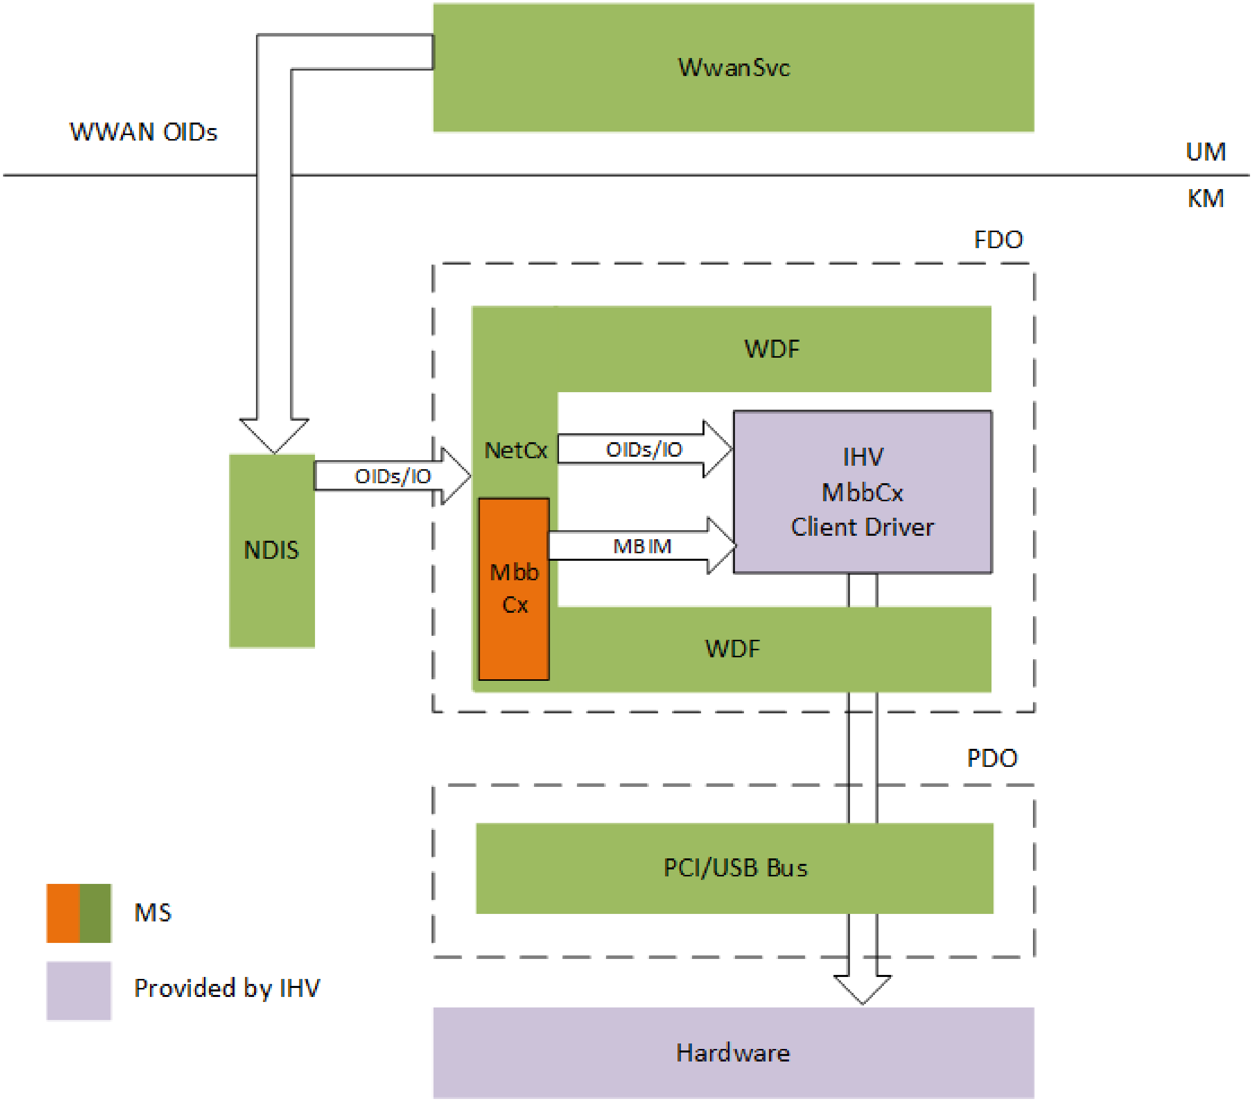
Introduction to the Mobile Broadband (MBB) WDF class extension (MBBCx)

Article • 12/15/2021

Starting in the next release of Windows 10, the Windows Driver Kit (WDK) includes a Mobile Broadband (MBB) WDF class extension that works with NetAdapterCx. MBB-NetAdapter client drivers are first and foremost fully fledged WDF client drivers, then they're NetAdapterCx client drivers just like other NIC drivers, and finally they're client drivers of the MBB class extension (MBBCx) that provides MBB media-specific functionality. The following block diagram illustrates the MBBCx architecture:



An MBB-NetAdapter client driver performs 3 categories of tasks based on its relationships with the framework:

- Call standard WDF APIs for common device tasks like Pnp and Power management.
- Call NetAdapterCx APIs for common network device operations like transmitting or receiving network packets.

- Call MbbCx APIs for MBB-specific control path operations like MBIM message handling.

Before you begin, you should familiarize yourself with these concepts:

- Windows Driver Foundation (WDF)
- NetAdapter class extension (NetAdapterCx)

The topics in this section assume you already know how to write a NetAdapterCx client driver for a basic NIC, so they focus only on MBBCx-specific code.

This section contains the following topics:

- Writing an MBBCx client driver

MB Driver Stack, Suspend, and Resume

Article • 03/14/2023

Overview

Microsoft provides an inbox class driver for mobile broadband (MBB) devices called the Mobile Broadband Class Driver (MBCD). This driver is based on the Mobile Broadband Interface Model (MBIM) specification, which is an interface for MBB devices (also known as modems) to communicate with Windows. The MBIM specification is based on USB. MBCD provides support for USB modems and modems that emulate USB through a technology called USB Device Emulation (UDE).

MBCD is a miniport driver that combines with the Network Driver Interface Specification (NDIS) port driver to form a single function driver. In the OSI Network Model, this driver logically sits on the top half of the Data Link Layer (layer 2). Network protocol drivers (such as IP) that logically sit on the Network layer (layer 3) receive data (SDUs) in segments (TCP) or datagrams (UDP) from the Transport Layer (layer 4) and send down data (PDUs) as packets to the Data Link Layer by invoking NDIS APIs. Generally, NDIS only involves a miniport driver when it is necessary.

OSI Network Model				
Layer			Protocol Data Unit (PDU)	Function
Host Layer	7	Application	Data	High level APIs including resource sharing and remote file access
	6	Presentation		Translation of data between a networking service and an application including character encoding, data compression, and encryption
	5	Session		Management of communication sessions, for example continuous information exchange in the form of multiple back-and-forth transmissions between two nodes
	4	Transportation	Segment	Reliable transmission of data segments between points on a network, including segmentation, acknowledgement, and multiplexing

Media Layer	3	Network	Packet	Management and structuring of multi-node networks including address mapping, routing, and traffic control
	2	Data Link	Frame	Reliable transmission of data frames between two nodes connected by the Physical layer
	1	Physical	Symbol	Transmission and reception of raw bit streams over a physical medium

The Network Layer is where network protocol drivers reside, including the NDIS Usermode I/O (NDISUIO) protocol driver. This driver serves an important role in the control and configuration of MBB devices. It is important to note that this layer is also conceptually where the IP portion of TCP/IP resides. You may think of these as siblings.

WwanSvc is the service primarily responsible for control of the modems, enumerating their capabilities, and their configuration. WwanSvc uses WWAN OIDs to issue commands to NDISUIO, which will pass these OIDs to NDIS. The MBCD miniport driver defines the OIDs that it supports and provides this to NDIS as part of the initialization of the function driver. Therefore, when NDIS receives an OID from NDISUIO it will involve the miniport as necessary.

The flow of a command from an application (such as the cellular UI) looks like this:

Application -> WwanSvc ---(OID)---> NDISUIO ----(OID)---> NDIS ----(OID)---> MBCD ---(MBIM)---> MBB Device.

The above provides an overview of the technologies involved for the control path. The data path is more complicated as there are several solutions in place. However, we can generalize the data path as:

Application -> TCP/IP --(packets)--> NDIS ----(frames)---> [Driver] ---> MBB Device.

[Driver] might be the legacy driver, the new modern driver, or a 3rd party IHV driver.

Hardware Lab Kit (HLK) Tests

See Steps for installing HLK .

In HLK Studio connect to the device Cellular modem driver and run test: TestPowerStates.

Via netsh, we can run the **TestPowerStates** HLK testlist. For more information on using the netsh tool, see **netsh-mbn** and **netsh-mbn-test-installation**.

```
netsh mbn test feature=power testpath="C:\\data\\test\\bin"
taefpath="C:\\data\\test\\bin"
```

This file showing the HLK test results should have been generated in the directory that the 'netsh mbn test' command was ran from: `TestPowerStates.htm`.

Manual Tests

Auto-connect after wake from hibernation (S4)

1. Ensure "Let Windows manage this connection" is checked in Cellular settings.
2. Put DUT into S4.

3. Wake DUT. Verify it automatically establishes a cellular connection and the user is able to browse the internet.

Connect Cellular manually after wake from hibernation (S4)

1. With Ethernet unplugged and Wi-Fi toggled off, uncheck "Let Windows manage this connection" in Cellular settings.
2. In an admin CMD prompt run the command: shutdown -h
3. Machine will hibernate. After more than 30 seconds press the machine's power button to wake from hibernation. Log back in, open Cellular settings, and click Connect to Cellular. Cellular should connect and the user should be able to browse the internet.

Auto-connect after wake from screen sleep

1. With Ethernet unplugged and Wi-Fi toggled off, verify an active cellular connection.
2. (Optional Step) Allow screen to sleep. You can set screen sleep to 1 minute under Settings -> System -> Power & sleep. The setting should not be set to "Never".
3. Wake the screen by using the mouse or keyboard and log back in. Cellular should stay connected and the user should be able to browse internet, including under the VAIL/WCOS system.

Log Analysis

Tips

- Ensure necessary ETW providers are included in the log, including MbbCx, NetAdapterCx, WwanSvc, and NdisUio.
- Check the device power state (Dx state) and the device power capabilities first
- Check the logs with power flows above
- OID and indication pair

MB Miniport Driver INF Requirements

Article • 03/14/2023

MB miniport drivers must have the following entries in their INF file:

INF

```
*IfType  = 243; IF_TYPE_WWANPP
*MediaType  = 9; <mark type="enumval">NdisMediumWirelessWan</mark>
*PhysicalMediaType  = 8; NdisPhysicalMediumWirelessWan
EnableDhcp  = 0; Disable DHCP

;Entries to be put in add-registry-section for NdisMediumWirelessWan
HKR, Ndi\Interfaces, UpperRange, 0, "flpp4, flpp6"
HKR, Ndi\Interfaces, LowerRange, 0, "ppip"
```

All the entries mentioned in the preceding code example, except UpperRange and LowerRange, should be under the same INF section as that of keywords such as AddReg and CopyFiles. UpperRange and LowerRange should be put in the add-registry-section of the INF file.

*IfType

Dual-mode devices can specify either of the *IfType* values from the following table:

Description	Name	IfType
GSM-based MB devices	IF_TYPE_WWANPP	243
CDMA-based MB devices	IF_TYPE_WWANPP2	244

*MediaType

MB miniport drivers must specify one of the MediaType values from the following table based on the type of packet framing the miniport driver is capable of interpreting in its send and receive data path.

Description	Name	MediaType
MB miniport drivers that interpret 802.3 packets must report this media type. This framework is only for migration of old miniport	NdisMedium802_3	0

drivers and is not recommended for production-quality miniport drivers.		
MB miniport drivers that are able to handle raw IP traffic must set this media type. This is the recommended media type to be used in production-quality miniport drivers.	NdisMediumWirelessWan	9

EnableDhcp

MB miniport drivers must specify one of the EnableDhcp values from the following table based on whether they implement DHCP server emulation.

Value	Description
0	Disable DHCP for this interface. The miniport driver does not implement DHCP server spoofing. This is the recommended value to be used in production-quality drivers.
1	Enable DHCP for this interface. The miniport driver implements DHCP server spoofing. That is, the miniport driver will need to spoof a DHCP server and ARP resolutions.

UpperRange

This keyword is set with one or more combinations of the following strings as applicable when media type is NdisMediumWirelessWan. NdisMedium802_3 miniport drivers should use the existing values in UpperRange.

Value	Description
"flpp4"	Miniport drivers specify "flpp4" if the MB device supports IPv4.
"flpp6"	Miniport drivers specify "flpp6" if the MB device supports IPv6. This value is needed only for devices that support IPv6.

LowerRange

This keyword must have, at the minimum, the following value when media type is NdisMediumWirelessWan. NdisMedium802_3 miniport drivers should use the existing values in LowerRange.

Value	Description
"ppip"	MB device type on the lower edge.

MB Miniport Driver Types

Article • 03/14/2023

Based on data packet handling, DHCP Server and ARP emulations, multiple MB miniport driver implementation types are possible. The following table represents the different possible implementation types and the required implementation for production quality miniport drivers.

Description	MediaType	EnableDhcp	ARP emulation
Ethernet emulation with DHCP emulation	NdisMedium802_3	1	Required
Ethernet emulation with no DHCP	NdisMedium802_3	0	Required
IP packet handling with DHCP emulation	NdisMediumWirelessWan	1	Not required
IP packet handling capability	NdisMediumWirelessWan	0	Not Required

During development or migration phases, miniport drivers can specify any of first three entries. However, production quality miniport drivers should use only the settings specified in the last entry of the table ("IP packet handling capability").

Production quality MB miniport drivers should specify the settings in the following table in the INF file.

Field in INF file	Recommended value(s)
*IfType	IF_TYPE_WWANPP / IF_TYPE_WWANPP2
MediaType	NdisMediumWirelessWan
EnableDhcp	0
UpperRange	"flpp4" and "flpp6" (if IPv6 supported)
LowerRange	"ppip"

MB Adapter General Attribute Requirements

Article • 03/14/2023

The following table describes the values that miniport drivers should set the member variables of the NDIS_MINIPORT_ADAPTER_GENERAL_ATTRIBUTES structure to. MB miniport drivers must use these values when they call NdisMSetMiniportAttributes from their *MiniportInitializeEx* function, during miniport driver initialization.

Field in INF file	Recommended values
IfType	GSM-based devices must specify IF_TYPE_WWANPP. CDMA-based devices specify IF_TYPE_WWANPP2. The value must match the *IfType value specified in the miniport driver's INF file.
MediaType	The value must match the *MediaType value specified in the miniport driver's INF file. For example, either **NdisMediumWirelessWan** or **NdisMedium802_3**.
PhysicalMediumType	The value must match the *PhysicalMediaType value specified in the miniport driver's INF file. The value must be **NdisPhysicalMediumWirelessWan**.
AccessType	If the value in MediaType is specified as **NdisMediumWirelessWan**, specify **NET_IF_ACCESS_POINT_TO_POINT** for AccessType. If MediaType is **NdisMedium802_3**, specify NET_IF_ACCESS_BROADCAST.

MB Raw IP Packet Processing Support

Article • 03/14/2023

MB miniport drivers that support Raw IP packet frames in their send/receive data path should observe the following guidelines:

Net buffer list (NBL) flags for RAW IP packet processing

- For IPv4 packets:

  The **NblFlags** member of the NET_BUFFER_LIST structure must be set to NDIS_NBL_FLAGS_IS_IPV4.

  The **NetBufferListFrameType** member of the NET_BUFFER_LIST structure must be set to 0x0800 (Ethertype IPv4) in network byte order.

- For IPv6 packets:

  The **NblFlags** member of NET_BUFFER_LIST structure must be set to NDIS_NBL_FLAGS_IS_IPV6.

  The **NetBufferListFrameType** member of the NET_BUFFER_LIST structure must be set to 0x86dd (Ethertype IPv6) in network byte order.

Miniport drivers can use the NdisSetNblFlag macro to set flags in the net buffer list. The following line demonstrates how to set IPv4 packet flag in the net buffer list:

```C++
NdisSetNblFlag(pNbl, NDIS_NBL_FLAGS_IS_IPV4);
```

Miniport drivers can use the NET_BUFFER_LIST_INFO to get and set information in a net buffer list. The following line demonstrates how to modify the **NetBufferListFrameType** OOB in the network buffer list for IPV4 packets:

```C++
Value = ConvertToNetworkByteOrder(0x0800);
```

```C++
NET_BUFFER_LIST_INFO(pNbl, NetBufferListFrameType) = Value;
```

Send Path Processing

The MB Service will set these flags in the NBL before passing the list to the miniport driver to send across the network. The miniport driver can verify the flags in the input NBL.

Receive Path Processing

Miniport drivers should set flags in the NBL before passing the NBL to the MB Service for received packets.

If your miniport driver implements Raw IP Packet Processing during its driver development phase, but still has DHCP server spoofing enabled (EnableDhcp = 1), your miniport driver should ensure following:

- The hardware address and its length set in DHCP response from the miniport driver should match the values of the **CurrentMacAddress** and **MacAddressLength** members specified by the miniport driver in the NDIS_MINIPORT_ADAPTER_GENERAL_ATTRIBUTES structure.
- Transaction ID (the **xid** member) of the DHCP response from the miniport driver should match exactly the transaction ID set in the DHCP request message from the client.

Guidelines for MB Miniport Driver IP Address Notifications

Article • 03/14/2023

MB miniport drivers that specify *EnableDhcp* equal to zero in their INF files can use the IP Helper and associated functions in kernel mode to create, change, and delete the IP address:

To use the IP Helper functions in kernel mode, miniport drivers must include the Netioapi.h header file, and link against Netio.lib.

When miniport drivers specify *EnableDhcp* equal to zero they are required to perform the following operations to notify the MB Service about any of the following events:

- Set IP address for the MB interface
- Set default gateway address
- Update DNS addresses

IP addresses and default gateways that are set by using the IP Helper API persist network connect or disconnect events, or both. Therefore, if the new IP address or default gateway, or both, values are different than the values currently set, the miniport driver should first clear the previous values before setting new values on a network connection event.

Note Miniport drivers can find the **LUID** and **Index** of the MB interface from the **NetLuid** or **IfIndex** members of **NDIS_MINIPORT_INIT_PARAMETERS** structure that is passed to the miniport driver's *MiniportInitializeEx* function.

Resetting the IP Address and Gateway Address

Certain changes to the TCP/IP stack, such as the loading of a mandatory filter driver, can remove the IP and gateway addresses set by the IP helper functions. Miniport drivers must reset the IP and gateway addresses if changes to the TCP/IP stack remove the settings.

Miniport drivers should use following procedure to be notified when the addresses are removed, and must be reset again.

1. During **driver initialization**, miniport drivers should specify a callback function to register for IP interface change notifications using **NotifyIpInterfaceChange**.

Windows will call the function wheneven an IP interface is added, deleted or changed.

2. During **adapter initialization**, miniport drivers should save in miniport driver's local adapter context the **LUID** value from the **NDIS_MINIPORT_INIT_PARAMETERS** structure that is passed to the miniport driver's *MiniportInitializeEx* function. The value contains the *NetLuid* which identifies adapter's interface, which is used in the notification callback.

3. In the **notification callback**, Windows passes the following parameters to the notification function registered with **NotifyIpInterfaceChange**:

   - A pointer to a **MIB_IPINTERFACE_ROW** structure, which contains the *NetLuid* of the miniport adapter's interface.
   - The type of notification, which can be **MibAddInstance**, **MibDeleteInstance** or **MibParameterNotification**.

   Miniport drivers should reset the IP and gateway addresses when the adapter is in a connected state, and the notification type is **MibAddInstance**, and the *NetLuid* in **MIB_IPINTERFACE_ROW** corresponds to one of the miniport driver's adapters, which was saved during adapter initialization.

   Miniport drivers should then follow the Setting the IP Address for the MB Interface and Setting Default Gateway Address procedures to reset the respective addresses.

4. During **driver unload**, miniport drivers should unregister the notification callback function using the **CancelMibChangeNotify2** IP helper function.

Setting the IP Address for the MB Interface

To set an IPv4 address, use the following procedure. You can use similar IP Helper functionality to set an IPv6 address.

1. Use the **GetUnicastIpAddressTable** IP Helper function to find all the IP address entries in the system.

2. For each entry whose **InterfaceLuid** value matches the **InterfaceLuid** of the MB interface:
   a. Find the IP address entry that matches the IP address used in previous connection. First time connections will not have a previous IP address.
   b. If the new IP address is different than the previous IP address, delete the IP address entry for previous connection IP addresses by using the **DeleteUnicastIpAddressEntry** IP Helper function.

   c. If the new IP address is the same as the previous IP address, verify that the desired entry already exists.

3. If the miniport driver did not find the desired IP address entry in the previous loop, it should add a new entry.

   a. Use the InitializeUnicastIpAddressEntry IP Helper function to initialize a MIB_UNICASTIPADDRESS_ROW structure and set the following members of the structure:
      i. Set the **InterfaceLuid** or **InterfaceIndex** members, as appropriate.
      ii. Set the **OnlinePrefixLength** member. This is the number of bits that have a value of one in the subnet mask. For example, if the subnet mask is 255.255.255.0, **OnlinePrefixLength** should be 24.
      iii. Set the **Address** member.
      iv. Set the **PrefixOrigin** member to **IpPrefixOriginManual**.

   b. Pass the initialized MIB_UNICASTADDRESS_ROW structure to the CreateUnicastIpAddressEntry IP Helper function to create the IP address entry.

Setting Default Gateway Address

To set an IPv4 gateway address, use the following procedure. You can use similar IP Helper functionality to set an IPv6 gateway address.

1. Use GetIpForwardTable2 IP Helper function to obtain all the routing entries in the system.

2. For each entry whose **InterfaceLuid** value matches the **InterfaceLuid** value of the MB interface and **DestinationPrefix** is "0.0.0.0/0", call the DeleteIpForwardEntry2 IP Helper function to delete the route if **NextHop** is not equal to the new gateway address. Otherwise, the routing entry is already in the system.

3. If the miniport driver did not find the desired routing entry in the previous loop, it should add a new entry by using the InitializeIpForwardEntry IP Helper function to initialize a MIB_IPFORWARD_ROW2 structure. Initialize the following members of the structure:

   InterfaceLuid or **InterfaceIndex** .

   Set **DestinationPrefix** to 0.0.0.0/0 for default gateway. (Prefix = 0.0.0.0 and PrefixLength = 0)

   Set **NextHop** to the IP address of the default gateway.

Other members are set to default values during initialization. Miniport drivers should use default values for those members.

4. Pass the **MIB_IPFORWARD_ROW2** structure to the **CreateIpForwardEntry2** IP Helper function to set a new default gateway address.

To Set DNS Addresses

- Set the **NameServer** registry key as described in MB DNS Updates to notify Windows about updated DNS addresses.

MB Miniport driver Error Logging

Article • 03/14/2023

MB miniport drivers should perform the following checks in their *MiniportInitializeEx* function, such as:

- The presence of the correct device firmware version required to support the MB driver model.
- An available COM port to communicate with the device.
- No resource conflicts.

If a miniport driver fails to obtain resources it requires, it should return NDIS_STATUS_RESOURCES from its MiniportInitializeEx function. Miniport drivers should call **NdisWriteErrorLogEntry** to log the details of failure to the Windows Event Log.

Miniport drivers should specify the error code in the first element of the last parameter in the call to NdisWriteErrorLogEntry (a variable-sized array of ULONGs) according to the information in the following table.

Error code	Description
WWAN_ERROR_UNSUPPORTED_FIRMWARE	The device is running an unsupported firmware version.
WWAN_ERROR_COM_PORT_CONFLICT	Unable to open COM port for communicating with the device.
WWAN_ERROR_RESOURCE_CONFLICT_OTHER	Any other resource conflict.

Miniport drivers can put other values in the remainder of the elements of variable-sized array.

MB Miniport Driver Performance Requirements

Article • 03/14/2023

The following table describes the expectations for MB miniport drivers to respond to different MB operations. For the best experience, miniport drivers should complete operations within the time identified in the "Best case time (sec)" column.

MB operation	Best case time (sec)	Worst case time (sec)
Time for device to initialize (to reach **WwanReadyStateInitialized**) after being inserted into the machine (OID_WWAN_READY_INFO)	1	5
Manual network registration (OID_WWAN_REGISTER_STATE)	0	50
Network scan operation (OID_WWAN_VISIBLE_PROVIDERS)	2	200
Packet-attach operation (OID_WWAN_PACKET_SERVICE)	1	5
Packet-detach operation (OID_WWAN_PACKET_SERVICE)	1	5
PDP activation (OID_WWAN_CONNECT)	2	10
PDP deactivation (OID_WWAN_CONNECT)	1	10
Update system with IP address, default gateway, and DNS address	1	5
NDIS_STATUS_LINK_STATE notification after PDP activation	2	10
Completion of the following PIN operations (OID_WWAN_PIN): Enter Enable Disable Change	1	4

MB operation	Best case time (sec)	Worst case time (sec)
Query OID_WWAN_PIN to get the current PIN state of the MB device	1	4
OID_WWAN_PIN_LIST response to get a list of supported PIN types	1	4
Time for SMS subsystem to be ready (should send the NDIS_STATUS_WWAN_SMS_CONFIGURATION unsolicited indication)	1	60
Time for miniport driver to complete all other WWAN OIDs except OID_WWAN_VENDOR_SPECIFIC which are not covered in this table	1	15

MB Device Readiness

Article • 03/14/2023

This topic describes the procedures to ensure that an MB device is accessible and ready to be used for network-related activities before the MB Service proceeds to setup data connections. The device is ready to use when the user subscription has been activated and subscriber-related information stored to the device or the Subscriber Identity Module (SIM card)

The MB Service assumes that a miniport driver automatically initializes its MB device's hardware (radio stack, SIM card or equivalent circuitry) after the system has loaded it, without waiting for any instruction from the service.

Miniport drivers set the initial ready-state of their MB device to **WwanReadyStateOff**. As they proceed with initializing, miniport drivers must send event notifications to inform the MB Service of changes to their device's ready state.

Miniport drivers must stop the initialization process if they run into any error conditions. After the error condition is cleared, miniport drivers can resume the initialization process until their device has reached the **WwanReadyStateInitialized** ready-state.

The following are examples of some error scenarios:

- If the device requires a SIM card and the miniport driver detects that no SIM card is present, the miniport driver must send a **WwanReadyStateSimNotInserted** ready-state event notification, and the miniport driver must remain in that state until the user inserts a SIM card into the device.

- If the device requires a SIM card and the miniport driver cannot read the SIM card that has been inserted (for example, a U-RIM is inserted into a GSM-based device or a USIM is inserted into a CDMA-based device) or the SIM card is not compatible with the device (for example, a 3G USIM is inserted into a 2G device, which cannot interpret the USIM format), the miniport driver must send a **WwanReadyStateBadSim** ready-state event notification, and the miniport driver must remain in that state until the user inserts a correct SIM card into the device.

- If the device is locked by the PIN (for devices that use SIM cards) or by a password (for devices that do not use SIM cards) that prevents further device initialization progress, the miniport driver must send a **WwanReadyStateDeviceLocked** ready-state event notification, and the miniport driver must remain in that state until the user enters the correct PIN or password.

- If the miniport driver detects that service activation is required to proceed, the miniport driver must send a **WwanReadyStateNotActivated** ready-state event notification, and it must remain in that state until the service has been activated. This is typical behavior for CDMA-based devices in North America.
- If the miniport driver runs into failures other than the ones mentioned previously, the miniport driver must send a **WwanReadyStateFailure** ready-state event notification, and it must remain in that state until the problem has been identified and corrected.

Be aware that the MB Service does not assume that miniport drivers can detect all these errors. Nor does the service assume the order in which miniport drivers detect these error conditions. However, it is best to implement the error scenarios in the order listed previously.

Until a miniport driver sends a **WwanReadyStateInitialized** ready-state event notification, the service will not proceed any further with network-related activities until the problem has been identified and corrected. However, the service may still send OIDs to the miniport driver.

Miniport drivers do not need to wait for the SMS subsystem to be ready before reporting the **WwanReadyStateInitialized** ready-state. Instead, miniport drivers should send a separate OID_WWAN_SMS_CONFIGURATION notification when the SMS subsystem is ready to send and receive SMS messages.

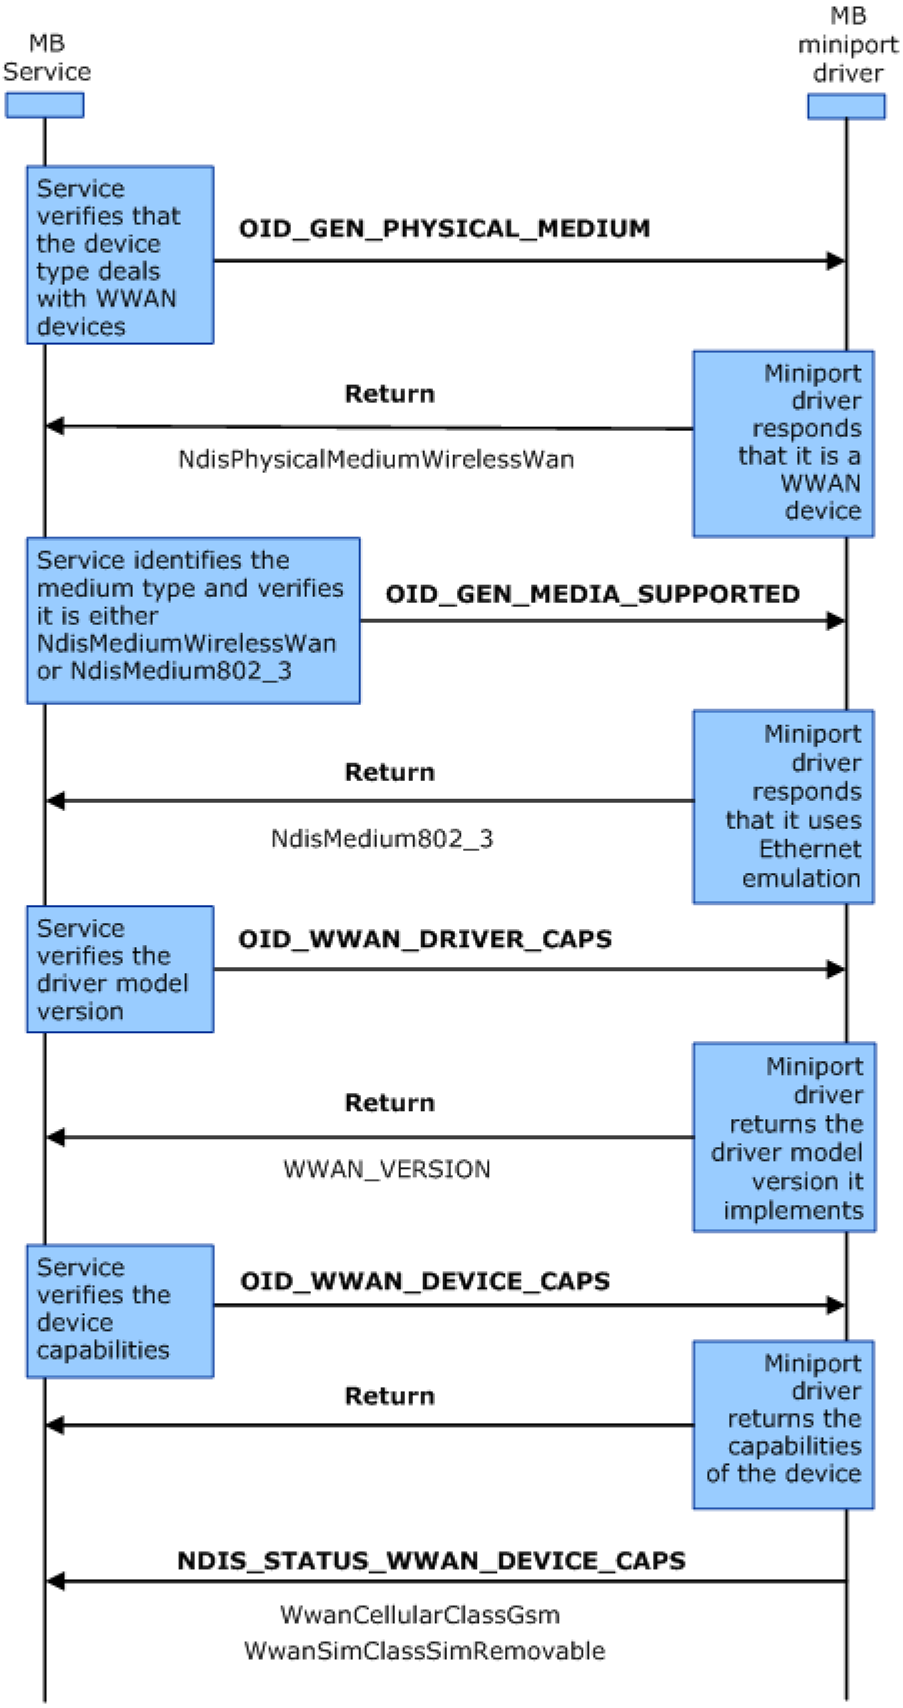
Emergency Mode Support

If the miniport driver indicates that it supports emergency call services while processing OID_WWAN_READY_INFO the miniport driver must set the **EmergencyMode** member of the **WWAN_READY_INFO** structure to **WwanEmergencyModeOn**. In this case, the miniport driver should continue to send registration notifications to the MB Service, but the service will not invoke any automatic configuration related functionalities.

Miniport drivers can specify that they support emergency call services even in scenarios where they detect that the SIM is no longer valid, perhaps because the subscription is unpaid, or service has been deactivated because the device has been reported stolen.

MB Miniport Driver Initialization

The following diagram represents the process taken to determine whether the interface is a qualified MB interface and to gather information about the device capabilities. These steps are performed for each enumerated MB interface when the MB Service starts up, as well as for each new interface arrival while the service is running. The labels in bold represent OID identifiers or transactional flow control. The labels in regular text represent the important flags within the OID structure.



MB Service
MB miniport driver
Service verifies that the device type deals with WWAN devices
OID_GEN_PHYSICAL_MEDIUM
Return
Miniport driver responds that it is a WWAN device
NdisPhysicalMediumWirelessWan
Service identifies the medium type and verifies it is either NdisMediumWirelessWan or NdisMedium802_3
OID_GEN_MEDIA_SUPPORTED
Return
Miniport driver responds that it uses Ethernet emulation
NdisMedium802_3
Service verifies the driver model version
OID_WWAN_DRIVER_CAPS
Return
Miniport driver returns the driver model version it implements
WWAN_VERSION
Service verifies the device capabilities
OID_WWAN_DEVICE_CAPS
Return
Miniport driver returns the capabilities of the device
NDIS_STATUS_WWAN_DEVICE_CAPS
WwanCellularClassGsm
WwanSimClassSimRemovable

To initialize an MB miniport driver, use the following procedure:

1. The MB Service sends a synchronous (blocking) OID_GEN_PHYSICAL_MEDIUM query request to identify the type of the MB device. The miniport driver responds with **NdisPhysicalMediumWirelessWan** to indicate that the MB device is a WWAN device.

2. The MB Service sends a synchronous (blocking) OID_GEN_MEDIA_SUPPORTED query request to the miniport driver to identify what kind of medium the MB device uses. The miniport driver responds with **NdisMedium802_3** to indicate that it uses Ethernet emulation.

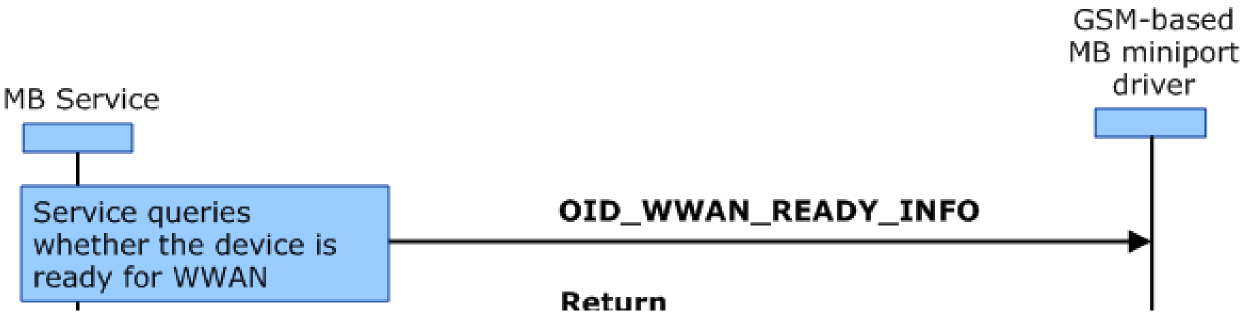
3. The MB Service sends a synchronous (blocking) OID_WWAN_DRIVER_CAPS query request to the miniport driver to identify what driver model version the miniport driver supports. The miniport driver responds with WWAN_VERSION.

4. The MB Service sends an asynchronous (non-blocking) OID_WWAN_DEVICE_CAPS query request to the miniport driver to identify the capabilities of the MB device. The miniport driver responds with a provisional acknowledgement that it has received the request, and it will send a notification with the requested information in the future.

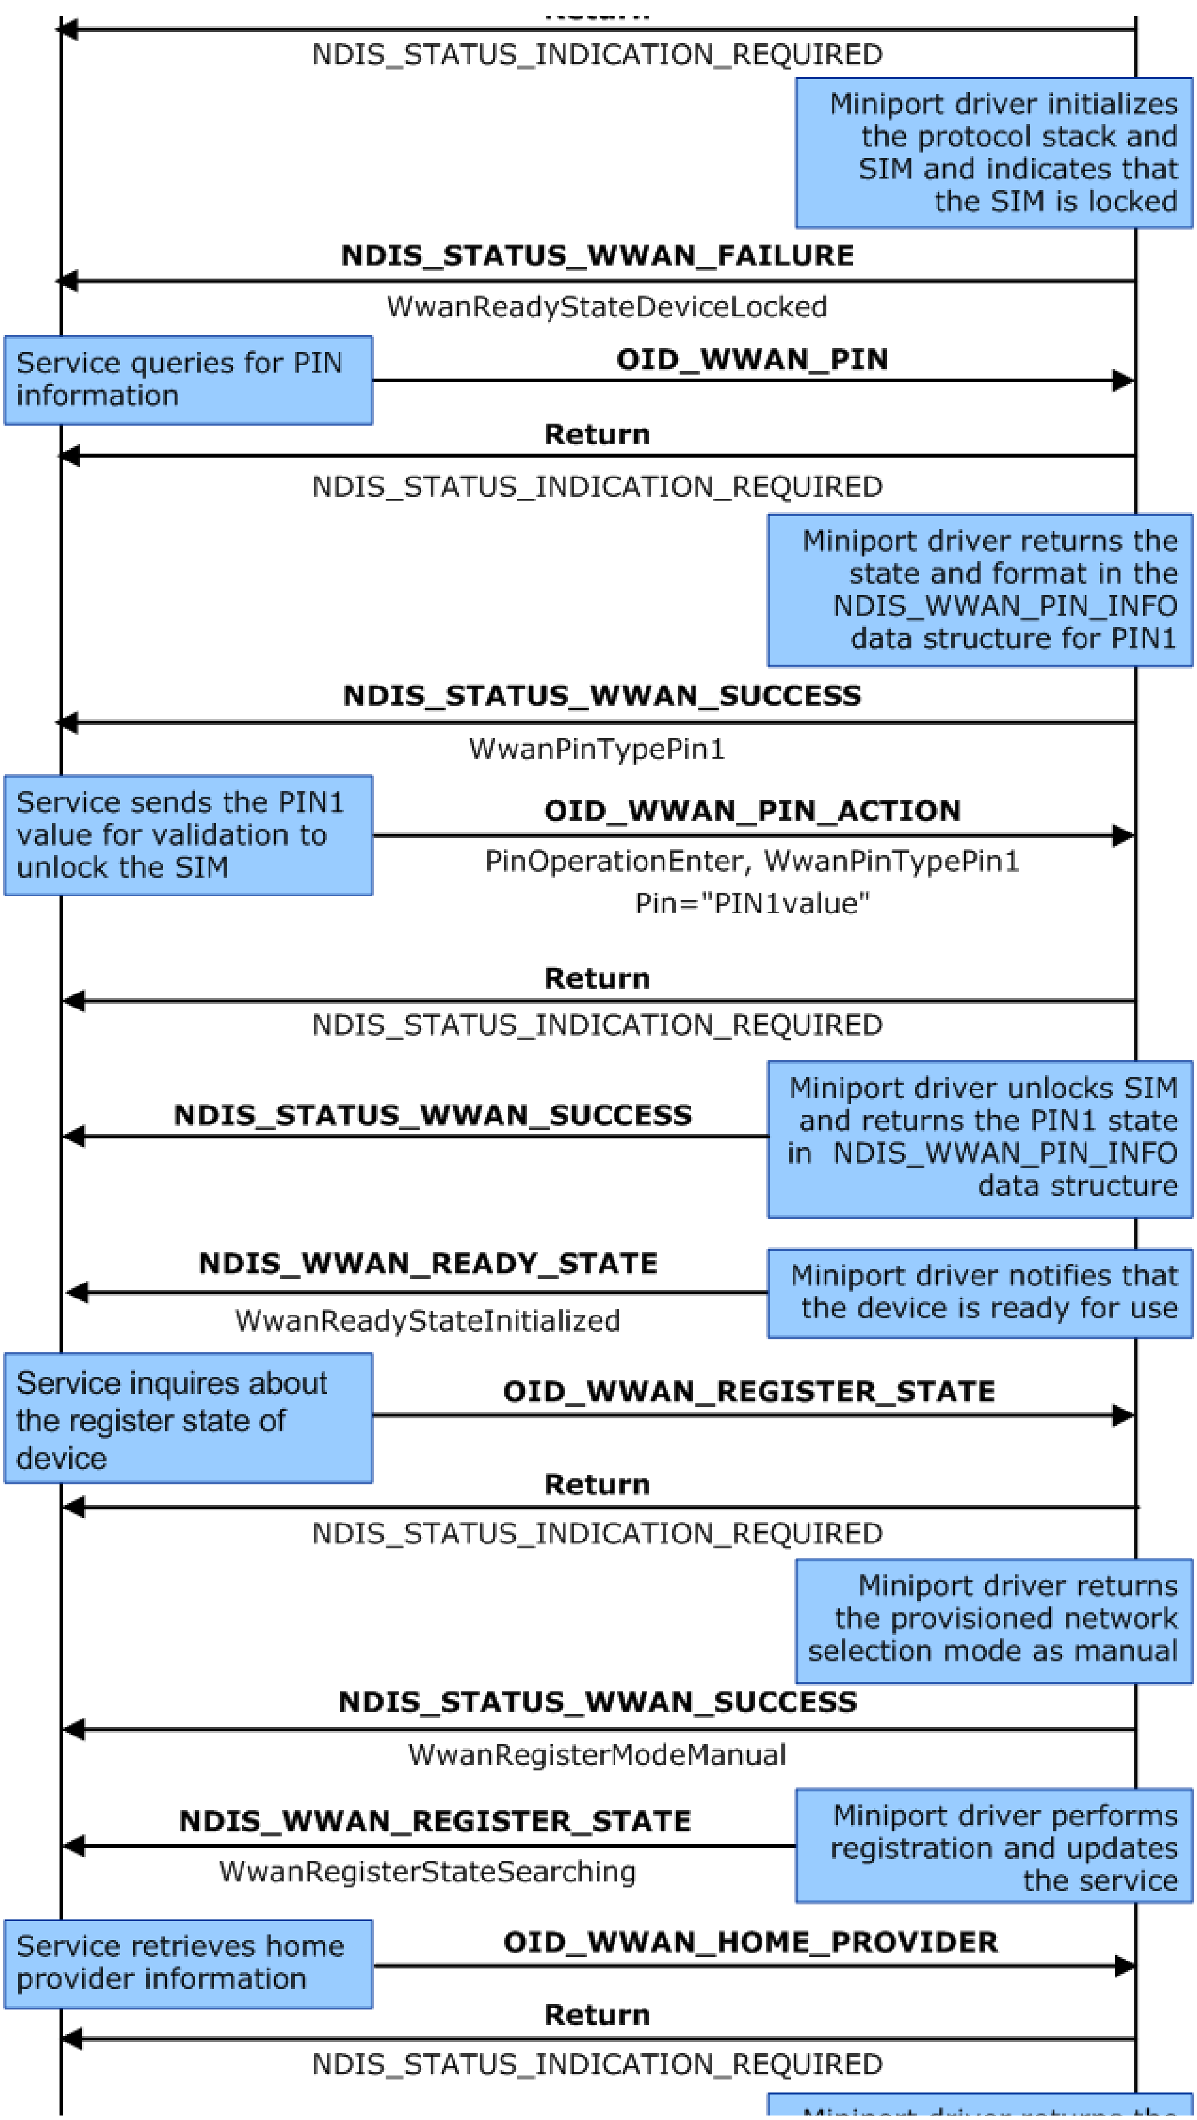
5. The miniport driver sends an **NDIS_STATUS_WWAN_DEVICE_CAPS** notification to the MB Service that indicates the capabilities of the MB device that the miniport driver supports. For example, if the miniport driver supports a GSM-based device, it should specify the **WwanCellularClassGsm** value in the **DeviceCaps.WwanCellularClass** member of the **NDIS_WWAN_DEVICE_CAPS** structure. If the miniport driver supports a CDMA-based device, it should specify **WwanCellularClassCdma**.

Initialization of SIM-Locked GPRS Device with a User-Defined Context

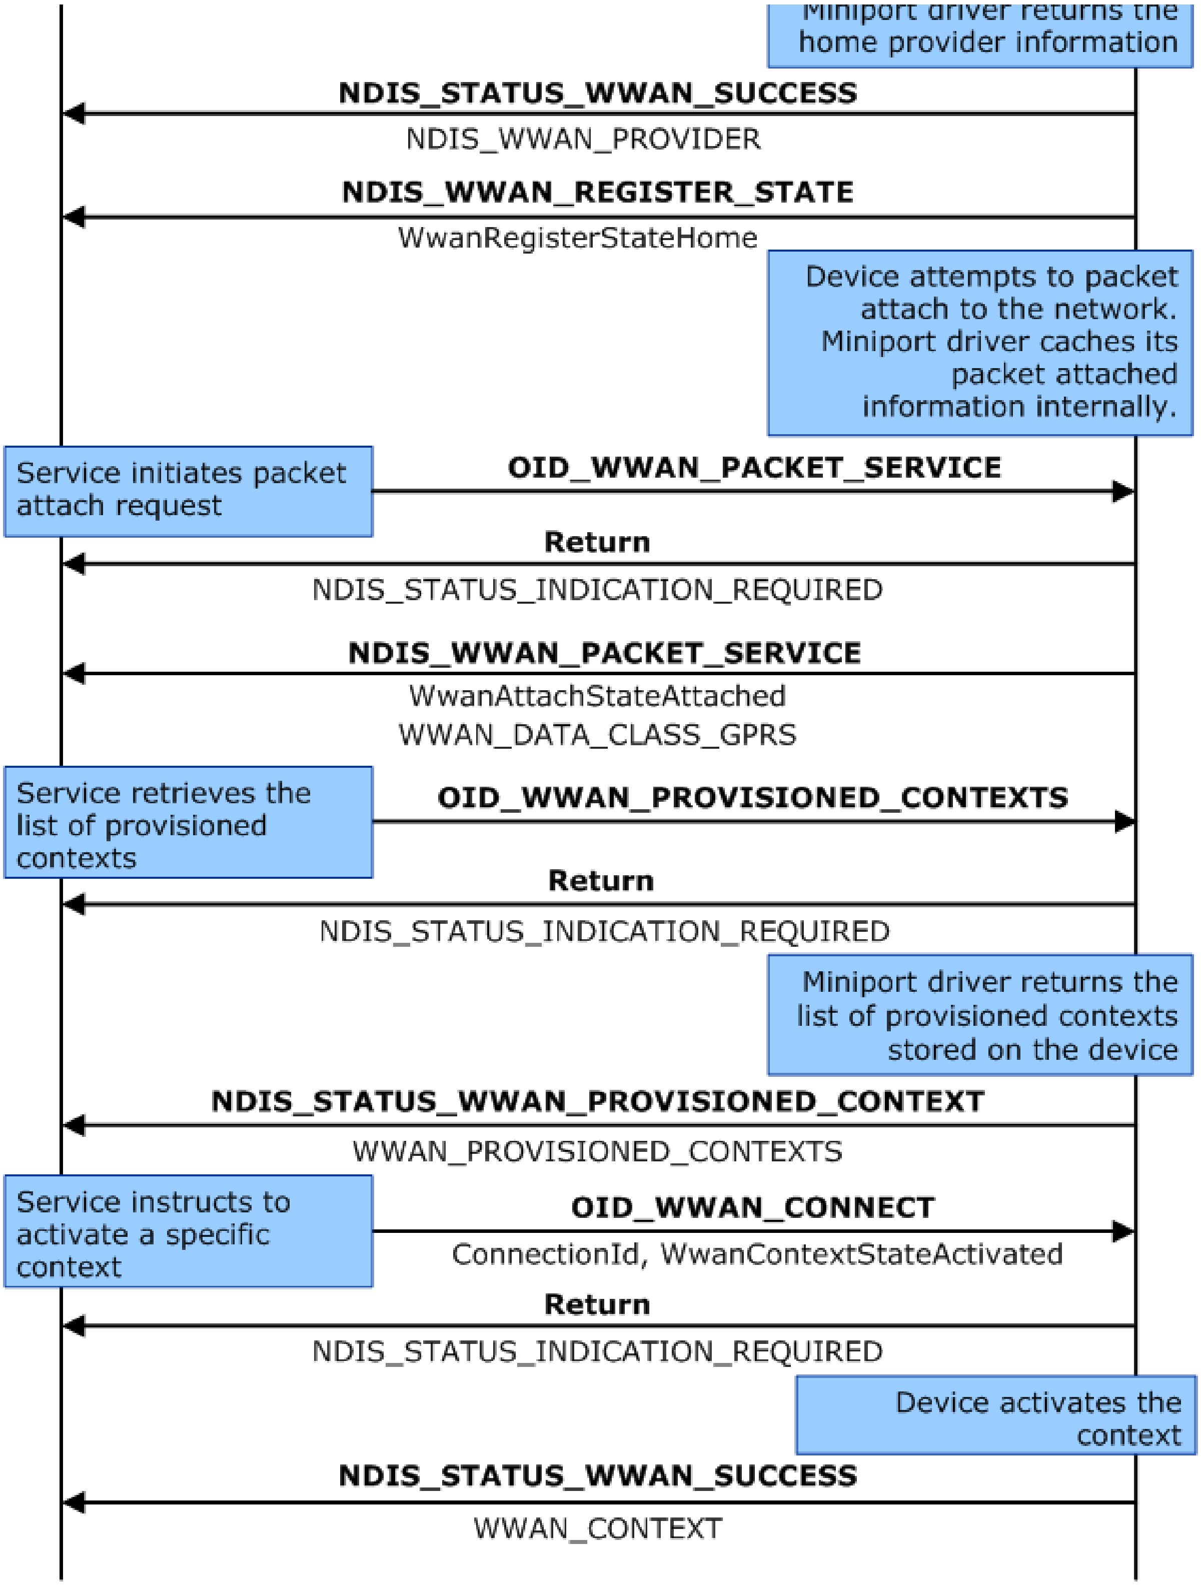
The following diagram illustrates the scenario in which the user enters a SIM PIN and manually configures an access point name string. The labels in bold are OID identifiers or transactional flow control, and the labels in regular text are the important flags within the OID structure.



GSM-based MB miniport driver
MB Service
Service queries whether the device is ready for WWAN
OID_WWAN_READY_INFO
Return



NDIS_STATUS_INDICATION_REQUIRED
Miniport driver initializes the protocol stack and SIM and indicates that the SIM is locked
NDIS_STATUS_WWAN_FAILURE
WwanReadyStateDeviceLocked
Service queries for PIN information
OID_WWAN_PIN
Return
NDIS_STATUS_INDICATION_REQUIRED
Miniport driver returns the state and format in the NDIS_WWAN_PIN_INFO data structure for PIN1
NDIS_STATUS_WWAN_SUCCESS
WwanPinTypePin1
Service sends the PIN1 value for validation to unlock the SIM
OID_WWAN_PIN_ACTION
PinOperationEnter, WwanPinTypePin1
Pin="PIN1value"
Return
NDIS_STATUS_INDICATION_REQUIRED
NDIS_STATUS_WWAN_SUCCESS
Miniport driver unlocks SIM and returns the PIN1 state in NDIS_WWAN_PIN_INFO data structure
NDIS_WWAN_READY_STATE
WwanReadyStateInitialized
Miniport driver notifies that the device is ready for use
Service inquires about the register state of device
OID_WWAN_REGISTER_STATE
Return
NDIS_STATUS_INDICATION_REQUIRED
Miniport driver returns the provisioned network selection mode as manual
NDIS_STATUS_WWAN_SUCCESS
WwanRegisterModeManual
NDIS_WWAN_REGISTER_STATE
WwanRegisterStateSearching
Miniport driver performs registration and updates the service
Service retrieves home provider information
OID_WWAN_HOME_PROVIDER
Return
NDIS_STATUS_INDICATION_REQUIRED



Miniport driver returns the home provider information
NDIS_STATUS_WWAN_SUCCESS
NDIS_WWAN_PROVIDER
NDIS_WWAN_REGISTER_STATE
WwanRegisterStateHome
Device attempts to packet attach to the network. Miniport driver caches its packet attached information internally.
Service initiates packet attach request
OID_WWAN_PACKET_SERVICE
Return
NDIS_STATUS_INDICATION_REQUIRED
NDIS_WWAN_PACKET_SERVICE
WwanAttachStateAttached
WWAN_DATA_CLASS_GPRS
Service retrieves the list of provisioned contexts
OID_WWAN_PROVISIONED_CONTEXTS
Return
NDIS_STATUS_INDICATION_REQUIRED
Miniport driver returns the list of provisioned contexts stored on the device
NDIS_STATUS_WWAN_PROVISIONED_CONTEXT
WWAN_PROVISIONED_CONTEXTS
Service instructs to activate a specific context
OID_WWAN_CONNECT
ConnectionId, WwanContextStateActivated
Return
NDIS_STATUS_INDICATION_REQUIRED
Device activates the context
NDIS_STATUS_WWAN_SUCCESS
WWAN_CONTEXT

To initialize a GSM-based device with PIN1 locked, implement the following steps:

1. The MB Service sends an asynchronous (non-blocking) OID_WWAN_READY_INFO query request to the miniport driver to identify the ready state of the device. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and that it will send a notification with the requested information in the future.

2. The miniport driver sends an NDIS_STATUS_WWAN_FAILURE notification to the MB Service to indicate to the MB Service that the subscriber identity module (SIM) is

locked.

3. The MB Service sends an asynchronous (non-blocking) OID_WWAN_PIN query request to the miniport driver. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and that it will send a notification with the requested information in the future.

4. The miniport driver sends an NDIS_STATUS_WWAN_SUCCESS notification to the MB Service.

5. The MB Service sends an asynchronous (non-blocking) OID_WWAN_PIN set request to the miniport driver. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and that it will send a notification with the requested information in the future.

6. The miniport driver sends an NDIS_STATUS_WWAN_SUCCESS notification to the MB Service.

7. The miniport driver sends an **NDIS_STATUS_WWAN_READY_INFO** notification to the MB Service that indicates to the MB Service that the state of the MB device is **WwanReadyStateInitialized**.

8. The MB Service sends an asynchronous (non-blocking) OID_WWAN_REGISTER_STATE query request to the miniport driver. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and it will send a notification with the requested information in the future.

9. The miniport driver sends an NDIS_STATUS_WWAN_SUCCESS notification to the MB Service.

10. The miniport driver sends an **NDIS_STATUS_WWAN_REGISTER_STATE** notification to the MB Service.

11. The MB Service sends an asynchronous (non-blocking) OID_WWAN_HOME_PROVIDER query request to the miniport driver. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and it will send a notification with the requested information in the future.

12. The miniport driver sends an NDIS_STATUS_WWAN_SUCCESS notification to the MB Service.

13. The miniport driver sends an **NDIS_STATUS_WWAN_REGISTER_STATE** notification to the MB Service.

14. The MB Service sends an asynchronous (non-blocking) OID_WWAN_PACKET_SERVICE request to the miniport driver. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and that it will send a notification with the requested information in the future.

15. The miniport driver sends an **NDIS_STATUS_WWAN_PACKET_SERVICE** notification to the MB Service.

16. The MB Service sends an asynchronous (non-blocking) OID_WWAN_PROVISIONED_CONTEXTS query request to the miniport driver. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and it will send a notification with the requested information in the future.

17. The miniport driver sends **NDIS_STATUS_WWAN_PROVISIONED_CONTEXTS** to the MB Service.

18. The MB Service sends an asynchronous (non-blocking) OID_WWAN_PROVISIONED_CONTEXTS set request to the MB Service. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and it will send a notification with the requested information in the future.

19. The miniport driver sends NDIS_STATUS_WWAN_SUCCESS to the MB Service.

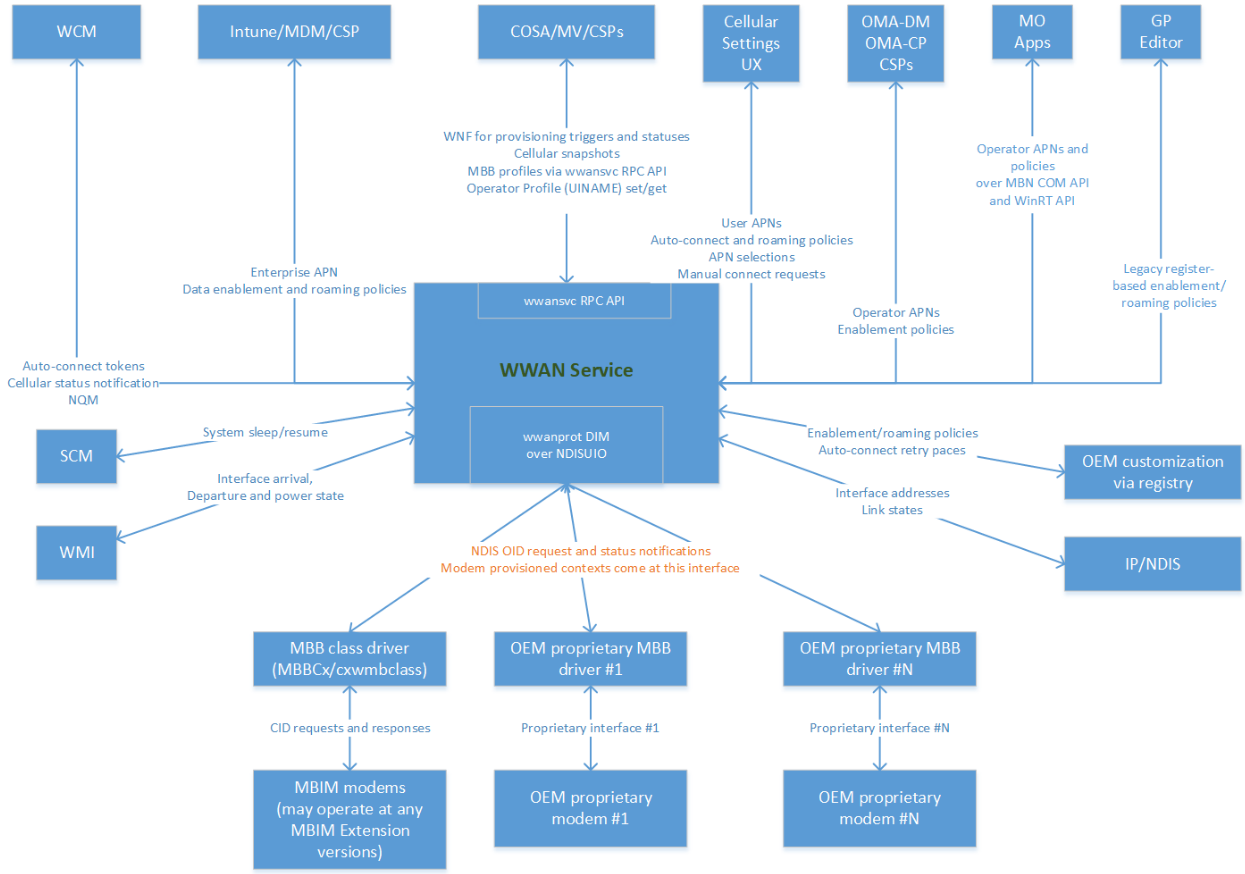
Cellular Architecture in Windows

The main component of the cellular stack in the OS is **WWAN Service (WwanSvc)** which controls and sets up all the data connection, states, and events. It interacts with a couple of client drivers to enable activities across the OS.



WCM
Intune/MDM/CSP

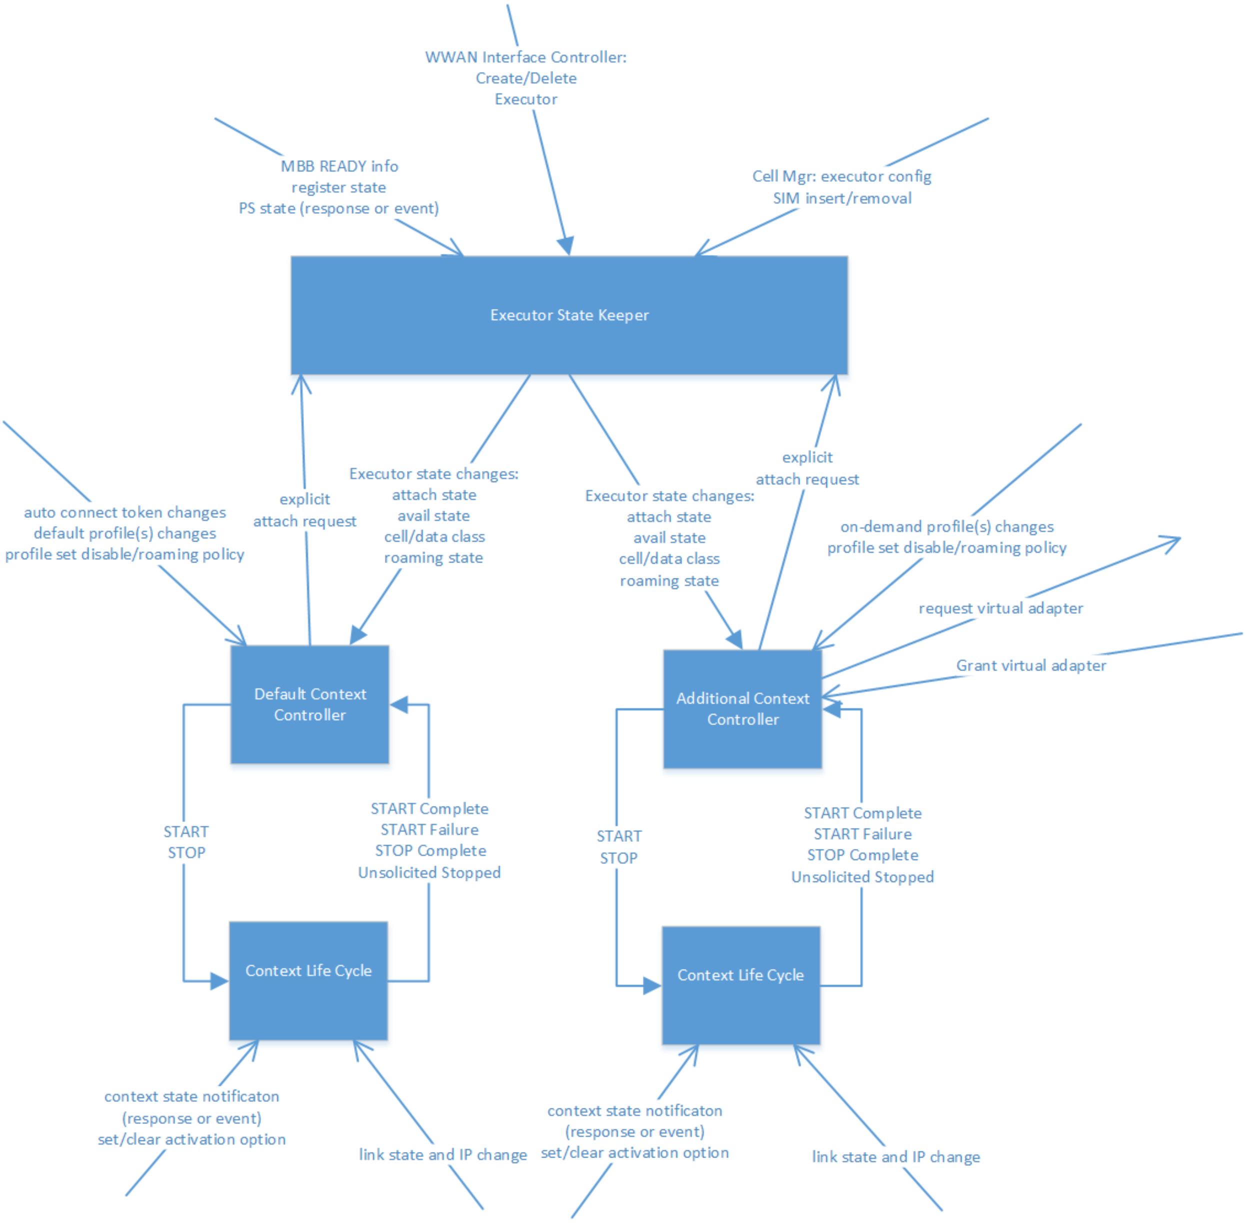
Interactions between the Default Context Controller and its immediate neighbors



Default Context Controller

The Default Context Controller controls the internet data connection. It manages the cellular data connection base on either auto-connect or manual connect, with or without a profile.

The Default Context Controller performs the following tasks:

- Performs auto-connect, back-off, and auto-retry for cell internet connection
- There is one instance of the Default Context Controller for each primary/physical interface, where each instance:
  - Receives and keeps related policy settings from various sources
  - Receives and keeps related state information (SIM state, reg state, packet service state, iWLAN state, ICCID/IMSI, etc.)
- MBB profile evaluation

    - Evaluates whether an MBB profile is applicable for the current policy settings and cellular states

- In the Vibranium release or older:
    - Keeps track of add/delete/update of related MBB profiles and keeps a list of them
    - Selects profiles for activation (priority rings, previous profile, auto-connect order, LKG profile, purchase profile, provisioned context profile, etc.)

- In the Manganese release:
    - Profile Administrator handles the profile selection for activation

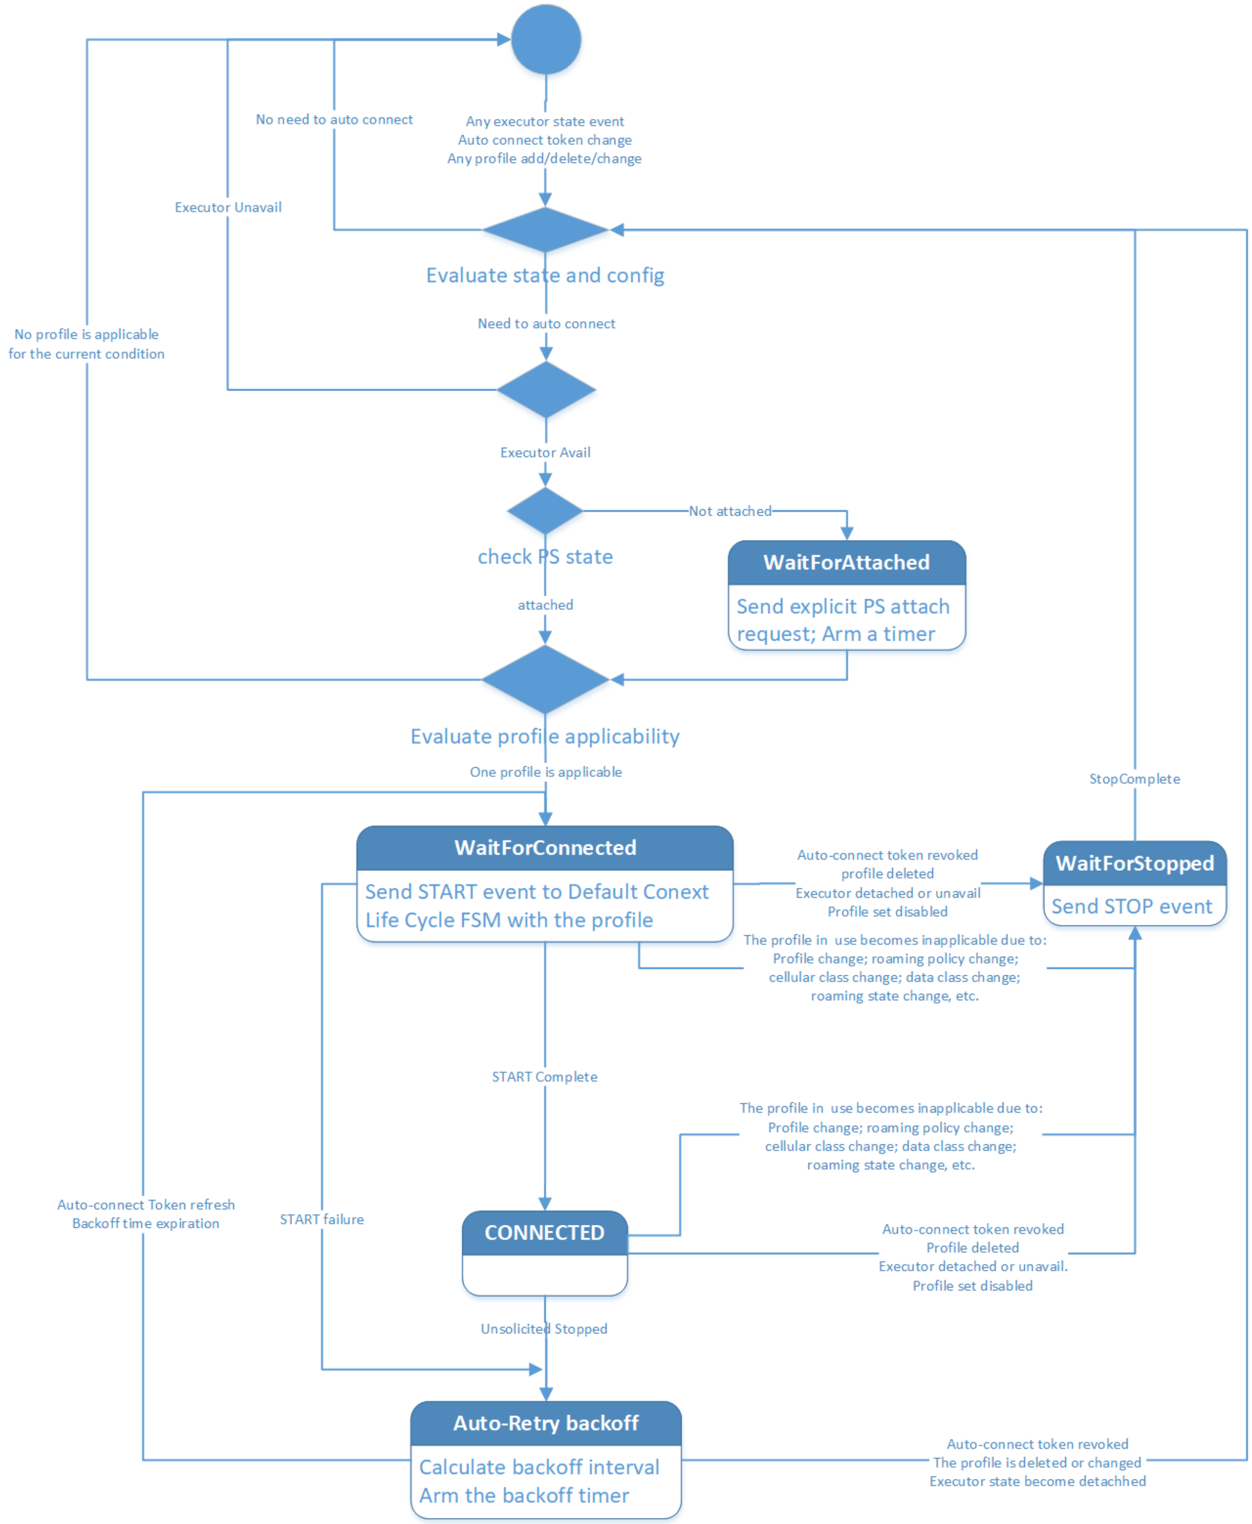
- Back-off interval calculation and timer

- Handles cellular Internet manual connect requests (profile or no-profile mode)

- Uses an instance of the class CWwanContextLifeCycle to activate a connection with an MBB profile

The Default Context Controller uses a finite state machine to manage its tasks.

Finite state machine transitions of the Default Context Controller



No need to auto connect
Any executor state event
Auto connect token change
Any profile add/delete/change
Executor Unavail
Evaluate state and config
No profile is applicable for the current condition
Need to auto connect
Executor Avail
Not attached
check PS state
WaitForAttached
Send explicit PS attach request; Arm a timer
attached
Evaluate profile applicability
One profile is applicable
StopComplete
WaitForConnected
Send START event to Default Conext Life Cycle FSM with the profile
Auto-connect token revoked
profile deleted
Executor detached or unavail
Profile set disabled
WaitForStopped
Send STOP event
The profile in use becomes inapplicable due to:
Profile change; roaming policy change;
cellular class change; data class change;
roaming state change, etc.
START Complete
The profile in use becomes inapplicable due to:
Profile change; roaming policy change;
cellular class change; data class change;
roaming state change, etc.
Auto-connect Token refresh
Backoff time expiration
START failure
CONNECTED
Auto-connect token revoked
Profile deleted
Executor detached or unavail.
Profile set disabled
Unsolicited Stopped
Auto-Retry backoff
Calculate backoff interval
Arm the backoff timer
Auto-connect token revoked
The profile is deleted or changed
Executor state become detachhed

Auto-connect

Policy settings that need to be met for auto-connect

Policy Setting	Config from	Config Unit
EnabledInternet	from users via UI in phones	per system

Policy Setting	Config from	Config Unit
highestConnCategory	from Admin/User/Operator/Device via UI	per interface
ClientDisableAutoConnect	from user via UI in desktops	per interface
OperatorServiceEnablement	from MO via OTA	per interface
GPolicyDisableAutoConnect	group policy via registry	per system
mdmDataEnablementPolicy	from MDM, notified via WNF (OnEnforced/OffEnforced/NoPolicy)	per system
mdmRoamingPolicy	from MDM, notified via WNF (DisabledEnforced/EnabledEnforced/NoPolicy)	per system

States that need to be concerned about auto-connect

State	Value
System power state	S0/S3/S4/D0/D3/D4
device power state	D0/D3/D4
Ready state	Initialized/ICCID
IMSI	affects applicability of IMSI-conditioned profiles
IWLAN state	affect applicability of IWLAN only/OK profiles
Registration state	Home/Roam/Partner
provider ID	may cancel back-off and trigger immediate retry
Packet service state	Detached/Attached
Current data class	may trip highestConnCategory policy and affect applicability of data class conditioned profiles
RnR State	RnR in progress

MB profile applicability for auto-connect

- SimIccID: Must match the ICCID of current SIM at the interface (except for AnyICCID)
- IsAdditionalPdpContextProfile: Must be false (except for purchase profile)
- ConnectionMode: Auto or auto-home
- ProfileCreationType: At or below the highestConnCategory (Admin/User/Operator/Device)
- CellularClass (v4): 3GPP/3GPP2
- RATApplicability (v4): LTE_eHRPD/3GPP_LEGACY
- RoamApplicability (v4): NonPartnerOnly/PartnerOnly/HomeOnly/ HomeAndPartner/PartnerAndNonpartner/AllRoaming; except for iWLAN profile and iWLAN available
- IMSI (v4): If present, must match current IMSI. For multi-app SIMs
- AdminEnable (v4): Is not administratively disabled
- AdminRoamControl (v4): Is not administratively roam-controlled out except for iWLAN profile and iWLAN available

Selection of MBB profiles for auto-connect in VB

- Priority rings:
  - Are based on ProfileCreationType: AdminProvisioned, UserProvisioned, OperatorProvisioned, and DeviceProvisioned.
  - An applicable profile in a higher priority ring excludes all profiles in lower priority rings.
- Modem provisioned profiles:
  - Are based on provisioned contexts.
  - Have the same ring as DeviceProvisioned profiles with subtle details.
- Purchase profiles are special.
- One round of auto-connect and retry attempts:
  - Will try all applicable profiles in the highest priority ring with any applicable profile, plus all applicable purchase profiles.
  - Each profile in one round has at most one chance.
  - If connection with a profile succeeds with a valid IP, the round stops and the profile is designated the last known good (LKG) profile.

Order of profiles in one round of attempts in VB

If one round of attempts has multiple MBB profiles, the order is:

- LKG profile if it is present and is a non-purchase profile.

- Non-purchase modem provisioned profiles. If there are more than one, the order of these profiles is unspecified.
- All non-purchase profiles with explicit AutoConnectOrder, in order of increasing AutoConnectOrder. If an AutoConnectOrder has more than one profiles, the order of these profiles is unspecified.
- All non-purchase profiles with no explicit AutoConnectOrder. If there are more than one, the order of these profiles is unspecified.
- All purchase profiles. If there are more than one, the order of these profiles is unspecified.

Exponential back-off

- Pause for a certain amount of time before retry after failures to activate all applicable MBB profiles in a retry round.
- Commonly used technique in random access media to avoid re-collision after a collision.
- Back-off happens after all profiles in one round of attempts fail to connect.
- There is no back-off between retries of two profiles inside one round.
- The base exponential back-off algorithm: Initial back-off 3 seconds, exponential factor 3, with cap of 24 hours. For example: 3, 9, 27, 81, ...
- Special network cause codes for slow-pace retry (initial back-off 300 seconds):
  - WWAN_ERR_3GPP_SO_NOT_SUBSCRIBED, // 33
  - WWAN_ERR_3GPP_AUTH_FAILURE, // 29
  - WWAN_ERR_3GPP_INSUFFICIENT_RESOURCES, // 26
  - WWAN_ERR_3GPP_UNKNOWN_PDP_ADDRESS_TYPE, // 28
  - WWAN_ERR_3GPP_ACTIVATION_REJECT /
- OEM can customize the initial back-off. Each code can have one of these three catagories:
  - Normal-pace: the same as the base case (3 seconds)
  - Slow-pace: 300 seconds
  - Glacier-pace: 24 hours (practically no retry)

Back-off cancelation or back-off timer expiration

- Back-off can be cancelled and retry commenced immediately in these situations:
  - Auto-connect hint from WCM
  - Auto-connect MBB profiles are added or updated
  - Device roams to a different MO
  - Highest connection category policy is changed

- If a manual connect request comes during back-off, back-off is canceled and manual connect procedure commences.

- Back-off will be cancelled and no auto-connect occurs in these situations:
  - The SIM is removed.
  - Cellular state is no longer available for connect (such as during deregistration or detachment).
  - Auto-connect token is revoked.
  - Cellular data is disabled.
  - Other policy settings are changed such that auto-connect is no longer possible.
  - Later events may re-trigger auto-connect in the event that back-off is cancelled and no auto-connect occurs.

- When the back-off timer expires naturally, retry starts and does the same thing as the initial auto-connect.

Manual Connect

- Bring-up of the data connection is initiated externally via the wwansvc RPC API:
  - In Cellular Setting UI or Network flyout, users uncheck the "let Windows keep this connected" box and then click the Connect button.
  - Starting with Windows 8, WCM may also bring-up the data connection.
  - Manual connect is only allowed if auto-connect is not in progress (idle or back-off).

- The connect request may be issued with or without a specific MBB profile. For Cellular UX since RS2:
  - If a specific MBB profile is given, only that MBB profile is used to connect.
  - If no specific MBB profile is given, the Default Context Controller picks MBB profiles and tries them one by one until the connection is either successfully activated with an MBB profile or all of them fail to connect.

- Is subject to similar set of policy settings as auto-connect.

- Is subject to similar set of cellular state information and restrictions as auto-connect.

- MBB profile applicability is subject to a similar set of rules as for auto-connect with one notable exception:
  - An MBB profile with a ConnectionMode of manual is applicable for manual connect.

- MBB profile selection and order are the same as for auto-connect.

- If no specific MBB profile is given and the MBB profiles in the a round all fail to connect successfully, then the manual connect request is completed with failure. There is no back-off and no retry.

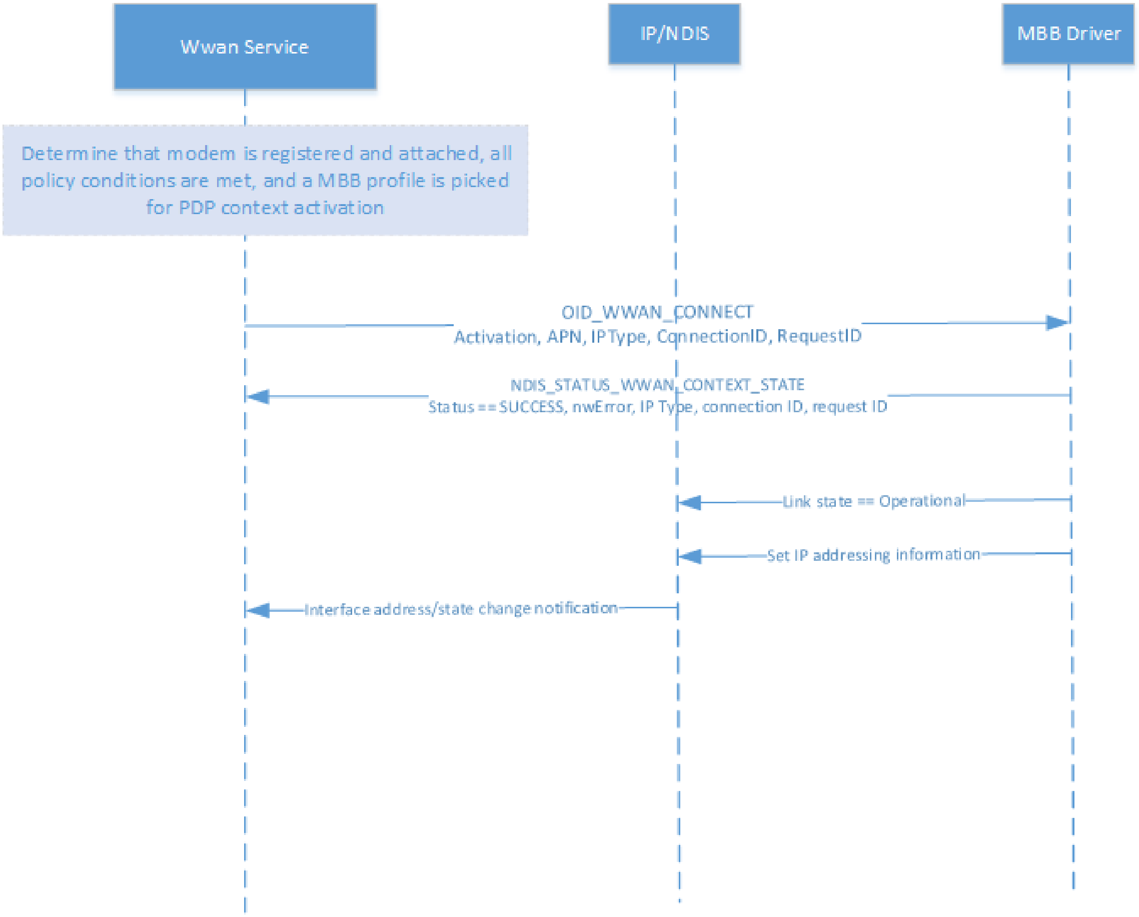
- If a specific MBB profile is given and the MBB profile fails to connect successfully, then the manual connect request is completed with failure. There is no back-off and no retry.

- If a successfully-connected manual connection gets disconnected later unsolicitedly, the state is reported but there is no back-off and no retry.

MB data connectivity flows

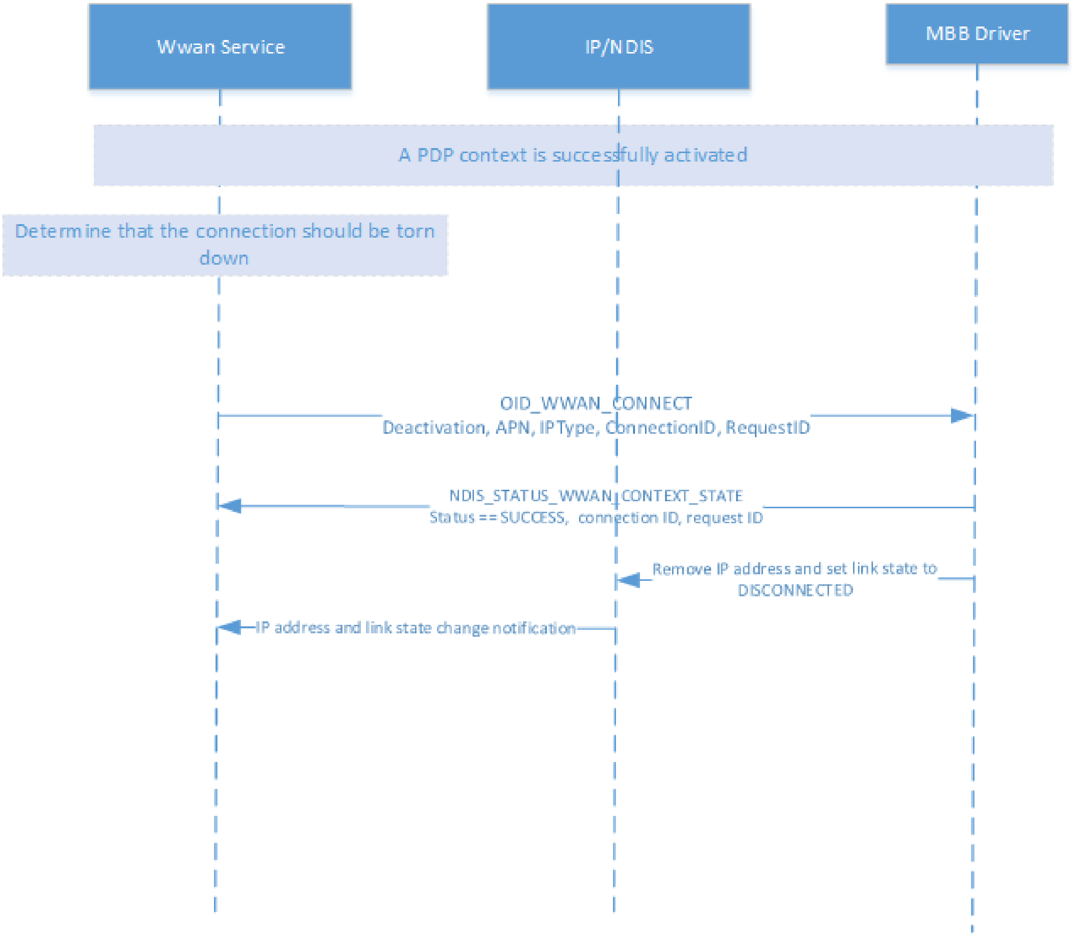
OID_WWAN_CONNECT is used to initiate the connection with the modem. Below are flows describing the data connection with the modem.

Successful Activation



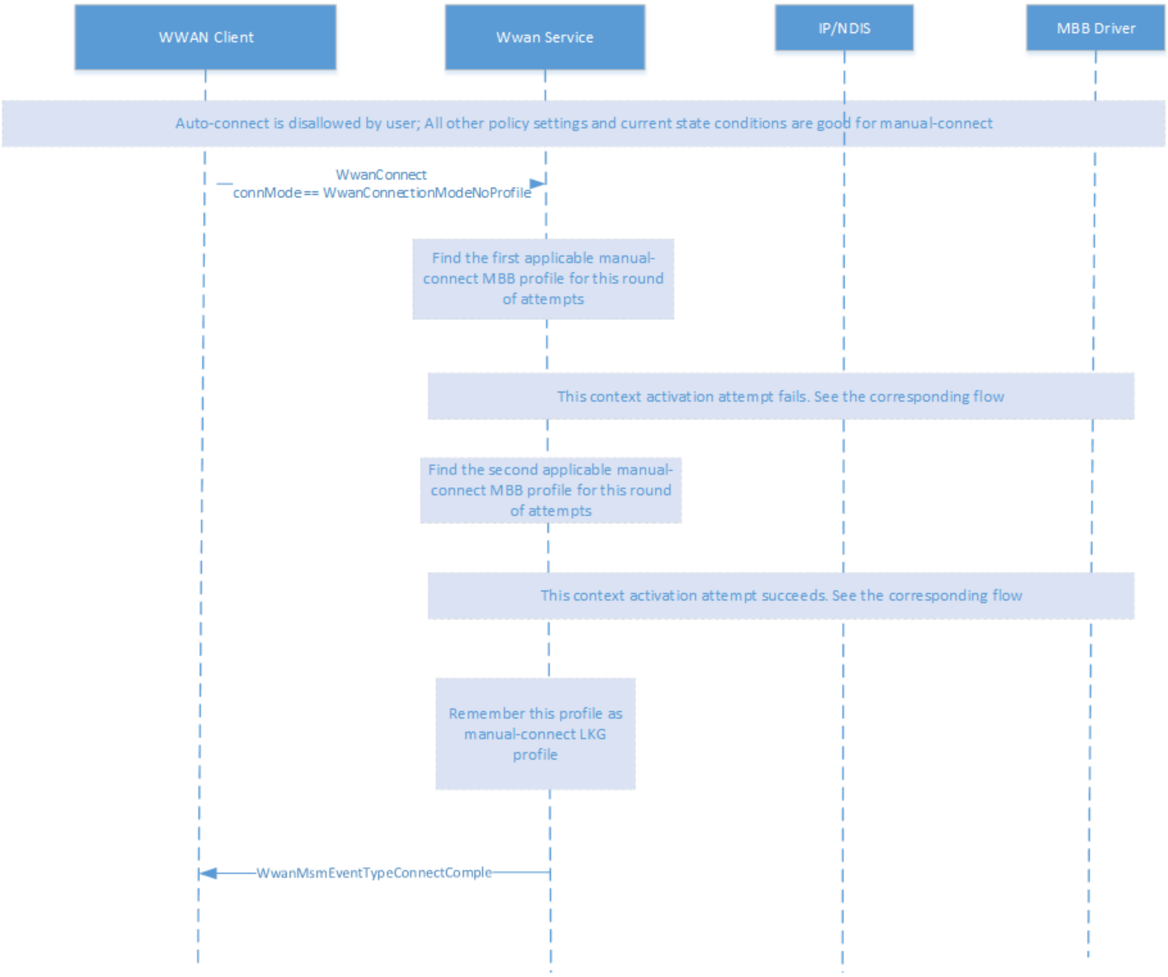
Wwan Service
IP/NDIS
MBB Driver
Determine that modem is registered and attached, all policy conditions are met, and a MBB profile is picked for PDP context activation
OID_WWAN_CONNECT
Activation, APN, IPType, ConnectionID, RequestID
NDIS_STATUS_WWAN_CONTEXT_STATE
Status == SUCCESS, nwError, IP Type, connection ID, request ID
Link state == Operational
Set IP addressing information
Interface address/state change notification

Successful Deactivation



Wwan Service
IP/NDIS
MBB Driver
A PDP context is successfully activated
Determine that the connection should be torn down
OID_WWAN_CONNECT
Deactivation, APN, IPType, ConnectionID, RequestID
NDIS_STATUS_WWAN_CONTEXT_STATE
Status == SUCCESS, connection ID, request ID
Remove IP address and set link state to DISCONNECTED
IP address and link state change notification

Manual Connect



WWAN Client
Wwan Service
IP/NDIS
MBB Driver
Auto-connect is disallowed by user; All other policy settings and current state conditions are good for manual-connect
WwanConnect
connMode== WwanConnectionModeNoProfile
Find the first applicable manual-connect MBB profile for this round of attempts
This context activation attempt fails. See the corresponding flow
Find the second applicable manual-connect MBB profile for this round of attempts
This context activation attempt succeeds. See the corresponding flow
Remember this profile as manual-connect LKG profile
WwanMsmEventTypeConnectComple

Hardware Lab Kit (HLK) tests

Connect the test machine with ATT SIM to HLK Server.

See Steps for installing HLK .

In HLK Studio, connect to the device Cellular modem driver and run the test: Win6_4.MB.GSM.Data.TestConnect.

Alternatively, run the **TestConnect** HLK testlist by **netsh** and **netsh-mbn-test-installation**.

```
netsh mbn test feature=connectivity param="AccessString=internet"
```

The file showing the HLK test results should have been generated in the directory that the 'netsh mbn test' command was ran.

Manual tests

After reboot, Cellular auto-connects

1. With Wi-Fi toggled off, verify active cellular connection. Systray should show Cellular connection bars and internet browsing should work.
2. Reboot DUT. After reboot, verify there is an active cellular connection. Systray should show Cellular connection bars.

Browse Internet using Cellular data with new SIM

1. Insert SIM card with an active data plan. If the device already has a SIM card, pop out the SIM card and insert a different SIM card from another operator.
2. With Wi-Fi toggled off, verify an active cellular connection. Swipe down from top of screen to bring up quick action center and Systray should show Cellular connection bars and a data icon.

Connect Cellular manually

1. With Ethernet unplugged and Wi-Fi toggled off, uncheck "Let Windows manage this connection" in Cellular settings.
2. Reboot DUT.
3. After boot, open Cellular settings and click Connect to Cellular. Cellular should connect and internet browsing should work.

After wake from hibernation (S4), Cellular auto-connects

1. Ensure "Let Windows manage this connection" is checked in Cellular settings.
2. Put DUT into S4.
3. Wake DUT and verify it automatically establishes a cellular connection. The user should be able to browse the internet.

After wake from hibernation (S4), connect Cellular manually

1. With Ethernet unplugged and Wi-Fi toggled off, uncheck "Let Windows manage this connection" in Cellular settings.
2. In an admin CMD prompt run command: shutdown -h

3. Machine will hibernate. After more than 30 seconds press the machine's power button to wake from hibernation. Log back in, open Cellular settings, and click Connect to Cellular. Cellular should connect and the user should be able to browse the internet.

After wake from screen sleep, Cellular auto-connects

1. With Ethernet unplugged and Wi-Fi toggled off, verify an active cellular connection.
2. (Optional) Allow the screen to sleep. You can set the screen sleep to 1 minute under Settings -> System -> Power & sleep. The setting should not be set to "Never".
3. Wake the screen by using the mouse or keyboard and log back in. Cellular should stay connected and the user should be able to browse internet (also via container for VAIL/WCOS).

MB data connectivity troubleshooting guide

1. Logs can be collected and decoded using these instructions: MB Collecting Logs
2. Open the .txt file in TextAnalysisTool
3. Load the Bacis Connectivity filter

MB Service Detection and Activation

Article • 03/14/2023

This topic describes the procedures to detect whether an MB device must have its service activated, and how to gain access to a provider's network.

Service Activation Detection

Miniport drivers can determine whether they must perform service activation in a couple of ways:

- For CDMA-based devices, in North America or other places where U-RIM is not used, there should be a flag on the device to indicate activation status. Miniport drivers should be able to detect the activation status during initialization without contacting the provider network. Miniport drivers should perform service activation automatically when the device first connects over-the-air to the home network. After activation has been completed, miniport drivers should clear the flag so that they will not need to perform service activation again.

  Miniport drivers inform the MB Service about service activation progress by sending **NDIS_STATUS_WWAN_READY_INFO** notifications during MB device initialization. Alternatively, to determine service activation status, the service may send an OID_WWAN_READY_INFO query request to a miniport driver. In both cases, the initial ready-state should be **WwanReadyStateNotActivated**. After service has been activated, miniport drivers should resume the initialization process and notify the service as the device ready-state changes.

- For GSM-based devices, there is no general method to detect whether a device must have its service activated. Miniport drivers can implement their own proprietary method, specific to its carrier, to perform service detection and activation.

MB Service Activation

Service activation refers to the process of activating the MB service subscription so that the device can gain access to the provider's network. The MB Service is not equipped with service activation logic because the exact activation procedure must be performed by the miniport driver and/or third-party software because the actual activation process varies from cellular technologies and is usually customized for different provider networks. Service activation can be automatic, or manual, or a combination of both.

Miniport drivers should only need to perform service activation one time for each new subscription.

For more information about service detection and activation, see OID_WWAN_SERVICE_ACTIVATION.

MB Radio State

Article • 03/14/2023

Overview

This topic describes the operations that are used to set and read an MB device's radio power state(s). These states can be controlled through software (airplane mode) or hardware (if the appropriate switch is present). This topic explains how the radio power states are controlled, how to test radio power state functionality, and how to investigate radio power state issues.

Terminology

System Radio State - System Radio State is a system-wide state. It is the most evident indicator of airplane mode state. System Radio State is managed by the Radio Management Service (RmSvc).

Radio Manager - RmSvc iterates several RadioManagers (MediaManagers) in the system like WlanRadioManager, BlueTooth, and WwanRadioManager. WwanRadioManager(.lib) is hosted in RmSvc.dll and manages the wwan side of the radio logic. WwanRadioManager uses the WWAN Service (WwanSvc) RPC to:

1. Query and set cellular radio.
2. Control the flow before and after airplane mode.

Radio Instance - Each RadioManager can include multiple radio instances. For example, WwanRadioManager can have two radio instances if there are two cellular modems in the system. Each radio instance is an abstract object and should map to one hardware radio module. In most cases, each radio instance maps to one cellular modem.

Relevant Services and Drivers

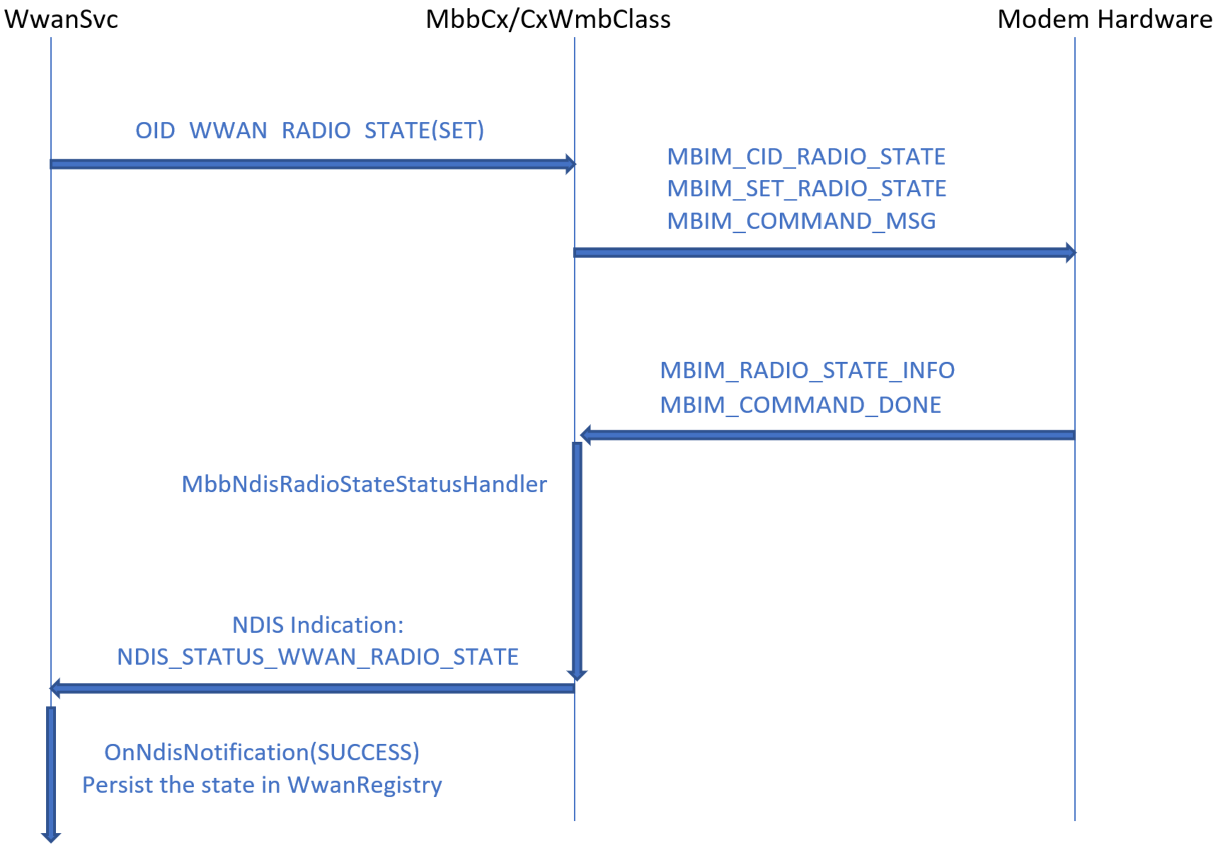
RmSvc.dll - Manages system-wide radio events like airplane mode. It also hosts all radio managers, including WwanRadioManager.

WwanSvc.dll - Cellular modems are managed by WwanSvc. Therefore, commands (OID/CID) are issued via WwanSvc. External requests from RmSvc or other components (UI) go via the WwanSvc RPC to query or set cellular radio state.

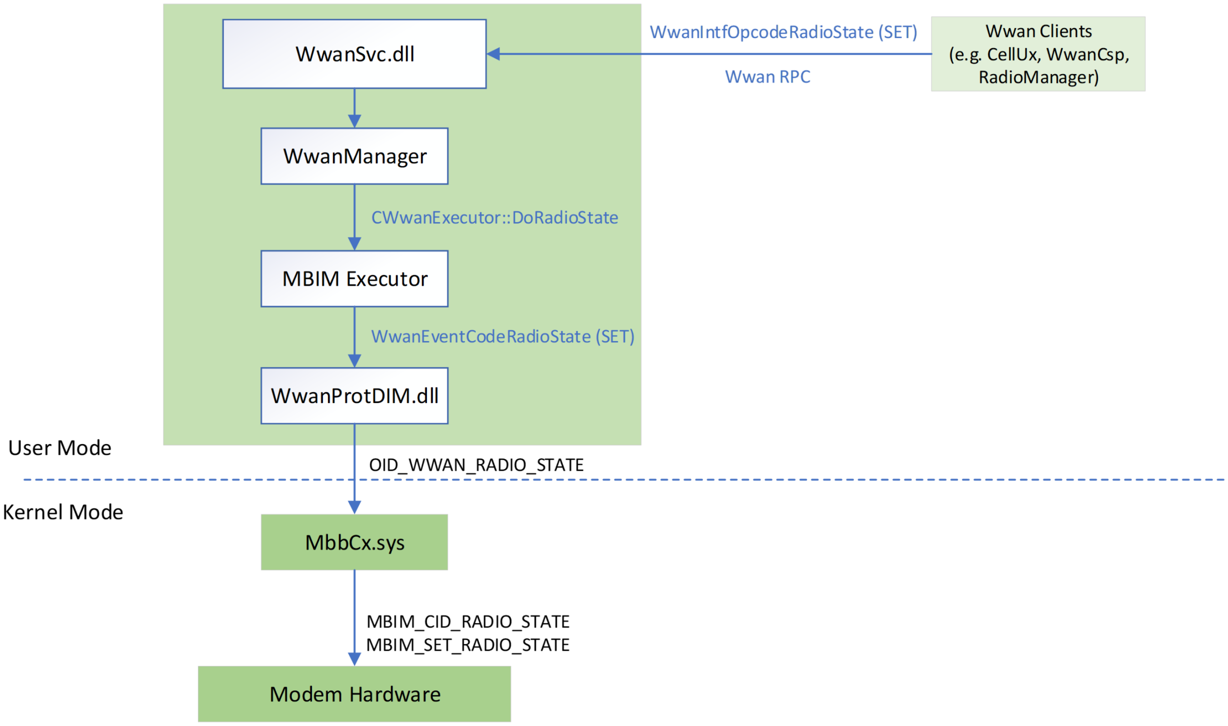
MbbCx.sys - The kernel-mode driver that manages device power state especially between D0 and Dx transition. On some system setups, the device is allowed to transition to Dx state and recover to D0 only when needed. MbbCx.sys manages the logic and control of radio state recovery before D0 and Dx.

Architecture/Flows

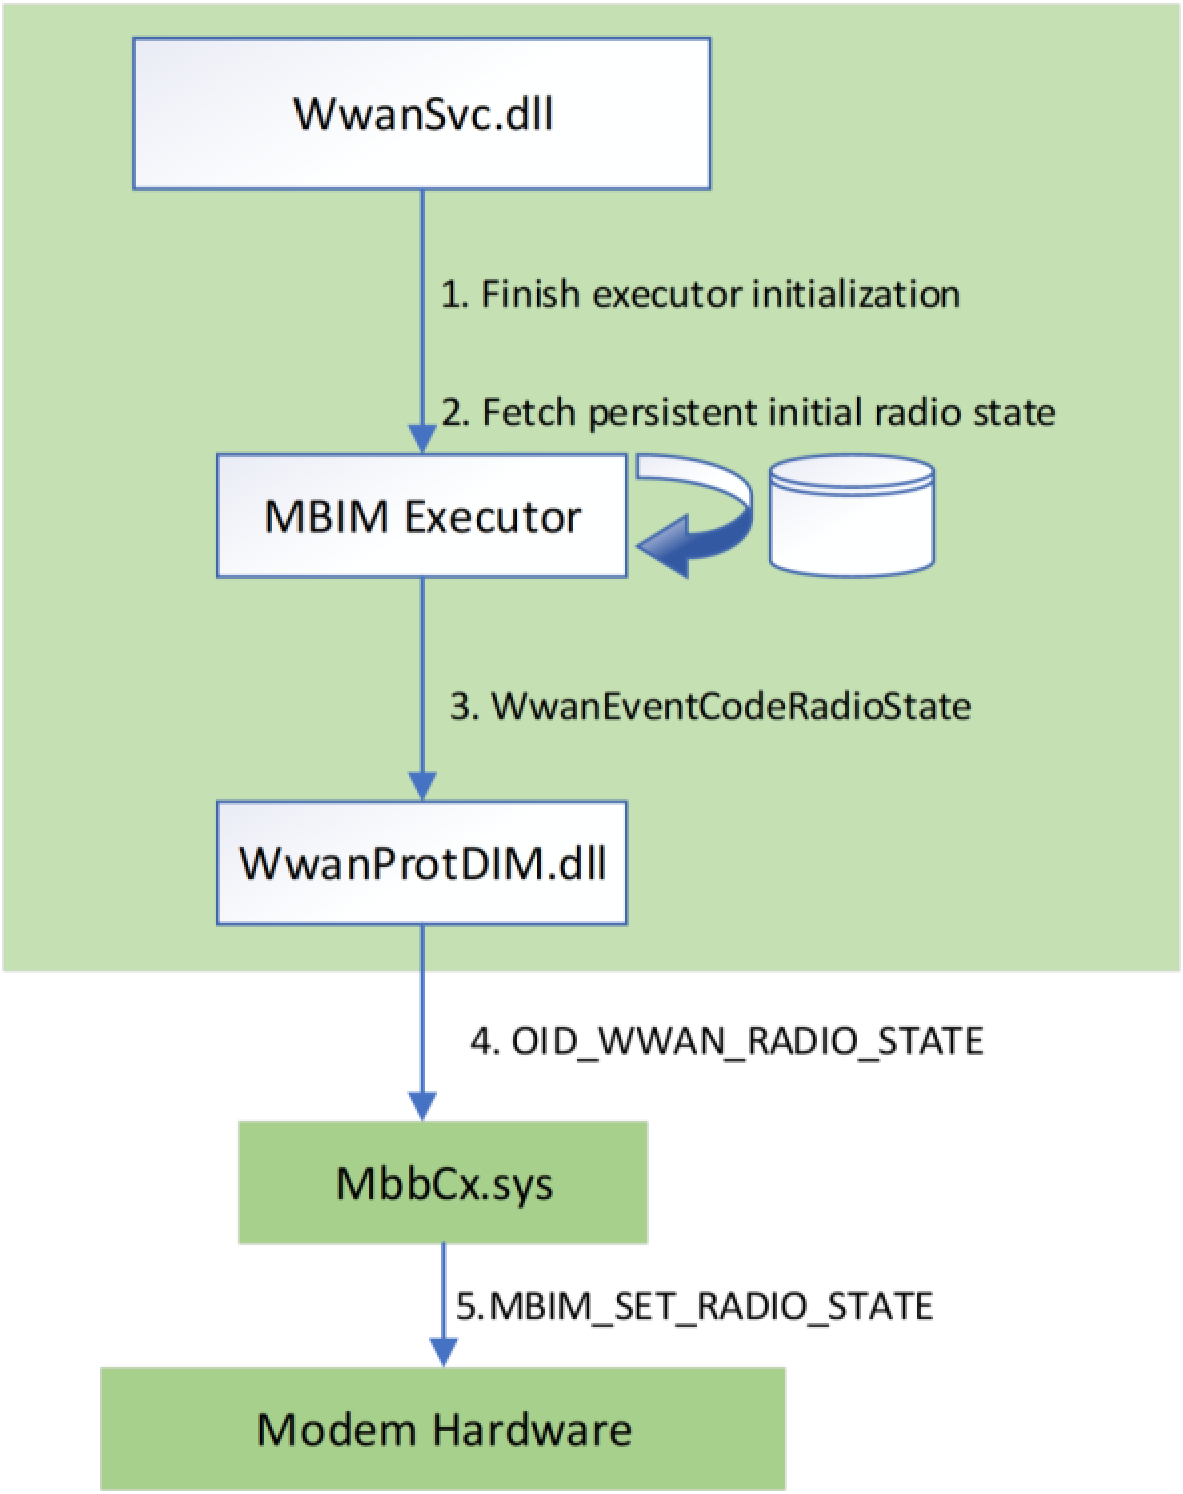
Radio Control from WwanSvc to Modem Hardware



SET Radio via WwanSvc API



Initial Radio State upon Device Arrival



MBIM_CID_RADIO_STATE

As seen in the above diagrams, the CID used in airplane mode operations is **MBIM_CID_RADIO_STATE**. This CID sets or returns information about a MB device's radio power state.

Query

The InformationBuffer on MBIM_COMMAND_MSG is not used. MBIM_RADIO_STATE_INFO is returned in the InformationBuffer of MBIM_COMMAND_DONE.

Set

The InformationBuffer on MBIM_COMMAND_MSG contains MBIM_SET_RADIO_STATE. MBIM_RADIO_STATE_INFO is returned in the InformationBuffer of MBIM_COMMAND_DONE.

Unsolicited Event

The Event InformationBuffer contains an MBIM_RADIO_STATE_INFO structure.

Parameters

	Set	Query	Notification
Command	MBIM_SET_RADIO_STATE	Empty	N/A
Response	MBIM_RADIO_STATE_INFO	MBIM_RADIO_STATE_INFO	MBIM_RADIO_STATE_INFO

Data Structures

Set

Offset	Size	Field	Type	Description
0	4	RadioState	MBIM_RADIO_SWITCH_STATE	Sets the software controlled radio state. See table below.

MBIM_RADIO_SWITCH_STATE

Types	Value
MBIMRadioOff	0
MBIMRadioOn	1

Query

The InformationBuffer will be **null** and InformationBufferLength will be **zero**.

Response

MBIM_RADIO_STATE_INFO

Offset	Size	Field	Type	Description
0	4	HwRadioState	MBIM_RADIO_SWITCH_STATE	The state of the W_DISABLE switch. If the device does not have a W_DISABLE switch, the function must return MBIMRadioOn in this field.
4	4	SwRadioState	MBIM_RADIO_SWITCH_STATE	Software configured radio state.

Notification

See the **MBIM_RADIO_STATE_INFO** table above.

Status Codes

This CID only uses Generic Status Codes.

Testing

Cellular Radio Tests

Function Name	Description
CellularRadioWinrtTest::VerifyCellularModemExistence	Assert winrt api can query cellular modem and radio state
CellularRadioWinrtTest::VerifyCellularRadioToggle	Assert winrt api can toggle radio state on each wwan adapter
CellularRadioRecoveryTest::VerifyCellularRadioRecoveryToOnAfterAPM	Assert cellular radio states are recovered to On when leaving Airplane Mode
CellularRadioRecoveryTest::VerifyCellularRadioRecoveryToOffAfterAPM	Assert cellular radio states remain off when leaving Airplane Mode

Function Name	Description
CellularRadioRecoveryTest::VerifyCellularRadioAcrossSvcRestart	Assert cellular radio states stay consistent across WwanSvc restarting
CellularRadioRecoveryTest::VerifyCellularRadioAcrossDevNodePnp	Assert cellular radio states stay consistent across device arrival/removal

CellularRadioTest.dll contains these tests.

Hardware Lab Kit (HLK) Tests

See Steps for installing HLK .

In HLK Studio connect to the device Cellular modem driver and run these tests:

- **TestRadioStateSoftware**
- **TestRadioStateHardware**

Alternatively you can run the **TestRadioStateHardware** and **TestRadioStateSoftware** HLK testlist by **netsh-mbn** and **netsh-mbn-test-installation**.

```
netsh mbn test feature=radio testpath="C:\data\test\bin"
taefpath="C:\data\test\bin" param="AccessString=internet"
```

The two files showing the HLK test results should have been generated in the directory that the 'netsh mbn test' command was ran from: `TestRadioStateSoftware.htm` and `TestRadioStateHardware.htm`.

Logs can be collected and decoded using these instructions: MB Collecting Logs.

Analyzing Logs

Useful keywords/regexp for filtering traces

- OID_WWAN_RADIO_STATE
- CWwanRadioInstance::OnSysRadioChange

- Entering CUIRadioManager::_SetSysRadio
- Leaving CUIRadioManager::_SetSysRadio
- CWwanRadioInstance::_SetSoftwareRadioState
- [WwanRadioManager]
- PostD0Entry: previousPowerState
- CWwanRadioManager::OnSystemRadioStateChange(.)+sysradiostate
- RMAPI(.)+OnSystemRadioStateChange
- RMAPI(.)+OnSystemRadioStateChange
- Wwan-svc(.)+radio
- mbbcx(.)+radio

Investigation tips

- Identify whether this is a global (system-wide) or local (cellular-only) radio issue.
- Differentiate device power state (D0-Dx) from radio state. They are different concepts but highly-correlated.
- Ensure necessary ETW providers are included in the log.
- Narrow down the area by using the scenario. For example:
  - If it's related to airplane mode, focus on RmSvc and WwanRadioManager.
  - If it's related to D0<->Dx, hibernation, or sleep transitions, focus on MBBCx.
  - If it's related to UI displays or state out-of-sync, start with WwanSvc.

WinRT API

Windows.Devices.Radios

Windows.Devices.Radios is owned by the Radio Management Service which manages all radio managers and instances. For the WWAN side, the RadioKind is RadioKind::MobileBroadband.

- GetRadiosAsync( )
- SetStateAsync( )

Windows.Networking.NetworkOperators

Windows.Networking.NetworkOperators documentation page

The only useful utility under this namespace for radio management is MobileBroadbandDeviceInformation.CurrentRadioState.

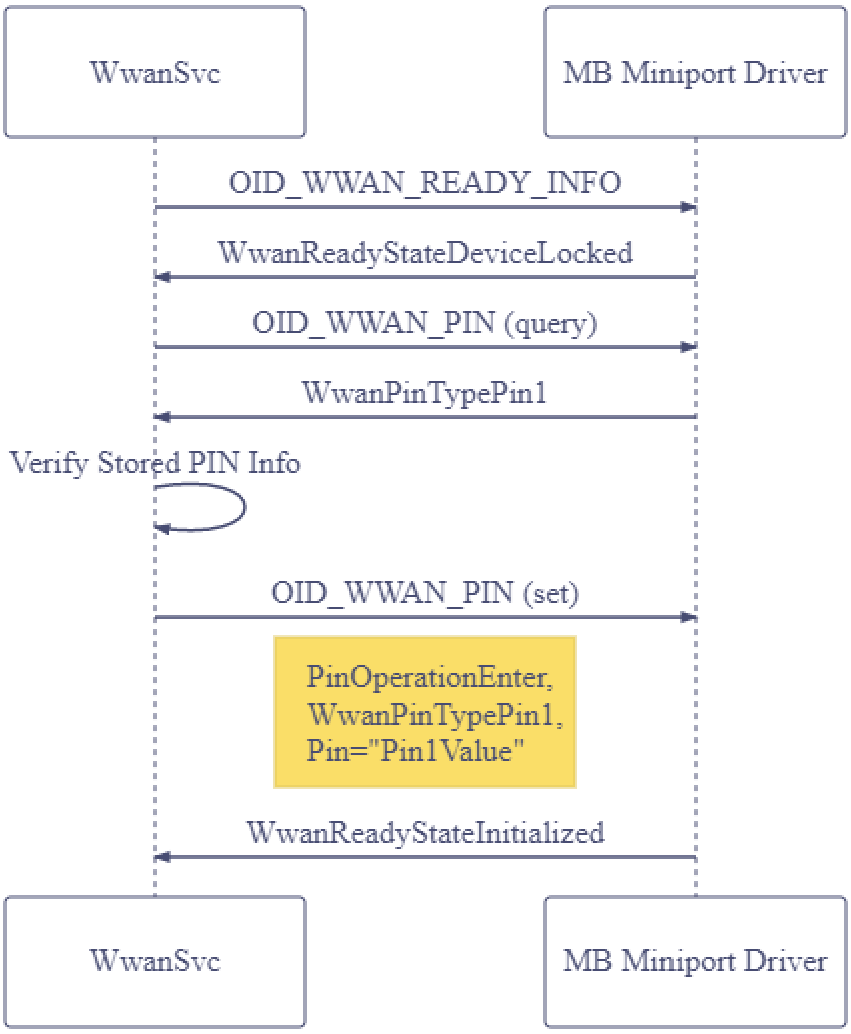
Auto-unlock after resuming from hibernation



MBIM_CID_MS_PIN_EX

This CID is described here: MBIM_CID_MS_PIN_EX

MBIM_CID_PIN_LIST

Description

This command returns a list of all the different types of Personal Identification Numbers (PINs) that are supported by the MB device and additional details for each PIN type, such as the length of the PIN (minimum and maximum lengths), PIN format, and PIN-entry mode (enabled/disabled/not-available). This CID also specifies the current mode of each PIN supported by the function. Functions must report all the PINs they support. However, PIN1 for multi-mode devices must only be reported once.

A PIN reported as PIN1 must comply with PIN1 guidelines: For CDMA-based devices this is a PIN that provides power-on verification or identification functionality, and for GSM-based devices this is a Subscriber Identity Module (SIM) PIN.

Functions must be able to return this information when the ready-state changes to MBIMSubscriberReadyStateInitialized or when the ready-state is MBIMSubscriberReadyStateDeviceLocked (PIN locked). Functions should also return this information in other ready-states wherever possible.

Query only

InformationBuffer of the Query message is empty. InformationBuffer of MBIM_COMMAND_DONE contains an MBIM_PIN_LIST_INFO.

Parameters

	Set	Query	Notification
Command	N/A	Empty	N/A
Response	N/A	MBIM_PIN_LIST_INFO	N/A

Data Structures

MBIM_PIN_MODE

Types	Value
MBIMPinModeNotSupported	0
MBIMPinModeEnabled	1
MBIMPinModeDisabled	2

MBIM_PIN_FORMAT

Types	Value
MBIMPinFormatUnknown	0
MBIMPinFormatNumeric	1
MBIMPinFormatAlphaNumeric	2

MBIM_PIN_DESC

Offset	Size	Field	Type	Description
0	4	PinMode	MBIM_PIN_MODE	See above table MBIM_PIN_MODE. This shows if the lock is enabled or not. It does not show if the lock state is locked or unlocked.
4	4	PinFormat	MBIM_PIN_FORMAT	See above table MBIM_PIN_FORMAT.
8	4	PinLengthMin	UINT32	The minimum number of characters in the PIN. Devices should not specify a value that is greater than 16. Devices should specify 0xffffffff, if the PIN length is not available.
12	4	PinLengthMax	UINT32	The maximum number of characters in the PIN. Devices should not specify a value that is greater than 16. Devices should specify 0xffffffff, if the PIN length is not available.

Query

The InformationBuffer shall be **null** and InformationBufferLength shall be **zero**.

Response

The following structure shall be used in the InformationBuffer:

MBIM_PIN_LIST_INFO

Offset	Size	Field	Type	Description
0	16	PinDescPin1	MBIM_PIN_DESC	MBIM_PIN_DESC structure describing PIN1. For GSMbased devices, this is a Subscriber Identity Module (SIM) PIN. For CDMA-based devices, power-on device lock is reported as PIN1.
16	16	PinDescPin2	MBIM_PIN_DESC	MBIM_PIN_DESC structure describing PIN2. This is a SIM PIN2 that protects certain SIM functionality.

Offset	Size	Field	Type	Description
32	16	PinDescDeviceSimPin	MBIM_PIN_DESC	MBIM_PIN_DESC structure describing the device-to-SIM-card PIN. This is a PIN that locks the device to a specific SIM.
48	16	PinDescDeviceFirstSimPin	MBIM_PIN_DESC	MBIM_PIN_DESC structure describing device-to-very-first-SIM-card PIN. This is a PIN that locks the device to the very first inserted SIM.
64	16	PinDescNetworkPin	MBIM_PIN_DESC	MBIM_PIN_DESC structure describing the network personalization PIN. This is a PIN that allows the device to be personalized to a network. For more information about this PIN type, see 3GPP specification 22.022.
80	16	PinDescNetworkSubsetPin	MBIM_PIN_DESC	MBIM_PIN_DESC structure describing the network subset personalization PIN. This is a PIN that allows the device to be personalized to a subset of a network. For more information about this PIN type, see 3GPP specification 22.022.
96	16	PinDescServiceProviderPin	MBIM_PIN_DESC	MBIM_PIN_DESC structure describing the Service Provider (SP) personalization PIN. This is a PIN that allows the device to be personalized to a service provider. For more information about this PIN type, see 3GPP specification 22.022.
112	16	PinDescCorporatePin	MBIM_PIN_DESC	MBIM_PIN_DESC structure describing the corporate personalization PIN. This is a PIN that allows the device to be personalized to a specific company. For more information about this PIN type, see 3GPP specification 22.022.

Offset	Size	Field	Type	Description
128	16	PinDescSubsidyLock	MBIM_PIN_DESC	MBIM_PIN_DESC structure describing the subsidy unlocks PIN. This is a PIN that allows the device to be restricted to operate on a specific network. For more information about this PIN type, see 3GPP specification 22.022.
144	16	PinDescCustom	MBIM_PIN_DESC	MBIM_PIN_DESC structure describing the custom PIN. This is a custom vendor-defined PIN type. It is not included in the above list.

Status Codes

Status Code	Description
MBIM_STATUS_PIN_REQUIRED	The PIN list operation failed because a PIN must be entered before this operation can proceed.

Testing

The following tests are run as part of the **TestPin** HLK test list:

Test Name	Description
PinListQueryRadioOn	This test attempts a pin list query with the radio on.
PinListQueryRadioOff	This test attempts a pin list query with the radio off.
NoPinSupport	This test verifies a device that does not support PIN1.
PinExSetEnableDisableWithValidPin	This test enables and disables PIN1 with a valid pin.
PinExSetDisableIncorrectPinWithValidLength	This test attempts to enable PIN1 with an incorrect pin with valid length.
PukEnableDisableThroughIncorrectPinExDisable	This test enables PUK1 by entering incorrect PIN1 multiple times and then disables PUK1.

Test Name	Description
PinExSetChangeWithBothInvalidAndValidPin	This test enables PIN1, immediately changes the PIN, and disables it.
RebootTestMachineToPutPinIntoLockState	This test reboots the device to make the modem enter lock state and prompt valid PIN entry.
PinExSetEnterWithValidPin	This test validates that the device is in lock state to request PIN code entry.

The **TestPowerStates** HLK test list also contains one relevant test -- **SimPinUnlockAfterHibernate**.

PIN Operations Log filter

Article • 12/15/2021

To make searching log files easier, below is a PIN-operation-specific filter file for the TextAnalysisTool.

To use this filter:

1. Copy and paste the lines below and save them into a text file named "WwanPin.tat."

2. Load the filter file into the TextAnalysisTool by clicking File > Load Filters.

```
<?xml version="1.0" encoding="utf-8" standalone="yes"?>
<TextAnalysisTool.NET version="2015-06-23" showOnlyFilteredLines="True">
  <filters>
    <filter enabled="n" excluding="n" backColor="90ee90" type="matches_text"
case_sensitive="n" regex="n" text="maybeUnlockPin" />
    <filter enabled="n" excluding="n" foreColor="800000" type="matches_text"
case_sensitive="n" regex="n" text="Received PinInfo" />
    <filter enabled="n" excluding="n" backColor="ffb6c1" type="matches_text"
case_sensitive="n" regex="n" text="maybeCapturePin" />
    <filter enabled="n" excluding="n" foreColor="800080" type="matches_text"
case_sensitive="n" regex="n" text="[Microsoft-Windows-WWAN-SVC-EVENTS]" />
    <filter enabled="n" excluding="n" foreColor="00008b" type="matches_text"

```

MB Provider Operations

Article • 03/14/2023

This topic describes the operations related to *home*, *preferred*, *multicarrier*, and *visible* network providers.

For more information about provider operations, see OID_WWAN_HOME_PROVIDER, OID_WWAN_PREFERRED_PROVIDERS, OID_WWAN_PREFERRED_MULTICARRIER_PROVIDERS, and OID_WWAN_VISIBLE_PROVIDERS.

MB Registration Operations

Article • 03/14/2023

Miniport drivers use OID_WWAN_REGISTER_STATE to process both *query* and *set* registration operations. For example, these operations may be to register with a network provider, query the registration state of the device with a provider's network, and send notifications when registration state changes.

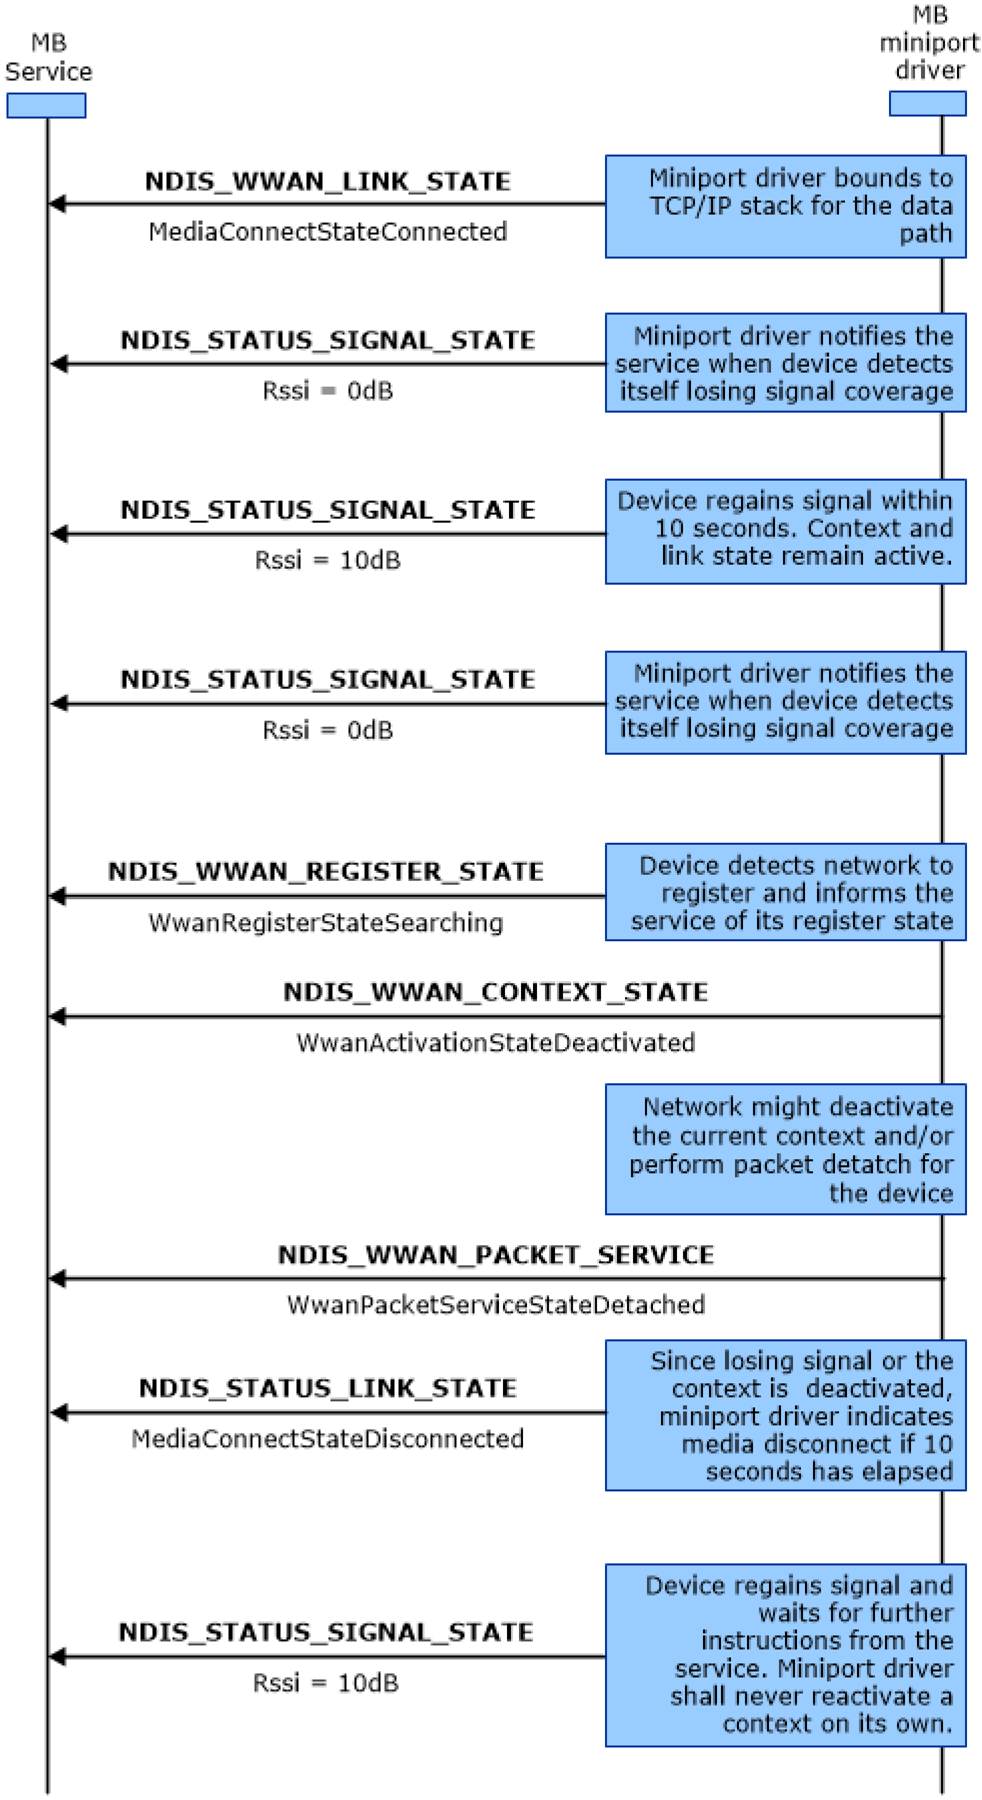
MB Packet Service Operations

Article • 03/14/2023

This topic describes the operations for losing and regaining packet data service, packet data service handoffs, and voice calls during packet data service connections.

Losing and Regaining Packet Data Service

The following diagram shows the process that miniport drivers should follow when they lose signal strength and packet service for various intervals. The labels in bold are OID identifiers or transactional flow control.The labels in regular text are the important flags within the OID structure.



MB Service
MB miniport driver
NDIS_WWAN_LINK_STATE
MediaConnectStateConnected
Miniport driver bounds to TCP/IP stack for the data path
NDIS_STATUS_SIGNAL_STATE
Rssi = 0dB
Miniport driver notifies the service when device detects itself losing signal coverage
NDIS_STATUS_SIGNAL_STATE
Rssi = 10dB
Device regains signal within 10 seconds. Context and link state remain active.
NDIS_STATUS_SIGNAL_STATE
Rssi = 0dB
Miniport driver notifies the service when device detects itself losing signal coverage
NDIS_WWAN_REGISTER_STATE
WwanRegisterStateSearching
Device detects network to register and informs the service of its register state
NDIS_WWAN_CONTEXT_STATE
WwanActivationStateDeactivated
Network might deactivate the current context and/or perform packet detatch for the device
NDIS_WWAN_PACKET_SERVICE
WwanPacketServiceStateDetached
NDIS_STATUS_LINK_STATE
MediaConnectStateDisconnected
Since losing signal or the context is deactivated, miniport driver indicates media disconnect if 10 seconds has elapsed
NDIS_STATUS_SIGNAL_STATE
Rssi = 10dB
Device regains signal and waits for further instructions from the service. Miniport driver shall never reactivate a context on its own.

To regain packet data service after it has been lost, use the following procedure:

1. The miniport driver sends NDIS_WWAN_LINK_STATE to the MB Service.

2. The miniport driver sends NDIS_WWAN_SIGNAL_STATE to the MB Service.

3. The miniport driver sends **NDIS_WWAN_SIGNAL_STATE** to the MB Service.

4. The miniport driver sends **NDIS_WWAN_SIGNAL_STATE** to the MB Service.

5. The miniport driver sends NDIS_WWAN_REGISTER_STATE to the MB Service.

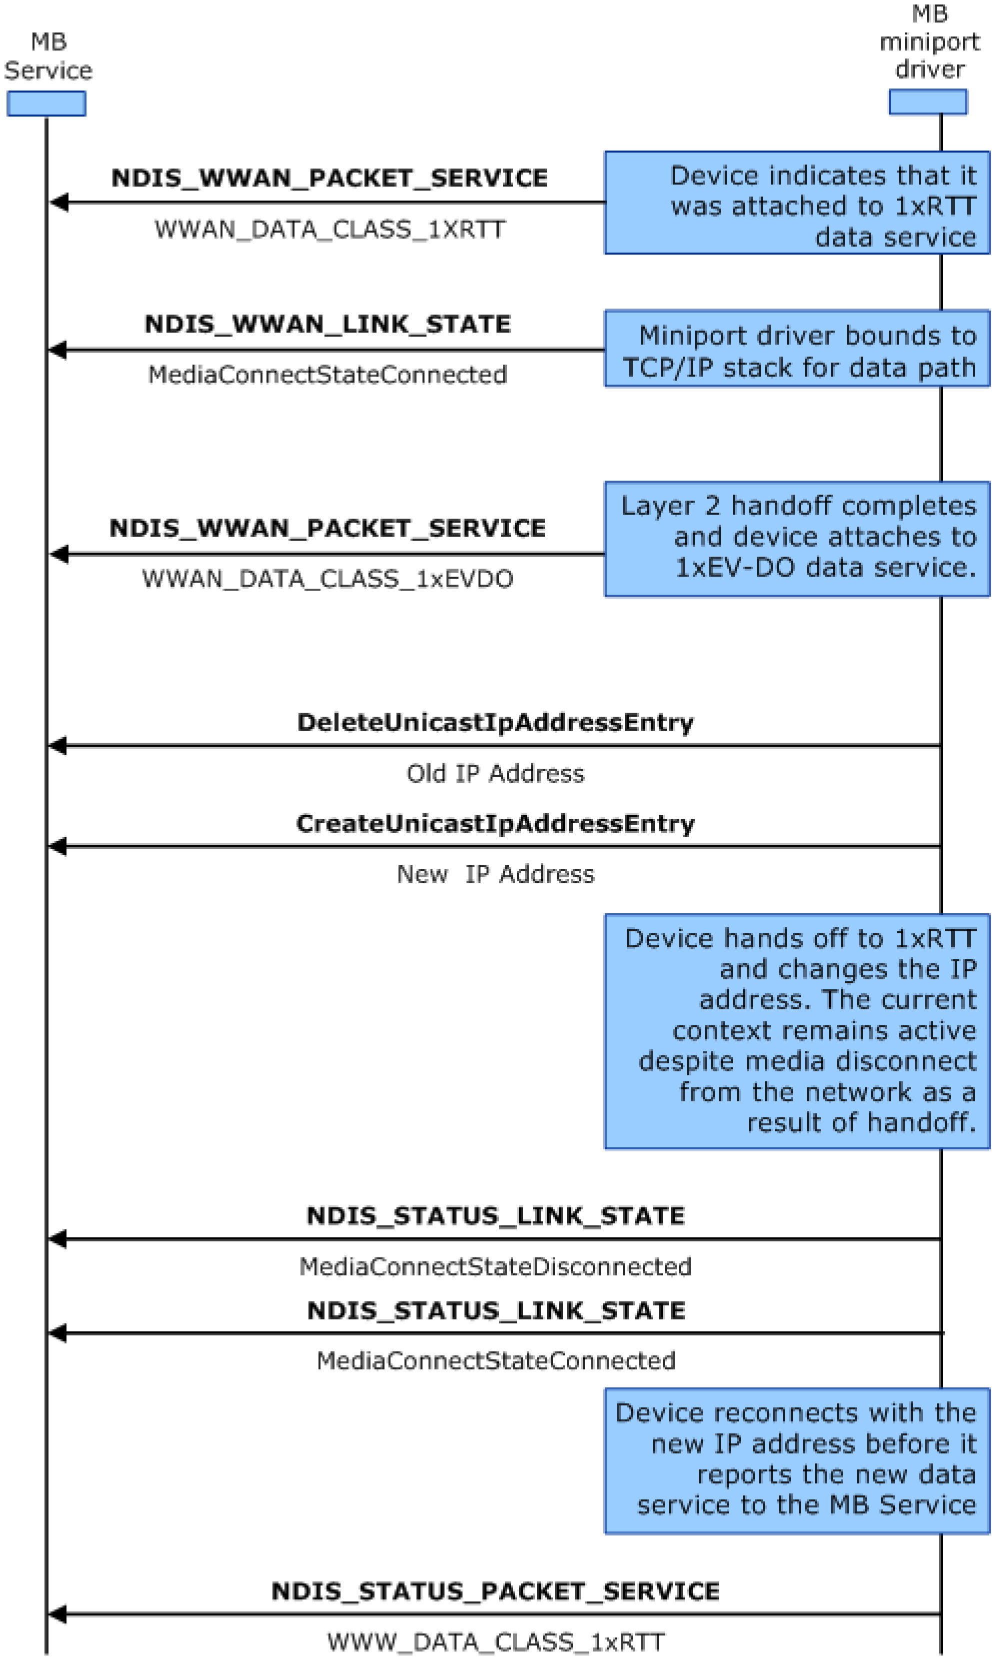
6. The miniport driver sends **NDIS_STATUS_WWAN_PACKET_SERVICE** to the MB Service.

7. The miniport driver sends **NDIS_STATUS_LINK_STATE** to the MB Service.

8. The miniport driver sends **NDIS_WWAN_SIGNAL_STATE** to the MB Service.

Packet Data Service Handoffs

The following diagram shows the steps that miniport drivers should follow when packet service moves between different GSM-based technologies, such as GPRS, EDGE, UMTS, HSDPA, or TD-SCDMA, or moves between different CDMA-based technologies, such as 1xRTT, EV-DO, or EV-DO RevA. The labels in bold are OID identifiers or transactional flow control. The labels in regular text are the important flags within the OID structure.



MB Service
MB miniport driver
NDIS_WWAN_PACKET_SERVICE
WWAN_DATA_CLASS_1XRTT
Device indicates that it was attached to 1xRTT data service
NDIS_WWAN_LINK_STATE
MediaConnectStateConnected
Miniport driver bounds to TCP/IP stack for data path
NDIS_WWAN_PACKET_SERVICE
WWAN_DATA_CLASS_1xEVDO
Layer 2 handoff completes and device attaches to 1xEV-DO data service.
DeleteUnicastIpAddressEntry
Old IP Address
CreateUnicastIpAddressEntry
New IP Address
Device hands off to 1xRTT and changes the IP address. The current context remains active despite media disconnect from the network as a result of handoff.
NDIS_STATUS_LINK_STATE
MediaConnectStateDisconnected
NDIS_STATUS_LINK_STATE
MediaConnectStateConnected
Device reconnects with the new IP address before it reports the new data service to the MB Service
NDIS_STATUS_PACKET_SERVICE
WWW_DATA_CLASS_1xRTT

Be aware that unless the IP address changes in the handoff process, the MB Service handles the handoff event transparently without disrupting the existing connection. However, miniport drivers must still notify the MB Service about media disconnect events if, and only if, the IP address changes.

Miniport drivers and the MB device they manage should be able to handle the layer-2 handoff between different air interfaces automatically, with minimal impact to the MB Service and other overlaying applications. The only possible impact is the change to the

IP address that might result from the technology handoff. In this case, miniport drivers should re-establish the MB connection before reporting the packet service change to the MB Service. Miniport drivers that do not implement DHCP functionality should use the IP Helper and associated functions. Miniport drivers that do implement DHCP functionality are not required to use the IP Helper functions.

To hand off packet data service, use the following procedure:

1. The miniport driver sends **NDIS_STATUS_WWAN_PACKET_SERVICE** to the MB Service.

2. The miniport driver sends NDIS_WWAN_LINK_STATE to the MB Service.

3. The miniport driver sends **NDIS_STATUS_WWAN_PACKET_SERVICE** to the MB Service.

4. The miniport driver calls the **DeleteUnicastIpAddressEntry** helper function with the old IP address

5. The miniport driver calls the **CreateUnicastIpAddressEntry** helper function with the new IP address

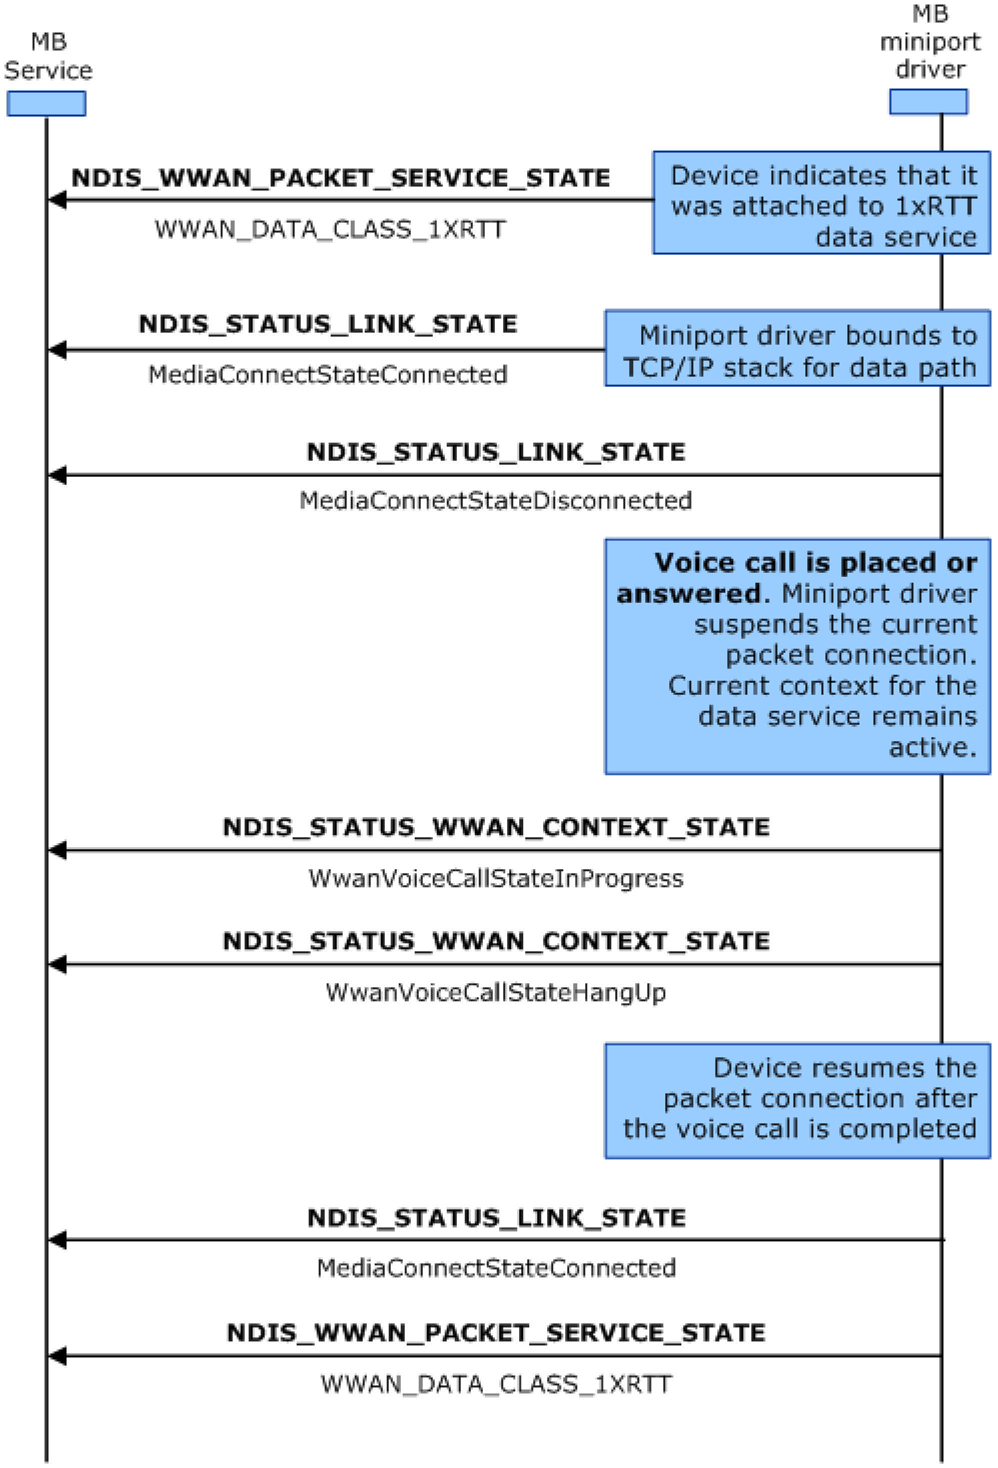
6. The miniport driver sends **NDIS_STATUS_LINK_STATE** to the MB Service.

7. The miniport driver sends **NDIS_STATUS_LINK_STATE** to the MB Service.

8. The miniport driver sends **NDIS_STATUS_WWAN_PACKET_SERVICE** to the MB Service.

Voice Calls during Packet Data Service Connections

The following diagram represents the process that miniport drivers should follow when a voice call is placed while packet data service is active. The diagram uses 1xRTT as an example, but the procedure applies to other air interfaces as well. The process outlined in the following graphic applies only to miniport drivers that return **WwanVoiceClassSeparateVoiceData** in the **WwanVoiceClass** member in response to an OID_WWAN_DEVICE_CAPS *query* request. The labels in bold represent OID identifiers or transactional flow control. The labels in regular text represent the important flags within the OID structure.



MB Service
MB miniport driver
NDIS_WWAN_PACKET_SERVICE_STATE
WWAN_DATA_CLASS_1XRTT
Device indicates that it was attached to 1xRTT data service
NDIS_STATUS_LINK_STATE
MediaConnectStateConnected
Miniport driver bounds to TCP/IP stack for data path
NDIS_STATUS_LINK_STATE
MediaConnectStateDisconnected
Voice call is placed or answered. Miniport driver suspends the current packet connection. Current context for the data service remains active.
NDIS_STATUS_WWAN_CONTEXT_STATE
WwanVoiceCallStateInProgress
NDIS_STATUS_WWAN_CONTEXT_STATE
WwanVoiceCallStateHangUp
Device resumes the packet connection after the voice call is completed
NDIS_STATUS_LINK_STATE
MediaConnectStateConnected
NDIS_WWAN_PACKET_SERVICE_STATE
WWAN_DATA_CLASS_1XRTT

The procedure assumes that accepting an incoming voice call will pre-empt any pre-existing packet connection. For miniport drivers that return **WwanVoiceClassSimultaneousVoiceData** in the **WwanVoiceClass** member in response to an OID_WWAN_DEVICE_CAPS *query* request, the current packet connection should not be affected.

Be aware that, by design, the MB Service does not support circuit voice nor does it prohibit the service. The process outlined in the graphic above applies only when the device can handle both data and circuit voice, but only one at a time. The process assumes that the voice call takes precedence over any potential pre-existing data connection. In this case, miniport drivers should suspend the data connection for the duration of the voice call. Afterwards, miniport drivers should resume the data service by re-establishing the MB connection automatically.

To handle voice calls during packet data service connections, use the following procedure:

1. For a successful Packet Data service connection, miniport drivers should send an NDIS_WWAN_PACKET_SERVICE_STATE notification to the MB service to indicate the current DataClass followed by an NDIS_STATUS_LINK_STATE notification to the MB service to indicate the media connect state as **MediaConnectStateConnected**.

2. When a voice call is placed or answered, miniport drivers should send an NDIS_STATUS_LINK_STATE notification to the MB service to indicate the media connect state as **MediaConnectStateDisconnected**.

3. Miniport drivers should then send an NDIS_STATUS_WWAN_CONTEXT_STATE notification to the MB service that indicates the *VoiceCall* state of the device as **WwanVoiceCallStateInProgress**.

4. On hangup, miniport drivers should send an NDIS_STATUS_WWAN_CONTEXT_STATE notification to the MB service that indicates the *VoiceCall* state of the device as **WwanVoiceCallStateHangup**.

5. The device resumes packet connection after the voice call is completed. Miniport drivers should send an NDIS_STATUS_LINK_STATE notification to the MB service to indicate the media connect state as **MediaConnectStateConnected**.

6. Miniport drivers should send an NDIS_WWAN_PACKET_SERVICE_STATE notification to the MB service that indicates the current DataClass.

See Also

For more information about packet service operations, see OID_WWAN_PACKET_SERVICE.

MB Signal Strength Operations

Article • 03/14/2023

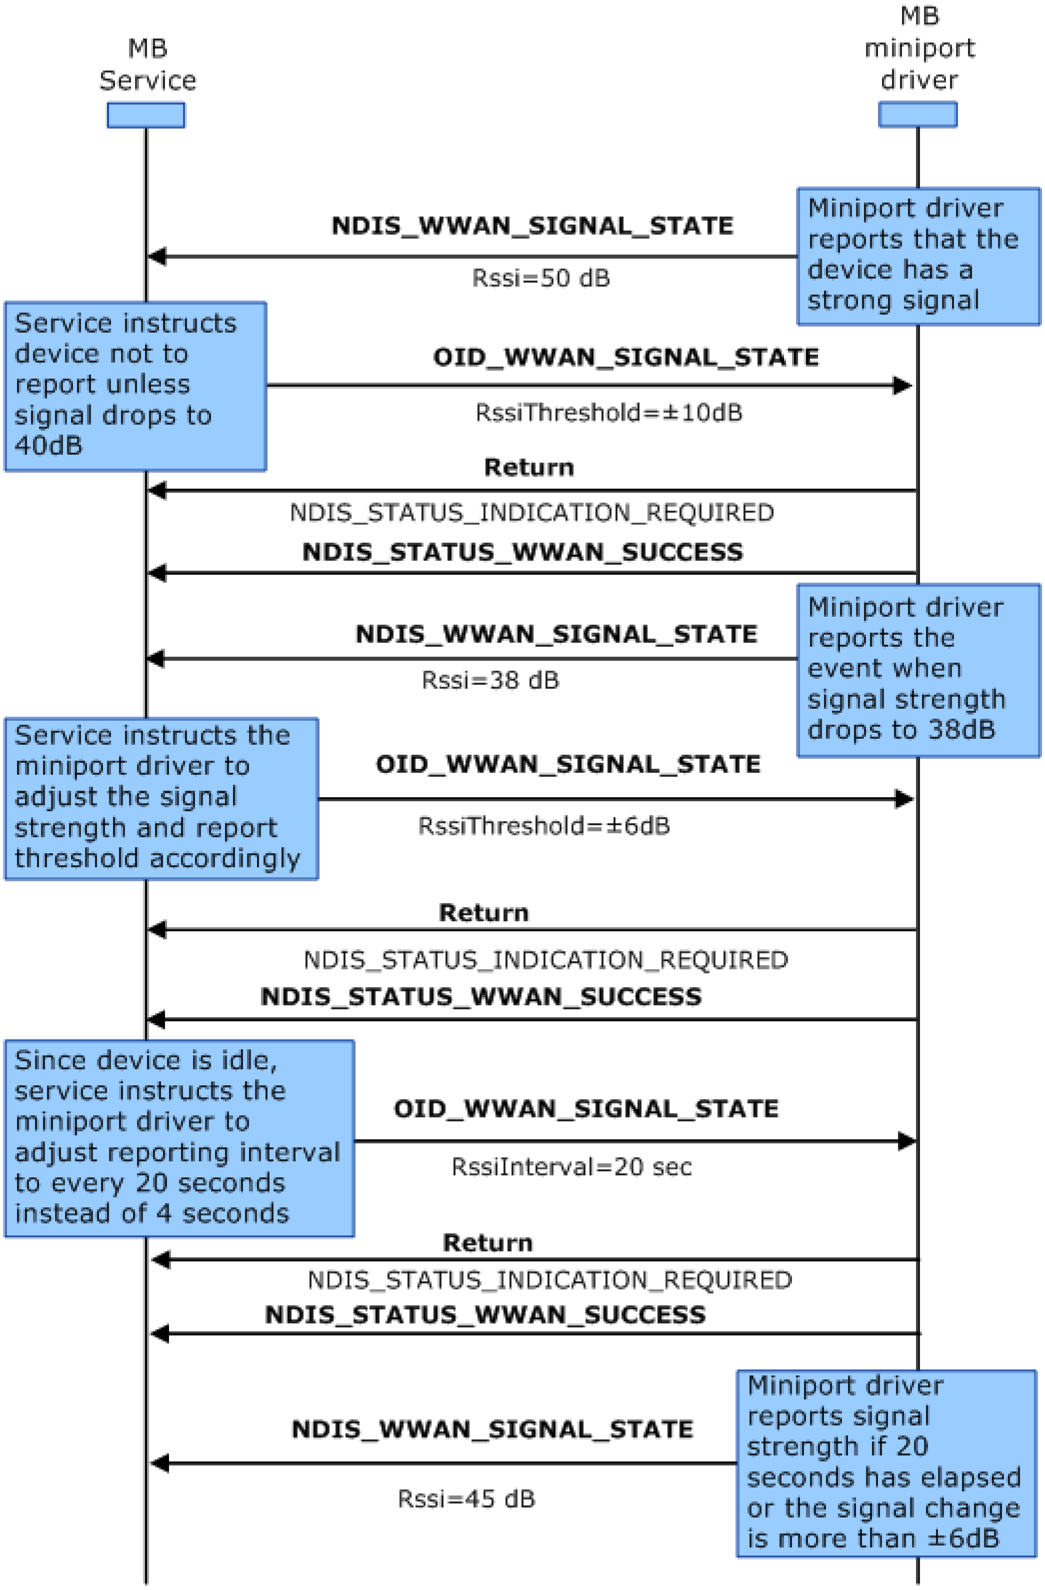
This topic describes the operations to report signal strength.

These operations require access to the network provider, but not to the Subscriber Identity Module (SIM card).

Be aware that in case of GSM-based devices, miniport drivers should send signal strength notifications only after the miniport driver has successfully registered with a network provider. For CDMA-based devices, miniport drivers can send signal strength notifications before the miniport driver has successfully registered with a network provider.

Signal Strength Indication Semantics

The following diagram shows the process that miniport drivers should follow to process signal strength indications. The MB Service adjusts the signal strength-reporting threshold and interval, based on the current device signal strength and how long the device has been idle. These actions are usually performed as part of the power management features provided by the MB Service. The labels in bold are OID identifiers or transactional flow control. The labels in regular text are the important flags within the OID structure.



MB Service
MB miniport driver
NDIS_WWAN_SIGNAL_STATE
Rssi=50 dB
Miniport driver reports that the device has a strong signal
Service instructs device not to report unless signal drops to 40dB
OID_WWAN_SIGNAL_STATE
RssiThreshold=±10dB
Return
NDIS_STATUS_INDICATION_REQUIRED
NDIS_STATUS_WWAN_SUCCESS
NDIS_WWAN_SIGNAL_STATE
Rssi=38 dB
Miniport driver reports the event when signal strength drops to 38dB
Service instructs the miniport driver to adjust the signal strength and report threshold accordingly
OID_WWAN_SIGNAL_STATE
RssiThreshold=±6dB
Return
NDIS_STATUS_INDICATION_REQUIRED
NDIS_STATUS_WWAN_SUCCESS
Since device is idle, service instructs the miniport driver to adjust reporting interval to every 20 seconds instead of 4 seconds
OID_WWAN_SIGNAL_STATE
RssiInterval=20 sec
Return
NDIS_STATUS_INDICATION_REQUIRED
NDIS_STATUS_WWAN_SUCCESS
NDIS_WWAN_SIGNAL_STATE
Rssi=45 dB
Miniport driver reports signal strength if 20 seconds has elapsed or the signal change is more than ±6dB

To update signal strength indications, use the following procedure:

1. The miniport driver sends **NDIS_WWAN_SIGNAL_STATE** to the MB Service.

2. The MB Service sends OID_WWAN_SIGNAL_STATE to the miniport driver. The miniport driver responds with a provisional acknowledgement (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and it will send a notification with the requested information in the future.

3. The miniport driver sends NDIS_STATUS_WWAN_SUCCESS to the MB Service.

4. The miniport driver sends **NDIS_WWAN_SIGNAL_STATE** to the MB Service.

5. The MB Service sends OID_WWAN_SIGNAL_STATE to the miniport driver. The miniport driver responds with a provisional acknowledgement (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and it will send a notification with the requested information in the future.

6. The miniport driver sends NDIS_STATUS_WWAN_SUCCESS to the MB Service.

7. The MB Service sends OID_WWAN_SIGNAL_STATE to the miniport driver. The miniport driver responds with a provisional acknowledgement (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and it will send a notification with the requested information in the future.

8. The miniport driver sends NDIS_STATUS_WWAN_SUCCESS to the MB Service.

9. The miniport driver sends **NDIS_WWAN_SIGNAL_STATE** to the MB Service.

MB Packet Context Management

Article • 03/14/2023

This topic describes the management of packet contexts, which are a specific set of network configuration parameters for setting up a *virtual circuit* or *flow* on top of the physical MB connection at layer 2. In GSM-based devices, this corresponds to the concept of a Packet Data Protocol (PDP). In CDMA-based devices, this corresponds to a network profile.

In most cases, the detailed settings of a packet context are either pre-provisioned by IHVs and/or network providers of the MB device, or provisioned through the network over-the-air (OTA) or using SMS. In either case, the end user is generally not required to provide most of the settings (for example, quality of service (QoS), security codes, mobile IP, and so on). However, the end user may need to provide the network access string, username, and password. It is these user configurable settings that constitute the content of a packet context from the perspective of the MB Service.

The MB driver model does not provide an explicit OID to set up or tear down the layer-2 connection for WWAN. Instead, activating the first packet context results in setting up the underlying layer-2 connection and deactivating the last packet context will effectively tear down the underlying layer-2 connection.

The MB driver model builds on these two constraints regarding the number of active packet contexts at any given time in the following manner:

1. Each packet context can be activated only one time.

2. Only a single packet context can be activated at any given time.

It is mandatory that any miniport driver that conforms to the MB driver model sets the **MaxActivatedContexts** member of the **WWAN_DEVICE_CAPS** structure to one, when responding to OID_WWAN_DEVICE_CAPS query requests. Even if a miniport driver sets this value to be greater than one, the MB Service ensures that, at most, only one packet context is activated at any given time.

Because each packet context can be activated no more than one time, a static packet context identifier can be used to identify the virtual circuit after being activated. The use of this static identifier is still valid as long as the first constraint still holds.

For more information about packet context management, see OID_WWAN_PROVISIONED_CONTEXTS and OID_WWAN_CONNECT.

Multiple PDP contexts

Article • 12/15/2021

Usage scenarios

UWP mobile broadband apps can take advantage of multiple Packet Data Protocol (PDP) contexts to activate a special PDP context and specify rules to route data traffic. These apps can create rules for specific destinations or for all data traffic.

When the mobile broadband app needs to exchange data with the network, it checks the available and connected networks. If the mobile broadband app has a special rule for any of these networks, it uses the Connection Manager API to open a special PDP context. If this connection is successful, the PDP context provides routing rules for this connection and transfers the data using networking APIs. The mobile broadband app should repeat this if it receives the NetworkStatusChanged event to see whether any connections have changed and whether it needs to open a PDP context for the new connection.

You can use multiple PDP contexts to enable premium services.

- Differentiated Billing – You can vary the data or billing restrictions by using multiple PDP contexts. For example, Contoso is a mobile operator that developed a data backup app for their customers. As a mobile operator, Contoso could create multiple PDP contexts and let premium subscribers use the app for free. All other subscribers are charged separately to use it.

- Rich Communication Services – A global initiative created by the GSM Association to provide rich communication services, such as an enhanced phonebook, enhanced messaging, and enriched calling. Rich Communication Services provide interoperability across mobile operators and offers new ways to use existing assets and capabilities to deliver high quality and innovative communication services.

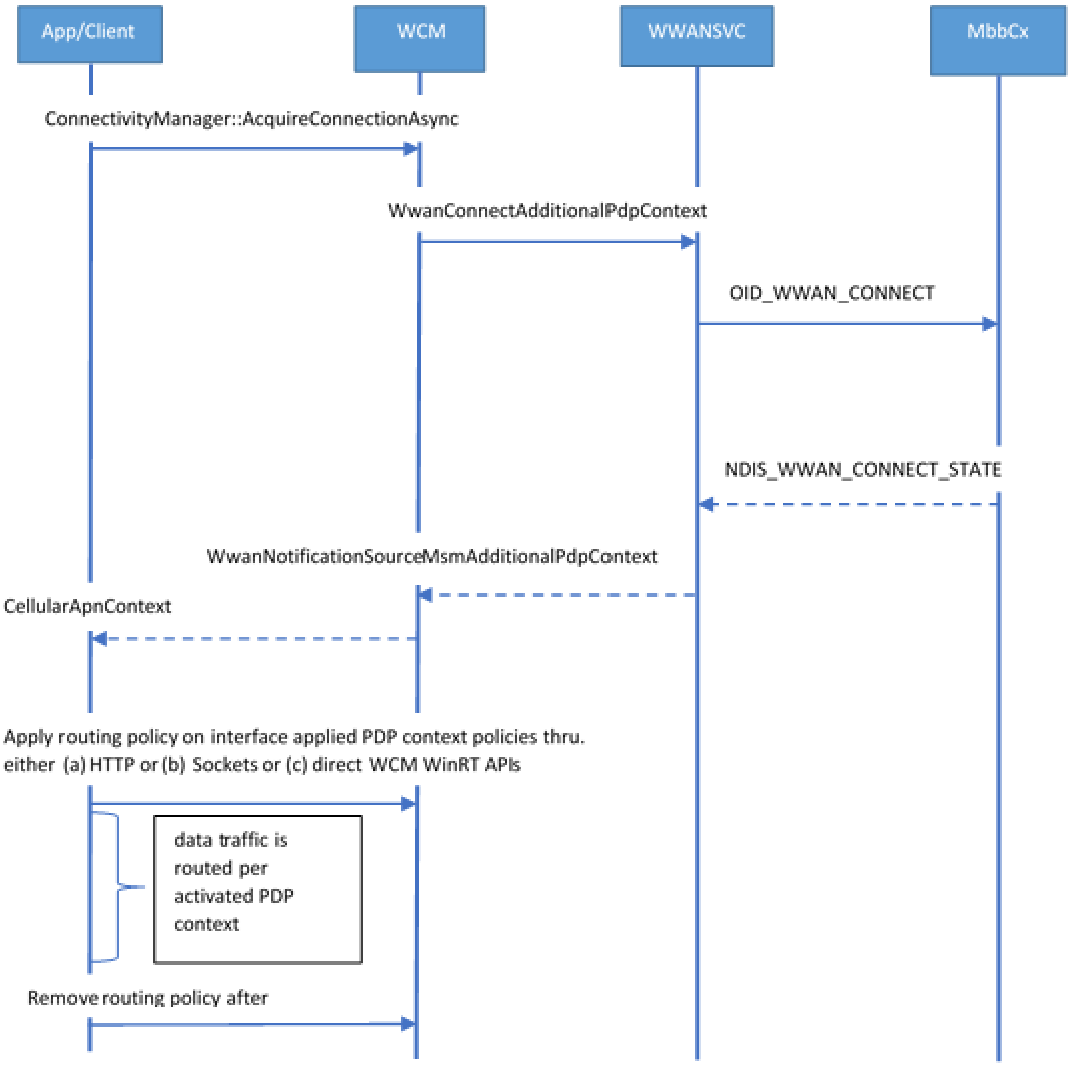
- Sponsored Connectivity – This allows users to a specific type of content without it going against their monthly data usage. The content provider makes an arrangement to reimburse the mobile operator by paying them directly, doing a revenue-sharing deal, or some other business arrangement.

- Personal Hotspot – Some mobile operators charge different rates when the connection is being used as a personal hotspot. You can use multiple PDP contexts to differentiate between the two.

For more information, see Developing apps using multiple PDP contexts.

Primary Flow

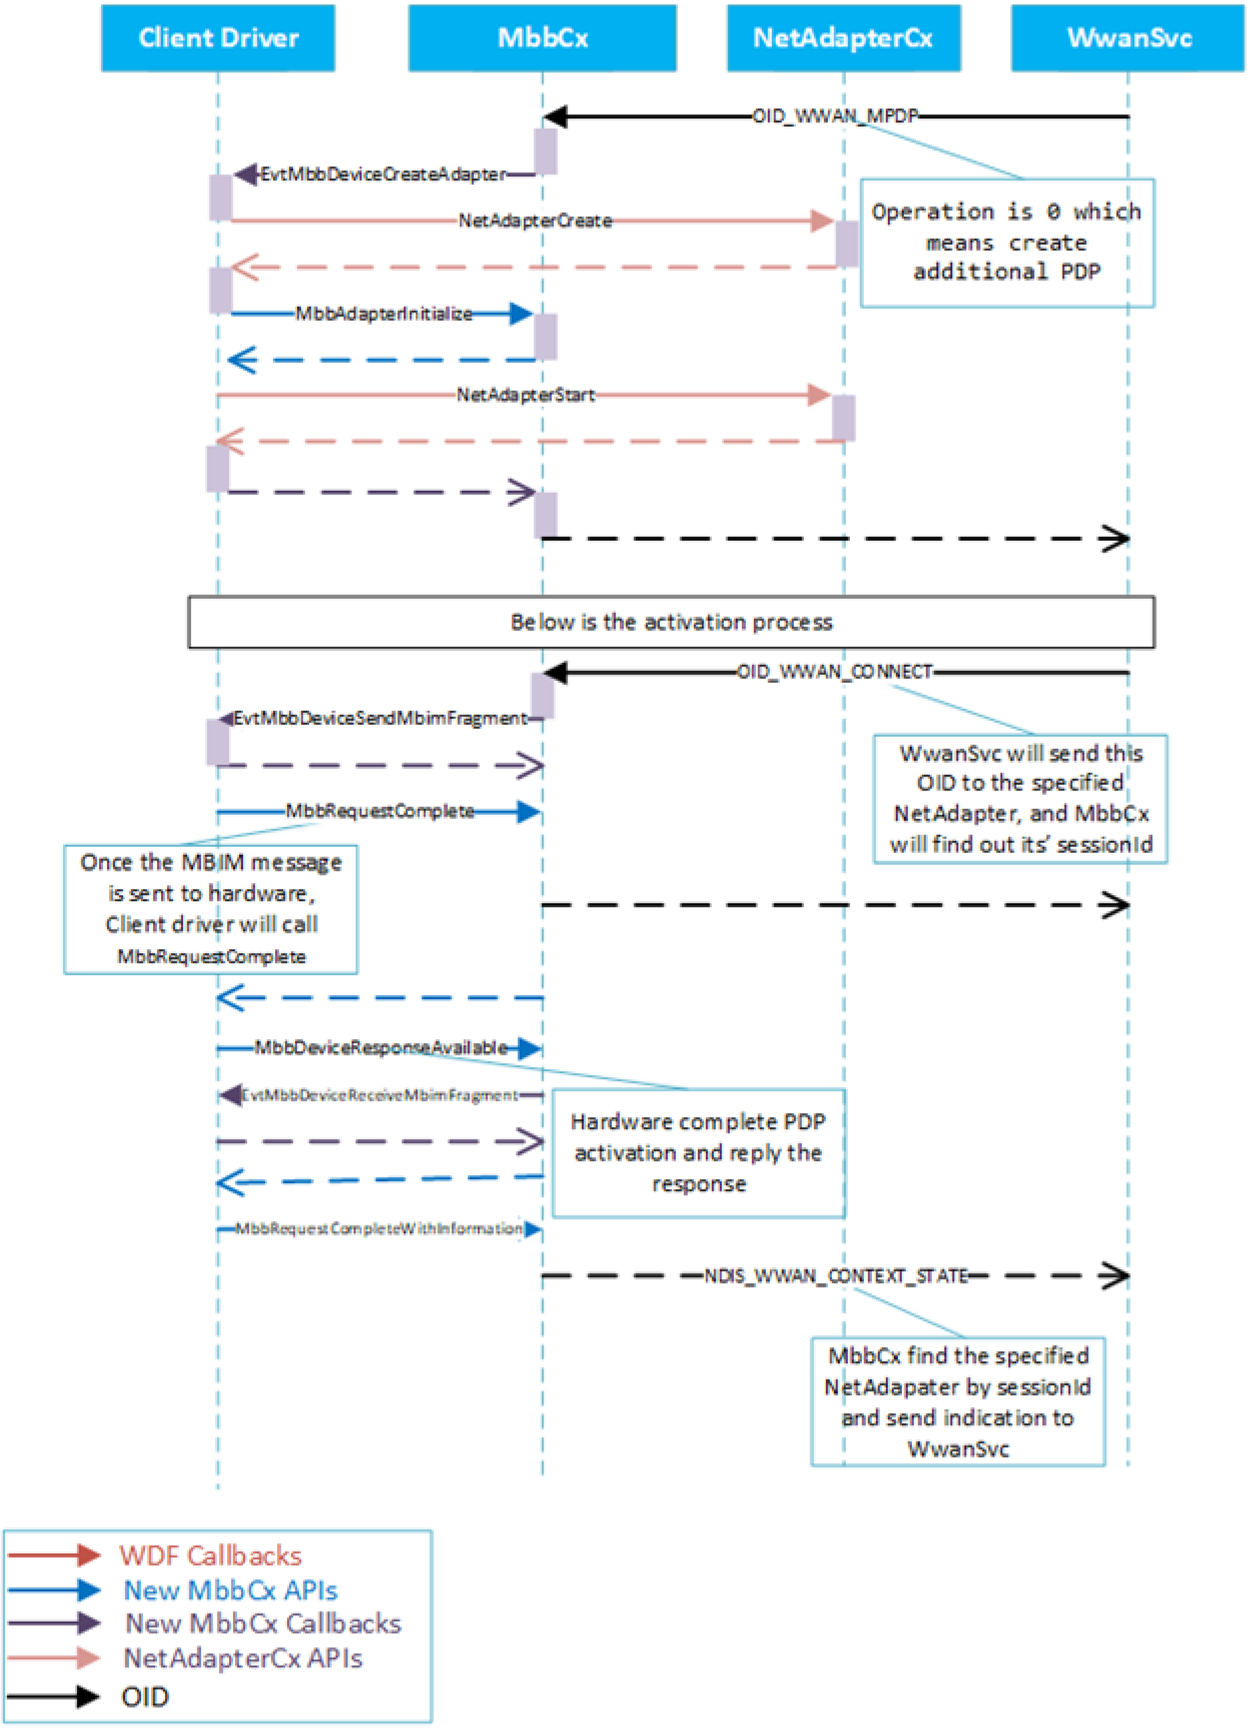
App activates additional PDP contexts:



App/Client
WCM
WWANSVC
MbbCx
ConnectivityManager::AcquireConnectionAsync
WwanConnectAdditionalPdpContext
OID_WWAN_CONNECT
NDIS_WWAN_CONNECT_STATE
WwanNotificationSourceMsmAdditionalPdpContext
CellularApnContext
Apply routing policy on interface applied PDP context policies thru. either (a) HTTP or (b) Sockets or (c) direct WCM WinRT APIs
data traffic is routed per activated PDP context
Remove routing policy after

UWP app activate additional PDP context connection

Additional NetAdapter Initialization

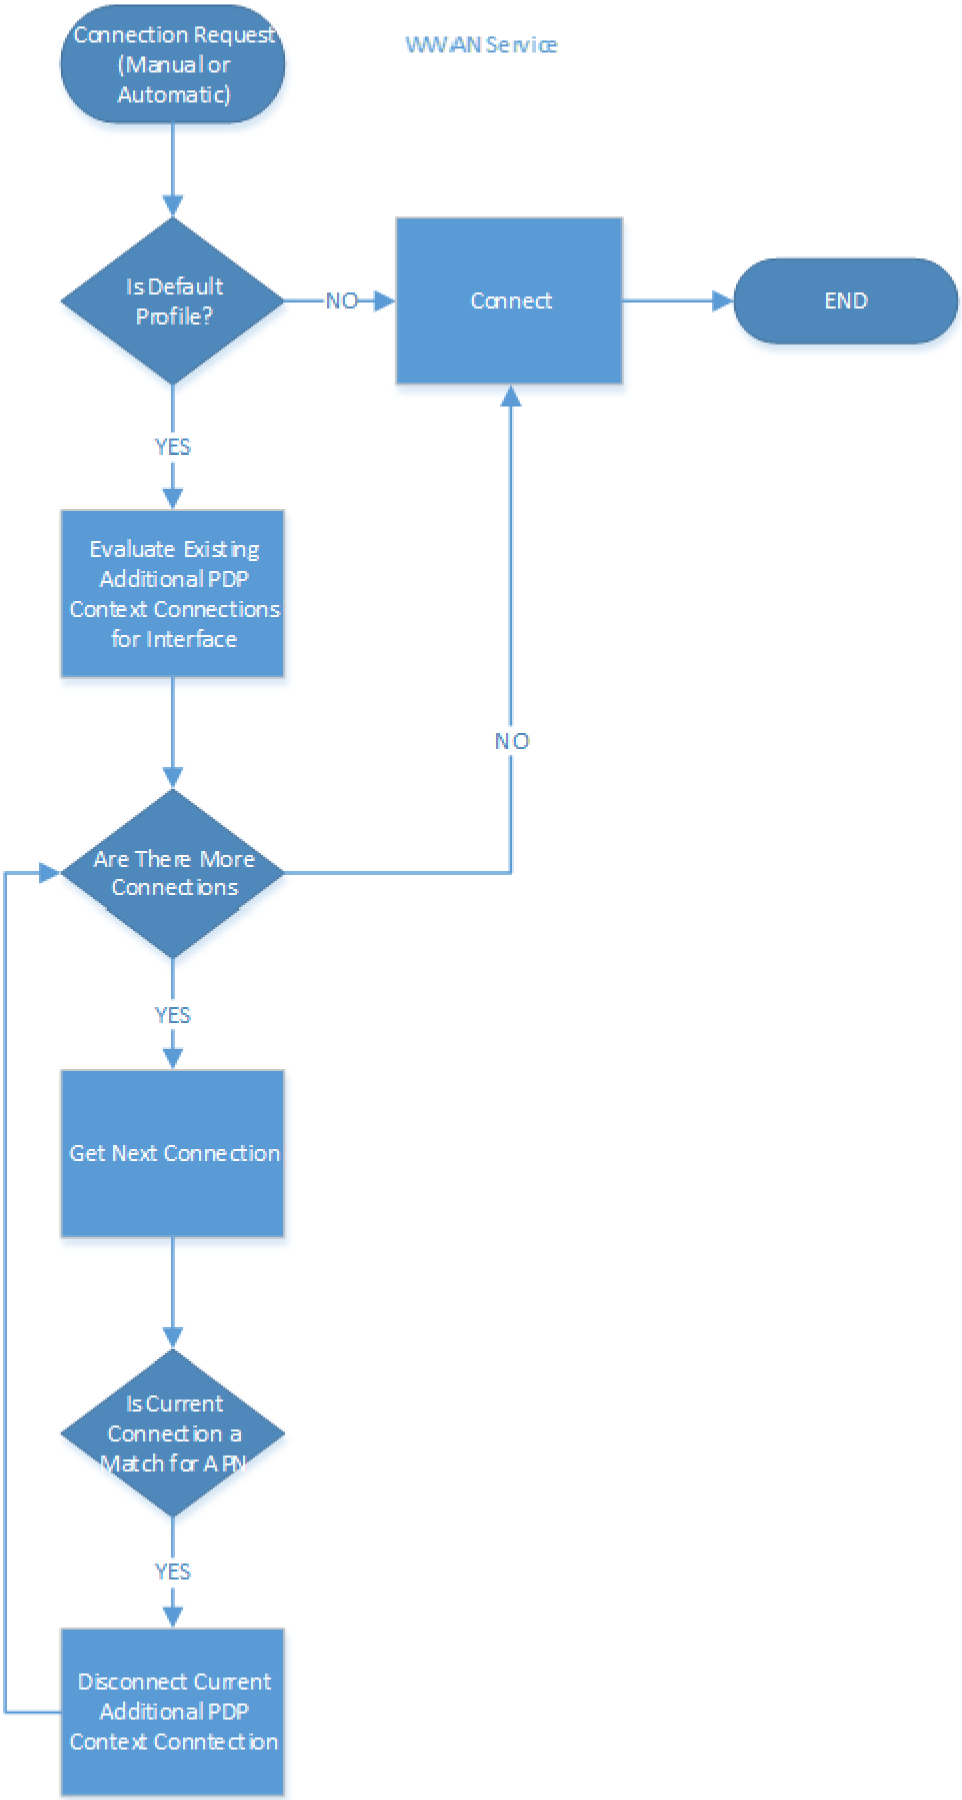


Client Driver
MbbCx
NetAdapterCx
WwanSvc
OID_WWAN_MPDP
EvtMbbDeviceCreateAdapter
Operation is 0 which means create additional PDP
NetAdapterCreate
MbbAdapterInitialize
NetAdapterStart
Below is the activation process
OID_WWAN_CONNECT
EvtMbbDeviceSendMbimFragment
WwanSvc will send this OID to the specified NetAdapter, and MbbCx will find out its' sessionId
MbbRequestComplete
Once the MBIM message is sent to hardware, Client driver will call MbbRequestComplete
MbbDeviceResponseAvailable
EvtMbbDeviceReceiveMbimFragment
Hardware complete PDP activation and reply the response
MbbRequestCompleteWithInformation
NDIS_WWAN_CONTEXT_STATE
MbbCx find the specified NetAdapater by sessionId and send indication to WwanSvc
WDF Callbacks
New MbbCx APIs
New MbbCx Callbacks
NetAdapterCx APIs
OID

Decision Logic in WwanSvc for Additional PDP Context Connections

1. Double check and update the "Is Default Profile" condition logic, as it is no longer applicable.

2. WCM should no longer use the *cost* property of the default profile.
3. If the new additional pdp context APN request coincides with the default internet APN, disconnect the current additional PDP context.



Connection Request (Manual or Automatic)
WWAN Service
Is Default Profile?
NO
Connect
END
YES
Evaluate Existing Additional PDP Context Connections for Interface
NO
Are There More Connections
YES
Get Next Connection
Is Current Connection a Match for APN
YES
Disconnect Current Additional PDP Context Connection

Hardware Lab Kit (HLK) Tests

See Steps for installing HLK .

In HLK Studio connect to the device Cellular modem driver and run the test: Win6_4.MB.GSM.Data.TestMPDP.

MB Multiple PDP context Troubleshooting Guide

1. Logs can be collected and decoded using these instructions: MB Collecting Logs
2. Open the .txt file in TextAnalysisTool
3. Load the Bacis Connectivity filter

MB DNS Updates

Article • 03/14/2023

This topic describes the operations to notify the MB Service about DNS address updates.

Miniport drivers should set the **NameServer** registry key to update Windows about DNS address changes. The following table describes the appropriate registry key, the expected value and an example string for IPv4 and IPv6 networks. If a miniport driver supports only IPv4 networks, it should set only the IPv4 registry key. Miniport drivers should set the appropriate registry key(s) before they notify Windows about media connect events by sending **NDIS_STATUS_LINK_STATE** notifications.

IPv4 / IPv6	Registry Key	Value	Example
IPv4	HKLM\SYSTEM\CurrentControlSet\Services\Tcpip\Parameters\Interfaces\InterfaceGUID\NameServer	Space-separated DNS server IPv4 addresses	10.20.30.41 10.20.30.40
IPv6	HKLM\SYSTEM\CurrentControlSet\Services\Tcpip6\Parameters\Interfaces\InterfaceGUID\NameServer	Space-separated DNS server IPv6 addresses	2001:4898:7001:f000:1:2:3:4 2001:4898:7001:f000:1:2:3:5

These operations should be used only when the miniport driver specifies **EnableDhcp** to equal zero in its INF file. That is, the miniport driver does not implement DHCP.

For more information about processing IP address notifications, see Guidelines for MB Miniport driver IP Address Notifications.

MB SMS Operations

Article • 03/14/2023

This topic describes the operations to configure, read/receive, send, and delete messages using Short Message Service (SMS) capabilities of an MB device.

SMS support is mandatory. Miniport drivers must set the appropriate send and receive SMS capability flags that they support when processing OID_WWAN_DEVICE_CAPS query requests in the **WwanSmsCaps** member of the **WWAN_DEVICE_CAPS** structure. If miniport drivers do not support SMS, they should specify WWAN_SMS_CAPS_NONE and return WWAN_STATUS_SMS_UNKNOWN_ERROR for all SMS-related OIDs.

Miniport drivers should only process SMS operations after OID_WWAN_READY_INFO returns **WwanReadyStateInitialize** as the device ready-state. Miniport drivers should process some SMS operations, such as sending a SMS message, only after the device is registered on a provider network (though not necessarily data service registration).

The MB Service does not differentiate between different message stores available in the device. Therefore, miniport drivers must handle all message stores and project a single virtual message store accessed by means of a virtual index. For example, if the device has three message stores, the miniport driver must handle all of them collectively and present them as a single message store to the service.

The MB driver model supports the following SMS Operations:

- SMS configuration
- Read SMS
- Send SMS
- Delete SMS

We recommend miniport drivers support SMS configuration, read, send, and delete operations, as well as notifying the user of any new SMS message received by a device.

For more information about SMS operations, see OID_WWAN_SMS_CONFIGURATION, OID_WWAN_SMS_READ, OID_WWAN_SMS_SEND, OID_WWAN_SMS_DELETE, and OID_WWAN_SMS_STATUS.

Testing

Automated SMS Tests

The following tests are automated and onboarded to the RI-TP. They are run daily and should pass 100%.

- MobilebroadbandExperience\SmsApi
- MobilebroadbandExperience\SMSCDMA
- MobilebroadbandExperience\SMSDecodingTests
- MobilebroadbandExperience\SMSEncodingTests
- WWAN\SMS\Service\UnitTests

SmsApi Tests have different versions that run on desktop and onecoreuap. Desktop still uses *vnelib.dll* (C++ version) because the CDMA part of SMS is not ported to *vnelibrary.dll* (C# version). Therefore you will find two versions of functional test lists.

Hardware Lab Kit (HLK) Tests

These are all the currently available HLK tests related to MB-SMS:

- TestSms
  - CDMA, GSM
- TestSmsStoreFull
  - CDMA, GSM
- TestWake
  - CDMA: IncomingDataPacket, RegisterStateChange
  - GSM: IncomingDataPacket, RegisterStateChange
- TestSimBad
  - GSM
- TestDeviceCapsEx
  - CDMA
  - GSM
- TestSIMNotInserted
  - GSM

Running Tests

Via netsh, you can run the test lists and HLK tests. For more information on using the netsh tool see **netsh mbn** and **netsh mbn test installation**.

```
netsh mbn test feature=sms testpath="C:\data\test\bin"
taefpath="C:\data\test\bin" param="AccessString=internet"
```

Logs can be collected and decoded using these instructions: MB Collecting Logs.

Special Messages

Operator Messages

Operators can provision devices to handle particular messages earlier. This is no longer available, but the feature has not been completely removed yet. The code ProvisioningEngine processes the Operator Notifications. For more information see Operator Notifications and Operator Events.

Broadcast Messages

For more information on emergency alerts through SMS see SmsBroadcastMessage and SmsBroadcastType.

UWP Capabilities for SMS

Legacy SMS API

There are two legacy SMS APIs, *sms* and *smsSend*.

Latest SMS API

MB Vendor Specific Operations

Article • 03/14/2023

This topic describes the operations to interface vendor specific operations to the MB Service.

For more information about vendor specific operations, see OID_WWAN_VENDOR_SPECIFIC.

USSD Overview

Article • 12/15/2021

Unstructured Supplementary Service Data (USSD) is a communication protocol used by Global System for Mobile Communications (GSM) devices to communicate with mobile network operators (typically referred to as simply "MO").

To understand USSD it is helpful to compare it to its most closely-related sibling: short message service (SMS). USSD and SMS are both GSM standards, meaning they were introduced as features in the second generation of mobile devices. In contrast with SMS however, USSD is a session-based connection. While SMS is used for short session-less messaging, USSD is typically used for command and control of a mobile device. As it is a necessary to maintain a session, USSD does not support store-and-forward capability as SMS does. Both USSD and SMS messages are sent with 7-bit GSM-compliant characters, but USSD maxes out at 184 characters in contrast with 160 for SMS.

USSD messages may be sent from a mobile phone by opening the dialer and typing a code. Not all codes are supported by every phone or MO. In some cases, the phone software or operating system may prevent manually sending codes. One required code that must be implemented is *#06#. This code returns the International Mobile Equipment Identifier (IMEI) of the modem, but some phones will prevent you from dialing this directly. If you follow conventional means of locating the IMEI of the modem through your phone's settings, that number was retrieved using this code.

If the phone hardware can directly handle a code's command like in the IMEI example, no network session will be initiated. Other codes that require network communication will open a session and then send a message consisting of a command and any necessary parameters, if applicable. One example of this is a code which checks your current balance and plan status with the MO.

USSD in Windows is implemented as a WinRT API surface. The implementation classes of this interface serve as the state machine for USSD sessions, but ultimately rely on WWAN Service to do the heavy lifting. These APIs are implemented with a factory pattern.

Implementing USSD

A key thing to remember is that the public facing API is defined by the IDL. Implementation can be confusing because of this, especially if you are unfamiliar with WinRT. Part of the confusion comes from the seemingly ambiguous use of the word 'factory'. A factory can refer to either a class implementation of a static interface or a true factory that provides an activatable interface to a runtime class.

This topic reviews WinRT concepts and then describes the implementation based on these concepts. You may always refer to the IDL for further clarification.

Interfaces

Interfaces define the Application Binary Interface (ABI). They describe the functions that you can call on any class that implements the interface.

Runtime Classes

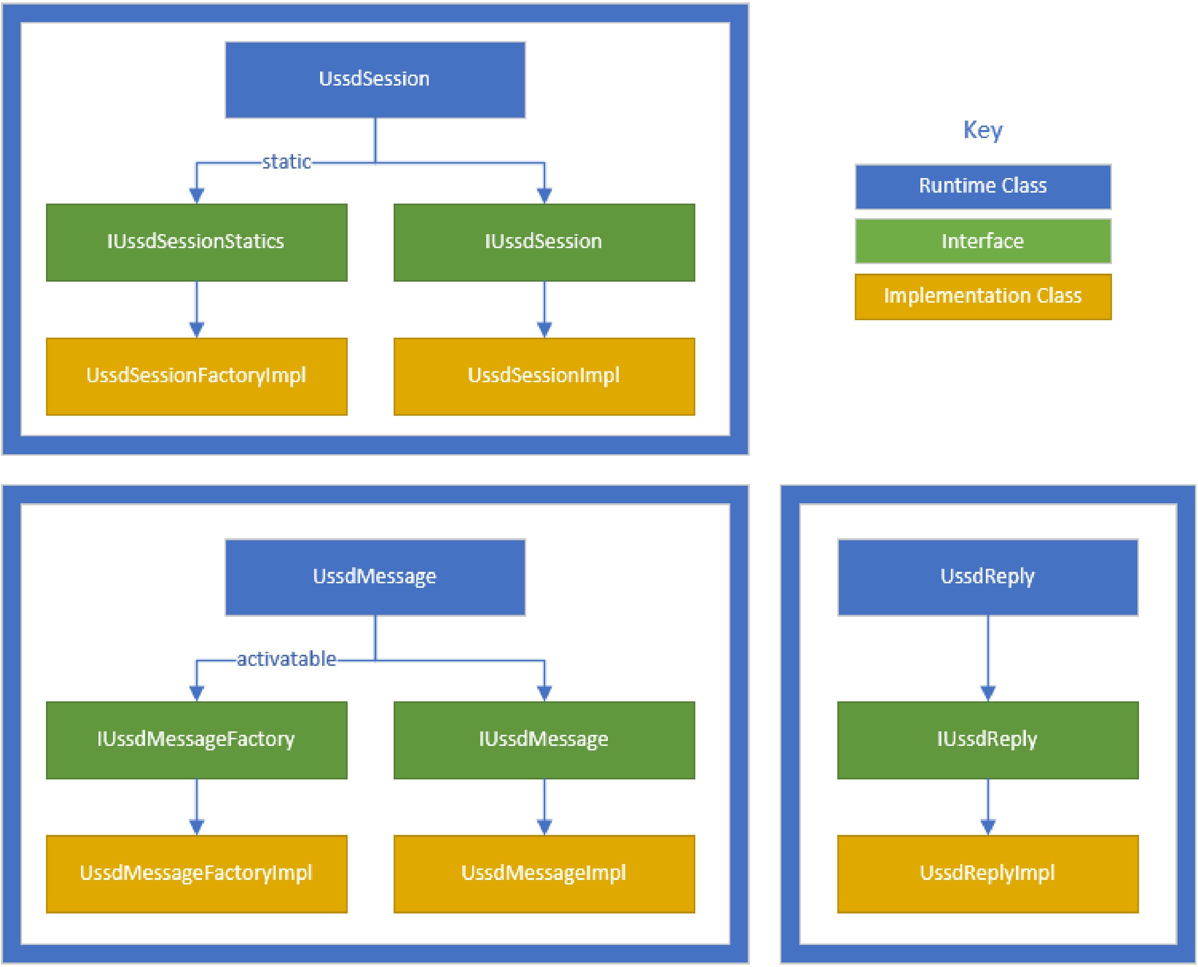
These are the actual classes. They represent, by name, what is ultimately exposed as class names to the ABI. Each runtime class may have zero or more interfaces (but must declare at least one default interface if it has one or more interfaces), zero or more static interfaces, and an activatable tag if necessary. Each of these interfaces are implemented in different files as different "Impl" classes yet they will appear to be a single, unified class to the ABI.

A typical interface appears as instance methods on an existing object.

A static interface appears to the client as static methods on the runtime class itself.

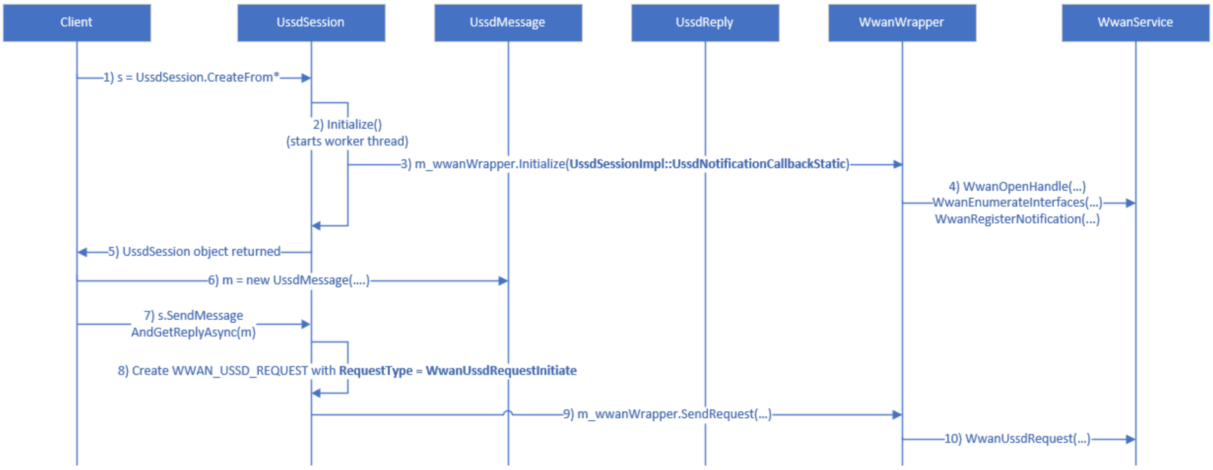
An activatable tag defines the factory interface that will produce an instance of a runtime class. This is completely obfuscated to the client, appearing as a constructor for that runtime class.

USSD Implementation



Flow: Open, Send, Receive, Close.

Open, Send



Client
UssdSession
UssdMessage
UssdReply
WwanWrapper
WwanService
1) s = UssdSession.CreateFrom*
2) Initialize()
(starts worker thread)
3) m_wwanWrapper.Initialize(UssdSessionImpl::UssdNotificationCallbackStatic)
4) WwanOpenHandle(...)
WwanEnumerateInterfaces(...)
WwanRegisterNotification(...)
5) UssdSession object returned
6) m = new UssdMessage(....)
7) s.SendMessage
AndGetReplyAsync(m)
8) Create WWAN_USSD_REQUEST with RequestType = WwanUssdRequestInitiate
9) m_wwanWrapper.SendRequest(...)
10) WwanUssdRequest(...)

1. The client uses one of the static functions UssdSession.CreateFromNetworkAccountId or UssdSession.CreateFromNetworkInterfaceId to create the UssdSession object.

2. Regardless of the API called, a network interface ID is required to initialize a UssdSession. In the case of *NetworkAccountID, steps are taken to retrieve the network interface ID from the Account ID. CreateInternal() is called to create a instance of UssdSession and invoke Initialize() on the newly-created instance. During the initialization steps, a worker thread is spun up and an event handle to trigger events for the thread is created. Steps 3 and 4 also take place during the instance's Initialize().

3. Initialize() is called on the WwanWrapper member object. This function accepts a static callback function as well as a context to allow the static function to map the callback to an object context.

4. WwanWrapper opens a handle to WwanService, enumerates interfaces, and subscribes to USSD notifications by providing a static callback function pointer and "this" as context.

5. The UssdSession object is returned to the client.

6. The client constructs a new UssdMessage by invoking the constructor with a message string. WinRT obfuscates the UssdMessageFactory in this process.

7. The client invokes SendMessageAndGetReplyAsync on the session object, passing the UssdMessage instance.

8. At this time SendMessageAndGetReplyAsync creates a special operation object called UssdSendMessageAndGetReplyOperation. From the its name, it appears that the object encapsulates the logic of a single message being sent down the stack (and waiting for reply), but this is not the case. WinRT requires a special out parameter for asynchronous operations, which we can see as the 2nd parameter on the definition for this function.

```
HRESULT SendMessageAndGetReplyAsync(
            [in] UssdMessage* message,
            [out, retval]
Windows.Foundation.IAsyncOperation<UssdReply>** asyncInfo);
```

   It is the IUssdSendMessageAndGetReplyOperation, a named interface through typedef, that satisfies this parameter by promising that this operation will inevitably return a UssdReply. This interface is not defined in the IDL, but is implemented by the UssdSendMessageAndGetReplyOperationImpl class. Note that the header for this class has a special extension:

```
class UssdSendMessageAndGetReplyOperationImpl :
    public Microsoft::WRL::RuntimeClass<

Windows::Networking::NetworkOperators::IUssdSendMessageAndGetReplyOpera
tion,

Windows::Internal::AsyncBaseFTM<IUssdSendMessageAndGetReplyCompletedHan
dler, Microsoft::WRL::SingleResult>>
```

The UssdSendMessageAndGetReplyOperation object allows WinRT to obfuscate the complexities of this asynchronous operation and all of the compartmentalization and memory proxying that goes along with it. For more information, see SendMessageAndGetReplyAsync.

For now, understand that the asynchronous operation described above simply calls back into the UssdSession object where the logic for this operation is actually contained. We can visualize for simplicity that the UssdSession itself encapsulates the work here. We can now assert that, despite the asynchronous nature, only one UssdMessage may be sent at a time.

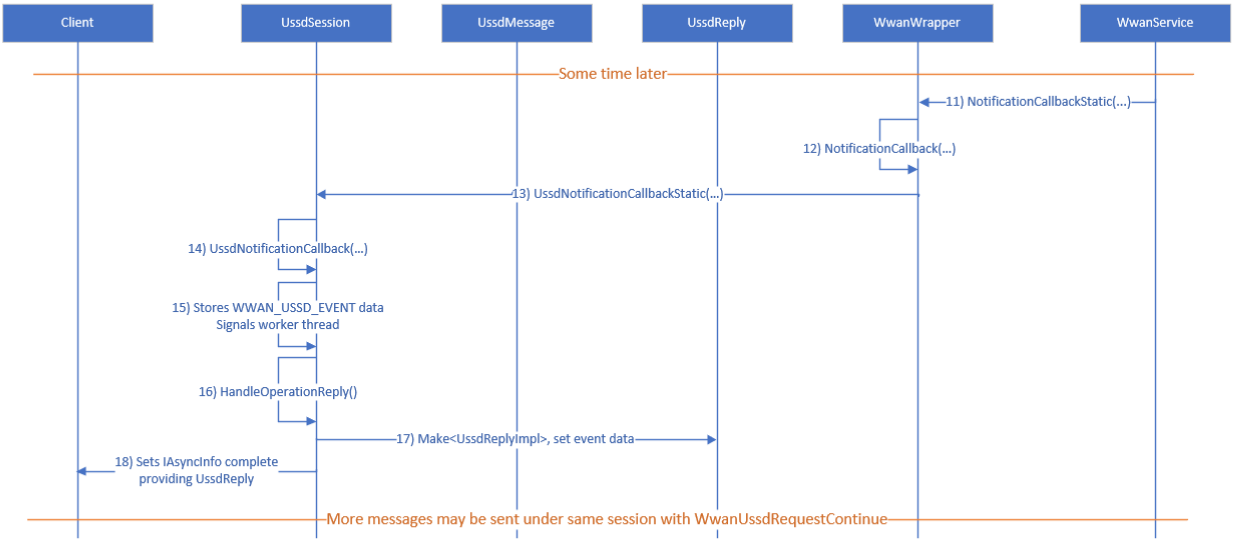
What the SendMessageAndGetReplyAsync function actually does:

- The UssdSession object changes to a busy state, stores the content of the UssdMessage, and fires off the asynchronous action.
- OnOperationStart() is the entry point for the asynchronous logic. Assume for this scenario that there is no active session. This function creates a WWAN_USSD_REQUEST object with RequestType=WwanUssdRequestInitiate.
- Steps 9 and 10 occur as actions taken by this function.

9. m_wwanWrapper.SendRequest is invoked to handle the work of passing the message to WwanService.

10. WwanWrapper uses the WwanService handle to invoke WwanService APIs to carry out the action.

Receive



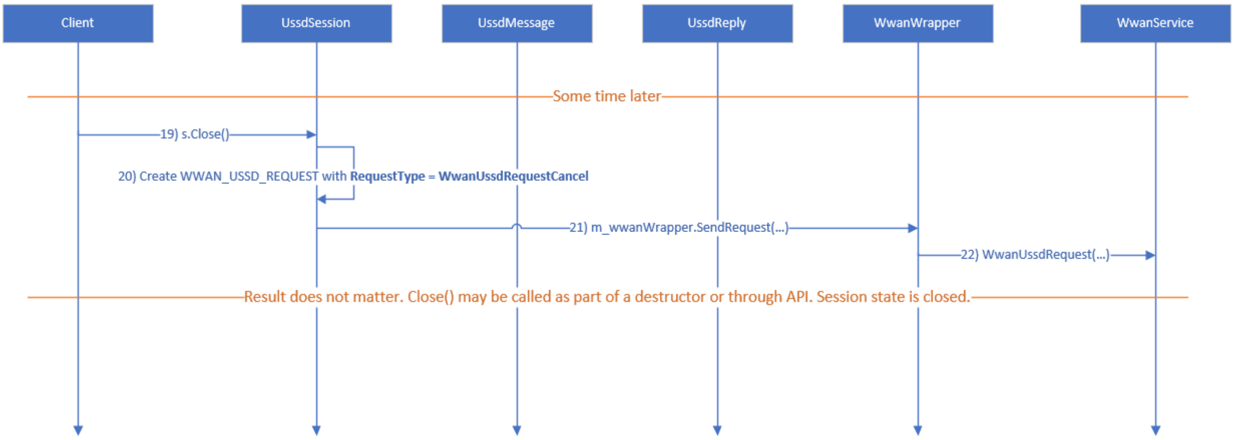
Client
UssdSession
UssdMessage
UssdReply
WwanWrapper
WwanService
Some time later
11) NotificationCallbackStatic(...)
12) NotificationCallback(...)
13) UssdNotificationCallbackStatic(...)
14) UssdNotificationCallback(...)
15) Stores WWAN_USSD_EVENT data
Signals worker thread
16) HandleOperationReply()
17) Make<UssdReplyImpl>, set event data
18) Sets IAsyncInfo complete
providing UssdReply
More messages may be sent under same session with WwanUssdRequestContinue

After step 10, we are left in a state where a request was sent to WwanService to initialize a new USSD session and send a USSD message under that session. After some time, the reply will be available.

11. WwanService will invoke the static callback function provided in step 4 with the context that was also attached.
12. The context will be used to retrieve the WwanWrapper instance and invoke NotificationCallback().
13. WwanWrapper will follow the same pattern as step 11, invoking a static callback to UssdSession, providing the context stored in step 3.
14. Similar to step 12, the context is used to invoke the callback on an instance of UssdSession.
15. The UssdSession stores the WWAN_USSD_EVENT (under a lock) and notifies the worker thread to handle the event.
16. HandleOperationReply() takes the existing UssdSendMessageAndGetReplyOperationImpl object and passes the event data to its internal handler.
17. The operation will construct and UssdReply and invoke FireCompletion() to mark the async action as finished.
18. WinRT obfuscates the completion of the asynchronous action to the client. (Either they have awaited the action or have callback logic.)

More messages can be sent under the same session. If the session was maintained, the future RequestType will be WwanUssdRequestContinue.

Close



Client
UssdSession
UssdMessage
UssdReply
WwanWrapper
WwanService
Some time later
19) s.Close()
20) Create WWAN_USSD_REQUEST with RequestType = WwanUssdRequestCancel
21) m_wwanWrapper.SendRequest(...)
22) WwanUssdRequest(...)
Result does not matter. Close() may be called as part of a destructor or through API. Session state is closed.

After step 18, the client has received the reply to their UssdMessage. They may or may not have continued to use the active UssdSession to send additional messages. We will assume that at some point in the future, the client will manually invoke Close() on the UssdSession. If the client does not explicitly invoke Close(), it will be called during the destructor of UssdSession.

19. Client invokes Close() on the UssdSession instance.
20. A WWAN_USSD_REQUEST is created with RequestType=WwanUssdRequestCancel.
21. The request is sent to m_wwanWrapper as in step 9.
22. The request is sent to WwanService as in step 10.

The result of this request is unimportant. For all intents and purposes, the session is closed. Even in the extreme edge case where the message is somehow never delivered, a new USSD session will always override an existing session.

Hardware Lab Kit (HLK) Tests

See Steps for installing HLK .

In HLK Studio connect to the device Cellular modem driver and run the test: Win6_4.MB.GSM.Data.TestUssd.

MB USSD Operations

MB USSD Operations

Article • 03/14/2023

This topic describes the operations to send and receive messages using the Unstructured Supplementary Service Data (USSD) capabilities of an MB device.

USSD support is optional and when supported is only available on GSM networks. Miniport drivers that support USSD must set the WWAN_CTRL_CAPS_USSD capability flag as part of the **WwanControlCaps** member of the **WWAN_DEVICE_CAPS** structure when processing OID_WWAN_DEVICE_CAPS requests. If miniport drivers do not support USSD, they must not set this flag and should return WWAN_STATUS_NO_DEVICE_SUPPORT for all USSD-related OIDs.

The MB driver model supports the following USSD operations: Device initiated operations:

- Sending a USSD message on a newly created USSD session
- Sending a USSD message on a newly created USSD session
- Sending a USSD message on an existing USSD session
- Terminating the USSD session

For more information on device initiated operations, see OID_WWAN_USSD.

Network initiated operations:

- Receiving a USSD message on a newly created USSD session
- Receiving a USSD message on an existing USSD session
- Termination the USSD session

For more information on network initiated operations, see **NDIS_STATUS_WWAN_USSD**.

The USSD protocol only allows a single USSD session at any time. For device initiated operations, the **RequestType** member of the **WWAN_USSD_REQUEST** structure indicates the purpose of the request OID:

- **WwanUssdRequestInitiate** is used to create a new USSD session and send the provided USSD string to the network. If a USSD session already exists, the driver must fail the request with an event of type **WwanUssdEventOtherLocalClient**. A USSD string must be present. For example, the length must be between 1 and 160 bytes.

- **WwanUssdRequestContinue** is used to send a USSD string on an existing session. A USSD string must be present. For example, the length must be between 1 and 160 bytes.

- **WwanUssdRequestCancel** is used to terminate the existing session. The driver must respond with an event of type **WwanUssdEventTerminated**, even if no session existed (which may happen during a concurrent release of the session from the network and the local client). The content of the USSD string must be ignored for this request; the string length is set to zero to indicate that there is no USSD string.

For network initiated operations, the **EventType** member of the WWAN_USSD_EVENT structure indicates the high level purpose of the indication:

- The event **WwanUssdEventNoActionRequired** is used for network initiated USSD notifications, or when no further information is needed after a mobile initiated operation. The event **WwanUssdEventActionRequired** is used for network initiated USSD requests, or when further information is needed after a mobile initiated operation. Both events require a non-empty USSD string to be present. The **SessionState** member is used to indicate if the USSD string is the first message of a USSD session; it must be set to **WwanUssdSessionStateNew** for the first message of a network initiated USSD session and to **WwanUssdSessionStateExisting** in all other cases.

- The event **WwanUssdEventActionRequired** also indicates that the session is still open. All other events indicate that the session has been closed.

- The events **WwanUssdEventNoActionRequired** and **WwanUssdEventActionRequired** are the only events that contain a USSD string. All other events must set the USSD string length to 0 to indicate that the string is absent. The value of the **SessionState** member is ignored if no string is present.

- The event **WwanUssdEventTerminated** is used to indicate that the USSD session has been terminated.

- The event **WwanUssdEventOtherLocalClient** is used to indicate that a new USSD session cannot be established because there is already a session opened. This includes sessions that are invisible to the MB stack such as a USSD session termination in the SIM.

- The event **WwanUssdEventOperationNotSupported** is used to indicate that the previous request is not supported by the driver or device.

- The event **WwanUssdEventNetworkTimeOut** is used to indicate that the session was closed due to a session timeout either by the network or locally. The driver or device is responsible for timing out an inactive USSD session after an implementation specific timeout.

MB Device Services

Article • 03/14/2023

Windows 7 introduced a NDIS (Network Device Interface Specification) based driver model for supporting Mobile Broadband (MB) devices. Windows 8 expanded the model to implement a standardized hardware interface for USB-based Mobile Broadband devices. This hardware interface specification is referred as the Mobile Broadband Interface Model (MBIM).

Windows 8 provides an updated class driver that works with devices conforming to the MBIM specification. This model is referred to as the MB Class Driver. However, no class driver can support all of the functionality exposed by an MB device. In order to allow IHV partners to continue to innovate, the MB Class Driver provide mechanisms, such as the **IMbnDeviceService interface** to allow IHVs to extend the behavior of the class driver functionality.

Note Functionality to extend MB devices services is accomplished via a user-mode application, not a kernel-mode driver extension.

While the class driver introduced in Windows 7 featured limited MB device feature support, the MB Class Driver in Windows 8 added native support for some additional features such as USSD, EAP-SIM/AKA and USB selective suspend, and offers an extensible device representation and control mechanisms. The Mobile broadband WinRT API overview provides some additional information about extending device services.

The MB Class Driver in Windows 8 enables vertical solution providers to use the Mobile Broadband API Interfaces to create enhanced user experiences that are outside of those provided by Windows. The extension mechanism is a way to augment, but not to replace, the functionality supported in the MB Class Driver itself. For example, an IHV can provide vendor-specific software that performs firmware updates on the device. Or, an IHV can provide vendor-specific software that provides value-add services such as SIM toolkit (STK) or Phonebook. The AppContainer mobile broadband pin, connection and management sample demonstrates Win32/COM Mobile Broadband APIs within the AppContainer to access and manage mobile broadband features.

In addition to providing a mechanism to extend the MB Class Driver' functionality, Windows also provides mechanisms to enable IHVs to deploy and install their value-add software through Windows Update (WU).

For more information see:

- The "MBIM Service and CID Extensibility" section of the Mobile Broadband Interface Model (MBIM) specification

MB Multimode Multicarrier

Article • 03/14/2023

This topic describes the support for MB multimode multicarrier that has been integrated into mobile broadband for Windows 8. Windows 8 introduces native support that allows users of carrier-unlocked mobile broadband devices that support carrier switching (most mobile broadband users outside the US) to select and connect to any supported carrier from within the Windows UI.

These features are targeted at IHVs to enable them to implement support for this scenario. They supplement the USB NCM (MBIM) spec (current version 1.0) that use the CIDs and device behavior required for supporting the MB multimode multicarrier scenario.

For more information see the following topics:

- MB Provider Operations
- OID_WWAN_PREFERRED_MULTICARRIER_PROVIDERS
- **NDIS_STATUS_WWAN_PREFERRED_MULTICARRIER_PROVIDERS**
- **NDIS_WWAN_PREFERRED_MULTICARRIER_PROVIDERS**

MB Multi-SIM operations

Article • 03/14/2023

Desktop Multi-Modem Multi-Executor Support

Traditionally, non-phone Windows devices have not been configured for multi-SIM modems because they have fewer physical space restraints than phones. This allows them to truly harness multiple active radios at the same time instead of having one modem with multiple SIM cards like a phone does; however, due to the rise of eSIM and scenarios in the enterprise , the demand for multi-SIM-per-modem support on non-phone devices has increased.

Most typical multi-SIM phone devices have dual SIM slots but are limited to one primary SIM card supporting data while the other only supports voice features. Such a limitation does not exist in the non-phone PC model as all SIM cards are used for data connection.

While the framework defined in this specification can theoretically support an unbounded number of modems and SIM cards, Windows 10, version 1703 and later supports only the dual-SIM/single-active (DSSA) scenario end to end.

NDIS Modem Interface Specification

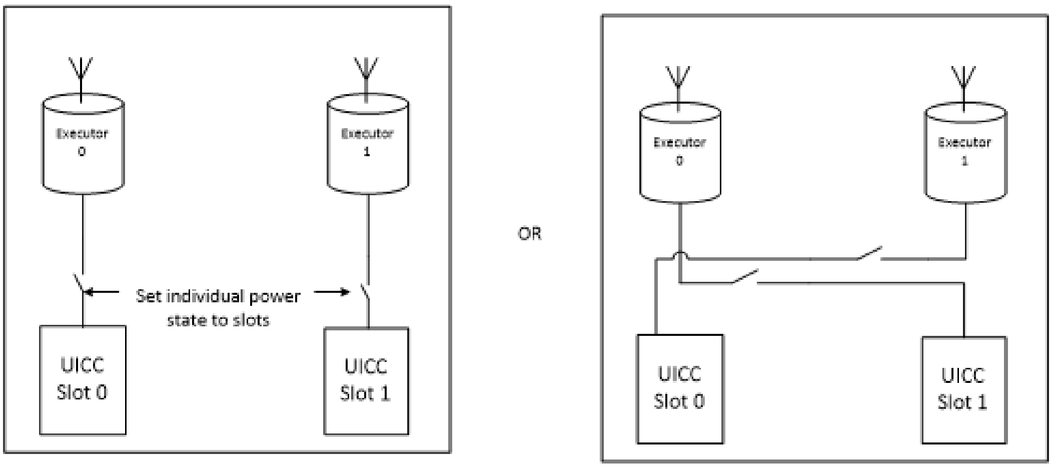
Existing Interface and Feature Gaps

It is possible to support dual-SIM/dual-active functionality with multiple independent modems, where each modem is a separate device and operates completely independently. However, this is outside this documentation’s scope, which instead focuses on a WWAN miniport modem that is capable of presenting multiple and simultaneous cellular stacks to the host. This section defines the various objects and establishes the terminology used in all MB documentation related to multi-SIM functionality.

Advancements in hardware have resulted in devices that can maintain simultaneous registrations with multiple cellular networks. In such devices, there are assumed to be “multiple instances of the cellular stack” running in parallel which are each able to maintain registration, monitor signal strengths, perform handovers and listen for incoming pages. Each instance of this “cellular stack” will be referred to as an *executor* for the rest of this document. For example, in a device capable of maintaining registrations with two networks simultaneously the modem hardware is considered to have two executors.

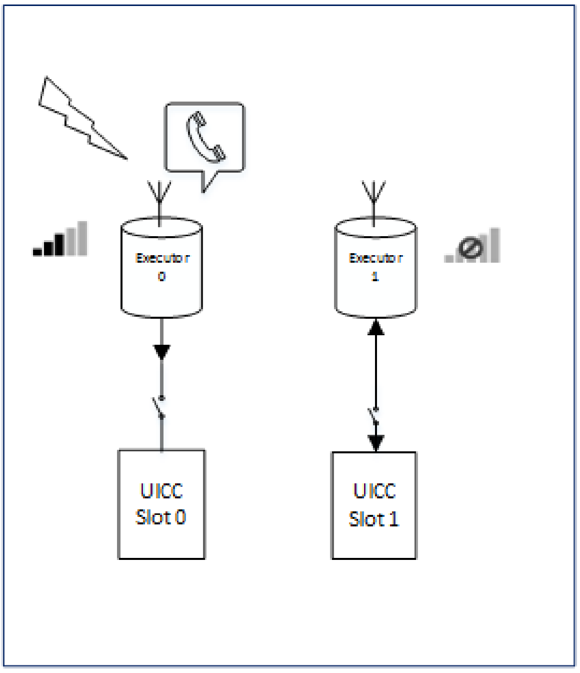
The executor is a logical representation of the hardware and may in fact be one single hardware transceiver being multiplexed. Exact hardware specifics are regarded as vendor implementation details and are out of scope for this specification. For an NDIS miniport driver, executors are exposed as multiple instances of a WWAN miniport adapter. For an MBIM modem, executors are represented by multiple MBIM functions on an enumerated composite device.

The following two images illustrate the logical view of a dual SIM modem. Each shows a possible combination of executor and UICC.



The cellular stack inside an executor is considered mostly self-contained except in the case of a Dual Standby modem implementation where the executor conducting traffic (voice and/or data) may prevent the other from maintaining registration.

The following diagram illustrates the logical view of a dual standby modem. Traffic on Executor 0, a phone call, causes Executor 1 to lose registration.



The Windows Desktop modem interface model in NDIS 6.7 does not accommodate such an architecture because it is based upon several implicit assumptions:

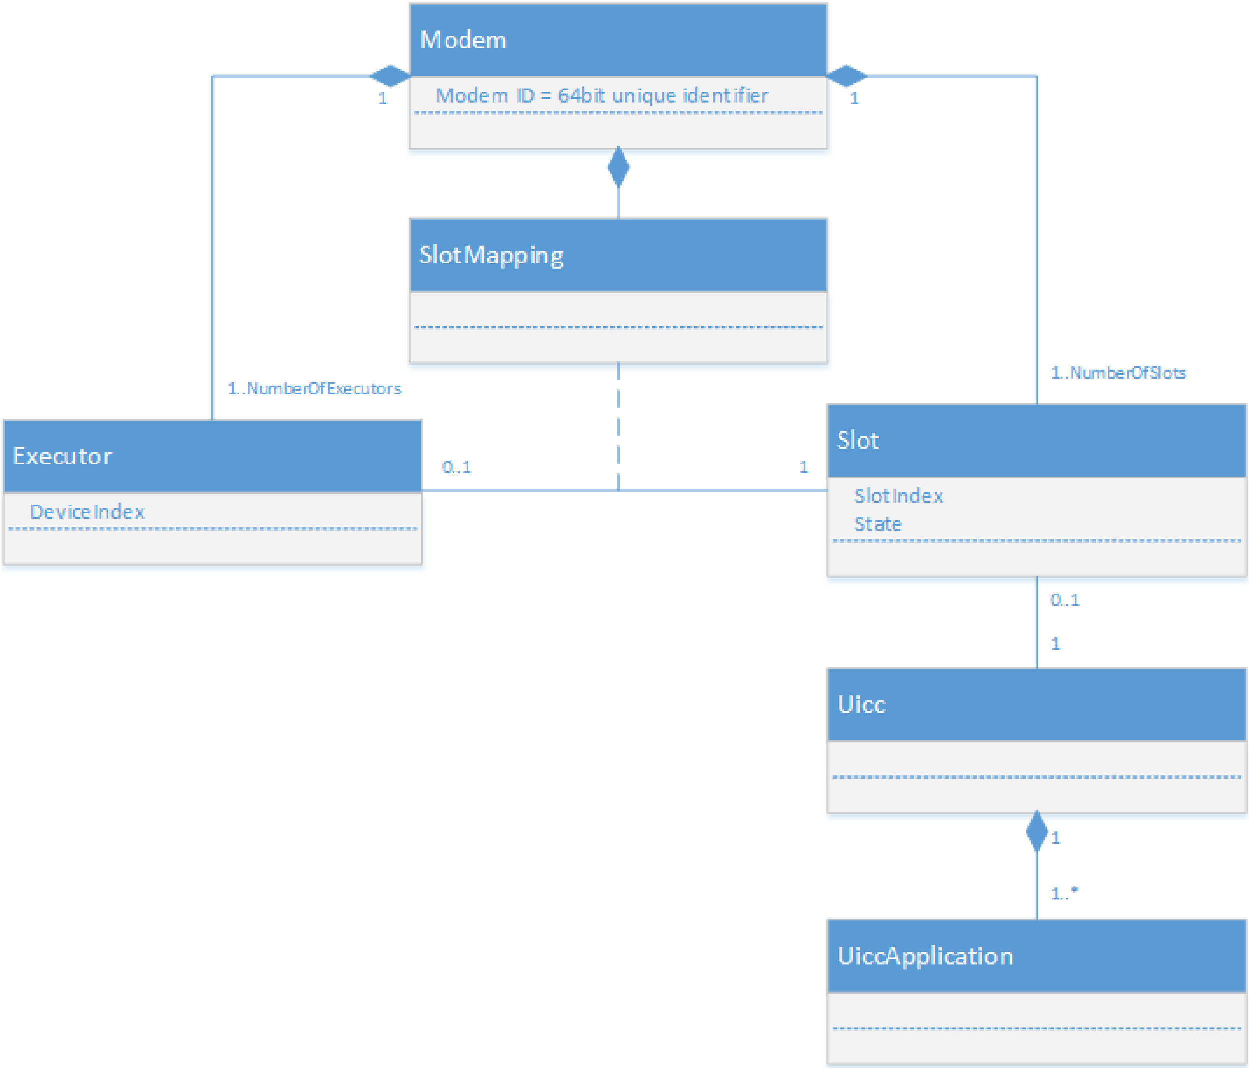
- The model assumes that there is a single executor within the modem.
- The model assumes that there is a single UICC card directly associated with the modem hardware.
- The UICC is treated as if it were a single-application SIM card.

By contrast, the Microsoft Radio Interface Layer (RIL) interface on Windows Mobile explicitly exposes the multiplicity of these assumptions. The Mobile Broadband interface in Windows Mobile exposes the ability to register independently through separate miniports and assumes that some basic configuration of the device has already been accomplished through the RIL interface. To provide equivalent functionality, Windows Desktop must provide mechanisms to discover the number of executors and slots, to access executors independently, to define the mapping between executors and slots, and to define the applications within the mapped UICC card that each executor will use.

For more information about cellular architecture and the differences between Windows 10 Mobile and Desktop, please see Cellular architecture and implementation.

Major Objects and Operations

The following figure shows an abstract model of a modem.



Each modem is identified by a globally unique identifier (GUID) and contains a set of one or more executors, each of which is capable of independent registration on a cellular network. Each executor has an associated executor index, an integer, beginning with 0 for the first executor. In addition, the modem exposes one or more slots that may contain UICC cards. It is assumed is that the number of slots is greater than or equal to the number of executors. Each slot has an associated index, also beginning with 0, and a current state related to the power state of the slot and availability state of a card in the slot (if any).

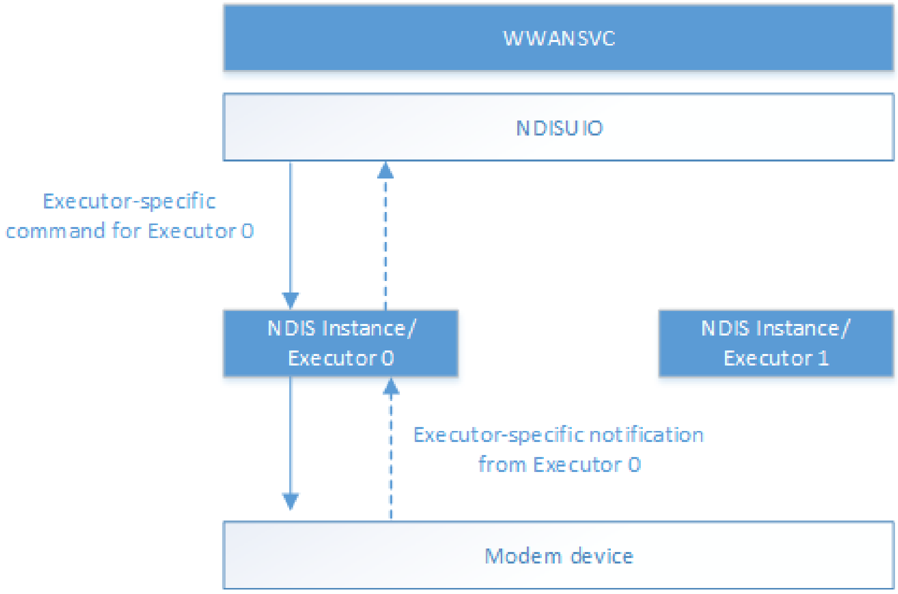
To maintain compatibility with existing modems, each executor operates with information provided by a UICC card in a single slot. The association between executors and slots is defined by slot mapping, which maps each executor to exactly one slot.

A slot may contain a UICC card; each card contains one or more UICC applications such as a USIM, CSIM, ISIM, or possibly other telephony and non-telephony applications such as PKCS#15 or Global Platform applications for an NFC secure element. The addressing and use of these individual UICC applications is a topic for future specification and out of scope of this documentation.

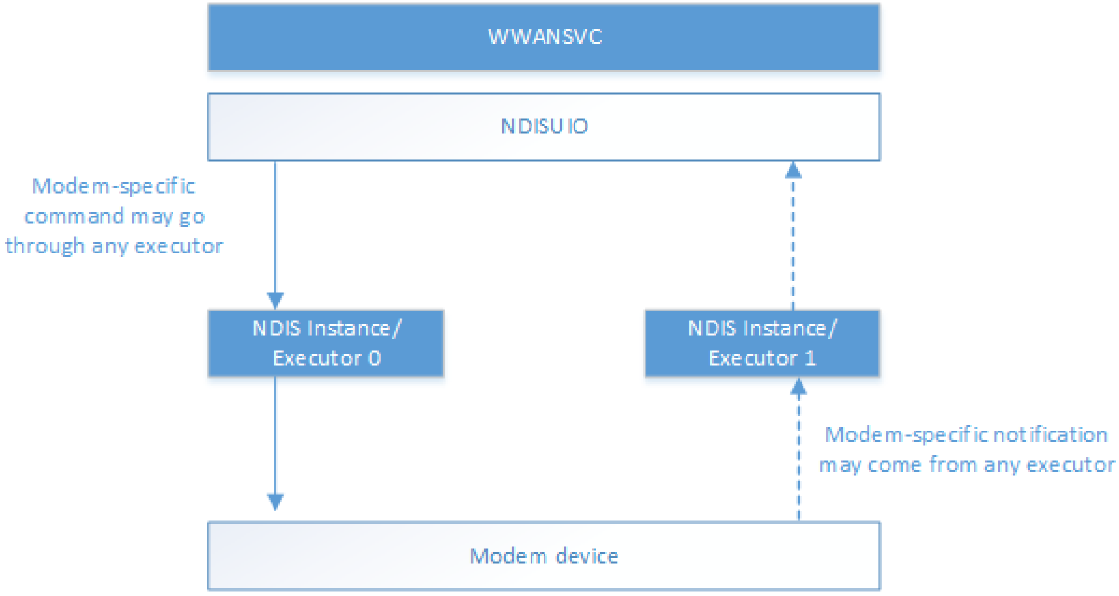
The Windows Desktop NDIS interface to the modem is characterized by the exchange of OIDs and NDIS notifications. In most cases these OIDs are directed to individual executors; however, a few commands and notifications are scoped to the modem.

For non-Windows Mobile operating systems, a multi-executor modem appears as one device with multiple physical WWAN miniport instances. Each physical miniport instance represents an executor that can maintain registration as an NDIS instance. Additional virtual instances may be created at runtime to manage context-specific packet data and device service sessions. Executor-specific commands and notifications are exchanged through the WWAN miniport NDIS physical instance representing that executor. Modem-specific commands (in other words, those that are not executor-specific) and their corresponding notifications may be sent to or come from any physical miniport instance.

The following two diagrams show the difference in executor-specific commands and notifications (the first diagram), where commands and notifications go through and come from the same executor, and modem-specific commands and notifications (the second diagram), where commands may go through any executor and come from any executor.



WWANSVC
NDISUIO
Executor-specific command for Executor 0
NDIS Instance/ Executor 0
NDIS Instance/ Executor 1
Executor-specific notification from Executor 0
Modem device



WWANSVC
NDISUIO
Modem-specific command may go through any executor
NDIS Instance/ Executor 0
NDIS Instance/ Executor 1
Modem-specific notification may come from any executor
Modem device

All OID set or query requests issued to a miniport instance are executed against the modem and executor with which the miniport instance is associated. Likewise, all unsolicited notifications and unsolicited Device Service events sent from a miniport instance are applicable to the modem and the executor with which the miniport instance is associated. For example, an unsolicited NDIS_STATUS_WWAN_REGISTER_STATE or NDIS_STATUS_WWAN_PACKET_SERVICE notification from a miniport indicates the registration (or packet service state) of the associated modem and the executor only and is unrelated to the state of other modem(s) or other executor(s).

When there are multiple modems and/or multiple executors in a device, the physical miniport adapter associated with that modem and executor combination issues non-context-specific unsolicited notifications related to a particular modem and executor combination.

In the same way, if a device has multiple modems and/or multiple executors, the physical miniport adapter instance associated with a particular modem and executor combination can receive non-context-specific OID query requests related to that modem and executor. The adapter receiving such a query request processes it according to the OID definition. If so chosen by miniport driver, this query request can be processed concurrently with any other in-process OID set or query requests in any instance of adapters associated with that modem and executor. All instances of a miniport adapter associated with a same modem and executor report the same state information for that cellular modem and executor (such as radio power state, registration state, packet service state, etc.).

For a device which has multiple modems and/or multiple executors, the physical miniport adapter instance associated with a modem and executor combination can receive non-context-specific OID set requests. The miniport driver shall keep track of the progress of such a request. If one such set request is in progress in any adapter and has not completed yet, a second such set request attempt (to any adapter instance associated with the same modem and executor) shall be queued and processed after the previous requests have completed.

The Windows 10 desktop WMBCLASS driver follows the specification outlined in the previous paragraph to handle this set request race condition, but if the race condition occurs at the modem layer the modem should follow the same guidance to queue up conflicting device-wide commands on the MBIM function if it is still processing another function that is linked to the same underlying device.

OIDs for Set and Query Requests

To query the number of devices (executors) and slots in the modem, as well as the number of executors that may be active concurrently, the host uses OID_WWAN_SYS_CAPS.

To query the capability of an executor, the host uses OID_WWAN_DEVICE_CAPS_EX.

To define the slot that is bound to each executor or query the current mapping, the host uses OID_WWAN_DEVICE_SLOT_MAPPINGS.

To query the status of a particular slot on the modem, the host uses OID_WWAN_SLOT_INFO_STATUS.

Per-device and Per-executor Commands

With the addition of the executor concept to non-Windows Mobile devices in Windows 10, version 1703 and later, OIDs are now split into two categories: per-device OIDs and per-executor OIDs. The table below explains which OIDs fall into which category.

Per-device or Per-executor	OID name
Per-device	OID_WWAN_DRIVER_CAPS
	OID_WWAN_ENUMERATE_DEVICE_SERVICE_COMMANDS
	OID_WWAN_ENUMERATE_DEVICE_SERVICES
	OID_WWAN_PRESHUTDOWN
	OID_WWAN_VENDOR_SPECIFIC
	OID_WWAN_SYS_CAPS
	OID_WWAN_DEVICE_SLOT_MAPPINGS
Per-executor	OID_WWAN_AUTH_CHALLENGE
	OID_WWAN_CONNECT
	OID_WWAN_DEVICE_CAPS

ⓘ Note

OID_WWAN_RADIO_STATE has been updated for Windows 10, version 1703 as well. See OID_WWAN_RADIO_STATE for more information.

MBIM Interface Update for Multi-SIM Operations

For non-Windows Mobile operating systems, a multi-executor modem appears as one USB composite device with multiple MBIM functions. Each MBIM function represents an executor that can maintain registration. Executor-specific commands and notifications are exchanged through the MBIM function representing that executor, while modem-specific commands (in other words, those that are not executor-specific) and their corresponding notifications may be sent to or come from any MBIM function that belongs to the same underlying USB composite device.

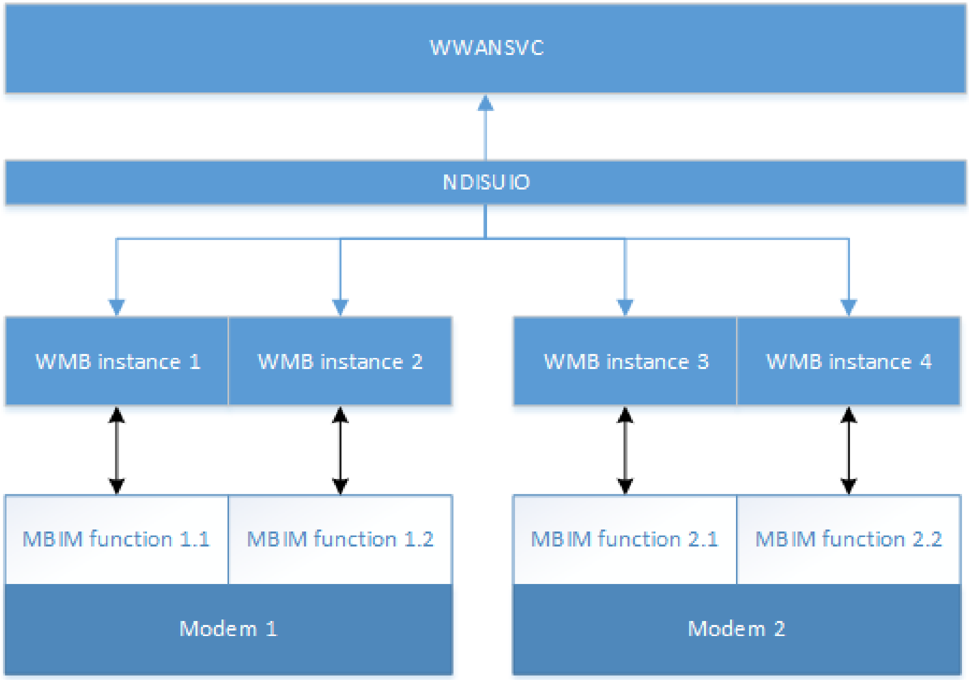
All CID set or query requests issued to a MBIM function are executed against the modem and executor with which the miniport instance is associated; likewise, all unsolicited notifications sent from a MBIM function are applicable to the modem and the executor with which the MBIM function is associated. In the same way, all unsolicited Device Service events sent from a miniport instance are applicable to the modem and the executor with which the MBIM function is associated. For example, an unsolicited MBIM_CID_REGISTER_STATE or MBIM_CID_PACKET_SERVICE notification from a MBIM function indicates the registration or packet service state of the associated modem/executor only and is unrelated to the state of other modem(s) or other executor(s).

When there are multiple modems and/or multiple executors in a device, non-context-specific unsolicited notifications related to a particular modem and executor combination shall be issued from the MBIM function associated with the aforementioned modem and executor.

In a device with multiple modems and/or multiple executors, non-context-specific CID query requests related to a particular modem and executor may be issued to the MBIM function associated with that modem and executor combination. The function receiving such a query request shall process it according to the CID definition. If so chosen by the modem firmware, such a query request may be processed concurrently with any other CID set or query requests being processed by any MBIM functions associated with that modem and executor. All MBIM functions associated with the same modem shall report the same state information for that cellular modem in addition to the executor that they represent.

When there are multiple modems and/or multiple executors in a device, non-executor-specific CID set requests may be issued to the MBIM function associated with that modem and executor. The modem shall keep track of the progress of such requests as a whole. If one such set request is in progress in any adapter and has not completed yet, a second such set request attempt (to any adapter instance associated with the same modem and executor) shall be queued and processed after the previous requests have been completed.

The following diagram illustrates the information flow between the WWANSVC and MBIM functions in two different modems.



This section contains the detailed modem-wide and per-executor CID descriptions for the defined device services. The definitions reference back to existing public MBIM1.0 specification. An MBIM-compliant device implements and reports the following device service when queried by CID_MBIM_DEVICE_SERVICES. The existing well-known services are defined in section 10.1 of the USB NCM MBIM 1.0 specification. Microsoft extends this to define the following service.

Service Name = **Basic Connect Extensions**

UUID = **UUID_BASIC_CONNECT_EXTENSIONS**

UUID Value = **3d01dcc5-fef5-4d05-0d3abef7058e9aaf**

The following CIDs are defined for **UUID_MS_BasicConnect**:

CID	Command Code	Minimum OS Version
MBIM_CID_MS_SYS_CAPS	5	Windows 10, version 1703
MBIM_CID_MS_DEVICE_CAPS_V2	6	Windows 10, version 1703
MBIM_CID_MS_DEVICE_SLOT_MAPPINGS	7	Windows 10, version 1703
MBIM_CID_MS_SLOT_INFO_STATUS	8	Windows 10, version 1703

All offsets in the following CID sections are calculated from the beginning of the InformationBuffer MBIM_COMMAND_MSG.

MBIM_CID_MS_SYS_CAPS

Description

This CID retrieves information about the modem. This can be sent on any of the MB instances exposed as a USB function.

Query

The InformationBuffer on MBIM_COMMAND_MSG contains the response data as MBIM_MS_SYS_CAPS_INFO.

Set

Not applicable.

Unsolicited Event

Not applicable.

Parameters

Operation	Set	Query	Notification
Command	Not applicable	Not applicable	Not applicable
Response	Not applicable	MBIM_MS_SYS_CAPS_INFO	Not applicable

Data Structures

Query

The InformationBuffer shall be null and InformationBufferLength shall be zero.

Set

Not applicable.

Response

The following MBIM_SYS_CAPS_INFO structure shall be used in the InformationBuffer.

Offset	Size	Field	Type	Description
0	4	NumberOfExecutors	UINT32	Number of MBB instances reported by this modem
4	4	NumberOfSlots	UINT32	Number of physical UICC slots available on this modem

Offset	Size	Field	Type	Description
8	4	Concurrency	UINT32	Number of MBB instances that may be active concurrently
12	8	ModemId	UINT64	Unique 64-bit identifier for each modem

The *NumberOfExecutors* field denotes the number of *executors* that are supported by the modem in its current configuration. This directly maps to the number of 'sub-phone' stacks the modem supports.

The *NumberofSlots* field denotes the number of slots that are physically present on the modem. Each slot reported must be capable of receiving a UICC card (the slots themselves can be a heterogeneous mix if needed – mini SIM, micro SIM, nano SIM or any standard as defined by ETSI). The number of slots must be equal to or greater than the number of executors supported. The 'greater than' provision allows use of non-telephony UICC such as for security, NFC, etc.

The *Concurrency* field denotes the number of executors (MBB instances) that may be active at the same time. It range must be *1 ≤ Concurrency ≤ NumberOfExecutors*. For example, a dual-standby modem would have a Concurrency of 1 while a dual-active modem would have a concurrency of 2

The *ModemId* field denotes the unique 64-bit identifier for a given modem hardware. An IHV may implement its own logic to generate a unique 64-bit value for each modem; for instance, hashing one of the IMEI numbers, randomly generating 64-bit numbers, etc. Once the 64-bit ID is generated, it should persist across reboots and SIM card removals/insertions.

Status Codes

This CID uses Generic Status Codes (see Use of Status Codes in Section 9.4.5 of the public USB MBIM standard).

MBIM_CID_MS_DEVICE_CAPS_V2

Description

This CID retrieves the capability information related to an executor. Since this CID is an extension of MBIM_CID_DEVICE_CAPS, only the changes from MBIM_CID_DEVICE_CAPS as stated in Section 10.5.1 of the public USB MBIM standard are presented here.

This CID continues to be query-only and will return a MBIM_MS_DEVICE_CAPS_INFO_V2 structure in response to MBIM_COMMAND_MSG with the MBIM service MSUUID_BASIC_CONNECT and CID MBIM_CID_MS_DEVICE_CAPS_V2.

Parameters

Operation	Set	Query	Notification
Command	Not applicable	Not applicable	Not applicable
Response	Not applicable	MBIM_MS_DEVICE_CAPS_INFO_V2	Not applicable

Data Structures

Query

The same as Section 10.5.1.4 of the public USB MBIM standard.

Set

Not applicable.

Response

The following MBIM_DEVICE_CAPS_INFO_V2 structure shall be used in the InformationBuffer. Compared with the MBIM_CID_DEVICE_CAPS structure defined in section 10.5.1 of the public USB MBIM standard, the following structure has a new field called *DeviceIndex*. Unless stated here, the field descriptions in Table 10-14 of the public USB MBIM standard apply here.

Offset	Size	Field	Type	Description
0	4	DeviceType	MBIM_DEVICE_TYPE	
4	4	CellularClass	MBIM_CELLULAR_CLASS	
8	4	VoiceClass	MBIM_VOICE_CLASS	
12	4	SimClass	MBIM_SIM_CLASS	For MBIM modems which support this CID, SimClass will always be reported as MBIMSimClassSimRemovable.
16	4	DataClass	MBIM_DATA_CLASS	
20	4	SmsCaps	MBIM_SMS_CAPS	
24	4	ControlCaps	MBIM_CTRL_CAPS	
28	4	MaxSessions	UINT32	
32	4	CustomDataClassOffset	OFFSET	
36	4	CustomDataClassSize	SIZE(0..22)	

Offset	Size	Field	Type	Description
40	4	DeviceIdOffset	OFFSET	
44	4	DeviceIdSize	SIZE(0..26)	
48	4	FirmwareInfoOffset	OFFSET	
52	4	FirmwareInfoSize	SIZE(0..60)	
56	4	HardwareInfoOffset	OFFSET	
60	4	HardwareInfoSize	SIZE(0..60)	
64	4	ExecutorIndex	UINT32	The executor index. It ranges from *0* to *n-1* where *n* is the number of MBB instances contained in the MBIM modem. Its value is always constant and independent of the enumeration order.
68		DataBuffer	DATABUFFER	The data buffer containing the *CustomDataClass*, *DeviceId*, *FirmwareInfo*, and *HardwareInfo* members.

Status Codes

This CID uses Generic Status Codes (see Use of Status Codes in Section 9.4.5 of the public USB MBIM standard).

MBIM_CID_MS_DEVICE_SLOT_MAPPINGS

Description

This CID sets or returns the device-slot mappings (in other words the executor-slot mappings).

Query

The InformationBuffer on MBIM_COMMAND_MSG is not used. MBIM_MS_DEVICE_SLOT_MAPPING_INFO is returned in the InformationBuffer of MBIM_COMMAND_DONE.

Set

The InformationBuffer of MBIM_COMMAND_MSG contains MBIM_MS_DEVICE_SLOT_MAPPING_INFO. MBIM_MS_DEVICE_SLOT_MAPPING_INFO is returned in the InformationBuffer of MBIM_COMMAND_DONE. Regardless of whether the Set CID succeeds or fails, the MBIM_MS_DEVICE_SLOT_MAPPING_INFO contained in the response represents the current device-slot mappings.

Unsolicited Events

Not applicable.

Parameters

Operation	Set	Query	Notification
Command	MBIM_MS_DEVICE_SLOT_MAPPING_INFO	Not applicable	Not applicable
Response	MBIM_MS_DEVICE_SLOT_MAPPING_INFO	MBIM_MS_DEVICE_SLOT_MAPPING_INFO	Not applicable

Data Structures

Query

The InformationBuffer shall be null and InformationBufferLength shall be zero.

Set

The following MBIM_MS_DEVICE_SLOT_MAPPING_INFO structure shall be used in the InformationBuffer.

Offset	Size	Field	Type	Description
0	4	MapCount (MC)	UINT32	Number of mappings, which is always equal to the number of devices/executors.
4	8 * MC	SlotMapList	OL_PAIR_LIST	The *i-th* pair of this list, where (0 <= i <= (MC-1)) records the index of the slot which is currently mapped to the *i-th* device/executor. The first element in the pair is a 4-byte field with the Offset into the DataBuffer, calculated from the beginning (offset 0) of this MBIM_MS_DEVICE_SLOT_MAPPINGS_INFO structure, to an UINT32. The second element of the pair is a 4-byte size of the record element. Since the type of the slot index is UINT32, the second element in the pair is always 4.
4 + (8 * MC)	4 * MC	DataBuffer	DATABUFFER	The data buffer that contains *SlotMapList*. Since the size of the slot is 4 bytes and MC is equal to the number of slot indices, the total size of DataBuffer is 4 * MC.

Response

The MBIM_MS_DEVICE_SLOT_MAPPING_INFO used in Set is also used in the InformationBuffer for Response.

Status Codes

Status Code	Description
MBIM_STATUS_BUSY	The operation failed because the device is busy. In the absence of any explicit information from the function to clear this condition, the host can use subsequent actions by the function (e.g., notifications or command completions) as a hint to retry the failed operation.
MBIM_STATUS_FAILURE	The operation failed (a generic failure).
MBIM_STATUS_VOICE_CALL_IN_PROGRESS	The operation failed because a voice call is in progress.
MBIM_STATUS_INVALID_PARAMETERS	The operation failed because of invalid parameters (e.g. slot numbers out of range or duplicated values in the mapping).

MBIM_CID_MS_SLOT_INFO_STATUS

Description

This CID retrieves a high-level aggregated status of a specified UICC slot and the card within it (if any). It may also be used to deliver an unsolicited notification when the status of one of the slots changes.

Query

The InformationBuffer of MBIM_COMMAND_MSG contains an MBIM_MS_SLOT_INFO_REQ structure. The InformationBuffer of the MBIM_COMMAND_DONE message contains an MBIM_MS_SLOT_INFO structure.

Set

Not applicable.

Unsolicited Events

The Event InformationBuffer contains an MBIM_MS_SLOT_INFO structure. The function sends this event in the event that the composite slot/card state changes.

Parameters

Operation	Set	Query	Notification
Command	Not applicable	MBIM_MS_SLOT_INFO_REQ	Not applicable
Response	Not applicable	MBIM_MS_SLOT_INFO	MBIM_MS_SLOT_INFO

Data Structures

Query

The following MBIM_MS_SLOT_INFO_REQ structure shall be used in the InformationBuffer.

Offset	Size	Field	Type	Description
0	4	SlotIndex	UINT32	The index of the slot to be queried.

Set

Not applicable.

Response

The following MBIM_MS_SLOT_INFO structure shall be used in the InformationBuffer.

Offset	Size	Field	Type	Description
0	4	SlotIndex	UINT32	The index of the slot.
4	4	State	MBIM_MS_UICC_SLOT_STATE	The state of the slot and card (if applicable).

The following MBIM_MS_UICCSLOT_STATE structure describes the possible states of the slot.

States	Value	Description
UICCSlotStateUnknown	0	The modem is still in the process of initializing so the SIM slot state is not deterministic.
UICCSlotStateOffEmpty	1	The UICC slot is powered off and no card is present. An implementation that is unable to determine the presence of a card in a slot that is powered off reports its state as UICCSlotStateOff.
UICCSlotStateOff	2	The UICC slot is powered off.
UICCSlotStateEmpty	3	The UICC slot is empty (there is no card in it).

States	Value	Description
UICCSlotStateNotReady	4	The UICC slot is occupied and powered on but the card within it is not yet ready.
UICCSlotStateActive	5	The UICC slot is occupied and the card within it is ready.
UICCSlotStateError	6	The UICC slot is occupied and powered on but the card is in an error state and cannot be used until it is next reset.
UICCSlotStateActiveEsim	7	The card in the slot is an eSIM with an active profile and is ready to accept commands.
UICCSlotStateActiveEsimNoProfiles	8	The card in the slot is an eSIM with no profiles (or no active profiles) and is ready to accept commands.

MBIM_MS_UICCSLOT_STATE transition guidance for multi-sim devices

Conforming to the correct UICC slot state transitions ensures that the OS handles all changes properly and displays the correct toast notifications to the user.

For the *SIM inserted* toast notification, the OS expects the embedded slot (SIM2/Slot 1) to be selected and the following state transition to occur upon the insertion of a SIM in the physical slot (SIM1/Slot 0).

Possible values of Slot 0 before SIM insertion	Possible values of Slot 0 after SIM insertion
UICCSlotStateEmpty	UICCSlotStateActive
UICCSlotStateOffEmpty	• UICCSlotStateActiveEsim • UICCSlotStateActiveEsimNoProfile

For the *SIM removed* toast notification, the OS expects the physical slot (SIM1/Slot 0) to be selected with a SIM inserted and the following state transition to occur upon the removal of the SIM from the physical slot (SIM1/Slot 0).

Possible values of Slot 0 before SIM removal	Possible values of Slot 0 after SIM removal
UICCSlotStateActive	UICCSlotStateEmpty
• UICCSlotStateActiveEsim • UICCSlotStateActiveEsimNoProfile	UICCSlotStateOffEmpty

Status Codes

This CID uses Generic Status Codes (see Use of Status Codes in Section 9.4.5 of the public USB MBIM standard).

Non-NDIS Mapping of Per-executor and Per-modem MBIM CIDs

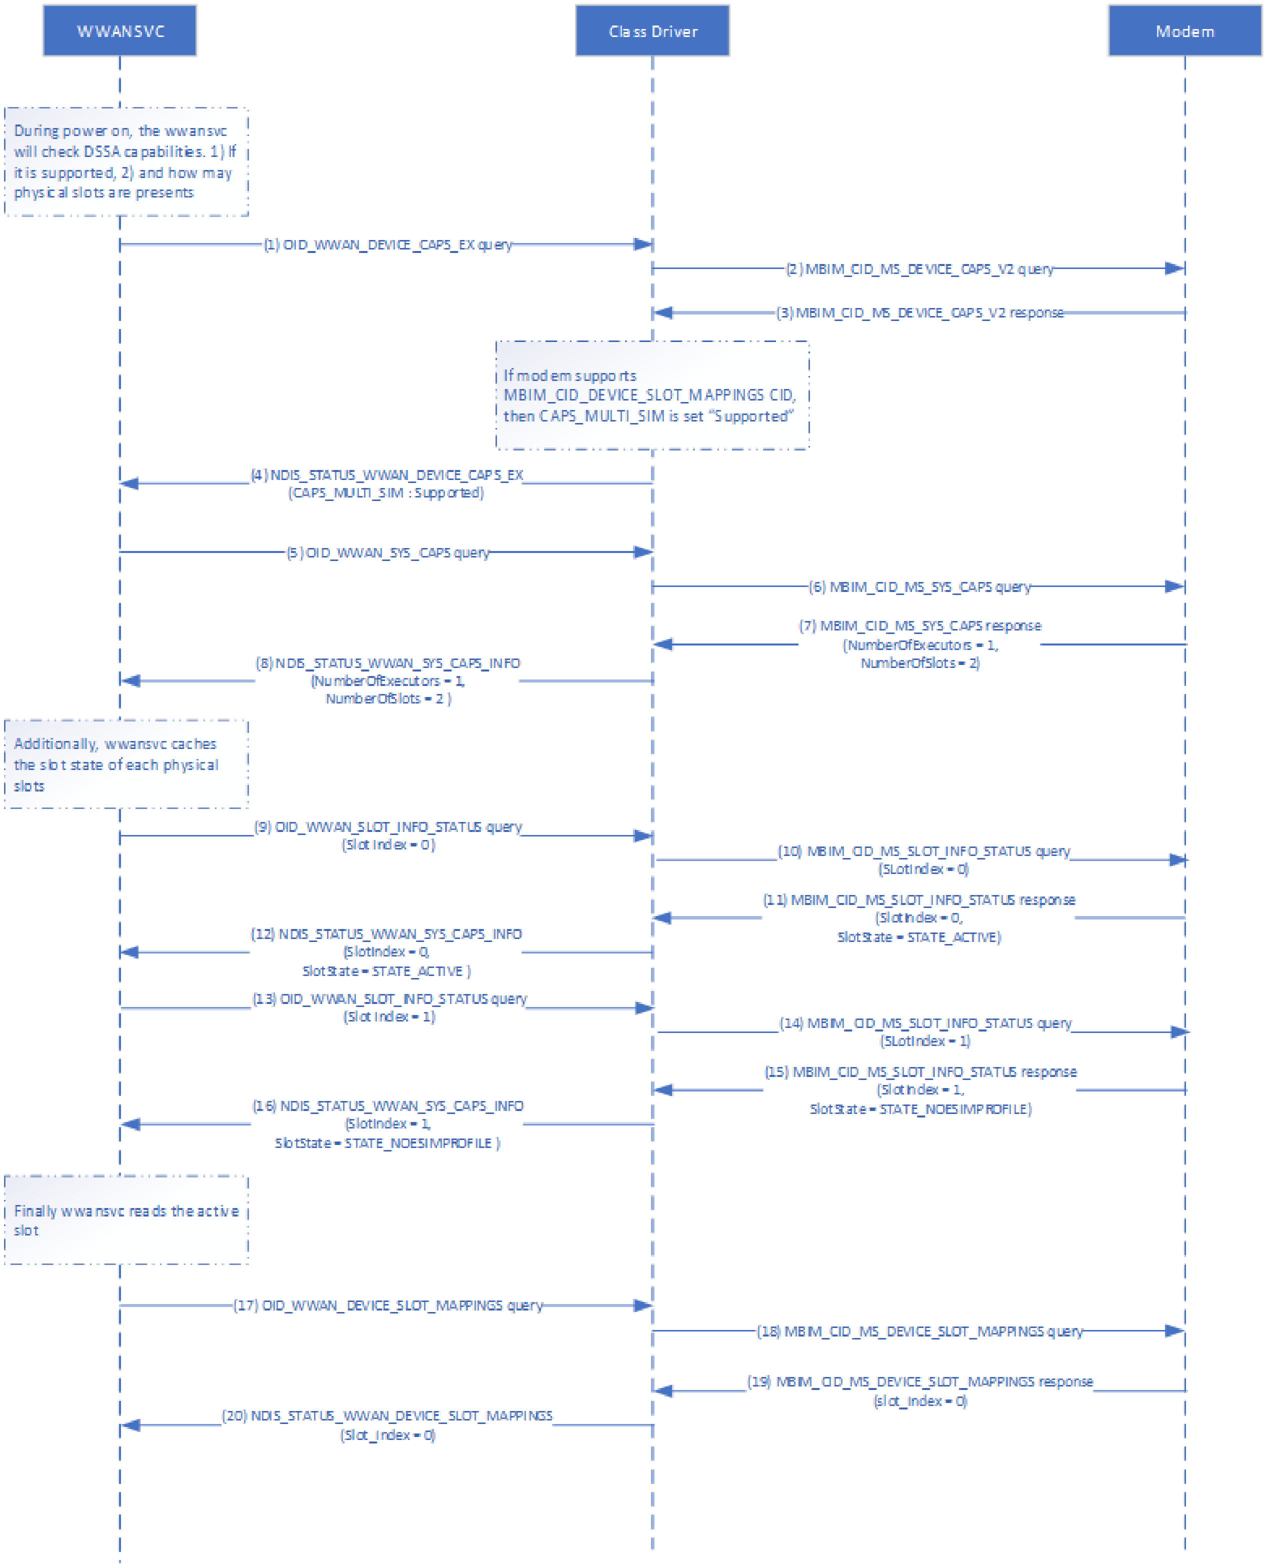
Most of the MBIM CIDs map or relate to NDIS OIDs, but there are a few commands that are used by the Windows WMB class driver that do not have an NDIS counterpart. This section provides clarity on whether those commands are per-modem or per-executor.

Per-device or Per-executor	CID Name
Per-device	CID_MBIM_MSEMERGENCYMODE
	CID_MBIM_MSHOSTSHUTDOWN
Per-executor	CID_MBIM_MSIPADDRESSINFO
	CID_MBIM_MSNETWORKIDLEHINT
	CID_MBIM_MULTICARRIER_CURRENT_CID_LIST

Dual SIM Single Active

Dual SIM single active (DSSA) is the only form of multi-SIM operation that is fully supported in Windows 10. DSSA allows for two SIM cards to be used with the modem, with the restriction that only one SIM can be active at any given time.

Architecture/Flow



WWANSVC
Class Driver
Modem
During power on, the wwansvc will check DSSA capabilities. 1) If it is supported, 2) and how may physical slots are presents
(1) OID_WWAN_DEVICE_CAPS_EX query
(2) MBIM_CID_MS_DEVICE_CAPS_V2 query
(3) MBIM_CID_MS_DEVICE_CAPS_V2 response
If modem supports MBIM_CID_DEVICE_SLOT_MAPPINGS CID, then CAPS_MULTI_SIM is set "Supported"
(4) NDIS_STATUS_WWAN_DEVICE_CAPS_EX (CAPS_MULTI_SIM : Supported)
(5) OID_WWAN_SYS_CAPS query
(6) MBIM_CID_MS_SYS_CAPS query
(7) MBIM_CID_MS_SYS_CAPS response (NumberOfExecutors = 1, NumberOfSlots = 2)
(8) NDIS_STATUS_WWAN_SYS_CAPS_INFO (NumberOfExecutors = 1, NumberOfSlots = 2)
Additionally, wwansvc caches the slot state of each physical slots
(9) OID_WWAN_SLOT_INFO_STATUS query (Slot Index = 0)
(10) MBIM_CID_MS_SLOT_INFO_STATUS query (SLotIndex = 0)
(11) MBIM_CID_MS_SLOT_INFO_STATUS response (SlotIndex = 0, SlotState = STATE_ACTIVE)
(12) NDIS_STATUS_WWAN_SYS_CAPS_INFO (SlotIndex = 0, SlotState = STATE_ACTIVE)
(13) OID_WWAN_SLOT_INFO_STATUS query (Slot Index = 1)
(14) MBIM_CID_MS_SLOT_INFO_STATUS query (SLotIndex = 1)
(15) MBIM_CID_MS_SLOT_INFO_STATUS response (SlotIndex = 1, SlotState = STATE_NOESIMPROFILE)
(16) NDIS_STATUS_WWAN_SYS_CAPS_INFO (SlotIndex = 1, SlotState = STATE_NOESIMPROFILE)
Finally wwansvc reads the active slot
(17) OID_WWAN_DEVICE_SLOT_MAPPINGS query
(18) MBIM_CID_MS_DEVICE_SLOT_MAPPINGS query
(19) MBIM_CID_MS_DEVICE_SLOT_MAPPINGS response (slot_index = 0)
(20) NDIS_STATUS_WWAN_DEVICE_SLOT_MAPPINGS (Slot_Index = 0)

Slot Switch Behavior

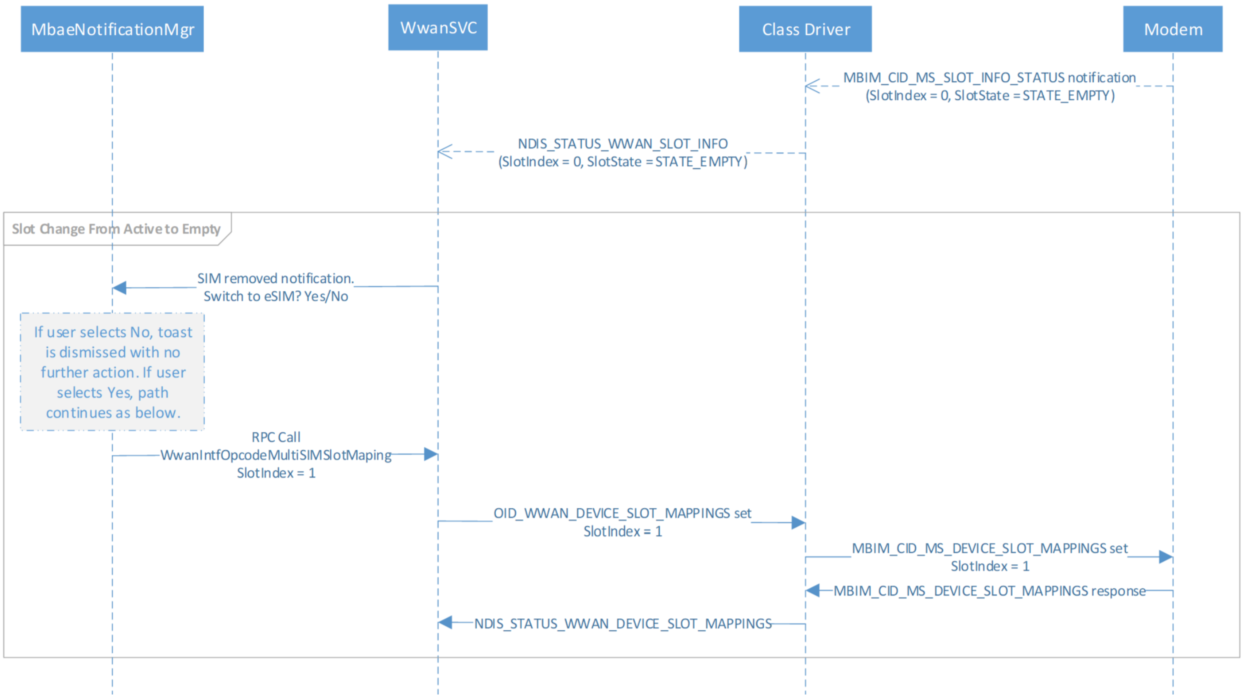
If DSSA is supported on the device, there are some scenarios where slot switch is performed either automatically or prompted by the user via notification toasts.

Out-of-Box Experience (OOBE)

- During OOBE, WwanSvc may perform a slot remap based on the state of the physical slot. If the physical slot is empty, then the embedded slot is selected. If the physical slot has a SIM, the physical slot is selected.

SIM Removal

- If the SIM is removed from the physical slot and the physical slot is the currently selected slot, a toast is displayed asking the user if they want to switch to the embedded slot.
- If the user selects "Yes" then the slot is switched.



MbaeNotificationMgr

SlotIndex = 1
MBIM_CID_MS_DEVICE_SLOT_MAPPINGS response
NDIS_STATUS_WWAN_DEVICE_SLOT_MAPPINGS

SIM Insert

- If auto-switch is enabled via regkey:
  - If the SIM is inserted in the physical slot while the selected slot is embedded, the slot is automatically switched to the physical slot and a toast is displayed informing the user about the switch.
  - The toast has a button that opens the settings page.
- If auto-switch is disabled via regkey
  - If the SIM is inserted in the physical slot while the selected slot is embedded, a toast is displayed asking if the user wants switch to the physical slot.
  - If user selects "Yes" then the slot is switched.

Use this registry key to configure auto-switch. It does not exist by default.

Hardware Lab Kit (HLK) Tests

See Steps for installing HLK .

In HLK Studio connect to the device Cellular modem driver and run the test: Win6_4.MB.GSM.Data.TestSlot. This test contains the following four tests:

Test Name	Description
QuerySlotMapping	This test verifies the test can successfully query devcie slot mapping.
SetSlotMapping	This test verifies the test can successfully set device slot mapping.
QuerySlotInfo	This test verifies the test can successfully query device slot information.
ValidateSlotInfoState	This test validates UICC Slot state against ReadyInfoState.

Alternatively, you can run the **TestSlot** HLK testlist by **netsh-mbn** and **netsh-mbn-test-installation**.

```
netsh mbn test feature=dssa testpath="C:\data\test\bin" taefpath="C:\data\test\bin"
param="AccessString=internet"
```

This file showing the HLK test results should have been generated in the directory that the 'netsh mbn test' command was ran from: `TestSlot.htm`.

Log Analysis

1. Logs can be collected and decoded using these instructions: MB Collecting Logs
2. Open the .txt file in the TextAnalysisTool
3. Load the DSSA filter

Here is an example log for querying and setting slot mappings:

MB Provisioned Context Operations

Article • 03/14/2023

Provisioning is vital for cellular-connectable devices because each mobile operator has different APN configurations for its network. APN configurations can generally be split into two categories:

1. APN configurations that are known to the OS because there are applications or clients above the OS that requires those connections.
2. APN configurations that are not made known to the OS because they are internally consumed by the modem for connections that are not leveraged by the OS and its clients.

Ideally, the modem should only store the APN configurations the OS does not have to know. However, IHV and OEM partners have traditionally provided the Internet and Purchase APNs, configurations known to the OS, in the modem as well. Before Windows 10, version 1703's release, Windows only read the Internet and Purchase APN configurations from the modem to establish Internet connections. Starting in Windows 10, version 1703, there might be additional cases in which the modem's APN configuration would have to be managed by Windows, especially if there are clients in the OS such as user settings or OMA-DM that want to change cellular configuration. This in turn could also affect the modem's APN configuration. For example, there might be an IMS stack in the modem that is using the IMS APN for SMS over IMS. Typically, those connections are not exposed to the OS, but under certain scenarios the IMS APN configuration may have to be changed. This change could be done through the OS. In order to support this, starting in Windows 10, version 1703 the OS can configure different types of APNs into the modem.

The USB forum's MBIM 1.0 and Microsoft NDIS each have an existing CID and OID respectively to allow the OS to set and query the APN configurations in the modem. For MBIM 1.0 it does this through MBIM_CID_PROVISIONED_CONTEXT while for NDIS it does this through OID_WWAN_PROVISIONED_CONTEXTS. However, the existing CID and OID were not designed with clear guidance on how the modem is expected to behave in various situations such as a power cycle or SIM swap. Devices that want to support OS configuring and updating of modem-provisioned contexts going forward will have to implement the newer version of the CID and OID in Windows 10, version 1703. To ensure backward compatibility, for IHVs/OEMs that want to support new hardware on OS versions older than 1703, they will have to continue to support the existing MBIM_CID_PROVISIONED_CONTEXT and OID_WWAN_PROVISIONED_CONTEXTS. Starting from Windows 10, version 1703, if the device supports the new version of the CID and OID then the OS will only use the newer version of the command to query and set APN context configuration in the modem.

MB Interface Update for Provisioned Context Operations

While MBIM has a command for retrieving and replacing contexts stored in the modem, it does not have a field to "disable" or "enable" a profile. Therefore, the existing MBIM_CID_PROVISIONED_CONTEXT must be updated for Windows 10, version 1703 to include this capability. Because MBIM does not have a versioning mechanism, a new MSFT proprietary CID is defined as MBIM_CID_MS_PROVISIONED_CONTEXT_V2.

Service Name = **Basic Connect Extensions**

UUID = **UUID_BASIC_CONNECT_EXTENSIONS**

UUID Value = **3d01dcc5-fef5-4d05-0d3abef7058e9aaf**

CID	Command Code	Minimum OS Version
MBIM_CID_MS_PROVISIONED_CONTEXT_V2	1	Windows 10, version 1703

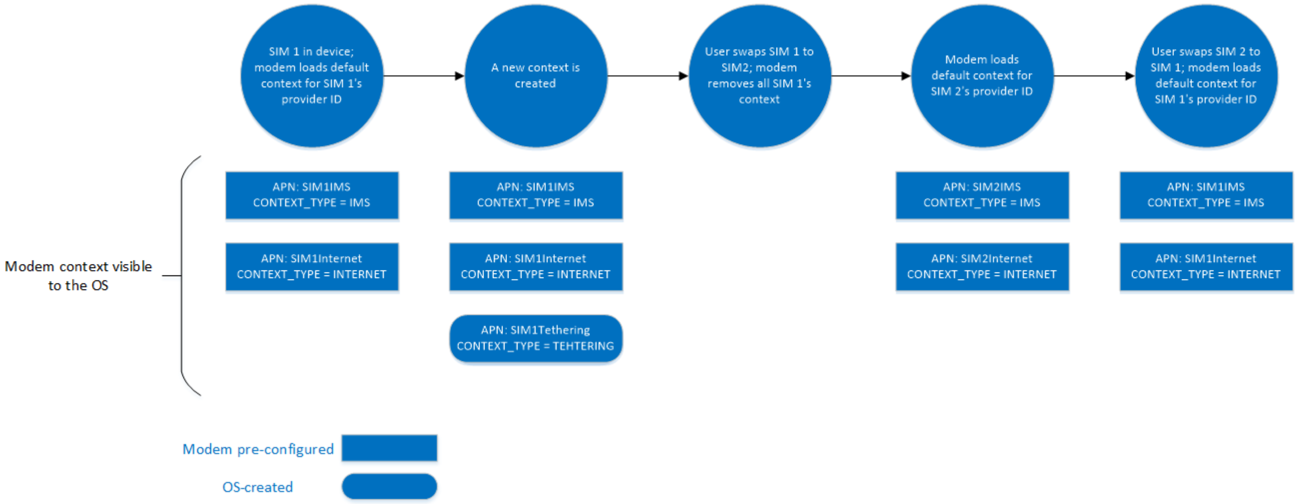
MBIM_CID_MS_PROVISIONED_CONTEXT_V2

Description

Although MBIM 1.0 has defined MBIM_CID_PROVISIONED_CONTEXT for the OS and its upper clients to manage provisioned contexts in the modem, Windows traditionally only queried the context in the modem but did not set it from the OS. Starting in Windows 10, version 1703, there is increasing need for the OS to be able to configure the contexts in the modem. For example, if there is an IMS stack in the modem that is opaque to the OS, the OS should be able to specify the IMS APN that the modem should use. Because each modem IHV can have its own proprietary way to store contexts in the modem, it is impossible for the OS to manage profiles on the ContextId level the way MBIM_CID_PROVISIONED_CONTEXT might suggest. Instead, from the OS's perspective it is more important to prescribe which context to use for each context type. Returning to the IMS example, regardless of how many existing provisioned contexts are in the modem, if the OS sets a context that has MBIM_CONTEXT_TYPE = IMS then all IMS traffic initiated by the modem should only be attempted on that context.

MBIM 1.0 specifies that MBIM_CID_PROVISIONED_CONTEXT can only call Query on contexts that match the Provider ID (MCC/MNC pair) of the inserted SIM card. For Set requests, MBIM_CID_PROVISIONED_CONTEXT can specify the Provider ID of the context that it wants to be stored. MBIM_CID_MS_PROVISIONED_CONTEXT_V2 specifies a similar but different behavior from MBIM 1.0. For each Query, the OS continues to expect the modem to only return contexts that match the Provider ID of the inserted SIM card. For Set, the command will no longer enable the OS to Set contexts that do not match the current Provider ID in the SIM card. It is expected that the Set request is to create a context for the current Provider ID of the presented SIM card. As an example, the user swaps from SIM 1 to SIM 2, then back to SIM 1. It is expected that during first SIM swap, the modem should resolve all its contexts before loading the context for SIM 2. When the user swaps back to SIM 1, SIM 1's factory default configuration should be restored. It is not expected for the modem to save runtime configuration across SIM swaps.

The following diagram illustrates a sample flow for when a user swaps from one SIM to another, then back to the first one.



SIM 1 in device; modem loads default context for SIM 1's provider ID
A new context is created
User swaps SIM 1 to SIM2; modem removes all SIM 1's context
Modem loads default context for SIM 2's provider ID
User swaps SIM 2 to SIM 1; modem loads default context for SIM 1's provider ID
Modem context visible to the OS
APN: SIM1IMS CONTEXT_TYPE = IMS

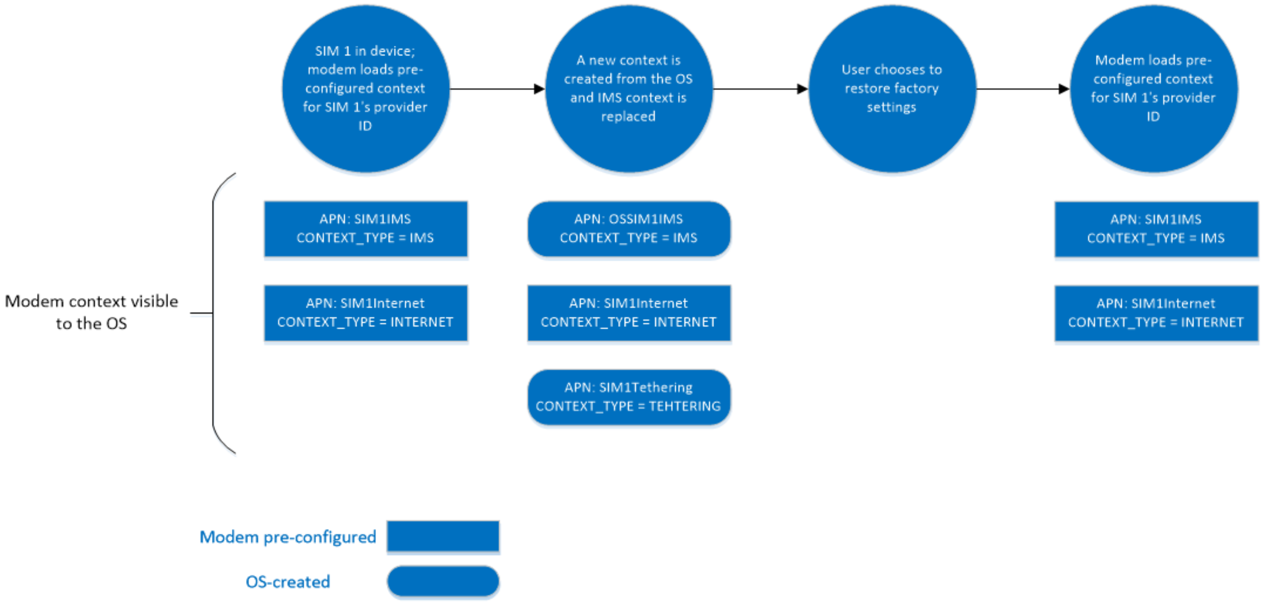
APN: SIM1IMS CONTEXT_TYPE = IMS
APN: SIM1Internet CONTEXT_TYPE = INTERNET
APN: SIM1Tethering CONTEXT_TYPE = TEHTERING
APN: SIM2IMS CONTEXT_TYPE = IMS
APN: SIM2Internet CONTEXT_TYPE = INTERNET
APN: SIM1IMS CONTEXT_TYPE = IMS
APN: SIM1Internet CONTEXT_TYPE = INTERNET
Modem pre-configured
OS-created

OEMs and IHVs that have preconfigured the modem should keep the original factory configuration in case the OS or user wants to restore the context settings in the modem to the original settings. Only the original factory contexts for the currently inserted SIM's Provider ID should be restored. The original factory setting preconfigured contexts should never be overwritten by the OS's configuration. The following diagram is an example flow for when a user chooses to restore factory settings:



SIM 1 in device; modem loads pre-configured context for SIM 1's provider ID
A new context is created from the OS and IMS context is replaced
User chooses to restore factory settings
Modem loads pre-configured context for SIM 1's provider ID
Modem context visible to the OS
APN: SIM1IMS CONTEXT_TYPE = IMS

APN: SIM1IMS CONTEXT_TYPE = IMS
APN: SIM1Internet CONTEXT_TYPE = INTERNET
Modem pre-configured
OS-created

It is expected for the modem to fail Query or Set requests when the SIM is missing, locked, or the Provider ID is inaccessible. The modem should have only one context per CONTEXT_TYPE per Provider ID. If the IHV or OEM decides to preconfigure modem contexts in the modem, it is important for it to make sure that the contexts are configured correctly for each provider for which it chooses to do so. In the case that the inserted SIM card has no IHV preconfigured contexts, the modem should not have any contexts without the OS's configuration. IHVs and OEMs have to make sure MBIM_MS_CONTEXT_SOURCE =

MbimMsContextSourceModemProvisioned so that the OS will use the modem's context for connection, if it exists, and not overwrite it from Windows's APN database.

How the modem maps handle the context and present it back through the existing MBIM_CID_PROVISIONED_CONTEXT is up to each IHV and is out of scope of this documentation.

The new MBIM_CID_MS_PROVISONED_CONTEXT_V2 command is almost identical to MBIM 1.0's existing MBIM_CID_PROVISIONED_CONTEXT command, but with several additions. The first provides the OS with the ability to enable or disable the context associated with a context type in the modem. When the context is disabled in the modem, the modem is expected not to use the stored context for any connection with the network, even those not made aware to the OS. If the OS requests a connection matching a disabled context in the modem, the modem should fail the request immediately without signaling to the network. The matching process should match all fields in the MBIM_MS_CONTEXT_V2 structure.

The MBIM_CONTEXT_IP_TYPE structure from MBIM 1.0 is only used for MBIM_CID_CONNECT. In MBIM_CID_MS_PROVISIONED_CONTEXT_V2, Microsoft has added the IP type as one of the parameters for each context. The modem should report MBIMContextIPTypeDefault if it is not configured for the given context.

In Windows 10, version 1703, with new hardware that supports MBIM_CID_MS_PROVISIONED_CONTEXT_V2, the legacy MBIM_CID_PROVISIONED_CONTEXT will not be used from first party components. If there are other legacy client/OS components that send down MBIM_CID_PROVISIONED_CONTEXT, the modem is expected to return results as it did in versions of Windows earlier than Windows 10, version 1703.

Query

MBIM_MS_PROVISIONED_CONTEXTS_INFO is returned from both Query and Set complete messages in the InformationBuffer.

For Query, the InformationBuffer is null.

Set

For Set, the InformationBuffer contains an MBIM_MS_SET_PROVISIONED_CONTEXT_V2 structure. In the Set operation, because each modem IHV can have proprietary ways of managing context storage, the OS no longer specifies the ContextId field and expects the modem to map the contexts to the appropriate slot. When the OS Sets contexts, it expects the modem to use it for all connections that match the MBIM_CONTEXT_TYPE of the given context. If the MBIM_CONTEXT_TYPE is not recognized by the modem, it should still store it even though it may not connect with it.

Unsolicited Event

The Event InformationBuffer contains an MBIM_MS_PROVISIONED_CONTEXTS_INFO_V2 structure. In some cases, the list of provisioned contexts is updated by the network either Over-The-Air (OTA) or by Short Message Service (SMS) that does not go over the MBIM_CID_MS_PROVISIONED_CONTEXT_V2 command from the OS. The function must update the list of provisioned contexts and tag MBIM_MS_CONTEXT_SOURCE = MbimMsContextSourceOperatorProvisioned accordingly. After that, functions must notify the host about updates using this event with the updated list.

Parameters

Operation	Set	Query	Notification
Command	MBIM_SET_MS_PROVISIONED_CONTEXT_V2	Not applicable	Not applicable
Response	MBIM_MS_PROVISIONED_CONTEXT_INFO_V2	MBIM_MS_PROVISIONED_CONTEXT_INFO_V2	MBIM_MS_PROVISIONED_CONTEXT_INFO_V2

Data Structures

Query

The InformationBuffer shall be NULL and InformationBufferLength shall be zero.

Set

The following MBIM_SET_MS_PROVISIONED_CONTEXT_V2 data structure shall be used in the InformationBuffer.

Offset	Size	Field	Type	Description
0	4	Operation	MBIM_MS_CONTEXT_OPERATIONS	Specifies the type of operation for which the SET command is used. If set to MbimMsContextOperationDelete then the context for the specified MBIM_CONTEXT_TYPES should be deleted and all other fields in MBIM_SET_MS_PROVISIONED_CONTEXT_V2 should be ignored. If set to MbimMsContextOperationRestoreFactory then all OS-created or modified contexts should be removed, the default factory preconfigured contexts should be loaded, and all other fields in MBIM_SET_MS_PROVISIONED_CONTEXT_V2 should be ignored.
4	16	ContextType	MBIM_CONTEXT_TYPES	Specifies the type of context being represented; for example, Internet connectivity, VPN (a connection to a corporate network), or Voice-over-IP (VOIP). For more information, see the MBIM_CONTEXT_TYPES table.
20	4	IPType	MBIM_CONTEXT_IP_TYPES	Specifies the type of context being represented; for example, Internet connectivity, VPN (a connection to a corporate network), or Voice-over-IP (VOIP). For more information, see the MBIM_CONTEXT_IP_TYPES table.
24	4	Enable	MBIM_MS_CONTEXT_ENABLE	Specifies whether the context could be used by the modem. If it is set to MbimMsContextDisabled, then any OS connection request that matches the context should be failed without signaling to the network. For more information, see the MBIM_MS_CONTEXT_ENABLE table.
28	4	Roaming	MBIM_MS_CONTEXT_ROAMING_CONTROL	Specifies whether roaming is allowed or not for this context. For more information, see the MBIM_MS_CONTEXT_ROAMING_CONTROL table.
32	4	MediaType	MBIM_MS_CONTEXT_MEDIA_TYPE	Specifies what type of media transport the context is used for. For more information, see the MBIM_MS_CONTEXT_MEDIA_TYPE table.
36	4	Source	MBIM_MS_CONTEXT_SOURCE	Specifies the creation source of the context. For more information, see the MBIM_MS_CONTEXT_SOURCE table.
40	4	AccessStringOffset	OFFSET	Offset in the data buffer to a string, AccessString, to access the network. For GSM-based networks, this would be an Access Point Name (APN) string such as "data.thephone-company.com". For CDMA-based networks, this might be a special dial code such as "#777" or a Network Access Identifier (NAI) such as "foo@thephone-company.com". This member can be NULL to request that the network assign the default APN. Note: Not all networks support this NULL APN convention, so a connect failure caused by an invalid APN is a possible outcome. The size of the string should not exceed 100 characters.
44	4	AccessStringSize	SIZE(0..200)	Size used for AccessString.
48	4	UserNameOffset	OFFSET	Offset in bytes, calculated from the beginning of this structure, to a string, UserName, that represents the username to authenticate. This member can be NULL.
52	4	UserNameSize	SIZE(0..510)	Size used for UserName .
56	4	PasswordOffset	OFFSET	Offset in bytes, calculated from the beginning of this structure, to a string, Password, that represents the username's password. This member can be NULL.
60	4	PasswordSize	SIZE(0..510)	Size used for Password.
64	4	Compression	MBIM_COMPRESSION	Specifies the compression to be used in the data connection for header and data. This member applies only to GSM-based devices. The Host sets this member to MBIMCompressionNone for CDMA-based devices. For more information, see the MBIM_COMPRESSION table.

Offset	Size	Field	Type	Description
68	4	AuthProtocol	MBIM_AUTH_PROTOCOL	Authentication type to use for the PDP activation. For more information, see the MBIM_AUTH_PROTOCOL table.
72	4	DataBuffer	DATABUFFER	The data buffer that contains AccessString, UserName, and Password.

The following data structures are used in the preceding table.

MBIM_MS_CONTEXT_ROAMING_CONTROL specifies the per-context roaming policy. The OS can specify whether the given context can be enabled during roaming or not. The modem should not self-activate the context without OS intervention if the roaming state does not satisfy the specified conditions. In cases in which the modem does not support partners, then all partner configurations should be treated as equivalent to home.

Type	Value	Description
MbimMsContextRoamingControlHomeOnly	0	Indicates whether the context is only allowed to be used in the home network or not.
MbimMsContextRoamingControlPartnerOnly	1	Indicates whether the context is only allowed to be used in partner roaming networks or not.
MbimMsContextRoamingControlNonPartnerOnly	2	Indicates whether the context is only allowed to be used in non-partner roaming networks or not.
MbimMsContextRoamingControlHomeAndPartner	3	Indicates whether the context is allowed to be used in home and partner roaming networks.
MbimMsContextRoamingControlHomeAndNonPartner	4	Indicates whether the context is allowed to be used in home and non-partner roaming networks.
MbimMsContextRoamingControlPartnerAndNonPartner	5	Indicates whether the context is allowed to be used in partner and non-partner roaming networks.
MbimMsContextRoamingControlAllowAll	6	Indicates whether the context is allowed to be used in any roaming condition.

MBIM_MS_CONTEXT_MEDIA_TYPE has been added to be able to specify whether the context is used for cellular or iWLAN when Wi-Fi offload becomes supported in future platforms. For example, if a context is set as cellular and the modem is currently Wi-Fi offloading then it should not initiate a connection by using that context.

Type	Value	Description
MbimMsContextMediaTypeCellularOnly	0	Indicates whether the context is only allowed to be used when registered over cellular.
MbimMsContextMediaTypeWifiOnly	1	Indicates whether the context is only allowed to be used when registered over iWLAN (Wi-Fi offload).
MbimMsContextMediaTypeAll	2	Indicates whether the context is allowed to be used when registered either through Cellular or Wi-Fi.

MBIM_MS_CONTEXT_ENABLE specifies whether a context is enabled or disabled.

Type	Value	Description
MbimMsContextDisabled	0	The provisioned context is disabled. The modem should not enable activation on this context from the OS and itself.
MbimMsContextEnabled	1	The provisioned context is enabled. The context can be enabled if other conditions are met; for example, if roaming is disallowed then the context should not be enabled during roaming.

MBIM_MS_CONTEXT_SOURCE has been added to give the OS visibility on how the modem context was created. This helps the OS to behave correctly after various situations such as factory reset, so it can know what should persist and what should be returned to default state based on various operator requirements.

Type	Value	Description
MbimMsContextSourceAdmin	0	The context was created by an Enterprise IT admin from the OS.

Type	Value	Description
MbimMsContextSourceUser	1	The context was created by the user through OS settings.
MbimMsContextSourceOperator	2	The context was created by the operator through OMA-DM or other channels.
MbimMsContextSourceModem	3	The context was created by the IHV or OEM that was included with the modem firmware.
MbimMsContextSourceDevice	4	The context was created by the OS APN database.

MBIM_MS_CONTEXT_OPERATIONS specifies the operations the OS can perform to configure contexts in the modem.

Type	Value	Description
MbimMsContextOperationDefault	0	Default operation including adding or replacing an existing context in the modem.
MbimMsContextOperationDelete	1	Delete operation requires the modem to delete an existing context in the modem.
MbimMsContextOperationRestoreFactory	2	Restore factory preconfigured context for the Provider ID of currently inserted SIM. All contexts replaced or created by OS should be removed and replaced. If there is no default preconfigured OS context for the current inserted SIM Provider ID, then the provisioned context in the modem should be removed.

The original MBIM_CONTEXT_TYPES from MBIM 1.0 is still valid. Microsoft is adding additional context types as more types of contexts were introduced since MBIM 1.0 was defined. The following table defines the new types being introduced. IHVs and OEMs may define other proprietary context types with other unique UUID values that will not be recognizable by the OS for its own purposes.

Type	Value	Description
MBIMMsContextTypeAdmin	5f7e4c2e-e80b-40a9-a239-f0abcfd11f4b	The context is used for administrative purposes such as device management.
MBIMMSContextTypeApp	74d88a3d-dfbd-4799-9a8c-7310a37bb2ee	The context is used for certain applications allowlisted by mobile operators.
MBIMMsContextTypeXcap	50d378a7-baa5-4a50-b872-3fe5bb463411	The context is used for XCAP provisioning on IMS services.
MBIMMsContextTypeTethering	5e4e0601-48dc-4e2b-acb8-08b4016bbaac	The context is used for Mobile Hotspot tethering.
MBIMMsContextTypeEmergencyCalling	5f41adb8-204e-4d31-9da8-b3c970e360f2	The context is used for IMS emergency calling.

Response

The following MBIM_MS_PROVISIONED_CONTEXT_INFO_V2 structure shall be used in the InformationBuffer.

Offset	Size	Field	Type	Description
0	4	ElementCount (EC)	UINT32	Count of MBIM_MS_CONTEXT_V2 structures that follow in the DataBuffer.
4	8 * EC	MsProvisionedContextV2RefList	OL_PAIR_LIST	The first element of the pair is a 4 byte Offset in bytes, calculated from the beginning (offset 0) of this MBIM_MS_PROVISIONED_CONTEXTS_INFO_V2 structure, to an MBIM_MS_CONTEXT_V2 structure (for more information, see the MBIM_MS_CONTEXT_V2 table). The second element of the pair is a 4-byte size of a pointer to the corresponding MBIM_MS_CONTEXT_V2 structure.
4 + 8 * EC		DataBuffer	DATABUFFER	Array of MBIM_MS_CONTEXT_V2 structuers.

MBIM_MS_CONTEXT_V2, used in the preceding table, provides information about a given context.

Offset	Size	Field	Type	Description
0	4	ContextId	UINT32	A unique ID for this context.

Offset	Size	Field	Type	Description
4	16	ContextType	MBIM_CONTEXT_TYPES	Specifies the type of context being represented; for example, Internet connectivity, VPN (a connection to a corporate network), or Voice-over-IP (VOIP). Devices should specify MBIMContextTypeNone for empty or un-provisioned contexts. For more information, see the MBIM_CONTEXT_TYPES table.
20	4	IPType	MBIM_CONTEXT_IP_TYPES	For more information, see the MBIM_CONTEXT_IP_TYPES table.
24	4	Enable	MBIM_MS_CONTEXT_ENABLE	Specifies whether the context could be used by the modem. If it is set to MbimMsContextDisabled, then any OS connection request that matches the context should be failed without signaling to the network. For more information, see the MBIM_MS_CONTEXT_ENABLE table.
28	4	Roaming	MBIM_MS_CONTEXT_ROAMING_CONTROL	Specifies whether roaming is allowed or not for this context. For more information, see the MBIM_MS_CONTEXT_ROAMING_CONTROL table.
32	4	MediaType	MBIM_MS_CONTEXT_MEDIA_TYPE	Specifies what type of media transport the context is used for. For more information, see the MBIM_MS_CONTEXT_MEDIA_TYPE table.
36	4	Source	MBIM_MS_CONTEXT_SOURCE	Specifies the creation source of the context. For more information, see the MBIM_MS_CONTEXT_SOURCE table.
40	4	AccessStringOffset	OFFSET	Offset in data buffer to a string, AccessString, to access the network. For GSM-based networks, this would be an Access Point Name (APN) string such as "data.thephone-company.com". For CDMA-based networks, this might be a special dial code such as "#777" or a Network Access Identifier (NAI) such as "foo@thephone-company.com". This member can be NULL, to request that the network assign the default APN. Note: Not all networks support this NULL APN convention, so a connect failure caused by an invalid APN is a possible outcome. The size of the string should not exceed 100 characters.
44	4	AccessStringSize	SIZE(0..200)	Size used for AccessString.
48	4	UserNameOffset	OFFSET	Offset in bytes, calculated from the beginning of this structure, to a string, UserName, that represents the username to authenticate. This member can be NULL.
52	4	UserNameSize	SIZE(0..510)	Sized used for UserName.
56	4	PasswordOffset	OFFSET	Offset in bytes, calculated from the beginning of this structure, to a string, Password, that represents the username's password. This member can be NULL.
60	4	PasswordSize	SIZE(0..510)	Size used for Password.
64	4	Compression	MBIM_COMPRESSION	Specifies the compression to be used in the data connection for header and data. This member applies only to GSM-based devices. The Host sets this member to MBIMCompressionNone for CDMA-based devices. For more information, see the MBIM_COMPRESSION table.
68	4	AuthProtocol	MBIM_AUTH_PROTOCOL	Authentication type to use for the PDP activation. For more information, see the MBIM_AUTH_PROTOCOL table.
72		DataBuffer	DATABUFFER	The data buffer that contains AccessString, UserName, and Password.

Notification

For more information, see the MBIM_MS_PROVISIONED_CONTEXT_V2 table.

Status Codes

For Query and Set operations:

Status Code	Description
MBIM_STATUS_READ_FAILURE	The operation failed because the device was unable to retrieve provisioned contexts.
MBIM_STATUS_NO_DEVICE_SUPPORT	The operation failed because the device does not support the operation.

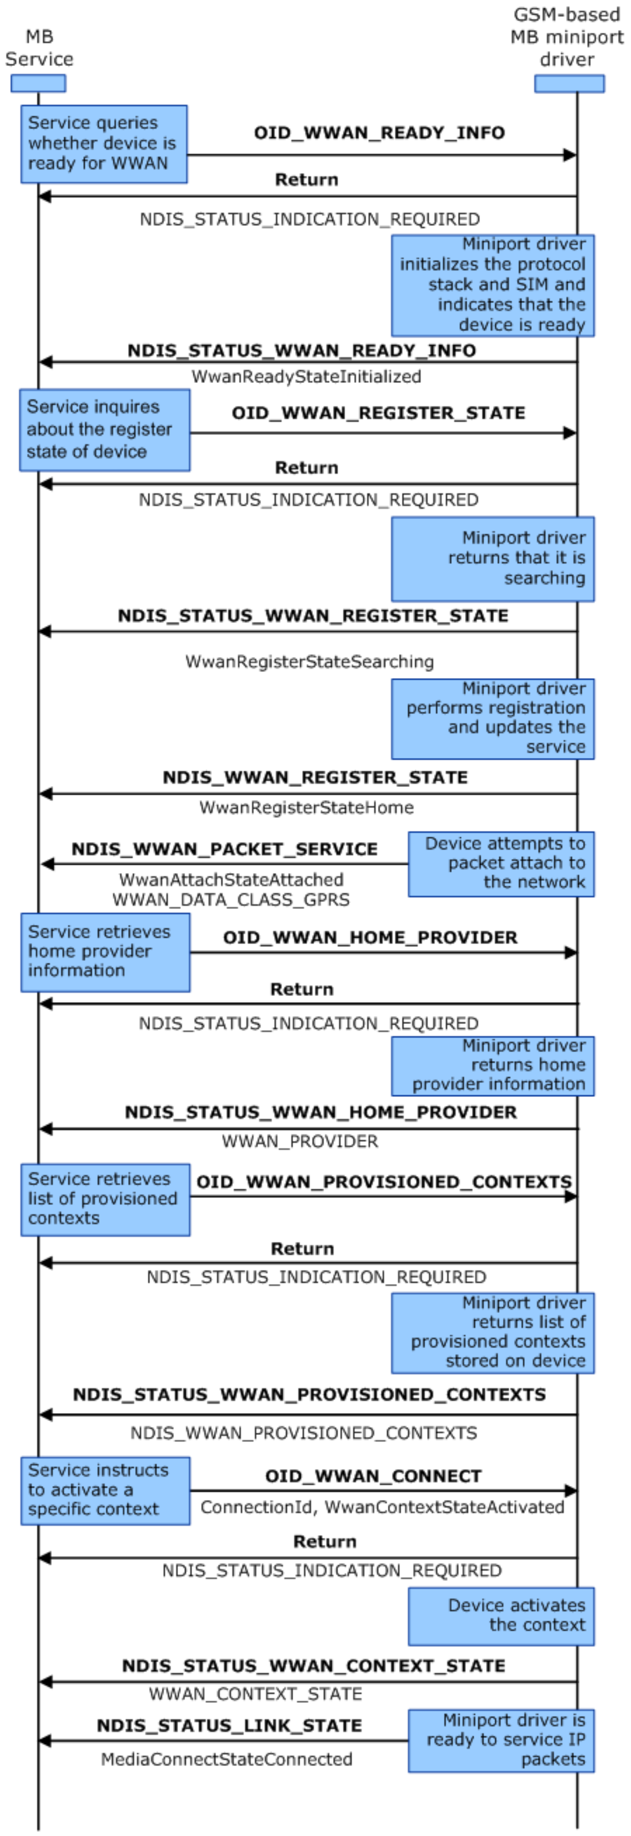
For Set operations only:

Status Code	Description
MBIM_STATUS_INVALID_PARAMETERS	The operation failed because of invalid parameters.
MBIM_STATUS_WRITE_FAILURE	The operation failed because the update request was unsuccessful.

Initialization of devices with a provisioned context

Initialization of a non-SIM-locked GPRS device with a provisioned context

The following diagram represents the optimal user experience for GSM-based MB devices. The out-of-box experience requires no user configuration. It is assumed that the device is configured to automatically select the network to register with. The labels in bold represent OID identifiers or transactional flow control. The labels in regular text represent the important flags within the OID structure.



MB Service
GSM-based MB miniport driver
Service queries whether device is ready for WWAN
OID_WWAN_READY_INFO
Return
NDIS_STATUS_INDICATION_REQUIRED
Miniport driver initializes the protocol stack and SIM and indicates that the device is ready
NDIS_STATUS_WWAN_READY_INFO
WwanReadyStateInitialized
Service inquires about the register state of device
OID_WWAN_REGISTER_STATE
Return
NDIS_STATUS_INDICATION_REQUIRED
Miniport driver returns that it is searching
NDIS_STATUS_WWAN_REGISTER_STATE
WwanRegisterStateSearching
Miniport driver performs registration and updates the service
NDIS_WWAN_REGISTER_STATE
WwanRegisterStateHome
NDIS_WWAN_PACKET_SERVICE
WwanAttachStateAttached
WWAN_DATA_CLASS_GPRS
Device attempts to packet attach to the network
Service retrieves home provider information
OID_WWAN_HOME_PROVIDER
Return
NDIS_STATUS_INDICATION_REQUIRED
Miniport driver returns home provider information
NDIS_STATUS_WWAN_HOME_PROVIDER
WWAN_PROVIDER
Service retrieves list of provisioned contexts
OID_WWAN_PROVISIONED_CONTEXTS
Return
NDIS_STATUS_INDICATION_REQUIRED
Miniport driver returns list of provisioned contexts stored on device
NDIS_STATUS_WWAN_PROVISIONED_CONTEXTS
NDIS_WWAN_PROVISIONED_CONTEXTS
Service instructs to activate a specific context
OID_WWAN_CONNECT
ConnectionId, WwanContextStateActivated
Return
NDIS_STATUS_INDICATION_REQUIRED
Device activates the context
NDIS_STATUS_WWAN_CONTEXT_STATE
WWAN_CONTEXT_STATE
NDIS_STATUS_LINK_STATE
MediaConnectStateConnected
Miniport driver is ready to service IP packets

To initialize a non-SIM-locked GSM-based device, implement the following steps:

1. The MB Service sends an asynchronous (non-blocking) OID_WWAN_READY_INFO query request to the miniport driver to identify the ready state of the device. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and it will send a notification with the requested information in the future.

2. The miniport driver sends an NDIS_STATUS_WWAN_READY_INFO notification to the MB Service that indicates to the MB Service that the state of the MB device is **WwanReadyStateInitialized**.

3. The MB Service sends an asynchronous (non-blocking) OID_WWAN_REGISTER_STATE query request to the miniport driver to identify the registration state of the device. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and it will send a notification with the requested information in the future.

4. The miniport driver sends an NDIS_STATUS_WWAN_REGISTER_STATE notification to the MB Service that indicates that the registration mode of the device is **WwanRegistraterModeAutomatic** and its current registration state is **WwanRegisterStateSearching**.

5. Later, when the device is registered to a network provider, the miniport driver sends an unsolicited NDIS_STATUS_WWAN_REGISTER_STATE notification to the MB Service that indicates that the current registration state of the device is **WwanRegisterStateHome**.

6. The device attempts to attach the packet service. When the packet service state changes to attached, the miniport driver sends an unsolicited NDIS_STATUS_WWAN_PACKET_SERVICE notification to the MB Service that indicates that the packet service is attached and current data class is **WWAN_DATA_CLASS_GPRS**.

7. The MB Service sends an asynchronous (non-blocking) OID_WWAN_HOME_PROVIDER query request to the miniport driver to retrieve home provider information. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that is has received the request, and it will send a notification with the requested information in the future.

8. The miniport driver sends an NDIS_STATUS_WWAN_HOME_PROVIDER notification to the MB Service that indicates the home provider details.

9. The MB Service sends an asynchronous (non-blocking) OID_WWAN_PROVISIONED_CONTEXTS query request to the miniport driver to retrieve the list of provisioned contexts. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and it will send a notification with the requested information in the future.

10. The miniport driver sends an NDIS_STATUS_WWAN_PROVISIONED_CONTEXTS notification to the MB Service that contains a list of WWAN_CONTEXT structures.

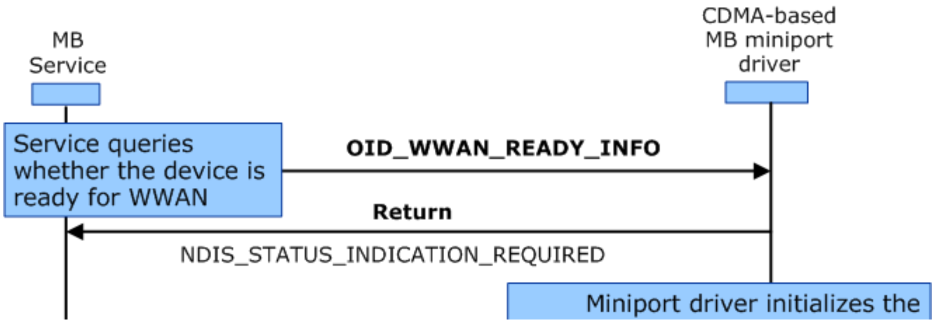
11. The MB Service sends an asynchronous (non-blocking) OID_WWAN_CONNECT set request to the miniport driver to activate the Packet Data Protocol (PDP) context. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and it will send a notification with the requested information in the future.

12. The miniport driver sends an NDIS_STATUS_WWAN_CONTEXT_STATE notification to the MB Service that indicates that the PDP context is activated.

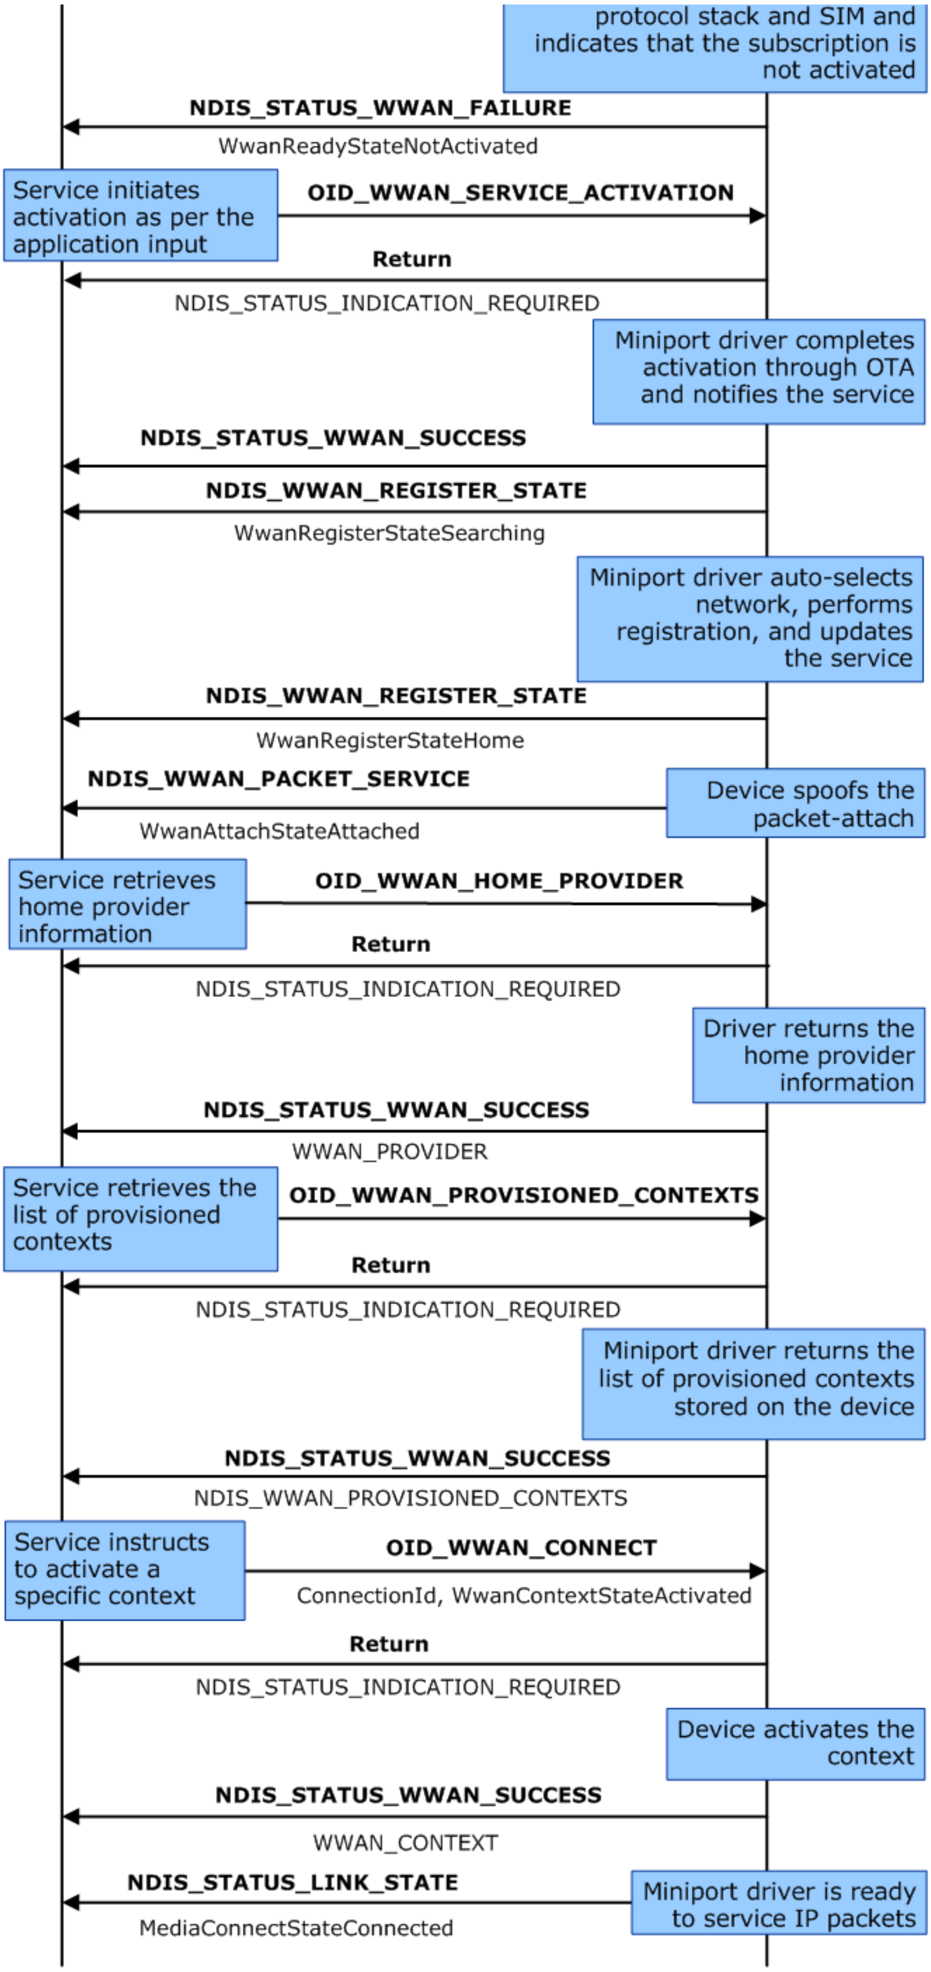
13. The miniport driver sends an NDIS_STATUS_LINK_STATE notification to indicate that the media connect state is **MediaConnectStateConnected**.

Initialization of a CDMA Packet Device with a Provisioned Context

The following diagram illustrates the optimal user experience for CDMA-based devices. The out-of-box experience does not require user configuration. This scenario assumes that the CDMA-based account has not been activated. Unlike GSM-based devices, a CDMA-based device automatically starts registration with the network after activation is complete. The labels in bold are OID identifiers or transactional flow control. The labels in regular text are the important flags within the OID structure.



MB Service
CDMA-based MB miniport driver
Service queries whether the device is ready for WWAN
OID_WWAN_READY_INFO
Return
NDIS_STATUS_INDICATION_REQUIRED
Miniport driver initializes the



protocol stack and SIM and indicates that the subscription is not activated
NDIS_STATUS_WWAN_FAILURE
WwanReadyStateNotActivated
Service initiates activation as per the application input
OID_WWAN_SERVICE_ACTIVATION
Return
NDIS_STATUS_INDICATION_REQUIRED
Miniport driver completes activation through OTA and notifies the service
NDIS_STATUS_WWAN_SUCCESS
NDIS_WWAN_REGISTER_STATE
WwanRegisterStateSearching
Miniport driver auto-selects network, performs registration, and updates the service
NDIS_WWAN_REGISTER_STATE
WwanRegisterStateHome
NDIS_WWAN_PACKET_SERVICE
Device spoofs the packet-attach
WwanAttachStateAttached
Service retrieves home provider information
OID_WWAN_HOME_PROVIDER
Return
NDIS_STATUS_INDICATION_REQUIRED
Driver returns the home provider information
NDIS_STATUS_WWAN_SUCCESS
WWAN_PROVIDER
Service retrieves the list of provisioned contexts
OID_WWAN_PROVISIONED_CONTEXTS
Return
NDIS_STATUS_INDICATION_REQUIRED
Miniport driver returns the list of provisioned contexts stored on the device
NDIS_STATUS_WWAN_SUCCESS
NDIS_WWAN_PROVISIONED_CONTEXTS
Service instructs to activate a specific context
OID_WWAN_CONNECT
ConnectionId, WwanContextStateActivated
Return
NDIS_STATUS_INDICATION_REQUIRED
Device activates the context
NDIS_STATUS_WWAN_SUCCESS
WWAN_CONTEXT
NDIS_STATUS_LINK_STATE
Miniport driver is ready to service IP packets
MediaConnectStateConnected

To initialize a CDMA-based packet device with a provisioned context, implement the following steps:

1. The MB Service sends an asynchronous (non-blocking) OID_WWAN_READY_INFO to the miniport driver. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and that it will send a notification with the requested information in the future.
2. The miniport driver sends NDIS_STATUS_WWAN_FAILURE to the MB Service.
3. The MB Service sends an asynchronous (non-blocking) OID_WWAN_SERVICE_ACTIVATION to the miniport driver. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and that it will send a notification with the requested information in the future.
4. The miniport driver sends NDIS_STATUS_WWAN_SUCCESS to the MB Service.
5. The miniport driver sends **NDIS_STATUS_WWAN_REGISTER_STATE** to the MB Service.
6. The miniport driver sends **NDIS_STATUS_WWAN_REGISTER_STATE** to the MB Service.
7. The miniport driver sends **NDIS_STATUS_WWAN_PACKET_SERVICE** to the MB Service.
8. The MB Service sends an asynchronous (non-blocking) OID_WWAN_HOME_PROVIDER to the miniport driver. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and that it will send a notification with the requested information in the future.
9. The miniport driver sends NDIS_STATUS_WWAN_SUCCESS to the MB Service.
10. The MB Service sends an asynchronous (non-blocking) OID_WWAN_PROVISIONED_CONTEXTS to the miniport driver. The miniport driver responds with a provisional acknowledgement (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and that it will send a notification with the requested information in the future.
11. The miniport driver sends NDIS_STATUS_WWAN_SUCCESS to the MB Service.
12. The MB Service sends an asynchronous (non-blocking) OID_WWAN_PROVISIONED_CONTEXTS to the miniport driver. The miniport driver responds with a provisional acknowledgment (NDIS_STATUS_INDICATION_REQUIRED) that it has received the request, and it will send a notification with the requested information in the future.
13. The miniport driver sends NDIS_STATUS_WWAN_SUCCESS to the MB Service.
14. The miniport driver sends **NDIS_STATUS_LINK_STATE** to the MB Service.

ⓘ Important

Bias-free communication

Microsoft supports a diverse and inclusive environment. This article contains references to terminology that the Microsoft **style guide for bias-free communication** recognizes as exclusionary. The word or phrase is used in this article for consistency because it currently appears in the software. When the software is updated to remove the language, this article will be updated to be in alignment.

A device could be required to not register to a network under various scenarios, such as when a specific SIM card is inserted or if a device does not want to register to a specific network. To address these situations, Windows 10, version 1703 is adding modem interfaces to enable the OS to configure blacklists for SIM cards and network providers.

At any time, the OS can configure the MCC/MNC pair in the modem to specify the SIM or network to which the device is not allowed to register. The interface is flexible enough to allow two different lists, one for SIM providers, and another for network providers. If the device did not attempt registration because a particular SIM or network provider was blacklisted, the modem must report the registration status as denied.

MB Interface Update for Network Blacklist Operations

A new MBIM command has been created to enable the OS to query and set the MCC and MNC pair with which the modem should not attempt registration when a matching SIM cards or network provider is present on the device. For this command, a new MSFT proprietary CID has been defined as MBIM_CID_MS_NETWORK_BLACKLIST.

Service Name = **Basic Connect Extensions**

UUID = **UUID_BASIC_CONNECT_EXTENSIONS**

UUID Value = **3d01dcc5-fef5-4d05-0d3abef7058e9aaf**

CID	Command Code	Minimum OS Version
MBIM_CID_MS_NETWORK_BLACKLIST	2	Windows 10, version 1703

MBIM_CID_MS_NETWORK_BLACKLIST

Description

Enterprises, users or mobile operators may specify the SIM cards and networks on which they do not want the modem to register. This command is used for the OS to be able to query and set the blacklists on the modem. There are two blacklists:

1. A SIM card blacklist – SIM cards whose provider is a member of the blacklist should not be allowed to register on any network.
2. A network provider blacklist – networks on the blacklist should not be allowed to register regardless of what SIM card is present on the device.

The modem has to maintain both blacklists per modem and persist across SIM swaps and power cycles. Both blacklists can be accessed with Query or Set at all times, regardless of the SIM state.

For the Set command it is expected to overwrite the existing blacklists in the modem with the Set command's payload.

Query

MBIM_MS_NETWORK_BLACKLIST_INFO is returned from completed Query and Set messages in the InformationBuffer. For Query, the InformationBuffer is NULL.

Set

For Set, the InformationBuffer contains an MBIM_MS_NETWORK_BLACKLIST_INFO. In the Set operation, a list of MNC/MCC combinations should be provided to the modem. When the SIM card's IMSI matches the MNC and MCC value specified, the modem should deregister from the network and should not try to reregister until a new SIM card that does not match the MNC/MCC is inserted.

Unsolicited Event

An Unsolicited Event is expected if any of the blacklist states have changed from actuated to not actuated, or vice versa; for example, if a SIM is inserted whose provider matches the SIM provider blacklist.

Parameters

Operation	Set	Query	Notification
Command	MBIM_MS_NETWORK_BLACKLIST_INFO	Not applicable	Not applicable
Response	MBIM_MS_NETWORK_BLACKLIST_INFO	MBIM_MS_NETWORK_BLACKLIST_INFO	MBIM_MS_NETWORK_BLACKLIST_INFO

Data Structures

Query

The InformationBuffer shall be NULL and InformationBufferLength shall be zero.

Set

The following MBIM_MS_NETWORK_BLACKLIST_INFO structure shall be used in the InformationBuffer.

Offset	Size	Field	Type	Description
0	4	BlacklistState	MBIM_MS_NETWORK_BLACKLIST_STATE	Indicates whether any of the blacklist conditions are met that result in the modem not registering to the network. For more information, see the MBIM_MS_NETWORK_BLACKLIST_STATE table.
4	4	ElementCount (EC)	UINT32	Count of MBIM_MS_NETWORK_BLACKLIST_PROVIDER structures that follow in the DataBuffer.

Offset	Size	Field	Type	Description
8	8 * EC	BlacklistProviderRefList	OL_PAIR_LIST	The first element of the pair is a 4 byte offset, calculated from the beginning (offset 0) of this MBIM_MS_NETWORK_BLACKLIST_INFO structure, to a MBIM_MS_NETWORK_BLACKLIST_PROVIDER structure. For more information, see the MBIM_MS_NETWORK_BLACKLIST_PROVIDER table. The second element of the pair is a 4-byte size of a pointer to the corresponding MBIM_MS_NETWORK_BLACKLIST_PROVIDER structure.
8 + (8 * EC)		DataBuffer	DATABUFFER	Array of MBIM_MS_NETWORK_BLACKLIST_PROVIDER structures.

The following data structures are used in the preceding table.

MBIM_MS_NETWORK_BLACKLIST_STATE describes the possible states of the two different blacklists.

Type	Mask	Description
MbimMsNetworkBlacklistStateNotActuated	0h	Both blacklist conditions are not met.
MbimMsNetworkBlacklistSIMProviderActuated	1h	Inserted SIM is blacklisted as its Provider ID matches the blacklist for SIM Provider ID.
MbimMsNetworkBlacklistNetworkProviderActuated	2h	Available networks are blacklisted since their Provider IDs are all in the blacklist for network Provider ID.

MBIM_MS_NETWORK_BLACKLIST_PROVIDER specifies the provider of the blacklist.

Offset	Size	Field	Type	Description
0	4	MCC	UINT32	As specified by 3GPP, MCC is part of IMSI and specifies the country of the provider.
4	4	MNC	UINT32	As specified by 3GPP, MNC is part of IMSI and specifies the network of the provider.
8	4	NetworkBlacklistType	MBIM_MS_NETWORK_BLACKLIST_TYPE	Specifies for which type of blacklist the MCC/MNC pair is used. For more information, see the MBIM_MS_NETWORK_BLACKLIST_TYPE table.

MBIM_MS_NETWORK_BLACKLIST_TYPE is used by the preceding data structure. It specifies which of the two blacklists will be used.

Type	Value	Description
MbimMsNetworkBlacklistTypeSIM	0	The MCC/MNC pair are used for SIM provider blacklist.
MbimMsNetworkBlacklistTypeNetwork	1	The MCC/MNC pair are used for network provider blacklist.

Response

For more information, see the MBIM_MS_NETWORK_BLACKLIST_INFO table.

Status Codes

For Query and Set operations:

Status Code	Description
MBIM_STATUS_READ_FAILURE	The operation failed because the device was unable to retrieve provisioned contexts.
MBIM_STATUS_NO_DEVICE_SUPPORT	The operation failed because the device does not support the operation.

For Set operations only:

Status Code	Description
MBIM_STATUS_INVALID_PARAMETERS	The operation failed because of invalid parameters.
MBIM_STATUS_WRITE_FAILURE	The operation failed because the update request was unsuccessful.

MB LTE Attach Operations

Article • 03/14/2023

LTE Attach APN Configuration for MBIM Modems

Traditionally, LTE attach has been considered part of registration and Windows has not directly been involved in LTE attach procedures. However, unlike typical circuit switch network registrations, LTE is a packet switch-only network and requires a default EPS bearer to be enabled for the device to maintain registration on the LTE network.

To establish a default EPS bearer with the network the device must request a PDP context activation during the LTE attach procedure, which requires Access Point Name (APN) specification. Per the 3GPP standard, there are four scenarios where a device can specify APN when it is trying LTE attach:

1. The device specifies a specific LTE attach APN.
2. The device specifies a specific LTE attach APN but the network decides to let the device attach on another APN instead during roaming.
3. The device does not specify a LTE attach APN and lets network assign one back to the device.
4. The device registered from a 2G/3G network to LTE and there was already at minimum one active PDP context. The network uses it as the LTE attach APN.

Today, all LTE attach APN information is provided by IHVs and OEMs directly in the modem for each provider for which it has configuration. However, it is not a fully scalable model for IHVs and OEMs to have all possible LTE attach APN settings for all operators around the globe. Starting in Windows 10, version 1703, new interfaces are defined for both NDIS OIDs and MBIM Microsoft proprietary CIDs to support LTE attach APN configuration from the OS.

Starting in Windows 10, version 1703, if the underlying hardware supports LTE attach APN configuration from the OS then the user will be able to configure the LTE attach APN from Settings. Hardware that has default LTE attach APN configurations must also make its configuration available by the OS.

This feature is supported by adding in two new OIDs and CIDs. For IHV partners that implement MBIM, only the CID version has to be supported.

MB Interface Update for LTE Attach Operations

Two new MBIM CIDs have been created to allow for LTE attach APN configuration and for the OS to retrieve the latest LTE attach status of the device. If IHV partners decide to support OS default LTE attach APN management then both commands must be supported.

Service Name = **Basic Connect Extensions**

UUID = **UUID_BASIC_CONNECT_EXTENSIONS**

CID	Command Code	Minimum OS Version
MBIM_CID_MS_LTE_ATTACH_CONFIG	3	Windows 10, version 1703
MBIM_CID_MS_LTE_ATTACH_STATUS	4	Windows 10, version 1703

MBIM_CID_MS_LTE_ATTACH_CONFIG

Description

LTE attach contexts can be different , depending on how the network interacts with the device during runtime. For the rest of this documentation, LTE attach context will be referred to as the current PDP context that is being used for LTE attach and default LTE attach context will be referred to as what is configured on the device performing LTE attach with when there is no other existing enabled PDP context. MBIM_CID_MS_LTE_ATTACH_CONFIG enables the OS to Query and Set the default LTE attach context of the inserted SIM's provider (MCC/MNC pair).

Although the LTE attach APN could be technically considered as a context, it differs from all other contexts stored in the modem. For all other contexts activation happens after registration and, based on various conditions, the OS can decide which context is the best fit for connection. However, the LTE attach context is enabled as part of device registration on the LTE network. The OS is unable to retrieve any network-related status before the completion of registration; because of this limitation, the OS must be able to configure LTE attach context for all different roaming conditions of the device to make sure the device can register on the LTE network regardless of what the roaming status is.

LTE attach context activation with the network does not require an OS-explicit connection request as the OS is not aware of any modem self-initiated context activation. Default LTE attach context falls into this category. When the OS issues a MBIM_CID_CONNECT request to enable a PDP context and the given PDP context matches all the following, the modem should complete the CID activation request with success without bringing up a new over-the-air bearer with the network:

1. There is an existing enabled PDP context that is initiated by the modem and not made available to the OS.
2. The PDP context matches the specified APN in the CID request.
3. The IP type of the enabled PDP context is compatible with the requested IP type in the CID.

This is important as the OS is not aware of all the PDP contexts that were initiated by the modem. This will reduce network noise and load. Otherwise, the modem should bring up a new over-the-air bearer matching OS APN specification as per a normal context activation request. The IP type compatibility is specified here:

IP type of the enabled PDP context within the modem	Compatible with requested IP type(s)	Incompatible with requested IP type
IPv4	Default; IPv4; IPv4v6; IPv4 and v6	IPv6
IPv6	Default; IPv6; IPv4v6; IPv4 and v6	IPv4
IPv4v6	Default; IPv4; IPv6; IPv4v6; IPv4 and v6	None

ⓘ **Note**

The modem should not bring up a second PDP context if only one of the IP type is enabled over the air. For example, if IPv4 is enabled and the host requests IPv4 and IPv6 then the modem should complete the activation request without bringing up an IPv6 bearer.

When the OS issues a MBIM_CID_CONNECT request to deactivate a PDP context then the modem should check the following:

1. Whether the device is LTE attached and the context to be deactivated is the only enabled PDP context to maintain LTE registration
2. Whether the context to be deactivated is also used by the modem internally for any services that are not exposed to the OS

If either of these are true, then the modem should complete the CID deactivation request but continue to maintain the over-the-air bearer with the network. Otherwise the modem should deactivate the context as per normal deactivation requests.

All default LTE attach APN configuration provided by the OS is per-provider and matches to the inserted SIM card's home Provider ID (MCC/MNC pair). The modem should only provide configured LTE attach context for the current inserted SIM's Provider ID when queried. The modem should always return three default LTE attach contexts that matches the inserted SIM's Provider ID, one for each roaming condition (home/partner/non-partner).

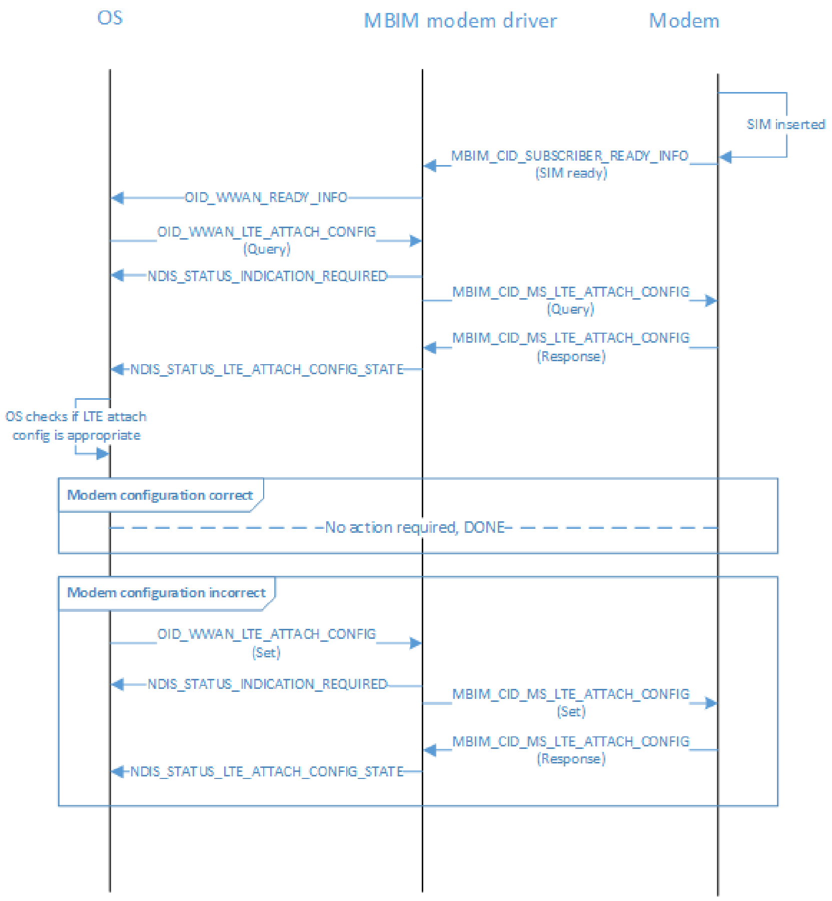
It is expected that across SIM swaps, the modem should clear its default LTE attach context before applying the configuration for the next SIM card. If the newly inserted SIM card has no default LTE attach context configuration, then the device should return NULL empty strings for the APN of the LTE attach context for all roaming conditions while keeping the context enabled. If the context is disabled, it is expected for the device to not attach on LTE because there is no usable configuration for LTE attach. When the user swaps back to a SIM card that was previously configured on the device, the modem should restore its factory default LTE attach configuration for the SIM card. It is not expected for run time configuration to persist across SIM swaps. At any time, there should only be one default LTE attach APN in the modem per roaming condition (home/partner/non-partner).

The OS will always set all three default LTE attach contexts when a Set command is issued, one for each roaming condition. If the list provided by the OS does not have exactly three then the Set command should be rejected. If one of the provided default LTE attach contexts is configured by the OS where the roaming condition matches the current registration status, then the modem should detach from the network and re-perform LTE attach with the newly specified LTE attach context. Otherwise, the device is expected to use the specified default LTE attach context the next time when roaming conditions match. If the device-specified default LTE attach context fails to register on LTE network, then the device should fall back to 3G/2G as appropriate. When the modem cannot differentiate between partner and non-partner networks, the modem should use the non-partner default LTE attach context for all roaming scenarios. If the OS configures default LTE attach context as IP type = default, then it is expected for the modem to assign the most appropriate IP type for LTE attach context. However, the OS expects the modem to still return partner roaming conditions and IP type of LTE attach context that reflects the configuration accurately.

IHVs and OEMs can preconfigure LTE attach context as the default configuration in the modem, but those contexts must be tagged as MBIM_MS_CONTEXT_SOURCE = MbimMsContextSourceModemProvisioned.

Per the 3GPP standard, the default LTE attach context can be split into two categories: UE-initiated and network-initiated. If the device is configured with a NULL empty access string, the device is expected not to provide any LTE attach context to the network and wait for the network to assign one back to the device. Just as prescribed by MBIM 1.0, if the LTE attach context's IP type is configured to be default then the modem should select the best IP type based on its internal algorithm.

The following diagram illustrates an example flow of LTE attach configuration.



OS
MBIM modem driver
Modem
SIM inserted

No action required, DONE
Modem configuration incorrect
OID_WWAN_LTE_ATTACH_CONFIG
(Set)
NDIS_STATUS_INDICATION_REQUIRED
MBIM_CID_MS_LTE_ATTACH_CONFIG
(Set)
MBIM_CID_MS_LTE_ATTACH_CONFIG
(Response)
NDIS_STATUS_LTE_ATTACH_CONFIG_STATE

Query

MBIM_MS_LTE_ATTACH_CONFIG_INFO is returned from completed Query and Set messages in the InformationBuffer. For Query, the InformationBuffer is NULL.

Set

For Set, the InformationBuffer contains an MBIM_MS_SET_LTE_ATTACH_CONFIG.

Unsolicited Events

The Event InformationBuffer contains an MBIM_MS_LTE_ATTACH_CONFIG_INFO structure. In some cases, the default LTE attach context is updated by the network either Over-The-Air (OTA) or by Short Message Service (SMS) that does not go over the

MBIM_CID_MS_LTE_ATTACH_CONFIG command from the OS. The function must update default LTE attach contexts and tag MBIM_MS_CONTEXT_SOURCE = MbimMsContextSourceOperatorProvisioned accordingly. After that, functions must notify the Host about updates that use this event with the updated list.

Parameters

Operation	Set	Query	Notification
Command	MBIM_SET_MS_LTE_ATTACH_CONFIG	Not applicable	Not applicable
Response	MBIM_MS_LTE_ATTACH_CONFIG_INFO	MBIM_MS_LTE_ATTACH_CONFIG_INFO	MBIM_MS_LTE_ATTACH_CONFIG_INFO

Data Structures

Query

The InformationBuffer shall be NULL and InformationBufferLength shall be zero.

Set

The following MBIM_MS_SET_LTE_ATTACH_CONFIG structure shall be used in the InformationBuffer. The Set command is only valid if the list contains an element count of three, one for each roaming condition (home/partner/non-partner).

Offset	Size	Field	Type	Description
0	4	Operation	MBIM_MS_LTE_CONTEXT_OPERATIONS	Specifies the type of operation for which the Set command is used. If set to MbimMsLteAttachContextOperationRestoreFactory then all other fields should be ignored. OS-created or -modified default LTE attach contexts should be removed and the default factory preconfigured default LTE attach contexts should be loaded. If the modem does not have a default configuration, then all roaming condition default LTE attach contexts should be set to an empty APN string and IP type = default.
4	4	ElementCount (EC)	UINT32	Count of MBIM_MS_LTE_ATTACH_CONTEXT structures that follow in the DataBuffer. This component is currently specified to three, one for each roaming condition (home/partner/non-partner).
8	8 * EC	MsLteAttachContextRefList	OL_PAIR_LIST	The first element of the pair is a 4-byte offset, calculated from the beginning (offset 0) of this MBIM_MS_LTE_ATTACH_CONFIG_INFO structure, to an MBIM_MS_LTE_ATTACH_CONTEXT structure (For more information, see the MBIM_MS_LTE_ATTACH_CONTEXT table). The second element of the pair is a 4-byte size of a pointer to the corresponding MBIM_MS_LTE_ATTACH_CONTEXT structure.
8 + (8 * EC)		DataBuffer	DATABUFFER	Array of MBIM_MS_LTE_ATTACH_CONTEXT structures.

The following structures are used in the preceding table.

MBIM_MS_LTE_ATTACH_CONTEXT_OPERATIONS describes the types of operations that can be used in the Set command.

Type	Value	Description
MbimMsLteAttachContextOperationDefault	0	Default operation for overwriting existing default LTE attach contexts in the modem. The OS will always replace all three default LTE attach context for roaming conditions.

Type	Value	Description
MbimMsLteAttachContextOperationRestoreFactory	1	Restore factory preconfigured default LTE attach context for the Provider ID of currently inserted SIM. All default LTE attach contexts replaced or created by the OS should be removed and replaced. If there is no default preconfigured default LTE attach context for the current inserted SIM Provider ID with one or more roaming conditions, then the default LTE attach should return an empty APN string and IP type = default.

MBIM_MS_LTE_ATTACH_CONTEXT specifies the context to be used for LTE attach configuration.

Offset	Size	Field	Type	Description
0	4	IPType	MBIM_CONTEXT_IP_TYPE	For more information, see the MBIM_CONTEXT_IP_TYPE table.
4	4	Roaming	MBIM_MS_LTE_ATTACH_CONTEXT_ROAMING_CONTROL	Indicates which roaming condition applies to this default LTE attach context. For more information, see the MBIM_MS_LTE_ATTACH_CONTEXT_ROAMING_CONTROL table.
8	4	Source	MBIM_MS_CONTEXT_SOURCE	Specifies the creation source of the context. For more information, see the MBIM_MS_CONTEXT_SOURCE table.
12	4	AccessStringOffset	OFFSET	Offset in data buffer to a string, AccessString, to access the network. For GSM-based networks, this would be an Access Point Name (APN) string such as "data.thephone-company.com". The size of the string should not exceed 100 characters. If the AccessString is empty, then the device expects the network to assign an access string back to the device. IP type still has to be specified in this case.
16	4	AccessStringSize	SIZE(0..200)	Size used for AccessString. This value should be 0 if the device expects the network to assign an access string back to the device for LTE attach.
20	4	UserNameOffset	OFFSET	Offset in bytes, calculated from the beginning of this structure, to a string, UserName, that represents the username to authenticate. This member can be NULL.
24	4	UserNameSize	SIZE(0..510)	Size used for UserName.
28	4	PasswordOffset	OFFSET	Offset in bytes, calculated from the beginning of this structure, to a string, Password, that represents the username's password. This member can be NULL.
32	4	PasswordSize	SIZE(0..510)	Size used for Password.
36	4	Compression	MBIM_COMPRESSION	Specifies the compression to be used in the data connection for header and data. This member applies only to GSM-based devices. The Host sets this member to MBIMCompressionNone for CDMA-based devices. For more information, see the MBIM_COMPRESSION table.
40	4	AuthProtocol	MBIM_AUTH_PROTOCOL	Authentication type to use for the PDP activation. For more information, see the MBIM_AUTH_PROTOCOL table.
44		DataBuffer	DATABUFFER	The data buffer that contains AccessString, UserName, and Password.

MBIM_MS_LTE_ATTACH_CONTEXT_ROAMING_CONTROL indicates which roaming condition applies to this default LTE attach context.

Type	Value	Description

Type	Value	Description
MbimMsLteAttachContextRoamingControlHome	0	Indicates whether the default LTE attach context is allowed to be used on home network or not.
MbimMsLteAttachContextRoamingControlPartner	1	Indicates whether the context is allowed to be used on partner roaming networks or not.
MbimMsLteAttachContextRoamingControlNonPartner	2	Indicates whether the context is allowed to be used on non-partner roaming networks or not.

MBIM_MS_CONTEXT_SOURCE specifies the creation source of the context.

Type	Value	Description
MbimMsContextSourceAdmin	0	The context was created by an Enterprise IT admin from the OS.
MbimMsContextSourceUser	1	The context was created by user through the OS settings.
MbimMsContextSourceOperator	2	The context was created by the operator through OMA-DM or other channels.
MbimMsContextSourceModem	3	The context was created by the IHV or OEM.
MbimMsContextSourceDevice	4	The context was created by the OS APN database.

Response

The following MBIM_MS_LTE_ATTACH_CONFIG_INFO structure shall be used in the InformationBuffer.

Offset	Size	Field	Type	Description
0	4	ElementCount (EC)	UINT32	Count of MBIM_MS_LTE_ATTACH_CONTEXT structures that follow in the DataBuffer. This component is currently specified to three, one for each roaming condition (home/partner/non-partner).
4	8 * EC	MsLteAttachContextRefList	OL_PAIR_LIST	The first element of the pair is a 4-byte offset, calculated from the beginning (offset 0) of this MBIM_MS_LTE_ATTACH_CONFIG_INFO structure, to an MBIM_MS_LTE_ATTACH_CONTEXT structure (For more information, see the MBIM_MS_LTE_ATTACH_CONTEXT table). The second element of the pair is a 4-byte size of a pointer to the corresponding MBIM_MS_LTE_ATTACH_CONTEXT structure.
4 + (8 * EC)		DataBuffer	DATABUFFER	Array of MBIM_MS_LTE_ATTACH_CONTEXT structures.

Notification

For more information, see the MBIM_MS_LTE_ATTACH_CONFIG_INFO table.

Status Codes

For Query and Set operations:

Status Code	Description
MBIM_STATUS_READ_FAILURE	The operation failed because the device was unable to retrieve provisioned contexts.
MBIM_STATUS_NO_DEVICE_SUPPORT	The operation failed because the device does not support the operation.

For Set operations only:

Status Code	Description
MBIM_STATUS_INVALID_PARAMETERS	The operation failed because of invalid parameters.
MBIM_STATUS_WRITE_FAILURE	The operation failed because the update request was unsuccessful.

MBIM_CID_MS_LTE_ATTACH_STATUS

Description

Per 3GPP requirement, although a device can specify the default LTE attach context to be used when LTE attaching to the network without any enabled PDP context, there might be situations where the device will LTE-attach on a PDP context that differs from the default LTE attach context configured on the device. The following is a list of all possible scenarios:

1. The UE specifies a specific LTE attach APN.
2. The UE specifies a specific LTE attach APN but the network decides to let the device attach on another APN instead during roaming.
3. The UE does not specify a LTE attach APN and lets network assign one back to the device.
4. The UE registered from 2G/3G network to LTE and there was already at minimum one active PDP context. The network uses it as the LTE attach APN.

When the device default LTE attaches, it should send a notification of MBIM_CID_MS_LTE_ATTACH_STATUS to the OS to provide details of the PDP context on the latest LTE attachment. Default LTE attach occurs when one of the following scenarios is fulfilled:

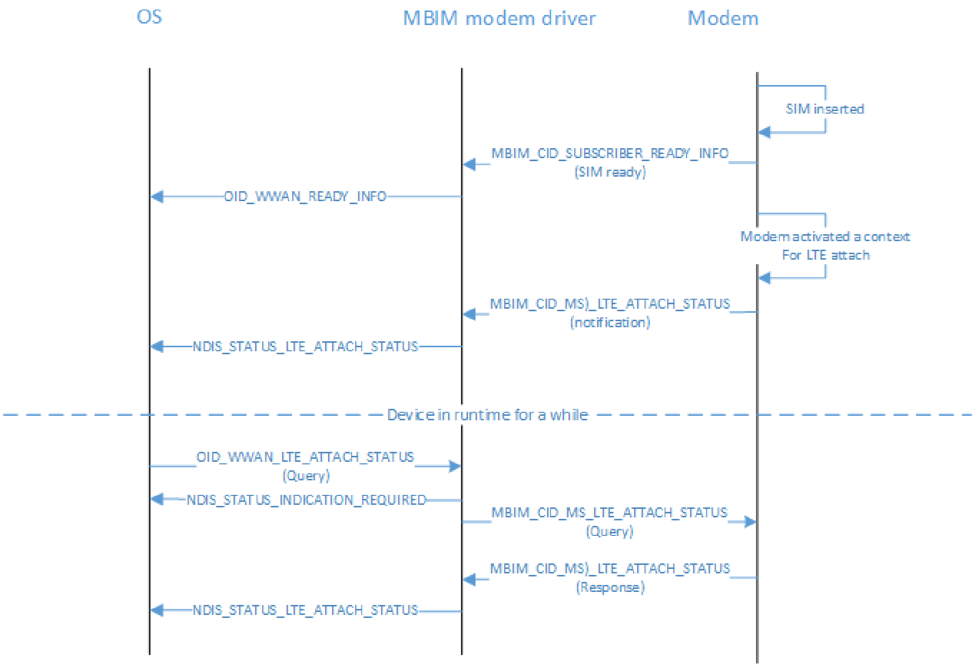
1. Device initially attaches to the LTE network.
2. Device hands up from 2G/3G to LTE without any prior enabled PDP context.

The LTE attach context returned from MBIM_CID_LTE_ATTACH_STATUS could be one of the following:

1. Default LTE attach context stored in the modem.
2. Default LTE attach context that was assigned back from the network.

During runtime, the OS should also be able to query what the last used attach information was for default LTE attach. The modem is expected to return the last known default LTE attach context. If the device was handed off from LTE to 2G/3G network, it is expected for the modem to return the context that was used for the previous LTE attach. Every time that the device deregisters from the network, it is expected for the APN to become empty.

The below diagram illustrates an example message flow for LTE attach status.



OS
MBIM modem driver
Modem
SIM inserted
MBIM_CID_SUBSCRIBER_READY_INFO
(SIM ready)
OID_WWAN_READY_INFO
Modem activated a context
For LTE attach
MBIM_CID_MS)_LTE_ATTACH_STATUS
(notification)
NDIS_STATUS_LTE_ATTACH_STATUS
Device in runtime for a while
OID_WWAN_LTE_ATTACH_STATUS
(Query)
NDIS_STATUS_INDICATION_REQUIRED
MBIM_CID_MS_LTE_ATTACH_STATUS
(Query)
MBIM_CID_MS)_LTE_ATTACH_STATUS
(Response)
NDIS_STATUS_LTE_ATTACH_STATUS

Query

MBIM_MS_LTE_ATTACH_STATUS is returned from Query complete messages in the InformationBuffer. For Query, the InformationBuffer is NULL.

Set

Set operations are not supported.

Unsolicited Events

The Event InformationBuffer contains an MBIM_MS_LTE_ATTACH_STATUS structure.

Parameters

Operation	Set	Query	Notification
Command	Not applicable	Not applicable	Not applicable
Response	Not applicable	MBIM_MS_LTE_ATTACH_STATUS	MBIM_MS_LTE_ATTACH_STATUS

Data Structures

Query

The InformationBuffer shall be NULL and InformationBufferLength shall be zero.

Set

Set operations are not supported.

Response

The following MBIM_MS_LTE_ATTACH_STATUS structure shall be used in the InformationBuffer.

Offset	Size	Field	Type	Description
0	4	LteAttachState	MBIM_MS_LTE_ATTACH_STATE	Indicates whether the device is currently attached to a LTE network or not. For more information, see the MBIM_MS_LTE_ATTACH_STATE table.
4	4	IPType	MBIM_CONTEXT_IP_TYPES	For more information, see the MBIM_CONTEXT_IP_TYPE table.
8	4	AccessStringOffset	OFFSET	Offset in data buffer to a string, AccessString, to access the network. For GSM-based networks, this would be an Access Point Name (APN) string such as "data.thephone-company.com". For CDMA-based networks, this might be a special dial code such as "#777" or a Network Access Identifier (NAI) such as "foo@thephone-company.com". This member can be NULL to request that the network assign the default APN. Note: Not all networks support this NULL APN convention. Therefore, a connect failure caused by an invalid APN is a possible outcome. The size of the string should not exceed 100 characters.
12	4	AccessStringSize	SIZE(0..200)	Size in bytes used for AccessString.
16	4	UserNameOffset	OFFSET	Offset in bytes, calculated from the beginning of this structure, to a string, UserName, that represents the username to authenticate. This member can be NULL.
20	4	UserNameSize	SIZE(0..510)	Size in bytes used for UserName.
24	4	PasswordOffset	OFFSET	Offset in bytes, calculated from the beginning of this structure, to a string, Password, that represents the username's password. This member can be NULL.
28	4	PasswordSize	SIZE(0..510)	Size in bytes used for Password.
32	4	Compression	MBIM_COMPRESSION	Specifies the compression to be used in the data connection for header and data. This member applies only to GSM-based devices. The Host sets this member to MBIMCompressionNone for CDMA-based devices. For more information, see the MBIM_COMPRESSION table.

Offset	Size	Field	Type	Description
36	4	AuthProtocol	MBIM_AUTH_PROTOCOL	Authentication type to use for the PDP activation. For more information, see the MBIM_AUTH_PROTOCOL table.
40	4		DataBuffer	DATABUFFER

The following data structure is used in the preceding table.

MBIM_MS_LTE_ATTACH_STATE indicates whether the device is currently attached to a LTE network or not.

Type	Value	Description
MbimMsLteAttachStateDetached	0	Indicates the device is not attached to LTE network.
MbimMsLteAttachStateAttached	1	Indicates the device is attached to LTE network.

Notification

For more information, see the MBIM_MS_LTE_ATTACH_STATUS table.

Status Codes

For Query and Set operations:

Status Code	Description
MBIM_STATUS_READ_FAILURE	The operation failed because the device was unable to retrieve provisioned contexts.
MBIM_STATUS_NO_DEVICE_SUPPORT	The operation failed because the device does not support the operation.

Hardware Lab Kit (HLK) Tests

See Steps for installing HLK .

In HLK Studio connect to device Cellular modem driver and run the test: Win6_4.MB.GSM.Data.TestLteAttach.

Alternatively, run the **TestLteAttach** HLK testlist by **netsh-mbn** and **netsh-mbn-test-installation**.

```
netsh mbn test feature=lte testpath="C:\\data\\test\\bin" taefpath="C:\\data\\test\\bin"
```

This file showing the HLK test results should have been generated in the directory that the 'netsh mbn test' command was ran from: `TestLteAttach.htm`.

Manual Tests

- Requirement: A sim with the correct APN setting and one more APN information for manual use.

1. Open Settings->Network & Internet -> Cellular
2. Click ***Advanced options***

Using Cellular Settings:

3. There should at least be an apn which is the setting from the sim information. You can get the APN's detailed information by clicking the APN and clicking the "view" button.

Using Manual Settings:

3. Follow the "Add an APN" section in Cellular settings to set the APN manually.
4. Attach the APN and check the attached status.

MB LTE Attach Troubleshooting Guide

1. Get all the Attach APN profiles under %ProgramData%\Microsoft\WwanSvc\DMProfiles
2. Understand which particular profile will be applied based on creation type priorities
3. Investigate the logs to check why the LTE Attach APN was wrongly configured
4. Collect and decode the logs using the instructions in Collecting Logs
5. Open the .txt file generated in the TextAnalysisTool
6. Load the LTE Attach filter

Sample log of LTE Attach

```

LTE Attach Log Filter

Article • 12/15/2021

To load a TextAnalysisTool filter for the LTE Attach operation:

1. Copy and paste the lines below and save them into a text file named "lte-attach.tat."
2. Load the filter file into the TextAnalysisTool by clicking File > Load Filters.

```
<?xml version="1.0" encoding="utf-8" standalone="yes"?>
<TextAnalysisTool.NET version="2014-04-22" showOnlyFilteredLines="True">
  <filters>
    <filter enabled="y" excluding="n" type="matches_text" case_sensitive="n"
regex="n" text="SaveModemConfiguredLteAttachConfig" />
    <filter enabled="y" excluding="n" type="matches_text" case_sensitive="n"
regex="n" text="[WwanProtDim] StatusCode :
NDIS_STATUS_WWAN_LTE_ATTACH_CONFIG (0x4004103d)" />
    <filter enabled="y" excluding="n" type="matches_text" case_sensitive="n"
regex="n" text="WwanPmSetDMConfigProfile" />

MB Protocol Configuration Options (PCO) operations

Article • 03/14/2023

Overview

The purpose of Protocol Configuration Options (PCO) is to transfer the external network protocol options associated with a packet data protocol (PDP) context activation. Windows NDIS definitions for PCO values have typically been generic in order to receive full PCO values from the modem and network in the future. However starting with Windows 10 version 1709 some modems are only able to pass up operator specific PCO elements to the OS. This topic defines the behavior of the current operator specific-only PCO implementation.

Flows

There are three scenarios where the PCO value will be passed to the host:

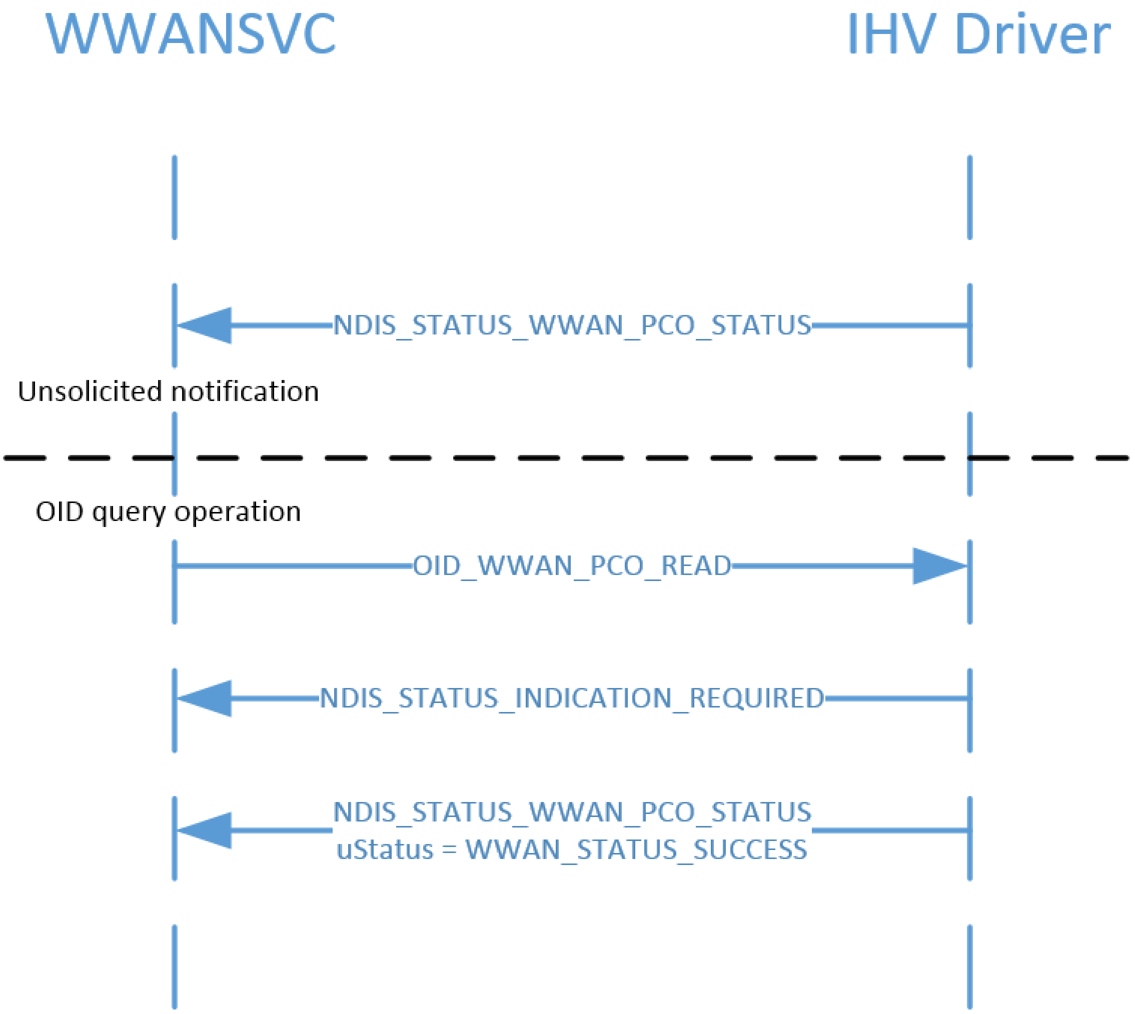
- When a new PCO value has arrived on an activated connection
- When an app or service queries for the latest PCO value from the modem
- When a connection is bridged or activated for the first time and a PCO value already exists in the modem

For the first scenario, the modem should send an NDIS_STATUS_WWAN_PCO_STATUS notification to the OS indicating a new PCO value change whenever a new PCO value is received from the network, with the appropriate NDIS port number to represent the corresponding PDN. To avoid draining the battery unnecessarily, the modem should avoid noisy notifications, as described in Modem behavior with Selective Suspend and Connected Standby.

For the second scenario, when an app or service queries for PCO value from the modem on an activated PDN connection, the host will send the modem an OID_WWAN_PCO query request to read the latest cached PCO value in the modem.

For the third scenario, when a connection is activated or bridged on the host, the modem should send an **NDIS_STATUS_WWAN_PCO_STATUS** notification when a PCO value already exists in the modem for the activated or bridged connection the host requested. The notification should be passed up from the corresponding NDIS port number of the PDN.

The following figure shows the scenario flow:



WWANSVC
IHV Driver
NDIS_STATUS_WWAN_PCO_STATUS
Unsolicited notification
OID query operation
OID_WWAN_PCO_READ
NDIS_STATUS_INDICATION_REQUIRED
NDIS_STATUS_WWAN_PCO_STATUS
uStatus = WWAN_STATUS_SUCCESS

Modem behavior with Selective Suspend and Connected Standby

When Selective Suspend is enabled, the modem can notify the OS whenever it receives a PCO data structure from the network. However, the modem should avoid unnecessary device wakeup. Otherwise, noisy PCO notifications from the network will wake the device up frequently and drain the battery unnecessarily.

When Connected Standby is enabled, the modem shouldn’t notify the OS when it receives PCO data structures from the network because it will not only wake up the device, but it will also wake up the OS, which is not necessary. Instead, the modem should cache all the latest PCO elements from the data structure and notify the OS once the OS exits Connected Standby. For an MBIM modem, it should cache all PCO data structures and only send PCO notifications to the OS after the host has subscribed to it. This will be done using the MBIM_CID_DEVICE_SERVICE_SUBSCRIBE_LIST CID when system power has returned to full power after coming out of Connected Standby.

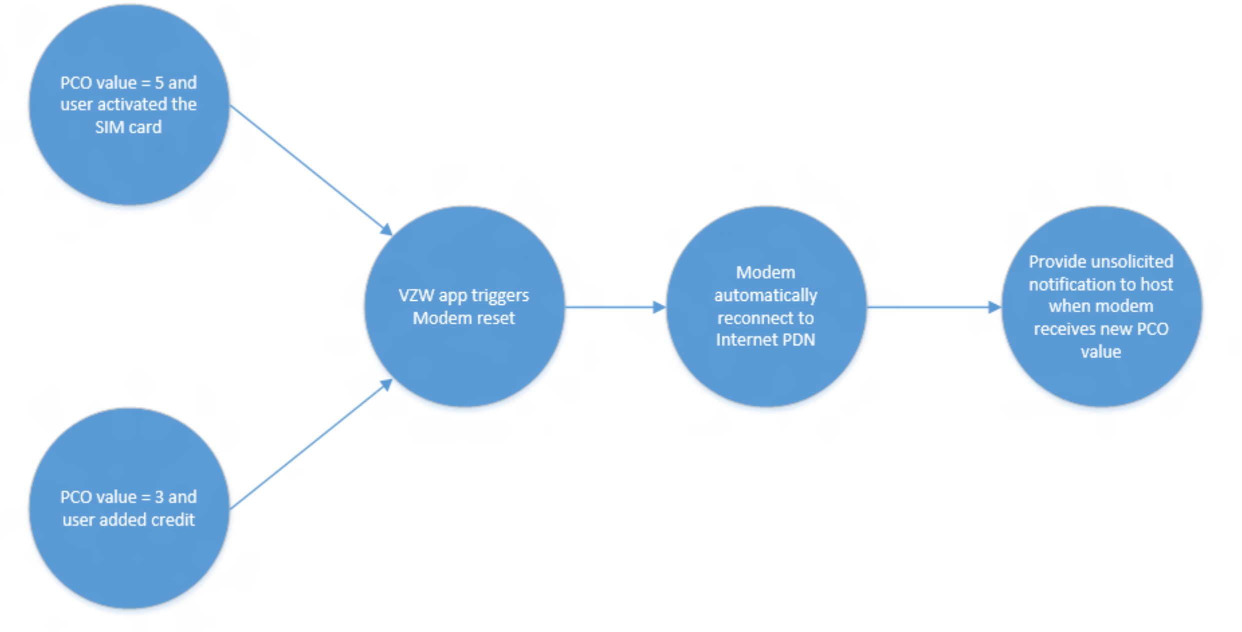
Resetting the modem based on PCO values

Based on PCO values received from the network, the modem will be reset in the following scenarios:

- The user completed self-activation after receiving PCO = 5 from the network. A new PCO value (3, 0 or anything Mobile Operator App can recognize) will be sent to the OS and the OS will pass it to Mobile Operator App.
- The user added more credit to their account after receiving PCO = 3. A new PCO value (0, or anything Mobile Operator App can recognize) will be sent to the OS and the OS will pass it to Mobile Operator App.

The host is not aware of the modem being reset, so the activated connections from the host will not be deactivated and the modem should automatically re-establish connection with those PDN after resetting. Upon establishing connection and receiving a new incoming PCO value from the network, the modem will provide an unsolicited NDIS_STATUS_WWAN_PCO_STATUS notification to the host.

The following diagram illustrates the modem's reset flow when one of these scenarios occurs, with Verizon Wireless as the example MO:



PCO value = 5 and user activated the SIM card
PCO value = 3 and user added credit
VZW app triggers Modem reset
Modem automatically reconnect to Internet PDN
Provide unsolicited notification to host when modem receives new PCO value

NDIS interface to the modem

For querying the status and payload of a PCO value the modem received from the operator network, see OID_WWAN_PCO. **OID_WWAN_PCO** uses the **NDIS_WWAN_PCO_STATUS** structure, which in turn contains a **WWAN_PCO_VALUE** structure representing the PCO information payload from the network.

For the status notification sent by a modem miniport driver to inform the OS of the current PCO state in the modem, see NDIS_STATUS_WWAN_PCO_STATUS.

MB CID to the modem

Service = **MBB_UUID_BASIC_CONNECT_EXT_CONSTANT**

Service UUID = **3d01dcc5-fef5-4d05-0d3a-bef7058e9aaf**

The following CIDs are defined for PCO:

CID	Command code	Minimum OS Version
MBIM_CID_PCO	9	Windows 10, version 1709

MBIM_CID_PCO

This command is used to query the PCO data cached in modem from the mobile operator network.

Query

The InformationBuffer contains an **MBIM_PCO_VALUE** in which the only relevant field is *SessionId*. *SessionId* is reserved for future use and will always be 0 in Windows 10, version 1709. The *SessionId* in a query indicates which IP data stream's PCO value is to be returned by the function.

Set

Not applicable.

Unsolicited Event

Unsolicited events contain an MBIM_PCO_VALUE and are sent when a new PCO value has arrived on an activated connection.

Parameters

Operation	Set	Query	Notification
Command	Not applicable	MBIM_PCO_VALUE	Not applicable

Operation	Set	Query	Notification
Response	Not applicable	MBIM_PCO_VALUE	MBIM_PCO_VALUE

Data Structures

MBIM_PCO_TYPE

Type	Value	Description
MBIMPcoTypeComplete	0	Specifies that the complete PCO structure will be passed up as received from the network and the header realistically reflects the protocol in octet 3 of the PCO structure, defined in the 3GPP TS24.008 spec.
MBIMPcoTypePartial	1	Specifies that the modem will only be passing up a subset of PCO structures that it received from the network. The header matches the PCO structure defined in the 3GPP TS24.008 spec, but the “Configuration protocol” of octet 3 may not be valid.

MBIM-PCO-TYPE

Offset	Size	Field	Type	Description
0	4	SessionId	UINT32	The SessionId in a query indicates which IP data stream’s PCO value is to be returned by the function.
4	4	PcoDataSize	UINT32	The length of PcoData, from 0 to 256. This value will be 0 in a query.
8	4	PcoDataType	UINT32	The PCO data type. For more info, see MBIM_PCO_TYPE.
12		PcoDataBuffer	DATABUFFER	The PCO structure from the 3GPP TS24.008 spec.

Status Codes

This CID only uses Generic Status Codes.

Hardware Lab Kit (HLK) Tests

See Steps for installing HLK .

In HLK Studio connect to the device Cellular modem driver and run the test: TestPco.

MB low level UICC access

Article • 03/14/2023

Overview

The Mobile Broadband Interface Model Revision 1.0, or MBIM1, defines an OEM- and IHV-agnostic interface between a host device and a cellular data modem.

An MBIM1 function includes a UICC smart card and provides access to some of its data and internal state. However, the smart card may have additional capabilities beyond those that are defined by the MBIM interface. These additional capabilities include support for a secure element for mobile payment solutions based upon near-field communication, or for remote provisioning of an entire UICC profile.

In a mobile broadband-enabled Windows device, the MBIM interface is used in addition to the Radio Interface Layer (RIL) interface. One of the features the RIL provides is an interface for low-level access to the UICC. This topic describes a set of Microsoft extensions to MBIM that describe this additional functionality at the MBIM interface.

The Microsoft extensions comprise a set of device service commands (both Set and Query) and notifications. These extensions do not include any new uses of device service streams.

MBIM service and CID values

Service name	UUID	UUID value
Microsoft Low-Level UICC Access	UUID_MS_UICC_LOW_LEVEL	C2F6588E-F037-4BC9-8665-F4D44BD09367

The following table specifies the command code for each CID, as well as whether the CID supports Set, Query, or Event (notification) requests. See each CID's individual section within this topic for more info about its parameters, data structures, and notifications.

CID	Command code	Set	Query	Notify
MBIM_CID_MS_UICC_ATR	1	N	Y	N
MBIM_CID_MS_UICC_OPEN_CHANNEL	2	Y	N	N
MBIM_CID_MS_UICC_CLOSE_CHANNEL	3	Y	N	N
MBIM_CID_MS_UICC_APDU)	4	Y	N	N
MBIM_CID_MS_UICC_TERMINAL_CAPABILITY	5	Y	Y	N
MBIM_CID_MS_UICC_RESET	6	Y	Y	N

Status codes

MBIM status codes are defined in Section 9.4.5 of the MBIM standard. In addition, the following additional failure status codes are defined:

Status Code	Value (hex)	Description
MBIM_STATUS_MS_NO_LOGICAL_CHANNELS	87430001	The logical channel open was not successful because no logical channels are available on the UICC (either it does not support them or all of them are in use).
MBIM_STATUS_MS_SELECT_FAILED	87430002	The logical channel open was not successful because SELECT failed.
MBIM_STATUS_MS_INVALID_LOGICAL_CHANNEL	87430003	The logical channel number is invalid (it was not opened by MBIM_CID_MS_UICC_OPEN_CHANNEL).

MBIM_SUBSCRIBER_READY_STATE

Type	Value	Description
MBIMSubscriberReadyStateNoEsimProfile	7	The card is ready but does not have any enabled profiles.

UICC responses and status

The UICC may implement either a character-based or record-based interface, or both. Although the specific mechanism is different, the result is that the UICC responds to each command with two status bytes (named SW1 and SW2) and a response (which may be empty). A normal success status is indicated by 90 00. However, if the UICC supports the card application toolkit and the UICC wishes to send a proactive command to the terminal, a successful return will be indicated by a status of 91 XX (where XX varies). The MBIM function, or terminal, is responsible for handling this proactive command just as it would handle a proactive command received during any other UICC operation (sending a FETCH to the UICC, handling the proactive command, or sending it to the host with MBIM_CID_STK_PAC). When the MBIM host sends either MBIM_CID_MS_UICC_OPEN_CHANNEL or MBIM_CID_MS_UICC_APDU it should consider both 90 00 and 91 XX as a normal status.

Commands must be able to return responses that are larger than 256 bytes. This mechanism is described in Section 5.1.3 of the ISO/IEC 7816-4:2013 standard. In this case, the card will return SW1 SW2 status words of 61 XX, rather than 90 00, where XX is either the number of remaining bytes or 00 if there are 256 bytes or more remaining. The modem must issue a GET RESPONSE with the same class byte repeatedly until all the data has been received. This will be indicated by the final status words 90 00. The sequence must be uninterrupted within a specific logical channel. Additional APDUs should be handled at the modem and should be transparent to the host. If handled in the host, there is no guarantee that some other APDU may asynchronously reference the card during the sequence of APDUs.

Comparison to IHVRIL

Sections 5.2.3.3.10 through 5.2.3.3.14 of the IHVRIL specification define a similar interface upon which this specification is based. Some differences include:

- The RIL interface does not provide a way to specify secure messaging. The MBIM command to exchange APDUs specifies this as an explicit parameter.

- The RIL interface does not clearly define the interpretation of the class byte within the APDU. The MBIM specification states that the class byte sent from the host must be present but is not used (and instead the MBIM function constructs this byte).
- The RIL interface uses a separate function to close all UICC channels in a group, whereas the MBIM interface accomplishes this with variant arguments to a single CID.
- The relationship between MBIM error status and UICC status (SW1 SW2) is more clearly defined than the relationship between RIL errors and UICC status.
- The MBIM interface distinguishes failure to allocate a new logical channel from failure to SELECT a specified application.
- The MBIM interface permits sending the modem terminal capability objects to send to the card.

MBIM_CID_MS_UICC_ATR

The Answer to Reset (ATR) is the first string of bytes sent by the UICC after a reset has been performed. It describes the capabilities of the card, such as the number of logical channels that it supports. The MBIM function must save the ATR when it is received from the UICC. Subsequently, the host may use the MBIM_CID_MS_UICC_ATR command to retrieve the ATR.

Parameters

Type	Set	Query	Notification
Command	Not applicable	Empty	Not applicable
Response	Not applicable	MBIM_MS_ATR_INFO	Not applicable

Query

The InformationBuffer of a Query message is empty.

Set

Not applicable.

Response

The InformationBuffer of MBIM_COMMAND_DONE contains the following MBIM_MS_ATR_INFO structure describing the answer to reset for the UICC attached to this function.

MBIM_MS_ATR_INFO

Offset	Size	Field	Type	Description
0	4	AtrSize	SIZE(0..33)	The length of **AtrData**.
4	4	AtrOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to a byte array called **AtrData** that contains the ATR data.

Offset	Size	Field	Type	Description
8	AtrSize	DataBuffer	DATABUFFER	The **AtrData** byte array.

Unsolicited events

Not applicable.

Status codes

The following status codes are applicable.

Status code	Description
MBIM_STATUS_SUCCESS	Basic MBIM status as defined for all commands.
MBIM_STATUS_BUSY	Basic MBIM status as defined for all commands.
MBIM_STATUS_FAILURE	Basic MBIM status as defined for all commands.
MBIM_STATUS_NO_DEVICE_SUPPORT	Basic MBIM status as defined for all commands.
MBIM_STATUS_SIM_NOT_INSERTED	Unable to perform the UICC operation because the UICC is missing.
MBIM_STATUS_BAD_SIM	Unable to perform the UICC operation because the UICC is in an error state.
MBIM_STATUS_NOT_INITIALIZED	Unable to perform the UICC operation because the UICC is not yet fully initialized.

MBIM_CID_MS_UICC_OPEN_CHANNEL

The host uses the MBIM_CID_MS_UICC_OPEN_CHANNEL command to request that the function open a new logical channel on the UICC card and select a specified UICC application (specified by its application ID).

The function implements this MBIM command using a sequence of UICC commands:

1. The function sends a MANAGE CHANNEL command to the UICC, as described by section 11.1.17 of the ETSI TS 102 221 technical specification, to create a new logical channel. If this command fails, the function returns the MBIM_STATUS_MS_NO_LOGICAL_CHANNELS status with SW1 SW2 and takes no further action.
2. If the MANAGE CHANNEL command succeeds, the UICC reports the channel number of the new logical channel to the function. The function sends a SELECT [by name] command where P1 = 04, as described by section 11.1.1 of the ETSI TS 102 221 technical specification. If this operation fails, the function sends a MANAGE CHANNEL command to the UICC to close the logical channel and returns the MBIM_STATUS_MS_SELECT_FAILED status with SW1 SW2 from the SELECT.
3. If the SELECT command succeeds, the function records the logical channel number and the channel group specified by the host for future reference. It will then return the logical channel number, SW1 SW2 from the SELECT, and the response from the SELECT to the host.

Parameters

Operation	Set	Query	Notification
Command	MBIM_MS_SET_UICC_OPEN_CHANNEL	Not applicable	Not applicable
Response	MBIM_MS_UICC_OPEN_CHANNEL_INFO	Not applicable	Not applicable

Query

Not applicable.

Set

The InformationBuffer of MBIM_COMMAND_MSG contains the following MBIM_MS_SET_UICC_OPEN_CHANNEL structure.

MBIM_MS_SET_UICC_OPEN_CHANNEL

Offset	Size	Field	Type	Description
0	4	AppIdSize	SIZE(0..32)	The size of the application ID (AppId).
4	4	AppIdOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to a byte array called **AppId** that defines the AppId to be SELECTed.
8	4	SelectP2Arg	UINT32(0..255)	The *P2* argument to the SELECT command.
12	4	ChannelGroup	UINT32	A tag value that identifies the channel group for this channel.
16	AppIdSize	DataBuffer	DATABUFFER	The **AppId** byte array.

Response

The InformationBuffer of MBIM_COMMAND_DONE contains the following MBIM_MS_UICC_OPEN_CHANNEL_INFO structure.

MBIM_MS_UICC_OPEN_CHANNEL_INFO

Offset	Size	Field	Type	Description
0	4	Status	BYTE[2]	SW1 and SW2, in that byte order. For more info, see the notes following this table.
4	4	Channel	UINT32(0..19)	The logical channel identifier. If this member is 0, then the operation failed.
8	4	ResponseLength	SIZE(0..256)	The response length in bytes.

Offset	Size	Field	Type	Description
12	4	ResponseOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to a byte array called **Response** that contains the response from the SELECT.
16	-	DataBuffer	DATABUFFER	The **Response** byte array data.

If the command returns MBIM_STATUS_MS_NO_LOGICAL_CHANNELS, the **Status** field shall contain the UICC status words SW1 and SW2 from the MANAGE CHANNEL command and the remaining fields will be zero. If the command returns MBIM_STATUS_MS_SELECT_FAILED, the **Status** field shall contain the UICC status words SW1 and SW2 from the SELECT command and the remaining fields will be zero. For any other status, the InformationBuffer shall be empty.

Unsolicited events

Not applicable.

Status codes

The following status codes are applicable:

Status code	Description
MBIM_STATUS_SUCCESS	Basic MBIM status as defined for all commands.
MBIM_STATUS_BUSY	Basic MBIM status as defined for all commands.
MBIM_STATUS_FAILURE	Basic MBIM status as defined for all commands.
MBIM_STATUS_NO_DEVICE_SUPPORT	Basic MBIM status as defined for all commands.
MBIM_STATUS_SIM_NOT_INSERTED	Unable to perform the UICC operation because the UICC is missing.
MBIM_STATUS_BAD_SIM	Unable to perform the UICC operation because the UICC is in an error state.
MBIM_STATUS_NOT_INITIALIZED	Unable to perform the UICC operation because the UICC is not yet fully initialized.
MBIM_STATUS_MS_NO_LOGICAL_CHANNELS	The logical channel open failed because no logical channels are available on the UICC (either it does not support them or all of them are in use).
MBIM_STATUS_MS_SELECT_FAILED	The logical channel open was not successful because SELECT failed.

MBIM_CID_MS_UICC_CLOSE_CHANNEL

The host sends MBIM_CID_MS_UICC_CLOSE_CHANNEL to the function to close a logical channel on the UICC. The host may specify a channel number or may specify a channel group.

If the host specifies a channel number, the function should check whether this channel was opened by a previous MBIM_CID_MS_UICC_OPEN_CHANNEL. If so, it should send a MANAGE CHANNEL command to the UICC to close the channel, return a status of MBIM_STATUS_SUCCESS, and return the SW1 SW2 from the MANAGE CHANNEL. If not, it should take no action and return the MBIM_STATUS_MS_INVALID_LOGICAL_CHANNEL failure status.

If the host specifies a channel group, the function determines which (if any) logical channels were opened with that channel group and sends a MANAGE CHANNEL command to the UICC for each such channel. It returns a status of MBIM_STATUS_SUCCESS with the SW1 SW2 of the last MANAGE CHANNEL. If no channels were closed it shall return 90 00.

Parameters

Operation	Set	Query	Notification
Command	MBIM_MS_SET_UICC_CLOSE_CHANNEL	Not applicable	Not applicable
Response	MBIM_MS_UICC_CLOSE_CHANNEL_INFO	Not applicable	Not applicable

Query

Not applicable.

Set

The InformationBuffer of MBIM_COMMAND_MSG contains the following MBIM_MS_SET_UICC_CLOSE_CHANNEL structure.

MBIM_MS_SET_UICC_CLOSE_CHANNEL

Offset	Size	Field	Type	Description
0	4	Channel	UINT32(0..19)	If nonzero, specifies the channel to be closed. If zero, specifies that the channel(s) associated with **ChannelGroup** are to be closed.
4	4	ChannelGroup	UINT32	If **Channel** is zero, this specifies a tag value and all channels with this tag are closed. If **Channel** is nonzero, this field is ignored.

Response

The InformationBuffer of MBIM_COMMAND_DONE contains the following MBIM_MS_UICC_CLOSE_CHANNEL_INFO structure.

MBIM_MS_UICC_CLOSE_CHANNEL_INFO

Offset	Size	Field	Type	Description
0	4	Status	BYTE[2]	SW1 and SW2 of the last MANAGE CHANNEL executed by the function on behalf of this command.

Unsolicited events

Not applicable.

Status codes

Status code	Description
MBIM_STATUS_SUCCESS	Basic MBIM status as defined for all commands.
MBIM_STATUS_BUSY	Basic MBIM status as defined for all commands.
MBIM_STATUS_FAILURE	Basic MBIM status as defined for all commands.
MBIM_STATUS_NO_DEVICE_SUPPORT	Basic MBIM status as defined for all commands.
MBIM_STATUS_SIM_NOT_INSERTED	Unable to perform the UICC operation because the UICC is missing.
MBIM_STATUS_BAD_SIM	Unable to perform the UICC operation because the UICC is in an error state.
MBIM_STATUS_NOT_INITIALIZED	Unable to perform the UICC operation because the UICC is not yet fully initialized.
MBIM_STATUS_MS_INVALID_LOGICAL_CHANNEL	The logical channel number is not valid (in other words, it was not opened with MBIM_CID_MS_UICC_OPEN_CHANNEL).

MBIM_CID_MS_UICC_APDU

The host uses MBIM_CID_MS_UICC_APDU to send a command APDU to a specified logical channel on the UICC and receive the response. The MBIM function should ensure that the logical channel was previously opened with MBIM_CID_MS_UICC_OPEN_CHANNEL and fail with status MBIM_STATUS_MS_INVALID_LOGICAL_CHANNEL if it was not.

The host must send a complete APDU to the function. The APDU may be sent with a class byte value defined in the first interindustry definition in section 4 of the ISO/IEC 7816-4:2013 standard, or in the extended definition in Section 10.1.1 of the ETSI TS 102 221 technical specification. The APDU may be sent without secure messaging or with secure messaging. The command header not authenticated. The host specifies the type of class byte, logical channel number, and secure messaging along with the APDU.

The first byte of the command APDU is the class byte, coded as defined by section 4 of the ISO/IEC 7816-4:2013 standard or section 10.1.1 of the ETSI TS 102 221 technical specification. The host may send 0X, 4X, 6X, 8X, CX, or EX class bytes. However, the function does not pass this byte directly to the UICC. Instead, before sending the APDU to the UICC the function will replace the first byte from the host with a new class byte (encoded as defined by section 4 of the ISO/IEC 7816-4:2013 standard or section 10.1.1 of the ETSI TS 102 221 technical specification) based upon the Type, Channel, and SecureMessaging values specified by the host:

Byte class	Description

Byte class	Description
0X	7816-4 interindustry, 1 <= channel <= 3, encodes security in low nibble if relevant
4X	7816-4 interindustry, 4 <= channel <= 19, no secure messaging
6X	7816-4 interindustry, 4 <= channel <= 19, secure (header not authenticated)
8X	102 221 extended, 1<= channel <= 3, encodes security in low nibble if relevant
CX	102 221 extended, 4 <= channel <= 19, no secure messaging
EX	102 221 extended, 4 <= channel <= 19, secure (header not authenticated)

The function shall return the status, SW1 SW2, and response from the UICC to the host.

Parameters

Operation	Set	Query	Notification
Command	MBIM_MS_SET_UICC_APDU	Not applicable	Not applicable
Response	MBIM_MS_UICC_APDU_INFO	Not applicable	Not applicable

Query

Not applicable.

Set

The InformationBuffer of MBIM_COMMAND_MSG contains the following MBIM_MS_SET_UICC_APDU structure.

MBIM_MS_SET_UICC_APDU

Offset	Size	Field	Type	Description
0	4	Channel	UINT32(1..19)	Specifies the channel on which the APDU will be sent.
4	4	SecureMessaging	MBIM_MS_UICC_SECURE_MESSAGING	Specifies whether the APDU is exchanged using secure messaging.
8	4	Type	MBIM_MS_UICC_CLASS_BYTE_TYPE	Specifies the type of class byte definition.
12	4	CommandSize	UINT32(0..261)	The **Command** length in bytes.
16	4	CommandOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to a byte array called **Command** that contains the APDU.
20	-	DataBuffer	DATABUFFER	The **Command** byte array.

The MBIM_MS_SET_UICC_APDU structure uses the following MBIM_MS_UICC_SECURE_MESSAGING and MBIM_MS_UICC_CLASS_BYTE_TYPE data structures.

MBIM_MS_UICC_SECURE_MESSAGING

Type	Value	Description
MBIMMsUiccSecureMessagingNone	0	No secure messaging.
MBIMMsUiccSecureMessagingNoHdrAuth	1	Secure messaging, command header not authenticated.

MBIM_MS_UICC_CLASS_BYTE_TYPE

Type	Value	Description
MBIMMsUiccInterindustry	0	Defined according to first interindustry definition in ISO 7816-4.
MBIMMsUiccExtended	1	Defined according to the extended definition in ETSI 102 221.

Response

The InformationBuffer of MBIM_COMMAND_DONE contains the following MBIM_MS_UICC_APDU_INFO structure.

MBIM_MS_UICC_APDU_INFO

Offset	Size	Field	Type	Description
0	4	Status	BYTE[2]	The SW1 and SW2 status words resulting from the command.
4	4	ResponseLength	SIZE	The Response length in bytes.
8	4	ResponseOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to a byte array called **Response** that contains the response from the SELECT.
12	-	DataBuffer	DATABUFFER	The **Response** byte array.

Unsolicited events

Not applicable.

Status codes

The following status codes are applicable:

Status code	Description
MBIM_STATUS_SUCCESS	Basic MBIM status as defined for all commands.
MBIM_STATUS_BUSY	Basic MBIM status as defined for all commands.

Status code	Description
MBIM_STATUS_FAILURE	Basic MBIM status as defined for all commands.
MBIM_STATUS_NO_DEVICE_SUPPORT	Basic MBIM status as defined for all commands.
MBIM_STATUS_SIM_NOT_INSERTED	Unable to perform the UICC operation because the UICC is missing.
MBIM_STATUS_BAD_SIM	Unable to perform the UICC operation because the UICC is in an error state.
MBIM_STATUS_NOT_INITIALIZED	Unable to perform the UICC operation because the UICC is not yet fully initialized.
MBIM_STATUS_MS_INVALID_LOGICAL_CHANNEL	The logical channel number is not valid (in other words, it was not opened with MBIM_CID_MS_UICC_OPEN_CHANNEL).

If the function can send the APDU to the UICC, it returns MBIM_STATUS_SUCCESS along with the SW1 SW2 status words and the response from the UICC (if any). The host must examine the status (SW1 SW2) to determine whether the APDU command succeeded on the UICC or the reason that it failed.

MBIM_CID_MS_UICC_TERMINAL_CAPABILITY

The host sends MBIM_CID_MS_UICC_TERMINAL_CAPABILITY to inform the modem about the capabilities of the host. The TERMINAL CAPABILITY APDU, specified in Section 11.1.19 of the ETSI TS 102 221 technical specification, must be sent to the card before the first application is selected (if it is supported). Therefore, the host cannot directly send the TERMINAL CAPABILITY APDU but rather sends the MBIM_CID_MS_UICC_TERMINAL_CAPABILITY command containing one or more terminal capability objects which would be stored persistently by the modem. On the next card insertion or reset, after the ATR, the modem would SELECT the MF and check whether TERMINAL CAPABILITY is supported. If so, the modem would send the TERMINAL CAPABILITY APDU with the information specified by the MBIM_CID_MS_UICC_TERMINAL_CAPABILITY command as well as any modem-generated information.

Parameters

Operation	Set	Query	Notification
Command	MBIM_MS_SET_UICC_TERMINAL_CAPABILITY	Empty	Not applicable
Response	Not applicable	MBIM_MS_TERMINAL_CAPABILITY_INFO	Not applicable

Query

The InformationBuffer shall be null and InformationBufferLength shall be zero.

Set

The InformationBuffer of MBIM_COMMAND_MSG contains the following MBIM_MS_SET_UICC_TERMINAL_CAPABILITY structure.

MBIM_MS_SET_UICC_TERMINAL_CAPABILITY

Offset	Size	Field	Type	Description
0	4	ElementCount	UINT32	The element count of terminal capability objects.
4	8*EC	CapabilityList OL_PAIR_LIST	An offset-length pair list for each terminal capability object TLV.	
4+8*EC	-	DataBuffer	DATABUFFER	A byte array of the actual terminal capability object TLVs.

Response

Responses will contain the exact SET command with the last sent terminal capability objects to the modem. Therefore, MBIM_MS_TERMINAL_CAPABILITY_INFO is identical to MBIM_MS_SET_UICC_TERMINAL_CAPABILITY.

MBIM_MS_TERMINAL_CAPABILITY_INFO

Offset	Size	Field	Type	Description
0	4	ElementCount	UINT32	The element count of terminal capability objects.
4	8*EC	CapabilityList OL_PAIR_LIST	An offset-length pair list for each terminal capability object TLV.	
4+8*EC	-	DataBuffer	DATABUFFER	A byte array of the actual terminal capability object TLVs.

Unsolicited events

Not applicable.

Status codes

Status code	Description
MBIM_STATUS_SUCCESS	Basic MBIM status as defined for all commands.
MBIM_STATUS_BUSY	Basic MBIM status as defined for all commands.
MBIM_STATUS_FAILURE	Basic MBIM status as defined for all commands.
MBIM_STATUS_NO_DEVICE_SUPPORT	Basic MBIM status as defined for all commands.

Status code	Description
MBIM_STATUS_SIM_NOT_INSERTED	Unable to perform the UICC operation because the UICC is missing.
MBIM_STATUS_BAD_SIM	Unable to perform the UICC operation because the UICC is in an error state.
MBIM_STATUS_NOT_INITIALIZED	Unable to perform the UICC operation because the UICC is not yet fully initialized.
MBIM_STATUS_MS_INVALID_LOGICAL_CHANNEL	The logical channel number is not valid (in other words, it was not opened with MBIM_CID_MS_UICC_OPEN_CHANNEL).

MBIM_CID_MS_UICC_RESET

The host sends MBIM_CID_MS_UICC_RESET to the MBIM function to reset the UICC or to query the passthrough state of the function.

When the host requests that the function reset the UICC, it specifies a passthrough action.

If the host specifies the *MBIMMsUICCPassThroughEnable* passthrough action, the function resets the UICC and, upon UICC power up, treats the UICC as if it were in a passthrough mode that enables communication between the host and UICC (even if the UICC has no Telecom UICC file system). The function does not send any APDUs to the card and does not interfere at any time with the communication between the host and the UICC.

If the host specifies the *MBIMMsUICCPassThroughDisable* passthrough action, the function resets the UICC and, upon UICC power up, treats the UICC as a regular Telecom UICC and expects a Telecom UICC file system to be present on the UICC.

When the host queries the function to determine the passthrough status, if the function responds with the *MBIMMsUICCPassThroughEnabled* status, it means that passthrough mode is enabled. If the function responds with the *MBIMMsUICCPassThroughDisabled* status, it means that passthrough mode is disabled.

Parameters

Type	Set	Query	Notification
Command	MBIM_MS_SET_UICC_RESET	Empty	Not applicable
Response	MBIM_MS_UICC_RESET_INFO	MBIM_MS_UICC_RESET_INFO	Not applicable

Query

The InformationBuffer shall be null and *InformationBufferLength* shall be zero.

Set

MBIM_SET_MS_UICC_RESET

The MBIM_SET_MS_UICC_RESET structure contains the passthrough action specified by the host.

Offset	Size	Field	Type	Description
0	4	PassThroughAction	MBIM_MS_UICC_PASSTHROUGH_ACTION	For more info, see MBIM_MS_UICC_PASSTHROUGH_ACTION.

MBIM_MS_UICC_PASSTHROUGH_ACTION

The MBIM_MS_UICC_PASSTHROUGH_ACTION enumeration defines the types of passthrough actions the host can specify to the MBIM function.

Types	Value
MBIMMsUiccPassThroughDisable	0
MBIMMsUiccPassThroughEnable	1

Response

MBIM_MS_UICC_RESET_INFO

The MBIM_MS_UICC_RESET_INFO structure contains the passthrough status of the MBIM function.

Offset	Size	Field	Type	Description
0	4	PassThroughStatus	MBIM_MS_UICC_PASSTHROUGH_STATUS	For more info, see MBIM_MS_UICC_PASSTHROUGH_STATUS.

MBIM_MS_UICC_PASSTHROUGH_STATUS

The MBIM_MS_UICC_PASSTHROUGH_STATUS enumeration defines the types of passthrough status the MBIM function specifies to the host.

Types	Value
MBIMMsUiccPassThroughDisabled	0
MBIMMsUiccPassThroughEnabled	1

Unsolicited events

Not applicable.

Status codes

Status code	Description

Status code	Description
MBIM_STATUS_SUCCESS	Basic MBIM status as defined for all commands.
MBIM_STATUS_BUSY	The device is busy.
MBIM_STATUS_FAILURE	The operation failed.
MBIM_STATUS_NO_DEVICE_SUPPORT	The device does not support this operation.

OID_WWAN_UICC_RESET

The NDIS equivalent for MBIM_CID_MS_UICC_RESET is OID_WWAN_UICC_RESET.

MB UICC application and file system access

Article • 03/14/2023

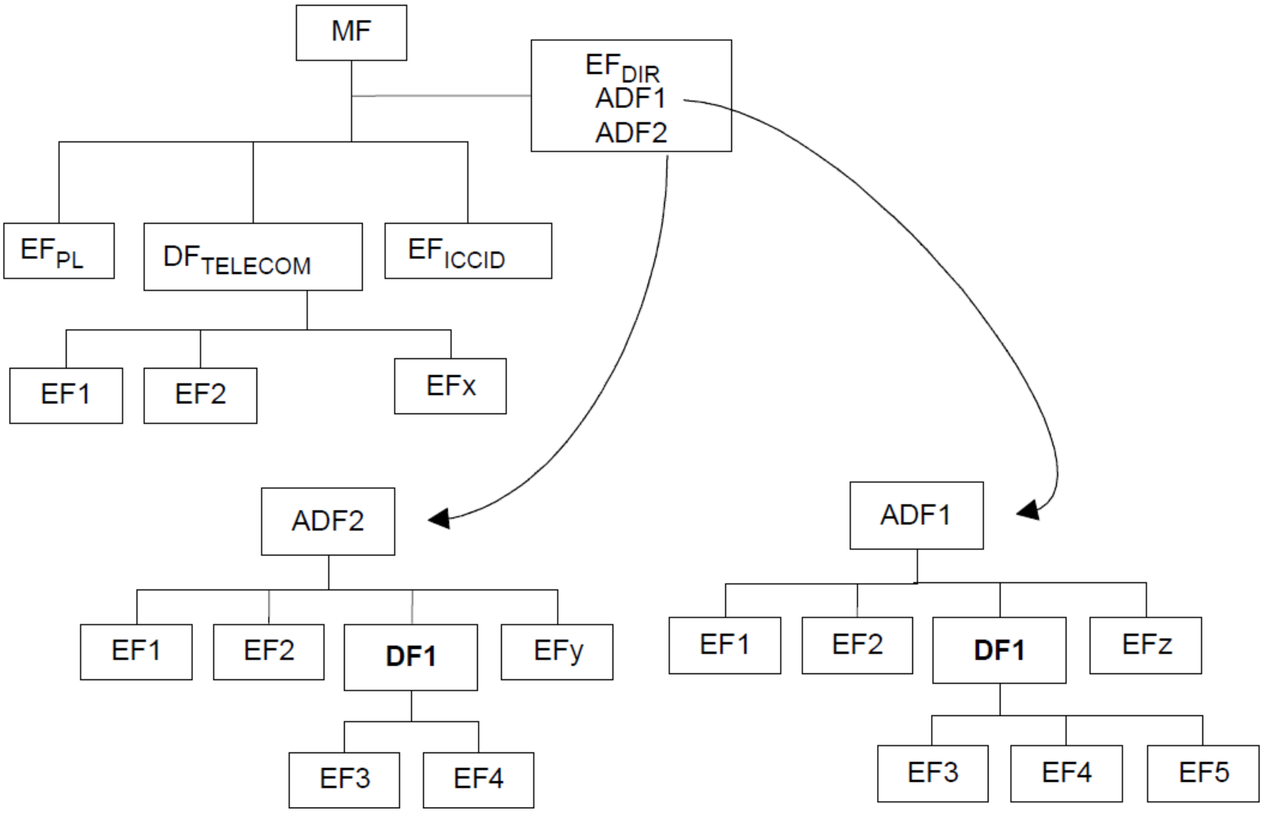
Overview

This topic specifies an extension to the Mobile Broadband Interface Model (MBIM) interface to permit accessing UICC smart card application and file systems. This extension to MBIM exposes logical access to the UICC's ETSI TS 102 221 technical specification -compliant applications and filesystems, and is supported in Windows 10, version 1903 and later.

UICC access and security

The UICC provides a file system and supports a set of applications that can run concurrently. These include the USIM for UMTS, CSIM for CDMA, and ISIM for IMS. The SIM is a legacy portion of the UICC that can be modeled as one of these applications (for GSM).

The following diagram from Section 8.1 of the ETSI TS 102 221 technical specification shows an example card application structure.



The UICC file system can be regarded as a forest of directory trees. The legacy SIM tree is rooted at a Master File (MF) and contains up to two levels of subdirectories (Dedicated Files, or DFs) containing Elemental Files (EFs) that hold various types of information. The SIM defines DFs under the MF, one of which, DFTelecom, contains information common to multiple access types such as the common phone book. Additional applications are effectively implemented as separate trees, each rooted in its own Application Directory File (ADF). Each ADF is identified by an application identifier that can be up to 128 bits long. A file under the card root (EFDir under the MF in the diagram) contains the application names and corresponding identifiers. Within a tree (the MF or an ADF), DFs and EFs might be identified by a path of file IDs, where a file ID is a 16-bit integer.

NDIS interface extensions

The following OIDs have been defined to support UICC application and file system access.

- OID_WWAN_UICC_APP_LIST
- OID_WWAN_UICC_FILE_STATUS
- OID_WWAN_UICC_ACCESS_BINARY
- OID_WWAN_UICC_ACCESS_RECORD
- OID_WWAN_PIN_EX2

MBIM service and CID values

Service name	UUID	UUID value
Microsoft Low-Level UICC Access	UUID_MS_UICC_LOW_LEVEL	C2F6588E-F037-4BC9-8665-F4D44BD09367
Microsoft Basic IP Connectivity Extensions	UUID_BASIC_CONNECT_EXTENSIONS	3D01DCC5-FEF5-4D05-9D3A-BEF7058E9AAF

The following table specifies the UUID and command code for each CID, as well as whether the CID supports Set, Query, or Event (notification) requests. See each CID's individual Section within this topic for more info about its parameters, data structures, and notifications.

CID	UUID	Command code	Set	Query	Notify
MBIM_CID_MS_UICC_APP_LIST	UUID_MS_UICC_LOW_LEVEL	7	N	Y	N
MBIM_CID_MS_UICC_FILE_STATUS	UUID_MS_UICC_LOW_LEVEL	8	N	Y	N
MBIM_CID_MS_UICC_ACCESS_BINARY	UUID_MS_UICC_LOW_LEVEL	9	Y	Y	N
MBIM_CID_MS_UICC_ACCESS_RECORD	UUID_MS_UICC_LOW_LEVEL	10	Y	Y	N
MBIM_CID_MS_PIN_EX	UUID_BASIC_CONNECT_EXTENSIONS	14	Y	Y	N

MBIM_CID_MS_UICC_APP_LIST

This CID retrieves a list of applications in a UICC and information about them. When the UICC in the modem is fully initialized and ready to register with the mobile operator, a UICC application must be selected for registration and a query with this CID should return the selected application in the **ActiveAppIndex** field in the MBIM_UICC_APP_LIST structure used in response.

Parameters

Operation	Set	Query	Notification
Command	Not applicable	Empty	Not applicable
Response	Not applicable	MBIM_UICC_APP_LIST	Not applicable

Query

The InformationBuffer of MBIM_COMMAND_MSG is empty.

Set

Not applicable.

Response

The InformationBuffer in MBIM_COMMAND_DONE contains the following MBIM_UICC_APP_LIST structure.

MBIM_UICC_APP_LIST (version 1)

Offset	Size	Field	Type	Description
0	4	Version	UINT32	The version number of the structure that follows. This field must be set to **1** for version 1 of this structure.
4	4	AppCount	UINT32	The number of UICC application **MBIM_UICC_APP_INFO** structures being returned in this response.
8	4	ActiveAppIndex	UINT32(0..NumApp - 1)	The index of the application selected by the modem for registration with the mobile network. This field must be between **0** and the **AppCount - 1**. It indexes to the array of applications returned by this response. If no application is selected for registration, this field contains **0xFFFFFFFF**.
12	4	AppListSize	UINT32	The size of the app list data, in bytes.
	8*AppCount	AppList	OL_PAIR_LIST	First element of the pair is a 4-byte field with the Offset of an app info in the DataBuffer. Second element of the pair is a 4-byte field with the size of the app info.
	AppListSize	DataBuffer	DATABUFFER	An array of **AppCount** * **MBIM_UICC_APP_INFO** structures.

MBIM_UICC_APP_INFO

Offset	Size	Field	Type	Description
0	4	AppType	MBIM_UICC_APP_TYPE	The type of the UICC application.
4	4	AppIdOffset	OFFSET	Offset for the application ID in the databuffer. Only the first AppIdSize bytes are meaningful. If the application ID is longer than MBIM_MAXLENGTH_APPID bytes, then AppIdSize specifies the actual length but only the first MBIM_MAXLENGTH_APPID bytes are in this field. This field is valid only when AppType is not MBIMUiccAppTypeMf, MBIMUiccAppTypeMfSIM, or MBIMUiccAppTypeMfRUIM.
8	4	AppIdSize	SIZE (0..16)	The size of the application ID, in bytes, as defined in Section 8.3 of the ETSI TS 102 221 technical specification. AppIdSize may contain a number greater than 16, but in this case only the first 16 (MBIM_MAXLENGTH_APPID) bytes are in the databuffer. This field is set to zero for the MBIMUiccAppTypeMf, MBIMUiccAppTypeMfSIM, or MBIMUiccAppTypeMfRUIM app types.
12		AppNameOffset	OFFSET	Offset for the application name in the databuffer. A UTF-8 string specifying the name of the application. The length of this field is specified by AppNameLength. If the length is greater than or equal to MBIM_MAXLENGTH_APPNAME bytes, this field contains the first MBIM_MAXLENGTH_APPNAME - 1 bytes of the name. The string is always null-terminated.
16	4	AppNameLength	SIZE (0..256)	The length, in bytes, of the application name. AppNameLength may contain a number equal to or greater than 256, but in these cases only the first 255 (MBIM_MAXLENGTH_APPNAME - 1) bytes are in the databuffer.
20	4	NumPinKeyRefs	SIZE (0..8)	The number of application PIN key references. In other words, the number of elements of PinKeyRef that are valid. Applications on a virtual R-UIM have no PIN key references.

Offset	Size	Field	Type	Description
24	4	KeyRefOffset	OFFSET	Offset of the PinKeyRef in the DataBuffer. The PinKeyRef is a byte array specifying the application's PIN key references for different levels of verification (keys for PIN1, PIN2, and possibly a universal PIN), as defined in Table 9.3 and Section 9.4.2 of the ETSI TS 102 221 technical specification. In the case of a single-verification card, or an MBB driver and/or modem that does not support different application keys for different applications, the first byte of the PinKeyRef field must be 0x01 (PIN1) and the second byte must be 0x81 (PIN2), as described in Section 9.5.1 of ETSI TS 102 221.
28	4	KeyRefSize	SIZE (0..8)	The size of PinKeyRef.
32		DataBuffer	DATABUFFER	The data buffer containing AppId, AppName, and PinKeyRef.of a single-verification card, or an MBB driver and/or modem that does not support different application keys for different applications, this field must be **0x01**.

MBIM_UICC_APP_TYPE

Type	Value	Description
MBIMUiccAppTypeUnknown	0	Unknown type.
MBIMUiccAppTypeMf	1	Legacy SIM directories rooted at the MF.
MBIMUiccAppTypeMfSIM	2	Legacy SIM directories rooted at the DF_GSM.
MBIMUiccAppTypeMfRUIM	3	Legacy SIM directories rooted at the DF_CDMA.
MBIMUiccAppTypeUSIM	4	USIM application.
MBIMUiccAppTypeCSIM	5	CSIM applicaton.
MBIMUiccAppTypeISIM	6	ISIM application.

Constants

The following constants are defined for MBIM_CID_MS_UICC_APP_INFO.

`const int MBIM_MAXLENGTH_APPID = 32`

`const int MBIM_MAXLENGTH_APPNAME = 256`

`const int MBIM_MAXNUM_PINREF = 8`

Unsolicited Events

Not applicable.

Status Codes

The following status codes are applicable:

Status code	Description
MBIM_STATUS_SUCCESS	Basic MBIM status as defined for all commands.
MBIM_STATUS_BUSY	Basic MBIM status as defined for all commands.
MBIM_STATUS_FAILURE	Basic MBIM status as defined for all commands.
MBIM_STATUS_NO_DEVICE_SUPPORT	Basic MBIM status as defined for all commands.
MBIM_STATUS_SIM_NOT_INSERTED	Unable to perform the UICC operation because the UICC is missing.
MBIM_STATUS_BAD_SIM	Unable to perform the UICC operation because the UICC is in an error state.
MBIM_STATUS_NOT_INITIALIZED	Unable to perform the UICC operation because the UICC is not yet fully initialized.

MBIM_CID_MS_UICC_FILE_STATUS

This CID retrieves information about a specified UICC file.

Parameters

Operation	Set	Query	Notification
Command	Not applicable	MBIM_UICC_FILE_PATH	Not applicable
Response	Not applicable	MBIM_UICC_FILE_STATUS	Not applicable

Query

The InformationBuffer of MBIM_COMMAND_MSG contains the target EF as an MBIM_UICC_FILE_PATH structure.

MBIM_UICC_FILE_PATH (version 1)

Offset	Size	Field	Type	Description

Offset	Size	Field	Type	Description
0	4	Version	UINT32	The version number of the structure that follows. This field must be **1** for version 1 of this structure.
4	4	AppIdOffset	OFFSET	The offset, in bytes, calculated from the beginning of this structure to the buffer containing the application ID.
8	4	AppIdSize	SIZE (0..16)	The size of the application ID, in bytes, as defined in Section 8.3 of the ETSI TS 102 221 technical specification. For 2G cards, this field must be set to zero (0).
12	4	FilePathOffset	OFFSET	The offset, in bytes, calculated from the beginning of this structure to the buffer containing the file path. The file path is an array of 16-bit file IDs. The first ID must be either **0x7FFF** or **0x3F00**. If the first ID is **0x7FFF**, then the path is relative to the ADF of the application desginated by **AppId**. Otherwise, it is an absolute path starting from the MF.
16	4	FilePathSize	SIZE (0..8)	The size of the file path, in bytes.
20		DataBuffer	DATABUFFER	The data buffer containing AppId and FilePath.

Set

Not applicable.

Response

The following MBIM_UICC_FILE_STATUS structure is used in the InformationBuffer.

MBIM_UICC_FILE_STATUS (version 1)

Offset	Size	Field	Type	Description
0	4	Version	UINT32	The version number of the structure that follows. This field must be **1** for version 1 of this structure.
4	4	StatusWord1	UINT32(0..256)	A return parameter specific to the UICC command.
8	4	StatusWord2	UINT32(0..256)	A return parameter specific to the UICC command.
12	4	FileAccessibility	MBIM_UICC_FILE_ACCESSIBILITY	The UICC file accessibility.
16	4	FileType	MBIM_UICC_FILE_TYPE	The UICC file type.
20	4	FileStructure	MBIM_UICC_FILE_STRUCTURE	The UICC file structure.

Offset	Size	Field	Type	Description
24	4	ItemCount	UINT32	The number of items in the UICC file. For transparent and TLV files, this is set to **1**.
28	4	Size	UINT32	The size of each item, in bytes. For transparent or TLV files, this is the size of the entire EF. For record-based files, this represents the total number of records.
32	16	FileLockStatus	MBIM_PIN_TYPE_EX[4]	An array of type MBIM_PIN_TYPE_EX that describes the access condition for each operation (READ, UPDATE, ACTIVATE, and DEACTIVATE in that order) on that file.

MBIM_UICC_FILE_ACCESSIBILITY

The MBIM_UICC_FILE_ACCESSIBILITY enumeration is used in the preceding MBIM_UICC_FILE_STATUS structure.

Type	Value	Description
MBIMUiccFileAccessibilityUnknown	0	File shareability unknown.
MBIMUiccFileAccessibilityNotShareable	1	Not shareable file.
MBIMUiccFileAccessibilityShareable	2	Shareable file.

MBIM_UICC_FILE_TYPE

The MBIM_UICC_FILE_TYPE enumeration is used in the preceding MBIM_UICC_FILE_STATUS structure.

Type	Value	Description
MBIMUiccFileTypeUnknown	0	File type unknown.
MBIMUiccFileTypeWorkingEf	1	Working EF.
MBIMUiccFileTypeInternalEf	2	Internal EF.
MBIMUiccFileTypeDfOrAdf	3	Dedicated file, a directory that is the parent of other nodes. This may be a DF or ADF.

MBIM_UICC_FILE_STRUCTURE

The MBIM_UICC_FILE_STRUCTURE enumeration is used in the preceding MBIM_UICC_FILE_STATUS structure.

Type	Value	Description
MBIMUiccFileStructureUnknown	0	An unknown file structure.
MBIMUiccFileStructureTransparent	1	A single record of variable length.
MBIMUiccFileStructureCyclic	2	A cyclic set of records, each of the same length.
MBIMUiccFileStructureLinear	3	A linear set of records, each of the same length.
MBIMUiccFileStructureBerTLV	4	A set of data values accessible by tag.

MBIM_PIN_TYPE_EX

The MBIM_PIN_TYPE_EX enumeration is used in the preceding MBIM_UICC_FILE_STATUS structure.

Type	Value	Description
MBIMPinTypeNone	0	No PIN is pending to be entered.
MBIMPinTypeCustom	1	The PIN type is a custom type and is none of the other PIN types listed in this enumeration.
MBIMPinTypePin1	2	The PIN1 key.
MBIMPinTypePin2	3	The PIN2 key.
MBIMPinTypeDeviceSimPin	4	The device to SIM key.
MBIMPinTypeDeviceFirstSimPin	5	The device to very first SIM key.
MBIMPinTypeNetworkPin	6	The network personalization key.
MBIMPinTypeNetworkSubsetPin	7	The network subset personalization key.
MBIMPinTypeServiceProviderPin	8	The service provider (SP) personalization key.
MBIMPinTypeCorporatePin	9	The corporate personalization key.
MBIMPinTypeSubsidyLock	10	The subsidy unlock key.
MBIMPinTypePuk1	11	The Personal Identification Number 1 Unlock Key (PUK1).
MBIMPinTypePuk2	12	The Personal Identification Number 2 Unlock Key (PUK2).
MBIMPinTypeDeviceFirstSimPuk	13	The device to very first SIM PIN unlock key.
MBIMPinTypeNetworkPuk	14	The network personalization unlock key.
MBIMPinTypeNetworkSubsetPuk	15	The network subset personalization unlock key.
MBIMPinTypeServiceProviderPuk	16	The service provider (SP) personalization unlock key.

Type	Value	Description
MBIMPinTypeCorporatePuk	17	The corporate personalization unlock key.
MBIMPinTypeNev	18	The NEV key.
MBIMPinTypeAdm	19	The administrative key.

Unsolicited Events

Not applicable.

Status Codes

The following status codes are applicable:

Status code	Description
MBIM_STATUS_BUSY	Basic MBIM status as defined for all commands.
MBIM_STATUS_FAILURE	Basic MBIM status as defined for all commands.
MBIM_STATUS_SIM_NOT_INSERTED	Unable to perform the UICC operation because the UICC is missing.
MBIM_STATUS_BAD_SIM	Unable to perform the UICC operation because the UICC is in an error state.
MBIM_STATUS_SHAREABILITY_CONDITION_ERROR	The file cannot be selected because it is not shareable and is currently being accessed by another application. The status word returned by the SIM is 6985.

MBIM_CID_MS_UICC_ACCESS_BINARY

This CID sends a specific command to access a UICC binary file, with structure type **MBIMUiccFileStructureTransparent** or **MBIMUiccFileStructureBerTLV**.

Parameters

Operation	Set	Query	Notification
Command	Not applicable	MBIM_UICC_ACCESS_BINARY	Not applicable
Response	Not applicable	MBIM_UICC_RESPONSE	Not applicable

Query

Reads a binary file. The InformationBuffer for MBIM_COMMAND_MSG contains an MBIM_UICC_ACCESS_BINARY structure. An MBIM_UICC_RESPONSE structure is returned in the InformationBuffer of MBIM_COMMAND_DONE.

MBIM_UICC_ACCESS_BINARY (version 1)

Offset	Size	Field	Type	Description
0	4	Version	UINT32	The version number of the structure that follows. This field must be set to **1** for version 1 of this structure.
4	4	AppIdOffset	OFFSET	The offset, in bytes, from the beginning of this structure to the buffer containing the application ID.
8	4	AppIdSize	SIZE (0..16)	The size of the application ID, in bytes, as defined in Section 8.3 of the ETSI TS 102 221 technical specification. For 2G cards, this field must be set to zero (0).
12	4	FilePathOffset	OFFSET	The offset, in bytes, calculated from the beginning of this structure to the buffer containing the file path. The file path is an array of 16-bit file IDs. The first ID must be either **0x7FFF** or **0x3F00**. If the first ID is **0x7FFF**, then the path is relative to the ADF of the application desginated by **AppId**. Otherwise, it is an absolute path starting from the MF.
16	4	FilePathSize	SIZE	The size of the file path, in bytes.
20	4	FileOffset	UINT32	The offset to be used when reading from the file. This field can be bigger than 256, and it combines both offset high and offset low as defined in the ETSI TS 102 221 technical specification.
24	4	NumberOfBytes	UINT32	The number of bytes to be read. For example, a client driver could use this function to read a transparent (binary) file that is larger than 256 bytes, although the maximum amount that can be read or written in a single UICC operation is 256 bytes per the ETSI TS 102 221 technical specification. It is the function's responsibility to split this into multiple APDUs and send back the result in a single response.
28	4	LocalPinOffset	OFFSET	The offset, in bytes, calculated from the beginning of this structure to the buffer containing the password. This is the local PIN (PIN2) and is used in case the operation requires local PIN validation.
32	4	LocalPinSize	SIZE (0..16)	The size of the password, in bytes.
36	4	BinaryDataOffset	OFFSET	The offset, in bytes, calculated from the beginning of this structure to the buffer containing the command-specific data. Binary data is only used for SET operations.

Offset	Size	Field	Type	Description
40	4	BinaryDataSize	SIZE (0..32768)	The size of the data, in bytes.
44		DataBuffer	DATABUFFER	The data buffer containing AppId, FilePath, LocalPin, and BinaryData.

Set

Not applicable.

Response

The following MBIM_UICC_RESPONSE structure is used in the InformationBuffer.

MBIM_UICC_RESPONSE (version 1)

Offset	Size	Field	Type	Description
0	4	Version	UINT32	The version number of the structurethat follows. This field must be **1** for version 1 of this structure.
4	4	StatusWord1	UINT32(0..256)	A return parameter specific to the UICC command.
8	4	StatusWord2	UINT32(0..256)	A return parameter specific to the UICC command.
12	4	ResponseDataOffset	OFFSET	The offset, in bytes, calculated from the beginning of this structure to the buffer containing the response data. The response data is only used for QUERY operations.
16	4	ResponseDataSize	SIZE (0..32768)	The size of the data, in bytes.
20		DataBuffer	DATABUFFER	The data buffer containing ResponseData.

Unsolicited Events

Not applicable.

Status Codes

The following status codes are applicable:

Status code	Description
MBIM_STATUS_BUSY	Basic MBIM status as defined for all commands.
MBIM_STATUS_FAILURE	Basic MBIM status as defined for all commands.

Status code	Description
MBIM_STATUS_SIM_NOT_INSERTED	Unable to perform the UICC operation because the UICC is missing.
MBIM_STATUS_BAD_SIM	Unable to perform the UICC operation because the UICC is in an error state.
MBIM_STATUS_SHAREABILITY_CONDITION_ERROR	The file cannot be selected because it is not shareable and is currently being accessed by another application. The status word returned by the SIM is 6985.
MBIM_STATUS_PIN_FAILURE	The operation failed due to a PIN error.

MBIM_CID_MS_UICC_ACCESS_RECORD

This CID sends a specific command to access a UICC linear fixed or cyclic file, with structure type of **MBIMUiccFileStructureCyclic** or **MBIMUIccFileStructureLinear**.

Parameters

Operation	Set	Query	Notification
Command	Not applicable	MBIM_UICC_ACCESS_RECORD	Not applicable
Response	Not applicable	MBIM_UICC_RESPONSE	Not applicable

Query

Reads contents of a record. The InformationBuffer for MBIM_COMMAND_MSG contains the following MBIM_UICC_ACCESS_RECORD structure. MBIM_UICC_RESPONSE is returned in the InformationBuffer of MBIM_COMMAND_DONE.

MBIM_UICC_ACCESS_RECORD (version 1)

Offset	Size	Field	Type	Description
0	4	Version	UINT32	The version number of the structure that follows. This field must be set to **1** for version 1 of this structure.
4	4	AppIdOffset	OFFSET	The offset, in bytes, from the beginning of this structure to the buffer containing the application ID.
8	4	AppIdSize	SIZE (0..16)	The size of the application ID, in bytes, as defined in Section 8.3 of the ETSI TS 102 221 technical specification. For 2G cards, this field must be set to zero (0).

Offset	Size	Field	Type	Description
12	4	FilePathOffset	OFFSET	The offset, in bytes, calculated from the beginning of this structure to the buffer containing the file path. The file path is an array of 16-bit file IDs. The first ID must be either **0x7FFF** or **0x3F00**. If the first ID is **0x7FFF**, then the path is relative to the ADF of the application desginated by **AppId**. Otherwise, it is an absolute path starting from the MF.
16	4	FilePathSize	SIZE	The size of the file path, in bytes.
20	4	RecordNumber	UINT32(0..256)	The record number. This represents the absolute record index at all times. Relative record access is not supported because the modem can perform multiple accesses on a file (NEXT, PREVIOUS).
24	4	LocalPinOffset	OFFSET	The offset, in bytes, calculated from the beginning of this structure to the buffer containing the password. The lock password is a null-terminated UTF-8 string of decimal digits.
28	4	LocalPinSize	SIZE (0..16)	The size of the password, in bytes.
32	4	RecordDataOffset	OFFSET	The offset, in bytes, calculated from the beginning of this structure to the buffer containing the command-specific data. Record data is only used for SET operations.
36	4	RecordDataSize	SIZE (0..256)	The size of the data, in bytes.
40		DataBuffer	DATABUFFER	The data buffer containing AppId, FilePath, LocalPin, and RecordData.

Set

Not applicable.

Response

An MBIM_UICC_RESPONSE structure is used in the InformationBuffer.

Unsolicited Events

Not applicable.

Status Codes

The following status codes are applicable:

Status code	Description
MBIM_STATUS_BUSY	Basic MBIM status as defined for all commands.
MBIM_STATUS_FAILURE	Basic MBIM status as defined for all commands.
MBIM_STATUS_SIM_NOT_INSERTED	Unable to perform the UICC operation because the UICC is missing.
MBIM_STATUS_BAD_SIM	Unable to perform the UICC operation because the UICC is in an error state.
MBIM_STATUS_SHAREABILITY_CONDITION_ERROR	The file cannot be selected because it is not shareable and is currently being accessed by another application. The status word returned by the SIM is 6985.
MBIM_STATUS_PIN_FAILURE	The operation failed due to a PIN error.

MBIM_CID_MS_PIN_EX

This CID is used to perform all PIN security operations as defined in Section 9 of the ETSI TS 102 221 technical specification. The CID is similar to MBIM_CID_MS_PIN, but extends it to support multi-app UICC cards. Only single-verification-capable UICCs are supported. Multi-verification-capable UICCs that support more than one application PIN are not supported. One application PIN (PIN1) is assigned to all ADFs/DFs and files on the UICC. However, each application can specify a local PIN (PIN2) as a level 2 user verification requirement, resulting in the need for additional validation for every access command. This scenario is what MBIM_CID_MS_PIN_EX supports.

Just like MBIM_CID_MS_PIN, with MBIM_CID_MS_PIN_EX the device only reports one PIN at a time. If multiple PINs are enabled and reporting multiple PINs is also enabled, then functions must report PIN1 first. For example, if subsidy lock reporting is enabled and the SIM's PIN1 is enabled, then the subsidy lock PIN should be reported in a subsequent query request only after PIN1 has been successfully verified. An empty PIN is permitted together with MBIMPinOperationEnter. An empty PIN is specified by setting the PinSize to zero. In this case, a SET command is similar to a QUERY and returns the state of the PIN referenced. This is fully aligned to the behavior of the VERIFY command as specified in Section 11.1.9 of the ETSI TS 102 221 technical specification.

Parameters

Operation	Set	Query	Notification
Command	MBIM_SET_PIN_EX	MBIM_PIN_APP	Not applicable
Response	MBIM_PIN_INFO_EX	MBIM_PIN_INFO_EX	Not applicable

Query

The following MBIM_PIN_APP structure is used in the InformationBuffer.

MBIM_PIN_APP (version 1)

Offset	Size	Field	Type	Description
0	4	Version	UINT32	The version number of the structure that follows. This field must be set to **1** for version 1 of this structure.
4	4	AppIdOffset	OFFSET	The offset, in bytes, from the beginning of this structure to the buffer containing the application ID.
8	4	AppIdSize	SIZE (0..16)	The size of the application ID, in bytes, as defined in Section 8.3 of the ETSI TS 102 221 technical specification. For 2G cards, this field must be set to zero (0).
12		DataBuffer	DATABUFFER	The AppId as defined in the ETSI TS 102 221 technical specification.

Set

The following MBIM_SET_PIN_EX structure is used in the InformationBuffer.

MBIM_SET_PIN_EX

Offset	Size	Field	Type	Description
0	4	PinType	MBIM_PIN_TYPE_EX	The PIN type. See the MBIM_PIN_TYPE_EX table in this topic.
4	4	PinOperation	MBIM_PIN_OPERATION	The PIN operation. See MBIM 1.0.
8	4	PinOffset	OFFSET	The offset, in bytes, calculated from the beginning of this structure to a string PIN that represents the PIN value with which to perform the action, or the PIN value required to enable or disable PIN settings. This field applies for all values of **PinOperation**.
12	4	PinSize	SIZE (0..32)	The size, in bytes, used for the PIN.
16	4	NewPinOffset	OFFSET	The offset, in bytes, calculated from the beginning of this structure to the **NewPin** string that represents the new PIN value to set when **PinOperation** is MBIMPinOperationChange or MBIMPinOperationEnter, for PinTypeMBIMPinTypePuk1 or PinTypeMBIMPinTypePuk2.
20	4	NewPinSize	SIZE (0..32)	The size, in bytes, used for the NewPin.

Offset	Size	Field	Type	Description
24	4	AppIdOffset	OFFSET	The offset, in bytes, calculated from the beginning of this structure to the buffer containing the application ID.
28	4	AppIdSize	SIZE (0..16)	The size of the application ID, in bytes, as defined in Section 8.3 of the ETSI TS 102 221 technical specification. For 2G cards, this field must be set to zero (0).
32		DataBuffer	DATABUFFER	The data buffer containing the Pin, NewPin, and AppId.

Response

The following MBIM_PIN_INFO_EX structure is used in the InformationBuffer.

Offset	Size	Field	Type	Description
0	4	PinType	MBIM_PIN_TYPE_EX	The PIN type. See the MBIM_PIN_TYPE_EX table in this topic.
4	4	PinState	MBIM_PIN_STATE	The PIN state. See MBIM 1.0.
8	4	RemainingAttempts	UINT32	The number of remaining attempts for any PIN-related operations such as enter, enable, or disable. Devices that do not support this information must set this member to 0xFFFFFFFF.

Unsolicited Events

Not applicable.

Status Codes

The following status codes are applicable:

Status code	Description
MBIM_STATUS_BUSY	Basic MBIM status as defined for all commands.
MBIM_STATUS_FAILURE	Basic MBIM status as defined for all commands.
MBIM_STATUS_SIM_NOT_INSERTED	Unable to perform the UICC operation because the UICC is missing.
MBIM_STATUS_BAD_SIM	Unable to perform the UICC operation because the UICC is in an error state.
MBIM_STATUS_PIN_DISABLED	The operation failed because the PIN is disabled.

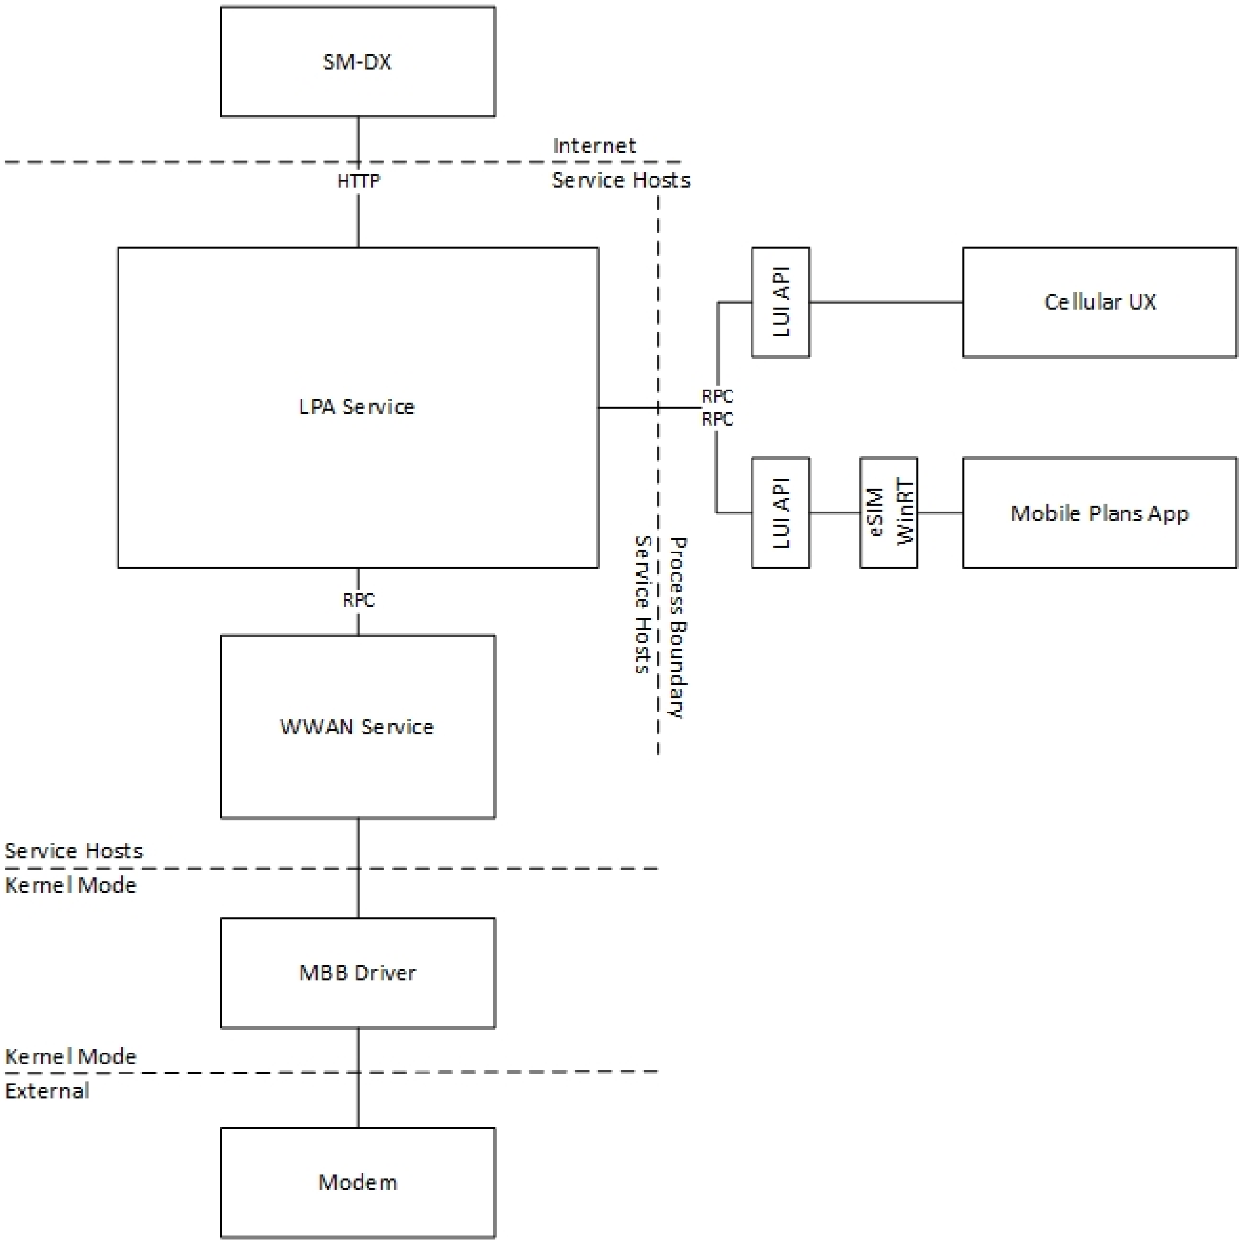
Status code	Description
MBIM_STATUS_PIN_REQUIRED	The operation failed because a PIN must be entered to proceed.
MBIM_STATUS_NO_DEVICE_SUPPORT	The operation failed because a SET on a corresponding PIN type is not supported by the device.

MB eSIM Operations

Article • 03/14/2023

eSIM Architecture

The Local Profile Assitant (LPA) component of the Windows operating system is the LPA Service while the low level UICC access is exposed through the WWAN Service. The LPA Service handles profile discovery, downloading profiles, and profile management.



MB Interface Update for eSIM Operations

The modem needs to support the following MB Low Level UICC access CIDs for eSIM functionality.

```
MBIM_CID_MS_UICC_ATR
MBIM_CID_MS_UICC_OPEN_CHANNEL
MBIM_CID_MS_UICC_CLOSE_CHANNEL
MBIM_CID_MS_UICC_APDU
MBIM_CID_MS_UICC_TERMINAL_CAPABILITY
MBIM_CID_MS_UICC_RESET
```

eSIM Service Initialization

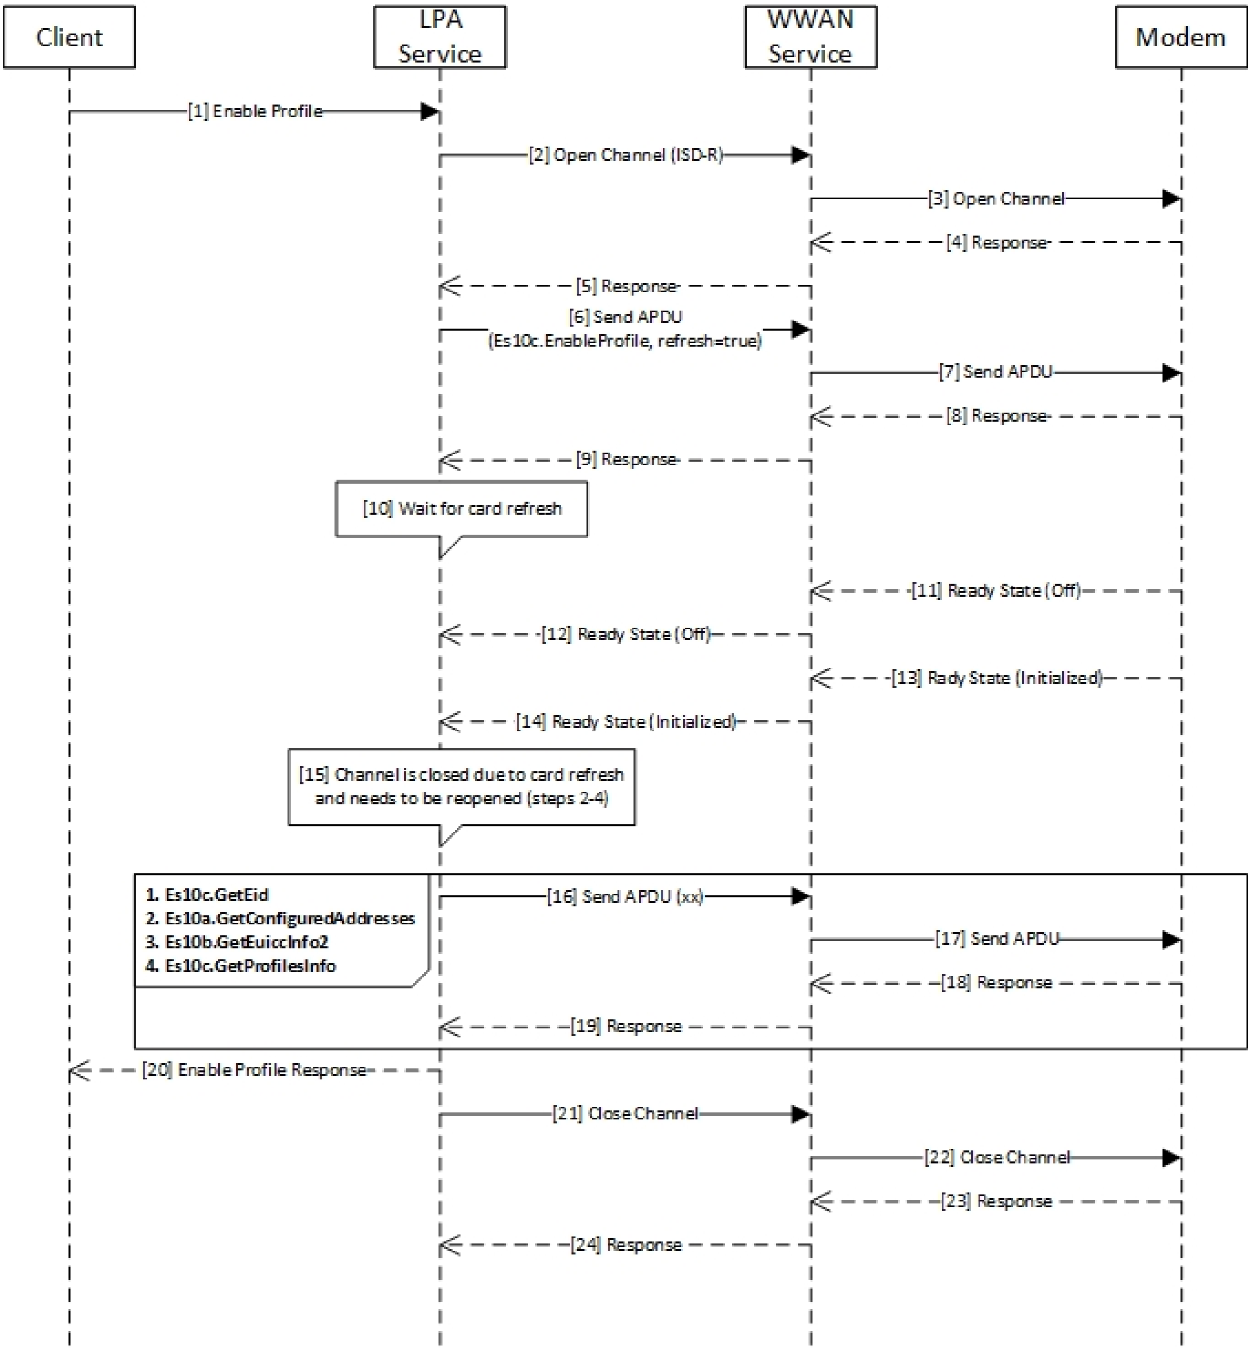
eSIM Profile Operations

eSIM Profile Operations include:

```
Enable Profile
Disable Profile
Delete Profile
Wipe eSIM
Update NickName
```

Below is a sample flow for the Enable Profile operation. The other Profile Operations follow a similar flow except that MBIM_CID_MS_UICC_APDU will contain the Es10c command for the respective operation.



Card Refresh

The eSIM Profile Operations expect that card refresh will be performed followed by the ready state change according to the MB eSIM MBIM ready state guidance.

Hardware Lab Kit (HLK) Tests

The following tests in the HLK can be used to verify eSIM functionality:

TestLowLevelUiccAccess

TestReadyInfo

TestResetPassthrough

Via netsh, we can run the **TestLowLevelUiccAccess** HLK testlist. For more information on using the netsh tool, see **netsh-mbn** and **netsh-mbn-test-installation**.

```
netsh mbn test feature=esim testpath="C:\data\test\bin"
taefpath="C:\data\test\bin" param="AccessString=internet"
```

The file showing the HLK test results should have been generated in the directory that the 'netsh mbn test' command was ran from: `TestLowLevelUiccAccess.htm`.

Manual Tests

Test eSIM profile management

1. Required resources: An eSIM and an activation code or a QR code for the profile download. The profile needs a confirmation code to download.
2. Open Settings->Network & Internet -> Cellular.
3. Click ***Manage eSIM profiles***.
4. Click ***Add a new profile***.
5. Choose ***Let me enter an activation code I have from my mobile operator*** and click ***Next***.
6. Scan the QR code or type in the activation code.
7. Wait until the confirmation page shows up. Fill in the confirmation code and click ***Next***.
8. Dismiss the dialog and then enable the profile.
9. Change the name of the profile. The new name should be displayed for the profile.
10. Delete the profile.
11. Install the profile again (repeating steps 4-7), but this time with the wrong confirmation code. For example, when scanning a QR code the code hash displays for a second before contacting the server. Very quickly click anywhere inside of it and hit the back key to delete a single character before it talks to the server.
12. You should see an error message and eventually land at the confirmation page again. Type in the correct confirmation code this time and click ***Next***.
13. Dismiss the dialog and delete the profile.

Test autoconnect after reboot

1. Make sure Ethernet is unplugged and Wi-Fi is toggled off. With a known good eSIM profile present on the physical eSIM in the device, browse to Settings -> Network & Internet -> Cellular -> Manage eSIM profiles -> eSIM profiles, select the profile, and click ***Use***. Verify that browsing the internet works normally.
2. Reboot the machine, login, and browse to Settings -> Network & Internet -> Cellular -> Manage eSIM profiles -> eSIM profiles. The profile should show as Active, systray should show Cellular connection bars, and browsing the internet should work normally.
3. Back in Manage eSIM profiles, select the profile, and click ***Stop using***. The profile should disconnect data.

MB eSIM Troubleshooting Guide

Follow this guide to debug eSIM issues.

Profile Download and Install Failures

1. Collect and decode the logs using the instructions in MB Collecting Logs
2. Open the .txt file generated in TextAnalysisTool
3. Load the eSIM Download and Install Filter

Here is sample success log for Profile Download and Install:

Firmware Upgrade for eSIM

Article • 03/14/2023

Overview

This document describes the Windows OS changes that support firmware updates for eSIM devices.

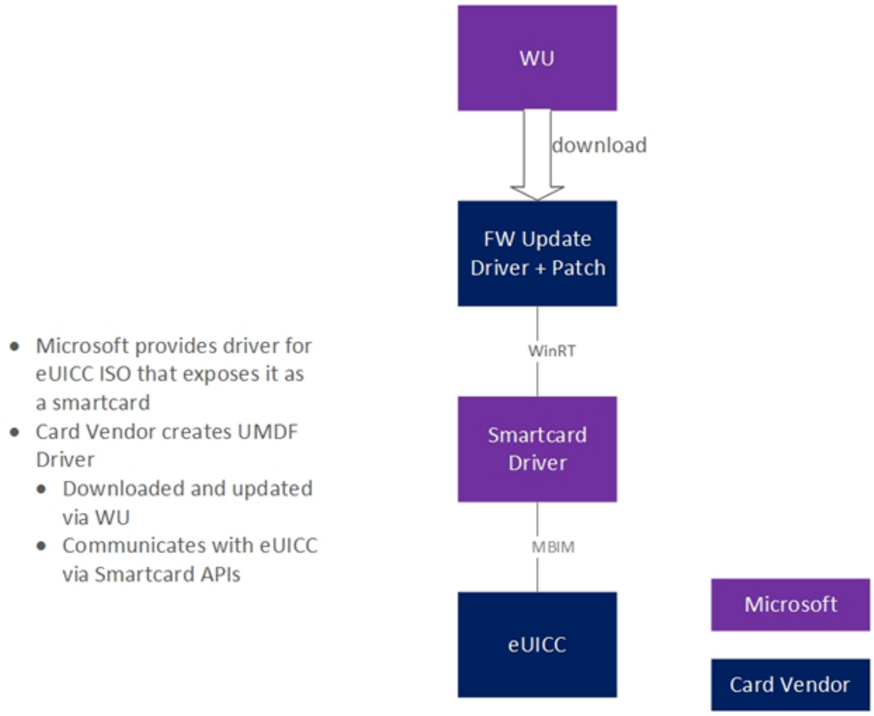
Windows Update (WU) is the model used for the firmware patches. In this model, the eSIM device vendor authors a UMDF driver and adds it to a WU package along with the firmware patch. The package is published to the WU and will be downloaded & installed on Windows devices containing the card vendor's eSIM device. Once installed the card vendor's driver writes the firmware patch using the Smart Card WinRT API. Microsoft enables this by providing a UMDF driver for the ISO interface of the eSIM and exposing it as a smart card via the existing Smart Card WinRT API.

The modem ISO interface has a 255-byte limitation as the max Application Protocol Data Unit (APDU) size and is therefore too slow for full firmware OS updates (TRC/PBL image). For full firmware OS updates, Microsoft provides a separate smart card UMDF driver which uses the SPB interface of the eSIM as the transport.

The following acronyms are used in this section:

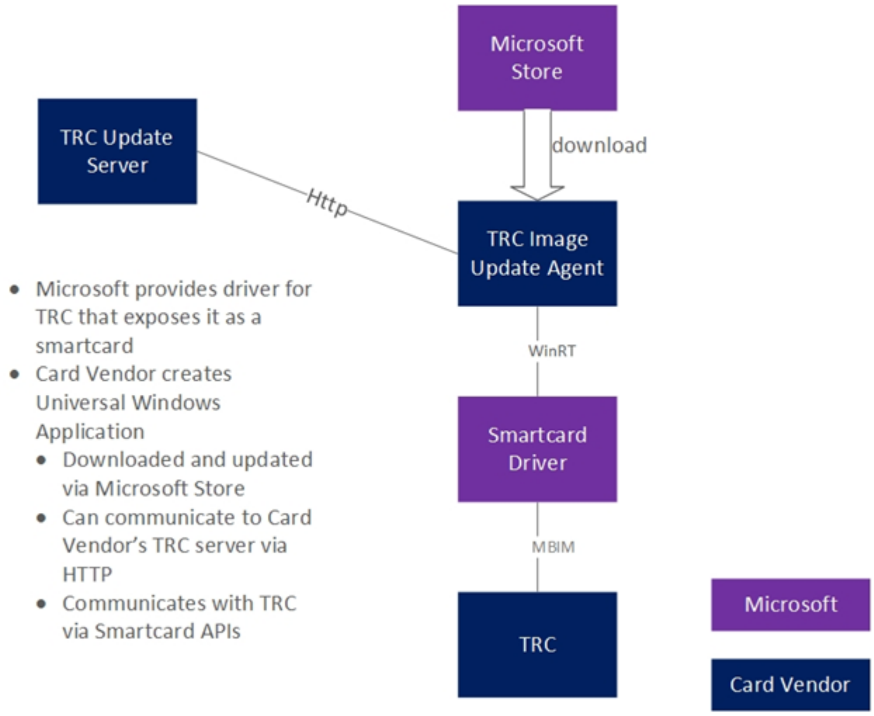
- **ACPI:** Advanced Configuration and Power Interface
- **APDU:** Application Protocol Data Unit
- **ATR:** Answer to Reset
- **eUICC:** Embedded Universal Integrated Circuit Card
- **FW:** Firmware
- **HCP:** Host Controller Protocol
- **HWID:** Hardware ID
- **ISO:** International Organization for Standardization
- **MF:** Master File
- **MSFT:** Microsoft
- **OEM:** Original Equipment Manufacturer
- **PBL:** Primary bootloader
- **RPC:** Remote Procedure Call
- **ScardSvr:** Smart Cards for Windows Service
- **Scard WinRT:** Smart Card Windows Runtime
- **SC DDI:** Smart Card DDI
- **sHDLC:** Simplified High Level Data Link Control
- **SPB:** Simple Peripheral Bus
- **SPI:** Serial Peripheral Interface
- **TRC:** Tamper Resistant Chip
- **WwanSvc:** WWAN Service

High Level Design for Firmware Patch Update



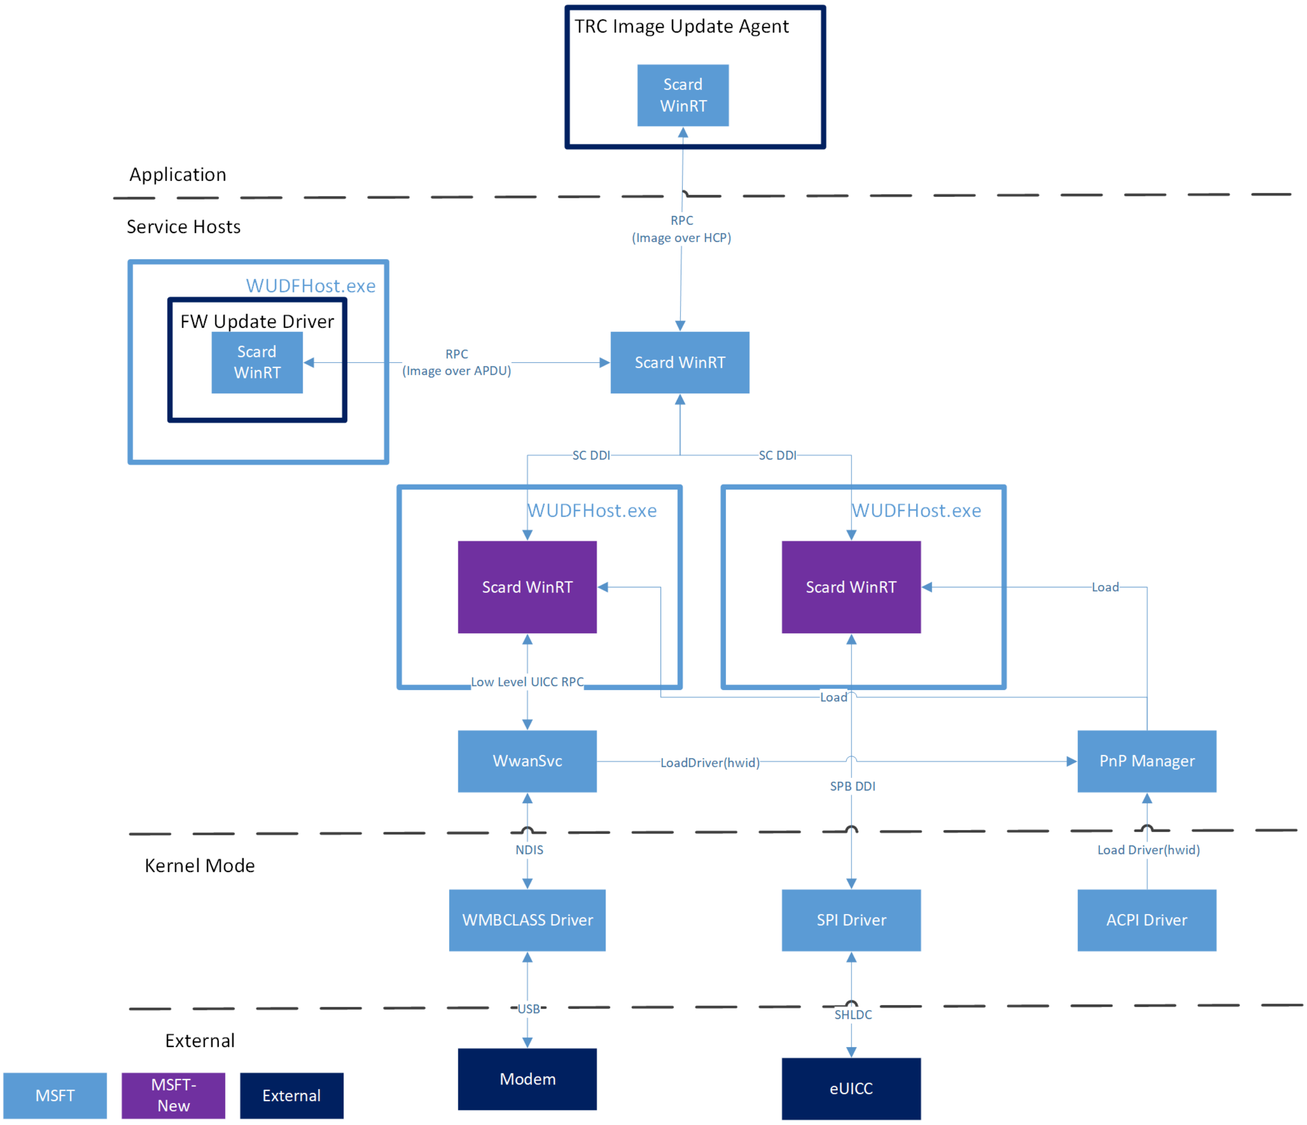
- Microsoft provides driver for eUICC ISO that exposes it as a smartcard
- Card Vendor creates UMDF Driver
  - Downloaded and updated via WU
  - Communicates with eUICC via Smartcard APIs

High Level Design for Firmware OS Update



- Microsoft provides driver for TRC that exposes it as a smartcard
- Card Vendor creates Universal Windows Application
  - Downloaded and updated via Microsoft Store
  - Can communicate to Card Vendor's TRC server via HTTP
  - Communicates with TRC via Smartcard APIs

Firmware Upgrade Architecture



For Windows 10, version 1703 the card vendor will deliver firmware updates on APDUs over the ISO interface. Updates for full images (PBL HCP) on HCP packets over the SPI interface are planned for the Windows 10, version 1709 time frame.

The ISO UMDF driver is loaded by the WWAN Service when the WWAN Service detects an eSIM based on the ATR information. The ISO UMDF driver sends APDUs to the eUICC via the modem using the low-level UICC access RPC of the WWAN Service.

The SPI UMDF driver is loaded by PnP based on the hardware ID in the ACPI entry for the eSIM card. The SPI UMDF driver sends sHDLC frames to the TRC on the card via the SPB IOCTL interface.

On the upper layer both drivers will implement the Smart Card DDI that provides low-level access for interacting with smart cards. This will expose both the ISO and SPI interfaces of the eSIM as a smart card via the Smart Card WinRT API.

In devices where the SPI interface to eSIM is available, OEMs are expected to add the Microsoft UICC SPI driver HWID to the ACPI table as a hardware compatible ID. The HWID for the Microsoft UICC SPI driver is ACPI\MSFTUICCSPB.

UMDF drivers

UMDF drivers will implement the following Smart Card IOCTLs:

Usage	DDI
Smart card states	IOCTL_SMARTCARD_GET_STATE IOCTL_SMARTCARD_IS_ABSENT IOCTL_SMARTCARD_IS_PRESENT IOCTL_SMARTCARD_POWER
Smart card attributes	IOCTL_SMARTCARD_GET_ATTRIBUTE IOCTL_SMARTCARD_SET_ATTRIBUTE

Usage	DDI
Smart card communication	IOCTL_SMARTCARD_SET_PROTOCOL IOCTL_SMARTCARD_TRANSMIT

Requirements for smart card devices

Define the following device properties:

Define	Name	Type	FormatID	Value
Device interface guid	System.Devices.InterfaceClassGuid -- PKEY_Devices_InterfaceClassGuid	Guid -- VT_CLSID	{026E516E-B814-414B-83CD-856D6FEF4822}, 4, DEVPROP_TYPE_GUID	{DEEBE6AD-9E01-47E2-A3B2-A66AA2C036C9}
ReaderKind	System.Devices.SmartCards.ReaderKind -- PKEY_Devices_SmartCards_ReaderKind	Byte -- VT_UI1 (should be INT16 Bug 9550228)	{D6B5B883-18BD-4B4D-B2EC-9E38AFFEDA82}, 2, DEVPROP_TYPE_BYTE	SmartCardReaderKind_Uicc
ReaderName	DEVPKEY_Device_ReaderName (0xD6B5B883, 0x18BD, 0x4B4D, 0xB2, 0xEC, 0x9E, 0x38, 0xAF, 0xFE, 0xDA, 0x82, 0x03)	String -- VT_LPWSTR (For variants: VT_BSTR)	{D6B5B883-18BD-4B4D-B2EC-9E38AFFEDA82}, 3, DEVPROP_TYPE_STRING	CustomName
AppAccessRestrictionsFlags	System.Devices.SmartCards.ReaderKind -- PKEY_Devices_SmartCards_AppAccessRestrictionsFlags	Byte -- VT_UI1	{D6B5B883-18BD-4B4D-B2EC-9E38AFFEDA82}, 4, DEVPROP_TYPE_BYTE	PrivilegedAppOnly (1)

The ISO UMDF driver sets additional custom dev properties on the Smart Card reader devnode:

Define	Name	Type	FormatID	Value
RadioName	DEVPKEY_MbbDevice_RadioName	: DEVPROP_TYPE_GUID	{41e061f2-9999-4b33-bf42-f950cbfd5f2e}, 1, DEVPROP_TYPE_GUID	RadioInterfaceGuid
SlotId	DEVPKEY_MbbDevice_SlotId	DEVPROP_TYPE_UINT32	{c4c66992-3bcc-4f96-9a85-bd807235fbe1}, 2, DEVPROP_TYPE_UINT32	SlotId
IsEmbedded	DEVPKEY_MbbDevice_IsEmbedded	DEVPROP_TYPE_BOOLEAN	{7d08a710-b448-4148-8049-0aa12e5fd2dd}, 3, DEVPROP_TYPE_BOOLEAN	IsEmbedded

These properties are used to uniquely name the smart card readers and identify the reader that is attached to the correct eSIM card. For example: IsEmbedded=True and SlotId=1.

The TRC Image Update Agent is required to have sharedUserCertificates capability which allows access to the Smart Card WinRT API. The sharedUserCertificates capability is a restricted capability that is only given to enterprises with certain credentials. Once the access is granted, the app can connect to the TRC on the device via the Smart Card API and send commands to the card.

It is expected that the firmware patch is carried over APDUs. Because the Smart Card WinRT API only exposes transmitting APDUs and not channel management functions such as open/close, the UMDF driver will inspect the APDUs and look for a SELECT by AID command. If the driver finds a SELECT by AID command, it will be interpreted as opening a logical channel using the Wwan RPC API. The UMDF driver will always validate that the AID is allowlisted, otherwise it will deny the request. Because there is no close or disconnect IOCTL in the SC DDI, the UMDF driver has no way of knowing when the transmission ends and when to close the logical channel. To prevent leaking of the logical channels, the UMDF driver will set a 5 minute timer when a logical channel is opened and will close the channel when the timer expires. The 5 minutes should be long enough as a firmware update is expected to run up to 2.5 minutes maximum. If the UMDF driver detects a new SELECT by AID command, then it will close the previously opened channel and reset the timer for the new logical channel. Note that 5 minute timeout is measured from the last transmitted APDU. In other words, transmitting an APDU over an existing channel resets the timer.

To prevent from opening channels against random UICC apps, the ISO UMDF driver will permit app IDs that are required for an update and restrict access to only these apps. The card vendor helps identify the app IDs and the OEM adds the IDs as registry entries. It is also expected that the UICC app in the card will perform digital signature checks on the firmware to protect against malicious apps sending data.

COSA Setting

`CellCore/PerDevice/eSIM/FwUpdate/AllowedAppIdList`

During a full firmware OS update it is important that the UICC apps that are involved are not accessed by the modem. To achieve this the TRC Image Update Agent will send a special APDU that instructs the eUICC to go in to the TRC/PBL mode. The TRC app will then ask the modem to go into the passthrough mode and reset the card. The card will boot as an empty MF. Once the update is done, the modem will be asked to reset the card again. This time both the modem and the card will get back to normal mode.

MB modem reset operations

Article • 03/14/2023

This section defines MBIM CID commands and data structures, as well as NDIS OID commands and data structures, for resetting the modem in a mobile broadband (MB) device. These commands and data structures are available in Windows 10, version 1709 and later.

MBIM_CID_MS_DEVICE_RESET

The host sends MBIM_CID_MS_DEVICE_RESET to the MBIM function to reset the modem device.

Service name	UUID	UUID value
Microsoft Basic IP Connectivity Extensions	UUID_BASIC_CONNECT_EXTENSIONS	3d01dcc5-fef5-4d05-0d3a-bef7058e9aaf

CID	Command code	Set	Query	Notify
MBIM_CID_MS_DEVICE_RESET	10	Y	N	N

Parameters

Type	Set	Query	Notification
Command	Empty	Not applicable	Not applicable
Response	Empty	Not applicable	Not applicable

Query

Not applicable.

Set

The InformationBuffer shall be NULL and *InformationBufferLength* shall be zero.

Response

The InformationBuffer shall be NULL and *InformationBufferLength* shall be zero.

Notification

Not applicable.

Status codes

The following status codes are applicable. Status is returned as an asynchronous response to a set operation after reset is complete.

Status code	Description
MBIM_STATUS_SUCCESS	The operation succeeded.
MBIM_STATUS_BUSY	The device is busy.
MBIM_STATUS_FAILURE	The operation failed.
MBIM_STATUS_NO_DEVICE_SUPPORT	The device does not support this operation.

OID_WWAN_DEVICE_RESET

The NDIS equivalent for MBIM_CID_MS_DEVICE_RESET is OID_WWAN_DEVICE_RESET.

eSIM Download and Install Log Filter

Article • 12/15/2021

To make searching log files easier, below is an eSIM download and install filter file for the TextAnalysisTool .

To use the eSIM download and install log filter:

1. Copy and paste the lines below and save them into a text file named "esimdownload.tat."

```
<?xml version="1.0" encoding="utf-8" standalone="yes"?>
<TextAnalysisTool.NET version="2015-08-17" showOnlyFilteredLines="True">
  <filters>
    <filter enabled="y" excluding="n" description="" type="matches_text"
case_sensitive="n" regex="n" text="RpcDownloadProfile" />
    <filter enabled="y" excluding="n" description="" type="matches_text"
case_sensitive="n" regex="n" text="LuiAsyncResult" />
    <filter enabled="y" excluding="n" description="" type="matches_text"
case_sensitive="n" regex="n" text="DownloadSequenceEvent" />
  </filters>
</TextAnalysisTool.NET>
```

2. Load the filter file into the TextAnalysisTool by clicking File > Load Filters.

eSIM Profile Operations Log Filter

Article • 12/15/2021

To make searching log files easier, below is an eSIM Profile Operation filter file for the TextAnalysisTool.

To use the eSIM Profile Operation log filter:

1. Copy and paste the lines below and save them into a text file named "esimoperation.tat." This filter is for the "EnableProfile" operation. For other operations, replace "RpcEnableProfile" with one of the strings below that is specific to the operation.

```
<?xml version="1.0" encoding="utf-8" standalone="yes"?>
<TextAnalysisTool.NET version="2015-08-17" showOnlyFilteredLines="True">
  <filters>
    <filter enabled="y" excluding="n" description="" type="matches_text"
case_sensitive="n" regex="n" text="RpcEnableProfile" />
    <filter enabled="y" excluding="n" description="" type="matches_text"
case_sensitive="n" regex="n" text="OpenChannel" />
    <filter enabled="y" excluding="n" description="" type="matches_text"
case_sensitive="n" regex="n" text="CloseChannel" />
    <filter enabled="y" excluding="n" description="" type="matches_text"
case_sensitive="n" regex="n" text="CardResetComplete" />
    <filter enabled="y" excluding="n" description="" type="matches_text"
case_sensitive="n" regex="n" text="LuiAsyncResult" />
    <filter enabled="y" excluding="n" description="" type="matches_text"
case_sensitive="n" regex="n" text="WwapiEsimUpdate" />
    <filter enabled="y" excluding="n" description="" type="matches_text"
case_sensitive="n" regex="n" text="SendApdu" />
  </filters>
</TextAnalysisTool.NET>
```

```
Enable Profile  - RpcEnableProfile
Disable Profile - RpcDisableProfile
Delete Profile  - RpcDeleteProfile
Set Nick Name   - RpcSetProfileNickname
Reset eSim      - RpcWipeEsim
```

2. Load the filter file into the TextAnalysisTool by clicking File > Load Filters.

MB eSIM MBIM ready state guidance

Article • 03/14/2023

This topic provides guidance on the expected MBIM ready state for eSIM scenarios on Windows 10, version 1709 and later. Conforming to the correct ready state ensures that the OS handles all changes properly for that scenario.

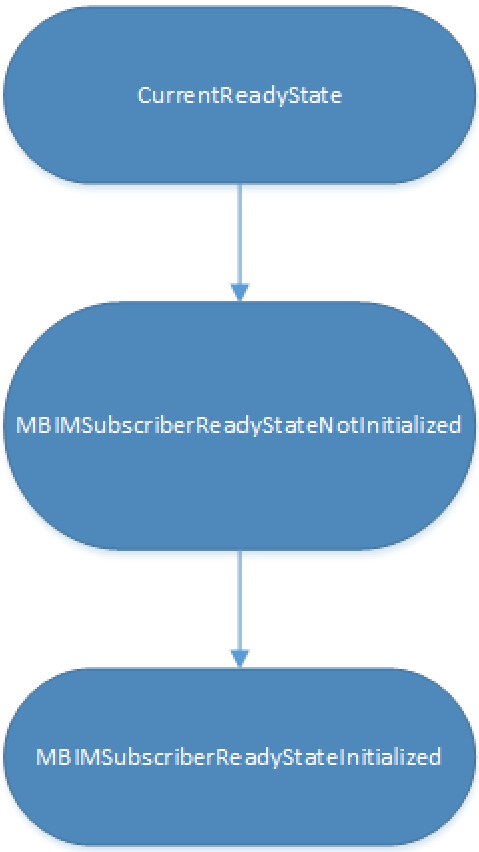
ⓘ Important

All scenarios and states in this topic assume that the eSIM capable card is mapped to the default executor, executor 0, and is powered ON.

Scenario	MBIM_MS_UICCSLOT_STATE	MBIM_SUBSCRIBER_READY_STATE
eSIM with MF only (no profiles)	MBIMMsUICCSlotStateActiveEsimNoProfiles	MBIMSubscriberReadyStateNoEsimProfile
eSIM with no enabled profiles	MBIMMsUICCSlotStateActiveEsimNoProfiles	MBIMSubscriberReadyStateNoEsimProfile
eSIM with profile enabled	MBIMMsUICCSlotStateActiveEsim	MBIMSubscriberReadyStateInitialized
eSIM in passthrough mode	MBIMMsUICCSlotStateActiveEsimNoProfiles	MBIMSubscriberReadyStateNotInitialized

When a change in both MBIM_MS_UICCSLOT_STATE and MBIM_SUBSCRIBER_READY_STATE is needed, the slot state change should precede the ready state change.

When enabling a new profile or switching between profiles, the ready state should have the following flow:



CurrentReadyState
MBIMSubscriberReadyStateNotInitialized
MBIMSubscriberReadyStateInitialized

For more info about MBIM_MS_UICCSLOT_STATE, see the MBIM_MS_UICCSLOT_STATE table on MB Multi-SIM Operations (MBIM_CID_MS_SLOT_INFO_STATUS).

For more info about MBIM_SUBSCRIBER_READY_STATE, see Section 10.5.2.3 of the public USB MBIM standard.

Access an eSIM in the inactive SIM slot

Article • 05/23/2022

Before the Windows 11, version 22H2 release, all eSIM access related CIDs in the MBIM interface target the SIM in the active SIM slot in DSSA modems. Active SIM slot refers to the SIM slot in a DSSA modem whose SIM is mapped to the device for active use for registration and data connection (or the only SIM slot in a single-SIM modem). As a result, eSIM functionality is applicable only if an eSIM resides in the active SIM slot in a DSSA modem. If an eSIM resides in the inactive slot in a DSSA modem, there is no access to the eSIM.

In the Windows 11, version 22H2 release, MBIMEx 4.0 introduces access to an eSIM in the inactive SIM slot. MBIMEx 4.0 extends the following CIDs with a slot ID element (and other necessary information) to support full access to an eSIM in the inactive slot of a DSSA modem, in addition to the eSIM in the active SIM slot.

- MBIM_CID_MS_UICC_ATR
- MBIM_CID_MS_UICC_OPEN_CHANNEL
- MBIM_CID_MS_UICC_CLOSE_CHANNEL
- MBIM_CID_MS_UICC_APDU
- MBIM_CID_MS_UICC_TERMINAL_CAPABILITY
- MBIM_CID_MS_UICC_RESET
- MBIM_CID_SUBSCRIBER_READY_STATUS

Download the MBIMEx 4.0 specification here .

For general information about MBIMEx 4.0, see MBIMEx 4.0 – 5G SA Phase 2 support.

MB Device-based Reset and Recovery

Article • 03/14/2023

Mobile Broadband (MB or MBB) Device-based Reset and Recovery is a technology in Windows 10, version 1809 and later that introduces a robust reset recovery mechanism for MBB devices and drivers. This mechanism enables MBB devices to avoid failures that cause malfunction, loss of connectivity, or unresponsiveness to operational commands, ultimately making the user experience seamless if errors do occur and reducing the chance of having to restart the system.

Device-based Reset and Recovery can be implemented with or without firmware dependencies. IHV or OEM partners can extend the software-based reset mechanisms available on all Windows PCs with supported device or firmware-level reset mechanisms to increase the rate of successful recovery.

MB Device-based Reset and Recovery architecture overview

The Windows MBB service initializes and controls cellular devices using the standard Mobile Broadband Interface Model (MBIM) interface, which is built on top of the USB transport extending the NCM specifications. Each command sent to the IHV device is sent as an MBIM command via the inbox Windows MBB class driver. Once the cellular modem is initialized using the MBIM protocol exchange, the data path can start between the host, modem, and the network. Any additional controls sent to the cellular device continue via the MBIM protocol exchange in parallel.

There are a number of failures that can occur on both the MBIM control path and the data path. In versions of Windows before Windows 10, version 1809, a simple error handling mechanism is built in. Whenever a MBIM command is sent and device becomes unresponsive, the mechanism attempts to reset the device by sending an MBIM reset command. However, because the failure is often due to an unresponsive MBIM interface in the first place, this reset does not always work. Furthermore, the mechanism doesn't address other failures that might occur such as the loss of connectivity due to data path failures.

MB Device-based Reset and Recovery introduces a centralized framework to detect a larger set of failures and coordinates recovery with a set of progressively impactful resets. If the device supports device-level reset, MB Device-based Reset and Recovery will incorporate the device-level resets after all software-based resets are exhausted. The reset and recovery framework redefines and replaces the existing reset mechanism based on MBIM command responsiveness.

MB Device-based Reset and Recovery detects and attempts to remedy the following types of failures:

Area of failure	Failure description
Control path	• A hang condition detected on MBIM protocol path. For more information about hang detection, see MB hang detection. • Failures due to MBB responding with incorrect state and/or information.
Data path	• Device-side failure resulting in data path failures. For example, endpoints not responding to data traffic, corrupted data from PHY, etc. • Modem/network-side failure. For example, the network not responding to IP traffic, DNS failure, packet loss, etc.

Some failures are not actionable from a recovery perspective, including but not limited to:

- Provisioning- or activation-related issues such as missing COSA settings or MO-initiated service denial
- Control path issues due to driver initialization failure (power- or hardware-related) or software bugs

However, once an actionable failure is detected, MB Device-based Reset and Recovery will attempt the following reset mechanisms. The reset options are listed in the order Windows will perform, from least to most impactful.

Software-based reset options, in the following table are available on all Windows 10, version 1809 MBB devices and can be disabled or configured by OEM patners.

Reset sequence	Reset type	Reset mechanism
1	Software only	Deactivate and activate the PDP context
2	Software only	Toggle Airplane Mode (APM) ON/OFF
3	Sofware only	Enable/disable the device at the Plug and Play (PnP) level

The following device-based reset options are enabled by OEMs with MBB device/firmware capabilities.

Reset sequence	Reset type	Reset mechanism

Reset sequence	Reset type	Reset mechanism
4	Device-based	Functional-level Device Reset (FLDR)
5	Device-based	Platform-level Device Reset (PLDR)

The order of recovery is altered, and in some cases certain reset mechanisms bypassed altogether, for certain types of failures. For example, if a command timeout occurs while toggling airplane mode, the OS does not toggle Airplane Mode to fix it. If the MBB device does not respond to any MBIM commands, then the OS will engage the Device-based reset mechanisms directly.

For UDE client drivers that enable an MBIM function, Windows 10, version 1809 contains a new API that can be used to request a reset whenever the UDECx client driver detects an error. The following section describes these new device-based reset mechanims including FLDR, PLDR, and UDECx reset for PCI.

Device-based resets

Function-level Device Reset (FLDR)

Function-level Device Reset is the lightest device-based reset in terms of system impact. It happens inside the device and is not visible to other devices, and the device stays connected to the bus throughout the reset and returns to a valid state (in other words, an initial state) after the process. This can be provided by either the bus driver or by the firmware. The bus driver implements an FLDR handler if the bus specification defines an in-band reset mechanism that fits the requirement. Firmware writers might override a bus-defined FLDR with their own implementation of FLDR that uses out-of-band signals, such as reset line or power toggling, while still following the requirements of FLDR.

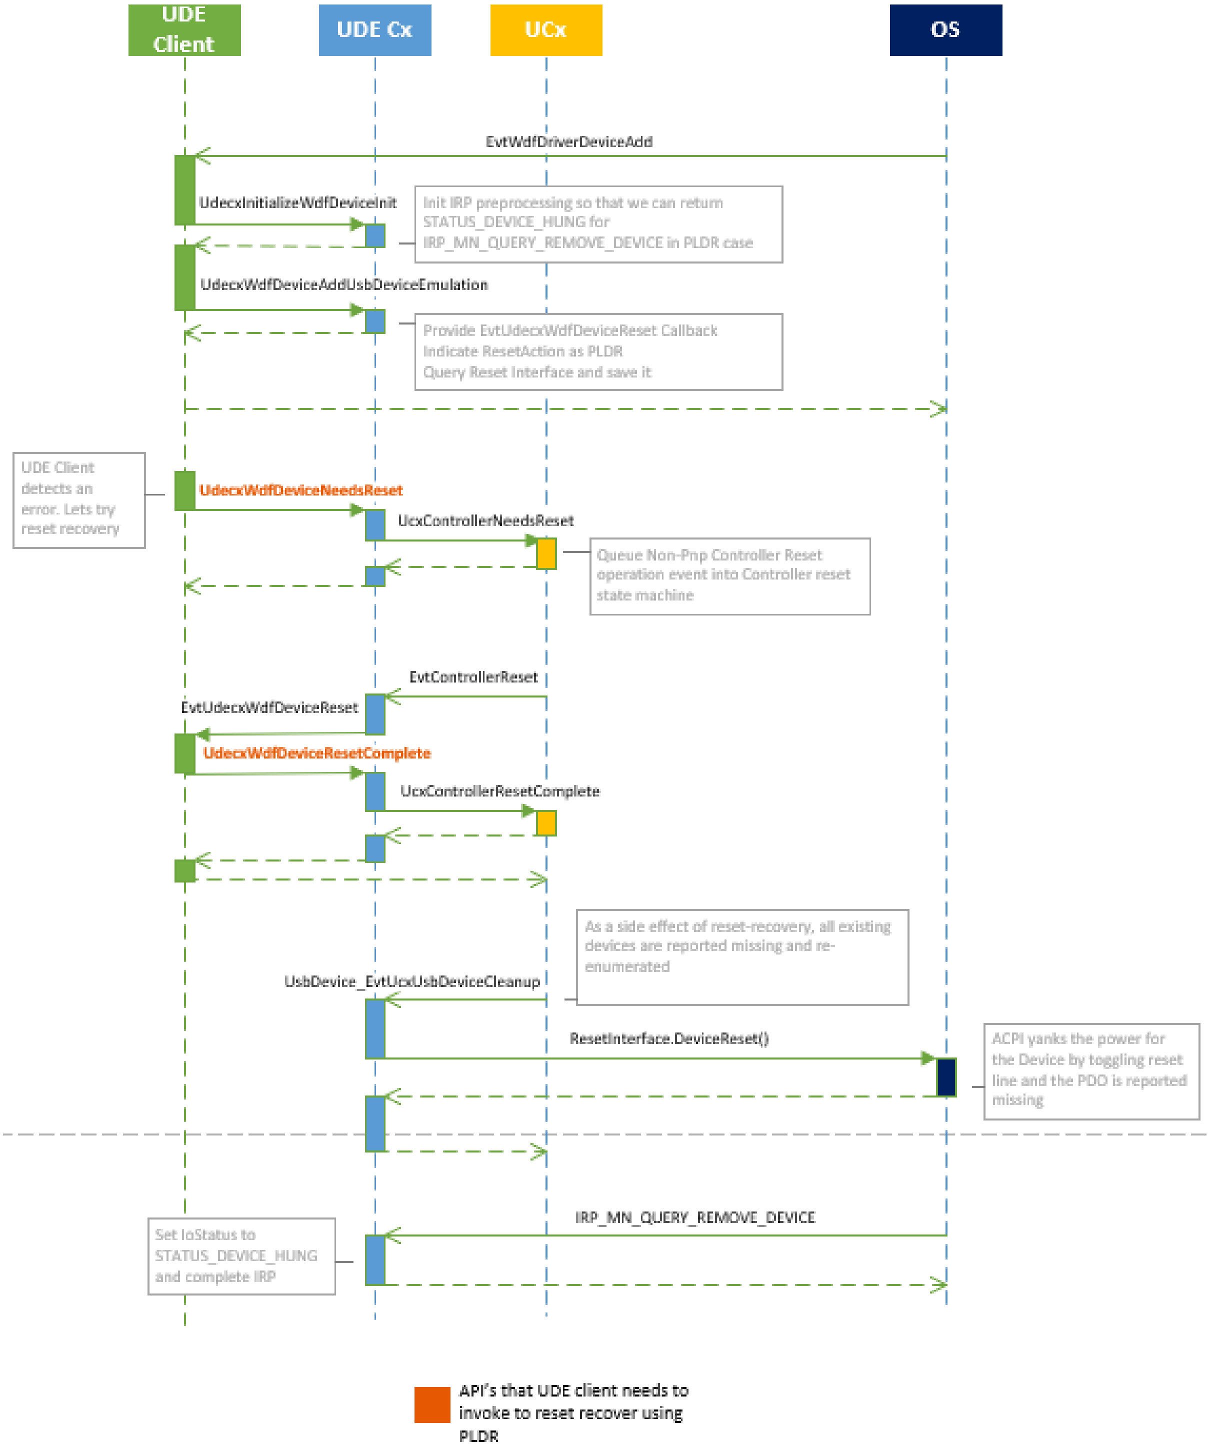
Platform-level Device Reset (PLDR)

Platform-level Device Reset is for cases where FLDR cannot be used, or as a last-resort supplement to FLDR. This reset mechanism causes the device to be reported as missing from the bus (during a power cycle, for example) or affects multiple devices (such as a shared power rail or reset line among devices). The reset method is specified in the ACPI table, which might be implemented as toggling a dedicated reset line or power-cycling the D3 power resource. When PLDR is performed, the OS tears down and rebuilds the stacks of all affected devices to ensure everything starts from a pristine state.

Reset recovery for UDE devices

For UDE client drivers that enable an MBIM function, Windows 10, version 1809 includes an API that can be used to request a reset whenever the UDECx client driver detects an error. The client driver requests a reset by calling a new method, **UdecxWdfDeviceNeedsReset**, specifying the reset type that it wants the UDECx to attempt for the device (if supported). These reset types are **PlatformLevelDeviceReset** and **FunctionLevelDeviceReset** and are values of the **UDECX_WDF_DEVICE_RESET_TYPE** enumeration. Once a reset is initiated, UDECx invokes the driver's *EVT_UDECX_WDF_DEVICE_RESET* callback function and ensures that no other callback is invoked during this process. The client driver is expected to perform any reset related operations such as releasing any resources, then signal reset completion by invoking **UdecxWdfDeviceResetComplete**.

The following flow diagram illustrates the UDE device reset process.



UDE Client
UDE Cx
UCx
OS
EvtWdfDriverDeviceAdd
UdecxInitializeWdfDeviceInit
Init IRP preprocessing so that we can return STATUS_DEVICE_HUNG for IRP_MN_QUERY_REMOVE_DEVICE in PLDR case
UdecxWdfDeviceAddUsbDeviceEmulation
Provide EvtUdecxWdfDeviceReset Callback
Indicate ResetAction as PLDR
Query Reset Interface and save it
UDE Client detects an error. Lets try reset recovery
UdecxWdfDeviceNeedsReset
UcxControllerNeedsReset
Queue Non-Pnp Controller Reset operation event into Controller reset state machine
EvtControllerReset
EvtUdecxWdfDeviceReset
UdecxWdfDeviceResetComplete
UcxControllerResetComplete
As a side effect of reset-recovery, all existing devices are reported missing and re-enumerated
UsbDevice_EvtUcxUsbDeviceCleanup
ResetInterface.DeviceReset()
ACPI yanks the power for the Device by toggling reset line and the PDO is reported missing
IRP_MN_QUERY_REMOVE_DEVICE
Set IoStatus to STATUS_DEVICE_HUNG and complete IRP
🟧 API's that UDE client needs to invoke to reset recover using PLDR

RnR triggers

WWAN Service organizes actionable failures into RnR triggers:

1. Bad connectivity
2. Radio state set/query failures/time-outs
3. Consecutive OID request time-outs
4. Initialization failures

RnR Trigger #1 - Bad connectivity

- Bad connectivity
- Limited Internet connectivity
- Lost Internet connectivity
- Routes not received correctly
- Routes unreachable
- Dead gateway
- DNS query failing

WCM detects based on various sources (NCSI etc.).

WCM publishes WNF_WCM_INTERFACE_CONNECTION_STATE.

```
struct WCM_WNF_INTERFACE_CONNECTION_STATE_INFO
{
    GUID InterfaceGuid;
    WCM_MEDIA_TYPE MediaType = wcm_media_unknown;
    // ConnectionState is one of the WCM_WNF_INTERFACE_CONNECTIVITY_STATE_*
values
    DWORD ConnectionState = 0;
    // TimeInBadStateMs tracks how long a connection is in a Bad state
    // It will reset back to zero when in a good state
    DWORD TimeInBadStateMs = 0;
    // ConnectivityTriggers is a bitmask of
WCM_WNF_INTERFACE_CONNECTIVITY_TRIGGER_* flags
    DWORD ConnectivityTriggers = 0;
    // fWasConnectedGood will be TRUE if a connection is ever in a good
state over the lifetime of an L2 connection
    // Once it is set to TRUE, it will never go FALSE until the interface
disconnects
    BOOLEAN fWasConnectedGood = FALSE;
    // When processing the WNF, walk the array of
WCM_WNF_INTERFACE_CONNECTION_STATE_INFO structs
    // until you reach the struct with afLastArrayValues == TRUE
    BOOLEAN fLastArrayValue = TRUE;
};
```

Recovery Process:

- Reset PDP context up to three times (see FSM transition diagram)
- Toggle APM once
- PnP disable and enable MBB device once
- Invoke FLDR once if supported
- Invoke PLDR once if supported

The process stops as soon as L3 connectivity is good.

Verification of outcome: L3 connectivity is good.

RnR trigger #2 - Radio state set/query failure or time-out

- No response or failure response for setting or querying radio state.
- OID_WWAN_RADIO_STATE set or query requests.
- Should never happen.
- Once it happens, OS and modem may end up in an inconsistent state.
- Indicates serious problem(s) in the modem.
- CWwanExecutor detects it and internally reports to CWwanResetRecovery.

Recovery process:

- Invoke PLDR if supported
- Otherwise, invoke PnP disable/enable

Verification of outcome: Send OID_WWAN_RADIO_STATE query and verify response.

RnR trigger #3 - Time-out of consecutive OID requests

- TXM times all outstanding OID requests and expects responses for each.
- If a “configurable” number of consecutive OID requests receive no response in time, TXM detects it and internally reports to CWwanResetRecovery.
- OIDs may be grouped in high/medium/low latency groups:
  - OID requests that are have no interaction with MO will have lower latency.
  - OID requests that result in interaction with MO will have medium latency.
  - OID_WWAN_CONNECT activation/deactivation request: ~180 seconds.

Recovery process:

- Invoke PLDR if supported
- Otherwise, invoke PnP disable/enable

Verification of outcome: Send OID_WWAN_RADIO_STATE query and verify response.

RnR Trigger #4 - Initialization failures

- Time-out of the device caps or device capsEx query during the initialization upon MB device arrival
- CWwanManager detects and acts on it

Recovery process:

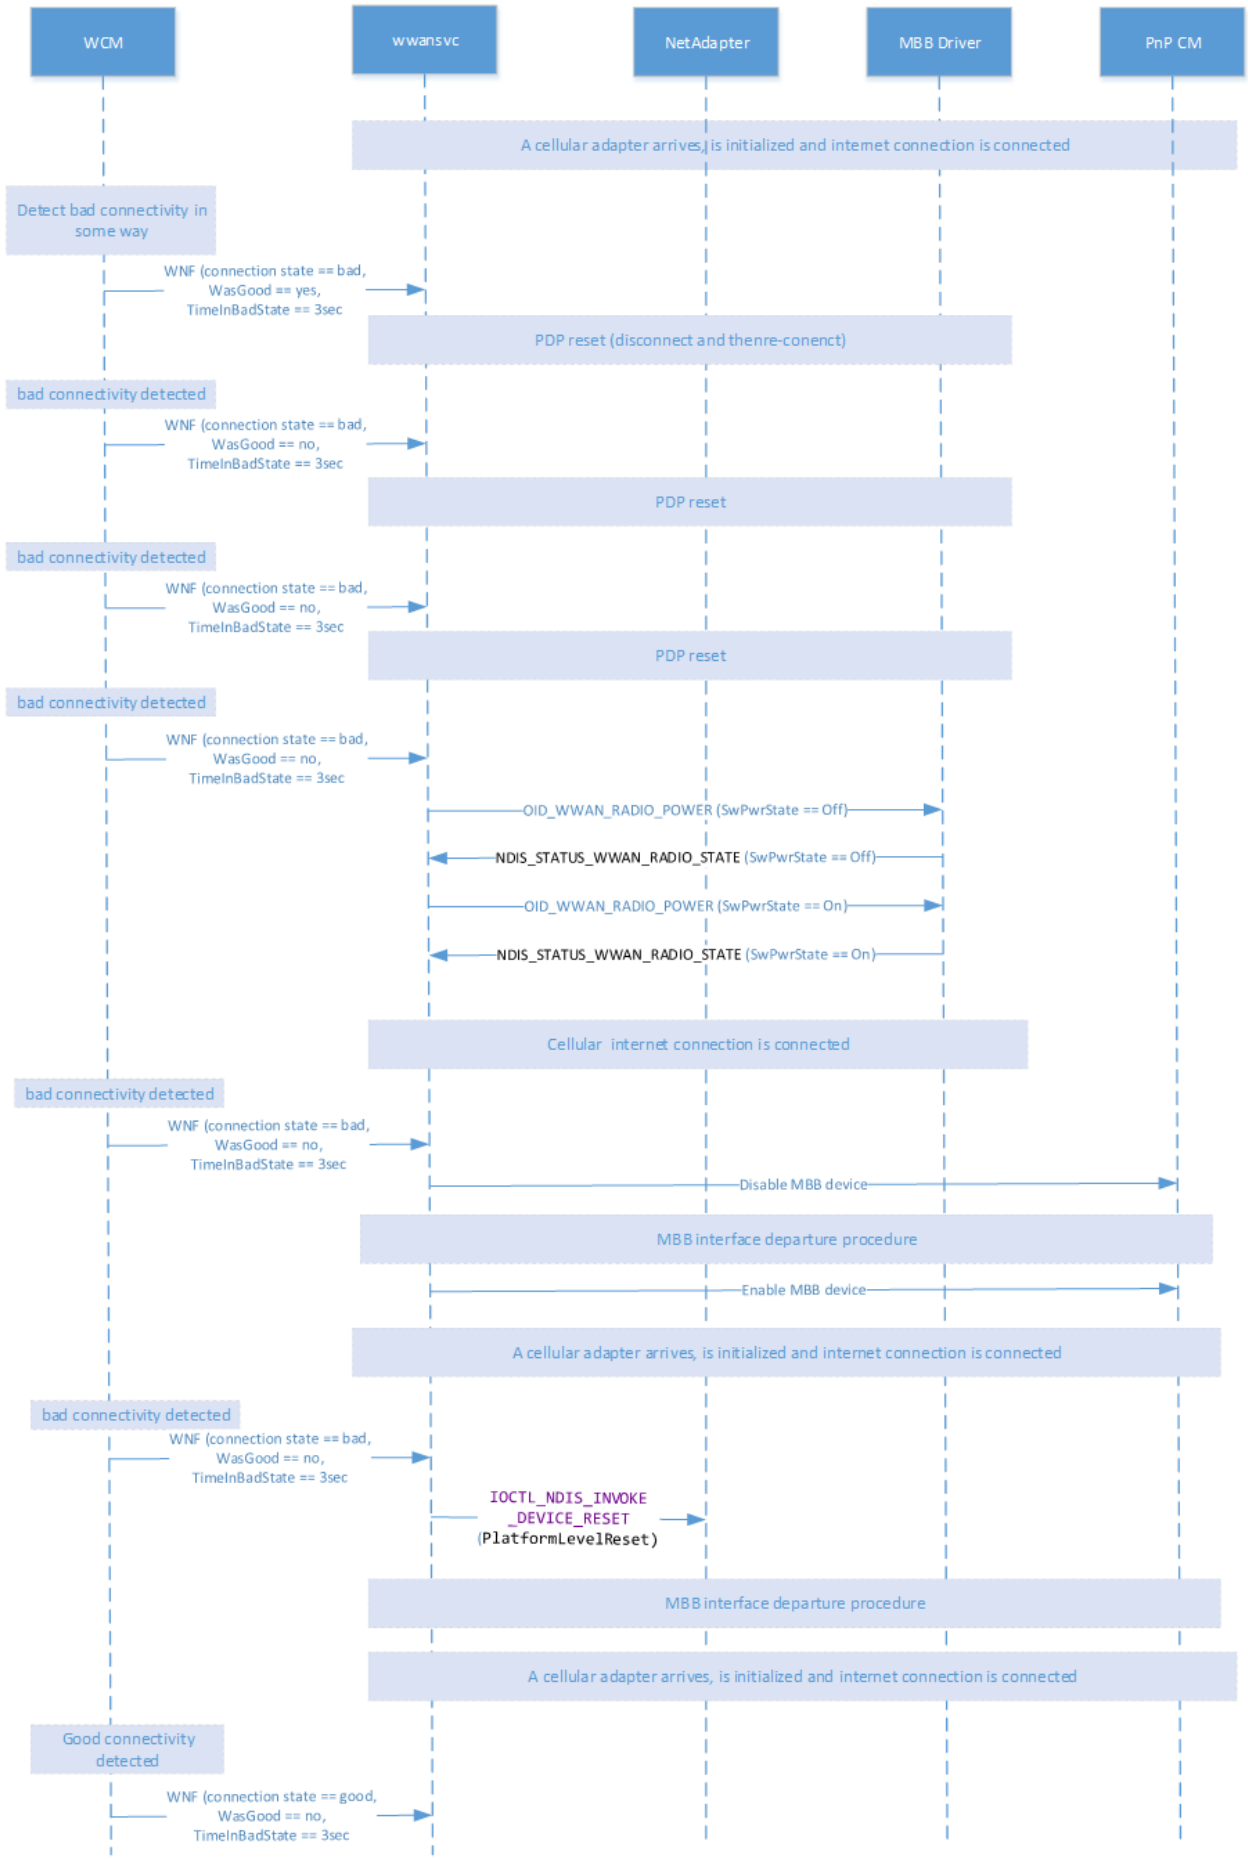
- Invoke PLDR if supported
- Otherwise, invoke PnP disable/enable

Verification of outcome: none

After PLDR or PnP disable/enable, the device departs and then re-arrives. Initialization upon arrival follows.

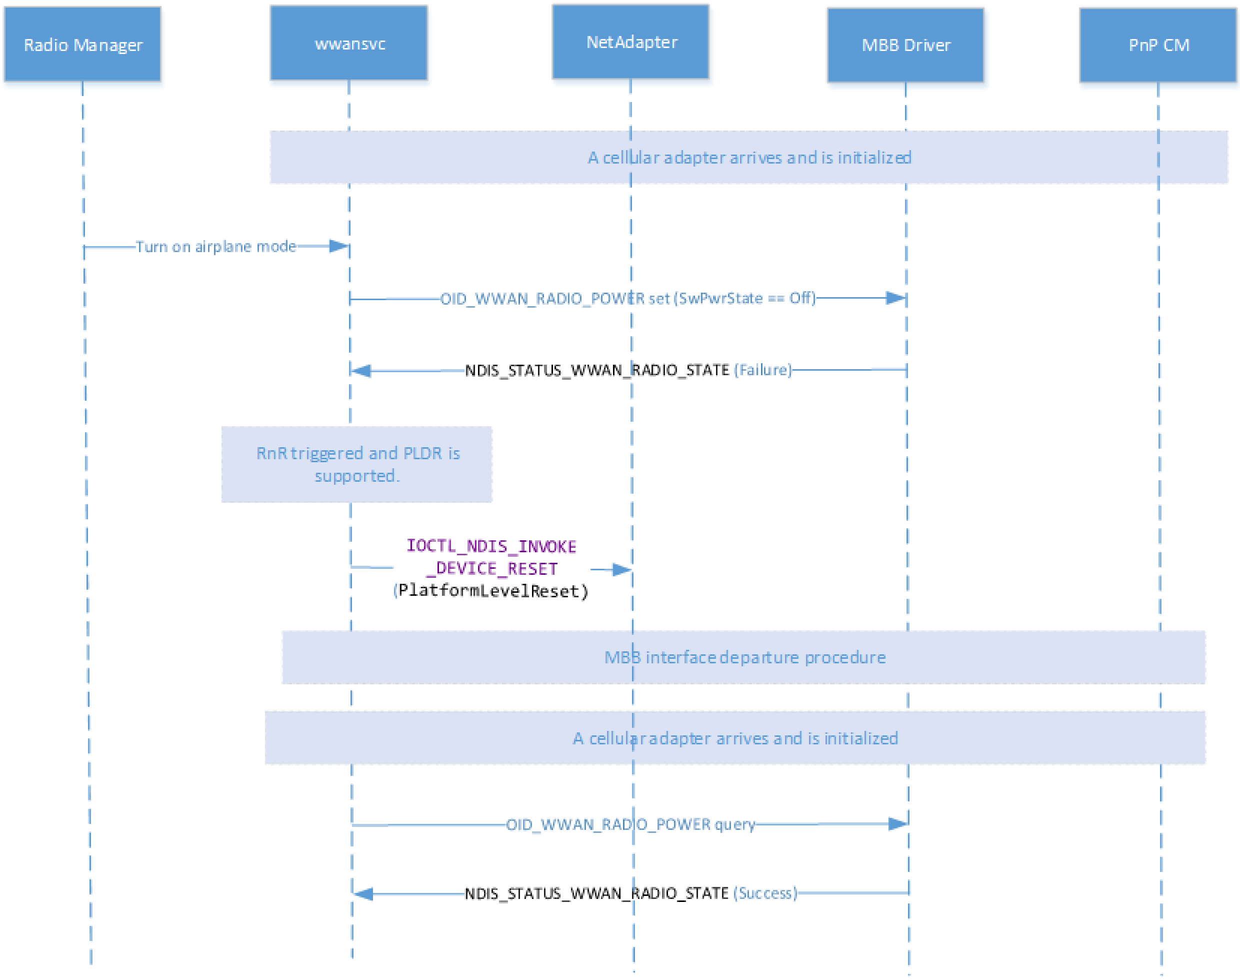
Primary flows

RnR for bad connectivity



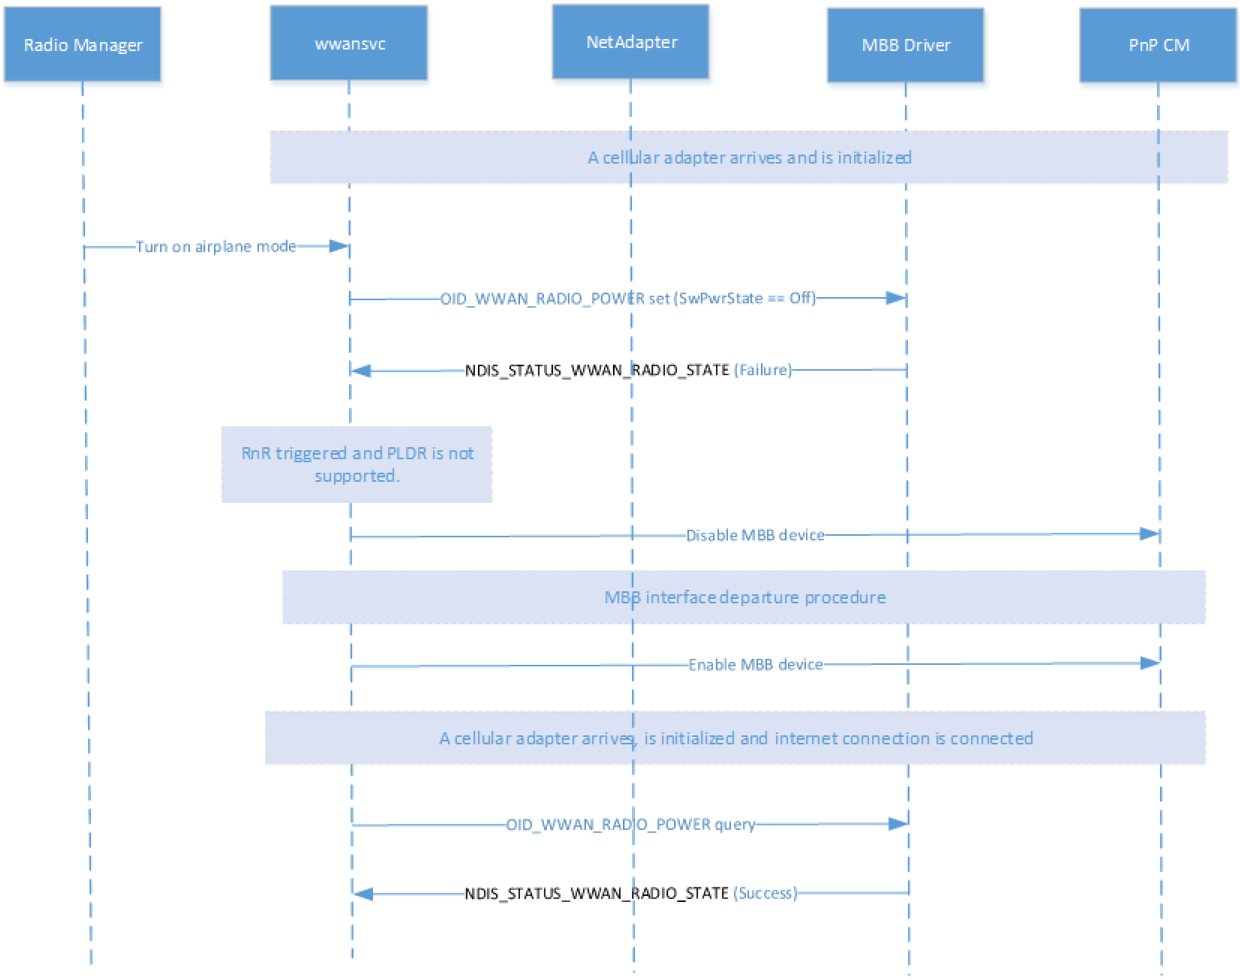
WCM
wwansvc
NetAdapter
MBB Driver
PnP CM
A cellular adapter arrives, is initialized and internet connection is connected
Detect bad connectivity in some way
WNF (connection state == bad, WasGood == yes, TimeInBadState == 3sec
PDP reset (disconnect and thenre-conenct)
bad connectivity detected
WNF (connection state == bad, WasGood == no, TimeInBadState == 3sec
PDP reset
bad connectivity detected
WNF (connection state == bad, WasGood == no, TimeInBadState == 3sec
PDP reset
bad connectivity detected
WNF (connection state == bad, WasGood == no, TimeInBadState == 3sec
OID_WWAN_RADIO_POWER (SwPwrState == Off)
NDIS_STATUS_WWAN_RADIO_STATE (SwPwrState == Off)
OID_WWAN_RADIO_POWER (SwPwrState == On)
NDIS_STATUS_WWAN_RADIO_STATE (SwPwrState == On)
Cellular internet connection is connected
bad connectivity detected
WNF (connection state == bad, WasGood == no, TimeInBadState == 3sec
Disable MBB device
MBB interface departure procedure
Enable MBB device
A cellular adapter arrives, is initialized and internet connection is connected
bad connectivity detected
WNF (connection state == bad, WasGood == no, TimeInBadState == 3sec
IOCTL_NDIS_INVOKE _DEVICE_RESET (PlatformLevelReset)
MBB interface departure procedure
A cellular adapter arrives, is initialized and internet connection is connected
Good connectivity detected
WNF (connection state == good, WasGood == no, TimeInBadState == 3sec

PLDR for radio power set failure



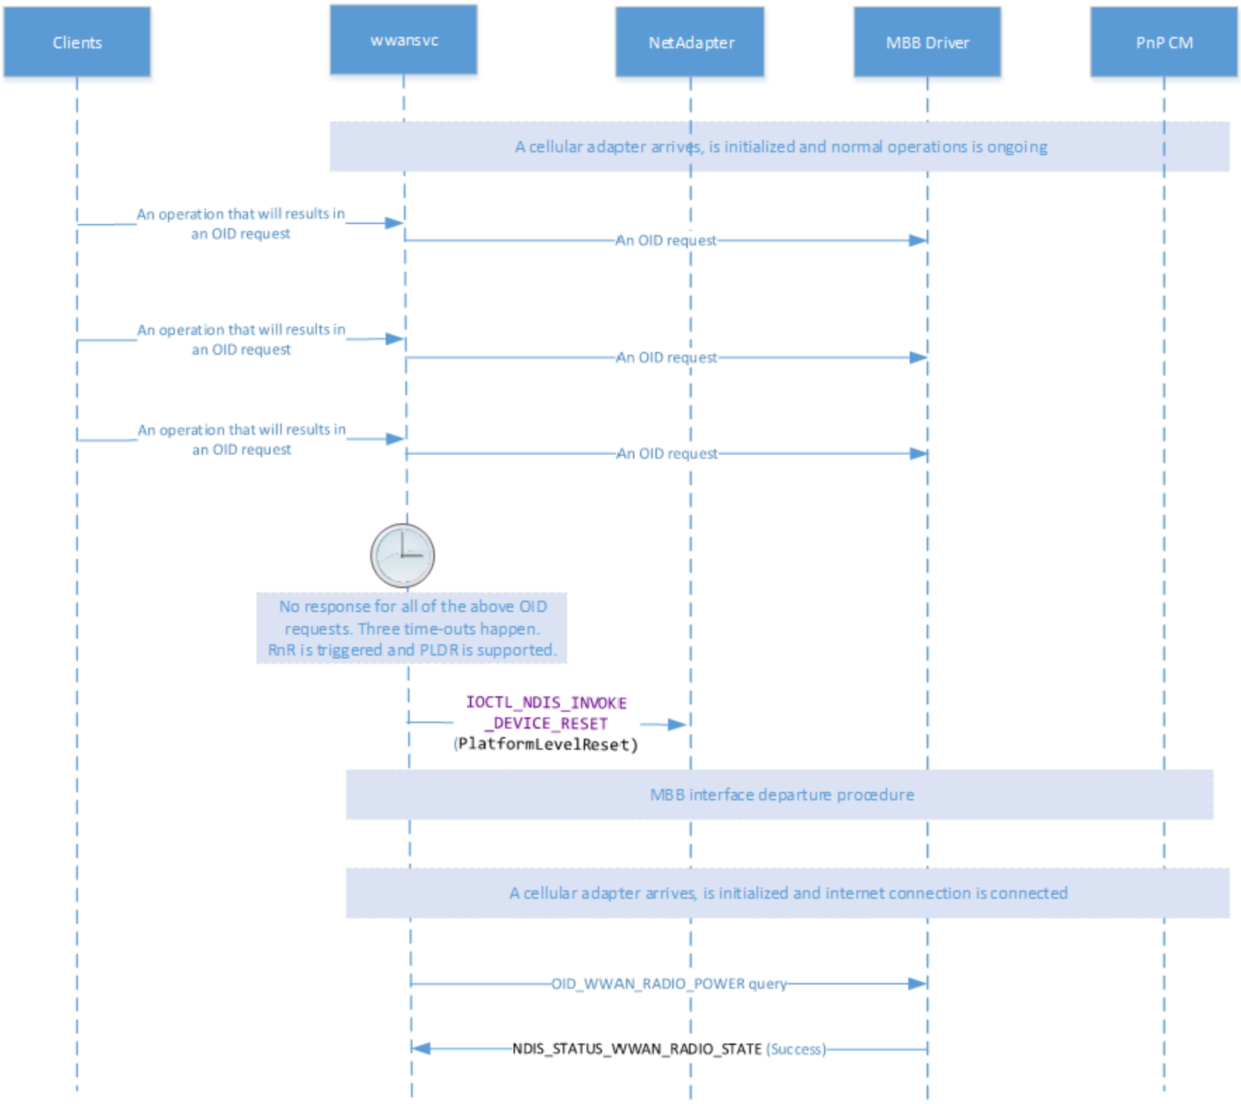
Radio Manager
wwansvc
NetAdapter
MBB Driver
PnP CM
A cellular adapter arrives and is initialized
Turn on airplane mode
OID_WWAN_RADIO_POWER set (SwPwrState == Off)
NDIS_STATUS_WWAN_RADIO_STATE (Failure)
RnR triggered and PLDR is supported.
IOCTL_NDIS_INVOKE_DEVICE_RESET (PlatformLevelReset)
MBB interface departure procedure
A cellular adapter arrives and is initialized
OID_WWAN_RADIO_POWER query
NDIS_STATUS_WWAN_RADIO_STATE (Success)

PnP disable/enable for radio state set failure



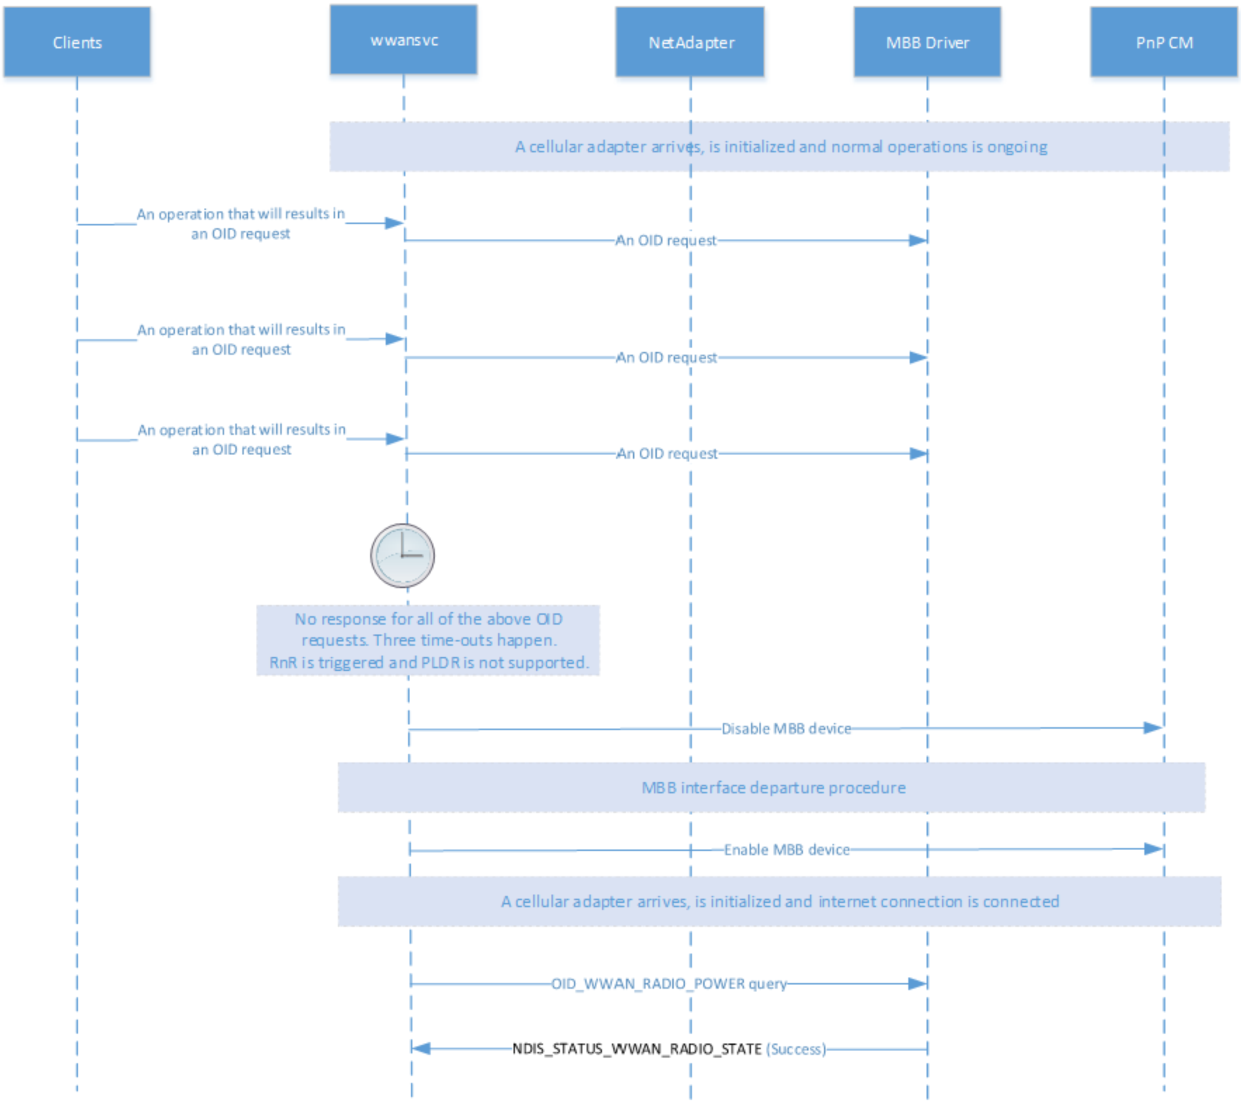
Radio Manager
wwansvc
NetAdapter
MBB Driver
PnP CM
A cellular adapter arrives and is initialized
Turn on airplane mode
OID_WWAN_RADIO_POWER set (SwPwrState == Off)
NDIS_STATUS_WWAN_RADIO_STATE (Failure)
RnR triggered and PLDR is not supported.
Disable MBB device
MBB interface departure procedure
Enable MBB device
A cellular adapter arrives, is initialized and internet connection is connected
OID_WWAN_RADIO_POWER query
NDIS_STATUS_WWAN_RADIO_STATE (Success)

PLDR for time-outs of consecutive OID requests



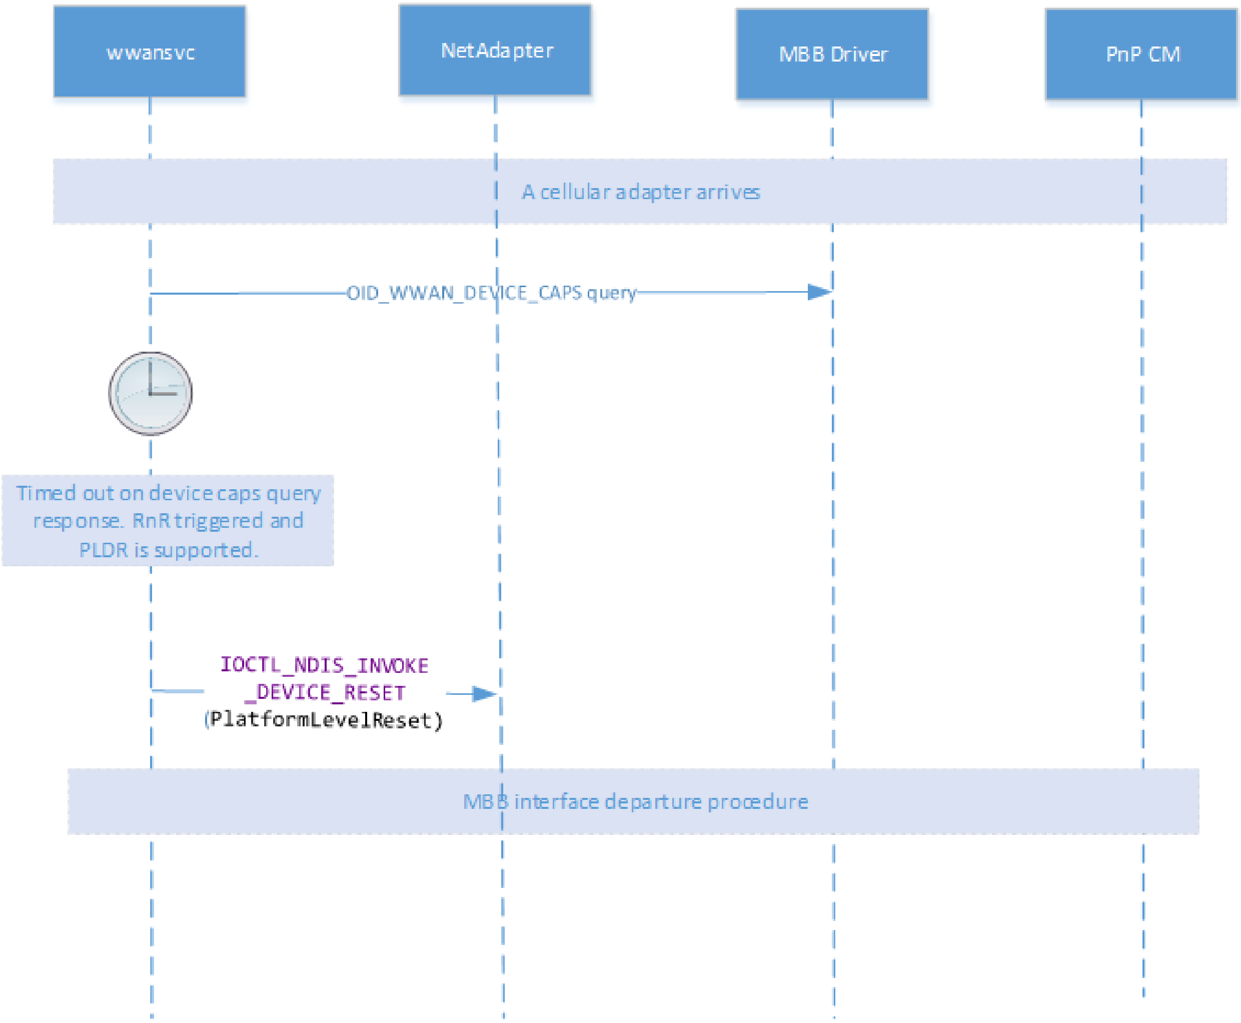
Clients
wwansvc
NetAdapter
MBB Driver
PnP CM
A cellular adapter arrives, is initialized and normal operations is ongoing
An operation that will results in an OID request
An OID request
An operation that will results in an OID request
An OID request
An operation that will results in an OID request
An OID request
No response for all of the above OID requests. Three time-outs happen. RnR is triggered and PLDR is supported.
IOCTL_NDIS_INVOKE _DEVICE_RESET (PlatformLevelReset)
MBB interface departure procedure
A cellular adapter arrives, is initialized and internet connection is connected
OID_WWAN_RADIO_POWER query
NDIS_STATUS_WWAN_RADIO_STATE (Success)

PnP disable/enable for time-outs of consecutive OID requests



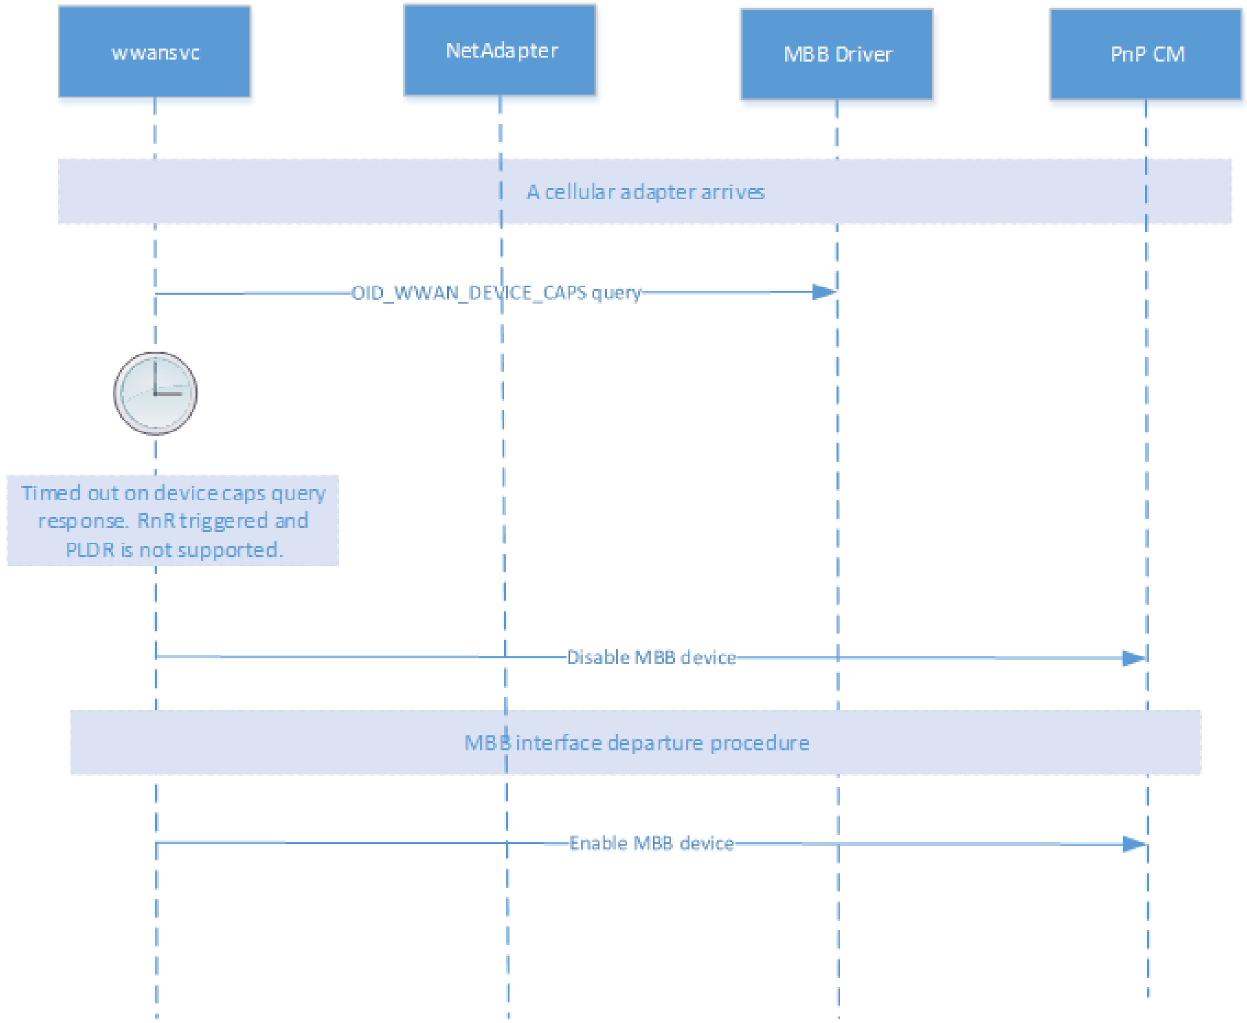
Clients
wwansvc
NetAdapter
MBB Driver
PnP CM
A cellular adapter arrives, is initialized and normal operations is ongoing
An operation that will results in an OID request
An OID request
An operation that will results in an OID request
An OID request
An operation that will results in an OID request
An OID request
No response for all of the above OID requests. Three time-outs happen. RnR is triggered and PLDR is not supported.
Disable MBB device
MBB interface departure procedure
Enable MBB device
A cellular adapter arrives, is initialized and internet connection is connected
OID_WWAN_RADIO_POWER query
NDIS_STATUS_WWAN_RADIO_STATE (Success)

PLDR for initialization failure



wwansvc
NetAdapter
MBB Driver
PnP CM
A cellular adapter arrives
OID_WWAN_DEVICE_CAPS query
Timed out on device caps query response. RnR triggered and PLDR is supported.
IOCTL_NDIS_INVOKE_DEVICE_RESET (PlatformLevelReset)
MBB interface departure procedure

PnP disable/enable for initialization failure



wwansvc
NetAdapter
MBB Driver
PnP CM
A cellular adapter arrives
OID_WWAN_DEVICE_CAPS query
Timed out on device caps query response. RnR triggered and PLDR is not supported.
Disable MBB device
MBB interface departure procedure
Enable MBB device

Requirements for MB Device-based Reset and Recovery

Requirements for FLDR

To support FLDR on a device, inside the Device() scope there must be a `_RST` method defined. When executed, the method must reset only that device, and should not touch another device. The device must also stay on the bus, connected.

```C++
Device(PCI0)
{
Device(USB0)
{
    Name(_ADR, 0x1d0000)
    Name(_S4D, 0x2)
    Name(_S3D, 0x2)
    …
    Method(_RST, 0x0, NotSerialized)
    {
            //
            // Perform reset of the USB0 device
            //
    }
}
}
```

Requirements for PLDR

In PLDR, devices that are affected by the reset of other device are expressed as sharing a `PowerResource` for reset. The devices declare their dependency on the `PowerResource` for reset, and that `PowerResource` implements the `_RST` method.

```C++
Device(PCI0)
{
PowerResource(URST, 0x5, 0x0)
{
    //
    // Dummy _ON and _OFF methods. All power resources must have these
    // two defined.
    // Method(_ON, 0x0, NotSerialized)
    {
    }
    Method(_OFF, 0x0, NotSerialized)
    {
    }
    Method(_RST, 0x0, NotSerialized)
    {
            //
            // Perform reset of the USB0 and USB1 devices
            //
    }
}
Device(USB0)
{
    Name(_ADR, 0x1d0000)
    Name(_S4D, 0x2)
    Name(_S3D, 0x2)
    …
    Name(_PRR, Package(0x1) { ^URST })
}
Device(USB1)
{
    Name(_ADR, 0x1d0001)
    Name(_S4D, 0x2)
    Name(_S3D, 0x2)
    …
    Name(_PRR, Package(0x1) { ^URST })
}
}
```

Alternatively, PLDR can be achieved by putting the device into the D3Cold power state and back to D0, essentially power cycling the device. In this case, having `_PR3` declared in the device scope is sufficient to support PLDR. ACPI will use `_PR3` to determine reset dependencies between devices if no `_PRR` is referenced in the device scope. For more information, see Resetting and recovering a device.

MB hang detection

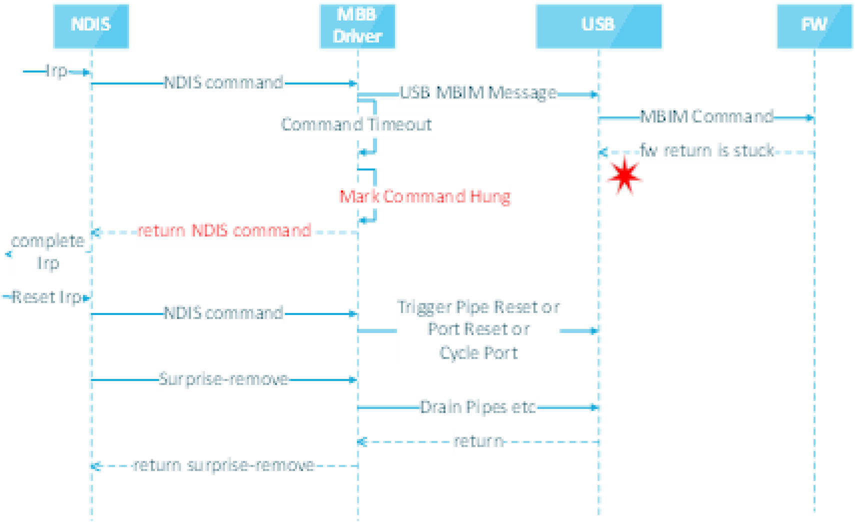
Article • 03/14/2023

Mobile Broadband (MB or MBB) hang detection is a technology in Windows 10, version 1809 and later that assists MBB client drivers in detecting hang conditions in the control path and recovering from them. It is a part of the Device-based Reset and Recovery feature that is aimed at recovering from a variety of possible error conditions for MBB devices and drivers.

The flow diagrams in this topic use USB as the underlying bus, although the reset mechanism is bus agnostic if the ACPI and bus stack define the interfaces described on this page.

The following flow diagram applies generically to all NDIS object identifiers (OIDs) and callbacks to miniport drivers. There might be cases where the recovery part of this process does not work if NDIS does not fully support reset recovery.



This hang detection and reset flow sequence consists of 3 phases:

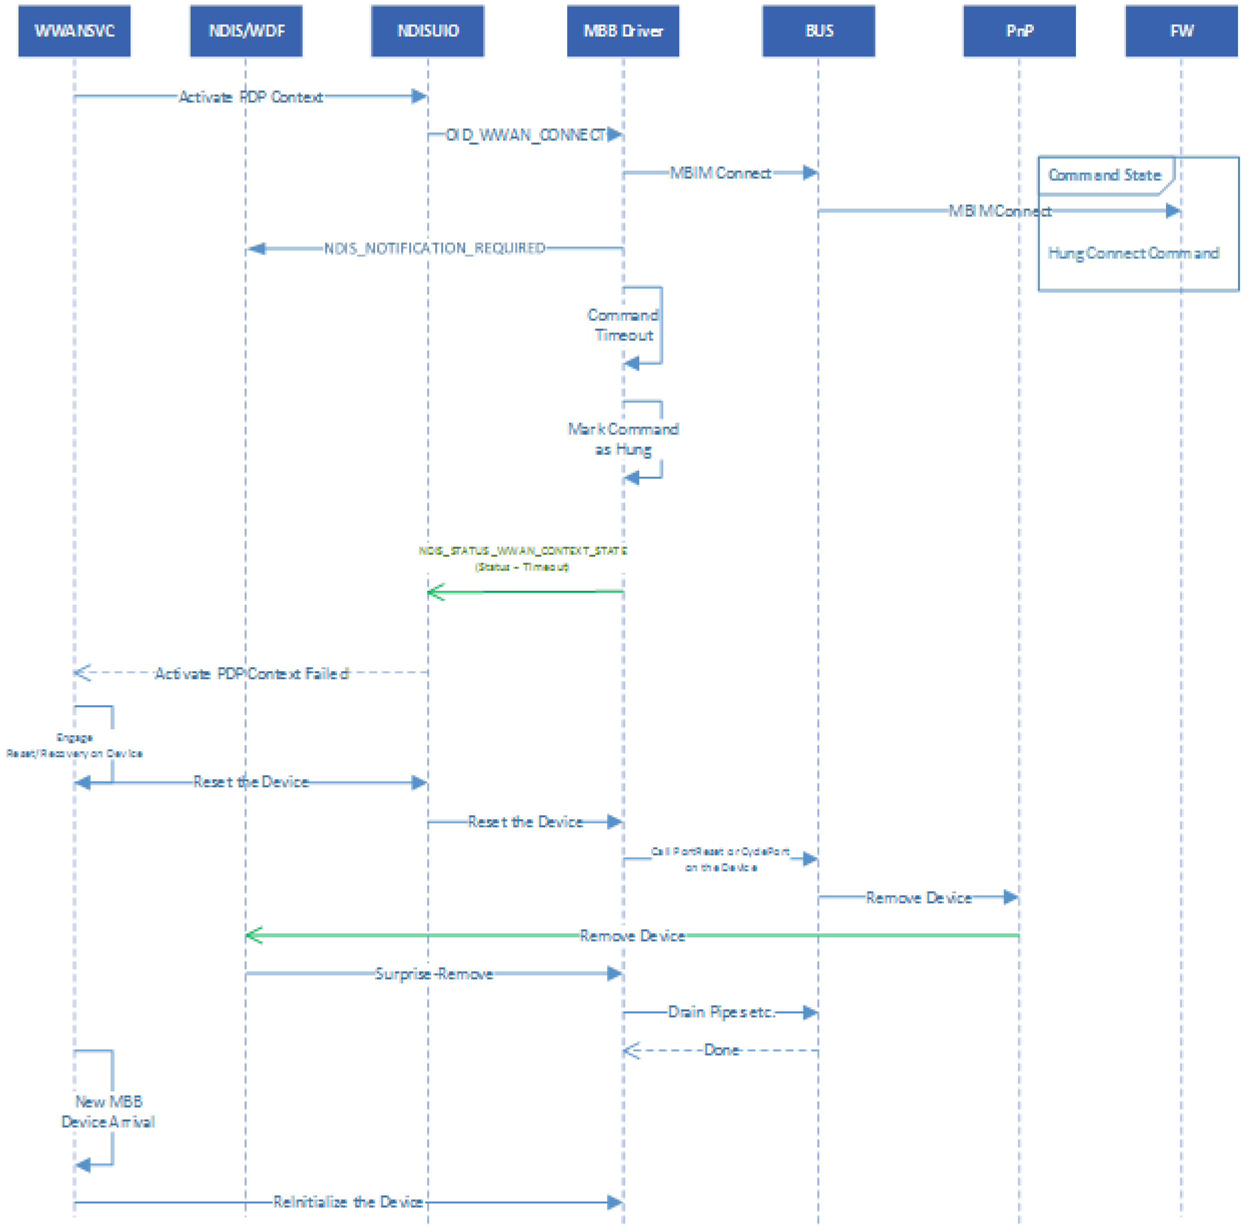
1. Hang detection
2. Any potential logging to get the states for further debugging
3. Reset – surprise removal handling

Hang detection

The service layer provides a hint to the driver to initiate a recovery whenever something wrong is detected at the user layer, since `WWANSvc` has a state machine managing the connectivity state of the cellular adapter. To support this, a private interface is defined that the driver uses to trigger a reset operation. There are a few cases where the driver originates its own commands down to the device to make sure the state machine is valid. If any of these commands time out, then the reset/recovery is triggered from the driver itself without having to communicate the operation back to user mode to initiate a recovery operation.

For more information about the private interface that UDE client drivers can use to trigger a reset operation, see MB Device-based Reset and Recovery.

This example uses OID_WWAN_CONNECT as an example for walking through the hang detection flow.



1. NDIS (via the protocol driver) receives an OID_WWAN_CONNECT.
2. NDIS passes OID_WWAN_CONNECT down to the class driver.
3. The class driver constructs an MBIM message for the Connect request.
4. The class driver sends the MBIM message to the MBIM function via the USB bus.

5. The firmware command times out, which could be because the firmware is hung or the MBIM command is taking a long time to complete.
6. The class driver returns the NDIS command without the firmware completion with NDIS_NOTIFICATION_REQUIRED. The result of OID_WWAN_CONNECT is returned with a solicited notification from the driver via NDIS_STATUS_WWAN_CONTEXT_STATE with **Status** set to **Timeout**, indicating that the underlying device didn't respond to the command.
7. NDIS completes the OID request to the protocol driver.
8. The protocol driver returns the call back to the service, which sees that the command failed.
9. The service triggers a reset operation on the device using the new OID interface.
10. After this point, the FDO calls the bus to surprise-remove and re-enumerate the MBB device. If the underlying bus is USB, then the FDO will call appropriate functions to reset the device.
11. If the appropriate ACPI methods are defined in UEFI, then either FLDR or PLDR will be triggered.

For more information about FLDR and PLDR, see MB Device-based Reset and Recovery.

Reset (Surprise-Removal)

Once the reset recovery can proceed, the bus causes the Plug and Play (PnP) manager to generate a surprise-remove IRP, provided the support is present at the ACPI/UEFI level. NDIS, on receiving the surprise-remove IRP, calls back into `WMBCLASS` for a surprise-remove PnP event callback. `WMBCLASS` handles the surprise-removal operation. At this point, all the commands, etc. must be completed and the data packets must be returned successfully back to NDIS. Otherwise, the surprise-removal operation will not complete. The rest of flow is identical to a real device surprise-remove on a bus, for example USB.

1. NDIS calls the PnP event for surprise-removal.
2. `WMBCLASS` ignores the return of hung MBIM command and returns the original NDIS command.
3. `WMBCLASS` returns the NDIS PnP callback for surprise-removal.

Recovery

After the surprise-removal, all drivers in the stack including `WMBCLASS` must release all resources so that the device object can be removed and re-enumerated by the bus. Failing to do so, the device will not be re-enumerated and will not be recovered.

Investigation tips

- Ensure the necessary ETW providers are included in log:

    1. netsh trace start wireless_dbg,provisioning persist=yes
    2. repro the scenario
    3. netsh trace stop
    4. Collect the files generated and attach them to the bug

- Follow the RnR trigger guidelines to identify the case that caused the RnR trigger.

MB SAR Platform Support

Article • 03/14/2023

Overview

Specific Absorption Rate (SAR) is the capability to change the MBB radio transmitter power in reaction to the proximity of the MBB antenna to the user. Traditionally, OEMs have implemented proprietary solutions for SAR. This requires the OEM to implement a device service command that is either only identified between their User Mode Driver (UMDF) and the modem or requires kernel mode components to directly interact with the modem. Some OEMs may even have a hybrid solution where they have both UMDF-modem and kernel mode-modem components. As radio radiation awareness has increased, standardizing the interface for OEM software components to pass through the SAR command to the modem introduces the following benefits:

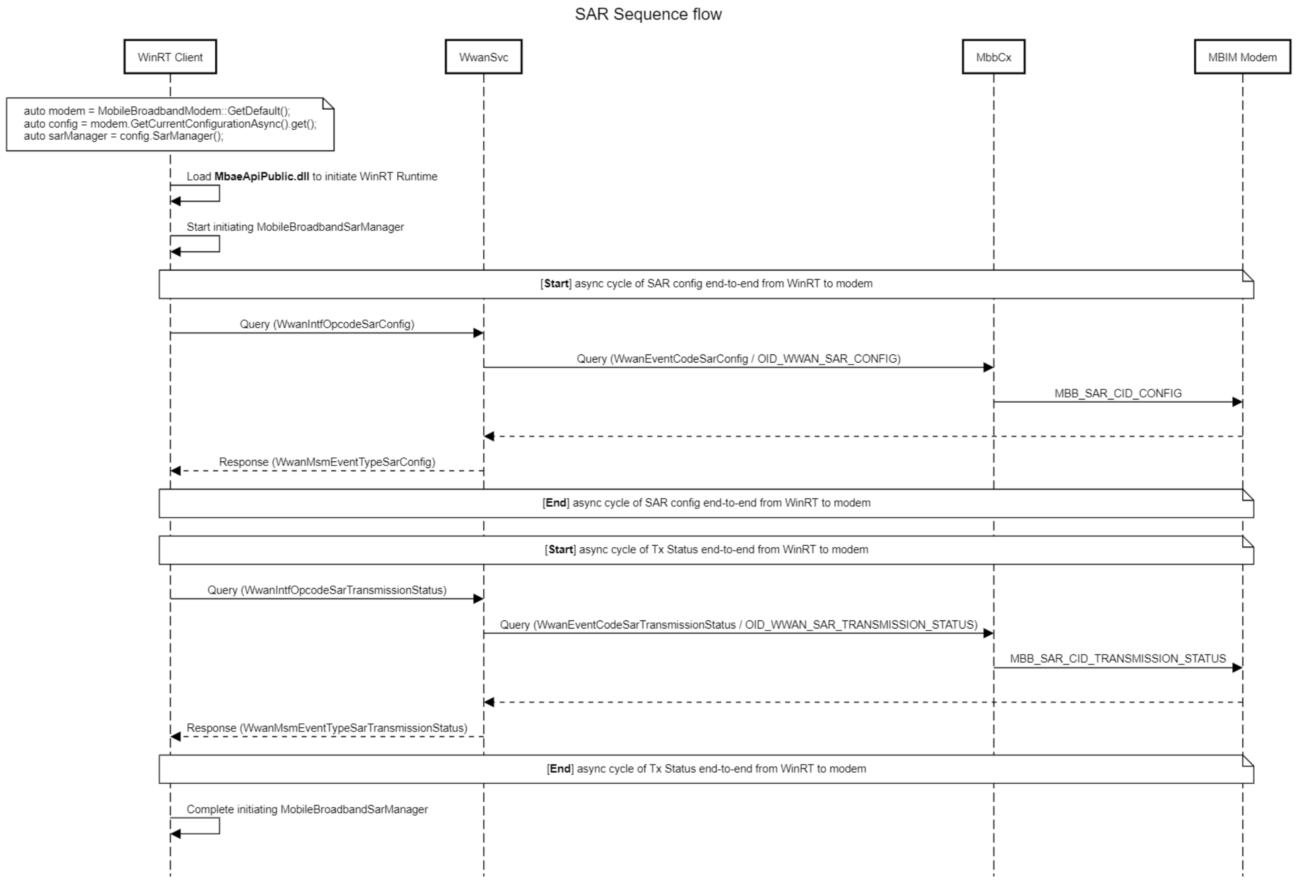
1. OEMs can move toward user mode components and makes the system more stable, as errors in user mode are not fatal to the system compared to kernel mode.
2. Windows provides a platform standard interface and reduces the proprietary implementation from OEMs.
3. Services in the platform that want to take advantage of SAR can retrieve the information from the modem.

Starting in Windows 10, version 1703, Windows supports passing through SAR configuration and modem transmission status. Windows will continue to leave the SAR business logic to IHVs and OEMs to use as a self-differentiating factor but will provide an interface to streamline the platform. Two new NDIS OIDs and two new MBIM CIDs have been defined to support this interface. Devices that want to take advantage of OS support must implement both commands.

This feature is supported by adding in two new OIDs and CIDs. For IHV partners that implement MBIM, only the CID version needs to be supported.

> **Note**
>
> This topic defines the interface for IHV partners to implement SAR platform support in their modem device drivers. If you are looking for info about customizing the SAR mapping table for a device, see **Customize a Specific Absorption Rate (SAR) mapping table**.

Flow



```

Complete initiating MobileBroadbandSarManager

MB Interface Update for SAR Platform Support

An MBIM-compliant device implements and reports the following device service when queried by CID_MBIM_DEVICE_SERVICES. The existing well-known services are defined in section 10.1 of the USB NCM MBIM 1.0 specification. Microsoft extends this to define the following service.

Service Name = **Microsoft SAR Control**

UUID = **UUID_MS_SARControl**

UUID Value = **68223D04-9F6C-4E0F-822D-28441FB72340**

CID	Minimum OS Version
MBIM_CID_MS_SAR_CONFIG	Windows 10, version 1703
MBIM_CID_MS_TRANSMISSION_STATUS	Windows 10, version 1703

MBIM_CID_MS_SAR_CONFIG

Description

This command sets or returns information about a MB device’s SAR back off mode and level. The MB device must act on the SAR back off command immediately by overwriting the current Transmit power limits and applying them to the transmitting antennas. If an antenna’s SAR configuration was not changed by the operating system, it should maintain its current setting. For example, if the operating system sets antenna 1 to be SAR back off index 1, then antenna 2’s configuration should be kept the same without any changes.

It is expected for devices that support this command to implement Query so they provide device information to the OS and its clients. For the Set command, it is between the IHV and the OEM to define which value of each field is acceptable. The typical expectation is that the SAR back off index is configurable for all antennas as a minimum baseline. If a Set request is sent with fields that are not supported by the device, then MBIM_STATUS_INVALID_PARAMETERS must be returned as the status code.

After each Query or Set response, the modem should return a MBIM_MS_SAR_CONFIG structure that contains information for all antennas on the device associated with Mobile Broadband.

Query

The InformationBuffer on MBIM_COMMAND_MSG is not used. MBIM_MS_SAR_CONFIG is returned in the InformationBuffer of MBIM_COMMAND_DONE.

Set

The InformationBuffer on MBIM_COMMAND_MSG contains a MBIM_MS_SAR_CONFIG. MBIM_MS_SAR_CONFIG is returned in the InformationBuffer of MBIM_COMMAND_DONE.

Unsolicited Events

Not applicable.

Parameters

Operation	Set	Query	Notification
Command	MBIM_MS_SET_SAR_CONFIG	Not applicable	Not applicable
Response	MBIM_MS_SAR_CONFIG	MBIM_MS_SAR_CONFIG	Not applicable

Data Structures

Query

The InformationBuffer shall be NULL and InformationBufferLength shall be zero.

Set

The following MBIM_MS_SET_SAR_CONFIG structure shall be used in the InformationBuffer.

Offset	Size	Field	Type	Description
0	4	SARMode	MBIM_MS_SAR_CONTROL_MODE	For more information, see the MBIM_MS_SAR_CONTROL_MODE table.
4	4	SARBackOffStatus	MBIM_MS_SAR_BACKOFF_STATE	For more information, see the MBIM_MS_SAR_BACKOFF_STATE table. If MBIM_MS_SAR_CONTROL_MODE is set to be device-controlled, then the OS will not be able set this field.
8	4	ElementCount (EC)	UINT32	Count of MBIM_MS_SAR_CONFIG structures that follow in the DataBuffer.

Offset	Size	Field	Type	Description
12	8 * EC	SARConfigStatusRefList	OL_PAIR_LIST	The first element of the pair is a 4-byte offset, calculated from the beginning (offset 0) of this MBIM_MS_SET_SAR_CONFIG structure, to an MBIM_MS_SAR_CONFIG_STATE structure. For more information, see the MBIM_MS_SAR_CONFIG_STATE table. The second element of the pair is a 4-byte size of a pointer to the corresponding MBIM_MS_SAR_CONFIG_STATE structure.
12 + (8 * EC)		DataBuffer	DATABUFFER	Array of MBIM_MS_SAR_CONFIG_STATE structures.

The following structures are used in the preceding table.

MBIM_MS_SAR_CONTROL_MODE specifies how the SAR back off mechanism is controlled.

Type	Value	Description
MBIMMsSARControlModeDevice	0	SAR back off mechanism is controlled by the modem device directly.
MBIMMsSARControlModeOS	1	SAR back off mechanism is controlled and managed by the operating system.

MBIM_MS_SAR_BACKOFF_STATE describes the state of SAR back off.

Type	Value	Description
MBIMMsSARBackOffStatusDisabled	0	SAR back off is disabled in the modem.
MBIMMsSARBackOffStatusEnabled	1	SAR back off is enabled in the modem.

MBIM_MS_SAR_CONFIG_STATE describes the possible states for SAR backoff for the antennas.

Offset	Size	Field	Type	Description
0	4	SARAntennaIndex	UINT32	An antenna index that corresponds to the **SARBackOffIndex** field in this table. It corresponds to the antenna number and is left to OEM implementation to index each antenna on the device. Any index is valid for this value. If this value is set to **0xFFFFFFFF** in a *Set* command, the **SARBackOffIndex** should be applied to all antennas. If this value is set to **0xFFFFFFFF** in response, it indicates that **SARBackOffIndex** is applied to all antennas.
4	4	SARBAckOffIndex	UINT32	A back off index that corresponds to the back off table that is defined by the OEM or modem vendor. The table has individual bands and associated back off parameters.

Response

The following MBIM_MS_SAR_CONFIG structure shall be used in the InformationBuffer. MBIM_MS_SAR_CONFIG specifies the configuration for SAR.

Offset	Size	Field	Type	Description
0	4	SARMode	MBIM_MS_SAR_MODE	For more information, see the MBIM_MS_SAR_CONTROL_MODE table.
4	4	SARBackOffStatus	MBIM_MS_SAR_BACKOFF_STATE	For more information, see the MBIM_MS_SAR_BACKOFF_STATE table.

Offset	Size	Field	Type	Description
8	4	SARWifiIntegration	MBIM_MS_SAR_ WIFI_HARDWARE_INTEGRATION	For more information, see the MBIM_MS_SAR_HARDWARE_WIFI_INTEGRATION table. This implies the device's Wi-Fi and Cellular SAR is integrated at the hardware layer and the device will automatically adjust SAR control for both radios.
12	4	ElementCount (EC)	UINT32	Count of MBIM_MS_SAR_CONFIG_STATE structures that follow in the DataBuffer.
16	8 * EC	SARConfigStatusRefList	OL_PAIR_LIST	The first element of the pair is a 4 byte offset, calculated from the beginning (offset 0) of this MBIM_MS_SAR_CONFIG structure, to an MBIM_MS_SAR_CONFIG_STATE structure. For more information, see the MBIM_MS_SAR_CONFIG_STATE table. The second element of the pair is a 4 -byte size of a pointer to the corresponding MBIM_MS_SAR_CONFIG_STATE structure.
16 + (8 * EC)		DataBuffer	DATABUFFER	Array of MBIM_MS_SAR_CONFIG_STATE structures.

The following MBIM_MS_SAR_HARDWARE_WIFI_INTEGRATION structure is used in the preceding table. It specifies whether Wi-Fi and Cellular are integrated at the hardware level.

Type	Value	Description
MBIMMsSARWifiHardwareIntegrated	0	Wi-Fi and Cellular modem SAR is integrated in the device.
MBIMMsSARWifiHardwareNotIntegrated	1	Wi-Fi and Cellular modem SAR is not integrated in the device.

Notification

Not applicable.

Status Codes

Error Code	Description
MBIM_STATUS_SUCCESS	The request was successfully processed.
MBIM_STATUS_BUSY	The device is currently busy.
MBIM_STATUS_FAILURE	The request failed.
MBIM_STATUS_NO_DEVICE_SUPPORT	Device does not support this command.
MBIM_STATUS_INVALID_PARAMETERS	The operation failed because of invalid parameters.
MBIM_STATUS_OPERATION_NOT_ALLOWED	The operation failed because the operation is not allowed.

MBIM_CID_MS_TRANSMISSION_STATUS

Description

This command is used to enable or disable the notification from the modem on transmit state. It is a per-executor command as each executor can have different channel transmit state. For example, a dual SIM modem might have one on LTE and the other on GSM. At the same time, it can be used to provide the transmit status of the modem. This notification could be used for clients that are interested in whether the modem is transmitting data or not. The modem should provide notification any time there is a start or end of TX traffic. If the duty cycle is too small and cannot be provided in real time to the host, then the TX state can be kept as active for a set time with a hysteresis timer before it sends an update of the state. As an example, it might be that there was a short burst of TX and the modem could not provide the start and end notification in time. The modem should send up notification when the TX traffic starts and should continue to monitor its TX traffic during the hysteresis timer. If no more TX traffic was generated within the timer's timeframe, then it should report that TX traffic has ended.

This is very useful in scenarios where both Wi-Fi and LTE are connected. If both LTE and Wi-Fi are in a transmitting state and proximity was detected, then Wi-Fi back off may be required. If LTE is not in transmitting state but Wi-Fi is, then Wi-Fi back off may not be required. This applies to general Wi-Fi/LTE connection and mobile hot spot scenarios.

The Wi-Fi back off mechanism and command is out of scope of this specification.

OEMs that use this command should be aware of the potential power impact as the modem may be sending up transmission-related notifications at all times, including reduced power states. The OS, by default, will not allow this notification to awake the AP during Modern Standby to improve power performance.

Query

The InformationBuffer on MBIM_COMMAND_MSG is not used. MBIM_MS_TRANSMISSION_STATUS_INFO is returned in the InformationBuffer of MBIM_COMMAND_DONE.

Set

The InformationBuffer on MBIM_COMMAND_MSG contains MBIM_MS_SET_TRANSMISSION_STATUS. MBIM_MS_TRANSMISSION_STATUS_INFO is returned in the InformationBuffer of MBIM_COMMAND_DONE.

Unsolicited Events

Unsolicited events contain MBIM_MS_TRANSMISSION_STATUS_INFO and are sent when there is a change to the active over-the-air (OTA) channels. For example, if a modem started uploading packet data, it would be required to set up uplink channels when it uses the network data channel so that it can upload payloads. This would trigger the notification to be provided to the operating system.

Parameters

Operation	Set	Query	Notification
Command	MBIM_MS_SET_TRANSMISSION_STATUS	Not applicable	Not applicable
Response	MBIM_MS_TRANSMISSION_STATUS_INFO	MBIM_MS_TRANSMISSION_STATUS_INFO	MBIM_MS_TRANSMISSION_STATUS_INFO

Data Structures

Query

The InformationBuffer on MBIM_COMMAND_MSG is not used. MBIM_MS_TRANSMISSION_STATUS_INFO is returned in the InformationBuffer of MBIM_COMMAND_DONE.

Set

The following MBIM_MS_SET_TRANSMISSION_STATUS structure shall be used in the InformationBuffer.

Offset	Size	Field	Type	Description

Offset	Size	Field	Type	Description
0	4	ChannelNotification	MBIM_MS_TRANSMISSION_STATUS_NOTIFICATION	For more information, see the MBIM_MS_TRANSMISSION_STATUS_NOTIFICATION table.
4	4	HysteresisTimer	UINT32	Hysteresis Indicator that is used by the modem to determine when to send the MBIMMsTransmissionStateInactive to the host. This value is the timer the modem sees as a continuous no-transmit activity before it sends an OFF indicator to host. This timer should be set in seconds, ranging from 1 second to 5 seconds.

The following MBIM_MS_TRANSMISSION_STATUS_NOTIFICATION structure is used in the preceding table. It specifies whether modem channel transmission is disabled or enabled.

Type	Value	Description
MBIMMsTransmissionNotificationDisabled	0	Modem channel transmission status notification disabled.
MBIMMsTransmissionNotificationEnabled	1	Modem channel transmission status notification enabled.

Response

The following MBIM_MS_TRANSMISSION_STATUS_INFO structure is used for response.

Offset	Size	Field	Type	Description
0	4	ChannelNotification	MBIM_MS_TRANSMISSION_STATUS_NOTIFICATION	For more information, see the MBIM_MS_TRANSMISSION_STATUS_NOTIFICATION table.
4	4	TransmissionStatus	MBIM_MS_TRANSMISSION_STATUS	For more information, see the MBIM_MS_TRANSMISSION_STATUS table. This indicates whether the modem has TX traffic every 5 seconds.
8	4	HysteresisTimer	UINT32	Hysteresis Indicator that is used by the modem to determine when to send the MBIMMsTransmissionStateInactive to the host. This value is the timer the modem sees as a continuous no-transmit activity before it sends an OFF indicator to host. This timer should be set in seconds, ranging from 1 second to 5 seconds.

The following MBIM_MS_TRANSMISSION_STATUS structure is used in the preceding table. It indicates whether modem is having TX traffic every 5 seconds.

Type	Value	Description
MBIMMsTransmissionStateInactive	0	The modem was not actively transmitting data without any continuous lapse of transmission for the last HysteresisTimer value.
MBIMMsTransmissionStateActive	1	The modem was actively transmitting data.

Notification

For more information, see the MBIM_MS_TRANSMISSION_STATUS_INFO table.

Status Codes

Error Code	Description
MBIM_STATUS_SUCCESS	The request was successfully processed.
MBIM_STATUS_BUSY	The device is currently busy.
MBIM_STATUS_FAILURE	The request failed.
MBIM_STATUS_NO_DEVICE_SUPPORT	Device does not support this command.
MBIM_STATUS_INVALID_PARAMETERS	The operation failed because of invalid parameters.
MBIM_STATUS_OPERATION_NOT_ALLOWED	The operation failed because the operation is not allowed.

Hardware Lab Kit (HLK) Tests

See Steps for installing HLK .

In HLK Studio connect to the device Cellular modem driver and run the test: Win6_4.MB.GSM.Data.TestSAR.

This test contains the following tests:

Test name	Description
QuerySarConfig	This test verifies the test can successfully query SAR configurations.
SetSarConfig	This test verifies the test can successfully set SAR configurations.
QuerySarTransmissionStatus	This test verifies the test can successfully query SAR transmission status.
SetSarTransmissionStatus	This test verifies the test can successfully set SAR transmission status.

MB base stations information query support

Article • 03/14/2023

Overview

The base stations information query interface is used to provide location based services with cellular base station information, such as *Base Station ID*, *Time Advance*, and other parameters that can be used to compute the geographical position of the mobile subscriber. The information gathered pertains to the cellular base station currently serving the subscriber, as well as neighboring cellular base stations.

This topic defines the base stations information query interface for Windows, as the MBIM 1.0 specification does not provide this information through any existing CIDs. This interface is available in Windows 10, version 1709 and later.

Serving and neighbor cell parameters are retrieved via Query/Response operations. A notification is also defined in this topic to indicate that the location of the device within the cellular network has changed.

MBIM_CID_BASE_STATIONS_INFO

This command retrieves information about the serving and neighbor cells known to the modem.

Service: **MBB_UUID_BASIC_CONNECT_EXTENSIONS**

Service UUID: **3d01dcc5-fef5-4d05-0d3a-bef7058e9aaf**

CID	Command code	Minimum OS version
MBIM_CID_BASE_STATIONS_INFO	11	Windows 10, version 1709

Parameters

Type	Set	Query	Notification
Command	Not applicable	MBIM_BASE_STATIONS_INFO_REQ	Not applicable
Response	Not applicable	MBIM_BASE_STATIONS_INFO	Not applicable

Query

The InformationBuffer of MBIM_COMMAND_MSG contains an MBIM_BASE_STATIONS_INFO_REQ struture. The InformationBuffer of MBIM_COMMAND_DONE contains an MBIM_BASE_STATIONS_INFO structure.

MBIM_BASE_STATIONS_INFO_REQ

The MBIM_BASE_STATIONS_INFO_REQ structure shall be used in the InformationBuffer for queries. It is used to configure aspects of the cell information, such as the maximum number of neighbor cell measurements, to send in response.

Offset	Size	Field	Type	Description
0	4	MaxGSMCount	SIZE	The maximum number of entries of GSM neighboring cells returned in the GSM network measurement reports of MBIM_GSM_NMR. Default capacity is 15.
4	4	MaxUMTSCount	SIZE	The maximum number of entries of UMTS neighboring cells returned in the UMTS measured results list in MBIM_UMTS_MRL. Default capacity is 15.
8	4	MaxTDSCDMACount	SIZE	The maximum number of entries of TDSCDMA neighboring cells returned in the TDSCDMA measured results list in MBIM_TDSCDMA_MRL. Default capacity is 15.
12	4	MaxLTECount	SIZE	The maximum number of entries of LTE neighboring cells returned in the LTE measured results list of MBIM_LTE_MRL. Default capacity is 15.
16	4	MaxCDMACount	SIZE	The maximum number of entries of CDMA cells returned in the CDMA measured results list in MBIM_CDMA_MRL. This list includes both serving and neighboring cells. Default capacity is 12.

Set

Not applicable.

Response

The MBIM_BASE_STATIONS_INFO structure shall be used in the InformationBuffer of MBIM_COMMAND_DONE for responses.

MBIM_BASE_STATIONS_INFO

The MBIM_BASE_STATIONS_INFO structure contains information about both serving and neighboring base stations.

Offset	Size	Field	Type	Description
0	4	SystemType	MBIM_DATA_CLASS	Indicates the system type (or types) for which serving cell information is valid. This member is a bitmask of one or more system types as defined in the MBIM_DATA_CLASS.
4	4	GSMServingCellOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to the buffer containing the GSM serving cell information. This member can be NULL when the technology of the serving cell is not GSM.
8	4	GSMServingCellSize	SIZE(0-44)	The size, in bytes, used for MBIM_GSM_SERVING_CELL_INFO.
12	4	UMTSServingCellOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to the buffer containing the UMTS serving cell information. This member can be NULL when the technology of serving cell is not UMTS.
16	4	UMTSServingCellSize	SIZE(0-60)	The size, in bytes, used for MBIM_UMTS_SERVING_CELL_INFO.
20	4	TDSCDMAServingCellOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to the buffer containing the TDSCDMA serving cell information. This member can be NULL when the technology of serving cell is not TDSCDMA.
24	4	TDSCDMAServingCellSize	SIZE(0-48)	The size, in bytes, used for MBIM_TDSCDMA_SERVING_CELL_INFO.
28	4	LTEServingCellOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to the buffer containing the LTE serving cell information. This member can be NULL when the technology of serving cell is not LTE.

Offset	Size	Field	Type	Description
32	4	LTEServingCellSize	SIZE(0-48)	The size, in bytes, used for MBIM_LTE_SERVING_CELL_INFO.
36	4	GSMNmrOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to the buffer containing the GSM Network Measurement report. This member can be NULL when no GSM neighboring network is returned in the measurement report.
40	4	GSMNmrSize	SIZE	The total size, in bytes, of the buffer containing the GSM Network Measurement report in the format of MBIM_GSM_NMR.
44	4	UMTSMrlOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to the buffer containing UMTS measured results list. This member can be NULL when no UMTS neighboring network is returned in the measurement report.
48	4	UMTSMrlSize	SIZE	The total size, in bytes, of the buffer containing the UMTS measured results list in the format of MBIM_UMTS_MRL.
52	4	TDSCDMAMrlOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to the buffer containing TDSCDMA measured results list. This member can be NULL when no TDSCDMA neighboring network is returned in the measurement report.
56	4	TDSCDMAMrlSize	SIZE	The total size, in bytes, of the buffer containing the TDSCDMA measured results list in the format of MBIM_TDSCDMA_MRL.
60	4	LTEMrlOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to the buffer containing the LTE measured results list. This member can be NULL when no LTE neighboring network is returned in the measurement report.

Offset	Size	Field	Type	Description
64	4	LTEMrlSize	SIZE	The total size, in bytes, of the buffer containing the LTE measured results list in the format of MBIM_LTE_MRL.
68	4	CDMAMrlOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to the buffer containing CDMA measured results list. This member can be NULL when no CDMA neighboring network is returned in the measurement report.
72	4	CDMAMrlSize	SIZE	The total size, in bytes, of the buffer containing the CDMA measured results list in the format of MBIM_CDMA_MRL.
76		DataBuffer	DATABUFFER	The data buffer containing *GSMServingCell*, *UMTSServingCell*, *TDSCDMAServingCell*, *LTEServingCell*, *GSMNmr*, *UMTSMrl*, *TDSCDMAMrl*, *LTEMrl*, and *CDMAMrl*.

GSM cell data structures

MBIM_GSM_SERVING_CELL_INFO

The MBIM_GSM_SERVING_CELL_INFO structure contains information about the GSM serving cell.

Offset	Size	Field	Type	Description
0	4	ProviderIdOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to a numeric (0-9) string called *ProviderId* that represents the network provider identity. This string is a concatenation of a three-digit Mobile Country Code (MCC) and a two or three-digit Mobile Network Code (MNC). This member can be NULL when no *ProviderId* information is returned.
4	4	ProviderIdSize	SIZE(0-12)	The size used for *ProviderId*.
8	4	LocationAreaCode	UINT32	The Location Area Code (0-65535). Use 0xFFFFFFFF when this information is not available.

Offset	Size	Field	Type	Description
12	4	CellID	UINT32	The Cell ID (0-65535). Use 0xFFFFFFFF when this information is not available.
16	4	TimingAdvance	UINT32	The Timing Advance (0-255) in bit periods, where a bit period is 48/13µs. Use 0xFFFFFFFF when this information is not available.
20	4	ARFCN	UINT32	The Absolute Radio Frequency Channel Number of the serving cell (0-1023). Use 0xFFFFFFFF when this information is not available.
24	4	BaseStationId	UINT32	The Base Station ID - the base station color code and the network identity code. Use 0xFFFFFFFF when this information is not available.

28	4	RxLevel	UINT32	The received signal strength of the serving cell (0-63), where
				`X = 0, if RSS < -110 dBm`
				`X = 63, if RSS > -47 dBm`
				`X = integer [RSS + 110], if -110 <= RSS <= -47`
				Use 0xFFFFFFFF when this information is not available.

32		DataBuffer	DATABUFFER	The data buffer containing *ProviderId*.

MBIM_GSM_NMR

The MBIM_GSM_NMR structure contains the network measurement report (NMR) of neighboring GSM cells.

Offset	Size	Field	Type	Description
0	4	ElementCount (EC)	UINT32	The count of NMR entries following this element.
4		DataBuffer	DATABUFFER	The array of NMR records, each specified as an MBIM_GSM_NMR_INFO structure.

MBIM_GSM_NMR_INFO

The MBIM_GSM_NMR_INFO structure contains information about a neighboring GSM cell.

Offset	Size	Field	Type	Description
0	4	ProviderIdOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to a numeric (0-9) string called *ProviderId* that represents the network provider identity. This string is a concatenation of a three-digit Mobile Country Code (MCC) and a two or three-digit Mobile Network Code (MNC). This member can be NULL when no *ProviderId* information is returned.
4	4	ProviderIdSize	SIZE(0-12)	The size used for *ProviderId*.
8	4	LocationAreaCode	UINT32	The Location Area Code (0-65535). Use 0xFFFFFFFF when this information is not available.
12	4	CellID	UINT32	The Cell ID (0-65535). Use 0xFFFFFFFF when this information is not available.
16	4	ARFCN	UINT32	The Absolute Radio Frequency Channel Number of the serving cell (0-1023). Use 0xFFFFFFFF when this information is not available.
20	4	BaseStationId	UINT32	The radio base station ID of the serving cell (0-63). Use 0xFFFFFFFF when this information is not available.

24	4	RxLevel	UINT32	The received signal strength of the serving cell (0-63), where
				`X = 0, if RSS < -110 dBm`
				`X = 63, if RSS > -47 dBm`
				`X = integer [RSS + 110], if -110 <= RSS <= -47`
				Use 0xFFFFFFFF when this information is not available.

28		DataBuffer	DATABUFFER	The data buffer containing *ProviderId*.

UMTS cell data structures

MBIM_UMTS_SERVING_CELL_INFO

The MBIM_UMTS_SERVING_CELL_INFO structure contains information about the UMTS serving cell.

Offset	Size	Field	Type	Description
0	4	ProviderIdOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to a numeric (0-9) string called *ProviderId* that represents the network provider identity. This string is a concatenation of a three-digit Mobile Country Code (MCC) and a two or three-digit Mobile Network Code (MNC). This member can be NULL when no *ProviderId* information is returned.
4	4	ProviderIdSize	SIZE(0-12)	The size used for *ProviderId*.
8	4	LocationAreaCode	UINT32	The Location Area Code (0-65535). Use 0xFFFFFFFF when this information is not available.
12	4	CellID	UINT32	The Cell ID (0-268435455). Use 0xFFFFFFFF when this information is not available.
16	4	FrequencyInfoUL	UINT32	The Frequency Info Uplink (0-16383). Use 0xFFFFFFFF when this information is not available.
20	4	FrequencyInfoDL	UINT32	The Frequency Info Downlink (0-16383). Use 0xFFFFFFFF when this information is not available.
24	4	FrequencyInfoNT	UINT32	The Frequency Info for TDD (0-16383). Use 0xFFFFFFFF when this information is not available.
28	4	UARFCN	UINT32	The UTRA Absolute Radio Frequency Channel Number for the serving cell (0-16383). Use 0xFFFFFFFF when this information is not available.
32	4	PrimaryScramblingCode	UINT32	The Primary Scrambling Code of the serving cell (0-511). Use 0xFFFFFFFF when this information is not available.
36	4	RSCP	INT32	The Received Signal Code Power of the serving cell. The range is -120 to -25, in units of 1dBm. Use 0 when this information is not available.

Offset	Size	Field	Type	Description
40	4	ECNO	INT32	The signal to noise ratio of the serving cell; the ratio of the received energy per PN chip for the CPICH to the total received. The range is -50 to 0, in units of 1dBm. Use 1 when this information is not available.
44	4	PathLoss	UINT32	The path loss of the serving cell (46-173). Use 0xFFFFFFFF when this information is not available.
48		DataBuffer	DATABUFFER	The data buffer containing *ProviderId*.

MBIM_UMTS_MRL

The MBIM_UMTS_MRL structure contains the measured results list (MRL) of neighboring UMTS cells.

Offset	Size	Field	Type	Description
0	4	ElementCount (EC)	UINT32	The count of MRL entries following this element.
4		DataBuffer	DATABUFFER	The array of MRL records, each specified as an MBIM_UMTS_MRL_INFO structure.

MBIM_UMTS_MRL_INFO

The MBIM_UMTS_MRL_INFO structure contains information about a neighboring UMTS cell.

Offset	Size	Field	Type	Description
0	4	ProviderIdOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to a numeric (0-9) string called *ProviderId* that represents the network provider identity. This string is a concatenation of a three-digit Mobile Country Code (MCC) and a two or three-digit Mobile Network Code (MNC). This member can be NULL when no *ProviderId* information is returned.
4	4	ProviderIdSize	SIZE(0-12)	The size used for *ProviderId*.

Offset	Size	Field	Type	Description
8	4	LocationAreaCode	UINT32	The Location Area Code (0-65535). Use 0xFFFFFFFF when this information is not available.
12	4	CellID	UINT32	The Cell ID (0-268435455). Use 0xFFFFFFFF when this information is not available.
16	4	UARFCN	UINT32	The UTRA Absolute Radio Frequency Channel Number for the serving cell (0-16383). Use 0xFFFFFFFF when this information is not available.
20	4	PrimaryScramblingCode	UINT32	The Primary Scrambling Code of the serving cell (0-511). Use 0xFFFFFFFF when this information is not available.
24	4	RSCP	INT32	The Received Signal Code Power of the serving cell. The range is -120 to -25, in units of 1dBm. Use 0 when this information is not available.
28	4	ECNO	INT32	The signal to noise ratio of the serving cell; the ratio of the received energy per PN chip for the CPICH to the total received. The range is -50 to 0, in units of 1dBm. Use 1 when this information is not available.
32	4	PathLoss	UINT32	The path loss of the serving cell (46-173). Use 0xFFFFFFFF when this information is not available.
36		DataBuffer	DATABUFFER	The data buffer containing *ProviderId*.

TDSCDMA cell data structures

MBIM_TDSCDMA_SERVING_CELL_INFO

The MBIM_TDSCDMA_SERVING_CELL_INFO structure contains information about the TDSCDMA serving cell.

Offset	Size	Field	Type	Description

Offset	Size	Field	Type	Description
0	4	ProviderIdOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to a numeric (0-9) string called *ProviderId* that represents the network provider identity. This string is a concatenation of a three-digit Mobile Country Code (MCC) and a two or three-digit Mobile Network Code (MNC). This member can be NULL when no *ProviderId* information is returned.
4	4	ProviderIdSize	SIZE(0-12)	The size used for *ProviderId*.
8	4	LocationAreaCode	UINT32	The Location Area Code (0-65535). Use 0xFFFFFFFF when this information is not available.
12	4	CellID	UINT32	The Cell ID (0-268435455). Use 0xFFFFFFFF when this information is not available.
16	4	UARFCN	UINT32	The UTRA Absolute Radio Frequency Channel Number for the serving cell (0-16383). Use 0xFFFFFFFF when this information is not available.
20	4	CellParameterID	UINT32	The Cell parameter ID (0-127). Use 0xFFFFFFFF when this information is not available.
24	4	TimingAdvance	UINT32	The Timing Advance (0-1023). This member is the same value for all timeslots. Use 0xFFFFFFFF when this information is not available.
28	4	RSCP	INT32	The Received Signal Code Power of the serving cell. The range is -120 to -25, in units of 1dBm in Q8 L3 filtered. Use 0xFFFFFFFF when this information is not available.
32	4	PathLoss	UINT32	The path loss of the serving cell (46-158). Use 0xFFFFFFFF when this information is not available.
36		DataBuffer	DATABUFFER	The data buffer containing *ProviderId*.

MBIM_TDSCDMA_MRL

The MBIM_TDSCDMA_MRL structure contains the measured results list (MRL) of neighboring TDSCDMA cells.

Offset	Size	Field	Type	Description

Offset	Size	Field	Type	Description
0	4	ElementCount (EC)	UINT32	The count of MRL entries following this element.
4		DataBuffer	DATABUFFER	The array of MRL records, each specified as an MBIM_TDSCDMA_MRL_INFO structure.

MBIM_TDSCDMA_MRL_INFO

The MBIM_TDSCDMA_MRL_INFO structure contains information about a neighboring TDSCDMA cell.

Offset	Size	Field	Type	Description
0	4	ProviderIdOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to a numeric (0-9) string called *ProviderId* that represents the network provider identity. This string is a concatenation of a three-digit Mobile Country Code (MCC) and a two or three-digit Mobile Network Code (MNC). This member can be NULL when no *ProviderId* information is returned.
4	4	ProviderIdSize	SIZE(0-12)	The size used for *ProviderId*.
8	4	LocationAreaCode	UINT32	The Location Area Code (0-65535). Use 0xFFFFFFFF when this information is not available.
12	4	CellID	UINT32	The Cell ID (0-268435455). Use 0xFFFFFFFF when this information is not available.
16	4	UARFCN	UINT32	The UTRA Absolute Radio Frequency Channel Number for the serving cell (0-16383). Use 0xFFFFFFFF when this information is not available.
20	4	CellParameterID	UINT32	The Cell parameter ID (0-127). Use 0xFFFFFFFF when this information is not available.
24	4	TimingAdvance	UINT32	The Timing Advance (0-1023). This member is the same value for all timeslots. Use 0xFFFFFFFF when this information is not available.
28	4	RSCP	INT32	The Received Signal Code Power of the serving cell. The range is -120 to -25, in units of 1dBm in Q8 L3 filtered. Use 0xFFFFFFFF when this information is not available.

Offset	Size	Field	Type	Description
32	4	PathLoss	UINT32	The path loss of the serving cell (46-158). Use 0xFFFFFFFF when this information is not available.
36		DataBuffer	DATABUFFER	The data buffer containing *ProviderId*.

LTE cell data structures

MBIM_LTE_SERVING_CELL_INFO

The MBIM_LTE_SERVING_CELL_INFO structure contains information about the LTE serving cell.

Offset	Size	Field	Type	Description
0	4	ProviderIdOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to a numeric (0-9) string called *ProviderId* that represents the network provider identity. This string is a concatenation of a three-digit Mobile Country Code (MCC) and a two or three-digit Mobile Network Code (MNC). This member can be NULL when no *ProviderId* information is returned.
4	4	ProviderIdSize	SIZE(0-12)	The size used for *ProviderId*.
8	4	CellID	UINT32	The Cell ID (0-268435455). Use 0xFFFFFFFF when this information is not available.
12	4	EARFCN	UINT32	The Radio Frequency Channel Number of the serving cell (0-65535). Use 0xFFFFFFFF when this information is not available.
16	4	PhysicalCellID	UINT32	The Physical Cell ID (0-503). Use 0xFFFFFFFF when this information is not available.
20	4	TAC	UINT32	The Tracking Area Code (0-65535). Use 0xFFFFFFFF when this information is not available.
24	4	RSRP	INT32	The Average Reference Signal Received Power. The range is -140 to -44, in units of 1dBm. Use 0xFFFFFFFF when this information is not available.
28	4	RSRQ	INT32	The Average Reference Signal Received Quality. The range is -20 to -3, in units of 1dBm. Use 0xFFFFFFFF when this information is not available.

Offset	Size	Field	Type	Description
32	4	TimingAdvance	UINT32	The Timing Advance (0-255). Use 0xFFFFFFFF when this information is not available.
36		DataBuffer	DATABUFFER	The data buffer containing *ProviderId*.

MBIM_LTE_MRL

The MBIM_LTE_MRL structure contains the measured results list (MRL) of neighboring LTE cells.

Offset	Size	Field	Type	Description
0	4	ElementCount (EC)	UINT32	The count of MRL entries following this element.
4		DataBuffer	DATABUFFER	The array of MRL records, each specified as an MBIM_LTE_MRL_INFO structure.

MBIM_LTE_MRL_INFO

The MBIM_LTE_MRL_INFO structure contains information about a neighboring LTE cell.

Offset	Size	Field	Type	Description
0	4	ProviderIdOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to a numeric (0-9) string called *ProviderId* that represents the network provider identity. This string is a concatenation of a three-digit Mobile Country Code (MCC) and a two or three-digit Mobile Network Code (MNC). This member can be NULL when no *ProviderId* information is returned.
4	4	ProviderIdSize	SIZE(0-12)	The size used for *ProviderId*.
8	4	CellID	UINT32	The Cell ID (0-268435455). Use 0xFFFFFFFF when this information is not available.
12	4	EARFCN	UINT32	The Radio Frequency Channel Number of the serving cell (0-65535). Use 0xFFFFFFFF when this information is not available.
16	4	PhysicalCellID	UINT32	The Physical Cell ID (0-503). Use 0xFFFFFFFF when this information is not available.

Offset	Size	Field	Type	Description
20	4	TAC	UINT32	The Tracking Area Code (0-65535). Use 0xFFFFFFFF when this information is not available.
24	4	RSRP	INT32	The Average Reference Signal Received Power. The range is -140 to -44, in units of 1dBm. Use 0xFFFFFFFF when this information is not available.
28	4	RSRQ	INT32	The Average Reference Signal Received Quality. The range is -20 to -3, in units of 1dBm. Use 0xFFFFFFFF when this information is not available.
32		DataBuffer	DATABUFFER	The data buffer containing *ProviderId*.

CDMA cell data structures

MBIM_CDMA_MRL

The MBIM_CDMA_MRL structure contains the measured results list (MRL) of both serving and neighboring CDMA cells.

Offset	Size	Field	Type	Description
0	4	ElementCount (EC)	UINT32	The count of MRL entries following this element.
4		DataBuffer	DATABUFFER	The array of MRL records, each specified as an MBIM_CDMA_MRL_INFO structure.

MBIM_CDMA_MRL_INFO

The MBIM_CDMA_MRL_INFO data structure is designed for the CDMA2000 network type. There can be more than one CDMA2000 serving cell at the same time. Both serving cells and neighboring cells will be returned in the same list. The **ServingCellFlag** field indicates whether a cell is a serving cell or not.

Offset	Size	Field	Type	Description
0	4	ServingCellFlag	UINT32	Indicates whether this is a serving cell. A value of 1 indicates a serving cell, while a value of 0 indicates a neighboring cell. There may be more than one serving cell at a time (notably while in a call).
4	4	NID	UINT32	The Network ID (0-65535). Use 0xFFFFFFFF when this information is not available.

Offset	Size	Field	Type	Description
8	4	SID	UINT32	The System ID (0-32767). Use 0xFFFFFFFF when this information is not available.
12	4	BaseStationId	UINT32	The Base Station ID (0-65535). Use 0xFFFFFFFF when this information is not available.
16	4	BaseLatitude	UINT32	The Base Station Latitude (0-4194303). This is encoded in units of 0.25 seconds, expressed in two's complement representation within the low 22 bits of the DWORD. As a signed value, North latitudes are positive. Use 0xFFFFFFFF when this information is not available.
20	4	BaseLongitude	UINT32	The Base Station Longitude (0-8388607). This is encoded in units of 0.25 seconds, expressed in two's complement representation within the low 23 bits of the DWORD. As a signed value, East longitudes are positive. Use 0xFFFFFFFF when this information is not available.
24	4	RefPN	UINT32	The Base Station PN Number (0-511). Use 0xFFFFFFFF when this information is not available.
28	4	GPSSeconds	UINT32	The GPS seconds, or the time at which this arrived from the base station. Use 0xFFFFFFFF when this information is not available.
32	4	PilotStrength	UINT32	The Signal strength of the pilot (0-63). Use 0xFFFFFFFF when this information is not available.

Unsolicited Event

Not applicable.

Status codes

This CID uses Generic Status Codes (see Use of Status Codes in Section 9.4.5 of the public USB MBIM standard).

MBIM_CID_LOCATION_INFO_STATUS

This CID retrieves the status of the cellular information which indicates the location of the device. It may also be used to deliver an unsolicited notification when the location information changes.

Service: **MBB_UUID_BASIC_CONNECT_EXTENSIONS**

Service UUID: **3d01dcc5-fef5-4d05-0d3a-bef7058e9aaf**

CID	Command code	Minimum OS version
MBIM_CID_LOCATION_INFO_STATUS	12	Windows 10, version 1709

> ⓘ Note
>
> MBIM_CID_LOCATION_INFO_STATUS is defined starting in Windows 10, version 1709, but is not currently supported by the OS. A modem can send this command as a notification, but the OS does not currently handle it.

Parameters

Type	Set	Query	Notification
Command	Not applicable	Not applicable	Not applicable
Response	Not appliable	MBIM_LOCATION_INFO	MBIM_LOCATION_INFO

Query

The InformationBuffer of the MBIM_COMMAND_MSG is not used. The InformationBuffer of the MBIM_COMMAND_DONE contains an MBIM_LOCATION_INFO structure.

Set

Not applicable.

Response

MBIM_LOCATION_INFO

Offset	Size	Field	Type	Description
0	4	LocationAreaCode	UINT32	The GSM/UMTS area code of the current location. Return 0xFFFFFFFF when the current system type is not applicable.

Offset	Size	Field	Type	Description
4	4	TrackingAreaCode	UINT32	The LTE tracking area code of the current location. Return 0xFFFFFFFF when the current system type is not applicable.
8	4	CellID	UINT32	The ID of the cellular tower. Return 0xFFFFFFFF when *CellID* is not available.

Unsolicited Events

The event InformationBuffer contains an MBIM_LOCATION_INFO structure.

This event is sent if the value of *Location Area Code/Tracking Area Code* changes to a valid value. This event is not sent when *CellID* changes or when *Location Area Code/Tracking Area Code* becomes invalid.

Status codes

This CID uses Generic Status Codes (see Use of Status Codes in Section 9.4.5 of the public USB MBIM standard).

OID_WWAN_BASE_STATIONS_INFO

The NDIS equivalent for MBIM_CID_BASE_STATIONS_INFO is OID_WWAN_BASE_STATIONS_INFO.

MB NITZ support

Article • 03/14/2023

Overview

Starting in Windows 10, version 1903, Windows supports Network Identity and Time Zone (NITZ) at the OS level for mobile broadband (MBB) devices. In previous versions of Windows, the only network time available at the OS level was Network Time Protocol (NTP), even though NITZ was supported at the modem level by all 3GPP-compliant modems. With NITZ support, Windows is able to receive unsolicited NITZ notifications from modems and publish necessary events to notify consumers of the NITZ timestamps.

For MBIM functions, no additional NITZ-related setup and provisioning is required. As long as a data connection is established over a cellular bearer, a modem can notify the OS any time it has received a NITZ timestamp from the network. Modems can receive NITZ notifications from the network infrastructure based on the mobile operator's own defined cadence and schedule, within the 3GPP specifications. NITZ notifications are unsolicited. Upon receiving the NITZ notification, the OS publishes the notification that NITZ data is available.

NDIS interface extension

The following OID has been defined to support NITZ.

- OID_WWAN_NITZ

MBIM service and CID values

Service name	UUID	UUID value
Microsoft Voice Extensions	UUID_VOICEEXTENSIONS	8d8b9eba-37be-449b-8f1e-61cb034a702e

The following table specifies the UUID and command code for each CID, as well as whether the CID supports Set, Query, or Event (notification) requests. See each CID’s individual Section within this topic for more info about its parameters, data structures, and notifications.

CID	UUID	Command code	Set	Query	Notify
MBIM_CID_NITZ	UUID_VOICEEXTENSIONS	10	N	Y	Y

MBIM_CID_NITZ

Parameters

Operation	Set	Query	Notification
Command	Not applicable	Not applicable	Not applicable
Response	Not applicable	MBIM_NITZ_INFO	MBIM_NITZ_INFO

Query

Queries the current network time. The InformationBuffer of MBIM_COMMAND_MSG is not used. The following MBIM_NITZ_INFO structure is used in the InformationBuffer of MBIM_COMMAND_DONE.

MBIM_NITZ_INFO

Offset	Size	Field	Type	Description
0	4	Year	UINT32	The year as an integer. For example, **2014**.
4	4	Month	UINT32	The month (1..12), where January == 1.
8	4	Day	UINT32	The day of the month, (1..31).
12	4	Hour	UINT32	The hour, (0..23).
16	4	Minute	UINT32	The minute, (0..59).
20	4	Second	UINT32	The second, (0..59).
24	4	TimeZoneOffsetMinutes	UINT32	The time zone offset, in minutes, from UTC. This value includes any adjustment for the current state of daylight saving time. This value should be set to 0xFFFFFFFF when time zone info is not available.

Offset	Size	Field	Type	Description
28	4	DaylightSavingTimeOffsetMinutes	UINT32	The offset for daylight saving time, in minutes. This value should be set to 0xFFFFFFFF when daylight saving time is not available.
32	4	DataClasses	UINT32	Data classes supported by this network. If this information is not available, this field should be set to MBIMDataClassNone.

Set

Not applicable.

Response

The InformationBuffer in MBIM_COMMAND_DONE contains an MBIM_NITZ_INFO structure.

Unsolicited Events

This unsolicited event provides the current network time and time zone information.

Status Codes

This CID only uses generic status codes defined in Section 9.4.5 of the MBIM specification revision 1.0 .

OID Definitions

- OID_WWAN_NITZ

Hardware Lab Kit (HLK) Tests

See Steps for installing HLK .

In HLK Studio connect to hte device Cellular modem driver and run the test: TestNitzInfo - GSM.

Manual Tests

[NITZ] Time update while roaming on Cellular

1. Place the Cobalt device in an RF cage with Cellular disabled.
2. Enable Airplane mode.
3. Disable Ethernet and all other connections.
4. Set the time mode to manual.
5. Set the time to 11:15AM 10/15/2016 UTC.
6. Verify that the time is set to the value given in the system tray.
7. Set the time mode to automatic.
8. Turn on Cellular.
9. Wait for the device to receive the NITZ information from the simulated cellular base station.
10. Verify that the time is set to the value sent by the simulated base station.

MB modem logging with DSS

Article • 03/14/2023

ⓘ Note

If you are planning for your modem to support `MBIM_CID_MODEM_LOGGING_CONFIG`, please provide feedback on this page so that we can best support you. This CID is currently experimental and has not been tested with a modem yet, as none support it.

This topic describes a new standard Windows mobile broadband (MBB) logging interface through Microsoft extensions to the USB MBIM 1.0 specification, available in Windows 10, version 1903 and later.

With this new logging interface, the OS can inform the MBB device to start, stop, and flush the logs to the OS file system through MBIM CID commands. Given the non-IP nature of the modem's logging payload, the data channel that the MBB service uses to transmit logging payloads to the OS uses the MBB Data Service Stream (DSS). DSS is defined in the Mobile Broadband Interface Model (MBIM) 1.0 specification.

The OS abstracts the modem's diagnostic functionalities and configurations across the entire MBB ecosystem with a set of Windows-specific MBB logging configurations. These MBB logging configs enable a modem's vendor to map the OS MBB logging requirements to the appropriate internal logging configurations. The logging configurations abstracted and defined by the OS include the MBB logging verbosity levels and the maximum flush time.

A modem keeps filling its logging buffer, up to the max buffer size, until the segment is filled and the MBIM framework transmits the segment to the OS, or it flushes the content of its buffer when the maximum flush time is reached (even if the segment is not filled). The OS defines a set of standard Windows MBB logging configuration levels, described later in this topic. Each config level specifies an OS abstraction of MBB logging details and verbosity.

OS abstraction of MBB config levels is mapped to the appropriate internal modem configuration by modems. The OS does not provide any additional configuration payloads, such as logging filters or masks, to modems other than the OS MBB configuration level.

For modems that support MBB logging, all MBB logging config levels except for MBIMLoggingLevelOem must be present on all BSP variants. In other words, the IHV or OEM must support PROD or LAB levels of MBB logging in both production and R&D versions of the BSP. LAB levels of MBB logging can only be disabled from the OS.

This new logging interface's design uses the control channel to set the logging parameters, and uses the data channel to receive modem logs because the data channel is designed to transfer bulk modem data. The advantage of this design is that bulk data does not need to be transferred over the control channel, thus keeping device performance consistent. It also scales well for higher throughput. The data channel is operated by DSS commands. An example flow for a modem might look like this:

1. The OS sends the MBIM_CID_MODEM_LOGGING_CONFIG CID to the modem to configure logging parameters such as MaxSegmentSize, MaxFlushTime, and the LoggingLevel.

2. Once the OS receives a successful response from the modem, it sends the MBIM_CID_DSS_CONNECT DSS command to the modem with a specific GUID for modem logging, the MBIMDssLinkActivate state, and a unique DSS session ID.
3. Once it receives a success status code, the OS prepares to receive fragments from the modem. These fragments are called DataServiceSessionRead packets.
4. DataServiceSessionRead packets continue to arrive until the OS issues another MBIM_CID_DSS_CONNECT command with the same DSS session ID and an MBIMDSSLinkDeactivate state.

Once the modem writes any logs to the newly created data channel, the modem calls **MbbDeviceReceiveDeviceServiceSessionData**, the data from which is available to apps via the WinRT layer : **MobileBroadbandDeviceService**. The modem logs should be formatted as printable string data that can be redirected to an ETW session.

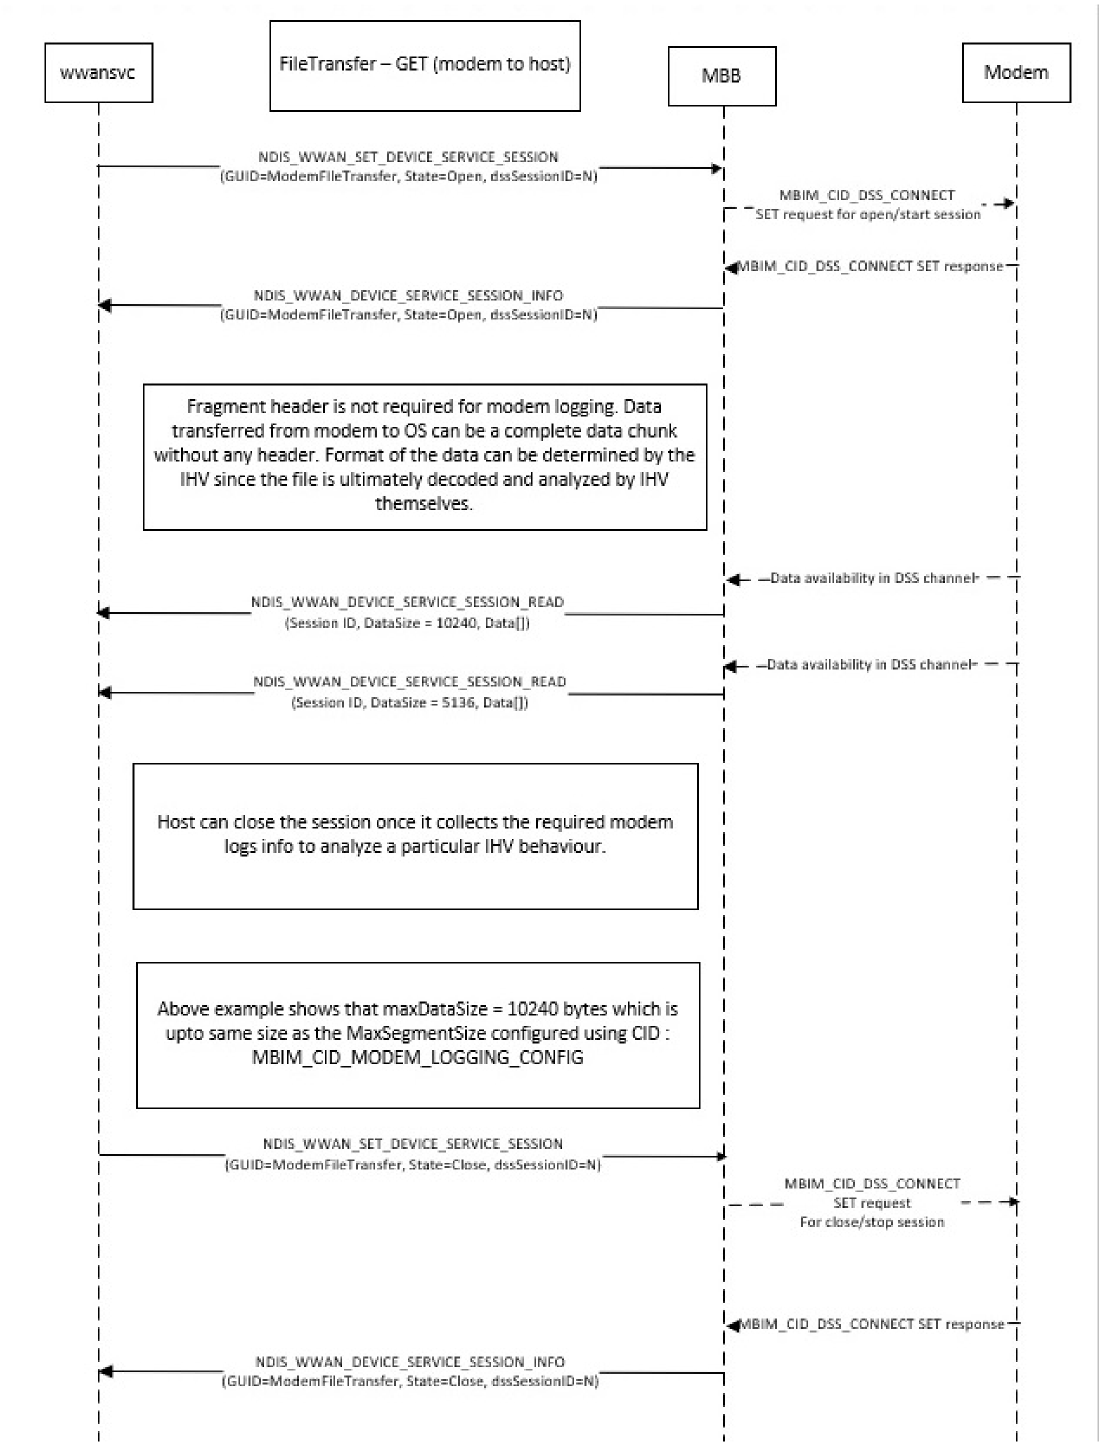
Modem logging data path

Moddem logging uses the MBIM Data Service Stream (DSS) to transfer the data for logging payloads. For more information about DSS, see Section 10.5.38 of the MBIM 1.0 specification .

When connecting or disconnecting from DSS, the following GUID is used for modem logging:

GUID	Value
ModemFileTransfer GUID	0EBB1CEB-AF2D-484D-8DF3-53BC51FD162C

The following flow diagram illustrates the DSS setup and tear down process.



wwansvc
FileTransfer – GET (modem to host)
MBB
Modem
NDIS_WWAN_SET_DEVICE_SERVICE_SESSION (GUID=ModemFileTransfer, State=Open, dssSessionID=N)
MBIM_CID_DSS_CONNECT SET request for open/start session
MBIM_CID_DSS_CONNECT SET response
NDIS_WWAN_DEVICE_SERVICE_SESSION_INFO (GUID=ModemFileTransfer, State=Open, dssSessionID=N)
Fragment header is not required for modem logging. Data transferred from modem to OS can be a complete data chunk without any header. Format of the data can be determined by the IHV since the file is ultimately decoded and analyzed by IHV themselves.
Data availability in DSS channel
NDIS_WWAN_DEVICE_SERVICE_SESSION_READ (Session ID, DataSize = 10240, Data[])
Data availability in DSS channel
NDIS_WWAN_DEVICE_SERVICE_SESSION_READ (Session ID, DataSize = 5136, Data[])
Host can close the session once it collects the required modem logs info to analyze a particular IHV behaviour.
Above example shows that maxDataSize = 10240 bytes which is upto same size as the MaxSegmentSize configured using CID : MBIM_CID_MODEM_LOGGING_CONFIG
NDIS_WWAN_SET_DEVICE_SERVICE_SESSION (GUID=ModemFileTransfer, State=Close, dssSessionID=N)
MBIM_CID_DSS_CONNECT SET request For close/stop session
MBIM_CID_DSS_CONNECT SET response
NDIS_WWAN_DEVICE_SERVICE_SESSION_INFO (GUID=ModemFileTransfer, State=Close, dssSessionID=N)

NDIS interface extension

The following OID has been defined in Windows 10, version 1903, to support modem logging.

- OID_WWAN_MODEM_LOGGING_CONFIG

MBIM service and CID values

Service name	UUID	UUID value
Microsoft Basic IP Connectivity Extensions	UUID_BASIC_CONNECT_EXTENSIONS	3d01dcc5-fef5-4d05-9d3a-bef7058e9aaf

The following table specifies the UUID and command code for each CID, as well as whether the CID supports Set, Query, or Event (notification) requests. See each CID's individual Section within this topic for more info about its parameters, data structures, and notifications.

CID	UUID	Command code	Set	Query	Notify
MBIM_CID_MODEM_LOGGING_CONFIG	UUID_BASIC_CONNECT_EXTENSIONS	TBD	Y	Y	Y

MBIM_CID_MODEM_LOGGING_CONFIG

This CID is used to configure the logs that are collected by the modem and how often they will be sent from the modem to the host over DSS. Logging must be configured before a logging session is started. Because this CID is part of connect extensions, it is optional for IHVs to support this CID. If an IHV supports modem logging via the DSS data channel, it must specify this as a capability. The capability can be advertised using the MBIM_BASIC_CID_DEVICE_SERVICES CID.

Parameters

Operation	Set	Query	Notification
Command	MBIM_MODEM_LOGGING_CONFIG	Not Applicable	Not applicable
Response	MBIM_MODEM_LOGGING_CONFIG	MBIM_MODEM_LOGGING_CONFIG	MBIM_MODEM_LOGGING_CONFIG

Query

Queries the current modem logging configuration. The InformationBuffer of MBIM_COMMAND_MSG is not used. The following MBIM_MODEM_LOGGING_CONFIG structure is used in the InformationBuffer of MBIM_COMMAND_DONE.

MBIM_MODEM_LOGGING_CONFIG

Offset	Size	Field	Type	Description
0	4	Version	UINT32	The version number of this structure. This field must be set to **1** for version 1 of this structure.
4	4	MaxSegmentSize	UINT32	Specifies the segment size, in kilobytes, for each fragment sent by the modem. If the maximum fragment size supported by the modem for Device Service Command exceeds the value set, then this value is set to the maximum supported segment size.

Offset	Size	Field	Type	Description
8	4	MaxFlushTime	UINT32	The time, in milliseconds, indicating the maximum time the modem waits before sending a log fragment. If the logs collected don't reach **MaxSegmentSize** within the **MaxFlushTime** duration since the last log fragment sent, then a log fragment is sent regardless of its size. If there is no logging data, then no notification is sent. If the device cannot handle smaller flush times, then the device returns the time that it can handle in the response. The response to a query or set contains the currently configured **MaxFlushTime**.
12	4	LevelConfig	MBIM_LOGGING_LEVEL_CONFIG	Configures the level for which logs are collected. The response to a query or set contains the currently configured **LevelConfig**.

> ⓘ Note
>
> If the modem is not able to provide log data to the OS at the requested **MaxSegmentSize** and **MaxFlushTimer**, it can choose its own values for these parameters and update the OS as a set response or an unsolicited event. The OS behavior does not change if **MaxSegmentSize** or **MaxFlushTimer** change, as it receives the data packets regardless and dumps them to a file.

The following MBIM_LOGGING_LEVEL_CONFIG enumeration is used in the preceding MBIM_MODEM_LOGGING_CONFIG structure.

Type	Value	Description
MBIMLoggingLevelProd	0	Intended for telemetry collection from a retail or production population. The resulting log should be capsule-sized and contains key modem or MBB state or failure information only.
MBIMLoggingLevelLabVerbose	1	Intended for the development of MBB products with low maturity. Verbose full-stack capture of modems. The resulting modem capture should enable the IHV to replay and fully recover the capture during the log.
MBIMLoggingLevelLabMedium	2	Intended for verification and field testing of MBB products with relative maturity and stability. The level of detail and verbosity provides enough data points for IHV engineers to triage most MBB failures.
MBIMLoggingLevelLabLow	3	Intended for self-host-level logging. Summary-level capture of full-stack capture modems. Enables a highlight-level understanding of the modem's state and OS interactions.
MBIMLoggingLevelOem	4	Reserved for OEM and IHV internal usage.

Set

A set command is used to set to configure the level, segment size, and maximum flush time for modem logging. An MBIM_MODEM_LOGGING_CONFIG structure is used in the InformationBuffer.

Response

The InformationBuffer in MBIM_COMMAND_DONE contains an MBIM_MODEM_LOGGING_CONFIG structure.

Unsolicited Events

Unsolicited events are supported for scenarios where the modem needs to inform the OS about internal changes. Currently, in Windows 10, version 1903, these scenarios do not occur.

Status Codes

This CID only uses generic status codes defined in Section 9.4.5 of the MBIM specification revision 1.0 .

DSS session behavior during inactivity

The following table describes how the DSS session behaves during various stages of inactivity:

Scenario	DSS session state
System sleep, modem-only sleep, reset and recovery	DSS session kept open
System shutdown, restart, hibernation	DSS session closed

MB 5G Operations Overview

Article • 03/14/2023

Windows 10, version 1903 is the first version of Windows to support a preview release of 5G mobile broadband driver development by IHV partners. *5G* is the friendly name for New Radio (NR), which was introduced in the 3GPP Release 15 specification. NR is a comprehensive set of standards that is envisioned to provide true long-term evolution to existing 4th generation LTE technologies, potentially covering all cellular communication needs from narrowband to ultra-broadband, and from nominal to mission-critical latency requirements. As a technology, 5G is expected to develop over a decade-long time frame.

This section describes the MBIM extensions first released in Windows 10 version 1903, which enable hardware partners to develop an MBB driver with data-class support for enhanced mobile broadband (eMBB) over 5G “non-standalone” EPC-based NR networks. The data-plane support and enablement for 5G throughput and commercialization requirements are not part of this Windows release and not described in this section.

In this section

MB 5G Operations Terminology

Windows 5G MBIM Interface

NDIS Interface for 5G Data Class Support

MBIMEx 2.0 – 5G NSA support

MBIMEx 3.0 – 5G SA Phase 1 support

MB 5G Operations Terminology

Article • 03/14/2023

This section uses the following terms:

Term	Definition
NR	New Radio. NR is the term used in 3GPP when referring to 5G.
MBB	Mobile broadband.
EPC	Enhanced Packet Core. The term used in 3GPP when referring to the LTE core network.
NGC	Next Generation Core. The term used in 3GPP when referring to the 5G core network. The NR-equivalent of EPC.
DC	Dual Connectivity. The network can support both LTE and 5G NR, including dual connectivity with which devices have simultaneous connections to LTE and NR.
SA	Standalone 5G. Refers to any NGC-based NR networks.
NSA	Non-standalone 5G. Refers to any EPC-based NR networks.
gNB	An NR radio base station that supports the NR air interface as well as connectivity to NGC.
RAT	Radio Access Technology.

Windows 5G MBIM Interface

Article • 03/14/2023

As of Windows 10, version 1903, 5G on the whole is still developing. From a network deployment perspective, 5G is expected to be deployed in two major phases:

- In Phase 1, most mobile network operators are expected to deploy 5G with the addition of 5G radio to the existing LTE radio and EPC core deployments, commonly known “nonstandalone 5G” networks.
- In Phase 2, mobile network operators are expected to replace EPCs and NGCs and densify the 5G radio deployment in parallel to enable true “standalone”, or NR-NGC-based 5G networks. Phase 2 interface extensions are not in scope in this topic or Windows release.

Interface extensions to support basic Phase 1 network requirements, or ”nonstandalone” EPC-based 5G networks, was introduced in Windows 10, version 1903. In order to be extensible and fully backward compatible with legacy modems, a new Microsoft MBIM extension version (2.0) is introduced.

The new Microsoft MBIM extension version is required because the MBIM 1.0 errata specification has a mechanism to add and advertise optional CIDs, but it lacks a mechanism to change the existing CIDs (new payloads or modified payload) or to introduce changes in any aspect that cannot be accommodated by optional CIDs. Each payload may consist of fixed sized members or dynamic sized (offset/size pairs) members. If one or more dynamically sized members exist, then the last member has a variable size buffer.

This spec also adds a new CID for the host to advertise its MBIM Release version and Extensions Release version to MBIM devices. For legacy drivers that are already in the field, this CID is optional so backward compatibility is fully maintained. For more details, see MBIMEx 2.0 – 5G NSA support.

NDIS Interface for 5G Data Class Support

Article • 03/14/2023

NDIS supports a revision number in the NDIS_HEADER. This permits adding new members to an OID message, which NDIS uses the optional service caps table in OID_WWAN_DEVICE_CAPS_EX.

The following NDIS OIDs and their data structures have been updated for 5G data class support.

- OID_WWAN_DEVICE_CAPS_EX
- OID_WWAN_REGISTER_STATE
- OID_WWAN_PACKET_SERVICE
- OID_WWAN_SIGNAL_STATE

The equivalent MBIM CID messages for these OIDs are described in MBIMEx 2.0 – 5G NSA support.

MBIMEx 2.0 – 5G NSA support

Article • 03/14/2023

Because the MBIM 1.0 errata specification lacks a mechanism to change existing CIDs with new or modified payloads, Windows 10, version 1903 introduces MBIM 1.0 Extension 2.0 to extend the interface to support 5G.

Versioning scheme

> **Note**
>
> In this section, the term *MBIMEx version* refers to the MBIM Extensions release number.

The host learns a device's MBIMEx version through two ways:

1. The MBIM EXTENDED FUNCTIONAL DESCRIPTOR.
2. The optional MBM_CID_VERSION message, if the device supports it and declares support for it.

If these two are different, the higher version dictates the MBIMEx version for the duration that the device stays enumerated to the host. The higher MBIMEx version is referred to as the device's *announced MBIMEx version*. A device's announced MBIMEx version can be lower than its native MBIMEx version, which is the highest MBIMEx version that the device supports. Devices can learn the host's MBIMEx version explicitly only via the MBIM_CID_VERSION message.

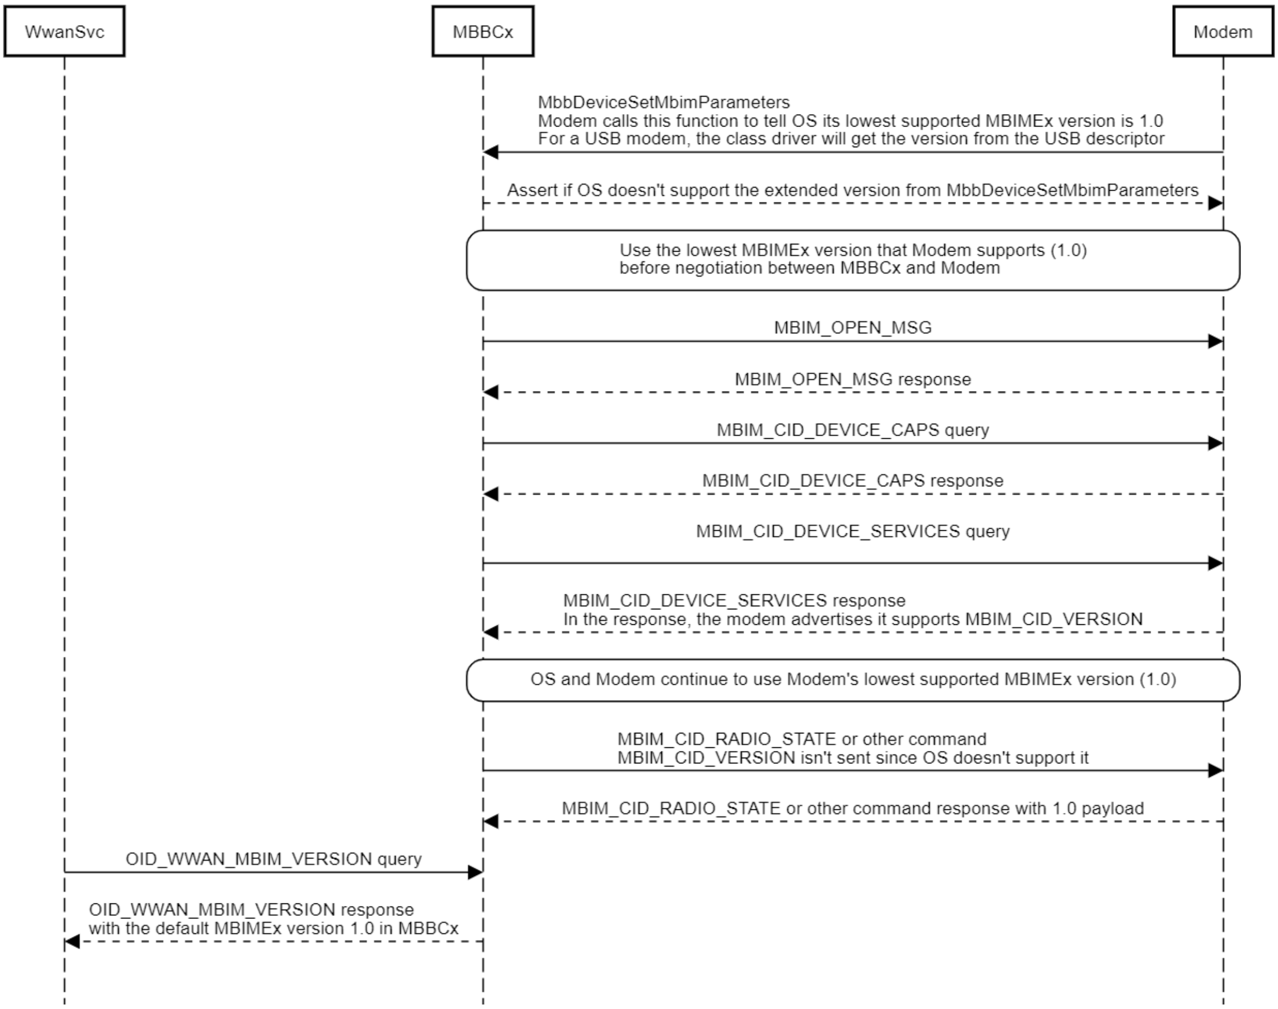
In any release, the host always queries the device for supported services and CIDs using MBIM_CID_DEVICE_SERVICES at the beginning of the device initialization sequence.

If a device supports MBIM_CID_VERSION and advertises its support in the MBIM_CID_DEVICE_SERVICES query response, then a host that does not understand MBIM_CID_VERSION or has an MBIMEx version lower than 2.0 ignores it. Meanwhile, a host that does understand MBIM_CID_VERSION and has a native MBIMEx version of 2.0 or higher sends a MBIM_CID_VERSION message to the device with the host's native MBIMEx version, and the CID is the first CID that is sent to the device after receiving the MBIM_CID_DEVICE_SERVICES response.

If the first CID that the device receives from the host after it responds to the MBIM_CID_DEVICE_SERVICES query is MBIM_CID_VERSION, the device knows the host's MBIMEx version.

If the first CID that the device receives from the host after it responds to the MBIM_CID_DEVICE_SERVICES query is any other CID, then the device assumes that the host's native MBIMEx version is 1.0.

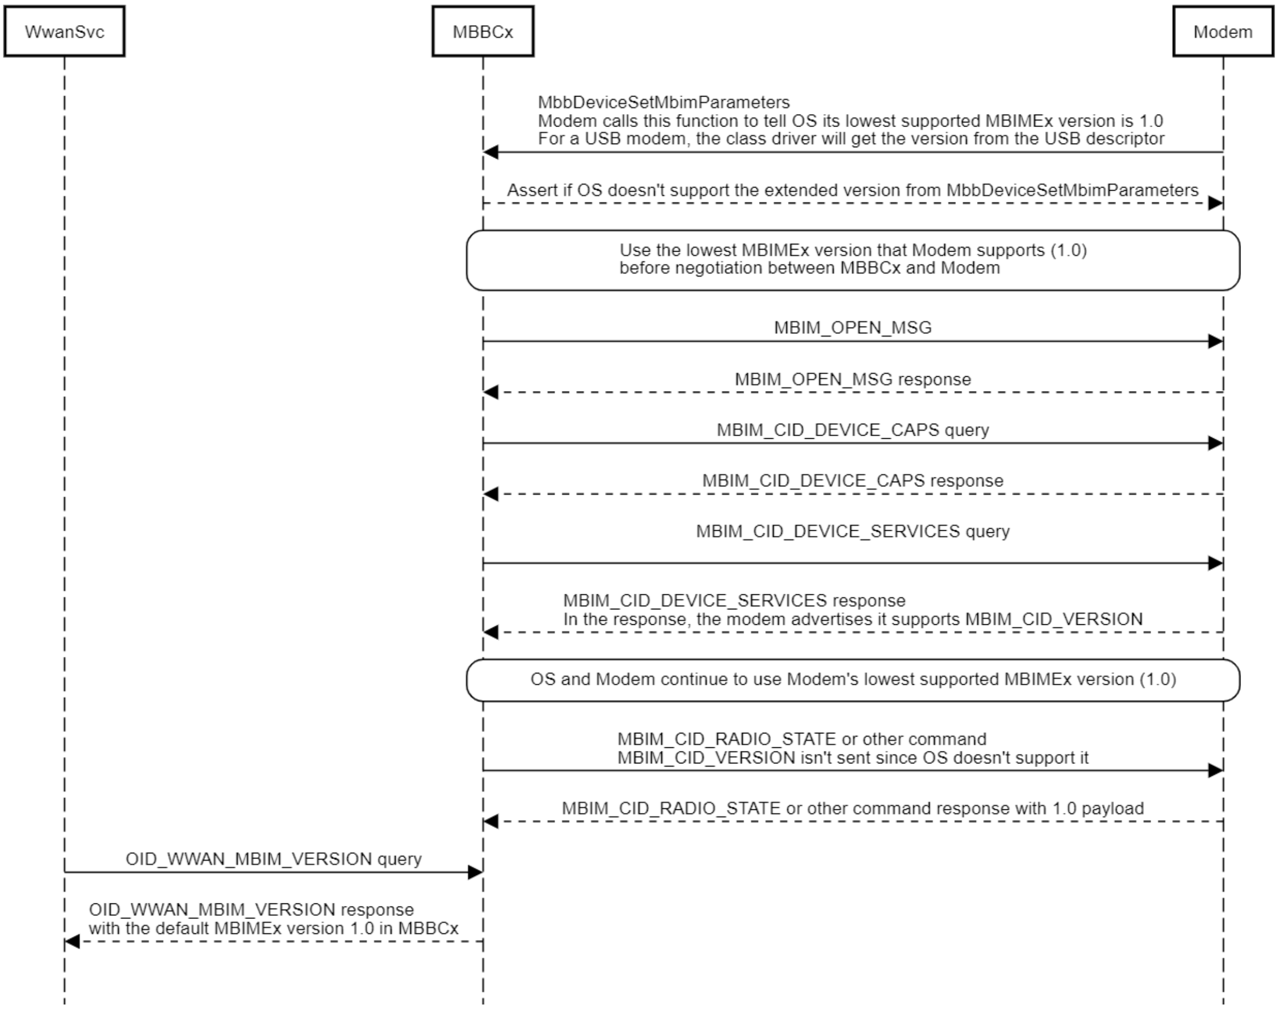
OS doesn't support MBIM_CID_VERSION and Modem's highest supported MBIMEx version is 3.0



WwanSvc
MBBCx
Modem
MbbDeviceSetMbimParameters
Modem calls this function to tell OS its lowest supported MBIMEx version is 1.0
For a USB modem, the class driver will get the version from the USB descriptor
Assert if OS doesn't support the extended version from MbbDeviceSetMbimParameters
Use the lowest MBIMEx version that Modem supports (1.0)
before negotiation between MBBCx and Modem
MBIM_OPEN_MSG
MBIM_OPEN_MSG response
MBIM_CID_DEVICE_CAPS query
MBIM_CID_DEVICE_CAPS response
MBIM_CID_DEVICE_SERVICES query
MBIM_CID_DEVICE_SERVICES response
In the response, the modem advertises it supports MBIM_CID_VERSION
OS and Modem continue to use Modem's lowest supported MBIMEx version (1.0)
MBIM_CID_RADIO_STATE or other command
MBIM_CID_VERSION isn't sent since OS doesn't support it
MBIM_CID_RADIO_STATE or other command response with 1.0 payload
OID_WWAN_MBIM_VERSION query
OID_WWAN_MBIM_VERSION response
with the default MBIMEx version 1.0 in MBBCx

If the device doesn't support MBIM_CID_VERSION, it will not respond to the MBIM_CID_DEVICE_SERVICES query with MBIM_CID_VERSION. Therefore the host will not send a MBIM_CID_VERSION message and assumes that the device's native MBIMEx version is 1.0.

OS' highest supported MBIMEx version is 3.0 and Modem doesn't support MBIM_CID_VERSION



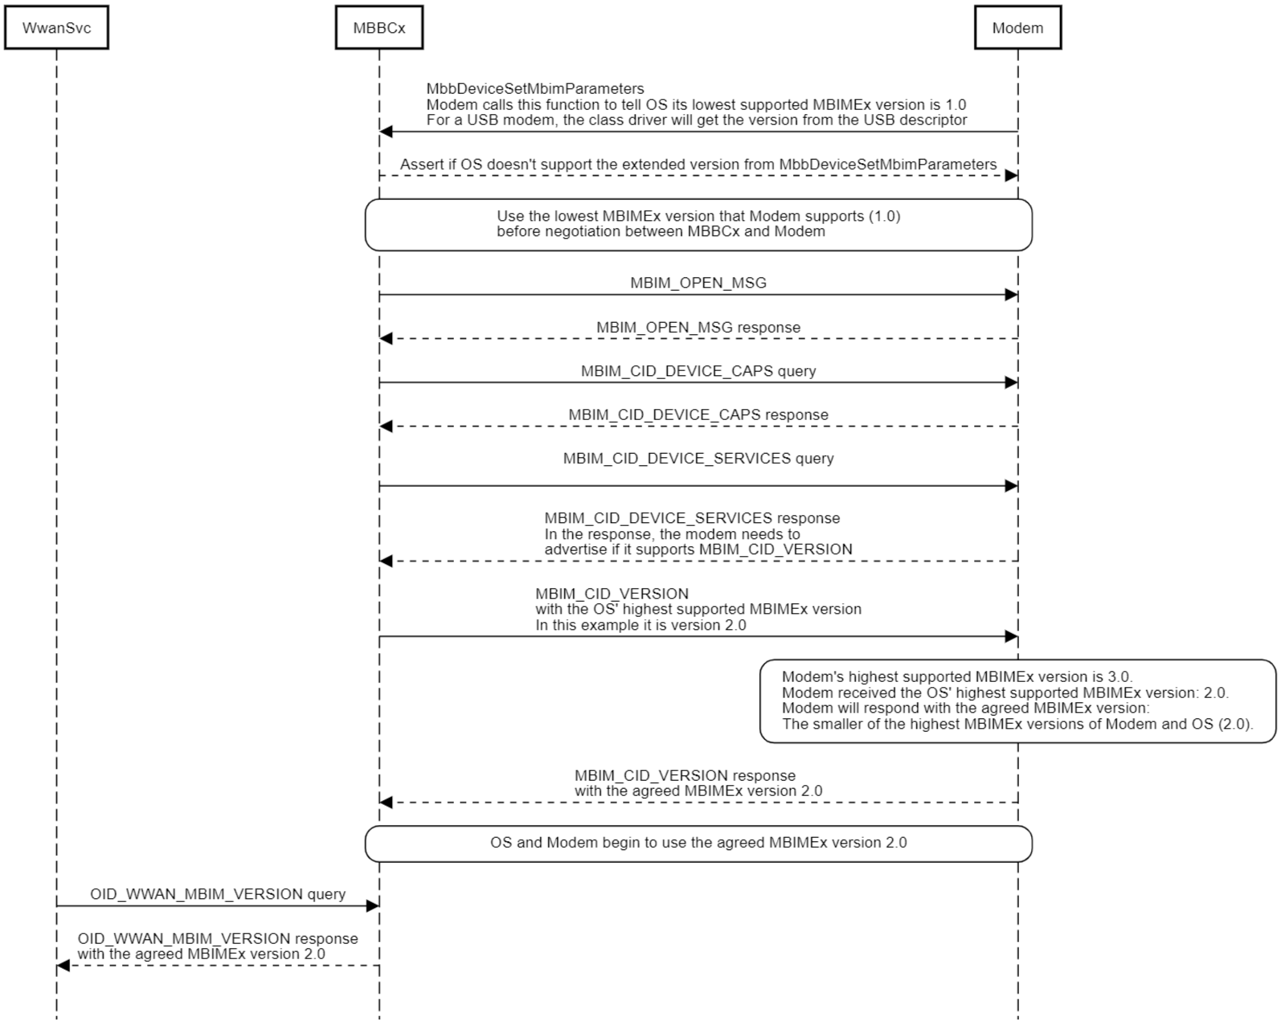
WwanSvc
MBBCx
Modem
MbbDeviceSetMbimParameters
Modem calls this function to tell OS its lowest supported MBIMEx version is 1.0
For a USB modem, the class driver will get the version from the USB descriptor
Assert if OS doesn't support the extended version from MbbDeviceSetMbimParameters
Use the lowest MBIMEx version that Modem supports (1.0)
before negotiation between MBBCx and Modem
MBIM_OPEN_MSG
MBIM_OPEN_MSG response
MBIM_CID_DEVICE_CAPS query
MBIM_CID_DEVICE_CAPS response
MBIM_CID_DEVICE_SERVICES query
MBIM_CID_DEVICE_SERVICES response
In the response, the modem advertises it supports MBIM_CID_VERSION
OS and Modem continue to use Modem's lowest supported MBIMEx version (1.0)
MBIM_CID_RADIO_STATE or other command
MBIM_CID_VERSION isn't sent since OS doesn't support it
MBIM_CID_RADIO_STATE or other command response with 1.0 payload
OID_WWAN_MBIM_VERSION query
OID_WWAN_MBIM_VERSION response
with the default MBIMEx version 1.0 in MBBCx

Feature-wise, a higher MBIMEx version is a superset of all lower MBIMEx versions. A host supports all devices with an announced MBIMEx version at or below the host's native MBIMEx version. If a device's announced MBIMEx version is higher than a host's native MBIMEx version, the host is not expected to support the device and the exact behavior of the host in this situation is undefined.

A device that intends to work with older hosts should initially advertise MBIMEx version 1.0 or the lowest host MBIMEx version with which the device is intended to work in an MBIM extended functional descriptor.

If the host sends MBIM_CID_VERSION with a higher MBIMEx version than the device initially advertised, then the device should indicate a higher MBIMEx version in the MBIM_CID_VERSION response up to the smaller of the host's native MBIMEx version and the device's native MBIMEx version.

OS' highest supported MBIMEx version is lower than Modem's



MbbDeviceSetMbimParameters
Modem calls this function to tell OS its lowest supported MBIMEx version is 1.0
For a USB modem, the class driver will get the version from the USB descriptor

Assert if OS doesn't support the extended version from MbbDeviceSetMbimParameters

Use the lowest MBIMEx version that Modem supports (1.0)
before negotiation between MBBCx and Modem

MBIM_OPEN_MSG

MBIM_OPEN_MSG response

MBIM_CID_DEVICE_CAPS query

MBIM_CID_DEVICE_CAPS response

MBIM_CID_DEVICE_SERVICES query

MBIM_CID_DEVICE_SERVICES response
In the response, the modem needs to
advertise if it supports MBIM_CID_VERSION

MBIM_CID_VERSION
with the OS' highest supported MBIMEx version
In this example it is version 2.0

Modem's highest supported MBIMEx version is 3.0.
Modem received the OS' highest supported MBIMEx version: 2.0.
Modem will respond with the agreed MBIMEx version:
The smaller of the highest MBIMEx versions of Modem and OS (2.0).

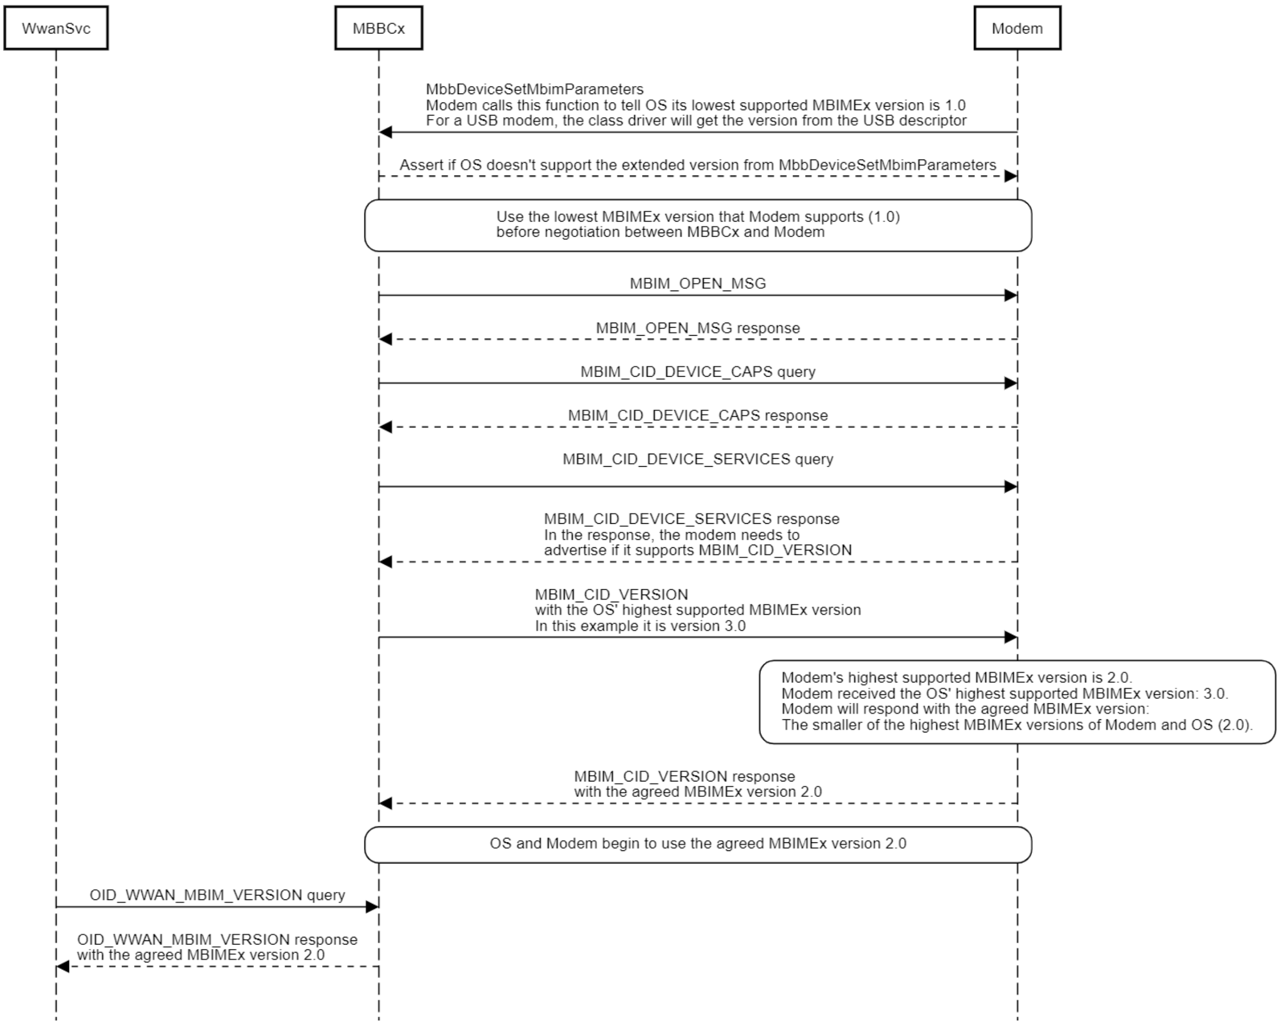
MBIM_CID_VERSION response
with the agreed MBIMEx version 2.0

OS and Modem begin to use the agreed MBIMEx version 2.0

OID_WWAN_MBIM_VERSION query

OID_WWAN_MBIM_VERSION response
with the agreed MBIMEx version 2.0

OS' highest supported MBIMEx version is higher than Modem's



WwanSvc
MBBCx
Modem
MbbDeviceSetMbimParameters
Modem calls this function to tell OS its lowest supported MBIMEx version is 1.0
For a USB modem, the class driver will get the version from the USB descriptor
Assert if OS doesn't support the extended version from MbbDeviceSetMbimParameters
Use the lowest MBIMEx version that Modem supports (1.0)
before negotiation between MBBCx and Modem
MBIM_OPEN_MSG
MBIM_OPEN_MSG response
MBIM_CID_DEVICE_CAPS query
MBIM_CID_DEVICE_CAPS response
MBIM_CID_DEVICE_SERVICES query
MBIM_CID_DEVICE_SERVICES response
In the response, the modem needs to
advertise if it supports MBIM_CID_VERSION
MBIM_CID_VERSION
with the OS' highest supported MBIMEx version
In this example it is version 3.0
Modem's highest supported MBIMEx version is 2.0.
Modem received the OS' highest supported MBIMEx version: 3.0.
Modem will respond with the agreed MBIMEx version:
The smaller of the highest MBIMEx versions of Modem and OS (2.0).
MBIM_CID_VERSION response
with the agreed MBIMEx version 2.0
OS and Modem begin to use the agreed MBIMEx version 2.0
OID_WWAN_MBIM_VERSION query
OID_WWAN_MBIM_VERSION response
with the agreed MBIMEx version 2.0

ⓘ Note

For example, a device supports MBIMEx version 2.0, but is intended to work with older versions of the OS that do not support MBIMEx 2.0. The device initially advertises MBIMEx version 1.0 in the USB descriptors and advertises support for the optional MBIM_CID_VERSION. When inserted into a host running Windows 10, version 1803, the host does not understand MBIM_CID_VERSION and does not send MBIM_CID_VERSION to the device. To the host, the device's MBIMEx version is 1.0. The host continues to send other CIDs in the initialization sequence. Upon receiving CIDs other than MBIM_CID_VERSION, the device knows that the host supports MBIMEx version 1.0. Both sides proceed to conform to MBIMEx version 1.0. Later, when the same device is inserted into a host running Windows 10, version 1903 with a native MBIMEx version of 2.0, the host sends MBIM_CID_VERSION to the device to inform it that the host's native MBIMEx version is 2.0. The device sends MBIM_CID_VERSION back in response with the device's announced MBIMEx version 2.0. From there, both sides proceed to conform to MBIMEx version 2.0.

The following table shows a compatibility matrix with three hypothetical hosts and three hypothetical devices, each with its native MBIMEx version stated. The devices advertise MBIMEx version 1.0 initially in the USB descriptor. The matrix shows how each of the devices behaves with each of the hosts.

Device (below) / Host (right)	Windows 10, version 1809 or earlier (native MBIMEx version 1.0)	Windows 10, version 1903 and later (MBIMEx version 2.0)

Device (below) / Host (right)	Windows 10, version 1809 or earlier (native MBIMEx version 1.0)	Windows 10, version 1903 and later (MBIMEx version 2.0)
4G device Native MBIMEx version 1.0	Device initially advertises MBIMEx 1.0. No MBIM_CID_VERSION exchange. Compatible device and host. Works by default with MBIMEx version 1.0.	Device initially advertises MBIMEx 1.0. No MBIM_CID_VERSION exchange. The host works with the device using MBIMEx 1.0.
5G NSA device Native MBIMEx version 2.0	Device initially advertises MBIMEx 1.0. No MBIM_CID_VERSION exchange. Device knows that the host has MBIMEx 1.0 and proceeds with MBIMEx 1.0.	Device initially advertises MBIMEx 1.0. Host sends MBIM_CID_VERSION to inform the device that the host supports MBIMEx 2.0. Device responds with MBIMEx 2.0. Both sides proceed with MBIMEx 2.0.

The following table lists all existing CIDs that are modified in MBIMEx version 2.0, and their modified payloads. All unmentioned payloads in these CIDs and all other CIDs not mentioned in the table carry over from MBIMEx version 1.0 and remain unchanged.

CID	Payload
MBIM_CID_REGISTER_STATE	MBIM_REGISTRATION_STATE_INFO_V2
MBIM_CID_PACKET_SERVICE	MBIM_PACKET_SERVICE_INFO_V2
MBIM_CID_SIGNAL_STATE	MBIM_SIGNAL_STATE_INFO_V2

MBIM service

Service name	UUID	UUID value
Microsoft Basic IP Connectivity Extensions	UUID_BASIC_CONNECT_EXTENSIONS	3D01DCC5-FEF5-4D05-9D3A-BEF7058E9AAF

MBIM_CID_VERSION

For MBB drivers that support MBIM Microsoft extension 2.0 or above, MBIM_CID_VERSION is a mandatory command for exchanging MBIM version information between the host and the device. For in-market devices with drivers that do not recognize this CID, the host will assume and provide backward compatibility.

The host sends this command as a query if it is supported by the device. The query contains the MBIM release number and MBIM Extensions release number that the host currently supports.

On the device side, the device adjusts its announced MBIM release number and MBIM Extensions release number based on the rules defined in versioning scheme, then sends them in the response to the host.

This command is defined under the **Basic Connect Extensions** service.

CID	Command code	UUID
MBIM_CID_VERSION	15	3d01dcc5-fef5-4d05-0d3abef7058e9aaf

Parameters

Operation	Set	Query	Notification
Command	Not applicable	MBIM_VERSION_INFO	Not applicable
Response	Not applicable	MBIM_VERSION_INFO	Not applicable

Query

Informs the device of the host's native MBIM release number and MBIM Extensions release number. The InformationBuffer contains the following MBIM_VERSION_INFO structure.

Offset	Size	Field	Type	Description
0	2	bcdMBIMVersion	UINT16	The MBIM release number of the sender in BCD, with an implied decimal point between bits 7 and 8. For example, `0x0100 == 1.00 == 1.0`. This is a little-endian constant, so the bytes are 0x00, then 0x01.
2	2	bcdMBIMExtendedVersion	UINT16	The MBIM Extensions release number of the sender in BCD, with an implied decimal point between bits 7 and 8. For example, `0x0100 == 1.00 == 1.0`. This is a little-endian constant, so the bytes are 0x00, then 0x01.

Set

Not applicable.

Response

The InformationBuffer in MBIM_COMMAND_DONE contains an MBIM_VERSION_INFO structure.

Unsolicited Events

Not applicable.

Status Codes

This CID only uses generic status codes defined in Section 9.4.5 of the MBIM specification revision 1.0.

MBIM_CID_MS_DEVICE_CAPS_V2

This CID is the same as defined on MB Multi-SIM operations, which itself is an extension of MBIM_CID_MS_DEVICE_CAPS as defined in Section 10.5.1 of the MBIM specification revision 1.0. For MBIM Extensions release 2.0, there are new data classes defined in the MBIM_DATA_CLASS table that enable the device to report its 5G capabilities. MBIMDataClass5G_NSA denotes that the device supports 5G Non-standalone (NSA), defined in 3GPP TS 37.340, and MBIMDataClass5G_SA denotes that the device supports 5G Standalone (SA), also defined in 3GPP TS 37.340.

If the device supports both new data classes, then both bits shall be set.

MBIM_DATA_CLASS

Types	Mask
MBIMDataClassNone	0h
MBIMDataClassGPRS	1h
MBIMDataClassEDGE	2h
MBIMDataClassUMTS	4h
MBIMDataClassHSDPA	8h
MBIMDataClassHSUPA	10h
MBIMDataClassLTE	20h
MBIMDataClass5G_NSA	**40h**
MBIMDataClass5G_SA	**80h**
Reserved	100h-8000h
MBIMDataClass1XRTT	10000h
MBIMDataClass1XEVDO	20000h
MBIMDataClass1XEVDORevA	40000h
MBIMDataClass1XEVDV	80000h
MBIMDataClass3XRTT	100000h
MBIMDataClass1XEVDORevB	200000h
MBIMDataClassUMB	400000h
Reserved	800000-40000000h
MBIMDataClassCustom	80000000h

MBIM_CID_REGISTER_STATE

This command is an extension for the MBIM_CID_REGISTER_STATE CID already defined in the MBIM specification revision 1.0. This extension adds a new member called **PreferredDataClasses** for the response structure.

Parameters

Operation	Set	Query	Notification
Command	MBIM_SET_REGISTRATION_STATE	Empty	Not applicable
Response	MBIM_REGISTRATION_STATE_INFO_V2	MBIM_REGISTRATION_STATE_INFO_V2	MBIM_REGISTRATION_STATE_INFO_V2

Query

The InformationBuffer is null and the InformationBufferLength is zero.

Set

Sets the registration state. The information is the same as described in the MBIM specification revision 1.0 .

Response

The InformationBuffer in MBIM_COMMAND_DONE contains the following MBIM_REGISTRATION_STATE_INFO_V2 structure. Compared with the MBIM_REGISTRATION_STATE_INFO structure defined in Section 10.5.10.6 of the MBIM specification revision 1.0 , the following structure has a new **PreferredDataClasses** field. Unless stated here, field descriptions in table 10-55 of the MBIM specification revision 1.0 apply to this structure.

MBIM_REGISTRATION_STATE_INFO_V2

Offset	Size	Field	Type	Description
0	4	NwError	UINT32	A network-specific error. Table 10-44 in the MBIM specification revision 1.0 documents the cause codes for NwError.
4	4	RegisterState	MBIM_REGISTER_STATE	See Table 10-46 in the MBIM specification revision 1.0 .
8	4	RegisterMode	MBIM_REGISTER_MODE	See Table 10-47 in the MBIM specification revision 1.0 .
12	4	AvailableDataClass	UINT32	A bitmap of the values in MBIM_DATA_CLASS that represents the supported data classes on the registered network, for the cell in which the device is registered. This value is set to MBIMDataClassNone if the **RegisterState** is not **MBIMRegisterStateHome**, **MBIMRegisterStateRoaming**, or **MBIMRegisterStatePartner**.
16	4	CurrentCellularClass	MBIM_CELLULAR_CLASS	Indicates the current cellular class in use for a multi-mode function. See Table 10-8 in the MBIM specification revision 1.0 for more information. For a single-mode function, this is the same as the cellular class reported in MBIM_CID_DEVICE_CAPS. For multi-mode functions, a transition from CDMA to GSM or vice versa is indicated with an updated **CurrentCellularClass**.

Offset	Size	Field	Type	Description
20	4	ProviderIdOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to a numeric (0-9) string called **ProviderId** that represents the network provider identity. For GSM-based networks, this string is a concatenation of a three-digit Mobile Country Code (MCC) and a two- or three-digit Mobile Network Code (MNC). GSM-based carriers might have more than one MNC, and hence more than one **ProviderId**. For CDMA-based networks, this string is a five-digit System ID (SID). Generally, a CDMA-based carrier has more than one SID. Typically, a carrier has one SID for each market that is usually divided geographically within a nation by regulations, such as Metropolitan Statistical Areas (MSA) in the United States. CDMA-based devices must specify MBIM_CDMA_DEFAULT_PROVIDER_ID if this information is not available. When processing a query request and the registration state is in automatic register mode, this member contains the provider ID with which the device is currently associated (if applicable). When the registration state is in manual register mode, this member contains the provider ID to which the device is requested to register (even if the provider is unavailable). When processing a set request and the registration state is in manual mode, this contains the provider ID selected by the host with which to register the device. When the registration state is in automatic register mode, this parameter is ignored. CDMA 1xRTT providers must be set to MBIM_CDMA_DEFAULT_PROVIDER_ID if the provider ID is not available.
24	4	ProviderIdSize	SIZE(0..12)	The size, in bytes, for **ProviderId**.
28	4	ProviderNameOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to a string called **ProviderName** that represents the network provider's name. This member is limited to, at most, MBIM_PROVIDERNAME_LEN characters. For GSM-based networks, if the Preferred Presentation of Country Initials and Mobile Network Name (PCCI&N) is longer than twenty characters, the device should abbreviate the network name. This member is ignored when the host sets the preferred provider list. Devices should specify a NULL string for devices that do not have this information.
32	4	ProviderNameSize	SIZE(0..40)	The size, in bytes, for **ProviderName**.

Offset	Size	Field	Type	Description
36	4	RoamingTextOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to a string called **RoamingText** to inform a user that the device is roaming. This member is limited to, at most, 63 characters. This text should provide additional information to the user when the registration state is either MBIMRegisterStatePartner or MBIMRegisterStateRoaming. This member is optional.
40	4	RoamingTextSize	SIZE(0..126)	The size, in bytes, for **RoamingText**.
44	4	RegistrationFlag	MBIM_REGISTRATION_FLAGS	Flags set per Table 10-48 in the MBIM specification revision 1.0.
48	4	PreferredDataClass	UINT32	A bitmap of the values in MBIM_DATA_CLASS that represent the enabled data classes on the device. The device can only operate using the data classes that are enabled.
Dynamic	4	DataBuffer	DATABUFFER	The data buffer that contains **ProviderId**, **ProviderName**, and **RoamingText**.

Unsolicited Events

Notifications contain an MBIM_REGISTRATION_STATE_INFO_V2 structure.

Status Codes

This CID only uses generic status codes defined in Section 9.4.5 of the MBIM specification revision 1.0.

MBIM_CID_PACKET_SERVICE

This command is an extension for the existing MBIM_CID_PACKET_SERVICE defined in the MBIM specification revision 1.0.

This extension adds a new member called **FrequencyRange** for the response structure and renamed the **HighestAvailableDataClass** member to **CurrentDataClass** to clarify its purpose.

The **CurrentDataClass** indicates the Radio Access Technology (RAT) with which the device is currently registered. It contains a single value from MBIM_DATA_CLASS.

The **FrequencyRange** indicates the frequency range that the device is currently using. This is valid only if the **CurrentDataClass** field indicates that the MBIMDataClass5G_NSA or MBIMDataClass5G_SA bit is set.

Parameters

Operation	Set	Query	Notification
Command	MBIM_SET_PACKET_SERVICE	Empty	Not applicable
Response	MBIM_PACKET_SERVICE_INFO_V2	MBIM_PACKET_SERVICE_INFO_V2	MBIM_PACKET_SERVICE_INFO_V2

Query

The InformationBuffer is null and the InformationBufferLength is zero.

Set

Information for set commands is described in the MBIM specification revision 1.0.

Response

The InformationBuffer in MBIM_COMMAND_DONE contains an MBIM_PACKET_SERVICE_INFO_V2 structure. Compared with the MBIM_PACKET_SERVICE_INFO structure defined in Section 10.5.10.6 of the MBIM specification revision 1.0, this new structure has the **CurrentDataClass** and **FrequencyRange** fields. Unless stated here, the field descriptions in Table 10-55 of the MBIM specification revision 1.0 apply here.

MBIM_PACKET_SERVICE_INFO_V2

Offset	Size	Field	Type	Description
0	4	NwError	UINT32	A network-specific error. Table 10-44 in the MBIM specification revision 1.0 documents the cause codes for NwError.
4	4	PacketServiceState	MBIM_PACKET_SERVICE_STATE	See Table 10-53 in the MBIM specification revision 1.0.
8	4	CurrentDataClass	MBIM_DATA_CLASS	The current data class in the current cell, specified according to MBIM_DATA_CLASS. Functions must set this member to MBIMDataClassNone if the function is not in the attached packet service state. Except for HSPA (in other words, HSUPA and HSDPA) and 5G DC, the function sets this member to a single MBIM_DATA_CLASS value. For HSPA data services, functions specify a bitwise OR of MBIMDataClass HSDPA and MBIMDataClassHSUPA. For cells that support HSDPA but not HSUPA, only HSDPA is indicated (implying UMTS data class for uplink data). Whenever the current data class changes, functions send a notification indicating the new value of **CurrentDataClass**.
12	8	UplinkSpeed	UINT64	Contains the uplink bit rate, in bits per second.
20	8	DownlinkSpeed	UINT64	Contains the downlink bit rate, in bits per second.
38	4	FrequencyRange	MBIM_FREQUENCY_RANGE	A bitmask of values in MBIM_FREQUENCY_RANGE that represents the frequency ranges that the device is currently using. This is only valid if the **CurrentDataClass** is either MBIMDataClass5G_NSA or MBIMDataClass5G_SA.

MBIM_FREQUENCY_RANGE

The following enumeration is used as a value in the preceding MBIM_PACKET_SERVICE_INFO_V2 structure.

Type	Value	Description

Type	Value	Description
MBIMFrequencyRangeUnknown	0	If the system type is not 5G.
MBIMFrequencyRange1	1	Frequency range 1 (FR1) in 3GPP TS 38.101-1 (Sub-6G).
MBIMFrequencyRange2	2	FR2 in 3GPP TS 38.101-2 (mmWave).
MBIMFrequencyRange1AndRange2	3	If both FR1 and FR2 carriers are connected.

Unsolicited Events

Notifications contain an MBIM_PACKET_SERVICE_INFO_V2 structure.

Status Codes

This CID only uses generic status codes defined in Section 9.4.5 of the MBIM specification revision 1.0.

MBIM_CID_SIGNAL_STATE

This CID is an extension to MBIM_CID_SIGNAL_STATE, introducing RSRP and SNR for signal state criteria. This new extension is only valid if the device indicates support of MBIM Extensions version 2.0. This extension is mandatory if the modem supports MBIMDataClass5G_(N)SA data classes.

The RSRP and SNR fields are only valid if the corresponding SystemType is either MGBIMDataClassLTE or MBIMDataClass5G_(N)SA. IF the modem reports RSRP and/or SNR, then the RSSI field shall be set to a value of **99**.

If the corresponding SystemType is MBIMDataClass5G_(N)SA, the RSRP field is mandatory and the SNR field is optional. If the corresponding SystemType is MBIMDataClassLTE, the RSRP and SNR fields are optional and the RSSI field can be used instead. In this case, the RSRP and SNR fields can be omitted by setting a zero (**0**) value for both **RsrpSnrOffset** and **RsrpSnrSize** members.

Parameters

Operation	Set	Query	Notification
Command	MBIM_SET_SIGNAL_STATE	Empty	Not applicable
Response	MBIM_SIGNAL_STATE_INFO_V2	MBIM_SIGNAL_STATE_INFO_V2	MBIM_SIGNAL_STATE_INFO_V2

Query

The InformationBuffer is null and the InformationBufferLength is zero.

Set

Information for set commands is described in the MBIM specification revision 1.0.

Response

The InformationBuffer in MBIM_COMMAND_DONE contains the following MBIM_SIGNAL_STATE_INFO_V2 structure.

MBIM_SIGNAL_STATE_INFO_V2

Offset	Size	Field	Type	Description
0	4	Rssi	UINT32	See Table 10.58 in the MBIM specification revision 1.0 .
4	4	ErrorRate	UINT32	See Table 10.58 in the MBIM specification revision 1.0 .
8	4	SignalStrengthInterval	UINT32	The reporting interval, in seconds.
12	4	RssiThreshold	UINT32	The difference in RSSI coded values that triggers a report. Use 0xFFFFFFFF if this does not matter.
16	4	ErrorRateThreshold	UINT32	The difference in ErrorRate coded values that trigger a report. Use 0xFFFFFFFF if this does not matter.
20	4	RsrpSnrOffset	OFFSET	The offset in bytes, calculated from the beginning of this structure, to the buffer containing RSRP and SNR signaling info. This member can be **NULL** when no RSRP and SNR signaling info is available.
24	4	RsrpSnrSize	SIZE	The size, in bytes, of the buffer containing the RSRP and SNR signaling info in the format of a MBIM_RSRP_SNR_INFO structure.
	4	DataBuffer	DATABUFFER	An MBIM_RSRP_SNR structure.

MBIM_RSRP_SNR

The following MBIM_RSRP_SNR structure is used in the **DataBuffer** of an MBIM_SIGNAL_STATE_INFO_V2 structure.

Offset	Size	Field	Type	Description
0	4	ElementCount	UINT32	The count of RSRP_SNR entries that follow this element.
4	4	DataBuffer	DATABUFFER	An array of RSRP_SNR records, each specified as an MBIM_RSRP_SNR_INFO structure.

MBIM_RSRP_SNR_INFO

An array of the following MBIM_RSRP_SNR_INFO structures is used in the **DataBuffer** of an MBIM_RSRP_SNR structure.

<table>
<tr><th>Offset</th><th>Size&gt;</th><th>Field</th><th>Type</th><th>Description</th></tr>
<tr><td>0</td><td>4</td><td>RSRP</td><td>UINT32</td><td>
<table>
<tr><th>RSRP value in dBm</th><th>Coded value (min = 0, max = 126)</th></tr>
<tr><td>Less than -156</td><td>0</td></tr>
<tr><td>Less than -155</td><td>1</td></tr>
<tr><td>...</td><td>...</td></tr>
<tr><td>Less than -138</td><td>18</td></tr>
<tr><td>...</td><td>...</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><td></td><td></td><td></td><td></td><td><table>
<tr><td>Less than -45</td><td>111</td></tr>
<tr><td>...</td><td>...</td></tr>
<tr><td>Less than -31</td><td>125</td></tr>
<tr><td>-31 or greater</td><td>126</td></tr>
<tr><td>Unknown or undetectable</td><td>127</td></tr>

Calculate signal bar
if(rsrp data exists)
{
Use rsrp/snr from LTE system to calculate signal bar based on rsrp/snr mapping table
}
else
{
Use rssi to calculate signal bar based on rssi mapping table
}
code WwanMsmEventTypeSignalState with NumberOfBars
Update signal bars

The OS shall process the registry settings for signal strength calculations in the following order:

Dataclass is CDMA (or its variant) or TDSCDMA

1. If a legacy signal bar mapping table exists under “per_iccid”, use this setting.
2. Else, if a legacy signal bar mapping table exists under “per_device”, use this setting.
3. Else, use the default signal bar mapping table in code.

Dataclass is GSM or WCDMA

1. If a GSM or WCDMA technology specific signal bar mapping table exists under “per_iccid”, use this setting.
2. Else, if a GSM or WCDMA technology specific signal bar mapping table exists under “per_device”, use this setting.
3. Else, if a legacy signal bar mapping table exists under “per_iccid”, use this setting.
4. Else, if a legacy signal bar mapping table exists under “per_device”, use this setting.
5. Else, use the default signal bar mapping table in code.
   a. RSSI >= 17; 5 bars
   b. RSSI >= 12; 4 bars
   c. RSSI >= 7; 3 bars
   d. RSSI >= 4; 2 bars
   e. RSSI >= 2; 1 bars
   f. else; 0 bars

Dataclass is LTE and RSRP is reported by the modem

1. If a LTE technology specific signal bar mapping table for RSRP exists under “per_iccid”, use this setting.
2. Else, if a LTE technology specific signal bar mapping table for RSRP exists under “per_device”, use this setting.
3. Else, use the default LTE RSRP signal bar mapping table in code.

ⓘ **Note**

If EnableLTESnrReporting is enabled but there is no SNR table for LTE or SNR reporting by the modem, only RSRP is used. Otherwise, the better of RSRP or SNR is converted to signal bars.

Dataclass is LTE and RSSI is reported by the modem

1. If a LTE technology specific signal bar mapping table exists under “per_iccid”, use this setting.
2. Else, if a LTE technology specific signal bar mapping table exists under “per_device”, use this setting.
3. Else, if a legacy signal bar mapping table exists under “per_iccid”, use this setting.
4. Else, if a legacy signal bar mapping table exists under “per_device”, use this setting.
5. Else, use the default signal bar mapping table in code.

Dataclass is NR

1. If a NR technology specific signal bar mapping table for RSRP exists under “per_iccid”, use this setting.
2. Else, if a NR technology specific signal bar mapping table for RSRP exists under “per_device”, use this setting.
3. Else, use the default NR RSRP signal bar mapping table in code.

ⓘ **Note**

If EnableNRSnrReporting is enabled, but no there is no SNR table for NR or SNR reporting by the modem, only RSRP is used. Otherwise, the better of RSRP or SNR is converted to signal bars.

Dataclass is NSA

1. If EnableLTEReportingOnNSA is not set or is set to **0**:
   a. Follow the Dataclass NR flow.
2. If EnableLTEReportingOnNSA is set to **1**:
   a. Follow the Dataclass LTE flows (RSRP or RSSI).
3. If EnableLTEReportingOnNSA is set to **2**:
   a. If FrequencyRange is FR1, follow the Dataclass LTE flows (RSRP or RSSI).
   b. If FrequencyRange is <> FR1, follow the Dataclass NR flow.
4. If EnableLTEReportingOnNSA is set to **3**:
   a. If FrequencyRange is FR2, follow the Dataclass LTE flows (RSRP or RSSI).
   b. If FrequencyRange is <> FR2, follow the Dataclass NR flow.
5. If EnableLTEReportingOnNSA is set to **4**:
   a. Calculate signal bar using the LTE and NR flows.
   b. Select the strongest.

ⓘ **Note**

If the LTE signal is not reported by the modem in 1-5, the NR signal is used. If the NR signal is not used, the LTE signal is applied.

COSA customizations for SignalBar calculation

EnableLTEReportingOnNSA:

0 = "Use 5G signal"

1 = "Use LTE signal"

2 = "Use LTE signal if camped on 5G frequency range 1"

3 = "Use LTE signal if camped on 5G frequency range 2"

4 = "Use the strongest signal of LTE and 5G"

EnableNRSnrReporting:

0 = "Use only RSRP"

1 = "Use both RSRP and SNR"

EnableLTESnrReporting:

0 = "Use only RSRP"

1 = "Use both RSRP and SNR"

Cellular/PerDevice/SignalBarMappingTable/SignalForBars/<SignalBar>

Modify the minimum signal strength value corresponding to the number of bars to be shown. Technology specific settings take precedence. Each number of bars needs to have a valid signal strength mapping for this setting to take effect.

Cellular/PerDevice/SignalBarMappingTable/SignalForBars/GERAN/<SignalBar>

Modify the minimum signal strength value corresponding to the number of bars to be shown when device is camped on GSM. Each number of bars needs to have a valid signal strength mapping for this setting to take effect.

Cellular/PerDevice/SignalBarMappingTable/SignalForBars/WCDMA/<SignalBar>

Modify the minimum signal strength value corresponding to the number of bars to be shown when device is camped on WCDMA. Each number of bars needs to have a valid signal strength mapping for this setting to take effect.

Cellular/PerDevice/SignalBarMappingTable/SignalForBars/LTE/<SignalBar>

Modify the minimum signal strength value corresponding to the number of bars to be shown when device is camped on LTE. Each number of bars needs to have a valid signal strength mapping for this setting to take effect.

Cellular/PerDevice/SignalBarMappingTable/SignalForBars/LTERSRP/<SignalBar>

Modify the minimum signal strength value corresponding to the number of bars to be shown, when device is camped on LTE. Each number of bars needs to have a valid signal strength mapping for this setting to take effect.

Cellular/PerDevice/SignalBarMappingTable/SignalForBars/LTERSSNR/<SignalBar>

Modify the minimum signal strength value corresponding to the number of bars to be shown when device is camped on LTE. Used when EnableLTESnrReporting is set to 1. Each number of bars needs to have a valid signal strength mapping for this setting to take effect.

Cellular/PerDevice/SignalBarMappingTable/SignalForBars/NRRSRP/<SignalBar>

Modify the minimum signal strength value corresponding to the number of bars to be shown when device is camped on 5G. Each number of bars needs to have a valid signal strength mapping for this setting to take effect.

Cellular/PerDevice/SignalBarMappingTable/SignalForBars/NRRSSNR/<SignalBar>

Modify the minimum signal strength value corresponding to the number of bars to be shown when device is camped on 5G. Used when EnableNRSnrReporting is set to 1. Each number of bars needs to have a valid signal strength mapping for this setting to take effect.

<SignalBar> can be 1-5 values.

If the OEM/MO fails to properly configure the mapping table for RSSI or it's incomplete, use the default mapping:

RSSI	Bars Displayed
[0,1]	0
[2,3]	1
[4,6]	2
[7,11]	3
[12,16]	4
[17,31]	5

If the OEM/MO fails to properly configure the mapping table for RSRP or it's incomplete, use the default mapping:

RSRP	Bars Displayed
[0,16]	0
[17,41]	1
[42,51]	2
[52,61]	3
[62,71]	4
[72,126]	5

If the OEM/MO fails to properly configure the mapping table for SNR or it's incomplete, use the default mapping:

SNR	Bars Displayed
[0,18]	0
[19,38]	1
[39,46]	2
[47,53]	3
[54,72]	4
[73,127]	5

MBIMEx 3.0 – 5G SA Phase 1 support

Article • 03/14/2023

Starting with Windows 11, Windows OS supports the first phase of features for 5G systems with the next generation core network. These 5G systems are commonly referred to as 5G SA networks. They contain the new 5G Core Network (5GC) and are independent of Enhanced Packet Core (EPC) as used in 5G NSA networks and 4G networks.

The first phase of features for 5G SA enables MBB functionality parity for Windows MBIM MBB devices on 5G SA networks compared to 5G NSA. These features include registration with 5GC and basic PDU sessions on default eMBB network slice. Note that this phase does not support more advanced 5G SA features such as multiple concurrent network slices and URSP rules.

A new MBIM Extensions Release number 3.0 introduces changes in the MBIM interface to support the first phase of features for 5G SA. This Extensions Release number is commonly referred to as MBIMEx 3.0. Download the MBIMEx 3.0 specification here.

An errata for MBIMEx 3.0 introduced in May 2022 updates and clarifies certain aspects of the original MBIMEx 3.0 specification published in April 2020. Download the MBIMEx 3.0 errata here. The errata is in section 7.1 “Errata for MBIMEx 3.0”.

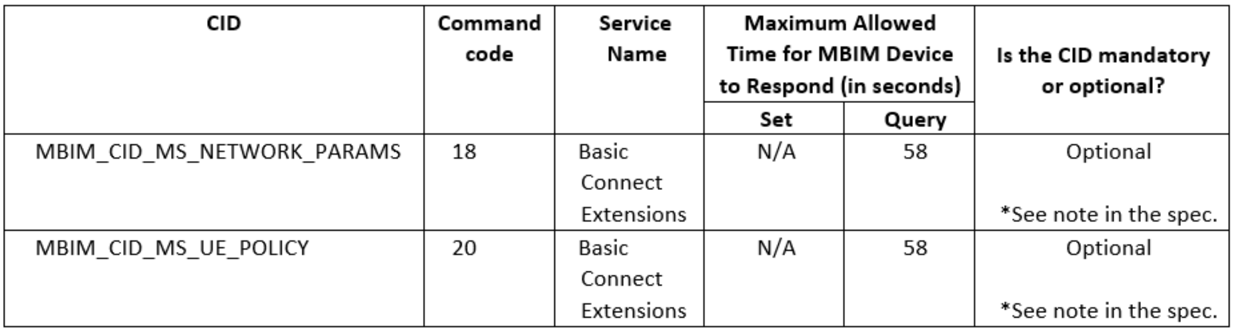
MBIMEx 4.0 – 5G SA Phase 2 support

Article • 03/14/2023

Windows 11, version 22H2 previews the 5G SA Phase 2 feature set. Additionally, it supports all Windows 11 cellular features such as 5G SA Phase 1. The 5G SA Phase 2 feature set includes support for end-to-end URSP handling and multiple concurrent eMBB network slices.

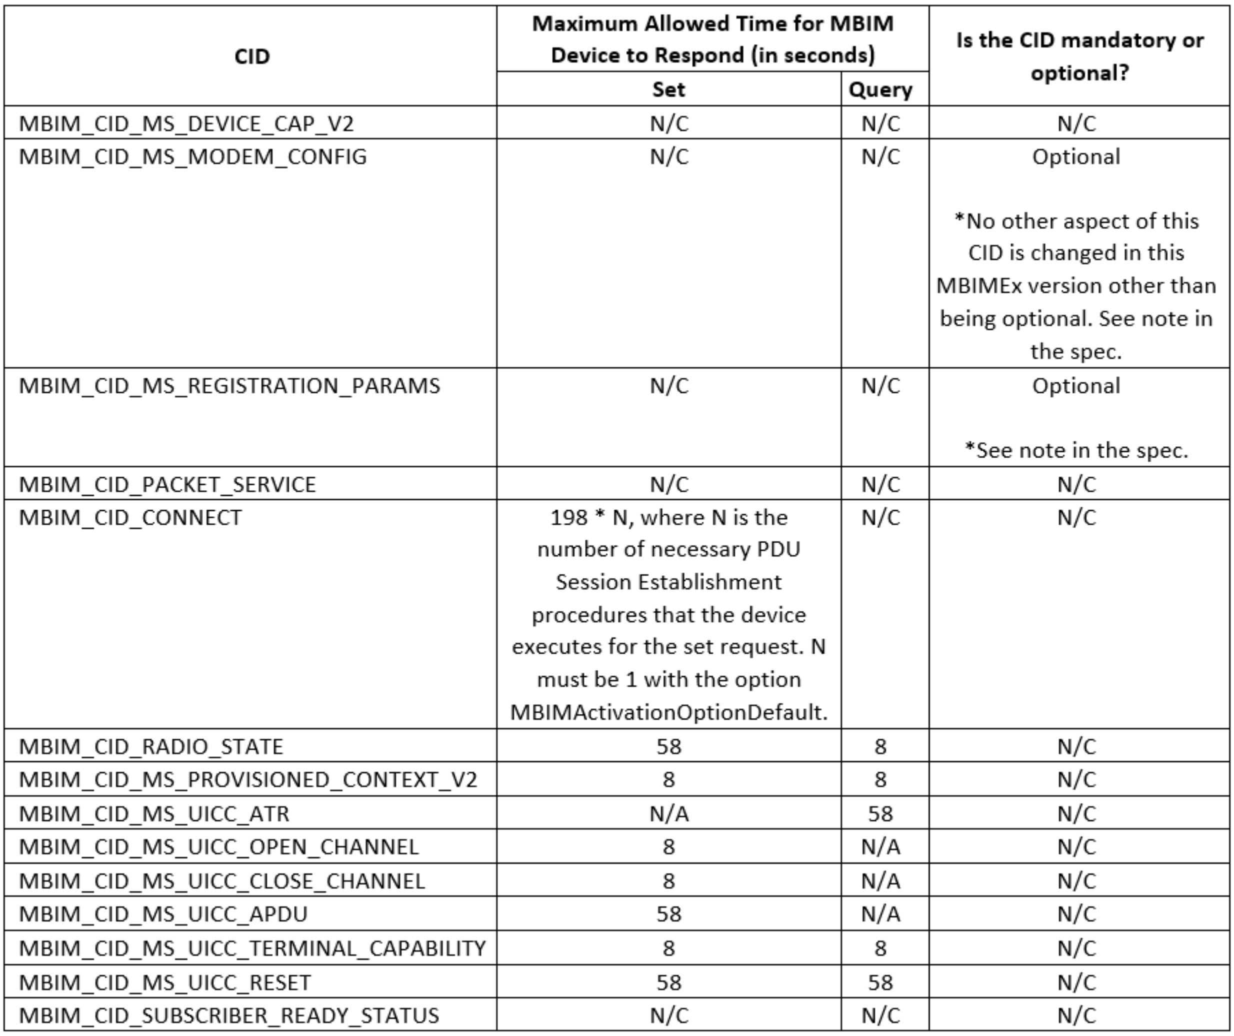
MBIM Extensions Release number 4.0 introduces support for 5G SA Phase 2 features. This Extensions Release number is commonly referred to as MBIMEx 4.0. URSP handling/usage and multiple concurrent eMBB network slices are the main additions in MBIMEx 4.0. All valid slice types (SST) are supported at the MBIM interface level in MBIMEx 4.0, but non-eMBB slice functionality is not implied in Windows 11, version 22H2 and is subject to additional host and device-level support and features. Download the MBIMEx 4.0 specification here. Section 4 “MBIM Interface Extensions for 5G NGC – Phase 2” contains the MBIMEx 4.0 specification.

MBIMEx 4.0 adds the following new CIDs:



CID	Command code	Service Name	Maximum Allowed Time for MBIM Device to Respond (in seconds)		Is the CID mandatory or optional?
			Set	Query	
MBIM_CID_MS_NETWORK_PARAMS	18	Basic Connect Extensions	N/A	58	Optional *See note in the spec.
MBIM_CID_MS_UE_POLICY	20	Basic Connect Extensions	N/A	58	Optional *See note in the spec.

MBIMEx 4.0 modifies the following existing CIDs:



CID	Maximum Allowed Time for MBIM Device to Respond (in seconds)		Is the CID mandatory or optional?
	Set	Query	
MBIM_CID_MS_DEVICE_CAP_V2	N/C	N/C	N/C
MBIM_CID_MS_MODEM_CONFIG	N/C	N/C	Optional *No other aspect of this CID is changed in this MBIMEx version other than being optional. See note in the spec.
MBIM_CID_MS_REGISTRATION_PARAMS	N/C	N/C	Optional *See note in the spec.
MBIM_CID_PACKET_SERVICE	N/C	N/C	N/C
MBIM_CID_CONNECT	198 * N, where N is the number of necessary PDU Session Establishment procedures that the device executes for the set request. N must be 1 with the option MBIMActivationOptionDefault.	N/C	N/C
MBIM_CID_RADIO_STATE	58	8	N/C
MBIM_CID_MS_PROVISIONED_CONTEXT_V2	8	8	N/C
MBIM_CID_MS_UICC_ATR	N/A	58	N/C
MBIM_CID_MS_UICC_OPEN_CHANNEL	8	N/A	N/C
MBIM_CID_MS_UICC_CLOSE_CHANNEL	8	N/A	N/C
MBIM_CID_MS_UICC_APDU	58	N/A	N/C
MBIM_CID_MS_UICC_TERMINAL_CAPABILITY	8	8	N/C
MBIM_CID_MS_UICC_RESET	58	58	N/C
MBIM_CID_SUBSCRIBER_READY_STATUS	N/C	N/C	N/C

By default, Windows 11, version 22H2 announces MBIMEx 3.0 as the highest supported MBIMEx version by the host. A special capability is available to change the default to MBIMEx 4.0 for IHVs and driver developers. Contact your TAM for support if a Microsoft engineering partner needs the capability for testing and development.

NDIS_STATUS_WWAN_ATR_INFO

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_ATR_INFO notification to respond to OID query requests of OID_WWAN_UICC_ATR.

This notification uses the **NDIS_WWAN_ATR_INFO** structure.

Requirements

Version: Windows 10, version 1607

Header: Ntddndis.h (include Ndis.h)

See also

OID_WWAN_UICC_ATR

NDIS_WWAN_ATR_INFO

MB low level UICC access

NDIS_STATUS_WWAN_AUTH_RESPONSE

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_AUTH_RESPONSE notification to inform the MB Service of a challenge response received from a previous challenge request issued using an OID_WWAN_AUTH_CHALLENGE query request.

Miniport drivers can also send unsolicited events with this notification.

This NDIS status notification uses the NDIS_WWAN_AUTH_RESPONSE structure.

Requirements

Version	Supported starting with Windows 8.
Header	Ndis.h

See also

OID_WWAN_AUTH_CHALLENGE

NDIS_WWAN_AUTH_RESPONSE

NDIS_STATUS_WWAN_BASE_STATIONS_INFO

Article • 03/14/2023

The NDIS_STATUS_WWAN_BASE_STATIONS_INFO notification is sent by modem miniport drivers in response to an OID_WWAN_BASE_STATIONS_INFO query request to provide the MB host with information about both serving and neighboring base stations.

This notification uses the NDIS_WWAN_BASE_STATIONS_INFO structure.

Requirements

Version: Windows 10, version 1709 **Header**: Ndis.h

See also

OID_WWAN_BASE_STATIONS_INFO

NDIS_WWAN_BASE_STATIONS_INFO

MB base stations information query operations

NDIS_STATUS_WWAN_CONTEXT_STATE

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_CONTEXT_STATE notification to send an event notification when the activation state of a particular context changes.

Miniport drivers can also send unsolicited events with this notification.

This notification uses the NDIS_WWAN_CONTEXT_STATE structure.

Remarks

Miniport drivers must also notify the MB Service when context state changes are not caused as a result of a *set* request from the MB Service. For example, miniport drivers must notify the MB Service if the network deactivates a context. Miniport drivers should not implement network initiated context activations.

Miniport drivers must notify Windows directly about all applicable context state changes, such as when processing NDIS_STATUS_WWAN_PACKET_SERVICE or NDIS_STATUS_WWAN_REGISTER_STATE status notifications.

Miniport drivers of MB devices that support separate voice and data connections must follow these guidelines:

- At the time of initialization, the VoiceCallState must be set to WwanVoiceCallStateNone.
- On the start of the voice call, send an event notification with VoiceCallState set to WwanVoiceCallStateInProgress. All the other members must reflect their current state. In case of no active connection during the voice call, the ConnectionId should be set to "0" .
- Once the voice call is completed, send an event notification with VoiceCallState set to WwanVoiceCallStateHangUp. All the other members must reflect their current state. In case of no active connection during the voice call hang up, the ConnectionId should be set to "0". After this event, the VoiceCallState must be set to **WwanVoiceCallStateNone** in the miniport driver.

Requirements

Version	Available in Windows 7 and later versions of

	Windows.
Header	Ndis.h

See also

NDIS_WWAN_CONTEXT_STATE

OID_WWAN_PROVISIONED_CONTEXTS

NDIS_STATUS_WWAN_DEVICE_CAPS

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_DEVICE_CAPS notification to respond to OID_WWAN_DEVICE_CAPS query requests.

Miniport drivers cannot use this notification to send unsolicited events.

This notification uses the **NDIS_WWAN_DEVICE_CAPS** structure.

Remarks

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ndis.h

See also

OID_WWAN_DEVICE_CAPS

NDIS_WWAN_DEVICE_CAPS

NDIS_STATUS_WWAN_DEVICE_CAPS_EX

Article • 03/14/2023

Miniport drivers use the **NDIS_STATUS_WWAN_DEVICE_CAPS_EX** notification to inform the MB service about the completion of a previous OID_WWAN_DEVICE_CAPS_EX query request.

Miniport drivers cannot use this notification to send unsolicited events.

This notification uses the **NDIS_WWAN_DEVICE_CAPS_EX** structure.

Requirements

Version	Windows 10, version 1703
Header	Ndis.h

See also

OID_WWAN_DEVICE_CAPS_EX

NDIS_STATUS_WWAN_DEVICE_RESET_STATUS

Article • 03/14/2023

The NDIS_STATUS_WWAN_DEVICE_RESET_STATUS notification is sent by a modem miniport driver to inform the MB host of the reset status of the modem device. This notification is sent as an asynchronous response to an OID_WWAN_DEVICE_RESET set request.

This notification uses the NDIS_WWAN_DEVICE_RESET_STATUS structure.

Requirements

Version: Windows 10, version 1709 **Header**: Ndis.h

See also

OID_WWAN_DEVICE_RESET

NDIS_WWAN_DEVICE_RESET_STATUS

MB modem reset operations

NDIS_STATUS_WWAN_DEVICE_SERVICE_EVENT

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_DEVICE_SERVICE_EVENT indication to notify the MB Service of device service changes.

Miniport drivers can only use this notification to send unsolicited events.

This notification uses the NDIS_WWAN_DEVICE_SERVICE_EVENT structure.

Requirements

Version	Supported starting with Windows 8.
Header	Ndis.h

See also

NDIS_WWAN_DEVICE_SERVICE_EVENT

NDIS_STATUS_WWAN_DEVICE_SERVICE_RESPONSE

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_DEVICE_SERVICE_RESPONSE indication to implement the transaction completion response for OID_WWAN_DEVICE_SERVICE_COMMAND.

Miniport drivers cannot use this notification to send unsolicited events.

This notification uses the **NDIS_WWAN_DEVICE_SERVICE_RESPONSE** structure.

Requirements

Version	Supported starting with Windows 8.
Header	Ndis.h

NDIS_STATUS_WWAN_DEVICE_SERVICE_SESSION

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_DEVICE_SERVICE_SESSION indication to report the completion of a device service session state change originated by OID_WWAN_DEVICE_SERVICE_SESSION.

Miniport drivers cannot use this notification to send unsolicited events.

This notification uses the **NDIS_WWAN_DEVICE_SERVICE_SESSION_INFO** structure.

Requirements

Version	Supported starting with Windows 8.
Header	Ndis.h

See also

OID_WWAN_DEVICE_SERVICE_SESSION

NDIS_WWAN_DEVICE_SERVICE_SESSION_INFO

NDIS_STATUS_WWAN_DEVICE_SERVICE_SESSION_READ

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_DEVICE_SERVICE_SESSION_READ notification to inform the MB Service that data has been received from an open device service session.

Miniport drivers can only use this notification to send unsolicited events.

This notification uses the NDIS_WWAN_DEVICE_SERVICE_SESSION_READ structure.

Requirements

Version	Supported starting with Windows 8.
Header	Ndis.h

See also

NDIS_WWAN_DEVICE_SERVICE_SESSION_READ

NDIS_STATUS_WWAN_DEVICE_SERVICE_SESSION_WRITE_COMPLETE

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_DEVICE_SERVICE_SESSION_WRITE_COMPLETE notification to report the status of a write operation on a device service session.

Miniport drivers cannot use this notification to send unsolicited events.

This notification uses the NDIS_WWAN_DEVICE_SERVICE_SESSION_WRITE_COMPLETE structure.

Requirements

Version	Supported starting with Windows 8.
Header	Ndis.h

See also

NDIS_WWAN_DEVICE_SERVICE_SESSION_WRITE_COMPLETE

NDIS_STATUS_WWAN_DEVICE_SERVICE_SUBSCRIPTION

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_DEVICE_SERVICE_SUBSCRIPTION notification to inform the MB Service about a device service subscription in response to an OID_WWAN_SUBSCRIBE_DEVICE_SERVICE_EVENTS set request.

Miniport drivers cannot use this notification to send unsolicited events.

This indication uses the **NDIS_WWAN_DEVICE_SERVICE_SUBSCRIPTION** structure.

Requirements

Version	Supported starting with Windows 8.
Header	Ndis.h

See also

OID_WWAN_SUBSCRIBE_DEVICE_SERVICE_EVENTS

NDIS_WWAN_DEVICE_SERVICE_SUBSCRIPTION

NDIS_STATUS_WWAN_DEVICE_SERVICE_SUPPORTED_COMMANDS

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_DEVICE_SERVICE_SUPPORTED_COMMANDS notification to report the completion of a query of OID_WWAN_ENUMERATE_DEVICE_SERVICE_COMMANDS.

Miniport drivers cannot use this notification to send unsolicited events.

This notification uses the **NDIS_WWAN_DEVICE_SERVICE_SUPPORTED_COMMANDS** structure.

Requirements

Version	Supported starting with Windows 8.
Header	Ndis.h

NDIS_STATUS_WWAN_DEVICE_SLOT_MAPPING_INFO

Article • 03/14/2023

Miniport drivers use the **NDIS_STATUS_WWAN_DEVICE_SLOT_MAPPING_INFO** notification to inform the MB service about the completion of a previous OID_WWAN_DEVICE_SLOT_MAPPING_INFO query or set request.

Miniport drivers cannot use this notification to send unsolicited events.

This notification uses the **NDIS_WWAN_DEVICE_SLOT_MAPPING_INFO** structure.

Requirements

Version	Windows 10, version 1703
Header	Ndis.h

See also

OID_WWAN_DEVICE_SLOT_MAPPING_INFO

NDIS_STATUS_WWAN_HOME_PROVIDER

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_HOME_PROVIDER notification to inform the MB Service about the completion of OID_WWAN_HOME_PROVIDER query requests.

Miniport drivers cannot use this notification to send unsolicited events.

This notification uses the **NDIS_WWAN_HOME_PROVIDER** structure.

Remarks

Miniport drivers must comply with the following rules when responding to OID_WWAN_HOME_PROVIDER query requests:

- GSM-Based Devices: The home provider name can be retrieved from the Subscriber Identity Module (SIM) using several methods, such as from the EFSPN elementary file in the SIM (EFSPN is defined in the 3GPP TS 31.102 under section Service Provider Name), or from the operator-specific extensions when the EFSPN is not provisioned. You should refer to the operator-specific requirements specifications for obtaining the home provider name, extracting MCC-MNC from IMSI, and performing a look up in the GSMA SE.13 database. Contact the operator when retrieving operator-specific home provider names if the EFSPN is not provisioned. If a SIM is not provisioned with a home provider name through EFSPN or any other mechanism, miniport drivers should set the provider name to **NULL**.

  For details about a SIM card's file system, see the 3GPP TS 11.11 specification. If the provider identification is not provisioned in the Subscriber Identity Module (SIM card), miniport drivers should return WWAN_STATUS_READ_FAILURE.

- CDMA-Based Devices: Returning the home provider name is mandatory. It is recommended that IHVs provide this information in their device as part of network personalization. If the provider identity is not available, miniport drivers for CDMA-based providers must set the **Provider.ProviderId** member of the NDIS_WWAN_HOME_PROVIDER structure to WWAN_CDMA_DEFAULT_PROVIDER_ID.

Miniport drivers must return this information when the device ready-state changes to **WwanReadyStateInitialized** and format all the members of the WWAN_PROVIDER structure, as appropriate.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ndis.h

NDIS_STATUS_WWAN_IP_ADDRESS_STATE

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_IP_ADDRESS_STATE notification to inform the MB service about changes to the IP configuration for an additional PDP context.

This notification uses the NDIS_WWAN_IP_ADDRESS_STATE structure.

Remarks

This notification must be sent on the NDIS port associated with the additional PDP context session.

Miniport drivers should send this notification after an additional PDP context has been successfully activated and the IP configuration has been acquired for that context. If the device indicates unsolicited IP configuration changes post-context activation, then miniport drivers should send an unsolicited indication with this notification with the updated IP configuration.

Requirements

Version	Available in Windows 8.1 and later versions of Windows.
Header	Ndis.h (include Ndis.h)

See also

NDIS_WWAN_IP_ADDRESS_STATE

NDIS_STATUS_WWAN_LTE_ATTACH_CONFIG

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_LTE_ATTACH_CONFIG notification to inform the mobile broadband (MB) service about the completion of a previous OID_WWAN_LTE_ATTACH_CONFIG Query or Set request.

Unsolicited events are sent if the default LTE attach context is updated by the network either over the air (OTA) or by short message service (SMS). In this case, the miniport driver must update the default LTE attach contexts and send this notification to the host OS with the updated list.

This status notification uses the **NDIS_WWAN_LTE_ATTACH_CONTEXTS** structure.

Requirements

Version: Windows 10, version 1703 **Header**: Ntddndis.h (include Ndis.h)

See also

MB LTE Attach Operations

OID_WWAN_LTE_ATTACH_CONFIG

NDIS_WWAN_LTE_ATTACH_CONTEXTS

NDIS_STATUS_WWAN_LTE_ATTACH_STATUS

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_LTE_ATTACH_STATUS notification to inform the mobile broadband (MB) service about the completion of a previous OID_WWAN_LTE_ATTACH_STATUS Query request.

Unsolicited events are sent if a context for LTE attach is activated, which could be when a SIM is inserted for example. In this case, the miniport driver should send this notification to the host OS.

This status notification uses the **NDIS_WWAN_LTE_ATTACH_STATUS** structure.

Requirements

Version: Windows 10, version 1703 **Header**: Ntddndis.h (include Ndis.h)

NDIS_WWAN_LTE_ATTACH_STATUS

NDIS_STATUS_WWAN_MODEM_CONFIG_INFO

Article • 03/14/2023

MBB drivers use the **NDIS_STATUS_WWAN_MODEM_CONFIG_INFO** notification to inform the MB service about the completion of a previous OID_WWAN_MODEM_CONFIG_INFO query request.

MBB drivers must only send an unsolicited **NDIS_STATUS_WWAN_MODEM_CONFIG_INFO** when the configuration state of the modem has changed.

This notification uses the **NDIS_WWAN_MODEM_CONFIG_INFO** structure.

Requirements

Version	Windows 10, version 1709
Header	Ndis.h

See also

OID_WWAN_MODEM_CONFIG_INFO

NDIS_WWAN_MODEM_CONFIG_INFO

NDIS_STATUS_WWAN_MODEM_LOGGING_CONFIG

Article • 03/14/2023

Miniport drivers use the **NDIS_STATUS_WWAN_MODEM_LOGGING_CONFIG** notification to inform the mobile broadband (MB) service about the completion of a previous OID_WWAN_MODEM_LOGGING_CONFIG Query or Set request.

Miniport drivers send this notification as an unsolicited event in scenarios where the modem needs to inform the OS about internal changes. Currently, in Windows 10, version 1903, these scenarios do not occur.

This notification uses the **NDIS_WWAN_MODEM_LOGGING_CONFIG** structure.

Requirements

Version: Windows 10, version 1903 **Header**: Ntddndis.h (include Ndis.h)

See also

MB modem logging with DSS

NDIS_WWAN_MODEM_LOGGING_CONFIG

NDIS_STATUS_WWAN_MPDP_LIST

Article • 03/14/2023

The **NDIS_STATUS_WWAN_MPDP_LIST** notification is sent by a mobile broadband miniport driver to inform the MB service about the completion of a previous OID_WWAN_MPDP query request.

This notification is not sent as an unsolicited event.

This notification uses the **NDIS_WWAN_MPDP_LIST** structure.

Requirements

Version: Windows 10, version 1809

Header: Ndis.h

NDIS_STATUS_WWAN_MPDP_STATE

Article • 03/14/2023

The **NDIS_STATUS_WWAN_MPDP_STATE** notification is sent by a mobile broadband miniport driver to inform the MB service about the completion of a previous OID_WWAN_MPDP set request.

This notification is not sent as an unsolicited event.

This notification uses the **NDIS_WWAN_MPDP_STATE** structure.

Requirements

Version: Windows 10, version 1809

Header: Ndis.h

NDIS_STATUS_WWAN_NETWORK_BLACKLIST

Article • 03/14/2023

ⓘ Important

Bias-free communication

Microsoft supports a diverse and inclusive environment. This article contains references to terminology that the Microsoft **style guide for bias-free communication** recognizes as exclusionary. The word or phrase is used in this article for consistency because it currently appears in the software. When the software is updated to remove the language, this article will be updated to be in alignment.

Miniport drivers use the **NDIS_STATUS_WWAN_NETWORK_BLACKLIST** notification to inform the mobile broadband (MB) service about the completion of a previous OID_WWAN_NETWORK_BLACKLIST Query or Set request.

Unsolicited events are sent if any of the blacklist states have changed from actuated to not actuated, or vice versa. For example, if a SIM is inserted whose provider matches the SIM provider blacklist.

This notification uses the **NDIS_WWAN_NETWORK_BLACKLIST** structure.

Requirements

Version: Windows 10, version 1703 **Header**: Ntddndis.h (include Ndis.h)

See also

MB Network Blacklist Operations

OID_WWAN_NETWORK_BLACKLIST

NDIS_WWAN_NETWORK_BLACKLIST

NDIS_STATUS_WWAN_NETWORK_PARAMS_STATE

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_NETWORK_PARAMS_STATE notification to inform the MB Service about changes to network configuration data and/or policy information.

Drivers send an NDIS_STATUS_WWAN_NETWORK_PARAMS_STATE notification in response to an OID query request of OID_WWAN_NETWORK_PARAMS.

This notification uses the **NDIS_WWAN_NETWORK_PARAMS_INFO** structure which contains a **WWAN_NETWORK_PARAMS_INFO** structure.

Remarks

For more information see OID_WWAN_NETWORK_PARAMS.

Requirements

Requirement	Value
Minimum supported client	Windows 11
Version	Windows Server 2022. NDIS 6.84 and later.
Header	Ndis.h

NDIS_STATUS_WWAN_NITZ_INFO

Article • 03/14/2023

Miniport drivers use the **NDIS_STATUS_WWAN_NITZ_INFO** notification to inform the mobile broadband (MB) service about the completion of a previous OID_WWAN_NITZ Query request.

Miniport drivers send this notification as an unsolicited event to provide the current network time and time zone intformation.

This notification uses the **NDIS_WWAN_NITZ_INFO** structure.

Requirements

Version: Windows 10, version 1903 **Header**: Ntddndis.h (include Ndis.h)

See also

MB modem logging with DSS

OID_WWAN_NITZ

NDIS_WWAN_NITZ_INFO

NDIS_STATUS_WWAN_PACKET_SERVICE

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_PACKET_SERVICE notification to inform the MB Service when packet service availability changes, including to notify of a change to the type of packet data service currently used.

Miniport drivers can also send unsolicited events with this notification.

This notification uses the NDIS_WWAN_PACKET_SERVICE_STATE structure.

Remarks

CDMA-based miniport drivers can automatically initiate packet-attach service if there is no resource allocation/release is possible and can send the event notification to the MB Service.

Miniport drivers should obey the following guidelines for event notifications:

- Miniport drivers should set **AvailableDataClasses** is set to WWAN_DATA_CLASS_NONE during miniport driver initialization. Thereafter, miniport drivers must notify the MB Service whenever there is any change to **AvailableDataClasses**.

- Miniport drivers should set **CurrentDataClass** to WWAN_DATA_CLASS_NONE during miniport driver initialization. Thereafter, miniport drivers must notify the MB Service whenever there is any change to **CurrentDataClass** . Miniport drivers should send an NDIS_STATUS_LINK_STATE notification if the change to **CurrentDataClass** results in a change of the transmit or receive link speed.

- Miniport drivers must notify the MB Service whenever there is any change in Packet Service attach state.

Miniport drivers should return *query* results according to the following rules:

- Miniport drivers must return WWAN_STATUS_SUCCESS with **WwanPacketServiceStateAttaching** whenever the device attempts to packet-attach.

- Miniport drivers should return WWAN_STATUS_SUCCESS with **WwanPacketServiceStateDetaching** whenever the device attempts to packet-detach.

- When the device is in final state, miniport drivers should return WWAN_STATUS_SUCCESS along with the appropriate current state (**WwanPacketServiceStateAttached** or **WwanPacketServiceStateDetached**)

- Miniport drivers must list all the available data-classes; not just the highest data-class available. This applies to both *query* operations as well as event notifications.

Miniport drivers should return *set* results according to the following rules:

- Return WWAN_STATUS_SUCCESS, if *set* request with **WwanPacketServiceActionAttach**, is issued by the Service and the device is already in the packet-attached state.

- Return WWAN_STATUS_SUCCESS, if *set* request with **WwanPacketServiceActionDetach**, is issued by the Service and the device is already in the packet-detached state.

- Never return transient states for the *set* request. Only the final states **WwanPacketServiceStateAttached** or **WwanPacketServiceStateDetached** must be returned after the successful completion of the packet service operation with WWAN_STATUS_SUCCESS

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ndis.h

NDIS_WWAN_PACKET_SERVICE_STATE

OID_WWAN_PACKET_SERVICE

NDIS_STATUS_WWAN_PCO_STATUS

Article • 03/14/2023

The **NDIS_STATUS_WWAN_PCO_STATUS** notification is sent by a modem miniport driver to inform the OS of the current Protocol Configuration Options (PCO) state in the modem. Modem miniport drivers will send this notification in the following three scenarios:

1. When a new PCO value has arrived on an activated connection.
2. When the modem has PCO value readily available when a connection is activated or bridged by the host.
3. In response to an OID_WWAN_PCO query request from the host.

When a new PCO value has arrived, this notification will be unsolicited and sent with the latest PCO value from the network. The notification will come up with the NDIS port number that corresponds to the activated connection's PDN.

When a connection is activated or bridged from the host, the modem should check whether it has the PCO value cached or not. If it does, it will send up a notification to the host with the NDIS port number that corresponds to the PDN that the host has activated or bridged.

This notification will be used to notify the host that an **OID_WWAN_PCO** query request has been completed, with the PCO value included in the notification. The host expects the modem to pass the complete structure of PCO values on the PDN corresponding to the port number.

If PCO functionality is supported by the modem but no PCO value is received from the network when the host sends an **OID_WWAN_PCO** query request, the modem should return an **NDIS_STATUS_WWAN_PCO_STATUS** notification with an empty WWAN_PCO_VALUE payload.

This notification uses the NDIS_WWAN_PCO_STATUS structure.

> ⓘ **Note**
>
> Currently, in Windows 10, version 1709 and later, some modems are only able to provide operator specific PCO elements. If a PCO data structure is received by modem but there is no applicable operator specific PCO element, to avoid unnecessary device wakeup, the modem should not advertise the PCO notification to the OS.

Requirements

Version: Windows 10, version 1709 **Header**: Ndis.h

WWAN_PCO_VALUE

MB Protocol Configuration Options (PCO) operations

NDIS_STATUS_WWAN_PIN_INFO

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_PIN_INFO notification to respond to OID query and set requests of OID_WWAN_PIN.

Miniport drivers cannot use this notification to send unsolicited events.

This notification uses the **NDIS_WWAN_PIN_INFO** structure.

Remarks

Miniport drivers should return information about the Personal Identity Number (PIN) that the MB device currently expects in response to a query request. Miniport drivers should return the status notification filled in as described in sections below in response to a set request.

Responding to WwanPinOperationEnter Requests

When miniport drivers use the NDIS_STATUS_WWAN_PIN_INFO notification to respond to **WwanPinOperationEnter** requests, they should implement these procedures:

- For successful **WwanPinOperationEnter** query requests, when the MB device no longer requires a PIN, miniport drivers must set **uStatus** to WWAN_STATUS_SUCCESS and **PinType** to **WwanPinTypeNone**.

- For failed **WwanPinOperationEnter** requests, miniport drivers must set **uStatus** to WWAN_STATUS_FAILURE and include applicable data as per the following details:

    - PIN Disabled or PIN Not Expected: For **WwanPinOperationEnter** set requests, when the corresponding PIN is either disabled or currently not expected by the MB device, miniport drivers must set **PinType** to **WwanPinTypeNone**. All other members are ignored.

    - PIN Not Supported: If the given PIN is not supported by the MB device, miniport drivers must set **uStatus** to WWAN_STATUS_NO_DEVICE_SUPPORT.

    - PIN Retrial: In this mode, the MB device requires the PIN to be re-entered as the **AttemptsRemaining** value is still non-zero for this particular type of PIN. Miniport drivers must set **PinType** to the same value as that of **PinType** in NDIS_WWAN_SET_PIN.

  - PIN Blocking: The PIN is blocked when **AttemptsRemaining** is zero. If the PIN unblock operation is not available, miniport drivers must set **uStatus** to WWAN_STATUS_FAILURE and **PinType** to **WwanPinTypeNone**. All the other members are ignored.

    Note If the MB device supports PIN unblock operations, miniport drivers should follow the PIN Unblocking step to respond to the request.

  - PIN Unblocking: The PIN is blocked when **AttemptsRemaining** is zero. To unblock the PIN, the MB device may request a corresponding PIN Unlock Key (PUK), if applicable. In this case, miniport drivers must set **PinType** to the corresponding WwanPinType*Xxx*PUK with the relevant details.

  - Blocked PUK: If the number of failed trials exceeds the preset value for entering the WwanPinType*Xxx*PUK, then the PUK becomes blocked. Miniport drivers must signal this by setting **uStatus** to WWAN_STATUS_FAILURE and **PinType** to **WwanPinTypeNone**. In case PUK1 is blocked, miniport drivers must send an NDIS_STATUS_WWAN_READY_INFO with **ReadyState** set to **WwanReadyStateBadSim**.

Responding to WwanPinOperationEnable, WwanPinOperationDisable, or WwanPinOperationChange Requests

When miniport drivers use the NDIS_STATUS_WWAN_PIN_INFO notification to respond to **WwanPinOperationEnable**, **WwanPinOperationDisable**, and **WwanPinOperationChange**, they should implement the following operations:

- For successful requests, miniport drivers must set **uStatus** to WWAN_STATUS_SUCCESS. For other members in WWAN_PIN_INFO, see the following circumstances.

- Miniport drivers must set **uStatus** to WWAN_STATUS_SUCCESS for PIN-enable and PIN-disable operations when the PIN is already in the requested state. Miniport drivers must set **PinType** to **WwanPinTypeNone**. Other members are ignored.

- When a PIN mode is changed from disabled to enabled, the PIN state should be WwanPinStateNone.

- If PIN1 is enabled, the PIN state shall become WwanPinStateEnter when power is cycled to the MB device.

- For all other PINs, the PIN state can change from WwanPinStateNone to WwanPinStateEnter depending on MB device specific conditions.

- PIN Not Supported: If a PIN operation is not supported by the MB device, miniport drivers must set **uStatus** to WWAN_STATUS_NO_DEVICE_SUPPORT. For example, enabling and disabling PIN2 is not typically supported by MB devices so the above error code must be returned. All other members are ignored.

- PIN Must be Entered: If a PIN operation requires a PIN to be entered, miniport drivers must set **uStatus** to WWAN_STATUS_PIN_REQUIRED and **PinType** to WwanPinType*Xxx*. Other members are ignored.

- PIN Change Operation: If the MB device restricts the change of PIN value only when it is in enabled state, a request to change in disabled state must be returned with WWAN_STATUS_PIN_DISABLED.

- PIN Retrial: On failure, miniport drivers must set **uStatus** to WWAN_STATUS_FAILURE, and **PinType** to the same value as specified in NDIS_WWAN_SET_PIN. Other members are ignored except for **AttemptsRemaining**. This may occur when an incorrect PIN is entered.

- PIN Blocking: The PIN is blocked when the number of **AttemptsRemaining** is zero. If the PIN unblock operation is not available, miniport drivers must set **uStatus** to WWAN_STATUS_FAILURE and **PinType** to **WwanPinTypeNone**. **AttemptsRemaining** should be set to 0 and all the other members are ignored.

  Note If the MB device supports PIN unblock operations, miniport drivers should follow the PIN Unblocking step to respond to the request.

- Unblocking PIN: The PIN is blocked when **AttemptsRemaining** is zero. To unblock the PIN, the MB device may request a corresponding PUK, if applicable. In this case, miniport drivers must set **uStatus** to WWAN_STATUS_FAILURE, **PinType** to the corresponding WwanPinType*Xxx*PUK, **PinState** to **WwanPinStateEnter**, and **AttemptsRemaining** should have the number of attempts allowed to enter a valid PUK.

  If PIN blocking results in the MB device or SIM becomes blocked, miniport drivers must send an event notification with **ReadyState** set to **WwanReadyStateDeviceLocked**.

- If there is an active PDP context at the time of PIN1 blocking, miniport drivers must deactivate the PDP context and send notifications to the operating system about the PDP deactivation and link state change.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ndis.h

OID_WWAN_PIN

NDIS_STATUS_WWAN_PIN_INFO

NDIS_STATUS_WWAN_PIN_LIST

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_PIN_LIST notification to respond to OID query requests of OID_WWAN_PIN_LIST.

Miniport drivers cannot use this notification to send unsolicited events.

This notification uses the **NDIS_WWAN_PIN_LIST** structure.

Remarks

This INDICATION is a response only notification to OID query requests of OID_WWAN_PIN_LIST. Unsolicited indications are not expected for this INDICATION.

Any change in the PIN-entry mode caused as a result of an OID_WWAN_PIN enable or disable operation will not result in an NDIS_STATUS_WWAN_PIN_LIST INDICATION.

Note that the current PinMode for all of the PINs that the device supports must be updated to reflect the current state by the miniport driver on each query request.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ndis.h

NDIS_STATUS_WWAN_PREFERRED_MULTICARRIER_PROVIDERS

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_PREFERRED_MULTICARRIER_PROVIDERS notification to respond to a previous OID_WWAN_PREFERRED_MULTICARRIER_PROVIDERS*query* request.

Miniport drivers may also use this notification to inform the MB Service about the update as a result of a OID_WWAN_PREFERRED_MULTICARRIER_PROVIDERS *set* request from the MB Service. A response to an OID_WWAN_PREFERRED_MULTICARRIER_PROVIDERS *set* request must contain zero elements in the **PreferredListHeader** member. Miniport drivers can also send unsolicited events with this notification to inform the MB Service that the Preferred Multi-Carrier Provider List (PMCPL) has changed.

This notification uses the **NDIS_WWAN_PREFERRED_MULTICARRIER_PROVIDERS** structure.

Requirements

Version	Supported starting with Windows 8.
Header	Ndis.h

See also

NDIS_WWAN_PREFERRED_MULTICARRIER_PROVIDERS

NDIS_STATUS_WWAN_PREFERRED_PROVIDERS

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_PREFERRED_PROVIDERS notification to inform the MB Service that the Preferred Provider List (PPL) has changed.

Miniport drivers can also send unsolicited events with this notification.

This notification uses the **NDIS_WWAN_PREFERRED_PROVIDERS** structure.

Remarks

In some cases, the PPL (for GSM-based devices) is updated by the network either Over-The-Air (OTA) or by Short Message Service (SMS). The miniport driver must update the PPL accordingly. Afterwards, miniport drivers must notify the MB Service about the updates using this INDICATION with the updated PPL. For GSM-based networks, the **PreferredListHeader** member of the NDIS_WWAN_PREFERRED_PROVIDERS structure must point to the updated PPL.

Miniport drivers use this INDICATION to inform the MB Service about the update as a result of a OID_WWAN_PREFERRED_PROVIDERS set request from the MB Service. A response to an OID_WWAN_PREFERRED_PROVIDERS set request must contain zero elements in the **PreferredListHeader** member.

Requirements

Version	Available in Windows 7 and later versions of Windows.

NDIS_STATUS_WWAN_PRESHUTDOWN_STATE

Article • 03/14/2023

The NDIS_STATUS_WWAN_PRESHUTDOWN_STATE notification is a one-way notification from the MBB driver to the host. The MBB driver sends up this notification when the modem has finished all operations required before shutdown.

This notification uses the NDIS_WWAN_PRESHUTDOWN_STATE structure.

Requirements

Version	Supported starting with Windows 10, version 1511.
Header	Ndis.h

NDIS_STATUS_WWAN_PROVISIONED_CONTEXTS

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_PROVISIONED_CONTEXTS notification to inform the MB Service about updates to the list of provisioned contexts as a result of a network update.

Miniport drivers can also send unsolicited events with this notification.

This notification uses the NDIS_WWAN_PROVISIONED_CONTEXTS structure.

Remarks

Miniport drivers must set the **ElementType** member of the NDIS_WWAN_PROVISIONED_CONTEXTS structure's **ContextListHeader** to **WwanStructContext**.

In some cases, the list of provisioned contexts is updated by the network either Over-The-Air (OTA) or by Short Message Service (SMS). The miniport driver must update the list of provisioned contexts accordingly. Thereafter, miniport drivers must notify the MB Service about the updates using this INDICATION with the updated list.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ndis.h

NDIS_STATUS_WWAN_RADIO_STATE

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_RADIO_STATE notification to inform the MB Service when the user changes the hardware radio power, or the device's software-based radio power state changes in response to an OID query or set request of OID_WWAN_RADIO_STATE.

Miniport drivers can also send unsolicited events with this notification.

This notification uses the **NDIS_WWAN_RADIO_STATE** structure.

Remarks

Miniport drivers should return both the current hardware-based and software-based radio power states in response to a query request

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ndis.h

NDIS_STATUS_WWAN_READY_INFO

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_READY_INFO notification to inform the MB Service of device ready-state changes in response to OID_WWAN_READY_INFO query requests.

Miniport drivers can also send unsolicited events with this notification.

This notification uses the **NDIS_WWAN_READY_INFO** structure.

Remarks

Miniport drivers must report all device ready-state changes as an unsolicited event. When the miniport driver initializes the MB device, the miniport driver must set the WWAN_READY_INFO **ReadyState** member to **WwanReadyStateOff**. Thereafter, miniport drivers must report any device ready-state change to the MB Service through this notification. For example, miniport drivers must report a device ready-state change when the **ReadyState** member changes from **WwanReadyStateOff** to **WwanReadyStateDeviceLocked**, or **WwanReadyStateBadSim**, or **WwanReadyStateSimNotInserted**, or any other different device ready-state.

Most device ready-state changes happen when the device initializes the radio stack and the SIM card (if required). A change can also happen during the course of a session between the MB Service and the miniport driver, such as user changing the SIM card. The behavior of the MB Service shall change accordingly based on the new device ready-state.

Requirements

Version	Available in Windows 7 and later versions of Windows.

NDIS_STATUS_WWAN_REGISTER_PARAMS_STATE

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_REGISTER_PARAMS_STATE notification to inform the MB Service about the 5G-specific registration parameters used by the MB device.

Drivers send an NDIS_STATUS_WWAN_REGISTER_PARAMS_STATE notification in response to an OID query or set request of OID_WWAN_REGISTER_PARAMS.

This notification uses the **NDIS_WWAN_REGISTER_PARAMS_INFO** structure which contains a **WWAN_REGISTRATION_PARAMS_INFO** structure.

Remarks

For more information see OID_WWAN_REGISTER_PARAMS.

Requirements

Requirement	Value
Minimum supported client	Windows 11
Version	Windows Server 2022. NDIS 6.84 and later.
Header	Ndis.h

See also

WWAN_REGISTRATION_PARAMS_INFO

OID_WWAN_REGISTER_PARAMS

NDIS_STATUS_WWAN_REGISTER_STATE

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_REGISTER_STATE notification to communicate changes to the MB device's registration state to the MB Service.

Miniport drivers can also send unsolicited events with this notification.

This notification uses the NDIS_WWAN_REGISTRATION_STATE structure.

Remarks

As the registration state of the device changes, the miniport driver must send appropriate indications so that the MB Service can reflect the correct state to the user.

Registration state changes due to a number of reasons. It may directly result from *set* requests from the MB Service for OID_WWAN_REGISTER_STATE such as a transient state transition from **WwanRegisterStateSearching** to **WwanRegisterStateHome**. It may also result from automatic operations by the miniport driver in the case of automatic provider selection. Finally, it may be caused by change of network availability, for example, losing network coverage may result in transition from **WwanRegisterStateHome** to **WwanRegisterStateDeregistered**.

Except for the changes caused by MB Service OID_WWAN_REGISTER_STATE requests, the miniport driver shall notify the MB Service whenever the registration state changes regardless of the underlying cause.

CDMA devices do not support the MB Service initiated registration and deregistration. However, a device initiated register state change notifications based on the availability or non-availability of the carrier network must be sent to the MB Service. CDMA devices must do automatic registration.

For devices that do automatic registration on power-up, irrespective of the current registration mode--auto or manual, the miniport driver must send the register state notification on successful registration.

For manual registration, the MB Service shall only initiate registration after the miniport driver indicates that **ReadyState** is **WwanReadyStateInitialized**.

Miniport driver must use the following guidelines while responding to *set* requests:

- Drivers must not respond with transient state for a *set* requests. Transient state for registration is **WwanRegisterStateSearching**.

- When **RegisterAction** is set to **WwanRegisterActionManual**, if the provider is not visible when the miniport driver receives the request, the miniport driver shall return error code WWAN_STATUS_PROVIDER_NOT_VISIBLE. The device must not switch to automatic registration because of a failure in setting the manual mode. If the device was earlier set to manually register to another network, this request should change the device to register to the network specified in the request. The value of **RegisterState** in response to the request should be set to **WwanRegisterStateDeregistered**.

- When **RegisterAction** is set to **WwanRegisterActionManual**, if the miniport driver has already registered with the same network that is been requested, it shall respond with WWAN_STATUS_SUCCESS.

- The driver should attempt to register to the requested data-class in the set OID_WWAN_REGISTER request. If the miniport driver cannot register to the requested data-class, it should register to the best possible data-class. This is also applicable when the device is already registered to a provider (automatic and manual registration mode) with some other data-class. Any change in the data-class should also result in NDIS_STATUS_WWAN_PACKET_SERVICE notification.

- When **RegisterAction** is set to **WwanRegisterActionManual**, and the Radio is OFF, the miniport driver must program the device to manual registration mode and complete the request with the transaction notification. The **RegisterState** should be set to **WwanRegisterStateDeregistered**. The device must attempt a manual registration when the Radio changes to ON state and the event notification must be sent.

- When **RegisterAction** is set to **WwanRegisterActionAutomatic**, and the Radio is OFF, the miniport driver must program the device to automatic registration mode and must complete the request with the transaction notification. The **RegisterState** should be set to **WwanRegisterStateDeregistered**. The device must do an automatic registration when the Radio goes to ON state and the event notification must be sent.

- In case of emergency state registration (**WwanRegisterStateDenied**), the **uStatus** should be set to WWAN_STATUS_SUCCESS and NDIS_STATUS_WWAN_READY_INFO notification must be sent with **EmergencyMode** set to **WwanEmergencyModeOn**.

- For using the state **WwanRegisterStateDeregistered** the miniport driver must use the following guidelines:

  - **WwanRegisterStateDeregistered** is used by the miniport drivers for notifying the MB Service that the Radio is OFF but the request for **RegisterAction** is completed.

  - **WwanRegisterStateDeregistered** is used by the miniport drivers for notifying the MB Service of a network initiated deregistration.

  - **WwanRegisterStateDeregistered** is used by the miniport drivers for notifying the MB Service of the lost connectivity to the network due to no network coverage.

- GSM and CDMA devices must send the register state notification to notify the availability or non-availability of the carrier for a PS connection. When the MB device detects the availability of the carrier network, it must send an event notification with one of the appropriate register states--**WwanRegisterStateHome**, **WwanRegisterStateRoaming**, or **WwanRegisterStatePartner**. On losing the carrier network signal, an event notification with **WwanRegisterStateDeregistered** must be indicated to the MB Service.

The miniport driver returns the query result according to the following rules:

- When the device is trying to lock on to a provider during registration, the miniport driver shall set **RegisterState** as **WwanRegisterStateSearching**. Both the **ProviderName** and **RoamingText** members should be set to **NULL**. In case of Manual register mode, **ProviderId** must be filled in with the ProviderId from the last manual registration set request. **ProviderId** can be set to **NULL** in case of automatic register mode.

- This is a transient state as the miniport driver will eventually move to a stable state at the end of registration, for example, **WwanRegisterStateHome**, **WwanRegisterStatePartner**, or **WwanRegisterStateRoaming** for a successful registration; or **WwanRegisterStateDenied** for an emergency state registration.

- If the device is not registered with any provider, the miniport driver shall return **WwanRegisterStateDeregistered**. Both the **ProviderName** and **RoamingText** members should be set to **NULL**. In case of Manual register mode, **ProviderId** must be filled in with the ProviderId from the last manual registration set request. **ProviderId** can be set to **NULL** in case of automatic register mode.

- If the device is registered with the home provider, the miniport driver shall set **RegisterState** as **WwanRegisterStateHome**. The **ProviderId** member shall be set to the home provider ID. The **ProviderName** must be set to the name of home provider network. The **RoamingText** member should be set to **NULL**.

- If the device is registered with a roaming provider, the miniport driver shall set **RegisterState** as **WwanRegisterStatePartner** if the provider is a preferred roaming partner or just **WwanRegisterStateRoaming** for a roaming partner, respectively. If the miniport driver does not distinguish the two, it shall set the value to **WwanRegisterStateRoaming**. The **ProviderId** member shall be set to the provider ID of the current provider the device is registered with and the **ProviderName** must be filled in with the current registered provider name. The **RoamingText** member should be set to some provider specific string value if exists or to **NULL** otherwise.

Requirements

Version	Available in Windows 7 and later versions of Windows.

OID_WWAN_SAR_CONFIG

NDIS_WWAN_SAR_CONFIG_INFO

NDIS_STATUS_WWAN_SAR_TRANSMISSION_STATUS

Article • 03/14/2023

Miniport drivers use the **NDIS_STATUS_WWAN_SAR_TRANSMISSION_STATUS** notification to inform the mobile broadband (MB) service about the completion of a previous OID_WWAN_SAR_TRANSMISSION_STATUS Query or Set request.

Unsolicited events are sent when there is a change to the active over-the-air (OTA) channels. For example, if a modem started uploading packet data, it would be required to set up uplink channels when it uses the network data channel so that it can upload payloads. This would trigger the notification to be provided to the operating system.

This notification uses the **NDIS_WWAN_SAR_TRANSMISSION_STATUS_INFO** structure.

Requirements

Version: Windows 10, version 1703 **Header**: Ntddndis.h (include Ndis.h)

See also

MB SAR Platform Support

NDIS_STATUS_WWAN_SET_HOME_PROVIDER_COMPLETE

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_SET_HOME_PROVIDER_COMPLETE notification to inform the MB Service about the completion of OID_WWAN_HOME_PROVIDER set requests.

This notification uses the **NDIS_WWAN_SET_HOME_PROVIDER** structure.

Requirements

Version	Supported starting with Windows 8.
Header	Ndis.h

NDIS_STATUS_WWAN_SERVICE_ACTIVATION

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_SERVICE_ACTIVATION notification to respond to OID set requests of OID_WWAN_SERVICE_ACTIVATION.

Miniport drivers cannot use this notification to send unsolicited events.

This notification uses the NDIS_WWAN_SERVICE_ACTIVATION_STATUS structure.

Remarks

Miniport drivers must return the service activation status in response to an OID set request of OID_WWAN_SERVICE_ACTIVATION.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ndis.h

NDIS_STATUS_WWAN_SIGNAL_STATE

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_SIGNAL_STATE notification to send a signal strength notification when measured signal strength travels outside the threshold within a pre-defined interval.

Miniport drivers can also send unsolicited events with this notification.

This notification uses the NDIS_WWAN_SIGNAL_STATE structure.

Remarks

By default, miniport drivers must notify the MB Service if the Rssi value changes by at least +/-5 decibels from the last reported value, or at a maximum frequency of one indication every 5 seconds. The threshold value is specified in the **SignalState.RssiThreshold** member of the NDIS_WWAN_SIGNAL_STATE structure; while the maximum frequency value is specified in the **SignalState.RssiInterval** member.

The **DeviceCaps.WwanCellularClass** member of the NDIS_WWAN_DEVICE_CAPS structure controls how the Rssi value will be interpreted by the MB Service. If **WwanCellularClass** is **WwanCellularClassGSM**, Rssi is reported as decibels above the device's sensitivity noise floor. If **WwanCellularClass** is **WwanCellularClassCDMA**, Rssi is reported as compensated RSSI (accounts for noise).

Applications should never poll for signal strength. Only in special situations, such as startup, an application might use a *query* request to obtain signal strength.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ndis.h

NDIS_STATUS_WWAN_SMS_CONFIGURATION

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_SMS_CONFIGURATION notification to inform the MB Service about either the completion of a previous OID_WWAN_SMS_CONFIGURATION query or set request, or an event notification in the case of change in SMS configuration.

Miniport drivers can also send unsolicited events with this notification.

This notification uses the **NDIS_WWAN_SMS_CONFIGURATION** structure.

Remarks

The miniport driver must send this unsolicited indication when the MB device's SMS subsystem is ready for SMS operation.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ndis.h

OID_WWAN_SMS_CONFIGURATION

NDIS_WWAN_SMS_CONFIGURATION

NDIS_STATUS_WWAN_SMS_DELETE

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_SMS_DELETE notification to inform the MB Service about the completion of a previous delete request through OID_WWAN_SMS_DELETE.

Miniport drivers cannot use this notification to send unsolicited events.

This notification uses the **NDIS_WWAN_SMS_DELETE_STATUS** structure.

Remarks

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ndis.h

See also

OID_WWAN_SMS_DELETE

NDIS_WWAN_SMS_DELETE_STATUS

NDIS_STATUS_WWAN_SMS_RECEIVE

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_SMS_RECEIVE notification to inform the MB Service about either the completion of a previous read request through a OID_WWAN_SMS_READ query request, or the arrival of a new class-0 (flash/alert) message from the network provider as an event notification.

Miniport drivers can also send unsolicited events with this notification.

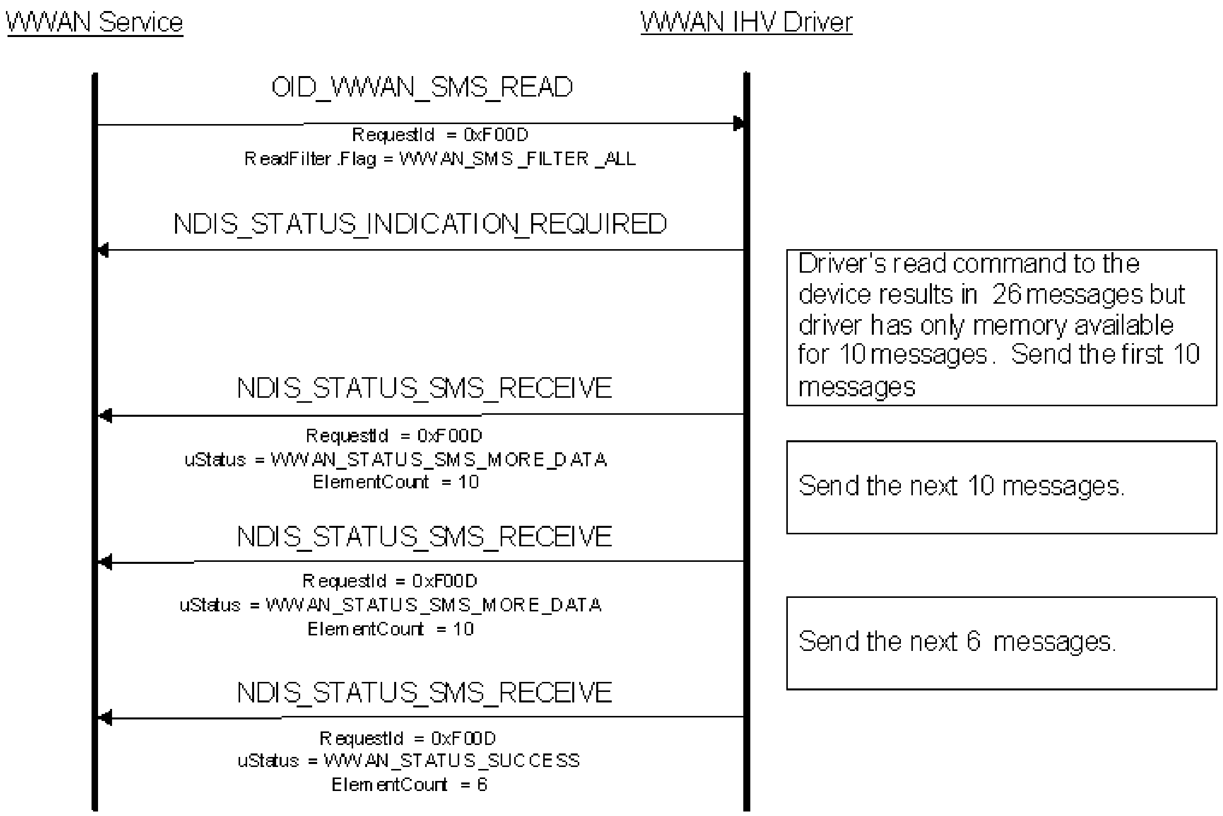
This notification uses the **NDIS_WWAN_SMS_RECEIVE** structure.

Remarks

RequestId is set to "0" by the miniport driver to indicate the arrival of the new class-0 (flash/alert) message. Arrival of new class-0 (flash/alert) messages is dependent on the current network registration state.

If the request for read results in retrieval of large number of SMS records that can't be accommodated in a pre-allocated buffer of miniport driver, then the SMS records can be sent to the MB Service in multiple indications. The uStatus in this case must be set to WWAN_STATUS_SMS_MORE_DATA for the intermediate transactions and the final transaction must end with WWAN_STATUS_SUCCESS.

The following diagram represents the usage of the multiple indication method for large number of SMS record retrieval:



Driver's read command to the device results in 26 messages but driver has only memory available for 10 messages. Send the first 10 messages

Send the next 10 messages.

Send the next 6 messages.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ndis.h

NDIS_STATUS_WWAN_SMS_SEND

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_SMS_SEND notification to inform the MB Service about the completion of a previous send request through OID_WWAN_SMS_SEND.

Miniport drivers cannot use this notification to send unsolicited events.

This notification uses the **NDIS_WWAN_SMS_SEND_STATUS** structure.

Remarks

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ndis.h

See also

OID_WWAN_SMS_SEND

NDIS_WWAN_SMS_SEND_STATUS

NDIS_STATUS_WWAN_SMS_STATUS

Article • 03/14/2023

Miniport drivers use the NDIS_STATUS_WWAN_SMS_STATUS notification to inform the MB Service about the following events:

- The MB device's message store is full.
- A new SMS text message has arrived, with the new message corresponding to *MessageIndex*.

Miniport drivers can also send unsolicited events with this notification.

This notification uses the NDIS_WWAN_SMS_STATUS structure.

Remarks

Miniport drivers must use NDIS_STATUS_WWAN_SMS_STATUS to inform the MB Service about the arrival of all non-class-0 (flash/alert) messages. To inform the MB Service about class-0 (flash/alert) message arrival, miniport drivers must use NDIS_STATUS_WWAN_SMS_RECEIVE.

This indication could be a transactional notification for a *query* request of OID_WWAN_SMS_STATUS or an unsolicited event.

Requirements

Version	Available in Windows 7 and later versions of Windows.
Header	Ndis.h

HOST Shutdown Device Service

Article • 12/15/2021

This topic provides guidelines for Mobile Broadband Interface Model (MBIM)-compliant devices to implement and report the described device service when queried by CID_MBIM_DEVICE_SERVICES.

The information in this topic applies to Windows 8 and later.

Microsoft Host Shutdown

The MBIM-compliant device implements and reports the following device service when queried by CID_MBIM_DEVICE_SERVICES. The existing well-known services are defined in section 10.1 of the USB NCM Mobile Broadband Interface Model (MBIM) V1.0 specification. Microsoft extends this to define the following service.

Service Name = **Microsoft Host Shutdown**

UUID = **UUID_MS_HOSTSHUTDOWN**

UUID Value = **883b7c26-985f-43fa-9804-27d7fb80959c**

Defined CIDs for UUID_MS_HOSTSHUTDOWN device service

CID	Minimum OS version
CID_MBIM_MSHOSTSHUTDOWN	Windows 8
CID_MBIM_MSHOSTPRESHUTDOWN	Windows 10, version 1511

CID_MBIM_MSHOSTSHUTDOWN

This command informs the device that the host is shutting down. The MB device may lose power.

CID: CID_MBIM_MSHOSTSHUTDOWN

Command Code: 1

Set: Yes

Query: No

Event: No

Set InformationBuffer payload: N/A

Query InformationBuffer payload: N/A

Completion InformationBuffer payload: N/A

Set: InformationBuffer on MBIM_COMMAND_MSG not used. InformationBuffer of MBIM_COMMAND_DONE not used.

Query: Unsupported

Unsolicited Event: Unsupported

Remarks

The Mobile Broadband Class Driver sends the host shutdown notification to mobile broadband devices supporting this device service, on each host state transition into S4 and S5 states.

This notification is to provide mobile broadband devices with an early indication to allow them to initiate a mobile network deregister message and initiate SIM electrical de-initialization.

The following information summarizes the list of host sent CIDs/CMDs to the device for various system transitions and device power state transitions:

- MSHOSTSHUTDOWN CID is sent to the device on host state transitioning into S4 and S5.
- MBIM_CMD_CLOSE is sent to the device when host puts the device into D3 mode.

	S0	S1/S2/S3	S4	S5
D0	MBIM_CMD_OPEN	N/A	N/A	N/A
D1	N/A	N/A	N/A	N/A
D2	N/A	N/A	N/A	N/A
D3	N/A	MBIM_CMD_CLOSE	MSHOSTSHUTDOWN	MSHOSTSHUTDOWN

CID_MBIM_MSHOSTPRESHUTDOWN

This command notifies the MBIM modem that the system is undergoing pre-shutdown and it should finish all its operations, deregister from the network, and store necessary information to the host for flashless modem cases. The pre-shutdown notification is sent down when the host is preparing to enter S4 and S5 states and is waiting for all services to shut down appropriately.

CID: CID_MBIM_MSHOSTPRESHUTDOWN

Command Code: 2

Set: Yes

Query: No

Notification: No

Set InformationBuffer payload: N/A

Query InformationBuffer payload: N/A

Completion InformationBuffer payload: N/A

Parameters:

	Set	Query	Notification
Command	CID_MBIM_SET_MSHOSTPRESHUTDOWN	N/A	N/A
Response	Empty	N/A	N/A

For the Set operation, InformationBuffer and InformationBufferLength are empty.

Status Codes:

Status code	Description
MBIM_STATUS_SUCCESS	Pre-shutdown operations completed by the modem.
MBIM_STATUS_NO_DEVICE_SUPPORT	The device does not support pre-shutdown and no pre-shutdown operations are needed.

IHV Guidance for Implementing Multimode and Multicarrier Capable MB Devices

Article • 12/15/2021

This topic provides information about implementing support for multiple Radio Access Technologies (RAT) and multiple operators in Windows. It supplements the USB NCM Mobile Broadband Interface Model (MBIM) V1.0 specification that outlines the CIDs required for supporting the multimode multicarrier scenario.

The information in this topic applies to:

- Windows 8

Supporting multimode devices with firmware switching

This topic provides guidance to IHVs for implementing support for multiple Radio Access Technologies (RAT) and multiple operators in Windows. A short summary of the most relevant sections of the spec is provided below.

A multimode network has multiple RATs or cellular classes. A multicarrier device is able to support multiple network providers within the same device. One of the many networks supported can be a multimode network.

In many places in this document it is required that multicarrier providers reported by a multicarrier device as part of CID processing must be set-able as home providers. This section describes how to determine if a provider is settable as a home provider. The ability to set a provider as a home provider may depend on many factors that are device dependent such as being visible, having firmware support for the provider, and having a SIM or equivalent to register with the provider. There may be additional factors. The device should ensure that the device requirements are met for a multicarrier provider before reporting it as a settable home provider

10.4.1 CID_MBIM_DEVICE_CAPS

The capable device will report multiple supported cellular classes in bmCellularClass of MBIM_DEVICE_CAPS as specified in Table 10-13 of the specification. It will also report support for multiple carriers via the MBIMCtrlCapsMultiCarrier Mask in MBIM_CTRL_CAPS (Table 10-13).

Single-carrier multi-mode devices must behave like GSM devices. Such devices must not set any CDMA related capabilities in their MBIM_DEVICE_CAPS_INFO.

10.4.6 CID_MBIM_HOME_PROVIDER

The home provider can be set as specified in **10.3.6.4.**

10.4.8 CID_MBIM_VISIBLE_PROVIDERS

The visible providers CID contain an Action field that specifies whether the host is expecting:

1. Value 0, where device performs a full scan in the context of current home provider.
2. Value 1, where device is being queried to locate visible multicarrier providers that are settable as home providers. The device may choose to accomplish this via a full scan, partial scan, or static list. The multicarrier preferred providers should be tagged as MBIM_PROVIDER_STATE_PREFERRED_MULTICARRIER in the visible providers result as specified in Table 10-34 of the specification.

When devices report a static list of visible multicarrier providers based on location information, programmed using CID_MBIM_LOCATION_INFO, the list should only contain providers valid for that location. As an extension of the above rule, devices should not report the currently registered provider if the location represented by its MCC (Mobile Country Code) is different than the location currently programmed in the device.

10.4.9 CID_MBIM_REGISTER_STATE

The device indicates the current cellular class using the dwCurrentCellularClass field of MBIM_REGISTRATION_STATE in Table 10-48 of the specification.

10.4.30 CID_MBIM_DEVICE_SERVICES

Multicarrier devices are required to report the UUID_MULTICARRIER (described below) device service in response to this CID.

Single-carrier multimode devices are not required to report UUID_MULTICARRIER device service in response to this CID.

10.4.39 CID_MBIM_MULTICARRIER_PROVIDERS

The device uses this CID to report the current and previously added preferred multicarrier providers. This CID is supported when device supports MBIMCtrlCapsMultiCarrier. When the host sets a multicarrier preferred provider, it is not required that the provider is settable as home provider. But when the list is queried by the host, the device should only return multicarrier preferred providers that are settable as home providers.

The following figure provides a sequence diagram of the steps involved in switching a device from its current mode based on a location hint specified by the host. The operation requires the use of a device service described below to get/set additional information from the device. One specific requirement is that the device should ensure that the host has had a chance to recover the pending notification from the device prior to it falling off the bus. The diagram also specifies the time bounds and performance expectations of the various operations.

MULTI-CARRIER DEVICE SERVICE

The IHV device will implement and report the following device service when queried by CID_MBIM_DEVICE_SERVICES. The existing well-known services are defined in the NCM MBIM spec in section 10.1. It is extended it to define the following service.

Service Name	UUID	UUID Value
Multi-carrier	UUID_MULTICARRIER	8b569648- 628d-4653-9b9f- 1025404424e1

Specifically, the following CIDs are defined for UUID_MULTICARRIER device service.

CID	Command Code	Query	Set	Event	Set InformationBuffer payload	Query InformationBuffer payload	Completion InformationBuff
CID_MBIM_MULTICARRIER_CAPABILITIES	1	Y	N	N	N/A	N/A	MBIM_MULTICARRIER_CAPABIL

CID	Command Code	Query	Set	Event	Set InformationBuffer payload	Query InformationBuffer payload	Completion InformationBuff
CID_MBIM_LOCATION_INFO	2	Y	Y	N	MBIM_LOCATION_INFO	N/A	MBIM_LOCATION_INFO
CID_MBIM_MULTICARRIER_CURRENT_CID_LIST	3	Y	N	N	N/A	UUID	MBIM_MULTICARRIERMODE_C

CID_MBIM_MULTICARRIER_CAPABILITIES

The command returns information about a MB device's multi-carrier capabilities. A device that requires a firmware reboot, and correspondingly a device removal/arrival should provide the host with a hint using the appropriate flag to enable the host to provide the appropriate user experience.

Query = **InformationBuffer on MBIM_COMMAND_MSG not used. MBIM_MULTICARRIER_CAPABILITIES returned in InformationBuffer MBIM_COMMAND_DONE**

Set = **Unsupported**

Unsolicited Event = **Unsupported**

MBIM_MC_FLAGS_NONE	0h	No flags set
MBIM_MC_FLAGS_STATIC_SCAN	1h	Indicates that the results reported for visible providers in scan results aren’t obtained from a full network scan. The result may be obtained from a hardcoded list.
MBIM_MC_FLAGS_¬¬FW_REQUIRES_REBOOT	2h	Indicates that the device requires powering cycle and rebooting to switch firmware.

Offset	Size	Field	Description
0	4	dwCapabilities	Returns the capabilities from MBIM_MULTICARRIER_FLAGS

CID_MBIM_LOCATION_INFO

The command is used to set/query the current location information of the host. This is useful to the device if it needs to filter the list of static (no physical scan) visible providers to the ones relevant to the current user location.

Query = **InformationBuffer on MBIM_COMMAND_MSG not used. MBIM_LOCATION_INFO returned in InformationBuffer MBIM_COMMAND_DONE**

Set = **InformationBuffer on MBIM_COMMAND_MSG contains MBIM_LOCATION_INFO**

Unsolicited Event = **Unsupported**

The country code specified by the host will be based on the Geographical Location GEOID available on Windows. For more information, see Table of Geographical Locations (Windows).

Offset	Size	Field	Description
0	4	Country	Geographical Location based on GEOID.

CID_MBIM_MULTICARRIER_CURRENT_CID_LIST

This command is used to query the CIDs currently supposed by a device service.

Query = **InformationBuffer on MBIM_COMMAND_MSG is a UUID for the device service. MBIM_MULTICARRIERMODE_CURRENT_CID_LIST returned in InformationBuffer MBIM_COMMAND_DONE**

Set = **Unsupported**

Unsolicited Event = **Unsupported**

Offset	Size	Field	Type	Description
0	4	CidCount	UINT32	Number of CIDs supported for this device service.
4		DataBuffer	DATABUFFER	CidList: List of CIDs supported for this device service. There must be CID Count number of entries in this list. Each CID is of type UINT32.

Mobile Broadband Device Firmware Update

Article • 09/27/2024

This article provides guidance to Mobile Broadband (MB) module manufacturers intending to support firmware upgrade devices via Windows Update (WU). The devices must be compliant with the USB NCM Mobile Broadband Interface Model (MBIM) V1.0 specification released by the USB-IF Device Working Group.

The information in this article applies to:

- Windows 8/Windows 10/Windows 11

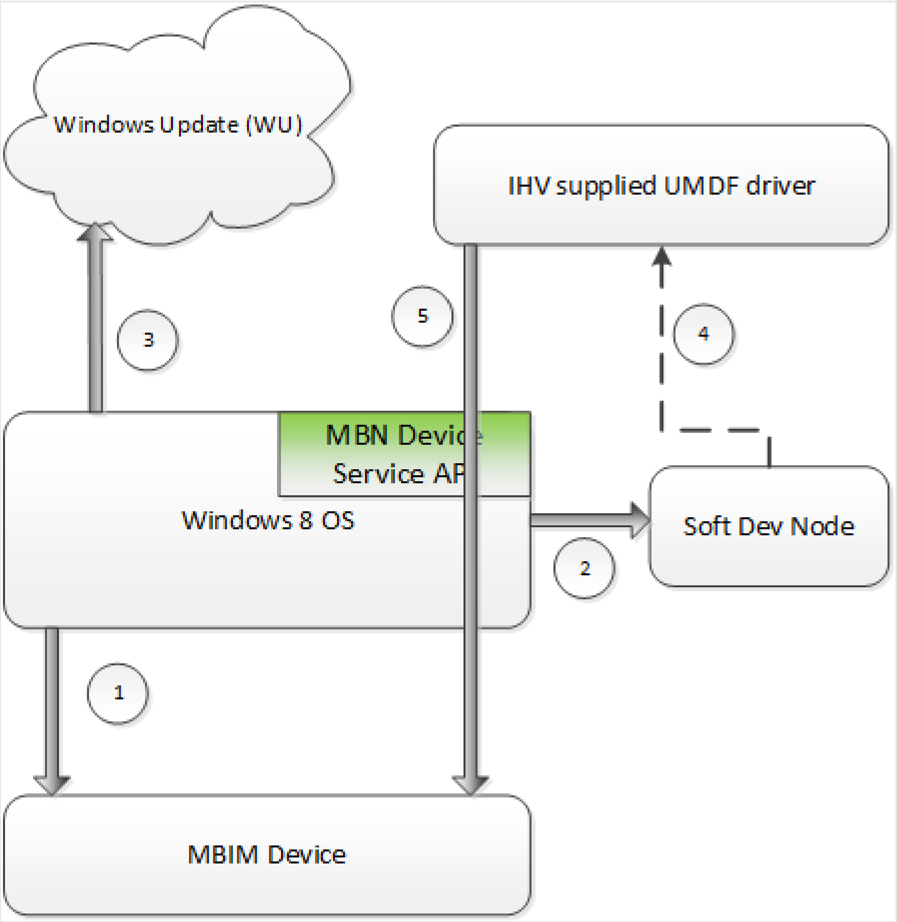
Device Requirements

To support firmware updates on Mobile Broadband using Windows Update, module or device manufacturers need to comply with the following requirements:

- UMDF (User Mode Driver Framework) based driver developed by the module or device manufacturer, packaged along with the INF file and firmware payload. Sample INF file and details are provided in the later part of this document
- Device firmware to implement the following functionalities:
  - Firmware ID Device Service (FID). For more information, see **FID Device Service**.
  - Firmware to support a firmware update device service. This is a device manufacturer specific device service that enables a UMDF driver to call into and execute/download the firmware payload and start the firmware update process.

Operational Overview

The following diagram shows the high level design and interaction between the three components involved: MBIM device, Windows 8 Operating System and IHV supplied firmware upgrade driver.



- When the WWAN Service detects the arrival of new MB device, it checks if device support Firmware ID (FID) Device Service. If it's present, it retrieves the FID, which is defined to be GUID. The Firmware Device Service specification that the IHV needs to the support on the device is described **below**.
- WWAN Service (Windows OS) generates “soft device-node” using the FID obtained above as the device hardware Id. This referred to as “Soft Dev Node” in the diagram above. The creation of the dev-node will kick start PnP subsystem (Windows OS) to find the best matched driver. In Windows 8, PnP system will first attempt to install a driver from the local store, if one is available, and in parallel OS will attempt to fetch a better matched driver from WU. The inbox NULL driver will used be used as default if better match driver isn't available to eliminate “Driver Not Found” issue.
- The IHV WU package, based on the FID match, is pulled down to the machine and installed. It's expected that the FID represents a unique firmware SKU (uniqueness here's defined by combination device VID/PID/REV and MNO). WU package would contain an IHV authored UMDF driver as well as a firmware payload.
- Once the IHV UMDF is loaded on the soft dev-node it's responsible for controlling the firmware update flow. It should be noted that the life time of the soft dev-node is tied to physical presence of the MBIM device. The UMDF driver shall perform the following steps to performing firmware updates
  - It's acceptable for the device to reboot multiple times during the firmware update process, but would cause the UMDF driver to get unloaded/reloaded

  - The entire firmware upgrade process, including reboots, should take place no more than 60 seconds.
  - After the firmware update is completed and device has reverted to MBIM mode, Windows should be notified. This is done by clearing the previously set DEVPKEY_Device_PostInstallInProgress property. The **IWDFUnifiedPropertyStore** interface describes how to set a property on dev-node. A previously set property can be cleared using DEVPROP_TYPE_EMPTY.
  - During OnPrepareHardware UMDF callback, the UMDF driver shall check if the firmware on the device needs to be updated. This is done by comparing the version of the firmware on the device against the one that came in via Windows Update. Additional guidance is provided later in the document regarding placement location of firmware binary. If firmware update is required, the UMDF driver should:
    - Schedule a work-item. The actual firmware upgrade happens in the context of the work-item.
    - Once the work-item is successfully scheduled, notify Windows about the start of firmware update. It's done by setting the DEVPKEY_Device_PostInstallInProgress property on the soft dev-node in the context of OnPrepareHardware UMDF callback.
    - It's important not to block the OnPrepareHardware callback while the firmware update is in progress. It's expected that OnPrepareHardware callback is completed within a second or two at the most.

Sample INF file for the WU Package

This section provides a sample INF that is part of the WU package. The key points to note in INF file are:

- The firmware binaries are independent of the UMDF driver.
- The firmware binaries are located in the driverstore directory, a path determined by the operating system and referenced in the INF using DIRID 13. The binaries can't be executable files containing PE/COFF headers.
- `%13%\<UniqueBinaryName>.bin`
- The INF file stores this location in the registry and the UMDF driver reads the registry value to discover the binary location.
- The following sample INF template highlights items that need to be filled by the IHV.

Firmware Identification Device Service (FID Device Service)

The MBIM compliant device will implement and report the following device service when queried by CID_MBIM_DEVICE_SERVICES. The existing well-known services are defined in the NCM MBIM spec in section 10.1. Microsoft Corporation extends this to define the following service.

Service Name = **Microsoft Firmware ID**

UUID = **UUID_MSFWID UUID**

Value = **e9f7dea2-feaf-4009-93ce-90a3694103b6**

Specifically, the following CID is defined for UUID_MSFWID device service:

CID = **CID_MBIM_MSFWID_FIRMWAREID**

Command Code = **1**

Query = **Yes**

Set = **No**

Event = **No**

Set InformationBuffer payload = **N/A**

Query InformationBuffer payload = **N/A**

Completion InformationBuffer payload = **UUID**

CID_MBIM_MSFWID_FIRMWAREID

The command returns the MNO or IHV assigned Firmware ID for the device. The UUID is encoded based on the guidelines in the MBIM specification.

Query = **InformationBuffer on MBIM_COMMAND_MSG not used. UUID returned in InformationBuffer MBIM_COMMAND_DONE.**

Set = **Unsupported**

Unsolicited Event = **Unsupported**

Code snippets for behavior of UMDF driver

As indicated earlier, the UMDF driver should indicate to the Windows when it starts and completes firmware upgrade. This section provides code snippets that show how the driver should notify Windows of these events.

C++

```
/**
 * This is the IPnpCallbackHardware*:OnPrepareHardware handler
 * in the UMDF driver. This is called every time the firmware
 * update is device is started. Since this handler should be
 * blocked from returning actual the firmware update process
 * should be done in a workitem
 */
HRESULT
CMyDevice::OnPrepareHardware(IWDFDevice* pDevice)
{
    HRESULT hr = S_OK;
    BOOL bFirmwareUpdateInProgress = FALSE;
    BOOL bFirmwareUpdateNeeded = FALSE;
    BOOL bFirmwareUpdateIsDone = FALSE;

    //
    // The snippets below demonstrates the steps for firmware
    // update against a MB device that loads the updated firmware
    // on device boot. So the firmware update driver needs to
    // send the new firmware down to the device and then tell
    // the device to initiate a stop/start. Once the device has
    // reappeared, it would have automatically loaded the
    // new firmware
    //

    //
    // First, determine if firmware update is in progress. This
    // can be based on some registry key that is saved when
    // firmware update is started
    //
```

```
        // Assuming this status is returned in bFirmwareUpdateInProgress
        if (bFirmwareUpdateInProgress)
        {
            //
            // If firmware update is in progress, check if its done. For
            // this it may be necessary to access the MB device. Note that
            // if the MB device (& hence the Firmware update device) needs
            // multiple stop/starts to do the firmware update. In that case
            // it will be marked as done at the end of the process
            //

            // Assuming this status is returned in bFirmwareUpdateIsDone
            if (bFirmwareUpdateIsDone)
            {
                //
                // Signal the completion of the firmware update
                // process.
                //
                SignalFirmwareUpdateComplete(pDevice);
            }

Mobile Broadband Implementation Guidelines for USB Devices

Article • 12/15/2021

This topic provides specific implementation guidance to help mobile broadband device manufacturers produce compliant USB devices for Windows. It should be used in conjunction with the USB NCM Mobile Broadband Interface Model (MBIM) V1.0 specification released by the USB-IF Device Working Group.

The information in this topic applies to:

- Windows 8
- Windows 8.1

Delaying MBIM Open

MBIM devices may require time to complete initialization when they receive MBIM OPEN message from the host. The device should wait for its initialization to complete before responding to the MBIM OPEN message. The device should not respond to the message with error status like MBIM_STATUS_BUSY and expect the host to poll the device with MBIM OPEN messages. Responding to MBIM OPEN with a status other than MBIM_STATUS_SUCCESS terminates the initialization process on the host.

Multi-carrier\Multi-subscription

Please refer to **IHV Guidance for Implementing Multimode- and Multicarrier- Capable MB Devices** for details.

MBIM_CID_HOME_PROVIDER

MBIM devices must not fail a SET MBIM_CID_HOME_PROVIDER request with the following listed status codes under the mentioned circumstances. The following statuses are valid for the QUERY MBIM_CID_HOME_PROVIDER request but are not applicable for a SET request.

- **MBIM_STATUS_SIM_NOT_INSERTED** - MBIM devices must not fail a SET MBIM_CID_HOME_PROVIDER request with status as MBIM_STATUS_SIM_NOT_INSERTED if the SIM for the new home provider is present but the SIM for the old home provider is not inserted.

- **MBIM_STATUS_BAD_SIM** - MBIM devices must not fail SET MBIM_CID_HOME_PROVIDER request with MBIM_STATUS_BAD_SIM if the SIM for the new home provider is good but the SIM for the old home provider is not bad.
- **MBIM_STATUS_PIN_REQUIRED** - MBIM devices must not fail SET MBIM_CID_HOME_PROVIDER request with MBIM_STATUS_PIN_REQUIRED regardless of whether the old or new SIM is pin locked.

MBIM_CID_VISIBLE_PROVIDERS

- **MBIM_STATUS_SIM_NOT_INSERTED** - When MBIM_VISIBLE_PROVIDERS_ACTION is set to MBIMVisibleProvidersActionRestrictedScan the MBIM device must not fail MBIM_CID_VISIBLE_PROVIDERS request with MBIM_STATUS_SIM_NOT_INSERTED because the SIM for the current home provider is not present.
- **MBIM_STATUS_PIN_REQUIRED** - When MBIM_VISIBLE_PROVIDERS_ACTION is set to MBIMVisibleProvidersActionRestrictedScan the MBIM device must not fail MBIM_CID_VISIBLE_PROVIDERS request with MBIM_STATUS_PIN_REQUIRED because the SIM for the current home provider is PIN locked.

Responding to Pin Operations

MBIM devices must follow these guidelines when responding to **MBIMPinOperationEnter** requests:

- For successful **MBIMPinOperationEnter** requests, when the device no longer requires a PIN, the device must set status to MBIM_STATUS_SUCCESS and **MBIM_PIN_INFO::Pin Type** to **MBIMPinTypeNone.**

- The device must set status to MBIM_STATUS_SUCCESS for PIN-enable and PIN-disable operations when the PIN is already in the requested state. The device must set **MBIM_PIN_INFO::PinType** to **MBIMPinTypeNone**. Other members are ignored.

- When a PIN mode is changed from Disabled to Enabled, the PIN state should be **MBIMPinStateUnlocked**.

- If PIN1 is enabled, the PIN state becomes **MBIMPinStateLocked** when the device is power cycled.

- For all other PINs, the PIN state can change from **MBIMPinStateUnlocked** to **MBIMPinStateLocked** depending on mobile broadband device specific conditions.

- PIN Not Supported: If a PIN operation is not supported by the device, the device must set status to MBIM_STATUS_NO_DEVICE_SUPPORT. For example, enabling and disabling PIN2 is not typically supported by mobile broadband devices so the above error code must be returned. All other members are ignored.

- PIN Must be Entered: If a PIN operation requires a PIN to be entered, the device must set status to MBIM_STATUS_PIN_REQUIRED and **MBIM_PIN_INFO::PinType** to **MBIMPinTypeXxx**. Other members are ignored.

- PIN Change Operation: If the device restricts the change of PIN value only when it is in enabled state, a request to change in disabled state must be returned with MBIM_STATUS_PIN_DISABLED.

- PIN Retrial: On failure, the device must set status to MBIM_STATUS_FAILURE, and **MBIM_PIN_INFO::PinType** to the same value as specified in **MBIM_SET_PIN**. Other members are ignored except for **MBIM_PIN_INFO::RemainingAttempts**. This may occur when an incorrect PIN is entered.

- PIN Blocking: The PIN is blocked when the number of **MBIM_PIN_INFO::RemainingAttempts** is zero. If the PIN unblock operation is not available, the device must set status to MBIM_STATUS_FAILURE and **MBIM_PIN_INFO::PinType** to **MBIMPinTypeNone**. **MBIM_PIN_INFO::RemainingAttempts** should be set to 0 and all the other members are ignored. **Note** If the device supports PIN unblock operations, the device should follow the PIN Unblocking step to respond to the request.

- Unblocking PIN: The PIN is blocked when **MBIM_PIN_INFO::RemainingAttempts** is zero. To unblock the PIN, the device may request a corresponding PUK, if applicable. In this case, the device must set status to MBIM_STATUS_FAILURE, **MBIM_PIN_INFO::PinType** to the corresponding **MBIMPinTypeXxxPUK**, **PinState** to **MBIMPinStateLocked**, and **MBIM_PIN_INFO::RemainingAttempts** should have the number of attempts allowed to enter a valid PUK.

- If PIN blocking results in the device or SIM becomes blocked, the device must send a MBIM_CID_SUBSCRIBER_READY_STATUS notification with **ReadyState** set to **MBIMSubscriberReadyStateDeviceLocked.**

- If there is an active PDP context at the time of PIN1 blocking, the device must deactivate the PDP context and send notifications to the operating system about the PDP deactivation and link state change.

- For successful requests, the device must set status to MBIM_STATUS_SUCCESS. Other members are ignored.

- For failed **MBIMPinOperationEnter** requests, the device must set status to MBIM_STATUS_FAILURE and include applicable data as per the following details:

- PIN Disabled or PIN Not Expected: For MBIMPinOperationEnter set requests, when the corresponding PIN is either disabled or currently not expected by the device, the device must set **MBIM_PIN_INFO::PinType** to **MBIMPinTypeNone**. All other members are ignored.

- PIN Not Supported: If the given PIN is not supported by the device, the device must set status to MBIM_STATUS_NO_DEVICE_SUPPORT.

- PIN Retrial: In this mode, the device requires the PIN to be re-entered as the **MBIM_PIN_INFO::RemainingAttempts** value is still non-zero for this particular type of PIN. The device must set **MBIM_PIN_INFO::PinType** to the same value as that of **MBIM_PIN_INFO::PinType** in **MBIM_SET_PIN**.

- PIN Blocking: The PIN is blocked when **MBIM_PIN_INFO::RemainingAttempts** is zero. If the PIN unblock operation is not available, the device must set status to MBIM_STATUS_FAILURE and **MBIM_PIN_INFO::PinType** to **MBIMPinTypeNone**. All the other members are ignored. **Note** If the device supports PIN unblock operations, the device should follow the PIN Unblocking step to respond to the request.

- PIN Unblocking: The PIN is blocked when **MBIM_PIN_INFO::RemainingAttempts** is zero. To unblock the PIN, the device may request a corresponding PIN Unlock Key (PUK), if applicable. In this case, the device must set **MBIM_PIN_INFO::PinType** to the corresponding **MBIMPinTypeXxxPUK** with the relevant details.

- Blocked PUK: If the number of failed trials exceeds the preset value for entering the **MBIMPinTypeXxxPUK**, then the PUK becomes blocked. The device must signal this by setting status to MBIM_STATUS_FAILURE and **MBIM_PIN_INFO::PinType** to **MBIMPinTypeNone**. In case PUK1 is blocked, the device must send a MBIM_CID_SUBSCRIBER_READY_STATUS with **ReadyState** set to **MBIMSubscriberReadyStateBadSim**.

- MBIM devices must follow these guidelines when responding to **MBIMPinOperationEnable**, **MBIMPinOperationDisable**, or **MBIMPinOperationChange** requests.

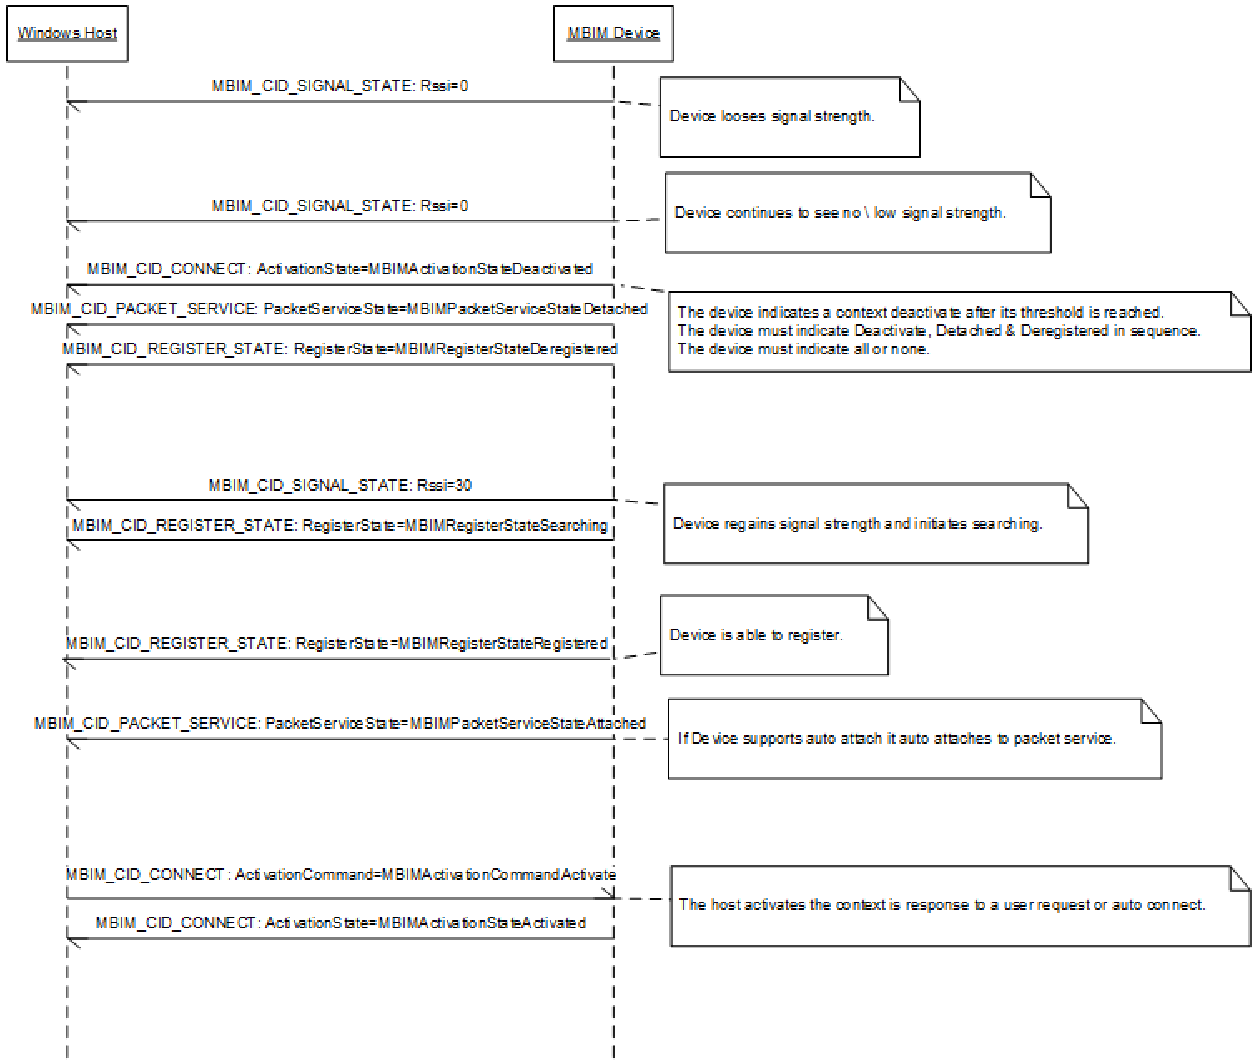
Auto Packet Service Attach

MBIM devices that support Auto Packet Service Attach manage the attachment and detachment of packet service from the mobile network at their discretion. The host may still send an attach request to such a device on user request. When the device receives the attach request from the host it should handle as follows:

- If the device is not attached and not in the middle of an attach operation and is capable of attaching then it should initiate a new attach procedure with the mobile network.
- If the device is not attached but in the middle of an auto attach operation then it should wait for the auto attach operation to complete and complete the attach request from the host with the status of the auto attach operation.
- If the device is already attached then it should complete the attach request from the host successfully.

Signal Strength Loss and Data Connection Loss

When a device loses signal strength the device must indicate **MBIMActivationStateDeactivated** followed by **MBIMPacketServiceStateDetached** followed by **MBIMRegisterStateDeregistered** in that order. If the device loses packet service while it is context activated the device must indicate **MBIMActivationStateDeactivated** followed by **MBIMPacketServiceStateDetached** in that order. The following sequence diagram shows the interaction between the host and the device.



Windows Host
MBIM Device
MBIM_CID_SIGNAL_STATE: Rssi=0
Device looses signal strength.
MBIM_CID_SIGNAL_STATE: Rssi=0
Device continues to see no \ low signal strength.
MBIM_CID_CONNECT: ActivationState=MBIMActivationStateDeactivated
MBIM_CID_PACKET_SERVICE: PacketServiceState=MBIMPacketServiceStateDetached
MBIM_CID_REGISTER_STATE: RegisterState=MBIMRegisterStateDeregistered
The device indicates a context deactivate after its threshold is reached.
The device must indicate Deactivate, Detached & Deregistered in sequence.
The device must indicate all or none.
MBIM_CID_SIGNAL_STATE: Rssi=30
MBIM_CID_REGISTER_STATE: RegisterState=MBIMRegisterStateSearching
Device regains signal strength and initiates searching.
Device is able to register.
MBIM_CID_REGISTER_STATE: RegisterState=MBIMRegisterStateRegistered
MBIM_CID_PACKET_SERVICE: PacketServiceState=MBIMPacketServiceStateAttached
If Device supports auto attach it auto attaches to packet service.
MBIM_CID_CONNECT: ActivationCommand=MBIMActivationCommandActivate
The host activates the context is response to a user request or auto connect.
MBIM_CID_CONNECT: ActivationState=MBIMActivationStateActivated

DNS Server Information

When Basic IP information (as defined in MBIM section 10.5.20.1) is provided via MBIM_CID_IP_CONFIGURATION, DNS server information (as defined in MBIM section 10.5.20.1) can also be provided via MBIM_CID_IP_CONFIGURATION. When DNS server information is updated, MBIM_CID_IP_CONFIGURAITON must have the complete Basic IP information obtained before. DNS server information can be provided solely via MBIM_CID_IP_CONFIGURATION even if the Basic IP information is not provided via MBIM_CID_IP_CONFIGURATION. This applies to both IPv4 and IPv6.

IPv6

For basic IP information (as defined in MBIM section 10.5.20.1), the expected IP Layer configuration mechanism is from router advertisement (RA). For DNS server information (as defined in MBIM section 10.5.20.1), the expected IP Layer configuration mechanism is DHCPv6.

- **Basic IP information from RA** - If a mobile network provides Basic IP information (as defined in MBIM section 10.5.20.1) via RA, then MBIM devices must allow RA packets to be forwarded to the host and must not intercept the RA packets or provide the Basic IP information present in the RA packets via MBIM_CID_IP_CONFIGURATION.
- **DNS server information from RA** - The only IP Layer configuration mechanism for DNS server information (as defined in MBIM section 10.5.20.1) supported by Windows is DHCPv6. MBIM devices must configure DNS server information, even if present in RA, via MBIM_CID_IP_CONFIGURATION.
- **Basic IP information and DNS server information from DHCPv6** - If a mobile network provides basic IP information and DNS server information (as defined in MBIM section 10.5.20.1) from DHCPv6, then MBIM devices must allow DHCPv6 packets to be forwarded to the host and must not intercept the DHCPv6 packets or provide the basic IP information and DNS server information present in the DHCPv6 packets via MBIM_CID_IP_CONFIGURATION.

MBIM_CID_RADIO_STATE

MBIM devices must not fail MBIM_CID_RADIO_STATE operations with status of MBIM_STATUS_SIM_NOT_INSERTED when SIM is not present. Radio operations must not be failed due to SIM absence.

Byte-Ordering Requirements for Authentication CIDs

Data in the byte array fields listed below must be in host-byte order.

MBIM_CID_SIM_AUTH

MBIM_SIM_AUTH_REQ

1. Rand1
2. Rand2
3. Rand3

MBIM_CID_AKA_AUTH

MBIM_AKA_AUTH_REQ

1. Rand
2. Autn

MBIM_AKA_AUTH_INFO

1. Res
2. IK
3. CK
4. Auts

MBIM_CID_AKAP_AUTH

MBIM_AKAP_AUTH_REQ

1. Rand
2. Autn

MBIM_AKAP_AUTH_INFO

1. Res
2. IK
3. CK
4. Auts

Setting Link MTU

Windows supports configuring Link Maximum Transmission Unit (MTU) only during device initialization. Windows does not update the Link MTU based on the MTU reported using MBIM_CID_IP_CONFIGURATION. Devices must communicate the network supported link MTU using the MBIM_FUNCTIONAL_DESCRIPTOR.wMaxSegmentSize. Link MTU values reported in this manner should be at least 1280 and at most 1500.

Mobile Broadband Collecting Logs

Article • 03/14/2023

Follow these steps to collect the logs related to mobile broadband on a Windows Desktop Device:

```
*  Open an Administrator Command Prompt window
*  Run the below command to start tracing
    *  netsh trace start wireless_dbg,provisioning overwrite=yes maxSize=999
level=5
*  <Repro the scenario for which you need to collect logs>
*  Run the below command to stop tracing
    *  netsh trace stop
```

The steps above generate two files:

1. NetTrace.etl - Contains the traces for the run
2. NetTrace.cab - Contains additional details about the system that will be useful for debugging

Collecting logs across a reboot

If the repro scenario includes a reboot update the start tracing command as follows:

```
*  netsh trace start wireless_dbg,provisioning overwrite=yes persist=yes
level=5
```

Please note that PII will be captured in the logs collected using the above method.

Decoding Logs

Run one of these commands to convert the .etl file to a .txt file that can be used for analysis:

`*` tracefmt`<ETL file location>`

`or`

`* netsh trace convert <ETL file location>`

Mobile Broadband Analyzing Logs

Article • 03/14/2023

TextAnalysisTool is an extensive text filtering tool that is useful for complex traces with numerous ETW providers. You can filter logs of interest using the .tat files.

To collect the logs, follow the steps in MobileBroadband Collecting logs.

Use the .tat filters included in the specific feature to filter the logs:

```
*   Copy and paste the lines into a <name>.tat file
*   Open the log of interest in TextAnalysisTool
*   Load the filter file(<name>.tat) into TextAnalysisTool by clicking File > Load Filters
```

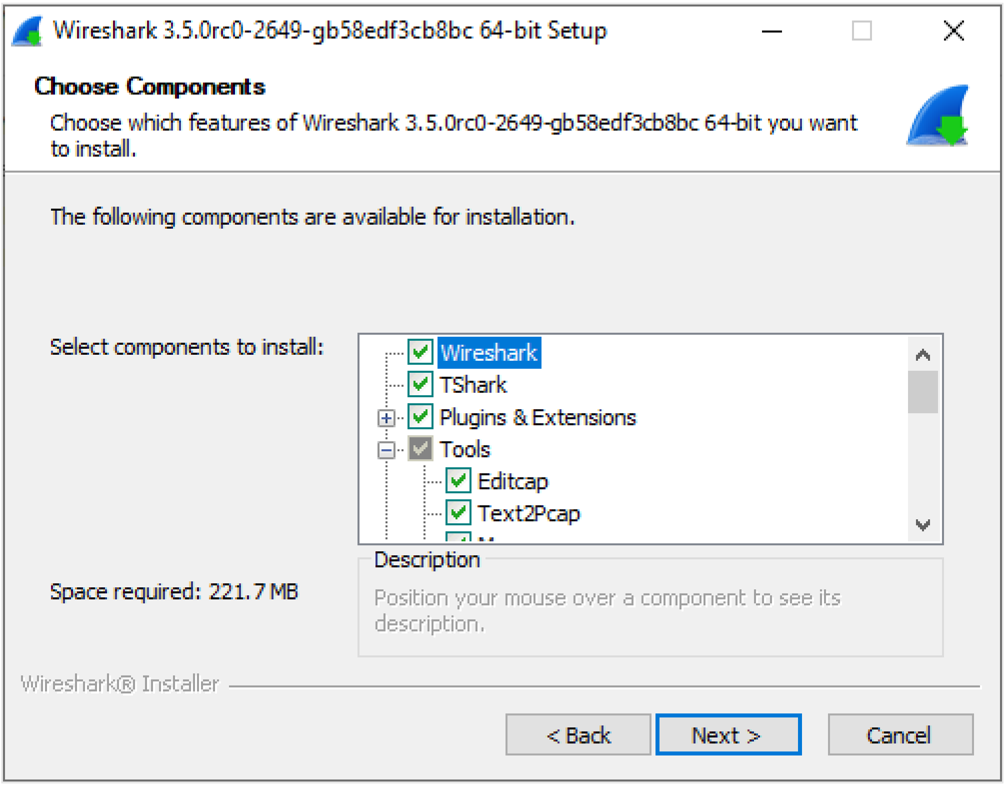
Analyzing Mobile Broadband Logs in Wireshark

Article • 10/06/2023

Follow these steps to diagnose the logs related to mobile broadband using Wireshark:

1. Download the ETW (Event Tracing for Windows) reader. Wireshark packages the ETW reader starting from version 3.5.

2. After you start the Wireshark installer, one of the steps is **Choose Components**.



Wireshark 3.5.0rc0-2649-gb58edf3cb8bc 64-bit Setup

Choose Components

Choose which features of Wireshark 3.5.0rc0-2649-gb58edf3cb8bc 64-bit you want to install.

The following components are available for installation.

Select components to install:

- ☑ Wireshark
- ☑ TShark
- ⊞ ☑ Plugins & Extensions
- ⊟ ☑ Tools
  - ☑ Editcap
  - ☑ Text2Pcap

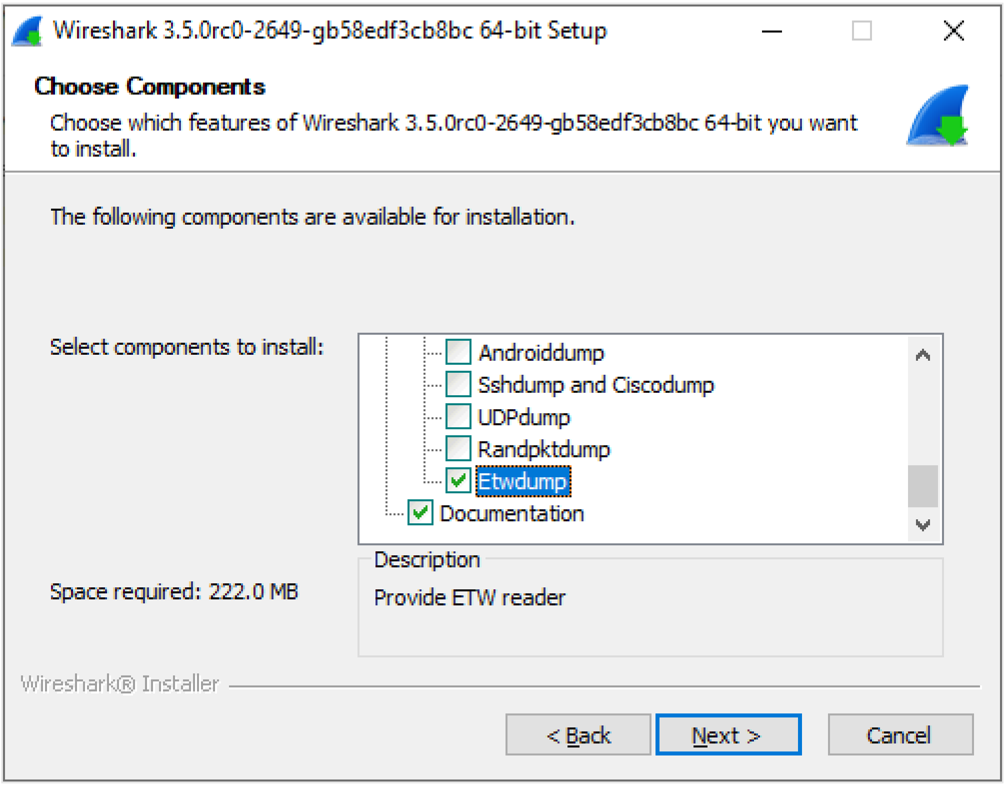
Space required: 221.7 MB

Description

Position your mouse over a component to see its description.

Wireshark® Installer

Expand Tools, scroll down, and select **Etwdump**.



Choose Components

Choose which features of Wireshark 3.5.0rc0-2649-gb58edf3cb8bc 64-bit you want to install.

The following components are available for installation.

Select components to install:

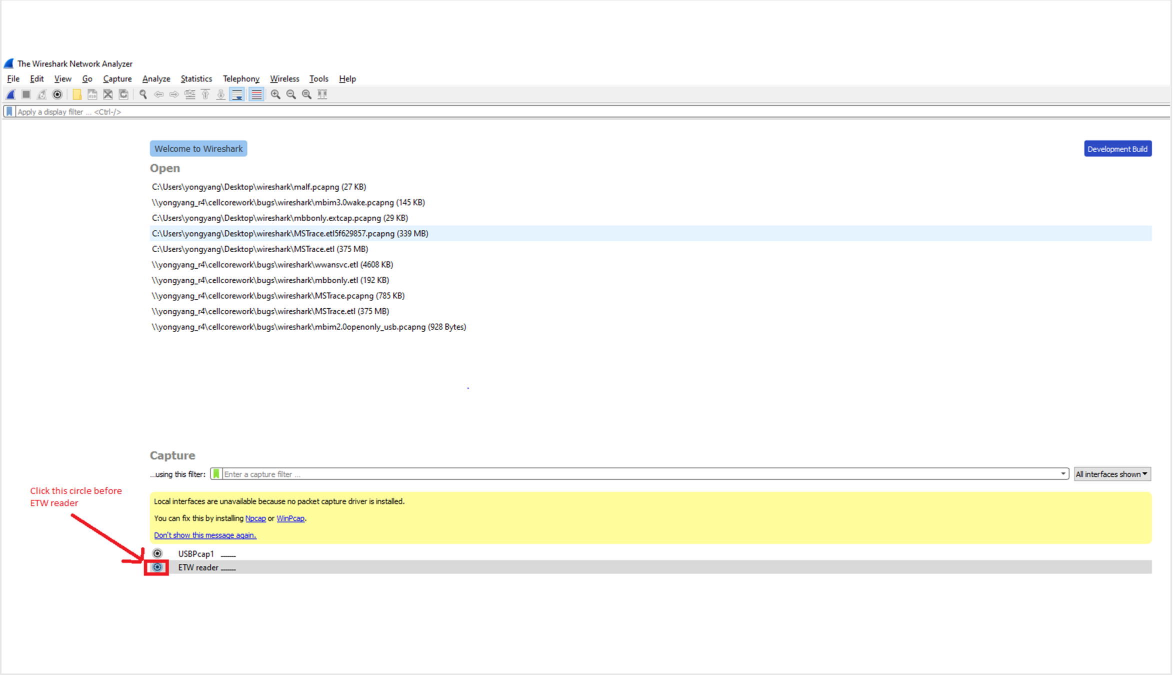
- □ Androiddump
- □ Sshdump and Ciscodump
- □ UDPdump
- □ Randpktdump
- ☑ Etwdump
- ☑ Documentation

Space required: 222.0 MB

Description

Provide ETW reader

3. Launch the ETW reader.



The Wireshark Network Analyzer
File Edit View Go Capture Analyze Statistics Telephony Wireless Tools Help
Apply a display filter ... <Ctrl-/>

Capture

...using this filter: Enter a capture filter ...

All interfaces shown

Local interfaces are unavailable because no packet capture driver is installed.

You can fix this by installing Npcap or WinPcap.

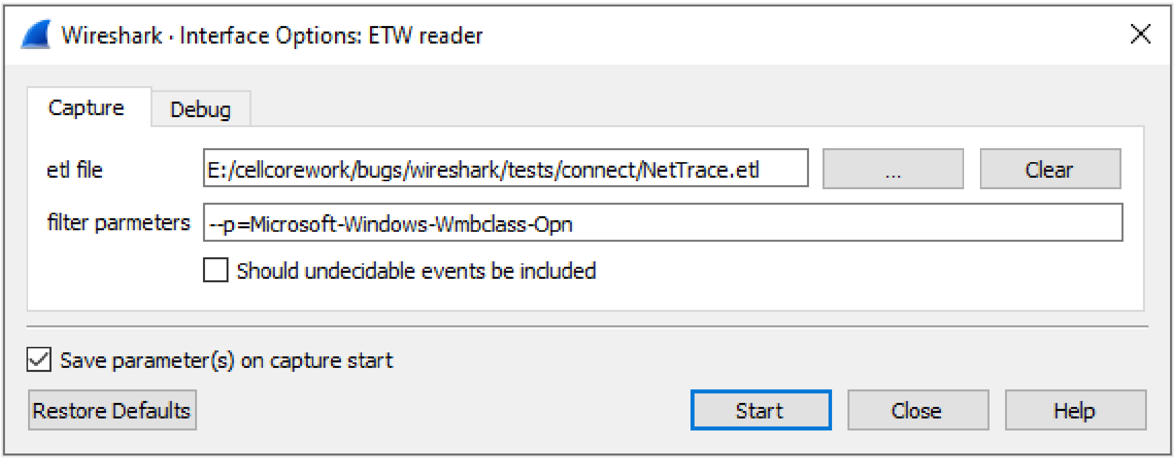
Don't show this message again.

USBPcap1

ETW reader

Click this circle before ETW reader

4. Option A. Click the "..." button to choose an ETL file to decode. You can set filter parameters to only decode events from specific providers. Then click the Start button to decode the file.



Wireshark · Interface Options: ETW reader

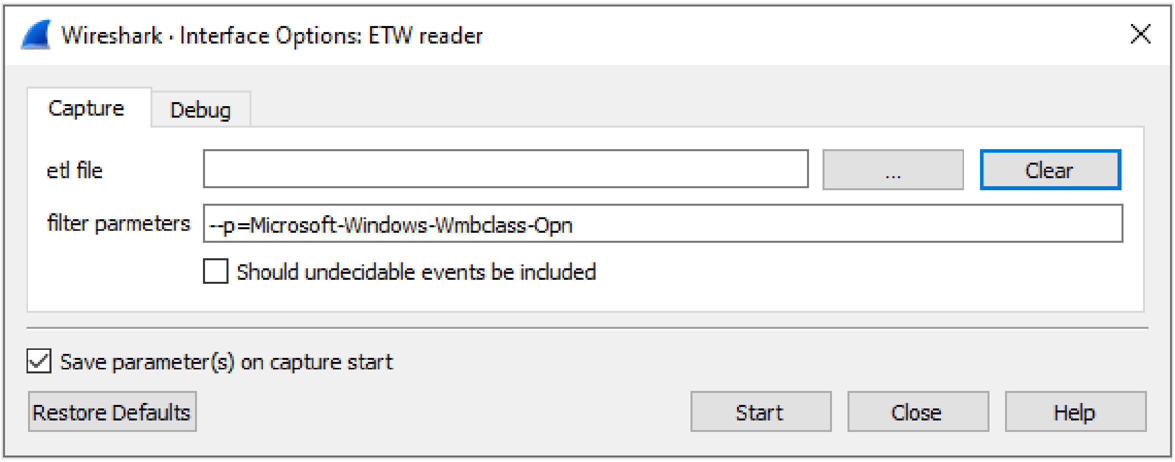
etl file: E:/cellcorework/bugs/wireshark/tests/connect/NetTrace.etl

filter parmeters: --p=Microsoft-Windows-Wmbclass-Opn

□ Should undecidable events be included

☑ Save parameter(s) on capture start

Option B. Start a live session instead of decoding the events from a file. Live sessions require an empty ETL file and you must specify filter parameters. Then click the Start button.



Wireshark · Interface Options: ETW reader

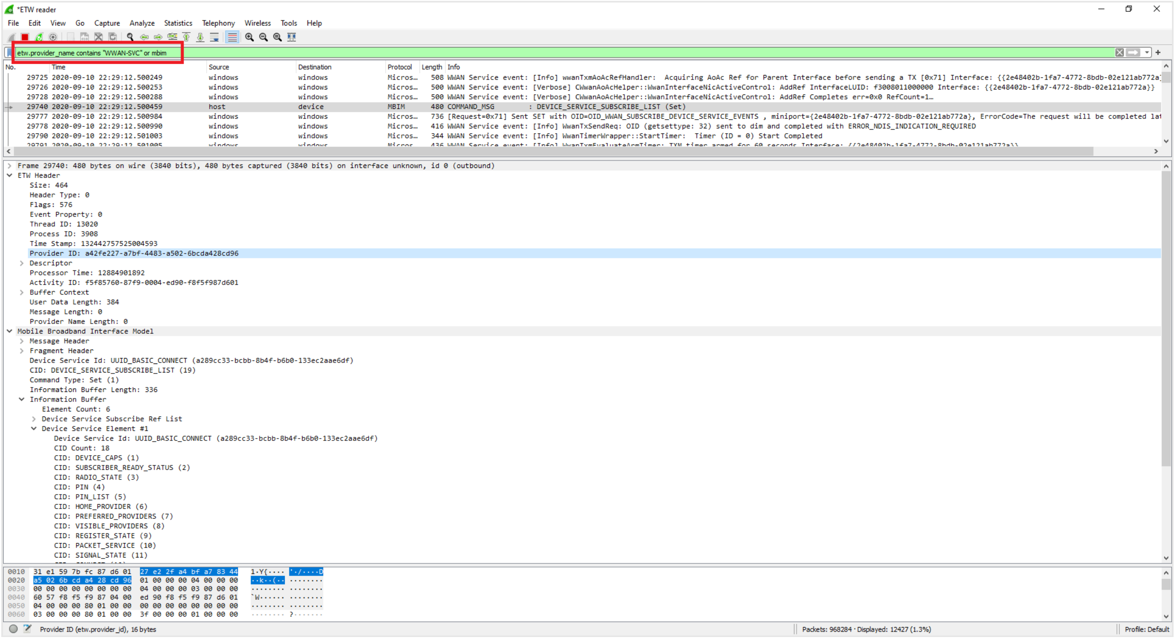
etl file:

filter parmeters: --p=Microsoft-Windows-Wmbclass-Opn

□ Should undecidable events be included

☑ Save parameter(s) on capture start

5. Wireshark will display the decoded ETW messages and MBIM messages from either a file or a live session. You may choose to filter relevant messages. The example below filters out the WWAN-SVC and MBIM messages.



*ETW reader

SMS PDU format: Automatic

Preferred MBIM Extended Version for decoding when MBIM_CID_VERSION not captured: 3.0

Mobilebroadband TextAnalysisTool Filters

Article • 12/15/2021

TextAnalysisTool is an extensive text filtering tool that is useful for complex traces with numerous ETW providers. You can filter logs of interest using the .tat files.

TextAnalysisTool filters:

- Basic Connectivity Log Filter
- DSSA Log Filter
- eSIM Download and Install Log Filter
- eSIM Profile Operations Log Filter
- LTE Attach Operation Log Filter
- PIN Operations Log Filter

netsh mbn test

Article • 12/15/2021

netsh mbn test is a test kit separate from the normal release version. You need to install the Hardware Lab Kit (HLK) client first to enable this feature.

HLK

Install the HLK client to enable the **netsh mbn test** function in DUT.

Alternatively, you can install **HLK Taef Tool** in the HLK package (path: installer\HLK-TAEF-TOOL-[arch-language]) to enable **netsh mbn test**.

Run the test command on the Device Under Test (DUT) that installed the HLK client.

Example:

```
netsh mbn test feature=connectivity param="AccessString=internet"
```

VHLK

You can also use the VHLK client to enable the **netsh mbn test** function in DUT.

Setup: Install VHLK on a host PC and run the script ConfigureTestSetup.ps1 <DUT's IP> from the location: C:\Program Files (x86)\Windows Kits\10\Hardware Lab Kit\Tests\amd64\Net\logo\Wwan

Then you can run the test command on the DUT.

Example:

```
netsh mbn test feature=connectivity param="AccessString=internet"
```

WLAN feature information

Article • 12/15/2021

This section contains specific WLAN feature information.

Wi-Fi network preference

Wi-Fi network preference is as follows.

1. User-defined networks are used first. These are listed in the Wi-Fi CPL as *Known networks*. A network becomes a *Known network* in the following cases.

   - The user manually taps on the network (including hotspots) in the Wi-Fi CPL.
   - The user adds the network manually from the Wi-Fi CPL.
   - Wireless network profiles that are roamed to the phone from Windows PCs.

   If multiple user-defined networks are found during the network scan, the most recently connected network is used.

   Note Wireless network profiles that are roamed to the phone from Windows PCs do not show up in the *Known networks* list until the phone has connected to the network once.

2. Hotspots (from a Store application or OEM plug-in) are prioritized next. If multiple hotspots are found, the following factors are used to decide preference.

   - Network security. Secure networks (any security type) are preferred over open networks.
   - Signal strength.

Note When there are multiple networks that have the same name or SSID, only the first configured network that uses the name or SSID is accepted.

Windows does not disconnect from a network once it is connected if the signal from the network is still present, even when a more preferred network becomes available. For example, if a user connects to a mobile operator hotspot at a store, and walks home while the signal from the hotspot is still present, the phone will not move to the user's configured home Wi-Fi network.

- Fast Roaming with 802.11k, 802.11v, and 802.11r

Fast Roaming with 802.11k, 802.11v, and 802.11r

Article • 10/04/2024

Improved WLAN roaming experiences are available to devices running Windows 10. Industry standard implementations that reduce the time needed for a device to roam from one wireless access point (AP) to another are supported.

802.11k (Neighbor Reports)

Wireless Access Points (APs) that support 802.11k are able to provide Neighbor Reports to devices running Windows 10. Neighbor Reports contain information about neighboring access points and allows the device to have a better understanding of its surroundings. Windows 10 takes advantage of this capability by shortening the list of channels that the device needs to scan before finding a neighboring AP to roam to.

802.11v (BSS Transition Management Frames)

APs that support 802.11v can now direct Windows 10 devices to roam to another AP that it deems will provide a better WLAN experience for the device. Windows 10 devices can now accept and respond to these Basic Service Set (BSS) Transition Management frames, leading to improved WLAN quality when connected to a network that supports 802.11v.

802.11r (Fast BSS Transition)

Fast BSS Transition reduces the time needed for a Windows 10 device to transition to an AP that supports 802.11r. This time reduction results from fewer frames being exchanged with the AP prior to data transfer. By decreasing the time before data transfer when the device roams from one AP to another, the connection quality is improved for latency sensitive applications, such as an active Skype call. Windows 10 supports Fast BSS Transitions over networks using 802.1X as the authentication method. Pre-Shared Key (PSK) and Open Networks are currently not supported.

With the combination of 802.11k, 802.11v, and 802.11r, Windows 10 takes advantage of established industry standards to improve the roaming experience for our users. VoIP applications can now take advantage of this improved roaming to deliver better call quality when users are not stationary.

Things to note

Not all Windows 10 devices support 802.11k, 802.11v, and 802.11r. The WLAN Radio driver must support these features to enable them to work on Windows 10. Please check with your device manufacturer to determine whether or not your device supports these features. In addition to device-side support, the network (AP Controllers and APs) must also support the features for the experience to work. Please check with your network administrator to see if these features are supported and have been enabled on the network in question.

Windows 10 continues to support Opportunistic Key Caching (OKC) when 802.11r is not available on the device or the network.

All three features require AP-side support and don't work unless those features are enabled on the APs.

WDI Miniport Driver Design Guide

Article • 09/27/2024

ⓘ **Important**

WiFiCx is the new Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features. The WDI driver model is now in maintenance mode and will only receive high priority fixes.

WLAN Device Driver Interface (WDI) is the new Universal Windows driver model for Wi-Fi drivers, for both Windows 10 for desktop editions (Home, Pro, Enterprise, and Education) and Windows 10 Mobile. The WLAN device manufacturer writes a WDI miniport driver to work with the Windows 10 OS implementation. WDI enables device manufacturers to write less code than the previous Native WLAN driver model. All new WLAN features introduced in Windows 10 require WDI-based drivers.

Vendor-supplied native WLAN drivers continue to work in Windows 10, but functionality is limited to the version of Windows for which they were developed.

The WDI requirements and interface specification are documented in this design guide. The key goals for the new model are:

- Improve the quality and reliability of Windows WLAN drivers.
- Reduce the complexity of the current driver model, which in turn reduces the complexity of the IHV driver and reduces the overall cost of IHV driver development.

The focus of this documentation is to specify the flow and behavior of Wi-Fi operations between Windows and the IHV driver component. It does not cover software interface signature (for example, the device driver interface model) and details about how the IHV component is loaded in Windows.

Design principles

The following principles guided the overall model and design of this protocol.

1. Minimize the chattiness of the traffic between the host component and the IHV component/device. This is particularly important for implementations on buses such as SDIO, which is inherently chatty.
2. Wi-Fi functionality (especially functionality that must be performed with low latency) is expected to be handled by the device.

3. All regulatory related functionality resides in the IHV component and is controlled by the IHV.
4. The Windows experience is controlled by the host component and the Windows operating system.
5. Windows has the ability to resurrect hung devices. It has enough state to reprogram the IHV component and recover within 10 seconds.
6. Operations that require lot of system memory or fast processors and are not vendor specific are handled by the host.

Definitions

Expand table

Term	Description
Device	The entire piece of hardware that connects to the bus. A device can have multiple radios in it (notably Wi-Fi and Bluetooth).
Wi-Fi adapter	The specific part of the device that implements Wi-Fi functionality as described in this specification.
Port	An object that represents a MAC and PHY state for a particular connection.
IHV component	The IHV-developed software component that represents the Wi-Fi Adapter/Device to the host.
Host	The host-side Microsoft/operating system software that interacts with the IHV component using the interfaces described in this specification.
Upper Edge Driver (UE)	UE refers to the WdiWiFi driver, called WDI in this documentation. The UE and the Lower Edge (LE) IHV driver combine into a complete NDIS miniport driver. The UE implements the core Wi-Fi logic.
Lower Edge Driver (LE)	LE refers to the IHV driver at the lower edge. The LE and UE combine into a complete NDIS miniport driver. The LE implements bus and hardware specific functions.
Functional Level Reset (FLR)	Functional Level Reset, as in the PCIe specification. This term refers to the reset of a

Term	Description
	function, versus a reset of the complete device which may have a composite function. The reset of such scope does not impair the other functions on the same device.
Platform Level Reset (PLR)	Platform Level Reset. This reset method impacts all functions on a device. It is very popular to build multiple functions on a device to reduce the cost and footprint. For example, Bluetooth is typically built with Wi-Fi on a chip. However, such a reset method resets all function units on the device.
Reset Recovery (RR)	RR refers to the event sequence of Reset and Recovery. For FLR, this includes: • The request to NDIS, which forwards the request to the bus to reset the Wi-Fi function. • Recovery of firmware context by the driver. • Reconnection to the access point if it was connected before the reset. For PLR, this includes: • The request to NDIS, which forwards the request to the bus. The bus interacts with PnP to surprise-remove the device. • Re-enumeration of the device. • Re-establishing the device stack. • Wi-Fi is restarted and reconnects.
WDI commands	The UE sends WDI OIDs and calls LE callbacks. All of these are called WDI commands.
MAC Address Randomization	In order to improve the privacy of Windows 10 users, configured Wi-Fi MAC addresses are used in some circumstances, such as before connecting to a particular Wi-Fi network or when initiating scans in specific conditions. This only applies to the station port. The system ensures that randomization is used appropriately, so important connectivity scenarios are not broken. The system manages changes of addresses by issuing OID_WDI_TASK_DOT11_RESET commands prior

Term	Description
	to issuing a scan or connect command. The reset command parameters include an optional MAC address argument. If the argument is present, the MAC address is reset to the specified value. If it is absent, the MAC address is left to the current value. When configuring randomized MAC addresses, the operating system uses the "locally administered" format defined for IEEE802 addresses.
ECSA	Extended Channel Switch Announcement.

Communication model, synchronization, and abort

Article • 12/15/2021

At a high level, this documentation defines two types of objects:

1. An adapter, which represents the Wi-Fi device.
2. A port, which represents distinct MAC and PHY entities in the adapter.

For more information about these objects, see Wi-Fi device model and objects. Commands, a set of permissible operations, are defined for each of these objects. Commands are further categorized into Properties and Tasks.

Property commands are simple commands (such as get signal strength, get current BSS list, and set packet filter). They complete in a short duration of time and are not complicated to implement.

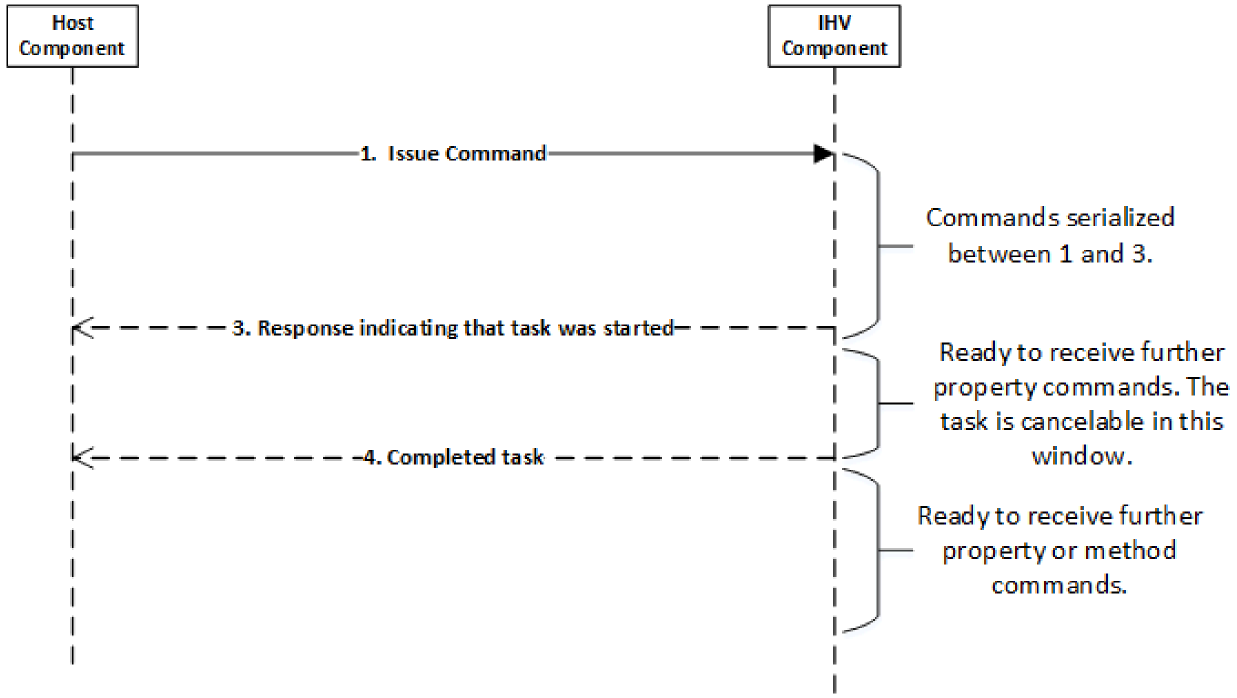
Task commands are complex operations that may take several seconds to complete. For example, a Wi-Fi Scan operation would be categorized as a task in this model.

All commands issued to the IHV component can be completed asynchronously.

Sequence of messages

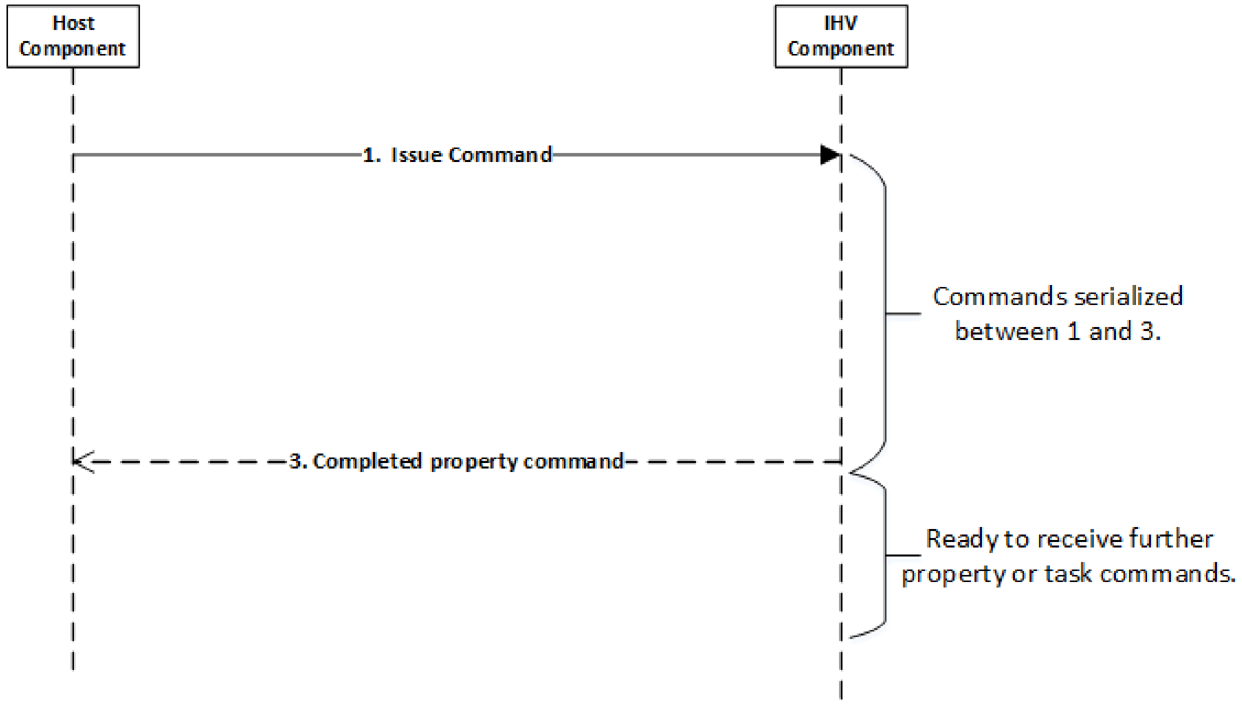
The sequence of messages for each type of command is shown in the following figures.

Figure 1 shows the task command sequence.



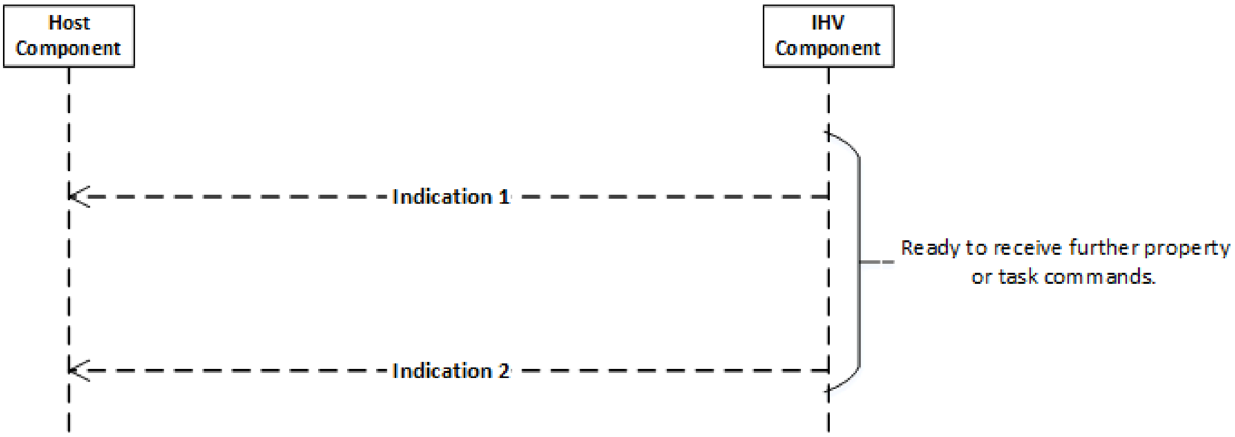
Host Component
IHV Component
1. Issue Command
3. Response indicating that task was started
4. Completed task
Commands serialized between 1 and 3.
Ready to receive further property commands. The task is cancelable in this window.
Ready to receive further property or method commands.

Figure 2 shows the property command flow.



Host Component
IHV Component
1. Issue Command
3. Completed property command
Commands serialized between 1 and 3.
Ready to receive further property or task commands.

Figure 3 shows the flow for indications.



Synchronization

To keep the IHV component implementation simple, the model defines the following synchronization rules:

1. Commands are always serialized between Steps 1 and 3 in Figure 1 and Figure 2. For example, no new commands are issued to the adapter until the indication from the adapter at Step 3. This also implies that all properties are serialized with each other.
2. All task commands are serialized between Steps 1 and 4 in Figure 1. For example, only one task runs on the adapter at a time. However, once a task is started (Step 3 in Figure 1), the adapter may get property command requests. Both Step 3 and Step 4 must finish before the next task command is sent.
3. Property set commands are of two types – those that can be sent after the task has started, and those that must be serialized with pending tasks.
4. Data path is not serialized with the command path, except for specific cases described later in the documentation.
5. The synchronization scope is adapter level scope.
6. A subset of tasks can be aborted after they have been started. This means that if a higher priority task (A) arrives while a lower priority task (B) is outstanding, B can be aborted by the host. Rationalization of prioritization decisions is beyond the scope of this documentation and is dependent on user scenarios.
7. For task commands, Step 4 can come before Step 3 has completed. However, if Step 4 is indicated, Step 3 cannot fail.

Abort

Most tasks can be aborted after they have been started. The purpose of the abort is to trigger the adapter to finish the task quickly by sending the complete indication (Step 4 in Figure 1). Abort is allowed only in the window between Steps 3 and 4 in Figure 1. On receiving the abort, the adapter must complete the task within 50 milliseconds. For most commands, upon receiving the abort, the adapter does not need to roll back to the state before the command was started. Race conditions exist between the abort command being issued and completions arriving to the host component. In this case, if the IHV component receives an abort for a task it has already completed, no further action is needed from the IHV component to process the abort operation. Aborting a task is simply a signal that the IHV component should clean up the task as soon as possible. Command completion semantics are not changed if an abort is issued. Both the completion for the abort property command, and the task completion indication must be appropriately notified in all cases.

Properties are expected to complete in short time so they cannot be aborted.

Task commands have a unique identifier that allows the host to target a specific command for abort.

Hang detection and recovery

Article • 12/15/2021

After a command is issued to the IHV component, the host starts a timer. If the timer expires before the IHV component completes (Step 3 message in the figures in Communication model, synchronization, and abort), the driver assumes that the IHV component is hung, resets the IHV component, and recovers if the precondition is correct.

The precondition is that the system will provide ACPI methods to reset the device, either at a bus or at the device level.

M1-M3 Hang Timeout is 10 seconds.

M3-M4 Task Hang Timeout is 30 seconds, or configurable based on task.

> ⓘ **Note**
>
> Some tasks may be expected to take longer than 30 seconds to complete (for example, Wi-Fi Direct Discover for the selected registrar bit in certain scenarios). In these cases, the host-initiated task timeout is adjusted accordingly to allow for 30 seconds longer than the maximum expected runtime of the task.

These are maximum upper bounds for the commands and processing that takes longer than this time is considered an error. It is expected that under a normal mode of operation (no CPU stress), most tasks and properties finish significantly sooner than the timeouts specified above. These values are specified with each task/property. The adapter should ensure that it does not have waits that would cause those execution times to be exceeded.

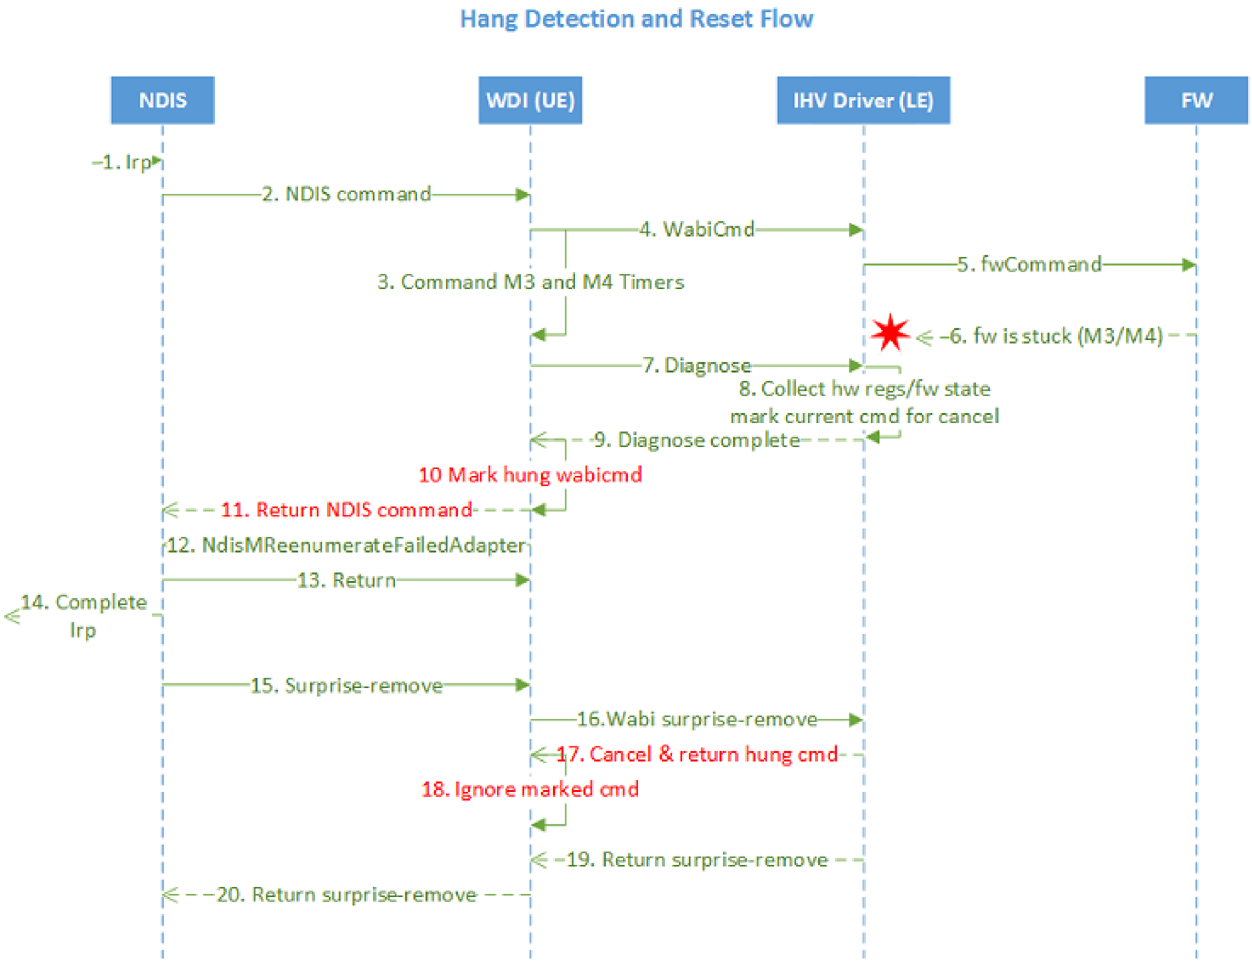
UE hang detection and recovery flow

Article • 12/15/2021

This diagram shows the UE hang detection and reset flow.



The diagram consists of main phases:

1. Hang detection
2. Log
3. Reset: surprise-remove handling

It is important to keep in mind that this feature addresses firmware hangs. It does not solve IHV driver hangs. IHV driver hangs can only be solved with a hard reboot. The driver must release all handles and other resources before it can be unloaded. If the driver can't be unloaded, the recovery does not work.

This flow diagram applies generically to all NDIS OIDs and callbacks to miniports. There may be exceptional cases where if NDIS or the Bus can't fully support reset recovery, the recovery part of the reset recovery won’t work. Two example cases are during miniport initialization or during a miniport halt operation.

Related topics

UE hang detection: steps 1-14

Reset (surprise remove): steps 15-20

UE hang detection: Steps 1-14

Article • 12/15/2021

Steps 1 through 14 of UE hang detection are described below. The steps correspond to the diagram shown in UE hang detection and recovery flow.

This example uses OID_SET_POWER.

1. NDIS receives a system power IRP or the NIC active references drop to 0.

2. NDIS generates an OID_SET_POWER D3 to the WDI driver.

3. WDI sets a timer for a WDI command (M1), including a task before it sends the WDI OID down to the LE. If the command is a task, an additional timer for the task is also set. Both timers can time out, but at most, only one can trigger a reset recovery.

4. WDI sends the WDI command to the LE. The recommendation for the LE is to remember the WDI OID in the adapter structure if it needs a firmware command to complete the OID. When the firmware completes the job for the WDI OID, the LE completes the OID and removes it from the adapter structure. Since WDI serializes OIDs to the LE, the LE needs only one slot to remember the pending WDI OID. If the firmware command is hung, the LE can return the OID at any time but no later than at surprise-remove (it can be in the context of surprise-remove) at Step 17 when the firmware has been disabled. For any other cases, the LE simply completes the WDI OID when the firmware completes the corresponding job, regardless of if it is before or after a diagnose callback. If the LE needs to remember the WDI OID after Diagnose, it needs another slot to remember it. However, for the OIDs received after Diagnose, the LE should not touch the firmware to avoid cascaded hangs.

5. The LE sends a command to the firmware.

6. If the firmware command timed out, it may be due to a firmware hanging or taking too long.

   - If the firmware is simply taking too long to complete the command after a time out, the LE can complete the WDI command. The UE handles it appropriately.
   - If the firmware is hung, the WDI command is not completed soon. The LE must complete it at surprise-remove at Step 16 when the hardware has been reset, so it is safe to complete without special handling for a potential race condition.

7. The WDI timer fires to generate a WDI Diagnose command. This WDI command is a call to the LE driver, *MiniportWdiAdapterHangDiagnose*, rather than a WDI OID.

8. LE collects hardware control register states, and optionally, the full firmware state.

    - The IHV driver is expected to collect hardware register content which is limited to 1KB, and return it in the function return. Additionally, in the pre-production environment, the LE should also try to dump the firmware context into files so that the IHV can do post-mortem debug thoroughly. The switch can be implemented as a registry key to control the collection of hardware registers and the firmware image.
    - The LE also marks the current command for cancellation. If command completion races to beat the diagnosis, it is acceptable if the LE does nothing for this command.
    - With this command pending, the UE may send further WDI commands as the consequence of Reset. These are in-flight commands or clean-up commands. After the diagnose call, the LE should process them without touching the firmware.

9. WDI receives the control register state.

10. WDI marks the hang WDI command so that it is indicated later by the LE.

11. WDI returns (completes) the NDIS command without the WDI completion. This is safe because WDI double-buffers NDIS commands.

12. WDI calls NDIS to reset and calls **NdisWriteErrorLogEntry** with *Error Code* of **NDIS_ERROR_CODE_HARDWARE_FAILURE** (0xc000138a). This results in an event recorded in the system event log with the module name of LE. The error event ID automatically pops up as (0xc000138a | 0xffff) – 0n5002. If the LE also uses the same error code to write error logs, the first DWORD of the data should contain the high bit set (0x80000000) to easily separate events by the LE. WDI uses 0x00000000 to 0x7fffffff for the first DWORD data.

13. The call returns.

14. NDIS completes the IRP.

After this point, NDIS calls the bus to surprise remove and re-enumerate us. It is important to note that WDI double-buffers NDIS commands so that it does not have to wait for the WDI command to return to complete the NDIS command. This eliminates the need for the LE to do cancel logics, which are notoriously complex to do.

The completion of NDIS OID_SET_POWER is necessary to avoid a deadlock of PnP operations. All PnP and power state changing events are serialized. This means that if a Set power OID does not return, NDIS is not able to return the Set power IRP, which means the Reset Recovery locks up with the Surprise-Remove IRP.

MiniportWdiAdapterHangDiagnose

Reset (surprise remove): steps 15-20

UE hang detection and recovery flow

Reset (surprise remove): steps 15-20

Article • 12/15/2021

The steps of reset (surprise-remove), which are Steps 15 through 20, are described below. The steps correspond to the diagram shown in UE hang detection and recovery flow.

Once the Reset Recovery can proceed, the bus causes PnP to generate a surprise-remove IRP. When NDIS receives the surprise-remove IRP, it calls back WDI for a surprise-remove PnP event callback. WDI forwards the surprise-remove as a WDI command to the LE, where the LE returns the hung WDI command. The rest of flow is identical to a real device surprise-remove on a bus (for example, USB).

Cleanup commands flow to the LE to facilitate the return of resources. In this state, the LE should not touch the hardware.

Step	Action
15	NDIS calls back the PnP event for surprise-remove.
16	WDI calls back the LE for surprise-remove.
17	The LE returns the hung WDI command. The LE only needs a slot for outstanding WDI commands because WDI serializes WDI commands to the LE, except Diagnose and Abort.
18	WDI ignores the return of the hung WDI command because it has returned the original NDIS command.
19	The LE returns WDI surprise-remove.
20	WDI returns NDIS PnP callbacks for surprise-remove.

Timings for diagnose call

Article • 12/15/2021

The timing requirements of Diagnose to collect debug information are as follows.

At the level of **DiagnoseLevelHardwareRegisters**, the LE is expected to collect device control registers no more than 1KB in the output buffer of the Diagnose call. This is the setting for a normal release product. It is intended for collecting the vital information of device control registers. The time limit to collect such information is 25ms.

At the level of **DiagnoseLevelFirmwareImageDump** or **DiagnoseLevelDriverStateDump**, the LE is expected to collect the device control registers and firmware full dump. If time permits, the LE can also collect the driver state, subject to the time limit. Except the control registers collected in the Diagnose output buffer, the firmware dump and driver state should be saved to files with the choice of names in %windir%\system32\drivers. The time to collect all debug information at either level should be within 25 seconds. These diagnose levels are meant to be used at the self-host phase.

LE hang detection

Article • 12/15/2021

Some firmware have a watchdog timer that can detect firmware hangs. Some IHV drivers (LE) have logic to detect if the firmware is not making forward progress. The UE allows the LE to indicate such conditions.

The indication should be on the Adapter port (for example, portid=0xFFFF). By default, the indications trigger the LE to perform the full reset recovery procedure -- calling diagnose, collecting debug information, and requesting PLDR.

When the LE or firmware watchdog timer detects that the firmware stalled, the expectations from the UE are as follows.

1. If in D0,
   a. The LE indicates NDIS_STATUS_WDI_INDICATION_FIRMWARE_STALLED.
   b. At the return from the indication, the LE returns (if any) the stalled WDI command.
   c. The UE starts the Reset Recovery (RR) procedure.

2. If in Dx, this can only happen with firmware detected stall.
   a. Firmware raises wake interrupt.
   b. On receiving a D0 command, indicates the wake reason of why the firmware stalled.
   c. After returning D0 WDI OID, the LE indicates NDIS_STATUS_WDI_INDICATION_FIRMWARE_STALLED.
   d. Finish the procedure as in D0: 1a, 1b, and 1c.

Complete NDIS command if outstanding
11. Surprise-remove-event
12. Return any wabi commands
13. Complete any commands

Hang detection in Dx

It is possible that the firmware stops progress in Dx. In this case, Dx is D3Hot for PCIe NIC and D2 for USB and SDIO. The NIC is armed to wake and expected to maintain access point association autonomously, or scan NLO if not associated.

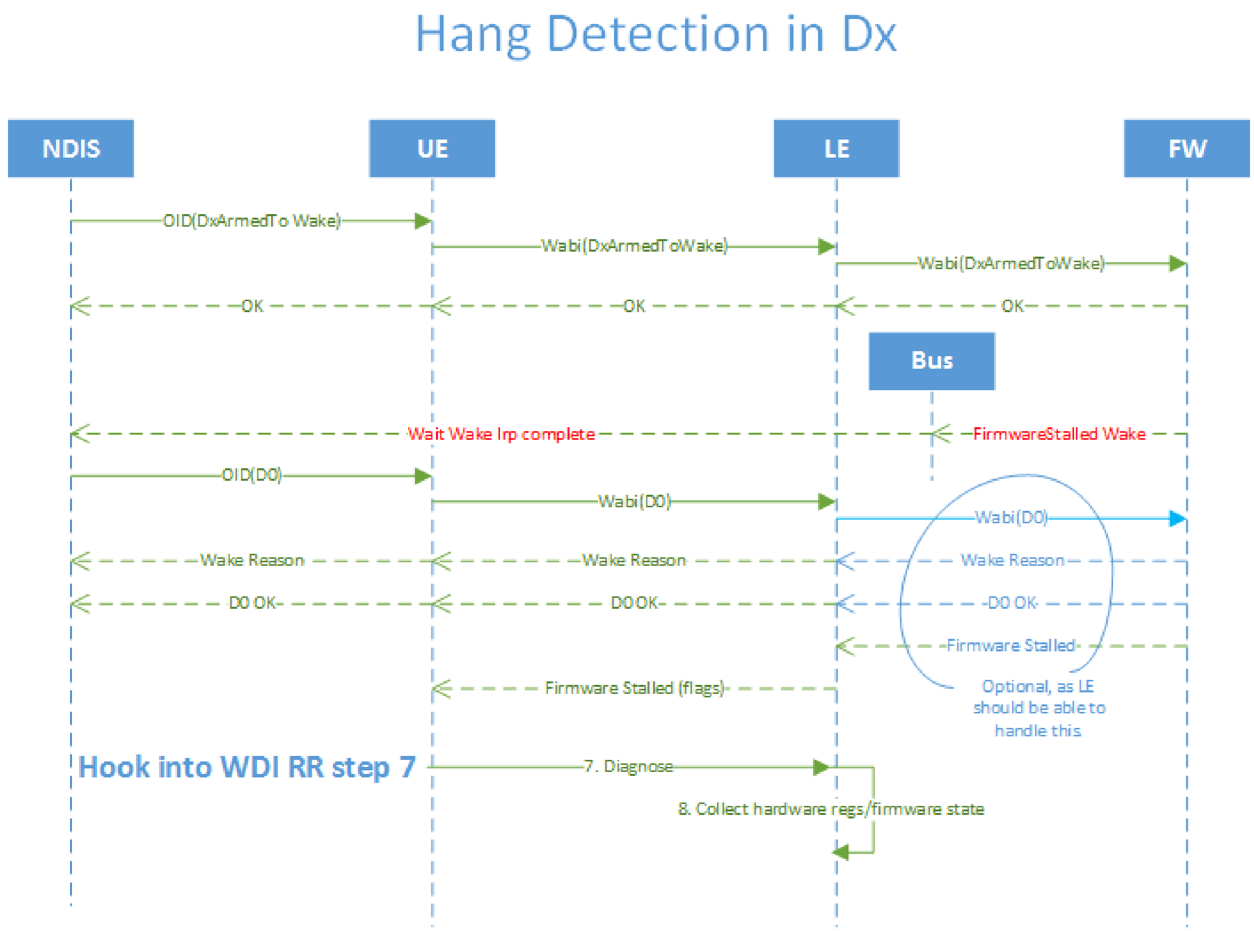
When the NIC is in Dx, the communication to the host is blocked because the bus could be in the power off state. Therefore, the LE is not able to detect stalled firmware. The firmware itself has to detect the condition and raise the wake line (if the wake portion of code is still alive) to bring the stack to D0, indirectly via ACPI or bus completing, NDIS wait_wake_irp. Due to this, NDIS sets D0 to the NIC.

The firmware asserts wake for such a condition. The LE should indicate a wake reason for the firmware stall. The wake reason **WDI_WAKE_REASON_CODE_FIRMWARE_STALLED** is defined as an enum with the other wake reasons.

For Reset Recovery to work in this scenario, at least two portions of the firmware must still function.

1. The hang detection code.
2. The code to assert wake interrupt.

If there is a lack of either one, the Host side does not know if the firmware is stalled and RR does not happen. This scenario is not part of the design goal.



OS module triggered reset recovery

This is informational for IHVs. In addition to UE and LE detected hangs, other OS components may detect hangs and/or trigger the UE to invoke the Reset Recovery procedure. Currently, the user mode wlansvc component in Windows 10 may request a Reset Recovery to UE when it detects a connection with Internet connectivity and subsequently loses the ability to access a DNS server without disassociation for some time. In the future, Microsoft may find additional cases to trigger a Reset Recovery to enhance end user experiences.

WDI_TLV_INDICATION_WAKE_REASON

PLDR

Article • 03/14/2023

Recovery of PLDR

After the surprise-remove, the drivers (both UE and LE) must release all resources so that the device object can be removed and re-enumerated (by the bus). If this does not happen, the device is not re-enumerated, and therefore not recovered.

WDI message structure

Article • 03/14/2023

All WDI command messages must start with a **WDI_MESSAGE_HEADER** structure. The command header is followed by zero or more type-length-value (TLV) structures.

The command message IDs defined for messages sent from the host to the Wi-Fi device are documented in WDI Task OIDs, WDI Property OIDs, and WDI Status Indications.

TLVs

The structure of TLVs is defined in the following table. The data in TLVs is in little-endian byte order.

Field	Type	Description
Type	UINT16	The type of the TLV structure. Unrecognized TLV types must be skipped without triggering errors.
Length of the Value buffer	UINT16	The size of the Value buffer in bytes.
Value	BYTE[*]	The payload buffer, which may contain a structure, a list of structures, or other TLVs. If there is more data than expected in a TLV, the additional data should be skipped without triggering errors.

There are two types of TLV groupings: statically sized TLV lists, and multi-TLV groups.

Statically sized TLV lists

Statically-sized TLV lists contain several statically sized members. They are analogous to standard C-style arrays.

In this example, **WDI_TLV_UNICAST_ALGORITHM_LIST** is defined as a list of WDI_ALGO_PAIRS.

Type: WDI_TLV_UNICAST_ALGORITHM_LIST

Length: N * sizeof(WDI_ALGO_PAIRS)

Value: WDI_ALGO_PAIRS[N]

This usage is specified in the TLV reference topics with array notation.

Multi-TLV groups

When the size of a given object is not known ahead of time, multi-TLV groups are used. This usage pattern specifies that N different variably sized TLVs are expected within a given buffer. The number of entries (N) is not known ahead of time, and is inferred by the number of matching TLVs in the given buffer.

In this example, the parent buffer is a WDI_MESSAGE_HEADER, which defines the end of the TLV buffer. Note that WDI_TLV_BSS_ENTRY may be interspersed between other different TLV types in the parent buffer.

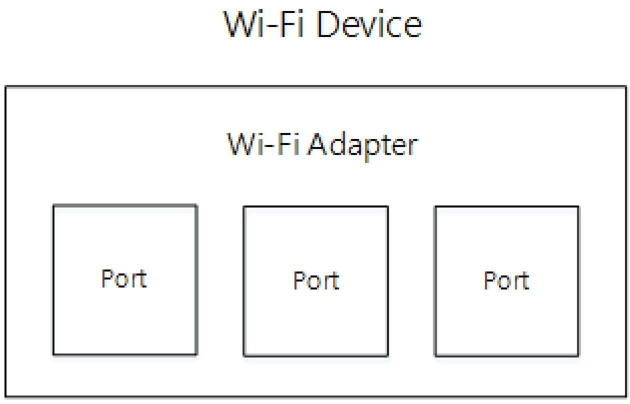
Offset	Field	Type
0	WDI_MESSAGE_HEADER	Message header
sizeof(WDI_MESSAGE_HEADER)	TLV_0 (WDI_TLV_BSS_ENTRY)	WDI_BSS_ENTRY
TLV_0 + L_0 + sizeof(TLV Header)	TLV_1 (WDI_TLV_BSS_ENTRY)	WDI_BSS_ENTRY
TLV_1 + L_1 + sizeof(TLV Header)	TLV_2 (WDI_TLV_BSS_ENTRY)	WDI_BSS_ENTRY
TLV_2 + L_2 + sizeof(TLV Header)	TLV_3 (OTHER_TLV_TYPE)	Some other TLV type
TLV_3 + L_3 + sizeof(TLV Header)	TLV_4 (WDI_TLV_BSS_ENTRY)	WDI_BSS_ENTRY

For TLVs that contain other TLVs, the TLV reference topics have a *Multiple TLV instances allowed* column. If this column is checked, the specified TLV is allowed to appear multiple times. For an example of this, see WDI_TLV_CONNECT_PARAMETERS.

Wi-Fi device model and objects

Article • 12/15/2021

The Wi-Fi device is used by the host in the context of two types of objects: adapter and port.



Adapter

The adapter object represents the Wi-Fi functionality in the Wi-Fi device. Commands and indications on this object are used to indicate state about the Wi-Fi interface. For systems with multiple Wi-Fi devices, each adapter object represents a different instance.

Port

One Wi-Fi adapter can be used simultaneously for multiple connections e.g. Infrastructure client and Wi-Fi Direct group owner. The port object is used to represent the state associated with each such connection. Each port holds the MAC state for the connection and any phy state specific to that connection.

There can be multiple ports in an adapter. Commands issued on a port should only affect the state maintained for that port.

The operating system configures each port with an operation mode, such as 802.11 station, Wi-Fi Direct Client, or Wi-Fi Direct Group Owner. The set commands that the firmware must be prepared to handle on a given port are determined by the operation mode and the state of the port. A port can be in one of two states: INIT and OP. The port is initially in the INIT state and transitions to the OP state only when the operating system issues a command to connect (in the case of infrastructure client) or to start an AP/GO. The port returns to the INIT state when OID_WDI_TASK_DOT11_RESET is sent to the IHV component.

Port availability requirements

Port type	Required count
Station Port	1
Wi-Fi Direct Device	1 (if supported)
Wi-Fi Direct Role (GO or Client)	1 or 2 (if supported)

Port concurrency requirements

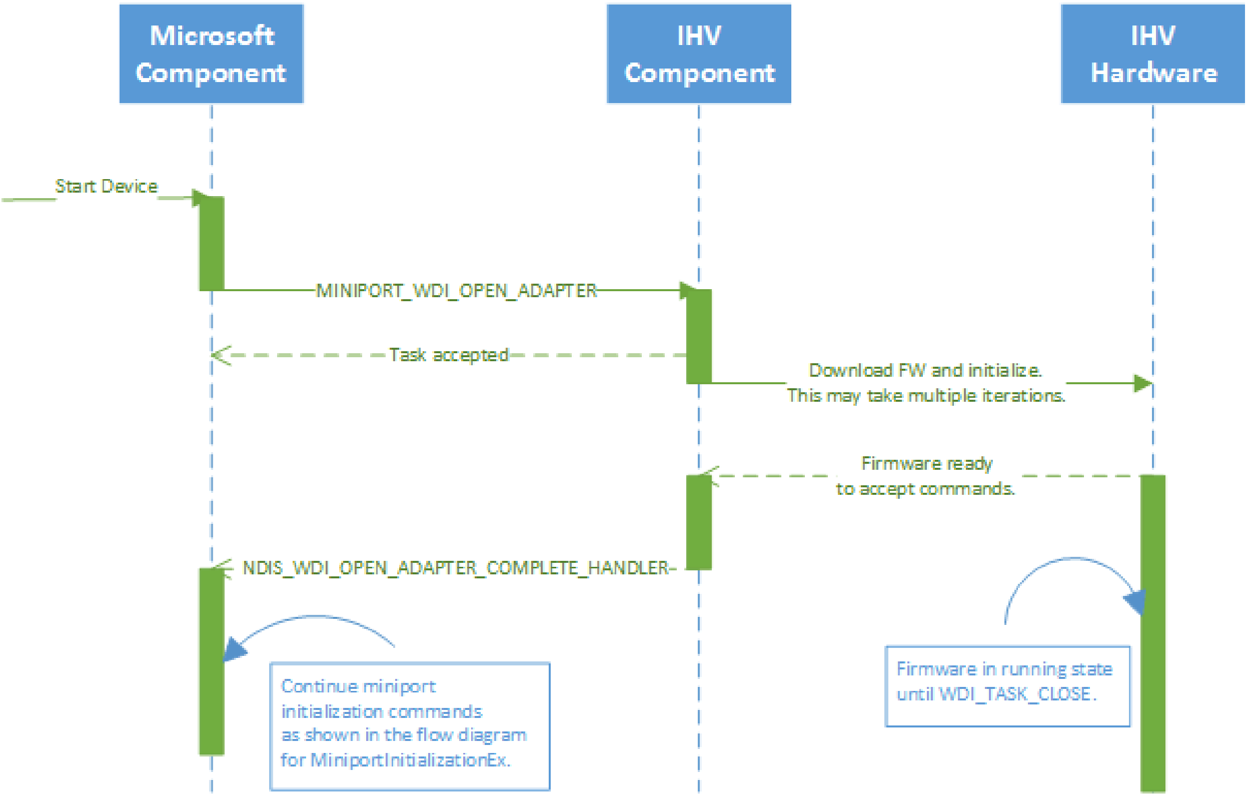
The following concurrency requirements for the different port types are as follows.

1. 1 Station Port is always available.
2. 1 Wi-Fi Direct Device port is always available.
3. 2 Wi-Fi Direct Role ports are available in the following configurations.
    a. 1 GO
    b. 1 Client
    c. 1 GO, 1 Client

Wi-Fi device initialization

Article • 12/15/2021

This topic describes the initialization of the Wi-Fi device after power-on. On power-up, most Wi-Fi devices come up in an uninitialized mode. The Wi-Fi device does not have sufficient ROM to hold the firmware, so the IHV component/driver programs the device with firmware as part of device boot-up. The following diagram shows the initialization sequence in a bus/interconnect independent way.



Microsoft Component
IHV Component
IHV Hardware
Start Device
MINIPORT_WDI_OPEN_ADAPTER
Task accepted
Download FW and initialize.
This may take multiple iterations.
Firmware ready
to accept commands.
NDIS_WDI_OPEN_ADAPTER_COMPLETE_HANDLER
Continue miniport
initialization commands
as shown in the flow diagram
for MiniportInitializationEx.
Firmware in running state
until WDI_TASK_CLOSE.

1. The IHV component is responsible for downloading the firmware to the adapter when the adapter is powered up. The exact mechanism to download the firmware is bus dependent. This operation is done in the context of the *MiniportWdiOpenAdapter* call. This is an asynchronous operation. The host is responsible for ensuring that the adapter is fully initialized and ready to process commands before further commands are sent to it. The exact mechanism is interconnect dependent.
2. Once the adapter is initialized, the host queries the adapter for various Wi-Fi properties, set properties, and creates ports (MACs) as part of miniport initialization.
3. After the ports are created and initialized, the adapter can receive task and property commands.

WDI task command priority and existing state

Article • 03/14/2023

When the adapter is in a particular state, new commands may come down to it that could affect the existing state (for example, a scan that affects existing connections). The table below describes how new commands should be prioritized against the existing state in the adapter. The columns describe how to service the existing state when the new command comes in.

New command Existing state Connection Quality (EAP) - Priority 1 P2P Listen - Priority 2 Connection Quality Latency (Media Streaming) - Priority 3 Existing Connections - Priority 4 Scan/P2P Discovery (forced) Important (delay scan) Pause Pause Throttle Scan/P2P Discovery (not forced) Important (skip scan) Maintain Important (skip scan) Throttle Station Connect, Roam, Disconnect Delay Connect Pause Pause Throttle P2P GO Start, GO Stop Delay Connect Pause Pause Throttle P2P Client Connect, Disconnect Delay Connect Pause Pause Throttle P2P Send Action Response Pause Pause Pause Throttle P2P Send Action Request Delay Send Maintain Pause Throttle

Term	Description
Important	Prioritize the existing state higher than the new request.
Maintain	Prioritize the existing state and the new command equally.
Throttle	Throttle down the servicing of the existing state so that it works, but prioritize the new command higher.
Pause	Stop servicing the existing state and attempt to finish the existing state as soon as possible.

WDI data transfer

Article • 03/14/2023

This section covers WDI data transfer. The following terminology is used in this section.

Term	Description
Target WLAN device (target)	A physical NIC.
Virtual WLAN device (port)	A virtual NIC (for example, P2P role ports).
WDI	A Microsoft WLAN component. It is a target-agnostic component.
Target Interface Layer (TIL)	A target-specific software layer that interfaces with the target through the bus-specific APIs. It creates and manages DMA channels and provides bus abstraction.
RX Manager / RxMgr	RxMgr performs receive processing steps that are not offloaded to the target.
RxEngine	RxEngine sends and receives data-synchronous messages to and from the target, interprets RX descriptor formats, and manages buffers for direct hardware to software RX DMA.
TX Manager / TxMgr	The WDI-compliant driver component that gets TX frames from the operating system, delivers them to the TxEngine at the appropriate time, and returns the completed TX frames back to the operating system.
TxEngine	The target-specific software component that handles the TX data transfer from host to target, and handles TX completion messages from the target.
Target Abstraction Layer (TAL)	The "lower-edge" that has a standardized API to the WDI compliant driver, but has a target-specific internal implementation. The TAL is a container layer for individual target-specific host software components such as TxEngine and RxEngine.

WDI receive operations and offloads

Article • 03/14/2023

These main categories of operation offloads are configurable.

- MSDU-level receive operations
- Frame forwarding (forwarding decision and actuation)
- Protocol/Task offloads

The following is a list of RX operations and offloads.

Function	Description	Ownership	Notes
Decryption	Decrypt the frame contents using the security type and security key specified for the sender.	Target	In host-implemented FIPS mode, the decryption is done within the host software. The target's decryption is bypassed.
A-MPDU deaggregation	Decompose an RX A-MPDU into individual MPDUs.	Target	
A-MSDU deaggregation	Decompose an RX A-MSDU into individual MSDUs.	Target/TAL	Each RX MSDU is placed into a separate buffer.
MSDU Security decap and de-MIC	For security types that involve an MSDU-level MIC, verify the received MIC. Decapsulate the security header and footer.	Target/TAL	The operating system performs countermeasures if needed.
Rx decap	Replace non-initial A-MSDU subframe headers with 802.11 headers, using the 802.11 header fields from the initial A-MSDU subframe as appropriate.	Target/TAL	During A-MSDU deaggregation, the non-initial MSDUs of the A-MSDU need their 802.3 header replaced by a generic 802.11 header. WDI always expects 802.11 headers.

Function	Description	Ownership	Notes
Rx reordering logic	For each RX MPDU, determine which slot of the Rx reordering array it goes to. Determine when a series of in-order frames is present. Determine when to release pending frames even if their preceding frames have not arrived.	Target/TAL	
Rx discard logic	Determine which Rx frames need to be discarded: 1. If it does not match any of the receive packet filters. 2. If the frame is encrypted, discard if: • A cipher key is not available to decrypt the packet. • The packet payload fails to decrypt successfully. • The packet payload fails the MIC verification. • The packet fails the replay mechanism defined for the cipher algorithm (see Rx PN/replay check). • A privacy exemption is defined for the packet's ether type that specifies an **WDI_EXEMPT_ ALWAYS** action. 3. If the frame is unencrypted, discard if: • A cipher key is available to decrypt the packet and a privacy exemption is defined for the packet's Ethertype that specifies a **WDI_EXEMPT_ON_ KEY_UNAVAILABLE** action. • The dot11ExcludeUnencrypted MIB is set to true.	Target/TAL makes all discard decisions.	

Function	Description	Ownership	Notes
Rx PN/replay check	Confirm that each MPDU has a distinct Packet Number that is larger than prior PNs.	This is a mandatory and always enabled offload except for streams associated with a reorder queue and reordering queue management is not fully offloaded to the target.	
Chatter offload	Avoid interrupting the host for each deferrable "noise" Rx frame. Instead, group the Rx noise frames and use a single interrupt to deliver all such frames.	Target	
Defragmentation	Reassemble 802.11 fragments into their original MSDU.	Target/TAL	
Rx reorder queuing	Store out-of-order Rx MPDUs until the missing prior MPDUs from the flow arrive.	Target/TAL	
Rx discard actuation	Discard Rx frames based on the specifications flagged by the Rx discard logic run at the target.	Target/TAL	
Higher-level protocol (task) offloads	Checksum	Checksum: Configurable offload at boot-up if required.	Checksum: The target passes its checksum offload capabilities as part of device caps to WDI during bring-up. For information about capabilities, see NDIS_TCP_IP_CHECKSUM_OFFLOAD.

Receive operations in Host-Implemented FIPS mode

In this mode, the target may indicate the received frame with either an 802.11 header or an 802.3 header. The frame must not be decrypted before indication.

If discard logic is offloaded to the target, it must mark received frames for discard if they meet any of the following criteria.

- Frames that have a bad CRC.
- Duplicate frames.
- Frames that do not match the configured packet filters.

The target must increment the appropriate MAC and PHY statistics for packets that are either received successfully or discarded by the port.

In addition, the target must perform discard actuation if offloaded.

The target should not strip the QoS flag from the 802.11 header on the RX path when operating in Host-implemented FIPS mode. The target should indicate the frame without modifying the QoS header.

For the case of fragmented packets, the payload type reported by the LE for FIPS mode is always **WDI_FRAME_MSDU_FRAGMENT** as the host is doing the defragmentation process. However, in non-FIPS mode, the reported payload type should be **WDI_FRAME_MSDU** as the Target/TAL is performing the defragmentation.

WDI transmit operations and offloads

Article • 03/14/2023

WDI operates in one of two Tx modes: Port queuing and PeerTID queuing. The target sets the mode with the TargetPriorityQueueing capability (true = WDI Port queuing, false = WDI PeerTID queuing).

The host performs the following operations.

- TX classification (only when **TargetPriorityQueueing** = false)
- TX queuing (either at a Port level or a PeerTID level)
- Transfer scheduling (scheduling frame download to the target)
- Host-Target TX flow control

The following is a list of TX operations and offloads.

Processing step	Description	Owner/Applicable offloads	Notes
High-level protocol (task) offloads	Checksum, LSO.	Checksum is a configurable offload at boot-up. Each frame has flags to specify the applicable checksum operations. WDI handles LSO segmentation transparently from the TAL/Target if applicable.	Checksum: The target passes to WDI its checksum offload capabilities as part of device caps during bringup. For capability information, see NDIS_TCP_IP_CHECKSUM_OFFLOAD. WDI handles LSO segmentation transparently from the TAL/Target if applicable.
TX encap	Update/replace the generic 802.11 header with the appropriate type of 802.11 frame header.	Target/TAL	The first contiguous buffer of the frame has space available at beginning (before the MAC header). This space is determined by the BackfillSize specified in the device parameters. For Non-EAPOL packets, the first buffer contains the MAC and LLC/SNAP headers, but not the payload. The first contiguous buffer for an EAPOL packet may contain part (or all) of the payload.

Processing step	Description	Owner/Applicable offloads	Notes
TX classification	Determine the TID. Determine the recipient based on unicast RA or DA.	WDI performs classification when **TargetPriorityQueueing** is false. WDI does not perform classification if **TargetPriorityQueueing** is true.	
TX queue	Store TX frames in separate queues.	WDI queues TX frames if needed.	WDI queues TX frames by port (**TargetPriorityQueueing** = true) or by recipient and traffic type (PeerId,TID) (**TargetPriorityQueueing** = false).
TX flow control	Prevent the overrunning of the TIL or target buffers with TX frames.	WDI/TIL/Target	See the section on Host-Target flow control.
Transfer scheduling	Select the TX queue from which to transfer frames to the TAL/TIL when there are multiple backlogged queues.	WDI if it needs to queue TX frames.	
A-MSDU aggregation	Determine which frames to group into an A-MSDU aggregate which must be maintained during retransmissions.	TAL/Target	
Fragmentation		TAL/Target	

Processing step	Description	Owner/Applicable offloads	Notes
WLAN scheduling	Determine which recipient to transmit to next, which traffic type to send, and how many frames to send.	Target	
Encryption	Encrypt the frame contents using the security type and security key specified for the recipient (or sender, for multicast frames). Add security encapsulation where applicable.	Target	For systems supporting FIPS, the encryption is done within the host software. The target's encryption is bypassed.
A-MPDU aggregation	Determine which frames to group into an A-MPDU aggregate, and which can be modified during a retransmission.	Target	
Retry	Retransmit MPDUs that are nacked or not acked by the recipient.	Target	

Operation in Host-Implemented FIPS mode

If the host provides FIPS for a given connection (host FIPS mode is set to true in WDI_TLV_CONNECTION_SETTINGS), the host encrypts the packets before they are submitted to the target. The target transmits the packets without additional changes that affect the data integrity of the packets. For example, the target must not perform transmit MSDU aggregation in this mode.

In the more common case where host-FIPS mode is not enabled (target-implemented encryption mode), the header 802.11 header is followed by the unencrypted payload data. If the packet requires encryption before transmission, the target encrypts the packet. It also performs QoS prioritization of packets, and may perform TCP layer offload operations (such as checksum or large send). For this send processing, the target may need to add additional headers into the packet (for example, QoS, HT headers, or IV).

TX Encapsulation: Population of 802.11 TX Frame Headers

The network data is submitted in 802.11 packet format to the port (target device). Each transmitted frame starts with a 802.11 MAC header. The host sets some of the fields of the MAC header, while the target sets other fields. The table below describes which fields of the 802.11 MAC header and cipher headers are populated by the host, and which should be populated by the target device.

Field name	**Subfield name**	**Target-implemented encryption mode**		**Host-implemented FIPS mode**	
		Set by host	**Set by target**	**Set by host**	**Set by target**
Frame Control	Protocol Version	X		X	
Frame Control	Type	X		X	
Frame Control	Subtype	X		X	
Frame Control	To DS	X		X	
Frame Control	From DS	X		X	
Frame Control	More Fragments	X		X	
Frame Control	Retry		X		X

Frame Control	Pwr Mgmt		X		X
Frame Control	More Data		X		X
Frame Control	Protected Frame		X	X	
Frame Control	Order	X		X	
Duration/Id			X		X
Address 1		X		X	
Address 2		X		X	
Address 3		X		X	
Sequence Control	Fragment Number	X			X
Sequence Control	Sequence Number		X		X
Address 4		X		X	
QoS Control			Added/populated by target.		Added/populated by target in the case of 11n QoS association.
HT Control			Added/populated by target.		Added/populated by target.

WDI_TXRX_CAPABILITIES

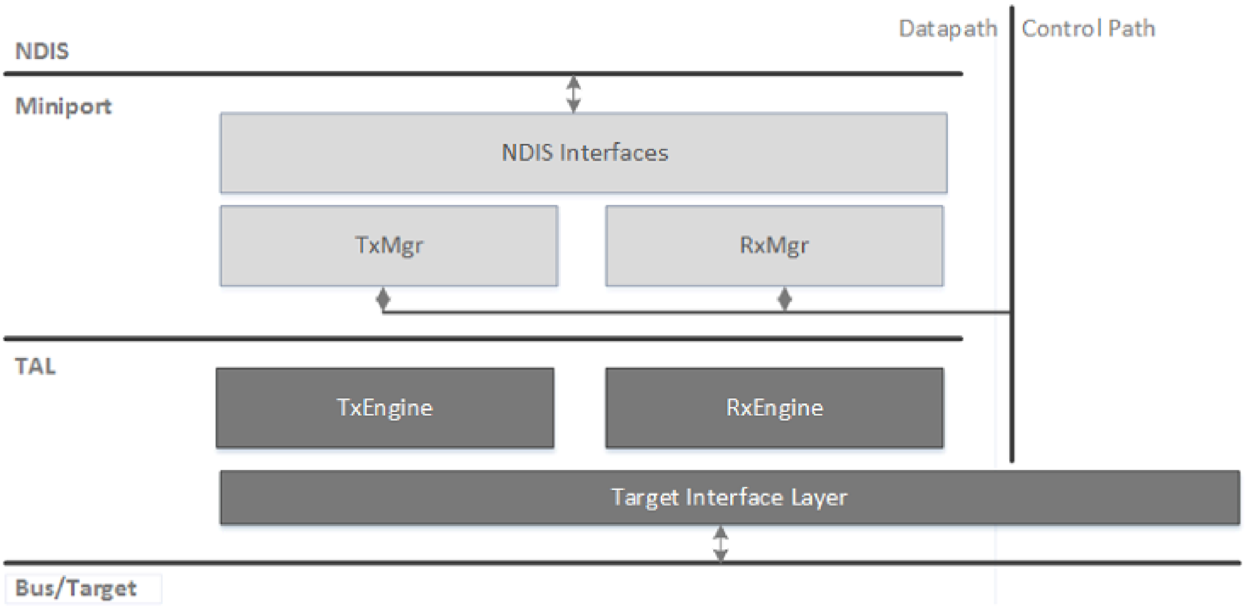
WDI datapath architecture

Article • 03/14/2023

To interoperate with existing WLAN target devices, the current version of the driver interface does not specify a host-controller interface (HCI) for TX/RX. Instead, it specifies a request/indication software interface between WDI and the Target Adaptation Layer (TAL).

The WDI component implements the NDIS datapath interfaces and the target-agnostic TX/RX functions performed by the host. It also maintains the state of individual virtual WLAN devices (ports) and peer-specific state.

The TAL provides the TX/RX WLAN functions for which the implementation depends on the host-controller interface, as well as the controller and bus interface functions.



In addition to the TX/RX function, the TAL provides a Target Interface Layer (TIL) that is used by the control and data paths. The responsibilities of the TIL are listed in the following table.

TIL function	Description
Management of Host-Target communication	Example: Allocate and manage the DMA channels required for control and data paths.
Bus adaptation/abstraction	Provide a standard host/target communication API that abstracts the communication differences between different bus types, software/hardware bus endpoints, and bus DMA engines.

WDI general datapath interfaces

Article • 03/14/2023

802.11 frame handling and frame metadata

802.11 frames are passed between WDI and the TAL in the form of **NET_BUFFER_LIST** (NBL) chains. Each NBL represents one MSDU. Through macros, the NBL structure provides operations on the data buffers and access to metadata, including operating system populated Wi-Fi TX metadata. The structure is extensible through its context and **MiniportReserved** members. **MiniportReserved[0]** points to a buffer of type **WDI_FRAME_METADATA**. This buffer is allocated by WDI in the TX path, and by the TAL in the RX path via the callback *NdisWdiAllocateWiFiFrameMetaData*. The TAL uses MiniportReserved[1] to store any additional frame metadata.

Datapath management requests and indications

For datapath management request and indication function reference, see WDI Datapath Management Functions.

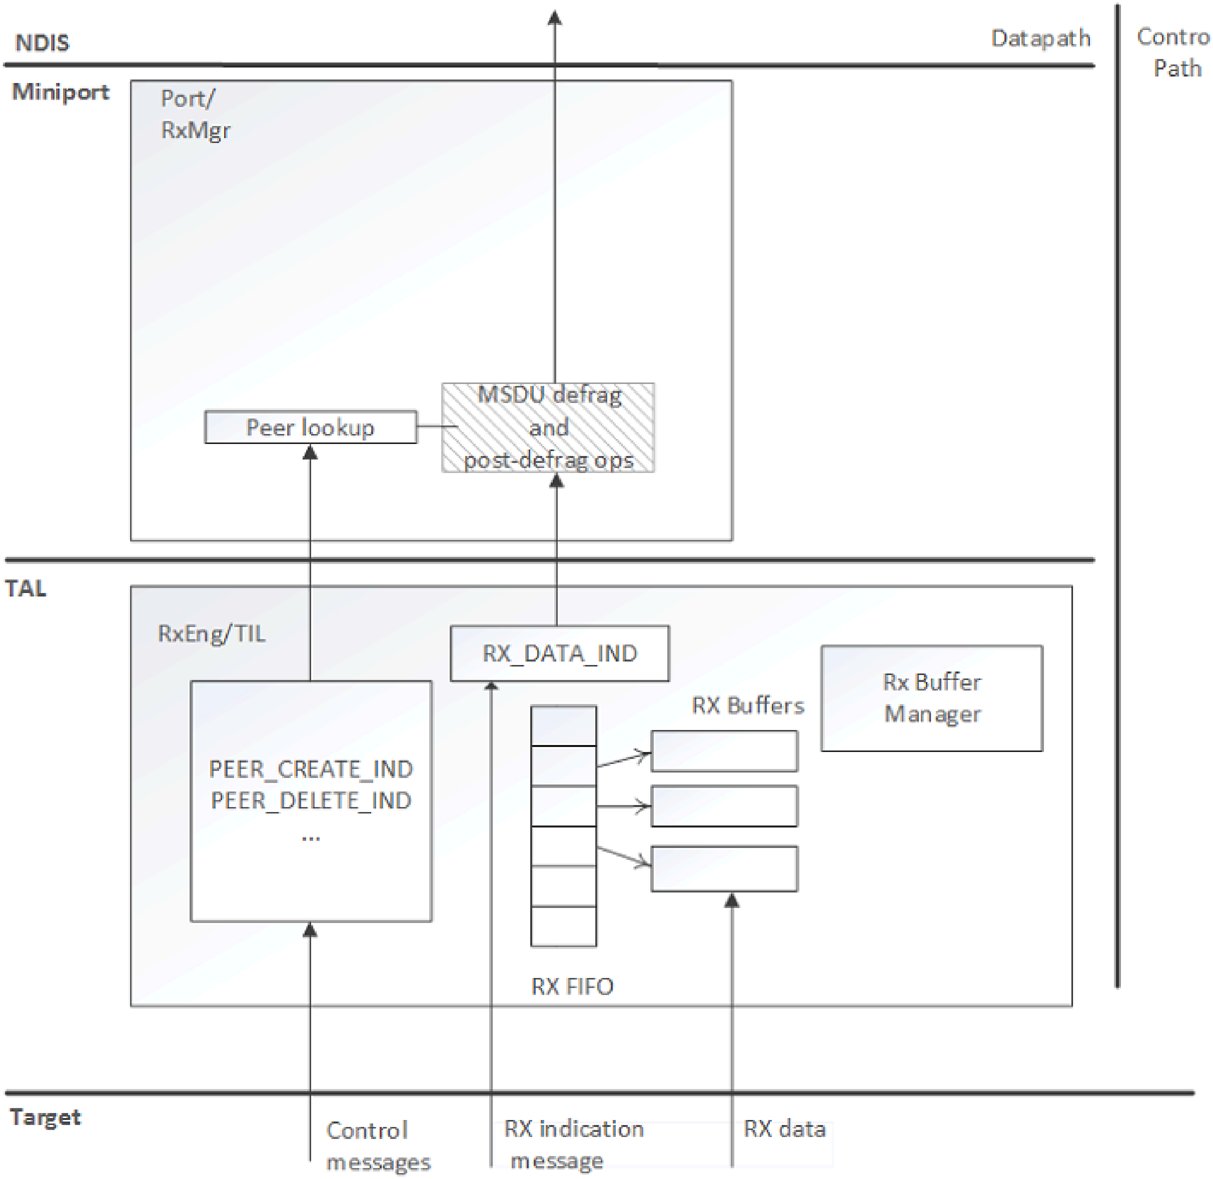
WDI RX path

Article • 03/14/2023

RX path components

The following diagram shows the RX path components.



RX Manager (RxMgr)

The RX Manager performs receive processing steps that are not offloaded to the target or performed by the RxEngine.

RX function	Description

RX function	Description
MSDU discard	Discard MSDUs with errors.
Queuing and throttling	Manage the DPC watchdog to prevent a bugcheck from too many indications per DPC, and too long at dispatch level. Provide backpressure to the RxEngine when appropriate to help with throttling.

RxEngine

The RxEngine sends and receives data-synchronous messages to and from the target, interprets RX descriptor formats, and manages buffers for direct hardware to software RX DMAs.

RX function	Description
Host-to-Target message construction	Construct host-to-target data path-related messages.
Target-to-Host message parsing	Parse and process target-to-host data-synchronous messages such as *NdisWdiRxInorderDataIndication*.
Interpretation of target RX descriptors	Provide an interface (functions) for querying RX frame attributes from the target-specific descriptor.
RX FIFO management	Provide a target-accessible FIFO for posting empty RX buffers for the target to fill. Remove buffers from the FIFO during *NdisWdiRxInorderDataIndication* processing, and provide replacement empty buffers.
RX buffer pool management	Maintain a pool of buffers for DMA transfer of receive frames.
MPDU discard	Discard MPDUs with errors. The target indicates the receive frames marked for discard - for example, due to FCS errors or ARQ duplication errors. This is only done if it is not implemented by the target.
MPDU reorder	Store MPDUs in order within an RX reordering array until the missing preceding MPDUs arrive. This is only done if it is not implemented by the target.

RX function	Description
MPDU PN chk	This is only done if it is not offloaded to the target.
MSDU Fragment Reassembly	This is only done if it is not offloaded to the target.

RX path requests and indications

For RX path request and indication function reference, see WDI RX Path Functions.

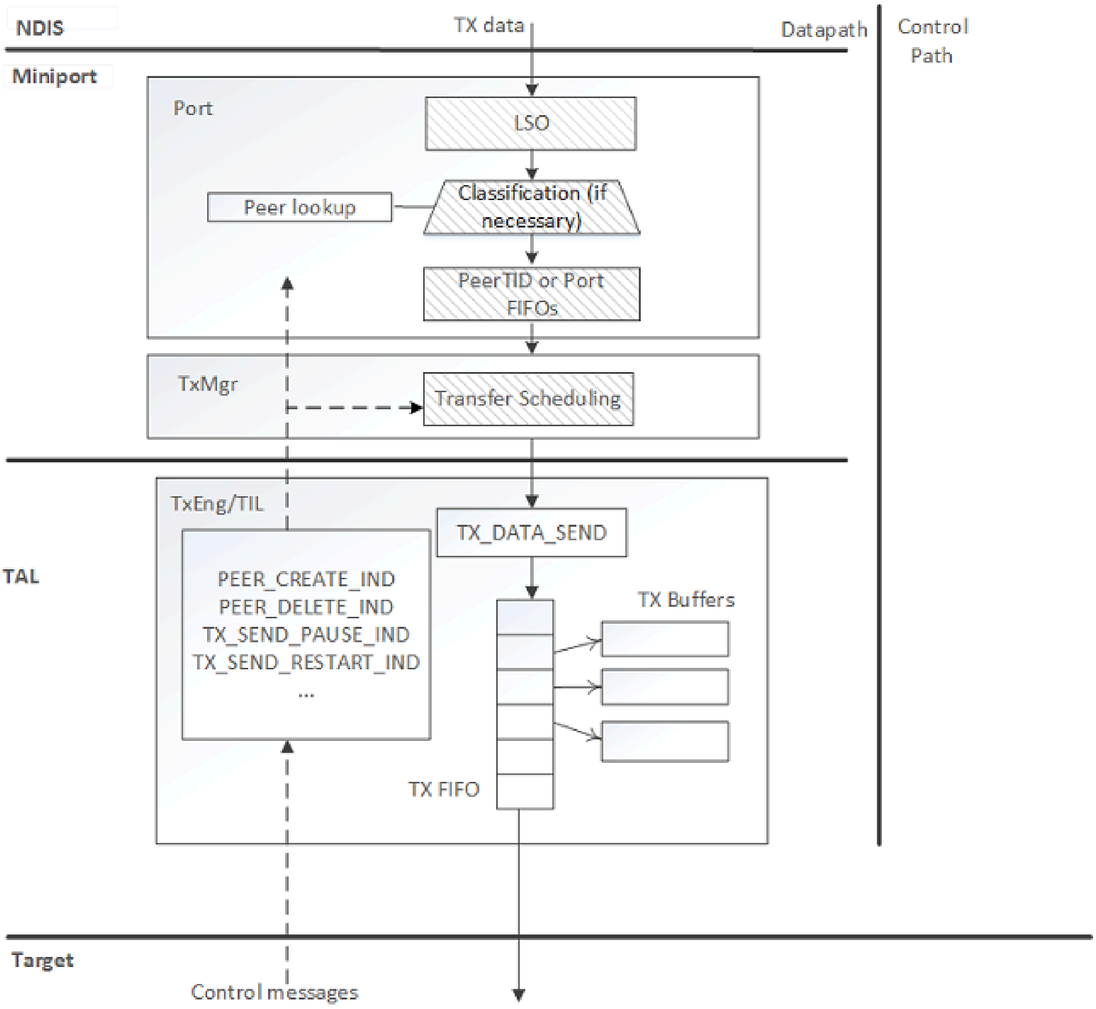
WDI RX Path Functions

WDI TX path

Article • 03/14/2023

TX path components

The following diagram shows the TX path components.



TX descriptors

The TAL uses a Target TX Descriptor (TTD) to inform the target of the size and location of the frame.

Different target WLAN devices may have different definitions of the TTD. Due to this, the TTD programming is done within the TAL, based on information provided by WDI. To program a TTD, WDI specifies a NET_BUFFER_LIST (NBL), through which the frame metadata, such as frame ID, extended TID, applicable task offloads, and encryption exemption action, is accessible.

The TAL transfers the TTD and the TX frame to the target. From the metadata in the TTD and fields within the frame's header, the target can determine the intended recipient of the transmit frame and how to transmit it.

Eventually, the target transmits the frame, and notifies the host when the transfer (and possibly transmission) is done. The target uses a TX completion message that specifies whether the transmission was successful, and the IDs of the frames whose transmission was completed.

Basic operation

Transmitting a data frame involves the following steps within the WLAN host TX software.

1. WDI obtains an NBL from NDIS and performs TX classification (if WDI is operating in PeerTID queuing mode).
2. The NBL is linked to a TTD obtained by querying the TAL. For efficiency, the TAL may preallocate TTDs from a lookaside list.
3. The TxMgr queues the transmit frame based on the PeerTID or Port, depending on the **TargetPriorityQueueing** mode.
4. The TxMgr provides the NBL and the attached TTD to the TxEngine, which in turn passes it to the TIL for transfer to the target. The TxEngine/TIL does not queue frames (for example, prior to making them available for DMA).
5. The TxEngine indicates the updated TX status of frames owned by the TxEngine/target using transfer completion (and transmit completion indication if applicable).
6. When a frame is both Transfer Complete (and if required, TX Complete), the TxMgr looks up the NBL using the frame ID, returns the TTD to the TxEngine's pool, and send-completes the frame to NDIS.

Host - target TX flow control

TX Flow control is necessary to avoid overwhelming the TIL and target resources.

The target-credit scheme and the pause/resume mechanism

The TxMgr queues and transfers TX frames to the target according to a credit-based scheme. The target provides the TX Engine with credit-update indications that specify the resources available for additional frames on the target. The number of credits used up by each frame on the target is determined at the time of TTD programming. The number of frames passed to the TxEngine as part of a send operation from a given queue is limited by the available credits and the cost of the frames at the head of the line in FIFO order.

To the TxMgr, credits have an abstract unit. The Target/TxEngine should use whatever definition of credit is most useful to the specific implementation.

The TAL uses pause/resume indications to stop/resume the flow of TX traffic from a given port, or destined to a particular receiver with a given TID. If the TxEngine gets a send request while the available credit is less than the maximum frame cost, the TxEngine pauses the traffic from the TxMgr (across all ports) until the next credit update from the target.

When WDI is in port queuing mode (**TargetPriorityQueueing** equals TRUE), pause/resume indications are only allowed/defined at a port or adapter level due to the absence of Peer,TID classification, and queuing.

Limiting the maximum frame count for send operations

To avoid the need for temporary queues in the TIL (for example, DMA rate matching queue), the number of frames that TxMgr passes to TxEngine in a send operation is limited by a maximum count specified by the TxEngine. This limit may be specific to the queue the TxMgr is attempting to send from and changes over time as more space is available in the TIL.

Host - target TX transfer scheduling

The TxMgr uses a single TX thread to submit frames to the TxEngine. There is a TX thread actively submitting frames to the TxEngine as long as there are backlogged queues.

The TxMgr schedules queues in the following manner depending on the queuing mode.

For WDI port queuing (**TargetPriorityQueueing** equals TRUE), the TxMgr services queues using Deficit Round Robin (DRR) across all backlogged port queues.

For WDI PeerTID queuing (**TargetPriorityQueueing** equals FALSE), the TxMgr services queues according to AC priority without starving any queues, and ensures that any bottlenecked resources in TIL and target are shared among RA-TID streams in a fair manner. It prevents slow streams from consuming a disproportionate share of such resources.

In general, the scheduler uses DRR to choose the Peer-TID queue to transmit from at any given time. For each queue, DRR associates a quantum parameter that limits the number of octets to send from the queue in each round. The TxEngine updates this parameter in each send operation involving the queue to match the expected size of one or two transmission opportunities.

In general, the DRR scheduler services only the RA-TID queues associated with the backlogged AC of highest priority. To prevent starvation, the scheduler periodically performs DRR across all backlogged queues.

Priority mapping for IHV reserved extended TIDs

Frames injected by the IHV with extended TID in the IHV reserved range map to the following extended ACs for the purposes of priority scheduling. The table is in order of increasing priority.

Extended TID	Extended AC
17	AC_BK
18	AC_BE
19	AC_VI
20	AC_VO
21	AC_PR0
22	AC_PR1
23	AC_PR2
24	AC_PR3

For WDI port queuing, all injected frames are treated equally regardless of the extended TID.

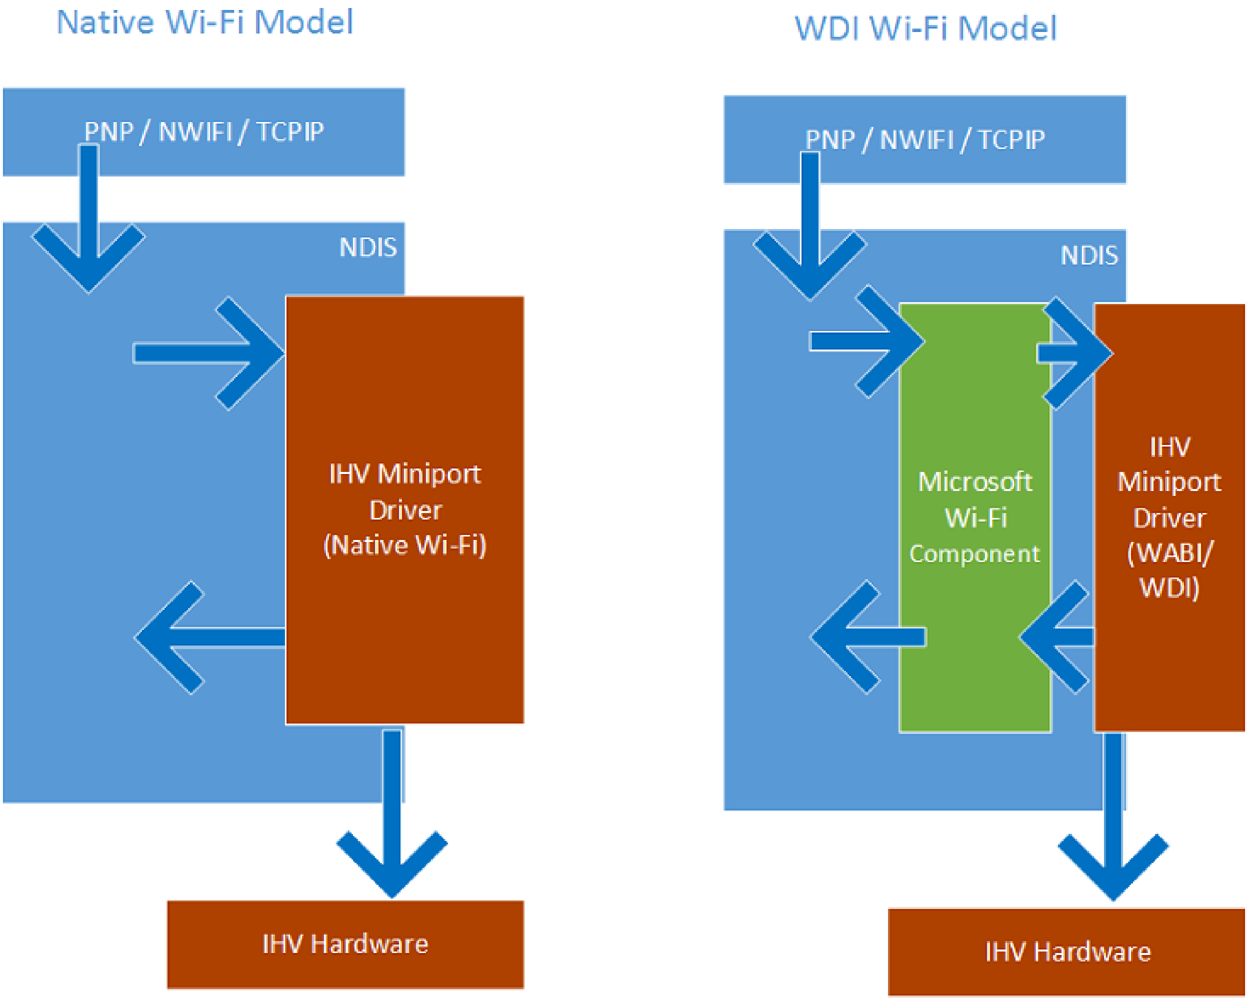
WDI IHV component model

Article • 03/14/2023

This section provides an overview of the NDIS interfaces for the WDI miniport driver and the expectations for those interfaces.

The IHV component in the WDI model is an NDIS miniport. It interfaces with the operating system and its networking stack using existing and new NDIS APIs. A Microsoft WLAN component sits between the WDI IHV miniport driver and the rest of the operating system. It provides a mapping between the WDI interfaces and the existing NDIS/Native WLAN interfaces. WDI commands are packaged as new NDIS OIDs and WDI indications are packaged as new NDIS indications. The data path interacts via NET_BUFFER_LIST structures using new handlers.

The figure below shows the overall architecture layout and a sample flow of messages (PNP actions, OIDs, and sends) from the operating system to the IHV miniport driver for both the old Native WLAN model and the new WDI WLAN model.



Besides assisting with the Native Wi-Fi interface requirements, the Microsoft WLAN component also handles most of the common NDIS requirements. For example, it handles the *MiniportPause* requirements from NDIS and converts them to WDI data and control path messages to ensure that NDIS requirements are met. However, it also provides the IHV miniport driver the ability to do additional work. The driver can register to be notified on *MiniportPause* call to do any additional cleanup it wants to do during *MiniportPause*.

WDI IHV driver interfaces

Article • 03/14/2023

The WDI IHV miniport is like any other NDIS miniport driver and it would follow the development practices and documentation for any NDIS miniport. A Native WLAN Miniport driver's responsibilities for the NDIS handlers are split between the MS Component and the WDI IHV driver. The Microsoft WLAN component takes care of the NDIS requirements that are applicable for all Wi-Fi miniports so that every IHV does not have to redo all that work. The mapping of and behavior changes for the NDIS handlers for the Native WLAN IHV miniport when applied to a WDI IHV miniport are described below.

- Driver installation
- DriverEntry
- MiniportSetOptions
- MiniportInitializeEx
- MiniportHaltEx
- MiniportDriverUnload
- MiniportPause
- MiniportRestart
- MiniportResetEx
- MiniportDevicePnPEventNotify
- MiniportShutdownEx
- MiniportOidRequest
- MiniportCancelOidRequest
- NdisMIndicateStatusEx
- MiniportDirectOidRequest
- MiniportCancelDirectOidRequest
- MiniportSendNetBufferLists
- MiniportCancelSend
- MiniportReturnNetBufferLists
- WDI handler: MiniportWdiOpenAdapter
- WDI handler: MiniportWdiCloseAdapter

Driver installation

There are no changes to the way the WDI IHV miniport driver is loaded and installed on the system. The INF and install process is similar to that of an IHV Native WLAN miniport driver. Like existing NDIS drivers, when the IHV driver needs to be loaded to work with the IHV's WLAN adapter, the operating system calls the IHV miniport driver's DriverEntry routine.

DriverEntry

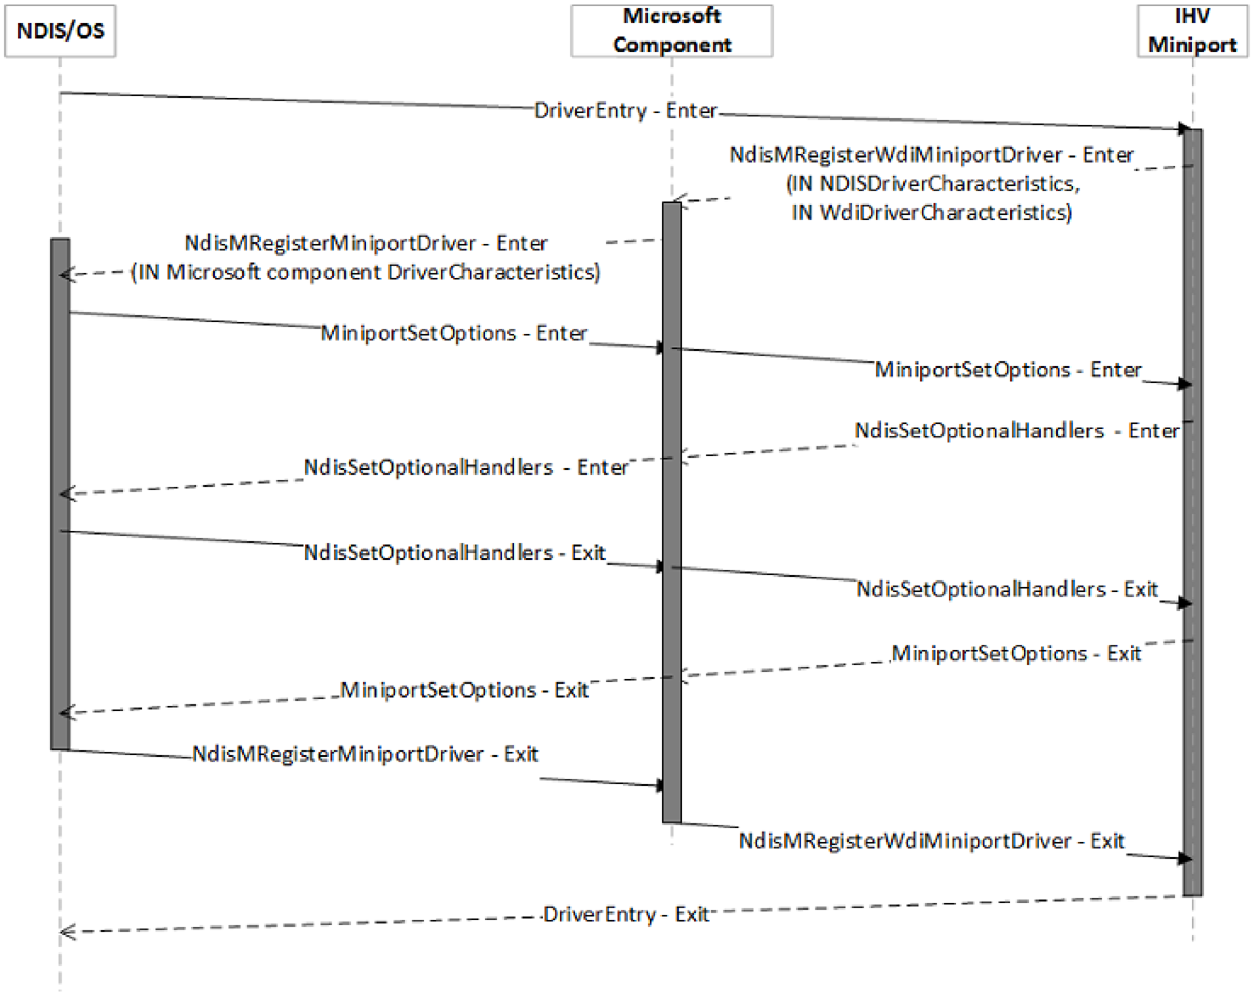
The operating system directly calls the WDI IHV miniport driver's DriverEntry routine. The IHV miniport follows most of the guidelines of a regular NDIS miniport's DriverEntry routine. The one exception is that instead of calling NdisMRegisterMiniportDriver, the IHV miniport calls NdisMRegisterWdiMiniportDriver to tell the operating system to enable the Microsoft WLAN component.

The following are the key parameters of NdisMRegisterWdiMiniportDriver.

- NDIS_MINIPORT_DRIVER_CHARACTERISTICS: This is the original NDIS structure that a Native Wi-Fi miniport uses to register with NDIS. For a WDI model, most of the handler parameters are optional. The only required handlers are **MINIPORT_OID_REQUEST_HANDLER** and **MINIPORT_DRIVER_UNLOAD**. **MINIPORT_OID_REQUEST_HANDLER** is used to pass WDI messages to the IHV driver. If any other handler is specified, the Microsoft WLAN component generally calls the handler after it has performed its own processing for the handler.
- NDIS_MINIPORT_DRIVER_WDI_CHARACTERISTICS: This is the new set of handlers that a WDI miniport driver must implement. It is used by the IHV driver to register additional handlers for the control path, and the full set of handlers for the data path.

When the IHV miniport calls NdisMRegisterWdiMiniportDriver, the Microsoft WLAN component updates the handlers of NDIS_MINIPORT_DRIVER_CHARACTERISTICS and call NDIS's NdisMRegisterMiniportDriver. The updates are done so that the Microsoft WLAN component can intercept the handlers for which it can provide assistance/simplification to the WDI IHV miniport driver.

Below is the typical flow of the DriverEntry process for the WDI IHV miniport driver



NDIS/OS
Microsoft Component
IHV Miniport
DriverEntry - Enter
NdisMRegisterWdiMiniportDriver - Enter
(IN NDISDriverCharacteristics,
IN WdiDriverCharacteristics)
NdisMRegisterMiniportDriver - Enter
(IN Microsoft component DriverCharacteristics)
MiniportSetOptions - Enter
MiniportSetOptions - Enter
NdisSetOptionalHandlers - Enter
NdisSetOptionalHandlers - Enter
NdisSetOptionalHandlers - Exit
NdisSetOptionalHandlers - Exit
MiniportSetOptions - Exit
MiniportSetOptions - Exit
NdisMRegisterMiniportDriver - Exit
NdisMRegisterWdiMiniportDriver - Exit
DriverEntry - Exit

For more information about DriverEntry, see DriverEntry of NDIS Miniport Drivers.

MiniportSetOptions

As shown in the above DriverEntry diagram, if the WDI IHV miniport has registered the *MiniportSetOptions* handler, the operating system calls that function in the context of the miniport driver calling NdisMRegisterWdiMiniportDriver.

If the IHV miniport driver registers any option handlers using NdisSetOptionalHandlers, those handlers may not be serialized through the WDI layer by the Microsoft component. Therefore, the IHV component is responsible for handling any synchronization requirements for those handlers.

MiniportInitializeEx

The WDI model splits the *MiniportInitializeEx* behavior into multiple WDI interface calls.

1. Call *MiniportWdiAllocateAdapter*.

   When the operating system finds an instance of the IHV hardware, this is the first call into the WDI IHV miniport driver. In this call, the WDI miniport performs the actions that are required to create a software representation (**MiniportAdapterContext**) of the device. It also determines information about the device to fill in the NDIS_MINIPORT_ADAPTER_REGISTRATION_ATTRIBUTES structure. The actual initialization of the device and the Wi-Fi stack is done later when the Microsoft component sends WDI commands down to perform specific initializations.

Using data obtained from the WDI IHV miniport driver, the Microsoft component calls **NdisMSetMiniportAttributes** and sets the NDIS_MINIPORT_ADAPTER_REGISTRATION_ATTRIBUTES on NDIS. Most fields of **NDIS_MINIPORT_ADAPTER_REGISTRATION_ATTRIBUTES** are filled with defaults by the Microsoft component. The IHV driver must populate the **MiniportAdapterContext** and **InterfaceType** fields.

Once this call returns from the IHV miniport driver, it starts receiving WDI commands via its *MiniportOidRequest* handler. During this call, the Microsoft component may not be able to perform reset/recovery operations, so any activity performed here should be quick and reliable.

2. Call *MiniportWdiOpenAdapter*.

   After *MiniportWdiAllocateAdapter*, the Microsoft component calls *MiniportWdiOpenAdapter* to load the firmware and initialize the hardware.

3. Multiple WDI commands using *MiniportOidRequest*.

   After *MiniportWdiOpenAdapter*, the Microsoft component sends the following tasks/properties/calls to the IHV miniport.

   a. Call *MiniportWdiTalTxRxInitialize* to initialize the data path and exchange handlers.
   b. Call OID_WDI_GET_ADAPTER_CAPABILITIES to get the adapter's capabilities.
   c. Call OID_WDI_SET_ADAPTER_CONFIGURATION to configure the adapter.
   d. Call OID_WDI_TASK_SET_RADIO_STATE to set the initial radio state if it is not already in the expected state.
   e. Call *MiniportWdiTalTxRxStart* to set up the data path.
   f. Call OID_WDI_TASK_CREATE_PORT to create the initial port.

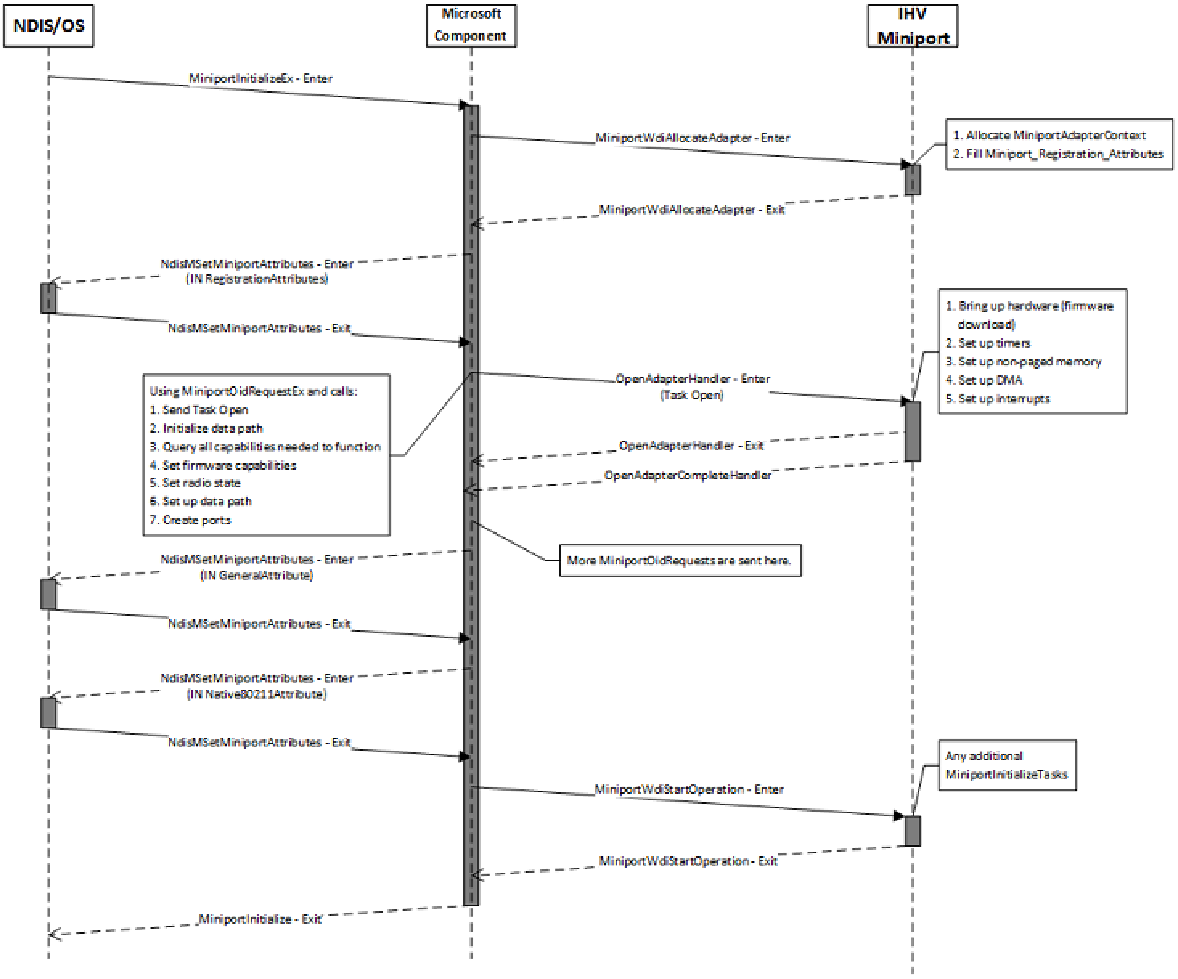
   Other commands may also be sent down to the IHV component as part of the MiniportInitializeEx processing of the Microsoft Component. However, until *MiniportWdiStartOperation* is called, the Microsoft component does not send any tasks down that need over-the-air communication. Except for OID_WDI_TASK_OPEN always being sent first, the order of the other commands/calls may change.

Using data obtained from the WDI IHV miniport driver, the Microsoft component calls NdisMSetMiniportAttributes and sets NDIS_MINIPORT_ADAPTER_GENERAL_ATTRIBUTES and NDIS_MINIPORT_ADAPTER_NATIVE_802_11_ATTRIBUTES on NDIS.

4. Call *MiniportWdiStartOperation*.

   This is an optional WDI miniport handler inside NDIS_MINIPORT_DRIVER_WDI_CHARACTERISTICS that the IHV driver can use to perform any additional MiniportInitializeEx tasks. It can also be used by the IHV miniport as a hint that the Microsoft component has finished initializing the miniport and the miniport can start any needed background activities.

   The diagram below shows the flow of MiniportInitializeEx.



NDIS/OS
Microsoft Component
IHV Miniport
MiniportInitializeEx - Enter
MiniportWdiAllocateAdapter - Enter
1. Allocate MiniportAdapterContext
2. Fill Miniport_Registration_Attributes
MiniportWdiAllocateAdapter - Exit
NdisMSetMiniportAttributes - Enter
(IN RegistrationAttributes)
NdisMSetMiniportAttributes - Exit
1. Bring up hardware (firmware download)
2. Set up timers
3. Set up non-paged memory
4. Set up DMA
5. Set up interrupts
Using MiniportOidRequestEx and calls:
1. Send Task Open
2. Initialize data path
3. Query all capabilities needed to function
4. Set firmware capabilities
5. Set radio state
6. Set up data path
7. Create ports
OpenAdapterHandler - Enter
(Task Open)
OpenAdapterHandler - Exit
OpenAdapterCompleteHandler
More MiniportOidRequests are sent here.
NdisMSetMiniportAttributes - Enter
(IN GeneralAttribute)
NdisMSetMiniportAttributes - Exit
NdisMSetMiniportAttributes - Enter
(IN Native80211Attribute)
NdisMSetMiniportAttributes - Exit
Any additional MiniportInitializeTasks
MiniportWdiStartOperation - Enter
MiniportWdiStartOperation - Exit
MiniportInitialize - Exit

If an intermediate operation fails, the Microsoft component undoes the previous operations and fails the miniport bring up. For example, if OID_WDI_TASK_CREATE_PORT fails, the data path is cleaned up, OID_WDI_TASK_CLOSE is sent, and the miniport fails.

MiniportHaltEx

In a Native Wi-Fi miniport, *MiniportHaltEx* is used to tell the miniport to stop operations and clean up the adapter instance. In the WDI model, the Microsoft component handles the original *MiniportHaltEx* call and splits it into multiple WDI interface calls.

1. Call *MiniportWdiStopOperation*.

   This is an optional WDI miniport handler inside **NDIS_MINIPORT_DRIVER_WDI_CHARACTERISTICS** that the IHV driver can use to undo the operations it performed in *MiniportWdiStartOperation*.

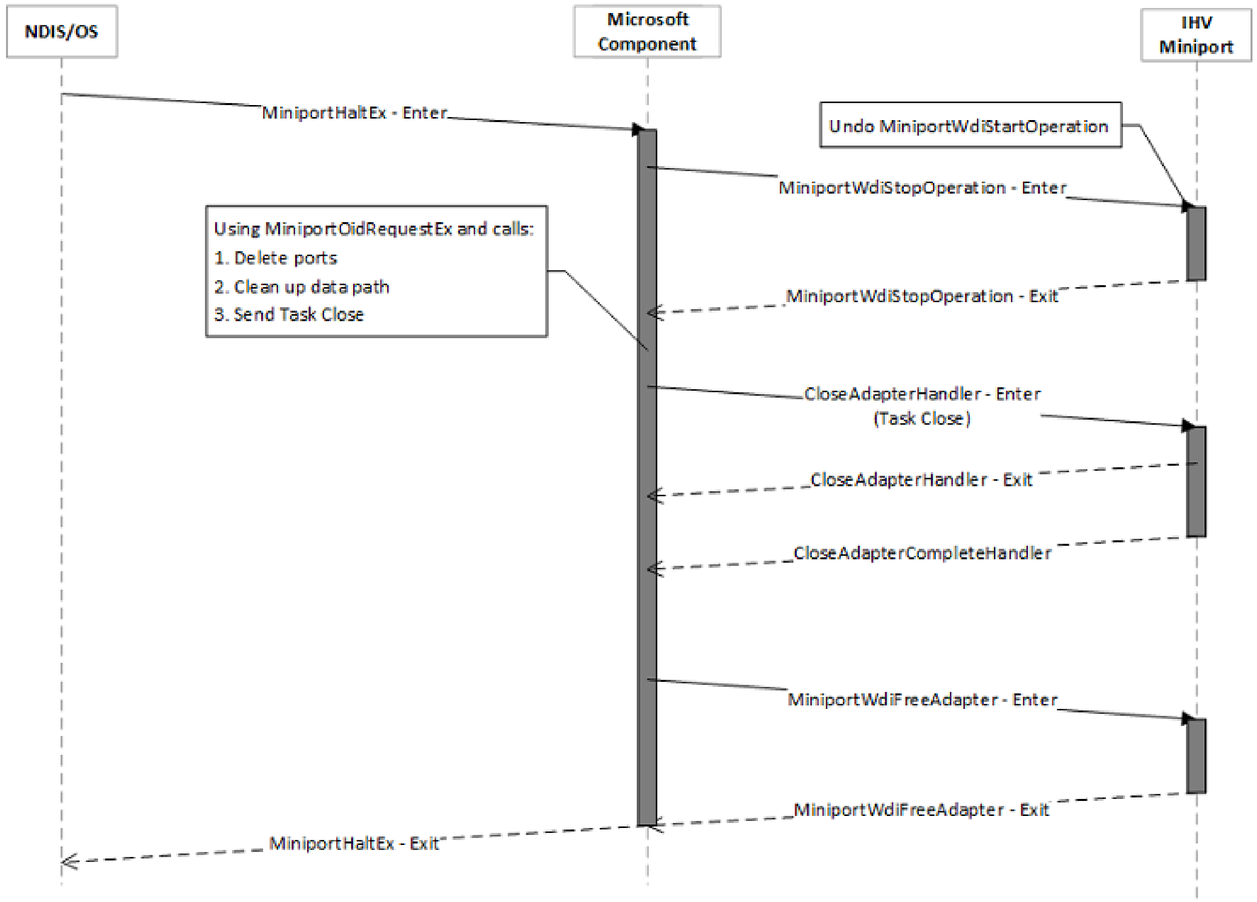
2. Multiple WDI Commands using *MiniportOidRequest*.

   After *MiniportWdiStopOperation*, the Microsoft component sends tasks/properties to the IHV miniport to clean up the current state of the IHV driver. This cleanup may include the following.

   a. Call OID_WDI_TASK_DISCONNECT/OID_WDI_TASK_STOP_AP to tear down any existing connections.
   b. Call OID_WDI_TASK_DELETE_PORT to delete all created ports.
   c. Call *MiniportWdiTalTxRxStop* to stop the data path.
   d. Call *MiniportWdiTalTxRxDeinitialize* to deinitialize the data path.
   e. Call to clean up the hardware state. This is sent to the IHV using the *MiniportWdiCloseAdapter* that has been registered by the IHV driver.

3. Once all of the above commands are called, the Microsoft component calls *MiniportWdiFreeAdapter* to have the IHV driver delete any software state it may have.

The diagram below shows the flow of MiniportHaltEx.



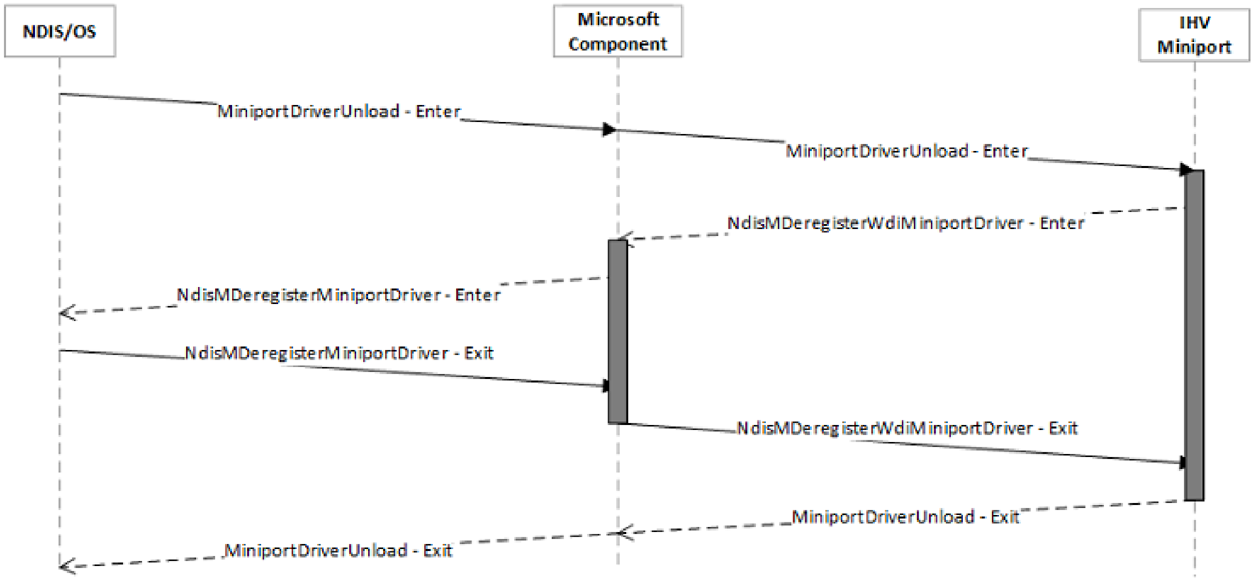
NDIS/OS
Microsoft Component
IHV Miniport
MiniportHaltEx - Enter
Undo MiniportWdiStartOperation
MiniportWdiStopOperation - Enter
Using MiniportOidRequestEx and calls:
1. Delete ports
2. Clean up data path
3. Send Task Close
MiniportWdiStopOperation - Exit
CloseAdapterHandler - Enter
(Task Close)
CloseAdapterHandler - Exit
CloseAdapterCompleteHandler
MiniportWdiFreeAdapter - Enter
MiniportWdiFreeAdapter - Exit
MiniportHaltEx - Exit

The MiniportHaltEx processing is not performed if the device is surprise removed or if the system is being powered off. For surprise removal, refer to the MiniportDevicePnPEventNotify handler behavior. For system shutdown, refer to the MiniportShutdownEx handler behavior.

MiniportDriverUnload

MiniportDriverUnload is the handler that is called before the WDI IHV miniport is unloaded. The WDI IHV miniport driver calls the Microsoft component to deregister itself. The Microsoft component calls **NdisMDeregisterMiniportDriver**.

The diagram below shows the flow of MiniportDriverUnload.

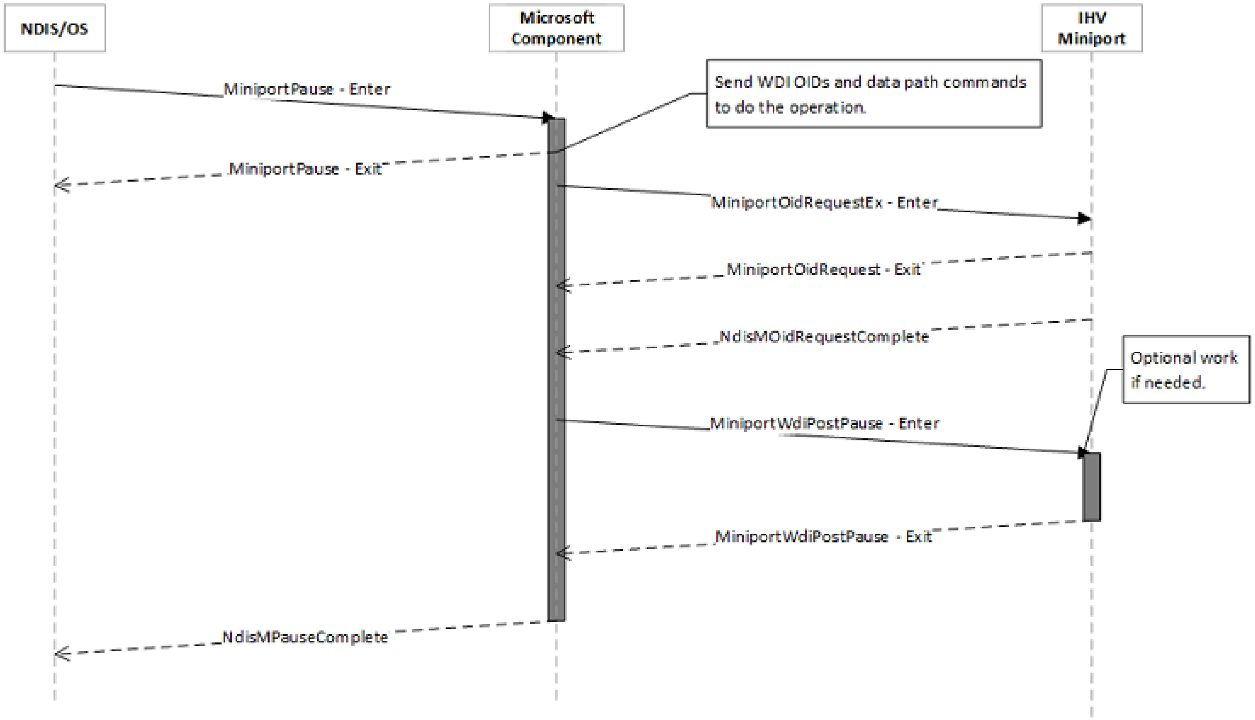


NDIS/OS
Microsoft Component
IHV Miniport
MiniportDriverUnload - Enter
MiniportDriverUnload - Enter
NdisMDeregisterWdiMiniportDriver - Enter
NdisMDeregisterMiniportDriver - Enter
NdisMDeregisterMiniportDriver - Exit
NdisMDeregisterWdiMiniportDriver - Exit
MiniportDriverUnload - Exit
MiniportDriverUnload - Exit

MiniportPause

The NDIS *MiniportPause* requirements are handled by the Microsoft component. As part of MiniportPause, the Microsoft component stops the data path and waits for it to clean up. The WDI IHV miniport can optionally register for a *MiniportWdiPostAdapterPause* callback that is called by the Microsoft component after it finishes the data path cleanup.

The diagram below shows the flow of MiniportPause.

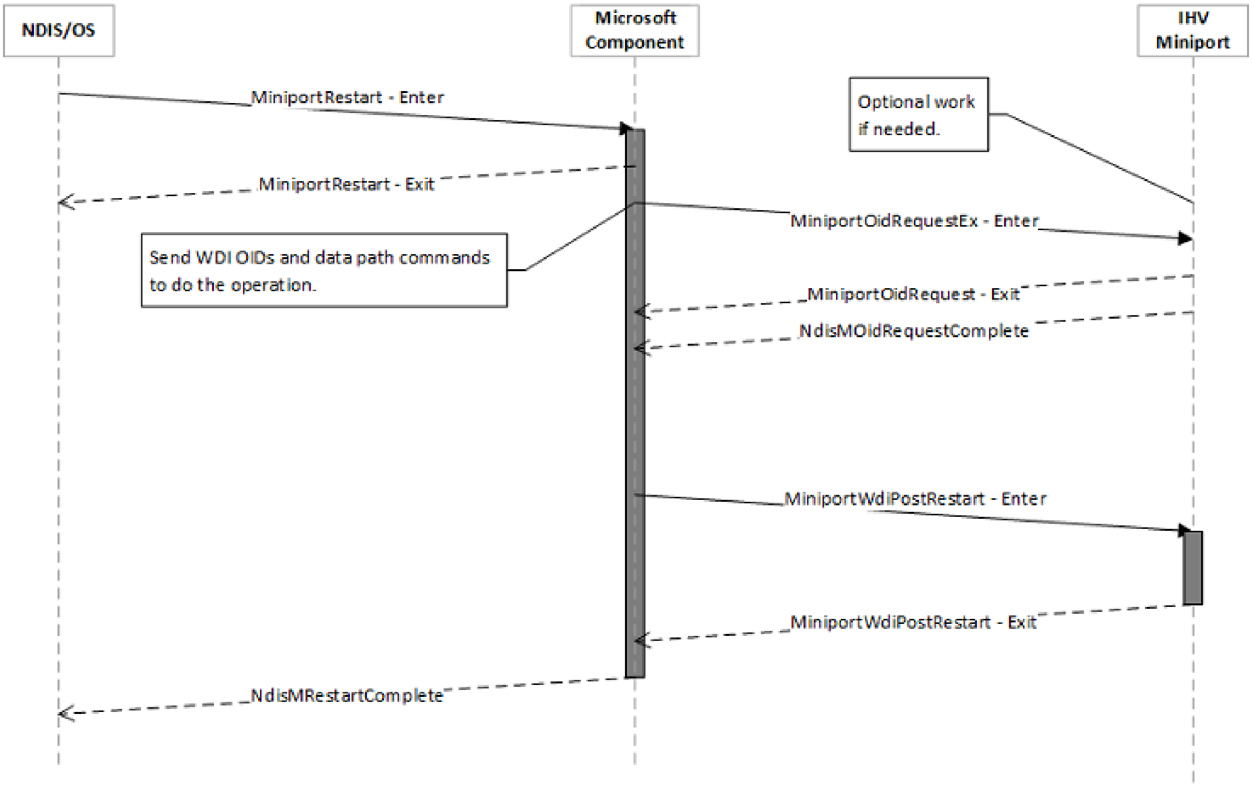


NDIS/OS
Microsoft Component
IHV Miniport
MiniportPause - Enter
Send WDI OIDs and data path commands to do the operation.
MiniportPause - Exit
MiniportOidRequestEx - Enter
MiniportOidRequest - Exit
NdisMOidRequestComplete
Optional work if needed.
MiniportWdiPostPause - Enter
MiniportWdiPostPause - Exit
NdisMPauseComplete

MiniportRestart

The NDIS *MiniportRestart* requirements are handled by the Microsoft component. As part of MiniportRestart, the Microsoft component undoes the data path pause work that it performed as part of MiniportPause. The WDI IHV miniport can optionally register for a *MiniportWdiPostAdapterRestart* callback that is called by the Microsoft component after it finishes restarting the data path.

The diagram below shows the flow of MiniportRestart.



NDIS/OS
Microsoft Component
IHV Miniport
MiniportRestart - Enter
Optional work if needed.
MiniportRestart - Exit
MiniportOidRequestEx - Enter
Send WDI OIDs and data path commands to do the operation.
MiniportOidRequest - Exit
NdisMOidRequestComplete
MiniportWdiPostRestart - Enter
MiniportWdiPostRestart - Exit
NdisMRestartComplete

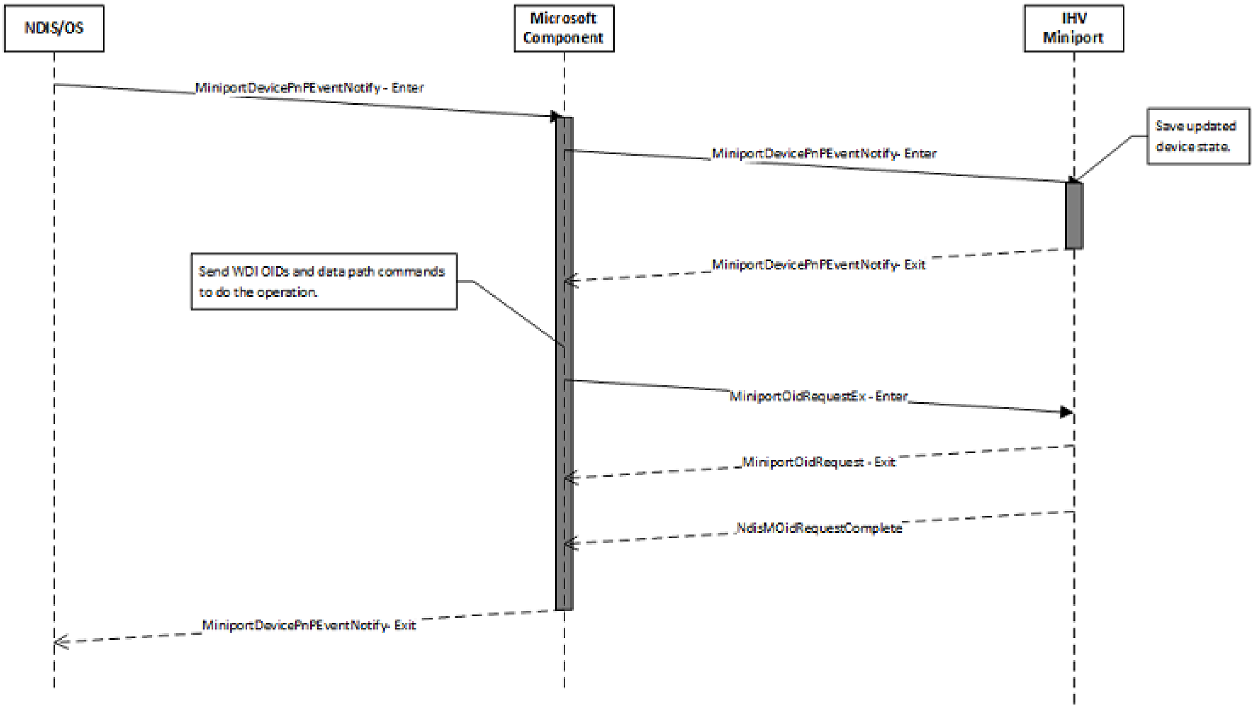
MiniportResetEx

MiniportResetEx is not handled by the Microsoft component. The WDI IHV miniport can optionally register for a *MiniportResetEx* callback that is called by the Microsoft component.

MiniportDevicePnPEventNotify

MiniportDevicePnPEventNotify is used to notify an NDIS driver of PNP events such as a device's surprise removal. When NDIS sends this notification, it is first forwarded to the WDI IHV miniport for processing. After the IHV component has finished processing it, the Microsoft component performs the appropriate processing for this event. The call that is forwarded into the IHV component is not serialized with other tasks and callbacks.

The diagram below shows the flow of MiniportDevicePnPEventNotify.

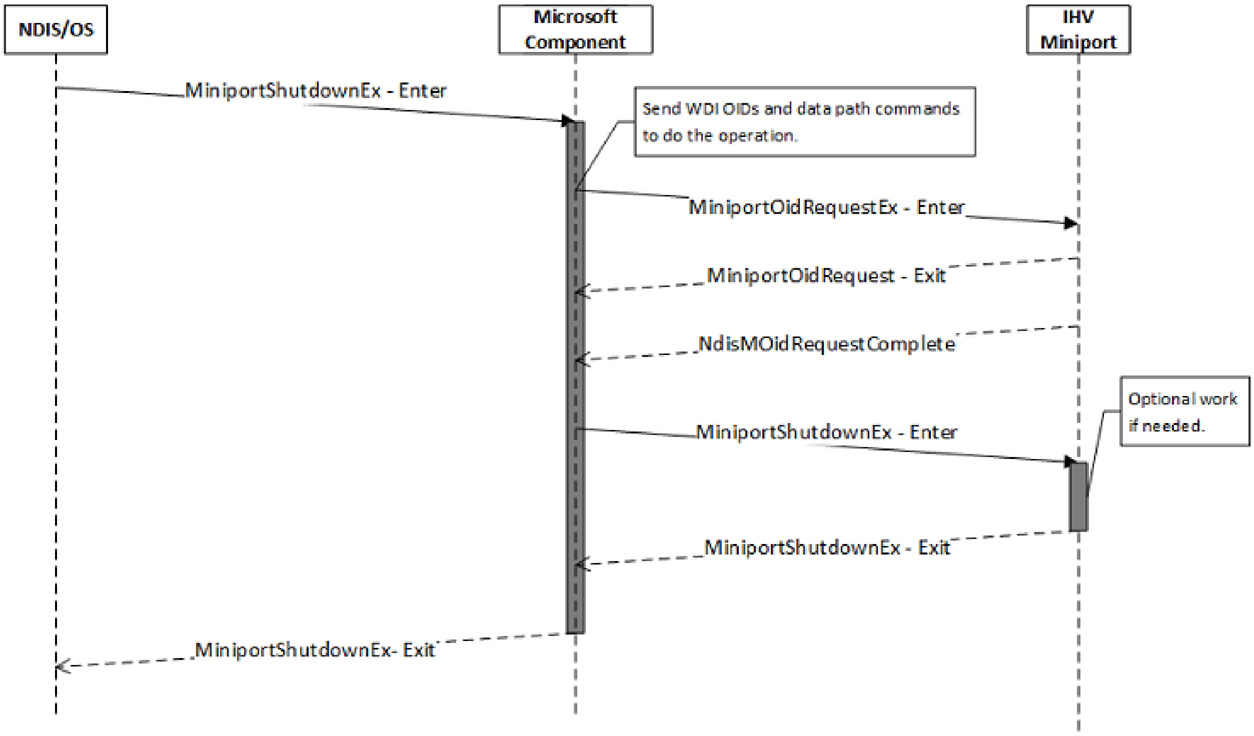


NDIS/OS
Microsoft Component
IHV Miniport
MiniportDevicePnPEventNotify - Enter
MiniportDevicePnPEventNotify- Enter
Save updated device state.
MiniportDevicePnPEventNotify- Exit
Send WDI OIDs and data path commands to do the operation.
MiniportOidRequestEx - Enter
MiniportOidRequest - Exit
NdisMOidRequestComplete
MiniportDevicePnPEventNotify- Exit

MiniportShutdownEx

MiniportShutdownEx is used to notify an NDIS driver about system shutdown events. When NDIS sends this notification, it is first handled by the Microsoft component. After the Microsoft component finishes processing it, it passes the event to the WDI IHV miniport for processing.

The diagram below shows the flow of MiniportShutdownEx.



NDIS/OS
Microsoft Component
IHV Miniport
MiniportShutdownEx - Enter
Send WDI OIDs and data path commands to do the operation.
MiniportOidRequestEx - Enter
MiniportOidRequest - Exit
NdisMOidRequestComplete
Optional work if needed.
MiniportShutdownEx - Enter
MiniportShutdownEx - Exit
MiniportShutdownEx- Exit

MiniportOidRequest

The *MiniportOidRequest* handler is a required handler that the WDI IHV miniport must implement. It is used by the Microsoft component to submit WDI commands to the IHV miniport. It is also used to forward OIDs that the Microsoft component does not handle to the IHV miniport.

The *MiniportOidRequest* call into the WDI IHV miniport should be considered as the M1 message for a WDI command. The completion of the OID (either via **NdisMOidRequestComplete** or via a return non-PENDING from *MiniportOidRequest*) should be considered as the M3 message for a WDI task/command.

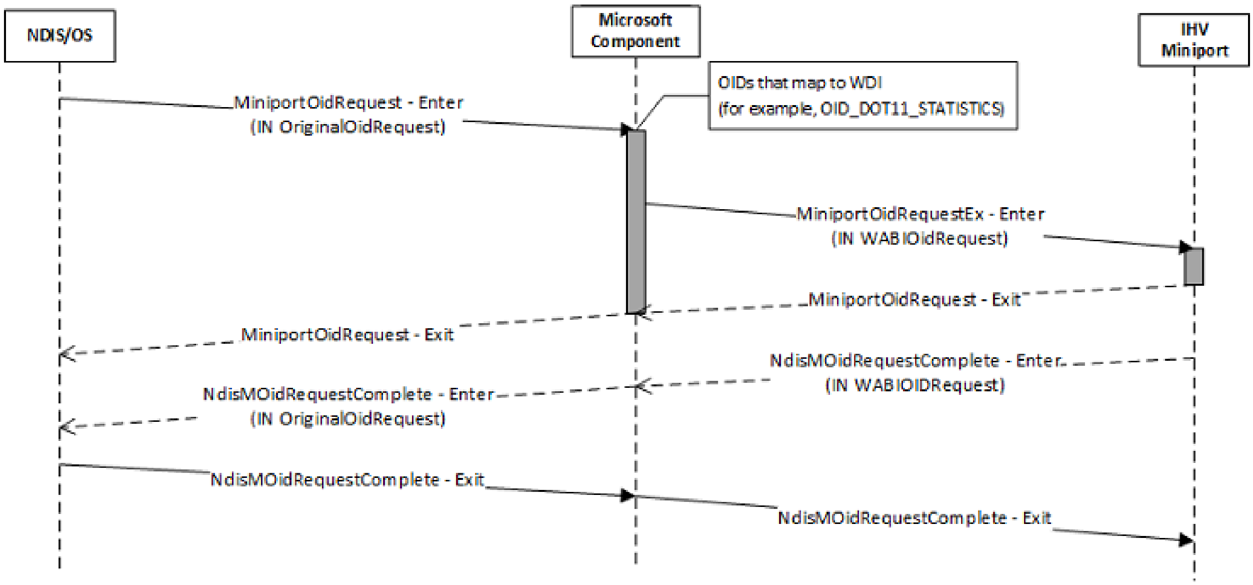
For every WDI command, there are two potential fields where an NDIS_STATUS code can be returned for the operation -- the status code from the *MiniportOidRequest* call (or **NdisMOidRequestComplete**), and the status code in the **WDI_MESSAGE_HEADER** field (either on the OID completion or via **NdisMIndicateStatusEx**). The Microsoft component always looks at the NDIS_STATUS from the OID completion before it looks at the **WDI_MESSAGE_HEADERStatus** field. The expectations of the IHV component for WDI OID processing are as follows.

1. WDI OIDs are submitted to the IHV component using an **NDIS_OID_REQUESTRequestType** of **NdisRequestMethod**, and the corresponding message and message length are in the **DATA.METHOD_INFORMATION.InformationBuffer** and **DATA.METHOD_INFORMATION.InputBufferLength** fields respectively.
2. The IHV component reports an error in the OID completion if there is an error while processing the command, and sets the Status field of the **WDI_MESSAGE_HEADER** to non-success if it has a Wi-Fi level failure.
3. For tasks and properties, the port number for the request is in the **WDI_MESSAGE_HEADERPortId** field. The **PortNumber** in the **NDIS_OID_REQUEST** is always set to 0.
4. For completion of the OID, it is acceptable for the *MiniportOidRequest* to return NDIS_STATUS_PENDING and complete the OID later (synchronously or asynchronously) with **NdisMOidRequestComplete**.
5. If the IHV component completes the OID with NDIS_STATUS_SUCCESS, it must populate the **BytesWritten** field of the OID request with the appropriate number of bytes, including space for the **WDI_MESSAGE_HEADER**.
6. If the IHV component does not have enough space in the **DATA.METHOD_INFORMATION.OutputBufferLength** field to fill the response, it completes the OID with NDIS_STATUS_BUFFER_TOO_SHORT and populates the **DATA.METHOD_INFORMATION.BytesNeeded** field. The Microsoft component may

attempt to allocate a buffer of the requested size and submit a new request to the IHV.

7. If it is a task, the task's M4 (NdisMIndicateStatusEx) must only be indicated if the task was reported as started successfully -- OID completion is successful and the **Status** in the WDI_MESSAGE_HEADER in OID completion was success.

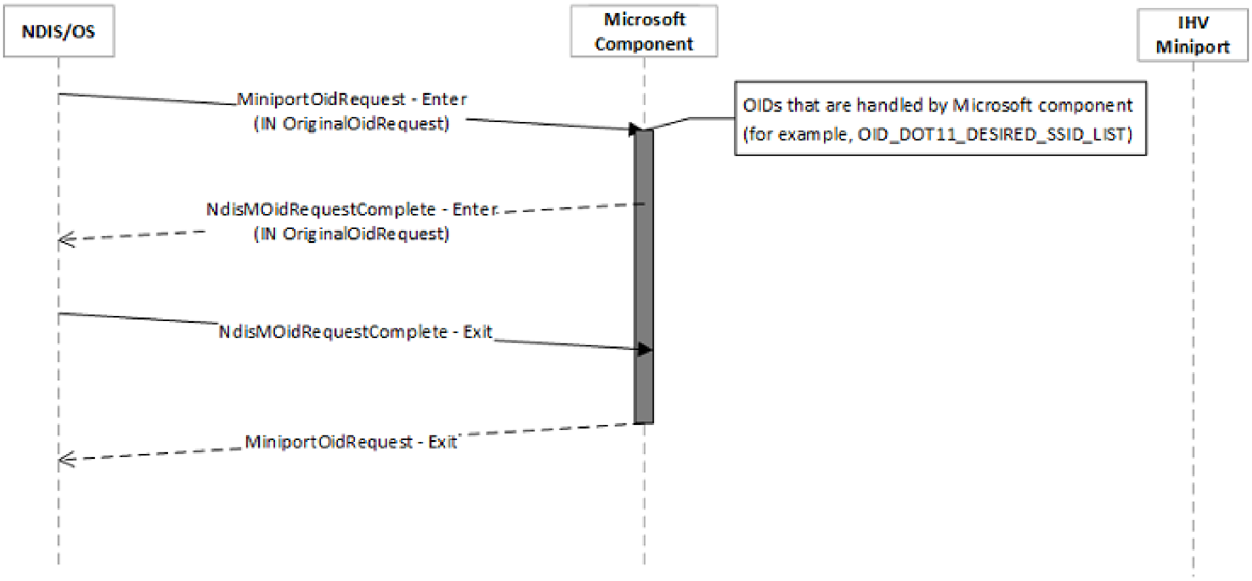
The diagram below shows an example of an NDIS OID request that maps to a single WDI command. When the OID request is submitted by the operating system, the Microsoft component converts it to a WDI OID request and submits the WDI OID request to the IHV miniport. When the IHV miniport completes the OID, the Microsoft component appropriately completes the original OID request.



NDIS/OS
Microsoft Component
IHV Miniport
OIDs that map to WDI
(for example, OID_DOT11_STATISTICS)
MiniportOidRequest - Enter
(IN OriginalOidRequest)
MiniportOidRequestEx - Enter
(IN WABIOidRequest)
MiniportOidRequest - Exit
MiniportOidRequest - Exit
NdisMOidRequestComplete - Enter
(IN WABIOIDRequest)
NdisMOidRequestComplete - Enter
(IN OriginalOidRequest)
NdisMOidRequestComplete - Exit
NdisMOidRequestComplete - Exit

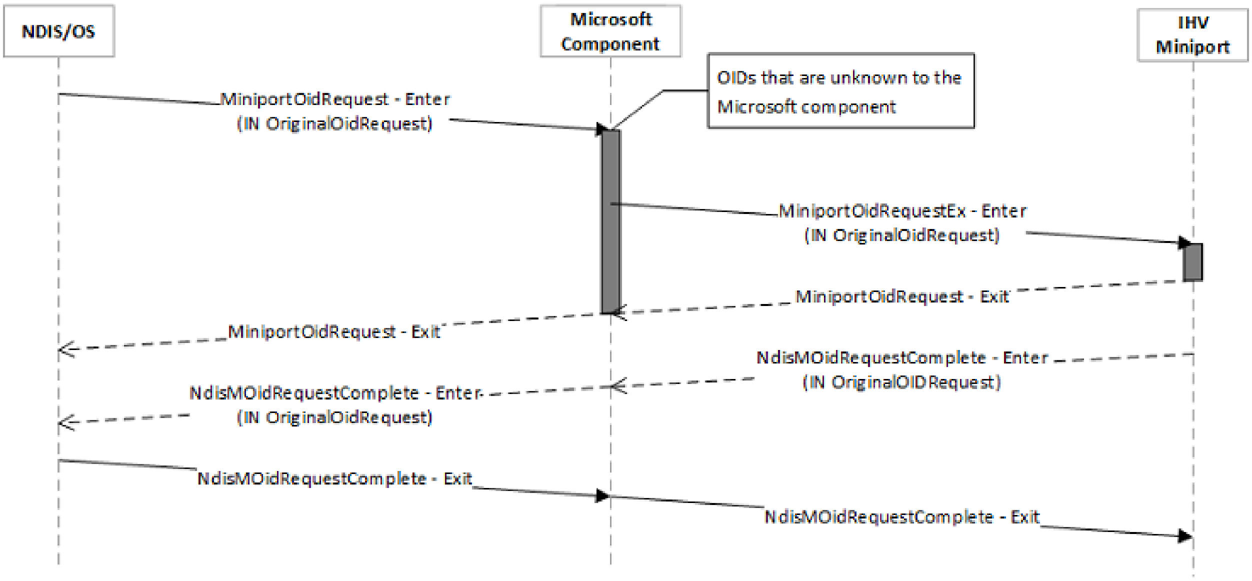
If the OriginalOidRequest maps to multiple WDI OidRequests and one of the WDI requests fails, the OriginalOidRequest also fails. If a subset of the intermediate operations already finished, the Microsoft component attempts to undo the operations that support clean up.

The diagram below shows an example of an NDIS OID request that is handled completed by the Microsoft component. When the OID request is submitted by the operating system, the Microsoft component processes and completes the OID. This OID is not passed to the WDI IHV miniport.



NDIS/OS
Microsoft Component
IHV Miniport
OIDs that are handled by Microsoft component (for example, OID_DOT11_DESIRED_SSID_LIST)
MiniportOidRequest - Enter (IN OriginalOidRequest)
NdisMOidRequestComplete - Enter (IN OriginalOidRequest)
NdisMOidRequestComplete - Exit
MiniportOidRequest - Exit

OIDs that are not understood by the Microsoft component are forwarded directly to the IHV component for processing.



NDIS/OS
Microsoft Component
IHV Miniport
OIDs that are unknown to the Microsoft component
MiniportOidRequest - Enter (IN OriginalOidRequest)
MiniportOidRequestEx - Enter (IN OriginalOidRequest)
MiniportOidRequest - Exit
MiniportOidRequest - Exit
NdisMOidRequestComplete - Enter (IN OriginalOIDRequest)
NdisMOidRequestComplete - Enter (IN OriginalOidRequest)
NdisMOidRequestComplete - Exit
NdisMOidRequestComplete - Exit

The behavior of MiniportOidRequest is unchanged for the WDI IHV miniport driver (as compared to a Native Wi-Fi miniport). The calls are serialized and the IHV miniport can either complete it synchronously or asynchronously with a call to NdisMOidRequestComplete.

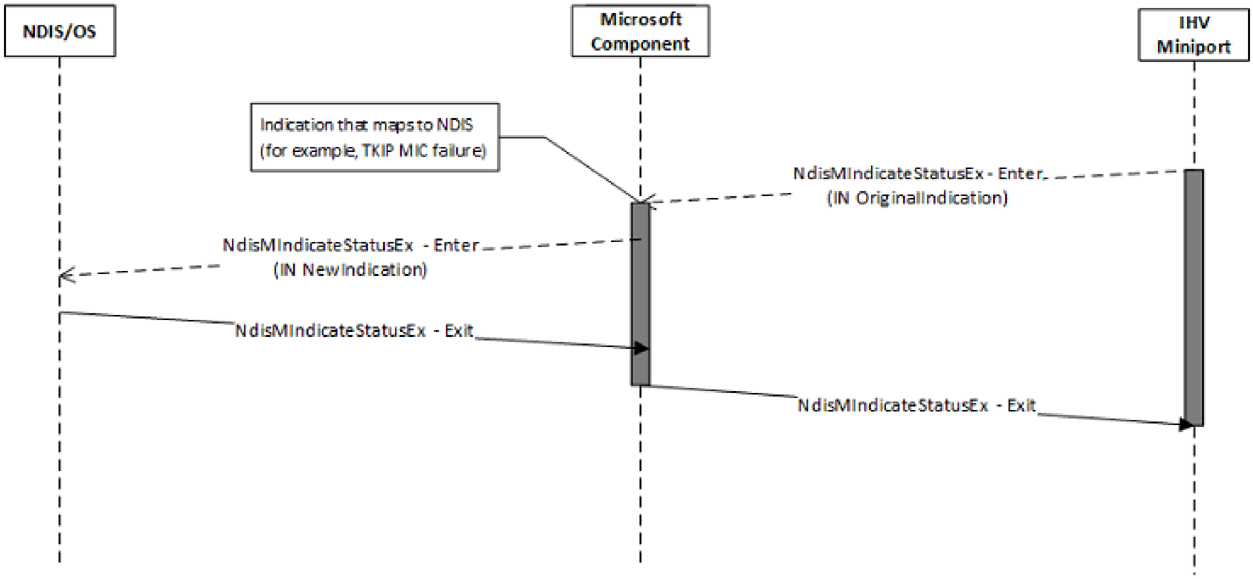
MiniportCancelOidRequest

This is an optional handler that is used by a WDI IHV miniport that needs to handle OIDs that are not mapped to WDI messages. This handler is not used for any WDI OIDs. WDI OIDs must complete quickly and there is no need for the IHV miniport driver to attempt to cancel a pending OID. Cancellation of WDI tasks is handled using the appropriate cancel task OID request. For unmapped OIDs, the expected behavior is defined by NDIS.

NdisMIndicateStatusEx

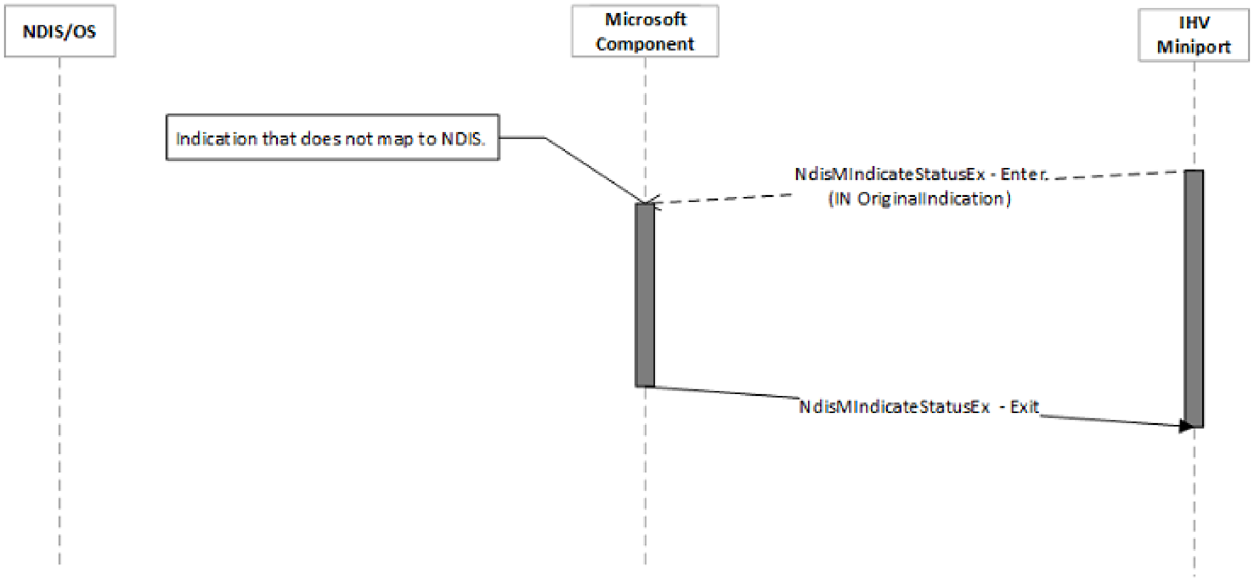
NdisMIndicateStatusEx is used by the WDI IHV miniport to send indications to the Microsoft component. The indications may be unsolicited indications such as TKIP MIC failures, or solicited indications for the completion (M4) for a task.

The diagram below shows an example of a WDI indication that has a corresponding NDIS/Native Wi-Fi indication. When the indication is submitted by the IHV miniport to the Microsoft component, the Microsoft component converts it to an existing indication and forwards it to the operating system.



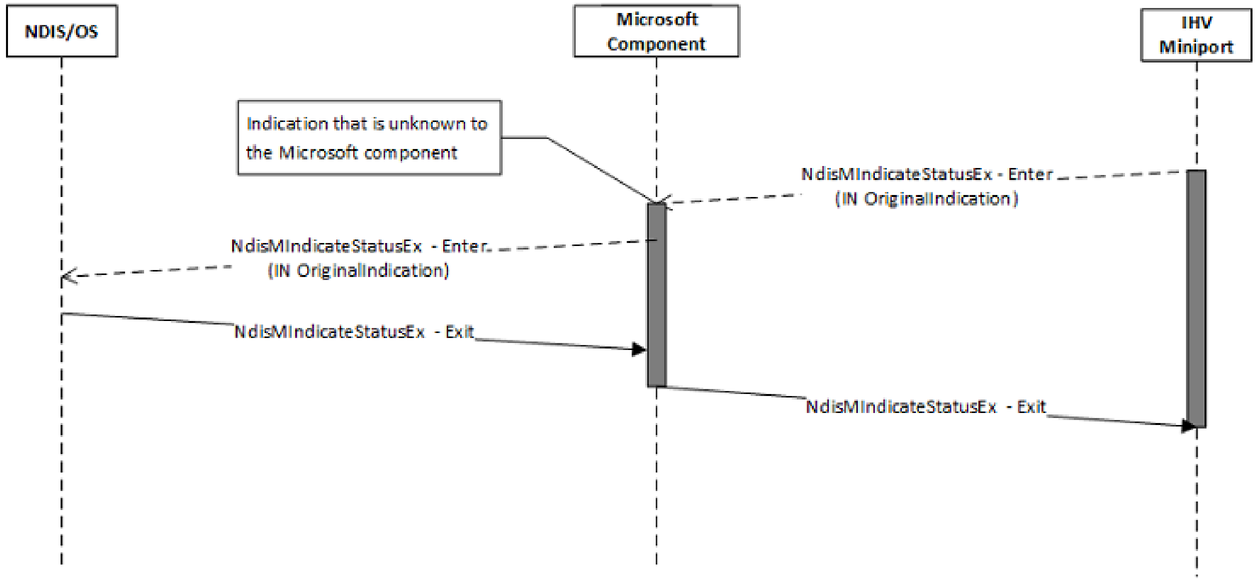
NDIS/OS
Microsoft Component
IHV Miniport
Indication that maps to NDIS (for example, TKIP MIC failure)
NdisMIndicateStatusEx - Enter (IN OriginalIndication)
NdisMIndicateStatusEx - Enter (IN NewIndication)
NdisMIndicateStatusEx - Exit
NdisMIndicateStatusEx - Exit

The diagram below shows an example of a WDI indication that has no corresponding NDIS/Native Wi-Fi indication. This is handled by the Microsoft component.



NDIS/OS
Microsoft Component
IHV Miniport
Indication that does not map to NDIS.
NdisMIndicateStatusEx - Enter (IN OriginalIndication)
NdisMIndicateStatusEx - Exit

The diagram below shows an indication that is not recognized by the Microsoft component. The indication is forwarded as-is to the operating system.



NDIS/OS
Microsoft Component
IHV Miniport
Indication that is unknown to the Microsoft component
NdisMIndicateStatusEx - Enter
(IN OriginalIndication)
NdisMIndicateStatusEx - Enter
(IN OriginalIndication)
NdisMIndicateStatusEx - Exit
NdisMIndicateStatusEx - Exit

The behavior of NdisMIndicateStatusEx is unchanged for the WDI IHV miniport driver (as compared to a Native Wi-Fi miniport).

MiniportDirectOidRequest

This is an optional handler that is registered by a WDI IHV miniport driver if it needs to handle Direct OIDs that are not mapped to WDI messages. All existing Direct OIDs for Wi-Fi Direct are mapped to WDI messages, so this handler is not required to support that functionality. Unsupported Direct OIDs are not serialized by the Microsoft component.

MiniportCancelDirectOidRequest

This is an optional handler that is used by a WDI IHV miniport that needs to handle Direct OIDs that are not mapped to WDI messages. For unmapped OIDs, the expected behavior is defined by NDIS.

MiniportSendNetBufferLists

This handler is not used in a WDI IHV miniport driver and should not be provided. The Microsoft component uses the data path handlers registered through NDIS_MINIPORT_DRIVER_WDI_CHARACTERISTICS to submit send packets to the IHV miniport.

MiniportCancelSend

This handler is not used in a WDI IHV miniport driver and should not be provided.

MiniportReturnNetBufferLists

This handler is not used in a WDI IHV Miniport driver and should not be provided. The Microsoft component uses the data path handlers registered through **NDIS_MINIPORT_DRIVER_WDI_CHARACTERISTICS** to return received packets to the IHV miniport.

WDI handler: MiniportWdiOpenAdapter

The *MiniportWdiOpenAdapter* handler is used by the Microsoft component to initiate the Open Task operation on the IHV driver. This call must complete quickly and if the open operation has been successfully started, the IHV must return NDIS_STATUS_SUCCESS on this call and call the **OpenAdapterComplete** handler that is passed into the **NDIS_WDI_INIT_PARAMETERS** parameter of *MiniportWdiAllocateAdapter*.

WDI handler: MiniportWdiCloseAdapter

The *MiniportWdiCloseAdapter* handler is used by the Microsoft component to initiate the Close Task operation on the IHV driver. This call must complete quickly and if the open operation has been successfully started, the IHV must return NDIS_STATUS_SUCCESS on this call and call the **CloseAdapterComplete** handler that is passed into the **NDIS_WDI_INIT_PARAMETERS** parameter of the *MiniportWdiAllocateAdapter*.

WDI NDIS interface restrictions

Article • 03/14/2023

The WDI IHV miniport driver has access to all of the functionality provided by NDIS and KMDF. It is recommended that the IHV driver use the KMDF primitives for talking to the rest of the operating system whenever possible. While the model does not restrict the IHV miniport from calling any of the NDIS APIs, some NDIS APIs are called by the Microsoft WLAN component so the IHV driver should not call them.

The WDI IHV miniport driver needs to be aware of the following restrictions on NDIS interfaces.

Function	Restrictions	Alternative
NdisMRegisterMiniportDriver	Disallowed	NdisMRegisterWdiMiniportDriver
NdisMDeregisterMiniportDriver	Disallowed	NdisMDeregisterWdiMiniportDriver
NdisMSetMiniportAttributes	Disallowed with **MiniportAttributes** types: NDIS_MINIPORT_ADAPTER_REGISTRATION_ATTRIBUTES NDIS_MINIPORT_ADAPTER_GENERAL_ATTRIBUTES NDIS_MINIPORT_ADAPTER_NATIVE_802_11_ATTRIBUTES	None. These are queried using WDI commands.
NdisMIndicateReceiveNetBufferLists	Disallowed	The WDI data path receive handler to indicate received packets.
NdisMSendNetBufferListsComplete	Disallowed	The WDI data path send handler to complete sent packets.

Native WLAN to WDI OID mapping

Article • 03/14/2023

The following table contains the mappings between Native 802.11 WLAN OIDs to WDI commands. This is not a static mapping and, depending on the current state, additional or fewer WDI commands may be sent down.

Note

Due to long DDI names, you may need to scroll the table horizontally to see all content. There is a scrollbar at the bottom of the page.

WDI tracing with WDILib

Article • 03/14/2023

The WDILib component currently supports tracing using WPP. The trace provider's GUID is {21ba7b61-05f8-41f1-9048-c09493dcfe38}. The following instructions can be used to collect and view the traces.

Start tracing

To collect traces, run the following command line from an Administrator command prompt.

PowerShell

```
netsh trace start wireless_dbg provider={21ba7b61-05f8-41f1-9048-
c09493dcfe38} level=0xff keywords=0xff
```

You can create a batch cmd file that contains the netsh trace command line. This allows you to expand the command to include IHV WPP events if desired.

PowerShell

```
@echo off
Setlocal
Rem
Rem Example trace script enabling both WDI and IHV WPP events
Rem

Rem
Rem replace IHV_WPP_GUID with your IHV driver GUID and desired trace flags
Rem
Set IHV_WPP_GUID={0160d072-248f-11e2-be71-082e5f28d97c} 0xff
Set WDI_WPP_GUID={21ba7b61-05f8-41f1-9048-c09493dcfe38} level=0xff
keywords=0xff

Rem
Rem Start the trace
Rem
netsh trace start wireless_dbg provider=%WDI_WPP_GUID%
provider=%IHV_WPP_GUID% globallevel=0xff
```

You can use 'wireless_dbg' to enable the rest of the operating system-side traces. Additional useful options are 'capture=yes' to enable packet traces and 'persistent=yes' to keep tracing enabled across reboots until it is stopped. This means you do not have to remember to enable tracing across reboots.

Alternatively, the trace provider GUID can be incorporated into the trace commands used for collecting the IHV component tracing.

Stop tracing

Once a repro is obtained, the tracing is stopped and traces saved with the following command.

PowerShell

```
netsh trace stop
```

This saves the traces in %TEMP%\NetTraces\NetTrace.etl.

Convert WPP traces to text

Traces are converted to text with any WPP to Text conversion tools. One option is to use Netsh.

PowerShell

```
netsh trace convert NetTrace.etl tmfpath=C:\TMF
```

In this example, C:\TMF contains the TMFs (generated from the wdiwifi.PDB by running tracepdb.exe). If the TMFs are not generated, the converted traces do not show up correctly.

Analyze traces

The converted text file (NetTrace.txt) can be viewed using any text viewer. If the viewer has the ability to add filters, using '[ERROR]', '[Wdi', and '[MSG ' filters may help scope the traces down to interesting lines.

Tracing on phones

To trace on phones, save the following text as wdiguids.txt, including the trace providers you want to trace.

Text

07a29c3d-26a4-41e2-856a-095b3eb8b6ef        Dhcpv6 Client
```

Using TShell, connect to the device, copy the files over, and begin tracing.

PowerShell

```
open-device 127.0.0.1
cmdd "mkdir \data\test\wlan"
putd wdiguids.txt \data\test\wlan
cmdd tracelog.exe '-start wdiwpp -f \data\test\wlan\wdiwpp.etl -cir 256 -rt
-ls -ft 1'
cmdd tracelog.exe '-enable wdiwpp -guid \data\test\wlan\wdiguids.txt -level
0x7fffffff -flag 0x7fffffff'
```

Run your scenario. To stop tracing and collect the logs, reconnect to TShell (if needed) and run the following commands.

PowerShell

```
cmdd tracelog.exe '-flush wdiwpp'
cmdd tracelog.exe '-stop wdiwpp'
getd \data\test\wlan\wdiwpp.etl
cmdd 'tracelog -flush WiFiDriver -f C:\data\systemdata\etw\wifidriver.etl'
getd 'C:\data\systemdata\etw\wifidriver.etl'
cmdd 'tracelog -flush WiFiSession'
getd 'C:\Data\SystemData\ETW\WiFi.etl.001'
getd 'C:\Data\SystemData\ETW\WiFi.etl.002'
getd 'C:\Data\SystemData\ETW\WiFi.etl.003'
```

WDI information collection for bugs

Article • 03/14/2023

Bugs in any non-trivial software are inevitable. In the driver development phase, bugs and debugging activities are expected to be a non-trivial part of the endeavor. Bugs may require joint company efforts, as they can be in the operating system, WDI UE, or WDI LE. It is crucial to collect relevant information to quickly narrow in on root causes. The information to collect varies widely depending on the nature of the bugs. Iterations of reproduction of a bug to collect further information are sometimes necessary, but it is critical to reduce these iterations as much as possible. Here are some rules to start with.

OS crash without kernel debugger attached

The operating system generates a crash dump. There are different types of crash dumps, such as mini-dumps and full dumps. While a mini-dump is small, it is often only good for triage. In order to root cause an issue, a full dump is almost always necessary. Enabling full dumps during the driver development and self-hosting phases is recommended. To enable full dumps:

1. From the desktop, right-click on **This PC** and choose **Properties**.
2. On the **Advanced** tab, go to the **Startup and Recovery** section and click on the **Settings...** button.
3. In the **Write debugging information** section, choose **Kernel memory dump** (rather than **Automatic memory dump**).

When an operating system crash occurs, a memory dump file is generated at %windir%\memory.dmp.

OS crash with kernel debugger attached

Developers or QA should have kernel debuggers attached if possible. A kernel debugger can quickly tell what is wrong and which direction to investigate further. The kd command '!analyze –v' is useful as the first command to run after a bug check. This command points to the location inside a module where the crash occurred and the reason (bug check code) for the crash.

When Reset Recovery is invoked

The Reset Recovery feature of WDI builds in the ability to collect live kernel dumps when Reset Recovery is invoked. The kernel dump enables developers to investigate the root causes post-mortem. Live kernel dumps are collected under %windir%\LiveKernelDumps.

Reset Recovery triggers

The current Reset Recovery triggers are listed below. More triggers may be added in the future.

- The UE detects a timeout of a WDI command (M3) sent to the LE.
- The UE detects a timeout of a WDI task (M4) sent to the LE.
- The LE detects and indicates a firmware hang.
- User mode requests a Reset Recovery. This is currently only for loss of internet connectivity. When the NIC is connected and has internet connectivity, wlansvc starts the internet loss state machine. If internet connectivity is lost and not regained within 35 seconds, wlansvc requests that WDI initiates a Reset Recovery. The 35 second timeout is subject to change in the future.

Events for Reset Recovery triggers

WDI calls NDIS to log an Error event to the system event log when it receives a Reset Recovery trigger. The event is in the LE name and the ID is 5002. The last two DWORDs are [TriggerType, ActiveWdiCommand]. The current trigger types are listed below.

- COMMAND_TIMER_ELAPSED (1)
- TASK_TIMER_ELAPSED (2)
- RESET_RECOVERY_OID_REQUEST (3)
- RESET_RECOVERY_FIRMWARE_STALLED (4)

ActiveWdiCommand may be 0 (no active command) if the trigger type is RESET_RECOVERY_OID_REQUEST or RESET_RECOVERY_FIRMWARE_STALLED.

This screenshot is an example view of eventvwr showing system.evtx. The trigger type is 3 and there is no active command.

When Wi-Fi malfunctions

If there is no crash but Wi-Fi does not function as expected, collect and analyze a trace log. To see if the issue is confined to the WDI UE and LE, a wlan_dbg trace should be included to see the operating system events for the context. Wlan_dbg contains WPP events that require operating system private symbols. The original etl trace should be reserved and included in communication.

Connected Standby issues

Sometimes, the Wi-Fi NIC does not go to low power (device_power_state_Dx). Other times, the device wakes up frequently. A SleepStudy report is helpful in first level triage. SleepStudy events are always on, but only collected if CS sessions are longer than 10 minutes. The events are also persistent (for example, you can inspect the study postmortem). To generate a SleepStudy, run the following command line in an Administrator command prompt.

CMD

```
Powercfg /SleepStudy
```

A report file named SleepStudy-report.html is generated. It should be opened outside %windiir%\system. The report breaks down what modules are keeping the system out of very low power state (DRIPS). It can also further break down which components are keeping the Wi-Fi NIC up (out of Dx).

WDI non-TLV versioning

Article • 03/14/2023

Data structures that are passed between WDI and the IHV miniport and contain a NDIS_OBJECT_HEADER (such as NDIS_MINIPORT_DRIVER_WDI_CHARACTERISTICS) follow the standard NDIS versioning model. The miniport must check the **Revision** and **Size** fields to ensure the fields it cares about are present, and ignore any extra fields or data without error. Ensure that newer revisions or larger sizes of such structures are not excluded.

All data structures without an NDIS_OBJECT_HEADER (such as WDI_FRAME_METADATA) follow the TLV versioning model, where WDI and the miniport use the size/revision determined by the lowest **WdiVersion** value from NDIS_WDI_INIT_PARAMETERS and NDIS_MINIPORT_DRIVER_WDI_CHARACTERISTICS.

For example, if WDI sets **WdiVersion** in NDIS_WDI_INIT_PARAMETERS to **WDI_VERSION_1_0**, and the miniport sets **WdiVersion** in NDIS_MINIPORT_DRIVER_WDI_CHARACTERISTICS to **WDI_VERSION_2_0**, then both WDI and the miniport should use the structure sizes and definitions compatible with **WDI_VERSION_1_0** for all structures without NDIS_OBJECT_HEADER fields. However, in the same situation but with structures that have an **NDIS_OBJECT_HEADER** field, WDI and the miniport may use a larger or newer structure as long as the **Revision** and **Size** fields are correctly set.

User-initiated feedback with IHV trace logging overview

Article • 12/15/2021

This topics in this section outline the steps required for collecting verbose IHV trace logs during user-initiated feedback (UIF) reports submitted via the Feedback tool. There are two separate scenarios in which the Feedback tool will collect logs. The first scenario is a snapshot of the system at the time when the user initiates the feedback. During this time, Windows collects the WMI auto-loggers and some other snapshot data. The second scenario involves the user reproducing the issue. During this feedback, Windows starts loggers with more verbose logging and larger file sizes to capture as much data as possible for the repro. This section describes the expectations for IHVs for each of these feedback scenarios.

In this section:

- Logging scenarios
- User-initiated feedback - normal mode
- User-initiated feedback - repro mode

Logging scenarios

Article • 12/15/2021

The events saved in IHV log files, for both repro mode and the auto-logger, should be appropriately throttled via flags/level/keywords to ensure that at least the past 30 minutes of the log events are always saved. Practically, you should target the 30 minute time period to cover one scan/WFD discovery, one connect/roam event, one disconnect event, several power transitions, and 10 minutes' worth of send and receive data. Because the IHV repro mode log is much larger than the normal IHV auto-logger, more verbose logging is expected.

The following scenarios might help you when logging:

- Getting connected
- Power transitions
- Radio management
- Roaming
- Hang/recovery
- Transition from Connected to Limited

User-initiated feedback with IHV trace logging

User-initiated feedback - normal mode

Article • 12/15/2021

In the normal user-initiated feedback (UIF) scenario, a user experiences a problem with Wi-Fi and submits a feedback report. This report collects a snapshot of the Wi-Fi subsystem, including Wi-Fi WMI auto-loggers, network statistics, etc. To collect IHV-specific logs, Microsoft provides a WMI auto-logger session with no initial ETW providers. Each IHV adds their set of ETW providers under the Microsoft-provided WMI auto-logger session registry entry. When the UIF report is submitted, the IHV auto-logger ETL is collected and sent to Microsoft for analysis. This log file is implemented using a circular buffer with a somewhat limited size (<= 1MB). The events saved in this log file should be appropriately throttled via flags/level/keywords to ensure that at least the past 30 minutes of the log events are always saved.

Microsoft-provided WMI auto-logger session

Microsoft provides a WMI auto-logger session with no initial ETW providers. When the IHV's drivers are installed, they must add the required WMI provider registry keys under the Microsoft-provided WMI auto-logger session key. The IHV should not change any of the auto-logger session registry values. However, all ETW provider options are available to the IHV including enable level, match any, match all, etc. This logging session always runs and has a limited circular buffer, so IHVs should set the provider EnableLevels appropriately.

The WMI auto-logger session is added to the HKLM registry hive with the following path:

`HKLM\SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSession`

The resulting ETL log file is located here:

`%SystemDrive%\System32\LogFiles\WMI\WifiDriverIHVSession.etl`

IHV driver INF changes

IHVs need to update their driver INF files to add the following registry key values so they can get verbose IHV logs during UIF normal mode. The following snippets provide a template for adding a single ETW provider to the auto-logger session. An IHV may add as many providers as they see fit. In addition, the enable level values are IHV-specific per

ETW provider, so they don't have to necessarily be the same as the Microsoft-defined values (TRACE_LEVEL_CRITICAL, TRACE_LEVEL_ERROR, etc.).

Enable the IHV auto-logger session

Because the IHV auto-logger session is initialized with no ETW providers, it is disabled by default. IHVs are required to enable this session by updating the "Start" value to **1** in their driver's INF file, as shown in this example:

INF

```
HKLM,SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSession,Start,%REG_DWORD%,1
```

Add IHV ETW providers

The following snippet shows how to add IHV ETW providers in the INF file:

INF

```
HKLM,SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSession\
<IHVProviderGUID_1>,Enabled,%REG_DWORD%,1
HKLM,SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSession\
<IHVProviderGUID_1>,,EnableLevel,%REG_DWORD%,<IHV_LogEnableLevelValue>
HKLM,SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSession\
<IHVProviderGUID_1>,MatchAnyKeyword,%REG_QWORD%,<IHV_MatchAnyKewordValue>

[The following is optional]
HKLM,SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSession\
<IHVProviderGUID_1>,MatchAllKeyword,%REG_QWORD%,<IHV_MatchAllKewordValue>

[Strings]
REG_DWORD = 0x00010001
REG_QWORD = 0x000B0001
```

Example values

This example illustrates a Native Wi-Fi custom level setting (enable all) with all Native Wi-Fi keywords:

INF

```
HKLM,SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSession\
{0BD3506A-9030-4f76-9B88-3E8FE1F7CFB6},Enabled,%REG_DWORD%,1
HKLM,SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSession\
{0BD3506A-9030-4f76-9B88-3E8FE1F7CFB6},,EnableLevel,%REG_DWORD%,0x04
HKLM,SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSession\
{0BD3506A-9030-4f76-9B88-
3E8FE1F7CFB6},MatchAnyKeyword,%REG_QWORD%,0x000FFFFF

Standard EnableLevel values:
0x5 - Verbose
0x4 - Informational
0x3 - Warning
0x2 - Error
0x1 - Critical
0x0 – LogAlways
```

User-initiated feedback with IHV trace logging

User-initiated feedback - repro mode

User-initiated feedback - repro mode

Article • 12/15/2021

User-initiated feedback (UIF) repro mode permits the system to collect more verbose logging while the user reproduces the bug. Like UIF normal mode, this is also accomplished by creating a new WMI logging session with IHV-defined ETW providers. After the repro mode is complete, the verbose logs are gathered and sent to Microsoft for analysis. There are IHV extension points for enabling or disabling verbose firmware logs. Repro logs are intended to be more verbose to be able to track down the reason the customer is having a problem. Therefore, the log file size for the repro mode log is set at a maximum size of 10MB. The IHV should use more verbose settings for ETW provider flags/level/keywords values.

The current UIF repro mode model requires that Microsoft is notified of all provider GUIDs, levels, and flags before the IHV feedback logs are included. Adding the providers to the registry, as indicated in this topic, enables an IHV to test the logs for appropriate levels.

Microsoft-provided WMI auto-logger session

Microsoft provides a WMI auto-logger session with no initial ETW providers. When the IHV's drivers are installed, they must add the required WMI provider registry keys under the Microsoft-provided WMI auto-logger session key. The IHV should not change any of the auto-logger session registry values. However, all ETW provider options are available to the IHV including enable level, match any, match all, etc.

> ⓘ **Important**
>
> The auto-logger is never enabled as an auto-logger. These values are used to validate the repro mode IHV logging described in Testing the repro mode logs. In addition, we might ask users to submit these logs manually by using the `netsh` tool. The provider GUIDs, level, and flags must also be submitted to Microsoft, along with a sample of the logs, so they will be included in repro mode UIFs (see Submitting IHV providers to Microsoft.

The WMI auto-logger session is added to the HKLM registry hive with the following path:

`HKLM,SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSessionRepro`

The resulting ETL log file is located here:

`%SystemDrive%\System32\LogFiles\WMI\WifiDriverIHVSessionRepro.etl`

IHV driver INF changes

IHVs need to update their driver INF files to add the following registry key values so they can get verbose IHV logs during UIF normal mode. The following snippets provide a template for adding a single ETW provider to the auto-logger session. An IHV may add as many providers as they see fit. In addition, the enable level values are IHV-specific per ETW provider, so they don't have to necessarily be the same as the Microsoft-defined values (TRACE_LEVEL_CRITICAL, TRACE_LEVEL_ERROR, etc.).

Add IHV ETW providers

The following snippet shows how to add IHV ETW providers in the INF file:

INF

```
HKLM,SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSession\
<IHVProviderGUID_1>,Enabled,%REG_DWORD%,1
HKLM,SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSession\
<IHVProviderGUID_1>,,EnableLevel,%REG_DWORD%,<IHV_LogEnableLevelValue>
HKLM,SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSession\
<IHVProviderGUID_1>,MatchAnyKeyword,%REG_QWORD%,<IHV_MatchAnyKewordValue>

[The following is optional]
HKLM,SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSession\
<IHVProviderGUID_1>,MatchAllKeyword,%REG_QWORD%,<IHV_MatchAllKewordValue>

[Strings]
REG_DWORD = 0x00010001
REG_QWORD = 0x000B0001
```

Example values

This example shows WDI UE informational level setting with all keywords:

INF

```
HKLM,SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSession\
{21ba7b61-05f8-41f1-9048-c09493dcfe38},Enabled,%REG_DWORD%,1
HKLM,SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSession\
{21ba7b61-05f8-41f1-9048-c09493dcfe38},,EnableLevel,%REG_DWORD%,0xFF
HKLM,SYSTEM\CurrentControlSet\Control\WMI\Autologger\WifiDriverIHVSession\
{21ba7b61-05f8-41f1-9048-
c09493dcfe38},MatchAnyKeyword,%REG_QWORD%,0x000FFFFF

Standard EnableLevel values:
0x5 - Verbose
0x4 - Informational
0x3 - Warning
0x2 - Error
0x1 - Critical
0x0 – LogAlways
```

ETW control callback

An IHV can register for the ETW control callback in its ETW logging code. This enables the IHV to be notified when ETW providers are enabled, disabled, or a capture control is initiated. This way, the IHV can turn on or off verbose firmware logs for repro mode.

> ⓘ **Note**
>
> If the ETW providers are shared between normal and repro mode, the IHV should key off the IHV-defined EnableLevel, defined in the INF file, to start/stop verbose firmware logs.

ETW callback function

The following snippet shows how to register for the ETW callback. This is only important if the IHV needs to take special action during the start and end of the UIF repro mode (like starting or stopping verbose firmware logging). If multiple ETW providers are used, IHVs might consider only implementing one callback to initiate firmware logging. All firmware logging must be routed to the IHV's ETW trace provider. The diagnostic tools for UIF will only collect traces for the IHV's ETW provider.

There are two ways to enable the ETW callback, depending on how you implemented ETW logging.

1. Manifested ETWs with autogenerated code via `MC.exe`. See Writing an Instrumentation Manifest for more details.
   a. The header in the following snippet (etwtracingevents.h) is an autogenerated ETW event header that was created via `MC.exe`. It is assumed that the ETW events have already been generated, so this topic will not focus on this part.
   b. MCGEN_PRIVATE_ENABLE_CALLBACK_V2 must be defined before including the autogenerated ETW header. Otherwise, the callback will not be called.
2. Registering for the ETW callback via the **EventRegister** API.

a. The ETW callback provider must be passed to the **EventRegister** function when registering the trace provider.

This snippet shows the prototype for the ETW callback function.

```C++
#include <evntprov.h>
extern
VOID
EtwEventControlCallback(
    _In_ LPCGUID SourceId,
    _In_ ULONG ControlCode,
    _In_ UCHAR Level,
    _In_ ULONGLONG MatchAnyKeyword,
    _In_ ULONGLONG MatchAllKeyword,
    _In_opt_ PEVENT_FILTER_DESCRIPTOR FilterData,
    _Inout_opt_ PVOID CallbackContext
    );
```

The following code is only required if you used autogenerated ETW events using the `MC.exe` tool.

```C++
#define MCGEN_PRIVATE_ENABLE_CALLBACK_V2 EtwEventControlCallback

#include "etwtracingEvents.h" // Generated from manifest - This must come
                              // after MCGEN_PRIVATE_ENABLE_CALLBACK_V2 is
                              // defined
```

The *ControlCode* parameter of the ETW callback indicates when the provider is enabled or disabled. The values are defined in `<evntrace.h>` and have the following values:

```C++
#define EVENT_CONTROL_CODE_DISABLE_PROVIDER 0
#define EVENT_CONTROL_CODE_ENABLE_PROVIDER  1
#define EVENT_CONTROL_CODE_CAPTURE_STATE    2
```

EVENT_CONTROL_CODE_ENABLE_PROVIDER

This flag enables the ETW provider and indicates that the UIF repro mode session has started. This should be used to initiate verbose firmware logging and/or packet logging.

EVENT_CONTROL_CODE_DISABLE_PROVIDER

This flag disables the ETW provider and indicates that the UIF repro mode session has ended. The IHV's implementation should flush and reset firmware logs at this point if the *Level* parameter matches the IHV-specified UIF repro mode level in the INF file (0xFF in the following section's sample).

EVENT_CONTROL_CODE_CAPTURE_STATE

This flag requests that the provider logs its state information. This is generally called to flush the in-memory logs to disk. The IHV's implementation should flush and reset firmware logs at this point if the *Level* parameter matches the IHV-specified UIF repro mode level in the INF file (0xFF in the following section's sample).

Sample code

The following is a sample ETW callback implementation that can be used as a template to enable verbose driver and firmware logging for UIF repro mode scenarios.

> ⓘ Note
>
> IHVs need to flush any pending firmware logs for both the **EVENT_CONTROL_CODE_CAPTURE_STATE** and **EVENT_CONTROL_CODE_DISABLE_PROVIDER** control codes.

After the **EVENT_CONTROL_CODE_CAPTURE_STATE** is invoked, the UIF diagnostics tool invokes the ETW callback two more times with the **EVENT_CONTROL_CODE_ENABLE_PROVIDER** control code. Therefore, to avoid re-enabling the firmware logging, the state machine moves from the *ReproModeStateCaptured* state to the *ReproModeStateFinal* state before moving back to the *ReproModeStateNotStarted* state. The **EVENT_CONTROL_CODE_DISABLE_PROVIDER** control code is only used to disable the provider. This is not part of the UIF process, but still needs to be honored.

IHVs should change the **IHV_ETW_REPRO_MODE_LEVEL** value in the following example to match the repro mode level set in the INF file.

C++

```cpp
#define IHV_ETW_REPRO_MODE_LEVEL 0xFF // This value must match the repro
mode
                                      // EnableLevel INF value
```

```
typedef enum _EtwReproModeState
{
    ReproModeStateNotStarted = 0,
    ReproModeStateStarted,
    ReproModeStateCaptured,
    ReproModeStateFinal
} EtwReproModeState;

static EtwReproModeState g_eReproModeLoggingEnabled =
ReproModeStateNotStarted;

VOID
EtwEventControlCallback(
    _In_ LPCGUID SourceId,
    _In_ ULONG ControlCode,
    _In_ UCHAR Level,
    _In_ ULONGLONG MatchAnyKeyword,
    _In_ ULONGLONG MatchAllKeyword,
    _In_opt_ PEVENT_FILTER_DESCRIPTOR FilterData,
    _Inout_opt_ PVOID CallbackContext
    )
{
    UNREFERENCED_PARAMETER(SourceId);
    UNREFERENCED_PARAMETER(MatchAnyKeyword);
    UNREFERENCED_PARAMETER(MatchAllKeyword);
    UNREFERENCED_PARAMETER(FilterData);
    UNREFERENCED_PARAMETER(CallbackContext);

    switch(ControlCode)
    {
        case EVENT_CONTROL_CODE_ENABLE_PROVIDER:
            if (Level == IHV_ETW_REPRO_MODE_LEVEL)
            {
                switch(g_eReproModeLoggingEnabled)
                {
                    case ReproModeStateNotStarted:
                        //
                        // Enable verbose Firmware logs.
                        //
                        g_eReproModeLoggingEnabled = ReproModeStateStarted;
                        break;

                    case ReproModeStateCaptured:
                        //
                        // The diagnostic tools will invoke the callback
after
                        // the capture with
EVENT_CONTROL_CODE_ENABLE_PROVIDER
                        // twice.
                        //
                        g_eReproModeLoggingEnabled = ReproModeStateFinal;
                        break;

                    case ReproModeStateFinal:
                        //
                        // The state machine is now complete, reset the
state.
                        //
                        g_eReproModeLoggingEnabled =
ReproModeStateNotStarted;
                        break;

                    case ReproModeStateStarted:
                    default:
                        break;
                }
            }
            break;

        case EVENT_CONTROL_CODE_DISABLE_PROVIDER:
            if (g_eReproModeLoggingEnabled == ReproModeStateStarted)
            {
                //
                // Merge verbose firmware logs into ETW log (if not done
already).
                // Disable verbose firmware logs
                //
                g_eReproModeLoggingEnabled = ReproModeStateNotStarted;
            }
            break;

        case EVENT_CONTROL_CODE_CAPTURE_STATE:
            if (Level == IHV_ETW_REPRO_MODE_LEVEL &&
                g_eReproModeLoggingEnabled == ReproModeStateStarted)
            {
                //
                // Merge verbose firmware logs into ETW log (if not done
already).
                // Disable verbose firmware logs
                //
                g_eReproModeLoggingEnabled = ReproModeStateCaptured;
            }
            break;
    }
}
```

Testing the repro mode logs

To test the IHV repro mode logs, the following commands can be used to start and stop capture.

> ⓘ Note
>
> The resulting ETL file will contain some OS logs.

- netsh wlan IHV startlogging
- netsh wlan IHV stoplogging

These commands are also used by customers to manually collect logs from a device.

Submitting IHV providers to Microsoft

The final step for IHVs to submit repro mode user-initiated feedback is to contact Microsoft and supply the requested provider GUIDs, levels, and flags along with sample log data for review. Once the logging is approved, the providers will be added to the user-initiated feedback system.

> ⓘ **Note**
>
> Any modifications to the provider GUIDs, levels, or flags after submission will have no effect on the UIF logs.

WDI TLV generator/parser topics

Article • 03/14/2023

The TLV generator and parser shared library allows IHV drivers to correctly parse TLVs into strongly typed C/C++ structures, or conversely generate a TLV byte blob from the structures. It also handles the versioning semantics so the IHV does not need to.

Article • 03/14/2023

Callee allocation model

An entry point within the driver receives a message or indication that contains TLVs. After the code extracts the message ID and determines if it is an ID that it wants to handle, it calls the generic parse routine and passes the TLV blob (after advancing past the WDI_MESSAGE_HEADER) to parse the TLVs into a C-structure.

```C
ndisStatus = Parse(
    cbBufferLength,
    pvBuffer,
    messageId,
    &Context,
    &pParsed);
```

After checking the return for errors, the code can cast the output buffer (*pParsed*) into a concrete type, such as in the below example.

```C
((WDI_INDICATION_BSS_ENTRY_LIST_PARAMETERS*)pParsed)
```

After the caller is finished with the parsed data, the caller must return the memory back to the parser. The parser needs to know the original message ID used to allocate so it frees the correct data.

```C
FreeParsed(messageId, pParsed);
pParsed = NULL;
```

Caller allocation model

In this model, the caller has already determined the correct specific TLV to parse and is possibly using a stack local to avoid allocations on the heap. The caller creates the local and calls a specific parse routine. The API does not need the message ID, and the parameter is strongly typed with one less level of indirection.

C

```
WDI_GET_ADAPTER_CAPABILITIES_PARAMETERS adapterCapabilitiesParsed;

ndisStatus = ParseWdiGetAdapterCapabilities(
    cbBufferLength,
    pvBuffer,
    &Context
    &adapterCapabilitiesParsed);
```

After the caller is finished using the structure, the caller should give the parser a chance to clean up any allocation it made during parsing, and wipe the structure so it is ready to be reused. The parameter is strongly typed, so the callee does not need any additional parameters.

C

```
CleanupParsedWdiGetAdapterCapabilities(&adapterCapabilitiesParsed);
```

After calling the CleanupParse API, all data in the structure is invalid.

Some messages do not have any associated data. For completeness of the API, appropriately named Parse methods are provided. These methods validate that the byte stream is empty. Typedefs are provided for the parameter type, but callers can also pass NULL for the out parameter if they use the Caller Allocation Model. In all cases, the Parser avoids any allocations by returning a constant empty parse structure. Callers should never write into this returned empty structure (hence the only field is named **_Reserved**). These messages are documented as "No additional data. The data in the header is sufficient".

Message direction

Most messages have a different format for their M1 versus their M0, M3, or M4. To accommodate for this, such messages have different parse and generate APIs. For M1 messages, the APIs follow the naming convention of Parse<*MessageName*>ToIhv or Generate<*MessageName*>ToIhv. For M0, M3, or M4 messages, the APIs follow the naming convention of Parse<*MessageName*>FromIhv or Generate<*MessageName*>FromIhv. However, to simplify code in the IHV miniport, defines are added to alias Parse<*MessageName*> to Parse<*MessageName*>ToIhv and Generate<*MessageName*> to Generate<*MessageName*>FromIhv. IHV code only needs to be aware of this aliasing if it needs to parse its own M3, or generate an M1.

Error codes

The TLV parser generator can return several different NDIS_STATUS codes. For more information, look at the WPP trace logs. The logs should always indicate the root cause. Here is a list of the most common error codes and what they mean.

NDIS_STATUS_INVALID_DATA	When parsing, this indicates that a fixed sized TLV is of the incorrect size. For lists, this means the overall size is not an even multiple of the individual element size, or there are more elements than there should be. This could also mean a list contained 0 elements, when 1 or more is required. If 0 elements is desired, then *Optional_IsPresent* should be set to false (the TLV header should not be in the byte stream).
NDIS_STATUS_BUFFER_OVERFLOW	When generating, this indicates that due to the number of elements in an array (list), it overflows the 2 byte **Length** field within the TLV header. You should reduce the number of elements. This can also occur when an outer TLV has too many (or too large of) inner TLVs, again overflowing the 2 byte **Length** field of the header. When parsing, this indicates a TLV header's **Length** field is larger than the outer TLV or the byte stream.
NDIS_STATUS_FILE_NOT_FOUND	When parsing, this indicates that a required TLV is not present in the byte stream. It is usually a bug with the generator of the byte stream.
NDIS_STATUS_RESOURCES	When generating, this indicates that the allocator failed.
NDIS_STATUS_UNSUPPORTED_REVISION	When parsing or generating, the **Context** parameter is NULL, or the **PeerVersion** is less than **WDI_VERSION_MIN_SUPPORTED**.

WDI TLV generator interface overview

Article • 03/14/2023

C++ overloaded function model

In this model, there is only one function call to generate a TLV byte array from your data structure.

```C++
WDI_INDICATION_BSS_ENTRY_LIST_PARAMETERS BssEntryList = ...;
BYTE* pOutput = NULL;
ULONG length = 0;
NDIS_STATUS ndisStatus = NDIS_STATUS_SUCCESS;

ndisStatus = Generate(
    &BssEntryList,
    cbHeaderLength,
    &Context,
    &length,
    &pOutput);
```

The second parameter can be very helpful. Sometimes, the TLV buffer is packed into a bigger data structure, and this parameter allows you to pre-reserve space at the beginning of the buffer for that header. The correct value for *cbHeaderLength* is often `sizeof(WDI_MESSAGE_HEADER)`.

For messages that have no associated data, there are still overloaded Generate APIs, but the first parameter is optional and may simply be passed in as `(EmptyMessageStructureType*)NULL`.

When you are done with the TLV data contained in *pOutput*, you must call back into the library to release the buffer.

```C++
    FreeGenerated(pOutput);
    pOutput = NULL;
```

C-style function model

In this model, there is a specific Generate routine for each top-level message or structure because C does not support overloaded functions. Otherwise, it behaves the same as the C++ model.

C

```
ndisStatus = GenerateWdiGetAdapterCapabilities(
    &adapterCapabilities,
    (ULONG)sizeof(WFC_COMMAND_HEADER),
    &Context,
    &length,
    &pOutput);
```

When you are done with the TLV byte array, call back to release the memory in the same way as the C++ model.

C

```
    FreeGenerated(pOutput);
    pOutput = NULL;
```

WDI TLV generator/parser memory interface

Article • 03/14/2023

The parser and generator internally use C++ with new/delete. This simplifies several implementation details. This means that consumers of the library must provide overloaded operator implementations of these APIs when linking to the library. This is the only C++ dependency that your code must take.

All APIs that do any allocations take a parameter *Context* typed as PCTLV_CONTEXT which has 2 fields: a ULONG_PTR named **AllocationContext** and a ULONG named **PeerVersion**. The **AllocationContext** field is passed through to the overloaded `new` operator. This allows consumers of the APIs to customize the allocation in various ways. For more information about the TLV_CONTEXT parameter, see WDI TLV versioning.

Warning Although you may be tempted to skip calling the library's cleanup routines (such as FreeParsed, CleanupParsed, and FreeGenerated), do not skip calling them! It might work on some code paths, but will lead to hard-to-diagnose memory leaks.

Here is a sample overloaded operator.

C++

```
/*++
Module Name:
    sample.cpp
Abstract:
    Contains sample code to override C++ new/delete for use with TLV
parser/generator library
Environment:
    Kernel mode
--*/
#include "precomp.h"

#define TLV_POOL_TAG (ULONG) '_VLT'

void* __cdecl operator new(size_t Size, ULONG_PTR AllocationContext)
/*++
  Override C++ allocation operator.
--*/
{
    PVOID pData = ExAllocatePoolWithTag(NonPagedPoolNx, Size, TLV_POOL_TAG);
    UNREFERENCED_PARAMETER(AllocationContext);
    if (pData != NULL)
    {
        RtlZeroMemory( pData, Size);
    }
    return pData;
}

void __cdecl operator delete(void* pData)
/*++
  Override C++ delete operator.
--*/
{
    if (pData != NULL)
    {
        ExFreePoolWithTag(pData, TLV_POOL_TAG);
    }
}
```

WDI TLV generator/parser special members

Article • 03/14/2023

Optional members

For any TLV that has optional child TLV members, the parent has one field named **Optional**. Within that field, there is one Boolean field for each optional child named **<*child_name*>_IsPresent**, which is set to TRUE by the parser if the child is present, and FALSE otherwise. Similarly, the generation APIs expect the field to be TRUE if it should be present in the TLV byte stream, and FALSE otherwise.

```C++
WDI_SET_FIRMWARE_CONFIGURATION_PARAMETERS fwConfig = { 0 };
NDIS_STATUS status;
status = ParseWdiSetAdapterConfiguration(
    pNdisRequest->DATA.METHOD_INFORMATION.InputBufferLength -
        sizeof(WDI_MESSAGE_HEADER),
    (PUINT8)pNdisRequest->DATA.METHOD_INFORMATION.InformationBuffer +
        sizeof(WDI_MESSAGE_HEADER),
    0,
    &fwConfig);

if (status == NDIS_STATUS_SUCCESS)
{
    if (fwConfig.Optional.MacAddress_IsPresent)
    {
        // Safe to use fwConfig.MacAddress
        fwConfig.MacAddress;
    }
}
```

Array members

When multiple children of the same type appear within the same parent (for example, <container />'s *isCollection* attribute), the parser and generator use a special structure to represent the array: ArrayOfElements. For C++ clients, this is a strongly typed template structure with clean up on destruction semantics. For C clients, explicitly named structures are created (for example, ArrayOfElementsOfUINT8). However, these structures are not automatically cleaned up because C does not support destructors, so users of the C APIs must be careful not to introduce memory leaks (or double-frees).

There are two important fields within ArrayOfElements: **ElementCount** and **pElements**. **ElementCount** is the count of elements within the array. **pElements** is a C-Style array of the elements. The elements can be iterated over as shown in this sample.

C++

```
for (UINT32 i = 0;
    i < pConnectTaskParameters->ConnectParameters.
            MulticastCipherAlgorithms.ElementCount;
    i++)
{
    // Safe to use pElements[i]
    pConnectTaskParameters->ConnectParameters.MulticastCipherAlgorithms.
        pElements[i];
}
```

The third field, **MemoryInternallyAllocated**, is used internally by the parser/generator. It should not be modified by the IHV.

Adding the WDI TLV generator/parser to your driver

Article • 03/14/2023

To add the WDI TLV generator/parser to your driver, follow these steps.

1. Add this include after dot11wdi.h and wditypes.hpp.

   `#include "TlvGeneratorParser.hpp"`

2. Add this library to the linker.

   `TLVGeneratorParser.lib`

3. Define, create, and write your memory APIs (overloaded operator new/delete).

4. Start calling the APIs.

WDI TLV generator/parser XML semantics

Article • 03/14/2023

TLV (Type-Length-Value) is a protocol design where each bit of data is contained in a stream of bytes that has a standard Type and Length header.

The TLV generator/parser XML file is a list of messages, containers (TLVs), and property groups (structs). This topic covers the XML syntax.

`<message />`

Describes a single top-level WDI message. There are only parser/generator functions for these message entries.

Attributes

- `commandId` - Symbolic constant that must be defined in dot11wdi.h.
- `type` - Type name to be exposed to the code (you use this type when calling into parser/generator functions).
- `description` - Description of the command.
- `direction` – Indicates whether this message describes the TLV stream as it goes from WDI to the IHV miniport as part of an M1 (called "ToIhv"), describes the TLV stream as it goes from the IHV miniport to WDI as an M0, M3, or M4 (called "FromIhv"), or it goes in both directions (called "Both"). See *Message Direction* in WDI TLV parser interface overview.

Content

List of container references (`<containerRef />`). These are the different TLVs that make up the message. They are references to types defined in the `<containers />` section.

Example

XML

```xml
<message commandId="WDI_SET_P2P_LISTEN_STATE"
         type="WDI_SET_P2P_LISTEN_STATE_PARAMETERS"
         description="Parameters to set listen state."
         direction="ToIhv">
  <containerRef id="WDI_TLV_P2P_CHANNEL_NUMBER"
                name="ListenChannel"
                optional="true"
                type="WFDChannelContainer" />
  <containerRef id="WDI_TLV_P2P_LISTEN_STATE"
                name="ListenState"
                type="P2PListenStateContainer" />
</message>
```

`<containerRef />`

Reference to a `<container />` defined in the `<containers />` section.

`<containerRef />` Attributes

- `id` - TLV ID that must be defined in wditypes.h.
- `name` - The name of the variable in the parent structure.
- `optional` - Specifies whether or not it is an optional field. False by default. Generated code enforces "optional-ness".
- `multiContainer` – Specifies whether or not the generated code should expect multiple TLVs of the same type. False by default. If false, generated code enforces that only one is present.
- `type` - Reference to a specific element’s "name" attribute in the `<containers />` section.
- `versionAdded` - Part of versioning. Indicates that this TLV container should not appear in byte streams to/from peers with a version less than the one indicated in this attribute.
- `versionRemoved` - Part of versioning. Indicates that this TLV container should not appear in byte streams to/from peers with a version greater than or equal to the one indicated in this attribute.

`<containerRef />` Content

None.

`<containerRef />` Example

XML

```xml
<containerRef id="WDI_TLV_P2P_CHANNEL_NUMBER"
              name="ListenChannel"
              optional="true"
              type="WFDChannelContainer"/>
```

`<containers />`

Describes all containers/TLVs used in WDI messages. Containers can be considered TLV buckets. There are 2 types: `<container />` and `<aggregateContainer />`.

`<container />`

TLV Container for a single structure reference or named type. It is statically sized, but may be a C-style array as long as it is statically sized.

`<container />` Attributes

- `name` - ID that is referenced by WDI messages/other containers.
- `description` - Friendly description of what the container is for.
- `type` – Type name to be exposed to the code.
- `isCollection` - Specifies whether or not generated code should expect many of the same size element within the same TLV (C-style array). The default is false (only expect one element of the given type).
- `isZeroValid` - Only valid when `isCollection` is true. Determines whether a zero element array is allowed. This is useful when the TLV stream needs to distinguish between an optional TLV that is not present versus one that is present but has zero length (like SSIDs). Since this distinction is rare, the default is false.

`<container />` Contents

One of `<groupRef />` or `<namedType />`.

`<container />` Example

XML

```xml
<container name="P2PListenStateContainer"
           description="Container for P2P Listen State setting."
           type="WDI_P2P_LISTEN_STATE_CONTAINER">
  <namedType name="ListenState"
             type="WDI_P2P_LISTEN_STATE"
             description="P2P Listen State."/>
</container>
```

`<groupRef />`

Reference to a property group (structure) defined in the `<propertyGroups />` section.

`<groupRef />` Attributes

- `name` - Name of the structure in the parent structure.
- `ref` - Reference to a named structure in a `<propertyGroups />` section.
- `description` – Friendly descriptor of what the structure is used for.

`<groupRef />` Content

None.

`<groupRef />` Examples

XML

```xml
<container name="WFDChannelContainer"
           description="Container for a Wi-Fi Direct channel."
           type="WDI_P2P_CHANNEL_CONTAINER">
  <groupRef name="Channel"
            ref="WFDChannelStruct"
            description="Wi-Fi Direct Channel." />
</container>
```

`<namedType />`

Reference to a raw type exposed by wditypes.hpp or dot11wdi.h. Uses default serializer (memcpy), so use at your own risk because of padding issues.

`<namedType />` Attributes

- `name` - Name of the structure in the parent structure.
- `type` - Type name to use in the actual code.
- `description` – Friendly description of what the structure is used for.

`<namedType />` Content

None.

`<namedType />` Example

XML

```xml
<container name="P2PListenStateContainer"
           description="Container for P2P Listen State setting."
           type="WDI_P2P_LISTEN_STATE_CONTAINER">
  <namedType name="ListenState"
             type="WDI_P2P_LISTEN_STATE"
             description="P2P Listen State."/>
</container>
```

`<aggregateContainer />`

TLV Container for many different containers. This is used for handling nested TLVs.

`<aggregateContainer />` Attributes

- `name` - ID that is referenced by WDI messages/other containers.
- `description` – Friendly description of what the container is for.
- `type` - Type name to be exposed to the code.

`<aggregateContainer />` Content

List of `<containerRef />`.

`<aggregateContainer />` Example

XML

```xml
<aggregateContainer
    name="P2PInvitationRequestInfoContainer"
    type="WDI_P2P_INVITATION_REQUEST_INFO_CONTAINER"
    description="Generic container for Invitation Request-related
containers.">
  <containerRef
    id="WDI_TLV_P2P_INVITATION_REQUEST_PARAMETERS"
    type="P2PInvitationRequestParamsContainer"
    name="RequestParams" />
  <containerRef
    id="WDI_TLV_P2P_GROUP_BSSID"
    type="MacAddressContainer"
    name="GroupBSSID"
    optional="true" />
  <containerRef
    id="WDI_TLV_P2P_CHANNEL_NUMBER"
    type="WFDChannelContainer"
    name="OperatingChannel"
    optional="true" />
  <containerRef
    id="WDI_TLV_P2P_GROUP_ID"
    type="P2PGroupIDContainer"
    name="GroupID" />
</aggregateContainer>
```

`<propertyGroups />`

Describes all structures used in all containers. Structures can either be used by a `<container />`, or referenced by another `<propertyGroup />` (nested structures). They are defined independently of TLVs containers so they can be re-used. They do not have a TLV header.

These definitions are necessary as they help to solve padding issues with structures and gives the code generator instructions on how to interpret the data.

> ⓘ Note
>
> Order matters here. All data offsets are implied based on the property group description, and data is written/parsed in the order it is defined here. These structures have to be defined here.

Primitive Field Types (`<bool/> <uint8/> <uint16/> <uint32/> <int8/> <int16/> <int32/>`)

These are the available primitive types, and are converted/marshalled appropriately by the generated code.

Attributes for Primitive Field Types

- `name` - Field name in the parent structure.
- `description` – Friendly description of what the property is for.
- `count` - How many of the given property there are. Default is one. Values greater than one make this property into a statically sized array in the code.

Contents for Primitive Field Types

None

`<propertyGroup />`

An individual structure.

`<propertyGroup />` Attributes

- `name` - ID that is referenced by WDI messages/other containers.
- `description` – Friendly description of what the property group is for.
- `type` - Type name to be exposed to the code.

`<propertyGroup />` Contents

There are several possible property types (struct fields).

- `<bool/> <uint8/> <uint16/> <uint32/> <int8/> <int16/> <int32/>`
- `<groupRef />`
- `<namedType />`

`<propertyGroup />` Example

XML

```xml
<propertyGroup name="P2PDiscoverModeStruct"
               type="WDI_P2P_DISCOVER_MODE"
               description="Structure definition for P2P Discover Mode
Parameters">
  <namedType name="DiscoveryType"
             type="WDI_P2P_DISCOVER_TYPE"
             description="Type of discovery to be performed by the port."/>
  <bool name="ForcedDiscovery"
        description="A flag indicating that a complete device discovery is
required. If this flag is not set, a partial discovery may be performed." />
  <namedType name="ScanType"
             type="WDI_P2P_SCAN_TYPE"
             description="Type of scan to be performed by port in scan
phase." />
  <bool name="ScanRepeatCount"
        description="How many times the full scan procedure should be
repeated. If set to 0, scan should be repeated until the task is aborted by
the host."/>
</propertyGroup>
<propertyGroup name="P2PDeviceInfoParametersStruct"
               type="WDI_P2P_DEVICE_INFO_PARAMETERS"
               description="Structure definition for P2P Device Information
Parameters.">
```

```
  <uint8 count="6"
         name="DeviceAddress"
         description="Peer's device address." />
  <uint16 name="ConfigurationMethods"
          description="Configuration Methods supported by this device." />
  <groupRef name="DeviceType"
            description="Primary Device Type."
            ref="WFDDeviceType" />
</propertyGroup>
```

WDI TLV versioning

Article • 03/14/2023

To maintain backwards compatibility, both WDI and the miniport use the TLV stream as a versioning boundary. The producer of the TLV byte stream must always generate a backwards compatible TLV and not include any newly added fields. This is accomplished by adding a **PeerVersion** to the *Context* parameter. This field should be initialized by the caller to the *WdiVersion* received during initialization.

Here is the type definition of the *Context* parameter, which is passed into every Parse and Generate API.

C++

```
typedef struct _TLV_CONTEXT
{
    ULONG_PTR   AllocationContext;
    ULONG       PeerVersion;
} TLV_CONTEXT, *PTLV_CONTEXT;
typedef const TLV_CONTEXT * PCTLV_CONTEXT;
```

AllocationContext is unmodified by the Parse and Generate APIs and continues to be passed through to the miniport-provided operator `new` callback. For more information, see WDI TLV generator/parser memory interface.

If a WDI-based single-binary driver runs against an older version of WDI, the generator in the miniport uses the **PeerVersion** to generate the older byte stream. Conversely, the parser consumes the older byte stream based on the **PeerVersion** and converts it into the new data structures.

If a miniport driver does not use the TLV parser generator library and instead writes their own TLV parser and generator, and the desire is to have a single binary running only older OS versions (and thus old versions of WDI), they must include this capability also. Their parser must accept the TLV grammar produced by older WDI, and their generator must only generate TLVs according to the older grammar.

The XML has been augmented to support this versioning with two attributes allowed on containerRefs: *versionAdded* and *versionRemoved*. This is what drives the parser and generator to adjust the byte stream according to the peer version.

Note The parser and generator assume that they are always linked with WDI_VERSION_LATEST. The miniport should always pass WDI_VERSION_LATEST for NDIS_MINIPORT_DRIVER_WDI_CHARACTERISTICS::**WdiVersion** when calling

NdisMRegisterWdiMiniportDriver rather than using a specific version, like WDI_VERSION_1_0, as they will become out of date and cause problems with the TLV parser generator because the other end might send a byte stream that is unexpected.

WDI TLV dumpers

Article • 03/14/2023

The parser generator library has routines to decode TLV byte arrays into trace statements.

C++

```
    typedef _Function_class_( TlvDumperCallback ) void( __stdcall
*TlvDumperCallback )(_In_ UINT_PTR Context, _In_z_ _Printf_format_string_
PCSTR Format, ...);

    void __stdcall TraceUnknownTlvByteStream(
        _In_ ULONG PeerVersion,
        _In_ ULONG BufferLength,
        _In_reads_bytes_( BufferLength ) UINT8 const * pBuffer );

    void __stdcall TraceMessageTlvByteStream(
        _In_ ULONG MessageId,
        _In_ BOOLEAN fToIhv,
        _In_ ULONG PeerVersion,
        _In_ ULONG BufferLength,
        _In_reads_bytes_( BufferLength ) UINT8 const * pBuffer );

    void __stdcall DumpUnknownTlvByteStream(
        _In_ ULONG PeerVersion,
        _In_ ULONG BufferLength,
        _In_reads_bytes_( BufferLength ) UINT8 const * pBuffer,
        _In_opt_ ULONG_PTR Context,
        _In_opt_ TlvDumperCallback pCallback );

    void __stdcall DumpMessageTlvByteStream(
        _In_ ULONG MessageId,
        _In_ BOOLEAN fToIhv,
        _In_ ULONG PeerVersion,
        _In_ ULONG BufferLength,
        _In_reads_bytes_( BufferLength ) UINT8 const * pBuffer,
        _In_opt_ ULONG_PTR Context,
        _In_opt_ TlvDumperCallback pCallback );
```

If you only need WPP tracing, use the Trace APIs as they are optimized to have the smallest impact to code size as well as log size (fewer strings in the ETL file). If you need a more general purpose dumper, use the Dump APIs as they include WPP tracing and also include a callback routine. The stub driver has an example of using this callback routine to redirect the output to the kernel debugger via DebugPrint APIs.

Unlike the Parse and Generate APIs, the dumper is very permissive. It attempts to make sense of the TLV bytes as best as it can, regardless of the canonical form for a given message or TLV. This means the dumper might correctly decode and dump something that the parser rejects.

Warning If the dumper successfully decodes the bytes into a human readable format, it does not mean the bytes are a well-formed TLV.

Like the Parse APIs, the *pBuffer* pointer and *BufferLength* parameters should exclude any headers and point directly at the first TLV.

The Message variants of the APIs include the message ID and the message direction to better disambiguate the TLV. This is helpful because the same TLV ID can be decoded in different ways depending upon context. For example, **WDI_TLV_BSSID** can directly contain a **WDI_MAC_ADDRESS** when part of OID_WDI_TASK_SCAN, or it can contain a list of **WDI_MAC_ADDRESS** when part of **WDI_TLV_P2P_ATTRIBUTES**.

WDI_TLV_ACCESS_NETWORK_TYPE

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ACCESS_NETWORK_TYPE is a TLV that contains an Access Network Type.

TLV Type

0x100

Length

The size (in bytes) of a UINT8.

Values

Type	Description
UINT8	The Access Network Type to be used in probe requests for the network being connected to.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ACTION_FRAME_BODY

Article • 03/14/2023

> This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ACTION_FRAME_BODY is a TLV that contains the body of an Action Frame.

TLV Type

0xBE

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that contains the body of an Action Frame.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ACTION_FRAME_DEVICE_CONTEXT

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ACTION_FRAME_DEVICE_CONTEXT is a TLV that contains an Action Frame device context.

TLV Type

0xAC

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that contains an Action Frame device context.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ADAPTER_NLO_SCAN_MODE

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ADAPTER_NLO_SCAN_MODE is a TLV that indicates whether scans should be performed in active or passive mode.

TLV Type

0x125

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	WDI_SCAN_TYPE value that indicates whether scans should be performed in active or passive mode.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ADAPTER_RESUME_REQUIRED

Article • 03/14/2023

WDI_TLV_ADAPTER_RESUME_REQUIRED is a TLV that specifies if adapter resume is required.

TLV Type

0xB7

Length

The size (in bytes) of a UINT8.

Values

Type	Description
UINT8	Specifies if adapter resume is required. Valid values are 0 (not required) and 1 (required). If set to 1, the firmware requires OS assistance to resume its context.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ADDITIONAL_BEACON_IES

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ADDITIONAL_BEACON_IES is a TLV that contains additional beacon IEs.

TLV Type

0x98

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	The array of beacon IEs. The Wi-Fi Direct port must add these additional IEs to the beacon packets when it is acting as a Group Owner. These are ignored when the Wi-Fi Direct port is operating in device or client mode.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ADDITIONAL_IES

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ADDITIONAL_IES is a TLV that contains additional Information Element (IE) settings.

TLV Type

0x8A

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_ADDITIONAL_BEACON_IES		X	An array of beacon IEs. The Wi-Fi Direct port must add these additional IEs to the beacon packets when it is acting as a Group Owner. This is ignored when the Wi-Fi Direct port is operating in device or client mode.
WDI_TLV_ADDITIONAL_PROBE_RESPONSE_IES		X	An array of probe response IEs. The Wi-Fi Direct port must add these additional IEs to the probe response packets when it is acting as a Wi-Fi Direct device or Group Owner. This is ignored when the Wi-Fi Direct port is operating in client mode.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_ADDITIONAL_PROBE_REQUEST_DEFAULT_IES		X	An array of additional probe request IEs. This offset is relative to the start of the buffer that contains this structure. The Wi-Fi Direct port must add these additional IEs to the probe request packets that it transmits. Note that a Wi-Fi Direct discover request may override the default probe request IEs.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ADDITIONAL_PROBE_REQUEST_DEFAULT_IES

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ADDITIONAL_PROBE_REQUEST_DEFAULT_IES is a TLV that contains additional probe request IEs.

TLV Type

0x70

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of probe request IEs. The Wi-Fi Direct port must add these additional IEs to transmitted probe request packets. **Note** A Wi-Fi Direct Discover Request may override the default probe request IEs.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ADDITIONAL_PROBE_RESPONSE_IES

Article • 03/14/2023

WDI_TLV_ADDITIONAL_PROBE_RESPONSE_IES is a TLV that contains probe response IEs.

TLV Type

0x93

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	The array of probe response IEs. The Wi-Fi Direct port must add these additional IEs to the probe response packets when it is acting as a Wi-Fi Direct device or Group Owner. This member is ignored when the Wi-Fi Direct port is operating in client mode.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ALLOWED_BSSIDS_LIST

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ALLOWED_BSSIDS_LIST is a TLV that contains a list of BSSIDs that are allowed to be used for association.

TLV Type

0xC2

Length

The size (in bytes) of the array of WDI_MAC_ADDRESS structures. The array must contain 1 or more structures.

Values

Type	Description
WDI_MAC_ADDRESS[]	A list of BSSIDs that are allowed to be used for association.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ANQP_ELEMENTS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ANQP_ELEMENTS is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ANQP_QUERY_PARAMETERS

Article • 03/14/2023

WDI_TLV_ANQP_QUERY_PARAMETERS is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ANQP_QUERY_STATUS

Article • 03/14/2023

WDI_TLV_ANQP_QUERY_STATUS is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_AP_ATTRIBUTES

Article • 03/14/2023

WDI_TLV_AP_ATTRIBUTES is a TLV that contains the attributes of an access point.

TLV Type

0x23

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_AP_CAPABILITIES			The access point capabilities.
WDI_TLV_UNICAST_ALGORITHM_LIST			The supported unicast algorithms.
WDI_TLV_MULTICAST_DATA_ALGORITHM_LIST			The supported multicast data algorithms.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_AP_BAND_CHANNEL

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_AP_BAND_CHANNEL is a TLV that specifies access point band and channel information.

Note This TLV was added in Windows 10, version 1511, WDI version 1.0.10.

TLV Type

0x127

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_BANDID			Specifies the identifier for the band.
WDI_TLV_CHANNEL_INFO_LIST		X	Specifies a list of channels to start the access point on.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

Header	Wditypes.hpp

OID_WDI_TASK_START_AP

WDI_TLV_AP_CAPABILITIES

Article • 03/14/2023

WDI_TLV_AP_CAPABILITIES is a TLV that contains the capabilities of an access point.

TLV Type

0x16

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	The scan SSID list size.
UINT32	The desired SSID list size.
UINT32	The privacy exemption list size.
UINT32	The association table size.
UINT32	The key mapping table size.
UINT32	The default key table size.
UINT32	The maximum length of the WEP key value.
UINT8	Specifies whether the AP supports radar detection. Valid values are 0 (not supported) and 1 (supported).

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ASSOCIATION_PARAMETERS_REQUESTED_TYPE

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ASSOCIATION_PARAMETERS_REQUESTED_TYPE is a TLV that contains the requested Association Parameter TLV types.

TLV Type

0xBB

Length

The size (in bytes) of the array of UINT16 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT16[]	The list of Association Parameters TLV types that are requested. Valid TLV types are WDI_TLV_PMKID (0x9F) and WDI_TLV_EXTRA_ASSOCIATION_REQUEST_IES (0x40).

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ASSOCIATION_REQUEST_DEVICE_CONTEXT

Article • 07/16/2024

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ASSOCIATION_REQUEST_DEVICE_CONTEXT is a TLV that contains vendor-specific information that is passed down to the port if the host decides to send a response to an incoming association request.

TLV Type

0x72

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Expand table

Type	Description
UINT8[]	Vendor-specific information that is passed down to the port if the host decides to send a response to an incoming association request.

Requirements

Expand table

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ASSOCIATION_RESPONSE_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ASSOCIATION_RESPONSE_PARAMETERS is a TLV that contains association response parameters for OID_WDI_TASK_SEND_AP_ASSOCIATION_RESPONSE.

TLV Type

0x97

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8	Specifies whether or not to accept the association request. Valid values are 0 (do not accept) and 1 (accept).
UINT16	Specifies the reason code. If accept request is set to 0, this field provides a reason code to send back to the peer adapter.

Requirements

Minimum supported client	Windows 10

Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ASSOCIATION_RESPONSE_RESULT_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ASSOCIATION_RESPONSE_RESULT_PARAMETERS is a TLV that contains association response result parameters.

TLV Type

0x76

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_MAC_ADDRESS	The MAC address of the peer adapter.
UINT8	A bit value that indicates whether the request from the peer station is a reassociation request. Valid values are 0 and 1. A value of 1 indicates that it is a reassociation request.
UINT8	A bit value that indicates whether the response from the peer station is a reassociation response. Valid values are 0 and 1. A value of 1 indicates that it is a reassociation response.

Type	Description
WDI_AUTH_ALGORITHM	The authentication algorithm for the association.
WDI_CIPHER_ALGORITHM	The unicast cipher algorithm for the association.
WDI_CIPHER_ALGORITHM	The multicast cipher algorithm for the association.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ASSOCIATION_RESULT

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ASSOCIATION_RESULT is a TLV that contains the results of an association.

TLV Type

0x35

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_BSSID			The BSSID of the BSS.
WDI_TLV_ASSOCIATION_RESULT_PARAMETERS			The association result parameters.
WDI_TLV_ASSOCIATION_REQUEST_FRAME		X	The association request that was used for association. This does not include the 802.11 MAC header.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_ASSOCIATION_RESPONSE_FRAME		X	The association response that was received. This does not include the 802.11 MAC header.
WDI_TLV_AUTHENTICATION_RESPONSE_FRAME		X	The authentication response that was received with a failure code. This does not include the 802.11 MAC header. It should only be included if the connection attempt failed during authentication exchange.
WDI_TLV_BEACON_PROBE_RESPONSE		X	The latest beacon or probe response frame received by the port. This does not include the 802.11 MAC header.
WDI_TLV_ETHERTYPE_ENCAP_TABLE		X	The Ethertype encapsulations for the association.
WDI_TLV_PHY_TYPE_LIST			The list of PHY identifiers that the 802.11 station uses to send or receive packets on the BSS network connection.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

Header	Wditypes.hpp

WDI_TLV_ASSOCIATION_RESULT_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ASSOCIATION_RESULT_PARAMETERS is a TLV that contains parameters for an association result.

TLV Type

0x2D

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	Specifies the completion status of the association attempt as defined in WDI_ASSOC_STATUS.
UINT32	The 802.11 status code sent by the peer in response to an authentication or association request from this port.
UINT8	Specifies whether the port sent an 802.11 association or an 802.11 reassociation request to the AP. This value should be set to 1 if a reassociation request was used.
WDI_AUTH_ALGORITHM	The authentication algorithm that the port negotiated with the peer during association.

Type	Description
WDI_CIPHER_ALGORITHM	The unicast cipher algorithm that the port negotiated with the peer during association.
WDI_CIPHER_ALGORITHM	The multicast data cipher algorithm that the port negotiated with the peer during association.
WDI_CIPHER_ALGORITHM	The multicast management cipher algorithm that the port negotiated with the peer during association.
UINT8	Specifies if the port has associated with a peer that supports distribution system (DS) services for ISO Layer 2 bridging on any station in the BSS network, including mobile stations and APs. This value should be set to 1 if this is supported.
UINT8	Specifies whether the port has performed port authorization during the association operation.
UINT8	Specifies whether 802.11 WMM QoS protocol has been negotiated for this association. This value should be set to 1 if it has been negotiated.
WDI_DS_INFO	Specifies whether the port is connected to the same DS as its previous association.
UINT32	When a (re)association fails with an 802.11 reason code of 30, this value indicates the value of the association comeback time requested by the peer.
WDI_BAND_ID (UINT32)	The band ID on which the association is established.
UINT32	The IHV association status. If the association failed, this can contain an IHV-defined status code. This is only used for debugging purpose.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_AUTH_ALGO_LIST

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_AUTH_ALGO_LIST is a TLV that contains a list of authentication algorithms.

TLV Type

0x3C

Length

The size (in bytes) of the array of WDI_AUTH_ALGORITHM structures. The array must contain 1 or more elements.

Values

Type	**Description**
WDI_AUTH_ALGORITHM[]	An array of authentication algorithms.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ASSOCIATION_RESPONSE_FRAME is a TLV that contains an authentication response frame.

TLV Type

0x124

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that contains the authentication response that was received with a failure code. This does not include the 802.11 MAC header.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_BAND_CAPABILITIES

Article • 03/14/2023

WDI_TLV_BAND_CAPABILITIES is a TLV that contains the capabilities of a band.

TLV Type

0x1A

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	The identifier for the band.
UINT8	Specifies whether the band is enabled or not.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_BAND_CHANNEL

WDI_TLV_BAND_ID_LIST is a TLV that contains a list of band IDs.

TLV Type

0xB6

Length

The size (in bytes) of the array of WDI_BAND_ID (UINT32) elements. The array must contain 1 or more elements.

Values

Type	Description
WDI_BAND_ID[]	An array of band IDs.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_BAND_INFO

Article • 03/14/2023

WDI_TLV_BAND_INFO is a TLV that contains band information.

TLV Type

0x27

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_BAND_CAPABILITIES			The capabilities of the band.
WDI_TLV_PHY_TYPE_LIST			A list of valid PHY types in this band.
WDI_TLV_CHANNEL_LIST			A list of valid channel numbers in this band.
WDI_TLV_CHANNEL_WIDTH_LIST			A list of channel widths in MHz

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_BEACON_FRAME is a TLV that contains a beacon frame.

TLV Type

0xA

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that specifies the beacon frame.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_BEACON_IES

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_BEACON_IES is a TLV that contains beacon IEs from an association.

TLV Type

0x78

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	The beacon IEs from an association.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_BEACON_PROBE_RESPONSE

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_BEACON_PROBE_RESPONSE is a TLV that contains the latest beacon or probe response frame received by the port.

TLV Type

0x30

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that specifies the latest beacon or probe response frame received by the port. This does not include the 802.11 MAC header.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_BITMAP_PATTERN

Article • 03/14/2023

WDI_TLV_BITMAP_PATTERN is a TLV that contains the byte array of a pattern.

TLV Type

0x68

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that contains the byte array of the pattern. Length = (Pattern length + 7)/8.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_BITMAP_PATTERN_AND_MASK

Article • 03/14/2023

WDI_TLV_BITMAP_PATTERN_AND_MASK is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_BITMAP_PATTERN_MASK

Article • 03/14/2023

WDI_TLV_BITMAP_PATTERN_MASK is a TLV that contains the bitmap pattern mask.

TLV Type

0xE4

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that contains the byte array of the pattern mask. The mask must have 1 bit per pattern byte, therefore the mask length should equal (pattern length + 7) / 8.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_BSS_ENTRY

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_BSS_ENTRY is a TLV that contains BSS entry information.

TLV Type

0x8

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_BSSID			The BSSID of the BSS.
WDI_TLV_PROBE_RESPONSE_FRAME		X	The probe response frame. If no probe response frame has been received, this is empty.
WDI_TLV_BEACON_FRAME		X	The beacon frame. If no beacon has been received, this is empty.
WDI_TLV_BSS_ENTRY_SIGNAL_INFO			The signal information (received signal strength and link quality) of the BSS.
WDI_TLV_BSS_ENTRY_CHANNEL_INFO			The logical channel number and band ID for the BSS entry.
WDI_TLV_BSS_ENTRY_DEVICE_CONTEXT		X	Device context about the peer. This context is provided from the IHV component and can be used to store per-BSS entry state that the IHV component wants to maintain. To avoid lifetime management issues, the IHV component must not use pointers in this field.
WDI_TLV_BSS_ENTRY_AGE_INFO		X (Note: This TLV is mandatory if the BSS list is maintained by the IHV component.)	The age information for this BSS entry, including the timestamp of when this entry was most recently discovered.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_DISCOVERED_SERVICE_ENTRY	X	X	The list of services found on the remote device, including the service information retrieved with a GAS query if the discovery request specified WDI_P2P_SERVICE_DISCOVERY_TYPE_SERVICE_INFORMATION as the discovery type.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_BSS_ENTRY_AGE_INFO

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_BSS_ENTRY_AGE_INFO is a TLV that contains age information for a BSS entry.

TLV Type

0xBA

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT64	Timestamp of when this BSS entry was most recently discovered. The timestamp should be obtained with NdisGetCurrentSystemTime or KeQuerySystemTime.
UINT8	Specifies whether this information is live (found during a currently running scan) or is coming from the IHV component's BSS list cache. Valid values are 0 (live) or 1 (cached).

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

Header	Wditypes.hpp

WDI_TLV_BSS_ENTRY_CHANNEL_INFO

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_BSS_ENTRY_CHANNEL_INFO is a TLV that contains BSS entry channel information.

TLV Type

0x3A

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_CHANNEL_NUMBER (UINT32)	The logical channel number on which the peer was discovered.
UINT32	The band ID for the BSS entry.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_BSS_ENTRY_DEVICE_CONTEXT

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_BSS_ENTRY_DEVICE_CONTEXT is a TLV that contains device context for the BSS entry.

TLV Type

0xD

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that specifies the context data. This context is provided by the IHV component and can be used to store per-BSS entry state that the IHV component wants to maintain. To avoid lifetime management issues, the IHV component must not use pointers in this TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_BSS_ENTRY_PHY_INFO

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_BSS_ENTRY_PHY_INFO is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_BSS_ENTRY_SIGNAL_INFO

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_BSS_ENTRY_SIGNAL_INFO is a TLV that contains signal information for a BSS entry.

TLV Type

0xB

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
INT32	The received signal strength indicator (RSSI) value of the beacon or probe response from the peer. This value is specified in units of decibels referenced to 1.0 milliwatts (dBm)
UINT32	The link quality specified by a value from 0 to 100. A value of 100 specifies the highest link quality.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_BSS_SELECTION_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_BSS_SELECTION_PARAMETERS is a TLV that contains WDI_BSS_SELECTION_FLAGS that are used by host for BSS selection.

TLV Type

0x10F

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	WDI_BSS_SELECTION_FLAGS that are used by the host for BSS selection.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_BSSID

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_BSSID is a TLV that contains the BSSID of a BSS.

TLV Type

0x2

Length

The size (in bytes) of a WDI_MAC_ADDRESS structure.

Values

Type	Description
WDI_MAC_ADDRESS	A Wi-Fi MAC address that specifies a BSSID.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_BSSID_INFO

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_BSSID_INFO is a TLV that contains BSSID information.

TLV Type

0x120

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8	AP reachability. Valid values are 1 (not reachable), 2 (unknown), and 3 (reachable).
UINT8	Security. If this is set to 1, it indicates that the AP identified by this BSSID supports the same security provisioning as used by the STA in its current association. If this is set to 0, it indicates that either this AP does not support the same security provisioning, or the security information is not available at this time.
UINT8	Key scope bit. If it is set to 1, it indicates the AP indicated by this BSSID has the same authenticator as the AP sending the report. If this bit is set to 0, it indicates a distinct authenticator or the information is not available.
UINT8	This is set to 1 if dot11SpectrumManagementRequired is true.
UINT8	This is set to 1 if dot11QosOptionImplemented is true.
UINT8	An AP sets the APSD subfield to 1 within the Capability Information field when dot11APSDOptionImplemented is true, and sets it to 0 otherwise.

Type	Description
UINT8	This is set to 1 if dot11RadioMeasurementActivated is true.
UINT8	This is set to 1 if dot11DelayedBlockAckOptionImplemented is true.
UINT8	This is set to 1 if dot11ImmediateBlockAckOptionImplemented is true.
UINT8	This is set to 1 if the AP represented by this BSSID includes an MDE in its Beacon frames.
UINT8	This is set to 1 to indicate that the AP represented by this BSSID is an HT AP, including the HT Capabilities element in its Beacon.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CANCEL_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CANCEL_PARAMETERS is a TLV that contains parameters for OID_WDI_ABORT_TASK.

TLV Type

0x2B

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
NDIS_OID	Specifies the OID from the original task being aborted.
UINT32	Specifies the transaction ID from the original task.
WDI_PORT_ID (UINT16)	Specifies the port ID from the original task.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CHANNEL_INFO_LIST

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CHANNEL_INFO_LIST is a TLV that contains a list of channels.

TLV Type

0x41

Length

The size (in bytes) of the array of WDI_CHANNEL_NUMBER (UINT32) structures. The array must contain 1 or more elements.

Values

Type	Description
UINT32[]	An array of Wi-Fi channels.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CHANNEL_LIST

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CHANNEL_LIST is a TLV that contains one or more channel numbers.

TLV Type

0x4

Length

The size (in bytes) of the array of WDI_CHANNEL_MAPPING_ENTRY structures. The array must contain 1 or more structures.

Values

Type	Description
WDI_CHANNEL_MAPPING_ENTRY[]	An array of channel mapping entries.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CHANNEL_NUMBER

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CHANNEL_NUMBER is a TLV that contains a channel number.

TLV Type

0x121

Length

The size (in bytes) of a UINT8.

Values

Type	Description
UINT8	The channel number.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CHANNEL_WIDTH_LIST

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CHANNEL_WIDTH_LIST is a TLV that contains a list of channel widths.

TLV Type

0xF5

Length

The size (in bytes) of the array of UINT32 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT32[]	A list of channel widths, specified in MHz.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CHECKSUM_OFFLOAD_CAPABILITIES

Article • 03/14/2023

WDI_TLV_CHECKSUM_OFFLOAD_CAPABILITIES is a TLV that contains checksum offload capabilities for IPv4 and IPv6.

TLV Type

0xCB

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_IPV4_CHECKSUM_OFFLOAD			Parameters for IPv4 checksum offload.
WDI_TLV_IPV6_CHECKSUM_OFFLOAD			Parameters for IPv6 checksum offload.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CHECKSUM_OFFLOAD_V4_RX_PARAMETERS (0xD2)

Article • 03/14/2023

WDI_TLV_CHECKSUM_OFFLOAD_V4_RX_PARAMETERS is a TLV that contains parameters for Rx checksum offload for IPv4.

Capability values are reported as documented in **NDIS_TCP_IP_CHECKSUM_OFFLOAD**. Use NDIS_OFFLOAD_NOT_SUPPORTED and NDIS_OFFLOAD_SUPPORTED when indicating capabilities through OID_WDI_GET_ADAPTER_CAPABILITIES.

TLV Type

0xD2

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	Encapsulation settings. Valid values are: • WDI_ENCAPSULATION_IEEE_802_11
UINT32	Specifies if offload of checksum with IP options is supported.
UINT32	Specifies if offload of checksum with TCP options is supported.
UINT32	Specifies if TCP checksum offload is enabled.
UINT32	Specifies if UDP offload is enabled.
UINT32	Specifies if IP checksum is enabled.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CHECKSUM_OFFLOAD_V4_TX_PARAMETERS (0xD1)

Article • 03/14/2023

WDI_TLV_CHECKSUM_OFFLOAD_V4_TX_PARAMETERS is a TLV that contains parameters for Tx checksum offload for IPv4.

Capability values are reported as documented in **NDIS_TCP_IP_CHECKSUM_OFFLOAD**. Use NDIS_OFFLOAD_NOT_SUPPORTED and NDIS_OFFLOAD_SUPPORTED when indicating capabilities through OID_WDI_GET_ADAPTER_CAPABILITIES.

TLV Type

0xD1

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	Encapsulation settings. Valid values are: • WDI_ENCAPSULATION_IEEE_802_11
UINT32	Specifies if offload of checksum with IP options is supported.
UINT32	Specifies if offload of checksum with TCP options is supported.
UINT32	Specifies if TCP checksum offload is enabled.
UINT32	Specifies if UDP offload is enabled.
UINT32	Specifies if IP checksum is enabled.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CHECKSUM_OFFLOAD_V6_RX_PARAMETERS (0xDD)

Article • 03/14/2023

WDI_TLV_CHECKSUM_OFFLOAD_V6_RX_PARAMETERS is a TLV that contains for Rx checksum offload for IPv6.

Capability values are reported as documented in **NDIS_TCP_IP_CHECKSUM_OFFLOAD**. Use NDIS_OFFLOAD_NOT_SUPPORTED and NDIS_OFFLOAD_SUPPORTED when indicating capabilities through OID_WDI_GET_ADAPTER_CAPABILITIES.

TLV Type

0xDD

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	**Description**
UINT32	Encapsulation type. Valid values are: • WDI_ENCAPSULATION_IEEE_802_11
UINT32	Specifies if offload of checksum of packets with IP extension headers is supported.
UINT32	Specifies if offload of checksum with TCP options is supported.
UINT32	Specifies if TCP checksum offload is enabled.
UINT32	Specifies if UDP offload is enabled.

Requirements

Minimum supported client	Windows 10

Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CHECKSUM_OFFLOAD_V6_TX_PARAMETERS (0xDC)

Article • 03/14/2023

WDI_TLV_CHECKSUM_OFFLOAD_V6_TX_PARAMETERS is a TLV that contains for Tx checksum offload for IPv6.

Capability values are reported as documented in **NDIS_TCP_IP_CHECKSUM_OFFLOAD**. Use NDIS_OFFLOAD_NOT_SUPPORTED and NDIS_OFFLOAD_SUPPORTED when indicating capabilities through OID_WDI_GET_ADAPTER_CAPABILITIES.

TLV Type

0xDC

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	Encapsulation type. Valid values are: • WDI_ENCAPSULATION_IEEE_802_11
UINT32	Specifies if offload of checksum of packets with IP extension headers is supported.
UINT32	Specifies if offload of checksum with TCP options is supported.
UINT32	Specifies if TCP checksum offload is enabled.
UINT32	Specifies if UDP offload is enabled.

Requirements

Minimum supported client	Windows 10

Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CIPHER_KEY_BIP_KEY

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CIPHER_KEY_BIP_KEY is a TLV that contains BIP cipher algorithm key data for OID_WDI_SET_ADD_CIPHER_KEYS.

TLV Type

0x51

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	Specifies BIP cipher algorithm key data.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CIPHER_KEY_BIP_GMAC_256_KEY

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CIPHER_KEY_BIP_GMAC_256_KEY is a TLV that contains BIP GMAC 256 cipher algorithm key data for OID_WDI_SET_ADD_CIPHER_KEYS.

TLV Type

0x165

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	Specifies BIP GMAC 256 cipher algorithm key data.

Requirements

Minimum supported client	Windows 10, version 2004
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CIPHER_KEY_CCMP_KEY

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CIPHER_KEY_CCMP_KEY is a TLV that contains CCMP cipher algorithm key data for OID_WDI_SET_ADD_CIPHER_KEY.

TLV Type

0x50

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	Specifies CCMP cipher algorithm key data.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CIPHER_KEY_GCMP_KEY

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CIPHER_KEY_GCMP_KEY (0x12F) is an unused TLV.

TLV Type

0x12F

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CIPHER_KEY_GCMP_256_KEY

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CIPHER_KEY_GCMP_256_KEY is a TLV that contains GCMP 256 cipher algorithm key data for OID_WDI_SET_ADD_CIPHER_KEYS.

TLV Type

0x164

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	Specifies GCMP 256 cipher algorithm key data.

Requirements

Minimum supported client	Windows 10, Version 2004
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CIPHER_KEY_ID

Article • 03/14/2023

>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CIPHER_KEY_ID is a TLV that contains a cipher key ID for OID_WDI_SET_ADD_CIPHER_KEYS and OID_WDI_SET_DELETE_CIPHER_KEYS.

TLV Type

0x4D

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	Specifies the cipher key ID.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CIPHER_KEY_IHV_KEY

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CIPHER_KEY_IHV_KEY is a TLV that contains an IHV key.

TLV Type

0x118

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that specifies the IHV key.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CIPHER_KEY_RECEIVE_SEQUENCE_COUNT

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CIPHER_KEY_RECEIVE_SEQUENCE_COUNT is a TLV that contains the receive sequence count.

TLV Type

0x4F

Length

The size (in bytes) of the array of UINT8 elements.

Values

Type	Description
UINT8[6]	Specifies the initial 48-bit value of Packet Number (PN), which is used for replay protection.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CIPHER_KEY_TKIP_INFO

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CIPHER_KEY_TKIP_INFO is a TLV that contains TKIP information.

TLV Type

0x4B

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_CIPHER_KEY_TKIP_KEY			Specifies the TKIP key material.
WDI_TLV_CIPHER_KEY_TKIP_MIC			Specifies the TKIP MIC material.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CIPHER_KEY_TKIP_KEY

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CIPHER_KEY_TKIP_KEY is a TLV that contains TKIP key material.

TLV Type

0x49

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that specifies the TKIP key material.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CIPHER_KEY_TKIP_MIC

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CIPHER_KEY_TKIP_MIC is a TLV that contains the TKIP MIC material.

TLV Type

0x4A

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that specifies the TKIP MIC material.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CIPHER_KEY_TYPE_INFO

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CIPHER_KEY_TYPE_INFO is a TLV that contains cipher key type information for OID_WDI_SET_ADD_CIPHER_KEYS and OID_WDI_SET_DELETE_CIPHER_KEYS.

TLV Type

0x4E

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_CIPHER_ALGORITHM	Specifies the cipher algorithm that uses the key.
WDI_CIPHER_KEY_DIRECTION	Specifies whether the key should be used for transmit only, receive only, or both.
UINT8	Specifies whether the port should delete the key on a roam. If this value is set to 0, the key must be deleted when the port disconnects from the BSS network or connects to the BSS network. If this value is set to 1, the key should be deleted on an explicit delete or on a reset request.
WDI_CIPHER_KEY_TYPE	Specifies the type of key being published.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CIPHER_KEY_WEP_KEY

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CIPHER_KEY_WEP_KEY is a TLV that contains a WEP key.

TLV Type

0x58

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that specifies the WEP key.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_COALESCING_FILTER_MATCH_COUNT

Article • 03/14/2023

WDI_TLV_COALESCING_FILTER_MATCH_COUNT is a TLV that contains the number of packets that have matched receive filters on the network port.

TLV Type

0x66

Length

The size (in bytes) of the a UINT64.

Values

Type	Description
UINT64	The number of packets that have matched receive filters on the network port.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_COMMUNICATION_CAPABILITIES

Article • 03/14/2023

WDI_TLV_COMMUNICATION_CAPABILITIES is a TLV that specifies the communication capabilities.

TLV Type

0xE

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	The maximum command size in bytes.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_COMMUNICATION_CONFIGURATION_ATTRIBUTES

Article • 03/14/2023

WDI_TLV_COMMUNICATION_CONFIGURATION_ATTRIBUTES is a TLV that contains the host-adapter communication protocol configuration attributes.

TLV Type

0x20

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_COMMUNICATION_CAPABILITIES		X	The communication capabilities.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CONFIGURED_CIPHER_KEY

Article • 03/14/2023

WDI_TLV_CONFIGURED_CIPHER_KEY is a TLV that contains a list of configured ciphers to be set in OID_WDI_GET_PM_PROTOCOL_OFFLOAD. Drivers must return any GTK or iGTK keys that are currently configured. This TLV is a value of the WDI_TLV_PM_PROTOCOL_OFFLOAD_80211RSN_REKEY TLV.

TLV Type

0x147

Length

The size (in bytes) of the following values.

Values

Type	Description
WDI_CIPHER_KEY_TYPE	The type of key being returned.
WDI_CIPHER_ALGORITHM	Specifies the cipher algorithm that uses this key.
WDI_TLV_CIPHER_KEY_GCMP_256_KEY	Contains GCMP_256 cipher algorithm key data. This is only present if the cipher algorithm is WDI_CIPHER_ALGO_GCMP_256.
UINT8[6]	The initial 48-bit value of the Packet Number (PN), which is used for replay protection. Optional if **CipherAlgorithm** is **WDI_CIPHER_ALGO_WEP40**, **WDI_CIPHER_ALGO_WEP104**, or **WDI_CIPHER_ALGO_WEP**.
TLV<LIST<UINT8>>	Present if and only if **CipherAlgorithm** is **WDI_CIPHER_ALGO_CCMP**. Contains CCMP cipher algorithm key data.
TLV<LIST<UINT8>>	Present if and only if **CipherAlgorithm** is **WDI_CIPHER_ALGO_GCMP**. Contains GCMP cipher algorithm key data.
WDI_TLV_CIPHER_KEY_TKIP_INFO	Present if and only if **CipherAlgorithm** is **WDI_CIPHER_ALGO_TKIP**.

Type	Description
WDI_TLV_CIPHER_KEY_BIP_GMAC_256_KEY	Present ony if cipher algorithm is WDI_CIPHER_ALGO_BIP_GMAC_256.
TLV<LIST<UINT8>>	Present if and only if **CipherAlgorithm** is **WDI_CIPHER_ALGO_BIP**.
TLV<LIST<UINT8>>	Present if and only if **CipherAlgorithm** is **WDI_CIPHER_ALGO_WEP40**, **WDI_CIPHER_ALGO_WEP104**, or **WDI_CIPHER_ALGO_WEP**.
TLV<LIST<UINT8>>	Present if and only if **CipherAlgorithm** is in the range of **WDI_CIPHER_ALGO_IHV_START** to **WDI_CIPHER_ALGO_IHV_END**.

Requirements

Minimum supported client	Windows 10, version 2004
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CONFIGURED_MAC_ADDRESS

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CONFIGURED_MAC_ADDRESS is a TLV that contains a custom MAC address.

TLV Type

0x99

Length

The size (in bytes) of a WDI_MAC_ADDRESS structure.

Values

Type	Description
WDI_MAC_ADDRESS	The MAC address that should be used for the port.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CONNECT_BSS_ENTRY

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CONNECT_BSS_ENTRY is a TLV that contains a list of candidate connect BSS entries.

TLV Type

0x34

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_BSSID			The BSSID of the BSS.
WDI_TLV_PROBE_RESPONSE_FRAME		X	The probe response frame. If no probe response has been received, this would be empty.
WDI_TLV_BEACON_FRAME		X	The beacon frame. If no beacon has been received, this would be empty.
WDI_TLV_BSS_ENTRY_SIGNAL_INFO			The signal information for this BSS entry.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_BSS_ENTRY_CHANNEL_INFO			The channel information for this BSS entry.
WDI_TLV_BSS_ENTRY_DEVICE_CONTEXT		X	The IHV provided context data about this peer.
WDI_TLV_PMKID		X	The 16 byte PMKID value for this BSS entry.
WDI_TLV_EXTRA_ASSOCIATION_REQUEST_IES		X	The IE to be included in the (re)association request frame for this BSSID. If present, this should be included in addition to the common IE.
WDI_TLV_FT_INITIAL_ASSOC_PARAMETERS		X	The initial Mobility Domain association parameters.
WDI_TLV_FT_REASSOC_PARAMETERS		X	The fast transition parameters (MDIE, R0KH-ID, PMKR0Name, SNonce). This is only present for Fast Transition (not during initial mobility domain association).
WDI_TLV_BSS_SELECTION_PARAMETERS		X	WDI_BSS_SELECTION_FLAGS that provide information used by the host for BSS selection.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CONNECT_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CONNECT_PARAMETERS is a TLV that contains parameters for OID_WDI_TASK_CONNECT and OID_WDI_TASK_ROAM.

TLV Type

0x33

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_CONNECTION_SETTINGS			The settings for the connection.
WDI_TLV_SSID	X		List of SSIDs that the port is allowed to connect to.
WDI_TLV_HESSID_INFO		X	List of HESSIDs that the port is allowed to connect to. This is an additional requirement to the SSID list.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_AUTH_ALGO_LIST			The list of authentication algorithms that the connection can use.
WDI_TLV_MULTICAST_CIPHER_ALGO_LIST			The list of multicast cipher algorithms that the connection can use.
WDI_TLV_UNICAST_CIPHER_ALGO_LIST			The list of unicast cipher algorithms that the connection can use.
WDI_TLV_EXTRA_ASSOCIATION_REQUEST_IES		X	The IE blobs that must be included in the association requests sent by the port. This is applicable to any BSSID that the device would associate with. It should be used in addition to the BSSID specific IEs.
WDI_TLV_PHY_TYPE_LIST		X	The list of PHYs that are allowed to be used for the association. If not specified, any supported PHY can be used. If specified, the device must only use the listed PHYs.
WDI_TLV_DISALLOWED_BSSIDS_LIST		X	The list of BSSIDs that are not allowed to be used for association. If specified, the adapter must not associate to any AP that is in this list.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_ALLOWED_BSSIDS_LIST		X	The list of BSSIDs that are allowed to be used for association. If WDI specifies 255.255.255.255 then all BSSIDs are allowed.
WDI_TLV_OWE_DH_IE		X	Diffie-Hellman Extension IE blob that must be included in the association request sent by the station when auth type is OWE. This is applicable to any BSSID that the device would associate with and should be included in addition to the other associated req vendor IEs.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CONNECTION_QUALITY_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CONNECTION_QUALITY_PARAMETERS is a TLV that contains the desired Wi-Fi Connection Quality Hint.

TLV Type

0xA3

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	The desired Wi-Fi Connection Quality Hint, as defined in WDI_CONNECTION_QUALITY_HINT.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CONNECTION_SETTINGS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_CONNECTION_SETTINGS is a TLV that contains connection settings for OID_WDI_TASK_CONNECT.

TLV Type

0x3F

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8	Specifies if this is a first-time connection request (value of 0) or a roaming connection (value of 1).
UINT8	Specifies if this is a connection to a network with hidden/non-broadcast SSIDs. This value is 1 when connecting to a hidden network.
UINT8	This sets the dot11ExcludeUnencrypted MIB. When this value is false (0) and the cipher algorithm is WEP, the port must connect to APs that do not set the privacy field in management frames.
UINT8	Specifies if MFP is enabled (1) or disabled (0). The station must advertise its 802.11w capabilities in the association request if and only if this value is set to 1 (enabled).
UINT8	Specifies if host-FIPS mode is enabled (1) or disabled (0).

Type	Description
WDI_ASSOC_STATUS (UINT32)	Specifies the roaming needed reason. If this is triggered due to NDIS_STATUS_WDI_INDICATION_ROAMING_NEEDED, this contains the reason from the roam indication.
WDI_ROAM_TRIGGER (UINT32)	Specifies whether this roam is a critical roam because the AP has set the Disassociation Imminent bit in its BSS Transition Request action frame.
UINT8	Specifies if 802.11v BSS transition is supported. If this bit is set to 1, the Station must set the BSS Transition field of the Extended capabilities element (Bit 19) to 1 in the association request.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_COUNTRY_REGION_LIST

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_COUNTRY_REGION_LIST is a TLV that contains a list of country or region codes.

TLV Type

0x12

Length

The size (in bytes) of the array of WDI_COUNTRY_REGION_LIST elements. The array must contain 1 or more elements.

Note WDI_COUNTRY_REGION_LIST is not a WDI structure. It is defined in the WDI TLV parser generator, and is used for documentation purposes only.

Values

Type	Description
WDI_COUNTRY_REGION_LIST[]	An array of country or region codes.

WDI_COUNTRY_REGION_LIST consists of the following elements.

Type	Description
UINT8[3]	A country or region code.

Requirements

Minimum supported client	Windows 10

Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CREATE_PORT_MAC_ADDRESS

Article • 03/14/2023

WDI_TLV_CREATE_PORT_MAC_ADDRESS is a TLV that contains a MAC address for OID_WDI_TASK_CREATE_PORT.

TLV Type

0xD9

Length

The size (in bytes) of a **WDI_MAC_ADDRESS** structure.

Values

Type	Description
WDI_MAC_ADDRESS	The MAC address to be used for port creation.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CREATE_PORT_PARAMETERS

Article • 03/14/2023

WDI_TLV_CREATE_PORT_PARAMETERS is a TLV that contains parameters for OID_WDI_TASK_CREATE_PORT.

TLV Type

0x28

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT16	A bitwise OR value of the operation modes the host may configure on the port being created. The operation modes are defined in **WDI_OPERATION_MODE**.
UINT32	The NDIS_PORT_NUMBER that will be associated with the created port. Unless the adapter wants to handle non-WDI OIDs, it does not need to do anything with this field.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_CURRENT_CHANNEL_PARAMETERS

Article • 03/14/2023

WDI_TLV_CURRENT_CHANNEL_PARAMETERS is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_DATAPATH_ATTRIBUTES

Article • 03/14/2023

WDI_TLV_DATAPATH_ATTRIBUTES is a TLV that contains datapath attributes.

TLV Type

0xB8

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_DATAPATH_CAPABILITIES		X	The datapath capabilities.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_DATAPATH_CAPABILITIES

Article • 03/14/2023

WDI_TLV_DATAPATH_CAPABILITIES is a TLV that contains datapath capabilities.

TLV Type

0xB9

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_INTERCONNECT_TYPE (UINT32)	Interconnect type.
UINT8	Maximum number of peers.
UINT8	Specifies transmit capability: Target priority queuing. Valid values are 0 and 1. If set to 0, WDI classifies Tx frames by Peer and TID and utilizes the full scheduler to select TX queues to transfer. It is recommended that this is set to false unless the target is capable of classification and Peer-TID queueing. If set to 1, WDI classifies Tx frames by Peer and TID and only provides queuing at a port level. WDI schedules backlogged port queues using a global DRR.

Type	Description
UINT16	Specifies transmit capability: Maximum number of Scatter Gather elements in frame. WDI coalesces frames as necessary such that the IHV miniport does not receive a frame that requires more scatter gather elements than specified by this capability. For best performance, it is suggested that this capability is set higher than the typical frame as the coalescing requires a memory copy. If this capability is not greater than max frame size divided by page size, WDI may be unable to successfully coalesce the frame and it may be dropped.
UINT8	Specifies transmit capability: Explicit Send Complete flag required. Valid values are 0 and 1. If set to 0, the target/TAL generates a TX send complete for all frames. If set to 1, the target/TAL generates TX send completion indication only for frames that have this flag set in the frame's metadata.
UINT16	Specifies transmit capability: Minimum effective frame size. When dequeuing frames, the TxMgr treats frames smaller than this value as having an effective size of this value.
UINT16	Specifies transmit capability: Frame size granularity. This value is equal to the granularity of memory allocation per frame. For the purposes of dequeuing, the TxMgr treats a frame as having an effective size equal to the frame size plus the least amount of padding such that the effective size is an integer multiple of this value. This value must be set to a power of two.
UINT8	Specifies transmit capability: Rx Tx forwarding. Valid values are 0 and 1. If set to 1, the target is capable of forwarding received frames.
UINT32	Specifies transmit capability: Maximum throughput, in units of 0.5 Mbps. This value is used for the allocation of descriptors and buffers.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_DEFAULT_TX_KEY_ID_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_DEFAULT_TX_KEY_ID_PARAMETERS is a TLV that contains the default key ID for packet transmission on a port for OID_WDI_SET_DEFAULT_KEY_ID.

TLV Type

0x54

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	Specifies the default key ID for packet transmission on a port.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_DELETE_CIPHER_KEY_INFO

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_DELETE_CIPHER_KEY_INFO is a TLV that contains information to identify a single cipher key to remove with OID_WDI_SET_DELETE_CIPHER_KEYS.

TLV Type

0x53

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_PEER_MAC_ADDRESS		X	Specifies the peer MAC address. At least one of WDI_TLV_PEER_MAC_ADDRESS or WDI_TLV_CIPHER_KEY_ID must be present.
WDI_TLV_CIPHER_KEY_ID		X	Specifies the cipher key ID. At least one of WDI_TLV_PEER_MAC_ADDRESS or WDI_TLV_CIPHER_KEY_ID must be present.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_CIPHER_KEY_TYPE_INFO			Specifies the cipher key type information.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_DELETE_PEER_STATE_PARAMETERS

Article • 03/14/2023

WDI_TLV_DELETE_PEER_STATE_PARAMETERS is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_DELETE_PORT_PARAMETERS

Article • 03/14/2023

WDI_TLV_DELETE_PORT_PARAMETERS is a TLV that contains parameters for OID_WDI_TASK_DELETE_PORT.

TLV Type

0x2A

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT16	Specifies the port number to delete.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_DEVICE_SERVICE_PARAMS_DATA_BLOB

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_DEVICE_SERVICE_PARAMS_DATA_BLOB is a TLV that contains information about a device service received from the IHV driver. This TLV is used in the NDIS_STATUS_WDI_INDICATION_DEVICE_SERVICE_EVENT status indication.

TLV Type

0x141

Length

The size, in bytes, of a `(UINT8 * (the number of elements in the list))`.

Values

Type	Description
TLV<List<UINT8>>	[Optional] The information received from the IHV driver.

Requirements

Minimum supported client: Windows 10, version 1809

Minimum supported server: Windows Server 2016

Header: Wditypes.hpp

WDI_TLV_DEVICE_SERVICE_PARAMS_GUID

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_DEVICE_SERVICE_PARAMS_GUID is a TLV that contains a GUID that identifies the device service to which this status indication belongs. This TLV is used in the NDIS_STATUS_WDI_INDICATION_DEVICE_SERVICE_EVENT status indication.

TLV Type

0x140

Length

The size, in bytes, of a GUID.

Values

Type	Description
GUID	The GUID that identifies the device service to which this status indication belongs (as defined by the IHV/OEM).

Requirements

Minimum supported client: Windows 10, version 1809

Minimum supported server: Windows Server 2016

Header: Wditypes.hpp

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_DEVICE_SERVICE_PARAMS_OPCODE is a TLV that contains the opcode specific to the device service. This TLV is used in the NDIS_STATUS_WDI_INDICATION_DEVICE_SERVICE_EVENT status indication.

TLV Type

0x13F

Length

The size, in bytes, of a UINT8.

Values

Type	Description
TLV<UINT8>	The opcode specific to the device service.

Requirements

Minimum supported client: Windows 10, version 1809

Minimum supported server: Windows Server 2016

Header: Wditypes.hpp

WDI_TLV_DISALLOWED_BSSIDS_LIST

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_DISALLOWED_BSSIDS_LIST is a TLV that contains a list of BSSIDs that are not allowed to be used for association.

TLV Type

0xC3

Length

The size (in bytes) of the array of WDI_MAC_ADDRESS structures. The array must contain 1 or more structures.

Values

Type	Description
WDI_MAC_ADDRESS[]	A list of BSSIDs that are not allowed to be used for association. If this is specified, the adapter must not associate to any AP that is not in this list

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_DISASSOCIATION_INDICATION_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_DISASSOCIATION_INDICATION_PARAMETERS is a TLV that contains disassociation indication parameters for NDIS_STATUS_WDI_INDICATION_DISASSOCIATION.

TLV Type

0xBC

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_MAC_ADDRESS	The MAC address of the peer associated with the disassociation indication.
WDI_ASSOC_STATUS (UINT32)	The trigger for the disassociation indication.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

Header	Wditypes.hpp

WDI_TLV_DISASSOCIATION_PARAMETERS

Article • 03/14/2023

WDI_TLV_DISASSOCIATION_PARAMETERS is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_DISCONNECT_DEAUTH_FRAME

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_DISCONNECT_DEAUTH_FRAME is a TLV that contains the received deauthentication frame.

TLV Type

0x37

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that contains the received deauthentication frame.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_DISCONNECT_DISASSOCIATION_FRAME

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_DISCONNECT_DISASSOCIATION_FRAME is a TLV that contains the received disassociation frame.

TLV Type

0x38

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that contains the received disassociation frame. This does not include the 802.11 MAC header.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_DISCONNECT_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_DISCONNECT_PARAMETERS is a TLV that contains parameters for OID_WDI_TASK_DISCONNECT.

TLV Type

0x36

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_MAC_ADDRESS	The MAC address of the peer to disassociate.
UINT16	The reason for the host-triggered disassociation. This value is provided in little endian byte order and should be appropriately copied into the reason code of the outgoing frame.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_DOT11_RESET_PARAMETERS

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_DOT11_RESET_PARAMETERS is a TLV that contains parameters for OID_WDI_TASK_DOT11_RESET.

TLV Type

0xA2

Length

The size (in bytes) of a UINT8.

Values

Type	Description
UINT8	If (and only if) this is set to 1, all MIB attributes for the port being reset are set to their default values.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ENABLE_WAKE_EVENTS

Article • 03/14/2023

WDI_TLV_ENABLE_WAKE_EVENTS is a TLV that contains the enabled wake events.

TLV Type

0x60

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	Specifies the enabled wake-on-LAN packet patterns using the flags as documented in NDIS_PM_PARAMETERS.EnabledWoLPacketPatterns.
UINT32	Specifies the enabled protocol offloads using the flags as documented in NDIS_PM_PARAMETERS.EnabledProtocolOffloads.
UINT32	Specifies the wake-up flags using the flags as documented in NDIS_PM_PARAMETERS.WakeUpFlags.
UINT32	Specifies the media-specific wake up events using the flags as documented in NDIS_PM_PARAMETERS.MediaSpecificWakeUpEvents.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_ETHERTYPE_ENCAP_TABLE

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ETHERTYPE_ENCAP_TABLE is a TLV that contains the Ethertype encapsulations for the association.

TLV Type

0x31

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_ETHERTYPE_ENCAPSULATION_ENTRY[]	An array of WDI_ETHERTYPE_ENCAPSULATION_ENTRY elements that specifies the Ethertype encapsulations for the association.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_EXTRA_ASSOCIATION_REQUEST_IES

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_EXTRA_ASSOCIATION_REQUEST_IES is a TLV that contains Information Elements (IEs) that must be included in association requests sent by the port.

TLV Type

0x40

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that contains the IEs that must be included in association requests sent by the port. These are applicable to any BSSID that the device associates with. They should be used in addition to the common and BSSID specific IEs.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_FIRMWARE_VERSION

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_FIRMWARE_VERSION is a TLV that contains the firmware version.

TLV Type

0xF4

Length

The size (in bytes) of the array of char elements. The array must contain 1 or more elements.

Values

Type	Description
char[]	The firmware version, stored as a null-terminated ASCII string.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_FT_AUTH_REQUEST

Article • 03/14/2023

ⓘ **Important**

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_FT_AUTH_REQUEST is a TLV that contains the Fast Transition authentication request byte blob.

TLV Type

0x119

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that contains the Fast Transition authentication request byte blob.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_FT_AUTH_RESPONSE

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_FT_AUTH_RESPONSE is a TLV that contains the Fast Transition authentication response byte blob.

TLV Type

0x10E

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that contains the Fast Transition authentication response byte blob.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_FT_FTE

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_FT_FTE is a TLV that contains a Fast Transition Element.

TLV Type

0x10B

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	A Fast Transition Element that contains the R0KHID and SNonce.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_FT_INITIAL_ASSOC_PARAMETERS

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_FT_INITIAL_ASSOC_PARAMETERS is a TLV that contains initial association parameters for Fast Transition.

TLV Type

0x105

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_TLV_FT_MDE	The MDIE of the BSS entry.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_FT_MDE

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_FT_MDE is a TLV that contains the MDIE of a BSS entry.

TLV Type

0x10D

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	The MDIE of a BSS entry.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_FT_PMKR0NAME

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_FT_PMKR0NAME is a TLV that contains a PMKR0Name or PMKR1Name (802.11r).

TLV Type

0x107

Length

The size (in bytes) of a WDI_TYPE_PMK_NAME structure.

Values

Type	Description
WDI_TYPE_PMK_NAME	A PMKR0Name or PMKR1Name (802.11r).

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_FT_R0KHID

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_FT_R0KHID is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_FT_R1KHID

Article • 03/14/2023

WDI_TLV_FT_R1KHID is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_FT_REASSOC_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_FT_REASSOC_PARAMETERS is a TLV that contains reassociation parameters for Fast Transition.

TLV Type

0x106

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_TLV_FT_MDE	The MDIE of the BSS entry.
WDI_TLV_FT_PMKR0NAME	The PMKR0Name. This is needed during Fast Transition. The STA needs to send the PMKR0Name during the authentication request to the AP.
WDI_TLV_FT_FTE	The Fast Transition Element that contains the R0KHID and SNonce.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_FT_RSNIE

Article • 03/14/2023

ⓘ Important

WDI_TLV_FT_RSNIE is a TLV that contains the Fast Transition RSN IE byte blob.

TLV Type

0x10C

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that contains the Fast Transition RSN IE byte blob.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_FT_SNONCE

Article • 03/14/2023

WDI_TLV_FT_SNONCE is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_FTM_NUMBER_OF_MEASUREMENTS

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_FTM_NUMBER_OF_MEASUREMENTS is a TLV that contains the number of measurements used to provide the round trip time (RTT) for a Fine Timing Measurement (FTM) request.

This TLV is used in WDI_TLV_FTM_RESPONSE.

TLV Type

0x15B

Length

The size (in bytes) of a UINT16.

Values

Type	Description
UINT16	The number of measurements used to provide the RTT.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_FTM_REQUEST_TIMEOUT

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_FTM_REQUEST_TIMEOUT is a TLV that contains the maximum time, in milliseconds, to complete a Fine Timing Measurement (FTM).

This TLV is used in the task parameters of OID_WDI_TASK_REQUEST_FTM.

TLV Type

0x161

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	The maximum time, in milliseconds, to complete the FTM. The timeout is set to 150 ms multiplied by the number of targets.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_FTM_RESPONSE

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_FTM_RESPONSE is a TLV that contains Fine Timing Measurement (FTM) response information from a BSS target.

This TLV is used in the payload data of an NDIS_STATUS_WDI_INDICATION_REQUEST_FTM_COMPLETE task completion indication.

TLV type

0x163

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

TLV	Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_BSSID	**WDI_MAC_ADDRESS**			The BSSID of the target to which this FTM response belongs.
WDI_TLV_FTM_RESPONSE_STATUS	**WDI_FTM_RESPONSE_STATUS**			The FTM response status. If success, the rest of the fields in this TLV are present.
WDI_TLV_RETRY_AFTER	UINT16			A duration, in seconds, that should pass before trying to request a new FTM from this target.
WDI_TLV_FTM_NUMBER_OF_MEASUREMENTS	UINT16			The number of measurements used to provide the round trip time (RTT). If the FTM response status was a success, this field is mandatory.

TLV	Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_BSS_ENTRY_SIGNAL_INFO	INT32			The received signal strength indicator (RSSI) from the FTM target. This is in units of decibels referenced to 1.0 milliwatts (dBm). If the FTM response status was a success, this field is mandatory.
Same as row above	UINT32			The link quality value of the FTM target, ranging from 0 through 100. A value of 100 specifies the highest link quality. If the FTM response status was a success, this field is mandatory.
WDI_TLV_RTT	UINT32			The measured roundtrip time (RTT), in picoseconds. If the FTM response status was a success, this field is mandatory.
WDI_TLV_RTT_ACCURACY	UINT32			The accuracy, or expected degree of closeness, of the provided RTT measurement to the true value. The unit is in picoseconds. For more information, see the WDI_TLV_RTT_ACCURACY.
WDI_TLV_RTT_VARIANCE	UINT64			If more than one measurement was used to calculate the RTT, this field provides the statistical variance of the measurements used.
WDI_TLV_LCI_REPORT_STATUS	**WDI_LCI_REPORT_STATUS**			If an LCI report was requested, this field provides the status result. If successful, the following fields are present and mandatory.

TLV	Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_LCI_REPORT_BODY	TLV<LIST<UINT8>>			The Location Configuration Information (LCI) report, as defined in Section 9.4.2.22.10 of the 802-11-2016 standard, including the LCI subelement and other Optional subelements available. In other words, this is the measurement report section of the Measurement Report element (as per Section 9.4.2.22 from the 802-11-2016 standard).

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_FTM_RESPONSE_STATUS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_FTM_RESPONSE_STATUS is a TLV that contains the Fine Timing Measurement (FTM) response status from a target BSS.

This TLV is used in WDI_TLV_FTM_RESPONSE.

TLV Type

0x159

Length

The size (in bytes) of a UINT32.

Values

Type	Description
WDI_FTM_RESPONSE_STATUS	The FTM response status.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_FTM_TARGET_BSS_ENTRY

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_FTM_TARGET_BSS_ENTRY is a TLV that contains information for a BSS target with which Fine Timing Measurement (FTM) procedures should be completed.

This TLV is used in the task parameters for OID_WDI_TASK_REQUEST_FTM.

TLV type

0x162

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

TLV	Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_BSSID	**WDI_MAC_ADDRESS**			The BSSID of the target BSS.
WDI_TLV_PROBE_RESPONSE_FRAME	TLV<LIST<UINT8>>		X	The probe response frame. If no probe response has been received, this field is empty.

TLV	Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_BEACON_FRAME	TLV<LIST<UINT8>>		X	The beacon frame. If no beacon has been received, this field is empty.
WDI_TLV_BSS_ENTRY_SIGNAL_INFO	INT32			The received signal strength indicator (RSSI) value of the beacon or probe response from the peer. This is in units of decibels referenced to 1.0 milliwatts (dBm).
	UINT32			The link quality value ranging from 0 through 100. A value of 100 specifies the highest link quality.
WDI_TLV_BSS_ENTRY_CHANNEL_INFO	UINT32			The logical channel number of the target BSS.
	UINT32			The Band ID of the target BSS.

TLV	Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_BSS_ENTRY_DEVICE_CONTEXT	TLV<LIST<UINT8>>			IHV component-provided context data about this peer. This can be usd to store per-BSS entry state that the IHV component wants to maintain. To avoid lifetime management issues, the IHV component must not use pointers in this field.
WDI_TLV_REQUEST_LCI_REPORT	UINT8			Possible values: • 0: LCI report not needed. • 1: LCI report should be requested.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_GET_AUTO_POWER_SAVE

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_GET_AUTO_POWER_SAVE is a TLV that contains auto power save information for OID_WDI_GET_AUTO_POWER_SAVE.

TLV Type

0xB3

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8	The firmware current AutoPSM state.
UINT8	Reserved.
UINT16	Reserved.
UINT16	The beacon interval in milliseconds.
UINT8	The listen interval, in the unit of the beacon interval (for example, 1).
UINT8	The listen interval in the last low power state (for example, 5). If there is no last low power state, set to 255.
WDI_POWER_SAVE_LEVEL (UINT32)	The power mode.
WDI_POWER_SAVE_LEVEL (UINT32)	The power mode in Dx.

Type	Description
WDI_POWER_MODE_REASON_CODE (UINT32)	The reason for entering the Power Save state and listen interval.
UINT64	Milliseconds since start.
UINT64	Milliseconds in power save mode.
UINT64	Number of received multicast packets, including broadcast.
UINT64	Number of sent multicast packets, including broadcast.
UINT64	Number of received unicast packets.
UINT64	Number of sent unicast packets.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_HESSID

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_HESSID is a TLV that contains a list of HESSIDs.

TLV Type

0xC8

Length

The size (in bytes) of the array of WDI_MAC_ADDRESS structures. The array must contain 1 or more structures.

Values

Type	Description
WDI_MAC_ADDRESS[]	A list of HESSIDs.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_HESSID_INFO

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_HESSID_INFO is a TLV that contains HESSID information, which includes a list of HESSIDs, the Access Network Type, and Hotspot Indication Element.

TLV Type

0xFF

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_ACCESS_NETWORK_TYPE			The Access Network Type to be used in probe requests for the network being connected to.
WDI_TLV_HESSID			The list of HESSIDs that the port is allowed to connect to.
WDI_TLV_HOTSPOT_INDICATION_ELEMENT			The Hotspot Indication Element to be used in the Association Request.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_HOTSPOT_DOMAIN_PARTNER

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_HOTSPOT_DOMAIN_PARTNER is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_HOTSPOT_INDICATION_ELEMENT

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_HOTSPOT_INDICATION_ELEMENT is a TLV that contains a Hotspot Indication Element that is used in a Association Request.

TLV Type

0x101

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	A Hotspot Indication Element that is used in a Association Request.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_IHV_DATA

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_IHV_DATA is a TLV that contains IHV-specific information that is used by the IHV extensibility module.

TLV Type

0xBD

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	IHV specific information that is used by the IHV extensibility module.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_IHV_NON_WDI_OIDS_LIST

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_IHV_NON_WDI_OIDS_LIST is a TLV that contains a list of non-WDI OIDs that the adapter wants to advertise to the operating system.

TLV Type

0x104

Length

The size (in bytes) of the array of UINT32 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT32[]	A list of non-WDI OIDs that the adapter wants to advertise to the operating system. The adapter should not assume that the operating system has already filtered non-WDI OIDs to match this list.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_IHV_TASK_DEVICE_CONTEXT

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_IHV_TASK_DEVICE_CONTEXT is a TLV that contains IHV-provided device context for NDIS_STATUS_WDI_INDICATION_IHV_TASK_REQUEST.

TLV Type

0xE0

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	The IHV-provided device context information that is forwarded to the IHV task.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_IHV_TASK_REQUEST_PARAMETERS

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_IHV_TASK_REQUEST_PARAMETERS is a TLV that contains the requested priority for NDIS_STATUS_WDI_INDICATION_IHV_TASK_REQUEST.

TLV Type

0xDF

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	The IHV-requested priority for this task. See **WDI_IHV_TASK_PRIORITY** for valid priority values.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_INCOMING_ASSOCIATION_REQUEST_INFO

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_INCOMING_ASSOCIATION_REQUEST_INFO is a TLV that contains information about the incoming association request.

TLV Type

0x8F

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_INCOMING_ASSOCIATION_REQUEST_PARAMETERS			The parameters for the incoming association request.
WDI_TLV_ASSOCIATION_REQUEST_FRAME			The association request frame.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_ASSOCIATION_REQUEST_DEVICE_CONTEXT		X	The vendor-specific information that is passed down to the port.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_INCOMING_ASSOCIATION_REQUEST_PARAMETERS

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_INCOMING_ASSOCIATION_REQUEST_PARAMETERS is a TLV that contains association request parameters.

TLV Type

0x7D

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_MAC_ADDRESS	The MAC address of the sender.
UINT8	A bit that indicates whether or not it is a reassociation request. A value of 1 indicates that it is a reassociation request.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_INDICATION_CAN_SUSTAIN_AP

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_INDICATION_CAN_SUSTAIN_AP is a TLV that contains the reason for a Can Sustain AP indication.

TLV Type

0xE7

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	The Can Sustain AP reason. See WDI_CAN_SUSTAIN_AP_REASON for possible reason values.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

See also

NDIS_STATUS_WDI_INDICATION_CAN_SUSTAIN_AP

WDI_TLV_INDICATION_STOP_AP

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_INDICATION_STOP_AP is a TLV that contains the reason for a Stop AP indication.

TLV Type

0xE6

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	The Stop AP reason. See WDI_STOP_AP_REASON for possible reason values.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

See also

NDIS_STATUS_WDI_INDICATION_STOP_AP

WDI_TLV_INDICATION_WAKE_PACKET

Article • 03/14/2023

WDI_TLV_INDICATION_WAKE_PACKET is a TLV that contains a wake packet for NDIS_STATUS_WDI_INDICATION_WAKE_REASON. When the wake reason is WDI_WAKE_REASON_CODE PACKET, the status must include the wake packet encapsulated in a WDI_TLV_INDICATION_WAKE_PACKET.

TLV Type

0x9D

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	The wake packet. The size is the size of the flat memory version of the packet that will be indicated in the normal receive path.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_INDICATION_WAKE_PACKET_PATTERN_ID

Article • 03/14/2023

WDI_TLV_INDICATION_WAKE_PACKET_PATTERN_ID is a TLV that contains the ID of the pattern that matches a wake packet.

TLV Type

0xB0

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	The ID of the pattern that matches the wake packet. The ID is defined when the pattern is added with OID_WDI_SET_ADD_WOL_PATTERN.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_INDICATION_WAKE_REASON

Article • 03/14/2023

WDI_TLV_INDICATION_WAKE_REASON is a TLV that contains a wake reason for NDIS_STATUS_WDI_INDICATION_WAKE_REASON.

TLV Type

0x9C

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	Specifies the wake reason.

Valid wake reason values are:

Wake reason	Value	Description
WDI_WAKE_REASON_CODE_PACKET	0x0001	A received packet matches the wake pattern.
WDI_WAKE_REASON_CODE_MEDIA_DISCONNECT	0x0002	Media disconnection.
WDI_WAKE_REASON_CODE_MEDIA_CONNECT	0x0003	Media connection.
WDI_WAKE_REASON_CODE_NLO_DISCOVERY	0x1000	NLO discovery.
WDI_WAKE_REASON_CODE_AP_ASSOCIATION_LOST	0x1001	Access point association lost.
WDI_WAKE_REASON_CODE_GTK_HANDSHAKE_ERROR	0x1002	GTK handshake error.
WDI_WAKE_REASON_CODE_4WAY_HANDSHAKE_REQUEST	0x1003	4-Way Handshake request.
WDI_WAKE_REASON_CODE_EAPID_REQUEST	0x1004	Reserved for future use.
WDI_WAKE_ REASON _CODE_INCOMING_M1	0x1005	Use WDI_WAKE_REASON_CODE_4WAY_HANDSHAKE_REQUEST instead.
WDI_WAKE_REASON_CODE_FIRMWARE_STALLED	0x1010	Firmware hang is detected (for example, by the watchdog timer) and wake logic is still functioning to wake the host.
WDI_WAKE_REASON_CODE_GTK_HANDSHAKE_REQUEST	0x1020	Group Key rekey request.

Requirements

Minimum supported client	Windows 10

Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_INTERFACE_ATTRIBUTES

Article • 03/14/2023

WDI_TLV_INTERFACE_ATTRIBUTES is a TLV that contains the attributes of an interface.

TLV Type

0x21

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_INTERFACE_CAPABILITIES			The capabilities of the interface.
WDI_TLV_FIRMWARE_VERSION			An ASCII string that specifies the firmware version.
WDI_TLV_IHV_NON_WDI_OIDS_LIST		X	List of non-WDI OIDs that the adapter wants to advertise to the operating system. The adapter should not assume that the operating system has already filtered non-WDI OIDs to match this list.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_INTERFACE_CAPABILITIES

Article • 03/14/2023

WDI_TLV_INTERFACE_CAPABILITIES is a TLV that contains the capabilities of the Wi-Fi interface.

TLV Type

0xF

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	The maximum transfer unit (MTU) size.
UINT32	The multicast list size for the adapter.
UINT16	The backfill size in bytes. This value cannot be greater than 256 bytes.
WDI_MAC_ADDRESS	The permanent MAC address for the adapter. If the device supports multiple permanent MAC addresses, the first MAC address that will be used by the device should be returned.
UINT32	The maximum supported send rate for this adapter in kbps.
UINT32	The maximum supported receive rate for this adapter in kbps.
UINT8	Specifies whether the radio is enabled by hardware. Valid values are 0 (disabled) and 1 (enabled).
UINT8	Specifies whether they radio is enabled by software. Valid values are 0 (disabled) and 1 (enabled).

Type	Description
UINT8	Specifies whether the interface supports PLR. Valid values are 0 (not supported) and 1 (supported).
UINT8	Specifies whether the interface supports FLR. Valid values are 0 (not supported) and 1 (supported).
UINT8	Specifies whether sending and receiving action frames is supported. Valid values are 0 (not supported) and 1 (supported).
UINT8	The supported number of RX spatial streams.
UINT8	The supported number of TX spatial streams.
UINT8	The number of channels that the adapter can work in concurrently, regardless of operation mode.
UINT8	Specifies whether antenna diversity is supported. Valid values are 0 (not supported) and 1 (supported).
UINT8	Specifies whether eCSA is supported. Valid values are 0 (not supported) and 1 (supported).
UINT8	Specifies whether the adapter supports MAC address randomization. Valid values are 0 (not supported) and 1 (supported).
WDI_MAC_ADDRESS	A bit mask that specifies for each address bit whether it can be randomized (0) or should keep the same value as the permanent address (1). The default is all zeros.
WDI_BLUETOOTH_COEXISTENCE_SUPPORT (UINT32)	The supported level of Wi-Fi - Bluetooth coexistence.
UINT8	Specifies non-WDI OID support. Valid values are: • 0 : Not supported. OIDs that the Microsoft component does not understand are not forwarded to the adapter. • 1 : Supported. OIDs that the Microsoft component does not understand are forwarded to the adapter. These OIDs will not contain WDI headers. To identify the adapter's port that the request came in on, use **NdisPortNumber** in the NDIS_OID_REQUEST and match it to the one in WDI_TASK_CREATE_PORT.

Type	Description
UINT8	Specifies whether the Fast Transition is supported. Valid values are 0 (not supported) and 1 (supported).
UINT8	Specifies whether Mu-MIMO is supported. Valid values are 0 (not supported) and 1 (supported).
UINT8	Specifies if the interface cannot support Miracast Sink. Valid values are 0 (supported) and 1 (not supported).
UINT8	Specifies if 802.11v BSS transition is supported. Valid values are 0 (not supported) and 1 (supported).
UINT8	Specifies if the device supports IP docking capability. Valid values are 0 (not supported) and 1 (supported). Added in Windows 10, version 1607, WDI version 1.0.21.
UINT8	Specifies if the device supports SAE authentication. Valid values are 0 (not supported) and 1 (supported). Added in Windows 10, version 1903, WDI version 1.1.8.
UINT8	Specifies if the device supports Multiband Operation (MBO). Valid values are 0 (not supported) and 1 (supported). Added in Windows 10, version 1903, WDI version 1.1.8.
UINT8	Specifies if the adapter implements beacon report measurements. Valid values are 0 (the adapter does not implement beacon report measurements) and 1 (the adapter implements its own 11k beacon report). Added in Windows 10, version 1903, WDI version 1.1.8.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

Header	Wditypes.hpp

WDI_TLV_IPV4_CHECKSUM_OFFLOAD

Article • 03/14/2023

WDI_TLV_IPV4_CHECKSUM_OFFLOAD is a TLV that contains checksum offload capabilities for IPv4.

TLV Type

0xCF

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_CHECKSUM_OFFLOAD_V4_TX_PARAMETERS			Parameters for Tx checksum offload for IPv4.
WDI_TLV_CHECKSUM_OFFLOAD_V4_RX_PARAMETERS			Parameters for Rx checksum offload for IPv4.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_IPV4_LSO_V2 (0xD3)

Article • 03/14/2023

WDI_TLV_IPV4_LSO_V2 is a TLV that contains Large Send Offload V2 parameters for IPv4.

TLV Type

0xD3

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	Encapsulation type. Valid values are: • WDI_ENCAPSULATION_IEEE_802_11
UINT32	The maximum offload size. Specified by the maximum number of bytes of TCP user data per packet.
UINT32	The minimum segment count. Specified by the minimum number of segments that should be present after segmentation.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_IPV6_CHECKSUM_OFFLOAD

Article • 03/14/2023

WDI_TLV_IPV6_CHECKSUM_OFFLOAD is a TLV that contains checksum offload capabilities for IPv6.

TLV Type

0xD0

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_CHECKSUM_OFFLOAD_V6_TX_PARAMETERS			Parameters for Tx checksum offload for IPv6.
WDI_TLV_CHECKSUM_OFFLOAD_V6_RX_PARAMETERS			Parameters for Rx checksum offload for IPv6.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_IPV6_LSO_V2 (0xD4)

Article • 03/14/2023

WDI_TLV_IPV6_LSO_V2 is a TLV that contains Large Send Offload V2 parameters for IPv6.

Capability values are reported as documented in **NDIS_TCP_IP_CHECKSUM_OFFLOAD**. Use NDIS_OFFLOAD_NOT_SUPPORTED and NDIS_OFFLOAD_SUPPORTED when indicating capabilities through OID_WDI_GET_ADAPTER_CAPABILITIES.

TLV Type

0xD4

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	Encapsulation type. Valid values are: • WDI_ENCAPSULATION_IEEE_802_11
UINT32	The maximum offload size. Specified by the maximum number of bytes of TCP user data per packet.
UINT32	The minimum segment count. Specified by the minimum number of segments that should be present after segmentation.
UINT32	Specifies if offload of checksum of packets with IP extension headers is supported.
UINT32	Specifies if offload of checksum with TCP options is supported.

Requirements

Minimum supported client	Windows 10

Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_KCK_CONTENT

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_KCK_CONTENT is a TLV that contains an IEEE 802.11 key confirmation key (KCK).

TLV Type

0x168

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	Specifies an IEEE 802.11 key confirmation key (KCK).

Requirements

Minimum supported client	Windows 10, version 2004
Minimum supported server	Windows Server 2016
Header	Wditypes.pp

WDI_TLV_KEK_CONTENT

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_KEK_CONTENT is a TLV that contains an IEEE 802.11 key encryption key (KEK).

TLV Type

0x169

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	Specifies an IEEE 802.11 key encryption key (KEK).

Requirements

Minimum supported client	Windows 10, version 2004
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_LCI_REPORT_BODY

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_LCI_REPORT_BODY is a TLV that contains the Location Configuration Report (LCI) for a Fine Timing Measurement (FTM) request.

This TLV is used in WDI_TLV_FTM_RESPONSE.

TLV Type

0x160

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	The LCI report.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_LCI_REPORT_STATUS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_LCI_REPORT_STATUS is a TLV that contains the status result of a Location Configuration Information (LCI) report, if one was requested during a Fine Timing Measurement (FTM) request.

This TLV is used in WDI_TLV_FTM_RESPONSE.

TLV Type

0x15F

Length

The size (in bytes) of a UINT32.

Values

Type	Description
WDI_LCI_REPORT_STATUS	The status of the LCI report.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_LINK_QUALITY_BAR_MAP

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_LINK_QUALITY_BAR_MAP is a TLV that contains the mapping of signal quality to Wi-Fi signal strength bars.

TLV Type

0xD8

Length

The size (in bytes) of the array of WDI_LINK_QUALITY_BAR_MAP_PARAMETERS elements. The array must contain 1 or more elements.

Note WDI_LINK_QUALITY_BAR_MAP_PARAMETERS is not a WDI structure. It is defined in the WDI TLV parser generator, and is used for documentation purposes only.

Values

Type	Description
WDI_LINK_QUALITY_BAR_MAP_PARAMETERS[]	An array of signal strength bar mapping parameters.

WDI_LINK_QUALITY_BAR_MAP_PARAMETERS consists of the following elements.

Type	Description
UINT8	The lower limit link quality (0-100) for the current signal strength bar.
UINT8	The upper limit of link quality (0-100) for the current signal strength bar.

Type	Description
UINT8	The signal strength bar number.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

WDI_TLV_LINK_STATE_CHANGE_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_LINK_STATE_CHANGE_PARAMETERS is a TLV that contains link state change parameters for NDIS_STATUS_WDI_INDICATION_LINK_STATE_CHANGE.

TLV Type

0x56

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_MAC_ADDRESS	Specifies the MAC address of the remote peer.
UINT32	Specifies the current TX link speed. This is a value, in kilobits per second, that is the current TX link speed for this virtualized port. The conversion is 1 kbps = 1000 bps.
UINT32	Specifies the current RX link speed. This is a value, in kilobits per second, that is the current RX link speed for this virtualized port. The conversion is 1 kbps = 1000 bps.
UINT8	Specifies the current link quality. This is a value between 0 and 100 that is the current link quality for this virtualized port.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_LOW_LATENCY_CONNECTION_QUALITY_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_LOW_LATENCY_CONNECTION_QUALITY_PARAMETERS is a TLV that contains low latency connection quality parameters.

TLV Type

0xF6

Length

The size (in bytes) of the array of all contained elements.

Values

Type	Description
UINT8	Specifies the maximum number of milliseconds that the port can be on a different channel during Active Scan or other multi-channel operations. The only instance in which this off-channel can be higher is if the adapter needs to do a passive scan.
UINT8	Specifies the link quality threshold for NDIS_STATUS_WDI_INDICATION_ROAMING_NEEDED. When the link quality is below this threshold, it is acceptable for the adapter to send NDIS_STATUS_WDI_INDICATION_ROAMING_NEEDED.

Requirements

Minimum supported client	Windows 10

Minimum supported server	Windows Server 2016

WDI_TLV_LSO_V1_CAPABILITIES (0xCC)

Article • 03/14/2023

WDI_TLV_LSO_V1_CAPABILITIES is a TLV that contains Large Send Offload V1 capabilities.

Capability values are reported as documented in **NDIS_TCP_IP_CHECKSUM_OFFLOAD**. Use NDIS_OFFLOAD_NOT_SUPPORTED and NDIS_OFFLOAD_SUPPORTED when indicating capabilities through OID_WDI_GET_ADAPTER_CAPABILITIES.

TLV Type

0xCC

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	The encapsulation type. Valid values are: • WDI_ENCAPSULATION_IEEE_802_11
UINT32	The maximum offload size. Specified by the maximum number of bytes of TCP user data per packet.
UINT32	The minimum number of segments that a large TCP packet must be divisible by before the transport can offload it to the hardware for segmentation.
UINT32	Specifies whether or not TCP options are supported for this offload.
UINT32	Specifies whether or not IP options are supported for this offload.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_LSO_V2_CAPABILITIES

Article • 03/14/2023

WDI_TLV_LSO_V2_CAPABILITIES is a TLV that contains Large Send Offload V2 capabilities.

TLV Type

0xCD

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_IPV4_LSO_V2			Large Send Offload V2 capabilities for IPv4.
WDI_TLV_IPV6_LSO_V2			Large Send Offload V2 capabilities for IPv6.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_MAC_STATISTICS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_MAC_STATISTICS is a TLV that contains per-peer MAC statistics for OID_WDI_GET_STATISTICS.

TLV Type

0xA6

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_MAC_ADDRESS	The MAC address of the peer that these counts are set for. For multicast and broadcast packets, this value is set to FF-FF-FF-FF-FF-FF-FF.
UINT64	The number of MSDU packets and MMPDU frames that the IEEE MAC layer of the 802.11 station successfully transmitted.
UINT64	The number of MSDU packets and MMPDU frames that the IEEE MAC layer of the 802.11 station successfully received. This member should not be incremented for received packets that failed cipher decryption or MIC validation.

Type	Description
UINT64	The number of unencrypted received MPDU frames that the MAC layer discarded when the IEEE 802.11 dot11ExcludeUnencrypted management information base (MIB) object is enabled. For more information about this MIB object, see OID_DOT11_EXCLUDE_UNENCRYPTED. MPDU frames are considered unencrypted when the Protected Frame subfield of the Frame Control field in the IEEE 802.11 MAC header is set to zero.
UINT64	The number of received MSDU packets that the 802.11 station discarded because of MIC failures.
UINT64	The number of received MPDU frames that the 802.11 station discarded because of the TKIP replay protection procedure.
UINT64	The number of encrypted MPDU frames that the 802.11 station failed to decrypt because of a TKIP ICV error.
UINT64	The number of received MPDU frames that the 802.11 discarded because of an invalid AES-CCMP format.
UINT64	The number of received MPDU frames that the 802.11 station discarded because of the AES-CCMP replay protection procedure.
UINT64	The number of received MPDU frames that the 802.11 station discarded because of errors detected by the AES-CCMP decryption algorithm.
UINT64	The number of encrypted MPDU frames received for which a WEP decryption key was not available on the 802.11 station.
UINT64	The number of encrypted MPDU frames that the 802.11 station failed to decrypt because of a WEP ICV error.

Type	Description
UINT64	The number of received encrypted packets that the 802.11 station successfully decrypted. For the WEP and TKIP cipher algorithms, the port must increment this counter for each received encrypted MPDU that was successfully decrypted. For the AES-CCMP cipher algorithm, the port must increment this counter on each received encrypted MSDU packet that was successfully decrypted.
UINT64	The number of encrypted packets that the 802.11 station failed to decrypt. For the WEP and TKIP cipher algorithms, the port must increment this counter for each received encrypted MPDU that was not successfully decrypted. For the AES-CCMP cipher algorithm, the port must increment this counter on each received encrypted MSDU packet that was not successfully decrypted. The port must not increment this counter for packets that are decrypted successfully, but are discarded for other reasons. For example, the port must not increment this counter for packets that are discarded because of TKIP MIC failures or TKIP/CCMP replays.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_MULTICAST_CIPHER_ALGO_LIST

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_MULTICAST_CIPHER_ALGO_LIST is a TLV that contains a list of multicast cipher algorithms.

TLV Type

0x3D

Length

The size (in bytes) of the array of WDI_CIPHER_ALGORITHM structures. The array must contain 1 or more elements.

Values

Type	Description
WDI_CIPHER_ALGORITHM[]	An array of multicast cipher algorithms.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_MULTICAST_DATA_ALGORITHM_LIST

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_MULTICAST_DATA_ALGORITHM_LIST is a TLV that contains an array of multicast data algorithm pairs.

TLV Type

0x14

Length

The size (in bytes) of the array of WDI_ALGO_PAIRS elements. The array must contain 1 or more elements.

Note WDI_ALGO_PAIRS is not a WDI structure. It is defined in the WDI TLV parser generator, and is used for documentation purposes only.

Values

Type	Description
WDI_ALGO_PAIRS[]	An array of authentication and cipher algorithm pairs.

WDI_ALGO_PAIRS consists of the following elements.

Type	Description
UINT8	Authentication algorithm as defined in WDI_AUTH_ALGORITHM.
UINT8	Cipher algorithm as defined in WDI_CIPHER_ALGORITHM.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_MULTICAST_LIST

Article • 03/14/2023

WDI_TLV_MULTICAST_LIST is a TLV that contains an array of multicast MAC addresses.

TLV Type

0x6A

Length

The size (in bytes) of the array of WDI_MAC_ADDRESS structures. The array must contain 1 or more structures.

Values

Type	Description
WDI_MAC_ADDRESS[]	An array of multicast MAC addresses.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_MULTICAST_MGMT_ALGORITHM_LIST

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_MULTICAST_MGMT_ALGORITHM_LIST is a TLV that contains an array of multicast management algorithm pairs.

TLV Type

0x15

Length

The size (in bytes) of the array of WDI_ALGO_PAIRS elements. The array must contain 1 or more elements.

Note WDI_ALGO_PAIRS is not a WDI structure. It is defined in the WDI TLV parser generator, and is used for documentation purposes only.

The size (in bytes) of the array of algorithm pairs.

Values

Type	Description
WDI_ALGO_PAIRS[]	An array of authentication and cipher algorithm pairs.

WDI_ALGO_PAIRS consists of the following elements.

Type	Description
UINT8	Authentication algorithm as defined in WDI_AUTH_ALGORITHM.

Type	Description
UINT8	Cipher algorithm as defined in WDI_CIPHER_ALGORITHM.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_NEIGHBOR_REPORT_ENTRY

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_NEIGHBOR_REPORT_ENTRY is a TLV that contains a neighbor report.

TLV Type

0x123

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_BSSID			The BSSID of the AP in the neighbor report.
WDI_TLV_BSSID_INFO			The BSSID information of the AP.
WDI_TLV_OPERATING_CLASS			The operating class of the AP indicated by this BSSID.
WDI_TLV_CHANNEL_NUMBER			The last known operating channel of the AP indicated by this BSSID.
WDI_TLV_PHY_TYPE			The PHY type of the AP indicated by this BSSID.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_NETWORK_LIST_OFFLOAD_CONFIG

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_NETWORK_LIST_OFFLOAD_CONFIG is a TLV that contains Network List Offload (NLO) configuration.

TLV Type

0xDA

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	Reserved field.
UINT32	The delay (in seconds) before the scan schedule starts.
UINT32	The period (in seconds) to scan in the first phase.
UINT32	The number of iterations in the fast scan phase.
UINT32	The period (in seconds) to scan in the slow scan phase. This phase lasts indefinitely until a new NLO command is set.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_NETWORK_LIST_OFFLOAD_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_NETWORK_LIST_OFFLOAD_PARAMETERS is a TLV that contains Network List Offload (NLO) parameters for OID_WDI_SET_NETWORK_LIST_OFFLOAD.

TLV Type

0x59

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_NETWORK_LIST_OFFLOAD_CONFIG			Specifies NLO configuration.
WDI_TLV_SSID_OFFLOAD	X	X	Specifies offload SSIDs. When this element is absent, the firmware should stop NLO scanning.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_NETWORK_OFFLOAD_CHANNELS

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_NETWORK_OFFLOAD_CHANNELS is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_NEXT_DIALOG_TOKEN

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_NEXT_DIALOG_TOKEN is a TLV that contains the dialog token to be used in the next Action frame.

TLV Type

0xE1

Length

The size (in bytes) of a UINT8.

Values

Type	Description
UINT8	The dialog token to be used in the next Action frame.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

See also

OID_WDI_GET_NEXT_ACTION_FRAME_DIALOG_TOKEN

WDI_TLV_OFFLOAD_SCOPE

Article • 03/14/2023

WDI_TLV_OFFLOAD_SCOPE is a TLV that contains the scope for network offloads.

TLV Type

0x143

Length

The size (in bytes) of the below values.

Values

Type	Description
UINT8	Specifies whether checksum offload parameters are applicable on all ports. Possible values: • 0: Not applicable • 1: Applicable
UINT8	Specifies whether LsoV1 offload parameters are applicable on all ports. Possible values: • 0: Not applicable • 1: Applicable
UINT8	Specifies whether LsoV2 offload parameters are applicable on all ports. Possible values: • 0: Not applicable • 1: Applicable
UINT8	Specifies whether RSC offload parameters are applicable on all ports. Possible values: • 0: Not applicable • 1: Applicable

Requirements

Minimum supported client: Windows 10, version 1709

Minimum supported server: Windows Server 2016

Header: Wditypes.hpp

WDI_TLV_OPERATING_CLASS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_OPERATING_CLASS is a TLV that contains the frequency band for a channel.

TLV Type

0xFA

Length

The size (in bytes) of a UINT8.

Values

Type	Description
UINT8	The frequency band for a channel.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_OPERATION_MODE

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_OPERATION_MODE is a TLV that contains the desired operation mode.

TLV Type

0x95

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	The desired operation mode, as defined in WDI_OPERATION_MODE.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_OS_POWER_MANAGEMENT_FEATURES

Article • 03/14/2023

WDI_TLV_OS_POWER_MANAGEMENT_FEATURES is a TLV that contains flags for OS power management features. This enables IHVs to indicate to the OS that they support an advanced power management feature called Nic Auto Power Saver (NAPS). NAPS permits the wireless adapter to enter *DX* in situations where network activity is idle.

TLV Type

0x144

Length

The size (in bytes) of the following values.

Values

Type	Description
WDI_OS_POWER_MANAGEMENT_FLAGS	A bitwise OR of **WDI_OS_POWER_MANAGEMENT_FLAGS** values that defines supported NAPS enablement scenarios.

Requirements

Minimum supported client: Windows 10, version 1803

Minimum supported server: Windows Server 2016

Header: Wditypes.hpp

WDI_TLV_OWE_DH_IE

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_OWE_DH_IE is a Diffie-Hellman Extension IE blob that must be included in the association request sent by the station when auth type is OWE. This is applicable to any BSSID that the device would associate with and should be included in addition to the other associated req vendor IEs.

TLV Type

0x16A

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that contains the IEs that must be included in association requests sent by the port. These are applicable to any BSSID that the device associates with. They should be used in addition to the common and BSSID specific IEs.

Requirements

Minimum supported client	Windows 10, version 2004

Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_ACTION_FRAME_DEVICE_CONTEXT

Article • 03/14/2023

WDI_TLV_P2P_ACTION_FRAME_DEVICE_CONTEXT is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_ACTION_FRAME_IES

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_ACTION_FRAME_IES is a TLV that contains action frame IEs.

TLV Type

0x90

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that specifies the set of IEs that are sent to the remote device.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_ACTION_FRAME_RESPONSE_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_ACTION_FRAME_RESPONSE_PARAMETERS is a TLV that contains Wi-Fi Direct Action Frame response parameters.

TLV Type

0xAD

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_P2P_ACTION_FRAME_TYPE	The type of Response Frame to be sent.
WDI_MAC_ADDRESS	The device address of the target peer Wi-Fi Direct device.
UINT8	The Wi-Fi Direct Dialog Token for this transaction.
UINT32	The send timeout. Specifies the maximum time, in milliseconds, to send this action frame.
UINT32	The post-ACK dwell time. Specifies the time to remain on listen channel, in milliseconds, after the incoming packet is acknowledged.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_ADVERTISED_PREFIX_ENTRY

Article • 03/14/2023

WDI_TLV_P2P_ADVERTISED_PREFIX_ENTRY is a TLV that contains a Wi-Fi Direct advertised prefix entry.

TLV Type

0x110

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_SERVICE_NAME			Name of the service, in UTF-8, with a maximum size of 255 bytes.
WDI_TLV_P2P_SERVICE_NAME_HASH			Hash of Service Name.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_ADVERTISED_SERVICE_ENTRY

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_ADVERTISED_SERVICE_ENTRY is a TLV that contains an advertised service entry.

TLV Type

0xFC

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_SERVICE_NAME			Name of the service, in UTF-8, up to 255 bytes.
WDI_TLV_P2P_SERVICE_NAME_HASH			Hash of Service Name.
WDI_TLV_P2P_SERVICE_INFORMATION		X	Service Information for this service.
WDI_TLV_P2P_SERVICE_STATUS			Service Status of this service.
WDI_TLV_P2P_ADVERTISEMENT_ID			An ID that uniquely identifies the service instance.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_CONFIG_METHODS			Configuration methods as defined in WDI_WPS_CONFIGURATION_METHOD. Only PIN display, PIN keypad, and WFDS are applicable.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_ADVERTISED_SERVICES

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_ADVERTISED_SERVICES is a TLV that contains a list of advertised services.

TLV Type

0xEF

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_ADVERTISED_SERVICE_ENTRY	X	X	A list of advertised services.
WDI_TLV_P2P_ADVERTISED_PREFIX_ENTRY	X	X	A list of advertised prefixes that are derived from the list of advertised services.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_ASP2_ADVERTISED_SERVICE_ENTRY	X	X	Added in Windows 10, version 1607, WDI version 1.0.21. A list of advertised ASP2 services.
WDI_TLV_P2P_SERVICE_UPDATE_INDICATOR			The service update indicator to include in ANQP responses if the driver supports responding to service information discovery ANQP requests.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_ADVERTISEMENT_ID

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_ADVERTISEMENT_ID is a TLV that contains an ID that uniquely identifies a service instance.

TLV Type

0xEA

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	An ID that uniquely identifies a service instance.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_ASP2_ADVERTISED_SERVICE_ENTRY

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_ASP2_ADVERTISED_SERVICE_ENTRY is a TLV that contains an ASP2 Advertised Service Entry.

Note This TLV was added in Windows 10, version 1607, WDI version 1.0.21.

TLV Type

0x12E

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_SERVICE_TYPE			Service Type of the service (UTF-8), up to 21 bytes.
WDI_TLV_P2P_SERVICE_TYPE_HASH			Hash of Service Type.
WDI_TLV_P2P_INSTANCE_NAME			Instance Type of the service (UTF-8), up to 63 bytes.
WDI_TLV_P2P_INSTANCE_NAME_HASH			Hash of "Instance Name, Service Type".
WDI_TLV_P2P_SERVICE_INFORMATION		X	Service Information for the service.
WDI_TLV_P2P_SERVICE_STATUS			Service Status of the service.
WDI_TLV_P2P_ADVERTISEMENT_ID			An ID that uniquely identifies the service instance.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_CONFIG_METHODS			Configuration methods as defined in WDI_WPS_CONFIGURATION_METHOD. Only **WDI_WPS_CONFIGURATION_METHOD_DISPLAY**, **WDI_WPS_CONFIGURATION_METHOD_KEYPAD**, and **WDI_WPS_CONFIGURATION_METHOD_WFDS_DEFAULT** are applicable.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_ASP2_SERVICE_INFORMATION_DISCOVERY_ENTRY

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_ASP2_SERVICE_INFORMATION_DISCOVERY_ENTRY is a TLV that contains an ASP2 Service Information Discovery Entry.

Note This TLV was added in Windows 10, version 1607, WDI version 1.0.21.

TLV Type

0x12D

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_SERVICE_NAME			Name of the service (UTF-8), up to 21 bytes.
WDI_TLV_P2P_INSTANCE_NAME			Instance name of the service (UTF-8), up to 63 bytes.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_SERVICE_INFORMATION		X	Request service information to be used for the ANQP query request to download service information for this Service.
WDI_TLV_P2P_SERVICE_UPDATE_INDICATOR		X	Service Update indicator to be used for the ANQP query request.
WDI_TLV_P2P_SERVICE_TRANSACTION_ID		X	Service transaction ID to be used for the ANQP query request.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_ATTRIBUTES

Article • 03/14/2023

WDI_TLV_P2P_ATTRIBUTES is a TLV that contains Wi-Fi Direct attributes.

TLV Type

0x25

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_CAPABILITIES			The Wi-Fi Direct capabilities.
WDI_TLV_P2P_INTERFACE_ADDRESS_LIST			An array of Wi-Fi Direct interface MAC addresses.

Requirements

Minimum supported client	Windows 10

WDI_TLV_P2P_BACKGROUND_DISCOVER_MODE

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_BACKGROUND_DISCOVER_MODE is a TLV that contains Wi-Fi Direct Background Discover Mode parameters.

TLV Type

0xCE

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_P2P_DISCOVER_TYPE	The type of discovery to be performed by the port.
WDI_P2P_SERVICE_DISCOVERY_TYPE	The type of Service Discovery to be performed by the port. The only valid values are WDI_P2P_SERVICE_DISCOVERY_TYPE_NO_SERVICE_DISCOVERY and WDI_P2P_SERVICE_DISCOVERY_TYPE_SERVICE_NAME_ONLY.
UINT32	The device visibility timeout. Specifies the maximum timeout (in milliseconds) for reporting a device entry. This is required for background scan only.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_CAPABILITIES

Article • 03/14/2023

WDI_TLV_P2P_CAPABILITIES is a TLV that contains Wi-Fi Direct capabilities.

TLV Type

0x17

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8	Specifies the concurrent Group Owner count.
UINT8	Specifies the concurrent Client count.
UINT32	Specifies the supported WPS version.
UINT8	Specifies whether Service discovery is supported. Valid values are 0 (not supported) and 1 (supported).
UINT8	Wi-Fi Direct Service Names Discovery support. Specifies whether, when given a list of service name hashes, the adapter can probe for service hashes and indicate the responses as they arrive. Valid values are 0 (not supported) and 1 (supported).
UINT8	Wi-Fi Direct Service Information Discovery support. Specifies whether, when given a list of service name hashes, the adapter can perform probes and ANQP queries to get full service information. Valid values are 0 (not supported) and 1 (supported).

Type	Description
UINT32	Specifies the maximum supported number of Service Name Advertisements bytes (to be sent in the beacon and probe responses). This sets a hard limit on the number of services that can be advertised.
UINT32	Specifies the maximum supported number of Service Information Advertisement bytes the adapter can respond to using the GAS protocol. This is only valid if the device supports responding to Service Advertisement queries. This value is for firmware optimization so that the firmware does not wake up the host to respond to every query. The operating system does not limit the number of service advertisements if the firmware has a limitation because there is a fallback in the operating system. If the firmware cannot handle the ANQP query response, it should pass up the request and the operating system handles it.
UINT8	Background discovery of Wi-Fi Direct devices and services. Specifies whether the adapter can periodically query for Wi-Fi Direct devices and service names so any new devices show up within 5 minutes of becoming visible. Valid values are 0 (not supported) and 1 (supported).
UINT8	Specifies whether Client Discoverability is supported. Valid values are 0 (not supported) and 1 (supported).
UINT8	Specifies whether infrastructure management is supported. Valid values are 0 (not supported) and 1 (supported).
UINT8	The maximum size of the secondary adapter type list.
UINT8[6]	The device address in network byte order.
UINT32	The discovery filter list size.
UINT8	The GO client table size.

Type	Description
UINT32	The maximum size, in bytes, of vendor specific extension IEs that can be added to WFD management frames.
UINT8	Specifies whether the adapter supports OID_WDI_P2P_LISTEN_STATE_PASSIVE_AVAILABILITY. Valid values are 0 (not supported) and 1 (supported).
UINT8	Specifies whether the adapter supports indicating updates to the GO operating channel(s). Valid values are 0 (not supported) and 1 (supported).
UINT8	Added in Windows 10, version 1511, WDI version 1.0.10. Specifies whether the adapter supports operating a GO on the 5GHz band. Valid values are 0 (not supported) and 1 (supported).
UINT8	Added in Windows 10, version 1607, WDI version 1.0.21. Specifies if the adapter, when provided with a list of ASP2 Service name instances, can probe for service hashes and indicate the responses as they arrive. Valid values are 0 (not supported) and 1 (supported).
UINT8	Added in Windows 10, version 1607, WDI version 1.0.21. Specifies if the adapter, when given a set of service name instances, can perform probes and ANQP queries to get the full service information. Valid values are 0 (not supported) and 1 (supported).

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_CHANNEL_ENTRY_LIST

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_CHANNEL_ENTRY_LIST is a TLV that contains a channel number list.

TLV Type

0xF9

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_OPERATING_CLASS			The frequency band for the channels.
WDI_TLV_CHANNEL_INFO_LIST			The channel number list.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_CHANNEL_INDICATE_REASON

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_CHANNEL_INDICATE_REASON is a TLV that contains a reason for sending an indication.

TLV Type

0x102

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	The reason for sending an indication. See WDI_P2P_CHANNEL_INDICATE_REASON for possible reasons.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_CHANNEL_LIST_ATTRIBUTE

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_CHANNEL_LIST_ATTRIBUTE is a TLV that contains channel list attributes.

TLV Type

0xD5

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_COUNTRY_REGION_LIST			The country/region list.
WDI_TLV_P2P_CHANNEL_ENTRY_LIST	X		The list of channels.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

Header	Wditypes.hpp

WDI_TLV_P2P_CHANNEL_NUMBER

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_CHANNEL_NUMBER is a TLV that contains Wi-Fi Direct channel number information.

TLV Type

0x82

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8[3]	The country or region code where the operating class and channel number are valid.
UINT8	The operating class/frequency band for the channel number.
WDI_CHANNEL_NUMBER (UINT32)	The channel number for the Wi-Fi Direct Device or Group.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_CONFIG_METHODS

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_CONFIG_METHODS is a TLV that contains Wi-Fi Direct configuration methods.

TLV Type

0xEB

Length

The size (in bytes) of a UINT16.

Values

Type	Description
UINT16	Configuration methods as defined in WDI_WPS_CONFIGURATION_METHOD. Only PIN display, PIN keypad, and WFDS are applicable.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_DEVICE_ADDRESS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_DEVICE_ADDRESS is a TLV that contains the device address of the Group Owner.

TLV Type

0x91

Length

The size (in bytes) of a WDI_MAC_ADDRESS structure.

Values

Type	Description
WDI_MAC_ADDRESS	The device address of the Group Owner.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_DEVICE_CAPABILITY

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_DEVICE_CAPABILITY is a TLV that contains Wi-Fi Direct device capabilities.

TLV Type

0x84

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8	A bitmap of the Wi-Fi Direct device capabilities as defined in Table 12 of the Wi-Fi Direct technical specification.
UINT8	A bitmap of the Wi-Fi Direct capabilities in the above device capability bitmap that are currently set by the operating system.
UINT32	A bitmask that indicates which WPS versions are enabled.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_DEVICE_FILTER_LIST

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_DEVICE_FILTER_LIST is a TLV that contains a list of Wi-Fi Direct devices and Group Owners to search for during Wi-Fi Direct device discovery.

TLV Type

0xCE

Length

The size (in bytes) of the array of WDI_MAC_ADDRESS structures. The array must contain 1 or more structures.

Values

Type	Description
WDI_MAC_ADDRESS[]	A list of Wi-Fi Direct devices and Group Owners to search for during Wi-Fi Direct device discovery.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_DEVICE_INFO

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_DEVICE_INFO is a TLV that contains Wi-Fi Direct device information.

TLV Type

0x96

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_DEVICE_INFO_PARAMETERS			The device information, including Wi-Fi Direct device address, supported configuration methods, and primary device type.
WDI_TLV_P2P_DEVICE_NAME			The device name for this device.

Requirements

Minimum supported client	Windows 10

Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_DEVICE_INFO_PARAMETERS

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_DEVICE_INFO_PARAMETERS is a TLV that contains Wi-Fi Direct device information parameters.

TLV Type

0x86

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8[6]	The Wi-Fi Direct Device Address of the peer.
UINT16	The configuration methods supported by the device.
UINT16	Primary device type: Main type category identifier.
UINT8[4]	Primary device type: OUI assigned to this device type.
UINT16	Primary device type: Subcategory type identifier.

Requirements

Minimum supported client	Windows 10

Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_DEVICE_NAME

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_DEVICE_NAME is a TLV that contains a device name.

TLV Type

0x92

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that specifies the device name for the device.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_DISCOVER_MODE

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_DISCOVER_MODE is a TLV that contains Wi-Fi Direct discovery mode information for OID_WDI_TASK_P2P_DISCOVER.

TLV Type

0xA9

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_P2P_DISCOVER_TYPE (UINT32)	The type of discovery to be performed by the port.
UINT8	A flag that indicates if a complete device discovery is required. Valid values are 0 (not required) and 1 (required). If this flag is set to 0, a partial discovery may be performed.
WDI_P2P_SCAN_TYPE (UINT32)	The type of scan to be performed by the port in scan phase.
WDI_P2P_SERVICE_DISCOVERY_TYPE (UINT32)	The type of Service Discovery to be performed.
UINT8	The scan repeat count. Specifies if the full scan procedure should be repeated. If set to 0, the scan should be repeated until the task is aborted by the host.

Type	Description
UINT32	The time between scans. If the scan repeat count is not set to 1, this time specifies how long (in milliseconds) device should wait before repeating the scan procedure after completing a full scan of the requested channels.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_DISCOVERED_SERVICE_ENTRY

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_DISCOVERED_SERVICE_ENTRY is a TLV that contains a discovered service entry.

TLV Type

0x112

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_SERVICE_NAME			The name of the service, in UTF-8, up to 255 bytes.
WDI_TLV_P2P_SERVICE_INFORMATION		X	The Service Information for the service.
WDI_TLV_P2P_SERVICE_STATUS			The Service Status of the service.
WDI_TLV_P2P_ADVERTISEMENT_ID			An ID that uniquely identifies the service instance.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_CONFIG_METHODS			The Configuration Methods as defined in WDI_WPS_CONFIGURATION_METHOD. Only PinDisplay, PinKeypad and WFDS are applicable.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_DISCOVERY_CHANNEL_SETTINGS

Article • 03/14/2023

> **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_DISCOVERY_CHANNEL_SETTINGS is a TLV that contains Wi-Fi Direct discovery channel settings.

TLV Type

0xE8

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_LISTEN_DURATION			The cycle duration and listen time.
WDI_TLV_BAND_CHANNEL	X		The list of channels to scan.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

Header	Wditypes.hpp

WDI_TLV_P2P_GO_INTERNAL_RESET_POLICY

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_GO_INTERNAL_RESET_POLICY is a TLV that contains the policy used by the firmware for operating channel selection after a Wi-Fi Direct GO Reset is stopped/restarted.

TLV Type

0xB2

Length

The size (in bytes) of a UINT32.

Values

Type	Description
WDI_P2P_GO_INTERNAL_RESET_POLICY (UINT32)	If an Wi-Fi Direct GO Reset is stopped/restarted by the IHV component on its own (for example, for Bluetooth co-ex spatial stream downgrade), this configuration defines the policy to be adopted by the firmware for operating channel selection after the reset.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

Header	Wditypes.hpp

WDI_TLV_P2P_GO_NEGOTIATION_CONFIRMATION_INFO

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_GO_NEGOTIATION_CONFIRMATION_INFO is a TLV that contains Wi-Fi Direct GO Negotiation Confirmation information.

TLV Type

0x88

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_GO_NEGOTIATION_CONFIRMATION_PARAMETERS			The Wi-Fi Direct GO Negotiation Confirmation parameters.
WDI_TLV_P2P_GROUP_ID		X	The Wi-Fi Direct Group ID.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_CHANNEL_NUMBER		X	The listen channel of the remote device. The GO negotiation confirmation frame must be sent on this channel whenever this is specified.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_GO_NEGOTIATION_CONFIRMATION_PARAMETERS

Article • 03/14/2023

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_GO_NEGOTIATION_CONFIRMATION_PARAMETERS is a TLV that contains incoming GO Negotiation Confirmation parameters.

TLV Type

0xAA

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8	The Wi-Fi Direct Status Code, as defined by the Wi-Fi Direct specification.
UINT8	Wi-Fi Direct Group capability bitmask. The bitmask matches those defined in Table 13-Group Capability Bitmap definition of the Wi-Fi Direct technical specification.
UINT8	The bits in the Group capability bitmap above that are set by the operating system.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

Header	Wditypes.hpp

WDI_TLV_P2P_GO_NEGOTIATION_REQUEST_PARAMETERS is a TLV that contains Wi-Fi Direct Group Owner negotiation request parameters.

TLV Type

0x6E

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8	Specifies the local Wi-Fi Direct GO Intent. Valid values are between 0 and 15.
UINT8	Specifies the tie-breaker field of GO Intent.
UINT16	Specifies the GO Configuration Timeout in milliseconds.
UINT16	Specifies the Client Configuration Timeout in milliseconds.
WDI_MAC_ADDRESS	Intended interface address. Specifies the local MAC address for future Wi-Fi Direct connections.
UINT8	Specifies the Wi-Fi Direct Group capability bitmask. The bitmask matches those defined in Table 13-Group Capability Bitmap definition of the Wi-Fi P2P technical specification.

Type	Description
UINT8	Specifies the bits set by the operating system in the Group capability bitmap above.

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_GROUP_OWNER_CAPABILITY is a TLV that contains Wi-Fi Direct Group Owner capability information.

TLV Type

0x77

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8	Specifies the Wi-Fi Direct Group capability bitmask. The bitmask matches those defined in Table 13-Group Capability Bitmap definition of the Wi-Fi P2P technical specification.
UINT8	Specifies the bits set by the operating system in the Group capability bitmap above.
UINT32	Maximum client count for this Group Owner.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

Header	Wditypes.hpp

WDI_TLV_P2P_INCLUDE_LISTEN_CHANNEL

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_INCLUDE_LISTEN_CHANNEL is a TLV that specifies whether the probe request should include the Listen Channel attribute during discovery.

Note This TLV was added in Windows 10, version 1607, WDI version 1.0.21.

TLV Type

0x128

Length

The size (in bytes) of a UINT8.

Values

Type	Description
UINT8	This parameter specifies whether the probe request should include the Listen Channel attribute during discovery. Valid values are 0 (do not include) and 1 (include).

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_INCOMING_FRAME_INFORMATION

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_INCOMING_FRAME_INFORMATION is a TLV that contains incoming Wi-Fi Direct action frame information.

TLV Type

0x79

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_INCOMING_FRAME_PARAMETERS			Specifies the incoming frame parameters.
WDI_TLV_P2P_ACTION_FRAME_IES			Specifies the IEs section of the received public action frame.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_ACTION_FRAME_DEVICE_CONTEXT		X	Specifies the vendor-specific information that is passed back down if the host decides to send a response to this incoming message. To avoid lifetime management issues, the IHV component must not use pointers in this field.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_INCOMING_FRAME_PARAMETERS

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_INCOMING_FRAME_PARAMETERS is a TLV that contains incoming Wi-Fi Direct action frame parameters.

TLV Type

0x7A

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_P2P_ACTION_FRAME_TYPE	The type of the incoming action frame.
WDI_MAC_ADDRESS	The MAC address of the remote peer.
UINT8	The Wi-Fi Direct Dialog Token for the transaction.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_INSTANCE_NAME

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_INSTANCE_NAME is a TLV that contains the Instance Name of the service.

Note This TLV was added in Windows 10, version 1607, WDI version 1.0.21.

TLV Type

0x12B

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	The Instance Name of the service in UTF-8, up to 63 bytes long.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_INSTANCE_NAME_HASH

Article • 03/14/2023

> ⓘ **Important**

WDI_TLV_P2P_INSTANCE_NAME_HASH is a TLV that contains the hash of "Instance Name, Service Type".

Note This TLV was added in Windows 10, version 1607, WDI version 1.0.21.

TLV Type

0x12C

Length

The size (in bytes) of a WDI_P2P_SERVICE_NAME_HASH structure.

Values

Type	Description
WDI_P2P_SERVICE_NAME_HASH	The hash of "Instance Name, Service Type".

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_INTERFACE_ADDRESS_LIST

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_INTERFACE_ADDRESS_LIST is a TLV that contains an address list for a Wi-Fi Direct interface.

TLV Type

0x18

Length

The size (in bytes) of the array of WDI_MAC_ADDRESS structures. The array must contain 1 or more structures.

Values

Type	Description
WDI_MAC_ADDRESS[]	An array of Wi-Fi MAC addresses.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_INVITATION_REQUEST_INFO

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_INVITATION_REQUEST_INFO is a TLV that contains Wi-Fi Direct Invitation Request information.

TLV Type

0x7B

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_INVITATION_REQUEST_PARAMETERS			The Wi-Fi Direct Invitation Request parameters.
WDI_TLV_P2P_GROUP_BSSID		X	The Group BSSID.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_CHANNEL_NUMBER		X	The operating channel for Wi-Fi Direct GO.
WDI_TLV_P2P_GROUP_ID			The Group ID for target Wi-Fi Direct GO.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_INVITATION_REQUEST_PARAMETERS

Article • 03/14/2023

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_INVITATION_REQUEST_PARAMETERS is a TLV that contains Wi-Fi Direct Invitation Request parameters.

TLV Type

0x7C

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT16	The Group Owner Configuration Timeout in milliseconds.
UINT16	The Client Configuration Timeout in milliseconds.
UINT8	The invitation flags as defined by the Wi-Fi Direct specification.
UINT8	A bit that indicates whether or not the outgoing Invitation Request is an invitation to a local Group Owner. Valid values are 0 and 1. This bit is set to 1 if it is an invitation to a local GO.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_LISTEN_CHANNEL is a TLV that contains Wi-Fi Direct channel information.

TLV Type

0x114

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8[3]	The country or region code where the operating class and channel number are valid.
UINT8	The operating class/frequency band for the channel number.
WDI_CHANNEL_NUMBER (UINT32)	The channel number for the Wi-Fi Direct Device or Group.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_LISTEN_DURATION

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_LISTEN_DURATION is a TLV that contains Wi-Fi Direct listen duration information.

TLV Type

0xE9

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	The duration, in milliseconds, of the listen cycle. The adapter is in listen state during this time.
UINT32	The duration, in milliseconds, that the adapter is expected to actively listen during the listen cycle. This duration must be less than listen cycle duration.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_LISTEN_STATE is a TLV that contains a Wi-Fi Direct listen state.

TLV Type

0x81

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_P2P_LISTEN_STATE	The desired Wi-Fi Direct listen state.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_PERSISTENT_GROUP_ID

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_PERSISTENT_GROUP_ID is a TLV that contains a Group ID of a Persistent Group to be used for a connection.

TLV Type

0xF1

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_DEVICE_ADDRESS			The device address of the Group Owner.
WDI_TLV_SSID			The Group SSID.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_PROVISION_DISCOVERY_REQUEST_INFO

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_PROVISION_DISCOVERY_REQUEST_INFO is a TLV that contains Wi-Fi Direct Provision Discovery Request information.

TLV Type

0x83

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_PROVISION_DISCOVERY_REQUEST_PARAMETERS			The Wi-Fi Direct Provision Discovery Request parameters.
WDI_TLV_P2P_GROUP_ID		X	The Group ID for the target Wi-Fi Direct GO. The Group ID is optional. In the case of Wi-Fi Direct services, this is the Group ID for the local Wi-Fi Direct GO that the remote side should join.
WDI_TLV_P2P_PROVISION_SERVICE_ATTRIBUTES		X	The Wi-Fi Direct Provision Service attributes.
WDI_TLV_P2P_PERSISTENT_GROUP_ID		X	The Group IP for the Persistent Group to be used for the connection. This field is valid if the Persistent Group flag in WDI_TLV_P2P_PROVISION_SERVICE_ATTRIBUTES is set to 1.
WDI_TLV_P2P_SERVICE_SESSION_INFO		X	Service Session information. This field is valid if WDI_TLV_P2P_PROVISION_SERVICE_ATTRIBUTES is present.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_PROVISION_SERVICE_ATTRIBUTES is a TLV that contains Wi-Fi Direct Provision Service attributes.

TLV Type

0xC6

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8	Wi-Fi Direct Status Code, as defined by the Wi-Fi Direct specification.
WDI_MAC_ADDRESS	Local MAC Address for future Wi-Fi Direct connection.
UINT8	Connection Capability bitmask.
UINT32	Feature Capability bitmask.
UINT32	Advertisement ID for the Service Instance.
WDI_MAC_ADDRESS	Service address for the Service instance.
UINT32	Session ID that uniquely identifies the Session to the Service.
WDI_MAC_ADDRESS	Session address that uniquely identifies the Session to the Service.

Type	Description
UINT16	GO Configuration Timeout in milliseconds.
UINT16	Client Configuration Timeout in milliseconds.
UINT8	A flag indicating if a Persistent Group will be used for the connection. The flag is set to 1 if a Persistent Group will be used.
UINT8	A flag indicating if this frame is part of a follow-on provision discovery. The flag is set to 1 if it is part of a follow-on provision discovery.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_RESPONSE_FRAME_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_RESPONSE_FRAME_PARAMETERS is an unused TLV.

Header	Wditypes.hpp

WDI_TLV_P2P_SECONDARY_DEVICE_TYPE_LIST

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_SECONDARY_DEVICE_TYPE_LIST is a TLV that contains a list of secondary device types.

TLV Type

0x94

Length

The size (in bytes) of the array of WDI_P2P_DEVICE_TYPE elements. An array length of 0 is allowed.

Note WDI_P2P_DEVICE_TYPE is not a WDI structure. It is defined in the WDI TLV parser generator, and is used for documentation purposes only.

Values

Type	Description
WDI_P2P_DEVICE_TYPE[]	An array of Wi-Fi Direct device types.

WDI_P2P_DEVICE_TYPE consists of the following elements.

Type	Description
UINT16	The main type category ID.
UINT8[4]	The OUI that is assigned to this device type.

Type	Description
UINT16	The subcategory ID.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_SEND_ACTION_FRAME_RESULT

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_SEND_ACTION_FRAME_RESULT is a TLV that contains information about an Action Frame that was sent to a peer.

TLV Type

0xAF

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_SEND_ACTION_FRAME_RESULT_PARAMETERS			The Wi-Fi Direct send Action Frame result parameters.
WDI_TLV_P2P_ACTION_FRAME_IES			The set of IEs sent to the remote device.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_SEND_ACTION_REQUEST_FRAME_PARAMETERS is a TLV that contains parameters for sending a Wi-Fi Direct action request frame with OID_WDI_TASK_P2P_SEND_REQUEST_ACTION_FRAME.

TLV Type

0x8B

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_P2P_ACTION_FRAME_TYPE	The type of request to send.
WDI_MAC_ADDRESS	The MAC address of the target peer device.
UINT8	The Direct Dialog Token for the transaction.
UINT32	The send timeout. The maximum time, in milliseconds, to send the action frame.
UINT32	The post-ACK dwell time. The time, in milliseconds, to remain on the listen channel after the incoming packet is acknowledged.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_SERVICE_INFORMATION is a TLV that contains Wi-Fi Direct Service Information.

TLV Type

0xEE

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	The Service Information for the service.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_SERVICE_INFORMATION_DISCOVERY_ENTRY

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_SERVICE_INFORMATION_DISCOVERY_ENTRY is a TLV that contains a Service Information Discovery Entry.

TLV Type

0x117

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_SERVICE_NAME			Name of the service (UTF-8), up to 255 bytes.
WDI_TLV_P2P_SERVICE_NAME_HASH			Hash of Service Name.
WDI_TLV_P2P_SERVICE_INFORMATION		X	Request service information to be used for the ANQP query request to download service information for this Service.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_SERVICE_UPDATE_INDICATOR		X	Service Update indicator to be used for the ANQP query request.
WDI_TLV_P2P_SERVICE_TRANSACTION_ID		X	Service transaction ID to be used for the ANQP query request.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_SERVICE_INFORMATION_ENTRY

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_SERVICE_INFORMATION_ENTRY is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_SERVICE_NAME

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_SERVICE_NAME is a TLV that contains the name of a service.

TLV Type

0xEC

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	The name of the service, in UTF-8, up to 255 bytes.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_SERVICE_NAME_HASH

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_SERVICE_NAME_HASH is a TLV that contains the hash of a service name.

TLV Type

0xED

Length

The size (in bytes) of a WDI_P2P_SERVICE_NAME_HASH structure.

Values

Type	Description
WDI_P2P_SERVICE_NAME_HASH	The hash of a WFDS Service Name.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_SERVICE_SESSION_INFO

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_SERVICE_SESSION_INFO is a TLV that contains Service Session information.

TLV Type

0xF0

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	Service Session Information.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_SERVICE_STATUS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_SERVICE_STATUS is a TLV that contains the Service Status of a service.

TLV Type

0xFB

Length

The size (in bytes) of a UINT8.

Values

Type	Description
UINT8	The Service Status of a service.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_SERVICE_TRANSACTION_ID

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_SERVICE_TRANSACTION_ID is a TLV that contains the Service transaction ID to be used for the ANQP query request.

TLV Type

0x116

Length

The size (in bytes) of a UINT8.

Values

Type	Description
UINT8	The Service transaction ID to be used for the ANQP query request.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_SERVICE_TYPE

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_SERVICE_TYPE is a TLV that contains the Service Type of the service.

Note This TLV was added in Windows 10, version 1607, WDI version 1.0.21.

TLV Type

0x129

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	The Service Type of the service in UTF-8, up to 21 bytes long.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_SERVICE_TYPE_HASH

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_SERVICE_TYPE_HASH is a TLV that contains the hash of Service Type.

Note This TLV was added in Windows 10, version 1607, WDI version 1.0.21.

TLV Type

0x12A

Length

The size (in bytes) of a WDI_P2P_SERVICE_NAME_HASH structure.

Values

Type	Description
WDI_P2P_SERVICE_NAME_HASH	The hash of Service Type.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_SERVICE_UPDATE_INDICATOR

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_SERVICE_UPDATE_INDICATOR is a TLV that contains a Wi-Fi Direct service update indicator.

TLV Type

0x115

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT16	The service update indicator to include in ANQP responses if the driver supports responding to service information discovery ANQP requests.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_P2P_WPS_ENABLED

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_P2P_WPS_ENABLED is a TLV that specifies if Wi-Fi Protected Setup is enabled.

TLV Type

0xF7

Length

The size (in bytes) of a UINT8.

Values

Type	Description
UINT8	Specifies if Wi-Fi Protected Setup is enabled. Valid values are 0 (not enabled) and 1 (enabled).

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

See also

OID_WDI_SET_P2P_WPS_ENABLED

WDI_TLV_PACKET_FILTER_PARAMETERS

Article • 03/14/2023

WDI_TLV_PACKET_FILTER_PARAMETERS is a TLV that contains packet filter parameters for OID_WDI_SET_RECEIVE_PACKET_FILTER.

TLV Type

0x47

Length

The size (in bytes) of a UINT32.

Values

Type	Description
WDI_PACKET_FILTER_TYPE (UINT32)	Specifies the desired Wi-Fi packet filter.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PEER_MAC_ADDRESS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_PEER_MAC_ADDRESS is a TLV that contains the MAC address of the peer.

TLV Type

0x4C

Length

The size (in bytes) of a WDI_MAC_ADDRESS structure.

Values

Type	Description
WDI_MAC_ADDRESS	Specifies the Wi-Fi MAC address of the peer.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PHY_CAPABILITIES

Article • 03/14/2023

WDI_TLV_PHY_CAPABILITIES is a TLV that contains PHY capabilities.

TLV Type

0x1B

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_PHY_TYPE	Specifies the PHY types.
UINT8	Specifies whether or not the PHY supports CF Poll.
UINT32	Specifies the MPDU maximum length.
UINT32	Specifies the operating temperature class.
UINT32	Specifies the antenna diversity support.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PHY_DATA_RATE_LIST

Article • 03/14/2023

WDI_TLV_PHY_DATA_RATE_LIST is a TLV that contains a list of data rates.

TLV Type

0x13

Length

The size (in bytes) of the array of WDI_DATA_RATE_LIST elements. The array must contain 1 or more elements.

Note WDI_DATA_RATE_LIST is not a WDI structure. It is defined in the WDI TLV parser generator, and is used for documentation purposes only.

Values

Type	Description
WDI_DATA_RATE_LIST[]	An array of data rates. Each data rate in the array must contain data rate flags and a data rate value.

WDI_DATA_RATE_LIST consists of the following elements.

Type	Description
UINT8	The data rate flags as defined in WDI_DATA_RATE_FLAGS.
UINT16	The data rate value.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PHY_INFO

Article • 03/14/2023

WDI_TLV_PHY_INFO is a TLV that contains PHY information.

TLV Type

0x26

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_PHY_CAPABILITIES			The phy capabilities.
WDI_TLV_PHY_TX_POWER_LEVEL_LIST			A list of TX power levels.
WDI_TLV_PHY_DATA_RATE_LIST			A list of data rates.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PHY_LIST

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_PHY_LIST is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PHY_STATISTICS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_PHY_STATISTICS is a TLV that contains per-PHY statistics for OID_WDI_GET_STATISTICS.

TLV Type

0xA7

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_PHY_TYPE	The type for this PHY.
UINT64	The number of MSDU packets and MMPDU frames that the IEEE PHY layer of the 802.11 station has successfully transmitted.
UINT64	The number of multicast or broadcast MSDU packets and MMPDU frames that the IEEE PHY layer of the 802.11 station has successfully transmitted.
UINT64	The number of MSDU packets and MMPDU frames that the 802.11 station failed to transmit after exceeding the retry limits defined by the 802.11 IEEE dot11ShortRetryLimit or dot11LongRetryLimit MIB counters.

Type	Description
UINT64	The number of MSDU packets and MMPDU frames that the 802.11 station successfully transmitted after one or more attempts.
UINT64	The number of MSDU packets and MMPDU frames that the 802.11 station successfully transmitted after more than one retransmission attempts. For MSDU packets, the port must increment this counter for each packet that was transmitted successfully after one or more of its MPDU fragments required retransmission.
UINT64	The number of MSDU packets and MMPDU frames that the 802.11 station failed to transmit because of a timeout as defined by the IEEE 802.11 dot11MaxTransmitMSDULifetime MIB object.
UINT64	The number of MPDU frames that the 802.11 station transmitted and acknowledged through a received 802.11 ACK frame.
UINT64	The number of times that the 802.11 station received a Clear To Send (CTS) frame in response to a Request To Send (RTS) frame. If this cannot be maintained per port, it can be maintained per channel.
UINT64	The number of times that the 802.11 station did not receive a CTS frame in response to an RTS frame. If this cannot be maintained per port, it can be maintained per channel.
UINT64	The number of times that the 802.11 station expected and did not receive an Acknowledgment (ACK) frame. If this cannot be maintained per port, it can be maintained per channel.

Type	Description
UINT64	The number of MSDU packets and MMPDU frames that the 802.11 station has successfully received. For MSDU packets, the port must increment this counter for each packet whose MPDU fragments were received and passed frame check sequence (FCS) verification and replay detection. The port must increment this member regardless of whether the received MSDU packet or MPDU fragment fail MAC-layer cipher decryption.
UINT64	The number of multicast or broadcast MSDU packets and MMPDU frames that the 802.11 station has successfully received. For MSDU packets, the port must increment this counter for each packet whose MPDU fragments were received and passed FCS verification and replay detection. The port must increment this member regardless of whether the received MSDU packet or MPDU fragment fail MAC-layer cipher decryption.
UINT64	The number of MSDU packets or MMPDU frames received by the 802.11 station when a promiscuous packet filter is enabled. If this cannot be maintained per port, it can be maintained per channel.
UINT64	The number if MSDU packets and MMPDU frames that the 802.11 station discarded because of a timeout as defined by the IEEE 802.11 dot11MaxReceiveLifetime MIB object. If this cannot be maintained per port, it can be maintained per channel.
UINT64	The number of duplicate MPDU frames that the 802.11 station received. The 802.11 station determines duplicate frames through the Sequence Control field of the 802.11 MAC header. If this cannot be maintained per port, it can be maintained per channel.
UINT64	The number of MPDU frames received by the 802.11 station for MSDU packets or MMPDU frames.

Type	Description
UINT64	The number of MPDU frames received by the 802.11 station for MSDU packets or MMPDU frames when a promiscuous packet filter was enabled.
UINT64	The number of MPDU frames that the 802.11 station received with FCS errors. If this cannot be maintained per port, it can be maintained per channel.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PHY_SUPPORTED_RX_DATA_RATES_LIST

Article • 03/14/2023

WDI_TLV_PHY_SUPPORTED_RX_DATA_RATES_LIST is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PHY_SUPPORTED_TX_DATA_RATES_LIST

Article • 03/14/2023

WDI_TLV_PHY_SUPPORTED_TX_DATA_RATES_LIST is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PHY_TX_POWER_LEVEL_LIST

Article • 03/14/2023

WDI_TLV_PHY_TX_POWER_LEVEL_LIST is a TLV that contains a list of power levels.

TLV Type

0x1C

Length

The size (in bytes) of the array of UINT32 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT32[]	An array of UINT32 elements that specifies power levels.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PHY_TYPE

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_PHY_TYPE is a TLV that contains a PHY type.

TLV Type

0x122

Length

The size (in bytes) of a UINT32.

Values

Type	Description
WDI_PHY_TYPE (UINT32)	The PHY type.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PHY_TYPE_LIST

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_PHY_TYPE_LIST is a TLV that contains an array of PHY types.

TLV Type

0x19

Length

The size (in bytes) of the array of WDI_PHY_TYPE values. The array must contain 1 or more values.

Values

Type	Description
WDI_PHY_TYPE[]	An array of PHY type values.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PHY_TYPE_LIST (unused)

Article • 03/14/2023

WDI_TLV_PHY_TYPE_LIST (0x69) is an unused TLV.

TLV Type

0x69

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PHY_TYPE_LIST

WDI_TLV_PLDR_SUPPORT

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_PLDR_SUPPORT is a TLV that specifies if PLDR (Platform Level Reset) is supported.

Note This TLV was added in Windows 10, version 1511, WDI version 1.0.10.

TLV Type

0x11A

Length

The size (in bytes) of a UINT8.

Values

Type	Description
UINT8	Specifies if PLDR is supported. This value is set to 0 if the device or bus does not support reset functionality (usually by querying the ACPI or PCI methods). A non-zero value specifies that reset functionality is supported.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

PLDR

WDI_TLV_PM_CAPABILITIES (0x42)

Article • 03/14/2023

WDI_TLV_PM_CAPABILITIES is a TLV that contains power management capabilities.

TLV Type

0x42

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	Specifies the power management supported flags. Valid flags are: • NDIS_PM_WAKE_PACKET_INDICATION_SUPPORTED • NDIS_PM_SELECTIVE_SUSPEND_SUPPORTED (0x00000002)
UINT32	Specifies the supported Wake-on-LAN patterns. Valid patterns are: • NDIS_PM_WOL_BITMAP_PATTERN_SUPPORTED (0x00000001) • NDIS_PM_WOL_MAGIC_PACKET_SUPPORTED (0x00000002) • NDIS_PM_WOL_IPV4_TCP_SYN_SUPPORTED (0x00000004) • NDIS_PM_WOL_IPV6_TCP_SYN_SUPPORTED (0x00000008) • NDIS_PM_WOL_IPV4_DEST_ADDR_WILDCARD_SUPPORTED (0x00000200) • NDIS_PM_WOL_IPV6_DEST_ADDR_WILDCARD_SUPPORTED (0x00000800) • NDIS_PM_WOL_EAPOL_REQUEST_ID_MESSAGE_SUPPORTED (0x00010000)
UINT32	Specifies the total number of Wake-on-LAN patterns.
UINT32	Specifies the maximum Wake-on-LAN pattern size.
UINT32	Specifies the maximum Wake-on-LAN pattern offset.

Type	Description
UINT32	Specifies the maximum Wake-on-LAN packet save buffer.
UINT32	Specifies the supported protocol offloads. Valid offloads are: • NDIS_PM_PROTOCOL_OFFLOAD_ARP_SUPPORTED (0x00000001) • NDIS_PM_PROTOCOL_OFFLOAD_NS_SUPPORTED (0x00000002) • NDIS_PM_PROTOCOL_OFFLOAD_80211_RSN_REKEY_SUPPORTED (0x00000080)
UINT32	Specifies the number of ARP offload IPv4 addresses.
UINT32	Specifies the number of NS offload IPv6 addresses.
NDIS_DEVICE_POWER_STATE	Specifies the minimum magic packet wake-up.
NDIS_DEVICE_POWER_STATE	Specifies the minimum pattern wake-up.
NDIS_DEVICE_POWER_STATE	Specifies the minimum link change wake-up.
UINT32	Specifies the supported wake-up events. Valid events are: • NDIS_PM_WAKE_ON_MEDIA_CONNECT_SUPPORTED (0x00000001) • NDIS_PM_WAKE_ON_MEDIA_DISCONNECT_SUPPORTED (0x00000002)
UINT32	Specifies the media-specific wake-up events. Valid events are: • NDIS_WLAN_WAKE_ON_NLO_DISCOVERY_SUPPORTED (0x00000001) • NDIS_WLAN_WAKE_ON_AP_ASSOCIATION_LOST_SUPPORTED (0x00000002) • NDIS_WLAN_WAKE_ON_GTK_HANDSHAKE_ERROR_SUPPORTED (0x00000004) • NDIS_WLAN_WAKE_ON_4WAY_HANDSHAKE_REQUEST_SUPPORTED (0x00000008)

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PM_PROTOCOL_OFFLOAD_80211RSN_REKEY

Article • 03/14/2023

WDI_TLV_PM_PROTOCOL_OFFLOAD_80211RSN_REKEY is a TLV that contains RSN Rekey protocol offload parameters. If TCK/iGTK key info is configured, drivers must return it when queried in OID_WDI_GET_PM_PROTOCOL_OFFLOAD via this TLV.

TLV Type

0x63

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_TLV_RSN_KEY_INFO	Rsn Eapol key parameters.
LIST<WDI_TLV_CONFIGURED_CIPHER_KEY>	A list of configured ciphers to be set in OID_WDI_GET_PM_PROTOCOL_OFFLOAD. Drivers must return any GTK or iGTK keys that are currently configured.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PM_PROTOCOL_OFFLOAD_GET

Article • 03/14/2023

WDI_TLV_PM_PROTOCOL_OFFLOAD_GET is a TLV that contains a protocol offload ID for OID_WDI_GET_PM_PROTOCOL_OFFLOAD.

TLV Type

0xA8

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	Specifies the protocol offload ID. This is an OS-provided value that identifies the offloaded protocol. Before the OS sends an Add request down or completes the request to the overlying driver, the OS sets ProtocolOffloadId to a value that is unique among the protocol offloads on a network adapter.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PM_PROTOCOL_OFFLOAD_IPv4ARP

Article • 03/14/2023

WDI_TLV_PM_PROTOCOL_OFFLOAD_IPv4ARP is a TLV that contains IPv4 ARP protocol offload parameters.

TLV Type

0x61

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	Specifies the protocol offload ID. This is an OS-provided value that identifies the offloaded protocol. Before the OS sends an Add request down or completes the request to the overlying driver, the OS sets ProtocolOffloadId to a value that is unique among the protocol offloads on a network adapter.
UINT8[4]	Specifies an optional IPv4 address to match with the Source Protocol Address (SPA) field of the ARP request. If the incoming ARP request has an SPA value that matches this IPv4 address, the network adapter sends an ARP response when it is in a low power state. If this is set to zero, the network adapter should respond to ARP requests from any remote IPv4 address.
UINT8[4]	Specifies the host IPv4 address the network adapter uses for the Source Protocol Address (SPA) field when sending an ARP response.
WDI_MAC_ADDRESS	Specifies the MAC address that the network adapter must use for the Source Hardware Address (SHA) field of the ARP response packet that it generates. However, it should use the current MAC address of the network adapter as the source address in the MAC header.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PM_PROTOCOL_OFFLOAD_IPv6NS

Article • 03/14/2023

WDI_TLV_PM_PROTOCOL_OFFLOAD_IPv6NS is a TLV that contains IPv6 NS protocol offload parameters.

TLV Type

0x62

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	Specifies the protocol offload ID. This is an OS-provided value that identifies the offloaded protocol. Before the OS sends an Add request down or completes the request to the overlying driver, the OS sets ProtocolOffloadId to a value that is unique among the protocol offloads on a network adapter.
UINT8[16]	Specifies an optional IPv6 address to match with the Source Address field in the IPv6 header of the NS message. If the incoming NS message has a Source Address value that matches this IPv6 address, the network adapter sends a neighbor advertisement (NA) message when it is in a low power state. If this is set to zero, the network adapter should respond to NS messages from any remote IPv6 address.
UINT8[16]	Specifies the solicited node IPv6 address.
UINT8[16]	Specifies one or two IPv6 addresses to match the Target Address field of an incoming NS message. If there is only one address, that address is stored in Target address 1, and Target address 2 is filled with zeros. If one of these addresses matches the Target Address field of an incoming NS message, the network adapter sends an NA message in response.
UINT8[16]	See description of Target address 1.

Type	Description
WDI_MAC_ADDRESS	Specifies the MAC address that the network adapter must use for the target link-layer address (TLLA) field of the NA message that it generates. However, it should use the current MAC address of the network adapter as the source address in the MAC header.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PM_PROTOCOL_RSN_OFFLOAD_KEYS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_PM_PROTOCOL_RSN_OFFLOAD_KEYS is a TLV that contains currently configured Rsn Eapol key information. This TLV is used in the NDIS_STATUS_WDI_INDICATION_CIPHER_KEY_UPDATED status indication.

TLV Type

0x149

Values

Type	Description
WDI_RSN_OFFLOAD_KEYS_CONTAINER	The currently configured Rsn Eapol key information.

Requirements

Minimum supported client: Windows 10, version 1803

Minimum supported server: Windows Server 2016

Header: Wditypes.hpp

WDI_TLV_PM_PROTOCOL_OFFLOAD_REMOVE

Article • 03/14/2023

WDI_TLV_PM_PROTOCOL_OFFLOAD_REMOVE is a TLV that contains the protocol offload ID to be removed with OID_WDI_SET_REMOVE_PM_PROTOCOL_OFFLOAD.

TLV Type

0x6C

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	Specifies the protocol offload ID.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PMKID

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_PMKID is a TLV that contains a PMKID value.

TLV Type

0x9F

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	A 16-byte PMKID value.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PORT_ATTRIBUTES

Article • 03/14/2023

WDI_TLV_PORT_ATTRIBUTES is a TLV that contains port attributes.

TLV Type

0x29

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_MAC_ADDRESS	Specifies the MAC address associated with the port.
UINT16	Specifies the port number.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_POWER_MANAGMENT_CAPABILITIES

Article • 03/14/2023

WDI_TLV_POWER_MANAGMENT_CAPABILITIES is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_POWER_STATE

Article • 03/14/2023

WDI_TLV_POWER_STATE is a TLV that contains a power state.

TLV Type

0x44

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	Specifies a power state. Valid values are: • 0x0001: Exit low power (D0) • 0x0003: Enter low power (D2) • 0x0004: Enter power off (D3, may not actually be powered off on some platforms)

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PRIVACY_EXEMPTION_ENTRY

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_PRIVACY_EXEMPTION_ENTRY is a TLV that contains a privacy exemption entry.

TLV Type

0x48

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT16	Specifies the IEEE EtherType in big-endian byte order.
WDI_EXEMPTION_ACTION_TYPE	Specifies the action type of the exemption.
WDI_EXEMPTION_PACKET_TYPE	Specifies the type of packet that the exemption applies to.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PROBE_RESPONSE_FRAME

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_PROBE_RESPONSE_FRAME is a TLV that contains a probe response frame.

TLV Type

0x9

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that specifies the probe response frame.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_PROTOCOL_OFFLOAD_ID

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_PROTOCOL_OFFLOAD_ID is a TLV that contains the protocol offload identifier.

TLV Type

0x166

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	Specifies the the protocol offload identifier.

Requirements

Minimum supported client	Windows 10, version 2004
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_RADIO_STATE

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_RADIO_STATE is a TLV that contains the state of the radio in hardware and software.

TLV Type

0xA1

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8	The current state of the radio in hardware. Valid values are 0 and 1.
UINT8	The current state of the radio in software. Valid values are 0 and 1.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_RADIO_STATE_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_RADIO_STATE_PARAMETERS is a TLV that contains radio state parameters for OID_WDI_TASK_SET_RADIO_STATE.

TLV Type

0xA0

Length

The size (in bytes) of a UINT8.

Values

Type	Description
UINT8	The desired radio state. Valid values are 0 (the radio is turned off) and 1 (the radio is enabled).

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_RECEIVE_COALESCE_OFFLOAD_CAPABILITIES

Article • 03/14/2023

WDI_TLV_RECEIVE_COALESCE_OFFLOAD_CAPABILITIES is a TLV that contains Rx coalesce offload capabilities.

TLV Type

0xCE

Length

The size (in bytes) of the below values.

Values

Type	Description
UINT8	Specifies whether or not Rx coalesce is enabled for IPv4. Valid values are 0 (not enabled) and 1 (enabled).
UINT8	Specifies whether or not Rx coalesce is enabled for IPv6. Valid values are 0 (not enabled) and 1 (enabled).

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_RECEIVE_COALESCING_CAPABILITIES

Article • 03/14/2023

WDI_TLV_RECEIVE_COALESCING_CAPABILITIES is a TLV that contains hardware assisted receive filter capabilities.

TLV Type

0x9A

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	Enabled filter types. A bitwise OR of flags that specify the types of receive filters that are enabled. The following flags are valid. NDIS_RECEIVE_FILTER_VMQ_FILTERS_ENABLED Specifies that VMQ filters are enabled. NDIS_RECEIVE_FILTER_PACKET_COALESCING_FILTERS_ENABLED Specifies that NDIS packet coalescing receive filters are enabled.
UINT32	Enabled queue types. A bitwise OR of flags that specify the types of receive queues that are enabled. The following flag is valid. NDIS_RECEIVE_FILTER_VM_QUEUES_ENABLED Specifies that virtual machine (VM) queues are enabled. VM queues are used when the miniport driver is enabled to use the VMQ interface.
UINT32	The number of VM queues that the network adapter supports.
UINT32	Supported VM queue properties. A bitwise OR of flags that specify the VM queue properties that the network adapter supports. The following flags are valid. NDIS_RECEIVE_FILTER_MSI_X_SUPPORTED The network adapter assigned an MSI-X table entry for each receive queue. Network adapters must not use one MSI-X table entry for multiple receive queues. This flag is mandatory for miniport drivers that support the VMQ or SR-IOV interface. NDIS_RECEIVE_FILTER_VM_QUEUE_SUPPORTED

Type	Description
	The network adapter provides the minimum requirements to support VM queue packet filtering. The miniport driver must set this flag if it is enabled to use the VMQ or SR-IOV interface. For more information about VMQ requirements for VM queue packet filtering, see Setting and Clearing VMQ Filters. For more information about SR-IOV requirements for VM queue packet filtering, see Setting a Receive Filter on a Virtual Port. NDIS_RECEIVE_FILTER_LOOKAHEAD_SPLIT_SUPPORTED The network adapter supports VM queues that split an incoming received packet at the lookahead offset. This offset is equal to or greater than the requested lookahead size. The network adapter uses DMA to transfer the lookahead and post-lookahead data to separate shared memory segments. **Note** Starting with NDIS 6.30, splitting packet data into separate lookahead buffers is no longer supported. Miniport drivers that support this version of NDIS must not set this flag. NDIS_RECEIVE_FILTER_DYNAMIC_PROCESSOR_AFFINITY_CHANGE_SUPPORTED The network adapter supports the ability to dynamically change one of the following processor affinity attributes: • The processor affinity of a VM queue in the VMQ interface. The processor affinity is changed through an OID set request of OID_RECEIVE_FILTER_QUEUE_PARAMETERS. • The processor affinity of a nondefault virtual port (VPort), which was created in the SR-IOV interface and is attached to the PCI Express (PCIe) physical function (PF) of the network adapter. The processor affinity is changed through an OID set request of OID_NIC_SWITCH_VPORT_PARAMETERS. NDIS_RECEIVE_FILTER_INTERRUPT_VECTOR_COALESCING_SUPPORTED The network adapter supports interrupt coalescing for received packets on any of the following: • Multiple VM queues in the VMQ interface. • Multiple VPorts that are attached to the PF in the SR-IOV interface. If this flag is set, the network adapter must coalesce receive interrupts for VM queues or VPorts that have the same processor affinity. NDIS_RECEIVE_FILTER_IMPLAT_MIN_OF_QUEUES_MODE Indicates that the number of VM queues available is the minimum number of queues available from any member of a Load Balancing Failover (LBFO) team. This flag applies to LBFO filters only. This flag is not set for miniports. NDIS_RECEIVE_FILTER_IMPLAT_SUM_OF_QUEUES_MODE Indicates that the number of VM queues available is the sum of all the queues available from every member of an LBFO team. This flag applies to LBFO filters

Type	Description
	only. This flag is not set for miniports. NDIS_RECEIVE_FILTER_PACKET_COALESCING_SUPPORTED_ON_DEFAULT_QUEUE The network adapter supports NDIS packet coalescing. Packet coalescing is only supported on the default receive queue of the network adapter. This receive queue has an identifier of NDIS_DEFAULT_RECEIVE_QUEUE_ID.
UINT32	Supported filter tests. A bitwise OR of flags that specify the test operations that a miniport driver supports. The following flags are valid. NDIS_RECEIVE_FILTER_TEST_HEADER_FIELD_EQUAL_SUPPORTED The network adapter supports testing the selected header field to determine whether it is equal to a given value. **Note** If the miniport driver supports the VMQ or SR-IOV interfaces, it must set this flag. NDIS_RECEIVE_FILTER_TEST_HEADER_FIELD_MASK_EQUAL_SUPPORTED The network adapter supports masking (that is, a bitwise AND) of the selected header field to determine whether the result is equal to a specified value. NDIS_RECEIVE_FILTER_TEST_HEADER_FIELD_NOT_EQUAL_SUPPORTED The network adapter supports testing the selected header field to determine whether it is not equal to a specified value.
UINT32	Supported headers. A bitwise OR of flags that specify the types of network packet headers that a miniport driver can inspect. The following flags are valid. NDIS_RECEIVE_FILTER_MAC_HEADER_SUPPORTED The network adapter can inspect the media access control (MAC) header of a network packet. The **SupportedMacHeaderFields** member defines the various fields from the MAC header that can be inspected. NDIS_RECEIVE_FILTER_ARP_HEADER_SUPPORTED The network adapter can inspect the Address Resolution Protocol (ARP) header of a network packet. The **SupportedArpHeaderFields** member defines the various fields from the ARP header that can be inspected. NDIS_RECEIVE_FILTER_IPV4_HEADER_SUPPORTED The network adapter can inspect the IP version 4 (IPv4) header of a network packet. The **SupportedIPv4HeaderFields** member defines the various fields from the IPv4 header that can be inspected. NDIS_RECEIVE_FILTER_IPV6_HEADER_SUPPORTED The network adapter can inspect the IP version 6 (IPv6) header of a network packet. The **SupportedIPv6HeaderFields** member defines the various fields from the IPv6 header that can be inspected. NDIS_RECEIVE_FILTER_UDP_HEADER_SUPPORTED The network adapter can inspect the User Datagram Protocol (UDP) header of a network packet. The **SupportedIPv6HeaderFields** member defines the various fields from the UDP header that can be inspected.

Type	Description
UINT32	Supported MAC header fields. A bitwise OR of flags that specify the types of MAC header fields that a miniport driver can inspect. The following flags are valid. NDIS_RECEIVE_FILTER_MAC_HEADER_DEST_ADDR_SUPPORTED The network adapter supports inspecting and filtering that are based on the destination MAC address in the MAC header. **Note** Starting with NDIS 6.30, miniport drivers that support the VMQ or SR-IOV interface must set this flag. NDIS_RECEIVE_FILTER_MAC_HEADER_SOURCE_ADDR_SUPPORTED The network adapter supports inspecting and filtering that are based on the source MAC address in the MAC header. NDIS_RECEIVE_FILTER_MAC_HEADER_PROTOCOL_SUPPORTED The network adapter supports inspecting and filtering that are based on the EtherType identifier in the MAC header. For example, the EtherType identifier for IPv4 packets is 0x0800. NDIS_RECEIVE_FILTER_MAC_HEADER_VLAN_ID_SUPPORTED The network adapter supports inspecting and filtering that are based on the VLAN identifier in the MAC header. NDIS_RECEIVE_FILTER_MAC_HEADER_PRIORITY_SUPPORTED The network adapter supports inspecting and filtering that are based on the priority tag in the MAC header. NDIS_RECEIVE_FILTER_MAC_HEADER_PACKET_TYPE_SUPPORTED The network adapter supports inspecting and filtering that are based on the packet type field of the IEEE 802.2 subnetwork access protocol (SNAP) header in an 802.3 MAC header.
UINT32	The maximum number of MAC header filters that the miniport driver supports.
UINT32	Maximum queue groups. This value is reserved.
UINT32	Maximum queues per queue group. This value is reserved.
UINT32	The minimum size, in bytes, that the network adapter supports for lookahead packet buffers. **Note** Starting with NDIS 6.30, splitting packet data into separate lookahead buffers is no longer supported. Miniport drivers that support this version of NDIS must set this member to zero.

Type	Description
UINT32	The maximum size, in bytes, that the network adapter supports for lookahead packet buffers. **Note** Starting with NDIS 6.30, splitting packet data into separate lookahead buffers is no longer supported. Miniport drivers that support this version of NDIS must set this member to zero.
UINT32	Supported ARP header fields. A bitwise OR of flags that specify the types of ARP header fields that a miniport driver can inspect. The following flags are valid. NDIS_RECEIVE_FILTER_ARP_HEADER_OPERATION_SUPPORTED The network adapter supports receive filtering on the ARP operation field. NDIS_RECEIVE_FILTER_ARP_HEADER_SPA_SUPPORTED The network adapter supports receive filtering on the ARP source protocol address (SPA) field. NDIS_RECEIVE_FILTER_ARP_HEADER_TPA_SUPPORTED The network adapter supports receive filtering on the ARP target protocol address (TPA) field.
UINT32	Supported IPv4 header fields. A bitwise OR of flags that specify the types of IPv4 header fields that a miniport driver can inspect. The following flag is valid. NDIS_RECEIVE_FILTER_IPV4_HEADER_PROTOCOL_SUPPORTED The network adapter supports receive filtering on the IPv4 protocol field.
UINT32	Supported IPv6 header fields. A bitwise OR of flags that specify the types of IPv6 header fields that a miniport driver can inspect. The following flag is valid. NDIS_RECEIVE_FILTER_IPV6_HEADER_PROTOCOL_SUPPORTED The network adapter supports receive filtering on the IPv6 protocol field.
UINT32	Supported UDP header fields. A bitwise OR of flags that specify the types of IPv6 header fields that a miniport driver can inspect. The following flag is valid. NDIS_RECEIVE_FILTER_UDP_HEADER_DEST_PORT_SUPPORTED The network adapter supports receive filtering on the UDP destination port field. **Note** If the received UDP packet contains IPv4 options or IPv6 extension headers, the network adapter can automatically drop the received packet and treat it as if it failed the UDP filter test.

Type	Description
UINT32	The maximum number of tests on packet header fields that can be specified for a single packet coalescing filter. For more information about packet coalescing, see NDIS Packet Coalescing. **Note** Network adapters that support packet coalescing must support five or more packet header fields that can be specified for a single packet coalescing filter. If the adapter does not support packet coalescing, the miniport driver must set this value to zero.
UINT32	The maximum number of packet coalescing receive filters that are supported by the network adapter. **Note** Network adapters that support packet coalescing must support ten or more packet coalescing filters. If the adapter does not support packet coalescing, the miniport driver must set this value to zero.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

NDIS_RECEIVE_FILTER_CAPABILITIES

WDI_TLV_RECEIVE_COALESCING_CONFIG

Article • 03/14/2023

WDI_TLV_RECEIVE_COALESCING_CONFIG is a TLV that contains receive coalescing configuration.

TLV Type

0xDB

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	A unique queue ID to queue packets matching this filter.
UINT32	A filter ID with a value from 1 to the number of filters supported.
UINT32	The maximum coalescing delay in milliseconds.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

See also

OID_WDI_SET_RECEIVE_COALESCING

WDI_TLV_RECEIVE_FILTER_FIELD (0x65)

Article • 03/14/2023

WDI_TLV_RECEIVE_FILTER_FIELD is a TLV that contains a receive filter test criterion for one field in a network header.

TLV Type

0x65

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	Specifies a bitwise OR of flags. The possible flag value is WDI_RECEIVE_FILTER_FIELD_MAC_HEADER_VLAN_UNTAGGED_OR_ZERO. If this flag is set, the network adapter must only indicate received packets that pass the following criteria: • The packet's MAC address matches the specified MAC header field test. • The packet either does not contain a VLAN tag or has a VLAN tag with an ID of zero.
NDIS_FRAME_HEADER (UINT32)	Frame header. Specifies the type of the frame header.
NDIS_RECEIVE_FILTER_TEST (UINT32)	Receive filter test. Specifies the type of test that the receive filter performs.
UINT32	Header field. Specifies the protocol-specific header field type with the union as documented in the NDIS_RECEIVE_FILTER_FIELD_PARAMETERS.HeaderField.
UINT8[16]	Field value. Specifies the value that the miniport adapter compares to the corresponding header field value in incoming packets. The location of the header field value is determined by the field type that is specified in the *header field* element. This value is in network byte order and is specified with the union as documented in the NDIS_RECEIVE_FILTER_FIELD_PARAMETERS.FieldValue.

Type	Description
UINT8[16]	Test result value. If the *receive filter test* element is set to ReceiveFilterTestMaskEqual, the network adapter first calculates a result from the value in the *field value* member and the header field value as specified by the *header field* member. The adapter then compares the calculated result with *result value*. This value is specified with the union as documented in the NDIS_RECEIVE_FILTER_FIELD_PARAMETERS.ResultValue.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_REPLAY_COUNTER

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_REPLAY_COUNTER is a TLV that contains a UINT64 value that represents a replay counter.

TLV Type

0x164

Length

The size (in bytes) of a UINT64.

Values

Type	Description
UINT64	A replay counter

Requirements

Minimum supported client	Windows 10, version 2004
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_REQUEST_LCI_REPORT

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_REQUEST_LCI_REPORT is a TLV that contains information for whether a Location Configuration Information (LCI) report should be requested from a target BSS during a Fine Timing Measurement (FTM) request.

This TLV is used in WDI_TLV_FTM_TARGET_BSS_ENTRY.

TLV Type

0x158

Length

The size (in bytes) of a UINT8.

Values

Type	Description
UINT8	Possible values: • 0: LCI report not needed. • 1: LCI report should be requested.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_RETRY_AFTER

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_RETRY_AFTER is a TLV that contains the duration, in seconds, that should pass before trying to request a new Fine Timing Measurement (FTM) from a target BSS.

This TLV is used in WDI_TLV_FTM_RESPONSE.

TLV Type

0x15A

Length

The size (in bytes) of a UINT16.

Values

Type	Description
UINT16	The duration, in seconds, that should pass before trying to request a new Fine Timing Measurement (FTM) from the target BSS.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_ROAMING_NEEDED_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_ROAMING_NEEDED_PARAMETERS is a TLV that contains the reason for a roam trigger. This is used in the NDIS_STATUS_WDI_INDICATION_ROAMING_NEEDED payload.

TLV Type

0x55

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_ASSOC_STATUS	Specifies the reason for a roam trigger. When a OID_WDI_TASK_ROAM is triggered, this reason is forwarded to it.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_RSN_KEY_INFO

Article • 03/14/2023

WDI_TLV_RSN_KEY_INFO is a TLV that contains Rsn Eapol key parameters. This TLV is a value of the WDI_TLV_PM_PROTOCOL_OFFLOAD_80211RSN_REKEY TLV.

TLV Type

0x148

Length

The size (in bytes) of the following values.

Values

Type	Description
UINT32	A UINT32 value that specifies the protocol offload ID. This is an OS-provided value that identifies the offloaded protocol. Before the OS sends an Add request down or completes the request to the overlying driver, the OS sets ProtocolOffloadId to a value that is unique among the protocol offloads on a network adapter.
UINT64	A UINT64 value that specifies the replay counter.
UINT8[16]	A UINT8 array that specifies the IEEE 802.11 key confirmation key (KCK).
UINT8[16]	A UINT8 array that specifies the IEEE 802.11 key encryption key (KEK).

Requirements

Minimum supported client: Windows 10, version 1803

Minimum supported server: Windows Server 2016

Header: Wditypes.hpp

WDI_TLV_RTT

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_RTT is a TLV that contains the measured roundtrip time (RTT), in picoseconds, for a Fine Timing Measurement (FTM) request.

This TLV is used in WDI_TLV_FTM_RESPONSE.

TLV Type

0x15C

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	The RTT.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_RTT_ACCURACY

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_RTT_ACCURACY is a TLV that contains the accuracy, or expected degree of closeness, of a roundtrip time (RTT) measurement to the true value for a Fine Timing Measurement (FTM) request. The unit is in picoseconds.

For example, if the current RTT is 66712.82 picoseconds (10 meters away from the target AP), but it is known through hardware profiling that the measurement could be off by +/-1 meter, then the RTT accuracy is 6671.28 picoseconds. It is the responsibility of the IHV to provide as specific an accuracy as possible based on the profiling of its hardware and the matching conditions when the actual FTM is taken. There are multiple variables affecting FTM accuracy and multiple possibilities for which of these variables can be measured and considered. The reason a more specific accuracy is desirable is because this is useful information that upper layers can consume, such as preferring measurements with higher accuracy when computing a position or to vary the computed position error based off the FTM accuracies. When profiling, a minimum 90% CDF should be used.

This TLV is used in WDI_TLV_FTM_RESPONSE.

TLV Type

0x15D

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	The RTT.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_RTT_VARIANCE

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_RTT_VARIANCE is a TLV that contains the statistical variance of the measurements used to calculate roundtrip time (RTT) during a Fine Timing Measurement (FTM) request, if more than one measurement was used.

This TLV is used in WDI_TLV_FTM_RESPONSE.

TLV Type

0x15E

Length

The size (in bytes) of a UINT64.

Values

Type	Description
UINT64	The statistical variance of the measurements used to calculate the RTT.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_SAE_ANTI_CLOGGING_TOKEN

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SAE_ANTI_CLOGGING_TOKEN is a TLV that contains the anti-clogging token for a Simultaneous Authentication of Equals (SAE) Commit request.

This TLV is used in WDI_TLV_SAE_COMMIT_REQUEST.

TLV Type

0x155

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	The anti-clogging token.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_SAE_COMMIT_REQUEST

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SAE_COMMIT_REQUEST is a TLV that contains parameters for a Simultaneous Authentication of Equals (SAE) Commit request.

This TLV is used in the command parameters for OID_WDI_SET_SAE_AUTH_PARAMS.

TLV type

0x150

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

TLV	Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_SAE_FINITE_CYCLIC_GROUP	UINT16			The Finite Cyclic Group used for SAE authentication.
WDI_TLV_SAE_SCALAR	TLV<LIST<UINT8>>			The Finite Field Element (FFE).

TLV	Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_SAE_ELEMENT	TLV<LIST<UINT8>>			The Encoded Field Element (EFE).
WDI_TLV_SAE_ANTI_CLOGGING_TOKEN	TLV<LIST<UINT8>>			The anti-clogging token as requested by the BSSID.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_SAE_COMMIT_RESPONSE

Article • 03/14/2023

ⓘ Important

This topic is part of the WDI driver model released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. WiFiCx is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SAE_COMMIT_RESPONSE is a TLV that contains the Simultaneous Authentication of Equals (SAE) Commit response frame.

This TLV is used in the payload data of NDIS_STATUS_WDI_INDICATION_SAE_AUTH_PARAMS_NEEDED.

TLV Type

0x14D

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	The SAE Commit response frame.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_SAE_CONFIRM

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SAE_CONFIRM is a TLV that contains the Confirm field for a Simultaneous Authentication of Equals (SAE) Confirm request.

This TLV is used in WDI_TLV_SAE_CONFIRM_REQUEST.

TLV Type

0x157

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	The Confirm field.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_SAE_CONFIRM_REQUEST

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SAE_CONFIRM_REQUEST is a TLV that contains parameters for a Simultaneous Authentication of Equals (SAE) Confirm request.

This TLV is used in the command parameters for OID_WDI_SET_SAE_AUTH_PARAMS.

TLV type

0x151

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

TLV	Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_SAE_SEND_CONFIRM	UINT16			The Send Confirm field, used as an anti-replay counter.
WDI_TLV_SAE_CONFIRM	TLV<LIST<UINT8>>			The Confirm field.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_SAE_CONFIRM_RESPONSE

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SAE_CONFIRM_RESPONSE is a TLV that contains the Simultaneous Authentication of Equals (SAE) Confirm response frame.

This TLV is used in the payload data of NDIS_STATUS_WDI_INDICATION_SAE_AUTH_PARAMS_NEEDED.

TLV Type

0x14E

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	The SAE Confirm response frame.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_SAE_ELEMENT

Article • 03/14/2023

> **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SAE_ELEMENT is a TLV that contains the Encoded Field Element (EFE) for a Simultaneous Authentication of Equals (SAE) Commit request.

This TLV is used in WDI_TLV_SAE_COMMIT_REQUEST.

TLV Type

0x154

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	A part of the EFE.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_SAE_FINITE_CYCLIC_GROUP

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SAE_FINITE_CYCLIC_GROUP is a TLV that contains the Finite Cyclic Group used in a Commit request for Simultaneous Authentication of Equals (SAE) authentication.

This TLV is used in WDI_TLV_SAE_COMMIT_REQUEST.

TLV Type

0x152

Length

The size (in bytes) of a UINT16.

Values

Type	Description
UINT16	The Finite Cyclic Group used for SAE authentication.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_SAE_INDICATION_TYPE

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SAE_INDICATION_TYPE is a TLV that contains the type of information needed to continue SAE authentication with a target BSSID, or notification that authentication cannot continue.

This TLV is used in the payload data of NDIS_STATUS_WDI_INDICATION_SAE_AUTH_PARAMS_NEEDED.

TLV Type

0x14B

Length

The size (in bytes) of a UINT32.

Values

Type	Description
WDI_SAE_INDICATION_TYPE	The type of information needed to continue SAE authentication with a target BSSID, or notification that authentication cannot continue.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_SAE_REQUEST_TYPE

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SAE_REQUEST_TYPE is a TLV that contains the type of Simultaneous Authentication of Equals (SAE) request frame to send to a target BSSID.

This TLV is used in the command parameters of OID_WDI_SET_SAE_AUTH_PARAMS.

TLV Type

0x14F

Length

The size (in bytes) of a UINT32.

Values

Type	Description
WDI_SAE_REQUEST_TYPE	The type of SAE request frame to send to the BSSID.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_SAE_SCALAR

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SAE_SCALAR is a TLV that contains the Finite Field Element (FFE) for a Simultaneous Authentication of Equals (SAE) Commit request.

This TLV is used in WDI_TLV_SAE_COMMIT_REQUEST.

TLV Type

0x153

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	The FFE.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_SAE_SEND_CONFIRM

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SAE_SEND_CONFIRM is a TLV that contains the Send Confirm field for a Simultaneous Authentication of Equals (SAE) Confirm request. The Send Confirm field is used as an anti-replay counter.

This TLV is used in WDI_TLV_SAE_CONFIRM_REQUEST.

TLV Type

0x156

Length

The size (in bytes) of a UINT16.

Values

Type	Description
UINT16	The Send Confirm field.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_SAE_STATUS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SAE_STATUS is a TLV that contains Simultaneous Authentication of Equals (SAE) authentication failure error status.

This TLV is used in the command parameters of OID_WDI_SET_SAE_AUTH_PARAMS and in the payload data of NDIS_STATUS_WDI_INDICATION_SAE_AUTH_PARAMS_NEEDED.

TLV Type

0x14C

Length

The size (in bytes) of a UINT32.

Values

Type	Description
WDI_SAE_STATUS	The SAE authentication failure error status.

Requirements

Minimum supported client: Windows 10, version 1903 **Minimum supported server**: Windows Server 2016 **Header**: Wditypes.hpp

WDI_TLV_SAFE_MODE_PARAMETERS

Article • 03/14/2023

WDI_TLV_SAFE_MODE_PARAMETERS is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_SCAN_DWELL_TIME

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SCAN_DWELL_TIME is a TLV that contains scanning dwell time settings.

TLV Type

0x7

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	Specifies the time in milliseconds to dwell on active channels. This is a hint and if the adapter decides to use its own dwell time, it must meet the Maximum Scan Time requirement.
UINT32	Specifies the time in milliseconds to dwell on passive channels. This is a hint and if the adapter decides to use its own dwell time, it must meet the Maximum Scan Time requirement.
UINT32	Specifies the time in milliseconds for total scan. If the adapter limits its dwell times to below the values specified above, it can ignore the Maximum Scan Time parameter.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

Header	Wditypes.hpp

WDI_TLV_SCAN_MODE

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SCAN_MODE is a TLV that contains scan mode parameters.

TLV Type

0x6

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8	The number of times the full scan procedure should be repeated. If this value is set to 0, the scan should be repeated until the task is aborted by the host.
WDI_SCAN_TYPE	Specifies the type of scan that should be performed. If WDI_SCAN_TYPE_ACTIVE is set, the device must only scan active channels.
UINT8	Specifies if live updates are needed and discovered entries must be reported when they are found, with the recommended throttling logic above. This value is always true when the Microsoft component manages the BSS list cache.
WDI_SCAN_TRIGGER	Specifies the trigger for the scan.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_SEND_ACTION_FRAME_REQUEST_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SEND_ACTION_FRAME_REQUEST_PARAMETERS is a TLV that contains parameters for OID_WDI_TASK_SEND_REQUEST_ACTION_FRAME.

TLV Type

0xBF

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_CHANNEL_NUMBER (UINT32)	The channel on which to send the action frame and also to linger on as specified in the post-ACK dwell time.
WDI_BAND_ID (UINT32)	The ID of the band on which to send the action frame.
WDI_MAC_ADDRESS	The MAC address of the target access point or peer adapter.
UINT32	The send timeout. Specifies the maximum time (in milliseconds) to send this Action Frame.
UINT32	The post-acknowledgment dwell time. Specifies the time (in milliseconds) to remain on listen channel after the incoming packet is acknowledged.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_SEND_ACTION_FRAME_RESPONSE_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SEND_ACTION_FRAME_RESPONSE_PARAMETERS is a TLV that contains parameters for OID_WDI_TASK_SEND_RESPONSE_ACTION_FRAME.

TLV Type

0xE2

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
WDI_CHANNEL_NUMBER (UINT32)	The channel on which to send the action frame and also to linger on as specified in the post-ACK dwell time.
WDI_BAND_ID (UINT32)	The ID of the band on which to send the action frame.
WDI_MAC_ADDRESS	The MAC address of the target access point or peer adapter.
UINT32	The send timeout. Specifies the maximum time (in milliseconds) to send this Action Frame.
UINT32	The post-acknowledgment dwell time. Specifies the time (in milliseconds) to remain on listen channel after the incoming packet is acknowledged.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_SET_AUTO_POWER_SAVE

Article • 03/14/2023

WDI_TLV_SET_AUTO_POWER_SAVE is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_SET_CIPHER_KEY_INFO

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SET_CIPHER_KEY_INFO is a TLV that contains cipher key mapping key information for OID_WDI_SET_ADD_CIPHER_KEYS.

TLV Type

0x52

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_PEER_MAC_ADDRESS		X	Specifies the MAC address of the peer that this key is associated with. If not present, assume this is a default key. At least one of peer MAC Address or cipher key ID must be present. This field must be present when key type is set to WDI_CIPHER_KEY_TYPE_PAIRWISE_KEY, and may be present when key type is set to WDI_CIPHER_KEY_TYPE_GROUP_KEY.
WDI_TLV_CIPHER_KEY_ID		X	Specifies the ID for this cipher key. At least one of peer MAC address or cipher key ID must be present. This field is not required for pairwise keys.
WDI_TLV_CIPHER_KEY_TYPE_INFO			Specifies the cipher key type information.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_CIPHER_KEY_RECEIVE_SEQUENCE_COUNT		X	Specifies the initial 48-bit value of Packet Number (PN), which is used for replay protection. This is optional if the cipher algorithm is WDI_CIPHER_ALGO_WEP40, WDI_CIPHER_ALGO_WEP104, or WDI_CIPHER_ALGO_WEP.
WDI_TLV_CIPHER_KEY_CCMP_KEY		X	Specifies the CCMP cipher algorithm key data. This is only present if the cipher algorithm is WDI_CIPHER_ALGO_CCMP.
WDI_TLV_CIPHER_KEY_GCMP_256_KEY		X	Contains GCMP_256 cipher algorithm key data. This is only present if the cipher algorithm is WDI_CIPHER_ALGO_GCMP_256.
WDI_TLV_CIPHER_KEY_TKIP_INFO		X	Specifies the TKIP information. This is only present if the cipher algorithm is WDI_CIPHER_ALGO_TKIP.
WDI_TLV_CIPHER_KEY_BIP_KEY		X	Specifies the BIP key. This is only present if the cipher algorithm is WDI_CIPHER_ALGO_BIP.
WDI_TLV_CIPHER_KEY_BIP_GMAC_256_KEY		X	Contains GMAC_256 cipher algorithm key data. This is only present if cipher algorithm is WDI_CIPHER_ALGO_BIP_GMAC_256.
WDI_TLV_CIPHER_KEY_WEP_KEY		X	Specifies the WEP key. This is only present if the cipher algorithm is WDI_CIPHER_ALGO_WEP40, WDI_CIPHER_ALGO_WEP104, or WDI_CIPHER_ALGO_WEP
WDI_TLV_CIPHER_KEY_IHV_KEY		X	Specifies the IHV cipher key. This is only present if WDI_TLV_CIPHER_KEY_TYPE_INFO is in the range WDI_CIPHER_ALGO_IHV_START to WDI_CIPHER_ALGO_IHV_END.

Requirements

Minimum supported client	Windows 10

Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_SET_CLEAR_RECEIVE_COALESCING

Article • 03/14/2023

WDI_TLV_SET_CLEAR_RECEIVE_COALESCING is a TLV that contains a filter ID for OID_WDI_SET_CLEAR_RECEIVE_COALESCING.

TLV Type

0x9B

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	The ID of the filter.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_SET_ENCAPSULATION_OFFLOAD_V4_PARAMETERS

Article • 03/14/2023

WDI_TLV_SET_ENCAPSULATION_OFFLOAD_V4_PARAMETERS is a TLV that is used by OID_WDI_SET_ENCAPSULATION_OFFLOAD to indicate if IPv4 offloading should be started.

TLV Type

0xFD

Length

The size (in bytes) of a UINT8.

Values

Type	Description
UINT8	Specifies if IPv4 offloading should be started. This value is set to NDIS_OFFLOAD_SET_ON if enabled, and set to NDIS_OFFLOAD_SET_OFF if disabled.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

See also

NDIS_OFFLOAD_PARAMETERS

WDI_TLV_SET_ENCAPSULATION_OFFLOAD_V6_PARAMETERS

Article • 03/14/2023

WDI_TLV_SET_ENCAPSULATION_OFFLOAD_V6_PARAMETERS is a TLV that is used by OID_WDI_SET_ENCAPSULATION_OFFLOAD to indicate if IPv6 offloading should be started.

TLV Type

0xFE

Length

The size (in bytes) of a UINT8.

Values

Type	Description
UINT8	Specifies if IPv6 offloading should be started. This value is set to NDIS_OFFLOAD_SET_ON if enabled, and set to NDIS_OFFLOAD_SET_OFF if disabled.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_SET_POWER_DX_REASON

Article • 03/14/2023

WDI_TLV_SET_POWER_DX_REASON is a TLV that contains the reason for a set power Dx.

TLV Type

0x103

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	The reason for a set power Dx. Valid values are: - WDI_SET_POWER_DX_REASON_SELETIVE_SUSPEND (1) When this value is set, it implies waking on any interesting external events without explicit **WDI_TLV_ENABLE_WAKE_EVENTS**. This is an idle low power where the device functions transparently to end users as if it were in D0. See WDI USB remote wake sequence for more information.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_SET_RECEIVE_COALESCING

Article • 03/14/2023

WDI_TLV_SET_RECEIVE_COALESCING is a TLV that contains received packet coalescing parameters for OID_WDI_SET_RECEIVE_COALESCING.

TLV Type

0x64

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_RECEIVE_COALESCING_CONFIG			Specifies coalescing filter configuration.
WDI_TLV_RECEIVE_FILTER_FIELD	X	X	Specifies a receive filter field.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_SSID

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SSID is a TLV that contains an SSID.

TLV Type

0x3B

Length

The size (in bytes) of the array of UINT8 elements. An array length of 0 is allowed.

Values

Type	Description
UINT8[]	An array of UINT8 elements that specifies an SSID.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_SSID_LIST

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SSID_LIST is an unused TLV.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_SSID_OFFLOAD

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SSID_OFFLOAD is a TLV that contains an SSID and hints about the SSID.

TLV Type

0x9E

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_SSID			The SSID.
WDI_TLV_UNICAST_ALGORITHM_LIST			The unicast algorithm list.
WDI_TLV_CHANNEL_LIST			The channel list.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_START_AP_PARAMETERS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_START_AP_PARAMETERS is a TLV that contains the parameters for OID_WDI_TASK_START_AP.

TLV Type

0xAB

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	The beacon period. If non-zero, this parameter specifies the beacon interval.
UINT32	The DTIM period. If non-zero, this parameter specifies the number of beacon intervals between transmissions of beacon frames that contain a TIM element with a DTIM Count field that equals zero. This value is transmitted in the DTIM Period field of beacon frames.
UINT8	This parameter sets the dot11ExcludeUnencrypted MIB. Valid values are 0 and 1.

Type	Description
UINT8	This parameter specifies if the device supports 802.11b speeds. Valid values are 0 (not supported) and 1 (supported). When this value is set to 1, the access point should allow clients using 11b rates to connect to it.
UINT8	Added in Windows 10, version 1511, WDI version 1.0.10. This parameter specifies whether to allow legacy SoftAP clients to connect. Valid values are 0 (not allowed) and 1 (allowed).
UINT8	Added in Windows 10, version 1511, WDI version 1.0.10. MustUseSpecifiedChannels. This parameter specifies whether the AP can only be started on the channels specified in OID_WDI_TASK_START_AP task parameters with **WDI_TLV_AP_BAND_CHANNEL**. Valid values are 0 and 1. If it is set to 1, the AP can only be started from the specified list. If it is not set, the list is meant to be a recommendation of channels that the firmware can pick from, and it may pick another channel if it is not possible to start the AP on any of the specified channels.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_STATION_ATTRIBUTES

Article • 03/14/2023

WDI_TLV_STATION_ATTRIBUTES is a TLV that contains the attributes of a station.

TLV Type

0x22

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_STATION_CAPABILITIES			The station capabilities.
WDI_TLV_UNICAST_ALGORITHM_LIST		X	The supported unicast algorithms.
WDI_TLV_MULTICAST_DATA_ALGORITHM_LIST		X	The supported multicast data algorithms.
WDI_TLV_MULTICAST_MGMT_ALGORITHM_LIST		X	The supported multicast management algorithms.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_STATION_CAPABILITIES

Article • 03/14/2023

WDI_TLV_STATION_CAPABILITIES is a TLV that contains the capabilities of a station.

TLV Type

0x11

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	The scan SSID list size.
UINT32	The desired BSSID list size.
UINT32	The desired SSID list size.
UINT32	The privacy exemption list size.
UINT32	The key mapping table size.
UINT32	The default key table size.
UINT32	The maximum length of the WEP key value.
UINT32	The maximum number per STA default key tables.
UINT8	Supported QoS flags. Specifies whether the device supports WMM. Valid values are 0 (not supported) and 1 (supported).

Type	Description
UINT8	Specifies whether host-FIPS mode is implemented. If the field is set to DOT11_EXTSTA_ATTRIBUTES_SAFEMODE_OID_SUPPORTED with no other bits set, the driver implements the 802.11 safe mode of operation. If the field is set to DOT11_EXTSTA_ATTRIBUTES_SAFEMODE_CERTIFIED, the NIC has received a validation certificate from the National Institute of Standards and Technology (NIST) under Federal Information Processing Standards (FIPS) Publication 140-2, Security Requirements for Cryptographic Modules. In this mode, the hardware is responsible for ensuring compliance to FIPS standard. If the field is set to zero (0), FIPS mode is not implemented by the NIC.
UINT8	Specifies whether 802.11w MFP capability is supported. Valid values are 0 (not supported) and 1 (supported).
UINT8	Specifies whether auto power save is supported. Valid values are 0 (not supported) and 1 (supported).
UINT8	Specifies whether the adapter maintains the Station BSS List cache. Valid values are 0 (no) and 1 (yes).
UINT8	Specifies whether the adapter may attempt association to a BSSID that is not specified in the Preferred BSSID list during a Station connect. Valid values are 0 (no) and 1 (yes).
UINT32	The maximum supported Network Offload List size.
UINT8	Specifies whether or not the adapter can track HESSIDs associated with SSIDs and connect/roam only to those APs that match the specified SSID+HESSID. Valid values are 0 (not supported) and 1 (supported).
UINT8	Specifies whether the adapter can offload connectivity to networks belonging to specific HESSIDs.
UINT8	Specifies whether disconnected standby is supported. Valid values are 0 (not supported) and 1 (supported).
UINT8	Specifies whether the driver supports the Fine Time Measurement (FTM) protocol as an initiator. Valid values are 0 (not supported) and 1 (supported).
UINT8	The maximum number of target STAs that can be queried per FTM request task.

Type	Description
UINT8	Specifics whether the driver supports the FIPS mode. If the field is set to DOT11_EXTSTA_ATTRIBUTES_SAFEMODE_OID_SUPPORTED with no other bits set, the driver implements the 802.11 safe mode of operation. If the field is set to DOT11_EXTSTA_ATTRIBUTES_SAFEMODE_CERTIFIED the NIC has received a validation certificate from the National Institute of Standards and Technology (NIST) under Federal Information Processing Standards (FIPS) Publication 140-2, Security Requirements for Cryptographic Modules. In this mode the hardware is responsible for ensuring compliance to FIPS standard. If the field is set to zero (0), FIPS mode is not implemented by the NIC. **Operating system support for FIPS is anticipated in a future release of Windows.** **NOTE** that FIPS mode requires the driver to indicate support for WDI_AUTH_ALGO_WPA3 auth and WDI_CIPHER_ALGO_GCMP_256 cipher pairs in the unicast and multicast algo pairs. It must also indicate support for WDI_AUTH_ALGO_WPA3 auth and WDI_CIPHER_ALGO_BIP_GMAC_256 cipher in the Multicast Management algo pairs.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_STATUS

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_STATUS is a TLV that contains a status value.

TLV Type

0x1

Length

The size (in bytes) of an NDIS_STATUS.

Values

Type	Description
NDIS_STATUS	The NDIS_STATUS value.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_SUPPORTED_GUIDS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_SUPPORTED_GUIDS is a TLV that contains a supported NDIS GUID.

Note This TLV was added in Windows 10, version 1607, WDI version 1.0.21.

TLV Type

0x130

Length

The size (in bytes) of a NDIS_GUID structure.

Values

Type	Description
NDIS_GUID	A supported NDIS GUID.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_TCP_OFFLOAD_CAPABILITIES

Article • 03/14/2023

WDI_TLV_TCP_OFFLOAD_CAPABILITIES is a TLV that contains TCP/IP offload capabilities.

Capability values are reported as documented in **NDIS_TCP_IP_CHECKSUM_OFFLOAD**. Use NDIS_OFFLOAD_NOT_SUPPORTED and NDIS_OFFLOAD_SUPPORTED when indicating capabilities through OID_WDI_GET_ADAPTER_CAPABILITIES. For a connection with FIPS mode, offloads are turned OFF by the UE.

TLV Type

0xCA

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_CHECKSUM_OFFLOAD_CAPABILITIES			Checksum offload capabilities.
WDI_TLV_LSO_V1_CAPABILITIES			Large Send Offload V1 capabilities.
WDI_TLV_LSO_V2_CAPABILITIES			Large Send Offload V2 capabilities.
WDI_TLV_RECEIVE_COALESCE_OFFLOAD_CAPABILITIES			Receive Offload capabilities.

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_OFFLOAD_SCOPE			Indicates whether offloads apply to the STA port only or on all ports. Currently applicable to 802.11ad adapters only.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_TCP_RSC_STATISTICS_PARAMETERS

Article • 03/14/2023

WDI_TLV_TCP_RSC_STATISTICS_PARAMETERS is a TLV that contains TCP RSC statistics for OID_WDI_TCP_RSC_STATISTICS.

TLV Type

0xF3

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT64	The total number of packets that were coalesced.
UINT64	The total number of bytes that were coalesced.
UINT64	The total number of coalescing events, which is the total number of packets that were formed from coalescing packets.
UINT64	The total number of RSC abort events, which is the number of exceptions other than the IP datagram length being exceeded. This count should include the cases where a packet is not coalesced because of insufficient hardware resources.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_TCP_SET_OFFLOAD_PARAMETERS

Article • 03/14/2023

WDI_TLV_TCP_SET_OFFLOAD_PARAMETERS is a TLV that contains TCP offload capabilities of a miniport adapter for OID_WDI_SET_TCP_OFFLOAD_PARAMETERS.

TLV Type

0xF2

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8	The IPv4 checksum setting of the miniport adapter. Valid values are: - **NDIS_OFFLOAD_PARAMETERS_NO_CHANGE** - The miniport driver should not change the current setting. - **NDIS_OFFLOAD_PARAMETERS_TX_RX_DISABLED** - Disabled. - **NDIS_OFFLOAD_PARAMETERS_TX_ENABLED_RX_DISABLED** - Enabled for transmit and disabled for receive. - **NDIS_OFFLOAD_PARAMETERS_RX_ENABLED_TX_DISABLED** - Enabled for receive and disabled for transmit. - **NDIS_OFFLOAD_PARAMETERS_TX_RX_ENABLED** - Enabled for transmit and receive.

Type	Description
UINT8	The IPv4 checksum setting for TCP packets. Valid values are: • **NDIS_OFFLOAD_PARAMETERS_NO_CHANGE** - The miniport driver should not change the current setting. • **NDIS_OFFLOAD_PARAMETERS_TX_RX_DISABLED** - Disabled. • **NDIS_OFFLOAD_PARAMETERS_TX_ENABLED_RX_DISABLED** - Enabled for transmit and disabled for receive. • **NDIS_OFFLOAD_PARAMETERS_RX_ENABLED_TX_DISABLED** - Enabled for receive and disabled for transmit. • **NDIS_OFFLOAD_PARAMETERS_TX_RX_ENABLED** - Enabled for transmit and receive.
UINT8	The IPv4 checksum setting for UDP packets. Valid values are: • **NDIS_OFFLOAD_PARAMETERS_NO_CHANGE** - The miniport driver should not change the current setting. • **NDIS_OFFLOAD_PARAMETERS_TX_RX_DISABLED** - Disabled. • **NDIS_OFFLOAD_PARAMETERS_TX_ENABLED_RX_DISABLED** - Enabled for transmit and disabled for receive. • **NDIS_OFFLOAD_PARAMETERS_RX_ENABLED_TX_DISABLED** - Enabled for receive and disabled for transmit. • **NDIS_OFFLOAD_PARAMETERS_TX_RX_ENABLED** - Enabled for transmit and receive.
UINT8	The IPv6 checksum setting for TCP packets. Valid values are: • **NDIS_OFFLOAD_PARAMETERS_NO_CHANGE** - The miniport driver should not change the current setting. • **NDIS_OFFLOAD_PARAMETERS_TX_RX_DISABLED** - Disabled. • **NDIS_OFFLOAD_PARAMETERS_TX_ENABLED_RX_DISABLED** - Enabled for transmit and disabled for receive. • **NDIS_OFFLOAD_PARAMETERS_RX_ENABLED_TX_DISABLED** - Enabled for receive and disabled for transmit. • **NDIS_OFFLOAD_PARAMETERS_TX_RX_ENABLED** - Enabled for transmit and receive.

Type	Description
UINT8	The IPv6 checksum setting for UDP packets. Valid values are: • **NDIS_OFFLOAD_PARAMETERS_NO_CHANGE** - The miniport driver should not change the current setting. • **NDIS_OFFLOAD_PARAMETERS_TX_RX_DISABLED** - Disabled. • **NDIS_OFFLOAD_PARAMETERS_TX_ENABLED_RX_DISABLED** - Enabled for transmit and disabled for receive. • **NDIS_OFFLOAD_PARAMETERS_RX_ENABLED_TX_DISABLED** - Enabled for receive and disabled for transmit. • **NDIS_OFFLOAD_PARAMETERS_TX_RX_ENABLED** - Enabled for transmit and receive.
UINT8	The Large Send Offload version 1 (LSOV1) setting. Valid values are: • **NDIS_OFFLOAD_PARAMETERS_NO_CHANGE** - The miniport driver should not change the current setting. • **NDIS_OFFLOAD_PARAMETERS_LSOV1_ENABLED** - LSOV1 is enabled. • **NDIS_OFFLOAD_PARAMETERS_LSOV1_DISABLED** - LSOV1 is disabled.
UINT8	The Internet Protocol Security (IPsec) offload setting. Valid values are: • **NDIS_OFFLOAD_PARAMETERS_NO_CHANGE** - The miniport driver should not change the current setting. • **NDIS_OFFLOAD_PARAMETERS_IPSECV1_DISABLED** - IPsec offload is disabled. • **NDIS_OFFLOAD_PARAMETERS_IPSECV1_AH_ENABLED** - The IPsec offload Authentication Header (AH) feature should be enabled for transmit and receive. • **NDIS_OFFLOAD_PARAMETERS_IPSECV1_ESP_ENABLED** - The IPsec offload Encapsulating Security Payload (ESP) feature should be enabled for transmit and receive. • **NDIS_OFFLOAD_PARAMETERS_IPSECV1_AH_AND_ESP_ENABLED** - The IPsec offload AH and ESP features are enabled for transmit and receive.

Type	Description
UINT8	The IPv4 Large Send Offload version 2 (LSOV2) setting. Valid values are: - **NDIS_OFFLOAD_PARAMETERS_NO_CHANGE** - The miniport driver should not change the current setting. - **NDIS_OFFLOAD_PARAMETERS_LSOV2_ENABLED** - LSOV2 for IPv4 is enabled. - **NDIS_OFFLOAD_PARAMETERS_LSOV2_DISABLED** - LSOV2 for IPv4 is disabled.
UINT8	The IPv6 Large Send Offload version 2 (LSOV2) setting. Valid values are: - **NDIS_OFFLOAD_PARAMETERS_NO_CHANGE** - The miniport driver should not change the current setting. - **NDIS_OFFLOAD_PARAMETERS_LSOV2_ENABLED** - LSOV2 for IPv6 is enabled. - **NDIS_OFFLOAD_PARAMETERS_LSOV2_DISABLED** - LSOV2 for IPv6 is disabled.
UINT8	The IPv4 connection offload setting. Valid values are: - **NDIS_OFFLOAD_PARAMETERS_NO_CHANGE** - The miniport driver should not change the current setting.
UINT8	The IPv6 connection offload setting. Valid values are: - **NDIS_OFFLOAD_PARAMETERS_NO_CHANGE** - The miniport driver should not change the current setting.
UINT8	Indicates Receive Segment Coalescing state for IPv4. Valid values are: - **NDIS_OFFLOAD_PARAMETERS_NO_CHANGE** - The RSC state is unchanged. - **NDIS_OFFLOAD_PARAMETERS_RSC_ENABLED** - The RSC state is enabled. - **NDIS_OFFLOAD_PARAMETERS_RSC_DISABLED** - The RSC state is disabled.

Type	Description
UINT8	Indicates Receive Segment Coalescing state for IPv6. Valid values are: - **NDIS_OFFLOAD_PARAMETERS_NO_CHANGE** - The RSC state is unchanged. - **NDIS_OFFLOAD_PARAMETERS_RSC_ENABLED** - The RSC state is enabled. - **NDIS_OFFLOAD_PARAMETERS_RSC_DISABLED** - The RSC state is disabled.
UINT32	The value is a bitwise OR of flags. This must be set to 0. There are no flags currently defined.
UINT8	The Internet protocol security (IPsec) offload version 2 setting of a miniport adapter that supports both IPv6 and IPv4. This specifies the setting for both IPv6 and IPv4 support. Valid values are: - **NDIS_OFFLOAD_PARAMETERS_NO_CHANGE** - The miniport driver should not change the current setting. - **NDIS_OFFLOAD_PARAMETERS_IPSECV2_DISABLED** - IPsec offload version 2 is disabled. - **NDIS_OFFLOAD_PARAMETERS_IPSECV2_AH_ENABLED** - The IPsec offload version 2 Authentication Header (AH) feature should be enabled for transmit and receive. - **NDIS_OFFLOAD_PARAMETERS_IPSECV2_ESP_ENABLED** - The IPsec offload version 2 Encapsulating Security Payload (ESP) feature should be enabled for transmit and receive. - **NDIS_OFFLOAD_PARAMETERS_IPSECV2_AH_AND_ESP_ENABLED** - The IPsec offload version 2 AH and ESP features are enabled for transmit and receive.

Type	Description
UINT8	The Internet protocol security (IPsec) offload version 2 setting of a miniport adapter that supports IPv4 and does not support IPv6. If the miniport driver supports IPv6, the IPsecV2 member specifies the IPv4 setting and this member is not used. Valid values are: • **NDIS_OFFLOAD_PARAMETERS_NO_CHANGE** - The miniport driver should not change the current setting. • **NDIS_OFFLOAD_PARAMETERS_IPSECV2_DISABLED** - IPsec offload version 2 is disabled. • **NDIS_OFFLOAD_PARAMETERS_IPSECV2_AH_ENABLED** - The IPsec offload version 2 Authentication Header (AH) feature should be enabled for transmit and receive. • **NDIS_OFFLOAD_PARAMETERS_IPSECV2_ESP_ENABLED** - The IPsec offload version 2 Encapsulating Security Payload (ESP) feature should be enabled for transmit and receive. • **NDIS_OFFLOAD_PARAMETERS_IPSECV2_AH_AND_ESP_ENABLED** - The IPsec offload version 2 AH and ESP features are enabled for transmit and receive.
UINT8	Encapsulated Packet Task Offload. A protocol driver sets this field to one of the following values. • **NDIS_OFFLOAD_SET_NO_CHANGE** (0) - The NVGRE task offload state is unchanged. • **NDIS_OFFLOAD_SET_ON** (1) - Enables NVGRE task offloads. • **NDIS_OFFLOAD_SET_OFF** (2) - Disables NVGRE task offloads.
UINT8	Encapsulation types. This field is effective only when the Encapsulated Packet Task Offload is set to **NDIS_OFFLOAD_SET_ON**. If the Encapsulated Packet Task Offload member is not set to **NDIS_OFFLOAD_SET_ON**, this member is zero. A protocol driver must set Encapsulation Types to the bitwise OR of the flags corresponding to encapsulation types that it requires. It can select from the following flags. • **NDIS_ENCAPSULATION_TYPE_GRE_MAC** (0x00000001) - Specifies GRE MAC encapsulation (NVGRE).

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

Header	Wditypes.hpp

WDI_TLV_TKIP_MIC_FAILURE_INFO

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_TKIP_MIC_FAILURE_INFO is a TLV that contains TKIP-MIC failure information.

TLV Type

0x57

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8	Specifies which cipher key type detected that the TKIP-MIC failure occurred. If this value is 1, the TKIP-MIC failure was detected through a default cipher key. If this value is 0, the TKIP-MIC failure was detected through a key mapping cipher key.
UINT32	Specifies the index of the cipher key in the default key array. Valid value range is from 0 through 3.
WDI_MAC_ADDRESS	Specifies the MAC address of the peer that transmitted the packet that failed MIC verification.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016

Header	Wditypes.hpp

WDI_TLV_UNICAST_ALGORITHM_LIST

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_UNICAST_ALGORITHM_LIST is a TLV that contains an array of unicast data algorithm pairs.

TLV Type

0x13

Length

The size (in bytes) of the array of WDI_ALGO_PAIRS elements. The array must contain 1 or more elements.

Note WDI_ALGO_PAIRS is not a WDI structure. It is defined in the WDI TLV parser generator, and is used for documentation purposes only.

Values

Type	Description
WDI_ALGO_PAIRS[]	An array of authentication and cipher algorithm pairs.

WDI_ALGO_PAIRS consists of the following elements.

Type	Description
UINT8	Authentication algorithm as defined in WDI_AUTH_ALGORITHM.
UINT8	Cipher algorithm as defined in WDI_CIPHER_ALGORITHM.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_UNICAST_CIPHER_ALGO_LIST

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_UNICAST_CIPHER_ALGO_LIST is a TLV that contains a list of unicast cipher algorithms.

TLV Type

0x3E

Length

The size (in bytes) of the array of WDI_CIPHER_ALGORITHM structures. The array must contain 1 or more elements.

Values

Type	Description
WDI_CIPHER_ALGORITHM[]	An array of unicast cipher algorithms.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_UNREACHABLE_DETECTION_THRESHOLD

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_UNREACHABLE_DETECTION_THRESHOLD is a TLV that contains the unreachable detection threshold.

TLV Type

0xB1

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	The unreachable detection threshold. Specifies the maximum amount of time, in milliseconds, before the 802.11 station determines that it has lost connectivity to a peer device. The station must include missed beacons in making this connectivity loss determination but can also use any other heuristics it desires.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_VENDOR_SPECIFIC_IE

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_VENDOR_SPECIFIC_IE is a TLV that contains a list of vendor-specific IEs.

TLV Type

0x5

Length

The size (in bytes) of the array of UINT8 elements. The array must contain 1 or more elements.

Values

Type	Description
UINT8[]	An array of UINT8 elements that specifies the vendor-specific IEs.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_VIRTUALIZATION_ATTRIBUTES

Article • 03/14/2023

WDI_TLV_VIRTUALIZATION_ATTRIBUTES is a TLV that contains virtualization attributes.

TLV Type

0x24

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_VIRTUALIZATION_CAPABILITIES			The virtualization capabilities.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_VIRTUALIZATION_CAPABILITIES

Article • 03/14/2023

WDI_TLV_VIRTUALIZATION_CAPABILITIES is a TLV that contains virtualization capabilities.

TLV Type

0x10

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT8	The number of supported ExtSTA ports.
UINT8	The number of supported Wi-Fi Direct Group ports. This count should only include Role ports. If this value is non-zero, it is assumed that a Wi-Fi Direct Device port is available.
UINT8	The number of supported legacy ExtAP ports.
UINT8	The maximum number of supported simultaneous AP/WFD Group Owners.
UINT8	The maximum number of separate channels that the device can operate in and maintain data connections on simultaneously. This limit should not include temporary multichannel operations like scans and Wi-Fi Direct negotiations.
UINT8	The maximum number of supported simultaneous STA/WFD clients.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_WAKE_PACKET_BITMAP_PATTERN

Article • 03/14/2023

WDI_TLV_WAKE_PACKET_BITMAP_PATTERN is a TLV that contains a wake-on-LAN pattern.

TLV Type

0x5B

Length

The sum (in bytes) of the sizes of all contained TLVs.

Values

Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_WAKE_PACKET_BITMAP_PATTERN_ID			Specifies the wake-on-LAN pattern ID.
WDI_TLV_BITMAP_PATTERN			Specifies the wake-on-LAN pattern.
WDI_TLV_BITMAP_PATTERN_MASK			Specifies the wake-on-LAN pattern mask. The length is (PatternLength + 7)/8.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_WAKE_PACKET_BITMAP_PATTERN_ID

Article • 03/14/2023

WDI_TLV_WAKE_PACKET_BITMAP_PATTERN_ID is a TLV that contains a wake-on-LAN pattern ID.

The pattern ID is an OS-provided value that identifies the wake-on-LAN pattern and is set to a value that is unique among the wake-on-LAN patterns on a network adapter. The pattern ID is set before the OS sends an add to the underlying drivers or completes the request to the overlying driver.

TLV Type

0xE3

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	The wake-on-LAN pattern ID.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

See also

WDI_TLV_WAKE_PACKET_EAPOL_REQUEST_ID_MESSAGE

Article • 03/14/2023

WDI_TLV_WAKE_PACKET_EAPOL_REQUEST_ID_MESSAGE is a TLV that contains the wake-on-LAN pattern ID of a EAPOL request ID message.

TLV Type

0x5F

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	Specifies the wake-on-LAN pattern ID.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_WAKE_PACKET_IPv4_TCP_SYNC

Article • 03/14/2023

WDI_TLV_WAKE_PACKET_IPv4_TCP_SYNC is a TLV that contains wake-on-LAN IPv4 TCP sync packet information.

TLV Type

0x5D

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	Specifies the wake-on-LAN pattern ID.
UINT8[4]	Specifies the IPv4 source address in the TCP SYN packet.
UINT8[4]	Specifies the IPv4 destination address in the TCP SYN packet.
UINT16	Specifies the TCP source port number in the TCP SYN packet.
UINT16	Specifies the TCP destination port number in the TCP SYN packet.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_WAKE_PACKET_IPv6_TCP_SYNC

Article • 03/14/2023

WDI_TLV_WAKE_PACKET_IPv6_TCP_SYNC is a TLV that contains wake-on-LAN IPv6 TCP sync packet information.

TLV Type

0x5E

Length

The sum (in bytes) of the sizes of all contained elements.

Values

Type	Description
UINT32	Specifies the WoL pattern ID.
UINT8[16]	Specifies the IPv6 source address in the TCP SYN packet.
UINT8[16]	Specifies the IPv6 destination address in the TCP SYN packet.
UINT16	Specifies the TCP source port number in the TCP SYN packet.
UINT16	Specifies the TCP destination port number in the TCP SYN packet.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_WAKE_PACKET_MAGIC_PACKET

Article • 03/14/2023

WDI_TLV_WAKE_PACKET_MAGIC_PACKET is a TLV that contains a pattern ID of a magic packet for OID_WDI_SET_ADD_WOL_PATTERN.

TLV Type

0x5C

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	Specifies the wake-on-LAN magic packet pattern ID.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_WAKE_PACKET_PATTERN_REMOVE

Article • 03/14/2023

WDI_TLV_WAKE_PACKET_PATTERN_REMOVE is a TLV that contains the wake packet pattern ID to be removed with OID_WDI_SET_REMOVE_WOL_PATTERN.

TLV Type

0x6B

Length

The size (in bytes) of a UINT32.

Values

Type	Description
UINT32	Specifies the wake packet pattern ID.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI_TLV_WFD_ASSOCIATION_STATUS

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

WDI_TLV_WFD_ASSOCIATION_STATUS is a TLV that contains the status code to be set when an association request is denied.

TLV Type

0x126

Length

The size (in bytes) of a UINT8.

Values

Type	Description
UINT8	The DOT11_WFD_STATUS_CODE to be set when an association request is denied.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Wditypes.hpp

WDI USB Selective Suspend Topics

Article • 03/14/2023

To save power, a USB device (such as a Wi-Fi NIC on USB) may go to low power state when idle. WDI supports the LE by utilizing NDIS native support for USB Selective Suspend.

In this section:

WDI NDIS idle detection

WDI and WLAN Selective Suspend capability

WDI USB suspend sequence

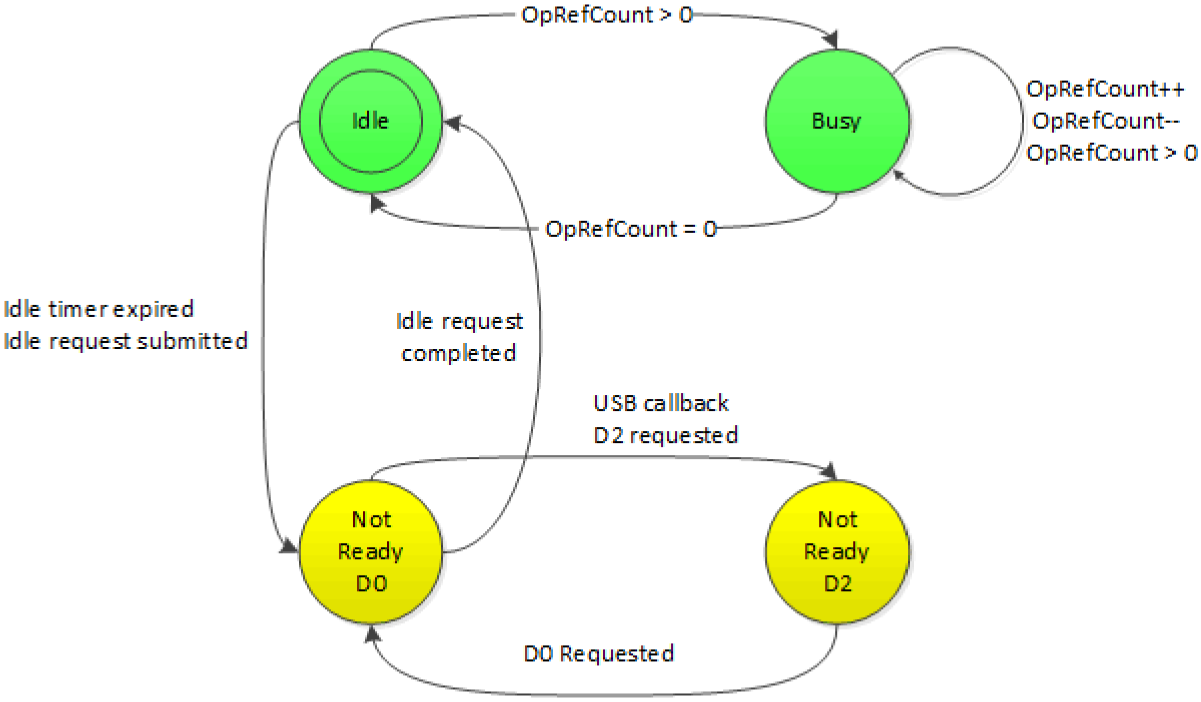
WDI USB resume sequence

WDI USB remote wake sequence

WDI NDIS idle detection

Article • 03/14/2023

This following diagram shows a simple state diagram of NDIS idle detection, which is used to drive USB selective suspend.



If the WDI device/driver supports USB selective suspend, NDIS detects its idle state to send the device into low power state (D2).

WDI and WLAN Selective Suspend capability

Article • 03/14/2023

To enable USB Selective Suspend support, the LE must report the capability. NDIS defines keywords for this feature. For more information, see Standardized INF Keywords for NDIS Selective Suspend.

- *SelectiveSuspend : {Enable, Disable}

- *SSIdleTimeout : idle timeout in seconds

WDI enables support based on the following sources.

- Device INF: This is written to the next item at device setup from the above keyword.
- Registry settings: This is set from the INF or the Advanced property sheet for the device in Device Manager.
- Power management capabilities in the return from OID_WDI_GET_ADAPTER_CAPABILITIES.
- Idle handlers in **NDIS_MINIPORT_DRIVER_WDI_CHARACTERISTICS**.
  - *MiniportWdiIdleNotification*
  - *MiniportWdiCancelIdleNotification*

The WDI driver exposes two callback functions for the LE.

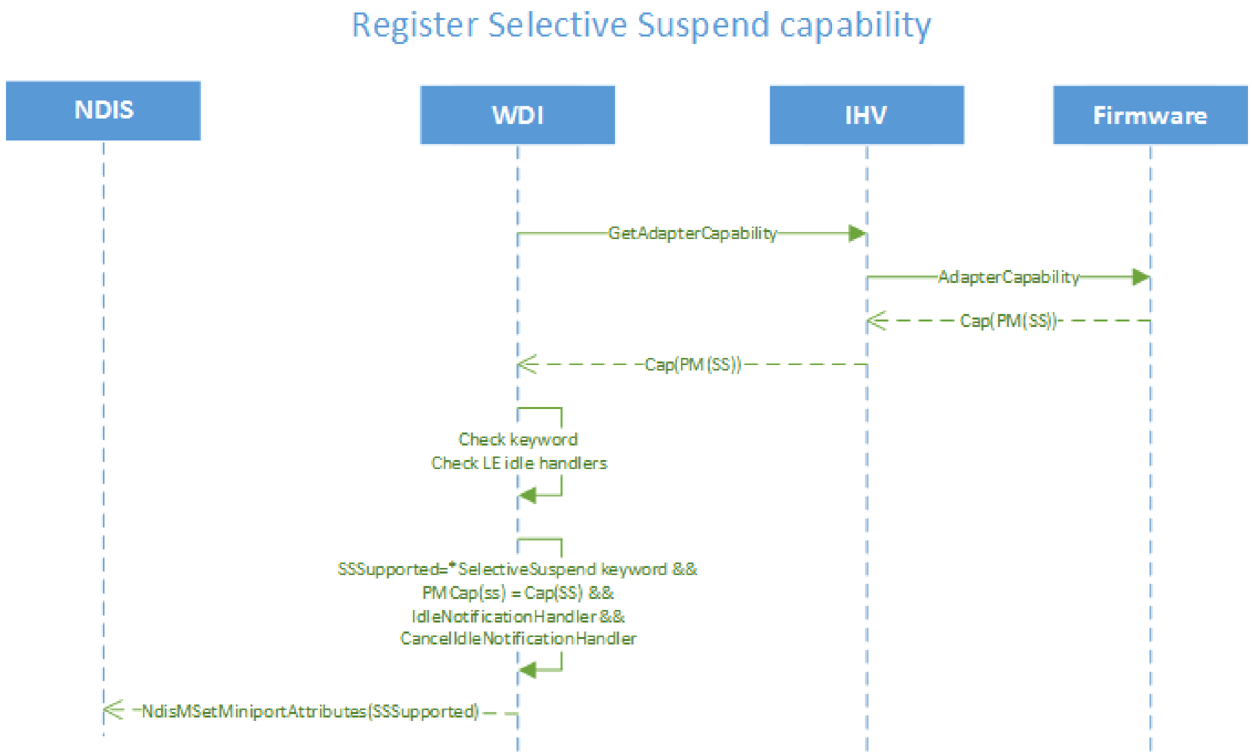
- **IdleNotificationComplete**

- **IdleNotificationConfirm**

WDI Selective Suspend capability registration

Article • 03/14/2023

The following is a flow diagram for registering the USB Selective Suspend capability.



Register Selective Suspend capability
NDIS
WDI
IHV
Firmware
GetAdapterCapability
AdapterCapability
Cap(PM(SS))
Cap(PM (SS))
Check keyword
Check LE idle handlers
SSSupported=*SelectiveSuspend keyword &&
PM Cap(ss) = Cap(SS) &&
IdleNotificationHandler &&
CancelIdleNotificationHandler
NdisMSetMiniportAttributes(SSSupported)

AdapterCap(PM(ss)), *SelectiveSuspend, **LeIdleNotificationHandler**, and **LeCancelIdleNotificationHandler** must be true or valid for WDI to register that WLAN supports Selective Suspend.

When WDI decides that Selective Suspend can be supported, WDI also registers an optional handler to NDIS.

MiniportWdiIdleNotification

WDI USB suspend sequence

Article • 03/14/2023

When NDIS detects idle for longer than the Selective Suspend idle timeout (*SSIdleTimeout*), NDIS calls the UE. The UE may veto the idle notification by returning NDIS_STATUS_BUSY. If the UE does not veto the idle notification, the UE calls the LE with **LeIdleNotificationHander**, and the LE may veto or accept.

The UE accepts idle notifications when there is no pending data, commands, or timers that may expire to send data or commands down to the LE.

When WDI receives a D2 OID, it processes the OID as if it is a regular D2, except that it sends the WDI OID with the reason code set to **WDI_SET_POWER_DX_REASON_SELETIVE_SUSPEND**.

The following flow diagram shows the suspend sequence.

WDI design guide topics

Article • 03/14/2023

This section describes requirements and recommendations for supporting features in the WLAN driver.

WDI low latency connection quality

WDI Extended channel switch announcement

WDI IHV extensible types

Develop and validate WDI drivers for Reset Recovery

WDI low latency connection quality

Article • 03/14/2023

A port can be configured for low latency mode operation if there is an application running on the system that needs low latency data traffic (for example, VoIP applications). When in this mode of operation, the driver should modify any behavior (such as scanning or better AP roaming) that would cause it to move off of the channel of the port that is configured for low latency mode. It should also follow the specified guidance for the NDIS_STATUS_WDI_INDICATION_LINK_STATE_CHANGE indication. The host provides **WDI_TLV_LOW_LATENCY_CONNECTION_QUALITY_PARAMETERS** that the port should use when it is in this mode. This specifies the maximum time that the port should be off channel and the minimum link quality value that the connection must fall down to before initiating a low latency roam (including sending NDIS_STATUS_WDI_INDICATION_ROAMING_NEEDED).

For scans, the host provides the maximum channel dwell time (there are different values for active and passive channels) and the adapter should not go above the maximum time. The host also throttles unnecessary scans. However, the adapter can throttle the scan further if the **WDI_SCAN_TRIGGER** is **WDI_SCAN_TRIGGER_BACKGROUND** or **WDI_SCAN_TRIGGER_ROAM**. If the adapter performs its own scans in this mode, it is recommended that it includes the SSID it is looking for (unless it is after a resume from sleep) to reduce the dwell time on a channel. In addition, it should avoid scanning multiple channels in single off-channel scan so that it is under the overall off-channel time limit.

The host considers NDIS_STATUS_WDI_INDICATION_ROAMING_NEEDED a strong request from the adapter to roam, so when in this mode, the adapter should be careful about how often this indication is sent up. If the adapter performs its own roaming/AP selection decisions, it must employ appropriate mechanisms (such as neighbor reports or PMKIDs) to find and select/rank APs.

To optimize the association process, the adapter should use the cached BSS entry for TSF timer synchronization during join if possible. The cached entry should be good enough for TSF timer synchronization, which is fresh enough most of time because it was obtained from a recent probe request. TSF synchronization can be done later, even when the driver decides to pick an AP that does not have an up-to-date cached probe response. The driver can disable Wi-Fi power save until it receives the next beacon, which usually occurs within 100ms.

When operating in multi-channel concurrency mode, it is recommended that the adapter employ ECSA or other mechanisms for enabling seamless/no jitter experience when performing channel multiplexing.

WDI Extended channel switch announcement (ECSA)

Article • 03/14/2023

To minimize the cases where the Wi-Fi Direct port causes the system to operate in Multi-Channel mode, multi-channel uses cases are not as performant as single channel use cases. We recommend that the device (driver/firmware) implements ECSA. This feature should exist completely on the IHV side.

Here are the suggested driver/firmware changes.

- Support bi-directional ECSA on the Wi-Fi Direct port.
- When the device is the Group Owner and is in Multi-Channel mode:
  - The driver must detect if the remote peer supports ECSA.
  - If the remote peer supports ECSA, engage ECSA to move the peer into the channel configuration that yields a single channel.
- When the device is the Client and is in Multi-Channel mode:
  - If an ECSA request comes from the remote peer, then support it.
- Send channel change notifications to the operating system with NDIS_STATUS_WDI_INDICATION_P2P_GROUP_OPERATING_CHANNEL.

WDI IHV extensible types

Article • 03/14/2023

The WDI model allows the IHV to support custom PHY type, authentication algorithms, and cipher algorithms. The IHV extension PHY type is used mainly for reporting purposes and does not change the operating system behavior. The IHV extension authentication and cipher algorithms are used with the IHV extensibility module and IHV profiles. When these are used for a connection, the host does not perform any matching for security settings before forwarding the candidate BSS list to the adapter.

Develop and validate WDI drivers for Reset Recovery

Article • 03/14/2023

The UE has a built-in hook for stressing reset and recovery by simulating firmware hangs. It exercises the UE and LE but not the actual firmware, which likely remains functional in the simulation. The code is in M1 UE. It is ideal if the IHV has mechanisms to inject firmware hangs. This exercises Reset Recovery on modules below the LE, specifically Bus, ACPI, and UEFI. There have been hard-to-debug issues in these lower layers regarding to Reset Recovery where the lower layer failed to actually reset the firmware.

OID_WDI_TASK_CHANGE_OPERATION_MODE

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_TASK_CHANGE_OPERATION_MODE configures the operation mode for the port.

OID_WDI_TASK_CONNECT

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_TASK_CONNECT requests that the IHV component connects to an Access Point or to a Wi-Fi Direct GO.

Object	Abort capable	Default priority (host driver policy)	Normal execution time (seconds)
Port	Yes. The abort must be followed by a dot11 reset.	4	10

As part of the connect, the IHV component must synchronize with, authenticate to, and associate to the BSS. The host provides the BSS entries that the IHV component can attempt to connect to. Once the IHV component has successfully connected to one of those entries, it should complete the connect process. If it is unable to connect to any of the BSS entries, it should complete the connect process with a failure.

The IHV component does not need to perform a scan to find candidate BSS entries. It can use the list provided by the host for the connect. It can attempt to connect to each one, one after another. The host sorts the networks by RSSI, but the IHV component can use its own order for connection. If the adapter does not specify "Connect BSS Selection Override", it must only use the entries provided by the host for the connect. The host may issue an abort on an outstanding connect. On receiving the abort, the port must end the connection attempts and report a completion to the host.

If the adapter specifies "Connect BSS Selection Override", it can perform scans on its own to find candidate BSS entries. It can connect to any BSS entry it finds as long as it meets the parameters configured by the host. It should optimize this selection to ensure that it meets any configured connection quality requirements. This could include optimizing roam scan, optimize AP selection, optimize association process, and minimize the security handshake needed. During a scan, if the device needs additional association parameters for a found BSS entry (for example, PMKID for roaming), it can send a NDIS_STATUS_WDI_INDICATION_ASSOCIATION_PARAMETERS_REQUEST indication to get the parameters. When available, the host configures these parameters with OID_WDI_SET_ASSOCIATION_PARAMETERS.

If the connect fails or is aborted, the port should not reset any settings that may have been configured outside of the connect command. It must support the host issuing a second connect call on the same port.

The status of the connect attempt for each BSS entry must be reported by the port at the end of the association attempt. This includes the successful attempt and also any failed attempts. At any time, the port must be associated with no more than one Access Point or Wi-Fi Direct GO.

While a connect is ongoing, the port must maintain any connections established on other ports (for example, Infrastructure or Wi-Fi Direct). However, the port may reduce the amount of medium access provided to the other ports to finish the connection. During the connect, the host can submit packet send requests on other ports.

If the authentication algorithm that is used for the connection requires 802.1x port authorization for network access, the host authorizes the port after the association operation has completed successfully.

The 802.11 station uses the PMKID cache for pre-authentication to access points that have enabled the Robust Security Network Association (RSNA) authentication algorithm. If the 802.11 station is associating or reassociating to a BSSID that has a provided PMKID, the 802.11 station must use the PMKID data in the RSN information element (RSN IE) of its Association or Reassociation frame.

If the port declares support for Host FIPS mode in **WDI_TLV_STATION_ATTRIBUTES**, HostFIPSModeEnabled may be set to 1 in the connection parameters.

If HostFIPSModeEnabled is set to 1, the following rules apply.

- The port must follow the guidelines for sending/receiving data frames in Send operations in FIPS mode and Receive operations in FIPS mode.
- The port must not declare support for any QoS protocol in the association request sent to a non-HT access point. QoS support is required for HT connections.
- The port must not negotiate TSpec and must not perform transmit MSDU aggregation.
- The port must ensure that the SPP A-MSDU capable bit (bit 10) of the RSN capabilities IE it transmits is set to zero. Only PP A-MSDU are supported in this mode.

The connection parameters must not have MFPEnabled and HostFIPSModeEnabled both set to 1. Management Frame Protection (802.11w) requires the port to encrypt/decrypt certain management and action frames, so it cannot be enabled for a connection using Host FIPS mode. In addition, Wake on Wireless LAN features are not applicable in Host-FIPS mode.

Task parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_CONNECT_PARAMETERS			The connection parameters.
WDI_TLV_CONNECT_BSS_ENTRY	X		The preferred list of candidate connect BSS entries. The port should attempt to connect to any of these BSS entries until the list is exhausted or the connection completed successfully. The port can reprioritize the entries if needed. If the adapter has set the Connect BSS Selection Override bit, then it can pick a BSS that is not in this list as long as it follows the Allowed/Disallowed list.

OID_WDI_TASK_CREATE_PORT

Article • 03/14/2023

OID_WDI_TASK_CREATE_PORT requests that a new 802.11 entity is created by the IHV component.

Object	Abort capable	Default priority (host driver policy)	Normal execution time (seconds)
Adapter	No	6	1

The operation mode of the created port is set to **WDI_OPERATION_MODE_STA** unless it has been specified in the task parameters.

If the MAC is to function as a Wi-Fi Direct device port, **uOpmodeMask** contains **WDI_OPERATION_MODE_P2P_DEVICE**. In this case, the IHV component driver must assign the MAC address reserved for the Wi-Fi Direct Device to this port and return it in the request completion indication.

Task parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_CREATE_PORT_PARAMETERS			Parameters for port creation.

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_CREATE_PORT_MAC_ADDRESS		X	This TLV is used when the UE recreates the non-primary port during resume from hibernation. When this TLV is present, the firmware must use this MAC address to create the port. This MAC address is guaranteed to be the MAC address that the firmware created for the port type prior to hibernation. The goal is to use the same NDIS port number and MAC address in order to match the states of the upper layers. Note that the WFC_PORT_ID can be different at recreation, but the port ID should not collide with any port ID of an existing port. This information is only used between the UE and LE/firmware.

OID_WDI_TASK_DISCONNECT

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_TASK_DISCONNECT is used to terminate a connection with a peer.

Object	Abort capable	Default priority (host driver policy)	Normal execution time (seconds)
Port	No	2	1

This command is used to disconnect from an Access Point or a Wi-Fi Direct GO, and also to disconnect clients of the port. When the disconnect is received, the port must disassociate and deauthenticate from the peer and clear the state associated with that peer. However, it must not reset any of the connection parameters that are not specific to this peer. The task must be completed only after the disconnect activity has been completed.

Task parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_DISCONNECT_PARAMETERS			The disconnect parameters.

Task completion indication

NDIS_STATUS_WDI_INDICATION_DISCONNECT_COMPLETE

Unsolicited indication

NDIS_STATUS_WDI_INDICATION_DISASSOCIATION When the port gets disconnected from the network, it sends the disassociation indication to the OS. The disconnect may be triggered by a command from the OS, or may be triggered from the network. Network triggered disconnects may be explicit from received disassociation or deauthentication packets, or may be implicit when the port cannot detect the presence of the peer it is connected to.

Before the disassociation indication is sent, the port must clear the state associated with the peer. This includes any keys and 802.1x port authorization information associated with the peer. The port must not trigger a roam on its own.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_TASK_DOT11_RESET

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_TASK_DOT11_RESET requests that the IHV component resets the MAC and PHY state on a specified port.

Object	Abort capable	Default priority (host driver policy)	Normal execution time (seconds)
Port	No	1	1

Prior to issuing a dot11 reset command, the WDI driver stops issuing new commands to IHV component and aborts any task in progress on the port. It also flushes its Rx and TX queues.

The dot11 reset combines the semantics of the 802.11 MLME and PLME reset primitive. When the IHV component receives a dot11 reset request, it should perform the following tasks.

- Reset the port's MAC entity to its initial state.
- Reset the port's MIB attributes so they are set to their default values, if bSetDefaultMIB is true.
- Reset the TX/Rx state machines for the PHY entity and set it to Rx state only to ensure no more frames are transmitted.
- Flush the adapter's Rx queue and complete the send for each packet in the TX queues.
- If the MAC address parameter is present, reset the port's MAC address to the specified value.
- Set the port state to INIT before completing the dot11 reset operation.

If the port being reset was operating as a STA, AP, or a Wi-Fi Direct Client or GO, the host would have triggered the disconnect task to request the IHV component to send disassociation to the peers before the reset. As such, the IHV component does not need to do it again.

Task parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_DOT11_RESET_PARAMETERS			Parameters for the dot11 reset.
WDI_TLV_CONFIGURED_MAC_ADDRESS		X	The MAC address that should be used for the port.

OID_WDI_TASK_P2P_DISCOVER

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_TASK_P2P_DISCOVER is issued to the device to perform Wi-Fi Direct discovery.

Object	Abort capable	Default priority (host driver policy)	Normal execution time (seconds)
Port	Yes. The port must be in a clean state after the abort.	6	15

The command contains properties which define either a specific set of Wi-Fi Direct devices to search for, or wildcard discovery.

Wi-Fi Direct discovery is mutually exclusive from standard Wi-Fi scanning. While this task is running, broadcast probe requests shall not be sent without a "DIRECT-" SSID, or a specific GO SSID. These probe requests must also include all necessary Wi-Fi Direct IEs.

The host may have search criteria which is not provided as part of the task parameters down to the device. The host may use the task abort mechanism if it has matched the required criteria, therefore it is important that the device can abort Wi-Fi Direct Discovery tasks quickly so as not to degrade scenario performance.

When the task has been completed (either normally or due to an abort), the port should be in a good state such that another discover request can be issued on that port.

Task parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_DISCOVER_MODE			Discovery mode information, such as scan type, count, and time between scans.
WDI_TLV_SCAN_DWELL_TIME			Scanning dwell time settings.
WDI_TLV_P2P_DISCOVERY _CHANNEL_SETTINGS	X	X	Scan duration and list of channels to scan. When specified, the listen settings override those specified in WDI_TLV_SCAN_DWELL_TIME. If this list is empty, the port must scan on all supported channels and use the listen settings from WDI_TLV_SCAN_DWELL_TIME.
WDI_TLV_SSID	X	X	A list of SSIDs that the port should scan for. There can be multiple SSIDs in this list and one of them can be a wildcard. When doing an active scan on a channel, the port must send a probe request for each SSID in the list. If this list is empty, the port must scan for all SSIDs.
WDI_TLV_P2P_SERVICE_NAME_HASH	X	X	A list of Service Hash names to be queried. Required if WDI_P2P_SERVICE_DISCOVERY_TYPE_SERVICE_NAME_ONLY or WDI_P2P_SERVICE_DISCOVERY_TYPE_ASP2_SERVICE_NAME_ONLY is specified.
WDI_TLV_VENDOR_SPECIFIC_IE		X	One or more IEs that must be included in the probe requests sent by the port. These IEs are not used for passive scan.
WDI_TLV_P2P_SERVICE_INFORMATION_DISCOVERY_ENTRY	X	X	An optional list of Service Information Discovery Entries to be queried. This is required if WDI_P2P_SERVICE_DISCOVERY_TYPE_SERVICE_INFORMATION is specified. The driver is expected to perform a P2P service discovery over probe request/response using the service name hash. For each service entry that contains service information, the driver is expected to perform an ANQP query request/response to query the service information.

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_ASP2_SERVICE_INFORMATION_DISCOVERY_ENTRY	X	X	Added in Windows 10, version 1607, WDI version 1.0.21. An optional list of ASP2 Service Information Discovery Entries to be queried. This is required if WDI_P2P_SERVICE_DISCOVERY_TYPE_ASP2_SERVICE_INFORMATION is specified. The driver is expected to perform a P2P service discovery over probe request/response using the service name hash. For each service entry that contains service information, the driver is expected to perform an ANQP query request/response to query the service information.
WDI_TLV_P2P_INCLUDE_LISTEN_CHANNEL		X	Added in Windows 10, version 1607, WDI version 1.0.21. Specifies whether the probe request should include the Listen Channel attribute during discovery.

Task completion indication

OID_WDI_TASK_P2P_SEND_REQUEST_ACTION_FRAME

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_TASK_P2P_SEND_REQUEST_ACTION_FRAME is issued to the device to send a Wi-Fi Direct Public Action Frame Request.

Object	Abort capable	Default priority (host driver policy)	Normal execution time (seconds)
Port	Yes. The port must be in a clean state after the abort.	3	5

This command is different than OID_WDI_TASK_P2P_SEND_RESPONSE_ACTION_FRAME, which is a significantly more time-sensitive operation.

When the device receives an acknowledgment for a request frame, it shall dwell on the same channel for 100ms and indicate any Wi-Fi Direct Public Action Frames it receives to the host.

While the maximum timeout has not expired, the device shall retry sending the Wi-Fi Direct Public Action frame to the remote device on the remote device’s listen channel.

The task is complete either when the local device receives an acknowledgment from the remote device for the action frame that was sent, the timeout expires, or the host aborts the operation. The device may indicate task completion after the same-channel dwell time has expired.

The host may decide to abort this operation and continue/retry the Wi-Fi Direct action frame exchange, so it is important that the device is able to abort this operation quickly.

Validation

For miniport drivers that support WDI version 1.1.8 and later, additional validation of the P2P IEs on outgoing P2P Action Frames has been added. This validation addresses a common problem in which the **Configuration Timeout** attribute of the P2P IE has not been converted form units of milliseconds, as provided to the LE in OID_WDI_TASK_P2P_SEND_REQUEST_ACTION_FRAME and OID_WDI_TASK_P2P_SEND_RESPONSE_ACTION_FRAME, to units of tens of milliseconds, which is the IE format.

The Wi-Fi Direct and Wi-Fi Direct Services HLK tests will fail for drivers supporting WDI version 1.1.8 and later if the **Configuration Timeout** attribute of the P2P IE is not encoded correctly on an outgoing action frame. For WDI versions 1.1.7 and earlier, the tests will print a warning to the test output.

The WDI interface itself is unchanged and continues to use units of milliseconds just as it did in versions 1.1.7 and earlier.

Task parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_SEND_ACTION_REQUEST_FRAME_PARAMETERS			Parameters such as action frame type, device address of target peer adapter, and dialog token.
WDI_TLV_P2P_GO_NEGOTIATION_REQUEST_INFO		X	GO Negotiation Request Parameters. THe port shall only examine this structure if wfdRequestFrameType is a GO Negotiation request.
WDI_TLV_P2P_INVITATION_REQUEST_INFO		X	Invitation Request Parameters. The port shall only examine this structure if wfdRequestFrameType is an Invitation request.

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_PROVISION_DISCOVERY_REQUEST_INFO		X	Provision Discovery Request Parameters. The port shall only examine this structure if wfdRequestFrameType is an Provision Discovery request.
WDI_TLV_BSS_ENTRY			The device discovery entry as returned by the Wi-Fi Direct Discovery task from the port. This is provided so the port does not need to remember its discovery database in order to send Wi-Fi Direct Action Frame Requests to remote Wi-Fi Direct devices without requiring a discovery.
WDI_TLV_VENDOR_SPECIFIC_IE		X	One or more IEs that must be included in the frame sent by the port.

Task completion indication

NDIS_STATUS_WDI_INDICATION_P2P_SEND_REQUEST_ACTION_FRAME_COMPLETE

OID_WDI_TASK_P2P_SEND_RESPONSE_ACTION_FRAME

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_TASK_P2P_SEND_RESPONSE_ACTION_FRAME is issued to the IHV component to send a Wi-Fi Direct Public Action Frame Request to a peer.

Object	Abort capable	Default priority (host driver policy)	Normal execution time (seconds)
Port	Yes. The port must be in a clean state after the abort.	3	5

When port receives an acknowledgment for a request frame, it shall dwell on the same channel for 100ms and indicate any Wi-Fi Direct Public Action Frames it receives to the host.

This task is time sensitive. The Wi-Fi Direct specification requires that sending Wi-Fi Direct action responses are only serviced within 100 milliseconds of receiving this packet.

While the maximum timeout has not expired, the port shall retry sending the Wi-Fi Direct to the remote device on the appropriate channel as defined by the following table. The table defines the explicit channel requirements for where to send the packets when the command is issued. The general rule is that the response packet shall be sent out on the same channel as the prior request.

Response Action Frame Type	Target Transmit Channel
GO Negotiation Response	Local Listen Channel
GO Negotiation Confirmation	Remote Listen Channel
Invitation Response	Local Listen or Local GO Operational Channel
Provision Discovery Response	Local Listen Channel or Remote GO Operational Channel

The task is complete either when local device receives an acknowledgment from the remote device for the action frame that was sent, the timeout expires, or the host aborts the operation. The device may indicate task completion after the same-channel dwell time has expired.

The host may decide to abort this operation and continue/retry the Wi-Fi Direct action frame exchange, so it is important that the device is able to abort this operation quickly.

Validation

For miniport drivers that support WDI version 1.1.8 and later, additional validation of the P2P IEs on outgoing P2P Action Frames has been added. This validation addresses a common problem in which the **Configuration Timeout** attribute of the P2P IE has not been converted form units of milliseconds, as provided to the LE in OID_WDI_TASK_P2P_SEND_REQUEST_ACTION_FRAME and OID_WDI_TASK_P2P_SEND_RESPONSE_ACTION_FRAME, to units of tens of milliseconds, which is the IE format.

The Wi-Fi Direct and Wi-Fi Direct Services HLK tests will fail for drivers supporting WDI version 1.1.8 and later if the **Configuration Timeout** attribute of the P2P IE is not encoded correctly on an outgoing action frame. For WDI versions 1.1.7 and earlier, the tests will print a warning to the test output.

The WDI interface itself is unchanged and continues to use units of milliseconds just as it did in versions 1.1.7 and earlier.

Task parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_ACTION_FRAME_RESPONSE_PARAMETERS			Parameters such as action frame type, device address of target peer adapter, and dialog token.

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_P2P_GO_NEGOTIATION_RESPONSE_INFO		X	GO Negotiation Response Parameters. The port shall only examine this structure if wfdRequestFrameType is a GO Negotiation Response.
WDI_TLV_P2P_GO_NEGOTIATION_CONFIRMATION_INFO		X	GO Negotiation Confirmation Parameters. The port shall only examine this structure if wfdRequestFrameType is a GO Negotiation Confirmation.
WDI_TLV_P2P_INVITATION_RESPONSE_INFO		X	Invitation Response Parameters. The port shall only examine this structure if wfdRequestFrameType is an Invitation Response.
WDI_TLV_P2P_PROVISION_DISCOVERY_RESPONSE_INFO		X	Provision Discovery Response Parameters. The port shall only examine this structure if wfdRequestFrameType is an Provision Discovery Response.
WDI_TLV_P2P_INCOMING_FRAME_INFORMATION			Information that was indicated from the previously received P2P Action Frame. The received indication is provided back to the port.

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_VENDOR_SPECIFIC_IE		X	One or more IEs that must be included in the frame sent by the port.

OID_WDI_TASK_REQUEST_FTM

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_TASK_REQUEST_FTM is issued to the LE to initiate Fine Timing Measurement (FTM) procedures with the listed BSS targets. The number of targets is less than or equal to the value of **FTMNumberOfSupportedTargets**, obtained from the station attributes.

This task should be completed as soon as all the FTM sessions with the targets are completed, the timeout has expired, or the host has aborted the operation.

When this task is completed, the driver should send an NDIS_STATUS_WDI_INDICATION_REQUEST_FTM_COMPLETE status indication that contains a list of FTM responses for each of the targets requested.

After this task is completed, the port should be in a good state and should be ready to process a new FTM request, because the host might immediately re-attempt the task with a new set of targets.

If the LE maintains a station BSS list cache, it can use this cache to obtain the parameters needed to issue FTM request to the targets and ignore the provided data. However, if the target BSSID is not found in the cache the LE needs to use the provided data to attempt the FTMs.

For each target, it is indicated if a Location Configuration Information (LCI) report should be requested. If indicated, the LE should request one from the target.

Task parameters

TLV	Type	Multiple TLV instances allowed	Optional	Description

TLV	Type	Multiple TLV instances allowed	Optional	Description
WDI_TLV_FTM_REQUEST_TIMEOUT	UINT32			The maximum time, in milliseconds, to complete the FTM. The timeout is set to 150 ms multiplied by the number of targets.
WDI_TLV_FTM_TARGET_BSS_ENTRY	WDI_FTM_TARGET_BSS_ENTRY	X		A list of the BSS targets with which FTM procedures should be completed.

Task completion indication

OID_WDI_TASK_ROAM

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_TASK_ROAM requests that the adapter tries to roam from the currently connected AP to a new one.

Object	Abort capable	Default priority (host driver policy)	Normal execution time (seconds)
Port	Yes. If aborted after disassociation, it must be followed by a dot11 reset.	4	10

The Microsoft component provides the list of preferred BSS entries that the adapter should consider for roaming.

When this command issued, if its currently associated, the adapter would need to disassociate from the currently connected AP and then roam to the new AP. In this case it would first indicate disassociation for the old AP, then indicate association result for the new AP and then complete the task.

It can also determine not to perform the roam and stay connected to the current AP. In this case it would only complete the task without any association or disassociation indications.

The scan and AP selection requirements for this task are same as for OID_WDI_TASK_CONNECT.

Task parameters

TLV	Multiple TLV instances allowed	Optional	Description

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_CONNECT_PARAMETERS			Connection parameters.
WDI_TLV_CONNECT_BSS_ENTRY	X		The preferred list of candidate connect BSS entries. The port should attempt to connect to these BSS entries until the list is exhausted, or the connection completed successfully. The port can reprioritize the entries if needed. If the adapter has set the Connect BSS Selection Override bit, then it can pick a BSS that is not in this list as long as it follows the Allowed/Disallowed list requirements.

OID_WDI_TASK_SCAN

Article • 03/14/2023

> ⓘ **Important**
>
> This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_TASK_SCAN requests a survey of BSS networks. The port performs a scan according to the requirements of the IEEE 802.11 specification.

Object	Abort capable	Default priority (host driver policy)	Normal execution time (seconds)
Port	Yes. The port must be in a clean state after the abort.	6 (background scan) 5 (user-initiated scan)	4

A task started message containing a WDI_TLV_STATUS is indicated once the port has started the scan and is ready to receive other commands.

Once a scan is started when enabled by LiveUpdatesNeeded, the port must provide incremental updates (using unsolicited indications of NDIS_STATUS_WDI_INDICATION_BSS_ENTRY_LIST) about discovered BSS entries. BSS entries that had previously been discovered but were not found by the port in the current scan should not be reported by the port. For power and performance reasons, the port should throttle indications and send updates to the host only when it has discovered 3 or more, or when it has discovered less than 3 entries but has not reported them to the host for more than 500 milliseconds. After the scan is completed, if the adapter does not manage BSS entries, it does not need to remember the BSS entries that it has discovered. Once the scan operation has finished, the port must send the task complete notification to the operating system and stop reporting BSS entries to the host. The scan command is used for finding legacy (non-Wi-Fi Direct networks) and the port should not include the Wi-Fi Direct IEs in the probe requests.

If the adapter does not manage BSS entries, the host remembers the BSS entries reported by the port from a scan for a finite period of time. It times out its cached entries and flushes them. If the adapter manages the BSS entries, it caches and times them out. The host may send the OID_WDI_SET_FLUSH_BSS_ENTRY command to explicitly flush the entries.

The host tracks BSS entries using their BSSID. If the port reports two BSS entries for the same BSSID, the host overwrites one with another.

While the scan is ongoing, the port must maintain the existing connections (for example, Infrastructure or Wi-Fi Direct). If connections already exist, the port should scan a subset of channels at a time and in between subsets, provide the other connections access to the medium. During the scan, the host can submit packet send requests to any port on the adapter.

In the indicated BSS entries, the port can include device specific context information. This context information is passed back to the device if the port is asked to connect to that BSS entry. However, this context may be cleared by the host automatically if the BSS entry is flushed.

The scan command can be aborted. On receiving the abort command, the port should stop trying to find new BSS networks and complete the scan task as soon as possible. When the task has been completed (either normally or due to an abort), the port should be in a good state such that another scan can be issued on that port.

The adapter must not violate regulatory restrictions when performing a scan.

Task parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_BSSID			BSSID of the network to scan for. If this is the broadcast MAC address, the station scans for all BSSIDs.
WDI_TLV_SSID	X		A list of SSID list that the port should scan for. There can be multiple SSIDs in this list and one of them can be a wildcard. When doing an active scan on a channel, the port must send a probe request for each SSID in the list. If this list is empty, the port must scan for all SSIDs.

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_VENDOR_SPECIFIC_IE		X	One or more IEs that must be included in the probe requests sent by the port. These IEs are not used for passive scan.
WDI_TLV_SCAN_MODE			Scan mode parameters.
WDI_TLV_SCAN_DWELL_TIME			Dwell time parameters.
WDI_TLV_BAND_CHANNEL	X	X	A list of recommended channels to scan. The adapter can perform a scan on a subset or superset of the channel list as long as it meets the Maximum Scan Time requirements. If this list is empty, the port must scan on all supported channels.

Task completion indication

NDIS_STATUS_WDI_INDICATION_SCAN_COMPLETE

Unsolicited indication

NDIS_STATUS_WDI_INDICATION_BSS_ENTRY_LIST

This notification is used by the device to tell the host about updates to the BSS entries. It can be sent at any time.

OID_WDI_TASK_SEND_REQUEST_ACTION_FRAME

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_TASK_SEND_REQUEST_ACTION_FRAME requests that the device sends an Action Frame Request to another device.

Object	Abort capable	Default priority (host driver policy)	Normal execution time (seconds)
Port	Yes. The port must be in a clean state after the abort.	3	5

This command is different from OID_WDI_TASK_SEND_RESPONSE_ACTION_FRAME, which is a significantly more time-sensitive operation.

When the device receives an acknowledgment for a request frame, it shall dwell on the same channel for the Post-ACK Dwell time as specified in the Task Parameters, and shall indicate to the host any Action Frames it receives and doesn't handle itself.

As long as the maximum timeout has not expired, the device shall retry sending the Public Action frame to the remote device on the remote device's listen channel.

The task is complete either when local device receives an acknowledgment from the remote device for the action frame that was sent, the timeout expires, or the host aborts the operation. The device may indicate task completion after the same-channel dwell time has expired.

The host may decide to abort this operation and continue/retry the public action frame exchange, so it is important that the device is able to abort this operation quickly.

Task parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_SEND_ACTION_FRAME_REQUEST_PARAMETERS			Parameters for sending an Action Frame Request.
WDI_TLV_ACTION_FRAME_BODY			The Action Frame body.

Task completion indication

NDIS_STATUS_WDI_INDICATION_SEND_REQUEST_ACTION_FRAME_COMPLETE

OID_WDI_TASK_SET_RADIO_STATE

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_TASK_SET_RADIO_STATE is used to set the Wi-Fi radio state for the adapter.

Object	Abort capable	Default priority (host driver policy)	Normal execution time (seconds)
Adapter	No	1	1

The task must be completed only after the disconnect activity has been completed.

The IHV component may also send unsolicited indications about radio state changes to the host.

Before the host turns off the radio, it disconnects all peers and stops any Group Owner that is running. The adapter is not expected to remember the station/GO profile information across a radio OFF/ON transition.

Task parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_RADIO_STATE_PARAMETERS			The desired state of the radio. If this set to 1, the radio is enabled. If this is set to 0, the radio is turned off.

Task completion indication

NDIS_STATUS_WDI_INDICATION_SET_RADIO_STATE_COMPLETE

Unsolicited indication

NDIS_STATUS_WDI_INDICATION_RADIO_STATUS This indication is used to report changes in the radio state for the adapter. This is sent both when a software radio change is triggered by the host and when a hardware radio state change is detected by the adapter.

OID_WDI_TASK_START_AP

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_TASK_START_AP requests that the IHV component configures a port to start a Wi-Fi Direct Group Owner on the specified port.

Object	Abort capable	Default priority (host driver policy)	Normal execution time (seconds)
Port	Yes. The abort must be followed by a dot11 reset.	4	1

During initialization, the driver sets the GO on 5GHz band capability in WDI_TLV_P2P_CAPABILITIES to indicate whether it can start the access point on the 5 GHz band.

If GO on 5 GHz band support is set, the adapter should start the AP on the Advertised Operating channel, and if that fails, it should try the list specified in the AP band channel list parameter. The operating system will provide a hint to the driver about whether this AP would provide internet connectivity by setting the **DOT11_WFD_GROUP_CAPABILITY_CROSS_CONNECTION_SUPPORTED** flag in WDI_TLV_P2P_GROUP_OWNER_CAPABILITY.

If **MustUseSpecifiedChannel** in WDI_TLV_START_AP_PARAMETERS is specified, the AP may return one of the following errors if it is unable to start the AP on the specified band/channel(s).

NDIS_STATUS_DOT11_AP_CHANNEL_CURRENTLY_NOT_AVAILABLE: Unable to start the AP on the specified channel(s) right now . Retry on the specified channel(s) later.

NDIS_STATUS_DOT11_AP_BAND_CURRENTLY_NOT_AVAILABLE: Unable to start the AP on the specified band(s) right now. Retry on the specified band(s) later.

NDIS_STATUS_DOT11_AP_CHANNEL_NOT_ALLOWED: Unable to start the AP on the specified channel(s) due to regulatory reasons.

NDIS_STATUS_DOT11_AP_BAND_NOT_ALLOWED: Unable to start the AP on the specified band(s) due to regulatory reasons.

Task parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_SSID			The SSID to be used by the AP.
WDI_TLV_START_AP_PARAMETERS			Additional parameters for this task.
WDI_TLV_AUTH_ALGO_LIST			The list of authentication algorithms that the connection can use.
WDI_TLV_MULTICAST_CIPHER_ALGO_LIST			The list of multicast cipher algorithms that the connection can use.
WDI_TLV_UNICAST_CIPHER_ALGO_LIST			The list of multicast cipher algorithms that the connection can use.
WDI_TLV_P2P_CHANNEL_NUMBER		X	If specified, this defines the operating channel determined in group formation. This may only be specified when the operating mode is Wi-Fi Direct GO.

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_AP_BAND_CHANNEL	X	X	Added in Windows 10, version 1511, WDI version 1.0.10. Optional list of bands and channels to start the access point on. If MustUseSpecifiedChannels is set to 1, the AP can only be started from this list. If it is not set, this list is meant to be a recommendation of channels that the firmware can pick from, and it may pick another channel if it is not possible to start the AP on any of the specified channels.

Task completion indication

OID_WDI_ABORT_TASK

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_ABORT_TASK is a property that is sent down to cancel a specific pending task.

Scope	Set serialized with task	Normal execution time (seconds)
Port	No	1

This command follows property semantics. It should be treated as a signal, should be handled as quickly as possible, and should be completed independently of task completion. The IHV component must then attempt to complete the pending task as soon as possible.

Command parameters

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_CANCEL_PARAMETERS			Information for the command that is being cancelled.

Command result

Contains a status of NDIS_STATUS_SUCCESS. There is no additional payload.

Examples

Original input task command:

Field	Subfield	Type	Value
NDIS_OID_REQUEST	Oid	NDIS_OID	OID(WDI_TASK_SCAN)
---	InputBufferLength	UINT32	0x210 (example)
---	InformationBuffer	PVOID	Pointer to memory block containing WDI_MESSAGE_HEADER + TLV payload

Field	Subfield	Type	Value
WDI_MESSAGE_HEADER	PortId	UINT16	0x0001 (example)
---	Reserved	UINT16	N/A
---	WiFiStatus	NDIS_STATUS	N/A
---	TransactionId	UINT32	0x1111 (example)
---	IhvSpecificId	UINT32	N/A
TLV Payload	TLV Payload	Various	Payload data

Abort task input command (with message header):

Field	Subfield	Type	Value
NDIS_OID_REQUEST	Oid	NDIS_OID	OID(WDI_ABORT_TASK)
---	InputBufferLength	UINT32	sizeof(WDI_MESSAGE_HEADER) + sizeof(WDI_TLV_CANCEL_PARAMETERS)
---	InformationBuffer	PVOID	Pointer to memory block containing WDI_MESSAGE_HEADER + TLV payload
WDI_MESSAGE_HEADER	PortId	UINT16	0x0001 (example)
---	Reserved	UINT16	N/A
---	WiFiStatus	NDIS_STATUS	N/A
---	TransactionId	UINT32	0x2222 (example)
---	IhvSpecificId	UINT32	0
WDI_TLV_CANCEL_PARAMETERS	OriginalTaskOid	NDIS_OID	OID(WDI_TASK_SCAN)
---	OriginalPortId	UINT16	0x0001 (example)
---	OriginalTransactionId	UINT32	0x1111 (example)

Abort task command result:

Field	Subfield	Type	Value
NDIS_OID_REQUEST	Oid	NDIS_OID	OID(WDI_TASK_SCAN)
---	OutputBufferLength	UINT32	sizeof(WDI_MESSAGE_HEADER)
---	InformationBuffer	PVOID	Pointer to memory block containing WDI_MESSAGE_HEADER
WDI_MESSAGE_HEADER	PortId	UINT16	0x0001 (example)

Field	Subfield	Type	Value
---	Reserved	UINT16	N/A
---	WiFiStatus	NDIS_STATUS	NDIS_STATUS_SUCCESS
---	TransactionId	UINT32	0x2222 (example)
---	IhvSpecificId	UINT32	N/A

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_GET_ADAPTER_CAPABILITIES

Article • 03/14/2023

OID_WDI_GET_ADAPTER_CAPABILITIES is a read-only property that is issued from the host to the adapter during initialization and requests the adapter's capabilities.

Scope	Set serialized with task	Normal execution time (seconds)
Adapter	Set not supported	1

Get property parameters

No additional parameters. The data in the header is sufficient.

Get property results

If the adapter supports Wi-Fi Direct, both WDI_TLV_AP_ATTRIBUTES and WDI_TLV_P2P_ATTRIBUTES must be specified.

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_COMMUNICATION_CONFIGURATION_ATTRIBUTES		X	Host-adapter communication protocol configuration attributes.
WDI_TLV_INTERFACE_ATTRIBUTES			Interface attributes.
WDI_TLV_STATION_ATTRIBUTES			Station attributes.
WDI_TLV_AP_ATTRIBUTES		X	Access point attributes.
WDI_TLV_VIRTUALIZATION_ATTRIBUTES		X	Virtualization attributes.
WDI_TLV_P2P_ATTRIBUTES		X	The Wi-Fi Direct attributes.
WDI_TLV_DATAPATH_ATTRIBUTES		X	Datapath attributes.
WDI_TLV_BAND_INFO	X	X	Band information.
WDI_TLV_PHY_INFO	X	X	PHY information.
WDI_TLV_PM_CAPABILITIES		X	Power management capabilities.
WDI_TLV_COUNTRY_REGION_LIST		X	Country or region codes.
WDI_TLV_RECEIVE_COALESCING_CAPABILITIES		X	Hardware assisted receive filter capabilities.

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_TCP_OFFLOAD_CAPABILITIES		X	TCP/IP offload capabilities.
WDI_TLV_SUPPORTED_GUIDS	X	X	Added in Windows 10, version 1607, WDI version 1.0.21. A list of GUIDs that are passed on to NDIS when WDI is queried for OID_GEN_SUPPORTED_GUIDS.
WDI_TLV_OS_POWER_MANAGEMENT_FEATURES			Added in Windows 10, version 1803, WDI version 1.1.6. Used to enable advanced OS power management features.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_GET_AUTO_POWER_SAVE

Article • 03/14/2023

ⓘ **Important**

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_GET_AUTO_POWER_SAVE gets the power save state of the port.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Not applicable	1

There is a trade-off between power saving and latency. When auto power save mode is set to be enabled with the OID_WDI_SET_CONNECTION_QUALITY command, the firmware tries to interact with the connected access point to go to power save mode as much as appropriate to save power. The firmware is also responsible for detecting if the connected access point confirms to the 802.11 specification and follows the power save mode protocol. If the access point does not conform (does not support power save mode correctly), the firmware should not go into power save mode, even when Auto Power Save is set to enabled. When Auto Power Save is set to disabled, the firmware focuses on low latency of sending and receiving packets. Examples of this are when streaming mode is on, and when the system is using AC power so low latency is preferred to saving power.

Get property parameters

No additional parameters. The data in the header is sufficient.

Get property results

TLV	Multiple TLV instances allowed	Optional	Description
WDI_TLV_GET_AUTO_POWER_SAVE			Auto power save information.

Requirements

Minimum supported client	Windows 10
Minimum supported server	Windows Server 2016
Header	Dot11wdi.h

OID_WDI_GET_BSS_ENTRY_LIST

Article • 03/14/2023

ⓘ Important

This topic is part of the **WDI driver model** released in Windows 10. The WDI driver model is in maintenance mode and will only receive high priority fixes. **WiFiCx** is the Wi-Fi driver model released in Windows 11. We recommend that you use WiFiCx to take advantage of the latest features.

OID_WDI_GET_BSS_ENTRY_LIST is used to ask the adapter to indicate the list of BSS networks that have been cached by the port.

Scope	Set serialized with task	Normal execution time (seconds)
Port	Set not supported	1

This is only used for an adapter that perform BSS list caching. When acting as a client, the port must report the BSS entry for the access point. In addition, if the port is performing background scans, it should report BSS entries that it has discovered in its scan.

When this request is received by the adapter, it must send NDIS_STATUS_WDI_INDICATION_BSS_ENTRY_LIST indications to the Microsoft component. These indications must contain the BSS entries that match the Get parameters. The adapter can send one or more NDIS_STATUS_WDI_INDICATION_BSS_ENTRY_LIST indications, but they must be completed before the property completes.
